The relative stability of $[M(A)(Met)]^+$ can be expressed in terms of $\Delta\log K$ parameter (the constant due to $[M(A)] + [M(Met)] \rightleftharpoons [M(A)(Met)] + M$ equilibrium). It can be seen that, $\Delta\log K$ is equal to −1.01 for $[Cu(en)(Met)]^+$ and is very low for $[Cu(dien)(Met)]^+$ (−4.31) and for $[Cu(Me_5dien)(Met)]^+$ (−3.44). It is known that the statistical value of $\Delta\log K$ depends on the geometry of the complex and for the distorted octahedral coordination sphere of Cu^{2+} with two different bidentate ligands was deduced as −0.9 [42,43]. The distinctly lower values observed in the case of mixed-ligand complexes with dien or Me_5dien are most likely caused by lower than six coordination number of Cu^{2+} [42,43].

It is also possible to calculate the $\log X_{M(A)(Met)}$ values (the constant due to $[M(A)_2] + [M(Met)_2] \rightleftharpoons 2[M(A)(Met)]$ equilibrium, (Table 1 row 7). In the ternary systems of dien the formation of mixed-ligand complexes is especially favoured (0.6) [44]. For the $[Cu(Me_5dien)(Met)]^+$ mixed-ligand species the $\log X_{M(A)(L)}$ value cannot be calculated, since the complex with 1:2 metal to ligand ratio is not formed in the Cu^{2+}–Me_5dien binary system [23]. It could be noticed that the $\log X_{M(A)(L)}$ value for the system with dien is distinctly higher than that for the system with en. The same effect was observed for the ternary systems with L-histidine and simple polyamines [41].

The species distribution curves for the Cu^{2+}–en–Met system at 1:2:1 molar ratio as a function of pH presented in Fig. 1 indicate that under these experimental conditions the $[Cu(en)(Met)]^+$ mixed-ligand species starts to form above pH 4 and reaches the maximum concentration at pH 6. Below this pH value the simple species with Met and H_2O are formed. The EPR spectrum at pH 4.1 is very similar to the spectrum observed for the Cu^{2+}–Met binary system in an acid solution (see above) and changes distinctly at

EPR	VIS
$g_{\|\|} = 2.234$, $g_\perp = 2.050$	$\lambda_{max} = 582$ nm
$A_{\|\|} = 193$, $A_\perp = 21$ x 10^{-4} cm^{-1}	$\varepsilon = 72$ $dm^3\ mol^{-1}cm^{-1}$

Fig. 1. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for the Cu^{2+}–en–Met ternary system at 1:2:1 molar ratio; $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

pH 4.8. At this pH the concentration of the $[Cu(Met)]^+$ species decreases but the $[Cu(en)]^{2+}$ species increases in the solution. Two patterns of copper hyperfine splitting of parallel orientation in EPR spectrum corresponding to the equilibrium between $[Cu(Met)]^+$ and $[Cu(en)]^{2+}$ (Table 2) are observed. In the pH range 5–6 a new spectrum appeared. It was obtained as separate by subtraction of the EPR signals from the equilibrial $[Cu(en)]^{2+}$ and $[Cu(en)_2]^{2+}$ species (with suitable contribution) present also in the Cu–en–Met ternary system at pH 5.6. The parameters of this new spectrum $g_{||} = 2.234$, $A_{||} = 193 \times 10^{-4}$ cm^{-1} (Fig. 1), should be assigned to the mixed-ligand species $[Cu(en)(Met)]^+$ predicted at this pH range (the concentration ca. 40%). Its parameters are very similar to those corresponding to the mixed-ligand species formed by en and α-Ala with copper(II) ions $[Cu(en)(\alpha\text{-Ala})]^+$ (Table 2). In addition, the energy of d-d transition (Figs. 1 and 2) for the $[Cu(en)(Met)]^+$ species is almost the same as for $[Cu(en)(\alpha\text{-Ala})]^+$ (Table 2). Furthermore, the expected S(thioether) → Cu(II) charge transfer (CT) band is not observed in the UV region for this ternary system. The existence of such CT transition around 320–360 nm is generally a good indication of thioether coordination [38,45,46]. This spectroscopic data indicate the formation of (NH_2,NH_2) and (NH_2,COO^-) chelates in the plane of $[Cu(en)(Met)]^+$ without the involvement of the sulphur atom in the metal ion coordination (Fig. 1).

The calculated concentrations of the copper(II) complex species formed in the Cu^{2+}–dien–Met system, with 1:1:2 molar ratio, reveal that complexation of $[Cu(dien)]^{2+}$ by Met begins above pH 6 and reaches the maximum concentration at pH 9 Fig. 3a. The formation of mixed-ligand species is preceded mainly by the appearance of simple complexes with Met and dien. At pH 3.3 three patterns of copper hyperfine splitting in EPR spectrum corresponding to equilibrium between $[Cu(dien)]^{2+}$ ($g_{||} = 2.234$, $A_{||} = 195 \times 10^{-4}$ cm^{-1}), $[Cu(Met)]^{2+}$ ($g_{||} = 2.312$, $A_{||} = 172 \times 10^{-4}$ cm^{-1}) and Cu^{2+}_{aqua} ($g_{||} = 2.42$, $A_{||} = 132 \times 10^{-4}$ cm^{-1}) are observed. As pH of the solution increases, the concentrations of $[Cu(Met)]^{2+}$ and Cu^{2+}_{aqua} decrease and about pH 5.5 the spectrum of the $[Cu(dien)]^{2+}$

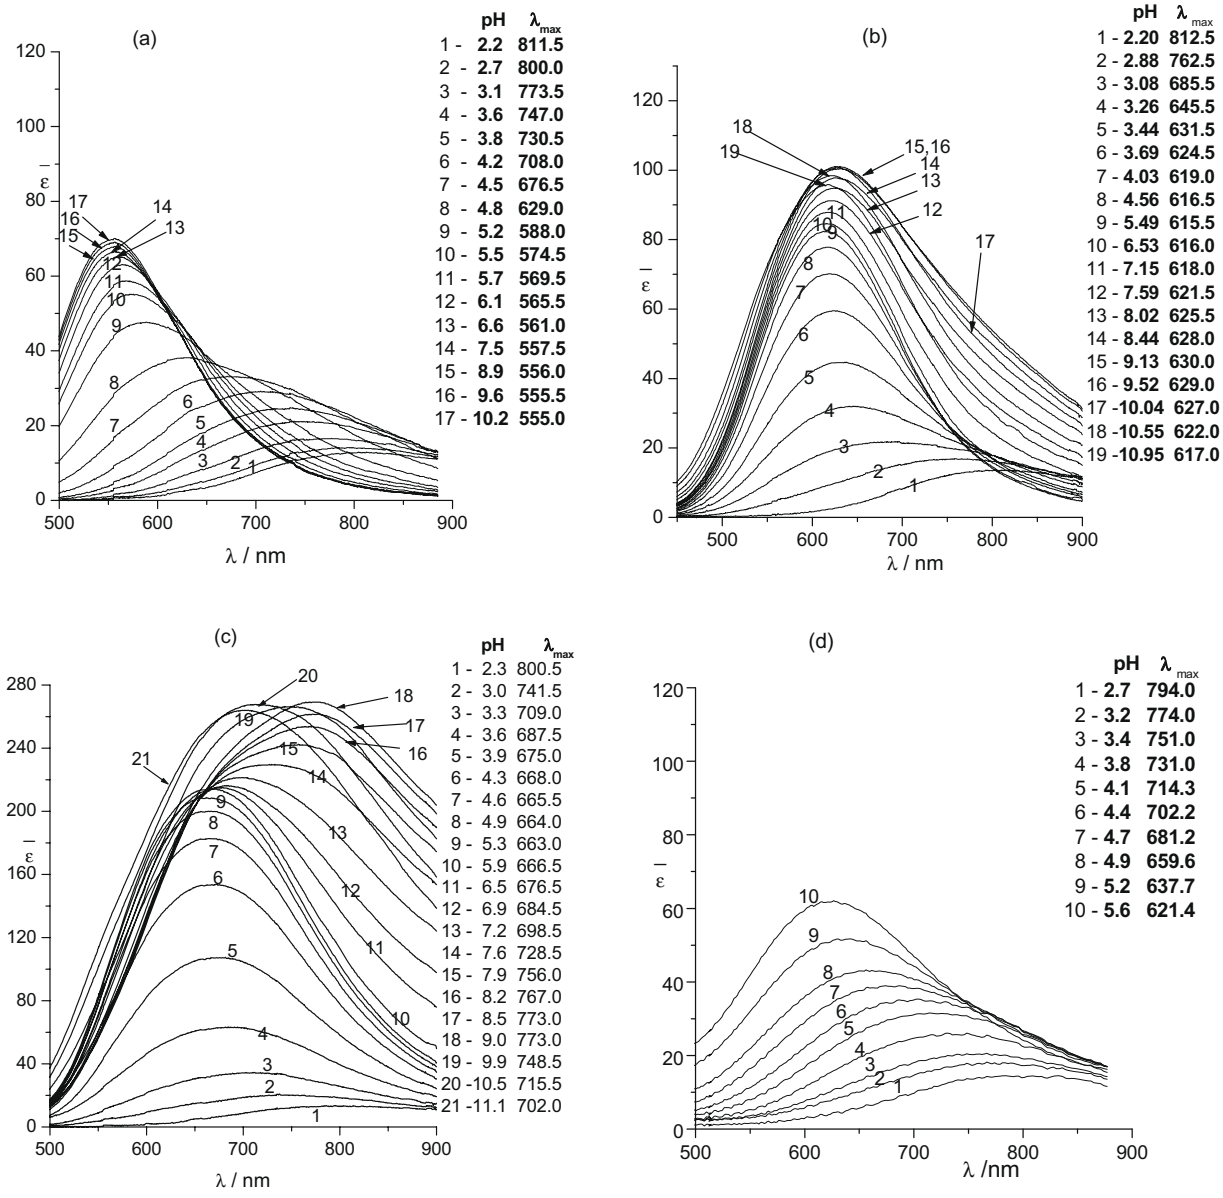

Fig. 2. pH-varied absorption spectra of the Cu^{2+}–en–Met system at 1:2:1 molar ratio (a), Cu^{2+}–dien–Met system at 1:1:2 molar ratio (b), Cu^{2+}–Me_5dien–Met system at 1:2:1 molar ratio (c) $c_{Cu^{2+}} = 4 \times 10^{-4}$ mol dm^{-3}, 2 cm cells), Cu^{2+}–Met system at 1:8 molar ratio (d) ($cCu^{2+} = 4 \times 10^{-4}$ mol dm^{-3}, 10 cm cell).

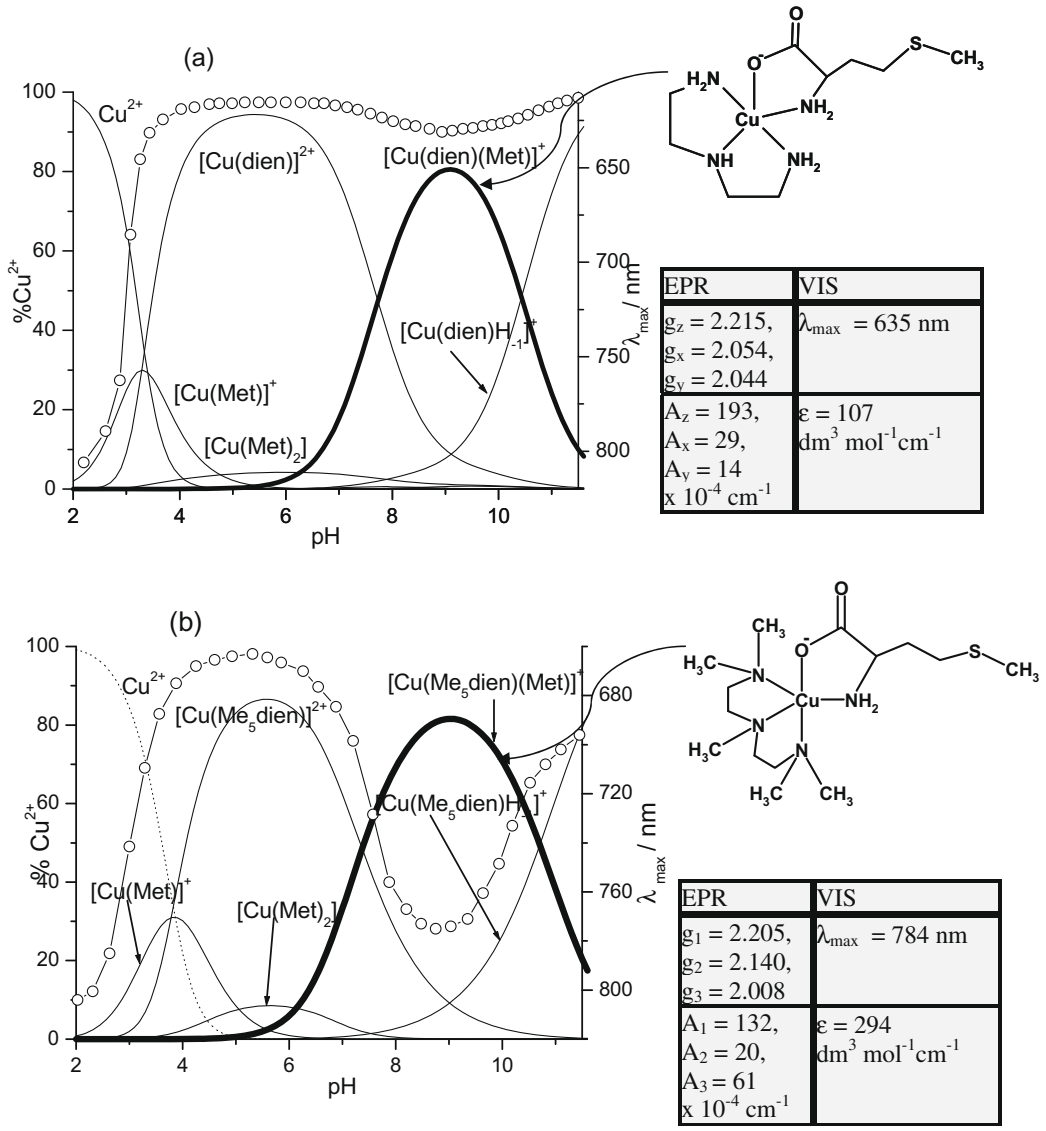

Fig. 3. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for the Cu^{2+}–dien–Met system at 1:1:2 molar ratio (a) and Cu^{2+}–Me_5dien–Met system at 1:2:1 molar ratio (b); $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

complex is only observed as dominant. In the pH range 7.5–10.5 a distinct change of EPR spectral feature could be noticed. A new spectrum is apparently different from that observed for Cu^{2+}–dien and should be ascribed to the predominant at this pH range mixed-ligand species $[Cu(dien)(Met)]^+$ (Fig. 3a). The spectral parameters calculated for this species (Table 2) are consistent with those corresponding to a five-coordinate species formed by α-alanine and dien in the copper(II) frozen solution (Table 2). So, Met similarly to α-Ala, completes the coordination number to five by binding amine nitrogen in Cu^{2+} plane and carboxylic oxygen in axial position. The presence of a weak rhombic distortion suggests that the geometry is slightly deviated from square pyramidal towards trigonal bipyramidal [47]. The effect of the $[Cu(dien)(Met)]^+$ species formation is also observed in the electronic spectral changes (Figs. 2b and 4d). From the comparison between the species distribution curves (Fig. 3a) and pH-varied absorption spectra of the Cu^{2+}–dien–Met system (Fig. 2b) the red shift of visible absorption maximum wavelength (circle in Fig. 3a) may be observed indicating the formation and decay of the mixed-ligand species. Its isolated electronic absorption spectrum at pH 9.1 (Fig. 4) demonstrates a characteristic of the five-coordinate complexes asymmetry [22,41]. The energy of d–d transition for $[Cu(dien)(Met)]^+$ (Fig. 3a) is almost identical to that stated for $[Cu(dien)(\alpha\text{-Ala})]^+$ (Table 2). Furthermore, a comparison of relative stability constants for mixed-ligand complexes of Met and α-Ala strongly confirms the proposed coordination mode. The relative stability constants, $\log K_{Cu(dien)(L)} - pK_{NH_3^+} - pK_{COOH}$, which takes into account the difference in the basicity of coordinating amino and carboxylic groups, for the ternary system with α-Ala (−7.89; [48]) is the same as this calculated for $[Cu(dien)(Met)]^+$ (Table 1). It suggests the same, ({NH_2, NH, NH_2}{NH_2, COO^-}, coordination mode, independently on amino-acid Fig. 3a).

The concentration distribution curves for the Cu^{2+}–Me_5dien–Met system together with the variations of visible absorption maximum wavelength are presented in Fig. 3b. It can be seen, that up to pH 7 the simple species with Me_5dien or Met are mainly formed. The EPR spectrum observed at pH 3.8 in the frozen solution of this ternary system corresponds to the existence of the equilibrium between $[Cu(Me_5dien)]^{2+}$, $[Cu(Met)]^+$ (see above) and $[Cu(H_2O)_6]^{2+}$ species. The increasing contribution of the $[Cu(Me_5dien)]^{2+}$ complex dominant between pH 5.0–6.0 is accompanied by a change of the recorded EPR spectra. The EPR parameters of the spectra ob-

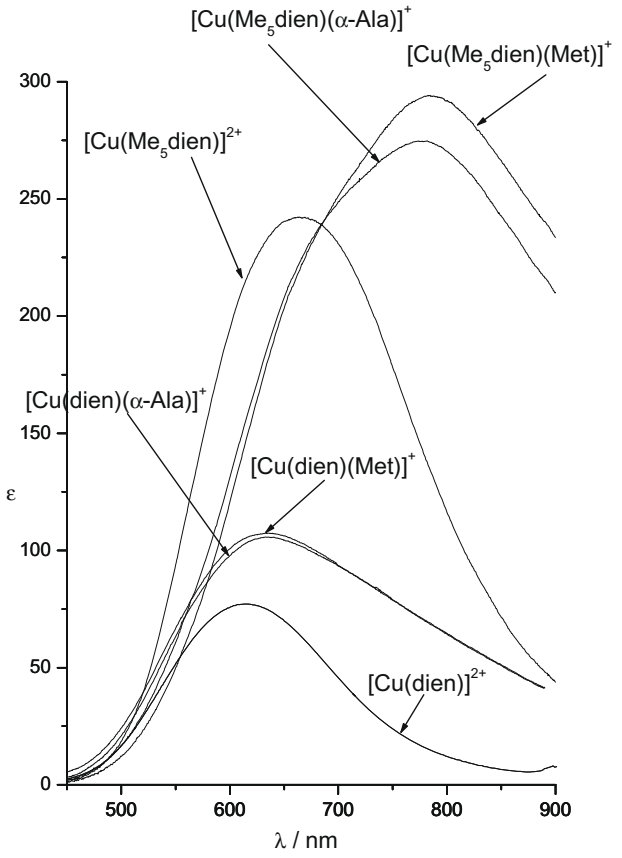

Fig. 4. Distribution-corrected absorption spectra for the $[Cu(dien)(Met)]^+$, $[Cu(dien)(\alpha\text{-Ala})]^+$, $[Cu(Me_5dien)(Met)]^+$, $[Cu(Me_5dien)(\alpha\text{-Ala})]^+$, $[Cu(Me_5dien)]^{2+}$, $[Cu(dien)]^{2+}$ species.

served in this pH range ($g_z = 2.238$, $g_x = 2.065$, $g_y = 2.050$ and $A_z = 185$, $A_x = 24$, $A_y = 14 \times 10^{-4}$ cm^{-1}) resemble quite closely those obtained for $[Cu(Me_5dien)]^{2+}$ (Table 2).

The $[Cu(Me_5dien)(Met)]^+$ species starts to form above pH 6 and reaches maximum concentration (ca. 80%) at pH ~9 (Fig. 3b). The pH-varied absorption spectra of Cu^{2+}-Me_5dien-Met ternary system are different from those for both Cu^{2+}–Me_5dien [26] and Cu^{2+}–Met binary systems (Figs. 3c and 2d). In addition, the pH dependence of λ_{max} in the visible spectra collected for the Cu^{2+}–Me_5dien–Met system clearly shows a significant red shift (the value of λ_{max} increases from 664 at pH ca. 5.5 to 775 nm at pH ca. 9 and then starts to decrease) which parallels the formation and decay of the $[Cu(Me_5dien)(Met)]^+$ species. This effect clearly indicates the structural change around the copper(II) ion and transition from a six to distorted five-coordination geometry while going from the simple to mixed-ligand species [20,22,23,26,41]. Moreover, the energy of d–d transition for $[Cu(Me_5dien)(Met)]^+$ (Figs. 3b and 4), is similar to those for five-coordinate mixed-ligand species containing Me_5dien and other α-amino acids [48], e.g. $[Cu(Me_5dien)(\alpha\text{-Ala})]^+$ (Fig. 4 and Ref. [41]). Similarly, the relative stability constants, $\log K_{Cu(Me_5dien)(L)} - pK_{NH_3^+} - pK_{COOH}$, calculated for the ternary system with α-Ala (−6.89; [48]) is close to this for the $[Cu(Me_5dien)(Met)]^+$ species (Table 1). These spectroscopic and potentiometric facts imply that the coordination modes in $[Cu(Me_5dien)(\alpha\text{-Ala})]^+$ and $[Cu(Me_5dien)(Met)]^+$ mixed-ligand species are the same, most probably without any interaction of the thioether sulfur of Met with Cu^{2+} ion (Fig. 3b).

The EPR measurements provide further information on the lack of the interaction between copper(II) and the sulfur atom. The values of the hyperfine splitting constants A and g parameters which are calculated from the separated EPR spectrum of the $[Cu(Me_5dien)(Met)]^+$ mixed-ligand species in frozen solution (Fig. 3b) are very close to these obtained for $[Cu(Me_5dien)(\alpha\text{-Ala})]^+$ (Table 2), $[Cu(Me_5dien)(\text{L-proline})]^+$ or $[Cu(Me_5dien)(\text{L-valine})]^+$ [48]. Thus, it can be concluded that geometry of the $[Cu(Me_5dien)(Met)]^+$ species is strongly deviated from square pyramidal towards trigonal bipyramidal, similarly as it was observed for other mixed-ligand species with Me_5dien due to the dominant bulky effect of two methyl substituents at each nitrogen atoms [23,26,29,41,48].

4. Conclusion

In the studied copper(II)-polyamine-Met ternary systems, the potentiometric, VIS and EPR results support the formation of the mixed-ligand complexes with $[Cu(A)(Met)]^+$ stoichiometry. The coordination in the $[Cu(en)(Met)]^+$ species, which reaches the maximum concentration at pH 6, is most likely realised by $\{NH_2, NH_2\}$ of en and $\{NH_2, COO^-\}$ of Met in the equatorial plane without the involvement of the sulphur atom in the copper(II) ion coordination. For the $[Cu(dien)(Met)]^+$ species, which predominates in basic solution, the geometry slightly deviated from square pyramidal is postulated. In this mixed-ligand species the binding of Cu^{2+} in the equatorial plane is realised by three amine nitrogens of dien and the amine nitrogen of Met whereas the carboxylic oxygen completes the coordination sphere at the axial position ($\{NH_2$, NH, $NH_2\}\{NH_2, COO^-\}$). The coordination mode in the $[Cu(Me_5dien)(Met)]^+$ species is the same as in the case of $[Cu(dien)(Met)]^+$, most probably without any interaction of the thioether sulfur of Met, but the geometry of this mixed-ligand species is strongly deviated from square pyramidal towards trigonal bipyramidal due to the dominant bulky effect of two methyl substituents at each nitrogen atoms.

Acknowledgment

We would like to express our gratitude to Ms. Jadwiga Kędzierska for her technical assistance in the EPR measurements.

ABSTRACT

The synthesis and characterization of new 3-substituted-4-diphenylphosphinosydnone imines (1,2,3-oxadiazolium-imines-5) are reported.

(R= ^{n}Bu, NMe_2 ; R'= Me, ^{t}Bu, Ph, CF_3)

These compounds react with $[PdCl_2(MeCN)_2]$ in MeCN to afford monomeric *cis*-P,N-coordinated palladium complexes.

1. Introduction

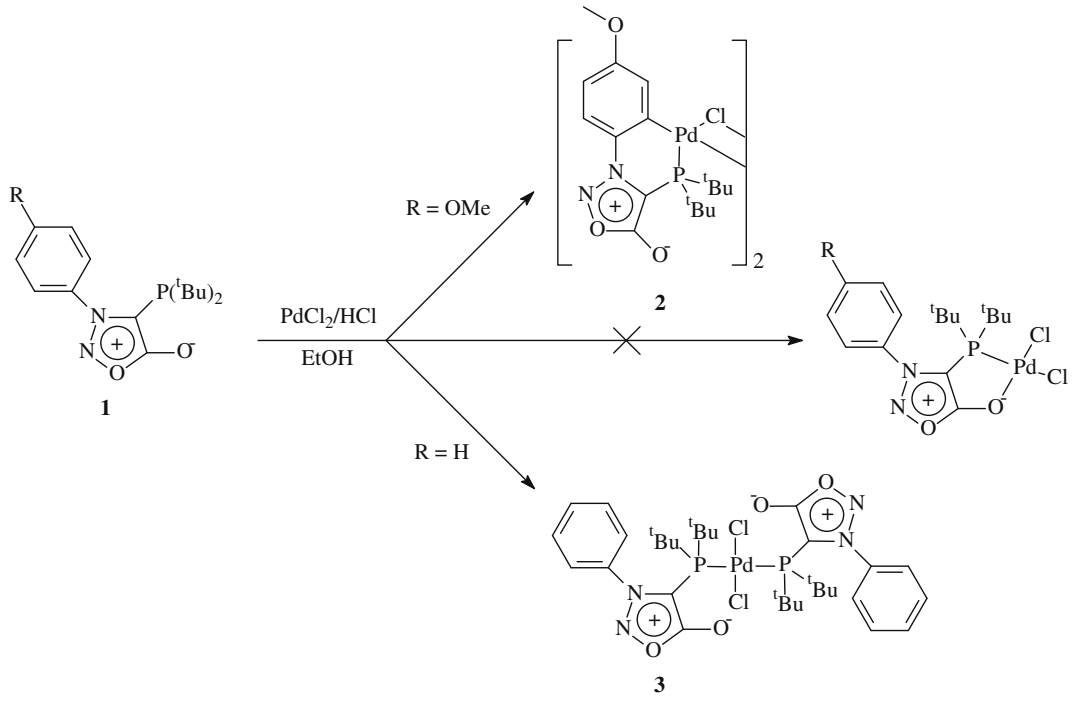
The synthesis and application of phosphorus ligands, especially for the cases where the phosphorus ligand contains another coordinating functionality, are of considerable interest [1]. By introducing the second donor atom (N, S, O, Se, As, P) into the ligand it is possible to obtain bidentate ligands with donor centers of different donor capability and steric properties. The use of a heterocyclic moiety as a part of the ligand system has attracted great attention in recent years. In this paper we report the synthesis of new type of bidentate ligand containing a mesoionic moiety.

The first attempt to prepare such complexes based on sydnones was described in [2]. 4-Phosphino derivatives of sydnones, **1**, were chosen as the subject of the investigation. It was suggested by the authors that the exocyclic oxygen atom, bearing a negative charge, of the sydnone ring can act as a second donor center. However, the reaction of 3-(4-methoxyphenyl)-4-(ditertbutylphosphino)-sydnone **1** (R = –OMe) with $PdCl_2$ in EtOH gave the cyclometallation product, **2**. The cyclometallation process does not occur in the absence of a donor substituent at the 3 position of the phenyl group (Scheme 1). In this case, only the formation of the bis(phosphine) complex **3** is observed.

Sydnone imines, **4** in Fig. 1, are nitrogen analogues of sydnones and their exocyclic nitrogen atom also bears a significant negative charge [3]. However, the electron donating properties of the exocyclic nitrogen atom in sydnone imines are substantially stronger than those of the oxygen atom in sydnones. Sydnone imines, in contrast to sydnones, form salts with strong acids. The pK_a values for sydnone imines **4** vary from 2.5 to 4.6, depending on the substituents [4,5]. In addition, sydnone imines **4** react with methyl iodide to give the quaternary ammonium salt of the exocyclic nitrogen [5,6].

4-Phosphino substituted derivatives of sydnone imines, **5** in Fig. 1, should be more prone to act as bidentate ligands than their sydnone analogues (**1** in Scheme 1). Thus, coordination of **5** to transition metals could give rise to chelated complexes, **6** in Fig. 1.

2. Results and discussion



2.1. Synthesis of 4-diphenylphosphinosydnone imines

To synthesize new 4-diphenylphosphino derivatives of the sydnone imines **5** we have used the reaction of 4-lithium derivatives of sydnone imines [7] with diphenylphosphine chloride (Scheme 2, Table 1). Both the lithiation of sydnone imines and the addition of Ph_2PCl were carried out at the temperatures below −90 °C. At higher temperatures the formation of large amounts of decomposition products was observed, especially at the lithiation stage. Furthermore, both *n*-BuLi and Ph_2PCl must be slowly added to the reaction mixture to avoid overheating of the solution.

The 3-substituted-4-diphenylphosphinosydnone imines obtained belong to the class of hemilabile ligands, which contain both soft and hard donor atoms. The π-acceptor character of the phosphorus atom can stabilize a metal center in a low oxidation state, while the π-donor ability of the nitrogen atom makes the metal atom more susceptible to oxidative addition reactions.

2.2. Bidentate coordination chemistry of 3-substituted-4-diphenylphosphinosydnone imines

Treatment of the 4-diphenylphosphinosydnone imine **5a** with $[PdCl_2(MeCN)_2]$ in MeCN resulted in the formation of only one product, **6a** (Scheme 3). According to the X-ray structural data of complex **6a**, the ligand coordinates with palladium by P(1) and N(6) atoms forming the five-membered metallocycle (Fig. 2).

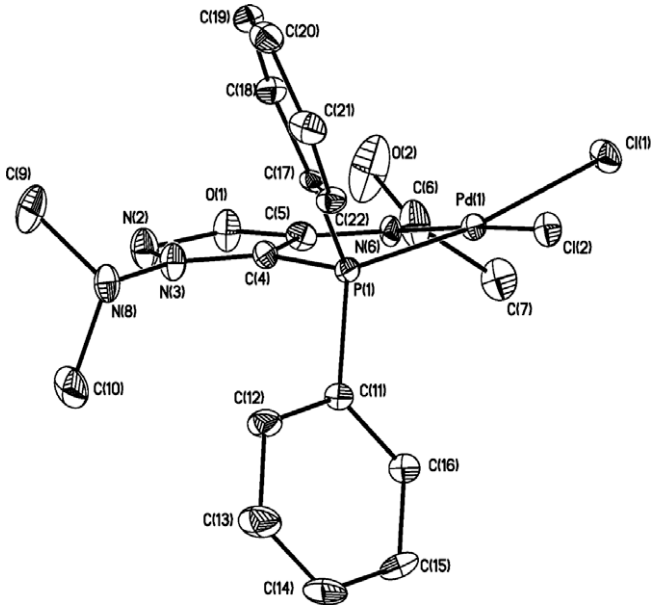

Fig. 3. General view of the complex **6e**, atoms represented by 50% thermal ellipsoids.

Very similar results were obtained in the case of phosphines **5b–f** (Scheme 3, Table 2).

The electron donating ability of N(6) in **5** is high. Even the presence of such electron-withdrawing groups as trifluoroacetyl (**5c**) does not prevent the formation of the chelate complex with palladium, although the yield of the product is low.

It should be noted that for compounds **5e** and **5f**, the dimethylamino group could provide an alternative coordination site. Nevertheless, the X-ray study of **6e** shows that the reactions of these compounds with $[PdCl_2(MeCN)_2]$ in MeCN give rise only to complexes in which the ligand acts as a bidentant ligand bound to palladium by the P(1) and N(6) atoms. (Fig. 3).

Despite the certain differences in the geometry of the ligands, the geometrical parameters of the two complexes **6a** and **6e** are similar (see Table 3). In both complexes the coordination of palladium is close to planar, with a slight tetrahedral distortion. The angles between the planes Pd(1)P(1)N(6) and Pd(1)Cl(1)Cl(2) are equal to 3.0(1)° and 8.5(1)° in **6a** and **6e**, respectively. The bite angles N(6)Pd(1)P(1) in both complexes are almost equal (87.13(9)° and 88.5(1)°). The five-membered metallocycles in **6a** and **6e** are characterized by an envelope conformation, with a deviation of the Pd(1) atom from the plane C(4)C(5)P(1)N(6) of 0.54 Å in **6a** and 0.32 Å in **6e**. In turn, the angles of bend along the P(1)···N(6) line in the complexes **6a** and **6e** are 20.5° and 12.2°. Despite the different substituents at N(3), the bond lengths of the metallocycles in **6a** and **6e** are almost the same. Comparing the geometrical parameters of the sydnone imine ring, one can conclude that the introduction of the Me_2N group leads to a slight shortening of the N(3)–C(4) bond, considerable shortening of the C(5)–N(6) and an increase of the N(6)–C(6) bond length.

Table 3
Selected bond lengths (Å) and angles (°) for the compounds **6a**, **6e** and **5e**.

Parameter	**6a**	**6e**	**5e**
Bond lengths			
Pd(1)–Cl(1)	2.361(1)	2.351(1)

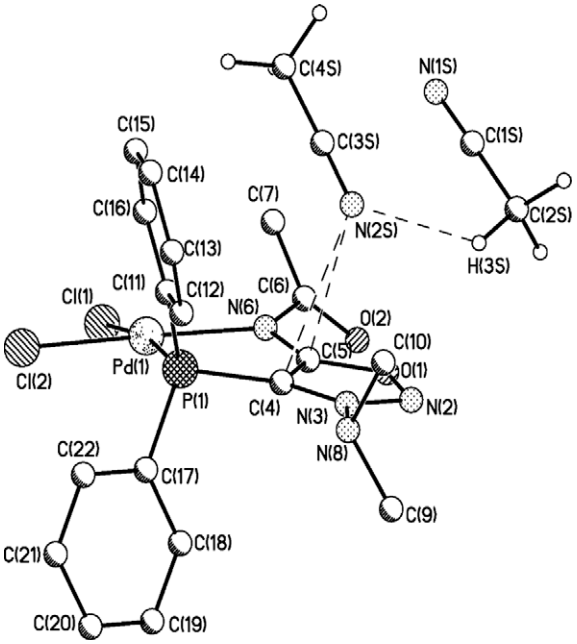

Fig. 4. The fragment of crystal packing illustrating the interaction of complex **6e** with acetonitrile molecules.

It should be mentioned that two solvate acetonitrile molecules in the crystal of **6e** are assembled into a dimer *via* the shortened C(1S)···C(3S) (3.344(3) Å) and N(2S)···H(3S) (2.51 Å) contacts (Fig. 4). In addition to the above contacts, one of the acetonitrile molecules participates in rather rare N···π binding with the mesoionic cycle, with a shortening of the N(2S)···C(4) and N(2S)···C(5) distances to 3.114(4) and 3.128(4) Å, respectively.

In order to analyze the influence of the complex formation on the distribution of bond lengths in the mesoionic moiety, we also performed an X-ray diffraction study of **5e** (Fig. 5). A comparison of the geometries of the free ligand **5e** and its complex **6e** shows that the coordination of N(6) to palladium causes the conjugation

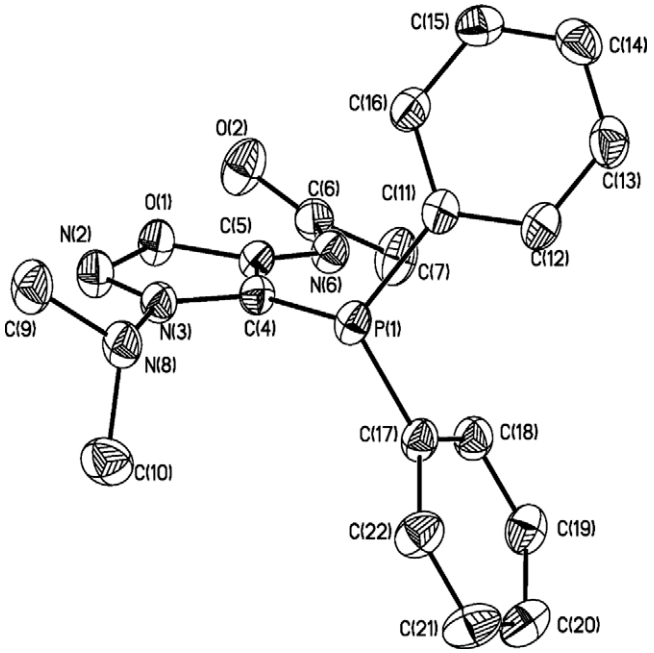

Fig. 5. General view of compound **5e**, atoms represented by 50% thermal ellipsoids.

of the N(6) atom with the π-system of the mesoionic ring and C=O group to decrease. As a result, the O(1)–C(5) bond in **5e** is considerably longer and the C(5) atom of the cycle deviates from the O(1)N(2)N(3)C(4) plane by 0.06 Å.

An analysis of IR spectra of the free ligands and the corresponding palladium complexes shows that the coordination of the mesoionic fragment by palladium atom gives no significant variation of the vibration spectrum character. The characteristic C=O and C=N bond vibrations of the mesoionic fragment are slightly blue shifted by 10–20 cm^{-1}.

The character of the chemical bonding in the mesoionic cycle, as well as the conjugation with the amide group, has been analyzed on the basis of a DFT calculation (m052x/6-311G(d,p)) of the molecule **5a** [8]. The obtained geometry is rather close to those observed in the complexes **6a** and **5e**. In particular, the C(5)–N(6) and C(6)–N(6) bond lengths are equal to 1.288 and 1.396 Å. An examination of the chemical bonding in **5a** has been performed within the "Atoms in Molecules" theory [9]. First of all, it should be noted that the charges obtained by integration over the atomic basins indicate that the most negative value is observed for the N(6) atom (−1.17 e). For comparison, the charge of the N(3) atom is significantly lower than those of the N(6) and N(8) atoms, which are −0.4 and −0.62 e. The total charge of the mesoionic cycle is close to zero (−0.02 e). According to the ellipticity values (ε) (the ratio of the Hessian eigenvalues in the critical points of the corresponding bonds), the mesoionic cycle is characterized by a significant contribution of π-character. Indeed, the maximum value of ε is observed for the N(2)–N(3) bond (0.41), while the minimum one – for the C(5)–O(1) bond (0.29). Both bonds formed by the N(6) atom are also characterized by substantial contributions of the π-component, with the ellipticity values being 0.20 and 0.30 for the N(6)–C(5) and N(6)–C(6) bonds, respectively.

The $^{31}P\{^1H\}$ NMR spectra of the obtained complexes show the variation of the chemical shift of the phosphorus atom (Table 4) upon complex formation.

2.2.1. Conclusion

In this work, the first representatives of 4-phosphorus substituted sydnone imines have been synthesized. It was shown that that these molecules can serve as hemilabile bidentante ligands and coordinate to a palladium atom by the phosphorus and exocyclic nitrogen N(6) atoms. The charge distribution in the mesoinic fragment was analyzed by DFT calculations, while the peculiarities of the geometries for the complexes were investigated by means of X-ray diffraction analysis. The presence of such a zwitterionic group as sydnone imine, which is unusual for palladium complexes, can provide them with rather unusual catalytic properties.

Table 4
$^{31}P\{^1H\}$ NMR parameters for the compounds **5a–f** and **6a–f**.

Compound	Chemical shifts (ppm) for compounds **5a–f**	Chemical shifts (ppm) for compounds **6a–f**
a	−35.91	−7.44
b	−35.89	−15.50
c	−35.84	13.48
d	−36.26	10.07
e	−35.83	−5.85
f	−35.81	−5.77

3. Experimental

3.1. General

Unless otherwise indicated, all the reactions were performed in a dry argon atmosphere. The starting sydnone imines **4a–b** [10], **4c** [11], **4d** [12], **4e** [13] and **4f** [6] were prepared according to the described procedures. All commercially available reagents were used without further purification. IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Nicolet Magna-IR 750 FT-IR spectrophotometer. ^1H NMR spectra were recorded on a Bruker Avance-400 spectrometer operating at a frequency of 400.13 MHz. ^{31}P NMR spectra were recorded on a Bruker Avance-400 spectrometer operating at a frequency of 161.98 MHz. Elemental analyses for C, H and N were performed on a Carlo Erba Elemental Analyzer – 1106 automatic analyzer. Melting points were determined with an electrically heated Gallenkamp apparatus.

3.2. Preparations

*3.2.1. N6-acetyl-3-butyl-4-diphenylphosphinosidnonimine (**5a**)*

To a solution of N6-acetyl-3-butylsidnonimine (0.5 g, 2.73 mmol) in THF (50 ml) at −90 °C, a 1.6 M solution of *n*-BuLi in hexane (1.9 ml, 3.00 mmol) was added. The solution was stirred for 10 min at the same temperature. Then chlorodiphenylphosphine (0.55 g, 3.13 mmol) was added. Reaction mixture was stirred for 10 min at the same temperature and then it was heated to room temperature. The solvent was removed under reduced pressure and the residue was dissolved in ethyl acetate, filtered through a layer of Al_2O_3 (2 × 3 cm) and washed away with ethyl acetate. The solvent was removed under reduced pressure and the residue was crystallized from a mixture of ether and hexane. Yield: 0.67 g (67%). M.p. 94–95 °C. *Anal.* Calc. for $C_{20}H_{22}N_3O_2P$ (367.39): C, 65.39; H, 6.04; N, 11.44. Found: C, 65.20; H, 6.50; N, 11.83%. IR data (KBr-pellet, cm^{-1}): 2960w, 2780w, 1660s, 1570vs, 1430m, 1250w, 1090m, 999m, 815w, 747w, 528m. ^1H NMR (DMSO-d_6): δ 0.76–0.80 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.12–1.28 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.81–1.87 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.95 (s, 3H, $COCH_3$), 4.75–4.79 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.28–7.45 (m, 6H, *p*-C_6H_5 + *m*-C_6H_5), 7.50–7.54 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −35.91 (s).

*3.2.2. N6-benzoyl-3-butyl-4-diphenylphosphinosidnonimine (**5b**)*

The title compound was prepared in the same way as compound **5a**, starting from **4b** (2 g, 8.16 mmol), 5.6 ml of a 1.6 M solution of *n*-BuLi in hexane (8.98 mmol) and 1.7 ml of chlorodiphenylphosphine (9.38 mmol). Yield 2.8 g (80%). M.p. 107–108 °C. *Anal.* Calc.

for $C_{25}H_{24}N_3O_2P$ (429.46): C, 69.92; H, 5.63; N, 9.78. Found: C, 69.32; H, 5.89; N, 9.50%. IR data (KBr-pellet, cm^{-1}): 3052vw, 2959vw, 2874vw, 1635s, 1571vs, 1432m, 1312m, 1240m, 1207m, 1090m, 989s, 814w, 735w, 695m, 533w. ^1H NMR (DMSO-d_6): δ 0.74–0.81 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.11–1.29 (m, 2H, CH_3CH_2-CH_2CH_2), 1.86–1.89 (m, 2H, $CH_3CH_2CH_2CH_2$), 4.84–4.87 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.19–7.26 (m, 2H, *o*-($NCOC_6H_5$)), 7.29–7.43 (m, 6H, *p*-$(C_6H_5)_2P$ + *m*-$(C_6H_5)_2P$), 7.45–7.48 (m, 3H, *p*-($NCOC_6H_5$) + *m*-($NCOC_6H_5$)), 7.54–7.62 (m, 4H, *o*-$(C_6H_5)_2P$). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −35.89 (s).

3.2.3. N6-trifluoroacetyl-3-butyl-4-diphenylphosphinosidnonimine (**5c**)

The title compound was prepared in the same way as compound **5a** starting from **4c** (0.7 g, 2.95 mmol), 2.1 ml of a 1.6 M solution of *n*-BuLi in hexane (3.39 mmol) and 0.63 ml of chlorodiphenylphosphine (3.54 mmol). Yield 0.7 g (56%). M.p. 125–126 °C. *Anal.* Calc. for $C_{20}H_{19}F_3N_3O_2P$ (421.36): C, 57.01; H, 4.55; N, 9.97. Found: C, 57.25; H, 5.01; N, 9.21%. IR data (KBr-pellet, cm^{-1}): 3052vw, 2963vw, 2874vw, 1653s, 1568vs, 1435w, 1202m, 1165s, 1132m, 1017m, 866w, 747w, 696w. ^1H NMR (DMSO-d_6): δ 0.77–0.81 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.24–1.30 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.84–1.91 (m, 2H, $CH_3CH_2CH_2CH_2$), 4.88–4.91 (m, 2H, CH_3CH_2-CH_2CH_2), 7.33–7.41 (m, 6H, *p*-C_6H_5 + *m*-C_6H_5), 7.52–7.56 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −35.84 (s).

3.2.4. N6-trimethylacetyl-3-butyl-4-diphenylphosphinosidnonimine (**5d**)

The title compound was prepared in the same way as compound **5a** starting from **4d** (1.0 g, 4.44 mmol), 3.0 ml of a 1.6 M solution of *n*-BuLi in hexane (4.89 mmol) and 0.92 ml of chlorodiphenylphosphine (5.10 mmol). Yield 1.56 g (86%). M.p. 104–105 °C. *Anal.* Calc. for $C_{23}H_{28}N_3O_2P$ (409.47): C, 67.47; H, 6.89; N, 10.26. Found: C, 67.30; H, 7.01; N, 10.63%. IR data (KBr-pellet, cm^{-1}): 3059w, 2956w, 2867w, 1634s, 1601vs, 1579s, 1475w, 1435m, 1383w, 1313w, 1172m, 1109w, 999m, 744w, 692w, 515vw. ^1H NMR (DMSO-d_6): δ 0.77–0.92 (m, 12H, $CH_3CH_2CH_2CH_2$ + $C(CH_3)_3$), 1.20–1.27 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.83–1.91 (m, 2H, CH_3CH_2-CH_2CH_2), 4.80–4.83 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.34–7.36 (m, 6H, *p*-C_6H_5 + *m*-C_6H_5), 7.51–7.54 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −36.26 (s).

3.2.5. N6-acetyl-3-dimethylamino-4-diphenylphosphinosidnonimine (**5e**)

The title compound was prepared in the same way as compound **5a** starting from **4e** (2.5 g, 14.70 mmol), 10.0 ml of a 1.6 M solution of *n*-BuLi in hexane (16.20 mmol) and 3.0 ml of chlorodiphenylphosphine (16.90 mmol). Yield 3.9 g (75%). M.p. 126–127 °C *Anal.* Calc. for $C_{18}H_{19}N_4O_2P$ (354.35): C, 61.01; H, 5.40; N, 15.81. Found: C, 60.59; H, 6.00; N, 15.20%. IR data (KBr-pellet, cm^{-1}): 2785w, 2459w, 1671s, 1580vs, 1435s, 1390w, 1265w, 1150m, 1121m, 1032w, 725m, 699m, 555w. ^1H NMR (DMSO-d_6): δ 1.86 (s, 3H, $COCH_3$), 3.07 (s, 6H, $(CH_3)_2N$), 7.35–7.37 (m, 6H, *m*-C_6H_5 + *p*-C_6H_5), 7.52–7.56 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −35.83 (s.).

3.2.6. N6-benzoyl-3-dimethylamino-4-diphenylphosphinosidnonimine (**5f**)

The title compound was prepared in the same way as compound **5a** starting from **4f** (2.0 g, 8.60 mmol), 5.9 ml of a 1.6 M solution of *n*-BuLi in hexane (9.50 mmol) and 1.8 ml of chlorodiphenylphosphine (9.90 mmol). Yield 2.5 g (70%). M.p. 123–124 °C. *Anal.* Calc. for $C_{23}H_{21}N_4O_2P$ (416.42): C, 66.34; H, 5.08; N, 13.45. Found: C, 65.99; H, 5.22; N, 13.25%. IR data (KBr-pellet, cm^{-1}): 3040w, 2878vw, 1620s, 1550vs, 1430m, 1340m, 1255m, 1140w, 1000m, 750w, 532w. ^1H NMR (DMSO-d_6): δ 3.15 (s, 6H, $(CH_3)_2N$), 7.22–7.27 (m, 2H, *o*-($NCOC_6H_5$)), 7.33–7.42 (m, 6H, *p*-$(C_6H_5)_2P$ + *m*-$(C_6H_5)_2P$), 7.57–7.65 (m, 7H, *p*-($NCOC_6H_5$) + *m*-($NCOC_6H_5$) + *o*-$(C_6H_5)_2P$). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −35.81 (s).

3.2.7. N6-acetyl-3-butyl-4-diphenylphosphinosidnonimine palladium dichloride (**6a**)

To a solution of N6-acetyl-3-butyl-4-diphenylphosphinosidnonimine **5a** (0.5 g, 1.36 mmol) in CH_3CN (10 ml), $[PdCl_2(MeCN)_2]$ (0.35 g, 1.36 mmol) was added. The solution was stirred for 30 min at room temperature. The solvent was removed under reduced pressure and the residue was crystallized from a mixture of CH_3CN and ether. Yield: 0.67 g (90%). M.p. 214 °C (dec.). *Anal.* Calc. for $C_{20}H_{22}Cl_2N_3O_2PPd$ (544.71): C, 44.10; H, 4.07; N, 7.71. Found: C, 44.29; H, 4.52; N, 7.13%. IR data (KBr-pellet, cm^{-1}): 3052w, 2964w, 2900w, 1671s, 1585vs, 1422m, 1377w, 1265w, 1080m, 1002m, 837w, 768w, 540w. ^1H NMR (DMSO-d_6): δ 0.57–0.60 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.00–1.07 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.26–1.29 (m, 2H, $CH_3CH_2CH_2CH_2$), 2.47 (s, 3H, $COCH_3$), 4.16–4.20 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.63–7.64 (m, 4H, *m*-C_6H_5), 7.73–7.76 (m, 2H, *p*-C_6H_5) 7.98–8.03 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −7.44 (s).

3.2.8. N6-benzoyl-3-butyl-4-diphenylphosphinosidnonimine palladium dichloride (**6b**)

The title compound was prepared in the same way as compound **6a** starting from **5b** (0.2 g, 0.475 mmol) and $[PdCl_2(MeCN)_2]$ (0.12 g, 0.475 mmol). Yield 0.25 g (85%). M.p. 194 °C (dec.). *Anal.* Calc. for $C_{25}H_{24}Cl_2N_3O_2PPd$ (606.78): C, 49.49; H, 3.99; N, 6.93. Found: C, 49.10; H, 4.20; N, 6.55%. IR data (KBr-pellet, cm^{-1}): 3059vw, 2963vw, 2874vw, 1656s, 1568vs, 1431m, 1257m, 1169vw, 1098w, 1013m, 747w, 688m. ^1H NMR (DMSO-d_6): δ 0.63–0.75 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.05–1.16 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.50–1.63 (m, 2H, $CH_3CH_2CH_2CH_2$), 4.05–4.18 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.18–7.25 (m, 2H, *o*-($NCOC_6H_5$)), 7.29–7.43 (m, 3H, *p*-($NCOC_6H_5$) + *m*-($NCOC_6H_5$)), 7.52–7.65 (m, 6H, *p*-$(C_6H_5)_2P$ + *m*-$(C_6H_5)_2P$), 8.04–8.21 (m, 4H, *o*-$(C_6H_5)_2P$). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ −15.50 (s).

3.2.9. N6-trifluoroacetyl-3-butyl-4-diphenylphosphinosidnonimine palladium dichloride (**6c**)

The title compound was prepared in the same way as compound **6a** starting from **5c** (0.2 g, 0.475 mmol) and $[PdCl_2(MeCN)_2]$ (0.12 g, 0.475 mmol). Yield 0.15 g (53%). M.p. 190 °C (dec.). *Anal.* Calc. for $C_{20}H_{19}Cl_2F_3N_3O_2PPd$ (598.68): C, 40.12; H, 3.20; N, 7.02. Found: C, 40.32; H, 3.05; N, 6.89%. IR data (KBr-pellet, cm^{-1}): 3050vw, 2963vw, 2877vw, 1665s, 1571vs, 1440w, 1220m, 1140m, 1120w, 1030m, 869vw, 758w, 675w. ^1H NMR (DMSO-d_6): δ 0.70–0.74 (m, 3H, $CH_3CH_2CH_2CH_2$), 1.11–1.18 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.52–1.67 (m, 2H, $CH_3CH_2CH_2CH_2$), 4.48–4.57 (m, 2H, $CH_3CH_2CH_2CH_2$), 7.53–7.59 (m, 4H, *m*-C_6H_5), 7.63–7.67 (m, 2H, *p*-C_6H_5), 8.09–8.17 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ 13.48 (s).

3.2.10. N6-trimethylacetyl-3-butyl-4-diphenylphosphinosidnonimine palladium dichloride (**6d**)

The title compound was prepared in the same way as compound **6a** starting from **5d** (0.5 g, 1.22 mmol) and $[PdCl_2(MeCN)_2]$ (0.32 g, 1.22 mmol). Yield 0.61 g (85%). M.p. 204 °C (dec.). *Anal.* Calc. for $C_{23}H_{28}Cl_2N_3O_2PPd$ (586.79): C, 47.08; H, 4.81; N, 7.16. Found: C, 46.95; H, 5.11; N, 7.64%. IR data (KBr-pellet, cm^{-1}): 2963w, 2874vw, 1723m, 1619vs, 1568m, 1479w, 1435m, 1095m, 1006m, 751w, 688w, 529m. ^1H NMR (DMSO-d_6): δ 0.69–0.77 (m, 12H, $CH_3CH_2CH_2CH_2$ + $C(CH_3)_3$), 1.11–1.16 (m, 2H, $CH_3CH_2CH_2CH_2$), 1.61–1.68 (m, 2H, $CH_3CH_2CH_2CH_2$), 4.59–4.69 (m, 2H, CH_3CH_2-CH_2CH_2), 7.48–7.65 (m, 6H, *p*-C_6H_5 + *m*-C_6H_5), 7.95–8.05 (m, 4H, *o*-C_6H_5). $^{31}P\{^1H\}$ NMR (DMSO-d_6): δ 10.07 (s.).

*3.2.12. N6-benzoyl-3-dimethylamino-4-diphenylphosphinosidnonimine palladium dichloride (**6f**)*

The title compound was prepared in the same way as compound **6a** starting from **5f** (0.5 g, 1.20 mmol) and [$PdCl_2(MeCN)_2$] (0.31 g, 1.20 mmol). Yield 0.68 g (95%). M.p. 189–190 °C (dec.). *Anal.* Calc. for $C_{23}H_{21}Cl_2N_4O_2PPd$ (593.75): C, 46.53; H, 3.56; N, 9.44. Found: C, 46.08; H, 3.28; N, 9.23%. IR data (KBr-pellet, cm^{-1}): 3052vw, 1639s, 1597vs, 1571s, 1446m, 1350w, 1279w, 1246m, 1158w, 1098m, 991m, 751w, 725w, 537w. ^{1}H NMR (DMSO-d_6): δ 3.20 (s, 6H, $(CH_3)_2N$), 7.19–7.26 (m, 2H, *o*-($NCOC_6H_5$)), 7.28–7.43 (m, 6H, *p*-($NCOC_6H_5$) + *m*-($NCOC_6H_5$)), 7.51–7.66 (m, 6H, *p*-$(C_6H_5)_2P$ + *m*-$(C_6H_5)_2P$)), 8.05–8.23 (m, 4H, *o*-$(C_6H_5)_2P$). ^{31}P{^{1}H} NMR (DMSO-d_6): δ −5.77 (s).

4. X-ray diffraction analysis

Crystals suitable for the X-ray diffraction analysis were obtained by slow evaporation from MeCN solutions. X-ray diffraction experiments of **5e** were carried out with a Bruker SMART 1000 CCD diffractometer (Mo Kα) = 0.71073 Å, ω-scans) at 110 K, while for **6a** and **6e** they were carried out with a Syntex P21 diffractometer (Mo Kα) = 0.71073 Å, ω-scans) at 153 K. The structures were solved by the direct method and refined by full-matrix least-squares against F^2 in anisotropic approximation for non-hydrogen atoms. The analysis of the Fourier density synthesis has revealed a disorder of the oxygen atom O(2) in **6e** over two positions with occupancies of 0.78 and 0.22. The positions of the hydrogen atoms were calculated. Crystal data and structure refinement parameters for **5e, 6a** and **6e** are given in Table 5. All calculations were performed using the SHELXTL software [14].

Supplementary data

CCDC 723513, 723514, and 723515 contain the supplementary crystallographic data for **5e**, **6a**, and **6e**. These data can be obtained free of charge via <http://www.ccdc.cam.ac.uk/conts/retrieving.html>, or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Herein the synthesis and binding studies of novel *trans*-A_2B-corrole and *trans*-A_2B_2-porphyrin derivatives are presented in comparing manganese(III)-organophosphonate (OP) binding (e.g., $M^{n+} \leftarrow O{=}PR(OR)_2$) capabilities. H_3(PFP-VC) [PFP-VC = 5,15-di(pentafluorophenyl)-10-(3-vinylphenyl)corrolate] was synthesized by way of literature procedures and was characterized by a variety of 2-D NMR spectroscopic techniques and single-crystal X-ray diffraction. These compounds represent the first example of 3-vinyl-phenyl-containing meso-substituted corroles or porphyrins. Mn(PFP-VC) (**3**) was treated separately with $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$, $(C_4H_9O)_2P{=}O(Me)$, $(C_2H_5O)_2P{=}O(CH_2COCH_3)$, $(CH_3CH_2O)_2P{=}O(Me)$, to give 1:1 adducts, as determined by UV–Vis spectroscopy (Job Plot), giving a *red* shift; $Ph_3P{=}O$, was also found to bind, but very weakly. The *trans*-A_2B_2-porphyrin analogue Mn(PFP-VP) (**4**) was also prepared by way of a literature procedure; related binding studies gave 1:1 organophosphonate-Mn(PFP-VP) adducts (Job Plot). A clean *blue* shift occurred for the Mn-porphyrins at higher organophosphonate loadings (K_a values: 6.7 (0.9)–11.9 (0.4) M^{-1}). DFT geometry optimizations of $O{=}P(OMe)_2Me$ binding and formal Mn–O or P–O cleavage products in the unsubstituted *neutral* Mn-corrolato and -porphyrinato systems with a range of metal-based spin states revealed greatest stability in formal phosphoryl oxygen binding (energies: 11–13 kcal/mol) for the Mn-corrole (*singlet*); the Mn-porphyrin (*sextet*) was also quite stable.

1. Introduction

Macrocyclic polypyrroles are motifs of great ubiquity, constituting a range of both synthetic metal complexes and natural systems (i.e., hemoglobin, corrin and chlorophylls) (Fig. 1). Of note, the porphyrin sub-class is crucial in oxygen-atom transfer [1], and in analyte binding (e.g., O_2), with the ability to host a variety of Lewis bases in forming important adducts in biology. Corroles, members of a currently greatly expanding class of contracted porphyrin, are gaining greater visibility through the sub-field's major contributors: Gross [2], Gryko [3,4], Kadish [5,6], and Paolesse [7]. Corroles differ from porphyrins in two important ways: they possess one direct pyrrole–pyrrole bond in place of one methine (C–H) linkage, and they are *tri*valent instead of divalent. This difference allows for metal-corrolato species to possess a likeness to Nature's hemes through their aromaticity on one hand, and a corrin-like structural cavity that bears a *tri*valent cavity instead of a monovalent core (Fig. 1) on the other hand. These features enable a stabilization of transition metal ions in valence states [8] that are systematically higher than those known in the respective porphyrins.

Through the study of transition metal coordination chemistry, adequate control of complex color, electronics, sterics, and molecular geometry can, in theory, be imparted, especially through the use of a rigid delocalized ligand corrole or porphyrin frame. A delocalized and rigid frame may also be fluorogenic. Mn-corrolato species, however, do not appear to be promising in this respect. Thus, to determine whether a porphyrin or corrole framework, or both, is of utility in the optical or otherwise sensing of organophosphonate is the goal of these solution studies. Since our primary focus here is on nerve agent model [O=P] oxygen metal ion binding, we also undertook theoretical calculations to fully determine M-corrole $O{=}P(OR)_2R$ binding energies using model systems. Understanding the features and substitutions that enhance, or detract from, the binding capabilities of metalloporphyrin derivatives are essential in the rational development of these systems as detection platforms in hazardous analyte sensing. Generally, metallocorroles

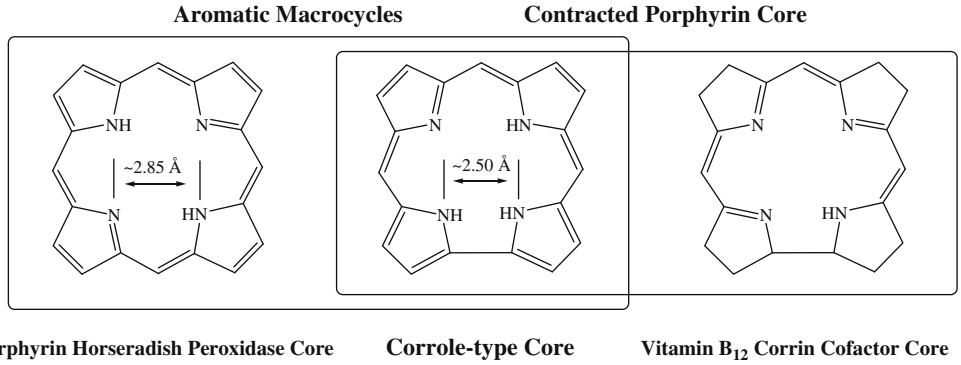

Fig. 1. A comparison of the macrocyclic porphyrin, corrole and corrin (vitamin B_{12} cofactor) frames. Note: the left and middle structures are the basis of geometry optimization calculations, illustrated below in Figs. 11 and 12.

and metalloporphyrins show some promise as selective analyte sensing platforms. Corroles have been explored as CO sensors of sufficient selectivity when testing with competitive analytes such as O_2 and N_2. The nature of the metal (e.g., Co^{3+}) as well as corrole substitution play essential parts in the Lewis acidity of the metal center [9], which is the sensing core. Metallocorroles also have good reproducibility and stability over a term of months as "electronic noses." In a related report, there was no loss of corrole "monomer" from a thin layer array over a four-week period of continual use [10]. Precedent for related metallo*porphyrin*-based sensors comes from reports by Di Natale and coworkers [11–13]. Porphyrin derivatives have also been the subject of computational efforts in the context of analyte selectivity [14–17].

The types of analytes we chose to study here are organophosphonates, relatives of the extremely deadly organophosphonate nerve agents (Fig. 2). While there have been significant efforts to fully decontaminate all stockpiles, undertaken in good faith to abide by the time-table set forth by the Chemical Weapons Convention (CWC), there are still significant amounts of organophosphonate-based chemical weapons in North America as well as in Eurasia that, to date await complete destruction and remediation. This impetus, along with potential terrorist agent development and use, support the need for continued investigations into improved real-time sensing devices [17].

Cyclic polypyrrole ligand-based sensing platforms may be able to efficiently and selectively mediate in techniques such as piezoelectric crystal sorption detection which are the centerpiece of portable and growingly reliable nerve agent detection/discernment. The possibility of metallocorroles serving in nerve agent detection and decontamination is suggestive from results reported by Gross and coworkers in which $Ph_3P{=}O$ forms an adduct with Mn(III)tpfcorrolato; this adduct can also be formed from the manganyl [Mn=O] species upon addition of PPh_3 [18]. The crystal structure in which triphenylphosphine oxide is coordinated to tris-pfp-Mn-corrole [19a,19b] can be compared to one in which there exists a free Mn(III)corrolato center [19c].

Mn-corrole-based organophosphonate nerve agent sensing can be explored in a variety of ways. Our approach involved preparing closely related Mn-corrolates that bear stability imparted from the pentafluorophenyl groups but that also contain a 10-position *meso*-aryl group that contains an attachment point. We were able to develop the corrole and the related porphyrin system for comparison. We also go further here theoretically, in determining how oxygen binding of organophosphonate nerve agent mimics, and how the phosphoryl oxygen can formally migrate from the Mn=O group; this can be treated theoretically (*vide infra*). While organophosphonates have different electronic and steric properties as the simpler $Ph_3P{=}O$ molecule [19], we can look at a variety of organophosphonate species: $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$, $(C_4H_9O)_2P{=}O(Me)$, $(C_2H_5O)_2P{=}O(CH_2COCH_3)$, $(CH_3CH_2O)_2P{=}O(Me)$, $Ph_3P{=}O$ (Fig. 2), and other analytes with compounds **3** or **4** (Scheme 1) [20].

In terms of the preparative chemistry of corroles, extremely practical pathways to A_2B-corroles have been reported by Gryko and coworkers [3,4]. Thus, we have prepared *meso*-thienyl-A_2B-corroles species with the well-known C_6F_5-substitution, and also the 3-vinylphenyl substitution which may facilitate chemisorption *via* sulfhydryl groups of functionalized surfaces [21]. We have also prepared the analogous porphyrin system to compare analyte binding in two closely related systems.

2. Results and discussion

2.1. Synthesis and characterization

Corrole preparation began with the generation of dipyrromethane prepared by the literature method of Lindsey and coworkers [22] involving the condensation of pyrrole and aldehyde. The synthesis of A_2B corroles were adapted from well-known literature reports [23,4], which begins with the dipyrromethane and involves the addition of benzaldehyde derivative followed by oxidation, usually effected by DDQ. We have previously reported 2- and 3-thienyl-dipyrromethanes [24a] as well as meso-substituted A_3-corroles that were prepared analogously as reported previously in *Polyhedron* [24b]. While the A_2B_2 porphyrin (Compound **2**) can sometimes be satisfactorily isolated as a by-product in the corrole-generating reaction above [25a], this species was prepared using more optimal conditions in accordance with a previously reported literature method [25b] to give a microcrystalline sample of

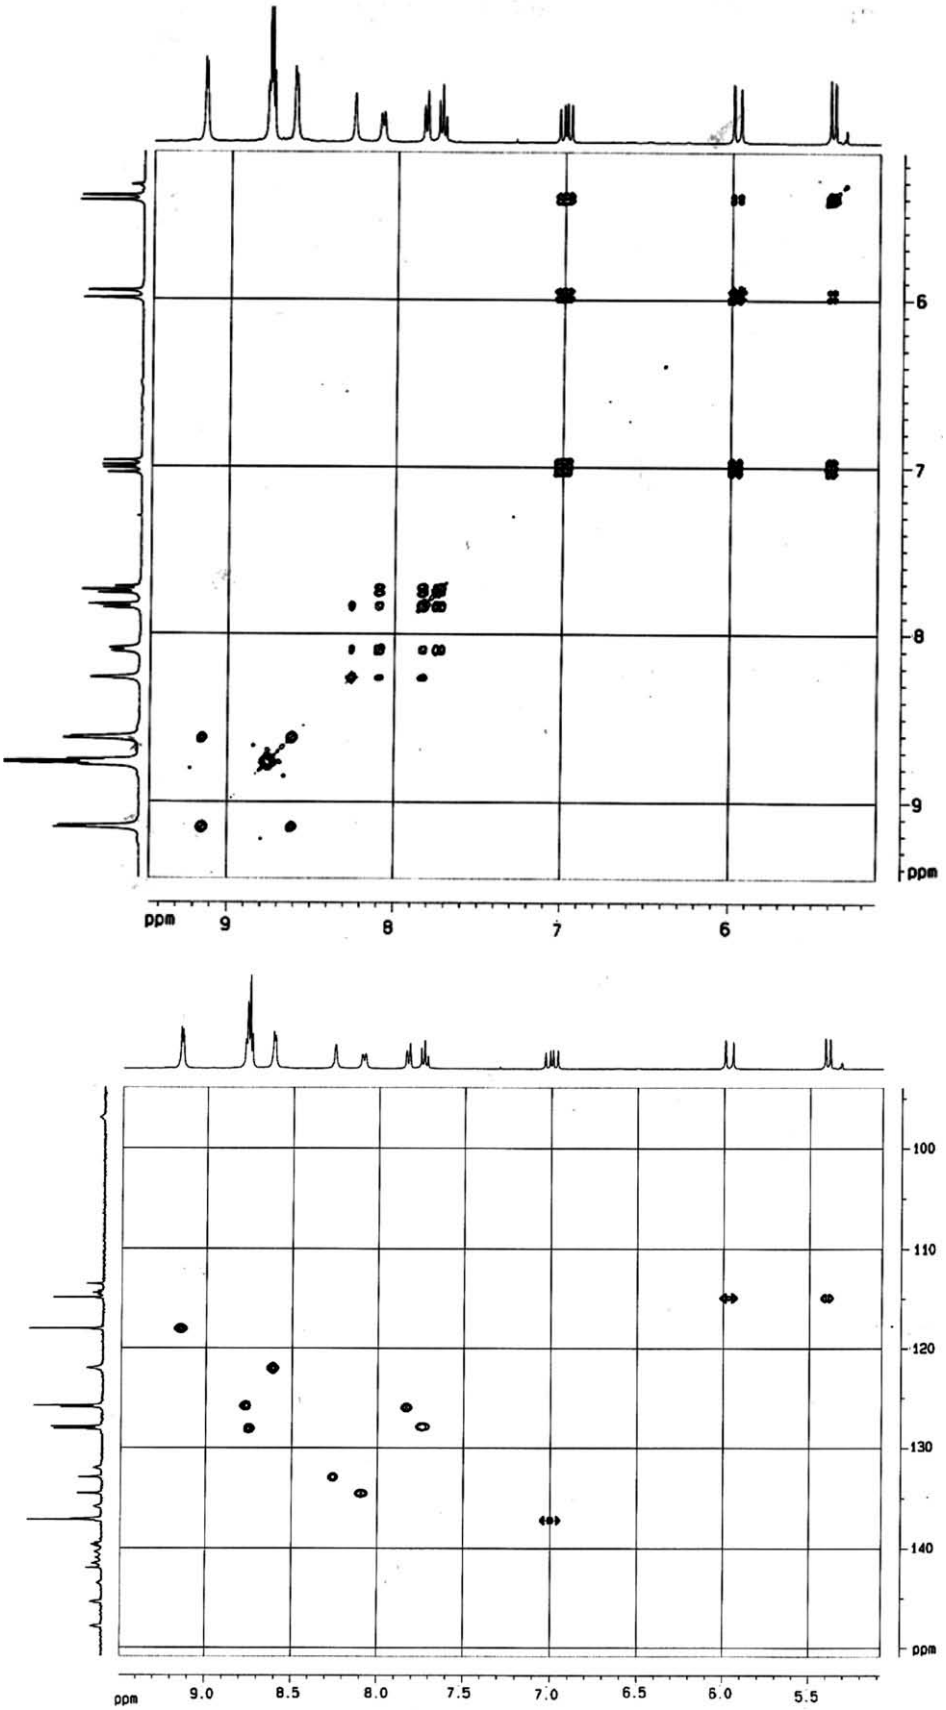

Fig. 3. (*top*) The aromatic portion of the ^{1}H–^{1}H COSY NMR spectrum showing all C–H protons, and (*bottom*) ^{1}H–^{13}C HMQC NMR spectrum showing all carbon resonances, for H_3(PFP-VC).

the species formulated as the Mn(III)porphyrinato chloride (**4**) [25c]. Thus, a solid of compound **2** was obtained through recrystallization in 37% yield (See Section 4). Suitability of this as an oxygen-atom transfer catalyst has been previously reported [20b,20d].

Characterization of the new compounds **1**–**4** reported herein was made mainly by spectroscopic techniques: ^{1}H NMR, ^{13}C NMR and UV–Vis spectroscopic studies (e.g., Fig. 3 and Supporting Information) as well as CV measurements. We also relied on 2-D NMR spectra, which are used conveniently because of the fully unsaturated nature of Compounds **1** and **2** which have resonances gathered in the aromatic region (5–9 ppm). The substitution (as in Compound **2**) as well as other corrole features give rise to clearly assignable cross-peaks in 2-D NMR spectra such as the ^{1}H–^{1}H COSY and ^{1}H–^{13}C HMQC NMR spectra of H_3(PFP-VC) provided in Fig. 3. For mass spectrometry, the presence of the expected species comes from the inspection of isotopic clusters centered at calculated values for complexes **1**–**4** (Supporting Information). Additional characterization is provided by single-crystal X-ray diffraction for compound **1**, presented below.

2.2. UV–Vis spectroscopic detection of organophosphonate via titrations in CH_2Cl_2

While fluorescence characteristics of corroles can be intense and unique, incorporation of Mn^{3+} renders the complexes non-fluorescent. Thus, herein we rely on UV–Vis absorption spectroscopic changes. Electronic absorption spectra of Mn(PFP-VC) (**3**) and Mn(PFP-VP) (**4**) with different organophosphonate species bearing various binding atoms will be presented in this section. Detailed titrimetric spectra are provided in Figs. 4–6 for Mn corroles and Figs. 7 and 8 for Mn-porphyrins. These trials all show a diminution in the Soret band at 411 nm when Compound **3** is used. A new band at 473–483 nm grows in as indicated by a label in each figure. Triphenyl phosphine was also tested as an analyte; it also has the capacity to bind through its (lone) oxygen atom, and, along with the sterics and rigidity of the phenyl groups, does so less efficiently, as shown by comparatively smaller changes in the spectrum (Supporting Information). This is surprising in light of the fact that a crystal structure of a closely related adduct is known. It is interesting to note that other, possibly better binding, phosphorus oxide species were *not* studied as of yet in this context.

A determination of ligand-to-metal complex stoichiometry in this reaction mixture was performed by the method of continuous variation. Titrimetric trials for A–D (Fig. 2) were performed, as shown e.g., in Fig. 4, in which a portion of Mn(PFP-VC) in dichloromethane was titrated by $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$ (**A**). Clear growth of new bands appear at 473 and 634 nm. The $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$ species is interesting in that there is a pendant amino group in virtually the same place as that seen for VX (Fig. 2), relative to the central phosphorus [26,27]. The next titration involved $(C_2H_5O)_2P{=}O(CH_2COCH_3)$ which afforded new bands in the electronic absorption spectra at 483 and 631 nm. The $(CH_3CH_2O)_2P{=}O(Me)$ species gave bands at 481 and 635 nm. Finally, $(C_4H_9O)_2P{=}O(Me)$ gave bands at 481 and 631 nm (Supporting Information). For these four species (Figs. 4–6, and S14) the Job plots involving the method of continuous variation were prepared; in all these cases (Insets of Figs. 4–6, and S14), the maximum peak at a mole fraction of ~0.5 is indicative that the solution stoichiometry is the expected 1:1 ligand-to-metal binding ratio. This is in accordance with the notion that the organophosphonate species will bind mainly through the phosphoryl [O=P] oxygen atom. The possibility of its binding through other heteroatoms, albeit more weakly, will not be considered herein.

There may be some concern that the Mn corrolato system valence state may change during, or prior to, analyte binding in light of (i) Mn^{4+} being an air stable metallocorrolate oxidation state and (ii) the involvement of stabilizing axial ligation [25e]. Importantly, to support our formulated Mn valence states, EPR spectroscopy for the $Ph_3P{=}O$ adduct of the Mn(tpf)corrolato species reported by Gross et al., reveals a Mn(III) ($S = 2$) metal center [19a]. This characterization excludes the possibility for the Mn(II) "radical cation" species [25d] and also for a Mn(IV) center. Compound **3** differs from the Mn(tpf)corrolato species only by the 10-position aryl group in which a 3-vinyl phenyl group replaces a pentafluorophenyl group. This small substitution will unlikely change the chemistry dramatically. Further experimental support that we do *not*

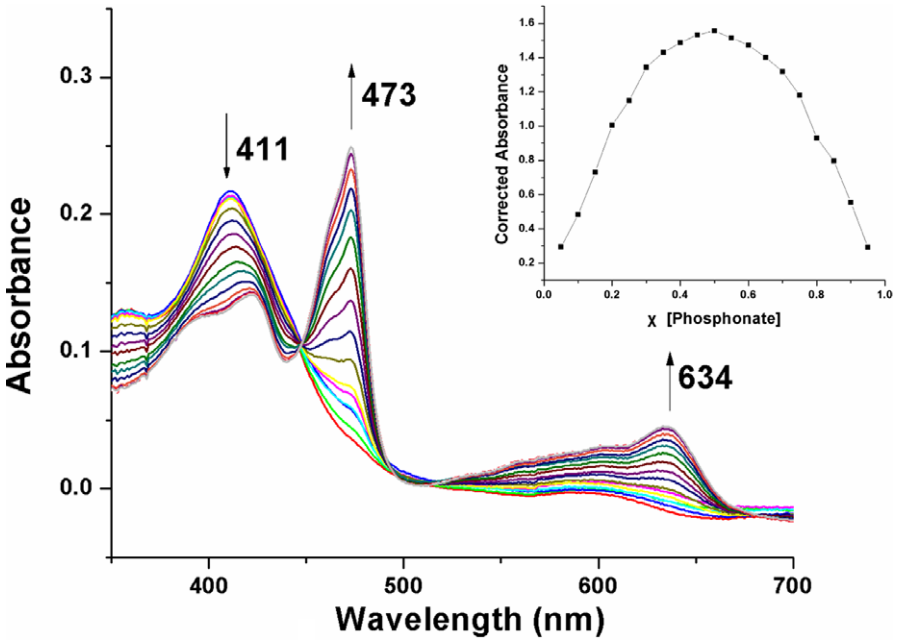

Fig. 4. Electronic absorption spectra of Mn(PFP-VC) [4.69×10^{-6} M] treated in dichloromethane with $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$ [5.06×10^{-3} M] (10–50 (by 10), 100–650 (by 50) μL). Inset: Job Plot for a (binary) mixture of **3** with $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$ showing a 1:1 stoichiometric correspondence.

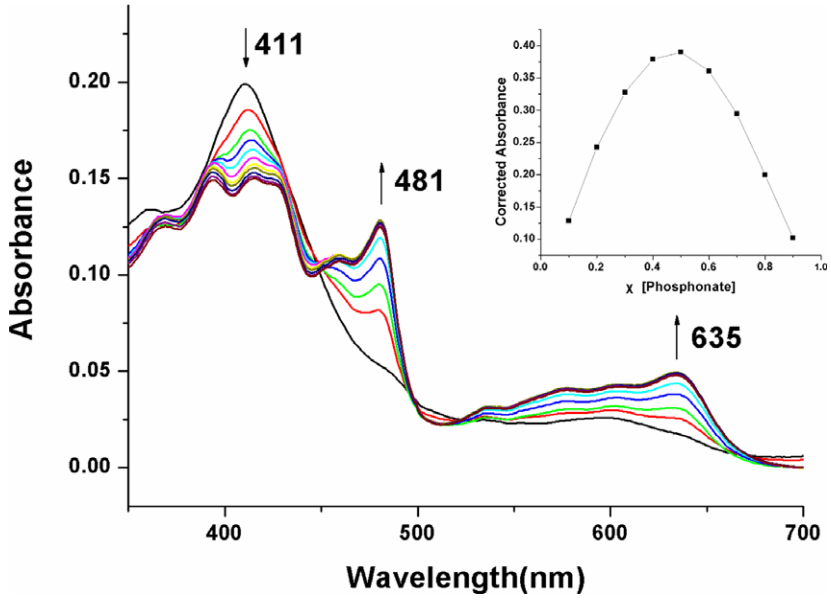

Fig. 6. Electronic absorption spectra of Mn(PFP-VC) [4.69×10^{-6} M] in the presence of various amounts (50–500 (by 50) μL) of $(CH_3CH_2O)_2P{=}O(Me)$ [2.74 M] in dichloromethane. Inset: Job Plot for a binary mixture of **3** with $(CH_3CH_2O)_2P{=}O(Me)$.

access *reduced* Mn-corrolato forms comes from the fact that electro-reduced forms of Mn(III) are unstable towards solvents, i.e., methylene chloride [25e], especially in the absence of a clear reductant. Additional support for Mn(III)corrolato ones comes from an analogous corrolazine compound reported by Goldberg and coworkers in which a shoulder at 722 nm in the UV–Vis spectrum is assigned to the Mn(III)O=PPh_3 adduct [19b]. In terms of Mn-corrole coordination, the Mn(III) species may exist in solution with one more axial MeCN. To further delve into the particulars of the valence state as well as a consideration of substrate/anion binding, we can turn to electrochemical studies discussed below that introduces a detailed report by Kadish and coworkers [25f] who have addressed how to best assign the valence state of the metal ion under various conditions [8].

We also studied the related binding for the *porphyrin* compound Mn(PFP-VP) with $(C_4H_9O)_2P{=}O(Me)$, $(C_2H_5O)_2P{=}O(CH_2COCH_3)$, and $(CH_3CH_2O)_2P{=}O(Me)$. These analytes were used in UV–Vis titrimetric trials whose results are plotted in Figs. 7 and 8 (and Supporting Information). All four assays give rise to clear changes compared to those of the Mn-corrole cases in that the Soret band undergoes moderate diminution and blue shifting only to give a new band in the range of 450–460 nm. While there is a clean spectral change, a much greater amount of analyte was required to effect this optical change than was needed in the corrole case, thus,

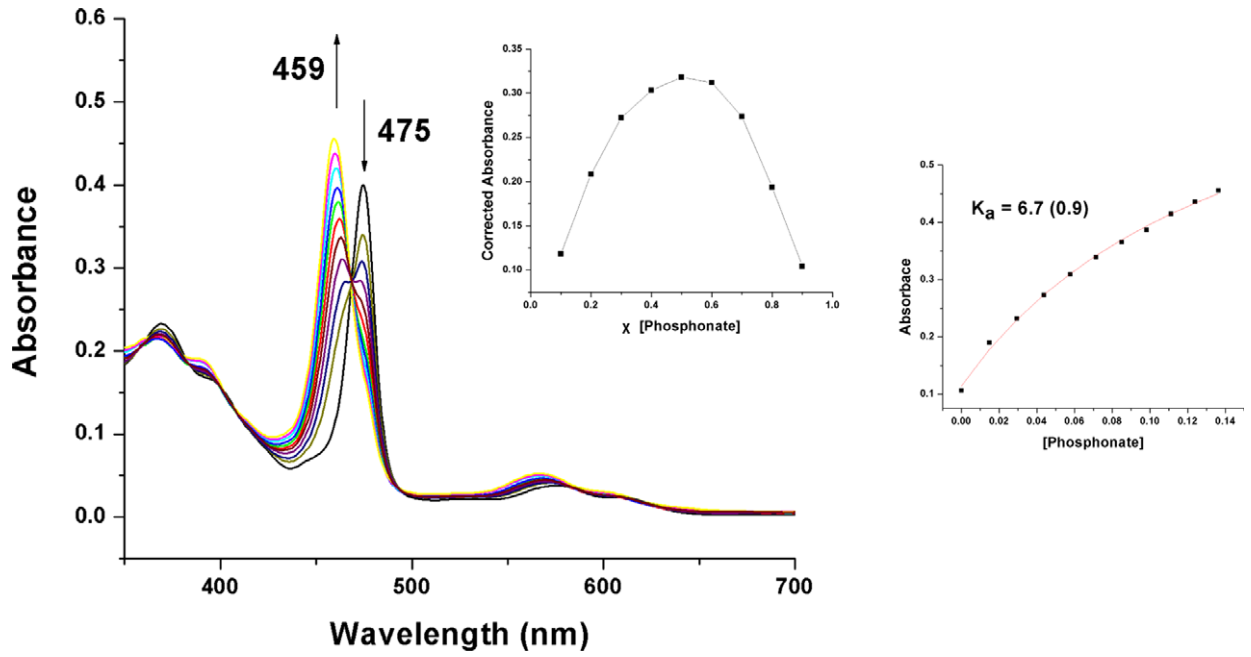

Fig. 7. Electronic absorption spectra of Mn(PFP-VP) [5.00×10^{-6} M] in dichloromethane upon titration with various amounts of $(C_2H_5O)_2P{=}O(CH_2COCH_3)$ [1.50 M] (20–200 (by 20) μL). Inset: Job Plot for a binary mixture of **4** with $(C_2H_5O)_2P{=}O(CH_2COCH_3)$.

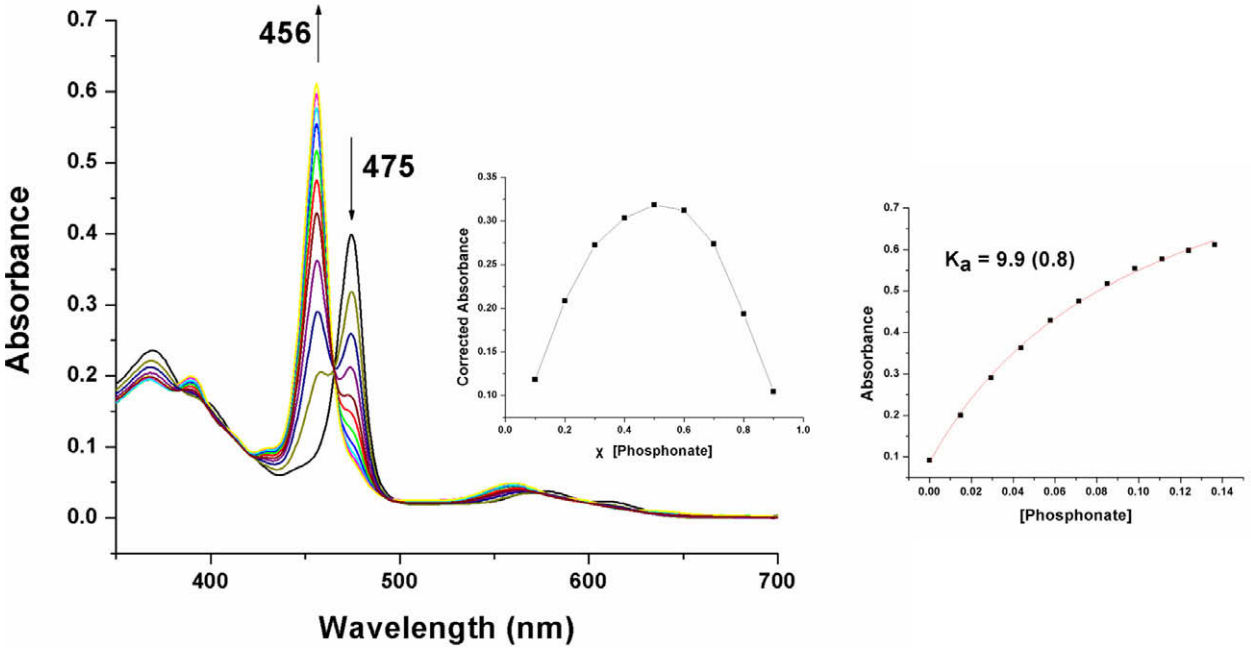

Fig. 8. Electronic absorption spectra of Mn(PFP-VP) [5.00×10^{-6} M] in dichloromethane in the presence of various amounts of $(C_2H_5O)_2P{=}O(Me)$ [1.50 M] (20–200 (by 20) μL). Inset: Job Plot for a binary mixture of **4** with $(C_2H_5O)_2P{=}O(Me)$.

these porphyrin-based systems are obviously less sensitive and less impressive as a potential sensing platform in the context of organophosphonates. This is in line with the tendency for a more in-plane metal ion in which a larger deviation from the [N_4] plane may encourage stronger analyte binding. The binding constants (K_a) values were measured by way of an equation reported by Valeur et al. [32] and are provided below as insets (Figs. 7 and 8). The binding constant for $(C_2H_5O)_2P{=}O(CH_2COCH_3)$ is 6.7 (0.9) M^{-1}; that for $(C_2H_5O)_2P{=}O(Me)$ is 9.9 (0.8) M^{-1}; and, that for $(C_4H_9O)_2P{=}O(Me)$ is 11.9 (0.4) M^{-1}.

As in the corrole case, we believe that this porphyrin system maintains an unchanged valence state upon binding. We should note, however, that a similarity in blue shifting pattern occurs for Mn=O formation. The oxo-Mn-(*meso*-tetrakis-2,3,5,6,-tetrafluoro-*N*,*N*,*N*-trimethyl-4-aniliniumyl)porphyrinato species (427 nm) gives a band at for the Mn(III)-porphyrinato at ~450 nm, upon

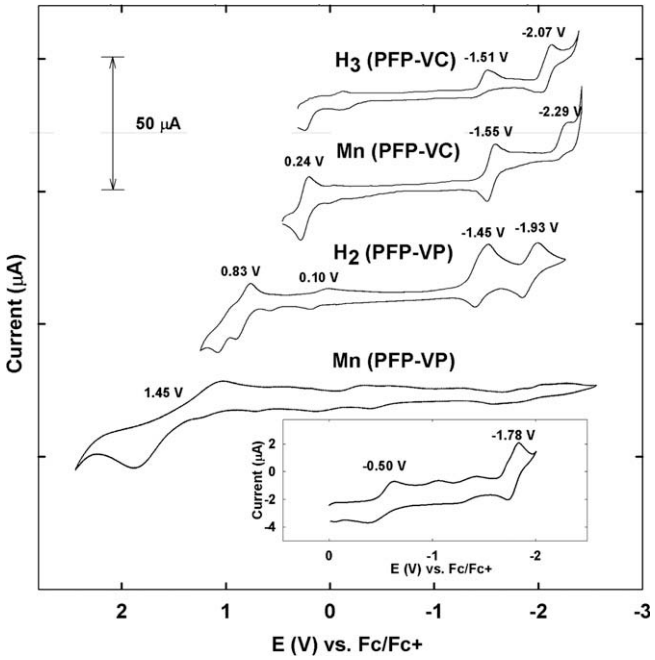

Fig. 9. Cyclic voltammetry data for compounds **1–4**, [3.0 mM], respectively, at room temperature in benzonitrile. Refer to Section 4 for further details. Half-wave potentials and peak potentials for **1–4** in benzonitrile. The inset is from a measurement of compound **4** at 1.0 mM.

carbamazepine epoxidation (10,11-position oxidation) [25c]. Thus further determinations for our porphyrin species will need to be made through future work.

2.3. Cyclic voltammetry (CV)

Electrochemistry often enables for the useful assignment of metal and ligand oxidations and affords a look at an analysis of the state of the M^{n+} of the metal complex, especially when considering transition metal ions such as manganese. A variety of recent reports of Mn-corrolates are available [25f]. The cyclic voltammograms have been obtained for compounds **1–4** and are provided below in Fig. 9. The cyclic voltammograms which include half-wave potentials/peak potentials (versus Ag/Ag^+ or Fc/Fc^+ or SCE) were obtained in PhCN. As revealed by the CV curve in Fig. 9, the reduction potentials for **3** are −1.55 and −2.29 V (versus SCE). This value is very similar to the reduction potentials of −1.51 and −2.07 V (versus SCE) for the metal free corrole **1** and has been assigned as corrole-centered reductions. The oxidation potential for **3** (0.24 V versus SCE) is assigned to the metal center, and is less than that for the Mn(tpf)corrole (0.71 V versus SCE), indicating **3** is more easily oxidized than the Mn(tpf)corrole [28]. A comparison to Mn(Mes_2Ph)corrole can also be made (Table 1). This species has been studied in considerable detail and has a variety of reduction and oxidation potentials depending on the solvent and axial anion coordination which are similar when in non aqueous media [25f].

Data was also obtained for the porphyrin-based species **2** and **4** (Scheme 1). For the free-base porphyrin, the first reduction occurs at −1.45, and −1.93 V, and the oxidization values occur at 0.10 and 0.83 V. For the Mn(III)-porphyrin chloride species, the first small $E_{1/2}$ reduction occurs at −0.50 with another occurring out at −1.78 V (Inset, Fig. 9); a broad $E_{1/2}$ of oxidation exists at 1.45 V.

2.4. Structural characterization of compound *1*

We also provide herein the crystal structure of 5,15-bis(pentafluorophenyl)-10-(3-vinylphenyl)corrole (**1**) (Fig. 10). The molecular structure of **1** confirms the presence of the vinyl moiety found also naturally in hemes; it points down and is suggestive of a clear surface anchoring group [21]. This serves as the first structural example of molecule with a 3-vinyl-phenyl dipyrrin/dipyrromethane fragment. There exists a plausible hydrogen bonding network between pairs of molecules as well (Supporting Information). Crystallographic packing structures provided for this structural solution separately along all three axes have been prepared (Supporting Information).

2.5. DFT calculations on bare corrole and porphyrin model systems

To try to understand the differences between neutral [28b] Mn–corrole and Mn–porphyrin organophosphonate binding and related transformations, we undertook DFT calculations using an unsubstituted corrole or porphyrin, oxygen atom, and the requiste phospho*nate*/*-ite* fragments. While calculations have previously been undertaken in trying to understand porphyrin M=O species, the details of M–O–P interactions are particularly informative in the present context. Electronic energies and geometries for formal M–O and P–O bond cleavage products for various metal-based spin states are illustrated in Figs. 11 and 12. The spin states in the corrole case were the singlet, triplet and quintet. Going from the bench-mark "Compound I"-like metal oxo species [1,29] the differences in energies in the middle section and those on the left represent the energy of formal O–M cleavage, whereupon the O-atom formally migrates from the metal to the phosphorus atom of the phospon*ite* ($POMe_2Me$). Going from the middle set to the right side set (in Fig. 11) formally signifies the attachment of the phosphine atom to the manganyl O-atom. This atom then becomes engaged as the donor atom in a Lewis base adduct with the metal center. The presence of the O=P bond, as well as a favorable dative interaction of ~10 kcal/mol gives this species (for the singlet) the lowest energy state. How the O-atom rearranges from an $X_2(L)$ donor to an L-type donor is a very interesting point for later consideration. A similar profile exists for the neutral Mn-porphyrinato and its derivatives (Fig. 12). Herein, the doublet, quartet, and sextet spin states were calculated. A much higher energy profile for the

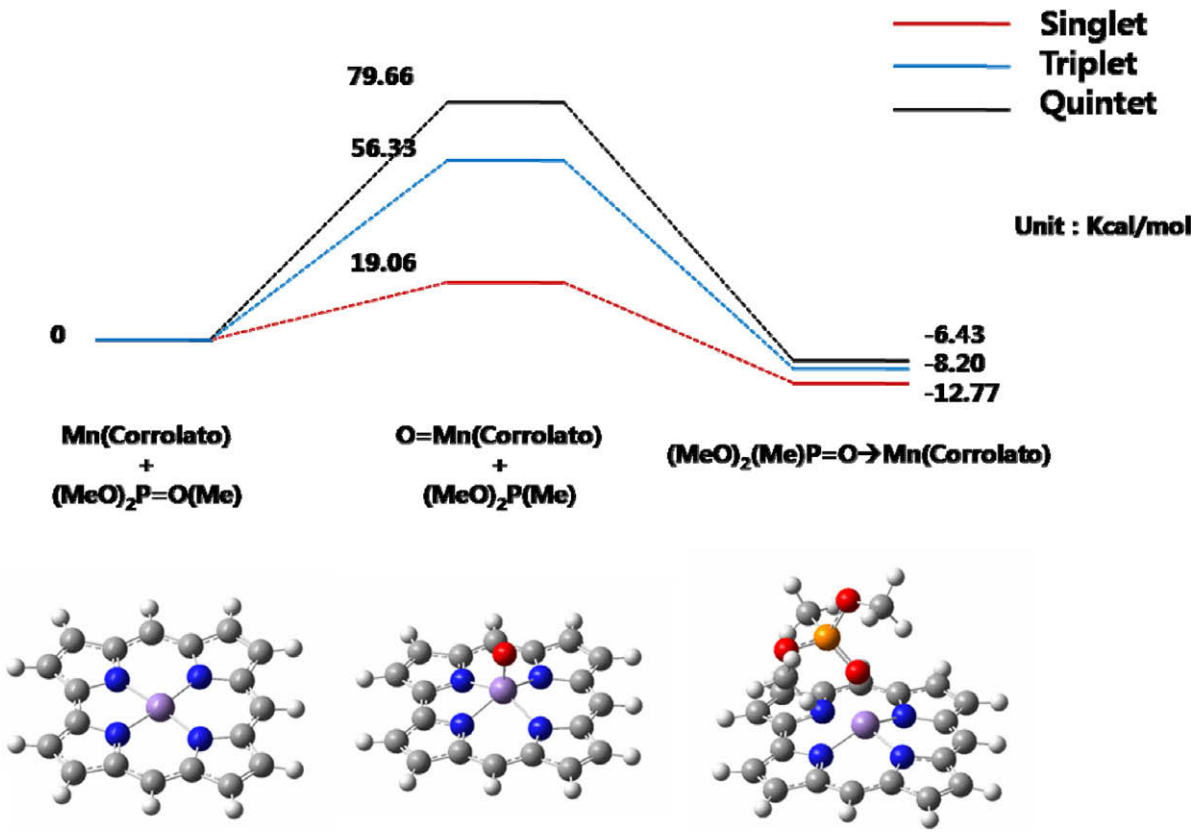

Fig. 11. Relative energies and geometries for three neutral manganese(III) corrolato species.

terminal oxo-derivative is evident, when compared to the corrolato counterpart. The oxo-intermediate is lowest for the doublet spin state; but the sextet actually "edges out" the doublet as the lowest energy species as the phosphonate adduct (right side set in Fig. 12). Clearly, the P═O will never oxidize the manganese in either the corrole or porphyrin case; and this obviously drives phosphine oxidation catalysis; how phosph*onites* might oxidize or *de*-oxidize in the context of nerve agent sensing and remediation is "food for thought." These calculations help in approaching or understanding the opportunities, and limitations of catalytic decontamination of organophosphonate-based chemical warefare agents. Structurally, the Mn–O–P angle in the Mn(pfp)corrolato is 158.6° and the metal exists 0.29 Å above the [N_4] mean plane [19a], the calculated Mn–O–P angles and manganese atom "out-of-plane" distances in these model systems depend on the spin state and are provided in Table 2 comparison for both the corrole and porphyrin adducts.

3. Conclusion

In this report we have described the preparation, characterization, and dynamics of new A_2B-corrole, *trans*-A_2B_2-porphyrin, and their manganese complexes. To our knowledge, this is the first

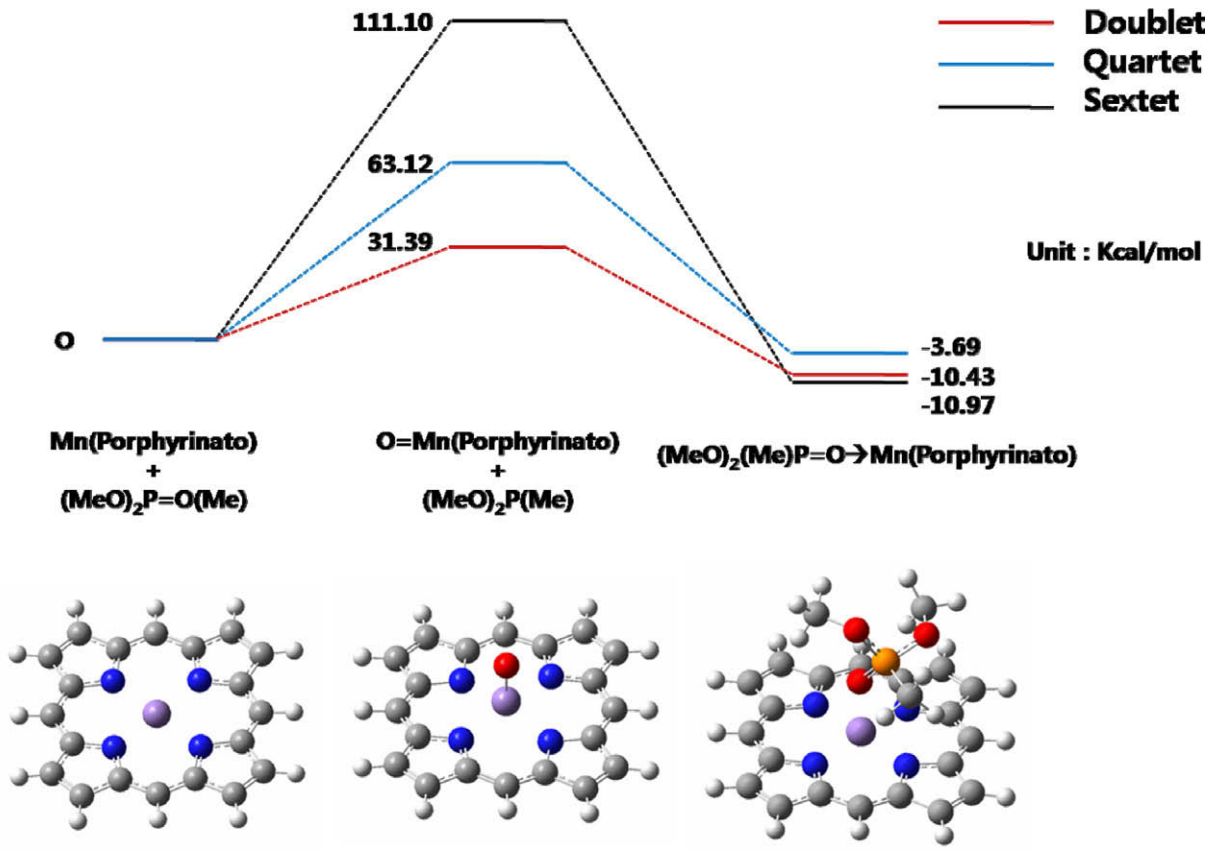

Fig. 12. Relative energies and geometries for three neutral manganese(II) porphyrinato species.

Table 2
Geometrical features in the calculated structures of Mn-porphyrinato and -corrolato species.

Mn-corrole multiplicity	Distance of Mn and [N_4] mean plane	Mn-corrole multiplicity	Mn–O–P angle
Singlet	0.54 Å	singlet	141.1°

Sextet	0.11 Å	sextet	139.8°

determination of OP sensing capabilities of metallocorroles and metalloporphyrins. Also this is the first report of a *meso* 3-vinylphenyl substituted polypyrrole species. The synthesis for the metallocorroles and metalloporphyrin species is adapted from the literature. We undertook detailed NMR spectral characterization and obtained the structure of the free-base corrole (**1**) through the use of single-crystal X-ray diffraction. We probed the possibility of selective sensing of nerve agent model organophosphonate species. The bonding of organophosphonate to the Mn^{n+} center is supported by the strong responses in the UV–Vis spectrum upon analyte titration. This technique gave quantification of 1:1 binding for the Mn(PFP-VC)corrole (**3**) (PFP-VC = 5,15-di(pentafluorophenyl)-10-(3-vinylphenyl)corrolate) with $(CH_3CH_2O)_2P{=}O(C_3H_6NMe_2)$, $(C_4H_9O)_2P{=}O(Me)$, $(C_2H_5O)_2P{=}O(Me)$, and $(CH_3COCH_2)P{=}O(OC_2H_5)_2$. The titrimetric data allows for the calculated K_a values in the case of the [Mn(PFP-VP)][Cl] which ranged from 6.7 to 11.9 M^{-1}. These studies confirm 1:1 binding through the use of Job plots for compound **4** as well. Cyclic voltammetry of compounds was acquired for **1**-**4**; the values of the Mn(PFP-VC)corrole can be compared to those for Mn(Mes_2Ph)corrolato that appear in a recent report from Kadish and coworkers [25f]. Modeling of $O{=}P(OMe)_2Me$ binding and formal M–O or P–O cleavage products in bare neutral Mn-corrole and -porphyrins with different metal-based spin states was undertaken. These efforts revealed the effect of $(MeO)_2P{=}O(Me)$ phosphoryl O-atom binding using three different metal-based spin states. Regarding the minimum bare corrole/porphyrin organophosphonate binding energies, greater stability occurred for the Mn-corrole (singlet) and the Mn-porphyrin (sextet) than for other spin states studied. From this data, we can support that the corrole is a more sensitive platform for organophosphonate sensing and has a possibility to optically detect organophosphonate on at least the *micro*molar level because of clear changes that occur in the UV–Vis spectrum. This sensitivity is probably inadequate for current nerve agent applications as a stand-alone method, however. But it is hoped that this report will enable various further studies, especially in realm of nanoscience, and with respect to piezoelectric studies in which the response involves acoustic signals of mass differences, not optical signals. Also, these compounds can be studied in the presence of a variety of decomposition products (CN^-, F^-, phosphonic acids) that could be present under real "battlefield" conditions. Future studies, may include catalysis with these species [20b]; also an expansion

of this same analyte binding can be made to the related manganese-corrolazines.

4. Experimental

4.1. General considerations

All reagents and solvents herein were of analytical grade and used as received from reliable commercial sources. The reagents 3-vinylbenzaldehyde, DMF, TFA, DDQ, $F_3B{\cdot}OEt_2$, $Mn(OAc)_2{\cdot}4H_2O$ were purchased from Aldrich, USA; pentafluorophenylcarboxaldehyde was acquired from TCI, Japan; toluene, dichloromethane, and chloroform were acquired from Merck [30]. Dipyrromethane was prepared by literature report [22]. The synthetic procedures for A_2B corroles and their metallocorroles were adapted from the literature [23]. All solvents used for NMR spectral analysis were purchased commercially and were of spectroscopic grade. ^{1}H NMR spectra were measured in $CDCl_3$ or CD_2Cl_2 with Bruker Avance 300 and 400 MHz spectrometers. Spectral signals were calibrated by the *protio* impurity of the deuterated solvent. Infrared spectra were recorded with a Bruker Equinox 55 spectrophotometer; UV–Vis spectra were obtained with a JASCO V-503 UV–Vis spectrometer. A Vario EL III CHNS elemental analyzer was used in obtaining microanalysis values. High resolution MALDI mass spectrometry was performed by the staff of the research supporting team at KAIST on a VG AUTOSPEC ULTIMA with a trisector double focusing magnetic sector analyzer at a resolution of 80 000.

4.2. Preparation of 5,15-bis(pentafluorophenyl)-10-(3-vinylphenyl) corrole [H_3(PFP-VC)], (**1**)

A mixture of 5-(pentafluorophenyl)dipyrromethane (5.13 g, 16.4 mmol) and 3-vinylbenzaldehyde (1.04 mL, 8.2 mmol) and a dichloromethane solution of TFA (80 μL), were dissolved in 800 mL dichloromethane. The reaction mixture was stirred for 12 h. DDQ (4.47 g, 19.6 mmol) in toluene was added dropwise over several minutes accompanied by vigorous stirring, which continued for 15 additional minutes. The volume of the reaction mixture was then reduced and the mixture was filtered through a pad of silica (silica gel, CH_2Cl_2:hexane = 1:1), followed by column chromatography (silica gel, CH_2Cl_2:hexane 1:4) which ultimately gave a dark green solid. This compound was further purified by preparative TLC to give pure corrole, H_3(PFP-VC) (613 mg, 10.2%). MALDI-TOF: m/z $[M+H]^+$: 733.137 (calc); 733.791 (obs). ^{1}H NMR(δ, CD_2Cl_2): 9.15 (d, J_{H-H} = 4.17 Hz, $2H_{3,18}$), 8.76 (m, $4H_{8,9,12,13}$), 8.62 (d, J_{H-H} = 3.98 Hz, $2H_{4,17}$), 8.26 (s, $1H_f$), 8.09 (d, J_{H-H} = 7.22 Hz, $1H_j$), 7.83 (d, J_{H-H} = 7.86 Hz, $1H_h$), 7.74 (t, J_{H-H} = 7.58 Hz, $1H_i$), 7.00 (dd, J_{H-H} = 17.60, 10.94, $1H_k$), 5.97 (d, J_{H-H} = 17.56, $1H_{l\text{-}trans}$), 5.40 (d, J_{C-H} = 10.98, $1H_{l\text{-}cis}$). ^{13}C-NMR: 147.87, 145.42, 143.49, 141.96, 141.52, 140.96, 140.37, 139.66, 137.19 (t, $^1J_{C-H}$ = 82.6 Hz, C_k), 135.88, 134.54 (d, $^1J_{C-H}$ = 159.9 Hz, C_j), 132.93 (d, $^1J_{C-H}$ = 164.3 Hz, C_f), 132.01, 128.11 (d, $^1J_{C-H}$ = 173.2 Hz, $C_{8,13}$), 127.91 (d, $^1J_{C-H}$ = 159.5, C_i), 125.97 (d, $^1J_{C-H}$ = 147.6 Hz, C_h), 125.81 (d, $^1J_{C-H}$ = 172.0 Hz, $C_{9,12}$), 122.02 (d, ^1J = 170.1 Hz, $C_{4,17}$), 118.06 (dd, ^1J = 173.1 Hz, 3.5 Hz, $C_{3,18}$), 114.93 (dd, ^1J = 159.7 Hz, 6 Hz, C_l), 114.47, 113.543. ν_{N-H} (KBr): 3421 cm^{-1}.

4.3. Preparation of 5,15-bis(pentafluorophenyl)-10,20-bis(3-vinylphenyl)porphyrin [H_2(PFP-VP)] (**2**)

5-(Pentafluorophenyl)dipyrromethane (0.50 g, 1.6 mmol) and 3-(vinylphenyl)benzaldehyde (0.20 mL, 1.6 mmol) were added to a portion of chloroform (160 mL); $BF_3{\cdot}OEt_2$ (65 μL) was then added dropwise to this reaction mixture. The reaction mixture was stirred for 1 h at RT; DDQ (0.27 g, 1.2 mmol) in toluene was then added slowly. After 1 h, the reaction mixture was filtered through a silica gel pad followed by purification via silica gel column chromatography (CH_2Cl_2: hexane = 1: 1) which gave a purple solution. This solution was then evaporated to give a purple solid (247 mg, 37.2%). ^{1}H NMR ($CDCl_3$): δ 8.97 (d, J_{H-H} = 4.8 Hz, $H_{3,9,13,19}$), 8.80 (d, J_{H-H} = 4.8 Hz, $H_{4,8,14,18}$), 8.26 (s, $2H_f$), 8.11 (d, J_{H-H} = 7.5 Hz, $2H_j$), 7.86 (d, J_{H-H} = 7.9 Hz, $2H_h$), 7.73 (t, J_{H-H} = 7.6, $2H_i$), 6.99 (dd, J_{H-H} = 17.6, 10.9 Hz, $2H_k$), 5.96 (d, J_{H-H} = 17.5, $2H_{l\text{-}trans}$), 5.42 (d, J_{H-H} = 11.0, $2H_{l\text{-}cis}$), −2.82 (s, $2H_{N-H}$). MALDI-TOF: m/z $[M+H^+]$ 847.184 (calc); 847.666 (obs). ν_{N-H} (KBr): 3321 cm^{-1}. *Anal.* Calc. for $C_{48}H_{24}N_4F_{10}$: C, 68.09; H, 2.86; N, 6.62. Found: C, 66.99; H, 2.91; N, 6.46%.

4.4. Preparation of 5,15-bis(pentafluorophenyl)-10-(3-vinylphenyl) corrolate manganese(III) [Mn(PFP-VC)] (**3**)

A small round-bottom flask was charged with 15 mL of dry DMF, H_3(PFP-VC) (0.05 g, 0.068 mmol), and $Mn(OAc)_2{\cdot}4H_2O$ (0.05 g, 0.20 mmol) and was heated to reflux for 20 minutes. The complete consumption of H_3(PFP-VC) was confirmed through the use of TLC assaying. The reaction mixture was then allowed to cool to room temperature after which time the solvent was removed under reduced pressure. The resulting residue was purified by silica gel column chromatography (1:1, hexane:ethyl acetate) to give pure Mn(PFP-VC). The yield was 50.0 mg (94%). MALDI-TOF: m/z (M^+): 784.052 (calc); 784.215 (obs). *Anal.* Calc. for $C_{39}H_{15}N_4F_{10}Mn$: C, 59.71; H, 1.93; N, 7.14. Found: C, 59.66; H, 3.04; N, 6.08%. λ_{max} (log ε/(M^{-1} cm^{-1})): 601 (3.56); 411 (4.60) [soret band]; 356 (4.47).

4.5. Preparation of 5,15-bis(pentafluorophenyl)-10,20-bis(3-vinylphenyl)porphyrinato manganese(III) [Mn(PFP-VP)] chloride (**4**)

H_2(PFP-VP) (85 mg, 0.1 mmol) and manganese acetate tetrahydrate (101 mg, 0.41 mmol) were dissolved in DMF (10 mL). The reaction mixture was refluxed for 1 h, and was then allowed to cool to room temperature. A TLC assay revealed no trace of free-base porphyrin. The reaction mixture was then placed into a NaCl aqueous solution containing a portion of ice, which allowed a green precipitate to form. This solid was isolated by filtration and dried affording a (green) solid formulated as the mono-chloride **4** (85.1 mg, 91.1%). MALDI-TOF: m/z ($M-Cl^+$) 899.107 (calc), 899.427 (obs). λ_{max} (log ε/(M^{-1} cm^{-1})): 609 (3.68); 576 (3.88); 475 (4.90) [Soret band]; 396 (4.52); 369 (4.67).

4.6. X-ray structural determination of compound **1**

A single crystal of **1** was mounted on a goniometer and data were collected on a Bruker P4 diffractometer equipped with a SMART CCD detector using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The structure was solved using direct methods and standard difference map techniques, and was refined by full-matrix least-squares procedures on F^2 with SHELXTL (version 5.10). Cell parameters were determined and refined by the SMART program [31a]. Data reduction was performed by using SAINT software [31a]. The data were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using the SADABS program [31b]. The structures were solved by direct methods using the program SHELXS-97 [31c] and refined by full matrix least-squares calculations (F2) by using the SHELXL-97 software [31d]. All non-H atoms were refined anisotropically against F^2 for all reflections. All hydrogen atoms were placed at their calculated positions and refined isotropically. Crystal data, data collection and refinement parameters are summarized in the caption of Fig. 10.

4.7. Modeling of analyte binding

For non-linear fitting, we have used Eq. (1) [32,33] to determine 1:1 stoichiometry in our Mn-corrole and Mn- porphyrin systems.

$$A = A_0 + \frac{A_{\lim} - A_0}{2c_0}\left[c_0 + c_M + \frac{1}{K_s} - \left[\left(c_0 + c_M + \frac{1}{K_s}\right)^2 - 4c_0c_M\right]^{1/2}\right] \quad (1)$$

The parameters are as follows: A = absorbance, C_0 = concentration of corrole or porphyrin; K_s = binding constant, C_M = concentration of organophosphonate analyte, A_0 = absorbance of corrole or porphyrin; A_{lim} = absorbance when analyte is bound completely.

4.8. Cyclic voltammetry (CV)

Measurements were carried out with a BAS 100B instrument (Bioanalytical Systems, Inc). A three-electrode system was used consisting of a gold disk working electrode, a platinum wire counter electrode, and an Ag/Ag^+ electrode (MF-2062 kit, Bioanalytical Systems, Inc.) as the reference electrode. The Ag/Ag^+ contained 0.1 M tetrabutylammonium perchlorate (TBAP) and 0.01 M $AgNO_3$ in benzonitrile. In 0.1 M TBAP, the $E_{1/2}$ of the ferrocene/ferrocenium ion couple was taken to be 0.067 V versus Ag/Ag^+ in benzonitrile. The values in electrochemical experiments are reported versus the ferrocene/ferrocenium ion [29] redox couple.

4.9. Computational details

The GAUSSIAN 03 program was used for all calculational work [34]. All geometries were processed *in silico* in the gas phase at 0 K. The following protocol was used for all calculations: (i) input geometries were derived from the crystallographic structures provided herein where possible, or by careful modification of closely related geometries and invoking chemical intuition. (ii) Density functional theory (DFT) geometry optimizations were performed using B3LYP hybrid functional with the LACVP* (double zeta) basis set. The basis set used the Lanl2DZ effective core potential (ECP) for the manganese atom, and 6-31G(d) for all other atoms.

[25] [a] The isolation of the porphyrin from the corrole reaction involves preparative TLC. This however would favor migration of Mn(II) which is not ionic; as the Mn(II) migrates on silica in air, it may decompose and become the oxo (manganyl) species (ligand oxidation may also occur). The Mn(II) species however, is less stable than the [Mn(III)Cl] porphyrin species which can be more completely synthesized as chloride salt as discussed herein and reported previously.;

[b] An Mn(III) porphyrinato would require the use of an anion for electroneutrality; this was not pursued in these calculations. The point of this work was to seek an understanding of the diversity of the various spin states, which was done through the analysis of neutral systems. A Mn(III)porphyrinato species would be more electron deficient at the metal center (on average) and this would be expected to *strengthen* the organophosphonate dative interaction.

ABSTRACT

The rhenium(I) complexes $[Re(O_2CCF_3)(CO)_3(L)]$ (**1**) and $[Re(O_2CCF_3)(CO)_2LL']$ ($L = Ph_2POCH_2CH_2OPPh_2$; $L' = PPh_n(OR)_{3-n}$; R = Me, Et; $n = 0–2$) (**2a–f**) have been synthesised by the reaction of the parent bromo derivatives with AgO_2CCF_3. These compounds have been characterized by microanalysis, IR, NMR, mass spectrometry and, in the cases of **1** and **2a**, by X-ray diffraction. The metal is in a distorted octahedral environment with the trifluoroacetate ligand acting in a monodentate manner.

1. Introduction

Transition metal carbonyl complexes are widely studied in chemistry because they have many different applications ranging from catalysts [1] to biochemistry [2]. Many properties of the complexes, such as redox potential of the metal centre, lability of the ligands, etc., are related to the synergistic effects of σ and π bonds between the metal centre and the CO ligands [3]. On the other hand, phosphines are also very common ligands with tuneable electronic properties that allow them to mimic those of CO ligands. Moreover, the possibility of modifying their steric properties explains their wide use in many coordination compounds. Replacement of the R groups from PR_3 compounds by OR groups to form mixed phosphites ($PR_n(OR)_{3-n}$; $n = 0–2$) modifies the electronic character of the ligand, enhancing its π-acceptor character and reducing its σ-donor behaviour [4]. These changes, in turn, modify the properties of the metal complex. We are interested in analysing the properties of carbonyl complexes that bear mono- and bidentate mixed phosphites and we have previously reported on the properties of $[ReX(CO)_3L]$ [5] and $[ReBr(CO)_2LL']$ [6] (X = Br, OTf; L = diphosphinite; L′ = mixed phosphite). Substitution of the bromo ligand by the potentially bidentate OTf ligand, did not produce relevant differences on the properties of the complex. Thus, we report here the carbonyl rhenium complexes $[Re(O_2CCF_3)(CO)_3(L)]$ and $[Re(O_2CCF_3)(CO)_2LL']$ ($L = Ph_2POCH_2CH_2OPPh_2$; $L' = PPh_n(OR)_{3-n}$; R = Me, Et; $n = 0–2$) bearing the more basic trifluoroacetate ligand to investigate its influence on the properties of the new complexes.

2. Experimental

2.1. General methods and instrumentation

All experimental manipulations were carried out under an argon atmosphere using Schlenk techniques. Solvents were purified by conventional procedures [7] and distilled prior to use. The complexes $[ReBr(CO)_3(L)]$ and $[ReBr(CO)_2LL']$ ($L = Ph_2POCH_2CH_2OPPh_2$; $L' = PPh_n(OR)_{3-n}$, R = Me, Et; $n = 0–2$) were prepared by previously described methods [6].

The ^1H, $^{31}P\{^1H\}$, $^{13}C\{^1H\}$ and $^{19}F\{^1H\}$ NMR (δ in ppm) spectra were obtained on a Bruker ARX-400 spectrometer operating at frequencies of 400, 161, 100 and 376 MHz, respectively. ^1H and $^{13}C\{^1H\}$ chemical shifts are referred to internal TMS. $^{19}F\{^1H\}$ and $^{31}P\{^1H\}$ chemical shifts are reported with respect to $CFCl_3$ and 85% H_3PO_4, respectively, with downfield shifts considered positive. Infrared spectra were recorded as KBr discs on a Bruker VECTOR IFS28 FT spectrophotometer. Mass spectra were recorded in the LSIMS (FAB^+), Cs^+ mode on a Micromass Autospec M instrument, using 3-nitrobenzyl alcohol as the matrix material. The conductivity values of 10^{-3} mol dm^{-3} solutions of the complexes in $MeNO_2$ at 25 °C were measured with a Crison GLP 32 conductimeter. Elemental analyses (C, H) were performed using a Fisons EA-1108 microanalyzer. Melting points were determined on a GallenKamp MFB-595 and are uncorrected.

2.2. Synthesis of the complexes

AgO_2CCF_3 was added to a dichloromethane solution of the precursor complex $[ReBr(CO)_2(X)(L)]$ (X = CO or L′) in a 1.5:1 molar

ratio. The mixture was heated under reflux for 2–3 h and the AgBr formed was removed from the resulting grey suspension by filtration through Celite. In the case of complex **1**, the concentration of the resulting solution afforded an oil, which was triturated with diethyl ether (5 mL) to give a beige solid. This solid was filtered off, washed with diethyl ether (2 × 3 mL), dried under vacuum and recrystallised from a mixture of CH_2Cl_2/diethyl ether. In the case of compounds **2**, white solids were obtained and these were recrystallised from a mixture of CH_2Cl_2/hexane.

2.2.1. [Re(O$_2$CCF$_3$)(CO)$_3$(L)] (**1**)

AgO_2CCF_3 (42.4 mg, 0.192 mmol) was added to a solution of [ReBr(CO)$_3$(L)] (100 mg, 0.128 mmol) in dichloromethane (20 mL). Yield ⩾ 58%. M.p. 211 °C. $\Lambda_{M(nitromethane)}$ = 3.5 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $C_{31}H_{24}O_7P_2F_3Re$: C, 45.7; H, 3.0. Found: C, 46.0; H, 3.1%. IR (cm^{-1}) ν_{CO}: 2041, 1967, 1932; $\nu_{asym(OCO)}$: 1692, $\nu_{sym(OCO)}$: 1420. ^{1}H NMR ($CDCl_3$, ppm): δ 7.56–7.21 (m, 20H, Ph), 4.33–4.07 (m, 4H, –CH_2CH_2–). $^{31}P\{^1H\}$ NMR ($CDCl_3$, ppm): δ 116.5 (s). $^{19}F\{^1H\}$ NMR ($CDCl_3$, ppm): δ −74.8 (s). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, ppm): δ 66.5 (s, br, –CH_2–), 114.7 (q, J_{CF} = 288 Hz, CF_3), 128.8–138.3 (Ph), 162.2 (qt, J_{CF} = 37 Hz, J_{CP} = 2 Hz, O_2CCF_3), 191.2 (m, 2CO *cis* to O_2CCF_3), 191.5 (t, J_{CP} = 7 Hz, CO *trans* to O_2CCF_3).

2.2.2. [Re(O$_2$CCF$_3$)(CO)$_2$(L)(L′)] (**2**)

AgO_2CCF_3 (33 mg, 0.15 mmol) was added to [ReBr(CO)$_2$LL′] (0.1 mmol) in CH_2Cl_2 (20 mL).

Compound **2a**, L′ = P(OMe)$_3$: Yield ⩾ 37%. M.p. 202 °C. $\Lambda_{M(nitromethane)}$ = 3.0 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $C_{33}H_{33}O_9P_3F_3Re$: C, 43.6; H, 3.7. 2.3. X-ray crystallography

Single crystals of compounds **1** and **2a** were mounted on a glass fibre and studied on a Bruker Smart CCD area-detector diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The crystal parameters and experimental details for data collection are summarized in Table 1. Absorption corrections were carried out using SADABS [8]. The structures were solved with the OSCAIL program [9] by the Patterson method and refined by full-matrix least-squares based on F^2 [10]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were included in idealised positions and refined with isotropic displacement parameters. Atomic scattering factors and anomalous dispersion corrections for all atoms were taken from the International Tables for X-ray Crystallography [11]. Details of crystal data and structural refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis

The bromo complexes [ReBr(CO)$_3$(L)] [5a] and [ReBr(CO)$_2$LL′] [6] [L = $Ph_2POCH_2CH_2OPPh_2$, L′ = $PPh_n(OR)_{3-n}$ n = 0–2] reacted with an excess of AgO_2CCF_3 in refluxing dichloromethane to give [Re(O_2CCF_3)(CO)$_3$L] (**1**) and [Re(O_2CCF_3)(CO)$_2$LL′] (**2**), respectively, as beige (**1**) or white (**2**) solids (Scheme 1). The new complexes are air-stable in the solid state and in solution at room temperature, and were characterized by elemental analysis, IR spectroscopy, mass spectrometry and, in the cases of compounds **1** and **2a**, by X-ray diffraction. Conductivity measurements on nitromethane solutions of the compounds show values that are consistent with non-electrolyte behaviour, in agreement with the coordination of the trifluoroacetate anion to the rhenium atom. The compounds were also studied in solution by NMR spectroscopy.

3.2. Description of the structures

3.2.1. [Re(O_2CCF_3)(CO)$_3$(L)] (*1*)

An ORTEP [12] drawing of the two molecules in the asymmetric unit, along with the numbering scheme adopted, is shown in Fig. 1. Selected bond lengths and bond angles are listed in Table 2. The asymmetric unit contains two different molecules with identical formulae. Both consist of a rhenium(I) atom coordinated in an octahedral arrangement by three *facially* disposed carbonyl ligands, two phosphorus atoms of the chelating phosphinite ligand $Ph_2POCH_2CH_2OPPh_2$, and an oxygen atom of a trifluoroacetate ion acting as a monodentate ligand. The main differences between the two molecules in the asymmetric unit are: (i) the seven-membered chelate ring adopts a twisted boat conformation [13] in molecule 1 whereas it adopts a twisted chair conformation [13] in molecule 2; (ii) the chelate angles are 86.5(1)° [Re(1)] and 90.0(1)° [Re(2)]; (iii) molecule 1 has surrounding Re(1) parameters that are more distorted from the ideal octahedral geometry than those for molecule 2; (iv) the orientation of the carboxylate moiety [C–CO_2] is different in the two molecules, being directed towards the bisector of the two CO ligands in molecule 1 [torsion angles 38.3(4) and 52.8(4)°] and almost parallel to one of them [torsion angle 1.3(6)°] and perpendicular to the other in molecule 2.

The Re–P bond lengths span from 2.431(2) to 2.456(2) Å, a narrower range than that found in the closely related triflato complex [Re(OSO_2CF_3)(CO)$_3$(L)] [5b]. The Re–C bond lengths range from 1.87(1) to 2.00(1) Å, and they are similar to those of the triflato complex [5b]. The Re–C bond distances *trans* to the phosphorus atoms are, on average, 0.08 Å longer than that *trans* to the oxygen atom, a greater but comparable difference, than that observed for the triflato complex (0.06 Å) [5b]. Those values are also in a comparable range to that found for other *fac*-tricarbonyl Re(I) complexes bearing related diphosphinite ligands [5c].

The trifluoroacetate group acts as a monodentate ligand in a similar way to other rhenium(I) compounds bearing this group as a ligand [14]. The OCO angle (∼129°) and the O–C bond lengths of the carboxylate moiety (1.20–1.23 Å), which are near to the ionic limit (1.250 Å) as defined by Hocking and Hambley [15], are indicative of a high ionic character (>90%) for the carboxylate–rhenium interaction.

3.2.2. [Re(O_2CCF_3)(CO)$_2$(L){P(OMe)$_3$}] (*2a*)

An ORTEP [12] drawing of the molecule, along with the numbering scheme adopted, is shown in Fig. 2. Selected bond lengths and bond angles are listed in Table 3. The compound consists of a rhenium(I) atom coordinated by two *cis* carbonyl ligands, two phosphorus atoms of the chelating bidentate phosphinite ligand $Ph_2POCH_2CH_2OPPh_2$, another phosphorus atom from a trimethylphosphite ligand and an oxygen atom of a trifluoroacetate group, which acts as a monodentate ligand. This arrangement results in an octahedral arrangement around the metal atom. The three phosphorus atoms are in meridional positions. The Re–C

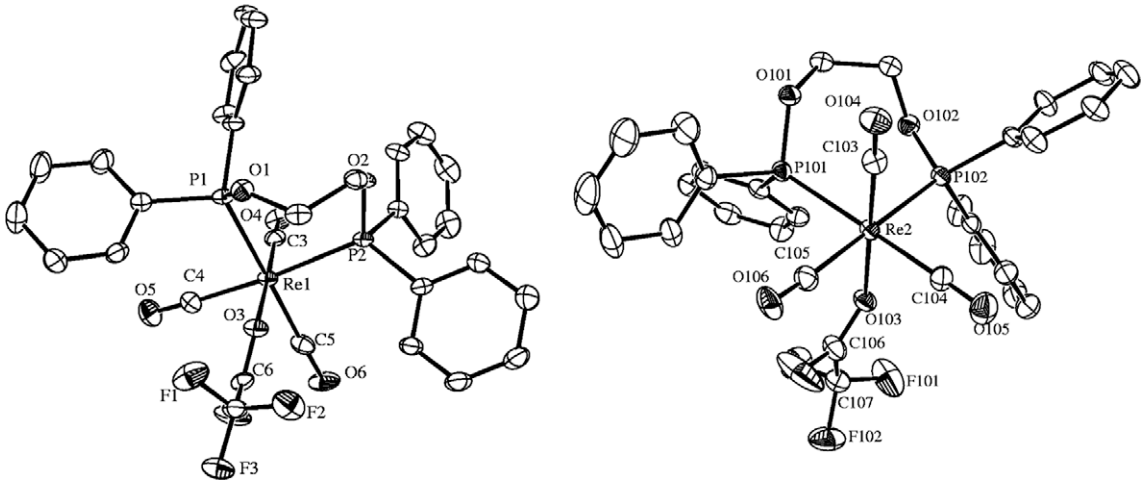

Fig. 1. Molecular structure of molecules 1 (left) and 2 (right) of compound **1**.

bond distances are 1.864(12) and 1.914(13) Å, with the shorter one corresponding to that *trans* to the trifluoroacetate ion. The bidentate phosphinite ligand shows two different Re–P bond lengths, 2.402(3) and 2.467(3) Å, with the shorter one corresponding to that *trans* to the phosphite ligand. The geometrical parameters for the trifluoroacetate ligand are similar to those observed for **1** and are consistent with its monodentate behaviour. The *cis* angles range from 82.2(2) to 95.9(4)°. It is noteworthy that the most distorted values are those of the trifluoroacetate ligand, probably due to the steric requirements of the phenyl groups of the bidentate phosphinite ligand in the direction of the position occupied by the trifluoromethyl group. In fact, the carboxylate moiety of the trifluoroacetate ligand is not parallel to any other ligand, but is directed towards the free space between a carbonyl and the phosphite ligand with very different torsion angles: 21.8(4)° with the carbonyl ligand and 69.9(3)° with the phosphite ligand [vectors defined as O(4)–O(3) versus Re–O(2) and Re–P(3)]. The seven-membered chelate ring adopts a twisted boat conformation [13] with a chelate P(1)–Re–P(2) angle of 87.8(1)°.

3.3. Spectroscopic studies

The IR spectrum of compound **1** shows three strong ν(CO) bands that are characteristic of the *fac*-Re^{I}(CO)$_3$ fragment [16] at 2041, 1967 and 1932 cm^{-1}. These bands are displaced to higher wavenumbers with respect to the precursor complex [ReBr(CO)$_3$(L)] [5a], in agreement with a minor electronic back-donation of the

Scheme 2. Fragmentation pathways for compounds **2a**–**f**.

rhenium atom to the CO ligands due to the replacement of Br by the trifluoroacetate ligand. Similarly, the IR spectra of compounds **2** display two strong ν(CO) bands, characteristic of *cis*-dicarbonyl compounds [6,17], and these are also displaced to higher energy with respect to the [ReBr(CO)$_2$(L)(L′)] compounds [6]. On the other hand, compounds **1** and **2** display a strong band at 1692–1697 cm^{-1} and a medium band at 1403–1418 cm^{-1} due to the asymmetric and symmetric modes of the carboxylate group of the O_2CCF_3 ligand [18]. The energy difference between the two bands is related to the coordination type of the carboxylate ligand and, in our case, this is in accordance ($\sim$290 cm^{-1}) with a monodentate behaviour of the ligand in all the complexes [19]. The X-ray diffraction studies of complexes **1** and **2a** confirm this behaviour.

The ^{1}H NMR spectrum of compound **1** does not show any relevant differences compared with that of the precursor. However, the ^{31}P{^{1}H} NMR spectrum of **1** shows a singlet at a lower field (δ = 116.5 ppm) than that of the precursor (δ = 105.3 ppm), as expected because of the electron-withdrawing characteristics of the trifluoromethyl group. In the case of compounds **2**, the ^{1}H NMR signals of the –CH_2CH_2– group of the bidentate phosphinite ligand (which appear as three multiplets with intensities 1:1:2 in the spectra of the parent bromide complexes), are two multiplets with intensities 1:3, except for compounds **2c** and **2d** in which they appear as three 1:2:1 and 1:1:2 multiplets, respectively. In all cases, these multiplets span in a similar but narrower region than those of the bromide precursors. On the other hand, the signals of the OR groups of the monodentate mixed-phosphite ligands, are similar to those of the parent bromide complexes but slightly upfield shifted. Compounds **2a**–**d** display ^{31}P{^{1}H} NMR spectra that are consistent with an ABM spin system (three double doublets), but compounds **2e**–**f** show signals corresponding to ABC and A_2B spin systems [20], respectively, reflecting the similarity between the P nuclei of both bidentate and monodentate phosphinite ligands. In all cases the signals are shifted downfield when compared to their bromide analogues. These shifts are consistent with the IR data discussed above and are in accordance with the presence of the more electron-withdrawing trifluoroacetate group, which reduces the rhenium π-back-donation to the phosphorus ligands. The mass spectra of compounds **2a**–**f** show, in all cases, five sets of peaks (see Section 2) displaying the rhenium isotope pattern. This allows us to propose possible fragmentation pathways for these compounds that would give rise to the identified fragments (Scheme 2).

The most abundant peak is, in all cases (except for **2a** – although in this case its abundance is also very high, 95.6%), that at m/z = 758, corresponding to loss of a carbonyl and the monodentate L′ ligand.

4. Conclusions

The synthesis and structural characterization of trifluoroacetatecarbonylrhenium(I) complexes bearing different mono- and bidentate mixed-phosphite ligands are described. The new complexes were prepared by the reaction of the parent bromo-complexes with silver trifluoroacetate. All the complexes were studied by spectroscopic techniques and, in the cases of complexes **1** and **2a**, structures in the solid state were determined by X-ray diffraction. In all cases the trifluoroacetate ligand behaves in a monodentate manner.

Supplementary data

CCDC 719369 and 719370 contains the supplementary crystallographic data for compounds **1** and **2a**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Two new dicyanamido-bridged di- and polynuclear complexes of Co(II), $[Co(dca)(tptz)(H_2O)]_2 \cdot 2(ClO_4)$ (**1**) and $[Co(dca)_2(imz)_2]_n$ (**2**) [dca, dicyanamide; tptz, 2,4,6-tris(2-pyridyl)1,3,5-triazine; and imz, imidazole] have been synthesized and characterized structurally, as well as magnetically. The X-ray single crystal structure determination of complex **1** shows that two symmetry related octahedral Co(II) ions are separated by dca ligand and other coordination sites are satisfied by tptz and aquo ligands. Each dinuclear unit is associated with each other by intramolecular hydrogen bonding interactions, giving rise to a 1D chain structure. On the other hand complex **2** is a 1D coordination polymer having $[Co(II)(imz)_2]$ units connected by double bridging dca ligands. These 1D chains interact through face-to-face π–π stacking interactions of the imz rings extending the dimensionality to a 2D supramolecular network. The variable temperature (300–2 K) magnetic measurements of both compounds reveal that dicyanamide exhibits a weak antiferromagnetic interaction between the metal centers.

1. Introduction

In the past few decades, tremendous progress has been made in supramolecular chemistry. A large number of beautiful and functional supramolecular architectures have been constructed, starting with well-defined building blocks via self-assembly process [1–4]. In this process, the small molecular building blocks that recognizes each other through direction specific molecular interactions such as coordination bonds, hydrogen bond, π–π stacking and C–H–π interaction etc. to form the extended architecture [5]. The particular attractive is the novel type of structural motifs, like honeycomb, grid, interdigitation, different degree of interpenetration, three dimensional channels are obtained depending upon the metal ions and organic linkers with different tunable properties [1–5]. One strategy to build an extended network is to utilize certain features of the bridging ligands, such as azide, [6] dicyanamide [7], carboxylate [8] and different neutral organic spacer [9] having versatile binding modes, conformational flexibility and the ability to form non-covalent interactions [10].

Among the abovementioned bridging ligand, dca acts as a remarkable building blocks for the construction of various functional coordination architectures such as discrete mononuclear, dinuclear, as well as 1D chains, tubes, or ladders, 2D sheets and 3D supramolecular networks, when terminal or bridging coligands (L) are introduced to form M–dca–L system having important magnetic property [11–16]. The different coordination modes of dca such as terminal, bidentate, tridentate and unusual μ_4-dca towards metal ions plays an important role for the construction of extended architecture [7].

The magnetic properties of polynuclear architecture depend on the nature of the paramagnetic metal center *i.e.* the spin state, the dimensionality of the system and on the type of bridging ligands. Although dca can mediate only weak interactions between paramagnetic metal centers and a few multidimensional dca bridged compounds exhibit long-range ferromagnetic ordering [7]. Among the first row transition metal ions containing an unpaired electron, the magnetic properties of Co(II) complexes are interesting and are affected by the several factors such as single-ion effects, spin–orbit coupling, distortion from regular stereochemistry, electron delocalization, crystal field mixing of the excited states into the ground

doi:10.1016/j.poly.2009.04.024

state etc. [17]. Thus, the interpretation of these magnetic results is challenging. To date, the synthesis of high spin polynuclear Co(II) complexes and their magnetic study at low temperature have been reported by several groups [18,19]. In contrast, there are only a few examples of structurally as well as magnetically characterized dca bridged discrete dinuclear compounds [15,16].

In this paper, we report the synthesis, structural characterizations and hence magnetic properties of two cobalt coordination compounds $[Co(dca)(tptz)(H_2O)]_2{\cdot}2(ClO_4)$ (**1**), $[Co(dca)_2(imz)_2]_n$ (**2**) [where dca = dicyanamide; tptz = 2,4,6-tris(2-pyridyl)1,3,5-triazine; and imz, imidazole]. Here, dca is used as a bridging ligand and coordination environment is varied by N-donor ligands *i.e.* tptz for complex **1**, and imz for complex **2**. In complex **1**, two symmetry related Co(II) atoms are separated through nitrile nitrogen atoms of dca ligand and tptz act as a chelating ligand. Each dinuclear unit is connected to each other by H-bonding forming 1D stair-case like structure. To the best of our knowledge this is the first example of dinuclear Co(II) complex bridged by dca ligand. Whereas complex **2** is a doubly end-to-end dca bridged 1D coordination polymer with trans coordinated imz ligands. The overall structure is stabilized by face-to-face π–π stacking and H-bonding interactions arising among the imz ligands. Variable temperature magnetic study of these complexes reveals weak antiferromagnetic coupling between the metal centers.

2. Experimental

2.1. Physical techniques

Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyzer. Infrared spectra were recorded on a Perkin–Elmer RX I FT-IR spectrophotometer using KBr pellets. Magnetic measurements were carried out in the "Servei de Magnetoquímica Universitat de Barcelona" on polycrystalline sample with a Quantum Design MPMS SQUID susceptometer operating at a magnetic field of approximately 1000 G between 2 and 300 K. The diamagnetic corrections were evaluated from Pascal's constants for all the constituent atoms.

2.2. Materials

High-purity 2,4,6-tris(2-pyridyl)-1,3,5-triazine and imidazole were purchased from the Aldrich Chemical Co. Inc. and used without further purification. High purity sodium dicyanamide was obtained from Fluka. All other chemicals were of AR grade.

Caution: Perchlorate salts are potentially explosive in the presence of organic compounds. Only a small amount of the materials should be prepared and handled with care.

2.3. Syntheses

2.3.1. Synthesis of $[Co(dca)(tptz)(H_2O)]_2{\cdot}2(ClO_4)$ (**1**)

A methanolic solution of tptz (0.5 mmol, 0.15 g) was added to an aqueous solution (5 mL) of $Co(ClO_4)_2{\cdot}6H_2O$ (1 mmol, 0.365 g) and sodium dicyanamide (2 mmol, 0.17 g) with continuous stirring for about 20 min. The resulting solution was filtered and the filtrate was kept at room temperature. After five days, orange crystals suitable for X-ray diffraction were obtained from the filtrate. Yield 84%. *Anal.* Calc. for **1** $C_{40}H_{28}Co_2N_{18}O_22(ClO_4)$: C, 43.33; H, 2.34; N, 22.75. Found: C, 43.35; H, 2.33; N, 22.71%.

2.3.2. Synthesis of $[Co(dca)_2(imz)_2]_n$ (**2**)

An aqueous solution (5 mL) of $CoCl_2{\cdot}6H_2O$ (1 mmol, 0.237 g) and sodium dicyanamide (2 mmol, 0.17 g) were mixed with constant stirring. Then an ethanolic solution of imidazole (1 mmol, 0.06 g) was added to the solution and stirred for about 30 min at room temperature. After three days, pink crystals suitable for X-ray diffraction were obtained from the filtrate. Yield 95%. *Anal.* Calc. for **2** $C_{10}H_8CoN_{10}$: C, 36.67; H, 2.44; N, 42.78. Found: C, 36.26; H, 2.45; N, 42.75%.

2.3.3. X-ray data collection and structure refinement

Single crystal X-ray diffraction study for **1** was carried out on a Bruker Smart Apex CCD diffractometer using graphite-monochromatizd Mo Kα radiation (0.71073 Å). The data were corrected for absorption by using the multi-scans program SADABS [20]. The structure was solved by direct and difference Fourier methods and refined by full-matrix least-squares on F^2 using SHELXL-97 [21] and SHELXS-97 program package [22], respectively. The single crystal data of complex **2** were collected on Enraf Nonius, CAD4 diffractometer and the structure was solved by direct methods and subsequently refined by full-matrix least-squares procedures on F^2 with allowance for anisotropic thermal motion of all non-hydrogen atoms employing the WINGX package with the relevant programs SIR-97 [23] and SHELXL-97 [22]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were placed geometrically and refined with isotropic thermal parameters. All calculations were carried out using PLATON and ORTEP-32 programs [24,25]. The unit-cell parameters, crystal system, space group and refinement details are summarized in Table 1.

3. Results and discussion

3.1. Infrared spectra

Complexes **1** and **2** display strong absorption bands at 2280, 2242 and 2162 cm^{-1}, respectively, which correspond to the ν(CN) of dca ligand [7]. The large shift towards high frequencies, compared with these of free dca (2232, 2179 cm^{-1}) confirmed that dca bridged between the metal centers. In complex **1**, the bands in the region 1645–1390 cm^{-1} and 950–900 cm^{-1} are observed

due to the C–N and C–C stretching and bending modes of the coordinated tptz ligand [26]. Besides this, IR spectrum of complex **1** shows absorption bands in the region of 3552–3200 cm^{-1} and 1160–1085 cm^{-1} which clearly indicate the presence of crystal water and perchlorate moiety respectively. Apart from this complex **2** a strong absorption band is observed in the range 1270–750 cm^{-1}, which may be assigned as C–C, C–N stretching and bending modes of the coordinated imz ligand.

3.2. Description of the crystal structures

3.2.1. Crystal structure of $[Co(dca)(tptz)(H_2O)]_2{\cdot}2(ClO_4)$ **1**

The ORTEP diagram of **1** (Fig. 1) shows that this is a discrete dinuclear complex where two symmetry related Co(II) atoms are separated by two dca anions in an end-to-end fashion. Each asymmetric unit contain one cobalt(II) atom which is octahedrally coordinated by three nitrogen atoms of tptz ligand, two nitrogen atoms of dca ligands and one oxygen atoms of aqua ligand. The equatorial coordination sites are composed by two nitrogen atoms (N7, N8) of bridging dca, one oxygen atom (O1) of coordinated water molecule and one nitrogen (N1) atom of central triazine ring whereas the axial coordination sites are occupied by two pyridyl nitrogen atoms (N4, N5) of tptz ligand with bond angle between them 147.30(12). Between Co-N(tptz) and Co-N(dca) bond distances (2.087(3)–2.196(3) and 2.030(4)–2.108(4) Å, respectively) the former is significantly larger. The cobalt···cobalt separation within dinuclear unit is 7.377(1) Å and comparable to similar type of $[Cd(dca)(tptz)(H_2O)]_2{\cdot}2(ClO_4)$ system [27]. The deviation from ideal octahedral geometry is reflected by bond length and angles given in Table 2.

Each dimer is connected to each other by H-bonding forming a stair-case 1D chain running along the crystallographic *a* axis (Fig. 2). The uncoordinated nitrogen atom (N6) of pyridyl ring of tptz ligand and coordinated water (H15w···N6, 2.22(6) Å, Table 3) play a role in the formation of this type of architecture. The two perchlorate counter anions present in the crystal lattice balance the electronic charge of the complex and also involved in H-bonding with coordinated water molecule (Table 3).

3.2.2. Crystal structure of $[Co(dca)_2(imz)_2]_n$ **2**

The molecular structure of **2** displays 1D polymeric pattern built up by cobalt ions, pairs of bridging dca and imz ligands (Fig. 3). The asymmetric unit contain one cobalt(II) atom which is coordinated through three nitrogen atoms coming from two bridging dca and one imz ligand, respectively. For symmetry reasons, the nitrogen atom N3, N4 and its symmetry related counter parts lie in the equatorial plane along with the cobalt atom whereas imz nitrogen atom (N1) and its symmetry related counter part lie in the trans-axial position with bond angle between them 180°. The Co–N(nitrile) bond distances of 2.161(2) and 2.164(3) Å are slightly higher than that involving the imz of 2.101(2) Å and those are comparable to similar type of $[Mn(dca)_2(im)_2]_n$ system where as im = imidazole [28]. The slight deviation from ideal octahedral geometry is due to the equatorial bond lengths and angles (Table 4). Similar to **1** here, dca anions coordinate through the nitrile nitrogen atoms and span the metals at 7.395(1) Å corresponding to the length of the crystallographic *c* axis. The metal–metal separation through the dca anions is in good agreement with the distance of 7.370 (1) Å found in the anionic dicyanamidometallate ladder–like 1D polymer $[(Ph_4As)_2\{Co_2(dca)_6(H_2O)\}{\cdot}H_2O\ CH_3OH]_n$ [29]. An interesting Hbonding network is formed by the amide nitrogen atom of the bridging dca ligands with the hydrogen atom of the secondary amine of imz ligands of a neighbouring unit (N2–H2, 0.86; H2···N5, 2.13 Å, Table 3) that leads to a supramolecular 2D arrangement. Similar type of hydrogen bonding interactions are also observed in $Co(biz)_2(dca)_2$ (biz = 2,2′biimidazole) system, where 1D chain structure is formed [30]. This 2D arrangement is further stabilized by face-to-face π–π stacking interactions arising among the imz rings and the chains are interlocked at a distance of 3.851(2) Å which is shown in Fig. 4.

3.3. Magnetic study and magneto-structural correlation of **1** and **2**

The magnetic property of complex **1** in the form of $\chi_M T$ versus *T* plot (χ_M is the molar magnetic susceptibility for two Co(II) ions) is shown in Fig. 5. The value of $\chi_M T$ at 300 K is 6.019 $cm^3\ K\ mol^{-1}$ which is greater than that expected for two isolated spin-only ions ($\chi_M T$ = 3.74 $cm^3\ K\ mol^{-1}$ for two isolated $S = 3/2$ ions) indicating that an important orbital contribution is involved. The $\chi_M T$ value of complex **1** is continuously decreased from room temperature to 4.41357 $cm^3\ K\ mol^{-1}$ at 20 K. The shape of these curves until 20 K can indicate not only antiferromagnetic coupling but also

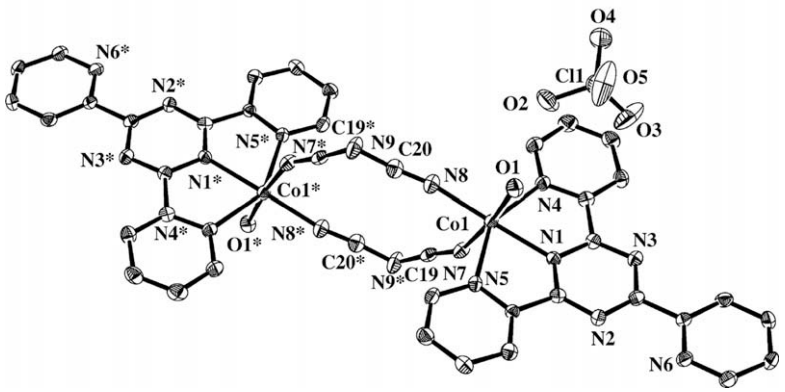

Fig. 1. ORTEP diagram (40% thermal ellipsoids) of **1** with atom labeling scheme. (Hydrogen atoms are removed for clarity.)

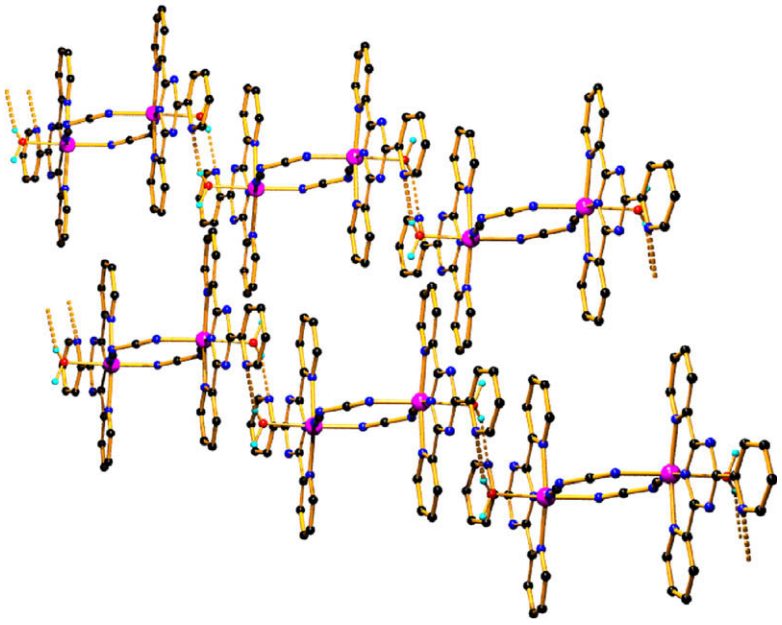

Fig. 2. H-bonded 1D chain structure of **1**. Perchlorate moieties are omitted for clarity.

spin–orbit coupling as typically observed for octahedral Co(II) ions. At low temperatures, there are significant differences in $\chi_M T$ values applying small magnetic fields which indicates the presence of a small amount of ferromagnetic or canted antiferromagnetic-ordered impurities, like α- or β-[Co(dca)$_2$] [7]. This feature (presence of magnetic ordered impurities) is very frequent in most of the Co–dca–L derivatives [18] and all calculations given below refer to the sample with the smallest amount of impurities.

On the other hand, for many years, the Lines' theory has been utilized to obtain the exchange coupling in dinuclear and trinuclear Co(II) complexes [31]. In this theory, it is assumed a perfect octahedral high-spin Co(II) complex where the single-ion excited states are well separated (>9000 cm^{-1}) from the ground state and can be neglected. The $^4T_{1g}$ ground state is split into a sextet, a quartet and a Kramers' doublet by spin–orbit coupling. The eigen values and eigen functions have been found by the diagonalization of the operator given in

$$H = -\frac{3}{2}\kappa\lambda\, L \cdot S$$

where κ and λ are the orbital reduction factor and the spin–orbit coupling parameters, respectively. The occurrence of the factor $-3/2$ is due to the analogy between the matrix elements of L within the $^4T_1$ state and that of the $-3/2L$ between the p functions. Applying Lines' formula to fit the magnetic data for dinuclear Co(II) complexes, the poor results are obtained. This is due to the lack of consideration of typical distortion with regard to the perfect octahedral geometry. Herrera et al. [32] have adapted a new method to solve this problem in mononuclear systems assuming axial distortion. In this case, the triplet orbital $^4T_{1g}$ ground state splits into a singlet $^4A_2$ and a doublet ^4E levels with a Δ energy gap.

The Hamiltonian involving the spin–orbit coupling, axial distortion and Zeeman interaction is given in

$$H = -A\kappa\lambda L \cdot S + \Delta\left[L_z^2 - \frac{1}{3}L(L+1)\right] + \mu_B(-A\kappa L + g_e S)H$$

where A, is the general factor that corresponds to 3/2 factor in Lines-equation. The factor A in the frame of T and P term isomorphism, which allows us to distinguish between the matrix elements of the orbital angular momentum operator calculated with the wave function of the ground $^4T_{1g}$ term with those calculated with P term basis. In the weak crystal field limit ($B \gg \Delta q$), $c = 0$ and $A = 1.5$ whereas in the strong crystal field limit ($B \ll \Delta q$), $c = -1/2$

and $A = 1$. No analytical expression for the magnetic susceptibility, which depends on A, κ, λ and Δ can be derived. The values of these parameters have to be determined through numerical matrix diagonalization [31]. Although not yet fully developed in the literature about Co(II) dinuclear complexes, the mononuclear system can be extrapolated to a dinuclear one, introducing the J coupling parameter between the two pure $S = 3/2$ states [32]. In Fig. 6, we illustrate this new situation. Now, instead of four parameters A, κ, λ and Δ we will deal with five parameters A, κ, λ, D and J_{Co-Co}, respectively. The values of these parameters have to be determined, again through numerical matrix diagonalization and FORTRAN program adapted to do these calculations which has been performed by one of us [32]. The best-fit values found using the experimental data for $T > 25$ K were: $A\kappa = 1.36$, $\Delta = 430\ cm^{-1}$; $J_{L-S} = -163.5\ cm^{-1}$ with $R = 4.4 \times 10^{-4}$. Taking into account that $A\kappa = 1.36$ and $J_{L-S} = A\kappa\lambda$ the real λ value in this complex will be $-120\ cm^{-1}$ (λ for the free ion is $-180\ cm^{-1}$). As it is shown in the Fig. 5, the calculated curve matches well the experimental data in the temperature range 28–300 K. At $T < 25$, the magnetic data deviate from the calculated curve due to the presence of a small amount of ferromagnetic or canted antiferromagnetic-ordered impurities. Consequence of this, we cannot determine the exchange pathways J_{Co-Co} between the Co(II) atoms, which normally manifested in this range of temperatures. The field dependence of the reduced molar magnetization, $M/N\beta$, at 2 K (Fig. 7), shows a saturation value at 50 *kOe* (2.29 $N\beta$ per cobalt(II) ion). The extrapolated saturation value is ca. 4.58 $N\beta$, lie slightly above the expected value for two Co(II) centers.

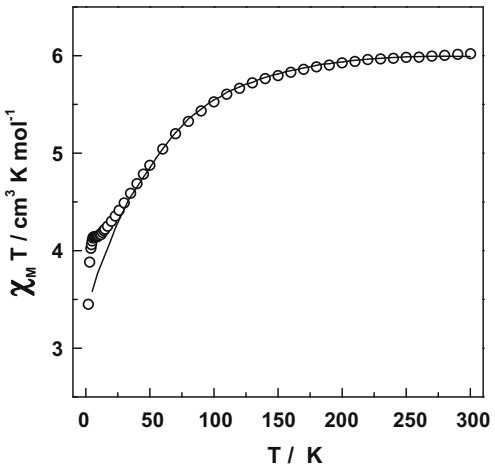

Fig. 5. Plot of the $\chi_M T$ vs T for complex **1**. Solid line represents the best fit obtained according to the method described in the text.

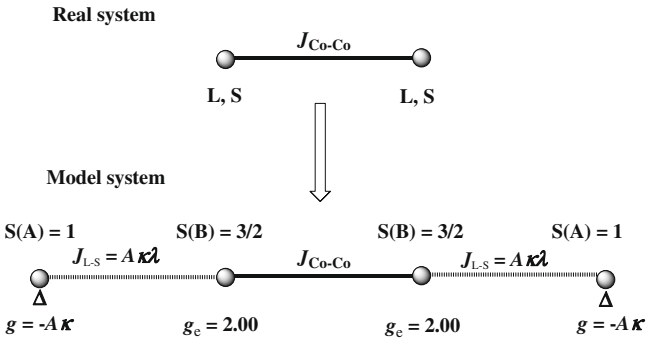

Fig. 6. Schematic representation of the spin–orbit coupling and exchange coupling parameter (J_{Co-Co}) in a dinuclear Co(II) complex.

Although for a Co(II) the ground term is $^4T_{1g}$ ($L = 1$; $S = 3/2$) the experimental $N\beta$ value at 2 K does not correspond to three unpaired electrons, because at this low temperature only the $J = 1/2$ doublet ($M_J = \pm 1/2$) is populated behaving, thus, as an effective spin $S' = 1/$

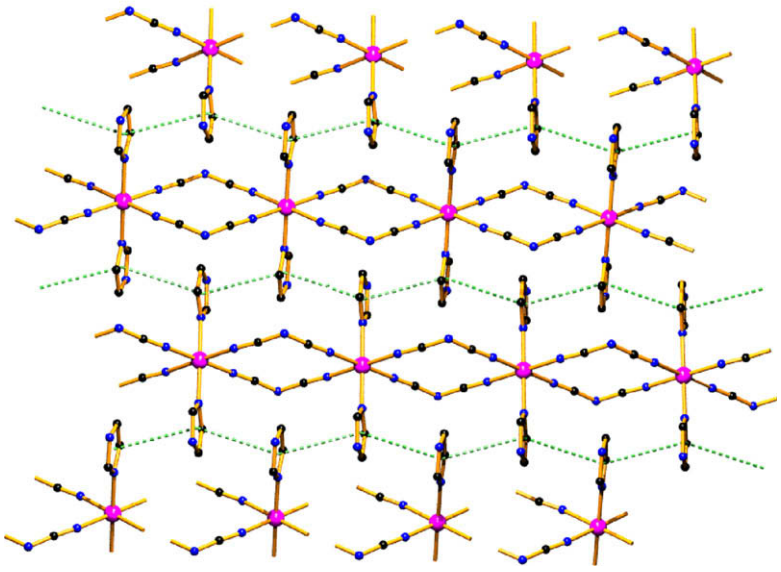

Fig. 4. Crystal packing of complex **2** showing three adjacent π interacting polymeric chains. (Hydrogen atoms are removed for clarity.)

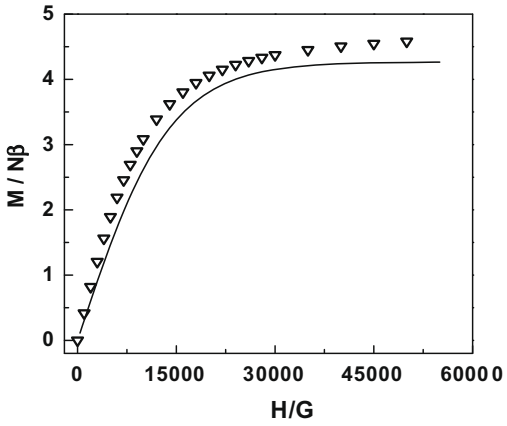

Fig. 7. Plot of the reduced magnetization ($M/N\beta$) for **1** at 2 K (for two cobalt(II) ions). Solid line represents the Brillouin formula for two Co(II) ions isolated with $S = 1$, $T = 2$ K and $A\kappa = 1.36$.

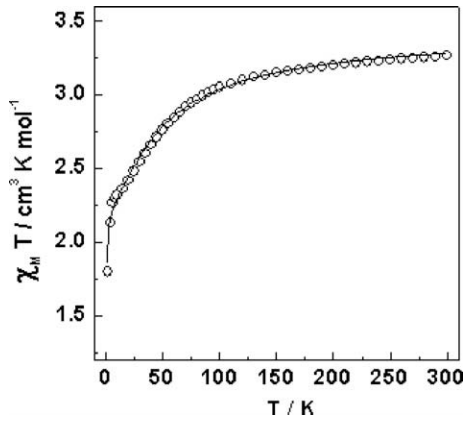

Fig. 8. Plot of $\chi_M T$ vs T of polycrystalline complex of **2**. Solid line corresponds to the best fit (see text).

2 with $g = (10 + 2A\kappa)/3$ [33]. The noticeable Δ (distortion) parameter agrees with the great distortion created by the chelated dca and tptz ligands (N7–Co–N8 angle = 85.9° and N5–Co–N4 = 147.3°, instead of 90° and 180° for a regular octahedron).

The magnetic properties of complex **2**, in the form of $\chi_M T$ versus T plot (χ_M is the molar magnetic susceptibility for one Co(II) ion) is shown in Fig. 8. The value of $\chi_M T$ at 300 K is 3.26 $cm^3\ K\ mol^{-1}$, which is large than that expected for spin-only case ($\chi_M T = 1.87\ cm^3\ K\ mol^{-1}$ K, $S = 3/2$). The $\chi_M T$ values are continuously decreased from room temperature to 1.795 $cm^3\ K\ mol^{-1}$ at 2 K. The global feature is characteristic of weak antiferromagnetic interactions. The small polynuclear systems can also be fitted through sophisticated computer programs, based on full diagonalization methods at low temperature region (where the effective spin $S' = 1/2$) [35,36]. One-dimensional systems of Co(II) atoms are frequently associated with anisotropic Ising systems, and they can be fitted in the low temperature zone assuming an effective spin $S' = 1/2$ [37]. Rueff et al. [38] have proposed a phenomenological approach for some low-dimensional Co(II) systems that allows to have an estimate the strength of the antiferromagnetic exchange interactions. They have postulated the phenomenological equation:

$$\chi_M T = A\exp(-E_1/kT) + B\exp(-E_2/kT)$$

in which $A + B$ equals the Curie constant [≈2.8–3.4 $cm^3\ mol^{-1}$ K for octahedral cobalt(II) ions], and E_1, E_2 represent the "activation energies" corresponding to the spin–orbit coupling and the antiferromagnetic exchange interaction, respectively. This equation adequately describes the spin–orbit coupling, which results in a splitting between discrete levels, and the exponential low-temperature divergence of the susceptibility. Very good results have been reported in one- and two-dimensional Co(II) complexes [39]. An important experimental feature in almost all octahedral Co(II) complexes is that $\chi_M T$ (or μ_{eff}) values at room temperature are greater than one isolated spin-only ion ($\chi_M T = 1.87\ cm^3\ mol^{-1}$ K for a $S = 3/2$ ion), indicating that an important orbital contribution is involved. Typical values of $\chi_M T$ (or μ_{eff}) are 2.75–3.4 $cm^3\ mol^{-1}$ K (4.7–5.2 μ_β) [32]. Lower values at r.t. indicate perturbation from ideal octahedral geometry [40]. An estimated J value has been calculated using the two exponential Rueff expression, mentioned above, which is suitable for any temperature greater than the possible T_c [34,35]. The fit values obtained with this procedure are: $A + B = 3.43\ cm^3\ K\ mol^{-1}$, ($A = 1.05$ and $B = 2.38$) which perfectly agrees with those given in the literature for the Curie constant ($C \approx 2.8$–$3.4\ cm^3\ K\ mol^{-1}$), $E_1/k = 46.71$ K, is of the same magnitude than those reported by Rueff et al. for several one- and two-dimensional Co(II) complexes [38]. As for the value found for the antiferromagnetic exchange interaction, it is very week ($E_2/k = 0.500$ K), corresponding to $J = -1.0$ K (=$-0.7\ cm^{-1}$) according to the Ising chain approximation, $\chi_M T \propto exp(J/2kT)$. The small J value is compatible with double $\mu_{1,5}$-dca bridge ligand which always give almost negligible coupling parameters [18]. Thus we can conclude that complex **2** behaves as a one-dimensional system which is weakly magnetically coupled by dca ligand and also intramolecular π–π interactions.

4. Conclusions

In this paper, we present structural and magnetic aspects of two novel dca bridged Co(II) complexes having two different coligands, namely tptz and imz. Complex **1** is a dinuclear Co(II) system extended to 1D chain through intermolecular H-bonding interactions. To the best of our knowledge, this is the first reported dicyanamido-bridged dinuclear Co(II) complex. In fact, dca bridged dinuclear complexes are few in literature, since dca has a strong tendency to form polynuclear structure. Probably, the bulkiness of the tptz ligand prevents the dinuclear moiety to propagate in a polynuclear fashion. Complex **2** is a 1D chain interlocked by face-to-face π–π stacking interactions to generate a 2D sheet. The magnetic behaviors of both the high-spin Co(II) complexes exhibit weak antiferromagnetic coupling. Further scope of this work aims at synthesis and study of different properties of various dca bridged complexes varying metal centers, as well as coligands.

Supplementary data

CCDC 697126 and 697128 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

The reaction of $[M(H_2L)_2]$ [M = Ni(II) Cu(II)] ($K^+H_2L^-$ = N-(pyridine-4-carbonyl)-hydrazine carbodithioate) with excess of ethylenediamine (en) gave mixed ligand complexes $[Ni(en)_2(4\text{-pytone})_2]$ (4-pytone = 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione), and $[Cu(en)_2](4\text{-pytol})_2{\cdot}H_2O$ (4-pytol = 5-(4-pyridyl)-1,3,4-oxadiazole-2-thiol). The metal complexes have been characterized with the aid of elemental analyses, IR, magnetic susceptibility and single crystal X-ray studies. Complexes (**1**) and (**2**) crystallize in monoclinic system, space group $P_{1\ 21}/n_1$ and C_2/c, respectively. The ligand after cyclization is present in the deprotonated thiol form in the Cu(II) complex where it is ionically bonded through sulfur. In the Ni(II) complex (**1**) bonding of the ligand take place through oxadiazole nitrogen and the ligand exists as the thione form.

1. Introduction

N-Aroyl dithiocarbazates and their salts could be converted to 1,3,4-oxadiazole derivatives, which are biologically important molecules [1,2]. The oxadiazole molecules act as spacer via coordination, hydrogen bonding and show intermolecular cooperative interaction [3]. Oxadiazole derivatives, which belong to an important group of heterocyclic compounds, have been the subject of extensive study in the recent past. Numerous reports have highlighted their chemistry and uses [1,3]. Oxadiazole derivatives show diverse biological activities, such as anti-tuberculostatic, antiinflamatory, analgesic, antipyretic and anticonvulsant [4,5]. Although some work have been reported on the metal complexes of 5-phenyl-1,3,4-oxadiazole-2-thione [6,7], 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione [8–13], 5-(3-pyridyl)-1,3,4-oxadiazole-2-thione [14] and 5-(2-pyridyl)-1,3,4-oxadiazole-2-thione [15]. Since 1,3,4-oxadiazole-2-thiones are biologically active compounds; information about their 3-dimensional structures may be of great interest for rational drug design. 1,3,4-oxadiazole-2-thione consists of an equilibrium mixture of its thione and thiol forms [16–19], therefore it will be of interest to investigate the bonding mode of oxadiazole in their complexes. In view of this, we have prepared and characterized the complexes of 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione/thiol formed after cyclization of the Ni(II) and Cu(II) complexes of N-(pyridine-4-carbonyl)-hydrazine carbodithioate in the presence of ethylenediamine which acts as a coligand.

2. Experimental

2.1. Materials and methods

Commercial reagents were used without further purification and all experiments were carried out in open atmosphere. Isonicotinic acid hydrazide (Sigma–Aldrich), CS_2 (S D Fine Chemicals, India) and KOH (Qualigens) were used as received. All the solvents were purchased from Merck Chemicals, India, and used after purification.

2.2. Preparations of potassium [N′-(pyridine-4-carbonyl)-hydrazine carbodithioate [$K^+(H_2L)^-$]]

The potassium N-(pyridine-4-carbonyl)-hydrazine carbodithioate (Fig. 1) was prepared by adding CS_2 (1.5 ml, 0.2 mmol) dropwise to a suspension of isonicotinic acid hydrazide (2.7 g, 20 mmol) in methanol (20 ml) in the presence of potassium hydroxide (1.2 g, 20 mmol). The reaction mixture was stirred continuously for 30 min and the yellow solid [$K^+(H_2L)^-$] which separated was filtered, washed with EtOH and dried. Yield: 77%. mp: 578K. ^{1}H NMR (DMSO-d_6, δ ppm): 10.60 (*s*, 2H, NH), 8.65,7.85

2.3. Preparation of [Ni (en)$_2$(4-pytone)$_2$] (**1**)

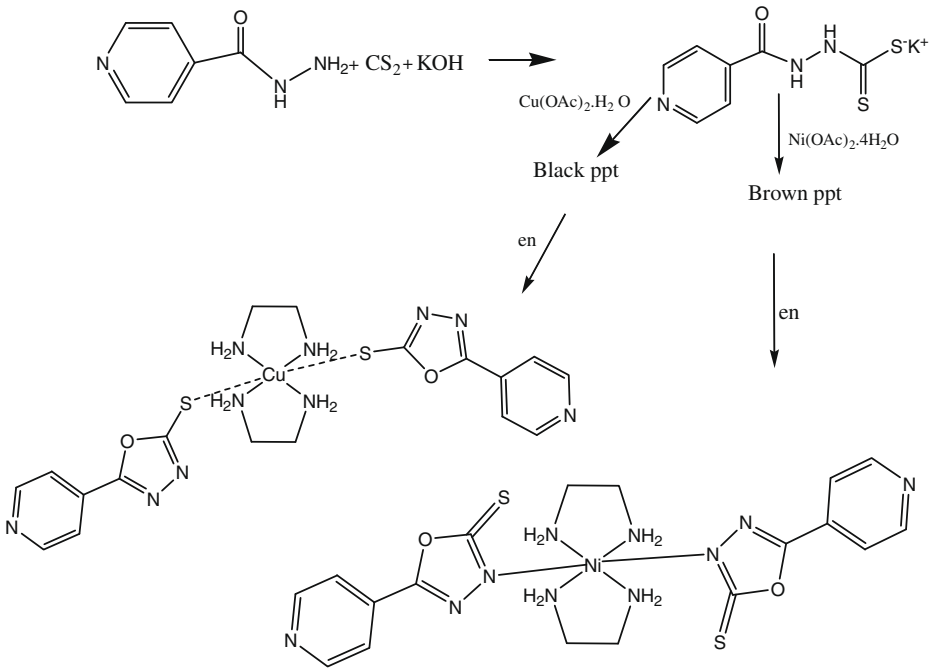
Freshly prepared potassium N-(pyridine-4-carbonyl)-hydrazine carbodithioate $[(K^+(H_2L)^-]$ (0.500 g, 2 mmol) was dissolved in water (20 ml) and an aqueous solution of $Ni(OAc)_2{\cdot}4H_2O$ (0.250 g, 1 mmol) was added to the above solution and stirred for 15 min. The brown solid which separated was filtered, washed with methanol–water mixture (50:50) and dried in vacuo. A methanol solution (10 ml) of ethylenediamine (0.30 ml, 4 mmol) was added to the methanol suspension of the above compound and after shaking for a few minutes the resulting clear brown solution was filtered and kept for crystallization. Brown single crystals of (**1**) suitable for an X-ray analysis were obtained by slow evaporation of its methanol solution over a period of 10 days, mp.535 K, yield 62%. *Anal.* Calc. UV–Vis Spectrum (λ_{max} Nujol, cm^{-1}): 12545, 18940, 25575, 29500.

2.4. Preparation of [Cu(en)$_2$] (4-pytol)$_2{\cdot}H_2O$ (**2**)

$Cu(OAc)_2{\cdot}H_2O$ (0.200 g, 1 mmol) and freshly prepared potassium N-(pyridine-4-carbonyl)-hydrazine-carbodithioate $[K^+(H_2L)^-]$ were dissolved separately in 15–20 ml water, mixed together and stirred for 30 min. The black solid which separated was filtered, washed successively with methanol–water mixture (50:50) and finally with methanol. A methanol solution (10 ml) of ethylenediamine (0.30 ml, 4 mmol) was added to the methanol suspension of the above compound and stirred for 1 h. A clear dark blue solution was obtained which was filtered and kept for crystallization. Dark blue needle shaped single crystals of (**2**) suitable for an X-ray analysis were obtained by slow evaporation of the above solution over a period of 8 days, mp.461 K, yield 55%. *Anal.* Calc. For $C_{18}H_{26}CuN_{10}O_3S_2$: C, 38.73; N, 25.09; H, 4.69; S, 11.49. Found: C, 38.65; N, 25.15; H, 4.56; S, 11.35%. IR data (KBr, cm^{-1}); ν(OH) 3415, ν(NH) 3254, 3101m, ν(C=N) 1605s; ν(C–O–C) 1283w; ν(N–N) 1053s; ν(C–S) 827m; ν(Cu–N) 479w. μ_B = 1.81 BM. UV–Vis Spectrum (λ_{max} Nujol, cm^{-1}): 17635, 26665, 28410.

2.5. Physical measurements

Carbon, hydrogen and nitrogen contents were estimated on a Carlo Erba 1108 model microanalyser. Magnetic susceptibility measurements were performed at room temperature on a Cahn Faraday balance using Hg $[Co(NCS)_4]$ as the calibrant. Electronic spectra were recorded on a SHIMADZU 1700 UV–Vis spectrophotometer as Nujol mull [20]. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100-FT IR spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded in d_6-DMSO on a JEOL AL 300 FT NMR spectrometer using TMS as an internal reference.



3. Crystal structure determination

Data for the structures **1** and **2** were obtained at 295(2) and 298(2) K, on an Oxford Gemini and a Bruker three-circle diffracto-

Scheme 1. Preparation of the ligand and the complexes.

metre, respectively equipped with a SMART 6000 CCD diffractometre using a graphite mono-chromated Mo Kα (λ = 0.71073 Å) radiation source (Table 1). The structure was solved by direct methods (SHELXL-97) and refined against all data by full matrix least-square on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. All hydrogen atoms were included in the refinement at geometrically ideal position and refined with a riding model [21,22].

The MERCURY and DIAMOND packages were used for molecular graphics [23,24]. Crystal structure diagrams were generated by use of the ORTEP-3 for windows program [25].

4. Results and discussion

The potassium salt of N-acyl hydrazine carbodithioate generates 1, 3, 4 oxadiazole-2-thione/ thiol (4-pytone/4-pytol) in neutral and alkaline medium, respectively by an internal ring closure reaction via desufurization [26]. The elemental analyses and physical measurements of complexes **1** and **2** indicated that both hydrazinic hydrogens from [-C(O)NHNHC(S)S$^-$-] moiety and one sulfur atom were missing from the resulting complexes. The compounds (**1**) and (**2**) were obtained by shaking [M(H_2L)$_2$] with a methanol solution of ethylenediamine taken in 1:4 molar ratio. The Scheme 1 depicts the formation of the complexes which contains 4-pytone/ 4-pytol as the ligand and ethylenediamine as coligand. The compounds (**1**) and (**2**) are insoluble in ethanol and chloroform but are soluble in MeOH, DMF and DMSO and melt at 535 and 461 K, respectively.

4.1. IR spectra

The IR spectrum of the ligand N-(pyridine-4-carbonyl)-hydrazine carbodithioate in KBr shows absorptions due to the stretching modes of NH (3289m, 3182m cm^{-1}), C=O (1676 cm^{-1}), CS

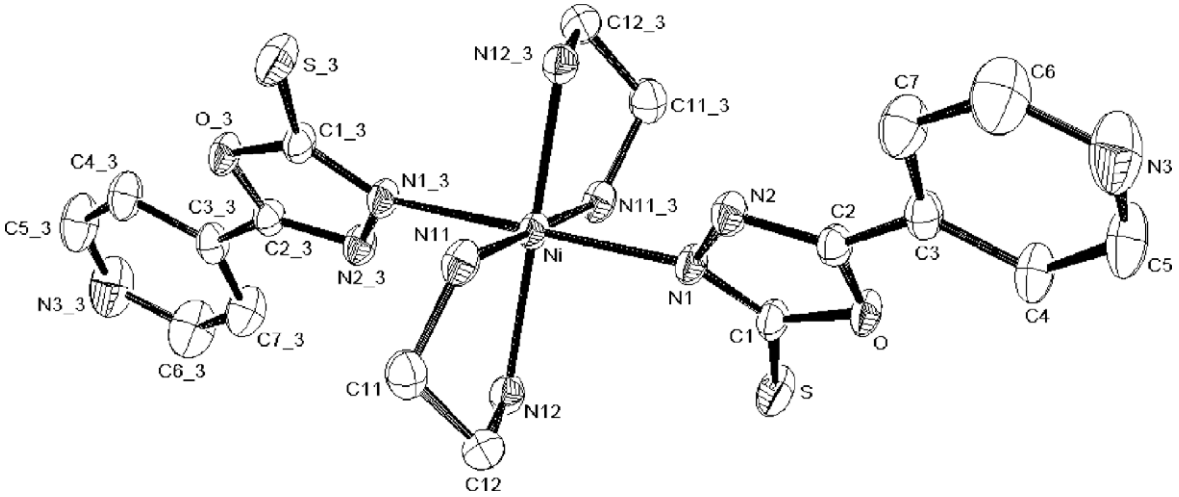

Fig. 2. Ortep plot of [Ni(en)$_2$(4-pytone)$_2$] showing atomic numbering scheme with ellipsoid of 30% probability.

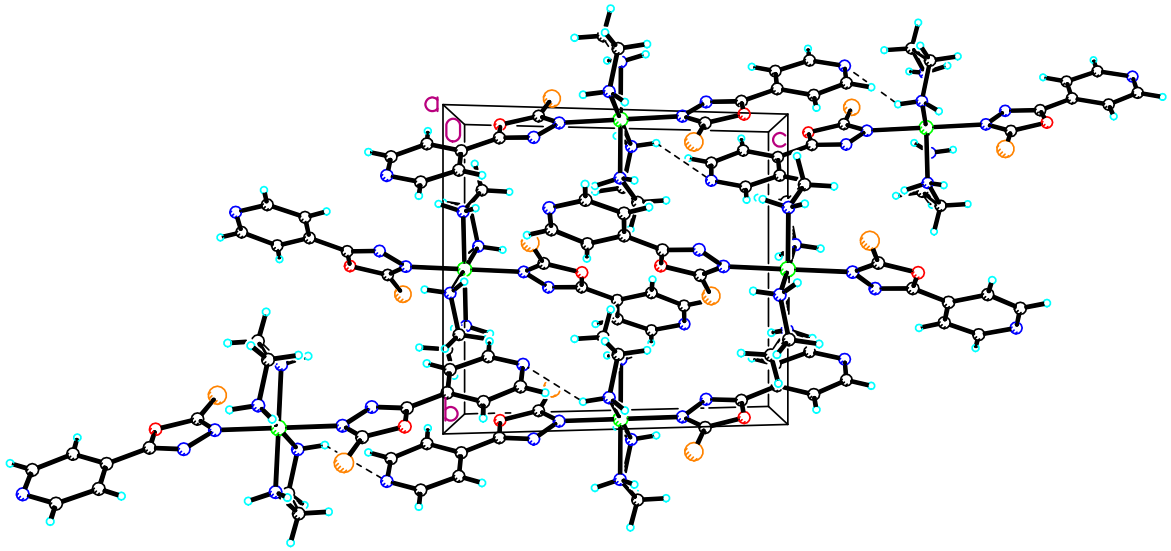

Fig. 3. Crystal packing of $[Ni(en)_2(pytone)_2]$ showing weak van der Walls' interactions.

(993 cm^{-1}), N–N (1062 cm^{-1}). The pyridine ring vibrations are observed at 985 and 693 cm^{-1}. The IR spectra of complexes (**1**) and (**2**) show bands in the region of 3320–3100 cm^{-1} due to the N–H stretching vibrations of en which are shifted to lower frequency than those encountered in the free en [27]. A negative shifts in ν(NH) and appearance of a new band near 520 cm^{-1} due to ν(M–N) suggests formation of a chelate. A negative shift of 166 cm^{-1} in ν(C=S) in complex (**2**) indicates conversion of C=S bond to C–S. In the complex (**1**), ν(C=S) shows a very little negative shift showing that the exocyclic sulfur is not participating in bonding but can be attributed to the involvement of sulfur in hydrogen bonding with NH_2 hydrogen of ethylenediamine. The new peaks appearing in the region of 1610–1600 cm^{-1} due to ν(C=N) (endocyclic) and ν(C–O–C)1285–1270 cm^{-1} suggest cyclization of the dithiolate moiety to 1,3,4-oxadiazole-2-thione via desulfurization. The IR data are thus consistent with the presence of an 1, 3, 4-oxadiazole moiety in compounds **1** and **2** [28].

4.2. Electronic spectra and magnetic moment

$[Cu(en)_2](4\text{-pytol})_2{\cdot}H_2O$ shows a magnetic moment of 1.81 BM, which indicates the presence of one unpaired electron. The presence of a broad band around 17635 cm^{-1} assigned to the envelope of the $^2B_1g \rightarrow {}^2A_1g$, ^2B_2g and ^2Eg transitions suggests a square planar geometry for the complex. Two other high energy bands observed at 26665 and 28410 cm^{-1}may be assigned to intraligand/charge transfer transitions. A magnetic moment of 2.90 BM for $[Ni(en)_2(4\text{-pytone})_2]$ and the presence of two bands at 12545 and 18940 cm^{-1} assigned to the $^3A_2g \rightarrow {}^3A_1g(F)$ (υ_1) and $^3T_1g(P)$ (υ_2) transitions, respectively, suggest a distorted octahedral geometry for the complex. Other two bands observed at 25575 and 29500 cm^{-1} may like wise be assigned to intraligand/charge transfer transitions [29].

4.3. Crystal structure description of complex (*1*)

Fig. 2 shows a ORTEP plot of $[Ni(en)_2(4\text{-pytone})_2]$ with the atomic numbering scheme. The elements of the structure are joint to each other in the crystal packing (Fig. 3) by means of an extended system of H-bonds where hydrogen belonging to the en are participating in the structure. The monomeric unit $[Ni(en)_2(4\text{-pytone})_2]$ possesses a centrosymmetry nickel at the inversion center. Its coordination environment is fulfilled by two axial (4-pytone) anions at trans position to each other, each bonded through oxadiazole nitrogen atom and the four equatorial sites are occupied by the two bidentate N, N′ ethylenediamine. The bonding of two en designated as, Ni–N(11) has a distance of 2.102(2) Å and that of Ni–N(12) occurs at a distance of 2.095(2) Å involve two five membered chelate rings C_2N_2Ni with bite angle of 82.71(9)°, and represent a major deviation from the octahedral geometry (Table 2). The geometry and bonding parameters within the en molecule agree with those of related compounds, e.g. Ni [trans $(L)_2$ $(en)_2$] {L = N-(5-chlorouracilato)} [30], isothiocyanato [31] and salicylato [32]. Weak intermolecular N–H···N interaction between pyridine nitrogen and NH_2 hydrogen atoms and N–H···S interaction stabilize the structure of compound **1**, (Table 4). The two N···S distances of 3.422(2) and 3.514(2) Å (Table 4) are close to the mean N···S distance reported for NH···S hydrogen bonds by Shrinivashan and Chacko [33]. The arrangement of the mono-

meric $[Ni(en)_2(4\text{-pytone})_2]$ units in the two dimensional architecture along the a axis provide a supramolecular network (Fig. 4).

4.4. Crystal structure description of complex (*2*)

Fig. 5 shows a molecular structure of compound **2** with the atom labeling scheme and weak Cu···S interaction. The crystallographic asymmetric unit consists of the complex cations $[Cu(en)_2]^{2+}$ and the 1, 3, 4-oxadiazole thiolate (4-pytol) anions. The complex cation consists of two ethylenediamine molecules which chelate Cu(II) in equatorial positions and two ionically bonded 1, 3, 4-oxadiazole -2-thiolate anions. The Cu–N distances are in the range (2.004–2.006 Å) (Table 3) which is normal for the Cu–N amine coordination. The bite angles for the CuC_2N_4 five membered rings are 84.62(9)° and 95.38(9)° indicating a substantial distortion in the molecule. Similar geometrical parameters for the coordination sphere have been reported for other diaquabis (ethylenediamine) Cu(II) salts [34,35]. Each $[Cu(en)_2]^{+2}$ forms a

pair of intermolecular Cu···S interaction with a distance of 3.09 Å which is well within the distance of 3.2 Å for the sum of van der Waals' radii of Cu and S [36] and greater than Cu–S covalent bond [37]. The Cu(II) in D_{2h} symmetry is bonded to four nitrogen atoms of en groups which offer interesting hydrogen bonding packing. The elements of the structure are joint to each other in the crystal packing (Fig. 6) by means of an extended system of H-bonds where hydrogen belonging to the en are participating in the structure. The hydrogen bonding parameters are listed in Table 5. A close cavity is formed by the weak N–H···O and O–H···S interactions (Fig. 7). In the solid state the complex is stabilized via intermolecular N–H···N interaction between oxadiazole nitrogen atoms and NH_2 hydrogen atoms as well as pyridine nitrogen atoms and NH_2 hydrogen atoms. The O–H···S interaction takes place between thiol sulfur and hydrogen atoms of the water molecule as well as weak N–H···O interaction between the oxygen atoms of the water molecule and hydrogen atoms (NH_2) of en. The two pyridine rings are almost parallel (<ACB = 89.63) but displaced with respect to each other. The displacement as measured by the angle formed between the ring centroids AB and the ring normal BC to the pyridine plane

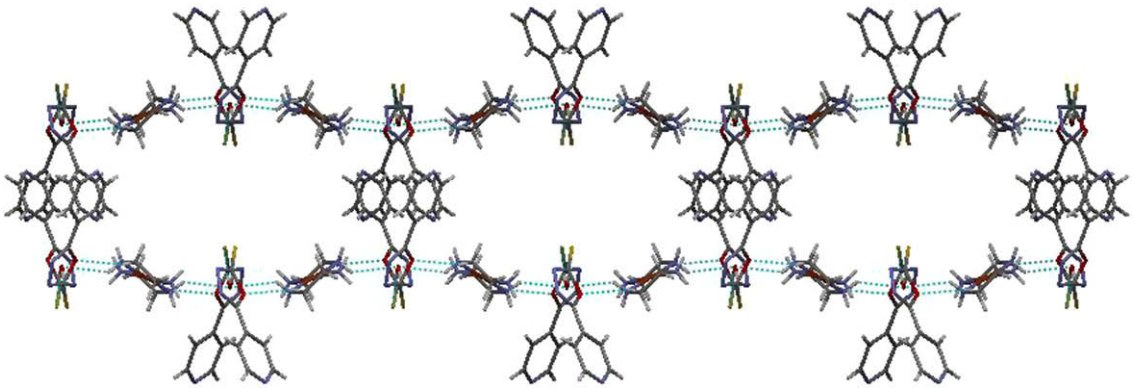

Fig. 7. Closed cavity formed by weak N–H···O and O–H···S interactions in complex **2**.

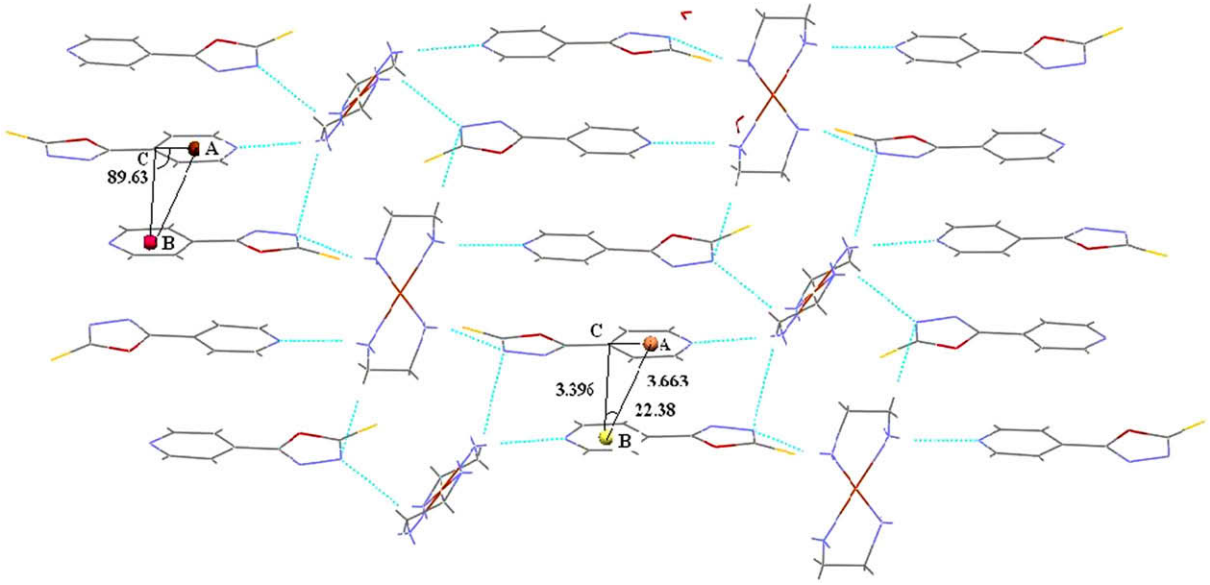

Fig. 8. π–π stacking and relative shift between two pyridine ring centroids in complex **2**.

shown in Fig. 8 was found to be 0.257 Å with a displacement angle of 22.38° and the ring centroids contacts (Cg···Cg) of 3.663 Å is well within the reported range [38].

5. Conclusions

We have reported here the synthesis and crystal structure of new Ni(II) and Cu(II) complexes of 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione/thiol having ethylenediamine as the coligand. The formation of a five membered C_2N_2M chelate ring with en is the common feature in both the complexes. Different bonding behavior of the ligand is clearly seen in complexes (**1**) and (**2**). The structure of the complex **1** is stabilized through weak intermolecular N–H···S, and N–H···N, hydrogen bonding and **2** is stabilized via weak O–H···S, N–H···N and a π–π stacking between the pyridine ring centroids.

Supplementary data

CCDC 686805 and 686806 contains the supplementary crystallographic data for $[Ni(en)_2(4\text{-pytone})_2]$ (**1**) and $[Cu(en)_2](4\text{-pytol})_2{\cdot}H_2O$ (**2**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Nanoporous and non-porous material

ABSTRACT

Two different synthetic approaches to prepare inclusion complexes of Keggin anion $[PW_{12}O_{40}]^{3-}$ and $[Cu_3(BTC)_2(H_2O)_3]_n$ (also known as HKUST-1) have resulted in the formation of two different materials $[Cu_3(C_9H_3O_6)_2(H_2O)_3]_2Na_3PW_{12}O_{40}{\cdot}nH_2O$ (**1**) and $[Na_6(BTC\text{-}H_2)_3(H_2O)_{15}][PW_{12}O_{40}]$ (**2**). Compound **1** is a thermally stable, nanoporous material with a type 1 adsorption isotherm. It contains the well-known MOF material $[Cu_3(BTC)_2(H_2O)_3]_n$ with half of its pores occupied by the guest Keggin anion. The second product **2** is a crystalline, 3D coordination polymer with a composition of $[Na_6(BTC\text{-}H_2)_3(H_2O)_{15}][PW_{12}O_{40}]$ (where BTC-H_3 stands for 1,3,5-benzene-tricarboxylic acid) and is a non-porous, highly water soluble and thermally unstable material. The compound **1** was prepared hydrothermally using precursors of HKUST-1 and $Na_3[(PW_{12}O_{40})]$ whereas **2** was obtained at room temperature from aqueous solutions containing $[Cu_3(BTC)_2(H_2O)_3]_n$ and $Na_3[(PW_{12}O_{40})]$ salts. The molecular structure of **2** is unique and features two distinct elements: an anionic Keggin ion $[PW_{12}O_{40}]^{3-}$ and a "bowl type" hexameric $[Na_6(C_9H_5O_6)_3(H_2O)_{15}]^{3+}$ macrocation which is formed by coordination of Na^+ ions by $(BTC\text{-}H_2)^-$ anions and water molecules. The macrocation extends in three dimensions due to Y type $(BTC\text{-}H_2)^-$ to form a porous MOF offering triangular voids. In this framework the globular Keggin ions support themselves above these voids by coordinating to Na^+ ions and render it completely nonporous. The complex has an unusual structure in the sense that the polyoxoanion is coordinated to $[Na_6(C_9H_5O_6)_3(H_2O)_{15}]^{3+}$ ions by using the three terminal oxygen atoms in a single M_3O_{13} triplet, when each one of them is also bridging between two Na^+ ions. In the crystal structure the POM anion is encapsulated by six octahedrally disposed $(BTC\text{-}H_2)^-$ moieties. H-bonding interactions among water molecules produce supramolecular water hexamers and dimers.

1. Introduction

Polyoxometalates (POMs) have received great attention because of their amazing electronic versatility and structural diversity [1–3] which enables them to have largest number of potential applications than any other class of cluster compounds [4–9]. Out of the various approaches which have been used to arrange or link POM building blocks to obtain solid-state materials with extended structures, coordination to the metal ion has been the most common one, owing to the sufficient charge density at the surface oxygen atoms of these POMs. In this regard, mostly *d*-block [10–19] and *f*-block [20–25] metal ions and sometimes *p*-block metal ions [26,27] have been used as linkers for assisting organization of POMs. The *s*-block elements [28–31] have received much less attention. At the same time the well-known Keggin POMs, though are amply used with coordination complexes to produce 0D to 2D materials [32–35] but the process of assembling them into 3D frameworks is still in its budding stage [36–38] which may be attributed to the steric requirements and the deficient charge density at their surfaces. On the other hand, simple incorporation of Keggin anions into various nanoporous materials like silica, zeolites and MCM-41, has been reported in literature to improve their catalytic properties by enhancing their surface area [39–41]. However, there are only a few examples known for assimilation of polyoxometalate anions into organic/inorganic hybrids [42–44]. The inclusion of these anions into MOF materials

[45–54] is highly selective and depends on the respective sizes of the accessible pores and that of the anionic species. Many new materials are thus expected to form as inclusion complexes and their formation may also depend on synthetic methods and materials being used. The latter may turn out to be an important but unexplored aspect so far.

In this pursuit we chose a combination of well-known polyoxometalate anion $[PW_{12}O_{40}]^{3-}$ and MOF material $Cu_3(BTC)_2(H_2O)_3{\cdot}xH_2O$. The latter, named as HKUST-1, is one of the first robust metal-organic framework (MOF) materials with a microporous structure that is reminiscent of zeolite frameworks [55]. The HKUST-1 is one of the highly cited MOFs because it has a large surface area, high pore volume, high chemical stability, high Lewis acidity and lability of coordinated water molecules. These properties enable it to be a potential candidate for adsorption, gas storage applications and catalysis [56]. A hydrothermal reaction at 120 °C between the Keggin and precursor compounds of $[Cu_3(BTC)_2(H_2O)_3]_n$ produced a Keggin-encapsulated polymeric open framework **1** similar to the one whose crystal structure has been earlier reported [44] by Yang et al. who prepared the compound by a different method. However, a room temperature synthesis carried by us, produced an entirely new ternary, 3D non-porous polymeric complex **2** consisting of Na, BTC and Keggin ions. Herein we present the synthesis of both the compounds, characterize **1** by powder XRD, IR and make a first time report of its thermal and adsorption characteristics *vis-à-vis* the parent MOF. We also wish to report here the X-ray crystal structure of the inorganic/organic hybrid $[Na_6(C_9H_5O_6)_3(H_2O)_{15}][PW_{12}O_{40}]$ **2**. Whereas **1** serves as an example of much less studied case of simple incorporation of Keggin anion into nanoporous HKUST-I, **2** stands for one of the rare examples of a unique, 3D extended non-porous network involving Keggin and Na^+ ions. Both materials have metal-BTC framework encapsulating the Keggin anions and differ basically in constitution from a porous $\{Mo_6\}_2$-based hybrid framework which offers chiral channels occupied by BTC molecules, instead [57].

Data/restraints/parameters	3240/3/205
Goodness-of-fit on F^2	1.030
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0218$, $wR_2 = 0.0534$
R indices (all data)	$R_1 = 0.0228$, $wR_2 = 0.0537$
Absolute structure parameter	0.032(14)
Largest difference in peak and hole	0.869 and −0.923 e Å^{-3}
CCDE number	699004

2. Experimental

2.1. General experimental

Powder X-ray diffraction patterns of all samples were obtained by a Rigaku diffractometer (D/MAX IIIB, 2 kW) using Ni-filtered Cu Kα-radiation (40 kV, 30 mA, $\lambda = 1.5406$ Å) and a graphite crystal monochromator. The crystal size and morphology were examined using a scanning electron microscope (SEM, JEOL JSM-840A). Thermogravimetric analyses (TGA) were performed with TA instrument model, TGA Q500 V6.7 with 10° C/min in N_2 atmosphere, on samples which were placed in a chamber having saturated NH_4Cl vapor for 24 h. The BET analyses were performed with N_2 adsorption–desorption isotherms at liquid nitrogen temperature (77 K) after dehydration under vacuum at 423 K for 12 h using Micromeritics Tristar 3000. The specific surface areas were evaluated using the Brunauer–Emmett–Teller (BET) method in the p/p_0 range of 0.05–0.2. IR spectra were recorded as KBr pellets on a Nicolet Magna-560 IR spectrophotometer.

2.2. Synthesis of $[Cu_3(C_9H_3O_6)_2(H_2O)_3]_2Na_3PW_{12}O_{40}{\sim}40{\cdot}H_2O$ (*1*)

To a 1:1 (w:w) mixture of water:ethanol (15 ml) added 1–2 drops of concentrated nitric acid to make its pH between 1.5 and 2.0. Added 0.210 g (1 mmol) of BTC-H_3 and 0.437 g (1.82 mmol)

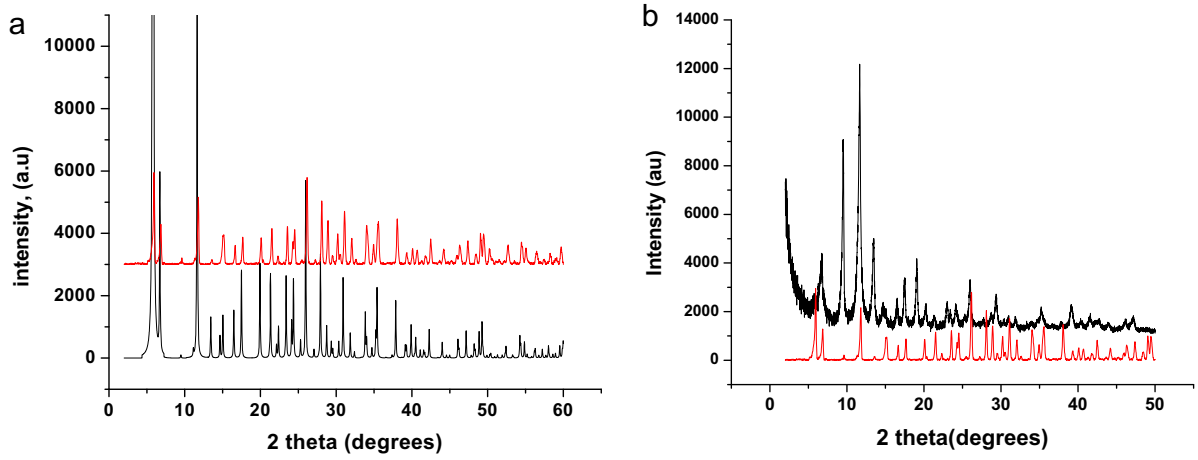

Fig. 1. Comparison of the XRD of (a) **1** (red) with that generated from the known crystal structure [44] (b) **1** (red) with $[Cu_3(BTC)_2(H_2O)_3$ (black). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

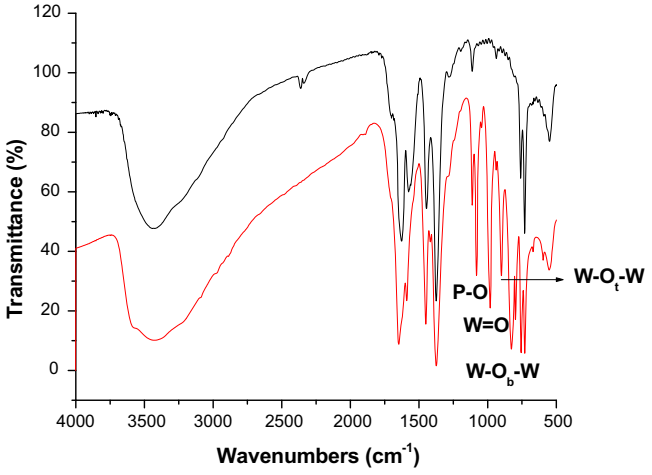

Fig. 2. A comparison of FT-IR of $[Cu_3(BTC)_2(H_2O)_3]$ (black) and **1** (red). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

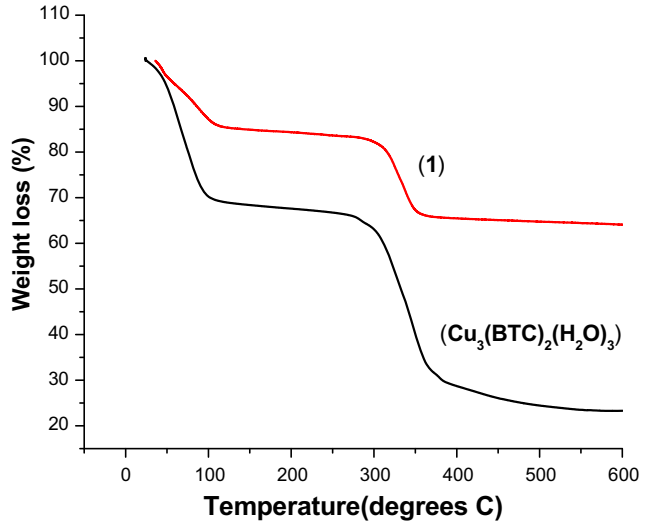

Fig. 3. A comparison of the TGA curves of $[Cu_3(BTC)_2(H_2O)_3]$ and **1**. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

of $Cu(NO_3)_2{\cdot}3H_2O$. Stirred the reaction mixture for 5 min and checked the pH which was ~1.5. Added anhydrous $Na_3[PW_{12}O_{40}]$ 2.948 g (1 mmol), stirred the mixture for 2 min and then transferred it to the autoclave Teflon reactor and heated at 120 °C for 12 h. Turquoise blue colored precipitates obtained were then filtered and washed with water many times and dried at 100 °C for 4–5 h. Yield 78% (based on W). *Anal.* Calcd. for $C_{36}H_{62}Cu_6Na_3O_{89}PW_{12}$ (partially dehydrated): H, 1.34; C, 9.38; O, 30.91; Cu, 8.27; Na, 1.49%. Found: H, 1.48; C, 9.10; O, 29.13; Cu, 7.53; Na, 1.29%. IR (cm^{-1}) ν_{OH} 3400, ν_{asym} and $\nu_{sym\ -COO}$ at 1648, 1450 and 1376, ν_{P-O} 1081, $\nu_{W=O}$ 981, ν_{W-Ot-W} 900, ν_{W-Ob-W} 829,795. The total number of water molecules were deduced from the TGA data.

2.3. Synthesis of $[Na_6(C_9H_5O_6)_3(H_2O)_{15}][PW_{12}O_{40}]$ (**2**)

For preparation of **2**, 0.950 g of $[Cu_3BTC_2]$ [56] and 3.50 g of $Na_3[PW_{12}O_{40}]$ were dissolved in 30 ml of deionized water preadjusted to pH 1.5 by adding a few drop of 1 M HNO_3 in it. The reaction mixture was stirred for 5 min, filtered and kept for slow evaporation at room temperature. Colorless, block type crystals appeared in the turquoise blue colored solution after several days (yield 38%). The mother liquor evaporated later on to give a turquoise blue powder of unknown composition. All attempts to prepare the compounds from direct reaction of $Na_3PW_{12}O_{40}$ with BTC-H_3 ended up in the crystallization $Na_3PW_{12}O_{40}$ itself, which may be due to the high acidity of $[PW_{12}O_{40}]^{3-}$ at this pH which suppresses the ionization of BTC-H_3. The presence of BTC as a pre-complexed ligand with Cu(II) ion somehow helps in the formation of the above-mentioned complex, with a much reduced extent of ionization, of course. *Anal.* Calc. for $C_{27}H_{45}Na_6O_{73}PW_{12}$: H, 1.15; C, 8.28;

nents and water upto 300 °C (Fig S2, Supporting data) with only 10% weight loss.

2.4. Single crystal X-ray diffraction studies

One of the above-mentioned colorless crystals was used for data collection on a Bruker SMART CCD diffractometer at room temperature with Mo Kα radiation. Table 1 gives the important cell and refinement parameters. The data were reduced correcting for Lorentz and polarization and absorption corrections, in a non-centrosymmetric space group R3 m. A total of 19 075 reflections were collected out of which 3240 (R_{int} = 0.032) were unique and 3138 were considered observed ($I > 2\sigma(I)$). The structure was solved by direct methods and refined on F^2 by full-matrix least-squares refinement methods using SHELXL97 program. The distinction between $-COO^-$ and –COOH groups was made on the basis of their bond lengths (C5–O12 1.332(10), C5–O13 1.223(10), C6–O14 1.257(8) Å) which correspond to a C–O single and C═O double bond between C5–O12 and C5–O13, respectively, whereas C6–O14 and C6–O14^{i} (i = $-x + y + 1, y, z$) are equal due to symmetry restrictions, corresponding to a delocalized partial double bond. The presence of both protonated and deprotonated carboxylates is also evident in IR spectra due to peaks at 1724, 1273, 1620 and 1403 cm^{-1} [57]. During refinements O2W water molecule showed disorder in terms of high thermal parameter. The disorder could be resolved by splitting O2W at two atomic positions with partial site occupancies of 0.56 and 0.44 and a common U_{iso} parameter. All non-hydrogen atoms, including O2W were refined anisotropically. Hydrogen atoms of the water molecules were located from difference Fourier synthesis. Their positional parameters were refined initially but in the final cycles they were not refined and were assigned an isotropic thermal parameter of 0.05. The O–H distances to the disordered O2W were fixed at 1.02(2) Å. All other hydrogens were fixed geometrically with U_{eq} set at 1.2U_{eq} of their carrier atoms. The Flack's parameter value of 0.03(1) indicates that the absolute configuration is correct. The final cycle of refinement for 205 parameters, 3 restraints gave GOF = 1.030, R_1 = 0.0218, wR_2 = 0.0534 for observed reflections and R_1 = 0.0228, wR_2 = 0.0537 for all reflections. In the final difference map, the deepest hole was −0.923 e Å^3 and the highest peak was 0.869 e Å^3. A platon check of the cif shows two 'A' level alerts which need some comment: the first of them is ratio U_{eq}(max)/U_{eq}(min) = 4.89 (highest 0.0850 for O1W and lowest 0.0174 for O4) being high for O element, since there are different types of oxygens for example both terminal and bridging of Keggin anion, terminal oxygens of BTC and also of solvent water molecules so high value of this ratio is not surprising. The second alert is regarding a high U_{eq} of Na atom as compared to its neighbors. The Na atom has a U_{eq} of 0.125 which is slightly on the higher side but is not unacceptable (values of this order are routinely seen during crystal structure solutions) and owing to the small U_{eq} of different types of coordinating O atoms around it, this value seems to be higher. However, there is no chance of it being wrongly labeled as is evident from the EDAX of the compound (Fig S3, Supporting data) which clearly shows the presence of Na in it.

3. Results and discussion

The phase **1** was characterized by IR, TGA, powder XRD methods. The XRD powder pattern of **1** matches with that generated for the already reported complex [44] $[Cu_3(BTC)_2(H_2O)_3]_4[\{(CH_3)_4N\}_2(HPW_{12}O_{40})]$ as shown in Fig. 1a, the small differences in intensities for some reflections in Fig. 1a may be attributable to the cations being different (Na^+ verus $(CH_3)_4N^+$) in the two compounds. In comparison to XRD pattern of $[Cu_3(BTC)_2(H_2O)_3$ (Fig 1b) there are significant differences in the intensities but not their Bragg positions. A comparison of the IR spectra of **1** with that of $[Cu_3(BTC)_2(H_2O)_3]$ clearly shows the presence of the Keggin ion $[PW_{12}O_{40}]^{3-}$ in it due to appearance of strong peaks at ν_{P-O} 1081, $\nu_{W=O}$ 981, ν_{W-Ot-W} 900, ν_{W-Ob-W} 829,795 cm^{-1} which are absent in HKUST-1 (see Fig. 2).

The thermal stability of **1** was studied using TGA and is compared to that of HKUST-1 (Fig. 3), which again shows that **1** is different than the latter. The first step in the curves is associated with the loss of water molecules [56] and second is attributable to the disintegration of the metal-organic structure. The as-synthesized, sample **1** shows a continuous weight loss of (16.5%) up to a temperature <100 °C corresponding to a theoretical loss of 16.3% due to 45 water molecules, both coordinated and in the lattice. A second weight loss (17.7%), starting at ~270 °C disintegrates the metal-organic structure with a calculated loss of 17.4% due to a

complete transformation into 6 molecules of CuO and one of $Na_3[PW_{12}O_{40}]$, per formula unit.

A SEM image of **1** (Fig S4, Supporting data) shows that the compound is homogeneous and crystalline in nature with octahedron shaped crystals having large particle size (av. $\geqslant$20 μm). To compare the permanent porosity of **1** with $[Cu_3(BTC)_2(H_2O)_3]$ we have obtained the N_2 adsorption–desorption isotherms of the purified samples at −196 °C after evacuation at 150 °C for 12 h. The nitrogen physiosorption isotherms (Fig. 4) for both compounds are of type I, however the BET surface area of **1** 519 m^2/g and a total pore volume of 0.26 cm^3/g are much smaller than those found for $[Cu_3(BTC)_2(H_2O)_3]$ by us and others [56]. A considerable decrease (~62%) in the surface area indicates that a large amount of Keggin anions get accumulated within the pores of the MOF material, which is consistent with the results of the reported crystal structure for the compound [44] which shows that alternate pores of the MOF are occupied by the Keggin anion. Such a decrease in surface area and percentage loss of weight in TGA has been seen in the case of an inclusion complex of another Keggin polyanion $K_7[PW_{11}O_{40}]\cdot nH_2O$ in the porous MIL-101 MOF [42].

A solid state UV–Vis absorption spectrum of **1** compared to $[Cu_3(BTC)_2(H_2O)_3]$ (Fig S5, Supporting data) shows that both of them exhibit an intense CT band centered at 472 nm (21 186 cm^{-1}) and another weak, very broad band centered at 700 nm (14 388 cm^{-1}). The latter is considered to be the *d*–*d* band typical of copper(II) carboxylate complexes [58] and shows a lot of vibrational fine structure in it. There is no significant shift in the spectra of the two compounds which indicates that incorporation of Keggin into $[Cu_3(BTC)_2(H_2O)_3]$ has not altered the immediate coordination sphere of the metal ion and in turn also supports its inclusion in the pores of the MOF only.

3.1. X-ray crystal structure of compound **2**

An ORTEP diagram of the asymmetric unit is shown in Fig. 5. The solid state structure of the polymer comprises of two components i.e. a macrocation $[Na_6(C_9H_5O_6)_3(H_2O)_{15}]^{3+}$ and the Keggin anion $[PW_{12}O_{40}]^{3-}$ as shown in Fig. 6. The hexameric macrocation is formed by the self-assembly of three dimeric $[Na_2(C_9H_5O_6)(H_2O)_5]^+$ units. In the dimeric unit each Na^+ ion is terminally bound by two water molecules (O2W, O3W) and carbonyl oxygen O13 of one of the protonated carboxylic groups of BTC-H_2. Third water molecule O1W bridges between two Na^+ ions in the dimer. Three such dimeric units are then joined to form a hexameric macrocation due to bridging bidentate coordination by the only deprotonated carboxylic group O14–C6–O14^i from three $[BTC\text{-}H_2]^-$ anions (i = $-x + y + 1, y, z$). The Na^+ ions in this hexameric, a puckered bowl shaped macrocation, are in turn coordinated to three terminally bonded, W=O (O_t) oxygens, O10 of the Keggin anion. The unusual feature here is that the Keggin anion $[PW_{12}O_{40}]^{3-}$ is coordinated to Na^+ ions via these three O_t oxygens O10 which belong to a single W_3O_{13} triplet and each O10 is bridging between two Na^+ ions of the dimeric unit, conforming the threefold symmetry of the lattice. Such coordination of a Keggin ion, through O_t of one M_3O_{13} triplet has only been seen in the molecular complex [{Na(dibenzo-18-crown-6)(MeCN)}$_3${$PMo_{12}O_{40}$}] [59] but to the best of our knowledge, they have never been found in a bridging coordination mode at the same time. This type of coordination places the globular Keggin anion like a "golf ball on a Tee" in the bowl of macrocation as shown in the top view (Fig. 6) and side view (Fig. 7).

The $[PW_{12}O_{40}]^{3-}$ unit has a classical α-Keggin type geometry, which consists of a central PO_4 tetrahedron surrounded by 12 WO_6 octahedrons (Fig. 6), present in the four W_3O_{13} groups. No

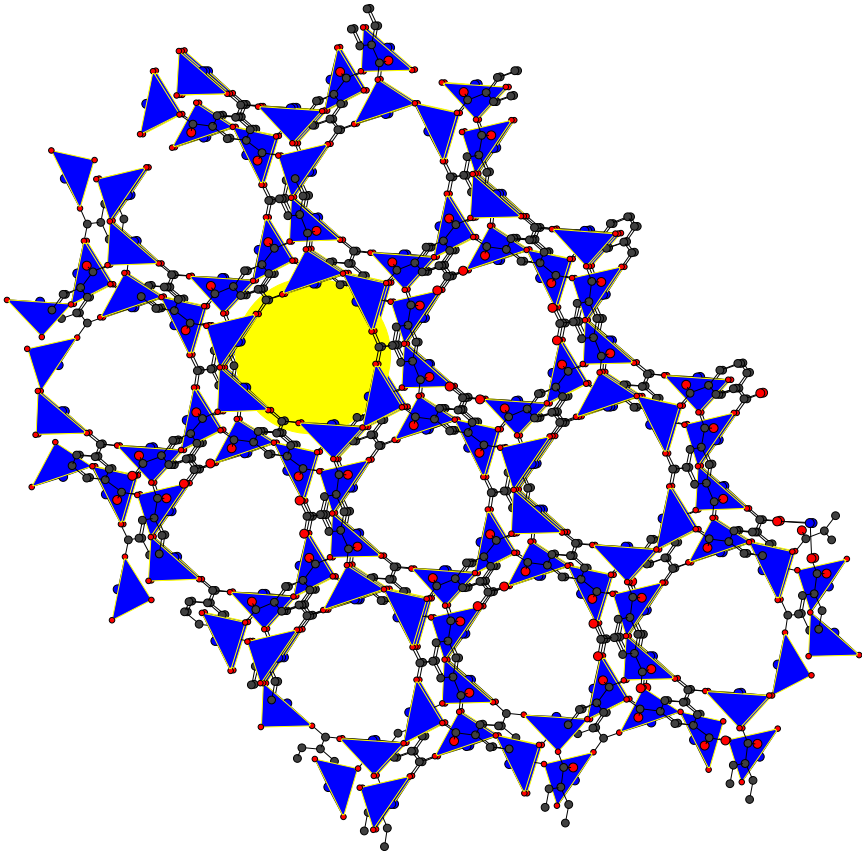

Fig. 8. Showing extended MOF formed by self-assembly of $[Na_6(C_9H_5O_6)_3(H_2O)_{15}]^{3+}$ cations. The Keggin anion and hydrogen atoms have been removed to show the channels and triangular voids (yellow dummy atom) down the *c* axis, Na octahedra (blue), C (black), O (red). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

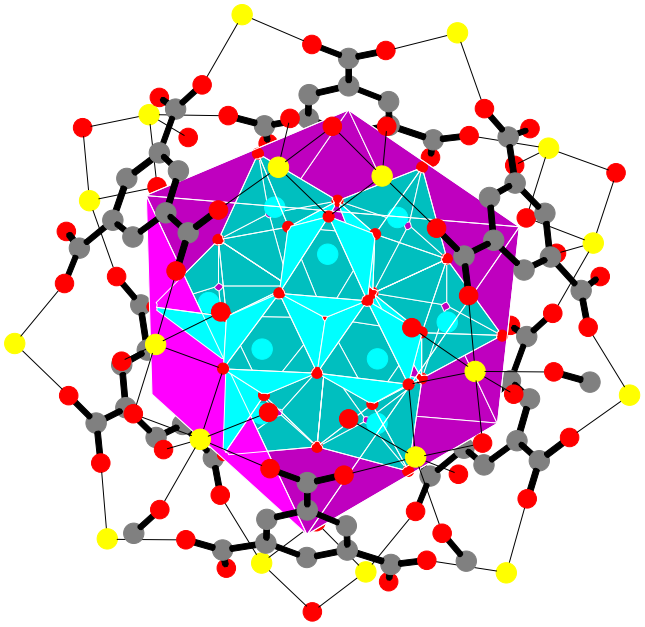

Fig. 9. Showing a Keggin anion encapsulated in an octahedral space (purple) created by six BTC anions, down the *c* axis, C (black), Na (yellow), W (cyan), O(red). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

disorder was seen in the anion unlike that reported earlier for same anion [29] and other similar anions containing α-Keggin structures [33,60–64]. The P–O distances 1.523(7), 1.561(12) Å fall in the range 1.52(2)–1.58(2) Å reported earlier [65]. The oxygen atoms are divided according to their different coordination environments into three groups, O_t (W=O), O_b (W–O–W) and O_c (P–O–W). The average observed distances (Table 2) in these categories 1.693(7), 1.909(4) and 2.441(7) Å, respectively, fall in the ranges 1.660(18)–1.719(17), 1.81(2)–1.935(16) and 2.33(3)–2.46(3) Å found [33,65] earlier.

The coordination polyhedrons around Na^+ ions in each dimeric unit may be defined as distorted, edge sharing octahedrons. A Na···Na interaction is present at 3.096(18) Å to augment this distortion. The Na–O bond lengths vary from the shortest Na–O1W 2.282(13) to the longest Na–O3W 2.801 Å. The three *trans* O–Na–O angles are O1W–Na–O14 170.9(6), O13–Na–O10 158.0(5) and O2W–Na–O3W 147.0(5), with the latter being largely responsible for the distortion, as discussed later. The coordination to Na^+ ions by the terminal oxygens of polyoxometalate anions has been seen in many crystals [59,66] Such interactions are most common for Na^+ ion than any other alkali metal ion with a coordination number of six, including the water molecules.

The self-assembly of three dimeric units via BTC forming a hexameric macrocation coupled with the Y type, four coordinating BTC ligand creates a 3D network with channels running down the *c* axis (Fig. 8). Each channel presents an equilateral triangular void with side being 8.2 Å (C6···C6^{i} i = −x + y, 2 − *x*,*z*). The Keggin anion sits on these triangular voids using three terminal oxygens of a single W_3O_{13} triplet like a tripod stand.

Although the 12 terminal oxygens of Keggin anion are in the same environment but this uneven distribution of the Keggin ion over the macrocation, using the three terminal oxygens like a 'Tee' may be attributed to the complementarity of the void. The shape and size of the void is tailor made to hold the Keggin anion in this position, just above the cavity totally in compliance with the threefold symmetry of the molecular and crystal system. In the extended 3D structure of the MOF each Keggin anion finds itself enclosed in a capsule created by six octahedrally disposed $(BTC\text{-}H_2)^-$ ligands (Fig. 9) with diagonal and edge (centroid to centroid) distances of 13.15 and 10.26 Å, respectively.

The 3D coordination polymer is further stabilized by an extensive network of strong H-bonding interactions. Looking down the channel axis i.e. parallel to the *c* axis, the three terminal oxygens O10 and O1 lie in a plane parallel to it and the remaining six terminal oxygens O7 are in a perpendicular plane. Unlike the three symmetry related O_t oxygens, O10 of Keggin anion which are coordinated to the macrocation from below, the O_t oxygens O1 at the other end are doubly H-bonded to six O2W water molecules belonging to the macrocation lying above it (Fig. 10a). Thus the molecules are stacked one above the other along the *c* axis due to alternate coordinating and H-bonding interactions. The six O2W water molecules have moved inside towards the triangular cavity to facilitate strong H-bonding interactions among them. This decreases ∠O3W–Na–O2W to 147° and distorts the coordination polyhedron around Na^+ ion as mentioned above. The driving force for this distortion is the formation of a H-bonded hexamer of O2W water molecules as described below. Each O2W water molecule in the dimeric $[Na_2(C_9H_5O_6)(H_2O)_5]^+$ entity is held at a O···O non-bonding distance of 2.39(3) Å (O2W···O2W^{vi}) and 3.30(3) Å (O2W···O2W^{iii}) (Table 3) from its counterparts in the adjacent and in the same dimer, respectively. Apparently ∠O2W–H21···O2W^{vi} is quite small (73°(2)) and H21···O2W^{vi} (2.48 Å) is

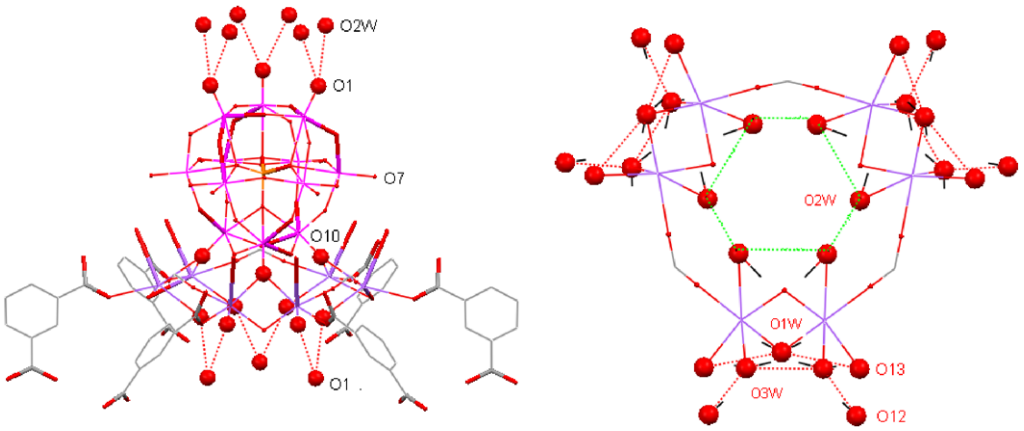

Fig. 10. (a) (Left) shows O2W···O1 H-bonding interactions and O10–Na coordinate bonds responsible for stacking along *c* axis. (b) (Right) shows a supramolecular water hexamer of O2W and dimer of O3W due to H-bonding. O (red), C (grey), W (pink), P (yellow), Na (blue). One carboxylate group from each $(BTC\text{-}H_2)$ ligand has been removed for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

Table 3
Showing important H-bonding interactions.

D–H···A	D···A	H···A	D–H···A
O12–H12···O3W	2.756(8)	1.96	162
O1W–H1W···O13	2.973(12)	2.44	120
O1W–H1W···O12^{i}	3.734(18)	2.92	157
O3W–H31W···O7	3.260(11)	2.31	163

O2W–H21···O1^{v}	2.923(17)	2.19	150

(i) $-y+1/3+1,+x-y+2/3+1,+z-1/3$; (ii) $-x+y-1/3,-x+1/3+1,+z+1/3$; (iii) $-x+y,+y,+z$; (iv) $x,+y,+z-1$; (v) $x,+x-y+2,+z-1$; (vi) $-x+y+1,+y,+z$.

longer than O2W···O2W^{vi} to call it a O2W–H21···O2W^{vi} H-bond. But considering that O2W is a disordered molecule (only atom of higher partial occupancy being used in H-bond calculations), position of H-atoms is not unambiguous and most importantly owing to the short O2W···O2W^{vi} distance, it is reasonable to consider that there exists a H-bond between O2W···O2W.^{vi} This interaction coupled with O2W–H22···O2W^{iii} H-bond creates a supramolecular water hexamer (Fig. 10b) out of O2W molecules. This water hexamer serves as a base of the bowl type $[Na_6(C_9H_5O_6)_3(H_2O)_{15}]^{3+}$ hexameric macrocation and coordinates to the six Na^+ ions in it. Apart from this O2W is intramolecularly H-bonded to O10 and donates H-bond to carboxylic O12 also, hence forming links between Keggin anion and BTC-H_2 ligand. The second terminally bonded water molecule O3W is self H-bonded to its counterpart in the dimeric unit $[Na_2(C_9H_5O_6)(H_2O)_5]^+$ thus producing a supramolecular water dimer. It also acts as a H-bond donor towards carbonyl O13 and terminal oxygens O7 and O10 of the Keggin ion and accepts a H-bond from the carboxylic O12. The bridging water molecule O1 W is acting as a H-bond donor to O13.

4. Conclusions

In conclusion, a hydrothermal synthesis of an inclusion complex from HKUST-I and Keggin anion $[PW_{12}O_{40}]^{3-}$ results in encapsulation of the guests in half of the pores of the nanoporous MOF forming **1**. Whereas a room temperature attempt to do the same has resulted in dissociation of the HKUST-1 nanoporous material, leading to a novel 3D extended network involving Na, BTC-H_2 and Keggin ions and is non-porous in nature. The inorganic/organic porous hybrid is formed by coordination assembly of Na^+, partially deprotonated $[BTC\text{-}H_2]^-$ anion and water molecules where the pores are completely occupied by the Keggin ions which reside on top of them. The Keggin ions are not diffused into the cavities in the hybrid material but rather form coordination bonds with Na^+ ions through three terminally bonded oxygens from one W_3O_{13} triplet which are also bridging between two Na^+ ions at the same time. This is a unique coordination mode of the Keggin ion, to the best of our knowledge and forms one of the lesser known alkali metal linked POM having 3D structures. Extensive H-bonding interactions result in the formation of supramolecular water hexamers and dimers in the crystal structure.

ABSTRACT

Co(II), Pd(II) and Ni(II) complexes with iminopyridine ligands have different coordination structures in the solid state, depending on the metal, pendant group of the pyridyl ring and recrystallization conditions. The iminopyridine ligand having an acrylate group, Ar–N=CH-2,6-C_5H_3N–CH_2–OCO–CH=CH_2 (**L**^{1}: Ar = 2,6-diisopropylphenyl), forms a Co(II) complex whose metal center has a trigonal pyramidal coordination with two chloride ligands and an *N,N'*-bidentate ligand **L**^{1}. Both **L**^{1} and the iminopyridine ligand with a CH_2OH pendant on the pyridyl ring, Ar–N=CH-2,6-C_5H_3N–CH_2–OH (**L**^{2}: Ar = 2,6-diisopropylphenyl), coordinate to the $PdCl_2$ moiety, giving complexes with a square–planar coordination. The reaction of **L**^{1} with [$NiBr_2(H_2O)_3$] and recrystallization of the products forms crystals which contain mono- and dinuclear complexes with aqua ligands and the *N,N'*-bidentate ligand. **L**^{2} is coordinated to the Ni(II) center as an *N,N',O*-tridentate ligand. Recrystallization of the products of the reaction of **L**^{2} with [$NiBr_2(H_2O)_3$] with and without excess H_2O in the solution yields crystals of the cationic octahedral complex with two aqua ligands [$NiBr(H_2O)_2$(**L**^{2})]Br and the neutral square pyramidal complex [$NiBr_2$(**L**^{2})], respectively.

1. Introduction

Iminopyridine derivatives have been extensively employed as ligands of transition metal complexes. The aromatic ligands whose conformation is fixed by coordination to a metal center act as a mesogen of liquid crystalline molecules, and Cu complexes with such ligands are expected to be liquid crystalline materials [1]. Iminopyridine ligands provide convenient building blocks of supramolecules, partly because ligands with various functional groups can be obtained easily by simple condensation reactions of amines and 2-formylpyridine derivatives, forming a new C=N bond [2–4]. Introduction of a polar hydroxy group on the iminopyridine ligand allows the formation of supramolecular assemblies with the molecules having a hydrogen-bond acceptor group, via hydrogen bonds [3,4]. Catalysis is another important research topic for transition metal complexes with iminopyridine ligands [5]. In particular, bis(imino)pyridine complexes of Fe and Co exhibit high activity for olefin polymerization [6,7]. Recently, we reported the synthesis of heterobimetallic complexes having Co, Pd and Ni metal centers and iminopyridine ligands, and their unique behavior as catalysts for polymerization [8]. During the study, we characterized mononuclear Co(II), Pd(II) and Ni(II) complexes which were prepared as intermediates for dinuclear complexes, and found different coordination modes of the ligand depending on the metal and the ligand. Herein, we report the syntheses and crystal structures of Co(II), Pd(II) and Ni(II) complexes having iminopyridine ligands with hydroxy or acrylate groups, and the interaction between the metal centers and these groups in the crystalline state.

2. Results and discussion

Iminopyridine ligands having an acrylate group, Ar–N=CH-2,6-C_5H_3N–CH_2–OCO–CH=CH_2 (**L**^{1}; Ar = 2,6-diisopropylphenyl) [8], and a hydroxy group, Ar–N=CH-2,6-C_5H_3N–CH_2–OH (**L**^{2}), were synthesized by the condensation reactions of 2,6-diisopropylaniline with the corresponding aldehyde (Chart 1). The reaction of

Scheme 1.

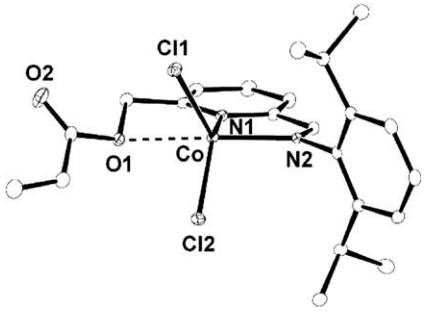

Fig. 1. ORTEP drawing of **1** with thermal ellipsoids shown at the 30% probability level. Hydrogen atoms are omitted for clarity.

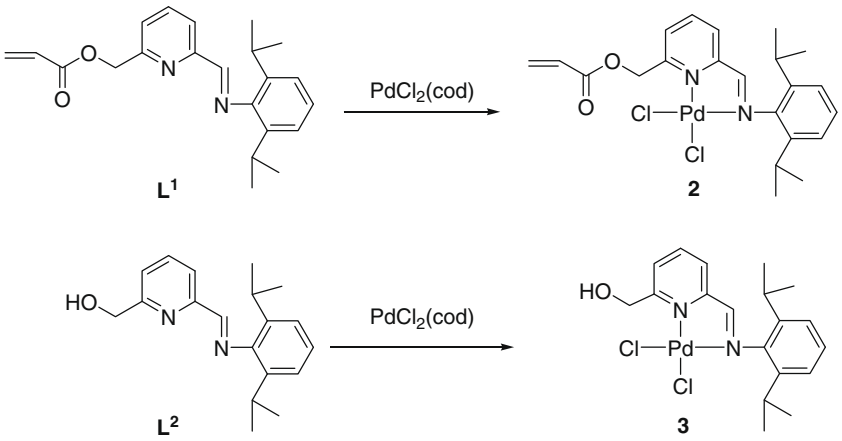

L^{1} with $CoCl_2$ afforded the Co-iminopyridine complex **1** (Scheme 1). The crystal structure of **1** is shown in Fig. 1. Table 1 summarizes selected bond parameters. Sum of the N1–Co–Cl1, N1–Co–Cl2 and Cl1–Co–Cl2 angles (353.46°) is close to 360°, and the coordination is recognized to be distorted trigonal pyramidal with the N2 atom at the apical position. The ether oxygen atom (O1) of the acrylate group seems to occupy the remaining apical site by a weak interaction with the Co center, with a distance of 2.690 Å. The Zr–Co bimetallic complex, with a similar coordination of the iminopyridine to Co, has a slightly longer Co–O distance (2.774 Å). Co complexes with acetyl- or ester-substituted iminopyridine ligands have a penta-coordinated structure with coordination of the carbonyl group (Co–O lengths = 2.327 and 2.374 Å) [9,10]. The bond parameters around Co are similar between $CoCl_2$(Ar–N=CH-2,6-C_5H_3N–CO–CH_3) (Ar = 2,6-diisopropylphenyl) and **1**, with the exception of the short Co–O bond in the former complex.

The reactions of **L**^{1} and **L**^{2} with [$PdCl_2$(cod)] (cod = 1,5-cyclooctadiene) afforded complexes **2** and **3**, respectively (Scheme 2). Fig. 2 shows the crystal structures of the Pd complexes with the *N*,*N*′-bidentate iminopyridine ligands. Each Pd center has a distorted square–planar geometry without any remarkable interaction with the acrylate or hydroxy pendant group. The square

In the case of **4b** (dimer complex), X1, X2, N1 and N2 indicate Br3, Br4, N3 and N4, respectively.

Scheme 2.

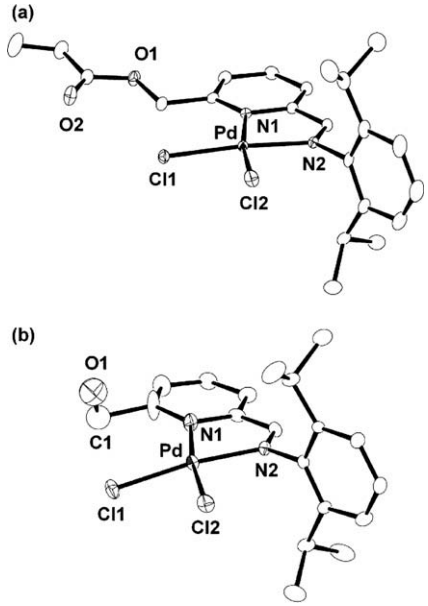

Fig. 2. ORTEP drawing of (a) **2** and (b) **3**·1.5$CHCl_3$ with thermal ellipsoids shown at the 30% probability level. Hydrogen atoms are omitted for clarity. Hydrogen atoms and solvating $CHCl_3$ molecules are omitted for clarity.

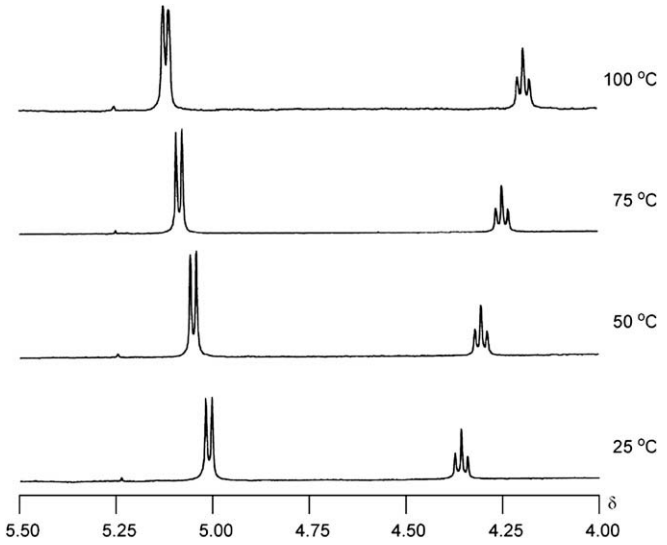

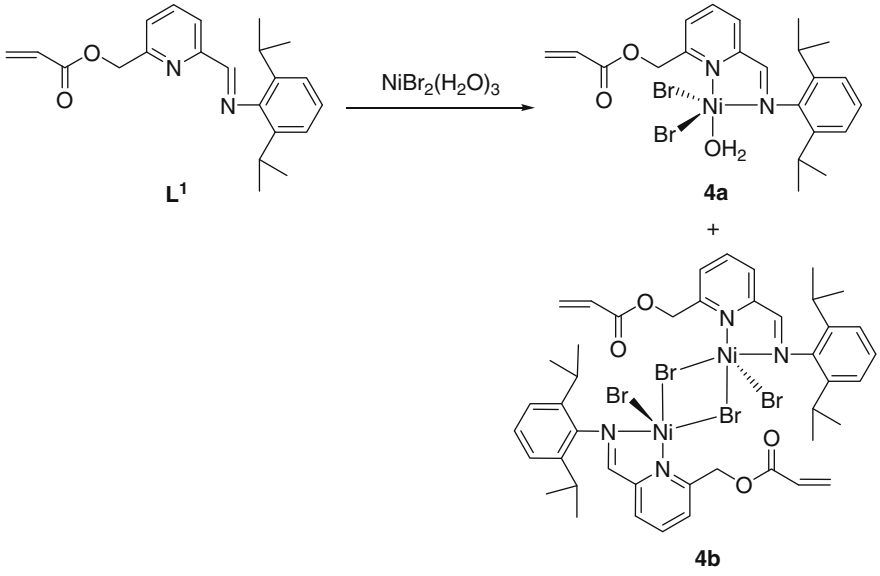

Fig. 3. ^1H NMR spectra of the hydroxymethyl region of **3** at 25–100 °C in $C_2D_2Cl_4$ (8.2 mM).

plane is orthogonally-oriented to the 2,6-diisopropylphenyl group owing to the sterically bulky isopropyl groups [6,7]. The CH_2–OH bond is orientated towards the Cl ligand with the distance Cl1–O1 = 3.046 Å, which indicates intramolecular hydrogen bonding in the crystal structure (Fig. 2b). The ^1H NMR spectrum of **3** (25 °C, $CDCl_3$) exhibits a triplet (J_{HH} = 8 Hz) assigned to the OH hydrogen at 4.67 ppm, which is at a much lower magnetic field than that of $\mathbf{L^2}$. Appearance of H–H coupling between the OH and CH_2 hydrogen of **3**, as well as the shift of the OH peak position, upon coordination of the ligand suggests Pd–Cl···H–O intramolecular hydrogen bonding in solution [11–13]. Fig. 3 shows the variable temperature ^1H NMR spectra of **3** in $ClCD_2CD_2Cl$. The triplet signal of the OH hydrogen shifts downfield by ca 0.17 ppm on raising the temperature from 25 to 100 °C. The OH and CH_2 hydrogen signals became somewhat broadened at 100 °C. The temperature-dependent change of the spectra may also suggest O–H···Cl hydrogen bonds in solution.

Elemental analysis of the product from the reaction of $\mathbf{L^1}$ and $[NiBr_2(H_2O)_3]$ indicates the formation of the aqua complex, $[NiBr_2(H_2O)L^1]$ (**4a**) [8], but X-ray crystallography of the crystals obtained from $CHCl_3$ revealed the presence of **4a** and a dinuclear complex with two bridging Br ligands, $[NiBr(\mu\text{-}Br)L^1]_2$, (**4b**) in a 1:1 ratio (Scheme 3). Fig. 4 shows the structure of the mononuclear and dinuclear complexes contained in the crystal lattice. Complex **4a** undergoes partial dissociation of the aqua ligand to yield the anhydrous dinuclear complex **4b** during the recrystallization. Chart 2 lists the penta-coordinated Ni(II) complexes with two Br, one aqua and one iminopyridine ligand, similar to **4a** [14,15]. The coordination of **4a** resembles that of a complex with an iminopyridine ligand with a methyl group next to the pyridine group (right in Chart 2), although the other complex (left) has different ligand positions. The reaction of an iminopyridine ligand with $[NiBr_2(dme)]$ (dme = 1,2-dimethoxyethane) gives dinuclear com-

Scheme 3.

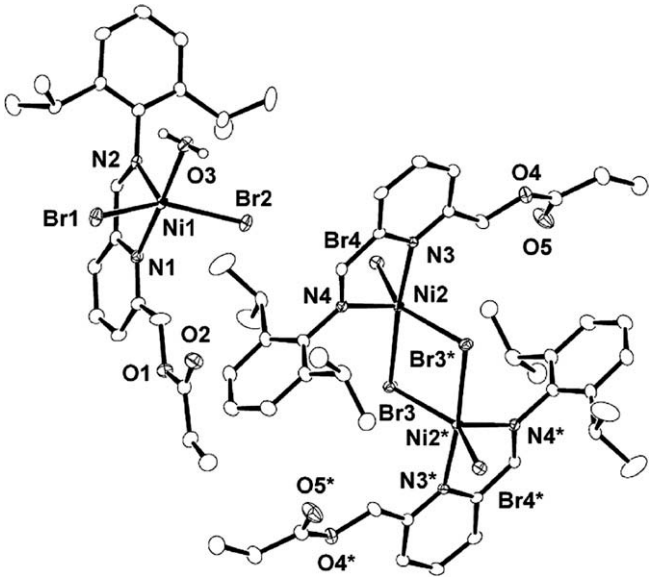

Fig. 4. ORTEP drawing of **4a** and **4b** with thermal ellipsoids shown at the 30% probability level. Hydrogen atoms except for O–H hydrogens are omitted for clarity. Atoms with asterisks are crystallographically equivalent to those having the same number without asterisks.

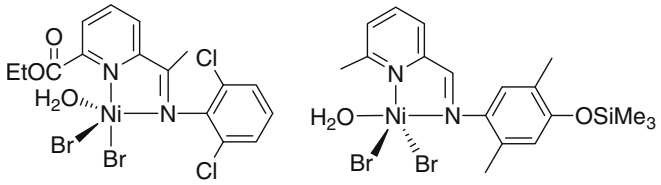

Chart 2.

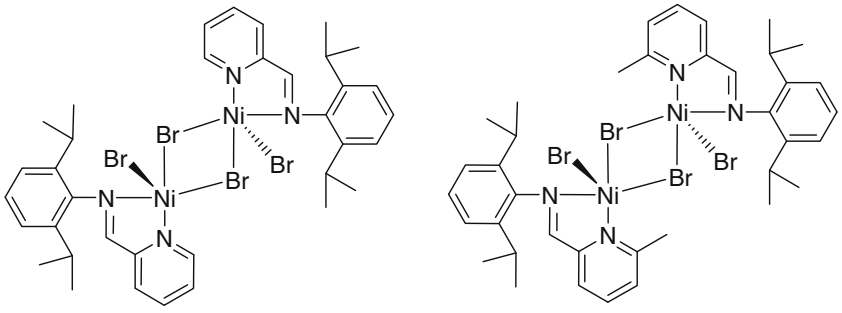
plexes with two bridging Br ligands (Chart 3) [16,17]. In the crystal structures of **4a** and **4b**, the acrylate group of the ligand does not interact with the Ni(II) centers.

The reaction of the ligand with the CH_2OH pendant, $\mathbf{L^2}$, with $[NiBr_2(H_2O)_3]$ yielded a Ni complex, **5a**, having an *N,N′,O*-coordination (Scheme 4). The crystal structure of **5a** shows a five-coordinate square pyramidal geometry with a Br atom (Br2) at the apical position (Fig. 5a). The Ni center lies 0.43 Å out of the basal plane composed of the N1, N2, Br1 and O1 atoms. A similar *N,N′,O*-coordination was observed in Ni(II) complexes with Ar–N=CCH_3-2,6-C_5H_3N–$COCH_3$ (Ar = 2,6-diisopropylphenyl) and Ar–N=CCH_3-2,6-C_5H_3N–$COOCH_2CH_3$ (Ar = 2,6-dimethylphenyl) [10,14], which have longer Ni–O bonds (2.334 and 2.402 Å) than that of **5a** (2.137 Å) (Chart 4). Recently, Gibson and co-workers reported a Fe(II) complex with a similar ligand to $\mathbf{L^2}$, Ar–N=CCH_3-2,6-C_5H_3N–$C(CH_3)_2OH$



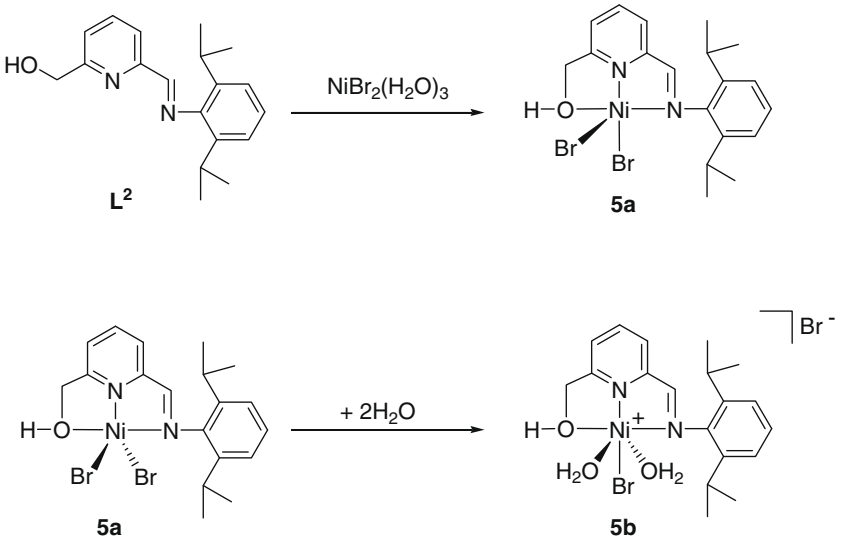


Chart 3.

Scheme 4.

(Ar = 2,6-diisopropylphenyl), in which the OH group is coordinated to Fe with a Fe–O bond distance of 2.173 Å (Chart 4) [18]. The bond length of the Ni and imine nitrogen (N2) is 0.13 Å longer than that of Ni and the pyridine nitrogen (N1). In contrast, **4a** and **4b** have shorter Ni–imine bonds than Ni–pyridine bonds. Therefore, coordination of the hydroxy group is likely to elongate the Ni–imine bond due to the *trans* influence of the O-ligand [19,20]. Other Ni-iminopyridine complexes with *N,N',O*-tridentate coordination have Ni–imine bonds approximately 0.1 Å longer than the Ni–pyridine bonds (Chart 4) [10,14,18]. Recrystallization of **5a** in the presence of an excess amount of H_2O caused dissociation of a Br ligand, resulting in the formation of the cationic aqua complex **5b** (Fig. 5b). The structure has a distorted octahedral geometry with two aqua ligands at *trans* positions. In analogy to **5a**, **5b** has longer Ni–imine bonds (2.127 Å) than Ni–pyridine bonds (2.006 Å). A similar replacement of a Br ligand with an aqua ligand was reported in a Ni(II) complex with the bidentate diphenyl(dipyrazolyl)methane ligand [21].

Intermolecular hydrogen bonding was observed in the aqua complexes **4a** and **5b**, as shown in Fig. 6. In the structure of **4a**, the short distance of H1···Br1* (2.596 Å) and the angle of H1–Br1*–Ni* (105.8°) indicate hydrogen bonding [22]. The distance H2···O2* (2.451 Å) is also related to an intermolecular interaction, although the non-linear O3–H2–O2* bonding (139.8°) suggests that the contribution of the H2–O2* hydrogen bond is minor. The structure of **5b** shows that H1 in the hydroxy group and H2 in the aqua ligand have an interaction with the free Br anion (Br2)

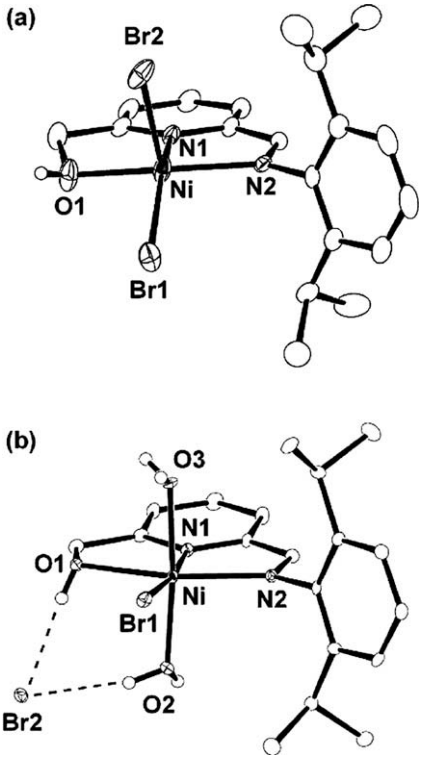

Fig. 5. ORTEP drawing of (a) **5a**·C_4H_8O and (b) **5b**·C_4H_8O with thermal ellipsoids shown at the 30% probability level. Hydrogen atoms except for O–H hydrogens and solvating THF molecules are omitted for clarity.

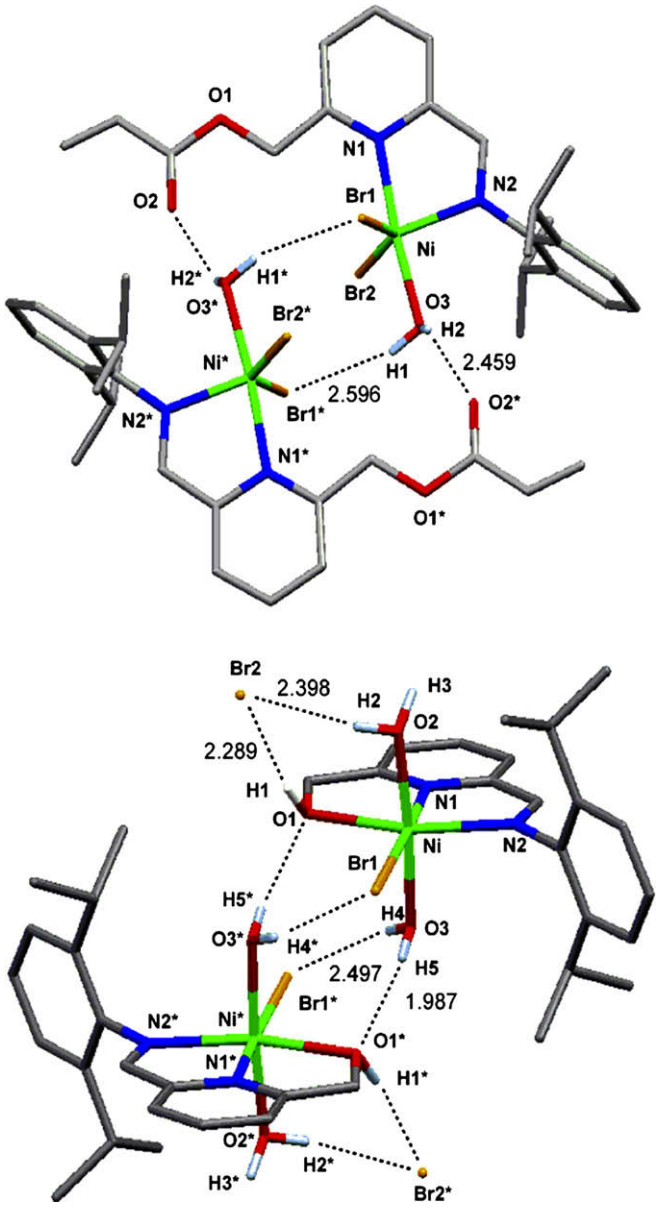

Fig. 6. Association of (a) **4a** and (b) **5b** via hydrogen bonding. Hydrogen atoms except for O–H hydrogens and solvating THF molecules are omitted for clarity. Selected angles for **4a** (°): H1–Br1*–Ni* 105.7, O3–H1–Br1* 160.2, O3–H2–O2* 138.9, Ni–O3–Br1* 102.8, Ni–O3–O2* 138.6. Selected angles for **5b** (°): H4–Br1*–Ni 86.1, O1–H1–Br2 177.4, O2–H2–Br2 160.2, O3–H4–Br1* 155.5, O3–H5–O1* 150.9, Ni–O1–Br2 105.8, Ni–O2–Br2 105.8, Ni–O3–Br1* 120.6, Ni–O3–O1* 125.7.

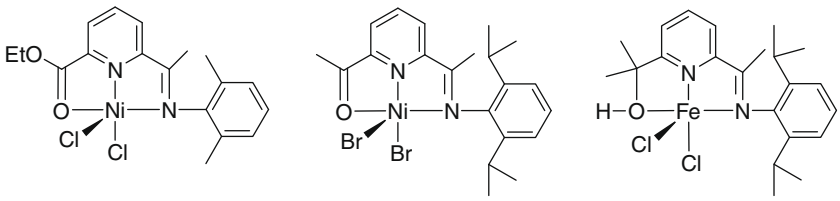

Chart 4.

with distances of 2.289 and 2.398 Å, respectively. The other aqua ligand shows hydrogen bonding with the Br1* and O1* atoms in the neighboring molecule in the crystal packing.

3. Conclusions

The crystal structures of iminopyridine complexes with an acrylate or a hydroxy pendant group were revealed by single-crystal X-ray diffraction studies. The weak interaction of the acrylate pendant group to the metal center was observed only in the case of the Co(II) complex. Coordination of the carbonyl oxygen atoms is unfavorable partly because it requires the formation of unstable 7-membered metallacycles. In the iminopyridine complexes with an hydroxy pendant group (**L²**), the ligand coordinates to the Ni(II) center in an *N,N′,O*-tridentate coordination fashion. Since coordination of an aqua ligand to Ni(II) caused the dissociation of the Br ligand in the presence of the coordinated hydroxy group, the coordination of the hydroxy group is presumably stronger than that of Br because of the chelate effect.

4. Experimental

4.1. General

6-Hydroxymethyl-2-pyridinecarboxaldehyde [23], $[PdCl_2(cod)]$ [24], **1** (green solid), **2** (yellow solid) and **4** (orange solid) were prepared according to the literature methods [8]. $[NiBr_2{\cdot}(H_2O)_3]$ and other chemicals were used as received from commercial suppliers. NMR spectra (^1H and $^{13}C\{^1H\}$) were recorded on Varian Mercury 300 and JEOL JNM LA-500 spectrometers. Elemental analyses were carried out with a Yanaco MT-5 CHN autocorder.

4.2. Synthesis of 2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine (**L²**)

A mixture of 6-hydroxymethyl-2-pyridinecarboxaldehyde (141.0 mg, 1.0 mmol), 2,6-diisopropylaniline (0.200 mL, 1.1 mmol) and acetic acid (1 drop) in EtOH (3 mL) was stirred for 14 h at room temperature. After the volatiles were evaporated under reduced pressure, the residue was washed with hexane (2 mL × 4) and dried under reduced pressure to give 2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine as a pale yellow solid (275.6 mg, 90%). *Anal.* Calc. for $C_{19}H_{24}N_2O$: C, 76.99; H, 8.16; N, 9.45. Found: C, 76.30; H, 7.99; N, 9.30%. ^1H NMR (300 MHz, $CDCl_3$): δ 8.31 (s, 1H, N=C*H*), 8.19 (d, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 7.78 (t, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 7.38 (d, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 7.20–7.11 (m, 3H, C*H* in aromatic group), 4.85 (s, 2H, CH_2), 3.90 (br, 1H, O*H*), 2.96 (quint, 2H, J^3 = 7 Hz, C*H*), 1.18 (d, 12H, J^3 = 7 Hz, CH_3). $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$): δ162.9 (s, N=*C*H), 159.2 (s, *ipso*), 153.8 (s, *ipso*), 148.6 (s, *ipso*), 137.7 (s, *C*H in pyridyl group), 137.4 (s, *ipso*), 124.8 (s, *C*H in pyridyl group), 123.3 (s, *C*H in aromatic group), 122.4 (s, *C*H in aromatic group), 120.1 (s, *C*H in pyridyl group), 64.2 (s, CH_2), 28.2 (s, *C*H), 23.7 (s, CH_3).

4.3. Synthesis of dichloro{2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine}palladium(II) (**3**)

A mixture of 2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine (68.0 mg, 0.23 mmol) and $[PdCl_2(cod)]$ (65.3 mg, 0.23 mmol) in THF (20 mL) was stirred for 12 h at room temperature. After the volatiles were evaporated under reduced pressure, the residue was extracted with THF. Crystallization from THF/Et_2O gave **3** as yellow solid (91.9 mg, 78%). *Anal.* Calc. for $C_{19}H_{24}N_2OCl_2Pd$: C, 48.17; H, 5.11; N, 5.91; Cl, 14.97. Found: C, 47.92; H, 5.32; N, 5.92; Cl, 15.38% ^1H NMR (300 MHz, $CDCl_3$): δ8.17 (t, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 8.07 (s, 1H, N=C*H*), 7.84 (d, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 7.80 (d, 1H, J^3 = 8 Hz, C*H* in pyridyl group), 7.36 (t, 1H, J^3 = 8 Hz, C*H* in aromatic group), 7.20 (d, 2H, J^3 = 8 Hz, C*H* in aromatic group), 5.15 (d, 2H, J^3 = 8 Hz, CH_2), 4.67 (t, 1H, J^3 = 8 Hz, O*H*), 3.31 (double quartet, 2H, J^3 = 7 Hz, C*H*), 1.41 (d, 6H, J^3 = 7 Hz, CH_3), 1.14 (d, 6H, J^3 = 7 Hz, CH_3). The low solubility of the complex made it impossible to obtain a $^{13}C\{^1H\}$ NMR spectrum.

4.4. Synthesis of dibromo{2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine}nickel(II) (**5a**)

$[NiBr_2{\cdot}(H_2O)_3]$ (54.5 mg, 0.20 mmol) was added to a solution of 2-hydroxymethyl-6-[(2,6-diisopropylphenyl)iminomethyl]pyridine (59.3 mg, 0.20 mmol) in THF (10 mL). After stirring at room temperature for 18 h, the solvent was reduced under vacuum. Et_2O was added to the solution to cause the separation of **5a** as an orange solid (68.9 mg, 67%). *Anal.* Calc. for $C_{19}H_{24}Br_2N_2Ni{\cdot}C_4H_8O$: C, 47.06; H, 5.49; N, 4.77; Br, 27.22. Found: C, 46.91; H, 5.52; N, 4.77; Br, 27.26%.

4.5. Synthesis of bisaqua(bromo){2-hydroxymethyl-6-[(2,6-diisopropylphenyl) iminomethyl]pyridine}nickel(II) bromide (**5b**)

Complex **5a** (19.1 mg, 0.037 mmol) was stirred in a mixture of THF and H_2O (30/1) for 20 h. After the solution was dried with $MgSO_4$, the solvent was slowly evaporated to cause the separation of **5b** as green crystals (11.5 mg, 59%). *Anal.* Calc. for $C_{19}H_{28}Br_2N_2O_3Ni{\cdot}C_4H_8O$: C, 44.34; H, 5.82; N, 4.50; Br, 25.65. Found: C, 44.12; H, 6.06; N, 4.40; Br, 25.63%.

4.6. Crystal structure determination

Intensity data were collected on a Rigaku Saturn CCD area detector or a Rigaku R-AXIS Rapid diffractometer with Mo Kα radiation. Crystals of **1–5b** suitable for an X-ray diffraction study were mounted on glass capillary tubes. Crystallographic data and details of refinement of the complexes are summarized in Table 2. A full matrix least-squares refinement was used for non-hydrogen atoms with the anisotropic thermal parameters method by the SHELXL-97 program. In the structure of **3**·1.5$CHCl_3$, disordered $CHCl_3$ molecules, C1 and O1 atoms were refined isotropically. The positional parameters for O–H hydrogen atoms, except for those in **3**·1.5$CHCl_3$, were refined isotropically, but other hydrogens were located by assuming an ideal geometry and were included in the structure calculation without further refinement of the parameters [25].

Supplementary data

CCDC 719682, 719683, 719684, 719685, 719686, 719687 contains the supplementary crystallographic data for **1**, **2**, **3**, **4**, **5a** and **5b**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

The synthesis, structural chemistry and magnetic properties of a series of new Cu(II) polymers with α,ω-dicarboxylic acids (sebacic (H_2seb), suberic (H_2sub), succinic (H_2suc) and adipic (H_2adip)) and 3-aminopyridine (3-apy) are described: $[Cu(Hsub)_2(3\text{-apy})_2{\cdot}2CH_3OH]_n$ (**1**); $[Cu(Hseb)_2(3\text{-apy})_2{\cdot}4CH_3OH]_n$ (**2**); $[Cu(Hsuc)_2(3\text{-apy})_2]_n$ (**3**); $[Cu(adip)(3\text{-apy})_2]_n{\cdot}n(H_2adip)$ (**4**). All four compounds feature a bis-monodentate bridging mode of the coordinated dicarboxylate moiety. Compounds **1** and **2** exhibit linear chains, whereas compound **3** shows two-dimensional structure. The 3-apy ligand acts as terminal ligand in **1**–**3**. Compound **4** contains a doubly deprotonated adipate ($adip^{2-}$) that connects Cu centers into linear chains. Additionally, 3-apy acts as a bridge in **4,** resulting in the formation of parallel two-dimensional layers distant enough to host neutral molecules of adipic acid. Magnetic susceptibility measurements of compounds **1** and **3** show Curie law behavior indicating that the $S = 1/2$ Cu(II) spin carriers are magnetically well isolated by the dicarboxylate ligands.

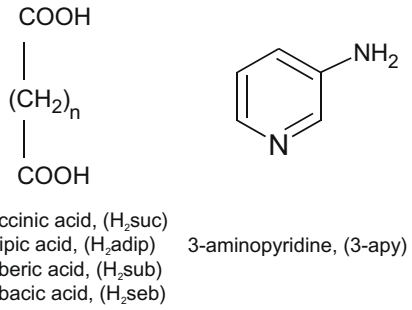
1. Introduction

The interest in research concerning coordination polymers remains high because of their capabilities in catalysis, selective separation processes, light-to-energy conversion, etc. [1]. The construction of the multicomponent system represents an important step in the development of novel molecular and supramolecular materials. For systems in which cationic metal nodes are connected, the emphasis lies in the choice of bridging ligands as critical elements for successful design. Prominent among the organic ligands used to construct extended structures are carboxylates, providing not only the necessary charge balance to permit construction of numerous neutral frameworks but also the ability to connect metal cations in a variety of coordination modes [2]. The coordination versatility can be enhanced by choosing bi- and multi-functional ligands that contain more than one carboxylate group (di-, tri- and polycarboxylates). For example, the oxalate ion ($C_2O_4^{2-}$), the first from a series of aliphatic dicarboxylates, has proved to be a versatile bridging species for the controlled assembly of 1D, 2D and 3D inorganic architectures and its coordination chemistry is well documented [3]. On the opposite, the coordination polymers based on longer aliphatic α,ω-dicarboxylates have received less attention. While the structural rigidity of oxalate units can have its advantage, higher homologs contain flexible alkyl chains which by their conformational freedom offer a greater degree of structural diversity. Recently, we have been investigating the Cu(II) coordination compounds of longer aliphatic monocarboxylates [4]. Along these lines, with a view to prepare novel coordination polymers, we have turned our attention to study the coordination behavior of aliphatic α,ω-dicarboxylates in combination with additional pyridine type ligand, namely 3-aminopyridine (3-apy) (Scheme 1). Besides the endocyclic N-atom that usually coordinates to metal center, 3-apy contains the additional functionality at the position 3: an amino group. Since the coordination compounds containing 3-apy as the additional linker are poorly documented, we have primarily set up to investigate the coordination chemistry of Cu/α,ω-dicarboxylates/3-apy system and determine: (i) the coordination geometry of the copper ion, (ii) which binding motif is preferred for carboxylate coordination, and (iii) whether the amino N atom on 3-apy can contribute to the coordination of the copper ion in any way.



2. Experimental

2.1. General procedures and materials

All manipulations were carried out under ambient conditions by using commercial grade solvents: Chemicals were used as received (Aldrich) without further purifications.

Scheme 1. Ligands discussed in this work.

2.2. Synthesis

2.2.1. $[Cu(Hsub)_2(3\text{-}apy)_2{\cdot}2CH_3OH]_n$ (**1**)

$CuBr_2$ (0.12 g) was dissolved in methanol (15 mL) and suberic acid (0.73 g) was added while heating and stirring. Upon the addition of 3-aminopyridine ligand (0.44 g) the solution became dark green. Green block-shaped crystals precipitated after standing one week at 4 °C with high yield (>90%). *Anal.* Calc. for $C_{28}H_{46}CuN_4O_{10}$: C, 50.78; H, 7.00; N, 8.46. Found: C, 50.85; H, 7.12; N, 8.55%.

2.2.2. $Cu(Hseb)_2(3\text{-}apy)_2{\cdot}4CH_3OH]_n$ (**2**)

$CuBr_2$ (0.12 g) was dissolved in methanol (12 mL). Sebacic acid (0.80 g) was added while heating and stirring. Upon the addition of 3-aminopyridine (0.45 g) the solution became dark green. Green block-shaped crystals precipitated with high yield (90%) after standing two weeks at 4 °C. *Anal.* Calc. for $C_{34}H_{62}CuN_4O_{12}$: C, 52.19; H, 7.99; N, 7.16. Found: C, 52.28; H, 7.70; N, 7.30%.

2.2.3. $[Cu(Hsuc)_2(3\text{-}apy)_2]_n$ (**3**)

$CuBr_2$ (0.12 g) was dissolved in methanol (17 mL). Succinic acid (0.55) g was added while heating and stirring. Upon the addition of 3-aminopyridine ligand (0.44 g) the color of the solution changed to dark green. On cooling slowly to ambient temperature, green crystalline product precipitated overnight. *Anal.* Calc. for $C_{18}H_{22}CuN_4O_8$: C, 44.49; H, 4.56; N, 11.53. Found: C, 44.55; H, 4.54; N, 11.58%.

2.2.4. $[Cu(adip)(3\text{-}apy)_2]_n{\cdot}n(H_2adip)$ (**4**)

$CuBr_2$ (0.12 g) was dissolved in methanol (13 mL). Adipic acid (0.23 g) was added while heating and stirring. Upon the addition of 3-aminopyridine ligand the color of the solution changed from brown to dark green. Slow cooling of the solution to 4 °C gave grass-green crystals with high yield (61%). $C_{22}H_{30}CuN_4O_8$: C, 48.75 H, 5.58; N, 10.34. Found: C, 48.50 H, 5.69; N, 10.43%.

2.3. Physical measurements

Elemental analyses were measured at the Faculty of Chemistry and Chemical Technology, University of Ljubljana with a Perkin–Elmer 240 C, H, N analyzer. Infrared spectra were recorded with a Perkin–Elmer Spectrum 100 FT-IR spectrometer using the Specac Golden Gate Diamond ATR as a solid sample support. The spectra for all studied compounds are contained in the Supplementary data. Magnetic susceptibility measurements were obtained with the use of a Quantum design SQUID MPMS-XL magnetometer. Measurements were performed on finely ground crystalline samples: 51.36 mg (**3**) and 30.49 mg (**1**) over the temperature range 1.8–300 K. The magnetic data were corrected for the sample holder, and the diamagnetic contributions. The presence of ferromagnetic impurities has been systematically checked by measuring the magnetization as a function of the field at 100 K. No presence of ferromagnetic impurities was detected for both samples. Physical characterizations of **2** and **4** have not been possible because of the high instability in air.

2.4. Crystallography

Single-crystal X-ray data were collected on a Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 150 K. Data reduction and integration were performed by DENZO-SMN software package [5]. The structures were solved by direct methods implemented in the SHELX-97 package and refined by a full-matrix least-squares method on F^2 against all reflections using the same program [6]. Hydrogen atoms were placed in geometrically calculated positions and were refined using a riding model, except those of the protonated carboxylic groups, which were found in a Fourier difference map and freely refined in all the reported structures. The 3-apy molecule is disordered over two positions in compounds **1** and **2**. The disorder was successfully modeled resulting in the partial occupancies of 0.5868 (0.4132) and 0.7290 (0.271) for compounds **1** and **2**, respectively. Crystallographic data are listed in Table 1. Figures depicting the structures were prepared by ORTEP3 [7], SHELXTL [8] and CRYSTALMAKER [9].

3. Results and discussion

Polymeric compounds are formed from the reaction of $CuBr_2$ with dicarboxylic acids: succinic (suc), adipic (adip), suberic (sub), and sebacic (seb) in the presence of 3-aminopyridine (3-apy) in methanol. Despite the approximately equivalent synthetic conditions, the structures of the isolated products differ significantly. For the comprehensible and comparative purposes, the structures are described in the order of increasing complexity, starting with isostructural one-dimensional polymers of suberic and sebacic acid and continuing with two-dimensional structures of succinic and adipic acid.

3.1. Structural description

3.1.1. One-dimensional polymers: $[Cu(Hsub)_2(3\text{-}apy)_2{\cdot}2\ CH_3OH]_n$ (**1**) and $[Cu(Hseb)_2(3\text{-}apy)_2{\cdot}4CH_3OH]_n$ (**2**)

The overall geometries are similar in both compounds, hence only the features of compound **1** will be described. The atom labeling scheme pertains to both structures, thus the comparison of the structural data is possible through the inspection of Table 2. A basic building unit as found in **1** is depicted in Fig. 1. Copper ion, located at the inversion center, is coordinated by two suberato ligands with the preserved hydroxylic group ($Hsub^-$) and two neutral 3-apy molecules. The $Hsub^-$ anions are bound with their carboxylate moieties to copper center in a monodentate manner with the Cu–O11 distance being 1.9722(13) Å. The remaining carboxylate oxygen O12 does not participate in the coordination (Cu–O12 > 3.2 Å). 3-Apy molecules complete the square-planar coordination with their endocyclic N-atoms at a distance of 2.0015(17) Å. The tendency of copper ions to accept additional ligands at the apical sites of the basal coordination plane and thus complete the octahedral coordination leads to the assembly of the above described monomeric units. The assembly takes place through the protonated carboxylic group of the dicarboxylate moiety, namely through the hydroxyl oxygen atom (O21). O21 from the adjacent building unit occupies the axial position with the Cu1–O21 ($-x+1, -y, -z$) distance being 2.5218(15) Å. Infinite chains that propagate along the *ac* diagonal are thus formed (Fig. 2). Intrachain Cu centers are separated by 13.2243(4) Å. There is no covalent bonding between the chains. The 3-apy molecules protrude from both sides of the chains perpendicular to the direction of their

propagation and are involved (through the noncoordinated NH_2 groups) in H-bonding with noncoordinated O atoms of the neighboring carboxylato moieties. Additionally, solvated methanol molecules are located between the chains and kept in the structure by H-bonds in both structures. The polyhedral view of the structure **1** is presented in Fig. 3.

3.1.2. Two-dimensional $[Cu(Hsuc)_2(3\text{-apy})_2]_n$ (**3**)

The basic building unit of **3** is similar to those of compounds **1** and **2**. The Cu atom, located at the inversion center is coordinated by two hydrogensuccinato ($Hsuc^-$) anions and two neutral 3-apy ligands (Fig. 4). The coordination of 3-apy takes place through

the endocyclic N atom with the Cu1–N1 distance of 1.9990(13) Å, whereas the $Hsuc^-$ is coordinated to Cu atom through one of the oxygen atoms of the deprotonated carboxylate group (Cu1–O11 2.0109(11) Å). The two remaining apical coordination sites are occupied by oxygen atoms from protonated carboxylic groups belonging to symmetry related hydrogensuccinato ligands (Cu1–O21 at $-x+2, y-0.5, -z+0.5$ 2.4636(11) Å) resulting in a distorted octahedral geometry around the copper center. Basic geometrical parameters are listed in Table 3. By contrast to the above described structures (compounds **1** and **2**), the mononuclear units are bridged by bis-monodentate dicarboxylic ligands to form two-dimensional layers perpendicular to *a* axis (Fig. 5). The difference could be ascribed to the conformation of the alkyl chain of the dicarboxylate unit. While the suberic and sebacic acid chains are in fully extended all *trans* conformations and as such facilitate chain

structure, the succinic acid in **3** adopt gauche orientation through the rotation around C12–C13 single bond (C11–C12–C13–C14 torsion angle of −77.9°). The geometrical requirements of the bridging succinate ligand thus enforce the formation of layers rather than chains. The formation of two-dimensional structure is further stabilized by strong hydrogen bonds of O–H···O type between the protonated and deprotonated carboxylic oxygen atoms of the two neighboring anions within the layer. No covalent interactions were observed between the layers, instead the crystal structure is stabilized by H-bonds of N–H···O type as well as through face-to-face π–π stacking interactions of the pyridine rings between the layers. The Cu–Cu separation within the same layer is 8.12533(14) Å, while the distance between the parallel layers equals the dimension of the unit cell edge *a*. The polyhedral view of **3** along the *c* axis is illustrated in Fig. 6.

3.1.3. Two-dimensional inclusion compound $[Cu(adip)(3\text{-}apy)_2]_n \cdot n(H_2adip)$ (**4**)

Unlike the complexes of suberic, sebacic and succinic acid which all contained monoprotonated dicarboxylic acid, the compound **4** contains adipic acid in its two forms: doubly deprotonated anion ($adip^{2-}$) and fully protonated molecule (H_2adip). Only the $adip^{2-}$ anion participates in coordination to the metal center. To fulfill a charge balance condition the overall stoichiometry should necessary be changed. Namely, the complex contains only one $adip^{2-}$ ligand per Cu^{2+} ion. Despite this requirement, the basic building unit is similar to those observed in the previously described compounds, while the necessary condition is achieved

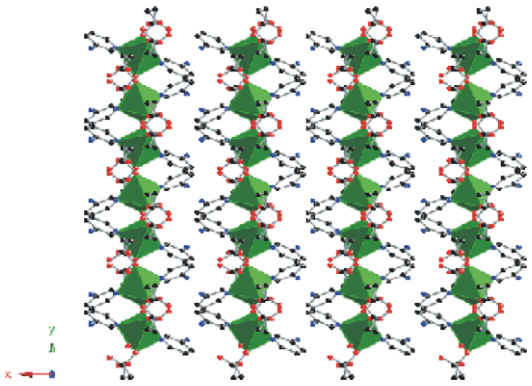

Fig. 6. A packing diagram of **3**, showing the arrangement of 2D layers, with 3-apy molecules dangling from the layers on both sides.

through the symmetry of the building unit (Fig. 7). The copper atom lies on an inversion center and is coordinated by two 3-apy molecules through endocyclic N atoms (Cu–N1 2.0209(14) Å). The $adip^{2-}$ anion is coordinated to the copper center in monodentate mode through one of the oxygen atoms (Cu1–O11 1.9746(12) Å). Only one half of the $adip^{2-}$ anion belongs to the asymmetric unit; the second half of the ligand is generated through the inversion center located at the midpoint of the alkyl chain. Consequently, the symmetry restrictions are reflected in the nature of Cu–Cu connectivity. $Adip^{2-}$ acts as a bis-monodentate bridging ligand that connects monomeric units into infinite chains along *b* axis. Four coordination sites of each copper atom are thus occupied: two by pyridine N atoms and two by O atoms from the dicarboxylate moieties. Surprisingly, the remaining two coordination sites are occupied by exocyclic 3-apy nitrogen atom of the amino group from the adjacent building unit at a longer distance (Cu1–N11 at $-x, -y+1, -z+1$ 2.6406(15) Å). The two-dimensional layers parallel to *ab* are thus formed (Fig. 8). The separation between the Cu centers bridged by 3-apy is 6.5407(2) Å, whereas the separation of those connected through dicarboxylate moiety equals the dimension of the unit cell edge *b*. In addition, the crystal contains adipic acid molecules captured between these polymeric layers (Fig. 9). The neutral H_2adip molecules lie on an inversion center located in the middle of the aliphatic chain, thus the asymmetric unit contains only half of the molecule. The "guest" molecule is kept in the structure by strong hydrogen bonds of O–H···O type as well as with hydrogen bonds of N–H···O type (see Table 4 for details).

3.2. Comments on the dicarboxylate ligation

It has to be noted, that the majority of the copper complexes with dicarboxylate ligands have polymeric structures. Only few examples of structures with discrete entities are known [10]. One feature is common to all these discrete structures; they all contain additional bifunctional N-ligands (i.e. 1,10-phenantroline, 2,2-bipyridine, etc.) that by chelation occupy two coordination sites and are large enough to prevent further interactions in the directions to polymer formation. As shown above, all here reported complexes have polymeric structure that is achieved through the bridging binding mode of the dicarboxylate moiety. The compounds **1–3** contain only partially deprotonated dicarboxylato ligands, while in **4** the coordinated ligand is fully deprotonated. Interestingly, the carboxylate binding motif is uniform, irrespective of the ionization state of the dicarboxylate moiety: both terminal functional groups are coordinated to metal centers in monodentate mode with only one of the two O atoms of each carboxylate group participating in coordination. This is not unprecedented, though not very frequently observed. In most of the reported copper complexes with saturated aliphatic dicarboxylates at least one of the carboxylate ends adopt *syn–syn* chelating mode, while the second end adopts either chelating, monodentate or monoatomic bridging arrangement.[1] It is worth noting that the related system with oxalate as the first from the homologous series of α,ω-dicarboxylates and aminopyridines has already been investigated [11]. However, the structures of none of the reported complexes resemble those

[1] A search through the CSD reveals that the frequency of the structures of Cu(II) complexes comprising linear aliphatic dicarboxylates is decreasing with the increasing number of carbon atoms of the alkyl chain. Namely, only three structures with sebacic, and six structures with suberic acid are reported, while the search gave 30 hits for complexes with adipic acid and 77 hits for complexes with succinic acid.

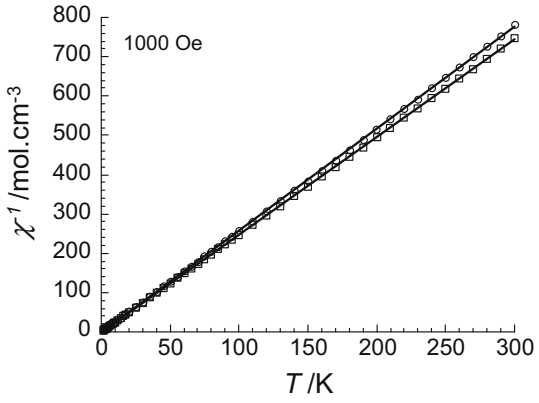

Fig. 10. Temperature dependence of the inverse of the susceptibility (□ defined as M/H per Cu^{II} metal ions) at 1000 Oe for **1** (○) and **3** (□).

reported in this work: Cu(II) centers are joined by bis-bidentate oxalato ligands.

3.3. Comments on the aminopyridine coordination

Simple neutral amino substituted pyridines (2-aminopyridine, 3-aminopyridine, 4-aminopyridine) have been used in copper coordination chemistry before. A survey through CSDB [12] for Cu coordination compounds comprising aminopyridine as the ancillary ligand gave 21, 15 and 26 hits for compounds with 2-, 3- and 4-apy, respectively. Although the amino group is a potential electron donor, there have been no structures reported with 2-apy or 4-apy as a bridging ligand; all compounds contain aminopyridine as a terminal ligand, coordinated through endocyclic nitrogen atom only. The engagement of both N atoms of the 3-apy ligand in compound **4** is rather rare, but not an exceptional phenomenon: among 15 reported Cu complexes comprising 3-apy, only one structures is known where 3-apy adopt a bridging role with both functional groups engaged in the coordination to the copper center [13].

3.4. Magnetic properties

While **2** and **4** are too unstable to be studied by magnetic measurements, the magnetic susceptibility (χ) of compounds **1** and **3** has been investigated. As shown in Fig. 10, the plot of $1/\chi$ versus T for both compounds in the 1.8–300 K temperature range reveals a linear dependence that extrapolate to zero at $T = 0$ K. This type of thermal property is known as a Curie Law and is expected for magnetically well-isolated spins. This result is not surprising considering the crystal structure described above. In both compounds, the dicarboxylate ligands arrange the magnetic Cu(II) sites far apart in space preventing any significant magnetic interactions. It is worth mentioning that the Curie constants deduced from the linear fit of the $1/\chi$ T experimental data are $C = 0.39$ and 0.40 cm^3 K/mol for **1** and **3**, respectively. These Curie constants are in very good agreement with the presence of an $S = ½$ Cu(II) spin with g factors of 2.03(2) and 2.07(2) for **1** and **2**.

4. Concluding remarks

In conclusion, we have illustrated by the examples the richness of the Cu(II) chemistry generated by dicarboxylato ligands acting as bridges. Cu(II) ion possesses centrosymmetric distorted octahedral geometry in all the complexes addressed in this work. Furthermore, they all feature uniform dicarboxylate binding motif; a bis-monodentate coordination seems to be preferred, regardless of the ionization state of the dicarboxylate moiety. The ability of aminopyridine ligand to participate in bridging with its amino group adds new dimensions and deserves further investigations. Studies to discern the generality of our observations to other aliphatic α,ω-dicarboxylates and aminopyridines are in progress.

Styrene epoxidation

ABSTRACT

Syntheses, characterizations, electrochemistry and catalytic properties for styrene epoxidation of three manganese(III) compounds $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**) $[Mn^{III}L^1(N_3)(H_2O)]\cdot dmf$ (**2**) $[Mn^{III}L^1(Cl)(H_2O)]$ (**3**) derived from the Schiff base compartmental ligand *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1) are reported. The three compounds are characterized by elemental analyses, IR, mass and UV–Vis spectra and conductance values. Single crystal X-ray structures of **1** and **2** have been determined. The structures of **1** and **2** show that these are mononuclear compounds having a salen type structure. In both structures, a dinuclear species is formed by bifurcated hydrogen bonding involving coordinated water molecule. The coordination of chloride in **3** is shown by conductance measurements. The compounds have also been characterized by UV–Vis and mass spectroscopic studies. Cyclic voltammetric and square wave voltammetric studies of the three compounds reveal that these undergo Mn(III)/Mn(II) reduction reversibly with the order of the ease of reduction as **3** > **2** > **1**. This order has been explained proposing the composition of active species in solution. Catalytic properties for epoxidation of styrene by all the three complexes using PhIO and NaOCl as oxidant have been studied. The order of both the styrene conversion and styrene epoxidation using the three title compounds is **3** > **1** > **2**. Again, it has been observed that more efficient conversion and epoxidation take place when PhIO is used as oxidant.

1. Introduction

Over the past few decades extensive studies have been made on the chemistry of manganese(III) complexes derived from Schiff base type ligands due to their important role in several metalloenzymes [1] and to understand their catalytic activities in many organic reactions [2–6].

The recent development of bioinorganic manganese chemistry has been stimulated by the involvement of manganese ions in many biological systems [1]. Manganese can exist in various oxidation states ranging from 0 to +7 in different complexes [7]. This property has been utilized by the living systems in the manganese containing enzymes that are involved in many diverse Redox functions. Manganese plays an important role in metalloenzymes such as catalase [8], superoxide dismutase [9], and photosystem II of green plants [10,11]. These proteins perform biological functions in different ways; disproportionation of H_2O_2 (psuedocatalase from *Lactobacillus planatrum*), dismutation of superoxide anion O_2^{2-} (superoxide dismutase), and involvement of oxomanganese entity as the key element of the oxygen evolving complex (OEC) which performs the light-induced oxidation of water into dioxygen, may be mentioned as some of the examples.

An important aspect of Mn(III) salen type complexes is their catalytic role in various organic reactions as catalysts. Synthetic metalloporphyrins and manganese(III) salen complexes are among the most efficient catalysts for the epoxidation of unfunctionalized olefins with high selectivities and yield. Epoxidation of olefins catalyzed by manganese(III) salen complexes has been studied extensively since Kochi and coworkers described in 1986 that they are highly effective, chemoselective, and stereoselective catalysts [12a]. At the beginning of the last decades, Jacobsen and Katsuki groups independently reported that manganese(III) complexes derived from the Schiff base ligand possessing a chiral center may be used as highly enantioselective catalyst [4–6]. The synthetic accessibility of the manganese(III)–Schiff base complexes from readily available and inexpensive precursors constitutes one of the vital attractive features. The salen type ligand system is easily obtainable from the condensation reaction between diamines and salicyldehyde derivatives and optimal selectivity can be achieved by

doi:10.1016/j.poly.2009.04.034

tuning the catalyst's steric and electronic properties [5]. Numerous salen type ligands have been prepared and utilized to investigate steric, electronic, and overall structural effects on the catalytic activity of manganese(III) center. Thus, manganese(III) complexes derived from salen type ligands can be used as laboratory and industrial homogeneous catalysts in the epoxidation of unfunctionalised alkenes using iodosylbenzene, sodium hypochlorite, hydrogen peroxide and alkyl hydroperoxides as the oxygen sources. The mechanism of the oxygen transfer from the intermediate oxo-metallic species to the olefin as well as the spin state of the intermediate oxo-metallic species, which exists possibly in a higher oxidation state, are still debatable issues [4,13]. Nevertheless, the [O = Mn(V) – salen Cl] species has been identified directly by mass spectroscopy [14] and indirectly by nuclear magnetic resonance spectroscopy [15] when iodosylbenzene was used as the oxygen source. Recently it has been reported that the mechanism and consequently the products depend on several factors like olefin [16], oxidant, counter-ion, structure of the Schiff base ligand, oxygen donor and added Lewis base [13b,17].

Using compartmental Schiff base ligands obtained on condensation of 3-ethoxysalicylaldehyde and diamines, a few 3d [18,19], 3d–3d [19] and 3d–4f [20] compounds have been previously reported. It has been observed that the $O(phenoxo)_2O(ethoxy)_2$ compartments of the mononuclear fragments derived from *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) [19b] (H_2L^1; Chart 1) and *N*,*N*′-ethylenebis(3-ethoxysalicylaldimine) [19a] (H_2L^2; Chart 1) are potential host sites for water molecules by forming bifurcated hydrogen bonds. Interesting examples of mononuclear inclusion products [18,19] and mononuclear–dinuclear cocrystals [19], resulted due to the hydrogen bonding interactions involving water and O_4 compartment, have been observed in complexes containing copper(II) in the salen-type cavity [19]. It will therefore be interesting to explore the inclusion phenomenon in complexes keeping other 3d metal ions in the salen type compartments. Manganese complexes will be additionally interesting for the scope of their catalytic properties. It may also be mentioned that manganese complexes are good members to enlighten the electrochemical aspects due to the possibility of various oxidation states of this metal center. We report here the syntheses, characterizations including single crystal X-ray structures of two complexes, electrochemistry, and catalytic roles for olefin epoxidation of three manganese(III) complexes derived from *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1; Chart 1).

2. Experimental

Caution! Perchlorate and azide complexes of metal ions are potentially explosive. Only a small amount of material should be prepared, and it should be handled with caution.

H_2L^1 H_2L^2

Chart 1. Chemical structures of the Schiff base ligands H_2L^1 and H_2L^2.

2.1. Materials and physical methods

The Schiff base ligand H_2L^1 was prepared by 2:1 condensation of 3-ethoxysalicylaldehyde and *o*-phenylenediamine in methanol. Iodosylbenzene (PhIO) was prepared by the hydrolysis of iodobenzene diacetate [21]. Styrene and styrene oxide were purchased from Aldrich and used in epoxidation experiment without further purification. The styrene oxide was used as standard sample in GC analysis. All the other reagents and solvents were purchased from commercial sources and used as received.

Elemental (C, H, and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Perkin–Elmer RXIFT spectrophotometer with samples as KBr disks. Magnetic susceptibility measurements of **1**–**3** at 300 K were carried out with a Sherwood Scientific Co., UK magnetic susceptibility balance. Electronic spectra were obtained with Hitachi U-3501 spectrophotometer. The electrospray ionization mass spectra were recorded on a Micromass Qtof YA 263 mass spectrometer. Molar conductivities (Λ_M) of 1 mM solution in dmf of complexes **1**–**3** were measured at 25 °C with a Systronics conductivity bridge. The electrochemical measurements of these complexes were performed at 25 °C under nitrogen atmosphere using a Bioanalytical Systems BAS 100B electrochemical analyzer. The concentration of the supporting electrolyte tetrabutylammonium perchlorate (TBAP) was 0.1 M, while that of complex was 1 mM. Cyclic voltammetric (CV) and square wave voltammetric (SWV) measurements were carried out with three-electrode assembly comprising a glassy carbon disk working electrode, platinum auxiliary electrode and an aqueous Ag/AgCl reference electrode (290 mV versus NHE). IR compensation was made automatically during each run. Under the experimental conditions used, the $E_{1/2}$ value of the ferrocene/ferrocenium couple was 420 mV in *N*,*N*-dimethylformamide. GC experiments were performed with Agilent 6890N Network GC systems.

2.2. Syntheses of the complexes

2.2.1. $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**)

To a stirred suspension of H_2L^1 (0.404 g, 1.00 mmol) in methanol (15 mL) was dropwise added a methanol solution (5 mL) of manganese(II) perchlorate hexahydrate (0.254 g, 1.00 mmol). After a few minutes a brown precipitate started to deposit. This was dissolved by adding the requisite amount of acetonitrile. After one hour stirring, the solution was filtered and the filtrate was kept for slow evaporation. The diffraction quality red crystals that deposited over a period of a few days were collected by filtration and washed with methanol (516 mg, 85%). *Anal.* Calc. for $C_{25}H_{28}N_2O_{10}ClMn$ (606.89): C, 49.48; H, 4.65; N, 4.62. Found: C, 49.52; H, 4.72; N, 4.75%. IR (KBr): ν = 3413(m) ν (H2O), 1594(s) ν (C=N), 1110(vs), 619(w) ν (ClO_4) cm^{-1}. MS(ESI+): *m*/*z*: 457 $[C_{24}H_{22}N_2O_4Mn]^+$. UV–Vis (dmf, λ_{max}/nm (ε/M^{-1} cm^{-1})): 410 (15 960), 307 (23 910). μ_{eff} = 4.76 BM.

2.2.2. $[Mn^{III}L^1(N_3)(H_2O)]\cdot dmf$ (**2**)

A solution of **1** (0.303 g, 0.50 mmol) in methanol (30 mL) was heated under reflux and to this hot solution was added an aqueous solution (5 mL) of sodium azide (0.130 g, 2.00 mmol). After a few minutes a dark brown precipitate started to deposit. The reflux was continued for 2 h and then after cooling the deposited solid was collected by filtration, washed with methanol and air dried. Recrystallization by diffusing diethylether into a dimethylformamide solution of the crude product yielded red crystals of diffraction quality (192 mg, 65%). $C_{27}H_{31}N_6O_6Mn$ (590.52): C, 54.92; H, 5.29; N, 14.23. Found: C, 54.85; H, 5.35; N, 14.40%. IR (KBr): ν = 3440(m) ν (H_2O), 1596(s) ν (C=N), 2028(vs) ν (N_3), 1660(m) ν (amide, dmf) cm^{-1}. MS(ESI+) *m*/*z*: 457 $[C_{24}H_{22}N_2O_4Mn]^+$. UV–Vis

(dmf, λ_{max}/nm (ε/M^{-1} cm^{-1})): 412 (17 440), 307 (26 100). μ_{eff} = 4.72 BM.

2.2.3. $[Mn^{III}L^1(Cl)(H_2O)]$ (**3**)

To a stirred solution of H_2L^1 (0.404 g, 1.00 mmol) in acetonitrile (15 mL) was dropwise added a methanol solution (5 mL) of manganese(II) chloride tetrahydrate (0.198 g, 1.00 mmol). Immediately an orange-red precipitate started to deposit. This was dissolved by adding the requisite amount of methanol. After one hour stirring, the solution was filtered and the filtrate was kept for slow evaporation. After two days, the compound that deposited was collected by filtration and washed with acetonitrile. Recrystallization from methanol–acetonitrile mixture yielded dark red colored crystalline compound (383 mg, 75%). *Anal.* Calc. for $C_{24}H_{24}N_2O_5ClMn$ (510.86): C, 56.43; H, 4.74; N, 5.48. Found: C, 56.34; H, 4.72; N, 5.62%. IR (KBr): ν = 3440(s) ν (H_2O), 1599(vs) ν (C=N). MS(ESI+) m/z: 457 $[C_{24}H_{22}N_2O_4Mn]^+$. UV–Vis (dmf, λ_{max}/nm (ε/M^{-1} cm^{-1})): 412 (13 240), 305 (22 840). μ_{eff} = 4.60 BM.

2.3. Crystal structure determination of $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**) and $[Mn^{III}L^1(N_3)(H_2O)]$·dmf (**2**)

The crystallographic data of these two compounds are summarized in Table 1. Intensity data of **1** and **2** were collected at 293 K and 296 K, respectively, on a Bruker-APEX II SMART CCD diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). For data processing and absorption correction the packages SAINT [22] and SADABS [22] were used. The structure was solved by direct and Fourier methods and refined by full-matrix least-squares based on F^2 using SHELXTL [23] and SHELXL-97 [24] packages. The non hydrogen atoms were refined anisotropically. For **1**, H(26), H(27) and H(28) have been located, while the other hydrogen atoms have been placed at geometrical positions with fixed thermal parameters. Three perchlorate oxygens are disordered over two sites and modeled accordingly. In the case of **2**, H(28) and H(29) have been located, while the other hydrogen atoms are placed at geometrical positions with fixed thermal parameters. The dimethylformamide molecule in compound **2** is highly disordered and difficult to model. Therefore it was eliminated using the SQUEEZE facility of PLATON [25]. The final least-squares refinements ($R1$) based on $I > 2\sigma(I)$ converged to 0.0454 and 0.0339 for **1** and **2**, respectively.

2.4. General method for styrene epoxidation

The epoxidation reactions were carried out at room temperature in acetonitrile under nitrogen atmosphere with constant stirring. The composition of the reaction mixture was 2.00 mmol of styrene, 2.00 mmol of chlorobenzene (internal standard), 0.10 mmol of Mn(III) complex (catalyst) and 2.00 mmol iodosylbenzene or sodium hypochlorite (oxidant) in 5.00 mL freshly distilled acetonitrile. When the oxidant was sodium hypochlorite, the solution was buffered to pH 11.2 with NaH_2PO_4 and NaOH [26]. The composition of reaction medium was determined by GC with styrene and styrene epoxide quantified by the internal standard method (chlorobenzene). All other products detected by GC were mentioned as others. For each complex the reaction time for maximum epoxide yield was determined by withdrawing periodically 0.1 mL aliquots from the reaction mixture and this time was used to monitor the efficiency of the catalyst on performing at least two independent experiments. Blank experiments with each oxidant and using the same experimental conditions except catalyst were also performed.

3. Results and discussion

3.1. Syntheses and characterization

Reaction of manganese(II) perchlorate and H_2L^1 produces the mononuclear manganese(III) complex $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**). Similarly, reaction of manganese(II) chloride and H_2L^1 produces the mononuclear manganese(III) complex $[Mn^{III}L^1(Cl)(H_2O)]$ (**3**). Clearly, aerial oxidation of manganese(II) to manganese(III) and metal assisted deprotonation of the phenolic moieties take place during the formation of **1** and **3**. As will be described below, the X-ray structure of **1** shows that the water and methanol molecules are coordinated to the metal center, while perchlorate exists as a counter anion in this molecule. The reaction of $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**) with sodium azide produces the compound $[Mn^{III}L^1(N_3)(H_2O)]$·dmf (**2**). As will be described below, the azide in this molecule is coordinated to the metal center. The molar conductivity (Λ_M) of **1** (80 Ω^{-1} cm^2 M^{-1}) is consistent with the values expected for 1:1 electrolytes (72–90 Ω^{-1} cm^2 M^{-1}) [27]. The poor conductivity of complexes **2** and **3** (ca. 10 Ω^{1} cm^2 M^{-1}) indicate that azide and chloride ion in these complexes are coordinated to the metal center and are not dissociated by dmf molecules in solution. The characteristic imine stretching of the complexes **1**, **2**, and **3** is observed at 1594, 1596 and 1599 cm^{-1} as a strong or very strong signal. The perchlorate vibrations in **1** takes place as a very strong and a weak signals at 1110 and 619 cm^{-1}, respectively. Appearance of two bands at 2028 and 1660 cm^{-1} indicates the presence of azide and dmf, respectively, in **2**. The IR spectra of the complexes **1**, **2** and **3** exhibit one medium or strong absorption at 3413, 3440 and 3440 cm^{-1} due to the coordinated water molecule. In contrast to the weak and broad water stretching observed in most of the crystal hydrates, the water stretching signal in the title compounds are medium or strong and sharp. As will be seen, the water molecule of one mononuclear unit forming bifurcated hydrogen bonds in the O_4 compartment of another molecule. It has been observed previously that separation of symmetric and

asymmetric stretching of encapsulated water molecule takes place in mononuclear copper(II) complexes derived from H_2L^1 and H_2L^2. In these copper(II) complexes, the water molecule is noncoordinated and highly encapsulated. The bifurcated hydrogen of the coordinated water molecule in **1**–**3** can not restrict the vibration in large extent. However, the vibration is partially restricted so that the signal becomes sharper with medium or strong intensity. The composition of **1**, **2** and **3** was further verified by electrospray ionization mass spectroscopy (ESI-MS positive). The ESI-MS spectra of all the three complexes in acetonitrile exhibits one peak at $m/z = 457$, which is assignable to $C_{24}H_{22}N_2O_4Mn^+$ (100%) cation. The UV–Vis spectra of the three complexes exhibit two bands at ca. 410 nm and 306 nm which can be assigned to phenolate→manganese(III) charge transfer and manganese(III)→imine ($d\rightarrow\pi^*$) metal to ligand charge transfer transitions, respectively. The observed magnetic moment at 300 K of **1**, **2** and **3** is 4.76, 4.72 and 4.60 B. M., respectively, indicating that the manganese(III) center in the title compounds exists in high spin state.

3.2. Description of the structure of $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**) and $[Mn^{III}L^1(N_3)(H_2O)]\cdot dmf$ (**2**)

The crystal structures of cationic part of **1** and **2** are shown in Figs. 1 and 2, respectively, while the bond lengths and angles around the coordination environment of these two complexes are listed in Tables 2 and 3, respectively. The structures show that both are mononuclear compound of manganese(III) having the metal center in the salen-type cavity of $[L^1]^{2-}$. The metal center in **1** and **2** is hexacoordinated. In **1**, the remaining two sites are occupied by one water molecule and one methanol molecule, while one water molecule and one azide anion occupy the remaining two coordination positions in the case of **2**. The charge of the compound **1** is balanced by a perchlorate anion. There is one dimethylformamide (dmf) molecule in **2** as solvent of crystallization.

The coordination environment of the metal ions in both **1** and **2** is slightly distorted tetragonal. The two phenolate oxygen atoms (O(1) and O(2)) and the two imine nitrogen atoms (N(1) and N(2)) define the basal plane. The average deviation (0.0007 Å for **1** and 0.024 Å for **2**) of the donor centers and the displacement (0.014 Å for **1** and 0.071 Å for **2**) of the metal center from the least-squares O(1)O(2)N(1)N(2) plane indicate that the N_2O_2 cavity

affords an almost perfect plane to the metal center. The axial positions of the metal center in **1** are occupied by the water and methanol oxygens (O(3) and O(4), respectively), while one water oxygen (O(3)) and one azide nitrogen (N(3)) occupy the axial positions in the case of **2**. In the basal plane, the metal–ligand bond distances involving the imine nitrogens (**1**: Mn(1)–N(1) = 1.998(2) Å, Mn(1)–N(2) = 1.982(3) Å. **2**: Mn(1)–N(1) = 1.98887(12) Å, Mn(1)–N(2) = 1.9896(12) Å) are slightly greater than the bond lengths involving phenoxo oxygens (**1**: Mn(1)–O(1) = 1.882(2) Å, Mn(1)–O(2) = 1.871(2) Å. **2**: Mn(1)–O(1) = 1.8856(10) Å, Mn(1))–O(2) = 1.8782(10) Å). As expected due to Jahn–Teller distortion of high spin manganese(III), the bond distances involving the axial water and methanol oxygen atoms in **1** (Mn(1)–O(3) = 2.235(2) Å, Mn(1)–O(4) = 2.261(3) Å) as well as involving water oxygen and azide nitrogen in **2** (Mn(1)–O(3) = 2.3114(13) Å, Mn(1)–N(3) = 2.1896(14) Å) significantly longer than the bond lengths involving the basal atoms. The *transoid* angles (**1**: 173.45(11)°, 175.13(9)°, and 175.17(9)°. **2**: 171.81(5)°, 174.65(4)°, and 172.44(5)°) and the *cisoid* angles (**1**: 82.47(10)–93.53(10)°. **2**: 82.64(5)–95.31(5)°) deviate slightly from the ideal values.

As shown in Figs. 3 and 4, each of the two hydrogen atoms of the coordinated water molecule ($H_2O(3)$) in both the compounds **1** and **2** forms bifurcated hydrogen bonds with one phenoxo and one ethoxy oxygen atoms of a symmetry related mononuclear molecule resulting in the formation of self-assembled dinuclear species. The geometries of the hydrogen bonds are summarized in Table 4. The ranges of the donor–acceptor contacts in **1** and **2** are 2.897–2.982 Å and 2.929–3.022 Å respectively, indicating that the hydrogen bonds responsible for the formation of dinuclear self-assembly may be considered as strong. Another interesting structural feature of compounds **1** and **2** is the presence of relatively strong π–π interaction. The aromatic ring C(1)C(2)C(3)C(4)C(5)C(6) of one molecule interacts with an aromatic ring (C(15A)C(16A)-C(17A)C(18A)C(19A)C(20A) for **1** and C(15B)C(16B)C(17B)C-(18B)C(19B)C(20B) for **2**) of a symmetry related molecule (A, $1-x$, $1-y$, $1-z$; B, $1-x$, $-y$, $1-z$). The distance between the two centroids is 3.622 and 3.696 Å, respectively, for **1** and **2**. The combined effect of hydrogen bonding and π–π interaction result

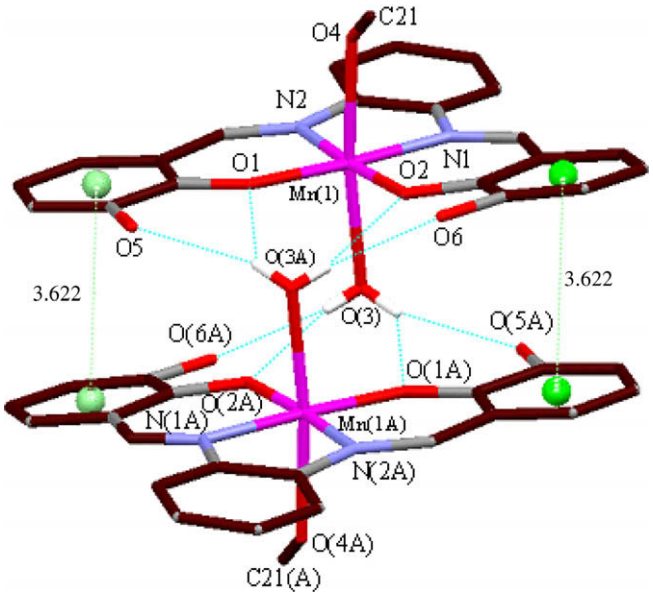

Fig. 3. Perspective view to demonstrate the bifurcated hydrogen bonds by coordinated water in $[Mn^{III}L^1(H_2O)(MeOH)](ClO_4)$ (**1**) resulting in the formation of self-assembled dinuclear aggregate. Some atoms have been omitted for clarity.

the mononuclear manganese(III) molecules are self-assembled to dinuclear species [28].

3.3. Electrochemistry

The electrochemical measurements have been carried out for complexes **1**–**3** in dmf. The results obtained in these measurements are summarized Table 5. All these complexes show only one reversible peak due to Mn(III)/Mn(II) couple. The cyclic voltammogram of the complexes **1**, **2** and **3** are shown in Figs. S1–S3 (in Supplementary Informations) respectively. The $E_{½}$ values of the Redox couples for **1**, **2** and **3** are $E_{½}$ = 90, 105 and 165 mV, respectively, while the ΔE_p values the couples are 70, 70, and 75 mV, respectively. The ΔE_p values for all the three complexes clearly indicate the reversible nature of the reduction process. The complimentary Redox potentials obtained from square wave voltammetry (SWV) is also given in the Table 5. The order of the $E_{½}$ values in **1**, **2**, and **3** indicates that the order of the feasibility of the reduction of manganese(III) center in the three complexes are **3** > **2** > **1**. Therefore, the order of the relative extent of the accumulation of negative charge on manganese(II) center in solution is **1** > **2** > **3**. The structures of the inner sphere of the complexes **1**, **2**

Complex	$E_{1/2}$ (mV)		ΔE_p[b] (mV)
	CV	SWV	
1	90	90	70
2	105	100	70
3	165	170	75

[a] All the potentials are against Ag/AgCl reference electrode and scan rate in all cases is 100 mV s^{-1} for cyclic voltammogram.
[b] For cyclic voltammogram.

and **3** in solid state are $[Mn^{III}L^1(H_2O)(MeOH)]^+$, $[Mn^{III}L^1(N_3)(H_2O)]$ and $[Mn^{III}L^1(Cl)(H_2O)]$, respectively. Evidently, in contrast to methanol in **1**, there are coordinated anions in **2** and **3**. Therefore, if the compositions in solution are same as in solid state, the reduction of the metal center should be easier in **1** than that in **2** or **3**. However, the reverse order is observed indicating the change of composition of the inner sphere in solution. As already discussed, azide and chloride in **2** and **3** are not substituted by solvent molecules in dmf solutions and therefore the active species of **1**, **2**, and **3** to undergo reduction may be considered to be $[Mn^{III}L^1(dmf)_2]$, $[Mn^{III}L^1(dmf)(N_3)]$ and $[Mn^{III}L^1(dmf)Cl]$, respectively. In that case, due to the presence of two dmf, there is a possibility of the accumulation of relatively more negative charge on the metal center in **1** resulting in the less positive $E_{½}$ value. It also seems that azide in **2** accumulates more negative charge on the metal center in **2** than that by chloride in **3**.

3.4. Epoxidation of styrene by complexes *1*, *2* and *3*

Epoxidation of styrene was carried out at room temperature with manganese(III) complexes, **1**, **2**, and **3**, as the catalysts and PhIO and NaOCl as oxidants. The deep red color of the solutions containing the Mn(III) complexes and the substrate was intensified after the addition of oxidant indicating the formation of oxo-metallic intermediates of the catalysts [4]. After completion of oxidation reaction of the alkene, the solution regains its initial color which suggests that the regeneration of the catalysts takes place. Because of the insolubility of the iodosylarenes in common organic solvents, we did not attempt to determine the rate law [29]. The percentage of conversion of styrene, selectivity for styrene oxide, yield of styrene oxide for each complex and reaction time to obtain maximum yield using both the oxidants are given in Table 6.

The data in Table 6 reveals that catalyst **3** converts styrene most efficiently in presence of both the oxidants. Nevertheless, all the catalysts are selective towards the formation of styrene epoxide despite of the formation of by-products which have been identified by GC-MS as benzaldehyde, phenylacetaldehyde, styrene epoxide derivative, alcohols etc. From the data it is also clear that complex **3** also exhibits the highest efficiency for styrene epoxide yield.

When the reactions are carried out with PhIO, styrene conversions were 87%, 80% and 95% for catalysts **1**, **2** and **3**, respectively.

Table 6
Epoxidation of styrene catalyzed by complexes **1**–**3** in acetonitrile.

Complex	Time(h)	Oxidant	Conversion (%)	Epoxide yield (%)	Selectivity (%)	
					Epoxide	Other
1	2.5	PhIO	87	74	85	15
	2	NaOCl	71	58	82	18
2	2.5	PhIO	80	65	81	19
	4	NaOCl	68	52	76	24
3	1.5	PhIO	95	87	92	8
	2	NaOCl	90	77	85	15

With NaOCl as oxidant, styrene conversion dropped to 71%, 68% and 90% for **1**, **2** and **3**, respectively. It is evident that from Table 6 that between NaOCl and PhIO, later acts as a better oxidant with respect to both styrene conversion and styrene epoxide selectivity. Figs. 5 and 6 show bar diagrams for the epoxidation of the styrene using PhIO and NaOCl as oxidant, respectively.

It is relevant to compare the catalytic performance of the title complexes with that of the current "best" systems. Kochi and coworker reported epoxide yields of 50-75% for the epoxidation of various types of olefins, including substituted styrenes, stilbenes, and cyclic and acyclic alkenes, within 15 min at ambient temperatures in acetonitrile using PhIO as the oxidant and several substituted Mn(III)–salen complexes as catalysts [12a]. Recently Silva et al. reported styrene epoxide yield ranging from 22.5% to 85.7% in presence of NaOCl as oxidant and from 71.2% to 98.3% in presence of PhIO as oxidant by using a number of manganese(III)–Schiff base complexes in acetonitrile [12b]. Evidently, as the epoxide yields for the title complexes range between 65 and 87% using PhIO as oxidant and between 52% and 77% using NaOCl as oxidant, the title

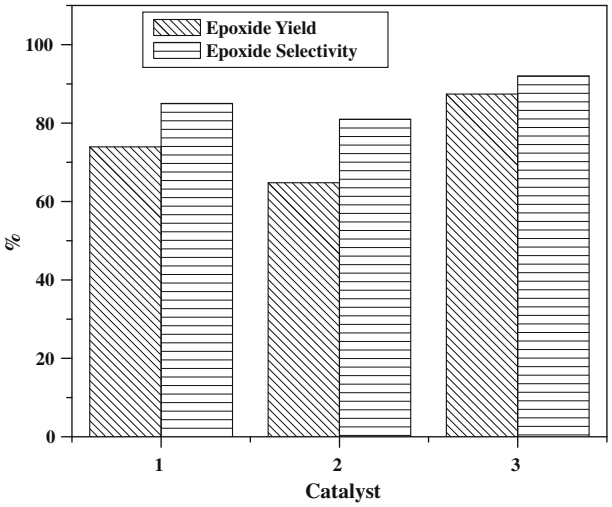

Fig. 5. Bar diagram showing the catalytic activity of complexes **1**–**3** with styrene in CH_3CN using PhIO as oxidant.

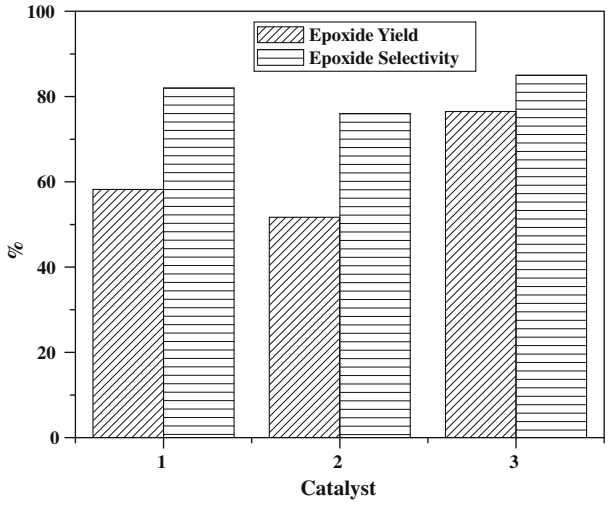

Fig. 6. Bar diagram showing the catalytic activity of complexes **1**–**3** with styrene in CH_3CN using NaOCl as oxidant.

compounds can be included in the family of "best" catalysts reported so far.

4. Conclusions

One aim of the present investigation is to explore the possibility of inclusion properties of water molecule in the O_4 compartment of the complexes of 3d metal ions, other than copper(II), derived from H_2L^1. It has been also observed that the combined effect of hydrogen bonding and $\pi-\pi$ interaction result the mononuclear manganese(III) molecules are self-assembled to dinuclear species. Another aim of the present study is to enlighten the electrochemical behavior of manganese complexes. It has been observed that the expected trend of the ease of reduction does not take place in the present series. However, the observation has been tentatively explained proposing the active species in solution. The final aim of this investigation is to explore the catalytic properties for styrene epoxidation by new manganese complexes. In parallel with our anticipation, the title compounds catalyze both the styrene conversion and epoxidation efficiently.

ABSTRACT

Four new coordination polymers $\{[Ni(HL)(H_2O)]\cdot H_2O\}_n$ (**1**), $\{[Co(HL)(H_2O)]\cdot H_2O\}_n$ (**2**), $\{[Co(HL)]\cdot 4H_2O\}_n$ (**3**) and $\{[Zn(HL)]\cdot 2H_2O\cdot 0.5C_2H_5OH\}_n$ (**4**) [H_3L = 5-(1H-imidazol-4-ylmethyl)aminoisophthalic acid] have been synthesized under hydrothermal conditions and characterized by single-crystal X-ray diffraction analyses. Complexes **1** and **2** display (3, 3)-connected 2D network with (4, 8^2) topology. While **3** and **4** exhibit a binodal (3, 6)-connected 2D network with a Schläfli symbol $(4^3)_2(4^6, 6^6, 8^3)$. The complexes **1**–**4** show remarkable thermal stability and **4** exhibits blue fluorescence with maximum emission at 413 nm upon excitation at 362 nm in the solid state at room temperature. In addition, the magnetic measurements of **3** indicate that there are antiferromagnetic interactions between the neighboring Co(II) centers.

1. Introduction

The rational design and synthesis of metal–organic frameworks (MOFs) have been of great interest in recent years in materials science and chemical research because they may provide a new strategy for achieving solid functional materials with potential applications in the areas of catalysis, gas storage, magnetism and optics [1–10]. Obviously the nature of the coordination sites, conformation, flexibility of organic ligands as well as the geometric preference, potential properties of the metal centers affected the structure and property of the final MOFs greatly. Over the past decades, there are varied examples of metal–organic coordination frameworks obtained by using imidazole-based ligands, for example 1,3,5-tris(1-imidazolyl)benzene, 1,3,5-tris(imidazol-1-ylmethyl)-2, 4,6-trimethylbenzene, 2,4,6-tris[4-(imidazol-1-ylmethyl)phenyl]-1, 3,5-triazine [11–16]. Such ligands were designed and used to investigate the influence of bridging ligand on formation and structure of supramolecular architectures, and MOFs with a broad range of structures including cage, one-dimensional (1D) tube, two-dimensional (2D) network, three-dimensional (3D) non-interpenetrating or interpenetrating frameworks have been reported [11–16]. On the other hand, MOFs with carboxylate-containing ligands are of increasing interest since the carboxylate groups can adopt varied coordination modes such as monodentate, bis-monodentate, chelating, and as a result diverse structures can be obtained [17–19].

In this study, we have designed a new carboxylate and imidazole containing ligand, namely 5-(1H-imidazol-4-ylmethyl)aminoisophthalic acid (H_3L), which has remarkable features as following: (a) the two carboxylate groups can be partially or completely deprotonated by tuning the reaction pH and thus different bridging and coordination modes could be expected in the formation of MOFs; (b) the flexible arms of H_3L can adopt varied conformations which would further generate diverse architectures; (c) the introduced aromatic and the imidazole groups can offer additional π–π and hydrogen bonding interactions to further consolidate the structure [20–22]. Herein, the syntheses, structure characterization and properties of four MOFs $\{[Ni(HL)(H_2O)]\cdot H_2O\}_n$ (**1**), $\{[Co(HL)(H_2O)]\cdot H_2O\}_n$ (**2**), $\{[Co(HL)]\cdot 4H_2O\}_n$ (**3**), and $\{[Zn(HL)]\cdot 2H_2O\cdot 0.5C_2H_5OH\}_n$ (**4**) are reported.

2. Experimental

2.1. Materials and measurements

All commercially available solvents and starting materials were used as received without further purification. FT-IR spectra were recorded on a Bruker Vector22 FT-IR spectrophotometer using KBr disks. Elemental analyses were taken on a Perkin–Elmer 240C elemental analyzer. The luminescent spectra for the solid samples were recorded at room temperature on an Aminco

Bowman Series 2 spectrophotometer with xenon arc lamp as the light source. In the measurements of the emission and excitation spectra, the pass width was 5.0 nm. All the measurements were carried out under the same conditions. Thermogravimetric analyses (TGA) were performed on a TGA V5.1A Dupont 2100 instrument heating from room temperature to 700 °C under N_2 with a heating rate of 20 °C/min. The magnetic susceptibilities in the temperature range of 1.8–300 K were measured on a Quantum Design MPMS7 SQUID magnetometer in a field of 2000 Oe. Diamagnetic corrections were made with Pascal's constants for all samples.

2.2. Synthesis of the ligand 5-(1H-imidazol-4-ylmethyl)aminoisophthalic acid (H_3L)

Ligand H_3L was prepared by reaction of imidazole-4-carboxaldehyde (0.96 g, 10 mmol) and 5-aminoisophthalic acid (1.81 g, 10 mmol) in methanol, followed by sodium borohydride reduction. The resulting white crystalline solid was obtained with a yield of 80% (2.1 g). 2.3. Synthesis of the complexes

2.3.1. Synthesis of{[Ni(HL)(H_2O)]·H_2O}$_n$ (**1**)

A mixture of H_3L (0.026 g, 0.10 mmol), $Ni(NO_3)_2{\cdot}6H_2O$ (0.029 g, 0.10 mmol), NaOH (0.10 mmol), CH_3CN (2 mL) and H_2O (8 mL) was kept in a 15 mL Teflon liner autoclave at 140 °C for 3 days. After the mixture was cooled to room temperature, green platelet crystals of complex **1** were collected with a yield of 46%. *Anal.* Calc. for $C_{12}H_{13}NiN_3O_6$ (**1**): C, 40.70; H, 3.70; N, 11.87. Found: C, 40.52; H, 3.67; N, 11.79%. IR (KBr pellet, cm^{-1}): 3423 (s), 1628 (ms), 1616 (ms), 1552 (s), 1532 (s), 1445 (s), 1415 (s), 1380 (s), 1353 (ms), 798 (m), 781 (m), 727 (s).

2.3.2. Syntheses of {[Co(HL)(H_2O)]·H_2O}$_n$ (**2**) and {[Co(HL)]·4H_2O}$_n$ (**3**)

A mixture of H_3L (0.026 g, 0.10 mmol), $Co(ClO_4)_2{\cdot}6H_2O$ (0.036 g, 0.10 mmol), C_2H_5OH (3 mL) and aqueous sodium bicarbonate solution (0.04 M, 5 mL) was kept in a 15 mL Teflon liner autoclave at 120 °C for 3 days. After the mixture was cooled to room temperature, pink platelet crystals of complex **2** and purple block crystals of **3** were collected with a yield of 24% and 37%, respectively. *Anal.* Calc. for $C_{12}H_{13}CoN_3O_6$ (**2**): C, 40.69; H, 3.70; N, 11.86. Found: C, 40.99; H, 3.41; N, 11.87%. IR (KBr pellet, cm^{-1}): 3284 (s), 1616 (s), 1556 (s), 1475 (ms), 1417 (s), 1349 (s), 1282 (ms), 1024 (m), 786 (s), 722 (s), 620 (m). *Anal.* Calc. for $C_{12}H_{17}CoN_3O_8$ (**3**): C, 36.94; H, 4.39; N, 10.77. 2.3.3. Synthesis of {[Zn(HL)]·2H_2O·0.5C_2H_5OH}$_n$ (**4**)

A mixture of H_3L (0.026 g, 0.10 mmol), $Zn(NO_3)_2{\cdot}6H_2O$ (0.030 g, 0.10 mmol), NaOH (0.10 mmol), C_2H_5OH (2 mL) and H_2O (8 mL) was kept in a 15 mL Teflon liner autoclave at 120 °C for 3 days. After the mixture was cooled to room temperature, colorless platelet crystals of complex **4** were collected with a yield of 44%. *Anal.* Calc. for $C_{13}H_{16}ZnN_3O_{6.5}$ (**4**): C, 40.70; H, 4.20; N, 10.95. Found: C, 40.74; H, 4.16; N, 10.87%. IR (KBr pellet, cm^{-1}): 3320 (s), 3142 (w), 1619 (s), 1572 (s), 1422 (s), 1364 (s), 782 (s), 727 (m), 621 (m).

2.4. Crystal structure determination

Crystallographic data of **1** and **2** were collected at 293 K on a Bruker SMART CCD system equipped with monochromated Mo Kα radiation (λ = 0.71073 Å) using ω–φ scan technique. The data integration and empirical absorption corrections were carried out by SAINT programs [23]. The structures were solved by direct methods (SHELXS-97) [24]. All the non-hydrogen atoms were refined anisotropically on F^2 by full-matrix least-squares techniques using the SHELXL-97 crystallographic software package [25]. The hydrogen atoms of water molecules in **1** and **2** and H1 in **1** were located from difference Fourier maps, and the other hydrogen atoms were generated geometrically. Crystallographic data for complexes **3** and **4** were carried out on a Rigaku RAXIS-RAPID Imaging Plate diffractometer at 200 K, using graphite-monochromated Mo Kα radiation (λ = 0.71075 Å). The structures of **3** and **4** were solved by direct

methods with SIR92 [26] and expanded using Fourier techniques [27]. All the non-hydrogen atoms were refined anisotropically on F^2 by full-matrix least-squares methods. All the hydrogen atoms except those of water molecules and H1 in **3** and **4** were generated geometrically and refined isotropically using the riding model, while the H1 in **3** and **4** were located from difference Fourier maps directly. Atoms of ethanol (C71, C72 and O7) in complex **4** are disordered with occupancy of 0.5. All calculations were performed using the TEXSAN crystallographic software package of Molecular Structure Corporation [28]. Details of the crystal parameters, data collection and refinements for **1**–**4** are summarized in Table 1. Selected bond lengths and angles for **1**–**4** are listed in Table 2.

3. Results and discussion

3.1. Syntheses of the complexes

Hydrothermal methods were employed in this work for the preparation and crystal growth of the title complexes, furthermore, pH value of the reaction plays a key role in the formation of coordination polymers with open frameworks, especially in those with carboxylate-containing ligands. Although different bases such as NaOH, $NaHCO_3$, triethylamine with different molar ratio of ligand to base were used in the preparation of complexes **1** and **4** to deprotonate the H_3L, only the addition of NaOH to the ligand with molar ratio 1:1 was successful and led to the formation of suitable single crystals of **1** and **4**. In the case of **2** and **3**, only the addition of $NaHCO_3$ solution with molar ratio 2:1 to the ligand was successful and suitable single crystals of **2** and **3** were obtained.

3.2. Crystal structures of complexes *1*–*4*

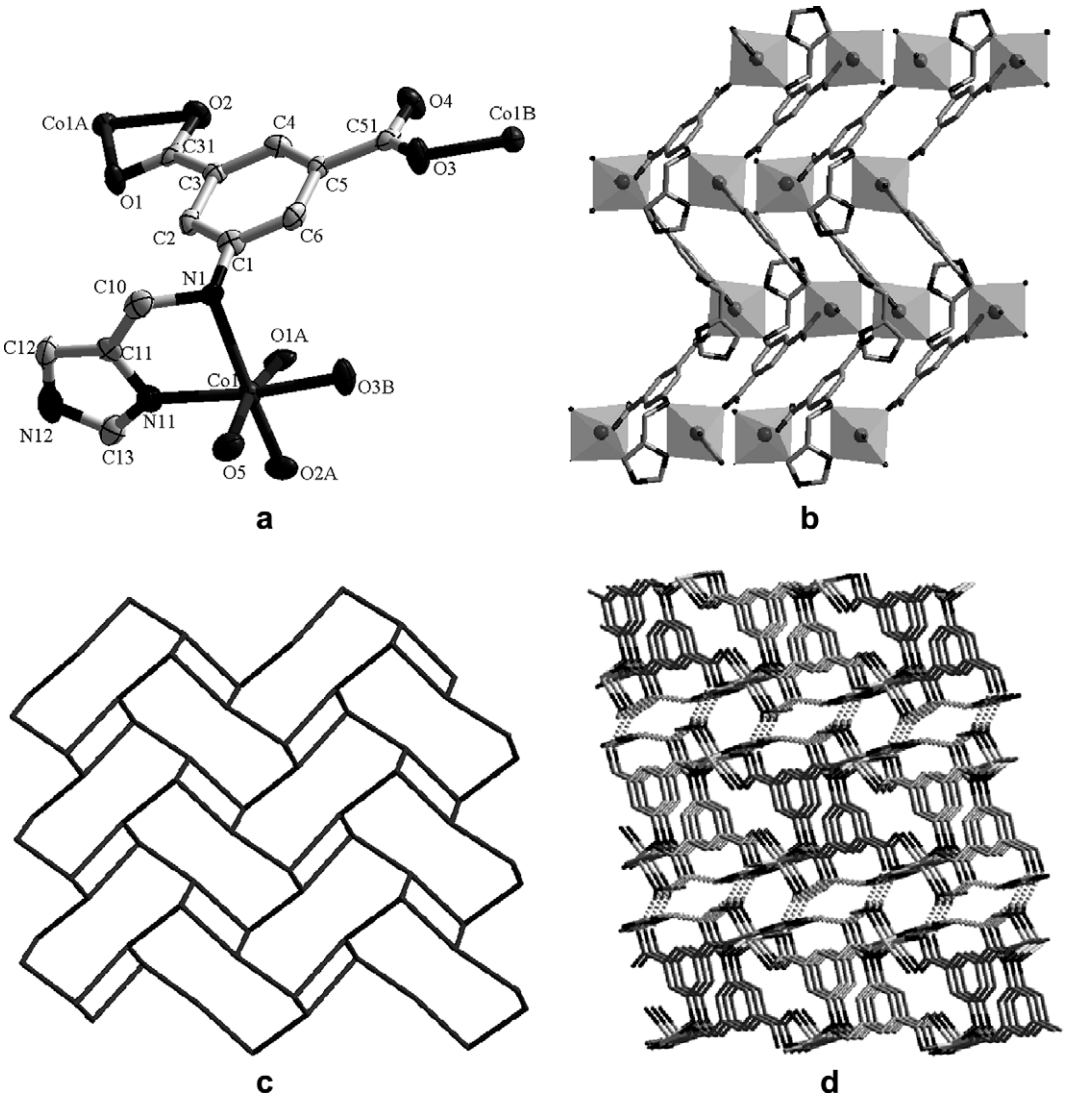
3.2.1. $\{[Ni(HL)(H_2O)]\cdot H_2O\}_n$ (*1*) and $\{[Co(HL)(H_2O)]\cdot H_2O\}_n$ (*2*)

Complexes **1** and **2** crystallize in the same monoclinic $P2_1/n$ space group with similar cell parameters (Table 1), and the results of X-ray crystallographic analysis indicate that they are isomorphous and isostructural. Thus, as a typical example, only the structure of **2** is described here in detail. The asymmetric unit of **2** consists of one Co(II) atom, one HL^{2-} ligand, one coordinated and one non-coordinated water molecule. As depicted in Fig. 1a, each Co(II) atom is six coordinated with a distorted octahedral geometry by two nitrogen atoms from one HL^{2-} ligand in a chelating mode, three oxygen atoms from two carboxylate groups of two different HL^{2-} ligands and one oxygen atom from a coordinated water molecule. The Co–O and Co–N bond lengths are in the range of 2.02(4)–2.17(3) Å and 2.04(4)–2.28(4) Å, respectively as listed in Table 2. On the other hand, each HL^{2-} ligand in **2** connects three Co(II) atoms through the Co–O and Co–N coordination interactions. Each carboxylate group coordinates with one metal atom, and one imidazole-nitrogen together with the amine-nitrogen chelate one Co(II) atom. The coordination modes of the HL^{2-} ligand appeared in **1**–**4** are summarized in Scheme 1. It is noticeable that two carboxylate groups of HL^{2-} ligand in **2** have different coordination fashion, one adopts a bidentate chelating mode and the other one acts a monodentate (Scheme 1a). The imidazole ring of the flexible arm is nearly perpendicular to the central benzene ring since the dihedral angel between them is 89.99°.

In complex **2**, the Co(II) atoms are linked together by the carboxylate groups from HL^{2-} ligands to form an infinite 1D zigzag chain if the Co–N connections are neglected. The 1D chains are further linked together through the Co–N coordination leading to the formation of a 2D network (Fig. 1b). As described above, each Co(II) is surrounded by three HL^{2-} ligands and each HL^{2-} ligand links three Co(II) atoms. Thus, both Co(II) atom and HL^{2-} ligand can be considered as 3-connected nodes in a ratio of 1:1 in **2**. Therefore, the complex **2** exhibits a (3, 3)-connected 2D network with a $(4, 8^2)$ topology as clearly shown in Fig. 1c. The 2D layers packed together through C–H···O and N–H···O hydrogen bonding interactions and face-to-face π–π interactions between imidazole ring planes with the centroid–centroid separation of 3.60 Å resulting a 3D framework (Fig. 1d).

3.2.2. $\{[Co(HL)]\cdot 4H_2O\}_n$ (*3*)

It is interesting that complexes **2** and **3** with different structure were obtained simultaneously by the same reaction (see Section 2). The asymmetric unit of **3** consists of one Co(II) atom and one HL^{2-} ligand. Fig. 2a shows the coordination environment of the Co(II) atom in **3**. The Co(II) center with octahedral coordination geometry is six coordinated by four carboxylic oxygen atoms from three different HL^{2-} ligands with Co–O bond distances ranging from 2.02(9)



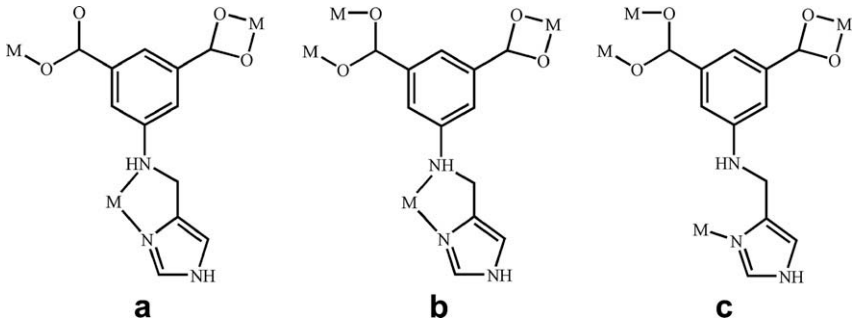


Fig. 1. (a) Coordination environment of Co(II) in **2** with the ellipsoids drawn at the 30% probability level, hydrogen atoms were omitted for clarity. (b) Polyhedral representation of the 2D layer structure of complex **2**. (c) (4, 8^2) topological grid in **2**. (d) 3D framework of **2** linked by hydrogen bonds indicated by dashed line.

Scheme 1. Coordination modes of HL^{2-} ligand.

to 2.25(9) Å and two nitrogen atoms from another HL^{2-} ligand with Co1–N bond lengths of 2.37(1) and 2.05(1) Å (Table 2). Each HL^{2-} ligand acts as a 4-connector to link four Co(II) atoms in complex **3** (Scheme 1b), which is different from that in complex **2** (and also **1**), one of the carboxylate group is coordinated with one Co(II) atom through a bidentate chelating mode, while the other one adopts a *syn-syn* μ_2-η^1:η^1 bridge to link two metal atoms forming a second building unit (SBU) of $Co_2(COO)_2$, the imidazole group without protonation coordinates to one Co(II) atom with the amine nitrogen via a chelating mode. Therefore, a 2D network is formed (Fig. 2b) through such connection of the HL^{2-} ligands.

In order to better identify the nature of the structure of complex **3**, suitable connectors should be confirmed by using the topological approach [29–31]. The net topology can be simplified by just

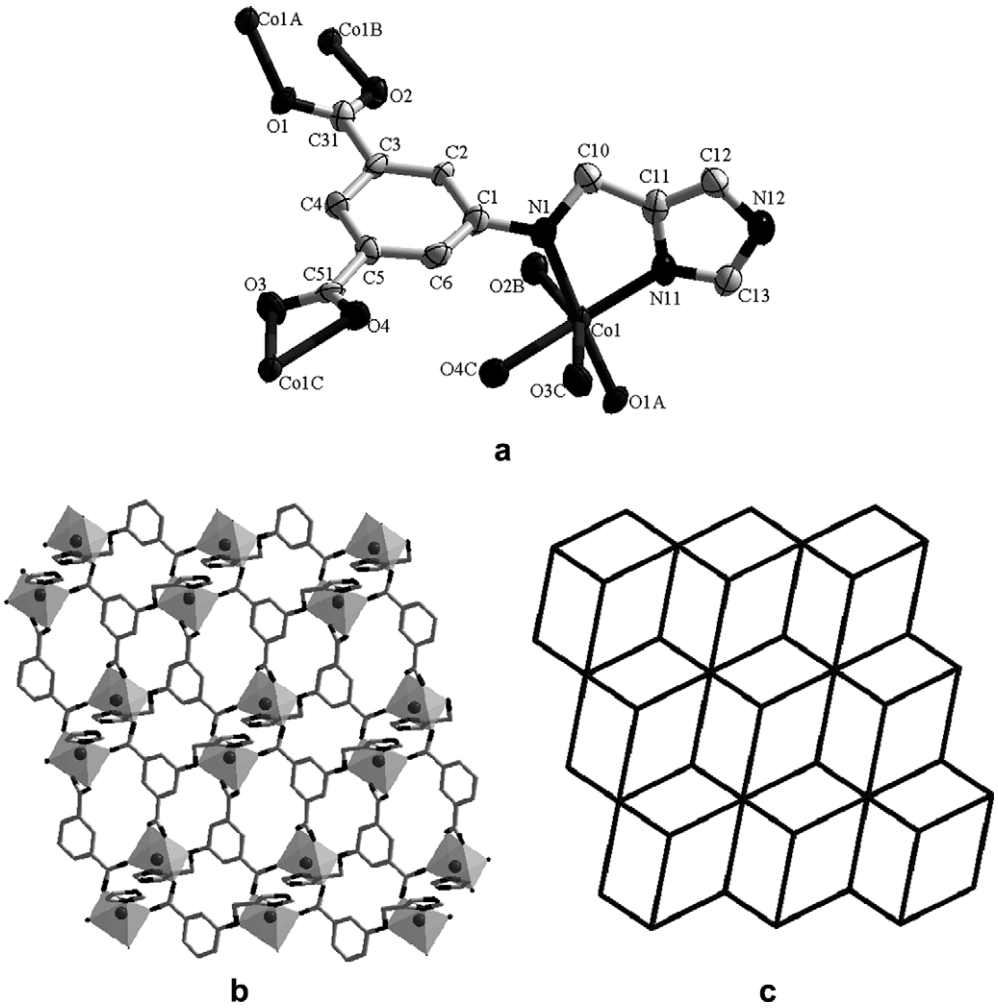

Fig. 2. (a) Coordination environment of Co(II) in **3** with the ellipsoids drawn at the 30% probability level, hydrogen atoms were omitted for clarity. (b) Polyhedral representation of the 2D layer structure in **3**. (c) A binodal (3, 6)-connected 2D network of complex **3**.

considering $Co_2(COO)_2$ units and HL^{2-} ligands. As discussed above, each HL^{2-} ligand can be considered as a three-connecting node since it links three $Co_2(COO)_2$ units. On the other hand, each $Co_2(COO)_2$ unit links six HL^{2-} ligands which can be regarded as a six-connecting node. Thus the topology of **3** is a binodal (3, 6)-connected 2D network (Fig. 2c) with a Schläfli symbol of $(4^3)_2(4^6, 6^6, 8^3)$. The long Schläfli notation is [4·4·4] for the 3-connected HL^{2-} nodes and $[4{\cdot}4{\cdot}4{\cdot}4{\cdot}4{\cdot}4{\cdot}6_2{\cdot}6_2{\cdot}6_2{\cdot}6_2{\cdot}6_2{\cdot}6_2{\cdot}8_8{\cdot}8_8{\cdot}8_8]$ for 6-connected $Co_2(COO)_2$ nodes, respectively.

3.2.3. $\{[Zn(HL)]\cdot 2H_2O\cdot 0.5C_2H_5OH\}_n$ (**4**)

Complex **4** also crystallizes in the triclinic $P\bar{1}$ space group with similar cell parameters to those of **3** (Table 1), and the single crystal X-ray crystallographic analysis confirmed that **3** and **4** have almost the same network structure. The difference between **3** and **4** is the coordination environment of the metal center and the coordination mode of the HL^{2-} ligand (Scheme. 1c). In complex **4**, the Zn(II) atom with a distorted square–pyramidal coordination geometry was bounded by four oxygen atoms from three HL^{2-} ligands and one nitrogen atom from the another ligand (Fig. 3a), however, no coordination of the amine nitrogen was found in **4**, which is different from that in **3**. Another difference between **3** and **4** is that solvent ethanol molecules were found in **4**, while there only are water molecules in **3**. There are also N–H···O hydrogen bonding interactions and face-to-face π–π interactions with centroid–centroid distance of 3.58 Å between the imidazole ring planes which makes **4** a 3D supramolecular framework (Fig. 3b).

3.3. Properties

3.3.1. Thermal properties

Thermalgravimetric analyses (TGA) were carried out to examine the thermal stabilities of complexes **1**–**4** by heating to 700 °C under flowing N_2. As shown in Fig. 4, complex **1** lost two water molecules in the temperature range of 40–210 °C with a weight loss of 10.7% (calculated: 10.2%), the decomposition of the residue was observed at ca. 370 °C and the final percentage weight (observed 20.8%) at the end of the decomposition of the complex is in accordance with the formation of NiO (calculated: 21.1%). The TGA curve of **2** showed a weight loss between 75 and 110 °C, corresponding to the loss of two water molecules (10.1% weight loss observed; 10.2% calculated). The decomposition of the residue was observed at ca. 270 °C, and the total weight loss of 77.2% indicates the completely decomposition to give Co_2O_3 (calculated: 76.5%). The TGA curve of **3** shows that the first weight loss of 18.4% (calculated: 18.5%) between 30 and 140 °C corresponds to the loss of the four lattice water molecules. The decomposition of the residue was observed at ca. 425 °C and the final percentage weight (observed 22.0%) at the end of the decomposition of the complex is in accordance with the formation of Co_2O_3 (calculated: 21.3%). The TGA

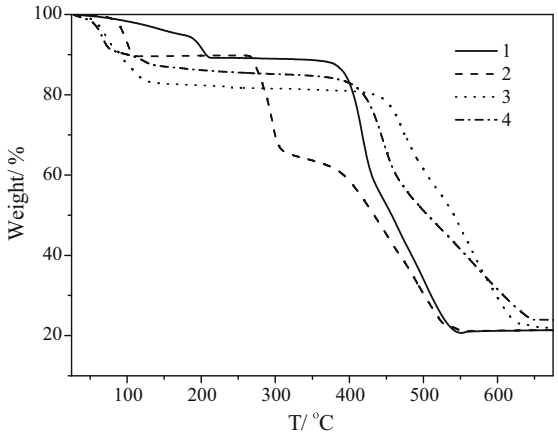

Fig. 4. The TGA curves of complexes **1**–**4**.

curve of **4** displayed two main steps of weight losses: the first step completed the loss of the ethanol molecule at 50 °C (6.0% weight loss observed; 6.1% calculated). The second step occurred between 70 and 180 °C with the loss of two lattice water molecules (9.2% weight loss observed; 9.4% calculated). The framework collapsed in the temperature range 390–645 °C, and the residual percentage

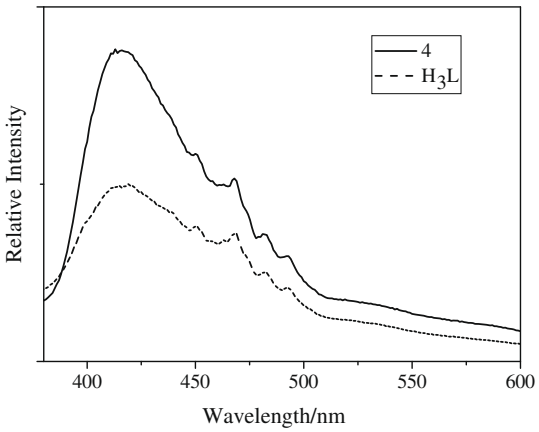

Fig. 5. The emission spectra of **4** and H_3L ligand.

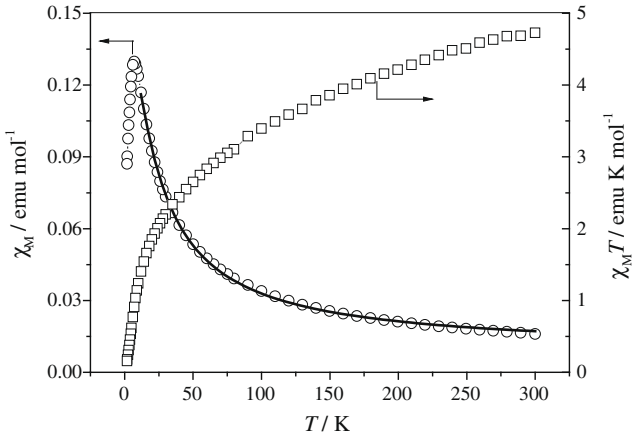

Fig. 6. The χ_M and $\chi_M T$ vs. T plots for **3** (the solid line shows the best fit to the model).

weight (observed 23.9%) at the end of the decomposition of the complex is in accordance with the formation of ZnO (calculated: 21.3%). All these results indicate that complexes **1**–**4** have high thermal stability.

3.3.2. Luminescent properties

Inorganic–organic hybrid coordination complexes, especially with d^{10} metal centers, have been investigated for fluorescence properties owing to their potential applications as luminescent materials [32–34]. Thus the luminescent spectra of complex **4** as well as free H_3L ligand were investigated in the solid state at room temperature. As shown in Fig. 5, complex **4** exhibits an intense broad photoluminescence with maximum emission at 413 nm upon excitation at 362 nm, which is close to the emission at 419 nm of the free H_3L ligand under the same conditions. Therefore the emission observed in **4** is attributed to the π–π^* intraligand photoluminescence due to its resemblance to that of H_3L ligand, and the enhancement and slight red-shift of **4** compared to that of the free ligand probably result from the fact that the coordination of Zn(II) ions increases the ligand conformational rigidity and thus reduces the loss of energy by thermal vibrational decay [35–37].

3.3.3. Magnetic property

The temperature dependent magnetic measurements of **3** were carried out ranging from 1.8 to 300 K with an applied field of 2 K Oe. As depicted in Fig. 6, the χ_M curve increases when the compound is cooled until a maximum is reached at 7 K with a value

of 0.13 emu mol^{-1} and then decreases rapidly, which is the nature of antiferromagnetic coupling between Co(II) ions [38]. The observed $\chi_M T$ value is 4.727 emu K mol^{-1} at room temperature, which is higher than the spin-only resulting from the orbital contribution of the octahedral Co(II) ions [39]. As the temperature decreases, the value of $\chi_M T$ decreases gradually, indicating the occurrence of dominant antiferromagnetic interactions within the neighboring Co(II) ions connected through the carboxylate groups. In order to get an estimate of the strength of the antiferromagnetic exchange interaction, one may use the following simple phenomenological equation: $\chi T = A\exp(-E_1/kT) + B\exp(-E_2/kT)$ [40], where $A + B$ equals the Curie constant, and E_1, E_2 hold for the "activation energies" corresponding to the spin–orbital and the antiferromagnetic exchange interaction, respectively. The best fit parameters $A + B = 3.23$ emu K mol^{-1} and $E_1/k = 88.56$ K are consistent with those given in the literature for Curie constant ($C \approx 2.8$–3.4 emu K mol^{-1}) and for the effect of spin–orbit coupling and site distortion (E_1/k of the order of +100 K) [40]. The $-E_2/k$ value is -10.24 K, corresponding to antiferromagnetic exchange interaction of $J = -20.48$ K with in the Ising chain approximation ($\chi T \propto \exp(+J/2kT)$).

4. Conclusions

Four new coordination polymers have been synthesized under hydrothermal conditions by using a new imidazol- and carboxylate-containing ligand 5-(1H-imidazol-4-ylmethyl)aminoisophthalic acid. TGA data showed that complexes **1**–**4** have high thermal stability and luminescent measurements showed that complex **4** exhibits blue fluorescence in the solid state at room temperature, the magnetic study of **3** indicates that there are antiferromagnetic interactions between the neighboring Co(II) centers. The varied coordination modes of the ligand found in present work prove that the ligand is a useful building block in the construction of new MOFs.

Orotato complex

ABSTRACT

The novel *catena-poly-μ*-orotatobis(butylamine)copper(II), $[Cu(\mu\text{-}HOr)(ba)_2]_n$ (**1**), and diaqua(orotato)copper(II), $[Cu_2(HOr)_2(H_2O)_4]$ (**2**), complexes have been prepared and characterized by elemental analysis, magnetic measurements, FT-IR spectroscopy, EPR spectroscopy, thermal analysis and X-ray diffraction. Both complexes crystallize in the monoclinic space group, $C2/c$ in **1** and $P2_1/n$ in **2**. In the complexes, the copper(II) ion is chelated by a deprotonated pyrimidine nitrogen atom and a carboxylate oxygen atom of the orotate. While the coordination sphere around Cu(II) is completed by two N atoms from butylamine groups and a carboxylic O atom in the axial position from a neighboring molecule in **1**, the square-planar environment of Cu(II) is completed by two water atoms and one axial position is occupied by the carbonyl oxygen atom from the symmetry related molecule in **2**. The coordination sphere should be described as a square pyramid and (4+1)-geometry in **1** and **2**, respectively. While complex **1** shows a polymeric arrangement, compound **2** has a dimeric arrangement. The non-covalent Cu(II)-π binding force is very important for stabilizing the crystal structure of **2**. The thermal decomposition of the complexes has been predicted by the help of thermal analysis (TG, DTG and DTA).

1. Introduction

The design and synthesis of coordination polymers have received much attention in coordination chemistry because of their interesting potential applications [1,2]. In order to prepare ideal coordination polymers, the key lies in the design and selection of the bridging ligands. Heterocyclic carboxylates have been extensively used to design polynuclear complexes [1–5]. In the present work, we selected the potentially interesting orotic acid (1,2,3,6-tetrahydro-2,6-dioxo-4-pyrimidine carboxylic acid, vitamin B13, H_3Or) and the orotate anions (H_2Or^- and HOr^{2-}) which are interesting multidentate ligands and they can coordinate through the nitrogen atoms of the pyrimidine ring, the carbonyl oxygen and the carboxyl oxygen atoms. Although the literature lists many reports on the coordinating presences of the orotate moiety in metal complexes [6–14], polymeric orotate complexes of copper(II) with neutral ligands are not known. The first copper(II)–orotate complex, $[Cu(HOr)(NH_3)_2]$ [8], and the first polymeric Cu(II)–orotate complexes, $[Cu(HOr)(H_2O)_2]_n$ [9], were reported by Mutikainen and Ha et al. in 1980 and 1999, respectively. X-ray structures of other monomeric Cu(II)–orotate complexes, $[Cu(HOr)(phen)]$ [10], $[Cu(HOr)(H_2O)(en)]\cdot H_2O$ [11], $[Cu(HOr)(tea)]\cdot H_2O$ [12], $[Cu(HOr)(bipy)(H_2O)]\cdot H_2O$ [13], (phen = 1.10-phenanthroline, en = ethylenediamine, tea = triethanolamine, bipy = 2,2′-bipyridine), *cis*-$[Cu(orotato)(NH_3)_2]$ and $[Cu(orotato)(H_2O)_4]\cdot H_2O$ [14], have been studied.

In the present paper, we describe the syntheses, spectroscopic (IR and EPR), thermal studies (TG, DTG, DTA) and crystal structures of the first mixed-ligand polymeric orotate complex of copper(II) with butylamine, μ-orotatobis(butylamine)copper(II), $[Cu(\mu\text{-}HOr)(ba)_2]_n$ (**1**), and the bis[diaqua(orotato)copper(II)] complex, $[Cu_2(HOr)_2(H_2O)_4]$ (**2**).

2. Experimental

2.1. Syntheses of complexes

2.1.1. $[Cu(\mu\text{-}HOr)(ba)_2]_n$ (**1**)

A solution of *n*-butylamine (0.30 g, 4 mmol) in water (5 mL) was added dropwise to a stirring solution of $[Cu(HOr)(H_2O)_2]$ (0.51 g, 2 mmol) in water (20 mL). The solution was heated to 50 °C in a temperature-controlled bath and refluxed with stirring for 5 h at 50 °C. The reaction mixture was then cooled to room temperature. Dark blue crystals were formed, filtered and washed with 10 mL of cold water, and then dried in air. *Anal.* Calc. for $C_{13}H_{24}N_4O_4Cu$: C, 42.91; H, 6.65; N, 15.40. Found: C, 42.88; H, 6.67; N, 15.58%. IR (KBr pellet, cm^{-1}): 3450(m), 3415(s), 3320(m), 2970(m),

2801(m), 1697(s), 1676(s), 1637(s), 1475(m), 1400(m), 1334(w), 1033(w), 956(w), 773(w), 597(w). μ-eff (298 K): 1.41 B.M.

2.1.2. [CuHOr(H_2O)$_2$] (**2**)

A solution of $Cu(CH_3COO)_2{\cdot}H_2O$ (0.80 g, 4 mmol) in water (20 mL) was added dropwise to a solution of orotic acid hydrate (0.63 g, 4 mmol) in pyridine (20 mL) with stirring at 60 °C. The mixture was refluxed with stirring for 2 h at 60 °C in a temperature-controlled bath, and then solution was cooled to room temperature. Violet crystals were formed, filtered and washed with 10 mL of water, and then dried in air. *Anal.* Calc. for $C_5H_6N_2O_6Cu$: C, 23.68; H, 2.38; N, 11.04. Found: C, 23.69; H, 2.41; N, 10.98%. IR (KBr pellet, cm^{-1}): 3519(s), 3317(s), 3180(s), 2977(s), 2811(s), 1660(vs, b), 1477(m), 1411(m), 1373(m), 1267(m), 1140(w), 1020(m), 891(m), 843(w), 802(s), 771(s), 713(m). μ-eff (298 K): 1.64 B.M.

2.2. Materials and measurements

All chemicals used were analytical reagents and commercially purchased. IR spectra were obtained with a Bruker Tensor 27 FT-IR spectrometer using KBr pellets in the 4000–400 cm^{-1} range. Elemental analysis for C, H and N were performed using a Carlo Erba 1106 microanalyzer. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. A Perkin–Elmer Diamond TG/DTA thermal analyzer was used to record simultaneous TG, DTG and DTA curves in a static air atmosphere at a heating rate of 10 $Kmin^{-1}$, in the temperature range 20–600 °C, using platinum crucibles.

The EPR spectra were recorded using a Varian E-109C model X-band spectrometer. The magnetic field modulation frequency was 100 kHz and the microwave power was around 10 mW.

2.3. Crystallographic analyses

X-ray diffraction data for compounds **1** and **2** were collected at 293 (2) K on a Stoe IPDS diffractometer. Data collection: Stoe X-AREA [15]. Cell refinement: Stoe X-AREA [15]. Data reduction: Stoe X-RED [15]. The structures were solved by direct methods using the program SHELXS-97 [16] with anisotropic thermal parameters for all non-hydrogen atoms. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods, using SHELXL-97 [17]. All hydrogen atoms for **1** were positioned geometrically and refined by a riding model with U_{iso} 1.2 or U_{iso} 1.5 times that of the attached atoms. The butylamine group shows two-positioned orientation disorder, the final site-occupancy factors for N(3)A–N(4)A/C(6)A–C(13)A being 38.4(6)% and 61.6(6)%. Restrains were applied to the water hydrogens to the idealized geometry for **2**. Other hydrogen atoms for **2** were positioned geometrically and refined by a riding model with U_{iso} 1.2 times that of the attached atoms. Molecular drawings were obtained using ORTEP-III for WINDOWS [18] and DIAMOND (demonstrated version) [19]. The crystal data and the refinement details of **1** and **2** are given in Table 1.

3. Results and discussion

3.1. IR spectra

The IR spectrum of **2** shows a strong band at 3519 cm^{-1} due to the O–H stretching vibrations of the H_2O ligand. The intense bands at 3450 and 3415 cm^{-1} are attributed to the NH_2 vibration of the butylamine ligand. The bands at *ca.* 3320 cm^{-1} are attributed to the ν(NH) vibrations of the orotato ligands. The relatively weak bands between 3180 and 2801 cm^{-1} can be assigned to both aromatic CH and aliphatic CH_2 stretching vibrations of the HOr and ba ligands, respectively. The position of the characteristic stretching modes of the carbonyl of the orotate moiety can be used to characterize the coordination mode of this ligand to metal ions. Carbonyl stretching bands of orotic acid were observed at 1729 and 1719 cm^{-1} for [$\nu_{C=O(acid)} + \nu_{C(2)=O}$], and 1700 and 1653 cm^{-1} for [$\nu_{C(6)=O} + \nu_{ring} + \nu_{C=C}$] [20]. These bands were shifted to 1697, 1676 and 1637 cm^{-1} in **1** and show a broad-strong absorption band at 1660 cm^{-1} due to overlapping of the two bands in **2**. The weak bands at 453 and 607 cm^{-1} are due to Cu–N and Cu–O stretching vibrations, respectively. From the IR spectra of **1** and **2**, it can be assumed that the orotate ligand is coordinated to the Cu(II) ions as a tridentate ligand through the N atom of the pyrimidine ring and two carboxyl O atoms (O_{acid}, N, O_{acid}).

3.2. Thermal analyses

3.2.1. Complex **1**

The first stage between 213 and 264 °C (DTA_{max} = 201, 213 and 264 °C) corresponds to the loss of two ba ligands (found 40.65, calcd. 41.19%). The following stages between 286 and 431 °C are related to the consecutive decomposition of the orotate ligand with exothermic effects (found 40.81, calcd. 40.55%). The final solid product of thermal decomposition was identified as CuO (found 81.46, calcd. 79.07%).

3.2.2. Complex **2**

The complex is decomposed in three stages and thermally stable up to 288 °C. The first stage between 288 and 338 °C is related to the dehydration and decarboxylation of the orotate ligand (DTG_{max} = 324 °C). In the temperature range of 338–409 °C, the following second and third stages involve the consecutive decomposition of the uracil ligand by exothermic effects (DTG_{max} = 368, 388 °C). The final decomposition product, namely CuO, was identified by IR spectroscopy.

3.3. Crystal structures

3.3.1. $[Cu(\mu\text{-}HOr)(ba)_2]_n$ (**1**)

A view of **1** and its atom-numbering scheme is shown in Fig. 1. Selected bond lengths and bond angels are given in Table 2. The crystallographic analyses reveal that the crystal structure of **1** is a one-dimensional wave-like polymer chain along the *b*-axis. The central metal ion adopts a distorted square pyramidal coordination sphere and is bound by two N atoms [N(3) and N(4)] from two butylamine ligands, an orotate dianion *via* the carboxylate oxygen O(4) and N(1), and a carboxylic O atom from a neighboring orotato ligand. Atoms N(1) and O(4) are bonded to Cu(1) to form a five-membered chelate ring [N(1)–Cu(1) = 2.003 (4) Å and O(4)–Cu(1) = 1.958 (3) Å]. All the N–Cu–N, N–Cu–O and O–Cu–O bond angles deviate significantly from 90° to 180°, presumably as a result of the steric constraints arising from the shape of the ligands.

The $M–O_{HOr}$ distances are 2.4243(12) Å for $Cu(1)–O(3)^{i}$ (i: $0.5 - x$, $0.5 + y$, $0.5 - z$) and 1.958(3) Å for Cu(1)–O(4). In this conformation, the HOr^{2-} ligand links two metal centers in a μ-bridging mode and each metal center connects two HOr^{2-} ligands to form one-dimensional chain along the *b*-axis (Fig. 2), in which metal atoms possess an 'S' shape with the $Cu–Cu^{i}$ (i: $0.5 - x$, $0.5 + y$, $0.5 - z$) distance being 5.4213(17) Å.

The orotate ligand in the complex is essentially planar (r.m.s. deviation is 0.0297 Å). Of all the N–C bonds in the uracil ring of the orotate ligand, N(1)–C(1) [1.368(5) Å] and N(1)–C(4) [1.353(6) Å] are the shortest. This indicates a significant π-electron delocalization within the C(3)–C(4)–N(1)–C(1) skeleton.

It should be noted that different kinds of hydrogen bonds are observed between the chains: (i) hydrogen bonding between the amino H atom of the HOr ligand and the coordinated carboxylic oxygen [N(2)···O(4): 3.017(5) Å], (ii): hydrogen bonding between the amino H atoms of butylamine ligands and the coordinated

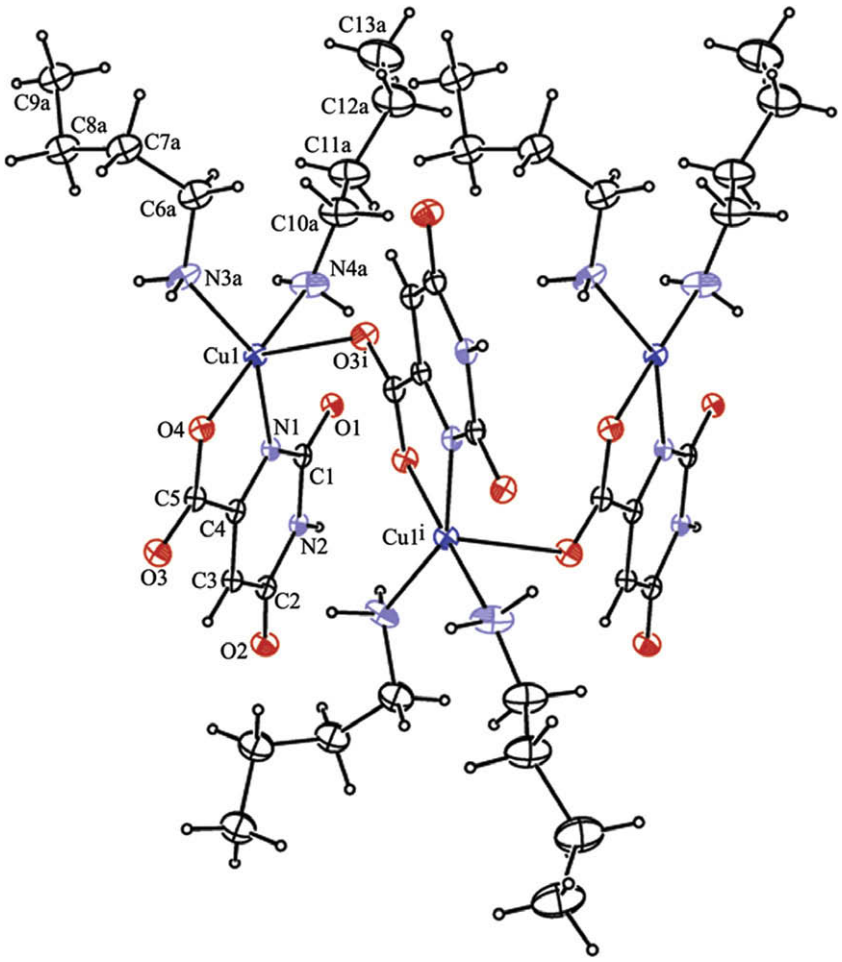

Fig. 1. ORTEP III view of $[Cu(\mu\text{-}HOr)(ba)_2]_n$ with the atom-numbering scheme (20% probability ellipsoids). The disordered part of the atoms has been omitted for clarity [i:$1/2 - x$, $-1/2 + y$, $1/2 - z$].

Symmetry code: (i): $2-x, 1-y, 1-z$.

carbonyl oxygen [N(3B)···O(1): 2.884(8) Å] and the uncoordinated carbonyl oxygen [N(4B)···O(2): 3.337(14) Å]. As a result of all these interactions, each chain is linked to other chains by the hydrogen-bonding interactions. The layers are further linked by C–H···O hydrogen bonds lying on the *bc* planes. There is also a weak intramolecular hydrogen bond (N–H···O) (Table 3).

3.3.2. $[Cu_2(HOr)_2(H_2O)_4]$ (**2**)

Complex **2** crystallizes in the monoclinic crystal system. A view of the molecule and its atom-numbering scheme are shown in Fig. 3. Selected bond lengths and bond angels are given in Table 2. Ha et al. [9] determined the crystal and molecular structure of the polymeric $[Cu(orotato)(H_2O)_2]_n$ complex, but it should be emphasized that in contrast to the polymeric complex of $[Cu(orotato)(H_2O)_4]_n$ [14] and $[Cu(orotato)(H_2O)_2]_n$ [9], compound **2** has a dimeric form of two $[Cu(HOr)(H_2O)_2]$ molecules.

Table 3
Hydrogen bonding interactions in **1**.

D–H···A	d(D–H) (Å)	d(H···A) (Å)	d(D···A) (Å)	∠ (DHA) (°)
N2–H2···O4^{i}	0.86	2.16	3.017 (5)	171
N3B–H3B1···O1^{ii}	0.90	2.04	2.897 (12)	159
N4B–H4B1···O2^{iii}	0.90	2.52	3.204 (13)	134
N4B–H4B2···O1	0.90	1.92	2.772 (12)	157
C6B–H6B1···O2^{iv}	0.97	2.52	3.146 (17)	122

Symmetry codes: (i) $x, -y+2, z-1/2$; (ii) $-x+1/2, y+5/2, -z+1/2$; (iii) $-x+1/2, -y+5/2, -z$; (iv) $-x+1/2, -y+3/2, -z$.

Square-planar copper(II) has a tendency to extend its coordination sphere to five, the so-called (4+1)-coordination geometry, or to six (4+2) or (4+1+1) geometries. In the present compound, the copper(II) ion is in distorted square pyramidal coordination sphere, which is extended to five (4+1) by an intermolecular *exo*-acid oxygen atom O(2), and it is also bound by the deprotonated N(1) nitrogen atom and the O(4) carboxylate oxygen atom of the bidentate orotate ligand. Two water oxygen atoms (O(5) and O(6)) complete the distorted square-planar environment around Cu(II). The N(1) and O(4) atoms are bonded to Cu(1) to form a five-membered chelate ring in **2** [N(1)–Cu(1) = 1.994(2) (3) Å and O(4)–Cu(1) = 1.956(2) Å]. The carbonyl O2 atom from a neighboring molecule occupies the axial coordination site [Cu(1)–O(2)^{i} = 2.9193(2) Å; i: $2-x, 1-y, 1-z$].

The orotato ligand is slightly deviated from planarity (the r.m.s. deviation is 0.6998 Å), the largest deviation from the mean plane is 1.0571 (2) Å for the O(4) atom. Of all the N–C bonds in the uracil ring of the orotato ligand, N(1)–C(1) [1.360(4) Å] and N(1)–C(4) [1.362(4) Å] are the shortest. This indicates that there is significant π-electron delocalization within the C(3)–C(4)–N(1)–C(1) skeleton. The bond distances and bond angles in the ring are consistent with those found in [9] (comparison in Table 2).

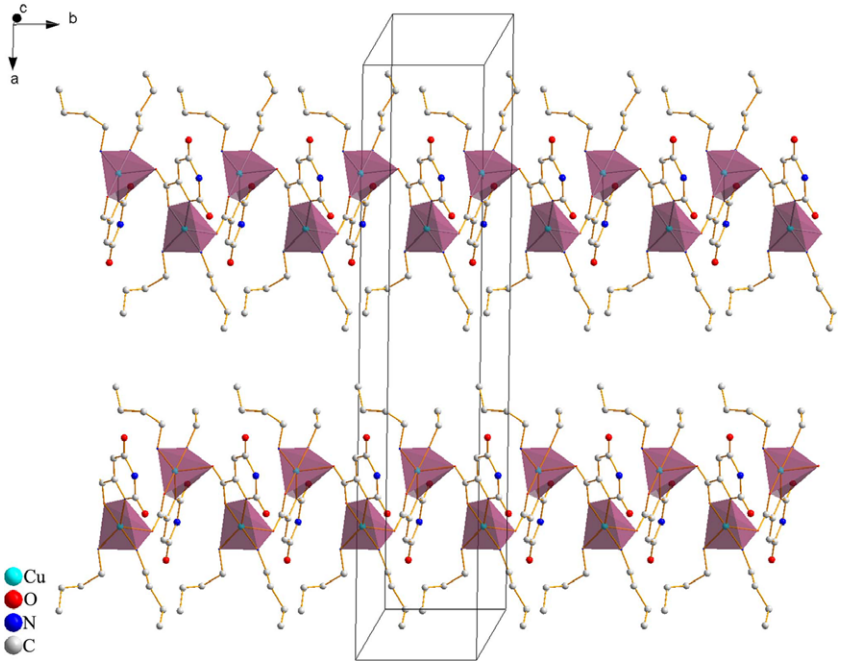

Fig. 2. Polyhedral representation of polymeric $[Cu(\mu\text{-}HOr)(ba)_2]_n$ molecules. Distorted octahedral are shaded dark. All H atoms and the disordered part of the atoms have been omitted for clarity.

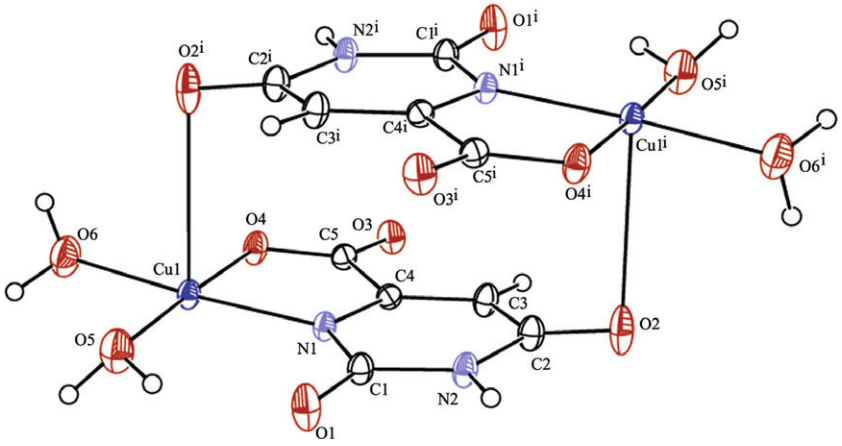

Fig. 3. ORTEP III view of $[Cu_2(HOr)_2(H_2O)_4]$ with the atom-numbering scheme (20% probability ellipsoids). The disordered part of the atoms has been omitted for clarity [i: $2-x, 1-y, 1-z$].

The stability of the columns is further enhanced by the formation of extensive intermolecular hydrogen bonds (indicated by dashed lines). Molecules of complex **2** are linked by a pair of Watson–Crick type hydrogen bonds, involving the O2═C2 and N2–H2 groups of each uracil ring, with a N2···O2^{iv} distance of 2.862(4) Å and N2–H2···O2^{iii} angle of 176° (the symmetry codes are listed under Table 4). A very similar type of intermolecular hydrogen bonding was reported before with the corresponding N···O distances of 2.83 Å [21] and 2.860(2) [14]. O_{water}–H···O intermolecular hydrogen bonds are also effective in **2** (Table 4). All these intermolecular interactions result in the formation of a two-dimensional network (Fig. 4). There is also an intramolecular O5–H5a···O1 hydrogen bond formed between the water hydrogen atom and the carbonyl oxygen atoms of the orotate ligand.

Table 4
Hydrogen bonding interactions in **2**.

D–H···A	*d*(D–H) (Å)	*d*(H···A) (Å)	*d*(D···A) (Å)	∠(DHA) (°)
O5–H5A···O1	0.838 (10)	2.07 (3)	2.776 (4)	142 (4)
O5–H5A···O2^{i}	0.838 (10)	2.58 (4)	3.068 (4)	118 (4)
O5–H5B···O3^{ii}	0.842 (10)	2.21 (3)	2.928 (4)	143 (4)
N2–H2···O2^{iii}	0.86	2.00	2.862 (4)	176
O6–H6A···O1^{iv}	0.844 (10)	2.52 (3)	3.239 (4)	143 (5)
O6–H6B···O3^{ii}	0.842 (10)	2.48 (3)	3.250 (4)	152 (5)

Symmetry codes: (i) $x-1/2, -y+3/2, z-1/2$; (ii) $x-1/2, -y+1/2, z-1/2$; (iii) $-x+2, -y+2, -z+1$; (iv) $x, y-1, z$.

Of greater interest is the Cu–π axial interaction which contributes to the crystal packing by forming an infinite chain of dimers. It is suggested that the π-type interaction between the chelated Cu^{2+} cation and the aromatic compounds can play a significant role in biological systems, e.g. in the active sites of copper enzymes. The Cu(II)···Cg^{ii} distance of 3.557(1) Å is close to the van der Waals contacts between the stacking bases in DNA (Fig. 5) [Cg = N1–C1–N2–C2–C3–C4 (uracil ring)]. It should be emphasized that the O2^{i}–Cu–Cg^{ii} angle deviates from linearity [151.9(6)°, (i) $2-x, 1-y, 1-z$; (ii) $1-x, 1-y, 1-z$]. Michalska et al. reported the same interaction in *cis*-$[Cu(HOr)(NH_3)_2]$ with the parameters Cu–X^{ii} (X = centroid, Cg) distance of 3.293(9) Å and O2^{i}–Cu–X^{ii} angle of 169.6(1)°. It is interesting that in the crystal structure of $[Cu(HOr)(en)(H_2O)]\cdot H_2O$, reported by Icbudak et al. [11], the vertical distance between the copper atom and the uracil ring is between 3.156 and 3.274 Å (private communication).

π–π stacking interactions between uracil rings have been observed in other Cu(II) complexes with orotic acid derivatives, the

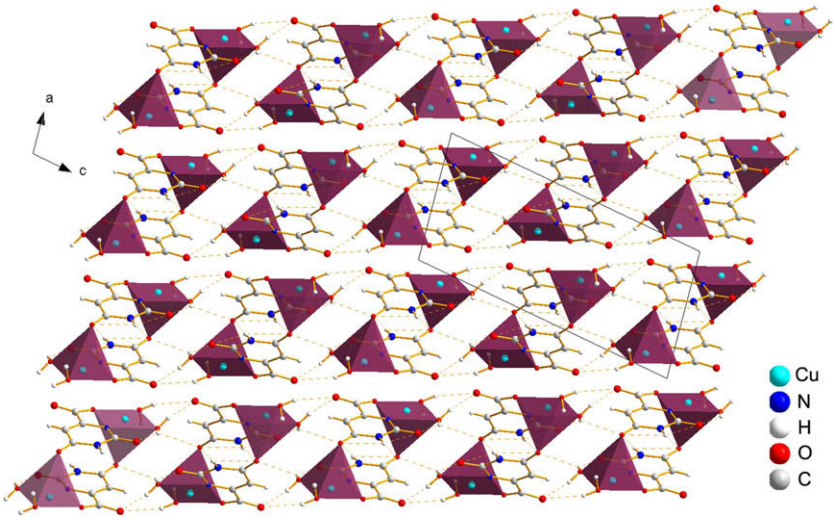

Fig. 4. A stereoscopic packing in the crystal of $[Cu_2(HOr)_2(H_2O)_4]$ (**2**) displaying the distorted square octahedral environment around the copper ions. Hydrogen bonds are indicated by dashed lines.

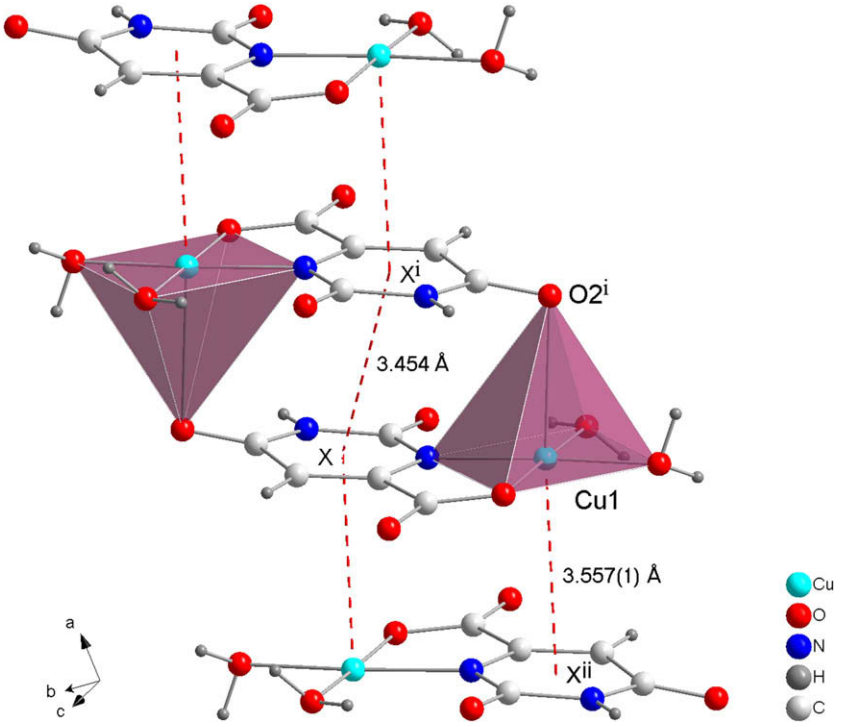

Fig. 5. The view of the dimer unit of $[Cu_2(HOr)_2(H_2O)_4]$ showing the axial Cu–O2^i bonds and Cu(II)···X (X = centroid, Cg) interactions (dashed lines). The π···π interaction is also shown. Symmetry codes are as follows: (i) $2-x, 1-y, 1-z$; (ii) $1-x, 1-y, 1-z$.

distance between partially overlapping uracil rings varies from 3.250(3) Å in the mononuclear $[Cu(5\text{-fluoroorotato})(NH_3)(H_2O)]$ complex [22] to 3.40 Å in the diamine(5-nitroorotato)copper(II) hydrate [23]. The same effect is found in **2** between the uracil rings, with the parameters shown in Fig. 5.

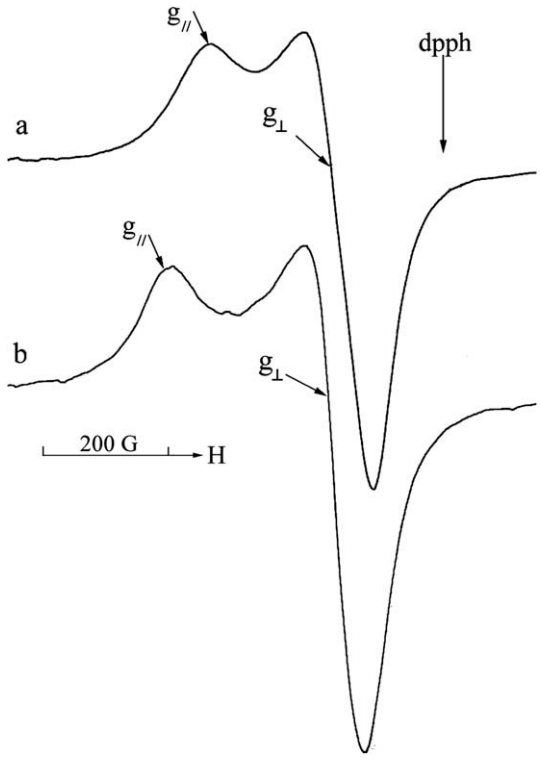

Fig. 6. Powder EPR spectra at room temperature (a) $[Cu(\mu\text{-HOr})(ba)_2]_n$ and (b) $[Cu_2(HOr)_2(H_2O)_4]$.

3.4. EPR investigations

The powder EPR spectra of the complexes **1** and **2** at room and liquid nitrogen temperature were recorded (Fig. 6). As can be seen from Fig. 6, only one $g_{\parallel}$ and one $g_{\perp}$ component were obtained due to the influence of the exchange interaction, which makes the hyperfine lines smaller. The g parameters were calculated, giving $g_{\parallel} = 2.197$, $g_{\perp} = 2.089$ and $g_{\parallel} = 2.232$, $g_{\perp} = 2.092$ for **1** and **2**, respectively. The g values are in the order of $g_{\parallel} > g_{\perp} > g_e$ (free electron g value, $g_e = 2.0023$). Considering these values, together with the observed characteristic $g_{\parallel}$ and $g_{\perp}$ values for Cu(II) complexes, it can be concluded that the paramagnetic center is axially symmetric.

4. Conclusions

We have successfully synthesized and characterized the novel *catena-poly*-μ-orotatobis(butylamine)copper(II), $[Cu(\mu\text{-HOr})(ba)_2]_n$ (**1**), and bis[diaqua(orotato)copper(II)], $[Cu_2(HOr)_2(H_2O)_4]$ (**2**), complexes. To our surprise, complex **1** is thermally stable up to about 288 °C, despite the water molecules contain within it. The presence of Cu^{2+}/Cu^{+} centers is mainly responsible for the oxidase activity of copper-containing enzymes and proteins, e.g. galactose oxidase (GAO) and ceruloplasmin (C_p). The experimental study on **2** has revealed the great importance of the non-covalent Cu(II)–π binding force between the chelated Cu^{2+} ion and the uracilate ligand. The powder EPR spectrum shows clearly that the paramagnetic center symmetry of the two complexes in the crystals is axial.

Supplementary data

CCDC 653990 and 653991 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the

Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Using Cu(II), Mn(II) or Co(II) salt and the flexible ligands, *N*-[(4-carboxyphenyl)-sulfonyl]glycine (H_3L_1) and *N*-[(3-carboxyphenyl)-sulfonyl]glycine (H_3L_2), a series of new coordination polymers, $[Mn(phen)(H_2O)_4][HL_1]$ (**1**), $[Co_3(L_1)_2(bipy)_3(H_2O)_6]_n{\cdot}8nH_2O$ (**2**), $[Cu_4(L_1)_2(OH)_2(bipy)_4]_n{\cdot}12nH_2O$ (**3**), $[Na(H_2L_1)(H_2O)]_n$ (**4**), $[Mn_2(HL_2)_2(dpe)_3(H_2O)_2]_n{\cdot}ndpe$ (**5**), (phen = 1,10-phenanthroline, bipy = 4,4′-bipyridine, dpe = 1,2-di(4-pyridyl)ethylene), varying from 0D to 3D, have been synthesized and structurally characterized. Compound **1** has a $[Mn(phen)(H_2O)_4]^{2+}$ cation and a HL_1^{2-} anion. Compound **2** features a new 1D triple chain, based on octahedral cobalt atoms bridged by bipy molecules and terminally coordinated by two H_3L_1 ligands. Compound **3** has a 2D layered structure, constructed from new alternating chains where H_3L_1, hydroxyl and water molecules simultaneously act as bridging ligands. Compound **4** possesses a bilayer structure in which two adjacent layers are pillared by H_3L_1 ligands into a 2D bilayer network. Compound **5** is a unique 3D coordination polymer in which each Mn center binds two *trans*-located dpe molecules. The thermal stability as well as magnetic properties of **5** was also studied. This work and our previous work indicate that the positional isomer of the anionic *N*-[(carboxyphenyl)-sulfonyl]glycine is important in the construction of these network structures, which are also significantly regulated by the metal centers.

1. Introduction

The rational design and assembly of inorganic coordination polymers or metal–organic frameworks has received remarkable attention and has developed rapidly in recent years. Being easily and efficiently synthesized from relatively simple subunits, these complexes exhibit fascinating structural topologies and potential applications as functional materials [1–4]. However, the control of dimensionality is still a major challenge in the design and synthesis of organic–inorganic frameworks because the final structure is frequently modulated by various factors such as solvent medium, the geometry of metal ions, coordination character of the organic ligand, temperature, metal–ligand ratio, template and counterion [5]. Among these factors, the selection of appropriate metal ions and organic ligands is often the key in the construction of complexes. Metal ions, and in particular their radii and coordination geometry determine the bridging pattern and coordination modes of the organic ligands, and thus the overall structures of the complexes. In the crystal engineering, the employment of ligand isomers as the organic component is an effective way to investigate the effect of the ligand geometry. Usually, ligand isomers having similar structures but different coordination modes would lead to different structural motifs, such as seen for benzenedicarboxylates. Benzenedicarboxylate anions have three structural isomers (phthalate, isophthalate and terephthalate) with different angles between the two carboxylato groups, which may exhibit different geometric effects on the construction of coordination polymers [6]. To date, a variety of metal organic frameworks have been reported, however, systematic studies of the isomeric effect on the generation of such coordination frameworks are surprisingly rare [7]. With this in mind, one crucial aim of this work was to explore the effect of two isomers on the structural assembly. This may provide further insights in designing new hybrid crystalline materials.

Furthermore, amino acid is one of the most important biological ligands. Recently, amino acids with flexible coordination modes have been utilized to construct metal–organic supramolecular networks [8]. To date, a number of Ln-amino acid and transition metal–amino acid complexes with mononuclear, binuclear or chain structural motifs have been synthesized [9]. Several reports of polynuclear transition metal clusters or various 3d–4f high-nuclearity clusters with different structural motifs have also

doi:10.1016/j.poly.2009.04.044

reported [10]. However, reports of metal complexes of amino acids with high dimensional structures are rare [11]. This may be due to deprotonated amino acids preferring to chelate metal centers through their amine N and carboxylic O atoms to form five-membered rings which prevent extension into high dimensional structures. In order to overcome this problem, our research has focused on designing a new versatile ligand which contains both carboxylate and amino acid groups by introduction of an aromatic carboxylato group at its amino group.

We have recently used such a multifunctional amino acid derivative, namely *N*-[(3-carboxyphenyl)-sulfonyl]glycine, to create a series of unusual metal–organic frameworks [12,13]. In comparison to benzenedicarboxylic acids, *N*-[(3-carboxyphenyl)-sulfonyl]glycine not only contains two bridging carboxylato moieties but also possesses another two potential coordination sites, i.e., the nitrogen atom and oxygen atoms of the sulfonate groups. This asymmetric geometry may produce beautiful new structural motifs and useful functional properties. To further probe the influence of systematic variations of ligand structures and metal ions on the overall molecular architectures, we extend the building blocks from the bent *N*-[(3-carboxyphenyl)-sulfonyl]glycine to its quasi-linear isomer *N*-[(4-carboxyphenyl)-sulfonyl]-glycine to explore the isomeric effect on network assembly. Herein, the synthesis and X-ray crystal structures of eight coordination networks, including our previous reported $[Mn_2(HL_2)_2(phen)_4]_n{\cdot}8nH_2O$ (**6**), $[Co_3(L_2)_2(bipy)_2(H_2O)_6]_n{\cdot}2nCH_3OH{\cdot}8nH_2O$ (**7**) and $[Ca(H_2O)_4Cu_2(bipy)_2(L_2)_2]_n{\cdot}4nH_2O$ (**8**), formed by Cu^{2+}, Mn^{2+}, Co^{2+} salts with H_3L_1 and H_3L_2 are reported (See Schemes 1 and 2). The influence of ligand isomerism and metal ions on the final structures of the assemblies is discussed.

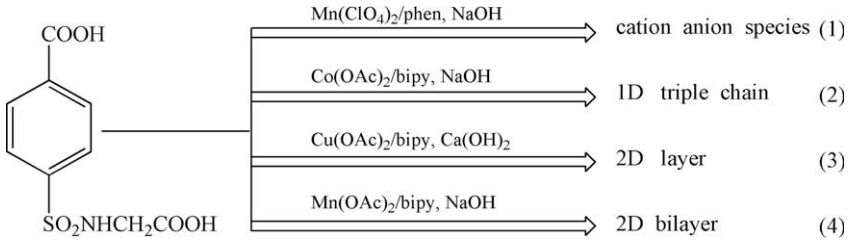
2. Experimental

2.1. Materials and instruments

All reagents used in the syntheses were of analytical grade. Elemental analyses for carbon, hydrogen and nitrogen atoms were performed on a Vario EL III elemental analyzer. The infrared spectra (4000–600 cm^{-1}) were recorded by using KBr pellet on an Avatar™ 360 E.S.P.IR spectrometer. The crystal structure determination was performed on a Bruker SMART APEX II CCD diffractometer equipped with graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å). Thermogravimetric analyses (TG) were carried out on a STA449C integration thermal analyzer. The PXRD patterns were recorded with a Rigaku D/Max 3III diffractometer with a scanning rate of four degrees per minute. Variable-temperature magnetic susceptibilities were measured using a MPMS-7 SQUID magnetometer.

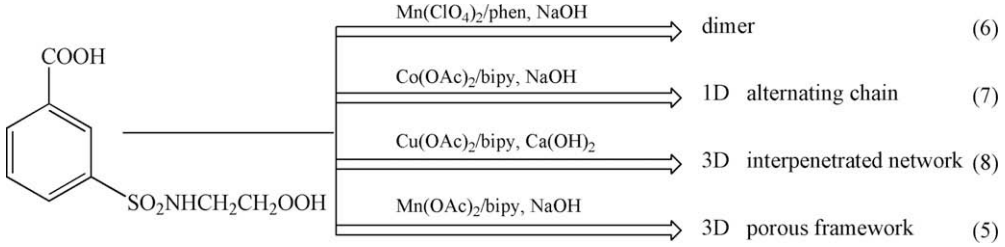
2.2. Synthesis of N-[(4-carboxyphenyl)-sulfonyl]glycine

To a solution of glycine (2.25 g, 0.03 mol) in NaOH 2 M (30 mL), 4-(chlorosulfonyl)benzoic acid (6.78 g, 0.03 mol) was added. The mixture was stirred at room temperature for 2 h, and the aqueous solution was then acidified to pH 4 with 6 M hydrochloric acid, upon which a white solid derivative began to crystallize at once with a yield of about 60%. *Anal.* Calc. for $C_9H_9NO_6S$: C, 41.70; H, 3.50; N, 5.40. Found: C, 41.79; H, 3.62; N, 5.58%. IR: 3287s, 1718s, 1432s, 1171m, 753m, 1336s, 897m.



2.3. Preparation of ***1*–*5***

2.3.1. $[Mn(phen)(H_2O)_4][HL_1]$ (***1***)



A mixture of $Mn(ClO_4)_2 \cdot 6H_2O$ (0.16 g, 0.5 mmol) and H_3L_1 (0.26 g, 1 mmol) was stirred into 15 mL of water. The pH was then adjusted to *ca.* 5 with 1 M NaOH. A solution of phen (0.21 g, 1 mmol) in ethanol (3 mL) was then added. The reaction mixture was heated on a water bath for 10 h at 70 °C, and then filtered. The yellow crystals were separated from the mother liquor by slow evaporation at room temperature after 4 weeks. *Anal.* Calc. for $C_{21}H_{23}MnN_3O_{10}S$: C, 44.69; H, 4.11; N, 7.44. Found: C, 44.51; H, 4.19; N, 7.50%. IR: 3413s, 1676s, 1411s, 1167m, 729m, 1345s, 851m.

2.3.2. $[Co_3(L_1)_2(bipy)_3(H_2O)_6]_n{\cdot}8nH_2O$ (***2***)

A mixture of $Co(OAc)_2{\cdot}4H_2O$ (0.13 g, 0.5 mmol) and H_3L_1 (0.13 g, 0.5 mmol) was stirred into 15 mL of water, and then refluxed for *ca.* 1 h. The pH was then adjusted to *ca.* 6 with 1 M NaOH. A solution of bipy (0.04 g, 0.25 mmol) in methanol (3 mL) was then

Scheme 1. Summary of the products obtained from the reactions of metal ions and H_3L_1.

Scheme 2. Summary of the products obtained from the reactions of metal ions and H_3L_2.

added. The reaction mixture was heated on a water bath for 10 h at 70 °C, and then filtered. The red crystals were separated from the mother liquor by slow evaporation at room temperature after 2 weeks. *Anal.* Calc. for $C_{48}H_{64}Co_3N_8O_{26}S_2$: C, 40.89; H, 4.58; N, 7.94. Found: C, 40.76; H, 4.67; N, 7.81%. IR: 3412s, 1684s, 1567s 1427s, 1127s, 1160m, 725m, 1396s, 864m.

2.3.3. $[Cu_4(L_1)_2(OH)_2(bipy)_4]_n \cdot 12nH_2O$ (**3**)

Complex **3** was synthesized using a procedure analogous to that of **2** except that $Cu(OAc)_2 \cdot H_2O$ was used instead of $Co(OAc)_2 \cdot 4H_2O$ and 1.2 mmol $Ca(OH)_2$ was added. Blue crystals were produced after 3 weeks. *Anal.* Calc. for $C_{29}H_{35}Cu_2N_5O_{13}S$: C, 42.44; H, 4.30; N, 8.53. Found: C, 42.56; H, 4.26; N, 8.68%. IR: 3415s, 1695s, 1427s, 1159m, 706m, 1332 s, 864m.

2.3.4. $[Na(H_2L_1)(H_2O)]_n$ (**4**)

An aqueous methanol solution of $Mn(OAc)_2 \cdot 4H_2O$ (0.12 g, 0.5 mmol), H_3L (0.13 g, 0.5 mmol) and bipy (0.04 g, 0.25 mmol) was stirred for 6 h at room temperature and then filtered. The pH was then adjusted *ca.* 6 with 1 M NaOH. The filtrate was allowed to stand for 1 week. The colorless crystals obtained were suitable for X-ray analysis. Yield: 26%. *Anal.* Calc. for $C_9H_{10}NNaO_7S$: C, 36.13; H, 4.37; N, 4.68. Found: C, 36.21; H, 3.52; N, 4.61%. IR: 3423s, 1714s, 1417s, 1109s, 1157m, 721m, 1362s, 814m.

2.3.5. $[Mn_2(HL_2)_2(dpe)_3(H_2O)_2]_n \cdot ndpe$ (**5**)

Complex **5** was synthesized in a procedure analogous to that of **4** except that dpe and H_3L_1 were used instead of bipy and H_3L_2. Yield: 35%. *Anal.* Calc. for $C_{66}H_{56}Mn_2N_{10}O_{14}S_2$: C, 57.13; H, 4.07; N, 10.10. Found: C, 57.01; H, 3.93; N, 9.98%. IR: 3423s, 1597s, 1420s, 1161m, 731m, 1389s, 857m.

2.4. Crystallographic data collection and structures determination

Single-crystals of **1–5** were put on a Bruker SMART APEX II CCD diffractometer equipped with a graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. The structures were solved by direct methods with SHELXS-97. A full-matrix least-squares refinement on F^2 was carried out using SHELXL-97. The crystallographic data and selected bond lengths and angles for **1–5** are listed in Table 1 and Table S1, Supplementary data. Hydrogen bonds parameters in **1–5** are listed in Table S2.

(MnN_2O_4) and the coordination polyhedron is a distorted octahedral geometry. The bond lengths of Mn1–O are in the range of 2.1451(13)–2.2070(13) Å. The phen molecule chelating to the Mn(II) ion with Mn1–N1 and Mn1–N2 bond distances of 2.3010(16) and 2.2738(15) Å, respectively. It is notable that even though HL_1^{2-} does not coordinate to the metal atoms, it plays an important templation role in the crystallization process of compound **1**. Each HL_1^{2-} group is involved in significant intermolecular hydrogen bonding interactions with coordinated water molecules through its two carboxylato groups. Finally, these cation–anion species are organized into a two-dimensional supramolecular architecture (Fig. 1b). The bond lengths and angles of the hydrogen bonding are in the range of 2.658(2)–2.8088(19) Å and 157.8–175.2°, respectively. By comparison, the previously reported $[Mn_2(HL_2)_2(phen)_4]_n{\cdot}8nH_2O$ (**6**) which displays a binuclear unit and further forms the 2D supramolecular structure through unique π–π stacking and hydrogen bonding interactions [13]. This structural discrepancy may arise from the different coordination modes displayed by the HL_1^{2-} and HL_2^{2-} ligands. The HL_1^{2-} acts as a bridging ligand in **6** (Scheme 3c) while HL_2^{2-} does not coordinate at all in **1**.

3.1.2. $[Co_3(L_1)_2(bipy)_3(H_2O)_6]_n{\cdot}8nH_2O$ (**2**)

Complex **2** crystallizes in the space group *C*2/*c*. As illustrated in Fig. 2a, the asymmetric unit contains three Co(II) ions, two L_1^{3-} anions, three bipy, six coordinated water and eight lattice water molecules. The L_1^{3-} ligands use the nitrogen atom and one carboxylato oxygen atom from the glycinato group to chelate one Co atom, while the remaining carboxylato oxygen atom from the glycinato group coordinates to another Co atom. The two carboxylato oxygen atoms of the $C_6H_5COO^-$ group are free, as shown in Scheme 3a. There are two crystallographically independent cobalt atoms, one of which (Co2) lies on a center of symmetry, while the other (Co1) lies on a general position. The geometries around the Co(II) ions are both distorted octahedra, giving rise to a [4+2] type of configuration. Co1 is coordinated by two carboxylato oxygen atoms from two L_1^{3-} ligands and two water molecules in the equatorial plane and two nitrogen atoms of bipy at the axial sites. Co2 is surrounded by one carboxylato oxygen atom, one nitrogen atom from a L_1^{3-} ligand and two water molecules in the equatorial plane and two nitrogen atoms of bipy in the axial position. The Co–O_{L1} and Co–N_{bipy} bond lengths are in agreement with those reported for carboxylate and bipy-containing Co(II) complexes. One inner Co1 atom and two outer Co2 atoms are bridged by single carboxylato group in a *syn–anti* mode to form a linear trinuclear cluster with an adjacent Co···Co distance of 5.736 Å. The similar carboxylato bridged linear trinuclear Co(II) complexes $[Co_3(O_2CMe)_6(bpy)_2]$, $[Co_3(O_2CPh)_6(base)_2]$, $[Co_3(O_2C(C_6H_4NO_2)_6(base)_2)]$ and $[Co_3(O_2CMe)_8]$ have also been reported in the literatures [14–16]. The trinuclear clusters in **2** are connected to each other through bipy bridges to give rise to a new 1D triple infinite chain extending along the *b*-axis (Fig. 2b), which is different from those of the known 1D polymers with linear chain [17], zigzag chain [18], helical chain [19], ladder chain [20], double-stranded chain [21] and 1D double chain motifs [22]. To the best of our knowledge, this is the first example of a 1D triple chain complex containing amino acid-type and linear trinuclear metal arrangements.

In addition, there exist aromatic ring stacking interactions in the trinuclear unit between benzene rings of L_1^{3-} ligands and pyridine rings of bipy, with the centroid to centroid distance being 3.77 Å and a dihedral angle of 4.16°. These π–π stacking interactions encourage the L_1^{3-} ligands to alternately decorate two sides of the 1D triple chain. Extensive hydrogen bonds between coordinated water molecules and lattice water molecules are also formed, which reinforce the intra- and inter-chain linkages, and result in the formation of a 3D extended framework. In **2**, the two types of weak interactions, namely hydrogen bonds and aromatic ring stacking interactions, play an important role in the self-assembly and stabilization of the supramolecular structure. Notably, a related compound $[Co_3(L_2)_2(bipy)_2(H_2O)_6]_n{\cdot}2nCH_3OH{\cdot}8nH_2O$ (**7**) is obtained by using H_3L_2 under similar conditions, however, this structure shows a 1D alternating chain with $[CoL(H_2O)]_2^{2-}$ binuclear and $[Co(bipy)_2(H_2O)_4]^{2+}$ mononuclear units along the *a*-direction [12]. Furthermore, the coordination mode of L_2^{3-} in **7** (Scheme 3d) is different from that of L_1^{3-} in **2**.

Scheme 3.

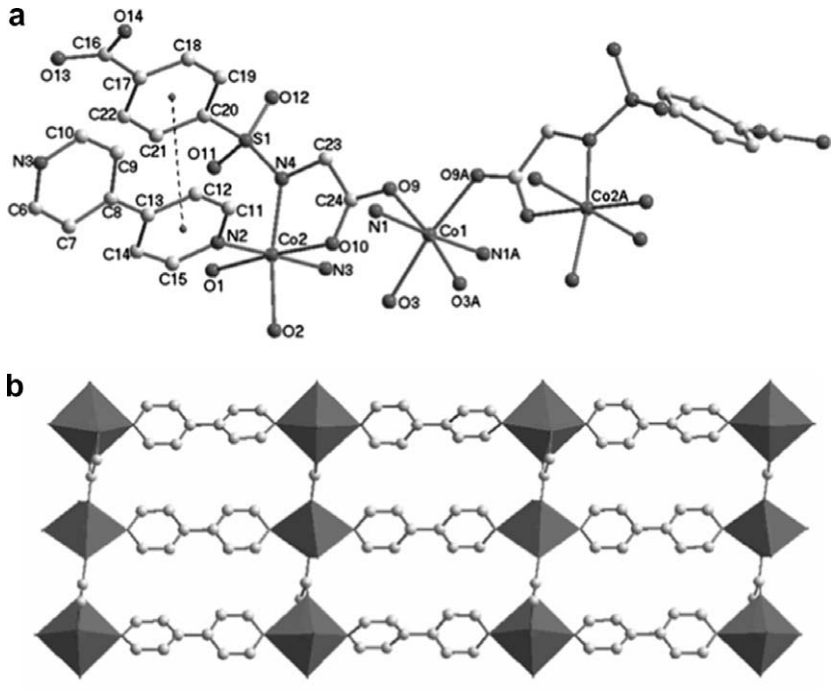

Fig. 2. (a) A perspective view of the discrete Co_3 cluster, hydrogen atoms and lattice water molecules are omitted for clarity. (b) The 1D triple polymeric chain architecture in **2**, the L_1^{3-} ligands are omitted for clarity.

*3.1.3. $[Cu_4(L_1)_2(OH)_2(bipy)_4]_n \cdot 12nH_2O$ (**3**)*

It can be seen from Fig. 3a that **3** contains tetranuclear Cu(II) units. Each tetranuclear unit is composed of four Cu(II) ions, two L_1^{3-} ligands, and two OH^- groups. There are also twelve intercalated water molecules per tetramer. Within the tetramer, there are three kinds of crystallographically independent Cu(II) ions with different coordination environments in the unit. Cu1 and Cu2 are bridged by one L_1^{3-} ligand and Cu2 and Cu3 are bridged by a hydroxyl group with distances of 5.374 and 3.369 Å between Cu1/Cu2 and Cu2/Cu3, respectively. The geometry of Cu1 can be considered as a distorted octahedral geometry with a $[N_4O_2]$ coordination sphere. The four equatorial coordination sites are occupied by N1, N2, N7 and N7A. Two oxygen atoms (O2, O2A) from two different glycinato groups occupy the axial coordination sites. The axial bond lengths (Cu1–O2, 2.354(4) Å) are considerably longer than the equatorial bond lengths (Cu(1)–N(7) = 2.013(4), Cu(1)–N(1) = 2.031(6), Cu(1)–N(2) = 2.079(6) Å) leading to the distortion from regular octahedral geometry. Cu2 is four-coordinated by one bridging carboxylato oxygen atom, two nitrogen atoms from different bipy ligands and one bridging hydroxyl group with a $[N_2O_2]$ coordination sphere. The Cu2–$O7_{OH}$ (1.917(4) Å) distance is shorter than that of Cu2–$O1_{L1}$ (1.969(4) Å), but the Cu2–N distances (Cu2–N3 = 2.045(4), Cu2–N4 = 2.042(4) Å) are the same within error. The Cu3 ion is coordinated by two bridged hydroxyl groups (O7, O7A) and two bipy nitrogen atoms (N5, N6) to form a square planar geometry. The Cu–O and Cu–N bond distances are 1.932(4), 2.039(6) and 2.050(6) Å, respectively.

The asymmetric unit in **3** forms uniform tetranuclear cycles ($Cu_1Cu_2Cu_3Cu_2$). The tetranuclear units are then connected together by the coordination bonds between oxygen atoms from the glycinato groups and Cu(II) ions to form a new $\cdots Cu_1Cu_2Cu_3Cu_2Cu_1Cu_2Cu_3Cu_2 \cdots$ 1D chain. These 1D chains are further interconnected by bipy ligands to generate a 2D wave-like rectangular grid layer along the *a*-axis, as shown in Fig. 3b and c.

It is interesting that the aromatic ring containing C(4) atom is almost parallel to the related pyridine ring containing N(1) atom in a tetranuclear unit. (the dihedral angle between two planes was *ca.* 12.13°) with a close intramolecular separation of *ca.* 3.83 Å. The stacking interactions encourage the L_1^{3-} ligands to lie alternatively above and below the 2D planes, and further extensive hydrogen bonds exist between coordinated water and lattice water molecules between the adjacent 2D layers, generating an overall 3D network. The structure of **3** is different from that of $[Ca(H_2O)_4Cu_2(bipy)_2(L_2)_2]_n \cdot 4nH_2O$ (**8**), which has a 2-fold 3D interpenetrating network where Cu atoms are joined by bipy to generate a 1D zigzag chain [12]. Every L_2^{3-} ligand adopts a tetradentate bridging mode to link one Ca and two Cu atoms in **8** (Scheme 3e) while L_1^{3-} acts as a tridentate bridging mode to link two Cu atoms forming a uniform chain in **3**.

*3.1.4. $[Na(H_2L_1)(H_2O)]_n$ (**4**)*

Single-crystal X-ray structural analysis shows that **4** is a bilayer structure in which two single layers are linked by H_2L_1 ligands to generate a 2D bilayer framework. Each sodium is primarily coordinated by two oxygen atoms [Na(1)–O(5), 2.4514(18); Na(1)–O(6), 2.4290(17) Å] from two different glycinato groups, two oxygen atoms [Na(1)–O(3), 2.4996(17); Na(1)–O(4), 2.4818(17) Å] from sulfonate groups, one oxygen atom from a carboxylato group of H_2L_1 [Na(1)–O(2), 2.4137(17) Å] and one oxygen atom from a water molecule [Na(1)–O(7), 2.491(2) Å] to furnish a distorted octahedral geometry (Fig. 4a). Unlike compounds **1–3**, oxygen atoms from both sulfonate groups and $C_6H_5COO^-$ groups coordinate to metal ions. The $H_2L_1^-$ ligand in **4** acts as a pentadentate ligand, as shown in Scheme 3b, where two carboxylato oxygen atoms from the glycinato group adopt a *syn–anti* bridging mode, while the other two oxygen atoms from the sulfonate group exhibit a *syn–syn* bridging mode, and the carboxylate from the $C_6H_5COO^-$ group adopts a monodentate coordination mode. Thus, each $H_2L_1^-$ ligand links five sodium atoms and each sodium center interacts with five $H_2L_1^-$ ligands.

On the basis of these connection modes, pairs of Na(1) centers are doubly bridged by oxygen atoms from glycinato and sulfonate groups to form an eight-membered ring with a Na···Na separation of 5.506 Å. These dinuclear units are arranged uniformly to form a

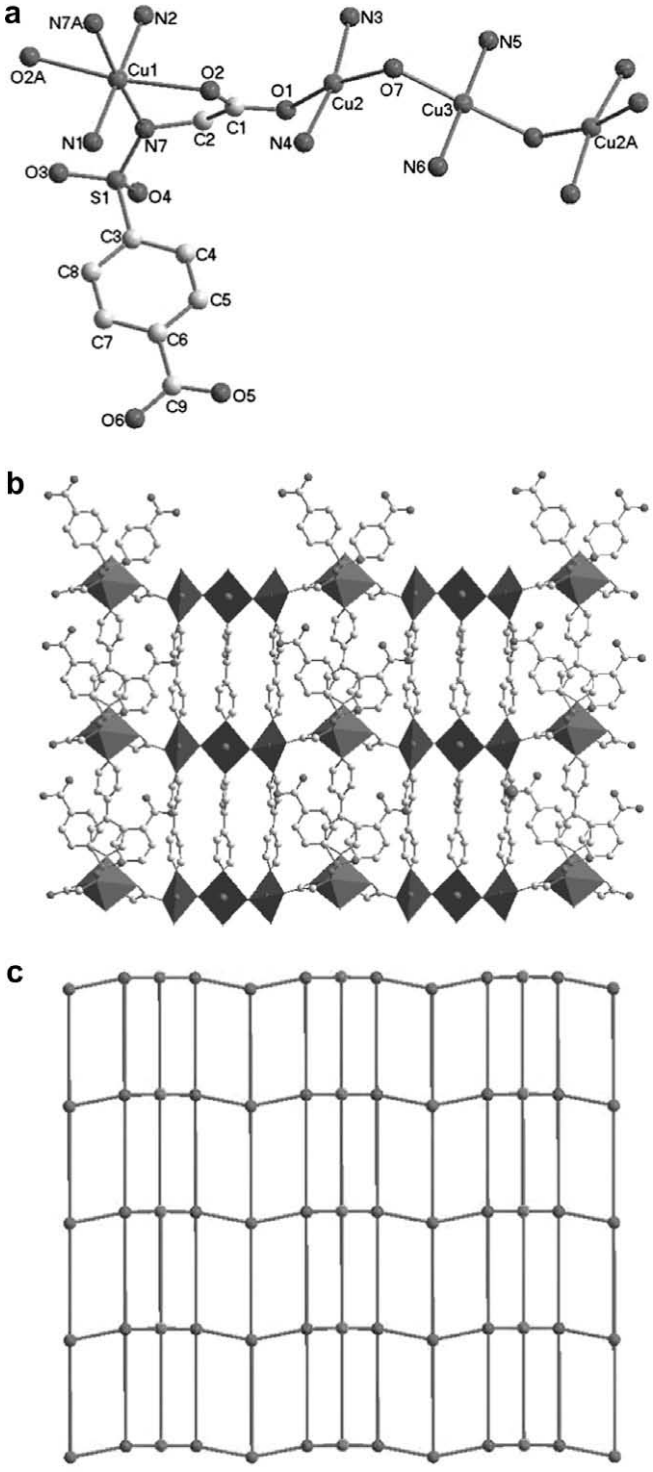

Fig. 3. (a) The coordination environment of a tetranuclear Cu(II) unit in **3**, hydrogen atoms, lattice water molecules and coordinated bipy are omitted for clarity. (b) 2D layer of **3** constructed from the 1D chain. (c) Schematic representation of a 2D layer structure.

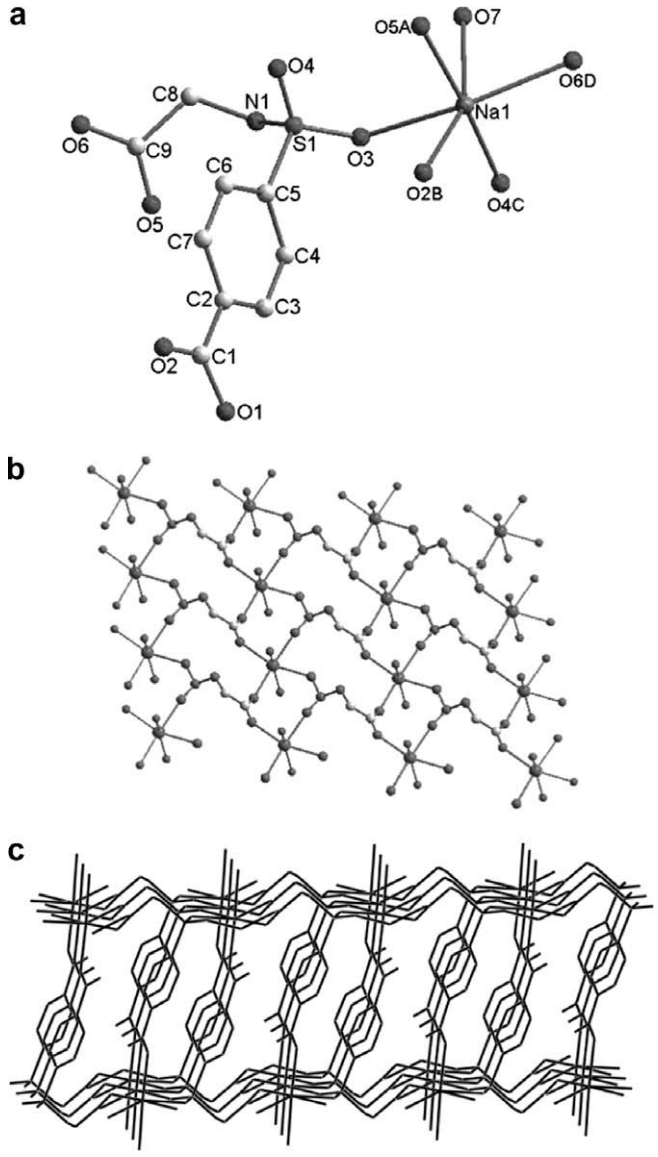

Fig. 4. (a) The local coordination environment of Na ion with atomic numbering scheme in **4**. (b) Perspective view of the single Na–H_3L sheet; (c) Side view along the *a*-axis showing bilayer motif in **4**.

1D chain. These chains are linked by $-SO_2NHCH_2COO-$ groups to build a 2D layer (Fig. 4b). Interestingly, the 2D layers are linked by $H_2L_1^-$ to generate a new 2D bilayer framework with a distance of 10.899 Å (based on Na...Na) between the two single layers (Fig 4c). The adjacent 2D bilayers are further linked to each other by O–H···O hydrogen bonds [O(7)–H(2W)···O(7A), 2.845(6) Å; O(7)–H(1W)···O(6), 2.992(3); O(1)–H(1)···O(5), 2.569(2) Å] to complete the final 3D supramolecular architecture. This is, to our knowledge, the first example of bilayer architecture assembled by alkali metal with amino acid derivatives.

3.1.5. $[Mn_2(HL_2)_2(dpe)_3(H_2O)_2]_n \cdot ndpe$ (5)

The fundamental building unit of **5** is composed of two Mn(II) cations, two monodentate coordinated dpe, one μ_2-dpe, two HL_2^{2-} anions, two coordinated water molecules and one guest dpe molecule. The coordinated and uncoordinated dpe molecules are disordered over two sites. For clarity, only one of these sites is shown in Fig. 5. The dpe molecules exist in three types of coordination modes (monodentate, bis-monodentate and uncoordinate) in **5**, which is unusual in the construction of polycarboxylate and dpe polymers. Each Mn center exhibits a distorted octahedral geometry with two pyridyl nitrogen atoms from two dpe ligands in the axial positions, and four oxygen atoms in the equatorial plane composed of three oxygen atoms from three HL_2^{2-} ligands and one from coordinated water molecule. The Mn–O bond distances fall in the range of 2.120(3)–2.189(2) Å, and the Mn–N bond distances are 2.296(3) and 2.304(3) Å, respec-

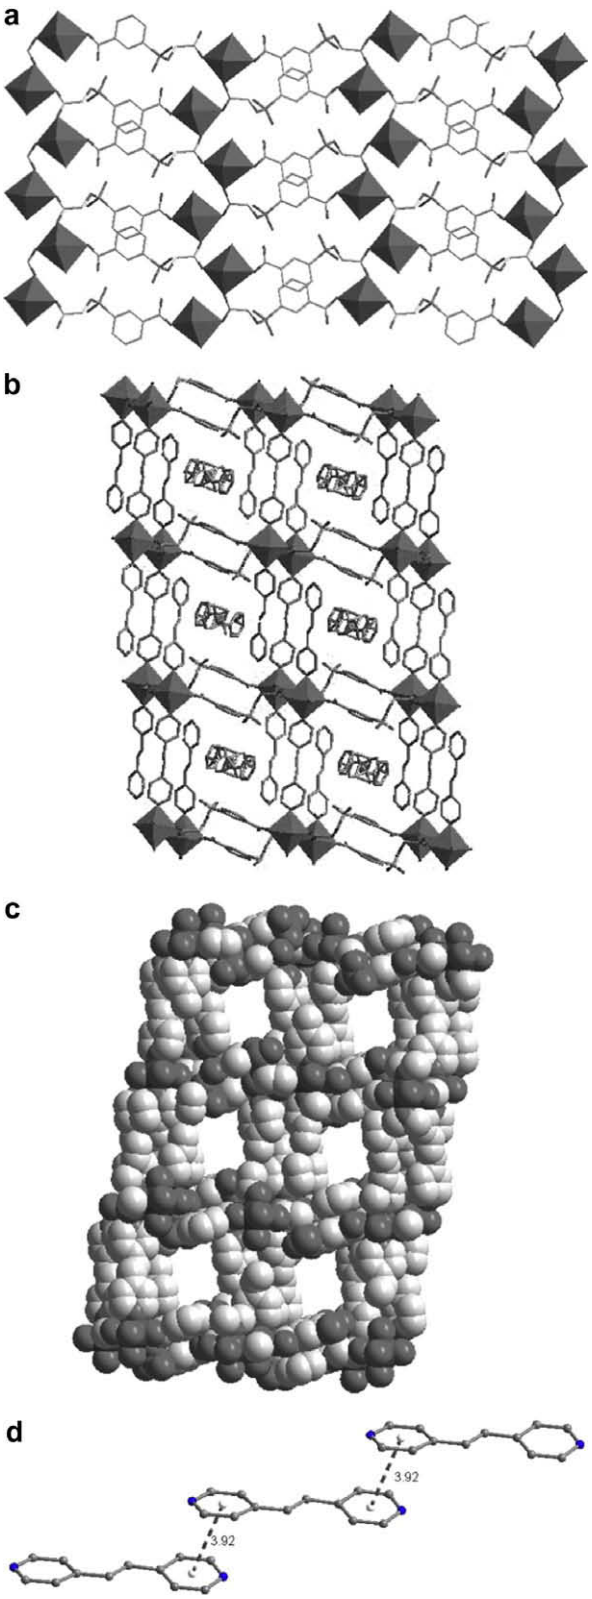

Fig. 5. (a) 2D sheets bridged by HL_2^{2-} molecules. (b) View of the channels formed by the 3D network. (c) Space-filling model of **5** as viewed down the *b*-axis (disordered guest dpe molecules are omitted for clarity). (d) A view of the 1D supramolecular dpe chain constructed by the intermolecular π–π aromatic stacking interactions.

tively. The HL_2^{2-} ligand displays both monodentate and bis-monodentate bridging coordination modes in the assemblies, as shown in Scheme 3f. In addition, two HL_2^{2-} ligands bridge two Mn(II) ions to form a 22-membered ring and another four Mn(II) ions and four HL_2^{2-} ligands form a 30-membered ring. Therefore, a $[Mn(HL_2)(H_2O)]_\infty$ layer is formed through an alternating arrangement of the 22- and 30-membered rings (Fig. 5a). The resulting 2D sheets are pillared by dpe to generate an overall 3D framework in which free disordered dpe are encapsulated as guest molecules (Fig. 5b and c). The adjacent dpe molecules in the channels stack along the *b*-axis through π–π stacking interactions through the pyridine rings to form a 1D supramolecular chain (Fig. 5d). Each Mn center binds two *trans*-located dpe molecules. One is a terminal dpe which lies in the interlayer region and the other is a bridging dpe which lies alternatively between the 2D planes to link the 2D layers into a 3D framework.

3.2. Structural diversity of *1*–*8*

It is noteworthy that a variety of framework structures can be achieved on the basis of the choice of the *N*-[(carboxyphenyl)-sulfonyl]glycine isomers. The slight positional differences of the carboxylato groups between these two isomers may lead to significant geometric diversification of the resulting coordination polymers. We have successfully isolated and characterized eight coordination polymers containing Mn, Co, Cu, Na and Ca centers varying from 0D to 3D. These results illustrate the isomeric effect of the bridging ligands on coordination polymers. In **1–8**, these isomers exhibit several coordination patterns as illustrated in Scheme 3, in which the glycinato and carboxylato groups can adopt the unidentate, chelating and bridging modes. Thus, the variation of the *N*-[(carboxyphenyl)-sulfonyl]glycine isomers used in the assembled process has a significant role in the structural diversity shown by **1–8**. Secondly, the N-donor auxiliary ligands are good connectors in mediating and constructing MOFs with specific structure. In this study, phen, bipy and dpe with different conformations and flexibility were used to investigate their influence on the structure of the complexes. The steric hindrance of the phen molecule may contribute to the formation of the discrete units of complexes **1** and **6**, while the introduction of the bipy and dpe leads to the polymeric structures of complexes **2**, **3**, **5**, **7** and **8**.

On the other hand, the choice of metal centers may also have a significant effect on the binding fashions of the *N*-[(carboxyphenyl)-sulfonyl]glycine isomers as well as the resultant extended networks of **1–8**. For *N*-[(4-carboxyphenyl)-sulfonyl]glycine/bipy systems containing **2** and **3**, two coordination modes of H_3L_1 are observed, and interestingly, two different types of 1D triple chain or 2D layer frameworks are generated depending on the metal centers Co or Cu. The structures of **7** and **8** are also metal-controlled, and notably, Co^{2+}-based complex **7** shows an alternating chain while a unique 3D interpenetrating architecture is formed in the case of mixed Ca^{2+} and Cu^{2+} in **8**. This is consistent with the fact that the radius of Cu^{2+} and Ca^{2+} ions are larger than that of Co^{2+} ion. This result indicates that the choice of metal ion has a significant effect on these polymeric structures as well as the binding modes of the ligands.

3.3. Thermal stability

Thermogravimetric experiments were conducted to study the thermal stability of **5**, which is an important parameter for porous metal–organic framework materials (Fig. S1, Supplementary data). The TGA curve for **5** suggests that the first weight loss of 16.37% in the region of 30–275 °C corresponds to the loss of two coordinated water and one guest dpe per formula unit (calculated 15.59%), which is also in agreement with the results of elemental analysis. The residual framework starts to decompose beyond 300 °C with a series of complicated weight losses and does not stop until heating ends at 550 °C. In principle, TGA measurements alone cannot

be used to determine the stability of an open structure since it may collapse without a notable change in the weight. As shown in Fig. 6, the peak positions of the simulated and experimental XRPD patterns for **5** are in agreement with each other, demonstrating the good phase purity of **5**. XPRD measurements at different temperatures (Fig. 6) show that after heating at 275 °C, the spectra are similar to the original one, suggesting its crystalline nature is still maintained after removing the guest dpe molecules.

3.4. Magnetic properties

The magnetic susceptibilities, χ_M, of **5** were measured in the 2–300 K temperature range, and shown as $\chi_M T$ and χ_M versus T plots in Fig. 7. The experimental $\chi_M T$ value of **5** at room temperature is 4.18 cm^3 K mol^{-1} per Mn(II) ion, close to the spin value expected for an uncoupled high-spin Mn(II) ion (4.38 cm^3 K mol^{-1}). The temperature dependence of the reciprocal susceptibilities ($1/\chi_M$) of **5** obeys the Curie–Weiss law above 5 K with $\theta = -2.1$ K, $C = 4.59$ cm^3·K/mol, $R = 4.9 \times 10^{-5}$, which indicates that antiferromagnetic interactions are operative in **5**. According to the structure of **5**, it could be presumed that the main magnetic interactions between the metal centers might happen between two carboxylate bridged Mn(II) ions, whereas the superexchange interactions between Mn(II) ions through the HL_2^{2-} and dpe bridges can be ignored because of the long length of the HL_2^{2-} and dpe ligands. The magnetic susceptibility data were fitted assuming that the carboxylate bridges Mn(II) ions to form a uniform chain with an exchange constant J, and then dpe and HL_2^{2-} connect the chains to form a 3D structure with an exchange constant zJ'. The susceptibility data were thus approximately analyzed by a chain mode of spin $S = 5/2$ [23,24]. The least-squares analysis of magnetic susceptibilities data led to $J = -0.18$ cm^{-1}, $g = 2.04$, $zJ' = -0.04$ cm^{-1} and $R = 1.65 \times 10^{-4}$, The J value indicates a weakly antiferromagnetic interaction between the nearest Mn(II) ions bridged by H_3L_1.

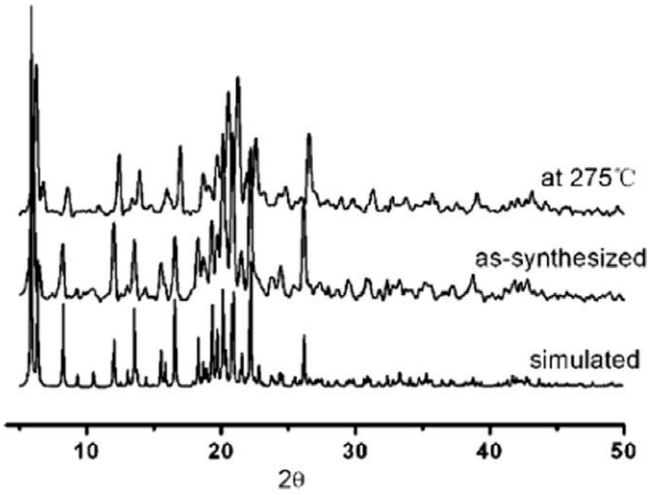

Fig. 6. Comparison of XRPD patterns of the simulated pattern from the single-crystal structure determination, the as-synthesized and the product after heating at 275 °C for **5**.

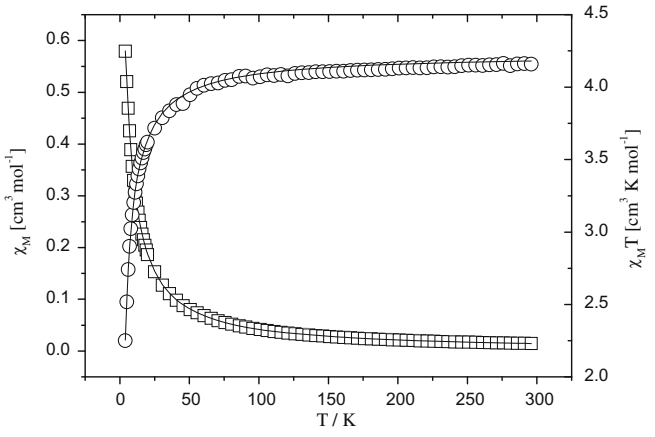

Fig. 7. Temperature dependence of $\chi_M T$ and χ_M for **5**. The solid line represents the theoretical values based on Eq. (1) described in the text.

4. Conclusions

In summary, we have successfully synthesized eight new complexes by using two versatile ligands, *N*-[(4-carboxyphenyl)-sulfonyl]glycine and its isomer *N*-[(3-carboxyphenyl)-sulfonyl] glycine. Their structures range from a 0D cation–anion species to a 3D network with different structural motifs and this result demonstrates that ligand isomers and metal centers have a tuning effect upon the motifs of the resultant structures. Subsequent work will be focused on the construction of new polymers by using these two isomers or other related amino acid derivatives as basic building units.

ABSTRACT

The present work deals with the imidorhenium(V) complexes of type $[ReCl_3(NC_6H_4Y\text{-}p)(L)]$, with Y = OCH_3(**1d**), CH_3(**1c**), H(**1b**), Cl(**1a**) where L is the pyridylimine Schiff base ligand obtained from facile condensation of pyridine-2-carboxaldehyde and *p*-phenylenediamine. Structural authentication of one representative (**1d**) reveals meridional disposition of three Cl atoms around the metal center in a distorted octahedral $ReCl_3N_3$ coordination environment. Re–$N^{pyridine}$ bond lying trans to Re≡NC_6H_4Y-*p* motif is lengthened by ~0.2 Å compared to Re–N^{imine} bond and is attributed to *trans* influence of imide nitrogen. The complexes, **1** are reactive towards dilute aqueous nitric acid furnishing amide bound hexavalent rhenium complexes, **2**. Six lines EPR spectra have been recorded for **2** in solution phase at ambient condition ($g_{iso} \sim 1.945$, $A_{av} \sim 493$ G) and magnetic susceptibility measurement indicates strong orbital coupling consistent with one electron paramagnetic nature (~1.45 μ_B). Re^{VI}/Re^{V} responses for **1** appear at higher potential (~0.95 V) that those observed for **2** (~0.12 V). Type **2** complexes are reduced (low Re^{VI}/Re^{V} reduction potential, +0.15 V) by $N_2H_5^+$ and NH_3OH^+ species under mild condition to regenerate **1**. The reduction with $N_2H_5^+$ is nearly five times faster than NH_3OH^+. Rate study suggests an associative pathway ($\Delta H^{\neq}$ = 11.61 kcal mol^{-1}, $\Delta S^{\neq}$ = −31.22 eu using $N_2H_5^+$ and $\Delta H^{\neq}$ = 10.74 kcal mol^{-1}, $\Delta S^{\neq}$ = −37.30 eu using NH_3OH^+) for amide → imine transformation. No such analogous amide → imine conversion has yet been achieved in metal free environment, accentuating the exclusive electronic role of variable metal valence. Further, the oxo complex, **6** does not exhibit intramolecular ligand oxidation suggesting decisive electronic role of the coligands (oxo/arylimido) in stabilizing higher metal valence.

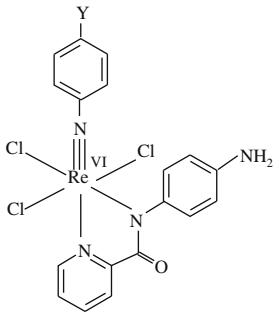
1. Introduction

Higher valent rhenium complexes have spurred interest owing to active participation as catalysts in various molecular transformations featuring key changes like functionality conversion [1], derivatization [2], cyclisation [3,4], oxygen atom transfer [5–7] in the products. Most of the oxygen atom transfer reactions between organic molecules characterizing the red-ox functional pairs like sulphide–sulphoxide; sulphoxide–sulphone; phosphine–phosphine oxide do not proceed at reasonable rates at normal temperature even recognized as thermodynamically favourable. To overcome the kinetic sluggishness, middle and late transition metals multiply bonded to heteroatom coligands have long been successfully employed [8–10] for oxidation of small molecules. Metal bound oxo → dioxo, phosphine → phosphine oxide transformations and metal catalysed sulphide → sulphoxide; pyridine oxide → pyridine; phosphine → phosphine oxide conversions mediated through oxygen atom transfer phenomenon have been authenticated in rhenium chemistry [11–21]. Moreover, abiological molecular oxotransferase incorporating $Re^{V}O$ motif has been established as useful catalyst to successfully accomplish reductions of stable inorganic moieties like ClO_4^-, NO_3^-, NO [22].



Structure-reactivity correlation reveals the prevalence of multiply bonded oxo (O^{2-}) coligand to the higher valent metal in the promising catalysts. Our programme focuses on the study of redox related organic functionality pair conversion assisted by imido (NR^{2-}) bonded higher valent rhenium complexes. Herein, we report ligand centered oxygen atom abstraction followed by reduction providing access to route of

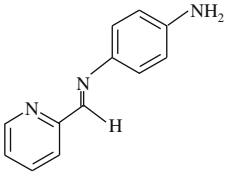
1

2



facile amide → imine conversion in secondary metal coordination sphere. The amide chelated imidorhenium(VI) complexes (**2**) were prepared by oxidation of imine bound imidorhenium(V) complexes (**1**) with dilute HNO_3. Complexes of type **2**, on reaction with either $N_2H_5^+$ or NH_3OH^+ undergoes outward oxygen atom transfer and reduced to the imine complex **1**. This observation is unprecedented in the sense of mobilizing a metal bound amide function (most inactive carboxylic acid derivative) to participate in electronic and geometrical changes resulting in the generation of reduced imine form.

The syntheses, representative structure determination of **1**, metal redox and spectroscopic properties of complexes are reported. The kinetic behaviour of outward oxygen atom transfer has been studied and a viable mechanism consistent with the experimental findings and kinetics is proposed.

2. Results and discussion

2.1. Synthesis

Facile condensation of pyridine-2-carboxaldehyde and *p*-phenylenediamine in a 1:1 molar ratio respectively, afforded a neutral condensate, N-p-aminophenyl-2-pyridinecarboxaldimine **L**, which has been employed as a bidentate ligand in the present

L, $C_{12}H_{11}N_3$

work. The violet coloured complexes **1**, $[Re(NC_6H_4Y\text{-}p)Cl_3L]$ (Y = Cl(**1a**), H(**1b**), CH_3(**1c**), OCH_3(**1d**)) are formed in good yields upon reacting $[Re(NC_6H_4Y\text{-}p)Cl_3(PPh_3)_2]$ with L in 1:1.5 molar ratio in benzene under reflux followed by chromatographic work up of the reaction mixture. In the product, two *trans* oriented PPh_3 groups are being substituted by the ligand L, Eq. (1).

$$[Re^{V}(NC_6H_4Y)Cl_3(PPh_3)_2] + L \rightarrow [Re^{V}(NC_6H_4Y)Cl_3(L)] + 2PPh_3 \quad (1)$$

1 reacts smoothly with aqueous nitric acid [23] in acetonitrile solution at room temperature under stirring condition resulting yellow picolinamide complexe (**2**). The feasibility of the reverse reaction **2** → **1** has been scrutinized with different reducing agents and successfully carried out using nitrogenous reagents like hydrazine sulphate (Eq. (2)) and hydroxylamine hydrochloride (Eq. (3)) at mild condition in acetonitrile medium.

$$[Re^{VI}(NC_6H_4Y)Cl_3(C_{12}H_{10}N_3O)] + 3N_2H_5^+ \rightarrow [Re^{V}(NC_6H_4Y)Cl_3(C_{12}H_{11}N_3)] + \frac{3}{2}N_2 + 3NH_4^+ + H_2O \quad (2)$$

$$4[Re^{VI}(NC_6H_4Y)Cl_3(C_{12}H_{10}N_3O)] + 6NH_3OH^+ \rightarrow 4[Re^{V}(NC_6H_4Y)Cl_3(C_{12}H_{11}N_3)] + 3N_2O + 6H^+ + 7H_2O \quad (3)$$

2.2. Magnetic moment, NMR and EPR spectra

The type **1** complexes are diamagnetic corresponding to low spin $5d^2$ electronic configuration and the effective magnetic moment data of complexes **2** confirm the presence of one unpaired electron ($5d^1$, $s = 1/2$) in a pseudo-octahedral environment although the magnetic moments are significantly lower (**2a**, 1.42 μ_B; **2b**, 1.45 μ_B; **2c**, 1.46 μ_B; **2d**, 1.47 μ_B) than the spin only value. The lowering could be attributed to appreciable orbital coupling [24] as encountered in other hexavalent rhenium species.

The type **1** complexes uniformly exhibit well separated NMR signals in solution consistent with diamagnetism. However, amide complexe (**2**) display paramagnetically shifted relatively broad peaks lacking well resolved spin-spin structures. The type **2** complexes are EPR active (Fig. 1, Table 1) in fluid solution at room temperature and display well resolved spectra consisting of six isotropic hyperfine lines due to the interaction of the unpaired electron with the nuclear spin of both rhenium isotopes ($I = 5/2$; ^{185}Re, 37.07%; ^{187}Re, 62.93%). The isotopic fine structure has not been resolved because of the small difference (1%) in the two nuclear quadrupole moments. There is a systematic increase in the separation between the adjacent hyperfine lines on going from lower to higher fields due to the second order effects [25]. The range of this variable hyperfine

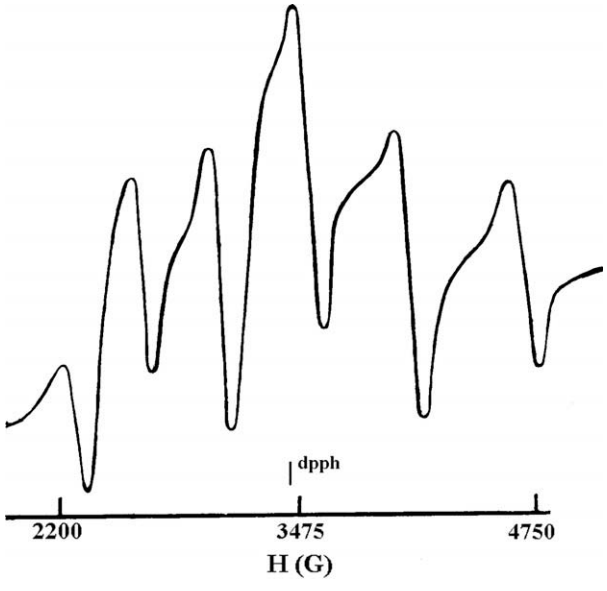


Fig. 1. EPR diagram of Complex **1d** in solution phase at 9.1 GHz and 298 K.

Table 1
EPR data for **2** at 298 K in dichloromethane-benzene (1:1) solution.

Complexes	Center field g	A (G, average)
2a	1.939	488
2b	1.945	492
2c	1.948	498
2d	1.957	496

spacing spans the domain 360-640 G, consistent with very high oxidation state (+VI) of the metal. Centre field g values and average hyperfine splitting A for the complexes fall in the ranges 1.939–1.957 and 488–498 G, respectively. Well resolved sextet EPR spectra in solution at ambient temperature are relatively rare for Re(VI) owing to the comparatively large line width followed by significant overlapping and only broad signals [26–28] are usually observed. However, Re(VI) complexes of type $[ReNX_4]^-$ (X = Cl, Br and NCS) follow similar spectral characteristics [29] at room temperature.

The spectra of **2** in a frozen (77 K) dichloromethane/toluene glass become axial and are characterized with individual g-tensors ~1.92 ($g_{||}$) and ~1.98 ($g_{\perp}$). The observed g inequality is consistent with a tetragonally distorted octahedral geometry. The hyperfine components due to the $g_{||}$ resonance (reference axis, Re≡NAr), especially the outer components have been resolved to a satisfactory extent whereas the components corresponding to $g_{\perp}$ absorptions overlap considerably. This observation corroborates that the rhombic field is not strong enough to split the perpendicular absorption into individual tensors (g_{xx} and g_{yy}). The separations between $g_{||}$ hyperfine lines are unequal and gradually increases towards higher field. It is noteworthy that the separations between $g_{||}$ hyperfine structures are larger (350–800 G) than those in isotropic solution (360–640 G) and the inter spacing between $g_{\perp}$ components are correspondingly smaller.

2.3. UV–visible and IR spectra

The electronic spectra for type **1** and **2** complexes were recorded in dichloromethane solution at room temperature. The Re^V chelates (**1**) display a relatively weak transition near 750 nm related to $5d_{xy} \rightarrow d_{yz}, d_{xz}$ excitation. Well separated moderately intense second band appeared at about 540 nm, presumably LMCT ($\pi_{Cl} \rightarrow Re^V$) in origin. Another highly intense band near 350 nm could be ascribed to bound aldimine based internal CT transition. Spectra of **2** are characterized with two peaks in higher energy (535 and 350 nm) and disappearance of lowest energy peak.

All IR spectra of **1** and **2** exhibit two primary N–H stretching modes near 3350 and 3280 cm^{-1} as sharp doublets for the asymmetric and symmetric vibrations, respectively. The strong bands observed in the range 1590–1610 cm^{-1} are assigned to C=N stretch and red shift of this azomethine absorption by ~25 cm^{-1} from free ligand to the complexes suggests weak π–accepting property of the coordinated ligand. Two Re–Cl stretches were observed in the region 320–340 cm^{-1}, consistent with *mer*-$ReCl_3$ motif for both types of complexes. Picolinamide bound complexes (**2**) uniformly exhibit another characteristic band near 1640 cm^{-1} for C=O function of the ligand.

2.4. Structure

The X-ray structure of **1d** has been determined. Molecular view, atom numbering scheme are presented in Fig. 2 and selected bond parameters are collected in Table 2.

The $ReCl_3$ fragment is uniformly disposed in a meridional fashion in the distorted octahedral complex. The Cl1, Cl2, Cl3 and N2 atoms define a good equatorial plane (mean deviation ~0.01 Å) from which the metal atom is displaced towards the imide nitrogen N4 by 0.30 Å. The five membered chelate ring (Re, N1, C5, C6 and N2) along with the pyridine moiety constitute a satisfactory plane (md < 0.02 Å) with which the p-aminophenyl group of the ligand L is obliquely oriented (dihedral angle ~70°). Trans influence of imido nitrogen (N4) is reflected in the Re–N1 bond length (2.236 Å), longer by about 0.19 Å compared to normal Re–N2 length (2.045 Å). The Re–N4 length, 1.714(3) Å and Re–N4–C13 angle, 173.9(2)° are consistent with the triply bonded ($\sigma^2\ \pi^4$), more or less linear arylimidorhenium ($Re^V{\equiv}NC_6H_4Y$) motif [30,31].

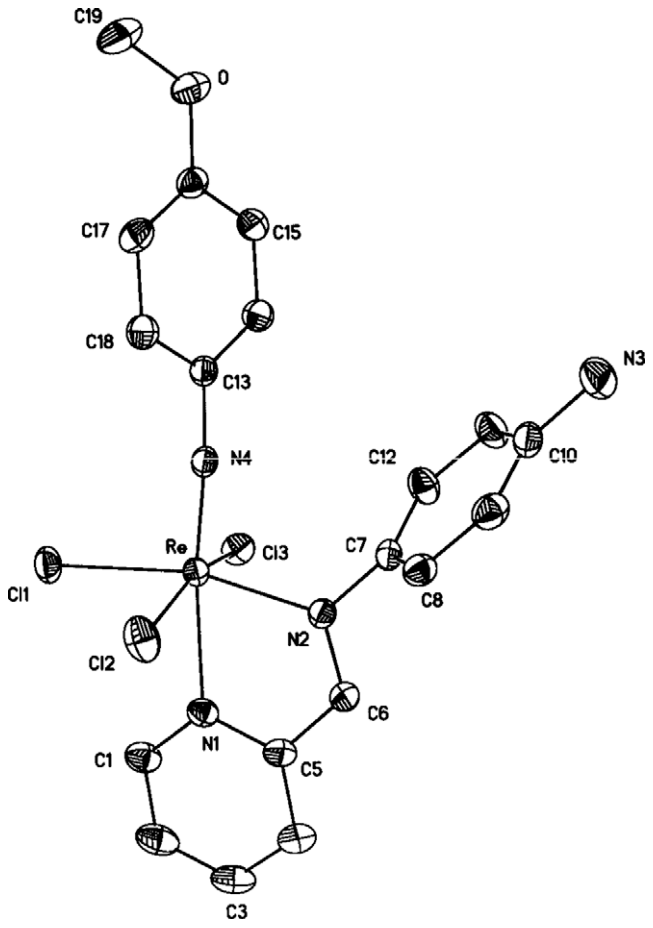

Fig. 2. A perspective view (25% probability thermal ellipsoids) and atom labeling scheme of **1d**. Hydrogen atoms have been omitted for clarity.

Table 2
Selected bond distances (Å) and angles (°) for **1d**.

Distances			
Re–N(4)	1.714(3)	Re–N(2)	2.045(2)
Re–N(1)	2.236(3)	Re–Cl(2)	2.3813(10)
Re–Cl(1)	2.3826(9)	Re–Cl(3)	2.3856(9)
Angles			
N(4)–Re–N(2)	98.63(11)	N(4)–Re–N(1)	173.01(10)
N(2)–Re–N(1)	74.85(10)	N(4)–Re–Cl(2)	99.72(9)
N(2)–Re–Cl(2)	87.34(7)	N(1)–Re–Cl(2)	82.69(7)
N(4)–Re–Cl(1)	96.51(8)	N(2)–Re–Cl(1)	164.81(7)
N(1)–Re–Cl(1)	90.09(7)	Cl(2)–Re–Cl(1)	88.83(4)
N(4)–Re–Cl(3)	95.56(9)	N(2)–Re–Cl(3)	91.71(7)
N(1)–Re–Cl(3)	82.29(7)	Cl(2)–Re–Cl(3)	164.66(4)
Cl(1)–Re–Cl(3)	88.12(3)		

Molecular packing reveals that one Cl atom of a molecule underwent two weak Cl···H contacts (2.829 and 2.898 Å) with two other proton donor molecules oriented in a nearly parallel manner to the acceptor. The donor fragments are linked through O···H interaction (2.461 Å) to form a trimeric assembly and the pattern is extended inside the lattice. Apart from the said interactions, the stability of the trimer is partly imparted from π–π stacking force operating between arylimido and aminophenyl groups (centroid···centroid distance – 3.885 Å) of two donor molecules.

2.5. Electrochemistry

All the two families are electroactive in acetonitrile solution at platinum electrode. The reduction potential data are collected in

Table 3
Cyclic voltammetric formal potentials at 298 K in acetonitrile solvent (TEAP, supporting electrolyte) at a platinum working electrode.[a,b,c,d]

Complex **1**	$E_{½}$ (Re^{VI}/Re^{V}),V (ΔE_p, mV)	Complex **2**	$E_{½}$,V (ΔE_p, mV)	
			Re^{VI}/Re^{V}	Re^{VII}/Re^{VI}

	1.67	0.37	
	2.22	0.54	
283	1.11	0.15	0.18(0.03)
	1.67	0.24	
	2.22	0.35	

[a] $\Delta H^{\neq}$ = 10.74 (0.62) kcal mol^{-1} and $\Delta S^{\neq}$ = −37.30 (2.1) eu.
[b] The initial concentration of **2** is 2.5×10^{-4} M.
[c] Least squares deviations are given in parentheses.

Table 3. The type **1** complexes display well-defined quasi-reversible anodic peak (peak to peak separation ~ 80 mV) near 0.95 V versus SCE. The response is tentatively assigned to the oxidation of Re^{V} to Re^{VI} and relevant to the redox reaction $\mathbf{1^+ + e \rightarrow 1}$. The potential increases with the increase in electron withdrawing power of Y (OCH_3 < CH_3 < H < Cl) and the observed trend follows usual Hammett order. The picolinamide complexes of type **2** exhibit two successive quasi-reversible (peak to peak separation ~ 80 mV) one electron signals near 0.15 and 1.50 V for Re(VI)/Re(V) and Re(VII)/Re(VI) couples respectively (Eq. (4)).

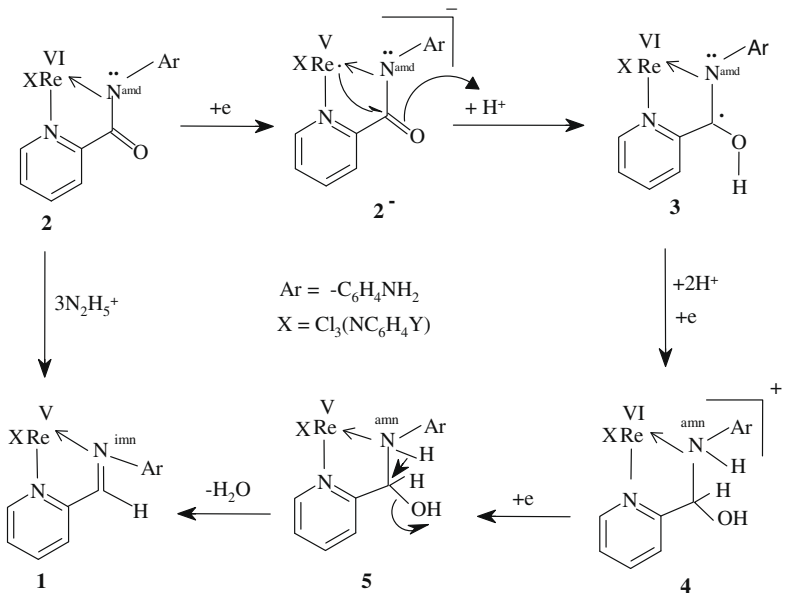
$$\mathbf{2} + \mathbf{e} \rightarrow \mathbf{2^-} \quad (4a)$$

$$\mathbf{2^+} + \mathbf{e} \rightarrow \mathbf{2} \quad (4b)$$

Lowering of reduction potential for Re^{VI}/Re^{V} couple by a substantial margin of ~0.8 V for type **2** complexes compared to that of **1** indicates superior stabilization of amide bound hexavalent rhenium in the former species [32]. Like **1**, type **2** complexes also exhibit substitution effect at Y of arylimido moiety in a usual manner.

2.6. Reduction kinetics

In order to understand the kinetic behaviour of amide → imine reduction, the progress of the reaction was monitored by spectrophotometry in acetonitrile solution. The conversion **2** → **1** was characterized by the increase in absorbance at 535 nm in the temperature interval 283–299 K. The second order rate constants at different temperatures and activation parameters for the reaction using $N_2H_5^+$ are collected in Table 4. Under pseudo-first order condition (excess hydrazine), the rates are found to be proportional to the concentration of amide complex **2** (Rate = k_{obsd} [2]), as evident from the linear plots of $-\ln(A_\alpha - A_t)$ versus time t at different hydrazine concentrations under variable temperatures. The plot between any set of k_{obsd} values and used hydrazine concentrations at any recorded temperature is linear in nature and the corresponding slope gives the second order rate constant k_2 as stated in Eq. (5). First order dependence of **2** and



$$\text{Rate} = k_2[\mathbf{2}][\mathbf{N_2H_5^+}](\mathbf{k_{obsd}} = \mathbf{k_2}[\mathbf{N_2H_5^+}]) \quad (5)$$

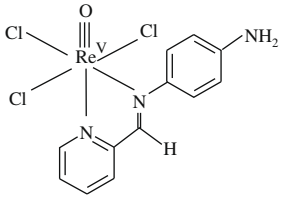
hydrazine on rate implies that the oxygen atom transfer reaction proceeds through the rate determining step involving close association ($\Delta S^{\neq}$ = −31.22 eu) of hexavalent metal amide substrate and the reducing agent.

The rate of reduction of **2** by $N_2H_5^+$ was found to be nearly five times faster than that measured with NH_3OH^+ (Table 5) at all recorded temperatures. The difference in rates can be reconciled by considering higher reducing ability of $N_2H_5^+$ (higher oxidation potential) over NH_3OH^+ (lower oxidation potential).

2.7. Reaction model

N_2H_4 has the unique ability to act as either one electron or multi electron (two and four) donor reducing agent depending on the reaction condition and nature of the oxidant. The number of proton and electron equivalents transferred from each equivalent of $N_2H_5^+$ is a requisite for the proposition of reduction mechanism. Isolation of ammonium salt from the products of **2** → **1** conversion is consistent with one electron and one proton donor function of $N_2H_5^+$, relevant to half cell reaction, $N_2H_5^+ \rightarrow ½N_2 + NH_4^+ + H^+ + e$.

Scheme 1.



2 → **1** conversion does not involve nucleophilic attack of hydrazine instead outward transfer of oxygen atom from the bonded ligand occurs through proton assisted amide C=O labilisation. In attempt to extend the reaction model (Scheme 1), the initiation is thought to occur via fast metal reduction (low Re^{VI}/Re^{V} reduction potential, ~0.15 V) by $N_2H_5^+$ to form the anionic complex $\mathbf{2}^-$. Lower metal valence (+V) in $\mathbf{2}^-$ considerably decreases the Lewis acidity of the metal and expansion of radius upon reduction substantially weakens Re-amido nitrogen bonding.

These electronic changes in $\mathbf{2}^-$ promote internal electron transfer [33] from pentavalent metal to the amide function and augmented oxygen basicity arising there from induces proton capture [34] to generate the radical based reactive Re(VI) species, **3**. Such electron transfer events are facile in $\mathbf{2}^-$ containing comparatively electron rich Re^{V} centre rather than in **2** incorporating electron poor Re^{VI} metal. Subsequent reduction of amido carbon and nitrogen sites in **3** resulted cationic α-hydroxyamine intermediate, **4** [35–39]. Finally, **4** undergo metal reduction followed by dehydration to regenerate **1**. Elimination of water from **5** is driven by stronger Re^{V}-imine bonding, resulting from metal electron density delocalization over π^* framework of aldimine ligand. The proposed mechanism indicates stepwise utilization of three equivalents of proton and three equivalents of electron derived from three equivalents of $N_2H_5^+$ for the reduction of one equivalent of **2**. This observed reaction stoichiometry is in complete agreement with Eq. (2).

In support of the existence of transient reduced species $\mathbf{2}^-$, we performed constant potential exhaustive reduction of **2** at +0.30 V in dry acetonitrile solvent under deareated condition. The coulomb count ratio suggests an almost quantitative one electron reduction of **2** to form stereoretentive Re^{V} analogue ($\mathbf{2}^-$), evident from the virtually superposable cyclic voltammogram of the electrogenerated species $\mathbf{2}^-$ (anodic scan) with that of **2** (cathodic scan). Attempts to isolate $\mathbf{2}^-$ did not succeed. Such an analogous transformation of N-substituted amide to imine has not yet been documented in metal free condition. Appreciable π-delocalisation in free amide makes amido oxygen feebly basic hindering the protonation step and no scope for induced electron transfer halts the successive stages of the transformation. Hence, the concerned **2** → **1** conversion is entirely metal regulated in electronic sense via easy accession of variable metal valence as required in different steps.

2.8. Coligand effect on intramolecular oxidation

π-acidic Re^{V} ion can be stabilized with the help of π-donor oxo and arylimido coligands. The scrutiny of imine → amide conversion in the Re^{V}-oxo complex (**6**), $[Re^{V}OCl_3L]$ can help us to understand role of electronic effect of coligands exerted on oxidation process. With the aim to investigate, we prepared the concerned oxo complex and allowed to react with aqueous HNO_3 under the same condition. The reaction was only ended up with no observable colour change and no isolation of the corresponding amide product. The observation implies that the Re^{VI} ion is better stabilized by arylimido

6

group compared to the oxo coligand. This is attributed to superior π-donor ability of arylimido group (NAr^{2-}) over oxo (O^{2-}) to efficiently stabilize the Re^{VI} centre as attested from the higher oxidation potential of oxo complex, **6** (1.55 V) than the imido complexes, **1** (~0.95 V) and the lower electronegativity of nitrogen than oxygen. Significantly high oxidation potential for the oxo complex renders the rhenium metal inactive for initial oxidation to promote imine → amide oxidation. Moreover, coulometric oxidation of $[Re^{V}OCl_3L]$ in dry acetonitrile solvent afforded no tractable Re^{VI} product which suggests that the Re^{VI} analogue is only stable in cyclic voltammetric short time scale.

3. Conclusion

Reported pyridylimine chelated type **1** imidorhenium(V) complexes are active towards inward oxygen atom transfer reaction in dilute nitric acid medium affording pyridylamide bound hexavalent rhenium analogues, **2**. Low Re^{VI}/Re^{V} potential for **2** provides the opportunity to scrutiny the reductive susceptibility with nitroge-

nous reducing agents like hydrazine sulphate and hydroxylamine hydrochloride. Rate measurements for **2**→**1** conversion reveal an associative pathway and on that basis reaction mechanism is proposed. The reduction mode explains the role of variable metal valence in proton mediated structural changes of the bound amide ligand in **2**. The oxo complex (**6**) does not respond to such imine→amide oxidation owing to considerably high metal oxidation potential.

Electroactive complexes of type **2** display Re^{VI}/Re^{V} and Re^{VII}/Re^{VI} voltammetric signals near ~0.1 and ~1.6 V in contrast to only one Re^{VI}/Re^{V} couple (~0.95 V) for **1**. The appearance of Re^{VII}/Re^{VI} response for **2** implies superior stabilizing effect of amide group for higher valent rhenium species. Type **2** complexes uniformly exhibit one electron paramagnetism and display well-resolved six lines EPR spectra at room temperature in solution.

4. Experimental

4.1. Materials and physical measurements

The starting materials $[Re(NC_6H_4Y)Cl_3(PPh_3)_2]$ [40] and $[ReOCl_3(PPh_3)_2]$ [41] and the ligand L [42] were synthesized by reported standard methods. All other chemicals were of reagent grade and used as received. Solvents were dried and distilled prior to use. The IR spectra were recorded on KBr pellets with a Perkin–Elmer FT-IR spectrometer. A Perkin–Elmer 2400 II elemental analyzer was used for microanalysis. The electronic spectra and kinetic studies were done using Hitachi U-3501 spectrophotometer fitted with thermostated cell compartments. Electrochemical measurements were performed using a PAR model Versastat-2 electrochemical analyzer, with a platinum working electrode. The supporting electrolyte was tetraethylammonium perchlorate (TEAP), and the potentials were referenced to saturated calomel electrode (SCE) without junction correction. X-band EPR spectra in solution and frozen glass states were recorded using a Bruker 300E spectrometer. Magnetic susceptibilities were measured on a PAR 155 vibrating sample magnetometer.

4.2. Preparation of complexes

4.2.1. Synthesis of $[Re^{V}(NC_6H_4Y)Cl_3(C_{12}H_{11}N_3)]$, 1

The same general procedure was used to synthesize the above complexes from $[Re^{V}(NC_6H_4Y)Cl_3(PPh_3)_2]$. Procedural details are given for one representative case (**1d**). Yields varied in the range 80–85%.

To a green suspension of $[Re^{V}(NC_6H_4Y)Cl_3(PPh_3)_2]$ (190 mg, 0.20 mmol) in 30 ml of benzene was added 60 mg (0.30 mmol) of L in 10 ml of benzene, and the mixture was heated to reflux for 2 h, affording a violet solution. The solvent was then removed under reduced pressure, and the dark mass thus obtained was subjected to chromatography on a silica gel column (25 × 1 cm, 60–120 mesh). Excess ligand and phosphine was eluted with benzene. A violet band was then eluted with benzene-acetonitrile (20:1) mixture. Solvent removal form the eluate under reduced pressure afforded $[Re^{V}(NC_6H_4OCH_3)Cl_3(L)]$, **1d** as a violet solid. Yield: 106 mg (82%). *Anal.* Calc. for $C_{19}H_{18}Cl_3N_4ORe$: C, 37.35; H, 2.95; N, 9.17. Found: C, 37.30; H, 2.98; N, 9.13. IR (cm^{-1}): 320, 335 (Re–Cl), 1595 (C=N). ^1H NMR [δ (*J*/Hz), $CDCl_3$ solution]: L, 9.39(H(1), d, 5.8); 6.83 (H(2), t, 7.5); 7.97 (H(3), t, 8.2); 7.34 (H(4), d, 7.4); 6.42(H(6), s); 7.44–7.53 (H(8,9,11,12), m); 16.06 (NH_2, s); NC_6H_4Cl, 7.05 (2H(o), d, 5.8); 7.12 (2H(m), d, 5.6).

4.2.2. Synthesis of $[Re^{VI}(NC_6H_4Y)Cl_3(C_{12}H_{10}N_3O)]$, 2

The same general method was used to prepare the above complexes from $[Re^{V}(NC_6H_4Y)Cl_3(C_{12}H_{11}N_3)]$, **1**. Procedural details are given for one representative case (**2d**). Yields are in the range 75–80%.

One hundred and two milligrams (0.17 mmol) of **1d** was dissolved in 25 ml acetonitrile, and 4.5 ml 1(N) nitric acid (acidity ~0.15 N) was added. The violet solution was stirred for 1 h, during which the colour turned yellowish brown. Solvent evaporation yields dark brown product. The mass thus obtained was thoroughly washed with cold water to remove adherent nitric acid and finally dried in vacuum over fused $CaCl_2$. Yield: 80 mg (77%). *Anal.* Calc. for $C_{19}H_{17}Cl_3N_4O_2Re$: C, 36.45; H, 2.72; N, 8.95. Found: C, 36.40; H, 2.75; N, 8.99. UV–vis (λ_{max}, nm (ε, M^{-1} cm^{-1}), CH_2Cl_2 solution): 535 (1600); 355 (12200). IR (cm^{-1}): 320, 335 (Re–Cl), 1595 (C=N), 1635 (C=O).

2c: *Anal.* Calc. for $C_{19}H_{17}Cl_3N_4ORe$: C, 37.41; H, 2.79; N, 9.19. Found: C, 37.45; H, 2.75; N, 9.22. UV–vis (λ_{max}, nm (ε, M^{-1} cm^{-1}), CH_2Cl_2 solution): 535 (1600); 355 (12000). IR (cm^{-1}): 320, 335 (Re–Cl), 1595 (C=N), 1635 (C=O).

2b: *Anal.* Calc. for $C_{18}H_{15}Cl_3N_4ORe$: C, 36.27; H, 2.52; N, 9.40. Found: C, 36.30; H, 2.57; N, 9.33. UV–vis (λ_{max}, nm (ε, M^{-1} cm^{-1}), CH_2Cl_2 solution): 535 (1600); 355 (12300). IR (cm^{-1}): 325, 335 (Re–Cl), 1595 (C=N), 1635 (C=O).

2a: *Anal.* Calc. for $C_{18}H_{14}Cl_4N_4ORe$: C, 34.28; H, 2.22; N, 8.89. Found: C, 34.32; H, 2.25; N, 8.81. UV–vis (λ_{max}, nm (ε, M^{-1} cm^{-1}), CH_2Cl_2 solution): 535 (1500); 355 (12400). IR (cm^{-1}): 320, 330 (Re–Cl), 1595 (C=N), 1635 (C=O).

4.2.3. Synthesis of 1 from 2

4.2.3.1. Hydrazine method. To a yellow–brown solution of **2** (125 mg, 0.20 mmol) in acetonitrile (25 ml) was added hydrazine sulphate (91 mg, 0.70 mmol) in 10 ml solvent. It was then stirred for 1.5 h at room temperature whereupon the solution gradually turned violet. The solvent was removed from the resulting solution under reduced pressure. The obtained violet mass (**1**) was washed with cold water to free adhered hydrazine and dried in vacuum over fused $CaCl_2$. Yield: 100 mg (82%).

4.2.3.2. Hydroxylamine method. To a yellow–brown solution of **2** (125 mg, 0.20 mmol) in acetonitrile (25 ml) was added hydroxylamine hydrochloride (28 mg, 0.40 mmol) in 5 ml solvent. It was then stirred for 8 h at room temperature. The solvent was removed from the resulting solution under reduced pressure. The obtained

violet mass (**1**) was washed with cold water to free adhered hydrazine and dried in vacuum over fused $CaCl_2$. Yield: 104 mg (84%).

*4.2.4. Synthesis of [$Re^VOCl_3(C_{12}H_{11}N_3)$], **6***

To a green solution of [$ReOCl_3(PPh_3)_2$] (208 mg, 0.25 mmol) in 30 ml of dichloromethane was added 60 mg (0.30 mmol) of L in 10 ml of dichloromethane, and the mixture was stirred for 20 min, affording a pink solution. The volume of the solvent was then reduced to one fifth under reduced pressure, and excess of n-hexane was added into it. It causes precipitation of the pink complex and the solution was then filtered. The pink product was collected by filtration and washed twice with diethyl ether. The mass was finally dried in vacuum over fused $CaCl_2$. The pink mass is unstable on silica gel column and can not be isolated by chromatography. Yield: 111 mg (88%). *Anal.* Calc. for $C_{12}H_{11}Cl_3N_3ORe$: C, 28.56; H, 2.18; N, 8.33. Found: C, 28.49; H, 2.24; N, 8.26. IR (cm^{-1}): 320, 335 (Re–Cl), 1595 (C=N), 998 (Re≡O).

4.3. X-ray crystallography

Dark violet single crystals of **1d** were obtained by slow diffusion of solvent pair (dichloromethane/hexane) at room temperature. Data were collected at $T = 293(2)$ K on a Siemens SMART CCD area-detector diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å, rotating anode source) in the range $1.88° = \theta = 30.55°$. All the data were corrected for Lorentz polarization and absorption [43]. The structure was generated by direct methods using SHELXS-97 [44] followed by successive Fourier synthesis and refined by full matrix least squares based on F^2 with SHELXL-97 [45]. Anisotropic displacement parameters were assigned to all non-hydrogen atoms. Significant crystal data are listed in Table 6. The crystallographic data have been deposited to CCDC.

Supplementary data

CCDC 673975 contains the supplementary crystallographic data for **1d**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

An hydroxyl substituted hexa(phenoxy)cyclotriphosphazene (**3**) is reacted with hexachlorocyclotriphosphazene, $N_3P_3Cl_6$, octachlorocyclotetraphosphazene, $N_4P_4Cl_8$ and poly(dichlorophosphazene), $(Cl_2P{=}N)_n$, to give cyclic compounds (**4** and **5**) and a polymeric compound (**6**). The newly synthesised compounds have been fully characterised by elemental analysis, MALDI-TOF mass spectrometry, gel permeation chromatography (**6**), FT-IR, ^{1}H, ^{13}C and ^{31}P NMR spectroscopy. The thermal stability and fluorescence spectral properties of all these novel compounds have been investigated. It was found that the thermal stability and fluorescence spectral properties of cyclic compounds **4** and **5** are superior to those of compound **6**.

1. Introduction

Cyclic and polymeric phosphazenes are an important class of inorganic heterocyclic ring systems in basic and applied science [1,2]. They are usually prepared by nucleophilic substitution reactions of alkoxides, aryloxides or amines on halocyclophosphazenes or high polymers [3–5], and their physical and chemical properties can be tailored via the appropriate substituted groups on the phosphorus atoms [6]. The design of materials containing cyclotriphosphazenyl groups have attracted attention because of their special properties, such as thermal stability, catalytic properties, electrical conductivity, liquid crystal and biomedical activity [7–9]. The thermal stability and flame resistance of polyphosphazenes that bear aryloxy side groups are especially well documented, and aryloxyphosphazene polymers have been developed commercially as foams for electrical, heat, and sound insulation [10–12]. Cyclotriphosphazenes have also been investigated as flame retardant additives for organic polymers [13]. Compositions that contain cyclotriphosphazenes or polyphosphazenes with commercial polymers are relatively easy to prepare, and flame retardant poly(urethane) [14], poly(methylmethacrylate) [15], polystyrene [16] and various other polymers [17] have been produced in this way.

Luminescent compounds are attracting much current research interest because of their many applications, including emitting materials for organic light emitting diodes, light harvesting materials for photocatalysis and fluorescent sensors for organic or inorganic analysers [18]. Cyclophosphazenes serve many advantageous purposes for useful luminescent materials for electroluminescent devices. For example, substituted cyclic phosphazenes are very stable and do not breakdown under very aggressive chemical conditions. Also the functional groups are projected above and below the cyclophosphazene plane and thus produce a rigid spherical core from which to grow the dendrons of interest. Therefore there has been considerable interest, recently, in fluorescent compounds based on cyclic phosphazene cores [19] or cyclolinear polymers with cyclotriphosphazene units [20] for the development of electroluminescent devices.

In phosphazene chemistry, there are many examples of organic or inorganic side group bearing cyclophosphazenes or polyphosphazenes [3–5]. However, there are limited examples of cyclophosphazenes and polyphosphazenes [21,22] or organic polymers [23,24] that bear an organic group substituted cyclophosphazene ring as the side group. Hence, we report the synthesis and characterisation of cyclophophazenes and polyphosphazene bearing hexaphenoxycyclotriphosphazenenyl groups, shown in Fig. 1. The thermal stability and fluorescence spectral properties of the cyclophosphazene compounds **4** and **5** are compared with compound **6**. The fluorescence quantum yields and lifetimes of these compounds are also investigated.

2. Experimental

2.1. Materials

Hexachlorocyclotriphosphazene(trimer) and octachlorocyclotetraphosphazene (Otsuka Chemical Co., Ltd.) were purified by

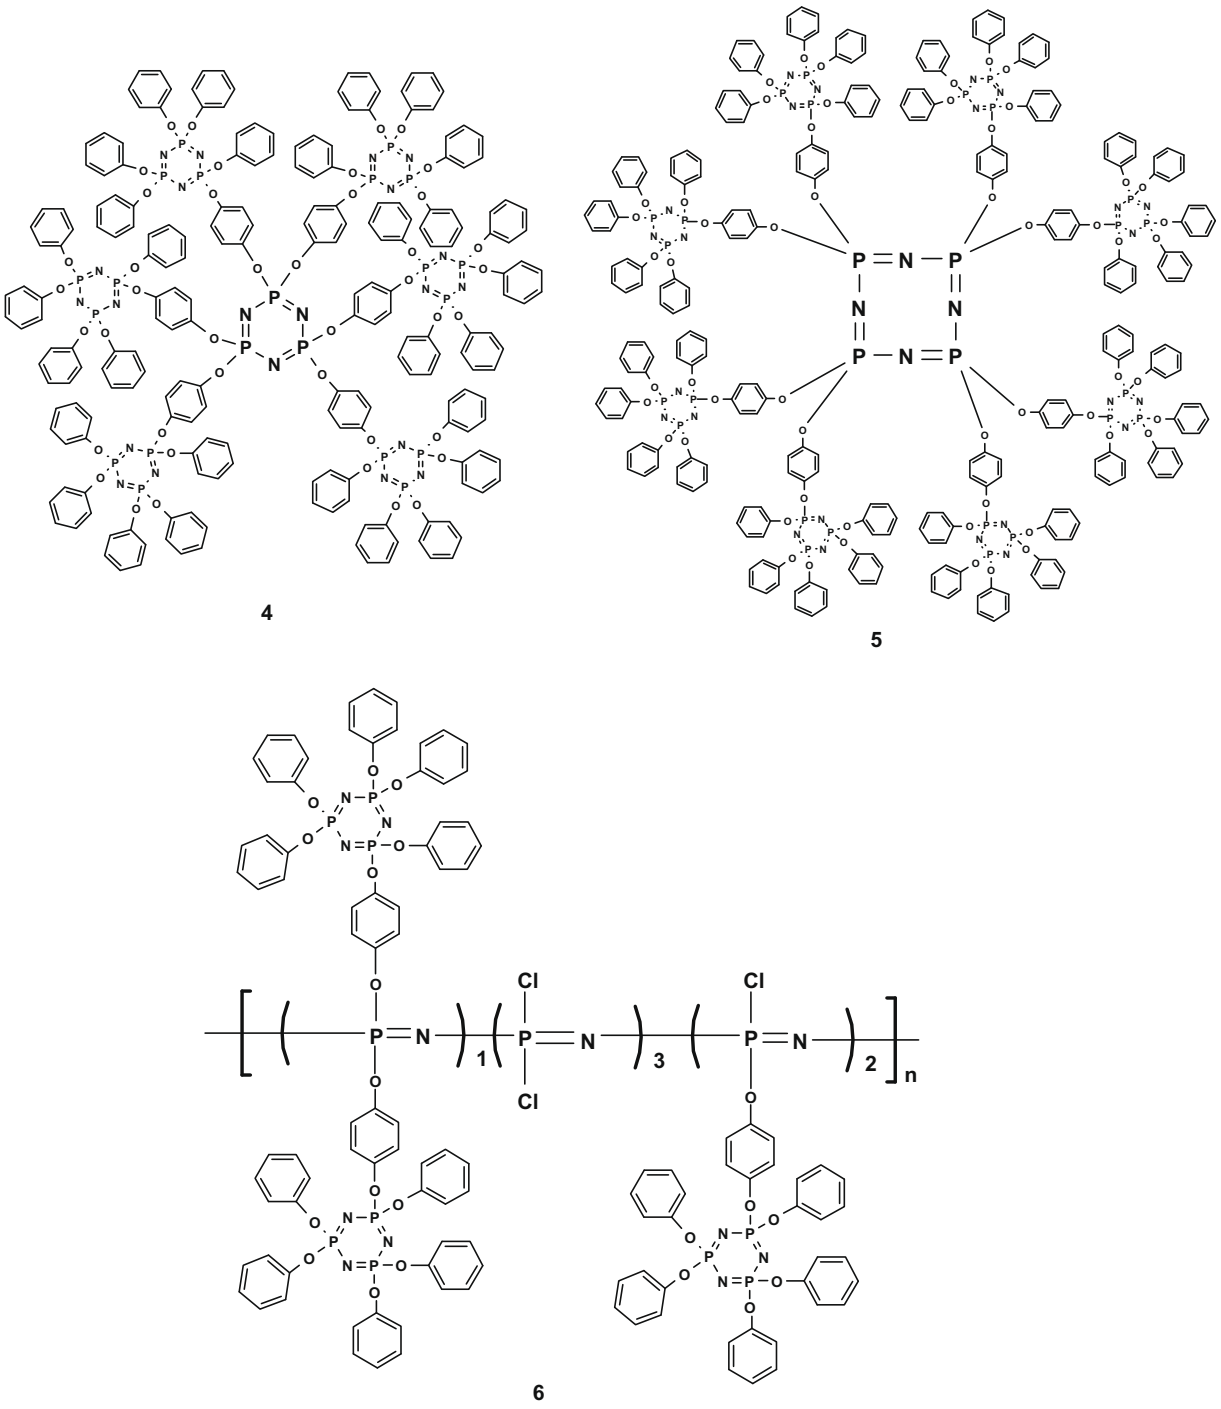

Fig. 1. Structures of the cyclic and polymeric phosphazenes **4–6**.

fractional crystallization from *n*-hexane. The crystallised hexachlorocyclotriphosphazene was further purified by vacuum sublimation before the ring opening polymerisation and only 60% of the material was allowed to be sublimed. The deuterated solvents ($CDCl_3$ and toluene) for NMR spectroscopy and the following chemicals were obtained from Merck: cyclohexene, ethanol, phenol, $Pd(OH)_2$, Cs_2CO_3, NaH, acetone, triethylamine, silica gel 60, tetrahydrofuran. 1,8,9-Anthracenetriol for the MALDI matrix was obtained from Fluka. All other reagents and solvents were reagent grade quality and obtained from commercial suppliers.

2.2. Equipment

Elemental analyses were carried out using a Thermo Finnigan Flash 1112 Instrument. UV/Vis spectra were recorded with a Shimadzu 2001 UV Pc spectrophotometer. Fluorescence excitation and emission spectra were recorded on a Varian Eclipse spectrofluoremeter using 1 cm pathlength cuvettes at room temperature. Infrared spectra were recorded on a Bio-Rad FTS 175C FT-IR spectrophotometer using KBr dyes. Mass spectra were acquired in linear modes with an average of 50 shots on a Bruker Daltonics Microflex mass spectrometer (Bremen, Germany) equipped with

a nitrogen UV–Laser operating at 337 nm. Gel permeation chromatography was performed with an Agilent 1100 series GPC system equipped with CHEMSTATION software with the addition of a GPC Add On to calculate the average molecular weights (*Mw* and *Mn*) against a polystyrene standard. The glove box (Plas Labs. 855-AC \ 220) was equiped with spectrograde N_2. Analytical thin layer chromatography (TLC) was performed on silica gel plates (Merck, Kieselgel 60, 0.25 mm thickness) with F_{254} indicator. Column chromatography was performed on silica gel (Merck, Kieselgel 60, 230–400 mesh; for 3 g crude mixture, 100 g silica gel was used in a column of 3 cm in diameter and 60 cm in length) and preparative thin layer chromatography was performed on silica gel 60 P F_{254}. ^{1}H, ^{13}C and ^{31}P NMR spectra were recorded in $CDCl_3$ and toluene-d_7 solutions on a Varian 500 MHz spectrometer. Thermal properties of compounds were investigated on a Mettler Toledo TGA/SDTA 851 Thermogravimetric Analysis (TGA) and Differential Scanning Calorimeter DSC 821^e (DSC) equipped with METTLER TOLEDO STAR^e software at a heating rate of 10 °C min^{-1} under nitrogen flow (50 ml min^{-1}).

2.3. Fluorescence quantum yields and lifetimes

Fluorescence quantum yields (Φ_F) were determined by the comparative method (Eq. (1)) [25],

$$\Phi_F = \Phi_F(\mathrm{Std})\frac{F.A_{\mathrm{Std}}.\eta^2}{F_{\mathrm{Std}}.A.\eta^2_{\mathrm{Std}}} \quad (1)$$

where F and F_{Std} are the areas under the fluorescence emission curves of the samples (**4**, **5** and **6**) and the standard, respectively. A and A_{Std} are the respective absorbance of the samples and standard at the excitation wavelengths, respectively. The refractive indices of the solvents were employed in calculating the fluorescence quantum yields in different solvents. 2-Aminopyridine (in 0.1 M H_2SO_4) ($\Phi_F = 0.60$) [26] was employed as the standard. Both the samples and standard were excited at the same wavelength. The molar concentration of compound **6** was calculated on the basis of the molecular mass of the repeating unit. The concentration of the solutions at the excitation wavelength was fixed at 1×10^{-5} mol dm^{-3}. Natural radiative (τ_0) life times were determined using the PHOTOCHEMCAD program which uses the Strickler–Berg equation [27]. The fluorescence lifetimes (τ_F) were evaluated using Eq. (2).

$$\Phi_F = \frac{\tau_F}{\tau_0} \quad (2)$$

2.4. Synthesis

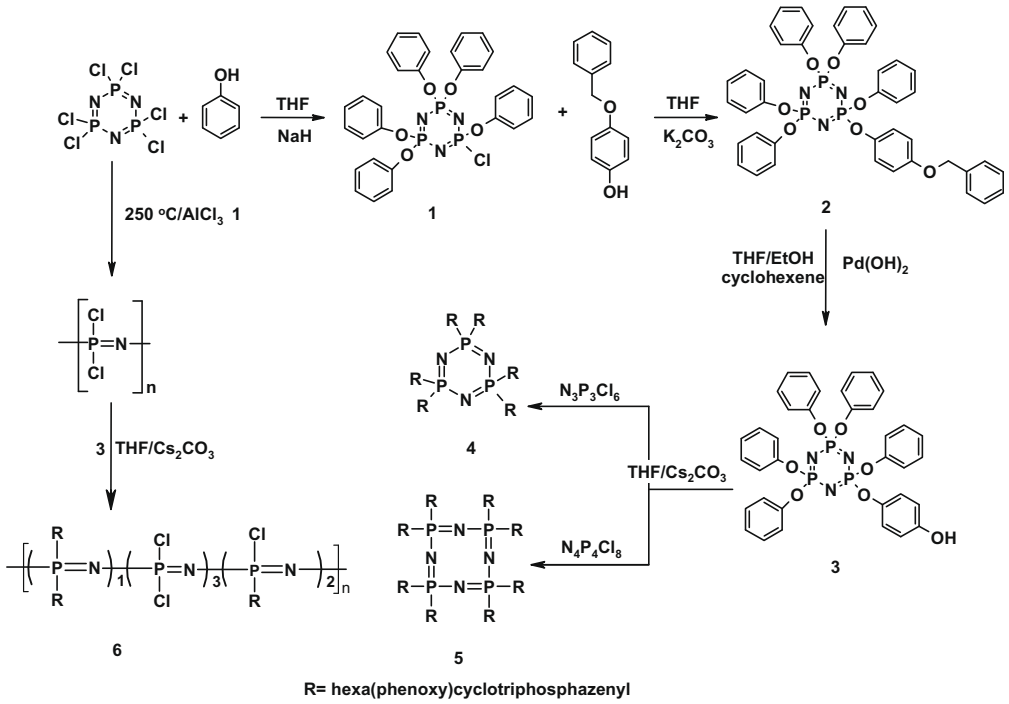
The 1,1,3,3,5-pentaphenoxy-5-chlorocyclotriphosphazatriene (**1**) [28], compounds (**2**, **3**) [29] and poly(dichlorophosphazene) [30] were prepared and purified according to the literature procedures.

2.5. Synthesis of compound *4*

The trimer $N_3P_3Cl_6$ (0.048 g, 0.141 mmol) and compound **3** (0.60 g, 0.84 mmol) were dissolved in dry THF (10 ml) under an argon atmosphere. After stirring for 15 min. at 40 °C, dry and finely powdered caesium carbonate (0.291 g, 0.9 mmol) was added portionwise over 15 min. with efficient stirring. The reaction mixture was stirred under an argon atmosphere at 80 °C for 24 h. The reaction mixture filtered, the volatile materials were evaporated under vacuum and the product was purified by preparative TLC on silica gel using hexane: THF (1:1) as the eluent. Compound **4** is a highly viscous oil; Yield: 0.351 g (57%). (*Anal.* Calc. for $C_{216}H_{174}N_{21}O_{42}P_{21}$ (4386): C, 59.15; H, 4.00; N, 6.71. Found: C, 58.75; H, 4.08; N, 6.60%). ^{1}H NMR ($CDCl_3$) δ = 11.85–12.08 (m, 174H, ArCH). $\{^1H\}^{13}C$ NMR ($CDCl_3$) δ = 137.62 (ArC), 128.84 (ArCH), 127.95 (ArC), 125.07 (ArCH), 77.5 (ArCH). $\{^1H\}^{31}P$ NMR (toluene-d_7) δ = 10.41 [m, 4P, > $P(OPh)_2$, B_2], 10.77 [m,2P > P(OPh)(OPhO),A], 10.1[s,1P, >PR_2, C_3]; $^2J_{P,P}$ = 90.88 Hz. MS (MALDI-TOF) *m*/*z* (%):4387 (100) $[M+H]^+$.

2.6. Synthesis of compound *5*

Octachlorocyclotetraphosphazene(tetramer), $N_4P_4Cl_8$, (0.06 g, 0.126 mmol) and compound **3** (0.72 g, 1.02 mmol) were dissolved in dry THF (10 ml) under an argon atmosphere. After stirring for 15 min. at 40 °C, dry and finely powdered caesium carbonate (0.39 g, 1.2 mmol) was added portionwise over 30 min with efficient stirring. The reaction mixture was stirred under an argon atmosphere at 80 °C for 48 h. The reaction mixture was filtered, the volatile materials were evaporated under vacuum and the product was purified by preparative TLC on silica gel using hexane: THF (1:1) as the eluent. Compound **5** is a highly viscous oil; Yield: 0.324 g (44%). (Anal. Calc. for $C_{288}H_{232}N_{28}O_{56}P_{28}$ (5848): C, 59.15; H, 4.00; N, 6.71. Found: C, 59.25; H, 4.08; N, 6.61%). ^{1}H NMR ($CDCl_3$) δ = 6.68–7.29 (m, 232H, ArCH). $\{^1H\}^{13}C$ NMR ($CDCl_3$) δ = 147.50 (ArC), 136.01 (ArCH), 128.49 (ArC), 125.76 (ArCH), 121.13 (ArCH). $\{^1H\}^{31}P$ NMR (toluene-d_7) δ = 9.83 [m,4P, >$P(OPh)_2$,B_2], 10.11 [m,2P, >P(OPh)(OPhO),A], −11.21[s,1P, >PR_2,X_4]; $^2J_{P,P}$ = 89.78 Hz. MS (MALDI-TOF) *m*/*z* (%):5849 (100) $[M+H]^+$.



2.7. Synthesis of compound *6*

Compound **3** (0.7 g, 1 mmol) was added to a THF solution of poly(dichlorophosphazene) [38 mg, 0.32 mmol (based on $NPCl_2$)] in 7 ml THF, under a nitrogen atmosphere. Then dry and finely powdered caesium carbonate (0.27 g, 1.27 mmol) was added quickly to the reaction mixture with efficient stirring, as an HCl acceptor. The reaction mixture was stirred under a nitrogen atmosphere at room temperature for 24 h and then refluxed for 7 days. The reaction mixture was then cooled to room temperature and poured into concentrated HCl (10 ml). The soluble materials were filtered off and the remaining polymer (**6**) was washed with water (2 × 100 ml) and ethanol (2 × 50 ml), and then dried in a vacuum oven for 8 h at 60 °C. Compound **6** is white amorphous material; Yield: 0.27 g (51%) (*Anal.* Calc. for $[C_{144}H_{116}Cl_8N_{18}O_{28}P_{18}]_n$: C, 51.05; H, 3.45; N, 7.44. Found: C, 50.67; H, 3.48; N, 7.41%). $\{^1H\}^{31}P$ NMR ($CDCl_3$) δ = 9.75 [br.s,∼12P, >$P(OPh)_2$ and >P(OPh)(OPhO)], −17.6 [br.s,∼3P, $Cl_2P{=}N$], −20.3 [br.s,∼2P, $RClP{=}N$],−20.8 [br.s,∼1P, $R_2P{=}N$] (GPC): $Mw = 4.95 \times 10^5$, $Mn = 1.56 \times 10^5$.

3. Results and discussion

3.1. Synthesis and characterisation

The synthetic route for the compounds presented in this work is shown in Scheme 1. Compound **1** was synthesised [28] by the reaction of phenol with trimer $N_3P_3Cl_6$, in the presence of NaH in THF. Compound **1** was reacted with 4-benzyloxyphenol in the presence of K_2CO_3 in THF to obtain compound **2**. The 4-benzyloxyphenoxy unit of compound **2** was converted to a 4-hydroxyphenoxy group with cyclohexene in a mixture of THF/ethanol, in the presence of $Pd(OH)_2$ as a catalyst to give compound **3** in good yield (90%), as reported in our earlier work [29]. Compounds **4** and **5** were obtained from nucleophilic displacement reactions of **3** with $N_3P_3Cl_6$ or $N_4P_4Cl_8$ under an argon atmosphere with caesium carbonate as the base. The products were purified by preparative TLC on silica gel using hexane:THF (1:1) as the eluent. The conventional methods

Scheme 1. Chemical structure and synthetic pathway of **1–6**.

[31,32] of thermal ring opening polymerisation of the trimer yields a high molecular weight (>l0^6) polymer, but for subsequent substitution reactions careful purification procedures are required to remove the unreacted trimer and partially crosslinked polymer. Sohn and coworkers described another ring opening polymerisation method of the trimer which gives relatively lower molecular weight (10^4–10^5) poly(dichlorophosphazene) with almost quantitative yield, and can be used without purification for subsequent substitution reactions [30]. Thus poly(dichlorophosphazene) was prepared via the ring opening polymerisation of the trimer in a sealed tube at 250 °C in the presence of $AlCl_3$ as a catalyst, as described in the literature procedure [30]. The average molecular weight of the prepared poly(dichlorophospazene) was 1.02×10^5, and the polydispersity index was 3.38, as determined by GPC {^{31}P NMR($CDCl_3$) $\delta = -17.6$ [s,1P,($Cl_2P{=}N$)]} and the total impurities, including starting material (trimer), tetramer and other oligomers, was less than 3%. Thus compound **3** was added a THF solution of poly(dichlorophosphazene) under a nitrogen atmosphere in a glove box with caesium carbonate, which was used as the base.

The new compounds were characterised by FT-IR, ^{1}H, ^{13}C and ^{31}P NMR, mass spectrometry and elemental analysis. All the results were consistent with the predicted structures, as shown in the experimental section. The FT-IR spectra feature peaks at around 1200 cm^{-1} (br) (P═N), 960 cm^{-1} (P–O) for a phosphazene ring and aromatic C–H stretching around 3200–3400 cm^{-1}, as expected [33]. The elemental analysis results and the mass spectral data for the newly synthesised cyclic compounds **4** and **5** were consistent with the assigned formulations. The mass spectra of these compounds were obtained by MALDI-TOF spectrometry. Many different MALDI matrices were investigated to find intense molecular ion peaks and low fragmentation. 1,8,9-Anthracenetriol MALDI matrix yielded the best MALDI-MS spectra. The MS spectra of **4** and **5** provided definitive characterisation. The peak group representing the protonated molecular ion of the **4** was observed at 4387 Da (Fig. 3s a) and the protonated molecular ion peak were observed at 5849 Da for **5** (Fig. 3s b). The average molecular weight and polydispersity index (PDI) of the polymer (**6**), determined by gel permeation chromatography, was 4.95×10^5 and 3.17, respectively. This large PDI value of compound (**6**) was an expected result because it originated from the preparation method of the starting polymer (PDI: 3.38). In particular, ^{31}P NMR spectra of **4** and **5** were analysed in two different spin systems as $(AB_2)_6C_3$ and $(AB_2)_8X_4$. The proton-decoupled ^{31}P NMR spectrum of **4** has the expected AB_2 and C_3 spin system parts, shown in Fig. 2. The resonances belonging to phenoxy substituted phosphorous atoms for the AB_2 pattern were observed at ca. 10.41 ppm for >P(OPh)$_2$ and at ca. 10.77 ppm for >P(OPh)(OPhOX) (X = trimer core). The resonance belonging to the trimer core phosphorus at ca. 10.1 ppm is observed in a C_3 spin system, yielding a single peak as expected. The proton-decoupled ^{31}P NMR spectrum of **5** has the expected AB_2 and X_4 spin system parts shown in Fig. 3. The resonances belonging to the phenoxy substituted phosphorous atoms for the AB_2 pattern were observed at ca. 9.83 ppm for >P(OPh)$_2$ and at ca. 10.11 ppm for >P(OPh)(OPhOX) (X = tetramer core). The resonance belonging to the tetramer core phosphorus at −11.21 ppm was observed in a X_4 spin system, yielding a single peak as expected [34]. The magnitude of $^2J_{(PP)}$ for the cyclic compounds **4**

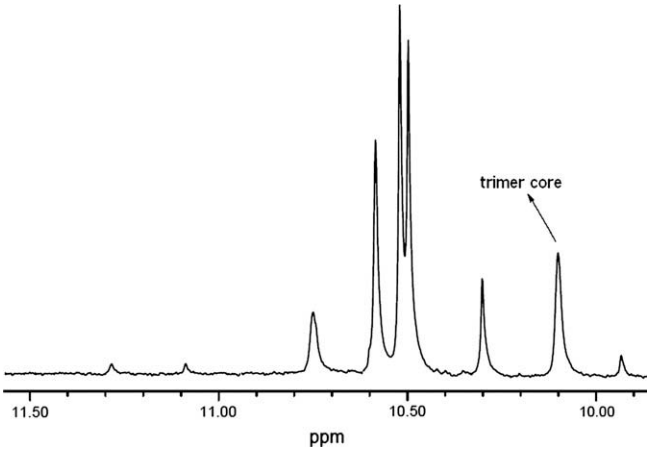


Fig. 2. Proton-decoupled ^{31}P NMR spectrum of **4** in toluene-d_7 solution.

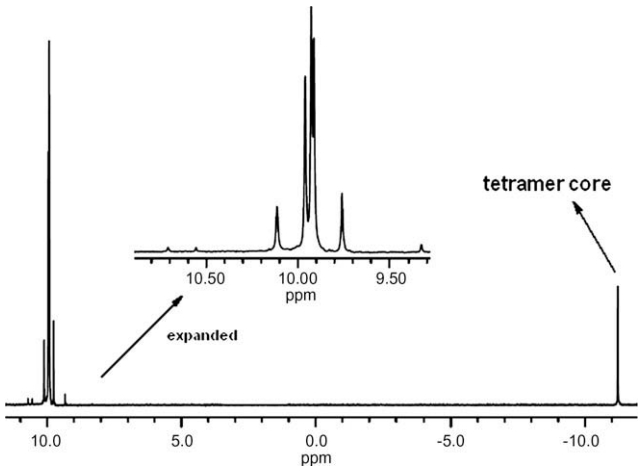

Fig. 3. Proton-decoupled ^{31}P NMR spectrum of **5** in toluene-d_7 solution.

and **5** have very similar coupling constants, 90.88 and 89.78 Hz, respectively. The integration of the AB_2 part to the remaining singlet of the proton-decoupled ^{31}P NMR spectra of cyclic compounds **4** and **5** gave a 6:1 phosphorus ratio that confirms the suggested structures. The structural characterisation of compound **6** was determined by ^{31}P NMR spectroscopy. The progress of the reaction was investigated by the removal of small aliquots and diluting them approximately one to one with deuterated chloroform. The ^{31}P NMR results are given in the Supplementary information in Fig. 1s. In the reaction of poly(dichlorophosphazene) with compound **3** there are three possible species, $NPCl_2$, NPClR and NPR_2 belong to the macromolecular phosphazene chain. The narrow singlet of poly(dichlorophosphazene) at −17.6 ppm broadens at the start of the reaction (Fig. 1s a and b). Approximately at −20.3 ppm there is a broad resonance that has been assigned to NPClR, that appears after 5 h room temperature reaction. After 24 h reaction at room temperature, the results are similar to the previous ^{31}P NMR spectrum, which is shown in Fig. 1s b. The reaction continued on refluxing and a broad resonance at approximately −20.8 ppm appeared after 1 h, which has been assigned to NPR_2 (Fig. 1s). On further reflux of up to 5 h, the intensities of the broad resonances at −17.6 and −20.3 ppm decrease whilst the intensity of the broad resonance at −20.8 ppm increases (Fig. 1s c and d). On the other hand, there is a broad singlet which belongs to the side units, at approximately 9.6 ppm, which shows increasing intensity with the reaction progress (Fig. 1s b–d). Further refluxing up to 7 days did not change the results and the ^{31}P NMR spectrum is similar to Fig. 1s d. The ^{31}P NMR spectrum of the isolated polymer (**6**) after 7 days reflux is given in Fig. 2s. The ^{31}P NMR spectrum of compound **6** (Fig. 2s) shows four groups of peaks; a broad singlet at 9.75 ppm belonging to the phosphorus atoms of the side unit, as expected, and an additional three broad peaks at −17.6 ($Cl_2P{=}N$), −20.3 (RClP=N) and −20.8 ppm ($R_2P{=}N$), belonging to the phosphorus atoms of the macromolecular polymer chain. The integration of the proton-decoupled ^{31}P NMR spectrum of the isolated polymer (Fig. 2s) gave approximately a 12:3:2:1 phosphorus ratio. Thus the repeating unit of compound **6** was suggested to be $[(NP(OR)_2)_1(NPORCl)_2(NPCl_2)_3]_n$.

3.2. Thermal properties

The glass transition temperatures (T_g) of all the compounds were clearly detected by differential scanning calorimetry (DSC) from −40 to 100 °C with a heating rate of 10 °C/min under nitrogen flow. The T_g of all the new phosphazene compounds (**4–6**) are represented in Table 1 and the DSC thermograms are given in the Supplementary information in Fig. 4s.

Table 1
Thermal properties and molecular weights of **4**, **5** and **6**.

Compound	T_g (°C)	T_d (°C)	*Mw*	*Mn*	Char yield (%)
4	26.2	422	4387	4387	33.3
5	24.5	445	5849	5849	64.6
6[a]	28.7	396	4.95×10^5	1.56×10^5	59.8

[a] Molecular weight determined by GPC.

Phosphazenes are attractive compounds due to their higher thermal stability and flame retardancy properties when compared to their organic homologues. Owing to the excellent thermal stability and char yield performance, aryloxy substituted polyphosphazene has attracted interest for its potential application in flame retardants [35]. For such reasons we have investigated the thermal stability of the compounds **4** and **5**, and compared the results with polymer **6** by determining the weight loss of a sample upon linearly increasing the temperature by conventional TGA at 10 °C/min up to 700 °C under nitrogen flow. According to the TGA thermograms of compounds **4–6** (Fig. 5s), they exhibit very good thermal stability with decomposition temperatures (T_d) in the range 396–445 °C (see Table 1). The decomposition onset temperatures (T_{on}) of compounds **4**,**5** and polymer **6** are 396, 423 and 347 °C, and the char yields reaches 33.3%, 64.6% and 59.8% at 700 °C, respectively. The increase of T_d from compound **4** to **5** can be explained by the increasing substitution degree of the cyclophosphazene chain. However, the partially substituted polymer **6** has a lower T_d (396 °C) when compared with **4** and **5**. This is an expected result with the depolymerisation effect of the unsubstituted P–Cl groups on the polymer chain overriding the thermal stability [36]. On the other hand, polyaryloxyphosphazenes always contains unreacted chlorine atoms based on the rigidity and the steric hindrance of the aryloxy nucleophiles. Therefore, if they are used as a flame retardant, poisonous gases are released, which limits their further application [36]. Therefore aryloxycyclophosphazenes are more useful candidates for flame retardant additives to organic polymers [35]. As a result, the high char yields and T_d values of these novel phosphazene compounds (**4**, **5**) make them good flame retardants in theory [37], and we can clearly say that the cyclic derivatives **4** and **5** have excellent thermal properties because of their high purity against the polymeric analogue **6**.

3.3. Ground state electronic absorption and fluorescence spectra

The absorption and fluorescence spectra of the phosphazene derivatives were measured in dichloromethane with dilute solutions of 1×10^{-5} mol dm^{-3} upon excitation at 260 nm. Absorption bands were observed for compounds **4** and **5** at 260 and 270 nm, and 230, 260 and 270 nm for polymer **6** (Fig. 4). The trend in absorption maximum amongst the phosphazene compounds is polymeric phosphazene derivative (**6**) > tetrameric core phosphazene derivative (**5**) > trimeric core phosphazene derivative (**4**), according to the number of phenol groups (Fig. 4). Fig. 5 shows the fluorescence emission spectra for the studied phosphazene compounds. Fluorescence emission peaks were observed at around 298 nm for all the compounds in dichloromethane. The cyclic phosphazene derivatives (**4** and **5**) showed higher fluorescence emission behaviour than the polymeric phosphazene derivative (**6**). When comparing between the cyclicphosphazenes, the tetrameric core phosphazene compound (**5**) showed higher fluorescence emission than the trimeric core phosphazene compound (**4**). Fig. 5 indicates that the cyclic phosphazenes compounds (**4**, **5**) are more fluorescent than the polymeric analogue (**6**). In contrast to the absorption spectra, the fluorescence emission is

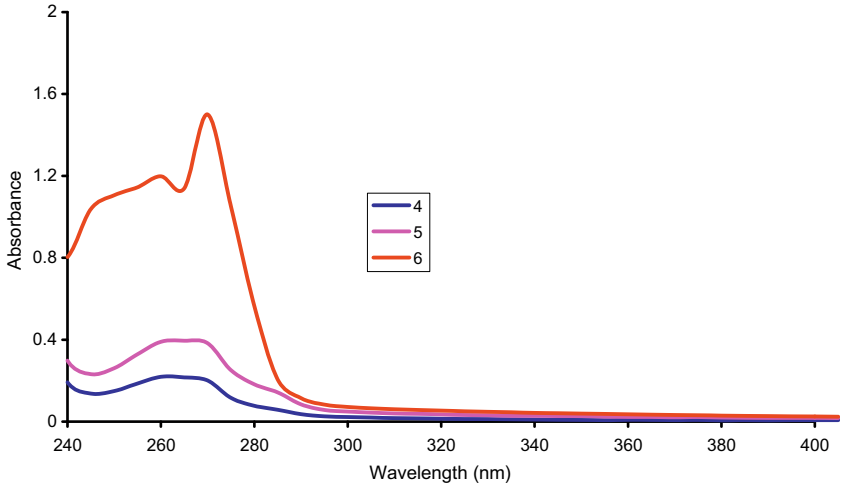

Fig. 4. The absorption spectra of **4**, **5** and **6** in dichloromethane. Concentration: 1×10^{-5} mol dm^{-3}.

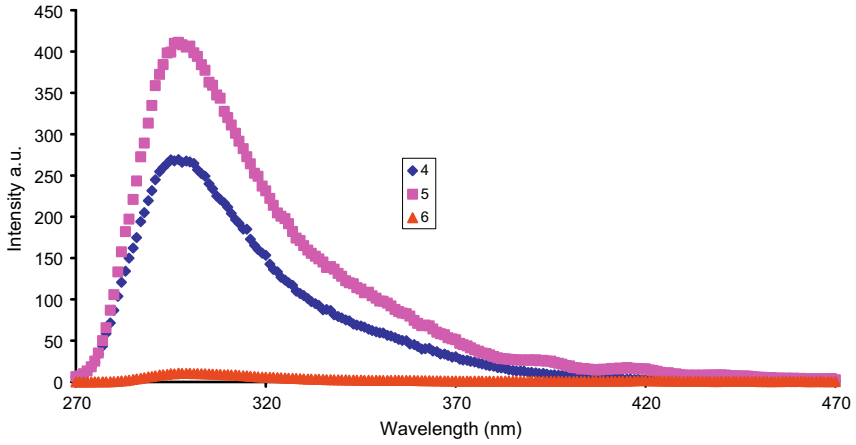

Fig. 5. The fluorescence emission spectra of **4**, **5** and **6** in dichloromethane. Concentration: 1×10^{-5} mol dm^{-3}. Excitation wavelength: 260 nm.

not related to the number of the phenol groups. We suggest that the arrangement of substituents is more effective than the number of substituents for the fluorescence emission behaviour of these compounds. This can be explained by non-covalent π–π interactions between the phenol groups. Crystal structure analysis of hexaphenoxycyclotriphosphazene has shown [38] that the six phenoxy groups reach almost perpendicularly above and below the nearly planar cyclotriphosphazene core. This structural features make it possible for the three phenoxy groups to be located on the same side of the $(PN)_3$ plane and the centroid–centroid distance of two phenyl groups are very close to the normal π–π stacking contact. This type of non-covalent π–π interaction can explain the higher fluorescence behaviour of the cyclic phosphazene compounds when compared to a polymeric phosphazene compound which is substituted with the same group. It can also support that the partially (unsubstituted PCl_2 groups on the polymer chain) substituted polymer **6** has reduced non-covalent π–π interactions. According to these results, the cyclic phosphazenes are more suitable candidates than the polymeric analogues for some applications such as organic light emitting devices.

3.4. Fluorescence quantum yields and lifetimes

The fluorescence quantum yields (Φ_F) of the phosphazene derivatives were measured in dichloromethane, and 2-aminopyridine in 0.1 M H_2SO_4 solution was used as the standard. The refractive indexes of the solvents were used for calculations of Φ_F. All the compounds were excited at 260 nm. The fluorescence quantum yield values are: 0.16 for **4**, 0.18 for **5** and 0.00033 for **6** in dichloromethane. The cyclic phosphazene derivatives (**4** and **5**) showed approximately 500 times larger Φ_F values than the polymeric phosphazene derivative (**6**). When we made a comparison between the cyclic phosphazenes, the tetrameric core phosphazene compound (**5**) showed a slightly higher fluorescence quantum yield than the trimeric core phosphazene compound (**4**). It can be explained that the non-covalent π–π interactions between the aryloxy groups on the cyclophosphazene core compounds have caused the higher fluorescence quantum yield values of the cyclophosphazene core compounds when compared to the polymeric phosphazene compound. The fluorescence lifetime refers to the average time a molecule stays in its excited state before fluorescing, and its value is directly related to that of Φ_F; i.e. the longer the lifetime, the higher the quantum yield of fluorescence. Any factor that shortens the fluorescence lifetime of a fluorophore indirectly reduces the value of Φ_F. Such factors include internal conversion and intersystem crossing. As a result, the nature and the environment of a fluorophore determine its fluorescence lifetime. The fluorescence lifetimes (τ_F) of phosphazene compounds were calculated using the Strickler–Berg equation [26]. A good correlation has been found between the experimental and the theoretically determined lifetimes for the unaggregated molecules [39]. Thus, we suggest that the values obtained using this equation

are an appropriate measure of the fluorescence lifetimes. The fluorescence lifetime (τ_F) values are: 0.14 ns for **4**, 0.32 ns for **5** and 0.00003 ns for **6** in dichloromethane. The τ_F values for the cyclic-phosphazene derivatives (**4** and **5**) are approximately 10000 times larger than the polymeric phosphazene derivative (**6**). A comparison between the cyclophosphazenes **4** and **5** shows the tetrameric core phosphazene compound (**5**) has a longer fluorescence lifetime value (τ_F) than the trimeric cored phosphazene compound (**4**) in dichloromethane. The rate constants for the fluorescence (k_F) and radiative lifetime (τ_0) were also measured for the synthesised phosphazene compounds in this study. The rate constants for fluorescence (k_F) values are: 1.11×10^9 for **4**, 0.57×10^9 for **5** and 12.0×10^9 for **6**, and the radiative lifetime (τ_0) values are: 0.89 ns for **4**, 1.76 ns for **5** and 0.083 ns for **6** in dichloromethane. The cyclophosphazene compounds **4** and **5** showed lower the rate constants for fluorescence (k_F) and showed longer radiative lifetime (τ_0) values when compared to the polymeric phosphazene derivative (**6**).

4. Conclusion

In summary, we have synthesised novel hexa(phenoxy)cyclotriphosphazenyl substituted cyclic and polymeric phosphazene compounds (**4–6**) for the first time. All the compounds were fully characterised by standard spectroscopic techniques. The thermal stability and fluorescence spectral properties of all the compounds were investigated. It was found that compounds **4** and **5** have higher thermal stability and fluorescence behaviour when compared with the polymeric phosphazene analogue (**6**). We suggest that the non-covalent π–π interactions between the phenoxy groups have resulted in the higher fluorescence behaviour of the cyclic phosphazene compounds when compared to the polymeric phosphazene compound. Thus, it can be suggested that cyclic phosphazenes are more suitable candidates than the polymeric analogue for some industrial applications such as flame retardant additives to polymers or light emitting electroluminescent devices.

ABSTRACT

The synthesis of a Mo(VI) Schiff base complex, *cis*-[MoO_2{(4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}-phenolate)$_2$}], *cis*-[$MoO_2(L)_2$] where L = 4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}phenol, derived from benzylamine and 3,5-di-*tert*-butylsalycilaldehyde is reported. Full characterization of this complex was accomplished with elemental analyses, spectroscopic studies (NMR, IR and electronic) and X-ray structure analysis. This complex was tested as a catalyst for the homogeneous oxidation of olefins. The Mo(VI) complex is catalytically active for the epoxidation of aliphatic substrates at 80 °C, yielding the epoxide as the sole product in yields up to 100% and turnover numbers up to 5000. Under the optimized conditions styrene was oxidized in an 81% conversion to produce styrene oxide, benzaldehyde, and acetophenone.

1. Introduction

As molybdenum is widely available to biological systems, the coordination chemistry of Mo(VI) has aroused considerable interest in view of its biochemical significance [1–4]. Apart from nitrogenases, where molybdenum can be a component of the multinuclear active sites [5], there are a number of mononuclear molybdenum enzymes that are often referred to as oxomolybdenum enzymes [2,3]. The latter can be divided into two groups: enzymes from the first group catalyze the oxidative hydroxylation of aldehydes and aromatic heterocycles in reactions that necessarily involve the cleavage of a C–H bond [2,3,6]. Mononuclear enzymes from the second group catalyze proper oxygen atom transfer reactions to or from an available electron lone pair of the substrates [7]. The present view of these enzymes indicates that the formal oxidation state of the molybdenum center cycles between 4+ and 6+ during the catalysis. The two-electron oxygen atom transfer seems to be the relevant mechanism in understanding the chemical role of enzymatic reactions. In order to mimic biological systems, a number of dioxomolybdenum complexes have been synthesized and characterized [8–27]. Molybdenum Schiff base complexes continue to serve as one of the most important models of molybdoenzymes due to their preparative accessibility [28–37].

Moreover, a broad variety of molybdenum complexes are highly active catalysts for olefin epoxidation in the homogeneous phase. Molybdenum catalysts are commercially applied to the production of propylene oxide using *tert*-butyl hydrogen peroxide (TBHP) as the oxidant [38]. TBHP as an oxidant has good thermal stability and is relatively easy to handle [38]. Furthermore, the by-product of the reaction, *tert*-butyl alcohol, is easy to separate by distillation and can be recycled or used for other industrial processes. This paper investigates the synthesis, spectral and structural characterization of a *cis*-dioxomolybdenum complex of a bidentate 4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}phenol Schiff base ligand. The oxo-transfer reaction from *cis*-[$MoO_2(L)_2$] to olefins is also reported.

2. Experimental

2.1. Materials and instrumentations

All of the reagents were supplied by Merck and Fluka, and were employed without further purification. IR spectra were recorded on a Unicam Matson 1000 FT-IR paragon 1000 spectrophotometer. ^{1}H NMR spectra of the ligand and the complex were recorded on a Bruker FT-NMR 500 MHz spectrometer using $CDCl_3$ and $(CD_3)_2SO$ as solvents. The electronic spectra were recorded on a CARY 100 Bio UV–Vis spectrophotometer. Elemental analyses (C, H and N) were performed using a Heraeus Elemental Analyzer CHN–O-Rapid (Elementar-Analysensysteme, GmbH).

2.2. Synthesis of cis-[MoO_2(4,6-bis(tert-butyl)-2-{(benzyl)iminomethyl}phenolate)$_2$], cis-[$MoO_2(L)_2$]

To a solution of 3,5-di-*tert*-butylsalicyldehyde [39] (1 mmol) in 25 mL methanol was added a solution of 1 mmol benzylamine in 15 mL methanol, and the reaction mixture was heated at reflux for 1 h. Then a methanolic solution of 0.5 mmol of $MoO_2(acac)_2$ [40] (15 mL) was added dropwise under stirring. The solution color changed to deep yellow and after 5 min yellow crystals of *cis*-[MoO_2(4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}phenolate)$_2$] started to precipitate. After the reflux was continued for 30 min, the product was filtered and washed with methanol (82% yield). X-ray quality crystals were obtained after recrystallization from a ethanol:chloroform (1:1) solvent mixture. Elemental *Anal.* Calc. for *cis*-[$MoO_2(L)_2$] ($C_{44}H_{56}MoN_2O_4$, FW = 772.85): C, 68.38; H, 7.30; N, 3.62. Found: C, 68.40; H, 7.31; N, 3.60%. Selected IR frequencies (KBr disk, cm^{-1}): 1622 (C=N), 1560, 1454, 1437, 1392, 1358, 1269, 1247. Electronic absorption spectrum in CH_3OH λ (nm) ($\varepsilon(M^{-1}\,cm^{-1})$): 342 (21122), 267 (76281), 240 (90424). ^1H NMR (500 MHz, DMSO-d_6, δ): 1.35 (s, 18H), 1.44 (s, 18H), 4.52 (d, 2H), 4.92 (d, 2H), 7.08 (m, 6H), 7.27 (m, 6H), 7.59 (d, 2H), 8.05 (s, 2H).

2.3. Single crystal X-ray diffraction

The crystal data of the title compound and the parameters of data collection are summarized in Table 1. A yellow transparent crystal was selected under ambient conditions. The crystal was mounted and centered in the X-ray beam using a video camera. The crystal evaluation and data collection were performed at 173 K on a Bruker CCD-1000 diffractometer with Mo Kα (λ = 0.71073 Å) radiation and a detector to crystal distance of 5.03 cm. The initial cell constants were obtained from three series of ω scans at different starting angles. Each series consisted of 30 frames collected at intervals of 0.3° in a 10° range about ω with an exposure time of 20 s per frame. The obtained reflections were successfully indexed by an automated indexing routine built in the SMART program. The final cell constants were calculated from a set of strong reflections from the actual data collection.

The data were collected using the full sphere routine by collecting four sets of frames with 0.3° scans in ω with an exposure time 20 s per frame. This dataset was corrected for Lorentz and polarization effects. The absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements [41] using SADABS software [42]. The systematic absences in the diffraction data were consistent for the space group *C2/c* [42], and yielded chemically reasonable and computationally stable results of refinement. The positions of almost all the non-hydrogen atoms were found by direct methods. The remaining atoms were located in an alternating series of least-squares cycles and difference Fourier maps. All non-hydrogen atoms were refined in full-matrix anisotropic approximation. All hydrogen atoms were placed in the structure factor calculation at idealized positions and were allowed to ride on the neighboring atoms with relative isotropic displacement coefficients. The ORTEP diagram was drawn at the 50% probability level. Hydrogen atoms were omitted for clarity. The resulting CIF file has been tested with PLATON [43] software.

2.4. Catalytic experiments

In a typical catalytic experiment, TBHP (1 mmol) was added to a solution of olefin (1 mmol), chlorobenzene (1 mmol) as an internal standard and *cis*-[$MoO_2(L)_2$] (2×10^{-4} mmol) in 1,2-dichloroethane (0.5 mL). The mixture was stirred at 80 °C under air and the course of the reaction was monitored using gas chromatography (Agilent Technologies Instruments 6890N, equipped with a capillary column (19019J-413 HP-5, 5% Phenyl Methyl Siloxane, Capillary 60.0 m × 250 μm × 1.00 μm) and a flame ionization detector). Assignments of products were made by comparison with authentic samples. All the reactions were run at least in duplicate.

3. Results and discussion

3.1. Crystal structure of cis-[$MoO_2(L)_2$]

The molecular structure of *cis*-[$MoO_2(L)_2$], crystal data and structure refinement are shown in Fig. 1 and Table 1, respectively. The selected bond distances and angles that are reported in Table 2 are in a good accord with those previously observed in analogous complexes with the MoO_2 moiety [16,18,44]. Like many other dioxomolybdenum(VI) complexes with nitrogen-donor-containing

bidentate ligands, this compound adopts a distorted octahedral geometry with the N atoms trans to the terminal oxo groups [16,18,44]. In the complex each of the Schiff base ligands behaves in a monoanionic bidentate manner, bonded to the *cis*-MoO_2^{2+} ion through the phenolic oxygen atom and an imine nitrogen atom. The O–Mo–O angle is significantly larger than 90°, which is expected due to a larger repulsion between oxygen atoms with short Mo–O bonds [16,31,37,45,46]. The O=Mo=O angle (107.65(12) Å) for *cis*-[MoO_2(L)$_2$] is typical for *cis*-dioxomolybdenum(VI) complexes [31,37,45,46]. The Mo=O distances are also as short as 1.7030(18) Å, as commonly observed for terminal oxygen atoms. These bonds are of double-bond character.

3.2. Catalytic oxidation of olefins

The catalytic performance of *cis*-[MoO_2(L)$_2$] was first studied in the homogeneous epoxidation of cyclooctene, used as a model substrate, and *tert*-butyl hydrogen peroxide as the oxygen donor. In a series of control experiments we evaluated the influence of several solvents. Epoxide conversion was found to be dependent on the solvent. For the given solvents in Table 3, benzene, toluene and 1,2-dichloroethane (DCE) produce the highest yields and the catalytic activity is the best when DCE is used as the solvent (100% conversion). With molar ratios of 1:5000:5000 for catalyst:substrate:oxidant at 80 °C as the optimized condition, a turnover number (TON) of up to 5000 can be achieved.

In this study, an attempt was also made to investigate the effect of temperature. The temperature-dependent curves for the yield of cyclooctene oxide in Fig. 2 show the epoxide yield is very low at lower temperatures (30 °C). Catalytic reactions run at higher temperatures led to a significant increase in the product yield. For example, at 50 °C, the *cis*-[MoO_2(L)$_2$] complex shows a moderate activity, reaching cyclooctene oxide yields of 74% for 1 h reaction time (Fig. 2). However, the activity increases considerably with an increase in temperature, so that at 70 and 80 °C, yields of 89% and 100% can be obtained, respectively.

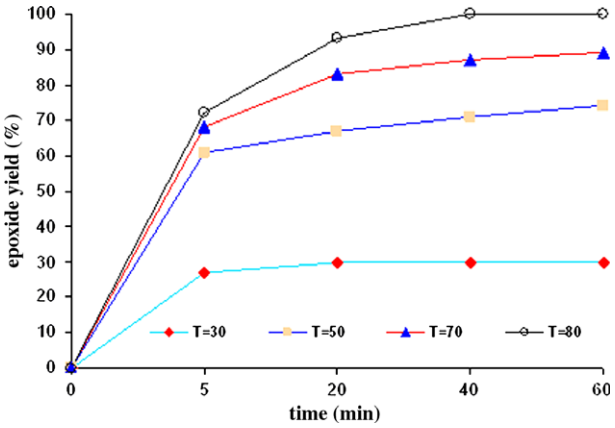

Fig. 2. Temperature effect on the epoxidation of cyclooctene with TBHP in the presence of *cis*-[MoO_2(L)$_2$].

This study was further extended to the catalytic epoxidation of several linear and cyclic olefins using *cis*-[MoO_2(L)$_2$] (Table 4). Generally the epoxide yields and selectivities were very good for aliphatic substrates, with the best epoxide yield and selectivity being obtained for cyclohexene in a short reaction time (Table 4, entry 1). The catalytic activity tends to decrease as the olefin becomes less electron rich, so that the lowest epoxide yields were obtained for styrene, α-methylstyrene and indene (Table 4, entries 10–12). Moreover, the present catalytic system was highly selective for the epoxide for all substrates except for styrene with benzaldehyde and acetophenone, and α-methylstyrene with acetophenone as side products. The relatively low activity for epoxidation of styrene, α-methylstyrene and indene does not seem to be caused by catalyst decomposition, since an increase in the reaction time for epoxidation of styrene leads to a significant increase in the conversion (Table 4, entry 10). It is worth pointing out that the *cis*-[MoO_2(L)$_2$] complex is quite stable under the oxidation reaction conditions. The significantly improved oxidation yield of styrene at higher reaction times can be good evidence for this stability (Table 4, entry 10).

In general, the mechanisms proposed for *t*-BuOOH-based epoxidation of olefins with Mo^{VI} complexes are heterolytic in nature, involving coordination of the oxidant to the metal center. The Lewis acidity of the Mo center increases the oxidizing power of the peroxo group and the olefin is subsequently deoxidized by nucleophilic attack on an electrophilic oxygen atom of the coordinated *tert*-butyl peroxide [47]. Spectroscopic and computational methods applied to molybdenum dioxo and oxodiperoxo complexes support a reaction mechanism involving an activation state formed between the complex, oxidant and olefin (Scheme 1) [48,49]. In this process, in higher conversions, the catalytic reaction may be prone to auto-retardation by coordination of the co-product *tert*-butanol to the molybdenum complex. *tert*-Butanol can compete with TBHP for coordination to the molybdenum center and form an inactive species that leads to the decreasing reaction rate [48]. Similarly, for complex *cis*-[MoO_2(L)$_2$], the initial reaction rates are much higher than those observed later in the reactions (Table 3 entries 5 and 9, and Fig. 3).

Previously, many systems have reported the oxidation of olefins by various transition metal complexes, such as Mn, V and Ru

Scheme 1. Proposed mechanism for epoxidation of cyclohexene with TBHP catalyzed by *cis*-[$MoO_2(L)_2$].

[50,51]. The complexes of these metals with Schiff base ligands have shown efficient catalytic activity for epoxidation, but the reaction times are usually long and are accompanied with low turnover numbers. Generally the present catalytic system, *cis*-[$MoO_2(L)_2$]/TBHP/DCE, has the following advantages in the oxidation of olefins: (i) reasonably low reaction time for the oxidation of aliphatic olefins, (ii) completely selective oxidation of aliphatic olefins to the corresponding epoxides, (iii) high turnover numbers of up to 5000, and (iv) easy preparation method of the catalyst.

4. Conclusions

The molybdenum complex, *cis*-[MoO_2(4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}phenolate)$_2$], was synthesized by the reaction of a bidentate Schiff base with $MoO_2(acac)_2$. This complex is employed as a novel catalyst for the epoxidation of alkenes with *tert*-butylhydroperoxide in DCE. In this study, we demonstrated that *cis*-[MoO_2(4,6-bis(*tert*-butyl)-2-{(benzyl)iminomethyl}phenolate)$_2$] promotes highly the catalytic epoxidation reaction associ-

ated with TBHP as the oxidant (epoxide yield and TON of up to 100% and 5000% respectively). Moreover, the epoxide yields show that the efficiency of the catalytic system is strongly dependent on the temperature, and the best yields were achieved at 80 °C.

Supplementary data

CCDC 675718 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

In this report, we present a simple wet chemical route to synthesize nano-sized silver particles, and their surface properties are discussed in detail. Silver nano particles of the size 40–80 nm are formed in the process of oxidation of glucose to gluconic acid by amine in the presence of silver nitrate, and the gluconic acid caps the nano silver particle. The presence of gluconic acid on the surface of nano silver particles was confirmed by XPS and FTIR studies. As the nano silver particle is encapsulated by gluconic acid, there was no surface oxidation, as confirmed by XPS studies. The nano silver particles have also been studied for their formation, structure, morphology and size using UV–Visible spectroscopy, XRD and SEM. Further, the antibacterial properties of these nano particles show promising results for *E. Coli*. The influence of the alkaline medium towards the particle size and yield was also studied by measuring the pH of the reaction for DEA, NaOH and Na_2CO_3.

1. Introduction

Metal nano particles have attracted a great deal of attention in recent years due to their optical, physical and chemical properties that differentiates them from bulk material properties. Hence they find wide application in various fields like catalysis, photonics, optoelectronics, information storage, antibacterial applications, etc. Silver powders, having ultra fine and uniformly distributed particle size, are of considerable use in the electronics industry as thick film conductors in integrated circuits due to their unique properties such as high electrical and thermal conductivity, high resistance to oxidation. Recently a method was perfected for using nano silver particles in inkjet printing that could see circuits get even smaller and cheaper [1]. Apart from electronic applications, it has been known for centuries that silver has bactericidal properties. Silver is a safe and effective bactericidal metal because it is non-toxic to animal cells and highly toxic to bacteria such as *Escherchia coli* (*E. coli*) and *Staphylococcus aureas* [2,3]. Silver based compounds have been used in recent years to prevent bacterial growth in applications such as burn care [4]. Silver doped polymer fabrics, catheters and polyurethane are well known for their antibacterial functionality [2,5]. Colloidal silver [6,7], nano silver coated fabric [8], nano silver metal oxide granules [9] and nano silver coated ceramic materials [10] are used for antibacterial applications. Nano silver in the form of powders as well as suspensions, due to the high surface to volume ratios, has been used in the above said applications as it enables the loading of small quantities of silver and thus makes the product cost effective. Researchers around the world are trying to produce nanosized mono dispersed powders by different methods. Pluym et al. prepared nano silver powders by the technique of spray pyrolysis, with the production at a rate of 1–2 g/h [11], but the silver particles tend to be agglomerated, irregular shaped, and hollow due to solvent evaporation.

There are several aqueous based chemical methods [12–23] reported in the literature to produce nano silver. While most of these reports deal with inorganic bases such as NaOH and Na_2CO_3 to control the pH to above 9, the contamination of silver with metals ions will cause limitations in specific applications such as electronics, and hence organic bases are required in the nano silver synthesis, as reported by Hsu and co-worker [23]. The same group used organic bases such as triethyl amine and pyridine for contamination-free silver nanoparticles, useful for micro-interconnects, that cure at relatively lower temperatures. Chaki et al. used a non-aqueous single-phase preparation of Ag clusters from silver benzoate using triethylamine as the organic base [12]. In both the organic base related studies, they have used external capping agents for stabilizing the powders or suspensions. In all the cases, the stability and antibacterial activity are dependent on the surface chemistry of the silver produced. For example, Kvítek et al. [24] have reported a SDS stabilized nano silver suspension to have better dispersion and antibacterial action. The best condition for high performance of nano silver, for either electronic or antibacterial applications, is that the particles should contain minimum or no capping agents so that the maximum surface is available for antibacterial action or sintering at low temperatures. Apart from the contamination issues, we have also found that the yield of the nano silver in the reduction reaction depends on the strength of the base.

In the present work, we have synthesised silver nanoparticles by an aqueous chemical method with an organic base and with no external capping agents, and carried out surface chemistry studies and compared the properties, such as stability and yield, with those obtained with inorganic bases, NaOH and Na_2CO_3. We made an attempt to synthesize nano silver colloids using a lower concentration of the reactants that could be stable for a few weeks without any surfactant. Nano silver colloids prepared in the absence of surfactant using inorganic bases such as NaOH and Na_2CO_3 settle down immediately. Hence we tried to explore the possibility of using an organic base, diethyl amine, that provides a good yield and low particle size in the absence of a protective agent. It is interesting to explore the surface chemistry of the nano silver particles that confirms the capping by gluconic acid, which prevents the oxidation/sulfidisation of the nano silver particle as confirmed by XPS studies. The suspensions made in this work using diethyl amine were found to be stable for nine months. The merits of this method are that it is a room temperature process with glucose as a reducing agent, which also modifies the surface after undergoing oxidation to stabilize the suspension without the requirement of other

Table 1
Details of the reaction parameters used in the silver nanoparticles synthesis, corresponding size of the particles measured from the SEM micrographs and λ_{max} observed for nano silver suspensions.

external capping or stabilizing agent. The resulting nano silver exhibit high antibacterial activity and is also useful for electronic interconnecting applications.

2. Experimental

2.1. Preparation of the nano silver suspension and powders

Analytical grade of silver nitrate (Ultrafine Chemicals), glucose, diethyl amine, sodium carbonate and sodium hydroxide (Qualigens) were used as starting materials. The different concentrations of aqueous solutions of silver nitrate and glucose solutions were mixed together and stirred to obtain a homogeneous solution. An aqueous solution of diethyl amine (DEA) of a pre-decided molarity was added to it quickly and stirred vigorously. Similar experiments were done with sodium carbonate and sodium hydroxide. The color of the solution changed to black, brown and then finally a light green colored precipitate was obtained for higher concentrations S5–S10. After decanting and washing repeatedly 2 to 3 times with distilled water, the precipitate was collected and dried in air at 50–60 °C. The final pale green colored dried powder was subjected to further characterization and antibacterial tests. The details of the reaction parameters for DEA are given in Table 1. For the samples S1–S4 low concentrations of reactants were used and suspensions were obtained which were stable for a few weeks when prepared using DEA in contrast to NaOH and Na_2CO_3, which settled immediately.

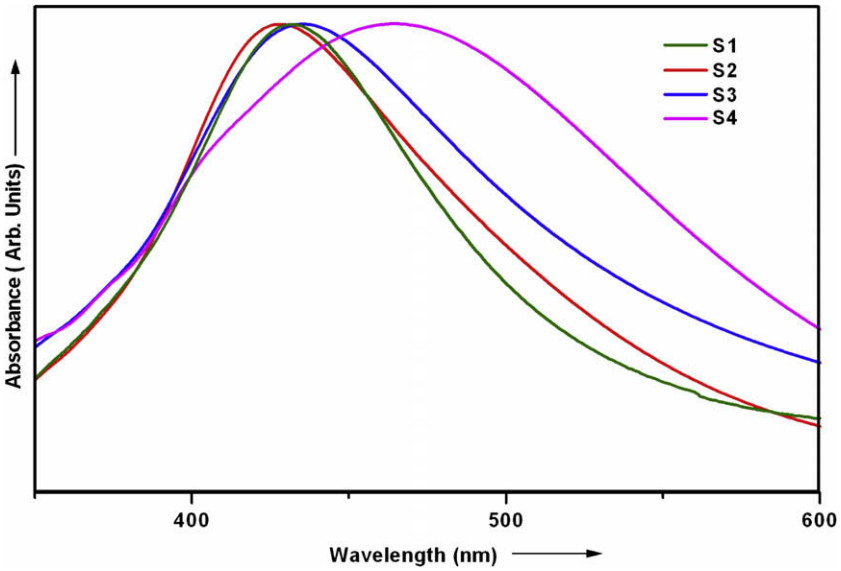

Fig. 2. UV–Visible absorption spectra for silver nanoparticles for samples S1, S2, S3 and S4.

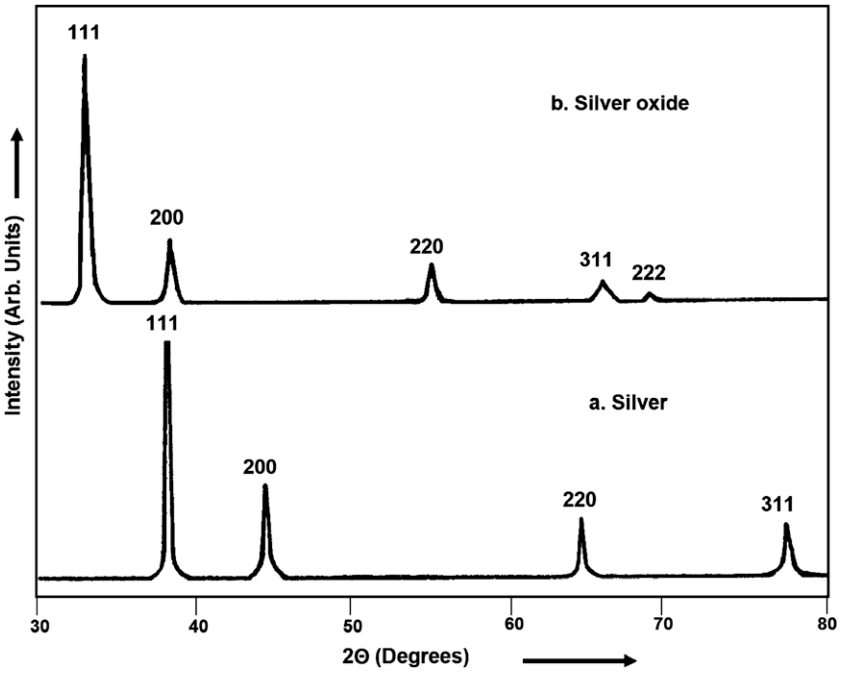

Fig. 3. XRD of (a) silver nanoparticles and (b) silver oxide particles.

To understand the exact role of glucose, the reactions were also performed without addition of glucose, keeping all the other reaction parameters the same. In these reactions, a black colored powder was collected as the end product. When the reactions were done without amine, the rate of reaction was found to be very slow and after 24 h the color of the solution changed to light brown. Silver nano particles thus prepared were in the form of either stable suspensions or powders, depending on the reactant concentrations as mentioned in Table 1.

2.2. Characterization of the nano silver powders

The powders obtained under the various conditions were characterized using different techniques. The particles were tested for their optical absorption property using a PELambda 650, Perkin–Elmer UV–Visible spectrometer, to ensure the formation of nano silver. The suspensions were tested as prepared. The powdered samples were prepared by dispersing them in water using stirring and sonication. The powdered samples were subjected to X-ray diffraction (XRD) studies on a Bruker AXS D8 Advanced XRD to understand their structure. The morphology, size and shape of the particles were obtained using an Hitachi Scanning Electron Microscope equipped with EDAX. A drop of nano silver suspension or dispersed nano silver powders in water was placed on the carbon tape on an aluminum stub and dried. Fourier Transform Infra Red (FTIR) spectroscopy was performed on a THERMO Nicolet Nexus 740 spectrometer. The powdered samples were mixed with KBr and pelletized at 1000 psi pressure. X-ray photoelectron spectroscopy (XPS) measurements were obtained on a KRATOS-AXIS 165 instrument equipped with dual aluminum–magnesium anodes using Mg Kα radiation. The X-ray power supply was run at 15 kV and 5 mA. The pressure of the analysis chamber during the scan was 10^9 Torr. The peak positions were based on calibration with respect to the C 1s peak at 284.6 eV. The obtained XPS spectra were fitted using a non-linear square method with the convolution of Lorentzian and Gaussian functions after polynomial background subtraction from the raw data.

2.3. Antibacterial test

Nutrient agar was poured on two disposable sterilized Petri dishes and was allowed to solidify. To understand the antibacterial activity of the nano silver powder, 0.1 gm of nano silver powder was mixed with 1 ml of *E. coli* bacterial water containing 170 CFU/ml. One milliliter of the *E. coli* bacterial water containing 170 CFU/ml was streaked on one agar plate and 1 ml of the bacterial water mixed with nano silver powder was streaked on the other plate and it was spread uniformly. Plates were incubated at 37 °C for 24 h. Growth of the colonies of bacteria was observed.

A zone of inhibition test was done on the nano silver coated plastic. The nano silver powder was ultrasonicated in acetone for 5 min and it was spin-coated on the plastic at 500 rpm. Nutrient agar was poured on two Petri dishes. The nano silver powder coated plastic and uncoated plastic were placed in the two Petri dishes and then the Nutrient agar was allowed to solidify. 1 ml of 170 cfu/ml concentrated *E. coli* bacterial water was streaked on the two Petri dishes. The plates were incubated at 37 °C for 24 h and then the zone of inhibition was observed.

3. Results and discussion

The silver mirror test is commonly used to detect the presence of an aldehyde group in an organic compound. Here excess ammo-

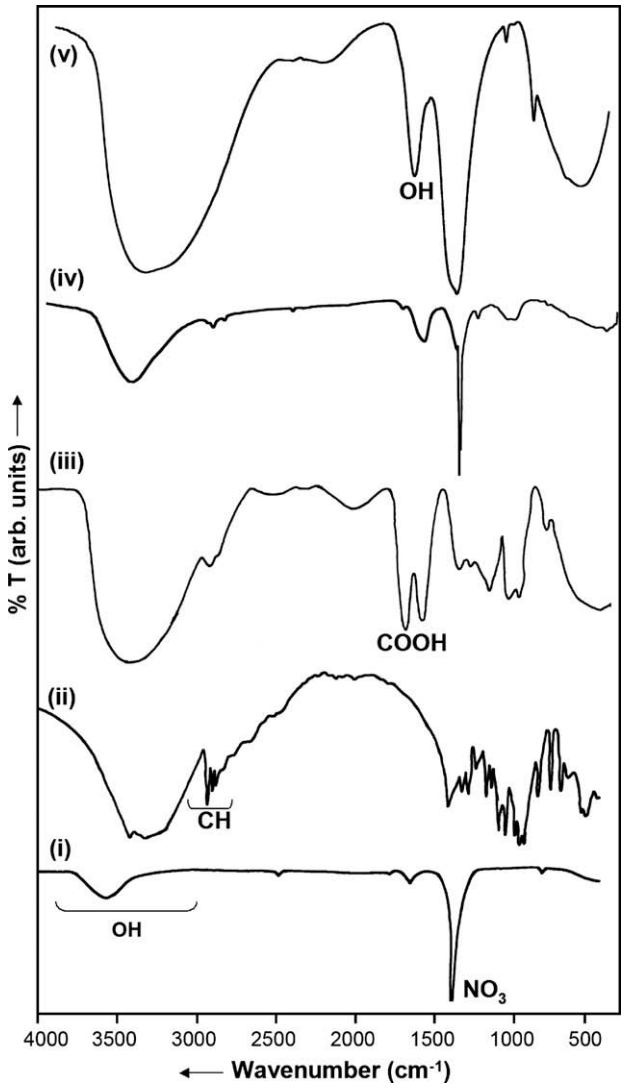

Fig. 4a. FTIR spectra for (i) silver nitrate (ii) glucose (iii) gluconic acid (iv) silver nanoparticles (v) silver oxide particles.

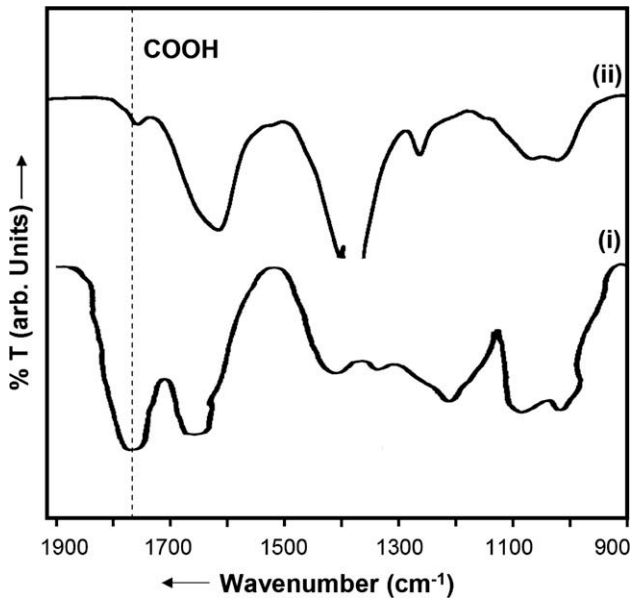

Fig. 4b. Enlarged FTIR spectra for (i) gluconic acid and (ii) resolved spectrum of silver nanoparticles in the wavenumber range 1900–900 cm^{-1}.

nia and silver nitrate are reacted in the presence of the aldehyde which oxidizes to form carboxylic acid and release silver, which deposits on the glass container wall to give silver mirror. The general reaction can be written as:

$$RCHO + 2Ag(NH_3)_2OH \rightarrow RCOONH_4 + 2Ag + 3NH_3 + H_2O \quad (1)$$

Following this reaction, the process was modified to get silver nano particles. Glucose was used as an aldehyde and an amine was used in the place of ammonia. The proposed reaction mechanism for this reaction is very similar to that of the silver mirror test. When the amine is dissolved in water, it withdraws hydrogen ions by leaving hydroxyl ions in solution. The hydrated amine ion further reacts with silver nitrate to form a complex of silver. The remaining hydroxyl ions oxidize the aldehyde group here in glucose to form gluconic acid and an electron is released in the process. This electron reduces the silver complex to get metallic silver. The DEA acts as a catalyst. The reactions can be written as follows:

$$NH(C_2H_5)_2 + H_2O \rightarrow {}^{+}NH_2(C_2H_5)_2 + {}^{-}OH \quad (2)$$

$$R\text{-}CHO + 2{}^{-}OH \rightarrow R\text{-}COOH + H_2O + 2e^{-} \quad (3)$$

$$Ag^{+} + e^{-} \rightarrow Ag^{0} + 2NH(C_2H_5)_2 \quad (4)$$

$$R = (CHOH)_4CH_2OH$$

Some reactions were carried out in the absence of glucose to confirm its exact role in the silver formation. It was observed that the absence of glucose in the reaction produces silver oxide (Ag_2O) instead of metallic silver. Here the silver complex formed with amine in presence of hydroxyl ions produces silver hydroxide which converts into silver oxide as:

$$2AgOH \rightarrow Ag_2O + H_2O \quad (5)$$

Although glucose is a known reducing agent, its activity on silver nitrate was observed to be very weak in the absence of amine, and both reactants remain unreacted for many hours. Yan et al., modified a fabric by using a similar process and deposited silver by heating the fabric [8]. To investigate the effect of the concentration of the precursors towards the particle size of the nano silver, different studies were performed by varying the concentrations of glucose, silver nitrate and diethyl amine, as mentioned in Table 1. The particle size was measured from SEM images and also from XRD data by calculating the average particle size using the Scherror formula, and both were found to be in agreement.

The $AgNO_3$:glucose molar ratio was changed from 1:0.5 to 1:2. The concentration of glucose did not show much influence on the particle size, but was found to be very essential to form metallic silver nano particles, without which an oxide is formed as shown in reaction (4), indicating the role of glucose as a reducing agent.

The concentration of silver nitrate is one of the most important factors that decide the particle size. As the concentration of silver nitrate is increased from 3 to 300 mM, correspondingly the particle size increases from 40 to 630 nm and grows towards bulk silver. The concentration of DEA was found to be another size controlling factor. In the case of S2–S4 (suspensions) as DEA the concentration is decreased from 115 to 23 mM, the particle size increases from 40 to 100 nm, as mentioned in Table 1. In the case of S5–S7 (powders) the increasing concentration of DEA shows a decrease in the average particle size from 110 to 63 nm.

The scanning electron micrograph and particle size distribution for the samples S2, S3 and S4 are shown in Fig. 1a–c. Nearly spherical particles are seen with a maximum number of particles in the size range of 40–50 nm, 50–70 nm and 80–100 nm for samples S2, S3 and S4, respectively. The sharp boundaries of the particles clearly show non-agglomeration of particles even after drying, indicating that some factor is controlling and maintaining the nano

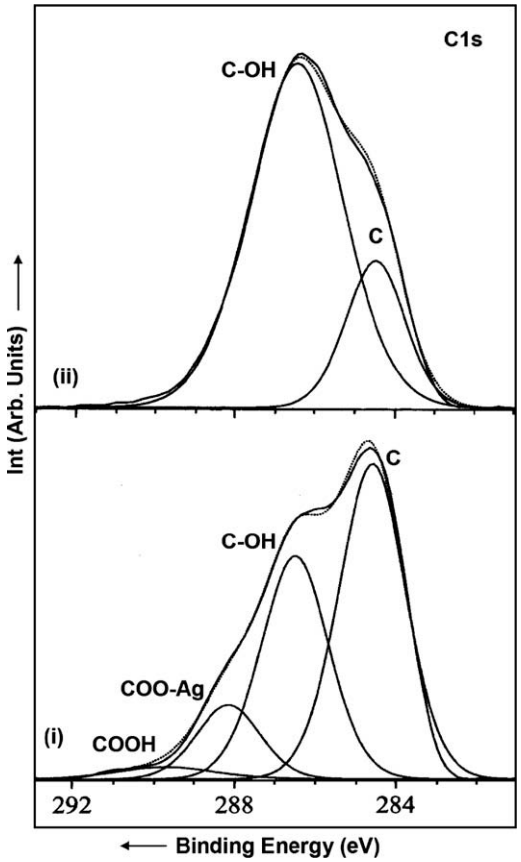

Fig. 5a. XPS core-lever spectra of C 1s for (i) silver and (ii) silver oxide particles.

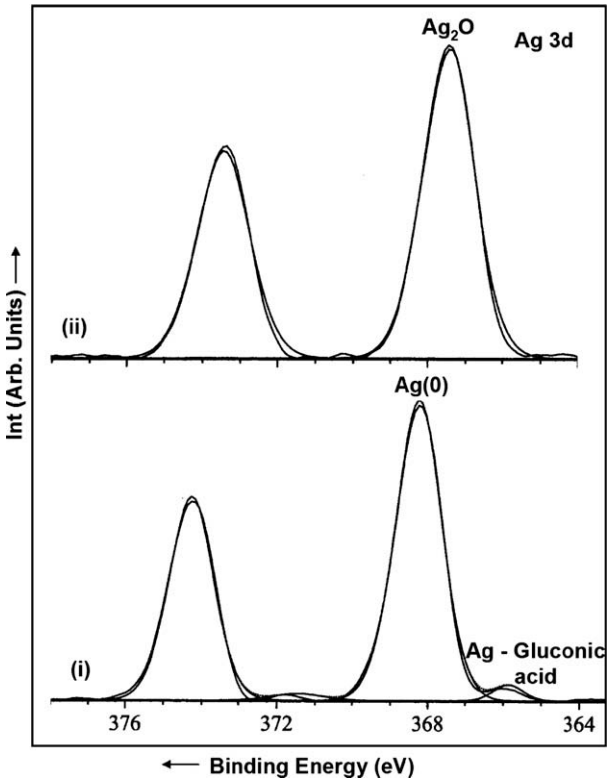

Fig. 5b. XPS core-level spectra for Ag 3d in (i) silver and (ii) Ag_2O particles.

size of the silver particles. Fig. 1d shows a typical micrograph for a powder sample (S7) used for XPS and FTIR studies. Here the particles in the size range of 60–70 nm are seen to be somewhat agglomerated as at some places necking between the particles is observed. This is obvious for nano powders prepared using higher concentrations of precursors and dried in air at 50–60 °C.

The change in the particle size also reflected in the optical absorption studies. The λ_{max} values observed in the UV–Visible absorption studies for samples S1, S2, S3 and S4 are depicted in Fig. 2. The samples S1 and S2 show a blue shift in λ_{max}, which is at 432 and 426 nm, respectively. The decrease in the silver nitrate concentration has resulted in a smaller particle size. The sample S3 and S4 were prepared with smaller concentrations of DEA as compared to S2 and show λ_{max} at 433 and 464 nm, respectively, as shown in Fig. 2. It clearly shows a red shift in λ_{max} from S2 to S4 with the decreasing concentration of DEA, and a decrease in the FWHM with an increase in concentration of DEA. The powder samples did not show any clear absorption peaks in UV–Visible range. This may be due to the agglomeration of the particles, observed in the SEM.

Typical XRD spectra are given in Fig. 3a and b for silver and silver oxide, respectively. The powdered silver nanoparticles show a cubic structure showing peaks at 2θ: 38.1 (1 1 1), 44.2 (2 0 0), 64.4 (2 2 0) and 77.472(3 1 1), which match exactly with the standard data. Fig. 3b shows the spectra for particles prepared in the absence of glucose. It shows the cubic phase of Ag_2O, which is in good agreement with the literature [25].

It was very interesting to understand the formation of nano particles with the change in reactant concentrations. This was possible only when the particles were studied by FTIR, to understand the remains of the organic molecules, if any, after completion of the reaction. The surface properties of the nano silver particles, studied using XPS, throw some light about their size controlling factors.

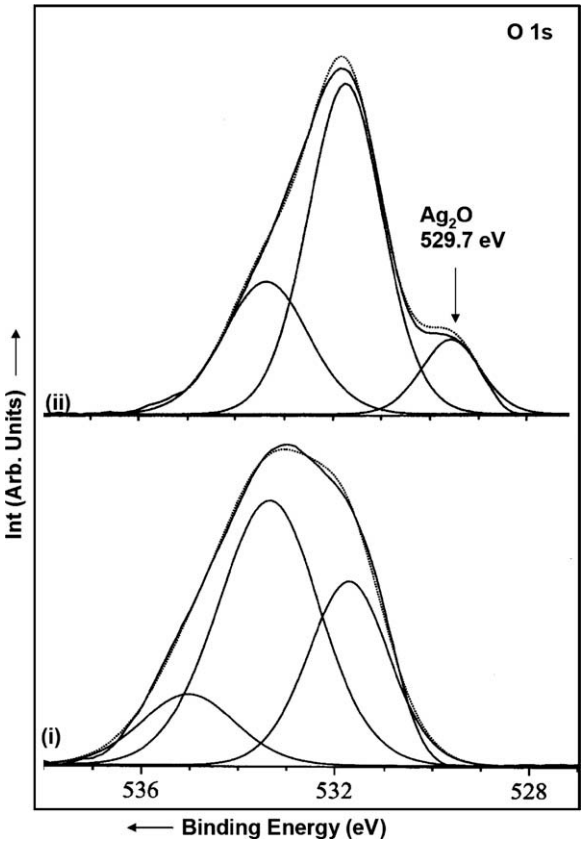

Fig. 5c. XPS core-level spectra for O 1s in (i) silver and (ii) silver particles.

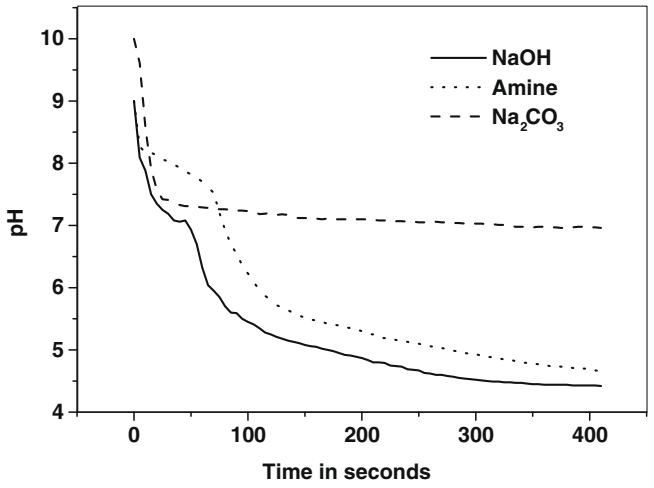
Fig. 4ai–v shows the FTIR spectra recorded for silver nitrate, glucose, gluconic acid, silver nanoparticles and silver oxide nanoparticles, respectively. The attempt made here is to do only a qualitative study. The IR spectrum for the silver nanoparticles (Fig. 4aiv) shows various peaks. The peaks at 3423 and 1605 cm^{-1} are very broad and strong, and can be assigned to the hydroxyl groups [25], either from glucose/gluconic acid, from adsorbed moisture or both. A prominent and very sharp peak is observed at 1384 cm^{-1} which was concluded to be due to the nitrate ions when compared with the FTIR spectrum for silver nitrate, as shown in Fig. 4ai. Some other smaller peaks present at 1740, 1400, 1250, 1100 and 1039 cm^{-1} were also observed. These peaks are absent in the silver oxide IR spectrum (v), which shows major peaks at 3380, 1651 and 1382 cm^{-1}, and are due to the OH group [26], adsorbed moisture and nitrate impurities, respectively. As explained in reaction (4), the gluconic acid is produced by oxidation of glucose and it may be present in the sample. Hence these IR peaks were also compared with the glucose and gluconic acid peaks. The smaller peaks in nano silver do not match with those of glucose (Fig. 4aii) but they match with many features in gluconic acid. The FTIR spectrum of gluconic acid (i) and the resolved spectrum for nano silver powder (ii) was compared in the wave number region from 900 to 1900 cm^{-1}, as depicted in Fig. 4b. The gluconic acid shows peaks at 1740, 1638, 1412, 1230, 1100, 1036 and 875 cm^{-1}. Almost all these peaks match with those for the nano silver sample. Thus a small amount of gluconic acid remains in the sample even after repetitive washings of the silver precipitate.

Fig. 5ai shows the core-level spectrum for C 1s for the nano silver powder. The broad peak can be fitted to four different components at binding energies 289.7, 288.1, 286.5 and 284.6 eV. The peak at 284.6 eV is mostly due to the carbon present on the sample surface due to handling [27]. This peak was observed in all samples. While discussing the other two components, it is necessary to consider the gluconic acid molecule, the presence of which

Table 2
Comparison of sodium carbonate, diethyl amine and sodium hydroxide.

	pK_b	Yield (%)	Particle size (nm)
Sodium carbonate	4.67	96	45
Diethyl amine	3	90	55
Sodium hydroxide	0.2	71	50



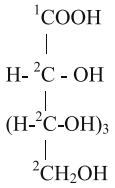


Fig. 6. Photograph of antibacterial test (a) control (b) control with nano silver particles (c) control with uncoated plastic and (d) control with nano silver coated plastic.

was observed in the FTIR studies. In one gluconic acid molecule, depending on the functional groups attached, there are two types of carbons in the atomic ratio 1:5, as numbered below.

The carbon in carboxylic group shows a binding energy at 289 ± 2 eV [28]. The component at 288.1 eV is due to C-1, which is a carboxylic group. Here the shift is observed towards a lower binding energy. This is in good agreement with the literature, where carboxylic groups attached to a metal particle like Co, Cu show a binding energy shift to 288.1 eV [29]. Also the standard data available for silver acetate shows a XPS peak for carbon at 288.1 eV [30,31]. It has been shown that the carboxylic acid group binds to silver surface in the case where citrate is used as the reducing agent. In this case, it was shown that two carboxylic groups of the citrate bind to the Ag surface, having the third group normal to the surface, which make the Ag particle charged, and that is responsible for the electrostatic stability [32]. However in the present case only one carboxylic acid is available on gluconic acid that is likely to bind with the Ag surface. The capping of the silver particle controls the grain growth but does not provide charge to the particles. The peak at 286.5 eV is due to C-2 (the carbon with OH groups) [33,34]. The intensities of the corresponding XPS peaks are fairly in agreement with the atomic ratio of these carbons in the molecule. A very small component at 289.7 eV may be due to some non-bonded gluconic acid. The C 1s spectrum was also recorded for silver oxide powders where only two components were observed, at 284.5 and 286.5 eV, as shown in Fig. 5aii. The former peak is due to a carbon impurity. The latter peak was unexpected and may be due to some unknown carbon contamination, as no C–O bond is possible in this sample.

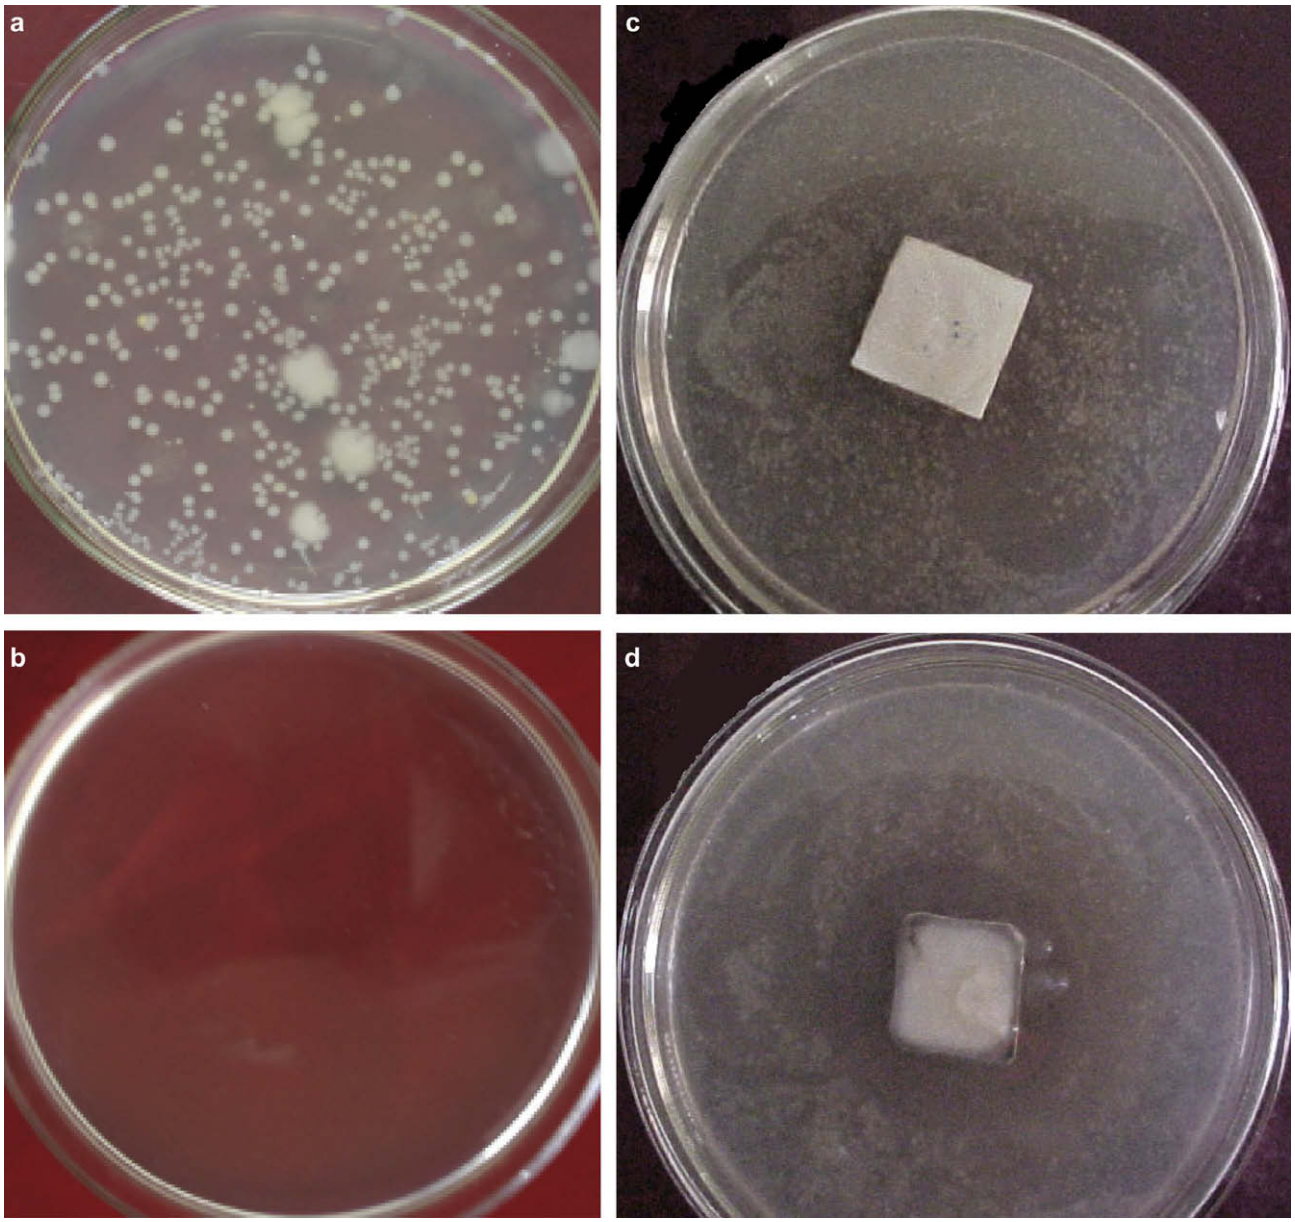

Fig. 7. pH of the reaction for NaOH, DEA and Na_2CO_3.

The core-level spectrum for Ag 3d, shown in Fig. 5bi, is fitted in two components, one is major and the second is very small in the% concentration ratio of (96:4). The peak at 368.2 eV is clearly due to metallic silver [25,35]. A surprising small peak shifted to lower binding energy at 365.8 eV may be due to the surface silver atoms surrounded by the six carbon chain of gluconic acid molecules. Unlike in the silver nanoparticles, silver oxide nanoparticles show only one peak at a binding energy of 367.4 eV, which is a characteristic for Ag_2O, as shown in Fig. 5bii.

Fig. 5c–i shows the core-level spectra for O 1s in the case of silver nanoparticles. It shows a broad peak which can be deconvoluted into three peaks at 535.0, 533.4 and 531.7 eV. The first peak can be assigned to the adsorbed water [36]. The component at 533.4 can be correlated to either C–O or C–OH present in the gluconic acid molecules [37–39]. The peak at 531.7 eV was observed in all samples, and can be attributed to adsorbed oxygen on the surface as an impurity in the form of either atomic oxygen or in the hydroxyl form [40]. Some of its contribution can also be due to organometallic oxygen. Hoof et al studied Co and Cu bonded with organic molecules and found the binding energy of O 1s at 531.6 eV [29]. Here if the silver atoms on the surface of the nanoparticles are bonded with carboxylic ions, the oxygen from the carboxylic group may show a binding energy at 531.7 eV. The peculiar peak of silver oxide at 529.6 eV, as shown in Fig. 5cii, is observed in the case of the silver oxide nanoparticles, but is absent in the silver nanoparticles. Other than the oxide peak, the silver oxide nanoparticles show two components at 533.3 and 531.7 eV, which can be attributed to hydroxyl groups which may be present on the surface of the oxide particles and surface adsorbed oxygen, respectively. This clearly tells us that the surface of the silver nanoparticles does not have any oxide layer as it is protected by gluconic acid molecules.

The reducing ability of aldehyde is dependant on the pH. As already mentioned, if only glucose is added the reduction rate is very slow at room temperature because of the low pH. We tried to explore the influence of different alkaline medium towards the particle size and yield of nano silver powder. The pK_b values, yield and particle size of nano silver powder for NaOH, Na_2CO_3 and DEA are listed in Table 2. The changes in the pH of the solution for NaOH, Na_2CO_3 and DEA are shown in Fig. 6.

The yield of the nano silver powder was found in increase with a decrease in the pK_b value. The lower the pK_b value, the stronger is the basicity of the alkaline medium. Under highly alkaline conditions, the aldehyde functional group in glucose gets converted to a ketone [41]. As ketones are weak reducing agents when compared with aldehydes, the yield of the nano silver prepared by sodium hydroxide ($pK_b = 0.2$) is less when compared with DEA and Na_2CO_3 [14,42]. The reaction mechanism is the same in each case. Gluconic acid formed as a by-product in the reaction acts as a capping agent. This imparts a negative charge on the surface, which was confirmed by immediate adsorption of negatively charged silver particles on the anion exchange resin Amberlite IRA 400 [43].

From all these results, the inference that can be drawn is like this. As mentioned in Table 1, an increase in concentration of DEA reduces the size of nano silver particle. As discussed earlier, the amine in aqueous solution forms a hydrated ion and hydroxy ions are left in the solution which in turn oxidizes glucose to form gluconic acid. If the concentration of amine is greater then the number of hydroxy ions are present is greater and the amount of gluconic acid formed also increases. These gluconic acid molecules present on the surface of the nano particles may act as a particle size controlling factor. So in turn the amine concentration is determining the size of the particles for a particular set of concentrations of silver nitrate and glucose, as mentioned in Table 1 (S2–S4). It is very easy to understand the increase in the size of particles with the concentration of $AgNO_3$, due to the increase in the ratio of available gluconic acid to silver particles. In the given set of conditions in Table 1, by increasing the concentration of glucose, the size remains unaffected as the glucose to gluconic acid conversion in the presence of amine is a size controlling factor and not just the glucose concentration. Just by changing the molar ratio of reactants, we can get a stable nano silver suspension or powder.

The reactions for samples S5–S10 can be scaled up to a total volume of 5 liters, which can yield 45–50 gm of nano silver powder which is quiet a substantial yield.

The powders of nano silver were tested for antibacterial properties on *E. coli*. The effect of the silver nano particles on *E. coli* is shown in the photograph in Fig. 6 for sample S7. The number of *E. coli* has been reduced by a considerable number because of the antibacterial action of the nano silver particles, whereas growth was observed in the control, as shown in Fig. 7a and b, respectively. The zone of inhibition observed for the nano silver powder coated plastic confirms the antibacterial action of the nano silver particles, whereas there was no zone of inhibition for the uncoated plastic, as shown in Fig. 7c and d, respectively. These observations clearly indicate the antibacterial properties of nano silver. It is interesting to observe that, although the nanoparticles contain traces of gluconic acid on the surface, as is evident from the XPS analysis, the surface of the nano silver particle is still available for efficient antibacterial activity.

4. Conclusions

The present work reveals a simple, cost effective wet chemical synthetic route to form nano silver powders. Silver nano particles are formed in a simple oxidation–reduction reaction in diethyl amine, glucose and silver nitrate. A blue shift in λ_{max} observed for an increase in the diethyl amine concentration in samples S2–S4 was found to be the size controlling factor. Detailed surface analysis studies using XPS and FTIR revealed the presence of gluconic acid that encapsulates the nano silver particle. The negative charge on the surface due to the presence of gluconic acid was confirmed by anion exchange resin. The antibacterial studies show very high activity against *E. coli*. This process of producing large scale silver nano powders with highly efficient antibacterial properties is certainly going to increase its commercial value and widen the application range.

ABSTRACT

Motivated by the application of the First Order Reversal Curve (FORC) technique to obtain a distribution of like spin domains in the spin crossover complexes $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ with M^{II} = Zn and Ni, we have performed Differential Scanning Calorimetry (DSC) experiments. We have measured the heat capacity in the heating and cooling modes and then calculated the enthalpy and the entropy variations at the phase transition. In the framework of an Ising-like model, we have converted the experimental thermal hysteresis into terms of physical parameters related to these compounds. We have also performed a statistical analysis of these parameters and concluded that the correlation between them increases with the dilution degree of these spin crossover complexes.

1. Introduction

Spin crossover (SCO) solids [1] are attractive molecular compounds containing transition metals with the electronic configuration $3d^{4-7}$ that are switchable between two states with different optical, magnetic, vibrational and volume properties: respectively the low-spin (LS) state and the high-spin (HS) state. The large majority of the known SCO complexes, prepared as nanoparticles, powder, crystallites or single crystals, are based on Fe(II,III) ions. A few examples of SCO complexes with cobalt(II,III), manganese(II,III) or chromium(II) have also been synthesised [2]. A thermally induced entropy driven spin transition can occur from the stable LS state at low temperatures to the HS state at higher temperatures. If the interactions of elastic origin between the spin changing molecules are strong enough, cooperative phenomena occur in steep phase transitions, accompanied by a hysteresis loop whose width depends on the intensity of these interactions.

In this paper, we study the behavior of solid solutions of the coordination polymer $[Fe(btr)_2(NCS)_2]\cdot H_2O$ (btr = 4,4′-bis-1,2,4-triazole) [3] that has a 2D network structure. The iron atom is related in a plane to four btr ligands and to two isothiocyanato groups in *trans* positions. The btr ligands of two consecutive planes are linked by hydrogen bonding to a non-coordinated water molecule. This compound displays a hysteretic and complete spin transition below room temperature [3], as shown in Fig. 1, under the form of the temperature dependence of the HS molar fraction, γ_{HS}. It is possible to obtain isomorphous compounds by replacing the iron ion by other transition metals such as nickel, cobalt, copper or zinc [4–7] which, contrary to the iron ion, exist only under one spin state. One thus can obtain a solid solution of the formula $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$, with M^{II} = Co, Cu, Ni, Zn. The strength of the ligand field determines the bistable character of the complex, and the presence of the thermal hysteresis loop is a signature of a first order phase transition. However, the progressive dilution [8] of a cooperative system isolates more and more the SCO molecules and the interactions can become insufficient [9,10] to favor a cooperative behavior; the hysteresis loop disappears and the transition becomes continuous. Above a threshold value, $x \geqslant 0.40$, the hysteresis loop was observed to collapse for the isostructural systems $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ where the dilution metal M^{II} = Co or Ni [11,12]. As the dilution increases, the transition is shifted to lower temperatures and the HS state is further stabilized. The thermal hysteresis loops, derived from magnetic measurements, for different concentrations of Zn atoms in $[Fe_xZn_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ are reported in Fig. 1. In the mean-field description, the "effective" interaction in a diluted system is proportional to the number of SCO neighbors, i.e. to the composition parameter x. We note a decrease of the hysteresis width as x increases, but the steepness and shape of the hysteresis loop is preserved.

Besides the magnetic and optical measurements [13], Mössbauer [13] and Raman spectroscopy [14], and calorimetric

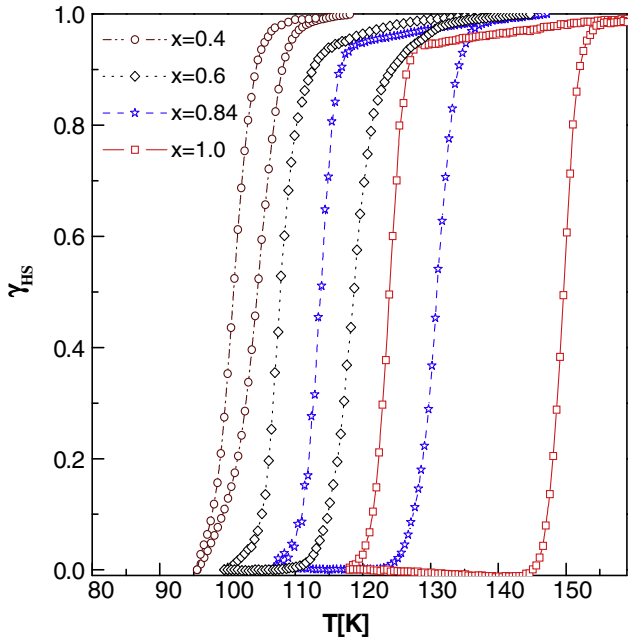

Fig. 1. $[Fe_xZn_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ for different dilution degrees ($x = 1$; 0.84; 0.6; 0.4) [15].

(heat capacity) measurements [13,15] are among the most commonly used methods to quantitatively evaluate the spin state. They make it possible to determine, besides the transition temperatures, relevant thermodynamic quantities such as the enthalpy ΔH and entropy changes ΔS associated to the spin transition. Typical values for the enthalpy change are between 10 and 20 kJ/mol, while the entropy change is normally between 50 and 80 J/mol/K [16].

Martin et al. [4] have studied, some time ago, the effect of dilution on the SCO behavior of $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$, using magnetic and calorimetric measurements for M = Co^{II} and Ni^{II}. In this paper, we complete this series with further calorimetric measurements on the Zn diluted system (M = Zn), and correct the thermodynamic data provided for the Ni diluted system that were only reported in the heating mode [4]. Simulated hysteresis loops using an Ising-like model, including new experimental parameters, are presented and a comparison with the previous simulated data [17,18] is provided.

2. Experimental

The diluted samples were prepared according to [4]. The calorimetric measurements were carried out in a $He_{(g)}$ atmosphere using a Perkin–Elmer DSC Pyris 1 instrument equipped with a cryostat and operating down to 100 K. The purge gas was $N_{2(g)}$. Temperatures and enthalpies were calibrated over the temperature range 100–300 K using the solid/solid and liquid/solid transitions of pure cyclopentane (⩾99%, Acros) (Table S1). The calibration sample was introduced in an aluminum pan and hermetically sealed using an encapsulating press. The calibration was made at a scan rate of 2 and 5 K/min using 47(2) mg and 49(1) mg of cyclopentane, respectively. The characteristic temperatures, which were assigned to the crystal/crystal transitions of cyclopentane, were obtained by the extrapolation of the onset peak temperatures [19]. An empty aluminum pan, identical to the one used for the sample, was used as a reference to obtain a reliable baseline. The system produces or uptakes energy in order to keep the temperature of the compound identical to the reference. This energy difference between two resistances (in mW) is transformed by PYRIS™ DSC Software 7.0 in specific heat C_p (J mol^{-1} K^{-1}). This function is plotted as a function of temperature of the sample and enables the transition temperature to be obtained, together with the associated changes of enthalpy and entropy of the transition. These temperatures were determined by taking into account T_{max} of the peaks.

Differential scanning measurements of the samples were carried out at a scan rate of 2 and 5 K/min, in the warming and cooling modes. 33.6 mg of each sample were encapsulated at room temperature in aluminum pans and hermetically sealed. The samples were maintained at room temperature for 5 min in order to allow the system to equilibrate, and were further cooled down from 298 to 110 K (or 100 K depending on the sample) with different scan rates. The samples were maintained at the lowest temperature for 5–10 min to reach equilibrium, followed by a similar scanning mode as on cooling between 110 K and room temperature. Each experiment was carried out twice to check the reproducibility.

3. Results and discussions

In Figs. 2 and 3 the DSC profiles of $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ (M = Zn, Ni) in the cooling (a) and heating modes (b) related to the same mass (33.6 mg) for different dilution degrees, obtained between 100 and 160 K, at a rate of 5 K/min, are presented. Exothermic and endothermic peaks are observed on cooling and warming respectively. As the dilution ratio increases, the peak amplitude decreases, as expected. Less data are provided for the Zn diluted system ($x \geqslant 0.7$) due to the working temperature range of our instrument. A summary of our measurements is given in Tables 1 and 2. The calorimetric measurements agree reasonably well with those observed from magnetic measurements [18]. The small differences in transition temperatures $T_{1/2}$ between DSC and magnetic data have their origin in the different rates at which the experiments were carried out.

In the thermograms, the enthalpy change corresponds to the peak area. The enthalpy change ΔH related to the conversion of 1mol of [Fe] mononuclear entities according to the relationship $\Delta H = \Delta H_{exp} M_x / x$, where ΔH_{exp} is the experimental value of the enthalpy change related to the mass unit of the sample, has been calculated directly from the DSC measurement. The evolution of ΔH with x is shown in Fig. 4. For the $[Fe_xNi_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ system, the enthalpy change variation is constant above $x \geqslant 0.8$ and decreases below that value, whereas for the $[Fe_xZn_{1-x}(btr)_2(NCS)_2]H_2O$ system, ΔH decreases more effectively as the dilution ratio increases. A hysteresis is observed in the variation of the enthalpy change in the heating and cooling modes, this one being larger for the system diluted with Ni than for the system diluted with Zn.

The relevant entropy changes ΔS near the transition temperature were determined from $\Delta S = \Delta H / T_{1/2}$. The entropy changes for both systems in the cooling and heating modes are shown in Fig. 5. Similarly, as x decreases, ΔS decreases, and no significant hysteresis effect is observed except for $x \geqslant 0.85$.

The thermodynamic values obtained for the enthalpy change variation are systematically smaller than those obtained by Martin et al. [4], but no comparison is possible for the heat capacity since no C_p values were reported. Our thermodynamic parameters were used for simple simulations in the frame of an Ising-like model, presented in the next section.

3.1. Simple simulations using some of the values of ΔH and ΔS

One remarkable model for the description of such bistable systems is the Ising-like model, which describes the interaction of two-level units, with energy levels having different energies and degeneracies. However, it permits the description of most of the

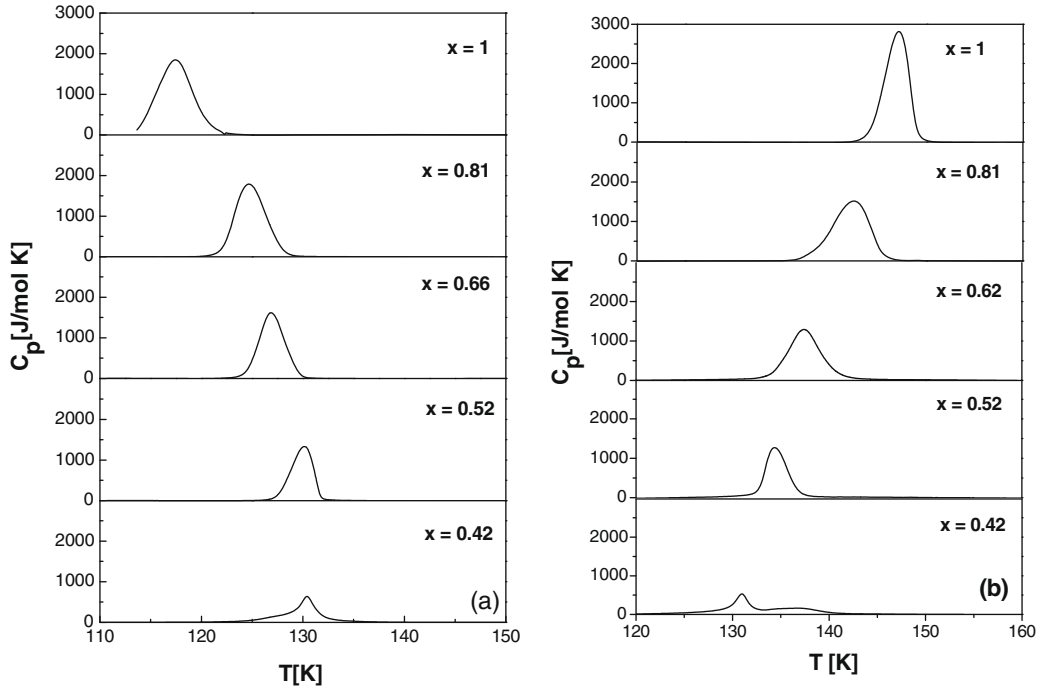

Fig. 2. Heat capacity profiles for $[Fe_xNi_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ recorded on cooling (a) and warming (b) modes ($x = 1$; 0.81; 0.66; 0.52; 0.42), clearly evidencing a hysteresis effect.

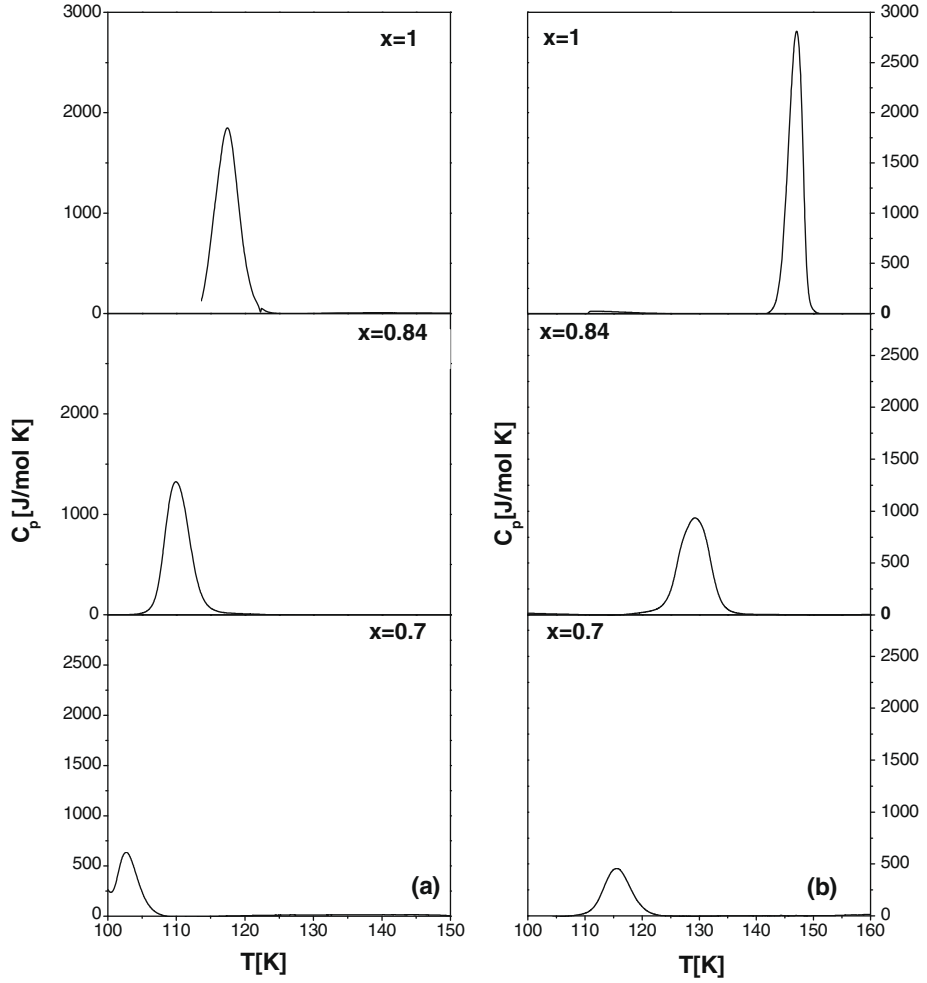

Fig. 3. Heat capacity profiles for $[Fe_xZn_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ recorded on cooling (a) and warming (b) modes ($x = 1$; 0.84; 0.7), clearly evidencing a hysteresis effect.

quasi-static properties of the SCO compounds with amazing success. The degeneracy ratio, $g = g_{HS}/g_{LS}$, is related to the entropy variation during the total conversion $\Delta S = R \ln g$, which can be determined from calorimetric measurements. The g value may be quite large (up to a few thousands because it involves both the spin degeneracies and the density of vibrational states). The Ising-like model was used for the description of static properties as well as for dynamical properties of SCO compounds [20].

The Ising Hamiltonian writes:

$$H = \frac{\Delta}{2}\sum_i \hat{\sigma}_i - \sum_{\langle i,j\rangle} J_{i,j}\hat{\sigma}_i\hat{\sigma}_j, \tag{1}$$

with fictitious spins $\hat{\sigma}$, with eigenvalues +1 in the HS state and −1 in the LS state. We shall use $\langle i,j\rangle$ to denote the sum over the nearest neighbor spins, and the reference sign for a cooperative interaction, favoring spin like states, is $J_{i,j} > 0$ with $\Delta = E(HS) - E(LS)$, being the energy gap. The Ising equivalent form involves a temperature-dependent energy gap accounting for the degeneracy ratio:

$$H = \frac{\Delta_{eff}(T)}{2}\sum_i \hat{\sigma}_i - \sum_{\langle i,j\rangle} J_{i,j}\hat{\sigma}_i\hat{\sigma}_j, \tag{2}$$

with:

$$\Delta_{eff} = \Delta - k_B T \ln g. \tag{3}$$

The equilibrium temperature $T_{1/2}$, for which $\gamma_{HS} = \gamma_{LS} = 1/2$, corresponds to a null effective field, irrespective of the interactions:

$$T_{1/2} = \Delta_{eff}/k_B \ln g. \tag{4}$$

Assuming that all sites are equivalent, the mean field treatment is performed as usual, so that the one-site mean field Hamiltonian can be written as:

$$H = \frac{\Delta_{eff}}{2}\hat{\sigma} - J\hat{\sigma} < \hat{\sigma} >, \tag{5}$$

where $< \sigma >= m$ is the "fictitious magnetization", that can be written as:

$$< \hat{\sigma} >= m = \tan h\left(\frac{2Jm + TS - \Delta}{2}\right). \tag{6}$$

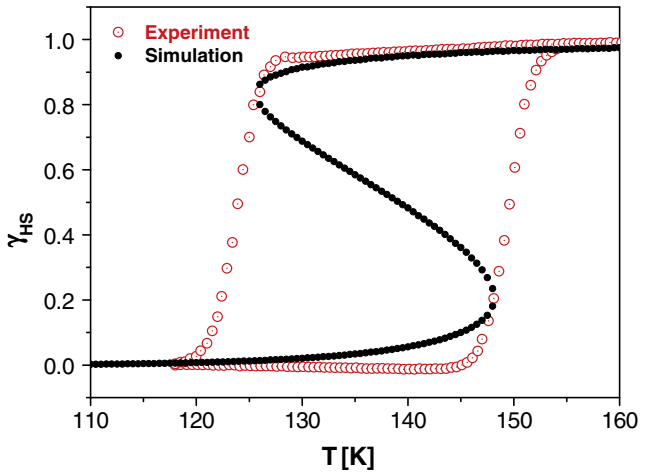

Fig. 6. Temperature variation of the HS fraction obtained for $[Fe(btr)_2(NCS)_2]\cdot H_2O$.

Fig. 6 presents a comparison between the experimental and computed temperature variation of the HS fraction obtained for $[Fe(btr)_2(NCS)_2]\cdot H_2O$. The values of the parameters used in these calculations are: J = 113K; $g = 2040$ ($< \Delta S > = 61.27 Jmol^{-1}K^{-1}$), $\Delta = 1021.35K$ ($< \Delta H > = 8491.5 Jmol^{-1}$).

3.2. Distribution of physical parameters derived from the FORC diagram

One important characteristic of SCO compounds is determined by the intensity of the elastic interactions inside the system. In the case of weak interactions, the reversible spin conversion between HS and LS states is gradual and characterized mainly by the transition temperature $T_{1/2}$ corresponding to equal amounts of HS and LS molecules ($\gamma_{HS} = 0.5$). If the interactions overpass a threshold value, the transition becomes abrupt and the system undergoes a first order phase transition with hysteresis, a desirable property in most of the potential applications in displays and data recording devices [21–23]. The hysteresis is described in most of the situations by $T_{1/2}$ of both heating and cooling modes. As hysteresis is a complicate non-linear phenomenon, using only two parameters appears to be insufficient to describe it fully.

The idea that in spin-transition solids the molecules are organized in domains, including molecules in the same spin state, has been proposed by Sorai and Seki [24]. They consider that the molecules are organized in domains with a certain critical size, succeeding in this way to predict the critical size that should have a domain in order to present a first order phase transition, which is characteristic for a transition accompanied by hysteresis. Over the past few years, the existence of such like spin domains were pointed out from experimental data, namely the observation of minor hysteresis loops for thermal, pressure and light-induced thermal transitions [25–27], X-ray diffraction [28] and neutron Laue scattering on single crystals [29]. In order to evidence the elastic domain distribution, the experimental First-order Reversal Curve (FORC) diagram method was suggested [18,30,31]. The method, applied initially to study the magnetic interactions in geological samples [32], is based on measuring a set of First Order Reversal Curves (FORC). To measure a FORC, one should saturate the sample in the HS (or LS) state followed by reducing (or increasing) temperature to a specific value, usually denoted as reversal temperature, T_r. From this point, the temperature is increased (or decreased) back to saturation and the HS molecules fraction is measured, being a function of two variables: reversal and actual temperatures. The interior area of the hysteresis loop is systematically covered by a set of these FORCs, selecting between 20 and 30 reversal temperatures. In the final step of the method, one has to calculate the mixed derivative of $\gamma_{HS}(T, T_r)$, also known as a FORC distribution. The contour plot of the FORC distribution is named a FORC diagram. Even if this experimental procedure is more time consuming compared to a classical major hysteresis loop measurement, the FORC diagram provides the experimentalist with a wealth of physical information which makes the method attractive. However, the FORC diagram in the switching temperature plane does not provide directly the physical information needed for the characterization of the spin transition material.

Unfortunately, temperature is not the best parameter to characterize the properties and the behavior of SCO materials. An elegant solution to this situation was to convert the FORC diagram from the temperature plane to a physical parameters plane [18]. The Ising-like model modified for SCO systems was an ideal tool for the conversion, and the detailed procedure is described in Ref. [18,33]. The main elements, the energy gap between the LS and HS states, Δ, and the interaction parameter, J, were correlated with the critical temperatures. In our previous work [18], the degeneracy ratio of HS and LS was overestimated since we approximated by using calorimetrical data obtained for another transition metal ion (Co^{II}) [5].

Here, we calculate the distribution of physical parameters for $[Fe(btr)_2(NCS)_2]\cdot H_2O$ and for a diluted one ($x = 0.84$, M = Zn) using

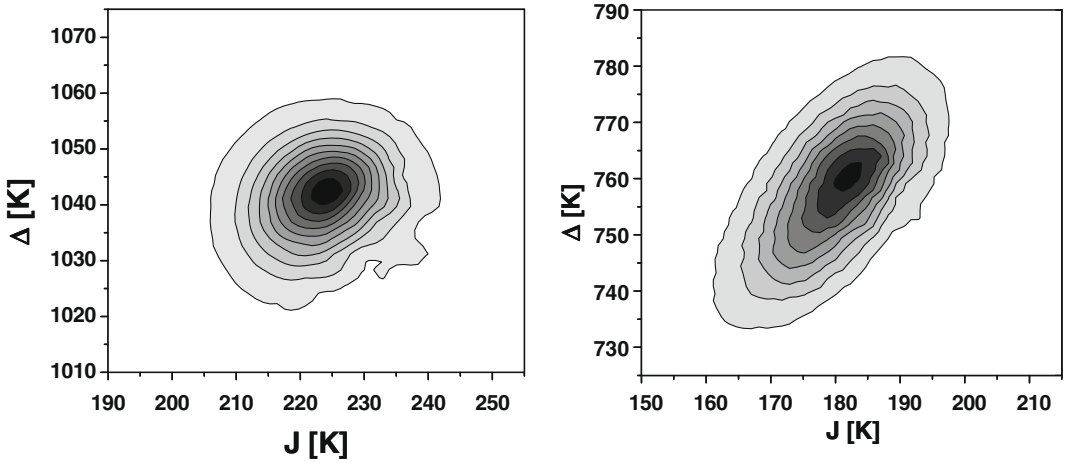

Fig. 7. The $P(\Delta, J)$ distributions of the undiluted system (left) and the mixed crystal system $Fe_{0.84}Zn_{0.16}(NCS)_2(btr)_2]\cdot H_2O$ (right) determined from the FORC data.

Table 3
Statistical analysis of the diagrams from Fig. 7.

x	$\bar{\Delta}$ (K)	$\sigma(\Delta)$ (K)	$\bar{J}$ (K)	$\sigma(J)$ (K)	$r_{\Delta J}$	$\bar{\Delta}$ (K)	$\sigma(\Delta)$ (K)	$\bar{J}$ (K)	$\sigma(J)$ (K)	$r_{\Delta J}$
0.8	1028	14.5	195	10.4	0.56	756	9.6	180	7.1	0.63
1.0	1225	8.8	235	8.3	0.16	1041	6.3	223	6.2	0.20

as the input degeneracy for Ising model the values determined from the calorimetric measurement presented above, i.e. $g = 2040$ for $x = 1.0$ and $g = 445$ for $x = 0.84$. The distributions obtained are presented in Fig. 7 and the statistical parameters that characterize them are reported in Table 3, on the right hand side. On the left hand side, one can find the averages $\bar{\Delta}$, $\bar{J}$, dispersions $\sigma(\Delta)$, $\sigma(J)$ and correlation $r_{\Delta J}$, as listed in Ref. [18].

We observed that even if the degeneracy was overestimated, the shape of the physical parameters diagrams did not suffer major modifications; the pure compound has a round shape distribution and the diluted one is more close to an ellipse. If we compare the results from a quantitative perspective, all the values obtained with our recently reliable degeneracy are smaller than in our initial study. The energy gap Δ was overestimated by 35% in the case of $x = 0.8$ compared with 17% for the non-diluted sample. If we refer to interactions, the modifications are below 8%. The only parameter that presents an opposite behavior is the correlation between Δ and J.

4. Conclusion

We have performed DSC measurements in the heating and cooling modes for a spin crossover compound $[Fe_xM_{1-x}(btr)_2(NCS)_2]\cdot H_2O$ (M^{II} = Ni, Zn) for pure and diluted cases. The heat capacity is dissymmetrical, for the pure compound $C_{p,heating} > C_{p,cooling}$ while for diluted compounds the situation is reversed $C_{p,heating} < C_{p,cooling}$. Entropy changes and the degeneracy ratio between HS and LS have been calculated from the experimental thermodynamical data and then we have applied the FORC technique in order to obtain the distribution of spin like domains on these compounds. We have also performed a statistical analysis on these distributions and found that the correlations between Δ and J increases with the dilution degree.

Ternary Cu(II) complexes
Phenanthroline
Sulfonamide derivatives
Oxidative DNA cleavage

ABSTRACT

Ternary copper(II) complexes (**1**–**3**) of 1,10-phenanthroline and ethylenediamine-R-sulfonamide derivatives (R = benzene, toluene and naphthalene rings) have been synthesized and characterized with the aid of X-ray diffraction and spectroscopic and electrochemical techniques. The crystal structures of the complexes show that the coordination polyhedron around copper(II) is distorted square planar. Both 1,10-phenanthroline and ethylenediamine-R-sulfonamide act as bidentate ligands. The three structures are stabilized by π–π stacking interactions. The interaction of the complexes with calf thymus DNA has been investigated by thermal denaturation studies which indicated that DNA was stabilized in the presence of the compounds. The increase in DNA stability induced by the complexes follows the order: **3** > **2** > **1**. All three complexes were found to be very efficient agents of plasmid DNA cleavage in the presence of ascorbate as reducing agent. Mechanistic studies of the DNA cleavage process performed with radical scavengers show that the reactive oxygen species involved in the DNA damage are the hydroxyl radical, singlet oxygen-like species, the superoxide and hydrogen peroxide.

1. Introduction

The success of cisplatin and other platinum anticancer drugs has stimulated a renaissance of inorganic medicinal chemistry and the search for complexes of other transition metals with interesting biological properties [1,2]. The continuous demand for new anticancer drugs has addressed chemotherapeutic research based on the use of essential metalloelements [3] since potential drugs developed in this way may be less toxic and more prone to exhibit antiproliferative activity against tumors. In this context, copper(II) and its complexes play an important role as suitable species for antiproliferative tests [4,5].

In recent years, there has been substantial interest in the rational design of novel transition metal complexes which bind and cleave duplex DNA with high sequential or structural selectivity [6–8]. An approach to the discovery of new metallodrugs involves binding an organic compound of known therapeutic value to a metal-containing fragment; this results in a metal–drug synergism in which the metal acts as a carrier and stabilizer for the drug until it reaches its target, while at the same time the organic drug carries and protects the metal preventing side reactions in its transit toward a second target of biological action [9]. Such combined effects may result in an important enhancement of the activity of the drug and the opening of new mechanism of action, such as when the well-known breast cancer drug tamoxifen is coordinated to iron (Ferrocifen) [10]. The use of transition metal complexes as artificial nucleases is an area of extensive research due to the diverse structural features and reactivity of such complexes [11,12].

For the past several years, our group has worked on the synthesis of copper–sulfonamide complexes in order to obtain novel antitumor agents. These complexes are especially attractive as anticancer agents because several substituted sulfonamides have been found to arrest the cell cycle, causing apoptosis in the M phase [13]. In this context, we have described the nuclease activity of several copper–sulfonamide complexes [14–21]. In the present paper, we report three new copper ternary complexes of substituted *N*-sulfonamides derived of ethylenediamine (Chart 1) and 1,10-phenanthroline. 1,10-Phenanthroline is a versatile ligand able to chelate copper to give mono-phen or bis-phen copper complexes at the oxidation state I or II [22]. In the presence of hydrogen peroxide, the $Cu^{I}(phen)_2$ complex efficiently cleaves DNA by oxidative attack on deoxyribose units in the DNA minor groove [23,24]. The presence of two organic ligands with biological properties and, on the other hand, the known nuclease ability of copper(II) complexes in the presence of reducing agents may lead to the development of new products with remarkable antitumoral properties.

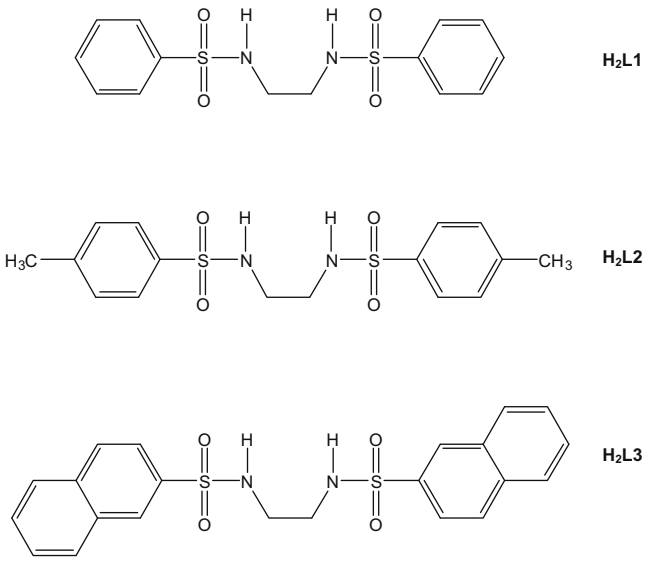

Chart 1. Scheme of the ligands.

2. Experimental

2.1. Materials and physical measurements

Reagents and solvents were commercially available (Sigma) in high purity and used as received. Plasmid pUC18 (0.25 μg/μL, 750 μM in nucleotides) in TE (tris 10 mM and EDTA 1 mM, pH 8.0) was purchased from Roche Diagnostics, Germany. CT-DNA (type XV) was from Sigma. Solutions of the metal complexes and other reagents for strand scission experiments were prepared fresh daily.

Elemental analyses (C, N, H, S) were performed on a Carlo Erba AAS instrument. Infrared spectra were recorded with a Mattson Satellite FT-IR spectrophotometer from 4000 to 400 cm^{-1} on KBr disks. Diffuse reflectance spectra (nujol mulls) of the complexes were performed on a Shimadzu 2101-PC UV–Vis spectrophotometer. UV–Vis spectra of the complex solutions were recorded with an HP 8453 instrument. Fast atom bombardment (FAB) mass spectra were obtained with a VG Autospec spectrometer with 3-nitrobenzyl alcohol as matrix. ESI mass (+ mode) analyses were performed on a Bruker Esquire 3000 plus LC-MS system. Electronic Paramagnetic Resonance (EPR) spectra of ground crystals were collected at the X-band frequency at room temperature with a Bruker ELEXSYS spectrometer. Cyclic voltammetry experiments were performed in a single compartment cell with a three-electrode system on a PAR 273A potentiostat/galvanostat. The working and auxiliary electrodes were platinum, and the reference electrode was Ag/AgCl. The supporting electrolyte was tetrabutylammonium perchlorate. Solutions of the complexes were deoxygenated by purging with nitrogen for 15 min prior to measurement.

2.2. Synthesis of the ligands

2.2.1. N,N′-(Ethane-1,2-diyl)dibenzenesulfonamide (H_2L1) and N,N′-(ethane-1,2-diyl)dinaphthalene-2-sulfonamide (H_2L3)

A solution containing 1 g of ethylenediamine (16.6 mmol) and 34 mmol of benzenesulfonylchloride (6.0 g) (for H_2L1) or naphthalenesulfonylchloride (7.7 g) (for H_2L3) in 6 mL of pyridine was heated at reflux for 10 h. The mixture was added to 10 mL of cold water and stirred for several minutes. The resulting solid was recrystallized from ethanol.

Anal. Calc. for $C_{14}H_{16}N_2S_2O_4$ (H_2L1) (340.06): C, 49.40; H, 4.74; N, 8.23; S, 18.84. Found: C, 49.35; H, 4.73; N, 8.27; S, 19.13%. Yield: 85%. IR (KBr) (ν_{max}/cm^{-1}): 3321, 3273 (N–H); 1324, 1157 (SO_2). FAB: m/z^+ 341 $[H_2L1 + H]^+$.

Anal. Calc. for $C_{22}H_{20}N_2S_2O_4$ (H_2L3) (440.09): C, 59.98; H, 4.58; N, 6.36; S, 14.56. Found: C, 59.32; H, 4.55; N, 6.36; S, 14.15%. Yield: 75%. IR (KBr) (ν_{max}/cm^{-1}): 3282 (N–H); 1336, 1156 (SO_2). FAB: m/z^+ 441 $[H_2L3 + H]^+$.

2.2.2. N,N′-(Ethane-1,2-diyl)bis(4-methylbenzenesulfonamide) (H_2L2)

This compound was obtained and characterized as previously reported [25].

2.3. Synthesis of [Cu(L1)(phen)] (**1**), [Cu(L2)(phen)]·H_2O (**2**) and [Cu(L3)(phen)](**3**)

0.5 mmoles of the ligand were dissolved in 30 mL of methanol (H_2L1 or H_2L2) or in a mixture of 35 mL methanol and 10 mL *N*,*N*′-dimethylformamide (H_2L3). To this solution were then added 2 mL of a methanolic solution of KOH (0.5 M) and 0.25 mmol of $Cu(CH_3COO)_2{\cdot}H_2O$. Separately, another solution was prepared by dissolving 0.5 mmol of 1,10-phenanthroline (phen) in 25 mL of methanol and then added dropwise under continuous stirring to the solution containing the ligand and the Cu(II) salt. The final green reaction mixture was stirred for an hour at 30 °C and was then left to stand at room temperature. Slow evaporation of this resulting solution provided well-developed blue crystals of the compounds that were suitable for X-ray diffraction.

Anal. Calc. for $C_{26}H_{22}CuN_4S_2O_4$ (**1**) (582.15): C, 53.64; H, 3.81; N, 9.62; S, 11.02. Found: C, 53.18; H, 3.94; N, 9.12; S, 11.18%. Yield: 72%. IR (KBr) (ν_{max}/cm^{-1}): 1269, 1135 $\nu(SO_2)$. Diffuse reflectance (λ_{max}, nm): 396 ($\pi \rightarrow \pi^*$), 590, 740sh (d–d). UV–Vis (λ_{max}, nm) in DMF: 386 ($\varepsilon = 1440\ M^{-1}\ cm^{-1}$), 627 ($\varepsilon = 305\ M^{-1}\ cm^{-1}$), ESI^+ mass spectra in DMF: m/z^+ 582.0 $[1+H]^+$.

Anal. Calc. for $C_{28}H_{28}CuN_4S_2O_5$ (**2**) (628.22): C, 53.53; H, 4.49; N, 8.92; S, 10.21. Found: C, 53.92; H, 4.32; N, 8.89; S, 10.24%. Yield: 65%. IR (KBr) (ν_{max}/cm^{-1}): 1266, 1133 $\nu(SO_2)$. Diffuse reflectance (λ_{max}, nm): 400 ($\pi \rightarrow \pi^*$), 590, 740sh (d–d). UV–Vis (λ_{max}, nm) in DMF: 386 ($\varepsilon = 1680\ M^{-1}\ cm^{-1}$), 623 ($\varepsilon = 265\ M^{-1}\ cm^{-1}$), ESI^+ mass spectra in DMF: m/z^+ 610.1 $[2\text{-}H2O+H]^+$.

Anal. Calc. for $C_{34}H_{26}CuN_4S_2O_4$ (**3**) (682.28): C, 59.85; H, 3.84; N, 8.21; S, 9.40. Found: C, 59.74; H, 3.89; N, 8.19; S, 9.32%. Yield: 76%. IR (KBr) (ν_{max}/cm^{-1}): 1279, 1122 $\nu(SO_2)$. Diffuse reflectance (λ_{max}, nm): 400 ($\pi \rightarrow \pi^*$), 630 (d–d). UV–Vis (λ_{max}, nm) in DMF: 629 ($\varepsilon = 215\ M^{-1}\ cm^{-1}$), ESI^+ mass spectra in DMF: m/z^+ 718.9 **3**+$2H_2O$+H]$^+$.

2.4. X-ray crystallography

A crystal of compound **1** (blue prismatic), compound **2** (blue needle) or compound **3** (blue plate) was mounted on a glass fiber and used for data collection. Crystal data were collected at 100.0(1) K, using a Bruker X8 Kappa APEXII diffractometer. Graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used throughout. The data were processed with APEX2 [26] and corrected for absorption using SADABS (transmissions factors: 1.000–0.099) [27]. The structure was solved by direct methods using the program SHELXS-97 [28] and refined by full-matrix least-squares techniques against F^2 using SHELXL-97 [29]. Positional and anisotropic atomic displacement parameters were refined for all nonhydrogen atoms. Hydrogen atoms were located in difference maps and included as fixed contributions riding on attached atoms with isotropic thermal parameters 1.2 times those of their carrier atoms. Criteria of a satisfactory complete analysis were the ratios of rms shift to standard deviation less than 0.001 and no significant features in final difference maps. Atomic scattering factors were from "International Tables for Crystallography" [30]. Molecular graphics were from PLATON [31] and SCHAKAL [32]. A summary of the crystal

data, experimental details and refinement results for the three complexes are listed in Table 1.

2.5. DNA-melting experiments

DNA-melting experiments were carried out by monitoring the absorption spectrum between 1000 and 200 nm of CT-DNA (50 μM base pairs) at different temperatures in both the absence and the presence of the ligands or the complexes in a ratio of 2.5:1 DNA to complex. Measurements were performed with an Agilent 8453 UV–Vis spectrophotometer equipped with a Peltier temperature controlled sample cell and driver (Agilent 89090A). Solutions containing the ternary complexes (**1**–**3**) and CT-DNA in borate buffer, pH 8 (1 mM borate, 2 mM NaCl) was stirred continuously and heated with a temperature increase of 1 °C min^{-1}. The temperature interval studied ranged from 25 to 90 °C. The melting point was obtained with the first derivative using the Savitsky–Golay algorithm.

2.6. pUC18 DNA cleavage

A typical reaction for complexes was undertaken by mixing 7 μL of 0.05 M borate buffer (pH 8.0), 1 μL of pUC18 (0.25 μg/μL), 6 μL of a solution of the tested complex at increasing concentrations to obtain final concentrations between 3 and 12 μM and 6 μL of ascorbate, in a 1000-fold molar excess relative to the concentration of the complex in borate buffer (0.05 M, pH 8.0). The mixtures were allowed to stand at 37 °C for 60 min, after which, 3 μL of a loading buffer solution consisting of 0.25% bromophenol blue, 0.25% xylene cyanole, and 30% glycerol was added. The solution was then subjected to electrophoresis on a 0.8% agarose gel in 0.5 × TBE buffer (0.045 M tris(hydroxymethyl)aminomethane (tris), 0.045 M boric acid, and 1 mM EDTA) containing 2 μL/100 mL of a solution of ethidium bromide (10 mg/mL) at 80V for about 2 h. The gel was photographed using a TDI Gel Printer Plus system.

To test for the presence of reactive oxygen species (ROS) generated during strand scission, reactive oxygen intermediate scavengers were added alternatively to the reaction mixtures. These scavengers were DMSO (0.4 M), *tert*-butyl alcohol (0.4 M), sodium formate (0.4 M), 1,4-diazabicyclo[2,2,2]octane (DABCO) (0.4 M), 4, 5-dihydroxy-1,3-benzenedisulfonic acid (Tiron) (0.1 M) and catalase (10 μg/mL, 650 U/mL). Assays in the presence of the minor groove binder distamycin (8 μM) and major groove binder methyl green (3 μM) or the copper(I) stabilizer neocuproine, at different concentrations (12, 120 and 240 μM) were also performed. Samples were treated as described above.

3. Results and discussion

3.1. Crystal structures of the complexes *1*–*3*

Figs. 1–3 show the molecular structure of complexes **1**–**3** respectively with the atomic labeling scheme adopted. The relevant structural parameters for the compounds are listed in Table 2. The crystal structures of compounds **1**–**3** consist of a discrete monomeric copper(II) species surrounded by two N atoms belonging to a phenanthroline molecule and two sulfonamido N atoms of the dideprotonated *N*-sulfonamide ligands in a distorted square-planar geometry.

Both, the dideprotonated sulfonamide ligand ($L1^{2-}$, $L2^{2-}$ or $L3^{2-}$) and the 1,10-phenanthroline, act as bidentate forming five-membered rings with the metal ion. The Cu–Nphen distances which range from 1.992(5) Å to 2.024(5) Å are similar to those reported for copper–phenanthroline complexes [33]. The Cu–Nsulfonamidato bond lengths lie in the range from 1.947(4) Å to 1977(5) Å and are normal distances for copper–sulfonamidato complexes [25]. The N–Cu–N angles that describe the coordination polyhedron [82.13(19)–104.67(19)° in **1**, 81.99(15)–103.64(15)° in **2** and 81.67(18)–103.30(2)° in **3**] deviate significantly from 90°. In all complexes, the smaller angle corresponds to that formed by the copper ion and the two phenanthroline nitrogen atoms, as a consequence of the constrained geometry of the phen rings [34–36].

The distortion of the square-planar geometry (commonly known as tetrahedrality) can be determined from the angle subtended by two planes, each encompassing the copper and two adjacent atoms. The tetrahedrality values of 46.46°, 34.0° and

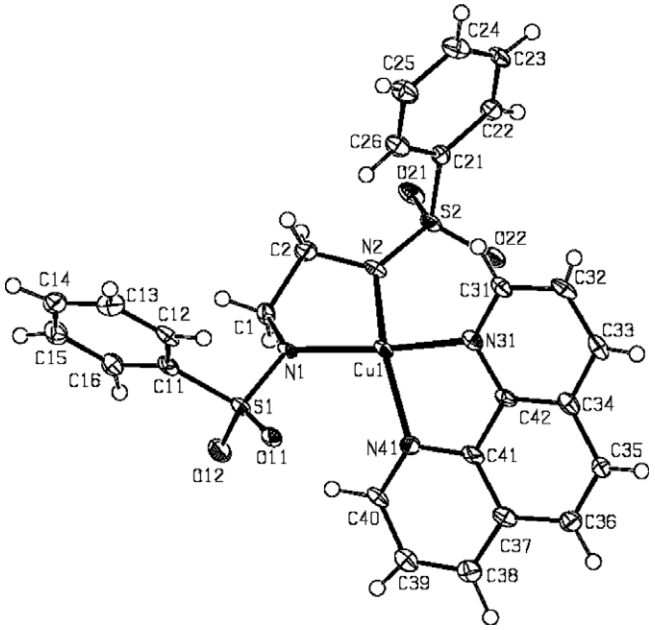

Fig. 1. ORTEP view of [Cu(L1)(phen)] (**1**).

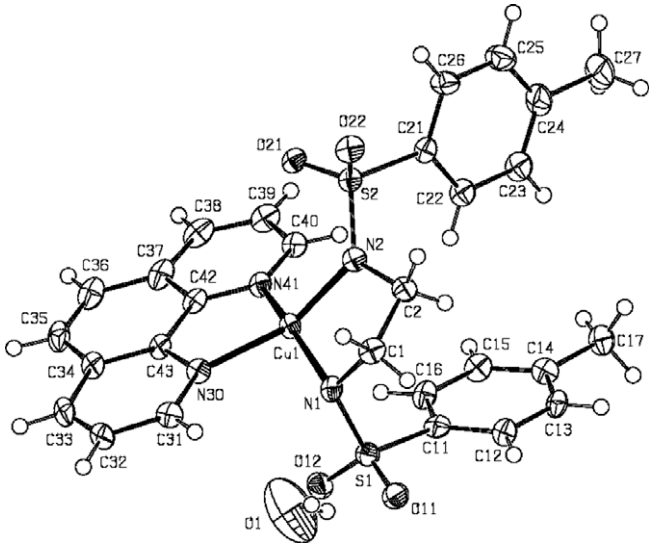

Fig. 2. ORTEP drawing of complex [Cu(L2)(phen)]·H_2O (**2**).

28.70° for **1**, **2** and **3**, respectively indicates that the copper ion adopts a significant distorted square-planar geometry. This distortion can be attributed to the presence of two bidentate ligands.

One remarkable aspect to be considered in the crystal structures of the compounds is the presence of the π–π stacking interactions which are similar for complexes **1** and **2** and have different characteristics for complex **3**. The structures of complexes **1** and **2** are stabilized by π–π interactions brought on by intermolecular parallel π–π stacking between the phenanthroline rings belonging to adjacent complex molecules (Fig. 4) [33,34,36,37]. The geometric parameters characterizing these interactions are summarized in Tables 3 and 4. In addition, the structure of complex **2** is stabilized by an intermolecular hydrogen bond of moderate strength [38] formed between the O(1) of a water molecule and the O(11) of the sulfonamide group [O(1)···O(11), 2.841(7) Å, O(1)–H(10B)···O(11), 168.1°].

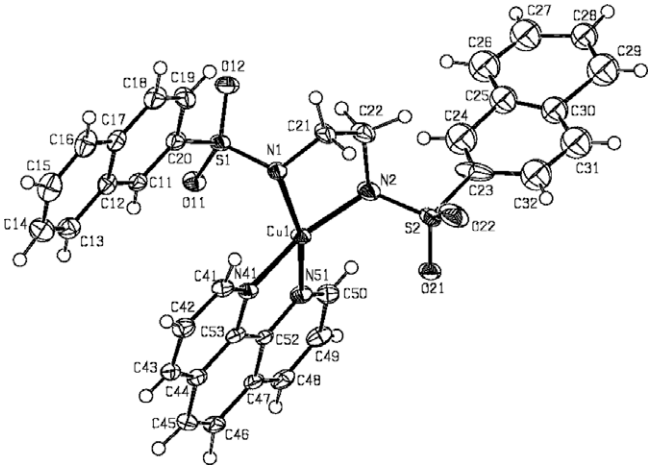

Fig. 3. ORTEP view of [Cu(L3)(phen)] (**3**).

Complex **3** presents strong π–π stacking interactions involving the phenanthroline molecules, the "Cu chelate" (the chelate ring formed by the copper atom and the coordinated phenanthroline, Cu1–N41–C53–C52–N51) and the naphthalene rings. Phen–phen and phen–"Cu chelate" interactions occur between neighboring complex molecules. Additional phen–naphthalen interactions occur between the resulting pairs and adjacent complex molecules, giving rise to 2D frameworks, parallel to *ac* plane (Fig. 5). The geometric parameters for these π–π interactions are summarized in Table 5. These π–π interactions are similar to those reported for other copper complexes of 1,10-phenanthroline [39,40].

3.2. Spectroscopic properties

All the complexes present the same infrared spectrum pattern. As for the sulfonamide group, the bands assigned to $\nu(SO_2)_{as}$ and $\nu(SO_2)_s$ vibrations are slightly shifted to lower frequencies with respect to those of the uncoordinated ligands. In general, the IR spectra are similar to those observed for other copper *N*-sulfonamide derivatives [17,41] with the modifications noted above being mainly due to ligand deprotonation at the sulfonamide group. In addition, the spectrum of the complex exhibits new bands at 1428, 1254, and 850 cm^{-1}, which are assigned to the characteristic vibrations of the coordinated phenanthroline molecules [42,43].

The diffuse reflectance spectra of complexes **1** and **2** exhibit a d–d maximum at 590 nm and a shoulder at about 740 nm while that of complex **3** shows a broad d–d maximum centered at about 630 nm. These bands correspond to ligand field transitions of distorted square planar complexes with CuN_4 chromophores [44]. The spectra of DMF solutions of complexes **1–3** show the same maxima at 630 nm, thus suggesting that all three compounds contain the same chromophore in solution. The shift of the d–d band position with respect to that in the diffuse reflectance spectra is probably a consequence of the coordination of solvent molecules. These results are in agreement with those obtained from the ESI experiments which show that the copper(II), a sulfonamidate ligand, and a phenanthroline species exist as a whole entity.

The EPR spectrum of the complex **1** (Fig. 6) is slightly rhombic. The EPR parameters obtained by simulation [45] are: $g_x = 2.042$, $g_y = 2.063$ and $g_z = 2.233$. For systems with $g_z > g_y > g_x$ the ratio $R = (g_y - g_x)/(g_z - g_y)$ indicates the ground state of the complex [46]. The *R* value of 0.12 for **2** suggests than the unpaired electron of copper(II) is in the d_{x2-y2} orbital. The EPR spectra of the complexes **2** and **3** are axial with the following EPR parameters $g_{||} = 2.218$ and 2.210 and $g_\perp = 2.057$ and 2.050, respectively. The $g_{||} > g_\perp$ indicates a mainly copper(II) d_{x2-y2} ground state.

3.3. Cyclic voltammetry experiments

The electrochemical profiles of the complexes were studied in DMF by cyclic voltammetry in the range of 1.0 to −1.0 V. In the three cases, the voltammograms show irreversible redox processes with one cathodic peak at −0.108 V, −0.144 V and −0.103 V for **1**–**3**, respectively (versus NHE) (Fig. S1). All the redox processes are clearly irreversible suggesting that the copper(I) species decompose at higher potential. The reduction peaks indicate that the stability of the copper(II) complex decreases as follows: **2** > **1** ≈ **3**.

3.4. Thermal denaturation studies

Since DNA is the primary pharmacological target of many antitumor compounds [47], the interaction between DNA and metal complexes is of paramount importance in understanding the mechanism of tumor inhibition for the treatment of cancer. Thus, the binding of the ligands and the complexes **1**–**3** to CT-DNA was studied by measuring changes in the melting temperature (T_m) of DNA that characterizes the transition from a double-stranded nucleic acid to a single stranded one [48]. The melting curves for complex **1** and the CT DNA are shown in Fig. 7. The three compounds produced a large increase in T_m (T_m = 50.8 °C for CT-DNA; T_m = 62.7, 64.6 and 69.9 °C for **1**, **2** and **3**, respectively) when the concentration ratio of DNA to complex is 2.5:1, which indicates a strong metal complex–DNA interaction that stabilizes the native DNA conformation [49]. The considerable increase of the melting temperature of DNA produced by the compounds is also indicative of an intercalative binding mode involving the phenanthroline molecule. The stronger interaction of complex **3** may be the result of the presence of a naphthalene ring in the sulfonamide ligand, which reinforces its DNA-binding propensity by stacking interaction. Moreover, our results reveal that the sulfonamide ligands have not significant effect on T_m of CT-DNA, suggesting that the free sulfonamides do not interact with the nucleic acid (data not shown).

3.5. Cleavage of pUC18 DNA

The DNA endonucleolytic cleavage, activated by metal ions, has been of interest to researchers [50]. Transition metal-mediated radical production may result in an efficient DNA cleavage. DNA cleavage is controlled by relaxation of the supercoiled circular form of pUC18 into the nicked circular and linear forms. When circular plasmid DNA is run in horizontal gel using electrophoresis, the fastest migration will be observed for the supercoiled form (Form I). If one strand is cleaved, the supercoils will relax to produce a slower-moving open circular form (Form II). If both strands are cleaved, a linear form (Form III) that migrates in between will be generated.

The ability of complexes **1**–**3** to cleave DNA was investigated by means of gel electrophoresis with supercoiled pUC18 in 0.05 M borate buffer (pH 8.0) and with ascorbate activation. Control

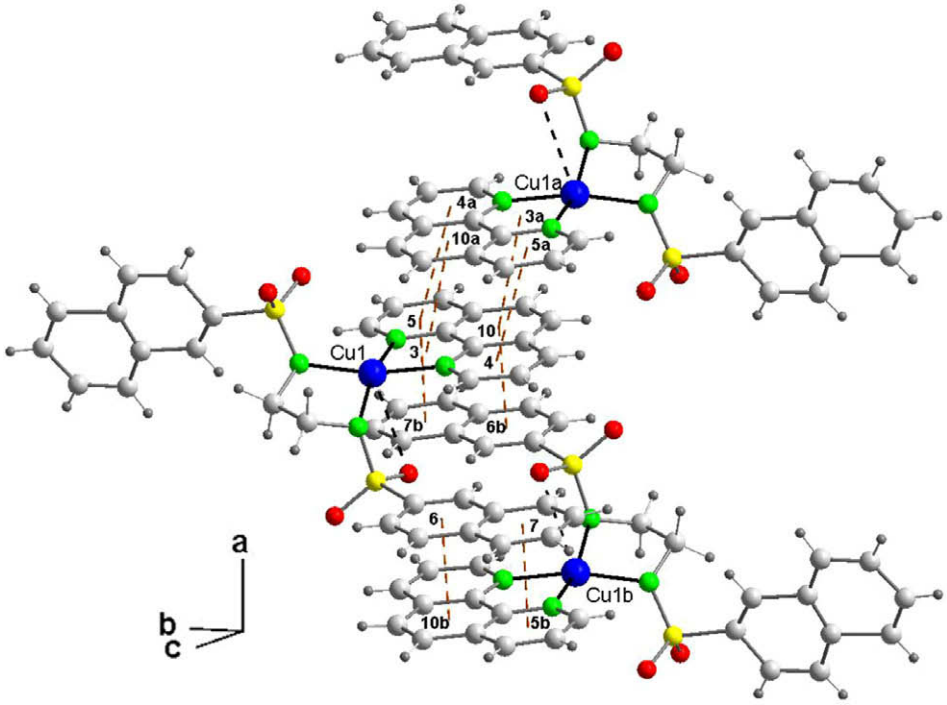

Fig. 5. Portion of the crystal packing of complex **3** showing the π–π interactions and the scheme of numeration of the rings.

experiments with $CuCl_2$ were also carried out under the same experimental conditions. All the complexes were found to exhibit nuclease activity (Fig. 8) and were more effective at higher concentrations. At 9 μM the complexes were able to transform almost completely Form I into Form II. At 12 μM the compounds induced complete degradation of the supercoiled Form I to yield open circular (Form II) and linear DNA (Form III) (lanes 10, 11 for complex **1**, lanes 14, 15 for complex **2** and lanes 18, 19 for complex **3**).

Neither the copper salt with ascorbate (lane 4) nor the copper complexes without ascorbate at the maximum concentration assayed (lanes 5, 6 and 7, respectively) yields significant strand scission, proving that both the copper complex and the ascorbate are required for the efficient DNA cleavage. Even though active, the three complexes exhibit lower nucleolytic efficiency as compared to that of the bis(*o*-phenanthroline)copper(II) complex, a well-known and very efficient chemical nuclease. Thus, at 12 μM $[Cu(phen)_2]^{2+}$ induces the conversion of DNA into small linear fragments and a considerable smear appears (lane 20).

3.6. DNA cleavage mechanism

We used different inhibiting reagents to study various aspects of the mechanism of pUC18 DNA cleavage induced by the complexes with ascorbate activation (Figs. 9 and 10).

The reduction of the copper(II) complexes during the DNA cleavage process was evaluated by adding neocuproine, a ligand that strongly chelates copper(I), to the reaction mixtures. The

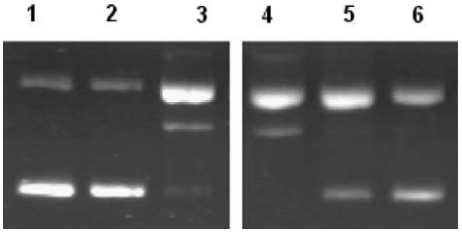

Fig. 9. Agarose gel electrophoresis of pUC18 plasmid treated with 12 μM complex **2** and 12 mM ascorbate in the presence of increasing concentrations of neocuproine. Incubation time: 1 h (37 °C). Lane 1: supercoiled DNA; lane 2: supercoiled DNA + ascorbate; lane 3: **2** without inhibitor; lane 4: **2** + neocuproine (12 μM); lane 5: **2** + neocuproine (120 μM); lane 6: **2** + neocuproine (240 μM).

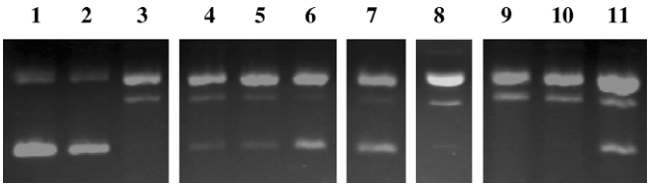

Fig. 10. Agarose gel electrophoresis of pUC18 plasmid treated with 12 μM complex **3** and 12 mM ascorbate in the presence of potential inhibitors. Incubation time: 1 h (37 °C). Lane 1: supercoiled DNA; lane 2: supercoiled DNA + ascorbate; lane 3: **3** without inhibitor; lane 4: **3** + DMSO (0.4 M); lane 5: **3** + *tert*-butyl alcohol (0.4 M); lane 6: **3** + sodium formiate (0.4 M); lane 7: **3** + DABCO (0.4 M); lane 8: **3** + Tiron (0.1 M); lane 9: **3** + distamycin (8 μM); lane 10: **3** + methyl green (3 μM); lane 11: **3** + catalase (6.5 units).

effect of neocuproine on the DNA cleavage induced by the complexes was tested at different concentrations. Results for complex **2** are shown in Fig. 9. The addition of neocuproine at a concentration equivalent to that of the compound (12 μM) (lane 4) did not attenuate the DNA cleavage; however higher concentrations of neocuproine (120 and 240 μM) (lanes 5 and 6) clearly inhibit the DNA strand scission mediated by **2** which indicates that Cu(I) is formed in the DNA damage reaction. Complexes **1** and **3** exhibit a similar behavior (data not shown). Generation of a Cu(I) complex induced in the presence of ascorbate was expected to lead to the activation of dioxygen that, in turn, could produce the intermediate or intermediates responsible for plasmid DNA strand scission. If the reaction follows a Fenton-like mechanism, several possible intermediates could be formed, depending on the number of electrons transferred from the complex to O_2. The possible intermediates are superoxide anion (O_2^-), hydrogen peroxide (H_2O_2) or hydroxyl radical (·OH). The three-electron reduced species, hydroxyl radical, is a well-accepted oxidant of DNA both free in solution and coordinated to a metal complex [50]. The presence of free diffusible radicals can be ascertained through their competitive reduction due to additional hydrogen-atom donors in the reaction mixture. Thus, we used several radical scavengers that might inhibit the DNA scission induced in the presence of the title Cu(II) complexes. Data for complex **3** are shown in Fig. 10. Complexes **1** and **2** presented the same behavior. The DNA breakdown mediated by complex **3** was clearly inhibited in the presence of the hydroxyl radical scavengers DMSO, *tert*-butyl alcohol and sodium formiate (lanes 4–6), indicating that the freely diffusible hydroxyl radical is one of the intermediates involved in the DNA scission process. The addition of DABCO decreased the cleavage efficiency of the compound (lane 7), which suggests the involvement of singlet oxygen-like entities in the DNA damage. The DNA cleavage was attenuated in the presence of Tiron (lane 8) as a consequence of the involvement of superoxide in the DNA scission. The significant reduction in the ability of the complex to cleave DNA in the presence of catalase (lane 11) implies that hydrogen peroxide is necessary for the breakdown of DNA. The cleavage is oxidative in nature as the enzyme catalase, which lowers solution concentrations of hydrogen peroxide, inhibited the cleavage reaction. From these results we concluded that a Cu(I) complex, the hydroxyl radical, singlet oxygen-like species, the superoxide, and hydrogen peroxide are the active species involved in the DNA cleavage induced by **3**. A metal bound species similar to that proposed for the $[Cu(phen)_2]^{2+}$, often formulated as $[CuOH]_2^+$ or $[CuO]^+$, remains a possibility [12,50]. A cupric superoxo (Cu^{II}–O_2^-) or cupric hydroperoxo (Cu^{II}–OOH) such as that suggested for peptidylglycine monooxygenase and dopamine β-hydroxylase may also serve as the active O_2-derived species [51–53].

In the presence of the minor groove binder distamycin and major groove binder methyl green (lanes 9 and 10, Fig. 10), no

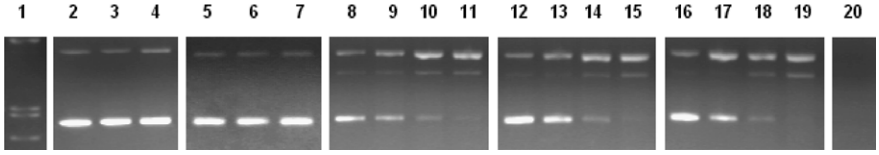

Fig. 8. Agarose gel electrophoresis of pUC18 plasmid DNA, in the presence of the complexes **1**–**3** or $CuCl_2$, with or without ascorbate activation. Incubation time: 1 h (37 °C). Lane 1: λDNA/EcoRI + Hind III Marker; lane 2: supercoiled DNA; lane 3: supercoiled DNA + ascorbate 12 mM; lane 4: 12 μM $CuCl_2$ + 12 mM ascorbate; lane 5: 12 μM **1** without ascorbate; lane 6: 12 μM **2** without ascorbate; lane 7: 12 μM **3** without ascorbate; lane 8: 3 μM **1** + 3mM ascorbate; lane 9: 6 μM **1** + 6 mM ascorbate; lane 10: 9 μM **1** + 9 mM ascorbate; lane 11: 12 μM **1** + 12 mM ascorbate; lane 12: 3 μM **2** + 3 mM ascorbate; lane 13: 6 μM **2** + 6mM ascorbate; lane 14: 9 μM **2** + 9 mM ascorbate; lane 15: 12 μM **2** + 12 mM ascorbate; lane 16: 3 μM **3** + 3mM ascorbate; lane 17: 6 μM **3** + 6 mM ascorbate; lane 18: 9 μM **3** + 9 mM ascorbate; lane 19: 12 μM **3** + 12 mM ascorbate; lane 20: 12 μM $[Cu(phen)_2]^{2+}$ + 12 mM ascorbate.

apparent inhibition of DNA damage was observed, a finding that implies a lack of interaction of the complexes through the grooves.

4. Conclusions

Ternary copper(II) complexes with ethylenediamine-R-sulfonamide derivatives and phenanthroline have been prepared and structurally characterized with the aid of X-ray crystallography. Their interaction with DNA has been studied with the aid of T_m measurements, which have indicated an intercalative mode of binding between DNA base pairs. The complexes act as efficient chemical nucleases upon ascorbate activation. The participation of hydrogen peroxide, hydroxyl radical, superoxide anion and singlet-oxygen-like entities in the scission process mediated by the compounds suggests a mechanism pathway involving a Fenton or a Haber–Weiss reaction. Results indicate that these compounds can be used as potential chemotherapeutical agents, although further investigations need to be carried out.

ABSTRACT

Li_2[1,2-$C_6H_4(NCH_2tBu)_2$] reacts with one equiv of [$TiCl_4(THF)_2$] in refluxing toluene to give the chelate compound [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] (**1**), isolated as a black product, while the reaction of the dilithio diamido salt with one equiv of [$ZrCl_4(THF)_2$] in refluxing toluene affords the dinuclear zirconium derivative [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}Cl(THF)(μ-Cl)]$_2$ (**2**), obtained as an orange solid. Treatment of the dilithio diamido salt with $TaCl_5$ in a 2:1 molar ratio in toluene yields [Ta{1,2-$C_6H_4(NCH_2tBu)_2$}$_2$Cl] (**3**) as a red product. The reaction of 1,2-$C_6H_4(NHCH_2tBu)_2$ with [$Zr(NMe_2)_4$] in toluene at room temperature affords the dinuclear zirconium complex [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}(NMe_2)(μ-NMe_2)]$_2$ (**4**). The dibenzyl derivative [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}(CH_2Ph)$_2$] (**5**) is obtained by the reaction of **1** with 2 equiv of Mg(CH_2Ph)Cl at −78 °C. Compound **1** reacts with the lithium amide reagent LiN($SiMe_3$)$_2$ to afford [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl{N($SiMe_3$)}] (**6**). The μ-oxo titanium derivative [(Ti{1,2-$C_6H_4(NCH_2tBu)_2$}{CH_2Ph})$_2$(μ-O)] **7** is precipitated when compound **5** is maintained in solution. The tendency of these compounds to coordinate donor ligands and their reactivity with Lewis acid reagents are described. All compounds were analytically and spectroscopically characterised and the molecular structures of the diamine 1,2-$C_6H_4(NHCH_2tBu)_2$ and the complexes **3** and **4** were established by single-crystal X-ray diffraction studies. The lack of correlation between the degree of metallacycle folding and phenylene ring distortion is observed in the solid state structures. The performance of precursors **1**, **3** and **5** were evaluated in ethylene polymerisation upon activation with B(C_6F_5)$_3$, methylaluminoxane (MAO) and sMAO as cocatalysts, with very modest activities.

1. Introduction

In recent years olefin polymerisation investigations have focused on the development of non-Cp based catalysts giving rise to previously unknown polymerisation behaviours and new polyolefin materials [1].

Bis(phenoxido-imino) group 4 metal complexes and titanium and zirconium derivatives with chelating diamido ligands [2,3] are currently receiving considerable attention, largely because of their potential use as homogeneous catalyst precursors for the α-olefin polymerisation process [4]. Chelating diamido ligands are versatile in view of the large number of possible available substituents attached to the nitrogen atoms [5]. Corresponding group 5 metal complexes are less active in polymerisation, so they have not been widely studied as potential catalysts for olefin polymerisation, although they are more tolerant of functionalised olefin monomers [6,7].

We are interested in the synthesis and chemical behaviour of MCp′(LL)X derivatives (Cp′ = substituted or unsubstituted η^5-cyclopentadienyl ring; LL = chelating diamido [8–10] and dialkoxo [11–13] ligands). The synthesis and characterisation of new chloro diamido complexes of titanium and zirconium $MCp^{R'}$[1,2-$C_6H_4(NR)_2$]Cl [M = Ti, Zr; $Cp^{R'}$ = η^5-C_5H_5, η^5-$C_5(CH_3)_5$, η^5-$C_5H_4(SiMe_3)$; R = *n*Pr, Np] have been described [8–10]. These complexes were tested as potential catalysts for ethylene and styrene polymerisation after activation with MAO. In this context, we report here a series of dichloro titanium, zirconium and chloro tantalum complexes bearing the bulky diamido ligand [1,2-$C_6H_4(NCH_2tBu)_2$]$^{2-}$ not supported by a cyclopentadienyl ring. The presence of the ligand [1,2-$C_6H_4(NCH_2tBu)_2$]$^{2-}$ in the metal

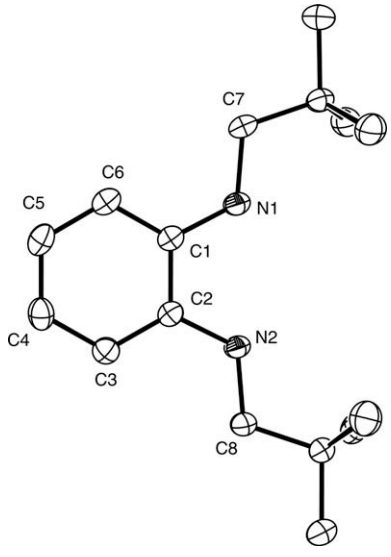
doi:10.1016/j.poly.2009.05.055

environment not only provides the delicate electronic balance and electronic relief to the Lewis acidic metal centre on account of its electron rich nitrogen atoms, but the bulky neopentyl substituents also render enough steric protection to the electrophilic metal centre.

2. Results and discussion

The synthesis of *N*,*N*′-alkyl 1,2-phenylenediamines 1,2-$C_6H_4(NHR)_2$ [R = $CH_2CH_2CH_3$ (*n*Pr), CH_2tBu (Np)] has been reported [8] in three steps, lithiation of the corresponding primary 1,2-phenylenediamine, reaction with the appropriate acyl chloride and reduction using $LiAlH_4$. However, no crystallographic data were published. In the course of the present study, the solid state structure of the compound 1,2-$C_6H_4(NHCH_2t$Bu$)_2$ has been confirmed by single-crystal X-ray diffraction (Fig. 1). Crystals suitable for the X-ray diffraction were obtained from methanol at room temperature. The angles around the nitrogen atom show the expected values for a geometry consistent with secondary amine species [14].

The addition of Li*n*Bu to a stirred suspension of the diamine 1,2-$C_6H_4(NHCH_2t$Bu$)_2$ in cold hexane resulted in the immediate deposition of the corresponding lithium salt, which further reacts in toluene with $[MCl_4(THF)_2]$ (M = Ti, Zr) or $TaCl_5$. This strategy allows the preparation of a series of titanium, zirconium and tantalum chloro derivatives synthesized by a metathesis reaction (Scheme 1). Reaction of Li_2[1,2-$C_6H_4(NCH_2t$Bu$)_2$] with one equiv of $[TiCl_4(THF)_2]$ in refluxing toluene produces the chelate compound [Ti{1,2-$C_6H_4(NCH_2t$Bu$)_2$}Cl_2(THF)] (**1**) isolated as a black product. According to literature precedents [15–17], the initial formation of a bis-diamido compound [Ti{1,2-$C_6H_4(NCH_2t$Bu$)_2$}$_2$] could be suggested, which quickly should undergo an exchange reaction with the remaining $[TiCl_4(THF)_2]$ to give complex **1**. The THF coordination seems to be the driving force for this process since it avoids the possibility of metal reduction that sometimes occurs during conventional $TiCl_4$ metathesis reactions. Treatment of the dilithio diamido salt with $[ZrCl_4(THF)_2]$ in refluxing toluene affords the dinuclear zirconium derivative [Zr{1,2-C_6H_4(NCH$_2t$Bu$)_2$}Cl(THF)(μ-Cl)]$_2$ (**2**), obtained as an orange solid. The reaction of Li_2[1,2-$C_6H_4(NCH_2t$Bu$)_2$] with $ZrCl_4$ or $[ZrCl_4(THF)_2]$ in a molar ratio of 2:1 and the ligand redox reactivity of the corresponding coordinated zirconium complexes have been recently described [18]. The standard procedure described for group 4 metal complexes was also used for tantalum. Thus, when the dilithio diamido salt reacts with $TaCl_5$ in 2:1 molar ratio in toluene, formation of [Ta{1,2-$C_6H_4(NCH_2t$Bu$)_2$}$_2$Cl] (**3**) as a red product is observed immediately.



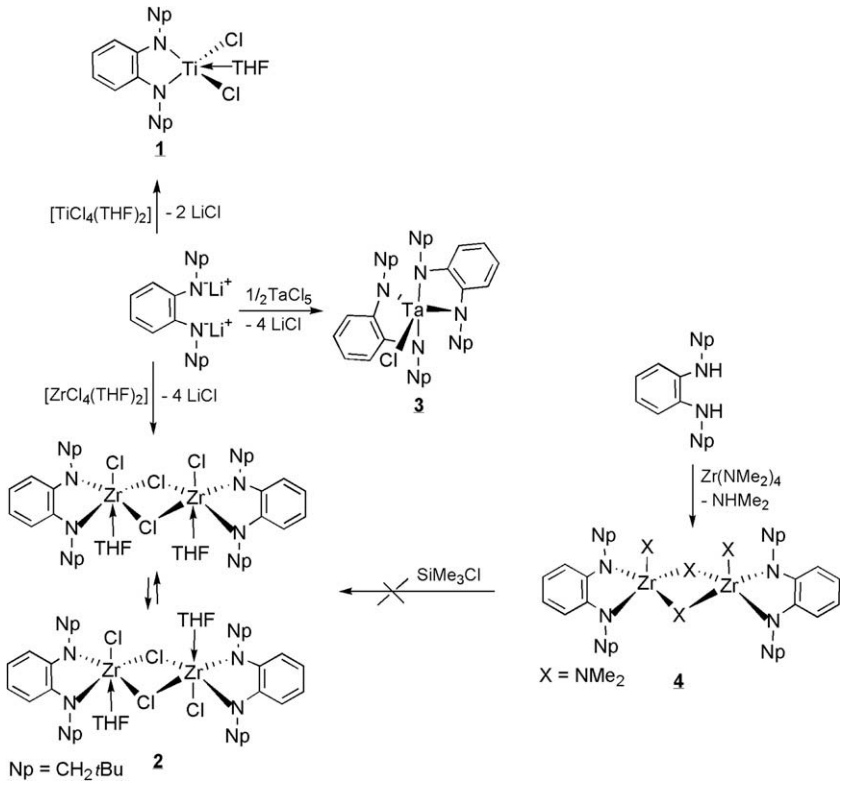


Fig. 1. ORTEP view of 1,2-$C_6H_4(NHCH_2t$Bu$)_2$ with 30% probability ellipsoids, hydrogen atoms have been omitted for clarity. Selected interatomic distances (Å) and angles (°): C(8)–N(2) = 1.457(2), C(2)–N(2) = 1.418(2), C(1)–C(2) = 1.418(2), C(2)–C(3) = 1.391(2), C(3)–C(4) = 1.400(2), C(4)–C(5) = 1.378(3), C(5)–C(6) = 1.400(3), C(1)–C(6) = 1.396(2), N(1)–C(7) = 1.454(2), N(1)–C(1) = 1.409(2), C(8)–N(2)–C(2) = 119.53(14), C(7)–N(1)–C(1) = 121.06(15).

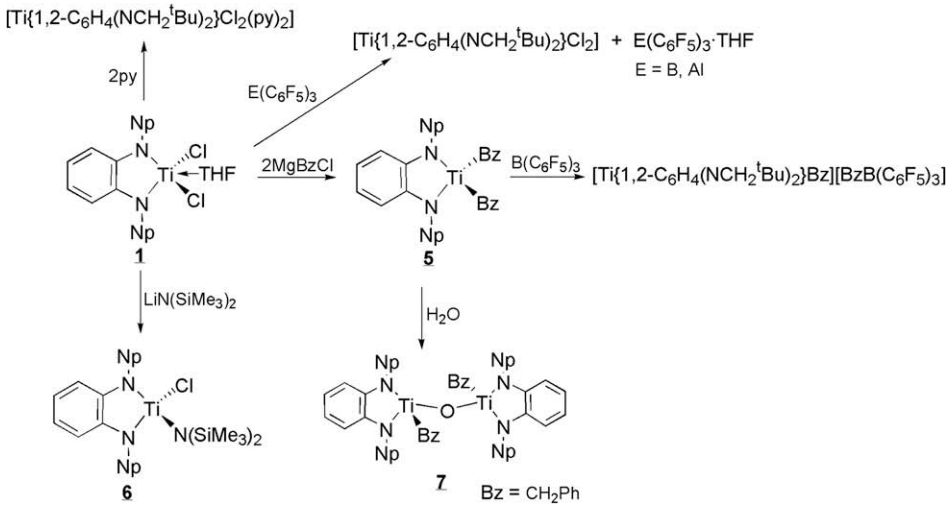
Complexes **1–3** are air and moisture sensitive in solution and in the solid state, although they can be stored unaltered for weeks under an inert atmosphere. The complexes were characterised by the usual analytical and spectroscopic methods (NMR spectra for different solvents are given in the Section 5 as consequence for resolution and assignment). The elemental analysis value found for **2** was inaccurate, caused by small amounts of LiCl in the mixture, which could not be removed. The molecular structure of **3** has been confirmed by single-crystal X-ray diffraction.

The formulation of **1** was based on NMR and analytical data in accordance with analogous complexes [19]. We suggest a five coordinate titanium centre in which the metal atom is surrounded by two chlorine atoms, the diamido chelating ligand and a molecule of coordinated THF to stabilise the final product. The ^{1}H NMR spectra (C_6D_6 or $CDCl_3$, 25 °C) are indicative of a C_{2v} symmetry and exhibits the expected signals assigned to the resonances arising for the phenylenediamido ligand, two signals for the phenyl ring, one signal for the methylenic and one singlet for the *tert*-butyl protons. The ^{1}H NMR spectra also indicate one coordinated THF molecule (δ 4.01 and 1.93 versus δ 3.76 and 1.85 for the free THF molecule in $CDCl_3$). Similar results were also observed in the ^{13}C NMR spectra under the same conditions. However, attempts to grow crystals of this product were unsuccessful.

The resonances observed in the NMR spectra at room temperature for the zirconium complex **2** in C_6D_6 or $CDCl_3$ broaden to a greater degree than those observed for the titanium species **1**. On the basis of the structural properties for the titanium compound **1** and the comparable amido compound **4**, we propose for **2** a dinuclear structure connected by two chlorine atoms comparable to that found in similar diamido complexes [20–24]. As in analogous compounds, in this structural disposition each zirconium centre must adopt an octahedral coordination surrounded by terminal diamido, one chloro and one THF ligand, with two chlorine atoms located in bridge positions. Variable temperature ^{1}H NMR studies were investigated for this compound. Resonances for the THF ligand are observed in the spectra at 40 °C. Upon cooling the sample to −70 °C all proton resonances sharpened and the data are consistent with the presence of two products (see Section 5). These spectroscopic observations suggest that at room temperature two rapidly interconverting forms are present in solution. These two forms are separated (with a 1:1 integrating ratio) at low temperature and would have the two diamido ligands and the two bridging chlorine atoms in the equatorial plane and the terminal THF and the chloro substituents in the *cis* or *trans* axial positions, respectively (Scheme 1).

We thought that problems for the spectroscopic characterisation of **2** might be eliminated by using an alternative synthetic route through amine elimination. The reaction of 1,2-C_6H_4(NHCH$_2t$Bu$)_2$ with $[Zr(NMe_2)_4]$ in toluene at room temperature affords the dinuclear zirconium complex [Zr{1,2-C_6H_4(NCH$_2t$Bu$)_2$}(NMe$_2$)(μ-NMe$_2$)]$_2$ (**4**) as a yellow solid in high yield (Scheme 1). The ^{1}H NMR spectra (C_6D_6 or $CDCl_3$, 25 °C) of **4** display three resonances for the NMe_2 fragments coordinated to the zirconium centre: one signal at δ 2.93 for six protons and two singlets at δ 2.85 and 1.55 (C_6D_6) integrating for three protons each one. The CH_2 attached to nitrogen atoms appears diastereotopic as doublets of an AB spin system. This spectroscopic pattern can be explained



Scheme 1. Synthesis of titanium, zirconium and tantalum phenylenediamido complexes.

by considering the complex as a dinuclear species connected through two NMe_2 units. The geometry at the zirconium atoms should be described as a distorted square pyramid with the NMe_2 fragment occupying axial positions and two NMe_2 units bridging the two metal centres. An indication of this conformation is provided by the proton resonance of the methyl groups positioned on the bridging amido ligand: two of which appear at δ 2.85, with the others at δ 1.55. Such a highfield shift would be expected if these methyl groups were positioned towards the phenylene ring and experience the influence of its magnetic anisotropy. On heating the sample, coalescence of the methyl signals of the NMe_2 is observed at 70 °C, indicating rapid positional equilibration of the NMe_2 moieties on the NMR timescale. For this process we have obtained Gibbs activation energy values ($\Delta G^{\#}$) of 65 ± 0.8 kJ/mol at 343 K. Similar results were also observed in the ^{13}C NMR spectra under the same conditions. The unequivocal arrangement of metal atoms in this complex has been established by X-ray diffraction studies (see *infra*). Addition of THF to C_6D_6 solutions of **4** did not reveal any tendency of THF coordination even upon heating the sample to 100 °C (in a Young's Teflon valve NMR tube). The lack of coordination could be ascribed to the crowded environment around zirconium which decreases the Lewis acidity at the metal and hinders THF approaching. The conversion of the amido compound **4** to the chloro derivative **2** was tried by using $SiMe_3Cl$ as a chloro transfer reagent, but a mixture of unidentified products was obtained.

The ^1H NMR spectra (C_6D_6 or CD_2Cl_2, 25 °C) of complex **3** show one signal for the CH_2 protons attached to the nitrogen atoms and two multiplets for the aromatic protons, indicating the presence of a molecule in solution that exhibits equivalent phenylenediamido fragment ligands in contrast to the molecular disposition observed in the solid state by X-ray diffraction studies (see *infra*). This fact prompted us to carry out structural investigations in solution. However, on cooling the sample to −70 °C unambiguous correlations could not be established and a clear resolution of the signals was not observed.

The coordinated THF molecule in **1** is labile and tends to dissociate from the titanium centre in the presence of a donor ligand. Conversion of **1** to [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}$Cl_2(py)_2$] was studied by NMR spectroscopy and occurs immediately at room temperature after adding free pyridine to a solution of **1** in $CDCl_3$ (Scheme 2). The NMR data show pyridine coordination [25] of two molecules with three broadened peaks at δ 9.62, 8.00 and 7.62 assigned to the coordinated pyridine and two multiplets at δ 3.76 and 1.85 due to free liberated THF, suggesting a six coordinated geometry around the titanium atom. The spectroscopic signals are broadened and the methylene resonances are not observed in the spectra, which indicate a coordination environment that is fluxional on the NMR timescale. Reactions of **1** with Lewis acids such as $E(C_6F_5)_3$ (E = B, Al) in $CDCl_3$ were monitored by NMR spectroscopy and show the abstraction of the coordinated THF to form [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2], concomitant with the formation of the adduct $E(C_6F_5)_3$·THF (Scheme 2). In a similar way, treatment of **2** with $B(C_6F_5)_3$ gives a CD_2Cl_2 solution in which the presence of a mixture of the species "Zr[1,2-$C_6H_4(NCH_2tBu)_2$]Cl_2" and $B(C_6F_5)_3$·THF is spectroscopically detected. We can conclude that the tendency of the titanium compound **1** and the zirconium complex **2** to coordinate donor ligands such as pyridine or THF reflects their acidic nature and the accessibility of the metal centre, and prompted us to investigate the polymerisation behaviour of this compound along with the reaction of the alkyl derivatives with different cocatalysts.

Methylation of **1** with MgMeCl in ether at −78 °C gave an unstable, intractable and unresolved mixture of products with a regrettably uninformative ^1H NMR spectrum. Due to the unexpected poor behaviour of the methyl ligand to create a stable coordination environment at the titanium centre, the use of voluminous ligands was explored to stabilise the alkyl compounds. The dibenzyl

Scheme 2. Reactions of the titanium phenylenediamido compound **1**.

derivative [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz_2] (**5**) (Bz = CH_2Ph) was obtained by the reaction in toluene of **1** with 2 equiv of MgBzCl in THF solution at −78 °C (Scheme 2). Recrystallisation from hexane at −30 °C affords, after filtration, higher purity material as a red oil. The ^1H NMR spectrum of **5** indicates that THF dissociation has occurred. The data are consistent with a compound with a degree of high symmetry. The four equivalent methylene protons in the "CH_2N" linkage appear as a singlet. The two equivalent benzyl ligands exhibit a singlet resonance integrating for four protons for the methylenic protons and three sets of *o*-, *m*-, and *p*-phenyl resonances. The expected signals for the phenylenediamido ligand are also observed. Complex **1** reacted readily with the lithium amide reagent $LiN(SiMe_3)_2$ to afford [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl{$N(SiMe_3)$}] (**6**) (Scheme 2). Thermolysis of **6** was carried out in the attempt to eliminate $SiMe_3Cl$ and to generate an imido [25] derivative, but after heating an NMR sample at 80 °C for 12 h only a mixture of unidentified products was observed.

When compound **5** is maintained in solution (toluene or hexane), the oxo derivative [(Ti{1,2-$C_6H_4(NCH_2tBu)_2$}{CH_2Ph})$_2$(μ-O)] **7** (Scheme 2) precipitates as red crystals, indicating the extreme sensitivity of **5** to moisture and confirming the formation of a benzyl derivative in the alkylating reaction of **1**. All attempts to obtain this product as a single and pure substance by controlled hydrolysis of **5** were unsuccessful with only a mixture of free amine and unidentified products being obtained. The molecular structure of **7** has been determined by X-ray diffraction methods although the crystals studied gave X-ray diffraction data of poor quality (Fig. 2).[2]

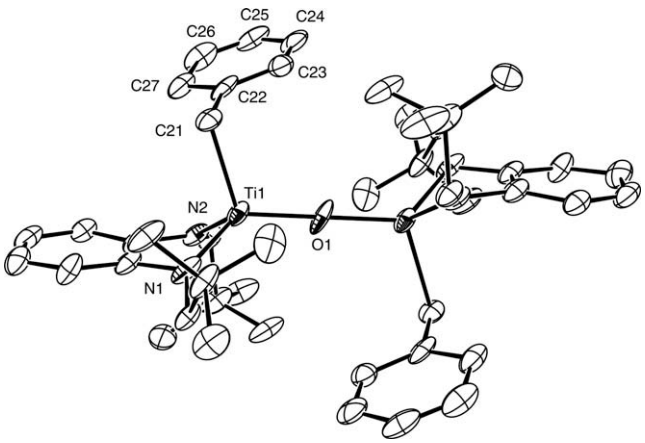


Fig. 2. X-ray thermal ellipsoid plot of **7** (30% probability level) showing the labelling scheme (hydrogen atoms have been omitted for clarity).

Compound **2** was treated with various alkylating reagents under different reaction conditions. However, all the attempts proved unfruitful and uninformative broad signals were observed in the corresponding NMR spectra.

Addition of $B(C_6F_5)_3$ to a solution of **5** in C_6D_6 at room temperature affords a cationic species, which was characterised by ^1H, ^{13}C and ^{19}F NMR spectroscopy. The NMR spectra featured downfield benzyl resonances assigned to a cationic-electron deficient benzyl titanium derivative. From these spectroscopic data, we propose the formation of the ionic [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz][$BzB(C_6F_5)_3$] species (Scheme 2). The large difference (4.5 ppm) between *p*-F and *m*-F chemical shifts of the [$BzB(C_6F_5)_3$]$^-$ anion suggests a strong interaction between the anion and the titanium centre, as observed for related cationic species [26–28]. The relative solubility of this complex in benzene is also consistent with its zwitterionic character. The same electrophilic reaction was tested and observed in CD_2Cl_2 at low temperature (−70 °C) and the spectroscopic study reveals that the abstraction reaction was facile even at this temperature. No reaction was observed when the tantalum complex **3** was reacted with $LiB(C_6F_5)_4$ in an attempt to form a cationic species from which activation of *t*Bu groups attached to nitrogen atoms due to the electronic deficiency could be enforced.

Given our interest in the polymerisation chemistry of diamido [9] or dialkoxo [11,12] early metal complexes, we undertook preliminary studies on α-olefin polymerisation and the complexes **1**, **3** and **5** were tested as catalysts for ethylene polymerisation in the presence of $B(C_6F_5)_3$, methylaluminoxane (MAO) and sMAO (MAO used as an $AlMe_3$-free solid) [29] as cocatalysts. The dichloro complex **1** and the dibenzyl compound **5** showed very low activity (≈10 Kg PE/mol_{cat} atm h). These activities are much lower than those of the best know non-cyclopentadienyl group 4 metal com-

[2] Crystal data for **7**: $C_{46}H_{66}N_4OTi_2$, M_r = 786.83, crystal size 0.39 × 0.34 × 0.22 mm^3, Triclinic, space group $P\bar{1}$, a = 9.915(5) Å, b = 11.342(6) Å, c = 11.626(11) Å, α = 70.75(4)°, β = 86.79(6)°, γ = 65.67(4)°, V = 1119.9(13) $Å^3$, Z = 1, ρ_{calcd} = 1.167 Mg m^{-3}, μ = 0.393 mm^{-1}, Mo Kα radiation (λ = 0.71073 Å). Data collection was performed at 200(2) K on a Nonius KappaCCD single crystal diffractometer. Reflections collected/unique 13251/3902 [R_{int} = 0.8802]. The final cycle of full matrix least-squares refinement based on 3902 reflections and 242 parameters converged to final values of $R_1(F^2 > 2\sigma(F^2))$ = 0.1853, $wR_2(F^2 > 2\sigma(F^2))$ = 0.4554, $R_1(F^2)$ = 0.2648, $wR_2(F^2)$ = 0.5446). Largest diff. peak/hole 0.879/−1.484 e$Å^{-3}$.

plexes such as McConville's titanium compounds [30], but are similar to other related complexes [31,32]. GPC results are indicative of polyethylenes that have very broad polydispersities (Mw/Mn values of 4–6) [9,31]. DSC measurements of the polymers show melting temperatures (T_m) for the polymers produced that are typical of high density polyethylene. These results may be a consequence of the gradual generation of low active Ti active species upon losing the diamido ligand from these diamido titanium precursors. It is a general observation that the complexes containing the *n*Pr amido ligand show higher polymerisation activities compared with the Np derivatives [8], suggesting that the activity is highly influenced by the steric effect [33] at the titanium centre caused by the *n*-propyl or neopentyl substituents at the nitrogen atom of the diamido ligand. Similar cases of strongly bulky substituents influencing catalytic polymerisation activity have been observed for related amidinate complexes [34,35]. The non-metallocene tantalum diamido complex **3** has no site for two alkyls, one of which is required for the propagation and the other of which is the source of cationic formation, and it was inactive in ethylene polymerisation.

3. Crystal structures of [Ta{1,2-$C_6H_4(NCH_2tBu)_2$}$_2$Cl] (3) and [Zr{(1,2-$C_6H_4(NCH_2tBu)_2$}(NMe_2)(μ-NMe_2)]$_2$ (4)

Red single crystals of **3**·C_6D_6 were grown in a saturated C_6D_6 solution at room temperature and the molecular structure established by X-ray diffraction studies. Selected bond lengths and angles for the structure are listed in Table 1. The molecular structure shows the tantalum atom bonded to a chlorine atom and two chelating phenylenediamido ligands (Fig. 3). In the crystal, the compound presents a twofold axis along the Ta–Cl bond. The coordination geometry of the Ta(V) centre can be described as a distorted trigonal bipyramid [36]. The Ta, Cl, N(2) and N(2)^i (i: $-x+1, y, -z+3/2$) atoms are in exactly the same plane, defining the trigonal bipyramidal equatorial plane. The N(1) and the N(1)^i atoms occupy the trigonal bipyramidal axial positions with a N(1)–Ta–N(1)^i angle of 167.37(10)°. Both N(1) and N(2) coordinated nitrogen atoms are essentially planar with a sum of angles of 359.5° and 354.7°, respectively. Ta–Cl [2.4123(8) Å] bond lengths compare well with related Ta(V) complexes [10]. Compound **3** is almost isostructural to the previously reported bisphenylenediamido Nb(V) complex [Nb{4,5-Me_2-1,2-$C_6H_2(NSiMe_3)_2$}$_2$Cl] [37].

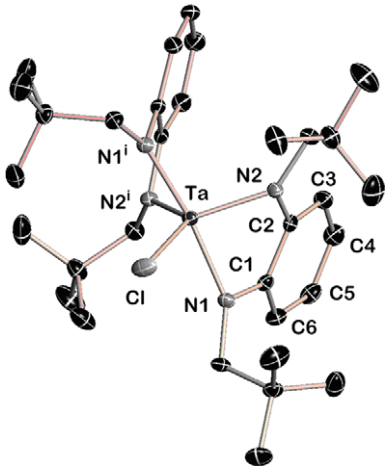

Fig. 3. X-ray thermal ellipsoid plot of **3** (50% probability level) showing the labelling scheme (i: $-x+1, y, -z+3/2$, hydrogen atoms have been omitted for clarity).

[a] E.s.d's are given in parentheses.
[b] Symmetry transformation used to generate equivalent atoms $-x+1, y, -z+3/2$.

The related chelating diamido ligands and the Ta atom form a "TaN_2C_2" metallacycle that is bent through the N···N axis (N(1)–Ta–N(2) and N(1)–C(1)–C(2)–N(2) planes dihedral angle of 52.05(9)°). The "TaN_2C_2" metallacycle structural parameters indicate that the phenylenediamido ligand is bonded to the metal in a η^4 fashion showing σ^2,π-enediamido behaviour [38]. This type of σ^2-*N*,*N*′-π-phenylenediamido coordination allows the donation of electron density from the phenylene ring to the metal and should quench the electrophilicity of Ta(V). Similar structural features have been reported for analogous X-ray structures of chelating phenylenediamido group 5 metal complexes found in the CSD [39]. Thus, the Ta(V) complexes [Ta(η^5-C_5Me_5){1,2-C_6H_4(NSiPr^i_3)$_2$}Cl_2], [Ta{η^5-1,3-$C_5H_3(SiMe_3)_2$}{1,2-$C_6H_4(NSiMe_3)_2$}Cl_2], and the Nb(V) derivative [Nb{4,5-Me_2-1,2-$C_6H_2(NSiMe_3)_2$}$_2$Cl] present sp^2 planar coordinated N atoms and are bent through the N···N axis "MN_2C_2" (M = metal) metallacycles (dihedral angle range 53.8–58.7°) [40,41]. The Ta–C(1) and Ta–C(2) bond lengths [2.588(2) and 2.559(2) Å, respectively] for compound **3** are in good agreement with π-bonding involving the C_{ipso} atoms at the phenylene ring. Slightly shorter Ta–C bond lengths (range 2.40–2.54 Å) are present in the previously described phenylenediamido Ta(V) complexes with a σ^2,π-enediamido type of coordination [40,41]. Rather short Ta–N bond lengths [1.9733(17) and 2.0108(18) Å] are observed in the molecular structure of **3**, consistent with a significant p_π–d_π contribution, similar to that found for other amido groups bound to tantalum [40–43]. The 1,2-$C_6H_4(NCH_2tBu)_2$ phenylenediamido ring is distorted with the carbon–carbon bond distances ranging from the longest bond for C(1)–C(2) (1.424(3) Å) to both C(3)–C(4) and

C(5)–C(6) as the shortest bonds (1.383(3), 1.377(3) Å), while the N–C_{ipso} distances (1.412(3) and 1.417(3) Å) are consistent with single bond formulation.

Yellow single crystals of **4** suitable for X-ray diffraction studies, grown in a saturated hexane solution at −40 °C, were used to unequivocally establish the molecular structure of this complex, shown in Fig. 4. Selected bond distances and angles for the structure are listed in Table 1. This compound crystallised as an enantiomeric pure isomer due to conformation chirality arising from the relative disposition of the phenylene rings in the solid state. By contrast, C_2-symmetry is inferred for **4** in solution as deduced from the NMR spectroscopic data.

The environment around each Zr atom is approximately square pyramidal with one of the NMe_2 ligands in the axial position. The zirconium atoms are not located in the planar base of the square pyramid, as distances of 0.728 Å from the Zr(2) to the N(4)N(3)N(6)N(5) plane and 0.726 Å from Zr(1) to the N(5)N(6)N(1)N(2) plane were measured. There is a central Zr(1)N(5)N(6)Zr(2) core that appears puckered (Zr(2)N(6)Zr(1) 99.94(18)°, Zr(2)N(5)Zr(1) 99.69(17)°). In this central unit, the Zr–N bond lengths range from 2.274(5) to 2.366(5) Å and the endocyclic angles at N(5) or N(6) are wider than those at Zr(1) or Zr(2). Within the molecule, the Zr–N bond lengths vary significantly, ranging from 2.024(5) to 2.366(5) Å, with the longest length corresponding to the bridging ligands (N(5) and N(6)) and the shortest to the distances between the metal and the terminal NMe_2 groups. This feature can be related to the degree of donation from the respective amido ligand to the metal centre, indicating a p_π–d_π bonding contribution for the amido moieties closer to it [18,30,44]. In addition, the sum of the angles around the nitrogen atoms in those groups (N(1), N(2), N(3) and N(4)) are essentially planar, with a tetrahedral disposition for the bridging N(5) and N(6) atoms.

As observed in **3**, and in similar structures reported for group 4 eneamido complexes [45,46], the "Zr[$C_6H_4(NCH_2tBu)$]" metallacycle is folded along the N···N axis (41.88° and 43.83° dihedral angles between the NZrN and NCCN planes). The "ZrN_2C_2" metallacycle's structural parameters indicate that the phenylenediamido ligands are bonded to the metal in a η^4 fashion showing a σ^2,π-enediamido manner [38]; the Zr–C_{ipso} bond distances [2.742(6)–2.808(6) Å range] are also in good agreement with π-bonding involving C_{ipso} atoms at the phenylene ring.

Analysis of the η^2-*N*,*N*′-phenylenediamido ligand's geometrical parameters reported in the CSD for group 4 and 5 metal complexes has been performed [8,10,37,40,41,47–50]. Bent and planar "MN_2C_2" metallacycles with wide folding through the N···N axis degree range have been reported (0–58° N-metal-N/N–C_{ipso}–C_{ipso}–N dihedral angle range) [51]. As should be expected, short M–C_{ipso} distances correspond to highly bent metallacycles and long M–C_{ipso} distances are found for planar or slightly bent metallacycles, with very few exceptions. The N–C_{ipso} bond lengths are in the 1.33–1.46 Å range for both group 4 and 5 η^2-phenylenediamido metal complexes. Furthermore, in the analysed complexes the phenylene ring is distorted, showing a long C_{ipso}–C_{ipso} bond length (range 1.41–1.47 Å) and two short ring bond lengths, generally corresponding to C(3)–C(4) and C(5)–C(6) (a range of 1.35–1.39 Å is observed in compound **3**, although in compound **4** the shortest bond length corresponds to C(4)–C(5) with values of 1.372(17) Å in one ring and 1.345(13) Å in the other one). Surprisingly, we have found that a distortion of the phenylene ring is present for both bent and planar "MN_2C_2" metallacycles and it seems not to depend on the degree of metallacycle folding. The absence of a direct correlation for the degree of metallacycle folding and phenylene ring distortion could imply that the phenylenediamido ligand ring distortion is not related to the π-coordination of the ligand.

4. Conclusions

In summary, we report the synthesis of early metal complexes stabilised by coordination of the $[1,2\text{-}C_6H_4(NCH_2tBu)_2]^{2-}$ ligand that are fully characterised by various methods. Direct reaction of $Li[1,2\text{-}C_6H_4(NCH_2tBu)_2]$ with $[TiCl_4(THF)_2]$ or $TaCl_5$ in toluene gives the monomeric derivatives in reasonable yield, while dimeric complexes were obtained for zirconium. The results indicate that monomeric titanium and tantalum complexes require the presence of additional Lewis base molecules to stabilise the final product. Reactions of the titanium compounds with Lewis acids show the abstraction of the coordinated Lewis base. Voluminous alkyl ligands are required to stabilise the alkyl compounds and the dibenzyl derivative $[Ti\{1,2\text{-}C_6H_4(NCH_2tBu)_2\}Bz_2]$ can be obtained.

η^2-Phenylenediamido group 4 and 5 metal complexes show distorted phenylene rings with the C_{ipso}–C_{ipso} bond length as the longest length and generally the two conjugated C–C bonds as

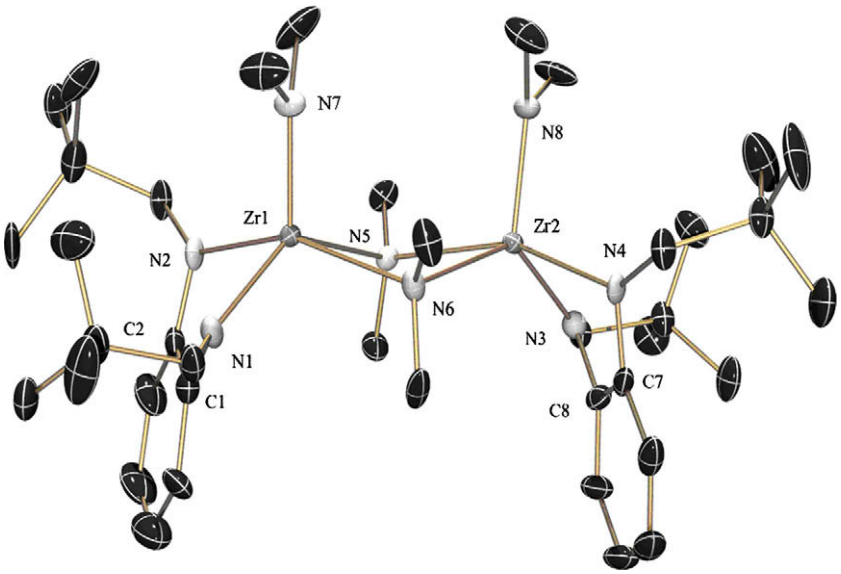

Fig. 4. X-ray thermal ellipsoid plot of **4** (30% probability level) showing the labelling scheme (hydrogen atoms have been omitted for clarity).

the shortest lengths. However, the direct correlation for the degree of metallacycle folding and phenylene ring distortion could imply that the phenylenediamido ligand ring distortion is not related to the π-coordination of the ligand.

5. Experimental

5.1. General considerations

All manipulations were performed with rigorous exclusion of oxygen and moisture under argon using Schlenk and high-vacuum line techniques or in a glove box model MO40-2. Solvents were predried by standing over activated 4 Å molecular sieves and then purified by distillation under argon before use by employing the appropriate drying/deoxygenated agent. Deuterated solvents were degassed by several freeze–thaw cycles and stored in ampoules equipped with Young's Teflon valves over activated 4 Å molecular sieves. C, H and N microanalyses were performed on a Perkin–Elmer 2400 microanalyzer. NMR spectra were recorded on a Bruker AV400 (^{1}H NMR at 400.13 MHz, ^{13}C NMR at 100.60 MHz and ^{19}F NMR at 376.40 MHz) spectrometer and chemical shifts were referenced to $SiMe_4$ via the ^{13}C resonances and the residual protons (^{1}H) of the deuterated solvent, while ^{19}F resonance were measured relative to external $CFCl_3$. Spectra were recorded at 25 °C unless otherwise stated. Li*n*Bu (1.6 M in hexane solution), MgMeCl (3 M in THF), MgBzCl (2 M in THF), pyridine, $LiN(SiMe_3)_2$ and $TaCl_5$ were purchased from Aldrich. $Br(C_6F_5)$ was purchased from ABCR. MAO, 30 wt% solution in toluene was received from Crompton GmbH. Compounds $[TiCl_4(THF)_2]$ [52], $[ZrCl_4(THF)_2]$ [52], $B(C_6F_5)_3$ [53–56], $Al(C_6F_5)_3{\cdot}0.5C_7H_8$ [7] and $[Zr(NMe_2)_4]$ [57], were synthesized following established procedures.

Polymerisation grade ethylene was used as received. Ethylene polymerisation was carried out in a glass reactor with magnetic stirring. The polymerisation solvent (toluene) was dried by refluxing over sodium-benzophenone and distilled before use in an inert atmosphere. MAO (Witco 10%) was used as a solution in toluene. Melting temperatures of the polymers were measured by differential scanning calorimetry (DSC) on a Perkin Elmer DSC6 instrument.

5.2. Synthesis of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] (**1**)

Li*n*Bu (1.6 M in hexane, 4.02 mmol, 2.5 mL) was slowly added to a suspension of 0.500 g (2.01 mmol) of 1,2-$C_6H_4(NHCH_2tBu)_2$ in hexane (50 mL) at −78 °C. The reaction mixture was warmed to room temperature over 4 h and a white precipitate of Li_2[1,2-$C_6H_4(NCH_2tBu)_2$] was formed with evolution of butane. The desired amount of the lithium salt (0.296 g, 1.14 mmol) and 0.380 g of $[TiCl_4(THF)_2]$ (1.14 mmol) were introduced in a Young's ampoule and toluene (50 mL) was charged at −78 °C. A red–brown suspension was immediately obtained. After 2 h, the reaction mixture was heated at reflux for 12 h. After cooling, all volatiles of the dark solution were removed under vacuum and the black product was extracted into hexane. Recrystallisation with cold hexane afforded the product identified as [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] **1**, as a black solid (0.268 g, 0.613 mmol, 54% yield). *Anal.* Calc. for $C_{20}H_{34}N_2Cl_2OTi$ (436.98 g/mol): C, 54.92; H, 7.77; N, 6.40. Found: C, 54.56; H, 8.59; N, 6.73%. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 7.36 (m, 2H, Ph), 7.07 (m, 2H, Ph), 4.25 (s, 4H, CH_2), 3.74 (m, 2H, THF), 1.26 (m, 2H, THF), 0.85 (s, 18H, *t*Bu). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ 7.54 (m, 2H, Ph), 7.24 (m, 2H, Ph), 4.31 (s, 4H, CH_2), 4.01 (m, 2H, THF), 1.93 (m, 2H, THF), 0.82 (s, 18H, *t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, C_6D_6, 25 °C): δ 126.0, 115.7 (Ph), 123.9 (*ipso*-Ph), 71.0 (CH_2), 66.9 (THF), 36.0 (*ipso*-*t*Bu), 28.9 (*t*Bu), 25.4 (THF).

5.3. Synthesis of [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}Cl(THF)(μ-Cl)]$_2$ (**2**)

The same procedure described for **1** using 0.300 g (1.15 mmol) of Li[1,2-$C_6H_4(NCH_2tBu)_2$] and 0.435 g of $[ZrCl_4(THF)_2]$ (1.15 mmol) gives [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}Cl(THF)(μ-Cl)]$_2$ **2**, obtained as an orange product which was washed with hexane (0.673 g, 0.700 mmol, 61% yield). The elemental analysis value found for **2** was inaccurate, caused by small amounts of LiCl in the mixture, which could not be removed. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 6.94 (br, 2H, Ph), 6.68 (br, 2H, Ph), 3.87 (br, 4H, CH_2), 1.08 (s, 18H, *t*Bu). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ 6.98 (br, 4H, Ph), 3.94 (br, 4H, CH_2), 0.89 (s, 18H, *t*Bu), THF resonances not observed. ^{1}H NMR (400 MHz, $CDCl_3$, 40 °C): δ 6.92 (br, 2H, Ph), 6.75 (br, 2H, Ph), 3.87 (br, 4H, CH_2), 3.89 (br, 2H, THF), 1.15 (m, 2H, THF), 1.07 (s, 18H, *t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, $CDCl_3$, 25 °C): δ 128.3, 114.7 (Ph), 74.0 (THF), 60.7 (*C*H_2N), 36.6 (*ipso*-*t*Bu), 25.5 (THF), 28.1 (*t*Bu), *ipso*-Ph not observed. ^{1}H NMR (400 MHz, CD_2Cl_2, −70 °C): **isomer A**: δ 6.98 (m, 2H, Ph), 6.86 (m, 2H, Ph), 4.00 (d, *J* = 14.4 Hz, 2H, AB spin system, CH_2), 3.34 (d, *J* = 14.4 Hz, 2H, AB spin system, CH_2), 4.31 (br, 2H, THF), 2.02 (m, 2H, THF), 0.92 (s, 18H, *t*Bu); **isomer B**: δ 6.37 (m, 2H, Ph), 6.30 (m, 2H, Ph), 4.30 (br, 2H, CH_2), 3.70 (br, 2H, CH_2), 4.40 (br, 2H, THF), 2.02 (m, 2H, THF), 0.92 (s, 18H, *t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, CD_2Cl_2, −70 °C): **isomer A**: δ 125, 116 (Ph), 75.0 (THF), 60 (*C*H_2N), 27 (THF), 28 (*t*Bu), *ipso* of Ph and *ipso* of *t*Bu not observed; **isomer B:** δ 119, 112 (Ph), 75.0 (THF), 58 (*C*H_2N), 27(THF), 30 (*t*Bu), *ipso* of Ph and *ipso* of *t*Bu not observed.

5.4. Synthesis of [Ta{1,2-$C_6H_4(NCH_2tBu)_2$}$_2$Cl] (**3**)

The same procedure described for **1** using 0.207 g (0.79 mmol) of Li[1,2-$C_6H_4(NCH_2tBu)_2$] and 0.14 g of $TaCl_5$ (0.40 mmol) gives [Ta{1,2-$C_6H_4(NCH_2tBu)_2$}$_2$Cl] **3** as a red solid (0.130 g, 0.183 mmol, 46% yield). *Anal.* Calc. for $C_{32}H_{52}N_4ClTa$ (709.18 g/mol): C, 54.19; H, 7.33; N, 7.89. Found: C, 54.32; H, 7.09; N, 7.73%. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 7.01 (m, 4H, Ph), 6.79 (m, 4H, Ph), 4.68 (s, 8H, CH_2), 0.71 (s, 36H, *t*Bu). ^{1}H NMR (400 MHz, CD_2Cl_2, 25 °C): δ 7.08 (m, 4H, Ph), 6.97 (m, 4H, Ph), 4.03 (s, 8H, CH_2), 0.75 (s, 36H, *t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, C_6D_6, 25 °C): δ 137.8 (*ipso*-Ph), 129.3, 119.2 (Ph), 66.9 (*C*H_2N), 30.1 (*ipso*-*t*Bu), 28.4 (*t*Bu).

5.5. Synthesis of [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}(NMe_2)(μ-NMe_2)]$_2$ (**4**)

A solution of 0.185 g (0.75 mmol) of 1,2-$C_6H_4(NHCH_2tBu)_2$ was added to 0.20 g of $Zr(NMe_2)_4$ (0.74 mmol) in toluene (50 mL). The solution was maintained at room temperature for 16 h and gradually became golden yellow. The volatiles were evaporated and hexane was added. The solution was set at −30 °C for 12 h and a microcrystalline yellow powder precipitated. The solid was isolated by filtration and dried in vacuum. Recrystallisation with cold hexane led to the product identified as [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}(N-Me_2)(μ-NMe_2)]$_2$ **4** (0.495 g, 0.581 mmol, 78% yield). *Anal.* Calc. for $C_{40}H_{76}N_8Zr_2$ (850.84 g/mol): C, 56.46; H, 8.93; N, 13.16. Found: C, 56.10; H, 9.01; N, 13.20%. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 6.99 (m, 2H, Ph), 6.90 (m, 2H, Ph), 3.88 (d, 2H, *J* = 13.2 Hz, AB spin system, CH_2), 3.65 (d, 2H, *J* = 13.2 Hz, AB spin system, CH_2), 2.93 (s, 6H, N*Me*$_2$), 2.85 (s, 3H, N*Me*$_2$), 1.55 (s, 3H, N*Me*$_2$), 0.87 (s, 18H, *t*Bu). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ 6.85 (m, 2H, Ph), 6.67 (m, 2H, Ph), 3.82 (d, 2H, *J* = 13.4 Hz, AB spin system, CH_2), 3.60 (d, 2H, *J* = 13.4 Hz, AB spin system, CH_2), 3.09 (s, 6H, N*Me*$_2$), 3.03 (s, 3H, N*Me*$_2$), 1.45 (s, 3H, N*Me*$_2$), 0.71 (s, 18H, *t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, C_6D_6, 25 °C): δ 135.1 (*ipso*-Ph), 120.1, 115.8 (Ph), 60.6 (*C*H_2N), 44.4, 43.2, 42.05 (N*Me*$_2$), 35.2 (*ipso*-*t*Bu), 28.8 (*t*Bu). ^{13}C{^{1}H} NMR (100.60 MHz, $CDCl_3$, 25 °C): δ 136.1 (*ipso*-Ph) 118.9, 115.2 (Ph), 60.4 (*C*H_2N), 44.1, 43.3, 42.3 (N*Me*$_2$), 35.3 (*ipso*-*t*Bu), 28.8 (*t*Bu).

5.6. [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}$Cl_2(py)_2$]

Pyridine was added at room temperature into a Teflon-valved NMR tube containing a chloroform-d (0.5 mL) solution of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)]. The reaction mixture turned brown and the ^1H and ^{13}C NMR spectra were obtained, showing the formation of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}$Cl_2(py)_2$]. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ 9.62 (br, 4H, py), 8.00 (br, 2H, py), 7.62 (br, 4H, py), 6.36 (m, 2H, Ph), 5.88 (m, 2H, Ph), 0.75 (s, 18H, *t*Bu), CH_2 protons not observed.

5.7. Reaction of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] with $B(C_6F_5)_3$ or $Al(C_6F_5)_3$

In a glovebox, chloroform-d or benzene-d_6 (0.5 mL) was added at room temperature to a Teflon-valved NMR tube containing the solid mixture of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] and $B(C_6F_5)_3$. The ^1H and ^{13}C NMR spectra obtained showed the formation of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2] with $B(C_6F_5)_3$·(THF) also present. **[Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2]**: ^1H NMR (400 MHz, C_6D_6, 25 °C): δ 7.34 (m, 2H, Ph), 7.00 (m, 2H, Ph), 4.16 (s, 4H, CH_2), 0.75 (s, 18H, *t*Bu). ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ 7.64 (m, 2H, Ph), 7.31 (m, 2H, Ph), 4.29 (s, 4H, CH_2), 0.86 (s, 18H, *t*Bu). $^{13}C\{^1H\}$ NMR (100.60 MHz, C_6D_6, 25 °C): δ 129.0, 116.0 (Ph), 67.8 (CH_2), 35.8 (*ipso*-*t*Bu), 28.6 (*t*Bu), *ipso*-Ph not observed. **$B(C_6F_5)_3$·(THF)**: ^1H NMR (400 MHz, C_6D_6, 25 °C): δ 3.23 (m, 2H, OCH_2), 0.85 (m, 2H, CH_2). ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ 4.25 (m, 2H, OCH_2), 2.13 (m, 2H, CH_2). $^{13}C\{^1H\}$ NMR (100.60 MHz, C_6D_6, 25 °C): δ 75.7 (THF), 25.4 (THF). ^{19}F NMR (376.40 MHz, $CDCl_3$, 25 °C): δ −128.7 (broad, *o*-C_6F_5), −143.7 (broad, *p*-C_6F_5), −160.7 (broad, *m*-C_6F_5). ^{19}F NMR (376.40 MHz, C_6D_6, 25 °C): δ −131.6 (broad, *o*-C_6F_5), −152.6 (broad, *p*-C_6F_5), −161.8 (broad, *m*-C_6F_5).

A similar procedure using [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2(THF)] and $Al(C_6F_5)_3$ gives a mixture of the same compound [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl_2] and $Al(C_6F_5)_3$.(THF). **$Al(C_6F_5)_3$·(THF)**: ^{19}F NMR (376.40 MHz, $CDCl_3$, 25 °C): δ −123.2 (s broad, *o*-C_6F_5), −151.7 (s broad, *p*-C_6F_5), −161.0 (s broad, *m*-C_6F_5).

5.8. Reaction of [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}Cl(THF)(μ-Cl)]$_2$ (**2**) with $B(C_6F_5)_3$

In a glovebox, dichloromethane-d_2 (0.5 mL) was added via a syringe at room temperature to a Teflon-valved NMR tube containing the solid [Zr{1,2-$C_6H_4(NCH_2tBu)_2$}Cl(THF)(μ-Cl)]$_2$ and $B(C_6F_5)_3$. The ^1H and ^{13}C NMR spectra were obtained showing formation of "Zr[1,2-$C_6H_4(NCH_2tBu)_2$]Cl_2" with $B(C_6F_5)_3$·(THF) also present. **Zr[1,2-$C_6H_4(NCH_2tBu)_2$]Cl_2**: ^1H NMR (400 MHz, CD_2Cl_2, 25 °C): δ 7.21 (m, 2H, Ph), 7.17 (m, 2H, Ph), 4.05 (s, 4H, CH_2), 0.88 (s, 18H, *t*Bu). **$B(C_6F_5)_3$·(THF)**: ^1H NMR (400 MHz, CD_2Cl_2, 25 °C): δ 4.28 (m, 2H, OCH_2), 2.12 (m, 2H, CH_2). ^{19}F NMR (376.40 MHz, CD_2Cl_2, 25 °C): δ −132.1 (broad, *o*-C_6F_5), −154.6 (broad, *p*-C_6F_5), −162.9 (broad, *m*-C_6F_5).

5.9. Synthesis of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz_2] (**5**)

A solution of **1** (0.250 g, 0.57 mmol) in toluene (50 mL) was cooled to −78 °C and a solution of $Mg(CH_2Ph)Cl$ in THF (2 M, 1.14 mmol, 0.57 mL) was added. The reaction immediately turned red. The mixture was warmed to room temperature and stirred for 5 h. The solvent was pumped off and subsequent extraction into hexane afforded a red oil, which was recrystallised from cold hexane giving the product identified as [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz_2] **5** (0.198 g, 0.416 mmol, 73% yield). *Anal.* Calc. for $C_{30}H_{40}N_2Ti$ (476.17 g/mol): C, 70.66; H, 8.40; N, 5.88. Found: C, 70.45; H, 8.51; N, 5.88%. ^1H NMR (400 MHz, C_6D_6, 25 °C): δ 7.26 (m, 2H, Ph), 7.15 (m, 2H, Ph), 6.99 (t, *J* = 7.2 Hz, CH_2Ph), 6.94 (t, *J* = 7.2 Hz, CH_2Ph), 6.86 (d, *J* = 7.2 Hz, CH_2Ph), 3.79 (s, 4H, CH_2), 2.40 (s, 4H, CH_2Ph), 0.71 (s, 18H, *t*Bu). ^1H NMR (400 MHz, CD_2Cl_2, 25 °C): δ 7.21 (m, 2H, Ph), 7.10 (m, 2H, Ph), 7.19 (t, *J* = 7.6 Hz, CH_2Ph), 6.94 (t, *J* = 7.6 Hz, CH_2Ph), 6.73 (d, *J* = 7.6 Hz, CH_2Ph), 3.84 (s, 4H, CH_2), 2.18 (s, 4H, CH_2Ph), 0.75 (s, 18H, *t*Bu). $^{13}C\{^1H\}$ NMR (100.60 MHz, C_6D_6, 25 °C): δ 128.7 (*ipso*-Bz), 129.3, 127.2, 125.3 (Bz), 126.7, 115.5 (Ph), 123.1 (*ipso*-Ph), 81.02 (CH_2Ph), 64.6 (CH_2N), 34.6 (*ipso*-*t*Bu), 28.6 (*t*Bu). $^{13}C\{^1H\}$ NMR (100.60 MHz, CD_2Cl_2, 25 °C): δ 144.4 (*ipso*-Bz), 129.1, 126.8, 124.9 (Bz), 122.8, 115.3 (Ph), 80.4 (CH_2Ph), 64.7 (CH_2N), 34.8 (*ipso*-*t*Bu), 28.5 (*t*Bu), *ipso*-Ph not observed.

5.10. Synthesis of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl{N(SiMe$_3$)}] (**6**)

Toluene (50 mL) was added to a mixture of **1** (0.200 g, 0.46 mmol) and Li[N(SiMe$_3$)]$_2$ (0.076 g, 0.46 mmol), at room temperature. The reaction immediately turned black. The mixture was stirred for 5 h. The solvent was pumped off and subsequent extraction into hexane afforded a black oil, which was recrystallised from cold hexane giving the product identified as [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Cl{N(SiMe$_3$)}] **6** (0.159 g, 0.325 mmol, 70% yield). *Anal.* Calc. for $C_{22}H_{44}N_3Si_2ClTi$ (489.5 g/mol): C, 53.95; H, 8.98; N, 8.57. Found: C, 53.98; H, 8.72; N, 8.36%. ^1H NMR (400 MHz, C_6D_6, 25 °C): δ 7.26 (m, 2H, Ph), 7.15 (m, 2H, Ph), 4.45 (d, *J* = 13.5 Hz, 2H, CH_2), 3.78 (d, *J* = 13.5 Hz, 2H, CH_2), 0.83 (s, 18H, *t*Bu), 0.15 (s, 18H, SiMe_3). $^{13}C\{^1H\}$ NMR (100.60 MHz, C_6D_6, 25 °C): δ 126.7, 115.5 (Ph), 123.1 (*ipso*-Ph), 67.7 (CH_2), 35.9 (*ipso*-*t*Bu), 28.6 (*t*Bu), 4.6 (SiMe_3).

5.11. Reaction of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz_2] with $B(C_6F_5)_3$

About 0.010 g (21.0 mmol) of [Ti{1,2-$C_6H_4(NCH_2tBu)_2$}Bz_2] and 0.011 g (21.0 mmol) of $B(C_6F_5)_3$ were placed in a Teflon-valved NMR tube and C_6D_6 was added at room temperature (when the reaction was cooled to −78 °C in CD_2Cl_2, the solvent was vacuum transferred into the NMR tube that had previously been placed in a thermostat-controlled bath). The NMR spectrum was obtained immediately at the desired temperature. ^1H NMR (400 MHz, C_6D_6, 25 °C): δ 7.50 (m, 2H, Ph), 7.20–6.99 (m, 12H, Ph), 5.89 (t, *J* = 7.2 Hz, CH_2Ph), 5.77 (t, *J* = 7.2 Hz, CH_2Ph), 5.26 (d, *J* = 7.2 Hz, CH_2Ph), 4.15 (d, *J* = 12.8 Hz, 4H, CH_2), 3.64 (d, *J* = 13.2 Hz, 4H, CH_2), 3.89 (br, 4H, CH_2Ph), 2.70 (br, 4H, CH_2Ph), 0.56 (s, 18H, *t*Bu). ^{19}F NMR (376.40 MHz, C_6D_6, 25 °C): δ −130.4 (s broad, *o*-C_6F_5), −160.5 (s broad, *p*-C_6F_5), −165.0 (s broad, *m*-C_6F_5). ^1H NMR (400 MHz, CD_2Cl_2, −70 °C): δ 8.10 (m, 2H, Ph), 7.65 (m, 2H, Ph), 7.30 (t, *J* = 7.6 Hz, CH_2Ph), 7.19 (t, *J* = 7.2 Hz, CH_2Ph), 7.00–6.73 (Ph), 5.91 (d, *J* = 6.8 Hz, CH_2Ph), 4.60 (d, *J* = 13.2 Hz, 2H, CH_2), 4.16 (d, *J* = 13.2 Hz, 2H, CH_2), 2.81 (br, 4H, CH_2Ph), 2.72 (br, 4H, CH_2Ph), 0.77 (s, 18H, *t*Bu). ^{19}F NMR (376.40 MHz, CD_2Cl_2, 25 °C): δ −131.3 (s broad, *o*-C_6F_5), −165.0 (s broad, *p*-C_6F_5), −167.7 (s broad, *m*-C_6F_5).

5.12. Single-crystal X-ray structure determination of compounds 1,2-$C_6H_4(NHCH_2tBu)_2$, **3**·C_6D_6, and **4**

Relevant crystallographic data and details of the refinements for the structures are given in Table 2. Crystals of **3**·C_6D_6 were grown by slow evaporation of a C_6D_6 solution. Crystals suitable for X-ray diffraction were measured at 100(2) K on a Bruker SMART APEX diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) and φ and ω scan modes. Crystal structures were solved by direct methods and all non-hydrogen atoms refined anisotropically on F^2 (program SHELXL-97) [58]. The deuterium atoms were located in a difference Fourier synthesis and refined with restrained C–D bond lengths. The methyl group hydrogen atoms were refined as rigid. Other hydrogen atoms were included

Table 2
Crystal data and structure refinement details for 1,2-$C_6H_4(NHCH_2tBu)_2$, **3**·C_6D_6, and **4**.

	1,2-$C_6H_4(NHCH_2tBu)_2$	**3**·C_6D_6	**4**

using a riding model. The deuterated benzene molecule is disordered over two sites. The programs use neutral atom scattering factors, $\Delta f'$ and $\Delta f''$ and absorption coefficients from the International Tables for Crystallography [59].

Suitable crystals of the diamine 1,2-$C_6H_4(NHCH_2tBu)_2$ and **4** were selected, manipulated under argon with perfluoropolyether and mounted on a glass fiber. The intensity data sets were collected at 200 K on a Bruker–Nonius KappaCCD diffractometer equipped with an Oxford Cryostream 700 unit. The structures were solved, using the WINGX package [60], by direct methods (SHELXS-97) and refined by least-squares against F^2 (SHELXL-97) [58]. All non-hydrogen atoms were anisotropically refined. In **4** C15, C30 and C32 were disordered in two positions, also, in **4** some SIMU and DELU restraints were applied. Hydrogen atoms were geometrically placed and left riding on their parent atoms, with the exception of the hydrogen atom on N(1) and N(2) for the diamine 1,2-$C_6H_4(NHCH_2tBu)_2$ that were found in the Fourier map and refined freely. Relevant crystallographic data and details of the refinements for the two structures are given in Table 2.

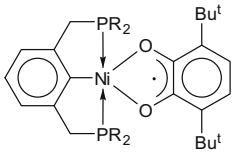
ABSTRACT



Structural study of dialkyl (PCP)-pincer *o*-semiquinonato nickel complexes indicated sloped relative positions of bi- and tri-dentate ligands. It became bright confirmation of propositions made on the base of their EPR spectra followed by molecular modelling.

1. Introduction

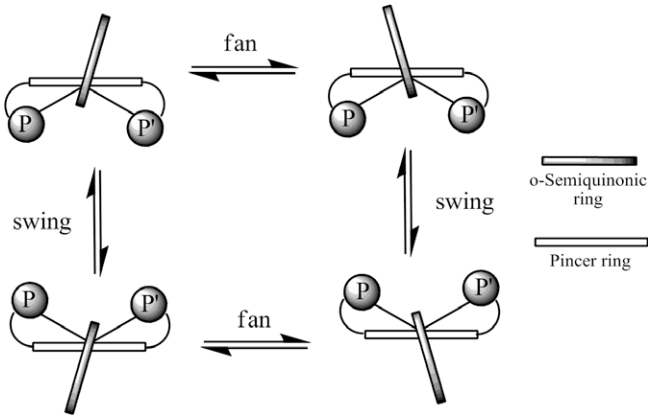
Previously we have communicated about new class of the spin labelled nickel compounds: the *o*-semiquinonato nickel complexes with the pincer ligands [1,2]. The structural study of 3,6-di-*tert*-butyl-*o*-semiquinonato nickel with 2,6-bis-(diphenylphosphinomethyl)phenyl (**1**) indicates a distorted square–pyramidal geometry of the inner coordination core [1]. Difference of the ligands occupying *trans*-positions towards oxygen atoms of the semiquinone causes an asymmetrical distribution of the spin density inside the *o*-semiquinonato ligand. The molecular motion which swaps oxygens being in the base of the pyramid and which is responsible for redistribution of the spin density in the *o*-semiquinonato fragment was called "swing" oscillation (Scheme 1). Similar rearrangements in the metal coordination sphere can be found as a stage of certain pincer complexes-catalyzed reactions, such as Heck coupling [3,4].

Using of pincer ligand with alkyl substituents (such as *cyclo*-hexyl (Cy), *iso*-propyl (*i*-Pr)) at the phosphorus atoms causes a difference of spin density on the pincer phosphoruses [5]. The molecular motion which is responsible for redistribution of spin density between the phosphorus atoms we have called "fan" oscillation (Scheme 1). We supposed that the complexes with the pincer ligands having alkyl substituents (*cyclo*-hexyl and *iso*-propyl having no axial symmetry along the P-alkyl bond) should have sloped relative positions of the planes of semiquinonato and pincer ligands (Scheme 1). This configuration should result in different spin density on the pincer phosphorus atoms. Here we report on structural investigation of two complexes of such type (**2** and **3**). Comparative analysis of two novel structures with previously published **1**, together with EPR data and results of molecular modelling, is presented here as well.

1 - R = Ph,

2 - R = Cy,

3 - R = *i*-Pr



2. Results and discussion

Structural study of **1** was carried out earlier [1]. Complexes **2** and **3** were obtained as previously described [5]. Slow evaporation of their pentane solutions gave X-ray quality single crystals. The X-ray diffraction study has shown that the Ni atom has a distorted square–pyramidal coordination mode in all three complexes (Fig. 1). In general, the bonds lengths and the angles in the chelate cycle of coordinated *o*-semiquinone are typical for the anion-radical coordination mode (Table 1).

It should be noted that the differences between C1–O1 and C2–O2 bonds lengths in the chelate cycles of the *o*-semiquinones, which reflect the asymmetry of the spin density distribution, in **2** and **3** are essentially larger than the same difference in **1** (Δ = 0.0154 Å in **2** and 0.0243 Å in **3** against 0.0085 Å in **1**). It causes the difference between HFC constants on semiquinonic pro-

Table 1
Structural data of nickel-*o*-semiquinonato chelate cycles for complexes **1**, **2** and **3**.

Complex	1	2	3
Ni1–O1	1.9238(10)	1.9306(10)	1.9377(8)
Ni1–O2	2.0595(10)	2.0664(11)	2.2165(10)
C1–O1	1.2975(17)	1.3076(18)	1.3006(16)
C2–O2	1.2890(17)	1.2922(17)	1.2763(14)
O1–Ni1–O2	81.60(4)	81.16(3)	78.35(3)[a]

[a] Small deviation of the angle O1–Ni1–O2 in **3** comparing with the same one in **1** and **2** is the consequence of the elongation of the Ni1–O2 bond.

Scheme 2. Resonance structures responsible for hyperfine coupling with semiquinonic protons.

tons in EPR spectra of the complexes (a_{H4}/a_{H5} = 2.2/3.4 G in **1**, 2.2/3.6 G in **2** and 2.2/3.8 G in **3**) (Scheme 2, Table 2). It is known that spin density transfer from the *o*-semiquinone to the phosphorus magnetic nuclei of the pincer metallo-fragment can be realized by two independent mechanisms: by spin polarization of the σ-skeleton through Ni–O σ-bonds and by direct interaction of the group Ni–P orbitals with the corresponding oxygen p-orbitals containing unpaired electron. The last mechanism is quite more effective comparing with the first one, but its effectiveness strongly depends on the angles between Ni–P bonds and chelate plane of the *o*-semiquinone. Phosphorus HFC constant is larger when this angle is close to 90° [6,7]. Examination of inner coordination core describes that the angles P1–Ni1–O2 in the complexes **2** and **3** are close to right angle (89.39° in **2** and 87.86° in **3**) comparing with the P2–Ni1–O2 (124.54° in **2** and 111.03° in **3**) whereas in **1** both angles are closer one to another (115.70° and 101.58°). It is the reason of the larger difference between phosphorus HFC constants a_{P1}/a_{P2} for **2** and **3** comparing with the same value for **1** (a_{P1}/a_{P2} = 27.8/14.7 G in **2**, 25.3/15.7 G in **3** and 25.6/25.6 G in **1**). The angles P1–Ni1–O2 and P2–Ni1–O2 (both relative to O2) are especially preferred in examination of phosphorus HFC constants because O2 has an excess of spin density comparing with O1 [1]. The asymmetry of the spin density distribution inside the *o*-semiquinone follows from the difference of the bonds lengths in the chains Ni1–O1–C1 and Ni1–O2–C2 according to Scheme 2. The

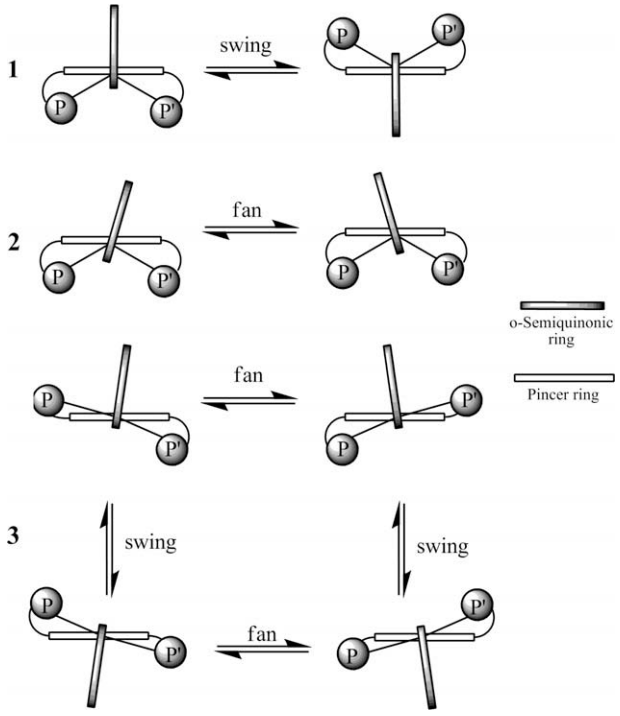
chelate cycle of each complex can be presented as a sum of the resonance structures **A** and **B** which are responsible for appearing of spin density on the protons H4 and H5. The excess of spin density on the O2 means that the resonance structure **B** predominates over the structure **A**. (Moreover it is bright confirmed by difference of the HFC constants on semiquinonic protons.) As it was already mentioned, this predomination in complexes **3** and **2** is larger than the same one in **1**. This fact is additional reason of larger difference between phosphorus splitting constants in EPR spectra of **2** and **3** comparing with the same difference in spectra of **1**.

In general the examination of relative positions of *o*-semiquinonato and pincer ligands evidence that their planes are more sloped in complexes **2** and **3** comparing with **1**. The angles between the planes of the aromatic rings of the pincer ligands and the planes of the pseudo-aromatic rings of the *o*-semiquinones are: 75.64° for **1**, 60.87° for **2** and 50.79° for **3**.

However, conformation of **1** is sufficiently sloped, whereas the phosphorus HFC constants are equal. We have proposed that the crystal packing causes a distortion of the complex geometry. To neglect this factor we have provided the molecular modelling of **1**, **2** and **3** using obtained crystal data as starting model. The geometry optimization in general keeps the structures unchanged but it makes molecule of complex **1** virtually symmetrical with virtually equal angles between the phosphorus atoms and the *o*-semiquinonic plane. This fact is in accordance with the equivalence of the phosphorus HFC constants in **1**. On the contrary, the angles between the ligands planes in **2** and **3** remain different; moreover the configuration of **3** remains more sloped than configuration of **2**. This result is in a good agreement with the ratio a_{P1}/a_{P2} of the phosphorus HFC constants (Table 2).

The phosphorus units in all complexes have distorted tetrahedral geometry. The most distorted is P1 unit in **2** (the largest deviation of the angles from tetrahedral 109.5°: Ni1–P1–C21 96.43°; Ni1–P1–C22 125.62°). Five-membered pincer chelate cycles containing phosphorus are not planar in all three complexes. They are bent around the axis Ni···CH_2 (–CH_2– bridge connecting phosphorus with pincer aryl ring). In this aspect the pincer coordination mode in **3** differs from that one in **1** and **2**. In **1** and **2** the phosphorus atoms lie at one side out from the plane of pincer aryl whereas in **3** the phosphorus cycles are inversed around the Ni1–C15 axis and the phosphorus atoms are situated at the different sides relative to the pincer aryl plane (Scheme 3). So, the complexes **1** and **2** are in configuration **B**, whereas the compound **3** is in configuration **A**.



Scheme 3. Possible configurations of phosphoruses chelate cycles.

The examination of the structural data collected up to nowadays shows that the configuration **A** is preferable for the five-coordinated pincer nickel complexes having distorted square–pyramidal geometry. They exist in the configuration **B** only in the case of the sterically hindered ligand at the top of the pyramid [8]. It means that the chelate unit in complex **3** is not so sterically hindered as in **1** and **2**.

All compounds **1**, **2** and **3** detect the structural tautomerism [5]. It means that moving along reaction coordinate which corresponds to rotation of one ligand relatively another has two minima of energy. It was shown previously [5] that complexes **1** and **2** demonstrate "pure" "swing" and "fan" oscillations correspondingly whereas for complex **3** both kinds of them are observed. The analysis of the structural data and the molecular modelling results allows us to build up improved schemes of these oscillations (Scheme 4).

In the case of "swing" oscillations (Scheme 4) the origin of the barrier between the tautomers is clear. For all three compounds such motion requires at least the concerted rotation of all substituents at both phosphorus atoms (Fig. 1, Scheme 4). Additionally, for **1** and **2** the inversion of both pincer chelate cycles is necessary (Fig. 1, Scheme 4). Doubtlessly, both factors should depend on the bulkiness of the substituents at phosphoruses. So the barrier magnitude in the case of **2** should be considerably larger than that in the cases of **1** and **3**, and it explains the absence of the "swing" oscillations for **2** (Scheme 4). For example, no "swing" oscillations

Scheme 4. "Swing" and "fan" oscillations for **1**–**3** (schematic view along basal O–Ni–C direction).

were observed for analogous complex with the pincer ligand having *tert*-butyl substituents at the phosphorus [5].

In the case of symmetrical 3,6-di-*tert*-butyl-*o*-benzosemiquinone the "swing" tautomers do not differ. One "swing" tautomer can be converted into another one by the simple rotation of the molecule. In the case of asymmetrical *o*-semiquinones they become structural isomers [2,5]. In contrast to the "swing" ones, the "fan" tautomers are the enantiomers. In crystal cell of **1**, **2** and **3** both enantiomers ("fan" tautomers) are present. In the case of **1**, the sloped geometry in the crystal appears as a result of the crystal packing. The molecular modelling (in vacuum) detects that this molecule have a configuration with orthogonal ligands planes. Moreover, the orientations of the phenyl groups directed towards the *o*-semiquinonato ligand are close one to another. In the molecular modelling result their positions become virtually equivalent. So, in solution complex **1** should not have "fan" tautomers. Sloped position of the ligands planes in the cases of **2** and **3** itself can't be the reason of the appearing of the "fan" tautomerism. In order to understand the origin of the barrier between the enantiomers one should pay attention to the orientation of the alkyl substituents at the phosphorus atoms which are directed towards the *o*-semiquinonato ligand. One of them (left in Fig. 1) is virtually parallel to the *o*-semiquinonato plane in the case of **2** and have the methyl groups directed away from the *o*-semiquinone in the case of **3**; whereas the other one (right in Fig. 1) is virtually orthogonal to the *o*-semiquinonato plane in **2** and have methyls directed towards the *o*-semiquinonato plane in **3**. Thus, the "fan" motion of the *o*-semiquinonato ligand requires a concerted rotation of at least two alkyl substituents at the phosphorus atoms. It is evident that these local minima of the energy can appear only in the case of alkyl phosphorus substituents having no axial symmetry along the P-alkyl bond. Analogous complex having phenyl or *tert*-butyl substituents at phosphorus atoms have no "fan" tautomers according to EPR data [5].

3. Conclusion

Two novel *o*-semiquinonato PCP-pincer complexes were structurally characterized. Structural features of inner coordination cores are in a good agreement with EPR data obtained earlier. Sloped relative positions of *o*-semiquinonato and pincer ligands together with the absence of axis symmetry of alkyl substituents at phosphoruses (*cyclo*-hexyl and *iso*-propyl) create the conditions for appearing of "fan" motion of *o*-semiquinone relative to pincer ligand which was observed earlier by EPR.

4. Experimental

The synthesis of **2** and **3** was described earlier [5]. Their X-ray quality single crystals were obtained from pentane solution by slow evaporation. The data were collected on a SMART APEX diffractometer (graphite-monochromated, Mo Kα-radiation, ω- and θ-scan technique, $\lambda = 0.71073$ Å). The structures were solved by direct methods and were refined on F^2 using SHELXTL package. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms in **2** were placed in calculated positions and were refined in the riding model. The hydrogen atoms in **3** were found from Fourier syntheses of electron density and were refined isotropically. SADABS was used to perform area-detector scaling and absorption corrections in **3**. Crystals of **2** were a twin therefore the TWINABS program (HKLF 5 format, MERG 0) was used and reflections were not merged.

4.1. Crystal data of complex **2**

$C_{46}H_{71}NiO_2P_2$; $M = 776.68$; $T = 100$ K; $\lambda = 0.71073$ Å; triclinic, space group $P\bar{1}$; $a = 10.8167(4)$ Å, $b = 11.1652(6)$ Å, $c = 19.0778(6)$ Å, $\alpha = 101.4930(10)°$, $\beta = 94.812(2)°$, $\gamma = 110.468(2)°$; $V = 2085.50(15)$ Å^3; $Z = 2$, $D_{Calc} = 1.237$ g sm^{-3}; $F(0\,0\,0) = 842$; θ(deg) 2.04–26.00; reflections collected: 16 368 unique: 16 368 ($R_{int} = 0.0000$); final R indices [$I > 2\sigma(I)$] $R_1 = 0.0428$, $wR_2 = 0.1096$; R indices (all data) $R_1 = 0.0614$, $wR_2 = 0.1174$.

4.2. Crystal data of complex **3**

$C_{34}H_{55}NiO_2P_2$; $M = 616.43$; $T = 100$ K; $\lambda = 0.71073$ Å; triclinic, space group $P\bar{1}$; $a = 10.8111(4)$ Å, $b = 11.7961(4)$ Å, $c = 15.4730(5)$ Å, $\alpha = 70.7220(10)°$, $\beta = 75.8570(10)°$, $\gamma = 62.9420(10)°$; $V = 1648.30(10)$ Å^3; $Z = 2$, $D_{Calc} = 1.242$ g sm^{-3}; $F(0\,0\,0) = 842$; θ(deg) 2.68–27.00; reflections collected: 15 315 unique: 7115 ($R_{int} = 0.0314$); final R indices [$I > 2\sigma(I)$] $R_1 = 0.0364$, $wR_2 = 0.0761$; R indices (all data) $R_1 = 0.0573$, $wR_2 = 0.0816$.

The molecular modelling was provided using "HYPERCHEM 8.0" software. The X-ray data were used as a starting model. The molecular mechanics "MM+" method with "bonds dipoles" options and all of force field components using "Fletcher–Reeves" algorithm was applied for geometry optimization.

ABSTRACT

The reaction of equimolecular amounts of (*E*)-N-(2,6-dichlorobenzylidene)(naphthalen-1-yl)methanamine (**1**) and $Pd(OAc)_2$ in acetic acid at 60 °C for 24 h produced a selective palladation at the 2 position of the naphthyl group of **1**, which afforded the new acetato-bridged five-membered cyclopalladated dimer (μ-OAc)$_2$[(κ²-***C,N***-Pd{($C_{10}H_6$)–CH_2–N=CH–(2,6-$Cl_2C_6H_3$)}]$_2$ (**2**), in which the imines adopted the *Z* configuration. A metathesis reaction between **2** and LiCl exchanged the acetato ligands of **2** for chloro ligands. This produced the dinuclear cyclopalladated compound (μ-Cl)$_2$[κ²-***C,N***-Pd{($C_{10}H_6$)–CH_2–N=CH–(2,6-$Cl_2C_6H_3$)}]$_2$ (**3**), which consisted of a mixture of stereoisomers with imines in the *E* and *Z* configuration. Bridge-splitting reactions of the dimers **2** and **3** with py-d_5 and PPh_3 yielded the mononuclear compounds *trans*-***N,L***-[κ²-***C,N***-Pd{($C_{10}H_6$)–CH_2–N=CH–(2,6-$Cl_2C_6H_3$)}(X)(L)]; **4** (X = OAc, L = py-d_5), **5** (X = OAc, L = PPh_3), **6** (X = Cl, L = py-d_5), **7** (X = Cl, L = PPh_3), in which the imine ligands adopted the *Z* configuration. In addition, **3** reacted with diphenylacetylene, which afforded the mononuclear organopalladium compound [κ²-***N,C1***-η²-***C3,C4***-Pd{(PhC=CPh)$_2$–$C_{10}H_6$–CH_2–N=CH–(2,6-$Cl_2C_6H_3$)}Cl] (**8**). This compound derived from the insertion of two alkyne molecules into the C–Pd σ bonds of **3** and presented the imine ligand in a *Z* configuration. The crystal structure of **8**·CH_2Cl_2 has been determined.

1. Introduction

Primary amines are the simplest of the N-donor ligands that can experience the cyclopalladation reaction [1]. In spite of this, methods for the direct cyclopalladation of some of these ligands have not been developed until quite recently [2]. Following these studies, the cyclo-platination, -ruthenation, -rhodation and -iridiation of some primary amines have been reported [3]. However, the cyclopalladation of primary amines remains a difficult task. For instance, in our current work on the cyclopalladation of primary amines [1,4], we were interested in obtaining cyclopalladated derivatives of the primary amine (naphthalen-1-yl)methanamine (**A** in Fig. 1) by direct cyclopalladation. The treatment of **A** with $Pd(OAc)_2$ in equimolecular amounts in toluene or acetic acid for different lengths of time and at varying temperatures did not produce the expected cyclopalladated derivative (**B** in Fig. 1) in acceptable yields and purity. These results contrast with the straightforward cyclopalladation reaction that (*R*)-1-(naphthalen-1-yl)ethanamine (**C** in Fig. 1) undergoes when it is treated with $Pd(OAc)_2$ in acetic acid, which produces its acetato-bridged five-membered cyclopalladated derivative (**D** in Fig. 1) [4b,5]. These results show that bulky substituents in the α position in relation to the heteroatom promote the cyclopalladation reaction. This is in accordance with previous reports [6].

We and other authors have introduced synthetic methods for the preparation by direct cyclopalladation of *exo*-cyclopalladated imines derived from benzylamines, 2-phenylethylamines, 2-phenylaniline, 2-*tert*-butyl-5-methoxy-phenylamine, and α-amino acids, such as phenylglicine and phenylalanine [7]. These compounds can be seen as protected cyclopalladated primary amines and α-amino acids; in the same way that *endo*-cyclopalladated imines have been treated as protected cyclopalladated aromatic ketones or aldehydes [8]. The *endo* and *exo* descriptors were initially introduced to differentiate between the structural isomers of *ortho*-cyclopalladated benzyl-benzylidene-amine (Fig. 2) [8]. However, the use of these descriptors has been extended to refer, in general, to cyclometallated imines with the C=N bond inside the metallacycle (*endo* cyclometallated imines) and outside the metallacycle (*exo* cyclometallated imines) [9].

In this paper, we report that the imine (*E*)-N-(2,6-dichlorobenzylidene)(naphthalen-1-yl)methanamine (**1**), which is easily

obtained by a condensation reaction between 2,6-dichlorobenzaldehyde and (naphthalen-1-yl)methanamine, reacts with $Pd(OAc)_2$ in acetic acid at 60 °C for 24 h to produce the new acetato-bridged *exo*-five-membered cyclopalladated dimer **2**. This new dimer is derived from the selective palladation of the 2 position of the naphthyl group of **1**. In addition, the chloro-bridged cyclopalladated derivative of **2** (compound **3**) reacts with diphenylacetylene to afford the mononuclear organopalladium compound [κ^2-***N,C1***-η^2-***C3,C4***-Pd{(PhC═CPh)$_2$–$C_{10}H_6$–CH_2–N═CH(2,6-$Cl_2C_6H_3$)}Cl], which results from the insertion of two alkyne molecules into the C–Pd σ bonds of **3**. These results are similar to those previously reported by us for the imine (*E*)-N-(2,6-dichlorobenzylidene)-1-phenylmethanamine [7i,10].

2. Results and discussion

Scheme 1 shows the new compounds prepared in this work and the labelling of the aromatic protons for the discussion that follows.

Imine **1** was prepared in high yield by a condensation reaction between 2,6-dichlorobenzaldehyde and (naphthalen-1-yl)methanamine. This compound was a pale yellow solid that was insoluble in ethanol and soluble in chloroform. It produced satisfactory elemental analysis, IR, DEPCI mass spectrum and ^{1}H NMR. The ^{1}H NMR of **1** showed a single set of signals, which indicated that it consisted of only one geometrical isomer in relation to the carbon–nitrogen double bond. ^{1}H–^{1}H COSY and NOESY experiments at 500 MHz enabled the assignation of almost all protons of **1**, and the cross-peak in the NOESY experiment between the CH═N and the CH_2 protons was indicative of an *E* configuration for imine **1**.

Treatment of equimolecular amounts of imine **1** and $Pd(OAc)_2$ in acetic acid at 60 °C for 24 h produced the new acetato-bridged *exo*-five-membered cyclopalladated dimer **2**, which was derived from the palladation of the 2 position of the naphthyl group of **1**. An alternative structure for compound **2**, with the 8 position of

Scheme 1. (i) 2,6-Dichlorobenzaldehyde, ethanol, reflux, 4h; (ii) $Pd(OAc)_2$, acetic acid, 60 °C, 24 h; (iii) LiCl, acetone, room temperature, 1 h 30 min; (iv) **4** and **6**: py-d_5, $CDCl_3$, room temperature. **5** and **7**: PPh_3, acetone, room temperature, 1 h; (v) diphenylacetylene, chloroform, reflux, 5 days.

the naphthyl group palladated and containing a six-membered metallacycle (Fig. 3), was discarded in view of the ^{31}P chemical shift of compounds **5** and **7**, 41.55 and 42.22 ppm, respectively. These shifts were in the range expected for mononuclear cyclopalladated compounds of general formula *trans*-***N,P***-[Pd(C,N)(X)(PPh_3)] (X = OAc, Cl, Br, I) that contain a five-membered pallacycle and a phenyl or naphthyl metallated carbon atom (42–40 ppm) [6a,7g,11]. The ^{31}P chemical shift of analogous compounds with a six-membered palladacycle appears in the interval 37–33 ppm [7a,d,f,12]. Furthermore, the X-ray molecular structure of compound **8** was in agreement with the proposed structure for **2**.

Compound **2** was a yellowish solid that was insoluble in acetic acid and soluble in chloroform. It afforded satisfactory elemental analysis, IR, positive ESI mass spectrum and ^{1}H NMR. In the IR spectrum, the asymmetric and symmetric stretchings of the carboxylic functions of **2** produced broad intense bands at 1568 and 1429 cm^{-1}, respectively, in accordance with the proposed bridging coordination mode of the acetato ligands of **2** [13]. The positive ESI mass spectrum produced intense signals corresponding to [(M/2)-OAc+acetonitrile]$^+$ and [(M/2)+Na]$^+$, which were consistent with the labile acetato-bridged dinuclear structure proposed for **2**. The most interesting features of the ^{1}H NMR at 300 MHz of **2** in $CDCl_3$ were the singlet produced by the methyl acetato protons and the AB spin system afforded by the CH_2 protons. These features were consistent with a *trans* folded structure with C_2 symmetry for **2**. Acetato-bridged cyclopalladated dimers usually present this structure, both in the solid state and in chloroform solution [14]. In addition, the coupling constant between the CH═N and the CH_2

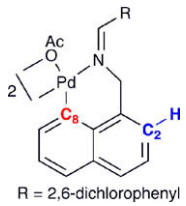

Fig. 3. An alternative structural isomer of **2**, which could be formed by direct cyclopalladation of imine **1**.

protons of 2.7 Hz was in agreement with the proposed *Z* configuration for the imine ligands of compound **2** [15]. Note the following: (i) in this paper the palladium atom is not taken into account to determine the *E* or *Z* configuration of the imine ligand in compounds **2**–**8**, and (ii) the coupling constant between the CH=N and CH_2 protons for the imine Ph–CH=N–CH_2–Ph (benzyl-benzylidene-amine), which adopts an *E* configuration, is *ca.* 1 Hz [15].

A metathesis reaction between **2** and LiCl yielded the expected chloro-bridged cyclopalladated dimer **3**. Compound **3** was a pale yellow solid that was soluble in chloroform. It afforded satisfactory elemental analysis, IR, positive MALDI-TOF mass spectrum and ^{1}H NMR. In the IR spectrum, the carbon–nitrogen double bond stretching appeared at 1635 cm^{-1}. The positive MALDI-TOF mass spectrum produced intense signals at $[M+(M/2)-Cl]^+$ and $[M-Cl]^+$, which were in agreement with the labile dimeric structure of compound **3** with bridging chloro ligands. The ^{1}H NMR at 400 MHz in $CDCl_3$ of compound **3** showed two methinic protons at 9.05 and 8.67 ppm and four signals for the CH_2 protons in the interval between 5.75 and 4.60 ppm. This suggests that compound **3** consisted of different stereoisomers with imines in the *Z* and *E* configuration [7g].

Bridge-splitting reactions of the cyclopalladated dimers **2** and **3** with py-d_5 and PPh_3 yielded the mononuclear cyclopalladated compounds **4**–**7**, which presented the py-d_5 or the PPh_3 ligand *trans* to the iminic nitrogen atom, in agreement with the antisymbiotic effect [16].

The mononuclear compounds **4** and **6** were prepared in an NMR tube, by treating $CDCl_3$ solutions of these compounds with py-d_5, and were not isolated. In both cases, a colour change of the initial yellow or pale yellow solution to a colourless solution indicated the quantitative transformation of the dimers **2** and **3** into the mononuclear compounds **4** and **6**. This was confirmed by the ^{1}H NMR at 400 MHz of the final colourless solutions, which were consistent with the quantitative formation of compounds **4** and **6**. The upfield shift of the *b* aromatic proton in relation to **1** was in agreement with a *trans* disposition of the py-d_5 and the iminic nitrogen [7g,17]. Furthermore, the downfield shift of the methinic proton in relation to **1** was indicative of a *Z* configuration of the imine ligand [7g]. Further evidence of the *Z* configuration of the imine ligands in compounds **4** and **6** was given by the coupling constant between the CH=N and CH_2 protons: 2.8 Hz for compound **4** and 2.4 Hz for compound **6** [15]. For compound **4**, the methyl protons of the acetato ligand appeared as a singlet at 1.97 ppm. This chemical shift was in accordance with an acetato ligand coordinated to a palladium(II) centre in a terminal mode [1,9a,15].

The mononuclear compounds **5** and **7** were obtained on a preparative scale and isolated. These compounds were pale yellow solids that were soluble in chloroform. They afforded satisfactory elemental analysis, IR, positive MALDI-TOF, and ^{1}H and ^{31}P{^{1}H} NMR spectra. In the IR spectrum, the q X-sensitive mode of the coordinated PPh_3 produced a medium intense band at *ca.* 1090 cm^{-1}. The carbon–nitrogen double bond stretching appeared at 1642 cm^{-1} for compound **5**, and 1652 cm^{-1} for compound **7**. For compound **5**, the asymmetric and symmetric stretchings of the carboxylic functions produced broad intense bands at 1604 and 1433 cm^{-1}, respectively, according to a unidentate mode of coordination for the acetato ligand [13]. In the positive MALDI-TOF experiment, both compounds gave an intense signal at $[M-X]^+$ (X = OAc for compound **5**, and X = Cl for compound **7**). This was in accordance with their structures, which contain labile terminal acetato and chloro ligands. In the ^{1}H NMR of compounds **5** and **7**, the upfield shift of the *b* proton in relation to **1**, and its coupling constant with the phosphorus *ca.* 6 Hz, were in accordance with a *trans* disposition between the phosphine ligand and the iminic nitrogen atom [7g]. The downfield shift of the methinic proton in relation to **1** was consistent with a *Z* configuration of their imine ligands. For compound **5**, the chemical shift of the methyl protons of the acetato ligand appeared as a singlet at 1.34 ppm. In addition, the ^{31}P chemical shifts of compounds **5** and **7** (41.55 ppm for compound **5**, and 42.22 ppm for compound **7**) were in the range expected for mononuclear cyclopalladated compounds of general formula *trans*-***N,P***-[Pd(C,N)(X)(PPh_3)] (X = OAc, Cl, Br, I) that contain a five-membered pallacycle and a phenyl or naphthyl metallated carbon atom (42–40 ppm) [6a,7g,11].

Interestingly, the chloro-bridged cyclopalladated dimer **3** reacted at reflux of chloroform with diphenylacetylene very slowly, but in a very clean reaction, which produced the mononuclear organopalladium compound **8**. This compound was derived from the insertion of two alkyne molecules into the C–Pd σ bonds of **3**. This is the third reported case of insertion of alkyne molecules into the C–Pd σ bond of a cyclopalladated compound that contains a palladated naphthyl group. Previously, (i) Pfeffer et al. [18] published the synthesis of *N*-methyl-benzo[d,e]quinolines and *N,N*-dimethyl-benzo[d,e]quinolinium salts by monoinsertion of internal alkynes into the C–Pd σ bond of *N,N*-dimethyl-1-aminonaphthalenes cyclopalladated derivatives, with the 8 position of the naphthyl group palladated (Fig. 4A I and II); and (ii) Nelson et al. [19] described the monoinsertion of dimethylacetylenedicarboxylate or diphenylacetylene into the C–Pd σ bond of *N,N*-dimethyl-α-(2-naphthyl)ethylamine cyclopalladated derivatives, with the 3 position of the naphthyl group palladated (Fig. 4A III). In addition, Beydoun et al. [20] reported a catalytic synthesis of *N*-methyl-benzo[d,e]quinolines by a reaction between 8-iodo-*N,N*-dimethyl-1-aminonaphthalene and internal alkynes, using a cyclopalladated compound as a precatalyst (Fig. 4B). These results and those described here show the potential of the cyclopalladation reaction in organic and organometallic synthesis, since starting from commercial naphthalene derivatives it allows the selective functionalisation of the 8, 3 and 2 positions of naphthyl groups.

Compound **8** was a yellow solid that was soluble in chloroform. It afforded satisfactory elemental analysis, IR, positive MALDI-TOF

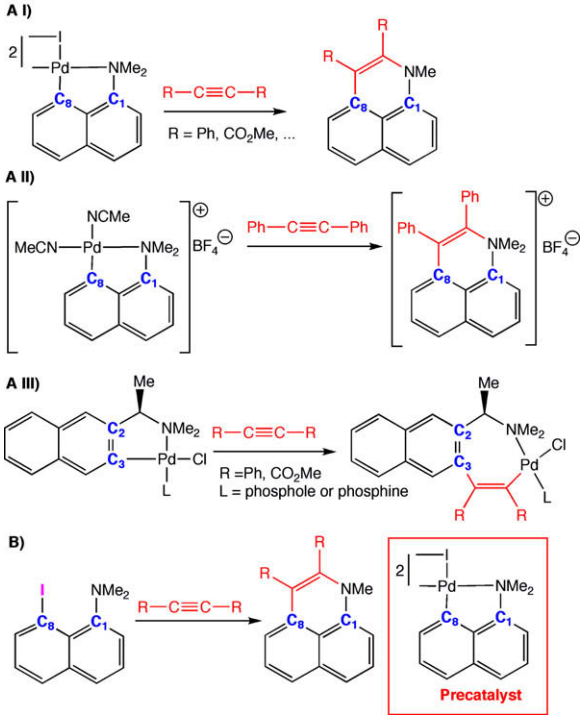

Fig. 4. (A) Previous reports on the insertion of alkynes into the C–Pd σ bond of cyclopalladated compounds containing a palladated naphthyl group: I and II) (Ref. [18]). III) (Ref. [19]). (B) A catalytic version of the stoichiometric reaction A I) (Ref. [20]).

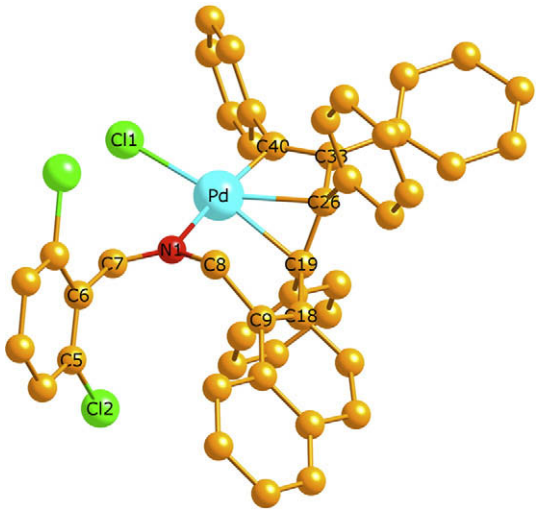

Fig. 5. X-ray molecular structure of compound **8**·CH_2Cl_2.

mass spectrum and ^{1}H NMR spectrum. In the IR spectrum, the stretching of the carbon–nitrogen double bond appeared at 1647 cm^{-1} and the positive MALDI-TOF produced an intense signal for $[M–Cl]^+$, according to the lability of the chloro ligand in compound **8**. In the ^{1}H NMR spectrum at 400 MHz, the most interesting features were the downfield shift of the methinic proton in relation to **1**, which suggested a *Z* configuration for the imine ligand [7g] and the AB spin system produced by the CH_2 protons, which was consistent with the lack of symmetry elements of molecule **8**. The structure of compound **8** was established by an X-ray diffraction study. Yellow crystals of the adduct **8**·CH_2Cl_2 suitable for the X-ray diffraction study were obtained by slow evaporation of the solvents of a solution of **8** in dichloromethane/methanol (1:1). Fig. 5 shows the X-ray molecular structure of compound **8**, and Table 1 gives selected distances and bond angles. The structure agrees with palladation of the 2 position of the naphthyl group of **1**, followed by a double insertion of diphenylacetylene into the Pd–C σ bonds of **3**. The molecule of **8** is chiral. The C19–C26–C33–C40 butadienyl fragment presents a *trans–cis* configuration and is η^2-κ^1 coordinated to palladium(II). Thus, this compound adopts the structure found in most organopalladium compounds derived from the insertion of two alkyne molecules into the C–Pd σ bonds of five- and six-membered cyclopalladated compounds, in which the resulting butadienyl fragment presents a *trans–cis* configuration and is η^2-κ^1 coordinated to palladium(II) [21].

Distances and angles around palladium(II) were within the normal range for this kind of organopalladium compound [10,22]. As expected, the carbon–carbon distance of the alkene unit coordinated η^2 to palladium(II) was larger than that of the alkene unit coordinated κ^1 to palladium(II): 1.407(1) and 1.331(4) Å, respectively. The alkene unit with an η^2 coordination mode did not deviate very much from planarity [torsion angle C18–C19–C26–C33 = −172.4(3)°]. In addition, the imine ligand adopted the *Z* configuration [torsion angle C8–N1–C7–C6 = −0.3(5)°]. The 2,6-dichlorophenyl group was almost perpendicular to the plane defined by the C7–N1–C8 atoms, which included the iminic function [torsion angle C5–C6–C7–N1 = 90.4(8)°]. The Pd–Cl [2.3195(15) Å] and Pd–N [2.139(3) Å] distances were shorter and longer respectively than the analogous distances in mononuclear cyclopalladated compounds of general formula *trans*-***N,P***-[Pd(C,N)Cl(phosphine)] [23]. This is due to the weaker *trans* influence of an η^2-coordinated alkene in relation to a metallated carbon atom, and to the stronger *trans* influence of a metallated carbon atom in relation to a phosphine ligand [24].

Work is in progress to find practical methods of deprotection of compounds **2**–**8** and to make more extensive the study of the reactivity of compounds **2** and **3** towards unsaturated molecules and electrophilic reagents.

As suggested by a reviewer, we studied the reaction between **3** and diphenylacetylene in a molar ratio **3**/diphenylacetylene = 1/2. The reaction was carried out in $CDCl_3$ at 60 °C and monitored by ^{1}H NMR over a period of 48 h. The ^{1}H NMR showed that the reaction solution was almost exclusively formed by compound **8** and the starting materials, compound **3** and diphenylacetylene.

3. Experimental

3.1. Instruments and reagents

Elemental analyses of C, H and N were performed with an Eager 1108 microanalyzer. Infrared spectra were recorded on a Nicolet Impact-400 spectrophotometer, using pressed discs of dispersed samples of compounds **1**–**8** in KBr. NMR experiments were recorded using Varian Inova 500, Varian Mercury 400, Varian Unity 300 and Bruker 250 instruments. Chemical shifts are reported in δ values (ppm) relative to $SiMe_4$ and coupling constants in Hz. The mass spectra were recorded with the following instruments: DEPCI with a ThermoFinnigan TRACE DSQ, using as reactive gas NH_3; Electrospray with a LC/MSD-TOF, using H_2O–CH_3CN 1:1 to introduce the sample; and MALDI-TOF$^+$ with a VOYAGER-DE-RP. All chemicals and solvents were of commercial grade and used as received.

3.2. Preparation of *1*

Twenty millimole of (naphthalen-1-yl)methanamine (3.144 g) and 20 mmol of 2,6-dichlorobenzaldehyde (3.502 g) were treated

Table 1

at reflux of ethanol (30 mL) for 4 h. The resulting solution was allowed to cool to room temperature, whereupon most of imine **1** separated as a pale yellow powder, which was filtered and dried under vacuum. Yield: 5.589 g (89%). Characterization data: *Anal.* Calc. for $C_{18}H_{13}Cl_2N$: C, 68.81; H, 4.17; N, 4.46. Found: C, 68.37; H, 4.19; N, 4.53%. DEPCI (+) (NH_3 reactive gas): $[M + H]^+ = 315.1$ (calc. 314.0) (base peak). IR (cm^{-1}): 1642 st C=N. ^1H NMR 500 MHz ($CDCl_3$) (selected data): 8.55 (s, CH=N), 8.13 (d, H_g, $^3J_{HH} = 8.4$), 7.88 (d, H_d, $^3J_{HH} = 8.4$), 7.80 (d, H_c, $^3J_{HH} = 8.4$), 7.30 (d, H_h and H_j, $^3J_{HH} = 8.0$), 7.17 (t, H_i, $^3J_{HH} = 8.0$), 5.40 (s, CH_2).

3.3. Preparation of **2**

A suspension formed by 0.194 (0.86 mmol) of $Pd(OAc)_2$, 0.270 (0.86 mmol) of **1** and 20 mL of acetic acid was treated at 60 °C for 24 h. The resulting suspension was allowed to cool to room temperature, whereupon most of compound **2** separated as a yellow powder, which was filtered and dried under vacuum. Yield: 0.254 g (62%). Characterization data: *Anal.* Calc. for $C_{40}H_{30}Cl_4N_2O_4Pd_2$: C, 50.18; H, 3.16; N, 2.93. Found: C, 50.06; H, 3.14; N, 2.90%. IR (cm^{-1}): 1568 (st as. OAc), 1429 (st s. OAc). ESI-(+): Intense peaks at $[(M/2)\text{-OAc} + \text{acetonitrile}]^+ = 460.96$ (calc. 460.97) (base peak) and $[(M/2) + Na]^+ = 500.99$ (calc. 500.94). ^1H NMR 300 MHz ($CDCl_3$) (selected data): 8.48 (t, CH=N, $^4J_{HH} = 2.7$), 7.72 (d, 1H, aromatic, $^3J_{HH} = 7.8$), 7.38 (d, 1H, aromatic, $^3J_{HH} = 8.7$), 6.96 (d, 1H, aromatic, $^3J_{HH} = 8.4$), 4.74, 4.68, 4.46, 4.41 (AB spin system, CH_2), 2.25 (s, OAc).

3.4. Preparation of **3**

A suspension formed by 0.629 g (0.66 mmol) of **2**, 0.111 g (2.62 mmol) of LiCl and 20 mL of acetone was stirred at room temperature for 1 h 30 min. The resulting suspension was concentrated under vacuum and the residue was eluted through a silica gel column with a solution of methanol in chloroform in a 2–100 volume ratio. The yellow band was collected and concentrated under vacuum. Addition of diethyl ether (5 mL) to the residue led to the precipitation of **3** as a pale yellow powder, which was filtered and dried under vacuum. Yield: 0.424 g (71%). Characterization data: *Anal.* Calc. for $C_{36}H_{24}Cl_6N_2Pd_2$: C, 47.51; H, 2.66; N, 3.08. Found: C, 47.04; H, 2.68; N, 3.11%. MALDI-TOF (+) (matrix = 2,5-hydroxibenzoic acid): Intense peaks at $[M+(M/2)\text{-Cl}]^+ = 1329.9$ (calc. 1326.7) and $[M\text{–Cl}]^+ = 875.1$ (calc. 872.8) (base peak). IR (cm^{-1}): 1635 st C=N. ^1H NMR 400 MHz ($CDCl_3$) (selected data) (mixture of stereoisomers): 9.05 s, 8.67 s (CH=N); 5.75 s, 5.18 d $^4J_{HH} = 2.4$, 5.07 s, 4.60 s (CH_2).

3.5. Preparation of the $CDCl_3$ solutions of **4** and **6**

ca. 10 mg of **2** or **3** were treated with 0.7 mL of $CDCl_3$ and two drops of py-d_5. The formation of a colourless solution was an indication of the quantitative transformation of compound **2** or **3** into the mononuclear compounds **4** or **6**. Characterization data: Compound **4**: ^1H NMR 400 MHz ($CDCl_3$ + py-d_5) (selected data): 8.88 (t, CH=N, $^4J_{HH} = 2.8$), 6.32 (d, H_b, $^3J_{HH} = 8.4$), 5.19 (d, CH_2, $^4J_{HH} = 2.8$), 1.97 (s, OAc). Compound **6**: ^1H NMR 400 MHz ($CDCl_3$ + py-d_5) (selected data): 9.65 (t, CH=N, $^4J_{HH} = 2.4$), 7.73 (d, 1H, aromatic, $^3J_{HH} = 8.4$), 6.29 (d, H_b, $^3J_{HH} = 8.4$), 5.21 (d, CH_2, $^4J_{HH} = 2.8$).

3.6. Preparation of **5**

A suspension formed by 0.100 g (0.1 mmol) of **2**, 0.055 g (0.2 mmol) of PPh_3 and 10 mL of acetone was stirred at room temperature for 1 h. The resulting suspension was concentrated under vacuum and the residue was treated with 5 mL of acetone/diethyl ether (1/1). Compound **5** precipitated as a pale yellow solid, which was filtered and dried under vacuum. Yield: 0.078 g (50%). Characterization data: *Anal.* Calc. for $C_{38}H_{30}Cl_2NO_2PPd$: C, 61.60; H, 4.08; N, 1.89. Found: C, 61.40; H, 4.06; N, 1.85%. MALDI-TOF (+) (matrix = 2,5-hydroxibenzoic acid): Intense peak at $[M\text{-OAc}]^+ = 682.1$ (calc. 681.0) (base peak). IR (cm^{-1}): 1642 st C=N, 1604 (st as. OAc), 1433 (st s. OAc), 1090 q X-sensitive mode of the coordinated PPh_3 ligand. ^1H NMR 400 MHz ($CDCl_3$) (selected data): 8.85 (t, CH=N, $^4J_{HH} = 2.4$), 6.90 (d, H_c, $^3J_{HH} = 8.8$), 6.68 (dd, H_b, $^3J_{HH} = 8.4$, $^4J_{PH} = 6.0$), 5.32 (s, CH_2), 1.34 (s, OAc). $^{31}P\{^1H\}$ NMR 121.6 MHz ($CHCl_3$, inset $P(OMe)_3$ in CD_3COCD_3) = 41.55 s.

3.7. Preparation of **7**

A suspension formed by 0.106 g (0.11 mmol) of **3**, 0.061 g (0.23 mmol) of PPh_3 and 10 mL of acetone was stirred at room temperature for 1 h. The resulting solution was concentrated under vacuum and the residue was treated with 5 mL of diethyl ether. Compound **7** precipitated as a pale yellow powder, which was filtered and dried under vacuum. Yield: 0.098 g (62%). Characterization data: *Anal.* Calc. for $C_{36}H_{27}Cl_3NPPd$: C, 60.27; H, 3.79; N, 1.95. Found: C, 60.10; H, 3.82; N, 1.99%. MALDI-TOF (+) (matrix = dithranol): Intense peak at $([M\text{–Cl}]^+ = 682.2$ (calc. 681.0) (base peak). IR (cm^{-1}): 1652 st C=N, 1095 q X-sensitive mode of the coordinated PPh_3 ligand. ^1H NMR 400 MHz ($CDCl_3$) (selected data): 9.71 (q, CH=N, $^4J_{HH} \approx {}^4J_{PH} = 2.4$), 7.86–7.81 (m, 6H, o-$PPh_3$), 6.88 (d, H_c, $^3J_{HH} = 8.8$), 6.68 (dd, H_b, $^3J_{HH} = 8.8$, $^4J_{PH} = 6.4$), 5.36 (s, CH_2). $^{31}P\{^1H\}$ NMR 101.26 MHz ($CHCl_3$, inset $P(OMe)_3$ in CD_3COCD_3): 42.22 s.

3.8. Preparation of **8**

A suspension formed by 0.248 g (0.27 mmol) of **3**, 0.194 g (1.09 mmol) of diphenylacetylene and 20 mL of chloroform was subjected to reflux temperature for 5 days. The resulting yellow solution was concentrated under vacuum and the residue was eluted through a silica gel chromatographic column with a solution of methanol in chloroform in a 2–100 volume ratio. The yellow band was collected and concentrated under vacuum. Addition of diethyl ether (5 mL) to the residue produced the precipitation of **8** as a yellow powder which was filtered and dried under vacuum. Yield: 0.303 g (69%). Characterization data: *Anal.* Calc. for $C_{46}H_{32}Cl_3NPd$: C, 68.08; H, 3.97; N, 1.72. Found: C, 67.66; H, 3.87; N, 1.78%. MALDI-TOF (+) (matrix = 2,5-hydroxibenzoic acid): Intense peak at $[M\text{–Cl}]^+ = 775.7$ (calc.775.1) (base peak). IR (cm^{-1}): 1647 st C=N, 1595, 1576, 1561 st arCC. ^1H NMR 400 MHz ($CDCl_3$) (selected data): 8.97 (s, CH=N), 7.64 (d, H_h and H_j, $^3J_{HH} = 8.0$), 7.38 (t, H_i, $^3J_{HH} = 8.0$), 6.76 (d, 1H, aromatic, $^3J_{HH} = 8.0$), 5.16, 5.12, 3.86, 3.83 (CH_2, AB spin system).

3.9. Crystal structure

Crystals for the X-ray determination of **8**·CH_2Cl_2 were obtained by slow evaporation of a solution of **8** in dichloromethane/methanol (1/1). A prismatic crystal (0.1 × 0.1 × 0.2 mm) was selected and mounted on a MAR345 diffractometer with an image plate detector. Unit-cell parameters were determined from 1665 reflections ($3 < \theta < 31°$) and refined by the least-squares method. Intensities were collected with graphite monochromatised Mo Kα radiation. The structure was solved by Direct methods, using the SHELXS computer program [25]. It was refined by full-matrix least-squares method with the SHELXL97 computer program [26]. The minimised function was $\Sigma\ w\ ||Fo|^2 - |Fc|^2|^2$, where $w = [\sigma^2(I) + (0.0579P)^2 + 0.6694P]^{-1}$, and $P = (|Fo|^2 + 2|Fc|^2)/3$. f, f' and f'' were taken from International Tables of X-ray Crystallography [27]. All H atoms were computed and refined, using a riding model with an isotropic

ABSTRACT

Three pyridine coordinated cyclopalladated complexes: (*S*)-chloro{2-[2-(4-*tert*-butyl)oxazolinyl]phenyl-*C,N*}(4-R-pyridine)palladium(II) (R = H, **2**; R = CF_3, **3**; R = NMe_2, **4**), have been synthesized and structurally characterized. While the crystal structure shows that **2** has a normal *N,N-trans*-conformation in the coordination sphere of palladium(II), **3** and **4** exhibit uncommon *N,N-cis*-conformations. From ^{1}H NMR measurements, the major coordination isomer in deuterated chloroform solution is *N,N-trans* configuration for three palladacycles. It was found that the three complexes catalyze effectively the methanolysis of the P═S pesticides including chiral thiophosphates but show different activity depending on the substituents of co-coordinated pyridine ring in **2**–**4**.

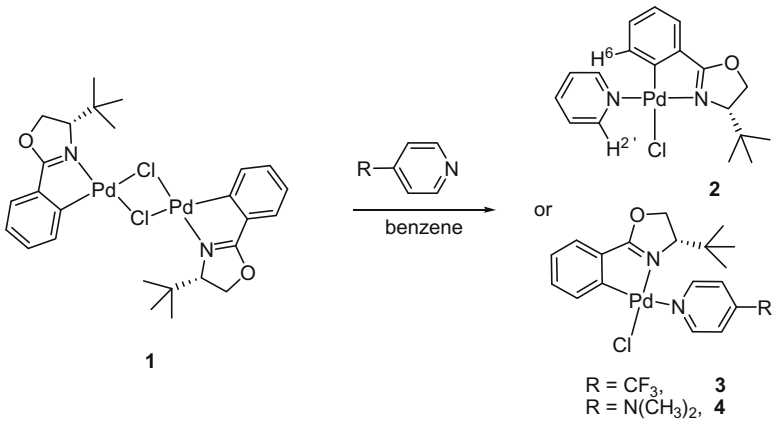
1. Introduction

After the discovery of the first cyclometallated derivatives [1,2], many palladacycle compounds have been synthesized and their use widely applied in organic synthesis, organometallic catalysis, and new molecular materials [3–12]. In recent years, the research groups of Ryabov [13], Gabbaie [14], and Tao [15] have investigated the catalytic properties of palladacycles for the hydrolysis of organic thiophosphates and demonstrated their remarkable catalytic activities. However, there are some problems accompanying the catalytic hydrolytic degradation of pesticides, including poor aqueous solubility of both the metal catalysts and organic phosphate substrates and the fact that the anionic hydrolytic products can bind to the metal ions thereby curtailing further catalysis. As an alternative strategy in catalytic decomposition of organic phosphate pesticides and related chemical warfare (CW) agents, the catalytic methanolysis of various organic phosphates with lanthanide and transition metal ions and some of their metal complexes as well as palladacycles have been explored in recent years [16–19].

As a part of our interest in the catalytic degradation of thiophosphates, we report here the synthesis, structural characterization, and preliminary catalytic properties of three palladacycles containing the (*S*)-4-*tert*-butyl-2-phenyl-2-oxazoline ligand (see Scheme 1). We have found that the structures and catalytic activities of these palladacycles can be significantly modified by changing the electronic property of the substituents on the mono-dentate pyridine ring in **2**–**4**.

2. Results and discussion

2.1. X-ray structure studies of complexes 2–4



The crystal data for the data collection and refinement of **2**–**4** are given in Table 1. Selected bond lengths, bond angles and torsion angles are listed in Table 2. ORTEP diagrams of **2**–**4** at the 50% probability level are given in Figs. 1–3.

For complex **2**, the palladium atom displays the expected square planar coordination with the pyridine and oxazoline nitrogen atoms positioned *trans* to one another. The dihedral angle between the planes {C1/Pd/N1} and {N2/Pd/Cl1} is 5.83° which indicates that the coordination sphere is almost square planar. The bond lengths and bond angles of palladacycle fall within the range of the values reported for other cyclopalladated derivatives of oxazoline ligands and other palladacycle compounds with two nitrogen atoms in the *trans* position [20–22].

For complexes **3** and **4**, it can clearly be seen that the pyridine and oxazoline nitrogen atoms are in a *cis* position (see Figs. 2 and 3), which is not so common for the *ortho*-palladated complexes

containing monodentate N or P ligands. The structure of **4** is quite different from the analog palladacycle compound (*S*)-chloro{2-[2-(4-*iso*-propyll)oxazolinyl]phenyl-*C*,*N*}(4-*N*,*N*-dimethylaminopyridine)palladium(II), which contains *iso*-propyl group on the oxazoline ring instead of *tert*-butyl group and has *N*,*N*-*trans* configuration in the coordination sphere of palladium atom. The *N*,*N*-*cis* configuration in *ortho*-palladated complexes is sometimes observed in solution by NMR, but the only other crystal structure of which we are aware is that of the palladacycle [Pd{$C_6H_4C(Me)$=$NC_{10}H_7$}Cl(4-Me-py)] ($C_{10}H_7$ = α-naphthyl) [23]. The torsion angles between the pyridine plane and the palladacycle plane (Pd/C1/C2/C7/N1) are 46.41° and 40.17° for complexes **3** and **4**, respectively. The effect of the strong donating phenyl ring on the pyridine can be observed since the σ-bound phenyl induces 0.142 and 0.118 Å elongation of the Pd–N (pyridine) bonds *trans* to it in **3** and **4**, respectively, compared with that in complex **2**. The Pd–Cl bonds in **3** and **4** are shorter by 0.074 and 0.067 Å than that in **2** since they are positioned to have less *trans* effect on the nitrogen donor. Another point of note is that the dihedral angles between the {C1/Pd/N1} and {N2/Pd/Cl1} planes are 8.89° and 7.93° in **3** and **4**, respectively. The maximum displacements of atom C1 are 0.121 and 0.109 Å in com-

plexes **3** and **4**, which indicates that the palladium coordination spheres in these two complexes have significant tetrahedral distortions. The other structural features of complexes **3** and **4**, including conformation of the palladacycle and oxazoline rings, are similar to those of **2**.

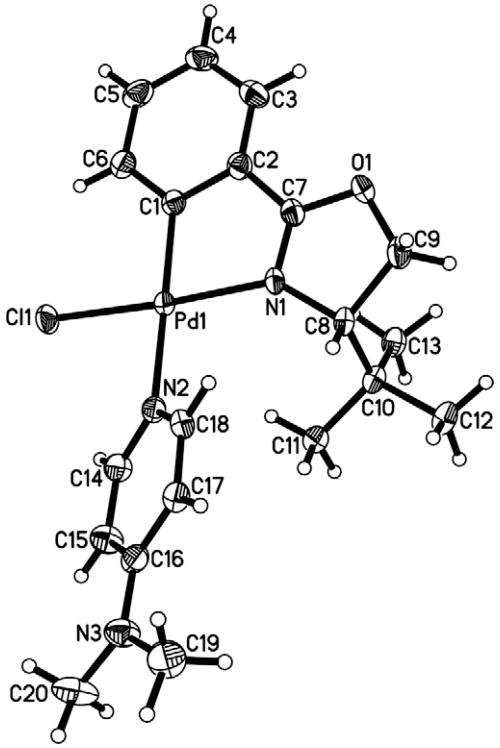

Fig. 3. Molecular structure of complex **4** showing the atom numbering. Displacement parameters are shown at the 50% level.

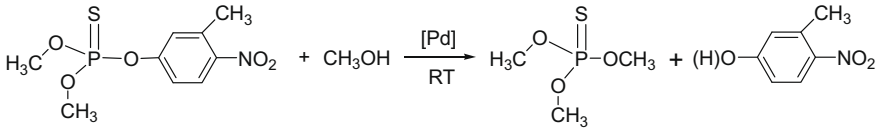

A question that might arise is "why complexes **3** and **4** have *N,N-cis* configuration while complex **2** has *N,N-trans* configuration?" The effects from electronic and steric factors of the mono-dentate pyridine ligands can be excluded, since all of three pyridine derivatives have almost the same sizes, and 4-dimethylamino- and 4-trifluoromethyl-substituent groups show opposite electronic effects. From NMR studies (see below), the majority coordination conformation is *N,N-trans* for all of three complexes. So for **2**, the molecular structure in the crystal is consistent with that in solution, while it may be that the thermodynamically stable *trans* isomers of **3** and **4** give way to a *cis* configuration in the solid state due to the more thermodynamically stable isomers in solution crystallizing out to form **3** and **4**. It can also be due to the stable packing of *tert*-butyloxazoline substituted palladacycle **4** *cis*-isomer during the crystallization, since the space group for **4** is $P2_12_12_1$, while the *iso*-propyl substituted (*S*)-chloro{2-[2-(4-*iso*-propyll)oxazolinyl]phenyl-*C,N*}(4-*N,N*-dimethylamino-pyridine)palladium(II) has a space group of $P2_1$ [22]. However the mechanism of how *trans* configuration in liquid state converts to *cis* isomer in solid state is still not clear from our knowledge.

To avoid the situation that the structure of **4** is due to the specific crystal sample, so eight more crystal samples were chosen to measure the cell parameters (see Supplementary data Table S1). It proved the cell parameters of all samples measured fall in the permitted error.

Furthermore XRD method was used to measure the powered sample of compound **4**. The result (see Supplementary data Table S2) indicated that the structure of **4** in the solid state is almost consistent with that from the X-ray single crystal analysis.

2.1.1. ^{1}H NMR spectra of complexes 2–4

For the palladacycle complexes with monodentate ligands, both *cis* and *trans* coordination isomers are observed in solution by NMR. The ^{1}H NMR spectra of **2**–**4** were recorded in $CDCl_3$, and

Scheme 2.

Table 3
Concentration dependence for the pseudo first-order rate constant of methanolysis of **5** promoted by **2–4** and corrected for buffer effects at [**5**] = 2.84×10^{-5} mol dm^{-3}, $^{s}_{s}$pH 10.80, triethylamine buffer, 25 °C.

[Pd] (mol dm^{-3}) × 10^5	k^{obs} (s^{-1} × 10)[a,b]		
	2	**3**	**4**

1.0	0.081 ± 0.003	0.32 ± 0.02	0.0053 ± 0.0002
0.5	0.0227 ± 0.008	0.101 ± 0.008	0.0023 ± 0.0001

[a] Rate constants determined at three different [buffer] from (1–3) × 10^{-3} mol dm^{-3}, and average values were used.
[b] Errors are calculated from standard deviation of the mean.

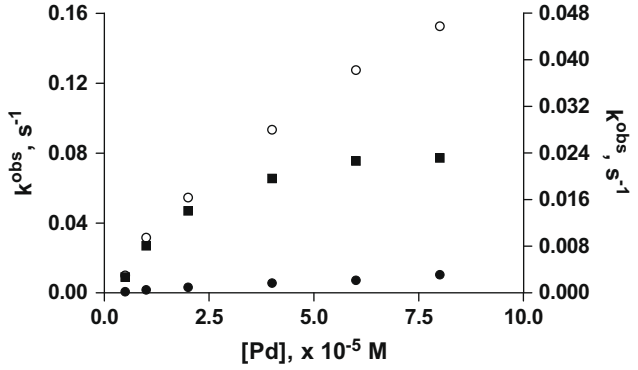

Fig. 4. Plot of k^{obs} vs. [Pd] for the methanolysis of **5** (2.84×10^{-5} M) at 25 °C, buffer triethylamine (1–3) × 10^{-3} M, $^{s}_{s}$pH 10.80. k^{obs} values of **2** (■) and **4** (●) are corresponding to the right *Y* axis, k^{obs} of **3** (○) is corresponding to the left *Y* axis.

showed the typical features of the *N,N-trans* conformation at first glance. The proton H^6 of the palladacycle ring is shifted upfield to δ 6.23, 6.21 and 6.44 ppm, respectively, for **2**–**4**. It is well known that the upfield shift of H^6 results from the shielding of pyridine ring which is at the *trans* position to the nitrogen in the palladacycle ligand and non-planar to phenyl ring [20]. Thus the palladium coordination geometry of palladacycle **3** and **4** in solution is quite different from those in crystal structures. Even using dissolved crystals of **3** and **4** in $CDCl_3$, the ^{1}H NMR spectra immediately showed the presence of upfield H^6 protons. For **4**, the chemical shift of the H^6 proton is almost the same as that in [Pd{C_6H_4C(Me)=NOH}(4-Me_2N-py)Cl], which exhibits *N,N-trans* conformation in solid state [20]. Thus the majority coordination conformation of palladacycle **4** in solution is *N,N-trans*. The detailed NMR spectra of **2**–**4** in different solvents such as CD_3OD, at different pH, and at different temperatures are undertaking and will be reported together with other palladacycles.

2.1.2. Catalytic activity

Preliminary work on methanolysis of the P=S pesticide fenitrothion **5** catalyzed by palladcycles **2**–**4** was investigated under buffered conditions (1–3 mM triethylamine, $^{s}_{s}$pH 10.80, *T* = 25 °C) (see Scheme 2). The concentration dependences of the methanolysis are listed in Table 3. It should be noticed that $^{s}_{s}$pH for neutral methanol is 8.4 [18], thus the $^{s}_{s}$pH 10.80 is not very strong basic in methanol.

All three palladacyles exhibit good catalytic activity but showed different concentration dependences (Fig. 4). Palladacyle **3** shows the highest activity with $k_2 = (2.2 \pm 0.1) \times 10^3$ M^{-1} s^{-1}, showing a little curvature at higher concentration. Compound **2** shows some saturation at the higher concentrations of the catalyst, while **4** shows good linearity but is the least active catalyst with a $k_2 = (0.039 \pm 0.001) \times 10^3$ M^{-1} s^{-1}. It can be seen that through

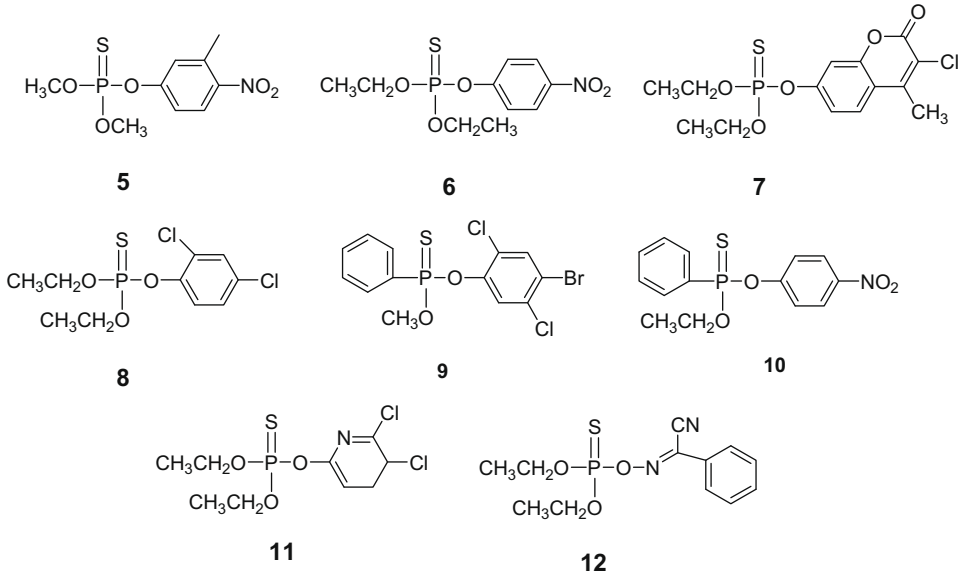

Fig. 5. Structures of the pesticides investigated in the catalytic methanolysis.

Table 4
Turnover experiments for the methanolysis of different phosphorothioate esters catalyzed by **2** at 0.05 M TEA, pH 10.80, 25 °C and ^{31}P NMR data of the substrates and product.

11	5.0×10^{-4}	10[b]	$(4.3 \pm 0.3) \times 10^{-4}$	1.7	61.14	69.63
12	1.0×10^{-3}	20[a]	$(7.1 \pm 0.3) \times 10^{-2}$	284	68.45	69.63

[a] [**2**] = 5.0×10^{-5} mol dm^{-3}.
[b] [**2**] = 2.5×10^{-4} mol dm^{-3}.

changing the electronic property of the substituent on mono-dentate pyridine ligand, the activity of the palladacycles can be greatly modified (the activity of **3** is about 56 times of that of **4**).

The activity of **3** is comparable to those of palladacycles in hydrolysis of pesticides reported by Kazankov, Ryabov [13] and Gabbaie [14]. At 0.01 mM of palladacycle catalysts and $^{s}_{s}$pH 10.80, the $\tau_{1/2}$ of the decomposition of fenitrothion with **2**–**4** is 8.6, 2.2, and 130s, respectively, which afforded the acceleration by 7.7×10^6–4.5×10^8 folds compared to the methoxide catalyzed background reaction ($\tau_{1/2} \approx 10^9$ s) [18].

At the optimized condition, triethylamine buffer $^{s}_{s}$pH 10.80, T = 25 °C, the reactivity of **2** to the decomposition of different thiophosphates (Fig. 5) were screened with turnover numbers (see Table 4). The final products were confirmed with ^{1}H and ^{31}P NMR spectra. We tried to use the chiral palladacycles for the asymmetric methanolysis. It was found that the alkoholysis kinetics of racemic thiophosphates letophos **9** and EPN **10** by **2** are strictly first order, showing no evidence of any kinetically significant chiral discrimination under the experimental conditions.

3. Conclusion

Cleavage of the chloro-bridge in cyclopalladated dimer complex of (*S*)-4-*tert*-butyl-2-phenyl-2-oxazoline by different pyridine derivatives resulted in high yields of three mononuclear palladacycles: (*S*)-chloro{2-[2-(4-*tert*-butyl)oxazolinyl]phenyl-*C*,*N*}(4-R-pyridine)palladium(II) (R = H, **2**, R = CF_3, **3**; R = $N(CH_3)_2$, **4**). In the solid state, the palladacycle containing the pyridine ligand (**2**) exhibits a commonly observed *N*,*N*-*trans* conformation in the palladium(II) coordination sphere, while **3** and **4** show the uncommon *N*,*N*-*cis*-conformation. In solution, the majority conformation isomers are *N*,*N*-*trans* for three palladacycles. The catalytic effect of **2**–**4** in promoting the methanolysis of fenitrothion is related to the electronic properties of the substituents on pyridine ring, with the highest activity with the CF_3 derivative, followed by pyridine and then the dimethylamino group. At 0.01 mol dm^{-3} of **3** at $^{s}_{s}$pH 10.80 gives a $\tau_{1/2}$ = 2.2 s for methanolysis of **5**, which corresponds to 4.0×10^8-fold acceleration compared to the background reaction. The large accelerations provided to the decomposition of P═S pesticides by these and other easily prepared palladacycles including pincer ligands are under active investigation for the eventual development of efficient methods of decomposing P═S pesticides.

4. Experimental

4.1. Materials and methods

All organometallic syntheses were performed in a dried argon atmosphere. Solvents were dried by standard methods. The ligand, (*S*)-4-*tert*-butyl-2-phenyl-2-oxazoline, and corresponding chloro-bridged palladacycle dimer **1** were prepared as described [21] and were characterized by ^{1}H NMR. Pyridine, 4-trifluromethylpyridine, *N*,*N*-dimethylaminopyridine, and methanol (99.8% anhydrous) were purchased from Aldrich and used without further purification. $HClO_4$ (70% aqueous solution) was obtained from BDH.

Fenitrothion (**5**, *O*,*O*-dimethyl *O*-(3-methyl-4-nitrophenyl) phosphorothioate), parathion (**6**, *O*,*O*-diethyl *O*-(4-nitrophenyl) phosphorothioate), coumaphos (**7**, *O*-(3-chloro-4-methyl-2-oxo-2H-chromen-7-yl) *O*,*O*-diethyl phosphorothioate), dichlofenthion (**8**, *O*,*O*-diethyl-*O*-(2,4-dichlorophenyl) phosphorothioate), letophos (**9**, O-4-bromo-2,5-dichlorophenyl *O*-methyl phenylphosphonothioate), and EPN (**10**, *O*-ethyl *O*-4-nitrophenyl phenylphosphorothioate), were purchased from Chem Service Inc. Chlorpyrifos (**11**, *O*,*O*-diethyl-*O*-[3,5,6-trichloro-2-pyridyl]-phosphorothiate) and phoxim (**12**, α-[[(diethoxyphosphinthioyl) zoxy]imino]benzene-acetonitrile) are gifts, obtained from Beijing Yoloo Pesticide Company Ltd., China. All structures of these pesticides are given in Fig. 5.

Caution: All the phosphorus substrates described herein are acetylcholinesterase inhibitors, for compounds **5**–**12** with oral LD50 values of 250, 2, 16, 270, 43, 8, 82, and 300 mg kg^{-1} in rats [24], respectively. The preparations of compounds **2**–**4** require the use of benzene which should be handle with care.

^{1}H NMR spectra were determined at 400 MHz using a Bruker Avance-400 NMR spectrometer. In $CDCl_3$, ^{1}H NMR spectra were referenced to the C**H**Cl_3 peak at 7.25 ppm. ^{31}P NMR spectra were referenced to an external standard of 70% phosphoric acid in water, and up-field chemical shifts are negative. Mass-spectra were determined using a VG Quattro mass spectrophotometer equipped with an electrospray source. IR spectra were obtained on NaBr pellets and melting points were measured on a Fisher–Johns melting point apparatus.

4.1.1. Preparation of the complexes ***2–4***

4.1.1.1 General procedure. To a solution of 118 mg (0.172 mmol) of dimers **1** in benzene (20 ml) was added pyridine or a substituted pyridine (0.38 mmol, 2.2 eq.). The mixture was stirred at room temperature for 3 h and then filtered through Celite. The Celite was washed with another 20 ml of dichloromethane and the combined organic layers stripped of solvent by rotary evaporation under reduced pressure. The pale white solid residue was re-crystallized from a mixture of hexane and dichloromethane (ratio 5:1) to afford the desired compounds, yields are 76%, 80%, and 86%, respectively.

4.1.2. X-ray crystal structure determination

Crystals suitable for diffraction measurements were prepared by diffusing *n*-hexane into a dichloromethane solution of the complex at room temperature.

Data collection of **2** was performed on a Bruker SMART CCD 1000 X-ray diffractometer and data were processed using the Bruker AXS Crystal Structure Analysis Package, Version 5.10 [25]. Neutral atom scattering factors were taken from Cromer and Waber [26]. The raw intensity data were integrated using the program SAINT-PLUS, which corrects for Lp and decay. Absorption corrections were applied using the program SADABS [27].

For **3** and **4**, data collection: APEX2 [28]; cell refinement: APEX2; data reduction: SAINT [28], programs used to solve structure: SHELXTL [29]; programs used to refine structure: SHELXTL; molecular graphics: SHELXTL, software prepare materials for publication: SHELTXL and PLATON [30]. Full structural details for each complex are given as Supplementary data.

*4.1.3. Catalytic methanolysis of fenitrothion (**5**) mediated by complexes **2–4***

The kinetics of decomposition of P═S pesticides were performed in methanol at the buffered condition, the detailed procedure was described in Ref. [19]. The concentration dependences for the methanolysis of **5** promoted by **2–4** were monitored using an OLIS-modified Cary 17 UV–Vis spectrophotometer (see Table 3 and Fig. 4). The plots of the k^{obs} values versus [Pd] indicate that these concentration dependent curves (see Fig. 4). The catalytic turnover experiments were performed for other P═S pesticides at the optimized condition (^s_spH 10.80, Table 4).

DFT and TDDFT calculations

ABSTRACT

The paper presents a combined experimental and computational study of novel tricarbonyl complex – *fac*-$[Re(CO)_3(tp)_2Cl]$ (tp = 1,2,4-triazolo-[1,5-a]pyrimidine). The compound has been characterized spectroscopically and structurally (by single-crystal X-ray diffraction). The absorption and emission spectra of the complex have been discussed on the basis of DFT and time-dependent (TD)DFT calculations.

1. Introduction

The d^6 transition metal complexes with heteroaromatic ligands have been the subject of intense investigations for many years. The interest of researches has been attracted mostly by their unique photophysical and photochemical properties, crucial for numerous potential and already introduced practical applications. The most frequently studied compounds of this type are complexes containing the $Re(CO)_3^+$ fragment. The photobehaviour of such complexes may be discussed in terms of three types of excited states: (i) metal-to-ligand charge transfer (MLCT) states, (ii) ligand-to-ligand charge transfer (LLCT) states, (iii) intraligand (IL) states. The latter one appears to lie at rather high energies in these complexes, and they are of little photochemical importance. The excited states of these compounds are often sufficiently long-lived to become engaged in energy transfer reactions. Currently, several *fac*-$Re(CO)_3^+$ complexes are used as electroluminescent materials in OLED-type devices [1–12].

Furthermore, the excited states of the discussed complexes may be both strong reductants and oxidants. The high reactivity of the reduced species may be utilized in photocatalysis. For example, photoexcitation of $[Re(CO)_3(bipy)Cl]$ in the presence of triethylamine produces $[Re(CO)_3(bipy)Cl]^-$ which loses the chloride ligand. The further reaction with CO_2 results in the photocatalytic CO_2 reduction to CO [10].

The recent application of the *fac*-$Re(CO)_3^+$ complexes as diagnostic and therapeutic radiopharmaceuticals has resulted in an added increase in the interest of this group compounds [11,12].

Here, we present the synthesis, spectroscopic characterization, crystal and molecular structure of the $[Re(CO)_3(tp)_2Cl]$ tricarbonyl with 1,2,4-triazolo-[1,5-a]pyrimidine (tp).

The basic skeleton of 1,2,4-triazolo-[1,5-a]pyrimidine differs from the purine ring in having a pyrimidine nitrogen atom in a bridgehead position with disappearance of the acidic H-proton of the five-membered ring. Because of the similarity of both systems, coordination compounds of 1,2,4-triazolo-[1,5-a]pyrimidine and its derivatives can be considered as model systems for various naturally occurring metal coordination compounds. Complexes with bidentately coordinated 1,2,4-triazolo-[1,5-a]pyrimidine can act as model systems for adenine, whereas compounds with bridging 1,2,4-triazolo-[1,5-a]pyrimidine are specially suited for mimicking imidazolato bridges in model compounds for metalloproteins [13].

2. Experimental

2.1. General procedure

The reaction was performed under an argon atmosphere. The solvents were dried before use, using the appropriate drying

reagents. $Re(CO)_5Cl$ and 1,2,4-triazolo-[1,5-a]pyrimidine (tp) were purchased from Aldrich, and used as received.

The IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. The electronic spectrum was measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer. Luminescence measurements were made on a Jobin-Yvon (SPEX) FLUOROLOG-3.12 spectrofluorometer at room temperature.

2.2. Preparation of $[Re(CO)_3(tp)_2Cl]$

$Re(CO)_5Cl$ (0.2 g, 0.55 mmol) and 1,2,4-triazolo-[1,5-a]pyrimidine (0.14 g, 1.16 mmol) in toluene (80 ml) were refluxed for 6 h. The resulting reaction mixture was allowed to cool to room temperature and reduced in volume to ~10 ml. The white solid was filtered off, washed with hexane, diethyl ether, and dried; yield 85%. Single crystals of complex $[Re(CO)_3(tp)_2Cl]$ were grown by the slow diffusion of diethyl ether into a solution of the complex dissolved in dichloromethane.

IR (KBr, cm^{-1}): ν_{CO} = 2019, 1907 and 1882 cm^{-1}; ν_{CN} and $\nu_{C=C}$ = 1621, 1532 and 1527 cm^{-1}. *Anal.* Calc. for $C_{13}H_8ClN_8O_3Re$: C, 28.60; H, 1.48; N, 20.53. Found: C, 28.16; H, 1.60; N, 20.95%.

2.3. Crystal structure determination and refinement

The crystal of $[Re(CO)_3(tp)_2Cl]$ was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at temperature of 200.0(3) K, with ω scan mode. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [14] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were found from difference Fourier synthesis and were refines as "riding" on their parent carbon atoms [d(C–H) = 0.93 Å] and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent carbon atom. SHELXS97 [15], SHELXL97 [16] and SHELXTL [17] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.4. Computational details

All calculations have been performed using the GAUSSIAN 03 [18] and TURBOMOLE [19] programs for electronic structure calculations. The geometry of the singlet ground state and the lowest triplet state of $[Re(CO)_3(tp)_2Cl]$ was optimized with the DFT method. The electronic spectrum was calculated with the TDDFT method [20]. The vertical excitation energies, together with the corresponding oscillator strengths, were calculated at the optimized structure of the ground electronic singlet and triplet states of the $[Re(CO)_3(tp)_2Cl]$. The calculations were carried out using hybrid B3LYP functional [21,22]. In the calculations the solvent effect was simulated using the polarizable continuum model (PCM) [23–26] and the Conductor-like Screening Model (COSMO) [27] with dichloromethane as solvent. The first of them was used in the GAUSSIAN calculations and the second one in the TURBOMOLE calculations. Two different basis sets have been used. The basis depicted as B1 consists of ECP LANL2DZ [28] basis set for rhenium with an additional d and f function with the exponent α = 0.3811 and α = 2.033 [29], respectively and B2 consists of ECP MWB60 [30] with an one additional f function with the exponent α = 0.48989. These basis sets were used in conjunction with the standard 6-31 + G** basis set for chloride, oxygen, carbon and nitrogen atoms [31–36] and the standard 6-31G basis set for hydrogen. The geometry of the several singlet and triplet excited states were optimized using TDDFT/B3LYP level of theory in the B2 basis. In the case of excited state geometry optimization the TURBOMOLE program was used.

3. Results and discussion

3.1. Preparation and infrared data

The title complex was prepared by refluxing of $[Re(CO)_5Cl]$ with 1,2,4-triazolo-[1,5-a]pyrimidine in toluene. It was isolated as air-stable, microcrystalline solid, soluble in common organic solvents. The infrared spectrum of $[Re(CO)_3(tp)_2Cl]$ displays three bands in the carbonyl stretching region: a sharp intense band at 2019 cm^{-1} and two lower-energy bands 1907 and 1882 cm^{-1}. This pattern corresponds to three CO units in a *fac* arrangement [37]. The characteristic bands of the C=C and C=N stretching modes of 1,2,4-triazolo-[1,5-a]pyrimidine are observed in the range 1630–1500 cm^{-1} [38].

3.2. Crystal structure

The crystallographic data for the title complex are given in Table 1. The perspective drawing of $[Re(CO)_3(tp)_2Cl]$ with atomic numbering is shown in Fig. 1. The coordination geometry at the Re atom is a distorted octahedron with the three carbonyl ligands arranged in a facial fashion. The 1,2,4-triazolo-[1,5-a]pyrimidine ligands are monodentately coordinated via the nitrogen atom of the triazolo rings. The selected bond lengths and angles of $[Re(CO)_3(tp)_2Cl]$ are given in Table 2. The average Re–C(CO) bond distance is 1.91 Å, and the average Re–N bond distance is 2.194(1) Å. These values are within the range expected for such complexes [39]. The tp substituents are close to planarity (maxi-

mum deviation of 0.018(2) Å exist for C(4) atom in one of the planes and 0.029(3) for atom C(11) in second plane) and are inclined at 57.16(6)°. The rhenium atom derives 0.199(4) and 0.048(4) Å from above mentioned weighted least squares planes. In the structure can be found some short intermolecular interactions (Table 3), which can be classified as weak hydrogen bonds [40,41]. *Via* these interactions a semiinfinite three-dimensional net is created (Fig. 2).

3.3. Optimized geometry

The geometry of $[Re(CO)_3(tp)_2Cl]$ was optimized in a singlet state by the DFT method with the B3LYP functional in B1 and B2 bases. The optimized geometric parameters are gathered in Table 2. The calculated bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations. The optimized geometry parameters obtained in both bases, B1 and B2, are quite similar.

3.4. Electronic structure

The complex $[Re(CO)_3(tp)_2Cl]$ is a closed-shell structure. Its molecular orbital diagram with several occupied and virtual molecular orbital contours is presented in Fig. 3. The HOMO–LUMO gap equals to 3.97 eV. The low-lying virtual orbitals correspond mainly to π^*_{tp} and π^*_{CO}. The LUMO, LUMO+1, LUMO+2 and LUMO+5 are centered on the 1,2,4-triazolo-[1,5-a]pyrimidine ligand. The higher virtual orbitals are mainly delocalized among Re and carbonyls.

The three highest occupied molecular orbitals are predominately localized on the rhenium atom, corresponding to the $(5d_{xy})^2$ $(5d_{xz})^2$ $(5d_{yz})^2$ occupation of the central ion. However, ligand contributions are also important. All these orbitals have a

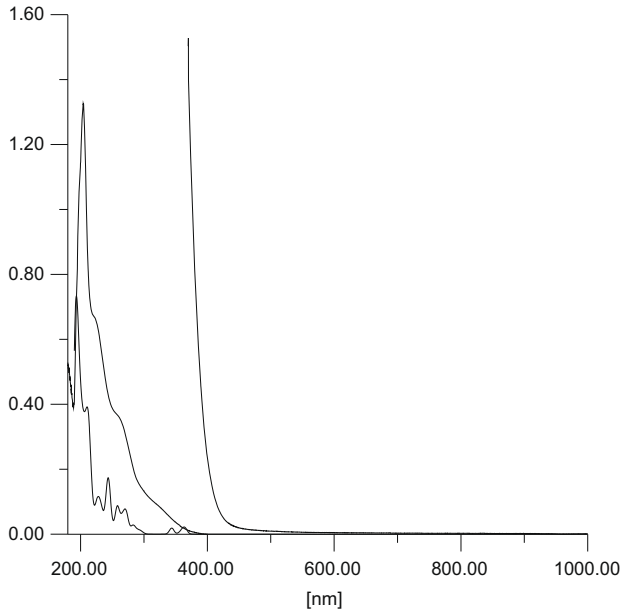

Fig. 4. The experimental and calculated electronic absorption spectra of $[Re(CO)_3(tp)_2Cl]$. Full line: the experimental spectrum measured in CH_2Cl_2. Blue dashed line: spectrum calculated in vacuum. Red dashed line: spectrum calculated in dichloromethane.

relatively considerable CO character. The HOMO-2 and HOMO-1 orbitals contain also an admixture of chloride p_π orbitals.

3.5. UV–Vis spectrum

The electronic absorption spectrum was measured at room temperature in dichloromethane, and the experimental absorption bands were assigned using the singlet excited states calculated with the time-dependent DFT method. The experimental and calculated electronic spectra of $[Re(CO)_3(tp)_2Cl]$ are compared in Fig. 4. Each calculated transition is represented by a GAUSSIAN function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. As seen in the Fig. 4, TDDFT/PCM calculations well reproduce the absorption spectrum of $[Re(CO)_3(tp)_2Cl]$ measured in dichloromethane. The lowest allowed absorption band, which occurs at 3.54 eV, has been calculated at 3.39 eV.

Table 4 shows the spin-allowed singlet–singlet electronic transitions calculated with the TDDFT method for $[Re(CO)_3(tp)_2Cl]$. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Table 4. The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions.

The low-energy absorption band of $[Re(CO)_3(tp)_2Cl]$ originates in the transitions between three highest occupied molecular orbitals and two lowest unoccupied molecular orbitals. As can be seen from the Fig. 3, the HOMO-2, HOMO-1 and HOMO are delocalized on the whole $Re(CO)_3Cl$ unit, whereas the LUMO and LUMO+1 are completely centered on the tp ligand. Accordingly, these transitions can be seen as mixed Re → tp (MLCT) and Cl → tp (LLCT) or a delocalized MLLCT (metal–ligand-to-ligand CT) description can be used.

The experimental absorption bands at 269.8 and 227.6 nm are also attributed to *metal–ligand-to-ligand charge transfers*, whereas the lowest energy band originates in the inter- and intra-ligand (IL) transitions (Table 4).

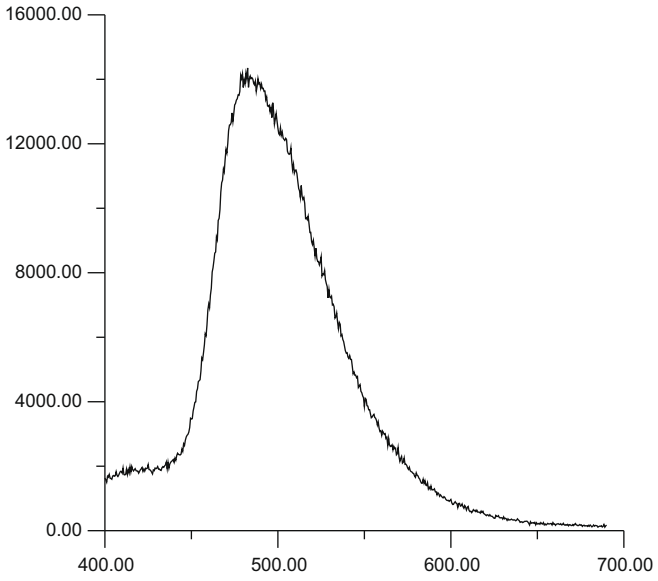

Fig. 5. The emission spectrum of $[Re(CO)_3(tp)_2Cl]$.

3.6. Emission spectrum

Emission properties of the title complex have been examined in the deaerated dichloromethane solution at room temperature. As indicated in Fig. 5, the title complex is a weak emitter. On the excitation at λ = 366 nm the emission is observed at λ_{max} = 482 nm. The peak is broad and structureless, in accordance with the ^{3}MLCT assignment of the emission for similar rhenium(I) tricarbonyl complexes [42].

The structure of several lowest singlet and triplet states was optimized for $[Re(CO)_3(tp)_2Cl]$ with the use of TURBOMOLE program in the B2 basis. The lowest triplet state was also optimized by the independent DFT calculations. The geometry obtained for the lowest triplet state was denoted T_1(A). The selected bond lengths and the calculated vertical emission energies are gathered in Table 5 for the optimized excited state structures. The values of bond lengths collected in the Table 5 shows that the rhenium–nitrogen and rhenium–chlorine bonds are shortened in the excited states, while rhenium–carbonyl bonds are elongated. The T_1(B) structure which has the longest Re–C(2) bond is described below. From the data in Table 5 it can be seen that the independent DFT optimization gives a higher emission energy than the TDDFT optimization. Both values are much smaller than the experimental emission energy. In the optimization of excited states geometry the geometry of the ground state was used as a starting guess. Since this may lead to a local minimum on the energy surface, we calculated the energy curves of lowest triplet along the metal–ligand bond stretching coordinates for all carbonyl and tp ligands. The remaining coordinates were optimized during such calculations. We located another minimum on the T_1 surface, denoted T_1(B) in Table 5. It has a long Re–C(2) bond of 2.14 Å comparing to that in T_1(A) equal to 1.97 Å, and it is of 7.4 kcal lower in energy than T_1(A). Both structures A and B are presented in Fig. 6, together with their singly occupied orbitals. In structure B a link between carbonyl carbon located trans to chlorine and a nitrogen atom from one tp ligand is formed, with d(C(2)–N(2)) = 1.45 Å. We calculated the energy curve along C2–N2 distance, changing stepwisely this parameter and optimizing the remaining ones. At each step we determined several singlet and triplet states by the TDDFT calculations. The resulting energy curves are presented in Fig. 7. On the left-hand side of Fig. 7 the energies of vertical singlet and triplet transitions were schematically depicted. The energy of the ground state (S0) in the T_1 geometry was also plotted in Fig. 7. There is an energy barrier of 5.9 kcal between A and B minima on T_1 curve. At the B minimum geometry the triplet state is lower in energy than the ground singlet state. The shape of the T_1 energy curve reveals that this state is nonemissive. Starting from T_1(A) minimum, which is close to the ground state geometry, the system passes over small energy barrier on T_1, and at geometry near to T_1(B) it reverts to the ground state through an intersystem crossing. From the second triplet state there is also a possibility of nonemissive return to the ground state through interaction with lowest triplet or singlet states. The luminescence most probably occurs from some higher triplet state, T_3–T_5, after intersystem crossing from the initially formed singlet excited state with a high oscillator strength. Such transition is calculated at 360 nm in the B2 basis. The emission energy calculated from states T_3, T_4 and T_5 (561 nm, 523 nm and 489 nm, Table 4) gives quite good agreement with the experimental data. From emissive state a reverse to a lower lying excited state is also possible and finally non-emissive return to the ground state. The radiative and nonradiative paths are depicted in Fig. 7 by solid and dashed green lines, respectively. Such a scheme is also in agreement with a weak emissive properties of $[Re(CO)_3(tp)_2Cl]$. As can be seen from the singly occupied MOs in Fig. 6 the T_1 state is of

Spectroscopy
Solvatochromic effect

ABSTRACT

Following our previous report on a novel class of C_4 symmetric porphyrazines bearing 2,5-dimethylpyrrolyl and methyl(3-pyridylmethyl)amino groups in the periphery, here we report the synthesis and characterization of unsymmetrical porphyrazines with peripheral 2,5-di(2-thienyl)pyrrolyl and dimethylamino groups that break the molecular C_4 symmetry. The porphyrazines were prepared *via* macrocyclization reactions of a dinitrile precursor. Variable-temperature ^{1}H NMR experiments, single crystal X-ray work and UV–Vis spectra in different solvents of the unsymmetrical magnesium porphyrazine provided information on the structural and electronic features of the entire macrocyclic system. A detailed discussion of the UV–Vis spectra in different solvents emphasizes the role played by the extended peripheral 2,5-di(2-thienyl)pyrrolyl substituent.

1. Introduction

Porphyrazines (pzs) functionalized in the periphery form a distinct class of novel macrocycles, along with the functionalized porphyrins and phthalocyanines [1]. Peripherally modified pzs can be substituted in the β-positions with sulfur, oxygen and nitrogen residues or have rings bound to both β,β-positions, which results in significant modulation of their electrochemical and optical properties [2]. Porphyrazines have been investigated as sensitizers for photodynamic therapy [3], metal ion probes [4], precursors to optical, magnetic and conductive materials for nanotechnology, electrophotography, optical data recording systems, electronic devices, photovoltaic cells, fuel cells, and electrochromic displays [5–9].

Porphyrazines containing annulated 5-membered heteroarenes (4,5-thiazole, 2,3-thiophene, 1,2,5-selenodiazole) have found applications as synthetic precursors [1,10]. There is limited data on pzs possessing 5-membered heteroaromatic rings substituted directly to the β-position of the porphyrazine system. Bisthienylethenes with heterocyclic aryl groups and a coplanar binuclear porphyrazine bearing six bis-(trimethylthiophenyl) photochromic functionalities at the periphery, have become candidates for various applications including information storage, imaging devices and switches [10,11].

Lately, we have reported the synthesis and characterization of unsymmetrical porphyrazines with peripheral 2,5-dimethylpyrrolyl and methyl(3-pyridylmethyl)amino groups bearing interesting optical and electrochemical properties [12]. In this study, we decided to extend this work to the synthesis to novel porphyrazine systems with peripheral 2,5-di(2-thienyl)-1*H*-pyrrole and dimethylamino substituents. We were encouraged with the data on conductive polymers, derivatives of 2,5-di(2-thienyl)-1*H*-pyrrole, which have revealed electrical and optical properties of metals or semiconductors while retaining the attractive mechanical properties and processing advantages of polymers [13,14]. Similarly, π-excessive chromophores possessing a thienylpyrrolyl π-conjugated system acting as an auxiliary donor, attached to a functionalized benzimidazole electron-withdrawing heterocyclic group have shown excellent solvatochromic properties, high thermal stabilities and good molecular optical non-linearities [15].

2. Experimental

1,4-Di(2-thienyl)-1,4-butanedione (**2**) was prepared according to a literature procedure by the double Friedel–Crafts reaction be-

tween thiophene and succinyl chloride, employing aluminium chloride as the Lewis acid catalyst in a one-step procedure with good yield [13,14].

2.1. Synthesis of 2-amino-3-[2,5-di(2-thienyl)-1H-pyrrol-1-yl]-(2Z)-butene-1,4-dinitrile (**3**)

A solution of diaminomaleonitrile (852 mg, 7.88 mmol), 1,4-di(2-thienyl)-butane-1,4-dione (1.97 g, 7.88 mmol) and trifluoroacetic acid (100 μL) in methanol (45 mL) was refluxed for 37 h. The reaction mixture was cooled down and most of the unreacted diketone crystallized to give white plates. The filtered solution was concentrated in vacuo. This material was chromatographed twice (hexane:EtOAc, 7:1–7:3) to give **3** (1.173 g, 46%) as small slightly yellow crystals: mp 200–202 °C, R_f 0.21 (hexane:EtOAc, 7:3). UV–Vis (CH_3OH): λ_{max}, nm (logε) 305 (4.43). IR (neat) cm^{-1} 3396, 3313, 3196, 2212 (CN), 1624, 1599, 1408, 1037, 776. ^1H NMR (400 MHz; DMSO-d_6): δ_H, ppm 8.30 (bs, 2H, NH_2), 7.56 (d, 2H, thienyl-H, ^3J = 4.0 Hz), 7.24 (d, 2H, thienyl-H, ^3J = 4.0 Hz), 7.15 (pt, 2H, thienyl-H, ^3J = 4.0 Hz), 6.66 (s, 2H, pyrrolyl-H). ^{13}C NMR (100 MHz; DMSO-d_6): δ_C, ppm 134.7, 132.8, 130.0, 128.2, 126.2, 125.1, 117.5, 113.2, 111.9, 87.9. HRMS (ES pos): m/z 323.0428 (calc. for $[M+H]^+$ 323.0425). *Anal.* Calc. for $C_{16}H_{10}N_4S_2$: C, 59.61; H, 3.13; N, 17.38. Found: C, 59.67; H, 3.08; N, 17.30%.

2.2. Synthesis of 2-(dimethylamino)-3-[2,5-di(2-thienyl)-1H-pyrrol-1-yl]-(2Z)-butene-1,4-dinitrile (**4**)

NaH (60% dispersion in mineral oil; 302 mg, 7.55 mmol) was suspended in THF (8 mL) at (−30 °C). Next **3** (486 mg, 1.51 mmol) in THF (5 mL) was added and stirred 30 min until the temperature raised to (−10 °C). Me_2SO_4 (358 μL, 3.78 mmol) was added dropwise to the solution for 1 h at (−10 °C) and then allowed to warm up slowly to room temperature (2 h) and stirring was continued for 21 h. Water (30 mL) was carefully added to the reaction mixture and then extracted with ethyl acetate (4 × 75 mL). The combined organic extracts were washed with water (2 × 50 mL), dried ($MgSO_4$), filtered and evaporated to dryness. This material was chromatographed (hexane:EtOAc, 7:3) to give **4** (404 mg, 76%) as orange crystals: mp 128–130 °C, R_f 0.25 (hexane:EtOAc, 7:3). UV–Vis (CH_3OH): λ_{max}, nm (logε) 317 (4.51). IR (neat): ν, cm^{-1} 3101, 2937, 2191 (CN), 1598, 1407, 1315, 1224, 1048, 786, 707. ^1H NMR (400 MHz; DMSO-d_6): δ_H, ppm 7.62 (d, 2H, thienyl-H, ^3J = 4.0 Hz), 7.35 (d, 2H, thienyl-H, ^3J = 4.0 Hz), 7.19 (pt, 2H, thienyl-H, ^3J = 4.0 Hz), 6.65 (s, 2H, pyrrolyl-H), 2.80 (s, 6H, $N(CH_3)_2$). ^{13}C NMR (100 MHz; DMSO-d_6): δ_C, ppm 135.1, 132.6, 132.4, 128.5, 126.8, 125.9, 118.6, 112.7, 111.5, 86.6, 42.1. HRMS (ES pos): m/z 351.0750 (calc. for. $[M+H]^+$ 351.0738). *Anal.* Calc. for $C_{18}H_{14}N_4S_2$: C, 61.69; H, 4.03; N, 15.99. Found: C, 61.76; H, 3.98; N, 15.93%.

2.3. {2,7,12,18-Tetrakis(dimethylamino)-3,8,13,17-tetrakis[2,5-di(2-thienyl)-1H-pyrrol-1-yl]porphyrazinato}magnesium (II) (**5**)

Mg turnings (36 mg, 1.50 mmol), a crystal of I_2, and 1-butanol (25 mL) were heated under reflux for 16 h. After the mixture was cooled to room temperature, dinitrile **4** (351 mg, 1.00 mmol) was added and the solution heated under reflux for a further 22 h. After being allowed to cool to room temperature, the dark green mixture was evaporated with toluene (2 × 50 mL). Next the mixture was dissolved in CH_2Cl_2 (250 mL), filtered through Celite and evaporated. Chromatography (CH_2Cl_2:CH_3OH, 25:1) was performed twice to give main product, porphyrazine **5** (84 mg, 24%) as a dark green solid: mp > 300 °C, R_f 0.39 (CH_2Cl_2:CH_3OH, 25:1). UV–Vis (CH_2Cl_2): λ_{max}, nm (logε) 348 (4.97), 440 (4.12), 524 (4.18), 727 (4.50). IR (neat): ν, cm^{-1} 3102, 2955, 2924, 2854, 1595, 1339, 1035, 762, 692. ^1H NMR (500 MHz; d_5-pyridine): δ_H, ppm 7.24 (2H, d, ^3J = 5.0 Hz), 7.13 (2H, s), 7.11 (2H, d, ^3J = 5.0 Hz), 7.03 (2H, d, ^3J = 5.0 Hz), 7.02 (s, 2H), 6.98 (d, 2H, ^3J = 5.0 Hz), 6.71 (s, 2H), 6.69 (d, 2H, ^3J = 5.0 Hz), 6.64 (s, 2H), 6.63 (m, 4H), 6.58 (2H, m), 6.57 (2H, m), 6.55 (2H, d, ^3J = 5.0 Hz), 6.42 (2H, t, ^3J = 5.0 Hz), 6.39 (2H, t, ^3J = 5.0 Hz), 3.59 (s, 6H), 3.48 (s, 6H), 3.41 (s, 6H), 3.18 (s, 6H). ^{13}C NMR (125 MHz; d_5-pyridine): δ_C, ppm 159.2, 158.0, 157.9, 154.1, 152.0, 152.0, 151.6, 151.3, 149.6[h], 149.2, 146.9, 145.7, 145.4, 145.2, 145.0, 144.2, 136.4, 136.3, 136.1, 136.1, 136.0, 135.6[h], 135.1, 134.7, 134.7, 134.3, 128.5, 128.3, 128.1, 128.1, 127.8, 127.7, 127.1, 127.0, 126.9, 124.9, 124.7, 124.1, 124.0, 123.5[h], 123.1, 112.4, 112.1, 110.0, 109.8, 109.5, 109.3, 108.5, 42.8, 42.6, 42.5, 42.3. MS (MALDI TOF): m/z 1426 $[M+H]^+$. Single crystals for X-ray analysis were grown at room temperature by slow evaporation of ethanol–chloroform (**5a**) and methanol–chloroform (**5b**, **5c**) mixtures.

*Crystal data for **5a**:* $C_{74}H_{62}MgN_{16}OS_8{\cdot}0.5H_2O$, M = 1481.19, triclinic, $P\bar{1}$ (no. 2), a = 13.9822(10) Å, b = 16.3084(7) Å, c = 18.5161(9) Å, α = 64.196(4)°, β = 72.889(5)°, γ = 67.092(6)°, V = 3461.5(4) Å^3, Z = 2, D_c = 1.421 g cm^{-3}, μ(Cu Kα) = 2.963 mm^{-1}, T = 173 K, very dark needles, Oxford Diffraction Xcalibur PX Ultra diffractometer; 10 825 independent measured reflections (R_{int} = 0.0611), F^2 refinement, R_1(obs) = 0.118, wR_2(all) = 0.404, 4886 independent observed absorption–corrected reflections [$|F_o| > 4\sigma(|F_o|)$, $2\theta_{max}$ = 126°], 939 parameters.

As the second product was isolated {2,7,12,17-tetrakis(dimethylamino)-3,8,13,18-tetrakis[2,5-di(2-thienyl)-1*H*-pyrrol-1-yl]porphyrazinato}magnesium (II) (**6**), which was unstable during drying at higher temperature. Chromatography (CH_2Cl_2:CH_3OH, 25:1) and (CH_2Cl_2) gave porphyrazine **6** (36 mg, 10%) as a green film: R_f 0.96 (CH_2Cl_2:CH_3OH, 25:1), R_f 0.44 (CH_2Cl_2). UV–Vis (CH_2Cl_2): λ_{max}, nm (logε) 350 (4.84), 424 (3.84), 534 (3.76), 742 (4.70). IR (neat): ν, cm^{-1} 3102, 2957, 2923, 2865, 1589, 1477, 1403, 1318, 1118, 1042, 860. ^1H NMR (400 MHz; d_5-pyridine): δ_H, ppm 7.13 (d, 8H, ^3J = 4.0 Hz), 7.05 (s, 8H), 6.59 (m, 16H), 3.42 (s, 24H). MS (MALDI TOF): m/z 1425 M^+.

2.4. 2,7,12,18-Tetrakis(dimethylamino)-3,8,13,17-tetrakis[2,5-di(2-thienyl)-1H-pyrrol-1-yl]porphyrazine (**7**)

In the dark, CF_3COOH (12 mL) was added to crude porphyrazine **5** (210 mg, 0.15 mmol), obtained after the macrocyclization reaction, and stirred for 30 min at room temperature. Next the solution was added to rapidly stirred ice-H_2O (150 mL) and neutralized with satd. $NaHCO_3$. Afterwards the brown–purple mixture was extracted with CH_2Cl_2 (5 × 300 mL) and evaporated to dryness. Chromatography (CH_2Cl_2) and (CH_2Cl_2–hexane, 1:1) gave porphyrazine **7** (17 mg, 8%) as a brown–violet film; R_f 0.48 (CH_2Cl_2–hexane, 1:1).

UV–Vis (CH_2Cl_2): λ_{max}, nm (logε) 336 (4.95), 432 (4.26), 509 (4.34), 679 (4.29), 752 (4.42). IR (neat): ν, cm^{-1} 3284, 3100, 2922, 2853, 1599, 1530, 1384, 1311, 1010, 841, 753, 687. ^1H NMR (500 MHz; d_5-pyridine): δ_H, ppm 7.26 (d, 2H, ^3J = 5.0 Hz), 7.16 (d, 2H, ^3J = 5.0 Hz), 7.08 (s, 1H), 7.01 (s, 1H), 7.00 (d, 2H, ^3J = 5.0 Hz), 6.98 (d, 2H, ^3J = 5.0 Hz), 6.83 (d, 2H, ^3J = 5.0 Hz), 6.67–6.74 (m, 14H), 6.63 (pt, 2H, ^3J = 5.0 Hz), 6.49 (pt, 2H, ^3J = 5.0 Hz), 6.46 (pt, 2H, ^3J = 5.0 Hz), 3.47 (s, 6H), 3.39 (s, 6H), 3.35 (s, 6H), 3.19 (s, 6H). ^{13}C NMR (125 MHz; d_5-pyridine): δ_C, ppm 159.2, 154.5, 154.2, 154.2, 152.7, 152.6, 151.9, 151.0, 148.8, 145.4, 145.2, 145.0, 144.2, 142.5, 140.4, 139.2, 138.4, 135.3, 134.7, 134.6, 134.3, 134.1, 128.4, 128.2, 128.1, 127.8, 127.6, 127.3, 127.3, 127.1, 126.4, 125.9, 125.7, 125.5, 125.2, 124.7, 124.6, 124.4, 123.9[h], 111.7, 110.3, 110.0, 109.8, 108.9, 107.0, 42.8, 42.7, 42.5, 42.5. MS (MALDI TOF): m/z 1403 $[M+H]^+$.

2.5. {2,7,12,18-Tetrakis(dimethylamino)-3,8,13,17-tetrakis[2,5-di(2-thienyl)-1H-pyrrol-1-yl]porphyrazinato}zinc (II) (**8**)

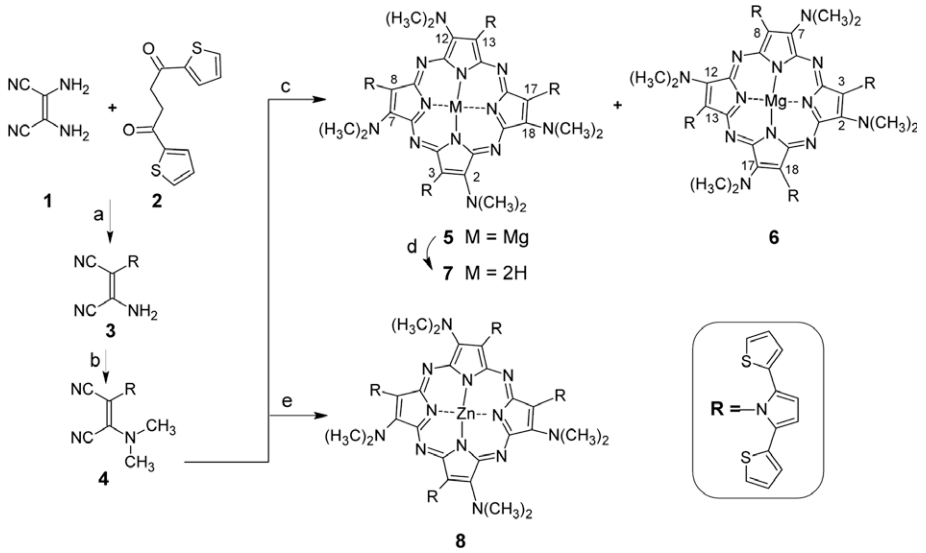
Dinitrile **4** (199 mg, 0.57 mmol), zinc acetate (53 mg, 0.29 mmol), 1,8-diazabicyclo[5.4.0]undec-7-ene (85 μL, 0.57 mmol) and 1-pentanol (2 mL) were heated at 130 °C for 20 h. After being allowed to cool to room temperature, the dark green–violet mixture was evaporated with toluene (2 × 50 mL) to dryness. Chromatography (hexane:EtOAc, 7:3) and (CH_2Cl_2 to CH_2Cl_2:CH_3OH, 200:1) gave the main product porphyrazine **8** (12.3 mg, 6%) as a dark green film (violet in solution): R_f 0.33 (CH_2Cl_2:CH_3OH, 200:1); R_f 0.53 (hexane:EtOAc, 7:3). UV–Vis (CH_2Cl_2): λ_{max}, nm (logε) 338 (5.05), 429 (4.17), 531 (4.19), 742 (4.52). IR (neat): ν, cm^{-1} 3102, 2957, 2927, 2859, 1725, 1595, 1410, 1287, 1125, 1039, 691. ^1H NMR (500 MHz; d_5-pyridine): δ_H, ppm 7.24 (d, 2H, ^3J = 5.0 Hz), 7.13 (d, 2H), 7.12 (s, 2H), 7.02 (2H, d, ^3J = 5.0 Hz), 7.01 (s, 2H), 6.98 (d, 2H, ^3J = 5.0 Hz), 6.72 (s, 2H), 6.70 (d, 2H, ^3J = 5.0 Hz), 6.65 (s, 2H), 6.64 (2H, d, ^3J = 5.0 Hz), 6.58 (m, 8H), 6.43 (pt, 2H, ^3J = 5.0 Hz), 6.41 (pt, 2H, ^3J = 5.0 Hz), 3.57 (s, 6H), 3.46 (s, 6H), 3.40 (s, 6H), 3.18 (s, 6H). ^{13}C NMR (125 MHz; d_5-pyridine): δ_C, ppm 159.2, 158.6, 157.9, 157.9, 153.9, 151.6, 147.8, 147.7, 146.5, 145.6, 145.2, 145.0, 144.7, 144.0, 134.4, 134.4, 134.0, 128.6, 128.2, 128.0, 127.9, 127.8, 127.6, 127.4, 126.9, 126.8, 126.8, 126.7, 125.5, 125.3, 125.1, 124.7, 124.4, 118.4, 117.0, 111.9, 111.7, 109.7, 109.6, 109.5, 109.3, 109.1, 42.5, 42.3, 42.2, 42.0. MS (MALDI TOF): m/z 1467 $[M+H]^+$.

3. Results and discussion

3.1. Synthesis

The Paal–Knorr reaction of diaminomaleonitrile **1** with 1,4-di(2-thienyl)-1,4-butanedione **2** was acid-catalysed (activation of the ketone functionality) using trifluoroacetic acid (TFA) in refluxing ethanol or methanol and led to the novel dinitrile system **3** after 37 h with moderate yield. Dinitrile **4** was easily synthesized from **3** using $(MeO)_2SO_2$/NaH in THF by a modification of the Sheppard's method [16]. The Linstead macrocyclization of **4** gave unsymmetrical magnesium porphyrazine **5** as the major product, accompanied by one isomer **6** [17]. Demetallation of **5** by removal of the magnesium ion with trifluoroacetic acid gave the free base porphyrazine **7** (Scheme 1). An identical pz system **8** with zinc (II) in the core was obtained, when the macrocyclization reaction of **4** was performed using $Zn(OAc)_2$ in pentanol with 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) as a base. All porphyrazines **5**–**8** were freely soluble in common organic solvents, thereby facilitating purification by column chromatography. Further recrystallization of **5** by slow evaporation of ethanol–chloroform or methanol–chloroform solutions led to crystals **5a**–**5c** suitable for single crystal X-ray analysis.

A previously performed macrocyclization reaction study using mixed 2,5-dimethylpyrrolyl-methyl(3-pyridylmethyl)amino maleonitrile led to C_4 symmetrical pz with an alternate order of substituents, whereas other isomers have only been isolated as the minor product [12]. Herein the dithienylpyrrolyl pz product **5** was surprisingly isolated as the main product and the symmetrical C_4 pz **6** possessing an alternate order of substituents appeared as a low-yielding and easily decomposing side product (see spectrum, Supplementary data). When a harsh method of macrocyclization adapted from the phthalocyanine approach was used ($Zn(OAc)_2$–DBU–pentanol), the pz **8** was isolated as the only reaction product [18]. Therefore the isolated products, **5** and **8**, possessing the disturbed order of substituents appear to be the only stable thermodynamically isomers.



3.2. NMR studies

The asymmetry imposed by the non-alternate order of both peripheral substituents resulted in the non-equivalent signals. Both pzs: unsymmetrical **5** and C_4 symmetrical **6**, representing various isomers might be easily distinguished by ^1H and ^{13}C NMR spectra. Dimethylamino groups in the structure of pz **5** appear as four signals at 3.59, 3.48, 3.41, 3.18 ppm in ^1H NMR and at 42.8, 42.6, 42.5, 42.3 ppm in ^{13}C NMR, whereas in the structure of pz **6** as only one signal at 3.42 ppm in ^1H NMR and at 42.5 ppm in ^{13}C NMR. The 1H–1H COSY, HMQC and HMBC spectra in pz structure **5**, were necessary to resolve the connectivities within each substituted pyrrolyl fragment of the porphyrazine ring (Table 1S, Supplementary data).

In the variable-temperature ^1H NMR spectra resonances received from aromatic 2,5-di(2-thienyl)-1*H*-pyrrol-1-yl groups were found within the regions of: 6.92–7.35 and 6.53–6.79 ppm, whereas the resonances from $N(CH_3)_2$ groups appeared as four signals within the region of: 2.92–3.67 ppm at the temperature range studied (243 → 343 K) (Fig. 1). The sharp proton NMR signals of the 2,5-di(2-thienyl)-1*H*-pyrrol-1-yl group underwent minor shifts, whereas the multiplicity of the signals changed significantly, e.g. a multiplet observed at 6.40 ppm at 343 K changed to two triplets at 6.46 and 6.42 ppm at 243 K. All resonances grouped within the region of 6.92–7.18 ppm at 343 K shifted upfield to the region of 7.08–7.35 ppm at 243 K. The most significant changes were found for all pyrrolyl singlet signals belonging to the 2,5-di(2-thienyl)-1*H*-pyrrol-1-yl groups. When the temperature raised, two of them shifted downfield (from 6.62 to 6.79 and 6.53 to 6.73 ppm) and the other two shifted upfield (from 7.08 to 7.00 and 7.21 to 7.08 ppm). Additionally at 343 K some complex, cross-ring type, resonances were found. By contrast, the $N(CH_3)_2$ proton signals were well resolved at 343 K but when the temperature decreased to 243 K, upfield shifting and broadening of the signals at 2.92 and 3.27 ppm was found. This fact might be attributed to the steric hindrance between positions 3, 8 and 13 in the macrocyclic core, which implies slower rotation of differently shielded $N(CH_3)_2$ groups in positions 7 and 12 at lower temperatures. The ^1H NMR signals arising from the $N(CH_3)_2$ groups present in positions 2 and 18 are sharp singlets at all temperatures studied, as the periphery is relatively less crowded and there is no significant barrier to rotation for both groups.

3.3. X-ray study of **5**

The X-ray structures of the ethanol, mixed methanol/water (see Supplementary data) and methanol complexes of **5a**, **5b** and **5c** are very similar, as can readily be seen from Fig. 2. The most noticeable features of the three structures are the orientations of the peripheral ligands and the dishing of the ring. In each structure the dithienylpyrrolyl ligands are unsurprisingly oriented approximately orthogonal to the "plane" of the porphyrazine ring (*vide infra*) while

Scheme 1. Reagents and conditions: (a) CH_3OH, TFA, Δ, 37 h (46%); (b) Me_2SO_4, NaH, DMF, −30–20 °C, 24 h (76%); (c) $Mg(OnBu)_2$, *n*BuOH, Δ, 22 h (**5** – 24%, **6** – 10%); (d) TFA, 20 °C, 30 min (8%); (e) $Zn(OAc)_2$, DBU, *n*PeOH, 130 °C, 20 h (6%).

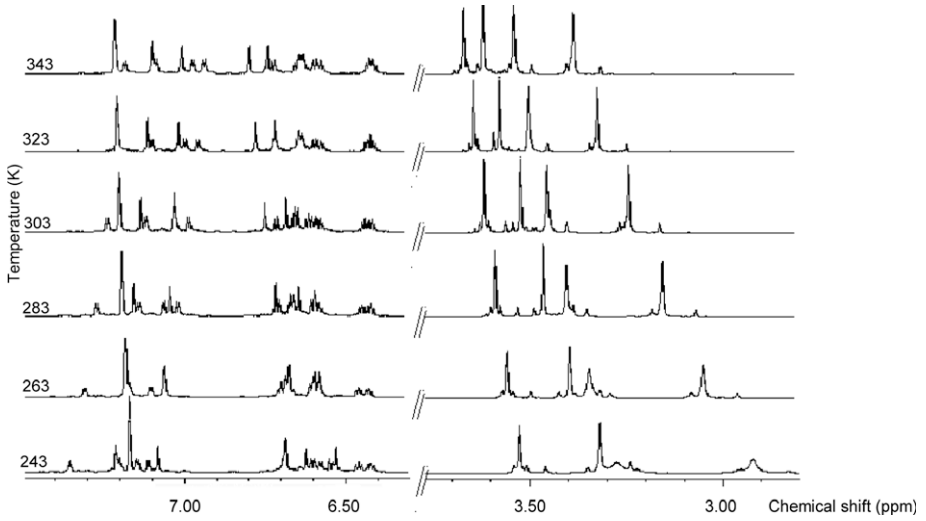


Fig. 1. Variable-temperature ^1H NMR spectra for **5** in pyridine-d_5.

the dimethylamine ligands are approximately parallel. The dishing of the porphyrazine rings can be quantified by considering the three "circles" of nitrogen atoms; the inner circle consists of the metal coordinated nitrogen atoms N(2), N(7), N(12) and N(17), the intermediate circle is comprised of the remaining four porphyrazine nitrogen atoms N(1), N(6), N(11) and N(16), and the peripheral circle consists of the eight nitrogen atoms N(21), N(36), N(39), N(54), N(57), N(72), N(75) and N(78), bound to the periphery of the porphyrazine ring. In the structure of **5a**, the magnesium lies ca. 0.49, 0.62 and 0.90 Å out of the inner, intermediate and peripheral circles respectively. The corresponding displacements for **5b** and **5c** are ca. 0.51, 0.62 and 0.80 Å and ca. 0.53, 0.66 and 0.88 Å, respectively. Also of note is the substitution pattern around the porphyrazine ring. Considering the periphery of the porphyrazine ring starting at N(1) and cycling round *via* N(6), N(11) and N(16), the ligand order in each complex is pyrrole–amine–pyrrole–amine–pyrrole–amine–amine–pyrrole, i.e. the "last" two ligands are reversed and thus break the potential molecular C_4 symmetry.

3.4. Spectroscopic and solvatochromic studies

The UV–Vis spectra of demetallated porphyrazine **7** exhibits an intense Soret band at 336 nm, Q-bands at 679 and 752 nm and an n–π^* transition at 509 nm. Alternatively, the precursor magnesium pz **5** and zinc pz **8** display intense Soret peaks at 348 and 338 nm and Q-band $\pi \rightarrow \pi^*$ transitions at 727 and 742 nm, respectively (Fig. 3). Q-band transitions of **5** and **8** are broad and complex, whereas in case of C_4 symmetrical isomer **6** the Q-band is sharp. Additionally for pzs **5** and **8**, less intense Soret bands at 440 and 429 nm, respectively, may be observed next to the intense Soret peaks. The resultant n–π^* transitions were visible for porphyrazines **5** and **8** as weak bands at 524 and 531 nm, respectively.

The UV–Vis spectroscopy was employed to evaluate the solvatochromic effects of **5**. In dichloromethane–methanol (1:1) solution pz **5** exhibits a Soret peak centred at 348 nm with a less intense Soret band at 442 nm and a broad Q-band at 723 nm, untypical for symmetrical metallated porphyrazine **6**, where a

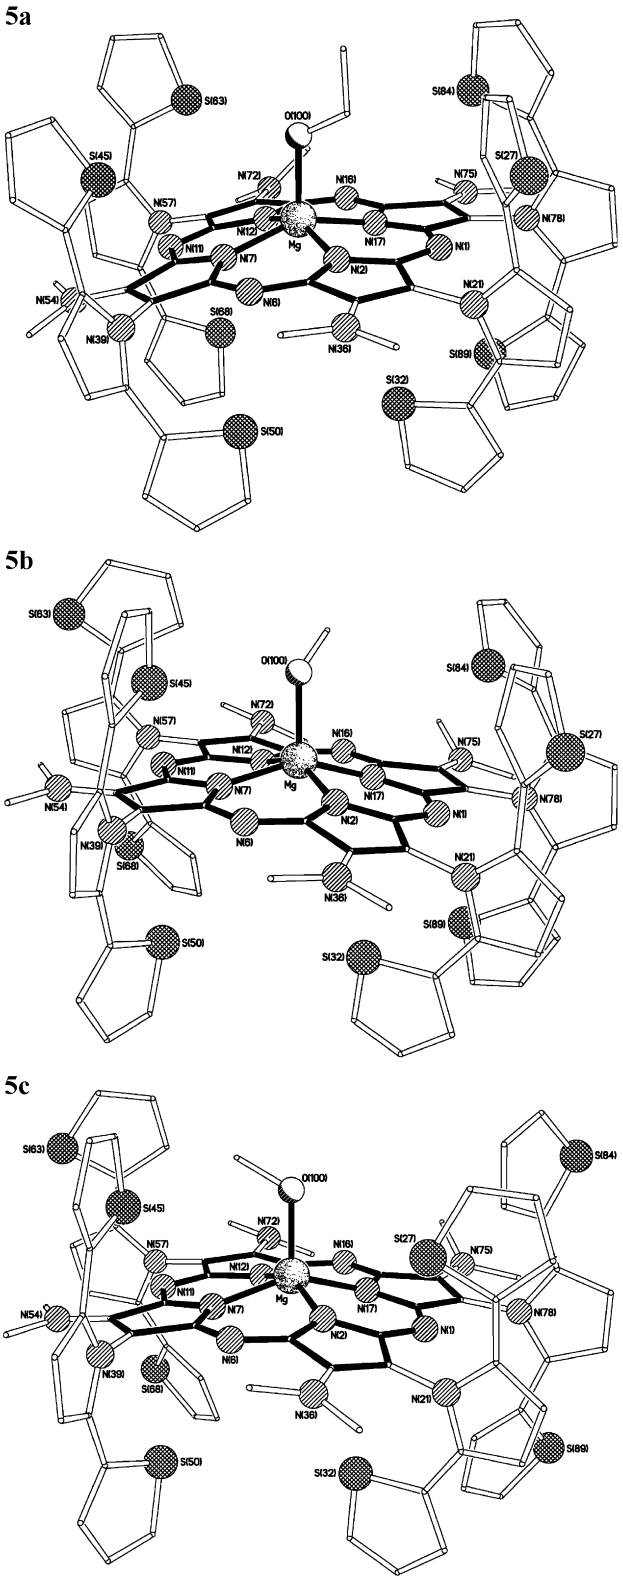

Fig. 2. The molecular structures of **5a**, **5b** and **5c**.

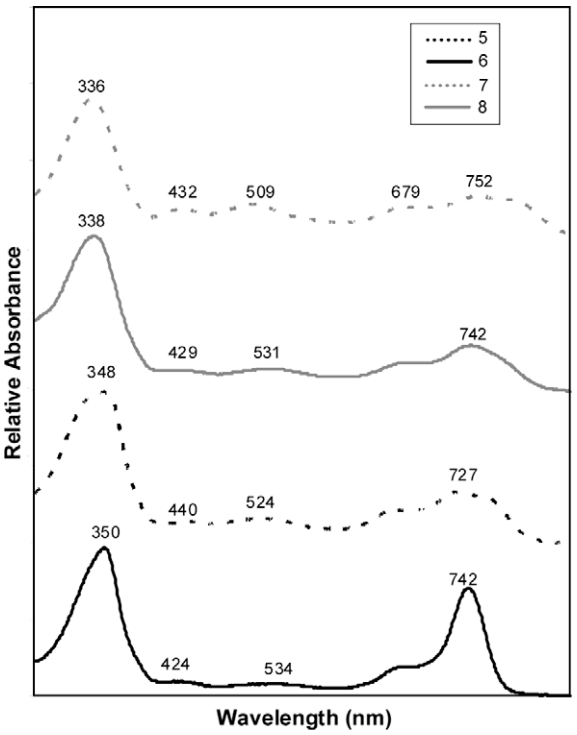
sharp and intense Q-band was found at 742 nm. The very weak peak at 516 nm was assigned to an n–π^* transition from the lone-pair of electrons on the external nitrogen atoms into a π^* ring orbital. It is obvious, that the solvent affects the photophysical and photochemical properties of pz **5**. However, changes observed for the novel 2,5-di(2-thienyl)pyrrolyl peripheral substituent present



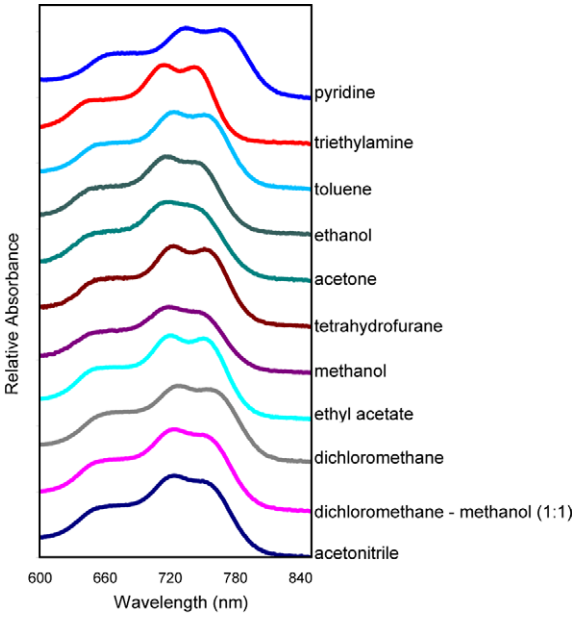


Fig. 3. Electronic absorption spectra of **5**–**8** in CH_2Cl_2:CH_3OH.

Solvent	Q-band (λ_{max}, nm)	Dipole moment (μ)	Refractive index (n_D)
methanol	719	1.70	1.328
acetonitrile	724	3.92	1.344
acetone	719	2.88	1.359
ethanol	718	1.69	1.3611
ethyl acetate	722, 750	1.78	1.372
triethylamine	714, 741	0.66	1.401
tetrahydrofurane	721, 751	1.75	1.407
dichloromethane	729, 753	1.60	1.445
toluene	727, 751	0.37	1.497
pyridine	734, 765	2.21	1.510

Fig. 4. The variation of the Q-band for **5** in various solvents (dipole moments and refractive indices [19,20].

in pz **5** are more significant than those for the previously described 2,5-dimethylpyrrolyl counterpart [12]. The absorption maximum of **5** in methanol, ethanol, acetone, acetonitrile are at the range 718–724 nm (Fig. 4). In triethylamine the Q-band of pz **5** exhibited the strongest hypsochromic shift at 714, 741 nm and an additional Q-band split was present. Whereas in pyridine, the strongest bathochromic shift and a split of the Q-band at 734 and 765 nm were observed. The Q-band split was also found in toluene, THF, ethyl acetate and dichloromethane. The long-wavelength maxima in the UV–Vis spectra of **5** were found to be sensitive to a change in the dielectric properties of the medium for coordinating solvents, with the magnitude of the red shift following the order ethanol < methanol < tetrahydrofurane < ethyl acetate < pyridine. The refractive index of the solvents triethylamine, acetone, tetrahydrofurane, toluene, dichloromethane and pyridine increased as the red shift of the Q-band increased. The largest red shift of the Q-band was observed in aromatic solvents, with the highest shift being observed for pyridine. Moreover, the Q-band split was observed only for solvents possessing refractive indices higher than 1.372. The presence of an additional band in the Q-region, indicating a loss of symmetry was explained in phthalocyanine systems by the distortion of the ring of the analyzed molecule. The position of the Q-band for pz system **5** in the range of solvents analyzed seems to result from both coordination and solvation [19,20].

4. Conclusion

Novel unsymmetrical pz bearing peripheral 2,5-di(2-thienyl)-1*H*-pyrrole and dimethylamino substituents were synthesized and characterized. The novel type of macrocyclic structure possesses an alternate order of substituents in three out of four fragments only. As a consequence, in the discussed structure, two dimethylamino groups and two dithienylpyrrolyl groups are in close vicinity. The asymmetry imposed by this non-alternate order of peripheral substituents, breaking C_4 symmetry, resulted in the non-equivalence of ^{1}H and ^{13}C NMR signals for all pz discussed. The X-ray structure of **5** revealed an almost perpendicular orientation of the bulky, dithienylpyrrolyl system to the core of the macrocycle.

The synthesis of this novel pz system was performed using both a Linstead macrocyclization and a $Zn(OAc)_2$-1,8-diazabicyclo[5.4.0]undec-7-ene – pentanol approaches. The unexpected direction of the reaction to unsymmetrical pzs **5** and **8** might be the result of their thermodynamic stability and thus instability of other kinetic isomers, which even if formed under the reaction conditions, are likely to decompose, similar to pz **6**.

As pz **5** exhibited significant solvatochromic changes in the UV–Vis spectrum in various solvents, the pzs described in this report are expected to find diverse applications as precursors to optical materials. The direction of this research will be continued and reported in due course.

ABSTRACT

The reaction of $(R\text{-}Ind)_2Ni$ (Ind = C_9H_7, indenyl) with an equivalent of a bulky aryl-substituted imidazolium salt in CH_2Cl_2/THF at 45 °C results in the corresponding *N*-heterocyclic carbene (NHC) indenylnickel(II) chloride of the type (R-Ind)Ni(L)Cl [R = 1-H, L = 1,3-bis(2,6-diisopropylphenyl)imidazol-2-ylidene (IPr), **1**; R = 1-Me, L = IPr, **2**] in high yield. Complexes **1** and **2** were characterized by elemental analysis, NMR spectroscopy and X-ray crystallography. The resulted NHC indenylnickel(II) complexes are capable of polymerizing styrene in the presence of $NaBPh_4$ to give atactic polystyrene with M_n values in the range of 10^4. The present studies show a close relationship between the structure and catalytic activity of the NHC indenylnickel(II) halides (including the previously reported indenylnickel(II) halides bearing alkyl-substituted NHC ligands), and complex **2** shows the highest catalytic activity. In comparison with its phosphine analogue (1-Me-Ind)Ni(PPh_3)Cl, complex **2** shows significant improvements in stability and catalytic performance.

1. Introduction

During the past decade there has been increasingly interesting in the application of *N*-heterocyclic carbenes (NHCs) as a structure principle for developing late transition metal-based homogeneous catalysts [1–4]. In many types of catalytic processes, NHCs have been used as a valid alternative to the traditional phosphine ligands due to their unique and tunable steric and electronic properties [5–7]. The replacement of phosphine ligands with electron-rich NHC ligands could represent significant catalytic activity in most cases. For example, benzannulated NHC Ni(II) complexes of the general formula $Ni(NHC)_2Br_2$ exhibited much higher catalytic activity than their phosphine analogues, $Ni(PPh_3)_2Br_2$, in reductive Ullmann coupling reactions of aryl bromides [8].

However, in comparison with the intensively studied NHC complexes of palladium, a relatively small number of well-defined NHC nickel complexes have been reported to date. Only recently have NHC complexes of nickel garnered more attention and emerged as effective catalysts for a series of reactions, such as C–F bond [9] or C–H bond activation [10], C–C or C–N cross-coupling reactions [8,11–14], olefin dimerization [15,16], polymerizations [17–24], and so on. The $(NHC)_nNi(CO)_m$ system has been used as a model for the understanding of electronic and steric effects of NHCs [25,26], nevertheless, the principles regulating their structures and reactivities remain unclear. This prompted us to develop the free NHC-based indenylnickel(II) complexes.

In fact, although tertiary phosphine analogues of the type $(R\text{-}Ind)Ni(PR'_3)X$ (X = halide, alkyl, alkynyl, imidate, thiolate) have been reported, and include examples that are effective precatalysts for the oligomerization or polymerization of ethylene, styrene and alkynes, the dehydrogenative oligomerization or polymerization of phenylsilane [27], NHC indenylnickel(II) complexes have received little attention until our recent report on a one-step facile synthetic method, i.e. the direct reaction of the bis-indenyl Ni(II) complex of $(1\text{-}H\text{-}Ind)_2Ni$ with an alkyl-substituted imidazolium salt, for the synthesis of alkyl-substituted NHC indenylnickel(II) complexes (1-H-Ind)Ni(iPr)X (iPr = 1,3-diisopropylimidazole-2-ylidene) in high yields [28,29]. This procedure needs no extra steps for the isolation and purification of the corresponding *N*-heterocyclic carbene, and provides simple access to NHC Ni(II) complexes with polydentate co-ligands. Despite our investigation, there has only been one example reported so far that such NHC complexes could be synthesized by the reaction of $(R\text{-}Ind)Ni(PPh_3)X$ with free NHC, mentioned briefly in one review [27]. To explore a simple route to a large number of complexes in this family would be desirable.

Herein we described the extension of our methodology to the synthesis of indenylnickel(II) chlorides bearing sterically bulky aryl-substituted NHC ligands, (1-H-Ind)Ni(IPr)Cl [IPr = 1,3-bis(2,6-diisopropylphenyl)imidazol-2-ylidene, **1**) and its alkyl-substituted indenyl derivative (1-Me-Ind)Ni(IPr)Cl (**2**). The present investigation enlarges the list of analogous complexes already described [28,29], to such an extent that comparative studies of

doi:10.1016/j.poly.2009.05.080

the relationship between their structures and catalytic activities in styrene polymerization may be possible. Their catalytic activities for styrene polymerization have also been compared to their tertiary phosphine analogues.

2. Experimental

2.1. General procedures

All manipulations were performed under pure argon with rigorous exclusion of air and moisture using standard Schlenk techniques. Solvents were distilled from Na/benzophenone ketyl under pure argon prior to use. Indene (Fluka) (dried over 4 Å molecular sieves) was distilled immediately before use. (1-H-Ind)$_2$Ni [28], (1-Me-Ind)$_2$Ni [30], 1,3-bis(2,6-diisopropylphenyl)imidazolium chloride (IPr·HCl [31], (1-H-Ind)Ni(iPr)X [iPr = 1,3-diisopropylimidazole-2-ylidene, X = Cl (**3**) and Br (**4**)] [28], (1-Me-Ind)Ni(PPh_3)Cl (**5**) [32] and CpNi(IPr)Cl (Cp = cyclopentadienyl, **6**) [33] were prepared by published methods. Elemental analysis was performed by direct combustion on a Carlo-Erba EA-1110 instrument. NMR ($CDCl_3$) spectra were measured on a Unity Inova-400 spectrometer at 25 °C, and were assigned by the assistance of 2D techniques (H–H correlation spectroscopy and C–H heteronuclear correlation spectroscopy). Molecular weight and molecular weight distribution were determined by gel-permeation chromatography (GPC) measurements calibrated to commercial polystyrene standards and performed on a PE PL-GPC50 apparatus with two PLgel 10 μm MIXED-B columns in THF (1.0 mL/min) at 40 °C.

2.2. Synthesis of (1-H-Ind)Ni(IPr)Cl (*1*)

A Schlenk flask was charged with 1,3-bis(2,6-diisopropylphenyl)imidazolium chloride (0.85 g, 2.00 mmol), CH_2Cl_2 (5 mL) and a stir bar. To this solution was added (1-H-Ind)$_2$Ni (0.57 g, 2.00 mmol) in 20 mL of THF via syringe at room temperature. The solution was stirred overnight at 45 °C, filtered and then evaporated to dryness. After being washed with hexane, the residue was extracted with hot toluene and recrystallized from concentrated toluene at −10 °C, yielding bright red crystals (0.32 g, 63%) suitable for elemental analysis and X-ray diffraction studies. M.p. 176–178 °C. *Anal.* Calc. for $C_{36}H_{43}ClN_2Ni$: C, 72.32; H, 7.25; N, 4.69. Found: C, 72.24; H, 7.43; N, 4.45%. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ 1.05 (d, 12H, *Me*), 1.34 (d, 12H, *Me*), 2.65 (br, 1H, *H*3), 3.07 (br, 2H, C*H*Me$_2$), 4.44 (br, 2H, C*H*Me$_2$), 6.38 (s, 1H, *H*1), 6.62 (br, 2H, *H*5/*H*8 and *H*2), 7.01 (s, 2H, C*H*=C*H*), 7.35-7.57 (m, 9H, *H*5/*H*8, *H*6, *H*7 and *Ph*). ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C): δ 23.1 (*Me*), 26.6 (*Me*), 29.0 (CHMe$_2$), 103.3 (*C*1), 118.1 and 118.2 (*C*2 and *C*5/*C*8), 124.7 and 125.5 (*m-Ph*, *C*6 and *C*7), 125.8 (C*H*=C*H*), 130.4 (*p-Ph*), 132.73 (*C*4 and *C*9), 136.8 (*o-Ph*), 146.7 (*ipso-Ph*), 175.4 ($C_{carbene}$); however, the assignment of some of these signals remains ambiguous, such as the resonance for *C*3 which is missing and should be presented at ca. 50.

2.3. Synthesis of (1-Me-Ind)Ni(IPr)Cl (*2*)

Following a procedure similar to the synthesis of **1**, (1-Me-Ind)$_2$Ni (0.62 g, 2.00 mmol) in 20 mL of THF was added to a solution of 1,3-bis(2,6-diisopropylphenyl)imidazolium chloride (0.85 g, 2.00 mmol) in CH_2Cl_2 (5 mL) at room temperature. After workup, dark red crystals (0.86 g, 70%) suitable for elemental analysis and X-ray diffraction studies were obtained from concentrated toluene at −10 °C. M.p. 206–207 °C. *Anal.* Calc. for $C_{37}H_{45}ClN_2Ni$: C, 72.62; H, 7.41; N, 4.58. Found: C, 72.31; H, 7.07; N, 4.47%. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ 0.95 (m, 9H, *Me* and 1-*Me*-Ind), 1.15 (d, 6H, *Me*), 1.23 (d, 6H, *Me*), 1.39 (d, 6H, *Me*), 2.55 (br, 2H, C*H*Me$_2$), 3.17 (br, 2H, C*H*Me$_2$), 4.16 (s, 1H, *H*3), 5.65 (d, 1H, *H*5), 6.01 (s, 1H, *H*2), 6.29 (m, 1H, *H*6), 6.57 (d, 1H, *H*8), 6.77 (d, 1H, *H*7), 7.01 (s, 2H, C*H*=C*H*), 7.32-7.53 (m, 6H, *Ph*). ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C): δ 12.2 (1-*Me*-Ind), 22.7 (*Me*), 23.6 (*Me*), 26.1 (*Me*), 27.0 (*Me*), 29.0 (CHMe$_2$), 58.1 (*C*3), 93.9 (*C*1), 103.8 (*C*2), 116.7 (*C*8), 117.0 (*C*5), 124.5 (*C*6), 124.6 (*m-Ph*), 125.5 (*C*7), 125.8 (CH=CH), 130.2 (*p-Ph*), 132.0 (*C*4), 134.0 (*C*9), 136.9 (*o-Ph*), 146.7 (*ipso-Ph*), 177.1 ($C_{carbene}$).

2.4. Structure determination

Suitable single crystals of **1** and **2** were sealed in a thin-walled glass capillary for X-ray structural analysis. Diffraction data were collected on a Rigaku Mercury CCD area detector at 193(2) K. The structures were solved by direct methods and refined by full-ma-

trix least-squares procedures based on F^2. All non-hydrogen atoms were refined with anisotropic displacement coefficients. Hydrogen atoms were treated as idealized contributions. The structures were solved and refined using SHELXS-97 and SHELXL-97 programs, respectively. Crystal data, collection and main refinement parameters are given in Table 1. Selected bond lengths (Å) and angles (°) for **1** and **2** are given in Table 2.

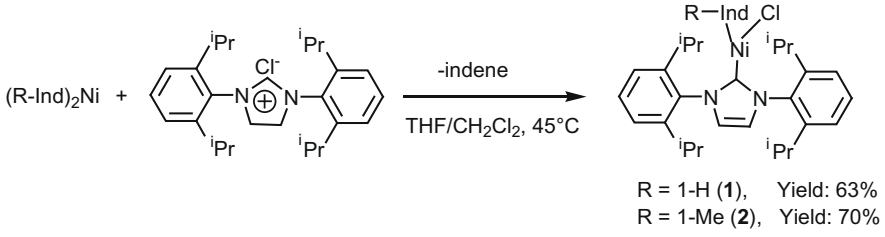
2.5. A typical procedure for the polymerization of styrene

A typical procedure for the polymerization of styrene is given as follows. Under dry argon, complex **1** (12.0 mg, 0.02 mmol), $NaBPh_4$ (47.9 mg, 0.14 mmol), toluene (0.2 mL), and styrene (0.7 mL, 6.0 mmol) were added into a dry glass ampule in turn. Then, the sealed ampule was placed in a water bath held at 80 °C. After a definite reaction time, the polymerization was stopped by adding 1 mL of 5% HCl/ethanol. After evaporation of the solvent and unreacted monomer, the resultant polymer was dissolved in THF, followed by precipitation in 95% ethanol. After filtration, the white polymer was dried in vacuo at room temperature overnight. The polymer yield was determined gravimetrically.

3. Results and discussion

3.1. Synthesis and structural characterization of *1* and *2*

Focusing on the nickel-based system, the bulky aryl-substituted NHC complexes exhibit unusual stability or reactivity in certain instances [8,25,34]. So, as a continuation of our previous work on NHC indenylnickel(II) complexes, it was considered to test whether the reported imidazolium salts metathesis and indene elimination reaction [28–29] could also occur between 1,3-bis(2,6-diisopropylphenyl)imidazolium chloride (IPr·HCl) and $(1\text{-H-Ind})_2Ni$, to yield the corresponding bulky aryl-substituted NHC indenylnickel(II) complex. Thus, a 1:1 (in molar ratio) mixture of $(1\text{-H-Ind})_2Ni$ and IPr·HCl was stirred at 45 °C in CH_2Cl_2/THF overnight. This reaction worked smoothly from the change of color from red to dark red. After workup, the designed NHC complex **1** was isolated as dark red crystals in ca. 63% yield (Scheme 1). The proposed structure for **1** was first supported by elemental analysis and NMR spectroscopy. The ^1H NMR and ^{13}C NMR data indicated the presence of one indenyl group and one *N*-heterocyclic carbene group, respectively. Moreover, in the ^{13}C NMR spectrum, a singlet $C_{carbene}$ atom signal appears at δ 175.4 ppm, which resembles a clear downfield shift compared to the reported Ni(II) complexes of $\Delta\delta \sim 9$ ppm for (1-H-Ind)Ni(iPr)Cl (**3**, δ = 166.3 ppm) [28] or $\Delta\delta \sim 6$ ppm for CpNi(IPr)Cl (**6**, δ = 169.3 ppm) [33]. The identity of this complex is further confirmed by X-ray analysis. To further ascertain the versatility of this synthetic approach, the similar reaction of the alkyl-substituted bis-indenyl Ni(II) complex of $(1\text{-CH}_3\text{-Ind})_2Ni$ with the same imidazolium salt was tested in turn. The analogous chloride **2** was isolated as dark red crystals in ca. 70% yield by a similar procedure (Scheme 1). Elemental analysis, NMR spectroscopy and X-ray analysis confirmed the expected product composition. In its ^{13}C NMR spectrum, the singlet $C_{carbene}$ atom signal appears at δ 177.1 ppm, which is very close to that of **1**. These results demonstrated undoubtedly that the imidazolium salt metathesis and indene elimination is a valid synthetic route to a variety of NHC indenylnickel(II) complexes.



Compared with the alkyl-substituted NHC indenylnickel(II) complexes (1-H-Ind)Ni(iPr)Cl (iPr = 1,3-diisopropylimidazole-2-ylidene, **3**) [28], both **1** and **2** are much more thermally stable and melt at ca. 177 °C for **1** and ca. 206 °C for **2** (the melting point of **3** is 147 °C). Besides, they are also much less sensitive to air and moisture than complex **3**, and can even be kept unchanged in the open air for several hours in the solid state, compared to only a few minutes for complex **3** [28]. Additionally, it is worth mentioning that the tertiary phosphine analogues, $(1\text{-H-Ind})Ni(PPh_3)Cl$ [35] or $(1\text{-Me-Ind})Ni(PPh_3)Cl$ (**5**) [32], decompose immediately in open air.

3.2. Crystal structures of *1* and *2*

Crystals of **1** and **2** suitable for X-ray structure determination were grown from cold toluene solution. The crystallographic and measurement data are shown in Table 1, and selective bond lengths and angles are listed in Table 2. The molecular structures of these complexes are shown as ORTEP drawings in Figs. 1 (**1**) and 2 (**2**).

The molecular structures of **1** and **2** are similar, and both are monomeric in the solid state. The nickel atom is bonded to the indenyl group in a highly unsymmetric mode. The bond lengths of Ni–C1, Ni–C2 and Ni–C3 equal 2.119(2), 2.019(3) and 2.028(2) Å in **1** and 2.132(3), 2.041(3) and 2.025(3) Å in **2**, respectively, which are within the normal bonding distances, while the other two carbon atoms of the five-ring of the indenyl group (C4 and C9) are considerably further away (Ni–C4 = 2.412(2), Ni–C9 = 2.437(2) Å in **1**; Ni–C4 = 2.385(3), Ni–C9 = 2.415(3) Å in **2**). Such a highly unsymmetric mode of the indenyl ligand is not only very similar to the reported NHC indenylnickel(II) complexes [28–29] but also common in the family of the corresponding tertiary phosphine indenylnickel(II) complexes [27].

The Ni–Ind interaction could be quantitatively calculated by the main geometrical parameters such as (a) the slip value represented by ΔM-C and (b) the hinge and fold angles (HA and FA) representing the bending of the indenyl ligand at C1/C3 and C4/C9, respectively [28]. For example, ΔM-C values close to zero indicate little distortion from η^5 hapticity, whereas values above ca. 0.5 Å indicate nearly η^3 hapticity; HA values of ca. 14° or greater are associated with nearly trihapto cases. Here, in complex **1**, ΔM-C = 0.35 Å, HA = 11.4°, FA = 12.74°; and in complex **2**, ΔM-C = 0.32 Å, HA = 10.1°, FA = 11.4° (Table 2). These values led us to propose that the Ni–Ind bonding fashion here can be described as an intermediate hapticity between the η^5- and η^3-modes, which is somewhat similar to that found in $(1\text{-H-Ind})_2Ni$ (ΔM-C = 0.42 Å, HA = 13.9°, FA = 13.1°) [27]. However, the larger parameter values (ΔM-C, HA, and FA) for **1** indicated a more unsymmetric Ni–Ind interaction is present in **1**. This phenomenon that the methyl substituent on

Scheme 1. Synthesis of NHC indenylnickel(II) complexes of **1** and **2**.

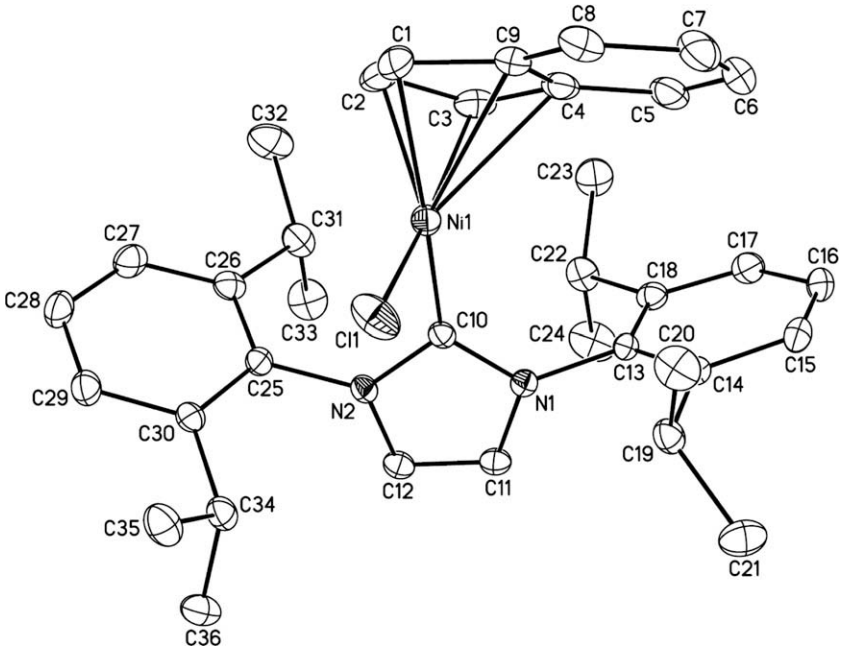


Fig. 1. The crystal structure of complex **1**.

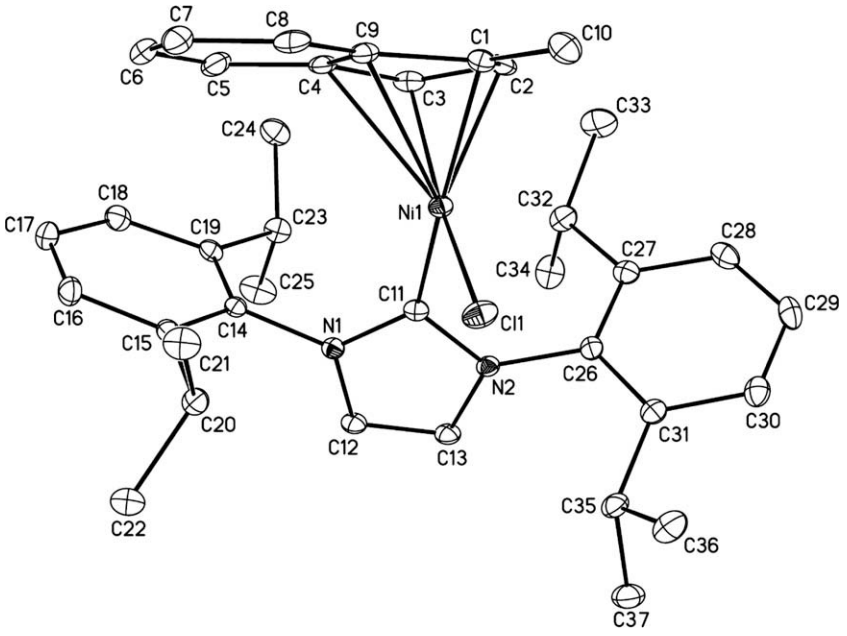

Fig. 2. The crystal structure of complex **2**.

the indenyl ligand of **2** leads to a less unsymmetric Ni-Ind interaction, i.e. represents a stronger Ni–Ind interaction, is very similar to the one found in its PPh_3-based analogous [32]. Furthermore, since the bond lengths of Ni–C1 and C2–C3 are longer than those of Ni–C3 and C1–C2 in **1** and **2**, respectively, it can be argued that the distortion in the hapticity of the indenyl ligand is not quite $\eta^5 \leftrightarrow \eta^3$ but rather $\eta^5 \leftrightarrow (\eta^1, \eta^2)$, i.e. the C1 = C2 occupy a single coordination site. In addition, the NMR data are also valuable in assessing the indenyl hapticity in solution [27]. For example, Zargarian has suggest that large chemical shift differences between H1 and H3 (>2 ppm) or C1 and C3 (>20 ppm) correlated well with a partial localization of bonding in the allyl moiety of the indenyl ligand in (I-H-Ind)Ni(PPh_3)Cl, since such a bonding type requires that C1 and C3 be quite different in terms of hybridization [35]. Herein we note that even if the assignment of these signals remains somewhat ambiguous, the H1 and H3 signals for **1** appear at 2.65 and 6.38 ppm, respectively, meanwhile the C1 and C3 signals for **2** appear at 58.1 and 93.3 ppm, respectively. The pairwise δ values are more than 3 ppm (H1/H3 in **1**) or 35 ppm (C1/C3 in **2**) apart, attesting to the greater sp^2 character of C1 in **1** and **2**, respectively [27].

Thus, the nickel atom is bonded to a Cl, $C_{carbene}$, C1, C2 and C3 of the indenyl group, to form a highly distorted square plane with C1 = C2 occupying a single coordination site (i.e. C1–C2 < C2–C3, Table 2). Such a coordinated fashion can be mainly attributed to the tendency of Ni(II) to avoid forming 18-electron complexes [27–28] and the unequal *trans* influences of the *N*-heterocyclic carbene and the halogen group [28]. Besides, as compared with 0.31 Å (ΔM-C), 12.1° (HA) and 9.1° (FA) reported for (1-H-Ind)Ni(iPr)Cl (**3**)

and 0.30 Å (ΔM-C), 12.3° (HA) and 9.5° (FA) reported for (1-H-Ind)Ni(iPr)Br (**4**) [28], the differences in these parameters among **1**, **2**, **3** and **4** demonstrate that the NHC ligand has a great influence on the Ni–Ind interaction presented in (R-Ind)Ni(NHC)X. The bulky IPr ligand possesses a more *trans* influence than the iPr ligand, which leads to a more unsymmetric Ni–Ind interaction. In addition, in comparison with the previously measured parameters for (I-H-Ind)Ni(PPh_3)Cl (i.e. ΔM-C = 0.26 Å) [35] and **5** (i.e. ΔM-C = 0.25 Å) [32], it is found that there is a more unsymmetric Ni–Ind interaction for NHC-based systems, which could be attributed to the stronger donor ability of the NHC ligand than that of PPh_3 [25] and a more unequal *trans* influences between the NHC ligand and the halogen group.

The Ni–$C_{carbene}$ bond lengths are almost the same for the two complexes (1.896(2) Å in **1** and 1.895(3) Å in **2**), and both are longer than that of 1.886(3) Å in **3** or 1.888(4) Å in **4** [28]. These data indicate that the ancillary ligand of (R-Ind)Ni(NHC)X, i.e. the indenyl moiety or the halogen atom has subtle effect on the Ni–$C_{carbene}$ interaction, meanwhile steric factor differences of the NHC ligands should be responsible for the weaker interaction between the nickel atom and the carbene carbon. Nevertheless, since alkyl-substituted NHCs are marginally more electron-donating than their aryl-substituted counterparts [25], it should be taken into account that small differences in donor capacities of NHC ligands may also play an important role in the Ni–$C_{carbene}$ interaction.

The Ni–Cl bond length of 2.1759(7) Å in **1** is slightly shorter than 2.1829(9) Å in **2**, and obviously shorter than that of 2.2025(7) Å in **3** [28]. The strongest Ni–Cl interaction in **1** might be a compensation for the weakening trend of the Ind–Ni interaction on going from **1** to **2** and then to **3**. Alternatively, a weakening trend of the Ni–Cl interaction is probably caused by the Cl–Ni π-donation [32]. However, it is well known that the X–M π-donation would destabilize d^8 complexes. In addition, the Ni–Cl distances in **1** or **2** are slightly shorter than that of 2.1822(7) Å in (I-H-Ind)Ni(PPh_3)Cl [35] or 2.1865(10) Å in **5** [32], respectively.

3.3. Catalytic activity of the free NHC indenylnickel(II) complexes for styrene polymerization

Previous studies had indicated that the neutral tertiary phosphine indenylnickel(II) complexes of (R-Ind)Ni(PR_3)X (X = halide) alone were inert toward the insertion of styrene, whereas the addition of proper amounts of $AgBPh_4$ (or $NaBPh_4$) and phosphine ligands led to the polymerization of styrene [36–41]. The role of $AgBPh_4$ (or $NaBPh_4$) was to abstract the halide ligand from these complexes, with the in situ formation of catalytically active cationic species, while addition of the phosphine ligand was needed to suppress the decomposition of the cationic species [27,39–41] unless the indenyl ligand tethered an amine moiety [36–38].

In the present paper, the catalytic activity of a series of free NHC indenylnickel(II) complexes for styrene polymerization has been investigated for the first time.[1] The preliminary results are listed in Table 3. The results show that the addition of a proper amount of $NaBPh_4$ is also necessary in the present case, which indicates that the present styrene polymerization also is catalyzed by the in situ generated electronically and coordinatively unsaturated species. For example, complex **1** alone shows no catalytic activity for styrene polymerization in toluene at 80 °C (Table 3, run 1), however, together with $NaBPh_4$, it shows considerable catalytic activity, i.e. 60% yield of polystyrene was obtained after 48 h polymerization (Table 3, run 2).

Table 3
Ni(II)-catalyzed homopolymerization of styrene.

Run	Initiator	$NaBPh_4$/[Ni]	t (h)	Yield (%)	$M_n \times 10^{-4}$	M_w/M_n
1	**1**	0	48	~0		
2	**1**	7	48	60	3.6	2.0
3	**2**	7	48	75	5.7	2.4
4	**3**	7	48	26	2.6	3.6
5	**4**	7	48	36	4.4	3.1
6[a]	**2**	7	48	33	3.3	2.6
7	**5**	7	48	24	0.4	2.4
8[a]	**5**	7	24	78	0.6	4.7
9	**6**	7	48	40	2.3	1.9

Conditions: styrene/[Ni] = 300:1 (molar ratio), toluene: 0.2 mL, T = 80 °C.
[a] $[NaBPh_4]/[Ni]/[PPh_3]$ = 7:1:1.

The influences of the indenyl ligand, the NHC ligand and the halide ligand on the catalytic activity of the corresponding Ni(II) complexes are investigated in turn. On the basis of the polymer yield, complex **2** shows the highest catalytic activity while complex **4** possess the lowest one (Table 3, runs 2–5). Meanwhile, the polystyrene with the highest number-average molecular weight (M_n = 57 000) was obtained with **2**. The diverse activities observed for these complexes may simply indicate that the catalytic active species remain ligated by the indenyl and carbene ligands, and the aryl-substituted NHC ligand together with the alkyl-substituted indenyl ligand are a benefit to enhance the catalytic activity of the NHC indenylnickel(II) complexes for the styrene polymerization. The difference in activity between **3** and **4** are probably due to their different thermal stabilities during the polymerization process [28,40].

All of the polymers obtained here are well soluble in THF and have very similar microstructures. Since a typical ^{13}C NMR spectrum ($CDCl_3$) of the obtained polystyrene shows characteristically broad signals of atactic polystyrene in the range of ca. 144–148 ppm [42], it is clear that the polystyrene obtained is an atactic polymer, which is very similar to those obtained by PPh_3-based indenylnickel(II) complexes [39–41] or by NHC-based cationic allylnickel(II) complexes [22].

It is worth noticing that the addition of a catalytic amount of other additives, i.e. PPh_3, is not necessary in the present case. For example, in the presence of one equivalent of PPh_3, the yield of polystyrene decreased greatly from 75% to 33% with a nearly half decrease of the number-average molecular weight (Table 3, runs 3 and 6). On the contrary, the addition of a catalytic amount of phosphine ligands is very necessary to styrene polymerization initiated by the phosphine analogues [39–41]. For example, in the absence of PPh_3, complex **5** shows a much lower catalytic activity, i.e. 24% yield of polystyrene with a relatively low number-average molecular weight (M_n = 4000) was obtained in the present conditions (Table 3, run 7). Notably, black powders appeared quickly in the glass ampule during this polymerization process, which indicated the decomposition of **5**. Otherwise, the addition of one equivalent of PPh_3 could efficiently suppress this decomposition and provide a much higher polymer yield (Table 3, run 8). Nevertheless, the polymer obtained still possesses a lower number-average molecular weight and a broadened molecular weight distribution. A similar phenomenon of decomposition was not observed in the styrene polymerization by NHC indenylnickel(II) complexes in the absence of PPh_3. The great difference of catalytic behaviors between the NHC indenylnickel(II) complexes and their tertiary phosphine analogues also indicates that the Ni center remains ligated by carbenes and the NHC ligands could provide a better coordination environment around the catalytic active Ni(II) species than the tertiary phophine ligands do in the indenylnickel(II) complexes.

Finally, the catalytic activity of CpNi(IPr)Cl (**6**) for the same polymerization has been investigated. As expect, its catalytic activity is lower than that of **1**, i.e. 40% yield of polystyrene was

[1] In one of our previous reports, i.e. Ref. [24], the catalytic activity of **4** for the polymerization of styrene had been mentioned briefly in comparison with the corresponding Ni(II) bromide containing an indenyl ligand tethered NHC moiety. However, we should point out that the reaction time of the styrene polymerization by **4** was incorrect, and it should be 48 h instead of the mentioned time of 24 h.

obtained after a 48 h polymerization (Table 3, run 9), which should be due to the so-called "indenyl effect" [32].

4. Conclusion

We have prepared two indenylnickel(II) complexes bearing a free bulky aryl-substituted NHC ligand via the reaction of the easily available metal precursor $(R\text{-}Ind)_2Ni$ and imidazolium salts. This procedure needs no extra step for the isolation and purification of the corresponding *N*-heterocyclic carbene, and could provide a valid synthetic route to a large number of NHC Ni(II) complexes containing polydentate ligands. The present work shows that the free NHC indenylnickel(II) halides are capable of polymerizing styrene in the presence of $NaBPh_4$, and a close relationship between their structures and catalytic activities is observed for the first time. The obtained results suggest that the presence of the bulky aryl-substituent on the NHC ligand, together with the alkyl-substituent on the indenyl ligand in these complexes, is of benefit not only to enhance their thermal/air stabilities but also to improve their catalytic activities. In comparison with the catalytic behaviors of PPh_3-based systems under the same conditions, the NHC-based ones show significant improvements in stability and catalytic performance. Further investigations focusing on developing the reactivity of NHC indenylnickel(II) complexes are in progress.

Supplementary data

CCDC 294978 and 665469 contain the supplementary crystallographic data for compounds **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Two new phenol based macroacyclic Schiff base ligands, 2,6-bis({*N*-[2-(phenylselenato)ethyl]}-benzimidoyl)-4-methylphenol (bpebmpH, **1**) and 2,6-bis({*N*-[3-(phenylselenato)propyl]}benzimidoyl)-4-methylphenol (bppbmpH, **2**) of the Se_2N_2O type have been prepared by the condensation of 4-methyl-2,6-dibenzoylphenol (mdbpH) with the appropriate (for specific reactions) phenylselenato(alkyl)amine. These ligands with Cu(II) acetate monohydrate in a 2:1 molar ratio in methanol form complexes of the composition $[(C_6H_2(O)(CH_3)\{(C_6H_5)C{=}N(CH_2)_nSe(C_6H_5)\}\{(C_6H_5)C{=}O\}_2Cu]$ (**3** ($n = 2$), **4** ($n = 3$)) with the loss of phenylselenato(alkyl)amine and acetic acid. In both these complexes, one arm of the ligand molecule undergoes hydrolysis, and links with Cu(II) in a bidentate (NO) fashion, as confirmed by single crystal X-ray crystallography of complex **3**. The selenium atoms do not form part of the copper(II) distorted square planar coordination sphere which has a *trans*-CuN_2O_2 core. The average Cu–N and Cu–O distances are, respectively, 1.973(3) and 1.898(2) Å. The N–Cu–N and O–Cu–O angles are, respectively, 167.4(11)° and 164.5(12)°. The compounds **1–4** have been characterized by elemental analysis, conductivity measurements, mass spectrometry, IR, electronic, ^1H and $^{77}Se\{^1H\}$ NMR spectroscopy and cyclic voltammetry. The interaction of complex **3** with calf thymus DNA has been investigated by a spectrophotometric method and cyclic voltammetry.

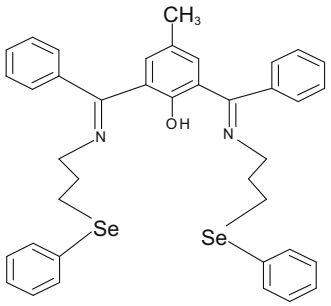
1. Introduction



Ligands bearing variable donor functionalities such as O, S, N and P in their structural framework have been studied for several years and continue to be an area of active research for understanding the properties of donors that offer the opportunity to design metal complexes for specific purposes and applications [1–27]. The coordination chemistry of organochalcogen ligands containing 'hard' donor atoms (such as N and O) along with a 'soft' donor (Se or Te) is interesting because such a ligand framework can provide insight into competitive coordination behaviour between the 'hard' and 'soft' donors towards the metal center [28,29] and also stabilize low as well as high oxidation states of a metal atom. Such molecular systems may be important in transition metal catalyzed asymmetric synthesis [30,31] and as single source precursors in MOCVD processes [32–34]. Recently Khandelwal et al. have reported some pyridine based acyclic [35,36] and phenol based cyclic [37] Schiff bases. In fact, a number of polydentate ligands bearing N_3N_2, N_3O_2, N_3S_2 and NS_2P_2 are well documented and among them, a few of the systems have shown promising catalytic, biological, environmental and material properties [38–41]. We report herein the design and synthesis of a new (Se_2N_2O) molecular system (bpebmpH, **1** and bppbmpH, **2**), having both 'hard' and 'soft' donors in the ligand framework, and its reactivity towards Cu(II) ions. We also report our findings on a DNA binding study with one of the synthesized Cu(II) complexes.

2. Experimental

All the chemicals used were of reagent grade. Solvents were purified by standard methods [42] and freshly distilled prior to use. The precursors 4-methyl-2,6-dibenzoylphenol (mdbpH) [43,44] and phenylselenato(alkyl) amine [45] were synthesized following the reported methods. Calf thymus DNA was obtained from Sigma and used as received. The sodium salt of CT-DNA was stored at 4 °C.

2.1. Physical measurements

Melting points of the compounds in the capillary tubes were recorded and are uncorrected. Elemental analyses were carried out on a Carlo-Erba Model DP 200 analyzer. The electrospray ion mass spectra (ESIMS) were recorded on a MICROMASS QUATTRO II triple quadrupole mass spectrometer. The solution was introduced into the ESI source through a syringe pump at the rate of 5 μL/min. The ESI capillary was set at 3.5 kV and the cone voltage was 40 V. The spectral print outs are the average of 6–8 scans. The ^{1}H NMR spectra were recorded on a Brucker AMX-400 FT NMR spectrophotometer in $CDCl_3$; the chemical shifts are recorded, relative to $SiMe_4$. The $^{77}Se\{^1H\}$ NMR spectra were recorded on the same instrument using Ph_2Se_2 as an external reference. Infrared spectra were recorded in the range 4000–400 cm^{-1} on a Nicolet Megna 750 FTIR spectrophotometer on a KBr disc. Electronic spectra were obtained with a Shimadzu UV-160A recording spectrophotometer.

2.1.1. Electrochemical measurements

Cyclic voltammetric measurements were carried out with an advanced electrochemical system, PARSTAT 2253 instrument equipped with a three-electrode system. The micro-cell model KO264 consisted of a glassy carbon working electrode, Pt wire as auxiliary electrode and a non-aqueous Ag/Ag^+ reference electrode with 0.1 M $AgNO_3$ in acetonitrile as the filling solution. Tetrabutylammonium perchlorate (0.1 M solution in CH_3CN) was used as the supporting electrolyte. Cyclic voltammograms with scan speeds of 50–350 mV/s were run in 10^{-4} M CH_3CN solution in a nitrogen atmosphere. Under these conditions the ferrocenium/ferrocene (fc^+/fc) couple shows a peak separation of 84 mV.

2.2. Synthesis of Schiff bases **1** and **2**

A solution of 4-methyl-2,6-dibenzoylphenol (mdbpH) (1.58 g, 5.0 mM) in dry acetonitrile (200 mL) was added drop-wise to a solution of the appropriate phenylselenato(ethyl)amine (2.0 g, 10.0 mM)/phenylselenato(propyl)amine (2.14 g, 10.0 mM) in acetonitrile (800 mL) in a 1:2 molar ratio respectively with stirring over a period of 7–8 h. The progress of the reaction was monitored by TLC. It took about 60 h for completion of the reaction. The organic solvent was removed under reduced pressure to obtain a viscous oily crude product. The product was purified by column chromatography (silica gel, 60–120 mesh, second fraction) using a solvent mixture of hexane:ethylacetate in 85:15 or 70:30 ratio. The characteristics of these compounds are given below.

2.2.1. 2,6-Bis({N-[2-(phenylselenato)ethyl]}benzimidoyl)-4-methylphenol(bpebmpH, **1**) [2,6-{$PhSe(CH_2)_2N{=}CPh\}_2C_6H_2$ (4-CH_3)(OH)]

Colour and state: yellow viscous liquid; yield: 2.48 g (73%). *Anal.* Calc. for $C_{37}H_{34}N_2OSe_2$: C, 65.29; H, 5.03; N, 4.11. Found: C, 65.23; H, 4.38; N, 4.08%. Positive ES–MS: *m/z* 683 [MH^+], 523, 500, 399, 158. FT IR (selected, cm^{-1}): *ν*(OH) 3450, *ν*(C=N) 1597, *ν*(C–O) 1252. UV–Vis λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$) ($CH_3CN$): 391 ($PhO^- \rightarrow Ph$). ^{1}H NMR ($CDCl_3$, δ ppm): 15.90 (s, 1H, OH), 7.90–7.20 (m, 22H, C_6H_5 and C_6H_2), 3.47 (t, 4H, N–CH_2), 2.99 (t, 4H, Se–CH_2), 2.03 (s, 3H, CH_3). $^{77}Se\{^1H\}$ NMR ($CDCl_3$, δ ppm): 288.

2.2.2. 2,6-Bis({N-[3-(phenylselenato)propyl]}benzimidoyl)-4-methylphenol(bppbmpH, **2**) [2,6-{$PhSe(CH_2)_3N{=}CPh\}_2C_6H_2$ (4-CH_3)(OH)]

Colour and state: yellow viscous liquid; yield: 3.29 g (93%). *Anal.* Calc. for $C_{39}H_{38}N_2OSe_2$: C, 65.74; H, 5.37; N, 3.93. Found: C, 65.63; H, 5.31; N, 3.96%. 2.3. Reactions of Schiff bases (**1**) and (**2**) with Cu(II)

A degassed solution of $Cu(OCOCH_3)_2.H_2O$ (0.10 g, 0.5 mM) in freshly distilled methanol (5 mL) was added to the degassed solution of the ligand *bpebmpH* (0.68 g, 1.0 mL)/*bppbmpH* (0.71 g, 1.0 mM) in dry methanol (15 mL) under an argon atmosphere. The reaction was carried out at room temperature with vigorous stirring. Precipitation of a green solid started almost immediately after mixing the reactants. After stirring the reaction mixture for 12 h, the precipitate thus obtained was filtered, washed with cold methanol and diethylether, and dried under vacuum. The characteristics of these complexes are given below.

2.3.1. Bis (2-[N-{2-(phenylselenato)ethyl}benzimidoyl]-6-benzoyl-4-methylphenolato)copper(II) (**3**) [(C_6H_2(O) (4-CH_3){PhC=N(CH_2)$_2$SePh}PhCO)$_2$.Cu]

Colour and state: dark green crystalline solid; yield: 0.42 g (79%). M.p.165 °C. *Anal.* Calc. for $C_{58}H_{48}N_2O_4Se_2Cu$: C, 65.81; H, 4.57; N, 2.64. Found: C, 65.12; H, 4.68; N, 2.51%. Positive ES–MS: *m/z* 1060 [MH^+]. FTIR (selected, cm^{-1}): *ν*(C=O) 1656, *ν*(C=N) 1531, *ν*(C–O) 1244, *ν*(Cu–N) 578, *ν*(Cu–O) 445. UV–Vis (nm) ($\varepsilon/M^{-1}cm^{-1}$)($CH_3CN$): 610 (167), 380 (10,080). ^{1}H NMR ($CDCl_3$, δ ppm): 7.90–7.20 (m, 34H, C_6H_5 and C_6H_2), 3.56 (t, 4H, N–CH_2), 3.05 (t, 4H, Se–CH_2), 2.07 (s, 3H, CH_3). Λ_M (10^{-3} M, CH_3CN, 298 K): 15 *S* cm^2 mol^{-1}.

2.3.2. Bis (2-[N-{3-(phenylselenato)propyl}benzimidoyl]-6-benzoyl-4-methylphenolato)copper(II) (**4**) [(C_6H_2(O)(4-CH_3) {PhC=N(CH_2)$_3$SePh}PhCO)$_2$.Cu)]

Colour and state: light green crystalline solid; yield: 0.29 g, (54%). M.p.176 °C. *Anal.* Calc. for $C_{60}H_{52}N_2O_4Se_2Cu$: C, 66.32; H, 4.82; N, 2.57. Found: C, 66.42; H, 4.61; N, 2.48%. Positive ES–MS: *m/z* 1088 [MH^+]. FTIR (selected, cm^{-1}): *ν*(C=O) 1657, *ν*(C=N)

1532, ν(C–O) 1244, ν(Cu–N) 569, ν(Cu–O) 445. UV–Vis (nm) (ε/M^{-1} cm^{-1}) (CH_3CN): 615 (170), 389 (10,100). ^1H NMR ($CDCl_3$, δ ppm): 7.90–7.20 (m, 34H, C_6H_5 and C_6H_2), 3.56 (t, 4H, N–CH_2), 2.85 (t, 4H, Se–CH_2), 2.19 (q, 4 H, mid-CH_2), 2.14 (s, 3H, CH_3). Λ_M (10^{-3} M, CH_3CN, 298 K): 70 S cm^2 mol^{-1}.

2.4. DNA binding studies

The experiments involving the interaction of the complex with CT-DNA were carried out in doubly distilled water buffer containing 5.0 mM Tris [Tris(hydroxymethyl)-aminomethane] and 50 mM NaCl and adjusted to pH 7.2 with hydrochloric acid. Solutions of CT-DNA gave ratios of absorbance at 260 and 280 nm of about 1.8–1.9, indicating that the DNA was free of protein contamination [46]. The DNA concentration per nucleotide was determined spectrophotometrically by employing a molar absorption coefficient of 6600 M^{-1} cm^{-1} at 260 nm after 1:100 dilution [47]. The complex was dissolved in 1% DMSO and 99% Tris–HCl buffer (5.0 mM Tris–HCl, 50 mM NaCl, pH 7.2) at a concentration of 3.0×10^{-5} M. An absorption titration was performed on 30 μmol L^{-1} compound by varying the concentration of nucleic acid. While measuring the absorption spectra, an equal amount of CT-DNA was added to both the compound solution and the reference solution to eliminate the absorbance of CT-DNA itself. Titration curves were constructed from the fractional change in absorption intensity as a function of DNA concentration. The intrinsic binding constant, K_b of the complex with CT-DNA was determined according to the following equation [48] through a plot of [DNA]/($\varepsilon_a - \varepsilon_f$) versus [DNA]/($\varepsilon_b - \varepsilon_f$)

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f), \quad (1)$$

where [DNA] is the concentration of DNA in base pairs, the apparent absorption coefficients ε_a, ε_f and ε_b correspond to A_{obsd}/[Cu], the extinction coefficient for the free copper complex and the extinction coefficient for the bound copper complex, respectively. In plots of [DNA]/($\varepsilon_a - \varepsilon_f$) versus [DNA]/($\varepsilon_b - \varepsilon_f$), K_b is given by the ratio of the slope to the intercept.

For the cyclic voltammetry, the supporting electrolyte was 50 mM NaCl, 5 mM Tris, pH 7.2 and an aqueous Ag/AgCl reference electrode with 3 M NaCl in saturated AgCl as the filling solution was used.

2.5. X-ray structure determination

Crystals of the complex 3 were grown as dark green needles by slow evaporation from the chloroform solution. Data were collected on a Nonius-Kappa CCD diffractometer and the structure solution and refinements were made by SHELXL-97 [49], as incorporated in the package WINGX [50]. Absorption corrections were made by MULTISCAN [51]. Non-hydrogen atoms were anisotropic and hydrogen atom positions were included in the riding mode. The ORTEP-3 program [52] was used to prepare the molecular drawings. Data collection parameters are given in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. Ligand syntheses and characterization

The monoprotic hybrid macroacyclic ligands **1** and **2** were synthesized via a one step dipodal condensation of 4-methyl-2,6-dibenzoylphenol with the appropriate phenylselenato(alkyl)amine in a 1:2 molar ratio in acetonitrile (Scheme 1).

The condensation product is dependent on the reaction conditions. In a concentrated solution of reactants, only one carbonyl group of phenol condenses with the amine group of the phenylselenato(alkyl)amine to give rise to open-chain end-off unsymmetrical ($SeNO_2$) ligands, whereas in dilute solution both arms condense to yield symmetrical (Se_2N_2O) ligands in high yield along with some one arm condensed products. The open-chain end-off unsymmetrical ($SeNO_2$) type ligands are less soluble in the solvent, and therefore separate out first as a yellow solid powder. However following the experimental conditions, open-chain end-off

Scheme 1. Synthesis of ligands 1 and 2.

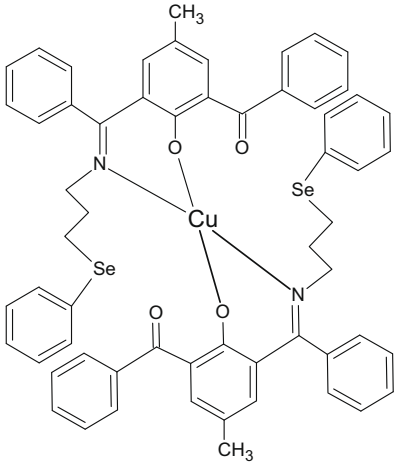
symmetrical (Se_2N_2O) macroacyclic ligands (**1**) and (**2**) were obtained in the pure form. Since the ligands (**1**) and (**2**) are obtained in good yield, after chromatographic workup, only these have been used for further characterization and complexation reactions.

The elemental analyses agreed well with their formulation. The ESI mass spectra of the ligands show the molecular ion peak along with typical isotopic patterns for selenium containing peaks. The molecular ion peak of these ligands corresponds to the condensation product of the precursors, 4-methyl-2,6-dibenzoylphenol with phenylselenato(ethyl)amine and phenylselenato(propyl)amine in a 1:2 molar ratio, respectively. The IR spectra of both ligands (**1**) and (**2**) show no N–H stretching frequency, suggesting that both the nitrogens are tertiary. The bands at 1597 cm^{-1} in **1** and 1581 cm^{-1} in **2** are attributable to ν(C=N). In addition, another band of low intensity appears in both the ligands at 1662 cm^{-1}, which may be due to ν(C=O). The appearance of this band may be due to presence of ethylacetate in traces, which was used as an eluent during the purification of the ligands by column chromatography. Further, a broad band appearing around 3450 in **1** and 3416 cm^{-1} in **2** due to ν(O–H) strongly suggests the presence of intramolecular hydrogen bonding between the phenolic hydrogen and azomethine nitrogen.

Intramolecular hydrogen bonding is also confirmed by significant deshielding of the phenolic (OH) proton signal by the order of 3.7 ppm as compared to 4-methyl-2,6-dibenzoylphenol (appears at δ 12.2 ppm) in their ^{1}H NMR spectra. The triplets due to N–CH_2 and Se–CH_2 protons in both ligands are appreciably shifted downfield as compared to the precursors 2- phenylselenato(ethyl)amine (δ 3.1 (t, 4H, N–CH_2), 2.9 (t, 4H, Se–CH_2)) and phenylselenato(propyl)amine (δ 2.9 (t, N–CH_2), 2.71 (t, Se–CH_2)). The appreciable deshielding in these proton signals along with the intensity ratios, as well as the disappearance of the –NH_2 signal [δ = 1.55 ppm {phenylselenato(ethyl)amine}, δ = 1.05 ppm {phenylselenato(propyl)amine}] suggest the condensation of the benzoyl oxygen of 4-methyl-2,6-dibenzoylphenol with the –NH_2 group of phenylselenato(alkyl)amine in a 1:2 molar ratio.

Structurally, this ligand framework is interesting as the presence of hetero (N, O, Se) donor sites could make it practical to design molecular complexes with a variety of coordination modes, depending on the nature of the central metal atom.

3.2. Synthesis and properties of complexes *3* and *4*



The reactivity of the selenium bearing ligands towards $Cu(OCOCH_3)_2H_2O$ has been studied by reacting them in a 2:1 molar ratio. The products obtained are found to have the composition $[(C_6H_2(O)(CH_3)\{(C_6H_5)C{=}N(CH_2)_nSe(C_6H_5)\}\{(C_6H_5)C{=}O\})_2Cu]$; n = 2, 3. The analytical data surprisingly suggests that one arm of the ligand is hydrolyzed at the C=N position, resulting in the release of the $PhSe(CH_2)_nNH_2$ moiety, whilst the other arm remains intact. The Cu(II) compounds are soluble in polar as well as non-polar solvents and are non-electrolytes.

The mass spectra of the Cu(II) complexes exhibit a molecular ion peak corresponding to a mass of double the partially hydrolyzed ligand plus one Cu(II) atom, suggesting the formation of complexes bearing a 2:1 ligand to metal stoichiometry. The ESIMS show a molecular ion peak with the typical isotopic patterns for selenium containing peaks.

In the infrared spectra of the Cu(II) complexes the absence of a ν(OH) absorption band suggests the combination of the phenolic proton with the CH_3COO^- ion of $Cu(OCOCH_3)_2H_2O$, and the linkage of the phenolic O with the Cu(II) ion. The combination of the phenolic proton of the ligand with the acetate group of $Cu(OCOCH_3)_2$-H_2O resulted in the release of water and the formation of CH_3COOH. The acid thus liberated probably catalyzes the hydrolysis of one arm of the ligand at the C=N position. Further, the ν(C=N) vibration is shifted to a lower frequency by ~50 cm^{-1}, suggesting the coordination of the azomethine N with Cu(II). However, the ν(C=O) band is found to be at almost the same position as in the precursor 4-methyl-2,6-dibenzoylphenol. This has been attributed to the non-involvement of the benzoyl O in coordination with the Cu(II) ion. Medium intensity bands, one in the 569–578 cm^{-1} region and one at 445 cm^{-1}, for both complexes can be assigned to ν(M–N) and ν(M–O), respectively [53,54].

The paramagnetic square planar Cu(II) complexes are expected to show three allowed absorption bands in the electronic spectra corresponding to the transitions: $e_g \rightarrow b_{1g}$ (d_{xz}, $d_{yz} \rightarrow d_{x2-y2}$), $a_{1g} \rightarrow b_{1g}$ ($d_{z2} \rightarrow d_{x2-y2}$), $b_{2g} \rightarrow b_{1g}$ ($d_{xy} \rightarrow d_{x2-y2}$) [55]. In the present investigation the Cu(II) complexes in CH_3CN show only one band in the 610–615 nm region before the charge transfer band takes over at higher energies. This band seems to have a major contribution from the $e_g \rightarrow b_{1g}$ transition, characteristic of a distorted square planar geometry [56].

The ^{1}H NMR spectra of the Cu(II) complexes do not show any phenolic proton signal, suggesting its displacement and coordination of the phenolic oxygen with Cu(II). Thus, based on the linkages in **3** and **4**, the partially hydrolyzed ligand molecules behave in a bidentate fashion and two molecules coordinate through the azomethine N and phenolic O atoms to one Cu(II) ion to give a N_2O_2 coordination sphere and forming two stable six membered rings around the Cu(II) ion. These binding modes are also confirmed by the X-ray crystal structure of complex **3**.

4

3.3. Crystal structure of complex **3**

The molecular structure of complex **3** is shown in Fig. 1. The two monoanionic ligands are bidentate, coordinating through the imino nitrogen and phenolic oxygen atoms, with both the nitrogen donors and the phenolic oxygen donors being *trans*. The copper coordination sphere is almost square planar, slightly distorted towards tetrahedral [O–Cu–O 167(11)°, N–Cu–N 164(12)°]. The Se atoms are not coordinated to Cu [Cu–Se 4.05, 4.82 Å]; they are on one side of the molecule and the phenol fragments are on the other side. There is no symmetry in the molecule as a whole. Both *cis* and *trans* complexes with the CuO_2N_2 core are known. The configuration is probably determined mainly by intraligand constraints e.g. chains linking N atoms or by steric interactions between the ligands. The latter effect probably accounts for the *trans* configuration here. The phenolic C–O distances in the complex [1.311(4) and 1.315(4) Å] are significantly shorter than that in mdbpH [1.360(4) Å] [43]. The average Cu–O and Cu–N bond lengths [1.898(2) and 1.973(3) Å, respectively] are similar to those in other *trans*-Schiff base complexes [57,58]. It is possible that the bond lengths in the *cis*-complexes are slightly longer [54] [Cu–N 1.964(2)–1.974(2) Å, Cu–O 1.926(2)–1.938(2) Å]. The Cu–N bonds in imino complexes, or where the rings are saturated, are longer [59–62]. One chelate ring, containing NO, is almost planar, with Cu slightly above the mean plane; the other ring is in a distorted boat configuration. The benzoyl O does not coordinate to the copper because the large Cu–N–CH_2CH_2SePh angle directs the ligand away from it [Cu–N1–C22 116.8(2)° and Cu–N2–C51 112.6(2)°, both wider than tetrahedral angles].

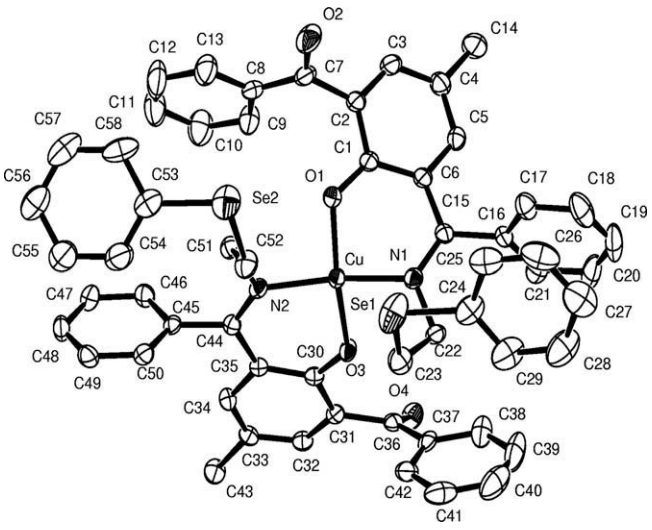


Fig. 1. Molecular structure of complex **3**.

Table 3
CV data of a 0.1 mM solution of the Schiff bases, bpebmpH **1** and bppbmpH **2** in CH_3CN/0.1 M NBu_4ClO_4 at a platinum electrode vs. Ag/0.1 M $AgNO_3$ at different scan rates.

3.4. Cyclic voltammetry

The electrochemical properties of the ligands and complexes were investigated by cyclic voltammograms (CV) in 0.1 M [NBu_4][ClO_4] in CH_3CN solution with 100–500 mV/s scan rates. All CV data were collected under a nitrogen atmosphere and potentials are reported with reference to Ag/0.1 M Ag^+. The results are summarized in Tables 3 and 4. The cyclic voltammograms of the ligands bpebmpH **1** and bppbmpH **2** (Fig. 2) exhibit an oxidation peak at

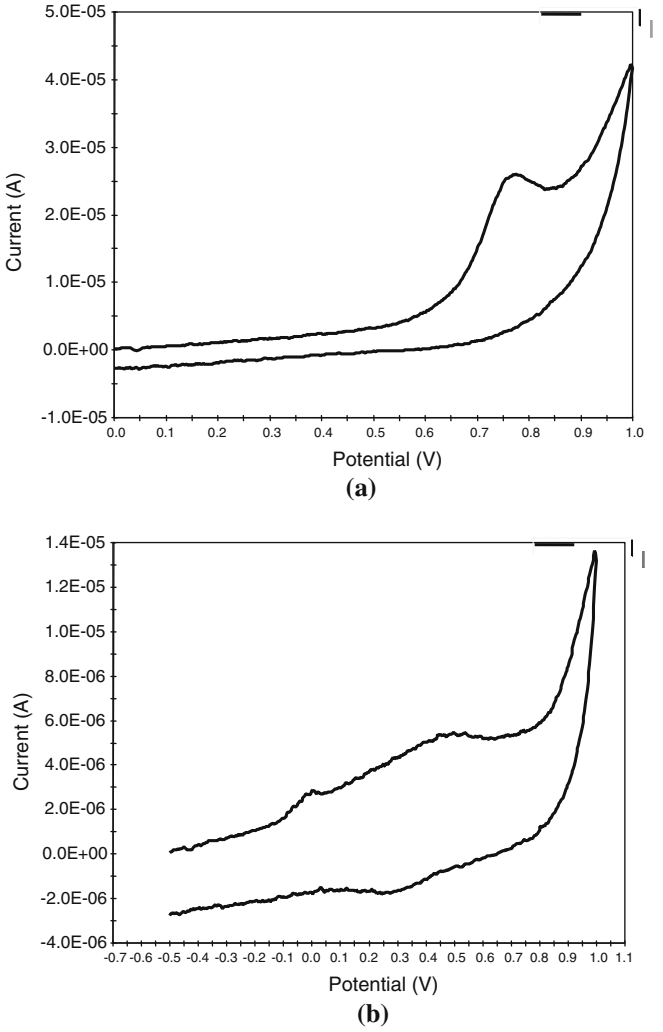

Fig. 2. Cyclic voltammograms of 0.1 mM solutions of the Schiff base bpebmpH **1** (a) and bppbmpH **2** (b) in CH_3CN/0.1 M NBu_4ClO_4 at a platinum electrode vs. Ag/0.1 M Ag^+ at 100 mV/s scan rate.

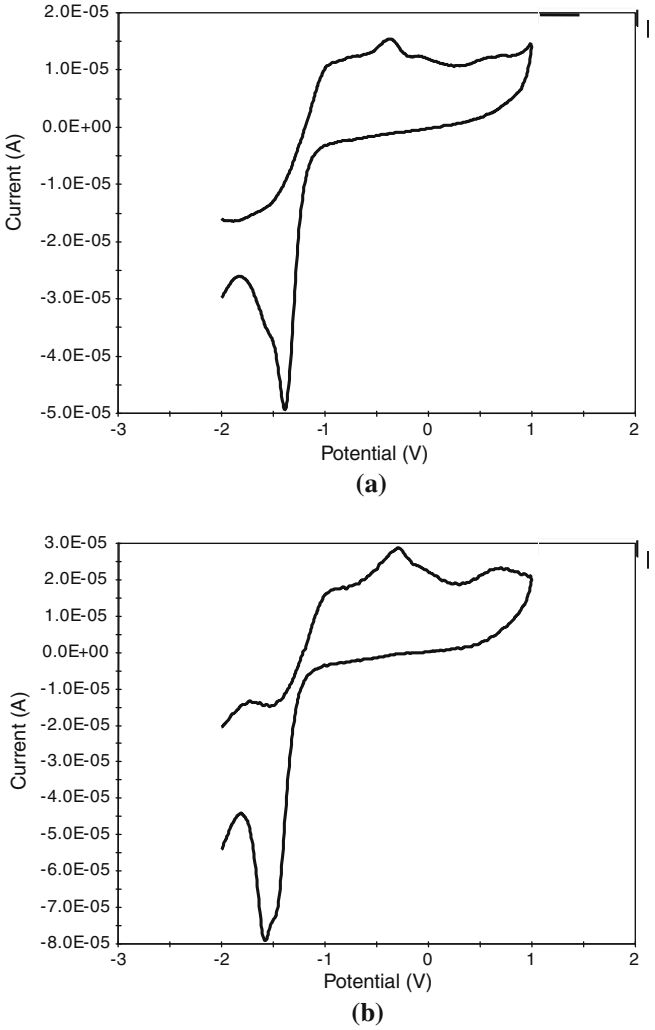

Fig. 3. Cyclic voltammograms of a 0.1 mM solution of complex **3** (a) and complex **4** (b) in CH_3CN/0.1 M NBu_4ClO_4 at a platinum electrode vs. Ag/0.1 M $AgNO_3$ at 200 mV/s scan rate.

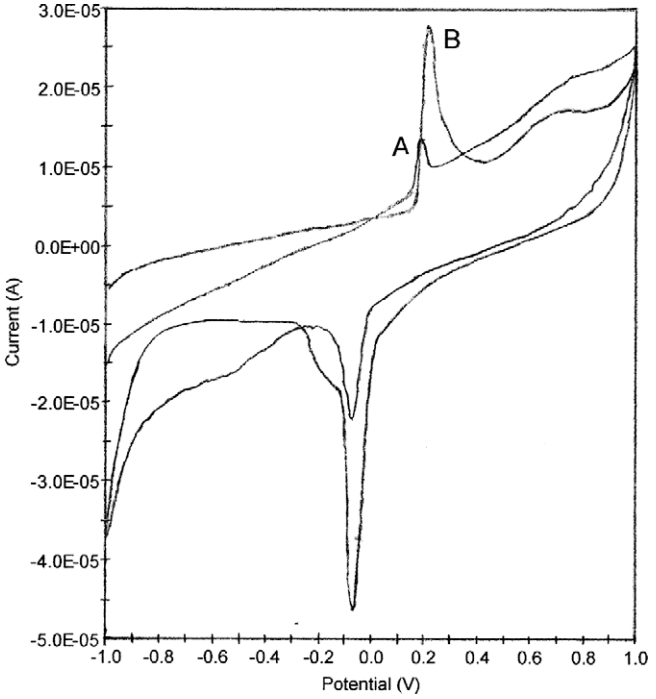

Fig. 5. Cyclic voltammograms of complex **3** (30 μM) in the absence (A) and the presence (B) of CT-DNA (30 μM) in 50 mM NaCl, 5 mM Tris, pH 7.2. Scan rate, 100 mV/s.

E_{pa} 0.778 and 0.567 V, respectively. The oxidation of **1** and **2** is electrochemically irreversible in spite of the strong intramolecular O–H···N hydrogen bond involving the phenol O and the imine N atoms. In the cyclic voltammograms of complexes **3** and **4** (Fig. 3), there is one oxidation peak (E_{pa} −0.494 (**3**), −0.405 V (**4**)) and one reduction peak (E_{pc} −1.422 (**3**), −1.550 V (**4**)). The reduction peaks for the complexes are due to Cu^{II} changing to Cu^{I}. The peak separation and current ratio between the related cathodic and anodic waves change with scan rate, indicating a quasi-reversible process. Free $Cu(CH_3COO)_2{\cdot}H_2O$ shows a different reduction

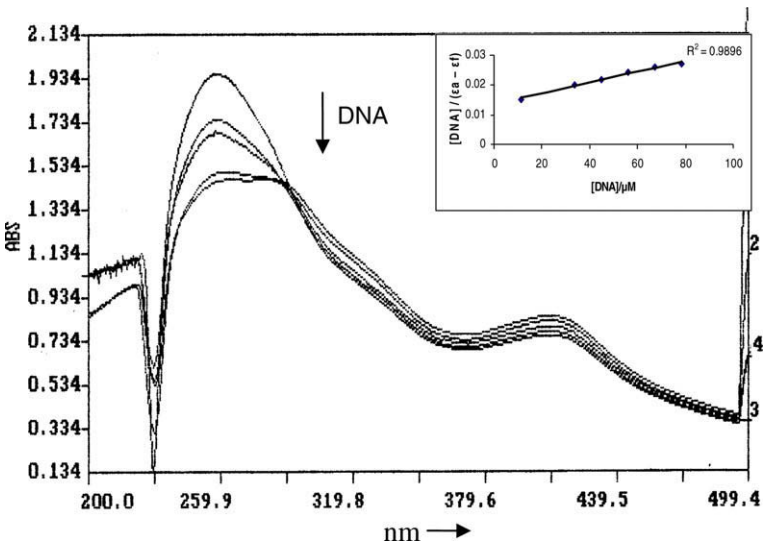

Fig. 4. Absorption spectra of complex **3** (30 μM) at 7.2 pH in the presence of increasing amounts of CT-DNA (0–80 μM). Inset: plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA] for the titration of DNA with the Cu(II) complex **3**.

Table 5
Cyclic voltammetric behaviour of complex **3** in the presence of CT-DNA.

Scan rate (mV/s)	R	E_{pa}/V (i_{pa})/μA	E_{pc}/V (i_{pc})/μA	ΔE_p (mV)	$E^{\circ\prime}$ (V)	i_{pa}/i_{pc}

	120	0.256 (88.62)	−0.052 (−65.38)	308	0.102	1.35

$\Delta E_p = (E_{pa} - E_{pc})$; $E^{\circ\prime} = 1/2(E_{pa} + E_{pc})$; complex 30 μM; R = [DNA]/[complex].
Supporting electrolyte: 50 mM NaCl + 5 mM Tris, pH 7.2; working electrode: Pt; reference electrode: Ag/AgCl.

peak at −0.707 V under similar conditions. The anodic peak potentials of the complexes are shifted to more negative values than that observed in the case of the ligand, which is in further conformity with the formation of a complex between the ligand and the Cu metal ion [63].

3.5. DNA binding properties of compound **3**

3.5.1. Absorption spectral studies

The application of electronic absorption spectroscopy is one of the most useful techniques for DNA binding studies [64]. Complex binding with DNA through intercalation usually results in hypochromism and bathochromism, due to the intercalative mode involving a strong stacking interaction between an aromatic chromophore and the DNA base pairs. The extent of the hypochromism commonly parallels the intercalative binding strength. The electronic absorption spectrum of complex **3** in 5 mM Tris–HCl/50 mM NaCl buffer exhibits bands around 408 and 264 nm. The band at 408 nm, arising from ligand-based transition, was used for the absorption spectral titration with CT-DNA. On incremental addition of DNA, the band shows only a small (6.0%) decrease in absorption accompanied by a small blue shift of 4 nm (Fig. 4). The binding constant K_b for the complex is found to be $1.46 \times 10^4\ M^{-1}$. These features are equivalent to those observed for the square planar Cu(II) complex Cu(*o*-VANAHE)$_2$ (*o*-VANAHE = 2(*o*-vanillinamine)-1-hydroxy-ethane; a bidentate Schiff base with a *trans*-CuN_2O_2 core) ($K_b = 7.3 \times 10^4\ M^{-1}$) [65]. The results suggest an association of the compound with DNA and it is also likely that this complex binds to the helix by intercalation [66].

3.5.2. Electrochemical studies

The cyclic voltammetric technique has been employed to study the interaction of the redox active Cu(II) complex with DNA in order to confirm the DNA bonding modes, suggested by the spectral studies. Typical CV behaviour of the copper complex in the absence (curve A) and presence (curve B) of CT-DNA is shown in Fig. 5. Summaries of the voltammetric results are given in Table 5. The cyclic voltammogram of complex **3** (v = 100 mV/s) in the absence of DNA featured the copper reduction of +2 to +1 at a cathodic peak potential, E_{pc}, of −0.068 V versus Ag/AgCl. Reoxidation of the +1 state occurred upon scan reversal at 0.192 V. The separation of the anodic and the cathodic peak potentials, ΔE_p, 260 mV (Table 5), indicates a quasi-reversible $1-e^-$ redox process. The formal potential, $E^{\circ\prime}$ (or voltammetric $E1/2$), taken as the average of E_{pc} and E_{pa}, was 0.062 V, in the absence of DNA. In presence of 30 μM DNA, at the same concentration of the complex, E_{pc} = −0.060 V and E_{pa} = 0.224 V. Thus, both the anodic and cathodic peak potentials shifted to more positive values versus a solution without DNA ($E^{\circ\prime}$ = 0.082 V). The value of ΔE_p in the presence of DNA was ca. 240 mV, showing that reversibility of the electron transfer process was maintained or even improved under these conditions. The apparent $E^{\circ\prime}$ shifted to more positive potentials by 20 mV in the presence of DNA. The peak current for reduction of the Cu(II) species, i_{pc}, decreased to 51% of that in the absence of DNA, for a solution with R = 30 (100 mV/s). The peak current for oxidation did not decrease under similar conditions. The ratio i_{pa}/i_{pc} was 0.61–0.71 with increasing R. Among the three kinds of binding modes for small molecules to DNA, Bard and coworkers [67] reported that if $E^{\circ\prime}$ shifted to a more negative value when small molecules interacted with DNA, the interaction mode was electrostatic binding. On the contrary, if $E^{\circ\prime}$ shifted to a more positive value, the interaction mode was intercalative binding. Thus, the observed results suggest that complex **3** interacts with DNA through an intercalative mode that involves a stacking interaction between the aromatic chromophore of the complex and the base pair of DNA.

4. Conclusions

In summary, two phenol based ligands **1** and **2** have been synthesized by dipodal condensation of 4-methyl-2,6-dibenzoylphenol with phenylselenato(alkyl)amine in acetonitrile in a 1:2 molar ratio respectively. The reaction of these ligands with Cu(II) metal ion revealed the cleavage of one arm of these ligands due to hydrolysis at the C=N position, leading to the release of the $PhSe(CH_2)_nNH_2$ (where n = 2, 3) moiety and the formation of a benzoyl group at one end. The partially hydrolyzed moiety of the ligands then forms complexes **3** and **4**, bearing a 2:1 ligand to metal stoichiometry in which two monoanionic ligands are bidentate coordinating through the azomethine N and phenolic O to one Cu(II) to give a N_2O_2 coordination sphere. Thus the phenolic proton of the ligand molecules is found to combine with the CH_3COO^- group of $Cu(OCOCH_3)H_2O$, liberating CH_3COOH. The structure of complex **3** revealed that the N_2O_2-donor sets of the two ligand fragments form a *trans*-distorted square planar configuration. Complex **3** shows binding with the helix of CT-DNA by intercalation.

5. Supplementary data

CCDC 706265 contains the supplementary crystallographic data for complex **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

A novel hydrazide-based mesogenic (*nematic*) Schiff-base, 4-hydroxy-*N*′-(4′-octadecyloxybenzylidene)benzohydrazide, (Hhodbbh) (abbreviated as HL^3), was prepared and its structure studied by elemental analyses, mass, NMR and IR spectra and single crystal XRD (triclinic space group $P\bar{1}$ with $Z = 2$) techniques. The Schiff-base behaves as a non-deprotonated bi-dentate species in its metal complexes of the general formula, $[M(HL^3)_2](OAc)_2$ [M = Mn, Co, Ni, Cu and Zn]. The IR and NMR spectral data imply bonding of HL^3 species through amidic oxygen and azomethine nitrogen atoms. The Mn^{II} and Co^{II} complexes show gradual decrease in the $\chi_M T$ product with lowering of temperature and negative Weiss constants characteristic of anti-ferromagnetic interaction. The Mn^{II} complex shows magnetic hysteresis loops at 2.0 K.

1. Introduction

Schiff-bases [1,2] play an important role in inorganic chemistry as they easily form stable complexes with most transition metal ions. The acid hydrazides, hydrazine derivatives and its metal complexes are known to exhibit a broad spectrum of biological, bactericidal and fungicidal activities and have great interest due to their analytical, industrial and pharmacological importance [3–5]. The chemistry of hydrazine derivatives has been investigated intensively in the last decade owing to their coordinative [3–5] and pharmacological activity [3–5] as well as their use in analytical chemistry as metal-extracting agents [5]. As a part of our investigation [6–10] on structural and spectroscopic studies of 3d metal complexes of a series of mesogenic organic Schiff-bases, we report here, the results of our investigations on synthesis, spectroscopic studies and crystal structure on a hydrazide-based mesogenic Schiff-base, 4-hydroxy-*N*′-(4′-octadecyloxybenzylidene)benzo-hydrazide (HL^3) and the corresponding 3d metal complexes.

2. Experimental

2.1. Starting materials

All reagents were purchased from commercial sources and used as received; 1-bromooctadecane, 4-hydroxybenzaldehyde and 4-hydroxybenzoic acid hydrazide are from Sigma–Aldrich, USA; all metal acetates and KOH are from Merck. The solvents received were dried using standard methods [11] when required.

2.2. Instrumentation

The ^{1}H NMR spectrum was recorded on a JEOL AL-300 MHz FT-NMR multinuclear spectrometer; C, H and N contents were microanalysed on an Elemental Vario EL III Carlo Erba 1108 analyser. Infrared spectra were recorded on a JASCO FT/IR (model-5300) spectrophotometer in the 4000–400 cm^{-1} region. The mass spectra were recorded on a JEOL SX-102 (EI/FAB) mass spectrometers. The UV–Vis spectra were recorded on a Shimadzu spectrophotometer, model, Pharmaspec, UV 1700. Magnetic susceptibility measurements were made at low temperature on a Quantum Design SQUID-based MPMSXL-5 type magnetometer. Single crystal X-ray data was collected at room temperature using a Bruker Smart Apex CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) with ω method.

2.3. X-ray crystallographic data collection and refinement of the structure

X-ray data for the compound **HL^3** ***[aa85]*** was collected at room temperature. Preliminary lattice parameters and orientation matrices were obtained from four sets of frames. Unit cell dimensions were determined from the setting angles of 2854 reflections in the range of $2.43° < \theta < 23.79°$. Integration and scaling of intensity data was accomplished using the SAINT program [12]. The structure was solved by direct methods using SHELXS97 [13] and refinement was carried out by full-matrix least-squares technique using SHELXL97 [13]. Anisotropic displacement parameters were included for all non-hydrogen atoms. The N-bound H atom and O-bound H atom were located in a difference Fourier map and their positions and isotropic parameters were refined. All other hydrogen atoms were positioned geometrically and treated as riding atoms, with C–H distances in the range of 0.93–0.97 Å and with U_{iso}(H) values of $1.5U_{eq}$(C) for methyl hydrogen and $1.2U_{eq}$(C) for other hydrogen atoms.

2.4. Variable temperature magnetic susceptibility measurements

The magnetisation of the powdered samples was measured over the temperature range 1.8–300 K. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T and the sample measurements were made at a magnetic field 0.5 T as well as at the weak magnetic field of 25 and 50 Oe. The SQUID magnetometer was calibrated with a palladium rod sample. Corrections were based on subtracting the sample holder signal and the contribution χ_D [-862.6×10^{-6} cm^3 mol^{-1} for the Mn^{II} complex and -815.94×10^{-6} cm^3 mol^{-1} for the Co^{II} complex] was estimated using Pascal constants. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$ (B.M.).

2.5. Synthesis and analysis

The synthesis of 4-hydroxy-*N*′-(4-(octadecyloxy)benzylidene)benzohydrazide (HL^3) (**2**) was achieved by proceeding through two major steps, *viz*., alkylation of 4-hydroxy benzaldehyde with *n*-octadecyl bromide, followed by Schiff-base formation. All the experimental details are given in Scheme 1.

[M(HL^3)$_2$(MeOH)$_n$](OAc)$_2$ (M = Mn, Co, Ni, Cu and Zn; *n* = 0 or 2) complexes were prepared by refluxing together hot dry chloroform solutions of the ligand, HL^3, (1.02 g, 2.0 mmol, in 30 mL) and the appropriate metal acetate (1.0 mmol, in 20 mL) for ~2 h at 70 °C. The solid complex that separated out in each case was filtered under suction and washed repeatedly with ethanol and dried over fused $CaCl_2$ in a desiccator.

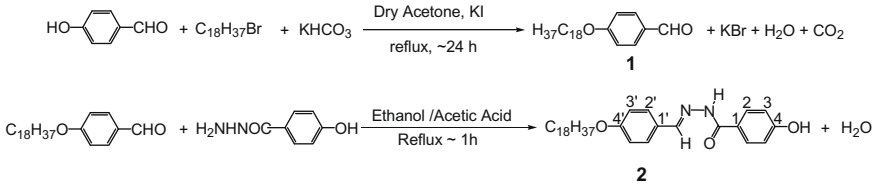
2.5.1. Preparation of 4-octadecyloxybenzaldehyde (**1**)

Equimolar amounts of 1-bromo octadecane (30 mmol, 10.25 g), 4-hydroxy benzaldehyde (3.66 g, 30 mmol) and potassium bicarbonate (3.00 g, 30 mmol) were suspended in 200 mL of dried acetone and refluxed for ~24 h in presence of KI (0.1–0.2 g) as catalyst and filtered while hot to remove the insoluble solids, neutralised with dil. 6 N HCl and extracted twice with $CHCl_3$. The chloroform extracts were concentrated to obtain a purple solid which, in turn, was purified by column chromatography over SiO_2 (by eluting with a mixture of *n*-hexane and chloroform (v/v, 1/1)); evaporation of this purified extract finally yielded 4-octadecyloxybenzaldehyde in the form of a white solid; yield: 82% (9.20 g).

2.5.2. Synthesis of 4-hydroxy-*N*′-(4′-octadecyloxybenzylidene)benzohydrazide, HL^3 (**2**)

The ligand, 4-hydroxy-*N*′-(4-(octadecyloxybenzylidene)benzohydrazide was prepared by refluxing together absolute ethanolic solutions of 4-octadecyloxybenzaldehyde (14.96 g, 40 mmol in 100 mL) and 4-hydroxybenzoic acid hydrazide (6.08 g, 40 mmol, in 50 mL) for ~1 h in presence of few drops of acetic acid and leaving the solution over night in the flask closed with guard tube. The micro-crystalline cream coloured product was filtered off by suction, thoroughly washed with cold ethanol and recrystallised from a mixture of absolute ethanol and chloroform (1:2 v/v) and dried at room temperature; yield 13.34 g (85%) as a cream coloured solid; m.p. 200 °C. ^{1}H NMR (300 MHz; DMSO-*d*^{6}; Me_4Si at 25 °C, *J* (Hz), ppm) δ = 0.854 (t, $^3J_{H-H}$ = 6.9, 3H, –CH_3), 1.745–1.422 (m, 32H, –CH_2), 4.012 (t, $^3J_{H-H}$ = 6.9, 2H, –OCH_2), 6.845 (d, $^3J_{H-H}$ = 8.4, 1H, –$C_{3'}H/C_{5'}H$), 6.980 (d, $^3J_{H-H}$ = 7.8, 1H, –C_2H/C_6H), 7.614 (d, $^3J_{H-H}$ = 8.4,1H, –$C_{2'}H$), 7.784 (d, $^3J_{H-H}$ = 8.4,1H, –$C_3H/-C_5H$), 8.571 (s, 1H, –NCH), 9.944(s, 1H, –NH), 11.351 (br s, 1H, –OH); FAB Mass (*m*/*z*): 154 ((HO)C_6H_4CO–NH–NH_3^+, 20), 121((HO)$C_6H_4CO^+$, 45); IR(KBr, cm^{-1}): 3439_{br} ν(O–H)$_{phenol}$, 3250_s ν_s(N–H)$_{amide}$, 1647_s ν(>C=O)$_{amide-I}$, 1510 ν(N–H)$_{amide-II}$, 1606_w ν(C=N), 1249s ν(C–O)$_{phenol}$; *Anal.* Calc. for $C_{32}H_{48}N_2O_3$(508.74): C, 75.60; H, 9.45; N_2H_4, 6.30; N, 5.50. Found: C, 75.56; H, 9.37; N_2H_4, 6.27; N, 5.47%.

2.5.3. Synthesis of [Mn(HL^3)$_2$](OAc)$_2$



Yield 1.10 g (85%) as a brown coloured solid; m.p. 220 °C (decompose). FAB Mass (*m*/*z*): 1074 ([Mn(HL^3)$_2$]$^+$, 100), 121 ((HO)$C_6H_4CO^+$, 35); IR(KBr, cm^{-1}): 3443_{br} ν(O–H)$_{phenol}$, 3246_s ν_s(N–H)$_{amide}$, 1629_s ν(>C=O)$_{amide-I}$, 1507 ν(N–H)$_{amide-II}$, 1610s ν(ionic acetate), 1367_w ν(ionic acetate), 1552_w ν(C=N), 1244_s ν(C–O)$_{phenol}$; 479s ν(Mn–N), 449s ν(Mn–O). *Anal.* Calc. for $MnC_{68}H_{102}N_4O_{10}$ (1190.50): C, 68.60; N, 4.71; N_2H_4, 5.37; Mn, 4.61. Found: C, 68.22; N, 4.73; N_2H_4, 5.35; Mn, 4.57%.

2.5.4. Synthesis of [Co(HL^3)$_2$](OAc)$_2$

Yield 0.84 g (70%) as a cream coloured solid; m.p. 225 °C (decompose). IR(KBr, cm^{-1}): 3443_{br} ν(O–H)$_{phenol}$, 3242_s ν_s(N–H)$_{amide}$, 1633_s ν(>C=O)$_{amide-I}$, 1604_s ν(ionic acetate), 1370_w ν(ionic acetate), 1501 ν(N–H)$_{amide-II}$, 1572w ν(C=N), 1241s ν(C–O)$_{phenol}$; 475s ν(Co–N), 458s ν(Co–O); *Anal.* Calc. $CoC_{68}H_{102}N_4O_{10}$ (1194.49): C, 68.37; N, 4.69; N_2H_4, 2.68; Co, 4.93. Found: C, 68.39; N, 4.64; N_2H_4, 2.65; Co, 4.90%.

2.5.5. Synthesis of [Ni(HL^3)$_2$](OAc)$_2$

Yield 0.94 g (79%) as an orange coloured solid; m.p. 250 °C. ^{1}H NMR (300 MHz; DMSO-*d*^{6}; Me_4Si at 25 °C, *J* (Hz), ppm) δ = 0.863 (t, $^3J_{H-H}$ = 6.3, 3H, –CH_3), 1.780–1.260 (m, 32H, –CH_2), 4.031 (t, $^3J_{H-H}$ = 6.0, 2H, –OCH_2), 6.857 (d, 1H, –$C_{3'}H/C_{5'}H$), 6.990 (d, 1H,

Scheme 1. Reaction steps involved in the synthesis of 4-*octadecyloxy benzaldehyde* (**1**) and 4-hydroxy-*N*′-(4-(octadecyloxy)benzylidene)benzohydrazide (**2**) (HL^3).

–C_2H/C_6H), 7.790 (d, 1H, –C_3H/–C_5H), 8.228 (s, 1H, –NCH), 9.618 (s, 1H, –NH), 11.230 (br s, 1H, –OH); FAB Mass (*m*/*z*): 1074 ($[Ni(HL^3)_2]^+$, 30), 509 ($[HL^3]^+$, 35), 154 ($(HO)C_6H_4CO–NH–NH_3^+$, 100), 121($(HO)C_6H_4CO^+$, 40); IR(KBr, cm^{-1}): 3440_{br} ν(O–H)$_{phenol}$, 3245_s ν_s(N–H)$_{amide}$, 1631_s ν(>C=O)$_{amide\text{-}I}$, 1597_s ν(ionic acetate), 1369_w ν(ionic acetate), 1501 ν(N–H)$_{amide\text{-}II}$, 1562w ν(C=N), 1250s ν(C–O)$_{phenol}$; 478s ν(Ni–N), 451s ν(Ni–O); *Anal.* Calc. for $NiC_{68}H_{102}N_4O_{10}$ (1194.25): C, 68.39; N, 4.69; N_2H_4, 2.68; Ni, 4.91. Found: C, 68.36; N 4.65; N_2H_4, 2.65; Ni, 4.88%.

2.5.6. Synthesis of $[Cu(HL^3)_2](OAc)_2$

Yield 0.86 g (72%) as a yellowish-green solid; m.p. 270 °C (decompose). FAB Mass (*m*/*z*): 1081 ($[Cu(HL^3)_2]^+$, 75), 571 ($[Cu(HL^3)$, 100), 121($(HO)C_6H_4CO^+$, 50). IR(KBr, cm^{-1}): 3438_{br} ν(O–H)$_{phenol}$, 3246_s ν_s(N–H)$_{amide}$, 1634_s ν(>C=O)$_{amide\text{-}I}$, 1498 ν(N–H)$_{amide\text{-}II}$, 1604_s ν(ionic acetate), 1375_w ν(ionic acetate), 1575w ν(C=N), 1246s ν(C–O)$_{phenol}$; 485s ν(Cu–N), 455s ν(Cu–O); *Anal.* Calc. $CuC_{68}H_{102}N_4O_{10}$ (1199.70): C, 68.11; N, 4.67; N_2H_4, 2.67; Cu, 5.30. Found: C, 68.14; N 4.65; N_2H_4, 2.65; Cu, 5.28%.

2.5.7. Synthesis of $[Zn(HL^3)_2(MeOH)_2](OAc)_2$

Yield 13.34 g (70%) as a cream coloured solid; m.p. 200 °C. ^1H NMR (300 MHz; DMSO-d^6; Me_4Si at 35 °C, *J* (Hz), ppm) δ = 0.861 (t, $^3J_{H-H}$ = 6.9, 3H, –CH_3), 1.745–1.422 (m, 32H, –CH_2), 4.012 (t, $^3J_{H-H}$ = 6.9, 2H, –OCH_2), 6.845 (d, $^3J_{H-H}$ = 8.4, 1H, –C_3·H/C_5·H), 6.980 (d, $^3J_{H-H}$ = 7.8, 1H, –C_2H/C_6H), 7.614 (d, $^3J_{H-H}$ = 8.4,1H, –C_2·H), 7.784 (d, $^3J_{H-H}$ = 8.4,1H, –C_3H/–C_5H), 8.561 (s, 1H, –NCH), 9.898(s, 1H, –NH), 11.351 (br, 1H, –OH); FAB Mass (*m*/*z*): 1147 ($[Zn(HL^3)_2(MeOH)_2]^+$, 85), 1079 ($[Zn(HL^3)_2]^+$, 67), 121($(HO)C_6H_4$-CO^+, 49); IR(KBr, cm^{-1}): 3446_{br} ν(O–H)$_{phenol/MeOH}$, 3242_s ν_s(N–H)$_{amide}$, 1629_s ν(>C=O)$_{amide\text{-}I}$, 1501 ν(N–H)$_{amide\text{-}II}$, 1608_s ν(ionic acetate), 1367_w ν(ionic acetate), 1582w ν(C=N), 1244s ν(C–O)$_{phenol}$; 481s ν(Zn–N), 452s ν(Zn–O); *Anal.* Calc. for $ZnC_{70}H_{110}N_4O_{12}$ (1265.03): C, 66.46; N, 4.43; N_2H_4, 2.53; Zn, 5.17. Found: C, 66.48; N 4.47; N_2H_4, 2.50; Zn, 5.14%.

3. Results and discussion

3.1. Magnetic and spectral investigation

The cream coloured Schiff-base ligand (HL^3), **2**, is soluble in hot chloroform, DMSO, DMF and pyridine but insoluble in water, methanol, ethanol and acetonitrile; the orange-coloured Ni^{II} complex, $[Ni(HL^3)_2](OAc)_2$ is soluble in chloroform, and hot DMSO and DMF; $[Zn(HL^3)_2(MeOH)_2](OAc)_2$ is soluble in only hot/cold DMSO; all other complexes are soluble in pyridine. The electrical conductivity values measured in saturated DMSO solutions (concentration < 10^{-3} M) of the complexes (102–109 ohm^{-1} cm^2/mol) imply their ionic nature [14]. The Schiff-base as well as $[Ni(HL^3)_2](OAc)_2$ showed a *nematic* mesophase under a polarising microscope while none of the other metal complexes under present study were found to show any mesogenic behaviour. The structures and purity of the parent ligand and of the complexes were checked and confirmed by elemental analyses and IR, ^1H NMR and FAB mass spectra.

The colour and electronic spectral data of the present complexes are included in Table 1. The overall geometry around the metal ion has been assigned (Table 1) on the basis of the nature of the electronic spectra, the denticity of the ligand (*vide*. IR and NMR data) and the number of the ligands coordinated to the metal ion (*vide* elemental analyses) within the coordination sphere. The Mn^{II} complex gives rise to extremely weak bands in the electronic spectrum presumably in an octahedral environment (square-planar units polymerically connected with M–M bonding). The cream-coloured complex, $[Co(HL^3)_2](OAc)_2$, may be understood to have a square pyramidal geometry with M–M bonding [15] based on the electronic spectral transition, $^4E_g(T_{2g}(F)) \leftarrow {}^4E_g(T_{1g}(F))$. The electronic spectrum of the orange-coloured Ni^{II} complex shows a single transition at 407 nm which can be assigned to the transition, $^1B_{1g} \leftarrow {}^1A_{1g}$, in a square-planar environment of the metal ion [16]; the colour (orange) of the complex and its diamagnetic nature corroborate the proposed geometry [17]. The spectral features of the yellowish-green coloured complex, $[Cu(HL^3)_2](OAc)_2$, imply square pyramidal geometry (with M–M bonding) owing to the transition, $x^2 - y^2 \leftarrow xz, yz$ arising at 677 nm [16].

In the IR spectrum of HL^3 the broad absorptions centred at 3439 and 3250 cm^{-1} may be assigned to the ν(O–H)$_{phenolic}$ and ν_s(N–H)$_{amide}$ vibrations [18]; further, the strong bands occurring at 1647 and 1510 cm^{-1} may be assigned [18] to ν(>C=O)$_{amide\text{-}I}$ and ν(N–H)$_{amide\text{-}II}$ modes of the amide moiety and the band at 1606 cm^{-1} may be assigned to ν(C=N) absorption of the azomethine moiety; these bands are shifted to lower frequencies in the complexes indicating coordination through the O and N atoms of

the carbonyl and azomethine groups, respectively [19]; such coordination is further substantiated by the appearance of new bands in the complexes characteristic of ν(M–O) and ν(M–N) in the 449–458 and 475–485 cm^{-1} regions, respectively [20–22].

A comparison of the ^1H NMR spectral data of the ligand with those of the Ni^{II} and Zn^{II} complexes shows that (i) the phenolic-O*H* signal remains almost unaltered in the spectra (11.351, 11.230 and 11.351 ppm for the ligand and the complexes, respectively) and (ii) there is a significant shift in the peak positions of the –N=C*H* (from 8.571 of the ligand to 8.228 and 8.561 ppm) and –N–*H* signals (from 9.944 of the ligand to 9.618 and 9.898 ppm) in the spectra of the Ni^{II} and Zn^{II} complexes, respectively. These results imply bonding through the amidic oxygen and the azomethine nitrogen atoms of the ligand to the metal ions.

3.2. Crystal structure and molecular association

The ligand $\mathbf{HL^3}$ ***[aa85]*** crystallised in the triclinic space group, *viz*., $P\bar{1}$ with $Z=2$, respectively. The crystal data and structure refinement details for HL^3 are given in Table 2. The molecular structure, atomic labelling scheme and the packing diagrams of the ligand are as shown in Figs. 1 and 2. The details of the hydrogen-bonded geometry of HL^3 are tabulated in Table 3. The crystal structure of HL^3 is stabilised by both intra- and intermolecular O(2)-H(2A)···N(3) and N(1)–H(1N)···O(3) hydrogen bond interactions. One pyridine molecule is linked through O(2)–H(2A)···N(3) hydrogen bonds, thereby forming infinite hydrogen bonded network chain.

3.3. Variable temperature magnetic susceptibility measurements

The magnetic properties of Mn^{II} and Co^{II} complexes were determined over the temperature range, 1.8–300 K. Plots of magnetic susceptibility χ_M and $\chi_M T$ product versus T are given in Fig. 3. The experimental $\chi_M T$ values for Mn^{II} and Co^{II} complexes at room temperature are 2.52 $cm^3\,mol^{-1}\,K$ (4.50 B.M.) and 3.31 $cm^3\,mol^{-1}\,K$ (5.15 B.M.), respectively, while the corresponding values for isolated, not coupled spin carriers are 4.375 B.M. for Mn^{II} and 1.87 B.M. for Co^{II} ions. The $\chi_M T$ product undergoes minima and maxima with decrease of temperature in both the complexes; the values corresponding to the minima are

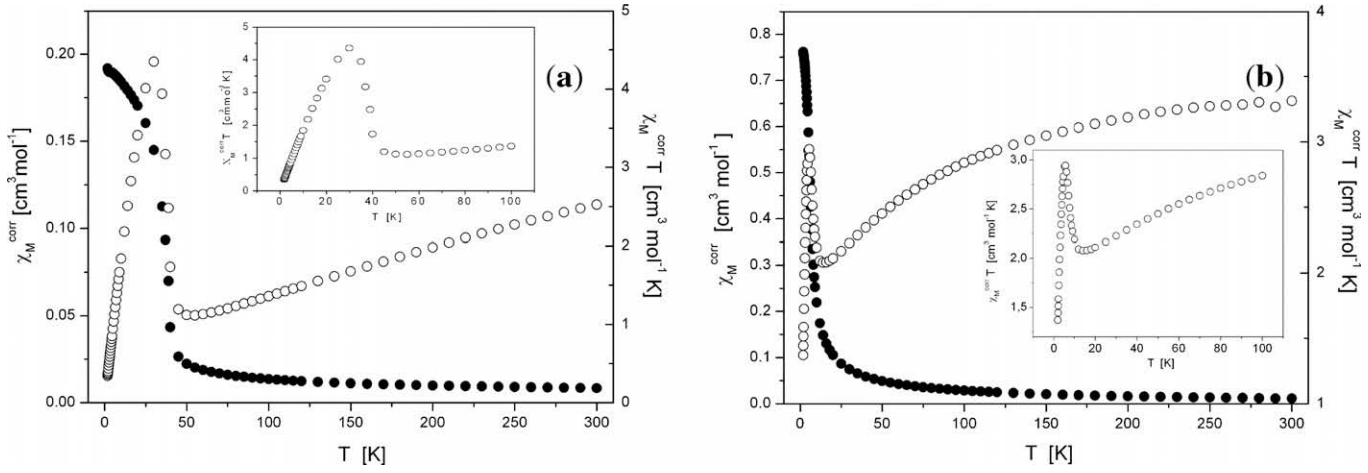

Fig. 3. Temperature dependence of χ_M(●) and $\chi_M T$ (○) versus T for Mn^{II} complex, and (b) Co^{II} complex.

1.11 $cm^3\ mol^{-1}\ K$ (2.99 B.M.) at 55 K in case Mn^{II} complex and 2.07 $cm^3\ mol^{-1}\ K$ (4.08 B.M.) at 14 K in the case of the Co^{II} complex while those of the maxima are 4.34 $cm^3\ mol^{-1}\ K$ (5.90 B.M.) at 30 K in the former complex and 2.94 $cm^3\ mol^{-1}\ K$ (4.86 B.M.) at 5.5 K in the latter. Following the maxima, the $\chi_M T$ values decrease with temperature up to 1.8 K to reach a minimum of 0.345 $cm^3\ mol^{-1}\ K$ (1.66 B.M.) in case of the Mn^{II} complex and 1.37 $cm^3\ mol^{-1}\ K$ (3.31 B.M.) in the Co^{II} complex.

Thus, the decrease of $\chi_M T$ value in the high-temperature region can be attributed to spin–orbit coupling effects [23] and/or anti-

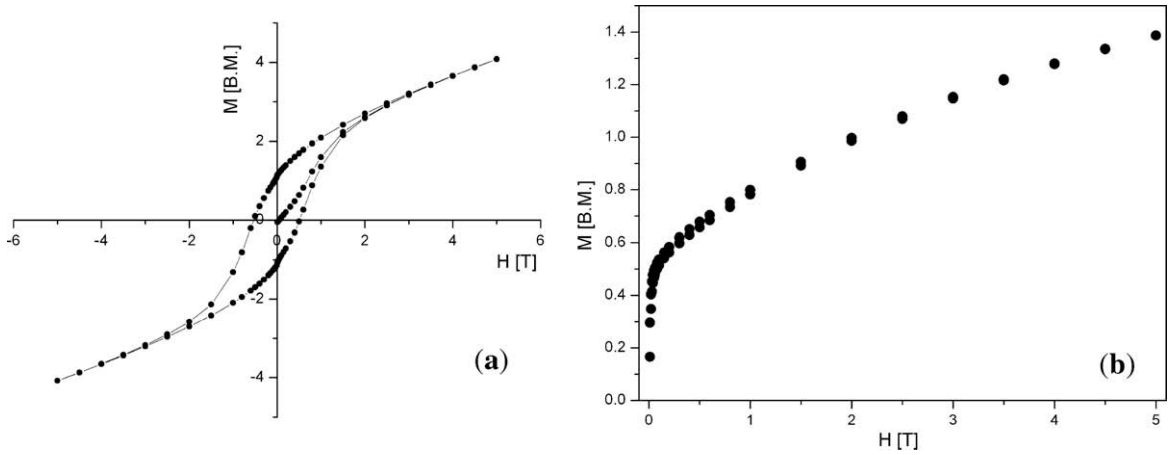

Fig. 4. Field dependence of the magnetisation at temperature 2 K for Mn^{II} complex (hysteresis loop) and (b) Co^{II} complex.

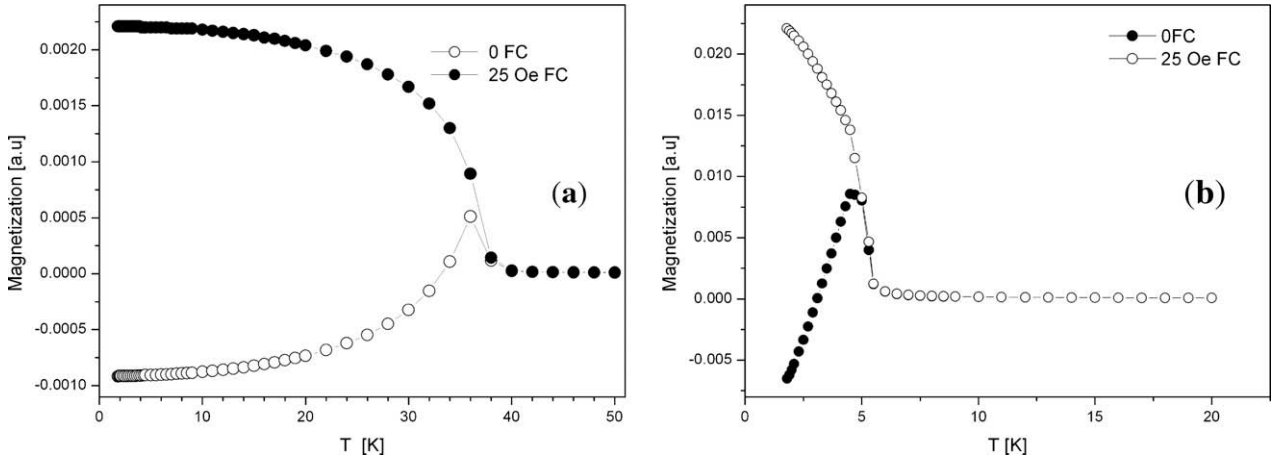

Fig. 5. Temperature dependence of magnetisation versus field (zero-field cooled and at 25 Oe field cooled versus T) for (a) Mn^{II} complex, and (b) Co^{II} complex.

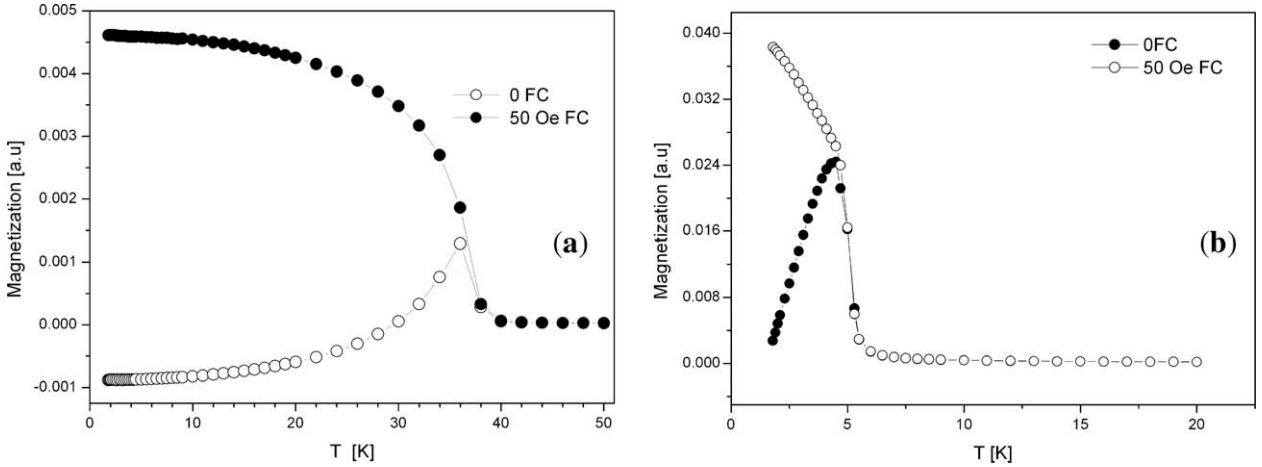

Fig. 6. Temperature dependence of magnetisation versus field (zero-field cooled and at 50 Oe field cooled versus *T*) for (a) Mn^{II} complex, and (b) Co^{II} complex.

ferromagnetic interactions, while the increase of $\chi_M T$ value in the low-temperature region is indicative of a weak ferromagnetic interaction between the two high-spin Mn^{II}/Co^{II} species [23]. Further, the data on the susceptibility values at Curie temperature and the Weiss constants (5.18 $cm^3 mol^{-1} K$, −321 K and 3.59 $cm^3 mol^{-1} K$ and −25.8 K for Mn^{II} and Co^{II} complexes) over the temperature range 150–300 K are consistent with the negative values of the Weiss constants implying presence of anti-ferromagnetic interactions in both the complexes at higher temperature range [24].

The variation of the magnetisation M versus magnetic field H at 2 K for the complexes is shown in Fig. 4; the ferromagnetic nature of the transition in the Mn^{II} complex is implied by the magnetic hysteresis loops at 2.0 K (Fig. 4a) (where the value of coercive field (H_c) = 0.5 T, the remnant magnetisation (M_r) = 1.02 B.M. and the upper limit of magnetisation is 4.08 B.M. at 5 T) which are characteristic of soft magnets [23]. In contrast, the corresponding curve of the Co^{II} complex is linear in the whole field range showing the magnetisation value of 1.38 B.M. at 5 T which is clearly smaller than the sum of two $S_{Co} = 3/2$ states of each Co^{II} ion but is consistent with the calculated one for two Co^{II} ions with an effective $S_{Co} = S_{eff} = 1/2$ state owing to the formation of ground Kramer′s doublet [23] due to the spin–orbit coupling interaction for each Co^{II} ion populated at 2.0 K. The ferromagnetic interaction of both the complexes in the low temperature range is further revealed by the temperature dependence of the field-cooled (FC) and the zero-field cooled (ZFC) magnetisation curves (Figs. 5 and 6). The FC curves, measured by cooling the samples within small fields of 25 and 50 Oe, increase sharply below the point of intersection with ZFC curve (40 ± 0.1 K in case of the Mn^{II} complex and 5 ± 0.1 K in case of the Co^{II} complex) and then saturate around 10.0 K in the case of the former.

4. Conclusions

The mesogenic (*nematic*) Schiff-base, 4-hydroxy-*N*′-(4′-octadecyloxybenzylidene)benzohydrazide, (HL^3) coordinates as a neutral bi-dentate species through amidic oxygen and azomethine nitrogen atoms to yield non-mesogenic complexes of the type, $[M(HL^3)_2](OAc)_2$, (M = Mn, Co, Cu and Zn) and a mesogenic Ni^{II} complex. The Mn^{II} and Co^{II} complexes show anti-ferromagnetic interaction and a weak ferromagnetic coupling at lower temperatures; further, the former complex shows magnetic hysteresis loops at 2.0 K.

Supplementary data

CCDC 685719 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Treatment of a *N*-arylanilido-imine ligand [*ortho*-$C_6H_4(NHAr)CH{=}N]_2CH_2CH_2$ (Ar = 2,6-$Me_2C_6H_3$) (**L**H_2) with one equiv. of $AlMe_3$ affords a monometallic complex [$C_6H_4(NHAr)$–CH=N)]$CH_2CH_2(C_6H_4(NAr)CH{=}NAlMe_2)$ (**1**). The monometallic complex **1** reacts with one equiv. of $ZnEt_2$ to give a heterobimetallic complex [$C_6H_4(NAr)$–CH=NZnEt]$CH_2CH_2[C_6H_4(NAr)$–CH=$NAlMe_2]$ (**2**). Both complexes were characterized by ^1H and ^{13}C NMR spectroscopy and elemental analyses, and the molecular structures of **1** and **2** were determined by X-ray diffraction analysis. The complexes **1** and **2** both are efficient catalysts for ring-opening polymerization of ε-caprolactone in the presence of benzyl alcohol yielding polymers with narrow polydispersity values and complex **2** initiates the polymerization in a controllable manner.

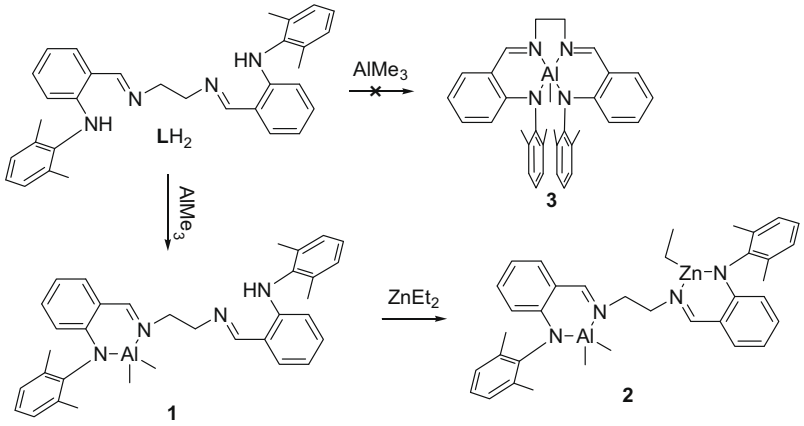
1. Introduction

In recent years, considerable efforts have been made to develop efficient catalysts for the ring-opening polymerization (ROP) of ε-caprolactone (CL), which has been a powerful tool for the synthesis of polyesters with controlled molecular weight and narrow molecular weight distribution [1–3]. So far, catalysts based on various metals such as magnesium [4–6], calcium [7,8], aluminium [9–16], titanium [17–20], iron [21,22], zinc [23–28], tin [29–31], and rare earth metal [32–35] have been reported. Among the reported catalysts, bimetallic complexes are relatively few. In some catalytic systems, bimetallic catalysts have been found to show cooperative effect and high catalytic activity. Coates and co-workers have suggested that the copolymerization of cyclohexene oxide/CO_2 by β-diketiminato Zn complexes takes place via a bimetallic Zn mechanism [36]. Lee et al. have also disclosed that the bimetallic anilido-imine zinc complexes show high activity for the copolymerization of cyclohexene oxide/CO_2 [37,38]. Recently we have reported several bimetallic anilido-imine Al or Zn complexes for the ROP of CL in the presence of BnOH [39]. To explore the cooperative effect of the metal centres, we have synthesized a new heterobimetallic complex containing Al and Zn metals with a ethylene bridged *N*-arylanilido-imine ligand. To the best of our knowledge, no heterobimetallic complex containing $AlMe_2$ and ZnEt groups has been reported so far. In the presence of BnOH, both complexes **1** and **2** were found to be efficient catalysts for the ROP of CL to give PCL, and the heterobimetallic complex **2** shows much higher catalytic activity in comparison to the monometallic complex **1**. Herein we report the synthesis and structure of the new monometallic aluminium complex [*o*-$C_6H_4(NHAr)CH{=}N]CH_2CH_2$ [*o*-$C_6H_4(NAr)CH{=}NAlMe_2$] (Ar = 2,6-$Me_2C_6H_3$) (**1**) and heterobimetallic Al/Zn complex [*o*-$C_6H_4(NAr)CH{=}NZnEt]CH_2CH_2[o$-$C_6H_4(NAr)$–CH=$NAlMe_2$] (**2**) as well as their catalytic property for the ROP of CL in the presence of BnOH.



2. Results and discussion

2.1. Synthesis and characterization of complexes 1 and 2

The free *N*-arylanilido-imine ligand [*ortho*-$C_6H_4(NHAr)CH{=}N]_2CH_2CH_2$ (Ar = 2,6-$Me_2C_6H_3$) (**L**H_2) was synthesized according to the literature procedure [39]. The complexes **1**, **2** were synthesized as described in Scheme 1. Both complexes **1**, **2** were obtained in high yields in toluene by alkane elimination reaction. Reaction of the free ligand **L**H_2 with one equiv. of $AlMe_3$ did not give the expected pentacoordinate complex **3** even when the reaction mixture was heated to reflux for several days. However, pentacoordinate aluminium complexes supported by various tetracoordinate ligands were synthesized successfully [40,41]. The tetracoordinate complex **1** was instead obtained probably due to either the low reactivity of NH or the bulky substitutes of the ligand. Complex **1** was characterized by ^1H and ^{13}C NMR spectroscopy and elemental analyses. The ^1H NMR spectrum of **1** exhibits resonances at δ 8.06 and 8.45 for the two different imino N=CH protons, at δ 10.28 in the low field region for the unreacted NH proton, and at δ −0.84 in the high field region for $AlMe_2$ protons. The ^1H NMR analysis

Scheme 1. Synthetic procedure of complexes **1** and **2**.

demonstrates that only one of the two NH groups in the free ligand $\mathbf{L}H_2$ has reacted with $AlMe_3$ in the reaction. The heterobimetallic complex **2** was then prepared by the reaction of complex **1** with one equiv. of $ZnEt_2$ in toluene with heating at 80 °C for 12 h. The disappearance of the NH signal in complex **1** and the appearance of resonance for ZnEt protons in the high field region demonstrate the formation of the desired complex **2**.

2.2. X-ray crystal structural analysis

Crystals of complexes **1** and **2** suitable for X-ray crystal structure determination were grown from the mixture of CH_2Cl_2/hexane at −20 °C. Their molecular structures are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles for **1** and **2** are given in Table 1. X-ray crystallographic analysis reveals that the Al centres in both complexes **1** and **2** adopt a distorted tetrahedral geometry and the Zn centre in complex **2** adopts a trigonal planar geometry. The Al and Zn centres in the two complexes are chelated by the imine and anilido nitrogen atoms of the bidentate ligand. In both complexes, the six-membered chelating ring is nearly planar, with the metal atom lying 0.1794 Å for **1**, 0.0199 Å (Al) and 0.0667 Å (Zn) for **2** out of the plane, respectively. The X-ray crystal structural analysis confirms the structure of complex **1** that contains only one aluminium centre and half of the ligand remains unreacted. The structural parameters of complex **1** are similar to those reported for related Al complexes with anilido-imine ligands [39,42], such as the Al–N distances and the torsion angles between

[d] Obtained from GPC analysis.

(1.864(6) Å) that is obviously shorter than normal Al–N values (1.870–1.963 Å) [39,42], and the imino C=N bond within the chelate ring does not retain its double bond character, being N(2)–C(7) 1.310(8) Å. These results, together with the fact that this six-membered chelating ring is nearly planar with the Al atom lying almost in the plane, imply better conjugation in this chelating ring. The N(1)–Al–N(2) angle (97.0(3)°) in complex **2** is bigger than that in complex **1** (95.0(8)°), while the C(16)–Al–C(17) angle (109.6(3)°) in complex **2** is smaller than the one in complex **1** (114.8(2)°). The structural parameters around the Zn centre in complex **2** are similar to those reported for related Zn complexes with anilido-imine ligands [39,43].

2.3. Ring-opening polymerization of ε-caprolactone

Complexes **1** and **2** were systematically investigated for the ROP of CL. Representative experimental results are summarized in Table 2. Both complexes show reasonable to good catalytic activities for the ROP of CL in the presence of BnOH, while no polymerization reaction takes place in the absence of BnOH (entries 1, 2). Under similar conditions, the catalytic activity of complex **2**/BnOH system is much higher than that of complex **1**/BnOH system. In comparison to the known catalyst systems, the catalytic activity of complex **1**/BnOH system is also lower than those of similar monometallic and bimetallic Al and Zn catalyst/BnOH systems, while the catalytic activity of complex **2**/BnOH system is higher than those of similar bimetallic Al catalyst/BnOH systems but lower than those of similar bimetallic Zn catalyst/BnOH systems [39]. These results imply that the catalytic activity of the Zn centre is much higher than the Al centre in **2**/BnOH catalyst system, which is in agreement with that the bond dissociation energy of Zn–O (284 kJ/mol) is much lower than that of Al–O (512 kJ/mol) [44]. The catalytic activity of the two catalyst systems is also dependent on the reaction temperature and increases upon elevating the reaction temperature from 20 to 70 °C.

The amount of BnOH has been found to be an important factor for affecting the catalytic activity of the catalyst system and controlling the molecular weight of the produced PCL [39,45]. In the present catalyst systems, the highest catalytic activity was observed with the BnOH/Al molar ratio being 1/1 for **1**/BnOH system, and the BnOH/metal molar ratio being about 2/2 for **2**/BnOH system. The reason why the BnOH/Al molar ratio of 1/1, instead of 2/1, for **1**/BnOH system shows the highest catalytic activity is not clear. For **1**/BnOH catalyst systems, the average degree of polymerization (DPn) of the obtained polymers (calculated by ^{1}H NMR) is close to the initial CL/BnOH molar ratio, and the number-averaged molecular weight (*M*n) of the polymers determined by gel permeation chromatography is proportional to the initial CL/BnOH molar ratio. Similar results have previously been reported for other initiator systems [45,46], which have been described as "immortal" polymerization. However, the DPn of the obtained polymers from **2**/BnOH catalyst system is obviously close to the CL/Zn molar ratio and the *M*n of the polymers is largely proportional to the CL/Zn molar ratio. A linear relationship between the *M*n and the CL/Zn molar ratio obtained from **2**/BnOH catalyst system is shown in Fig. 3, which is also indicative of "living" character of the polymerization process. Gel permeation chromatography (GPC) analysis of the obtained polymer samples indicates that the molecular weight distribution of the polymers produced by both catalyst systems is relatively narrow with the polydispersity indexes (PDI) ranging from 1.10 to 1.78. Based on these results, it seems that the Zn centre in **2**/BnOH catalyst system plays a major role in the catalyzed polymerization reaction while the polymerization occuring at the Al centre might be too slow to be taken into account.

^{1}H NMR spectroscopic analysis on the PCL samples shows that the polymer chain is capped with a benzyl ester group on one end and a hydroxylmethyl group on the other end. The ^{1}H NMR spectrum of a typical polymer sample is shown in Fig. 4, in which the

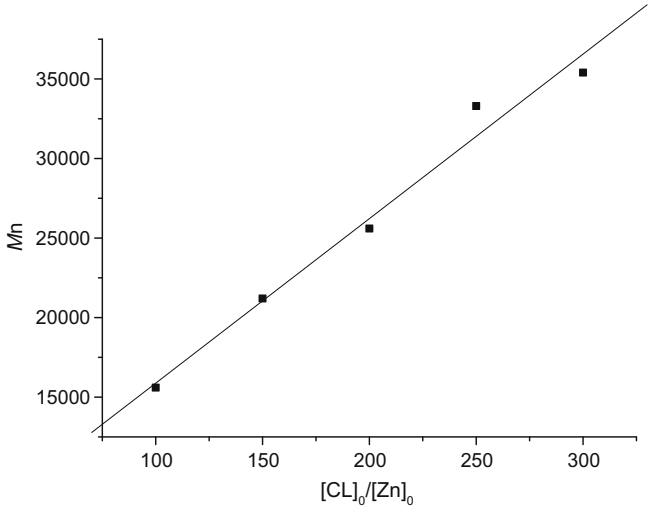

Fig. 3. The relationship between *M*n of the polymer and the initial mole ratio $[CL]_0/[Zn]_0$ for the polymerization of CL catalyzed by **2** and BnOH in toluene at 70 °C.

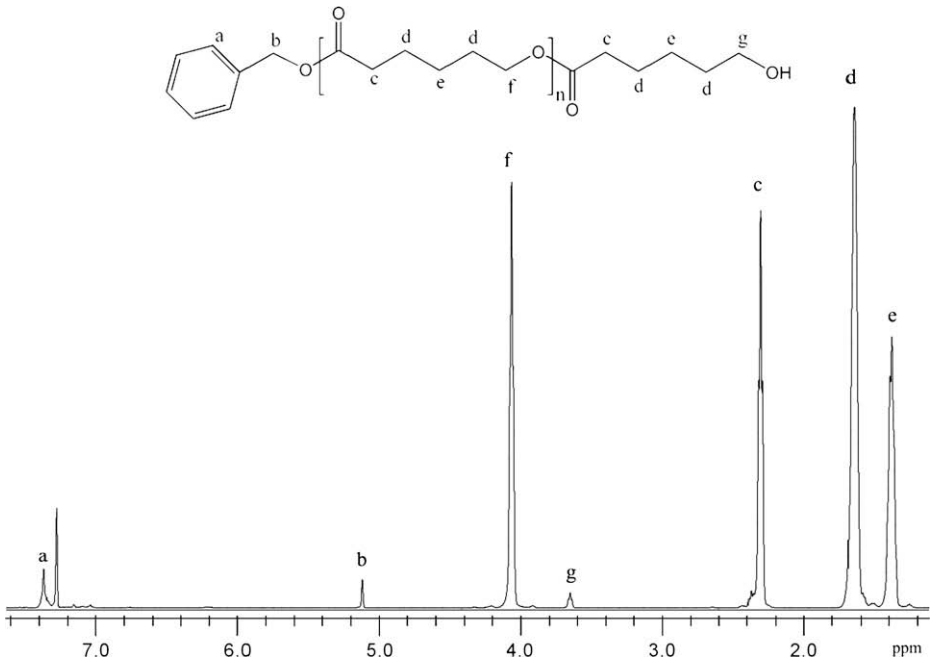

Fig. 4. ^{1}H NMR spectrum of a typical polymer sample.

signals of the methylene protons (c–f) at δ 2.33, 1.66, 1.40, 4.08, and the signals of the ending benzyl group (a, b) at δ 7.37 (ph) and 5.13 (CH_2) as well as the resonances of the terminal methylene protons (CH_2OH, g) at δ 3.67 all appear clearly. Hence, we deduce that BnOH reacts with the alkyl metal complexes to form metal benzyloxides as the catalytic active species. To further confirm that the metal benzyloxides form and act as the active catalysts in these systems, a reaction of complex **2** with BnOH (1:2) in $CDCl_3$ was monitored by ^{1}H NMR at room temperature. The ^{1}H NMR spectrum of the reaction mixture is shown in Fig. 5A. The disappearance of the resonances for protons of Zn*Et* and half of AlMe_2 in high field region and the appearance of the broad PhCH_2OM (M = Al and Zn) signals in the region of δ 4.3–4.6 demonstrate the formation of a bimetal dibenzyloxide complex. After CL was added to the above reaction mixture at room temperature, the formation of M–PCL–OCH_2Ph intermediates was clearly detected by ^{1}H NMR spectrum as shown in Fig. 5B, which indicates the benzyloxy metal complexes are indeed the catalytic active species. The ^{1}H NMR spectrum of the M–PCL–OCH_2Ph intermediates is quite similar to the one of the PCL sample as shown in Fig. 4. The remaining Al*Me* signal can still be seen at δ −0.80 after the polymer chains have been formed, which indicates that the Al–Me bond is stable to the ROP of CL.

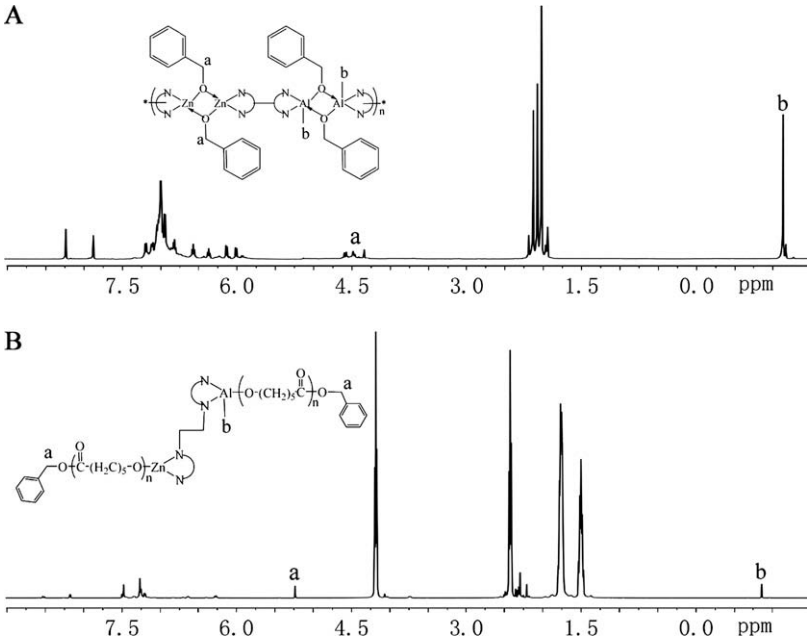

Fig. 5. ^{1}H NMR spectra of the reaction mixture of complex **2** with BnOH (1:2) in $CDCl_3$ (A) and the reaction mixture of complex **2**, BnOH and CL in $CDCl_3$ at room temperature (B).

Based on above results and discussion, the mechanism for the present polymerization systems is similar to the one proposed previously for the *N*-arylanilido-imine Al and Zn catalyst systems [39]. The metal benzyloxide complexes are the active catalysts which are produced by the reaction of the alkyl metal complexes with BnOH. The polymerization reaction takes place by repeated coordination of the CL monomer to the metal centres and insertion into the M–O bonds to form the polymerization intermediates LM–OP (where P refers to the polymer chain). The polymerization reaction stops when the monomer is totally consumed. Free polymers can be released by the addition of excess BnOH or acetic acid. BnOH acts as a co-initiator as well as a chain transfer regent (if there is excess BnOH) in the polymerization procedure.

3. Conclusion

In conclusion, mononuclear Al complex **1** and binuclear Al/Zn complex **2** supported by the *N*-arylanilido-imine ligand have been synthesized and fully characterized. The structures of the two complexes were determined by X-ray crystallography. Both complexes are efficient catalysts for the ring-opening polymerization of CL in the presence of BnOH. The catalytic activity of the binuclear complex **2**/BnOH system is much higher than that of the mononuclear Al complex **1**/BnOH system. Both catalyst systems produce PCL with narrow molecular weight distribution and capped with a benzyl ester group on one end and a hydroxylmethyl group on the other end. The ROP reaction of CL catalyzed by complex **2**/BnOH system takes place in a living fashion and the *M*n of the obtained polymers increases linearly with increase in the CL/Zn molar ratio. The formation and reaction of the metal benzyloxide complexes during the polymerization were confirmed by ^{1}H NMR spectroscopy.

4. Experimental

4.1. General procedures

All reactions were performed using standard Schlenk techniques in an atmosphere of high purity nitrogen or glove-box techniques. Toluene, hexane, THF were dried by refluxing over sodium and benzophenone and distilled under nitrogen prior to use. C_6D_6 was dried over activated 4 Å molecular sieves and vacuum-transferred to a sodium-mirrored air-free flask. $CDCl_3$, CH_2Cl_2 were dried over CaH_2 for 48 h and vacuum-transferred to an air-free flask. $AlMe_3$ and $ZnEt_2$ were purchased from Aldrich and used as received. ^{1}H and ^{13}C NMR spectra were measured using a Varian Mercury-300 NMR spectrometer or a Bruker AVANCE-500 NMR spectrometer. The elemental analysis was performed on a Perkin–Elmer 2400 analyzer. The GPC measurements were performed on a Waters-410 system using THF as the eluent (flow rate: 1 mL/min, at 35 °C). Molecular weights and molecular weight distributions were calculated using polystyrene as standard.

4.2. Synthesis of (C_6H_4(NHAr)–CH=N)CH_2CH_2(C_6H_4(NAr)CH=N$AlMe_2$) (**1**)

$AlMe_3$ (2.1 mL, 1.0 M in toluene, 2.1 mmol) was added to a solution of **L**H_2 (1.0 g, 2.1 mmol) in 20 mL of toluene at −78 °C. The reaction mixture was allowed to warm to room temperature and then stirred at 80 °C overnight, during which a clear yellow solution was formed. After removal of the solvent, the crude product was purified by recrystallization from a mixture of CH_2Cl_2/hexane to give the product as yellow crystalline solids (1.04 g, 93% yield). *Anal.* Calc. for $C_{34}H_{39}AlN_4$ (530.68): C, 76.95; H, 7.41; N, 10.56. Found: C, 76.90; H, 7.43; N, 10.58%. ^{1}H NMR (300 MHz, $CDCl_3$, 293 K): δ −0.84 (s, 6H, AlCH_3), 2.06 (s, 6H, CH_3), 2.17 (s, 6H, CH_3), 3.96 (s, 4H, NCH_2), 3.46 (m, 2H, NCH_2), 5.99–7.26 (m, 12H, Ph-*H*), 8.06 (s, 1H, C*H*=NAr), 8.45 (s, 1H, C*H*=NAr), 10.28 (s, 1H, N*H*). ^{13}C {1H} NMR (75 MHz, CDCl3, 293 K): δ −8.27, 18.58, 18.67, 56.84, 114.73, 114.99, 115.43, 116.01, 125.81, 126.43, 128.48, 128.64, 128.88, 129.06, 131.26, 133.84, 136.14, 136.79, 136.86, 142.46, 156.02, 165.63, 171.89.

4.3. Synthesis of (C_6H_4(NAr)CH=NZnEt)CH_2CH_2(C_6H_4(NAr)–CH=N$AlMe_2$) (**2**)

$ZnEt_2$ (1.9 mL, 1.0 M in toluene, 1.9 mmol) was added to a solution of 1 (1.0 g, 1.9 mmol) in 20 mL of toluene at −78 °C. The reaction mixture was allowed to warm to room temperature and then stirred at 80 °C overnight. After removal of the solvent, the crude product was purified by recrystallization from a mixture of CH_2Cl_2/hexane to give the product as yellow crystalline solids (1.07 g, 90% yield). Anal. Calc. for $C_{36}H_{43}AlN_4Zn$ (624.12): C, 69.28; H, 6.94; N, 8.98. Found: C, 69.27; H, 6.95; N, 8.97%. ^{1}H NMR (500 MHz, C_6D_6, 293 K): δ −0.11 (s, 6H, AlCH_3), 0.84 (q, 2H, ZnCH_2), 1.22 (t, 3H, $ZnCH_2CH_3$), 2.50 (s, 6H, CH_3), 2.53 (s, 6H, CH_3), 3.60 (s, 2H, NCH_2), 3.71 (s, 2H, NCH_2), 6.51–7.73 (m, 12H, Ph-*H*), 8.06 (s, 1H, C*H*=NAr), 8.13 (s, 1H, C*H*=NAr). 13C {1H} NMR (125 MHz, C_6D_6, 293 K): δ −1.00, 12.35, 14.30, 18.61, 18.65, 58.86, 60.85, 113.40, 114.58, 114.24, 114.69, 115.20, 117.16, 124.80, 126.04, 129.15, 129.37, 133.28, 135.02, 136.10, 136.69, 136.85, 137.70, 143.03, 147.92, 156.11, 156.58, 170.22, 170.92.

4.4. Polymerization of CL

In general, the polymerization experiments were performed as follows. To a rapidly stirred solution of CL in toluene (the amounts of CL and toluene were calculated based on the conditions given in Table 2), a solution of a catalyst (0.19 mmol) and appropriate amount of BnOH in toluene (3 mL) was added under a nitrogen atmosphere at the desired temperature. After the reaction mixture was stirred for a prescribed period or until the reaction mixture became very viscous and could not be stirred, the reaction was

[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

quenched by the addition of excess acetic acid aqueous solution (1.0 N). The polymer was then precipitated by adding MeOH (100 mL) into the mixture, collected on a frit, washed with MeOH (3 × 10 mL) and dried in vacuo up to a constant weight.

4.5. Crystal structure determination

Single crystals of **1** and **2** suitable for X-ray structural analysis were obtained from CH_2Cl_2/hexane. Diffraction data were collected at 293 K on a Rigaku R-AXIS RAPID IP diffractometer equipped with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Details of the crystal data, data collections, and structure refinements are summarized in Table 3. The structures were solved by direct methods and refined by full-matrix least-squares on F^2. All nonhydrogen atoms were refined anisotropically and the hydrogen atoms were included in idealized positions. All calculations were performed using the SHELXTL crystallographic software packages [47].

Supplementary data

CCDC 703678 and 703679 contains the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Metallosupramolecular architecture

ABSTRACT

Three new Cu(II) supramolecular complexes [Cu($\mathbf{L_1}$)Cl_2]·2DMF (**1**), [Cu($\mathbf{L_2}$)Cl_2] (**2**) and [Cu($\mathbf{L_3}$)Cl_2]·DMF (**3**) ($\mathbf{L_1}$ = 3,3′-bis(2-benzimidazolyl)-2,2′-dipyridine, $\mathbf{L_2}$ = 3,3′- bis(N-ethyl-2-benzimidazolyl)-2,2′-dipyridine and $\mathbf{L_3}$ = 3,3′-bis(N-benzyl-2-benzimidazolyl)-2,2′-dipyridine) have been prepared and characterized by elemental analysis, IR spectra and single crystal X-ray diffraction. X-ray structural analysis of $\mathbf{L_1}$, $\mathbf{L_2}$·3.5H_2O and $\mathbf{L_3}$·H_2O indicates that all three ligands adopt the *trans* conformation with the two benzimidazole fragments located on opposite sides of the dipyridyl backbone. While in complexes **1**–**3**, all the ligands display the *cis* conformation and behave as bidentate chelating reagents to coordinate with Cu(II). The inorganic chloride ions always act as a reliable hydrogen bonded acceptor in these structures, and the resulting C–H···Cl_2Cu supramolecular synthons play a significant role in the formation and stabilization of the structures. Moreover, additional non-covalent interactions, such as C–H···π, are also identified to extend the discrete (0-D) or low-dimensional (1-D) motifs into high-dimensional architectures.

1. Introduction

As stated by Desiraju and Steiner, – there is a growing need to simultaneously assess different interactions and establish their hierarchy – and non-covalent interactions have received much interest in organic and inorganic crystal engineering [1–4]. One of the challenges of crystal engineering today is to clarify the relative roles of various synthons in crystal structures. In this regard, the role of X–H···Cl (X = O and N) and C–H···π interactions in the development of the supramolecular structures of hybrid organic/inorganic metal halides has recently received specific attention [5–7]. However, in this contribution, our interest in weak interactions has focused primarily on the so-called C–H···Cl inorganic supramolecular synthons and C–H···π interactions. To our delight, the previous studies have revealed that the formation of halide-involved hydrogen bonds in metal complexes depends on the coordination environments [8–11]. Moreover, the C–H···Cl contacts and charge–assisted (for strengthening non-covalent forces) terminal M–Cl bonds of chlorometallates have been found to play a decisive role in the formation of supramolecular architectures of crystalline solids [8,12–16]. Thus, it is significant to further explore the nature of such interactions by establishing appropriate chemical systems with a C–H donor for the acceptance of the chloride anion. To achieve this aim, one of the available strategies is to assemble metal chlorides with pre-designed receptors that can serve as proton donors. This idea has been reinforced by several recent works showing the potential utility of C–H···Cl–M hydrogen bonding (M = transition metal) in the self-assembly of tape- and sheet-shaped structures [17–20]. Another possible strategy is the choice of suitable organic ligands possessing one site for coordinating to the metal centers in well-defined geometries and the another site for non-covalent interactions.

In this context, we selected the ligand 3,3′-bis(2-benzimidazolyl)-2,2′-dipyridine ($\mathbf{L_1}$) and its N-substituted derivatives 3,3′-bis(N-ethyl-2-benzimidazolyl)-2,2′-dipyridine ($\mathbf{L_2}$) and 3,3′-bis(N-benzyl-2-benzimidazolyl)-2,2′-dipyridine ($\mathbf{L_3}$) as potential building blocks due to their bifunctional characters. In virtue of the free-rotation of the C–C bond, the two imino moieties of the bis-benzimidazolyl groups can coordinate to a metal ion to serve as the first coordination sphere and the acidic aromatic C–H groups may serve as the second coordination sphere to donate multifold hydrogen bonds with chloride anions [21,22]. In such a metal complex, the metallation of the ligand greatly enhances the electron-deficient character of the benzimidazolyl group, which will reinforce the C–H···Cl hydrogen bonding [23]. Furthermore, the substitution effect of the ligands may dramatically affect their coordination tendency [24], and it still remains a continuing challenge to prove

Scheme 1. Reaction pathways for synthesis of ligands L_1–L_3 and complexes **1**–**3**.

such an effect of the ligands on the formation of weak hydrogen bonding and further supramolecular frameworks. Herein, we will present the synthesis and characterization of two new ligands L_2 and L_3 as well as three copper(II) complexes **1**–**3** based on this series of ligands (see Scheme 1) to further illustrate the above-mentioned issues.

2. Experimental

2.1. Materials and instruments

2,2′-Bipyridyl-6,6′-dicarboxylic acid was prepared according to the procedure reported by Dholakia et al. [25], and the ligand L_1 was synthesized according to the literature method [24]. All other reagents were of commercial grade and were used as received. Elemental analyses (C, H, N) were carried out on a Flash 1112 elemental analyzer. FT-IR spectra (KBr pellet) were recorded in the range 4000–400 cm^{-1} on a Nicolet Avatar-360 spectrometer. ^1H NMR spectra were recorded on a Bruker DPX-400 spectrometer in DMSO with TMS as an internal standard.

2.2. Synthesis of 3,3′-bis(N-ethyl-2-benzimidazolyl)-2,2′-dipyridine (L_2)

Under N_2 atmosphere, a suspension of KOH (224 mg, 4 mmol) and 2,2′-bipyridyl-6,6′-dicarboxylic acid (776 mg, 2 mmol) in anhydrous DMF (20 mL) was stirred for 1 h at 70 °C. Then, bromoethane (4 mmol) was added. The mixture was heated at 70 °C for 12 h and then poured into ice. The product was purified by column chromatography using ethyl acetate/hexane (3:1) as the eluent. 610 mg, 67% yield. *Anal.* Calc. for $C_{28}H_{24}N_6$: C, 75.65; H, 5.44; N, 18.91. Found: C, 75.81; H, 5.36; N, 18.83%. Main IR bands (cm^{-1}): 1614w, 1557w, 1444m, 1392w, 767s, 744s. ^1H NMR (δ ppm): 8.32 (d, 2H, H_{Py}), 8.08 (d, 2H, H_{Py}), 7.57 (q, 2H, H_{Py}), 7.46 (d, 4H, H_{Ar}), 7.23 (d, 4H, H_{Py}), 4.18 (d, 4H, H_{CH_2}), 1.18 (d, 6H, H_{CH_3}).

2.3. Synthesis of 3,3′-bis(N-benzyl-2-benzimidazolyl)-2,2′-dipyridine (L_3)

Under N_2 atmosphere, a suspension of Na_2CO_3 (424 mg, 4 mmol) and 2,2′-bipyridyl-6,6′-dicarboxylic acid (776 mg, 2 mmol) in anhydrous DMF (20 mL) was stirred for 1 h at 70 °C. Then, benzyl bromide (4 mmol) was added. The mixture was heated at 70 °C for 24 h and then poured into ice. The product was purified by column chromatography using ethyl acetate/hexane (3:1) as the eluent. 732 mg, 64% yield. *Anal.* Calc. for $C_{38}H_{28}N_6$: C, 80.26; H, 4.96; N, 14.78. Found: C, 80.41; H, 5.15; N, 14.61%. Main IR bands (cm^{-1}): 1614w, 1558w, 1454m, 755s, 739s. ^1H NMR (δ ppm): 8.35 (d, 2H, H_{Py}), 7.93(d, 2H, H_{Py}), 7.35 (q, 2H, H_{Py}), 7.19–7.28 (m,18H, H_{Ar}), 5.56 (d, 4H, H_{CH_2}).

2.4. Synthesis of [Cu(**L₁**)Cl₂]·2DMF (**1**)

A mixture of **L₁** (194.5 mg, 0.5 mmol) and $CuCl_2{\cdot}2H_2O$ (84.5 mg, 0.5 mmol) in DMF (10 mL) was stirred for 3 h at 60 °C. The solution was filtered and the filtrate was diffused by diethyl ether. After several days, single crystals suitable for X-ray analysis were obtained (269.0 mg, 80% yield). *Anal.* Calc. for $C_{30}H_{30}Cl_2CuN_8O_2$: C, 53.85; H, 4.52; N, 16.75. Found: C, 54.01; H, 4.62; N, 16.67%. Main IR bands (cm^{-1}): 1648s, 1593w, 1561, 1449s, 764s, 754s.

2.5. Synthesis of [Cu(**L₂**)Cl₂] (**2a**)

A mixture of **L₂** (250.2 mg, 0.5 mmol) and $CuCl_2{\cdot}2H_2O$ (84.5 mg, 0.5 mmol) in DMF (10 mL) was stirred for 3 h at 60 °C. The solution was filtered and the filtrate was diffused by diethyl ether. After several days, single crystals suitable for X-ray analysis were obtained (208.0 mg, 72% yield). *Anal.* Calc. for $C_{28}H_{24}Cl_2CuN_6$: C, 58.08; H, 4.18; N, 14.52. Found: C, 58.36; H, 4.32; N, 14.31%. Main IR bands (cm^{-1}): 1561m, 1475s, 1454s, 1436s, 1402s, 756s.

2.6. Synthesis of [Cu(**L₃**)Cl₂]·DMF (**3**)

A mixture of **L₃** (293.4 mg, 0.5 mmol) and $CuCl_2{\cdot}2H_2O$ (84.5 mg, 0.5 mmol) in DMF (10 mL) was stirred for 3 h at 60 °C. The solution was filtered and the filtrate was diffused by diethyl ether. After several days, single crystals suitable for X-ray analysis were obtained (291.0 mg, 75% yield). *Anal.* Calc. for $C_{41}H_{35}Cl_2CuN_7O$: C, 63.44; H, 4.54; N, 12.63. Found: C, 63.28; H, 4.34; N, 12.76%. Main IR bands (cm^{-1}): 1677s, 1454s, 763s, 734m.

2.7. X-ray crystallography

Intensity date were collected at 291(2) K on a Bruker APEX II CCD diffractometer with Mo Ka radiation (λ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2 with SHELXL-97 [26]. All non-hydrogen atoms were refined anisotropically, whereas hydrogen atoms were placed in geometrically calculated positions. Crystal data and structure refinements are summarized in Tables 1 and 2. Selected bond lengths and bond angles are given in Table 3.

3. Results and discussion

3.1. Structural description of the ligands

The three ligands were prepared through the Phillips reaction [27], involving refluxing the aryl diamine with pyridine dicarboxylic acid, and the Ullmann coupling reaction [28] (see Scheme 1). Compound **L_1** is a polydentate ligand which has been previously reported [24,29]. In order to further investigate the molecular conformation of such ligands and the influence of the substituents, the crystal structures of **L_1**, **L_2**·3.5H_2O and **L_3**·H_2O have been determined. As shown in Figs. 1–3, all free ligands adopt the *trans* conformation in the solid state with the two benzimidazolyl groups on opposite sides of the 2,2′-dipyridine backbone, which is similar to that of other semi-rigid podal-type ligands such as bis(2-benzimidazolyl)biphenyl [30]. In each case, the flexibility of the ligand is provided by the torsional twist along the central C–C bond. The pyridyl–pyridyl and benzimidazole–benzimidazole dihedral angles in **L_1** (72.5° and 99.3°) are significantly larger than those in **L_2** or **L_3** (49.7° and 50.7° or 46.1° and 45.7°). This may be ascribed to the intramolecular N–H···N hydrogen bonds in **1**, which also consolidates the molecular conformation.

3.2. Structural description of complexes *1–3*

Ligands **L_1**, **L_2** and **L_3** are almost insoluble in diethyl ether at room temperature, however, they have good solubility in DMF. For the preparation of **1–3**, the two reaction components first were dissolved in DMF and stirred for 3 h at 60 °C, then the resulting solution was filtered and the filtrate was diffused by diethyl ether. After several days, single crystals of **1–3** were obtained.

The X-ray single crystal structure of [Cu(**L_1**)Cl_2]·2DMF (**1**) indicates that the coordination environment around Cu(II) is a distorted tetrahedron provided by one ligand **L_1** and two chloride ions, as depicted in Fig. 4. Interestingly, the ligand **L_1** in this case adopts the *cis* conformations with two benzimidazolyl groups on the same side of the dipyridyl skeleton, which is different from the *trans* style in the free ligand. The coordination motif in **1** is a discrete mononuclear molecule with the presence of intramolecular C–H···Cl contacts, as observed in other related systems [31,32]. In addition, C–H···π interactions (see Table 4) are also observed, in which the pyridyl rings are donors and the benzimidazoyl rings are acceptors. As a consequence, the discrete mononuclear units are assembled into a 3-D network (see Fig. 5). It should be noted that no intermolecular C–H···Cl hydrogen bonding is found in this structure. It must be pointed out that the DMF molecules are disordered over two sites and have been modelled with a 61.8(2):38.2(2) ratio. Interestingly, these disordered DMF molecules are trapped in the lattice by the formation of C–H···O hydrogen bonds (Table 4).

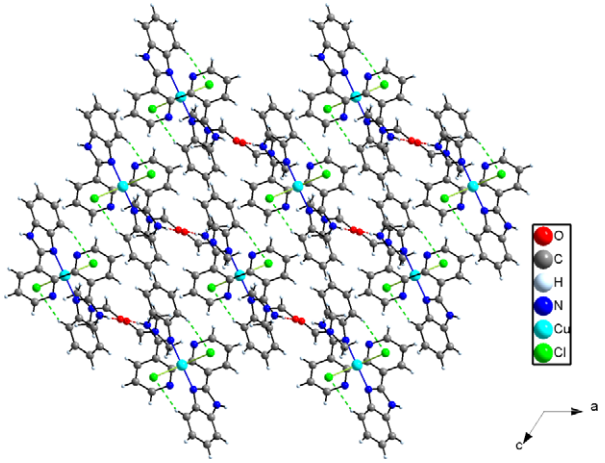

Fig. 5. View of the 3-D network of **1**. Intramolecular C–H···Cl hydrogen bonds are shown in green and C–H···O in red. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

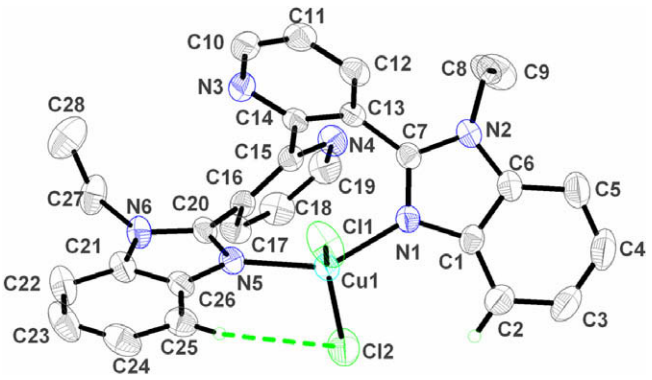

Fig. 6. Molecular structure of **2** showing one intramolecular C–H···Cl hydrogen bond. Irrelevant H atoms are omitted for clarity.

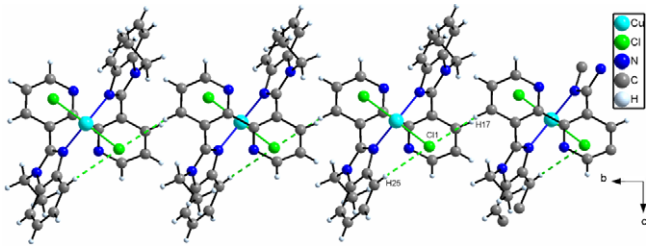

Fig. 7. 1-D chain in **2** along the *b* axis. The C–H···Cl hydrogen bonds are shown in green. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The structural analysis of [Cu(**L**$_2$)Cl$_2$] (**2**) reveals that each Cu(II) ion is coordinated by two nitrogen atoms from one **L**$_2$ ligand and two chloride ions to result in a distorted tetrahedral sphere, as in **1** (see Fig. 6). Unlike in **1**, there is only one intramolecular C–H···Cl bond in **2**. Moreover, the Cl1 ions are involved in intermolecular C–H···Cl interactions. The Cu–Cl1 bond of one molecule is linked with the pyridyl C–H of the adjacent molecule, and the C···Cl distance (3.674 Å) is in the normal range of C–H···Cl hydrogen bonding [9]. With this assembly, the [Cu(**L**$_2$)Cl$_2$] units are connected to each other to form a 1-D chain along the *b* axis (see Fig. 7). The 1-D chains are further assembled with the aid of C–H···π contacts to afford a 2-D layered structure along the *ac* plane. C–H···π contacts are established between the pyridyl and benzimidazolyl donors and acceptors (see Table 4). Furthermore, the layers are linked to each other by C–H···π interactions between the C-H donors of ethyl groups and the pyridyl rings, resulting in the final 3-D supramolecular lattice, as shown in Fig. 8. This results in the ethyl groups protruding out from the 1-D chains, and thus they are close to the adjacent pyridyl rings to effectively link the 2-D layers together.

As depicted in Fig. 9, the Cu(II) ion in **3** also displays a distorted tetrahedral geometry. In the crystal structure, the DMF molecules are also disordered over two sites and have been modelled with a 73.0(3):27.0(3) ratio. However, no intramolecular C–H···Cl interaction is found in this case**.** Instead, the chloride ions are only involved in intermolecular C–H···Cl interactions (Table 4). Thus, the [Cu(**L**$_3$)Cl$_2$] units are linked to each other via such secondary forces to produce a 1-D wave-like chain along the *c* axis (see Fig. 10). This stacking, with additional C–H···π secondary interactions between the phenyl donors and the acceptors of benzimidazolyl, leads to the formation of 2-D layered structures, which are eventually extended into a 3-D network (see Fig. 11). It should be noted that the DMF molecules are trapped in this lattice by C–H···O and C–H···π interactions (see Table 4).

3.3. Structural comparison of complexes *1*–*3*

The Cu(II) centers in complexes **1**–**3** adopt a similar distorted tetrahedral geometry, coordinating to two nitrogen atoms from the ligand and two chloride ions. In each case, the ligand acts as a bidentate chelator with four planar groups connected by three hinges. The two benzimidazole groups and Cu(II) form nine-membered chelating rings, which exhibit a twisted boat–boat conformation (see Fig. 12). Geometrical constraints within such a chelated ring cause the intra-ligand N–Cu–N angles to be 139.1° in **1**, 140.5° in **2** and 138.8° in **3**, which are significantly larger than those (92.6°) of a similar bis(benzimidazole) complex containing a seven-membered chelating ring [33]. Analysis of the Cu(II) coordination spheres in each complex reveals that the ligand binding ability in **1** and **2** is stronger than that in **3**, as indicated by their slightly shorter Cu–N bond distances (see Table 3). This result may be related to the conformational discrepancy of the ligands in **1–3**, which gives rise to different steric hindrance. Another outstanding feature is that the size and shape of the ligands have a significant effect on the formation of different C–H···Cl hydrogen bonding. As demonstrated by the above structural descriptions, the substituents of the ligands cause their distinct sizes, which in turn lead to the intra- or intermolecular C–H···Cl interactions. Furthermore, the ligand configuration will also be changed by the substituents, which may be reflected by the pyridyl–pyridyl and

benzimidazolyl–benzimidazolyl dihedral angles that are remarkably different in these structures (64.1° and 78.2° in **1**, 58.8° and 48.6° in **2**, and 50.8° and 62.0° in **3**). This will also affect the resultant hydrogen bonding modes.

3.4. The role of C–H···Cl and C–H···π interactions in the structural assembly

Detailed geometrical parameters for related secondary interactions are listed in Table 4. For C–H···Cl bonds, the H···Cl distances

range from 2.74 to 2.88 Å, being considerably shorter than the sum of van der Waals radii (2.95 Å), and the C–H···Cl angles range from 155° to 164°, falling in the normal range for C–H···Cl hydrogen bonds [14]. Further examination of the C–H···Cl contacts reveals two different types of hydrogen bonding patterns: linear (in **2** and **3**) and asymmetric bifurcated interactions (in **2**). Thus, while the ligands coordinate to Cu(II), diverse conformations that achieve these interactions are observed. In **1**, intramolecular C–H···Cl and C–H···π interactions are found, but not the intermolecular C–H···Cl type. This result may be due to the formation of linear intramolecular C–H···Cl interactions which causes a significant perturbation in the formation of intermolecular C–H···Cl interactions. This opinion can be further confirmed by the structural analysis of complexes **2** and **3**. That is, both intra and intermolecular C–H···Cl hydrogen bonds are found in **2**, and only an intermolecular C–H···Cl contact is formed in **3**. The difference in the hydrogen bonding modes results in their structural diversity. In **1**, the intramolecular C–H···Cl hydrogen bonding is preserved within the 0-D coordination motif, whereas in **2** and **3**, the intermolecular C–H···Cl hydrogen bonds lead to the formation of a 1-D chain array and a 2-D layer. Examination of the overall crystalline lattices of **1**–**3** shows that the 3-D packing largely depends on the accessibility of the pyridyl or phenyl rings in the supramolecular networks. This is particularly true for complex **3**, in which significant intermolecular C–H···Cl hydrogen bonds occur. In this case, the phenyl rings protrude out from the [Cu(**L$_3$**)Cl$_2$] units and are closer to the adjacent chloride ions. As a result, the intermolecular C–H···Cl hydrogen bonds effectively link the [Cu(**L$_3$**)Cl$_2$] units together. Except for the intermolecular C–H···Cl hydrogen bonds, the aggregation of these networks into the final architectures appears to be largely regulated by other weaker secondary interactions such as C–H···π interactions. This phenomenon is also observed in complexes **1** and **2**. The C–H···π contacts increase the dimensionality of the supramolecular architecture from 0-D to 3-D, and from 1-D to 3-D in **2**, as well as from 2-D to 3-D in **3**, which play a decisive role in the final structures.

4. Conclusion

The metallosupramolecular systems presented in this research demonstrate that the inorganic synthon C–H···Cl$_2$Cu(II) plays a significant role in the construction and stabilization of crystalline architectures. Interestingly, the size and shape of the ligand may have a remarkable effect on the formation of different intra- and/or intermolecular C–H···Cl hydrogen bonding. Furthermore, the overall higher-dimensional supramolecular networks for these complexes are modulated by the synergistic effect of the primary C–H···Cl hydrogen bonding and the complementary C–H···π interactions.

Supplementary data

CCDC 659366, 299930, 299931, 288137, 299933 and 288138 contain the supplementary crystallographic data for **L$_1$**, **L$_2$**·3.5H$_2$O, **L$_3$**·H$_2$O, **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Displacement of the labile THF molecules in BrRe(CO)$_3$(THF)$_2$ (**1**) by the diphosphine ligands 2-(ferrocenylidene)-4,5-bis(diphenylphosphino)4-cyclopenten-1,3-dione (fbpcd) and 2-(3-ferrocenylprop-2-ynylidene)-4,5-bis(diphenylphosphino)4-cyclopenten-1,3-dione (fpbpcd) yields the mononuclear compounds *fac*-BrRe(CO)$_3$(fbpcd) (**2**) and *fac*-BrRe(CO)$_3$(fpbpcd) (**3**), respectively. The new ligand fpbpcd ligand has been synthesized from 3-ferrocenylpropynal and the parent diphosphine ligand 4,5-bis(diphenylphosphino)-4-cyclopenten-1,3-dione (bpcd) through a Knoevenagel condensation. **2** and **3** have been isolated and fully characterized by IR and NMR spectroscopies (^{1}H and ^{31}P), ESI mass spectrometry, and X-ray diffraction analysis in the case of **3**. The electrochemical properties of compounds **2** and **3** have been examined by cyclic voltammetry, and the nature of the HOMO and LUMO levels in these systems has been confirmed by MO calculations at the extended Hückel level. The redox and MO data are discussed relative to the redox and orbital properties of related functionalized diphosphines based on the bpcd platform.

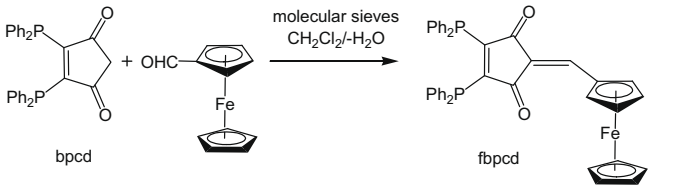
1. Introduction

New inorganic and organometallic systems that can promote energy- and electron-transfer reactions are highly sought after as device components in optoelectronic applications, photosynthetic mimics, redox switches, and model systems for directional charge-transfer processes [1]. The synthesis and photophysical study of new luminescent organometallic complexes continue to command the attention of a diverse group of researchers. Many dyad and triad arrays possessing an energetically accessible LUMO typically give rise to long-lived charge-transfer species, a condition tantamount for the successful fabrication of photosynthetic and OLED devices [2]. While many derivatives exhibit a low-lying LUMO and promote long-lived charge separated species, the search for new systems with tunable LUMO levels remains a universal priority.



While diphosphine ligands are ubiquitous in transition-metal chemistry, only a few documented paradigms exist that display significant luminescent behavior [3]. Undoubtedly, the principal factor responsible for the disappointing photophysical data (i.e., efficient non-radiative decay) experimentally found in the overwhelming majority of diphosphine-substituted metal compounds is the absence of a low-lying π^* acceptor LUMO on the diphosphine ligand. The absence of an energetically accessible diphosphine LUMO radically changes the emissive behavior relative to those compounds containing an α-diimine or related heterocyclic ligand that possess a π^* LUMO that is localized on the ancillary heterocyclic residue [4].

Our groups maintain a longstanding interest in the synthesis and physical study of organometallic complexes containing the unsaturated diphosphine ligands 2,3-bis(diphenylphosphino) maleic anhydride (bma) and 4,5-bis(diphenylphosphino)-4-cyclopenten-1,3-dione (bpcd) [5,6]. These particular ligands are unique vis-á-vis the common diphosphine ligands dppm, (Z)-1,2-Ph$_2$PCH=CHPPh$_2$, and 1,2-bis(diphenylphosphino)benzene because both bma and bpcd exhibit a one-electron reduction at relatively low potential (<−1.1 V), with electron accession occurring at a π^*-based LUMO that is localized about the central platform ring [7]. The superb electron reservoir properties displayed by bma and bpcd have been shown to modulate ligand substitution in selected mononuclear compounds having electron counts in excess of 18e- [8].

doi:10.1016/j.poly.2009.05.049

In our quest to prepare new, second-generation ligands based on bpcd, we have instituted Knoevenagel condensation reactions between bpcd and selected aldehydes [9]. Here the union of the bpcd platform with a redox-active appendage and/or light-harvesting moiety facilitates, in theory, the tuning of the HOMO–LUMO gap and emission properties in a given metal complex. We have successfully employed this concept in the synthesis of several new ligands [10], with Eq. (1) showing the reaction for the preparation of 2-(ferrocenylidene)-4,5-bis(diphenylphosphino)-4-cyclopenten-1,3-dione (fbpcd) [11]. The dynamic isomerization of this particular ligand has been investigated in the triosmium clusters 1,2-$Os_3(CO)_{10}$(fbpcd) and 1,2-$Os_3(CO)_{10}$(fbpcd) [11], and its redox properties have been recently reported in the case of the platinum(II) complex Pt(mnt)(fbpcd) [10b].

(1)

Given the importance of d^6 complexes in multicomponent redox relays [12], coupled with our interest in the coordination chemistry of the fbpcd ligand with different metal systems, we have prepared and examined the redox properties of the new rhenium(I) compound *fac*-BrRe(CO)$_3$(fbpcd) (**2**). The synthesis of the conjugated enyne derivative of fbpcd, whose structure is depicted below, and its use as a ligand in the synthesis of *fac*-BrRe(CO)$_3$(fpbpcd) (**3**) are also described herein.

2. Experimental

2.1. Materials and equipment

The $BrRe(CO)_5$ employed in the synthesis of $BrRe(CO)_3(THF)_2$ (**1**) was prepared from $Re_2(CO)_{10}$ [13]. **1** was prepared according to the published procedure and typically used within one week of preparation [14]. The bpcd ligand used in the synthesis of the title diphosphines fbpcd and fpbpcd was synthesized from 4,5-dichloro-4-cyclopenten-1,3-dione and Ph_2PSiMe_3 [15], with the former ferrocene-containing ligand prepared from ferrocenecarboxaldehyde and bpcd [11]. The acetylferrocene used in the preparation of 3-ferrocenylpropynal [16] was synthesized according the procedure of Parshall et al. [17]. $Re_2(CO)_{10}$ was purchased from Pressure Chemical Co., while the chemicals ferrocene, ferrocenecarboxaldehyde, hexachlorocyclopentadiene, and diethyl chlorophosphate were purchased from Aldrich Chemical Co. and used as received. The reaction and NMR solvents employed in these studies were distilled from an appropriate drying agent under argon using Schlenk techniques or obtained from an Innovative Technology solvent purification system. All distilled solvents were stored in Schlenk storage vessels equipped with high-vacuum Teflon stopcocks [18]. The tetra-*n*-butylammonium perchlorate (TBAP) electrolyte was purchased from Johnson Matthey Electronics and recrystallized from hexane/ethyl acetate and dried under vacuum for at least 36 h prior to use.

The IR spectra were recorded on a Nicolet 6700 FT–IR spectrometer in amalgamated NaCl cells capable of handling air-sensitive samples. The quoted ^1H and ^{31}P NMR spectral data were recorded at 500 and 201 MHZ, respectively, on a Varian VXR-500 spectrometer. The ^{31}P NMR spectra were collected in the proton-decoupled mode and the reported chemical shifts referenced to external H_3PO_4 (85%), taken to have δ=0. UV–Vis spectra for **2** and **3** were recorded on a Hewlett–Packard 8452A diode array spectrometer in Schlenk-modified 1.0 cm quartz UV–Vis cells. The ESI-APCI mass spectra were recorded at the University of the Pacific (**2**) and UNT (**3**) mass spectrometry facilities, respectively, in the positive ionization mode. The matrices employed for the collection of the mass spectra were MeOH (**2**) and MeCN/KI (**3**).

2.2. Synthesis of *fac*-BrRe(CO)$_3$(fbpcd) (**2**) from BrRe(CO)$_3$(THF)$_2$ (**1**) and fbpcd

To a small Schlenk tube under argon flush was charged 0.10 g (0.20 mmol) of **1** and 0.14 g (0.21 mmol) of fbpcd, followed the addition of 25 mL of CH_2Cl_2 via syringe. The solution was stirred at room temperature for 1 h and then examined by IR analysis, which revealed the consumption of **1** and the presence of the desired product. The volatiles were removed under vacuum and the crude residue recrystallized from toluene at −20 °C. **2** was isolated by filtration under argon as an air-sensitive, purple-blue solid in 95% yield (0.19 g). IR (CH_2Cl_2): ν(CO) 2040 (vs), 1966 (s), 1912 (s), 1720 (w, sym dione), 1676 (s, antisym dione) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} 358 (ε=6100), 578 (ε=1500). ^1H NMR ($CDCl_3$): δ 4.19 (s, 5H, Cp), 4.81 (s, 1H, Cp), 4.85 (s, 1H, Cp), 4.98 (s, 1H, Cp), 5.35 (s, 1H, Cp), 7.36–7.91 (m, 21H, alkenyl and aryl). ^{31}P NMR ($CDCl_3$): δ 23.03 (d, $^3J_{P-P}$=11 Hz), 23.55 (s, $^3J_{P-P}$=11 Hz). ESI–MS: *m/z* 1033.59 for $[\mathbf{2}+Na]^+$ and 1012.90 for $[\mathbf{2}+H]^+$.

2.3. Synthesis of fpbpcd from bpcd and 3-ferrocenylpropynal

0.10 g (0.22 mmol) of bpcd and 51 mg (0.22 mmol) of 3-ferrocenylpropynal in 30 mL of a 5:1 mixture of CH_2Cl_2/MeOH were stirred in the presence of 3 Å molecular sieves for 48 hr at room temperature. The solution slowly acquired a green–blue color indicative of the condensation product fpbpcd, and TLC analysis using CH_2Cl_2 as an eluent confirmed the presence of trace amounts of the starting materials and a prominent green–blue streak belonging to the desired ligand (R_f = 0.5). The solution was filtered under argon and the volatiles removed under vacuum, after which the residue was washed with hexane to remove the unreacted bpcd and 3-ferrocenylpropynal. Yield of green–blue fpbpcd: 0.10 g (68%). Given the air sensitivity of the product and the poor quality NMR spectra obtained due to paramagnetic impurities, the fpbpcd ligand was characterized by IR spectroscopy and used directly in the next step. IR (CH_2Cl_2): ν(CO) 1715 (w, sym dione), 1674 (s, antisym dione) cm^{-1}.

2.4. Synthesis of *fac*-BrRe(CO)$_3$(fpbpcd) (**3**) from BrRe(CO)$_3$(THF)$_2$ (**1**) and fpbpcd

The synthesis of **3** followed the procedure outlined for **2**. Here 0.10 g (0.20 mmol) of **1**, 0.14 g (0.20 mmol) of fpbpcd, and 25 mL of CH_2Cl_2 were stirred at room temperature for 1 h. IR analysis at this point confirmed the presence of the desired product, after

which the solution was dried under vacuum to afford crude **3**. Recrystallization of **3** from toluene at −20 °C, followed by filtration under argon, gave **3** as an air-sensitive, green–blue solid in 91% (0.19 g). IR (CH_2Cl_2): ν(CO) 2041 (vs), 1967 (s), 1914 (s), 1729 (w, sym dione), 1687 (s, antisym dione) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} 394 (ε = 12000), 608 (ε = 3800). ^1H NMR ($CDCl_3$): δ 4.27 (s, 5H, Cp), 4.54 (bs, 20H, Cp), 4.67 (bs, 2H, Cp), 6.80 (s, 1H, alkenyl), 7.15–7.81 (m, 2H, aryl). ^{31}P NMR ($CDCl_3$): δ 22.76 (d, $^3J_{P-P}$=12 Hz), 23.90 (s, $^3J_{P-P}$=12 Hz). ESI–MS: *m/z* 1073.13 for $[\mathbf{3}+K]^+$.

2.5. Electrochemical studies

The quoted cyclic voltammetric data were recorded on a PAR Model 273 potentiostat/galvanostat, equipped with positive feedback circuitry to compensate for *i*R drop. The cyclic voltammograms were recorded under oxygen- and moisture-free conditions in a homemade three-electrode cell. A platinum disk was utilized as the working and auxiliary electrode, and the reference electrode utilized a silver wire as a quasi-reference electrode, with the reported potential data standardized against the formal potential of the $Cp^*_2Fe/Cp^*_2Fe^+$ (internally added) redox couple, taken to have $E_{1/2}$=−0.20 V [19].

2.6. Extended Hückel MO calculations

The extended Hückel calculations on compounds **2** and **3** were carried out using the original program developed by Hoffmann [20], as modified by Mealli and Proserpio [21]. The weighted H_{ij}'s contained in the program were used in the calculations, and the input Z-matrices were constructed by using the available X-ray data for **3** and related compounds.

2.7. X-ray crystallographic data

Single crystals of $\mathbf{3}\cdot 1/2H_2O$ suitable for X-ray diffraction analysis were grown from an acetone solution containing **3** that had been layered with Et_2O. The X-ray data were collected on an APEX II CCD-based diffractometer at 100(2) K. The frames were integrated with the available APEX2 [22] software package using a narrow-frame algorithm, and the structure was solved and refined using the SHELXTL program package [23]. The molecular structure was checked using PLATON [24], and all nonhydrogen atoms were refined anisotropically. Except for the water solvent whose hydrogens were not located, all other hydrogen atoms were assigned calculated positions and allowed to ride on the attached carbon atom. The refinement for $\mathbf{3}\cdot 1/2H_2O$ converged at R = 0.0165 and $wR2$ = 0.0432 for 8316 independent reflection with $I > 2\sigma(I)$. The X-ray data and processing parameters are reported in Table 1, with selected bond distances and angles quoted in Table 2.

3. Results and discussion

3.1. Synthesis, spectroscopic data, and redox properties of *fac*-$BrRe(CO)_3$(fbpcd) (**2**)

Displacement of the THF ligands in $BrRe(CO)_3(THF)_2$ (**1**) by fbpcd is rapid and gives **2** in essentially quantitative yield as assessed by IR spectroscopy. While **2** may be isolated by column chromatography over silica gel, this leads to considerable material loss and oxidation of the ferrocene appendage, which in turn introduces unwanted paramagnetic impurities in the NMR sample. Alternatively, **2** could be isolated by recrystallization in toluene at low temperature in high yield, making this the preferred method of isolation. We would add that **2** may also be prepared by heating $BrRe(CO)_5$ in the presence of fbpcd but the yield of **2** is lower and the reaction is accompanied by decomposition, complicating the purification of the desired product. **2** is mildly air sensitive, especially in solution, but may be handled in the atmosphere for a short period of time. The structure of **2** is shown below.

compound **2**

2 was thoroughly characterized by IR, NMR, and UV–Vis spectroscopies, and mass spectrometry. The IR spectrum revealed terminal carbonyl stretching bands at 2041 (vs), 1967 (s), and 1914 (s) cm^{-1} characteristic of the signature *fac*-Re$(CO)_3$ moiety [25], in addition to two lower energy ν(CO) bands observed at 1729 (w) and 1687 (s) cm^{-1} ascribed to the vibrationally coupled symmetric and antisymmetric carbonyl stretching bands associated with the dione platform [26]. The ^{1}H NMR spectrum exhibited a 5H singlet at δ 4.19 for the unsubstituted Cp ring, with the alkenyl-substituted Cp ring displaying four 1H singlets at δ 4.81, 4.85, 4.98, and 5.35. The lone alkenyl hydrogen and the aromatic hydrogens appear as a set of overlapping resonances from δ 7.36–7.91. Two inequivalent ^{31}P resonances were observed in the ^{31}P NMR spectrum of **2** at δ 23.03 and 23.55 consistent with the formulated structure. The ESI mass spectrum of **2** revealed a strong molecular ion for the sodium-containing species [**2**+Na]$^+$ based on a *m/z* peak at 1033.59, along with a weak *m/z* peak at 1012.90 for [**2**+H]$^+$. Finally, the UV–Vis spectrum of **2** (Fig. 1) recorded in CH_2Cl_2 showed two featureless bands at 358 and 578 nm, whose assignments are ascribed to a $d\pi$(Re) → π^*(dione) MLCT and a charge-transfer-to-solvent (CTTS) transition involving the ferrocene and CH_2Cl_2, respectively [5a,27].

The redox properties of **2** were examined by cyclic voltammetry (CV) in CH_2Cl_2 containing 0.25 M TBAP as the supporting electrolyte. The CV of **2** (not shown) recorded over the potential range of 1.0 V to −1.0 V and at a scan rate of 250 mV/s revealed two diffusion-controlled waves at $E_{1/2}$ = 0.71 and −0.65 V belonging to 0/1$^+$ and 0/1$^-$ redox couples [28]. The site of the two redox waves was verified by extended Hückel MO calculations, which revealed HOMO and LUMO levels at −11.80 eV and −10.42 eV, respectively. The HOMO in **2** is best viewed as an iron-based d_{z2} orbital that is similar in nature to the a_{1g} HOMO found in ferrocene [29]. The computationally observed LUMO traces its parentage to the ψ_4 MO associated with the π system of dione ring, whose calculated energy and nodal pattern are in excellent agreement with those data reported for other bpcd-substituted compounds prepared by our groups [6a,10,30]. The relatively low energy of this π^* orbital renders it a superb electron reservoir and accounts nicely for the observed one-electron reduction found by CV.

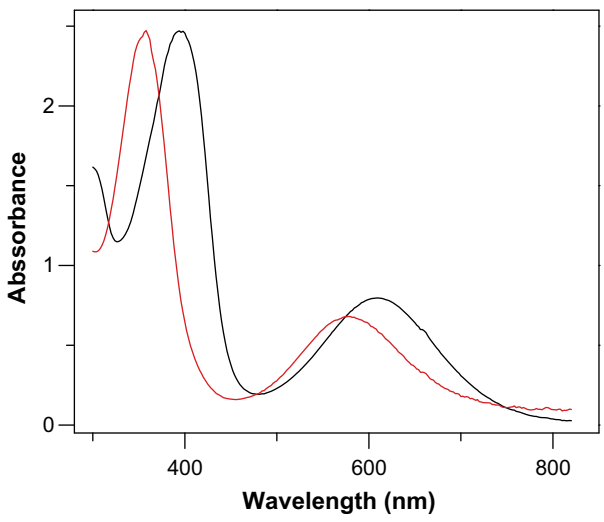

Fig. 1. UV–Vis spectra for **2** (red line; ca. 4e-4 M) and **3** (black line; ca. 2e-4 M) in CH_2Cl_2 solvent. The ordinate values displayed are for **2**, with **3** plotted alongside using arbitrary absorbance units.

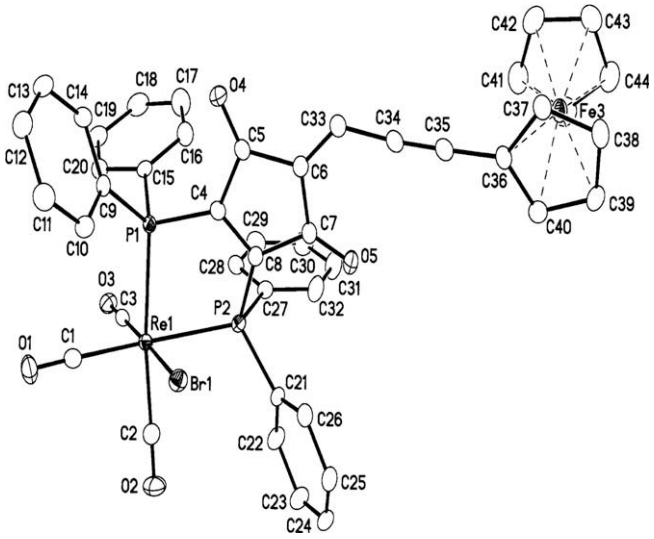

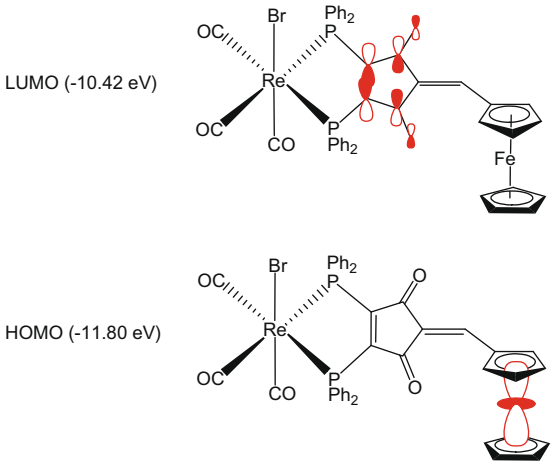

Fig. 2. Perspective view of **3** · 1/2H_2O showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level. The solvent molecule has been omitted for clarity.

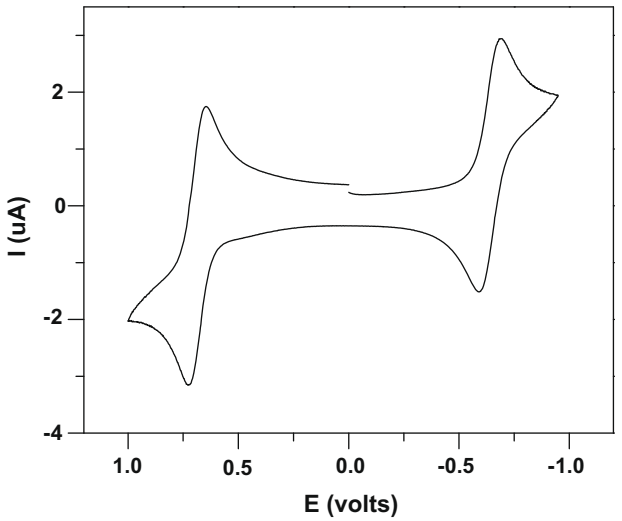
3.2. Synthesis, spectroscopic data, and redox properties of *fac*-BrRe$(CO)_3$(fpbpcd) (**3**)

Knoevenagel condensation of 3-ferrocenylpropynal with an equimolar amount of bpcd in a solvent mixture composed of CH_2Cl_2/MeOH (5:1) in the presence of 3 Å molecular sieves, whose function is to absorb the liberated water, furnishes the new ligand 2-(3-ferrocenylprop-2-ynylidene)-4,5-bis(diphenylphosphino)4-cyclopenten- 1,3-dione (fpbpcd). Isolated yields of fpbpcd were on the order of ca. 70% for samples that were purified by recrystallization. The fpbpcd ligand exhibits a green–blue color and undergoes facile oxidation in solution upon exposure to oxygen, making characterization of the ligand by NMR spectroscopy problematic. The IR spectrum of the ligand revealed two ν(CO) bands at 1715 (w) and 1674 (s) for the kinematically coupled dione carbonyl groups consistent with the proposed structure.

Treatment of either BrRe$(CO)_5$ or **1** with a slight excess of fpbpcd affords the corresponding diphosphine-substituted compound **3**, whose structure is depicted below. As discussed earlier, reactions using **1** as a starting material were cleaner and afforded **3** in higher yields. **3** was isolated by recrystallization as a



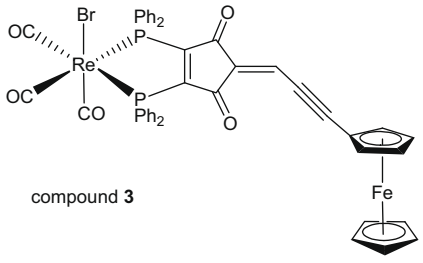


Fig. 3. Cathodic scan cyclic voltammogram of **3** (ca. 10^{-3} M and 0.25 V/s) in CH_2Cl_2 containing 0.25 M TBAP at room temperature.

green–blue solid and was characterized by a combination of IR, NMR, and UV–Vis spectroscopies, mass spectrometry, and X-ray diffraction analysis. The IR spectrum for **3** reveals terminal ν(CO) bands at 2041 (vs), 1967 (s), and 1914 (s) cm^{-1}, along with symmetric and antisymmetric dione ν(CO) bands at 1729 and 1687 cm^{-1}. These carbonyl frequencies relative to those recorded for **2** indicate that the electron-donating properties of the two diphosphine ligands are similar in magnitude. The UV–Vis spectrum (Fig. 1) shows a slight bathochromic shift of the two principal absorption bands compared to **2**, with maxima appearing at 394 nm and 608 nm. The spectroscopic assignments for these UV–Vis bands are assumed to be the same as those in **2** (*vide supra*). The ^{1}H NMR spectrum shows the cyclopentadienyl hydrogens at δ 4.27, 4.54, and 4.67 in a 5:2:2 integral ratio, and the lone vinyl hydrogen on the enyne chain appears as a singlet at δ 6.80. The aromatic hydrogens were observed as a multiplet from δ 7.15–7.81. The inequivalent phosphines in **3** appear as doublets in the ^{31}P NMR spectrum at δ 22.76 and 23.90 and exhibit a $^3J_{P-P}$ coupling of 12 Hz. The ESI mass spectrum recorded in MeCN/KI gave a strong molecular ion at *m/z* 1073.13 for $[\mathbf{3}+K]^+$ consistent with the formulated structure.

compound **3**

The unequivocal identity of **3** and the presence of the enyne linking moiety that serves to tether the bpcd and ferrocene groups were established by X-ray diffraction analysis. The solid-state structure of $\mathbf{3}\cdot 1/2H_2O$ is depicted in Fig. 2. The rhenium center is six-coordinate with the fpbpcd ligand situated *trans* to two of the three facial CO groups. The mean Re–P bond distance of 2.4487 Å and the bond angle of 81.01(2)° for the P(1)–Re(1)–P(2) linkage agree with those values reported for the octahedral rhenium(I) compounds *fac*-$BrRe(CO)_3$(bma) [5a], *fac*-$BrRe(CO)_3$(tbpcd) [10c], $ReCl_2[(Z)\text{-}Ph_2PCH{=}CHPPh_2]_2$ [31], and $ClRe(CO)_3$[3,4-Me_2-3′,4′- bis(diphenylphosphino)tetrathiafulvalene] [32]. The Re–CO bond distances range from 1.970(2) Å [Re(1)–C(2)] to 1.918(2) Å [Re(1)–C(3)] with the latter axial CO group displaying the shortest Re–CO bond distance. The Re(1)–Br(1) vector reveals a bond length of 2.6333(2) Å, whose value is in excellent agreement with the Re–Br distance found in the diphosphine-substituted compounds *fac*-$BrRe(CO)_3[\eta^2\text{-}(Ph_2PCH_2)_3CMe]$ [33], *fac*-$BrRe(CO)_3[Ph_2PO(CH_2)_2OPPh_2]$ [34], and *fac*-$BrRe(CO)_3$[1,2-$(HOCH_2P)_2C_6H_4$] [35]. The five-membered metallocyclic ring defined by the atoms Re(1)–P(2)–C(8)–C(4)–P(1) is distinctly non-planar and exhibits a fold angle of 29.49(4)° along the P(1) ··· P(2) hinge. The enyne carbons are nearly planar on basis of the observed torsion angle of ca. −165° for the C(6)–C(33)–C(34)–C(35) atoms. The remaining bond distances and angles are unremarkable and require no comment.

The cyclic voltammetric properties of **3** were examined in CH_2Cl_2 under conditions identical to those employed in the investigation of **2**. The CV of **3**, which is shown in Fig. 3, recorded over the potential range of 1.0 V to −1.0 V and at a scan rate of 250 mV/s revealed well-defined diffusion-controlled waves at $E_{1/2}$ = 0.68 and −0.65 V ascribed to $0/1^+$ and $0/1^-$ redox couples. These half-wave potentials are identical to those redox data recorded for **2**, suggesting identical HOMO and LUMO levels in the two different rhenium(I) products. This latter assumption was subsequently corroborated by extended Hückel MO calculations, which revealed HOMO and LUMO levels at −11.86 eV and −10.39 eV, respectively. The orbital composition of these important frontier molecular orbitals in **3** resembles the HOMO and LUMO levels computed for **2** and will not be reproduced here.

4. Conclusions

The new rhenium(I) compounds *fac*-$BrRe(CO)_3$(fbpcd) (**2**) and *fac*-$BrRe(CO)_3$(fpbpcd) (**3**) have been synthesized and their redox properties investigated by cyclic voltammetry. Both compounds exhibit well-defined $0/1^+$ and $0/1^-$ redox couples attributed to ferrocene oxidation and diphosphine reduction, respectively, with the HOMO and LUMO compositions in **2** and **3** corroborated by extended Hückel MO calculations. The π^*-based LUMO in compounds **2** and **3** is localized on the dione platform and remains unchanged to that found in the parent bpcd ligand. The selection of aldehydes more electron rich than ferrocenecarboxaldehyde will facilitate the tuning of the HOMO level in our bpcd-derived condensation products, and this aspect is under active investigation. Future time-resolved photophysical studies are planned and these data will be disseminated in due course.

5. Supplementary data

CCDC 727855 contains the supplementary crystallographic data for $\mathbf{3}\cdot 1/2H_2O$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 IEZ, UK; Fax: (+44) 1223-336-033; or email: deposit@ccdc.cam.ac.uk.

Acknowledgement

Continued financial support from the Robert A. Welch Foundation (Grant B-1093) is greatly appreciated. Prof. Andreas H. Franz (UP) and Ms. Nicole Ledbetter (UNT) are thanked for their expertise and help in recording the mass spectra for compounds **2** and **3**.

Fluorinated thiolate ligands
Phosphane ligands
Variable temperature ^{19}F NMR

ABSTRACT

The reactions of OsO_4 with excess of HSC_6F_5 and $P(C_6H_4X\text{-}4)_3$ in ethanol afford the five-coordinate compounds $[Os(SC_6F_5)_4(P(C_6H_4X\text{-}4)_3)]$ where X = OCH_3 **1a** and **1b**, CH_3 **2a** and **2b**, F **3a** and **3b**, Cl **4a** and **4b** or CF_3 **5a** and **5b**. Single crystal X-ray diffraction studies of **1** to **5** exhibit a common pattern with an osmium center in a trigonal-bipyramidal coordination arrangement. The axial positions are occupied by mutually *trans* thiolate and phosphane ligands, while the remaining three equatorial positions are occupied by three thiolate ligands. The three pentafluorophenyl rings of the equatorial ligands are directed upwards, away from the axial phosphane ligand in the arrangement "3-up" (isomers **a**). On the other hand, $^{31}P\{^1H\}$ and ^{19}F NMR studies at room temperature reveal the presence of two isomers in solution: The "3-up" isomer (**a**) with the three C_6F_5-rings of the equatorial ligands directed towards the axial thiolate ligand, and the "2-up, 1-down" isomer (**b**) with two C_6F_5-rings of the equatorial ligands directed towards the axial thiolate and the C_6F_5-ring of the third equatorial ligand directed towards the axial phosphane. Bidimensional ^{19}F–^{19}F NMR studies encompass the two sub-spectra for the isomers **a** ("3-up") and **b** ("2-up, 1-down"). Variable temperature ^{19}F NMR experiments showed that these isomers are fluxional. Thus, the ^{19}F NMR sub-spectra for the "2-up, 1-down" isomers (**b**) at room temperature indicate that the two S-C_6F_5 ligands in the 2-up equatorial positions have restricted rotation about their C–S bonds, but this rotation becomes free as the temperature increases. Room temperature ^{19}F NMR spectra of **3** and **5** also indicate restricted rotation around the Os–P bonds in the "2-up, 1-down" isomers (**b**). In addition, as the temperature increases, the ^{19}F NMR spectra tend to be consistent with an increased rate of the isomeric exchange. Variable temperature $^{31}P\{^1H\}$ NMR studies also confirm that, as the temperature is increased, the **a** and **b** isomeric exchange becomes fast on the NMR time scale.

1. Introduction

The first molecular polythiolate-complexes of ruthenium and osmium, $[M(SR)_4(CH_3CN)]$ (M = Ru, Os; R = C_6HMe_4-2,3,5,6 or $C_6H_2{}^iPr_3$-2,4,6), were reported by Koch and Millar in 1983 [1]. On these systems, the experimental M–S_{ax} bond length is substantially longer than the average of the Ru–S_{eq} bond length, as theoretically predicted for these diamagnetic low-spin d^4 complexes [2]. In these complexes two of the aromatic rings of equatorial thiolates are projected towards the axial CH_3CN ligand and the other one is directed towards the axial sulfur (arrangement "2-up, 1-down"). In addition, these compounds were the first examples of five-coordinate ruthenium and osmium complexes bearing a formal +4 oxidation state. In 1985, these authors reported [3] the rare carbonyl M^{IV} compounds, $[M(SR)_4(CO)]$, where the overall structure is similar to that of $[M(SR)_4(CH_3CN)]$, with the CO occupying an axial position in the trigonal-bipyramidal coordination arrangement, in contrast however the three equatorial thiolates are oriented in the direction of the CO (arrangement "3-up"). In a note, the authors remark the fact that the ^1H NMR spectra of all their $[M(SR)_4L]$ compounds are complex and thus, for example $[Ru(SC_6HMe_4\text{-}2,3,5,6)_4(CH_3CN)]$ in $CDCl_3$ exhibits five singlets between δ 6.6 and 7.2 ppm which are assigned to the aromatic protons of the thiolate ligands, ten singlets between δ 1.8 and 2.7 ppm which are assigned to the methyl groups of the thiolate ligands and two resonances at δ 1.0 and 0.89 ppm assigned to the CH_3CN ligand. The interpretation was that both the "3-up" isomer and the "2-up, 1-down" isomer are present in solution and that these two isomers are not interconverting rapidly on the NMR time scale due to a hindered rotation of the ligands at the Ru–S_{eq} bonds.

Other five-coordinate ruthenium and osmium compounds with these sterically hindered aromatic thiolate ligands were reported [4,5]. In 1992 [5], for one of the compounds "2-up, 1-down", the authors found out that rotation about the Ru^{IV}–S bonds and C–S bonds is not observed on the NMR time scale from room temperature to nearly 60 °C.

For a long time, we have also been involved in the synthesis and reactivity studies of five-coordinate Os^{IV}-polythiolate-complexes [6–12], of general formula $[OsX(SR_F)_3(PR_3)]$ (X = Cl, SR_F; SR_F = SC_6F_5, SC_6F_4H-4, SC_6H_4F-4, SC_6H_5; PR_3 = tertiary phosphane). Up to now, all members of these series -characterized by X-ray crystallography- have shown, invariably, the orientation "3-up" for the equatorial thiolates, probably because the axial tertiary phosphane hinders that a R_F group could lie near of such an axial position. In general the structures in solution, according to ^1H, ^{31}P and ^{19}F NMR spectra of some members of the series, are as expected if the solid-state structure is maintained in solution. Some compounds however, undergo a measurable isomerisation that had not been exhaustively investigated since generally only room temperature NMR spectra were available, and it was not possible to assign the isomers with certainty [7]. In fact, except for the "3-up" isomer, none other specific isomer had been accurately assigned in solution.

On the other hand, restricted rotation of polyfluoro-phenyl/alkyl groups has been observed in a variety of coordination and organometallic compounds [12–21]. For example $[Os(SC_6F_5)_3(SC_6F_4(SC_6F_5)$-2)] and $[Os(SC_6F_4H)_2(SOC_6F_3H)(PPh_3))]$ exhibited restricted rotation of groups C_6F_5 or C_6F_4H about their C–S bonds [12], whereas complexes $[IrCp^*\{(CF_2)_nCF_3\}(PMe_3)_2]^+$ (n = 1, 2, 3, 5, 7, 9, 11) exhibited restricted rotation about their Ir–C σ-bonds [13] and complex $[Pd(C_6F_5)_2(Me_2–TpzT)]$ (Me_2–TpzT = 2,4,6-tris(3,5-dimethylpyrazol-1-yl)-1,3,5-triazine) exhibited restricted rotation about its Pd–C_6F_5 bonds [15]. The corresponding fluxional processes can be accompanied by conformational changes in the molecules and dynamic ^{19}F NMR studies of fluoro-thiolate complexes, $[W(SC_6F_5)_3(CO)Cp]$ [20], have revealed that isomeric forms exist due to different orientations of the SC_6F_5 ligands and the isomers undergo exchange as a result of rotations about W–SC_6F_5 bonds.

We now report the structural characterization of the compounds $[Os(SC_6F_5)_4(P(C_6H_4X$-4)$_3)]$, where X = OCH_3 **1**, CH_3 **2**, F **3**, Cl **4** or CF_3 **5**, both in the solid-state by X-ray diffraction studies, and in solution by $^{31}P\{^1H\}$ and ^{19}F NMR investigation of structural changes depending of temperature. These fluorinated systems offer the possibility to distinguish clearly the structural details of these types of five-coordinated osmium(IV) molecules and their structural changes.

2. Results and discussion

The reactions of OsO_4 with excess of HSC_6F_5 and $P(C_6H_4X$-4)$_3$ in ethanol afford the pentacoordinated, diamagnetic compounds $[Os(SC_6F_5)_4(P(C_6H_4X$-4)$_3)]$ where X = OCH_3 **1**, CH_3 **2**, F **3**, Cl **4** or CF_3 **5**. A general preliminary information about the preparation of these compounds has been mentioned [9]. Pentafluorobenzenethiol is dissolved in ethanol and then osmium tetraoxide is added. The mixture quickly turns black, the phosphane is added and the mixture refluxed turning green/brown. In addition to the formation of $[Os(SC_6F_5)_4(P(C_6H_4X$-4)$_3)]$, the recently reported persulfurated complex, $[Os(SC_6F_5)_3(SC_6F_4(SC_6F_5)$-2)] [12] **6**, is present as an additional product of these reactions.

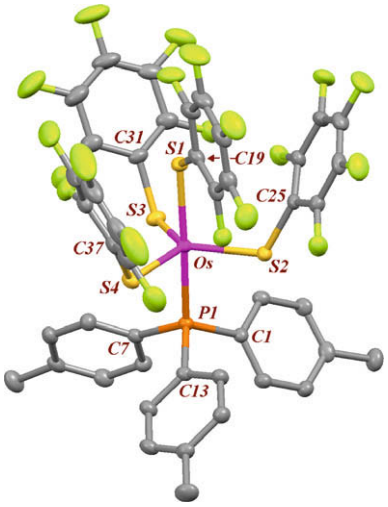

Fig. 1. Molecular structure of complex $[Os(SC_6F_5)_4(P(C_6H_4CH_3$-4)$_3)]$, **2a** [22]. H atoms have been omitted in the figure, and displacement ellipsoids are drawn at the 25% probability level.

The yields of **1**–**5** and **6** depend strongly on the relative proportion of phosphane ligand present always in excess to accomplish the required reduction of the osmium. Thus, the compound $[Os(SC_6F_5)_4(P(C_6H_4OCH_3$-4)$_3)]$ **1** is obtained in 70% yield when the molar ratio OsO_4:$P(C_6H_4OCH_3$-4)$_3$ is 1:6, while the yield drops down to only 9% when this ratio is 1:1.75. The formation of **6** depends just as well of this ratio.

The products were isolated by passage through a chromatographic column. These osmium(IV) diamagnetic complexes were characterized by elemental analyses, FAB^+-mass spectrometry, single crystal X-ray structure determinations and variable temperature $^{31}P\{^1H\}$ and ^{19}F NMR studies.

The FAB-mass spectra show low intensities signals of M^+ (X = Cl **4**) or $[M–H]^+$ (X = CF_3 **5**, F **3**, CH_3 **2**). A common high intensity signal on all the spectra is that corresponding to $[Os(SC_6F_5)_3(P(C_6H_4X$-4)$_3)]^+$. Also, peaks corresponding to $[P(C_6H_4X$-4)$_3)]^+$ and $[P(C_6H_4X$-4)$_2)]^+$ ions, with medium to high intensities are found on all FAB-mass spectra of compounds **1**–**5**.

The NMR studies show that each one of these products exists as a pair of isomers (**a**) and (**b**).

In the solid-state, compounds $[Os(SC_6F_5)_4(P(C_6H_4X$-4)$_3)]$ **1a**–**5a** share the trigonal-bipyramidal coordination geometry invariably observed for all Os^{IV} complexes formulated as $[OsX(SR_F)_3(PR_3)]$ (X = Cl, SC_6F_5, SC_6F_4H-4; SR_F = SC_6F_5, SC_6F_4H-4; PR_3 = tertiary phosphane) [6–8,10,11] (Fig. 1). The nature of the X substituent in the phosphane has none or little influence on the arrangement of ligands around the Os^{IV} ion. Axial positions are occupied by mutually *trans* thiolate and phosphane ligands, with S1–Os1–P1 angles in the short range 173.20(4)–177.23(4)°. Apparently there is no correlation between structural parameters and the *trans* influence of the phosphanes present in complexes **1a**–**5a**. Variations observed for Os1–S1 and Os1–P1 bond lengths are limited and virtually fall within the standard uncertainties for these parameters, 0.001–0.002 Å. Within experimental accuracy, any attempts to correlate phosphane basicity and solid-state structures would then be of questionable significance. Equatorial coordination sites are occupied by three thiolate ligands, with pentafluorophenyl groups

$$OsO_4 + HSC_6F_5(\text{excess}) + P(C_6H_4X\text{-}4)_3(\text{excess}) \xrightarrow{\text{Ethanol}} \underset{\textbf{1-5}}{[Os(SC_6F_5)_4(P(C_6H_4X\text{-}4)_3)]} + \underset{\textbf{6}}{[Os(SC_6F_5)_3(SC_6F_4(SC_6F_5)\text{-}2)]}$$

oriented away from the axial phosphane ligand, in the arrangement "3-up" (isomer **a**), in order to minimize the overall steric hindrance for peripheral phenyl rings in this molecule.

Although molecular structures are similar for all studied complexes, two points deserve to be commented. We previously reported that in the complex $[Os(SC_6F_5)_4(PPh_3)]$, which crystallizes with three crystallographically independent molecules in the asymmetric unit [10], the axial thiolate ligand gives rise to rotamers due to a non-restricted rotation about Os–S(*ax*) and S(*ax*)–C(*ipso*) σ-bonds. Similar results, although of limited extent, may be found among compounds **1a–5a** by inspecting the S(*eq*)–Os–S(*ax*)–C(*ipso*) torsion angles (Table 2). On the basis of these data, complexes **1a–5a** can be roughly classified in two groups: **1a–2a** (S4–Os–S1–C19 torsion angle close to 60°) and **3a–5a** (S4–Os–S1–C19 torsion angle close to 71°). This flexibility of orientation observed for the axial thiolate ligand is also present for the equatorial ligands, which experiment libration motions, particularly for S3-thiolate. Again, complexes **1a** and **2a** are differentiated from **3a–5a** (Fig. 2).

The second point of interest is about **3a**, which is the only member of this series crystallizing in a non-centrosymmetric achiral space group (*NA* crystal-structure type in the Flack's classification [23]). The measured crystal revealed to be a sample twinned by inversion, with components of the twin in the ratio 0.72(1):0.28(1) (see Section 4 and Fig. 2). A non-racemic mixture of configurations 0.72-*Λ*, 0.28-*Δ* was thus crystallized in the case of **3a** (the chiral axis is defined by P–Os bond). The other crystallized complexes of the series (**1a**, **2a**, **4a** and **5a**) are necessarily *Λ*,*Δ*-racemates, as they crystallize in centrosymmetric space groups (*CA* crystal-structure type in the Flack's classification [23]). In other words, **3a** in the solid-state represents an example of a co-crystallization associated with a partial spontaneous resolution. The factor promoting this resolution should probably be searched in crystallization conditions rather than in compound formulas or intermolecular interactions in the solid-sate. Single crystals were obtained either by crystallization from an acetone–ethanol solution of a powder sample, or directly by slow evaporation of chromatographed fractions (eluent: hexane-CH_2Cl_2) of the crude from the synthesis reactions. On the other hand, multiple crystal structure determinations on multiple crystallization crops would be necessary, in order to check if **3a** is systematically resolved in a more or less similar enantiomeric excess upon crystallization, and that such a resolution never occur for other complexes.

Although TLC for each of the products **1–5** shows only one spot, and in all the determined X-ray diffraction structures of these products the osmium center displays the same arrangement "3-up" for the equatorial thiolate ligands, the NMR studies show that each one of these products exists as the pair of isomers "3-up" (**a**) and "2-up, 1-down" (**b**) as depicted in the following scheme (Scheme 1).

The room temperature $^{31}P\{^1H\}$ NMR spectra of each product **1–5**, and the previously reported $[Os(SC_6F_5)_4(P(C_6H_5)_3)]$ [7] **7**, show two singlets suggesting the presence of two isomers. In all cases, the signal at low field corresponds to the more abundant isomer

Table 2

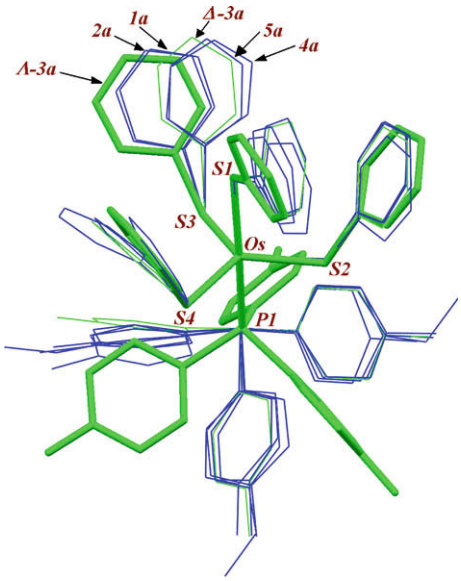

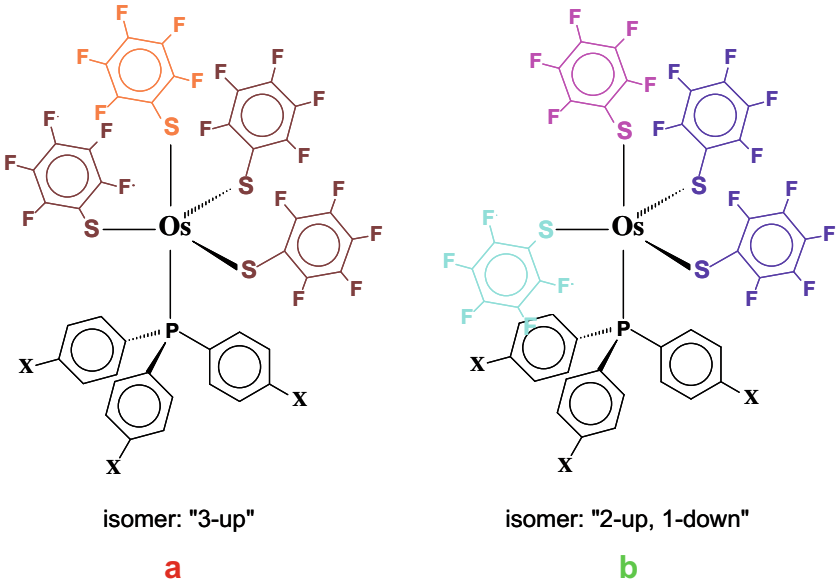

Fig. 2. A least-squares overlay [22] of molecular structures of complexes **1a–5a**. For the sake of clarity, F atoms of thiolate and of CF_3 groups, and all H atoms were omitted in the figure. The fit is carried out considering Os, P and S atoms (coordination sphere), while other atoms are free. In the case of complexes crystallizing in centrosymmetric space groups (blue bonds), *Δ* configuration has been arbitrarily selected. For **3a** (green bonds), both *Λ* and *Δ* configurations, forming a non-racemic mixture in the crystal, have been fitted.

$[Os(SC_6F_5)_4(P(C_6H_4Cl\text{-}4)_3)]$ **4**	6.59	4.03	3.8
$[Os(SC_6F_5)_4(P(C_6H_4CF_3\text{-}4)_3)]$ **5**	8.52	6.08	4.4

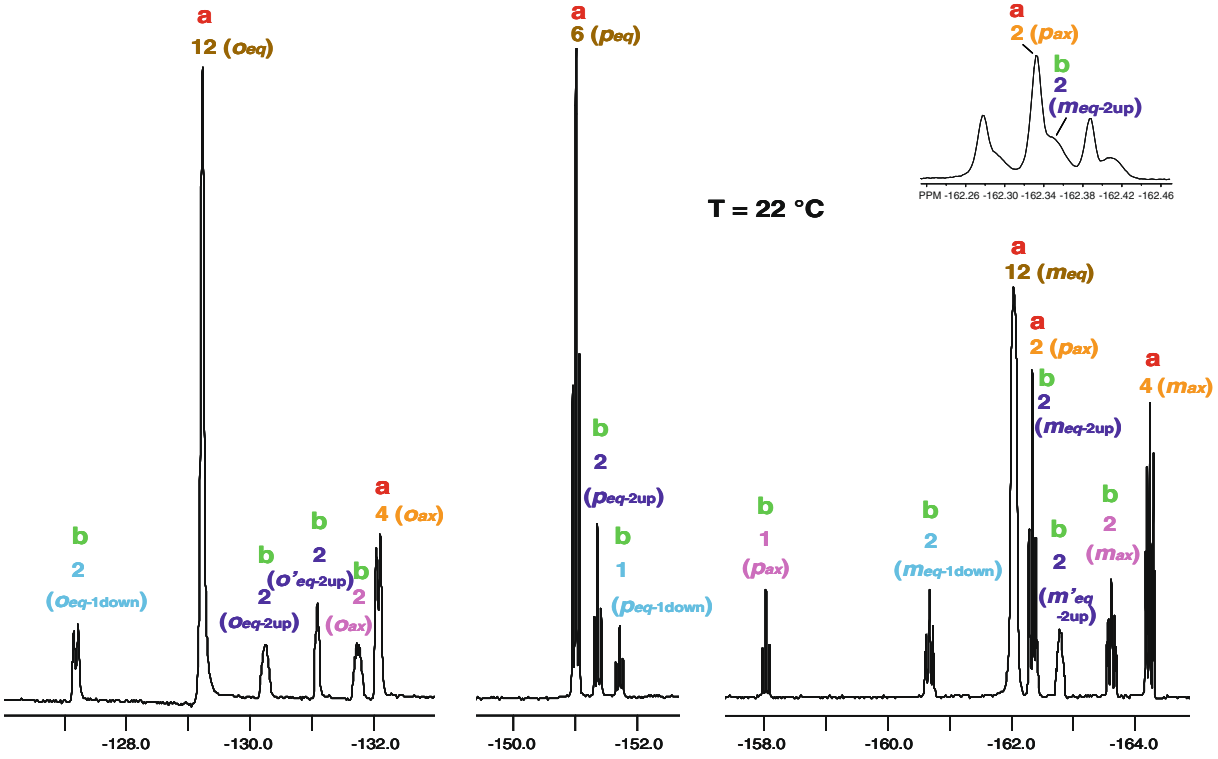

Fig. 3. ^{19}F NMR spectrum of $[Os(SC_6F_5)_4(P(C_6H_4CH_3\text{-}4)_3)]$ **2** at 22 °C in $C_6D_5CD_3$. The letter-labels identify the isomers: a, isomer "3-up"; b, isomer "2-up, 1-down". Numbers correspond to the relative integrals, which show that the ratio a/b is 2:1 in this product.

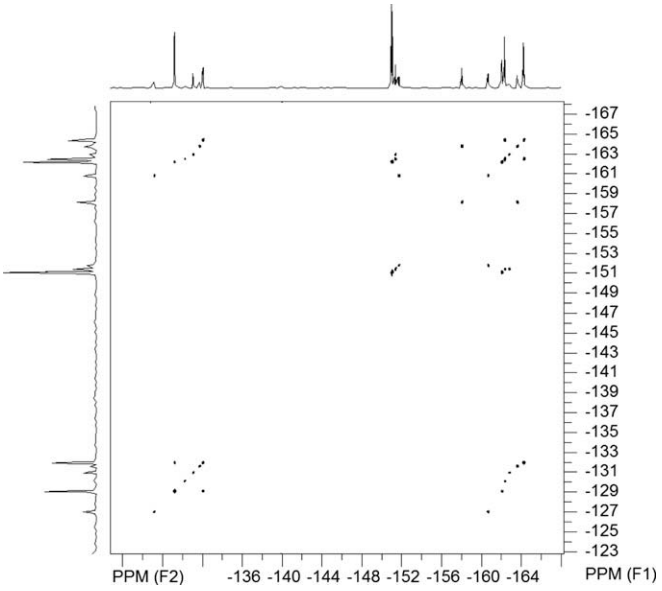

Fig. 4. $^{19}F–^{19}F$ COSY NMR spectrum of $[Os(SC_6F_5)_4(P(C_6H_4CH_3\text{-}4)_3)]$ **2** at 22 °C.

which, as deduced from the ^{19}F NMR studies below, is the "3-up" isomer (**a**). Table 3 indicates the relative abundances calculated from the $^{31}P\{^1H\}$ NMR spectra at room temperature, including the corresponding data from **7** for comparison purposes. These relative abundances are the same as those calculated from the ^{19}F NMR spectra.

Although the relative abundance of isomer **a** seems to growth with the electronegativity of the X substituent on the phosphane $P(C_6H_4X\text{-}4)_3$, the **a**/**b** ratio is probably a combination of electronic factors influencing the ability to undergo the required inversion of configuration at the sulfur atoms as well as solvent-complex interactions with the changing dipolar moments of the substituted phenyl rings.

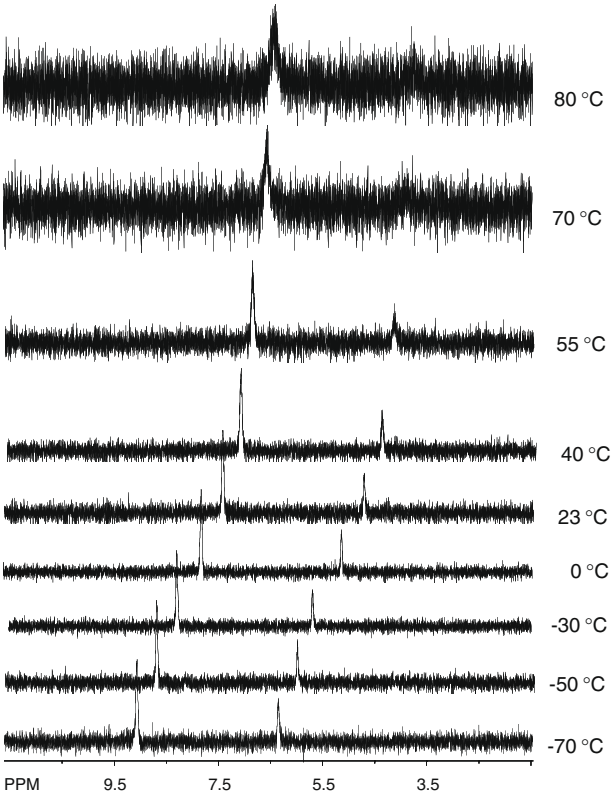

Fig. 6. Variable temperature $^{31}P\{^1H\}$ NMR spectra of $[Os(SC_6F_5)_4(P(C_6H_4CH_3\text{-}4)_3)]$ **2** in $C_6D_5CD_3$

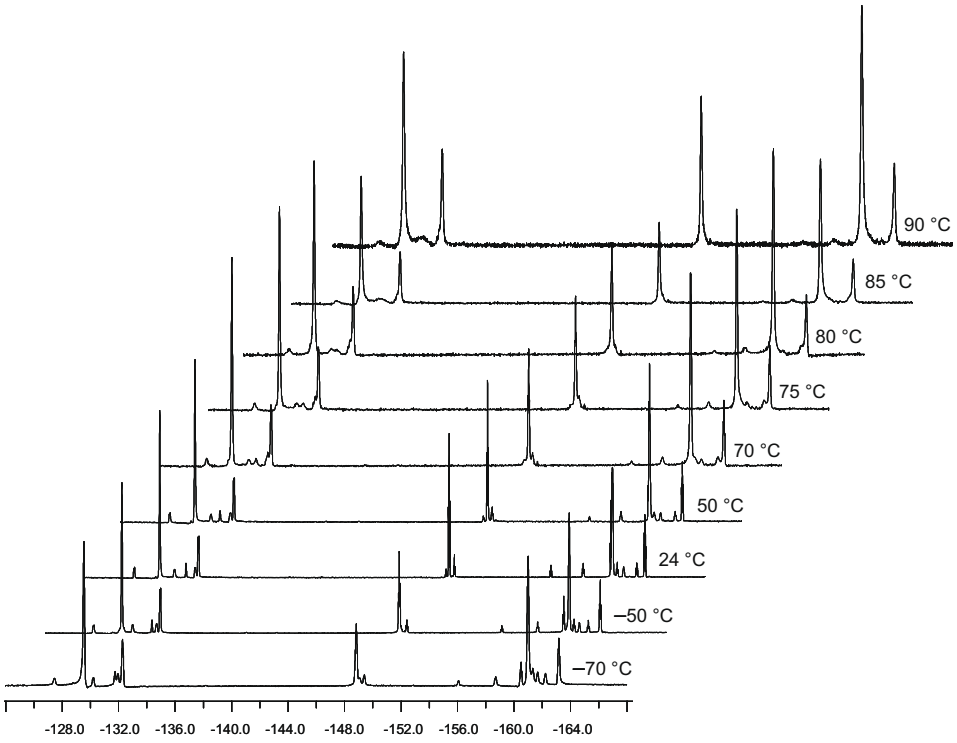

Fig. 5. Variable temperature ^{19}F NMR spectra of $[Os(SC_6F_5)_4(P(C_6H_4Cl\text{-}4)_3)]$ **4** in $C_6D_5CD_3$.

Room temperature ^{19}F NMR spectra of each product **1–5,** and the previously reported $[Os(SC_6F_5)_4(P(C_6H_5)_3)]$ [7,10] **7**, exhibit two independent sub-spectra, one for each of the isomers present in solution. $^{19}F–^{19}F$ NMR experiments were used to unambiguously identify each set of signals. The sub-spectrum of the isomer **a** "3-up" consists of two groups of signals with three absorptions each, corresponding to *ortho*, *para* and *meta*-fluorine atoms of C_6F_5 rings, at low, medium and high field, respectively [24,25]. One of these groups arises from the three equivalent equatorial thiolate ligands (A_2BC_2 spin system, relative integrals 6:3:6), and the second group from the axial thiolate ligand (another A_2BC_2 spin system, relative integrals 2:1:2). The sub-spectrum of the isomer **b** "2-up, 1-down" consists of three groups of signals: the group from one equatorial thiolate ligand in the orientation 1-down, which consists of three *ortho*, *para* and *meta* absorptions (A_2BC_2 spin system, relative integrals 2:1:2), the group from the two equatorial thiolate ligands in the orientation 2-up, which consists of five *ortho*, *ortho′*, *para*, *meta* and *meta′* signals (AA′BCC′ spin system, relative integrals 2:2:2:2:2), and the group of the axial thiolate ligand, which consists of three *ortho*, *para* and *meta* signals (A_2BC_2 spin system, relative integrals 2:1:2). The group of five signals from the two equatorial thiolate ligands in the orientation 2-up is consistent with two equivalent C_6F_5-groups restricted to rotate about their C–S bonds, where the two *ortho* (as well as *meta*) fluorine atoms in each ring are magnetically non-equivalent. Of course, the relative integrals between signals of isomer **a** and signals of isomer **b** are specific of each product. Fig. 3 shows the ^{19}F NMR spectrum at room temperature of the product **2** ($X = CH_3$), where the described assignments are illustrated whereas Fig. 4 shows the corresponding $^{19}F–^{19}F$ NMR spectrum.

For all "3-up" isomers, the room temperature $^{19}F–^{19}F$ NMR spectra show a significant magnetic coupling between $F_{ortho-equatorial}$ and $F_{ortho-axial}$ nuclei. These nuclei are eight bonds apart with a S–Os–S intermediate fragment and therefore, a conventional contact coupling mechanism is unlikely. On the other hand, the three equatorial thiolates on the "3-up" isomers form a bowl-like cavity which surrounds the axial thiolate with a very close spatial proximity to the *ortho* fluorine nuclei and therefore suggesting a through-space coupling mechanism.

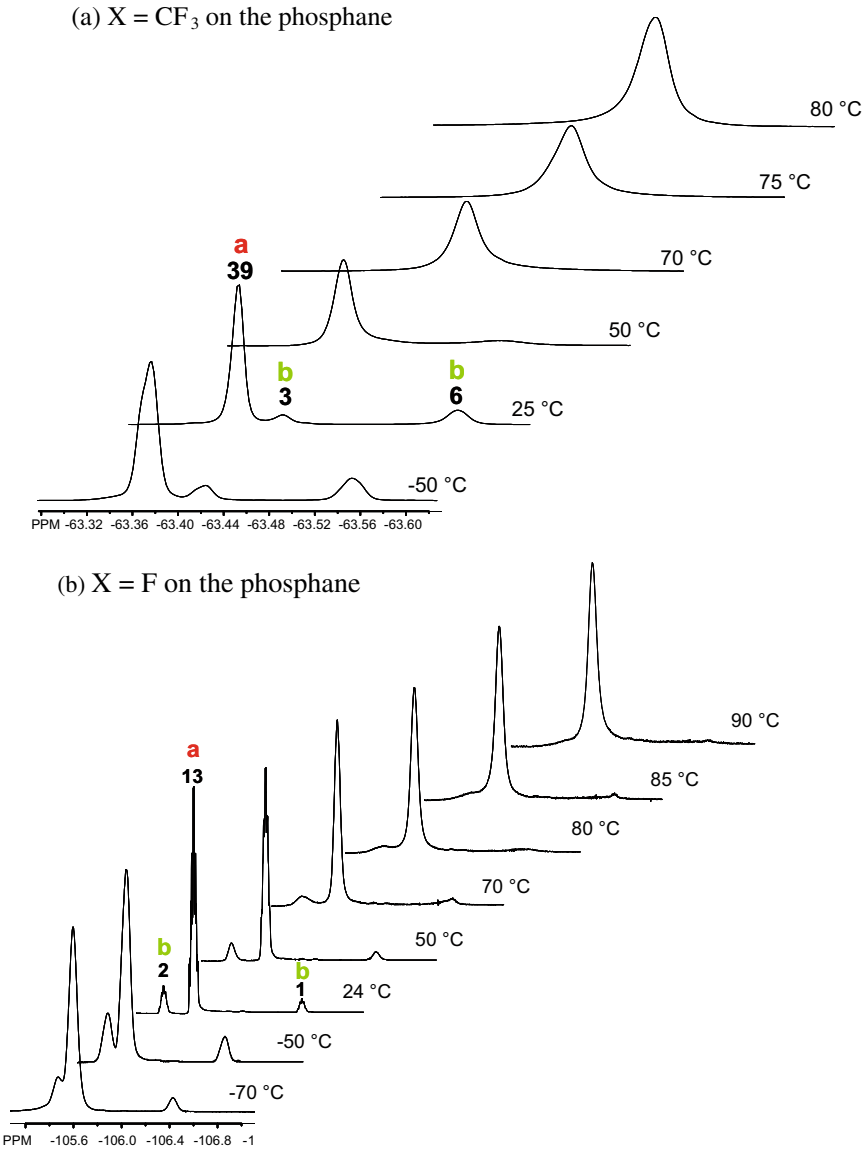

Fig. 7. Variable temperature ^{19}F NMR spectra on the phosphane–fluorine region of (a) $[Os(SC_6F_5)_4(P(C_6H_4CF_3\text{-}4)_3)]$ **5** and (b) $[Os(SC_6F_5)_4(P(C_6H_4F\text{-}4)_3)]$ **3** in $C_6D_5CD_3$; a corresponds to isomer "3-up" and b to isomer "2-up, 1-down". Numbers correspond to the relative integrals, which show that the ratio a/b is 4.4:1 in these products.

The ^{19}F NMR spectra of each product **1**–**5**, and **7**, registered from −80 °C to +90 °C, indicate that these products undergo fluxional processes in solution. Fig. 5 shows variable temperature ^{19}F NMR spectra of product **4** (X = Cl) in $C_6D_5CD_3$. In general, for isomers **b** "2-up, 1-down" in the series **1**–**5** and **7**, as the temperature is increased, the two *ortho* and *ortho*′ signals (relative intensities 2:2), from the two equivalent 2-up equatorial thiolates, broaden and eventually coalesce giving rise to a single *ortho* signal (intensity 4) at *ca.* 85–90 °C. The coalescence of the corresponding *meta* and *meta*′ signals follows a similar pattern, while at high temperatures the corresponding *para* absorption of these 2-up equatorial thiolate ligands exhibits chemical shift almost coincident with the *para* signal of the 1-down equatorial thiolate of the same isomer **b**, and with the *para* signal of the three 3-up equatorial thiolates of the isomer **a**. As the temperature is increased, the ^{19}F NMR spectra of **1**–**5**, and **7** tend to simplify until they resemble the spectra of the isomer **a**. The coalescence at high temperatures (85–90 °C) of the *ortho* and *ortho*′ signals from the two 2-up equatorial thiolates is consistent with free C–S bond rotations at these temperatures, with estimated $\Delta G^{\ddagger}$ values of 69–70 kJmol^{-1}. In addition, the tendency of both ^{19}F NMR sub-spectra of the isomers **a** and **b** (low temperatures) to merge into a single spectrum corresponding to the isomer **a** (high temperatures) suggests that a rapid conversion between isomers **a** and **b** occurs also and simultaneously. To investigate this process further, we have measured the $^{31}P\{^1H\}$ NMR spectra at variable temperature and found that, as the temperature is increased, both singlets from isomers **a** and **b** broaden and decrease in height, although at 80 °C (or inclusive 95 °C) their coalescence is still not completed (Fig. 6). This is a reversible process since the original spectra are obtained as the temperature is restored back. We conclude that two fluxional processes are being simultaneously observed: the C–S bond rotation of the two 2-up equatorial thiolates in the isomer **b** and the conversion between isomers **a** and **b** which involves inversion of configuration at the sulfur atoms.

Except for subtle differences in chemical shifts and some variations in the relative positions of the *para* and *meta* signals, the ^{19}F NMR spectra in the C_6F_5-region of these products **1**–**5** and **7** are all comparable.

In addition, the room temperature ^{19}F NMR spectrum of **5** (X = CF_3), in the CF_3-region of the phosphane ligand, exhibits: one singlet corresponding to equivalent CF_3 groups at the *para*-positions of the phenyl substituents of the phosphane in the isomer "3-up" **5a** and two singlets (relative integrals 3:6) corresponding to non-equivalent CF_3 groups of the phenyl substituents of the phosphane in the isomer "2-up, 1-down" **5b**. The corresponding spectrum of **3** (X = F) on the fluorine-region of the phosphane, also exhibits the same pattern of signals, corresponding to the *para*-fluorine nuclei in the phenyl substituents of the phosphane ligand of the isomers: **3a**: one doublet of triplets of triplets, corresponding to three equivalent C_6H_4F-4 substituents in this isomer, and **3b**: two doublets of triplets of triplets, relative integrals 2:1, corresponding to two equivalent C_6H_4F-4 rings plus another non-equivalent C_6H_4F-4 ring one in this isomer "2-up, 1-down". In each of these two products **3** or **5**, these additional signals at low field tend to coalesce into only one signal as the temperature increases (Fig. 7). The spectra of these two products **3** and **5** at low field corroborate the existence of the isomers "3-up" and "2-up, 1-down" in solution and show that, at low temperatures, the isomer "2-up, 1-down" exhibits restricted rotation of the osmium–phosphorous bond imposed by the pending thiolate ring giving rise to a system involving an unusual asymmetrical phosphane.

3. Conclusions

We report here the reactions of OsO_4 with HSC_6F_5 and $P(C_6H_4X\text{-}4)_3$ in ethanol to afford the five-coordinate compounds $[Os(SC_6F_5)_4(P(C_6H_4X\text{-}4)_3)]$ where X = OCH_3 **1a** and **1b**, CH_3 **2a** and **2b**, F **3a** and **3b**, Cl **4a** and **4b** or CF_3 **5a** and **5b**. Single crystal X-ray diffraction studies of **1**–**5** exhibit a common pattern with an osmium center in a trigonal-bipyramidal coordination arrangement with the axial positions occupied by mutually *trans* thiolate and phosphane ligands and the three C_6F_5-rings of the equatorial thiolate ligands directed towards the axial thiolate ligand (isomers **a** "3-up"). On the other hand, $^{31}P\{^1H\}$ and ^{19}F NMR studies at room temperature reveal accurately the presence of two isomers in solution: the "3-up" isomer (**a**) above mentioned, and the "2-up, 1-down" isomer (**b**) with two C_6F_5-rings of the equatorial ligands directed towards the axial thiolate and the C_6F_5-ring of the third equatorial ligand directed towards the axial phosphane. In addition, at low temperatures, the NMR studies reveal restricted rotations about specific bonds in the molecules. As the temperature increases, the ^{19}F and $^{31}P\{^1H\}$ NMR spectra tend to be consistent with an increased rate of these rotations about bonds in the isomers, as well as with an increased rate of the isomeric exchange.

4. Experimental

All reactions were carried out under argon atmospheres using conventional Schlenk-tube techniques. Thin-layer chromatography (TLC) (Merck, silica gel 60 F_{254}) was used to monitor the progress of the reactions under study with hexane–dichloromethane (4:1) as eluent. The starting materials: osmium tetraoxide, pentafluorobenzenethiol and phosphanes were used as received from Aldrich Chemical Co. and Strem. The products were separated by passage through a silica gel chromatographic column with hexanes–dichloromethane as eluent.

Melting points were obtained on a Fisher–Johns melting point apparatus and are uncorrected.

Infrared spectra were recorded on a 750 Nicolet Fourier Transform Magna-IR Spectrometer. The samples were prepared as KBr pellets. Data are expressed in wavenumbers (cm^{-1}) with relative intensities (vs = very strong, s = strong, m = medium, w = weak).

$^{31}P\{^1H\}$, ^{19}F, and COSY ^{19}F–^{19}F NMR spectra were recorded on a Varian Mercury VX400 spectrometer operating at 162 MHz, and 376 MHz, respectively. $^{31}P\{^1H\}$ NMR spectra were also recorded on a Varian Mercury VX300 spectrometer operating at 121 MHz. Chemical shifts are relative to H_3PO_4 $\delta = 0$ (^{31}P) and CCl_3F $\delta = 0$ (^{19}F), using $C_6D_5CD_3$ and $CDCl_3$ as solvents. The $\Delta G^{\ddagger}$ values reported in this paper have been calculated from variable temperature (VT) ^{19}F NMR data with the Eyring equation, estimating the rate constant at the coalescence temperature on the basis of the chemical shift difference at low temperature.

Positive ion FAB mass spectra were recorded on a Jeol JMS-SX102A mass spectrometer operated at an accelerating voltage of 10 kV. Samples were desorbed from a 3-nitrobenzyl alcohol (NOBA) matrix using 3 keV xenon atoms. Mass measurements in FAB are performed at a resolution of 3000 using magnetic field scans and the matrix ions as the reference material.

Elemental analyses were determined by Galbraith Laboratories Inc.

4.1. $[Os(SC_6F_5)_4(P(C_6H_4OCH_3\text{-}4)_3)]$ **1**

Pentafluorobenzenethiol (0.8 mL, 6.0 mmol) was dissolved in ethanol (15 mL), then osmium tetraoxide (0.25 g, 1.0 mmol) was added. The mixture rapidly turned black. $P(C_6H_4OCH_3\text{-}4)_3$ (0.62 g, 1.75 mmol) was added and the mixture refluxed for 4 h turning green. The solvent was distilled off under vacuum and the solid product was purified through a silica gel chromatographic column eluted with hexane–dichloromethane 4:1. Two fractions with compounds **1** and $[Os(SC_6F_5)_3(SC_6F_4(SC_6F_5)\text{-}2)]$ [12] **6** were separated

and dried under vacuum at room temperature for 4 h. Single crystals of **1** were obtained by slow evaporation of an acetone–ethanol solution of the compound.

4.4. *[Os(SC$_6$F$_5$)$_4$(P(C$_6$H$_4$Cl-4)$_3$)]* ***4***

Pentafluorobenzenethiol (0.8 mL, 6.0 mmol) was dissolved in ethanol (15 mL), then osmium tetraoxide (0.25 g, 1.0 mmol) was added. The mixture rapidly turned black. P(C_6H_4Cl-4)$_3$ (0.67 g, 1.82 mmol) was added and the mixture was stirred at room temperature for 9 h. The resulting solution was concentrated at *ca.* 50% under reduced pressure to give a brown precipitate. It was filtered off, washed with ethanol (15 mL) and hexane (15 mL) and dried under vacuum. Additional purification was necessary through a silica gel chromatographic column with hexane–dichloromethane 4:1 as eluent. Slow evaporation of the eluent affords brown crystals of **4**. With scope for increasing the yield of **4**, the filtrate was refluxed for 3 h giving a green product, **6**, which was also purified through a silica gel chromatographic column with hexane–dichloromethane 4:1 as eluent.

4.7. X-ray diffraction data

X-ray diffraction data for complexes **1a–5a** were measured on single crystals at 296(1) K, using a Bruker P4 diffractometer [26]. Data were corrected for absorption effects on the basis of ψ-scans (**1a–2a**) or crystal faces indexation (**3a–5a**). Essential X-ray data are given in Table 1, and details may be found in the deposited CIF, along with full geometric parameters. The structures were solved and refined using SHELXS97 and SHELXL97 software [27]. For **3a**, Wilson's statistics are in agreement with a non-centrosymmetric space group, and systematic extinction expected for a 2_1 axis is not observed, allowing to rule out space groups *P*2/*n* and *P*2$_1$/*n*. A refinement in space group *Pn* including 654 measured Friedel pairs (R_1 = 0.037) indicated a degree of twinning by inversion for the crystal. The fractional contribution of the inverted model was then refined, converging to *x* = 0.72(1) and R_1 = 0.025. For **5a**, each CF_3 groups of the phosphane ligand is disordered over two sites, by a rotation of *ca.* 60° about the C–CF_3 σ-bond. Site occupation factors for disordered F atoms were fixed to 1/2. In order to get a sensible geometry, C–F bond lengths were restrained to 1.31(1) Å and F...F separations within each disordered part were restrained to 2.09(2) Å. For disordered F atoms in each CF_3 group, U_{ij} displacement parameters were restrained to be similar with standard deviation of 0.04 Å^2, and to approximate to isotropic behavior. Complex **5a** crystallizes as a monohydrate, the lattice water molecule being disordered over two sites with occupancies 1/2. Drawings of Figs. 1 and 2 were made using the Mercury program [22].

Supplementary data

CCDC 716480, 716481, 716482, 716483, 716484 contains the supplementary crystallographic data for **1a–5a**. Zinc azaphthalocyanine
Tetrapyrazinoporphyrazine
Pyridin-3-yloxy
Dichlorobis(quinoline-N)zinc(II)

ABSTRACT

Phthalocyanines (Pc), which are peripherally substituted with pyridin-3-yloxy groups, have shown promise as sensitizers for photodynamic cancer therapy (PDT). Some aza-analogues (AzaPc) are reported here. Four monomers were synthesized, i.e. 5,6-di(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile, and three pyrazine-2,3-dicarbonitriles, substituted with pyridin-3-yloxy- in combination with H, Me and Ph groups. Cyclotetramerizations of these monomers with the reagent $Zn(quinoline)_2Cl_2$ yielded the targeted ZnAzaPcs in 20–40% yields.

The cyclotetramerizations were accompanied, and apparently initiated, by complexation between zinc(II) and the pyridin-3-yloxy groups attached to the pyrazine-dicarbonitriles. Two such zinc(II) complexes were isolated and characterized. Identifications of all new substances were primarily based on NMR spectra, where the pulse techniques COSY, NOESY, HSQC and HMBC were applied. Molecular ions of the ZnAzaPcs were determined by mass spectrometry (MALDI-TOF). The UV–Vis spectra of these macrocycles were as expected, with Q-band absorptions at 630–650 nm and molar extinction coefficients, ε, 70 000–100 000. Eight peripheral pyridin-3-yloxy groups induced a small blue shift of the Q-band, from 636 nm for unsubstituted ZnAzaPc, to 630 nm, whereas a red shifted Q-band at 650 nm resulted from the combination of phenyl and pyridin-3-yloxy substituents. Improved solubilities were observed for the unsymmetrical ZnAzaPcs compared to octa(pyridin-3-yloxy)ZnAzaPc.

1. Introduction

Zinc phthalocyanines, ZnPc, with peripheral pyridin-3-yloxy substituents have been investigated previously and were found to be promising sensitizers for photodynamic therapy (PDT); by Wöhrle et al. [1–3] some years ago, and more recently by Vicente et al. [4]. Efficient PDT requires sensitizers with good solubility in polar solvents, strong UV–Vis Q-band absorption in the vicinity of 700 nm, and the ability to induce high production of singlet oxygen. The Q-bands of tetrapyrazinoporphyrazines, or azaphthalocyanines (AzaPc), are found at shorter wavelengths than for Pc, due to the increased number of nitrogen atoms in the macrocyclic skeleton. However, this may be compensated by introducing peripheral substituents, such as thien-2-yl or *t*-butylsulfanyl, which induce substantially red shifted AzaPc Q-bands [5–7]. The singlet oxygen quantum yields (Φ_Δ) for ZnAzaPcs are subject to similar variations, i.e. the lowest value ($\Phi_\Delta = 0.487$) was found for unsubstituted ZnAzaPc, and the highest value ($\Phi_\Delta = 0.672$) was found for tetra(*t*-butylsulfanyl)-tetra(thien-2-yl)ZnAzaPc [7].

The first aim of the present study is exploration of methods for the synthesis of octa(pyridin-3-yloxy)ZnAzaPc. An expected challenge for this cyclotetramerization is the known replacement of aryloxy substituents on pyrazine-dicarbonitriles by strong nucleophiles [8,9]. Consequently, the classical Linstead synthesis will not be suitable since metal alkoxides are used to induce cyclotetramerizations by this method.

Syntheses of similar ZnAzaPcs, substituted with pyridin-3-yloxy groups in combination with H, Me or Ph groups are expected to give a more detailed picture of this type of macrocycles. Characteristics of the ZnAzaPcs may indicate potential applications of these or similar compounds.

2. Experimental

2.1. Materials and methods

Electron impact (EI) mass spectra, or electron spray ionization (ESI) mass spectra were obtained of compounds **2**–**5** on a Finnigan MAT 95XL spectrometer, at 70 eV electron energy and 1.0 mA electron current for EI, and in positive mode for ESI on an Agilent 6210 Time of flight instrument, with MeOH + H_2O + AcOH/cap230 °C/3 kV. MALDI-TOF mass spectra of compounds **8** and **9** were recorded on a Bruker Ultraflex III MALDI-TOF-TOF mass spectrometer operated in TOF mode. Each sample was dissolved in pyridine, diluted with methanol (10× the volume of pyridine), spotted onto the target plate, airdried at ambient temperature and covered with the matrix solution which consisted of α-cyano-4-hydroxycin-

namic acid, acetonitrile and trifluoroacetic acid. IR spectra were obtained on a Thermo Nicolet Nexus FT-IR spectrometer with a Smart Endurance reflexion cell. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker Avance DPX 400 NMR spectrometer or on a Bruker Avance Digital 600 NMR spectrometer at 100.4, 399.65 or 600.18 MHz, respectively. Chemical shifts are given relative to internal tetramethyl silane (TMS) when $CDCl_3$ was used as solvent. Chemical shifts are calibrated relative to the DMSO signal at 2.50 ppm for ^{1}H, and 39.51 ppm for ^{13}C when DMSO-d_6 was used as solvent. The NMR pulse techniques COSY, NOESY, HSQC and HMBC were used to correlate ^{1}H and ^{13}C NMR signals for all new compounds. UV–Vis spectra were recorded on a Cary 50 UV–Vis spectrophotometer. Melting points were obtained on a Büchi 530 melting point apparatus and are uncorrected. Merck Kieselgel 60F 254 was used for thin layer chromatography (TLC) and Merck silica 63–200 μm was used for column chromatography. 3-Hydroxypyridine was obtained from Janssen Chimica. 5,6-Dichloropyrazine-2,3-dicarbonitrile, (**1**), was obtained as in [8,10], 5-chloropyrazine-2,3-dicarbonitrile (**3a**), as in [11], 5-chloro-6-methylpyrazine-2,3-dicarbonitrile (**3b**), and 5-chloro-6-phenylpyrazine-2,3-dicarbonitile (**3c**), were obtained as in [12].

2.2. Synthesis

2.2.1. Compounds **2**, **4a–c** and **5**

*2.2.1.1. General procedure for the synthesis of compounds **2** and **4**.* Triethylamine (4.3 mmol) was added dropwise to a stirred solution of **1** (2 mmol) and 3-hydroxypyridine (4.2 mmol) in acetone (20 ml), and the reaction mixture was stirred at ambient temperature for 4 h to give **2**. Stirred solutions of **3a–c** (2 mmol) and 3-hydroxypyridine (2.2 mmol) were treated dropwise with triethylamine (2.3 mmol) and were stirred at ambient temperature for 1 h to give **4a–c**. Triethylammonium chloride, which separated from all the reaction mixtures, was removed by filtration. The products **2**, **4a** and **4c** were chromatographed on silica with acetone, compound **4b** was eluted from a silica column with a 1:1 mixture of acetone and DCM.

*2.2.1.2. 5,6-Di(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile (**2**).* Yield of tan powder, 0.53 g (84%), m.p. 185–186 °C. ESIMS: *m/z* (% rel. int.) 300 (23.6), 316 (M, 100), 317 (M+1, 18.5). *Anal.* Calc. for $C_{16}H_9N_6O_2$: (M+H$^+$) 317.07812. Found: 317.0782. *2.2.1.5. 5-(Pyridin-3-yloxy)-6-phenylpyrazine-2,3-dicarbonitrile (**4c**).* Yield of a white powder, 0.53 g (89%), m.p. 170–171 °C. EIMS: *m/z* (% rel. int.) 270 (100), 299 (M, 75), 300 (M+1, 12.4). *Anal.* Calc. for $C_{17}H_9N_5O$: 299.08071. Found: 299.00433. UV–Vis (DCM): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 340 (16 400), 300 (13 300). IR: ν, cm^{-1} 3050 (*CH*, aromatic, w), 2237 (*CN*, w), 1522, 1474, 1379, 1324, 1231, 1182, 1019, 839, 806, 765, 701, 685. ^{1}H NMR ($CDCl_3$): δ, ppm 7.48 (1H, pyridine *H5*, ddd, $J_{5,4}$ = 8.4 Hz, $J_{5,6}$ = 4.7, $J_{5,2}$ = 0.8 Hz), 7.59 (3H, overlap pyridine *H4* and phenyl *H3, H5*, m), 7.63 (1H, phenyl *H4*, m), 8.28 (2H, phenyl *H2, H6*, m), 8.55 (1H, pyridine *H2*, dd, $J_{2,4}$ = 2.8 Hz, $J_{2,5}$ = 0.8 Hz), 8.64 (1H, pyridine *H6*, dd, $J_{6,5}$ = 4.7 Hz, $J_{6,4}$ = 1.4 Hz). ^{13}C NMR ($CDCl_3$): δ, ppm 112.5 and 113.0 (*CN* at pyrazine *C2, C3*), 124.5 (pyridine *C5*), 127.3 and 127.6 (pyrazine *C2, C3*), 129.1 (phenyl *C3, C5*), 129.3 (pyridine *C4*), 130.1 (phenyl *C2, C6*), 131.8 (phenyl *C1*), 132.7 (phenyl *C4*), 143.3 (pyridine *C2*), 148.0 (pyrazine *C6*),148.1 (pyridine *C3*), 148.2 (pyridine *C6*), 156.9 (pyrazine *C5*).

*2.2.1.6. 5-(Propyl-1-oxy)pyrazine-2,3-dicarbonitrile (**5**).* A solution of **3a** (2 mmol, 0.33 g) in 1-propanol (15 ml) was heated under reflux for 144 h. The solvent was removed under reduced pressure, and the liquid residue was chromatographed on silica with DCM. A colourless oil, which crystallized upon cooling to −16 °C, was isolated by filtration with hexane. Yield 0.3 g (81%), m.p. 41–42 °C. EIMS: *m/z* (% rel. int.) 147 (93.5), 188 (M, 16.5). *Anal.* Calc. for $C_9H_8N_4O$: 188.0698. Found: 188.0701. ^{1}H NMR ($CDCl_3$): δ, ppm 1.07 (3H, t, $J_{3,2}$ = 7.4 Hz), 1.88 (2H, qt, $J_{2,3}$ = 7.4 Hz, $J_{2,1}$ = 6.7 Hz), 4.45 (2H, t, $J_{1,2}$ = 6.7 Hz), 8.45 (1H, s). ^{13}C NMR ($CDCl_3$): δ, ppm 10.3 (CH_3), 21.7 (CH_2), 71.0 (CH_2O), 112.9 (*CN* at pyrazine C2), 113.3 (*CN* at pyrazine C3), 125.1 (pyrazine *C2*), 131.2 (pyrazine *C3*), 140.7 (pyrazine *C6*), 160.4 (pyrazine *C5*).

*2.2.1.7. Reaction of **4a** with 1-propanol.* A solution of **4a** (1 mmol, 0.23 g) in 1-propanol (10 ml) was heated under reflux for 19 h. The solvent was removed under reduced pressure, and the liquid residue was chromatographed on silica. Compound **5** (0.2 mmol, 38 mg) was eluted from the column with DCM and was obtained as a white solid, m.p. 37–39 °C. TLC on silica gave R_f (DCM) = 0.55, as for compound **5** which had been obtained from **4a** and 1-propanol. A tan solid was eluted from the column with acetone and was isolated by filtration with diethyl ether and hexane. Yield 0.167 g (75%), m.p. 87–92 °C. TLC R_f (acetone) = 0.82, the same as for compound and **4a**.

2.2.2. Compounds **6** and **7**

2.2.2.1. Dichlorobis(quinoline-N)zinc(II) (Scheme 2). This compound, also referred to as Zn(quinoline)$_2$Cl$_2$, was prepared as in [13]. ^{1}H NMR (DMSO-d_6): δ, ppm 7.54 (2H, *H3*, dd, $J_{3,4}$ = 8.3 Hz, $J_{3,2}$ = 4.2 Hz), 7.61 (2H, *H6*, ddd, $J_{6,5}$ = 8.2 Hz, $J_{6,7}$ = 6.9 Hz, $J_{6,8}$ = 1.2 Hz), 7.77 (2H, *H7*, ddd, $J_{7,8}$ = 8.5 Hz, $J_{7,6}$ = 6.9 Hz, $J_{7,5}$ = 1.5 Hz), 7.99 (2H, *H5*, ddd, $J_{5,6}$ = 8.2 Hz, $J_{5,7}$ = 1.5 Hz, $J_{5,8}$ = 0.6 Hz), 8.04 (2H, *H8*,

dddd, $J_{8,7}$ = 8.5 Hz, $J_{8,6}$ = 1.2 Hz, $J_{8,4}$ = 0.9 Hz, $J_{8,5}$ = 0.6 Hz), 8.38 (2H, *H4*, ddd, $J_{4,3}$ = 8.3 Hz, $J_{4,2}$ = 1.8 Hz, $J_{4,8}$ = 0.9 Hz), 8.92 (2H, *H2*, dd, $J_{2,3}$ = 4.2 Hz, $J_{2,4}$ = 1.8 Hz). ^{13}C NMR (DMSO-d_6): δ, ppm 121.5 (*C3*), 126.6 (*C6*), 127.9 (*C10*), 128.1 (*C5*), 128.8 (*C8*), 129.5 (*C7*), 136.1 (*C4*), 147.6 (*C9*), 150.6 (*C2*)

2.2.2.2. Dichlorobis(pyridine-N)zinc(II) (Scheme 2). The crude product from a reaction of **4a** with excess Zn(quinoline)$_2$Cl$_2$ was sonicated with pyridine, which subsequently was removed under reduced pressure. The methanol extract from this reaction mixture gave some crystals, which were identified as dichlorobis(pyridine-N)zinc(II), apparently formed by an exchange of quinoline in dichlorobis(quinoline-N)zinc(II) with pyridine. M.p. 201–204 °C.

^{1}H NMR (DMSO-d_6): δ, ppm 7.41 (4H, m, *H3, H5*), 7.82 (2H, m, *H4*), 8.58 (4H, m, *H2, H6*). ^{13}C NMR (DMSO-d_6): δ, ppm 124.0 (*C3, C5*), 136.4 (*C4*), 149.5 (*C2, C6*).

*2.2.2.3. 5,6-Di(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile[ZnCl$_2$] complex (**6**).* A stirred mixture of **2** (0.6 mmol, 190 mg), Zn(quinoline)$_2$Cl$_2$ (0.5 mmol, 197 mg) and quinoline (0.3 ml) was flushed with nitrogen for 10 min, then heated at 175–180 °C for 20 min and cooled to ambient temperature. The dark reaction mixture was rinsed with diethyl ether, stirred with methanol (10 ml) for 30 min and then with acetone (15 ml) for 30 min. A pale gray–green solid was isolated by filtration. Yield 153 mg (56% for $C_{16}H_8N_6O_2ZnCl_2$, M = 452), m.p. ca. 345 °C decomp. UV–Vis (pyridine): 0.03 mg/ml: Trace of absorption at 630 nm, too strong absorption for measuring at 300 nm. IR: ν, cm^{-1} 3070 (*CH*, aromatic, w), 2240 (*CN*, w), 1614 (w), 1545, 1435 (s), 1361 (w), 1276 (w), 1236 (s), 1192 (w), 1104 (w), 1054, 1036 (w), 949 (w), 926 (w), 869 (w), 807, 692, 645, 618 (w). ^{1}H NMR (DMSO-d_6): δ, ppm 7.64 (2H, *H5*, dd, $J_{5,4}$ = 8.4 Hz, $J_{5,6}$ = 4.7 Hz), 7.89 (2H, *H4*, ddd, $J_{4,5}$ = 8.4 Hz, $J_{4,2}$ = 2.8 Hz, $J_{4,6}$ = 1.3 Hz), 8.62 (2H, *H6*, dd, $J_{6,5}$ = 4.7 Hz, $J_{6,4}$ = 1,2 Hz), 8.67 (2H, *H2*, d, $J_{2,4}$ = 2.7 Hz). ^{13}C NMR (DMSO-d_6): δ, ppm 113.5 (*CN*), 123.5 (pyrazine *C2, C3*), 125.1 (pyridine *C5*), 129.6 (pyridine *C4*), 142.9 (pyridine *C2*), 147.9 (pyridine *C6*), 148.2 (pyridine *C3*), 151.7 (pyrazine *C5, C6*).

Neither ^{1}H nor ^{13}C NMR signals, characteristic of quinoline, were found for this compound.

*2.2.2.4. 5-(Pyridin-3-yloxy)-6-methylpyrazine-2,3-dicarbonitrile[Zn (quinoline)Cl$_2$]complex (**7**).* Compound **4b** (0.84 mmol, 200 mg) and Zn(quinoline)$_2$Cl$_2$ (0.8 mmol, 315 mg) were ground together in a mortar, transferred to a round-bottomed flask, flushed with nitrogen, stirred and heated at 155 °C for 10 min. The dark solid was rinsed with diethyl ether, stirred with methanol (10 ml) for 24 h, and a dark solid, 175 mg, was isolated by filtration and rinsed with acetone on the filter. This solid was stirred with THF (15 ml) for 30 min, and a dark solid, 77 mg, was isolated by filtration. UV–Vis (pyridine): λ_{max}, nm (ε, M^{-1} cm^{-1}) 635 (66 000), 575 (19 000), 365 (55 000). A pale green solid, 90 mg, m.p. 217–221 °C (green melt) was obtained from the THF filtrate upon evaporation and trituration with a small amount of methanol.Yield of compound **7** ($C_{21}H_{14}N_6OZnCl_2$, M = 502), is ca. 20%. IR: ν, cm^{-1} 2238 (*CN*, w), 1541 (w), 1509 (w), 1480 (w), 1439 (w), 1395 (s), 1315, 1223, 133, 1101, 1052, 945, 823 (s), 788, 689 (s), 646 (w). ^{1}H NMR (DMSO-d_6): δ, ppm 2.72 (3H, C*H*$_3$, s), *pyridine:* 7.60 (1H, *H5*, ddd, $J_{5,4}$ = 8.4 Hz, $J_{5,6}$ = 4.7 Hz, $J_{5,2}$ = 0.8 Hz), 7.80 (1H, *H4*, ddd, $J_{4,5}$ = 8.4 Hz, $J_{4,2}$ = 2.8 Hz, $J_{4,6}$ = 1.4 Hz), 8.58 (1H, *H6*, dd, $J_{6,5}$ = 4.9 Hz, $J_{6,4}$ = 1.4 Hz), 8.59 (1H, *H2*, dd, $J_{2,4}$ = 2.7 Hz, $J_{2,5}$ = 0.7 Hz), *quinoline:* 7.54 (1H, *H3*, dd, $J_{3,4}$ = 8.3 Hz, $J_{3,2}$ = 4.2 Hz), 7.62 (1H, *H6,* ddd, $J_{6,5}$ = 8.1 Hz, $J_{6,7}$ = 6.9 Hz, $J_{6,8}$ = 1.3 Hz), 7.77 (1H, *H7*, ddd, $J_{7,8}$ = 8.4 Hz, $J_{7,6}$ = 6.9 Hz, $J_{7,5}$ = 1.5 Hz), 7.99 (1H, *H5*, ddd, $J_{5,6}$ = 8.2 Hz, $J_{5,7}$ = 1.5 Hz, $J_{5,8}$ = 0.6 Hz), 8.03 (1H, *H8*, dddd, $J_{8,7}$ = 8.4 Hz, $J_{8,6}$ = 1.3 Hz, $J_{8,4}$ = 0.9 Hz, $J_{8,5}$ = 0.6 Hz), 8.37 (1H, *H4*, ddd, $J_{4,3}$ = 8.3 Hz, $J_{4,2}$ = 1.8 Hz, $J_{4,8}$ = 0.9 Hz), 8.91 (1H, *H2*, dd, $J_{2,3}$ = 4.2 Hz, $J_{2,4}$ = 1.8 Hz). ^{13}C NMR (DMSO-d_6): δ, ppm 20.0 (C*H*$_3$), 113.6 (*CN*), 114.1 (*CN*), 125.7 (pyrazine *C3*),128.0 (pyrazine *C2*), 152.3 (pyrazine *C6*), 158.4 (pyrazine *C5*), 124.9 (pyridine *C5*), 129.61 (pyridine *C4*), 143.1 (pyridine *C2*), 147.6 (pyridine *C6*), 148.5 (pyridine *C3*), *quinoline*: 121.5 (*C3*), 126.6 (*C6*), 128.0 (*C10*), 128.1 (*C5*), 128.9 (*C8*), 129.59 (*C7*), 136.1 (*C4*), 147.7 (*C9*), 150.6 (*C2*).

*2.2.3. Compounds **8** and **9a–c***

*2.2.3.1. General procedure for the synthesis of compounds **8** and **9a–c**.* Compound **2** or **4** (1.0 mmol) and Zn(quinoline)$_2$Cl$_2$ (1.2 mmol) were ground in a mortar and transferred to a round-bottomed flask. The stirred reaction mixtures were flushed with nitrogen for 15 min at ambient temperature, then heated under nitrogen at 190–195 °C for 2.5 h (compound **2**) and at 170–175 °C for 1 h (compounds **4a–c**). The dark solids were rinsed with diethyl ether, stirred for 30 min at ambient temperature with methanol (25 ml), and then with THF (30 ml). Sonication of the solids with pyridine (10 ml), removal of the pyridine under reduced pressure, sonication with methanol (10 ml) and filtration, gave dark solids which were washed with acetone and THF. Compounds **8**, **9a** and **9c** were applied to silica columns with DMF:THF (1:1) and eluted with DMF:THF (1:10) and gradually increasing ratios of DMF until most colored material had been eluted. Compound **9b** was chromatographed on silica with pyridine. The solvents were removed under reduced pressure, diethyl ether was added to the dark solids, which were isolated by filtration and rinsed with acetone on the filter. The products were finally dried at 0.1 mm Hg for 3 h.

*2.2.3.2. [Octa(pyridin-3-yloxy)-(octazaphthalocyaninato)]zinc(II) (**8**).* Yield of a black solid 0.07 g (20%). UV–Vis (pyridine): λ_{max}, nm (ε, M^{-1} cm^{-1}) 630 (81 000), 575 (19 000), 375 (70 000), 315 (sh, 90 000). ^{1}H NMR (DMSO-d_6): δ, ppm *pyridine*: 7.86 (8H, *H5,* dd, $J_{5,4}$ = 8.2 Hz, $J_{5,6}$ = 4.9 Hz), 8.27 (8H, *H4,* ddd, $J_{4,5}$ = 8.2 Hz, $J_{4,2}$ = 3.0 Hz, $J_{4,6}$ = 1.3 Hz), 8.98 (8H, *H2*, m), 8.98 (8H, *H6*, m). ^{13}C NMR (DMSO-d_6): δ, ppm 124.9 (pyridine *C5*), 130.6 (pyridine *C4*), 142.0, 143.8 (pyridine *C2*), 147.5 (pyridine *C6*), 148.9, 149.4 (pyridine *C3*), 151.5 (probably pyrazine *C5, C6*). MS (MALDI-TOF) *m/z* 1329.168 [M+H$^+$]. *Anal.* Calc. for $C_{64}H_{32}N_{24}O_8Zn$: 1328.21 (M), $C_{64}H_{33}N_{24}O_8Zn$: 1329.21 (M+H$^+$). The expected isotopic pattern for zinc was found at *m/z* (calcd.% rel. int.) 1329.168 (100), 1330.168 (81), 1331.168 (91), 1332.168 (65), 1333.168 (67), 1334.168 (40), 1335.173 (16).

*2.2.3.3. [Tetra(pyridin-3-yloxy)-(octazaphthalocyaninato)]zinc(II) (**9a**).* Yield of a black shiny powder 0.053 g (22%). UV–Vis (pyridine): λ_{max}, nm (ε, M^{-1} cm^{-1}) 635 (91 000), 580 (20 000), 365 (66 000), 315 (sh, 69 000). ^{1}H NMR (DMSO-d_6): δ, ppm 9.4–9.3 (pyrazine *H6*), 9.1–8.9 (pyridine *H2*), 8.95–8.75 (pyridine *H6*), 8.6–8.3 (pyridine *H4*), 7.9–7.7 (pyridine *H5*). ^{13}C NMR (DMSO-d_6): δ, ppm 125–126 (pyridine *C5*), 129–130 (pyridine *C4*), 137–138 (pyrazine *C6*), 142–143 (pyridine *C2*), 146–147 (pyridine *C6*). MS (MALDI-TOF) *m/z* 957.104 [M+H$^+$]. *Anal.* Calc. for $C_{44}H_{20}N_{20}O_4Zn$: 956.13 (M), for $C_{44}H_{21}N_{20}O_4Zn$: 957.13 (M+H$^+$). The expected isotopic pattern for zinc was found at *m/z* (calcd.% rel. int.) 957.104 (100), 958.107 (57), 959.107 (74), 960.108 (44), 961.109 (54), 962.111 (25).

*2.2.3.4. [Tetra(pyridin-3-yloxy)-tetramethyl(octazaphthalocyaninato)]zinc(II) (**9b**).* Yield of a dark, blue/purple powder 0.1 g (39%). UV–Vis (pyridine): λ_{max}, nm (ε, M^{-1} cm^{-1}) 635 (122 000), 575 (27 000), 365 (91 000), 315 (sh, 91 200) (see Fig. 1). UV–Vis (DMSO): λ_{max}, nm (ε, M^{-1} cm^{-1}) 635 (70 000), 575 (18 000), 360 (53 000). ^{1}H NMR (DMSO-d_6): δ, ppm 3.3–3.0 (C*H*$_3$), 7.85–7.5 (pyridine *H5*),

The expected isotopic pattern for zinc was found at *m/z* (calcd.% rel. int.) 1261.260 (100), 1262.260 (84), 1263.260 (93), 1264.260 (66), 1265.261 (68), 1266.261 (41).

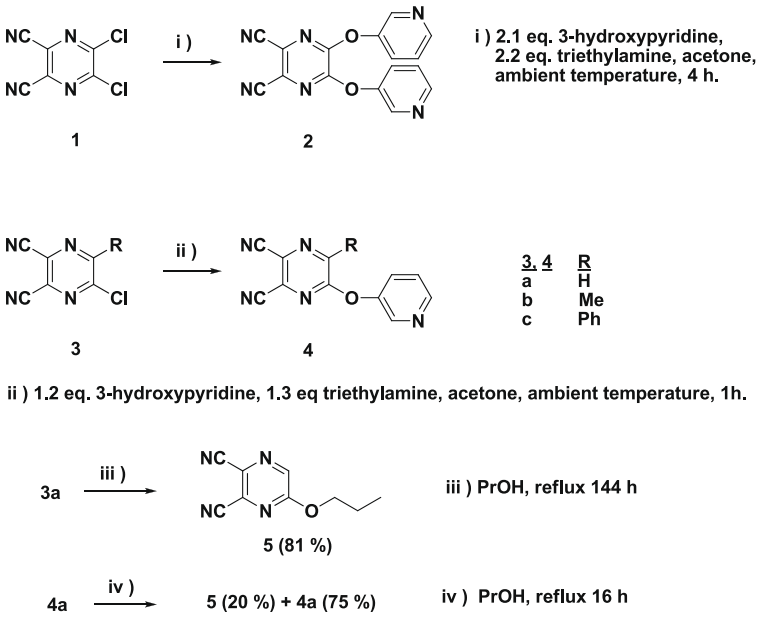
3. Results and discussion

3.1. Synthesis and characterization

3.1.1. Monomers *2, 4* and *5*

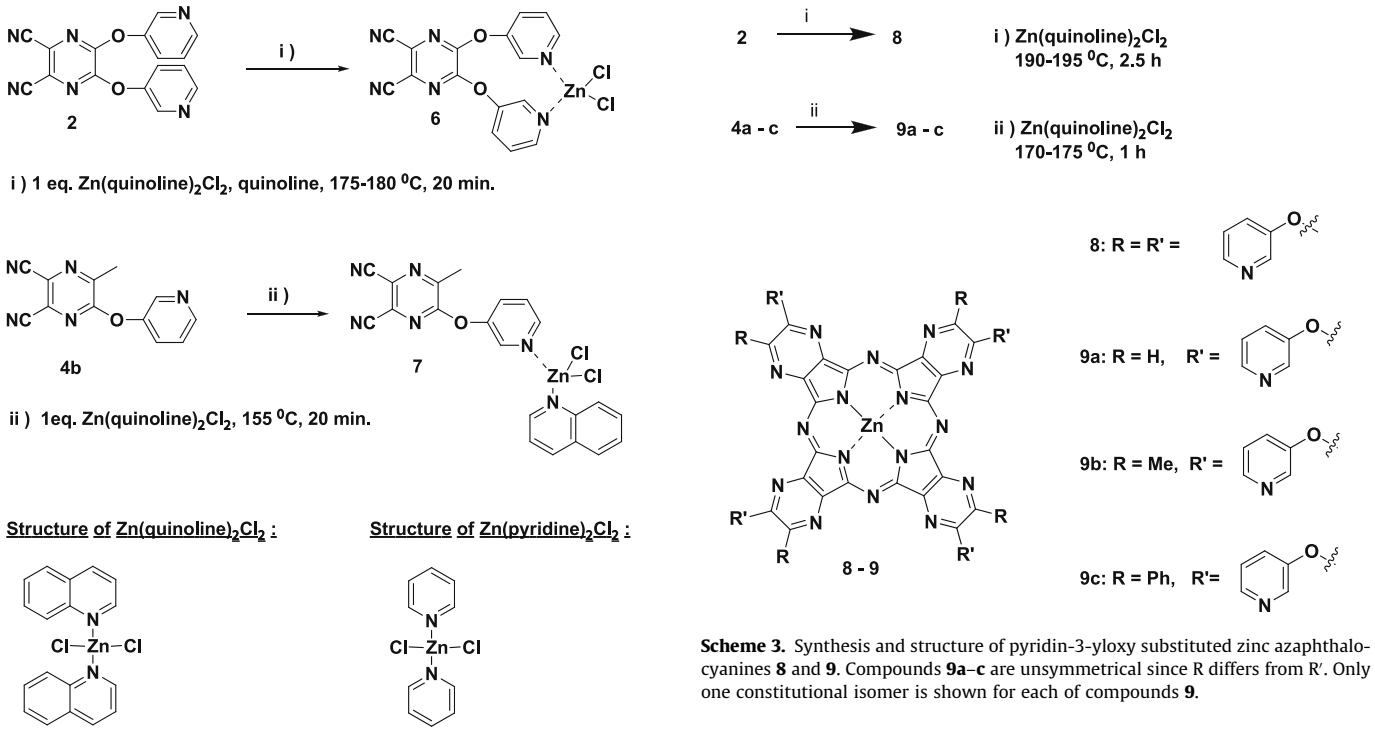
5,6-Di(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile (**2**) was obtained in 84% yield from a reaction of 5,6-dichloropyrazine-2,3-dicarbonitrile (**1**) with 3-hydroxypyridine and triethylamine in acetone at ambient temperature. Compounds **4a–c**, namely 5-(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile (**4a**), 5-(pyridin-3-yloxy)-6-methylpyrazine-2,3-dicarbonitrile (**4b**) and 5-(pyridin-3-yloxy)-6-phenylpyrazine-2,3-dicarbonitrile (**4c**), were obtained in good yields by the same procedure (Scheme 1).

In order to reveal potential instability of pyridin-3-yloxy substituted pyrazines **2** and **4** towards nucleophiles, compound **4a** was heated under reflux with propanol for 19 h. Chromatography of the product mixture separated unreacted **4a** (75%) from the reaction product 5-(1-propyloxy)pyrazine-2,3-dicarbonitrile (**5**), (20%). This product is identical to an authentic sample of **5** which was obtained from **3a** and 1-propanol (Scheme 1). Therefore, considering the weak nucleophilicity of 1-propanol compared to alkoxide ions, the use of metal alkoxides is ruled out for cyclotetramerizations of compounds **2** and **4**. This is in accordance with our previous experience with 5,6-di(phenoxy)pyrazine-2,3-dicarbonitrile [8]. Recently, the formation of a metal free AzaPc, obtained from prolonged heating in quinoline of di(aryloxy)pyrazine-2,3-dicarbonitrile, has been reported [9]. However, quinoline solutions of compounds **2** and **4** merely gave brown or black reaction mixtures after prolonged heating.



3.1.2. Reactions of compounds *2* and *4* with zinc(II) salts to form zinc complexes *6* and *7*

A known method for one-step syntheses of zinc(II) complexes of phthalocyanines and azaphthalocyanines is treatment of hot quinoline solutions of the monomers with zinc(II) acetate. This method was tested for cyclotetramerizations of compounds **2** and **4**, but resulted in extensive decomposition of these monomers.



The salt Zn(quinoline)$_2$Cl$_2$, prepared from zinc(II) chloride and quinoline, has been used successfully for cyclotetramerizations of amino-substituted pyrazine-dicarbonitriles [13] and was tested in reactions with compounds **2** and **4**. At low temperatures, namely 1 h at 100 °C, or 15 min at 140 °C, no reaction was observed between equimolar amounts of Zn(quinoline)$_2$Cl$_2$ and **2**. However, a reaction at 180 °C for 20 min between a quinoline solution of **2** and 0.8 molar equivalents of Zn(quinoline)$_2$Cl$_2$ gave a pale blue–gray powder which was identified as 5,6-di(pyridin-3-yloxy)pyrazine-2,3-dicarbonitrile[ZnCl$_2$] complex (**6**). This complex is high melting and decomposes at approximately 345 °C. The suggested structure is shown in Scheme 2, together with the structure of Zn(quinoline)$_2$Cl$_2$. Identification of compound **6** is primarily based on NMR analysis, i.e. all hydrogen and carbon atoms were identified, and the integral of each hydrogen atom is in accord with structure **6**. The two cyano groups which are attached to the pyrazine ring were clearly identified as one signal at δ 113 ppm. The NMR spectra also exclude the presence of quinoline. However, the pale blue color and the UV–Vis spectrum of **6**, indicate the presence of a small amount of AzaPc **8**. Compound **6** was obtained in approximately 50% yield.

A similar reaction between equimolar amounts of **4b** and Zn(quinoline)$_2$Cl$_2$ at 155 °C for 10 min, gave 5-(pyridin-3-yloxy)-6-methylpyrazine-2,3-dicarbonitrile-[Zn(quinoline)Cl$_2$] complex (**7**) in approximately 20% yield. The structure of **7**, as shown in Scheme 2, would result from the replacement of one quinoline group of Zn(quinoline)$_2$Cl$_2$ with compound **4b**. The structure of **7** was confirmed by NMR analysis; the integrals for the methyl, pyridine and quinoline hydrogen atoms were as expected, and all the ^{1}H and ^{13}C NMR signals were accounted for and identified by the pulse techniques COSY, HSQC and HMBC.

The formations of compounds **6** and **7** strongly indicate that complexation between the pyridin-3-yloxy substituents and Zn(quinoline)$_2$Cl$_2$ is the initial reaction between this zinc complex and the monomers **2** or **4**. The electron withdrawing effect on the pyrazine moiety of **2** or **4** by zinc complexed to their pyridin-3-yloxy groups, is expected to promote the targeted cyclotetramerizations of **2** and **4**. However, purifications of these ZnAzaPcs necessarily involve destruction of the peripheral zinc-pyridin-3-yloxy complexes. These complexes will undoubtedly be weak, and excess pyridine is expected to be sufficiently nucleophilic to replace the pyridin-3-yloxy groups of these peripheral zinc complexes. A reaction of **4a** with excess Zn(quinoline)$_2$Cl$_2$ gave in fact some of the product Zn(pyridine)$_2$Cl$_2$ which has been known for many years [14,15]. The structure of Zn(pyridine)$_2$Cl$_2$ is shown in Scheme 2. We report both the NMR spectra of this compound and of Zn(quinoline)$_2$Cl$_2$ since these have not been reported earlier. The formation of Zn(pyridine)$_2$Cl$_2$ could either happen by exchange of quinoline in Zn(quinoline)$_2$Cl$_2$, or by replacement of **4a** in a complex analogous to **7**.

Scheme 1. Syntheses of pyrazine-2,3-dicarbonitriles substituted with pyridin-3-yloxy, methyl and phenyl groups.

Scheme 2. Reactions of pyrazine-2,3-dicarbonitriles **2** and **4b** with $Zn(quinoline)_2Cl_2$. Structures of $Zn(quinoline)_2Cl_2$ and $Zn(pyridine)_2Cl_2$.

Scheme 3. Synthesis and structure of pyridin-3-yloxy substituted zinc azaphthalocyanines **8** and **9**. Compounds **9a–c** are unsymmetrical since R differs from R′. Only one constitutional isomer is shown for each of compounds **9**.

3.1.3. Zinc azaphthalocyanines *8* and *9a–c*

The syntheses and structures of substituted ZnAzaPcs **8** and **9a–c** are shown in Scheme 3. Attempts to use dry zinc(II) acetate and quinoline for the synthesis of these compounds were unsuccessful; mostly dark tarry solids were obtained. Compounds **8** and **9** were prepared by dry condensations of monomers **2** or **4a–c** with $Zn(quinoline)_2Cl_2$, at 190–195 °C (compound **2**) or at 170–175 °C (compounds **4**). The peripheral complexations between the pyridin-3-yloxy substituents of monomers **2** and **4**, and $Zn(quinoline)_2Cl_2$, had to be taken into account when methods were considered for purification of macrocycles **8** and **9**. The crude products were separated from most of the unreacted zinc reagent by extraction with methanol and THF. In order to replace peripheral zinc attached to the pyridin-3-yloxy groups, the dark solids were sonicated with excess pyridine, which subsequently was removed under reduced pressure. The dark powders **8**, **9a** and **9c** were chromatographed on silica with THF mixed with DMF, whereas pyridine was used as eluent for compound **9b**. Compounds **8** and **9** were obtained in fair yields (20–40%). The symmetric monomer **2** affords only one macrocyclic isomer, namely **8**, but the monomers 4a–**c** are unsymmetric and consequently, four constitutional isomers of **9a–c** may be formed. The NMR spectra are in accordance with this, since the hydrogen signals of **8** are sharp and with well

defined coupling constants, whereas the corresponding signals of **9a–c** are broad and with unresolved splittings of the signals.

Mass spectrometry (MALDI-TOF) of compounds **8** and **9** showed the calculated molecular ions with the expected isotopic clusters characteristic of zinc. Due to low solubilities of these macrocycles, the compounds were dissolved in pyridine, diluted with methanol, then dried at ambient temperature before being covered with matrix and injected into the spectrometer.

UV–Vis spectra of unsubstituted ZnPc and ZnAzaPc show Q-bands at, respectively, 674 and 636 nm. This 38 nm blue shift for ZnAzaPc compared to ZnPc is ascribed to the additional nitrogen atoms in the AzaPc macrocycle.

Q-bands of compounds **8** and **9** are found at 630 nm (**8**), 635 nm (**9a**, **9b**) and 650 nm (**9c**). The UV–Vis spectrum of **9b** is shown in Fig. 1. Compared to unsubstituted ZnAzaPc, these data show that eight pyridin-3-yloxy groups of compound **8** induce a small blue shift (6 nm) of the Q-band, and four phenyl combined with four pyridin-3-yloxy substituents of **9c** induce a 14 nm red shift of the Q-band. These observations compare well with a reported Q-band at 645 nm for octa(aryloxy)ZnAzaPc where the peripheral substituents were bulky aryloxy groups [9]. A series of MgAzaPc substituted with alkoxy groups, has been reported as well, and the Q-bands were observed at 625 nm [8].

4. Conclusion

Peripheral pyridin-3-yloxy substituents complicate syntheses of the substituted ZnAzaPc compared to the corresponding ZnPc for several reasons. Strong nucleophiles easily replace the pyridin-3-yloxy groups attached to the starting monomers; i.e. the pyrazine-2,3-dicarbonitriles. Consequently the Linstead method for cyclotetramerization, which includes the use of metal alkoxides, must be excluded. Another known method, where diiminoimides are used as precursors for cyclotetramerizations, must be excluded as well, since the transformation of the dicarbonitriles to diiminoimides involves strong alkoxide ions.

We have found one successful direct synthesis of pyridin-3-yloxy substituted ZnAzaPc by using $Zn(quinoline)_2Cl_2$ as a reagent. However, these cyclotetramerizations are accompanied by peripheral complexation between the zinc(II) salt and the pyridin-3-yloxy substituents. Consequently purification of these ZnAzaPcs will be somewhat elaborate.

The electronic absorption spectrum of octa(pyridin-3-yloxy)ZnAzaPc, **8**, shows a Q-band which is blue shifted by 6 nm compared to unsubstituted ZnAzaPc, i.e. the pyridin-3-yloxy groups show insignificant substituent effects. The combination of phenyl and pyridin-3-yloxy substituents induce a Q-band at 650 nm, and this 14 nm red shift can be ascribed to the phenyl substituents.

The low solubility in organic solvents of ZnAzaPcs **8** and **9** combined with Q-bands far below 700 nm, make these compounds of little interest for use as sensitizers in PDT. However, the possibility of metal complexing of the peripheral pyridin-3-yloxy substituents is an interesting feature.

ABSTRACT

The XRD structure and the influence of the conformation in the molecular orbitals of the pteridine-benzoylhydrazone ligand (BZLMH = benzoylhydrazone of 6-acetyl-1,3,7-trimethyllumazine, lumazine = (1*H*,3*H*)-pteridin-2,4-dione) have been studied. Complexes of BZLMH with nickel(II), zinc(II) and mercury(II) have been prepared and spectroscopically characterized by IR, NMR and fluorescence spectroscopy; also XRD studies have allowed to establish two different coordinative patterns in the complexes $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O \cdot CH_3CN$ (**2**) and $[Zn(NO_3)(BZLMH)(H_2O)](NO_3)$ (**3**). Compound (**2**) is a trinuclear hydroxo-centered complex with a central hydroxo group bridging the three nickel(II) ions. The $[Ni_3(\mu_3\text{-}OH)]^{5+}$ core is planar with the benzoylhydrazone ligands coordinated in the bis-bidentate [O(4),N(5)]-[N(61),O(63)] mode. The zinc(II) compound displays a BPT coordination geometry in which the BZLMH ligand acts in a tridentate fashion using N(5), N(61) and O(63) donor atoms. Fluorescence spectroscopic properties of benzoylhydrazone (BZLMH) are studied and the fluorescence band shift and changes in intensity is modulated by complexation with different metal ions (Ni^{2+}, Zn^{2+} and Hg^{2+}), so the binding is signaled such a possible cause.

1. Introduction

The metallochemistry of biomolecules has been largely focused on proteins amino acids, nucleic acids and carbohydrates [1–4]. In this setting, small coenzymes have received less recognition as ligands for metal centers; a lot of work in this area has consideration given to the chemistry and biological role of pteridines and underlying heterocyclic structures of coenzymatic constituents (pterins, lumazines, flavins) of some enzymes [5]. On the other hand, heterocyclic hydrazones constitute an important class of biologically active drugs which have attracted attention of medicinal chemists due to their wide ranging pharmacological properties like antifungal, antibacterial and anticonvulsant compounds [6–9], their metallochemistry being interesting since it is generally agreed that the complexes of some *3d* elements play an important role in biochemistry [10].

The correct choice of the ligands is fundamental due the properties of biological active molecules can be tailored to very specific conversions according to an appropriate design of them. To aid the rationally-based design, interesting general concepts have been developed. One of the most important is the ligand flexibility required for some reactions, whereas in other reactions higher selectivities and activities are obtained with more rigid ligand systems.

Once the N5–O4 coordination chemistry of unfunctionalized lumazines was extensively reported [11–13], we tried to expand it to polydentate behaviors by anchoring in the pyrazine ring substituents with both biological interest and coordination abilities. In this way, more versatile ligands such as a 6-acetyllumazine (DLMAceM) [14], its thiosemicarbazone derived ligand TSCLMH [15] and several lumazine 6-substituted azines [16] have been used, thus reporting new polydentate coordination behaviors including tri-, tetra- and doubly bidentate ones- quite different from the usual N5–O4 bidentate ligand-to-metal bonding found in metal-lumazine complexes. Furthermore, the ligand design has been extended introducing in the pyrazine ring the benzoylhydrazone substituent; this versatile branch, together with the pteridine one, allows a wide set of bonding-to-metal modes including from monodentate to polydentate bridging, the biological activities of many of these compounds being related to their metal chelating abilities [17]. Thus, in a previous paper [18], good results about both tri- and tetradentate behaviors of the hybrid benzoylhydrazone-pteridine ligand (BZLMH) has been already reported.

Here, the XRD structure of the BZLMH hybrid ligand is studied, this compound being into our knowledge the first reported hydrazone-derived from a pteridine moiety. Also, *ab initio* MO calculations have been carried out to characterize from the theoretical point of view the potential ligand-to-metal binding sites. Furthermore, some Ni(II), Zn(II) and Hg(II) complexes have been isolated and studied in order to establish the coordination behavior of BZLMH, in which the four available donors atoms (O4, N5, N61,

doi:10.1016/j.poly.2009.05.061

O63) make it possible for the ligand to be bidentate, tridentate, tetradentate or doubly bidentate.

We have also focused this work to the study of luminescent properties of BZLMH ligand and above-described complexes because the luminescence of lumazine and benzoylhydrazone ligands are very well-known [15,19–25] and have been widely used to obtain fluorescent sensors. To place of rigid chromophoric framework in the ligand with a π-conjugation system can be an efficient method for obtaining new luminescent materials. In this work, we have tested the luminescent properties of the ligand BZLMH and related compounds, as well as the sensibility of the fluorescence to the presence of Ni(II), Zn(II) and Hg(II) ions.

2. Experimental

2.1. Materials and instrumentation

The pro-ligand 6-acetyl-1,3,7-trimethyllumazine was obtained according to the literature methods [26]; then, the multifunctional ligand BZLMH was synthesized as previously described [18]. Other starting compounds such as benzohydrazide, $Ni(ClO_4)_2 \cdot 6H_2O$, $Zn(NO_3)_2 \cdot 6H_2O$, $Hg(NO_3)_2 \cdot H_2O$ and $Hg(ClO_4)_2 \cdot 3H_2O$ are commercially available and reagent grade acetonitrile, ethanol and methanol were used without purification. Microanalyses were carried out with a Thermo Finnigan Flash EA 1112. The IR spectra were recorded between 4000 and 400 cm^{-1} using KBr pellets on a Perkin–Elmer 1760 FT-IR. The solution ^1H, ^{13}C NMR spectra and ^1H–^{15}N HMBC were recorded from DMSO-d_6 solution on Bruker Avance 400 and 500 spectrometers. The chemical shifts were referenced to residual solvent resonance external TMS in the ^1H and ^{13}C spectra and nitromethane in the ^1H–^{15}N HMBC. The mass spectra were performed on a Hewlett–Packard HP 5989GC/LC/MS apparatus. The UV-Vis spectra were recorded between 1200 and 250 nm with solid samples on a Perkin–Elmer Lambda 19, while fluorescence spectra were measured using a Varian Cary Eclipse machines.

2.2. Synthesis of complexes

Caution! Perchlorate salts are potentially explosive and should only be used in small quantities and handled with the necessary precautions.

2.2.1. $Ni(BZLMH)_2(ClO_4)_2 \cdot 3H_2O$ (**1**)

$Ni(ClO_4)_2 \cdot 6H_2O$ (183 mg, 0.5 mmol) and acetonitrile (10 mL) were put into a flask and stirred. BZLMH (183 mg, 0.5 mmol) solved in acetonitrile (15 mL) was added in one portion and the reaction mixture was stirred at 50 °C for 3 h. After that, we isolated a greenish powdered material (yield 30-35%).

Anal. Calc. for $C_{36}H_{42}N_{12}O_{17}Cl_2Ni$: C, 41.4; H, 4.1; N, 16.1. Found: C, 41.0; H, 4.3; N, 16.2; M, 1077.4. Main IR peaks (KBr, cm^{-1}): 3445 (ν(N–H), w), 1721, 1669 (ν(C=O). m, vs), 1621 ($\nu(C{=}N)_{azom}$, vs), 1553 (ν(C=N), m), 1459, 1292 (ν(C=C) + ν(C–N), m). UV–Vis [solid, λ (nm)]: 9500; 13700; 21300.

The slow evaporation for several weeks of resulting solution afforded a too small quantity of green crystals of $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O \cdot CH_3CN$ (**2**); so, only XRD, IR and elemental analysis were performed. *Anal.* Calc. for $C_{60}H_{70}N_{21}O_{33}Cl_5Ni_3$: C, 36.6; H, 3.6; N, 14.9. Found: C, 36.1; H, 3.3; N, 14.5; M, 1965.6. Main IR peaks (KBr, cm^{-1}): 3402 (ν(N–H), w), 1730, 1641 (ν(CO), m, vs), 1614 ($\nu(C{=}N)_{azom}$, vs), 1560 (ν(C=N), s), 1465, 1296 (ν(C=C) + ν(C–N), m), 1022 (ν(N–N), w).

2.2.2. $[Zn(NO_3)(BZLMH)(H_2O)](NO_3)$ (**3**)

Compound **3** was prepared by similar reported method adding the BZLMH (183 mg, 0.5 mmol) ligand solved in acetonitrile to the $Zn(NO_3)_2 \cdot 6H_2O$ (149 mg, 0.5 mmol) solution in the same solvent. Orange crystals of this compound, suitable for X-ray diffraction, were grown at room temperature by diffusion of acetone into their acetonitrile solution (yield 55–60%).

Anal. Calc. for $C_{18}H_{20}N_8O_{10}Zn$: C, 37.7; H, 3.5; N, 19.5. Found: C, 37.3; H, 3.9; N, 19.4; M, 573.8. Main IR peaks (KBr, cm^{-1}): 3440, 3220 (ν(N–H), w), 1722, 1673 (ν(C=O), w, m), 1566 (ν(C=N), w), 1471, 1295 (ν(C=C) + ν(C–N), m), 1000 (ν(N–N), w). ^1H NMR data (δ, ppm, DMSO-d_6): 1.1 (12H, s, Me_4Si), 2.1 (3H, s, C(61)Me), 2.5 (3H, s, C(7)Me), 2.9 (3H, s, N(3)Me), 3.5 (3H, s, N(1)Me), 7.5 (2H, m, Ph), 7.9 (3H, m, Ph), 10.9 (1H, s, NH). ^{13}C NMR data (δ, ppm, DMSO-d_6): 14.8 (s, C(62)), 25.5 (s, C(71)), 28.4 (s, C(3)), 28.8 (s, C(1)), 123.9 (s, C(4A)), 128.1–131.5 (s, C_{arom}), 133.6 (s, C(6)), 144.8 (s, C(61)), 145.8 (s, C(1A)), 150.6 (s, C(2)), 157.1 (s, C(7)), 159.5 (s, C(4)). ^1H–^{15}N HMBC data (δ, ppm, DMSO-d_6): 120.1 (N(1)), 155.5 (N(3)), 170.2 (N(61)), 325.1 (N(5), N(8)), 365.1 ($MeNO_2$).

2.2.3. $Hg(NO_3)_2(BZLMH)$ (**4**)

To a stirred methanolic solution of BZLMH ligand (183 mg, 0.5 mmol) was added a solution of $Hg(NO_3)_2 \cdot H_2O$ (171 mg, 0.5 mmol) in methanol (10 mL) and the resulting yellow solution was stirred for 3 h. For this time a precipitated yellow compound was obtained (yield 55–60%).

Anal. Calc. for $C_{18}H_{18}N_8O_9Hg$: C, 31.3; H, 2.7; N, 16.2. Found: C, 31.1; H, 2.7; N, 16.0; M, 690.9. Main IR peaks (KBr, cm^{-1}): 3774, 3439 (ν(N–H), w), 1722, 1661 (ν(C=O), m, s), 1556 (ν(C=N), m), 1462, 1270 (ν(C=C) + ν(C–N), m), 1013 (ν(N–N), w). ^1H NMR data (δ, ppm, DMSO-d_6): 1.1 (12H, s, Me_4Si), 2.6 (3H, s, C(61)Me), 2.8 (3H, s, C(7)Me), 3.3 (3H, s, N(3)Me), 3.6 (3H, s, N(1)Me), 7.6 (2H, m, Ph), 7.9 (3H, m, Ph), 11.5 (1H, s, NH). ^{13}C NMR data (δ, ppm, DMSO-d_6): 15.3 (s, C(62)), 25.3 (s, C(71)), 28.5 (s, C(3)), 29.0 (s, C(1)), 123.7 (s, C(4A)), 127.6–131.9 (s, C_{arom}), 132.9 (s, C(6)), 144.5 (s, C(61)), 146.1 (s, C(1A)), 150.5 (s, C(2)), 158.0 (s, C(7)), 159.5 (s, C(4)), 199.0 (s, C(63)). ^1H–^{15}N HMBC data (δ, ppm, DMSO-d_6): 155.2 (N(3)), 300.2 (N(61)), 365.1 ($MeNO_2$).

2.2.4. $Hg(ClO_4)(BZLM)(BZLMH)$ (**5**)

A solution of BZLMH (183 mg, 0.5 mmol) in ethanol was added to a suspension of $Hg(ClO_4)_2 \cdot 3H_2O$ (227 mg, 0.5 mmol) in ethanol (10 mL). The mixture was stirred and heated for 3-4 h until the color of the solution turned to yellow and a precipitated compound was obtained (yield 25–30%).

Anal. Calc. for $C_{36}H_{35}N_{12}O_{10}ClHg$: C, 41.9; H, 3.4; N, 16.3. Found: C, 41.9; H, 3.4; N, 15.9; M, 1031.8. Main IR peaks (KBr, cm^{-1}): 3456 (ν(N–H), w), 1722, 1667 (ν(C=O), m, s), 1555 (ν(C=N), m), 1503, 1268 (ν(C=C) + ν(C–N), m). ^1H NMR data (δ, ppm, DMSO-d_6): 1.1 (12H, s, Me_4Si), 2.5 (3H, s, C(61)Me), 2.9 (3H, s, C(7)Me), 3.3 (3H, s, N(3)Me), 3.6 (3H, s, N(1)Me), 7.5 (2H, m, Ph), 7.9 (3H, m, Ph), 11.1 (1H, s, NH). ^{13}C NMR data (δ, ppm, DMSO-d_6): 14.9 (s, C(62)), 25.5 (s, C(71)), 28.4 (s, C(3)), 28.9 (s, C(1)), 123.8 (s, C(4A)), 127.5–131.7 (s, C_{arom}), 133.4 (s, C(6)), 144.7 (s, C(61)), 145.9 (s, C(1A)), 150.6 (s, C(2)), 157.2 (s, C(7)), 159.5 (s, C(4)), 166.5 (s, C(63)). ^1H–^{15}N HMBC data (δ, ppm, DMSO-d_6): 23.1 (N(1)), 155.4 (N(3)), 170.3 (N(61)), 295.3 (N(5), N(8)), 365.1 ($MeNO_2$).

2.3. XRD experimental details

Details of the crystallographic data collection and refinement parameters are given in Table 1. For compound $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O \cdot CH_3CN$ (**2**), the perchlorate anions are disordered over two positions with a relative occupancy of 0.5. The CIF files have been deposited at the Cambridge Crystallographic Data Center and allocated the deposition numbers CCDC 650849, 650850, 650851.

The data were collected on a Nonius Kappa CCD diffractometer (graphite-monocromated Mo Kα radiation psi-scan technique, λ = 0.71073 Å) at room temperature. Empirical absorption correction (SADABS [27]) was applied. The structures were solved by SIR-04, expanded by Fourier-difference syntheses and refined with SHELXL-97, incorporated in WINGX 1.64 crystallographic collective package [28,29]. All non-hydrogen atoms were refined with anisotropic thermal parameters by full matrix least-squares procedures on F^2. Hydrogen atoms from methyl groups were placed in idealized positions, and treated using riding models; N–H hydrogens were found from difference map and refined isotropically. Graphics were obtained with PLATON [30].

2.4. Computational methods

Theoretical calculations were carried out on benzoylhydrazone of 6-acetyl-1,3,7-trimethyllumazine (BZLMH) by using *ab initio* methods with GAUSSIAN03 program package [31], as described previously [15].

3. Results and discussion

3.1. Ligand characterization: X-ray diffraction study and ab initio calculations

The significant IR bands of this ligand are close to those found in related compounds with lumazine and hydrazone derivatives. It exhibits a ν(N–H) in the 3222–3204 cm^{-1} region. The vibrational activity of carbonyl groups appears as two different bands located at 1698 and 1655 cm^{-1}, being the first one, weaker, being mainly due to ν(C(2)=O) whereas the second one it must be assigned to ν(C(4)=O) [14,15,32]. We also can observe a broad corresponding to the ν(C(63)=O) [32] (*ca.* 1708 cm^{-1}). The absorption bands located at 1603 cm^{-1} in the IR spectra of BZLMH are attributed to ν(C=N$_{azom}$) and the band at 1551 cm^{-1} for this organic ligand is assignable to ν(C=N) of pteridine ring. The infrared bands for ν(C=C) + ν(C–N) vibrations are located at 1451 and 1292 cm^{-1} [33,34].

In the ^{1}H NMR spectrum of BZLMH in DMSO-d$_6$ the *ortho* protons of benzenic framework show a broad signal at 7.9 ppm due to coupling with the remaining hydrogens of the ring. The hydrogens at *meta* and *para* positions appear being a multiplet (*ca.* 7.55 ppm) due to the strong coupling. The ^{13}C NMR and the ^{1}H–^{13}C NMR spectra allow us assign unequivocally the carbon signals of the ligand. In the ^{1}H–^{15}N NMR spectrum, we observed three different signals for the N(1), N(3) and N(62) nitrogens at 120, 155 and 295 ppm correlate with the hydrogen methyl groups C(1), C(3) and C(62), respectively, and a fourth broad signal for both N(5) and N(8) nitrogens atoms at 325 ppm, which could be explained by the similar environment in the pyrazine ring.

UV–Vis experiments for BZLMH showed three bands at 243, 282 and 341 nm assignable to $\pi \rightarrow \pi^*$ transitions [35] at pH of the ligand (pH 5.13). This experiment was also carried out at different pH values to obtain information about the ligand deprotonation, but not with extreme values of pH because the hydrolysis of hydrazone ligand takes place, possibly for the break of azometinic bond. To pH values between 3 and 4 we can observe some changes which we can assign to the possible behavior like a base of hydrazonic N(62).

The structure of BZLMH was also resolved by X-ray diffraction and included at this work for an unambiguous characterization (Fig. 1). The pteridine fragment shows similar geometry for other lumazine ligands, so pyrimidine and pyrazine rings are roughly planar with dihedral angle 1.39(9)°. On the other hand, the angle between the pteridine and the plane defined by the side chain in six position is 14°. The pteridine skeleton displays a C(2)=O(2) bond (1.213(2) Å) shorter than the C(4)=O(4) one (1.224(2) Å), as it is usual for related 2,6-dioxo heterocycles [36–41]. The rings are virtually planar, with average torsion angles of 1.4° and 1.5° (pteridine rings) and 1.6° (benzene ring). The benzene ring is angled by 41.7(1)° with the pteridine ring. The bonds distances near the donor atoms suggest the electronic delocalization in the chain C=N-NH-CO showing N(61)–N(62) (1.377 Å) and N(62)-C(63) (1.379 Å) bonds shorter than those expected for a single bond; this fact suggests the delocalization of the N(62) electron lone pair to the adjacent atoms. The bonds C(61)-N(61), N(61)–N(62) *y* N(62)–C(63) adopt the *EEZ* conformation.

The BZLMH molecules are packed *via* hydrogen bond resulting in helicoidal chains following the *b* axis through intermolecular interactions between the N(62)–H and oxygen atom of carbonylic group of pteridine in four position (N(62)–H(62)···O(4) (−*x*, ½ + *y*, ½−*z*)) [*d*(N(62)–O(4)) = 3.091(2) Å and (N(62)-H(62)···O(4)) = 173(2)°]). This arrangement is favoured by π-stacking interactions between the benzene ring and the pyrazine and pyrimidine rings of

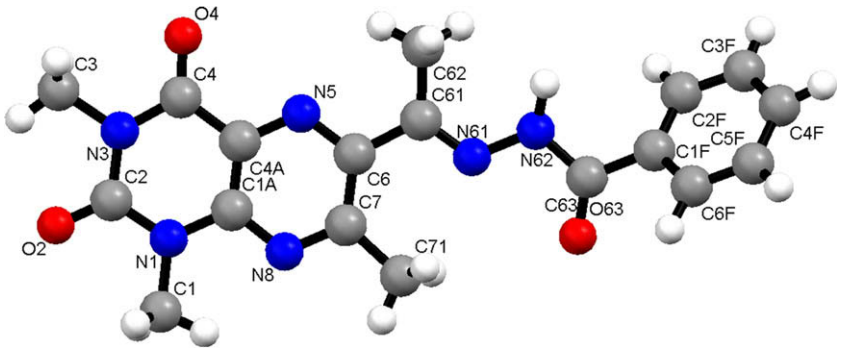

Fig. 1. The molecular structure for benzoylhydrazone of 6-acetyl-1,3,7-trimethyllumazine (BZLMH). Selected bond lengths/Å: O(63)–C(63) 1.211(3), O(2)–C(2) 1.213(2), O(4)–C(4) 1.224(2), C(6)–C(61) 1.491(3), N(61)–C(61) 1.277(3), N(61)–N(62) 1.377(2), N(62)–C(63) 1.379(3)). Selected bond angles/°: O(4)–C(4)–C(4A) 124.3(2), O(4)–C(4)–N(3) 121.2(2), N(61)–C(61)–C(6) 115.6(2), C(61)–N(61)–N(62) 119.7(2), N(61)–C(61)–C(62) 125.7(2), C(62)–C(61)–C(6) 118.7(2), N(61)–N(62)–C(63) 115.2(2), O(63)–C(63)–N(62) 122.6(2), N(62)–C(63)–C(1F) 115.4(2), O(63)–C(63)–C(1F) 122.0(2).

neighbouring molecules [42]. Data for these interactions are given in Table 2.

To elucidate the nature of the frontier orbitals in the BZLMH molecule, MO *ab inito* calculations were performed using two different optimized conformations *a* (C7–C6–C61–N61 torsion = 0.5°) and *b* (C7-C6-C61–N61 torsion = 180°) simulating the structural arrangements displayed in the metal-free and the complexed forms, respectively. The B3LYP/6-31G* MO results for BZLMH molecule (Table 3) shows the greater contributions to the HOMO (σ) are those from N(62) and N(61) atoms. Moreover, the HOMO-1 for both conformations is mainly localized over the carbonylic O(4) and (N8) atoms; finally, depending on the conformation *a* or *b*, this MO also exhibits contribution for carbonylic oxygen atom O(63) (*a* conformation) and N(5) atom (*b* conformation). The HOMO-2 seems to be mainly located over the carbonylic O(63) in both conformations. Also the LUMO's description is very similar, this fact being related with the structural similarity between them and the absence of electrons in this molecular orbital. With respect to the π-coordination, the data of Table 3 indicate this molecule can act in some extent as π-acceptor through the N(5) and N(8) atoms in *b* conformation. Therefore, we might state this ligand could show until four different coordinative behaviors: bidentate, tridentate, tetradentate or doubly bidentate ligand, through the O(4), N(5), N(61) and O(63) sites.

Accordingly, we have assembled the coordination capacity of hydrazone branch with that of the lumazine derivative, making available to the metal ligation two additional coordination sites (N(61) and O(63)) which could replace and/or extend the chelate properties of the original pterine ligand (N(5) and O4)). Thus, we have reacted BZLMH ligand with different metallic salts $Ni(ClO_4)_2 \cdot 6H_2O$, $Zn(NO_3)_2 \cdot 6H_2O$, $Hg(NO_3)_2 \cdot H_2O$ and $Hg(ClO_4)_2 \cdot 3H_2O$ in equimolar quantities, obtaining, as crystalline solids, the trinuclear green $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O \cdot CH_3CN$ and the mononuclear orange $[Zn(NO_3)(BZLMH)(H_2O)](NO_3)$ compounds, in order to explore its coordination chemistry with particular emphasis on probing its possible binding modes.

3.2. Crystallographic studies

3.2.1. Crystal structure of $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O \cdot CH_3CN$ (**2**)

The structure of trinuclear nickel(II) compound (**2**) is given in Fig. 2. Selected bond distances and angles for (2) are listed in Table 4. This structure consists of a trinuclear hydroxo-centered nickel(II) complex. The three Ni(II) ions form an equilateral triangle with Ni–Ni distances at around 3.66 Å; the Ni-$O_{hydroxo}$ bond distances are about 2.15 Å and the angles are in the range 59.54–60.36°. The $[Ni_3(\mu_3\text{-}OH)]^{5+}$ core moiety is a strongly flattened tetrahedron being the $O_{hydroxo}$ atom 0.35 Å out of the plane formed by the metallic atoms. The Ni(II) centers show an octahedral environment, where each BZLMH molecule acts as doubly bidentate ligand binding to a nickel atom through O(4) and N(5) atoms and to another one by imine nitrogen atom (N(61)) and the benzoyl oxygen atom (O(63)). The Ni(1) and Ni(2) ions complete their coordination spheres with central $O_{hydroxo}$ and a acetonitrile molecule N-bonded to the metal, while Ni(3) ion bonds to $O_{hydroxo}$ and a water molecule (Fig. 3). The chelate rings Ni–O4–C4–C4A–N5 and Ni–N61–N62–C63–O63 show *trans* disposition, being angled by 20° to each other in the three octahedrons. Pteridine moieties are almost planar and they form angles of 4.7°, 5.2° and 3.9° with their chelates rings M–O4–C4–C4A–N5 for each Ni(1), Ni(2) and Ni(3) entity, respectively. In the trimeric Ni-complex, the benzoylhydrazone ligand displays a double-bidentate coordination mode like in the already reported dimeric Cu-TSCLMH complex [15] but the different conformational abilities of BZLMH and TSCLMH ligands could provide a feasible reason to justify the appearance of structures with different nuclearity.

We can observe some changes at pteridine-chain–phenyl angles, with respect to the free ligand, due each organic ligand is bonded to two different metal ions. The most significative change is produced at pteridine–phenyl angle, which shows values between 77° and 86° while at free ligand it was 41.4°. In addition to this, the coordination of BZLMH causes some differences with respect to metal-free structure: a small shortening (0.040–0.049 Å) in the N(62)–C(63) bond and a lengthening in the C(63)–O(63) bond (0.020–0.039 Å), which have also been observed in other complexes with related hydrazones [43]; bond lengths are as follows: N(62)–C(63) 1.336(7), 1.330(7) and 1.339(6) Å; C(63)–

Table 3
Atomic orbital contributions to the LUMO to HOMO-2 molecular orbitals of BZLMH (DFT 6-31G*).

MO	Conformation *a*		Conformation *b*	
	Energy, eV (symmetry[b])	Contribution[a]	Energy (eV) (symmetry[b])	Contribution[a]

	(σ)	N8: 0.141	(π)	N8: 0.161

[a] The contribution of one atom is calculated as the sum of the squared coefficients of that atom AOs in the LCAO that defines the MO.
[b] orbitals with p_z component lower than 30% were considered σ, whereas those with this component higher than 70% were assumed as π.

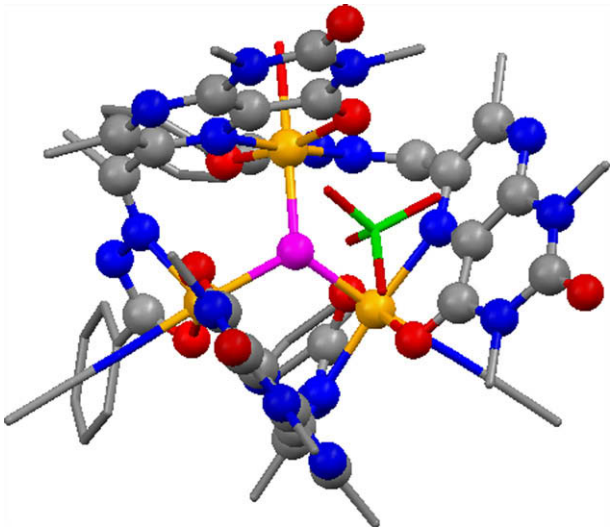

Fig. 2. The molecular structure of trimetallic cation $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2]^{5+}$ at the compound **2** showing the perchlorate anion trapped inside. Ni atoms are coloured as orange and the central μ_3-OH oxygen atom is depicted as magenta; the other atoms are shown as usually. For clarity, neither hydrogen atoms nor atom labels are displayed.

O(63) 1.230(6), 1.242(6) and 1.249(6) Å. These facts confirm the geometry of the ligand could be described according the keto form with a small contribution of the enol form [17,44].

The crystal structure expands by eight hydrogen bonds which result in two chains extended along the *a* axis, with the involvement of three perchlorate groups. Two perchlorate groups are hydrogen-bonded to the ligand and water molecules, while the third one is captured inside the trimer unit, only connecting with the central hydroxo group.

3.2.2. Crystal structure of $[Zn(NO_3)(BZLMH)(H_2O)](NO_3)$ (**3**)

The molecular structure for Zn(II) compound (**3**) was also confirmed by X-ray diffraction methods. This structure is a bipyramidal trigonal zinc(II) having a tridentate BZLMH ligand (Fig. 4). Selected bond parameters are listed in Table 4. The ligand binds the metal ion *via* carbonyl oxygen atom O(63) and imine and pyrazine nitrogen atoms (N(61), N(5)); the nitrate O(1 N) and water O(1 W) ligands bring the coordination number to five. In this process, the benzoylhydrazone ligand forms two five-membered chelate rings and the chelate bite angles for both five membered rings are similar (N(5)–Zn–N(61) 72.2(2)° and N(61)-Zn-O(63) 74.1(2)°). As previously found in other metal complexes [44,45] the Zn-N(61) bond is shorter than Zn-N(5) bond, by *ca.* 0.109 Å. The two Zn–O(1N) and Zn-O(3N) bond distances also differ by 0.483 Å being the Zn–O(3N) significantly longer (2.513(8) Å), so this nitrate anion could be defined as a monodentate ligand. The shape of the polyhedra has been quantified using the Δ parameter proposed by Muetterties and Guggenberg [46]. The Δ values clearly assign slightly distorted bipyramidal trigonal for the coordination environment in this compound (Δ = 0.23).

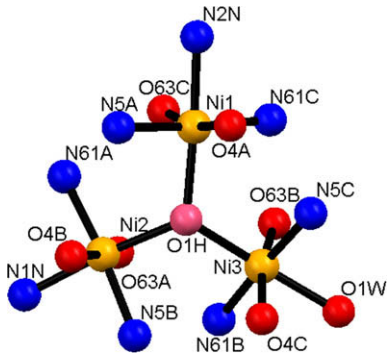

Fig. 3. Coordination environment for each Ni(II) ion in the $[Ni_3(BZLMH)_3(OH)(H_2O)(CH_3CN)_2](ClO_4)_5 \cdot 2H_2O{\cdot}CH_3CN$ complex.

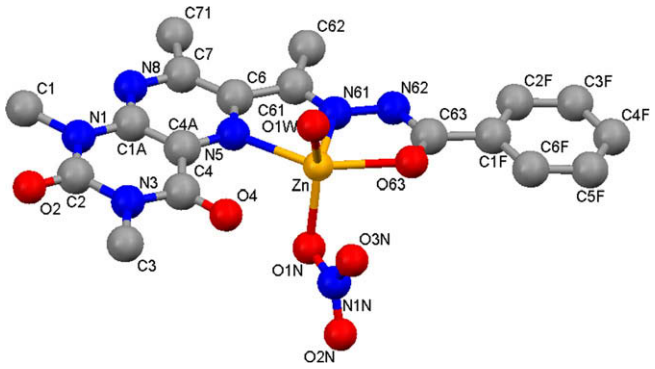

Fig. 4. Structure of the $[Zn(NO_3)(BZLMH)(H_2O)]^+$ cation (for clarity, hydrogen atoms were removed).

$[Zn(NO_3)(BZLMH)(H_2O)](NO_3)$ (**3**) is packed *via* hydrogen bonding in which perpendicular sheets to crystallographic *b* axis are formed by one hydrogen bond between the coordinated water molecule and the O(4) atom from carbonyl group (O(1W)–O(4) = 2.870 Å) and three intermolecular bonds (O(1W)-O(5N) = 2.810 Å (½ + *x*, ½−*y*, *z*−½); N(62)-O(4N) = 2.830 Å (1 + *x*, *y*, *z*); O(1W)–O(2N) = 2.801 Å (*x*−1, *y*, *z*)) between the water molecule and N(62)-H and oxygen atoms of both nitrates.

In addition to these interactions, a detailed analysis of the short aromatic ring-ring contacts (Table 2) (with centroid–centroid distances <6.0 Å and slipping angles β and $\gamma < 60°$) reveals the existence of π-stacking interactions [42] following the *a* axis. For symmetry reasons, such interaction (Fig. 5) is displayed by the parallel six-membered rings of pyrazine and phenyl of two adjacent $[Zn(NO_3)(BZLMH)(H_2O)]^+$ ions (symmetry code = ½ + ×, ½−*y*, *z*−½), with a centroid–centroid vector of 3.7 Å and slipping angles (between the centroid–centroid vector and the normal to each stacked plane) $\beta = 16.5°$ and $\gamma = 19.5°$ (angle between planes containing aromatic rings $\alpha = 4.4°$).

3.3. Spectral studies of the complexes

Spectral characterization of complexes was carried out by IR, NMR and UV–Vis spectroscopy. The significant IR bands of these complexes are close to those found in other compounds with lumazine and hydrazone derivatives. These exhibit a ν(N–H) in the 3800–3400 cm^{-1} region. The bands assignable to the C=N and C=O stretching vibrations are shifted with respect to their position in the spectra of uncoordinated BZLMH ligand. The vibrational activity of carbonyl groups appears as two bands. The higher (over 1700–1720 cm^{-1}) is mainly due to ν(C2=O) and the other one (*ca.* 1650–1670 cm^{-1}) must be assigned to ν(C4=O) [18]. In all complexes, both bands are shifted with respect to their position in the IR spectrum of the free ligand. The absorption bands located at 1603 cm^{-1} in the IR spectra of BZLMH are attributed to $\nu(C{=}N_{azom})$ and the band at 1553 cm^{-1} for this organic ligand is assignable to ν(C=N) of pteridine ring. These bands are shifted in the corresponding complexes, indicating the involvement of the N(5) and N(61) atoms in coordination to the metal ion.

The spectra of Ni(II) and Hg(II) perchlorate compounds also show a strong ν(Cl–O) band between 1100 and 1120 cm^{-1}, while Zn(II) and Hg(II) nitrate compounds displayed a strong band corresponding to ν(N–O) of the nitrate group at 1385 cm^{-1}.

The ligand BZLMH and its Zn(II) and Hg(II) complexes have well resolved ^1H, ^{13}C and ^1H–^{15}N spectra. In the ^1H NMR spectrum of the ligand, the N(62)–H proton appears at 10.99 ppm and also for Zn(II) complex. Other signals in the ^1H spectrum are the phenolic protons at 7.90 and 7.55 ppm and the signals due to the methyl groups at 3.54 (C(1)–H), 3.34 (C(3)–H), 2.92 (C(62)–H) and 2.50 (C(71)–H). The spectrum of the Zn(II) and Hg(II) complexes are similar to that of the uncomplexed ligand. The most notable differences are the upfield shift of the C(62)–H proton to 2.77 ppm for zinc complex (**3**). The C_{arom}, C6 and C62 signals of ^{13}C spectrum also show significant field shift together with the N(61) one in ^1H–^{15}N HMBC spectrum. These shifts are mainly resulting from an increased delocalization after coordination of imine nitrogen N(61) and carbonylic oxygen atoms O(63) to the zinc ion [33,34].

The main differences between the ^{13}C NMR spectra of ligand and nitrate and perchlorate mercury compounds are retrieved in the downfield shift of the C(7), C(1A) and C(6) for nitrate complex and C(7), C(6) for perchlorate complex. These shifts can be also justified by the involvement of the pyrazine and benzohydrazide donor atoms in the coordination of the Hg(II). In this way, the ^1H–^{15}N HMBC showed downfield shift for donor atom N(61) for Hg/NO_3 complex, while Hg/ClO_4 compound displayed upfield shift for N(5), N(8) and N(61) signals. These chemical shifts suggest bidentate coordination (N(5), N(61)) for Hg/ClO_4 complex and a tridentate coordination (N(5), N(61), O(63)) for Hg/NO_3 compound.

The UV–Vis absorption spectrum of $Ni(BZLMH)_2(ClO_4)_2 \cdot 3H_2O$ (**1**) compound exhibits the characteristic bands at 9500, 13700 and 21300 cm^{-1}, assignable to $^3T_{2g}(F) \leftarrow {}^3A_{2g}$, $^3T_{1g}(F) \leftarrow {}^3A_{2g}$, $^3T_{1g}(P) \leftarrow {}^3A_{2g}$ transitions in an idealized O_h symmetry. The position of the observed spectral bands permits to calculate the ligand field parameters, 10*Dq* (9500 cm^{-1}) and B (432 cm^{-1}). These results also agree with the expected octahedral environment for the Ni(II) complex in which N(5), N(61), O(63) tridentation of the ligand could be proposed. We might suggest that this compound may be a possible intermediate first formed and isolated as a solid compound that later evolves to afford the trimer nickel(II) compound (**2**).

3.4. Luminescence studies

Fluorescent transition-metal complexes containing rigid chromophoric ligands with π-conjugation system have been studied intensively because of their potential use. Moreover, to extend the π-conjugation only by synthesis and modification of organic composition may be difficult and tedious. Synthesis of inorganic/organic coordination complexes by using functional ligands and transition-metal centers can be an useful method to obtain new photoluminescent materials. In the current work, we try to obtain this kind of system with organic ligand (BZLMH) and complexes previously cited.

It is important to bear in mind that the luminescent properties of lumazine and benzoylhydrazone ligands are very well known and have been widely used in order to obtain fluorescent sensors [19–24]. Thus, we have borrowed this previous knowledge to study the luminescence of BZLMH ligand, a new lumazine derivative ligand incorporating the photochemically active benzoylhydrazide

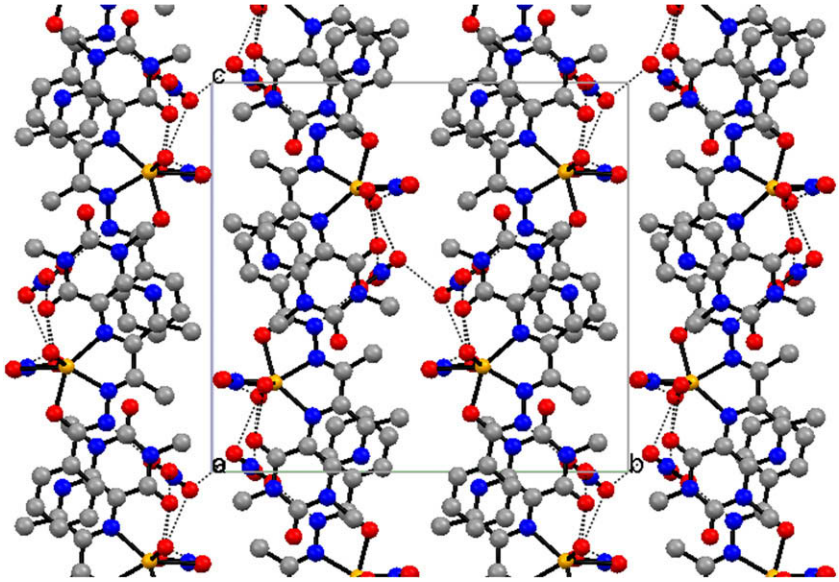

Fig. 5. View down the *a* axis of the H-bonds and π-stacking interactions in the structure of the Zn(II) complex (**3**).

group that could enhance the delocalization of π electrons. Moreover, this substituent could increase the fluorescence intensity of lumazine in BZLMH ligand possibly due to the internal photo induced ceto-enol tautomerism [19,47–50]. In this context, the fluorescence spectroscopy of BZLMH ligand and its nickel compound (**1**), monomeric zinc complex (**3**) and mercury (II) complexes (**4**) and (**5**) is described. Luminescence spectra were obtained using 10^{-3} M BZLMH and metal complexes solutions in DMSO (λ_{exc} = 420 nm).

The free ligand shows a strong luminiscence band centered at 492 nm while fluorescence intensity of Ni-complex (**1**) decreases by a factor of six and exhibits a band centered at 480 nm, which is 12 nm blue-shifted compared to the free ligand. In the same experiment performed with Zn(II) complex (**3**) a blue shift (11 nm) of the fluorescence band is observed (Fig. 6). In contrast with the results for nickel and zinc compound, Fig. 6 also shows enhancement and blue shift of fluorescence for mercury-nitrate (**4**) (λ_{max} = 465 nm) and mercury-perchlorate (**5**) (λ_{max} = 485 nm) complexes while uncomplexed ligand showed a luminescence band centered at 492 nm. Probably, the structures of mercury compounds (**4**) and (**5**) are different from that related Ni(II) and Zn(II) complexes and it could suggest that the ligand coordination mode in both mercury complexes makes the energy transfer from the Hg(II) ion to the ligand more effective than that in complexes with Ni(II) and Zn(II) [51]. On the other hand, if these data are compared with those already reported for the related TSCLMH ligand and complexes [15], a possible relation between the decrease of the fluorescence absorption and the metal-complexation through increasing polydentate modes could be pointed out, since, in general, from complexes with the tetra- or tridentate lumazine derivative bound to metal to those showing bidentate mode, an increase of the fluorescence signal can be observed.

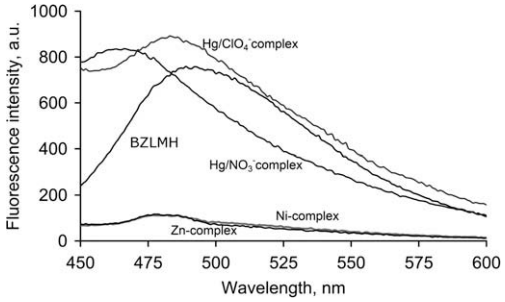

Fig. 6. Fluorescence spectra at room temperature (λ_{exc} = 420 nm) of BZLMH and Ni, Zn, Hg-complexes (DMSO 10^{-3} M).

4. Conclusions

We have studied the XRD crystal structure and the coordination behavior of BZLMH, in which the four possible donors atoms make it possible for the ligand to be tetradentate, tridentate, bidentate or doubly bidentate. In addition to the Rh(III) and Co(II) previously reported structures, the Ni(II) trimer and Zn(II) monomer structures presented here are new examples of the varied coordination chemistry of these hybrid ligands, forming a basis for future comparison with complexes of the same ligand with others metals and different geometry. The versatile coordinative behavior of BZLMH can be related with the rotational ability of both pteridine and benzoylhydrazone moieties to each other.

In this study, the sensibility of the BZLMH fluorescence to the presence of Ni(II), Zn(II) and Hg(II) ions has been found. The BZLMH system recently investigated show good affinity for Hg^{2+} due to the pronounced changes in photophysical properties such as emission wavelength and intensity of Hg(II) complexes. Keeping in mind the importance of Hg^{2+} ions as environmental pollutants, we think that these results are very interesting for future development and practical applications [52].

Supplementary data

CCDC 650849, 650850 and 650851 contains the supplementary crystallographic data for BZLMH, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Iridium

ABSTRACT

The mononuclear complexes $[(\eta^6\text{-arene})Ru(ata)Cl]PF_6$ {*ata* = 2-acetylthiazole azine; arene = C_6H_6 [(**1**)PF_6]; *p*-^{i}PrC_6H_4Me [(**2**)PF_6]; C_6Me_6 [(**3**)PF_6]}, $[(\eta^5\text{-}C_5Me_5)M(ata)]PF_6$ {M = Rh [(**4**)PF_6]; Ir [(**5**)PF_6]} and $[(\eta^5\text{-Cp})Ru(PPh_3)_2Cl]$ {η^5-Cp = η^5-C_5H_5 [(**6**)PF_6]; η^5-C_5Me_5 (Cp^*) [(**7**)PF_6]; η^5-C_9H_7 (indenyl); [(**8**)PF_6]} have been synthesised from the reaction of 2-acetylthiazole azine (*ata*) and the corresponding dimers $[(\eta^6\text{-arene})Ru(\mu\text{-Cl})Cl]_2$, $[(\eta^5\text{-}C_5Me_5)M(\mu\text{-Cl})Cl]_2$, and $[(\eta^5\text{-Cp})Ru(PPh_3)_2Cl]$, respectively. In addition to these complexes a hydrolysed product (**9**)PF_6, was isolated from complex (**4**)PF_6 in the process of crystallization. All these complexes are isolated as hexafluorophosphate salts and characterized by IR, NMR, mass spectrometry and UV–Vis spectroscopy. The molecular structures of [**2**]PF_6 and [**9**]PF_6 have been established by single-crystal X-ray structure analyses.

1. Introduction

Recent interest in half- sandwich platinum group metal complexes with symmetrical Schiff bases come from the fact they can serve as synthetic models related to biological systems [1–7], as homogeneous catalysts in systems like [8–17], and supported chemical processes [18,19], and very recently as non-linear optical (NLO) materials [20,21]. Their attractiveness does also come from their preparative accessibility, their structural variability in addition to many of these novel ruthenium complexes combine an appropriate balance between the electronic and steric environment around the metal core.

Moreover, some of the nitrogen-donor ligands impart to the catalyst for good tolerance towards various organic functionalities, air, and moisture, thus widening the scope and limit's of their application. Of the above mentioned ligands, Schiff bases are of a great interest for creating new active and selective ruthenium catalytic systems [22,23]. There are few reports of half-sandwich Ru(II), Rh(III) and Ir (III) complexes with *N*,*N*-donor polypyridyl azine Schiff base ligands [24,25], but there are no reports with thiazole azine ligand in the literature. Complexes imparting other than pyridyl azine ligands are yet to be explored, in view of the fact that ring size and the substituents in the heterocyclic ring system significantly modifies the acidity and regulate the physical and chemical properties of the complexes [26,27]. The arene and cyclopentadienyl platinum group metal complexes containing thiazole azine ligand is being reported for the first time.

In the present communication we focus on the synthetic methodology applied for the development of homogeneous and immobilized half- sandwich ruthenium, rhodium and iridium complexes bearing Schiff base (*ata*) as a specific *N*,*N*-bidentate bridging ligand has shown below.

2-acetylthiazole azine *(ata)*

Ligand used in this study

2. Experimental

2.1. General remarks

All solvents were dried and distilled prior to use. Ruthenium trichloride trihydrate (Arora Matthey Ltd.), 2-acetylthiazole (Aldrich)

were purchased and used as received. $[(\eta^6\text{-}C_6H_6)Ru(\mu\text{-}Cl)Cl]_2$, $[(\eta^6\text{-}p\text{-}^iPrC_6H_4Me)Ru(\mu\text{-}Cl)Cl]_2$, $[(\eta^6\text{-}C_6Me_6)Ru(\mu\text{-}Cl)Cl]_2$ [28–30], $[(\eta^5\text{-}C_5Me_5)M(\mu\text{-}Cl)Cl]_2$ (M = Rh, Ir) [31–33], $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ [34], $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)_2Cl]$, $[(\eta^5\text{-}C_9H_7)Ru(PPh_3)_2Cl]$ [33,35,36] and ligand *ata* [37,38] were prepared according to literature methods. NMR spectra were recorded on AMX-400 MHz spectrometer. Infrared spectra were recorded as KBr pellets on a Perkin–Elmer 983 spectrophotometer; elemental analyses of the complexes were performed on a Perkin–Elmer-2400 CHN/S analyzer. Mass spectra were obtained from ZQ mass spectrometer by ESI method. Absorption spectra were obtained at room temperature using a Perkin–Elmer Lambda 25 UV–Vis spectrophotometer.

2.2. Single crystal X-ray structure analyses

Crystals suitable for X-ray diffraction study for compound [**2**]PF_6 and [**4**]PF_6 were grown by slow diffusion of diethylether into dichloromethane solution of complexes [**2**]PF_6 and [**4**]PF_6, respectively. The bright orange crystals of compound [**2**]PF_6, the red color crystal of [**4**]PF_6 were mounted on a Stoe-Image Plate Diffraction system equipped with a ϕ circle goniometer, using Mo Kα graphite monochromated radiation (λ = 0.71073 Å) with ϕ range 0–200°, increment of 1.2°, D_{max}–D_{min} = 12.45–0.81 Å. X-ray intensity data were collected with Mo Kα graphite monochromatic radiation at 296 (2) K, with 0.3°ω scan mode and 10 second per frame. The intensity data were corrected for Lorentz and polarization effects. The structures were solved by direct methods using the program SHELXS-97 [39]. Refinement and all further calculations were carried out using SHELXL-97 [40]. The H-atoms were included in calculated positions and treated as riding atoms using the SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. The data collection parameters and bond lengths and angles are presented in Tables 1 and 2, respectively. Figs. 1 and 2 were drawn with ORTEP [41].

2.3. General procedure for the preparation of the mononuclear complexes [**1**]PF_6–[**3**]PF_6

A mixture of $[(\eta^6\text{-arene})Ru(\mu\text{-}Cl)Cl]_2$ (arene = C_6H_6, p-$^iPrC_6H_4Me$ and C_6Me_6) (0.07 mmol), ligand *ata* (0.18 mmol) and 2.5 equivalents of NH_4PF_6 in dry methanol (15 ml) was stirred at room temperature for 6 h. The precipitate was separated by filtration, washed with cold methanol and diethyl ether to remove excess ligand and dried under vacuum.

2.3.2. $[(\eta^6\text{-}p\text{-}^iPrC_6H_4Me)Ru(ata)Cl]PF_6$ ([**2**]PF_6)

Dark orange solid, yield 86 mg (89%): *Anal.* Calc. for $C_{20}H_{24}ClS_2N_4RuPF_6$ (651.5): C, 36.07; H, 3.63; N, 8.41. Found: C, 36.18; H, 3.68; N, 8.35%.

^{1}H NMR ($CDCl_3$, δ): 8.55 (d, 1H, J_{H-H} = 2.88 Hz), 8.06 (d, 1H, J_{H-H} = 3.20 Hz), 7.98 (d, 1H, J_{H-H} = 3.2 Hz), 7.71 (d, 1H, J_{H-H} = 2.80 Hz), 5.90 (d, 1H, J_{H-H} = 2.8 Hz, $Ar_{p\text{-}cy}$), 5.87 (d, H, J_{H-H} = 2.4 Hz, $Ar_{p\text{-}cy}$), 5.72 (d, 1H, J_{H-H} = 4 Hz, $Ar_{p\text{-}cy}$), 5.68 (d, 1H, J_{H-H} = 2.8 Hz, $Ar_{p\text{-}cy}$), 2.93 (sept, 1H, J_{H-H} = 4.4 Hz, $CH(CH_3)_2$), 2.56 (s, 3H, tz-Me), 2.47 (s, 3H, tz-Me), 2.28 (s, 3H, $Ar_{p\text{-}cy}$–Me), 1.26 (d, 3H, $CH(CH_3)_2$), 1.18 (d, 3H, $CH(CH_3)_2$); ESI-MS (m/z): 525.1 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 844s; 1629, 1406, 763, 558.

2.3.3. $[(\eta^6\text{-}C_6Me_6)Ru(ata)Cl]PF_6$ ([**3**]PF_6)

Orange–yellow solid, yield 85 mg (88%): *Anal.* Calc. for $C_{22}H_{28}ClN_4S_2RuPF_6$ (694.1): C, 38.07; H, 4.07; N, 8.07. Found: C, 38.11; H, 4.18; N, 8.02%.

^{1}H NMR ($CDCl_3$, δ): 8.75 (d, 1H, J_{H-H} = 2.98 Hz), 8.52 (d, 1H, J_{H-H} = 3.20 Hz), 7.98 (d, 1H, J_{H-H} = 3.20 Hz), 7.62 (d, 1H, J_{H-H} = 3.2 Hz), 2.56 (s, 3H, tz-Me), 2.47 (s, 3H, tz-Me), 2.28 (s, 18H), ESI-MS (m/z): 549.14 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 844s; 1624, 1437, 1409, 769, 558.

2.4. General Procedure for the preparation of the mononuclear complexes [**4**]PF_6 and [**5**]PF_6

A mixture of $[(\eta^5\text{-}C_5Me_5)M(\mu\text{-}Cl)Cl]_2$ (M = Rh, Ir) (0.07 mmol), ligand *ata* (0.15 mmol) and 2.5 equivalents of NH_4PF_6 in dry methanol (15 ml) was refluxed for 4 h. The reaction mixture was cooled over night at room temperature during this time dark yellow color crystalline compound formed. It was separated by filtration, washed with cold methanol and diethyl ether to remove excess ligand and dried under vacuum.

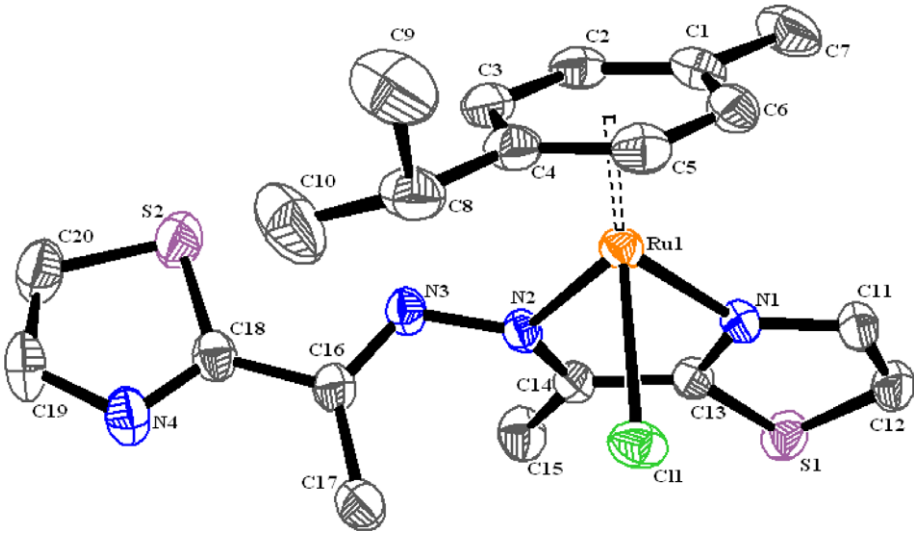

Fig. 1. Molecular structure of [**2**]PF_6 at 50% probability level. Hydrogen atoms, and hexafluorophosphate anion have been omitted for clarity.

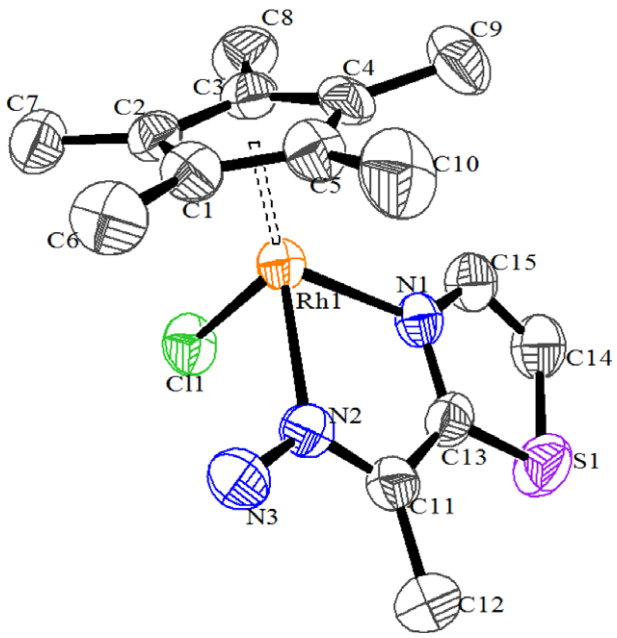

Fig. 2. Molecular structure of [**9**]PF_6 at 50% probability level. Hydrogen atoms and hexafluorophosphate anion have been omitted for clarity.

*2.4.1. [(η^5-C_5Me_5)Rh(ata)Cl]PF_6 ([**4**]PF_6)*

Dark yellow color, yield 86 mg (85%): *Anal.* Calc. for $C_{20}H_{25}ClN_4S_2RhPF_6$ (668.89): C, 35.91; H, 3.77; N, 8.38. Found: C, 36.00; H, 3.89; N, 8.29%.

^{1}H NMR (CD_3CN, δ): 8.33 (d, 1H, J_{H-H} = 5.58 Hz), 8.05 (d, 1H, J_{H-H} = 3.2 Hz), 7.82 (d, 1H, J_{H-H} = 2.8 Hz), 7.68 (d, 1H, J_{H-H} = 3.2 Hz), 2.57 (s, 3H, tz-Me), 2.50 (s, 3H, tz-Me), 1.77 (s, 15H, C_5Me_5); ESI-MS (*m*/*z*): 523.1 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 1626, 1458, 759, 558.

*2.4.2. [(η^5-C_5Me_5)Ir(ata)Cl]PF_6 ([**5**]PF_6)*

Dark yellow color, yield 95 mg (84%): *Anal.* Calc. for $C_{20}H_{25}ClN_4S_2IrPF_6$ (818.21): C, 31.68; H, 3.32; N, 7.39. Found: C, 31.70; H, 3.48; N, 7.48%.

^{1}H NMR (CD_3CN, δ): 8.58 (d, 1H, J_{H-H} = 3.28 Hz), 8.26 (d, 1H, J_{H-H} = 3.26 Hz), 7.88 (d, 1H, J_{H-H} = 2.88 Hz), 7.68 (d, 1H, J_{H-H} = 3.24 Hz), 2.57 (s, 3H, tz-Me), 2.40 (s, 3H, tz-Me), 1.99 (s, 15H, C_5Me_5); ESI-MS (*m*/*z*): 613.18 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 1631, 1495, 760, 558.

*2.5. General Procedure for the preparation of the mononuclear complexes [**6**]PF_6- [**8**]PF_6*

A mixture of [(η^5-Cp)Ru(PPh_3)$_2$Cl] (η^5-Cp = η^5-C_5H_5, η^5-C_5Me_5, η^5-C_9H_7) (0.1 mmol), ligand *ata* (0.12 mmol) and 1.5 equivalents of NH_4PF_6 in dry ethanol (15 ml) was refluxed for 10 h. It was changed to dark red color from dark yellow color. The solvent was evaporated on rotary evaporator and residue was dissolved in dichloromethane and filtered to remove ammonium chloride and filtrate was evaporated to 2 ml and excess hexane was added to induce dark color precipitate.

*2.5.1. [(η^5-C_5H_5)Ru(ata)(PPh_3)]PF_6 ([**6**]PF_6)*

Orange color, yield 60 mg (73%): *Anal.* Calc. for $C_{33}H_{30}N_4S_2RuP_2F_6$ (823.75): C, 48.12; H, 3.67; N, 6.80. Found: C, 48.11; H, 3.73; N, 6.75%.

^{1}H NMR ($CDCl_3$, δ) 8.52 (d, 1H, J_{H-H} = 2.80 Hz), 8.12 (d, 1H, J_{H-H} = 3.2 Hz), 7.77 (d, 1H, J_{H-H} = 3.2 Hz), 7.68 (d, 1H, J_{H-H} = 3.2 Hz), 7.46–7.23 (m, 15H), 4.57 (s, 5H, C_5H_5), 2.57 (s, 3H, tz-Me), 2.50 (s, 3H, tz-Me); ESI-MS (*m*/*z*): 678.78 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 1626, 1458, 766, 558. ^{31}P {^{1}H} ($CDCl_3$): 49.34 ppm.

*2.5.2. [(η^5-C_5Me_5)Ru(ata)(PPh_3)]PF_6 ([**7**]PF_6)*

Orange color, yield 68 mg (76%): *Anal.* Calc. for $C_{38}H_{40}N_4S_2RuP_2F_6$ (893.88): C, 51.06; H, 4.51; N, 6.27. Found: C, 51.10; H, 4.62; N, 6.24%.

^{1}H NMR ($CDCl_3$, δ) 8.87 (d, 1H, J_{H-H} = 2.80 Hz), 8.52 (d, 1H, J_{H-H} = 3.2 Hz), 7.87 (d, 1H, J_{H-H} = 3.2 Hz), 7.79 (d, 1H, J_{H-H} = 3.2 Hz), 7.46–7.23 (m, 15H), 2.57 (s, 3H, tz-Me), 2.50 (s, 3H, tz-Me), 2.19 (s, 15H, C_5Me_5); ESI-MS (*m*/*z*): 748.88 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 1621, 1479, 749, 558. ^{31}P {^{1}H} ($CDCl_3$): 48.54 ppm.

*2.5.3. [(η^5-C_9H_7)Ru(ata)(PPh_3)]PF_6 ([**8**]PF_6)*

Yellowish brown color, yield 66 mg (76%): *Anal.* Calc. for $C_{37}H_{35}N_4S_2RuP_2F_6$ (876.83): C, 50.68; H, 4.02; N, 6.39. Found: C, 50.61; H, 4.19; N, 6.34%.

^{1}H NMR ($CDCl_3$, δ) 8.52 (d, 1H, J_{H-H} = 2.80 Hz), 8.12 (d, 1H, J_{H-H} = 3.2 Hz), 7.77 (d, 1H, J_{H-H} = 3.2 Hz), 7.68 (d, 1H, J_{H-H} = 3.2 Hz), 7.46–7.23 (m, 20H), 4.87(t, 1H), 4.71 (d, 2H); 2.57 (s, 3H, tz-Me), 2.50 (s,

3H, tz-Me); ESI-MS (*m*/*z*): 731.87 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 1629, 1468, 763, 558. $^{31}P\{^1H\}$ ($CDCl_3$): 54.42 ppm.

2.5.4. [(η^5-C_5Me_5)Rh(ata)Cl]PF_6 ([**9**]PF_6)*

The complex [**4**]PF_6 (50 mg, 0.074 mmol) was dissolved in 20 ml of dichloromethane in a small diameter test tube and layered with diethylether and it was sealed and kept at room temperature. Dark orange crystalline compound was observed after three days. The crystalline compound was separated by filtration and washed with diethylether and dried at room temperature.

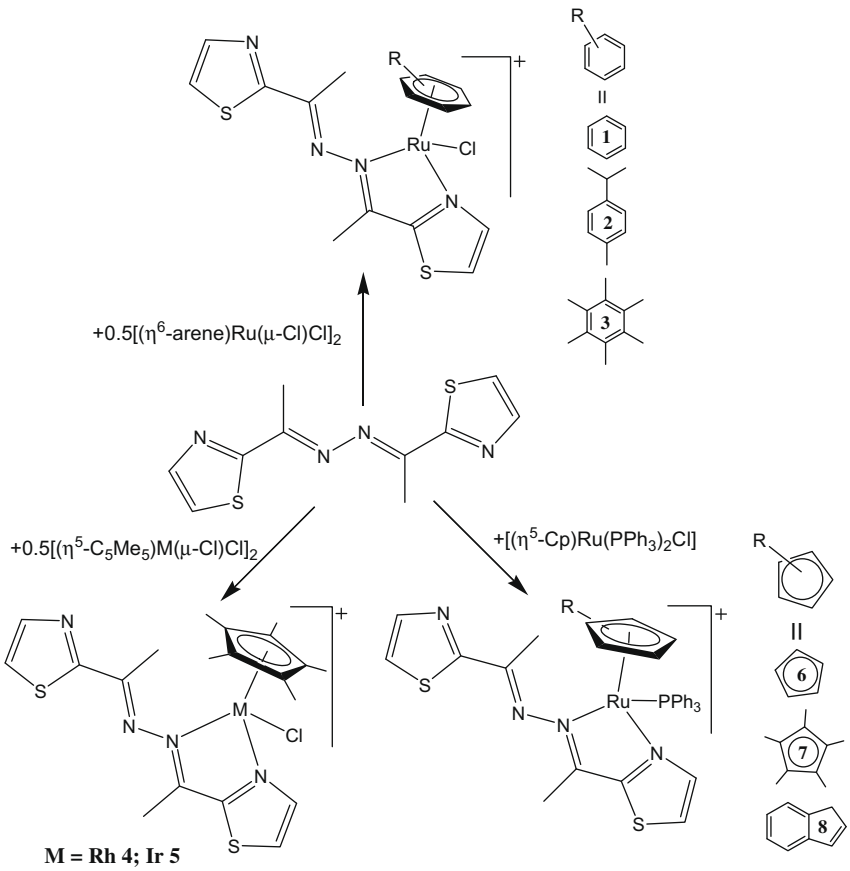
Anal. Calc. for $C_{15}H_{22}ClF_6N_3PRhS$ (559.73): C, 32.19; H, 3.96; N, 7.51. Found: C, 32.00; H, 3.99; N 7.29%.

^1H NMR (CD_3CN, δ): 8.23 (d, 1H, J_{H-H} = 5.58 Hz), 7.89(d, 1H, J_{H-H} = 2.8 Hz), 4.78 (s, 2H, NH_2), 2.61 (s, 3H, tz-Me), (s, 15H, C_5Me_5); ESI-MS (*m*/*z*): 415.72 (100%) $[M-PF_6]^+$; IR (KBr, cm^{-1}): $\nu_{(P-F)}$ 845s; 759, 558, 1626, 1458, 2891.

3. Results and discussion

Mononuclear cationic arene ruthenium complexes having *ata* ligand viz., [(η^6-C_6H_6)Ru(*ata*)Cl]PF_6 [**1**]PF_6, [(η^6-*p*-^{i}PrC_6H_4Me)Ru(*ata*)Cl]PF_6 [**2**]PF_6, and [(η^6-C_6Me_6)Ru(*ata*)Cl]PF_6 [**3**]PF_6 (Scheme 1) have been expediently prepared by the reaction of arene ruthenium dimers [(η^6-arene)Ru(μ-Cl)Cl]$_2$ (arene = C_6H_6, *p*-^{i}PrC_6H_4Me, C_6Me_6) and two equivalents of 2-acetylthiazole azine (*ata*) in methanol at room temperature in the presence of NH_4PF_6. These complexes are isolated as hexafluorophosphate salts.

Similarly, the pentamethylcyclopentadienyl Rh and Ir dimers [(η^5-C_5Me_5)M(μ-Cl)Cl]$_2$ (M = Rh, Ir) with the 2-acetylthiazole azine (*ata*) ligand at 50 °C leads to the formation of the mononuclear cationic complexes [(η^5-C_5Me_5)Rh(*ata*)Cl]PF_6 [**4**]PF_6 and [(η^5-C_5Me_5)Ir(*ata*)Cl]PF_6 [**5**]PF_6 (Scheme 1) which are isolated as their hexafluorophosphate salts.



The cyclopentadienyl ruthenium triphenylphosphine complexes [(η^5-C_5H_5)Ru(PPh_3)$_2$Cl], [(η^5-C_5Me_5)Ru(PPh_3)$_2$Cl] and [(η^5-C_9H_7)Ru(PPh_3)$_2$Cl] with the 2-acetylthiazole azine (*ata*) ligand in methanol at 70 °C leads to the formation of the mononuclear cationic complexes [(η^5-C_5H_5)Ru(*ata*)PPh_3]PF_6 [**6**]PF_6, [(η^5-C_5Me_5)Ru(*ata*)PPh_3]PF_6 [**7**]PF_6 and [(η^5-C_9H_7)Ru(*ata*)PPh_3]PF_6 [**8**]PF_6 (Scheme 1) by replacement of one triphenylphosphine and chloride which are isolated as their hexafluorophosphate salts.

In order to prepare the dinuclear complexes we have used two fold metal-to-ligand or one fold metal to mononuclear complexes concentration, but we were not successful in either of the cases. This could be due to the steric strain from arene or pentamethylcyclopentadienyl ligands already present on metal atoms.

3.1. Characterization

The mononuclear complexes were fully characterized by IR, NMR (^1H and ^{31}P), and electronic spectroscopy. Analytical data of the complexes conformed well to their respective formulations. Further information about composition of the complexes has also been obtained from Mass spectrometry.

Infrared spectra of the ligand display an absorption band at 1606 cm^{-1} (*ata*) assignable to the C=N Bond, consistent with the fact that C=N stretching frequencies of Schiff bases appear in the range 1680–1603 cm^{-1} [42–44] and complexes display the same band at higher wave numbers and appeared around 1626 cm^{-1}. The bands associated with thiazole ring such as C=N and C=S appeared at about 1430 and 1406 cm^{-1}, these values are showing less wave numbers as compared to free ligand (1490 and 1417 cm^{-1}),

Scheme 1.

respectively. The shift in the position of $\nu_{C=N}$ of both azine and thiazole suggested that the coordination of the metal ion is through thiazole and azine of nitrogen and not through the thiazole sulfur. Strong band in the region 844 cm^{-1} have been assigned to counter ion PF_6.

The ^1H NMR spectrum of free ligand (*ata*) exhibit a characteristic set of three resonances for the thiazole ring protons and methyl protons of N=C–CH_3 group. Upon coordination with the metal atom, the mononuclear cationic complexes [**1**]PF_6 to [**5**]PF_6 exhibited six distinct resonances assignable to thiazolyl ring and N=C–CH_3 protons of the *ata* ligand indicating formation of mononuclear complexes. Besides these signals complexes [**1**]PF_6 and [**3**]PF_6 exhibit a singlet for the protons of the benzene ring and protons of the hexamethylbenzene at δ 6.50 and 2.28, respectively. Complex **2** exhibit a singlet at δ = 2.28 for methyl protons, a septet at δ = 2.82 for the CH proton of the isopropyl group. Interestingly we observe an unusual pattern for the diastereotopic methyl protons of the isopropyl group and diastereotopic CH protons of the *p*-cymene ligand showing two doublets at δ = 1.26–1.18, and four doublets in the range δ = 5.90–5.68 instead of one doublet and two doublets, respectively with reference to the starting precursor. This unusual pattern is due to the diastereotopic methyl protons of the isopropyl group and aromatic protons of the *p*-cymene ligand, since the ruthenium atom is stereogenic due to the coordination of four different ligand atoms and chiral nature of metal atom [45,46,52].

Complexes **[4]PF_6** and **[5]PF_6** exhibit a singlet for the methyl protons of the pentamethylcyclopentadienyl ligand at δ 1.77 and 1.99 ppm. Complexes **[6]PF_6** and **[7]PF_6** exhibit a singlet at δ 4.57 and 2.19 for the protons of cyclopentadienyl ligand and methyl protons of pentamethylcyclopentadienyl ligands respectively. Complex **[8]PF_6** exhibits a characteristic three sets of signals such as multiplet, triplet and doublet, for the protons of the indenyl ligand in the range of 7.46, 4.81 and 4.71, respectively. The protons of the triphenylphosphine ligand exhibit a multiplet at δ = 7.22 to 7.55.

The ^{31}P NMR spectra of complexes [**6**]PF_6, [**7**]PF_6, and [**8**]PF_6 showing down field shift compared to starting precursors viz. δ 49.34, 48.54, and 54.42 ppm, respectively. This down field chemical shift of phosphorus nucleus indicates the formation of cationic complexes.

3.2. Molecular structure presentation

The molecular structures of [(η^6-*p*-^{i}PrC_6H_4Me)Ru(*ata*)Cl]$^+$ (**2**) and [(η^5-C_5Me_5)Rh(*ata**)Cl]$^+$ (**9**) (*ata** = hydrolysed product of *ata*) (N($CH_2CH_2SCC(CH_3)$)N–NH_2) have been established by single-crystal X-ray analysis of their hexafluorophosphate salts. All the cationic complexes show a typical piano-stool geometry with the metal centre being coordinated by the arene/pentamethylcyclopentadienyl ligand, a terminal chloride and the chelating *ata*/*ata** ligand. The metal atom is in octahedral arrangement with two *cis*-nitrogen atoms of the *ata*/*ata** ligand acting as a bidentate chelating ligand through two neighbouring thiazole and azine nitrogen atoms. The molecular structures of complexes [**2**]PF_6 and [**9**]PF_6 are shown in Figs. 1 and 2, respectively, and bond lengths and angles are presented in Table 2.

In the mononuclear complexes [**2**]PF_6 and [**9**]PF_6 the metal to nitrogen bond distance (2.087(3), and 2.097(4) Å) of the thiazole is shorter than the corresponding azine N-metal distance (2.104(2) and 2.136(5) Å) which are comparable to those in [(η^6-C_6Me_6)RuCl–(C_5H_4N-2-CH=N=C_6H_4-p-NO_2)]PF_6 [47], [Ru(mes)Cl-{C_5H_4N-2-C(Me)=N(CHMePh)}]BF_4 [48], [(η^5-C_5Me_5)RhCl(C_5H_4N-2-CH=N=C_6H_4-*p*-NO_2)]BF_4 [49]. The Rh–N bond distance (2.097(4) and 2.136(5) Å) in [**9**]PF_6 is slightly longer than the corresponding distances of ruthenium complex **2** (2.104(3) Å), while the M–Cl [2.406(8) and 2.396(15)] bond lengths show no significant differences in both the cations and other reported values [50]. The N–M–N bond angles [75.58(10)° in **2** and 75.88(17)° in **9**] are similar to those in other reported complexes [(η^5-C_5Me_5)Ru(PPh_3)(C_5H_4N–CH=N–N=CH–C_5H_4N)]BF_4 and [(η^5-C_9H_7)Ru–(PPh_3)(C_5H_4N-2-CH=N=C_6H_4-*p*-NO_2)]PF_6 [75.90(2) and 75.53(8)°] [51].

The distances between the ruthenium atom and centroid of η^6-*p*-^{i}PrC_6H_4Me ring is 1.692 Å in complex [**2**]PF_6, whereas the distance betwen the rhodium atom and the centroid of the η^5-C_5Me_5 ring is 1.782 Å in complex [**9**]PF_6**.** These bond distances are comparable to those in the related complex cations [(η^6-*p*-^{i}PrC_6H_4Me)Ru(pyNp)Cl]PF_6 and [(η^5-C_5Me_5)Ir(pyNp)Cl]PF_6 (PyNp=2-(2-pyridyl)-1,8-naphthyridine) (1.68 and 1.79 Å) [52].

The solid state molecular structures of representative complexes have been presented in Figs. 1 and 2, respectively.

4. UV–Vis spectroscopy

Electronic absorption spectra of complexes [**1**]PF_6 to [**4**]PF_6 and [**6**]PF_6 and [**7**]PF_6 were acquired in acetonitrile, at 10^{-5} M concentration in the range 250–550 nm and spectral data are summarized in Table 3. The spectra of these complexes are characterized by two main features, viz., an intense ligand–localized or intra-ligand $\pi \rightarrow \pi^*$ transition in the ultraviolet region and metal-to-ligand charge transfer (MLCT) $d\pi(M) \rightarrow \pi^*$ (*ata*-ligand) bands in the visible region [53]. Since the low spin d^6 configuration of the mononuclear complexes provides filled orbitals of proper symmetry at the Ru(II), Rh(III) and Ir(III) centres, these can interact with low lying π^* orbitals of the ligands. All these complexes show an intense band in the region 310–320 nm and a low energy absorption band in the visible region 407–425 nm. The high intensity band in UV region is assigned to inter and intra-ligand π–π^* transitions [54,55],

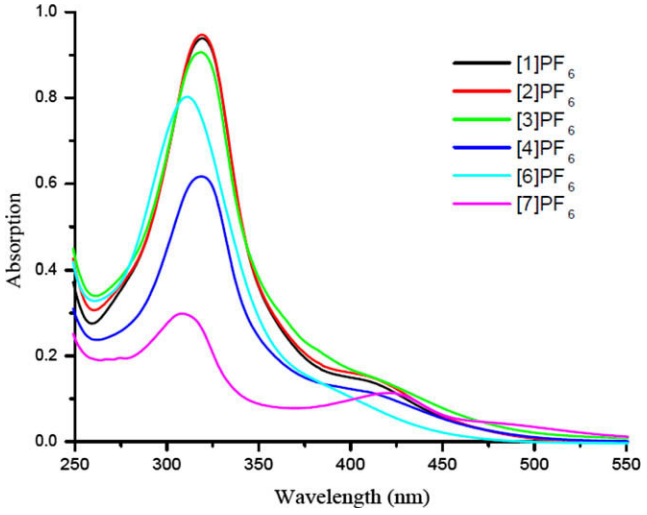


Fig. 3. UV–Vis electronic spectra of complexes in acetonitrile at 298 K.

Table 3
UV–Vis spectral data for selected complexes in acetonitrile at 298 K.

Sl. No.	Complex	λ_{max} (nm)/$\varepsilon \times 10^{-5}$ M^{-1} cm^{-1}
1	[(η^6-*p*-^{i}PrC_6H_4Me)Ru(*ata*)Cl]$^+$	320 (0.93) 412
2	[(η^6-C_6H_6)Ru(*ata*)Cl]$^+$	319(0.95) 415
3	[(η^6-C_6Me_6)Ru(*ata*)Cl]$^+$	319 (0.90) 420
4	[(η^5-C_5Me_5)Rh(*ata*)Cl]$^+$	310 (0.80) 413
6	[(η^5-C_5H_5)Ru(*ata*)PPh_3]$^+$	320 (0.61) 407
7	[(η^5-C_5Me_5)Ru(*ata*)PPh_3]$^+$	310 (0.29) 425

while the low energy absorption band in the visible region is assigned to metal-to-ligand charge transfer (MLCT) (t_{2g}–π^*). Electronic Spectra of these complexes are presented in Fig. 3.

5. Conclusions

In summary, in this work ligand *ata* reacted with series of arene and cyclopentadienyl ruthenium, rhodium and iridium complexes giving novel series of mononuclear complexes [**1**]PF_6 to [**8**] PF_6 in good yield, which are remarkably stable in air as well as in solution. In all these complexes, the metal is bonded with the major coordinated sites N1 and N2 and not with the other possible coordinated sites N1 and S1, where as our effort to make binuclear complexes by using other binding sites, i.e., N3 and N4 or N3 and S2 was not fruitful.

ABSTRACT

In 10% (v/v) $CH_3CN–H_2O$ media, the parent complex $[Ru(bpy)_2(sqphen)]^+$ (***I***$^+$) coexists with its conjugate acid $[Ru(bpy)_2(sqphenH)]^{2+}$ (HI^{2+}): $HI^{2+} \rightleftharpoons H^+ + I^+$; (deprotonation constant, $K_a^{ox} = 0.01$; (bpy = 2,2′-bipyridine; sqphen = 5,6-dioxolene-1,10-phenanthroline-O,O). Electrochemical reduction, and also chemical reductions with quinol and ascorbic acid, produced the corresponding catechol complex $[Ru(bpy)_2(catphen)]$ ($\boldsymbol{I}_R$), which also in solution coexists with its conjugate acid, $[Ru(bpy)_2(catphenH)]^+$ (HI_R^+) (deprotonation constant, $K_a^{red} = 0.002$). Progressive increase in [ascorbic acid] led to rate saturation, indicating adduct formation (formation constant, $Q = 990 \pm 80\ M^{-1}$). Added H^+, and also redox-innocent Lewis acid Zn^{2+}, increased $E_{1/2}$ but decreased the chemical reduction rates. Only an insignificant solvent isotope effect (k_{H_2O}/k_{D_2O}) was noted. An increased percentage of CH_3CN in the solvent also retards the rate. $[Ru(bpy)_2(sqphen)]^+$ (***I***$^+$) reacts at a much slower rate than $[Ru(bpy)_2sq]^+$ (sq = the unsubstituted semiquinone). Phen in the substituted ligand sqphen is known to become a much weaker base (sqphen < phen); O,O-coordination to the $Ru^{II}(bpy)$ center further lowers the basicity of sqphen. Catphen (O,O) in $\boldsymbol{I}_R$, produced on reduction of ***I***$^+$, is a stronger base than the O,O-coordinated sqphen in ***I***$^+$.

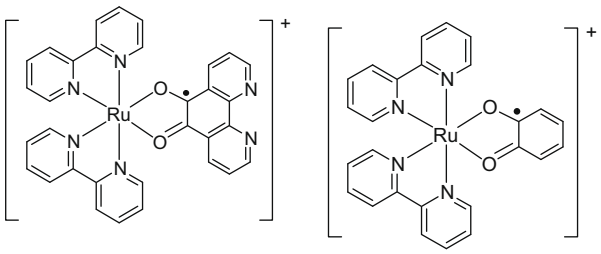
1. Introduction

Transition metal complexes with organic radicals are receiving much current attention [1–5] because of their presence in the active sites of metalloproteins [3,4]. The best understood example is galactose oxidase which features a single Cu(II) ion coordinated to a modified tyrosyl-radical [1,2]. It is only due to this intricate bonding situation that the enzyme can perform the specific two-electron oxidation of alcohols to aldehydes. Metal complexes of dioxolenes and derivatives form another interesting group of metallo-radical complexes [6,7], often implicated in biology. Three randomly selected examples are: (a) Cr complexes of catecholamines [8], (b) V complexes with catechol-like ligands [9]; and (c) the group comprising of ubiquinone, semi-ubiquinone, menaquinone and their metal complexes [10–12].

In recent years, a large number of dioxolene complexes have been synthesized and subjected to detailed physicochemical studies [13–35] to understand the role of the metal centers and also to see the effect(s), if any, of structural modifications on such ligands. However, kinetic and mechanistic studies with metallo-radical complexes are scant. Consequently, many important mechanistic issues have not been addressed [36]. This is especially true with metal–dioxolenes.

In this backdrop, we report here the kinetics and mechanism of the reduction of the radical ligand sqphen in $[Ru(bpy)_2(sqphen)]^+$ (***I***$^+$, sqphen is 5,6-dioxolene-1,10-phenanthroline-O,O) with ascorbic acid and quinol to the corresponding catechol in $[Ru(bpy)_2(catphen)]$ ($\boldsymbol{I}_R$). We also have included some of our results on the same reaction induced electrochemically. This work enables a comparison of the reactivity of coordinated sqphen in ***I***$^+$ with that of semiquinone (sq) in $[Ru(bpy)_2(sq)]^+$ (Fig. 1), studied earlier [37].

We believe that the present work should lead to a better understanding of the effect(s), if any, structural modifications on the ligand might have, and should also shed some light on the possible role of the metal ion in modifying the physicochemical properties of the ligand.



2. Experimental

2.1. Materials

The hexafluorophosphate salt $[Ru(bpy)_2(sqphen)](PF_6)$, (bpy = 2,2′-bipyridine) was prepared as reported [38] (yield: 55%). *Anal.*

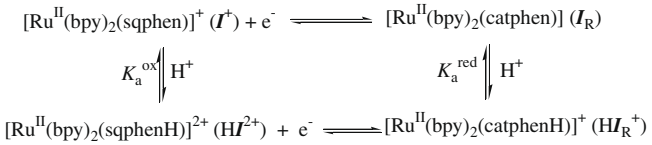
$[Ru(bpy)_2(sqphen)]^+$ ($\boldsymbol{I}^+$) $[Ru(bpy)_2(sq)]^+$

Fig. 1. Schematic drawing of the structures of $[Ru(bpy)_2(sqphen)]^+$ ($\boldsymbol{I}^+$) and $[Ru(bpy)_2(sq)]^+$.

Calc. for $RuC_{32}H_{22}N_6O_2PF_6$: C, 50.0; H, 2.86; N, 10.94. Found: C, 49.7; H, 3.0; N, 10.7%. FAB MS: *m/z* 768 (M^+, ~2%), 623 (M^+–PF_6, ~10%). IR (KBr, cm^{-1}): 1612, 1590 (C=C, C=N), 1448 (semiquinone stretching), 837 (PF_6^-). L-Ascorbic acid (G.R., E. Merck) was used as received. Care was taken to prevent oxidation and photodegradation of the L-Ascorbic acid by storing it in the dark when not in use. 1,4-Dihydroxybenzene (quinol, A.R., B.D.H) was crystallized from acetonitrile (25 g in 30 mL) under nitrogen, dried under vacuum, and stored at 0 °C [39]. Acetonitrile (G.R., E. Merck), used as a co-solvent, was purified by shaking with dilute aqueous sodium hydroxide, followed by washing successively with water, dilute acid and water. Water was removed partially by drying with sodium sulfate. This partially dried solvent was stirred with a small amount of P_2O_5. The solvent was decanted from the solid and fractionally distilled at atmospheric pressure (b.p. 81–82 °C). About one fifth of the acetonitrile was left in the distilling flask at the end of the distillation. The whole operation was carried out in an efficient fume cupboard.

2.2. Stoichiometry measurements



Spectrophotometric titration of the Ru^{II}-complex (0.10 mM) was conducted in 0.05 M $HClO_4$ for ascorbic acid and at pH 5.2 for quinol in 10% (v/v) CH_3CN–H_2O mixture; the ratio, T_C:T_R = was varied in the range 5:1–1:5 [T_C and T_R symbolize the total analytical concentration of the Ru^{II}-complex and the reducing agent, *R* respectively; *R* = H_2A for ascorbic acid and *R* = H_2Q for quinol].

2.3. Physical measurements and kinetics

Microanalyses (C, H, N) were performed using a Perkin–Elmer 4100 elemental analyzer. Electrochemical experiments were performed on a CH-660A (USA) electrochemical instrument using a conventional three-electrode cell assembly comprising saturated Ag/AgCl as the reference electrode and platinum as the working electrode. Ferrocene (Fc) was added at the end of each experiment as an internal standard. For all measurements, the Fc/Fc^+-couple appeared at 0.41 V (*versus* Ag/AgCl).

All solutions were prepared in doubly distilled, freshly boiled water. Kinetics were determined at 25.0 °C and at ionic strength *I* = 0.10 M, maintained with KCl in 10% (v/v) CH_3CN–H_2O media. The salt, $\boldsymbol{I}[PF_6]$ is sparingly soluble in water but dissolves in CH_3CN. Its initial dissolution in a few drops of CH_3CN followed by the addition of the necessary volume of H_2O provides an easy way to dissolve $\boldsymbol{I}[PF_6]$ in 10% (v/v) CH_3CN–H_2O media, as used in the kinetic studies.

Reactions with either ascorbic acid or quinol bleach the NIR absorption band of $\boldsymbol{I}^+$. Kinetics were monitored *in situ* in a thermostatted cell housing (CPS-240A) of a Shimadzu UV1601PC spectrophotometer, following the decrease in the absorbance for the peak (978 nm) of this band under first-order conditions ($T_R \gg T_C$).

Scheme 1. Various Ru(II)–dioxolene complexes coexisting in pH-dependent redox equilibria.

Reaction solutions were deaerated with argon gas prior to kinetic measurements.

3. Results and discussion

3.1. Protic equilibria

In 10% (v/v) CH_3CN–H_2O media and at pH 5.23, $\boldsymbol{I}^+$ exhibits a broad shoulder at ~610 nm (see Supplementary data, Fig. S1), at pH 5.23. A decrease in the media pH reversibly red shifts the shoulder to a lower energy and the changes were found to be reversible. The changes plausibly reflect the reversible protonation of the coordinated sqphen. The shoulder in question arises from an intra-ligand $\pi \rightarrow \pi^*$ charge transfer from bpy to sqphen [40]. Protonation stabilizes (lowers) the π^*-based LUMO of sqphen. Naturally, the shoulder arising out of a $\pi \rightarrow \pi^*$ charge transfer shifts to lower energy (see Supplementary data, Fig. S1). Acidification thus also eases electron addition to sqphen and turns $E_{1/2}$ for the sqphen/catphen couple in $\boldsymbol{I}^+$ more positive [38]. Addition of a redox-innocent Lewis acid, also shifts $E_{1/2}$ to a more positive potential. For example, $E_{1/2}$ increased from −0.285 V to −0.257 V (*versus* Fc^+/Fc couple) at pH 7 in the presence of 0.0032 M $Zn(ClO_4)_2$ (see Supplementary data, Fig. S2).

We employ the square scheme shown above to simulate the pH-dependent redox behavior (see Supplementary data, Fig. S2) of the complex (Scheme 1).

The scheme leads [40] to Eq. (1) (see Supplementary data)

$$E_{1/2} = E_0 - 0.059 \log\{(K_a^{ox} + [H^+])/(K_a^{red} + [H^+])\} \quad (1)$$

where K_a^{ox} and K_a^{red} are the acid dissociation constants for $H\boldsymbol{I}^{2+}$ and $H\boldsymbol{I}_R^+$ respectively.

The best-fit (Fig. 2, *r* = 0.98) of the $E_{1/2}$ *versus* $[H^+]$ data (see Supplementary data, Fig. S2) to Eq. (1) yielded K_a^{ox} = 0.01, K_a^{red} = 0.002 and a slope (=0.055) close to the theoretically expected value (0.059) for a one-electron transfer process. The sequence of deprotonation constants, $K_a^{ox} > K_a^{red}$, is expected because the reduced ligand (catphen in $\boldsymbol{I}_R$) bears a higher electron density and should deprotonate less readily. When compared with some analogous species, the order of protonation constants turns out to be: phen (9×10^4) [41] > sqphen (1.9×10^2) [42]; catphen in $\boldsymbol{I}_R$ (500) > sqphen in $\boldsymbol{I}^+$ (100).[1] Three aspects of this sequence seem important: (a) substitution of phen with sq makes phen a weaker base, (b) coordinated (O,O) sqphen is a weaker base than free sqphen, and (c) coordinated (O,O) sqphen is a weaker base than coordinated (O,O) catphen. These results indicate good electronic communication among the parts Ru^{II}, phen and sq of $\boldsymbol{I}^+$.

3.2. The reaction products

Addition of excess ascorbic acid (H_2A) or quinol (hydroquinone or 1,4-dihydroxybenzene, H_2Q) selectively bleaches the NIR band in $\boldsymbol{I}^+$. Selective bleaching of this MLCT band ($d_{Ru(II)} \rightarrow \pi^*_{sqphen}$) [38] strongly indicates selective reduction of the sqphen radical.

[1] For the best fit of the $E_{1/2}$ versus $[H^+]$ data, it requires $K_a^{ox} = 1.0 \times 10^{-2}$ M and $K_a^{red} = 2.0 \times 10^{-3}$ M whence $(K_a^{ox})^{-1}$ and $(K_a^{ox})^{-1}$ are, respectively, 100 M^{-1} and 500 M^{-1}.

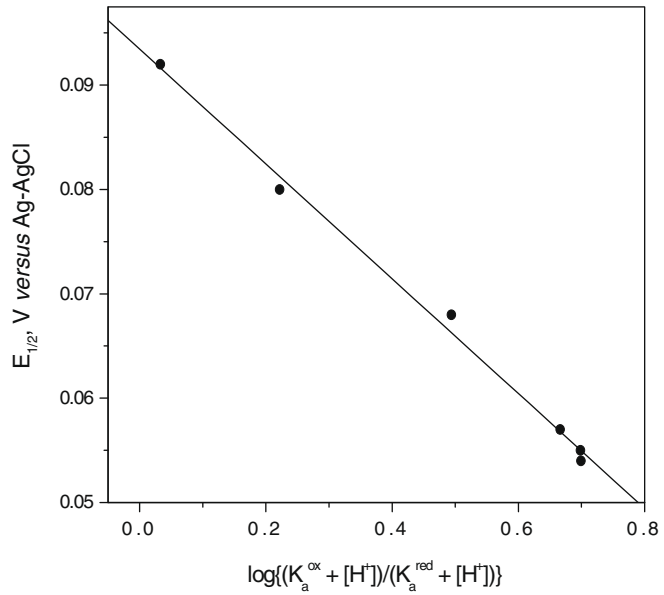


Fig. 2. $E_{1/2}$ vs. [H$^+$] data (black points) fitted to Eq. (1). The solid line presents the best-fit.

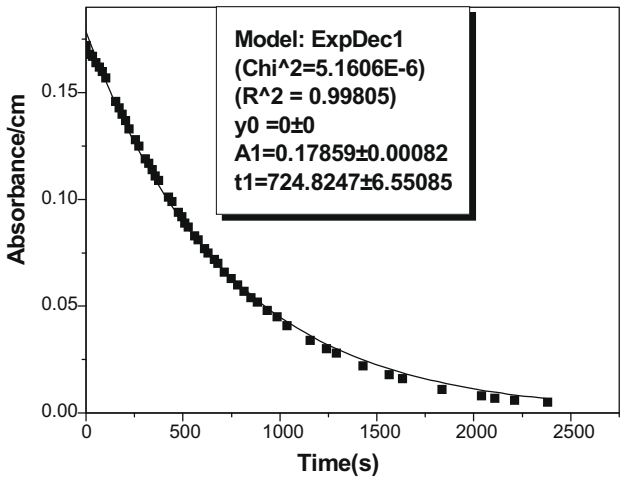

Fig. 3. A typical fit (solid curve) of absorbance vs. time data (black squares) to Eq. (3) for the ascorbate reaction in 10% (v/v) CH_3CN–H_2O media. T_C = 0.10 mM, T_{H2A} = 4.0 mM, I = 0.1 M, T = 25.0 °C.

Bleaching of this MLCT band leads to reduction of [Ru(bpy)$_2$(sqphen)]$^+$ ($\boldsymbol{I}^+$) to [Ru(bpy)$_2$(catphen)] ($\boldsymbol{I}_R$) and [Ru(bpy)$_2$(sqphenH)]$^{2+}$ (H$\boldsymbol{I}^{2+}$) to [Ru(bpy)$_2$(catphenH)]$^+$ (H$\boldsymbol{I}_R^+$). This is well-established in the literature [43–46].

Again, spectrophotometric titration curves (absorbance *versus* T_R) for both ascorbic acid and quinol yielded a break point at T_C:T_R = 2:1, indicating ascorbic acid and quinol are quantitatively oxidized respectively to dehydroascorbic acid and 1,4-benzoquinone (T_R and T_C being the analytical concentrations of the reducing agents and $\boldsymbol{I}^+$ respectively). One-electron reduction of $\boldsymbol{I}^+$ produces $\boldsymbol{I}_R$; but ascorbic acid is a two-electron donor. Therefore, the immediate product of the first act of electron transfer should be the radical species $H_2A^{\cdot+}$ or $A^{\cdot-}$. We anticipate that in the next step the ascorbate radical rapidly reduces another molecule of $\boldsymbol{I}^+$, leading to the final products – dehydroascorbic acid along with another molecule of $\boldsymbol{I}_R$. We studied the reactions of ascorbic acid in the range [H$^+$] = 0.01 – 0.10 M, where H$\boldsymbol{I}_R^+$ (pK_a^{red} = 2.7) is nearly exclusive in the final products (Eq. (2A)). In contrast, the products of the reactions with quinol in the pH range 5.40–7.22 ($\boldsymbol{I}_R$ formed exclusively), are two moles of $\boldsymbol{I}_R$ and one mole quinone (Eq. (2B)).

$$2I^+ + H_2A \rightarrow 2HI_R^+ + A \quad (2A)$$

$$2I^+ + H_2Q \rightarrow 2I_R + 2H^+ + Q \quad (2B)$$

3.3. Kinetics

All the reactions, under the experimental conditions, obeyed first-order kinetics (Eq. (3)), where the factor 2 at the right hand side appears due to the stoichiometry of the reactions

$$A_t = A_\infty + (A_0 - A_\infty)\exp(-2k_0t) \quad (3)$$

The absorbance (A_t)–time (t) data for more than four half-lives in each set of kinetics yielded an excellent fit to Eq. (3) (Fig. 3), whence the first-order rate constants (k_o) were evaluated. Tables 1 and 2 display some representative k_o values for the quinol and ascorbic acid reactions, extracted through such a fitting. Added H$^+$, and also Zn^{2+}, increases $E_{1/2}$ for the one-electron, reversible sqphen/catphen couple in $\boldsymbol{I}^+$ but retards its reduction with ascorbic acid and quinol (Tables 1 and 2). This observation is strong evidence against a pure outer-sphere reduction.

Table 1
Some representative first-order rate constants[a] (k_o) for the oxidation of quinol by $\boldsymbol{I}^+$.

pH	10^3 T_{H2Q} (M)	$10^4 k_0$ (s^{-1})
5.80	100	10.3
6.46	100	12.2
6.76	100	14.3
7.06	100	23.5
7.22	100	41.5

5.80	180	13.9
5.80	250	18.2
5.80	300	23.0
5.40	100	12.6[b1]
5.40	100	13.8[b2]

[a] 10% (v/v) CH_3CN–H_2O mixed media, ionic strength I = 0.10 M (KCl), T = 25.0 °C, [$\boldsymbol{I}^+$] = 0.10 mM.
[b1] In 50% D_2O.
[b2] In 89% D_2O.

3.4. Effect of D_2O on rate

Substitution of up to 89 mol% of D_2O for the solvent H_2O had only modest and opposite effects on the reaction rates for quinol (k_{H_2O}/k_{D_2O} = 1/1.34) and ascorbic acid (k_{H_2O}/k_{D_2O} = 1.38) [47]. Such small kinetic isotope effects are normally expected for simple electron transfer reactions [48]. Much more dramatic effects are usually observed when the electron transfer is coupled with the movement of a proton in equilibrium with solvent protons [36,49–51].

3.5. Effect of pH on rate

3.5.1. Reactions with quinol (H_2Q)

The observed first-order rate constants, k_o, for quinol oxidation were determined in the brief pH range 5.40–7.22; these reactions are is too slow below pH 5, but are too fast above pH 7.5. In the experimental pH range 5.40–7.22, $\boldsymbol{I}^+$ exclusively dominates over H$\boldsymbol{I}^{2+}$ (pK_a^{red} = 2.7), yet, k_o exhibits an inverse proton dependence (Fig. 4). Evidently, the inverse proton dependence arises from the rapid H_2Q/HQ^- equilibrium (Eq. (4); pK_a = 9.96) [52,53] and the expected greater kinetic activity of the conjugate base, HQ^- over the parent acid

Table 2
Some representative first-order rate constants[a] (k_0) for the oxidation of ascorbic acid by I^+.

pH	$10^3\ T_{H2A}$ (M)	$10^4 k_0$ (s^{-1})
2.00	1.0	4.0
2.00	2.0	4.6
2.00	3.0	6.3
2.00	4.0	6.7
2.01	4.0	5.5[b1]

1.40	4.0	5.8
1.30	4.0	5.7
1.22	4.0	4.7
1.15	4.0	4.0
1.00	4.0	2.4
1.52	4.0	5.3[c1]
1.52	4.0	4.9[c2]
1.52	4.0	4.1[c3]
1.52	4.0	2.8[d1]
1.52	4.0	2.3[d2]
1.52	4.0	1.8[d3]

[c(1–3)] In the presence of $[Zn^{2+}] = 0.005$, 0.01 and 0.20 M, respectively.
[d(1–3)] In presence of 20%, 30% and 40% (v/v) CH_3CN–H_2O, respectively.
[a] Unless stated otherwise, the reactions are carried out in 10% (v/v) CH_3CN–H_2O mixed media, ionic strength $I = 0.10$ M (KCl), $T = 25.0$ °C, $[I^+] = 0.10$ mM.
[b1] In 50% D_2O.
[b2] In 89% D_2O, in b1 and b2, pH meter readings were 1.61. Reported pH is pD = pH + 0.4.

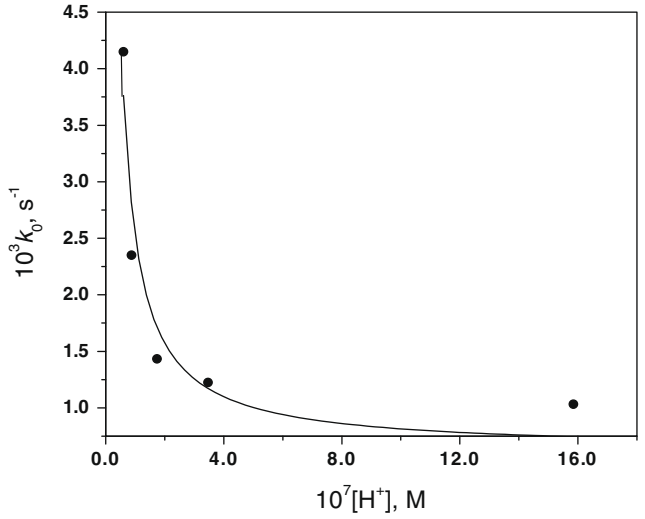

Fig. 4. Experimental k_o (solid circles) for the quinol redox fitted (smooth curve) to Eq. (7). $T_C = 0.10$ mM, $T_{H2Q} = 0.10$ M, $I = 0.1$ M, $T = 25.0$ °C, 10% (v/v) CH_3CN–H_2O media.

$$H_2Q \rightleftharpoons H^+ + HQ^-; \quad pK_a = 9.96 \tag{4}$$
$$I^+ + H_2Q \rightarrow \text{Products}; \quad k_1 \tag{5}$$
$$I^+ + HQ^- \rightarrow \text{Products}; \quad k_2 \tag{6}$$

Eq. (7) was derived from on Eqs. (4)–(6).

$$K_0 = (k_1[H^+] + k_2K_a)T_{H_2Q}/(K_a + [H^+]) \tag{7}$$

The observed first-order rate constants, k_o yielded an agreeable fit (Fig. 4) to Eq. (7). T_{H2Q} represents the total concentration of quinol. The best-fit of k_o to Eq. (7) yielded $k_1 = (6 \pm 2) \times 10^{-3}\ M^{-1}\ s^{-1}$ and $k_2 = (17 \pm 5)\ M^{-1}\ s^{-1}$, which shows that kinetically HQ^- is much more reactive than H_2Q.

3.5.2. Reaction with ascorbic acid (H_2A)

The kinetics of the reaction with ascorbic acid is measurable by the conventional technique only in acidic solutions where each of the four species, HI^{2+}, I^+, H_2A and HA^- might be kinetically significant. The following reaction scheme, Eqs. (8)–(13), is therefore drawn:

$$HI^{2+} \rightleftharpoons H^+ + I^+; \quad K_a^{ox} \tag{8}$$
$$H_2A \rightleftharpoons H^+ + HA^-; \quad K'_a \tag{9}$$
$$HI^{2+} + H_2A \rightarrow P; \quad k_1 \tag{10}$$
$$HI^{2+} + HA^- \rightarrow P; \quad k_2 \tag{11}$$
$$I^+ + H_2A \rightarrow P; \quad k_3 \tag{12}$$
$$I^+ + A^- \rightarrow P; \quad k_4 \tag{13}$$

Under the experimental conditions, $\{K'_a \ll [H^+]\ (0.01–0.10\ M)\}$, the scheme leads to Eq. (14) where T_{H2A} defines the total concentration of ascorbic acid.

$$k_o(K_a^{ox} + [H^+])\ [H^+] = \{k_1[H^+]^2 + (k_2K'_a + k_3K_a^{ox})[H^+] + k_4K'_aK_a^{ox}\}T_{H_2A} \tag{14}$$

A plot of the left hand side of Eq. (14) against $[H^+]$ (Fig. 5) yielded a fair straight line ($r > 0.97$) with finite slope = $(2.95 \pm 0.3) \times 10^{-5}\ M^{-1}\ s^{-1}$ $[= k_2K'_a + k_3K_a^{ox}) \cdot T_{H_2A}]$, but statistically insignificant intercept. The acid variation experiments therefore demonstrate the insignificance of the k_1 and k_4 paths and that only k_3 and/or k_2 path(s) is (are) contributing to the overall rate. Due to the proton ambiguity, individual contributions from the k_2 and k_3 paths cannot be evaluated. Nevertheless, not the conjugate acid form of an oxidant, but the conjugate base of the reductant is generally the better oxidant [54–57] and in many examples, HA^- has much greater kinetic activity over its parent acid H_2A. Therefore, the k_2 path ($HI^{2+} + HA^-$) should contribute more than the k_3 path ($I^+ + H_2A$). Moreover, as we see that the k_1 path ($HI^{2+} + H_2A$) has no contribution, it is expected that the k_3 path ($I^+ + H_2A$) also would not be operative as I^+ is expected to be less oxidizing than HI^{2+}. Using the literature data for $pK'_a = 4.03$ [58], and assuming no significant contribution from k_3, we estimated a value of 79 $M^{-1}\ s^{-1}$ as the upper limit for k_2.

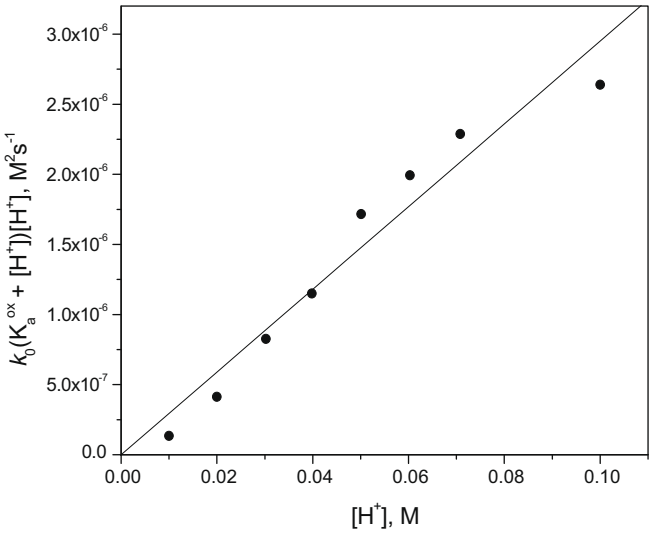

Fig. 5. Graphical verification of Eq. (14) and that the k_1 and k_4 paths contribute negligibly ($T_{H2A} = 4.0$ mM).

3.6. Effect of T_{H2A} and T_{H2Q} on k_o

A progressive increase in T_{H2A} tends to saturate k_o and the kinetics is not so simple as observed for quinol where no indication of rate saturation was observed, even at the highest [quinol] studied (Table 2). A double reciprocal plot between $1/k_o$ and $1/T_{H2A}$ was found to be fairly linear ($r = 0.978$), indicating a rapid adduct formation equilibrium with the formation constant $Q = 990 \pm 80\ M^{-1}$ prior to the rate step (Eq. (15)).

$$HI^{2+} + \text{Ascorbic acid} \overset{Q}{\rightleftharpoons} \text{Intermediate adduct} \overset{k}{\rightarrow} \text{products} \quad (15)$$

This Q value appears to be too large for a simple outer-sphere interaction [59] and suggests some kind of specific bonding, not mere electrostriction. Hydrogen-bonding with the two adjacent oxygen atoms from ascorbic acid (see Supplementary data Fig. S3) seems a distinct possibly [60–62].

The ascorbate anion is also notable for its unusually high rate of complex formation [63]. The high formation constant (Q) observed here may also be a consequence of a high formation rate, but relatively small dissociation rate for the adduct formed. Rate saturation was absent in the reactions with quinol; k_o increased linearly up to the maximum T_{H2Q} (0.30 M) studied.

3.7. Effect of solvent composition

λ_{max} for the $d_{Ru(II)} \rightarrow \pi^*_{sqphen}$ (SOMO) band (at the NIR) [38,64] of $\boldsymbol{I}^+$ blue- shifts from 978 nm to 930 nm on changing the solvent from 10% (v/v) CH_3CN–H_2O to neat acetonitrile. Presumably, the reduced solvent polarity (increased proportion of less polar CH_3CN in CH_3CN–H_2O mixture) destabilizes the singly occupied MO of the semiquinone and decreases the electron acceptance by this moiety. In agreement with this presumption, k_o for ascorbic acid decreased with an increased percentage of CH_3CN (20–40%; v/v) in the mixed CH_3CN–H_2O solvent (Table 2, d^{1-3}). However, decreased solvent polarity is also expected [65] to decrease K'_a and hence $[HA^-]$ (Eq. (9)). Such a decrease in the concentration of the more active form of the reductant may singly or additionally be a cause for the decreased k_o.

4. Conclusions

The protonated radical ligand, $sqphenH^+$ in $[Ru(bipy)_2(sqphen)]^+$ ($H\boldsymbol{I}^{2+}$) ($pK_a^{ox} = 2.0$) is a stronger acid than the one-electron reduced ligand $catphenH^+$ in $[Ru(bipy)_2(catphenH)]^+$ ($H\boldsymbol{I}_R^+$) ($pK_a^{red} = 2.7$). $E_{1/2}$ for the sqphen/catphen reduction couple increases on addition of H^+, and also Zn^{2+}, but either, when added, slow down the rate of the chemical reduction with ascorbic acid. A simple outer-sphere reaction is discarded as a possibility. Reductions with ascorbic acid redox indeed demonstrate an intermediate adduct formation. The solvent isotope effect is negligible and the electron transfer seems to proceed without proton movement at the rate-determining step. Sqphen in $[Ru(bipy)_2(sqphen)]^+$ is reduced at a rate much slower compared to the reduction of unsubstituted sq (semiquinone) in $[Ru(bipy)_2(sq)]^+$. This is plausibly because substitution with phen stabilizes sq through electron drainage from phen to sq via extended conjugation, and renders reduction difficult. Again, this same extended conjugation renders phen of sqphen less basic than phen itself. The sequence of basicity is: phen (9×10^4) [41] > sqphen (1.9×10^2) [42]; catphen in $\boldsymbol{I}_R$ $(500)^1$ > sqphen in $\boldsymbol{I}^+$ $(100)^1$ and shows that: (a) substitution of phen with sq makes phen a weaker base, (b) O,O-coordinated sqphen is a weaker base than free sqphen, and (c) coordinated (O,O) sqphen is a weaker base than coordinated (O,O) catphen. These results indicate good electronic communication among the parts Ru^{II}, phen and sq of $\boldsymbol{I}^+$.

ABSTRACT

This paper presents examples of mixed-ligand Co(II), Cu(II), Ni(II) and Mn(II) complexes, with a distorted octahedral coordination geometry, with 2,2′-dipyridyl or 1,10-phenanthroline and phosphortriamide ligands. The complexes of the general type $ML_2{\cdot}Lig$ (where M = Co(II), Cu(II), Ni(II), Mn(II); $L^- = \{Cl_3C(O)NP(O)R_2\}^-$ (R = NHBz, $NHCH_2CHCH_2$, NEt_2); Lig = 2,2′-dipyridyl or 1,10-phenanthroline) were synthesised and characterised by means of X-ray diffraction, IR and UV–Vis spectroscopy. The phosphortriamide ligands are coordinated *via* oxygen atoms of phosphoryl and carbonyl groups involved in six-membered metal cycles. The additional ligands 2,2′-dipyridyl or 1,10-phenanthroline are coordinated to the central atom, forming five-membered cycles.

1. Introduction

There has been significant growth in the field of coordination chemistry of carbacylamidophosphates over the last ten years. The main research interest concerns urea phosphate derivates of the type $[R^1_2NC(E)NHP(E)R^2_2]$ (E = O, S, Se; $R^1 = CCl_3$, Ar, $R^2 = CH_3$, Ar, C_2H_5), which have been studied as potential chelates to a range of late transition metals through both phosphorous and chalcogen donor atoms [1–3]. On the other hand, carbacylamidophosphates containing the structural frame [C(O)NHP(O)] of the above compounds have been known for a considerable time [4]. There has recently been a resurgence of interest in their coordination chemistry as a consequence of the steric control that this ligand system may impart compared to, for example, β-diketonates [5]. The especially interesting feature of carbacylamidophosphate ligands is the bidentate or μ^2-bidentate chelate character of their coordination to the central atom [6,7]. Carbacylamidophosphate complexes with the common formula $M(L)_2$ are neutral species with an unsaturated coordination sphere of metal ions that readily coordinate additional bidentate chelate donor groups like 2,2′-dipyridyl or 1,10-phenanthroline [8–10].

Investigations in this field are still actively in progress today. Thus, [11] reports the first example of a mixed-ligand Mn(II) complex $[Mn(acac)_2(bpy)]$ with a trigonal-prismatic coordination geometry with simple, bidentate ligands. Based on the very small energy differences for the calculated trigonal-prismatic and octahedral structures, it has been concluded that crystal packing effects must contribute significantly in determining the trigonal-prismatic structure of $[Mn(acac)_2(bpy)]$, even though our investigations confirm the common tendency to form a distorted octahedral coordination geometry for heteroligand Mn(II) and Co(II) complexes with the 2,2′-dipyridyl or 1,10-phenanthroline and phosphortriamidic ligands.

In this paper, we report the synthesis and study of heteroligand complexes of Co(II), Cu(II), Ni(II) and Mn(II) obtained from 2,2′-dipyridyl or 1,10-phenanthroline and the phosphortriamidic ligands N,N′-tetraethyl-N″-trichloracetylphosphorictriamide (R = $N(C_2H_5)_2$) [HL^1], N,N′-diallyl-N″-trichloracetylphosphorictriamide (R = $NHCH_2CHCH_2$) [HL^2] and N,N′-dibenzylamidol-N″-trichloracetylphosphorictriamide (R = NHBz) [HL^3].

2. Experimental

2.1. Synthesis

All chemicals were commercial products of reagent grade, used without further purification.

2.1.1. $H(L^1)$

N,N′-tetraethyl-N″-trichloroacetylphosphortriamide $H(L^1)$ was prepared by [12].

2.1.2. $H(L^2)$, $H(L^3)$

The syntheses of N,N′-diallyl-N″-trichloroacetylphosphorylamide $H(L^2)$ and N,N′-dibenzyl-N″-trichloroacetylphosphorylamide $H(L^3)$ were carried out according to the following general scheme:

$$CCl_3C(O)NHP(O)Cl_2 + 5H_2NR \rightarrow CCl_3C(O)NHP(O)(NHR)_2 \cdot RNH_2 + 2H_3NRCl,$$

$$R = CH_2CHCH_2, CH_2Ph.$$

The solution of the corresponding amine (250 mmol) in 30 ml of dry chloroform was placed into a four-neck round-bottomed flask (0.5 l) equipped with a condenser, mechanical stirrer, dropping funnel and thermometer, and it was then cooled to 0 °C. The dichloride of trichloroacetylamidophosphoric acid [13] 14.9 g (50 mmol) was dissolved in 150 ml of chloroform and slowly added to the previous amine solution, while stirring, over about 20 min. (The internal temperature was not allowed to rise above 5 °C). The stirring was continued for about 40 min. The resulting mixture, containing the ligand, $2H_3NRCl$ and excess of amine, was filtered off, the mother liquor was evaporated and the residue was treated with 100 ml of aqueous HCl (10%). The crude product, precipitated as a crude brown crystalline powder, was collected by filtration and recrystallised from aqueous 2-propanol (90% yield). The compounds were air stable, soluble in alcohols and hot acetone, and insoluble in non-polar aprotic solvents and water. M.p. (HL^2) = 85–87 °C. M.p. (HL^3) = 144–146 °C.

The sodium salts $[Na(L^1)]$, $[Na(L^2)]$ and $[Na(L^3)]$ were obtained from methanol solutions by treatment of the ligands with an equimolar ratio of sodium methoxide. All the salts were white fine-grained substances, soluble in alcohols and acetone, and insoluble in non-polar aprotic organic solvents.

2.1.3. $[Co(L^1)_2$·Phen$]$

A solution of $[NaL^1]$ (2 mmol) in methanol (10 ml) was added to a solution of hydrated cobalt (II) chloride or nitrate (1 mmol) in methanol (15 ml). The solution was then quenched with 30 ml of a 2-propanol solution of 1,10-phenanthroline 0.18 g (1 mmol), stirred under heating, and cooled, and the formed sodium chloride or nitrate was filtered off. After a while, orange crystals precipitated from the bleached solution. They were filtered, washed with cool

2-propanol, and dried over $CaCl_2$ (yield 0.73 g (77%)). Single crystals of $[Co(L^1)_2$·Phen] were prepared by slow crystallization from 2-propanol–methanol (5:1) mixture. The complex as prepared is soluble in non-polar aprotic solvents, and is less soluble in acetone and cooled alcohols.

2.1.4. $[M(L^2)_2$·Phen] (M = Co; Mn; Ni) and $[M(L^2)_2$·Phen] (M = Co; Mn; Cu)

All of the complexes mentioned above were obtained according to the general procedures described previously, using the respective metals and sodium salts of the ligands (average yield 70–90%).

$[M(L^3)_2$·Phen] (M = Co; Cu) and $[Co(L^3)_2$·Dipy$]\cdot CH_3OH$. These complexes were obtained in the same manner as the complexes based on HL^2.

The compositions of the compounds obtained were proposed based on C, H, N analysis (Table 1).

2.2. Methods

2.2.1. UV–Vis spectroscopy, IR-spectroscopy

The IR spectra of the compounds were recorded on an UR-10 spectrometer in the range 400–4000 cm^{-1} (samples as KBr pellets). Electronic diffuse reflectance spectra were recorded on a SPECORD M-40 (Carl Zeiss, Jena) UV–Vis spectrometer. UV–Vis absorption spectra were measured at room temperature in absolute acetonitrile on a KSVU-23 "LOMO" spectrometer.

2.2.2. Crystallography

Crystallographic data for the compounds $H(L^2)$, $Co(L^1)_2$·Phen, $Mn(L^2)_2$·Dipy and $[Co(L^3)_2\cdot Dipy]\cdot CH_3OH$ are summarised in Table 2. All the above structures were solved by direct methods and refined by the full-matrix least-squares technique with anisotropic approximations for the main non-hydrogen atoms using the SHELXS97 and SHELXL97 programs. The data of the structures were corrected for Lorentz and polarization effects. The SADABS absorption correction was applied for $Mn(L^2)_2$·Dipy and $[Co(L^3)_2\cdot Dipy]\cdot CH_3OH$ [14].

2.2.3. $[HL^2]$, $[Co(L^1)_2$·Phen]

2.2.3.1. Crystal data. All crystallographic measurements were performed at room temperature on an "Xcalibur-3" diffractometer (Mo$K\alpha$ radiation, CCD-detector, graphite monochromator, ω-scans). The data for the both structures were corrected for Lorentz and polarization effects. The semi-empirical from equivalents absorption correction was applied.

2.2.4. $[Mn(L^2)_2\cdot Dipy]$, $[Co(L^3)_2\cdot Dipy]\cdot CH_3OH$

2.2.4.1. Crystal data. All crystallographic measurements for both compounds were performed at room temperature on a Bruker Smart Apex II diffractometer operating in the ω and φ scan modes. In the structure $[Mn(L^2)_2\cdot Dipy]$ the chlorine atoms of both CCl_3 groups C12Cl1–3 and C20Cl4–6 and carbon atoms C21–23 of terminal CH_2CHCH_2 group are disordered over three positions each, with multiplicities 0.50, 0.25, 0.25; 0.55, 0.20, 0.25 and 0.30, 0.50, 0.20, respectively. The atoms N7C13–15, N8C16–18 and C25–26 of other $—NCH_2CHCH_2$ groups are disordered over two positions each, with multiplicities 0.70, 0.30; 0.70, 0.30 and 0.50, 0.50, respectively. In the structure $[Co(L^3)_2\cdot Dipy]\cdot CH_3OH$ the chlorine atoms of the $C54Cl_3$ and $C70Cl_3$ groups are disordered over two positions each, with multiplicities 0.849, 0.151 and 0.457, 0.543, respectively. Hydrogen atoms were placed at calculated positions as a "riding" model in both structures.

3. Results and discussion

3.1. IR-Spectroscopy

The spectra of all the complexes reveal significantly lower frequencies of ν(PO) than those of their sodium salts, $\Delta\nu$(PO) = 10–50 cm^{-1}, reflecting the coordination *via* the phosphoryl oxygen atom (Table 3) [4,6]. In the case of the $Co(L^2)_2$·Phen and $Ni(L^2)_2$·Phen compounds, the position of the ν(PO) absorption band can be identified ambiguously. The ν(CO) values of the complexes are

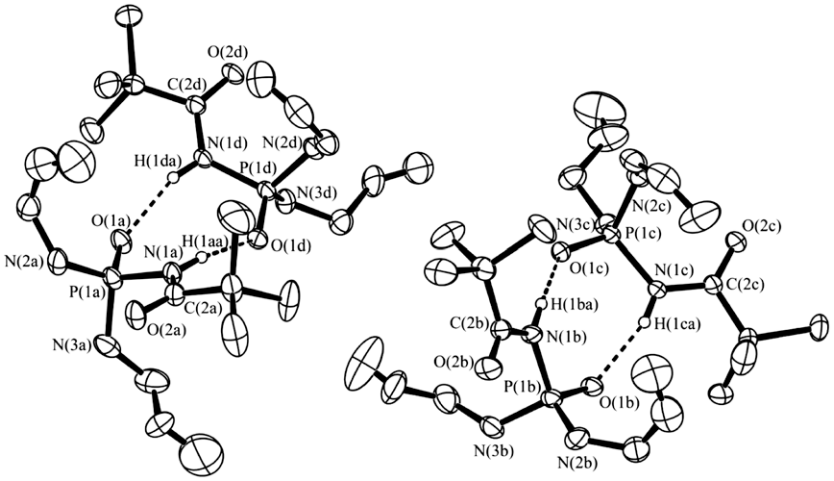

Fig. 1. Independent part of the N-(N′,N″-diallylaminophosphinyl)-trichloroacetamide (hydrogen atoms of allylamidic groups are omitted).

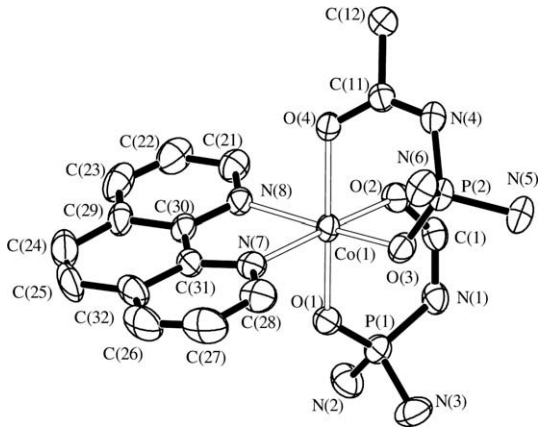

Fig. 2. Fragment of the structure of *bis*-N-(N′,N″-tetraethylaminophosphinyl)-trichloroacetamido–1,10-phenanthroline cobalt(II) (chlorine atoms, ethyl groups and protons are omitted).

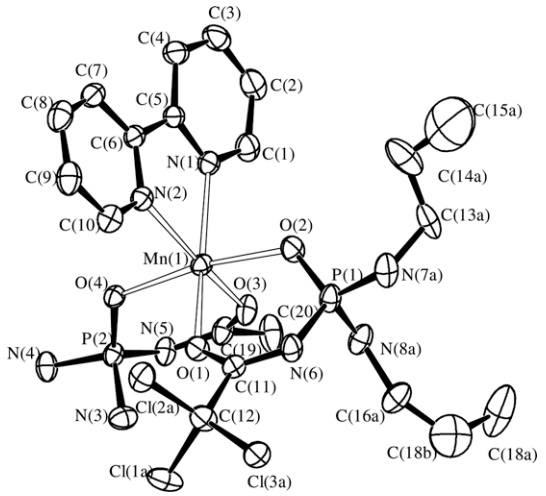

Fig. 3. Fragment of the structure of *bis*-N-(N′,N″-diallylaminophosphinyl)-trichloroacetamido-2,2′-dipyridyl manganese(II) (all protons, chlorine atoms in one molecule of ligand are omitted).

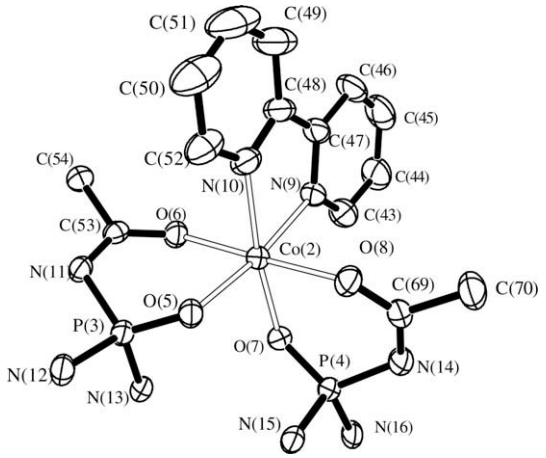

Fig. 4. Fragment of the structure of *bis*-N-(N′,N″-dibenzylaminophosphinyl)-trichloroacetamido-2,2′-dipyridyl cobalt(II) methanol solvate (chlorine atoms, benzyl groups and protons are omitted).

shifted to lower frequencies ($\Delta\nu$(CO) = 50–63 cm^{-1}). These facts can be explained by the fact that $(L^1)^-$, $(L^2)^-$ and $(L^3)^-$ display a bidentate coordination mode *via* the oxygen atoms of the phosphoryl and carbonyl groups, as in the deprotonated forms of the ligands. The absorption bands of dipyridyl and phenanthroline molecules in the IR spectra of the compounds are overlapped by the bands of the ligands or have low intensities.

3.2. UV–Vis Spectroscopy

The UV–Vis absorption spectra of the compounds $Co(L^2)_2$·Phen, $Ni(L^2)_2$·Phen, $Co(L^2)_2$·Dipy and $[Co(L^3)_2$·Dipy]·CH_3OH prove the octahedral environment of the metal atoms. Thus, in the absorption spectrum of $Co\{L\}_2$·Lig, a band corresponding to the transition $^4T_{1g}(P) \rightarrow {}^4T_{1g}$ is observed near 470 nm (for $Co(L^2)_2$·Phen – 465, 484.4 nm; for $Co(L^2)_2$·Dipy – 468, 483 nm; for $[Co(L^3)_2$·Dipy]·CH_3OH – 464, 484.4 nm) [15]. The transition $^4A_{2g} \rightarrow {}^4T_{1g}$ in the absorption spectrum of $Cu(L^3)_2$·Phen is very weak and appears as a peak near 670 nm. The transition $^3A_{2g} \rightarrow {}^3T_{1g}(^3F)$ is observed in the spectrum of the $Ni(L^2)_2$·Phen complex near 600 nm.

3.3. Description of the structures

We succeeded in confirming the conclusions about the structures of the obtained compounds (based on IR and UV–Vis spectroscopy data) by the results of full X-ray analysis of the compounds $Co(L^1)_2$·Phen, $Mn(L^2)_2$·Dipy and $[Co(L^3)_2$·Dipy]·CH_3OH. The geometry of the ligand HL^2 and the complexes, and the atom-labeling scheme are shown in Figs. 1–4. Selected bond lengths and angles are collected in Tables 4 and 5.

3.3.1. $H(L^2)$

The unique part of $H(L^2)$ consists of four molecules of ligands that are coupled into dimers by the H-bond function of the phosphoryl oxygen atoms. The hydrogen atoms of the amidic group form an eight-membered cycle (Fig. 1). The dimers are linked into polymer chains by means of hydrogen bonding with oxygen atoms of carbonyl groups and hydrogen atoms of allylamide groups. Table 4 lists the geometrical parameters of the hydrogen bonding for $H(L^2)$.

In the structure of $H(L^2)$, as in most carbacylamidophosphates [16], the carbonyl and phosphoryl groups are in *anti*-positions to each other. The phosphorus atom in the molecule of N,N′-diallyl-N″-trichloroacetylphosphortriamide has a slightly distorted tetrahedral configuration. The environment of the nitrogen atoms of the trichloroacetylamide group is practically planar. The P–N(1)

*** The unit cell consists of 4 independent molecules (the bond lengths are averaged).

distance of trichloroacetylamide (av. 1.6938 Å) is longer than the P–N distance in the allylamide group (1.6074 Å [17]).

The intramolecular distances between the carbonyl oxygen and phosphorus atoms (2.95 Å for molecule **A**, 2.96 Å for molecule **B**, 3.01 Å for molecule **C** and 3.04 Å for molecule **D**) are considerably shorter than the sum of Van der Waals radii (3.3 Å) (Fig. 1). This may be rationalised in terms of a strong attractive interaction between $P^{\delta+}$–$O^{\delta-}$. Similar contacts were found in $C_6H_5C(O)NHP(O)(OCH_3)_2$ [18] and $CCl_3C(O)NHP(O)[N(CH_2CH_2)_2O]_2$ [19], studied earlier.

3.3.2. $[Co(L^1)_2{\cdot}Phen]$, $[Mn(L^2)_2{\cdot}Dipy]$, $[Co(L^3)_2{\cdot}Dipy]{\cdot}CH_3OH$

The complexes $[Co(L^1)_2{\cdot}Phen]$, $[Mn(L^2)_2{\cdot}Dipy]$ and $[Co(L^3)_2{\cdot}Dipy]{\cdot}CH_3OH$ have a molecular structure. In all the complexes, the organic ligands are coordinated in the bidentate manner *via* oxygen atoms of phosphoryl and carbonyl groups, forming six-membered chelates (Figs. 2–4 respectively). The corresponding bond lengths M–O(P) for $[Co(L^1)_2{\cdot}Phen]$ and $[Co(L^3)_2{\cdot}Dipy]{\cdot}CH_3OH$ are in the 2.044–2.106 Å range (Table 5). The corresponding ranges of the carbonyl groups for these complexes are the longest ones, 2.094(3)–2.152(3) Å. In the case of $[Mn(L^2)_2{\cdot}Dipy]$, the similar bond lengths are rather longer 2.115(2) and 2.147(2) Å (for M–O(P)). Similarly, the M–O bond lengths for the carbonyl groups increase by an average of 0.06 Å. This fact can be explained by the stronger affinity of the phosphoryl group to metal ions than the carbonyl group.

The chelate (O)PNC(O) frames of all the phosphoryl ligands form planar six-membered rings with the central atom. A decrease in the P–N and C–N distances in the coordinated ligand compared to the free ligand (Table 5) and an increase in the P=O and C=O distances demonstrates the presence of π-conjugation in the chelate fragments.

The phosphorous atoms of the title compounds have a slightly distorted tetrahedral geometry. The maximum deviation is for the angle NPO, 114.3–115.9(5)°, which is involved in the formation of the six-membered chelate rings, whereas in the free ligands this angle is less than that in the tetrahedron and equals 105.40(9) for $H(L^1)$, 106.44° for $H(L^2)$ and 106.82(8) for $H(L^3)$ (Table 6). The carbonyl atom has a sp^2-character. The planar bidentate chelating dipyridyl and phenanthroline ligands are coordinated into

five-membered rings. The coordination polyhedra in all the above structures are distorted octahedrons.

In the structure $[Co(L^3)_2{\cdot}Dipy]{\cdot}CH_3OH$ two types of irregular hydrogen bonds occur (Fig. 5). The parameters of all the hydrogen bonds are given in Table 7.

The complex molecules Co(1) and Co(2) are complementarily connected into dimer units by hydrogen atoms of the benzylamide group and nitrogen atoms of the chelate (H(4N)···N(11) and H(12N)···N(3)). Such units are associated by singular hydrogen bonds, which form between the free chelate nitrogen atom and benzylamide protons of the next unit, such as (N(14)···H(7N)).

4. Conclusion

In this contribution it has been shown that carbacylphosphotriamidic ligands, like β-diketonates, form stable coordination compounds of the composition $ML_2{\cdot}Lig$ (where M = Co(II), Mn(II); Cu(II), Ni(II), L = $\{Cl_3C(O)NP(O)R_2\}^-$ (R = $NHCH_2Ph$, $NHCH_2CHCH_2$, NEt_2); Lig = 2,2′-dipyridyl or 1,10-phenanthroline). Stable heteroligand complexes of Co(II) and Mn(II), with a distorted octahedral coordination geometry, have been realised. In the three structures studied, the organic ligands were coordinated *via* oxygen atoms of phosphoryl and carbonyl groups, forming six-membered cycles.

On the basis of X-ray studies, it was verified that the bond length M–O(P) in all the structures discussed is shorter than the M–O(C) bond length. This confirms the fact that the phosphoryl group has a greater affinity towards metal ions as compared to the carbonyl group.

For the first time in the chemistry of carbacylamidophosphates, intermolecular H-bonds with the participation of amidic protons and the coordinated phosphoryl oxygen of a neighboring ligand in the same complex molecule have been registered.

Supplementary data

CCDC 670292, 656940, 643803 and 643802 contains the supplementary crystallographic data for HL^2, $[Co(L^1)_2{\cdot}Phen]$, $[Mn(L^2)_2{\cdot}Dipy]$ and $[Co(L^3)_2{\cdot}Dipy]{\cdot}CH_3OH$, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Cobalt(II) and nickel(II)

ABSTRACT

Four new coordination polymers of cobalt(II) and nickel(II) with functionalized dicarboxylate ligands, namely, $[Co^{II}L^1(2,2'\text{-bpy})(H_2O)]$ (**1**), $[Ni^{II}L^1(2,2'\text{-bpy})(H_2O)]\cdot H_2O$ (**2**), $[Co^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**3**) and $[Ni^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**4**), where H_2L^1 = 2,5-dibenzoylterephthalic acid, H_2L^2 = 4,6-bis(4-methylbenzoyl) isophthalic acid and 2,2′-bpy = 2,2′-bipyridine, were synthesized and characterized by elemental analysis, IR spectra and thermogravimetric analysis. Complex **1** exhibits a zigzag chain with a C–H···π interaction between the phenyl ring proton and the phenyl ring of an adjacent chains to form a 2D supramolecular sheet. Complex **2** contains two helical chains which extend into 2D via a C–H···π interaction between the pyridine ring proton and the pyridine ring. Complexes **3** and **4** are isomorphous with helical chains that extend in the same direction and further link to one another by supramolecular forces into a 2D structure. Moreover, magnetic and luminescence properties have been investigated for **1** and **2**, respectively.

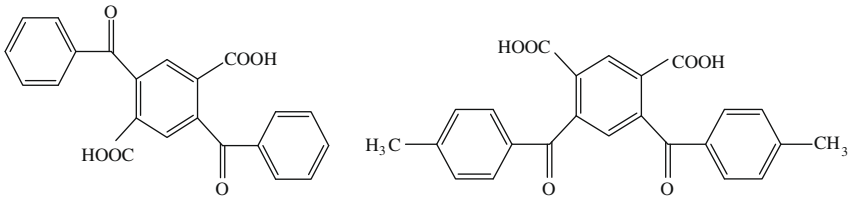
1. Introduction

The design and synthesis of metal–organic frameworks (MOFs) are continuously attractive among coordination and material chemistry, not only due to the frequently novel motifs of their architectures but also their potential applications in gas storage, chemical separations, ion exchange, non-linear optics, magnetism and heterogeneous catalysis [1–17]. A great variety of interesting architectures have been reported including helix, brick wall, honeycomb, layer, ladder, grids, boxes and herringbone [18–26], of which helical coordination polymers are particularly attractive because of their fascinating structures and applications in many fields [27–34]. Although discrete helices and low-dimensional helical coordination polymers are now abundant, the assembly of such helical units into higher order networks is still a challenge.

In an attempt to construct helical frameworks, we choose functionalized dicarboxylate ligands to give birth to new complexes. So four new coordination polymers of Co(II) and Ni(II) were obtained by using benzoyl-substituted terephthalic acid (H_2L^1) and methylbenzoyl-substituted isophthalic acid (H_2L^2) (Chart 1) as ligands. The choice of these ligands was based on the following considerations: (1) Each ligand has six oxygen atoms potentially available for metal coordination; (2) the aromatic substituent may rotate around the central phenyl ring. This flexibility may be significant in realizing interesting structures; (3) the extended π-system of the substituted ligands, which are derived from terephthalic and isophthalic acid, may be useful for luminescent and/or magnetic properties of coordination polymers. In addition, in this work we also introduce 2,2′-bipyridine as an auxiliary ligand to control the structure and dimensionality of the resulting coordination polymers [35–37]. The synthesis and structural characterization of four new coordination polymers $[Co^{II}L^1(2,2'\text{-bpy})(H_2O)]$ (**1**), $[Ni^{II}L^1(2,2'\text{-bpy})(H_2O)]\cdot H_2O$ (**2**), $[Co^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**3**) and $[Ni^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**4**) are reported here. Furthermore, interesting luminescence and magnetic properties have been studied for complexes **1** and **2**, respectively.



2. Experimental

2.1. Materials and physical measurements

Reagents were purchased commercially and were used without further purification. The ligands H_2L^1 and H_2L^2 were synthesized according to the literature method [38]. The FI-IR spectra were recorded using KBr pellets in the range 4000–400 cm^{-1} on a Mattson Alpha-Centauri spectrometer. Elemental analyses for C, H and N were performed on a Perkin–Elmer 2400 Elemental Analyzer. The thermal behaviors were studied by TGA on a Perkin–Elmer Thermal Analyzer under N_2 with a heating rate of 5 °C/min. The fluorescence spectrum for **2** was obtained using a Cary Eclipse luminescence spectrophotometer (VARIAN. USA). The temperature-dependent magnetic susceptibility of **1** was measured with crystalline samples on a Quantum Design MPMS XL-5 Squid magnetometer in a magnetic field of 1000 Oe under the temperature range 2–300 K.

2.2. Synthesis

2.2.1. Synthesis of $[Co^{II}L^1(2,2'\text{-bpy})(H_2O)]$ (**1**)

To a mixture containing H_2L^1 (18.7 mg, 0.05 mmol), $Co(NO_3)_2{\cdot}6H_2O$ (0.73 mg, 0.025 mmol) and 20 mL H_2O, was added aqueous NaOH (0.05 M) to adjust the pH of the mixture to be 5.0, and then 2,2′-bpy (0.40 mg, 0.025 mmol) was added. The resulting mixture was stirred for 30 min and then filtered. Upon standing the filtrate for about a month, the purple-colored cube-shaped crystals were obtained, washed by H_2O and air-dried (yield: 54% based on $Co(NO_3)_2{\cdot}6H_2O$). *Anal.* Calc. for $C_{32}H_{21}CoN_2O_7$: C, 63.53; H, 3.47; N, 4.63. Found: C, 63.43; H, 3.6; N, 4.42%. IR (KBr, cm^{-1}): 1678s, 1594m, 1560m, 1395s, 1326m, 1246m, 1020w, 951w, 929w, 770s, 532s.

2.2.2. Synthesis of $[Ni^{II}L^1(2,2'\text{-bpy})(H_2O)]{\cdot}H_2O$ (**2**)

To a mixture containing H_2L^1 (18.7 mg, 0.05 mmol), $Ni(NO_3)_2{\cdot}6H_2O$ (0.72 mg, 0.025 mmol) and 20 mL H_2O, was added aqueous NaOH (0.05 M) to adjust the pH of the mixture to be 8.0, and then 2,2′-bpy (0.40 mg, 0.025 mmol) was added. The resulting mixture was stirred for 30 min and then transferred to a Teflon-lined stainless steel vessel (25 mL), sealed, heated to 160 °C and maintained at that temperature for 3 days, then finally cooled at a rate of 5 °C/h to room temperature. Blue-colored cube-shaped crystals were obtained, washed by H_2O and air-dried (Yield: 72% based on $Ni(NO_3)_2{\cdot}6H_2O$). *Anal.* Calc. for $C_{32}H_{23}NiN_2O_8$: C, 61.71; H, 3.7; N, 4.5. Found: C, 61.62; H, 3.85; N, 4.42%. IR (KBr, cm^{-1}): 1673s, 1660m, 1576m, 1552s, 1490w, 1353s, 1249s, 1026w, 772s, 634w, 521m.

2.2.3. Synthesis of $[Co^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**3**)

The pH of an aqueous solution containing H_2L^2 (20.2 mg, 0.05 mmol), $Co(NO_3)_2{\cdot}6H_2O$ (0.73 mg, 0.025 mmol) and 18 mL H_2O was adjusted with K_2CO_3 to 6.0, and then 2,2′-bpy (0.40 mg, 0.025 mmol) was added. The resulting mixture was stirred for 30 min, filtered, and then transferred to a Teflon-lined stainless steel vessel (25 mL), sealed, heated to 150 °C and maintained at that temperature for 4 days, then finally cooled at a rate of 5 °C/h to room temperature. This afforded purple-colored cube-shaped crystals of **3**, which were washed by H_2O and air-dried (Yield: 66% based on $Co(NO_3)_2{\cdot}6H_2O$). *Anal.* Calc. for $C_{68}H_{49}Co_2N_4O_{13}$: C, 65.39; H, 3.93; N, 4.49. Found: C, 65.28; H, 4.14; N, 4.30%. IR (KBr, cm^{-1}): 1657s, 1603s, 1582m, 1384s, 1260m, 920w, 896m, 768s, 738m, 655w, 506w.

2.2.4. Synthesis of $[Ni^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**4**)

Complex **4** was synthesized by starting with $Ni(NO_3)_2{\cdot}6H_2O$ (0.72 mg, 0.025 mmol) under similar conditions to **3**, except that the pH of the reaction mixture was 8.5. Blue-colored cube-shaped crystals of **4** were obtained (Yield 58% based on $Ni(NO_3)_2{\cdot}6H_2O$).

2.3. X-ray crystallography

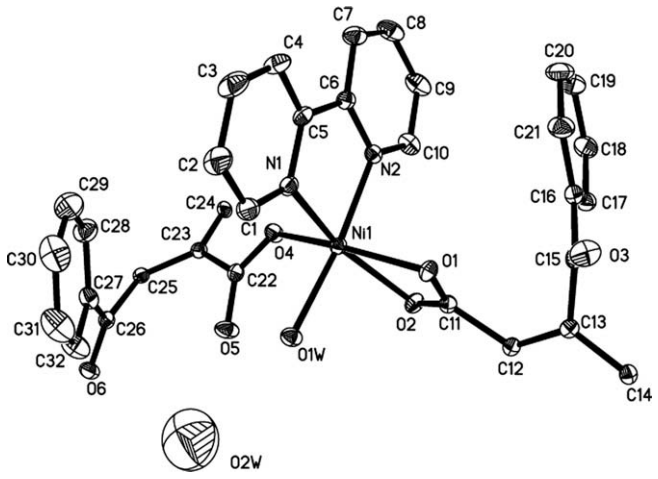
Single crystals of **1**–**4** were glued to a fiberglass for data collection on a SMART (Bruker, 2002) diffractometer equipped with Mo Kα radiation. Empirical absorption corrections were applied to the data using ABSCOR [39]. The structure was solved by the direct method followed by the difference Fourier method and refined by full-matrix least-squares on F^2 using the SHELXTL-97 package [40]. All non-hydrogen atoms were refined anisotropically, the hydrogen atoms of organic ligands and coordinated water were located geometrically. Due to the small crystallographic disorder for **2**, hydrogen atoms of the lattice water molecule were not located. The crystal data and structure refinements of **1**–**4** are summarized in Table 1 and selected bond lengths and angles are listed in the supplementaryinformation (S1 Table S1).

3. Results and discussion

3.1. Structure description

3.1.1. Structure description of *1*

Crystallographic analysis shows that complex **1** is an infinite zigzag chain coordination polymer. As shown in Fig. 1a, the Co atom is five-coordinate with two carboxylate O atoms (O1 and O3) of two different L^1 ligands, two N atoms (N1 and N2) of the chelating 2,2′-bpy and one O atom (O1 W) of the aqua ligand. The coordination geometry can be described as distorted trigonal bipyramidal with its equatorial plane defined by the O(1), N(2) and O(1 W) atoms; the axial positions are occupied by O(3) and N(1). The Co–O bond lengths, from 2.012(2) to 2.107(2) Å, and the Co–N bond lengths, from 2.086(2) to 2.131(2) Å, are within the normal range [41–43]. The two carboxylate groups show monodentate coordination (Scheme 1a) and the dihedral angles between the 1-, 4-carboxylate groups and their corresponding phenyl rings are both 173.26°. In the overall structure of **1**, units of $[Co(bpy)]^{2+}$ are connected by the bridging L^1 ligands to generate a zigzag chain with a pitch of 15.65 Å. Adjacent chains extend into



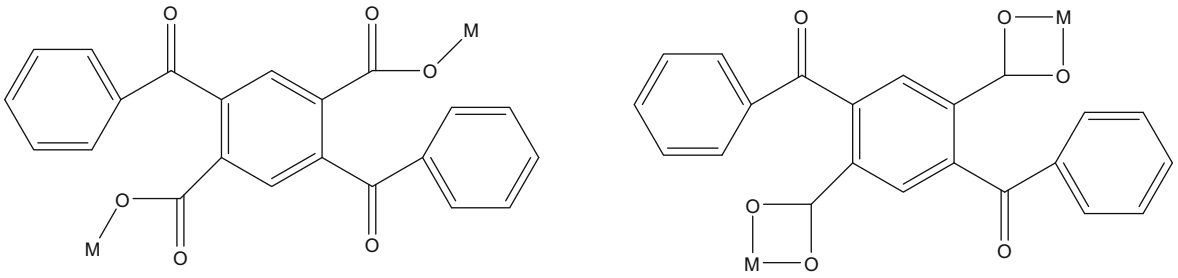


Fig. 2a. Coordination environment of the Ni atom in **2** with the ellipsoids draw at the 30% probability level, all hydrogen atoms are omitted for clarity.

Scheme 1. The L^1 ligand adopts two distinct coordination modes, namely bridging bis(mono-dentate) and chelating bisdentate coordination modes.

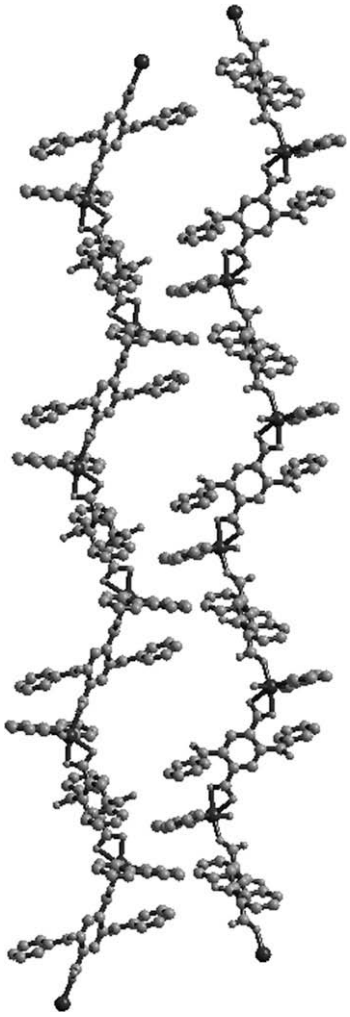

Fig. 2b. A perspective views of two infinite helical chains in **2**.

a 2D supramolecular sheet via a C–H···π interaction between the C–H moiety of the benzene rings in one chain and the benzene rings of adjacent chains (H···π 3.60 Å, C–H···π 146°, Fig. 1b).

3.1.2. Structure description of *2*

Crystallographic determination shows that there are two helical chains with opposite directions. In complex **2** the Ni atom is six-coordinate with a distorted octahedral geometry. The six-coordinate atoms are two N atoms of the 2,2′-bpy ligand (N1 and N2), two O atoms (O1 and O2) of a chelating carboxylate group, an O atom (O4) from the other monodentate carboxylate group of the L^1 ligand and an O atom (O1 W) of an aqua ligand (Fig. 2a). The average Ni–O and Ni–N bond lengths are 2.093(2) and 2.043(2) Å, respectively. The dihedral angles between the 1-, 4-carboxylate groups and their corresponding phenyl rings are both 145.89 (or 148.1)°. Doubly chelate (both carboxylate groups chelating) and doubly monodentate L^1 ligands alternate with the Ni atoms in complex **2** (Scheme 1a and b).

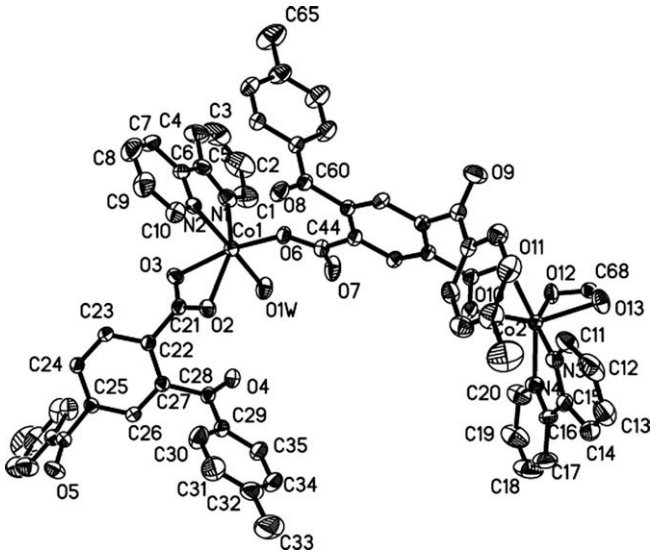

Fig. 3a. Coordination environment of the Co(1) and Co(2) atoms in **3** with the ellipsoids drawn at the 30% probability level, all hydrogen atoms are omitted for clarity.

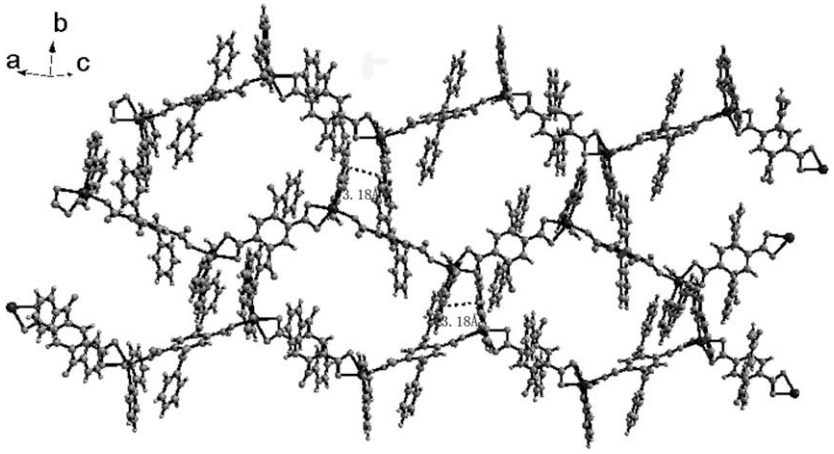
It is clear from the above description that subtle differences exist in the coordination of the same ligand with Ni and Co ions. The combination of two twisted carboxylate groups and the rotated phenyl ring result in two strand chains in **2**, the two distinct chains coexist and are oppositely arranged via a C–H···π interaction (Fig. 2b). The $[Ni(bpy)]^{2+}$ units are joined by independent L^1 spacers to generate an infinite helical chain with a period of 20.09 Å. Those chains further extend into 2D via a C–H···π interaction between the pyridine ring proton and the pyridine ring of adjacent chains (H···π 3.18 Å, C–H···π 96°, Fig. 2c).



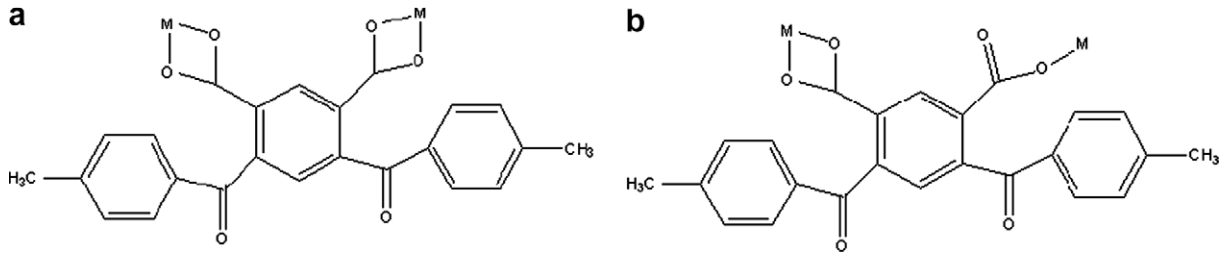


Fig. 2c. The perspective view of a 2D helical diagram in **2** via C–H···π interactions.

Scheme 2. The coordination modes of the deprotonated H_2L^2 ligand.

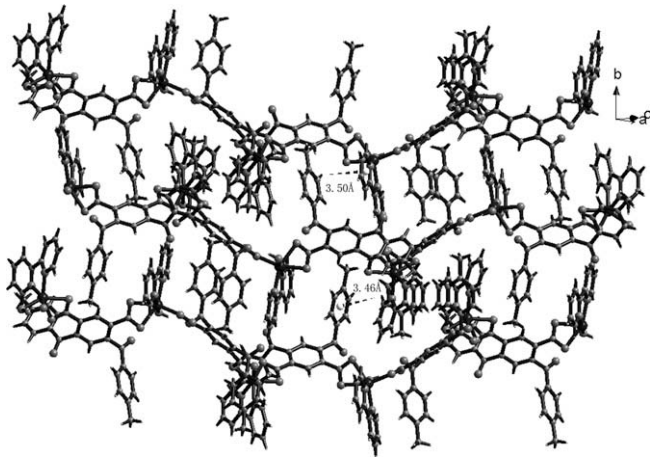

Fig. 3b. The 2D diagram of helical chain via C–H···π interactions in **3**.

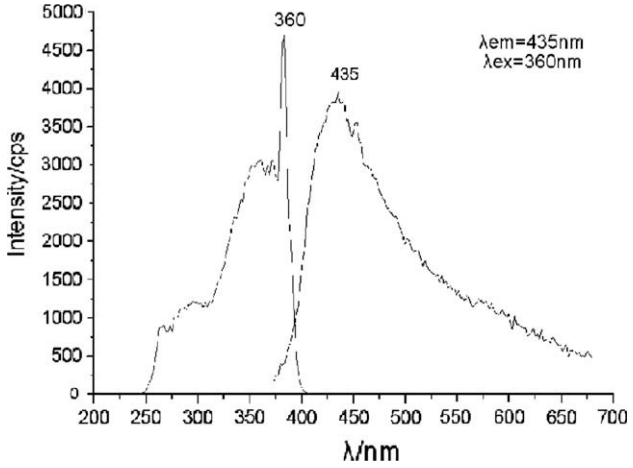

Fig. 4. Solid-state photoluminescent spectra of **2**.

*3.1.3. Structure description of **3** and **4***

Complex **3** is also a helical chain. As shown in Fig. 3a, there are two kinds of Co atoms (Co(1) and Co(2)) in **3**. The Co(1) is six-coordinate with a distorted octahedral geometry. The equatorial plane is defined by N(1), N(2), O(2) and O(1 W) atoms; the axial positions are occupied by O(3) and O(6) atoms (O(3)–Co(1)–O(6) 160.84(8)°). The Co(1)–O and Co(1)–N bond lengths are 2.024(2)–2.246(2) Å and 2.090(2)–2.100(2) Å, respectively. Co(2) is also six-coordinate, but the coordination polyhedron is more like a trigonal antiprism. In this complex Co(1) adopts the chelate-monodentate carboxylate groups coordination and Co(2) employs chelate carboxylate groups coordination (Scheme 2a and b) to afford an infinite helical chain with a period of 25.60 Å. These chains progress in one direction and further extend into a 2D supramolecular sheet via C–H···π interactions between the pyridine ring proton and a phenyl ring (H···π 3.50, 3.46 Å and C–H···π 117, 101°, Fig. 3b).

Complex **4** is isostructural with **3** but Ni atoms instead of Co atoms.

The different coordination polymers formed under slightly different reaction conditions, such as the pH is lower for **1** and **3** than for **2** and **4**, otherwise we can only obtain a precipitate not a crystalline product, which suggests that the assembly is sensitive to the synthetic conditions, including temperature (ambient or under hydrothermal conditions), pH and the nature of ligand and metal ion. At the same time, supramolecular forces also play an important role in constructing the MOFs.

3.2. Thermal analysis

The thermal stability of **1**–**4** were studied by TGA and are recorded in Fig. S1a–d (in the Supplementary data). For **1**, the weight loss incurred between 118 and 256 °C corresponds to the loss of the coordinated water molecule (Obsd. 3.01%, Calc. 2.98%). Subsequent weight loss from 300 to 402 °C is probably due to organic ligand decomposition (Obsd. 64.7%, Calc. 63.5%). The residue is Co_2O_3 (Obsd. 27.57%, Calc. 27.46%). For **2**, the TG curve exhibits three steps of weight loss. The first step is 2.84% from 100 to 140 °C and is possibly due to the loss of the water molecule of crystallization (Calc. 2.89%). The second weight loss is 2.99% in the temperature range 140–180 °C, ascribable to the loss of the aqua ligand (Calc. 2.89%). The third step from 200 to 400 °C is due to the decomposition of the organic ligand (Obsd. 65.71%, Calc. 61.71%). The remaining residue is probable NiO (Obsd. 13.62%, Calc. 12.05%). Complexes **3** and **4** are isomorphic with three steps of weight loss. For **3**, the first step is 1.40% in the temperature range 100–200 °C, corresponding to the loss of the coordinated

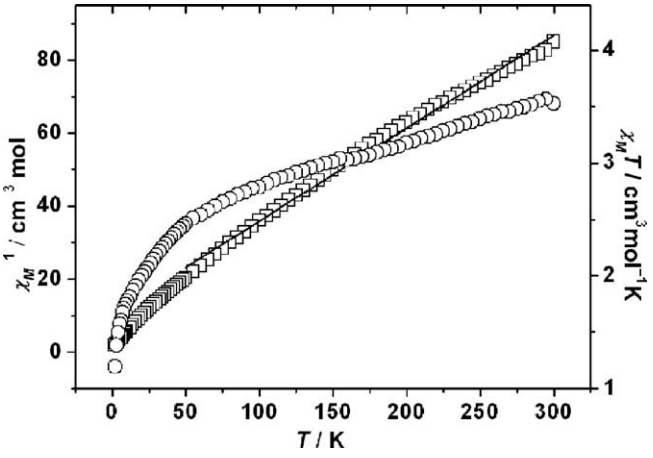

Fig. 5. Plots of the temperature dependence of $\chi_M T$ and $\chi_M{}^{-1}$ at 2–300 K.

water molecule (Calc. 1.44%). The second step is due to the release of the organic ligand in the temperature range 200–550 °C (Obsd. 64.17%, Calc. 65.38%), and the remaining weight (Obsd. 12.46%, Cacl. 13.30%) is assigned to Co_2O_3.

3.3. Luminescence properties

The solid-state luminescence of **2** was investigated. An intense emission at $\lambda em = 435$ nm upon excitation at $\lambda ex = 360$ nm (Fig. 4) was observed. The solid-state photoluminescence property of the free H_2L^1 ligand was analyzed (Fig. S2) in comparison. It is clear that the emission of **2** is blue shifted compared with the free H_2L^1 ligand, and this is assigned to an intraligand $\pi \rightarrow \pi^*$ transition and charge-transfer transition between the coordinated ligand and the metal center [44–47].

3.4. Magnetic properties

The magnetic properties of **1** were studied in the temperature range 2–300 K (Fig. 5). The $\chi_M T$ value at 300 K is 3.528 cm^3 K mol^{-1}, larger than the value for a spin-only $S = 3/2$ system (1.875 emu K mol^{-1}). This is expected as there is a significant first-order orbital contribution to the magnetic moment for a five-coordinate high spin cobalt(II) ion [48]. Upon lowering the temperature $\chi_M T$ decreases to 1.191 cm^3 K mol^{-1} at 2 K. The fitting of the curve for the $\chi_M{}^{-1}$ versus T plot to the Curie–Weiss law gives a good result in the temperature range of 50–300 K with $C = 3.931$ cm^3 K mol^{-1} and $\theta = -41.191$ K, consistent with the presence of an antiferromagnetic interaction in **1**.

4. Conclusions

In summary, $[Co^{II}L^1(2,2'\text{-bpy})(H_2O)]$ (**1**), $[Ni^{II}L^1(2,2'\text{-bpy})(H_2O)]\cdot H_2O$ (**2**), $[Co^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**3**) and $[Ni^{II}_2(L^2)_2(2,2'\text{-bpy})_2(H_2O)]$ (**4**), four new coordination polymers, were synthesized and characterized. In addition, magnetic and luminescence properties have been studied for **1** and **2**, respectively. It is anticipated that more metal–organic frameworks (MOFs) employing L^1, L^2 or other analogous ligands will be produced and possibly realized in functioned materials.

ABSTRACT

New tri-functional ligands of the type $R_2NCOCH_2SCH_2CONR_2$ (where R = iso-propyl, *n*-butyl or iso-butyl) were prepared and characterized. The coordination chemistry of these ligands with uranyl and lanthanum(III) nitrates was studied by using the IR, ^{1}HNMR and elemental analysis methods. Structures for the compounds $[UO_2(NO_3)_2(^iPr_2NCOCH_2SCH_2CON^iPr_2)]$ $[UO_2(NO_3)_2(^iBu_2NCOCH_2SCH_2CON^iBu_2)]$, $[La(NO_3)_3(^iPr_2NCOCH_2SCH_2CON^iPr_2)_2]$ and $[La(NO_3)_3(^iBu_2NCOCH_2SCH_2CON^iBu_2)_2]$ were determined by single crystal X-ray diffraction. These structures show that the ligand acts as a bidentate chelating ligand and bonds through both the carbamoyl groups to the uranyl and lanthanum(III) nitrate groups. Solvent extraction studies show that the ligand can extract the uranyl ion from the nitric acid medium but does not show any ability to extract the americium (III) ion.

1. Introduction

The coordination chemistry of actinide and lanthanide ions is not only very important for the development of new extractants for the separation and purification of actinide ions from irradiated nuclear fuel but also for the technology concerning the storage of highly radioactive waste materials [1–3]. Tri-functional diglycolamide ligands (Fig. 1a) show excellent extraction properties for trivalent actinide metal ions over the tetra or hexavalent actinide ions and extensive solvent extraction studies have been reported over the last 10 years [4,5]. The coordination chemistry of these ligands with lanthanide and actinide ions has been reported recently by us [6] and others [7,8] and shows that the ligand acts as a tridentate chelating ligand and bonds through both the carbamoyl oxygen and ethereal oxygen atoms to the metal centre. The replacement of ethereal oxygen by the CH_2 group in the glutaramide ligand (Fig. 1b) shows extraction for the hexavalent and tetravalent ions but not for the trivalent ions [9]. The coordination chemistry of glutaramide shows that it acts as a monodentate ligand and bridges uranyl nitrate in the solid state to form a linear polymeric chain arrangement [10]. The solvent extraction studies on tri-functional ligands having the "thio" group in place of the oxygen atom in diglycolamide (called thio-diglycolamide, Fig. 1c) reported by Sasaki et al. show extraction for hexavalent, tetravalent and trivalent actinides and lanthanides from the perchloric acid medium [11–13]. The observed distribution data show that its extraction properties are much superior to those of malanomides but poorer than those of diglycolamides. Sasaki et al. have proposed a tridentate mode of bonding for these ligands with the metal ion similar to those of diglycolamide ligands [13]. However, no structural work is reported to support this proposal. Since, the perchloric acid is no where used in the nuclear fuel reprocessing cycle, it is more relevant to carry out the extraction studies from nitric acid medium rather than that of perchloric acid. We report herein the synthesis of some new thio-diglycolamide ligands and their coordination chemistry with the uranyl and lanthanum(III) nitrates and their preliminary extraction studies with uranyl and americium(III) ions from nitric acid medium.

2. Experimental

2.1. General considerations

All the starting materials and other chemicals were reagent grade and were used as received. FTIR spectra were obtained on a JASCO-610 FTIR spectrometer and the samples were mounted as a nujol mull. The ^{1}H NMR spectra in $CDCl_3$, on a Bruker 500 MHz spectrometer and the peak positions are calibrated with respect to the internal residual solvent peaks. Elemental analyses were performed by the Analytical Chemistry Division of Bhabha Atomic Research Centre, Mumbai.

2.2. Synthesis of $[(^iC_3H_7)_2NCOCH_2SCH_2CON\{(^iC_3H_7)_2]_2$ (**1**)

N,*N*-Di-isopropyl chloroacetamide (50 g, 0.279 mol) and $Na_2S{\cdot}9H_2O$ (34 g, 0.14 mol) in ethanol (100 mL) were refluxed for 24 h. The volume of the solution was reduced (50 mL) and ca. 300 mL of water was added. The viscous organic residue obtained was extracted with 100 mL of chloroform, dried over anhydrous sodium sulfate and filtered. Removal of the solvent yielded a pasty solid which was re-dissolved in hot hexane and filtered. The solution on slow evaporation yielded a pale yellow solid, which was filtered and washed with cold hexane and dried. Yield: 25 g (57%). Elemental *Anal.* Calc. for $[(^iC_3H_7)_2NCOCH_2SCH_2CON(^iC_3H_7)_2]$; $C_{16}H_{32}N_2O_2S$: C, 60.7; H, 10.1; N, 8.8. Found: C, 60.6; H, 9.9; N, 8.9%. IR (KBr, Nujol, ν/cm^{-1}): 1643 (CO). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 1.20 (d, 7.2 Hz, 12H, CH_3), 1.38 (d, 6.9 Hz, 12H, CH_3), 3.52 (s, 4H, SCH_2), 3.97 (m, 4H, CH).

2.3. Synthesis of $[(^iC_4H_9)_2NCOCH_2SCH_2CON(^iC_4H_9)_2]$ (**2**)

This was prepared similarly to **1** by taking $^iBu_2NCOCH_2Cl$ (10 g, 0.0486 mol) and $Na_2S{\cdot}9H_2O$ (5.5 g, 0.0229 mol). Yield: 95%. Elemental *Anal.* Calc. for $[(^iC_4H_9)_2NCOCH_2SCH_2CON(^iC_4H_9)_2]$; $C_{20}H_{40}N_2O_2S$: C, 64.5; H, 10.7; N, 7.5. Found: C, 64.1; H, 10.4; N, 8.0%. IR (KBr, Nujol, ν/cm^{-1}): 1640 (CO). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 0.89 (d, 6.5 Hz, 12H, CH_3), 0.92 (d, 7 Hz, 12H, CH_3), 1.91 (m, 2H, CH), 2.02 (m, 2H, CH), 3.14 (d, 8 Hz, 4H, NCH_2), 3.20 (d, 7.5 Hz, 4H, NCH_2), 3.52 (s, 4H, SCH_2).

2.4. Synthesis of $[(^nC_4H_9)_2NCOCH_2SCH_2CON\{(^nC_4H_9)_2]$ (**3**)

This was prepared similarly to **1** by taking Bu_2NCOCH_2Cl (25 g, 0.1216 mol) and $Na_2S{\cdot}9H_2O$ (14.5 g, 0.0604 mol). Yield: 89%. Elemental *Anal.* Calc. for $[(^nC_4H_9)_2NCOCH_2SCH_2CON(^nC_4H_9)_2]$, $C_{20}H_{40}N_2O_2S$: C, 64.5; H, 10.7; N, 7.5. Found: C, 64.2; H, 11.0; N, 7.7%. IR (KBr, Nujol, ν/cm^{-1}): 1639 (CO). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 0.91 (t, 7.5 Hz, 6H, CH_3), 0.94 (t, 7.5 Hz, 6H, CH_3), 1.31 (m, 8H, CH_2), 1.52 (m, 8H, CH_2), 3.27 (m, 8H, CH_2), 3.48 (s, 4H, SCH_2).

2.5. Synthesis of $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2SCH_2CON\{(^iC_3H_7)_2]$ (**4**)

To a solution of $(^iC_3H_7)_2NCOCH_2SCH_2CON(^iC_3H_7)_2$ (691 mg, 2.18 mmol) in chloroform, solid $[UO_2(NO_3)_2{\cdot}6H_2O]$ (502 mg, 1 mmol) was added and stirred for few minutes until all uranyl nitrate dissolves to give a clear solution. The solution was filtered and layered with iso-octane. The solution on slow evaporation deposited a pasty solid which was washed in di-isopropyl ether to remove the excess ligand and yield a fine yellow powder. The solution was filtered and the solid residue was washed in iso-propyl ether, hexane and dried. This crude product was crystallized from dichloromethane/iso-octane mixture as a yellow crystalline solid. Yield: 714 mg (92%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2SCH_2CON(^iC_3H_7)_2]$; $C_{16}H_{32}N_4O_{10}SU$: C, 27.0; H, 4.5; N, 7.9. Found: C, 27.5; H, 4.9; N, 8.0%. IR (KBr, Nujol, ν/cm^{-1}): 1610, 1577 (CO), 927 (O=U=O). ^1H NMR (25 °C, CD_2Cl_2, δ in ppm): 1.51 (d,6.5 Hz, 24H, CH_3), 3.74 (br, 4H, SCH_2), 4.14 (m, 4H, CH).

2.6. Synthesis of $[UO_2(NO_3)_2(^iC_4H_9)_2NCOCH_2SCH_2C)N\{(^iC_4H_9)_2]$ (**5**)

This compound was prepared similarly to **4**, by taking $[(^iC_4H_9)_2NCOCH_2]_2S$ (750 mg, 2.016 mmol) and $[UO_2(NO_3)_2{\cdot}6H_2O]$ (502 mg, 1 mmol). The crude product was crystallized from chloroform/ dodecane mixture as a yellow crystalline solid. Yield: 738 mg (95.5%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2(^iC_4H_9)_2NCOCH_2SCH_2CON(^iC_4H_9)_2]$; $C_{20}H_{40}N_4O_{10}SU$: C, 31.3; H, 5.2; N, 7.3. Found: C, 30.9; H, 4.9; N, 7.1%. IR (KBr, Nujol, ν/cm^{-1}): 1610, 1579 (CO), 936 (O=U=O). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 1.01 (d, 7 Hz, 12H, CH_3), 1.10 (d, 6.5 Hz, 12H, CH_3), 2.17 (m, 2H, CH), 2.29 (m, 2H, CH), 3.45 (d, 7.5 Hz, 4H, NCH_2), 3.88 (s, 4H, SCH_2), 3.97 (d, 6.5 Hz, 4H, NCH_2).

2.7. Synthesis of $[UO_2(NO_3)_2(C_4H_9)_2NCOCH_2SCH_2CON(^nC_4H_9)_2]$ (**6**)

This was prepared similarly to **4**, by taking $[(^nC_4H_9)_2NC(O)CH_2]_2S$ (760 mg, 2.04 mmol) and $[UO_2(NO_3)_2{\cdot}6H_2O]$ (502 mg, 1 mmol). The crude product was crystallized from chloroform/iso-octane mixture as a yellow solid. Yield: 718 mg (93%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2(C_4H_9)_2NCOCH_2SCH_2CON(^nC_4H_9)_2]$; $C_{20}H_{40}N_4O_{10}SU$: C, 31.3; H, 5.2; N, 7.3. Found: C, 31.7; H, 5.5; N, 7.3%. IR (KBr, Nujol, ν/cm^{-1}): 1610, 1579 (CO), 929 (O=U=O). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 0.88 (t, 7.5 Hz, 6H, CH_3), 1.06 (t, 7.5 Hz, 6H, CH_3), 1.40 (br, 4H, CH_2), 1.49 (br, 4H, CH_2), 1.81 (br, 8H, CH_2), 3.57 (br, 4H, NCH_2), 3.80 (br, 4H, NCH_2), 3.98 (br, 4H, SCH_2).

2.8. Synthesis of $[La(NO_3)_3\{(^iC_3H_7)_2NCOCH_2SCH_2CON\{(^iC_3H_7)_2\}_2]$ (**7**)

To a chloroform solution of $[(^iC_3H_7)_2NC(O)CH_2]_2S$ (1.053 g, 3.33 mmol), $[La(NO_3)_3{\cdot}6H_2O]$ (476 mg, 1.09 mmol) was added and stirred till a clear solution is obtained. The solution was filtered and layered with iso-octane. The solution on slow evaporation yielded a white solid. This was washed with di-isopropyl ether, filtered, washed with hexane and finally dried to get a white powder. This powder was dissolved in hot ethanol and allowed to evaporate slowly at room temperature to give a white crystalline compound. Yield: 989 mg (93%). Elemental *Anal.* Calc. for $[La(NO_3)_3\{(^iC_3H_7)_2NCOCH_2SCH_2CON(^iC_3H_7)_2\}_2{\cdot}H_2O]$; $C_{32}H_{66}N_7O_{14}S_2La$: C, 39.4; H, 6.8; N, 10.0. Found: C, 40.1; H, 6.7; N, 10.3%. IR (KBr, Nujol, ν/cm^{-1}): 3534 (H_2O), 1610–1577 (br) (CO). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 1.26 (d, 7 Hz, 12H, CH_3), 1.41 (d, 6.5 Hz, 12H, CH_3), 1.64 (s, 4H, SCH_2), 3.99 (m, 4H, NCH).

2.9. Synthesis of $[La(NO_3)_3\{(^iC_4H_9)_2NCOCH_2SCH_2CON(^iC_4H_9)_2\}_2]$ (**8**)

This was prepared similarly to **7**, by taking $[(^iC_4H_9)_2NCOCH_2]_2S$ (684 mg, 1.83 mmol) and $[La(NO_3)_3{\cdot}6H_2O]$ (265 mg, 0.612 mmol). Yield: 622 mg (95%). Elemental *Anal.* Calc. for $[La(NO_3)_3\{(^iC_4H_9)_2NCOCH_2SCH_2CON(^iC_4H_9)_2\}_2]$; $C_{40}H_{80}N_7O_{13}S_2La$: C, 44.9; H, 7.4; N, 9.2. Found: C, 44.7; H, 7.9; N, 9.1%. IR (KBr, Nujol, ν/cm^{-1}): 1601–1580 (br) (CO). ^1H NMR (25 °C, $CDCl_3$, δ in ppm): 0.92 (d, 6.5 Hz, 12H, CH_3), 0.95 (d, 6.5 Hz, 12H, CH_3), 1.95 (m, 2H, CH), 2.04 (m, 2H, CH), 3.13 (d, 7.5 Hz, 4H, NCH_2), 3.22 (d, 7.5 Hz, 4H, NCH_2), 3.54 (s, 4H, SCH_2).

2.10. Synthesis of $[La(NO_3)_3\{(^nC_4H_9)_2NC(O)CH_2SCH_2C(O)N\{(^nC_4H_9)_2\}_2]$ (**9**)

This was prepared similarly to **7**, by taking $[(^nC_4H_9)_2NCOCH_2]_2S$ (1130 mg, 3.04 mmol) and $[La(NO_3)_3{\cdot}6H_2O]$ (438 mg, 1.01 mmol).

Yield: 985 mg (91%). Elemental *Anal.* Calc. for $[La(NO_3)_3\{(^nC_4H_9)_2N\text{-}COCH_2SCH_2CON(^nC_4H_9)_2\}_2]$; $C_{40}H_{80}N_7O_{13}S_2La$: C, 44.9; H, 7.4; N, 9.2. Found: C, 44.8; H, 7.6; N, 9.1%. IR (KBr, Nujol, ν/cm^{-1}): 1602–1580 (br) (CO).^{1}H NMR (25 °C, $CDCl_3$, δ in ppm): 0.95 (m, 12H, CH_3), 1.33 (m, 8H, CH_2), 1.57 (m, 8H, CH_2), 3.29 (m, 8H, CH_2), 3.49 (s, 4H, SCH_2).

2.11. ES-MS spectra

The electron spray ionization mass spectrometric detection of positive ions was performed using a MICROMASS-Q-TOF MICRO instrument. The samples **7** and **8** in CH_2Cl_2 were introduced with a syringe pump. Nitrogen was employed as both the drying and spraying gas with at source temperature of 90 °C. The cone voltage was set to 30 V, the voltage applied on the capillary was 1162 kV and sample solution flow rate was 5 μL min^{-1}. Spectra were recorded from m/z of 50 to 2000.

2.12. Solvent extraction studies

Distribution studies were performed by using a (0.2 M) solution of $[(^iC_4H_9)_2NCOCH_2SCH_2N(^iC_4H_9)_2]$ in chloroform, toluene or nitrobenzene with the 1 M HNO_3 as an aqueous phase spiked with ^{233}U or ^{241}Am tracers in a thermostated water bath for 1 h at 25 ± 0.1 C. Assay of organic and aqueous phases were done in duplicate by alpha counting using a dioxane based liquid scintillator for ^{233}U and gamma counting directly for the ^{241}Am. The distribution ratio (D) is defined as the ratio of the concentration of uranium in the organic phase to that of the aqueous phase.

2.13. X-ray diffraction studies of *4*, *5*, *7* and *8*

Data for the crystals **4**, **5**, **7** and **8** were measured with the Mo Kα radiation (λ = 0.71073 Å) using the MARresearch Image Plate System. The crystals were positioned at 70 mm from the Image Plate. Ninety-five frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [14]. The structures were solved using direct methods with the SHELXS program [15]. All non-hydrogen atoms in these structures were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon atoms were included in the geometric positions and given thermal parameters equivalent to 1.2 times those of the atoms to which they attached. Empirical absorption corrections were carried out using the difabs program [16]. The structures were refined to convergence on F^2 using SHELXL [15]. Selected crystallographic data for **4**, **5**, **7** and **8** are summarized in Table 1.

3. Results and discussion

3.1. Synthesis of thio-diglycolamide ligands

Reaction of carbamoyl methyl chloride with sodium sulfide in ethanol yielded the corresponding thio-diglycolamide ligands. The IR spectra of all ligands show the presence of the carbamoyl group in the synthesized compounds. The ^{1}HNMR spectra show the expected peaks and multiplicities and integration. The CH_2 proton resonance appears at slightly up-field (δ = 3.52 ppm) with respect to the starting R_2NCOCH_2Cl (δ = 4.01 ppm) and the analogous diglycolamide $R_2NCOCH_2OCH_2CONR_2$ (δ = 5.7 ppm) [6] shows that the more electronegative chloride or oxygen is replaced by the less electronegative sulfur atom. The C, H, N analysis supports the expected stoichiometry for the compounds.

3.2. Uranyl complexes

Reaction of $[UO_2(NO_3)_2{\cdot}6H_2O]$ with the thio-glycolamide ligand in dichloromethane yielded compounds of the type $[UO_2(NO_3)_2(R_2NCOCH_2SCH_2CONR_2)]$. The IR spectra of **4**–**6** show that the water molecules from the starting compound $[UO_2(NO_3)_2{\cdot}6H_2O]$ are completely replaced by the thio-glycolamide ligand and that the ligand is bonded through both carbamoyl groups to the metal centre. The observed frequency differences for the carbamoyl groups ($\Delta\nu_{CO}$ = 30–60 cm^{-1}, where $\Delta\nu_{CO} = \nu_{CO(\text{free ligand})} - \nu_{CO(\text{complex})}$) are consistent with the supposition that the carbamoyl group is bonded to the uranyl group directly in the reported compounds. Similar differences are also observed in the compounds of amides with uranyl nitrate such as $[UO_2(NO_3)_2{\cdot}(^iC_3H_7CON\{^iC_4H_9\}_2)_2]$ [17] and $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2\text{-}CON(^iC_3H_7)_2]$ [18]. The ^{1}H NMR of the compounds show that the CH_2 protons are deshielded by ca. 0.3–0.4 ppm with respect to the free ligands. This shows clearly that ligands are also bonded to the metal centre in solution. The C, H and N analysis revealed that the metal to ligand ratio is 1:1 in all the compounds. Structures for the compounds $[UO_2(NO_3)_2[(^iPr_2NCOCH_2SCH_2CON^iPr_2)]$ and $[UO_2(NO_3)_2(^iBu_2NCOCH_2SCH_2CON^iBu_2)]$ were determined using X-ray diffraction methods and confirm the spectral and analysis results.

The structures of the compounds $[UO_2(NO_3)_2[(^iPr_2NCOCH_2\text{-}SCH_2CON^iPr_2)]$ and $[UO_2(NO_3)_2[(^iBu_2NCOCH_2SCH_2CON^iBu_2)]$ are

shown in Figs. 2 and 3, respectively and the relevant bond lengths and angles are given in Table 2. These structures show that the thio-diglycolamide ligand bonds to uranyl nitrate in a bidentate chelating fashion through the carbamoyl oxygen atoms. They show further that the thio-ether group is un-coordinated in both these structures (U–S ≈ 4.8 Å). These structures are very similar to that of the uranyl nitrate–malonamide compound $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2CON(^iC_3H_7)_2]$ [18], in which the malonamide acts as a bidentate chelating ligand and bonds through both carbomoyl oxygen atoms. The coordination number around uranium(VI) is eight and the geometry is hexagonal bi-pyramidal. Four oxygen atoms from two nitrates and two oxygen atoms from the organic ligand form the planar hexagon. The two uranyl oxygen atoms occupy the axial positions. The observed U–O(amide) bond distances 2.352(4) and 2.374(5) Å in **4** and 2.358(6) and 2.385(5) Å in **5** are slightly shorter than the values observed in $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2CON(^iC_3H_7)_2]$ (2.41(2) Å) [18], $[UO_2(NO_3)_2Ph\{EtO\}POCH_2CONEt_2]$ (2.426(8) Å), $[UO_2(NO_3)_2Ph_2POCH_2CONEt_2]$ (2.404(5) Å) [19] and $[UO_2(NO_3)_2C_6H_5SOCH_2CON(C_4H_9)_2]$ (2.442(9) Å) [20] and comparable in magnitude with those observed in $[UO_2(NO_3)_2(C_5H_7N_2CH_2CO^iBu_2]$ (2.364(7)–2.377(9) Å) [21], $[UO_2(NO_3)_2(\text{tetrabutyl-glutaramide})]_n$ (2.37(2) Å) [10] and $[UO_2(NO_3)_2\cdot(^iC_3H_7CON\{^iC_4H_9\}_2)_2]$ (2.349(5) Å) [17]. The average U=O (1.757(5)–1.767(5) Å) and U–O(NO_3) (2.507(7)–2.526(7) Å) [10,17–21] bond distance are normal and agree well with the earlier reported uranyl nitrate neutral ligand compounds. As is apparent from Fig. 3, the butyl group bonded to N41 has high thermal motion. The interesting future of the structure is that the thio-glycolamide ligand acts as a bidentate chelating ligand, indeed the carbamoyl groups are connected by a three atom bridge CH_2–S–CH_2. However, the structure of the analogous glutaramide complex of uranyl nitrate $[UO_2(NO_3)_2(\text{glutaramide})]_n$ shows the bridging bidentate mode of bonding for the ligand, though the carbamoyl groups are also connected by a three atom bridge CH_2–CH_2–CH_2 [10]. The structure of the analogous diglycolamide ligand shows the tridentate chelating mode of bonding with the uranyl nitrate [6]. The structural studies clearly revealed that the nature of the complexes formed between the uranyl nitrate and bi-functional amide ligands is decided by the groups bridging the two carbamoyl (amide) groups. The eight-membered metallocyclic ring has the boat conformation with M–S distance of ≈4.8–4.9 Å in both structures. The structural studies revealed that the thio-glycolamide ligand behaves in a similar fashion to the malonamides in regards to its coordination behavior and not to the diglycolamides.

3.3. Lanthanum complexes

Reaction of $[La(NO_3)_3\cdot 6H_2O]$ with the thio-glycolamide ligand in ethanol yielded compounds of the type $[La(NO_3)_3[(R_2NCOCH_2SCH_2CONR_2)_2]$. The IR spectra of **7–9** show that the ligands are bonded through both the carbamoyl groups to the metal centre (Δ_{CO} = 30 cm^{-1}, $\Delta_{CO} = \nu_{CO(\text{free ligand})} - \nu_{CO(\text{complex})}$). The spectrum of **7** further shows a sharp peak at ca. 3534 cm^{-1} due to the presence of a water molecule in the solid state. The ^1H NMR spectra of **7–9** show the expected peak multiplicities and integrations. The spectra are very similar to those of free ligands without any deshielding of CH_2 protons, indicating that the ligands are weakly bonded to the metal nitrate in solution. This is further supported by the ES-MS of **7** and **8** which show peaks corresponding to the free ligands (LH^+, 100%) at 317.19 and 373.29, respectively for **2** and **3** and no peak corresponding to the complex **7** and **8** (see the Supplementary data). This shows that the compounds are dissociated in solution. The C, H and N analysis revealed that the metal to ligand ratio is 1:2 in the compounds in the solid state.

The structures for the compounds $[La(NO_3)_3(^iPr_2NCOCH_2SCH_2CON^iPr_2)_2\cdot(H_2O)]$ and $[La(NO_3)_3(^iBu_2NCOCH_2SCH_2CON^iBu_2)]$ were determined using X-ray diffraction methods and confirm the IR spectral and analysis results. The structures of the compounds $[La(NO_3)_3(^iPr_2NCOCH_2SCH_2CON^iPr_2)_2]$ (H_2O) and $[La(NO_3)_3[(^iBu_2NCOCH_2SCH_2CON^iBu_2)_2]$ are shown in Figs. 4 and 5, respectively and the relevant bond distances and angles are given in Table 3. These structures show that the thio-diglycolamide ligand bonds to lanthanum (III) nitrate in a bidentate chelating fashion through the

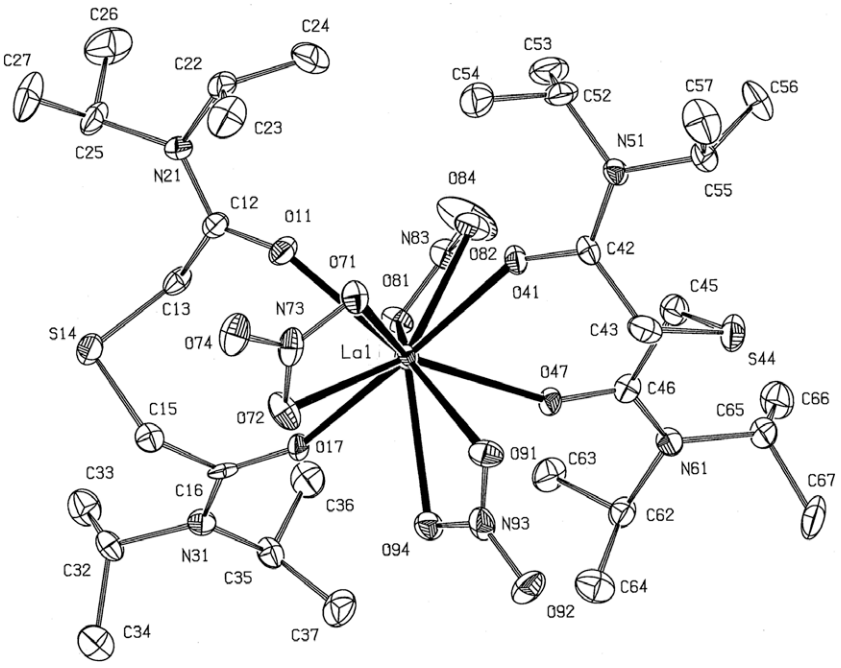

Fig. 4. Molecular structure of **7** (with 30% probability, hydrogen atoms omitted for clarity and water molecules are not shown).

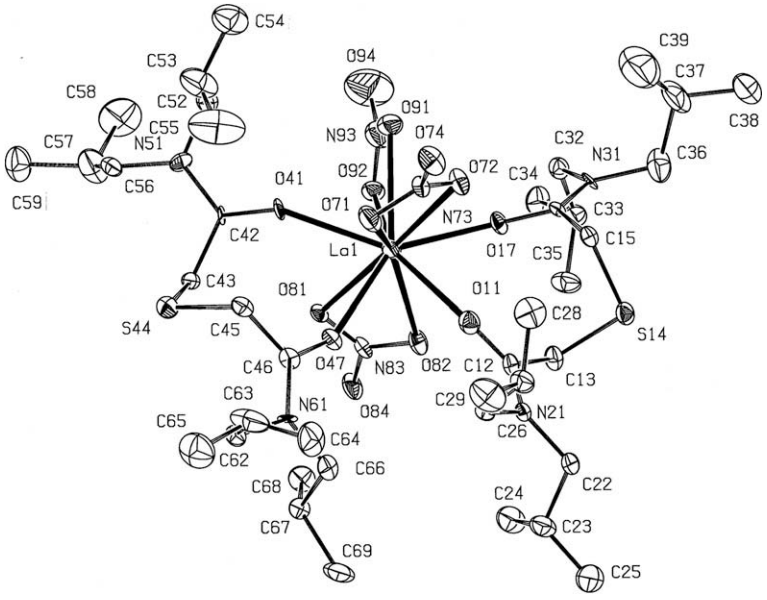

Fig. 5. Molecular structure of **8** (with 30% probability, hydrogen atoms omitted for clarity).

carbamoyl oxygen atoms. They show further that the thio-ether group is un-coordinated. These structures are very similar to those of lanthanide nitrate–malonamide compounds reported in the literature [22,23]. The coordination number around lanthanum(III) is ten and the geometry is a distorted bi-capped square-anti-prism. The average La–O(NO_3) (2.642(3) Å in **7** and 2.636(7) Å in **8**) [22–24] and La–O(amide) (2.537(3) Å in **7** and 2.500(8) Å in **8**) [22,23] bond distances are normal and comparable to those of the reported values. It is interesting to note that the structure of analogous diglycolamide shows the tridentate chelating mode of bonding with the lanthanide nitrate [6,7]. The structural studies revealed that the thio-glycolamide ligand behaves in a similar fashion to the malonamide ligands in its coordination behavior. The eight member metallocyclic ring has a boat conformation with La–S distances of ≈5.05–5.07 Å.

3.4. Solvent extraction studies

The distribution ratio for uranium and americium was determined with thio-glycolamide ligand **4** (0.2 M) in different diluents such as, chloroform, toluene, decanol and nitrobenzene from 1 M HNO_3 (Table 4). These data indicate that the thio-glycolamide ligand shows an appreciable extraction for uranium in both chloroform and toluene and poor extraction in decanol and nitrobenzene. It indicates clearly that the thio-diglycolamide is bonded to uranyl nitrate in solution (chloroform or toluene) and is responsible for

Am(III)	5.2×10^{-4}	3.1×10^{-4}	4.8×10^{-3}	negligible

Aqueous phase = 1 M HNO_3.

the extraction. This is supported by the observed ^{1}H NMR spectrum of the compound **5**, which shows a downfield shift for the CH_2 protons adjacent to the donor centres. The ligand did not show any extraction capability for Am(III) in all for diluents studied. It indicates that there is no bonding or only very week interaction between metal and ligand in all diluents studied. The ^{1}H NMR and ES-MS data for the chemically similar lanthanum compound **8** in chloroform supports this observation. The observed distribution data for uranyl and Am(III) from nitric acid medium in all the diluents clearly indicate that the thio-glycolamide behaves similar to that of glutaramide in its extraction behavior [9].

Our observed distribution data for Am(III) from nitric acid medium is completely different to those data reported by Sazaki et al. for a similar type of ligand, when the extraction was carried out from an non-complexing perchloric acid medium [11–13]. The observed extraction for Am(III) or Ln(III) from perchloric acid may be due the presence of strong bonding between thio-glycolamide and Am(III) in solution in the absence of the strongly complexing nitrate ion.

4. Conclusions

New class of tri-functional ligands thio-diglycolamide have been synthesized and their coordination chemistry with the uranyl and lanthanum(III) nitrates is studied. The structural studies revealed that the ligands behave similarly to those of malonamides in solid state. The solvent extraction studies from nitric acid medium show that thio-diglycolamide behaves similarly to those of glutaramides in solution.

Supplementary data

CCDC 725543, 725544, 725545 and 725543 contain the supplementary crystallographic data for **4**, **5**, **7** and **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Treatment of the Schiff base ligands 4-(NC_5H_4)$C_6H_4C(H)$=N[2′-$(OH)C_6H_4$] **(a)**, 3,5-($N_2C_4H_3$)$C_6H_4C(H)$=N[2′-(OH)-C_6H_4] **(b)** and 3,5-($N_2C_4H_3$)$C_6H_4C(H)$ =N[2′-(OH)-5′-$^tBuC_6H_3$] **(c)** with palladium (II) acetate in toluene gave the poly-nuclear cyclometallated complexes [Pd{4-(NC_5H_4)$C_6H_3C(H)$=N[2′-$(O)C_6H_4$]}]$_4$ **(1a)**, [Pd{3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N[2′-(O)-C_6H_4]}]$_4$ **(1b)** and [Pd{3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N[2′-(O)-5′-$^tBuC_6H_3$]}]$_4$ **(1c)** respectively, as air stable solids, with the ligand acting as a terdentate [C,N,O] moiety after deprotonation of the –OH group. Reaction of the cyclometallated complexes with triphenylphosphine gave the mononuclear species [Pd{4-(NC_5H_4)$C_6H_3C(H)$ =N[2′-$(O)C_6H_4$]}(PPh_3)], **(2a)**, [Pd{3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N[2′-$(O)C_6H_4$]}(PPh_3)], **(2b)** and [Pd{3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N[2′-(O)-5′-$^tBuC_6H_3$)}(PPh_3)], **(2c)** in which the polynuclear structure has been cleaved and the coordination of the ligand has not changed [C,N,O]. When the cyclometallated complexes **1b** and **1c** were treated with the diphosphines $Ph_2P(CH_2)_4PPh_2$ (dppb), $Ph_2PC_5H_4FeC_5H_4PPh_2$ (dppf) and $Ph_2P(CH_2)_2PPh_2$ (*t*-dppe) in a 1:2 molar ratio the dinuclear cyclometallated complexes [{Pd[3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N{2′-$(O)C_6H_4$}]}$_2$(μ-$Ph_2P(CH_2)_4PPh_2$)], **(3b)**, [{Pd[3,5-($N_2C_4H_3$)$C_6H_3C(H)$ =N{2′-(O)-5′-$^tBuC_6H_3$}]}$_2$(μ-$Ph_2P(CH_2)_4PPh_2$)], **(3c)**, [{Pd[3,5-($N_2C_4H_3$)$C_6H_3C(H)$=N{2′-$(O)C_6H_4$}]}$_2$(μ-$Ph_2P(\eta^5$-$C_5H_4)Fe(\eta^5$-$C_5H_4)PPh_2$)], **(4b)**, [{Pd[3,5-($N_2C_4H_3$-$C_6H_3C(H)$=N{2′-(O)-5′-$^tBuC_6H_3$}]}$_2$(μ-$Ph_2P(\eta^5C_5H_4)Fe(\eta^5C_5H_4)$P-$Ph_2$)], **(4c)** and [{Pd[3,5-($N_2C_4H_3$)C_6H_3-C(H)=N{2′-(O)-5′-$^tBuC_6H_3$}]}$_2$(μ-$Ph_2P(CH$=$CH)PPh_2$)], **(5c)** were obtained as air stable solids.

1. Introduction

The chemistry of cyclometallated transition metal complexes has attracted much attention in past decades. They are usually classified according to the metal, to the donor atom, or to chelate ring size; by far the most well-studied examples are five-membered palladacycles [1]. They exhibit a good number of applications which range from the use as chiral auxiliaries [2], as building blocks for molecular architectures of higher complexity [3] or as compounds with interesting mesogenic [4] and luminescent and electronic properties [5], as well as their potential use in medicine and biology [6] and in catalytic and synthetic processes [7].

We have been interested in palladium(II) and platinum(II) cyclometallated complexes derived from [C,N,X] (X = O, S) terdentate ligands. Those derived from [C,N,S] thiosemicarbazones [8–13] or from Schiff bases with phenolate oxygen atoms [14–17] show tetranuclear structures, with eight- membered Pd_4X_4 cores (X = O, S), bearing two different types of P–X bonds: $P–X_{chelating}$ and $P–X_{bridging}$, which bind the ligand tightly to the metal centre. More recently, we have shown that reaction of the tetranuclear tetramers derived from thiosemicarbazones (X=S) with bis(diphenylphosphino)methane caused cleavage of the tetranuclear structure to give new mononuclear complexes in which the phosphine is monodentate, where one phosphorus atom is uncoordinated. These complexes represent a new class of bidentate [*P*,*S*] chelating metalloligands capable of coordinating a second metal centre and, therefore, may be used as building blocks in the construction of polynuclear structures [18].

On the other hand, ligands with pyridine and pyrimidine rings have been extensively studied as building blocks in the construction of supramolecular assemblies [19–27]. We reasoned that the combination of the unusual structure shown by the cyclometallated tetramers with ligands containing pyridine o pyrimidine rings could result in a new type of metalloligands with potential applications in the construction of supramolecular aggregates, and these results are presented herein.

2. Results and discussion

For the convenience of the reader the compounds and reactions are shown in Schemes 1 and 2. The compounds described in this

paper were characterised by elemental analysis (C, H, N) and by IR and by ^{1}H, ^{31}P–{^{1}H} spectroscopy and, in part, FAB mass spectrometry (data in Section 3).

Reaction of the Schiff base ligands **a**, **b** and **c** with palladium (II) acetate in toluene at 60 °C gave [Pd{4-(NC$_5$H$_4$)C$_6$H$_3$C(H)=N[2′-(O)C$_6$H$_4$]}]$_4$, **1a**, [Pd{3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N[2′-(O)-C$_6$H$_4$]}]$_4$, **1b** and [Pd{3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N[2′-(O)-5′-^{t}BuC$_6$H$_3$]}]$_4$, **1c**, respectively, as air stable solids. The IR spectra showed the shift of the ν(C=N) stretch toward lower wavenumbers, as compared to the free ligand, due to N-coordination of the imine [28,29]. The absence of the ν(O–H) band (present in the spectra of the free ligands at 3415, **a**, 3336, **b** and 3226, **c**, cm^{-1}) was in accordance with loss of the –OH proton. The absence of ν(COO) bands in the IR spectra precludes the formation of the compounds as the typical dinuclear species with bridging acetate ligands, as found earlier when using palladium (II) acetate as the metal salt. Unfortunately the insolubility of **1a**, **1b** and **1c** precluded their characterization in solution. Nevertheless, the characterization of their phosphine derivatives, *vide infra*, unambiguously established metallation at the phenyl ring through the position adjacent to the imino group. However, the tetrameric nature of the complexes has not been unequivocally determined. The tetranuclear disposition of similar complexes have been described by us [14,16,17] and others [15,30]; their spectra and reactivity were similar to the one shown by **1a**, **1b** and **1c**, however, only the FAB-mass spectra **1c** showed the expected molecular ion whilst **1a** and **1b** spectra showed peaks corresponding to 2/3 and 1/2, respectively of the mass expected for a tetramer. Consequently, the tetranuclear formulation given here for complexes **1a**, **1b** and **1c** is only tentative.

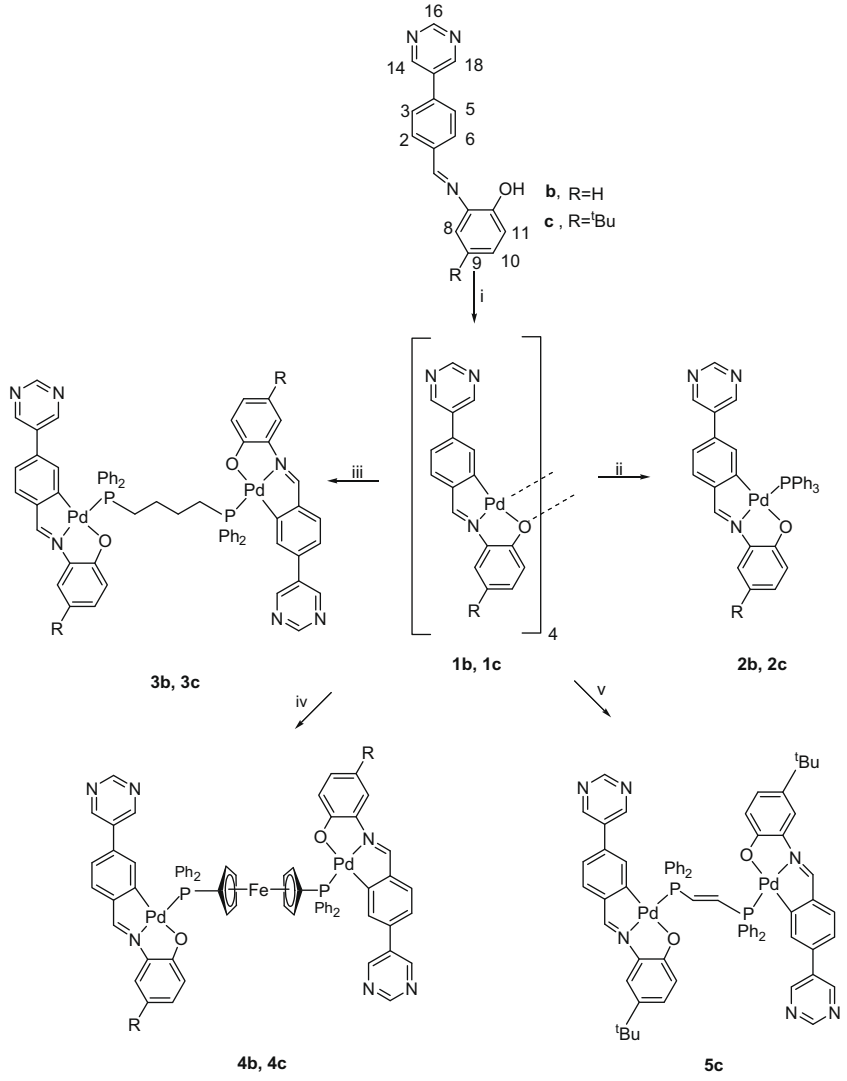
Treatment **a**, **b** and **c** with PPh$_3$ in 1:4 molar ratio afforded the mononuclear complexes [Pd{4-(NC$_5$H$_4$)C$_6$H$_3$C(H)=N[2′-(O C$_6$H$_4$]}-(PPh$_3$)] **2a**, [Pd{3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H) =N-[2′-(O)C$_6$H$_4$]}(PPh$_3$)] **2b**, and [Pd{3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N[2′-(O)-5′-^{t}BuC$_6$H$_3$)}-(PPh$_3$)] **2c**. The proton resonances were unequivocally assigned (see Section 3). The spectra showed the absence of the signal corresponding to *H6* consequent on Pd–C bond formation. The H5 resonance was coupled to the ^{31}P nucleus, with ^4J(PH) *ca.* 4 Hz, and to H3 [^3J(H3H5) = 1.7 Hz]. The signal assigned to HC=N was as a doublet by coupling to the ^{31}P nucleus with ^4J(PH) *ca.* 10 Hz. In the ^{31}P–{^{1}H} spectra the phosphorus resonance was a singlet *ca.* δ34.5 ppm, in agreement with a phosphorus *trans* to nitrogen arrangement [14,16,17,31–34]. The signals assigned to the H5 and H14, H18 protons were strongly shifted to lower frequency, as compared to the uncoordinated ligands due to shielding of phosphine phenyl rings. We have previously observed similar shifts in related complexes, confirming the relative *trans* disposition of the nitrogen atom and the phosphine ligand [14,16,9]. The H15, H17 protons in **2a** and H16 in **2b** and **2c** were also affected by the shielding but to a lesser extent. Coordination of the palladium atom trough the C=N nitrogen, was confirmed by the shift to lower wavenumbers of the ν(C=N) band, as compared to the free ligand [14,16,17,27,28]. Absence of the ν(OH) band in the IR spectra and of the O*H* resonance in the ^{1}H NMR spectra was in agreement with the presence of a phenolate oxygen bonded to the palladium atom [14,16,17]. These findings were observed for the remaining compounds and shall not be discussed further (see Section 3). The mass FAB spectra showed the cluster of peaks characteristic of the [M]$^+$ fragment at 640, **2a**, 641, **2b**, and 697, **2c**, uma.

Reaction of **1b–1c** with the diphosphines, dppb, *trans*-dppe and dppf in 1:2 molar ratio gave the dinuclear cyclometallated complexes [{Pd[3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N{2′-(O)C$_6$H$_4$}]}$_2$(μ-Ph$_2$P-(CH$_2$)$_4$PPh$_2$)] **3b**, [{Pd[3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N{2′-(O)-5′-^{t}BuC$_6$-H$_3$}]}$_2$(μ-Ph$_2$P(CH$_2$)$_4$PPh$_2$)] **3c**, [{Pd[3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N{2′-(O)C$_6$H$_4$}]}$_2$-(μ-Ph$_2$P(η^5-C$_5$H$_4$)Fe(η^5-C$_5$H$_4$)PPh$_2$)] **4b**, [{Pd[3,5-(N$_2$-C$_4$H$_3$)C$_6$H$_3$C(H)=N{2′-(O)-5′-^{t}BuC$_6$H$_3$}]}$_2$(μ-Ph$_2$P(η^5C$_5$H$_4$)Fe-(η^5C$_5$H$_4$)P-Ph$_2$)] **4c** and [{Pd[3,5-(N$_2$C$_4$H$_3$)C$_6$H$_3$C(H)=N{2′-(O)-5′-^{t}BuC$_6$H$_3$}]}$_2$(μ-PPh$_2$(*trans*-(CH)$_2$)PPh$_2$)] **5c**, as air stable solids (see Section 3). Again, as with **2b** and **2c**, the spectroscopic data confirm the proposed structures for **1b** and **1c**. Thus, the most noticeable characteristics were the absence of the ν(OH) band and the shift to lower wavenumbers of the ν(C=N) band in the IR spectra; and in the ^{1}H NMR spectra, absence of the H6 resonance and coupling of the H5 and *H*C=N protons to the ^{31}P nucleus, as a consequence of the coordination of the diphosphine. In the ^{31}P–{^{1}H} NMR spectra only one singlet was assigned for the two equivalent nuclei; accordingly, only one set of signals was observed for the two equivalent metallated moieties, in accordance with the symmetric nature of the dinuclear complexes. The mass FAB spectra of the complexes showed the set of peaks corresponding to the [MH]$^+$ ions with the expected isotopic pattern.

As for reactivity of complex **1a** with the aforementioned diphosphines, although the IR data seemed similar to that of the **b** and **c** derivatives, the products were to insoluble for NMR characterization and their mass spectra did not show the expected peaks for the molecular ions; thus, their isolation was not pursued further.

Scheme 1. (i) Pd(OAc)$_2$, toluene; (ii) PPh$_3$ (chloroform, 4:1 molar ratio).

3. Experimental



3.1. General procedures

Solvents were purified by standard methods [35]. Chemicals were reagent grade. The phosphines PPh$_3$, Ph$_2$P(CH=CH)PPh$_2$ (*trans*-dppe), Ph$_2$P(CH$_2$)$_4$PPh$_2$ (dppb) and Ph$_2$PC$_5$H$_4$FeC$_5$H$_4$PPh$_2$ (dppf) were purchased from Aldrich-Chemie. Microanalyses were carried out using a Carlo Erba Elemental Analyzer, Model 1108. IR spectra were recorded as KBr discs on a Perkin–Elmer 1330. NMR spectra were obtained as CDCl$_3$ and CD$_3$SOCD$_3$ solutions and referenced to SiMe$_4$ (^{1}H) or 85% H$_3$PO$_4$ (^{31}P–{^{1}H}) and were recorded on a BRUKER AV-300F or BRUKER AC-500F spectrometers. All chemical shifts were reported downfield from standards. The FAB mass spectra were recorded using a Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix.

4. Syntheses

4.1. Preparation of 4-(NC$_5$H$_4$)C$_6$H$_4$C(H)=N[2-(OH)C$_6$H$_4$] (a)

4-(NC$_5$H$_4$)C$_6$H$_4$COH (0.508 g, 2.77 mmol) was added to a solution of 2-aminophenol (0.305 g, 2.79 mmol) in 50 cm^3 of dry chloroform. The solution was heated under reflux in a Dean-Stark apparatus for 8 h. After cooling to room temperature the chloroform was removed to give a yellow solid. Yield 99%. *Anal.* calc. C$_{18}$H$_{14}$N$_2$O requires C, 78.8; H, 5.1; N, 10.2. Found: C, 78.9; H, 5.1; N, 10.1%. IR: ν(O–H), 3415sh cm^{-1}; ν(C=N), 1600s, m cm^{-1}. RMN ^{1}H (300 MHz, CDCl$_3$, δ

Scheme 2. (i) $Pd(OAc)_2$ (toluene); (ii) PPh_3 (chloroform, **2b**, acetone, **2c**, 4:1 molar ratio); (iii) dppb (acetone, **3b**, chloroform, **3c**, 2:1 molar ratio); (iv) dppf (chloroform **4b**, acetone, **4c**, 2:1 molar ratio); (v) *t*-dppe, (acetone, 2:1 molar ratio).

ppm, *J* Hz): δ = 8.77 [s, 1H, *HC*=N); 8.72 (d, 2H, H15,H17, ^3J(H14H15) = 6.1 Hz]; 8,68 (s, br, 1H, –OH/ resonance taken from a spectrum recorded in DMSO-d^6); 8.05 [d, 2H, H2,H6 ó H3,H5, ^3J(H2H3) = 8.3 Hz]; 7.77 [d, 2H, H3,H5 or H2,H6, ^3J(H2H3) = 8.3 Hz]; 7,57 [d, 2H, H14, H18, ^3J(H14H15) = 6.1 Hz]; 7.35 [dd, 1H, H8, ^3J(H8H9) = 8.2 Hz, ^4J(H8H10) = 1.4 Hz], 7.26 [m, 1H, H10, ^3J(H9H10) = ^{3}J(H10H11) = 8.2 Hz; ^4J(H8H10) = 1.4 Hz]; 7,04 [dd, 1H, H11, ^3J(H10H11) = 8.2 Hz, ^4J(H9H11) = 1.3 Hz]; 6.94 [m, 1H, H9, ^3J(H8H9) = ^3J(H9H10) = 8.2 Hz, ^4J(H9H11) = 1.3 Hz].

Ligands **b** and **c** were prepared similarly as yellow solids.

3,5-($N_2C_4H_3$)C_6H_4C(H)=N[2′-(OH)-C_6H_4] (b). Yield 95%. *Anal.* calc. $C_{17}H_{13}N_3O$ requires C, 74.2; H, 4.8; N, 15.3. Found: C, 74.2; H, 4.9; N, 15.4%. IR: ν(O–H), 3336s cm^{-1}; ν(C=N), 1621s cm^{-1}. RMN ^{1}H (300 MHz, $CDCl_3$, δ ppm, *J* Hz): δ = 9.26 (s, 1H, H16); 9.08 (s, br 1H, –OH/ resonance taken from a spectrum recorded in DMSO-d^6); 9.02 (s, 2H, H14, H18); 8.77 (s, 1H, HC=N); 8.08 [d, 2H, H3, H5 or H2, H6, ^3J(H2H3) = 8.2 Hz]; 7.72 [d, 2H, H3, H5 or H2, H6, ^3J(H2H3) = 8.2 Hz]; 7.35 [dd, 1H, H8, ^3J(H8H9) = 7.8 Hz, ^4J(H8H10) = 1.4 Hz]; 7.23 [m, 1H, H10, ^3J(H9H10) = ^3J(H10H11) = 7.8 Hz, ^4J(H8H10) = 1,4 Hz]; 7.05 [dd, 1H, H11, ^4J(H8H10) = 7.8 Hz, ^4J(H9H11) = 1.2 Hz]; 6.94 [m, 1H, H9, ^3J(H8H9) = ^3J(H9H10) = 7.8 Hz, ^4J(H9H11) = 1.2 Hz].

3,5-($N_2C_4H_3$)C_6H_4C(H)=N[2′-(OH)-5′-^{t}BuC_6H_3] (c). Yield 80%. *Anal.* calc. $C_{21}H_{21}N_3O$ requires C, 76.1; H, 6.4; N, 12.7. Found: C, 76.2; H, 6.5; N, 12.7%. IR: ν(O–H), 3226sh, m cm^{-1}; ν(C=N), 1622m cm^{-1}. RMN ^{1}H (300 MHz, $CDCl_3$, δ ppm, *J* Hz): δ = 9.25 (s, 1H, H16); 9.01 (s, 2H, H14, H18); 8.89 (s, br 1H, –OH/resonance taken from a spectrum recorded in DMSO-d^6); 8.76 (s, 1H, HC=N); 8.07 [d, 2H, H3, H5 or H2, H6, ^3J(H2H3) = 8.3 Hz]; 7.70 [d, H3,H5 or H2, H6, ^3J(H2H3) = 8.3 Hz]; 7.34 [d, 1H, H8, ^4J(H8H10) = 2.2 Hz]; 7.27 [dd, 1H, H10, ^3J(H10H11) = 8.5 Hz, ^4J(H8H10) = 2,2 Hz]; 6.97 [d, 1H, H11, ^3J(H10H11) = 8.5 Hz], 1.35 (s, 9H, ^{t}Bu).

4.2. Preparation of [Pd{4-(NC_5H_4)C_6H_3C(H)=N[2-(O)C_6H_4]}]$_4$ (1a)

A pressure tube containing 4-(NC_5H_4)C_6H_4C(H)=N[2′-(OH)C_6H_4] (0.125 g, 0.456 mmol), palladium acetate (0.101 g, 0.452 mmol) and 20 cm^3 of dry toluene was sealed under argon. The resulting mixture was heated at 60 °C for 24 h. After cooling to room temperature the resulting violet solid was filtered off and dried under vacuum. Yield 26%. *Anal.* calc. $C_{72}H_{48}N_8O_4Pd_4$ requires C, 57.1; H, 3.2; N, 7.4. Found: C, 57.0; H, 3.1; N, 7.3%. IR: ν(C=N), 1579sh, cm^{-1}. FAB-MS: *m*/*z* = 1136.1 $[(3/4M)H]^+$.

Compounds **1b** and **1c** were prepared similarly as violets solids.

[Pd{3,5-($N_2C_4H_3$)C_6H_3C(H)=N[2′-(O)-C_6H_4]}]$_4$ (1b). Yield 43%. *Anal.* calc. $C_{68}H_{44}N_{12}O_4Pd_4$ requires C, 53.8; H, 2.9; N, 11.1. Found: C, 53.7; H, 2.7; N, 11.2%. IR: ν(C=N), 1590s cm^{-1}. FAB-MS: m/z = 760.0 [(M/2)H]$^+$.

[Pd{3,5-($N_2C_4H_3$)C_6H_3C(H)=N[2′-(O)-5′-^{t}BuC_6H_3]}]$_4$ (1c) Yield 21%. *Anal.* calc. $C_{84}H_{76}N_{12}O_4Pd_4$ requires C, 57.9; H, 4.4; N, 9.6. Found: C, 57.8; H, 4.5; N, 9.7%. IR: ν(C=N), 1580m cm^{-1}. FAB-MS: m/z = 1741.2 [M]$^+$; 871.3 [(M/2)H]$^+$.

4.3. Preparation of [Pd{4-(NC_5H_4)C_6H_3C(H)=N[2-(O)C_6H_4]}(PPh_3)] (2a)

PPh_3 (16 mg, 0.015 mmol) was added to a suspension of **1a** (24 mg, 0.016 mmol) in chloroform (20 cm^3). The mixture was stirred for 72 h and the solvent removed to give a violet solid which was recrystallized from dichloromethane/hexane. Yield 68%. *Anal.* calc. $C_{36}H_{27}N_2OPPd$ requires C, 67.5; H, 4.3; N, 4.4. Found: C, 67.6; H, 4.3; N, 4.5%. IR: ν(C=N), 1537sh cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.38 [d, 2H, H15,H17, ^3J(H14H15) = 5.9 Hz]; 7.98 [d, 1H, *H*C=N, ^4J(PH) = 10.1 Hz], 7.22 [d,1H, H2, ^3J(H2H3) = 7.7 Hz]; 7.12 [dd, 1H, H8, ^3J(H8H9) = 8.0 Hz, ^4J(H8H10) = 1.5 Hz]; 7.10 [dd, 1H, H3, ^3J(H2H3) = 7.7 Hz, ^4J(H3H5) = 1.7 Hz]; 6.97 [m, 1H, H10, ^3J(H10H11) = 8.5 Hz, ^3J(H9H10) = 7.1 Hz, ^4J(H8H10) = 1.5 Hz]; 6.65 [d, 2H, H14, H18, ^3J(H14H15) = 5.9 Hz]; 6.54 [dd, 1H, H11, ^3J(H10H11) = 8.5 Hz, ^4J(H9H11) = 1,0 Hz]; 6.42 [dd, 1H, H5, ^4J(PH5) = 3.8 Hz, ^4J(H3H5) = 1.7 Hz]; 6.37 (t, 1H, H9). ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 34.60s. FAB-MS: m/z = 640.1 [M]$^+$.

Compounds **2b** and **2c** were prepared as violets solids following a similar procedure to that used for **2a**, but using reaction times of 24 h and acetone as solvent in the case of **2c**.

[Pd{3,5-($N_2C_4H_3$)C_6H_3C(H)=N[2′-(O)C_6H_4]}(PPh_3)] (2b). Yield 71%. *Anal.* calc. $C_{35}H_{26}N_3OPPd$ requires C, 65.5; H, 4.1; N, 6.5. Found: C, 65.6; H, 4.3; N, 6.4%. IR: ν(C=N), 1583m cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.03 (s, 1H, H16); 8.13 (s, 2H, H14, H18); 7.98 [d, 1H, *H*C=N, ^4J(PH) = 10 Hz]; 7.24 [d, 1H, H2, ^3J(H2H3) = 7.7 Hz], 7.12 [dd, 1H, H8, ^3J(H8H9) = 8.0 Hz, ^4J(H8H10) = 1.4 Hz]; 7.05 [dd, 1H, H3, ^3J(H2H3) = 7.7 Hz, ^4J(H3H5) = 1.7 Hz]; 6.97 [m, 1H, H10, ^3J(H10H11) = 8.3 Hz, ^3J(H9H10) = 8 Hz, ^4J(H8H10) = 1.4 Hz]; 6.54 [dd, 1H, H11, ^3J(H10H11) = 8.3 Hz, ^4J(H9H11) = 0.9 Hz]; 6.38 [t, 1H, H9, ^3J(H8H9) = ^3J(H9H10) = 8 Hz, ^4J(H9H11) = 0.9 Hz]; 6.28 [dd, 1H, H5, ^4J(PH5) = 3.7 Hz, ^4J(H3H5) = 1.7 Hz]. ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 34.46s. FAB-MS: m/z = 641.1 [M]$^+$.

[Pd{3,5-($N_2C_4H_3$)C_6H_3C(H)=N[2′-(O)-5′-^{t}BuC_6H_3)}(PPh_3)] (2c). Yield 67%. *Anal.* calc. $C_{39}H_{34}N_3OPPd$ requires C, 67.1; H, 4.9; N, 6.0. Found: C, 67.2; H, 4.8; N, 6.1%. IR: ν(C=N), 1580m cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.02 (s, 1H, H16); 8.14 (s, 2H, H14, H18); 7.98 [d, 1H, HC=N, ^4J(PH) = 10.2 Hz], 7.23 [d, 1H, H2, ^3J(H2H3) = 7.7 Hz]; 7.07–7.02 (m, 3H, H3, H8, H10); 6.48 [d, 1H, H11, ^3J(H10H11) = 8,6 Hz]; 6.25 [dd, 1H, H5, ^4J(PH5) = 3.7 Hz, ^4J(H3H5) = 1.7 Hz]; 1.27 (s, 9H, ^{t}Bu). ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 34.46s. FAB-MS: m/z = 697.2 [M]$^+$.

4.4. Preparation of [{Pd[3,5-($N_2C_4H_3$)C_6H_3C(H)=N{2-(O)C_6H_4}]}$_2$(μ-$Ph_2P(CH_2)_4PPh_2$)] (3b)

$Ph_2P(CH_2)_4PPh_2$ (11.3 mg, 0.013 mmol) was added to a suspension of **1b** (21.0 mg, 0.014 mmol) in acetone (20 cm^3). The mixture was stirred for 72 h and the solvent removed to give a violet solid which was recrystallized from acetone/hexane. Yield 65%. *Anal*calc. $C_{62}H_{50}N_6O_2P_2Pd_2$ requires C, 62.8; H, 4.2; N, 7.1. Found: C, 62.9; H, 4.1; N, 7.2%. IR: ν(C=N), 1583s cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.02 (s, 1H, H16); 8.15 (s, 2H, H14, H18); 7.95 [d, 1H, *H*C=N, ^4J(PH) = 1000 Hz]; 7.18 [d, 1H, H2, ^3J(H2H3) = 7.8 Hz]; 7.09 [dd, 1H, H8, ^3J(H8H9) = 8.3 Hz, ^4J(H8H10) = 1.5 Hz]; 7.01 [dd, 1H, H3, ^3J(H2H3) = 7.8 Hz, ^4J(H3H5) = 1.6 Hz]; 6.91 (m, 1H, H10); 6.38–6.34 [m, 2H, H9, H11]; 6.29 [m, 1H, H5, ^4J(PH5) = 3.5 Hz, ^4J(H3H5) = 1.6 Hz]. ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 30.22s. FAB-MS: m/z = 1186.1 [MH]$^+$.

Compounds **3c, 4b, 4c and 5c** were obtained as violet solids following a similar procedure to the one described for **3b** but using the appropriate phosphine.

[{Pd[3,5-($N_2C_4H_3$)C_6H_3C(H)=N{2′-(O)-5′-^{t}BuC_6H_3}]}$_2$(μ-$Ph_2P(CH_2)_4PPh_2$)] (3c). Yield 47%. *Anal.* calc. $C_{70}H_{66}N_6O_2P_2Pd_2$ requires C, 64.8; H, 5.1; N, 6.5. Found: C, 64.6; H, 5.3; N, 6.4%. IR: ν(C=N), 1578m cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.01(s, 1H, H16); 8.15 (s, 2H, H14, H18); 7.91 [d, 1H, *H*C=N, ^4J(PH) = 10.1 Hz]; 7.18 [d, 1H, H2, ^3J(H2H3) = 7.7 Hz]; 7.05 [d, 1H, H8, ^4J(H8H10) = 2.3 Hz]; 7.00 [dd, 1H, H3, ^3J(H2H3) = 7.7 Hz, ^4J(H3H5) = 1.8 Hz]; 6.98 [dd, 1H, H10, ^3J(H10H11) = 8.8 Hz, ^4J(H8H10) = 2.3 Hz]; 6.33 [d, 1H, H11, ^3J(H10H11) = 8.8 Hz]; 6.27 [dd, 1H, H5, ^4J(PH5) = 3.7 Hz, ^4J(H3H5) = 1.8 Hz]; 1.28 (s, 9H, ^{t}Bu). ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 30.33s. FAB-MS: m/z = 1298.2 [MH]$^+$.

[{Pd[3,5-($N_2C_4H_3$)C_6H_3C(H)=N{2′-(O)C_6H_4}]}$_2$(μ-$Ph_2P(\eta^5$-$C_5H_4)Fe(\eta^5$-$C_5H_4)PPh_2$)] (4b). Yield 65%. *Anal.* calc. $C_{68}H_{50}N_6O_2P_2$-$FePd_2$ requires C, 62.2; H, 3.8; N, 6.4. Found: C, 62.4; H, 3.9; N, 6.5%. IR: ν(C=N), 1582s cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.02 (s, 1H, H16); 8.07 (s, 2H, H14, H18); 7.91 [d, 1H, HC=N, ^4J(PH) = 10.4 Hz]; 7.22 [d, 1H, H2, ^3J(H2H3) = 7.7 Hz]; 7.09-7.03 (m, 2H, H3, H8); 6.95 (m, 1H, H10); 6.56 (d, 1H, H11); 6.32 (t, 1H, H9); 6.21 [m, 1H, H5, ^4J(PH5) = 3.8 Hz, ^4J(H3H5) = 1.4 Hz]. ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 24.56s. FAB-MS: m/z = 1314.1 [MH]$^+$.

[{Pd[3,5-($N_2C_4H_3$)C_6H_3C(H)=N{2′-(O)-5′-^{t}BuC_6H_3}]}$_2$(μ-$Ph_2P(\eta^5C_5H_4)Fe(\eta^5C_5H_4)$-$PPh_2$)] (4c). Yield 69%. *Anal.* calc. $C_{76}H_{66}N_6O_2P_2FePd_2$ requires C, 64.0; H, 4.7; N, 5.9. Found: C, 64.2; H, 4.5; N, 5.8%. IR: ν(C=N), 1584m cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9,01 (s, 1H, H16); 8.07 (s, 2H, H14, H18); 7.94 [d, 1H, HC=N, ^4J(PH) = 10,5 Hz]; 7.22 [d, 1H, H2, ^3J(H2H3) = 7.8 Hz]; 7.06–7.01 [m, 3H, H3, H8, H10); 6.50 (d, 1H, H11, ^3J(H10H11) = 8.6 Hz]; 6.19 [m, 1H, H5, ^4J(PH5) = 3.8 Hz, ^4J(H3H5) = 1.6 Hz]; $(CH)_{ferrocene}$ = 5.19–4.32 (m, 4H); 1.28 (s, 9H, ^{t}Bu). ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 24.67s. FAB-MS: m/z = 1426.2 [MH]$^+$.

[{Pd[3,5-($N_2C_4H_3$)C_6H_3C(H)=N{2′-(O)-5′-^{t}BuC_6H_3}]}$_2$(μ-Ph_2P(CH=CH)PPh_2)] (5c). Yield 89%. *Anal*calc. $C_{68}H_{62}N_6O_2P_2Pd_2$ requires C, 64.3; H, 4.9; N, 6.6. Found: C, 64.3; H, 4.8; N, 6.7%. IR: ν(C=N), 1579m cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.00 (s, 1H, H16); 8.14 (s, 2H, H14, H18); 7.92 [d, 1H, *H*C=N, ^4J(PH) = 10,1 Hz]; 7.19 [d, 1H, H2, ^3J(H2H3) = 7.8 Hz]; 7.08 [d, 1H, H8, ^4J(H8H10) = 2.3 Hz], 7.05–7.00 (m, 2H, H3, H10); 6.41 [d, 1H, H11, ^3J(H10H11) = 9.4 Hz]; 6.22 (m, 1H, H5); 1.29 (s, 9H, ^{t}Bu) ppm. ^{31}P–{^{1}H} NMR (121.49 MHz, $CDCl_3$, δ ppm) 30.96s. FAB-MS: m/z = 1268.2 [MH]$^+$.

Acknowledgments

We thank the Ministerio de Ciencia e Innovación (Projects CTQ2006-15621-C02-02/BQU, CTQ2006-15621-C02-01/BQU), the Xunta de Galicia and the Universidad de la Coruña for financial support.

Supramolecular synthon

ABSTRACT

Eight new silver(I) double salts: $AgL^1{\cdot}2AgCF_3COO$ (**1**), $AgL^1{\cdot}3AgNO_3$ (**2**), $2AgL^2{\cdot}5AgCF_3COO{\cdot}2CH_3CN{\cdot}H_2O$ (**3**), $4AgL^3{\cdot}6AgCF_3COO{\cdot}5CH_3CN$ (**4**), $4AgL^4{\cdot}6AgCF_3COO{\cdot}5CH_3CN$ (**5**), $2AgL^5{\cdot}4AgCF_3COO{\cdot}NC(CH_2)_4CN$ (**6**), $2AgL^5{\cdot}4AgCF_3COO{\cdot}2CH_3CN$ (**7**) and $AgL^6{\cdot}2CF_2(CF_2COOAg)_2{\cdot}2CH_3CN$ (**8**) (L^1 = 4-iodophenylethynide; L^2 = 3,4-dichlorophenylethynide; L^3 = 3-chlorophenylethynide; L^4 = 3-bromophenylethynide; L^5 = 2-chlorophenylethynide; L^6 = 2-fluorophenylethynide) have been synthesised and characterized by X-ray crystallography. All compounds contain the silver–halophenylethynide supramolecular synthon R_X–C≡C⊃Ag_n (n = 4, 5). In particular, the three-dimensional supramolecular structures in **1** and **2** are stabilized by strong Ag···I interactions, while that in **3** is consolidated by both Ag···Cl and van der Waals type F···Cl interactions. In isomorphous compounds **4** and **5**, the presence of respective F···Cl or F···Br contact contributes to the stability of the network. The silver aggregates in **6**, **7** and **8** are stabilized by Ag···Cl or Ag···F interactions between the *ortho*-halo substituent and the Ag_n basket.

1. Introduction

The silver(I) cation, like other easily-polarizable metal cations, tends to associate with 'soft' non-metals such as sulfur, selenium, tellurium and iodine. Accordingly, intermolecular interactions of the type Ag···X (X = F, Cl, Br, I) have been used in the design and assembly of supramolecular structures [1]. Besides using halogen ions in their bare forms [2], several reports have demonstrated the feasibility of using X-aryl moieties to incorporate silver···halogen interactions into coordination networks. The Ag···I-aryl interaction (with Ag···I distances in the range of 2.719–3.357 Å) commonly occurs [1], while Ag···Br-aryl and Ag···Cl-aryl are less studied [3], and Ag···F-aryl is rarely reported.

In recent years, we have carried out a systematic investigation on the construction of silver–organic coordination networks based on silver–ethynide supramolecular synthons, which comprise silver aggregates stabilized by argentophilicity and silver–ethynide interactions of the σ, π and mixed (σ, π) types [4]. Among the compounds studied thus far, two examples exhibit significant silver···halogen interaction involving the F^- and $PF_2O_2^-$ ions [5]. Therefore, it is of interest to us to investigate the role played by the silver···halogen interactions in coordination network assembly based on the silver–ethynide supramolecular synthon [4b,6]. In this paper, we report the synthesis and structure characterization of eight new silver(I) halophenylethynide complexes: $AgL^1{\cdot}2AgCF_3COO$ (**1**), $AgL^1{\cdot}3AgNO_3$ (**2**), $2AgL^2{\cdot}5AgCF_3COO{\cdot}2CH_3CN{\cdot}H_2O$ (**3**), $4AgL^3{\cdot}6AgCF_3COO{\cdot}5CH_3CN$ (**4**), $4AgL^4{\cdot}6AgCF_3COO{\cdot}5CH_3CN$ (**5**), $2AgL^5{\cdot}4AgCF_3COO{\cdot}NC(CH_2)_4CN$ (**6**), $2AgL^5{\cdot}4AgCF_3COO{\cdot}2CH_3CN$ (**7**) and $AgL^6{\cdot}2CF_2(CF_2COOAg)_2{\cdot}2CH_3CN$ (**8**) (L^1 = 4-iodophenylethynide; L^2 = 3,4-dichlorophenylethynide; L^3 = 3-chlorophenylethynide; L^4 = 3-bromophenylethynide; L^5 = 2-chlorophenylethynide; L^6 = 2-fluorophenylethynide), which are stabilized by both silver(I)–ethynide and silver(I)···halogen interactions. In addition, C—H···X (X = Br, Cl) hydrogen bonds exist in **4** and **5**, respectively, and multiple halogen···halogen van der Waals interactions contribute to network stabilization in **3**, **4**, **5** and **6**.

2. Experimental

2.1. General

All chemicals are used as received from Aldrich® with no further purification. Degassing and desiccation are not performed for solvents of analytical reagent grade.

2.1.1. Synthesis of polymeric silver(I) halophenylethynides

$[AgL^1]_n$. (4-Iodophenylethynyl)trimethylsilane (1.00 g, 3.33 mmol) was dissolved in a mixed solvent of 20 mL acetonitrile, 2 mL triethylamine and 40 mL methanol, to which was subsequently added 10 mL acetonitrile solution containing dissolved silver nitrate (0.623 g, 3.66 mmol). A white precipitate formed immediately. After stirring for 10 h, the crude polymeric product was filtered off and washed with 20 mL acetonitrile, 10 mL diethyl

ether and 10 mL distilled water trice, and then stored under −10 °C in wet form. Yield: 72% (based on TMS-C≡CPhI-4). IR: ν = 2034 cm^{-1} (w, $\nu_{C\equiv C}$).

[AgL^2]$_n$. 3,4-Dichlorophenylacetylene (1.00 g, 5.85 mmol) was dissolved in a mixture of 2 mL triethylamine and 60 mL acetonitrile, to which a 10 mL acetonitrile solution of silver nitrate (1.00 g, 5.88 mmol) was subsequently added. After stirring for 10 h, the crude polymeric salt was filtered off and washed with 20 mL acetonitrile and 10 mL distilled water trice, and then stored under −10 °C in wet form. Yield: 80%, IR: ν = 2026 cm^{-1} (w, $\nu_{C\equiv C}$). Similar procedures were conducted in obtaining the following four crude polymeric silver salts.

[AgL^3]$_n$. This material was prepared employing 3-chlorophenylacetylene. Yield: 80%, IR: ν = 2010 cm^{-1} (w, $\nu_{C\equiv C}$).

[AgL^4]$_n$. This material was prepared employing 3-bromophenylacetylene. Yield: 80%, IR: ν = 2010 cm^{-1} (w, $\nu_{C\equiv C}$).

[AgL^5]$_n$. This material was prepared employing 2-chlorophenylacetylene. Yield: 60%, IR: ν = 2025 cm^{-1} (w, $\nu_{C\equiv C}$).

[AgL^6]$_n$. This material was prepared employing 2-fluorophenylacetylene. Yield: 56%, IR: ν = 2054 cm^{-1} (w, $\nu_{C\equiv C}$).

2.1.2. Synthesis of silver(I) halophenylethynide complexes

*2.1.2.1. AgL^1·2AgCF$_3$COO (**1**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in 1 mL distilled water, and subsequently [AgL^1]$_n$ (~0.050 g) was added. The mixture was stirred vigorously for 1 h. During that time, 0.1 mL acetonitrile was introduced. The undissolved solid was then filtered off, and the filtrate stored under 25 °C in the dark. Crystallization happened two weeks later. Elemental Analysis (calculated): C: 18.78% (18.56%), H: 0.51% (0.52%). IR: ν = 2032 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.2. AgL^1·3AgNO$_3$ (**2**).* AgNO$_3$ (0.600 g, 3.5 mmol) was dissolved in a mixture of 1 mL distilled water and 0.2 mL acetonitrile, and subsequently [AgL^1]$_n$ (~0.050 g) was added. The mixture was stirred for 1 h. The undissolved solid was then filtered off, and the filtrate was stored under 25 °C in the dark. Crystallization happened two weeks later. Elemental Analysis (calculated): C: 11.16% (11.38%), H: 0.50% (0.48%). IR: ν = 2022 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.3. 2AgL^2·5AgCF$_3$COO·2CH$_3$CN·H$_2$O (**3**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in 1 mL distilled water, and subsequently [AgL^2]$_n$ (~0.050 g) was added. The mixture was stirred vigorously for 1 h. During that time, 0.1 mL acetonitrile was introduced. The undissolved solid was then filtered off, and the filtrate stored under 25 °C in the dark. Small plate-like crystals were obtained two months later. Elemental analysis (calculated): C: 20.30% (20.45%), H: 1.06% (0.92%), IR: ν = 2048 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.4. 4AgL^3·6AgCF$_3$COO·5CH$_3$CN (**4**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in 1 mL distilled water, and subsequently [AgL^3]$_n$ (~0.050 g) was added. The mixture was stirred vigorously for 1 h. During that time, 0.4 mL acetonitrile was introduced. The undissolved solid was then filtered off, and the filtrate stored under 25 °C in the dark. Plate-like crystals were obtained in one week. Elemental analysis (calculated): C: 25.75% (25.90%), H: 1.40% (1.25%). IR: ν = 2065, 2000 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.5. 4AgL^4·6AgCF$_3$COO·5CH$_3$CN (**5**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in 1 mL distilled water, and subsequently [AgL^4]$_n$ (~0.050 g) was added. The mixture was stirred vigorously for 1 h. During that time, 0.4 mL acetonitrile was introduced. The undissolved solid was then filtered off, and the filtrate stored under 25 °C in the dark. Needle-like crystals were obtained in one week. Elemental analysis (calculated): C: 23.85% (24.18%), H: 1.28% (1.16%). IR: ν = 2048, 2012 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.6. 2AgL^5·4AgCF$_3$COO·NC(CH$_2$)$_4$CN (**6**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in the mixture of 1 mL distilled water, 0.5 mL acetonitrile and 0.1 mL adiponitrile, to which [AgL^5]$_n$ (~0.050 g) was added subsequently. The mixture was stirred for 4 h. The undissolved solid was then filtered off. Colorless block-like crystals were formed one week later. Elemental analysis (calculated): C: 24.21% (24.37%), H: 1.20% (1.09%). IR: ν = 2041 cm^{-1} (w, $\nu_{C\equiv C}$).

*2.1.2.7. 2AgL^5·4AgCF$_3$COO·2CH$_3$CN (**7**).* AgBF$_4$ (0.384 g, 2 mmol) and AgCF$_3$COO (0.220 g, 1 mmol) were dissolved in 1 mL distilled water, and subsequently [AgL^5]$_n$ (~0.050 g) was added. The mixture was stirred vigorously for 1 h. During that time, 0.4 mL acetonitrile was introduced. The undissolved solid was then filtered off, and the filtrate stored under 25 °C in the dark. Plate-like crystals were obtained in one week. Elemental analysis (calculated): C: 23.19% (23.15%), H: 1.10% (0.97%). IR: ν = 2058 cm^{-1} ($\nu_{C\equiv C}$).

*2.1.2.8. AgL^6·2Ag$_2$C$_3$F$_6$(COO)$_2$·2CH$_3$CN (**8**).* AgBF$_4$ (0.384 g, 2 mmol), hexafluoroglutaric acid (0.120 g, 0.5 mmol) and Ag$_2$O (0.116 g, 0.5 mmol) were dissolved in a mixture of 1 mL distilled water and 0.2 mL acetonitrile, to which [AgL^6]$_n$ (~0.050 g) was added subsequently. The mixture was stirred for 4 h and filtered afterwards. Colorless needle-like crystals were formed after two weeks. Elemental analysis (calculated): C: 21.81% (21.72%), H: 1.00% (0.83%). IR: ν = 2057 cm^{-1} (w, $\nu_{C\equiv C}$).

2.2. X-ray crystallography

Selected crystals were used for data collection on a BrukerAXS Kappa APEX2 CCD diffractometer at 293 K using frames of oscillation range 0.5° (Phi scan and Omega scan) with 2° < θ < 28° (compound **1**, **2**, **3**, **6**, **7**, **8**) or on a BrukerAXS SMART 1000 CCD diffractometer at 293 K using frames of oscillation range 0.3° (Omega scan) with 2° < θ < 28° (compound **4**, **5**). Empirical absorption corrections based on multi-scan method were applied using the SADABS program [7]. The structures were solved by the direct method and refined by full-matrix least squares based on F^2 using the programs in SHELXTL package [8]. The crystal data and details of refinement are summarized in Table 1.

3. Results and discussion

*3.1. AgL^1·2AgCF$_3$COO (**1**)*

As shown in Fig. 1, compound **1** features a centrosymmetric Ag$_6$ aggregate derived from two inversion-related Ag$_4$ baskets sharing one silver edge (Ag3···Ag3a). An ethynide group (C1≡C2) is attached to each Ag$_4$ basket in the μ_4–η^2, η^2, η^1, η^1 ligation mode. The distances between silver atoms range from 2.815(1) to 3.238(1) Å, suggesting the existence of significant argentophilic interaction. Such silver baskets and ethynide ligation mode are consistent with those in the previously established R–C≡C⊃Ag$_n$ (n = 4, 5) supramolecular synthon [4b,6].

The connection of Ag$_6$ aggregates by bridging trifluoroacetate ligands across crystallographic inversion centers gives rise to a two-dimensional coordination network, as shown in Figs. 1 and 2. The carboxyl group containing oxygen atoms (O3, O4) adopts the μ_4–O,O,O',O' ligation mode generates a centrosymmetric (AgCF$_3$COO)$_2$ unit (Fig. 2). The distance between two silver atoms (Ag1···Ag1a) within this unit is 2.993(1) Å, which lies within the argentophilic distance range; under such linkage, the silver

aggregates are extended into an infinite silver chain along the *a* direction. Furthermore, the Ag_6 aggregates in parallel silver chains are also cross-linked by the other independent trifluoroacetate ligand (containing O1, O2) acting in the μ_3–*O,O,O′* mode to form a web-like layer in the *ab* plane, as shown in Figs. 1 and 2. It is notable that bridging between silver chains is assisted by silver···fluoro close contact. The bridged Ag2···F9 distance is 3.088(1) Å, being slightly shorter than the sum of van der Waals radii of F and Ag on the Bondi scale [9]. This kinds of close contact between silver and fluorine rarely occurs, though an example of this interaction was reported in our previous work on the crystal structure of $Ag_2C_4{\cdot}2AgF{\cdot}10AgC_2F_5CO_2{\cdot}CH_3CN{\cdot}12H_2O$ [5].

As shown in Fig. 3, the iodophenyl ethynide ligands are arrayed between the above-mentioned web-like layers, alternatively running parallel or anti-parallel with respect to the *c* axis. Their ethynide terminals are inserted into corresponding silver baskets, while

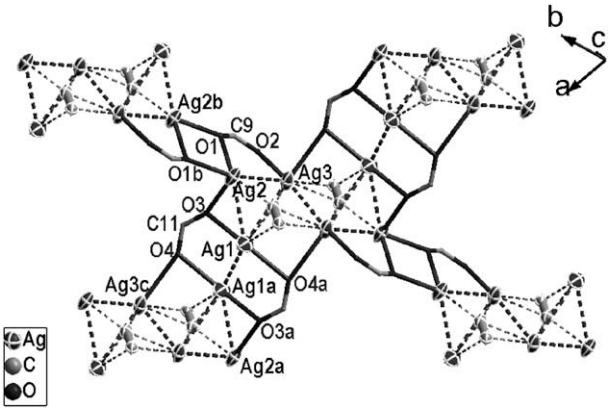

Fig. 2. Two-dimensional coordination network lying in the *ab* plane of complex **1**. CF_3 moieties of trifluoroacetate ions are omitted for clarity. Symmetry code: a 2 − *x*, −*y*, 1 − *z*; b 1 − *x*, 1 − *y*, 1 − *z*; c 1 + *x*, *y*, *z*.

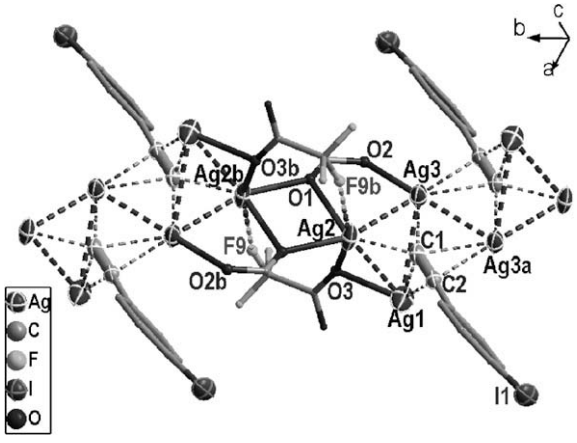

Fig. 1. Two Ag_6 aggregates in complex **1**, which are linked by carboxyl groups and Ag···F close contacts. For clarity, some CF_3 moieties of trifluoroacetate anions and all hydrogen atoms are omitted. Selected bond lengths [Å]: C1≡C2 1.222(6), C1···Ag1 2.341(5), C1···Ag2 2.164(5), C1···Ag3 2.253(4), C1···Ag3a 2.523(5), C2···Ag1 2.842(5), C2···Ag3a 2.673(5), Ag1···Ag2 3.026(1), Ag1···Ag3 3.238(1), Ag2···Ag3 2.781(1), Ag3···Ag3a 2.815(1). Symmetry code: a 1 − *x*, −*y*, 1−*z*; b 1 − *x*, 1 − *y*, 1 − *z*.

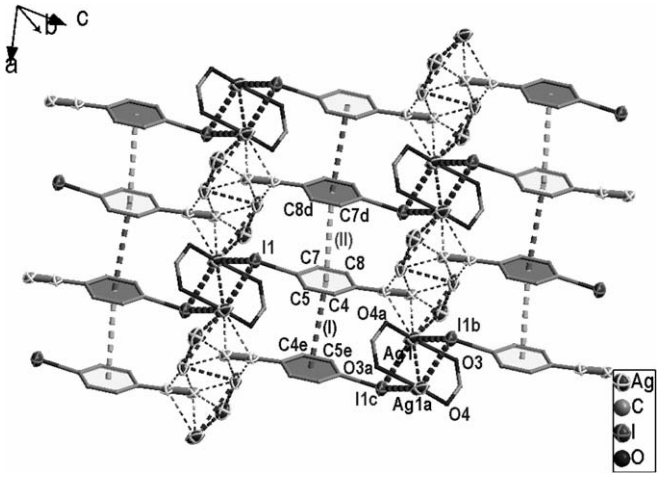

Fig. 3. Packing diagram of complex **1** in the *ac* plane. Trifluoroacetate anions are omitted for clarity, except for one bridging carboxyl moiety. Symmetry code: a 2 − *x*, −*y*, 1 − *z*; b *x*, *y*, 1 + *z*; c 2 − *x*, −*y*, −*z*; d 1 − *x*, −*y*, −*z*; e 2 − *x*, −*y*, −*z*.

each iodophenyl group is coordinated to a pair of silver atoms of the $(AgCF_3COO)_2$ structural unit by adopting the μ_2–*I* mode. The distance between silver and iodine atoms are 2.906(1) Å (Ag1···I1c) and 3.394(1) Å (Ag1···I1b), indicating the presence of strong silver···iodine interactions. The interlaced phenyl rings are stacked via two types of edge-to-edge π···π interaction of intermediate strength [6b]: C4–C5···C5e–C4e 3.670(1) Å and C7–C8···C8d–C7d 3.563(1) Å. The corresponding center-to-center distances of adjacent phenyl rings are 4.149(1) Å (**I**) and 4.199(1) Å (**II**). Thus the iodophenyl ethynide ligands connect the web-like layers altogether to generate a 3D network.

3.2. $AgL^1{\cdot}3AgNO_3$ (**2**)

In the non-centrosymmetric structural unit (Fig. 4) of compound **2**, the ethynide group (C1≡C2) inserts into a stand-alone Ag_4 basket in the μ_4–$\eta^2, \eta^2, \eta^1, \eta^1$ ligation mode, being similar to that in complex **1**. The distances between the silver atoms range from 2.909(1) to 3.021(1) Å. Three of the four silver atoms are coordinated by nitrate ions. There is one intramolecular C—H···O hydrogen bond between C8 and O9, in which the C···O distance is 3.177(6) Å and ∠OHC is 165°.

As shown in Fig. 4, adjacent structural units in compound **2** are linked by nitrate ions (upper limit of Ag—O bonding distance taken as 2.61 Å) [10] and silver···iodo interactions in the μ_2–*I* mode: each unit is connected to twelve neighboring ones (see Supplementary Material) to yield a three-dimensional network directly. The Ag···I distances are 3.211(1) Å for Ag1···I1 and 2.814(1) Å for Ag4···I1, respectively. With reference to the van der Waals radii of silver (1.72 Å) and iodine (1.95 Å) on the Bondi scale [9], the two contacts are ranked as strong silver···iodo interactions.

Along the *b* direction, the contents in the *ac* plane are arranged in the infinite sequence: silver baskets, nitrate ions, silver baskets, organic ligands, ... As shown in Fig. 5, the phenyl rings are interlaced by 60° and stacked alternately, forming face-to-face π···π interaction (centroid-to-centroid distance 3.595(1) Å) along the *c* direction. Alternatively, adjacent layers containing the π stacks are linked via silver···iodo interaction and bridged by nitrate anions attached to silver baskets: each iodine atom interacts with two vertices belonging to silver baskets in adjacent layers, and the linkages of nitrate anions occur mainly between silver baskets that are aligned head-to-head. In this manner, a three-dimensional network built by nitrate linkages and silver···iodo interactions is stabilized by inter-layer π···π interaction.

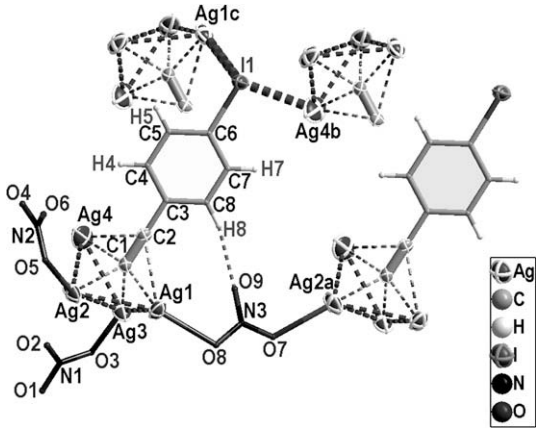

Fig. 4. Coordination geometry in **2** (50% thermo ellipsoids for Ag atoms), and the bridging of adjacent units. Selected bond lengths [Å]: C1≡C2 1.225(7), C1···Ag1 2.308(6), C1···Ag2 2.234(5), C1···Ag3 2.191(6), C1···Ag4 2.304(6), C2···Ag1 2.873(6), C2···Ag4 2.683(6), Ag1···Ag2 3.054(1), Ag1···Ag3 3.012(1), Ag2···Ag3 2.947(1), Ag2···Ag4 3.011(1), Ag3···Ag4 2.909(1), O9···C8 3.177(5). Symmetry code: a 1 + *x*, *y*, 1 + *z*; b 1 + *x*, 1 − *y*, 0.5 + *z*; c *x*, 1 − *y*, 0.5 + *z* .

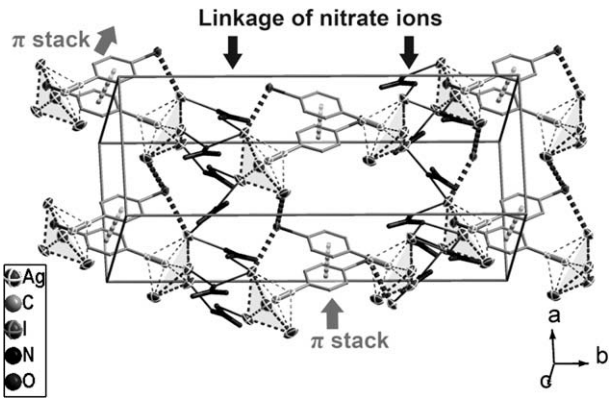

Fig. 5. Unit-cell content of complex **2**. Hydrogen atoms are omitted for clarity. Only those nitrate anions that bridge the silver baskets are included.

3.3. $2AgL^2{\cdot}5AgCF_3COO{\cdot}2CH_3CN{\cdot}H_2O$ (**3**)

In the structural unit of compound **3**, two parallelly aligned 3,4-dichlorophenylethynide ligands are inserted into separate Ag_5 baskets by adopting the μ_5–$\eta^2, \eta^2, \eta^2, \eta^1, \eta^1$ and μ_4–$\eta^2, \eta^2, \eta^2, \eta^1$ ligation modes. The silver baskets share one edge to give an Ag_8 aggregate, and such aggregates are anchored and stabilized by trifluoroacetate anions (Fig. 6). The Ag_8 aggregates are further connected together by sharing type Ag5···Ag6 edges of length 3.201(1) Å to form a silver chain. Two types of face-to-face π···π interactions occur between neighboring phenyl rings to form a zigzag stack alongside the extended silver chain. The distances between the ring centroids are 3.999(1) and 3.899(1) Å (average inter-planar distance: 3.63 and 3.71 Å), respectively.

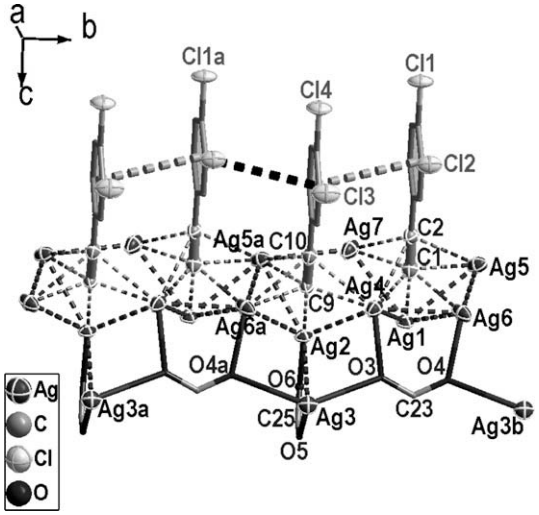

Fig. 6. Metal-ligand bonding in **3**. All hydrogen atoms, acetonitrile molecules, a water molecule, and CF_3 moieties of trifluoroacetate anions are omitted for clarity. Selected bond lengths [Å]: C1≡C2 1.191(11), C9≡C10 1.216(10). C1···Ag1 2.089(7), C1···Ag4 2.524(8), C1···Ag5 2.567(7), C1···Ag6 2.662(8), C1···Ag7 2.413(7), C2···Ag4 2.984(8), C2···Ag5 2.989(7), C2···Ag7 2.677(7), C9···Ag2 2.070(7), C9···Ag4 2.387(7), C9···Ag5a 2.476(7), C9···Ag6a 2.362(7), C10···Ag4 2.780(7), C10···Ag5a 2.959(7), C10···Ag6a 2.732(7), Ag1···Ag4 3.136(1), Ag1···Ag5 3.020(1), Ag1···Ag6 3.179(1), Ag1···Ag7 3.009(1), Ag2···Ag3 3.080(1), Ag2···Ag5a 2.951(1), Ag2···Ag6a 3.065(1), Ag4···Ag2 2.954(1), Ag4···Ag6 2.920(1), Ag5···Ag6 3.201(1), Ag7···Ag5a 3.097(1). Symmetry code: a *x*, *y* − 1, *z*; b *x*, *y* + 1, *z*.

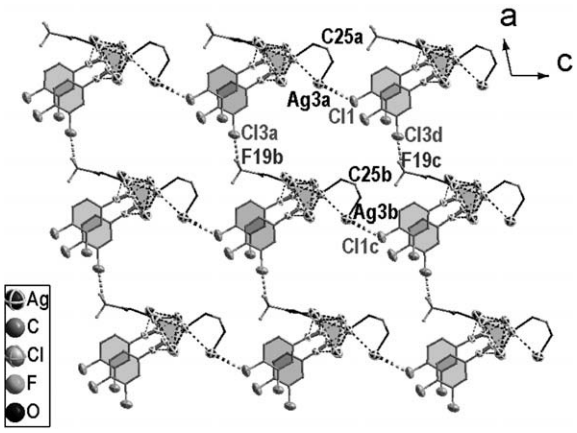

Fig. 7. Packing diagram of **3** viewed along *b* direction. The trifluoroacetate anions containing F19 are displayed, as well as the carboxyl groups of the anions containing C25. Other anions, hydrogen atoms and acetonitrile molecules are omitted for clarity. Symmetry code: a $x, -y, z-0.5$; b $x-0.5, 0.5-y, z-0.5$; c $x-0.5, 0.5+y, z$; d $x, 1+y, z$.

As shown in Fig. 6, independent atom Ag3 alone lies outside the silver basket and is anchored by type μ_4–*O*,*O*′,*O*′ (O3–O4) and μ_3–*O*,*O*′ (O5–O6) trifluoroacetate groups with further stabilization by argentophilic interaction (Ag3···Ag2 3.080(1) Å). Weak inter-chain silver···chloro interaction between Ag3 and Cl1 (Ag3···Cl1 3.287(2) Å) occurs in the *c* direction to generate a supramolecular layer, and inter-layer F···Cl contact in the *a* direction is of the van der Waals type [9,11] (F19···Cl3 3.23(1) Å). (Fig. 7).

3.4. $4AgL^3{\cdot}6AgC_2F_5COO{\cdot}5CH_3CN$ (**4**) and $4AgL^4{\cdot}6AgC_2F_5COO{\cdot}5CH_3CN$ (**5**)

Compound **4** and **5** are nearly isomorphous with the same kind of centrosymmetric structural unit. In compound **4** (Fig. 8), four parallel-related ethynides are inserted into respective Ag_5 baskets by adopting μ_5–$\eta^2,\eta^2,\eta^2,\eta^1,\eta^1$ (C9≡C10 and C17≡C18), μ_5–$\eta^2,\eta^2,\eta^1,\eta^1,\eta^1$ (C25≡C26) μ_5–$\eta^2,\eta^1,\eta^1,\eta^1,\eta^1$ (C1≡C2) ligation modes. The only difference in compound **5** is that C17≡C18 adopts the μ_5–$\eta^2,\eta^2,\eta^1,\eta^1,\eta^1$ mode. By sharing edges, the Ag_5 baskets are further united to form a columnar fragment. Four phenyl rings in each fragment are aligned on the same side of the silver column and stacked via weak face-to-face π···π interactions. Each fragment and its inversion-related neighbors share three Ag···Ag edges to generate an infinite column (Fig. 8).

In both **4** and **5**, C—H···X (X = Br, Cl) hydrogen bonds and weak halogen···halogen interactions are observed between the silver

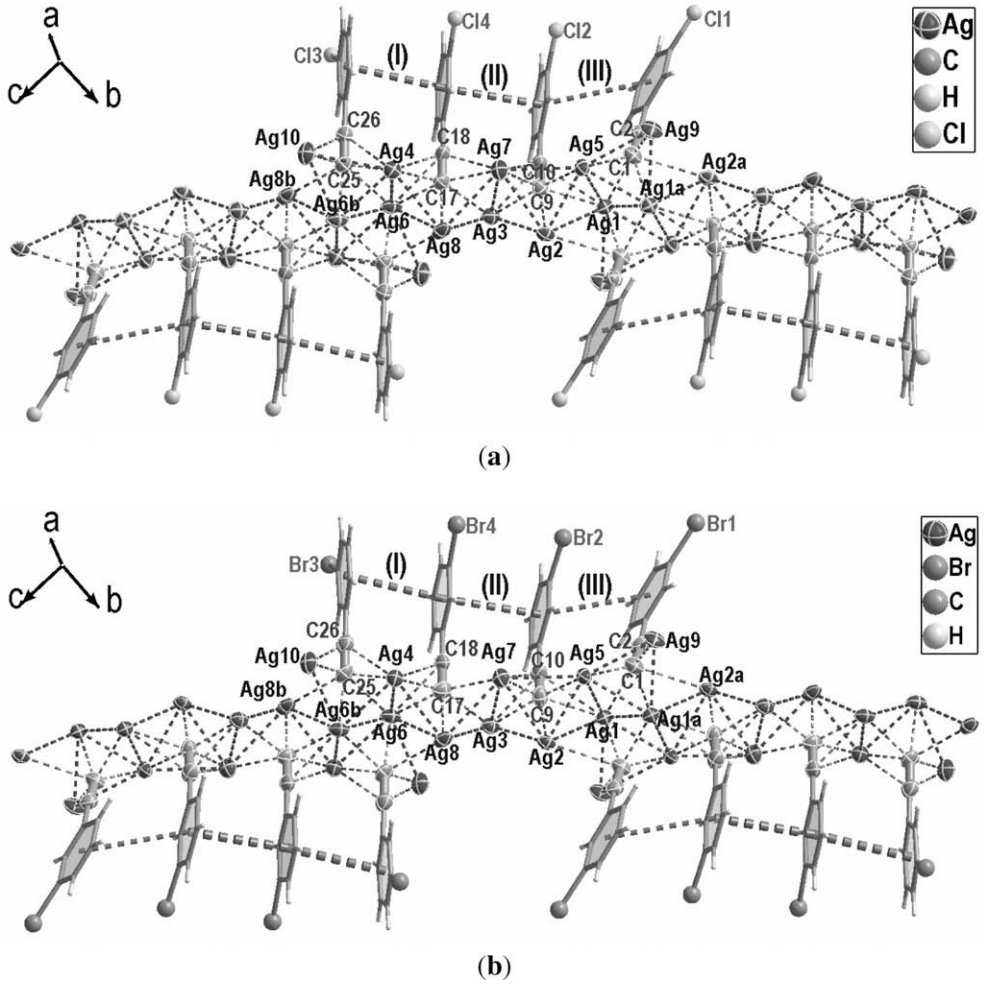

Fig. 8. Extension of silver chain in **4** (**a**) and **5** (**b**). Acetonitrile molecules and trifluoroacetate anions and a minor disordered part of Cl5/Br5 with C55 to C60 (of both) are omitted for clarity. Selected bond lengths [Å], **4**: C1≡C2 1.203(8), C9≡C10 1.211(9), C17≡C18 1.193(9), C25≡C26 1.200(9), C···Ag: 2.101(7) (C17···Ag8) to 3.022(8) (C18···Ag7), Ag···Ag: 2.882(1) (Ag6···Ag6b) to 3.277(1) (Ag4···Ag10)). **5**: C1≡C2 1.224(16), C9≡C10 1.203(16), C17≡C18 1.205(16), C25≡C26 1.200(15), C···Ag: 2.131(11) (C17···Ag8) to 3.012(13) (C25···Ag8b), Ag···Ag: 2.883(2) (Ag6···Ag6b) to 3.262(2) (Ag3···Ag7). Symmetry code **4**: a $1-x, 2-y, -z$; b $1-x, 1-y, 1-z$. **5**: a $1-x, 2-y, 1-z$; b $1-x, 1-y, 2-z$. Ring centroid-to-centroid distance in the sequence (**I**), (**II**), (**III**): **4**, 3.844(1), 3.810(1), 4.276(1) Å; **5**: 3.860(1), 3.860(1), 4.219(1), respectively.

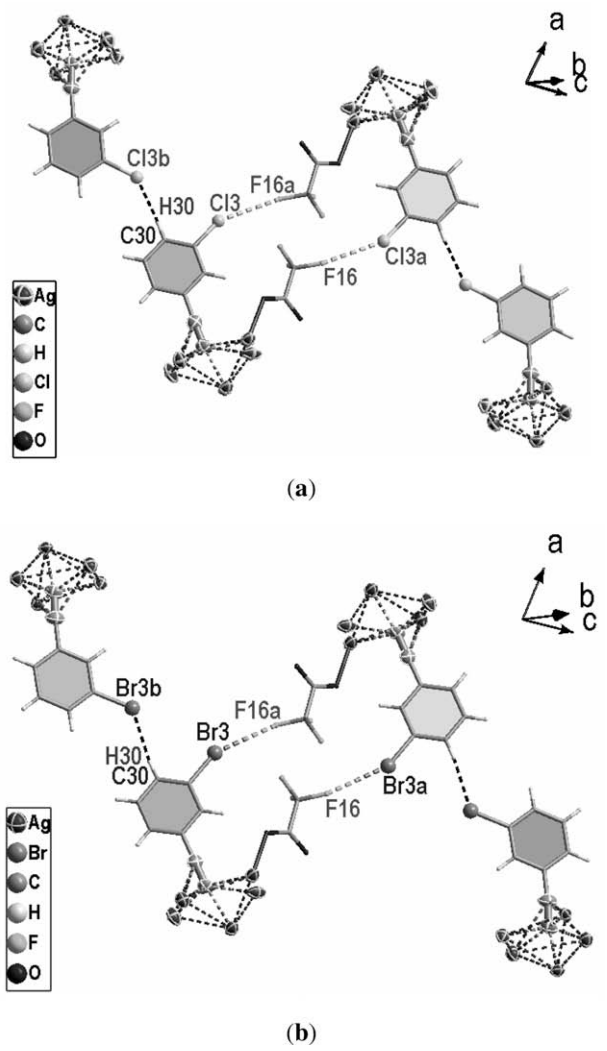

Fig. 9. Weak halogen···halogen interactions and C—H···X (X = Cl, Br) type hydrogen bonds in the crystal structure of **4** (**a**) and **5** (**b**). Symmetry code **4**: a 2 − *x*, 1 − *y*, 1 − *z*; b 2 − *x*, 1 − *y*, −*z*; **5**: a 2 − *x*, 1 − *y*, 2 − *z*; b 2 − *x*, 1 − *y*, 1 − *z*.

columns, leading to a three-dimensional supramolecular architecture [11–13] (Fig. 9). Hydrogen bonds occur between the halogen-substituted phenyl rings: *d*(Cl2b···C30) = 3.380(8) Å, ∠CHCl = 126° for **4**, *d*(Br2b···C30) = 3.456(9) Å, CHBr = 132° for **5**, while halogen···halogen interactions are observed between the Cl or Br atom at the *meta* position of the phenylethynide moiety and a fluorine atom of the CF_3COO^- anion: *d*(Cl3···F16) = 3.195(9) Å for **4** and *d*(Br3···F16) = 3.19(1) Å for **5**. Although the inter-halogen contacts are close to the sums of their van der Waals radii, their presence and attractive nature contribute to the stability of the network. It is noted that in compound **3**, van der Waals type Cl···F interaction also occurs between the *meta* chlorine atom and the fluorine atom of a CF_3COO^- anion.

3.5. $2AgL^5 \cdot 4AgCF_3COO \cdot NC(CH_2)_4CN$ (**6**) and $2AgL^5 \cdot 4AgCF_3COO \cdot 2CH_3CN$ (**7**)

In the structural units of these two complexes, parallelly-related ethynide ligands are inserted into Ag_5 baskets by adopting the μ_5–$\eta^2, \eta^2, \eta^1, \eta^1, \eta^1$(C1≡C2), μ_5–$\eta^2, \eta^1, \eta^1, \eta^1, \eta^1$(C9≡C10) (in **6**) and the μ_5–$\eta^2, \eta^2, \eta^2, \eta^2, \eta^1$(C1≡C2), μ_5–$\eta^2, \eta^2, \eta^1, \eta^1, \eta^1$(C9≡C10) (in **7**) ligation modes, with π···π interactions occurring between the phenyl rings. The centroid-to-centroid distances are 3.928(1) Å (**6**, average inter-planar distance 3.58 Å) and 3.941(2) Å (**7**, average inter-planar distance 3.54 Å) (Figs. 10 and 11). Both silver···chloro interaction and chloro···fluoro interaction are observed in complex **6** (Ag6···Cl1 3.191(4) Å, Ag7···Cl1 3.006(5) Å, Ag1···Cl2 3.404(1) Å, Cl2···F12 3.165(4) Å; Ag7 and Ag6 together represent a disordered silver atom with site occupancy ratio Ag6:Ag7 = 13:12.). The distance between Cl1 and Ag6/Ag7 is significantly smaller than the sum of their van der Waals radii by 0.3–0.5 Å [9], indicated a strong silver···halogen interaction. On the other hand, both silver···chloro and chloro···fluoro short contacts occur at Cl2, which has never been observed in our previous works. In **7**, only silver···chloro interaction is observed: Cl2···Ag6 3.280(3) Å, indicating a moderately-strong silver···halogen interaction.

In complex **6**, two adjacent inversion-related structural units are held by argentophilic interactions (Ag3···Ag3b and Ag5···Ag5a) to form a silver column in the *a* direction (Fig. 12a), and such columns are further expanded to a two-dimensional supramolecular structure via the linkage of adiponitrile molecules, as shown in Fig. 13a. In **7**, a silver column parallel to *a* axis is similarly formed (sharing edges Ag1···Ag1b and Ag3···Ag3a) (Fig. 12b), which is expanded into a three-dimensional supramolecular structure via the formation of two hydrogen bonds: C5–H5···F18 (C5···F18: 3.274(9) Å, ∠CHF = 170°) and C28–H20···O7 (C28···O7: 3.236(12) Å, ∠CHO = 162°) [13], as shown in Fig. 13b.

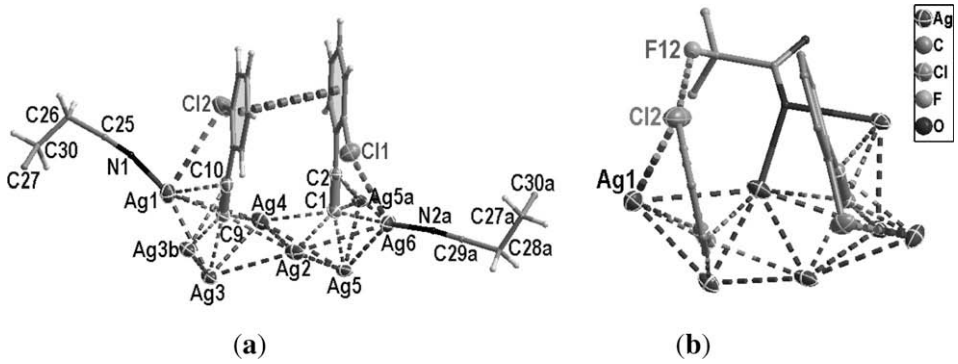

Fig. 10. (**a**) Coordination geometry of complex **6** (thermal ellipsoid 50%). All trifluoroacetate ions, hydrogen labels and disordered groups are omitted for clarity. Selected bond lengths [Å]: C1≡C2 1.217(5), C9≡C10 1.224(4), C1···Ag2 2.270(3), C1···Ag4 2.740(3), C1···Ag5 2.193(4), C1···Ag6 2.249(6), C1···Ag5a 2.626(3), C2···Ag6 2.602(6), C2···Ag5a 2.916(3), C9···Ag1 2.236(5), C9···Ag2 2.748(5), C9···Ag3 2.211(3), C9···Ag4 2.285(4), C9···Ag3b 2.532(4), C10···Ag1 2.687(4), C10···Ag3b 2.772(4), Cl1···Ag6 3.191(4), Cl2···Ag1 3.404(1), Ag1···Ag3 3.093(1), Ag1···Ag4 3.299(1), Ag2···Ag3 3.190(1), Ag2···Ag4 2.919(1), Ag2···Ag5 2.810(1), Ag3···Ag3b 2.832(1), Ag3···Ag4 2.780(1), Ag4···Ag5 3.234(1), Ag5···Ag6 3.078(3), Ag5···Ag5a 2.808(1). Symmetry code: a 1 + *x*, *y*, 1 + *z*; b − *x*, 1 − *y*, 1 − *z*. (**b**) Ag···Cl···F interaction. Cl2···F12: 3.165(4) Å.

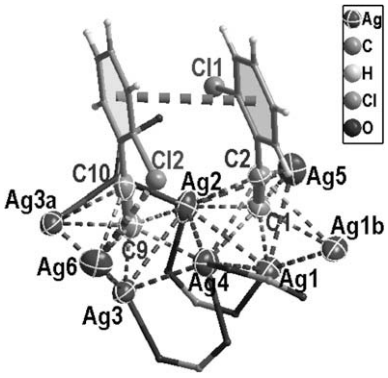

Fig. 11. Coordination geometry of complex **7** (thermal ellipsoid 50%). All CF_3 moieties of trifluoroacetate ions, acetonitrile molecules and hydrogen labels are omitted for clarity. Selected bond lengths [Å]: C1≡C2 1.219(6), C9≡C10 1.226(9), C1···Ag1 2.167(5), C1···Ag2 2.320(5), C1···Ag4 2.580(7), C1···Ag5 2.318(6), C1···Ag1b 2.608(5), C2···Ag2 2.982(5), C2···Ag4 2.937(7), C2···Ag5 2.850(7), C2···Ag1b 2.959(5), C9···Ag2 2.778(7), C9···Ag3 2.180(6), C9···Ag4 2.397(6), C9···Ag6 2.297(8), C9···Ag3a 2.599(6), C10···Ag6 2.618(8), C10···Ag3a 2.983(5), Cl2···Ag6 3.280(3), Ag1···Ag2 2.908(1), Ag1···Ag4 3.123(2), Ag1···Ag5 2.988(2), Ag1···Ag1b 2.862(1), Ag2···Ag3 3.160(1), Ag2···Ag4 3.011(2), Ag2···Ag5 3.236(2), Ag3···Ag4 2.804(1), Ag3···Ag6 3.134(2), Ag3···Ag3a 2.818(1). Symmetry code: a $1-x, 1-y, 1-z$; b $2-x, 1-y, 1-z$.

3.6. $AgL^6{\cdot}2CF_2(CF_2COOAg)_2{\cdot}2CH_3CN$ (**8**)

In compound **8**, the 2-fluorophenylethynide ligand is connected to a butterfly-shaped Ag_5 basket by adopting the μ_4–$\eta^2, \eta^2, \eta^1, \eta^1$ ligation mode (Fig. 14). The lone Ag5 atom is coordinated linearly by two acetonitrile ligands and a carboxylate oxygen atom: Ag···O (2.622(2) Å). One of the two independent hexafluoroglutarate dianions adopts a bent conformation to anchor on the Ag_5 basket, while the other one is fully extended. The distance between F13 and Ag2 is 3.106(3) Å, being approximately equal to the sum of their van der Waals radii [9].

By sharing one edge (Ag1···Ag1a), two inversion-related Ag_5 baskets form an Ag_8 aggregate. A halogen···π interaction (Fig. 15) is observed between F3 and the centroid of the phenyl ring belonging to an inversion-related unit (F3···centroid 3.292(2) Å; closest F···C contact F3a···C7 3.351(4) Å) [14] The centrosymmetric Ag_8 aggregates are further linked by bent hexafluoroglutarate dianions to form a silver–organic chain along the *a* axis, in which each carboxyl group adopts the μ_3–*O,O,O′*, mode. Notably, short F···Ag contacts are also observed between fluorine and silver atoms of adjacent Ag_8 aggregates: Ag3···F1c 3.044(2) Å, Ag4···F5c 2.915(2) Å (Fig. 15), being significantly shorter than the sum of their van der Waals radii, 3.19 Å [9]. On the other hand, along the *b* direction, the Ag_8 aggregates are linked by unbent hexafluoroglutaric dianions to yield a two-dimensional metal–organic network.

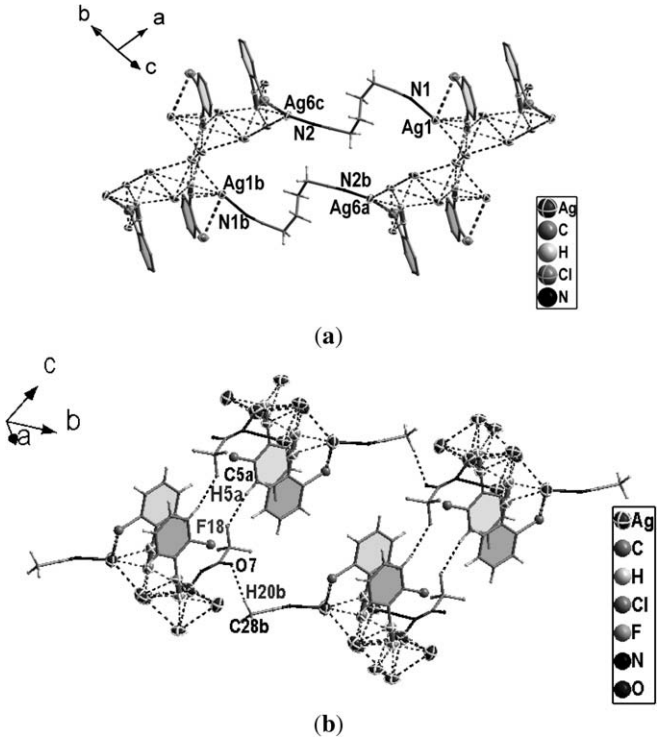

Fig. 13. (**a**) The two-dimensional coordination network of **6**. Symmetry code: a $-x, 1-y, 1-z$; b $1-x, 1-y, -z$; c $x-1, y, z-1$. (**b**) The 3D structure of **7** constructed by hydrogen bonds. Symmetry code: a $1-x, 1-y, 2-z$; b $x, 1+y, z$.

In this two-dimensional framework, the hexafluoroglutaric dianions form a loop structure, and the void space in the middle of it is filled by two linear $Ag(CH_3CN)_2$ moieties (N—Ag—N = 169°) oriented parallel to the *c* axis. The silver atom Ag5 of such a moiety is connected to the surrounding dianions via two weak Ag···O coordination interactions (Ag5···O5 2.622(2) Å, Ag5···O8 2.884(2) Å) and a C—H···F type hydrogen bond (C10···F8 3.296(5) Å, ∠CHF = 155°) A close contact of 3.002(2) Å is also observed between the ligand-unsupported Ag5 atom and F11a in the perfluoro arm of the surrounding dianion. Although this moiety does not serve as a bonding-linkage unit, it fills the ligand-inaccessible void space to stabilize the overall framework structure (Fig. 16).

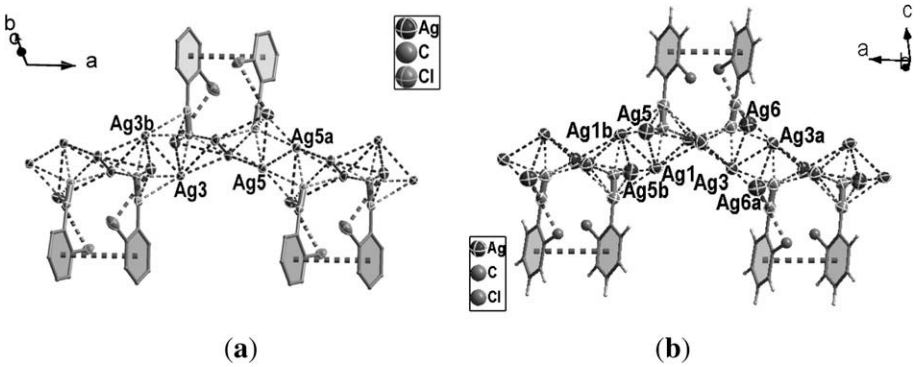

Fig. 12. (**a**) Formation of silver column in complex **6**. Symmetry code: a $1-x, 1-y, 1-z$; b $-x, 1-y, 1-z$. (**b**) Formation of silver column in **7**. Symmetry code: a $1-x, 1-y, 1-z$; b $2-x, 1-y, 1-z$. Hydrogen atoms, trifluoroacetate ions and acetonitrile/adiponitrile molecules are omitted for clarity.

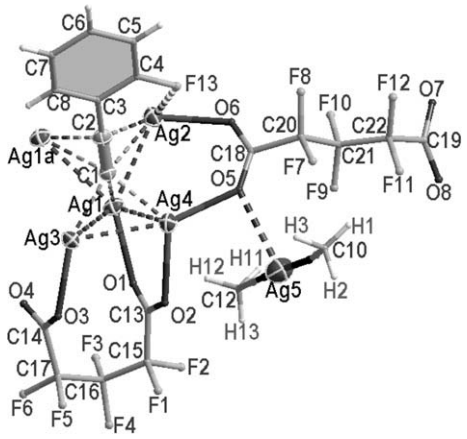

Fig. 14. Coordination geometry and atom labeling of **8**. Labels of hydrogen atoms are omitted. Selected bond lengths [Å]: C1≡C2 1.223(3), C1···Ag1 2.297(3), C1···Ag2 2.513(3), C1···Ag3 2.257(2), C1···Ag4 2.301(3), C1···Ag1a 2.554(3), C2···Ag2 2.609(3), C2···Ag1a 2.671(3), Ag1···Ag2 2.915(1), Ag1···Ag3 2.901(1), Ag1···Ag4 2.829(1), Ag1···Ag1a 3.012(1), Ag3···Ag4 2.876(1), Ag2···F13 3.106(3), O5···Ag5 2.622(2). Symmetry code: a $-x$, $1-y$, $1-z$.

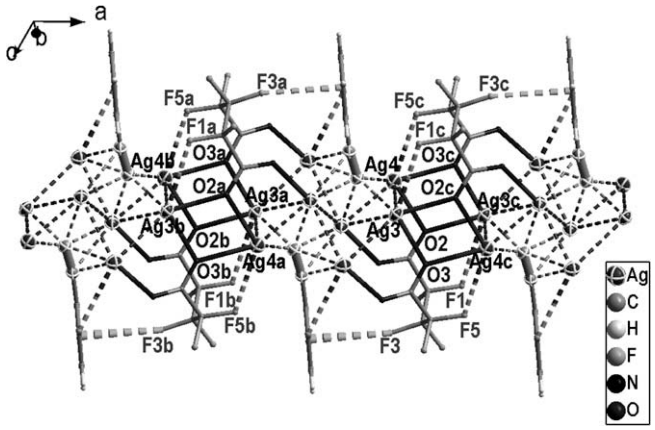

Fig. 15. The bridging linkage of Ag_8 clusters in **8** along the *a* direction. Acetonitrile molecules, Ag5 and the unbent hexafluoroglutarate anion are omitted for clarity. Symmetry code: *a* $-x$, $1-y$, $1-z$; b $x-1$, y, z; c $1-x$, $1-y$, $1-z$.

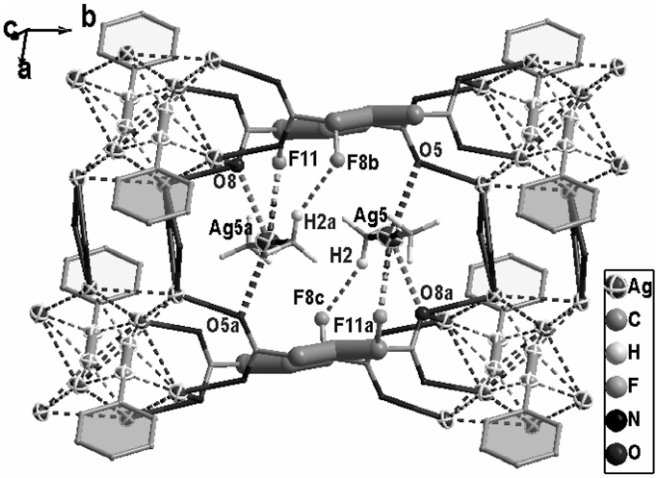

Fig. 16. Packing diagram of complex **8**. Symmetry code: a $1-x$, $-y$, $1-z$; b $-x$, $-y$, $1-z$; c $1+x$, y, z.

4. Conclusion

We have synthesised eight silver(I) halophenyl ethynide complexes bearing the supramolecular synthon R_X–C≡C⊃Ag_n (n = 4, 5; R_X = halophenyl). Strong silver···iodo interactions in two of the structures play an important role in constructing high-dimensional coordination networks, while in the other six complexes, silver···chloro interactions and chloro···fluoro, bromo···fluoro interactions are observed. The silver···iodo contacts in crystals are significantly shorter than those of silver···chloro and silver···fluoro, indicating that the silver···iodo interaction has greater strength, since the van der Waals radius of iodine is larger than those of the other two (I: 198 pm, Cl: 175 pm, F: 147 pm).

It is notable that, in compound **1** and **2**, the ligation mode of ethynide ligands toward Ag_n baskets is μ_4– rather than μ_5–, though the latter mode is commonly observed in our previous studies [4b,6]. Moreover, the respective ratios of ancillary ligands to the ethynide ligand are also smaller than expected. This is probably due to the significant strength of the silver···iodine interaction, the μ_2–*I* ligation mode, and the rigidity of the iodophenyl ligand which together account for little accessible void space for the accommodation of ancillary ligands. A better understanding of the role of silver···halogen interactions on stabilization of coordination networks needs to be further investigated.

Within the limited number of complexes reported here, all halogen atoms at the *para* position of the phenyl ring are observed to form silver···halogen interactions, while van der Waals type halogen (Cl, Br)···fluoro interactions are observed on all substituents at the *meta* position. This is an interesting phenomenon unnoticed in the past. On the other hand, *ortho* chloro atoms in **6** and **7** form moderate to strong silver···chloro interactions due to their relatively close location to the silver baskets; for the same reason, they are not involved in the generation of higher-dimensional structures.

The silver···fluoro close contacts observed in **8** are different from the silver···chloro(*ortho*) interactions in **6** and **7**: the strong electron-withdrawing fluoro substituent on the phenyl ring facilitates the formation of charge-induced F···π interaction. On the other hand, though the silver···fluoro interaction that involves contacts significantly shorter than the sum of respective van der Waals radii is not well-recognized due to too few reports in the literature, the occurrence of unusually large number of such contacts in one structure indicated its potentially significant role in the stabilization of coordination networks.

The present report demonstrates the feasibility of using halogen-substituted phenylethynide synthons R_X–C≡C⊃Ag_n (n = 4, 5) in the construction of silver(I) coordination and supramolecular networks. Variation on the type and the position of halogen substituents on the phenyl ring leads to network structures of different dimensionality due to the presence of subtle weak interactions in supramolecular organization. Further systematic investigation employing multi-substituted halophenylethynide ligands is required in order to shed additional light on the role of weak supramolecular interactions involving halogen atoms in the stabilization of coordination networks.

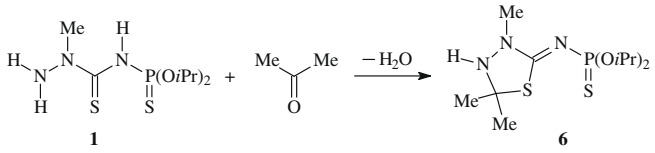
5: Yield: 1.03 g (81%). M.p. 84 °C. ^{1}H NMR ($CDCl_3$): δ = 1.34 (t, $^3J_{H,H}$ = 6.0 Hz, 6H, CH_3, *i*Pr), 1.36 (t, $^3J_{H,H}$ = 6.0 Hz, 6H, CH_3, *i*Pr), 3.13 (d, $^3J_{H,H}$ = 4.7 Hz, 3H, CH_3, Me), 4.67 (d. sept, $^3J_{POCH}$ = 7.3 Hz, $^3J_{H,H}$ = 6.1 Hz, 2H, OCH), 7.25 (br. s, overlapping with the solvent signal, PNH), 9.00 (br. s, 1H, MeNH) ppm. ^{31}P NMR ($CDCl_3$): δ = −6.7 (q, $^3J_{POCH}$ = 6.2 Hz, $^2J_{PNH}$ = 7.5 Hz) ppm. *Anal.* Calc. for $C_8H_{19}N_2O_3PS$ (254.28): C, 37.79; H, 7.53; N, 11.02. Found: C, 37.63; H, 7.59; N, 10.93%.

A solution of **1** (2 mmol, 0.57 g) in anhydrous acetone (10 mL) was left for two days. Afterwards X-ray suitable crystals of **6** were formed.

6: Yield: 0.64 g (98%). M.p. 128 °C. ^{1}H NMR ($CDCl_3$): δ = 1.31 (d, $^3J_{H,H}$ = 6.2 Hz, 6H, CH_3, *i*Pr), 1.32 (d, $^3J_{H,H}$ = 6.2 Hz, 6H, CH_3, *i*Pr), 1.63 (s, 6H, CH_3, $S(CH_3)_2CN$), 3.25 (s, 3H, CH_3, CH_3N), 4.37 (br. s, 1H, NH), 4.76 (d. sept, $^3J_{POCH}$ = 10.9 Hz, $^3J_{H,H}$ = 6.2 Hz, 2H, OCH) ppm. ^{31}P NMR ($CDCl_3$): δ = 67.3 (t, $^3J_{POCH}$ = 10.8 Hz) ppm. *Anal.* Calc. for $C_{11}H_{25}N_3O_2PS_2$ (326.43): C, 40.47; H, 7.72; N, 12.87. Found: C, 40.62; H, 7.66; N, 12.79%.

2.2. Physical measurements



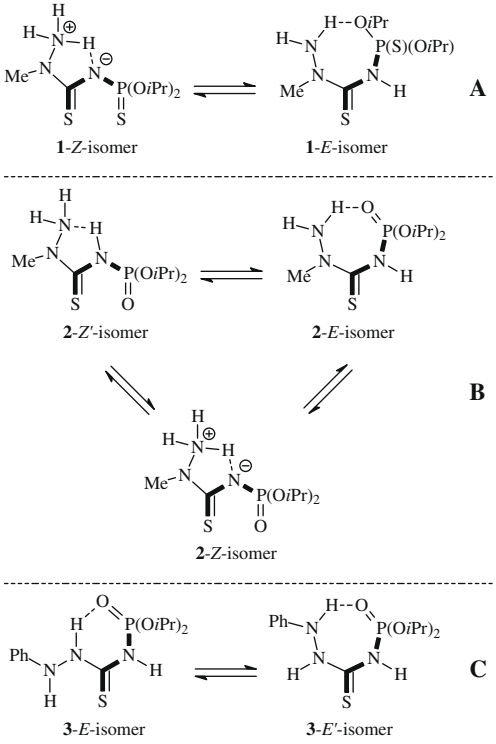
NMR spectra in were obtained on a Bruker Avance 300 MHz spectrometer at 25 °C. ^{1}H and ^{31}P NMR spectra were recorded at 299.948 and 121.420 MHz, respectively. Chemical shifts are reported with reference to $SiMe_4$ (^{1}H) and H_3PO_4 (^{31}P). Elemental analyses were performed on a CHNS HEKAtech EuroEA 3000 analyzer.

2.3. Crystal structure determination and refinement

The X-ray data for **4** was collected on a STOE IPDS-II diffractometer with graphite-monochromatized Mo Kα radiation generated by fine-focus X-ray tube operated at 50 kV and 40 mA. The images were indexed, integrated and scaled using the X-Area data reduction package [12]. Data were corrected for absorption using the PLATON program [13]. The structures were solved by direct methods using the SHELXS-97 program [14] and refined first isotropically and then anisotropically using SHELXL-97 [14]. Hydrogen atoms were revealed from $\Delta\rho$ maps and those bonded to C were refined using appropriate riding models. H atoms bonded to N were freely refined.

3. Results and discussion

Compounds **1–5** were synthesized by the treatment of methylhydrazine, phenylhydrazine or methylamine with the isothiocyanates $(iPrO)_2P(S)NCS$ or $(iPrO)_2P(O)NCS$ (Scheme 1). Recrystallization of **1** from an acetone solution gave the substituted 1,3,4-thiadiazolidine **6** after two days (Scheme 2). It should be noted that the recrystallization of **2** or the ethyl analog NH_2–N(Et)–C(S)–NH–P(S)(O*i*Pr)$_2$ (**7**) do not lead to the formation of the corresponding heterocycle, even when the compounds are heated in acetone solution under reflux for two days. Their compositions were proven by the microanalysis data.



Scheme 2.

Condensation of isocyanates with phenylsubstituted hydrazines are reported to yield 1-substituted semicarbazides [10,15]. The reaction between monoalkylhydrazines and isocyanates give 2-substituted alkyl semicarbazides [10,16] due to the greater nucleophilic character of the secondary amine groups.

The ^{31}P NMR spectra of **1** in $CDCl_3$ and acetone-d_6 contain two signals at 58.6, 64.2 ($CDCl_3$) and 65.9, 67.0 (acetone-d_6) ppm. The integral intensity ratio changes from 3.0:1 to 1.0:1.0 for the high- and low-field signals, respectively. When the crystalline material is dissolved, two lines can be observed in the ^{31}P NMR spectra, indicating that the equilibrium reaction shown in Scheme 3, **A** is slow on the NMR timescale. We suppose that in a solution of **1** both *Z*- and *E*-forms are present, as was previously observed for **7** [10], which are both stabilized by intramolecular hydrogen bonds (Scheme 3 **A**). The high-field signals are in the same region as was observed in the ^{31}P NMR spectra of the thiourea analog **4** (δ = 57.5 ppm). Surprisingly, the low-field signals are in the area characteristic for the deprotonated form of *N*-thiophosphorylated thioureas [7,8]. This fact means that the **1**-*Z*-isomer is in a zwitterionic form (Scheme 3 **A**).

The ^{31}P NMR spectra of **2** contain three signals at −7.4, −4.6 and 4.5 ppm in $CDCl_3$, and two signals at −7.7 and 3.9 ppm in acetone-d_6. The relative integral intensities are 1.4:1.8:1 and 3.5:1.0, respectively. The high-field signals are in the same region as was observed in the ^{31}P NMR spectra of the thiourea analog **5** (δ = −6.7 ppm). Thus, the high-field signal corresponds to the **2**-*E*-isomer, while the signal at −4.6 ppm in $CDCl_3$ solution indicates the occurrence of the **2**-*Z*′-isomer (Scheme 3 **B**). The low-field signals are in the area characteristic for deprotonated *N*-phosphorylthioureas [7,8]. This fact testifies that the *Z*-isomer is partially in the zwitterion (**2**-*Z*′-isomer) form in $CDCl_3$, but is completely in this form in acetone-d_6 solution (Scheme 3 **B**).

Scheme 3.

There are two signals in the ^{31}P NMR spectra of **3** both in $CDCl_3$ and acetone-d_6 solutions. The signals are at −6.0 to −4.6 ppm with integral intensities ratio close to 1:1. The signals have practically the same chemical shift, as was observed for the *N*-phosphorylthiourea Ph–NH–C(S)–NH–P(O)(O*i*Pr)$_2$ [17]. This, along with a non-significant difference in the values for the high- and low-field signals, testifies about the one *E*-isomer form, but with different hydrogen bond formations (Scheme 3 **C**).

The substituted 1,3,4-thiadiazolidine **6** shows one signal at 67.3 ppm in the ^{31}P NMR spectrum. The signal is in the area characteristic for deprotonated *N*-thiophosphorylthioureas [7,8].

The ^{1}H NMR spectra of **1–6** contain all the characteristic signals (see Section 2).

Crystals of **5** were obtained by recrystallization from a dichloromethane–*n*-hexane solution (Table 1). The molecular conformation is shown in Fig. 1, and geometric parameters are given in Table 2. Compound **5** crystallizes in the space group $P2_1/c$. The parameters of the C=S, C–N, P–N and P=O bonds observed for **5** (Table 2) are in the typical range for *N*-phosphorylated thiourea derivatives [7,8,18]. The S(1)–C(1)–N(1)–P(1) backbone in the crystal phase has an *E*-conformation. The crystal structure of **5** is stabilized by an intramolecular hydrogen bond of the type N(2)–H(2)···O(3)=P(1). Molecules of **5** in the crystal structure form polymeric chains due to N(1)–H(1)···O(3)#1=P(1)#1 H-bonds (Table 4).

Crystals of **6** were obtained by recrystallization of **1** from an acetone solution (Table 1). The molecular conformation is shown in Fig. 2, and geometric parameters are given in Table 3. Compound **6** crystallizes in the space group *P*−1. There are intermolecular hydrogen bonds of the type N(3)–H(3)···S(1)#1–P(1)#1 in the crystal (Table 4), which are formed between the sulfur atoms of the P=S groups and the hydrogen atoms of the NH fragment of two molecules. As a result of the intermolecular interactions, a

E-isomer of the C(1)–S(2) and P(1)–N(1) fragments. The phosphorus atom is in a distorted-tetrahedral environment. The five-membered heterocycle is in a half-chair conformation with a maximal deviation of the N(3) [0.1909(19)°] and C(3) [−0.222(2)°] atoms from the least-square plane.

4. Conclusions

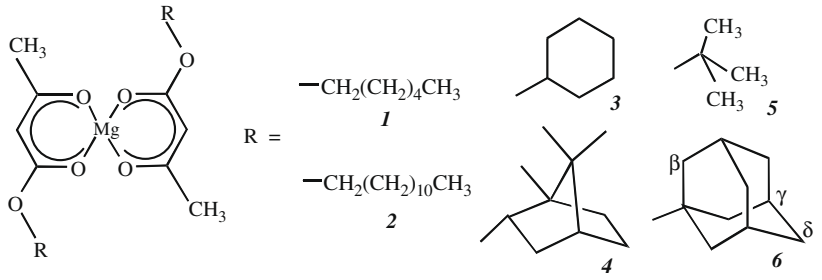
In summary, we have demonstrated the syntheses of new *N*-(thio)phosphorylated thiosemicarbazides and thioureas by the addition of (thio)phosphorylisothiocyanate to the corresponding hydrazine or amine.

An *E*-arrangement of the C=S and P–N bonds in the SCNP backbones was found for the thiosemicarbazide **3** and thioureas **4** and **5**. The thiosemicarbazides **1** and **2** are presence as a mixture of *E*- and *Z*-conformation isomers, stabilized by H-bonds in $CDCl_3$ and acetone-d_6 solutions. It was also established that the *Z*-isomers are partially or completely in the zwitterionic form.

Recrystallization of **1** from acetone solution gave the substituted 1,3,4-thiadiazolidine **5** after two days. Nothing similar was observed for **2** and the ethyl analog **7**.

Single crystal X-ray diffraction studies showed that the thiourea **5** forms both intra- and intermolecular hydrogen bonds, which in turn lead to polymeric chain formation. According to the X-ray data, the substituted heterocycle **6** forms intermolecular hydrogen bonds. As a result of the intermolecular interactions, a centrosymmetric dimer is formed.

5. Supplementary data



CCDC 720583 and 720584 contains the supplementary crystallographic data for 5 and 6. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

be stored for a long time (over a month) over molecular sieves without losing its fitness as a solvent for the syntheses described below.

2.2. Synthesis of the complexes

Bis(ethyl acetoacetato)magnesium(II) ($(EtAcac)_2Mg$) was synthesized by the procedure described in [10], mp 253–254 °C (lit. 250–252 °C).

Magnesium β-ketoesterates of higher alcohols were synthesized by two methods.

Method 1: To a solution of the proligand (30 mmol) and anhydrous triethylamine (30 mmol, 3.03 g) in dry DMF (200 ml) was added dropwise a solution of anhydrous magnesium chloride (15 mmol, 1.43 g) in dry DMF (70 ml) with vigorous stirring under an argon atmosphere. On termination of the addition, the reaction mixture was stirred for another 3 h. The starting substances were fed and the reaction was carried out in complete isolation from atmospheric moisture. DMF-soluble magnesium complexes were isolated as follows. On the termination of stirring, the precipitate $(C_2H_5)_3N{\cdot}HCl$ was filtered off, and the solvent was evaporated under 25 hPa vacuum. The solid residue was dried under 12 Pa vacuum at 60 °C to remove the remnants of the solvent; the pure complexes were isolated by crystallization. DMF-insoluble magnesium complexes (derivatives of *tert*-butyl, cyclohexyl and 1-adamantyl acetoacetate) precipitated as a result of the reaction in the form of a voluminous white precipitate. The precipitate was filtered off and washed twice with distilled water by vigorous stirring for 3 h to remove $(C_2H_5)_3N{\cdot}HCl$. The end product was dried under 12 Pa vacuum at 60 °C for 2 h and then purified by crystallization or washed with a hot solvent.

Method 2 (ligand-exchange route): The synthesis was carried out by gradual and continuous distilling of acetylacetone at 13 hPa and 60 °C off a solution of bis(acetylacetonato)magnesium(II) (3 mmol, 670 mg) in 100 ml of dimethylacetamide containing the higher β-ketoester (6 mmol). The course of the process was monitored and its exchange mechanism verified by means of a qualitative reaction of $FeCl_3$ with acetylacetone contained in the distillate. On the termination of the process, the oily residue was held under 12 Pa vacuum at 60 °C for 2 h to remove the traces of the solvent, then treated with hexane (or ethanol in the case of cyclohexyl acetoacetate), and the end product precipitate formed in this case was filtered off, then purified by crystallization.

2.2.1. Bis(hexyl acetoacetato)magnesium(II)

Complex **1** was prepared by method 1 using hexyl acetoacetate (30 mmol, 5.58 g), and was purified by crystallization from hexane at 5 °C. Yield: 4.7 g, 81%. *Anal.* Calc. for $C_{20}H_{34}O_6Mg$ (MW 394.79): C, 60.85; H, 8.68. Found: C, 60.81; H, 9.01%. Mp 152–154 °C. IR (KBr, cm^{-1}): 2863, 2931, 2959, 1659 (shoulder), 1637, 1565, 1526, 1471, 1429, 1386, 1365, 1289, 1263, 1182, 1080, 1016, 986, 956, 918, 778, 731, 599, 573, 510, 437.

Complex **1** was also prepared by method 2 using hexyl acetoacetate (6 mmol, 1.12 g), and was purified by crystallization from hexane at 5 °C. Yield: 861 mg, 73%. The compound was identified by its melting point and by comparing IR spectra of samples prepared by methods 1 and 2.

2.2.2. Bis(dodecyl acetoacetato)magnesium(II)

Complex **2** was prepared by method 1 using dodecyl acetoacetate (30 mmol, 8.11 g), and was purified by crystallization from hexane at 5 °C. Yield: 7.12 g, 85%. *Anal.* Calc. for $C_{32}H_{58}O_6Mg$ (MW 563.11): C, 68.26; H, 10.38. Found: C, 68.15; H, 10.75%. Mp 122–124 °C. IR (KBr, cm^{-1}): 2854, 2925, 2956, 1656 (shoulder), 1634, 1566, 1521, 1473, 1418, 1397, 1374, 1294, 1262, 1181, 1083, 1016, 962, 913, 774, 738, 711, 595, 519, 433.

Complex **2** was also prepared by method 2 using dodecyl acetoacetate (6 mmol, 1.62 g), and was purified by crystallization from hexane at 5 °C. Yield: 1.26 g, 75%. The compound was identified by its melting point and by comparing IR spectra of samples prepared by methods 1 and 2.

2.2.3. Bis(cyclohexyl acetoacetato)magnesium(II)

Complex **3** was prepared by method 1 using cyclohexyl acetoacetate (30 mmol, 5.52 g). Yield: 5.45 g, 93%. *Anal.* Calc. for $C_{20}H_{30}O_6Mg$ (MW 390.76): C, 61.48; H, 7.74. Found: C, 61.89; H, 7.90%. Mp 302–305 °C (decomposition). IR (KBr, cm^{-1}): 2939, 2856, 1656 (shoulder), 1632, 1548, 1458, 1424, 1370, 1320, 1276, 1181, 1132, 1067, 1028, 998, 964, 914, 880, 850, 829, 775, 736, 608, 563, 538, 488, 459, 419.

Complex **3** was also prepared by method 2 using cyclohexyl acetoacetate (6 mmol, 1.1 g). Yield: 875 mg, 75%. The compound was identified by its melting point and by comparing IR spectra of samples prepared by methods 1 and 2.

2.2.4. Bis(bornyl acetoacetato)magnesium(II)

Complex **4** was prepared by method 1 using bornyl acetoacetate (30 mmol, 7.15 g), and was crystallized from toluene at 5 °C. Yield: 5.9 g, 79%. *Anal.* Calc. for $C_{28}H_{42}O_6Mg$ (MW 498.94): C, 67.41; H, 8.48. Found: C, 67.58; H, 8.54%. Mp 289–291 °C (decomposition). IR (KBr, cm^{-1}): 2939, 2856, 1656 (shoulder), 1632, 1548, 1458, 1424, 1370, 1320, 1276, 1181, 1132, 1067, 1028, 998, 964, 914, 880, 850, 829, 775, 736, 608, 563, 538, 488, 459, 419.

Complex **4** was also prepared by method 2 using bornyl acetoacetate (6 mmol, 1.43 g), and was purified by crystallization from toluene at 5 °C. Yield: 1.05 g, 70%. The compound was identified by its melting point and by comparing IR spectra of samples prepared by methods 1 and 2.

2.2.5. Bis(tert-butyl acetoacetato)magnesium(II)

Complex **5** was prepared by method 1 using *tert*-butyl acetoacetate (30 mmol, 4.74 g), and was purified by repeated washing with hot toluene. Yield: 4.52 g, 89%. *Anal.* Calc. for $C_{16}H_{26}O_6Mg$ (MW 338.68): C, 56.74; H, 7.74. Found: C, 57.05; H, 7.94%. Mp

276–278 °C (decomposition). IR (KBr, cm^{-1}): 2932, 2981, 3010, 1656 (shoulder), 1634, 1543, 1481, 1466, 1456, 1428, 1396, 1373, 1296, 1283, 1260, 1196, 1166, 1071, 1039, 1001, 964, 837, 779, 738, 592, 568, 470, 433.

2.2.6. Bis(1-adamantyl acetoacetato)magnesium(II)

Complex **6** was prepared by method 1 using 1-adamantyl acetoacetate (30 mmol, 7.1 g), and was crystallized from toluene at 5 °C. Yield: 6.4 g, 87%. *Anal.* Calc. for $C_{28}H_{38}O_6Mg$ (MW 494.91): C, 67.95; H, 7.74. Found: C, 67.82; H, 8.18%. Mp 305–306 °C. IR (KBr, cm^{-1}): 2854, 2910, 1659 (shoulder), 1633, 1548, 1458, 1424, 1365, 1348, 1323, 1280, 1258, 1186, 1114, 1080, 1054, 1037, 999, 965, 914, 875, 803, 782, 756, 739, 718, 684, 620, 591, 532, 450, 424.

2.3. Physical measurements

The IR spectra were recorded in KBr pellets in the range 4000–400 cm^{-1} on a SPECORD M 80 spectrophotometer equipped with an IBM-compatible operating computing system. The elemental analysis was carried out on a CARLO ERBA 1106 analyzer.

The ^1H NMR spectra were recorded on a VARIAN VXR-300 spectrometer in $CDCl_3$ and DMSO-d6 solutions with an internal TMS standard. The ^{13}C NMR spectra were recorded on a BRUKER AVANCE 400 spectrometer in $CDCl_3$, DMSO-d6 and C_7D_8 (toluene-d8) solutions with an internal TMS standard.

2.4. X-ray crystallography

Suitable colorless single crystals of complex **6** were formed by crystallization from toluene. The single crystal X-ray diffraction data collection for the complex was performed on a BRUKER SMART APEX II diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 100 K. Reflection intensities were integrated using SAINT software and corrected for absorption by a numerical method using SADABS [11]. The structure was solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXTL software package [12]. All non-hydrogen atoms were refined anisotropically. During the structure refinement, the atoms of the disordered toluene solvent molecule near the threefold axis, which is perpendicular to the aromatic ring plane, were observed but could not be modelled satisfactorily. The SQUEEZE routine in PLATON [13] was used to modify the structure factors in the HKL file, which correspond to the disordered toluene molecule. Two molecules of toluene correspond to one molecule of complex in the unit cell. All hydrogen atoms were positioned geometrically and refined using a riding model with $U_{iso}(H) = 1.5U_{eq}(C)$ for CH_3 and $U_{iso}(H) = 1.2U_{eq}(C)$ for CH and CH_2 groups. A summary of the crystal data, data collection parameters and convergence results are compiled in Table 1.

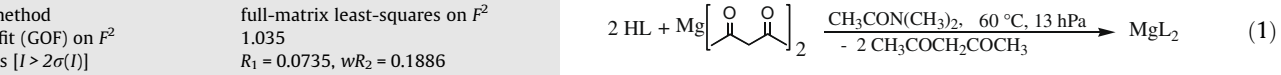
Largest difference in peak and hole (e Å^{-3})	0.810 and −0.577

3. Results and discussion



3.1. Synthesis

For magnesium β-diketonates, synthesis methods based on the reaction of metallic magnesium with dicarbonyl proligand HL in a water–ethanol solution (or toluene) and on exchange reactions between a magnesium salt and NaL or HL in an aqueous-alcoholic medium were proposed [14]. Magnesium complexes are always isolated from water-containing solutions as $MgL_2{\cdot}2H_2O$ hydrate. Since β-dicarbonyl compounds of magnesium are very prone to add water molecules and other Lewis bases, to obtain pure MgL_2 products is a non-trivial problem [1]. This concerns equally other magnesium complexes, such as carboxylates [15]. Anhydrous volatile complexes of magnesium with β-diketones are purified by sublimation. Among the unconventional methods, the solid-phase synthesis of magnesium β-diketonates is noteworthy [16]; sublimation is also employed in this case to purify the products.

At the same time, the use of procedures, developed for β-diketonates, for the synthesis of bis-chelates of magnesium with β-ketoesters involves a big problem, namely the possibility of transesterification or hydrolysis of the proligand in the course of the reaction. These side processes are noticeably catalyzed by alkalis. For this reason, the exchange reaction with magnesium methylate in absolute methanol is unsuitable, which is confirmed by the results given by Baker et al. [17] for a NMR spectroscopic study of the H^+-D^+ equilibrium between the magnesium complex $(CH_3O)_2MgL'$ (HL′ = methyl acetoacetate) and deuterated methanol in the presence of magnesium methylate.

Zaugg et al. described the preparation of a complex of magnesium with ethyl acetoacetate by the interaction of magnesium oxide (fresh calcined) with the proligand in benzene with azeotropic removal of water [10]. Our attempts to reproduce this procedure for β-ketoesters of higher alcohols have failed. This fact may be accounted for as proceeding from spatial concepts. Probably, the presence of bulky substituents hinders the simultaneous access of two proligand molecules to the magnesium oxide molecule.

The literature reports a method for the preparation of higher metal β-diketonates from acetylacetone derivatives by an exchange reaction (the reaction was carried out under hard conditions: 160 °C, in a CO_2 stream) [18]. The idea of this method was utilized by us for the synthesis of magnesium β-ketoesterates under mild conditions with continuous, slow removal of acetylacetone together with the solvent under vacuum. A disadvantage of the method is partial resinification of the reaction mass, which complicates the purification of products and makes it unsuitable in the case of β-ketoesters of tertiary alcohols.

(1)

It turned out in practice that an alternative method, which involves the interaction between anhydrous magnesium chloride in an aprotic solvent and β-ketoesters in the presence of triethyl-

[a] Signals due to the presence of oligomer.

amine under the conditions of complete isolation from atmospheric moisture, is most suitable. The experimental technique which is employed in the syntheses of organolithium compounds is well suited for this method [19].

$$2\,HL + MgCl_2 \xrightarrow[DMF]{+\,2\,(C_2H_5)_3N} MgL_2 + 2\,(C_2H_5)_3N{\cdot}HCl \qquad (2)$$

The coordination compounds obtained are stable against atmospheric moisture; they are also stable against water when being washed free from amine hydrochloride. The preparation of identical compounds by two alternative synthesis methods is one of the proofs of their chemical structure.

3.2. Infrared spectra

When interpreting the IR spectra, special attention was paid to the range 1750–1450 cm^{-1}, where disappearance of absorption bands of parent β-ketoesters ($\nu_{(c=o)}$, 1750–1720 cm^{-1}) was observed, and absorption bands of stretches of the C–O and C–C bonds conjugated in the chelate ring (1640–1400 cm^{-1}) appeared. In the low frequency region, absorption bands appeared, which may be assigned to M–O bond stretches, mixed with chelate ring deformation vibrations (600–550 cm^{-1}) and C–CH_3 deformation vibrations [20]. IR spectra corroborate the absence of coordinated water in the molecules of the magnesium complexes synthesized.

3.3. ^{1}H and ^{13}C NMR spectra

Anhydrous alkaline-earth β-diketonates, such as magnesium β-diketonates, are known to be coordinatively unsaturated compounds, which gives rise to the formation of strong intermolecular bridge bonds and oligomerization of these complexes [21]. For alkaline-earth complexes, the presence of oligomeric forms both in solution and in the gas phase, as well as for derivatives containing branched alkyl substituents (dipivaloylmethane) has been established [22,23]. In comparison with β-diketonates, in complexes of magnesium with β-ketoesters formation of extra intermolecular bonds through the ester group oxygen atom may be assumed, due to which they may be still more associated. On the other hand, the complexes under investigation contain bulky alkyl groups, the steric effects of which must affect the degree of oligomerization [1]. The presence of oligomeric forms of the complexes in solutions can be indicated by the splitting of signals in ^{1}H NMR spectra [24].

Signals in the ^{1}H NMR spectra of the complexes under investigation were assigned by comparing them with the spectrum of the simplest analog, bis(ethyl acetoacetato)magnesium(II), and

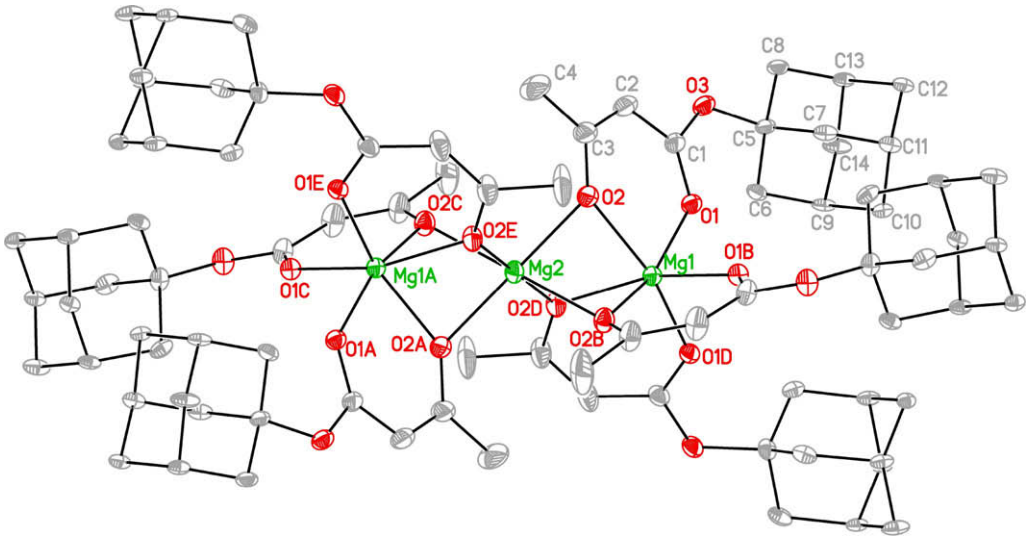

Fig. 1. Molecular structure of $(AdAcac)_2Mg$ (**6**). Hydrogen atoms are omitted for clarity.

taking into account the integral intensities of the peaks. In the spectrum of $(EtAcac)_2Mg$ there are a classical triplet (1.11 ppm, $J = 7$ Hz) and a classical quartet (3.90 ppm, $J = 7$ Hz) of ethoxy group protons, as well as singlets of the methyl group and methine proton in a strong and a weak field respectively.

The ^1H NMR spectra of the magnesium β-ketoesterates synthesized are complex in character. In a strong field, they are a sequence of overlapping multiplets, which is due to the peculiarities of the stereochemical structure of the hydrocarbon skeleton of the ester group. At the same time, the non-equivalence of multiplet splitting in the resonance region of the chelate ring methine proton (weak-field region) in the spectra of the same compound in solvents with different donor properties indicates that the compounds under investigation exist in solutions as a monomer–oligomer equilibrium. Chemical shifts of the main signals of the ^1H NMR spectra are listed in Table 2.

To obtain additional information, which allows one to determine the structure of the synthesized magnesium complexes in solution, we made use of ^{13}C NMR spectroscopy. Spectra of complex **1** in DMSO, $CDCl_3$ and C_7D_8 have been taken. As could be expected for a monomer, there are 10 individual ^{13}C $\{^1H\}$ resonance signals: 186.71 (OCO), 171.72 ($OCCH_3$), 82.53 (CH chelate ring), 61.80 (OCH_2), 31.35 ($OCCH_3$), 29.23, 27.86, 25.44, 22.41 (CH_2), 14.23 ppm (CH_3) in the spectrum of a solution of complex **1** in DMSO. The spectra of solutions of complex **1** in $CDCl_3$ and C_7D_8 are a superposition of peaks due to the presence of the monomer and oligomer.

3.4. Structure of bis(1-adamantyl acetoacetato)magnesium(II)

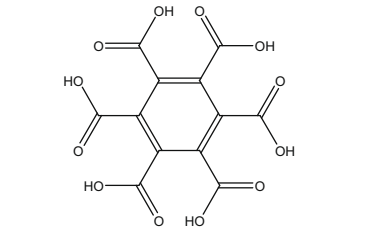
The molecular structure of **6**, along with the atom labelling scheme, is shown in Fig. 1. Selected bond lengths and angles are summarized in Table 3. Complex **6** crystallizes in the trigonal system with one molecule per unit cell. The asymmetric unit contains 1/6 of the compound. The whole molecule is generated by the inversion centre and the threefold axis. All Mg atoms occupy special positions on the threefold axis. Compound **6** is centrosymmetrical; Mg2 occupies a position on the inversion centre. The distance between neighboring magnesium atoms is 2.8779(18) Å. The Mg1 and Mg1A atoms are coordinated by ligand molecules with the formation of planar β-dicarbonylic metallocycles and form a distorted octahedral coordination environment (Fig. 1) with bond lengths and angles (Table 3) which are in good agreement with the related structure of $(EtAcac)_2Mg$ [25]. The mean deviation from the metallocycle plane (Mg1–O1–C1–C2–C3–O2) is 0.0111 Å; the torsion angles between the planes are 73.7°. The C1–O1 and C2–C3 lengths (Table 3) characterize the presence of double bonds between the corresponding atoms, which is characteristic of β-dicarbonyl complexes. The Mg2 coordination polyhedron is formed by bridging oxygen atoms (O2, O2A, O2B, O2C, O2D, O2E), which create a slightly distorted octahedron with a Mg2–O2 length of 2.079(2) Å and angles: O2–Mg2–O2C = 101.74(9)°, O2–Mg2–O2B = 78.26(9)°, O2–Mg2–O2A = 180.00 ° (Fig. 1).

Table 3
Selected bond lengths and bond angles for $(AdAcac)_2Mg$.

Bond Lengths (Å)		Angles (°)	
Mg1–O1 N	2.029(2)	O1–Mg1–O1A	92.00(10)
Mg1–O2 N	2.101(2)	O1–Mg1–O2B	107.32(9)
Mg2–O2 N	2.080(2)	O1–Mg1–O2A	85.22(8)
Mg1–Mg2	2.8799(17)	O1–Mg1–O2	160.55(9)
C1–O1	1.247(4)	O2–Mg1–O2A	77.30(11)
C3–O2	1.305(5)	O2C–Mg2–O2	180.00(9)
C1–C2	1.417(5)	O2D–Mg2–O2	101.76(9)
C2–C3A	1.344(6)	O2B–Mg2–O2	78.24(9)
		Mg2–O2–Mg1	87.08(9)
		Mg1–Mg2–Mg1A	180.0

4. Conclusions

The reaction of anhydrous magnesium salt with proligand in aprotic solvent in the presence of triethylamine under conditions of complete isolation from atmospheric moisture is most suitable for the preparation of anhydrous complexes of magnesium with β-ketoesters of higher alcohols. This method is apparently universal and can be used for the synthesis of anhydrous β-ketoesterates of other metals.



Taking into account that bis(1-adamantyl acetoacetato)magnesium(II) is a trimer in the crystalline state, it may be assumed with a high degree of probability that the other magnesium β-ketoesterates, which contain less bulky substituents, also have a trimeric structure. The compounds can exist in solutions as monomers or as a monomer–oligomer mixture, depending on the electron-donating properties of the solvent. The solubility of the synthesized complexes in a number of organic solvents, including non-polar ones, can be utilized to develop efficient drug formulations using Solid Lipid Nanoparticles (SLN) technologies.

Supplementary data

CCDC 686206 contains the supplementary crystallographic data for **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

mellitic acid (mlt)

diethylenetriamine (dien)

spermidine (spd)

Chart 1.

weighing; diethylenetriamine (Aldrich) was transformed into the corresponding hydrochloride and was used in this form. The purities of mlt, dien and spd, checked by potentiometric titrations with standard solutions of NaOH, were always higher than 99.5%. Sodium hydroxide and hydrochloric acid solutions were prepared by diluting concentrated Fluka ampoules and were standardised against potassium biphthalate and sodium carbonate, respectively. All the solutions were prepared by using ultrapure water (conductivity < 0.1 μS cm^{-1}) and grade A glassware.

2.2. Potentiometric measurements

Potentiometric titrations were carried out (at 25.0 ± 0.1 °C) using an apparatus consisting of a Metrohm Model 713 potentiometer, equipped with a combined glass electrode (Ross type 8102, from Orion) and a Metrohm Model 765 motorized burette. Estimated accuracy was ±0.2 mV and ±0.003 mL for e.m.f. and titrant volume readings, respectively. The apparatus was connected to a PC, and automatic titrations were performed using a suitable computer program to control titrant delivery, data acquisition and to check for e.m.f. stability. All titrations were carried out under magnetic stirring and presaturated N_2 was bubbled through the purified solution in order to exclude O_2 and CO_2 inside. A volume of 25 mL of the solution containing mlt at $C_L = 0.001$, 0.002 mol L^{-1} and the amine hydrochloride at $C_A = 0.001$ mol L^{-1} was titrated with standard NaOH up to 80–90% neutralization. Separate titrations of HCl at the same ionic strength as the sample under study, were carried out to determine standard electrode potential E^0 and to obtain pH $-\log [H^+]$ readings. The reliability of the calibration in the alkaline range was checked by calculating pK_w values.

2.3. Calorimetric measurements

The measurements were carried out using a Tronac model 450 Isoperibolic Titration calorimeter, coupled with a Keithley 196 system Dmm digital multimeter. A volume of 50 mL of solution, containing amine hydrochloride at $C_A = 0.001$, 0.002 mol L^{-1} and at $t = 25.000 \pm 0.001$ °C was titrated with a Na_6mlt standard solution. The titrant was delivered by a 2.5 mL capacity Hamilton syringe, model 1002TLL. A computer program was used for the acquisition of calorimetric data. Accuracy was checked by titrating a THAM (Tris-(hydroxymethyl)amino-methane) buffer with HCl. The heat of dilution was measured before each experiment. The accuracy of calorimetric apparatus was $Q \pm 0.008$ J and $v \pm 0.001$ cm^3.

2.4. Diffractometric measurements

Colourless crystals with an average radius of 0.2 mm were obtained by slow evaporation from water solutions. Data were collected on a a four-circles P4 Siemens diffractometer [Mo Kα ($\lambda = 0.71073$ Å)]. Cell parameters were obtained by the least-square refinement of centred angles referred to about 35 reflections in the $3.03 \leqslant 2\theta \leqslant 14.16°$ range. All reflections were collected at a fixed rate with the ω-scan technique up to $2\theta = 50°$. No decay was detected monitoring three standard reflections every 197 collected data. When necessary, Lorenz polarization and profile fitting corrections were achieved [18]. Data collections and reductions were accomplished by P3/V (Release 4.21/V. Siemens Analytical X-Ray Instruments Inc., Madison, Wisconsin, USA).

2.5. Calculations

All the parameters relative to alkalimetric purity determination were refined using the nonlinear least squares computer program ESAB2M. Formation constants were calculated using the nonlinear least squares computer programs STACO and BSTAC. Speciation profiles were obtained using the computer program ES4EC. Details of calculation methods and programs have already been reported [19].

Formation constants were extrapolated to zero ionic strength as already reported [20]. Both BSTAC and STACO computer programs can deal with potentiometric data obtained in variable ionic strength conditions. The dependence on ionic strength of formation constants was taken into account using the Debye–Hückel type equation:

$$\log \beta = \log^T \beta - z^* 0.51 \sqrt{I}/(1 + 1.5\sqrt{I}) + CI \quad (1)$$

where

$$C = (0.025 \pm 0.015) z^*, \quad \text{at } I \leq 0.15$$

$$z^* = \Sigma z^2_{\text{reactants}} - \Sigma z^2_{\text{products}}$$

(β = stoichiometric formation constant; ${}^T\beta$ = formation constant at infinite dilution; z = component charge).

Calorimetric titration data were analysed by the computer program ES5CM [21]. Concentrations and thermodynamic parameters are given in the molar scale. Errors are given as standard devia-

tions. Protonation thermodynamic parameters of mlt, dien and spd used in the calculations are shown in Table 1 at I = 0 mol L^{-1} and t = 25 °C [9,13,22–25]. The interactions of amines with Cl$^-$ [23,25] and mellitate with Na$^+$ [13] were taken into account in the calculations.

Structures were solved by the new SIR2004 [26] and the refinement was managed by SHELXL97 [27]. In both structures a water molecule too disordered by dynamic or statistical motions was treated with the squeeze exclusion from the used reflection data. Published material was organized with the whole WINGX package [28] along with PARST97 [29]. Crystal data and structure refinement for I (dien–mlt) and II (spd–mlt) were reported in Table 2.

3. Results and discussion

3.1. Formation and stability of triamine–mellitate species and predictive relationships

Formation constants of dien–mlt and spd–mlt species were obtained by performing on the potentiometric data several trials with different sets of complex species. The speciation models selected, for both sytems, are those which very well fit experimental data. Tables 3 and 4 show thermodynamic formation parameters at t = 25 °C and I = 0, 0.15 mol L^{-1} in NaCl, according to the following reactions (charges omitted):

$$pA + L + rH = A_pLH_r \quad (2)$$

$$pH_iA + H_jL = A_pLH_r \quad pi + j = r \quad (3)$$

where A = amine and L = mellitate anion.

It was found for both systems the formation of species with p = 1 and r = 2…5. In addition, were also found the following species: A_2LH_6, for A = dien; ALH_6, for A = spd. As can be seen the stability of these species is quite high and increases with the charge of both polyammonium cation and polycarboxylic anion, reaching a maximum value when the amine is completely protonated and the ligand completely deprotonated. This trend was also observed in the preceding works on species formed by several polyamines and inorganic, carboxylic and nucleotidic ligands [9,10]. The comparison between the formation constant values of dien–mlt species with those of spd–mlt species having the same stoichiometry, shows high differences: $\Delta\log\beta$ (difference between logβ^0 of

			total	0.53 ± 0.02	0.345 ± 0.02			

[a] At I = 0.15 mol L^{-1} in NaCl.
[b] ζ = Charge product = $z_{cation}|z_{anion}|$.
[c] Expressed in kJ mol^{-1}.

spd–mlt species with $\log\beta^0$ of dien–mlt species) for ALH_2, ALH_3, ALH_4, ALH_5 species, are 3.52, 6.21, 5.42, 6.35, respectively. Since the most probable reactions, referring to the same A_pLH_r species, are different for species containing dien respect to those containing spd, to give a more reliable picture of the stability it is better to compare log*K* values showed in Table 4. When the charges involved in the formation reaction are the same, these differences are not high. Moreover, there is a very good linear trend of log*K* versus ζ (charge products = z_{cation} $|z_{anion}|$): $\log K^0/\zeta = 0.51 \pm 0.08$, 0.55 ± 0.08, for dien and spd systems, respectively and $\log K^0/\zeta = 0.53 \pm 0.02$ considering dien and spd systems altogether; $\log K/\zeta$ (at $I = 0.1$ in NaCl) = 0.33 ± 0.06, 0.36 ± 0.07, for dien and spd systems, respectively and $\log K/\zeta = 0.345 \pm 0.02$ considering dien and spd systems altogether (see Table 4). By using the crude approximation $n = \zeta/2$, where n is the number of possible salt bridges, we obtain a mean formation free energy:

$$-\Delta G^0 = 6.1 \pm 0.3 \text{ kJ mol}^{-1}$$

which is consistent with $-\Delta G^0 = 6.3$ kJ mol^{-1} for species formed by several amines with several carboxylic ligands, as reported in our preceding work [10]. As pointed up in preceding works [6,30], the influence of the structure on the stability, such us the length of the methylene chain in the diamines and in general the distance between aminogroups, is a less important factor respect to that constituted by the charges in the formation reaction. Nevertheless the charges distance in the cation molecule is a factor to take in consideration for the prediction of the stability of these types of complexes. In fact the predictive power of equations containing the ζ term was generally increased by the introduction of a term which accounts for the distance of aminogroups. As an example the $R_{C/N}$ parameter, *i.e* the ratio of the number of C atoms with respect N atoms, is 1.33 for dien and 2.33 for spd [30,31]. It was found that the distance between the charges in the protonated amine is an unfavourable factor for the stability for species containing pyrophosphate or ATP. The species containing mlt show an opposite trend: when the charges involved in the formation reaction are the same, the species spd–mlt are more stable than those of dien.

3.2. ΔH and $T\Delta S$ contributions

Enthalpic and entropic formation parameters of the dien–mlt and spd–mlt species, according to the reactions 2 and 3, are shown in Tables 3 and 4, respectively. The formation of these species is generally exothermic, except for the reactions: $2H_3A^{3+} + L^{6-} = A_2LH_6^0$, with A = dien and $H_3A^{3+} + L^{6-} = ALH_3^{3-}$, with A = spd. This is in line with the results of Ref. [10], where, for the reaction of fully protonated amines with unprotonated carboxylate ligands ($j = 0$, in Eq. (3)), ΔH^0 values were always positive. $T\Delta S^0$ values are also a fairly linear function of charges involved in the formation reaction: for example $T\Delta S^0/\zeta = 0.4 \pm 1.6$ kJ mol^{-1} for dien system. Table 5 reports formation enthalpy and entropy values of the species formed by spd with citrate (cit), 1,2,3-tricarballylate (tca), 1,2,3,4-butanetetracarboxylate (btc) [9] and mlt, referring to the reaction of completely protonated amine with unprotonated carboxylate ligand, confirming the strict dependence of them on the ligand charge.

Table 5
Comparison of thermodynamic formation parameters[a] of spd-carboxylate species at $I = 0$ mol L^{-1} and $t = 25$ °C.

[c] Expressed in kJ mol^{-1}.

3.3. Relevance of triamine–mellitate species

Speciation diagrams of the dien–mlt and spd–mlt systems clearly show the differences between them. Primarily, the formation percentages of spd–mlt species are higher than those containing dien and secondarily, the ALH_3 species formed by spd is absolutely predominant in a wide pH range (pH 6–9).

In the dien–mlt system, at $C_A = C_L = 1$ mmol L^{-1}, without background salt and $t = 25$ °C (Fig. 1a): in the acidic pH range 3–5, the ALH_5 species prevails, with a maximum formation percentage of 50.8 at pH 3.8; the ALH_4 and A_2LH_6 species achieve the formation percentages of 35.5 at pH 5.1 and 12.8 at pH 4.8, respectively. In the pH range 7–8, of interest for many natural waters, the main species are ALH_2 and ALH_3: at pH 7, $\%ALH_2 = 36.3$, $\%ALH_3 = 53.9$; at pH 8, $\%ALH_2 = 85.1$, $\%ALH_3 = 4.3$. At higher pH values the formation percentages of ALH_2 further increase (90.6, at pH 8.6). In the spd–mlt system (Fig. 1b), in the same conditions discussed for dien–mlt system, in the acidic pH range 2–5, ALH_6 and ALH_5 species achieve high formation percentages: the former, 69%, at pH 2.9; the latter, 73.4%, at pH 4.5; ALH_4 represents a minor species, with a maximum formation percentage of 15.5, at pH 5.2. In the pH range 7–8, there is almost only the ALH_3 species, with formation percentages from 99.1 to 98.7. At pH 9.5, ALH_3 species prevails with a formation percentage of 71.8 and ALH_2 achieves 27.9%.

3.4. Sequestering ability of mellitate towards amines and dependence on ionic strength, temperature and pH

The sequestering power of a ligand towards a metal or a cation such as a protonated amine can be expressed by the function $\sum(\%)$

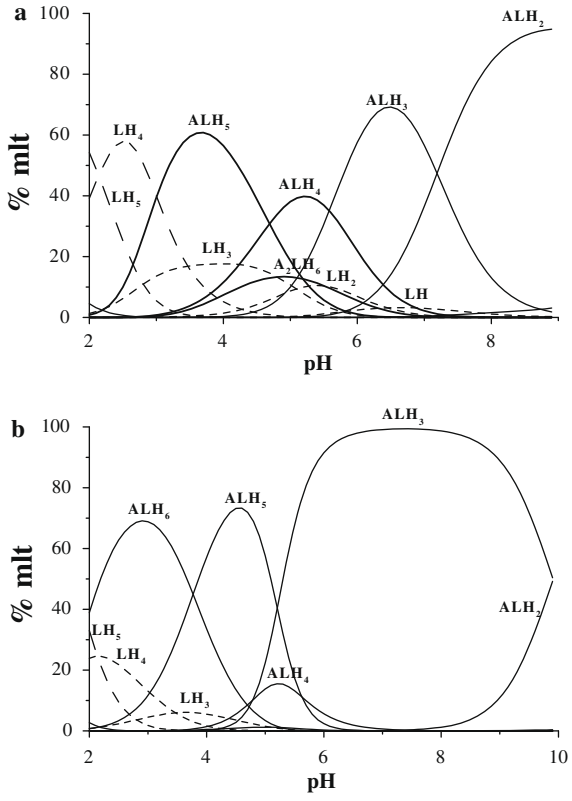

Fig. 1. Speciation diagrams of amine (A)-mlt (L) vs. pH at $C_A = C_L = 1$ mmol L^{-1}, without background salt and $t = 25$ °C. Indexes refer to reaction (2). Ligand protonated species are shown by dashed lines. (a): A = dien; (b): A = spd.

versus pL, where $\sum(\%)$ is the total percentage of amine protonated complexed and $pL = -\log [L]_{tot}$. Since this function is a typically sigmoidal curve (or a dose response curve), which rapidly increases over a relatively small change in concentration, we can use the Boltzmann type equation (with asymptotes of 100 for $pL \to -\infty$ and 0 for $pL \to +\infty$):

$$\Sigma(\%) = 100 \times \left[\frac{1}{1 + e^{(pL - pL_{50})/S}} - 1\right] \quad (4)$$

where pL_{50} is an empirical parameter, which defines the ligand concentration necessary to sequester 50% of cation and S is a measure of the slope in flex of the function ($\sum\%$) versus pL. The pL_{50} parameter is very useful because gives a representation of the binding ability of a ligand (L) towards a specific cation in the investigated conditions [24].

Fig. 2 reports the dependence on ionic strength of the sequestering power of mlt towards spd, showing the decreasing of the sequestering ability with the increasing of the ionic strength. Moreover, pL_{50} values, at C_{spd} = trace and t = 25 °C, are: (at pH 6), 7.67, 6.26, 5.76, 5.93 at I = 0, 0.05, 0.15, 0.1 mol L^{-1}, respectively; (at pH 7.4), 9.31, 7.22, 6.75, 6.51, at I = 0, 0.05, 0.15, 0.1 mol L^{-1}, respectively, with S = 0.434 in all cases. These results indicate a clear dependence of pL_{50} on I, as showed in Fig. 3. This dependence is very well described by a second order polynomial equation. For example, for spd–mlt species, we have:

$$\text{at pH 6} \quad pL_{50} = 7.67 - 8.13\, I^{1/2} + 8.3\, I \quad \sigma = 0.004$$

$$\text{at pH 7.4} \quad pL_{50} = 9.31 - 12.2\, I^{1/2} + 12.8\, I \quad \sigma = 0.011$$

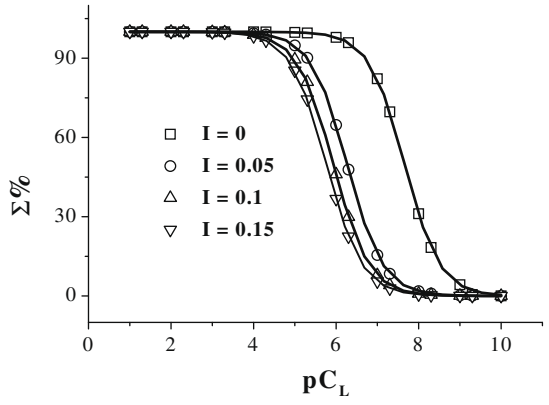

Fig. 2. Sequestration diagram for spd–mlt species at several ionic strengths (expressed in mol L^{-1}), at C_A = trace and t = 25 °C.

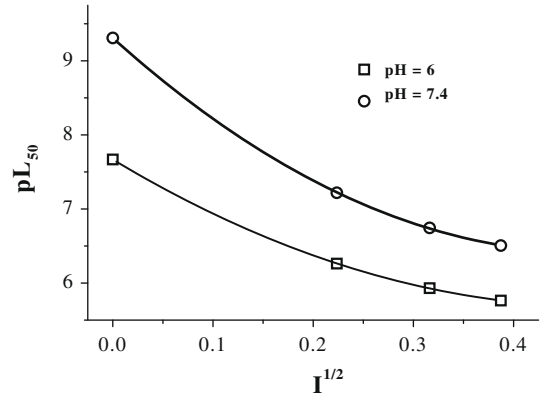

Fig. 3. pL_{50} vs. I (expressed in mol L^{-1}) for spd–mlt species at C_A = trace and t = 25 °C.

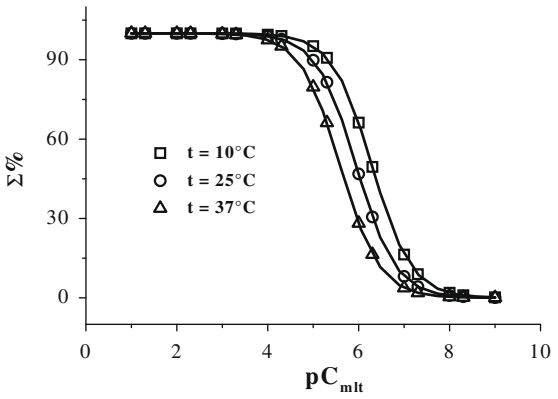

Fig. 4. Sequestration diagram for dien–mlt at C_A = trace, pH 7.4, I = 0 mol L^{-1} and at several temperatures.

For dien–mlt species there is a decrease of pL_{50} with the increasing of the ionic strength, too. For example, at C_{dien} = trace, t = 25 °C and pH 6, pL_{50} values are 5.25, 3.78 at I = 0, 0.15 mol L^{-1}, respectively; at pH 7.4, pL_{50} values are 5.95, 4.02 at I = 0, 0.15 mol L^{-1}, respectively. At the same pH value, the binding ability of mlt is significantly higher towards spd than towards dien. At pH 6, $pL_{50\ (spd)} - pL_{50\ (dien)}$ = 2.42, 1.99, at I = 0, 0.15 mol L^{-1}, respectively, at pH 7.4, $pL_{50\ (spd)} - pL_{50\ (dien)}$ = 3.36, 2.49, at I = 0,

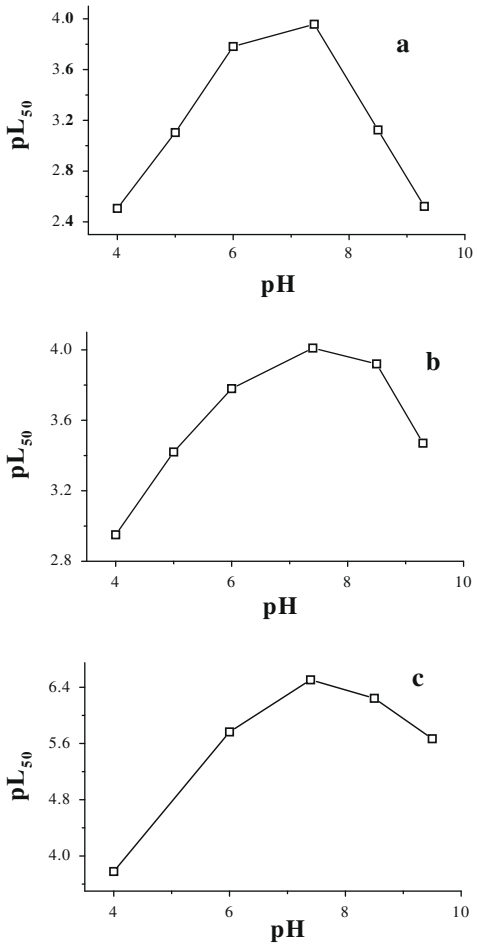

Fig. 5. pL_{50} vs. pH for amine(A)-mlt species at C_A = trace, I = 0.15 mol L^{-1} in NaCl and t = 25 °C. (a): en; (b): dien; (c): spd.

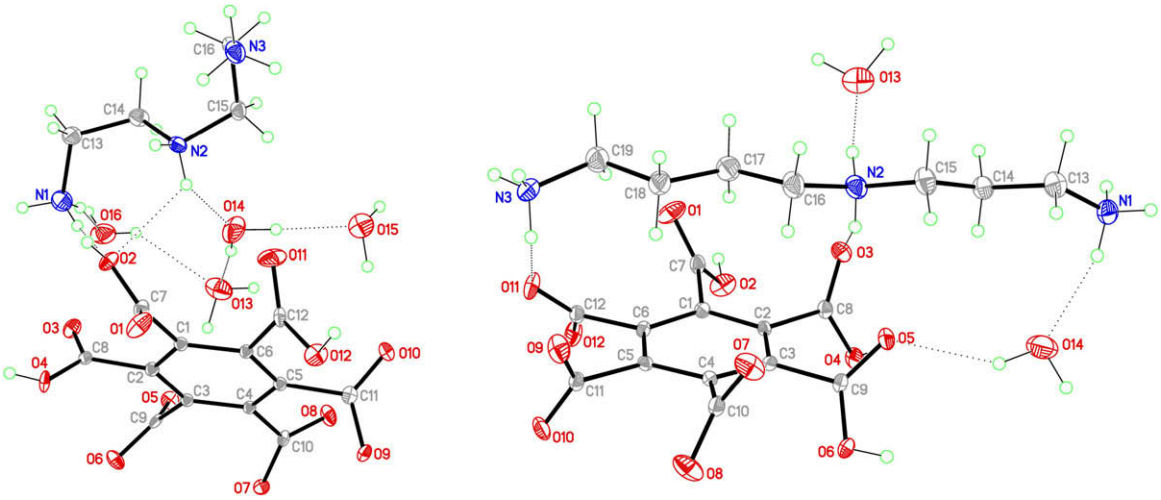

Fig. 6. Molecular representation of the asymmetric units for I and II. All non-hydrogen atoms are drawn with thermal ellipsoids at 30% of probability level.

0.15 mol L^{-1}, respectively. The sequestering ability of mlt towards a diamine, such as ethylenediamine, in the same pH and ionic strength conditions, further decreases. Sequestering ability of mlt towards amines is also influenced by the temperature, with a decreasing with the increasing of the temperature, as showed in Fig. 4. A linear type equation of pL_{50} versus t, well fits our data, for example for dien–mlt species we have:

at pH 6 $\quad pL_{50} = 6.56 - 0.026t \quad \sigma = 0.034$

at pH 7.4 $\quad pL_{50} = 5.79 - 0.022t \quad \sigma = 0.018$

Fig. 5a–c reports pL_{50} versus pH, at $I = 0.15$ mol L^{-1} in NaCl and $t = 25$ °C for en (data from Ref. [8]), dien and spd, showing that, with the increasing of pH, pL_{50} firstly increases, secondarily achieves a maximum value and finally decreases. If we ipotize that the dependence of pL_{50} on pH can be described by a Gaussian equation, the pH values which correspond to the pL_{50} maximum value are 6.77, 7.29, 7.69, for en, dien and spd, respectively.

3.5. Crystal structure

Several mellitate cocrystals with ammonium organic cations have been lately studied because of the great number of hydrogen bonds connected with the straightforward crystal engineering applications, biological and biomimetic behaviours, self assembly properties. Solid state structures, extended also to different protonation degrees of the potentially six chelated anions, often evidence the possibility to separate positive and negative supramolecular layers directed by noncovalent interactions [32,33]. However, few structures recorded in the crystallographic data-base concern mellitate anions with aliphatic ammonium species [34].

The asymmetric unit of I is occupied by one H_3dien^{3+} cation, one H_3L^{3-} anion, and four water molecules (Fig. 6). As already shown the O–H···O intermolecular hydrogen interactions between anionic units allow the formation of puckered supramolecular layers. The cationic units are obviously located between these anionic layers. Because of the short spacer between cationic centres (N atoms), every NH donor group bridges at least two close O acceptor atoms of the H_3L^{3-} units, whereas NH groups of same diethylentriammonium unit are, on their turn, bridged by central O acceptors. These interactions keep H_3L^{3-} units around a central trication in a pattern representable with the complex $R_1^2(7)R_2^1(5)R_2^3(6)R_2^1(5)R_2^1(7)R_2^2(9)$ graph-set [35]. Water molecules further enhance the hydrogen bonding network which holds the 3D solid state structure.

Asymmetric unit of II is occupied by one H_3spd^{3+} cation, one H_3L^{3-} anion and three water molecules (Fig. 6). Again hydrogen interactions among planar mlt species determines the formation of puckered supramolecular anionic layers able to embed water molecules and cations. Every ammonium ion is tightly coupled with a mlt unit because of the simultaneous presence of two N–H···O interactions involving N atoms on the opposite side of the longer N–H spacer and O acceptors on the opposite side of the mlt aromatic unit (graph-set $R_2^2(16)$). The spd moiety is almost planar and lays just 3.6 Å over the mlt aromatic plane, this allows also non-polar interactions (C–H···π) reinforcing the 1:1 molecular recognition. The other N–H···O interactions dock other spd–mlt units of the superior supramolecular layer, whereas other interactions involving also water molecules reinforce the overall hydrogen bonding network responsible for the crystal packing. Selected geometrical parameters, hydrogen bond lengths and angles are collected in Tables S1–S3 in the Supplementary data.

3.6. Comparisons

It is possible to compare the stability constants of dien– and spd–mlt species with those of the same amines with several carboxylate ligands published in preceding papers [6,9]. For example, considering the formation reaction $H_2dien^{2+} + L^{z-}$, with L = malonate ($z- = 2$), 1,2,3-tricarballylate ($z- = 3$), 1,2,3,4-butanetetracarboxylate ($z- = 4$), mlt ($z- = 6$) log$K$ = 2.1, 3.1, 4.2, 6.4, respectively. Moreover, for the formation reaction $H_3dien^{3+} + H_2L^{(z-2)-}$, with L = tca, btc, mlt, log$K$ = 2.5, 3.5, 5.9, respectively. In the case of spd: for the formation reaction $H_2spd^{2+} + L^{z-}$, with L = malate (mala, $z- = 2$), tca, btc, mlt, logK = 1.7, 2.4, 3.5, 8.0, respectively: for the formation reaction $H_3spd^{3+} + H_2L^{(z-2)-}$, with L = tca, btc, mlt, log$K$ = 1.1, 2.7, 6.2, respectively. All these examples, regarding the same amine, show that the stability regularly increases with the increasing of the ligand charge.

Table 6
Comparison between the formation stability constants of some alkaline earth metal–mellitate and triamine-mellitate species, at $I = 0$ mol L^{-1} and $t = 25$ °C.

Reaction	$B^{2+} = H_2dien^{2+}$ [a]	$B^{2+} = H_2spd^{2+}$ [a]	$B^{2+} = Mg^{2+}$ [b]	$B^{2+} = Ca^{2+}$ [b]
	logK			
$L^{6-} + B^{2+}$	6.4	8.0	6.39	7.50
$HL^{5-} + B^{2+}$	5.7		5.28	5.84

[a] This work.
[b] Ref. [13].

Another useful comparison can be made with the stability of alkaline earth metals-mellitate species. For example, the stability difference, regarding the formation reaction between unprotonated mellitate with H_2dien^{2+} and Mg^{2+}, is 0.01, as reported in Table 6. As can be seen, when reagent charges are the same, despite the nature of the cations is totally different, the stability is quite similar, confirming the determining role of the charges on the stability.

4. Final remarks

It was found, in solution for both the systems, the formation of several species having quite high stabilities, increasing with the charge of both polyammonium cation and polycarboxylic anion. There is a very good linear trend of log$K$ versus ζ (charge products = z_{cation} $|z_{anion|}$). By using the crude approximation $n = \zeta/2$, where n is the number of possible salt bridges, we obtain a mean energy value, $-\Delta G^0 = 6.1 \pm 0.3$ kJ mol^{-1}, which is consistent with results reported in our preceding work [10]. $T\Delta S^0$ values are also a fairly linear function of charges involved in the formation reaction: for example for dien system, $T\Delta S^0/\zeta = 0.4 \pm 1.6$ kJ mol^{-1}.

Speciation diagrams of the dien–mlt and spd–mlt systems show that the formation percentages of spd–mlt species are higher than those containing dien and that the ALH_3 species formed by spd is absolutely predominant in a wide pH range (pH 6–9).

The pL_{50} parameter, which gives a measure of the binding ability of mlt towards the triaminic cation, shows a clear dependence on ionic strength, temperature and pH. The sequestering ability of mlt towards each triamine: decreases with the increasing of the ionic strength, with a trend very well described by a second order polynomial equation; decreases with the increasing of the temperature, with a trend well described by a linear type equation; increases, with the increasing of pH, achieves a maximum value and finally decreases.

Diffractometric studies in the solid state fully support the formation of dien–mlt and spd–mlt complex species. The crystal structures is shown in Fig. 6: the asymmetric unit of I occupied by H_3dien^{3+} cation, H_3L^{3-} anion and four water molecules; the asymmetric unit of II occupied by H_3spd^{3+} cation, H_3L^{3-} anion and three water molecules. Moreover hydrogen bonding network, responsible for the crystal packing is strengthened by other interactions involving water molecules.

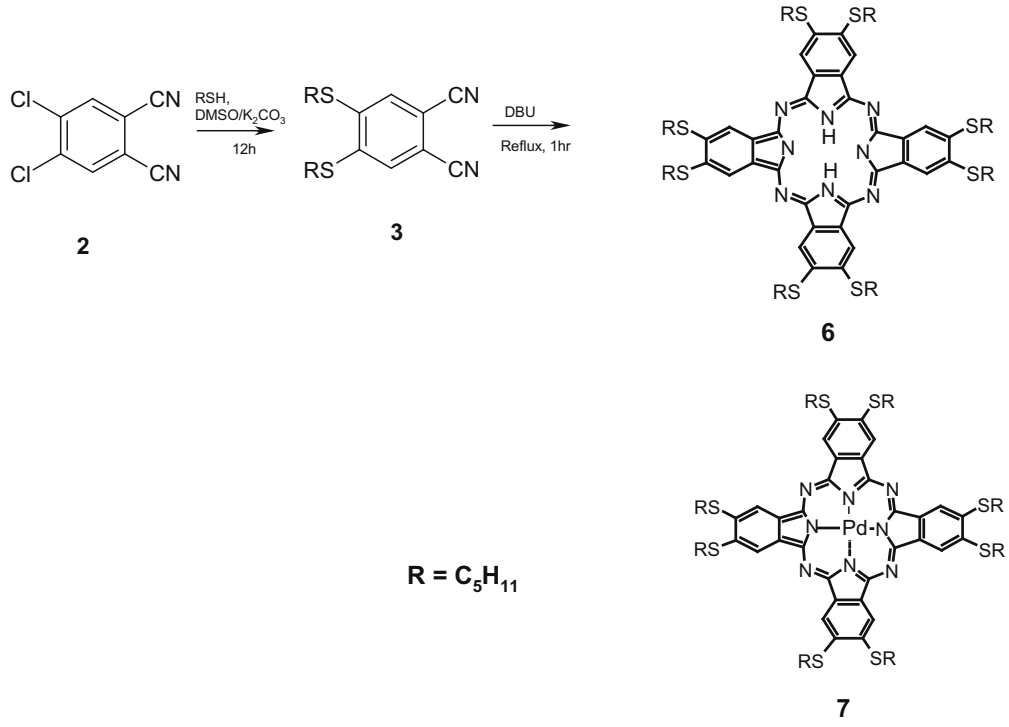
2. Experimental

2.1. Materials and equipment

1-Pentanol, dimethylformamide (DMF), pentanethiol, dimethylsulfoxide (DMSO) 1.8-diazabicyclo[5, 4, 0] undec-7-ene (DBU), cerium chloride, potassium carbonates, dichloromethane (DCM), 1-chloronaphthalene (CNP) and palladium (II) chloride were purchased from Sigma–Aldrich. Methanol, ethanol and chloroform were purchased from Merck. Chromatography was performed on silica gel 60 (0.04–0.063 mm). 1,2-Dichloro-4,5-dicyanobenzene (**2**) [25,26], 3,6-bis(pentathio)-4,5-dicyanobenzene (**1**) and 1,2-bis(pentylthiol)-4,5-dicyanobenzene (**3**) [24,27], were synthesised as reported in literature. The synthesis of palladium-2,3,9,10,16,17,23,24,-octakis(pentylthio)phthalocyanine (**7**) has been reported before [24]. UV–Vis spectra were recorded on a Cary 500 UV/Vis/NIR spectrophotometer, ^{1}H NMR spectra were recorded using a Bruker EMX 400 MHz NMR spectrometer. IR spectra (KBr pellets) were recorded on a Perkin–Elmer spectrum 2000 FTIR.

2.2. Binding and kinetic studies



For all binding studies, $PdCl_2$ was dissolved in ethanol and the H_2Pc or PdPc complexes in DCM. In order to minimize dilution effects, very small volumes (μl) of the $PdCl_2$ stock solution were added to 2 mL of the Pc solution, and changes were monitored spectroscopically. For kinetic studies, varying concentrations of $PdCl_2$ (0–1×10^{-2} M) in ethanol were added to a fixed concentration (5×10^{-6} M) of the H_2Pc or PdPc derivatives, and the absorbance changes accompanying each addition monitored with time.

For equilibrium studies, the steady increase in absorbance of the Q band of the Pc product formed with increase in Pd (II) ion concentration was noted and used in the determination of the binding constants as well as number of bound Pd (II) ions, according to Eq. (1):

$$\mathrm{Log}[(A_{eq} - A_o)/(A_\infty - A_{eq})] = \log K + n \log[\mathrm{Pd}] \quad (1)$$

where A_{eq} is the equilibrium absorbance of the Pd-bound Pc (product); A_o, the initial absorbance before the addition of $PdCl_2$, and A_∞, the maximum attainable absorbance of the product. K is the binding constant, and n is the number of bound Pd(II) ions.

The complexes formed by the interaction between Pd(II) and unmetallated complexes **4** and **6** could be isolated by evaporating the solvents (ethanol/DCM) and recrystalyzing in ethanol. Elemental analyses for the complex between Pd and **4**:

2.3. Synthesis

2.3.1. Metal-free 1,4,8,11,15,18,22,25,-octakis(pentylthio)phthalocyanine (4), Scheme 1

In refluxing pentanol (10 ml), 3,6-bis(pentathio)-4,5-dicyanobenzene **(1)** (0.5 g, 1.5 mmol) and DBU (1.70 g, 11.17 mmol) were added. The solution was heated to reflux for 5 h. The solution was then allowed to cool and the solvent removed under reduced pressure, followed by titration with cold methanol to precipitate the product. The black precipitate was dissolved in DCM and passed through a silica column, DCM was used as the eluting solvent to afford **4**. Yield: 0.18 g (37%), UV/Vis [(CNP, λ_{max}/nm, (log ε)] 813 (5.05), 719 (3.5). *Anal.* Calc. for $C_{72}H_{98}N_8S_8$: C, 64.80; H, 6.87 N, 8.01, S, 20.32. Found: C, 64.87; H, 7.47, N, 7.71, S, 20.44%. ^{1}H NMR (400 mHz); δ ppm; ($CDCl_3$), 8.00 (8H, s, H_{arom}), 3.32–3.35 (16H, t, Ar–SCH_2–), 2.15–2.00 (16H, m, Ar–SCH_2–CH_2–), 1.65–1.2 (32H, m, $H_{aliphatic}$), 1.00–0.80 (24H, t, CH_3); [IR (KBr pellets) ν_{max}/cm^{-1}]; 1320, 1278, 1217, 1186, 1142, 1077, 939, 808, 736, 668 (C–S–C), 577, 499, 418; 3057 (N–H), 2953 (C–H), 2922 (C–H), 2358, 2336, 1865, 1791, 1730, 1652(C=N), 1556, 1538,1505, 1456.

2.3.2. Palladium-1,4,8,11,15,18,22,25,-octakis(pentylthio)phthalocyanine (5), Scheme 2

In refluxing pentanol (10 ml), 3,6-bis(pentathio)-4,5-dicyanobenzene **(1)** (0.5 g, 1.5 mmol), $PdCl_2$ (0.12 g, 0.75 mmol) and DBU (1.70 g, 11.17 mmol) were added. Reflux was continued for a further 18 h. Reaction was then cooled down and the solvent removed under reduced pressure, followed by titration with cold methanol to precipitate the product. The black precipitate was dissolved in DCM and passed through a silica column, DCM was used as the eluting solvent to afford **5**. Yield: 0.12 g (40%), UV/Vis [CNP, λ_{max}/nm, (log ε)] 750 (4.5), 679 (4.11). *Anal.* Calc. $C_{72}H_{96}N_8PdS_8$: C, 60.20; H, 6.74; N, 7.80. Found: C, 59.63; H, 6.87; N, 7.51%. ^{1}H NMR (400 MHz, $CDCl_3$) δ ppm: 8.71 (8H, s, Ar–H), 4.10 (16H, s, S–CH_2), 1.52–1.21 (48H, m, –$(CH_2)_3$), 1.21–0.92 (24H, m, –CH_3);[IR (KBr pellets) ν_{max}: 2929, 2859, 1732, 1650(C=N), 1572, 1466, 1338, 1293, 1236, 1163, 941, 799, 750, 650(C–S–C).

2.3.3. Metal-free 2,3,9,10,16,17,23,24,-octakis(pentylthio)phthalocyanine (6)

Compound **3** (0.5 g, 0.95 mmol) was heated in pentanol (5 ml) in the presence of DBU (1.66 ml, 1 mmol) with stirring and heated under reflux for 1 h in a nitrogen atmosphere. After cooling, the dark green product was precipitated with methanol, filtered and then purified using silica gel packed column chromatography with DCM as eluent. Yield: 0.37 g (74%), UV/Vis [(CNP, λ_{max}/nm, (log ε)] 737 (5.12), 710 (5.04), 673 (4.51), 640 (4.40), 457 (4.43). *Anal.* Calc. for $C_{72}H_{98}N_8S_8$: C, 64.80; H, 6.87 N,8.01, S, 20.32. Found: C, 65.93; H, 7.75, N, 6.16, S,19.91%. ^{1}H NMR (400 mHz); δ ppm ($CDCl_3$) 8.37 (8H, s, H_{arom}), 3.44–3.40 (16H, s, Ar–SCH_2–), 2.14–2.09 (16H, q, Ar–SCH_2–CH_2–), 1.82–1.78 (16H, q, $H_{aliphatic}$), 1.66–1.60 (16H, q, $H_{aliphatic}$), 1.31–1.22 (24H, t, CH_3–); [IR (KBr pellets) ν_{max}/cm^{-1}]; 3449 (N–H), 2957, 2926, 2858 (C–H), 1648(C=N), 1592, 1507, 1461, 1400, 1325, 1325, 1073, 1026, 935, 868, 749, 681 (C–S–C).

3. Results

3.1. Synthesis and characterization

The syntheses of complexes **4**–**6** were achieved by treating the corresponding phthalonitriles (**1** or **3**) with palladium chloride in 1-pentanol for complex **5**, Scheme 2 or with DBU only for unmetalated complexes **4** and **6**, Schemes 1 and 3, respectively. Column chromatography with silica gel was employed to obtain the pure products. The MPc derivatives were characterized by UV–Vis, IR and NMR spectroscopies, and elemental analyses. The analyses were consistent with the predicted structures. The sharp peak for the C≡N vibrations in the IR spectra of phthalonitriles **1** or **3** at ~2200 cm^{-1} disappeared after conversion into phthalocyanines

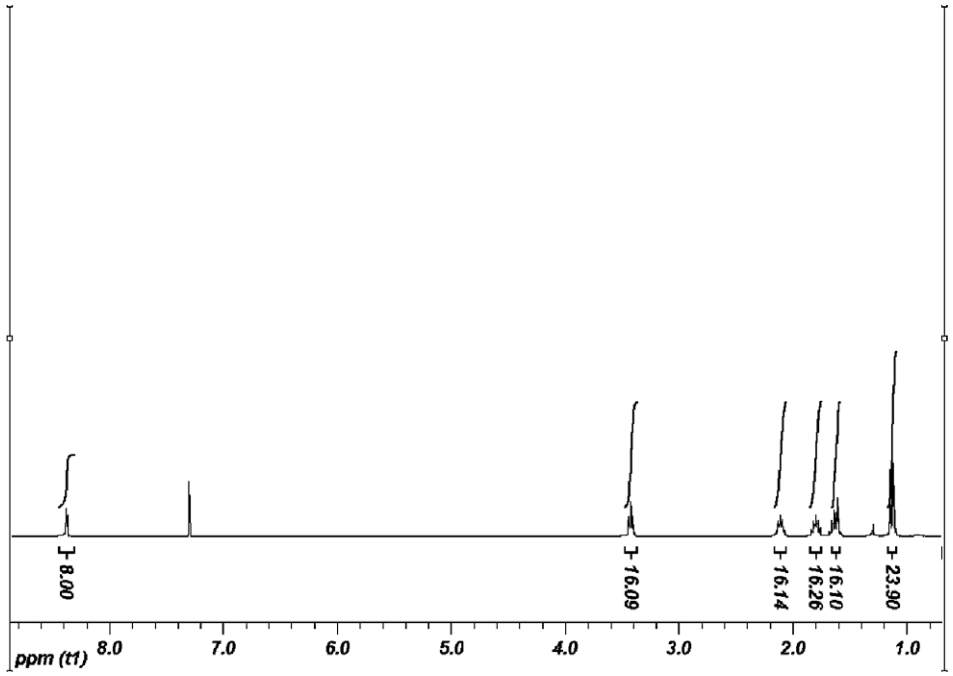

Fig. 1. ^{1}H NMR spectrum of **6** in $CDCl_3$.

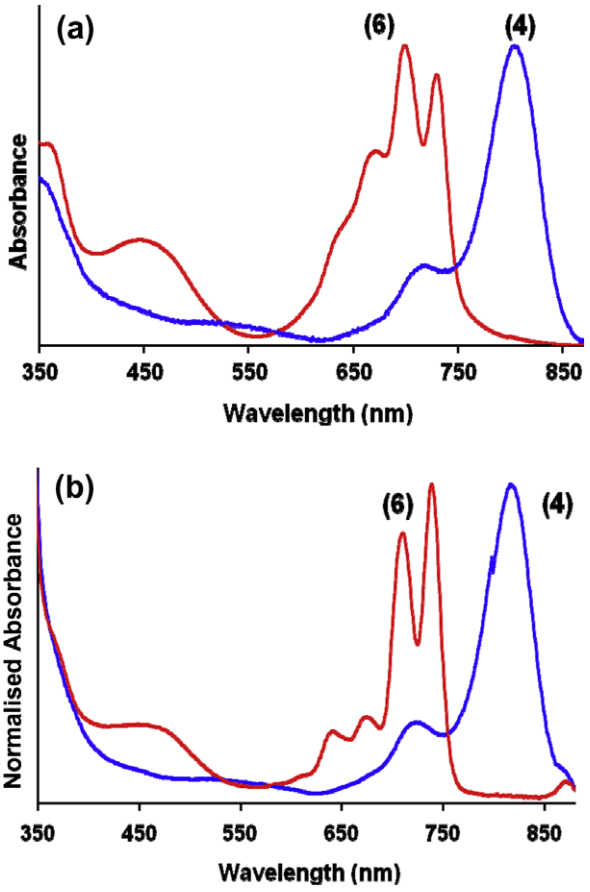

Fig. 2. Electronic absorption spectra of **4** and **6** in (a) DCM and (b) CNP. Concentration $\sim 1 \times 10^{-5}$ M.

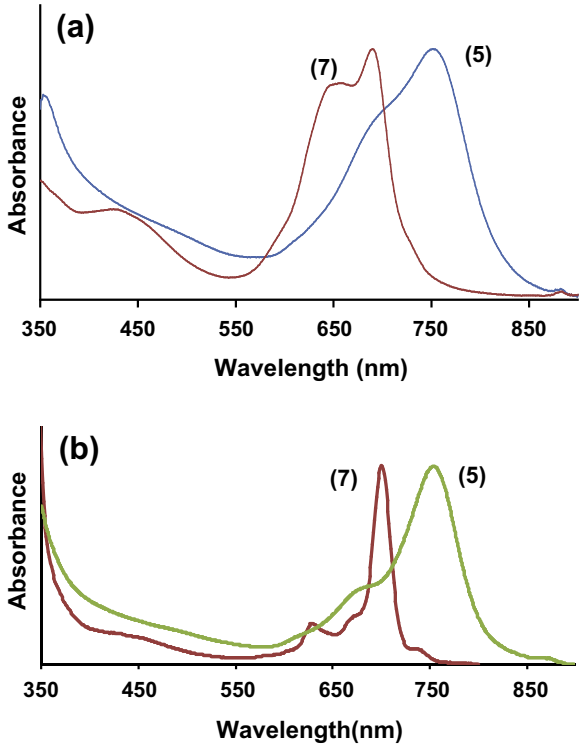

Fig. 3. Electronic absorption spectra of **5** and **7** in (a) DCM (b) CNP. Concentration $\sim 1 \times 10^{-5}$ M.

and there was appearance of a C≡N band at 1652, 1650 and 1645 cm^{-1} for **4**, **5** and **6,** respectively. The phthalocyanines showed vibrations due to C–S–C group between 650 and 688 cm^{-1}.

The ^{1}H NMR spectra of MPc derivatives in $CDCl_3$ showed all the substituent and Pc ring protons in their respective regions, Fig. 1. A singlet, assigned to Pc aromatic ring protons, appeared in the range 8.00–8.71 (integrating for 8 protons) in the ^{1}H NMR spectra of **4–6**. The S–CH_2 protons were observed between 3.32 and 4.10, integrating for a total of 16 protons for each complex (**4–6**). The rest of the aliphatic protons were observed between 1.2 and 2.15 intergrading for 48 protons for each complex (**4–6**). The methyl protons occurred between 0.8 and 1.31 intergrading for 24 protons. The cavity protons of the unmetalatted phthalocyanines [**4** and **6**] were not observed due to aggregation of the molecules in $CDCl_3$.

Pcs exhibit limited solubility in most solvents but substitution at the peripheral (β) and non-peripheral (α) positions allows for improved solubility [28]. Non-peripheral substitution in Pcs has been reported to result in higher solubility in comparison with peripheral substitution [29]. Fig. 2a shows the ground state electronic absorption spectra of **4** and **6** in DCM, while the spectra of **5** and **7** in the same solvent are shown in Fig 3a. It can be observed from these figures that the spectra of the non-peripherally substituted complexes: **4** and **5**, are significantly red-shifted relative to those of their peripherally substituted counterparts, as expected. The red shifting for non-peripherally substituted derivatives is attributed to greater electron density enhancement caused by substitution at the non-peripheral substitution compared with that at the peripheral position. The Q band for **4** is observed at 801 nm in DCM. For **6**, the components of the split Q band are observed at 698

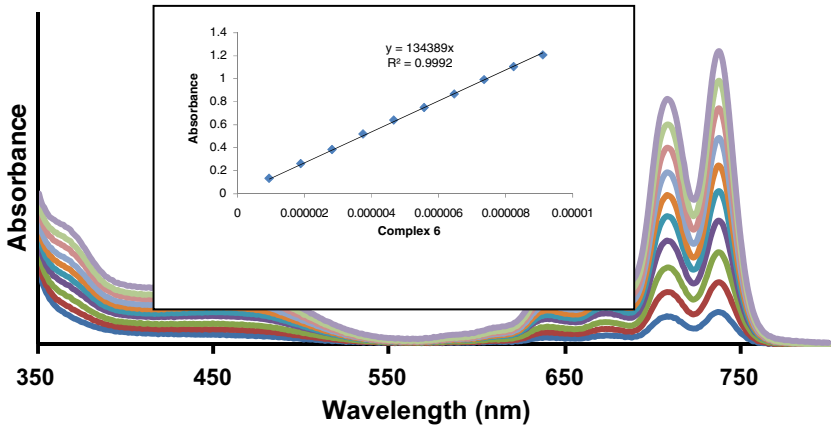

Fig. 4. (a)Absorption spectra of compound **6** in CNP at different concentrations. Inset: Beer–Lambert Plot.

and 730 nm in DCM. The spectrum of **4** does not show the typical split Q band expected for unmetalated phthalocyanines; it is known that the resolution of the split of the Q band decreases with increasing wavelength [30], hence for **4**, the large red shift must have resulted in an unsplit Q band. The Q bands for the metallated derivatives **5** and **7** are observed at 747 and 693 nm, respectively in DCM (Fig. 3a). The spectra for all complexes are broad in DCM, suggesting aggregation in this solvent. DCM is a non-coordinating solvent; hence it lacks the capacity to prevent π–π stacking of the PdPc units. Figs. 2b and 3b, respectively show the ground state absorption spectra of **4** and **6,** and **5** and **7** in CNP. The spectra in CNP are narrower than those in DCM for both the metallated (**5**,**7**) and unmetalated (**4**,**6**) derivatives, which is ascribed to the lower tendencies of the complexes to aggregate in CNP. However, complex **5** still shows broad spectrum in CNP. Aggregation in Pcs is usually depicted by broadening and/or splitting of Q band, indicating the presence of additional electronic levels of aggregates. Beer–Lambert law was obeyed for the complexes in CNP, even for concentrations less than 1×10^{-5} mol dm^{-3} (Fig. 4a). However in DCM, Beer–Lambert law was obeyed only at lower concentrations (>1×10^{-6} mol dm^{-3}), confirming the presence of aggregates. The Q band maxima of the Pcs are red shifted in CNP compared to DCM. In CNP, the Q band for **4** was at 813 nm compared to 801 nm in DCM, while the split Q band of **6** appeared at 707 and 736 nm in CNP compared to 693 and 731 nm in DCM. The Q band for **5** appears at 750 nm while that of **7** appears at 699 nm in CNP. Aromatic solvents have been known to result in red shift of the Q band in phthalocyanine complexes [31], hence the observed red shift in CNP. The observed spectral red-shifts in CNP relative to those in DCM could also be interpreted in terms of the higher refractive index of CNP [31].

3.2. Pd(II) binding to Pcs

3.2.1. Metal-free 1,4,8,11,15,18,22,25,-octapentylthiophthalocyanine (4)

It is possible that binding of Pd(II) to complex **4** and **6** will occur at the thio groups or at the central core of the Pc skeleton. On

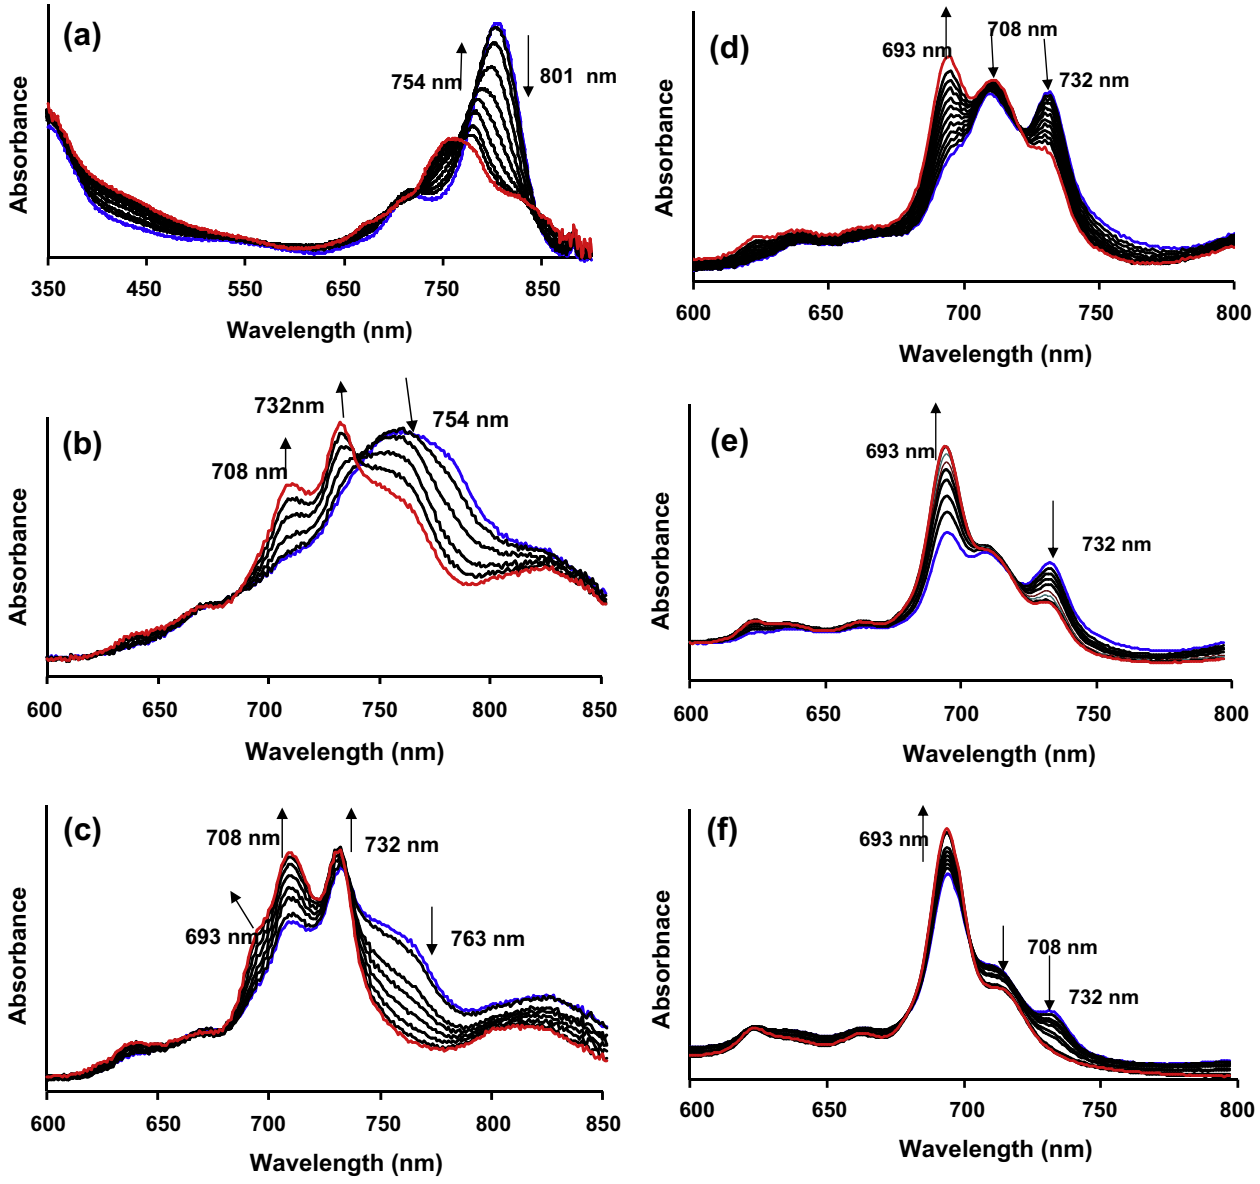

Fig. 5. UV–Vis spectral changes observed on addition of $PdCl_2$ in ethanol to complex **4** (concentration = 5×10^{-6} M) in DCM. Concentration of $PdCl_2$ (a) 6.5×10^{-4}–3.05×10^{-3} M (b) $3.05\ 10^{-3}$–7.20×10^{-3} M (c) 7.20×10^{-3}–1.0×10^{-2} M (d) 1.0×10^{-2}–1.18×10^{-2} M (e) 1.18×10^{-2}–1.32×10^{-2} M (f) 1.32×10^{-2}–1.5×10^{-2} M. The first spectrum in (b) is the same as the last spectrum in (a), the first spectrum in (c) is the same as the last spectrum in (b), and so on.

addition of Pd(II) to a solution of **4**, spectral changes shown in Fig. 5 were observed. The first part shown in Fig. 5a consists of a decrease in the Q band intensity (at 801 nm in DCM) accompanied by broadening and the shift of the band to high energy (754 nm). These spectral changes are consistent with formation of aggregates observed on metal binding in thio substituted MPc complexes [21]. The lack of clear isosbestic points, suggests that there may be more than two species in solution. Higher aggregates could also be present in solution. Further addition of Pd(II) resulted in spectral changes shown in Fig. 5b, which consist of the decrease in the broad peak at 754 nm and the formation of a split peak with maxima at 708 and 732 nm. The observed split in Q band suggests that a PdPc complex has not formed yet and the complex is still H_2Pc with Pd(II) ions coordinated to the pentylthio groups or the PdPc complex has formed with unsymmetrical substitution of Pd ions on the ring. Further addition of $PdCl_2$ resulted in the formation of a new band at 693 nm and the gradual disappearance of the split Q band (Fig. 5c and d). Elemental analysis confirmed to binding of four Pd(II) ions at this stage, see Section 2 for the data. The ^1H NMR spectra of the complex isolated at this stage showed a change in chemical shift of the protons relative to what obtained in the original ligand (**4**), the most conspicuous shift being the macrocyle protons indicating a change in electron distribution [15,18,20]. The singlet peak shifted downfield from 8.00 to 8.30 ppm which indicated higher resonance of the ring protons due to desheilding effect that resulted from reduced mesomeric effect of the sulfur lone pairs of electrons on the ring when part of those lone pairs were used in coordination with Pd ions. The IR spectrum of this complex also showed a dramatic change compared with that of 4. The bands between 1000 and 600 cm^{-1} showed conspicuous split, especially at 939, 808, and 736 cm^{-1}.

A gradual disappearance of the split Q band and the appearance of a new single Q band that was blue shifted compared to the original split Q band were observed on further addition of Pd(II) ions, Fig. 5e. The final spectrum in Fig. 5f is typical of a metallated phthalocyanine complex [32], and suggests the formation of a symmetrically substituted PdPc complex. No further spectral changes were observed on addition of more Pd ions.

The equilibrium studies for the binding of Pd(II) ions to complex **4**, were carried out for using Eq. (1). A plot $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ (Fig. 6), gave an equilibrium constant of $K = 1.2 \times 10^9$ dm^3 mol^{-1} and n of 5, thus showing that five Pd(II) ions are coordinated to the to the Pc at the end of the reaction.

When a large excess of $PdCl_2$ was added to **4**, spectral changes shown in Fig. 7 were observed, these consisted of direct formation of the final spectrum in Fig. 5f. These changes occurred with time allowing for the calculation of rate constants assuming first order kinetics since Pd(II) is in excess. The rate constants were obtained by first plotting absorbance versus time for each concentration of Pd(II) (ranging from 1.5×10^{-3} to 5.0×10^{-3}) to obtain initial rates, the latter were then plotted against [Pd(II)] (Fig. 7 inset) to get the rate constant from the slope using least square analysis. The value of the rate constant was 1.38×10^{-5} dm^3 mol^{-1} s^{-1}. When low concentrations ($<1 \times 10^{-4}$ M) of Pd(II) ions were employed for complex **4**, changes with time observed in Fig. 7 were not observed probably due to the slow nature of the spectral changes.

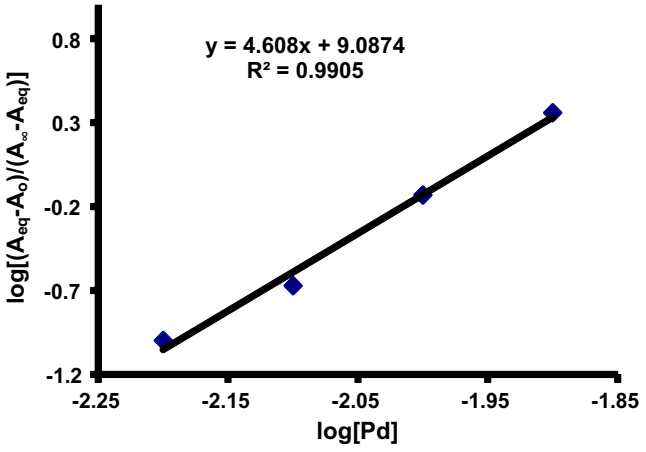

Fig. 6. Plot of $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ for complex **4** in DCM.

3.2.2. Metal-free 2,3,9,10,16,17,23, 24,-octapentylthiophthalocyanine (6)

The spectra generated on the addition of Pd(II) ions to complex **6** are shown in Fig. 8. For **6**, The Q band is split since this complex is blue shifted compared to **4**. Non-peripherally substituted MPc complexes show more red shifting compared to peripherally substituted. The absorption spectrum of the Pc before the addition of Pd(II) ions is shown in Fig. 8a(i). With the addition of Pd(II) ions the intensity of the peaks at 693 and 731 nm decreased and a new single peak appeared at 714 nm (Fig. 8a(ii)). This spectrum resembles that of MPc suggesting the insertion of the metal into

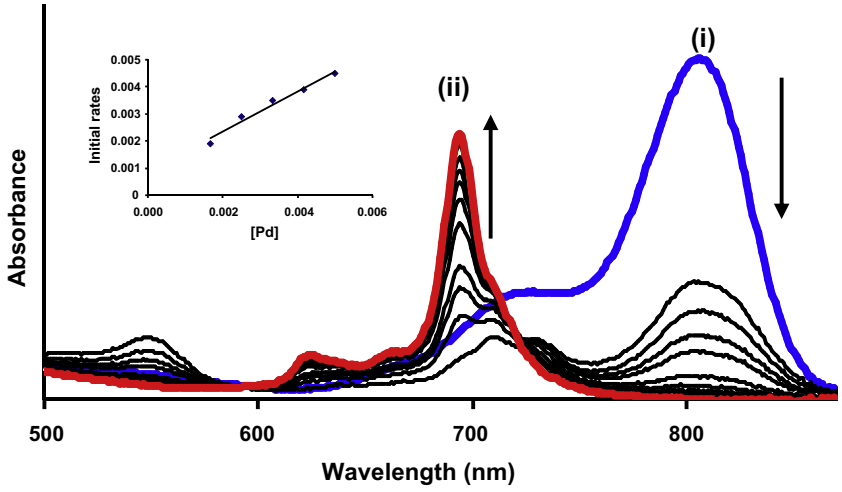

Fig. 7. UV–Vis spectral changes observed on addition of excess $PdCl_2$ in ethanol (concentration = 3×10^{-3} M) to a solution of complex **4** (1×10^{-5} M) in DCM. (i) before and (ii) after addition of $PdCl_2$. Inset: Plot of initial rates versus the concentration Pd.

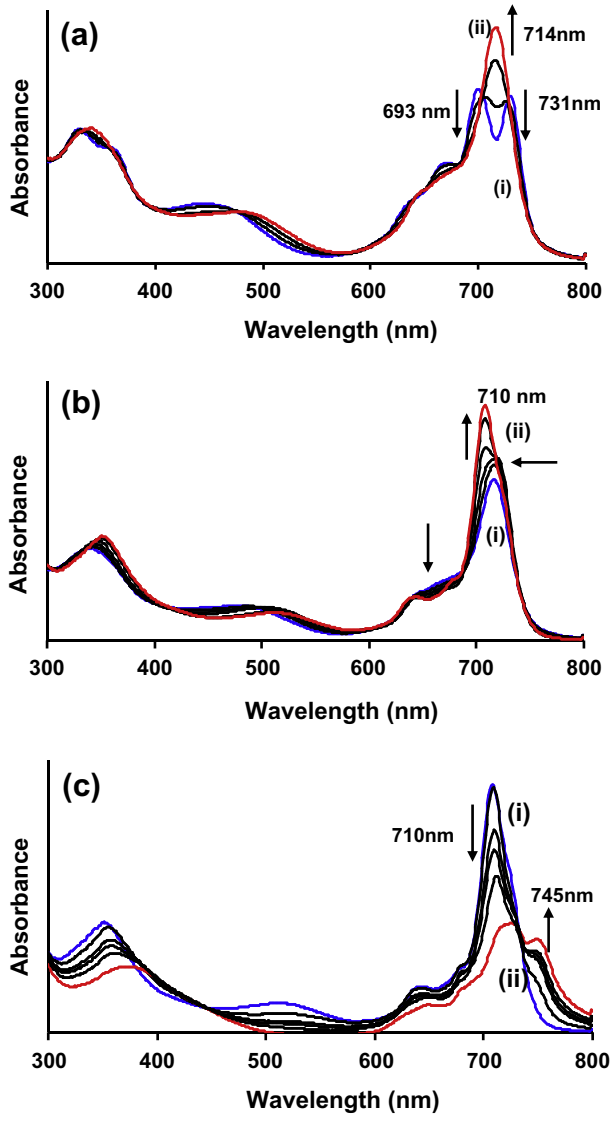

Fig. 8. UV–Vis spectral changes observed on addition of $PdCl_2$ in ethanol to complex **6** (concentration = 5×10^{-6} M) in DCM. Concentration of $PdCl_2$ (a) 4.00×10^{-4}–4.61×10^{-4} M, (b) 4.61×10^{-4}–5.06×10^{-4} M, (c) 5.06×10^{-4}–5.5×10^{-4} M. The first spectrum in (b) is the same as the last spectrum in (a), the first spectrum in (c) is the same as the last spectrum in (b).

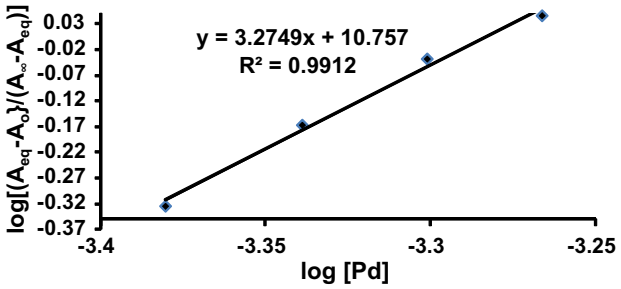
the center of the Pc ring. The spectral changes could not be due to symmetric substitution of the Pd ions on the ring since a split Q band would still be observed. The ^{1}H NMR spectra of the complex formed here also show change in chemical shift of some of the peaks due to change in electronic distribution of the complex on coordination with Pd ions. The aromatic and S–CH_2 protons did not show significant shift while the aliphatic and methyl protons were observed as mutiplets and triplets at 1.24–1.19 ppm and 1.08–0.91 ppm integrating to 48 and 24 protons respectively. Elemental analysis of the complex at this stage confirmed the coordination of one Pd(II) ion, most probably into the center of the ring hence no splitting in the Q band. The same type of spliting that was observed in the IR spectrum of **4** was also noticed in the spectrum of **6** at 935, 868 and 749 cm^{-1}.

Further addition of Pd(II) ions resulted in increase in the intensity accompanied by blue-shifting of the peak at 714 nm (Fig. 8b) to 710 nm. The blue shifting is as a result of the binding of Pd(II) ions to the peripheral sulfur, which engages the lone pair of electrons on sulfur and therefore cancels their mesomeric contribution



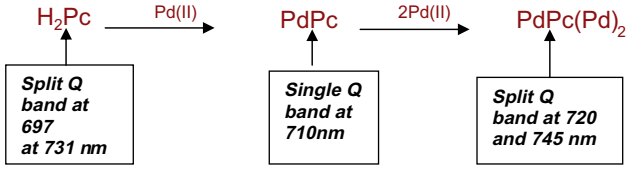


Fig. 9. Plot of $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ for complex **6** in DCM.

Scheme 4. Possible processes involved in Pd(II) coordination to 6.

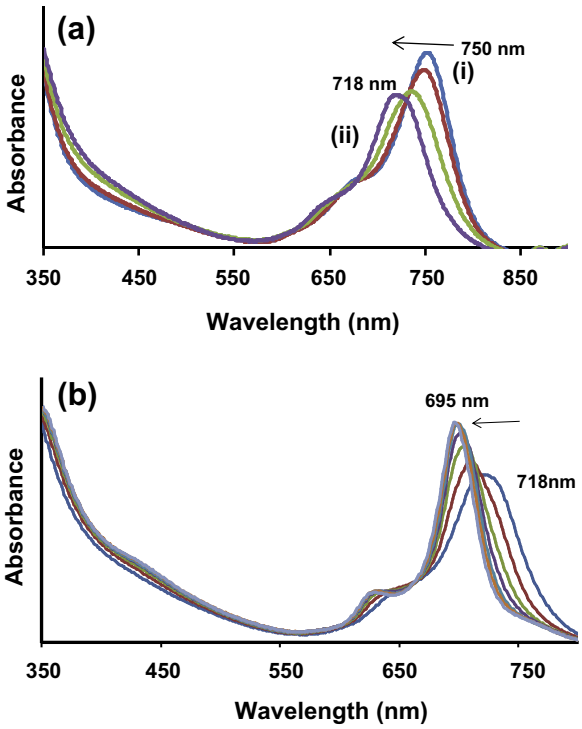
to the ring electron density. As the addition of Pd(II) ions continued the broad peak around 710 nm started disappearing and a split band emerged at 720 and 745 nm as shown in Fig. 8c. This spectroscopic response might be due to unsymmetric substitution of Pd(II) ions. As was the case with complex **4**, no further spectral changes were observed on addition of more Pd ions. The number of Pd(II) ions bound to the Pc and equilibrium constant was determined for complex **6** using Eq. (1) and Fig. 9.

A plot $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ (Fig. 9), gave an equilibrium constant of $K = 5.7 \times 10^{10}$ dm^3 mol^{-1} and n of 3 for complex **6**, thus showing that three Pd(II) ions are coordinated to the to the Pc at the end of the reaction. Probably the two at the periphery coordinated to adjacent sulfur instead of opposite ones giving rise to the loss of symmetry. The possible processes occurring during the addition of Pd ion to solutions of complex **6** are shown by Scheme 4.The nature of Pd(II) binding differ between complexes **4** and **6** in that in **4**, five Pd ions are coordinated, while for complex **6** three Pd ions are coordinated. The differences in the binding abilities of the two compounds (**4** and **6**) could be due to accessibility of binding sites. Also the modes of coordination of Pd(II) ions may be different for peripherally (**6**) and non-peripherally (**4**) substituted complexes since in the latter there is a possibility of coordination between pentylthio groups on adjacent benzene groups.

3.2.3. Palladium octapentylthiophthalocyanine complexes *5* and *7*

Both **4** and **5** are non-peripherally substituted, however **5** has a central Pd(II) ion unlike **4** which is unmetalated. The same applies to **6** and **7**, which are both peripherally substituted, but the latter has a central Pd(II) ion and the former is unmetalated.

Fig. 10a(i) shows the spectra of **5** before and after addition of Pd(II) ions. On addition of Pd(II) ions, reduction in intensity coupled with blue shifting from 750 to 718 nm of the Q band was observed (Fig. 10a(ii)). Effect of further addition of Pd(II) ions is depicted in Fig. 10(b), and consists of continued blue-shifting of the Q band from 718 to 695 nm and there is narrowing of the Q band and its increase in its intensity. The continuous shift towards the blue is consistent with the engagement of S lone pairs in the substituents, thereby reducing the ring electron density and consequently causing the blue shift. The Q band maximum at 695 nm is



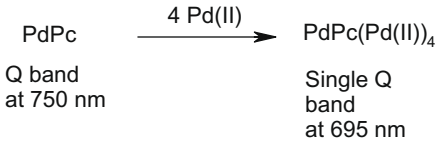


Fig. 10. UV–Vis spectral changes observed on addition of $PdCl_2$ in ethanol to complex **5** (concentration = 5×10^{-6} M) in 1-chloronaphthalene. Concentration of $PdCl_2$ (a) 9.00×10^{-5}–4.00×10^{-4} M (b) 4.00×10^{-4}–1.5×10^{-3} M. The first spectrum in (b) is the same as the last spectrum in (a).

Scheme 5. Possible processes involved in Pd(II) coordination to complex **5**.

similar to the final spectrum obtained for **4** following addition of Pd(II) ions (Q band at 693 nm), suggesting that the final complexes are the same.

The possible processes occurring during the addition of Pd(II) ion to solutions of complex **5** are shown by Scheme 5.

A plot $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ for **5** (Fig. 11), gave an equilibrium constant of $K = 1.66 \times 10^{13}$ dm^3 mol^{-1} and n of 4, thus showing that 4 Pd(II) ions are coordinated to the to the Pc at the end of the reaction, with the equilibrium favouring the

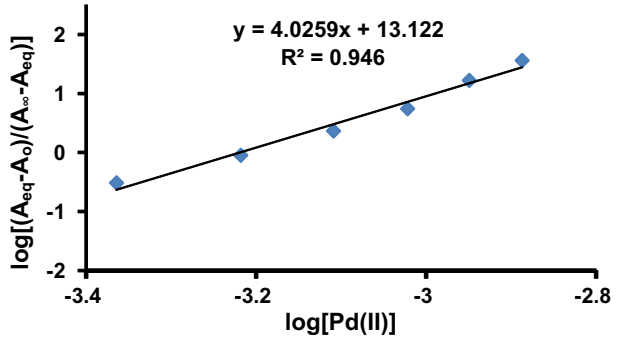

Fig. 11. Plot of $\log[(A_{eq}-A_o)/(A_\infty-A_{eq})]$ versus $\log[Pd^{II}]$ for complex **5** in CNP.

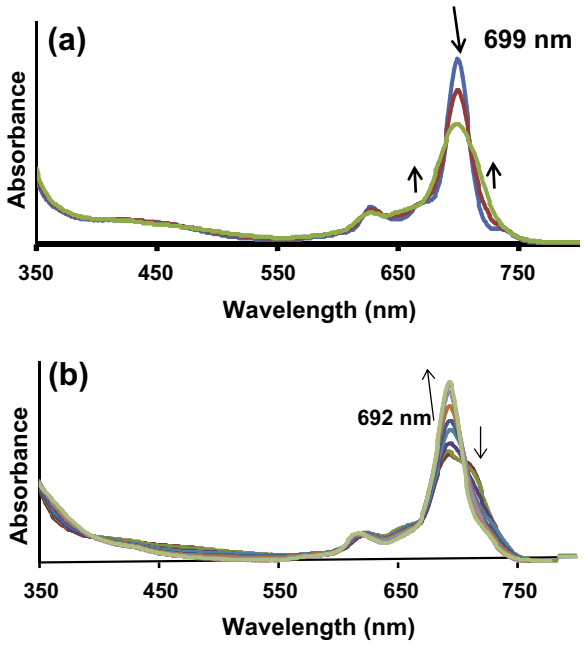

Fig. 12. UV–Vis spectral changes observed on addition of $PdCl_2$ in ethanol to complex **7** (concentration = 8×10^{-6} M) in 1-chloronaphthalene. Concentration of $PdCl_2$ (a) 3.00×10^{-5}–2.50×10^{-4} M (b) 2.50×10^{-4}–1.5×10^{-3} M. The first spectrum in (b) is the same as the last spectrum in (a).

formation of the complex with four Pd(II) ions coordinated all at the ring in a symmetrical fashion since the Q band of the final spectrum is not split.

For complex **7** which is peripherally substituted, Fig. 12a and 12b show that on titration with Pd(II) ions, the final spectrum shows a split Q band, suggesting unsymmetrical substitution by the Pd(II) ions as was the case with **6**, which is also peripherally substituted. Thus the point of substitution (peripheral or non-peripheral) determines the nature of binding (symmetrical or non-symmetrical) of Pd(II) ions to the MPc complexes.

4. Conclusions

Octasubstituted pentylthio derivatised phthalocyanines have been employed for the binding of Pd(II) binding. Each of the complexes gave a distinct spectroscopic response. Only three Pd ions could be bound to **6**, while for **4** five Pd ions could be bound. The final spectra for Pd(II) binding to **4** is similar to the spectra for coordination of Pd(II) to the corresponding **5** showing that similar complexes are formed. For complexes **6** and **7**, the final spectrum is split. The observed results show that the molecular architecture and symmetry play vital roles in the binding process and the nature of the final product.

(Merk, p.a.), chromium(III) nitrate nonahydrate (Aldrich 99%) and sulfuric acid (Cicarelli, p.a.), oxygen (99.99%). Aqueous solutions were prepared in milliQ deionised water (HPLC quality).

In experiments performed at pH 1–3, the pH of the solutions was achieved by addition of $HClO_4$ solution. In experiments at pH 7.0–7.5 the buffer used was 4-(2-hydroxyethyl-1-pyperazineetanesulfonic acid (Hepes). Concentration of stock solutions of $HClO_4$ was determined using standards analytical methods.

Caution: Cr^{VI} are human carcinogens, and Cr^{V} complexes are mutagenic and potential carcinogens [10]. Contact with skin and inhalation must be avoided. Acrylonitrile is a carcinogen and must be handled in a well-ventilated fume hood [11].

2.2. Methods

2.2.1. Spectrophotometric measurements

Spectrophotometric measurements were performed by monitoring absorbance changes using a Jasco-V-550 spectrophotometer with a fully thermostated cell compartment (±0.2 °C). Disappearance of Cr^{VI} in reactions with digal and trigal was followed spectrophotometrically at 350 nm under pseudo-first-order conditions, using at least a 50-fold molar excess of substrate over Cr^{VI}. Reactant solutions were previously thermo stated and transferred into a 1.0 cm path length cell immediately after mixing. Experiments were performed at 33 °C unless otherwise stated and mixtures of sodium perchlorate and perchloric acid were used to maintain a constant ionic strength (I) 1.0 M. The disappearance of Cr^{VI} was followed until at least 80% conversion. In the kinetic measurements, the initial concentration of Cr^{VI} was kept at 6.0×10^{-4} M and the digal/trigal concentration was varied from 0.03 to 0.09 M, [$HClO_4$] was kept constant at 0.2 M. Multiple measurements showed the reproducibility of the method. Rate constant (k_6, k_5) were deduced from multiple determinations and were within ±10% error for each other. The first-order dependence of the rate upon [Cr^{VI}] was verified in a set of experiments where the $[Cr^{VI}]_0$ was varied between 0.3 and 0.6 mM but temperature, $[digal]_0$ or $[trigal]_0$, [H^+] and I were kept constant.

The presence of superoxoCr^{III}, CrO_2^{2+}, in mixtures of digal or trigal/Cr^{VI} was investigated by periodic scanning UV–Vis spectrophotometry in the 220–500 nm region of O_2-saturated solutions, 1.26 mM, containing 0.1 M digal or trigal, [$HClO_4$] = 0.2 M, [Cr^{VI}] = 0.047 mM, I = 1.0 M at 25 °C. Periodic scanning of the reaction mixture showed that the Cr^{VI} band at 350 nm decreased in intensity, while new peaks at 290 and 247 nm, characteristic of CrO_2^{2+} grew in.

2.2.2. Chromium determination in polygal/Cr^{VI} supernatant mixtures

Perchloric acid used in the reaction mixture of polygal/Cr^{VI} protonates the carboxylate groups of polygal, producing its aggregation in particles of different sizes, which depends on the experimental conditions. In all experiences, polygal was generated by direct reaction of sodium polygalacturonate solutions with perchloric acid. Different mass of sodium polygalacturonate (25–1200 mg) were dissolved in 31.0 mL of distilled water at 60 °C, with constant stirring. 1.10 mL of $HClO_4$ 3.83 M was added to a heterogeneous mixture, which was then incubated for 10 min. Finally, 2.0 mL Cr^{VI} 0.30 M was added. The final composition of the mixture was [$HClO_4$] = 0.12 M, [Cr^{VI}] = 0.0176 M, [polygal] = 0.73–35.2 g/L. Reaction mixture was kept in close recipients thermostitazed at 60 °C. After 24 h of stirring, 2.0 mL aliquot of the suspension were centrifuged during 30 min at 5000 rpm. About 200–300 μL of the clear supernatant were taken and dried in a porcelain cap and calcinated until total elimination of organic material. The yellow solid [12] was taken up to a final volume of 5.0 mL with H_2SO_4 0.10 N and measurements of the absorbance at 350 nm allowed calculation of the [Cr^{VI}].

2.2.3. EPR measurements

The EPR spectra were obtained on a Bruker EMX0 spectrometer operating at X-band frequencies (~9–10 GHz). Microwave generation was means with a Bruker 04 ER and measured with a Bruker EMX 048T frequency meter. Spectra were recorded as first derivatives of the microwave absorption in 1024 point at 20 ± 1 °C using 10 mW microwave power, 100 kHz modulation frequency, and 0.29–2.00 G modulation amplitude. g-Values were determined by reference to (dpph) (g_{iso} = 2.0036) as an external standard. In EPR measurements, scanning speed and scans number were fixed in order to reduce the time used in each measurement. This was done to avoid fluctuations in the EPR signal during the sample scanning. Power values used in the EPR experiments did not overcome 10 mW in order to avoid signal saturation.

Long-lived oxo-Cr^{V}-oligouronic and polygal complexes were generated by reaction of $K_2Cr_2O_7$ with an aqueous solution containing GSH at 25 °C. In the experiments [Cr^{VI}] = [GSH]. Final concentration in mixtures polygal/GSH/Cr^{VI}, where [Cr^{VI}] = [GSH] = 0.012–0.014 M; [polygal] = 19.2–23.0 g/L.

All the EPR spectra were simulated using the PEST WINSIM [13] program assuming 100% Lorentzian line shapes. The spectral parameters for each Cr^{V} species were similar in all simulations, with a maximum deviation of ±0.0001 in the g_{iso} values. Values for a_{iso} (^{1}H) were included in the simulations only when were greater than the line width of the oxo-Cr^{V} species.

2.2.4. Polymerization test

The presence of free radicals in the reactions of digal and trigal with Cr^{VI} was tested by acrylonitrile polymerization test. About 0.2 mL of acrylonitrile was added to a solution of Cr^{VI} (0.0027 mmol) and digal/trigal (0.07 mmol) in $HClO_4$ 0.20 M (0.5 mL). After a few minutes at 33 °C, a white precipitate appeared. 0.5 mL of acrylonitrile was added to a reaction mixture containing 53.1 g/L of polygal and 8.0 mM of Cr^{VI}, in 2.0 mL of $HClO_4$ 0.01 M. The mixture was left 2.0 h at 60 °C. After this time, the white precipitate could be seen. ^{13}C NMR of a D_6-DMSO solution of the white solid and FT-IR of the solid showed the pattern characteristic of polyacrilonitrile. Blank experiments with either Cr^{VI} or polygal gave no detectable white precipitates. Control experiments (without Cr^{VI} or reductant present) did not show the formation of a precipitate. The possible reaction of Cr^{V} or Cr^{IV} with acrylonitrile was tested with Na[Cr^{V}O(ehba)$_2$] [14] and [Cr^{IV}O(ehba)$_2$] [15] (ehba = 2-ethyl-2-hydroxybutanoic acid). No precipitation occurred on mixing the Cr^{V} or Cr^{IV} complexes with acrylonitrile under the same conditions as those used in the Cr^{VI} + digal/trigal/polygal reactions.

2.2.5. Effect of external reducing agent (Na_2SO_3) in polygal/Cr^{VI} mixture

Reaction mixture of polygal and perchloric acid were 35.2 mg/L and 0.12 M, respectively. About 0.9 mmol of Na_2SO_3 and 2.0 mL of Cr^{VI} solution 0.3 M were added to 34.1 mL of the reaction mixture.

2.2.6. HCO_2H and CO_2 determination in polygal/Cr^{VI} mixtures

Supernatant of polygal/Cr^{VI} reaction mixture was employed to analyse oxidation products. Carbon dioxide was measured in 35.0 g/L polygal and Cr^{VI} 2.90 mmol/L mixture, in $HClO_4$ 0.12 M. The reaction mixture was continuously stirred and flushed with pure nitrogen at 60 °C. Gaseous products were passed trough three flasks containing NaOH solution. Once the reaction finished, NaOH solutions were titrated with standard HCl in order to determine the carbon dioxide generated. Supernatant was filtered employing a 0.2 μm of porous diameter membrane and analysed by HPLC, showing the presence of formic acid with retention time (R_t) 13.20 min. An aminex HPX-87H column at 25 °C and 0.6 mL/min flow, detection at 220 nm, was used for this experiment. Co

chromatography of polygal reaction mixture with a formic acid solution of known concentration afforded an increment in the 13.20 min peak, confirming identity of detected product. Additionally supernatant polygal/Cr^{VI} reaction mixture was taken to pH 2 with KOH 0.5 M, filtrated to eliminate $KClO_4$ and then distilled. To 5.0 mL of the distillate, 1.0 mL of $HgCl_2$ (2.0%) was added at 80 °C and a white precipitate of Hg_2Cl_2 was observed, which indicate the presence of a reducing compound [16]. Peak area versus [HCO_2H] calibration curves were obtained by HPLC and used for formic acid quantification.

3. Results and discussion

3.1. Digal, trigal or polygal/Cr^{VI} reaction intermediates

Time-dependent UV/Vis spectra of digal/Cr^{VI} and trigal/Cr^{VI} reaction mixtures showed absorbance decrease at 350 nm and 420–470 nm, while absorbance at 570 nm increased, without an isosbestic point, Fig. 1.

The lack of an isosbestic point indicated that there were two or more competing reactions at any time and that, intermediate chromium species coming from Cr^{VI} to Cr^{III} reduction, were present in appreciable concentrations. At the end of reaction, two d–d-bands ascribed to Cr^{III} were observed at λ_{max} 411 nm (ε = 17.5 M^{-1} cm^{-1}) and λ_{max} 570 nm (ε = 15.2 M^{-1} cm^{-1}), corresponding to $^4A_{2g} \rightarrow {}^4T_{1g}$ and $^4A_{2g} \rightarrow {}^4T_{2g}$ transitions of $[Cr(OH_2)_6]^{3+}$ ion [17]. Therefore, it was confirmed that Cr^{III} aqua ion was the only inorganic product under our experimental conditions.

3.1.1. Oxo-Cr^V species characterization by EPR spectroscopy

Presence of oxo-Cr^V-di or trigal species can be identified with great sensitivity by EPR spectroscopy, where strong and narrow isotropic signals were observed at room temperature in X-band spectra. Assignment of the structures of the oxo-Cr^V species in solutions have, therefore, been made on the basis of the isotropic EPR parameters g_{iso}, A_{iso} and $^1Ha_{iso}$.

3.1.1.1. Digal chromium(V) complexes. Multiplicity of EPR signals of digal/Cr^{VI} reaction mixture at pH 1–3 could not be resolved because the shf coupling constants were lower than the line width. Spectra were simulated with three singlets in order to obtain information from the average g_{iso} values of oxo-Cr^V species in the reaction mixture. At pH 7.0, EPR signals showed lower line width, and $^1Ha_{iso}$ values were obtained. Table 1 shows the results obtained from the experimental spectra simulation (Fig. 2).

The ^{53}Cr A_{iso} value belonging to oxo-Cr^V/digal species was 17.3×10^{-4} cm^{-1}, characteristic of oxo-Cr^V pentacoordinate species [18–21]. This result was in agreement with previous works where it was found that five-coordinated oxo-Cr^V species have higher g_{iso} and lower ^{53}Cr A_{iso} values than the corresponding six-coordinated species [21–23]. Taking into account spectral parameters, we were able to assign the g_{iso} 1.9780/1.9784 to a bischelate, where digal bounds an oxo-Cr^V through the carboxylate group and the oxygen of pyranosic ring Fig. 3a. Considering that digal acid is under the pyranosic form in water [24], coordination through the fragment of β-hydroxiacids was discarded because it implies formation of a six member chelate ring, which it is not a favourable situation [21]. g_{iso} = 1.9788 value belongs to a bischelate pentacoordinate oxo-Cr^V species, bound to carboxylate group and three alcoxy group [21], [$Cr^VO(O^{6(6')}$, O^{ring}-digal)/$O^{1'(3)}$,$O^{2'(4)}$-digal) (Fig. 3b).

At pH 7.0 the digal/Cr^{VI} reaction mixture afforded oxo-Cr^V complexes coordinated to a diolate group where the triplets were assigned to species [Cr^VO(*cis*-$O^{1'(3)}$,$O^{2'(4)}$-digalacturonate)$_2$] and mixed species [Cr^VO(*cis*-$O^{1'}$,$O^{2'}$-digalacturonate)(*cis*-O^3,O^4-digalacturonate)]$^-$ (Fig. 4).

3.1.1.2. Trigal chromium(V) complexes. Table 2 shows the results obtained after simulation of the EPR signals at different pH value (Fig. 5).

At pH 2.0 the mayor species (73.8%) presents a g_{iso} 1.9786 value. This signal was assigned to a bischelate of oxo-Cr^V pentacoordinate, where the metal is being bound by two molecules of trigal, through carboxylate groups and a ring oxygen [$Cr^VO(O^{CO2}$, O^{ring}-trigal)$_2$]$^-$. The other species with g_{iso} 1.9790/3 in a minor proportion was ascribed to [Cr^V $O(O^{CO2}$, O^{ring}-trigal)(*cis*-O–O-trigal)]$^-$ complex. At pH 3.0, the EPR spectrum shows that the species [Cr^V $O(O^{CO2}$, O^{ring}-trigal)$_2$]$^-$(g_{iso} 1.9786) and [$Cr^VO(O^{CO2}$, O^{ring}-trigal)(*cis*-O,O-trigal]$^-$(g_{iso}1.9792) were preponderant. A triplet signal at g_{iso} 1.9796 was assigned to [Cr^VO(*cis*-O,O-trigal)$_2$]$^-$ species. At pH 4.0, the proportion of species [Cr^VO(*cis*-O,O-trigal)$_2$]$^-$ (g_{iso} 1.9796 and 1.9800) were 39% of the $[Cr^V]_T$ in the reaction mixture, meanwhile at pH 7.0 the species of oxo-Cr^V-*cis*-diolate afforded the 100% of the $[Cr^V]_T$ in the solution. So, oxo-Cr^V species distribution with pH follows the same tendency observed in others uronic acids and polyhidroxocarboylic compounds [25].

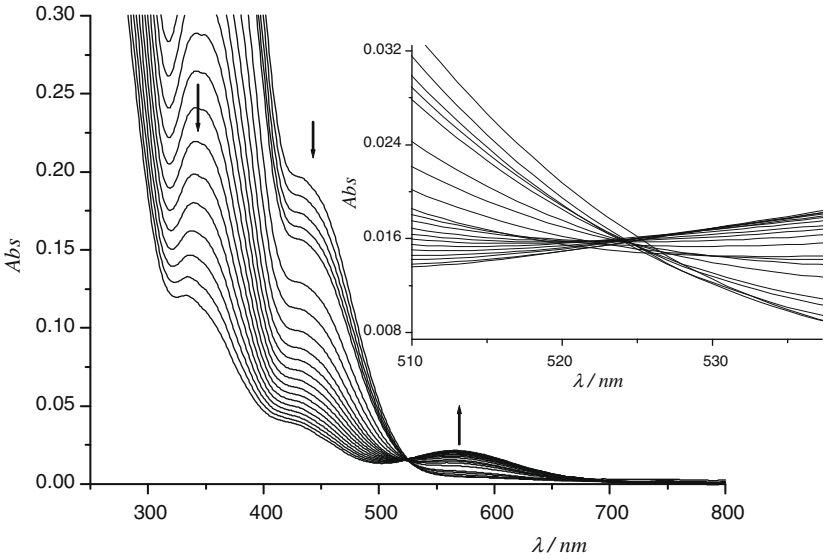

Fig. 1. Time evolution of the UV/Vis spectra from a mixture of trigal (0.04 M) and Cr^{VI} (1.35 mM) over a period of 2.0 h; [$HClO_4$] = 0.20 M; T = 33 °C and I = 1.0 M.

* [Cr^{VI}] = [GSH] = 5.59 mM.

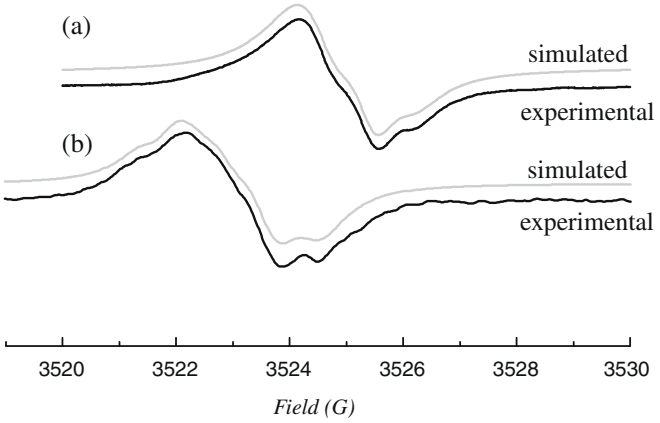

Fig. 2. Experimental and simulated X-band EPR spectra of mixtures digal/Cr^{VI}: (a) pH 3; [Cr^{VI}] = [GHS] = 1.22 mM; [digal] = 0.19 M; (b) pH 7; [Cr^{VI}] = [GSH] = 5.59 mM; [digal] = 0.28 M. T = 20 °C; $\nu \approx$ 9.76 GHz; I = 1.0 M; mod. amp. = 0.40–0.29 G.

3.1.1.3. Polygal chromium(V) complexes. EPR spectra of polygal with Cr^{VI} reaction mixture showed more complex and less resolved signals than in the former system. In general, the signals were very wide at every concentration of protons studied, which indicated the contribution of several Cr^{V} isomers. In a polygal/Cr^{VI} reaction mixture at pH 2–3, after 20 h of reaction, EPR spectra were composed by three signals (Fig. 6), g_{iso} values presented in Table 3.

The signal with average g_{iso} = 1.9783/5 belongs to species where the oxo-Cr^{V} was coordinated to two alcoxo groups and two carboxylate groups, meanwhile the signal with average g_{iso} = 1.9752/7 belongs to [$Cr^{V}O(O^{CO2}$,O-polygal)$(H_2O)_2]^{+}$ specie. Unlike the results observed in the olygomers, there was approximately a 20% of species in this pH range, where the oxo-Cr^{V} group is being coordinated with four alcoholate groups (g_{iso} 1.982–1.981) at the beginning of the reaction. As it is observed on Fig. 7, the proportion of species with average g_{iso} = 1.9783/5 increases with time, meanwhile the others decreases, at 50 h the species oxo-Cr^{V}-$(O_2CR)_2$ are clearly predominant.

The numerous chelating sites and the flexibility of the polymer chain, allowed the formation of several oxo-Cr^{V} species, coordinated with α-hydroxycarboxylate and diolates at acidic pH. Anyway, the predominant species with g_{iso} 1.9783 during reaction time, indicated that the coordination mode of $Cr^{V}O(O^{CO2}$, O^{ring}-polygal$)_2]^{-}$ was the most suitable from the thermodynamic point of view at acidic pH. Reaction mixture of polygal/Cr^{VI}/GSH at pH 7.0, showed an average g_{iso} = 1.9796. Fig. 8 shows time evolution of a reaction mixture of GSH/Cr^{VI} in presence of polygal.

In this figure, it is possible to notice that Cr^{V} produced by redox reaction between Cr^{VI} and GSH was coordinated faster by GSH than by the polymer. The specie Cr^{V}–GSH (g_{iso} 1.9857) exchanged GSH for polygal, affording g_{iso} = 1.9796, which belongs to species of oxo-Cr^{V} coordinated to four alcoholate groups. Therefore, at pH 7.0, average g_{iso} value indicates that coordination between Cr^{V} and polygal took place mainly through the alcoholate groups of the ligand.

3.2. Intermediacy of Cr^{II}

It is known that Cr^{IV} oxidizes alcohols as a two-electron oxidant to yield Cr^{II} and the oxidized organic product. The fact that Cr^{II} is

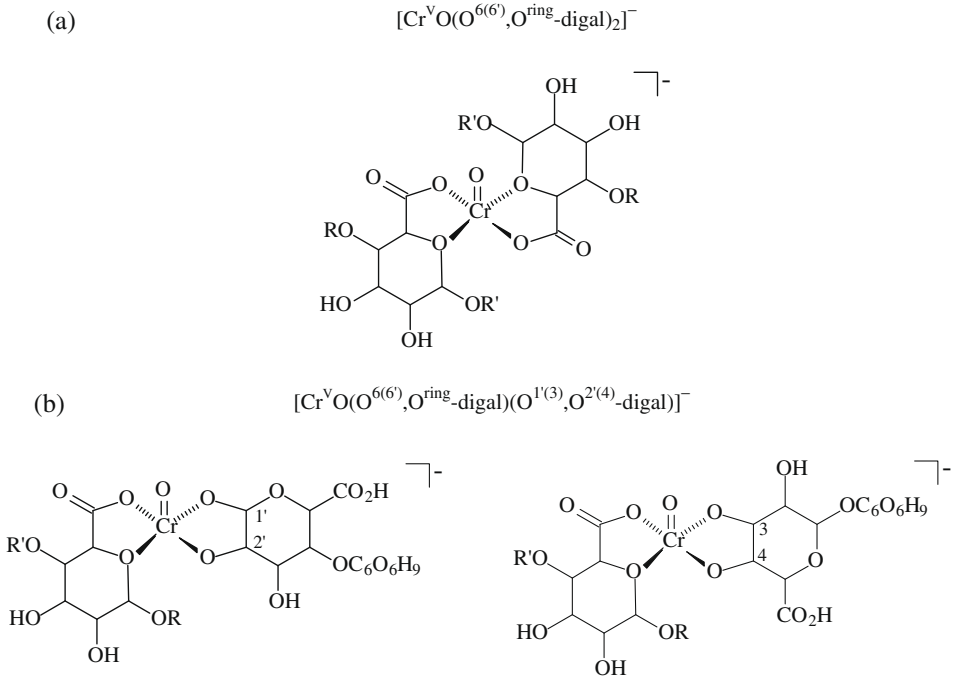

Fig. 3. Structures of Cr^{V} complexes with digal at pH 1–3. R = H and R′ = $C_6O_6H_9$ (coordination through the reducing residue) or R = $C_6O_6H_9$ y R′ = H (coordination through the non reducing residue).

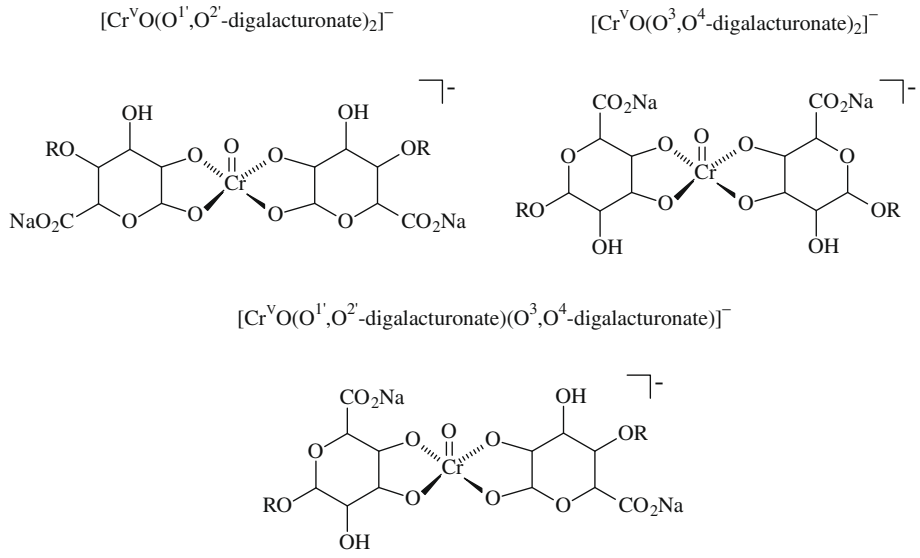

Fig. 4. Structures of Cr^{V} complexes with digal at pH 7.

involved in the oxidation mechanism of several alcohols by Cr^{IV} and Cr^{VI} in $HClO_4$ was demonstrated by conversion to CrO_2^{2+} upon reaction with molecular oxygen [26–30]. At high $[O_2]$ and low $[Cr^{VI}]$ the reaction of Cr^{II} with O_2 can compete successfully with the reaction of Cr^{II} with Cr^{VI} and the autocatalytic consumption of CrO_2^{2+} by Cr^{II}. If Cr^{II} is intermediate specie in the redox reaction, CrO_2^{2+} should be detected. The interdemiacy of Cr^{II} in the reaction of digal or trigal with Cr^{VI}, was monitored by the formation of CrO_2^{2+}, using low $[Cr^{VI}]$ and high $[O_2]$. A periodic scanning of O_2-saturated solution (1.26 mM) of a Cr^{VI} + digal or trigal reaction mixture in 0.20 M $HClO_4$ showed two absorption bands at 290 and 247 nm, characteristic of CrO_2^{2+} (Fig. 9).

Inset Fig. 9 shows CrO_2^{2+} absorption at 247 nm versus time. CrO_2^{2+} absorbance at 247 nm was calculated in the following way:

Table 2

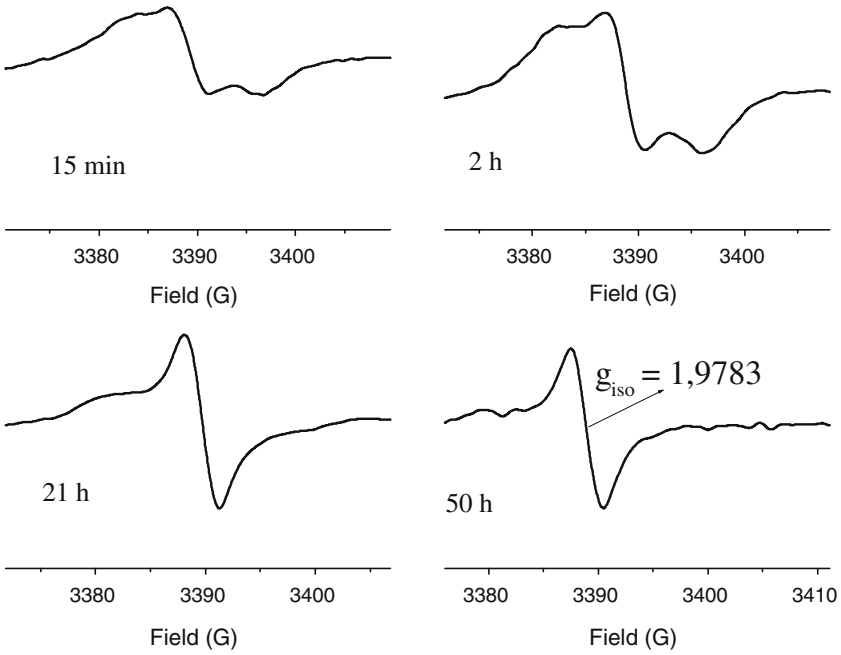

Fig. 7. EPR espectra time evolution of oxo-Cr^{V}-polygal species at acidic pH.

$$Abs^{247}(CrO_2^{2+}) = Abs^{247} - Abs^{350} \times (\varepsilon 1)^{-1} \times (\varepsilon 2)$$

where $\varepsilon 1$ and $\varepsilon 2$ represent the molar absorption coefficient of Cr^{VI} at 350 and 247 nm, respectively. In the experimental condition used $\varepsilon 1 = 1550\ M^{-1}\ cm^{-1}$ and $\varepsilon 2 = 1900\ M^{-1}\ cm^{-1}$. Keeping in mind that the molar absorption coefficient of CrO_2^{2+} at 247 nm is 7000 $M^{-1}\ cm^{-1}$ [27], the maximum concentration of CrO_2^{2+} (t_{max} = 12.1 - min) was 37%.

These spectroscopic results showed that Cr^{II} was produced in the redox reaction and this fact was taken as evidence that Cr^{IV} was implied in the redox mechanism of digal or trigal oxidation by Cr^{VI} in acidic media. The yielding of CrO_2^{2+} is expected to approach 100% if the reaction takes place exclusively through the $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ pathway [27]. In these reactions $[CrO_2^{2+}]_{max}$ reached a value of 37% suggesting that one half of the $HCrO_4^-$ was reacting through a pathway that involved Cr^{II} .This behaviour was observed in another related systems [31]. Under the present kinetic measurements conditions, Cr^{IV} reacted with digal or trigal much faster than Cr^{VI}. High reactivity of Cr^{IV} against alcohols and aldehydes [27], neutral carbohydrates, aldonic, uronic, aldaric acids [32] and polysaccharides [33] has been experimentally demonstrated. This implies that Cr^{V} was the only chromium intermediate that accumulates in the reaction mixtures as can be seen by EPR.

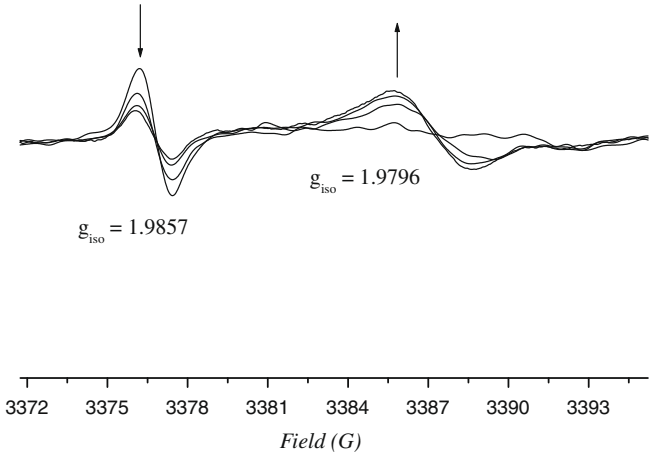

Fig. 8. EPR espectra time evolution of polygal/Cr^{VI}/GSH mixtures at pH 7.

3.3. Rate studies

Absorbance curves versus time at 350 nm of the digal or trigal/Cr^{VI} mixtures showed a monotonic decrease which cannot be described by a single exponential decay. These kinetics profiles were adequately described by the set of consecutive first-order reactions of Scheme 1. It is known that Cr^{V} species absorb strongly at 350 nm and may superimpose Cr^{VI} absorbance yielding the wrong interpretation of spectrophotometric absorbance decay values, especially when the Cr^{VI} and Cr^{V} decay rates are of the same order [34]. So, considering the Cr^{V} absorption superimposition, the absorbance at 350 nm, at any time during the redox reaction, is given by:

$$Abs^{350} = \varepsilon^{VI}[Cr^{VI}] + \varepsilon^{V}[Cr^{V}] \quad (1)$$

Combining Eq. (1) with rate expressions [35] derived from Scheme 1 yields

$$Abs^{350} = Abs_0 e^{-2k6t} + k_6 \varepsilon^{V}[Cr^{VI}]_0 (e^{-k5t} - e^{-2k6t})/(2k_6 - k_5) \quad (2)$$

In Eq. (2), ε^{V} refers to the molar absorptivity of Cr^{V}-digal or Cr^{V}-trigal at 350 nm (ε^{V} 1800 $M^{-1}\ cm^{-1}$). Parameters k_6 and k_5 refer to the rate of disappearance of Cr^{VI} and Cr^{V}, respectively, and were evaluated from a non-linear iterative computer fit of Eq. (2). It must be noted that in Eq. (2), k_6 appears in the numerator of the pre-exponential term and $2k_6$ appears in the denominator and in the exponential terms because, according to the proposed reaction scheme, only half of the Cr^{VI} reaches Cr^{III} through a Cr^{V} intermediate. At $HClO_4$ 0.2 M, in the 0.03–0.09 M digal or trigal range, the calculated values of k_6 and k_5 were very close ($k_6/k_5 \approx 2.50$–$1.95/1$). This fact implied that the slow redox steps involved the reduction of Cr^{VI} and Cr^{V}. The simulation of the kinetic profiles employing k_6 and k_5 values obtained from Eq. (2), showed that the maximal $[Cr^{V}]$ represented 33.3% of the total Cr in $HClO_4$ 0.2 M and trigal 0.09 M (Fig. 10).

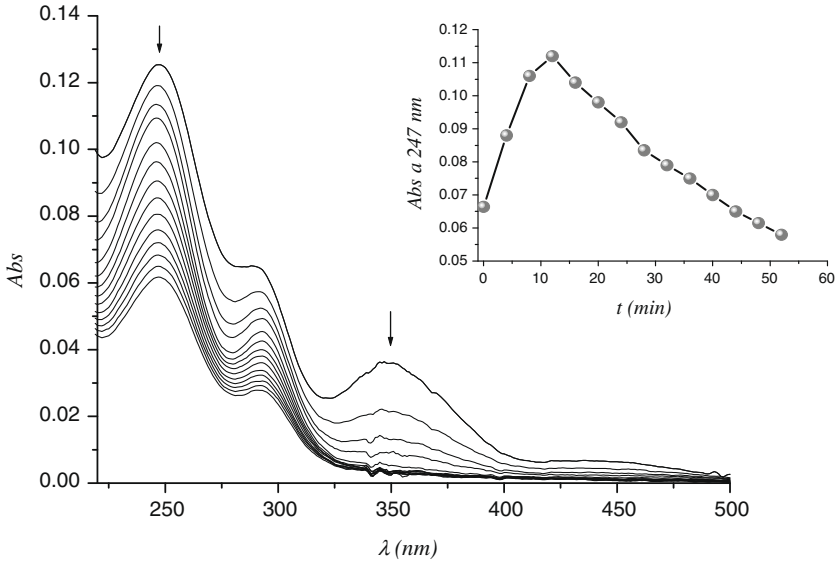

Fig. 9. CrO_2^{2+} formation of (λ_{max} 290, 247 nm) from the reaction between 0.10 M trigal, 1.26 mM O_2, 0,20 M $HClO_4$ and 0.047 mM Cr^{VI}, at 25 °C and I = 1,0 M. Spectra recorded every 4 min. Inset shows CrO_2^{2+} absorption at 247 nm vs. time.

$$2\,Cr^{VI} \longrightarrow Cr^{V} + Cr^{III} \longrightarrow Cr^{III}$$

Scheme 1.

These results were consistent with the fact that absorbance at 350 nm reflects changes in [Cr^{VI}] and [Cr^{V}]. The calculated kinetics parameters, k_6 and k_5, for various [trigal] and [digal] at fixed [$HClO_4$] are summarized in Table 4.

In 0.1 M $HClO_4$, the Cr^{V} EPR signal of a 155:1 digal:Cr^{VI} mixture grows and decays at 20 °C (Fig. 11).

The rate constants for the formation and disappearance of the intermediate Cr^{V} were calculated from the variation of the intensity of the EPR signal versus time, and the k_6 and k_5 values were obtained using Eq. (3) derived from Scheme 1 for the total Cr^{V} in the mixture at any time.

$$h = A\,k_6(\exp(-2k_6t) - \exp(-k_5t))/(k_5 - 2k_6) \quad (3)$$

where A depends on the spectrometer settings (gain, power, modulation, etc.).

In the range of substrate employed in this work, plots of k_6 and k_5 versus [trigal] and [digal] gave good straight lines from which values of k_{6h} and k_{5h} were determined (Fig. 12).

For 0.2 M $HClO_4$ the rate laws for the Cr^{VI} and Cr^{V} disappearance are then given by

$$-d[Cr^{VI}]/dt = 2k_{6h}[S][Cr^{VI}] \text{ and } -d[Cr^{V}]/dt = k_{5h}[S][Cr^{VI}]$$

where $k_{6h} = 0.027(3)\ M^{-2}\ s^{-1}$; $k_{5h} = 0.013(1)\ M^{-2}\ s^{-1}$ and S = digal

where $k_{6h} = 0.024(2)\ M^{-2}\ s^{-1}$; $k_{5h} = 0.010(1)\ M^{-2}\ s^{-1}$ and S = trigal

The fact that CrO_2^{2+} was detected in the redox reaction of digal and trigal with Cr^{VI}, coupled with the observation of Cr^{V} species and the successful trapping of organic radicals using acrylonitrile

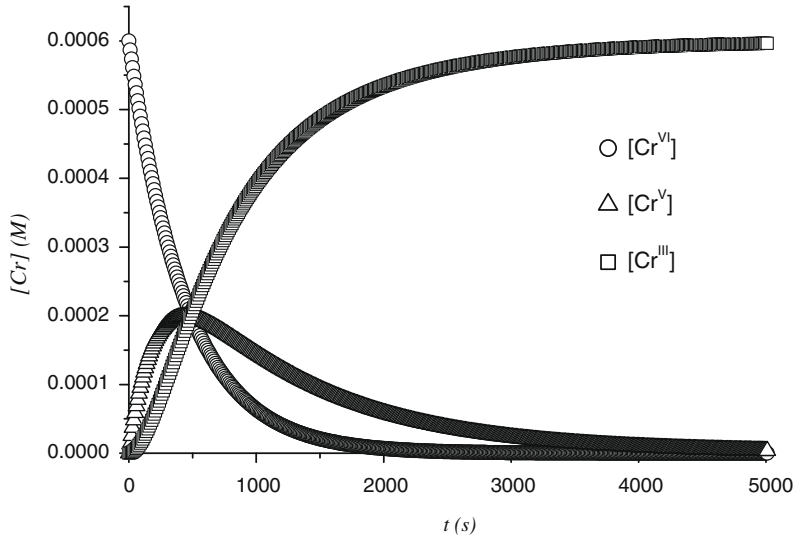

Fig. 10. Simulated kinetics profiles for Cr species. [Cr] calculated using k_6 = 0.00224 s^{-1}, k_5 = 0.00093 s^{-1}; [trigal] = 0.09 M; [$HClO_4$] = 0.20 M; T = 33 °C; I = 1.0 M; $[Cr]_T$ = 0.6 mM.

Table 4
Observed pseudo-first-order rate constants (k_6 and k_5) for different concentrations of digal–trigal at [$HClO_4$] 0.20 M.

[Digal or trigal] (M)	0.03	0.048	0.06	0.09
	$10^3\ k_6/s^{-1}$			
Digal	0.86(9)	1.3(1)	1.6(2)	2.4(2)
Trigal	0.69(7)	1.2(1)	1.4(1)	2.2(2)
	$10^3\ k_5/s^{-1}$			
Digal	0.36(4)	0.61(6)	0.81(8)	1.2(1)
Trigal	0.28(3)	0.52(5)	0.61(6)	0.93(9)

T = 33 °C; $[Cr^{VI}]_0$ = 0.6 mM; I = 1.0 M.

indicated that reaction occured through both one and two electron pathways involving Cr^{IV} and Cr^{V} intermediates species. However, under conditions employed in the kinetics measurements, Cr^{IV} reacted with digal and trigal faster than Cr^{VI} and does not accumulate in the reaction mixture. Therefore, Cr^{IV} should be involved in fast steps of the reaction pathway. In Scheme 2, a mechanism is proposed which combines $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$ pathways, and takes into account: (a) kinetics results, (b) the polymerization test of acrylonitrile, (c) detection of oxo-Cr^{V} intermediates by EPR (d) observation of CrO_2^{2+}.

In the [$HClO_4$] under study, Cr^{VI} may exist as $HCrO_4^-$ [36], and this species is proposed as the reactive form of Cr^{VI}, in agreement with the first-order dependence of the reaction rate on [Cr^{VI}]. It is known that the chromic oxidation of alcohols, glycols and dicarboxylic acids are preceded by the formation of a chromate ester [36,37], so we proposed that the first step of the mechanism in Scheme 2 involves the formation of sustrate-Cr^{VI} mono-chelate (Eq. (4)), this chromate ester should be formed rapidly prior to the redox steps. The formation of the chromate ester is followed by the slow redox step where the C–C bond cleavage is proposed to occur through an acid catalyzed two-electron redox process to yield Cr^{IV}, HCO_2H and oxidized substrate (Eq. (5)).

The formation of Cr^{IV} was consistent with the observation of CrO_2^{2+}, the product of the reaction of Cr^{II} with O_2, which is taken as evidence of the Cr^{IV} formation [27,28]. After the slow redox step,

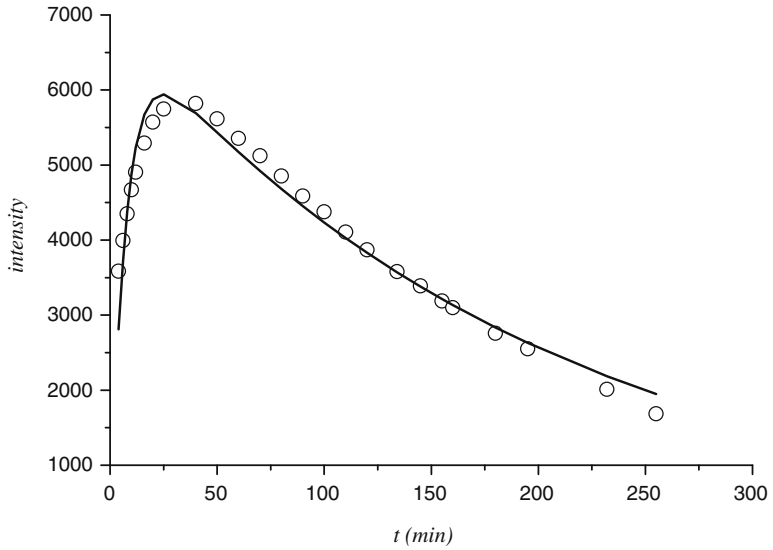

Fig. 11. Intensity of Cr^{V} EPR signals vs. time. [Cr^{VI}] = 0.97 mM, [digal] = 0.15 M [$HClO_4$] = 0.1 M, I = 1.0 M; T = 20 °C; mod. amp. = 2.0 G.

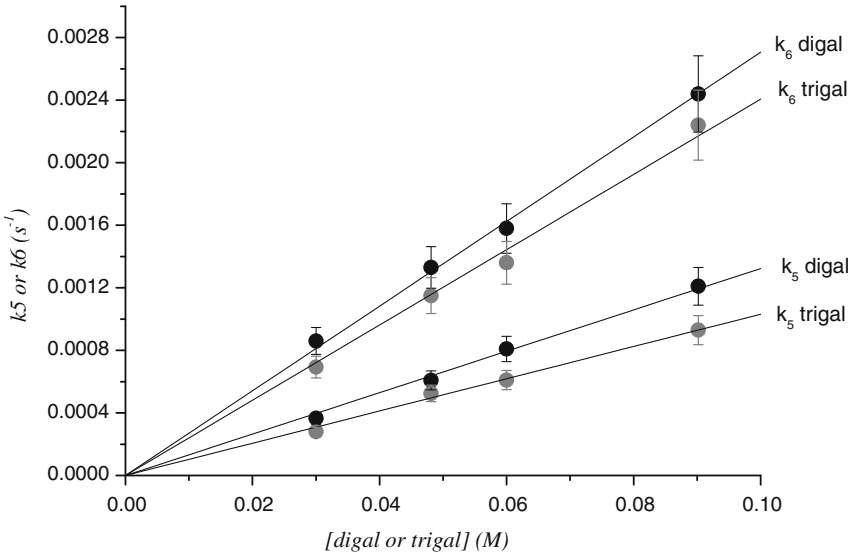

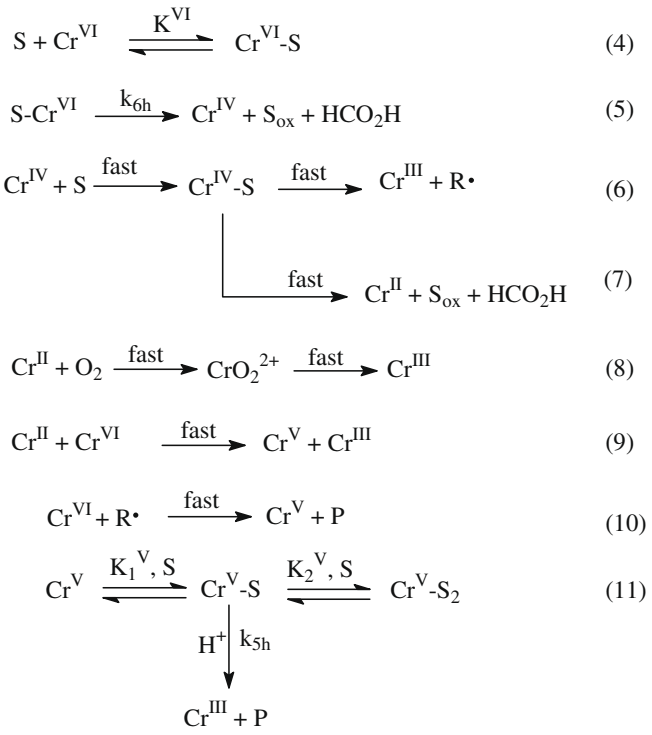

Fig. 12. Effect of [digal or trigal] on k_6 and k_5 at 33 °C; I = 1.0 M at [$HClO_4$] 0.2 M.

Scheme 2.

Cr^{IV} is predicted to react with excess substrate to yield Cr^{III} and radical or Cr^{II} and oxidize substrate through two alternative fast steps (Eqs. (6) and (7)). The first parallel step was supported by the observed polymerization of acrylonitrile when it was added to the reaction mixture, while the second one, by the formation of CrO_2^{2+}. Cr^{V} was produced by fast reaction of Cr^{II} with Cr^{VI} Eq. (9). Under the conditions used in the kinetic experiments, Eq. (8) can be neglected. The kinetic data indicate that Cr^{V} formed in the fast steps can further oxidize digal and trigal through an acid catalyzed step to yield Cr^{III} and the oxidized substrate as the final redox products. In Scheme 2, it is proposed that Cr^{V} reacts with digal or trigal to form an oxo-Cr^{V}-digal/trigal monochelate that yields the redox products through an acid catalyzed step ((11)). This proposal is in agreement with the EPR spectra at $[HClO_4]$ 0.20 M.

3.4. Cr^{VI} reduction and Cr^{III} retention by polygal

The redox reaction between Cr^{VI} and polygal and the tendency of the polysaccharide matrix in retaining Cr^{III} coming from redox reaction was studied. Under strong acidic media, polygal was fully protonated producing insoluble aggregates which consist in polymer chains joined by hydrogen bonds between the carboxyl and hydroxyl groups [38]. At pH 7.00, the polymer was soluble, due to the presence of deprotonated carboxylate groups. Speed of aggregation depends on the experimental conditions (acidity, temperature, shaking, etc.) and was standardized in order to obtain particles of uniform size. Reaction mixture of polygal/Cr^{VI} was performed keeping $[Cr^{VI}]$, $[HClO_4]$ and temperature constant. The amount of polygal was varied between 25 and 1200 mg. Absorbance measurements at 350 nm versus time performed on mixtures polygal/Cr^{VI} showed the disappearance of Cr^{VI}. At the same time, absorbance values at 570 nm did not show the corresponding increment of Cr^{III} because it was capturated on the solid matrix of the polymer as a cyan-coloured solid. The polygal efficiency in Cr^{III} retention – coming from the reduction of Cr^{VI} – was defined in Eq. (12) as *%E*.

$$\%E = 100 \times \left([Cr^{VI}]_0 - [Cr]_{final}\right)/[Cr^{VI}]_0 \quad (12)$$

Fig. 13 and Table 5 show the obtained results varying the mass of polygal.

As we can see, employing 990 mg of polygal, *%E* is almost 90%. Increasing the amount of polygal from 990 to 1200 mg does not produce a significative increment on the *%E* value. The chromium analysis on the solid, confirm the results of the supernatant. For the experience with 1200 mg of polygal, analysis of the solid afforded 23 mg Cr per solid g, which represents 88.5% of the initial $[Cr^{VI}]_0$ coincident with the value showed in Table 5, considering the experimental error. The efficiency of polygal for eliminating Cr was higher, as demonstrated in the determination of *%E* at different times even though the speed of redox process was low. Considering an amount of 780 mg polygal, in the experimental conditions of Table 5, the *%E* was 39.0 and 74.0 for 3.0 and 10 h, respectively. In order to check if the speed of reduction of $[Cr^{VI}]$ by polygal was the limiting process of the reaction, the same

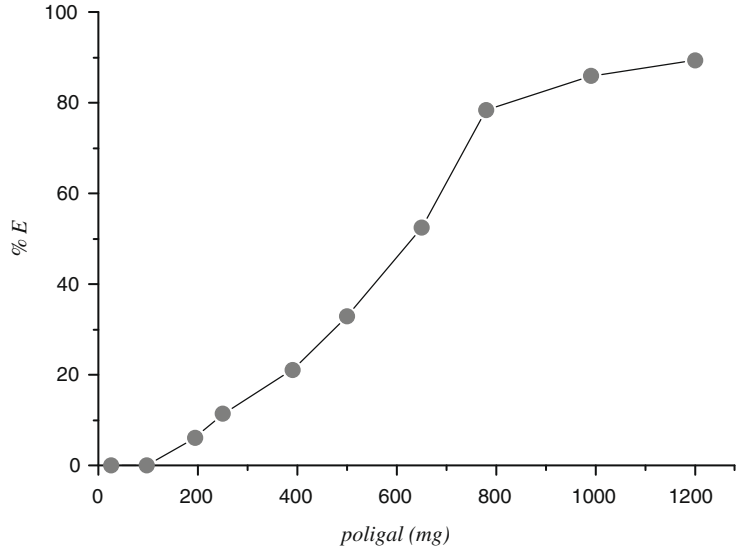

Fig. 13. Effect of [polygal] on *%E* at 60 °C; *I* = 1,0 M, *t* = 24 h at $[HClO_4]$ 0.12 M.

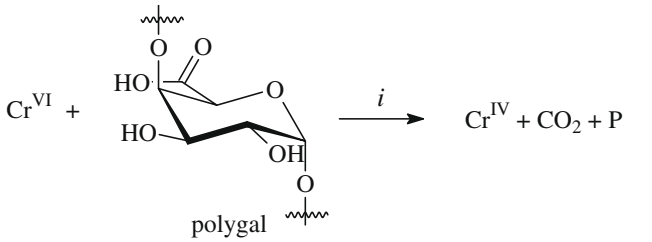

Table 5
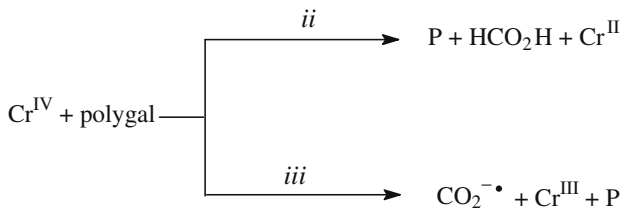
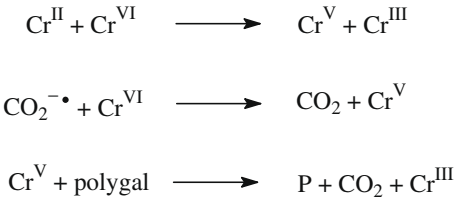
Effect of [polygal] on %*E* at 60 °C; I = 1.0 M, t = 24 h at [$HClO_4$] 0.12 M.



Polygal (mg)	$[Cr]_f$ (mM)	%*E*
1200	1.86	89.4
990	2.46	87.0
780	3.80	78.4
650	7.64	56.6
500	11.79	33.0
390	13.45	23.6
250	15.35	12.8
195	16.30	7.4
97.5	17.6	0
25	17.6	0



reaction mixture added with 0.9 mmol Na_2SO_3 was prepared. The reduction of Cr^{VI} to Cr^{III} was almost instantaneous and the %*E* value reached 90%, practically the same value obtained after 24 h without the addition of Na_2SO_3. This result confirms that Cr^{VI} reduction was the limiting step in the chromium elimination by polygal.

3.5. Polygal/Cr^{VI} reactions mixture: oxidation product

The oxidation of polygal with Cr^{VI} afforded two products: HCO_2H (determined by HPLC) and CO_2 determined by titration in alkaline medium. The quantification of these products afforded 0.3 mol HCO_2H and 1.1 mol CO_2 per mol Cr^{VI}. According to the experimental conditions employed, the formic acid could react with Cr^{VI} affording CO_2. The last reaction is slower than Cr^{VI}-polygal reaction [39] and the concentration of HCO_2H was lower than the carboxylate groups in polygal. Consequently, the transformation of formic acid in CO_2 by oxidation with Cr^{VI} was discarded. In the proposed mechanism (Scheme 3), if the consecutive steps (ii) and (iii) occur in the same proportion then, the stoichiometry of the global reaction could be written as the following reaction (Eq. (13)).

Scheme 3.

$$Cr^{VI} + 1.5\ \text{polygal} \rightarrow Cr^{III} + 1.5\ P + 1.25\ CO_2 + 0.25\ HCOOH \quad (13)$$

According to this stoichiometry, 1.25 mol of CO_2 and 0.25 mol of HCOOH per mol of Cr^{VI} should be produced, which is in agreement with the experimental results. The absence of signals belonging to monomers or oligomers of low molecular weight in the HPLC chromatograms of the supernatant reaction mixture, discarded the participation of the glucosidic linkage α (1–4) in the redox reaction with Cr.

Scheme 3 adjusts the reaction mechanism for oxidation of oxygenated compounds with Cr^{VI}, in agreement with sequences combination: $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$.

4. Conclusions

The results presented in this report showed that digal, trigal and polygal were able to reduce Cr^{VI} to Cr^{III}. The redox reaction took place through the combination of $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$ pathways related with Cr^{V} and radical species in digal–trigal/Cr^{VI} mixtures.

Besides, in this report the results evidence that polygal was able to reduce Cr^{VI} to Cr^{III} and trap efficiently the last form of chromium, so it turns out to be an interesting model for the study of biomaterials which possess a high proportion of this polymer in its composition. Since polygal is better as a Cr^{III} chelating agent than as a reducing agent of Cr^{VI}; the elimination of chromium from contaminated waste water could be more efficient employing biomaterial containing polygal. The results obtained are particularly important because the majority of the chromium remediation methods employed so far are meant for the reduction Cr^{VI} to Cr^{III}; without considering the free Cr^{III} in solution. Due to the fact that Cr^{III} could be oxidized biologically [40] or chemically under extreme environmental conditions [41], new methods of elimination of chromate from water should consider the elimination of chromium in both oxidation states [9].

EPR measurements show that species where Cr^{V} bounds to a ligand through the α-alcoxocarboxylate groups (or 2-O^{ring} carboxylate) predominate in acidic medium, meanwhile at pH 7.0 the species $[Cr^{V}O(\textit{cis}\text{-diolate})_2]^-$ predominate, as can be seen on aldonic acids, others uronic acids and polyhidroxocarboylic compounds [18,20,25].

Scheme 1. Synthesis of mixed-ligand complexes.

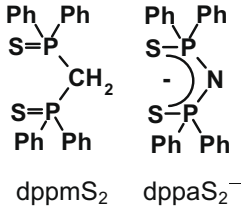

Fig. 1. Phosphinesulfide ligands.

2.2. X-ray measurements

X-ray crystallographic measurements were made on a Rigaku Saturn 70 CCD area detector with graphite-monochromated Mo Kα radiation. The crystal-to-detector distance was 54.90 mm. The data were collected at a temperature of −150 ± 1 °C to a maximum 2θ value of 57.5°. 1800 oscillation images were collected and the data were processed by using the CrystalClear software [11]. Absorption corrections were made by the numerical method for complex **1** and **2**, and by the spherical method for complex **3**. The intensity of the diffraction for complex **3** was weaker than that of the others, so complex **3** gave relatively high refinement residuals**.** The structure was solved by direct methods (SIR-92 [12]) and was refined by full matrix least squares procedures (SHELX-97 [13]). The non-hydrogen atoms are refined anisotropically and the positions of all hydrogen atoms were fixed at calculated positions. All calculations were performed by using the CrystalStructure crystallographic software package [14].

2.3. Synthesis of mixed-ligand Cu(1) complexes

2.3.1. [Cu(dmp)(dppmS$_2$)]PF$_6$ (*1*)

dmp (0.11 g, 0.50 mmol) and dppmS2 (0.22 g, 0.50 mmol) were dissolved in 10 ml of acetone. [Cu(CH$_3$CN)$_4$]PF$_6$ (0.19 g, 0.50 mmol) was then gradually added to the solution. After the solution was stirred for 2 h at room temperature, addition of diethylether (20 ml) to the solution gave orange crystals, which are collected by filtration. Yield 0.33 g (76%). *Anal.* Calc. for [Cu($C_{14}H_{12}N_2$)-($C_{25}H_{22}P_2S_2$)]PF6: C, 54.13; H, 3.96; N, 3.24. Found: C, 54.26; H, 4.14; N, 2.75%. ^{31}P NMR (acetone-d_6, 25 °C): δ 35.0.

2.3.2. [Cu(dmp)(dppaS$_2^-$)] (*2*)

dmp (0.11 g, 0.5 mmol) and K(dppaS$_2^-$) (0.24 g, 0.5 mmol) were dissolved in 10 ml of acetone. [Cu(CH$_3$CN)$_4$]PF$_6$ (0.19 g, 0.5 mmol) was then gradually added to the solution. The solution was stirred for 2 h at room temperature and an orange powder was obtained. Recrystallization of the powder from acetone/diethylether gave orange crystals. Yield 0.31 g (85%). *Anal.* Calc. for [Cu($C_{14}H_{12}N_2$)-($C_{24}H_{20}NP_2S_2$)]: C, 63.36; H, 4.48; N, 5.83. Found: C, 63.18; H, 4.21; N, 5.69%. ^{31}P NMR (acetone-d_6, 25 °C): δ 31.8.

2.3.3. [Cu(dpp)(dppaS$_2^-$)] (*3*)

This complex was prepared by a similar method used for the preparation of complex **3**; use of dpp (0.17 g, 0.5 mmol) instead of dmp gave purple crystals. Yield 0.29 g (71%). *Anal.* Calc. for [Cu($C_{24}H_{16}N_2$)($C_{24}H_{20}NP_2S_2$)]: C, 68.27; H, 4.30; N, 4.98. Found: C, 67.84; H, 4.09; N, 5.01%. ^{31}P NMR (acetone-d_6, 25 °C): δ 31.2.

3. Result and discussion

3.1. Synthesis and crystal structures

Treatment of [Cu(CH$_3$CN)$_4$]PF$_6$ with equimolar amount of dmp and dppmS$_2$ in acetone gave the mixed-ligand complex **1**. Attempt to prepare a similar complex to complex **1** by using dppaS$_2$ instead of dppmS$_2$ gave complex **2** containing dppaS$_2^-$ in which a proton on an amine moiety is eliminated from dppaS$_2$. Use of KdppaS$_2$ and dmp also led complex **2** readily. Treatment of KdppaS$_2$ and [Cu(CH$_3$CN)$_4$]$^+$ with dpp instead of dmp gave complex **3**.

The single crystals with X-ray quality of **1–3** were obtained by gradual addition of diethylether into the reaction solution. Structural data are summarized in Table 1. The structure of complex cation **1** is shown in Fig. 2. It was found that the complex has the tetrahedral structure in which each copper center is coordinated by dmp and dppmS$_2$ chelate ligands. Selected bond lengths, bond angles and torsion angles of **1** are shown in Table 2. The S–P bond lengths of **1** in dppmS$_2$ are 1.9670(7) and 1.9784(7) Å. Since it has been reported that P–S single-bond distance is 2.14 Å and P=S double-bond distance ranges from 1.916 to 1.959 Å, the P–S bond length in **1** shows the bonds almost have double-bond character [15]. The bond angle of S–Cu–S is 108.10(2)°, which is similar to that in the ideal tetrahedral structure. The chelate ring made of Cu-dppmS$_2$ moiety is like a twist boat, as deduced from the torsion angles within the chelate ring ranging from 14.6(2)° to 75.38(12)°.

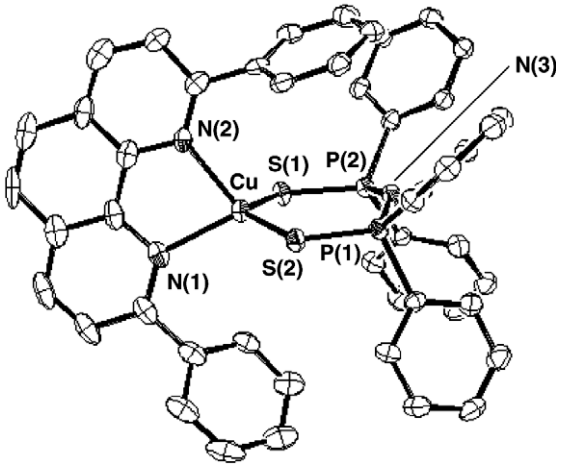

Fig. 4. X-ray structure of complex of **3**.

The structures of complex **2** and **3** containing $dppaS_2^-$ are described in Figs. 3 and 4. The selected bond lengths, bond angles and torsion angles of **2** and **3** are summarized in Tables 3 and 4, respectively. Complex **2** showed two independent molecules in the unit cell. The coordination geometry in one of the molecules is almost similar to each other. There are little differences between the structures of two independent molecules; the maximum of deviation for the corresponding bond angles is no more than 3.0°. In the $dppaS_2^-$ complexes, the S–P bond lengths range from 2.0043(8) to 2.0145(8) Å, which are slightly longer than those of **1**. The elongation should reflect the decrease of the P–S bond order, as shown in other reported transition metal complexes containing $dppaS_2^-$ ligand [10]. The bond angle of S–Cu–S in **2** is 117.77(2)° and 119.01(2)°, which is larger than that of **1**. It suggests that the chelate ring of $dppaS_2^-$ is somewhat more planar than that of $dppmS_2$. In addition, torsion angles within the chelate in **2** (11.28(4)–44.25(10)°) is smaller than those in **1** and the mean deviations from the least-squares planes which consists of six atoms in Cu-$dppaS_2$ chelate ring of two independent complexes of **2** are 0.238 and 0.256 Å, whereas that of **1** is 0.439 Å. They also show the planarity of the chelates in **2.** It should be caused by the negative charge on the imino nitrogen of the anionic ligand, $dppaS_2^-$, which promotes delocalization of π-electron within the S–P–N–P–S chelate. The coordination environment of **3** is similar to that of **2**. However, the torsion angles within the chelate ring of $dppaS_2^-$ are much smaller than those in **2**, and the mean deviation from the least-squares plane in Cu-$dppaS_2$ chelate ring of **3** is the smallest of the three complexes (0.120 Å). So they suggest that **3** has a more planar chelate ring of $dppaS_2^-$. It may be due to the repulsion from bulky phenyl rings of dpp, which forces the chelate ring of the $dppaS_2^-$ to be more planar.

3.2. Spectroscopic properties

NMR spectra have been measured to study the structures of the mixed-ligand complexes in solution. In the ^{31}P NMR spectra of **1**, a signal assigned as $dppmS_2$ was observed as a distinct singlet at δ 35.0, which is slightly shifted compared with the free ligand (δ 35.3), and no signals assigned to free ligand were observed. In addition, the phosphorus signal of **1** was shifted to higher field than that of $[Cu(dppmS_2)_2]PF_6$, which shows a singlet signal at δ 35.3. It suggests that the complexes keep mixed-ligand coordination even in solution. The spectra of **2** and **3** also show only a singlet signal of $dppaS_2^-$ moiety.

The absorption spectra of **1–3** in acetone are shown in Fig. 5. The absorption maximum of complex **1** is 457 nm with moderate intensity. ($\varepsilon = 3.1 \times 10^3\ mol^{-1}\ dm^3\ cm^{-1}$) It has been reported that mixed-ligand copper(I) complexes containing phenanthroline derivatives and diphosphines show absorption maxima ranging from 400 to 360 nm which have been assigned to MLCT transitions [2–4]. The band maximum of **1** are shifted to lower energy compared with the [Cu(diimine)(diphosphine)] complexes, but the

band is reasonably assigned to MLCT involving the π^* orbitals of the dmp ligand, because the coordination of the sulfide having weaker σ-donor character leads to a decrease of energy levels of $d\sigma^*$ orbitals interactions in the complex and a decrease of the CT excitation energy [16]. However, there is another shoulder band in the lower energy region (500–550 nm) for complex **1**. The two bands may arise from two MLCT transitions to different π^* orbitals of the phen ligand as shown in $[Ru(bpy)(CN)_4]^{2-}$ which contains two quite distinct MLCT absorptions associated with the bpy ligand [17]. A second possibility is that the second absorption band might be assigned to a LLCT (ligand-to-ligand charge transfer) from the electron-rich S-donor ligand to the electron-poor phen ligands.

The absorption maximum of complex **2** is 427 nm. The absorption band is also assigned to MLCT transition involving the π^* orbital of dmp, whereas the maximum is shifted to higher energy

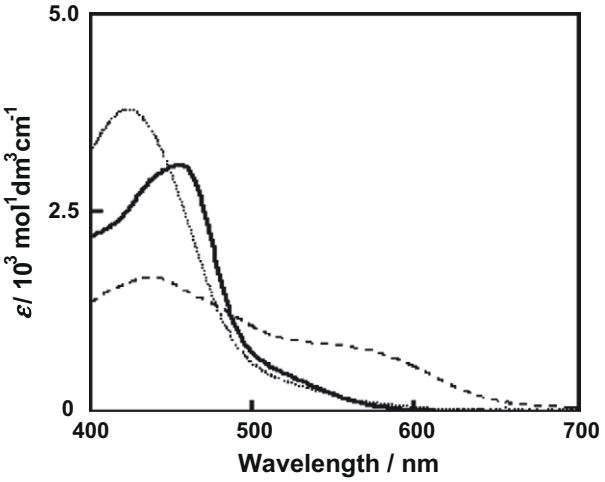

Fig. 5. Absorption spectra of complex cation **1** (solid line), **2** (dotted line) and **3** (dashed line) in acetone at room temperature.

than that of complex **1** which should reflect the stronger ligand field of $dppaS_2^-$. The shoulder band in lower energy region may be assigned to the second MLCT or LLCT as discussed for complex **1**. Complex **3** has an absorption maximum at 578 nm, which is shifted to lower energy due to extended π conjugated system of dpp compared with dmp. In order to confirm this hypothesis, the redox processes have been studied by cyclic voltammetry. Unfortunately, the redox potential in the cathodic region is too negative to estimate the potential for a diimine/diimine$^-$ redox couple. However, shoulder cathodic current in complex **3** was observed at −1.85 V versus SCE, which are clearly less negative than that of complex **1** and **2**. It may suggest that the red shift observed for dpp complex is reflected in a less negative ligand-based reduction process.

Both **1** and **2** show photoluminescence in the solid state as shown in Fig. 6. The emission maxima for **1** and **2** are 592 and 661 nm, respectively. The emissive excited states are assigned to MLCT transitions involving of the π^* orbital of dmp, as deduced from the luminescent behavior of $[Cu(dmp)2]^+$ and other mixed-ligand complexes. The Stokes shift observed for **2** (240 nm) is considerably large, whereas that of **1** is ca. 140 nm. It has been shown that a relatively large Stokes shift observed in Cu(I) com-

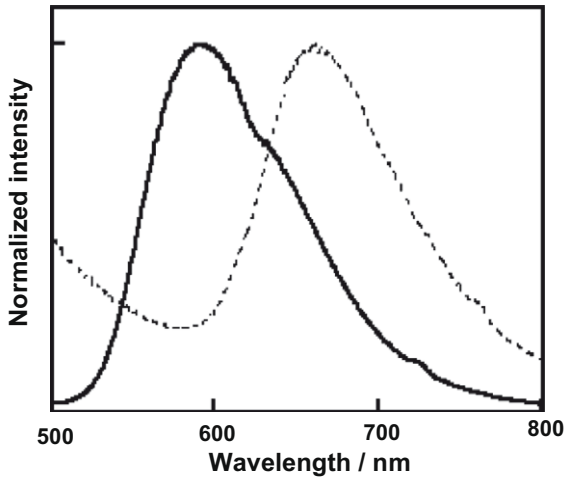

Fig. 6. Solid-state emission spectra of **1** (solid line) and **2** (dotted line) at room temperature.

plexes results from flattening distortion which occurs in the MLCT excited state [1a]. It suggests that the extent of distortion on excitation may become larger in **2** than **1**, which has relatively higher planarity of phosphinesulfide chelate than **1** as shown by X-ray analysis.

For both **1** and **2**, no emission is observed in solution. It contrasts with the fact that $[Cu(dmp)(dppe)]^+$ and $[Cu(dmp)(dppp)]^+$ emit in solution [2,4b]. It may be caused by the fact that coordination sphere around the copper atom of the diphosphine sulfide complexes is less crowded than the diphosphine complexes. The less crowded structure allows (1) the metal center to facilitate tetragonal flattening distortion of the excited luminophore and (2) the solvent molecules to attack the metal center in the excited states. These quenching mechanism [1a] should effectively affect the photophysical properties in solution.

4. Conclusions

Mixed-ligand Cu(I) complexes containing diimine and chelating phosphinesulfide ligands were synthesized. The isolated complexes, which have pseudo tetrahedral structure, were relatively stable in air. Two complexes of dmp show emission in the solid state, and their bands are assigned to MLCT.

5. Supplementary data

CCDC 715718, 715719 and 715720 contain the supplementary crystallographic data for **1**, **2** and **3**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

[Hg(quin)$_2$(OH$_2$)], aquabis(quinoline-2-carboxylato-κ^2*N*,*O*)mercury(II) (**1**), [(quinH$_2$)(HgCl$_3$)]·2quinH·H$_2$O, quinolinium-2-carboxylic acid trichloromercurate(II) bis(quinolinium-2-carboxylate) monohydrate (**2**), [Hg(quin)$_2$(EtOH)]·H$_2$O, bis(ethanol-κ*O*)bis-(quinoline-2-carboxylato-κ^2*N*,*O*)mercury-(II) monohydrate (**3**), [HgCl(quin)(quinH)], chloro(quinoline-2-carboxylato-κ^2*N*,*O*)(quinoline-2-carboxylic acid-κ^2*N*,*O*)mercury(II) (**4**) (Scheme 1).

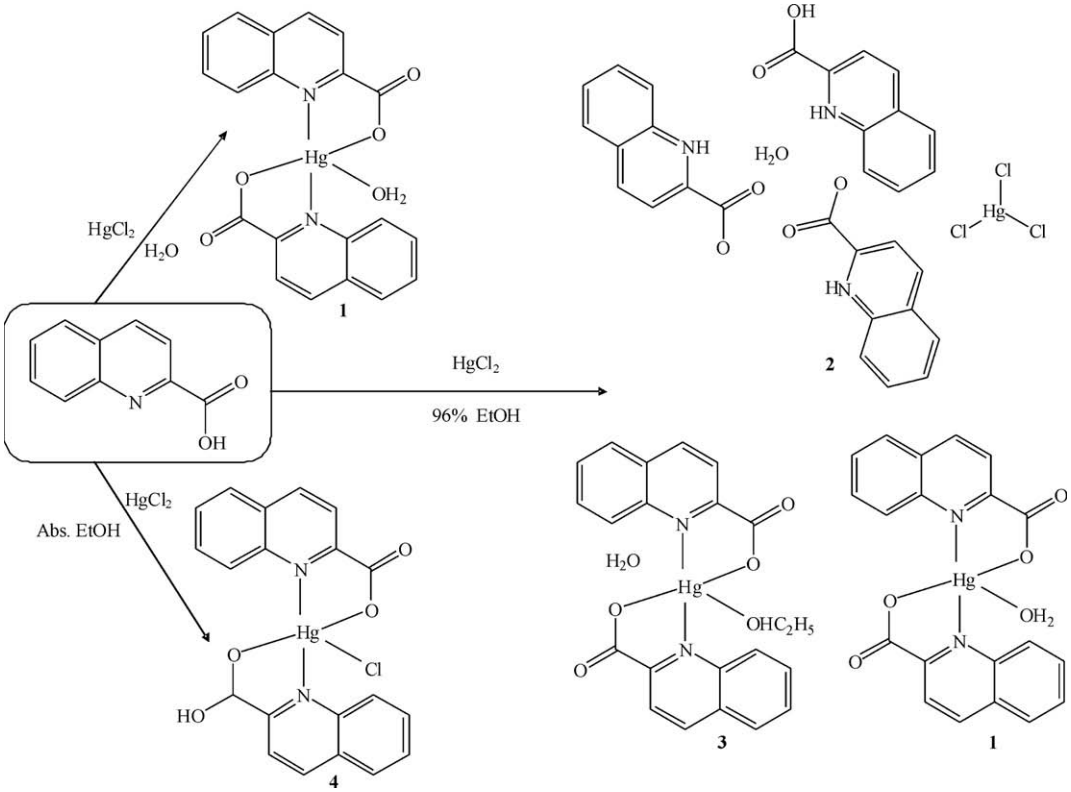
2. Experimental

2.1. Materials and methods

All starting materials were of reagent grade and were used as received without further purification. Elemental analyses of C, H and N were carried out by Analytical Services Laboratories of the Institute Ruđer Bošković. The mercury content in the complexes was determined by complexometric titration, with diethyl dithiocarbamate, in the solution obtained after decomposition of the specimen in *aqua regia* [9]. IR spectra were obtained from KBr pellets in the range 4000–450 cm^{-1} with a Perkin–Elmer Spectrum RX I spectrometer. One- and two-dimensional homo- and heteronuclear ^{1}H, ^{13}C NMR spectra were recorded with a Bruker AV 600 spectrometer, operating at 600.133 MHz for the ^{1}H nucleus and 150.917 MHz for the ^{13}C nucleus. Samples were measured from DMSO-d$_6$ solutions at 25 °C (298 K) in 5 mm NMR tubes. Chemical shifts, in ppm, are referred to TMS. FID resolution in ^{1}H and ^{13}C NMR spectra was 0.29 and 0.54 Hz per point, respectively. The following measurement techniques were used: standard ^{1}H and ^{13}C gated proton decoupling, APT, COSY, HMQC and HMBC. The 2D NMR spectra were measured in a pulsed field gradient mode (z-gradient).

2.2. Preparative procedures and analytical data

2.2.1. [Hg(quin)$_2$(OH$_2$)] (**1**)



A solution of quinH (0.32 g, 1.85 mmol) in 40 mL H$_2$O was added dropwise to a solution of HgCl$_2$ (0.25 g, 0.92 mmol) in 10 mL H$_2$O. The colorless crystals were filtered off, washed with a small amount of water and dried in air. Yield: 0.48 g (92%). ^{1}H NMR (DMSO-d$_6$, ppm): δ_H 7.80 (t, J_{HH} = 7.51 Hz, H-6), 7.96 (t, J_{HH} = 7.25 Hz, H-7), 8.17 (d, J_{HH} = 8.03 Hz, H-5), 8.27 (bs, H-4), 8.29 (bs, H-8), 8.69 (d, J_{HH} = 7.45 Hz, H-3), 13.10 (bs, COO*H*). ^{13}C NMR (DMSO-d$_6$, ppm): δ_C 120.79 (d, J_{CH} = 168.12 Hz, C-4), 128.04 (d, J_{CH} = 163.93 Hz, C-5), 128.58 (d, J_{CH} = 163.27 Hz, C-6), 128.88 (s, C-2), 129.37 (d, J_{CH} = 161.83 Hz, C-8), 130.72 (d, J_{CH} = 163.19 Hz, C-7), 138.05 (d, J_{CH} = 166.98 Hz, C-3), 146.22 (s, C-10), 148.70 (s, C-9), 166.09 (s, *C*OOH). *Anal.* Calc. for C$_{20}$H$_{14}$N$_2$O$_5$Hg: C, 42.64; H, 2.51; N, 4.98; Hg, 35.63. Found: C, 42.98; H, 2.75; N, 4.80; Hg, 35.12%.

2.2.2. Mixture of [Hg(quin)$_2$(OH$_2$)] (**1**), [(quinH$_2$)(HgCl$_3$)]·2quinH·H$_2$O (**2**) and [Hg(quin)$_2$(EtOH)]·H$_2$O (**3**)

A solution of quinH (0.32 g, 1.85 mmol) in 30 mL aqueous EtOH was added dropwise to an aqueous ethanol solution of HgCl$_2$ (0.25 g, 0.92 mmol) in 10 mL. The clear solution was allowed to stand for one week. The obtained colorless crystals of various shapes were filtered off, washed with a small amount of ethanol and dried in air. Yield: 0.35 g.

2.2.3. [HgCl(quin)(quinH)] (**4**)

A solution of quinH (0.32 g, 1.85 mmol) in 30 mL abs. EtOH was added dropwise to a solution of HgCl$_2$ (0.25 g, 0.92 mmol) in 10 mL abs. EtOH. The clear solution was allowed to stand for one week. The colorless crystals were filtered off, washed with a small

Scheme 1. Preparation of compounds **1**–**4**.

amount of absolute ethanol and dried in air. Yield: 0.08 g (15%). ^{1}H NMR (DMSO-d_6, ppm): δ_H 7.77 (t, J_{HH} = 7.52 Hz, H-6), 7.92 (t, J_{HH} = 7.17 Hz, H-7), 8.13 (d, J_{HH} = 8.01 Hz, H-5), 8.19 (bs, H-4), 8.20 (bs, H-8), 8.61 (bs, H-3), 13.36 (bs, CO*OH*). ^{13}C NMR (DMSO-d_6, ppm): δ_C 120.82 (d, J_{CH} = 167.96 Hz, C-4), 128.07 (d, J_{CH} = 163.89 Hz, C-5), 128.61 (d, J_{CH} = 163.79 Hz, C-6), 128.92 (s, C-2), 129.34 (d, J_{CH} = 165.57 Hz, C-8), 130.78 (d, J_{CH} = 165.58 Hz, C-7), 148.78 (s, C-9), 166.02 (s, *C*OOH). *Anal.* Calc. for $C_{20}H_{13}N_2O_4ClHg$: C, 41.64; H, 2.25; N, 4.82; Hg, 34.50. Found: C, 41.33; H, 2.37; N, 4.65; Hg, 34.25%.

After isolation of [HgCl(quin)(quinH)] 0.20 g of a mixture of $[Hg(quin)_2(OH_2)]$ (**1**), $[(quinH_2)(HgCl_3)]\cdot 2quinH\cdot H_2O$ (**2**) and $[Hg(quin)_2(EtOH)]\cdot H_2O$ (**3**) was also obtained.

2.3. X-ray crystallography

Selected crystallographic and refinement data for structures **1**–**4** obtained by the single crystal X-ray diffraction method are reported in Table 1. Data collection for structures **1** and **3** were carried out on an Oxford Diffraction Xcalibur four-circle kappa geometry diffractometer with Sapphire 2 CCD detector, while for compounds **2** and **4** the intensity data were collected on the same diffractometer but with a Sapphire 3 CCD detector by applying the CRYSALIS Software system, Version 171.26 [10a]. The unit cell parameters were calculated and refined from the full data set, the Lorentz-polarization effect was corrected and the intensity data reduced by the CRYSALIS RED application of the CRYSALIS Software system, CRYSALIS Software system, Version 1.171.31.8 [10a] for data sets **2** and **4**, while data for **1** and **3** were reprocessed with CRYSALIS RED, Version 1.171.33.27 [10b]. The diffraction data were corrected for absorption effects by the multi-scanning method. **1** is a superstructure along the *b*-axis as can be nicely seen from a simulated precession photograph of the [*h k* 0] zone, showing strong reflections in every third row along $b*$. Structure of **3** decomposed during data collection so the data set is not complete; however 80% of the data were enough for a well refined structure. All attempts to get another crystal of good diffraction quality failed.

All structures were solved by direct methods and refined on F^2 by weighted full-matrix least-squares. Programs SHELXS97 and SHELXL97 [11] integrated in the WINGX Software system [12] were used to solve and refine all four structures. All non-hydrogen atoms, with exception of the disordered H_2O molecule in **3** (O2A and O2B with occupancies of 0.750(8) and 0.250(8), respectively) were refined anisotropically. H-atoms belonging to the bound and crystallization water molecules in **1** and **2**, respectively, and that of the ethanol molecule in **3** were found in the difference-Fourier map and were refined with restrained distances. Other H-atoms (except those on the disordered H_2O molecule of crystallization in **3**, which were not found nor could be modeled reliably) were placed in geometrically idealized positions [Csp^2–H 0.93 Å with U_{iso}(H) = 1.2 U_{eq}(C); O–H 0.82 Å with U_{iso}(H) = 1.5 U_{eq}(O)] and were constrained to ride on their parent atoms by using the appropriate SHELXL97 HFIX instructions. In **4** the hydrogen atom H2 on quin/quinH is both statistically and structurally disordered (by the presence of a twofold axis along the Hg–Cl bond). However small electron-density was found in a difference-Fourier map and this H-atom was given an occupancy factor of 0.5. The molecular geometry calculations and drawings were performed by ORTEP-3 [13], PLATON [14] and MERCURY [15].

The general and crystallographic data for compounds **1**–**4** are listed in Table 1. The main geometrical features for structures **1**–**4** are given in Tables 2–5, respectively. Hydrogen bond geometry is given in Table 6 for compounds **1**–**4**.

3. Results and discussion

3.1. General aspects of preparation

In aqueous media mercury(II) chloride reacts with 2-quinaldic acid giving pure aquabis(quinoline-2-carboxylato-κ^2-*N,O*)mercury, $[Hg(quin)_2(OH_2)]$ (**1**) in an almost quantitative yield. If the reaction is performed in aqueous alcohol, a mixture of $[Hg(quin)_2(OH_2)]$ (**1**), $[(quinH_2)(HgCl_3)]\cdot 2quinH\cdot H_2O$ (**2**) and $[Hg(quin)_2(EtOH)]\cdot H_2O$ (**3**) is obtained. All attempts to separate these complexes failed due to their very similar solubility in common solvents. When the reaction is carried out in absolute alcohol a small amount of [HgCl(quin)(quinH)] (**4**) is obtained (cca 15% by mass). By concentration of the filtrate, again the mixture of **1**–**3** is obtained and single crystals of each compound could be separated by hand.

3.2. Structural studies

3.2.1. Structure of $[Hg(quin)_2(OH_2)]$ (**1**)

The asymmetric unit in the superstructure of **1** consists of three structurally slightly different molecules of $[Hg(quin)_2(OH_2)]$, Fig. 1a. The mercury atom is coordinated by two nitrogen and two oxygen atoms from two *N,O*-coordinating quinaldate ligands. The fifth coordination site is occupied by an oxygen atom from a water molecule. The N–Hg–N angle is in the range 167.57(11)–170.36(11)° (Table 2) and shows tendency towards linear coordination, which is in agreement with the distances Hg–N that are the shortest and range from 2.190(3) to 2.241(3) Å. The Hg–O distances are longer (2.310(4)–2.437(3) Å) and the coordination can therefore be described as deformed 2 + 3 trigonal-bipyramidal. This is confirmed by the index of the degree of trigonality, τ of 0.67 (calculated for the first molecule only as a difference between two largest angles divided by 60). This index is zero for a perfectly square-pyramidal and a unity for perfectly trigonal-bipyramidal geometry [16].

In all three molecules the Hg–O(OH_2) distance is longer than Hg–O(quin). Such bound water molecules are not uncommon in mercury compounds. The distance Hg–OH_2 can be even longer than in **1** such as in the structure of aquabromo(6-carboxypyridine-2-carboxylato-*O,N,O′*)mercury(II) [3] where it amounts to 2.634(5) Å. In that compound the mercury atom is also five-coordinated. Shorter Hg–OH_2 bonds are found in some organomercury compounds where

the coordination of mercury is linear, *e.g.* in the structure of mercurated acetic acid it is 2.17(3) Å [17], or in a tetramercurated methane derivative, bis(aquamercurio)-bis-(sulfatomercurio)methane where it is 2.131(11) Å [18]. The C–O distances in the carboxylic groups are in the range 1.231(5)–1.263(6) Å.

All hydrogen atoms on the bound water molecules act as hydrogen bond donors and the carboxylic group oxygen atoms as acceptors. Four hydrogen bonds of the type O–H···O connect each molecule with four different neighboring ones into two-dimensional layers parallel to (1 0 0), Fig. 1b, Table 6. The layers are connected by π···π interactions. The shortest centroid (Cg) to centroid distances are: Cg3–Cg3 ($-x, -y, -z$) distance is 3.543(6) Å, slippage 1.055 Å (Cg3 is the centroid of the ring N1, C12–C15, C20); Cg4–Cg4 ($1-x, -y, -z$) is 3.564(6) Å, slippage 0.760 Å (Cg4 is the centroid of the ring N2, C22–C25, C3).

3.2.2. Structure of $[(quinH_2)(HgCl_3)]\cdot 2quinH\cdot H_2O$ (**2**)

The asymmetric unit of compound **2** (Fig. 2a) consists of a formally isolated trichloromercurate(II) anion, $[HgCl_3]^-$, two zwitterionic quinolinium-2-carboxylate molecules, quinH, a quinolinium-2-carboxylic cation, $[quinH_2]^+$, and one water molecule of crystallization. In the presence of large cations such as $[quinH_2]^+$ the major structural isomer adopted by $[HgCl_3]^-$ is a dimeric edge-shared bitetrahedron $[Hg_2Cl_6]^{2-}$ [19–26]. In some structures additional two Hg···Cl interactions connect the $[HgCl_3]^-$ anions into endless chains. In **2** each Hg atom is surrounded by five Cl^- ions forming a deformed trigonal-bipyramid with one short, two slightly longer bonds, and two long mercury to chlorine contacts [Hg1–Cl1 2.374(1) Å, Hg1–Cl2 2.427(1) Å, Hg1–Cl3 2.458(1), Hg1···Cl2^a ($a = 1-x, 2-y, 1-z$) 2.995(1), Hg1···Cl3^b ($b = 2-x, 2-y, 1-z$) 3.2076(11) Å] (Table 3). The two long contacts connect the $[HgCl_3]^-$ anions into endless chains along [1 0 0]. The Hg1–Cl1 bond distance value belongs to the covalent bond characteristic for trigonal mercury and chlorine (sum of the covalent radii of trigonal mercury and chlorine atoms is 2.38 Å), while Hg1–Cl2 and Hg1–Cl3 covalent bonds are more similar to mercury to chlorine covalent bonds characteristic for tetrahedral mercury (2.47 Å) [27–30]. The two long contacts are shorter than the van der Waals' radii sum for mercury and chlorine (3.23–3.60 Å) [27–31], but longer than mercury to chlorine covalent bond. According to Ref. [19–26] Hg–Cl distances of 2.3–2.6 Å are clearly formal covalent bonds, while Hg···Cl contacts up to 3.35 Å, and even longer, are considered to be interactions. Regarding such geometrical parameters, obviously, there is no clear definition about the border between a formal mercury to chlorine bond and a long contact which results in a structural variety for chloromercurate(II) systems. Polymeric chains of the $[HgCl_3]^-$ anions are found in

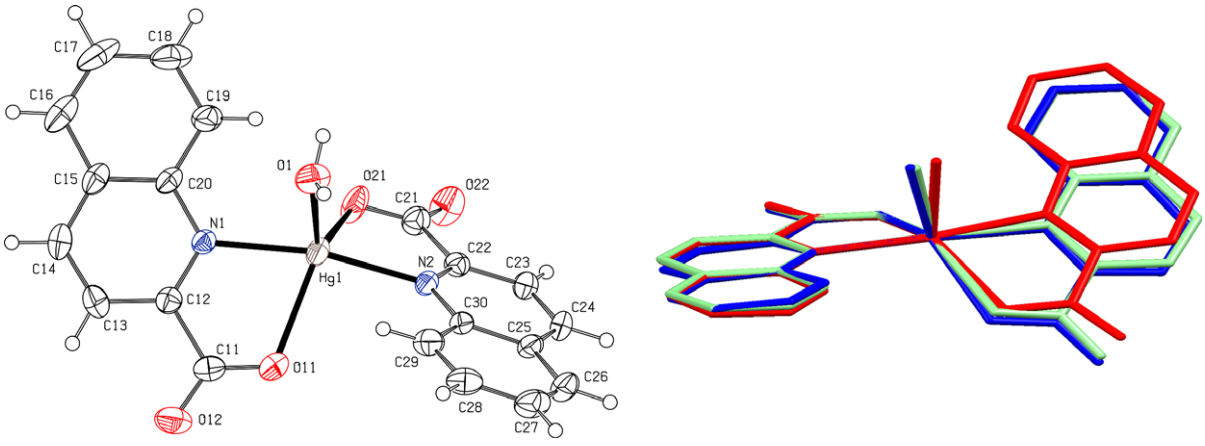

Fig. 1a. (a) ORTEP drawing of $[Hg(quin)_2(OH_2)]$, aquabis(quinoline-2-carboxylato-κ^2N,O)mercury(II), **1**, with the atomic numbering scheme. The thermal ellipsoids are drawn at the 40% probability level at 296 K. Only one of the three independent molecules in the asymmetric unit is shown. Other molecules have an analogous numbering scheme (Hg2, O2, N3, O31, O32, C31–40, N4, O41, O42, C41–50; Hg3, O3, N5, O51, O52, C51–C60, N6, O61, O62, C61–C70; Supplementary material, Fig. S1). (b) Diagram of the overlapping of three independent molecules.

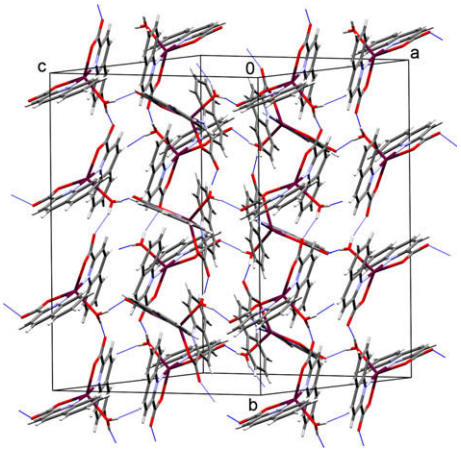

Fig. 1b. Packing of **1** in the unit cell. Hydrogen bonds are shown by blue dashed lines. Mercury is shown in purple color. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

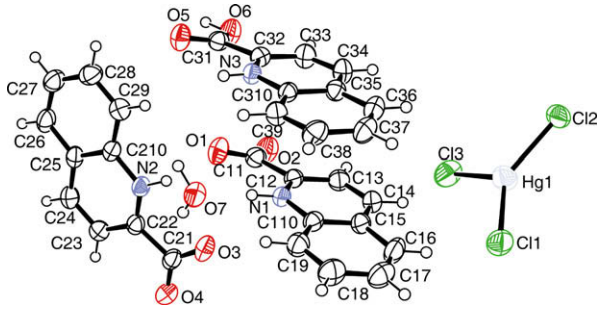

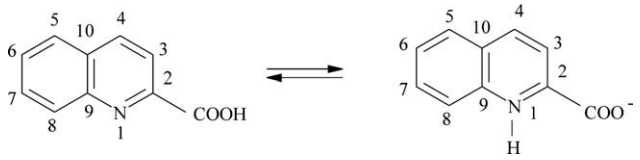

Fig. 2a. ORTEP drawing of the asymmetric unit of $[(quinH_2)(HgCl_3)]\cdot 2quinH\cdot H_2O$, quinolinium-2-carboxylic acid trichloromercurate(II) bis(quinolinium-2-carboxylate) monohydrate, **2**, with the atomic numbering scheme. The thermal ellipsoids are drawn at the 50% probability level at 296 K.

structures of triethylammonium catena(bis-μ_2-chloro)-chloromercury) (refcode: DORSIM) [32], catena(tetraethylammonium trichloro-mercury(II)) (refcode: EAMCHG [33], catena-(bis(chloro-(*N*,*N*,*N*′,*N*′-tetrakis(*N*-methylcarbamoylmethyl)ethane-1,2-diamine)-mercury(II)) tetrakis(μ_2-chloro)-dichloro-di-mercury(II)sesquihydrate) (refcode: NIMFOF) [34]. All these structures comprise 3 + 2 mercury coordination geometry revealing three formally coavlent mercury to chlorine bonds and two longer contacts which complete a trigonal-bipyramidal configuration. The longest Hg···Cl distances in these three mercury polymers amount 3.050(3) Å, 3.054(3) Å and 3.154(5) Å in the structure with refcodes NIMFOF, EAMCHG and DORSIM, respectively. The deformed 3 + 2 mercury coordination in **2** is confirmed by the bond angle range from 83.88(3)° for Cl2–Hg1–Cl2^a ($a = 1-x, 2-y, 1-z$) to 132.97(4)° for the Cl1–Hg1–Cl2 angle (Table 3).

Existence of two ligand molecules in the zwitterionic form *i.e.*, as quinolinium-2-carboxylate molecules, is revealed on the basis of the –COO fragment geometry (Table 3, Scheme 2). The C–O bond values for the carboxylate group are in the range 1.232(4) Å (for the O1–C11 bond) to 1.255(4) Å (for the O2–C11 bond). A similar bond range in the –COO fragment is found in the structure of the ligand itself [35] and in the structure of (benzoato-κ^2-*O*,*O*)(quinoline-2-carboxylato-κ^2-*N*,*O*(quinoline-2-carboxylic acid-κ^2-*N*,*O*)copper(II) [35], which contains the neutral ligand coordinated to the copper(II) ion.

The zwitterionic C–O bonds amount 1.263(2) Å and 1.248(2) Å in the ligand itself [35]. The quinolinium-2-carboxylic cation in **2**

Scheme 2. Tautomeric forms of quinoline-2-carboxylic acid and enumeration of the atoms.

contains a carboxylic –COOH group with the C–O dimensions 1.204(4) Å (for keto O5–C31 bond) and 1.290(4) Å (for the O6–C31 bond). The corresponding C–O bond distances in the ligand are 1.314(2) Å and 1.221(2) Å [35], while in the copper complex the corresponding bond distance values are 1.187(3) Å and 1.306(3) Å [36].

There are no hydrogen bonds between cations and anions, only cations and neutral zwitterions are interlaced by hydrogen bonds of the N–H···O and O–H···O type (Table 6; Fig. 2b). There are four hydrogen bonds of the N–H···O type; one being intramolecular (N1–H11N···O1 in one of the zwitterions), while the other three are formed by all three NH groups with the carboxylate O1 and O3 atoms and the water oxygen atom O7. The N···O distances are in the range 2.688(4)–2.870(4) Å. There are also three O–H···O hydrogen bonds, two of them formed by a water molecule acting as a double proton donor, and one by the –COOH carboxylic group [O···O range varies from 2.503(4) Å for the O6–H16O···O2 bond to 2.801(5) Å for the O7–H17O···O4 bond].

3.2.3. Structure of $[Hg(quin)_2(EtOH)]\cdot H_2O$ (**3**)

The structure of **3** consists of molecules of $[Hg(quin)_2(EtOH)]$ and H_2O molecules of crystallization, Fig. 3a. The mercury atom is coordinated by two quinaldate ligands at similar Hg–O distances as in **1** (2.313(5)–2.393(4) Å, Table 4), whereas the Hg–N distances are slightly longer (2.252(4) and 2.263(4) Å). At the fifth coordination site there is an oxygen atom from the ethanol molecule at the distance of 2.524(6) Å. These atoms form a square-pyramidal coordination which is not usual for Hg so dimers are often formed as is the case in **3**. There is a Hg···O contact of 2.785(4) Å with the carboxylate oxygen atom O11 from the neighboring centrosymmetrically related molecule ($-x, -y, -z$) connecting them into dimers and forming a 5 + 1 octahedral coordination around the mercury

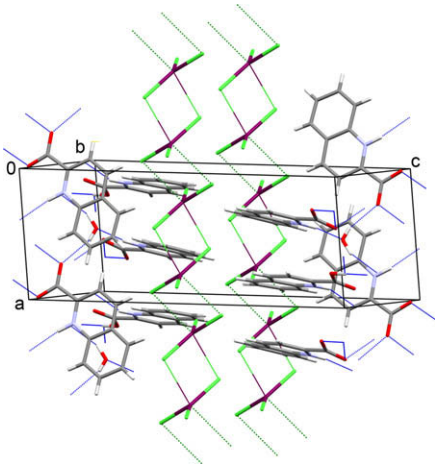

Fig. 2b. Packing of **2** in the unit cell. Hydrogen bonds are shown by blue dashed lines. Mercury is shown in purple color. Contacts Hg1···Cl2 are drawn by thin purple and green lines, Hg1···Cl3 contacts are drawn by dashed green lines. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

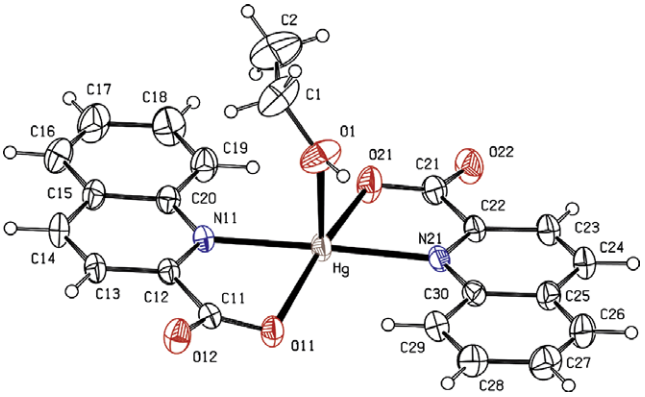

Fig. 3a. ORTEP drawing of $[Hg(quin)_2(EtOH)]\cdot H_2O$, bis(ethanol-κ*O*)bis(quinoline-2-carboxylato-κ^2N,O)mercury-(II) monohydrate, **3**, with the atomic numbering scheme. The thermal ellipsoids are drawn at the 50% probability level at 296 K.

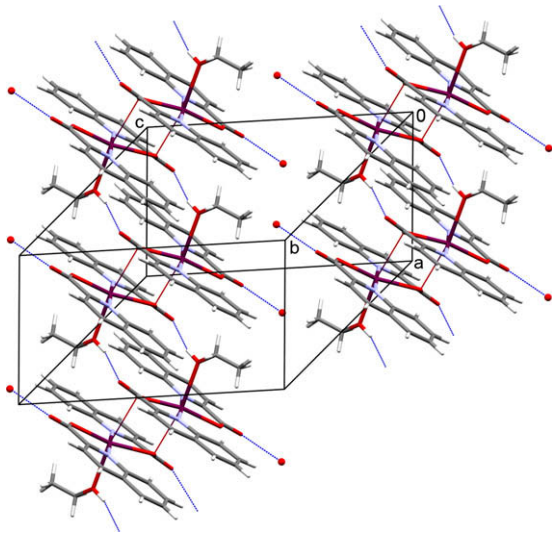

Fig. 3b. Packing of **3** in the unit cell. Hydrogen bonds are shown by blue dashed lines, and the Hg···O contacts by thin purple and red lines. Mercury is shown in purple color. The solvent H_2O molecule is shown as a small red ball. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

atom, Fig. 3b. Within the dimers there are also π···π interactions between the rings. The closest distance between the centroid of the ring defined by atoms N11, C12–15, C20 and the centroid of the centrosymmetrical pair (−*x*, −*y*, −*z*) of the ring defined by C25–C30 is 3.560(6) Å (slippage 0.681 Å). The carboxylic C–O bond lengths are in the range 1.218(8)–1.266(6) Å. As expected, the longer C–O distances include oxygen atoms that are bound to the mercury atom.

The dimeric molecules are connected by short hydrogen bonds between the hydrogen atom from the ethanol hydroxyl group and an oxygen from the carboxylic group (O1–H1···O12(1 − *x*, −*y*, −*z*) 2.661(7) Å, Table 6) into chains along [1 0 0]. The chains are connected by van der Waals and π···π interactions with neighboring chains. The shortest centroid (N21, C22–C24, C30) to centroid (the same ring related by −*x*, 1 − *y*, −*z*) distance is 3.661(6) Å, slippage 1.101 Å. Hydrogen atoms on the disordered H_2O molecules were not found, however, from the distance O2A···O22 (1 + *x*, *y*, *z*) of 2.707(8) Å, a hydrogen bond is expected.

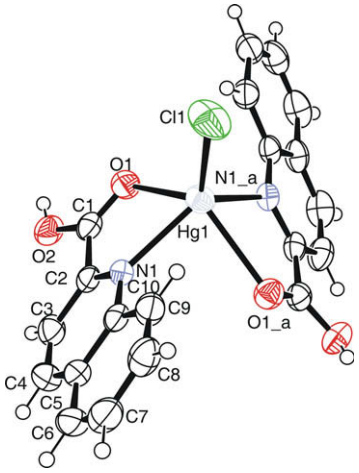

Fig. 4a. ORTEP drawing of [HgCl(quin)(quinH)], chloro(quinoline-2-carboxylato-κ^2N,O)(quinoline-2-carboxylic acid-κ^2N,O)mercury(II), **4**, with the atomic numbering scheme. The thermal ellipsoids are drawn at the 50% probability level at 296 K.

3.2.4. [HgCl(quin)(quinH)] (**4**)

Compound **4** (Fig. 4a) has twofold symmetry with the axis along the Hg1–Cl1 bond. The formula and the symmetry necessarily implicate both statistical and structural hydrogen atom disorder between the two ligands, $[quin]^-$ and quinH, maintaining complex neutrality.

Mercury is coordinated *via* the Cl1 atom (Hg1–Cl 2.361(1) Å) and *via N,O*-donor atoms of the bidentate quinaldate ion, $[quin]^-$, and one neutral quinaldic acid, quinH, [Hg1–O1 2.491(2) and Hg1–N1 2.287(2) Å] in a very irregular square-pyramidal coordination (Table 5). The coordination sphere is better described as 4 + 1 than 3 + 2 geometry according to the bond distance values and the bond angles range around the mercury atom [69.93(6)–123.02(7)°]. The τ value of 0.03 (see Ch. 3.2.1) reveals that the mercury coordination is in agreement with the square-pyramidal model. The geometry of this complex is similar to iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) recently reported by us [5], which contains a particularly short Hg–I bond distance comparable with the distance in the yellow form of HgI_2 [37] (2.615(6) and 2.620(6) Å). The mercury to chlorine bond distance in **4** is slightly shorter than the sum (2.39 Å) of the covalent radii for trigonal Hg (1.39 Å) and for chlorine (0.99 Å), and significantly longer than the radii sum for linear Hg and chlorine (2.29 Å) [27–30]. In the structure of $HgCl_2$ itself the mercury coordination can be described as 2 + 4 octahedral with the shortest Hg–Cl bond distance of 2.274(10) Å [38]. The Hg1–N1 bond distance of 2.287(2) Å is comparable with those found in **3** and in the iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) complex (2.298(3) Å) [5]. In relation to the Hg–N bond distances in the complexes which do not contain an Hg–Cl bond *i.e.*, complexes **1** and **3**, the value for the Hg1–N1 bond distance is longer in **4** (2.287(2) Å). The Hg1–O1 distance of 2.491(2) Å is also longer than in **1** or **3** and is comparable with 2.481(2) Å for the mercury to oxygen distance found in the iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) complex [5]. The covalent radii sum for trigonally coordinated Hg with N or O amounts to 2.09 Å and 2.05 Å, respectively.

The mercury to oxygen contacts are longer to some extent then the mercury to nitrogen contacts. These considerations are supported by the bond angles range being between 123.02(7)° for the N1–Hg1–N1^a ($a = -x, y, 0.5 - z$) angle and 69.93(6)° for the O1–Hg1–N1 angle. A similar situation is not found in the iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) complex [5] *i.e.*, the largest angle is N2′–Hg1–I1 of 125.11(6)°, while angle N2′–Hg1–N2 amounts to 109.78(13)°. The reason for that is a par-

ticular tendency of mercury to form strong covalent bonds with iodine atoms. The bite angle values are comparable in both complex **4** and the iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) complex and reflect the stereochemical rigidity of quinaldic and picolinic acid.

The 3 + 2 mercury coordination is found in the polymeric μ-bromo-μ-pyridine-3-carboxylato-$\kappa^3O,O':N$–mercury(II) complex [39] where mercury is coordinated by two Br atoms, two carboxylate atoms (Hg–O 2.353(6) Å and 2.478(7) Å) and an N atom (2.265(5) Å). It is obvious that the strongest bonds are to the N and halogen atom as is found in complex **4** and the iodo complex as well.

Geometry of the COO fragment in both ligands, $[quin]^-$ and quinH, is averaged between the carboxylic acid and carboxylate ion geometry (C1–O1 and C1–O2 bonds amount to 1.232(3) Å and 1.277(3) Å, respectively) (Scheme 2) supporting the hydrogen atom disorder. Similar values are found in iodo(picolinato-κ^2N,O)(picolinic acid-κ^2N,O)mercury(II) [5], 1.233(4) Å and 1.271(4) Å, while in the bromo derivative [39] these values are slightly affected by participation of carboxylate oxygen atoms in the coordination of Hg (1.226(11) Å and 1.259(10) Å). In the structure of the ligand itself, quinoline-2-carboxylic acid quinolinium-2-carboxylate [35], two tautomeric forms occur in the crystal: the neutral molecule and the zwitterion. In the neutral molecule of quinoline-2-carboxylic acid the C–O bond distances are 1.314(2) Å and 1.221(2) Å, while in the zwitterion they are 1.263(2) Å and 1.248(2) Å.

The intermolecular hydrogen bond O2–H2···O2 ($-x$, y, $3/2 - z$) of 2.443(3) Å connects molecules of the complex into infinite chains along the [1 0 1] direction (Fig. 4b).

3.3. Spectroscopy

3.3.1. IR spectra

The IR spectral data of quinH and its mercury(II) complexes **1** and **4** were analyzed. Their assignments were based on the literature data regarding other metal complexes with quinH [40–42]. In the solid state quinH exists in both neutral (C_9H_6NCOOH) and zwitterionic ($C_9H_6NH^+COO^-$) tautomeric forms [35].

In the IR spectrum of quinH absorption bands which support such structure were observed. The medium intensity band due to the C=O stretching vibration is observed at 1700 cm^{-1}. The antisymmetric (ν_{as}) and symmetric (ν_s) modes of the COO^- group were observed at 1650, 1618 cm^{-1} and 1380, 1317 cm^{-1}, respectively.

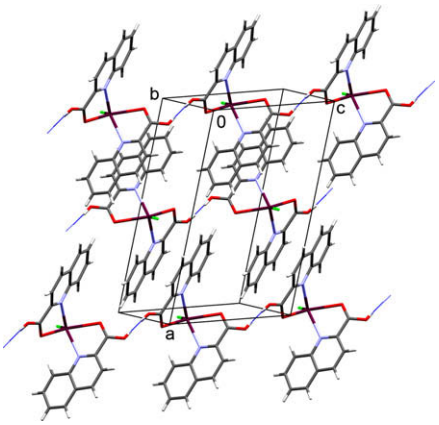

Fig. 4b. Packing of **4** in the unit cell (only one half of the unit cell is shown $b \leqslant 0.5$). Hydrogen bonds are shown by blue dashed lines. Mercury is shown in purple color. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

In the spectrum of **1** there is no band due to C=O stretching in the vicinity of 1700 cm^{-1}. Absorption bands at 1662, 1619 cm^{-1} were assigned as ν_{as} and the band at 1374 cm^{-1} as ν_s of COO^-.

In the IR spectra of **4** bands which indicate the existence of a coordinated quinaldate anion as well as a neutral quinaldic acid molecule were observed. The C=O stretching is found at 1699 cm^{-1}. Medium strong absorption bands at 1662 and 1623 cm^{-1} are assigned as ν_{as}. The corresponding symmetric stretch absorption of COO^- is observed at 1374 cm^{-1}.

Broad absorption bands in the 3100–1800 cm^{-1} region of the IR spectrum of quinH indicate the existence of N–H···O and O–H···O types of hydrogen bonds. In the IR spectra of complexes **1** and **2**, broadness, disappearing and lower intensity of bands in this region were observed, which implies different hydrogen bonding pattern in the mercury(II) complexes.

3.3.2. ^1H and ^{13}C NMR spectra

The NMR spectra of quinH, **1** and **4** are in agreement with their structures. The ^1H and ^{13}C NMR spectra revealed existence of monomercurated species in a DMSO-d_6 solution. The assignments of protons are supported by COSY spectra and the carbon atoms are confirmed by HMQC and HMBC measurements. The C-3 and C-10 signals in **4** are not observed because of the relaxation effects of nitrogen and mercury atoms.

The effects of mercury on both ^1H and ^{13}C chemical shifts are small and insufficient to clarify the conformation of the complexes in the solutions.

4. Conclusion

In this work we report the synthesis, IR, ^1H and ^{13}C NMR spectroscopy, and crystal and molecular structures determined by X-ray single crystal diffraction of several mercury(II) complexes with quinaldic acid: [Hg(quin)$_2$(OH$_2$)], aquabis(quinoline-2-carboxylato-κ^2N,O)mercury(II) (**1**), [(quinH$_2$)(HgCl$_3$)]·2quinH·H$_2$O, quinolinium-2-carboxylic acid trichloromercurate(II) bis(quinolinium-2-carboxylate) monohydrate (**2**), [Hg(quin)$_2$(EtOH)]·H$_2$O, bis(ethanol-κO)bis(quinoline-2-carboxylato-κ^2N,O)mercury-(II) monohydrate (**3**), [HgCl(quin)(quinH)], chloro(quinoline-2-carboxylato-κ^2N,O)(quinoline-2-carboxylic acid-κ^2N,O)mercury(II) (**4**).

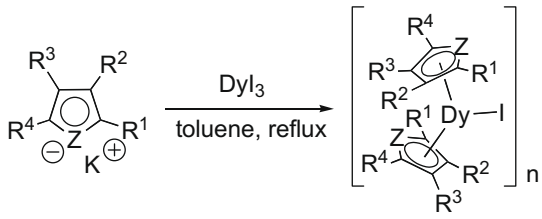
The ligand, quinaldic acid is coordinated to Hg^{2+} ion as an *N,O*-chelating quinaldate ion, $quin^-$, in structures **1**, **3** and **4**. Different coordination polyhedra are obtained: in **1** a deformed 2 + 3 trigonal-bipyramidal with the fifth coordination site occupied by a water molecule, in **3** the fifth square-pyramidal coordination site is occupied by an ethanol molecule and in **4,** which resembles the 4 + 1 irregular square-pyramidal coordination, there is a chlorine atom attached to mercury at the fifth coordination site. In the structure of **3** centrosymmetrical dimers are formed by Hg···O contacts and a 5 + 1 effective mercury coordination is established. The structure of compound **2** is completely different, containing a trichloromercurate(II) anion, $[HgCl_3]^-$, two zwitterionic quinolinium-2-carboxylate molecules, quinH, a quinolinium-2-carboxylic cation, $[quinH_2]^+$, and one water molecule of crystallization. The$[HgCl_3]^-$ moieties are interconnected by two long Hg···Cl contacts into endless chains of $[HgCl_3]_n^{n-}$ anions revealing the 3 + 2 mercury coordination sphere.

The coordination spheres of mercury in compounds **1**–**4** are established on the basis of bond distances and angle values taking into account the criteria for characteristic and effective coordination spheres such as covalent and van der Waals' radii of Hg and donor atoms (N, O, Cl).

The crystal structures are characterized by O–H···O and N–H···O intermolecular hydrogen bonds (in **1** there is also one O–H···O intramolecular hydrogen bond and in **2** there are three N–H···O

intramolecular hydrogen bonds). These bonds form various crystal packing motifs: two-dimensional layers parallel to (1 0 0) in **1**, a 3D network in **2**, chains along [1 0 0] in **3** and infinite chains along the [1 0 1] direction in **4**.

Supplementary data



CCDC 719374, 719375, 719376, 719377 contain the supplementary crystallographic data for **1**–**4**. These data can be obtained free of charge *via* http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Structure factor tables are available from the authors. The Supplementary data also contains a Figure of **1** with the numbering scheme of all three independent molecules (Fig. S1) and a simulated precession photograph of the [*h k* 0] zone of **1** (Fig. S2).

1a: $R^1=R^2=R^4=tBu$, $R^3=H$, Z=CH, n=1
1b: $R^1=R^2=R^4=SiMe_3$, $R^3=H$, Z=CH, n=1
1c: $R^1=R^4=tBu$, $R^2=R^3=Me$, Z=P, n=1
1d: $R^1=R^4=SiMe_3$, $R^2=R^3=Me$, Z=P, n=2

Scheme 1. Synthesis of unsolvated organodysprosium(III) complexes.

Cp‴ (1,2,4-tris-trimethylsilyl-cyclopentadienyl), Dtp (1,4-bis-*t*-butyl-2,3-dimethylphospholyl) and Dsp (1,4-bis-trimethylsilyl-2,3-dimethylphospholyl). The reason for this selection is that stable divalent complexes of thulium(II) have been obtained with these ligands [2f–i,k].

The reaction works quite well and good yields have been obtained in all cases, thus establishing the generality of the method.

We had previously found that, despite its high paramagnetism, **1a** displayed a usable NMR spectrum in which three peaks could be assigned to the three inequivalent *t*Bu groups. Likewise, we found that **1b–d** also had interpretable NMR spectra. In **1b**, unlike in **1a**, two substituents on the ring ($SiMe_3$ groups) are equivalent. This might be due to free rotation of the substituted cyclopentadienyl around the centroid–Dy axis. In **1c** and **1d**, only peaks corresponding to the bulky *t*Bu or $SiMe_3$ on the phospholyl ring could be detected; presumably the phospholyl ring methyls are too close to the paramagnetic Dy center to be detected: note that the ring protons on **1a** and **1b** were not detected either.

2.2. Crystal structures of complexes *1b–d*

Complexes **1b–d** could be further characterised by their X-ray crystal structures and Figs. 1–3 represent ORTEP plots of these complexes; the X-ray data of all compounds are summarised in Table 1.

These structures confirm the η^5-bonding mode of the cyclopentadienyl and phospholyl ligands around dysprosium.

First of all, it is interesting to note that whilst the phospholyl complex possessing the Dsp ligand **1d** is a solid-state dimer, complex **1c** with the closely related Dtp ligand is a monomer. Thus, a subtle modification on the ligand substituents (from *t*-butyl in **1c** to trimethylsilyl in **1d**) can have a strong influence on the structure of the complexes. This change reflects the smaller steric bulk of the relatively flexible trimethylsilyl group, which is able to bend away from the cyclopentadienyl plane, more so than the more rigid *t*-butyl group.

Compounds **1b** and **1c** belong to the class of 7-coordinated unsolvated bis(π-complexed) halides; there are relatively few such compounds described in the literature that are structurally characterised [2i–k,8]. The structural features of **1b** and **1c** can be assessed by comparison with that of the previously described **1a** (Table 1); dimer **1d** (with the Dsp ligand) is different since it is 8-coordinated.

The four parameters in Table 2 were chosen because they can be used as indicators of the influence of the ligand. The metal–centred bond lengths and angles as defined above are expected to increase with the steric bulk of the ligand. The most precise indicator is the length of the Dy–I bond, which clearly points to the highest steric bulk of the Cp^{ttt} ligand. This confirms the earlier findings in

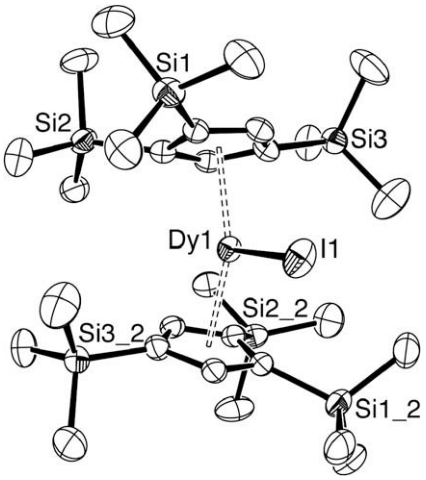

Fig. 1. An ORTEP plot of one molecule of **1b** (hydrogen atoms omitted). There are two other independent molecules in the unit cell (not represented).

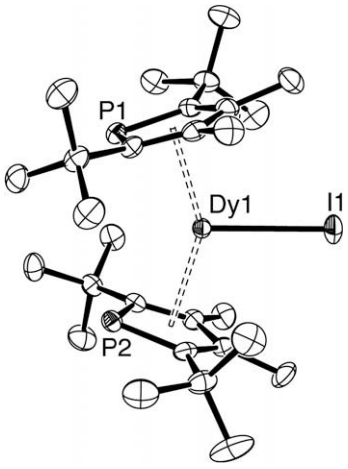

Fig. 2. An ORTEP plot of one molecule of **1c** (hydrogen atoms omitted).

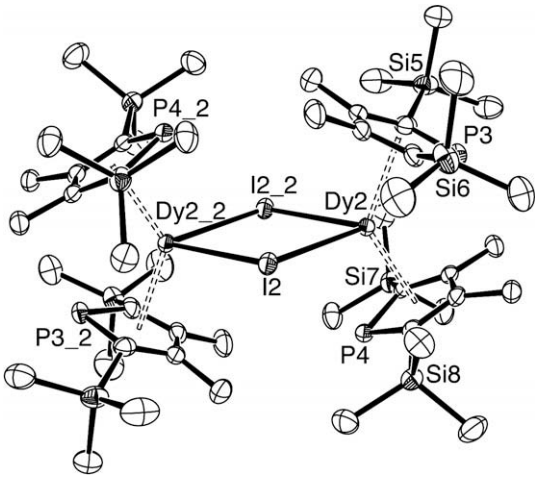

Fig. 3. An ORTEP plot of the dimeric structure of **1d** (hydrogen atoms omitted). There is one other independent dimer in the unit cell (not represented).

thulium chemistry [2f–i,k]. It is more difficult to compare the Dtp and the Cp‴ ligands from the dihedral and Ct–Dy–Ct angles. The Dy–C bond lengths have a high variability and a bias may exist

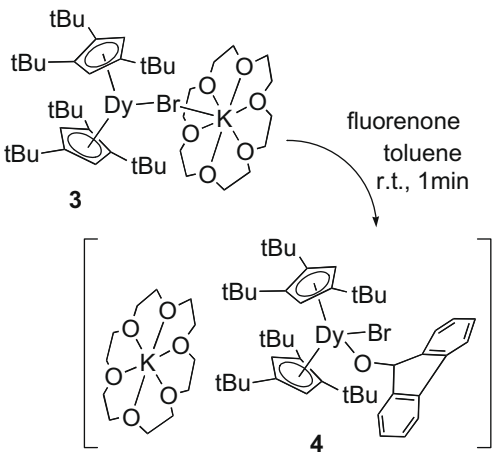
because of the heterocyclic nature of Dtp. However, it is clear that the Dsp ligand is the smallest from the dimeric solid-state nature of **1d**. Thus, a tentative classification of the ligands according to decreasing steric bulk would be Cp^{ttt} > Dtp > Cp$''$ > Dsp.

2.3. Attempted reduction of compounds *1b–d*

We found earlier that compound **1a** could be successfully reduced into **2** by reaction of KC_8 in the presence of crown ether (Scheme 2).



In order to try to find new dysprosium(II) compounds, we decided to subject compounds **1b–d** to the same reaction conditions. With compounds **1c** and **1d**, no apparent reduction occurred, whilst with **1b**, degradation quickly happened. With KC_8 in the absence of crown ether, no reaction took place with **1a**, **1c** and **1d**, whereas with **1b**, a red colour initially appeared and several new peaks were observed in the proton spectrum, which might be indicative of the transient presence of Dy^{II} species; however the colour gradually turned to light orange and no defined compound could be isolated. Therefore it seems that the stability of any Dy^{II} species is extremely sensitive to the ligand environment.

Scheme 2. Reduction of **1a** into an organodysprosium(II) complex.

2.4. A new organodysprosium(II) oxidation product

Since we have not been able to widen the scope of organodysprosium(II) complexes, in order to get more insight into the chemistry of these species, we decided to attempt to oxidise **2** with an aromatic ketone, a reaction which is known to occur with Sm^{II} and Yb^{II} precursors [9]. When fluorenone was added to a solution of **2**, a dark red colour developed but we were unable to isolate a solid complex. However, when the bridging halide in the organodysprosium(II) complex was changed from iodide to bromide and the reaction was performed with precursor **3**, an oxidation product (**4**) was isolated (Scheme 3).

Scheme 3. Oxidation of **3** into the organodysprosium(III) zwitterionic complex **4**.

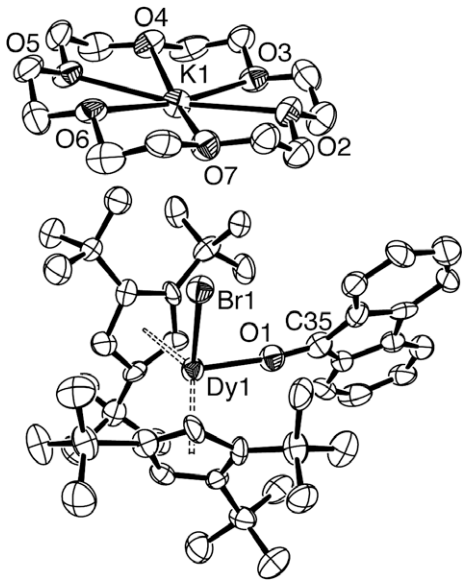


Fig. 4. An ORTEP plot of the charge-separated ionic complex **4** (hydrogen atoms omitted).

Compound **4** was characterised by X-ray crystallography (Fig. 4).

This figure clearly shows that **4** is a charge-separated ionic complex, where the potassium atom encapsulated by the crown ether is no longer bonded to the bromide (K1–Br1 distance = 4.6 Å). **4** is not a simple adduct of **3** with fluorenone, since this molecule has been reduced to the radical anion by electron transfer from dysprosium, as definitively proven by the length of the C35–O1 bond distance (1.32(1) Å), which points to a single bond; in fluorenone, this bond length is 1.22 Å [10]. Thus, the oxidation state of dysprosium in **4** is +III.

3. Conclusion

We have synthesized three new unsolvated organodysprosium(III) complexes with very bulky phospholyl and cyclopentadienyl ligands, one of which is interestingly a solid-state dimer, and attempted to reduce them in organodysprosium(II) species. The success of this reduction seems to be extremely sensitive to the ligand environment and reaction conditions. We have also been able to oxidise an organodysprosium(II) complex into a new, unprecedented charge-separated ionic organodysprosium(III) ketyl complex. We are still trying to discover more organodysprosium(II) complexes by finding new stabilising ligand environments.

4. Experimental

4.1. General data

All reactions were performed under high purity argon with purified dry and deoxygenated solvents, because of the exceedingly air-sensitive nature of all organolanthanide complexes synthesised in this study. The following compounds: sodium 1,2,4-tris-trimethylsilylcyclopentadienide (NaCp‴) [6], potassium 1,4-bis-*t*-butyl-2,3-dimethylphospholide (KDtp) [2g], potassium 1,4-bis-trimethylsilyl-2,3-dimethylphospholide (KDsp) [7] and complexes **1a** and **2** [2j] were prepared as previously described. All other reagents were commercial and used as received from the suppliers. NMR data were obtained at 300 MHz on a Bruker Avance 300 instrument, IR spectra were measured on a Perkin–Elmer Paragon 1000 spectrometer, and elemental analyses were obtained from the "Centre de Microanalyse de l'Université de Bourgogne", Dijon, France. Despite several attempts with highly purified complexes, it was only possible to get meaningful analyses for **1c**.

4.2. Syntheses

*General procedure (GP) for the preparation of complexes **1b–d**:* In the glovebox a mixture of DyI_3 (1.0 eq) and K(L) or Na(L) (2.2 eq) was prepared in a Schlenk tube fitted with a J. Young valve. Toluene (20 mL) was condensed onto this mixture at −78 °C and the suspension was allowed to warm to room temperature. Under stirring the reaction was heated to reflux for 48 h. After that time the yellow solution was cooled to room temperature and centrifuged. The solvent was evaporated and the crude product was recrystallised from pentane at −30 °C.

4.2.1. Synthesis of [Cp‴$_2$DyI] (**1b**)

From the reaction of DyI_3 (0.20 g, 0.37 mmol) and NaCp‴ (0.26 g, 0.85 mmol) according to the GP, **1b** was obtained as yellow powder in 66% yield (0.21 g, 0.24 mmol). ^{1}H NMR (C_6D_{12}): δ −70.1 (br s, 36H, $w_{1/2} \approx 1.5$ kHz, Si(CH_3)$_3$), −224 (br s, 18H, $w_{1/2} \approx 0.6$ kHz, Si(CH_3)$_3$). T_{subl} 210 °C/10^{-3} mbar. IR (NaCl, Nujol, cm^{-1}) 2952(vs), 2925(vs), 2868(sh), 2856(vs), 1459(m), 1452(sh), 1428(m), 1375(m), 1243(m), 1140(m), 1000(w), 940(w), 854(sh), 822(vs), 748(m), 680(w), 647(w), 637(w), 625(w). Crystals suitable for X-ray analysis were grown by from sublimation.

4.2.2. Synthesis of [Dtp$_2$DyI] (**1c**)

From the reaction of DyI_3 (0.20 g, 0.37 mmol) and K(Dtp) (0.20 g, 0.77 mmol) according to the GP, **1c** was obtained as yellow powder in 75% yield (0.21 g, 0.28 mmol) ^{1}H NMR (C_6D_{12}): δ −241 (br s, $w_{1/2} \approx 2.5$ kHz, C(CH_3)$_3$). Mp dec. > 140 °C. IR (NaCl, Nujol, cm^{-1}) 2959(vs), 2924(vs), 2860(vs), 1463(vs), 1381(s), 1362(s), 1246(w), 1201(w), 1136(w), 1023(w), 728(w), 614(w). *Anal.* Calc. for $C_{28}H_{48}DyIP_2$ = 736.03: C, 45.7; H, 6.6. Found: C, 46.2; H, 6.8%. Crystals suitable for X-ray analysis were grown in pentane at −30 °C.

4.2.3. Synthesis of [{Dsp$_2$DyI}$_2$] (**1d**)

From the reaction of DyI_3 (0.20 g, 0.37 mmol) and K(Dsp) (0.23 g, 0.77 mmol) according to the GP, **1d** was obtained as yellow powder in 70% yield (0.21 g, 0.26 mmol). ^{1}H NMR (C_6D_{12}): δ −214 (br s, $w_{1/2} \approx 1.5$ kHz, Si(CH_3)$_3$). T_{subl} 220 °C/10^{-3} mbar. IR (NaCl, Nujol, cm^{-1}) 2953(vs), 2923(vs), 2869(sh), 2856(vs), 1462(vs), 1380(s), 1248(m), 1138(w), 918(w), 830(m), 748(w), 680(w), 641(w). Crystals suitable for X-ray analysis were grown by sublimation.

4.2.4. Reaction of [K(18-crown-6)][(Cp^{ttt})$_2$DyBr] (**3**) with fluorenone

Addition of fluorenone (10 mg, 59 μmol) to a solution of **3** (60 mg, 59 μmol) in toluene (4 mL) led to an immediate colour change from dark red to brown. After 24 h [K(18-crown-6)][(Cp^{ttt})$_2$DyBr(fluorenone ketyl)] (**4**) precipitated from the solution in 82% yield (58 mg, 48 μmol). Crystals suitable for X-ray analysis were grown from toluene at room temperature.

4.3. X-ray experimental data

Crystals for X-ray analysis were obtained as described above. The crystals were handled in the dry box and mounted on a fiberglass needle using Paratone-N oil. Data collection were performed at 150 K on a Nonius KappaCCD diffractometer, using graphite-monochromated Mo Kα radiation (λ = 0.71069 Å). All pertinent tables are given in the supplementary material.

Supplementary data

CCDC 711601, 711602, 711603 and 711604 contain the supplementary crystallographic data for **1b**, **1c**, **1d** and **4**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Materials and methods

Lead acetate trihydrate, $HSCH_2CH_2NMe_2{\cdot}HCl$, hexadecylamine (HDA) and other materials were obtained from SD Fine Chemicals and Fluka and were used without further purification. Bis(methylaminoethyl)diselenide [^{1}H NMR($CDCl_3$) δ: 2.26 (s, NMe_2); 2.63 (t, 7.1 Hz, $SeCH_2$); 3.05 (t, 7.1 Hz, NH_2)] was prepared by the reaction of Na_2Se_2 with $Me_2NCH_2CH_2Cl$ in DMF as described in the literature [33]. Diselenodipropionic acid, prepared by the reaction between Na_2Se_2 and $BrCH_2CH_2COOH$ in water, on esterification with methanol in the presence of sulfuric acid gave diselenodimethylpropionate and was purified by vacuum distillation (145 °C/3 mm) [^{1}H NMR ($CDCl_3$) δ: 2.81 (t, 7.2 Hz, $SeCH_2$); 3.09 (t, 7.1 Hz $SeCH_2CH_2$); 3.69 (s, COOMe)] [34]. Solvents were dried and distilled before use under a nitrogen atmosphere. HPLC grade toluene was used for optical studies. Melting points were determined in capillary tubes and are uncorrected.

Elemental analyses were carried out by the Radio Chemistry Division, B.A.R.C. IR spectra were recorded on a Bomem MB-102 FT IR spectrometer. ^{1}H NMR spectra were recorded on a Bruker Avance-200 NMR spectrometer operating at 200 MHz. Chemical shifts is relative to internal chloroform peak (δ 7.26 ppm). UV–Vis absorption spectra were recorded on a Chemito Spectrascan UV 2600 double beam spectrophotometer. Fluorescence spectra were recorded using a Hitachi F-4010 spectrofluorometer.

Thermogravimetric analyses (TGA) were carried out on a Nitzsch STA PC-Luxx TG-DTA instrument, which was calibrated with $CaC_2O_4{\cdot}H_2O$. TG curves were recorded at a heating rate of 5 °C min^{-1} under a flow of nitrogen. X-ray powder diffraction data were collected on a Philips X-ray diffractometer (Model PW 1729) using Cu Kα radiation. EDAX measurements were carried out on a JEOL JSM-T330A instrument. A JEOL-2000FX transmission electron microscope operating at accelerating voltages up to 200 kV was used for TEM studies. The samples for TEM were prepared by placing a drop of nanoparticles dispersed in acetone on a carbon coated copper grid.

2.2. Synthesis of complexes

2.2.1. $[Pb(SCH_2CH_2NMe_2)_2]$ (**1**)

To a methanolic solution of $HSCH_2CH_2NMe_2{\cdot}HCl$ (402 mg, 2.84 mmol) was added NaOMe (12.5 ml of 0.1 N, 5.87 mmol) in methanol and stirred for 5 min. To this a methanolic solution of $Pb(OAc)_2{\cdot}3H_2O$ (531 mg, 1.40 mmol) was added with stirring at room temperature under a nitrogen atmosphere. The whole was stirred for 3 h and colorless solution was dried *in vacuo* and the residue was washed with cold hexane (2×5 cm^3). The product was extracted with dichloromethane (3×10 cm^3) and filtered through a filtration assembly and the filtrate was evaporated under vacuum to give a white powder in 69% yield (401 mg), mp 130 °C. *Anal.* Calc. for $C_8H_{20}N_2PbS_2$: C, 23.1; H, 4.9; N, 6.7; S, 15.4. Found: C, 22.9; H, 4.7; N, 6.5; S, 15.2%. ^{1}H NMR (in $CDCl_3$) δ: 2.43 (s, 12H, NMe_2); 3.18 (t, 7 Hz, 4H, SCH_2); 3.74 (t, 7 Hz, 4H, NCH_2).

2.2.2. $[Pb(SeCH_2CH_2NMe_2)_2]$ (**2**)

A methanolic solution (20 cm^3) of $Pb(OAc)_2{\cdot}3H_2O$ (453 mg, 1.19 mmol) was added with stirring to a freshly prepared methanolic solution of $NaSeCH_2CH_2NMe_2$ (prepared from $(Me_2NCH_2CH_2Se)_2$ (364 mg, 1.20 mmol) and $NaBH_4$ (98 mg, 2.58 mmol)) under an argon atmosphere at room temperature. After 3 h, dark green solution was dried *in vacuo* and oily residue was washed with cold hexane (2×5 cm^3) and dried again *in vacuo*. The residue was extracted with CH_2Cl_2 (3×10 cm^3), filtered through a G3 filtration unit. The filtrate was evaporated under reduced pressure to give a light green solid, which was recrystallized from dichloromethane–hexane mixture (480 mg, 79%). Ageing of this complex was evident as it tended to become insoluble in organic solvents after keeping for few days, although microanalysis was unaltered. *Anal.* Calc. for $C_8H_{20}N_2PbSe_2$: C, 18.9; H, 4.0; N, 5.5. Found: C, 18.5; H, 3.9; N, 5.4%. UV–Vis λ_{max} ($CHCl_3$): 340 nm. ^{1}H NMR (in $CDCl_3$) δ: 2.43 (s, 12H, NMe_2); 3.34 (br, 4H, $SeCH_2$); 3.53 (br, 4H, NCH_2).

2.2.3. $[Pb(SeCH_2CH_2COOMe)_2]$ (**3**)

Prepared similar to **2** from $Pb(OAc)_2{\cdot}3H_2O$ (214 mg, 0.56 mmol) and $NaSeCH_2CH_2COOMe$ (prepared from $(MeCOOCH_2CH_2Se)_2$ (190 mg, 0.57 mmol) and $NaBH_4$ (48 mg, 1.27 mmol)) as a pale yellow crystalline solid in 90% yield (275 mg), mp 95 °C, melts with decomposition. *Anal.* Calc. for $C_8H_{14}O_4PbSe_2$: C, 17.8; H, 2.6. Found: C, 17.4; H, 2.1%. IR (Nujol) cm^{-1} 1654 and $1720_{(\nu C=O)}$. UV–Vis λ_{max} ($CHCl_3$): 360 nm. ^{1}H NMR (in $CDCl_3$) δ: 2.88 (m, 4H, $SeCH_2$); 3.08, 3.86 (each t, 7 Hz, 4H, $SeCH_2-$); 3.70 (s, 6H, COOMe).

2.3. Preparation of PbE nanoparticles

2.3.1. Thermolysis in HDA

In a three necked flask fitted with a thermometer, HDA (1.5 g) was degassed at 100 °C under an argon atmosphere for 1 h with continuous stirring. To this, a solution of **2** (130 mg, 0.26 mmol) in dichloromethane (3 cm^3) was injected rapidly. The temperature dropped to 80 °C and raised again slowly to maintain at 120 °C. The hot solution at the end of 25 min was cooled to 70 °C and methanol was added to precipitate brownish-black powder of PbSe, which was given a thorough washing with methanol followed by centrifuging and drying under vacuum.

2.3.2. Furnace pyrolysis

In a small quartz boat, **2** (100 mg, 0.2 mmol) was pyrolysed at 250 °C in a furnace under an argon atmosphere for 30 min where upon a black powder formed. After cooling the furnace to room temperature the black powder was collected. Similarly **1** and **3** were pyrolysed.

2.4. X-ray crystallography

Colorless single crystals of $[Pb(ECH_2CH_2NMe_2)_2]$ (E = S or Se) were obtained from hexane solution of the freshly prepared samples. X-ray data were collected on a Rigaku AFC 7S diffractometer at 298(2) K using graphite monochromated Mo Kα (0.71073 Å) radiation employing the $\omega - 2\theta$ scan technique. The unit cell parameters were determined from 25 reflections measured by random search routine. The intensity data were corrected for Lorentz, polarization and absorption effects [35]. The structures were solved using the SHELXS97 [36] and refined using the SHELXL97 [37] computer programs. The non-hydrogen atoms were refined anisotropically. Crystallographic data and refinement details are given in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopy

Reactions of $Pb(OAc)_2{\cdot}3H_2O$ with sodium salts of β-functionalized ethylchalcogenolate ligands gave homoleptic chalcogenolate complexes of composition, $[Pb(ER)_2]$ (ER = $SCH_2CH_2NMe_2$ (**1**), $SeCH_2CH_2NMe_2$ (**2**), $SeCH_2CH_2COOMe$ (**3**)) (Eq. (1)). Freshly prepared **1–3** are soluble in dichloromethane, chloroform and methanol, but solubility decreases with aging and finally leading to a poorly soluble product.

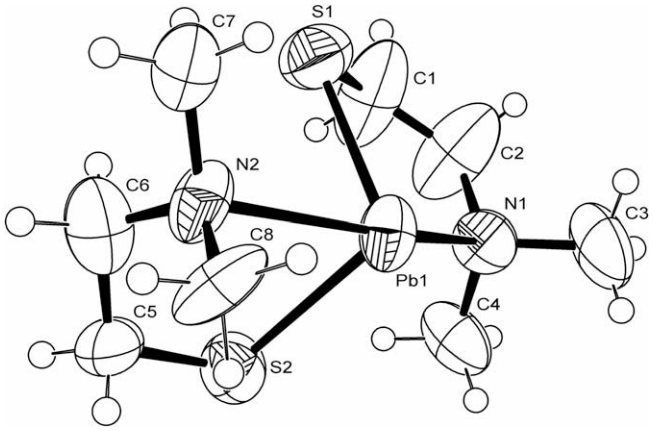
The IR spectrum of **3** showed absorption at 1720 cm^{-1} attributed to free carbonyl group which is slightly shifted to lower wave-number relative to diselenide (1734 cm^{-1}) [34]. Absorption spectra of **2** and **3** in chloroform displayed a peak at 340 and 360 nm, respectively. These absorptions occur at lower energy than the corresponding diselenides and may be attributed to the transition in the selenolate group and metal–ligand charge transfer (MLCT) transitions. The ^{1}H NMR spectra of **1**–**3** showed singlets due to methyl protons whereas XCH_2 (X = N or CO) and ECH_2 resonances appeared either triplets or broad signal.



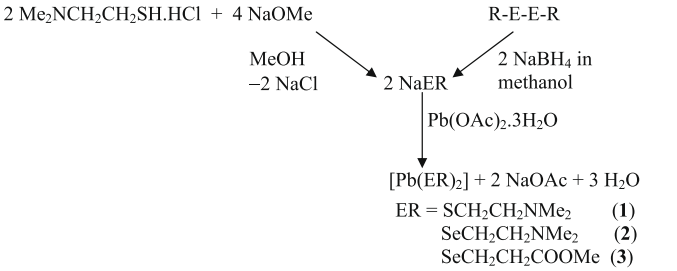


Fig. 1. Molecular structure of $[Pb(SCH_2CH_2NMe_2)_2]$, ORTEP drawn with 50% probability.

(1)

3.2. Structures of **1** and **2**

The molecular structures of $[Pb(ECH_2CH_2NMe_2)_2]$ (E = S or Se) have been established unambiguously by X-ray crystallography (Figs. 1 and 2), and selected bond lengths and angles are given in Table 2. Unlike bis(dithiolato)lead(II) complexes which are associated through secondary Pb···S interactions in the solid state [4–6], these complexes are discrete molecules and are isomorphous. The lead ion is coordinated to two non-planar five-membered chelating $Me_2NCH_2CH_2E$ ligands. The overall geometry around lead is distorted trigonal bipyramidal with nitrogen atoms occupying the axial positions. Two chalcogen atoms and stereochemically active lone pair of electrons occupy the equatorial positions. The repulsion of the lone pair of electrons is manifested in deviation of N(1)–Pb(1)–N(2) (158.0°) and E(1)–Pb(1)–E(2) (95.9(2)° for S and 97.03(11)° for Se) angles from idealized values of 180° and 120°, respectively. Significant difference between the two structures is observed in the torsion angles in one of the chelate rings (N(1)–C(2)–C(1)–E(1); 41(8)° (E = S) and 50(4)° (E = Se)). The two Pb–S and Pb–Se distances are essentially similar and are in the range reported in the literature [30,38]. One of the Pb–N distances is slightly longer than the other.

Although the structure of **3** resembles to that of $[Pb(SCH_2CH_2NH_2)_2]$ reported earlier [11], the latter exhibits a chain structure formed through NH···S hydrogen bridges. The absence of NH···S hydrogen bonding in **1**, results in contraction of the S–Pb–S angle (95.9(2)°) while the N–Pb–N angle (158.0(6)°) has opened up from the corresponding angles, (99.2(1)° and 149.3(3)°, respectively) in $[Pb(SCH_2CH_2NH_2)_2]$ [11]. The Pb–N bond is slightly elongated (av. 2.626 Å) in **1** as compared to the corresponding cysteamin derivative (2.593(9)°) indicating weaker coordination of tertiary nitrogen atom in **1**.

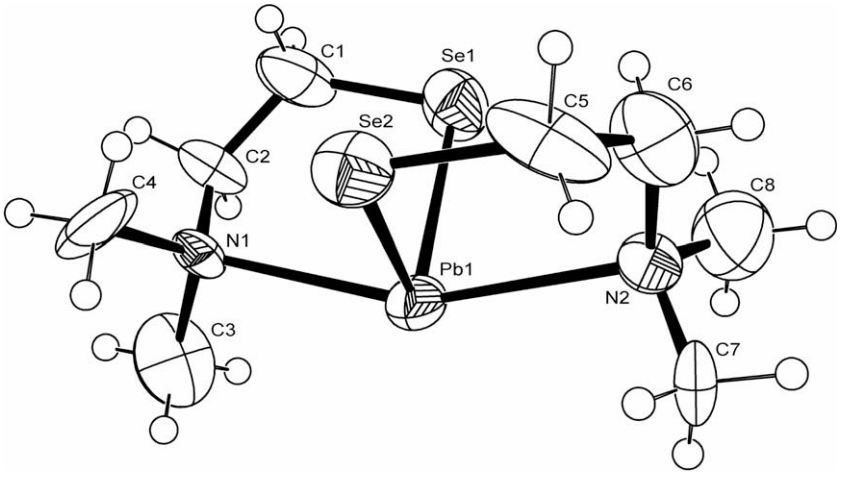

Fig. 2. Molecular structure of $[Pb(SeCH_2CH_2NMe_2)_2]$, ORTEP drawn with 50% probability.

Lead(II) complexes show different degree of distortion in the coordination sphere of lead depending on the steric requirements of the lone pair of electrons. Thus structures can vary between those where the lone pair has no steric influence (holodirected) or exert steric demands (hemidirected) [39,40]. In both the structures (**1** and **3**), the lone pair has pronounced influence (hemidirected) on overall geometry of the molecules, as a consequence there is a void which is manifested on Pb–S (shorter) and Pb–N (longer) bond distances. In fact the two distances (Pb–S and Pb–N) are comparable (av. 2.62 Å) despite significant difference in the ionic radii of sulfur and nitrogen.

3.3. Thermal studies

TG curve of **2** (Supplementary data) showed that the complex underwent a single step decomposition at 190 °C to lead selenide as inferred from the TG weight loss (% weight loss found (calcd.): 46.2 (43.8)). Pyrolysis of these complexes were carried out under different conditions. Pyrolysis at 200–250 °C in a furnace under a flowing argon atmosphere for 1 h afforded a black residue of cubic PbE (E = S or Se) as revealed by their XRD patterns (Fig. 3) [41,42]. The EDAX analysis (Found (calcd.): Pb, 74.3 (72.4); Se, 25.7 (27.6)%) for the residue obtained from **2** further confirmed the formation of PbSe. The average size estimated from Scherrer equation [43] for these particles is 50 (from **1**) and 34 nm (from **2** and **3**). PbS nanoparticles prepared using $[Pb(S_2CNR_2)_2]$ (R = Et or Bu^i) in TOPO at >150 °C have size >60 nm [12], while $[Pb(S_2CNBu^i{}_2)_2]$ gave a mixture of cubic and smaller spherical particles.

Decomposition of **2** in HDA yielded cubic phase of PbSe nanoparticles (supplementary data) with an average diameter of 13 nm estimated using Scherrer equation. The TEM picture (Fig. 4) showed that they were spherical in nature with an average size of 15 nm. A slight difference in the particle size estimated from the XRD pattern and TEM is because in XRD line width does not directly determine the particle size [44]. SAED pattern confirmed the cubic phase of these particles as determined by XRD. It has been reported earlier that the shape and size of PbSe markedly depend (10–120 nm) on the concentration of acetic acid when these particles were prepared by hot injection route using lead–oleate [23]. The PbSe nanoparticles synthesized by the reaction of lead carbox-

Table 2

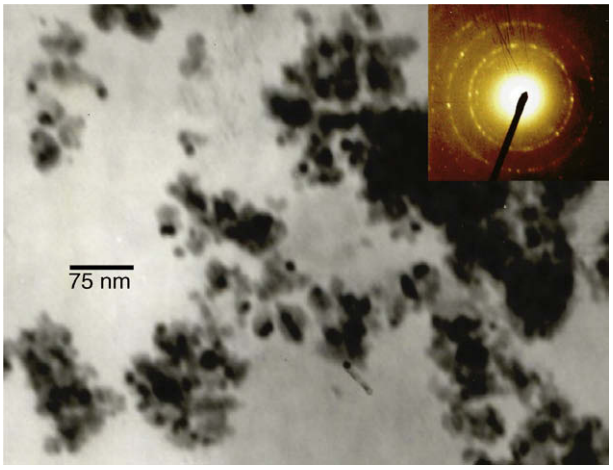

Fig. 4. TEM picture of PbSe nanoparticles obtained by pyrolysis $[Pb(SeCH_2CH_2NMe_2)_2]$ in HDA at 120 °C (inset shows corresponding SAED pattern).

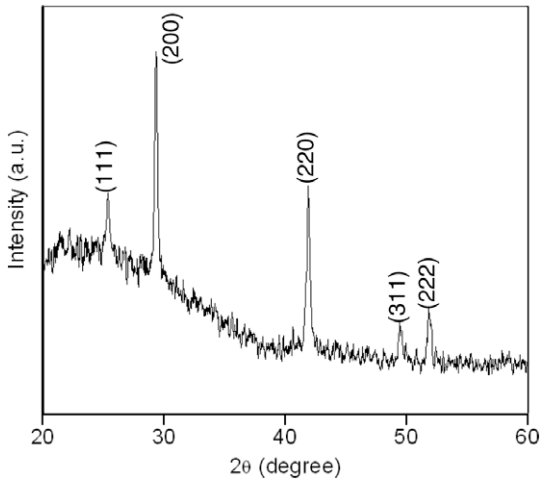

Fig. 3. XRD pattern of PbSe nanoparticles obtained by the pyrolysis of $[Pb(SeCH_2CH_2COOMe)_2]$ in a furnace at 200 °C for 1 h.

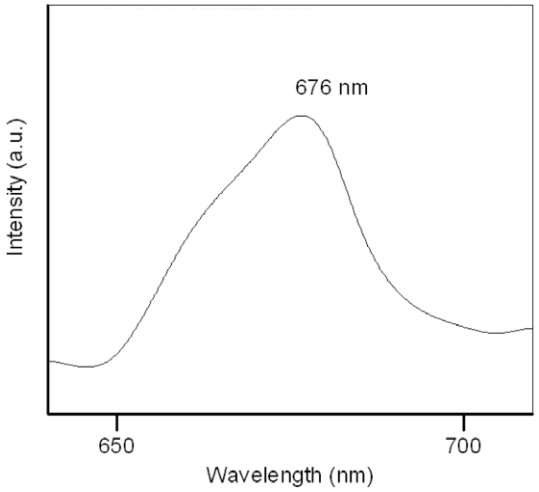

Fig. 5. Excitation profile of PbSe nanoparticles obtained by the pyrolysis of $[Pb(SeCH_2CH_2NMe_2)_2]$ in HDA at 120 °C.

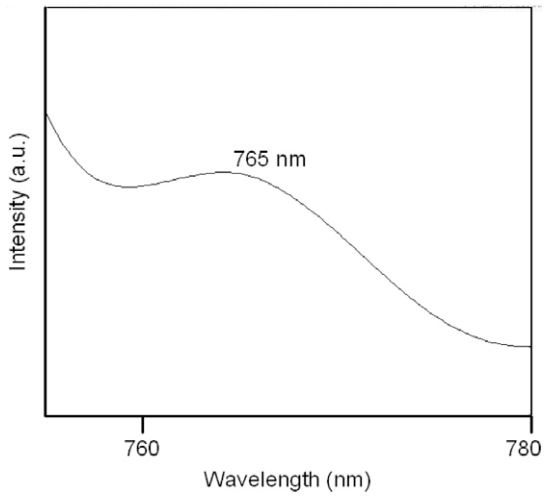

Fig. 6. Emission profile of PbSe nanoparticles obtained by the pyrolysis of $[Pb(SeCH_2CH_2NMe_2)_2]$ in HDA at 120 °C.

ylate and SeO_2 in the presence of TOP (trioctyl phosphine) yield cubic shaped PbSe nanoparticles of 15.6 nm as measured by TEM [45]. Recently, O'Brien et al. [12] have prepared cubic shaped lead selenide nanocrystals using $Pb(Se_2CNMeHex^n)_2$.

3.4. Optical properties

The absorption spectrum of PbSe nanoparticles obtained by pyrolysis of **2** in HDA showed very broad exciton peak 732 nm, which is blue shifted with respect to the bulk PbSe (λ_{max} 4745 nm) [28] showing the quantum confinement of the particles. The spectrum showed a small amount of tailing which may be due to the formation of some bulk PbSe. The excitation profile of PbSe nanoparticles (Fig. 5) displayed a peak at 676 whereas emission profile (Fig. 6) showed a broad peak at 765 nm corresponding to the band edge emission.

4. Conclusion

The complexes $[Pb(ER_2)_2]$ (ER = $SCH_2CH_2NMe_2$, $SeCH_2CH_2NMe_2$, $SeCH_2CH_2COOMe$) have been synthesized and the former two have been structurally characterized. They adopt a distorted trigonal bipyramidal configuration around lead. These complexes have been demonstrated for their use as molecular precursors for the synthesis of PbE nanoparticles at moderately low temperatures.

Acknowledgements

We thank Drs. T. Mukherjee and D. Das for encouragement of this work. The authors are grateful to Dr. S.K. Gupta and his group for SEM and EDAX measurements and Dr. V.K. Manchanda and his group for providing microanalysis of these complexes.

Appendix A. Supplementary data

CCDC 698265 and 698266 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.05.054.

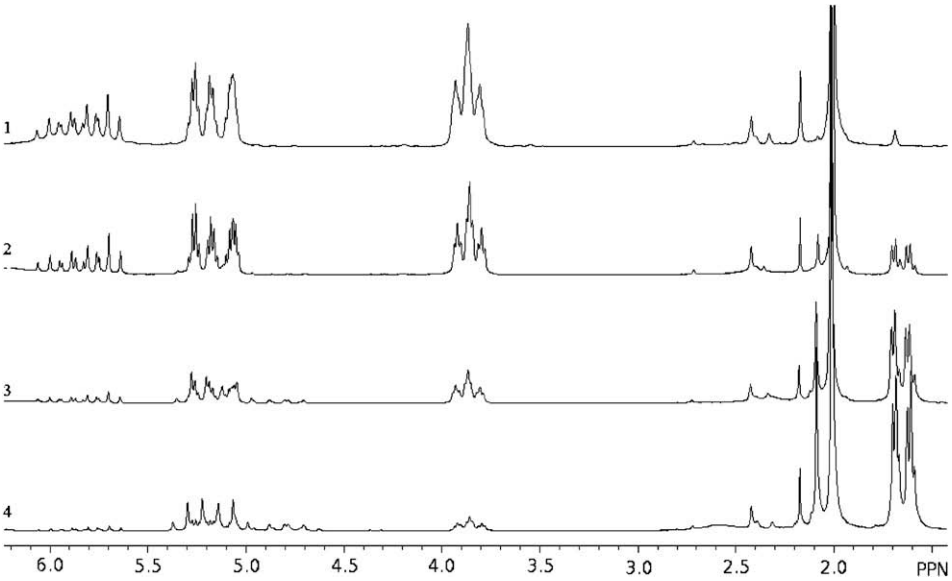

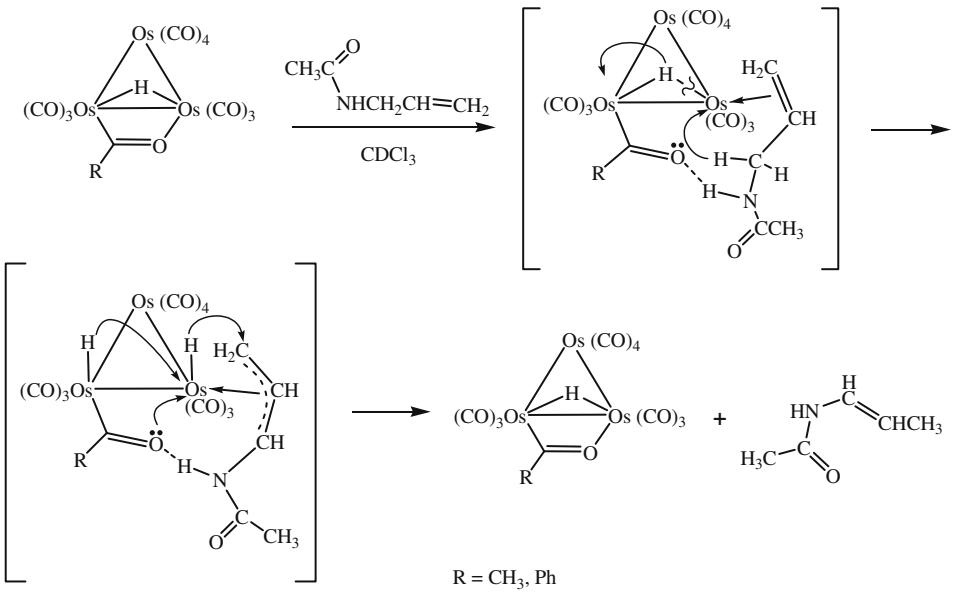

Fig. 1. The time dependence of ^{1}H NMR spectrum of the **2** and N-allylacetamide reaction mixture. The interval between spectra recording is 2 week.

Scheme 1.

whereas the insertion of the electron donating NEt_2 group into the phenyl ring enhances the cluster stability but lowers its catalytic activity.

An increase in the reaction temperature to 55 °C also did not promote the isomerization of N-allylacetamide catalyzed by clusters **1–3**. Therefore microwave irradiation was used to accelerate the N-allylacetamide isomerization in the presence of **1, 2**, and (μ-H)Os_3(μ-O=CNHCHMeCOOEt)$(CO)_{10}$ (**3**) clusters. It is known that the effect of microwave irradiation on solutions causes not only rapid heating of solutions. It also activates diffusion and mass transfer processes, changes the solvent ordering strength and the structure of a solvate shell of dissolved molecules, thus overall accelerating the chemical processes [13,14]. The irradiation of cluster complexes and N-allylacetamide solutions in $CDCl_3$ was performed in NMR tubes. To prevent sample heating over 45 °C a single irradiation time was no more than 30 s, after which the solution was cooled to ~18 °C. In total, the exposure time for each reaction mixture did not exceed 30 min. The course of the reaction was monitored by NMR spectroscopy. As a result, the following facts are revealed:

- Irradiation of N-allylacetamide solutions with **1** or **3** leads to a decrease in reaction times by 5–8%.
- Irradiation accelerates the isomerization rate of N-allylacetamide in the presence of **2** by more than 3000-fold.

Two test experiments were performed. In the first one, the solution of N-allylacetamide and cluster **2** was irradiated for 4 min, as described above, and then heated at 45 °C for 4 h. The 4 min microwave irradiation resulted in 50% isomerization of N-allylacetamide, whereas no changes were observed after 4 h heating. In the second test experiment, the similar solution was heated at 45 °C, but no visible changes were observed in the ^{1}H NMR spectra after 4 h.

Undoubtedly, the use of a conventional microwave oven without temperature control and stirring may sometimes cause local overheating of the solution. However, the reaction mixture overheating due to microwave irradiation cannot account for a 3000-fold acceleration of the allylic rearrangement. According to the literature, 50 ml of $CHCl_3$ is heated up to ~50 °C by the 1 min microwave irradiation (2450 MHz, 600 W) [15]. Since we have used an open system, strong overheating of the reaction mixture during 20–30 s irradiation is unlikely, and the local overheating cannot affect the reaction so drastically. Furthermore, such a dramatic effect was observed only for the reaction with $(\mu\text{-H})Os_3(\mu\text{-O=CPh})(CO)_{10}$, while the effect of microwave irradiation on the allylic rearrangement was minimum for $(\mu\text{-H})Os_3(\mu\text{-O=CMe})(CO)_{10}$ and $(\mu\text{-H})Os_3(\mu\text{-O=CNHCHMeCOOEt})(CO)_{10}$ complexes.

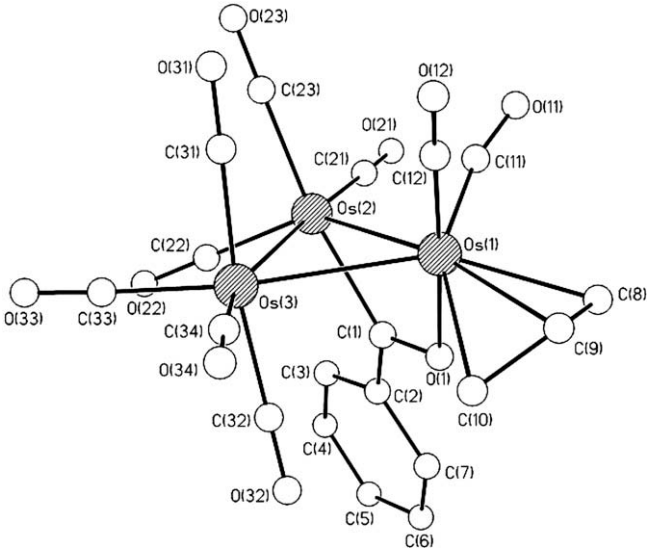

Fig. 2. Molecular structure of $Os_3\{(\mu,\eta^2\text{-O=CC}_6H_5)(\eta^3\text{-}C_3H_5)\}(CO)_9$ [18]. Selected distances (Å) and bond angles (°): Os(1)–Os(2) = 2.843(1), Os(2)–Os(3) = 2.836(1), Os(1)–Os(3) = 2.840(1), Os(1)–C(8) = 2.248(1), Os(1)–C(9) = 2.247(2), Os(1)–C(10) = 2.273(2), Os(1)–O(1) = 2.138(2), Os(2)–C(1) = 1.916(1); Os(2)–Os(3)–C(1) = 89.37(3), Os(2)–Os(1)–O(1) = 89.3(2), C(8)–C(9)–C(10) = 121.3(9).

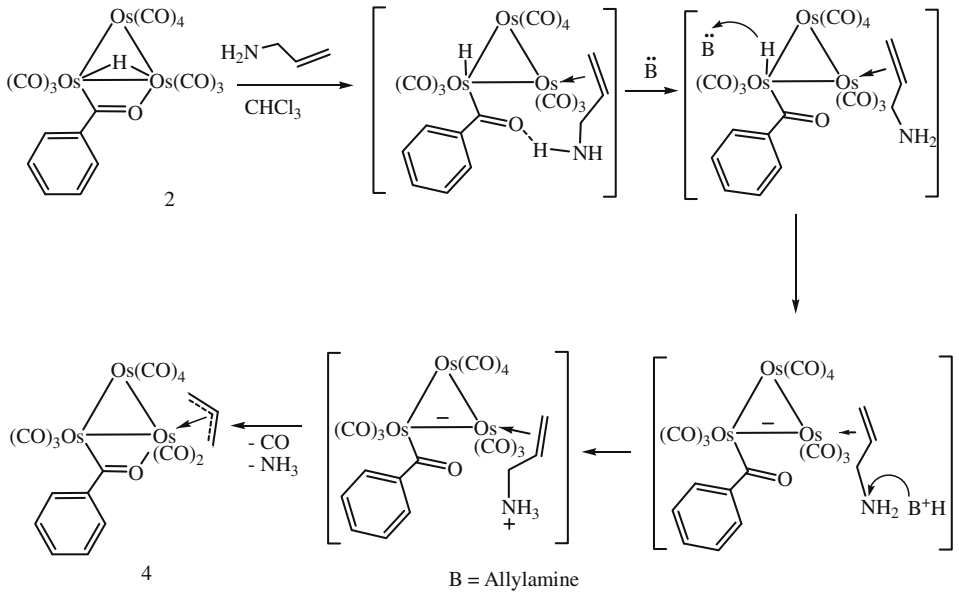

Unfortunately, we cannot at present unambiguously interpret the results obtained.

If the formation of NH···O=C hydrogen bond followed by Os–O bond dissociation is the key step of the N-allylacetamide isomerization (as described above), then the isomerization of allylamine, which has not yet been described, shall proceed under similar conditions. We have studied the isomerization of allylamine in the presence of $(\mu\text{-H})Os_3(\mu\text{-O=CPh})(CO)_{10}$ (**2**) in $CDCl_3$ and dioxane. The course of the reactions was controlled by TLC and ^1H NMR spectra of the reaction mixtures. No apparent solvent effect was observed. After chromatography of the reaction mixture, two yellow compounds were isolated and characterized.

One of these compounds was starting complex **2** (~30%). In the CO stretching region, the IR spectrum of the second product was similar to that of $Os_3(CO)_9$ with chelate-bridging ligands [16]. No NH bands were detected in the IR spectrum. The ^1H NMR spectrum confirmed the presence of the Ph group and the $\eta^3\text{-}C_3H_5$ ligand coordinated to the metal atom [17].

The single crystal of this complex was obtained and its X-ray diffraction analysis (Fig. 2) was reported in preliminary communication [18]. The η^3-allyl ligand is located in the position close to that of equatorial CO in **2**; C(8) and C(9) atoms are equidistant within the error limit, while C(10) is more remote. The bridging O(1)–C(1)–Ph ligand is located almost axially relative to the Os_3 triangle; the Os_3/Os(1)O(1)C(1)Os(2) interplanar angle is 103.40°.

Therefore, instead of the expected allylamine isomerization, the C–N bond breaks at room temperature with the coordination of the allyl fragment formed to the osmium atom in $Os_3(CO)_9(\mu,\eta^2\text{-O=C-Ph})(\eta^3\text{-}C_3H_5)$ (**4**) cluster. Transition metal complexes with the η^3-allyl ligand are mainly formed in their reactions with allyl halogenides and allylic alcohols [19,20]. Few examples of C–N bond cleavage under mild conditions and the formation of π-complexes can be mentioned. Platinum η^3-allyl complexes were synthesized at room temperature starting from allylamine and cationic Pt(II) complexes [21]. The ruthenium η^3-allyl complex was obtained by moderate heating of $[(C_5Me_5)RuCl_2]_n$ and allylamine solution in CH_2Cl_2 [22]. A similar complex was obtained by boiling the THF solution of allylamine and $[RuClH(CO)(PPh_3)]$ [23]. In most of these publications, the authors propose that C–N bond cleavage is caused by hydrogen atom transfer from the metal atom to the nitrogen of the coordinated allylamine. We also suggest that in our reaction,

Scheme 2.

the key step of C–N bond cleavage is the transfer of the terminal hydrogen atom as H^+ from the osmium atom to the nitrogen atom of allylamine (Scheme 2). The acidity of the terminal hydrogen atom in triosmium clusters and its abstraction with amines are known [24–26]. The proposed mechanism is shown below.

The reaction of allylamine with **2** was also studied at 65 °C. Cluster complex **3** forms along with an oily product, as in the reaction at room temperature. Although the composition and structure of this oily product has not been determined exactly, IR, ^1H, $C^{13}\{^1H\}$ NMR and mass spectral data indicate that it is a mixture of oligomers containing not more than 10 allylamine fragments.

3. Conclusions

The results obtained allow us to suppose that cluster complexes with the hemilabile bridging –C=O group are promising as catalysts for various processes. The capability of the substrate to form a hydrogen bond with the oxygen atom of the bridging ligand followed by Os–O bond cleavage and the formation of a vacant coordination site is likely to be a necessary condition of the catalytic activity of these clusters. In this case, the Os–O bond strength and hence the catalytic activity of the clusters strongly depend on the organic radical bonded by the bridging –C=O group.

4. Experimental

Deuterated solvents were used without further purification. Other solvents were distilled before the use. $Os_3(CO)_{10}(NCMe)_2$ [27], (μ-H)Os_3(μ-O=CR)$(CO)_{10}$ (R = Me (**1**); Ph (**2**)) [28], (μ-H)Os_3(μ-O=CNHCH$_2$CH=CH$_2$)$(CO)_{10}$ [29], (μ-H)Os_3(μ-O=CNHCHMeCOOEt)$(CO)_{10}$ [30] cluster complexes were prepared using the methods described in the literature. Analytical and preparative chromatography was performed on Silufole™ plates as well as on glass plates coated by the Silica gel 60 PF_{254}. IR spectra were obtained using a Scimitar FTS 2000 spectrofotometer. ^1H and ^{13}C NMR spectra were recorded on Bruker MSL-300 at 300 MHz (^1H) and Bruker DPX-250 at 250.1 MHz (^1H) or 62.3 MHz (^{13}C) spectrometers in $CDCl_3$ or in a $CDCl_3/CCl_4$ mixture (internal standard – TMS). The numeration of hydrogen atoms for signal assignment in ^1H NMR of $Os_3(CO)_9(\mu,\eta^2\text{-O=C-Ph})(\eta^3\text{-}C_3H_5)$ complex (**3**) corresponds to the numeration for carbon atoms given in Fig. 2. The mass spectra were measured on an Aligent 1100 HPLS-MS spectrometer using the electrospray ionization technique. A conventional microwave oven (2450 Hz, 600 W) was used to irradiate the samples. Elemental analyses were performed using a EURO EA 3000 C H N elemental analyzer or by manual burning, OsO_4 being caught by a low temperature trap.

4.1. Isomerization of N-allylacetamide

4.1.1. At room temperature

All reactions were performed in NMR tubes at room temperature. The clusters (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=C-Me})$ (**1**) (30 mg, 3.4×10^{-2} mmol), (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=CPh})$ (**2**) (30 mg, 3.1×10^{-2} mmol), and (μ-H)Os_3(μ-O=CNHCHMeCOOEt)$(CO)_{10}$ (**3**) (30 mg, 2.9×10^{-2} mmol) were dissolved in 0.5 ml of $CDCl_3$. Twenty six milligrams (0.29 mmol) of N-allylacetamide was added to each of the obtained solutions. The reactions courses were monitored by disappearance of starting N-allylacetamide signals (–CH_2–N) and arising of the N-(prop-1-enyl)acetamide signals (=CH–CH_3) in ^1H NMR spectra (Fig. 1).

4.1.2. At microwave irradiation

Reactions were performed in NMR tubes. The clusters **2** (30 mg, 3.1×10^{-2} mmol), **1** (30 mg, 3.3×10^{-2} mmol), and (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=}CC_6H_4NEt_2)$ (30 mg, 2.5×10^{-2} mmol) were dissolved in 0.5 ml of $CDCl_3$. N-allylacetamide (30 mg, 0.3 mmol) was added to each solution. The samples were irradiated for 8–30 min, the single irradiation time being no more 30 s with following cooling to ~18 °C. The reaction monitoring was as outlined above. The 50% conversion of N-allylacetamide is reached for 8 min in the presence of cluster **2**. No visible changes of NMR spectra were observed at microwave irradiation of N-allylacetamide solutions in the case **1** and **3** clusters.

4.2. Reaction of allylamine with [(μ-H)$Os_3(CO)_{10}(,\eta^2$-O=CPh)]

4.2.1. At room temperature in $CDCl_3$

To the solution of (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=CPh})$ (**2**) cluster (30 mg, 3.1×10^{-2} mmol) in 0.5 ml $CDCl_3$ 40 mg (0.7 mmol) freshly distilled over NaOH allylamine was added. The solution has been kept at room temperature for two months. The reaction course was monitored by disappearance of the allylamine signals and arising of coordinated allyl ligand signals in new complex **4** in ^1H NMR spectra of the reaction mixture. When reaction finished the solution was evaporated to dryness in vacuum and the residue was chromatographed on TLC plates using petroleum ether as eluent. Two yellow fractions were isolated with R_f 0.85 (starting (μ-H)$Os_3(CO)_{10}$(μ-O=CPh) (**2**); 8.5 mg, 28.6%) and R_f 0.65 ($Os_3(CO)_9(\mu,\eta^2\text{-O=CPh})(\eta^3\text{-Allyl})$ (**4**); 9.7 мг., 32.4%).

4.2.1.1. Cluster 4. IR (hexane, ν_{CO}/cm^{-1}): 2098 w, 2055 s, 2023 m, 2013 s, 1999 m, 1994 m, 1976 w. ^1H NMR ($CDCl_3$, 250 MHz): δ 7.68 (d, 2H, H^3, H^7); 7.57 (dd, 1H, H^5); 7.36 (dd, 2H, H^4, H^6); 5.36 (m, 1H, H^9); 5.23 (dd, $^3J_{HH}$ = 7 Hz, $^2J_{HH}$ = 3 Hz, 1H, $H^{8\beta,10\beta}$); 4.88 (dd, $^3J_{HH}$ = 7 Hz, $^2J_{HH}$ = 3 Hz, 1H, $H^{8\beta,10\beta}$); 2.59 (dd, $^3J_{HH}$ = 12 Hz, $^2J_{HH}$ = 3 Hz 1H, $H^{8\alpha,10\alpha}$); 1.72 (dd, $^3J_{HH}$ = 12 Hz, $^2J_{HH}$ = 3 Hz 1H, $H^{8\alpha,10\alpha}$) ppm. *Anal.* Calc. for $C_{19}H_{10}O_{10}Os_3$: C, 23.54; H, 1.03; Os, 58.71. Found: C, 23.82; H, 1.16; Os, 58.35%.

4.2.2. At room temperature in d_8-dioxane

To the solution of (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=CPh})$ (**2**) cluster (30 mg, 3.1×10^{-2} mmol) in 0.5 ml d_8-dioxane 42 mg (0.7 mmol) freshly distilled over NaOH allylamine was added. The solution has been kept at room temperature for nine weeks. The reaction course was controlled as described above. When reaction finished the solution was evaporated to dryness in vacuum and residue was chromatographed on TLC plates using petroleum ether as eluent. Two yellow fractions were isolated with R_f 0.85 (starting (μ-H)$Os_3(CO)_{10}$(μ-O=CPh) (**2**); 7.8 mg, 26.2%) and R_f 0.65 ($Os_3(CO)_9(\mu,\eta^2\text{-O=CPh})(\eta^3\text{-Allyl})$ (**4**); 8.6 мг., 28.7%.

4.2.3. At 65 °C in $CDCl_3$

The solution of (μ-H)$Os_3(CO)_{10}(\mu,\eta^2\text{-O=CPh})$ (**2**) (36 mg, 3.8×10^{-2} mmol) and allylamine (140 mg, 2.46 mmol) in 4 ml $CHCl_3$ in sealed glass ampoule was heated at 65 °C for 50 h. The color was turned from light yellow to orange and an oily product on the solution surface was formed. When reaction was finished, the oil was removed and the solution was evaporated in vacuum to dryness. Chromatography on TLC plates of the residue (eluent – petroleum ether) gave two main yellow fraction with R_f 0.85 (unreacted **2**, 19 mg, 52.5%) and 0.65 (**4**, 7 mg, 18%).

4.2.3.1. The oily product. IR (thin film, ν/cm^{-1}): 3420 vs, 2965 vs, 2036 m, 1956 m, 1610 s, 1509 s, 1459 s, 1150 w, 994 w, 945 w, 882 w, 755 w, 578 w. ^1H NMR (methanol-d_4, 250 MHz): δ 8.5 (br. 3H, $NR_{4-x}H_x^+$), 5.97 (m, 1H, CH=CH_2), 5.42 (m, 2H, CH_2=CH), 3.57 (m, 2H, CH_2–N), 3.03 (br. m, 6H), 2.6 (br. m, 1.7H), 2.15 (br. m, 4.8H), 1.9–0.85 (br. m, 14H) ppm. $^{13}C\{^1H\}$ NMR (methanol-d_4, 63 MHz : δ 130 (–CH=CH_2), 121 (CH_2=CH–), 43 (br.) 41 (br.), 36 (br.), 32 (br.), 28 (br.), 15 (br.), 18 (br.) ppm. MS (ESI+): *m*/*z* 505 (25%), 448 (25%), 391 (35%); 334 (60%); 277 (100%); 220 (85%); 163 (30%).

4.3. The synthesis of (μ-H)$Os_3(CO)_{10}$(,η^2-O=C-$C_6H_4NEt_2$) (**5**) cluster

The solution of $Os_3(CO)_{10}(NCMe)_2$ (130 mg, 0.139 mmol) and 4-(diethylamino)benzaldehyde (56 mg, 0.316 mmol) in 7 ml dioxane was heated at 80 °C for 30 min. After that the reaction mixture was evaporated at reduced pressure and the solid residue was chromatographed on glass plates coated with silicagel using petroleum ether as eluent. The extraction of the main yellow fraction with R_f 0.65 gave (μ-H)$Os_3(CO)_{10}$(μ,η^2-O=$CC_6H_4NEt_2$) (**5**) (88 mg, 62%). IR (hexane, ν_{CO}/cm^{-1}): 2106 w, 2066 s, 2055 s, 2023 s, 2015 s, 2008 w, 1993 w, 1977 w. ^{1}H NMR ($CDCl_3$, 250 MHz): δ 7.63 (m, 2H), 6.55 (m, 2H) (aromatic H); 3.43 (q, 4H, $-NCH_2-$); 1.23 (t, 6H, Me); -13.73 (s, 1H, μ-H). *Anal* Calc. for $C_{22}H_{15}NO_{12}Os_3$: C, 25.02; H, 1.43; Os, 54.04. Found: C, 25.20; H, 1.50; Os, 53.82%.

(SP → TBP), the Cu···Cu separation increases, thus the Cu···Cu distance parameter reflects the coordination sphere arrangement and only through that suggests the magnitude of the AFM interaction [2,4–6]. The main key factor crucial for the magnitude of the AFM interaction of this type of complexes is, however, the electronic structure of the carboxylate group carbon atom (O_2C). A larger orbital $2p_x$ population (the *x*-axis is along the R–C bond in O_2CR) of the carbon atom in the symmetric HOMO orbital gives a larger $|2J|$ value [6–11]. Thus, the characteristic magnitude of the AFM interaction for the methanoate dicopper *paddle-wheel* $[Cu_2(\mu\text{-}O_2CR)_4L_2]$ complexes is reported to be 390–560 cm^{-1} [1–3,6,12–16]. Such a magnitude is exceeded only by complexes having benzoyl formate $-2J \sim 650\ cm^{-1}$ [9,17], carboxysilanes and carboxygermanes $-2J \sim 1000$–$1200\ cm^{-1}$ [3,10] as the 'R' group in O_2CR (Scheme 1d–f). On the other hand, the vast majority of the carboxylates show significantly weaker AFM interaction (*e.g.* acetates $-2J \sim 300\ cm^{-1}$) [2,6,7,18]. The axial ligand L in $[Cu_2(\mu\text{-}O_2CR)_4L_2]$ is suggested not to take a stronger role for the AFM interaction, though certain effects are noticed [6]. The application of a 2-methylpyridine (2-mpy) molecule next to the carboxylate anion may serve as an additional ligand at the terminal position (one coordination site) of the mononuclear, binuclear or polynuclear coordination compound enabling additional stabilization due to its π-system and steric hindrance. Therefore, methanoate and 2-mpy as ligands could show interesting structural possibilities giving significant insight into the coordination moiety construction. Many examples are found in the literature confirming the key role for the AFM interaction magnitude of the dicopper *paddle-wheel* building blocks. Nevertheless, the binuclear methanoate central core $[Cu_2(\mu\text{-}O_2CR)_4]$ environment has not been so clearly described, despite a number of different types of coordination compounds with $[Cu_2(\mu\text{-}O_2CH)_4]$ building blocks that have been reported [2,3,16,19–24].

Herein, several methanoato complexes, *e.g.* mononuclear $[Cu(O_2CH)_2(2\text{-mpy})_2]$ (**1**), binuclear $[Cu_2(\mu\text{-}O_2CR)_4(2\text{-mpy})_2]$ (**2**) and two hybrids of mononuclear and binuclear building blocks in polymeric $\{[Cu(\mu\text{-}O_2CH)_2(2\text{-mpy})_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**3**) and $\{Na_2[Cu(\mu\text{-}O_2CH)_2(O_2CH)_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**4**) are presented and described.

2. Experimental

2.1. Physical measurements

C,H,N analyses were performed with a Perkin–Elmer 2400 CHN Elemental Analyzer. Metal analysis was carried out electrogravimetrically with Pt electrodes. Vibrational spectra were recorded by KBr pellets on a Perkin–Elmer FT-IR 1720x spectrometer. Electronic spectra were recorded as nujol mulls with a Perkin–Elmer Lambda 19 UV/Vis/NIR spectrometer. X-band powder EPR spectra for **4** were recorded at various temperatures on a Bruker Elexsys E500 electron spin resonance spectrometer. The room temperature magnetic susceptibility data of the powdered samples were obtained with a Sherwood Scientific MSB-1 balance using $Hg[Co(NCS)_4]$ as a calibrant. The instrument uses the Evans's method. The effective magnetic moments (per one copper atom) were calculated using the equation $\mu_{eff}/\mu_B = 2.828(\chi_M T)^{1/2}$. The magnetic susceptibility for **4** was additionally measured with a Quantum Design SQUID MPMS-XL-5 magnetometer, equipped with a 5 T magnet. These data were investigated in the temperature interval 2–300 K in a magnetic field strength of $H = 1000$ Oe and were corrected for the experimentally determined contribution of the sample holder. Corrections for the temperature dependant paramagnetism and the diamagnetic response of the compounds, due to the closed atomic shells as estimated from the Pascal's constants, were applied [25].

Scheme 1. Several carboxylate O_2CR ligands differing in the 'R' group covalently bonded to the carboxylate O_2C carbon atom.

2.2. X-ray crystallography

The single crystal data for **1** and **3** were collected on a Nonius Kappa CCD diffractometer with graphite monochromated Mo Kα radiation. They were processed using the DENZO-SMN program [26]. Both structures were solved by direct methods using SIR97 [27]. The positions of all the other hydrogen atoms in **1** and **3** were obtained from the difference Fourier map. Full-matrix least-squares refinement on *F* magnitudes was employed with anisotropic displacement factors for all non-hydrogen atoms using XTAL3.6 [28]. The parameters of the hydrogen atoms were not refined. The numbers of total measured and unique reflections are 20,070 and 2660 for **1**, while 9942 and 2741 for **3**, respectively. 2495 and 2553 reflections with 190 and 160 parameters were used for the refinement for **1** and **3**, respectively.

Figs. 1–3 were drawn using PLATON [29]. Details of the crystal data, data collection and refinement parameters are listed in Table 1. The selected bond lengths and angles are presented in Table 2.

2.3. Materials

β-$[Cu(\mu\text{-}O_2CH)_2]_n$ was isolated from methanoic acid (20 mL) and caustic copper(II) carbonate $Cu_2(OH)_2CO_3$ (2.0 g, 9.0 mmol) at room temperature. $Cu_2(OH)_2CO_3$ was prepared from the starting solutions of $CuSO_4{\cdot}5H_2O$ (15.2 g, 60 mmol) in 160 mL of water and $Na_2CO_3{\cdot}10H_2O$ (21.6 g, 75 mmol) in 240 mL of water at 65 °C. All reagents were obtained commercially and were used without further purification.

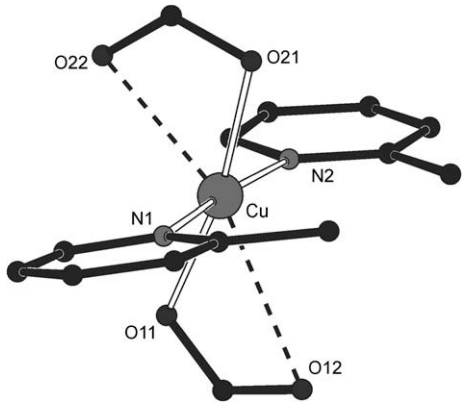

Fig. 1. The mononuclear complex **1** shows a *trans* orientation of the methanoate and 2-mpy ligands, the methyl 2-mpy groups are however *cis*. The dashed lines connecting the semi-coordinated O22 and O12 atoms with the central copper(II) ion clearly reflect the strong distortion from the theoretical elongated octahedral coordination sphere. Hydrogen atoms are omitted for clarity.

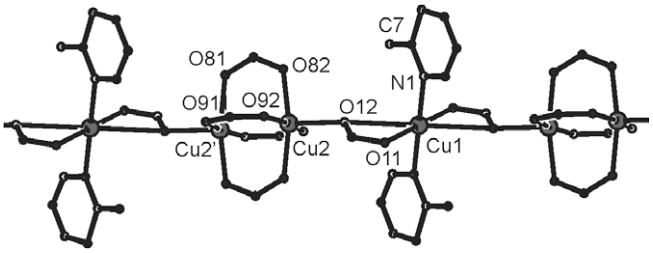

Fig. 2. Polymeric molecular structure of **3** composed of the mononuclear octahedral and the binuclear *paddle-wheel* units. H atoms are omitted for clarity.

2.4. Synthesis

Bis(methanoato-κ^2*O*,*O*′)-bis[(2-methylpyridine-κ*N*)copper(II)] **1**: 0.44 g (2.0 mmol) of $Cu_2(OH)_2CO_3$ in 1.0 mL of HCOOH was slowly added to 10 mL of 2-mpy and left at 40 °C for 5 min. The resulting mixture was then filtered and the filtrate was left at 6 °C for one day, giving violet crystals of **1**. Due to an instability of **1** in air, only single crystal XRD analysis was performed for this compound. The single crystals were preserved by the liquid nitrogen when removed from the mother-liquid for the XRD data collection. If the homogeneous violet product of **1** was filtered at room temperature, dried in air and then left in a desiccator above KOH for one day, the binuclear complex **2** is the final product. This was proven by IR and powder XRD analysis. Average yield for **2** by this procedure is 30%.

Tetrakis(μ-methanoato-κ*O*:κ*O*′)bis[(2-methylpyridine-κ*N*)copper(II)] **2**: The following synthesis procedure is different, as already described [1]. β-[μ-$Cu(O_2CH)_2]_n$ (0.46 g, 3.0 mmol) was slowly added to a liquid mixture of ethanol 20 mL and 2-mpy (6.7 mL) with heating and stirring. After boiling, the saturated solution was filtered off and left at 6 °C for one day. Light green crystals of **2** were filtered off, dried in air for 20 min and in a desiccator above KOH for a day. Average yield 40%. *Anal.* Calc. for $C_{16}H_{18}Cu_2N_2O_8$: C, 38.9; H, 3.68; N, 5.68; Cu, 25.8. Found: C, 39.0; H, 3.74; N, 5.67; Cu, 25.7%. 3. Results and discussion

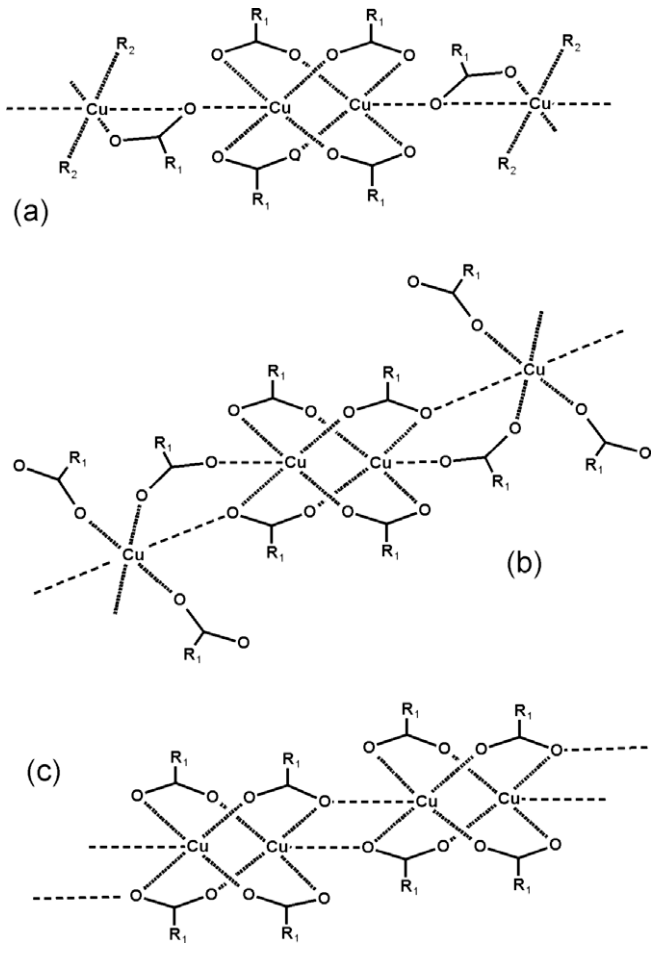
3.1. Description of the crystal structures



Mononuclear complex $[Cu(O_2CH)_2(2\text{-mpy})_2]$ (**1**) is composed of two methanoate anions and two 2-methylpyridine (2-mpy) molecules in a *trans* orientation (Fig. 1). The coordination sphere is highly unsymmetrical with two 2-mpy nitrogen atoms (Cu–N1 2.001(3), Cu–N2 2.012(4) Å) and two methanoate oxygen atoms (Cu–O11 1.945(3), Cu–O21 1.992(3) Å) in the basal square around the central copper(II) ion (Table 2). The semi-coordinated methanoate oxygen atoms (Cu–O22 2.472(3), Cu–O12 2.825(3) Å) are more distant, thus forming an elongated *z*-axis. This axis is strongly distorted, seen as an inclination of the Cu–O22 and Cu–O12 lines away from the normal vector of the basal plane (N1/N2/O11/O21) by 26.27(6)° (O22) and 43.94(6)° (O12), respectively. Therefore, the coordination sphere in **1** can be described either as a highly distorted octahedron, or as a distorted square-pyramid or even as a square-plane, putting the semi-coordinated O12 and O22 inside or outside the coordination sphere. The ligands are *trans* oriented, the 2-mpy methyl groups are, however, *cis*. Since no stronger H-bonds or π-stacking ($c_g\cdots c_g$ < 4.0 Å) are present to stabilize this heavily distorted molecular structure, compound **1** clearly reflects its instability outside the mother-liquid (see Section 2). It seems that numerous weak C–H···O contacts (Table 2) and π-stackings may maintain a solid compound in the mother-liquid, where these interactions are possible mostly due to 2-mpy acting as a solvent and as a ligand. A similar distorted coordination polyhedron (4+1+1) around copper(II) ion has also been observed in the crystal structure of $[Cu(O_2CCHCl_2)_2(2\text{-mpy})_2]$ [30].

The compound $[Cu_2(\mu\text{-}O_2CH)_4(2\text{-mpy})_2]$ (**2**) is much more stable than **1** (**2** is also the final product of the decomposition of **1** outside the mother-liquid (see the Section 2). A reason for such stability is found in a formation of the regular *paddle-wheel* type of binuclear complex with four methanoate bridges and 2-mpy as axial ligands, as previously described [3]. The stability of the compound is additionally strengthened by stronger π-stacking than in **1**, giving $c_g\cdots c_g$ 3.584(2), 3.819(2) Å. Several related methanoate *paddle-wheel* complexes have been described [12,13,15,21–24,31,32].

A combination of mononuclear and binuclear building blocks is found in the polymeric chain type of structure of $\{[Cu(\mu\text{-}O_2CH)_2(2\text{-mpy})_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**3**) (Fig. 2). Some preliminary details of **3** have already been presented [19]. The mononuclear unit in **3** is formed by two chelate methanoate anions and two 2-mpy molecules in a *trans* orientation, similar as in **1**. However, the mononuclear methanoates in **3** are symmetrically assembled and the methyl groups of 2-mpy are *trans* to each other as well. The elongated octahedral coordination sphere is formed by two 2-mpy nitrogen atoms (Cu1–N1 1.978(2) Å) and two methanoate oxygen atoms (Cu1–O11 1.971(2) Å) in the basal plane, while two semi-coordinated methanoate oxygen atoms (Cu1–O12 2.662(2) Å) form the elongated O12–Cu–O12′ Jahn–Teller axis. The distortion of the octahedral coordination is less severe than in **1**, as this moiety in **3** is centrosymmetric and the Jahn–Teller or *z*-axis is 36.12(6)° inclined from the normal vector of the octahedral basal square-plane (N1/N1′/O11/O11′) compared to 26.27(6)° and 43.94(6)° found in **1**. The binuclear building blocks in **3** are of the *paddle-wheel* $[Cu_2(\mu\text{-}O_2CH)_4]$ type, as in the central core structure of **2** (Fig. 2). The axial positions in **3** are, however, without 2-mpy ligands as seen in **2**, but with the methanoate oxygen atoms (O12) that are in the semi-coordinated positions of the mononuclear building blocks as well (Cu_{mono}–O12 2.662(2), Cu_{bi}–O12 2.123(2) Å). Additional stabilization of the chain type structure in **3** is by weak inter-chain π-stacking ($c_g\cdots c_g$ 4.001(4) Å) and C–H···O contacts (Table 2). The methanoate O12–C1–O11 bridges of the chain in **3** also serve as inter-chain double C–H···O contacts (C1···O11^{iii} 3.305(3) Å, C1–H1···O11^{iii} 133°; $^{iii}1-x, 2-y, -z$) in $R_2^2(6)$ supramolecular synthons [33], as presented in Fig. 3. Similar supramolecular synthons between two methanoate groups, as found in **3** between the mononuclear units, have been observed in only two other copper(II) complexes, but there between the binuclear *paddle-wheel* methanoates $[Cu_2(\mu\text{-}O_2CH)_4(2\text{-mpy})_2]$ (**2**), and $[Cu_2(\mu\text{-}O_2CH)_4(3\text{-mpy})_2]$ [3]; and some for the other binuclear

methanoate complexes, e.g. with rhodium and molybdenum [34,35].

A similar binuclear-mononuclear chain type of a structure as in the molecular **3**, is found in the ionic compound $\{Na_2[Cu(\mu\text{-}O_2CH)_2(O_2CH)_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**4**) (Scheme 2). Its synthesis and crystal structure determination were reported previously [20], however the other basic characterization, accompanied with a comparison to the other related methanoate complexes, is presented herein. As in **3**, the binuclear building blocks in **4** are of the *paddle-wheel* central core type, while the mononuclear units differ. The ligands in the mononuclear building blocks in **4** are solely methanoates, namely four oxygen atoms of four anions (two terminal and two bridging) completing the basal square of the elongated octahedral coordination sphere (Cu–O 1.937(6), 1.987(6) Å), while the semi-coordinated (Jahn–Teller) positions are occupied by oxygen atoms of another two methanoates. The last two oxygen atoms (semi-coordinated in the mononuclear unit) are also a part of the binuclear $[Cu_2(\mu\text{-}O_2CH)_4]$ units (Cu_{mono}–O 2.492(5), Cu_{bi}–O 1.965(5) Å). The axial position of the binuclear *paddle-wheel* building blocks in **4** is, however, occupied by an oxygen methanoate anion, where this last methanoate ligand is a triatomic bridge to the equatorial position of the mononuclear building block Cu_{bi}(axial)–O–C–O–Cu_{mono}(equatorial), and not a bridge and a chelate as in **3**. Only one methanoate ligand enables the mononuclear–binuclear bridge in **3**, while two methanoates are involved in each bridge in **4** (Scheme 2). If we assume a neutral charge for the binuclear $[Cu_2(\mu\text{-}O_2CH)_4]$, four methanoates remain per one mononuclear copper(II) cation in **4**, thus this polymeric coordination moiety as a whole is anionic, with two sodium counter cations. On the other hand, two methanoates and two 2-mpy ligands per one mononuclear copper(II) cation in **3** give a final neutral polymeric molecular complex. The sodium counter ions in **4** are surrounded by seven methanoate oxygen atoms (Na···O 2.319(9)–2.699(9) Å) [20]. Some non-methanoate examples of related alternate mononuclear–binuclear chain type of complexes are reported in the literature [36–40]. Only four complexes among them show similar coordination polymers as **3**, of the general formula $\{[Cu(\mu\text{-}O_2CR)_2(L)_2][Cu_2(\mu\text{-}O_2CR)_4]\}_n$, but they are not identical. The bridging carboxylate group between the monomeric and dimeric units in the crystal structures of the 3,3-dimethylbutyrato complex (L = 2,6-dimethylpyridine) [40] and 3,5-dinitrobenzoato complex (L = methanol) [39] are not chelating in the monomeric units. On the other hand, the benzoate complex (L = 3,5-dimethylpyrazole) [37] and the acetate complex (L = 1,4-bis[2-(5-phenyloxazoly)]benzene) [36] have similar coordination modes, though the carboxylate groups in the monomeric unit of the benzoate complex [37] are in a *cis* position and the acetate complex [36] is two-dimensional because the second ligand L forms a bridge too.

Scheme 2. The bridging mode in certain chain types of polymeric complexes. The building blocks are mononuclear and binuclear, as in **3** (a: R_1 = H, R_2 = 2-mpy) and **4** (b: R_1 = H), or solely binuclear, as seen for $[Cu_2(\mu\text{-}O_2CR)_4]_n$ (c).

3.2. Magnetic and spectroscopic analysis

The room temperature magnetic susceptibility data (Evans) give μ_{eff} = 1.14 μ_B for **2**, that is significantly lower compared to the vast majority of the dicopper *paddle-wheel* complexes $[Cu_2(\mu\text{-}O_2CR)_4]$ ($\mu_{eff} \sim$ 1.4–1.5 μ_B), but in agreement with the values for the previously presented methanoates of this type [1,41]. The room temperature measurements for the polymeric **3** and **4** give μ_{eff} = 1.42 and 1.43 μ_B, respectively (no susceptibility measurements were done for the unstable mononuclear **1**). Due to similar room temperature values of μ_{eff}/μ_B for **3** and **4**, but different for **2**, the temperature dependant magnetic susceptibility measurements (SQUID) were performed for **4** (**2** and **3** have already been already reported) [3,19]. The molar magnetic susceptibility as $\chi_M \cdot T$ versus T of **4** gradually decreases upon lowering temperature from 300 K to 100 K (Fig. 4). The curve then becomes parallel with the x-axis (100–25 K) at about 0.43 $cm^3\ K\ mol^{-1}$, and then again turns down (25–2 K). The 300–100 K step is characteristic for a strong antiferromagnetic (AFM) interaction due to the binuclear units with spin S = 1 at higher temperature, turning to the S = 0 ground state at lower temperatures. Therefore $\chi_M \cdot T$ of the binuclear units in **4** is 0 below 100 K. The constant $\chi_M \cdot T$ value (0.43 $cm^3\ K\ mol^{-1}$) in the region 100–25 K is typical for the paramagnetic S = ½ species, attributed to the mononuclear building blocks within the chain

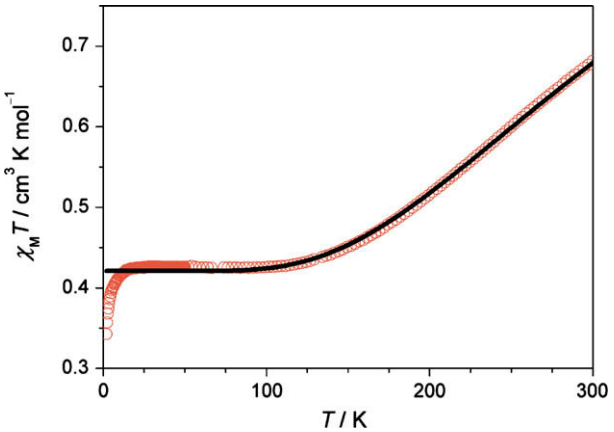


Fig. 4. Graph $\chi_M \cdot T$ *vs.* T with experimental (○) and calculated (solid line) curves for compound **4**. Parameters are: $2J = -477\ cm^{-1}$, g = 2.12.

in **4**. The final decrease of the $\chi_M \cdot T$ value below 25 K is possibly due to a weak AFM interaction between adjacent copper(II) species from mononuclear and/or binuclear units. Only the $\chi_M \cdot T(T)$ data for $T > 50$ K were fitted with Eq. (1):

$$\chi_M = \frac{2Ng^2\beta^2}{kT(3+e^{-2J/kT})} + \frac{Ng^2\beta^2}{4kT}, \quad (1)$$

where the first term was derived by Bleaney and Bowers and describes the behaviour of two copper(II) ions per molecule in the binuclear units, while the second term accounts for the mononuclear units of paramagnetic copper(II) ions [25]. The results of the calculations are $2J = -477\ cm^{-1}$ and $g = 2.12$. An almost identical shape of the $\chi_M \cdot T$ versus T graph was shown previously for complex **3** [19]. Herein the presented data for **3** ($2J = -444\ cm^{-1}$, $g = 2.12$) were obtained by a recalculation and they reveal slightly different values as reported originally. A literature survey of the AFM interaction magnitude for the methanoate *paddle-wheel* complexes show $-2J = 390–560\ cm^{-1}$ [1–3,6,12–16]. Thus, a similar room temperature μ_{eff} values (1.42, 1.43 μ_B) for the structurally related **3** and **4** are in agreement with the almost identical $\chi_M \cdot T(T)$ shape of the curve. Therefore, the higher μ_{eff}/μ_B value for the polymeric **3** and **4** than for the isolated binuclear complex **2** (1.14 μ_B) is attributed to an average μ_{eff} value of the binuclear moiety (two Cu(II) ~ 1.1 μ_B each) and the mononuclear unit (Cu(II) ~ 1.9 μ_B). A similar susceptibility analysis as for the room temperature data (Evans) was performed on the temperature dependent data (SQUID) of the polymeric **3** and **4**. Since it is reasonable to consider that only mononuclear building blocks participate in the paramagnetic signal in the graph $\chi_M \cdot T$ *versus* T (Fig. 4) in the region 25–100 K for **4**, the same constant value of $\chi_M \cdot T$ to the total susceptibility also at higher temperatures may be assumed. In this case we can subtract the mononuclear contribution of the product $(\chi_M \cdot T)_{mono}$ 0.40 and 0.43 $cm^3\ K\ mol^{-1}$ for **3** and **4**, respectively, (at room temperature) from the total measured $(\chi_M \cdot T)_{total}$ (0.65 $cm^3\ K\ mol^{-1}$ and 0.68 $cm^3\ K\ mol^{-1}$ for **3** and **4**, respectively). This difference $(\chi_M \cdot T)_{total} - (\chi_M \cdot T)_{mono} = (\chi_M \cdot T)_{bi}$ is thus 0.25 $cm^3\ K\ mol^{-1}$ for **3** and **4,** corresponding to $\mu_{eff} = 1.41\ \mu_B$ per dimer or 1.01 μ_B per each Cu(II). The last value (1.01 μ_B) is smaller than the 'Evans' room temperature μ_{eff}/μ_B of the isolated methanoate binuclear complex **2** ($\mu_{eff} = 1.14\ \mu_B$). This discrepancy can be explained by more accurate temperature dependant measurements and fitting, where temperature independent paramagnetism is additionally included.

The room temperature X-band EPR spectrum of solid **4** reveals a very broad signal at 300 mT. By decreasing the temperature below 200 K, signals of the elongated axial anisotropic symmetry are noticed giving $g_{\perp(x,y)} = 2.080(5)$ and $g_z = 2.304(5)$ (Fig. 5, 172 K). A further decrease of the temperature shows additional splitting of $g_\perp$, giving at 102 K $g_x = 2.042(5)$ and $g_y = 2.075(5)$, and a shift of g_z to 2.349(5), suggesting rhombic symmetry. These results are in good agreement with the susceptibility data (see Fig. 4). On the other hand, the axial symmetry signals are reported for the structurally related **3** already at room temperature [19], suggesting differences between **3** and **4** not seen from the susceptibility data. Interestingly, the typical spin $S = 1$ signals for the dicopper(II) *paddle-wheel* complexes were noticed for the isolated binuclear complex **2** [17], but not for the polymeric **3** and **4**, the last two also having the *paddle-wheel* building blocks. The axial symmetry signals found for **3** and **4** may well be assigned to spin $S = ½$ of the mononuclear building blocks. Namely, both complexes show a distorted elongated axial symmetry within the copper(II) mononuclear coordination sphere. The spin $S = 1$ signals expected for the binuclear *paddle-wheel* units are probably of a very low intensity, due to a very strong AFM interaction, the methanoate bridges playing the key role. An extreme broadening of the EPR signals in the spectra measured at room temperature is described also for the chain complexes formed only of $[Cu_2(\mu\text{-}O_2CR)_4]$ binuclear *paddle-wheel* building blocks (Scheme 2c) [18,42–45]. In the EPR spectra of these complexes recorded at lower temperatures, the $S = 1$ signals appear and usually also $S = ½$ signals of mononuclear impurities, whose intensity increase relatively to the $S = 1$ signals by decreasing the temperature. Eventually only the $S = ½$ signals remain, since the $S = 1$ state turns to $S = 0$ as the ground state of the complex with the AFM interaction. At least for these $[Cu_2(\mu\text{-}O_2CR)_4]_n$ complexes, the high temperature broadening of the signals is not related to the $S = ½$ species or an extremely strong AFM interaction. On comparison to the chain complexes formed solely of binuclear building blocks, one structural detail should be stressed as differing in the two polymeric complexes **3** and **4**. The magnetic interaction of the binuclear *paddle-wheel* complexes $[Cu_2(\mu\text{-}O_2CH)_4]_n$ takes place via the carboxylate intra-binuclear bridges, *e.g.* the equatorial oxygen atoms of the square-pyramidal coordination sphere. Therefore, the central copper ion d orbital $\{d_{x^2-y^2}\}^1$ is magnetic, while the axially oriented $\{d_{z^2}\}^2$ is not. One of the binuclear equatorial oxygen atoms in **4** is on the other side, also in the axial position of the mononuclear building block, towards which the non-magnetic $\{d_{z^2}\}^2$ orbital of the mononuclear copper(II) is oriented. No such bridges are found for **3** (Scheme 2). For $[Cu_2(\mu\text{-}O_2CR)_4]_n$, the high temperature broadening with lower temperature narrowing of the $S = 1$ EPR signals was explained by the $S = 1$ spin disturbing the adjacent $S = 1$ spin species [42–44]. In our case, in **4** the mononuclear $S = ½$ and the binuclear $S = 1$ species may disturb each other at high temperature, while the disturbance reason is not present at lower temperatures. Since the mononuclear $S = ½$ species are of the same number as the binuclear $S = 1$ species in a chain (not as an impurity), accompanied by the strong AFM interaction within the binuclear units, the $S = ½$ EPR signals are seen for **4** only at temperatures below 200 K. Differences in the EPR spectra of **3** and **4** are therefore probably related to their different bridging modes.

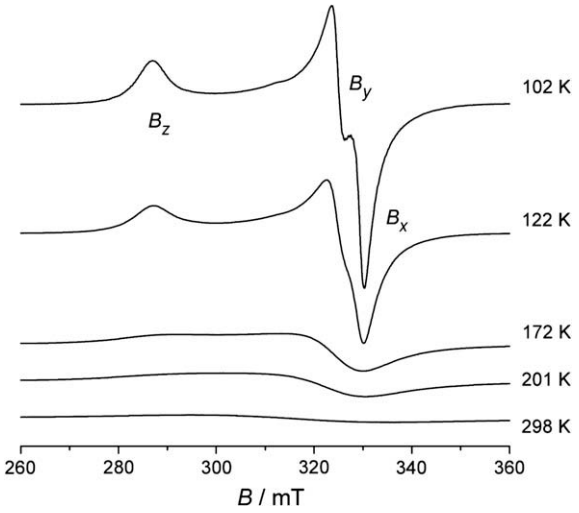

Fig. 5. X-band EPR spectra of complex **4**. The low intensity isotropic-like broad signal at room temperature gradually transforms by decreasing the temperature into three rhombic symmetry signals.

4. Conclusions

Several methanoate complexes, namely $[Cu(O_2CH)_2(2\text{-mpy})_2]$ (**1**) (2-mpy = 2-methylpyridine), $[Cu_2(\mu\text{-}O_2CH)_4(2\text{-mpy})_2]$ (**2**), $\{[Cu(\mu\text{-}O_2CH)_2(2\text{-mpy})_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**3**) and $\{Na_2[Cu(\mu\text{-}O_2CH)_2(O_2CH)_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (**4**) have been synthesized and analyzed with an emphasis on their structural and magnetic properties. The mononuclear complex **1** shows *trans* oriented ligands

with asymmetric and a highly distorted octahedral coordination sphere. The compound is very unstable, most probably due to the unexpected *cis* orientation of the methyl groups of the 2-mpy ligands, non-symmetric chelate methanoates and stabilization only by weak C–H···O contacts. Compound **1** easily decomposes outside the mother-liquid, giving the binuclear *paddle-wheel* compound **2**. The other three herein described complexes **2**–**4** are much more stable. Isolated binuclear *paddle-wheel* molecules are found for **2**, while alternating mononuclear and binuclear building blocks are present in the chain type of structures in **3** and **4**. Magnetic susceptibility analysis shows a strong antiferromagnetic interaction for complexes **2**–**4**, with $-2J = 440–490\ cm^{-1}$, suggesting clearly the main role of the methanoate intra-binuclear bridges for the magnitude of this interaction. The inter-binuclear connections as C–H···O and π-stacking in the 'isolated' binuclear **2**, or even different types of mononuclear building blocks coordinative connecting the *paddle-wheel* species in the polymeric **3** and **4**, seem not to have a significant role in the AFM interaction. On the other hand, the EPR spectra suggest that the spin $S = ½$ species (mononuclear moiety) give higher intensity signals than the $S = 1$ species (binuclear *paddle-wheel*), especially due to a strong AFM interaction, giving a less populated $S = 1$ state even at room temperature. The involvement of the binuclear equatorial carboxylate oxygen atom simultaneously with the axial position of the mononuclear coordination sphere in **4** may be the reason for the broad EPR signal at room temperature, hiding the expected $S = ½$ spin symmetry signals of the mononuclear copper(II) unit.

5. Supplementary data

CCDC 718843 and 718842 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

cis-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] (H_2-dcbpy = 4,4′-dicarboxy-2,2′-bipyridine) and Na_4[Tb(TsPc)(acac)] (TsPc = tetrasulfonated phthalocyanines; acac = acetylacetone) are reported, and this system is suggested as an alternative for improving PDT.

2. Experimental

2.1. Apparatus

The ultraviolet–visible (UV–Vis) spectra were recorded on a Hitachi U-3501. Infrared spectra were registered on a Protegé 460 series FTIR spectrometer, using solid samples pressed in KBr pellets. Cyclic voltammetry was performed with an AUTOLAB® Model PGSTAT 30 potentiostat/galvanostat, by employing a conventional three-electrode cell arrangement with a glassy carbon disk working electrode, a platinum wire auxiliary electrode, and an Ag/AgCl reference electrode. The pH measurements were accomplished by means of a DM-20 pH meter from Digimed. The photochemical experiments were carried out using an Osram 150 W/l system equipped with a Xenon Lamp, in an 8500 model with selective filter λ_{max}/550 nm (transmit > 90% above 550 nm). Luminescent measurements were performed using a FLUOROLOG 3 ISA/Jobin-Yvon spectrofluorimeter equipped with an R928P Hamamatsu photomultiplier and Xenon Lamp 450 W/ozone free. A Corning filter (transmit > 90% in the 250–400 nm range; with no transmission in the visible range) was used in the light beam entrance. Excitation and emission slits were 8 and 4 nm, respectively. The singlet oxygen yield values were determined in an apparatus consisting of a Nd-YAG laser (Continuum, Santa Clara, CA) with excitation (8 nm half life) provided by the third harmonic at 355 nm. The luminescent decay kinetics was detected by employing a germanium detector operating at liquid nitrogen temperature. A silicon filter was used to avoid any fluorescent signal interfering with the singlet oxygen measurements. Pheophorbide-a in deuterated ethanol was used as reference [16]. NO release was measured with an ISO–NOP NO meter from Word Precision Instruments.

2.2. cis-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] synthesis

The *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] complex was prepared using *cis*-[Ru(dcbpyH$_2$)$_2$Cl$_2$]·2H$_2$O as the starting reagent. *cis*-[Ru(H_2-dcbpy)$_2$Cl$_2$]·2H$_2$O was obtained according to the procedure previously employed to synthesize *cis*-[Ru(bpy)$_2$Cl$_2$]·2H$_2$O [17]. *cis*-[Ru(H_2-dcbpy)$_2$Cl$_2$]·2H$_2$O (0.100 g, 0.14 mmol) was dissolved in distilled H_2O, and this solution was degassed for 30 min for oxygen removal. Gaseous NO was then generated by reaction between nitric acid solution (50%V/V) and metallic copper. The produced gaseous mixture was passed through a concentrated NaOH solution, to eliminate NO_2^- traces. The nitric oxide was then bubbled through the *cis*-[Ru(H_2-dcbpy)$_2$Cl$_2$]·2H$_2$O complex solution for 40 min, and the reaction mixture was stirred for another 6 h. This operation was repeated for three times, and a precipitate was formed during this procedure. The resulting brown precipitate was collected by filtration, washed with diethyl ether, and stored under vacuum in the dark. A typical yield for *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] (53.6%) was obtained. (*Anal.* Calc. for $C_{24}H_{16}N_5O_9ClRu$: C, 43.96; H, 2.14; N, 10.68. Found: C, 42.77; H, 2.26; N, 10.32%).

2.3. Na$_4$[Tb(TsPc)(acac)] synthesis

The Na_4[Tb(TsPc)(acac)] complex was synthesized using terbium acetylacetonate, Tb(acac)$_3$, as the starting reactant. The latter complex was prepared as described in the literature [18]. Then, the sodium salt of phthalocyanine-tetrasulfonate (0.100 g, 0.10 mmol), Na_4(TsPc), was dissolved in dimethylsulfoxide (DMSO, 0.5 mL), under stirring. The reaction was carried out under argon flux for 4 h, by refluxing stoichiometric amounts of (TsPc)$^{4-}$ and Tb(acac)$_3$ in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, 30 μL). It seems that the role of DBU in this reaction is the formation of the phthalocyanine dianion (TsPc)$^{6-}$, which reacts with terbium acetylacetonate. Propanone (80.0 mL) was added after the reflux, and the mixture was frozen overnight. The obtained green precipitate was filtered and washed with propanone and diethyl ether, and dried under vacuum. Na_4[Tb(TsPc)(acac)] (47%). *m/z* 358.9602 (Tb^{3+} fragment).

2.4. Cell culture and MTT assay

The B16F10 murine melanoma was purchased from the ATCC (Rockville, MD) and grown in RPMI-1640 medium supplemented with 10% fetal bovine serum. To determine cell growth *in vitro*, B16F10 cells were plated at an amount of 10 000 cells/well on a 96-well plate. Cells were grown in MEM + 10% FBS + nonessential amino acids. Cell numbers were determined at 24 h intervals, by replacing the culture medium with 0.1 mL of an MTT solution in serum-free DMEM without phenol red [0.5 mg of MTT (Sigma, St. Louis, MO) per mL]. Cells were incubated at 37 °C for 2 h, and then 200 μL of solubilizing solution (80% isopropanol, 20% DMSO, and 4% Tween 20) were added to each well. After mixing, absorbance was determined at 562 nm with a plate reader.

3. Results and discussion

The nitrosyl ruthenium complex was ascribed as *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] mainly on the basis of elemental analysis with one deprotonated bipyridine type ligand. Addition of 0.1 M aqueous HCl or HPF_6 resulted in precipitation, which we tentatively ascribed as *cis*-[Ru(H-dcbpy)$_2$(Cl)(NO)]Cl$_2$ or *cis*-[Ru(H-dcbpy)$_2$-(Cl)(NO)](PF$_6$)$_2$. The electronic absorption data (Fig. 1) of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] displays a band at 305 nm (λ_{max}0.1 mol L^{-1} HCl; log ε 4.13) and a shoulder at 323 nm (log ε 3.97). The highest energy band is attributed to intraligand transitions involving NO and the H_2-dcbpy ligands, while the shoulder at 323 nm is due to the metal ligand charge transfer band (MLCT) with contributions from the $d\pi(Ru^{II}) \rightarrow \pi^*(NO)$ and $d\pi(Ru^{II}) \rightarrow \pi^*$(H-dcbpy$^-$) transitions [10]. In pH ⩾ 9.0 the UV–Vis spectrum of an aqueous solution containing *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] shows band in the 450 nm region (NaOH), which is characteristic of bonded nitrite obtained by electrophilic attack of the hydroxide ion [7,10,12–13]. The

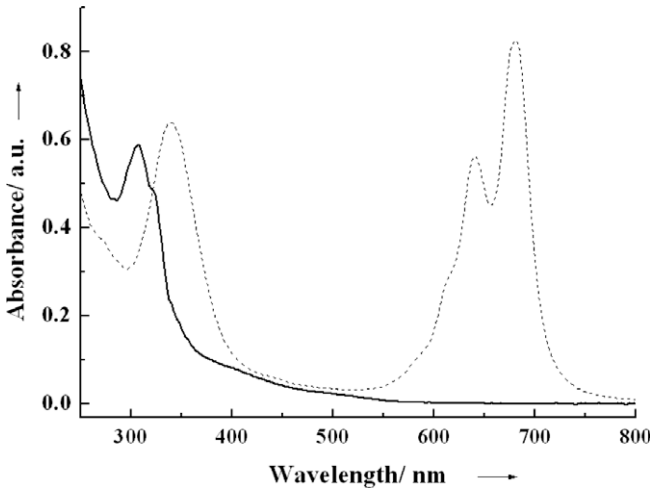

Fig. 1. Absorption spectrum in the UV–vis region: (—) *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)], 5.2×10^{-5} mol L^{-1}, in HCl 0.1 mol L^{-1}; (- - - -) Na_4[Tb(TsPc)(acac)], 1.2×10^{-5} mol L^{-1}, in aqueous solution.

nitrosyl ruthenium complex was also characterized by FTIR. The spectrum displays the typical NO frequency stretching at 1932 cm^{-1} (Ru–NO^+), as previously described for similar systems [10,12]. The cyclic voltammogram of the *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] complex was performed in aqueous solution using KCl (0.1 mol L^{-1}) as the supporting electrolyte (Supplementary data: Fig. 1). A reversible cathodic wave can be seen at 0.10 V (versus Ag/AgCl), attributed to the redox process of the nitrosyl group ($NO^{+/0}$), and there is an irreversible wave at −0.50 V (versus Ag/AgCl), due to the $NO^{0/-}$ redox process. The electronic spectrum of Na_4[Tb(TsPc)(acac)] (Fig. 1) in aqueous solution displays absorption bands at 342 nm (λ_{max} in H_2O; log ε 4.54), 642 (log ε 4.49) and 682 (log ε 4.64), typical of phthalocyanine. These bands are designated as *B* band or Soret in the case of $\lambda_{max}(H_2O)$/nm 342, and *Q* bands for $\lambda_{max}(H_2O)$/nm 642 and 682 [19,20].

The fluorescence measurements in aqueous solution indicate that the emission of the nitrosyl ruthenium complex is silent when it is excited at 376 nm, although [Tb(TsPc)(acac)]$^{4-}$ presents an emission band at 691 nm (λ_{em} in H_2O; Fig. 2). The fluorescence intensity of the phthalocyanine chromophore is lower than that of the rare earth phthalocyanine compound, and the emission of the Tb^{3+} ion is observed only when the excitation is performed at 356 nm (λ_{ex} in H_2O), using a filter which transmits above λ_{max} = 550 nm (Supplementary data: Fig. 2) [21].

The photolysis of an aqueous solution containing equimolar amounts of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] and Na_4[Tb(TsPc)(acac)] in phosphate buffer solution (pH 5.0) is fascinating. NO release, accounted for by NO-sensor measurement, is observed during light irradiation at $\lambda_{max} \geqslant 550$ nm (Fig. 3). A similar experiment was performed with *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] (Fig. 3) in the presence of an equimolar amount of Na_4(TsPc), but no signal was detected using NO-sensor.

NO release from *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] in the presence of [Tb(TsPc)(acac)]$^{4-}$ during photolysis at $\lambda_{max} \geqslant 550$ nm was quantitatively analyzed under argon atmosphere. The experiment was conducted until a maximum of 30 min, to avoid chemical filter interference. The measured NO concentration using NO-sensor after 30 min was 1.21 ± 0.14 μmol L^{-1}, which corresponds to 4% of the starting *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] concentration. The amount of NO release seems to be dependent on oxygen concentration, once the NO concentration measured in aerated condition was 1.51 ± 0.11 μmol L^{-1}, which suggests an effect of oxygen on the photochemical pathway of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] when it is photolysed in the presence of [Tb(TsPc)(acac)]$^{4-}$. The most probable photochemical pathway for NO release from the aerated

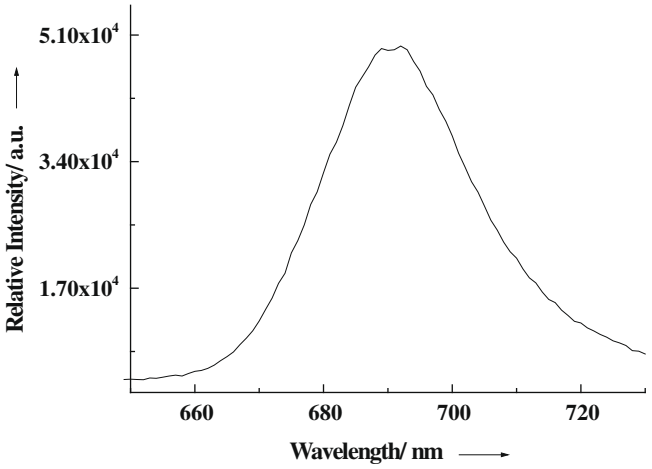

Fig. 2. Na_4[Tb(TsPc)(acac)] emission spectrum (λ_{ex}= 376 nm in H_2O) in aqueous solution. [complex] = 2.4 × 10^{-5} mol L^{-1}.

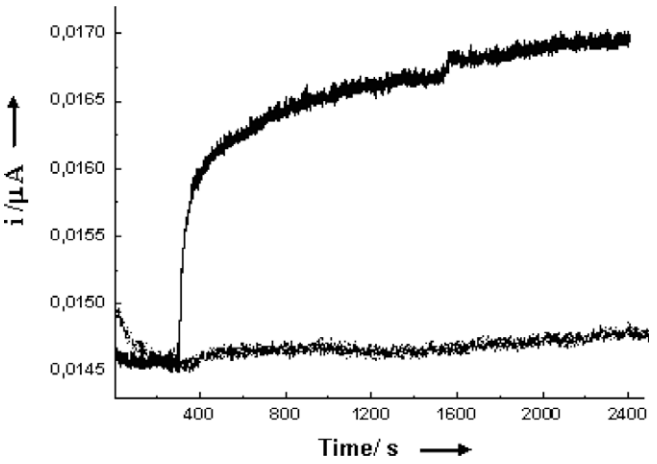

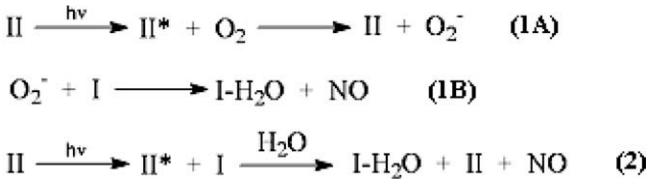

Fig. 3. Chronoamperograms of NO release by photolysis ($\lambda_{max} \geqslant 550$ nm): (**A**) *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] complex and (**B**) the mixture of nitrosyl ruthenium and the terbium phthalocyanine complexes. [nitrosyl complex] = [terbium phthalocyanine complex] = 3.0 × 10^{-5} mol L^{-1}, in phosphate buffer solution (pH 5.0).

aqueous solution mixture containing *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] and [Tb(TsPc)(acac)]$^{4-}$ involves a photoinduced electron transfer that is most likely a chemical reduction of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] (Scheme 1) by former superoxide. The assumption for superoxide formation (Scheme 1- Eq. 1A and 1B) is based on the qualitative assay using ferrocytochrome-C, a well-known superoxide scavenger [22]. Knowing that the superoxide reduction potential is −0.31 V versus Ag/AgCl, we can suppose that there is a favorable driving force for the reduction of *cis*-[Ru(H-dcbpy$^-$)$_2$- (Cl)(NO)] [23]. The second possible explanation for the photoinduced NO release comes from intermolecular photoinduced electron transfer (Scheme 1 Eq (2)), an assumption that is based mainly on the results from luminescence spectroscopy.

Changes in the fluorescence spectrum of [Tb(TsPc)(acac)]$^{4-}$ in phosphate buffer solution pH 5.0 (λ_{exc} = 376 nm) upon addition of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] can be observed. Differences in the shape and position of the fluorescence bands when only free [Tb(TsPc)(acac)]$^{4-}$ is present in the medium and when it is in the presence of the nitrosyl ruthenium complex are small, but the fluorescence intensity is diminished by 20% for an equimolar amount of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)]. This quenching efficiency might be caused by hydrogen bonding interaction. From the Stern–Volmer analysis of I_0/I versus [*Q*] plots, it can be seen that the interaction [Tb(TsPc)(acac)]$^{4-}$–*cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] obeys a Stern–Volmer type analysis, forming a 1:1 stoichiometric association in aqueous solution. Fig. 4 depicts the Stern–Volmer plots based on the relation $I_0/I = 1 + K_D[Q]$, where $K_D = 9.0 \times 10^3$ is the interaction constant for a 1:1 stoichiometry [24], which we have tentatively ascribed to hydrogen bonding interaction taking place as represented in Fig. 5.

Phthalocyanines are known to generate singlet oxygen ($^1O_2$) upon photoirradiation, which was also observed for the terbium phthalocyanine tetrasulfonate compound when it was irradiated at λ_{max} = 691 nm [3]. The measured singlet oxygen quantum yield

Scheme 1. Photochemistry intermolecular electron transfer mechanism; **I** is *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] and **II**, the sensitizer Na_4[Tb(TsPc)(acac)] complex.

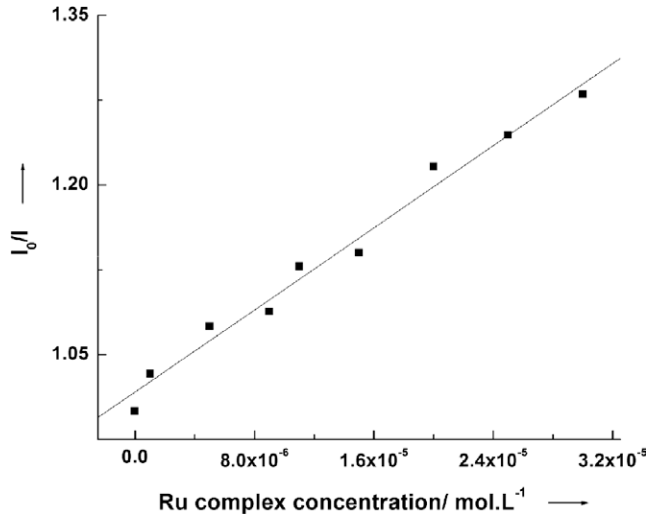

Fig. 4. Stern–Volmer plot for quenching of the fluorescence of ([Tb(TsPc)(acac)]$^{4-}$ (1.4×10^{-6} mol L^{-1}) in the presence of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)], monitored at λ_{em} = 691 nm (λ_{ex} = 376 nm).

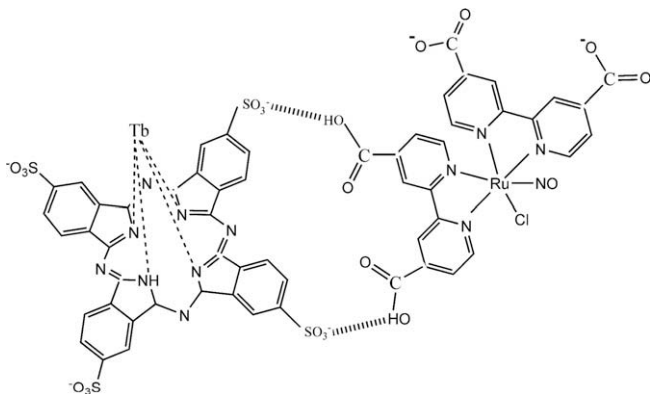

Fig. 5. Schematic diagram assumed for the self-assembled structure.

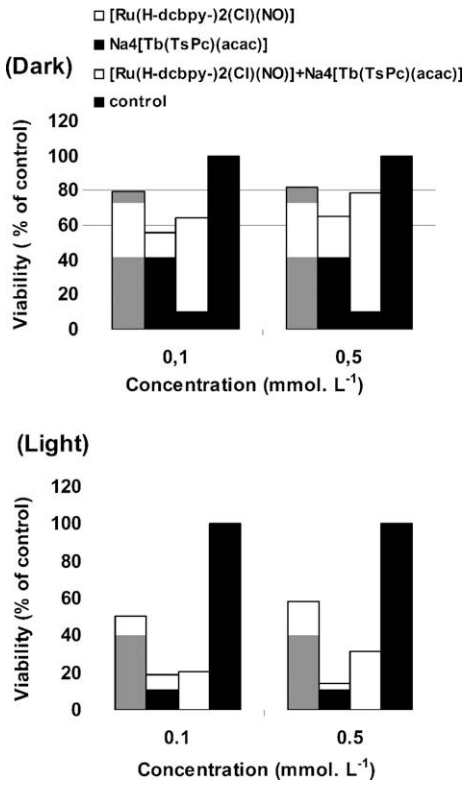

Fig. 6. Cell viability of the B16F10 cell line after treatment with *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] and [Tb(TsPc)(acac)]$^{4-}$, as measured via the MTT assay. Results are represented as a percentage of the relative absorbance with respect to the control cells (100%, in black).

was 0.41, a value that can be taken as promising for a photosensitizer to be applied in the photodynamic therapy (PDT) of cancer [3–5]. To investigate whether [Tb(TsPc)(acac)]$^{4-}$–*cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)], a NO release and $^1O_2$ producing agent, inhibits its cell viability, we have performed experiments using B16F10 cells. Fig. 6 depicts the cell viability experiment showing the cytotoxic effects of *cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] in the presence of an equal amount of [Tb(TsPc)(acac)]$^{4-}$ under visible light irradiation in B16F10 cells, which was performed using 100–500 μmol L^{-1} of each complex. The solution containing [Tb(TsPc)(acac)]$^{4-}$–*cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] strongly inhibits the cell viability in a light irradiation-dependent manner. The best result was achieved when the concentration of 100 μmol L^{-1} was used, which reduced cell viability to 20% of the control. The hypothesis for the cancer cell activity (não seria melhor mudar esta palavra pois o cancer é destruído) obtained by using [Tb(TsPc)(acac)]$^{4-}$–*cis*-[Ru(H-dcbpy$^-$)$_2$(Cl)(NO)] mainly involves $^1O_2$ formation, a well-known anticancer agent. The concomitant production of NO in this system could also improve its anticancer capacity due to the corroborative effect of NO, once it can induce apoptosis in a variety of cell types [7–10]. Apparently, as the concentration of *cis*-[Ru(H-dcbpy$^-$)$_2$- (Cl)(NO)] increases in the solution containing [Tb(TsPc)(acac)]$^{4-}$, cell activity decreases. Maybe NO is consumed by $^1O_2$ in a typical oxidation process, which could explain the cell viability decrease when a mixture of rare earth and nitrosyl ruthenium complexes was used as sensitizer [25]. On the other hand, the NO release agent itself decreases cell viability, which could be an indication that at low oxygen concentration the system could improve anticancer activity.

4. Conclusion

Our results document the effect of the concomitant formation of NO and $^1O_2$ on a cancer cell line. The amount of species employed in the cell viability experiments is around 1% of IC_{50}.

phenyl[iminodiacetate-O,O′,N]borane **1** and carry out a substitution nucleophilic reaction with benzyl bromide **a**, 3-methylbenzyl bromide **b**, 4-methylbenzyl bromide **c**, phenacyl bromide **d**, 2-bromo-4′-chloroacetophenone **e** and 2-bromo-4′-phenylacetophenone **f**, under reflux of acetonitrile/benzene (80/20) or acetonitrile to obtain (N → B) phenyl[N-alkyliminodiacetate-O,O′,N]boranes **2**–**7**, (Fig. 1). Effectively, the yields are between 40% and 80%. ^{1}H, ^{13}C and ^{11}B NMR and their high resolution mass spectra (HRMS) data of the compounds **2**–**7** are giving in the experimental part. Their ^{1}H NMR spectra clearly show the AB coupling patterns for the diastereotopic CH_2COO protons, which indicates the presence of the intramolecular N → B coordination bond. The $\delta(^{11}B)$ values confirm the tetrahedral environment of the boron nucleus, since they lie in the range reported previously for analogous boron heterocycles [9–11,13–16,19]. All compounds exhibit the expected ^{13}C NMR spectra. Suitable crystals of **2**, **4** and **5** were obtained for X-ray analysis and an ORTEP view and crystallographic numbering of **2**, **4** and **5** are giving in Figs. 2–4, respectively. Selected bond distance and torsion angles are listed in Tables 1–3. In general the bond distances are within the values characteristic of analogous compounds [17,19]. Compounds **2** and **4** crystallized with two independent molecules **2A**, **2B** and **4A**, **4B**, respectively and **5** exhibits only one. The conformations of the two five member ring in all molecules are different and not planar, as indicated by the torsion angles values (Tables 1–3). This can be due in part to the following intermolecular interactions: $O_{9A}\cdots H_{5A}$ 2.288,

3. Conclusion

The new method for the synthesis of six (N → B) phenyl[N-alkyliminodiacetate-O,O′,N]boranes improved the yields, evade to use bases and avoid the use of anhydrous reaction conditions. Therefore, the identification of all compounds by NMR, their high resolution mass spectra (HRMS) data are reported, as well as the crystal structure of compounds **2**, **4** and **5** gives evidence of the N-alkylation of **1** and establish the bicyclic structures due to N → B coordination bond.

4. Experimental

4.1. General procedure and measurements

The reagents were purchased from Aldrich Co. (N → B) phenyl [iminodiacetate-O,O′,N]borane (**1**) was prepared as described previously [14]. ^{1}H, ^{13}C and ^{11}B NMR spectra were recorded on a Jeol GLX-270, Jeol Eclipse-400 and Bruker Avance and 300-DPX spectrometers, DMSO-d_6 was used as solvent. The high resolution mass spectra (HRMS) were taken on Agilent Technologies, model LC/MSD-TOF spectrometer, coupled to HPLC 1100 with ESI as ionization source. Melting points were taken in open capillary tubes on a Gallenkamp MFB-595 apparatus and are uncorrected.

4.2. Preparation of compounds **2**–**7**

The procedure outlined below is general for the preparation of compounds **2**–**7**.

4.2.1. Synthesis of (N → B) phenyl [N-benzyliminodiacetate-O,O′,N]borane (**2**)

A suspension of 0.80 g (3.65 mmol) of (N → B) phenyl[iminodiacetate-O,O′,N]borane **1**, 0.62 g (3.6 mmol) of benzyl bromide **a**, 0.62 g (3.65 mmol) and 1.11 g (10.95 mmol) of $KHCO_3$ in 100 ml of a mixture of acetonitrile/benzene (80/20) was placed into a 250 ml flask equipped with a magnetic stirrer and a Dean–Stark trap. The suspension was refluxed for 8 h. After being cooled to room temperature, the solution was filtered and Na_2SO_4 anhydrous was added to the solution, which was filtered and the solvent was evaporated under vacuum. The solid obtained was crystallized from dichloromethane/hexane to yield 0.68 g (61%) of compound **2** as a white crystals, mp 227 °C. ^{1}H NMR δ(DMSO-d_6, J = Hz): CH_2CO 4.40 (H_A, d, J = 16.5), 3.90 (H_B, d, J = 16.5), CH_2N 3.80 (s), H aromatics 7.40–7.60 (m). ^{13}C NMR: $C_1$169.10, C_2 57.90, R group C_3 60.80, C_4 132.80, $C_{5,9}$ 128.90, $C_{6,8}$ 129.50, C_7 127.60, B-Phenyl C_o 131.60, C_m128.80, C_p130.60. ^{11}B NMR: +12.50. HRMS: $C_{17}H_{17}BNO_4$ $[M^+ + 1]^+$ Calc. 310.1245, found 310.1249, error 1.2415.

4.2.2. Synthesis of (N → B) phenyl[N-(3-methyl)benzyliminodiacetate-O,O′,N]borane (**3**)

Prepared from 1.0 g (4.56 mmol) of compound **1**, 0.84 (4.56 mmol) of 3-methylbenzyl bromide **b** and 1.39 g (13.7 mmol) of $KHCO_3$ in 120 ml of acetonitrile. The residue was crystallized from a mixture of dichloromethane/ether, 0.59 g (40%) of compound **4** were obtained as white solid, mp 251 °C ^{1}H NMR δ(DMSO-d_6, J = Hz), CH_2CO 4.05 (H_A, d, J = 16.57), 3.45 (H_B, d, J = 16.57), CH_2N 3.55 (s), CH_3 2.34 (s), H aromatics 7.0–7.24 (m), 7.40–7.62 (m). ^{13}C NMR: C_1 167.9, C_2 57.8, R group C_3 61.9, C_4 141.1, C_5 130.5, C_6 132.6, C_7 125.7, C_8 128.5, C_9 129.9, C_{10} 21.6, B-Phenyl C_o 135.7, C_m128.1, C_p130.9. ^{11}B NMR: +11.38. HRMS: $C_{18}H_{19}BNO_4$ $[M^+ + 1]^+$ Calc. 324.1401, found 324.1400, error −0.5091.

4.2.3. Synthesis of (N → B) phenyl[N-(4-methyl)benzyliminodiacetate-O,O′,N]borane (**4**)

Prepared from 1.0 g (4.56 mmol) of compound **1**, 0.62 (4.56 mmol) of 4-methylbenzylbromide **c** and 1.39 g (13.7 mmol) of $KHCO_3$ in 120 ml of acetonitrile. The residue was crystallized from a mixture of dichloromethane/ether, 1.10 g (75%) of compound **5** were obtained as white crystals, mp 187–189 °C. ^{1}H NMR δ(DMSO-d_6, J = Hz), CH_2CO 4.05 (H_A, d, J = 16.5), 3.47 (H_B, d, J = 16.5), CH_2N 3.65 (s), CH_3 2.36 (s), H aromatics 7.42–7.61 (m), 7.21($H_{5,9}$, d, J = 7.9), 7.09 ($H_{6,8}$ d, J = 7.9), ^{13}C NMR: C_1 167.5, C_2 58.1, R group C_3 60.9, C_4 139.9, $C_{5,9}$ 129.1, $C_{6,8}$ 127.4, C_7 128.8, C_{10} 20.9, B-Phenyl C_o 132.9, C_m 127.6, C_p128.7. ^{11}B NMR: +11.78. HRMS: $C_{18}H_{19}BNO_4$ $[M^+ + 1]^+$ Calc. 324.1401, found 324.1400, error −0.5091.

4.2.4. Synthesis of N → B) phenyl [N-phenacyliminodiacetate-O,O′,N]borane (**5**)

Among of 1.0 g (4.56 mmol) of compound **1**, 0.9 g (4.56 mmol) of phenacyl bromide **d** and 1.39 g (13.7 mmol) of $KHCO_3$ in 100 ml of a mixture of acetonitrile/benzene (80/20). The residue was dissolved from a mixture of dichloromethane/acetonitrile and precipitate with ether to produce 1.04 g (67.5%) of compound **6** were obtained as white crystals. mp 254–255 °C. ^{1}H NMR δ(DMSO-d_6, J = Hz): CH_2CO 4.60 (H_A, d, J = 17.38), 4.34 (H_B, d, J = 17.38), CH_2N 4.53 (s), H aromatics 7.40–7.60 (m), 7.54 ($H_{7,9}$, t, J = 7.0), 7.63 (H_8, t, J = 7.0). ^{13}C NMR: C_1 170.37, C_2 61.31, R group C_3 65.51, C_4 193.10, C_5 134.81, $C_{6,10}$ 129.38, $C_{7,9}$ 127.98, C_8 134.65. B-Phenyl C_o 133.13, C_m128.29, C_p129.66. ^{11}B NMR: +11.61. HRMS: $C_{18}H_{17}BNO_5$ $[M^+ + 1]^+$ Calc. 338.1194, found 338.1188, error −1.8620.

4.2.5. Synthesis of N → B) phenyl[N-(4-chloro) phenacyliminodiacetate-O,O′,N]borane (**6**)

Among of 1.0 g (4.56 mmol) of compound **1**, 1.06 g (4.56 mmol) of 2-bromo-4′-chloroacetophenone **e** and 1.39 g (13.7 mmol) of $KHCO_3$ in 100 ml of a mixture of acetonitrile/benzene (80/20). The residue was dissolved from a mixture of dichloromethane/acetonitrile and precipitate with ether to produce 1.19 g (73.5%) of compound **7** were obtained as white crystals, mp 226–227 °C. ^{1}H NMR δ(DMSO-d_6, J = Hz): CH_2CO 4.59 (H_A, d, J = 17.4), 4.33 (H_B, d, J = 17.4), CH_2N 4.51 (s), H aromatics 7.39–7.46 (m), 7.56 ($H_{6,10}$, d, J = 8.7), 7.54 ($H_{7,9}$, d, J = 8.7). ^{13}C NMR: C_1 170.59, C_2 61.57, R group C_3 65.60, C_4 192.60, C_5 139.79, $C_{6,10}$ 130.17, $C_{7,9}$ 129.86, C_8 133.88, B-Phenyl C_o133.88, C_m128.61, C_p129.98. ^{11}B NMR: +12.38. HRMS: $C_{18}H_{16}BNO_5Cl$ $[M^+ + 1]^+$ Calc. 372.0804, found 372.0808, error 0.9210.

*4.2.6. Synthesis of N → B) phenyl[N-(4-phenyl)phenacylimino diacetate-O,O',N]borane (**7**)*

Among of 1.0 g (4.56 mmol) of compound **1**, 1.25 g (4.56 mmol) of 2-bromo-4'-phenylacetophenone **f** and 1.39 g (13.7 mmol) of $KHCO_3$ in 100 ml of a mixture of acetonitrile/benzene (80/20). The residue was dissolved from a mixture of dichloromethane/acetonitrile and precipitate with ether to produce 1.52 g (80.8%) of compound **7** were obtained as yellow crystals, mp 248–249 °C. ^{1}H NMR δ(DMSO-d_6, J = Hz): CH_2CO 4.62 (H_A, d, J = 17.5), 4.36 (H_B, d, J = 17.5), CH_2N 4.56 (s), H aromatics 7.41–7.49 (m), 7.62 (H_6, d, J = 7.2), 7.81 (H_7 d, J = 7.2), 7.72 (H_{10}, d), 7.49 ($H_{11,12}$ 7.49 m) ^{13}C NMR: $C_1$170.68, C_2 61.67, R group C_3 65.84, C_4 192.94, C_5 146.15, C_6 127.76, C_7 128.03, C_8 139.29, C_9 129.51, C_{10} 127.85, C_{11} 129.98, C_{12} 133.91. B-Phenyl C_o133.46, C_m128.61, C_p129.51. ^{11}B NMR: +12.92. HRMS: $C_{24}H_{21}BNO_5$ $[M^+ + 1]^+$ Calc. 414.1507, found 414.1509, error 0.4110.

*4.3. Crystal structure determination of compounds **2**, **4** and **5***

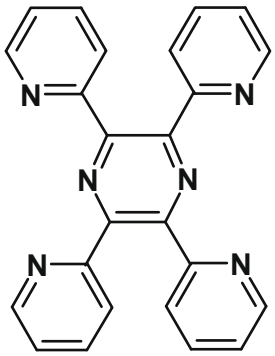
Diffraction data from compound **2** were collected on an Enraf-Nonius CCD diffractometer at 293 K. Compound **2** with two independent molecules, $C_{17}H_{16}BN\,O_4$ (MW 309.12) crystallized in the space group $P\,2_1/n$, monoclinic; from dichloromethane/hexane as white colourless block, size 0.3 × 0.2 × 0.1 mm^3 with a = 10.934 (2), b = 16.927 (4), c = 17.100 (3) Å, V = 3111.0 Å (1)^3, α = 90.00°, β = 100.58 (10)°, γ = 90.00°, ρ = 1.320 mg/m^3, Z = 8, μ = 0.093 mm^{-1}, F(0 0 0) = 1296. Data collection: a total of 12763 reflections were measured, 6988 were independent and of these 4544 were considered observed [$F_o > 4.0\sigma(F_o)$]. Solution and refinement: direct methods, all non hydrogen atoms were refined anisotropically, R = 0.0499, Rw = 0.1174, $w = 1/\sigma^2$, GOF = 1.017, largest residual electron density peak/hole in the final difference map: 0.185/−0.281 eÅ^{-3}.

Compound **4** with two independent molecules, $C_{18}H_{18}BNO_4$ (MW 323.14) crystallized in the space group $P\,2_1/c$, monoclinic; from dichloromethane/ether as white colourless block, size 0.3 × 0.2 × 0.1 mm^3 with a = 11.2761 (4), b = 20.2614 (11), c = 15.2577 (6) Å, V = 3485.9 (3) Å^3, α = 90.00°, β = 89.953 (1)°, γ = 90.00°, ρ = 1.231 mg/m^3, Z = 8, μ = 0.086 mm^{-1}, F(0 0 0) = 1360. Data collection: a total of 19902 reflections were measured, 7054 were independent and of these 3803 were considered observed [$F_o > 4.0\sigma(F_o)$]. Solution and refinement: direct methods, all non hydrogen atoms were refined anisotropically, R = 0.0602, Rw = 0.1432, $w = 1/\sigma^2$, GOF = 1.040, largest residual electron density peak/hole in the final difference map: 0.296/−0.342 eÅ^{-3}.

Compound **5**, $C_{18}H_{16}BNO_5$ (MW 337.13) crystallized in the space group $P\,2_1/c$, monoclinic; from dichloromethane/ether as white colourless block size 0.3 × 0.3 × 0.2 mm^3 with a = 7.14030 (10), b = 18.7329 (5), c = 12.3949 (3) Å, V = 1645.10 (6) Å^3, α = 90.00°, β = 97.130 (1)°, γ = 90.00°, ρ = 1.361 mg/m^3, Z = 4, μ = 0.099 mm^{-1}, F(0 0 0) = 704. Data collection: a total of 6705 reflections were measured, 3719 were independent and of these 2324 were considered observed [$F_o > 4.0\sigma(F_o)$]. Solution and refinement: direct methods, all non hydrogen atoms were refined anisotropically, R = 0.0430, Rw = 0.1497, $w = 1/\sigma^2$, GOF = 0.716, largest residual electron density peak/hole in the final difference map: 0.188/−0.168 eÅ^{-3}.

Data reduction and molecular graphics were performed by WINGX program set [23]. All calculations were carried out with SHELX-S-97 and SHELX-L-97 [24]. Atomic scattering factors were taken from the International Tables for X-ray crystallography [25].

Supplementary data



CCDC 714540, 714541 and 714542 contains the supplementary crystallographic data for compounds **2**, **4** and **5**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

The authors thank the "Consejo Nacional de Ciencia y Tecnología" (Conacyt-México) for financial support and for scholarship to R.M. Flores Ancona and M. López Martínez. We also acknowledge the help to Ing. Marco Antonio Leyva for X-ray crystallography.

2,3,5,6-tetrakis(2-pyridyl)pyrazine

(tppz)

Scheme 1.

JASCO 7580 spectrophotometer. ^{1}H NMR spectra were recorded on a Bruker DRX-500 MHz, Avance spectrometer at ambient temperature in DMSO-d_6. Cyclic voltammograms were recorded by using a SAMA Research Analyzer M-500. Three electrodes were utilized in this system, a glassy carbon disk working electrode (ϕ 5 mm), a platinum wire auxiliary electrode and a Ag/AgCl reference electrode. The platinum disk working electrode was manually cleaned with 1-μm diamond polish prior to each scan. The supporting electrolyte, tetrabutylammonium hexafluorophosphate (TBAH), was twice recrystallized from ethanol–water (1/1) and vacuum-dried at 110 °C overnight. DMSO was distilled over CaH_2 and degassed under vacuum prior to use in the cyclic voltammetry. The solutions were deoxygenated by bubbling with Ar for 15 min. The procedure was performed at room temperature and the Ar atmosphere was maintained over the solution during measurements. Ferrocene (E^o = 0.665 V versus NHE, ΔE_p = 60 mV) was used as an internal reference [43]. The range of potential studied was between +1 and −2.2 V.

Emission spectra were taken on a CARY ECLIPS spectrophotometer. The spectra were measured in DMSO solution at room temperature. Solutions were taken in a 1 cm path length fused silica cell. Absolute emission quantum yields (Φ) were determined by comparison of the integrated emission intensity with that of Rhodamine B under identical conditions. Rhodamine B solutions absorb in plastics and should be kept in glass. *Caution:* Rhodamine B is suspected to be carcinogenic.

2.2. Synthesis of [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol

In a glass test tube, a solution of $CdCl_2{\cdot}H_2O$ (0.04 g, 0.2 mmol) in 5 mL 1:1 (V/V) ethanol/acetone was carefully layered on top of a solution of tppz (0.0388 g, 0.1 mmol) in 5 mL chloroform using ethylene glycol (3 mL) as an interlayer. After 5 days at room temperature, colorless single-crystals suitable for X-ray crystallography appeared at the boundary, in a yield of 22%. *Anal.* Calc. for $C_{26}H_{22}Cd_2Cl_4N_6O_2$: C, 38.21; H, 2.71; N, 10.28. Found: C, 38.55; H, 2.76; N, 10.39%. ^{1}H NMR (δ ppm, 500 MHz, DMSO-d_6, 298 K): 8.57 (d, 4H), 8.09 (d, 4H), 7.84 (dd, 4H), 7.59 (dd, 4H).

2.3. Synthesis of [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone

A solution of tppz (0.37 g, 0.95 mmol) in 20 mL ethanol was slowly added to a solution of $RhCl_3{\cdot}xH_2O$ (0.25 g, 0.95 mmol) in 25 mL ethanol. The mixture was heated at reflux temperature for 5 h while being stirred vigorously. Upon cooling, a fine brown–green powder product was precipitated and filtered out. The product was washed with cold ethanol followed by diethyl ether and air dried. The yield of [Rh(tppz)Cl_3] was 0.493 g (86.8%). A mixture of [Rh(tppz)Cl_3] (0.298 g, 0.5 mmol) and 2,2′-bipyridine (0.078 g, 0.5 mmol) in 90 mL 2:1 (V/V) ethanol/water was heated at reflux temperature for 1 h. To the solution was then added $AgNO_3$ (0.17 g, 1 mmol) and the resulting solution was stirred at reflux temperature for 1 h. The solution was cooled to −5 °C overnight and filtered through Celite to remove the fine white AgCl precipitate. The filtrate was evaporated to dryness on the rotary evaporator. The brown powdery residue was dissolved in 20 mL water and precipitated from solution as a hexafluorophosphate salt by the addition of NH_4PF_6 (0.326 g, 2 mmol). The PF_6^- counter ion increased the solubility of the complex in polar organic solvents and resulted in easier purification. The product, [Rh(tppz)(bpy)Cl][PF_6]$_2$ was collected by suction filtration, washed with cold water and diethyl ether, and air dried. The crude product

2.4. X-ray crystallography

The colorless crystals of [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol were grown at the boundary of a Cd(II) solution in acetone/ethanol (1:1 V/V) and a tppz solution in $CHCl_3$ in the presence of ethylene glycol as an interlayer solvent. The yellow–green crystals of [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone were grown by the slow evaporation of a 1:1 acetonitrile/acetylacetone solution of the complex. Single-crystal X-ray diffraction measurements of the complexes were carried out on a Bruker Apex II, using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at 120(2) K. Unit cell parameters were determined by the least-squares calculations with θ angles ranging from 2.06° to 28.99° for [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol and 1.47° to 25.99° for [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone.

The structures were solved by direct method and refined by full-matrix least-squares against F^2 in anisotropic (for non-hydrogen atoms) approximation. All hydrogen atoms were located from the difference Fourier syntheses and placed in geometrically calculated positions. All hydrogen atom positions were refined in an isotropic approximation in the riding model with the U_{iso}(H) parameters equal to 1.5 U_{eq}(Ci) for methyl groups and 1.2 U_{eq}(Ci) for other carbon atoms, where U(Ci) are the equivalent thermal parameters of the atoms to which corresponding H atoms are bonded. All calculations were performed on an IBM PC/AT using the SHELXTL version 5.1 software [44], giving a final R_1 = 0.0278, WR_2 = 0.0690 (for 3392 reflections with $I > 2\sigma(I)$) for [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol and R_1 = 0.0478, WR_2 = 0.1076 (for 6030 reflections with $I > 2\sigma(I)$) for [Rh(tppz)(bpy)Cl][PF_6]$_2$ acetyl acetone. The largest diffraction peak and hole on the final difference-Fourier map were 1.238 and −0.622 e Å^{-3} for [{$CdCl_2$}$_2$(μ-tppz)]. ethylene glycol and 1.719 and −0.479 e Å^{-3} for [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone. Further details of the structural analyses are given in Table 1.

3. Results and discussion

The selected bond lengths and angles of complexes [Rh(tppz)(bpy)Cl][PF_6]$_2$ and [{$CdCl_2$}$_2$(μ-tppz)] are listed in Tables 2 and 3, respectively.

There are three general classes of structures that arise from the tridentate-coordination mode of the tppz ligand, including the [M(tppz)], [M(tppz)$_2$], and [M$_2$(μ-tppz)] structures. The simplest of these are the [M(tppz)] structures that involve coordination of one mono-tridentate tppz to a single metal, leaving the other side free [45]. This binding mode is observed for the mononuclear Rh(III) complex [Rh(tppz)(bpy)Cl][PF_6]$_2$. Fig. 1 shows the coordination geometry of the ligands about the Rh(III) ion. A distorted octahedral coordination at Rh(III) is defined by the N donor atoms of a tppz ligand bound in a κ-N(3),N(4),N(5) mode with the N(3) and N(5) atoms *trans* to each other, the N donor atoms of a bpy ligand and one Cl^- anion. The N(2) atom of the bpy ligand is *trans* to Cl^-.

The pyridyl rings of the uncoordinated tppz molecule are planar within experimental errors, but the tppz ligand as a whole is far from being planar due to the steric effects between the hydrogen atoms on the 3-pyridyl positions. Low energy conformations of tppz are predicted to have each pyridyl ring twisted from coplanarity with the pyrazine by roughly 50° [8,45,46]. For the tppz ligand, the dihedral angle between the mean planes of the two coordinated pyridyl rings is 3.97° whereas that between the two uncoordinated pyridyl rings is 48.92°. It deserves to be noted that the free N(6) and N(8) pyridyl nitrogen atoms are up and down from the pyrazine ring. It seems that the weak hydrogen bonds involving N(6)···H(12A) (2.523 Å) and N(8)···H(23A) (2.535 Å) occur in the structure of [Rh(tppz)(bpy)Cl][PF_6]$_2$. The pyridyl rings of bpy ligand are nearly coplanar, with a dihedral angle between the mean planes of 2.68°.

Table 3

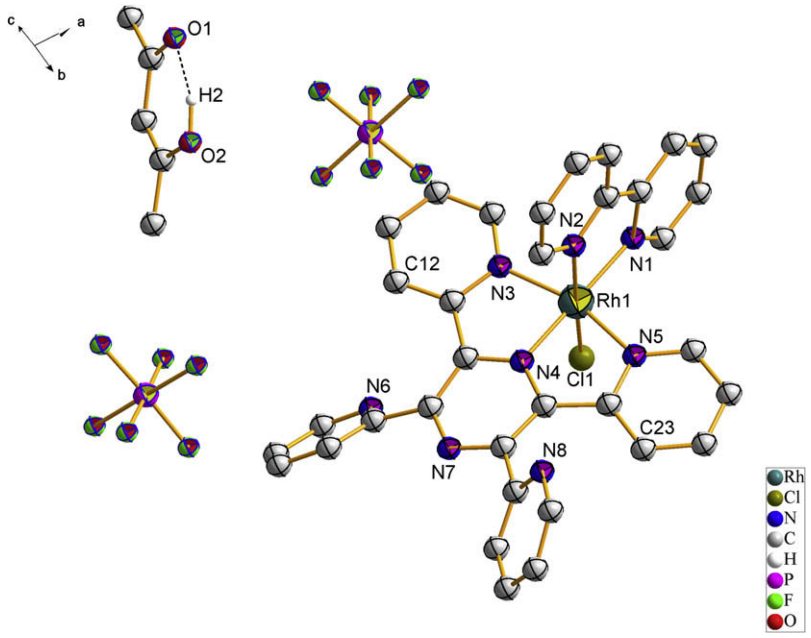

Fig. 1. View of the coordination environment of Rh(III) in [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone.

The bite angles are defined as N–Rh–N angles involving the nitrogen atoms of a tppz or bpy ligand. The ideal bite angles for a tridentate ligand in an octahedral environment would be 90° and 180°. The Rh–tppz bite angles are less than the ideal angles at 81.10°, 80.79° and 161.87°. The ideal bite angle for bpy in an octahedral coordination geometry is 90°. The Rh–bpy bite angle (N(2)–Rh(1)–N(1) = 80.14°) is less than 90°.

The shortness of the Rh–N(pyrazine) bond compared with the Rh–N(pyridine) bonds (Table 2) is suggested to be due to the stronger π-accepting properties of the pyrazine ring. Crystallography revealed one acetylacetone molecule (enol form) per complex [Rh(tppz)(bpy)Cl][PF_6]$_2$ in the crystal structure. This solvent of crystallization has an intramolecular hydrogen bond between the O atom of the carbonyl group and the enolic H atom (O(2)–H(2)···O(1), d(H···O) = 1.65 Å). In the keto–enol tautomerism, the enol form is usually unstable, does not survive long, and changes into the keto form. This is because the oxygen is more electronegative than carbon and thus forms stronger multiple bonds. Hence, a carbon–oxygen (carbonyl) double bond is more than twice as strong as a carbon–oxygen single bond, but a carbon–carbon double bond is weaker than two carbon–carbon single bonds. 1,3-Diketones, such as acetylacetone, are particularly prone to form stable enols or enolates because of conjugation of the enol or enolate with the other carbonyl group and the stability gained in forming a six-membered ring (hydrogen bonded in the case of the enol or containing the counter ion in the case of the enolate).

The Rh^{III}–Cl bond length of 2.3258(10) Å is larger than the Rh–N distances. The Rh^{III}–Cl distance compares well with the reported

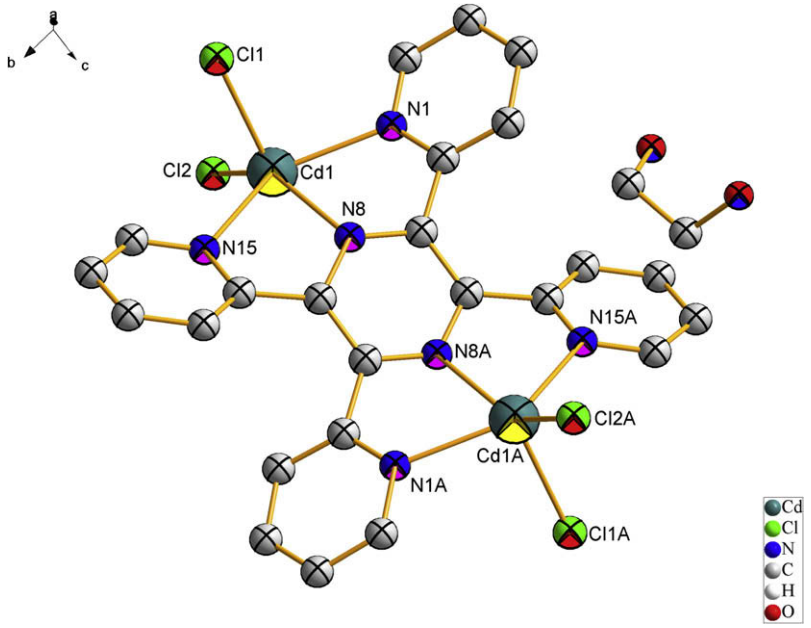

Fig. 2. The structure of one of the independent complex molecules, [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol. H atoms have been omitted.

Rh^{III}–Cl distances [47–49]. The Rh^{III}–Cl bond length is shorter than the average Ru^{II}–Cl bond length that was derived from the *cis,cis*-[{Ru(DMSO)Cl_2}$_2$(μ-tppz)]·2Me_2CO·2H_2O structure [42]. The shorter Rh^{III}–Cl distance indicates significant σ bonding in this bond. A π donation from the Cl^- ligand to Rh(III) is not possible because of its d^6 (t_{2g}^6) electron configuration. Fig. 1 also shows two PF_6^- counter ions. The P–F bond lengths range from 1.578 (4) to 1.604(3) Å, with an average of 1.596(8) Å. The lattice structure is further stabilized by a network of weak hydrogen bonds between the H atoms of the acetylacetone or pyridyl rings of the tppz ligand and the F atoms of the PF_6^- anions, with C–H···F distances of 2.409–3.950 Å.

The literature reveals many crystal structures of the [M_2(μ-tppz)] binding mode [14,29,31,32,34,38,39,41,42,50]. The major significance of these complexes is that they can serve as precursors for mixed valence complexes. The binding mode [M_2(μ-tppz)] is observed for the dinuclear Cd(II) complex [{$CdCl_2$}$_2$(μ-tppz)] (Fig. 2). The Cd(II) compound is a neutral and centrosymmetric dinuclear complex in which the tppz ligand functions in a

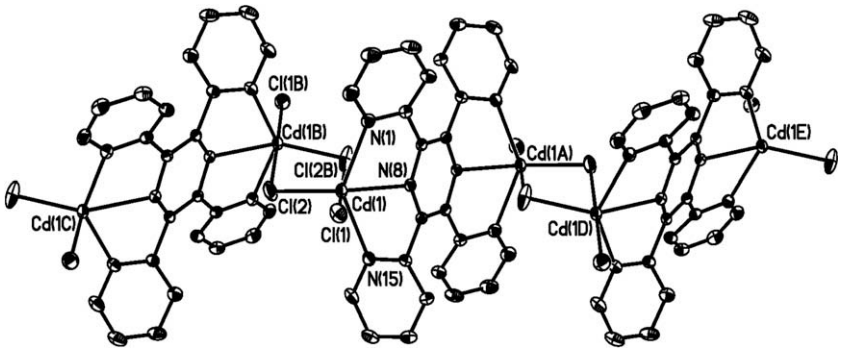

Fig. 3. The infinite chain of [{$CdCl_2$}$_2$(μ-tppz)] is formed by additional coordination Cd(1)–Cl(2)$_{-x+1,y,-z+1/2}$ 3.0431(8) Å.

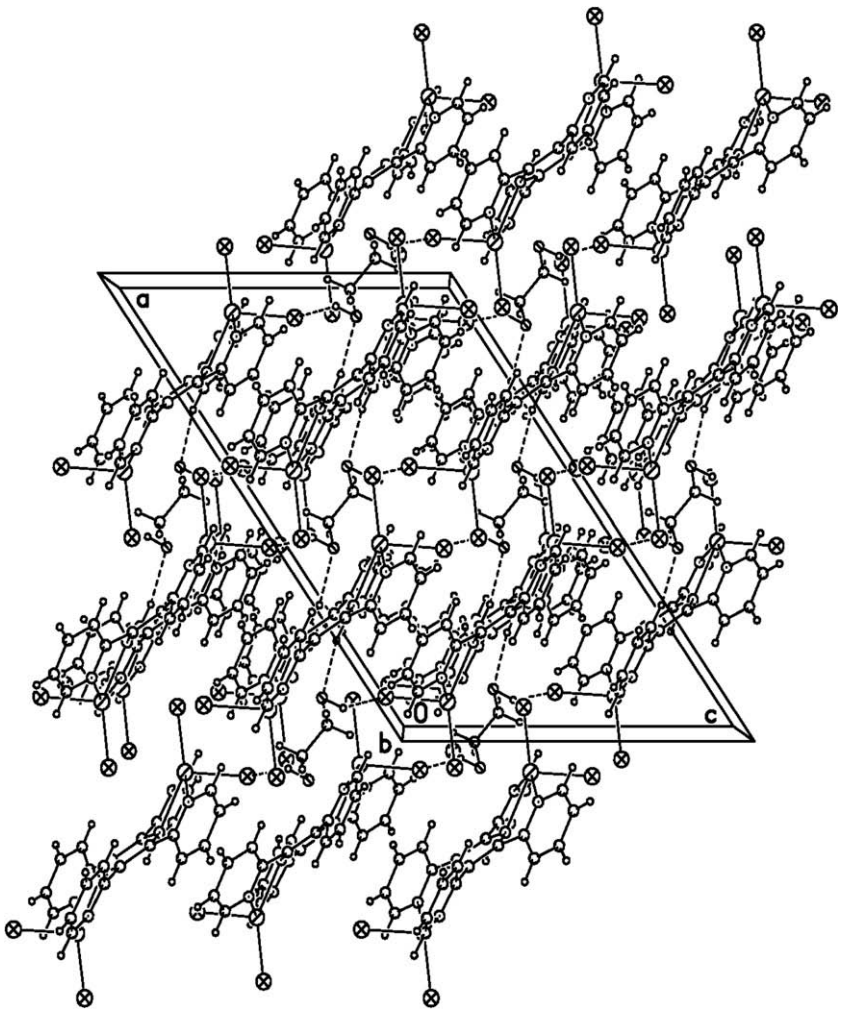

Fig. 4. Fragment of crystal packing (projection along the *b* crystal axis) of [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol. In the crystal, hydrogen bonds between the complex and ethylene glycol solvate molecules are presented: O(1S)–H(1S)...Cl(1)$_{-x+1/2,y-1/2,-z+1/2}$.

bis-tridentate bridging manner to link two Cd(II) ions that are separated by 7.286 Å. Each Cd(II) center is five-coordinated by three N donor atoms of tppz in one plane and two Cl^- ions normal to this plane; the Cl–Cd(II)–Cl angle is 101.72(3)°. The molecular structures of five-coordinate transition metal complexes show an extensive range from regular trigonal bipyramidal (RTBP) to regular square-based pyramidal (RSBP). The structure index parameter, $\tau = (\beta - \alpha/60)$, was evaluated by the two large angles ($\alpha < \beta$) in the five-coordinated geometry, where $\tau = 1.0$ for a RTBP geometry and $\tau = 0.0$ for a RSBP [51]. The coordination geometry around Cd(II) is slightly distorted from regular square-based pyramidal, as ascertained by the observed τ value of 0.20. One Cl^- and three nitrogen atoms of the tppz ligand constitute the basal plane of the square pyramid, and the remaining Cl^- occupies the apical position (Fig. 2). The Cd^{II}–N(pyrazine) distance is very slightly longer than the Cd^{II}–N(pyridyl) distances. The π-accepting property of tppz is saturated by two Cd(II) metal centers, leading to the longer distance. The Cd^{II}–Cl distances of 2.4492(8) and 2.5161(7) Å compare well with the reported Cd^{II}–Cl distances [52,53]. However, if one accepts weak intermolecular Cd···Cl ($1-x$, y, $1/2-z$) interactions of 3.0431(8) Å, the coordination geometry can be described as being based on an octahedron (Fig. 3). The Cd···Cl weak coordination leads to the formation of a 1D chain in the solid state (Fig. 3). The Cd(1)···Cd(1B) distance through the two bridging chloride ligands is 4.211 Å. The two Cd(II) ions are, respectively, below and above the plane of the pyrazine moiety of the bridging tppz ligand. This conformation probably minimizes steric strain while at the same time maximizes the bonding interaction of the tppz ligand with the Cd(II) ions. The dihedral angle between the mean planes of the two coordinated pyridyl rings is 44.83°. The dihedral angles between the pyrazine ring and each of the pyridyl rings are 36.19° (C(2)–C(6)/N(1)) and 34.42° (C(10)–C(14)/N(15)). Unlike the bidentate complexes of tppz, the two pyridine rings of most tridentate tppz complexes do not bow out of the pyrazine ring plane. Instead, the pyrazine ring twists to push one pyridine ring up and the other ring down. The two pyridine rings then rotate in the opposite direction to bring their lone pairs close to the metal ion [45]. Fig. 4 shows the fragment of crystal packing (projection along the *b* crystal axis) of [{$CdCl_2$}$_2$(μ-tppz)].ethylene glycol. In the crystal, hydrogen bonds between the complex and ethylene glycol solvate molecules are presented (O(1S)–H(1S)···Cl(1)).

Data for the infrared spectra for tppz, and the mono and bimetallic complexes were obtained as solids in KBr. Predominant vibrations for the free tppz ligand are associated with ν(C=C), ν(C=N) and ring stretching. The reported separation between ν(C=C) and ν(C=N) is close to 20 cm^{-1} for polypyridyl ligands [54,55], and thus the observed vibrational absorption bands for tppz at 1592 and 1567 cm^{-1} may be due to either different ν(C=N) on the pyrazine and pyridine rings or ν(C=C) and ν(C=N) with coincidental equivalence of the different rings [55]. An intense band at 1393 cm^{-1} is assigned to ring stretching of both the pyrazine and pyridine rings of tppz. The FT-IR spectrum of [Rh(tppz)(bpy)Cl][PF_6]$_2$ shows a absorption pattern in the 4000–400 cm^{-1} region similar to the bpy and tppz ligands. A strong band at 1617 cm^{-1} is assigned to ν(C=O) of the acetylacetone. The strong absorption band at 841 cm^{-1} is assigned to ν(P–F) and demonstrates the existence of PF_6^- as a counter ion [54].

The FT-IR bands of [{$CdCl_2$}$_2$(μ-tppz)] were assigned by a comparison with the free tppz values. This complex shows moderately sharp absorptions at 1595, 1572 and 1395 cm^{-1}, which are assigned to the stretching of the coordinated tppz ligand.

The results obtained from the ^{1}H NMR spectra support the structures obtained from the X-ray analysis and suggest that the structures of the complexes [Rh(tppz)(bpy)Cl][PF_6]$_2$ and [{$CdCl_2$}$_2$(μ-tppz)] are retained in DMSO-d_6 solution. The NMR assignment for the mixed ligand complex [Rh(tppz)(bpy)Cl][PF_6]$_2$ is aided by integration values and comparison to the known systems bpy, tppz, [Ru(L)(tppz)Cl]ClO_4 (L = 2,2′-dipyridylamine) [7], [Ru(tppz)(4,4′-(CH_3)bpy)Cl]PF_6 [56], [Ru(dpk)(tppz)Cl][ClO_4] (dpk = 2,2′-dipyridylketone) [57] and [Ru(tpy)(tppz)][PF_6]$_2$ (tpy = 2,2′:6′,2″-terpyridine) [8]. Metal-free tppz shows four well-resolved ^{1}H NMR signals (8.05, 7.80, 7.23 and 8.38 ppm) at room temperature [8,58]. In the ^{1}H NMR spectrum of [Rh(tppz)(bpy)Cl][PF_6]$_2$ in DMSO-d_6, the bpy protons are non-equivalent as one ring is *trans* to Cl and one ring is *trans* to the pyrazine nitrogen of tppz. Therefore, the protons on each ring of bpy are non-equivalent and integrate with relative value (1). The non-equivalency for the tppz protons arises from the coordination of one end of the ligand to Rh(III), with the subsequent upfield shift of the resonances produced by an increase in electronic density due to π-backbonding. The resonances of the uncoordinated tppz rings shift downfield, as observed for similar complexes [7,8,56,57].

All the pyridine rings of [{$CdCl_2$}$_2$(μ-tppz)] are magnetically equivalent, and only 4 signals attributable to coordinated tppz can be observed in the ^{1}H NMR spectrum. This means that both the cadmium atoms have the same coordination environment.

The electronic absorption spectroscopy of [Rh(tppz)(bpy)Cl][PF_6]$_2$ was found to be quite complicated due to the many possible transitions. It is possible to have tppz $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions as well as ligand field (LF) ($t_{2g}^6 \rightarrow e_g$), MLCT (Rh → tppz and/or Rh → bpy) and LMCT (Cl → Rh) transitions. The electronic absorption spectroscopy of $4d^6$ and $5d^6$ complexes with polypyridyl ligands is characterized by intense ligand $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions in the ultraviolet region and metal (dπ) → ligand (π^*)

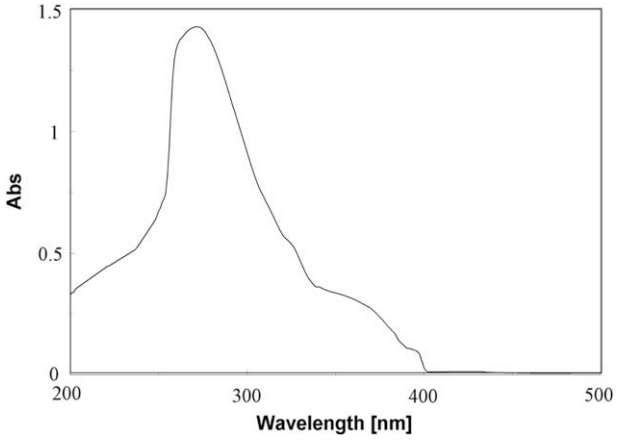

Fig. 5. Absorption spectrum of [Rh(tppz)(bpy)Cl][PF_6]$_2$ in DMSO.

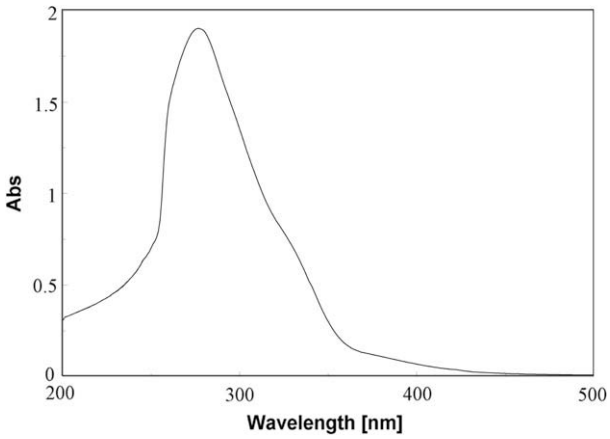

Fig. 6. Absorption spectrum of [{$CdCl_2$}$_2$(μ-tppz)] in DMSO.

charge transfer (MLCT) transitions in the visible region [7,20,55,59–61]. In general only the first spin-allowed LF band of Rh(III) complexes may be observed, the second band frequently being obscured by the CT absorption [59]. The electronic spectrum of $[Rh(tppz)(bpy)Cl][PF_6]_2$ was taken in DMSO (Fig. 5). The intense absorption bands at 272 and 322 nm most likely arise from the spin-allowed ligand-centered (LC) ($\pi \rightarrow \pi^*$) transitions. The absorption band (shoulder) at about 355 nm is assigned as the $d\pi(Rh) \rightarrow \pi^*(tppz)$ charge transfer transition (MLCT) on the basis of the assignments of mononuclear tppz complexes of Ir(III), Rh(III), Ru(II) and Os(II) [7,28,55,59–62], while the weak shoulder at about 398 nm is most likely a LF transition.

The absorption spectrum of $[\{CdCl_2\}_2(\mu\text{-tppz})]$ in DMSO (Fig. 6) displayed a band at 277 nm. This intense band is assigned to a LC ($\pi \rightarrow \pi^*$) transition.

A representative cyclic voltammogram of $[\{CdCl_2\}_2(\mu\text{-tppz})]$ at a glassy carbon electrode is given in Fig. 7. The voltammetric response of this complex shows an irreversible wave at −1.175 V which can be attributed to cadmium reduction process, since cadmium(II) nitrate shows a peak at −0.67 V. Upon formation of a tppz bridged dinuclear complex, the bridging tppz becomes easier to reduce due to stabilization of the π^* orbital induced by the coordination of the second electron deficient metal center. For example, in $[Ru(tpy)(tppz)]^{2+}$ (tpy = 2,2′:6′,2″-terpyridine), two reduction couples of tppz ($tppz^{0/-}$ and $tppz^{-/2-}$) were observed at −0.97 and 1.60 V, while in $[(tpy)Ru(\mu\text{-tppz})Ru(tpy)]^{4+}$, two reduction couples of tppz were recorded at −0.35 and −0.84 V [20,58,63]. In a neutral complex $[\{CdCl_2\}_2(\mu\text{-tppz})]$, the $tppz^{0/-}$ and $tppz^{-/2-}$ couples were observed at −1.58 and −1.88 V, respectively.

The cyclic voltammogram of $[Rh(tppz)(bpy)Cl][PF_6]_2$ is shown in Fig. 8. The electrochemical behavior of $[Rh(tppz)(bpy)Cl][PF_6]_2$ is characterized by metal based and ligand based reductions. The first irreversible two-electron reduction (−0.71 V) is assigned as Rh(III/I), the second and third reductions (−1.11 and −1.67 V) are assigned as $tppz^{0/-}$ and $tppz^{-/2-}$, and the fourth reduction (−1.96 V) is assigned as $bpy^{0/-}$. The $tppz^{0/-}$ and $tppz^{-/2-}$ couples occur prior to the $bpy^{0/-}$ reduction due to the larger π system of tppz ligand as a result of the

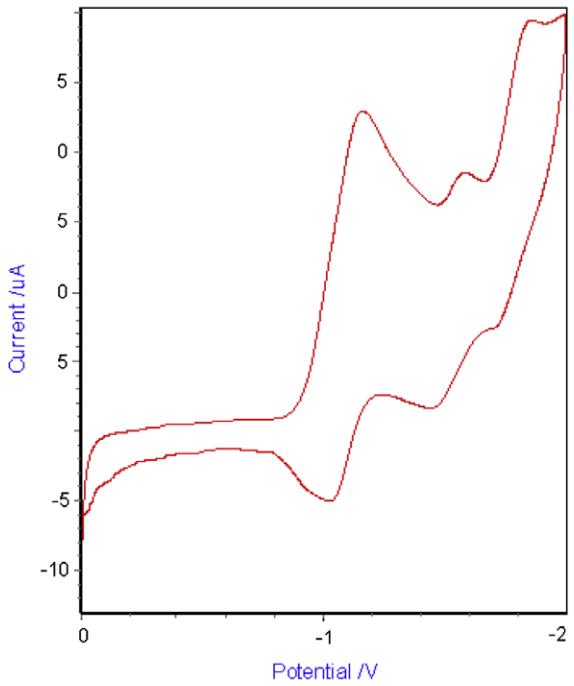

Fig. 7. Cyclic voltammogram of $[\{CdCl_2\}_2(\mu\text{-tppz})]$ in DMSO at a scan rate of 100 mVs^{-1}; 0.1 M TBAH as the supporting electrolyte.

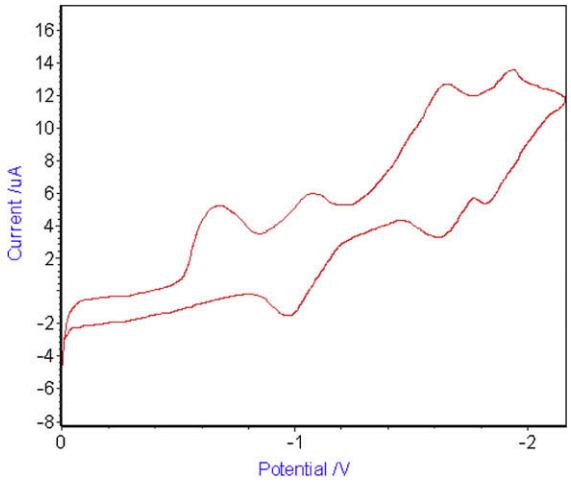

Fig. 8. Cyclic voltammogram of $[Rh(tppz)(bpy)Cl][PF_6]_2$ in DMSO at scan rate of 100 mVs^{-1}; 0.1 M TBAH as the supporting electrolyte.

two extra pyridyl rings on tppz as well as the extra electron accepting character of the pyrazine ring. Tppz has a substantially lower energy π^* orbital than bpy. The two-electron reduction of Rh(III) therefore results in accumulation of an electron on the metal center and destabilizes the complex. This can rationalize the "electron-transfer chemical-reaction (EC)" process, in which the chemical reaction involves loss of a chloride ion, which proceeds and leads to the irreversible process at the first reduction wave. In *cis*-$[Rh(bpy)_2X_2]^+$ (X = Cl^-, Br^-, and I^-), the irreversible Rh(III/I) couple was observed at a negative potential [64]. The electrochemistry reported for the $[Rh^{III}(SacSac)_3]$ (SacSac = dithioacetylacetone) complex indicates a structural instability associated with reduction of this species, consistent with the expectation for addition of the electron into a d_σ-type (d^*) orbital [65,66].

The photoluminescence properties of both complexes were studied at room temperature in DMSO solution. Because of the low solubility of the complexes, we have been forced to study the spectral and emission measurements in DMSO solution. Since tppz itself hardly fluoresces, the fluorescence of the tppz complexes may result from the change in the lowest excited state from the n,π^* triplet to the π,π^* singlet, which becomes lower in energy than the n,π^* triplet due to the complexation with the metal ion as a strong Lewis acid [23,67,68]. In the absence of metal ions, the

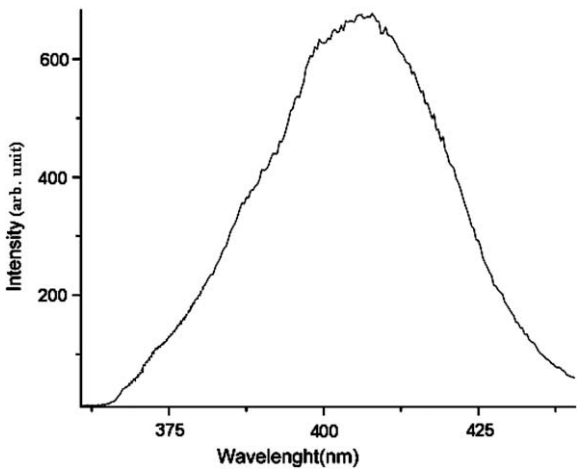

Fig. 9. Emission spectrum of $[\{CdCl_2\}_2(\mu\text{-tppz})]$ in DMSO at room temperature (λ_{exc} = 277 nm).

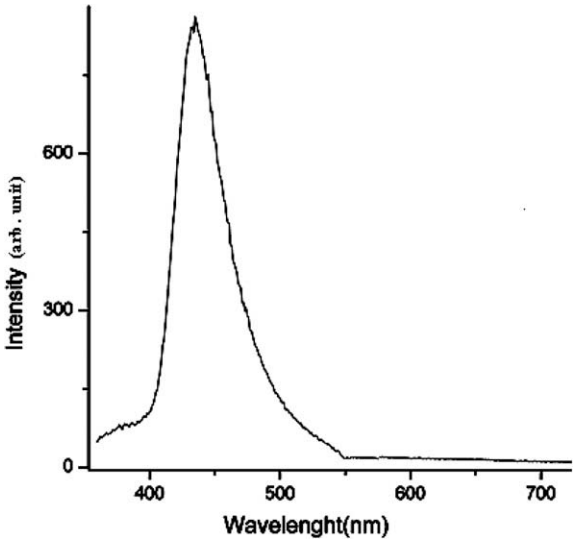

Fig. 10. Emission spectrum of $[Rh(tppz)(bpy)Cl][PF_6]_2$ in DMSO at room temperature (λ_{exc} = 322 nm).

fluorescence of the ligand is probably quenched by the occurrence of a photoinduced electron transfer (PET) process due to the presence of lone pairs of electrons of the donor atoms in the ligand. PET is an electron transfer which occurs when certain photoactive materials interact with light. The fluorescent emission of $[\{CdCl_2\}_2(\mu\text{-tppz})]$ at the excitation wavelength of 277 nm is shown in Fig. 9. Although $CdCl_2$ is not luminescent, interestingly many cadmium coordination complexes containing polypyridyl ligands show an intense fluorescence band upon excitation at the ligand's absorption band in solution as well as in the solid state. No emissions originating from metal-centered and MLCT or LMCT excited states are expected for the Cd(II) complexes, since the Cd(II) ion is difficult to oxidize or reduce due to its d^{10} configuration [52,69–73]. Thus, the emission observed at 406 nm (Φ = 0.29) in $[\{CdCl_2\}_2(\mu\text{-tppz})]$ is tentatively assigned to the $^1(\pi-\pi^*)$ intraligand fluorescence.

The emission spectrum of a deoxygenated solution of $[Rh(tppz)(bpy)Cl][PF_6]_2$ at the excitation wavelength of 322 nm is shown in Fig. 10. The maximum emission peak of this complex is located at 435 nm ($\Phi = 8 \times 10^{-3}$). Since electrochemical data indicated that the reduction orbital of the metal center is d^*, instead of π^* in nature, participating luminescence, the following emission in $[Rh(tppz)(bpy)Cl][PF_6]_2$ can thus be ruled out: metal-to-ligand charge transfer (MLCT), sigma-bond-to-ligand charge transfer (SBLCT), halide-to-ligand charge transfer (XLCT), ligand-to-ligand charge transfer (LLCT) or ligand-centered (LC) emission [74]. This conclusion in turn supports the πd^* emission assignment at room temperature. For the complexes *cis*-$[Rh(bpy)(DPA)Cl_2]$ and *cis*-$[Rh(phen)(DPA)Cl_2]$ (DPA = the deprotonated form of 2,2′-dipyridylamine), only a one-electron reduction process occurs at the metal with elimination of a Cl^- anion. Based on the luminescence and electrochemical data, the emission of these complexes was assigned as πd^* [74]. Some pseudo-octahedral Rh(III) complexes which contain the *ortho*-metallated phenylpyridine anion as a ligand are phosphorescent at room temperature [75].

4. Conclusion

In this study, two tppz complexes, $[Rh(tppz)(bpy)Cl][PF_6]_2$.acetylacetone and $[\{CdCl_2\}_2(\mu\text{-tppz})]$.ethylene glycol, have been synthesized and characterized.

Luminescent polynuclear d^{10} metal complexes such as Cd(II) are of great interest because of their potential application in chemical optical sensors, photosensitization and electroluminescent devices. It is interesting that the dinuclear complex $[\{CdCl_2\}_2(\mu\text{-tppz})]$ has a very strong emission band centered at 406 nm upon excitation at 277 nm. Metal ions can enhance or quench the fluorescence emission of polypyridyl ligands. Quenching of fluorescence of a ligand by transition metal ions during complexation is a rather common phenomenon which is explained by processes such as magnetic perturbation, redox activity and electronic energy transfer. Enhancement of fluorescence through complexation is, however, of much interest as it opens up the opportunity for photochemical applications of these complexes [52]. The fluorescent intensity of the dinuclear Cd(II) complex is significantly stronger than that of free tppz, probably due to the conformational rigidity enhancement of the coordinated tppz, thereby reducing the non-radiative decay of the intraligand $^1(\pi-\pi^*)$ excited state. Thus, $[\{CdCl_2\}_2(\mu\text{-tppz})]$ may be used as an advanced material for light emitting diode devices and may be an excellent candidate for solvent-resistance fluorescent material because it is almost insoluble in most common solvents such as methanol, ethanol, acetone, $CHCl_3$, CH_2Cl_2 and water.

Rhodium (III) complexes have played a central role in the understanding of the electrochemical, photochemical and photophysical processes of d^6 complexes. The mononuclear Rh(III) complex, $[Rh(tppz)(bpy)Cl][PF_6]_2$, shows only an irreversible two-electron reduction process at the metal center with elimination of chloride. At room temperature, this complex shows a blue emission, assigned as πd^* phosphorescence. The electrochemical data also provide evidence in support of the assigned πd^* emission of the complex. In summary, $[Rh(tppz)(bpy)Cl][PF_6]_2$ is an example for the rational design of a transition metal complex which under ambient conditions exhibits a phosphorescence at relatively short wavelength.

5. Supplementary material

CCDC 716058 and 716059 contains the supplementary crystallographic data for $[\{CdCl_2\}_2(\mu\text{-tppz})]$.ethylene glycol and $[Rh(tppz)(bpy)Cl]$ $[PF_6]_2$.acetylacetone. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

different physiological conditions. Moreover, one of the earlier reports described a mononuclear Cu(II) complex showing lower chemical nuclease activity than its dinuclear analogue [20] and opened the scope of studying the structure function relationship based upon the nuclearity of the metal complexes. All these data acted as a motivation to carry out DNA binding and cleavage studies of **1** and **2** as well as the free pro-ligand. Both **1** and **2** showed moderate DNA binding property, with binding constants of the order of $10^4\ M^{-1}$, as was obtained from UV–Vis DNA titration data of the respective complexes. To investigate the mode of the binding interaction of these two complexes with the DNA double strands, circular dichroic (CD) spectra of DNA in absence and presence of both complex solutions were performed. These analyses indicated intercalation as the probable mode of interaction, without any significant change in the right handed helicity of the DNA strands, although viscosity measurements of DNA solutions in absence and presence of solutions of **1** and **2** proved conclusively that both **1** and **2** interact with the same via non-classical mode, probably by producing kinks or bends in the DNA structure. The plasmid DNA, pUC19, cleavage ability of **1**, **2** and the free pro-ligand in the presence or absence of H_2O_2 or scavengers like sodium azide and DMSO were also carried out. Of the two complexes studied, the dinuclear one was seen to have stronger chemical nuclease activity than the mononuclear one and in both the cases the complexes were more potent chemical nucleases than the free ligand. The scavengers of hydroxyl and superoxide radicals were seen to reduce the extent of cleavage to a considerable extent for **1** where as for **2** they had no effect. Thus the oxidative cleavage mechanism for **1** was surely dependent on both singlet oxygen and diffusible hydroxyl radicals, i.e. reactive oxygen species (ROS), but for **2** the cleavage must have taken place by some other mechanism.

Hydrazones and molecules having hydrazide residues in their structures are capable of showing antifungal and antibacterial activities, and thus we explored the Cu(II)-hydrazone complexes and the free pro-ligand from this point of view as well. Complex **2** showed antimicrobial activity towards both Gram positive and Gram negative bacteria where as the free pro-ligand and **1** showed no activity.

Thus in this paper, we report, along with the crystal structures of the two Cu(II)-hydrazone complexes, the binding and cleavage properties of the complexes with CT-DNA and super coiled (SC) pUC19 DNA, respectively, as well as their antimicrobial activity.

2. Experimental

2.1. Materials

Benzhydrazide, pyridine-2-carboxaldehyde, Cu(II) perchlorate hexahydrate and sodium azide (Fluka) were used as received without further purification. All the solvents were of reagent grade. The CT-DNA and plasmid supercoiled (SC) pUC19 DNA were purchased from Bangalore GeNei; the Tris buffer, sodium chloride and hydrochloric acid (AR) were from Merck. Tris(hydroxymethyl)-aminomethane–HCl (Tris–HCl) buffer was prepared using deionized and sonicated triple-distilled water.

2.2. Physical measurements

Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyzer. The infrared spectra were recorded on a Perkin–Elmer RX I FT-IR spectrophotometer with a KBr disc. The electronic spectra were recorded, in acetonitrile or in 5 mM Tris–50 mM NaCl buffer (pH ~7.5), on a Perkin–Elmer Lambda 40 (UV–Vis) spectrophotometer. Electrochemical studies were carried out with a VersaStat- PotentioStat II cyclic voltammeter using saturated calomel electrode (SCE) as the reference electrode in a three-electrode system. The CD spectra were recorded on a Jasco J-720 spectropolarimeter, in the same buffer medium, at room temperature, with $1/r = 1/3$, where $r = [1]/[DNA]$. The final spectrum was an average of five cycles and the spectra for the buffer had been subtracted automatically.

The fluorescence study, for the DNA–ethidium bromide assay, was done using a Hitachi 4010 FluoroMax spectrofluorimeter. A solution of CT-DNA [50 μM] was incubated with ethidium bromide [EthBr] at 27 °C for half an hour. The fluorescence spectrum of this solution was then recorded, subtracting the reading for the buffer only. Subsequent addition of the complexes, **1** and **2** were done with $[complex]_{Tot}/[DNA]_{Tot}$ up to 1.5.

Viscosity measurements were conducted on an Ubbelodhe viscometer, immersed in a thermostated water bath maintained at 298 K. The relative viscosities of the samples were determined using the equation $\eta = (t - t_0)/t_0$, where t_0 is the flow time for buffer alone and t is the flow time of either only DNA solution or DNA solution + different concentrations of complexes **1** and **2**.

The pro-ligand HPBH, **1** and **2** were studied for their antimicrobial activity against Gram negative bacteria *Escherichia coli* MTCC 739, Gram positive bacteria *Staphylococcus aureus* MTCC 96, and yeast *Saccharomyces cerevisiae* MTCC 170. The antimicrobial tests were carried out in Luria-Bertani medium (1% Bacto-Tryptone, 1% NaCl, 0.5% Yeast extract, pH 7.0) for bacteria and YPD medium (1% Yeast extract, 2% Peptone, 2% Dextrose, pH 5.0) for yeast. 1.8% agar was used for preparing the plates.

The minimum inhibitory concentration (MIC), the lowest concentration of the compound which inhibits microbial growth, was determined by broth dilution and cup agar diffusion assay. The compounds were tested in the 1–1000 μg/ml range. The inoculum was obtained by O/N broth cultures. The growth was measured by determining OD_{600} after 24 h incubation at 37 °C for bacteria and 48 h at 30 °C for yeast. For the cup assay, the zone of inhibition around the cup (if any) was checked.

The CT-DNA was dissolved in Tris buffer and its purity was checked from the absorbance ratio A260/A280. For all the solutions this ratio was in the range 1.8–1.9. Therefore no further deproteinization of the solutions was performed. The concentration of CT-DNA was determined from the absorption intensity at 260 nm with a known ε value of $6600\ M^{-1}\ cm^{-1}$ [21].

The cleavage of Supercoiled (SC) pUC19 DNA (Bangalore Genie) by **2** was investigated by agarose gel electrophoresis. Briefly, the reaction was carried out by mixing plasmid DNA (0.50 μg) and different concentrations of **1** and **2** (10–30 μM), with and without hydroxyl radical/singlet oxygen scavengers (5.6 μL DMSO, 4 mM NaN_3, respectively), in Tris–HCl (50 mM) buffer containing 18 mM NaCl, (pH 7.2) to yield a final volume of 15 μL. The samples were then incubated for 1 h at 37 °C, followed by the addition of loading buffer containing bromophenol blue (0.25%), xylene cyanole (0.25%) and glycerol (30%). The reaction products were subjected to electrophoresis on 1% agarose gel in 1X TBE buffer (45 mM Tris, 45 mM H_3BO_3, 1 mM EDTA) containing 2 μL/100 ml of ethidium bromide (10 mg/ml) at 80 V for 2 h. The resolved bands were visualized under UV light and photographed. The extent of cleavage of the SC DNA was quantified by measuring the intensities of the bands using the Gel Documentation System (Bio Rad). The intensity of the band relative to the plasmid supercoiled form has been multiplied by 1.43 to take account of its reduced affinity for ethidium bromide [22].

It is worth mentioning here that to ascertain the nuclearity and probable structure of **2** after dissolution in aqueous buffer medium, we performed IR and UV–Vis analysis on the residue obtained after evaporation of the aqueous solution of the same. These spectra matched with that of the solid crystalline product of the complex.

This indicated the retention of structure for **2** after dissolution in water.

2.3. Preparation of the ligand and complexes

2.3.1. Synthesis of ligand HPBH

The pro-ligand was synthesized by condensing benzhydrazide with pyridine-2-carboxaldehyde following a method reported elsewhere [23]. The resulting light yellow solution was used without further purification.

Caution! Perchlorate salts are potentially explosive and should be prepared in small quantity and handled with much care.

2.3.2. Synthesis of [{Cu (PBH)$_2$] (**1**)

To a methanolic solution (20 ml) of copper perchlorate hexahydrate (0.370 g, 1 mmol), a solution of the hydrazone pro-ligand (**HPBH)** (1 mmol) was added and the mixture was stirred at room temperature for 30 min. The final solution was kept in a refrigerator, yielding dark green square crystals suitable for X-ray diffraction after 1 day. The crystals were isolated by filtration and were air-dried. Yield: 67%

Anal. Calc. for $C_{26}H_{20}CuN_6O_2$: C, 60.99; H, 3.94; N, 16.41. Found: C, 60.95; H, 3.91; N, 16.40%.

2.3.3. Synthesis of [{Cu (PBH) ($\mu_{1,1}$-NNN)}$_2$] (**2**)

The isolation of single crystals of **2** afforded a great challenge and so the whole reaction was carried out at −4 °C in a salt-ice mixture. The crystals of **1** (1 mmol) were dissolved in 1:1 methanol–acetonitrile mixture by stirring and to it was added 1 mmol of sodium azide (0.065 g) solution dissolved in minimum quantity of ice cold water. The reaction mixture was not stirred any further after this addition and was refrigerated immediately. Single crystals suitable for X-ray diffraction were isolated after few hours. Yield: 73%.

Anal. Calc. for $C_{26}H_{20}Cu_2N_{12}O_2$: C, 47.34; H, 3.06; N, 25.48. Found: C, 47.31; H, 3.01; N, 25.44%.

2.4. X-ray data collection and structure refinement

Data collection for **1** was made using a Bruker SMART CCD area detector diffractometer equipped with a Mo Kα radiation (λ = 0.71073 Å) source in the φ and ω scan modes at 296 K whereas for **2**, a Rigaku rotating anode single-crystal X-ray diffractometer at the University of St. Andrews was used and data were initially collected at 93 K. Crystallographic data for complexes **1** and **2** are provided in Table 1.

Table 1

3. Results and discussion

3.1. Infrared spectra

The IR spectra of the complexes in the region 4000–400 cm^{-1} were analyzed in comparison with that of the free ligand. The data gave evidence for the coordination of the ligand PBH$^-$ to the metal ion via two nitrogen atoms and one oxygen atom. The infrared spectra of both **1** and **2** displayed IR absorption bands at 1610 and 1615 cm^{-1} respectively which could be assigned to the C=N stretching frequencies of the coordinated ligand **PBH**$^-$, whereas for the free ligand the same band was observed at 1663 cm^{-1}. The shifts of this band on complexation towards lower wavenumbers indicated coordination of the azomethine nitrogen to the metal centre [21]. In the spectrum of **2** a strong bifurcated band at 2169 and 2234 cm^{-1} indicated the presence of a bridging azide group [24]. The ligand coordination to the metal centre was substantiated by two bands at 407 cm^{-1} for **1**, and at 426 cm^{-1} for **2** which can be attributable to ν_{Cu-N}.

3.2. Electronic spectra

The electronic spectra of **1** and **2** in acetonitrile solution showed a strong absorption band around 280 nm. This band is clearly charge-transfer in origin. The band around 387 nm for the free pro-ligand was assigned to the n–π^* transition of the azomethine group. In the spectra of the complexes, the bands for the azomethine chromophore giving rise to the n–π^* transition were shifted to lower frequencies, indicating that the imine nitrogen atom was involved in coordination to the metal ion [25]. The visible spectrum of **1** displayed a single broad band at 590 nm. This spectral feature is consistent with the tetragonally distorted six-coordinate geometry of the Cu(II) complexes. As the axial bonds in tetragonally distorted complexes are far longer than the four basal bonds, the t_{2g} to e_g transition splits into two components. The longer axial bonds lead to the stabilization of d_{z2}, d_{xz} and d_{yz} orbitals and as a consequence a series of transitions ($d_{x2-y2} \leftarrow d_{z2}$, $d_{x2-y2} \leftarrow d_{xz}$ and $d_{x2-y2} \leftarrow d_{yz}$) are expected, which in most cases are observed as blue shifted broad bands [26]. The appearance of such a broad band in the blue shifted region indicate a tetragonally distorted geometry around the Cu(II) centre of **1**. The visible band for **2** was observed at 673 nm, which could be attributed to a distorted square pyramidal geometry around Cu(II). In general typical Cu(II) complexes of SP or distorted SP geometries exhibit a band in the range 550–660 nm, whereas the corresponding TBP complexes usually show a maximum at $\lambda > 800$ nm with a higher energy shoulder [27–29]. This indicates that the solution spectra of **2** is adequately explained by a *d*–*d* transition for the Cu(II) ion in a distorted SP geometry where the absorption band observed in the visible region results from a $^2E \rightarrow {}^2B_1$ transition.

3.3. Crystal Structure of [{Cu(PBH)$_2$](**1**)

An ORTEP diagram of **1** is presented in Fig. 1 with its atom numbering scheme, and bond dimensions are listed in Table 2. Complex **1** is a simple Cu(II) hydrazone monomer where two mono-negative hydrazone ligands PBH$^-$ coordinate the central metal ion in a *mer* arrangement, and the coordination sphere is occupied by a N_4O_2 donor set from the two ligand units. A similar structure with Mn(II)

with the same ligand has been reported by us previously [7]. The axial positions of the distorted octahedron are occupied by N1a and O1a of one hydrazone ligand unit and these two bonds are, as usual, much longer than the four basal bonds. The axial *trans* base angle [150.13°(6)] shows considerable deviation from its ideal value. One of the basal planes is occupied by the remaining nitrogen atom (N2a) of the ligand which spans the axial position, and the remaining basal positions are occupied by other nitrogen and oxygen donors (N1b, N2b, O1b) from the other hydrazone ligand unit.

The monomeric units form H-bonded dimeric structures (Fig. 2, Table 3) where the H atom residing upon C4b is linked to O1a of a neighboring mononuclear unit.

3.4. Crystal Structure of [{Cu(PBH)($\mu_{1,1}$-NNN)}$_2$] (**2**)

An ORTEP diagram of **2** with the atom numbering scheme is given in Fig. 3. Bond dimensions about the copper atoms are listed in Table 4. The structural study reveals that **2** is a non-centrosymmetric dimer in which the copper centers are five-coordinate, bonded to three coordinating atoms [N_2O] from the PBH^- ligand and the nitrogen atoms from two bridging azide ligands. Recently our group reported a very similar structure where cyanate served as a bridge between the two metal centers, though it was centrosymmetric [8]. The small Cu–Cu separation (3.211 Å) is achieved through the *end-on* bridging mode of the azide ligand. The azide ligands span the axial positions of one Cu(II) center and the basal position of the other, and thus coordinate in a base apical fashion. The average axial Cu–N_{azide} bond length is 2.423 Å where as the average basal Cu–N_{azide} bond length is 1.964 Å which gives Δd = 0.459 Å for the Cu–N_{azide} bonds. The average bridge angle is found to be 93.52°. The geometry of the Cu(II) centres is distorted square pyramidal with τ = 0.262, [$\tau = |\beta - \alpha|/60°$, where β and α are the two largest angles around the central atom; τ = 0 and 1 for the perfect square pyramidal and trigonal bipyramidal geometries, respectively] [30].

3.5. DNA binding study

3.5.1. Electrochemical studies

The electrochemical studies of **1** and **2** alone and CT-DNA added to the solutions of **1** and **2** were performed in Tris buffer medium. For **1** alone, there was an irreversible reduction–oxidation band (Fig. 4a), the reduction band in the Tris buffer medium was

observed at −181.50 mV whereas the oxidation band was observed at 66 mV. Upon addition of DNA solution the reduction band shifted to a more positive value of −122.50 mV, whereas the oxidation band shifted towards a more negative value of 54.25 mV.

For **2** in the same buffer medium, one irreversible reduction band at 134.50 mV was observed (Fig. 4b). The same reduction band was obtained at 118.75 mV by adding CT-DNA to the metal complex solution. The shift of the reduction band to a more negative value upon addition of CT-DNA to **2** implies lower reducibility of the species present in that solution.

The results of the CV clearly indicate that **1** and **2** interact with DNA strands via two different mechanisms.

3.5.2. Electronic absorption titration, CD spectral analyses and ethidium bromide assay

Before adding CT-DNA to **1** and **2**, their behavior in a buffer solution at room temperature was monitored by UV–Vis spectroscopy for 24 h. Liberation of the ligand [PHB^- and N_3^-] was not observed under these conditions. This suggests that the complexes are stable under the conditions studied.

The UV–Vis titrations of **1** and **2** with CT-DNA were done in Tris buffer medium in the wave length range of 800–200 nm. For **1**, a distinct band appeared at 486 nm (Fig. 5a), which was obviously charge transfer in origin. This band upon addition of successive amounts of CT-DNA (0–50 μM) showed significant hypochromism along with a small blue shift of the band to 476 nm. For **2**, in the UV region a band at 358 nm (Fig. 5b) was observed. Upon addition of successive amounts of DNA (0–50 μM) to the solution of **2** this band showed considerable hyperchromism without any significant band shift.

As was reported previously [22], a significant change in band intensity upon addition of DNA to metal complexes imply interaction of the same with the DNA base pairs, so in this case also we can conclude that the complexes interact with the DNA double strands. The apparent binding constants of **1** and **2** with CT-DNA were calculated from the absorption titration data using the following equation [31–35],

$$1/\Delta A = 1/\Delta A_{max} + 1/K_{app}\Delta A_{max} \times 1/(C_D - C_O) \quad (1)$$

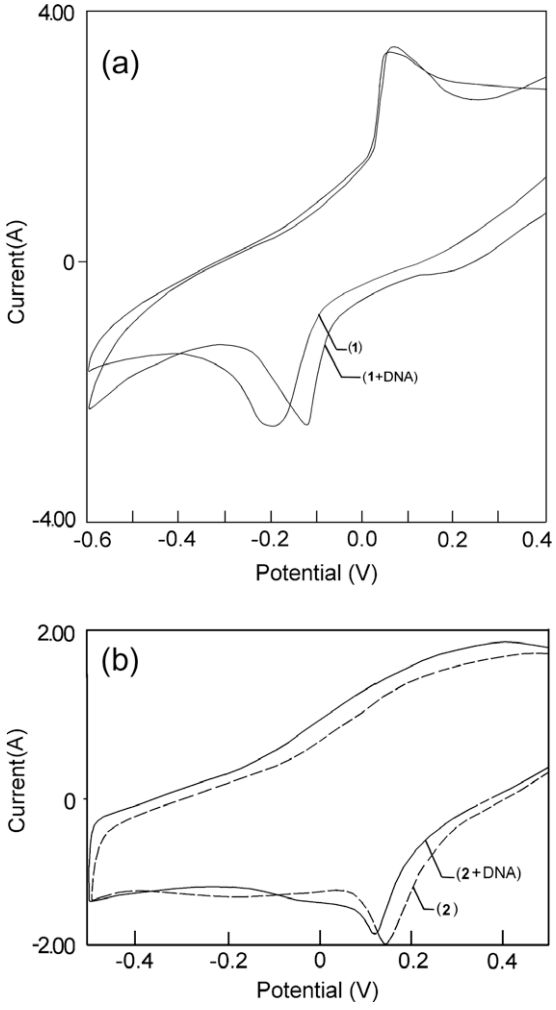

Fig. 4. Cyclic voltammograms showing changes in peak position of (a) **1** and (b) **2** upon addition of CT-DNA.

where C_D and C_O are the concentrations of CT-DNA and the complexes at various stages of the titration, respectively, and ΔA is the change in absorbance upon adding DNA to the complex solution. A plot of $1/\Delta A$ versus $1/(C_D - C_O)$ gave $1/\Delta A_{max}$ from its intercept and $1/K_{app}\ \Delta A_{max}$ from its slope. The K_{app} value obtained for **1** was $2.048 \times 10\ M^{-1}$ (±0.006) and for **2** with CT-DNA $1.644 \times 10^4\ M^{-1}$ (±0.008). The hypochromism and higher binding constant value for **1** with DNA may indicate it has a stronger interaction with DNA [13].

The CD spectral analysis is very useful when it comes to the investigation of morphological changes in DNA double strands due to the interaction with small molecules. The band at 275 nm, due to base stacking, and at 246 nm, due to right handed helicity of the strands, are very sensitive towards the interaction with such small molecules. Any change in the base stacking pattern or the helicity of the strands is manifested by either a change in the band position, the intensity, or both. A simple electrostatic interaction or groove binding has nearly no or a very insignificant effect on the band at 275 nm, whereas the same band undergoes considerable change in intensity due to intercalation by small molecules [36,37]. In this case the CD spectra of CT-DNA in the presence of both **1** and **2** showed a considerable increase in the intensity of the band at 275 nm, whereas the band at 248 nm did not show any significant change (Fig. 6). The intensity increase of the band at 275 nm was less pronounced for **1** than for **2**. This indicates that both **1** and **2** might interact with the DNA double strands by the intercalative mode between the base pairs of DNA strands without any significant change in the right handed helicity of the DNA.

EthBr is a well known DNA intercalator with a very high DNA binding constant [$K_{EthBr} \sim 10^7\ mole^{-1}$] [38]. On its own, it has no emission band at 618 nm when excited at 510 nm, but when it intercalates with DNA a strong fluorescence emission is observed at 618 nm when excited at 510 nm [38]. If the complexes under test could intercalate with the DNA base pairs more strongly than EthBr, then successive addition of **1** and **2** will show a progressive decrease in the intensity of this emission [38]. When solutions of **1** and **2** were added to a solution containing DNA and EthBr in a 50:1 mmolar ratio, even in large excess, there was no change in the fluorescence intensity of the original solution. Even when $[complex]_{Tot.}/[DNA]_{Tot.}$ was 1.5, the intensity of the fluorescence band due to intercalation of EthBr with DNA did not show any reduction. So the probe for the binding mode of the complexes with DNA involving EthBr assay did not yield any specific result.

3.5.3. Viscosity measurement

With the addition of some small molecules (like ethidium bromide), the viscosity of a DNA solution may increase with an increase in the concentration of the former additive. This is because of the fact that the small molecules intercalate between the DNA base pairs and lengthen it, and thus raise the viscosity of the solution containing DNA. On the other hand a molecule which binds to the grooves of DNA does not alter the viscosity of the DNA on addition to the DNA solution [e.g. Hoechst 33258]. Lastly, if the viscosity of DNA solution decreases with the addition of an additive, then it indicates non-classical interactions like the formation of bend or kinks in the double helical structure [39,40]. In the present case, the relative viscosities of the DNA solutions decreased progressively with progressive increase in the concentrations of both **1** and **2**. The initial drop of relative viscosity upon addition of the Cu(II) complexes for **1** was more pronounced than for **2**. For **2** the viscosity of DNA decreased steadily with the rise in concentration of **2**, whereas the same for **1** remained nearly unaltered for quite a large concentration interval after the initial drop, after which the viscosity of DNA solution showed a marked decrease upon addition of further aliquots of **1**. In Fig. 7 η/η_o is plotted against [Complex]/[DNA], where η is the relative viscosity of a solution of DNA solution containing a definite concentration of either **1** or **2** and η_o is the relative viscosity of DNA solution only. This proved that **1** and **2** interact with DNA double strands via a non-classical interaction mode.

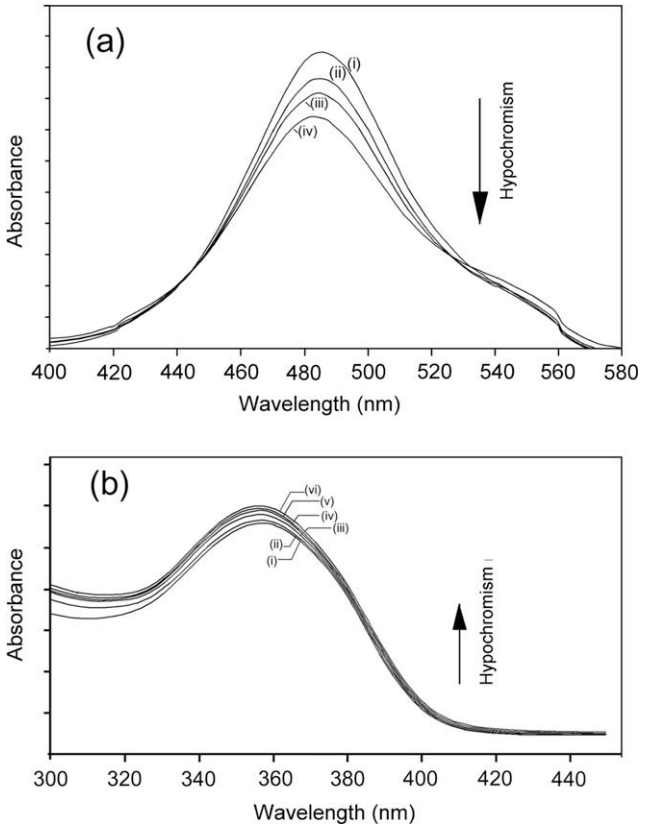

Fig. 5. Changes in the absorption spectra of (a) **1** and (b) **2** on titration with increasing CT-DNA concentration (0–50 μM).

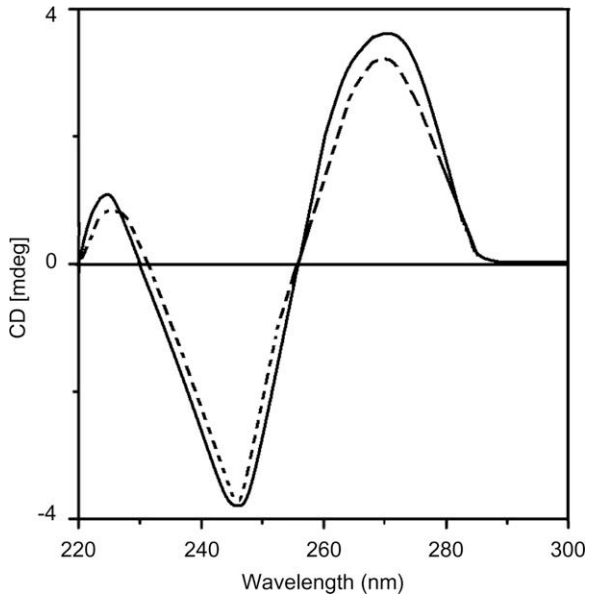

Fig. 6. CD spectra of CT-DNA (dashed line) and CT-DNA + **2** (solid line) in 5 mM Tris–50 mM NaCl buffer (pH ~7.5).

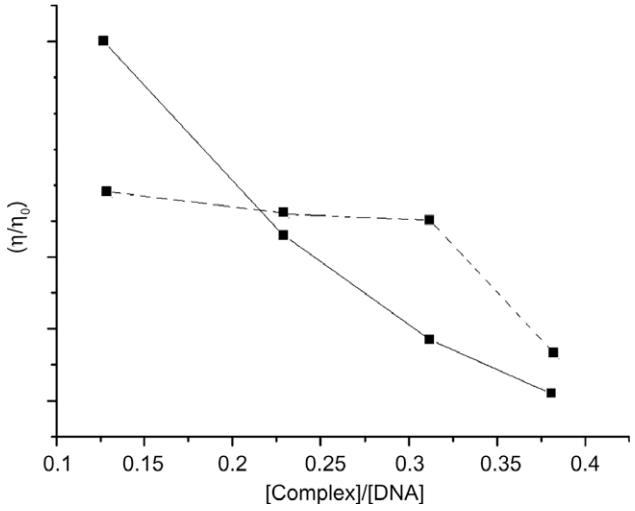

Fig. 7. The plot showing the effect of increasing concentrations of **1** and **2** on the viscosity of DNA. The dotted line shows the variation of viscosity of DNA with increasing concentration of **1** whereas the solid line shows the same effect for **2**.

3.6. DNA cleavage study

The effect of both **1** and **2** on SC plasmid DNA pUC19 in the presence of H_2O_2 and other additives have been investigated by agarose gel electrophoresis. In a typical reaction mixture 0.5 μg of the SC DNA was mixed with different concentrations of the complexes and H_2O_2 in a total volume of 15 μL and these solutions were incubated at 37 °C for 1 h. The electrophoresis was carried out at 100 V for 2 h and the bands were stained with ethidium bromide and visualized under UV light. The different bands were compared with the un-cleaved SC DNA control [the composition of various lanes for both the gels are depicted as footnotes to Figs. 8a and 9a).

For **1** and **2**, in the presence of H_2O_2, with a variation of the concentration from 10 to 30 μM, the cleavage of the super coiled form increased (Figs. 8 and 9, lane 3–7), yielding the nicked circular form for **1** and both the nicked circular form and the linear form for **2** in a regular dose dependent manner. At the highest dose of the complexes [30μM] in the presence of H_2O_2, **2** showed a nearly four times greater ability to cleave pUC19 than **1** (Figs. 8b and 9b, lane 7), and thus is a far better choice as a chemical nuclease. Both were seen to be nearly completely inactive to cleave DNA in the absence of H_2O_2, as is evident from lane 8 of Figs. 8 and 9. The effect of the ligand alone on pUC19 is insignificant in comparison to both the complexes. This proves the cooperative increase of nuclease activity of **1** and **2** after complexation of the ligand with Cu(II).

The hydroxyl radical quencher DMSO and the singlet oxygen quencher sodium azide have different effects towards the cleavage activities by **1** and **2**. For **1**, both of these two quenchers are seen to have an effect reducing the cleavage of the super coiled form of the DNA (Fig. 8a lane 10 and 11). This indicates that the cleavage activity of **1** is produced by the generation of reactive oxygen species (ROS) in solution in the presence of H_2O_2. For **2**, these two quenchers have no effect on the cleavage activity of the plasmid super coiled DNA (Fig. 9a lane 11 and 12), and thus it could be concluded that the oxidative DNA cleavage for **2** takes place via a mechanism which does not involve diffusible hydroxyl radicals or singlet oxygen.

3.7. Antimicrobial study

The antimicrobial activity of **2** against *Staphylococcus aureus* and *Escherichia coli* showed MIC values ranging from 50 to 100 μg/ml. The activity against yeast was not significant (EC_{50} > 400 μg/ml) (Table 5). **1** and the free ligand show no significant activity against the same strains of microbes. The trend in antimicrobial activity can be correlated to the respective compound's DNA cleavage activity. **2** being the most potent chemical nuclease among **1**, **2** and the free ligand LH, showed maximum antibacterial activity.

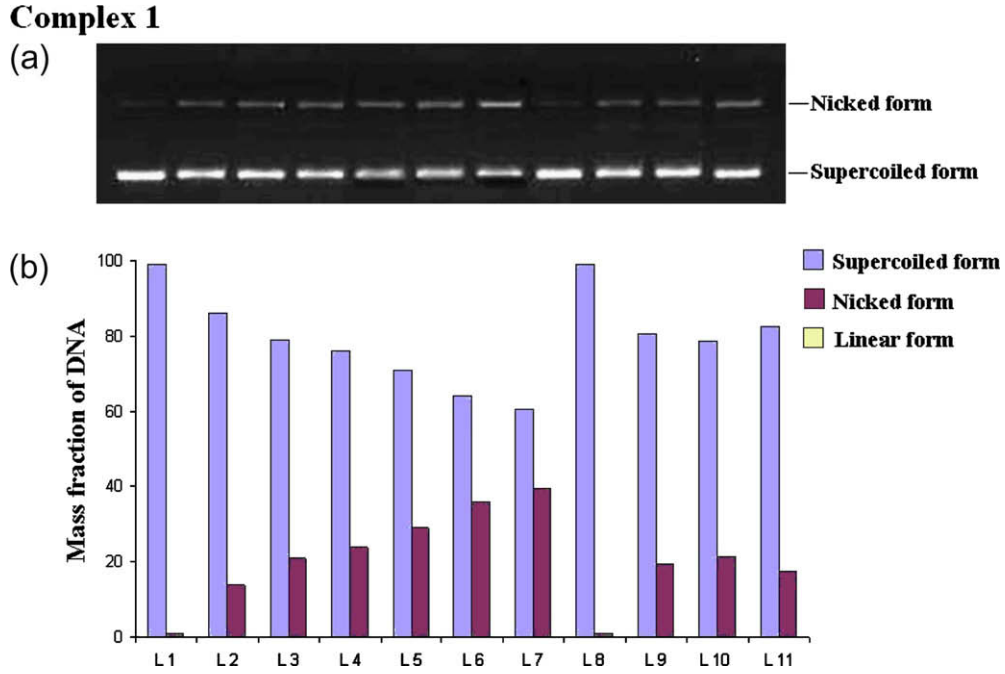

Fig. 8. Agarose gel electrophoresis diagrams and corresponding histograms showing cleavage of SC pUC19 DNA(0.5 μg) by **1** in a dose and time dependent manner in Tris–HCl/NaCl (50 mM, pH 7.2), Lane1: DNA control, 2: DNA + H_2O_2 (60 μM), 3: DNA + H_2O_2 + **1** (10 μM), 4: DNA + H_2O_2 + **1** (15 μM), 5: DNA + H_2O_2 + **1** (20 μM), 6: DNA + H_2O_2 + **1** (25 μM), 7: DNA + H_2O_2 + **1** (30 μM), 8: DNA + **1** (20 μM), 9: DNA + H_2O_2 + LH(20 μM), 10: DNA + H_2O_2 + **1** (20 μM) + DMSO (μL), 11: DNA + H_2O_2 + **1** (20 μM) + NaN_3 (4 mM).

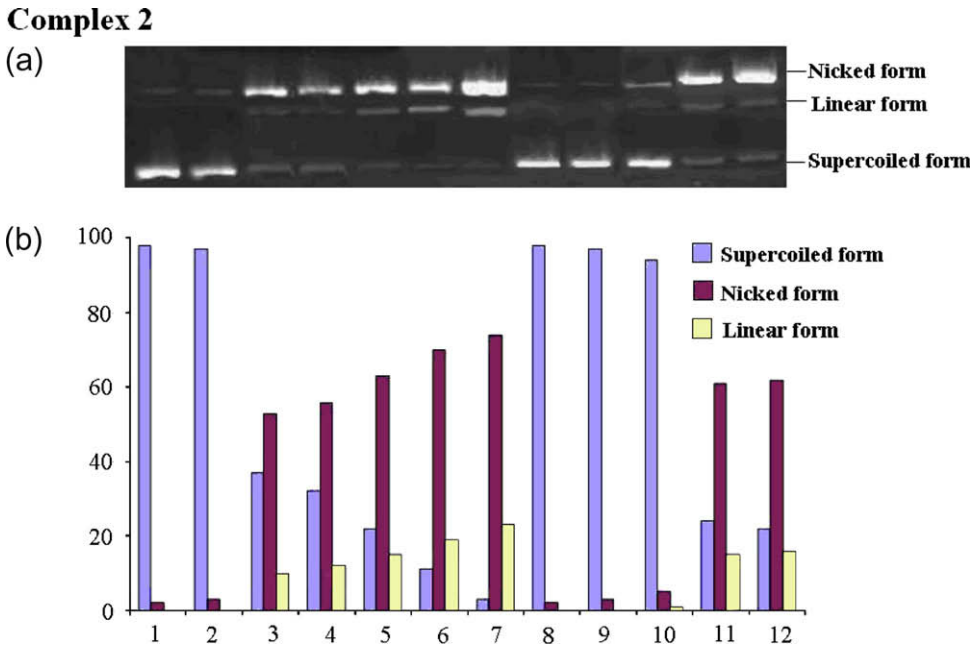

Fig. 9. Agarose gel electrophoresis diagrams and corresponding histograms showing cleavage of SC pUC19 DNA(0.5 μg) by **2** in a dose and time dependent manner in Tris–HCl/NaCl (50 mM, pH 7.2), Lane1: DNA control, 2: DNA + H_2O_2 (60 μM), 3: DNA + H_2O_2 + **2** (10 μM), 4: DNA + H_2O_2 + **2** (15 μM), 5: DNA + H_2O_2 + **2** (20 μM), 6: DNA + H_2O_2 + **2** (25 μM), 7: DNA + H_2O_2 + **2** (30 μM), 8: DNA + **2** (20 μM), 9: DNA + H_2O_2 + Cu(II) (20 μM), 10: DNA + H_2O_2 + LH(20 μM), 11: DNA + H_2O_2 + **2** (20 μM) + DMSO (μL), 12: DNA + H_2O_2 + **2** (20 μM) + NaN_3 (4 mM).

Table 5
MIC values of **2** against different microorganisms.

Microorganisms	MIC (μg/ml)
Escherichia coli MTCC 739	50–100
Staphylococcus aureus MTCC 96	50–100
Saccharomyces cerevisiae MTCC 170	EC_{50} > 400

This fact is again supported by the point that **2** showed more activity against recombination deficient bacterial strain *E. Coli* $DH_{5\alpha}$, indicating that **2** might have DNA damaging activity.

4. Discussion

In the free pro-ligand fragment, HPBH, both the aromatic rings can rotate freely and thus may not favour their interaction with DNA base pairs, whereas for both the complexes at least the pyridyl rings get fixed due to their coordination to the metal centres [Supplementary Fig. S1]. Thus the complexes can now easily interact and even intercalate within the DNA base pairs. This could be one of the reasons why the ligand did not show any binding ability with DNA double strands whereas both the complexes did. The reason why complex **2** showed higher nuclease activity than **1** could be attributed to the presence of coordinatively unsaturated Cu(II) centers in **2** in comparison to **1**. The reason why complex **2** showed higher antimicrobial activity than both **1** and the free ligand HPBH could be attributed to the higher nuclease activity of **2** in comparison to both **1** and the free ligand.

5. Conclusion

By choosing proper experimental conditions, we have been able to synthesize an azido bridged dinuclear hydrazone Cu(II) complex, **2**, from its mononuclear precursor **1**. From the structural description it is clear that the pyridyl N and the enolato O in **2** have shorter bond distances with the Cu(II) ions than in **1**. More over the axial bond in **2** is much longer than all the bond lengths in **1**. Both complexes showed moderate binding ability with CT-DNA, though with respect to their chemical nuclease activity or antimicrobial activity **2** was found to be a far better choice than **1**. This difference in activity in going from the mononuclear to the dinuclear complex could be attributed to the presence of coordinatively unsaturated Cu(II) centers in **2** in comparison to **1**. Antimicrobial studies using **2** against Gram positive, Gram negative bacteria and yeast showed a good degree of inhibition of bacterial growth. Complex **2** has DNA binding and cleavage properties as is mentioned and is more active towards a recombination deficient bacterial strain, indicating the cell inhibitory effect has its origin in it's greater nuclease activity.

Scheme 1. Structure of aminopyrazine, (ampyz) and 2,3-pyrazinedicaroxamide, (pyzdic).

2,3-pyrazine dicarboxamide were purchased from Sigma Aldrich Company.

2.2. Synthesis of the complexes

2.2.1. Synthesis of $[Ag_2(amPyz)(NO_3)_2]_n$, **1**

To an aqueous solution (20 cm^3) of $AgNO_3$ (0.34 g, 2.0 mmol), 0.095 g (1 mmol) of aminopyrazine in 15 cm^3 ethanol was added dropwise under continuous stirring. A brown precipitate was formed, filtered off, and the clear filtrate was left undisturbed for a week. Very tiny brown crystals suitable for X-ray measurements were formed, collected by filtration and dried in air with a yield of 80% with respect to the ligand. *Anal.* Calc.: C, 11.05; H, 1.16; N, 16.18; Ag, 49.57. Found: C, 11.12; H, 1.10; N, 16.23; Ag, 49.20%. FT-IR, KBr (cm^{-1}) (v, very; s, strong; m, medium; w, weak; br, broad; sh, shoulder): 3331 s, br, 3153 s, br, 1646 vs, 1585 vs, 1533 s, 1481 sh, 1207 m, 1041 m, 1004 m, 822 s, 607 s, 427 m, 409 m, 388 s, 367 m, 343 m, 294 m, 270 s.

2.2.2. Synthesis of $\{[Ag(2,3\text{-}pyzdica)](NO_3)\}_n$, **2**

To an aqueous solution (20 cm^3) of $AgNO_3$ (0.34 g, 2.0 mmol), 0.34 g (2 mmol) of 2,3-pyrazinedicarboxamide in 15 cm^3 ethanol was added dropwise under continuous stirring. The clear mixture was left undisturbed for a week. Colourless needles suitable for X-ray measurements were formed, collected by filtration and dried in air with a yield of 60% with respect to the ligand. *Anal.* Calc.: C, 21.45; H, 1.80; N, 20.85; Ag, 32.11. Found: C, 22.15; H, 1.20; N, 21.34; Ag, 32.19% (the sample was not so pure). FT-IR, KBr (cm^{-1}) (v, very; s, strong; m, medium; w, weak; br, broad; sh, shoulder): 3430 vs, 3308 vs, 3198 vs, 1695 s, 1672 s, 1611 s, 1560 s, 1533 m, 1381 vs, br, 1191 m, 1102 s, 1060 m, 878 m, 823 m, 739 s, 700 s, 648 s, 343 m, 294 w, 270 s.

2.3. X-ray crystallography

Crystallographic measurements were made on a Siemens Smart CCD diffractometer with graphite monochromated Mo Kα radiation. The structures were solved by direct methods and subsequently refined by full-matrix least-squares, including anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were refined isotropically with use of geometrical restraints. The calculations were carried out with the SHELXTL program package [20]. The rocking curve width for complex **1** is 1.6° (rocking curve measures how much the molecules are ordered in the crystal structure. A narrow curve around 0.5° is an indication for good crystals).

2.4. Network analysis

The topology of the nets were established by computing the vertex symbol (extended Schläfli or long symbol) [21] with OLEX [22,23] and comparing both the symbol and the experimental net with the ideal net. The cumulative coordination sum up to the 10th sphere was calculated with the nearest neighbour function in CRYSTALMAKER 8.1.5 [24]. Abbreviations for 3D-nets have been taken from O'Keeffe and Yaghi, Reticular Chemistry Structure Resource [25], where crystallographic coordinates and other useful details for 3D-nets can be obtained.

2.5. Corrosion test

2.5.1. Preparation of the metal specimen

Commercial mild steel with chemical composition of: C, 0.37; Si, 0.23; Mn, 1.21; P, 0.021; S, 0.017; Cu, 0.016; Ni, 0.02; Cr, 0.02 and V, 0.003 wt% was employed as working electrodes. Before measurement, the specimens were ground on a series of emery papers down to 1200 grit.

2.5.2. Electrolyte

The solutions were prepared using distilled water and A.R. nitric acid. The complexes were dissolved separately in distilled water by warming and stirring for 5 min. A stock solution of 0.03 M of complex **1** and 0.01 M of complex **2** were prepared from which different concentrations were then prepared. These solutions were tested in the presence of 0.1 M HNO_3 acid at room temperature.

2.5.3. Electrochemical measurements

A three-electrode cell assembly consisting of working electrode (the mild steel to be tested with cross section area is 0.95 cm^2), counter electrode (a platinum mesh of negligible impedance) and reference electrode (saturated calomel electrode) was used for electrochemical measurements. The temperature of the electrolyte was maintained at 27 °C.

Potentiodynamic measurements have been achieved by connecting the electrochemical cell to a Wenking MP87 Potentiostate instrument. Plotting potential versus current the polarization curves (Tafel curves) were obtained. The corresponding anodic and cathodic Tafel slopes (β_a and β_c) were calculated as the slopes of these curves after corrosion potential (E_{corr}) by ±50 mV (since at the beginning of the experiment all the metals show the same corrosion behavior) using a computer least square analysis. The corrosion currents (I_{corr}) were determined as the points at which the extrapolates of both anodic and cathodic slopes cross. The sweep rate used in this study was 30 mV/min. The percentage reduction in the corrosion current (% I_{corr}) was calculated from the following relationship:

$$\%\ I_{corr} = 100 \times \left[1 - \frac{I_{corr}}{(I_{corr})_0}\right]$$

where $(I_{corr})_0$ and I_{corr} are the corrosion current for the mild steel in the absence and the presence of certain concentration of the inhibitors, respectively.

3. Results and discussion

3.1. Synthesis and IR spectral analysis

The newly synthesized complexes for this study were simply obtained through direct reaction between aqueous solutions of the metal salt ($AgNO_3$) and ethanolic solutions of different organic ligands which afforded crystalline complexes suitable for X-ray diffraction measurements. The IR spectrum of **1** shows a number of bands which can be assigned to the functional groups of the ligands as well as the coordination of the ligand to the silver ion. The two strong broad bands at 3331 and 3153 cm^{-1} are assigned to (ν_{as} NH_2) and (ν_s NH_2) vibration frequencies of aminopyrazine, respectively. The nitrate group vibration frequencies appear as a strong band at 1533 cm^{-1} and as a weak shoulder at 1481 cm^{-1} which confirm the bridging coordination of the nitrate group to

the silver (I) ions ($\mu_{O,O'}$-NO_3) [17]. In complex **2** the (ν_{as} NH_2) and (ν_s NH_2) of 2,3-pyrazinedicarboxamide appear as very strong sharp bands at 3430, 3308 and 3198 cm^{-1}. The two very strong bands found at 1695 and 1672 cm^{-1} were assigned to the vibration frequencies of the two amide carbonyl groups, (ν C=O). The nitrate vibration frequencies appear as very strong broad band, (ν_s NO_3) at 1381 and strong sharp band, (ν_{as} NO_3) at 1533 cm^{-1} [26].

3.2. Structure description

Pyrazine and its derivatives have a remarkable ability to form monomeric as well as 1D, 2D and 3D polymeric structures when reacted with silver(I) salts. This structural diversity of silver(I) pyrazino complexes is often dependent on the counter ions and the solvents used [11].

The crystal data and structure refinement for complexes **1** and **2** are found in Table 1, and the atom numbering scheme are shown in Figs. 1 and 4, respectively.

3.2.1. Structure of $[Ag_2(ampyz)(NO_3)_2]_n$, *1*

The molecules in the crystal structure are disordered and the crystals are twinned with a β angle close to 90° simulating an orthorhombic system. The twinning law is described (in SHELXL terminology) by TWIN 1 0 0 0 −1 0 0 0 −1 matrix with 0.991(3)/0.009(3) volume ratio. Silver(I) is coordinated to two NO_3 groups each through one of their O-atoms, and one aminopyrazine ligand *via* one N-atom, in a distorted trigonal planar coordination geometry, the silver(I) ion being 0.162 Å out of the plane defined by O1/N1/O3^i. Both the NH_2 group and the H2 atom connected to atoms C2 have 0.5 occupancy. The Ag–N bond distance (see Table 2) is slightly shorter than those reported for similar tri-coordinated silver(I) pyrazine complexes $[Ag_2(pyz)_3](BF_4)_2$, $[Ag_2(2,3\text{-}Me_2\text{-}pyz)_3](SbF_6)_2$ and $\{[Ag_2(pyrazine)_3](CF_3SO_3)_2{\cdot}2H_2O\}_n$ where Ag–N bond distances ranges from 2.244 to 2.500 Å [11]. Also the Ag–O bond distances are shorter than those found for [Ag(2,5-dimethylpyrazine)$(NO_3)]_n$ and $[Ag_4(3\text{-aminopyridine})_3(NO_3)_4]_n$ ranging from 2.44 to 2.58 Å [27]. The bridging $\mu_{O,O'}$-NO_3 groups connect silver(I) ions forming rather flat helices running along the *b*-axis. The $\mu_{N,N'}$-aminopyrazine ligand as bridging ligand further connects these chains to form a (6,3)-2D sheet structure, with three-connected Ag^+ nodes linked by nitrate ions or pyrazine (see Fig. 2).

Strong intermolecular hydrogen bonds of the type N–H···O and also weaker C–H···O (see Table 3) extend this structure to three-dimensions. The nitrate oxygen not coordinating to silver bind to the pyrazine amine functionality, and the amine protons bind to two different nitrates in adjacent sheets, thus extending the dimensionality in the *c*-direction to give a 3D network structure. In this way also the nitrates become three-connected nodes, linking two silver ions and connected also another nitrate through the NO···H–N–H···ON hydrogen bond link.

The topology of the resulting 3D-net needs to be checked carefully to avoid possible confusion with other networks [28]. It is clear from visual inspection that the net in **1** is part of the (10,3) family (thus the connectivity at each node is three and the shortest circuit between nodes is 10), described by Wells [29] and discussed in detail by others [30–32]. Node assignment and a schematic

drawing of one of the 10-gons are depicted in Fig. 3a. As can be seen in Fig. 3b the net contains helices with alternating chirality in the rows defined by the projection on the *a*,*c*-plane. This is characteristic of the (10,3)-d or 10^3-**utp** net whose most symmetric form is shown in Fig. 3c for comparison. To further support this assignment the vertex symbol was calculated, and found to be $10_2{\cdot}10_4{\cdot}10_4$, in agreement with a **utp**-net. However, vertex symbols are sometimes not unique, and it so happens that another, more common, (10,3)-net has the same symbol, namely the **ths**-net, also known as the (10,3)-b net. In such cases the coordination sequence needs to be calculated, that is we sum all neighbours starting from a central node and usually going up to the 10th coordination sphere. This cumulated value, often referred to as the C10 or TD10 value [25], was calculated to 622 for structure **1** in agreement with the **utp** assignment and clearly different from the C10 value of 608 for the **ths**-net.

However, the network structure of **1** is complicated by the 50% disorder of the amine group, which means that this link will be absent in 25% of the network. In theory one could therefore construct a much more complicated network where some 10-gons have been replaced by 16-gons. However, the network analysis should be a tool in understanding the chemistry and such a complicated exercise would add nothing to our overall perception of the structure. In fact, one could argue that in the absence of the amine, there will be a very weak C–H···O hydrogen bond interaction. Moreover, considering the entire network with three different links from each of the two nodes, the overall effect will be that only 5% of the links in the net are missing, thus the **utp** description is nevertheless adequate. In Fig. 3d, a projection in the *b*,*c*-plane is shown of both the network and all atoms in the structure. In this plot the 50% disorder has been dealt with by removing every second amine group in a regular fashion.

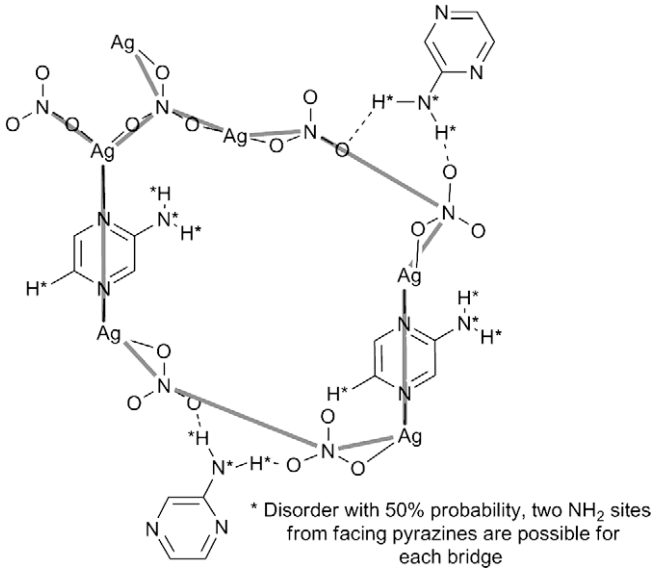

Fig. 3a. Schematic drawing of $[Ag_2(ampyz)(NO_3)_2]_n$, **1** showing one of the (10,3) rings (the nitrates and the silver ions are three-connected nodes).

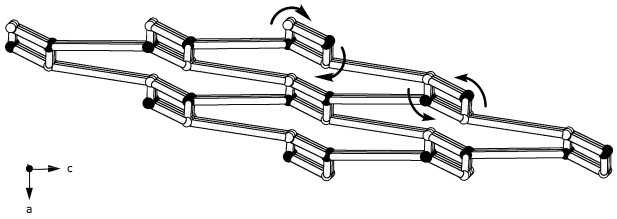

Fig. 3b. A perspective view of $[Ag_2(ampyz)(NO_3)_2]_n$, **1** on the *a*,*c*-plane showing helices superimposed on the entire structure.

3.2.2. Structure of {[Ag(2,3-pyzdic)](NO$_3$)}$_n$, ***2***

The silver(I) ion is linearly coordinated to two 2,3-pyrazinedicarboxamide each *via* the bridging $\mu_{N,N'}$-pyrazine ring thus forming 1D chains, Fig. 5a. The Ag–N bond distances (Table 4) are longer than the normal range reported for similar linear silver(I) pyrazine complexes; $[Ag(pyz)](BF_4)$ and $[Ag_2(C_{20}H_{28}N_2)_2(NO_3)_2{\cdot}1.5MeOH{\cdot}H_2O]_n$ (2.187(3)–2.260(5) Å) and the bond angles are also smaller than

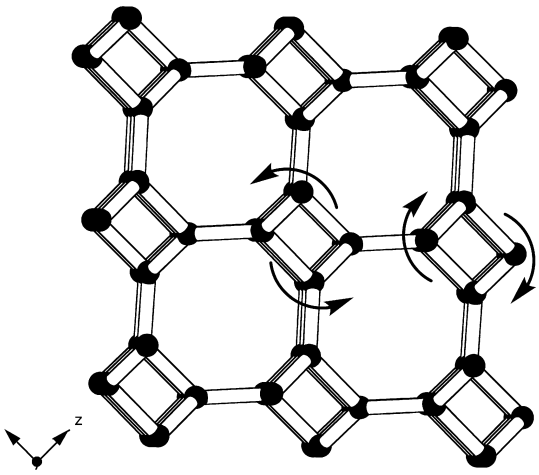

Fig. 3c. Ideal 10^3-**utp** net.

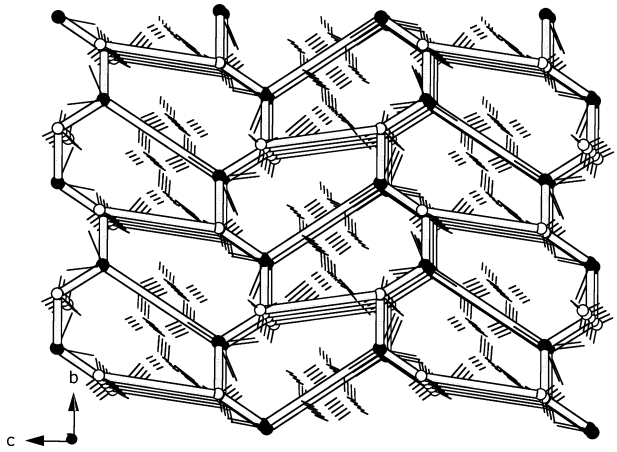

Fig. 3d. A perspective view of $[Ag_2(ampyz)(NO_3)_2]_n$, **1** on the *b*,*c*-plane showing all atoms and network in the structure.

reported for these compounds (173.6(2) and 173.80(14)°) [11]. These longer bond distances and smaller angle are attributed to strong interamolecular hydrogen bonding, N8–H8B···O7^{iv} between the two carboxamido groups of each two adjacent ligand moieties. Strong interactions are also found between the silver(I) ion and both the nitrate oxygen atom and the carboxamido group oxygen atom of the above chain ligand. These interactions in addition to strong intermolecular N–H···O hydrogen bonding (Table 5) are responsible for the extension of the structure to form a 3D network, Fig. 5b. In contrary with complex **1**, however, this network does not reveal any easily recognizable 3D-net. While a network analysis is, in principle, always possible, this structure needs to be described by at least three different nodes, and in addition the possibility of Ag–O bonds complicates the matter further. We thus conclude that such an analysis will not lead to a better understanding of the structure and refrain from pursuing this point further.

3.3. Corrosion test

The potentiodynamic polarization curves (Tafel curves) for mild steel in 0.1 M nitric acid, using different concentrations of $[Ag_2(ampyz)(NO_3)_2]_n$, **1** and $\{[Ag(pyzdic)](NO_3)\}_n$, **2**, at room temperature are presented in Fig. 6a and b, respectively. Corrosion currents were determined by the intersection of the cathodic and anodic Tafel lines and open-circuit potential. The electrochemical parameters for the used inhibitors obtained from their polarization curves are summarized in Table 6. Fig. 7 shows the corrosion inhibition efficiencies (represented as the surface coverage θ) as a function of inhibitor concentrations. An increase in the surface coverage and corrosion inhibitory effect is observed with increasing concentration.

3.3.1. Corrosion inhibition

Tafel lines of approximately equal slopes [16] indicate that both complexes have both cathodic and anodic inhibitory effects in 0.1 M HNO_3 media [33]. E_{corr} are shifted to more anodic values as the concentrations of both inhibitors were increased. This means that the inhibitor molecules were adsorbed on the metal surface and behaved as mixed type inhibitors with dominant anodic inhibitory action [34,35]. Corrosion current, I_{corr} decreases with increasing inhibitors concentrations [36,37]. A concentration of 10^{-4} M of complex **1**, $[Ag_2(ampyz)(NO_3)_2]_n$, gives 37% inhibition efficiency, while the same concentration, 10^{-4} M of complex **2**, $\{[Ag(pyzdic)](NO_3)\}_n$, gives only 10% inhibition efficiency. This increased activity of complex **1** at low concentrations can be explained on the basis of structure activity relationship. The *O*,*O*′-bridging nitrates present in the

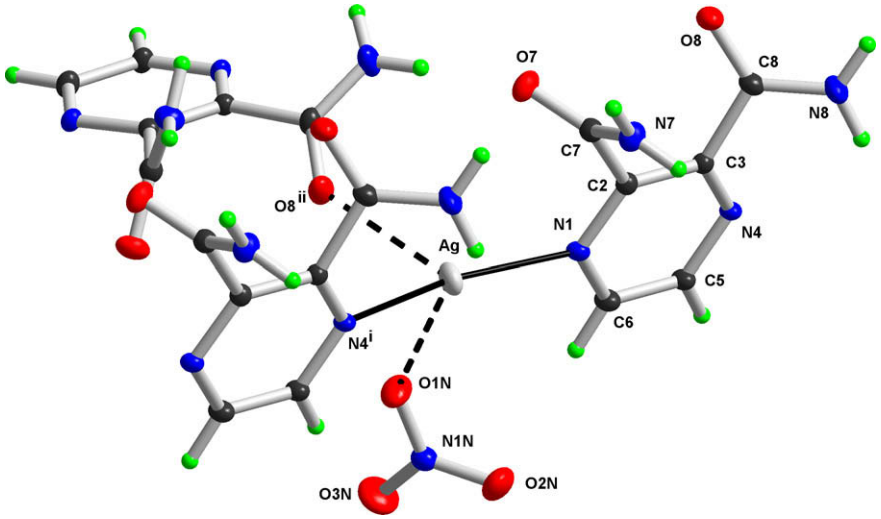

Fig. 4. Numbering scheme with atomic displacement ellipsoids drawn at 50% probability level for $\{[Ag(2,3\text{-pyzdic})](NO_3)\}_n$, **2**. The close Ag–O contacts are shown as broken lines. For symmetry codes see Table 4.

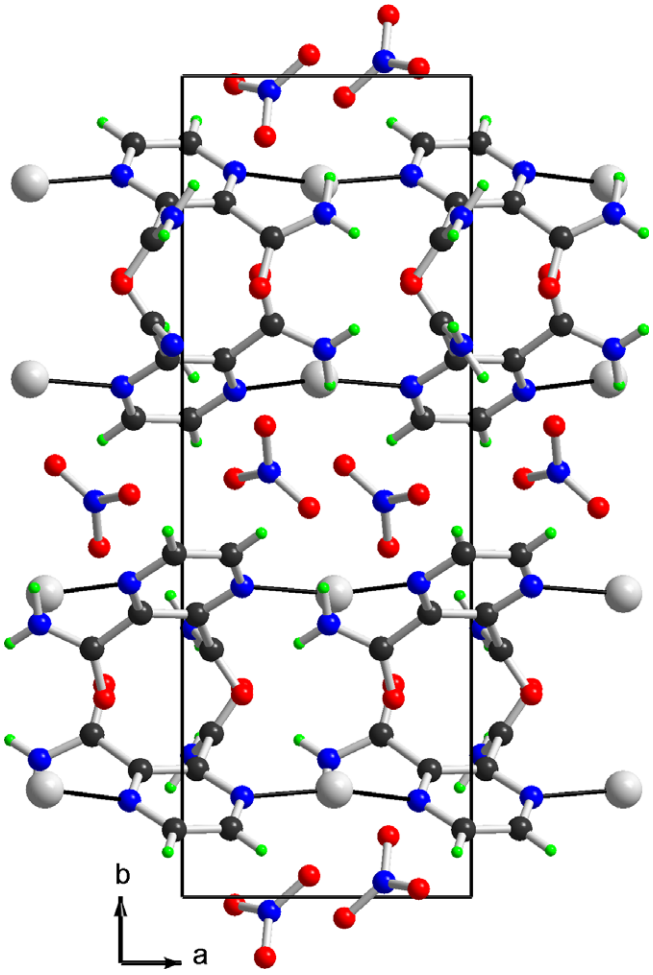

Fig. 5a. Projection of the content of the unit cell along the *c*-axis of {[Ag(2,3-pyzdic)](NO$_3$)}$_n$, **2**. 1D chains are built up in the *a*-direction.

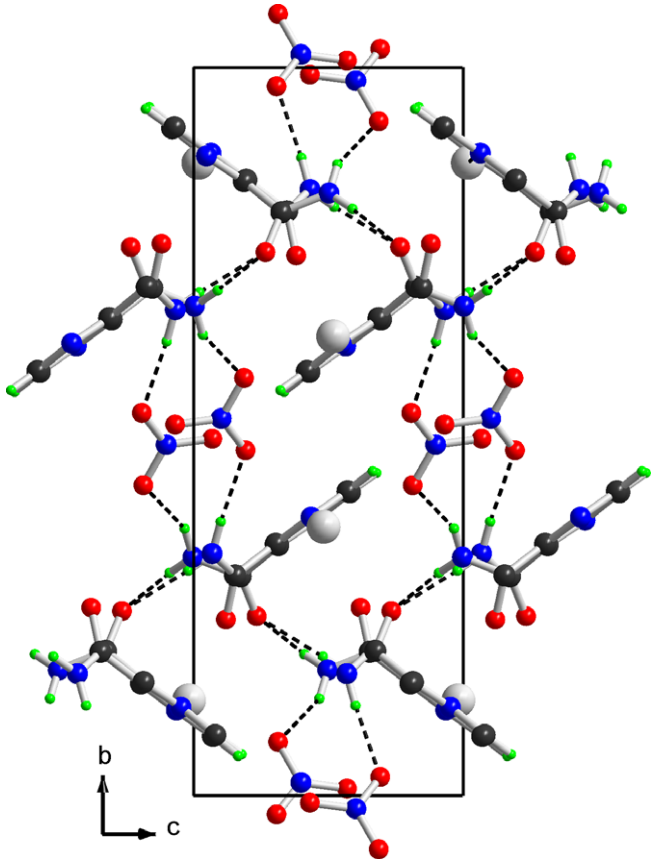

Fig. 5b. Projection of the content of the unit cell along the *a*-axis of {[Ag(2,3-pyzdic)](NO$_3$)}$_n$, **2**. An extensive hydrogen bonding pattern is built up in the *b*,*c*-plane, thus supporting the 3D crystal structure.

structure of complex **1** are oxidizing passivating inhibitors which cause a large anodic shift of the corrosion potential due to the formation of different oxides [38]. The nonporous chromium oxide then protects the mild steel surface from further corrosion at higher inhibitor concentrations (see Fig. 6a), and a cathodic shift of the corrosion current is recognized. Complex **2** has non-coordinated nitrate groups, which can be solvated easily, so their effects are minimized in low concentrations. Also the presence of lone pairs of electrons on both pyrazine nitrogen atoms and on the amino group nitrogen atom enhances the adsorption of both inhibitors to the mild steel surface. Maximum corrosion inhibition efficiencies are 68% for 2×10^{-3} M of complex **1** and 50% for 10^{-3} M of complex **2**. These results are comparable to those reported for 4-aminopiperidine and piperazine free ligands in perchloric acid medium, which were 63.54% and 62.03%, respectively [39].

3.3.2. Adsorption isotherms

Different equations have been developed to model surface adsorption, and in this present investigation two of these were used.

The Langmuir adsorption isotherm is described by

$$\left[\frac{\theta}{(1-\theta)}\right] = KC \qquad (1)$$

in which K is the equilibrium constant of the adsorption reaction, C is the inhibitor concentration in bulk of the solution and θ can be obtained from Eq. (2) as:

	1×10^{-3} M	−450	0.35	32	32	50

$$\theta = \frac{1 - R_{inh}}{R_0} \quad (2)$$

In this expression (R_{inh}) and (R_0) are the corrosion rates in the presence and absence of the inhibitor, respectively. Only complex **2** (Fig. 8a) fits to the Langmuir equation with equilibrium constant of adsorption, $K = 898$.

The kinetic-thermodynamic model is somewhat more elaborate, as can be seen in the below equation:

$$\log\left[\frac{\theta}{(1-\theta)}\right] = \log K' + y \log C \quad (3)$$

Here, K' is a constant related to the binding constant K, by the following relationship, in Eq. (4), where y is the number of inhibitor molecules occupying one active site and $1/y$ represents the number of active sites of the surface occupied by one molecule of the inhibitor.

$$K = K'^{1/y} \quad (4)$$

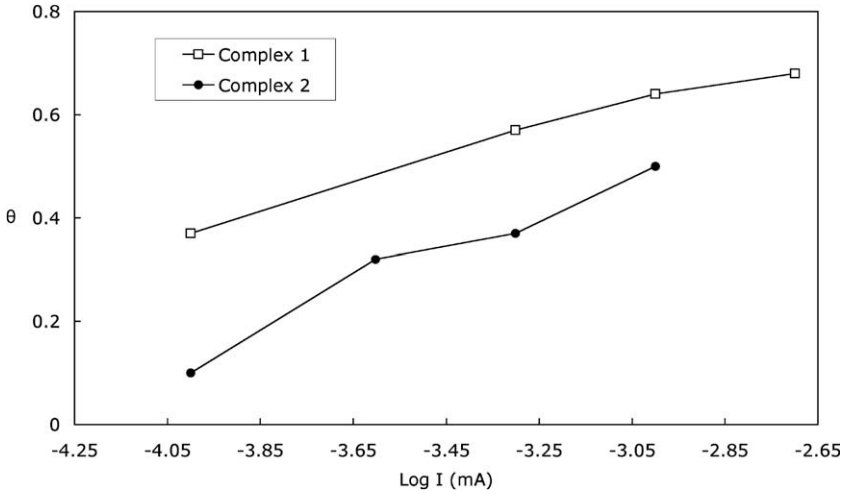

Fig. 7. Plot of inhibition efficiency against inhibitor concentrations.

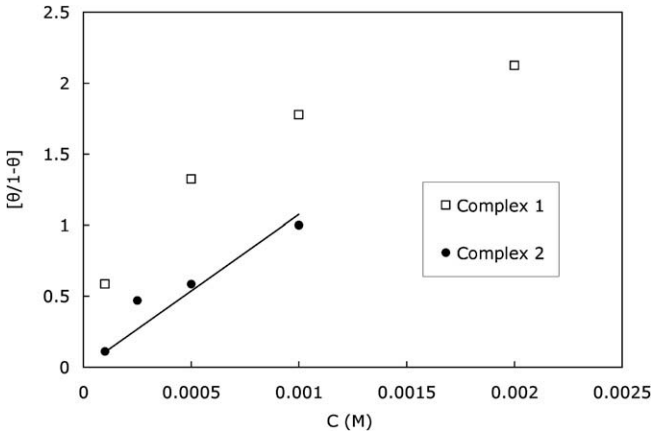

Fig. 8a. Langmuir adsorption isotherms, where only complex **2** fits to Langmuir equation with equilibrium constant of adsorption, $K = 898$.

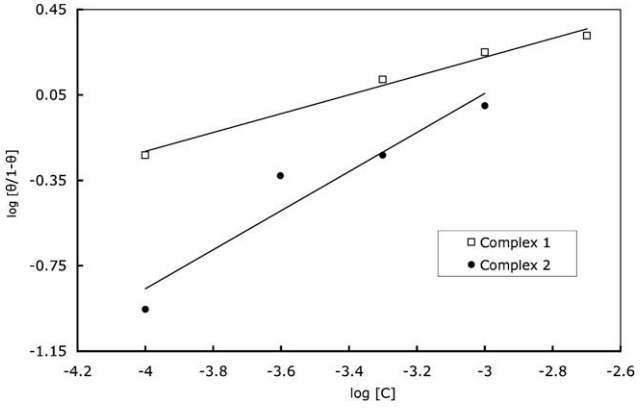

Fig. 8b. Both complexes **1** and **2** fit the kinetic-thermodynamic model, with binding constants $K = 3263$ and 1147, respectively.

Both complexes **1** and **2** (Fig. 8b) fit to the kinetic-thermodynamic model. For complex **1**: $y = 0.44$ and $1/y = 2.27$. This means that more than one layer of the inhibitor are adsorbed on the surface of the steel. The binding constant, $K = 3263$ indicates a strong interaction between the inhibitor molecules and the surface. In case of complex **2**, $y = 0.92$, $1/y = 1.09$ and the binding constant $K = 1147$, which indicates that multilayer inhibitor molecules are also formed on the surface of the mild steel, but with weaker binding interaction than complex **1**. This value of binding constant for inhibitor **2** agrees with the value of equilibrium constant of adsorption for the same inhibitor calculated from Langmuir adsorption isotherm. The high negative values of Gibb's free energies for complexes **1** and **2** are $-20\,009$ and $-17\,402$ kJ K^{-1} mol^{-1}, respectively; indicate that both complexes are chemically adsorbed on the surface of the mild steel used.

4. Conclusion

The results obtained in the present study allow us to draw the following conclusions: (i) The inhibition efficiency measured through electrochemical tests can reach about 68% for inhibitor **1** at concentration of 2×10^{-3} M at 27 °C and about 50% for inhibitor **2** at concentration of 1×10^{-3} M. (ii) The electrochemical results obtained from potentiodynamic polarization indicate that the inhibitor molecules were adsorbed on the metal surface and behaved as mixed type corrosion inhibitors with dominant anodic inhibitory action for mild steel in nitric acid medium. (iii) The free energy changes indicate chemisorption mechanisms for both complexes on the surface of the mild steel used.

5. Supplementary data

CCDC 712117 and 712118 contain the supplementary crystallographic data for compounds **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

tetrakis-acetonitrilecopper(I) hexafluorophosphate [20] were synthesised according to established procedures. Dry KBr for FTIR was supplied in small sachets by Thermo Fisher. All other reagents were obtained commercially as ACS grade and used without further purification. IR spectra were recorded on a Bruker TENSOR 27 spectrometer. Single crystal X-ray diffraction data were collected on a Bruker CCD-1000 diffractometer with Mo Kα radiation. Thermal data (TGA) were measured on a Perkin Elmer TGA 7, CHN analyses were performed using a Perkin Elmer 2400 CHNS Analyzer, and analyses for Mo and Cu were obtained using ICP-OES at the Forschungzentrum Jülich (Jülich, Germany) ZCH elemental analysis service.

2.2. Preparation of $[Cu(CH_3CN)_4]_2[Mo_8O_{26}Cu_2(CH_3CN)_4]$ (**1**) and $[Cu(CH_3CN)_4]_4[Mo_8O_{26}]\cdot 2CH_3CN$ (**2**) and their decomposition to $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16H_2O$ (**3**)

tetrakis-Acetonitrilecopper(I) hexafluorophosphate (0.428 g, 1.14 mmol) was added to a solution of tetrabutylammonium dimolybdate (0.40 g, 0.51 mmol) in acetonitrile (20 mL), resulting in instantaneous production of a yellow–brown precipitate. After reflux for 3 days under an inert atmosphere the resulting suspension was hot filtered to give a pale green solution. Crystallisation by diffusion of diethyl ether into the acetonitrile solution produced red–orange crystals of β-octamolybdate **1**, and colourless crystals of **2**. Note: higher rates of ether diffusion favour crystallisation of **1**. Both **1** and **2** decompose upon exposure to air, rapidly forming a hygroscopic brown material with the stoichiometry $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16H_2O$ (**3**) (0.024 g, 0.014 mmol, 11%). While **1** and **2** could not be recovered quickly enough to record individual yields, FTIR spectra were obtained by very rapidly transferring crystals to KBr. FTIR of **1** (KBr disc): cm^{-1} 3500 (s), 2976 (w), 2927 (w), 2363 (vw), 2254 (vw), 1616 (m), 1404 (w), 1365 (w), 1046 (w), 950 (vs), 915 (vs), 848 (s), 715 (s), 666 (s), 560 (w). FTIR of **2** (KBr disc): cm^{-1} 3474 (m), 2967 (w), 2926 (w), 2363 (vw), 2254 (vw), 2135 (w), 2099 (vw), 1655 (m), 1613 (m), 1405 (w), 1365 (w), 950 (vs), 910 (vs), 846 (s), 712 (s), 672 (s), 560 (w). FTIR of **3** (KBr disc): cm^{-1} 3442 (s), 2926 (w), 1619 (m), 10 310 (w), 942 (s), 907 (s), 707 (s). Elemental *Anal.* Calc. for $C_{1.2}CuH_{33.8}Mo_8N_{0.6}O_{42}$ (**3**): C, 0.82; H, 1.94; N, 0.48; Cu, 14.52; Mo, 43.84. Found: C, 0.83; H, 1.75; N, 0.42; Cu, 14.70; Mo, 43.60%. Thermogravimetric analysis of **3** is consistent with this formula, indicating a mass loss of *ca.* 18% by 250 °C.

2.3. Synthesis of $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16H_2O$ (**3**) via $[Cu(CH_3CN)_4]_4[Mo_8O_{26}]\cdot 2CH_3CN$ (**2**)

tetrakis-Acetonitrilecopper(I) hexafluorophosphate (0.070 g, 0.19 mmol) was added to a solution of tetrabutylammonium octamolybdate (0.050 g, 0.023 mmol) in acetonitrile (5 mL), producing a yellow solution. After stirring for 7 h, the now slightly cloudy solution was filtered before vapour diffusion of diethyl ether produced colourless crystals of **2**. These rapidly decomposed upon removal from the mother liquor, producing **3** (0.031 g, 95%).

2.4. Single crystal structure determination

Suitable single crystals of **1** and **2** were mounted on the end of a thin glass fibre under ambient conditions using Fomblin oil, and X-ray diffraction intensity data were measured at 193 K on a Bruker CCD-1000 diffractometer [λ(Mo Kα) = 0.7107 Å, graphite monochromator]. For each compound, initial cell constants were obtained from three 30 frame series of ω scans at different starting angles, while final cell constants were calculated from a set of strong reflections from the actual data collection. These datasets were corrected for Lorentz and polarization effects and the absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements [21] using SADABS software [22]. Structure solution and refinement was carried out using the SHELXTL program suite [22]. Compound **1** crystallized in the space group $P\bar{1}$ and **2** in *P2(1)/n*. Both structures were solved by a combination of direct methods and difference Fourier syntheses and refined against F^2 by the full-matrix least-squares technique. Hydrogen atoms were placed in the structure factor calculation at idealized positions and were allowed to ride on the neighboring atoms with relative isotropic displacement coefficients. Crystal data, data collection parameters and refinement statistics for **1** and **2** are listed in Table 1.

3. Results and discussion

3.1. Synthesis of $[Cu(CH_3CN)_4]_2[Mo_8O_{26}Cu_2(CH_3CN)_4]$ (**1**) and $[Cu(CH_3CN)_4]_4[Mo_8O_{26}]\cdot 2CH_3CN$ (**2**); decomposition to $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16H_2O$ (**3**)

The red β-octamolybdate $[Cu(CH_3CN)_4]_2[Mo_8O_{26}Cu_2(CH_3CN)_4]$ (**1**, Fig. 1) and colourless α-octamolybdate $[Cu(CH_3CN)_4]_4[Mo_8O_{26}]\cdot 2CH_3CN$ (**2**, Fig. 3), have both been characterized by high quality crystal structures, and are formed in the same reaction between tetrabutylammonium dimolybdate and *tetrakis*-acetonitrile copper(I) hexafluorophosphate in refluxing acetonitrile. Upon removal from the mother liquor, both materials rapidly decompose (e.g. within seconds) forming insoluble, hygroscopic dark brown materials with identical FTIR spectra – thus preventing their characterization by elemental analysis or thermal techniques. FTIR spectra of **1** and **2** (see Supplementary data), which appear very similar, were obtained before complete decomposition by pipetting crystals on to a filter paper and rapidly transferring them to dry KBr. In addition to FTIR, the dark brown material has been characterized by full elemental analysis (Mo, Cu, C, H and N) and TGA to reveal the composition $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16\ H_2O$ (**3**). This indicates that **3** is formed by rapid expulsion of acetonitrile from the structure with an accompanying uptake of atmospheric water, while its insolubility suggests formation of a Cu(I) linked $\{Mo_8\}$ coordination polymer.

Octamolybdates such as **1** and **2** are typically synthesized by acidifying aqueous solutions of sodium molybdate [8], and

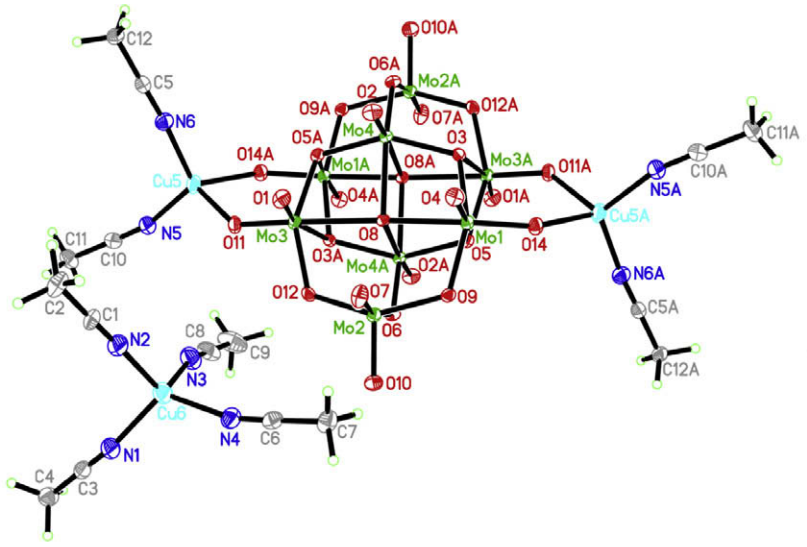

Fig. 1. ORTEP representation of the $[Cu(CH_3CN)_4]^+$ cation and $[Mo_8O_{26}Cu_2(CH_3CN)_4]^{2-}$ cluster anion in **1**. Thermal ellipsoids are drawn at the 30% probability level. C atoms are grey; N, blue; O, red; Mo, green; Cu, cyan; H atoms are white spheres of arbitrary radius. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

although we have previously observed rearrangement of hexamolybdate anions to such species upon treatment with Ag(I) [17–19], to our knowledge they have not previously been synthesized by self-assembly of small molybdate building blocks in organic media. One unusual alkoxo-substituted $\{Mo_8\}$ cluster, constructed from two weakly bridged, readily dissociated corner sharing $\{Mo_4\}$ units has previously been assembled from $(NBu_4)_2[Mo_2O_7]$ in methanol [23]. However, this is a fundamentally different type of isopolyanion to the more highly condensed α- and β-octamolybdates reported here.

The ability of our conditions to induce condensation of molybdate polyhedra may be a consequence of the Lewis acidity of Cu(I), with coordination of terminal Mo=O groups to Cu(I) activating them as leaving groups in an analogous fashion to protonation in aqueous systems. It is also worth noting that interconversion of α- and β-octamolybdates has previously been observed [24], suggesting that **1** and **2** form via a common reaction pathway. Mixtures of **1** and **2** are also obtained by refluxing α-$\{Mo_8\}$ (as $(NBu_4)_4[Mo_8O_{26}]$) and $[Cu(CH_3CN_4](PF_6)$ in acetonitrile, while compound **2** could be prepared exclusively by simple, room temperature cation metathesis of $(NBu_4)_4[Mo_8O_{26}]$ with $[Cu(CH_3CN_4]$ (PF_6), leading to a high yield (95%) of isolated **3**. This implies that the uncoordinated octamolybdate cluster **2** forms first and then, given sufficient thermal energy, displaces acetonitrile ligands from $[Cu(CH_3CN)_4]^+$ to form **1**. As such, **1** can be seen as an intermediate step in the conversion of **2** to the almost acetonitrile free Cu(I) octamolybdate **3**.

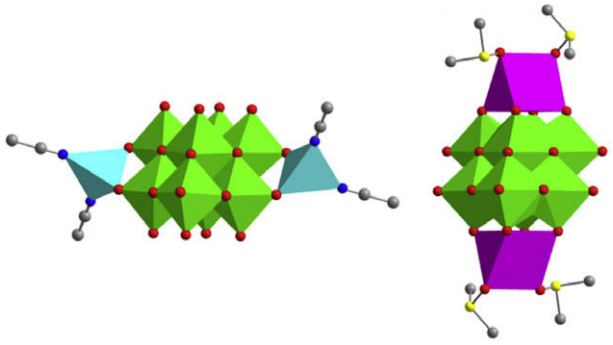

Fig. 2. Polyhedral representation comparing the derivatised β-octamolybdate anions $[Mo_8O_{26}Cu_2(CH_3CN)_4]^{2-}$ (**1**, this work) and $[Ag_2Mo_8O_{26}(dmso)_4]^{2-}$ (Ref. [17]). Colour scheme is as Fig. 1, with Ag purple, S yellow and H omitted. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.2. X-ray structural characterization

Good quality X-ray structural data were obtained for both **1** and **2**. The cluster anion in compound **1**, which crystallises in the space group $P\bar{1}$, is a β-octamolybdate cluster composed of two oxygen

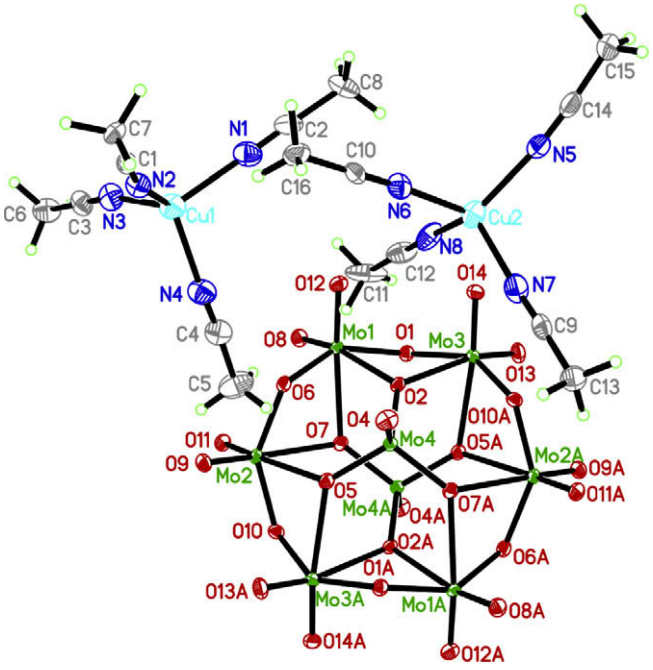

Fig. 3. ORTEP representation of the $[Mo_8O_{26}]^{4-}$ cluster anion and two crystallographically independent $[Cu(CH_3CN)_4]^+$ cations in **2**. The acetonitrile solvent molecule has been omitted for clarity. Colour scheme as for Fig. 1.

centred $\{Mo_4O_{13}\}$ units (Fig. 1) with $\{Cu(CH_3CN)_2\}$ units bound to terminal oxo positions on opposite sides of the cluster.

The cluster anion in **1** is comparable to our previously isolated $[Ag–Mo_8O_{26}–Ag]^{2-}$ synthon, $[Ag_2Mo_8O_{26}(dmso)_4]^{2-}$ [17], with terminal ligation provided by CH_3CN rather than DMSO. However, the geometries and locations of the transition metal heteroatoms in these structures are different (Fig. 2). Each Ag(I) in $[Ag_2Mo_8O_{26}(dmso)_4]^{2-}$ has a trigonal prismatic geometry and binds to four terminal Mo=O groups on the "top" or "bottom" of the cluster, while the preference of Cu(I) for tetrahedral coordination means that in **1** the two Cu(I) atoms each coordinate to two terminal oxo positions on the "sides" of the cluster. In this way, the β-octamolybdate cluster in **1** is comparable to a number of transition metal derivatised β-octamolybdates. However, these clusters typically feature completely oxidized transition metals with terminal coordination sites occupied by more strongly binding amine ligands such as example di-2-picolylamine [25] or 1,10-phenanothroline [26]. As such, **1** can be seen as an isolated, reactive intermediate cluster or "synthon" – with its propensity to form networks indicated by the rapid formation of the presumed coordination polymer $Cu_4[Mo_8O_{26}]\cdot 0.6CH_3CN\cdot 16H_2O$ (**3**) upon removal from acetonitrile saturated environments.

In **1**, the β-$\{Mo_8\}$ cluster is formed by two $\{Mo_4O_{13}\}$ units which are connected off centre to each other with the central μ5-oxo position (O8) of each $\{Mo_4O_{13}\}$ unit positioned directly above/below one of the surrounding Mo atoms (Mo4) of the other tetramolybdate subunit, Mo–O distances are displayed in Table 2. A further six bridging oxo ligands complete the link between the equatorial coordination sites of each $\{Mo_4O_{13}\}$ unit and the axial coordination sites of its partner. The two symmetry related Cu(I) atoms each coordinate to two terminal oxo sites, with a slight lengthening of the Mo–O distances indicating a corresponding weakening of the Mo–O double bond character (Table 2). While bond valence sum calculations [27] suggest roughly equal probabilities for a fully oxidized molybdate cluster coordinated to Cu(I), or a mixed valence cluster coordinated to Cu(II), the *pseudo*-tetrahedral Cu coordination environment provides a clear indicator that copper is in the +1 oxidation state. Slight distortion from idealized tetrahedral geometry is indicated by the tight O–Cu–O angle (87.9(2)°) resulting from coordination to the molybdate oxygen sites, while the terminal acetonitrile ligands coordinate with Cu–N distances that are slightly shorter than those observed in the accompanying $[Cu(CH_3CN)_4]^+$ cation (Table 1). Nonetheless, these ligands appear to be highly labile, as indicated by expulsion of acetonitrile in the ambient atmosphere leading to formation of **3**. The extended structure of **1** is constructed from layers of molybdate clusters running parallel to the crystallographic *ab* plane, separated by layers of $[Cu(CH_3CN)_4]^+$ cations; note that the numerous short contacts between the acetonitrile ligands and molybdate oxygens (C···O distances ranging from *ca.* 2.94 to 3.18 Å) may be responsible for the distortion observed in the $[Cu(CH_3CN)_4]^+$ cation (two large N–Cu–N angles of 119.9(2) and 117.4(2)°).

Compound **2** crystallises in $P2(1)/n$ and is simply an α-$[Mo_8O_{26}]^{4-}$ cluster anion accompanied by $[Cu(CH_3CN)_4]^+$ cations. The α-octamolybdate cluster anion in **2** can be viewed as an $\{Mo_6O_{18}\}$ belt capped by two $\{MoO_4\}$ tetrahedra (Fig. 3); selected bond lengths and angles are shown in Table 3. There are two crystallographically independent $[Cu(CH_3CN)_4]^+$ positions present with Cu–N distances ranging from 1.975(9) to 2.021(9) Å. More significant distortion is observed in the N–Cu–N bond angles of these *pseudo*-tetrahedral cations, which range from *ca.* 100 to 120°. Such distortion is to be expected from the combination of such coordinatively flexible d^{10} metal cations with large molybdate anions capable of exerting substantial crystal packing forces. In the extended structure, alternating layers of octamolybdate clusters and cations/solvent propagate parallel to a plane described by the crystallographic *b* axis and a line intersecting *c* at 31.68°.

4. Conclusions

$[Cu(CH_3CN)_4](PF_6)$ is capable of inducing aggregation of $[Mo_2O_7]^{2-}$ to form larger molybdate species, presumably as a consequence of the Lewis acidity of Cu(I), and also provides a source of Cu(I) that can coordinate to the resulting polyoxoanions. This is shown by the isolation of a novel $\{Cu(CH_3CN)_2\}$ derivatised β-octamolybdate cluster anion, in which the preference of Cu(I) for tetrahedral coordination results in it occupying a different coordination site on the cluster anion to the previously described $\{Ag(DMSO)_2\}$ analogue. As such, $[Cu(CH_3CN)_4](PF_6)$ is an interesting reagent for use in non-aqueous POM chemistry. In this study, the isolation of cluster anions belonging to known structural types suggests the absence of templation effects from the $[Cu(CH_3CN)_4]^+$ cation, in contrast to our previous work with several organic cations. This may be because the high lability of the Cu(I)–N coordination bond compared to covalent bonds, coupled with the absence of hydrogen bonding groups that can interact strongly with molybdate anions, limits the ability of this $[Cu(CH_3CN_4]^+$ to template molybdates. In future studies, we aim to use organic co-cations to help stabilise compound **1**, and exploit its reactivity as a building block for reaction with organic ligands and coordination clusters.

reported relative to TMS. Infrared spectra were obtained with a Digilab FTS 3100 Excalibur HE spectrophotometer with solid samples prepared as KBr disks. Microanalyses were obtained on a Carlo Erba EA 1108 elemental analyser.

2.3. Synthesis of [Re(dhp)(PPh_3)$_2$]I (**1**)

To a suspension of 0.100 g (115 μmol) of *cis*-[$ReO_2I(PPh_3)_2$] in 25 cm^3 of ethanol was added 0.078 g (242 μmol) of H_2dhp. After the mixture was heated under reflux for 2 h, it was cooled to room temperature and a brown precipitate was removed by filtration. Recrystallization from dichloromethane/ethanol gave brown crystals, which were suitable for X-ray diffraction study. Yield = 46% (0.063 g). *Anal.* Calc. for $C_{55}H_{43}N_3O_2P_2IRe$. 0.59 CH_2Cl_2: C, 55.50; H, 4.71; N, 3.49. Found: C, 55.31; H, 4.71; N, 3.22%. IR (cm^{-1}): ν(Re–N) 512 m, 527 m, ν(Re–O) 446 m, ν(C=N) 1596s. ^{1}H NMR(ppm): 7.68–7.56 (m, 32H), 7.52 (d, 2H), 7.31 (t, 1H), 7.15 (t, 2H), 6.97 (d, 2H), 6.82 (t, 2H).

2.4. Synthesis of [Re(dhp)(PPh_3)$_2$](ReO_4) (**1a**)

H_2dhp (0.066 g, 209 μmol) was added to a solution of *trans*-[$ReOBr_3(PPh_3)_2$] (0.100 g, 103 μmol) in 20 cm^3 methanol, and the mixture was heated under reflux for 90 min. After cooling to room temperature, a brown precipitate was collected by filtration. The mother liquor was left to evaporate slowly at room temperature, and after two days brown crystals, suitable for X-ray diffraction study, were collected. They were washed with ethanol and diethyl ether. Yield = 42% (0.055 g). *Anal.* Calc. for $C_{55}H_{43}N_3O_6P_2Re_2$: C, 51.76; H, 3.40; N, 3.29. Found: C, 51.43; H, 3.61; N, 3.52%. IR (cm^{-1}): ν(Re–N) 501 m, 529 m, ν(Re–O) 453 m, ν(C=N) 1601s, ν(Re^{VII}=O) 898vs.

2.5. Synthesis of fac-[Re(CO)$_3$(H_2dhp)Br] (**2**)

H_2dhp (0.079 g, 250 μmol) was dissolved in 10 cm^3 of toluene, and added to 0.100 g (246 μmol) of [$Re(CO)_5Br$] in 10 cm^3 of toluene. The mixture was heated under reflux for 2 h under nitrogen, and then cooled to room temperature. An orange precipitate was removed by filtration, and it was washed with ethanol and diethyl ether. Orange crystals, suitable for X-ray diffraction study, were obtained from the slow evaporation of the mother liquor at room temperature. Total yield = 69% (0.113 g). *Anal.* Calc. for $C_{22}H_{15}N_3O_5BrRe$: C, 39.59; H, 2.27; N, 6.30. Found: C, 39.16; H, 2.24; N, 6.58%. IR (cm^{-1}): ν(C≡O)$_{fac}$ 2026s, 1907s, ν(Re–N(1)) 473 m, ν(Re–N(2)) 438 m; ν(C=N) 1635s, 1598s. ^{1}H NMR (ppm): 10.48 (s, 1H), 10.39 (s, 1H), 9.43 (d, 1H), 9.38 (t, 1H), 8.59 (d, 1H), 8.18–8.46 (m, 4H), 8.12 (t, 1H), 6.86–7.32 (m, 5H).

2.6. X-ray crystallography

Intensity data collection was performed at 200 K on a Nonius Kappa CCD detector system using the ω scan technique with Mo Kα radiation. Intensities were corrected for Lorentz and polarization effects. The structures were solved by direct methods and were refined by full-matrix least-squares procedures using the SHELXL-97 package [21]. Crystal and structure refinement data for **1, 1a** and **2** are given in Table 1. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were idealized and fixed. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. [Re(dhp)(PPh_3)$_2$]I (**1**)

The compound was synthesized by the reaction of *cis*-[$ReO_2I(PPh_3)_2$] with two molar equivalents of H_2dhp in refluxing ethanol under nitrogen. The surprising aspect of this reaction is the reduction of the *cis*-dioxorhenium(V) center to rhenium(III) in the product **1**. The fact that the reaction yield is low (less than 50%) would seem to indicate that **1** may be the product of a disproportionation reaction, with perrhenate also being produced in the process, according to the equation.

$$2[ReO_2I(PPh_3)_2] + H_2dhp \rightarrow [Re(dhp)(PPh_3)_2]I + H[ReO_4] + HI$$

In order to test this assumption, we have also reacted *trans*-[ReOBr$_3$(PPh$_3$)$_2$] with a twofold molar excess of H$_2$dhp in methanol. The compound [Re(dhp)(PPh$_3$)$_2$](ReO$_4$) (**1a**) was isolated as the only product. Both **1** and **1a** are 1:1 electrolytes in DMF, and are only soluble in acetonitrile, DMSO and DMF.

The single peaks in the infrared spectrum of **1** at 446 and 1596 cm^{-1} are assigned to ν(Re–O) and ν(C=N), respectively, which illustrate the identical structural environment of the two hydroxyphenyliminomethyl fractions of the chelate dhp in the complex. The ^{1}H NMR spectrum consists of poorly-resolved broad peaks, showing paramagnetic shifts and line broadening of the signals.

The molecular structure of the complex cation of **1** is illustrated in Fig. 1. The rhenium(III) is placed on a mirror plane at the center of a distorted pentagonal–bipyramid (interestingly, the rhenium in **1a** does not lie on any symmetry element, which is due to a twist in the Re–O(1)–N(1)–Re chelate ring). The basal plane is defined by the phenolate oxygens O(1) and O(2), the imino nitrogens N(1) and N(3), and the pyridinic nitrogen N(2). The two phosphorus atoms are in *trans* axial positions.

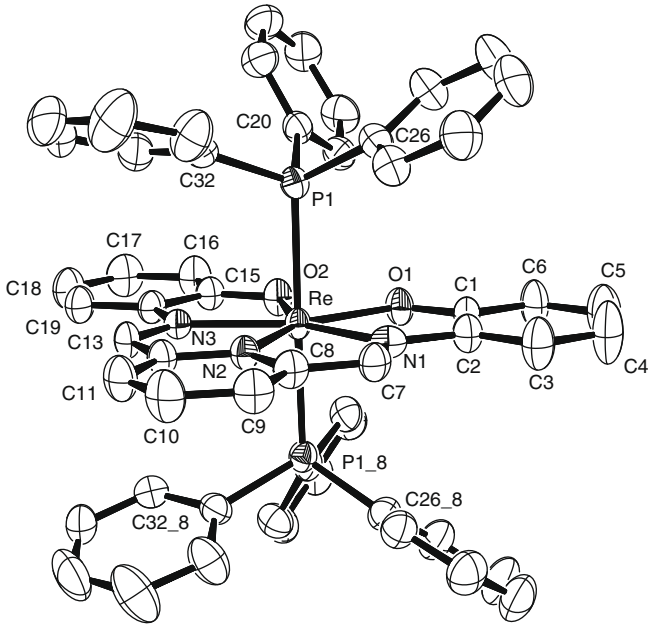

Fig. 1. Structure of the complex cation of compound **1**. The iodide, hydrogens and dichloromethane solvent of crystallization have been omitted for clarity.

Selected bond distances and angles are given in Table 2. Distortion from an ideal rhenium-centered pentagonal bipyramid in **1** mainly results in a nonlinear P(1)–Re–P(1a) axis of 172.81(3)°, with the angles P(1)–Re–O(1) = 87.87(2)°, P(1)–Re–O(2) = 86.56(2)°, P(1)–Re–N(1) = 92.18(2)°, P(1)–Re–N(2) = 93.41(2)° and P(1)–Re–N(3) = 90.04(2)°. Dhp acts as a dianionic pentadentate chelate, with the bite angles O(1)–Re–N(1) = 73.6(1)°, O(2)–Re–N(3) = 73.9(1)°, N(1)–Re–N(2) = 71.2(1)° and N(3)–Re–N(2) = 70.9(1)°. The corresponding Re–N(1) and Re–N(3) bond lengths are 2.105(4) and 2.111(4) Å, respectively, and the average Re–O bond length equals 2.073(3) Å. The observed range for rhenium(V)–imino nitrogen bond lengths is 2.03(1)–2.15(1) Å [22,23], and for Re^V–O (phenolate) the observed range is 2.015(2)–2.097(5) Å [24]. The intraligand distances are all within the expected ranges, with the N(1)–C(7) [1.311(6) Å] and N(3)–C(13) [1.312(6) Å] showing unequivocally that dhp is coordinated in the diimine, rather than the diamine, form.

The bond parameters of **1a** are similar to those in **1** and do not warrant any discussion (see Table 2).

Amongst the numerous examples of seven-coordinate rhenium(III) complexes in the literature are the compounds [Re(terpy)$_2$X]Y$_2$ (X = OH, Cl, NCS; Y = PF$_6$, SCN), which were obtained by the reaction of 2,2′:6′,6″-terpyridine (terpy) with [ReO$_2$(py)$_4$]$^+$ [25]. This reduction/substitution route of the oxorhenium(V) moiety was also observed in the synthesis of the seven-coordinate complex [Re^{III}(PPh$_3$)(mdt)] from the reaction of Hmdt (5-methoxy-5,6-diphenyl-4,5-dihydro-2H-[1,2,4]triazine-3-thione) with *trans*-[ReOCl$_3$(PPh$_3$)$_2$] or [ReO$_2$I(PPh$_3$)$_2$] [26]. The same technique has been used to prepare the five-coordinate rhenium(III) complex [Re(PPh$_3$)$_2$(mbm)$_3$] from *trans*-[ReOCl$_3$(PPh$_3$)$_2$] and *p*-methoxybenzyl mercaptan (Hmbm) [27]. However, the most convenient method for the preparation of rhenium(III) complexes is by ligand substitution reactions of [ReX$_3$(MeCN)(PPh$_3$)$_2$] [28–30].

3.2. *fac*-[Re(CO)$_3$(H$_2$dhp)Br] (**2**)

The rhenium(I) complex **2** was prepared by the reaction of [Re(CO)$_5$Br] with an equimolar quantity of H$_2$dhp in refluxing toluene.

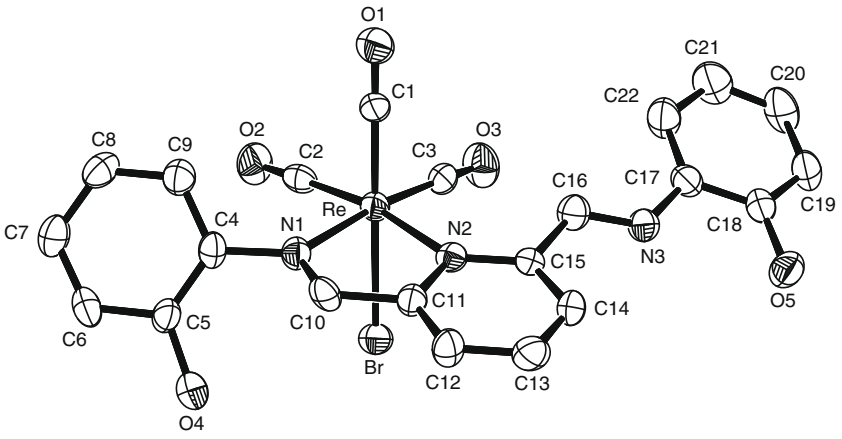

Fig. 2. ORTEP drawing of **2**, with thermal ellipsoids shown at 40% probability.

The infrared spectrum exhibits a sharp, strong band at 2026 cm^{-1} and a broad, intense absorption at 1907 cm^{-1}, attributed to ν(C≡O) of the *fac*-$[Re(CO)_3]^+$ unit. Two medium intensity peaks at 438 and 473 cm^{-1} are assigned to ν(Re–N(1)) and ν(Re–N(2)), respectively. The ^1H NMR spectrum is complex and integrates for 13 protons in the aromatic region, with two singlets at 10.48 and 10.39 ppm, assigned to the methine protons H(10) and H(16), respectively.

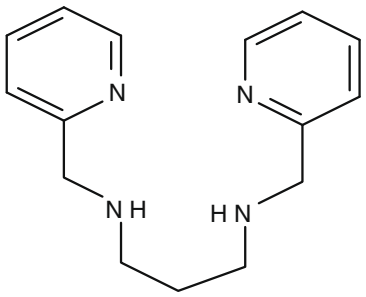
A perspective view of the asymmetric unit of **2** is shown in Fig. 2. The X-ray results show that the complex contains the chemically robust *fac*-$[Re(CO)_3]^+$ core in a distorted octahedral geometry. The metal is coordinated to three carbonyl donors in a *facial* orientation, to the neutral imino nitrogen N(1), the pyridinic nitrogen N(2) and a bromide. The imino nitrogen N(3) and the two phenolic oxygens O(4) and O(5) are uncoordinated. The Re–CO bond lengths [average of 1.902(7) Å] fall in the range observed [1.900(2)–1.928(2)] Å for similar complexes [31,32]. The Re–N(1) bond [2.167(5) Å] is significantly shorter than the Re–N(2) [2.241(4) Å] one, and they are typical to other similar bonds [33–35]. The distortion from octahedral ideality is mainly the result of the *trans* angles, which fall in the range 168.8(2)–178.4(2)° (Table 2). These distortions are mainly the result of the constraints imposed by the bidentate coordination of H_2dhp, with a bite angle of 74.7(2)°. As a result, the bromide distorts the two nitrogen atoms less [average Br–Re–N angle is 84.8(1)°] then the two carbonyl carbons [average Br–Re–C angle is 89.8(2)°].

The H_2dhp intraligand bonding distances show the effect of the coordination on the imine group, with the N(1)–C(10) bond [1.284(9) Å] markedly longer than the free N(3)–C(16) bond [1.261(8) Å]. Also, the N(1)–C(10) bond length is shorter than the corresponding bonds in **1** [average 1.312(6) Å], illustrating the higher Lewis acidity of the rhenium(III) centre. The C(4)–C(9) and C(17)–C(22) phenolic rings make dihedral angles of 50.78° and 21.27° with the pyridyl ring, and 36.65° with each other.

It has been shown before that the *fac*-$[Re(CO)_3]^+$ core has a low affinity for anionic oxygen donor atoms [36]. However, neutral tridentate ligands of the N_3-donor atom type like bis(imidazol-2-ylmethyl)amine and bis(quinoline-2-ylmethyl)amine (L^3) have been used to give cationic species of the type *fac*-$[Re(CO)_3L^3]Br$ [37]. Bidentate nitrogen-donor ligands like *N,N′*-dimethylpiperazine and bis(diethylamino)methane (L) have been reacted with $[Re(CO)_5X]$ (X = Cl, Br) to produce the complexes $[Re(CO)_3(L)X]$ [38]. Complexes of the type $[Re^I(CO)_3(L)_2Cl]$, with different monodentate pyridine derivatives L, have been prepared by using $[Re(CO)_5Cl]$ as starting material [39].

4. Conclusion

The reaction of the potentially pentadentate Schiff base ligand 2,6-bis(2-hydroxyphenyliminomethyl)pyridine (H_2dhp) with *cis*-$[ReO_2I(PPh_3)_2]$ or *trans*-$[ReOBr_3(PPh_3)_2]$ leads to the disproportionation of rhenium(V), to form the seven-coordinate rhenium(III) cation $[Re(dhp)(PPh_3)_2]^+$ and perrhenate. However, in its reaction with $[Re(CO)_5Br]$, H_2dhp acts as a bidentate chelate in the product *fac*-$[Re(CO)_3(H_2dhp)Br]$.



5. Supplementary data

CCDC 721475, 721476 and 721477 contain the supplementary crystallographic data for **1, 1a** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. N,N′-bis(2-pyridylmethyl)-1,3-propanediamine (also called: 1,7-bis-(2′-pyridyl)-2,6-diazaheptane), abbreviated as pypn.

obtained on a Bruker-EMX*plus* electron spin resonance spectrometer (field calibrated with DPPH (g = 2.0036).

2.2. Synthesis of the ligand

The ligand pypn was synthesised according to the literature [13] and was isolated as the tetrahydrochloride salt (pypn·4HCl). The purity of the ligand was verified by spectroscopic techniques (NMR, IR) and elemental analysis.

2.3. Synthesis of complexes *1*, *2* and *3*

A mixture of sodium acetate trihydrate (0.54 g, 4 mmol) and ligand hydrochloride pypn•4HCl (0.40 g, 1 mmol) in absolute ethanol (30 mL) was stirred while boiling (10 min, water bath), then cooled and the sodium chloride which precipitated was filtered off. Then 1 mmol of metal perchlorate hexahydrate (for compounds **1** and **3**), iron(III) nitrate trihydrate (for compound **2**) in absolute ethanol (20 mL) was added dropwise to the filtrate and the solution was stirred for 10 min at room temperature. The solution was filtered to remove any undissolved material and was left concentrated in the open air. After few days crystals suitable for X-ray were formed and they were collected, washed with the mother liquid and dried at room temperature. Compound **1**: purple, plate crystals; yield: 0.39 g (75%). *Anal.* Calc. for $C_{30}H_{42}Cl_4Cu_2N_8O_{17}$: C, 34.1; H, 4.0; N, 10.6; Cu, 12.0. Found: C, 33.9; H, 4.2; N, 10.7; Cu, 11.9%. Compound **2**: red block crystals; yield: 0.22 g, (50%). *Anal.* Calc. for $C_{15}H_{18}Cl_2FeN_5$: C, 40.5; H, 4.5; N, 15.7; Fe, 12.6. Found: C, 40.8; H, 4.2; N, 15.5; Fe, 12.3%. Compound **3**: colorless needle-shaped crystals; yield: 0.25 g, (55%). *Anal.* Calc. for $C_{15}H_{20}Cl_2N_4O_4Zn$: C, 39.5; H, 4.4; N, 12.3; Fe, 14.3. Found: C, 39.8; H, 4.2; N, 12.1; Zn, 14.1%.

2.4. Synthesis of complexes *4*, *5* and *6*

These complexes were obtained by a similar method described above, but in this case by adding 2 mmol of ammonium thiocyanate, or sodium azide dissolved in 5 mL of ethanol, or 5 mL of water, respectively. Compound **4**: red needle-shaped crystals; yield: 0.35 g, (65%). *Anal.* Calc. for $C_{17}H_{20}ClCoN_6O_4S_2$: C, 38.5; H, 3.8; N, 15.8; Co, 11.1. Found: C, 38.7; H, 3.5; N, 15.7; Co, 11.4%. Compound **5**: red needle-shaped crystals; yield: 0.40 g, (80%). *Anal.* Calc. for $C_{15}H_{20}ClCoN_{10}O_4$: C, 36.1; H, 4.0; N, 28.1; Co, 11.8. Found: C, 36.2; H, 3.9; N, 28.0; Co, 11.6%. Compound **6**: colorless needle crystals; yield: 0.26 g, (50%). *Anal.* Calc. for $C_{17}H_{20}N_6S_2Zn$: C, 46.6; H, 4.6; N, 19.2; Zn, 14.9. Found: C, 46.3; H, 4.8; N, 18.9; Zn, 14.7%. *Note:* Azide and perchlorate compounds are potential explosive. They must be handled with care and used in small quantities.

2.5. X-ray crystallography

For compounds **1, 2** and **6**: A suitable crystal was selected from the mother liquid and mounted to a glass fiber using the oil-drop method; data were collected on a Nonius KappaCCD diffractometer (graphite-monochromated Mo Kα radiation). The intensity data were corrected for Lorentz and polarization effects, for absorption and extinction. The structure was solved by direct methods. The programs COLLECT [14], SHELXS-97[15], SHELXL-97 [15] were used for

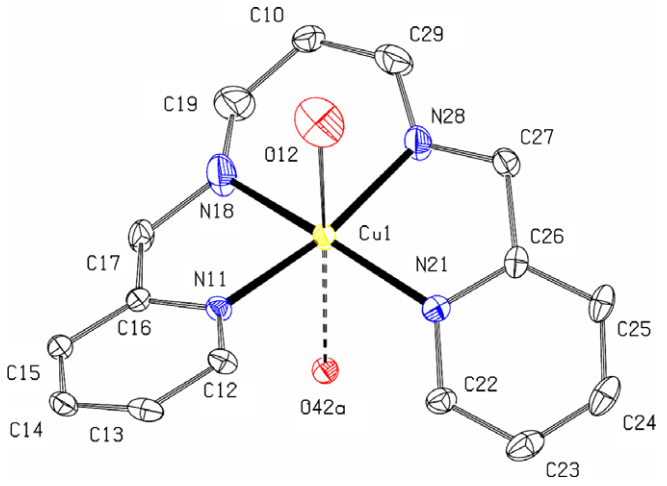

Fig. 1. Atomic displacement plot (30% probability level) of the the molecular structure of **1**. Hydrogen atoms and the water molecule are omitted for clarity. Only one of the oxygen atoms connected to the Cu-atom is shown, due to the severe disordering of the perchlorate anions.

data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. All non-hydrogen atoms were refined anisotropically. All H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Details of compound **1**: the disordered perchlorate anions were refined as rigid groups. The H atoms were geometrically fixed and allowed to ride on the attached atoms. H atoms of the disordered water molecules were not located. Details of compound **5**: the disordered perchlorate anion was refined as a rigid group in two positions with population parameters 0.7 and 0.3.

For compounds **3, 4 and 6**: the crystal data were collected on a Siemens SMART three-circle CCD diffractometer using monochromatic Mo Kα radiation (λ = 0.71073 Å). The structure was solved by the direct method and refined by full matrix least squares, based on F^2 using the SHELX-TL software package [16]. An empirical absorption correction based on symmetric equivalent reflections was applied using the SADABS program [17,18]. All the hydrogen positions were initially located in the difference map and for the final refinement the hydrogen atoms were placed geometrically and held in the riding mode. The last cycles of the refinement included atomic positions for all the atoms, anisotropic thermal parameters for all non-hydrogen atoms and isotropic thermal parameters for all the hydrogen atoms.

Crystallographic data are presented in a summary Table 1.

3. Results and discussion

3.1. Crystal and molecular structure of $[Cu(pypn)(ClO_4)_2](H_2O)_{1/2}$ (1)

The structure of **1** consists of a $[Cu(pypn)]^{2+}$ cation, two disordered semi-coordinating ClO_4^- anions and a disordered water molecule. The structure is depicted in part in Fig. 1 together with the numbering scheme. Selected bond distances and angles are listed in Table 2. The Cu-atom has a distorted elongated octahedral coordination with the basal plane comprised of four nitrogens from the chelating pypn ligand (Cu–N distances vary from 2.000(6) to 2.019(8) Å) and with trans-equatorial angles of 168.3(3) (N11–Cu–N28) and 164.7(4)° (N18–Cu–N21). The conformation around the Cu ions can be described as $m_s m_a$ [19]. The apical positions are occupied by two oxygen atoms of the two different disordered perchlorate anions (Cu–O distances vary from 2.49(2) to 2.61(1) Å). The lattice structure is stabilized by a weak hydrogen bonding between the oxygen of the perchlorate anion and the N18 hydrogen atom (N18···O 3.36(2) Å). Details of the hydrogen bonds are given in Table 3.

3.2. Crystal and molecular structure of $[Fe(pypn)Cl_2](NO_3)$ (2)

The structure of **2** is depicted in Fig. 2, together with the numbering scheme. Selected bond distances and angles are listed in Table 2.

The Fe(III) ion has an octahedral geometry comprised of four nitrogens from the chelating pypn ligand in a non-planar orientation with the $m_s f$ [19] conformation (Fe–N distances vary from 2.145(2) to 2.175(2) Å) and two *cis*-oriented chloride anions (Fe–Cl distances 2.2598(7) and 2.2754(7) Å). The angles are 165.69(7), 169.05(5) and 169.98(5)° (for N21–Fe–N18, N11–Fe–Cl2, N28–Fe–Cl1, respectively). The lattice structure is stabilised by a medium strong hydrogen bond between the N18 hydrogen atom to a neighboring chloride anion (N···Cl distance 3.288(2) Å) and between the N28 hydrogen atom to the oxygen atoms of the nitrate anion (N···O distances 2.919(2) and 3.183(3) Å) (see Fig. 3 for details). Details of the hydrogen bond geometries are given in Table 3. The bond distances and angles of this structure are comparable to a related type of structure, $[Fe(pypn)Cl_2](ClO_4)$, in the literature [12], which gives also the same type of hydrogen bonds.

3.3. Crystal and molecular structure of $[Zn(pypn)Cl](ClO_4)$ (3)

A plot showing the numbering scheme of compound **3** is presented in Fig. 4, and selected bond distances and angles are given

Table 3

* Disordered atom.
** Bifurcated H-bonds.

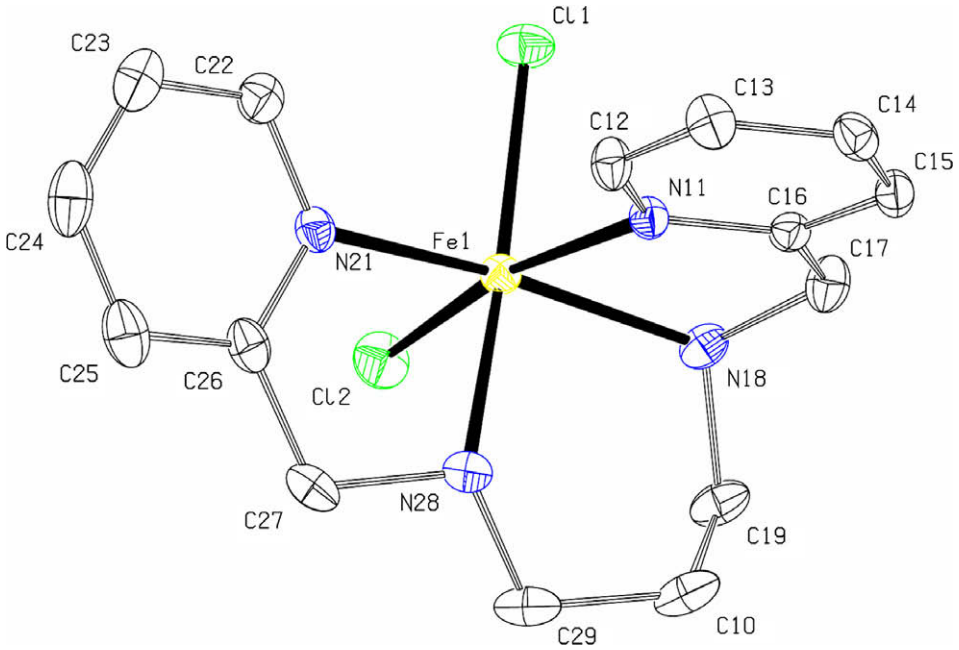

Fig. 2. Atomic displacement plot (30% probability level) of the cationic part of the molecular structure of **2**. Hydrogen atoms and nitrates have been omitted for clarity.

in Table 2. The Zn(II) ion is five coordinated with four nitrogen atoms of a chelating pypn ligand (Cu–N distances from 2.087(2) to 2.176(2) Å). The fifth position is occupied by chloride ion with a Cu–Cl distance of 2.2813(7) Å. The basal angles are 168.59(9) and 130.19(9)° (for N2–Zn–N4 and N1–ZnN3).

The distortion of the Zn coordination polyhedron from trigonal bipyramidal can be best described by the structural parameter τ (τ describes the relative amount of trigonality; $\tau = 0$ corresponds to for square pyramidal geometry and $\tau = 1$ to trigonal bipyramidal) [20]. For the title compound, $\tau = 0.64$, indicating that the coordination geometry can be described as a significantly distorted trigonal bipyramid.

The lattice structure is stabilised by hydrogen bonding of which one H bond is from the N2 hydrogen atom to a neighboring chloride ion (N···Cl distance 3.327(2) Å). The other H bond is from the N3 hydrogen atom to the oxygen atom of a perchlorate anion (N···O distance 3.041(5) Å) (see Fig. 5). Details of the hydrogen bonds are given in Table 3.

3.4. Crystal and molecular structure of $[Co(pypn)(NCS)_2](ClO_4)$ **(4)**

The structure of **4** consists of a $[Co(pypn)(NCS)_2]^+$ cation, in which the starting Co^{2+} has been oxidized to Co^{3+} and one disordered non-coordinating ClO_4^- anion. The structure is depicted in

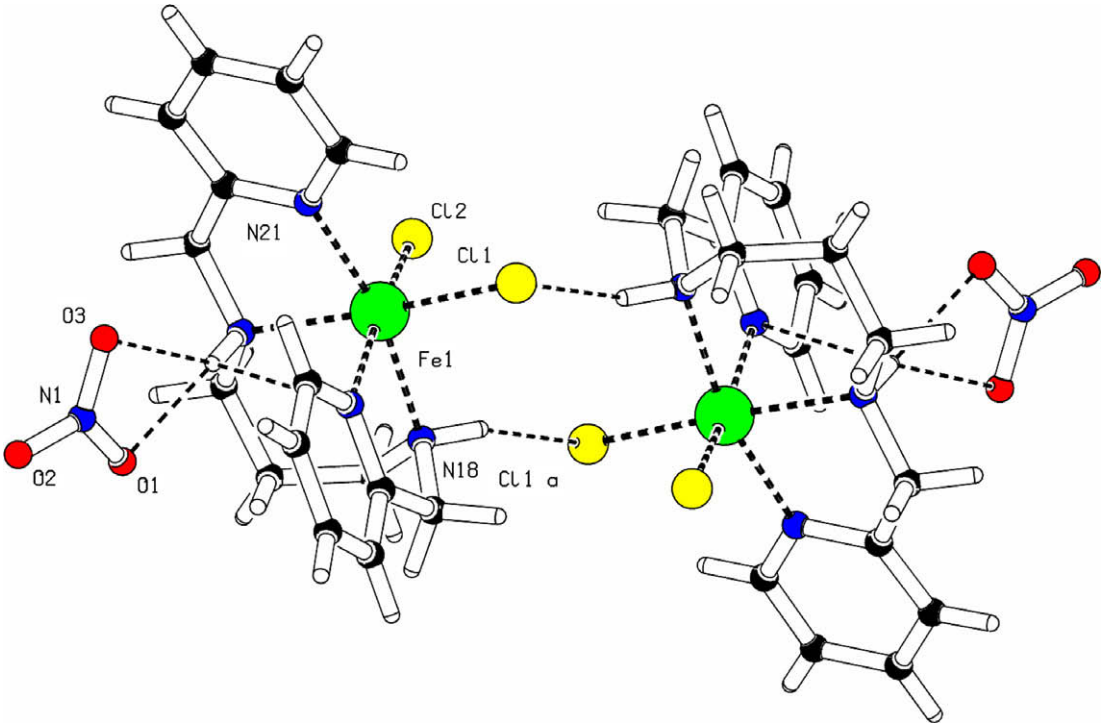

Fig. 3. The hydrogen bond system of **2**, showing a dimerisation with both Cl and NO_3 displayed.

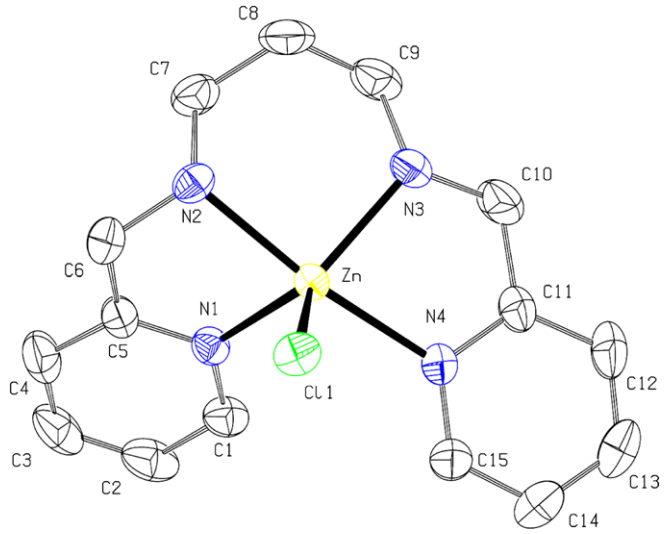

Fig. 4. Atomic displacement plot (30% probability level) of the cationic part of the molecular structure of **3**. The non-coordinating perchlorate anion and the hydrogen atoms are omitted for clarity.

Fig. 6 together with the numbering scheme. Selected bond distances and angles are listed in Table 2.

The Co(III) ion has an octahedral geometry comprised of four nitrogens from the chelating pypn ligand displaying the *m,f* [19] conformation (Co–N distances vary from 1.936(2) to 1.957(3) Å) and two *cis*-oriented nitrogen atoms of two thiocyanate anions (Co–N distances 1.912(3) and 1.899(3) Å). The angles are almost linear, 175.71(12), 175.79(12) and 179.04(11)° (for N1–Co–N5), N3–Co–N6, N2–Co–N4, respectively). The lattice structure is stabilised by a medium to strong hydrogen bonding (for definitions: see Refs. [21,22]) between the N4 and N6 hydrogen atoms to the oxygen atoms of the perchlorate anions (N···O distances from 2.994(5) to 3.257(15) Å). Details of the hydrogen bonds are given in Table 3.

3.5. Crystal and molecular structure of $[Co(pypn)(N_3)_2](ClO_4)$ (5)

The structure of **5** consists of a $[Co(pypn)(N_3)_2]^+$ cation, in which the starting Co^{2+} has been oxidized to Co^{3+} and one disordered non-coordinating ClO_4^- anion. The structure is depicted in Fig. 7 together with the numbering scheme. Selected bond distances and angles are listed in Table 2.

The Co(III) ion has an octahedral geometry comprised of four nitrogens from the chelating pypn ligand with the *m,f* [19] conformation (Co–N distances vary from 1.943(3) to 1.966(3) Å) and two nitrogen atoms of two azide anions (Cu–N distances 1.933(3) and 1.962(3) Å). The angles are almost linear, 175.13(15), 179.11(14) and 179.70(15)° (for N4–Co–N11), N21–Co–N18, N1–Co–N28, respectively). The lattice structure is stabilized by a medium strong hydrogen bonding between the N18 hydrogen atom and the nitrogen atoms of neighboring azide anions (N18···N_{azide} 3.067(5) and 3.321(5) Å) and between the N28 hydrogen atom to the oxygen atoms of neighboring perchlorate anions (N28···O_{ClO4} 3.043(6) and 3.438(6) Å). Details of the hydrogen bonds are given in Table 3.

3.6. Crystal and molecular structure of $[Zn(pypn)(NCS)_2]$ (6)

The structure of **6** is depicted in Fig. 8 together with the used numbering scheme. Selected bond distances and angles are listed in Table 2.

The Zn atom has an octahedral geometry comprised of four nitrogens from the chelating pypn ligand with the *m,f* [19] conformation (Zn–N distances vary from 2.161(6) to 2.187(8) Å) and two nitrogen atoms of two thiocyanato anions (Zn–N distances 2.055(8) and 2.229(11) Å). The ligand is folded in such a way that the NCS anions are in a cis position. The angles are 167.9(3), 169.8(3) and 170.1(3)° (for N4–Zn–N6), N2–Zn–N5, N1–Zn–N3, respectively). The lattice structure is stabilised by a medium strong hydrogen bond between the N4 hydrogen atom to the sulfur atom of one of the thiocyanato anion (N···S distance 3.524(8) Å),

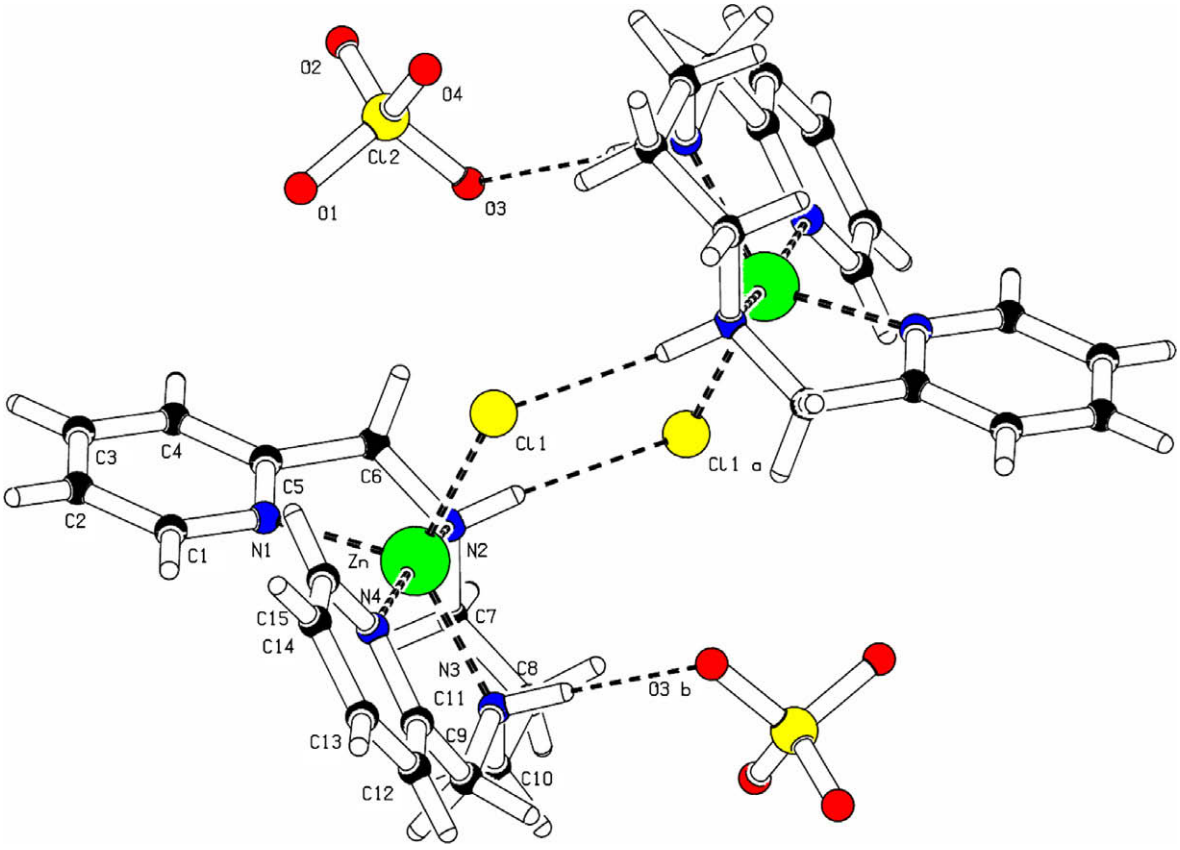

Fig. 5. The hydrogen bond system of **3**, showing a latticed dimerisation of 2 units.

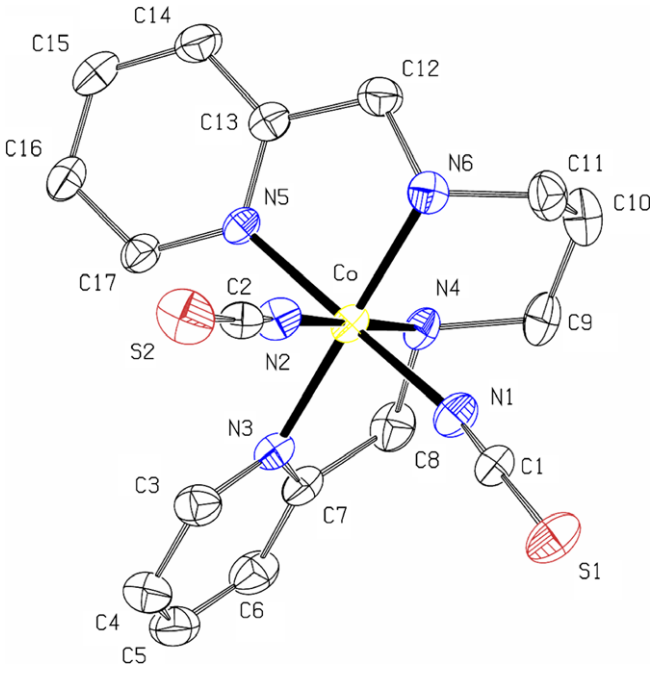

Fig. 6. Atomic displacement plot (30% probability level) of the cationic part in the molecular structure of **4**. Hydrogen atoms and non-coordinating anions are omitted for clarity.

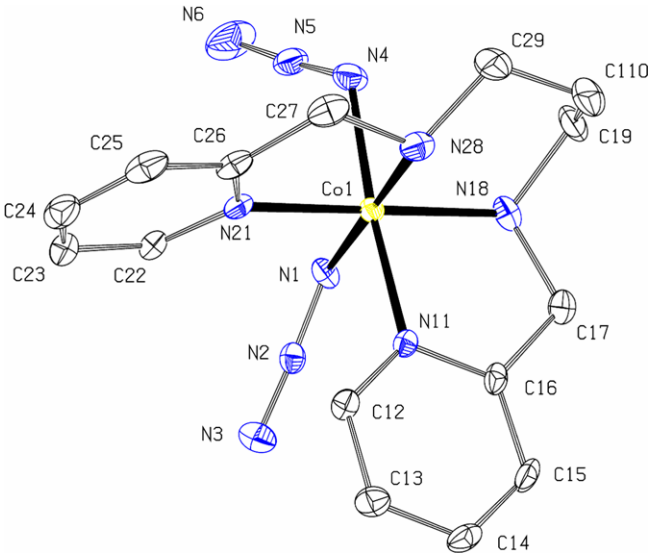

Fig. 7. Atomic displacement plot (30% probability level) of the cationic part in the molecular structure of **5**. Hydrogen atoms and non-coordinating anions are omitted for clarity.

forming in this way a type of dinuclear unit (Fig. 9). Details of the hydrogen bonds are given in Table 3.

3.7. Spectroscopy, IR, ligand field and EPR

The most relevant IR and the ligand field parameters are given in Table 4. In the IR spectra the most characteristic bands are from the NH vibrations, the pyridyl ring vibrations and the anions. The

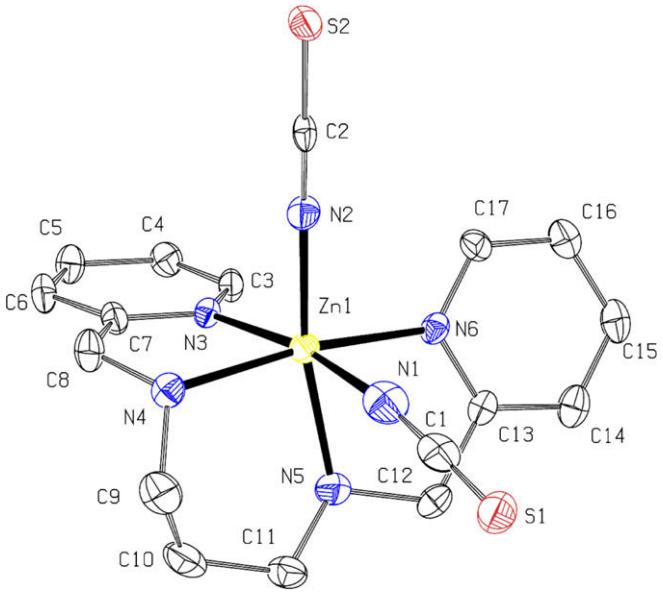

Fig. 8. Atomic displacement plot (30% probability level) of the molecular structure of **6**. Hydrogen atoms have been omitted for clarity.

NH vibrations are found between 3140 and 3255 cm^{-1}, as single bands (compounds **1, 3** and **6**), or as split broad bands (compounds **2, 4** and **5**), which arise from the molecular symmetry or from solid-state effects [1]. The pyridyl ring vibrations are found between 1604–1613 and 1572–1575 cm^{-1}, while these vibrations are observed at 1590 and 1570 cm^{-1} in the free ligand [1]. The bands of the anions are given in Table 4 and are according to the literature [23].

The ligand field transitions measured as a solid with the diffuse reflectance technique are observed for compound **1** (Cu^{2+} compound) as a broad band with a maximum at 17.2 $\times$ 10^3 cm^{-1} and for compounds **4** and **5** (Co^{3+} compounds) as two bands at 17.9 and 10.4 $\times$ 10^3 cm^{-1} and at 18.9 and 12.5 $\times$ 10^3 cm^{-1}, for compounds **4** and **5**, respectively. These are normal ligand field transitions for (distorted) octahedral Cu^{2+} and Co^{3+} geometries [24]. For compound **2** a very broad band with a maximum at around 18.0 ± 0.5 $\times$ 10^3 cm^{-1} is observed, which is attributed to a charge-transfer band of the Fe^{3+} ion.

The EPR spectra of compound **1** was recorded as a polycrystalline powder at RT and 77 K and shows a $S = 1/2$ spectrum with a $g_{\perp}$ of 2.06 and an unresolved $g_{//}$ of 2.18, which are values are consistent with a d_{x2-y2} based geometry [24].

4. Concluding remarks

In the present study 6 different transition metal (Fe^{3+}, Co^{3+}, Cu^{2+}, Zn^{2+}) compounds with the tetradentate ligand (N,N′-bis(2-Pyridylmethyl)-1,3-propanediamine, have been synthesised and fully characterized by IR, LF and X-ray structure analysis. Depending on the metal cation and the anion, different types of structures and a large variety of interesting H-bonding patterns were observed, including the formation of lattice dimers. Compounds **2** and **3** appeared to contain coordinated Cl^- ions, which originated from the remaining HCl in the used ligand. Compounds **4, 5** and **6** have quite strongly coordinated anions, i.e. N_3^- and NCS^-. The ligand folding around the metal ions is in all cases $m_s f$ [19] except for compound **1**, where it is $m_s m_a$. The overall charge of the compounds is compensated by perchlorate, or nitrate ions.

Our present ligand is related with (N,N′-bis(2-Pyridylmethyl)-1,2-ethanediamine) (abbreviated as pyen), which contains one CH_2 group less than pypn. In the CSD (Cambridge Structural Database), to the best of our knowledge, no crystal structures of that ligand containing the thiocyanate anion are present; with the azide anion only one Ni^{2+} compound has been published [25]. Related to

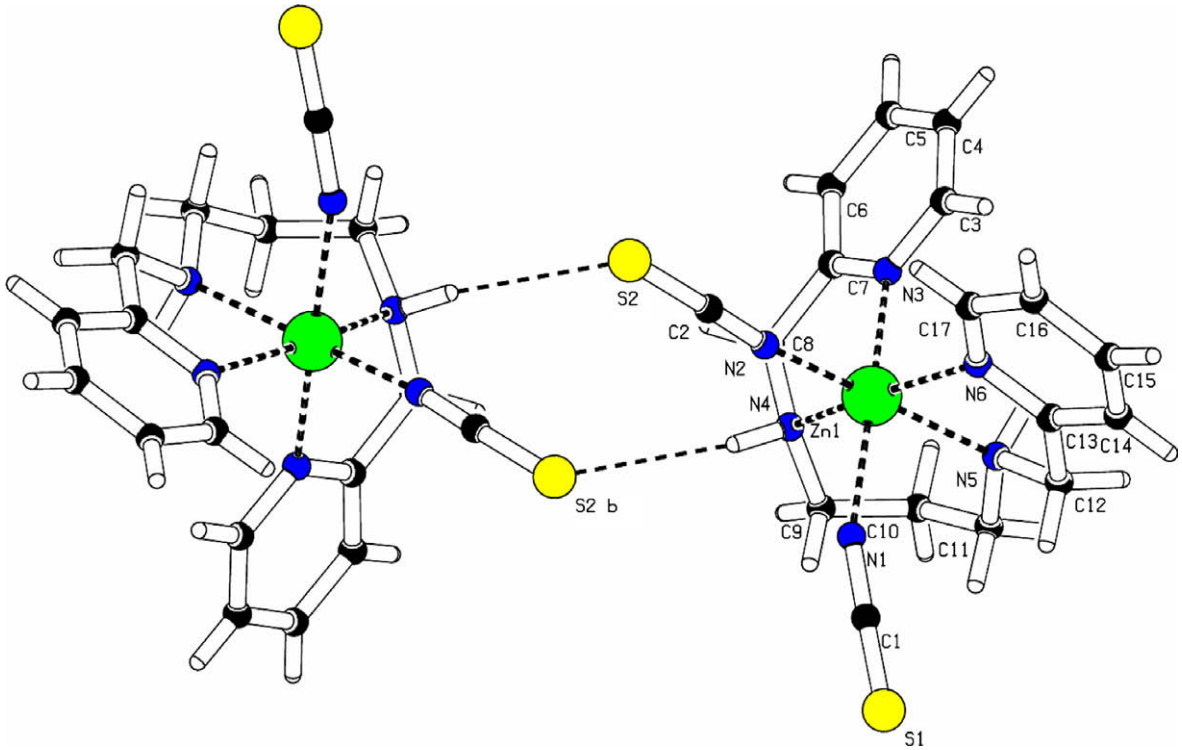

Fig. 9. The hydrogen bond system of **6**, showing a dimerization in the lattice through NH···S bonds.

Table 4
Diffuse reflectance and IR details of the compounds.

	Compound	Colour	Diffuse reflectance Max (10^3 cm^{-1})		Infrared		
					NH	Pyridyl ring	Anion
1.	$[Cu(pypn)(ClO_4)_2](H_2O)_{1/2}$	purple	17.2		3255	1613 1573	1056(br)
2.	$[Fe(pypn)Cl_2](NO_3)$	brown-red	18.0 ± 0.5		3215 3124	1607 1575	1290

5.	$[Co(pypn)(N_3)_2](ClO_4)$	red	10.4	17.9	3198 3140	1610 1575	2024(N_3) 1058(ClO_4)
6.	$[Zn(pypn)(NCS)_2]$	colorless			3252	1604 1573	2075(CN)

compound **1** is the compound $[Cu(pyen)(ClO_4)_2]$ [26]. In that case however the perchlorate anion is bridging between two Cu ions, contrary to compound **1**. For comparison with compound **2** with pyen, the crystal structure of $[Fe(pyen)Cl_2](ClO_4)$ is known [27], which has the same ligand conformation as compound **2**. Only the hydrogen bond is quite different, as the perchlorate ions are bridging between two ions, and not the chloride as in **2**.

Supplementary data

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-723651, 723652, 723653, 723654, 723655, 723756, for compounds **1, 2, 3, 4, 5** and **6**, respectively. Copies of available material can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, (fax: +44-(0)1223-336033 or Email: deposit@ccdc.cam.ac.uk.

reactivity of $[ReCl_3(MeCN)(PPh_3)_2]$ towards the dpk ligand. The $[ReCl_3(MeCN)(PPh_3)_2]$ complex has proven to be useful precursor in the synthesis of Re(III) compounds [16–18]. The $[ReCl_3(MeCN)(PPh_3)_2]$ also easily reacts with di-2-pyridylketone to give $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ (**1**) with rarer N,O-coordination of dpk ligand. The solid $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ can be handled in air without significant degradation, but rapid isomerisation with oxidation of coordinated PPh_3 occurs in organic solvents at room temperature in the presence of atmospheric oxygen. In fact, the starting purple solution of $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ in chloroform turns to dark red and crystals of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ (**2**) with N,N-coordination of dpk ligand are deposited.

N,N′,O coordination mode of monoanionic form of $(2\text{-py})_2CO$ has been confirmed in the $[ReOBr_3(dpk\text{-}OH)]\cdot 2(dpkH^+Br^-)$ (**3**), isolated from the reaction of $[ReOBr_3(PPh_3)_2]$ with excess of di-2-pyridylketone in acetone in air.

The structures of all the complexes $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ (**1**), $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ (**2**) and $[ReOBr_3(dpk\text{-}OH)]\cdot 2(dpkH^+Br^-)$ (**3**) have been proven by X-ray diffraction. The complexes $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$, which are stable in solution, have been also studied by UV–vis spectroscopy. The electronic spectra of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$ have been discussed in detail using the density functional theory (DFT) and time-dependent DFT (TDDFT) calculations.

Currently the density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [19]. Recent studies have also supported the TDDFT method to be applicable for open- and closed-shell of 5d-metal complexes giving good assignment of experimental spectra [20–22].

2. Experimental

2.1. General procedure

The reagents used to the synthesis were commercially available and were used without further purification. The $[Re(MeCN)Cl_3(PPh_3)_2]$ [16] and $[ReOBr_3(PPh_3)_2]$ [23] complexes were prepared according to the literature methods.

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–vis 8500 in the range 1000–180 nm in acetonitrile solution. Elemental analyses (CHN) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ (**1**)

$[Re(MeCN)Cl_3(PPh_3)_2]$ (0.5 g, 0.58 mmol) and di-2-pyridylketone (0.11 g, 0.60 mmol) in CH_2Cl_2 (80 cm^3) were heated under argon atmosphere for 5 h. The starting material gradually dissolved and the color of the reaction solution became blue-purple. The volume of the reaction solution was condensed to 10 cm^3 and allowed to cool to room temperature. Dark pink microcrystalline precipitate was formed and filtered off.

IR (KBr; ν/cm^{-1}): 1646(s) $\nu_{C=O}$; 1608(w), 1590(m), 1572(m) and 1538(w) ν_{CN} and $\nu_{C=C}$.

Anal. Calc. for $C_{29}H_{23}Cl_3N_2OPRe$: C, 47.13; H, 3.14; N, 3.79. Found: C, 47.61; H, 3.42; N, 3.62%.

2.3. Preparation of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ (**2**)

A solution of $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ in chloroform was stood for several days in air and dark red crystals were deposited.

IR (KBr; ν/cm^{-1}): 1649(vs) $\nu_{C=O}$; 1609(m), 1591(m), 1575(m) and 1542(w) ν_{CN} and $\nu_{C=C}$; 1135(vs) and 1119(vs) $\nu_{Re=O}$.

Anal. Calc. for $C_{29}H_{23}Cl_3N_2O_2PRe$: C, 46.13; H, 3.07; N, 3.71. Found: C, 46.79; H, 3.30; N, 3.45%.

2.4. Preparation of $[ReOBr_3(dpk\text{-}OH)]\cdot 2(dpkH^+Br^-)$ (**3**)

A mixture of $[ReOBr_3(PPh_3)_2]$ (0.50 g, 0.52 mmol), di-2-pyridylketone (0.28 g, 1.52 mmol) and acetone (100 ml) was stirred at room temperature for 12 h. Half of the solvent was removed and diethyl ether (50 ml) was added to precipitate the product as green solid, which was filtered off and dried. Yield 85%. Crystals suitable for X-ray investigation were obtained by recrystallization from acetonitrile.

IR (KBr; ν/cm^{-1}): 1683(vs) $\nu_{C=O}$; 1599(s), 1579(s) and 1520(s) ν_{CN} and $\nu_{C=C}$; 958(s) $\nu_{Re=O}$.

Anal. Calc. for $C_{33}H_{27}Br_4N_6O_5Re$: C, 36.25; H, 2.49; N, 7.69. Found: C, 36.89; H, 2.37; N, 7.39%.

2.5. Crystal structures determination and refinement

The X-ray intensity data of **1**, **2** and **3** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption correction [24] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their adjacent atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the aromatic parent atoms and equal 1.5 times the value of equivalent temperature factor of the oxygen atom (OH). SHELXS97 [25], SHELXL97 [26] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.6. Computational details

The ground states geometries of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$ were optimized without any symmetry restrictions with the DFT method using the hybrid B3LYP functional of GAUSSIAN-03 [28–30].

The calculations were performed using ECP basis set LANL2DZ [31] with an additional *d* and *f* function with the exponent α = 0.3811 and α = 2.033 [32] for rhenium and the standard 6-31G basis set for other atoms. For chloride, bromide, oxygen, nitrogen and phosphorous atoms, diffuse and polarization functions were added [33–38]. Vibrational frequencies of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$ were calculated to ensure that optimized geometries represented minima.

The electronic spectra of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$ were calculated with the TDDFT method, and the solvent effect (acetonitrile) was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [39–42].

Natural bond orbital (NBO) calculations for $[ReOBr_3(dpk\text{-}OH)]$ were performed with the NBO code [43] included in GAUSSIAN-03.

2.7. Magnetic measurement

Magnetization measurements of polycrystalline samples were carried out with a Quantum Design SQUID magnetometer (MPMSXL-5-type) at a magnetic field of 0.5 T over the temperature range 1.8–300 K. Magnetization measurements versus magnetic field (0–5 T) were made at 2 K.

Corrections are based on subtracting the sample – holder signal and contribution χ_D estimated from the Pascal constants [44] and equal – 376 × 10^{-6} for complex Re(III). The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M^{corr} \times T)^{1/2}$ B.M.

3. Results and discussion

3.1. Preparation and infrared data

The [$ReCl_3$(dpk-N,O)(PPh_3)] (**1**) complex was prepared in good yield by ligand exchange reaction starting from [$ReCl_3$(MeCN)-(PPh_3)] and di-2-pyridylketone (dpk):

[$ReCl_3$(MeCN)(PPh_3)$_2$] + dpk → [$ReCl_3$(dpk-N,O)(PPh_3)] + PPh_3 + MeCN

The solid [$ReCl_3$(dpk-N,O)(PPh_3)] can be handled in air without significant degradation, but rapid isomerisation with oxidation of coordinated PPh_3 occurs in organic solvents at room temperature in the presence of atmospheric oxygen. The [$ReCl_3$(dpk-N,N′)-($OPPh_3$)] (**2**) compound has been isolated during crystallization of [$ReCl_3$(dpk-N,O)(PPh_3)] from chloroform in air.

The [$ReOBr_3$(dpk-OH)]·2(dpkH$^+$Br$^-$) (**3**) compound has been obtained in the reaction of [$ReOBr_3$(PPh_3)$_2$] with excess of di-2-pyridylketone in acetone in a system open to the atmosphere. In this case the carbonyl oxygen atom of the di-2-pyridylketone is subject to nucleophilic attack by water and *gem*-diol form of dpk is formed.

The elemental analyses of the **1**, **2** and **3** complexes are in good agreement with their formulation. The selected frequencies observed in the IR spectra of **1**, **2** and **3** complexes are given in Section 2.

A band due to the ν(C=O) vibration of dpk appears at 1646, 1649 and 1683 cm^{-1} for **1**, **2** and **3**, respectively. In the case of **3** this band is consequence of ν(C=O) vibration of the protonated ligand present in the outer coordination sphere. The characteristic bands corresponding to the ν(CN), ν(C=C) modes of dpk and dpk-OH are observed in the range 1610–1500 cm^{-1}. The strong ν(Re=O) stretching band of **3** is found at 958 cm^{-1}. The medium intensity band at 3045 cm^{-1} assignable to ν(OH) vibrations confirms the monoanionic *gem*-diol form of *dpk* in the coordination sphere of **3**. The strong bands at 1135 and 1119 cm^{-1} in the IR spectrum of **2** confirm the presence of the coordinated $OPPh_3$ molecule [45].

3.2. Crystal structures

The crystallographic data of the **1**, **2** and **3** complexes are summarized in Table 1. The short intra- and intermolecular contacts [46,47] detected in the **1**, **2** and **3** are gathered in Table 2. The perspective drawings of **1**, **2** and **3** are presented in Figs. 1–3, and the selected bond distances and angles of **1**, **2** and **3** are collected in Tables 3–5, respectively.

The overall structure of **1** can be considered as a distorted octahedral with the largest deviation from the expected 90° bond angles coming from the bite angle di-2-pyridylketone coordinated in N,O-mode. It equals to 76.08(14)°, and it is similar to that reported for the related [Ru(Cp)(dpk-N,O)] (78.38(7)°) [13]. The bite angles O–M–N in the structures with α-iminoketo chelate ligands bounded to transition metals depend mainly on the size of the metal center, the smallest values (down to 67°) were found for Ag^I complexes and the largest angles (up to 85°) were observed for compounds with Cu^{II} [48].

The electron rich central ion of **1** shows larger affinity towards the less basic but strongly π accepting carbonyl oxo atom, and the Re–O(1) is slightly shorter than the Re–N(1) bond (Table 3). The pyridyl rings of dpk ligand are planar in the range of experimental error and they are inclined at 5.9(3)°.

The chloride ions of **1** are arranged in a *facial* fashion, typical of the [ReX_3(L–L)(PPh_3)] compounds with bipy-like ligands [49]. In the [ReX_3(L–L)(PPh_3)] complexes with two excellent π acceptor ligands coordinated to π-donor rhenium(III) center the back-bonding

Table 2

C(11)	Br(2)#5	2.90	3.787(4)	159.4
C(29)	Br(98)#6	2.91	3.715(4)	145.7
C(51)	O(2)#4	2.46	3.316(4)	153.7

#1: 0.5 + *x*, 1.5 − *y*, 1 − *z*; #2: 0.5 − *x*, 2 − *y*, −0.5 + *z*; #3: −0.5 + *x*, 2.5 − *y*, 1 − *z*; #4: 1 − *x*, 1 − *y*, 1 − *z*; #5: 2 − *x*, −*y*, −*z*; and #6: 3 −1 + *x*, *y*, *z*.

effect is maximized in the *facial* disposition, which ensures minimum competition between the two ligands for identical metal orbitals.

The *fac* geometry of chloride ions are also confirmed in complex **2**. However, in this case *facial* arrangement seems to be sustained by steric advantages. Phosphine oxides are purely donor in character, and lack acceptor properties favor the meridional configuration of chloride ligands in the complexes $[ReX_3(L–L)(OPPh_3)]$ with approximately planar L–L ligands. The di-2-pyridylketone is coordinated to the Re(III) center of **2** in a nonplanar N,N-mode, and nonplanarity seems to be responsible for *fac* Chloride arrangement in **2**. Upon coordination of di-2-pyridylketone to the rhenium *via* two nitrogen atoms, a six-membered cycle is formed, and the formed ring shows a *boat* conformation with the rhenium and the carbonyl group off the plane defined by the two nitrogen and two carbon atoms. The planar in the range of experimental error pyridyl rings are inclined at 51.3(2)°. By forming a six-membered chelate ring dpk allows Re(III) center to achieve a geometry that is closer to octahedral than is possible for α-iminoketo which form five-membered chelate.

The asymmetric unit of **3** contains one complex molecule [$ReOBr_3$(dpk-OH)], two bromide anions and two 2-pyridyl-2-pyrydiniumketone cations. In complex molecule of **3** monoanionic gem-diol form $(2\text{-py})_2C(OH)O^-$ coordinates to the Re(V) center through the deprotonated hydroxy group and two pyridyl nitrogen atoms. The coordination sphere of [$ReOBr_3$(dpk-OH)] is completed by two bromide and terminal oxo ligands, and the geometry about Re(V) can be described as a very distorted octahedral.

The oxygen atom of dpk-OH is coordinated in *trans* position to the terminal oxo ligand. The high concentration of electronic density along the Re–O axis strongly influences the positions of the adjacent halogen atoms, which are pushed away. The planar in the range of experimental error pyridyl rings of the diol are inclined at 72.72(10)°. Aromatic rings of cations are inclined at distinctly smaller angles: 24.8(2)° and 22.4(2)°. The pyridine ring is in *trans* arrangement to the pyrydinium ring in one of cations and *cis* in second one.

The Re–N bond lengths of **1** and **2** are similar to those found for the rhenium(III) polypyridyl compounds ($[ReCl_2(bipy)_2]PF_6$ – 2.094(5) and 2.096(5) Å [50] and in the $[ReL(terpy)_2]^{2+}$ (L = Cl, OH, NCS) complexes – about 2.10 Å [51]) and significantly shorter than comparable distances of **3**, where metal-to-ligand π-back bonding is not possible.

The Re–Cl(3) distance of **1** is affected by *trans* influence of triphenylphospine and is longer than the Re—Cl(1) and Re—Cl(2) bond lengths located in *trans* positions to the dpk ligand.

The Re–O_t bond length of **3** falls in the range 1.639–1.76 Å, which is typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicates the presence of a triple bond Re≡O [52]. The interatomic distance between the rhenium atom and the oxygen atom of dpk-OH ligand is somewhat shorter in comparison with an ideal single Re–O bond length (ca. 2.04 Å) [53], and indicates small delocalization in the O(2)–Re(1)–O(1) moiety. In keeping with that, the O(1)–Re(1)–O(2) angle is equal 157.10(11), notably less than 180°.

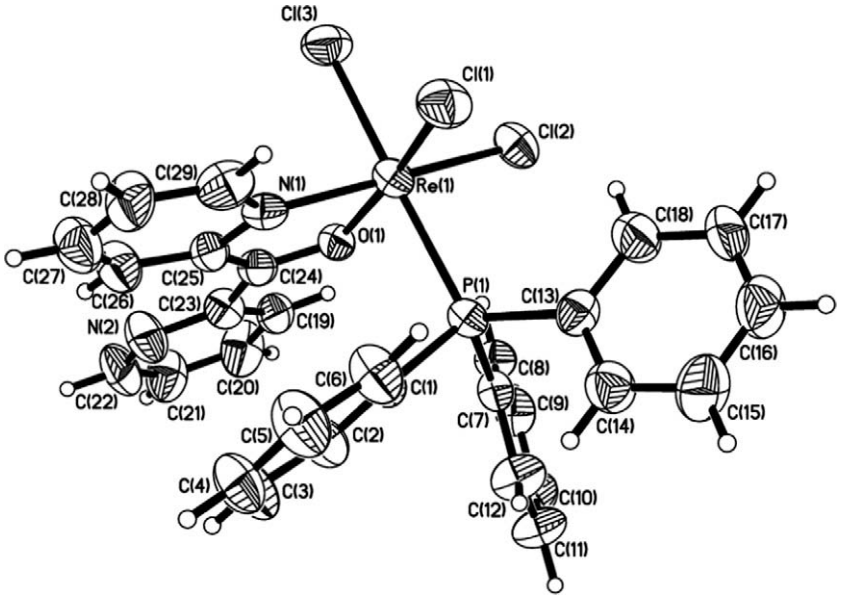

Fig. 1. The molecular structure of **1**.

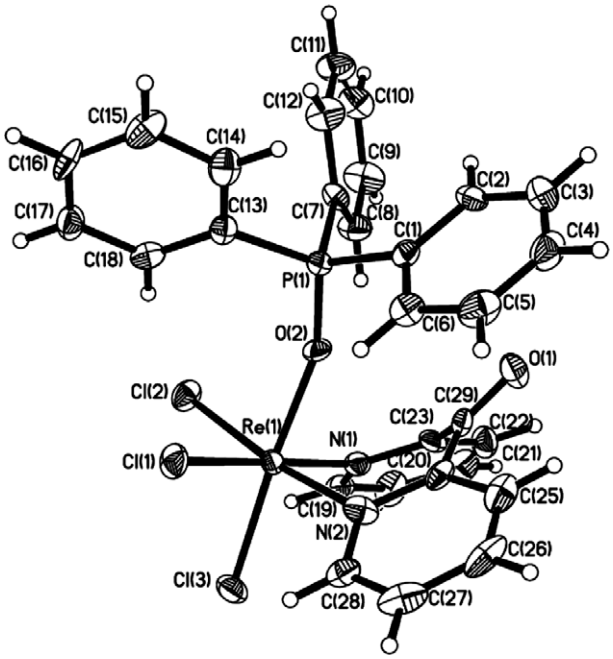

Fig. 2. The molecular structure of **2**.

In all the compounds the molecules (and ions in **3**) are connected via intermolecular interaction to the three-dimensional nets, however, in compounds **1** and **2** the intermolecular bonds are weak due to absence of strong hydrogen bond donors. In **3** the medium strength hydrogen bonds link molecules and ions to the $[ReOBr_3(dpk\text{-}OH)]\cdots Br^-\cdots Hdpk^+$ trimers and $Br^-\cdots Hdpk^+$ dimers and these clusters are connected via weak C–H···A hydrogen bonds to the three-dimensional net.

3.3. Magnetic properties

The magnetic properties of **2** under the form molar magnetic susceptibility (χ_M) and $\chi_M T = f(T)$ are shown in Fig. 4.

The complex **2** shows in the whole temperature range lowering of the magnetic moment from 2.59 B.M. at 300 K up to 0.91 B.M. at 1.8 K.

This behavior is characteristic of mononuclear Re(III) complexes ($^3T_{1g}$ ground state) with d^4 low-spin octahedral [54–62] and arise from the large spin–orbit coupling ($\zeta = 2500\ cm^{-1}$ [63]),which gives diamagnetic ground state. It seems that in room temperature, in accordance Boltzmann's distribution, it is populated higher magnetic state, which is depopulated with temperature lowering and decreasing of the magnetic moment is observed.

The variation of the magnetization *M* versus the magnetic field *H* for complex **2** at 2 K is shown in Fig. 5.

The magnetization versus magnetic field curve for complex very slowly increases and indicates value of the magnetization 0.36 B.M at 5 T, confirms that the ground state of the complex is diamagnetic.

Table 3
The experimental bond lengths (Å) and angles (°) for **1**.

Bond lengths	Experimental	Bond angles	Experimental
Re(1)–O(1)	1.997(3)	O(1)–Re(1)–N(1)	76.08(14)
Re(1)–N(1)	2.091(4)	N(1)–Re(1)–Cl(1)	93.88(12)
Re(1)–Cl(1)	2.3314(15)	N(1)–Re(1)–Cl(2)	168.94(12)
Re(1)–Cl(2)	2.3524(15)	N(1)–Re(1)–Cl(3)	86.62(12)
Re(1)–Cl(3)	2.3979(15)	O(1)–Re(1)–Cl(1)	169.79(10)
Re(1)–P(1)	2.4469(15)	O(1)–Re(1)–Cl(2)	93.77(10)
		O(1)–Re(1)–Cl(3)	89.52(10)

		Cl(3)–Re(1)–Cl(1)	91.74(6)
		O(1)–Re(1)–P(1)	90.43(10)
		N(1)–Re(1)–P(1)	95.04(12)
		Cl(1)–Re(1)–P(1)	88.61(5)
		Cl(2)–Re(1)–P(1)	89.33(5)
		Cl(3)–Re(1)–P(1)	178.28(5)

3.4. Geometry optimization

The geometries of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)]$ complexes were optimized by the DFT method with the B3LYP functional. The geometry of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ was optimized in triplet and singlet states, and geometry of $[ReOBr_3(dpk\text{-}OH)]$ – in singlet state. For complex $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ the energy of the triplet state is of 22.12 kcal/mol smaller in comparison with the singlet state. It is in good agreement with the magnetic measurements. The effective magnetic moment of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ is equal to 2.59 B.M. at 300 K and decreases with temperature lowering (to 0.91 B.M. at 1.8 K). This behavior is characteristic of mononuclear octahedral Re(III) complex with d^4 low-spin ($^3T_{1g}$ ground state). The optimized geometric parameters of $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ (triplet state)

and [$ReOBr_3$(dpk-OH)] (singlet state) are gathered in Tables 4 and 5, respectively. Generally, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.5. Molecular orbitals

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] and [$ReOBr_3$(dpk-OH)] are presented in Tables 6 and 7, respectively. The selected contours of frontier orbitals of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] and [$ReOBr_3$(dpk-OH)] are presented in Figs. 6 and 7, respectively.

Among the highest occupied MOs of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] the largest numbers constitute π orbitals of the phenyl rings with a contribution from Cl atoms. The rhenium d_{xz}, d_{yz} and d_{xy} orbitals make main contributions into the HOMO−2, HOMO−1 and HOMO with α spin and HOMO, LUMO and LUMO+1 with β spin. In all these molecular orbitals, the rhenium d_{xz}, d_{yz} and d_{xy} orbitals bear

LUMO+6	−0.792	π^*(dpk), d_z^2	−1.178	$\pi^*(OPPh_3)$
LUMO+7	−0.735	d_z^2	−0.862	$\pi^*(OPPh_3)$

Table 7
The energy and character of the selected molecular orbitals for [$ReOBr_3$(dpk-OH)].

	E (eV)	Character
HOMO−5	−8.123	π(dpk-OH), π(Br), $\pi(O_t)$
HOMO−4	−7.932	π(Br), $\pi(O_t)$
HOMO−3	−7.648	π(dpk-OH), π(Br), $\pi(O_t)$
HOMO−2	−7.550	π(Br), π(dpk-OH)
HOMO−1	−7.291	π(Br)
HOMO	−6.264	d_{yz}(Re), π(Br)
LUMO	−3.066	d_{yz}, π(O)
LUMO+1	−2.860	d_{yz}, π(O)
LUMO+2	−1.903	π^*(dpk-OH), d_{yz}
LUMO+3	−1.532	π^*(dpk-OH), $d_{x^2-y^2}$
LUMO+4	−1.378	$d_{x^2-y^2}$
LUMO+5	−1.349	π^*(dpk-OH)
LUMO+6	−0.673	π^*(dpk-OH)
LUMO+7	−0.270	d_z^2

antibonding character towards the p_π orbitals of the chloride ions and oxygen donor. The d_z^2 rhenium orbital has a significant contribution in the LUMO+7 with α spin and the LUMO+11 with β spin, whereas the LUMO+10 with α spin and the LUMO+13 with β have predominantly $d_{x^2-y^2}$ character. Among the lowest unoccupied MOs of[$ReCl_3$(dpk-N,N′)($OPPh_3$)], the largest numbers constitute π orbitals of the dpk ligand. The π phenyl ring orbitals of the triphenylphosphine oxide ligand participate in the higher unoccupied orbitals.

The HOMO of [$ReOBr_3$(dpk-OH)] is mainly localized on the d_{xy} rhenium orbital and p_π chloride orbitals. The LUMO and LUMO+1 are also to a large extent formed by rhenium dπ atomic orbital (d_{xz} and d_{yz} orbitals) with some contribution of p_π oxygen orbitals. The LUMO+4 is of $d_{x^2-y^2}$ character, and d_z^2 rhenium orbital contributes to the LUMO+7.

3.6. NBO analysis

The nature of rhenium–terminal oxygen interaction in [$ReOBr_3$(dpk-OH)] has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 8. Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$(1)\sigma_{AB} = c_A h_A + c_B h_B,$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$(2)\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Le-

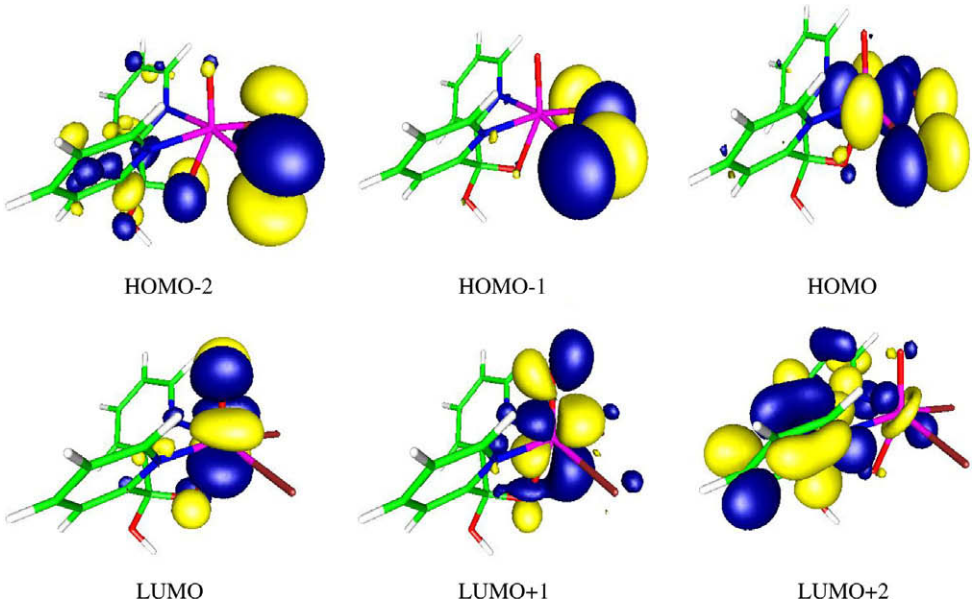

Fig. 7. The selected HOMO and LUMO orbitals for [$ReOBr_3$(dpk-OH)].

Table 8
The occupancy of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for [$ReOBr_3$(dpk-OH)].

BD	Occupancy	Composition of NBO	BD*	Occupancy
Re–O_t	1.994	$0.566(d)_{Re} + 0.825(p)_O$	$0.825(d)_{Re} - 0.566(p)_O$	0.255
Re–O_t	1.984	$0.566(d)_{Re} + 0.824(p)_O$	$0.824(d)_{Re} - 0.566(p)_O$	0.307

*Denotes antibond NBO.
BD: denotes two-center bond.

wis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [43].

The detected natural Re–O_t bond orbitals of **3** are π orbitals – the p_x and p_y oxygen orbitals and d_{xz} and d_{yz} rhenium orbitals are involved in their formation. Not detected σ_{Re-O_t} bond has character of predominant Coulomb-type interactions between the central ion and ligands [64]. The terminal oxo ligand of **1** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand.

3.7. Electronic spectra

The experimental and calculated electronic spectra of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] and [$ReOBr_3$(dpk-OH)] are presented in Figs. 8 and 9, respectively. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Tables 9 and 10 present the most important electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] and [$ReOBr_3$(dpk-OH)]. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Tables 9 and 10. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. As seen in Figs. 8 and 9, TDDFT/PCM calculations well reproduce the absorption spectra of [$ReCl_3$(dpk-N,N′)($OPPh_3$)] and [$ReOBr_3$(dpk-OH)] in terms of the energy of the experimental bands and calculated transitions.

3.8. [$ReCl_3$(dpk-N,N′)($OPPh_3$)]

The low-energy absorption band at 761.0 nm originates from the transition between HOMO and LUMO+2 with β spins. As can be seen from the Fig. 6, the β HOMO is delocalized on central ion, chloride ions and dpk ligand, whereas the β LUMO+2 are formed of d_{Re} orbitals and π^*-bonding orbitals of dpk ligand. Accordingly, the transition can be seen as a delocalized MLLCT (*Metal–Ligand-to-Ligand CT*) transition. The same character can be assigned to the experimental absorptions at 487.1, 372.7 and 266.9 nm.

The investigated complex is of large size; the numbers of basis functions are equal to 646. The calculated electron transitions (100) do not comprise all the experimental absorption bands; the
