**Abstract**—Density functional theory combined with the restricted open-shell Hartree–Fock method using the B3LYP, BLYP, and B3PW91 exchange-correlation functionals in the 6-311G\*\* basis has been applied to determine equilibrium geometry of water-containing clusters  ${}^1(\text{H}_3\text{O}^+-n\text{H}_2\text{O})$  with  $n = 1-3, 5, 6$  and  ${}^1(\text{H}_3\text{O}^+-3\text{H}_2\text{O})\text{Cl}^-$ . The SA-MCSCF simulation has revealed a series of electronic terms of hydroxonium ion and energy profiles of its formation. Energy profiles of  $\text{H}_3\text{O}^+$  interaction with  $\text{H}_2\text{O}$  have been simulated and analyzed. Vibrational spectra have been simulated for all the mentioned complexes in the equilibrium state, and regularities of changes of the fundamental vibrational frequencies with the increasing nuclearity of the complexes have been discovered.

**Keywords:** hydroxonium ion, aquatic complex, vibrational spectrum, potential energy surface, DFT, ROHF

**DOI:** 10.1134/S1070363215050011

Microstructure of the upper atmosphere is known for its diversity and determines a number of macroscopic atmospheric processes. For instance, smaller constituents of air (clusters of water molecules with hydroxonium ion as well as certain inorganic and organic molecules) participate in formation of aerosols that enter the lower atmosphere via mass transfer and turbulent diffusion and enhance formation of clouds, thunderstorms, typhoons, hurricanes, and tornados [1]. Acting as catalyst, hydroxonium ion determines the rate of aerosols formation and the composition of related oxidation reactions.

Besides the above-mentioned phenomena, a number of reactions occur in the low-temperature plasma at the height above 100 km, involving cations [ $\text{O}^+$ ,  $\text{O}_2^+$ ,  $\text{O}_4^+$ ,  $\text{H}^+$ ,  $\text{H}_2^+$ ,  $\text{OH}^+$ ,  $\text{HO}_2^+$ ,  $\text{H}_2\text{O}^+$ ,  $(\text{O}_2^+-\text{H}_2\text{O})$ ,  $\text{H}_3\text{O}^+$ ,  $(\text{H}_3\text{O}^+-\text{H}_2\text{O})$ ,  $(\text{H}_3\text{O}^+-2\text{H}_2\text{O})$ , and  $(\text{H}_3\text{O}^+-\text{OH})$ ], anions ( $\text{O}^-$ ,  $\text{O}_2^-$ ,  $\text{O}_3^-$ ,  $\text{H}^-$ , and  $\text{OH}^-$ ), neutral atoms (O and H [2]) and molecules ( $\text{H}_2$ ,  $\text{O}_2$  and  $\text{H}_2\text{O}$ , their intermolecular interactions removing restrictions on deactivation or singlet oxygen generation [3–5];  $\text{O}_3$ ), free radicals (OH and  $\text{HO}_2$  yielding excited oxygen and  $\text{H}_2\text{O}_2$  molecules [6] via recombination), excited atoms  $\{\text{O}({}^1\text{D}_1)$  [7],  $\text{O}({}^1\text{S}_0)\}$ , and excited singlet oxygen  $\text{O}_2$  ( ${}^1\Delta_g$ ) [8–10]. Furthermore, the  $\text{H}_3\text{O}^+-n(\text{H}_2\text{O})$  ( $n =$

1–9) small clusters existing in the gas phase may distort the radio signals. In view of the above, study of electronic and spectral properties of such objects is important for resolving fundamental issues related to catalytic reactions in plasma and practical safety issues of aviation and space flights.

Experimental and theoretical studies of structure, photochemical, and physico-chemical properties of various water clusters have been addressed in a number of contributions [11–19]. In particular, it has been demonstrated that the binding energy per water molecule increases from 27 kJ/mol in the  $(\text{H}_2\text{O})_2$  dimer to 35–40 kJ/mol in the  $(\text{H}_2\text{O})_5$  and  $(\text{H}_2\text{O})_6$  clusters, remaining constant in the larger clusters [17–19].

Geometry of hydroxonium ion clusters with several (up to 10) water molecules in gas and condensed phase has been studied in detail as well [20–30]. However, selectivity of the intermolecular bonding involving hydroxonium ion and its effect on the cluster nuclearity have remained the open issues so far. Furthermore, the reported lengths of hydrogen bonds and OH groups in the mentioned clusters have been uncertain; potential energy surfaces of hydroxonium ion formation and decomposition have not been analyzed; assignments of vibrations of O–H bond of

hydroxonium ion and the protonated  $\text{H}^+(\text{H}_2\text{O})_n$  ( $n = 5-8$ ) systems to the vibrational frequencies have been ambiguous [24]; IR spectroscopy data for hydroxonium ion has been contradictory [26–38].

This work aimed to elucidate the features of hydroxonium ion interaction with water molecules, to analyze the possibility of hydroxonium ion formation (from ground as well as excited states of the fragments) and decay, and to reveal the changes of vibrational frequencies as well as charge and spin parameters of  $\text{H}_3\text{O}^+$  with the increasing nuclearity of its small aqueous clusters.

Study of structure and reactivity of water clusters with hydroxonium ion and chlorine atom will aid in resolving certain ecological problems, since these clusters may participate in the processes affecting the local weather changes at industrial districts where chlorine is among other pollutants. Furthermore, particles of sea salt containing chlorine are constant components of coastal and oceanic air [40].

Optimization of natural geometry parameters of  $\text{H}_2\text{O}$  molecules,  $\text{H}_3\text{O}^+$  ions, and  $\text{H}_3\text{O}^+-n\text{H}_2\text{O}$  ( $n = 1-3, 5$ , and 6) complexes was performed using the density functional theory (DFT) in the frame of the restricted Hartree-Fock method [41] with B3LYP, BLYP, and B3PW91 exchange-correlation potentials in the 6-311G\*\* basis as implemented in GAMESS [42] software package. Vibrational and electronic spectra were simulated using the B3LYP functional and the 6-311G\*\* basis allowing the best coincidence between the experimental and the simulated O–H dissociation energy and geometry parameters of  $\text{H}_2\text{O}$  molecule [18, 25–28]. On top of that, the B3LYP and B3PW91 functionals could adequately reproduce vibrational frequencies of the  $\text{H}_3\text{O}^+$  ion and its clusters with water molecules [15, 16, 23, 31–35]. Cross-sections of potential energy surfaces of formation and decomposition of  $\text{H}_3\text{O}^+$  ion and  $\text{H}_3\text{O}$  neutral molecule ( $\text{H}^+ + \text{H}_2\text{O} \leftrightarrow \text{H}_3\text{O}^+$ ,  $\text{H} + \text{H}_2\text{O}^+ \leftrightarrow \text{H}_3\text{O}^+$ ,  $\text{H} + \text{H}_2\text{O} \leftrightarrow \text{H}_3\text{O}$ ) were obtained in the frame of the SA-MCSCF method via averaging over the first 20 states in the active space of 14 electrons at the 20 MO (14, 20).

**Structure of hydroxonium ion in the gas phase and cross-sections of potential energy surface of its formation.** To date, two models of formation of  $\text{H}_3\text{O}^+$  and  $\text{H}_5\text{O}_2^+$  ions have been mainly considered. The Eigen model assumes addition of a proton to an isolated water molecule to form the  $\text{H}_3\text{O}^+$  ion (known as hydroxonium ion). The second structure described

by the Zundel model is an ion of water dimer with a proton equally belonging to the both parent molecules. In the Eigen structure, the excessive charge of hydrated proton is delocalized between the three hydrogen atoms, whereas the Zundel structure contains the excessive charge localized at a single hydrogen atom located between the water molecules. The O–H bond lengths and bond angles in the  $\text{H}_3\text{O}^+$ ,  $\text{H}_2\text{O}$ , and  $\text{H}_5\text{O}_2^+$  particles simulated via quantum-chemical methods using different basis functions [16, 18, 20, 21, 25, 27–29, 33, 35, 36] as well as these determined from vibrational and NMR spectral data are significantly discrepant (Table 1).

The O–H bond lengths determined in this work for the isolated hydroxonium ion and water molecule differed by no more than 0.01–0.03 Å, and the difference between the H–O–H bond angles in those particles was of 8.2°–15.7° depending on the functional used. The O–H bond length in the  $\text{H}_5\text{O}_2^+$  complex was somewhat longer, of 1.190–1.210 Å depending on the simulation method and basis (Table 1).

The optimized parameters of equilibrium states of the Zundel [25, 30] and Eigen [21, 30] hydroxonium ions, water molecule [18, 25–28], and the  $\text{H}_3\text{O}^+-n(\text{H}_2\text{O})$  ( $n = 2, 3$ ) complexes [18, 23, 29, 30] obtained by us using the DFT method with different functionals (Tables 1 and 2) coincided with the results of spectral [16, 42], resonance, and X-ray diffraction measurements as well as with the simulation data [16, 18–20, 25, 27–29, 33, 35, 36].

The O–H bond in the  $\text{H}_3\text{O}^+$  ion (the Eigen model) was strong [ $d_e(\text{O–H})$  5.29 eV] (see figure), similarly to the O–H bond in the  $\text{H}_2\text{O}$  molecule [ $d_e(\text{O–H}) = 5.12$  eV] [18].

Cross-sections of potential energy surfaces of the  $\text{H} + \text{H}_2\text{O}^+ \leftrightarrow \text{H}_3\text{O}^+$ ,  $\text{H}^+ + \text{H}_2\text{O} \leftrightarrow \text{H}_3\text{O}^+$ , and  $\text{H}^0 + \text{H}_2\text{O}^0 \leftrightarrow \text{H}_3\text{O}^0$  reactions are shown in the figure.

As expected, the ground state term of the  $\text{H}_3\text{O}^0$  neutral system was dissociative (figure, curve 1). A special interest should be given to the term of the corresponding excited doublet state (figure, curve 2) ( $S = 0.5$ )  $^2\text{H}_3\text{O}^{0*}(\uparrow)$  located in the close neighborhood of the ground state term and dissociating following the  $^2\text{H}_3\text{O}^{0*}(\uparrow) - ^2[^3\text{H}_2\text{O}^*(\uparrow\uparrow) + ^2\text{H}^0(\downarrow)]$  scheme. The minimum of the latter term is located at  $R = 1.2 \pm 0.05$  Å. The well depth in the minimum point was of  $d_e = 2.20$  eV. Probably, this excited state acts as a highly reactive short-living intermediate in fast

processes involving H<sub>2</sub>O and H<sub>2</sub>O<sup>+</sup> under conditions of ionizing irradiation in the upper atmosphere.

The simulation (see figure) revealed that collision of the H<sub>2</sub>O<sup>+</sup> ion with the H atom resulted in a barrier-free formation of the (H<sub>3</sub>O)<sup>+</sup> ground state (see figure, curve 3) ( $D_e$  5.29 eV) with low electron affinity ( $E = 1.07$ ). Such term behavior was due to the structure change coming from the pseudo crossing of energy terms (curves 3 and 7). In view of that, we concluded that the barrier-free formation of hydroxonium ion occurred via the [<sup>1</sup>H<sub>2</sub>O<sup>0</sup>(↑↓) + H<sup>+</sup>] – [<sup>1</sup>H<sub>3</sub>O<sup>+</sup>(↑↓)] scheme, the cross-section of the potential energy surface corresponding to the [<sup>2</sup>H<sub>2</sub>O<sup>+</sup>(↑) + <sup>2</sup>H<sup>0</sup>(↓)] reaction remaining dissociative. In the course of decomposition of hydroxonium ion (curve 3), the proton drained the electron density and eliminated as a hydrogen atom at the dissociation limit.

Hence, the equilibrium ground state of hydroxonium ion was fairly stable in the gas phase in the absence of free electrons; however, the H<sub>3</sub>O<sup>+</sup> +  $e =$  H<sub>3</sub>O<sup>\*</sup> reaction was equivalent to the transition between the terms of the H<sub>3</sub>O<sup>+</sup> state (figure, curve 3) and the

equilibrium excited state H<sub>3</sub>O<sup>\*</sup> (curve 2), the latter could either decompose into the H<sub>2</sub>O<sup>\*</sup> and H particles or be deactivated via transition into the term of the ground state of the H<sub>3</sub>O neutral molecule (curve 1) followed by dissociation into H<sub>2</sub>O and H. In the both cases, the process should be accompanied by the energy release. Let us recall that an electron addition to the H<sub>3</sub>O<sup>+</sup> ion to yield H<sub>3</sub>O followed by the H<sub>3</sub>O<sup>+</sup> +  $e =$  H<sub>3</sub>O<sup>\*</sup> → H<sub>3</sub>O → H<sub>2</sub>O + H dissociation (necessarily involving the H<sub>3</sub>O<sup>\*</sup> excited state and accompanied by the energy release) is among the major redox processes in the upper atmosphere.

Noteworthy, the dissociative limit of the cross-section of the <sup>1</sup>H<sub>3</sub>O<sup>+</sup> potential energy surface characterizing the reaction of water molecule with a proton {[<sup>1</sup>H<sub>2</sub>O<sup>0</sup> + H<sup>+</sup>] ↔ [<sup>1</sup>H<sub>3</sub>O<sup>+</sup>(↑↓)]}, (figure, curve 7) was located at the area of higher energy than those of curves 3–6 describing the reactions involving the H<sub>2</sub>O<sup>+</sup> ion. Therefore, decomposition of hydroxonium ion without the electron trapping should follow the [<sup>1</sup>H<sub>2</sub>O<sup>0</sup> + H<sup>+</sup>] ↔ [<sup>1</sup>H<sub>3</sub>O<sup>+</sup>(↑↓)] → H<sub>2</sub>O<sup>+</sup>(↑) + H(↓) scheme, as mentioned above.

<sup>a</sup> ROB3LYP. <sup>b</sup> ROBLYP. <sup>c</sup> ROB3PW91, data from this work.

In view of the above, irradiation of water with the protons beam should result in generation of atomic and/or molecular hydrogen and in water ionization (the  $\text{H}_2\text{O}^+$  ions formation), whereas electron trapping with hydroxonium ion should be accompanied by energy release. The conclusion has been supported by the data reported in [44] demonstrating that the protons interaction with water differs depending on the protons velocity. Note that intersection of curves 7 and 10 in the figure caused by the spin-orbital interaction can yield the short-living metastable excited state of the  $^3\text{H}_3\text{O}^{+*}(\uparrow\uparrow)$  ion, further decomposing to form  $\text{H}_2\text{O}^+$ .

**Structure and hygroscopicity of small clusters of hydroxonium ion with water.** The available data has led to conclusion that interaction of hydroxonium ion with water molecules results in formation of intermolecular complexes, their stability being determined by the strongest hydrogen bond between the hydrogen atom and the oxygen atom of water molecule. The strongest O–H hydrogen bond was formed in the  $\text{H}_5\text{O}_2^+$  complex (Table 3).

The individual  $\text{H}_5\text{O}_2^+$  ion showing the specific electronic, geometry, and spectral parameters (Table 1) could exclusively exist in the gas phase at very low pressure and temperature: according to the performed simulation, any contact of the mentioned ion with one or several water molecules led to its transformation into the intermolecular complex (cluster)  $n\text{H}_2\text{O}$ ,  $n = 1-6$  (Tables 1 and 2) with the altered properties. Hence, the  $\text{H}_5\text{O}_2^+ - n(\text{H}_2\text{O})$  clusters should yield the  $\text{H}_3\text{O}^+ - (n+1)(\text{H}_2\text{O})$  ones, in agreement with the data of Jiang et al. [24].

Hydroxonium ion  $\text{H}_3\text{O}^+$  formed an unsymmetrical system with two water molecules (Table 2). Each of the water molecules of the formed structure was connected with a hydrogen atom of the hydroxonium ion via a single hydrogen bond,  $R[\text{O}(\text{H}_3\text{O}^+) - \text{O}(\text{H}_2\text{O})] = 2.491 \pm 0.004 \text{ \AA}$ . The O–H bonds of the hydroxonium ion participating in the hydrogen bonding were extended to  $1.045 \text{ \AA}$  at the average, whereas the third O–H bond became shorter, of  $0.966 \text{ \AA}$  (Table 2). Such complexes were observed in the atmosphere at the height of above 100 km as well as in the ionosphere; under those conditions, the complexes could interact with metal ions and further participate in catalytic processes of aerosols formation. Similar trends were observed in the case of the complex of hydroxonium ion with five water molecules (Table 2).

The  $\text{H}_3\text{O}^+ - 3\text{H}_2\text{O}$  complex was a regular pyramid with the hydroxonium ion located in its vertex. The

Cross-sections of energy surface of electronic terms of hydroxonium ion formation. See notation for 1–7 in the text.

base of the pyramid consisted of three water molecules. Oxygen atoms of water molecules were located in the vertexes of the equilateral triangle,  $\angle\text{OOO} \approx 60^\circ$  and  $R(\text{O} - \text{O})_{\text{H}_2\text{O}} = 4.269 \pm 0.01 \text{ \AA}$ . The lateral edge of the pyramid was of  $R[\text{O}(\text{H}_3\text{O}^+) - \text{O}(\text{H}_2\text{O})] = 2.559 \text{ \AA}$ , the angles at the pyramid vertex being practically equal ( $112.05^\circ$ ) (Table 2). Those results coincided well with the earlier reported data [16, 24, 29, 30].

The complex of hydroxonium ion with six water molecules could be viewed as a symmetrical pyramid with the  $\text{H}_3\text{O}^+$  ion in its vertex (Table 2). Each of the hydrogen atoms of the hydroxonium ion was connected with one water molecule via a hydrogen bond  $\{R[\text{O}(\text{H}_3\text{O}^+) - \text{O}(\text{H}_2\text{O})] = 1.549 \text{ \AA}\}$ , and oxygen atoms of the three water molecules nearest to the hydroxonium ion formed an isosceles triangle  $\Delta\text{OOO}$  with  $R(\text{O} - \text{O}) = 3.825 \pm 0.005 \text{ \AA}$  and the  $[\text{O}(\text{H}_2\text{O}) -$

**Table 3.** Separation energy of water molecules in  $2(\text{H}_2\text{O})$  dimer and molecular complexes of hydroxonium ion with water molecules

Complex	$E_b$ , eV	Complex	$E_b$ , eV
$\text{H}_5\text{O}_2^+$	1.39	$\text{H}_2\text{O} - \text{H}_2\text{O}$	0.28
$\text{H}_3\text{O}^+ - 2\text{H}_2\text{O}$	1.25	$\text{H}_3\text{O}^+ - 3\text{H}_2\text{O}$	0.95
$\text{H}_3\text{O}^+ - 5\text{H}_2\text{O}$	0.61	$3\text{H}_2\text{O} - \text{H}_3\text{O}^+ - \text{H}_2\text{O}$	0.089

$\text{O}(\text{H}_3\text{O}^+) - \text{O}(\text{H}_2\text{O})$ ] angle at the vertex of  $97^\circ \pm 0.1^\circ$ . The rest three water molecules were also symmetrically located around the central oxygen atom of the  $\text{H}_3\text{O}^+$  ion with the  $\angle \text{O}(\text{H}_2\text{O})\text{O}(\text{H}_3\text{O}^+)\text{O}(\text{H}_2\text{O})$  angle being of  $80.5 \pm 0^\circ$ . The edges of that isosceles triangle were  $4705 \pm 0.005$  Å long. The length of the hydrogen bond O–H between the nearest water molecule and the hydroxonium atom in the  $\text{H}_3\text{O}^+ - 6\text{H}_2\text{O}$  complex was of 1.55 Å, somewhat shorter than that in water dimer  $R(\text{O} - \text{H}) = 2.004$  Å according to the simulation].

Hence, the O–H bond length in the symmetrical complexes of hydroxonium ion with three and six water molecules was marginally changed with the complex nuclearity (1.015–1.023 Å), and the bond angles decreased from  $112.2^\circ$  to  $106.3^\circ$ , the lowest values being observed for the  $(\text{H}_3\text{O}^+ - 3\text{H}_2\text{O})\text{Cl}^-$  system (Table 1).

The length of the O–H bond forming the hydrogen bonding between hydroxonium ion and water molecules increased with increasing the number of water molecules in hydrate shell of the  $\text{H}_3\text{O}^+$  ion (Table 1).

Increase of the O–H bond length was the most prominent in the case of the complex with chloride ion  $(\text{H}_3\text{O}^+ - 3\text{H}_2\text{O})\text{Cl}^-$  (by 0.03 Å). The obtained values were in good accordance with the data reported earlier for the similar systems [45].

It has been earlier qualitatively considered that propensity of the  $\text{H}_3\text{O}^+$  ion to form hydrogen bonds should be significantly higher and its O–H bonds should be somewhat longer as compared to the corresponding parameters of water molecules. The  $\angle \text{HOH}$  angle in the  $\text{OH}_3^+$  ion should be higher than that in water molecule ( $104^\circ 31'$ ), however remaining below the tetrahedral one ( $109^\circ 28'$ ) [16].

Indeed, our simulation revealed that strength of the O–H hydrogen bonds between hydrogen atom of the hydroxonium ion and oxygen atom of the water molecule in the  $(\text{H}_3\text{O}^+ - n\text{H}_2\text{O})$  ( $n = 1-6$ ) clusters decreased with the increased nuclearity of the cluster, remaining higher than that in the  $\text{H}_2\text{O} - \text{H}_2\text{O}$  dimer (Table 3). That evidenced about the higher hygroscopicity of small clusters of hydroxonium ion with water molecules  $(\text{H}_3\text{O}^+ - n\text{H}_2\text{O})$  ( $n < 10$ ) as compared with that of water clusters  $n(\text{H}_2\text{O})$ .

To conclude, hygroscopicity of the  $(\text{H}_3\text{O}^+ - n\text{H}_2\text{O})$  clusters decreased with increasing number of the water molecules ( $n$ ); simultaneously the O–H bonds of water molecules and the cation participating in the hydrogen

bonding became shorter, the O–O distances between the adjacent water molecules in the first shell decreased with more of the water molecules in the second shell; the H–O–H angles in the water molecules forming the hydration shell of the hydroxonium ion ranged in between  $105.35^\circ$  and  $109.0^\circ$ ; the angles between the O–H bonds of the hydroxonium ion in the symmetrical complexes steadily decreased.

**Stereospecificity of intermolecular interactions between hydroxonium ion and water molecules in the small clusters.** It is generally accepted that oxygen atom of a hydroxonium ion forms four equivalent hybrid orbitals ( $sp^3$  hybridization) with three of them belonging to the covalent bonds and the forth being populated with a pair of non-bonding electrons (lone-electron pair). In this instance, electronic structure of hydroxonium ion is similar to that of ammonia molecule.

According to the structural data on molecular orbitals (MO) of the  $\text{H}_3\text{O}^+$  ion (Tables 4 and 5) and the  $\text{NH}_3$  molecule, all the molecular orbitals had the similar structure, with the highest occupied molecular orbital (HOMO) being majorly determined by the contribution from  $2p_z$  atomic orbital (AO) with certain admixture of  $2s(\text{O})$  and  $1s(\text{H}_{1,2,3})$  AOs. The lone-electron pair of ammonia is known to participate in the ammonium ion formation ( $\text{NH}_3 + \text{H}^+ = \text{NH}_4^+$ ); however, the  $\text{OH}_4^+$  ion cannot be formed, and existence of the unstable  $\text{H}_4\text{O}^{2+}$  particle is questionable [46].

It was therefore of interest to investigate stereospecificity of formation of the O–H hydrogen bonds by hydroxonium ion in the course of its hydration. The  $\text{O} \cdots \text{H}$  hydrogen bond in the  $\text{H}_3\text{O}^+ - (\text{H}_2\text{O})_n$  clusters should grow stronger with the enhanced polarization of the charge density (high in the absolute value and of the opposite signs) at the O and H atoms of the different molecules participating in the hydrogen bonding. Comparison of the charges at atoms obtained via the different simulation methods revealed that the charge at the oxygen atom of  $\text{H}_3\text{O}^+$  ranged in between  $+0.047$  and  $-0.029$   $e$ , even its lowest value being below that at the oxygen atom in water molecule ( $-0.5$   $e$ ) (Table 4), whereas the charges at the hydrogen atoms of  $\text{H}_3\text{O}^+$  were more positive than those at the hydrogen atoms of  $\text{H}_2\text{O}$ .

It could be presumed that  $\text{H}_3\text{O}^+$  ions were capable of strong hydrogen bonding with oxygen atoms of  $\text{H}_2\text{O}$  molecules (the hydrogen bond being stronger than that in water dimer) and weaker hydrogen bonding between  $\text{H}_3\text{O}^+$  oxygen and  $\text{H}_2\text{O}$  hydrogen atoms.

<sup>a</sup> Charges at atoms of water molecule simulated via those methods were of:  $q(\text{O}) -0.50 e$  and  $q(\text{H}) +0.25 e$ .

Indeed, the simulation revealed asymmetry of hydrogen bonds in the  $\text{H}_3\text{O}^+–4\text{H}_2\text{O}$  cluster. Analysis of cross-sections of potential energy surface pointed at formation of only three strong hydrogen bonds between hydrogen atoms of the hydroxonium ion and oxygen atoms of water molecules (Table 3). As expected, the weakest hydrogen bond was formed via coordination of the  $\text{H}_2\text{O}$  molecule at the oxygen atom in the vertex of trigonal pyramid of the hydroxonium ion. Strength of the weakest hydrogen bond decreased with the increasing nuclearity of the cluster. For instance, the well depth in the potential energy cross-section was the smallest (0.04 eV) in the case of hydroxonium ion complex with six water molecules. That evidenced about expulsion of the hydroxonium ion out of the water cluster of any nuclearity, due to the stronger hydrogen bond in the water dimer  $\text{H}_2\text{O}–\text{H}_2\text{O}$  as compared with the  $\text{O}–\text{H}_2\text{O}$  bond at the vertex of the  $\text{H}_3\text{O}^+$  pyramid.

**IR spectra of water molecule, hydroxonium ion, and its clusters with water.** Hydroxonium ions  $\text{H}_3\text{O}^+$  can be found in the form of thermally unstable particles in the gas phase, in the form of hydrated hydrogen ions in water and aqueous acids (even though their lifetimes are very short,  $T_{1/2} = 10^{-13}$  s), in the form of  $\text{H}_3\text{O}^+$  trigonal pyramid with the  $\text{H}–\text{O}–\text{H}$  bond angle of  $\approx 115^\circ$  in crystalline acids, and in certain minerals and artificial inorganic compounds. In some

complex minerals the presence of hydroxonium ion has been suggested theoretically; certain crystal hydrates contain associates of hydroxonium ions with water molecules [16]. Thermally unstable, the  $\text{H}_3\text{O}^+$  ions decompose with elimination of water in the gas phase, for instance, upon heating of the acidic form of zeolite in vacuum.

Earlier reports have marked formation of  $\text{H}_3\text{O}^+$  and their role in redox processes in the Earth atmosphere [1], in the molecular adsorption of water at oxides surface (in certain cases, for example, for dehydroxylated alumina [47], the dissociative adsorption of water yielding surface hydroxyl group being the preceding stage), in biological systems (for example, biological action of ionizing radiation leading to the local acidification of the aqueous system along the charged particle track caused by hydroxonium ion rather than water radiolysis products:  $\text{OH}$ ,  $\text{H}$ ,  $\text{O}_2^-$ , or  $\text{H}_2\text{O}_2$  [48]).

Despite a number of experimental studies having confirmed the presence of  $\text{H}_3\text{O}^+$  particles, hydroxonium ion has remained scarcely studied so far. In particular, there have been much less of spectrochemical and theoretical studies of hydroxonium ion as compared to similar reports on other hydroxyl compounds and water. Infrared spectroscopy has been recognized as a powerful method to determine the presence of water, hydroxyl groups, and hydroxonium

<sup>a</sup> Structures of MO of  $\text{H}_3\text{O}^+$  ion and  $\text{NH}_3$  molecule as simulated via different methods were qualitatively the same.

ion in liquid, gaseous, and crystalline hydroxyl-containing compounds; however, the studies have revealed different absorption bands in the spectrum of  $\text{H}_3\text{O}^+$  [16]. Being fairly broad, these bands have not been accurately located. On top of that, the bands assigned to hydroxonium ion overlap with these of water molecules, giving rise to continuous adsorption at 900–1800  $\text{cm}^{-1}$ , further complicating experimental study of hydroxonium ion complexes with water.

The early studies have aimed to estimate parameters of hydroxonium ion in the gas phase reasoning from the similarity between electronic structures of water and the  $\text{H}_3\text{O}^+$  ion. It has been assumed that the O–H bond should be about 0.99–1.0 Å long, since the length of the corresponding bonds of free and bound water is of 0.96–0.98 Å. Hence, the presence of associates of hydroxonium ion with water molecules has been suggested for the compounds with O–H bonds longer than 0.98 Å.

According to the IR spectroscopy data, the band of degenerate deformation vibration of the  $\text{H}_3\text{O}^+$  ion was stronger than that of the symmetric deformation vibration. Furthermore, the former band was narrower than the stretching bands; the stretching bands were somewhat stronger but more diffuse, strongly overlapped, and could not be easily identified in the spectrum.

Comparison of IR spectra of water molecule and hydroxonium ion revealed that positions of the  $\nu(\text{OH})$  stretching bands were not characteristic for identification of hydroxonium ion structure. The band of doubly degenerate deformation vibration seemed the only characteristic signal pointing at the presence of hydroxonium ion [16]. For instance, a band at 1650  $\text{cm}^{-1}$  assigned to deformational vibrations of  $\text{H}_3\text{O}^+$  as well as other deformational bands of  $\text{H}_3\text{O}^+$  at 1120 and 1150  $\text{cm}^{-1}$  have been observed in the spectra of mica, phlogopite, and muscovite as well as optical crystals of hexagonal lithium periodate [49].

It has been concluded that a broad strong IR absorption band in the spectra of hydrated titanium dioxide  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  with maxima at 3800–2600  $\text{cm}^{-1}$  is due to the presence of the free terminal OH groups and the groups participating in hydrogen bonding, whereas the low  $\nu(\text{OH})$  values (2851–2592  $\text{cm}^{-1}$ ) have been attributed to the presence of hydroxonium ion in the structure [50]. Since it is generally assumed that the  $\delta(\text{HOH})$  deformational vibrations of the  $\text{H}_3\text{O}^+$  ion are manifested at 1670–1800  $\text{cm}^{-1}$ , a group of the bands with maximums at 1696 and 1685  $\text{cm}^{-1}$  has been considered characteristic of hydroxonium ion in the  $\text{TiO}_2 \cdot \text{H}_2\text{O}$  structure [50].

In the case of perchloric acid hydrate  $\text{HClO}_4 \cdot \text{H}_2\text{O}$ , the bands assigned to deformational vibrations of the

$\text{H}_3\text{O}^+$  ion have been observed at 1670 and 2820–2400  $\text{cm}^{-1}$ . The spectrum of the  $\text{HClO}_4 \cdot 2\text{H}_2\text{O}$  hydrate contains deformational  $\delta(\text{HOH})$  vibration bands of the  $\text{H}_5\text{O}_2^+$  ion at 1680  $\text{cm}^{-1}$  [51]. Similarly, deformational vibrations give rise to the bands at 2780 and 1680  $\text{cm}^{-1}$  in the case of  $\text{HNO}_3 \cdot \text{H}_2\text{O}$  [52] and at 1700  $\text{cm}^{-1}$  in the case of hydrated liquid  $\text{SO}_2$  [53]. The mentioned bands as well as low-frequency  $\nu(\text{OH})$  bands below 2900  $\text{cm}^{-1}$  have been assigned to O–H vibrations of the  $\text{H}_3\text{O}^+$  ion; however, its characteristic bands are found in a different spectral range [54, 55].

Fundamental frequencies of hydroxonium ion ( $\nu_1 = 3370$ ,  $\nu_2 = 938$ ,  $\nu_3 = 3575$ , and  $\nu_4 = 1670$   $\text{cm}^{-1}$ ) have been determined theoretically using the transition equations [56] as well as via the Hartree–Fock method implemented in GAUSSIAN-98 software package (in the 3-21G or 6-311G basis accounting for the scaling factors of 0.9085 and 0.9051 as recommended in Ref. [57]). The quantum-chemical simulation performed in [56] has not allowed for unambiguous prediction of vibrational spectrum of hydroxonium ion, leading to significant deviations from the known values:  $\nu_1 = 3490$  [54] and 3760  $\text{cm}^{-1}$  [55],  $\nu_2 = 960$  [54] and 1050  $\text{cm}^{-1}$  [55],  $\nu_3 = 3610$  [54] and 3870  $\text{cm}^{-1}$  [55], and  $\nu_4 = 1590$  [54] and 1550  $\text{cm}^{-1}$  [55]. The accuracy of the bands positions found in Ref [54] has been claimed as of below  $200 \times 10^2$   $\text{m}^{-1}$  ( $\nu_1$ ,  $\nu_3$ , and  $\nu_4$ ) and below  $100 \times 10^2$   $\text{m}^{-1}$  ( $\nu_2$ ).

Analysis of results of simulation of IR spectra of  $\text{H}_2\text{O}$ ,  $\text{H}_3\text{O}^+$ , and  $\text{H}_3\text{O}^+(\text{H}_2\text{O})_n$  clusters taking into account the animation structure allows for confident assignment of the bands to stretching, deformational, and librational vibrations of the listed particles. Comparison of the spectra concludes about shifting of the maximums, changing the bands width, and appearance of new peaks with increasing the cluster nuclearity and evolution of its structure.

The simulated spectrum of  $\text{H}_2\text{O}$  contained a pair of weak single bands corresponding to the symmetric 3778  $\text{cm}^{-1}$  (3652–3857  $\text{cm}^{-1}$  [16, 33]) and asymmetric 3935  $\text{cm}^{-1}$  (3756–3913  $\text{cm}^{-1}$  [16, 18]) stretching along with a stronger deformational band at 1650  $\text{cm}^{-1}$  (1595–1650  $\text{cm}^{-1}$  [16, 18]) and a translational band.

In contrast to the IR spectrum of  $\text{H}_2\text{O}$ , that of the  $\text{H}_3\text{O}^+$  ion contained three lines making up a strong broad band in the region of stretching vibrations, two of the lines corresponding to asymmetric vibrations, at 3607 and 3706  $\text{cm}^{-1}$  (3518–3560  $\text{cm}^{-1}$  [28, 36]) and a weaker one at 3535  $\text{cm}^{-1}$  being assigned to symmetric

stretching (3389–3491  $\text{cm}^{-1}$  [27]). Two degenerate deformational vibrations were observed at 1677 and 1687  $\text{cm}^{-1}$  (1625 and 1638  $\text{cm}^{-1}$  [37]), whereas symmetric deformational (umbrella) band was found at 891  $\text{cm}^{-1}$  (954  $\text{cm}^{-1}$  [39]). Detailed information of the simulated fundamental vibrational frequencies in IR spectra of water molecule, hydroxonium ion, and their associates (1 to 6 water molecules) is collected in Table 6. The determined parameters well coincided with theoretical data and experimental spectroscopy studies [16, 18, 27–29, 32–37], thus indirectly confirming validity of the performed simulations.

Let us analyze evolution of characteristic bands of  $\text{H}_3\text{O}^+$  and  $\text{H}_2\text{O}$  upon formation of their small clusters and increasing the clusters nuclearity.

Characteristic frequencies of the isolated  $\text{H}_3\text{O}^+$  ion were as follows:  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+) = 3607$  and 3706  $\text{cm}^{-1}$  (3518–3560  $\text{cm}^{-1}$  [28, 36]),  $\nu_{\text{s}}(\text{OH})(\text{H}_3\text{O}^+) = 3535$   $\text{cm}^{-1}$  (3389–3491  $\text{cm}^{-1}$  [27]),  $\delta_{\text{as}}(\text{HOH})(\text{H}_3\text{O}^+) = 1677$  and 1687  $\text{cm}^{-1}$  (1625 and 1638  $\text{cm}^{-1}$  [37]), and  $\delta_{\text{s}}(\text{HOH})(\text{H}_3\text{O}^+)$  (umbrella) 891  $\text{cm}^{-1}$  (954  $\text{cm}^{-1}$  [39]) (Table 6). All stretching bands of  $\text{H}_3\text{O}^+$  revealed the red shift by 150–200  $\text{cm}^{-1}$ , and the deformational bands showed the blue shift by 30–50  $\text{cm}^{-1}$  as compared with IR spectrum of water.

Appearance of the isolated  $\text{H}_5\text{O}_2^+$  particles resulted in the combination bands absent in the IR spectra of water and hydroxonium ions,  $\text{cm}^{-1}$ :  $\delta(\text{HOH})(\text{H}_2\text{O}) + \nu(\text{OH})(\text{H}_2\text{O}) = 1756(21) + 1707(0.014)$ ;  $\nu(\text{OH})(\text{H}_2\text{O}) + \delta(\text{HOH}) \text{H}_2\text{O} = 1554(2.6) + 1468(6.7)$ ;  $\nu_{\text{as}}(\text{OH})(\text{H}_2\text{O})$  3825 ( $\text{H}_2\text{O}$ )(1), 3815 ( $\text{H}_2\text{O}$ )(2);  $\nu_{\text{s}}(\text{OH})(\text{H}_2\text{O})$  3731 ( $\text{H}_2\text{O}$ )(1), 3744 ( $\text{H}_2\text{O}$ )(2);  $\nu(\text{OH})(\text{H}_2\text{O})$  975(26) (proton transfer between the  $\text{H}_2\text{O}$  molecules). Two of the combination vibration maximums possessed the blue shift, and the other two vibrations revealed the red shift as compared with the simulated deformational frequencies of water molecule (1650  $\text{cm}^{-1}$ ) and hydroxonium ion (1677 and 1687  $\text{cm}^{-1}$ ). Frequencies of asymmetric and symmetric stretching of  $\text{H}_5\text{O}_2^+$  were lower than those of water ( $\nu_{\text{as}} = 3935$  and  $\nu_{\text{s}} = 3778$   $\text{cm}^{-1}$ ) but higher than those of hydroxonium ion ( $\nu_{\text{as}} = 3607$  and 3706  $\text{cm}^{-1}$ ,  $\nu_{\text{s}} = 3535$   $\text{cm}^{-1}$ ). On top of that, IR spectrum of isolated  $\text{H}_5\text{O}_2^+$  particles contained a maximum at  $\nu(\text{OH})(\text{H}_2\text{O})$  975(26)  $\text{cm}^{-1}$  corresponding to a proton transfer between the  $\text{H}_2\text{O}$  molecules. Frequency of that maximum was somewhat higher than the  $\delta_{\text{umbr}} = 891$   $\text{cm}^{-1}$  (954  $\text{cm}^{-1}$  [39]) of the symmetric (umbrella) deformational vibration of the  $\text{H}_3\text{O}^+$  ion.

**Table 6.** Theoretical and experimental vibrational frequencies ( $\nu$ ,  $\text{cm}^{-1}$ ) of  $\text{H}_2\text{O}$  molecule,  $\text{H}_3\text{O}^+$  ion, and  $^1(\text{H}_5\text{O}_2^+)$ ,  $^1(\text{H}_3\text{O}^+-2\text{H}_2\text{O})$ ,  $^1(\text{H}_3\text{O}^+-3\text{H}_2\text{O})$ ,  $^1(\text{H}_3\text{O}^+-5\text{H}_2\text{O})$ ,  $^1(\text{H}_3\text{O}^+-6\text{H}_2\text{O})$ , and  $(\text{H}_3\text{O}^+-3\text{H}_2\text{O})\text{Cl}^-$  complexes

Vibra- tion type	$\text{H}_2\text{O}$	$\text{H}_3\text{O}^+$	$\text{O}_2\text{H}_5^+$	$\text{H}_3\text{O}^+-2\text{H}_2\text{O}$	$\text{H}_3\text{O}^+-3\text{H}_2\text{O}$	$\text{H}_3\text{O}^+-5\text{H}_2\text{O}$	$\text{H}_3\text{O}^+-6\text{H}_2\text{O}$	$(\text{H}_3\text{O}^+-3\text{H}_2\text{O})\text{Cl}^-$

$\nu_{\text{umbr}}$	—	891, 954 [39]	—	1282	1271	1516	1442	1529
$\nu_{\text{as}}$	3935, 3756 [18], 3913 [16], 3798 [33], 3756 [33]	3607, 3706, 3560 [28], 3550 [28], 3519 [36]	3826, 3815, 3693 [28, 29], 3662 [28, 29]	3898 ( $\text{H}_2\text{O}$ ) (I), 3878 ( $\text{H}_2\text{O}$ ) (II), 3718 ( $\text{H}_2\text{O}$ ) [35], 3724 ( $\text{H}_2\text{O}$ ) [35], 2337 ( $\text{H}_3\text{O}^+$ ), 3775 ( $\text{H}_3\text{O}^+$ ), 2381 ( $\text{H}_3\text{O}^+$ ) [35], 3626 ( $\text{H}_3\text{O}^+$ ) [35], 3580 ( $\text{H}_3\text{O}^+$ ) [35]	3915 ( $\text{H}_2\text{O}$ ) (I), 3906 ( $\text{H}_2\text{O}$ ) (II), 3864 ( $\text{H}_2\text{O}$ ) (III), 3725 ( $\text{H}_2\text{O}$ ) [35], 2805 ( $\text{H}_3\text{O}^+$ ), 2753 ( $\text{H}_3\text{O}^+$ ), 2804 ( $\text{H}_3\text{O}^+$ ) [35]	3857 ( $\text{H}_2\text{O}$ ) (I), 3875 ( $\text{H}_2\text{O}$ ) (II), 3919 ( $\text{H}_2\text{O}$ ) (III), 3940 ( $\text{H}_2\text{O}$ ) (IV), 3943 ( $\text{H}_2\text{O}$ ) (V), 3961 ( $\text{H}_3\text{O}^+$ )	4002 ( $\text{H}_2\text{O}$ ) (I), 3957 ( $\text{H}_2\text{O}$ ) (II), 3954 ( $\text{H}_2\text{O}$ ) (III), 3914 ( $\text{H}_2\text{O}$ ) (IV), 3852 ( $\text{H}_2\text{O}$ ) (V), 3815 ( $\text{H}_2\text{O}$ ) (VI), 2741 ( $\text{H}_3\text{O}^+$ ), 2661 ( $\text{H}_3\text{O}^+$ )	3976 ( $\text{H}_2\text{O}$ ) (I), 3957 ( $\text{H}_2\text{O}$ ) (II), 3829 ( $\text{H}_2\text{O}$ ) (III), 3283 (HCl), 3283 ( $\text{H}_3\text{O}^+$ ), 2504 ( $\text{H}_3\text{O}^+$ )

IR spectrum of the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  complex contained a diffuse band at  $3775\text{--}3897\text{ cm}^{-1}$  caused by symmetric and asymmetric vibrations of two water molecules. The band position was almost the same as the range of the corresponding band in the water spectrum, but its intensity was lower. The medium-

intensity band at  $\nu(\text{OH})(\text{H}_3\text{O}^+) = 3775(4.5)\text{ cm}^{-1}$  corresponding to a large-amplitude ( $0.65\text{--}1.50\text{ \AA}$ ) asymmetric vibration of the only free O–H bond of the  $\text{H}_3\text{O}^+$  ion could be hardly identified without the amination representation due to overlap with the  $\nu_s(\text{H}_2\text{O}) = 3778\text{ cm}^{-1}$  band.

The spectrum of the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  cluster contained a strong band absent in IR spectra of  $\text{H}_2\text{O}$ ,  $\text{H}_3\text{O}^+$ , and  $\text{H}_5\text{O}_2^+$ . The first maximum of that band was assigned to asymmetric stretching of hydroxonium ion  $2337(94.6) \text{ cm}^{-1}$  with one of the O–H bonds of  $\text{H}_3\text{O}^+$  participating in the hydrogen bonding was extended and the other similar bond was shortened; the terminal O–H ( $\text{H}_3\text{O}^+$ ) bond was inactive in the vibration. The second maximum was assigned to a symmetric stretching of hydroxonium ion  $2564(28.4) \text{ cm}^{-1}$  with the both O–H bonds participating in the hydrogen bonding extending and shortening synchronously. The presence of those bands  $\nu_{\text{as}}(\text{OH}) = 2337(94.6)$  and  $\nu_{\text{s}}(\text{OH}) = 2564(28.4) \text{ cm}^{-1}$  in IR spectrum of  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  could be considered characteristic of the presence of  $\text{H}_3\text{O}^+$  particle in the discussed system.

Deformational vibrations of hydroxonium ion  $[1697(0.7) \text{ and } 1720(0.7) \text{ cm}^{-1}]$  and of water  $[1619(0.6) \text{ and } 1637(0.3) \text{ cm}^{-1}]$  were always mutually combined, complicating their assignment without considering the animation.

A medium-intensity band  $\delta(\text{HOH})\text{H}_3\text{O}^+$  with maximum at  $1282(5.3) \text{ cm}^{-1}$  in IR spectrum of the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  complex was also a characteristic one, pointing at the presence of hydroxonium ion in the complex. It revealed a blue shift as compared with an umbrella band of  $\text{H}_3\text{O}^+$  ( $891 \text{ cm}^{-1}$ ).

Similarly to the other above-discussed IR spectra, that of  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  contained the  $\nu(\text{OH})$  bands with maximums at  $3915(3)$ ,  $3906(3)$ , and  $3864(3) \text{ cm}^{-1}$  (asymmetric stretching of  $\text{H}_2\text{O}$ ), at  $3804(1.2)$ ,  $3785(1.4)$ , and  $3756(1.2) \text{ cm}^{-1}$  (symmetric stretching of  $\text{H}_2\text{O}$ ), and at  $2966\text{--}2753 \text{ cm}^{-1}$  (similar to the band at  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+) = 2337(94.6)$  and  $\nu_{\text{s}}(\text{OH})(\text{H}_3\text{O}^+) = 2564(28.4) \text{ cm}^{-1}$  in IR spectrum of the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  complex).

The peak at  $2966(11.1) \text{ cm}^{-1}$  in IR spectrum of  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  corresponded to symmetric stretching of  $\text{H}_3\text{O}^+$  with large amplitude of vibration of all the three hydrogen atoms. The strongest IR peak at  $2753(70.3) \text{ cm}^{-1}$  reflected asymmetric stretching in  $\text{H}_3\text{O}^+$ . The both peaks revealed the blue shift as compared to the corresponding bands in the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  spectrum. Noteworthy, the third stretching maximum at  $2805(62.5) \text{ cm}^{-1}$  was observed in the  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  spectrum, assigned to the  $\nu(\text{OH})$  vibration with abnormally high amplitude ( $0.44\text{--}1.56 \text{ \AA}$ ) of one of the three hydrogen atoms of hydroxonium ion. That could be rationalized as proton transfer from the  $\text{H}_3\text{O}^+$  ion to

the hydrogen-bonded water molecule. That vibration revealed a small contribution from symmetric stretching of the bound water. All those three strong maximums could serve as characteristic signals of hydroxonium ion presence in the  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  complex, in contrast to the weak deformation bands in hydroxonium ion  $[1742(0.3) \text{ and } 1729(0.4) \text{ cm}^{-1}]$  and in water molecule  $[1668(0.4)$ ,  $1650(1.3)$  and  $1636(1.4) \text{ cm}^{-1}]$ .

Another characteristic band pointing at the presence of the  $\text{H}_3\text{O}^+$  ion in the  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  cluster was a medium-intensity peak at  $1271(5.7) \text{ cm}^{-1}$ ; similarly to the case of the  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  complex, it was shifted towards high-frequency range as compared to the corresponding band of isolated hydroxonium ion ( $891 \text{ cm}^{-1}$ ).

Similarly to the spectra of complexes of lower nuclearity, IR spectrum of the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  complex (with one of the O–H bonds of hydroxonium ion remaining free) contained a weak diffuse band at  $3700\text{--}4000 \text{ cm}^{-1}$  consisting of a set of asymmetric and symmetric vibration bands of  $\text{H}_2\text{O}$  molecules not involved in the hydrogen bonding. In particular, the band contained a peak with maximum at  $3961(2.8) \text{ cm}^{-1}$  assigned to the stretching of terminal O–H group of the  $\text{H}_3\text{O}^+$  cation. That vibration with large amplitude ( $0.46\text{--}1.5 \text{ \AA}$ ) of the only hydrogen atom not involved in the hydrogen bonding could be considered as a vibration describing the proton elimination. However, that vibration could not be used as a characteristic signal of the presence of hydroxonium ion in the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  complex without the vibration animation analysis. Noteworthy, the symmetrical vibrations of the two water molecules with only a single OH group participating in the hydrogen bonding shifted towards lower frequency range  $[3494(21.5) \text{ and } 3374(21.8) \text{ cm}^{-1}]$  (Table 6). The both peaks assigned to symmetrical vibrations of water molecules in IR spectrum of the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  clusters were fairly strong, pointing at a variety of hydrogen bonding types in the complex.

Furthermore, IR spectrum of the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  cluster contained a band at  $2500\text{--}2750 \text{ cm}^{-1}$  revealing two strong maximums. They corresponded to symmetrical  $[2588(60.5) \text{ cm}^{-1}]$  and asymmetrical  $[2696(42.5) \text{ cm}^{-1}]$   $\nu(\text{OH})(\text{H}_3\text{O}^+)$  stretching. The presence of that band in IR spectrum is a characteristic signal of the presence of  $\text{H}_3\text{O}^+$  ion in the structure.

The  $1500\text{--}1800 \text{ cm}^{-1}$  band in the spectrum of the same cluster contained eight maximums corresponding to combination deformational bands of hydroxonium ion and water molecule as well as to those of various

water molecules. Only in the cases of four high-frequency maximums the contribution from the  $\delta(\text{H}_3\text{O}^+)$  vibration was higher than that of water deformational vibration:  $1773(13.3) = \delta(\text{H}_3\text{O}^+) + 2\delta(\text{H}_2\text{O}) + \nu(\text{OH})(\text{H}_3\text{O}^+)$ ;  $1733(0.08) = \delta(\text{H}_3\text{O}^+) + 2\delta(\text{H}_2\text{O}) + \nu(\text{OH})(\text{H}_3\text{O}^+)$ ;  $1696(1.2) = \delta(\text{H}_3\text{O}^+) + 3\delta(\text{H}_2\text{O})$ ;  $1681(2.7) = 2\delta(\text{H}_3\text{O}^+) + \delta(\text{H}_2\text{O})$ .

All those maximums revealed the blue shift by 20–100  $\text{cm}^{-1}$  with respect to the similar vibrations of water and hydroxonium ion; however, the most high-frequency peak was the strongest one, and could therefore serve as a signal of the presence of  $\text{H}_3\text{O}^+$  ion in the complex.

A broad band at 800–1200  $\text{cm}^{-1}$  in the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  cluster spectrum consisted of a set of combination deformational bands of hydroxonium ion and water molecules as well:  $\delta(\text{H}_3\text{O}^+) + \delta(\text{H}_2\text{O}) + \nu(\text{OH})(\text{H}_3\text{O}^+) + \nu(\text{OH})(\text{H}_2\text{O})$ . The maximums at 852(4.0) and 831(2.6)  $\text{cm}^{-1}$  corresponded to torsion and deformational bands of water:  $\nu_{\text{tors}}(\text{H}_2\text{O}) + \delta(\text{H}_2\text{O})$ . A weak band at 701(0.6)  $\text{cm}^{-1}$  was a combination torsion vibration of water molecule and hydroxonium ion:  $\nu_{\text{tors}}(\text{H}_3\text{O}^+) + 2\nu_{\text{tors}}(\text{H}_2\text{O})$ .

The maximum at 1515(6.3)  $\text{cm}^{-1}$  in the same spectrum was assigned to a combination  $\text{H}_3\text{O}^+$  umbrella and torsion water vibrations:  $\delta_{\text{umb}}(\text{H}_3\text{O}^+) + 2\nu_{\text{tors}}(\text{H}_2\text{O})$ . That maximum was similar to the corresponding peaks in the  $\text{H}_3\text{O}^+$ ,  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$ , and  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  spectra, characteristic of the presence of the  $\text{H}_3\text{O}^+$  ion in the complexes; but in the case of the  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$  cluster that signal was shifted towards high-frequency domain.

Two strong maximums at 2741(40.3) and 2661(40.1)  $\text{cm}^{-1}$  in IR spectrum of the  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}$  complex corresponded to asymmetric stretching of hydroxonium ion, whereas a maximum at 2977(19.4)  $\text{cm}^{-1}$  was assigned to the symmetric stretching of  $\text{H}_3\text{O}^+$ . The strongest maximum of umbrella deformation at 1442(7.9)  $\text{cm}^{-1}$ , a part of a weak band at 1400–1800  $\text{cm}^{-1}$ , could serve as confirmation of hydroxonium ion presence in that complex.

Hence, the increasing number of water molecules in the  $\text{H}_3\text{O}^+-n\text{H}_2\text{O}$  complex resulted in appearance of a group of the maximums at 1400–1500  $\text{cm}^{-1}$  and 1700–1800  $\text{cm}^{-1}$  assigned to the  $\delta(\text{HOH}) = \delta(\text{HOH})(\text{H}_3\text{O}^+) + \delta(\text{HOH})(\text{H}_2\text{O})$  (medium) and  $\delta(\text{HOH}) = \delta(\text{HOH})(\text{H}_2\text{O}) + \delta(\text{HOH})(\text{H}_3\text{O}^+)$  (weak) combination bands, correspondingly, on top of the overlapping maximums at 1550–

1650  $\text{cm}^{-1}$  [ $\delta(\text{HOH})(\text{H}_3\text{O}^+)$  and  $\delta(\text{HOH})(\text{H}_2\text{O})$ ]. Frequency and intensity of the combination bands with the higher  $\delta(\text{HOH})(\text{H}_3\text{O}^+)$  contribution grew higher with the increasing cluster nuclearity; therefore, those bands could be considered a signal pointing at the presence of the  $\text{H}_3\text{O}^+$  ions in the system.

Another characteristic indication of the presence of the  $\text{H}_3\text{O}^+$  ion in the  $\text{H}_3\text{O}^+-n\text{H}_2\text{O}$  complex ( $n \rightarrow 1$ ) was a presence of strong well-resolved maximums in a relatively narrow range of the IR spectrum, 2300–3000  $\text{cm}^{-1}$ . Importantly, position of the  $\nu(\text{OH})(\text{H}_3\text{O}^+)$  band in the case of the complexes containing a free O–H bond in the  $\text{H}_3\text{O}^+$  ion ( $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$  and  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$ ) and in the complexes with all the O–H bonds forming the hydrogen bonds ( $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$  and  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}$ ) differed by  $\approx 400$   $\text{cm}^{-1}$ ; whereas the positions of the  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  or  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  bands in the spectra of the clusters of the same type but different nuclearity were different by only 10–20  $\text{cm}^{-1}$ :  $\text{H}_3\text{O}^+-2\text{H}_2\text{O}$ ,  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  2564(28.4) and  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  2337(94.6)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}$ ,  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  2588(60.5) and  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  2697(42.5)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$ ,  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  2966(11.1) and  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  2753(70.3)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}$ ,  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  2978(19.4) and  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  2741(40.3)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-3\text{H}_2\text{O}$ ,  $\nu(\text{OH})(\text{H}_3\text{O}^+)$  2805(62.5)  $\text{cm}^{-1}$  (transfer of  $\text{H}^+$  to  $\text{H}_2\text{O}$ ) (0.44–1.56 Å);  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}$ ,  $\nu_{\text{as}}(\text{OH})(\text{H}_3\text{O}^+)$  2662(40.1)  $\text{cm}^{-1}$ .

The spectra of the  $\text{H}_3\text{O}^+-n\text{H}_2\text{O}$  ( $n \rightarrow 3$ ) clusters contained a band with maximums at 3100–3500  $\text{cm}^{-1}$  evidencing about hydrogen bonding of the water molecules (with one of the O–H bonds being associated and the other one, terminal, remaining free). Hereafter the number of the coordination sphere of water molecule with respect to the hydroxonium ion is enumerated in the parentheses after the  $\text{H}_2\text{O}$  symbol. Those maximums appeared exclusively in the presence of water molecules connected via a hydrogen bond with one another. Evidently, the higher was the coordination sphere number, the closer was the  $\nu_s(\text{OH})(\text{H}_2\text{O})$  frequency to that of  $\nu(\text{OH})$  of isolated water molecule:  $\text{H}_3\text{O}^+-5\text{H}_2\text{O}(\text{I})$ ,  $\nu_s(\text{OH})(\text{H}_2\text{O})$  3494(21.5) and 3374(21.8)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}(\text{I})$ ,  $\nu_s(\text{OH})(\text{H}_2\text{O})$  3285(35.4), 3242(30.5), and 3171(23.6)  $\text{cm}^{-1}$ ;  $\text{H}_3\text{O}^+-6\text{H}_2\text{O}(\text{II})$ ,  $\nu_s(\text{OH})(\text{H}_2\text{O})$  3774(7.1), 3664(7.5), and 3637(7.0)  $\text{cm}^{-1}$ .

Another important indication of the presence of  $\text{H}_3\text{O}^+$  ions [either isolated or part of the  $\text{H}_3\text{O}^+-n\text{H}_2\text{O}$  ( $n \rightarrow 1$ ) complexes] was the presence of strong maximum at 890–1500  $\text{cm}^{-1}$  assigned to the umbrella  $\delta$

(HOH) deformation. Frequency of that maximum increased with the growing cluster nuclearity:  $\nu_{\text{umbr}} = 891$  ( $n = 1$ ), 1282 ( $n = 2$ ), 1272 ( $n = 3$ ), 1516 ( $n = 5$ ), and 1442 ( $n = 6$ )  $\text{cm}^{-1}$ . The listed bands could be used for elucidation of the  $\text{H}_3\text{O}^+ - n\text{H}_2\text{O}$  complex structure in the gas phase.

In the case of the  $(\text{H}_3\text{O}^+ - 3\text{H}_2\text{O})\text{Cl}^-$  complex, the frequency of symmetric stretching of water molecules were lower as compared to the other complexes. At the same time, deformational and asymmetric stretching vibrations of the chlorine-containing complex were similar to those of aqueous complexes of hydroxonium ion.

Noteworthy, the vibrational spectra were simulated at 298 K in the gas phase. It is therefore unclear whether the discussed trend of the umbrella vibration shift will be preserved at higher temperature. According to the experiment, vibrations of hydroxonium ion in the condensed phase were marginally different from the corresponding vibrations of water molecules [31].

To conclude, the study of hydroxonium ion and its small clusters with water molecules has revealed that the  $\text{H}_3\text{O}^+$  ion is formed upon collision of water molecule and a proton via a barrier-free mechanism. Electron trapping with hydroxonium ion should be accompanied with the energy release. The  $\text{H}_3\text{O}^+ - n\text{H}_2\text{O}$  ( $n \leq 6$ ) small clusters are less stable and more hygroscopic as compared to water clusters. Therefore, the hydroxonium ion clusters can be viewed as a nucleus of the condensed phase with the hydroxonium ion being expelled to the surface rather than coordinated in the interior (since oxygen atom of  $\text{H}_3\text{O}^+$  is not involved in the hydrogen bonding with water molecules). The presence of  $\text{H}_3\text{O}^+$  in the aquatic clusters is reflected in the IR spectra in the appearance of well resolved relatively strong maximums at 2300–2900  $\text{cm}^{-1}$ , absent in the spectra of water clusters and assigned to symmetric and asymmetric stretching of the hydrogen-bound O–H ( $\text{H}_3\text{O}^+$ ) bonds. The maximums of  $\nu_s(\text{OH})(\text{H}_3\text{O}^+)$  are located at  $\approx 400$   $\text{cm}^{-1}$  higher frequency in the cases of the clusters with all the three O–H bonds of  $\text{H}_3\text{O}^+$  interacting with water molecules as compared to the clusters containing a single free (terminal) O–H bond in the hydroxonium ion. Symmetric deformation (umbrella) band at 900–1450  $\text{cm}^{-1}$  is another important indication of the presence of  $\text{H}_3\text{O}^+$  in its aquatic clusters; frequency of that vibration increases with the higher cluster nuclearity.
