PHASE PORTRAIT OF THE MATRIX RICCATI EQUATION*

MARK A. SHAYMAN†

Abstract. The matrix Riccati equation which arises from optimal control and filtering problems is a quadratic differential equation on the space of real symmetric $n \times n$ matrices. It is closely related, via compactification of the phase space, to the differential equations on the Grassmann manifold and the Lagrange-Grassmann manifold whose flows are generated by the action of one-parameter subgroups of the general linear group and of the symplectic group respectively. We determine the complete phase portraits of the Riccati equations on all three spaces. The asymptotic behavior of *every* solution is described. The phase portraits are characterized topologically as well as set-theoretically. Although the Riccati equation is not generally a Morse-Smale vector field, we are able to show that it possesses suitable generalizations of many of the important properties of Morse-Smale vector fields. In particular, the Riccati equation satisfies a generalized version of the Morse inequalities for a Morse-Smale dynamical system. In fact, for the Riccati equation, the inequalities are actually equalities.

Key words. Riccati differential equation, phase portrait, Grassmann manifold, Lagrange-Grassmann manifold, Schubert cell decomposition, Morse-Smale flows

CONTENTS

1. Introduction.

By the matrix Riccati differential equation (RDE) we mean the quadratic differential equation

$$\dot{K} = B_{21} + B_{22}K - KB_{11} - KB_{12}K$$

* Received by the editors March 17, 1983, and in revised form August 10, 1984. This research was partially supported by the National Science Foundation under grant ECS-8301015. A summary of the results described in this paper was presented at the Conference on Information Sciences and Systems, the Johns Hopkins University, March 1983.

defined on the vector space $\mathbb{R}^{m\times n}$ of real $m\times n$ matrices. B_{21}, B_{22}, B_{11}, B_{12} are constant real matrices of dimensions $m\times n$, $m\times m$, $n\times n$, and $n\times m$ respectively.

The matrix Riccati equation plays a critical role in a wide variety of applications which include transmission line phenomena, the theory of stochastic processes, optimal control and filtering, diffusion problems, and invariant imbedding [32]. It is also of independent mathematical interest because it is the description in local coordinates of the differential equation on the Grassmann manifold whose flow is given by the action of a 1-parameter subgroup of the general linear group. This is discussed below.

We are particularly interested in the Riccati equation which arises in optimal control and filtering problems. It has the form

$$\dot{K} = -Q - A'K - KA + KLK$$

defined on the space $\mathbb{R}^{n\times n}$ of real $n\times n$ matrices. A, L, Q are constant real $n\times n$ matrices with L and Q symmetric and L nonnegative definite. The vector space $S(n)$ of real symmetric $n\times n$ matrices is an invariant manifold for this differential equation, and it is the restriction to $S(n)$ which is important in the applications. Thus, we will regard this differential equation as defined on $S(n)$, and call it the *symplectic Riccati differential equation* (SRDE) for reasons which will become apparent. The role of the SRDE in linear quadratic control problems is described in [5].

It has been known at least since the time of Poincaré that the topology of certain differential equations in the plane could be clarified by extending the domain to the projective plane. It was observed by C. Schneider [33] that the natural compactification of the domain $\mathbb{R}^{m\times n}$ for the RDE is the Grassmann manifold $G^n(\mathbb{R}^{n+m})$ of n-dimensional subspaces of $\mathbb{R}^{n+m}$. We will refer to the Riccati equation on $G^n(\mathbb{R}^{n+m})$ as the *extended Riccati differential equation* (ERDE). The natural compactification of the domain $S(n)$ for the SRDE has been described by R. Hermann and C. Martin [16], [27]. It is the so-called Lagrange-Grassmann manifold $\mathscr{L}(n)$ consisting of those subspaces belonging to $G^n(\mathbb{R}^{2n})$ on which a certain skew-symmetric bilinear form vanishes identically. We will refer to the symplectic Riccati equation on $\mathscr{L}(n)$ as the *extended symplectic Riccati differential equation* (ESRDE). The compactification of the domains of the RDE and SRDE is useful when investigating the behavior of trajectories at infinity. However, the principal advantage of the compactifications is that for both the ERDE and the ESRDE, the flow is obtained from the action of a 1-parameter subgroup of a matrix Lie group. For the ERDE, the Lie group is the general linear group $\mathrm{Gl}(n+m,\mathbb{R})$ while for the ESRDE, the Lie group is the symplectic group $\mathrm{Sp}(n,\mathbb{R})$.

The primary purpose of this paper is to give the complete phase portrait for the Riccati equation arising from the control and filtering applications, i.e. the symplectic Riccati differential equation on $S(n)$. However, the procedure we follow leads us to first determine the complete phase portraits for the ERDE and the ESRDE. Our results describe the asymptotic behavior of *every* solution for the ERDE, ESRDE, and SRDE. Under generic assumptions, the distinctive features of the phase portraits of Riccati equations are (1) a nonwandering set which consists of tori of various dimensions, and (2) stable and unstable manifolds which are unions of so-called Schubert cells. It was shown recently [18] that matrix Riccati equations on $G^n(\mathbb{R}^{n+m})$ are not generically Morse-Smale.[1] Our results show that although Riccati equations are generally not Morse-Smale, their phase portraits reflect the topology of the underlying manifold in an analogous way. For example, we show that Riccati vector fields satisfy a suitable

[1] This corrects the contrary announcement in [19].

generalization of the Morse-Smale inequalities. In fact, for the Riccati equation, the inequalities are actually equalities. We also use the phase portrait of the Riccati equation to obtain new derivations of the mod 2 Betti numbers for the Grassmann manifold and the Lagrange-Grassmann manifold.

In the penultimate section, we extend our results to include almost all of the Riccati equations which are excluded by the generic assumptions in force throughout the earlier sections. Under the relaxed assumptions, the connected components of the nonwandering set are products of Grassmannians, while the stable and unstable manifolds remain unions of Schubert cells.

Much of the research on Riccati equations has focused on the "stabilizing" equilibrium point of the SRDE, i.e. the equilibrium point K^+ which has the property that every eigenvalue of the closed loop plant matrix $A-LK^+$ has negative real part. However, recent work has also involved study of periodic solutions [29], [18], [19], [37] and convergence (and nonconvergence) of trajectories to equilibrium points other than K^+ [8]. Although there is a vast literature on Riccati equations, as far as we are aware, our results provide for the first time a complete description of the asymptotic behavior of every solution under assumptions which are satisfied by almost every SRDE which arises from control and filtering problems.

We have used similar techniques to obtain the phase portrait for the matrix Riccati equation in which the coefficient matrices are periodic functions of time [38], [40].

2. Extension of the phase space. In this section, we review how the RDE is extended to the ERDE on $G^n(\mathbb{R}^{n+m})$ [33], and how the SRDE is extended to the ESRDE on $\mathscr{L}(n)$ [16], [27]. Let $\psi:\mathbb{R}^{m\times n}\to G^n(\mathbb{R}^{n+m})$ be defined by $\psi(K)=\operatorname{Sp}\left[\begin{smallmatrix} I_n \\ K \end{smallmatrix}\right]$, the column space of the $(n+m)\times n$ full rank matrix $\left[\begin{smallmatrix} I_n \\ K \end{smallmatrix}\right]$. Let $G_0^n(\mathbb{R}^{n+m})$ consist of those subspaces in $G^n(\mathbb{R}^{n+m})$ which are complementary to the m-dimensional subspace $\operatorname{Sp}\left[\begin{smallmatrix} 0 \\ I_m \end{smallmatrix}\right]$. Then ψ embeds the Euclidean space $\mathbb{R}^{m\times n}$ in $G^n(\mathbb{R}^{n+m})$ as the open and dense subset $G_0^n(\mathbb{R}^{n+m})$. In fact, $(G_0^n(\mathbb{R}^{n+m}), \psi^{-1})$ is one of the standard charts for the manifold $G^n(\mathbb{R}^{n+m})$. (See Appendix.) Thus, $G^n(\mathbb{R}^{n+m})$ can be viewed as a compactification of $\mathbb{R}^{m\times n}$.

Let $K(t, K_0)$ denote the solution of the RDE for the initial point K_0. Let B denote the $(n+m)\times(n+m)$ matrix $\left[\begin{smallmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{smallmatrix}\right]$. Define a flow on $G^n(\mathbb{R}^{n+m})$ by $S(t, S_0)=e^{Bt}(S_0)$, where $e^{Bt}(S_0)$ is the image of the subspace S_0 under $e^{Bt}\in \mathrm{Gl}(n+m, \mathbb{R})$. It is straightforward to verify that we have

$$\psi(K(t, K_0)) = S(t, \psi(K_0))$$

whenever $K(t, K_0)$ exists. This means that the RDE is the local expression with respect to the chart $(G_0^n(\mathbb{R}^{n+m}), \psi^{-1})$ for the differential equation on $G^n(\mathbb{R}^{n+m})$ which corresponds to the flow $S(t, S_0)$. To say this another way, if we use the embedding ψ to identify $\mathbb{R}^{m\times n}$ with $G_0^n(\mathbb{R}^{n+m})$, then the restriction to $G_0^n(\mathbb{R}^{n+m})$ of the flow $S(t, S_0)$ on $G^n(\mathbb{R}^{n+m})$ is identified with the flow of the RDE. $K(t, K_0)$ ceases to exist (due to finite escape time) precisely when $S(t, \psi(K_0))$ leaves the subset $G_0^n(\mathbb{R}^{n+m})$. By the *extended Riccati differential equation* (ERDE), we mean the differential equation on $G^n(\mathbb{R}^{n+m})$ whose flow is given by $S(t, S_0)=e^{Bt}(S_0)$. Thus, the flow of the ERDE is given by the action of a one-parameter subgroup of $\mathrm{Gl}(n+m, \mathbb{R})$ on $G^n(\mathbb{R}^{n+m})$.

Next we describe how the symplectic Riccati differential equation is extended to the Lagrange-Grassmann manifold $\mathscr{L}(n)$. Let J denote the $2n\times 2n$ matrix $\left[\begin{smallmatrix} 0 & I \\ -I & 0 \end{smallmatrix}\right]$, and define a skew-symmetric bilinear form ω on $\mathbb{R}^{2n}$ by $\omega(x, y)=x'Jy$. Then $\mathscr{L}(n)$ is defined to be the subset $\{S\in G^n(\mathbb{R}^{2n})\colon \omega(x, y)=0, \forall x, y\in S\}$ of $G^n(\mathbb{R}^{2n})$. If the standard inner product is assigned to $\mathbb{R}^{2n}$, then $\mathscr{L}(n)=\{S\in G^n(\mathbb{R}^{2n})\colon J(S)=S^\perp\}$. We will say that a subspace S of $\mathbb{R}^{2n}$ (of any dimension) is Lagrangian iff $J(S)\perp S$.

Let $\mathrm{Sp}(n, \mathbb{R})$ denote the symplectic group, i.e. $\mathrm{Sp}(n, \mathbb{R}) = \{P \in \mathrm{Gl}(2n, \mathbb{R}): P'JP = J\}$. Let $\mathrm{sp}(n, \mathbb{R})$ denote its Lie algebra. $\mathrm{sp}(n, \mathbb{R})$ consists of all $2n \times 2n$ real matrices H which satisfy $JH + H'J = 0$. This is equivalent to requiring that H have the partitioned form $\left[\begin{smallmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{smallmatrix}\right]$ with each submatrix $n \times n$, $H_{12} = H'_{12}$, $H_{21} = H'_{21}$, and $H_{22} = -H'_{11}$. If $S \in \mathscr{L}(n)$ and $P \in \mathrm{Sp}(n, \mathbb{R})$, then $P(S) \in \mathscr{L}(n)$, so $\mathrm{Sp}(n, \mathbb{R})$ acts on $\mathscr{L}(n)$. In fact, it can be shown [16] that $\mathscr{L}(n)$ is a homogeneous space of $\mathrm{Sp}(n, \mathbb{R})$. It can also be shown [17] that $\mathscr{L}(n)$ is the homogeneous space $U(n)/O(n)$, where $U(n)$ and $O(n)$ are the unitary and orthogonal groups respectively.

It is easy to check that if K is an $n \times n$ matrix, then $\mathrm{Sp}\left[\begin{smallmatrix} I_n \\ K \end{smallmatrix}\right]$ belongs to $\mathscr{L}(n)$ iff K is symmetric. Thus we can define $\phi: S(n) \to \mathscr{L}(n)$ by $\phi(K) = \mathrm{Sp}\left[\begin{smallmatrix} I_n \\ K \end{smallmatrix}\right]$. Let $\mathscr{L}_0(n)$ consist of those subspaces in $\mathscr{L}(n)$ which are complementary to the n-dimensional subspace $\mathrm{Sp}\left[\begin{smallmatrix} 0 \\ I_n \end{smallmatrix}\right]$. Then ϕ embeds the Euclidean space $S(n)$ in $\mathscr{L}(n)$ as the open and dense subset $\mathscr{L}_0(n)$. Thus, $\mathscr{L}(n)$ can be viewed as a compactification of $S(n)$.

Let $K(t, K_0)$ denote the solution of the SRDE for the initial point K_0, and let $H \in \mathrm{sp}(n, \mathbb{R})$ denote the $2n \times 2n$ matrix

$$\begin{bmatrix} A & -L \\ -Q & -A' \end{bmatrix}.$$

H is often referred to as the Hamiltonian matrix associated with the Riccati equation. Define a flow on $\mathscr{L}(n)$ by $S(t, S_0) = e^{Ht}(S_0)$. We have

$$\phi(K(t, K_0)) = S(t, \phi(K_0))$$

whenever $K(t, K_0)$ exists. Thus, $S(t, S_0)$ is the extension to $\mathscr{L}(n)$ of the flow of the SRDE on $S(n)$. By the *extended symplectic Riccati differential equation* (ESRDE), we mean the differential equation on $\mathscr{L}(n)$ whose flow is given by $S(t, S_0) = e^{Ht}(S_0)$. Thus, the flow of the ESRDE is given by the action of a one-parameter subgroup of $\mathrm{Sp}(n, \mathbb{R})$ on $\mathscr{L}(n)$.

In the next three sections, we successively determine the phase portraits of the ERDE, ESRDE, and SRDE. When we consider the ESRDE, we will drop the assumption that the symmetric matrix L be nonnegative definite. However, when we consider the SRDE, we will reinstate this assumption.

The use of the Grassmann manifold in the theory of the Riccati equation is closely related to the use of the state-costate equations in the study of the Riccati equation. Partition the matrix e^{Ht} as

$$\begin{bmatrix} P_{11}(t) & P_{12}(t) \\ P_{21}(t) & P_{22}(t) \end{bmatrix}.$$

Then it is well known [5, p. 156] that the solution of the SRDE with initial condition K_0 is given by

$$(*) \qquad K(t, K_0) = (P_{21}(t) + P_{22}(t)K_0)(P_{11}(t) + P_{12}(t)K_0)^{-1}.$$

This formula is valid in the largest time interval containing 0 on which the indicated inverse exists. This formula is equivalent to the formula

$$(**) \qquad \phi(K(t, K_0)) = S(t, \phi(K_0))$$

given above, which relates the flow of the ESRDE on $\mathscr{L}(n)$ to the flow of SRDE on

$S(n)$. To see this, note that

$$\begin{aligned} S(t, \phi(K_0)) &= e^{Ht}\left(\mathrm{Sp}\begin{bmatrix} I \\ K_0 \end{bmatrix}\right) \\ &= \mathrm{Sp}\begin{bmatrix} P_{11}(t)+P_{12}(t)K_0 \\ P_{21}(t)+P_{22}(t)K_0 \end{bmatrix} \\ &= \mathrm{Sp}\begin{bmatrix} I \\ (P_{21}(t)+P_{22}(t)K_0)(P_{11}(t)+P_{12}(t)K_0)^{-1} \end{bmatrix} \\ &= \phi((P_{21}(t)+P_{22}(t)K_0)(P_{11}(t)+P_{12}(t)K_0)^{-1}). \end{aligned}$$

Thus, (**) is equivalent to the formula

$$\phi(K(t, K_0)) = \phi((P_{21}(t)+P_{22}(t)K_0)(P_{11}(t)+P_{12}(t)K_0)^{-1}).$$

Since ϕ is injective, this is equivalent to (*).

Since (*) is equivalent to (**), we could use (*) and thereby avoid introducing the Grassmann manifold. This would have two drawbacks. The first is that the ERDE and the ESRDE turn out to be extremely interesting differential equations in themselves, when studied from the point of view of differentiable dynamical systems on compact manifolds. The second drawback is that the phase portrait of the Riccati equation (even when considered in the usual sense as a differential equation on $S(n)$) is closely related to the topology of the Grassmann manifold. In particular, we shall see that the Schubert cell decomposition of the Grassmann manifold plays an essential role in the description of the phase portrait. If we were to avoid introducing the Grassmann manifold, we would be losing the key insight obtainable from its topology.

3. Phase portrait of the extended Riccati differential equation. In this section, we determine the complete phase portrait for the ERDE on $G^n(\mathbb{R}^{n+m})$. We make the following assumptions which we denote collectively as Assumption A1: (1) the $n+m$ eigenvalues of B are distinct, and (2) if λ_i and λ_j are a pair of eigenvalues with the same real part, then $\lambda_i = \bar{\lambda}_j$. (Overbar denotes complex conjugation.) Each of these assumptions holds generically. These assumptions are relaxed considerably in § 6.

We fix some notation. Let p denote the number of real eigenvalues of B, and let q denote the number of conjugate pairs of nonreal eigenvalues of B. (So $p+2q = n+m$.) Let $r = p+q$, and let $E_1, \cdots, E_r$ denote the primary components of B ordered according to increasing real part of the corresponding eigenvalue(s). Thus, each E_j is either one-dimensional or two-dimensional. Also, if $i<j$ and if λ_i and λ_j are eigenvalues which correspond to E_i and E_j respectively, then $\mathrm{Re}\,\lambda_i < \mathrm{Re}\,\lambda_j$.

In the very special case where B has only real eigenvalues (i.e. $q=0$), the phase portrait of the ERDE was described by C. R. Schneider [33]. This reference also considers the corresponding discrete dynamical system associated with the Riccati equation in which the coefficient matrices are periodic. Similar results in the discrete case were obtained by S. Batterson [1]. N. Kuiper has considered the discrete case in the special case when $n=1$ or $m=1$ [22].

3.1. Nonwandering set, stable and unstable manifolds. The Grassmann manifold $G^n(\mathbb{R}^{n+m})$ can be given the structure of a metric space by defining on it the so-called "gap metric" ρ. (See [14] for details concerning this metric.) If $S_1, S_2 \in G^n(\mathbb{R}^{n+m})$ and if P_1, P_2 are the orthogonal projections onto S_1, S_2 respectively, then $\rho(S_1, S_2) =^{\mathrm{def}} \|P_1 - P_2\|$ (operator norm). $G^n(\mathbb{R}^{n+m})$ is a compact (and hence complete) metric space in the metric ρ.

The gap metric is widely used by analysts. However, topologists define a topology on $G^n(\mathbb{R}^{n+m})$ in a different way. Let $V_n(\mathbb{R}^{n+m})$ denote the set of all $(n+m)\times n$ full rank matrices with real entries. $V_n(\mathbb{R}^{n+m})$ is an open subset of $\mathbb{R}^{(n+m)\times n}$ and thus has the standard Euclidean topology. ($V_n(\mathbb{R}^{n+m})$ is known as a Stiefel manifold.) Define a mapping q: $V_n(\mathbb{R}^{n+m})\to G^n(\mathbb{R}^{n+m})$ with $q(Y)$ the column space Sp Y of the matrix Y. Then $G^n(\mathbb{R}^{n+m})$ is given the quotient topology induced by the surjective map q. In other words, a subset U of $G^n(\mathbb{R}^{n+m})$ is open if and only if $q^{-1}(U)$ is open in $V_n(\mathbb{R}^{n+m})$. It is not hard to show that the quotient topology is in fact the same as the topology induced by the gap metric.

The standard definition of a complex-valued almost periodic function [12] can be generalized to a function which takes values in a complete metric space. Let (X, ρ_X) be a complete metric space, and let $f:\mathbb{R}\to X$ be a continuous function. We say that f is almost periodic if and only if given any sequence of real numbers $\{\alpha_n\}_1^\infty$, there exists a subsequence $\{\alpha_{n_j}\}$ such that the sequence of translates $\{f(t+\alpha_{n_j})\}$ converges uniformly in t as $j\to\infty$. This generalizes the so-called Bochner definition of an almost periodic complex-valued function. We will need several basic properties of almost periodic functions with values in either a complete metric space or in a Banach space. These are summarized in Appendix B.

Since the flow of the ERDE is given by $S(t, S_0) = e^{Bt}(S_0)$, it follows immediately that S_0 is an equilibrium point iff S_0 is B-invariant. Given our assumptions on B, it is clear that the equilibrium points consist of those n-dimensional subspaces which are direct sums of various of the primary components. If B has only real eigenvalues, there are $\binom{n+m}{n}$ equilibrium points, but in general there will be fewer.

One of the principal features of the phase portrait of the ERDE is the presence of invariant tori of various dimensions. The existence of invariant tori of dimension at least two was first described in a recent paper by Hermann and Martin [18] on the periodic orbits of the ERDE. It will prove convenient to view equilibrium points and isolated periodic orbits as zero-dimensional and one-dimensional invariant tori, respectively.

Let $l=(l_1,\cdots,l_r)$ be an (unordered) partition of n into r parts such that $0\leqq l_j\leqq \dim E_j$, $j=1,\cdots,r$. Let $G^{l_j}(E_j)$ denote the Grassmann manifold of all l_j-dimensional subspaces of E_j, and let $T(l)=\{S_1\oplus\cdots\oplus S_r\colon S_j\in G^{l_j}(E_j), j=1,\cdots,r\}$. Then $T(l)$ is isomorphic to the product $G^{l_1}(E_1)\times\cdots\times G^{l_r}(E_r)$. Since E_j has dimension equal to one or two, $G^{l_j}(E_j)$ consists of a single point unless $\dim E_j=2$ and $l_j=1$ in which case it is the projective line, which is topologically the circle S^1. Thus, $T(l)$ is a torus, and the dimension of $T(l)$ is equal to $\sum_{j=1}^r l_j(\dim E_j - l_j)$. Let $S\in T(l)$. Then $S=S_1\oplus\cdots\oplus S_r$ with S_j an l_j-dimensional subspace of E_j. $e^{Bt}(S)=e^{Bt}(S_1)\oplus\cdots\oplus e^{Bt}(S_r)$ which belongs to $T(l)$ since $S_j\subset E_j$ and E_j is B-invariant. Thus, the torus $T(l)$ is both positively and negatively invariant with respect to the flow of the ERDE.

Next we consider the flow on the invariant torus $T(l)$. Let k denote the dimension of $T(l)$. If $k=0$, then $T(l)$ is an equilibrium point. Thus, we suppose that $k>0$. Let $j_1,\cdots,j_k$ denote the elements of the set $\{j\colon l_j=1 \text{ and } \dim E_j=2\}$. For each $\nu=1,\cdots,k$, let $\sigma_{j_\nu}\pm i\omega_{j_\nu}$ be the conjugate pair of eigenvalues corresponding to the 2-dimensional primary component E_{j_ν}. We can choose a basis for E_{j_ν} such that the matrix for the restriction $B|E_{j_\nu}$ is

$$\begin{bmatrix} \sigma_{j_\nu} & \omega_{j_\nu} \\ -\omega_{j_\nu} & \sigma_{j_\nu} \end{bmatrix}.$$

Then the matrix for $e^{Bt}|E_{j_\nu}$ is

$$e^{\sigma_{j_\nu}t}\begin{bmatrix} \cos\omega_{j_\nu}t & \sin\omega_{j_\nu}t \\ -\sin\omega_{j_\nu}t & \cos\omega_{j_\nu}t \end{bmatrix}.$$

It follows that if S_{j_ν} is any 1-dimensional subspace of E_{j_ν}, then S_{j_ν} is e^{BT}-invariant iff T is an integer multiple of π/ω_{j_ν}. Let $S = S_1 \oplus \cdots \oplus S_r \in T(l)$. If $j \notin \{j_1, \cdots, j_k\}$, then either $S_j = 0$ or $S_j = E_j$. In either case $e^{BT}(S_j) = S_j$, $\forall t$. Thus, $e^{BT}(S) = S$ iff $e^{BT}(S_{j_\nu}) = S_{j_\nu}$, $\nu = 1, \cdots, k$. Thus, $e^{BT}(S) = S$ iff T is an integer multiple of each of the numbers π/ω_{j_ν}, $\nu = 1, \cdots, k$. Such a T exists iff $\{\pi/\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are commensurable, or equivalently iff $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are commensurable. Thus, if $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are commensurable, then every orbit on $T(l)$ is periodic with minimum period equal to the least common multiple of the numbers π/ω_{j_ν}, $\nu = 1, \cdots, k$. Otherwise, no orbit on $T(l)$ is periodic.

Suppose that $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are not necessarily all commensurable. By choice of basis, we may assume that $B = \operatorname{diag}\{B_1, \cdots, B_r\}$ where $B_i = [\sigma_i]$ if $\dim E_i = 1$ and $B_i = \left[\begin{smallmatrix} \sigma_i & \omega_i \\ -\omega_i & \sigma_i \end{smallmatrix}\right]$ if $\dim E_i = 2$. Let $\tilde{B}$ be the matrix obtained from B by setting every entry on the main diagonal equal to 0. For fixed t, the restriction $e^{\tilde{B}t}|E_i$ differs from $e^{Bt}|E_i$ only by a constant factor. It follows that if $S_0 \in T(l)$, $e^{\tilde{B}t}(S_0) = e^{Bt}(S_0)$. Given such an S_0, let $X_0 \in V_n^0(\mathbb{R}^{n+m})$, the compact subset of $V_n(\mathbb{R}^{n+m})$ consisting of those matrices which have orthonormal columns, with $q(X_0) = S_0$. Then $S(t, S_0) = q(e^{\tilde{B}t}X_0)$. Since each entry of $e^{\tilde{B}t}X_0$ is a periodic function, it follows from AP 3 in Appendix B that $e^{\tilde{B}t}X_0$ is almost periodic. Since $e^{\tilde{B}t}$ is orthogonal, $e^{\tilde{B}t}X_0 \in V_n^0(\mathbb{R}^{n+m})$ for all t. Since the restriction of the continuous mapping q to the compact set $V_n^0(\mathbb{R}^{n+m})$ is uniformly continuous, it follows from AP 5 that $q(e^{\tilde{B}t}X_0)$ is almost periodic. Hence, $S(t, S_0)$ is almost periodic.

The preceding argument shows that if $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are not all commensurable, then every motion on $T(l)$ is almost periodic, but not periodic. It is easy to see that if no pair of $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are commensurable, then every trajectory on $T(l)$ is dense in $T(l)$. However, if at least two of the ω_{j_ν} are commensurable, then no trajectory is dense.

There is one additional property of the motion on $T(l)$ which we will need to use later. Let $S_0, \tilde{S}_0 \in T(l)$. Since $S(t, S_0)$ and $S(t, \tilde{S}_0)$ are almost periodic, it follows from AP 6 that if $\rho(S(t, S_0), S(t, \tilde{S}_0)) \to 0$ as $t \to \infty$ or $t \to -\infty$, then $S_0 = \tilde{S}_0$.

We summarize the preceding analysis as a theorem, which is mostly due to Hermann and Martin [18].

THEOREM 1. *$T(l)$ is a torus of dimension $k = \sum_{j=1}^r l_j(\dim E_j - l_j)$ which is both positively and negatively invariant. If $k = 0$, $T(l)$ is an equilibrium point. If $k > 0$ and $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ are all commensurable, then each $S \in T(l)$ generates a periodic motion with period equal to the least common multiple of $\{\pi/\omega_{j_\nu}: \nu = 1, \cdots, k\}$. Otherwise, each $S \in T(l)$ generates an almost periodic motion which is dense in $T(l)$ iff no pair of the ω_{j_ν} are commensurable. In all cases, if $S, \tilde{S} \in T(l)$ with $\rho(e^{Bt}(\tilde{S}), e^{Bt}(S)) \to 0$ as $t \to \infty$ or $t \to -\infty$, then $S = \tilde{S}$.*

Let $T(l)$ be an invariant torus, and let $W^s(T(l))$ and $W^u(T(l))$ be the *stable* and *unstable manifolds* respectively for $T(l)$. In other words, $W^s(T(l)) = \{S_0 \in G^n(\mathbb{R}^{n+m}): S(t, S_0) \to T(l) \text{ as } t \to \infty\}$ and $W^u(T(l)) = \{S_0 \in G^n(\mathbb{R}^{n+m}): S(t, S_0) \to T(l) \text{ as } t \to -\infty\}$. Define a flag (i.e. strictly increasing sequence) of subspaces $0 = M_0 \subset M_1 \subset \cdots \subset M_r = \mathbb{R}^{n+m}$ by $M_k = \bigoplus_{j=1}^k E_j$, $k = 1, \cdots, r$. Define a second flag of subspaces $0 = N_0 \subset N_1 \subset \cdots \subset N_r = \mathbb{R}^{n+m}$ by $N_k = \bigoplus_{j=1}^k E_{r-j+1}$, $k = 1, \cdots, r$. We refer to $\{M_k\}_1^r$ as the *stable flag* associated with the ERDE, and we refer to $\{N_k\}_1^r$ as the *unstable flag* associated with the ERDE. The next theorem describes the sets $W^s(T(l))$ and $W^u(T(l))$.

THEOREM 2.

(a)

$$W^s(T(l)) = \left\{ S \in G^n(\mathbb{R}^{n+m}): \dim S \cap M_k = \sum_{i=1}^k l_i, k = 1, \cdots, r \right\}.$$

(b)

$$W^u(T(l)) = \left\{ S \in G^n(\mathbb{R}^{n+m}) \colon \dim S \cap N_k = \sum_{i=1}^{k} l_{r-i+1},\ k = 1, \cdots, r \right\}.$$

Proof. (a) Let

$$\tilde{W}^s(T(l)) = \left\{ S \in G^n(\mathbb{R}^{n+m}) \colon \dim S \cap M_k = \sum_{i=1}^{k} l_i,\ k = 1, \cdots, r \right\}.$$

The collection of sets $\{\tilde{W}^s(T(l))\}_l$ (where l ranges over all unordered partitions of n into r parts such that $0 \leqq l_i \leqq \dim E_i$, $i = 1, \cdots, r$) is a partition of $G^n(\mathbb{R}^{n+m})$. Hence, it suffices to show that $\tilde{W}^s(T(l)) \subseteq W^s(T(l))$ for all l. Let $S_0 \in \tilde{W}^s(T(l))$. By starting with a basis for $S_0 \cap M_1$ and successively extending to bases for $S_0 \cap M_2, \cdots, S_0 \cap M_r = S_0$, it is straightforward to show that there exists a basis for S_0 of the form $\{v_{ij} + w_{ij} \colon i$ is such that $l_i \neq 0$ and $j = 1, \cdots, l_i\}$ where $v_{ij} \in E_i$, $w_{ij} \in M_{i-1}$, and such that $\{v_{ij}\}$ is linearly independent. Letting $S_1 = \operatorname{Sp}\{v_{ij}\}$, we have $S_1 \in T(l)$. By choice of basis, we may assume that $B = \operatorname{diag}\{B_1, \cdots, B_r\}$ where $B_i = [\sigma_i]$ if $\dim E_i = 1$ and $B_i = \left[\begin{smallmatrix} \sigma_i & \omega_i \\ -\omega_i & \sigma_i \end{smallmatrix}\right]$ if $\dim E_i = 2$, and where $\sigma_1 < \sigma_2 < \cdots < \sigma_r$. Using the standard inner product on $\mathbb{R}^{n+m}$, it follows that $E_i \perp E_k$ whenever $i \neq k$. Consequently, $v_{ij} \perp v_{kp}$ whenever $i \neq k$. However, by using the Gram-Schmidt process, it is clear that the basis $\{v_{ij} + w_{ij}\}$ can be chosen in such a way that $v_{ij} \perp v_{ip}$ and such that v_{ij} has unit length. Thus, without loss of generality, we may assume that $\{v_{ij}\}$ is an orthonormal basis for S_1.

Let $\tilde{B}$ be the matrix obtained from B by setting every entry on the main diagonal equal to 0. Then $e^{Bt}x = e^{\sigma_i t} e^{\tilde{B}t}x$, $\forall x \in E_i$. Extend $v_{i1}, \cdots, v_{il_i}$ to an orthonormal basis for E_i by adding vectors $\{u_{ik} \colon k = l_i + 1, \cdots, \dim E_i\}$. We use $\{v_{ij}, u_{ik}\}$ to denote the resulting orthonormal basis for $\mathbb{R}^{n+m}$. Another basis for $\mathbb{R}^{n+m}$ is $\{v_{ij} + w_{ij}, u_{ik}\}$. Let $X(t)$, $Y(t)$, $Z(t)$ be the matrices whose columns are $\{e^{\tilde{B}t}v_{ij}\}$, $\{e^{\tilde{B}t}u_{ik}\}$, $\{e^{-\sigma_i t} e^{Bt}w_{ij}\}$ respectively. Then $S(t, S_1) = \operatorname{Sp} X(t)$ and $S(t, S_0) = \operatorname{Sp}(X(t) + Z(t))$. Since $e^{\tilde{B}t}$ and $[X(0), Y(0)]$ are both orthogonal matrices, $[X(t), 0]$, $[X(t), Y(t)]^{-1}$ is the orthogonal projection onto $S(t, S_1)$. Since $[X(t) + Z(t), 0]$, $[X(t) + Z(t), Y(t)]^{-1}$ is a projection onto $S(t, S_0)$ (in general not orthogonal), it follows from a basic property of the gap metric [14, p. 361] that

$$\begin{aligned}
\rho(S(t, S_1), S(t, S_0)) &\leqq \|[X(t), 0][X(t), Y(t)]^{-1} \\
&\quad - [X(t) + Z(t), 0][X(t) + Z(t), Y(t)]^{-1}\| \\
&= \|[X(t), 0]([X(t), Y(t)]^{-1} - [X(t) + Z(t), Y(t)]^{-1}) \\
&\quad - [Z(t), 0][X(t) + Z(t), Y(t)]^{-1}\| \\
&\leqq \|[X(t), 0]\|\, \|[X(t), Y(t)]^{-1}\|\, \|[X(t) + Z(t), Y(t)]^{-1}\|\, \|[Z(t), 0]\| \\
&\quad + \|[Z(t), 0]\|\, \|[X(t) + Z(t), Y(t)]^{-1}\|.
\end{aligned}$$

Since $[X(t), Y(t)]$ is an orthogonal matrix and the orthogonal group is compact, it follows that $[X(t), 0]$ and $[X(t), Y(t)]^{-1}$ are bounded. The compactness of the orthogonal group together with the fact that $Z(t) \to 0$ as $t \to \infty$ implies that $[X(t) + Z(t), Y(t)]^{-1}$ is bounded. Then the fact that $Z(t) \to 0$ as $t \to \infty$ implies that $\rho(S(t, S_1), S(t, S_0)) \to 0$ as $t \to \infty$. Thus, $\tilde{W}^s(T(l)) \subseteq W^s(T(l))$ which shows that $\tilde{W}^s(T(l)) = W^s(T(l))$ and completes the proof of (a).

The proof of (b) is completely analogous to the proof of (a). □

Remark 1. We have defined $W^s(T(l))$ only in terms of asymptotic convergence. However, it follows easily from the inequality in the proof of Theorem 2 that $W^s(T(l))$ has the additional property that given any $\varepsilon > 0$, there exists $\delta > 0$ such that if $S_0 \in W^s(T(l))$ with $d(S_0, T(l)) < \delta$, then $d(S(t, S_0), T(l)) < \varepsilon$, for all $t \geqq 0$. Corresponding statements apply to $W^u(T(l))$.

COROLLARY 1. *The sets* $\{W^s(T(l))\}_l$ *are a partition of* $G^n(\mathbb{R}^{n+m})$. *The sets* $\{W^u(T(l))\}_l$ *are also a partition of* $G^n(\mathbb{R}^{n+m})$.

For a flow ϕ_t on a manifold M, $x \in M$ is called a *wandering point* [2], [42] if there exists a neighborhood U of x in M and some $t_0 > 0$ such that $\phi_t(U) \cap U$ is empty whenever $|t| > t_0$. The subset of M consisting of all points which are not wandering points is called the *nonwandering set.* The next corollary follows immediately from Theorem 1 and Corollary 1 of Theorem 2.

COROLLARY 2. *The nonwandering set of the* ERDE *is the disjoint union* $\bigsqcup_l T(l)$ *of the invariant tori.*

We will use Ω to denote the nonwandering set of the ERDE.

From the proof of Theorem 2, we know that if $S_0 \in W^s(T(l))$, then there exists $S_1 \in T(l)$ such that $S(t, S_0) \to S(t, S_1)$ as $t \to \infty$. Similarly, if $S_0 \in W^u(T(l'))$, then there exists $S_2 \in T(l')$ such that $S(t, S_0) \to S(t, S_2)$ as $t \to -\infty$. Let η_j denote the projection onto the subspace E_j along the subspace $\bigoplus_{i=1, i\neq j}^{r} E_i$, $j = 1, \cdots, r$. Define a mapping $\Pi_+ : G^n(\mathbb{R}^{n+m}) \to \Omega$ by

$$\Pi_+(S) = \eta_1(S \cap M_1) \oplus \eta_2(S \cap M_2) \oplus \cdots \oplus \eta_r(S \cap M_r).$$

From the construction of the subspace S_1 in the proof of Theorem 2, it follows that $S_1 = \Pi_+(S_0)$. In other words, $S(t, S_0) \to S(t, \Pi_+(S_0))$ as $t \to \infty$. Similarly, we define a mapping $\Pi_- : G^n(\mathbb{R}^{n+m}) \to \Omega$ by

$$\Pi_-(S) = \eta_1(S \cap N_r) \oplus \eta_2(S \cap N_{r-1}) \oplus \cdots \oplus \eta_r(S \cap N_1).$$

It is easily seen that $S_2 = \Pi_-(S_0)$. Thus, $S(t, S_0) \to S(t, \Pi_-(S_0))$ as $t \to -\infty$.

The problem we now consider is: given $S_1 \in T(l)$, describe the subset $\Pi_+^{-1}(S_1)$ of $W^s(T(l))$ ($\Pi_-^{-1}(S_1)$ of $W^u(T(l))$ which contains those subspaces S_0 with the property that $S(t, S_0) \to S(t, S_1)$ as $t \to \infty$ ($t \to -\infty$).

Let $T(l)$ be an invariant torus, and let S_1 be a given point in $T(l)$. Let $W^s(S_1) = \Pi_+^{-1}(S_1)$, and let $W^u(S_1) = \Pi_-^{-1}(S_1)$.

THEOREM 3.

(a)

$$W^s(S_1) = \left\{ S \in W^s(T(l)) \colon \dim S \cap [M_{k-1} \oplus (S_1 \cap E_k)] = \sum_{i=1}^{k} l_i,\ k = 1, \cdots, r \right\}.$$

(b)

$$W^u(S_1) = \left\{ S \in W^u(T(l)) \colon \dim S \cap [N_{k-1} \oplus (S_1 \cap E_{r-k+1})] = \sum_{i=1}^{k} l_{r-i+1},\ k = 1, \cdots, r \right\}.$$

Proof. (a) Suppose $S \in W^s(S_1)$. Then it follows from the proof of Theorem 2 that there exists a basis for S of the form $\{v_{ij} + w_{ij} \colon 1 \leqq i \leqq r$ such that $l_i \neq 0;\ j = 1, \cdots, l_i\}$ where $v_{ij} \in E_i$, $w_{ij} \in M_{i-1}$, and $\{v_{ij}\}$ is a basis for S_1. It follows immediately that $S \cap [M_{k-1} \oplus (S_1 \cap E_k)] = \operatorname{Sp}\{v_{ij} + w_{ij} \colon 1 \leqq i \leqq k$ such that $l_i \neq 0;\ j = 1, \cdots, l_i\}$ which has dimension $\sum_{i=1}^{k} l_i$.

Conversely, suppose $S \in W^s(T(l))$ and $\dim S \cap [M_{k-1} \oplus (S_1 \cap E_k)] = \sum_{i=1}^{k} l_i$, $k = 1, \cdots, r$. Then $\dim S \cap [M_{k-1} \oplus (S_1 \cap E_k)] = \dim S \cap M_k$, so $S \cap [M_{k-1} \oplus (S_1 \cap E_k)] =$

$S \cap M_k$. Hence, $\eta_k(S \cap M_k) = \eta_k(S \cap [M_{k-1} \oplus (S_1 \cap E_k)]) \subseteq \eta_k(M_{k-1} \oplus (S_1 \cap E_k)) = S_1 \cap E_k$, which implies that $\Pi_+(S) = S_1$, completing the proof of (a).

The proof of (b) is analogous to the proof of (a). □

It is worth noting that the last conclusion in Theorem 1 implies that if $S_1 \neq S_2$, then $W^s(S_1)$ and $W^s(S_2)$ ($W^u(S_1)$ and $W^u(S_2)$) are disjoint.

3.2. Topology of the stable and unstable manifolds. Next we consider the topological structure of the subsets $\{W^s(T(l))\}$ and of the subsets $\{W^u(T(l))\}$, and their relationship to the topology of the Grassmann manifold $G^n(\mathbb{R}^{n+m})$.

Let X be a locally compact topological space. A *cell decomposition* of X is partition $\{X_i\}_{i \in I}$ of X into disjoint subsets such that (1) $\{X_i\}_{i \in I}$ is locally finite; (2) X_i is homeomorphic to $\mathbb{R}^{n_i}$ for some n_i; (3) $\bar{X}_i - X_i$ is the union of some of the cells $\{X_j: \dim X_j < \dim X_i\}$.

There is a well-known cell decomposition of $G^n(\mathbb{R}^{n+m})$ which is sometimes referred to as the *Schubert cell decomposition* of the Grassmann manifold. (See e.g. [15, p. 194].) It is constructed by first choosing a flag of subspaces $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_{n+m-1} \subset V_{n+m} = \mathbb{R}^{n+m}$ such that $\dim V_j = j, j = 0, \cdots, n+m$. To emphasize that this flag contains a subspace for each dimension between 0 and $n+m$, we will refer to it as a *complete flag*. (If B has any nonreal eigenvalues, then $r < n+m$, so the flags $\{M_j\}$ and $\{N_j\}$ are not complete.) For each $(n+m)$-tuple $a = (a_1, \cdots, a_{n+m})$ such that $a_j = 0$ or $a_j = 1$ and $\sum_{j=1}^{n+m} a_j = n$, let $U(a) = \{S \in G^n(\mathbb{R}^{n+m}): \dim S \cap V_j = \sum_{i=1}^{j} a_i,\ j = 1, \cdots, n+m\}$. Then the $\binom{n+m}{n}$ sets $\{U(a)\}$ partition $G^n(\mathbb{R}^{n+m})$, and it is not hard to show that $U(a)$ is homeomorphic to Euclidean space of dimension $\sum_{j=1}^{n+m} a_j(j - \sum_{i=1}^{j} a_i)$. To show this, we observe that by choosing a basis, we may assume that $V_j = \operatorname{Sp}\{e_1, \cdots, e_j\}$, where $e_1, \cdots, e_{n+m}$ are the standard basis vectors for $\mathbb{R}^{n+m}$. Let $j_1 < j_2 < \cdots < j_n$ be the n elements of the set $\{j: a_j = 1\}$. Then each $S \in U(a)$ has a unique $(n+m) \times n$ basis matrix Z_S in column echelon form. Specifically, rows $j_1, \cdots, j_n$ of Z form an $n \times n$ identity submatrix, and $z_{ik} = 0$ if $i > j_k$. Otherwise z_{ik} is arbitrary. For example, if $n = 2$, $m = 3$, and $a = (0, 1, 0, 0, 1)$, then each $S \in U(a)$ is spanned by a unique matrix of the form

$$Z_S = \begin{bmatrix} z_{11} & z_{12} \\ 1 & 0 \\ 0 & z_{32} \\ 0 & z_{42} \\ 0 & 1 \end{bmatrix}.$$

The correspondence $S \leftrightarrow Z_S$ gives a homeomorphism (in fact, a real-analytic isomorphism) between $U(a)$ and Euclidean space of dimension $\sum_{j=1}^{n+m} a_j(j - \sum_{i=1}^{j} a_i)$. This dimension is also given by the formula $\sum_{k=1}^{n} (j_k - k)$.

The decomposition $G^n(\mathbb{R}^{n+m}) = \bigsqcup_a U(a)$ is the Schubert cell decomposition of $G^n(\mathbb{R}^{n+m})$. The closure of the cell $U(a)$ is the set $\{S \in G^n(\mathbb{R}^{n+m}): \dim S \cap V_j \geqq \sum_{i=1}^{j} a_i,\ j = 1, \cdots, n+m\}$. It is called a *Schubert variety*.

Let $T(l)$ be a given invariant torus. Refine $\{M_j\}$ to a complete flag by inserting a subspace M_j' between M_{j-1} and M_j whenever $\dim E_j = 2$. Since $W^s(T(l)) = \{S \in G^n(\mathbb{R}^{n+m}): \dim S \cap M_j = \sum_{i=1}^{j} l_i,\ j = 1, \cdots, r\}$, it follows that $W^s(T(l))$ is a union of one or more of the $\binom{n+m}{n}$ cells $U(a)$ which correspond to the complete flag. Let $S \in W^s(T(l))$. Then the dimensions of each of $S \cap M_j$ $(j = 1, \cdots, r)$ are completely determined by the assumption that S belongs to $W^s(T(l))$. Let j be given, and suppose that $\dim E_j = 2$. Then there is a subspace M_j' which is between M_{j-1} and M_j in the complete flag. There are three cases to consider.

(1) If $l_j = 0$, then $\dim S \cap M_j = \dim S \cap M_{j-1}$, and this must also be the dimension of $S \cap M_j'$.

(2) If $l_j = 2$, then $\dim S \cap M_j = \dim S \cap M_{j-1} + 2$, which implies that $\dim S \cap M_j' = \dim S \cap M_{j-1} + 1$.

(3) If $l_j = 1$, then $\dim S \cap M_j = \dim S \cap M_{j-1} + 1$, and there are two possibilities: $\dim S \cap M_j' = \dim S \cap M_{j-1}$ or $\dim S \cap M_j' = \dim S \cap M_j$.

Suppose that the given invariant torus $T(l)$ is k-dimensional. Then $\{j\colon l_j = 1$ and $\dim E_j = 2\}$ contains exactly k elements, say $j_1, \cdots, j_k$. If $S \in W^s(T(l))$, the analysis in the preceding paragraph shows that there are 2^k possible choices for the set of dimensions in which S intersects the $n+m$ subspaces in the complete flag. Thus, $W^s(T(l))$ is the union of exactly 2^k cells $U(a)$ which correspond to the complete flag. Each cell is given by fixing a vector $b = (b_1, \cdots, b_k)$ with b_j equal to 0 or 1, and setting $W^s(T(l)), b) = \{S \in W^s(T(l))\colon \dim S \cap M_{j_\nu}' = \dim S \cap M_{j_\nu - 1} + b_\nu,\ \nu = 1, \cdots, k\}$.

To determine the dimension of $W^s(T(l), b)$, we determine the vector $a = (a_1, \cdots, a_{n+m})$ which corresponds to the given vectors $l = (l_1, \cdots, l_r)$ and $b = (b_1, \cdots, b_k)$. Let $j \in \{1, \cdots, r\}$ and set $j' = \sum_{i=1}^{j-1} \dim E_i + 1 = \dim M_{j-1} + 1$. If $\dim E_j = 1$, then $a_{j'} = l_j$. If $\dim E_j = 2$ and $l_j = 0$, then $a_{j'} = 0$ and $a_{j'+1} = 0$. If $\dim E_j = 2$ and $l_j = 2$, then $a_{j'} = 1$ and $a_{j'+1} = 1$. If $\dim E_j = 2$ and $l_j = 1$, then $j = j_\nu$ for some ν, and we have $a_{j_\nu'} = b_\nu$ and $a_{j_\nu'+1} = 1 - b_\nu$. With this definition of a, it follows that $W^s(T(l), b)$ is analytically isomorphic to Euclidean space of dimension $\sum_{\gamma=1}^{n+m} a_\gamma(\gamma - \sum_{i=1}^{\gamma} a_i)$. It is straightforward to show that the dimension of $W^s(T(l), b)$ can be reexpressed as

$$\sum_{j=1}^{r} l_j\left(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i\right) + k - \sum_{\nu=1}^{k} b_\nu.$$

This proves part (a) of the next theorem. The proof of part (b) is completely analogous to the proof of (a).

THEOREM 4. *Let $T(l)$ be a k-dimensional invariant torus. Then* (a) *$W^s(T(l))$ is the disjoint union of 2^k cells. Exactly $\binom{k}{\nu}$ of these cells have dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i) + \nu$, $\nu = 0, \cdots, k$.* (b) *$W^u(T(l))$ is the disjoint union of 2^k cells. Exactly $\binom{k}{\nu}$ of these cells have dimension $\sum_{j=1}^{r} l_{r-j+1}(\dim N_{j-1} - \sum_{i=1}^{j-1} l_{r-i+1}) + \nu$, $\nu = 0, \cdots, k$.*

The next result describes the topology of the sets $W^s(S_1)$ and $W^u(S_1)$.

THEOREM 5. *Let $T(l)$ be an invariant torus, and let $S_1 \in T(l)$. Then* (a) *$W^s(S_1)$ is analytically isomorphic to Euclidean space of dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)$.* (b) *$W^u(S_1)$ is analytically isomorphic to Euclidean space of dimension $\sum_{j=1}^{r} l_{r-j+1}(\dim N_{j-1} - \sum_{i=1}^{j-1} l_{r-i+1})$.*

Proof. Let $k = \dim T(l)$, and let $j_1, \cdots, j_k$ be the elements of $\{j\colon l_j = 1$ and $\dim E_j = 2\}$. Refine $\{M_j\}_1^r$ to a complete flag in two steps. First, define $M_{j_\nu}' = M_{j_\nu - 1} \oplus (S_1 \cap E_{j_\nu})$ and insert it between $M_{j_\nu - 1}$ and M_{j_ν}, $\nu = 1, \cdots, k$. This refines $\{M_j\}_1^r$ at each j such that $\dim E_j = 2$ and $l_j = 1$. Second, if $\dim E_j = 2$ and $l_j = 0$ or 2, insert any subspace M_j' between M_{j-1} and M_j. The refined flag is now a complete flag, and with respect to this flag, we have $W^s(S_1) = W^s(T(l), b)$ provided that $b = (1, 1, \cdots, 1)$. It then follows from the proof of Theorem 4 that $W^s(S_1)$ is analytically isomorphic to Euclidean space of dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)$.

The proof of (b) is analogous to the proof of (a). □

The next result shows that the ERDE has either a unique asymptotically stable equilibrium point or a unique orbitally asymptotically stable periodic orbit, but not both. In fact, somewhat more than this is true.

THEOREM 6. (a) *If $\sum_{j=\nu+1}^{r} \dim E_j = n$ for some ν, then there exists an equilibrium point whose stable manifold is open and dense. Otherwise, there exists a periodic orbit whose stable manifold is open and dense.* (b) *If $\sum_{j=1}^{\nu} \dim E_j = n$ for some ν, then there*

exists an equilibrium point whose unstable manifold is open and dense. Otherwise, there exists a periodic orbit whose unstable manifold is open and dense.

Proof. (a) *Suppose that* $\sum_{j=\nu+1}^{r} \dim E_j = n$ for some ν. Let $l_j = 0$, $j = 1, \cdots, \nu$ and let $l_j = \dim E_j$, $j = \nu+1, \cdots, r$. Then $T(l)$ is a 0-dimensional invariant torus, and hence an equilibrium point. By Theorem 2, $S \in W^s(T(l))$ iff $\dim S \cap M_k = \sum_{j=1}^{k} l_j$, $k = 1, \cdots, r$, which implies that $W^s(T(l)) = \{S \in G^n(\mathbb{R}^{n+m})\colon \dim S \cap M_\nu = 0\}$. Since $\dim M_\nu = m$, the complement of $W^s(T(l))$ is therefore a proper subvariety of $G^n(\mathbb{R}^{n+m})$, which shows that $W^s(T(l))$ is open and dense in $G^n(\mathbb{R}^{n+m})$.

Now suppose that there does not exist ν such that $\sum_{j=\nu+1}^{r} \dim E_j = n$. Since $\dim E_j$ is 1 or 2, there must exist ν such that $\dim E_{\nu+1} = 2$ and $\sum_{j=\nu+1}^{r} \dim E_j = n+1$. Let $l_j = 0$, $j = 1, \cdots, \nu$, let $l_{\nu+1} = 1$, and let $l_j = \dim E_j$, $j = \nu+2, \cdots, r$. Then $T(l)$ is a 1-dimensional invariant torus, and hence a periodic orbit. $S \in W^s(T(l))$ iff $\dim S \cap M_\nu = 0$, $\dim S \cap M_{\nu+1} = 1$, and $\dim S \cap M_k = 1 + \sum_{j=\nu+2}^{k} \dim E_j$, $k = \nu+2, \cdots, r$, or equivalently $W^s(T(l)) = \{S \in G^n(\mathbb{R}^{n+m})\colon \dim S \cap M_\nu = 0, \dim S \cap M_{\nu+1} = 1\}$. Since $\dim M_{\nu+1} = m+1$, it follows that $\dim S \cap M_{\nu+1} \geqq 1$ for every $S \in G^n(\mathbb{R}^{n+m})$. Thus, the complement of $W^s(T(l))$ is $\{S \in G^n(\mathbb{R}^{n+m})\colon \dim S \cap M_\nu \geqq 1\} \cup \{S \in G^n(\mathbb{R}^{n+m})\colon \dim S \cap M_{\nu+1} \geqq 2\}$, which is a subvariety of $G^n(\mathbb{R}^{n+m})$. Since $\dim M_\nu = m-1$ and $\dim M_{\nu+1} = m+1$, this is a proper subvariety. (Alternatively, note that $W^s(T(l))$ is nonempty since it contains the periodic orbit $T(l)$.) This completes the proof of (a). The proof of (b) is completely analogous. □

If $T(l)$ is a k-dimensional invariant torus, Theorem 4 describes the stable manifold $W^s(T(l))$ of $T(l)$ as the union of 2^k cells. We now describe the topology of $W^s(T(l))$ in greater detail. To avoid cumbersome notation and to serve as an illustration, we consider a concrete example. However, the example contains all of the features of the general case. Furthermore, it will become obvious that the proof for the general result follows step-by-step the analysis of the example.

Let $n = 3$ and $m = 5$, so the ERDE is a differential equation on $G^3(\mathbb{R}^8)$, which is 15-dimensional. Let $r = 6$, and suppose that $\dim E_1 = 1$, $\dim E_2 = 2$, $\dim E_3 = 1$, $\dim E_4 = 2$, $\dim E_5 = 1$, $\dim E_6 = 1$. Let $l = (l_1, \cdots, l_6) = (0, 1, 0, 1, 0, 1)$. Then $l_2 = 1$, $l_4 = 1$, $\dim E_2 = 2$, $\dim E_4 = 2$, so $T(l)$ is a 2-dimensional invariant torus. By Theorem 4, $W^s(T(l))$ is the union of 4 open cells of dimensions 9, 10, 10, 11. By changing basis, we may assume that when the flag $M_0 \subset M_1 \subset M_2 \subset M_3 \subset M_4 \subset M_5 \subset M_6$ is refined to a complete flag by inserting subspaces M_2' and M_4' between M_1, M_2 and between M_3, M_4 respectively, the flag $V_0 \subset V_1 \subset V_2 \subset V_3 \subset V_4 \subset V_5 \subset V_6 \subset V_7 \subset V_8$ is obtained, where $V_j = \mathrm{Sp}\{e_1, \cdots, e_j\}$. ($e_j$ is the jth standard basis vector of $\mathbb{R}^8$.) The 4 cells are given by

$$
\begin{aligned}
U_1 = \{S \in G^3(\mathbb{R}^8)\colon\ & \dim S \cap V_1 = 0, \dim S \cap V_2 = 1,\\
& \dim S \cap V_3 = 1, \dim S \cap V_4 = 1, \dim S \cap V_5 = 2,\\
& \dim S \cap V_6 = 2, \dim S \cap V_7 = 2, \dim S \cap V_8 = 3\},\\
U_2 = \{S \in G^3(\mathbb{R}^8)\colon\ & \dim S \cap V_1 = 0, \dim S \cap V_2 = 0,\\
& \dim S \cap V_3 = 1, \dim S \cap V_4 = 1, \dim S \cap V_5 = 2,\\
& \dim S \cap V_6 = 2, \dim S \cap V_7 = 2, \dim S \cap V_8 = 3\},\\
U_3 = \{S \in G^3(\mathbb{R}^8)\colon\ & \dim S \cap V_1 = 0, \dim S \cap V_2 = 1,\\
& \dim S \cap V_3 = 1, \dim S \cap V_4 = 1, \dim S \cap V_5 = 1,\\
& \dim S \cap V_6 = 2, \dim S \cap V_7 = 2, \dim S \cap V_8 = 3\},
\end{aligned}
$$

$$U_4 = \{S \in G^3(\mathbb{R}^8): \dim S \cap V_1 = 0, \dim S \cap V_2 = 0,$$
$$\dim S \cap V_3 = 1, \dim S \cap V_4 = 1, \dim S \cap V_5 = 1,$$
$$\dim S \cap V_6 = 2, \dim S \cap V_7 = 2, \dim S \cap V_8 = 3\}.$$

These cells are isomorphic to $\mathbb{R}^9$, $\mathbb{R}^{10}$, $\mathbb{R}^{10}$, $\mathbb{R}^{11}$ respectively. They are parametrized using column echelon form as follows:

$$\operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ 1 & 0 & 0 \\ 0 & y_3 & z_3 \\ 0 & y_4 & z_4 \\ 0 & 1 & 0 \\ 0 & 0 & z_6 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ 1 & 0 & 0 \\ 0 & y_4 & z_4 \\ 0 & 1 & 0 \\ 0 & 0 & z_6 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ 1 & 0 & 0 \\ 0 & y_3 & z_3 \\ 0 & y_4 & z_4 \\ 0 & y_5 & z_5 \\ 0 & 1 & 0 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ 1 & 0 & 0 \\ 0 & y_4 & z_4 \\ 0 & y_5 & z_5 \\ 0 & 1 & 0 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}.$$

U_1 U_2 U_3 U_4

These 4 cells can be modified in an obvious way to obtain 4 charts W_1, W_2, W_3, W_4 which cover $W^s(T(l))$.

$$\operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ 1 & 0 & 0 \\ x_3 & y_3 & z_3 \\ 0 & y_4 & z_4 \\ 0 & 1 & 0 \\ 0 & y_6 & z_6 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ 1 & 0 & 0 \\ 0 & y_4 & z_4 \\ 0 & 1 & 0 \\ 0 & y_6 & z_6 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ 1 & 0 & 0 \\ x_3 & y_3 & z_3 \\ 0 & y_4 & z_4 \\ 0 & y_5 & z_5 \\ 0 & 1 & 0 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ 1 & 0 & 0 \\ 0 & y_4 & z_4 \\ 0 & y_5 & z_5 \\ 0 & 1 & 0 \\ 0 & 0 & z_7 \\ 0 & 0 & 1 \end{bmatrix}.$$

W_1 W_2 W_3 W_4

Each of these charts is a submanifold chart relative to one of the standard charts for $G^3(\mathbb{R}^8)$. (The standard charts for the Grassmann manifold are described in Appendix A.) Thus, $W^s(T(l))$ is an embedded submanifold of $G^3(\mathbb{R}^8)$.

$T(l)$ is itself covered by 4 submanifold charts $\bar{W}_1$, $\bar{W}_2$, $\bar{W}_3$, $\bar{W}_4$ defined by

$$\operatorname{Sp}\begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ x_3 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & y_6 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} 0 & 0 & 0 \\ x_2 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & y_6 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ x_3 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & y_5 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \operatorname{Sp}\begin{bmatrix} 0 & 0 & 0 \\ x_2 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & y_5 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

$\bar{W}_1$ $\bar{W}_2$ $\bar{W}_3$ $\bar{W}_4$

The mapping $\Pi_+: G^n(\mathbb{R}^{n+m}) \to \Omega$ maps $W^s(T(l))$ onto $T(l)$. We will also use Π_+ to denote its restriction to $W^s(T(l))$. If $S_1 \in T(l)$, then $\Pi_+^{-1}(S_1) = W^s(S_1)$. Consequently,

the fiber $\Pi_+^{-1}(S_1)$ is isomorphic to Euclidean space of dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)$, which in this example is equal to 9. It is clear that $\Pi_+^{-1}(\bar{W}_i) = W_i$, $i = 1, 2, 3, 4$. Also there is an obvious isomorphism γ_i: $W_i \to \bar{W}_i \times \mathbb{R}^9$ with the property that if p_i: $\bar{W}_i \times \mathbb{R}^9 \to \bar{W}_i$ is the natural projection, then $p_i \circ \gamma_i$ is the restriction of Π_+ to W_i. For example, let $i = 1$, let S denote the element of W_1 whose coordinates are $(x_1, x_3, y_1, y_3, y_4, y_6, z_1, z_3, z_4, z_6, z_7)$, and let $\bar{S}$ denote the element of $\bar{W}_1$ whose coordinates are (x_3, y_6). Then $\gamma_1(S) = (\bar{S}, (x_1, y_1, y_3, y_4, z_1, z_3, z_4, z_6, z_7))$.

The analysis given for the preceding example can be applied essentially unchanged to describe the structure of $W^s(T(l))$ for an arbitrary invariant torus $T(l)$. If k denotes the dimension of $T(l)$, then by Theorem 4, $W^s(T(l))$ is the union of 2^k cells, the largest of which has dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i) + k$. From these cells we obtain 2^k submanifold charts for $W^s(T(l))$. Thus, $W^s(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $\sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i) + k$. The projection Π_+: $W^s(T(l)) \to T(l)$ is defined as above. If $S_1 \in T(l)$, then $\Pi_+^{-1}(S_1) = W^s(S_1)$ which is isomorphic to Euclidean space of dimension $d_s = \sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)$. Each chart W_i $(i = 1, \cdots, 2^k)$ for $W^s(T(l))$ is the inverse image of a chart $\bar{W}_i$ for $T(l)$. Also, there exist real-analytic isomorphisms γ_i: $W_i \to \bar{W}_i \times \mathbb{R}^{d_s}$ such that $p_i \circ \gamma_i = \Pi_+ | W_i$. Thus, Π_+: $W^s(T(l)) \to T(l)$ is a locally trivial bundle with $\mathbb{R}^{d_s}$ as fiber. It is easy to see that the transition functions for this bundle are invertible polynomial mappings of $\mathbb{R}^{d_s}$ (rational functions in which the denominators are functions only of base point).

The next theorem summarizes these conclusions as well as the analogous results for the unstable manifolds.

THEOREM 7. *Let $T(l)$ be a k-dimensional invariant torus. Then*

(a) *$W^s(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $k + d_s$, where $d_s = \sum_{j=1}^{r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)$.*

(b) *Π_+: $W^s(T(l)) \to T(l)$ is a locally trivial bundle with fiber $\mathbb{R}^{d_s}$ and polynomial transition functions.*

(c) *$W^u(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $k + d_u$, where $d_u = \sum_{j=1}^{r} l_{r-j+1}(\dim N_{j-1} - \sum_{i=1}^{j-1} l_{r-i+1})$.*

(d) *Π_-: $W^u(T(l)) \to T(l)$ is a locally trivial bundle with fiber $\mathbb{R}^{d_u}$ and polynomial transition functions.*

3.3. Morse theory and structural stability. Next, we wish to determine exactly when the ERDE is a *Morse-Smale vector field.* By definition [42], a Morse-Smale vector field is a smooth vector field on a compact manifold with the following 3 properties: (1) The nonwandering set is the union of a finite number of equilibria $x_1, \cdots, x_m$ and a finite number of closed orbits $\gamma_1, \cdots, \gamma_n$ of the flow. (2) Every equilibrium point and every closed orbit is hyperbolic. (3) The stable and unstable manifolds of the x_i, γ_j intersect each other only transversally.

We start with a lemma. Suppose that $\mathbb{R}^k = F_1 \oplus \cdots \oplus F_k$ with $\dim F_j = 1$ for each j. Define two complete flags $\{V_j\}_1^k$, $\{W_j\}_1^k$ such that $V_j = \bigoplus_{i=1}^{j} F_i$, $W_j = \bigoplus_{i=1}^{j} F_{k-i+1}$. Let $\alpha = (\alpha_1, \cdots, \alpha_k)$ and $\beta = (\beta_1, \cdots, \beta_k)$ be such that $\alpha_i = 0$ or 1, $\beta_i = 0$ or 1, and $\sum_{i=1}^{k} \alpha_i = n = \sum_{i=1}^{k} \beta_i$. Define $X(\alpha) = \{S \in G^n(\mathbb{R}^k)$: $\dim S \cap V_j = \sum_{i=1}^{j} \alpha_i$, $j = 1, \cdots, k\}$ and $Y(\beta) = \{S \in G^n(\mathbb{R}^k)$: $\dim S \cap W_j = \sum_{i=1}^{j} \beta_{k-i+1}$, $j = 1, \cdots, k\}$.

LEMMA 1. (a) *$X(\alpha) \cap Y(\beta)$ is nonempty iff $\sum_{i=1}^{j} \alpha_i \leqq \sum_{i=1}^{j} \beta_i$, $j = 1, \cdots, k$.*

(b) *$X(\alpha)$ and $Y(\beta)$ intersect transversally.*

Proof. (a) First suppose that the intersection is nonempty, and let $S \in X(\alpha) \cap Y(\beta)$. By construction, $V_j \oplus W_{k-j} = \mathbb{R}^k$. Thus, $\dim S \cap V_j + \dim S \cap W_{k-j} \leqq \dim S = n$, which implies that $\sum_{i=1}^{j} \alpha_i + \sum_{i=1}^{k-j} \beta_{k-i+1} \leqq n$. Hence, $\sum_{i=1}^{j} \alpha_i \leqq n - \sum_{i=1}^{k-j} \beta_{k-i+1} = \sum_{i=1}^{j} \beta_i$.

Conversely, suppose that $\sum_{i=1}^{j}\alpha_i \leqq \sum_{i=1}^{j}\beta_i$, $j=1,\cdots,k$. Let $j_1<\cdots<j_n$ be the elements of $\{j\colon \alpha_j=1\}$, and let $l_1<\cdots<l_n$ be the elements of $\{l\colon \beta_l=1\}$. Then $j_p=\min\{j\colon \sum_{i=1}^{j}\alpha_i=p\}$ and $l_p=\min\{l\colon \sum_{i=1}^{l}\beta_i=p\}$. Since $\sum_{i=1}^{j}\alpha_i\leqq\sum_{i=1}^{j}\beta_i$, it follows that $l_p\leqq j_p$ for all p. Let f_i be a basis vector for the 1-dimensional subspace F_i, $i=1,\cdots,k$. Define a subspace S by $S=\mathrm{Sp}\{f_{j_1}+f_{l_1},\ f_{j_2}+f_{l_2},\cdots,f_{j_n}+f_{l_n}\}$. We claim that $S\in X(\alpha)\cap Y(\beta)$.

Since $j_1<\cdots<j_n$ and $l_i\leqq j_i$ for all i, it follows immediately that $\dim S\cap V_j=0$ for $j<j_1$, $\dim S\cap V_j=1$ for $j_1\leqq j<j_2,\cdots,\dim S\cap V_j=n-1$ for $j_{n-1}\leqq j<j_n$, $\dim S\cap V_j=n$ for $j_n\leqq j$. But this is equivalent to the condition that S belong to $X(\alpha)$. We also have $k-l_n+1<\cdots<k-l_1+1$ and $k-j_i+1\leqq k-l_i+1$ for all i. This implies that $\dim S\cap W_j=0$ for $j<k-l_n+1$, $\dim S\cap W_j=1$ for $k-l_n+1\leqq j<k-l_{n-1}+1,\cdots,\dim S\cap W_j=n-1$ for $k-l_2+1\leqq j<k-l_1+1$, $\dim S\cap W_j=n$ for $k-l_1+1\leqq j$. But this is equivalent to the condition that S belong to $Y(\beta)$. Thus, $S\in X(\alpha)\cap Y(\beta)$, so the intersection is nonempty.

(b) If $X(\alpha)$ and $Y(\beta)$ are disjoint, the assertion is trivially satisfied, so we can assume that $X(\alpha)\cap Y(\beta)$ is nonempty. Then (a) implies that $\sum_{i=1}^{j}\alpha_i\leqq\sum_{i=1}^{j}\beta_i$, $i=1,\cdots,k$. Define $j_1,\cdots,j_n$ and $l_1,\cdots,l_n$ as in the proof of (a). Also define $f_1,\cdots,f_k$ as in (a). Let $S_0\in X(\alpha)\cap Y(\beta)$. Let $J=\{j_1,\cdots,j_n\}$. Since $S_0\in X(\alpha)$, S_0 has a basis of the form $\{f_{j_1}+\sum_{i=1}^{j_1-1}z_{i1}f_i, f_{j_2}+\sum_{i=1,i\notin J}^{j_2-1}z_{i2}f_i,\cdots,f_{j_n}+\sum_{i=1,i\notin J}^{j_n-1}z_{in}f_i\}$. Let Z_0 be the $k\times n$ rank n matrix whose columns are the coordinates of these basis vectors with respect to the basis $\{f_1,\cdots,f_k\}$ for $\mathbb{R}^k$. Then the ipth entry of Z_0 is 1 if $i=j_p$, 0 if $i>j_p$, z_{ip} if $i<j_p$ and $i\notin J$, and 0 if $i<j_p$ and $i\in J$.

Now, let $M=\mathrm{Sp}\{f_{j_1},\cdots,f_{j_n}\}$ and let $N=\mathrm{Sp}\{f_i\colon i\notin J\}$. Corresponding to the indicated bases for M and N is a chart for $G^n(\mathbb{R}^k)$ which parametrizes all the subspaces which are complementary to N. In particular, S_0 is contained in this chart. This chart associates the $(k-n)n$ coordinates $\{a_{ip}\colon 1\leqq i\leqq k \text{ with } i\notin J, 1\leqq p\leqq n\}$ with the subspace $\mathrm{Sp}\{f_{j_p}+\sum_{i=1,i\notin J}^{k}a_{ip}f_i\colon p=1,\cdots,n\}$. It follows that if v is an arbitrary tangent vector to $G^k(\mathbb{R}^n)$ at S_0, then there exist $\{a_{ip}\}$ such that $v=d/dt|_{t=0}S(t)$, where $S(t)$ is the curve in $G^k(\mathbb{R}^n)$ with $S(0)=S_0$ described by

$$S(t)=\mathrm{Sp}\left\{f_{j_p}+\sum_{\substack{i=1\\ i\notin J}}^{j_p-1}z_{ip}f_i+t\sum_{\substack{i=1\\ i\notin J}}^{k}a_{ip}f_i\colon p=1,\cdots,n\right\}.$$

Let

$$S_1(t)=\mathrm{Sp}\left\{f_{j_p}+\sum_{\substack{i=1\\ i\notin J}}^{j_p-1}(z_{ip}+ta_{ip})f_i\colon p=1,\cdots,n\right\},$$

$$S_2(t)=\mathrm{Sp}\left\{f_{j_p}+\sum_{\substack{i=1\\ i\notin J}}^{j_p-1}z_{ip}f_i+t\sum_{\substack{i=j_p+1\\ i\notin J}}^{k}a_{ip}f_i\colon p=1,\cdots,n\right\},$$

$$v_1=\frac{d}{dt}\bigg|_{t=0}S_1(t),\qquad v_2=\frac{d}{dt}\bigg|_{t=0}S_2(t).$$

Then $S_1(0)=S_2(0)=S_0$, and $v_1+v_2=v$.

It is clear that $S_1(t)\in X(\alpha)$ for all t. Thus, v_1 is a tangent vector to the submanifold $X(\alpha)$ at S_0. We claim that $S_2(t)\in Y(\beta)$ for all t, which implies that v_2 is a tangent vector to the submanifold $Y(\beta)$ at S_0. This would show that $T_{S_0}(X(\alpha))+T_{S_0}(Y(\beta))=T_{S_0}(G^n(\mathbb{R}^k))$ and thereby complete the proof.

To prove the claim, let $Z_2(t)$ be the $k\times n$ rank n matrix whose columns are the coordinates of the indicated basis vectors for $S_2(t)$ with respect to the basis $\{f_1,\cdots,f_k\}$

for $\mathbb{R}^k$. Then the ipth entry of $Z_2(t)$ is 1 if $i=j_p$, 0 if $i\in J$ but $i\neq j_p$, z_{ip} if $i<j_p$ and $i\notin J$, and ta_{ip} if $i>j_p$ and $i\notin J$. Let $Z_2^q(t)$ be the submatrix of $Z_2(t)$ consisting of its first q rows, $q=1,\cdots,k$. The matrix $Z_2(t)$ maps $\mathbb{R}^n$ isomorphically onto the n-dimensional subspace of $\mathbb{R}^k$ consisting of all k-tuples which give the coordinates (with respect to the basis $\{f_1,\cdots,f_k\}$ for $\mathbb{R}^k$) for vectors belonging to $S_2(t)$. If $y\in\mathbb{R}^n$, then $Z_2(t)y$ represents a vector in $S_2(t)\cap W_{k-q}$ iff $y\in\ker Z_2^q(t)$. Thus, $\dim S_2(t)\cap W_{k-q}=\dim\ker Z_2^q(t)=n-\operatorname{rank} Z_2^q(t)$.

To show that $S_2(t)\in Y(\beta)$ is equivalent to showing that $\dim S_2(t)\cap W_j=\dim S_0\cap W_j$, $j=1,\cdots,k$. In turn, this is equivalent to showing that $\operatorname{rank} Z_2^q(t)=\operatorname{rank} Z_2^q(0)$ for all t. Observe that rows $j_1,\cdots,j_n$ of $Z_2(t)$ form an identity submatrix. Consequently, row operations can be performed on $Z_2(t)$ to remove every entry of the form ta_{ip} and thus obtain the matrix $Z_2(0)$. Furthermore, note that in each column, the entry "1" occurs above every entry of the form ta_{ip}. This means that the row operations used to reduce $Z_2(t)$ to $Z_2(0)$ are such that the row operations applied to the submatrix $Z_2^q(t)$ involve only rows in the submatrix. This implies that the rank of each such submatrix is preserved. Hence, $\operatorname{rank} Z_2^q(t)=\operatorname{rank} Z_2^q(0)$ for all t, $q=1,\cdots,k$. This completes the proof. □

It follows easily from Lemma 1 that stable and unstable manifolds for the ERDE always intersect transversally.

PROPOSITION 1. *Let $T(l)$ and $T(l')$ be invariant tori. Then $W^s(T(l))$ and $W^u(T(l'))$ intersect transversally.*

Proof. We have $E_1\oplus\cdots\oplus E_r=\mathbb{R}^{n+m}$. Obtain a refined direct sum decomposition $F_1\oplus\cdots\oplus F_{n+m}=\mathbb{R}^{n+m}$ by decomposing E_j into a direct sum of 2 1-dimensional subspaces whenever $\dim E_j=2$. In doing this, we preserve the ordering so that it still corresponds to increasing real part of the eigenvalues. Define complete flags $\{V_j\}_1^{n+m}$, $\{W_j\}_1^{n+m}$ by $V_j=\bigoplus_{i=1}^j F_i$, $W_j=\bigoplus_{i=1}^j F_{n+m-i+1}$. Then $\{V_j\}$ and $\{W_j\}$ refine the stable and unstable flags $\{M_j\}$ and $\{N_j\}$ respectively. By Theorem 4, $W^s(T(l))$ and $W^u(T(l'))$ are each disjoint unions of finitely many cells corresponding respectively to the complete flags $\{V_j\}$ and $\{W_j\}$. In the notation of Lemma 1, each cell for $W^s(T(l))$ is of the form $X(\alpha)$ for some α, while each cell for $W^u(T(l'))$ is of the form $Y(\beta)$ for some β. By Lemma 1, $X(\alpha)$ and $Y(\beta)$ intersect transversally. Since $X(\alpha)$ and $Y(\beta)$ are embedded submanifolds of $W^s(T(l))$ and $W^u(T(l'))$ respectively, we conclude that $W^s(T(l))$ and $W^u(T(l'))$ intersect transversally. □

The next question we consider is whether or not every equilibrium point of the ERDE is hyperbolic. Suppose that S_0 is an equilibrium point. Then S_0 is of the form $S_0=E_{j_1}\oplus\cdots\oplus E_{j_k}$ for some k and indices $j_1,\cdots,j_k$. Let $J=\{j_1,\cdots,j_k\}$ and let $W_0=\bigoplus_{j=1,j\notin J}^r E_j$. Then W_0 is an m-dimensional B-invariant subspace which is complementary to the n-dimensional B-invariant subspace S_0. Let $\{\alpha_i\}_1^n$ and $\{\beta_j\}_1^m$ denote the eigenvalues of the restrictions $B|S_0$ and $B|W_0$ respectively. A calculation of Hermann and Martin [19] shows that the eigenvalues of the linearization of the ERDE at S_0 are $\{\beta_j-\alpha_i\colon i=1,\cdots,n;\ j=1,\cdots,m\}$. It follows that if B satisfies Assumption A1, then none of these nm eigenvalues have zero real part. Thus, we have

PROPOSITION 2. *Every equilibrium point of the* ERDE *is hyperbolic.*

If $T(l)$ is a 1-dimensional invariant torus, then $T(l)$ is a periodic orbit. For the ESRDE, Hermann and Martin [19] have discussed the Poincaré map associated with such a periodic orbit. We use a similar approach here to analyze the Poincaré maps for the ERDE. It is worth noting that periodic orbits may lie on invariant tori of dimension 2 or greater. However, if this is the case, there are uncountably many periodic orbits.

Let $T(l)$ be a 1-dimensional invariant torus. Then there exist indices $j_0, \cdots, j_k$ such that the elements of $T(l)$ are the subspaces of the form $\tilde{S} \oplus E_{j_1} \oplus \cdots \oplus E_{j_k}$ where $\sum_{i=1}^{k} \dim E_{j_i} = n-1$, $\dim E_{j_0} = 2$, and $\tilde{S}$ is any 1-dimensional subspace of E_{j_0}. Let $\alpha_1 = a + ib$ and $\beta_1 = a - ib$ denote the pair of complex conjugate eigenvalues of $B|E_{j_0}$ chosen so that $b > 0$, and let $\tau = \pi/b$. Let $\alpha_2, \cdots, \alpha_n$ denote the eigenvalues of $B|E_{j_1} \oplus \cdots \oplus E_{j_k}$. Let $J = \{j_0, j_1, \cdots, j_k\}$, let $V = \bigoplus_{j=1, j \notin J}^{r} E_j$, and let $\beta_2, \cdots, \beta_m$ denote the eigenvalues of $B|V$. By making a change of basis, we may assume that $E_{j_0} = \mathrm{Sp}\{e_1, e_{n+1}\}$, $E_{j_1} \oplus \cdots \oplus E_{j_k} = \mathrm{Sp}\{e_2, \cdots, e_n\}$, and $V = \mathrm{Sp}\{e_{n+2}, \cdots, e_{n+m}\}$. We may also assume that

$$B = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}$$

where $B_{11} = \mathrm{diag}\{a, D_1\}$ with D_1 $(n-1) \times (n-1)$, B_{12} is 0 except for the $(1, 1)$ entry which is equal to b, $B_{21} = -B_{12}'$, and $B_{22} = \mathrm{diag}\{a, D_2\}$ with D_2 $(m-1) \times (m-1)$. Let

$$e^{Bt} = \begin{bmatrix} C_{11}(t) & C_{12}(t) \\ C_{21}(t) & C_{22}(t) \end{bmatrix}.$$

Then $C_{11}(t) = \mathrm{diag}\{e^{at} \cos bt, e^{D_1 t}\}$, $C_{12}(t)$ is 0 except for its $(1, 1)$ entry which is $e^{at} \sin bt$, $C_{21}(t) = -C_{12}'(t)$, and $C_{22}(t) = \mathrm{diag}\{e^{at} \cos bt, e^{D_2 t}\}$.

We construct a Poincaré map at the point $S_0 = \mathrm{Sp}\{e_1, \cdots, e_n\} \in T(l)$. S_0 corresponds to the origin in the chart $Y \to \mathrm{Sp}\begin{bmatrix} I \\ Y \end{bmatrix}$ for $G^n(\mathbb{R}^{n+m})$, where $Y \in \mathbb{R}^{m \times n}$. Let W denote this chart. The τ-periodic solution $e^{Bt}(S_0)$ is contained in this chart except for those values of t for which $\cos bt = 0$. The expression for $e^{Bt}(S_0)$ in the local coordinates of this chart is $\tilde{Y}(t)$ where the $m \times n$ matrix $\tilde{Y}(t)$ is 0 except for its $(1, 1)$ entry which is $-\tan bt$.

Let U denote the subset of W consisting of the subspaces of the form $\mathrm{Sp}\begin{bmatrix} I \\ Y \end{bmatrix}$ where $y_{11} = 0$. Then U is a codimension 1 submanifold of W which intersects the periodic orbit transversally at S_0. Let $S_1 = \mathrm{Sp}\begin{bmatrix} I \\ Y \end{bmatrix} \in U$. $e^{Bt}(S_1) \in W$ iff $C_{11}(t) + C_{12}(t)Y$ is nonsingular, which is equivalent to $\cos bt$ being nonzero. If this is the case, then

$$e^{Bt}(S_1) = \mathrm{Sp}\begin{bmatrix} I \\ (C_{21}(t) + C_{22}(t)Y)(C_{11}(t) + C_{12}(t)Y)^{-1} \end{bmatrix}.$$

Then $e^{Bt} \in U$ iff the $(1, 1)$ entry of $(C_{21}(t) + C_{22}(t)Y)(C_{11}(t) + C_{12}(t)Y)^{-1}$ is 0. This is equivalent to having $\tan bt = 0$. It follows that if $t = \tau$, $e^{B\tau}(S_1) \in U$. Thus, the restriction of $e^{B\tau}$ to the submanifold U is a Poincaré map for the periodic orbit $T(l)$. Since $C_{12}(\tau) = 0$ and $C_{21}(\tau) = 0$, the Poincaré map is given in local coordinates by the map $Y \to C_{22}(\tau) Y C_{11}(\tau)^{-1}$, which is a linear map. Here Y is an $m \times n$ matrix with $y_{11} = 0$. It is easily verified that the eigenvalues of this linear map (and hence of the derivative of the Poincaré map at S_0) are as given in the following result. Note that $e^{-\alpha_1 \tau} = -e^{-a\tau}$ and $e^{\beta_1 \tau} = -e^{a\tau}$.

PROPOSITION 3. *Let $T(l)$ be a 1-dimensional invariant torus. Then (using the above notation) the $mn-1$ eigenvalues of the derivative of the associated Poincaré map are $\{e^{(\beta_j - \alpha_i)\tau}: i = 1, \cdots, n; j = 1, \cdots, m$ and $(i, j) \neq (1, 1)\}$.*

COROLLARY. *Every 1-dimensional invariant torus is a hyperbolic periodic orbit.*

Proof. It follows from Proposition 3 and Assumption A1 that none of the $mn-1$ eigenvalues of the derivative of the Poincaré map are on the unit circle. □

We can now state necessary and sufficient conditions for the ERDE to be a Morse-Smale vector field. Recall that B has p real eigenvalues and $2q$ nonreal eigenvalues.

THEOREM 8. *The* ERDE *is a Morse-Smale vector field iff either of the following two conditions is satisfied*: (i) $\min(n, m) \leqq 1$, (ii) $q \leqq 1$.

Proof. If either (i) or (ii) is satisfied, there can be no invariant tori of dimension greater than one. From Propositions 1, 2, 3, it follows that the ERDE is Morse-Smale. On the other hand, if $n \geqq 2$, $m \geqq 2$, and $q \geqq 2$, the nonwandering set of the ERDE contains at least one invariant torus of dimension greater than one and therefore cannot be Morse-Smale. □

Remark 2. In the case where B has only real eigenvalues (i.e. $q = 0$), the nonwandering set contains only equilibrium points. In this very special case, C. R. Schneider proved that the ERDE is Morse-Smale and described the phase portrait [33]. By demonstrating the existence of invariant tori of dimension greater than one, Hermann and Martin showed that the ERDE is not Morse-Smale if $\min(n, m) \geqq 2$ and $q \geqq 2$ [18]. However, Theorem 8 includes a new result, namely that the ERDE is Morse-Smale whenever there are no invariant tori of dimension greater than one.

We now consider the structural stability of the ERDE. Let ϕ_t^1 and ϕ_t^2 be two flows on a manifold M. ϕ_t^1 and ϕ_t^2 are said to be *topologically equivalent* if there exists a homeomorphism of M which sends orbits of ϕ_t^1 into orbits of ϕ_t^2 [42]. Let $\chi(M)$ denote the set of all C^r, $r > 0$, vector fields on M. $\chi(M)$ forms a vector space, and given a C^r norm, $r < \infty$, a Banach space. A vector field $X \in \chi(M)$ is said to be *structurally stable* if there is some neighborhood N of X in $\chi(M)$ such that every vector field $\tilde{X} \in N$ is topologically equivalent to X.

It is also useful to define a weaker form of equivalence. Let $\Omega(\phi_t^1)$ and $\Omega(\phi_t^2)$ denote the nonwandering sets of ϕ_t^1 and ϕ_t^2. We say [42] that ϕ_t^1 and ϕ_t^2 are *topologically equivalent on* Ω if there exists a homeomorphism of $\Omega(\phi_t^1)$ onto $\Omega(\phi_t^2)$ which maps orbits into orbits. Then $X \in \chi(M)$ is said to be *Ω-stable* if there is a neighborhood N of X in $\chi(M)$ such that every vector field $\tilde{X} \in N$ is topologically equivalent on Ω to X.

We recall that each ERDE corresponds to an infinitesimal generator $B \in \mathrm{gl}(n+m, \mathbb{R})$. ($\mathrm{gl}(n+m, \mathbb{R})$ denotes the vector space of all $(n+m) \times (n+m)$ real matrices, which is the Lie algebra of the general linear group $\mathrm{Gl}(n+m, \mathbb{R})$.) We will say that the ERDE determined by B is *structurally stable within the class of* ERDE's if there exists a neighborhood N of B in $\mathrm{gl}(n+m, \mathbb{R})$ such that the vector field determined by B is topologically equivalent to the vector field determined by every $\tilde{B} \in N$. By replacing "topologically equivalent" with "topologically equivalent on Ω", we obtain the definition of the ERDE determined by B being *Ω-stable within the class of* ERDE's.

THEOREM 9. *Suppose that* $B \in \mathrm{gl}(n+m, \mathbb{R})$ *satisfies Assumption* A1. *If* $\min(n, m) \leqq 1$ *or* $q \leqq 1$, *the associated* ERDE *is structurally stable. Otherwise, the associated* ERDE *is not Ω-stable within the class of* ERDE's.

Proof. If $\min(n, m) \leqq 1$ or $q \leqq 1$, then the associated ERDE is Morse-Smale by Theorem 8. This implies that it is structurally stable [30]. Now suppose that $\min(n, m) \geqq 2$ and $q \geqq 2$. Then the nonwandering set contains at least one invariant torus of dimension $k \geqq 2$. Let $a_1 \pm ib_1, \cdots, a_q \pm ib_q$ be the nonreal eigenvalues of B. Given any neighborhood N of B in $\mathrm{gl}(n+m, \mathbb{R})$, we can find $\tilde{B}$, $\hat{B} \in N$ such that the imaginary parts of the eigenvalues of $\tilde{B}$ ($\hat{B}$) are all commensurable (all noncommensurable). Then every invariant torus of $\tilde{B}$ ($\hat{B}$) of dimension at least 2 contains periodic (almost periodic) orbits. Thus, the ERDE's associated with $\tilde{B}$ and $\hat{B}$ are not topologically equivalent on Ω. Hence, the ERDE associated with B cannot be Ω-stable within the class of ERDE's. □

Remark 3. It was conjectured in the recent paper [9] that the ERDE is structurally stable provided that the generator B has distinct eigenvalues. However, Theorem 9

shows that this conjecture is false. The assumption of distinct eigenvalues does not even imply Ω-stability within the class of ERDE's.

We have considered structural stability of the phase portrait in the *global* sense. One can also consider structural stability in a local sense by investigating what happens to the phase portrait in a neighborhood of an equilibrium point when the differential equation is perturbed. Local structural stability of the Riccati equation is studied in [6].

Morse theory relates the global phase portrait of a gradient vector field to the topology of the underlying manifold. This was extended by Smale [43] to the class of Morse-Smale vector fields. Let X be a Morse-Smale vector field on a compact ν-dimensional manifold M with equilibria $x_1, \cdots, x_m$ and closed orbits $\gamma_1, \cdots, \gamma_n$. Let $W^s(x_i)$ and $W^s(\gamma_j)$ denote the stable manifolds of x_i and γ_j respectively. Define the index of x_i to be $\operatorname{Ind}(x_i) = \dim W^s(x_i)$, and define the index of γ_j to be $\operatorname{Ind}(\gamma_j) = \dim W^s(\gamma_j) - \dim \gamma_j = \dim W^s(\gamma_j) - 1$. Define the Morse series for the vector field X to be the polynomial

$$M_X(t) = \sum_i t^{\operatorname{Ind}(x_i)} + \sum_j (1+t) t^{\operatorname{Ind}(\gamma_j)}.$$

Let $b_i(M, K)$ denote the ith Betti number of M for the coefficient field K. Let $P_K(M; t)$ denote the Poincaré polynomial of M for the coefficient field K. In other words,

$$P_K(M; t) = \sum_{i=0}^{\nu} b_i(M, K) t^i.$$

Then it follows from Smale's result that each coefficient of $M_X(t)$ is greater than or equal to the corresponding coefficient of $P_{Z_2}(M; t)$. In other words, the coefficient of t^i in $M_X(t)$ is greater than or equal to $b_i(M, Z_2)$. Further generalizations of the theory of Morse index are described in [10].

As an application of Theorem 8, we will obtain a new calculation of the mod 2 Betti numbers of the Grassmann manifold based on the phase portrait of the Riccati differential equation. We will use the following result due to E. E. Floyd [13]:

THEOREM. *If a transformation of period* 2 *acts on a compact manifold M, and if F is its fixed point set, then*

$$\sum_i b_i(F, Z_2) \leqq \sum_i b_i(M, Z_2).$$

Using Floyd's theorem, we can obtain a lower bound on the sum of the mod 2 Betti numbers for the Grassmann manifold.

LEMMA 2. $\sum_i b_i(G^n(\mathbb{R}^{n+m}), Z_2) \geqq \binom{n+m}{n}$.

Proof. The proof is by induction on $n+m$. If $n+m=1$, the assertion is trivial. Suppose that the assertion holds for $G^k(\mathbb{R}^p)$ whenever $p < n+m$. Let $P = \operatorname{diag}\{d_1, \cdots, d_{n+m}\}$ with $d_1 = d_2 = \cdots = d_{n+m-1} = 1$ and $d_{n+m} = -1$. P induces a diffeomorphism of $G^n(\mathbb{R}^{n+m})$ (which we also denote by P) given by $S \to P(S)$, where $P(S)$ is the image of the subspace S under P. Let F denote the fixed point set of this period 2 transformation. F consists of all n-dimensional P-invariant subspaces. Let $V = \operatorname{Sp}\{e_1, \cdots, e_{n+m-1}\}$ and let $W = \operatorname{Sp}\{e_{n+m}\}$. Then $F = \{S_1 \oplus S_2 \colon S_1 \in G^n(V), S_2 \in G^0(W)\} \sqcup \{S_1 \oplus S_2 \colon S_1 \in G^{n-1}(V), S_2 \in G^1(W)\}$. Thus, F is isomorphic to $G^n(\mathbb{R}^{n+m-1}) \sqcup G^{n-1}(\mathbb{R}^{n+m-1})$. By the induction hypothesis,

$$\sum_i b_i(F, Z_2) \geqq \binom{n+m-1}{n} + \binom{n+m-1}{n-1} = \binom{n+m}{n}.$$

Applying Floyd's theorem, we obtain

$$\sum_i b_i(G^n(\mathbb{R}^{n+m}), Z_2) \geqq \binom{n+m}{n},$$

which completes the proof. □

THEOREM 10. *$b_s(G^n(\mathbb{R}^{n+m}), Z_2)$ is equal to the number of partitions of s into n parts of size less than or equal to m.*

Proof. Choose B to have distinct real eigenvalues. Then the ERDE has $\binom{n+m}{n}$ equilibrium points and no other invariant tori. Also, $\dim E_j = 1$ for all j, $r = n+m$, and $\dim M_j = j$ for all j. Let $l = (l_1, \cdots, l_{n+m})$ be such that $l_j = 0$ or 1 and $\sum_{j=1}^{n+m} l_j = n$. By Theorem 7, $\dim W^s(T(l)) = \sum_{j=1}^{n+m} l_j(j-1-\sum_{i=1}^{j-1} l_i)$. This expression can be simplified by letting $j_1 < j_2 < \cdots < j_n$ denote the elements of $\{j\colon l_j = 1\}$. Using the fact that $\sum_{i=1}^{j_\nu - 1} l_i = \nu - 1$, we obtain the formula

$$\dim W^s(T(l)) = \sum_{\nu=1}^{n} (j_\nu - \nu).$$

Thus, $T(l)$ is an equilibrium point of index s iff $\sum_{\nu=1}^{n} (j_\nu - \nu) = s$. This shows that $(j_1 - 1, j_2 - 2, \cdots, j_n - n)$ is a partition of s into n parts of size at most m (with $j_1 - 1 \leqq \cdots \leqq j_n - n$). On the other hand, suppose that $(c_1, \cdots, c_n)$ is a partition of s into n parts of size at most m with $c_1 \leqq \cdots \leqq c_n$. Define $j_\nu = c_\nu + \nu$, $\nu = 1, \cdots, n$. Then $1 \leqq j_1 < \cdots < j_n \leqq n+m$. This means that there is a unique choice of l for which $j_1, \cdots, j_n$ are the elements of $\{j\colon l_j = 1\}$. Furthermore, the index of the corresponding equilibrium point is s. Consequently, the number of equilibrium points of index s is equal to the number of partitions of s into n parts of size at most m. Let m_s denote this number. Thus, m_s is the coefficient of t^s in the Morse series for the vector field we are considering. The sum $\sum_s m_s$ must equal the number of equilibrium points $\binom{n+m}{n}$. By Theorem 8, the vector field is Morse-Smale. Hence, $m_s \geqq b_s(G^n(\mathbb{R}^{n+m}), Z_2)$ for all s. Applying Lemma 2, we have

$$\binom{n+m}{n} = \sum_s m_s \geqq \sum_s b_s(G^n(\mathbb{R}^{n+m}), Z_2) \geqq \binom{n+m}{n},$$

which implies that $b_s(G^n(\mathbb{R}^{n+m}), Z_2) = m_s$ for all s, completing the proof. □

As we have seen, the ERDE is not generally Morse-Smale, due to the existence of invariant tori of dimension greater than one in the nonwandering set. However, we propose to define a Morse series $M_B(t)$ for the ERDE with generator B as follows: For each invariant torus $T(l)$, define the index of $T(l)$ to be $\operatorname{Ind}(T(l)) = \dim W^s(T(l)) - \dim T(l)$. Then we define the Morse series to be

$$M_B(t) = \sum_l (1+t)^{\dim T(l)} t^{\operatorname{Ind}(T(l))}.$$

Note that if every invariant torus has dimension less than 2, this definition coincides with the definition of the Morse series for a Morse-Smale vector field. Also note that the factor $(1+t)^{\dim T(l)}$ is precisely the Poincaré polynomial for the invariant torus $T(l)$. Thus, our definition of $M_B(t)$ is analogous to the definition of the Morse series for the gradient vector field corresponding to a Morse-Bott function, i.e. a function with nondegenerate critical submanifolds.

Having defined a Morse series for the ERDE, it is natural to ask whether Morse-type inequalities hold. The next result shows that this is indeed the case. In fact, if Z_2 is the coefficient field, the ERDE satisfies Morse-type *equalities.*

THEOREM 11. *Suppose that* $B \in \mathrm{gl}(n+m, \mathbb{R})$ *satisfies Assumption* A1. *Then*

$$M_B(t) = P_{Z_2}(G^n(\mathbb{R}^{n+m}); t).$$

Proof. In § 3.2, we discussed how the choice of a complete flag of subspaces gives a cell decomposition of $G^n(\mathbb{R}^{n+m})$ into the union of $\binom{n+m}{n}$ cells $\{U(a)\}$. If $j_1 < j_2 < \cdots < j_n$ are the n elements of the set $\{j: a_j = 1\}$, then we noted that $\dim U(a) = \sum_{i=1}^{n} (j_i - i)$. By an argument analogous to the one used in the proof of Theorem 10, it follows that the number of cells of dimension s is equal to the number of partitions of s into n parts of size less than or equal to m. Thus, the number of cells of dimension s is equal to $b_s(G^n(\mathbb{R}^{n+m}), Z_2)$. Hence,

$$P_{Z_2}(G^n(\mathbb{R}^{n+m}); t) = \sum_{\substack{\text{all} \\ \text{cells}}} t^{\dim \text{ cell}}.$$

In the special case where the complete flag is chosen so as to refine the stable flag $M_0 \subset M_1 \subset \cdots \subset M_r$, we know from Theorem 4 that each stable manifold $W^s(T(l))$ is a disjoint union of cells. Furthermore, if $\dim T(l) = k$, then $W^s(T(l))$ is the union of 2^k cells, and $\binom{k}{\nu}$ of these cells have dimension equal to $\dim W^s(T(l)) - k + \nu = \mathrm{Ind}\, T(l) + \nu$, $\nu = 0, \cdots, k$. The Binomial Theorem then implies that

$$(1+t)^k t^{\mathrm{Ind}\,(T(l))} = \sum_{\substack{\text{all cells} \\ \text{in } W^s(T(l))}} t^{\dim \text{ cell}}.$$

If we sum this equation over all the invariant tori $T(l)$, the left-hand side gives the Morse series $M_B(t)$ while the right-hand side gives $P_{Z_2}(G^n(\mathbb{R}^{n+m}); t)$. □

4. Phase portrait of the extended symplectic Riccati differential equation. In this section, we determine the complete phase portrait for the ESRDE on the Lagrange-Grassmann manifold $\mathscr{L}(n)$. We make the following assumptions which we denote collectively as Assumption A2: (1) the $2n$ eigenvalues of the infinitesimal generator $H = \begin{bmatrix} A & -L \\ -Q & -A' \end{bmatrix}$ are distinct, (2) if λ_i and λ_j are a pair of eigenvalues with the same real part, then $\lambda_i = \bar{\lambda}_j$, and (3) H has no eigenvalues on the imaginary axis. Note that we place no individual restrictions on the matrices A, L, Q other than requiring that L and Q be symmetric. Assumptions (1) and (2) are relaxed considerably in § 6.

As discussed in § 2, the ESRDE is the differential equation on $\mathscr{L}(n)$ whose flow is given by $S(t, S_0) = e^{Ht}(S_0)$. However, it will be convenient to extend the ESRDE to a differential equation on $G^n(\mathbb{R}^{2n})$. The flow on $G^n(\mathbb{R}^{2n})$ is given by $S(t, S_0) = e^{Ht}(S_0)$, but where we now permit the initial point S_0 to be any element of $G^n(\mathbb{R}^{2n})$. Regarded as a differential equation on $G^n(\mathbb{R}^{2n})$, the ESRDE is a special case of the ERDE, so all the results of the preceding section apply to characterize the phase portrait. Since $\mathscr{L}(n)$ is an invariant manifold of the ESRDE on $G^n(\mathbb{R}^{2n})$, the phase portrait for the ESRDE on $\mathscr{L}(n)$ is the intersection of the phase portrait on $G^n(\mathbb{R}^{2n})$ with the submanifold $\mathscr{L}(n)$. For example, the nonwandering set on $\mathscr{L}(n)$ is the intersection of $\mathscr{L}(n)$ with the nonwandering set on $G^n(\mathbb{R}^{2n})$. The corresponding statement applies to the stable and unstable manifolds. Thus, from a *set-theoretic* point of view, the phase portrait of the ESRDE on $\mathscr{L}(n)$ is immediately obtained from the results in § 3. However, these results do not furnish a *geometric* description of the phase portrait. For example, we know that the nonwandering set is the intersection with $\mathscr{L}(n)$ of finitely many tori, but we do not know the topological structure of these intersections. It is the problem of describing the geometry of the phase portrait which we consider in this section.

Since the Hamiltonian matrix H belongs to the Lie algebra $\mathrm{sp}(n,\mathbb{R})$, i.e. $JH+H'J=0$—it follows that the eigenvalues of H come in pairs. If λ is an eigenvalue, then so is $-\lambda$. Let $2p$ denote the number of real eigenvalues of H, and let $4q$ denote the number of nonreal eigenvalues of H. Let $E_1,\cdots,E_r,E_{r+1},\cdots,E_{2r}$ denote the primary components of H. (Thus, when we apply results from § 3, we must use $2r$ in place of r.) We assume that the order of the indexing is determined by increasing real part of the corresponding eigenvalues. This implies that if E_j corresponds to a real eigenvalue λ, then E_{2r-j+1} corresponds to $-\lambda$. Similarly, if E_j corresponds to a conjugate pair $\lambda,\bar{\lambda}$, then E_{2r-j+1} corresponds to $-\lambda,-\bar{\lambda}$. In particular, $\dim E_j=\dim E_{2r-j+1}$. Note also that $E_1,\cdots,E_r$ correspond to eigenvalues with negative real part, while $E_{r+1},\cdots,E_{2r}$ correspond to eigenvalues with positive real part.

4.1. Nonwandering set. We begin by describing two known results. The first lemma was proved by A. C. M. Van Swieten [46] and generalizes a result of J. E. Potter [31] and K. Mårtensson [25]. (A proof is included in [35].)

LEMMA 3. *Let $\tilde{H}\in\mathrm{sp}(n,\mathbb{R})$ and let $p(s)$ denote its characteristic polynomial. Suppose that $p(s)=p_1(-s)p_2(s)$ with $p_1(-s)$ and $p_2(s)$ relatively prime. Let $S_1=\ker p_1(\tilde{H})$ and let $S_2=\ker p_2(\tilde{H})$. Then $x_2'Jx_1=0$, $\forall x_1\in S_1$, $\forall x_2\in S_2$.*

Let $L^+(H)$ denote the direct sum of the primary components of H corresponding to its eigenvalues with *negative* real part, and let $L^-(H)$ denote the direct sum of the primary components of H corresponding to its eigenvalues with *positive* real part. Since H is assumed to have no eigenvalues on the imaginary axis, $L^+(H)$ and $L^-(H)$ are each n-dimensional. It then follows from Lemma 3 that $L^+(H)\in\mathscr{L}(n)$ and $L^-(H)\in\mathscr{L}(n)$. The next result was proved by Shayman [37].

LEMMA 4. *Let $\tilde{H}\in\mathrm{sp}(n,\mathbb{R})$ and suppose that $\tilde{H}$ has no eigenvalues on the imaginary axis. Let $\tau>0$ be fixed. There exists a bijection δ of the set of n-dimensional Lagrangian $e^{\tilde{H}\tau}$-invariant subspaces onto the set of all $e^{\tilde{H}\tau}$-invariant subspaces of $L^+(\tilde{H})$, which is given by $\delta(S)=S\cap L^+(\tilde{H})$ and $\delta^{-1}(N)=N\oplus([J(N)]^\perp\cap L^-(\tilde{H}))$. Furthermore, S is $\tilde{H}$-invariant iff $\delta(S)$ is $\tilde{H}$-invariant.*

We will first characterize the nonwandering set of the ESRDE under the additional assumption that the imaginary parts of all the eigenvalues of H are commensurable. Later we will remove this assumption.

Let $l=(l_1,\cdots,l_r,l_{r+1},\cdots,l_{2r})$ be such that $\sum_{i=1}^{2r}l_i=n$ and $0\leqq l_i\leqq\dim E_i$, $\forall i$. The corresponding invariant torus for the ESRDE on $G^n(\mathbb{R}^{2n})$ is

$$T(l)=G^{l_1}(E_1)\times\cdots\times G^{l_r}(E_r)\times G^{l_{r+1}}(E_{r+1})\times\cdots\times G^{l_{2r}}(E_{2r}).$$

If $\dim T(l)=0$, then $T(l)$ consists of a single equilibrium point. Otherwise, the additional assumption we have made concerning the imaginary part of the eigenvalues of H implies that every motion on $T(l)$ is periodic with the same minimum period $\tau>0$.

Let $S\in T(l)$. For the moment, suppose that $\dim T(l)>0$, so that S generates a periodic motion of period $\tau>0$. Let $S=S_1\oplus\cdots\oplus S_r\oplus S_{r+1}\oplus\cdots\oplus S_{2r}$ with $S_j\in G^{l_j}(E_j)$. By Lemma 4, $S\in\mathscr{L}(n)$ iff $S_{r+1}\oplus\cdots\oplus S_{2r}=[J(S_1\oplus\cdots\oplus S_r)]^\perp\cap L^-(H)$. Since S is $e^{H\tau}$-invariant, it follows that $S_1\oplus\cdots\oplus S_r$ is $e^{H\tau}$-invariant. Since $JH+H'J=0$, it follows that $[J(S_1\oplus\cdots\oplus S_r)]^\perp$ is also $e^{H\tau}$-invariant. It is clear that $e^{H\tau}$ has the same primary components as does H, namely $E_1,\cdots,E_{2r}$. This implies that $[J(S_1\oplus\cdots\oplus S_r)]^\perp\cap L^-(H)=([J(S_1\oplus\cdots\oplus S_r)]^\perp\cap E_{r+1})\oplus\cdots\oplus([J(S_1\oplus\cdots\oplus S_r)]^\perp\cap E_{2r})$. It is an easy consequence of Lemma 3 that $J(E_i)\perp E_j$ provided that $j\neq 2r-i+1$. It follows that $[J(S_1\oplus\cdots\oplus S_r)]^\perp\cap L^-(H)=([J(S_r)]^\perp\cap E_{r+1})\oplus\cdots\oplus([J(S_1)]^\perp\cap E_{2r})$. We conclude that $S\in\mathscr{L}(n)$ iff $S_{2r-i+1}=[J(S_i)]^\perp\cap E_{2r-i+1}$, $i=1,\cdots,r$.

We claim that $\dim [J(S_i)]^\perp \cap E_{2r-i+1} = \dim E_{2r-i+1} - \dim S_i$. To show this, we note that the $e^{H\tau}$-invariance of S implies the $e^{H\tau}$-invariance of S_i which implies the $e^{H\tau}$-invariance of $[J(S_i)]^\perp$. It follows that

$$[J(S_i)]^\perp = \bigoplus_{j=1}^{2r} [J(S_i)]^\perp \cap E_j = \Bigg(\bigoplus_{\substack{j=1 \\ j \neq 2r-i+1}}^{2r} E_j \Bigg) \oplus ([J(S_i)]^\perp \cap E_{2r-i+1}).$$

Thus, $2n - \dim S_i = 2n - \dim E_{2r-i+1} + \dim [J(S_i)]^\perp \cap E_{2r-i+1}$ which establishes the claim. We conclude that $T(l) \cap \mathscr{L}(n)$ is empty unless $l_{2r-i+1} = \dim E_{2r-i+1} - l_i$, $i = 1, \cdots, r$. Since $\dim E_i = \dim E_{2r-i+1}$, this is equivalent to the condition that $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. If l satisfies this constraint, then

$$T(l) \cap \mathscr{L}(n) = \{S_1 \oplus \cdots \oplus S_r \oplus ([J(S_r)]^\perp \cap E_{r+1}) \oplus \cdots \oplus ([J(S_1)]^\perp \cap E_{2r}): \\ S_i \in G^{l_i}(E_i),\ i = 1, \cdots, r\}.$$

This shows that $T(l) \cap \mathscr{L}(n)$ is isomorphic to $G^{l_1}(E_1) \times \cdots \times G^{l_r}(E_r)$ and is therefore a torus. Since $\dim E_i = \dim E_{2r-i+1}$ and $l_i + l_{2r-i+1} = \dim E_i$, $\dim T(l) \cap \mathscr{L}(n) = \frac{1}{2} \dim T(l)$.

The above conclusions were derived under the assumption that $\dim T(l) > 0$. If $\dim T(l) = 0$, then $T(l)$ consists of a single equilibrium point S. Since S is H-invariant, S is $e^{H\tau}$-invariant for any τ, and all of the preceding arguments remain valid. Thus $S \in \mathscr{L}(n)$ iff $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. If this condition is satisfied, then $S = S_1 \oplus \cdots \oplus S_r \oplus ([J(S_r)]^\perp \cap E_{r+1}) \oplus \cdots \oplus ([J(S_1)]^\perp \cap E_{2r})$. If $l_i = 0$, then $S_i = 0$ and $[J(S_i)]^\perp \cap E_{2r-i+1} = E_{2r-i+1}$, while if $l_i = \dim E_i$, then $S_i = E_i$ and $[J(S_i)]^\perp \cap E_{2r-i+1} = 0$.

Now we will remove the additional assumption that the imaginary parts of all the eigenvalues of H are commensurable. We need the following lemma. Recall that the real canonical form for a semisimple (i.e. diagonalizable real matrix is a matrix which is zero except for 1×1 blocks and 2×2 blocks centered on the main diagonal. Each 2×2 block is of the form $\left[\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right]$ and corresponds to the pair of complex conjugate eigenvalues $a \pm ib$.

LEMMA 5. *Let $\tilde{H} \in \mathrm{sp}(n, \mathbb{R})$ and suppose that $\tilde{H}$ is semisimple and has no eigenvalues on the imaginary axis. Then there exists $P \in \mathrm{Sp}(n, \mathbb{R})$ such that $P^{-1}\tilde{H}P$ has the form $\left[\begin{smallmatrix} D & 0 \\ 0 & -D' \end{smallmatrix}\right]$, where (1) D is a semisimple matrix in real canonical form; (2) every eigenvalue of D has negative real part; (3) the blocks on the main diagonal of D are ordered by increasing real part of the corresponding eigenvalues.*

Proof. Clearly there exist $\tilde{P} \in \mathrm{Gl}(2n, \mathbb{R})$ and D as above such that

$$\tilde{H}\tilde{P} = \tilde{P} \begin{bmatrix} D & 0 \\ 0 & -D' \end{bmatrix}.$$

Let $\tilde{P} = [V, W]$ with V, W each $2n \times n$, and let $R = V'JW$. Then $\tilde{H}V = VD$ and $\tilde{H}W = -WD'$. Hence, $0 = V'(J\tilde{H} + \tilde{H}'J)W = -RD' + D'R$, showing that D' commutes with R.

Since $\mathrm{Sp}\ V = L^+(\tilde{H})$ and $\mathrm{Sp}\ W = L^-(\tilde{H})$, it follows from Lemma 3 that $V'JV = 0$ and $W'JW = 0$. Consequently,

$$\tilde{P}'J\tilde{P} = \begin{bmatrix} 0 & R \\ -R' & 0 \end{bmatrix}$$

which implies that R is nonsingular. Define $P = [V, WR^{-1}]$. Then $P'JP = J$, so

$P \in \mathrm{Sp}(n, \mathbb{R})$. Also, it follows easily from the fact that D' commutes with R^{-1} that

$$\tilde{H}P = P\begin{bmatrix} D & 0 \\ 0 & -D' \end{bmatrix},$$

which completes the proof. □

We can now prove the following result.

PROPOSITION 4. *Let $T(l)$ be an invariant torus for the* ESRDE *on $G^n(\mathbb{R}^{2n})$. Then $T(l) \cap \mathscr{L}(n)$ is nonempty iff $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. If l satisfies this condition, then* $T(l) \cap \mathscr{L}(n) = \{S_1 \oplus \cdots \oplus S_r \oplus ([J(S_r)]^{\perp} \cap E_{r+1}) \oplus \cdots \oplus ([J(S_1)]^{\perp} \cap E_{2r})$: $S_i \in G^{l_i}(E_i)$, $i = 1, \cdots, r\}$.

Proof. We have already proved this result in the special case where the imaginary parts of all the eigenvalues of H are commensurable. If H does not satisfy this condition, use Lemma 5 to express H in the form

$$H = P\begin{bmatrix} D & 0 \\ 0 & -D' \end{bmatrix}P^{-1}$$

with $P \in \mathrm{Sp}(n, \mathbb{R})$ and D as described in the statement of the lemma. Modify D by changing the imaginary parts of its complex eigenvalues so that they are all commensurable. Let $\tilde{D}$ denote the resulting matrix, and set

$$\tilde{H} = P\begin{bmatrix} \tilde{D} & 0 \\ 0 & -\tilde{D}' \end{bmatrix}P^{-1}.$$

Then $\tilde{H} \in \mathrm{sp}(n, \mathbb{R})$. If $\tilde{E}_1, \cdots, \tilde{E}_{2r}$ denote the primary components of $\tilde{H}$ ordered according to increasing real part of the corresponding eigenvalues, then $\tilde{E}_i = E_i$, $\forall i$. Thus, the invariant tori for $\tilde{H}$ are the same as those for H. Since we already know that the result holds for $\tilde{H}$, it must hold for H as well. □

Given any integers $l_1, \cdots, l_r$ satisfying $0 \leqq l_i \leqq \dim E_i$, there is obviously a unique choice for $l_{r+1}, \cdots, l_{2r}$ such that $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. Furthermore, this choice of $l_{r+1}, \cdots, l_{2r}$ is such that the conditions $\sum_{i=1}^{2r} l_i = n$ and $0 \leqq l_i \leqq \dim E_i$ $(i = r+1, \cdots, 2r)$ are satisfied. Consequently, there is exactly one invariant torus for the ESRDE on $\mathscr{L}(n)$ for each choice of integers $l_1, \cdots, l_r$ which satisfy $0 \leqq l_i \leqq \dim E_i$, $i = 1, \cdots, r$. This implies that there are $(1 + \dim E_1) \cdots (1 + \dim E_r)$ invariant tori in all. This number is equal to $2^p 3^q$.

Suppose that l corresponds to an invariant torus $T(l) \cap \mathscr{L}(n)$. By Proposition 4, it is clear that $\dim T(l) \cap \mathscr{L}(n)$ is equal to the cardinality of the set $\{j: 1 \leqq j \leqq r, l_j = 1, \dim E_j = 2\}$. Thus, a k-dimensional invariant torus is specified by choosing $l_1, \cdots, l_r$ as follows: (1) Choose $l_{j_1} = 1, \cdots, l_{j_k} = 1$ where $j_1, \cdots, j_k$ are such that $\dim E_{j_1} = 2, \cdots, \dim E_{j_k} = 2$. (2) For $j \notin \{j_1, \cdots, j_k\}$, choose either $l_j = 0$ or $l_j = \dim E_j$. It follows that the number of k-dimensional invariant tori for the ESRDE on $\mathscr{L}(n)$ is $\binom{q}{k} 2^{p+q-k}$, $k = 0, \cdots, q$.

Suppose that $T(l) \cap \mathscr{L}(n)$ is a k-dimensional invariant torus $(k > 0)$, and let $j_1 < j_2 < \cdots < j_k$ denote the elements of $\{j: 1 \leqq j \leqq r, l_j = 1, \dim E_j = 2\}$. Let $\sigma_{j_\nu} \pm i\omega_{j_\nu}$ be the conjugate pair of eigenvalues corresponding to the 2-dimensional primary component E_{j_ν}, $\nu = 1, \cdots, k$. $T(l)$ is a $2k$-dimensional invariant torus for the ESRDE on $G^n(\mathbb{R}^{2n})$. Since the pair of complex conjugate eigenvalues corresponding to the primary component $E_{2r-j_\nu+1}$ is $-\sigma_{j_\nu} \pm i\omega_{j_\nu}$, it follows from Theorem 1 that each $S \in T(l)$ generates a periodic motion if the $2k$ numbers $\omega_{j_1}, \cdots, \omega_{j_k}, \omega_{j_1}, \cdots, \omega_{j_k}$ are commensurable, in which case the period is given by the least common multiple of $\pi/\omega_{j_1}, \cdots, \pi/\omega_{j_k}$. Otherwise each $S \in T(l)$ generates an almost periodic motion. However, this motion

is never dense in $T(l)$ since each imaginary part is repeated twice in the list $\omega_{j_1}, \cdots, \omega_{j_k}$, $\omega_{j_1}, \cdots, \omega_{j_k}$. It also follows from Theorem 1 that if $S, \tilde{S} \in T(l)$ and $e^{Ht}(\tilde{S}) \to e^{Ht}(S)$ as $t \to \infty$ or $t \to -\infty$, then $S = \tilde{S}$. We obtain the following theorem.

THEOREM 12. (a) *The nonwandering set of the* ESRDE *on* $\mathscr{L}(n)$ *is a union of invariant tori. There are exactly* $\binom{q}{k}2^{p+q-k}$ *tori of dimension* k, $k = 0, \cdots, q$. (b) *If* $T(l) \cap \mathscr{L}(n)$ *is a* 0*-dimensional invariant torus, then* $T(l) \cap \mathscr{L}(n)$ *is an equilibrium point.* (c) *If* $T(l) \cap \mathscr{L}(n)$ *is a* k*-dimensional invariant torus with* $k > 0$, *and if* $\{\omega_{j_\nu}: \nu = 1, \cdots, k\}$ *are commensurable, then each* $S \in T(l) \cap \mathscr{L}(n)$ *generates a periodic motion with period equal to the least common multiple of* $\{\pi/\omega_{j_\nu}: \nu = 1, \cdots, k\}$. *Otherwise, each* $S \in T(l) \cap \mathscr{L}(n)$ *generates an almost periodic motion which is dense in* $T(l) \cap \mathscr{L}(n)$ *iff no pair of the* ω_{j_ν} *are commensurable. In all cases, if* $S, \tilde{S} \in T(l) \cap \mathscr{L}(n)$ *with* $e^{Ht}(\tilde{S}) \to e^{Ht}(S)$ *as* $t \to \infty$ *or* $t \to -\infty$, *then* $S = \tilde{S}$.

Proof. (a) All that remains to be proven is that the $\binom{q}{k}2^{p+q-k}$ invariant tori exhaust the nonwandering set of the ESRDE on $\mathscr{L}(n)$. By Corollary 2 of Theorem 2, the nonwandering set of the ESRDE on $G^n(\mathbb{R}^{2n})$ is the union of the invariant tori $\{T(l)\}$. Since $T(l) \cap \mathscr{L}(n)$ is either empty or is one of the $\binom{q}{k}2^{p+q-k}$ invariant tori for the ESRDE on $\mathscr{L}(n)$, these tori exhaust the nonwandering set. (b) Already proven. (c) All of the assertions follow from the corresponding statements for the flow in $T(l)$ except the claim that each $S \in T(l) \cap \mathscr{L}(n)$ generates a dense trajectory iff no pair of the ω_{j_ν} $(\nu = 1, \cdots, k)$ are commensurable. $T(l) \cap \mathscr{L}(n)$ is a k-dimensional torus by the isomorphism $T(l) \cap \mathscr{L}(n) \cong G^1(E_{j_1}) \times \cdots \times G^1(E_{j_k})$. If $S \in T(l) \cap \mathscr{L}(n)$, then by Proposition 4, S has the form $S = S_1 \oplus \cdots \oplus S_r \oplus ([J(S_r)]^\perp \cap E_{r+1}) \oplus \cdots \oplus ([J(S_1)]^\perp \cap E_{2r})$. The isomorphism identifies S with $(S_{j_1}, \cdots, S_{j_k}) \in G^1(E_{j_1}) \times \cdots \times G^1(E_{j_k})$ and the motion $e^{Ht}(S)$ with the motion $(e^{Ht}(S_{j_1}), \cdots, e^{Ht}(S_{j_k}))$. The motion $e^{Ht}(S_{j_\nu})$ traverses the circle $G^1(E_{j_\nu})$ with period π/ω_{j_ν}. It follows immediately that $(e^{Ht}(S_{j_1}), \cdots, e^{Ht}(S_{j_k}))$ winds densely in $G^1(E_{j_1}) \times \cdots \times G^1(E_{j_k})$ iff no pair of the ω_{j_ν} are commensurable. By the isomorphism, the same conclusion applies to the motion $e^{Ht}(S)$ in $T(l) \cap \mathscr{L}(n)$. □

4.2. Stable and unstable manifolds. In § 3.2, we described how the choice of a complete flag of subspaces gives rise to a cell decomposition of the Grassmann manifold. In particular, *any* complete flag for $\mathbb{R}^{2n}$ gives a cell decomposition of $G^n(\mathbb{R}^{2n})$. However, if we wish to obtain a cell decomposition for the submanifold $\mathscr{L}(n)$ from the cell decomposition for $G^n(\mathbb{R}^{2n})$, we must choose the complete flag in a special way.

Let $V_1 \subset \cdots \subset V_{2n}$ be the complete flag for $\mathbb{R}^{2n}$ given by $V_j = \operatorname{Sp}\{e_1, e_2, \cdots, e_j\}$ for $j = 1, 2, \cdots, n$, and $V_j = \operatorname{Sp}\{e_1, e_2, \cdots, e_n, e_{2n}, e_{2n-1}, \cdots, e_{3n-j+1}\}$ for $j = n+1, n+2, \cdots, 2n$. We will call $\{V_j\}_1^{2n}$ the *standard symplectic flag for* $\mathbb{R}^{2n}$. Let $a = (a_1, \cdots, a_{2n})$ be such that $a_i = 0$ or 1 and $\sum_{i=1}^{2n} a_i = n$. Let $U(a) = \{S \in G^n(\mathbb{R}^{2n}): \dim S \cap V_j = \sum_{i=1}^{j} a_i,\ j = 1, \cdots, 2n\}$. Let $j_\nu = \min\{j: \sum_{i=1}^{j} a_i = \nu\}$, $\nu = 1, \cdots, n$. As noted previously, $U(a)$ is real-analytically isomorphic to Euclidean space of dimension $\sum_{j=1}^{2n} a_j(j - \sum_{i=1}^{j} a_i)$. This dimension is also given by the expression $\sum_{\nu=1}^{n}(j_\nu - \nu)$. Let N denote this dimension. Also define $d = \sum_{i=1}^{n} a_i$. Note that $j_d \leqq n$ and $j_{d+1} > n$.

Let $Z(a)$ denote the set of all $2n \times n$ rank n matrices X which have the following form: (1) Rows $j_1, j_2, \cdots, j_d, 3n - j_n + 1, 3n - j_{n-1} + 1, \cdots, 3n - j_{d+1} + 1$ form an $n \times n$ identity submatrix. (2) Let $J = \{j_1, j_2, \cdots, j_d, 3n - j_n + 1, 3n - j_{n-1} + 1, \cdots, 3n - j_{d+1} + 1\}$. If $j \notin J$ and $k \leqq d$, then x_{jk} is 0 if $j > j_k$ and is arbitrary otherwise. If $j \notin J$ and $k > d$, then x_{jk} is 0 if $n < j < 3n - j_{n+d-k+1} + 1$ and is arbitrary otherwise. Then the mapping $X \mapsto \operatorname{Sp} X$ maps $Z(a)$ isomorphically onto $U(a)$. Note that we are parametrizing the subspaces in $U(a)$ by associating each $S \in U(a)$ with the unique matrix X in "modified column echelon form" whose columns span S. By saying that X is in "modified column

echelon form," we mean that X would be in column echelon form if the order of rows $n+1, n+2, \cdots, 2n$ and of columns $d+1, d+2, \cdots, n$ were reversed. The reordering of the rows corresponds to the fact that the standard symplectic flag is derived from the ordered basis $\{e_1, e_2, \cdots, e_n, e_{2n}, e_{2n-1}, \cdots, e_{n+1}\}$ for $\mathbb{R}^{2n}$ rather than from the standard ordered basis for $\mathbb{R}^{2n}$.

Example 1. Let $n=5$, $a=(0\,1\,1\,0\,0\,1\,1\,0\,0\,1)$. Then $j_1=2, j_2=3, j_3=6, j_4=7, j_5=10$, and $d=2$. Then the matrices in $Z(a)$ are those which have the form

$$X=\left[\begin{array}{ccccc} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & x_{43} & x_{44} & x_{45} \\ 0 & 0 & x_{53} & x_{54} & x_{55} \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & x_{83} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{array}\right].$$

In this case, $U(a)$ is isomorphic to $\mathbb{R}^{13}$.

We wish to determine the structure of the intersection of $U(a)$ with the Lagrange-Grassmann manifold $\mathscr{L}(n)$.

LEMMA 6. *$U(a)\cap\mathscr{L}(n)$ is empty unless $a_i+a_{2n-i+1}=1$, $i=1,\cdots,n$.*

Proof. Let $S\in U(a)$ and let X be the unique matrix in $Z(a)$ such that $S=\operatorname{Sp} X$. Partition X as $\left[\begin{smallmatrix}\alpha\\ \beta\end{smallmatrix}\right]$ with α, β each $n\times n$. Suppose that the condition $a_i+a_{2n-i+1}=1$ does not hold for all i. Then there exists an integer j with $1\leqq j\leqq n$ such that $a_j=1$ and $a_{2n-j+1}=1$.

Now, S is Lagrangian iff $X'JX=0$, which is equivalent to the condition that $\alpha'\beta$ be symmetric. Since $a_j=1$, the jth row of α is one of the rows from the $n\times n$ identity submatrix in X. Consequently, there is some $k\leqq d$ such that $\alpha_{jk}=1$. It then follows from the structure of X that $\alpha_{ik}=0$ for all $i>j$. Since $a_{2n-j+1}=1$, the jth row of β is also one of the rows from the $n\times n$ identity submatrix in X. Hence, there is some $\nu>d$ such that $\beta_{j\nu}=1$. It follows from the structure of X that $\beta_{i\nu}=0$ for all $i<j$. This implies that the (k,ν)th entry of $\alpha'\beta$ is 1. On the other hand, the (ν,k)th entry of $\alpha'\beta$ is 0 since $k\leqq d$ and the first d columns of β are identically 0. Hence, $\alpha'\beta$ cannot be symmetric. Thus, $S\notin\mathscr{L}(n)$. □

We now assume that $a=(a_1,\cdots,a_{2n})$ satisfies the additional condition that $a_i+a_{2n-i+1}=1$, $i=1,\cdots,n$. Let $S\in U(a)$, and let X be the unique matrix in $Z(a)$ such that $S=\operatorname{Sp} X$. We will determine the equations which the N free parameters in X must satisfy in order for S to be Lagrangian. Note that if $P\in\operatorname{Sp}(n,\mathbb{R})$, then $S\in\mathscr{L}(n)$ iff $P(S)\in\mathscr{L}(n)$.

It is trivial to verify that if θ belongs to the orthogonal group $O(n)$ then the matrix

$$P_1=\left[\begin{array}{c|c} \theta & 0 \\ \hline 0 & \theta \end{array}\right]$$

is symplectic. In particular, P_1 is symplectic if θ is a permutation matrix. It is also trivial to verify that for any j such that $1\leqq j\leqq n$, the matrix P_2^j which is obtained from I by replacing row j with row $n+j$ and replacing row $n+j$ with $-(\text{row } j)$ is symplectic. We can choose $P_1\in\operatorname{Sp}(n,\mathbb{R})$ such that the first d rows of P_1X are the first d rows of

the $n \times n$ identity matrix. Since $a_i + a_{2n-i+1} = 1$, $i = 1, \cdots, n$, it follows that the jth row of X belongs to the identity submatrix of X iff the $(n+j)$th row of X does *not* belong. Since

$$P_1 = \left[\begin{array}{c|c} \theta & 0 \\ \hline 0 & \theta \end{array}\right]$$

with θ a permutation matrix, it follows that the identity submatrix of P_1X consists of rows $1, 2, \cdots, d$, $n+d+1$, $n+d+2, \cdots, 2n$. Let $\tilde{X}$ be the matrix $P_2^{d+1}P_2^{d+2} \cdots P_2^n P_1 X$. Then the first n rows of $\tilde{X}$ form an identity submatrix. Rows $n+1, \cdots, n+d$ of $\tilde{X}$ are the nontrivial rows from among rows $n+1, \cdots, 2n$ of X. Rows $n+d+1, \cdots, 2n$ of $\tilde{X}$ are the nontrivial rows from among rows $1, \cdots, n$ of X, each multiplied by -1. Write $\tilde{X}$ in partitioned form as $\tilde{X} = [\begin{smallmatrix} I \\ Y \end{smallmatrix}]$ with Y $n \times n$. Then S is Lagrangian iff Y is symmetric.

Example 2. Let X be the matrix in Example 1. Then

$$\tilde{X} = \left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & x_{83} & 0 & 0 \\ -x_{11} & -x_{12} & -x_{13} & -x_{14} & -x_{15} \\ 0 & 0 & -x_{43} & -x_{44} & -x_{45} \\ 0 & 0 & -x_{53} & -x_{54} & -x_{55} \end{array}\right].$$

We see that if $S = \operatorname{Sp} X$ with X given by Example 1, then $S \in \mathscr{L}(n)$ iff $x_{11} = -x_{73}$, $x_{12} = -x_{83}$, $x_{14} = x_{43}$, $x_{15} = x_{53}$, $x_{45} = x_{54}$. Thus, if $n = 5$ and $a = (0\,1\,1\,0\,0\,1\,1\,0\,0\,1)$, then $U(a) \cap \mathscr{L}(n)$ is isomorphic to $\mathbb{R}^8$.

The preceding example actually includes all of the features of the general case which we now consider. It is not hard to see from the structure of X that the zero entries of Y occur symmetrically with respect to the main diagonal. Also, the number of zero entries on the main diagonal is equal to d. The total number of zero entries in Y is $n^2 - \dim U(a) = n^2 - N$. Thus, the number of parameters in Y which are above the main diagonal is $\frac{1}{2}n(n-1) - \frac{1}{2}(n^2 - N - d) = \frac{1}{2}(N + d - n)$. This is the number of independent linear constraints imposed by the requirement that Y be symmetric. It follows that $U(a) \cap \mathscr{L}(n)$ is isomorphic to Euclidean space of dimension $N - \frac{1}{2}(N + d - n) = \frac{1}{2}(N + n - d)$. This proves the next lemma.

LEMMA 7. *Suppose that $a_i + a_{2n-i+1} = 1$, $i = 1, \cdots, n$. Then $U(a) \cap \mathscr{L}(n)$ is isomorphic to Euclidean space of dimension*

$$\frac{1}{2}\left[n - d + \sum_{j=1}^{2n} a_j \left(j - \sum_{i=1}^{j} a_i\right)\right].$$

Lemmas 6 and 7 show that the intersections of the $\binom{2n}{n}$ cells $U(a)$ with $\mathscr{L}(n)$ gives a partition of $\mathscr{L}(n)$ into 2^n disjoint subsets $\{U(a) \cap \mathscr{L}(n)\colon a_i + a_{2n-i+1} = 1, i = 1, \cdots, n\}$, with each subset isomorphic to Euclidean space of some dimension.

We are now in a position to describe the geometric structure of the stable and unstable manifolds for the ESRDE on $\mathscr{L}(n)$. Let $l = (l_1, \cdots, l_{2r})$ with $l_1, \cdots, l_{2r}$ nonnegative integers satisfying $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. (This condition implies

that $\sum_{i=1}^{2r} l_i = n$.) By Proposition 4, $T(l) \cap \mathscr{L}(n)$ is an invariant torus for the ESRDE on $\mathscr{L}(n)$ and $\dim T(l) \cap \mathscr{L}(n) = \frac{1}{2} \dim T(l)$. Let k denote the dimension of $T(l) \cap \mathscr{L}(n)$. Define the stable flag of subspaces $M_1 \subset M_2 \subset \cdots \subset M_{2r} = \mathbb{R}^{2n}$ by setting $M_j = \bigoplus_{i=1}^{j} E_i$, $j = 1, \cdots, 2r$. Define the unstable flag of subspaces $N_1 \subset N_2 \subset \cdots \subset N_{2r} = \mathbb{R}^{2n}$ by setting $N_j = \bigoplus_{i=1}^{j} E_{2r-i+1}$, $j = 1, \cdots, 2r$. As in the discussion preceding Theorem 4, we refine $\{M_j\}$ to a complete flag by inserting a subspace M_j' between M_{j-1} and M_j whenever $\dim E_j = 2$. Since $\dim T(l) = 2k$, the set $\{j\colon l_j = 1 \text{ and } \dim E_j = 2, j = 1, \cdots, 2r\}$ contains $2k$ elements, say $j_1, \cdots, j_{2k}$. Then $W^s(T(l))$ is the union of exactly 2^{2k} cells $U(a)$ which correspond to the complete flag. Each cell is given by fixing a vector $b = (b_1, \cdots, b_{2k})$ with $b_j = 0$ or 1, and setting $W^s(T(l), b) = \{S \in W^s(T(l))\colon \dim S \cap M_{j_\nu}' = \dim S \cap M_{j_\nu - 1} + b_\nu,\ \nu = 1, \cdots, 2k\}$. The analysis preceding Theorem 4 shows that the dimension of $W^s(T(l), b)$ is

$$\sum_{j=1}^{2r} l_j \left(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i \right) + 2k - \sum_{\nu=1}^{2k} b_\nu.$$

It follows from Lemma 5 that by making a symplectic change of coordinates in $\mathbb{R}^{2n}$, we can require that the complete flag be the standard symplectic flag $V_1 \subset \cdots \subset V_{2n}$ defined at the beginning of this subsection. Using the fact that $\dim E_j = \dim E_{2r-j+1}$ and our assumption that $l_j + l_{2r-j+1} = \dim E_j$, it follows that $j_{k+1} = 2r - j_k + 1$, $j_{k+2} = 2r - j_{k-1} + 1, \cdots, j_{2k} = 2r - j_1 + 1$. In the discussion preceding Theorem 4, it is shown that each choice of the vector b uniquely determines a vector $a = (a_1, \cdots, a_{2n})$ such that $W^s(T(l), b) = U(a)$. By Lemmas 6 and 7, it follows that $U(a) \cap \mathscr{L}(n)$ is nonempty iff $a_i + a_{2n-i+1} = 1$, $i = 1, \cdots, n$. Using the facts that $\dim E_j = \dim E_{2r-j+1}$ and $l_j + l_{2r-j+1} = \dim E_j$, it is easily seen from the procedure for determining a from l and b that $a_i + a_{2n-i+1} = 1$, $i = 1, \cdots, n$ iff $b_{2k-\nu+1} = b_\nu$, $\nu = 1, \cdots, k$. Thus, $W^s(T(l), b) \cap \mathscr{L}(n)$ is nonempty iff $b_{2k-\nu+1} = b_\nu$, $\nu = 1, \cdots, k$. Hence, exactly 2^k of the 2^{2k} cells in $W^s(T(l))$ intersect $\mathscr{L}(n)$.

Suppose that $b_{2k-\nu+1} = b_\nu$, $\nu = 1, \cdots, k$, so that $W^s(T(l), b) \cap \mathscr{L}(n)$ is nonempty. Using the fact that $\sum_{i=1}^{n} a_i = \sum_{j=1}^{r} l_j$, it follows from Lemma 7 that $W^s(T(l), b) \cap \mathscr{L}(n)$ is isomorphic to Euclidean space of dimension $\frac{1}{2}(N + n - d)$, where N is the dimension of $W^s(T(l), b)$ and $d = \sum_{j=1}^{r} l_j$. Using the assumption that $b_{2k-\nu+1} = b_\nu$, $\nu = 1, \cdots, k$, the dimension is given by the formula

$$\frac{1}{2}\left\{ n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j \left(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i \right) \right\} + k - \sum_{\nu=1}^{k} b_\nu.$$

This proves part (a) of the next theorem. The proof of part (b) is completely analogous.

THEOREM 13. *Suppose that $T(l) \cap \mathscr{L}(n)$ is a k-dimensional invariant torus. Then*

(a) *The stable manifold $W^s(T(l)) \cap \mathscr{L}(n)$ is the disjoint union of 2^k cells. Exactly $\binom{k}{\nu}$ of these cells have dimension*

$$\frac{1}{2}\left\{ n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j \left(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i \right) \right\} + \nu, \qquad \nu = 0, \cdots, k.$$

(b) *The unstable manifold $W^u(T(l)) \cap \mathscr{L}(n)$ is the disjoint union of 2^k cells. Exactly $\binom{k}{\nu}$ of these cells have dimension*

$$\frac{1}{2}\left\{ n - \sum_{j=1}^{r} l_{2r-j+1} + \sum_{j=1}^{2r} l_{2r-j+1} \left(\dim N_{j-1} - \sum_{i=1}^{j-1} l_{2r-i+1} \right) \right\} + \nu,$$

$\nu = 0, \cdots, k$.

Suppose that $T(l) \cap \mathscr{L}(n)$ is a k-dimensional invariant torus, and let $S_1 \in T(l) \cap \mathscr{L}(n)$. Recall from § 3.1 that $W^s(S_1) = \Pi_+^{-1}(S_1) = \{S_0 \in G^n(\mathbb{R}^{2n})\colon e^{Ht}(S_0) \to$

$e^{Ht}(S_1)$ as $t\to\infty\}$, and $W^u(S_1)=\Pi_-^{-1}(S_1)=\{S_0\in G^n(\mathbb{R}^{2n})\colon e^{Ht}(S_0)\to e^{Ht}(S_1)$ as $t\to-\infty\}$. By Theorem 5, $W^s(S_1)$ and $W^u(S_1)$ are isomorphic to Euclidean space of dimensions $\sum_{j=1}^{2r} l_j(\dim M_{j-1}-\sum_{i=1}^{j-1} l_i)$ and $\sum_{j=1}^{2r} l_{2r-j+1}(\dim N_{j-1}-\sum_{i=1}^{j-1} l_{2r-i+1})$ respectively. The next result describes the topology of the sets $W^s(S_1)\cap\mathscr{L}(n)=\{S_0\in\mathscr{L}(n)\colon e^{Ht}(S_0)\to e^{Ht}(S_1)$ as $t\to\infty\}$ and $W^u(S_1)\cap\mathscr{L}(n)=\{S_0\in\mathscr{L}(n)\colon e^{Ht}(S_0)\to e^{Ht}(S_1)$ as $t\to-\infty\}$.

THEOREM 14. *Let $T(l)\cap\mathscr{L}(n)$ be a k-dimensional invariant torus, and let $S_1\in T(l)\cap\mathscr{L}(n)$. Then*

(a) *$W^s(S_1)\cap\mathscr{L}(n)$ is analytically isomorphic to Euclidean space of dimension $\frac{1}{2}\{n-\sum_{j=1}^{r} l_j+\sum_{j=1}^{2r} l_j(\dim M_{j-1}-\sum_{i=1}^{j-1} l_i)\}$.*

(b) *$W^u(S_1)\cap\mathscr{L}(n)$ is analytically isomorphic to Euclidean space of dimension $\frac{1}{2}\{n-\sum_{j=1}^{r} l_{2r-j+1}+\sum_{j=1}^{2r} l_{2r-j+1}(\dim N_{j-1}-\sum_{i=1}^{j-1} l_{2r-i+1})\}$.*

Proof. From Lemma 5, it follows that by making a symplectic change of coordinates in $\mathbb{R}^{2n}$ if necessary, we may assume that H has the form $\left[\begin{smallmatrix} D & 0 \\ 0 & -D \end{smallmatrix}\right]$ with D as described in the statement of that lemma. This means that the standard symplectic flag $V_1\subset\cdots\subset V_{2n}$ refines the stable flag $M_1\subset\cdots\subset M_{2r}$. It follows that the cell decomposition of $G^n(\mathbb{R}^{2n})$ determined by the standard symplectic flag decomposes $W^s(T(l))$ into a union of 2^{2k} cells $\{W^s(T(l), b)\}$.

Let $m_i=\dim M_i$ for $i=0,1,\cdots,2r$. (So $m_0=0$.) It is not hard to see that by making an additional symplectic change of coordinates given by a matrix of the form $\theta=\operatorname{diag}\{\theta_1,\cdots,\theta_r,\theta_1,\cdots,\theta_r\}$ where θ_i is a special orthogonal matrix of size equal to $\dim E_i$, we may also assume that S_1 is spanned by $\{e_{m_{i-1}+j}\colon 1\leqq i\leqq r$ such that $l_i\neq 0$; $j=1,\cdots,l_i\}\cup\{e_{3n-m_{i-1}+1-j}\colon r+1\leqq i\leqq 2r$ such that $l_i\neq 0$; $j=1,\cdots,l_i\}$. (Note that θ commutes with H, so H is unaffected by the additional change of coordinates.) It then follows that the standard symplectic flag can be obtained by using S_1 to refine the stable flag by the procedure described in the proof of Theorem 5. This implies that $W^s(S_1)=W^s(T(l), b)$ for the choice $b=(1,\cdots,1)$. By the proof of Theorem 13, $W^s(T(l), b)\cap\mathscr{L}(n)$ is isomorphic to Euclidean space of dimension $\frac{1}{2}\{n-\sum_{j=1}^{r} l_j+\sum_{j=1}^{2r} l_j(\dim M_{j-1}-\sum_{i=1}^{j-1} l_i)\}$, which completes the proof of (a).

The proof of (b) is completely analogous to the proof of (a). □

Theorem 6 shows that the ERDE has either an equilibrium point or a periodic orbit whose stable manifold is open and dense. The next result shows that the ESRDE always has an equilibrium point whose stable manifold is open and dense in the Lagrange-Grassmann manifold.

THEOREM 15. *The* ESRDE *has an equilibrium point whose stable manifold is open and dense in $\mathscr{L}(n)$, and an equilibrium point whose unstable manifold is open and dense in $\mathscr{L}(n)$.*

Proof. Let $l=(l_1,\cdots,l_{2r})$ with $l_j=0, j=1,\cdots,r$ and $l_j=\dim E_j, j=r+1,\cdots,2r$. Then $T(l)\cap\mathscr{L}(n)$ is a 0-dimensional invariant torus, and hence an equilibrium point. By an argument similar to that used in the proof of Theorem 6, $S\in W^s(T(l))$ iff $S\cap M_r=0$. (Recall that M_r is the n-dimensional subspace $E_1\oplus\cdots\oplus E_r$.) Thus, $W^s(T(l))\cap\mathscr{L}(n)=\{S\in\mathscr{L}(n)\colon S\cap M_r=0\}$, which is open and dense in $\mathscr{L}(n)$.

To obtain an equilibrium point whose region of attraction in backward time is open and dense in $\mathscr{L}(n)$, redefine l to be $(l_1,\cdots,l_{2r})$ with $l_j=\dim E_j, j=1,\cdots,r$ and $l_j=0, j=r+1,\cdots,2r$. Then $T(l)\cap\mathscr{L}(n)$ is an equilibrium point. (Recall that N_r is the n-dimensional subspace $E_{r+1}\oplus\cdots\oplus E_{2r}$.) Then $W^u(T(l))\cap\mathscr{L}(n)=\{S\in\mathscr{L}(n)\colon S\cap N_r=0\}$, which is open and dense in $\mathscr{L}(n)$. □

If $T(l)\cap\mathscr{L}(n)$ is a k-dimensional invariant torus, Theorem 13 describes the stable manifold $W^s(T(l))\cap\mathscr{L}(n)$ as the union of 2^k cells. We will now show that $W^s(T(l))\cap\mathscr{L}(n)$ is an embedded submanifold of $\mathscr{L}(n)$ and is a bundle over the torus $T(l)\cap\mathscr{L}(n)$. Rather than introducing additional and cumbersome notation, we analyze a concrete

example which illustrates all of the features of the general case. In fact, the proof of the general results follows step-by-step the analysis of the example.

Let $n=5$. $\mathscr{L}(5)$ is a 15-dimensional submanifold of $G^5(\mathbb{R}^{10})$, which is itself 25-dimensional. Let $r=3$, and suppose that $\dim E_1=2$, $\dim E_2=1$, $\dim E_3=2$, $\dim E_4=2$, $\dim E_5=1$, $\dim E_6=2$. By Lemma 5, there is no loss of generality in assuming that $E_1=\mathrm{Sp}\{e_1, e_2\}$, $E_2=\mathrm{Sp}\{e_3\}$, $E_3=\mathrm{Sp}\{e_4, e_5\}$, $E_6=\mathrm{Sp}\{e_6, e_7\}$, $E_5=\mathrm{Sp}\{e_8\}$, $E_4=\mathrm{Sp}\{e_9, e_{10}\}$, where $\{e_1, \cdots, e_{2n}\}$ is the standard basis for $\mathbb{R}^{2n}$.

Let $l=(1,0,1,1,1,1)$. Then $T(l)\cap\mathscr{L}(5)$ is a 2-dimensional invariant torus. By Theorem 13, $W^s(T(l))\cap\mathscr{L}(5)$ is the union of 4 cells of dimensions 8, 9, 9, 10. Refine the flag $M_1\subset M_2\subset M_3\subset M_4\subset M_5\subset M_6$ to the standard symplectic flag $V_1\subset\cdots\subset V_{10}$. Relative to this complete flag, $W^s(T(l))\cap\mathscr{L}(5)$ is the union of the 4 cells defined by

$$
\begin{aligned}
U_1=\{S\in\mathscr{L}(5)&: \dim S\cap V_1=1, \dim S\cap V_2=1, \dim S\cap V_3=1,\\
&\dim S\cap V_4=2, \dim S\cap V_5=2, \dim S\cap V_6=3,\\
&\dim S\cap V_7=3, \dim S\cap V_8=4, \dim S\cap V_9=5, \dim S\cap V_{10}=5\},\\
U_2=\{S\in\mathscr{L}(5)&: \dim S\cap V_1=1, \dim S\cap V_2=1, \dim S\cap V_3=1,\\
&\dim S\cap V_4=1, \dim S\cap V_5=2, \dim S\cap V_6=2,\\
&\dim S\cap V_7=3, \dim S\cap V_8=4, \dim S\cap V_9=5, \dim S\cap V_{10}=5\},\\
U_3=\{S\in\mathscr{L}(5)&: \dim S\cap V_1=0, \dim S\cap V_2=1, \dim S\cap V_3=1,\\
&\dim S\cap V_4=2, \dim S\cap V_5=2, \dim S\cap V_6=3,\\
&\dim S\cap V_7=3, \dim S\cap V_8=4, \dim S\cap V_9=4, \dim S\cap V_{10}=5\},\\
U_4=\{S\in\mathscr{L}(5)&: \dim S\cap V_1=0, \dim S\cap V_2=1, \dim S\cap V_3=1,\\
&\dim S\cap V_4=1, \dim S\cap V_5=2, \dim S\cap V_6=2,\\
&\dim S\cap V_7=3, \dim S\cap V_8=4, \dim S\cap V_9=4, \dim S\cap V_{10}=5\}.
\end{aligned}
$$

These cells are isomorphic to $\mathbb{R}^8$, $\mathbb{R}^9$, $\mathbb{R}^9$, $\mathbb{R}^{10}$ respectively. To parametrize each cell, we first parametrize the corresponding cell for $G^5(\mathbb{R}^{10})$ as in Example 1. Then we impose the linear constraints which must be satisfied in order for the subspaces to belong to $\mathscr{L}(5)$. The linear constraints are determined as in Example 2. We obtain

$$
\mathrm{Sp}\begin{bmatrix}
1 & 0 & 0 & 0 & 0\\
0 & -x_{93} & x_{23} & x_{24} & x_{25}\\
0 & -x_{94} & x_{24} & x_{34} & x_{35}\\
0 & 1 & 0 & 0 & 0\\
0 & 0 & x_{25} & x_{35} & x_{55}\\

\end{bmatrix}
\qquad U_2
$$

$$\mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & -x_{93} & x_{13} & x_{14} & x_{15} \\ 1 & 0 & 0 & 0 & 0 \\ 0 & -x_{94} & x_{14} & x_{34} & x_{35} \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & x_{15} & x_{35} & x_{55} \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_{93} & x_{94} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{array}\right], \qquad \mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & -x_{103} & x_{13} & x_{14} & x_{15} \\ 1 & 0 & 0 & 0 & 0 \\ 0 & -x_{104} & x_{14} & x_{34} & x_{35} \\ 0 & -x_{105} & x_{15} & x_{35} & x_{45} \\ 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & x_{103} & x_{104} & x_{105} \end{array}\right].$$

U_3 U_4

These 4 cells can be modified in an obvious way to obtain 4 charts W_1, W_2, W_3, W_4 which cover $W^s(T(l)) \cap \mathscr{L}(5)$. They are given by

$$\mathrm{Sp}\left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ -x_{63} & -x_{93} & x_{23} & x_{24} & x_{25} \\ 0 & -x_{94} & x_{24} & x_{34} & x_{35} \\ 0 & 1 & 0 & 0 & 0 \\ 0 & -x_{95} & x_{25} & x_{35} & x_{55} \\ \hline 0 & 0 & x_{63} & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_{93} & x_{94} & x_{95} \\ 0 & 0 & 0 & 0 & 1 \end{array}\right], \qquad \mathrm{Sp}\left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ -x_{63} & -x_{103} & x_{23} & x_{24} & x_{25} \\ 0 & -x_{104} & x_{24} & x_{34} & x_{35} \\ 0 & -x_{105} & x_{25} & x_{35} & x_{45} \\ 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & x_{63} & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & x_{103} & x_{104} & x_{105} \end{array}\right],$$

W_1 W_2

$$\mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & -x_{93} & x_{13} & x_{14} & x_{15} \\ 1 & 0 & 0 & 0 & 0 \\ 0 & -x_{94} & x_{14} & x_{34} & x_{35} \\ 0 & 1 & 0 & 0 & 0 \\ 0 & -x_{95} & x_{15} & x_{35} & x_{55} \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & x_{93} & x_{94} & x_{95} \\ 0 & 0 & 0 & 0 & 1 \end{array}\right], \qquad \mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & -x_{103} & x_{13} & x_{14} & x_{15} \\ 1 & 0 & 0 & 0 & 0 \\ 0 & -x_{104} & x_{14} & x_{34} & x_{35} \\ 0 & -x_{105} & x_{15} & x_{35} & x_{45} \\ 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & x_{103} & x_{104} & x_{105} \end{array}\right].$$

W_3 W_4

Each of these charts is a submanifold chart relative to one of the standard charts for $\mathscr{L}(5)$. (The standard charts for the Lagrange-Grassmann manifold are described in the appendix.) Thus, $W^s(T(l)) \cap \mathscr{L}(5)$ is an embedded submanifold of $\mathscr{L}(5)$.

$T(l) \cap \mathscr{L}(5)$ is itself covered by 4 submanifold charts $\bar{W}_1$, $\bar{W}_2$, $\bar{W}_3$, $\bar{W}_4$ given by

$$\mathrm{Sp}\left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ -x_{63} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & -x_{95} & 0 & 0 & 0 \\ \hline 0 & 0 & x_{63} & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & x_{95} \\ 0 & 0 & 0 & 0 & 1 \end{array}\right], \quad \bar{W}_1$$

$$\mathrm{Sp}\left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ -x_{63} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & -x_{105} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & x_{63} & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & x_{105} \end{array}\right], \quad \bar{W}_2$$

$$\mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & -x_{95} & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & x_{95} \\ 0 & 0 & 0 & 0 & 1 \end{array}\right], \quad \bar{W}_3$$

$$\mathrm{Sp}\left[\begin{array}{ccccc} -x_{73} & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & -x_{105} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & x_{73} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & x_{105} \end{array}\right], \quad \bar{W}_4$$

Let Ω denote the nonwandering set of the ESRDE on $G^n(\mathbb{R}^{2n})$. Then $\Omega \cap \mathscr{L}(n)$ is the nonwandering set of the ESRDE on $\mathscr{L}(n)$. We have the mappings $\Pi_+ : G^n(\mathbb{R}^{2n}) \to \Omega$ and $\Pi_- : G^n(\mathbb{R}^{2n}) \to \Omega$ defined earlier. Let $\hat{\Pi}_+$ and $\hat{\Pi}_-$ denote the restrictions to $\mathscr{L}(n)$ of Π_+ and Π_- respectively. $\hat{\Pi}_+$ maps $W^s(T(l)) \cap \mathscr{L}(n)$ onto $T(l) \cap \mathscr{L}(n)$. We will also use $\hat{\Pi}_+$ to denote its restriction to $W^s(T(l)) \cap \mathscr{L}(n)$. If $S_1 \in T(l) \cap \mathscr{L}(n)$, then $\hat{\Pi}_+^{-1}(S_1) = W^s(S_1) \cap \mathscr{L}(n)$. Thus, the fiber $\hat{\Pi}_+^{-1}(S_1)$ is isomorphic to Euclidean space of dimension $\frac{1}{2}\{n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)\}$, which in this example is equal to 8. It is clear that $\hat{\Pi}_+^{-1}(\bar{W}_i) = W_i$, $i = 1, 2, 3, 4$. Furthermore, there is an obvious isomorphism $\gamma_i : W_i \to \bar{W}_i \times \mathbb{R}^8$ with the property that if $p_i : \bar{W}_i \times \mathbb{R}^8 \to \bar{W}_i$ is the natural projection, then $p_i \circ \gamma_i$ is the restriction of $\hat{\Pi}_+$ to W_i.

The analysis of the example can be applied essentially unchanged (but at the expense of introducing some rather cumbersome notation) to describe the structure of $W^s(T(l)) \cap \mathscr{L}(n)$ for an arbitrary invariant torus $T(l) \cap \mathscr{L}(n)$. If k is the dimension of $T(l) \cap \mathscr{L}(n)$, then by Theorem 13, $W^s(T(l)) \cap \mathscr{L}(n)$ is the union of 2^k cells, the largest of which has dimension $\frac{1}{2}\{n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)\} + k$. From these cells we obtain 2^k submanifold charts for $W^s(T(l)) \cap \mathscr{L}(n)$. Thus, $W^s(T(l)) \cap \mathscr{L}(n)$ is an embedded submanifold of $\mathscr{L}(n)$ of dimension $\frac{1}{2}\{n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)\} + k$. We have the projection $\hat{\Pi}_+ : W^s(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$. If $S_1 \in T(l) \cap \mathscr{L}(n)$, then $\hat{\Pi}_+^{-1}(S_1) = W^s(S_1) \cap \mathscr{L}(n)$ which is isomorphic to Euclidean space of dimension $d_s = \frac{1}{2}\{n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)\}$. Each chart W_i $(i = 1, \cdots, 2^k)$ for $W^s(T(l)) \cap \mathscr{L}(n)$ is the inverse image of a chart $\bar{W}_i$ for

$T(l) \cap \mathscr{L}(n)$. Also, there exist isomorphisms $\gamma_i: W_i \to \bar{W}_i \times \mathbb{R}^{d_s}$ such that $p_i \circ \gamma_i = \hat{\Pi}_+ | W_i$. Hence, $\hat{\Pi}_+: W^s(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$ is a locally trivial bundle with $\mathbb{R}^{d_s}$ as fiber. The transition functions for this bundle are invertible polynomial mappings of $\mathbb{R}^{d_s}$.

The next theorem summarizes these conclusions as well as the corresponding results for the unstable manifolds.

THEOREM 16. *Let $T(l) \cap \mathscr{L}(n)$ be a k-dimensional invariant torus. Then*

(a) *$W^s(T(l)) \cap \mathscr{L}(n)$ is an embedded submanifold of $\mathscr{L}(n)$ of dimension $k + d_s$, where $d_s = \frac{1}{2}\{n - \sum_{j=1}^{r} l_j + \sum_{j=1}^{2r} l_j(\dim M_{j-1} - \sum_{i=1}^{j-1} l_i)\}$.*

(b) *$\hat{\Pi}_+: W^s(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$ is a locally trivial bundle with fiber R^{d_s} and polynomial transition functions.*

(c) *$W^u(T(l)) \cap \mathscr{L}(n)$ is an embedded submanifold of $\mathscr{L}(n)$ of dimension $k + d_u$, where $d_u = \frac{1}{2}\{n - \sum_{j=1}^{r} l_{2r-j+1} + \sum_{j=1}^{2r} l_{2r-j+1}(\dim N_{j-1} - \sum_{i=1}^{j-1} l_{2r-i+1})\}$.*

(d) *$\hat{\Pi}_-: W^u(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$ is a locally trivial bundle with fiber $\mathbb{R}^{d_u}$ and polynomial transition functions.*

4.3. Morse theory and structural stability. Next we determine exactly when the ESRDE is a Morse-Smale vector field on $\mathscr{L}(n)$. We start with a lemma. Let $V_1 \subset \cdots \subset V_{2n}$ be the standard symplectic flag defined at the beginning of § 4.2. Define a second complete flag $W_1 \subset \cdots \subset W_{2n}$ with $W_j = \{e_{n+1}, e_{n+2}, \cdots, e_{n+j}\}$ for $j \leqq n$ and $W_j = \{e_{n+1}, e_{n+2}, \cdots, e_{2n}, e_n, e_{n-1}, \cdots, e_{2n-j+1}\}$ for $j > n$. Let $\alpha = (\alpha_1, \cdots, \alpha_{2n})$ and $\beta = (\beta_1, \cdots, \beta_{2n})$ be such that $\alpha_i = 0$ or 1, $\beta_i = 0$ or 1, $\alpha_i + \alpha_{2n-i+1} = 1$, $\beta_i + \beta_{2n-i+1} = 1$, $i = 1, \cdots, n$. It follows trivially that $\sum_{i=1}^{2n} \alpha_i = n = \sum_{i=1}^{2n} \beta_i$. Define $X(\alpha) = \{S \in G^n(\mathbb{R}^{2n})$: $\dim S \cap V_j = \sum_{i=1}^{j} \alpha_i, j = 1, \cdots, 2n\}$ and $Y(\beta) = \{S \in G^n(\mathbb{R}^{2n})$: $\dim S \cap W_j = \sum_{i=1}^{j} \beta_{2n-i+1}, j = 1, \cdots, 2n\}$.

LEMMA 8. *$X(\alpha) \cap \mathscr{L}(n)$ and $Y(\beta) \cap \mathscr{L}(n)$ intersect transversally as submanifolds of $\mathscr{L}(n)$.*

Proof. If $X(\alpha) \cap \mathscr{L}(n)$ and $Y(\beta) \cap \mathscr{L}(n)$ are disjoint, then the assertion holds trivially. So we may assume that $X(\alpha) \cap \mathscr{L}(n)$ and $Y(\beta) \cap \mathscr{L}(n)$ have nonempty intersection. Since $X(\alpha) \cap Y(\beta)$ is nonempty, it follows from Lemma 1 that $\sum_{i=1}^{j} \alpha_i \leqq \sum_{i=1}^{j} \beta_i, j = 1, \cdots, 2n$. Let $j_1 < \cdots < j_n$ be the elements of $\{j: \alpha_j = 1\}$, and let $l_1 < \cdots < l_n$ be the elements of $\{l: \beta_l = 1\}$. Since $\sum_{i=1}^{j} \alpha_i \leqq \sum_{i=1}^{j} \beta_i$ for all j, it follows that $l_p \leqq j_p$, $p = 1, \cdots, n$.

Let $S_0 \in (X(\alpha) \cap \mathscr{L}(n)) \cap (Y(\beta) \cap \mathscr{L}(n))$. We must show that $T_{S_0}(X(\alpha) \cap \mathscr{L}(n)) + T_{S_0}(Y(\beta) \cap \mathscr{L}(n)) = T_{S_0}(\mathscr{L}(n))$. The proof of this requires only slight modification of the proof of part (b) of Lemma 1. To each subspace S belonging to the cell $X(\alpha) \cap \mathscr{L}(n)$ is a $2n \times n$ matrix Z such that $\operatorname{Sp} Z = S$. If $j_d \leqq n$ and $j_{d+1} > n$ (i.e. $\sum_{i=1}^{n} \alpha_i = d$), then rows $j_1, j_2, \cdots, j_d, 3n - j_n + 1, 3n - j_{n-1} + 1, \cdots, 3n - j_{d+1} + 1$ form an $n \times n$ identity submatrix. (See e.g. the parametrization of the cells U_1, U_2, U_3, U_4 in the discussion prior to Theorem 16.) There is also a standard chart for $\mathscr{L}(n)$ whose elements are described by $2n \times n$ matrices with an identity submatrix in these same n rows. (The standard charts for $\mathscr{L}(n)$ are described in the appendix.) Let v be an arbitrary tangent vector to $\mathscr{L}(n)$ at S_0. Then there is a curve $S(t)$ in $\mathscr{L}(n)$ with $S(0) = S_0$ such that $d/dt|_{t=0} S(t) = v$. Furthermore, we can choose $S(t)$ so that it corresponds to a straight line in local coordinates. Analogous to the procedure used in the proof of Lemma 1, we construct curves $S_1(t)$ and $S_2(t)$ in $\mathscr{L}(n)$ with $S_1(0) = S_2(0) = S_0$ and such that $\dot{S}_1(0) + \dot{S}_2(0) = \dot{S}(0) = v$. By construction, it is clear that $S_1(t) \in X(\alpha) \cap \mathscr{L}(n)$ for all t. Thus, $\dot{S}_1(0) \in T_{S_0}(X(\alpha) \cap \mathscr{L}(n))$.

It remains only to show that $S_2(t) \in Y(\beta) \cap \mathscr{L}(n)$ for all t. Since $S_0 \in Y(\beta)$, it suffices to show that $\dim S_2(t) \cap W_j = \dim S_0 \cap W_j, j = 1, \cdots, 2n$. Let $Z_2(t)$ be the $2n \times n$ full rank matrix which corresponds to $S_2(t)$ via the chart described above. For each

$q \in \{1, \cdots, n\}$, let $Z_2^q(t)$ denote the submatrix of $Z_2(t)$ consisting of its first q rows. For each $q \in \{n+1, \cdots, 2n\}$, let $Z_2^q(t)$ denote the submatrix of $Z_2(t)$ consisting of the first n rows of $Z_2(t)$ together with the last $q-n$ rows of $Z_2(t)$. Now, $Z_2(t)$ maps $\mathbb{R}^n$ isomorphically onto $S_2(t)$. Furthermore, $Z_2(t)$ maps $\ker Z_2^q(t)$ onto $S_2(t) \cap W_{2n-q}$. It follows that $\dim S_2(t) \cap W_{2n-q} = \dim S_2(0) \cap W_{2n-q}$ iff $\operatorname{rank} Z_2^q(t) = \operatorname{rank} Z_2^q(0)$. It follows easily from the structure of $Z_2(t)$ that row operations can be used to transform $Z_2(t)$ to $Z_2(0)$. Furthermore, the row operations are such that row operations applied to the submatrix $Z_2^q(t)$ involve only rows in the submatrix. Thus, $\operatorname{rank} Z_2^q(t) = \operatorname{rank} Z_2^q(0)$ for each q. We conclude that $\dim S_2(t) \cap W_j = \dim S_0 \cap W_j$, $j = 1, \cdots, 2n$ which completes the proof. □

Using Lemma 8, we can show that stable and unstable manifolds for the ESRDE always intersect transversally.

PROPOSITION 5. *Let $T(l) \cap \mathscr{L}(n)$ and $T(l') \cap \mathscr{L}(n)$ be invariant tori for the* ESRDE *on $\mathscr{L}(n)$. Then $W^s(T(l)) \cap \mathscr{L}(n)$ and $W^u(T(l')) \cap \mathscr{L}(n)$ intersect transversally.*

Proof. By making a symplectic change of coordinates, if necessary, we may assume that H has the form $\left[\begin{smallmatrix} D & 0 \\ 0 & -D' \end{smallmatrix}\right]$ with D as described in the statement of Lemma 5. Then the complete flags $\{V_j\}_1^{2n}$ and $\{W_j\}_1^{2n}$ defined prior to Lemma 8 refine the stable and unstable flags $\{M_j\}_1^{2r}$ and $\{N_j\}_1^{2r}$ respectively. By Theorem 13, $W^s(T(l)) \cap \mathscr{L}(n)$ and $W^u(T(l')) \cap \mathscr{L}(n)$ are each disjoint unions of finitely many cells corresponding respectively to the complete flags $\{V_j\}_1^{2n}$ and $\{W_j\}_1^{2n}$. In the notation of Lemma 8, each cell for $W^s(T(l)) \cap \mathscr{L}(n)$ is of the form $X(\alpha) \cap \mathscr{L}(n)$ for some α, while each cell for $W^u(T(l')) \cap \mathscr{L}(n)$ is of the form $Y(\beta) \cap \mathscr{L}(n)$ for some β. By Lemma 8, $X(\alpha) \cap \mathscr{L}(n)$ and $Y(\beta) \cap \mathscr{L}(n)$ intersect transversally. Since $X(\alpha) \cap \mathscr{L}(n)$ and $Y(\beta) \cap \mathscr{L}(n)$ are embedded submanifolds of $W^s(T(l)) \cap \mathscr{L}(n)$ and $W^u(T(l')) \cap \mathscr{L}(n)$ respectively, it follows immediately that $W^s(T(l)) \cap \mathscr{L}(n)$ and $W^u(T(l')) \cap \mathscr{L}(n)$ intersect transversally. □

From Proposition 2, we know that if the ESRDE is considered as a differential equation on $G^n(\mathbb{R}^{2n})$, then every equilibrium point is hyperbolic. Since every equilibrium point of the ESRDE on $\mathscr{L}(n)$ is also an equilibrium point of the ESRDE on $G^n(\mathbb{R}^{2n})$, we have.

PROPOSITION 6. *Every equilibrium point of the* ESRDE *on $\mathscr{L}(n)$ is hyperbolic.*

In a recent paper [19], Hermann and Martin have discussed the Poincaré map associated with a 1-dimensional invariant torus (i.e. a periodic orbit) for the ESRDE on $\mathscr{L}(n)$. However, there is an error in the analysis which results in an incorrect conclusion regarding the eigenvalues of the derivative of the Poincaré map.

Let $T(l) \cap \mathscr{L}(n)$ be a 1-dimensional invariant torus. It follows from Proposition 4 that each element of $T(l) \cap \mathscr{L}(n)$ is of the form $E_{j_1} \oplus \cdots \oplus E_{j_{r-1}} \oplus \tilde{S} \oplus ([J(\tilde{S})]^{\perp} \cap E_{2r-j_0+1})$ where $j \in \{j_1, \cdots, j_{r-1}\}$ iff $2r-j+1 \notin \{j_1, \cdots, j_{r-1}\}$, j_0 and $2r-j_0+1$ do not belong to $\{j_1, \cdots, j_{r-1}\}$, $\dim E_{j_0} = 2$, and $\tilde{S}$ is any 1-dimensional subspace of E_{j_0}. Let $\lambda_1 = a + ib$ denote one of the pair of complex conjugate eigenvalues of $H|E_{j_0}$ chosen so that $b > 0$. Let $\lambda_2 = -a + ib$, and let $\tau = \pi/b$. Let $\lambda_3, \cdots, \lambda_n$ denote the eigenvalues of $H|E_{j_1} \oplus \cdots \oplus E_{j_{r-1}}$. The proof of Lemma 5 is easily modified to show that by making a symplectic change of basis, we may assume that $E_{j_0} = \operatorname{Sp}\{e_1, e_{n+2}\}$, $E_{2r-j_0+1} = \operatorname{Sp}\{e_2, e_{n+1}\}$, $E_{j_1} \oplus \cdots \oplus E_{j_r} = \operatorname{Sp}\{e_3, \cdots, e_n\}$, and $E_{2r-j_1+1} \oplus \cdots \oplus E_{2r-j_r+1} = \operatorname{Sp}\{e_{n+3}, \cdots, e_{2n}\}$. We may also assume that

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}$$

where $H_{11} = \operatorname{diag}\{a, -a, D_1\}$ with D_1 $(n-2) \times (n-2)$, H_{12} is 0 except for its $(1, 2)$ and

(2, 1) entries which are equal to b, $H_{21} = -H_{12}$, and $H_{22} = -H_{11}'$. Let

$$e^{Ht} = \begin{bmatrix} C_{11}(t) & C_{12}(t) \\ C_{21}(t) & C_{22}(t) \end{bmatrix}.$$

Then $C_{11}(t) = \operatorname{diag}\{e^{at}\cos bt, e^{-at}\cos bt, e^{D_1't}\}$, $C_{12}(t)$ is 0 except for its (1, 2) and (2, 1) entries which are $e^{at}\sin bt$ and $e^{-at}\sin bt$ respectively, $C_{21}(t) = -C_{12}'(t)$, and $C_{22}(t) = \operatorname{diag}\{e^{-at}\cos bt, e^{at}\cos bt, e^{-D_1't}\}$.

We construct a Poincaré map at the point $S_0 = \operatorname{Sp}\{e_1, \cdots, e_n\} \in T(l) \cap \mathscr{L}(n)$. S_0 corresponds to the origin in the chart $Y \to \operatorname{Sp}\begin{bmatrix} I \\ Y \end{bmatrix}$ for $\mathscr{L}(n)$, where $Y \in S(n)$. Let W denote this chart. The τ-periodic solution $e^{Ht}(S_0)$ is contained in this chart except for those values of t for which $\cos bt = 0$. The expression for $e^{Ht}(S_0)$ in the local coordinates of this chart is $\tilde{Y}(t)$ where the $n \times n$ symmetric matrix $\tilde{Y}(t)$ is 0 except for its (1, 2) and (2, 1) entries, which are $-\tan bt$.

Let U denote the subset of W consisting of the subspaces of the form $\operatorname{Sp}\begin{bmatrix} I \\ Y \end{bmatrix}$ where $y_{12} = y_{21} = 0$. Then U is a codimension 1 submanifold of W which intersects the periodic orbit transversally at S_0. Let $S_1 = \operatorname{Sp}\begin{bmatrix} I \\ Y \end{bmatrix} \in U$. $e^{Ht}(S_1) \in W$ iff $C_{11}(t) + C_{12}(t)Y$ is nonsingular, which is equivalent to $\cos^2 bt - y_{11}y_{22}\sin^2 bt$ being nonzero. If this is the case, then

$$e^{Ht}(S_1) = \operatorname{Sp}\begin{bmatrix} I \\ (C_{21}(t) + C_{22}(t)Y)(C_{11}(t) + C_{12}(t)Y)^{-1} \end{bmatrix}.$$

Then $e^{Ht}(S_1) \in U$ if the (1, 2) and (2, 1) entries of $(C_{21}(t) + C_{22}(t)Y)(C_{11}(t) + C_{12}(t)Y)^{-1}$ are 0. This is equivalent to having $\cos bt \sin bt(1 + y_{11}y_{22}) = 0$. It follows that if $t = \tau$, $e^{H\tau}(S_1) \in U$. Thus, the restriction of $e^{H\tau}$ to the submanifold U is a Poincaré map for the periodic orbit $T(l) \cap \mathscr{L}(n)$. Since $C_{12}(\tau) = C_{21}(\tau) = 0$, the Poincaré map is given in local coordinates by the map $Y \to C_{22}(\tau)YC_{11}(\tau)^{-1}$, which is a linear map. Here Y is a symmetric matrix with $y_{12} = y_{21} = 0$. It is easily verified that the eigenvalues of this linear map (and hence of the derivative of the Poincaré map at S_0) are as given in the following result. Note that $e^{-\lambda_1\tau} = -e^{-a\tau}$ and $e^{-\lambda_2\tau} = -e^{a\tau}$.

PROPOSITION 7. *Let $T(l) \cap \mathscr{L}(n)$ be a 1-dimensional invariant torus. Then (using the above notation) the $\frac{1}{2}n(n+1) - 1$ eigenvalues of the derivative of the associated Poincaré map are $\{e^{-(\lambda_i + \lambda_j)\tau}: 1 \leqq i \leqq j \leqq n$ and $(i, j) \neq (1, 2)\}$.*

COROLLARY. *Every 1-dimensional invariant torus for the* ESRDE *on $\mathscr{L}(n)$ is a hyperbolic periodic orbit.*

Proof. It follows from Proposition 7 and Assumption A2 that none of the $\frac{1}{2}n(n+1) - 1$ eigenvalues of the derivative of the Poincaré map are on the unit circle. □

We can now obtain necessary and sufficient conditions for the ESRDE to be a Morse-Smale vector field. Recall that H has $2p$ real eigenvalues and $4q$ nonreal eigenvalues.

THEOREM 17. *The* ESRDE *is a Morse-Smale vector field on $\mathscr{L}(n)$ iff $q \leqq 1$.*

Proof. If $q \leqq 1$, there can be no invariant tori of dimension greater than one. From Theorem 12 and Propositions 5, 6, 7, it follows that the ESRDE is Morse-Smale. On the other hand, if $q \geqq 2$, it follows from Theorem 12 that the nonwandering set of the ESRDE contains at least one invariant torus of dimension greater than one and therefore cannot be Morse-Smale. □

We now consider the structural stability of the ESRDE on $\mathscr{L}(n)$. Every ESRDE corresponds to an infinitesimal generator $H \in \operatorname{sp}(n, \mathbb{R})$. We will say that the ESRDE determined by H is *structurally stable within the class of* ESRDE's if there exists a neighborhood N of H in $\operatorname{sp}(n, \mathbb{R})$ such that the vector field determined by H is topologically equivalent to the vector field determined by every $\tilde{H} \in N$. By replacing

"topologically equivalent" with "topologically equivalent on Ω," we obtain the definition of the ESRDE determined by H being *Ω-stable within the class of* ESRDE's. To avoid any possible confusion, let us recall that except in these definitions, the symbol "Ω" is used to denote the nonwandering set of the ESRDE on $G^n(\mathbb{R}^{2n})$. The nonwandering set of the ESRDE on $\mathscr{L}(n)$ is therefore $\Omega \cap \mathscr{L}(n)$.

THEOREM 18. *Suppose that $H \in \mathrm{sp}(n, \mathbb{R})$ satisfies Assumption A2. If $q \leqq 1$, the associated* ESRDE *is a structurally stable vector field on $\mathscr{L}(n)$. Otherwise, the associated* ESRDE *is not Ω-stable within the class of* ESRDE's.

Proof. If $q \leqq 1$, then the associated ESRDE is Morse-Smale by Theorem 17. This implies that it is structurally stable [30]. On the other hand, if $q \geqq 2$, then the nonwandering set contains at least one invariant torus of dimension at least 2. Let $a_1 + ib_1, \cdots, a_q + ib_q$ be the nonreal eigenvalues of H in the first quadrant of the complex plane. Given any neighborhood N of H in $\mathrm{sp}(n, \mathbb{R})$, we can find $\tilde{H}$, $\hat{H} \in N$ such that the imaginary parts of the eigenvalues of $\tilde{H}$ ($\hat{H}$) in the first quadrant are all commensurable (all noncommensurable). Then every invariant torus of $\tilde{H}$ ($\hat{H}$) of dimension at least 2 contains periodic (almost periodic) orbits. Thus, the ESRDE's associated with $\tilde{H}$ and $\hat{H}$ are not topologically equivalent on Ω. Hence, the ESRDE associated with H cannot be Ω-stable within the class of ESRDE's. □

Remark 4. If $q = 1$, then by Theorems 17 and 18, the ESRDE is a Morse-Smale vector field on $\mathscr{L}(n)$ and is structurally stable. However, considered as a vector field on $G^n(\mathbb{R}^{2n})$, the ESRDE is neither Morse-Smale nor structurally stable. The reason for this is that Ω contains at least one 2-dimensional invariant torus, while $\Omega \cap \mathscr{L}(n)$ contains only invariant tori of dimensions less than or equal to 1. Note that by saying that $q = 1$ for the ESRDE, we mean that H has 2 pairs of complex conjugate eigenvalues, or a total of 4 nonreal eigenvalues. This is different from saying that $q = 1$ for the ERDE, which in § 3 we took to mean that B has a single pair of complex conjugate eigenvalues.

The Betti numbers of the Lagrange-Grassmann manifold $\mathscr{L}(n)$ were determined by A. Borel [4]. In the case where the coefficient field is Z_2, the Poincaré polynomial of $\mathscr{L}(n)$ was found to be $(1+t)(1+t^2)\cdots(1+t^n)$. As an application of Theorem 17, we will obtain a new calculation of this result based on the phase portrait of the ESRDE. We need the following lemma which gives a lower bound for the sum of the mod 2 Betti numbers of the Lagrange-Grassmann manifold.

LEMMA 9. $\sum_i b_i(\mathscr{L}(n), Z_2) \geqq 2^n$.

Proof. By induction on n. Let $n = 1$. $\mathscr{L}(1) = G^1(\mathbb{R}^2)$, which is the projective line. The projective line is homeomorphic to S^1, for which the sum of the mod 2 Betti numbers is 2. So the assertion holds for $\mathscr{L}(1)$.

Suppose that the assertion holds for $\mathscr{L}(n-1)$. Let P be the $2n \times 2n$ matrix $\mathrm{diag}\{d_1, \cdots, d_{2n}\}$ with $d_i = 1$ for $i = 1, \cdots, n-1, n+1, \cdots, 2n-1$ and $d_n = d_{2n} = -1$. P induces an isomorphism of $G^n(\mathbb{R}^{2n})$ onto itself by $S \to P(S)$. Since $P \in \mathrm{Sp}(n, \mathbb{R})$, it follows that P maps $\mathscr{L}(n)$ onto itself. Let $F = \{S \in G^n(\mathbb{R}^{2n}) : P(S) = S\}$, the fixed point set of the mapping P. Let $V = \mathrm{Sp}\{e_1, \cdots, e_{n-1}, e_{n+1}, \cdots, e_{2n-1}\}$ and let $W = \mathrm{Sp}\{e_n, e_{2n}\}$. V and W are the eigenspaces of P corresponding to the eigenvalues 1 and -1 respectively. Since F is the set of all n-dimensional invariant subspaces of P, it follows that F is the disjoint union $\{S_1 \oplus S_2 : S_1 \in G^n(V), S_2 \in G^0(W)\} \sqcup \{S_1 \oplus S_2 : S_1 \in G^{n-1}(V), \quad S_2 \in G^1(W)\} \sqcup \{S_1 \oplus S_2 : S_1 \in G^{n-2}(V), S_2 \in G^2(W)\}$, where $G^j(V)$ and $G^j(W)$ denote the Grassmann manifolds of all j-dimensional subspaces of V and W respectively.

Let $S \in F$. Write $S = S_1 \oplus S_2$ with $S_1 \subset V$, $S_2 \subset W$. Since $PJ = JP$, we have $J(S) = J(S_1) \oplus J(S_2)$ with $J(S_1) \subset V$, $J(S_2) \subset W$. Since $V \perp W$, $J(S) \perp S$ iff $J(S_1) \perp S_1$ and

$J(S_2)\perp S_2$. A necessary condition for $J(S_1)\perp S_1$ and $J(S_2)\perp S_2$ is that $\dim S_1 \leqq \frac{1}{2}\dim V$ and $\dim S_2 \leqq \frac{1}{2}\dim W$. Thus, if $S \in F \cap \mathscr{L}(n)$, then $\dim S \cap V = n-1$ and $\dim S \cap W = 1$. So $F \cap \mathscr{L}(n) = \{S_1 \oplus S_2 : S_1 \in G^{n-1}(V), S_2 \in G^1(W), J(S_1)\perp S_1, J(S_2)\perp S_2\}$, which shows that $F \cap \mathscr{L}(n)$ is isomorphic to $\mathscr{L}(n-1)\times\mathscr{L}(1)$. Applying the induction hypothesis, we conclude that the sum of the mod 2 Betti numbers for $F \cap \mathscr{L}(n)$ is at least $2^{n-1}\cdot 2 = 2^n$. Applying Floyd's theorem (see § 3.3) to the period 2 mapping $P: \mathscr{L}(n) \to \mathscr{L}(n)$, we conclude that the sum of the mod 2 Betti numbers for $\mathscr{L}(n)$ is at least 2^n, completing the proof. □

THEOREM 19. *The Poincaré polynomial for $\mathscr{L}(n)$ using Z_2 as the coefficient field is*

$$P_{Z_2}(\mathscr{L}(n); t) = (1+t)(1+t^2)\cdots(1+t^n).$$

Proof. Choose H to have distinct real eigenvalues. (Since $H \in \operatorname{sp}(n, \mathbb{R})$, this implies that 0 is not an eigenvalue.) Then the ESRDE has 2^n equilibrium points and no other invariant tori. Also, $\dim E_j = 1$ for all j, $r = n$, and $\dim M_j = j$ for all j. Let $l = (l_1, \cdots, l_{2n})$ be such that $l_j = 0$ or 1 and $l_j + l_{2n-j+1} = 1$, $j = 1, \cdots, n$. By Theorem 16, $\dim W^s(T(l)) \cap \mathscr{L}(n) = \frac{1}{2}\{n - d + \sum_{j=1}^{2n} l_j(j - 1 - \sum_{i=1}^{j-1} l_i)\}$, where $d = \sum_{j=1}^{n} l_j$. Let $j_1 < j_2 < \cdots < j_n$ denote the elements of $\{j: l_j = 1\}$. Using the fact that $\sum_{i=1}^{j_\nu - 1} l_i = \nu - 1$, we obtain

$$\dim W^s(T(l)) \cap \mathscr{L}(n) = \frac{1}{2}\left\{n - d + \sum_{\nu=1}^{n}(j_\nu - \nu)\right\}.$$

It is easy to see that the condition $l_j + l_{2n-j+1} = 1$ implies that

$$\sum_{\nu=1}^{d} j_\nu + \sum_{\nu=d+1}^{n}(2n+1-j_\nu) = \sum_{j=1}^{n} j = \frac{1}{2}n(n+1).$$

Using this equation to substitute for $\sum_{\nu=1}^{d} j_\nu$ and simplifying gives

$$\dim W^s(T(l)) \cap \mathscr{L}(n) = \sum_{\nu=d+1}^{n}(j_\nu - n),$$

which is the sum of an $(n-d)$-element subset of $\{1, 2, \cdots, n\}$. Letting l take on each of its 2^n possible values, $\dim W^s(T(l)) \cap \mathscr{L}(n)$ takes on the values of the sums of each of the 2^n subsets of $\{1, 2, \cdots, n\}$. Since $\dim W^s(T(l)) \cap \mathscr{L}(n)$ is the index of the equilibrium point $T(l) \cap \mathscr{L}(n)$, this implies that the Morse series for the vector field corresponding to H has factored form

$$M_H(t) = (1+t)(1+t^2)\cdots(1+t^n).$$

By Theorem 17, the ESRDE which corresponds to H is Morse-Smale. Let m_s denote the coefficient of t^s in the polynomial $M_H(t)$. Then the Morse-Smale inequalities give $m_s \geqq b_s(\mathscr{L}(n), Z_2)$. To show that this is actually an equality for each s, it suffices to show that $\sum_s m_s = \sum_s b_s(\mathscr{L}(n), Z_2)$. Since $\sum_s m_s = 2^n$, this follows immediately from Lemma 9. Thus, $m_s = b_s(\mathscr{L}(n), Z_2)$ for all s, which is equivalent to the conclusion that the Poincaré polynomial for $\mathscr{L}(n)$ using Z_2 as coefficients is $(1+t)(1+t^2)\cdots(1+t^n)$. □

We have seen that the ESRDE is not generally Morse-Smale, due to the existence of invariant tori of dimension greater than one in the nonwandering set. However, we can still define a Morse series $M_H(t)$ for the ESRDE corresponding to the generator H. For each invariant torus $T(l) \cap \mathscr{L}(n)$, define the index of $T(l) \cap \mathscr{L}(n)$ to be $\operatorname{Ind}(T(l) \cap \mathscr{L}(n)) = \dim W^s(T(l)) \cap \mathscr{L}(n) - \dim T(l) \cap \mathscr{L}(n)$. Then define the Morse series to be

$$M_H(t) = \sum_l (1+t)^{\dim T(l)\cap\mathscr{L}(n)} t^{\operatorname{Ind}(T(l)\cap\mathscr{L}(n))},$$

where the sum is over all $l=(l_1,\cdots,l_{2r})$ such that $l_i+l_{2r-i+1}=\dim E_i$, $i=1,\cdots,r$. The following result shows that the ESRDE satisfies Morse-type *equalities* provided that Z_2 is used as the coefficient field.

THEOREM 20. *Suppose that* $H\in \mathrm{sp}(n,\mathbb{R})$ *satisfies Assumption A2. Then*

$$M_H(t)=P_{Z_2}(\mathscr{L}(n);t).$$

Proof. Let $\{V_j\}_1^{2n}$ denote the standard symplectic flag for $\mathbb{R}^{2n}$ described at the beginning of § 4B. Corresponding to this complete flag is a cell decomposition of $\mathscr{L}(n)$ into the union of 2^n cells. The cells are given by $U(a)\cap\mathscr{L}(n)$ where $a=(a_1,\cdots,a_{2n})$ is such that $a_i+a_{2n-i+1}=1$, $i=1,\cdots,n$ and $U(a)=\{S\in G^n(\mathbb{R}^{2n})\colon \dim S\cap V_j=\sum_{i=1}^j a_i,\ j=1,\cdots,2n\}$. By Lemma 7, $\dim U(a)\cap\mathscr{L}(n)=\frac{1}{2}\{n-d+\sum_{j=1}^{2n}a_j(j-\sum_{i=1}^j a_i)\}$, where $d=\sum_{j=1}^n a_j$. This formula can be simplified by letting $j_1<j_2<\cdots<j_n$ denote the elements of $\{j\colon a_j=1\}$. By the same manipulations used in the proof of Theorem 19 (but with a_j in place of l_j), we obtain

$$\dim U(a)\cap\mathscr{L}(n)=\sum_{\nu=d+1}^{n}(j_\nu-n).$$

It follows that

$$\sum_{\substack{\text{all}\\ \text{cells}}} t^{\dim \text{cell}}=(1+t)(1+t^2)\cdots(1+t^n),$$

which is equal to $P_{Z_2}(\mathscr{L}(n);t)$.

By Lemma 5, there is no loss of generality in assuming that the complete flag $\{V_j\}_1^{2n}$ refines the stable flag $\{M_i\}_1^{2r}$ which corresponds to H. Then by Theorem 13, each stable manifold $W^s(T(l))\cap\mathscr{L}(n)$ is a disjoint union of some of the 2^n cells corresponding to the complete flag $\{V_j\}_1^{2n}$. If $\dim T(l)\cap\mathscr{L}(n)=k$, then $W^s(T(l))\cap\mathscr{L}(n)$ is the union of 2^k cells, and $\binom{k}{\nu}$ of these cells have dimension equal to $\dim W^s(T(l))\cap\mathscr{L}(n)-k+\nu=\mathrm{Ind}\,(T(l)\cap\mathscr{L}(n))+\nu$, $\nu=0,\cdots,k$. The Binomial Theorem then implies that

$$(1+t)^k t^{\mathrm{Ind}\,(T(l)\cap\mathscr{L}(n))}=\sum_{\substack{\text{all cells in}\\ W^s(T(l))\cap\mathscr{L}(n)}} t^{\dim\text{cell}}.$$

If we sum over all the invariant tori $T(l)\cap\mathscr{L}(n)$, the left-hand side gives $M_H(t)$ while the right-hand side gives $P_{Z_2}(\mathscr{L}(n);t)$. □

5. Phase portrait of the symplectic Riccati differential equation. In this section, we determine the phase portrait for the SRDE, i.e. for the differential equation

$$\dot K=-Q-A'K-KA+KLK$$

on the vector space $S(n)$ of real symmetric $n\times n$ matrices. As was described in § 2, there is a natural embedding of $S(n)$ in the Lagrange-Grassmann manifold $\mathscr{L}(n)$ given by $\phi\colon S(n)\to\mathscr{L}(n)$, where $\phi(K)=\mathrm{Sp}\left[\begin{smallmatrix}I\\K\end{smallmatrix}\right]$. The image of ϕ is the open and dense subset $\mathscr{L}_0(n)$ of $\mathscr{L}(n)$ consisting of those n-dimensional Lagrangian subspaces which are complementary to $\mathrm{Sp}\{e_{n+1},\cdots,e_{2n}\}$. Let $K(t,K_0)$ denote the solution of the SRDE with initial condition K_0. The solution $S(t,\phi(K_0))$ of the ESRDE on $\mathscr{L}(n)$ with initial condition $\phi(K_0)$ is given by $S(t,\phi(K_0))=e^{Ht}(\phi(K_0))$ where $H=\left[\begin{smallmatrix}A & -L\\ -Q & -A'\end{smallmatrix}\right]$. The solutions $K(t,K_0)$ and $S(t,\phi(K_0))$ are related by the equation

$$(*)\qquad \phi(K(t,K_0))=S(t,\phi(K_0))$$

which holds whenever $K(t,K_0)$ exists. Equivalently, the equation holds for the largest time-interval containing 0 for which $S(t,\phi(K_0))$ remains in the subset $\mathscr{L}_0(n)$.

It is important to note that the phase portrait of the SRDE is by no means the same as the phase portrait of the ESRDE, and by themselves the results in § 4 do not characterize the phase portrait of the SRDE. Firstly, the nonwandering set $\Omega \cap \mathscr{L}(n)$ of the ESRDE may intersect $\mathscr{L}(n) - \mathscr{L}_0(n)$. Thus, there may be equilibria, periodic solutions, and almost periodic solutions which are contained in $\mathscr{L}(n) - \mathscr{L}_0(n)$ and hence correspond to no solutions in the phase portrait of the SRDE. Also, there may be points in the nonwandering set of the ESRDE which are contained in $\mathscr{L}_0(n)$ but which generate periodic or almost periodic solutions which intersect $\mathscr{L}(n) - \mathscr{L}_0(n)$. The corresponding points in $S(n)$ are not nonwandering points since they generate solutions which escape in finite time. Thus, the first obstacle to recovering the phase portrait of the SRDE from that of the ESRDE is the possibility that $\Omega \cap \mathscr{L}(n)$ intersects $\mathscr{L}(n) - \mathscr{L}_0(n)$.

The second obstacle is that even if $\Omega \cap \mathscr{L}(n)$ is completely contained in $\mathscr{L}_0(n)$, there may be solutions of the ESRDE which cross the hypersurface $\mathscr{L}(n) - \mathscr{L}_0(n)$ in the process of converging to invariant tori in $\Omega \cap \mathscr{L}(n)$. The corresponding solutions of the SRDE do not converge to the corresponding invariant tori for the SRDE. Rather, the solutions escape in finite time.

It is clear that the phase portrait of the SRDE can be recovered from that of the ESRDE provided we can determine which nonwandering points of the ESRDE belong to $\mathscr{L}_0(n)$ and provided we can identify which solutions of the SRDE escape in either finite forward or backward time. This will be done in the next two subsections. It is interesting to note that it is at this final stage that system-theoretic concepts play a key role in the solution of the mathematical problem. The results for the ESRDE place no individual restrictions on L and Q other than the requirement that they be symmetric. In particular, they apply even when the SRDE is a linear Lyapunov differential equation ($L = 0$) or when the SRDE corresponds to a zero-sum differential game (L indefinite). However, when we seek to recover the phase portrait of the SRDE from that of the ESRDE it becomes important that the SRDE correspond to a control (or filtering) problem (L nonnegative definite) and not to a differential game. Controllability of the associated linear system also becomes important. No assumption on Q is required in order to obtain the phase portrait of the SRDE. Thus, the characterization we obtain is applicable to Riccati equations which correspond to control problems with conflicting objectives (Q indefinite). However, if we wish to obtain results concerning the asymptotic signature of solutions, then it becomes important that Q be nonnegative definite and that the associated linear system be observable.

5.1. Nonwandering set. By Theorem 12, the nonwandering set of the corresponding ESRDE is a union of invariant tori. Furthermore, there are exactly $\binom{q}{k} 2^{p+q-k}$ tori of dimension k, $k = 0, \cdots, q$. In particular, there are 2^{p+q} equilibrium points. However, it is by no means clear that this is the nonwandering set of the SRDE. The problem is that some or all of the points of a given invariant torus (for the ESRDE) may belong to $\mathscr{L}(n) - \mathscr{L}_0(n)$ and therefore not correspond to any points in the space $S(n)$ of symmetric matrices. For example, it is easy to construct a matrix H which satisfies Assumption A2 but for which $L = 0$. Then the corresponding SRDE is

$$\dot{K} = -Q - A'K - KA$$

which is a *linear* matrix equation. We can arrange to have all the eigenvalues of A belong to the open left half plane. It follows immediately that the SRDE has a unique equilibrium point. Since the corresponding ESRDE has 2^{p+q} equilibrium points, it follows that $2^{p+q} - 1$ of these must belong to $\mathscr{L}(n) - \mathscr{L}_0(n)$. We see that Theorem 12

cannot tell the whole story of the nonwandering set for the SRDE since it evidently fails to distinguish between linear and quadratic matrix differential equations. To say this another way, the extension of the Riccati equation from $S(n)$ to the compactification $\mathscr{L}(n)$ blurs the distinction between linear and quadratic equations.

The main result of this subsection is that Theorem 12 *does* describe the nonwandering set of the SRDE provided that a controllability condition is satisfied. Recall that the pair (A, B) is *controllable* if the matrix $[B, AB, \cdots, A^{n-1}B]$ has full rank. It was proven independently by Shayman [41], [35] and by Lancaster and Rodman [23] that if $L = BB'$ with (A, B) controllable, then every n-dimensional Lagrangian H-invariant subspace is complementary to $\mathrm{Sp}\{e_{n+1}, \cdots, e_{2n}\}$.

Thus, every equilibrium point for the ESRDE actually belongs to the subset $\mathscr{L}_0(n)$ and hence corresponds to an equilibrium point for the SRDE on $S(n)$. This result was generalized by Shayman [37]. It was proved that if $L = BB'$ with (A, B) controllable and if H has no eigenvalues on the imaginary axis, then for any $T > 0$, every n-dimensional Lagrangian e^{HT}-invariant subspace is complementary to $\mathrm{Sp}\{e_{n+1}, \cdots, e_{2n}\}$. Hence, every periodic orbit for the ESRDE belongs to $\mathscr{L}_0(n)$ and therefore corresponds to a periodic orbit for the SRDE on $S(n)$.

The following result generalizes the existing results to show that in the presence of controllability, every nonwandering point for the ESRDE is contained in $\mathscr{L}_0(n)$ and thus corresponds to a nonwandering point for the SRDE on $S(n)$. Recall that $L^+(H)$ ($L^-(H)$) denotes the invariant subspace associated with the eigenvalues of H with negative (positive) real part.

LEMMA 10. *Suppose that $L = BB'$, (A, B) is controllable, and H has no eigenvalues on the imaginary axis. Let $S \in \mathscr{L}(n)$ and suppose that S is of the form $S = S^+ \oplus S^-$ where $S^+ \subseteq L^+(H)$ and $S^- \subseteq L^-(H)$. Then $S \in \mathscr{L}_0(n)$.*

Proof. Since (A, B) is controllable and H has no imaginary axis eigenvalues, it is well known (see e.g. [47]) that the SRDE has a unique equilibrium point K^+ (K^-) which has the additional property that every eigenvalue of $A - BB'K^+$ ($A - BB'K^-$) is in the open left (right) half-plane. Furthermore, the difference $\Delta \equiv K^+ - K^-$ is positive definite. It is also well-known (see e.g. [35]) that $\phi(K^+) = L^+(H)$ and $\phi(K^-) = L^-(H)$.

Let k denote dim S^+. Then there exist $n \times k$ and $n \times (n-k)$ full rank matrices D^+, D^- such that

$$S^+ = \mathrm{Sp}\begin{bmatrix} D^+ \\ K^+D^+ \end{bmatrix} \quad \text{and} \quad S^- = \mathrm{Sp}\begin{bmatrix} D^- \\ K^-D^- \end{bmatrix}.$$

Since $S \in \mathscr{L}(n)$, we must have $J(S^+) \perp S^-$, which implies that $(D^-)'\Delta D^+ = 0$. Now,

$$S = \mathrm{Sp}\begin{bmatrix} D^+ & D^- \\ K^+D^+ & K^-D^- \end{bmatrix},$$

so $S \in \mathscr{L}_0(n)$ if and only if the $n \times n$ matrix $[D^+ \ D^-]$ is nonsingular. Suppose there exists $y \in \mathbb{R}^k$ and $z \in \mathbb{R}^{n-k}$ such that $[D^+ \ D^-]\begin{bmatrix} y \\ z \end{bmatrix} = 0$. Then $D^+y = -D^-z$. Premultiplying both sides by $z'(D^-)'\Delta$ gives $0 = -z'(D^-)'\Delta D^-z$. Since $\Delta > 0$, this implies that $D^-z = 0$ and hence $D^+y = 0$ as well. Since D^+ and D^- each have full rank, $y = 0$ and $z = 0$. Thus, $[D^+ \ D^-]$ is nonsingular, which completes the proof. □

COROLLARY. *Suppose that H satisfies Assumption* A2 *and that $L = BB'$ with (A, B) controllable. Then the nonwandering set of the* ESRDE *is contained in $\mathscr{L}_0(n)$.*

The following theorem completely characterizes the nonwandering set of the SRDE.

THEOREM 21. *Suppose that H satisfies Assumption* A2 *and that* $L = BB'$ *with* (A, B) *a controllable pair. Then*

(a) *The nonwandering set of the* SRDE *on* $S(n)$ *is a union of invariant tori. There are exactly* $\binom{q}{k}2^{p+q-k}$ *tori of dimension* k, $k = 0, \cdots, q$.

(b) *Each invariant torus is given by* $\phi^{-1}(T(l) \cap \mathscr{L}(n))$, *where* $l = (l_1, \cdots, l_{2r})$ *is such that* $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$, *and* $T(l) \cap \mathscr{L}(n)$ *is as described by Proposition* 4.

(c) *If* $\phi^{-1}(T(l) \cap \mathscr{L}(n))$ *is a* 0*-dimensional invariant torus, then it is an equilibrium point.*

(d) *If* $\phi^{-1}(T(l) \cap \mathscr{L}(n))$ *is a* k*-dimensional invariant torus with* $k > 0$, *and if the associated imaginary parts* $\{\omega_{j_\nu} : \nu = 1, \cdots, k\}$ *are commensurable, then each* $K \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$ *generates a periodic motion with period equal to the least common multiple of* $\{\pi/\omega_{j_\nu} : \nu = 1, \cdots, k\}$. *Otherwise, each* $K \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$ *generates an almost periodic motion, which is dense in* $\phi^{-1}(T(l) \cap \mathscr{L}(n))$ *iff no pair of the* ω_{j_ν} *are commensurable. In all cases, if* $K_1, K_2 \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$ *with* $K(t, K_2) \to K(t, K_1)$ *as* $t \to \infty$ *or* $t \to -\infty$, *then* $K_1 = K_2$.

Proof. It follows from (*) and Lemma 10 that ϕ is a real-analytic isomorphism of the nonwandering set of the SRDE onto the nonwandering set of the ESRDE. Since the restriction of ϕ^{-1} to the nonwandering set of the ESRDE (which is compact) is uniformly continuous, it follows from AP 5 (see Appendix B) that ϕ^{-1} takes almost periodic motions to almost periodic motions. All of the other assertions follow from the corresponding results for the ESRDE (Theorem 12). □

Remark 5. It is proven in [35] that if H has no imaginary axis eigenvalues, then at least 2^{p+q-1} of the equilibrium points of the ESRDE are contained in $\mathscr{L}(n) - \mathscr{L}_0(n)$. Since they do not belong to the image of ϕ, these equilibrium points do not correspond to equilibrium points of the SRDE on $S(n)$. Thus, controllability is necessary as well as sufficient for ϕ to be an isomorphism of the nonwandering set of the SRDE onto the nonwandering set of the ESRDE.

If C is a $p \times n$ matrix, the pair (C, A) is said to be observable if the pair (A', C') is controllable. The following result describes the signatures of the points on the invariant tori for the SRDE.

THEOREM 22. *Suppose that H satisfies Assumption* A2 *and that* $L = BB'$, $Q = C'C$ *with* (A, B) *controllable and* (C, A) *observable. Then if* $K \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$, *then* K *is nonsingular and has exactly* $\sum_{i=1}^{r} l_i$ *positive eigenvalues.*

Proof. It is well known (see e.g. [48]) that if $L = BB'$, $Q = C'C$ with (A, B) controllable and (C, A) observable, then $K^+ > 0$ and $K^- < 0$. Let $k = \sum_{i=1}^{r} l_i$. From the proof of Lemma 10, there exist $n \times k$ and $n \times (n-k)$ full rank matrices D^+, D^- with $(D^-)'\Delta D^+ = 0$ such that

$$\operatorname{Sp}\begin{bmatrix} I \\ K \end{bmatrix} = \operatorname{Sp}\begin{bmatrix} D^+ & D^- \\ K^+D^+ & K^-D^- \end{bmatrix}.$$

Thus, $K = [K^+D^+ \;\; K^-D^-][D^+ \;\; D^-]^{-1}$. Let $M = \operatorname{Sp} D^+$. Then $\Delta^{-1}(M^\perp) = \operatorname{Sp} D^-$. Since $[D^+ \;\; D^-]$ is nonsingular, M and $\Delta^{-1}(M^\perp)$ are complementary subspaces in $\mathbb{R}^n$. It is easy to verify that if $x \in M$, then $x'Kx = x'K^+x$, while if $x \in \Delta^{-1}(M^\perp)$, then $x'Kx = x'K^-x$. The assertions of the theorem follow immediately from this together with the fact that $K^+ > 0$ and $K^- < 0$. □

Using Proposition 4, it is easy to actually compute the invariant tori for the SRDE on $S(n)$. The first step is to determine the primary components $E_1, \cdots, E_{2r}$ of H. Choose $l = (l_1, \cdots, l_{2r})$ such that $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. Next, construct the elements $S \in T(l) \cap \mathscr{L}(n)$ by forming the direct sums $S = S_1 \oplus \cdots \oplus S_r \oplus$

$([J(S_r)]^{\perp} \cap E_{r+1}) \oplus \cdots \oplus ([J(S_1)]^{\perp} \cap E_{2r})$ where S_i is any l_i-dimensional subspace of E_i, $i = 1, \cdots, r$. Given any $S \in T(l) \cap \mathscr{L}(n)$, choose *any* basis for S and let $\begin{bmatrix} X \\ Y \end{bmatrix}$ be the $2n \times n$ matrix whose columns are this basis. (X and Y are each $n \times n$.) Since $S \in \mathscr{L}_0(n)$ by Lemma 10, X is automatically nonsingular. Then $\phi^{-1}(S)$ is the symmetric matrix YX^{-1}. By this method, we can construct each invariant torus $\phi^{-1}(T(l) \cap \mathscr{L}(n))$. This procedure is illustrated in detail in § 5.4. In the special case where $T(l) \cap \mathscr{L}(n)$ is 0-dimensional, this procedure is the well-known eigenvector method for constructing the equilibrium points of the SRDE [24], [31], [25].

5.2. Stable and unstable manifolds. In this subsection, we describe the stable and unstable manifolds for the SRDE on $S(n)$. The following lemma is an easy consequence of the results in [7] and [26]. Let K^+ and K^- denote the unique stabilizing and destabilizing equilibrium points as referred to in the proof of Lemma 10.

LEMMA 11. *Suppose that $L = BB'$ with (A, B) controllable and H has no eigenvalues on the imaginary axis. Then $K(t, K_0)$ has no finite escape time in forward time if and only if $K_0 \leqq K^+$, and has no finite escape time in backward time if and only if $K_0 \geqq K^-$.*

Suppose that H satisfies A2 and that $L = BB'$ with (A, B) controllable. Let $F_+ = \{K \in S(n): K^+ \geqq K\}$ and let $F_- = \{K \in S(n): K \geqq K^-\}$. Thus, $K(t, K_0)$ has a finite escape time in forward (backward) time iff $K_0 \notin F_+$ ($K_0 \notin F_-$). By Theorem 21, the nonwandering set of the SRDE is a union of tori, with one torus for each $l = (l_1, \cdots, l_{2r})$ which satisfies $l_i + l_{2r-i+1} = \dim E_i$, $i = 1, \cdots, r$. For each such l, let $R^s(l)$ ($R^u(l)$) denote the stable (unstable) manifold of the invariant torus $\phi^{-1}(T(l) \cap \mathscr{L}(n))$. In other words, $R^s(l) = \{K_0 \in S(n): K(t, K_0) \to \phi^{-1}(T(l) \cap \mathscr{L}(n))$ as $t \to \infty\}$ and $R^u(l) = \{K_0 \in S(n): K(t, K_0) \to \phi^{-1}(T(l) \cap \mathscr{L}(n))$ as $t \to -\infty\}$. By (*), it follows immediately that $R^s(l) = \phi^{-1}(W^s(T(l)) \cap \mathscr{L}(n)) \cap F_+$ and that $R^u(l) = \phi^{-1}(W^u(T(l)) \cap \mathscr{L}(n)) \cap F_-$.

As in § 4, we let Ω denote the nonwandering set of the ESRDE regarded as a differential equation on $G^n(\mathbb{R}^{2n})$. Then $\Omega \cap \mathscr{L}(n)$ is the nonwandering set of the ESRDE on $\mathscr{L}(n)$. We recall from § 4.2 the definition of the projections $\hat{\Pi}_+: \mathscr{L}(n) \to \Omega \cap \mathscr{L}(n)$ and $\hat{\Pi}_-: \mathscr{L}(n) \to \Omega \cap \mathscr{L}(n)$. Let η_j denote the projection onto the subspace E_j along the subspace $\bigoplus_{i=1, i \neq j}^{2r} E_i$, $j = 1, \cdots, 2r$. Then $\hat{\Pi}_+(S) = \eta_1(S \cap M_1) \oplus \cdots \oplus \eta_{2r}(S \cap M_{2r})$, and $\hat{\Pi}_-(S) = \eta_1(S \cap N_{2r}) \oplus \cdots \oplus \eta_{2r}(S \cap N_1)$. We can now prove the following result which describes the asymptotic behavior of every solution of the SRDE.

THEOREM 23. *Suppose that H satisfies Assumption* A2 *and that $L = BB'$ with (A, B) a controllable pair. Let $K_0 \in S(n)$ and let $l_i = \dim \phi(K_0) \cap M_i - \dim \phi(K_0) \cap M_{i-1}$, $i = 1, \cdots, 2r$, and let $l_i' = \dim \phi(K_0) \cap N_{2r-i+1} - \dim \phi(K_0) \cap N_{2r-i}$, $i = 1, \cdots, 2r$. Let $l = (l_1, \cdots, l_{2r})$ and let $l' = (l_1', \cdots, l_{2r}')$. Then*

(a) *If $K_0 \notin F_+$, then $K(t, K_0)$ has a finite escape time in forward time.*

(b) *If $K_0 \in F_+$, then $K_0 \in R^s(l)$. Furthermore, $K(t, K_0) \to K(t, \phi^{-1}(\hat{\Pi}_+(\phi(K_0))))$ as $t \to \infty$.*

(c) *If $K_0 \notin F_-$, then $K(t, K_0)$ has a finite escape time in backward time.*

(d) *If $K_0 \in F_-$, then $K_0 \in R^u(l')$. Furthermore, $K(t, K_0) \to K(t, \phi^{-1}(\hat{\Pi}_-(\phi(K_0))))$ as $t \to -\infty$.*

Proof. (a) and (c) follow immediately from Lemma 11. (b) From the definition of l, we have $\dim \phi(K_0) \cap M_j = \sum_{i=1}^{j} l_i$, $j = 1, \cdots, 2r$. By Theorem 2, this implies that $\phi(K_0) \in W^s(T(l)) \cap \mathscr{L}(n)$, so $K_0 \in R^s(l)$. Let $S_1 = \hat{\Pi}_+(\phi(K_0)) \in T(l) \cap \mathscr{L}(n)$. Then $\phi(K_0) \in W^s(S_1) \cap \mathscr{L}(n)$, so $\rho(S(t, \phi(K_0)), S(t, S_1)) \to 0$ as $t \to \infty$. (Recall that ρ denotes the gap metric.) Since $\mathscr{L}_0(n)$ is an open subset of the metric space $\mathscr{L}(n)$ and $T(l) \cap \mathscr{L}(n) \subset \mathscr{L}_0(n)$, there exists an open set U such that $T(l) \cap \mathscr{L}(n) \subset U \subset \bar{U} \subset \mathscr{L}_0(n)$. Since $S(t, S_1) \in T(l) \cap \mathscr{L}(n)$, it follows that $S(t, \phi(K_0)) \in \bar{U}$ for sufficiently large t. Since the restriction of ϕ^{-1} to the compact set $\bar{U}$ is uniformly continuous, the fact

that $\rho(S(t, \phi(K_0)), S(t, S_1)) \to 0$ as $t \to \infty$ implies that $\|\phi^{-1}(S(t, \phi(K_0))) - \phi^{-1}(S(t, S_1))\| \to 0$ as $t \to \infty$. Thus, $\|K(t, K_0) - K(t, \phi^{-1}(\hat{\Pi}_+(\phi(K_0))))\| \to 0$ as $t \to \infty$, which proves (b). The proof of (d) is analogous to the proof of (b). □

We recall from § 4.1 that the total number of invariant tori for the ESRDE on $\mathscr{L}(n)$ and hence for the SRDE on $S(n)$ is $\Pi_{j=1}^{r}(1 + \dim E_j) = 2^p 3^q$. Theorem 23 describes 2 partitions of $S(n)$ determined by the phase portrait of the SRDE. The first partition consists of the stable manifolds $\{R^s(l)\}$ together with the region $S(n) - F_+$ of points which generate motions which escape in finite forward time. The second partition consists of the unstable manifolds $\{R^u(l)\}$ together with the region $S(n) - F_-$ of points which generate motions which escape in finite backward time. Each partition contains $1 + 2^p 3^q$ sets.

Theorem 23 describes the asymptotic behavior of *every* solution of the SRDE. If $K(t, K_0)$ converges to an invariant torus as $t \to \infty$ (or as $t \to -\infty$), the theorem specifies not only which torus $\phi^{-1}(T(l) \cap \mathscr{L}(n))$ it converges to, but also which motion on the torus $K(t, K_0)$ approaches.

An interesting implication of Theorem 23 is that no trajectories of the SRDE approach infinity asymptotically. A trajectory either reaches infinity in finite time or converges to an invariant torus. This behavior is very different from that of a linear matrix differential equation. In the linear case, there can be solutions which grow exponentially and hence approach infinity in the limit as $t \to \infty$. It is the assumption of controllability which prohibits this behavior for the SRDE. The convergence of solutions when (A, B) is stabilizable (rather than controllable) is considered in [8].

A classical result in the theory of the Riccati equation is that $K(t, K_0) \to K^-$ as $t \to \infty$ iff $K_0 < K^+$, and $K(t, K_0) \to K^+$ as $t \to -\infty$ iff $K_0 > K^-$. (See e.g. [47].) It is easy to show how these results follow from Theorem 23. We noted earlier that $\phi(K^-)$ is the sum of the primary components of H which correspond to its right half-plane eigenvalues. In other words, $\phi(K^-) = E_{r+1} \oplus \cdots \oplus E_{2r}$. Thus, the equilibrium point $\phi(K^-)$ of the ESRDE is the invariant torus $T(l) \cap \mathscr{L}(n)$ for $l = (l_1, \cdots, l_{2r})$ with $l_i = 0$, $i = 1, \cdots, r$, and $l_i = \dim E_i$, $i = r+1, \cdots, 2r$. By Theorem 23

$$R^s(l) = \{K_0 \in F_+ : \dim \phi(K_0) \cap M_j = \sum_{i=1}^{j} l_i, j = 1, \cdots, 2r\}.$$

For the given l, the condition that

$$\dim \phi(K_0) \cap M_j = \sum_{i=1}^{j} l_i, \qquad j = 1, \cdots, 2r$$

is equivalent to the condition that $\phi(K_0) \cap M_r = 0$. Since $\phi(K^+)$ is the sum of the primary components of H which correspond to its left half-plane eigenvalues, we have $M_r = E_1 \oplus \cdots \oplus E_r = \phi(K^+)$. Since $\phi(K_0) \cap \phi(K^+) = 0$ iff $K^+ - K_0$ is nonsingular, we have $R^s(l) = \{K_0 \in S(n) : K^+ \geqq K_0$ and $\det(K^+ - K_0) \neq 0\} = \{K_0 \in S(n) : K_0 < K^+\}$. By an analogous argument, it follows from Theorem 23 that the unstable manifold of K^+ is $\{K_0 \in S(n) : K_0 > K^-\}$.

The following result describes the asymptotic signature of every solution of the SRDE which does not have a finite escape time. It follows immediately from Theorem 22 together with the fact that the set of nonsingular symmetric matrices of a given signature is open in $S(n)$.

THEOREM 24. *Suppose that H satisfies Assumption* A2 *and that $L = BB'$, $Q = C'C$ with (A, B) controllable and (C, A) observable. If $K_0 \in R^s(l)$ ($R^u(l)$), then for sufficiently large positive (negative) t, $K(t, K_0)$ is nonsingular and has exactly $\sum_{i=1}^{r} l_i$ positive eigenvalues.*

5.3. Genericity. Theorems 21 and 23 give a complete description of the phase portrait of the Riccati equation

$$(**) \qquad \dot{K} = -Q - A'K - KA + KBB'K$$

provided that Assumption A2 is satisfied and (A, B) is controllable. If we fix m and consider those Riccati equations for which B is $n \times m$, we can specify each such equation by a triple $(A, B, Q) \in \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times S(n)$. It is clear that an open and dense subset of triples satisfy the controllability condition and conditions (1) and (2) of A2. However, the set of triples (A, B, Q) which violate condition (3) of A2 has nonempty interior in $\mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times S(n)$. To see this, note that since $H \in \mathrm{sp}(n, \mathbb{R})$, its spectrum is symmetrical with respect to both coordinate axes. Hence, if $\left[\begin{smallmatrix} A_0 & -B_0B_0' \\ -Q_0 & -A_0' \end{smallmatrix}\right]$ has an imaginary axis eigenvalue with multiplicity one (or more generally, with any odd multiplicity) the same is true for $\left[\begin{smallmatrix} A & -BB' \\ -Q & -A' \end{smallmatrix}\right]$ provided (A, B, Q) is sufficiently close to (A_0, B_0, Q_0). This is easily illustrated by the case where $n = m = 1$. Let $H = \left[\begin{smallmatrix} a & -b^2 \\ -q & -a \end{smallmatrix}\right]$. It is straightforward to check that H has imaginary axis eigenvalues iff $a^2 + b^2q \leqq 0$. This inequality defines a region with nonempty interior in $\mathbb{R} \times \mathbb{R} \times \mathbb{R}$.

The preceding analysis shows that although Theorems 21 and 23 apply to a very large class of Riccati equations of the form (**), they do not apply to an open and dense subset.

However, the Riccati equation which arises in optimal control and filtering problems is more specialized than (**). It is of the form

$$(***) \qquad \dot{K} = -C'C - A'K - KA + KBB'K.$$

If we fix m and p and consider those Riccati equations for which B is $n \times m$ and C is $p \times n$, we can specify each such equation by a triple $(A, B, C) \in \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n}$. As before, it is clear that an open and dense subset of triples (A, B, C) satisfy the controllability condition and conditions (1) and (2) of Assumption A2. Wonham proved [49] that stabilizability of (A, B) and detectability of (C, A) imply the existence of a stabilizing solution to the algebraic Riccati equation. It is well known [21] that the existence of a stabilizing solution implies that H has no imaginary axis eigenvalues. Since stabilizability and detectability are generic properties, we conclude that the set of triples (A, B, C) which satisfy condition (3) of Assumption A2 contains a subset which is open and dense. Thus, we obtain

PROPOSITION 8. *The subset of* $\mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n}$ *consisting of those triples* (A, B, C) *for which* (A, B) *is controllable and Assumption* A2 *holds contains a subset which is open and dense in* $\mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n}$.

Thus, Theorems 21 and 23 give a complete description of the phase portrait for an open and dense subset of the Riccati equations of the form (***).

The following result is an interesting consequence of Proposition 8.

PROPOSITION 9. *Let* $H \in \mathrm{sp}(n, \mathbb{R})$ *with* $H = \left[\begin{smallmatrix} A & -L \\ -Q & -A' \end{smallmatrix}\right]$. *If* L *and* Q *are nonnegative definite, then every imaginary axis eigenvalue of* H *has even multiplicity.*

Proof. Suppose H has an imaginary axis eigenvalue of odd multiplicity. Then the same is true for every matrix $\tilde{H}$ in some neighborhood of H in $\mathrm{sp}(n, \mathbb{R})$. If L and Q are nonnegative definite, we can express L and Q as $L = BB'$, $Q = C'C$ for some B and C. By Proposition 8, arbitrarily small perturbations in A, B, and C can be chosen so that the resulting matrix $\tilde{H} \in \mathrm{sp}(n, \mathbb{R})$ has no imaginary axis eigenvalues, a contradiction. □

5.4. Example. In this subsection, we illustrate how our results are applied to a concrete example. Consider the SRDE

$$\dot{K} = -Q - A'K - KA + KLK$$

where

$$A=\frac{1}{9}\begin{bmatrix}-42 & 26 & -6 & -16\\ 6 & -70 & -30 & -16\\ -18 & 2 & -153 & 80\\ 24 & 24 & 24 & -45\end{bmatrix},\qquad L=\frac{1}{9}\begin{bmatrix}28 & -8 & 4 & 0\\ -8 & 28 & 4 & 0\\ 4 & 4 & 34 & 0\\ 0 & 0 & 0 & 18\end{bmatrix},$$

$$Q=\frac{1}{9}\begin{bmatrix}-56 & 22 & -110 & 60\\ 22 & -168 & -68 & -4\\ -110 & -68 & -704 & 420\\ 60 & -4 & 420 & -292\end{bmatrix}.$$

By direct calculation, the eigenvalues of H are determined to be $-2\pm 2i$, $-1\pm 4i$, $1\pm 4i$, $2\pm 2i$. Thus, Assumption A2 is satisfied. Furthermore, it is easily verified that $L>0$. If we set $B=L^{1/2}$, then $BB'=L$ and (A, B) is trivially controllable since B is nonsingular.

Since $p=0$ and $q=2$, we conclude from Theorem 21(a) that the nonwandering set consists of 4 0-dimensional invariant tori, 4 1-dimensional invariant tori, and 1 2-dimensional invariant torus. The 0-dimensional invariant tori are equilibrium points, and they correspond to $l=(2,2,0,0)$, $l=(2,0,2,0)$, $l=(0,2,0,2)$, and $l=(0,0,2,2)$. The 1-dimensional invariant tori are isolated periodic orbits, and they correspond to $l=(2,1,1,0)$, $l=(1,2,0,1)$, $l=(1,0,2,1)$, and $l=(0,1,1,2)$. By Theorem 21(d), they have periods $\pi/4$, $\pi/2$, $\pi/2$ and $\pi/4$ respectively. The 2-dimensional invariant torus corresponds to $l=(1,1,1,1)$. Since the imaginary parts $\{4, 2\}$ are commensurable, it follows from Theorem 21(d) that every motion on this torus is periodic with period $\pi/2$. Thus, the Riccati equation has uncountably many periodic orbits.

Using the procedure described in Lemma 5, we can find a symplectic matrix P such that

$$PHP^{-1}=\left[\begin{array}{cccc|cccc}-2 & 2 & 0 & 0 & 0 & 0 & 0 & 0\\ -2 & -2 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & -1 & 4 & 0 & 0 & 0 & 0\\ 0 & 0 & -4 & -1 & 0 & 0 & 0 & 0\\ \hline 0 & 0 & 0 & 0 & 2 & 2 & 0 & 0\\ 0 & 0 & 0 & 0 & -2 & 2 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 4\\ 0 & 0 & 0 & 0 & 0 & 0 & -4 & 1\end{array}\right].$$

One such P is given by

$$P=\frac{1}{3}\left[\begin{array}{cccc|cccc}-4 & 3 & -10 & 4 & -2 & 1 & -2 & 0\\ 2 & -6 & -10 & 4 & 1 & -2 & -2 & 0\\ -4 & -6 & 5 & -2 & -2 & -2 & 1 & 0\\ 0 & 0 & -6 & 9 & 0 & 0 & 0 & 3\\ \hline -2 & 2 & -8 & 4 & -2 & 1 & -2 & 0\\ 1 & -4 & -8 & 4 & 1 & -2 & -2 & 0\\ -2 & -4 & 4 & -2 & -2 & -2 & 1 & 0\\ 0 & 0 & -6 & 6 & 0 & 0 & 0 & 3\end{array}\right].$$

which has as its inverse the matrix

$$P^{-1}=\frac{1}{3}\left[\begin{array}{cccc|cccc} -2 & 1 & -2 & 0 & 2 & -1 & 2 & 0 \\ 1 & -2 & -2 & 0 & -1 & 2 & 2 & 0 \\ -2 & -2 & 1 & 0 & 2 & 2 & -1 & 0 \\ 0 & 0 & 0 & 3 & 0 & 0 & 0 & -3 \\ \hline 2 & -1 & 2 & 0 & -4 & 2 & -4 & 0 \\ -2 & 4 & 4 & 0 & 3 & -6 & -6 & 0 \\ 8 & 8 & -4 & 6 & -10 & -10 & 5 & -6 \\ -4 & -4 & 2 & -6 & 4 & 4 & -2 & 9 \end{array}\right].$$

From P^{-1} it follows that the primary components of H are

$$\underset{E_1}{\mathrm{Sp}\begin{bmatrix} -2 & 1 \\ 1 & -2 \\ -2 & -2 \\ 0 & 0 \\ 2 & -1 \\ -2 & 4 \\ 8 & 8 \\ -4 & -4 \end{bmatrix}}, \quad \underset{E_2}{\mathrm{Sp}\begin{bmatrix} -2 & 0 \\ -2 & 0 \\ 1 & 0 \\ 0 & 3 \\ 2 & 0 \\ 4 & 0 \\ -4 & 6 \\ 2 & -6 \end{bmatrix}}, \quad \underset{E_3}{\mathrm{Sp}\begin{bmatrix} 2 & 0 \\ 2 & 0 \\ -1 & 0 \\ 0 & -3 \\ -4 & 0 \\ -6 & 0 \\ 5 & -6 \\ -2 & 9 \end{bmatrix}}, \quad \underset{E_4}{\mathrm{Sp}\begin{bmatrix} 2 & -1 \\ -1 & 2 \\ 2 & 2 \\ 0 & 0 \\ -4 & 2 \\ 3 & -6 \\ -10 & -10 \\ 4 & 4 \end{bmatrix}}.$$

We have $K^+=\phi^{-1}(T((2,2,0,0))\cap\mathscr{L}(4))=\phi^{-1}(E_1\oplus E_2)$. Using the bases for E_1 and E_2 given above, we can write $E_1\oplus E_2$ as $\mathrm{Sp}\left[\begin{smallmatrix}X\\Y\end{smallmatrix}\right]$ with X and Y each 4×4. By Lemma 10, $E_1\oplus E_2$ is complementary to $\mathrm{Sp}\{e_5, e_6, e_7, e_8\}$, so X is nonsingular. Using the formula $K^+=YX^{-1}$, we obtain

$$K^+=\begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & -4 & 2 \\ 0 & 0 & 2 & -2 \end{bmatrix}.$$

We have $K^-=\phi^{-1}(T((0,0,2,2))\cap\mathscr{L}(4))=\phi^{-1}(E_3\oplus E_4)$. Let $K_1=\phi^{-1}(T((2,0,2,0))\cap\mathscr{L}(4))=\phi^{-1}(E_1\oplus E_3)$, and $K_2=\phi^{-1}(T(0,2,0,2)\cap\mathscr{L}(4))=\phi^{-1}(E_2\oplus E_4)$. Using the same method as was used to compute K^+, we obtain

$$K^-=\begin{bmatrix} -2 & 0 & 0 & 0 \\ 0 & -3 & 0 & 0 \\ 0 & 0 & -5 & 2 \\ 0 & 0 & 2 & -3 \end{bmatrix},$$

$$K_1=\frac{1}{9}\begin{bmatrix} -13 & -4 & 2 & 0 \\ -4 & -22 & 2 & 0 \\ 2 & 2 & -37 & 18 \\ 0 & 0 & 18 & -27 \end{bmatrix}, \qquad K_2=\frac{1}{9}\begin{bmatrix} -14 & 4 & -2 & 0 \\ 4 & -23 & -2 & 0 \\ -2 & -2 & -44 & 18 \\ 0 & 0 & 18 & -18 \end{bmatrix}.$$

Next, we consider the 2-dimensional invariant torus, $\phi^{-1}(T((1,1,1,1)) \cap \mathscr{L}(4))$. By Proposition 4, $T((1,1,1,1)) \cap \mathscr{L}(4)$ consists of those 4-dimensional subspaces of $\mathbb{R}^8$ which are of the form $S_1 \oplus S_2 \oplus ([J(S_2)]^{\perp} \cap E_3) \oplus ([J(S_1)]^{\perp} \cap E_4)$ where S_1 and S_2 are 1-dimensional subspaces of E_1 and E_2 respectively. These subspaces are precisely those of the form

$$S(\theta_1, \theta_2) = \operatorname{Sp} P^{-1} \left[\begin{array}{cccc} \cos\theta_1 & 0 & 0 & 0 \\ -\sin\theta_1 & 0 & 0 & 0 \\ 0 & \cos\theta_2 & 0 & 0 \\ 0 & -\sin\theta_2 & 0 & 0 \\ \hline 0 & 0 & \sin\theta_1 & 0 \\ 0 & 0 & \cos\theta_1 & 0 \\ 0 & 0 & 0 & \sin\theta_2 \\ 0 & 0 & 0 & \cos\theta_2 \end{array}\right]$$

$$= \operatorname{Sp} \left[\begin{array}{cc} -2\cos\theta_1 - \sin\theta_1 & -2\cos\theta_2 \\ \cos\theta_1 + 2\sin\theta_1 & -2\cos\theta_2 \\ -2\cos\theta_1 + 2\sin\theta_1 & \cos\theta_2 \\ 0 & -3\sin\theta_2 \\ \hline 2\cos\theta_1 + \sin\theta_1 & 2\cos\theta_2 \\ -2\cos\theta_1 - 4\sin\theta_1 & 4\cos\theta_2 \\ 8\cos\theta_1 - 8\sin\theta_1 & -4\cos\theta_2 - 6\sin\theta_2 \\ -4\cos\theta_1 + 4\sin\theta_1 & 2\cos\theta_2 + 6\sin\theta_2 \end{array}\right.$$

$$\left.\begin{array}{cc} 2\sin\theta_1 - \cos\theta_1 & 2\sin\theta_2 \\ -\sin\theta_1 + 2\cos\theta_1 & 2\sin\theta_2 \\ 2\sin\theta_1 + 2\cos\theta_1 & -\sin\theta_2 \\ 0 & -3\cos\theta_2 \\ \hline -4\sin\theta_1 + 2\cos\theta_1 & -4\sin\theta_2 \\ 3\sin\theta_1 - 6\cos\theta_1 & -6\sin\theta_2 \\ -10\sin\theta_1 - 10\cos\theta_1 & 5\sin\theta_2 - 6\cos\theta_2 \\ 4\sin\theta_1 + 4\cos\theta_1 & -2\sin\theta_2 + 9\cos\theta_2 \end{array}\right].$$

Let $X(\theta_1, \theta_2)$ and $Y(\theta_1, \theta_2)$ denote the upper and lower submatrices respectively in the indicated basis matrix for $S(\theta_1, \theta_2)$. By Lemma 10, $S(\theta_1, \theta_2)$ is complementary to $\operatorname{Sp}\{e_5, e_6, e_7, e_8\}$, so $X(\theta_1, \theta_2)$ is nonsingular for all θ_1, θ_2. Since $\phi^{-1}(S(\theta_1, \theta_2)) = Y(\theta_1, \theta_2)X(\theta_1, \theta_2)^{-1}$, the 2-dimensional invariant torus for the SRDE is given by $\{Y(\theta_1, \theta_2)X(\theta_1, \theta_2)^{-1} : 0 \leqq \theta_1, \theta_2 < \pi\}$.

Next, we consider the 1-dimensional invariant tori. We could use Proposition 4 to describe each of the 4 1-dimensional invariant tori in a manner analogous to the description of the 2-dimensional invariant torus given above. Each torus would be described in the form $\{Y(\theta)X(\theta)^{-1} : 0 \leqq \theta < \pi\}$ where $X(\theta)$ and $Y(\theta)$ are each 4×4

matrix functions of θ, and $X(\theta)$ is invertible for every θ. However, there is an alternate method for computing the 1-dimensional invariant tori which has the advantage of not requiring the inversion of a matrix function of θ. The procedure is described in our paper [37].

In [37], the procedure is used to compute every periodic orbit under the additional assumption that if λ_j and λ_k are eigenvalues of H such that $\operatorname{Re}\lambda_j > 0$, $\operatorname{Im}\lambda_j > 0$, $\operatorname{Re}\lambda_k > 0$, $\operatorname{Im}\lambda_k > 0$, then $\operatorname{Im}\lambda_j$ and $\operatorname{Im}\lambda_k$ are noncommensurable. This assumption implies that the motion on every invariant torus of dimension greater than 1 is almost periodic. Consequently, the only periodic orbits are the 1-dimensional invariant tori. Without the additional assumption, the procedure can still be used to compute every 1-dimensional invariant torus. However, it cannot be used to compute periodic orbits which lie on invariant tori of dimension greater than 1.

The general idea is that each 1-dimensional invariant torus is bounded by a pair of equilibrium points, and these equilibrium points can be used to determine the torus in a computationally attractive way. To use this method, we find those pairs of equilibrium points K_α, K_β satisfying $K_\alpha \leqq K_\beta$, $\dim\ker(K_\beta - K_\alpha) = n-2$, and such that there are no other equilibrium points K which satisfy $K_\alpha \leqq K \leqq K_\beta$. There are $q2^{p+q-1}$ such pairs K_α, K_β. Given one such pair, we find an orthogonal matrix Z such that $Z'(K_\beta - K_\alpha)Z = \operatorname{diag}\{\gamma, \delta, 0, \cdots, 0\}$ with $0 < \delta \leqq \gamma$. Let

$$X(\theta) = \begin{bmatrix} \frac{1}{2}\gamma + \frac{1}{2}\gamma\cos\theta & \frac{1}{2}\sqrt{\gamma\delta}\sin\theta \\ \frac{1}{2}\sqrt{\gamma\delta}\sin\theta & \frac{1}{2}\delta - \frac{1}{2}\delta\cos\theta \end{bmatrix},$$

and let $\hat{X}(\theta)$ be the $n \times n$ matrix which has $X(\theta)$ as its upper left-hand 2×2 submatrix and has zeros for all its remaining entries. Then the unique 1-dimensional invariant torus $\{K(\theta): 0 \leqq \theta < 2\pi\}$ satisfying $K_\alpha \leqq K(\theta) \leqq K_\beta$ for all θ is given by $K(\theta) = K_\alpha + Z\hat{X}(\theta)Z'$.

It is easily checked that the pairs (K_1, K^+), (K_2, K^+), (K^-, K_1), and (K^-, K_2) each satisfy the 3 conditions on the pair (K_α, K_β) described above. Thus, the 4 1-dimensional invariant tori can be computed from these 4 pairs of equilibria. We will use this procedure to compute the 1-dimensional invariant torus $\phi^{-1}(T(2,1,1,0) \cap \mathscr{L}(4))$. It follows from the analysis in [37] that this periodic orbit is bounded by the equilibrium points $\phi^{-1}(T((2,0,2,0)) \cap \mathscr{L}(4))$ and $\phi^{-1}(T((2,2,0,0)) \cap \mathscr{L}(4))$, i.e. by K_1 and K^+. Thus, it is this pair of equilibrium points which is used to compute $\phi^{-1}(T((2,1,1,0)) \cap \mathscr{L}(4))$. We obtain

$$K(\theta) = \frac{1}{18}\begin{bmatrix} -22-4\cos\theta & -4-4\cos\theta & 2+2\cos\theta & 6\sin\theta \\ -4-4\cos\theta & -40-4\cos\theta & 2+2\cos\theta & 6\sin\theta \\ 2+2\cos\theta & 2+2\cos\theta & -73-\cos\theta & 36-3\sin\theta \\ 6\sin\theta & 6\sin\theta & 36-3\sin\theta & -45+9\cos\theta \end{bmatrix}.$$

The 3 other 1-dimensional invariant tori can be computed in a similar way.

Next, we illustrate the convergence results. Let K_0 be the matrix

$$\begin{bmatrix} -2 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & -4 & 2 \\ 0 & 0 & 2 & -2 \end{bmatrix},$$

and suppose we want to determine the behavior of the solution $K(t, K_0)$ as $t \to -\infty$. Since $K_0 - K^-$ is nonnegative definite, $K_0 \in F_-$. In other words, $K(t, K_0)$ has no finite

escape time as t decreases from 0. Consequently, $K(t, K_0)$ must approach one of the 9 invariant tori as $t \to -\infty$. To determine which torus the solution approaches, we use the unstable flag $N_1 \subset N_2 \subset N_3 \subset N_4$, where $N_1 = E_4$, $N_2 = E_3 \oplus E_4$, $N_3 = E_2 \oplus E_3 \oplus E_4$, and $N_4 = E_1 \oplus E_2 \oplus E_3 \oplus E_4 = \mathbb{R}^8$. By straightforward linear algebra, one finds that $\dim \phi(K_0) \cap N_1 = 0$, $\dim \phi(K_0) \cap N_2 = 1$, $\dim \phi(K_0) \cap N_3 = 2$, and $\dim \phi(K_0) \cap N_4 = 4$. Applying Theorem 23(d), we conclude that K_0 belongs to the unstable manifold of $\phi^{-1}(T((2,1,1,0)) \cap \mathscr{L}(4))$, which is the 1-dimensional invariant torus described in detail above.

At this point, we know that $K(t, K_0)$ approaches the invariant torus $\phi^{-1}(T((2,1,1,0)) \cap \mathscr{L}(4))$ as $t \to -\infty$. However, we can actually determine exactly which motion on the torus it approaches. To do this, we first compute the subspaces $\phi(K_0) \cap N_1$, $\phi(K_0) \cap N_2$, $\phi(K_0) \cap N_3$, $\phi(K_0) \cap N_4$, and then their images under the projections η_4, η_3, η_2, η_1 respectively. From this, we obtain

$$\hat{\Pi}_-(\phi(K_0)) = \mathrm{Sp}\left[\begin{array}{rrrr} -4 & -1 & 0 & 2 \\ 5 & -1 & 0 & 2 \\ 2 & -4 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ \hline 4 & 1 & 0 & -4 \\ -10 & 2 & 0 & -6 \\ -8 & 16 & 2 & 5 \\ 4 & -8 & -2 & -2 \end{array}\right].$$

Let X and Y denote the upper and lower submatrices of the indicated matrix. Then

$$\phi^{-1}(\hat{\Pi}_-(\phi(K_0)) = YX^{-1} = \frac{1}{9}\begin{bmatrix} -13 & -4 & 2 & 0 \\ -4 & -22 & 2 & 0 \\ 2 & 2 & -37 & 18 \\ 0 & 0 & 18 & -18 \end{bmatrix}.$$

We see that this matrix is in fact $K(\theta)$ for $\theta = 0$. By Theorem 23(d), the solution $K(t, K_0)$ converges to the periodic solution $K(t, \phi^{-1}(\hat{\Pi}_-(\phi(K_0))))$ as $t \to -\infty$.

6. Generalizations. In this section, we generalize the results in §§ 3, 4, and 5 to permit the infinitesimal generator (B or H) to have multiple eigenvalues. The results extend naturally provided we assume that the generator is semisimple (diagonalizable).

6.1. Extended Riccati differential equation. In this subsection, we generalize the results in § 3 concerning the phase portrait of the ERDE on $G^n(\mathbb{R}^{n+m})$. In place of Assumption A1, we assume only that the $(n+m) \times (n+m)$ matrix B is semisimple.

Let $\mu_1 < \mu_2 < \cdots < \mu_r$ denote the distinct real parts of the eigenvalues of B. Redefine E_i to be the direct sum of the primary components of B corresponding to all those eigenvalues of B with real part μ_i, and let n_i denote the dimension of E_i. Let $l = (l_1, \cdots, l_r)$ and $T(l)$ be defined as in § 3.1 (but using the new definition of E_i). $T(l)$ is no longer a torus. Instead, $T(l)$ is isomorphic to the product of Grassmann manifolds $G^{l_1}(\mathbb{R}^{n_1}) \times \cdots \times G^{l_r}(\mathbb{R}^{n_r})$ which has dimension equal to $\sum_{i=1}^{r} l_i(n_i - l_i)$.

It is clear that $T(l)$ is both positively and negatively invariant with respect to the flow of the ERDE. The argument given to establish the almost periodicity assertion in Theorem 1 is easily adapted to show that every motion on $T(l)$ is at worst almost periodic. It should be noted, however, that in contrast to the situation when Assumption

A1 is in force, a given $T(l)$ may contain equilibria, periodic motions of different periods, and nonperiodic almost periodic motions. Thus, the generalization of Theorem 1 is the following:

THEOREM 1′. *$T(l)$ is a product of Grassmann manifolds $G^{l_1}(\mathbb{R}^{n_1})\times\cdots\times G^{l_r}(\mathbb{R}^{n_r})$ of dimension $\sum_{j=1}^{r} l_j(n_j-l_j)$ which is both positively and negatively invariant. Every motion on $T(l)$ is almost periodic.*

Let $W^s(T(l))$, $W^u(T(l))$, $\{M_j\}_1^r$, Π_+, Π_-, $W^s(S_1)$, $W^u(S_1)$ be defined as in § 3.1. (Of course, the new definition of E_j must be used.) Trivial changes in the proof of Theorem 2 show that it holds in the new setting with no change in wording. Furthermore, $S(t, S_0)\to S(t, \Pi_+(S_0))$ as $t\to\infty$, and $S(t, S_0)\to S(t, \Pi_-(S_0))$ as $t\to-\infty$. No changes are required in either the statement or proof of Theorem 3.

To decompose the stable manifolds into cells, refine the stable flag $\{M_i\}_1^r$ to a complete flag

$$M_{11}\subset M_{12}\subset\cdots\subset M_{1n_1}\subset M_{21}\subset M_{22}\subset\cdots\subset M_{2n_2}\subset\cdots\subset M_{r1}\subset M_{r2}\subset\cdots\subset M_{rn_r}$$

where $M_{in_i}=M_i$. Let $l=(l_1,\cdots,l_r)$ be fixed. Let $b\equiv\{b_{ij}: j=1,\cdots,n_i;\ i=1,\cdots,r\}$ be such that $b_{ij}=0$ or 1 and $\sum_{j=1}^{n_i} b_{ij}=l_i$, $i=1,\cdots,r$. Let $W^s(T(l), b)\equiv\{S\in G^n(\mathbb{R}^{n+m}): \dim S\cap M_{ik}=\sum_{j=0}^{i-1} l_j+\sum_{j=1}^{k} b_{ij}, \forall i, k\}$ where we define $l_0=0$ for convenience. Then $W^s(T(l), b)$ is a subset of $W^s(T(l))$, and is a Schubert cell with respect to the complete flag $\{M_{ik}\}$. It is straightforward to show that

$$\dim W^s(T(l), b)=\sum_{i=1}^{r}\sum_{j=1}^{n_i} b_{ij}\left(\sum_{k=0}^{i-1}(n_k-l_k)+\sum_{k=1}^{j}(1-b_{ik})\right),$$

where we define $n_0=0$ for convenience. It follows immediately from this formula that $W^s(T(l))$ contains a unique cell of lowest dimension, and this dimension is equal to $\sum_{i=1}^{r} l_i\sum_{k=0}^{i-1}(n_k-l_k)$.

Recall from § 3.3 that $b_i(M, K)$ denotes the ith Betti number of the manifold M for the coefficient field K, and $b_s(G^n(\mathbb{R}^{n+m}), Z_2)$ is equal to the number of partitions of s into n parts of size less than or equal to m. From the formula above for $\dim W^s(T(l), b)$ together with some combinatorial analysis, we obtain the following generalization of Theorem 4. (The result for $W^u(T(l))$ is obtained in a completely analogous manner.)

THEOREM 4′. *$W^s(T(l))$ ($W^u(T(l))$) is the disjoint union of $\binom{n_1}{l_1}\cdots\binom{n_r}{l_r}$ cells. The number of cells of dimension*

$$\sum_{i=1}^{r} l_i\sum_{k=0}^{i-1}(n_k-l_k)+\nu \qquad \left(\text{dimension } \sum_{i=1}^{r} l_{r-i+1}\sum_{k=0}^{i-1}(n_{r-k+1}-l_{r-k+1})+\nu\right),$$

$$\nu=0, 1, \cdots, \sum_{i=1}^{r} l_i(n_i-l_i),$$

is equal to

$$\sum_{(\nu_1,\cdots,\nu_r)}\prod_{i=1}^{r} b_{\nu_i}(G^{l_i}(\mathbb{R}^{n_i}), Z_2),$$

where the summation is over all $(\nu_1,\cdots,\nu_r)$ satisfying $\nu_1+\cdots+\nu_r=\nu$ and $0\leqq\nu_i\leqq l_i(n_i-l_i)$, $i=1,\cdots,r$.

The generalization of Theorem 5 is as follows:

THEOREM 5′. *Let $S_1\in T(l)$. Then*

(a) *$W^s(S_1)$ is analytically isomorphic to Euclidean space of dimension*

$$\sum_{i=1}^{r} l_i\sum_{k=0}^{i-1}(n_k-l_k).$$

(b) *$W^u(S_1)$ is analytically isomorphic to Euclidean space of dimension*

$$\sum_{i=1}^{r} l_{r-i+1} \sum_{k=0}^{i-1} (n_{r-k+1} - l_{r-k+1}).$$

Proof. To prove (a), refine $\{M_j\}_1^r$ by first inserting the subspace $M_{j-1} \oplus (S_1 \cap E_j)$ between M_{j-1} and M_j, $j = 1, \cdots, r$. Then refine the resulting flag to a complete flag in any way. It follows from Theorem 3 and the proof of Theorem 4′ that $W^s(S_1)$ coincides with the unique lowest-dimensional cell in the decomposition of $W^s(T(l))$ determined by the complete flag. The assertion then follows immediately from Theorem 4′. (b) is proved analogously. □

It is no longer true that the ERDE has either an equilibrium point or a periodic orbit whose stable (unstable) manifold is open and dense. Instead, there is an invariant Grassmann manifold whose stable (unstable) manifold is open and dense. The proof of Theorem 6 can be modified in an obvious way to obtain

THEOREM 6′. (a) *Suppose that $\sum_{j=\nu+2}^{r} n_j < n \leqq \sum_{j=\nu+1}^{r} n_j$, let $k = n - \sum_{j=\nu+2}^{r} n_j$, and let $l_j = 0$ for $j \leqq \nu$, $l_{\nu+1} = k$, $l_j = n_j$ for $j \geqq \nu+2$. Then $T(l)$ is isomorphic to $G^k(\mathbb{R}^{n_{\nu+1}})$ and $W^s(T(l))$ is open and dense.*

(b) *Suppose that $\sum_{j=1}^{\nu-1} n_j < n \leqq \sum_{j=1}^{\nu} n_j$, let $k = n - \sum_{j=1}^{\nu-1} n_j$, and let $l_j = n_j$ for $j \leqq \nu-1$, $l_\nu = k$, $l_j = 0$ for $j \geqq \nu+1$. Then $T(l)$ is isomorphic to $G^k(\mathbb{R}^{n_\nu})$ and $W^u(T(l))$ is open and dense.*

Let $l = (l_1, \cdots, l_r)$ be fixed. From Theorem 4′, $W^s(T(l))$ is the union of $\binom{n_1}{l_1} \cdots \binom{n_r}{l_r}$ cells, with a unique highest dimensional cell which has dimension $\sum_{i=1}^{r} l_i \sum_{k=0}^{i} (n_k - l_k)$. By an obvious generalization of the argument preceding Theorem 7, the other $\binom{n_1}{l_1} \cdots \binom{n_r}{l_r} - 1$ cells can be "thickened" to give $\binom{n_1}{l_1} \cdots \binom{n_r}{l_r}$ submanifold charts for $W^s(T(l))$ (relative to the standard charts for $G^n(\mathbb{R}^{n+m})$). Thus, $W^s(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $\sum_{i=1}^{r} l_i \sum_{k=0}^{i} (n_k - l_k)$. Π_+ maps $W^s(T(l))$ onto $T(l)$, and if $S_1 \in T(l)$, then by Theorem 5′, $\Pi_+^{-1}(S_1)$ is isomorphic to Euclidean space of dimension $d_s \equiv \sum_{i=1}^{r} l_i \sum_{k=0}^{i-1} (n_k - l_k)$. Each of the $\binom{n_1}{l_1} \cdots \binom{n_r}{l_r}$ charts W_i for $W^s(T(l))$ is the inverse image of a corresponding chart $\bar{W}_i$ for $T(l) \cong G^{l_1}(\mathbb{R}^{n_1}) \times \cdots \times G^{l_r}(\mathbb{R}^{n_r})$. Furthermore, there exist real analytic isomorphisms $\gamma_i : W_i \to \bar{W}_i \times \mathbb{R}^{d_s}$ such that $p_i \circ \gamma_i = \Pi_+ | W_i$, where $p_i : \bar{W}_i \times \mathbb{R}^{d_s} \to \bar{W}_i$ is the natural projection. Hence, $\Pi_+ : W^s(T(l)) \to T(l)$ is a locally trivial bundle with $\mathbb{R}^{d_s}$ as fiber. The transition functions are invertible polynomial mappings of $\mathbb{R}^{d_s}$. Thus, Theorem 7 generalizes to give

THEOREM 7′.

(a) *$W^s(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $\sum_{i=1}^{r} l_i \sum_{k=0}^{i} (n_k - l_k)$.*

(b) *$\Pi_+ : W^s(T(l)) \to T(l)$ is a locally trivial bundle with fiber $\mathbb{R}^{d_s}$ and polynomial transition functions, where $d_s = \sum_{i=1}^{r} l_i \sum_{k=0}^{i-1} (n_k - l_k)$.*

(c) *$W^u(T(l))$ is an embedded submanifold of $G^n(\mathbb{R}^{n+m})$ of dimension $\sum_{i=1}^{r} l_{r-i+1} \sum_{k=0}^{i} (n_{r-k+1} - l_{r-k+1})$.*

(d) *$\Pi_- : W^u(T(l)) \to T(l)$ is a locally trivial bundle with fiber $\mathbb{R}^{d_u}$ and polynomial transition functions, where $d_u = \sum_{i=1}^{r} l_{r-i+1} \sum_{k=0}^{i-1} (n_{r-k+1} - l_{r-k+1})$.*

Lemma 1 is unaffected by the relaxation of the assumptions. Consequently, Proposition 1 generalizes to give

PROPOSITION 1′. *For any pair $l = (l_1, \cdots, l_r)$ and $l' = (l'_1, \cdots, l'_r)$, $W^s(T(l))$ and $W^u(T(l'))$ intersect transversally.*

In contrast to the situation when Assumption A1 is in force, it is no longer true that every equilibrium point is hyperbolic. Let S_0 be an equilibrium point, let $\{\alpha_i\}_1^n$ denote the eigenvalues of the restriction $B|S_0$, and let $\{\beta_j\}_1^m$ denote the remaining eigenvalues of B. It is easily shown that even if B is nondiagonalizable, the eigenvalues

of the linearization of the ERDE at S_0 are $\{\beta_j - \alpha_i : i = 1, \cdots, n; j = 1, \cdots, m\}$. It follows immediately that S_0 is hyperbolic if and only if $\{S_0\} = T(l)$ for some l. Thus, the correct generalization of Proposition 2 (which is valid even if B is not semisimple) is

PROPOSITION 2'. *The hyperbolic equilibrium points of the* ERDE *are* $\{T(l) : \dim T(l) = 0\}$.

If $\dim T(l) = 1$, then there exists $j_0 \in \{1, \cdots, r\}$ such that $l_{j_0} = 1$, $n_{j_0} = 2$, and $l_i = 0$ or $l_i = n_i$ for $i \neq j_0$. Topologically, $T(l)$ is a circle. There are 2 cases to consider depending on whether $B|E_{j_0}$ has a real eigenvalue of multiplicity 2 or a pair of complex conjugate eigenvalues. In the first case, every point on $T(l)$ is B-invariant and hence an equilibrium point. In the second case, $T(l)$ is an isolated periodic orbit. The construction of a Poincaré map for $T(l)$ and the calculation of the eigenvalues of its derivative are identical to the construction and calculation which establish Proposition 3. Consequently, in place of the corollary to that result we have

PROPOSITION 3'. *If* $\dim T(l) = 1$, *then either every point on* $T(l)$ *is an equilibrium point, or* $T(l)$ *is a hyperbolic periodic orbit.*

Under the assumption that B is semisimple, it follows from Theorem 1', Proposition 1', Proposition 2', and Proposition 3' that the ERDE is Morse-Smale if and only if each $T(l)$ has dimension at most 1 and each 1-dimensional $T(l)$ is a periodic orbit rather than a circle of equilibria. It is clear that excepting the trivial cases where $n = 0$ or $m = 0$, a necessary condition for the ERDE to be Morse-Smale is that Assumption A1 be satisfied.

By analogy to the definition of the Morse series for a Morse-Bott function (i.e. a function with nondegenerate critical submanifolds), we define the Morse series for the ERDE with semisimple generator B to be

$$M_B(t) = \sum_l P_{Z_2}(T(l); t)\, t^{\mathrm{Ind}\,(T(l))},$$

where $P_{Z_2}(T(l); t)$ is the Poincaré polynomial of $T(l)$ for the coefficient field Z_2 and $\mathrm{Ind}\,(T(l)) = \dim W^s(T(l)) - \dim T(l)$. By Theorem 1', $P_{Z_2}(T(l); t) = \Pi_{i=1}^r P_{Z_2}(G^{l_i}(\mathbb{R}^{n_i}); t)$. In the special case when $T(l)$ is a k-dimensional torus, this simplifies to $(1+t)^k$. Thus, the definition of $M_B(t)$ given here reduces to the definition given in § 3.3 if Assumption A1 is satisfied.

The next result generalizes Theorem 11 to show that the ERDE satisfies Morse-Bott type *equalities.*

THEOREM 11'. *Suppose that* $B \in \mathrm{gl}\,(n+m, \mathbb{R})$ *is semisimple. Then*

$$M_B(t) = P_{Z_2}(G^n(\mathbb{R}^{n+m}); t).$$

Proof. By refining the stable flag to a complete flag, we obtain a decomposition of $G^n(\mathbb{R}^{n+m})$ into $\binom{n+m}{n}$ cells. As in the proof of Theorem 11, we have

$$P_{Z_2}(G^n(\mathbb{R}^{n+m}); t) = \sum_{\substack{\text{all} \\ \text{cells}}} t^{\dim \text{cell}}.$$

It follows from Theorem 4' that

$$t^{\mathrm{Ind}\,T(l)} \prod_{i=1}^r P_{Z_2}(G^{l_i}(\mathbb{R}^{n_i}); t) = \sum_{\substack{\text{all cells} \\ \text{in } W^s(T(l))}} t^{\dim \text{cell}}.$$

Summing this equation over all choices for l, the left-hand side gives $M_B(t)$ while the right-hand side gives $P_{Z_2}(G^n(\mathbb{R}^{n+m}); t)$. □

6.2. Extended symplectic Riccati differential equation. In this subsection, we generalize the results in § 4 concerning the phase portrait of the ESRDE on $\mathscr{L}(n)$. In place of Assumption A2, we assume only that the $2n \times 2n$ matrix H is semisimple and has no eigenvalues on the imaginary axis.

Let $\mu_1 < \mu_2 < \cdots < \mu_{2r}$ denote the distinct real parts of the eigenvalues of H. Redefine E_i to be the direct sum of the primary components of H corresponding to all those eigenvalues of H with real part μ_i, and let n_i denote the dimension of E_i. Since $H \in \mathrm{sp}(n, \mathbb{R})$, $\mu_i = -\mu_{2r-i+1}$ and $n_i = n_{2r-i+1}$.

Let $l = (l_1, \cdots, l_{2r})$ and $T(l)$ be defined as in § 4.1. $T(l)$ is isomorphic to the product of Grassmann manifolds $G^{l_1}(\mathbb{R}^{n_1}) \times \cdots \times G^{l_{2r}}(\mathbb{R}^{n_{2r}})$ which has dimension equal to $\sum_{i=1}^{2r} l_i(n_i - l_i)$. Essentially the same argument as that given in § 4.1 shows that Proposition 4 holds with no change in wording. Thus, $T(l) \cap \mathscr{L}(n)$ is nonempty if and only if $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$, in which case $T(l) \cap \mathscr{L}(n)$ is isomorphic to $G^{l_1}(\mathbb{R}^{n_1}) \times \cdots \times G^{l_r}(\mathbb{R}^{n_r})$. In particular, $\dim T(l) \cap \mathscr{L}(n) = \frac{1}{2} \dim T(l)$. We obtain the following generalization of Theorem 12.

THEOREM 12′. *The nonwandering set of the* ESRDE *has* $(n_1+1) \cdots (n_r+1)$ *connected components,* $\{T(l) \cap \mathscr{L}(n) : l_i + l_{2r-i+1} = n_i,\ i = 1, \cdots, r\}$. $T(l) \cap \mathscr{L}(n)$ *is isomorphic to* $G^{l_1}(\mathbb{R}^{n_1}) \times \cdots \times G^{l_r}(\mathbb{R}^{n_r})$. *Every motion on* $T(l) \cap \mathscr{L}(n)$ *is almost periodic.*

Next we consider the structure of the stable manifold $W^s(T(l)) \cap \mathscr{L}(n)$ and the unstable manifold $W^u(T(l) \cap \mathscr{L}(n))$ of $T(l) \cap \mathscr{L}(n)$, where $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$. Refine the stable flag $\{M_i\}_1^{2r}$ to a complete flag $\{M_{ij} : j = 1, \cdots, n_i;\ i = 1, \cdots, 2r\}$. By making a symplectic change of basis if necessary, we may assume $\{M_{ij}\}$ is the standard symplectic flag for $\mathbb{R}^{2n}$. From § 6.1, we know that $W^s(T(l))$ is the union of

$$\left[\binom{n_1}{l_1} \cdots \binom{n_r}{l_r}\right]^2$$

cells $\{W^s(T(l), b)\}$. It follows from Lemmas 6 and 7 that $W^s(T(l), b) \cap \mathscr{L}(n)$ is nonempty if and only if $b_{ij} + b_{2r-i+1, n_i - j+1} = 1$, all i, j. Thus, exactly $\binom{n_1}{l_1} \cdots \binom{n_r}{l_r}$ cells have nonempty intersection with $\mathscr{L}(n)$. Suppose that $b_{ij} + b_{2r-i+1, n_i-j+1} = 1$, all i, j. Using the formula for $\dim W^s(T(l), b)$ from § 6.1 together with Lemma 7 gives

$$\dim W^s(T(l), b) \cap \mathscr{L}(n) = \frac{1}{2}\left[n - \sum_{i=1}^{r} l_i + \sum_{i=1}^{2r} \sum_{j=1}^{n_i} b_{ij}\left(\sum_{k=0}^{i-1} (n_k - l_k) + \sum_{k=1}^{j} (1 - b_{ik})\right)\right].$$

The following generalization of Theorem 13 is an easy consequence.

THEOREM 13′. *Suppose that* $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$. $W^s(T(l)) \cap \mathscr{L}(n)$ $(W^u(T(l)) \cap \mathscr{L}(n))$ *is the disjoint union of*

$$\binom{n_1}{l_1} \cdots \binom{n_r}{l_r} \textit{ cells.}$$

The number of cells of dimension

$$\frac{1}{2}\left[n - \sum_{i=1}^{r} l_i + \sum_{i=1}^{2r} l_i \sum_{k=0}^{i-1} (n_k - l_k)\right] + \nu$$

$$\left(\textit{dimension } \frac{1}{2}\left[n - \sum_{i=1}^{r} l_{2r-i+1} + \sum_{i=1}^{2r} l_{2r-i+1} \sum_{k=0}^{i-1} (n_{2r-k+1} - l_{2r-k+1})\right] + \nu\right),$$

$$\nu = 0, 1, \cdots, \sum_{i=1}^{r} l_i(n_i - l_i),$$

is equal to

$$\sum_{(\nu_1,\cdots,\nu_r)} \prod_{i=1}^{r} b_{\nu_i}(G^{l_i}(\mathbb{R}^{n_i}), Z_2),$$

where the summation is over all $(\nu_1, \cdots, \nu_r)$ *satisfying* $\nu_1 + \cdots + \nu_r = \nu$ *and* $0 \leqq \nu_i \leqq l_i(n_i - l_i)$, $i = 1, \cdots, r$.

The generalization of Theorem 14 is as follows:

THEOREM 14′. *Suppose that* $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$. *Let* $S_1 \in T(l) \cap \mathscr{L}(n)$. *Then*

(a) $W^s(S_1) \cap \mathscr{L}(n)$ *is analytically isomorphic to Euclidean space of dimension*

$$\frac{1}{2}\left[n - \sum_{i=1}^{r} l_i + \sum_{i=1}^{2r} l_i \sum_{k=0}^{i-1} (n_k - l_k)\right].$$

(b) $W^u(S_1) \cap \mathscr{L}(n)$ *is analytically isomorphic to Euclidean space of dimension*

$$\frac{1}{2}\left[n - \sum_{i=1}^{r} l_{2r-i+1} + \sum_{i=1}^{2r} l_{2r-i+1} \sum_{k=0}^{i-1} (n_{2r-k+1} - l_{2r-k+1})\right].$$

Proof. (a) As in the proof of Theorem 14, it is clear that by making a symplectic change of coordinates, we may assume that the standard symplectic flag refines the stable flag $\{M_j\}_1^{2r}$ and that S_1 is spanned by $\{e_{m_{i-1}+j} : 1 \leqq i \leqq r$ such that $l_i \neq 0; j = 1, \cdots, l_i\} \cup \{e_{3n-m_{i-1}+1-j} : r+1 \leqq i \leqq 2r$ such that $l_i \neq 0$; $j = 1, \cdots, l_i\}$ where $m_i = \dim M_i$. Then (as in the proof of Theorem 5′) $W^s(S_1)$ coincides with the lowest dimensional cell in the decomposition of $W^s(T(l))$ induced by the standard symplectic flag. In other words, $W^s(S_1) = W^s(T(l), \mathrm{b})$ where $b_{ij} = 1$ for $j = 1, \cdots, l_i$ and $b_{ij} = 0$ for $j = l_i + 1, \cdots, n_i$. Then $W^s(S_1) \cap \mathscr{L}(n) = W^s(T(l), b) \cap \mathscr{L}(n)$ coincides with the lowest dimensional cell in the corresponding decomposition of $W^s(T(l)) \cap \mathscr{L}(n)$, and is therefore isomorphic to Euclidean space. The dimension formula follows immediately from Theorem 13′.

The proof of (b) is analogous to the proof of (a). □

Theorem 15 remains true under the weaker assumptions, and its proof is unchanged. Thus, the ESRDE has an equilibrium point whose stable manifold is open and dense in $\mathscr{L}(n)$, and an equilibrium point whose unstable manifold is open and dense in $\mathscr{L}(n)$.

Theorem 16 generalizes to give the following result in a manner which is analogous to the generalization of Theorem 7 to give Theorem 7′.

THEOREM 16′. *Suppose that* $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$. *Then*

(a) $W^s(T(l)) \cap \mathscr{L}(n)$ *is an embedded submanifold of* $\mathscr{L}(n)$ *of dimension*

$$\frac{1}{2}\left[n - \sum_{i=1}^{r} l_i + \sum_{i=1}^{2r} l_i \sum_{k=0}^{i} (n_k - l_k)\right].$$

(b) $\hat{\Pi}_+ : W^s(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$ *is a locally trivial bundle with fiber* $\mathbb{R}^{d_s}$ *and polynomial transition functions, where*

$$d_s = \frac{1}{2}\left[n - \sum_{i=1}^{r} l_i + \sum_{i=1}^{2r} l_i \sum_{k=0}^{i-1} (n_k - l_k)\right].$$

(c) $W^u(T(l)) \cap \mathscr{L}(n)$ *is an embedded submanifold of* $\mathscr{L}(n)$ *of dimension*

$$\frac{1}{2}\left[n - \sum_{i=1}^{r} l_{2r-i+1} + \sum_{i=1}^{2r} l_{2r-i+1} \sum_{k=0}^{i} (n_{2r-k+1} - l_{2r-k+1})\right].$$

(d) $\hat{\Pi}_-: W^u(T(l)) \cap \mathscr{L}(n) \to T(l) \cap \mathscr{L}(n)$ *is a locally trivial bundle with fiber* $\mathbb{R}^{d_u}$ *and polynomial transition functions, where*

$$d_u = \frac{1}{2}\left[n - \sum_{i=1}^{r} l_{2r-i+1} + \sum_{i=1}^{2r} l_{2r-i+1} \sum_{k=0}^{i-1} (n_{2r-k+1} - l_{2r-k+1}) \right].$$

Lemma 8 is unaffected by the weakened assumptions. Consequently, Proposition 5 holds with no changes required in the proof other than the replacement of Theorem 13 by Theorem 13′. Hence, $W^s(T(l)) \cap \mathscr{L}(n)$ and $W^u(T(l')) \cap \mathscr{L}(n)$ intersect only transversally.

It is no longer true that every equilibrium point of the ESRDE is hyperbolic. Let S_0 be an equilibrium point and let $\{\lambda_i\}_1^n$ denote the eigenvalues of the restriction $H|S_0$. It is easily shown that even if H is nondiagonalizable, the eigenvalues of the linearization of the ESRDE at S_0 are $\{-\lambda_j - \lambda_i : 1 \leqq i \leqq j \leqq n\}$. It follows immediately that the correct generalization of Proposition 6 (which is valid even if H is not semisimple) is

PROPOSITION 6′. *The hyperbolic equilibrium points of the* ESRDE *are* $\{T(l)$: $l_j = 0$ *or* $l_j = n_j$ *and* $l_j + l_{2r-j+1} = n_j$, $j = 1, \cdots, r\}$.

Thus, the ESRDE has exactly 2^r hyperbolic equilibria.

If $\dim T(l) \cap \mathscr{L}(n) = 1$, then each element of $T(l) \cap \mathscr{L}(n)$ is of the form $E_{j_1} \oplus \cdots \oplus E_{j_{r-1}} \oplus \tilde{S} \oplus ([J(\tilde{S})]^{\perp} \cap E_{2r-j_0+1})$ where $j \in \{j_1, \cdots, j_{r-1}\}$ iff $2r-j+1 \notin \{j_1, \cdots, j_{r-1}\}$, j_0 and $2r-j_0+1$ do not belong to $\{j_1, \cdots, j_{r-1}\}$, $\dim E_{j_0} = 2$, and $\tilde{S}$ is any 1-dimensional subspace of E_{j_0}. Topologically, $T(l) \cap \mathscr{L}(n)$ is a circle. There are 2 cases to consider depending on whether $H|E_{j_0}$ has a real eigenvalue of multiplicity 2 or a pair of complex conjugate eigenvalues. In the first case, every point on $T(l) \cap \mathscr{L}(n)$ is H-invariant and hence an equilibrium point. In the second case, $T(l) \cap \mathscr{L}(n)$ is an isolated periodic orbit. The construction of a Poincaré map for $T(l) \cap \mathscr{L}(n)$ and the calculation of the eigenvalues of its derivative are identical to the construction and calculation which establish Proposition 7. Consequently, in place of the corollary to that result we have

PROPOSITION 7′. *If* $\dim T(l) \cap \mathscr{L}(n) = 1$, *then either every point on* $T(l) \cap \mathscr{L}(n)$ *is an equilibrium point, or* $T(l) \cap \mathscr{L}(n)$ *is a hyperbolic periodic orbit.*

Under the assumption that H is semisimple and has no eigenvalues on the imaginary axis, it follows from Theorem 12′ and Propositions 5, 6′, 7′ that the ESRDE is Morse-Smale if and only if $T(l) \cap \mathscr{L}(n)$ has dimension at most 1 and each 1-dimensional $T(l) \cap \mathscr{L}(n)$ is a periodic orbit rather than a circle of equilibria. It is clear that a necessary condition for the ESRDE to be Morse-Smale is that Assumption A2 be satisfied.

We define the Morse series for the ESRDE with semisimple generator H to be

$$M_H(t) = \sum_l P_{Z_2}(T(l) \cap \mathscr{L}(n); t) t^{\operatorname{Ind}(T(l) \cap \mathscr{L}(n))}$$

where $P_{Z_2}(T(l) \cap \mathscr{L}(n); t)$ is the Poincaré polynomial of $T(l) \cap \mathscr{L}(n)$ for the coefficient field Z_2, $\operatorname{Ind}(T(l) \cap \mathscr{L}(n)) = \dim W^s(T(l)) \cap \mathscr{L}(n) - \dim T(l) \cap \mathscr{L}(n)$, and the summation is over those l satisfying $l_i + l_{2r-i+1} = n_i$, $i = 1, \cdots, r$. By Theorem 12′, $P_{Z_2}(T(l) \cap \mathscr{L}(n); t) = \Pi_{i=1}^{r} P_{Z_2}(G^{l_i}(\mathbb{R}^{n_i}); t)$. The definition of $M_H(t)$ specializes to that given in § 4.3 if Assumption A2 is satisfied.

The next result generalizes Theorem 20 to show that the ESRDE satisfies Morse-Bott-type *equalities*. It is proven by using Theorem 13′ in place of Theorem 13 in the proof of Theorem 20.

THEOREM 20′. *Suppose that* $H \in \operatorname{sp}(n, \mathbb{R})$ *is semisimple and has no eigenvalues on the imaginary axis. Then*

$$M_H(t) = P_{Z_2}(\mathscr{L}(n); t).$$

6.3. Symplectic Riccati differential equation. In this subsection, we generalize the results in § 5 concerning the phase portrait of the SRDE on the space $S(n)$ of symmetric matrices. From Lemma 10 and Theorem 12′, we immediately obtain the following generalization of Theorem 21.

THEOREM 21′. *Suppose that H is semisimple and has no eigenvalues on the imaginary axis, and that $L = BB'$ with (A, B) controllable. The nonwandering set of the* SRDE *has $(n_1+1)\cdots(n_r+1)$ connected components, $\{\phi^{-1}(T(l)\cap\mathscr{L}(n))\colon l_i + l_{2r-i+1} = n_i,\ i = 1,\cdots,r\}$. $\phi^{-1}(T(l)\cap\mathscr{L}(n))$ is isomorphic to $G^{l_1}(\mathbb{R}^{n_1})\times\cdots\times G^{l_r}(\mathbb{R}^{n_r})$. Every motion on $\phi^{-1}(T(l)\cap\mathscr{L}(n))$ is almost periodic.*

No change in proof is required to show that Theorem 22 remains true under the weakened assumptions that H is semisimple and $L = BB'$, $Q = C'C$ with (A, B) controllable and (C, A) observable.

Let F_+, F_-, $R^s(l)$, $R^u(l)$ be as defined in § 5.2. No essential changes in the proof of Theorem 23 are required to show that it holds under the weakened assumptions that H is semisimple with no eigenvalues on the imaginary axis and $L = BB'$ with (A, B) controllable.

Since Theorem 22 holds under the weakened assumptions stated above, it follows immediately that Theorem 24 holds under the assumptions that H is semisimple and $L = BB'$, $Q = C'C$ with (A, B) controllable and (C, A) observable.

Theorems 21′ and 23 describe the nonwandering set and the asymptotic behavior of every solution of the SRDE assuming only that H is semisimple with no eigenvalues on the imaginary axis and that $L = BB'$ with (A, B) controllable. If in addition $Q = C'C$ with (C, A) observable, then Theorems 22 and 24 describe the (constant) signature of every nonwandering solution as well as the asymptotic signature of every solution.

While Theorem 21′ shows that every nonwandering solution is almost periodic, it does not specify which of these solutions are actually constant or periodic. However, prior results are available which do this. Since they apply even when H is not semisimple, their description is deferred to the next subsection.

6.4. Nondiagonalizable case. The phase portraits of the ERDE, ESRDE, and SRDE are considerably more complicated when the infinitesimal generators (B for the ERDE, H for the ESRDE and SRDE) are not semisimple.

First we consider the ERDE in the case where the $(n+m)\times(n+m)$ matrix B is nondiagonalizable. The sets $\{T(l)\}$ can be defined as in § 6.1. As before, $T(l)$ is isomorphic to the product $G^{l_1}(\mathbb{R}^{n_1})\times\cdots\times G^{l_r}(\mathbb{R}^{n_r})$ and is both positively and negatively invariant under the flow of the ERDE.

In contrast to the case where B is semisimple, it is generally not true that every motion on $T(l)$ is almost periodic. For example, if $n = m = 1$ and

$$B = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix},$$

then the ERDE is a differential equation on $G^1(\mathbb{R}^2)$, which is topologically the circle S^1. The only choice for l is $l = (1)$ for which $T(l) \cong G^1(\mathbb{R}^2)$. It is clear that $T(l)$ contains exactly 1 equilibrium point,

$$\operatorname{Sp}\begin{bmatrix} 1 \\ 0 \end{bmatrix},$$

and that every motion converges to this point as $t \to \pm\infty$.

In general, when B is not diagonalizable, the motion on $T(l)$ can be quite complicated. For example, the set of equilibria is the subvariety of $G^n(\mathbb{R}^{n+m})$ consisting of all n-dimensional B-invariant subspaces. The geometric structure of this subvariety

is still not completely understood although a number of results have been obtained in recent years. (See e.g. [11], [45], [44], [20], [39]). Similarly, given $T>0$, the set of points on nontrivial T-periodic orbits consists of those n-dimensional subspaces of $\mathbb{R}^{n+m}$ which are e^{BT}-invariant but not B-invariant.

We next consider the ESRDE assuming only that the Hamiltonian matrix H has no eigenvalues with zero real part. Proposition 4 remains valid as stated with only minor modification of the proof required. Thus, the ESRDE has $(n_1+1)\cdots(n_r+1)$ invariant manifolds given by $\{T(l)\cap\mathscr{L}(n)\colon l_i+l_{2r-i+1}=n_i,\ i=1,\cdots,r\}$, with $T(l)\cap\mathscr{L}(n)$ isomorphic to $G^{l_1}(\mathbb{R}^{n_1})\times\cdots\times G^{l_r}(\mathbb{R}^{n_r})$. Of course, $T(l)\cap\mathscr{L}(n)$ now may contain wandering points.

Since the equilibrium set of the ESRDE consists of $\{S\in\mathscr{L}(n)\colon H(S)\subseteq S\}$, it is clear that the equilibrium set is contained in the union of the $\{T(l)\cap\mathscr{L}(n)\}$. By Lemma 4, the mapping $S\to S\cap L^+(H)$ is a bijection of the equilibrium set onto the set of all invariant subspaces of the restriction $H|L^+(H)$. It is shown in [36] that this bijection is actually an isomorphism of projective varieties. Hence, the problem of describing the structure of the equilibrium set reduces to that of describing the variety of invariant subspaces of $H|L^+(H)$, and the results in the papers referred to above can again be applied.

If $S\in\mathscr{L}(n)$ generates a nontrivial periodic orbit of period $T>0$, then S is e^{HT}-invariant, but not H-invariant. It is clear that all such S belong to the union of the $\{T(l)\cap\mathscr{L}(n)\}$. By Lemma 4, the mapping $S\to S\cap L^+(H)$ gives a bijection of the set of points which generate nontrivial T-periodic orbits and the set of all subspaces of $L^+(H)$ which are e^{HT}-invariant but not H-invariant.

Finally, we consider the SRDE assuming only that $L=BB'$ with (A, B) controllable and that H has no eigenvalues on the imaginary axis. By Lemma 10, each invariant manifold $T(l)\cap\mathscr{L}(n)$ for the ESRDE is completely contained in $\mathscr{L}_0(n)$ and hence corresponds to an invariant manifold $\phi^{-1}(T(l)\cap\mathscr{L}(n))$ for the SRDE. $\phi^{-1}(T(l)\cap\mathscr{L}(n))$ is isomorphic to $G^{l_1}(\mathbb{R}^{n_1})\times\cdots\times G^{l_r}(\mathbb{R}^{n_r})$, and the union of the manifolds $\{\phi^{-1}(T(l)\cap\mathscr{L}(n))\}$ contains all of the equilibria and periodic orbits.

Let $A^+=A-BB'K^+$. A well-known result of J. C. Willems [47] states that there is a bijection of the set of all A^+-invariant subspaces of $\mathbb{R}^n$ onto the equilibrium set of the SRDE. This bijection is given by $M\to K^+P(M)+K^-(I-P(M))$, where $P(M)$ is the projection onto the A^+-invariant subspace M along $\Delta^{-1}(M^\perp)$. (Recall that $\Delta=K^+-K^-$.) It is shown in [36] that by identifying the equilibrium set with its image under the embedding ϕ, the bijection is an isomorphism of projective varieties. Consequently, the geometric structure of the equilibrium set is the same as that of the variety of invariant subspaces of A^+. This fact is used in [36] to obtain a description of some of the geometric properties of the equilibrium set.

In [37], we have generalized Willems' result to classify the periodic orbits as well as the equilibrium points. Given any $T>0$, the mapping $M\to K^+P(\mathrm{M})+K^-(I-P(\mathrm{M}))$ is a bijection of the set of e^{A^+T}-invariant subspaces of $\mathbb{R}^n$ onto the set of points which generate T-periodic motions. Of course, the subspaces which are e^{A^+T}-invariant but not A^+-invariant correspond to the points which generate nonconstant T-periodic motions.

More generally, let M be an arbitrary subspace of $\mathbb{R}^n$, let $P(M)$ denote the projection onto M along $\Delta^{-1}(\mathrm{M}^\perp)$, and let $K=K^+P(\mathrm{M})+K^-(I-P(\mathrm{M}))$. Then it follows easily that

$$\mathrm{Sp}\begin{bmatrix} I \\ K \end{bmatrix} = S^+\oplus S^-$$

where

$$S^+ = \mathrm{Sp}\begin{bmatrix} I \\ K^+ \end{bmatrix} P(\mathrm{M}) \quad \text{and} \quad S^- = \mathrm{Sp}\begin{bmatrix} I \\ K^- \end{bmatrix} (I - P(M)).$$

From the definition of $P(M)$ it follows that $P(\mathrm{M})'\Delta(I - P(\mathrm{M})) = 0$, which implies that $S^- \subseteq [J(S^+)]^\perp \cap L^-(H)$. Define a new Hamiltonian matrix $\tilde{H}$ by setting $\tilde{H}x = -x$, $\forall x \in L^+(H)$ and $\tilde{H}x = x$, $\forall x \in L^-(H)$. The $\tilde{H}$-invariance of S^+ implies the $\tilde{H}$-invariance of $[J(S^+)]^\perp$. Consequently, $[J(S^+)]^\perp = ([J(S^+)]^\perp \cap L^+(\tilde{H})) \oplus ([J(S^+)]^\perp \cap L^-(\tilde{H})) = L^+(H) \oplus ([J(S^+)]^\perp \cap L^-(H))$, which implies that $\dim [J(S^+)]^\perp \cap L^-(\mathrm{H}) = n - \dim S^+ = \dim S^-$. Hence, $S^- = [J(S^+)]^\perp \cap L^-(\mathrm{H})$. Thus, if K is of the form $K^+P(\mathrm{M}) + K^-(I - P(\mathrm{M}))$ with M an arbitrary subspace of $\mathbb{R}^n$, then $\phi(\mathrm{K})$ is of the form $S^+ \oplus ([J(S^+)]^\perp \cap L^-(\mathrm{H}))$ with S^+ an arbitrary subspace of $L^+(\mathrm{H})$. In other words, ϕ gives a one-to-one correspondence between the set of symmetric matrices of the form $K^+P(\mathrm{M}) + K^-(I - P(\mathrm{M}))$ and the subset of $\mathscr{L}(n)$ consisting of subspaces of the form $S^+ \oplus ([J(\mathrm{S}^+)]^\perp \cap L^-(\mathrm{H}))$.

Now, $S^+ \oplus ([J(S^+)]^\perp \cap L^-(H)) \in T(l) \cap \mathscr{L}(n)$ if and only if S^+ is of the form $S^+ = S_1 \oplus \cdots \oplus S_r$ with $S_i \in G^{l_i}(E_i)$. It is well-known that A^+ is the matrix for $H|L^+(H)$ with respect to the basis given by the columns of $\left[\begin{smallmatrix} I \\ K^+ \end{smallmatrix}\right]$. (See e.g. [35].) Let F_i denote the A^+-invariant subspace of $\mathbb{R}^n$ corresponding to the eigenvalues of $H|E_i$. In other words,

$$\begin{bmatrix} I \\ K^+ \end{bmatrix} (F_i) = E_i, \quad i = 1, \cdots, r.$$

Since

$$S^+ = \begin{bmatrix} I \\ K^+ \end{bmatrix} (M),$$

it follows that $\phi(K) \in T(l) \cap \mathscr{L}(n)$ if and only if M is of the form $W_1 \oplus \cdots \oplus W_r$ with $W_i \in G^{l_i}(F_i)$, $i = 1, \cdots, r$. We obtain the following result, which extends to the invariant manifolds $\{\phi^{-1}(T(l) \cap \mathscr{L}(n))\}$ the classification theorem in [47] for the equilibria and in [37] for the periodic orbits.

THEOREM 25. *Suppose that $L = BB'$ with (A, B) controllable and that H has no imaginary axis eigenvalues. Then $K \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$ if and only if K is of the form*

$$K = K^+P(M) + K^-(I - P(M)),$$

where M is of the form $M = \bigoplus_{i=1}^r W_i$ with $W_i \in G^{l_i}(F_i)$ and $P(M)$ is the projection onto M along $\Delta^{-1}(M^\perp)$.

The proof of Theorem 22 remains valid if the assumptions are weakened to include only that $L = BB'$ with (A, B) controllable and $Q = C'C$ with (C, A) observable. Thus, under these assumptions, every $K \in \phi^{-1}(T(l) \cap \mathscr{L}(n))$ is nonsingular and has exactly $\sum_{i=1}^r l_i$ positive eigenvalues. This result is also an easy consequence of Theorem 25 together with the fact that $K^+ > 0$ and $K^- < 0$.

7. Conclusion. In this paper, we have given a complete description for the phase portraits of the extended Riccati differential equation (ERDE) on the Grassmann manifold, the extended symplectic Riccati differential equation (ESRDE) on the Lagrange-Grassmann manifold, and the symplectic Riccati differential equation (SRDE) on the space of real symmetric matrices. The results are true under very general conditions. In particular, our characterization of the phase portrait of the SRDE applies to an open and dense subset of the Riccati equations which arise from the optimal control and filtering problems.

Let us briefly recapitulate the principal features of the three phase portraits. Under Assumption A1, the nonwandering set of the ERDE is a union of finitely many invariant tori of various dimensions. The 0-dimensional invariant tori are the equilibrium points. The 1-dimensional invariant tori are isolated periodic orbits. The motion on an invariant torus of dimension greater than one is either periodic or almost periodic, depending on whether or not the imaginary parts of the associated eigenvalues are commensurable.

The key to describing the stable and unstable manifolds of the invariant tori is to associate with the ERDE a stable and unstable flag of subspaces. Each flag induces a partition of the Grassmann manifold into disjoint subsets. In the case of the stable (unstable) flag, the induced partition is precisely the partition of the phase space into the stable (unstable) manifolds of the invariant tori. By refining the stable (unstable) flag to a complete flag, a Schubert cell decomposition of the Grassmann manifold is obtained. The stable (unstable) manifold of a k-dimensional invariant torus is decomposed into the union of 2^k cells.

Although the ERDE is generally *not* a Morse-Smale vector field, it has several properties which bear striking resemblance to important properties of Morse-Smale vector fields. The nonwandering set of a Morse-Smale vector field is by definition the union of finitely many equilibrium points (0-dimensional invariant tori) and periodic orbits (1-dimensional invariant tori). As noted above, the nonwandering set of the ERDE is a union of finitely many invariant tori, but whose dimension may be greater than one. The stable and unstable manifolds of a Morse-Smale vector field are embedded submanifolds. We have proven that this is the case for the ERDE. For a Morse-Smale vector field, each stable (unstable) manifold is a bundle over the corresponding connected component of the nonwandering set (point or closed orbit) with Euclidean space as fiber. We have proven that each stable (unstable) manifold for the ERDE is a bundle over the corresponding invariant torus with Euclidean space as fiber. By definition, the stable and unstable manifolds of a Morse-Smale vector field always intersect transversally. We have shown that the same is true for the stable and unstable manifolds of the ERDE. The global phase portrait of a Morse-Smale vector field is related to the topology of the underlying manifold by the Morse inequalities for a dynamical system. We have seen that the ERDE satisfies a natural generalization of these inequalities. In fact, for the ERDE, they are actually *equalities.*

The ESRDE is a differential equation on the Lagrange-Grassmann manifold $\mathscr{L}(n)$. But it is useful to extend it to a differential equation on the Grassmann manifold $G^n(\mathbb{R}^{2n})$. When viewed as a differential equation on $G^n(\mathbb{R}^{2n})$, the ESRDE is a special case of the ERDE. Thus, the results for the ERDE give a complete description of the phase portrait for the ESRDE on $G^n(\mathbb{R}^{2n})$. To obtain the phase portrait for the ESRDE on $\mathscr{L}(n)$, we make use of the fact that the submanifold $\mathscr{L}(n)$ is both positively and negatively invariant under the flow of the ESRDE on $G^n(\mathbb{R}^{2n})$. Consequently, the nonwandering set of the ESRDE on $\mathscr{L}(n)$ is the intersection with $\mathscr{L}(n)$ of the nonwandering set of the ESRDE on $G^n(\mathbb{R}^{2n})$. Under Assumption A2, we have shown that a given invariant torus for the ESRDE on $G^n(\mathbb{R}^{2n})$ either does not intersect $\mathscr{L}(n)$ or intersects $\mathscr{L}(n)$ in a torus of one-half its dimension. Thus, the nonwandering set of the ESRDE on $\mathscr{L}(n)$ is a union of invariant tori. In fact, if $2p$ ($4q$) denotes the number of real (nonreal) eigenvalues of the associated Hamiltonian matrix H, then there are $\binom{q}{k}2^{p+q-k}$ invariant tori of dimension k, $k=0, 1, \cdots, q$.

It follows from the invariance of $\mathscr{L}(n)$ under the flow that the stable (unstable) manifolds of the invariant tori for the ESRDE on $\mathscr{L}(n)$ are obtained by intersecting with $\mathscr{L}(n)$ the stable (unstable) manifolds of the corresponding invariant tori for the ESRDE on $G^n(\mathbb{R}^{2n})$. If the stable (unstable) flag is refined to a complete flag in a way

which respects the symplectic structure, then the stable (unstable) manifold of each k-dimensional invariant torus (for the ESRDE on $\mathscr{L}(n)$) is the union of 2^k cells in the decomposition of $\mathscr{L}(n)$ determined by the complete flag.

The ESRDE is generally not a Morse-Smale vector field. However, like the ERDE, it exhibits properties which resemble those of a Morse-Smale vector field. The stable and unstable manifolds are embedded submanifolds of $\mathscr{L}(n)$, and are bundles over the corresponding tori with Euclidean spaces as fibers. The stable and unstable manifolds always intersect transversally. In addition, the phase portrait of the ESRDE is related to the topology of $\mathscr{L}(n)$ by generalized Morse inequalities. In fact, for the ESRDE, they are actually *equalities.*

There is one interesting difference between the phase portraits of the ERDE and the ESRDE. The ERDE has either an equilibrium point or a periodic orbit whose stable (unstable) manifold is open and dense in the phase space. However, the ESRDE always has an equilibrium point whose stable (unstable) manifold is open and dense.

Finally, we turn to the symplectic Riccati differential equation (SRDE) on the space $S(n)$ of real symmetric $n \times n$ matrices. It is this differential equation which is crucial to the optimal control and filtering applications. We have given a complete description of the phase portrait. We have shown that if (A, B) is controllable, the nonwandering set of the SRDE is analytically isomorphic to the nonwandering set of the corresponding ESRDE. Thus, under Assumption A2, there are $\binom{q}{k}2^{p+q-k}$ k-dimensional invariant tori, $k = 0, 1, \cdots, q$. Altogether, there are $2^p 3^q$ invariant tori. The asymptotic behaviour of a given motion at $t \to \infty$ ($t \to -\infty$) can be determined from the asymptotic behavior of the corresponding motion of the ESRDE, provided the former motion does not escape in finite positive (negative) time. Either the motion converges to a motion on one of the $2^p 3^q$ invariant tori as $t \to \infty$ ($t \to -\infty$), or it escapes in finite positive (negative) time. By combining our characterization of the stable and unstable manifolds for the ESRDE with a known result concerning finite escape times, we have described the asymptotic behavior of every solution of the SRDE.

We have a comment regarding the computational problems involved in determining the phase portrait for a given Riccati equation. To determine the number of invariant tori only requires determining how many of the eigenvalues of the Hamiltonian matrix H are real. To actually construct the invariant tori and their stable and unstable manifolds, it is necessary to find the eigenvectors of H. (See § 5.4 for an example.) Since H is assumed to have distinct eigenvalues, both of these tasks are reasonable from a numerical standpoint. In contrast, it is *not* reasonable to ask for the number of periodic orbits. There are either finitely many (in fact, $q2^{p+q-1}$) or uncountably many periodic orbits. Unless $q \leqq 1$, there exist arbitrarily small perturbations of H which produce either situation. Thus, it is not numerically feasible to determine whether or not there are finitely many periodic orbits.

The results for the ERDE extend in a natural way to the more general case where Assumption A1 is replaced by the assumption that the generator B is semisimple. The invariant manifolds in the nonwandering set are now products of Grassmannians instead of tori, and there is an invariant Grassmann submanifold which has a stable (unstable) manifold which is open and dense in $G^n(\mathbb{R}^{n+m})$. The stable and unstable manifolds remain unions of Schubert cells. If a Morse series is defined by analogy to the Morse series for a Morse-Bott function, the ERDE satisfies Morse inequalities—in fact as equalities.

The results for the ESRDE extend naturally to the case where Assumption A2 is replaced by the weaker assumption that the generator H is semisimple and has no eigenvalues on the imaginary axis. The connected components of the nonwandering set are now products of Grassmann manifolds, but as before, there is an equilibrium

point whose stable (unstable) manifold is open and dense in $\mathscr{L}(n)$. The stable and unstable manifolds are again unions of cells, and Morse inequalities are satisfied as equalities.

The results for the SRDE are generalized to the case where H is semisimple (diagonalizable) with no imaginary axis eigenvalues, and $L = BB'$ with (A, B) controllable. In this case, the connected components of the nonwandering set are products of Grassmann manifolds. A given solution either escapes in finite forward (backward) time or converges to an almost periodic solution on one of these products as $t \to \infty$ ($t \to -\infty$). For a convergent solution, our results give an explicit formula for the limiting motion. If $Q = C'C$ with (C, A) observable, then our results also describe the constant signature of every nonwandering solution and the asymptotic signature of every nonescaping solution.

When the generator matrices are nondiagonalizable, the phase portraits of the ERDE, ESRDE, and SRDE are considerably more complicated. There are still invariant manifolds which are products of Grassmannians and which contain all of the equilibrium points and periodic orbits. However, in contrast to the semisimple case, these invariant manifolds may contain wandering points. An indication of the degree of complexity resulting from nondiagonalizability is given by the complicated geometric structure of the variety of invariant subspaces of a nondiagonalizable matrix.

In this paper, we have not dealt explicitly with the RDE defined on the space $\mathbb{R}^{m\times n}$ of real $m \times n$ matrices. However, it should be clear that our description of the phase portrait of the ERDE will yield the complete phase portrait of the RDE provided two results become available: (1) A description of which nonwandering points for the ERDE belong to $G^n(\mathbb{R}^{n+m}) - G_0^n(\mathbb{R}^{n+m})$ (the hypersurface at infinity) or a sufficient condition on the generator matrix B for the nonwandering set of the ERDE to be completely contained in $G_0^n(\mathbb{R}^{n+m})$ (and hence correspond to the nonwandering set of the RDE); (2) A description of exactly which initial points K_0 generate solutions which escape in finite forward or backward time. Some work in the direction of these problems is described by J. Medanic [28].

Appendix A. Standard charts for the Grassmann and Lagrange–Grassmann manifolds. First we describe the so-called *standard charts* for the Grassmann manifold $G^n(\mathbb{R}^{n+m})$ of all n-dimensional subspaces of $\mathbb{R}^{n+m}$. Let $\alpha = (\alpha_1, \cdots, \alpha_n)$ be a multi-index. (I.e. $\alpha_1, \cdots, \alpha_n$ are integers satisfying $1 \leqq \alpha_1 < \alpha_2 < \cdots < \alpha_n \leqq n+m$). Let $e_1, \cdots, e_{n+m}$ denote the standard basis vectors for $\mathbb{R}^{n+m}$, and let L_α denote the m-dimensional subspace $\operatorname{Sp}\{e_j : j \notin \{\alpha_1, \cdots, \alpha_n\}\}$. Let W_α denote the subset of $G^n(\mathbb{R}^{n+m})$ consisting of those subspaces which are complementary to L_α. In other words, $W_\alpha = \{S \in G^n(\mathbb{R}^{n+m}) : S \cap L_\alpha = 0\}$.

Let $S \in W_\alpha$, and let X be any $(n+m) \times n$ full rank matrix such that $\operatorname{Sp} X = S$. In other words, the columns of X form a basis for S. Since S is complementary to L_α, rows $\alpha_1, \cdots, \alpha_n$ of X form a nonsingular $n \times n$ submatrix. It follows that by performing column operations on X, we can obtain a new basis matrix for S, call it $\tilde{X}$, such that rows $\alpha_1, \cdots, \alpha_n$ form an identity submatrix.

Let $\tilde{W}_\alpha$ denote the set of all $(n+m) \times n$ matrices such that rows $\alpha_1, \cdots, \alpha_n$ form an identity submatrix. We have seen that each $S \in W_\alpha$ is spanned by some $\tilde{X} \in \tilde{W}_\alpha$. Furthermore, it is clear that no two matrices in $\tilde{W}_\alpha$ can span the same subspace. Thus, there is a bijection $\phi_\alpha : W_\alpha \to \tilde{W}_\alpha$ with $\phi_\alpha(S)$ the unique matrix in $\tilde{W}_\alpha$ whose columns span S. Since $\tilde{W}_\alpha$ can be identified with $\mathbb{R}^{mn}$ in a natural way, we can regard ϕ_α as a bijection of W_α onto $\mathbb{R}^{mn}$. It can be shown [3] that $\phi_\alpha : W_\alpha \to \mathbb{R}^{mn}$ is actually a homeomorphism. The pair (W_α, ϕ_α) is called a *standard chart* for $G^n(\mathbb{R}^{n+m})$. By associating each $S \in W_\alpha$ with a point in $\mathbb{R}^{mn}$, the mapping ϕ_α parametrizes the subset

W_α of $G^n(\mathbb{R}^{n+m})$. Since any $S \in G^n(\mathbb{R}^{n+m})$ must be complementary to L_α for some α, the $\binom{n+m}{n}$ open subsets $\{W_\alpha\}$ cover $G^n(\mathbb{R}^{n+m})$. Thus, the standard charts parametrize all of $G^n(\mathbb{R}^{n+m})$.

As an example, suppose that $n=2$ and $m=3$. There are $\binom{5}{2}=10$ standard charts for $G^2(\mathbb{R}^5)$. If $\alpha=(2,5)$, then W_α consists of those $S \in G^2(\mathbb{R}^5)$ which are complementary to the subspace $L_\alpha = \mathrm{Sp}\{e_1, e_3, e_4\}$. The mapping ϕ_α^{-1} is given by

$$\begin{bmatrix} x_{11} & x_{12} \\ x_{31} & x_{32} \\ x_{41} & x_{42} \end{bmatrix} \longrightarrow \mathrm{Sp} \begin{bmatrix} x_{11} & x_{12} \\ 1 & 0 \\ x_{31} & x_{32} \\ x_{41} & x_{42} \\ 0 & 1 \end{bmatrix}.$$

We now describe the standard charts for the Lagrange-Grassmann manifold $\mathscr{L}(n)$, which is an embedded submanifold of $G^n(\mathbb{R}^{2n})$. $G^n(\mathbb{R}^{2n})$ is covered by $\binom{2n}{n}$ charts $\{W_\alpha\}$ as described above. As in § 4.2, we define the standard symplectic flag $\{V_j\}_{j=1}^{2n}$ by $V_j = \mathrm{Sp}\{e_1, e_2, \cdots, e_j\}$ for $j=1,2,\cdots,n$, and $V_j = \mathrm{Sp}\{e_1, e_2, \cdots, e_n, e_{2n}, e_{2n-1}, \cdots, e_{3n-j+1}\}$ for $j=n+1, n+2, \cdots, 2n$. This complete flag determines a cell decomposition of $G^n(\mathbb{R}^{2n})$ into $\binom{2n}{n}$ cells. There is a cell $U(a)$ for every $a=(a_1,\cdots,a_{2n})$ such that $a_i=0$ or 1 for each i and $\sum_{i=1}^{2n} a_i = n$. Specifically, $U(a)=\{S \in G^n(\mathbb{R}^{2n})$: $\dim S \cap V_j = \sum_{i=1}^{j} a_i, j=1,\cdots,2n\}$. Let $j_1 < \cdots < j_n$ denote the elements of the set $\{j: a_j = 1\}$. Let $d = \sum_{i=1}^{n} a_i$. Set $\alpha_i = j_i$ for $i=1,\cdots,d$ and $\alpha_i = 3n+1-j_{n+d+1-i}$ for $i=d+1,\cdots,n$. It is straightforward to show that if $S \in U(a)$, then S is complementary to L_α and hence an element of W_α. Thus, $U(a) \subset W_\alpha$.

Lemma 6 shows that $U(a) \cap \mathscr{L}(n)$ is empty unless $a_i + a_{2n-i+1} = 1$, $i=1,\cdots,n$. This condition on $a=(a_1,\cdots,a_{2n})$ is equivalent to the requirement that $\alpha_1,\cdots,\alpha_d$, $\alpha_{d+1}-n,\cdots,\alpha_n-n$ are all distinct. Since $G^n(\mathbb{R}^{2n})$ is covered by the cells $\{U(a)\}$, it follows trivially that $\mathscr{L}(n)$ is covered by the cells $\{U(a) \cap \mathscr{L}(n)$: $a_i + a_{2n-i+1} = 1, i = 1,\cdots,n\}$. Since $U(a) \subset W_\alpha$, $\mathscr{L}(n)$ is covered by the open sets $\{W_\alpha \cap \mathscr{L}(n)$: $\alpha_1,\cdots,\alpha_d, \alpha_{d+1}-n,\cdots,\alpha_n-n$ are all distinct$\}$, where we define $d = \max\{j: \alpha_j \leqq n\}$. It is clear that there are 2^n choices for $\alpha=(\alpha_1,\cdots,\alpha_n)$ which satisfy the additional requirement that $\alpha_1,\cdots,\alpha_d, \alpha_{d+1}-n,\cdots,\alpha_n-n$ be distinct. Thus, there are 2^n open sets $W_\alpha \cap \mathscr{L}(n)$ in the covering of $\mathscr{L}(n)$.

Fix $\alpha=(\alpha_1,\cdots,\alpha_n)$ such that $\alpha_1,\cdots,\alpha_d, \alpha_{d+1}-n,\cdots,\alpha_n-n$ are distinct. Let $S \in W_\alpha$, and let X be the unique matrix in $\tilde{W}_\alpha$ such that $S = \mathrm{Sp}\, X$. By a procedure analogous to the one described immediately prior to Example 2 in § 4.2, we can find $P \in \mathrm{Sp}(n,\mathbb{R})$ such that the matrix $\tilde{X} = PX$ has the following structure: The first n rows of $\tilde{X}$ form an identity submatrix. Rows $n+1,\cdots,n+d$ of $\tilde{X}$ are the nontrivial rows from among rows $n+1,\cdots,2n$ of X. Rows $n+d+1,\cdots,2n$ of $\tilde{X}$ are the nontrivial rows from among rows $1,\cdots,n$ of X, each multiplied by -1.

For example, suppose that $n=3$ and that $\alpha=(1,2,6)$. Note that $d=2$ and that α_1, α_2, and α_3-3 are distinct. $X \in \tilde{W}_\alpha$ iff X is of the form

$$X = \left[\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ x_{31} & x_{32} & x_{33} \\ \hline x_{41} & x_{42} & x_{43} \\ x_{51} & x_{52} & x_{53} \\ 0 & 0 & 1 \end{array}\right].$$

Then

$$\tilde{X} = \left[\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ \hline x_{41} & x_{42} & x_{43} \\ x_{51} & x_{52} & x_{53} \\ -x_{31} & -x_{32} & -x_{33} \end{array}\right].$$

Since $P \in \mathrm{Sp}(n, \mathbb{R})$, S is Lagrangian iff $P(S)$ is Lagrangian. If we write X in partitioned form as $\tilde{X} = \left[\begin{smallmatrix} I \\ Y \end{smallmatrix}\right]$, then $P(S)$ is Lagrangian iff Y is symmetric. Thus, the condition that $Y = Y'$ gives the conditions which the n^2 coordinates in the matrix X must satisfy in order for the subspace S to belong to $\mathscr{L}(n)$. In the example, it follows that $S \in \mathscr{L}(3)$ iff $x_{51} = x_{42}$, $x_{31} = -x_{43}$, and $x_{32} = -x_{53}$. Thus, the subset $W_\alpha \cap \mathscr{L}(3)$ is parametrized by the matrices of the form

$$X = \left[\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -x_{43} & -x_{53} & x_{33} \\ \hline x_{41} & x_{42} & x_{43} \\ x_{42} & x_{52} & x_{53} \\ 0 & 0 & 1 \end{array}\right]$$

which may be regarded as points in $\mathbb{R}^6$. In exactly this way, 2^n charts which cover $\mathscr{L}(n)$ are obtained by intersecting with $\mathscr{L}(n)$ those standard charts W_α for $G^n(\mathbb{R}^{2n})$ for which α satisfies the additional requirement that $\alpha_1, \cdots, \alpha_d, \alpha_{d+1} - n, \cdots, \alpha_n - n$ be distinct. The image of the restriction $\phi_\alpha | W_\alpha \cap \mathscr{L}(n)$ may be identified with $\mathbb{R}^{n(n+1)/2}$. It is the 2^n submanifold charts $\{(W_\alpha \cap \mathscr{L}(n), \phi_\alpha | W_\alpha \cap \mathscr{L}(n))\}$ which we refer to as the standard charts for $\mathscr{L}(n)$.

Appendix B. Properties of almost periodic functions. It is straightforward to show that many of the basic properties of complex-valued almost periodic functions generalize to the case where the values are in a complete metric space. (For properties requiring algebraic structure, one takes X to be a Banach space.) By making obvious changes in the proofs of the corresponding results for complex-valued almost periodic functions in [12, Chaps. 1 and 2], the following properties can be verified:

AP 1. Let (X, ρ) be a complete metric space and let $f: \mathbb{R} \to X$ be continuous. Then f is almost periodic if and only if given any $\varepsilon > 0$, there exists $L = L(\varepsilon)$ such that given any s, there exists $\tau \in [s, s + L]$ such that $\rho(f(t), f(t+\tau)) < \varepsilon$ for all $t \in \mathbb{R}$.

AP 2. Let (X, ρ) be a complete metric space and let $f: \mathbb{R} \to X$ be a continuous periodic function. Then f is almost periodic.

AP 3. Let $\{(X_i, \rho_i)\}_{i=1}^r$ be complete metric spaces and let $f_i: \mathbb{R} \to X_i$ be almost periodic, $i = 1, \cdots, r$. If $f: \mathbb{R} \to X_1 \times \cdots \times X_r$ is defined by $f(t) = (f_1(t), \cdots, f_r(t))$, then f is almost periodic (relative to the product metric).

AP 4. Let $\{X_i\}_{i=1}^3$ be Banach spaces, and let $\alpha: X_1 \times X_2 \to X_3$ be a product mapping. (That is, α is bilinear and $\|\alpha(x_1, x_2)\| \leqq \|x_1\| \, \|x_2\|$.) If $f_i: \mathbb{R} \to X_i$ $(i = 1, 2)$ are almost periodic and if $f: \mathbb{R} \to X_3$ is defined by $f(t) = \alpha(f_1(t), f_2(t))$, then f is almost periodic.

AP 5. Let (X_1, ρ_1) and (X_2, ρ_2) be complete metric spaces, and let $f: \mathbb{R} \to X_1$ be almost periodic. Let Ω be a subset of X_1 which contains the image of f. If $F: \Omega \to X_2$ is uniformly continuous, then $F \circ f$ is almost periodic.

AP 6. Let (X, ρ) be a complete metric space, and let $f_i: \mathbb{R} \to X$ be almost periodic, $i = 1, 2$. If $\rho(f_1(t), f_2(t)) \to 0$ as $t \to \infty$, then $f_1(t) = f_2(t)$, $\forall t$.

AMBUSH STRATEGIES IN SEARCH GAMES ON GRAPHS*

STEVE ALPERN† AND MIROSLAV ASIC‡

Abstract. A blind searcher and a blind hider move at below unit speed along a finite length graph Q known to both, until the first time T when they meet. A two person zero-sum game arises if the searcher pays the hider T units. We consider circumstances under which it may be optimal for the searcher to "lie in wait" at a node of Q, hoping the hider will come to him. We also explicitly define a notion of "equilibrium in distribution" for such games, which has been implicit in the literature. We show that for the graph consisting of two nodes connected by three arcs of equal length there are optimal ambush strategies but there is no equilibrium in distribution.

Key words. search, game, graph, zero-sum

1. Introduction. Let Q be a graph with known arc lengths and a distinguished point q_0. A search (or "hide and seek" or "Princess and Monster" [8]) game may be played on Q as follows. The searcher starts at q_0 at time 0 and moves about Q at unit speed until the first (capture) time T that he coincides with the hider. Meanwhile the hider may move in any continuous way about Q. Both players know Q and q_0 but they cannot see each other. This scheme defines a two person zero-sum game with the capture time T (or an increasing function $U(T)$) as the payoff to the maximizing hider. The existence of the minimax value $V = V(Q, q_0)$, and of optimal searcher strategies and ε-optimal hider strategies, has been recently established by S. Gal [7, Appendix 1] using Ky Fan's minimax theorem. The existence question is also dealt with in [3], [4].

Search games have been analyzed for several specific graphs but up to now solutions (optimal strategies and V) have been obtained only by imposing an additional "nonloitering" assumption which prevents the searcher from waiting at any node. The "nonloitering" assumption is pragmatic in that it seems to make solutions easier, indeed possible. A better justification is that in some cases [5], [6] it gives an accurate model when graphs are used to analyze search games in multidimensional regions, where there is no analogue of waiting at a node. However it cannot be denied that in analyzing search games on graphs per se, an essential question is at which nodes, when, and how long the searcher should wait "in ambush." This is a problem which should not be assumed away.

In this paper we present the first analysis of a search game on a graph which obtains a solution *without* the "nonloitering" assumption. The graph we study consists of two nodes (one is q_0) joined by three unit length arcs (Fig. 1).

Our analysis of the search game on this graph has another feature which also distinguishes it from all previously studied search games. For those games [7, p. 51] "... there exists a function $P(t)$, which decreases exponentially in t, such that for all t both the searcher and the hider can keep the probability of capture after time t around $P(t)$. ... we use this property to show that optimal strategies for $U(T) = T$ are still optimal for more general cost functions $U(T)$." This important property, which we formalize in § 2 as an "equilibrium in distribution" does *not* hold for the search game on the "three arc" graph and hence the strategies we find optimal there when

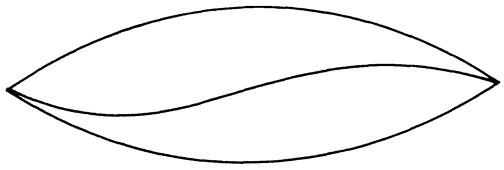

FIG. 1. *"Three arc" graph.*

$U(T) = T$ are not uniformly optimal for all U. It is probably the lack of an equilibrium in distribution for this game that makes our solution so technically difficult.

The questions dealt with here were inspired by suggestions in Gal's book [7] and in fact our initial results were obtained in the course of writing a review [2] of that book. Some of our results were first announced in that review and the details have appeared in the working paper [3].

The paper is organized as follows: Section 2 gives the formal definition of a search game on a graph and includes our new definition of an "equilibrium in distribution." Section 3 gives an analysis of ambush strategies on the k-arc graph. Section 4 gives a complete solution of the search game on three arcs.

2. Formal definition of a search game. In this section we describe the formal game theoretic background we will need to solve the "k-arc" games. We closely follow the presentation and notation of Gal's book, "Search Games" [7]. A search game Γ will be described by specifying a search space Q, pure strategy sets $\mathcal{S}$ and $\mathcal{H}$, and a nondecreasing utility function U. In this paper we will always take Q to be a graph with its shortest path metric d, although other metric spaces may be used. The pure searcher ($\mathcal{S}$) and hider ($\mathcal{H}$) strategy sets are given subsets of the space Cont(Q) consisting of all continuous functions from the nonnegative real numbers into Q. We endow $\mathcal{S}$ and $\mathcal{H}$ with the relative topology coming from the topology of "uniform convergence on compact subsets" on Cont(Q). It is customary to assume that the searcher has unit maximal speed, or that $\mathcal{S} \subset \mathcal{L}$ where

$$\mathcal{L} = \{f \in \text{Cont}(Q): d(f(t_1), f(t_2)) \leqq |t_1 - t_2| \text{ for all } t_1, t_2\}.$$

To each pair of pure strategies S in $\mathcal{S}$ and H in $\mathcal{H}$ (capital letters will denote pure strategies) there corresponds a unique "capture time" $T = T(S, H)$ defined as the least t such that $S(t) = H(t)$. If no such t exists then we define T to be infinity. We then define Γ to be the two person zero-sum game with the payoff to the maximizing hider given by $C(S, H) = U(T(S, H))$. More generally we allow the players to choose mixed strategies. Let $\mathcal{S}^*$ and $\mathcal{H}^*$ denote respectively the spaces of all regular Borel probability measures on $\mathcal{S}$ and $\mathcal{H}$. If the players choose "mixed strategies" s in $\mathcal{S}^*$ and h in $\mathcal{H}^*$ (lower case for mixed strategies) then the expected payoff to the maximizing hider is

$$c(s, h) = \int C(S, H)\, d(s \times h).$$

If

$$\inf_{s \in \mathcal{S}^*} \sup_{h \in \mathcal{H}^*} c(s, h) = \sup_{h \in \mathcal{H}^*} \inf_{s \in \mathcal{S}^*} c(s, h),$$

then we call this common number the value of the game and denote it by V, or by $V(U)$ if we wish to emphasize its dependence on U for fixed Q, $\mathcal{S}$ and $\mathcal{H}$. Gal [4] has applied Ky Fan's Minimax Theorem to establish sufficient conditions for the existence of a value for search games.

GAL'S THEOREM. *Suppose* $\Gamma = \Gamma(Q, \mathcal{S}, \mathcal{H}, U)$ *is a search game satisfying*

(i) $\mathcal{S}$ *is compact and*

(ii) U *is left continuous.*

Then Γ *has a value.*

Condition (i) will be satisfied in practice by taking $\mathcal{S}$ to be a closed subset of $\mathcal{L}$, since any such set is compact by the Arzela–Ascoli theorem. In order to find explicit solutions to certain search games on graphs, it has been necessary to restrict the searcher to pure strategies which are "nonloitering." Formally S is nonloitering if $\{t: S(t)$ is a node of Q (of degree $> 2)\}$ has Lebesgue measure zero. The anomaly is that this assumption, which in practice helps us to find the value, at the same time removes the condition (compactness of $\mathcal{S}$) which theoretically enables us to assert the existence of the value. Specifically the nonloitering strategies in $\mathcal{L}$ do not form a closed subset of $\mathcal{L}$.

Condition (ii) above is our replacement for Gal's requirement that $C(S, H)$ be lower semicontinuous in both variables. However, our condition implies his because $T(S, H)$ is lower semicontinuous and a nondecreasing left continuous function of a lower semicontinuous function is lower semicontinuous.

Gal's theorem allows for the possibility that the value is infinite although for combinatorially finite graphs the value is always finite (see [4, § 3]).

In estimating the function $c(s, h)$ for specific graphs it is helpful to use the formulae

$$c(s, h) = \int_0^\infty U(t)\, dF(s, h)(t) \quad \text{and}$$

$$c(s, h) = \int_0^\infty (1 - F(s, h)(t))\, dt \quad \text{when } U = I$$

$(I(t) \equiv t)$ where $F(s, h)$ is the cumulative distribution of capture times corresponding to the mixed strategies s and h,

$$F(s, h)(t) = \Pr(T \leqq t) = (s \times h)\{(S, H): T(S, H) \leqq t\}.$$

For any cumulative probability distribution F we write $U(F) = \int_0^\infty U(t)\, dF(t)$, which is the payoff corresponding to that distribution. For s in $\mathcal{S}^*$ and h in $\mathcal{H}^*$ we define

$$[F^-(s)](t) = \inf_h F(s, h)(t) \quad \text{and}$$

$$[F^+(h)](t) = \sup_s F(s, h)(t).$$

Intuitively $F^-(s)$ is the distribution the searcher can guarantee by playing s, and similarly for $F^+(h)$. An estimate on the distribution of T yields an estimate on the expected value of $U(T)$ so that if the value exists then we always have:

$$\sup_{h \in \mathcal{H}^*} U(F^+(h)) \leqq V(U) \leqq \inf_{s \in \mathcal{S}^*} U(F^-(s)).$$

If the left and right side of this inequality are equal, then we will say the game $\Gamma(Q, \mathcal{S}, \mathcal{H}, U)$ has an "equilibrium in distribution," which is a strictly stronger property than merely having a value. This notion has appeared in the search game literature as early as [1] but we make it precise for the first time here. All the search games which have been explicitly solved prior to this paper have equilibria in distribution. However the search game on three arcs solved in § 4 does not have an equilibrium in distribution and for that game, $\sup_h U(F^+(h)) < V(U) = \inf_s U(F^-(s))$ in the case that $U = I$.

Associated with *every* game $\Gamma(Q, \mathcal{S}, \mathcal{H}, U)$ where $\mathcal{S}$ is compact is a distribution E of capture times which we call the "equilibrium distribution." For all t this distribution satisfies $\sup_s [F^-(s)](t) = E(t) = \inf_h [F^+(h)](t)$. The existence of each number $E(t)$ follows from applying Gal's theorem to the game $\Gamma(Q, \mathcal{S}, \mathcal{H}, U_t)$, where U_t is the characteristic function of (t, ∞), and setting $E(t)$ equal to the value. We emphasize that E does not depend on the utility function U and that its existence is more general than that of an equilibrium in distribution for the game.

Suppose we can find mixed strategies s in $\mathcal{S}^*$ and h_m in $\mathcal{H}^*$, $m = 1, 2, 3, \ldots$, such that $F^-(s) = E$ and $F^+(h_m)$ converges in distribution to E. (The latter assumption means that $[F^+(h_m)](t)$ converges to $E(t)$ at all continuity points t for E.) It then follows for all continuous U for which $U(E)$ is finite that

$$U(F^-(s)) = U(E) = \lim_{m \to \infty} U(F^+(h_m)),$$

or that $\Gamma(Q, \mathcal{S}, \mathcal{H}, U)$ has an equilibrium in distribution and value $U(E) = \int_0^\infty U\, dE(t)$. We call the situation described in this paragraph a "uniform equilibrium in distribution."

To illustrate the above ideas on equilibria in distribution, we consider the simple class of games Γ_a played on the closed unit interval $[0, 1]$ with the searcher starting at the point a. By symmetry we may assume that $0 \leqq a \leqq \frac{1}{2}$. Every hider pure strategy is dominated by one of the immobile strategies H_i, $i = 0, 1$, which stay at i forever. So we restrict our attention to the mixtures $h_p = pH_0 + (1-p)H_1$ for $0 \leqq p \leqq 1$. Similarly let S_i, $i = 0, 1$, be the pure strategy of going at unit speed first to end i and then to end $1-i$, and let $s_q = qS_0 + (1-q)S_1$.

In the symmetric case $a = \frac{1}{2}$ we have $F^-(s_{1/2}) = F^+(h_{1/2}) = E$, where $E(t)$ is respectively 0, $\frac{1}{2}$ and 1 on the intervals $[0, \frac{1}{2})$ $[\frac{1}{2}, \frac{3}{2})$, and $[\frac{3}{2}, \infty)$. Hence $\Gamma_{1/2}$ has a uniform equilibrium in distribution. In fact for any utility U we have $U(F^-(s_{1/2})) = U(E) = \frac{1}{2}U(\frac{1}{2}) + \frac{1}{2}U(\frac{3}{2}) = U(F^+(h_{1/2}))$.

If $0 < a < \frac{1}{2}$ then for $0 \leqq t < 1 - a$ the hider can ensure $E(t) = 0$ by using H_1 (waiting at the further end). For $1 - a \leqq t < 1 + a$ the strategies $s_{1/2}$ and $h_{1/2}$ ensure that $E(t) = \frac{1}{2}$. For $t \geqq 1 + a$ the searcher can ensure that $E(t) = 1$ by using S_0. The thing to observe is that for both players the strategies needed to optimize $E(t)$ depend on t, so there is not a uniform equilibrium in distribution. If the utility function U has zero variation outside one of the three intervals determined by $1 - a$ and $1 + a$, then the strategies given above for that interval are optimal and produce an equilibrium in distribution. Suppose however that this is not true of U, for example if $U(T) = 0$ for $T < \frac{1}{2}$, $U(T) = 1$ for $\frac{1}{2} \leqq T < 1$, and $U(T) = 2$ for $1 \leqq T$. This corresponds to the hider getting one utility unit if uncaught at time $\frac{1}{2}$ and another unit if still uncaught at time 1. The payoff matrix in this case is given by

	H_0	H_1
S_0	0	2
S_1	2	1

.

It is easily computed that the value V is $\frac{4}{3}$ and that the unique optimal strategies are $s_{1/3}$ and $h_{1/3}$. To check that this game does not have an equilibrium in distribution, consider the conservative distributions $F^+(h_p)$, $0 \leqq p \leqq 1$. Observe that $(F^+(h_p))(\frac{1}{2}) = p$ with the supremum achieved by S_0, and $(F^+(h_p))(1) = \max[p, 1-p]$ with the supremum achieved by $S_{1-[2p]}$. Since for this U we have $U(F^+(h)) = (1 - (F^+(h))(\frac{1}{2})) +$

$(1-(F^+(h))(1))$ it follows that $U(F^+(h_p))=(1-p)+(1-\max[p,1-p])$. Therefore $\sup_h U(F^+(h))=\sup_p (2-p-\max[p,1-p])=1$ which is strictly less than the value $V(U)=\frac{4}{3}$, and $\Gamma_a(U)$ does not have an equilibrium in distribution. For the sake of completeness we conclude by observing that in the trivial end-starting game Γ_0 there is a uniform equilibrium in distribution and $V(U)=U(1)$.

3. Searcher ambush strategies for the k-arc game. Let Γ_k denote the search game on the graph consisting of k unit length arcs between two nodes A (searcher starting point) and B. From this point onwards the utility function U is identical with the capture time T. S. Gal [5], [6] has shown that the nonloitering version of this game has a uniform equilibrium in distribution with $E(t)=1-((k-1)/k)^{[t]}$ and hence a nonloitering value V^* equal to k. For this nonloitering game he established that the searcher "random oscillation" strategy s^* of going back and forth between A and B at unit speed with equiprobable and independent choices among the k arcs satisfies $F^-(s^*)=E$ and is therefore optimal. An ε-optimal hider mixed strategy $h^*(\varepsilon)$ with conservative distribution $F^+(h^*(\varepsilon))$ approaching (as $\varepsilon\to 0$) E is to wait at B until time $1-\varepsilon$ and then use a random oscillation.

In this section we implicitly (using Gal's Minimax Theorem) define an ambush mixed strategy $\hat{s}=\hat{s}_k$ for the searcher which waits at A for $0\leqq t\leqq 2$ with positive probability. Our analysis (Lemma 1) of $\hat{s}$ shows that for $k>3$ (more than three arcs) the searcher can improve by loitering and that the (unrestricted) value V_k satisfies $V_k<V_k^*=k$, where V^* denotes nonloitering value. For $k=3$ our analysis gives that $V_3\leqq 3$ which shows that there are optimal search strategies which loiter but leaves open the question (settled negatively in section four) of whether the searcher can strictly improve his performance in the three arc game by loitering.

LEMMA 1. *The (unrestricted) value V_k of the search game on k arcs satisfies $V_k\leqq(2k+p_k-1)/(2-2p_k)$ where $p_k=(k^2-k+1)^{-1}$. In particular $V_3\leqq 3$ and $V_k<k$ (k is the nonloitering value) for $k>3$.*

Proof. Consider the following searcher mixed strategy $\hat{s}$ (which of course depends on k): In the first two units of time either wait at the starting point A, with probability p_k; or randomly pick two distinct arcs and take the first to B and the second back to A, each at unit speed, with probability $1-p_k$. In either case $\hat{s}(2)=A$. Starting at time 2, pretend the game is just beginning and play any fixed optimal strategy—which exists by Gal's Theorem.

To estimate $c(\hat{s},H)$ we first partition $\mathcal{H}=\mathcal{H}_1\cup\mathcal{H}_2$ where $H\in\mathcal{H}_1$ if and only if $H(t)=A$ for some t with $0\leqq t\leqq 2$. Observe that for any $H\in\mathcal{H}$

$$1-F(\hat{s},H)(1)=\text{Prob}\,(T>1)\leqq(1)(p_k)+((k-1)/k)(1-p_k).$$

Now suppose $H_1\in\mathcal{H}_1$ and consider Prob $(T>2)$, that is, $1-F(\hat{s},H_1)(2)$. If the searcher was waiting at A, then Prob $(T>2)=0$. On the other hand, if the searcher searched distinct arcs, then the best case for the hider occurs when he is on distinct arcs at $t=1$ and $t=2$. In this case the probability that $T>2$ is given by $(k^2-3k+3)/(k^2-k)$ which is the probability that two independently chosen, random distinct pairs of numbers from $\{1,\cdots,k\}$ disagree in both coordinates. Therefore for all $H_1\in\mathcal{H}_1$ we have

$$1-F(\hat{s},H_1)(2)=\text{Prob}\,(T>2)\leqq(0)(p_k)+((k^2-3k+3)/(k^2-k))(1-p_k).$$

If $H_2\in\mathcal{H}_2$ then

$$1-F(\hat{s},H_2)(2)=\text{Prob}\,(T>2)\leqq(1)(p_k)+((k-2)/k)(1-p_k).$$

We have chosen p_k so that our estimates on Prob $(T>2)$ are the same for $\mathcal{H}_1$ and $\mathcal{H}_2$.

For any $H \in \mathcal{H}$ we may estimate $c(\hat{s}, H)$ by the formula

$$c(\hat{s}, H) \leqq 1 + 1(1 - F(\hat{s}, H)(1)) + V_k(1 - F(\hat{s}, H)(2))$$

because if $T > 2$ then since the searcher is playing optimally from time 2 the expected value of $T-2$ is no more than V_k. Thus by separately estimating $c(\hat{s}, H)$ for $H \in \mathcal{H}_1$ and $H \in \mathcal{H}_2$ by our above formulae, and obtaining the same result in each case (by choice of p_k), we obtain for all H in $\mathcal{H}$ that

$$c(\hat{s}, H) \leqq 1 + [p_k + ((k-1)/k)(1-p_k)] + [(p_k + (1-p_k)((k-2)/k))V_k].$$

It now follows from the definition of V_k that

$$V_k \leqq 1 + [p_k + ((k-1)/k)(1-p_k)] + [(p_k + (1-p_k)((k-2)/k))V_k].$$

The desired estimate on V_k is now obtained by solving for V_k in the above inequality.

4. Counter-ambush hider strategies in the 3-arc game. In this section we give a complete solution, without employing the nonloitering assumption, to the search game on the three arc graph. We have already indicated (in § 3) two distinct searcher strategies, one nonloitering (s^*) and one ambush ($\hat{s}$), which ensure that the expected capture time will not exceed 3 (on average). The hider strategy $h^*(\varepsilon)$ which Gal showed to be effective (guarantees $T \geqq 3$) against all nonloitering strategies gives only $T = 2 - \varepsilon$ against the (admittedly bad) strategy S_A of waiting at A. However (Theorem 1) the hider still has strategies which guarantee that the expected capture time is not much less than 3, and hence $V = 3$, even if the searcher is allowed to loiter.

The basic idea for the hider in countering ambush strategies is simple. The random oscillation strategy $h^*(\varepsilon)$ sometimes (actually one third of the time) involves going to and leaving a node by the same arc. But this is foolish since now the searcher could be waiting at that node, so that nodes should be entered only when required to change arcs. So it is preferable for the hider to modify $h^*(\varepsilon)$ by choosing the sequence of arcs at say time zero and, when the same arc occurs consecutively, waiting a small distance δ from the intervening vertex for a period of length 2δ. At the end of that waiting period he should resume the oscillation strategy. For technical reasons we have not been able to establish directly that this modified strategy $h^*(\varepsilon, \delta)$ guarantees that $c(s, h^*(\varepsilon, \delta)) \geqq 3 - \varepsilon$ for all s. The problem is that once ε and δ (or their distributions) are known, it is perhaps possible for the searcher to search points δ-near the vertex in the hope of finding a waiting hider.

To get around this problem, we use Gal's Minimax Theorem and show that against any given searcher strategy s (in particular an optimal one) there is a hider mixed strategy similar to what we have described above as $h^*(\varepsilon, \delta)$ in which the distributions of ε and δ depend on the searcher strategy s. The dependence of ε on s is described in the measure theoretic Lemma 3. This and the other technical result, Lemma 2, are perhaps best left until after Theorem 1, which will motivate their use.

Our final result, Corollary 1, shows that while both the nonloitering and unrestricted version of the 3-arc game both have value 3, only the former has an equilibrium in distribution.

LEMMA 2. *Let* $X = \{x = (x_1, x_2, \cdots) : x_1 = 0$ *and for all* i, $x_i = 0$ *or* 1 *and* $x_i x_{i+1} = 0\}$. *Let* $\phi : X \to R$ *be defined by* $\phi(x) = \sum_{n=1}^{\infty} \prod_{i=1}^{n} r_i(x)$, *where* $r_i(x) = (\frac{1}{3})^{x_i}(\frac{2}{3})^{1-x_i-x_{i+1}}$. *Then for all* x *in* X, $\phi(x) = 2$.

Proof. We will define vectors $e(q)$ in X, $0 \leqq q \leqq \infty$, such that $\phi(e(q)) = 2$ for all q, and such that for all x in X, $\phi(x) = \phi(e(q))$ for some q.

If $q=0,1,2,\cdots$, let $e=e(q)$ be defined by $e_1=e_2=\cdots=e_q=0$ and for $m=1,2,\cdots$; $e_{q+2m}=1$ and $e_{q+2m-1}=0$. For example $e(3)=(0,0,0,0,1,0,1,0,1,\cdots)$. We define $e(\infty)=(0,0,\cdots)$.

Fix any finite q and let $r_i=r_i(e(q))$. Then $r_i=\frac{2}{3}$ for $1\leqq i\leqq q$ and for $m=1,2,\cdots$ we have $r_{q+2m}=\frac{1}{3}$ and $r_{q+2m-1}=1$. It follows that $\prod_{i=1}^{n} r_i=(\frac{2}{3})^n$ for $n=1,\cdots,q$ and that for $m=0,1,2,\cdots$ we have

$$\prod_{i=1}^{q+2m} r_i=(\tfrac{2}{3})^q(\tfrac{1}{3})^m=\prod_{i=1}^{q+2m+1} r_i.$$

Therefore

$$\begin{aligned}\sum_{n=1}^{\infty}\prod_{i=1}^{n} r_i&=\sum_{n=1}^{q-1}\prod_{i=1}^{n} r_i+\sum_{m=0}^{\infty}\left(\prod_{i=1}^{q+2m} r_i+\prod_{i=1}^{q+2m+1} r_i\right)\\&=\sum_{n=1}^{q-1}(\tfrac{2}{3})^n+2\sum_{m=0}^{\infty}(\tfrac{2}{3})^q(\tfrac{1}{3})^m\\&=\frac{(\frac{2}{3})-(\frac{2}{3})^q}{(\frac{1}{3})}+2(\tfrac{2}{3})^q/(\tfrac{2}{3})\\&=2-3(\tfrac{2}{3})^q+3(\tfrac{2}{3})^q=2.\end{aligned}$$

Thus $\phi(e(q))=2$ for $q<\infty$. For $q=\infty$ we have

$$\phi(e(\infty))=\phi((0,0,\cdots))=\sum_{n=1}^{\infty}\prod_{i=1}^{n}(\tfrac{2}{3})=2.$$

To show that for all x in X, $\phi(x)=\phi(e(q))$ for some q, we introduce a map $g\colon X\to X$ such that ϕ is constant on orbits of g and such that each orbit converges to some $e(q)$, with respect to the metric $\rho(x,y)=\sum 2^{-i}|x_i-y_i|$ on X. Since the function $\phi\colon X\to R$ is continuous with respect to ρ, this will imply that $\phi(x)=\lim\phi(g^j(x))=\phi(e(q))=2$.

Define the map $g=X\to X$ by $\bar{x}=g(x)$, where $\bar{x}$ is determined as follows. If $x=e(q)$ for some q, set $\bar{x}=x$. Otherwise there is a least m such that $x_m=1$, $x_{m+1}=0$ and $x_{m+2}=0$. Define $\bar{x}$ by $\bar{x}_m=0$, $\bar{x}_{m+1}=1$ and $\bar{x}_i=x_i$ for all other i. For example $g((0,0,0,1,0,1,0,0,\cdots))=(0,0,0,1,0,0,1,0,\cdots)$. To establish that $\phi(g(x))=\phi(x)$, fix any x in X and write $\bar{x}=g(x)$. Let $r_i=r_i(x)$ and $\bar{r}_i=r_i(\bar{x})$. Observe that for i not equal to $m-1$, m, or $m+1$ we have $\bar{r}_i=r_i$, because r_i depends only on x_i and x_{i+1}. For the remaining three indices we have $r_{m-1}=1$, $r_m=\frac{1}{3}$, $r_{m+1}=\frac{2}{3}$, $\bar{r}_{m-1}=\frac{2}{3}$, $\bar{r}_m=1$ and $\bar{r}_{m+1}=\frac{1}{3}$. Observe that $r_{m-1}r_mr_{m+1}=\bar{r}_{m-1}\bar{r}_m\bar{r}_{m+1}$ so that $\prod_{i=1}^{n} r_i=\prod_{i=1}^{n}\bar{r}_i$ for n not equal to $m-1$ or m. Next compute

$$\prod_{i=1}^{m-1} r_i+\prod_{i=1}^{m} r_i=\left(\prod_{i=1}^{m-2} r_i\right)(r_{m-1}+r_{m-1}r_m),$$

$$\begin{aligned}\prod_{i=1}^{m-1}\bar{r}_i+\prod_{i=1}^{m}\bar{r}_i&=\left(\prod_{i=1}^{m-2}\bar{r}_i\right)(\bar{r}_{m-1}+\bar{r}_{m-1}\bar{r}_m)\\&=\left(\prod_{i=1}^{m-2} r_i\right)(\bar{r}_{m-1}+\bar{r}_{m-1}\bar{r}_m).\end{aligned}$$

Since $r_{m-1}+r_{m-1}r_m=\bar{r}_{m-1}+\bar{r}_{m-1}\bar{r}_m$ it follows from the above calculations that

$$\sum_{n=m-1}^{m}\prod_{i=1}^{n} r_i=\sum_{n=m-1}^{m}\prod_{i=1}^{n}\bar{r}_i.$$

Hence

$$\phi(g(x)) = \sum_{n=1}^{\infty} \prod_{i=1}^{n} \bar{r}_i = \left(\sum_{n=1}^{m-2} + \sum_{n=m-1}^{m} + \sum_{n=m+1}^{\infty}\right)\left(\prod_{i=1}^{n} \bar{r}_i\right)$$

$$= \left(\sum_{n=1}^{m-2} + \sum_{n=m-1}^{m} + \sum_{n=m+1}^{\infty}\right)\left(\prod_{i=1}^{n} r_i\right)$$

$$= \phi(x).$$

Finally, we must show that $\lim g^j(x)$ is always one of the $e(q)$. Let $q_n(x)$ be the number of ones in the first $2n$ coordinates of x. Clearly $n - q_n(x)$ is a nondecreasing sequence of natural numbers with a limit (possibly ∞) which we denote $q(x)$. If $q = q(x)$ is finite, then the sequence $g^j(x)$ is eventually equal to $e(\bar{q})$ where $\bar{q} = 2q$ or $2q-1$. If $q(x)$ is infinite then $g^j(x)$ converges to $e(\infty) = (0, 0, \cdots)$. Hence for all x in X,

$$\phi(x) = \phi\left(\lim_{j\to\infty} g^j(x)\right) = \phi(e(q(x))) = 2.$$

LEMMA 3. *Given any mixed strategy s in $\mathcal{S}^*$ there exist arbitrarily small positive numbers ε such that the following condition holds for s-a.e. pure strategies S in $\mathcal{S}$:*

(4.1) *If for some positive integer m, $S(m-\varepsilon)$ is a vertex, then for all δ with $0 < |\delta| \leqq 1$, $d(S(m-\varepsilon), S(m-\varepsilon+\delta)) < |\delta|$.*

Proof. For any S in $\mathcal{S}$ and any positive integers m and n, let $J(S, m, n)$ be the subset of $[0, 1]$ consisting of all ε such that $S(m-\varepsilon)$ is a vertex (A or B) and $d(S(m-\varepsilon), S(m-\varepsilon \pm 1/n)) = 1/n$. Clearly the distance between distinct points of $J(S, m, n)$ is at least $2/n$ so certainly $J(S, m, n)$ is finite. Consequently the set $J(S) = \cup_{m,n} J(S, m, n)$ is countable and so $\mu(J(S)) = 0$, where μ denotes Lebesgue measure on $[0, 1]$. Let F be the subset of $[0, 1] \times \mathcal{S}$ defined by letting (ε, S) belong to F if and only if ε belongs to $J(S)$. Observe that (ε, S) belongs to F exactly for those pairs which fail to satisfy condition (4.1). Applying Fubini's theorem to the characteristic function f of the set F yields

$$\int_0^1 \int_{\mathcal{S}} f(\varepsilon, S)\, ds\, d\mu = \int_{\mathcal{S}} \int_0^1 f(\varepsilon, S)\, d\mu\, ds = \int_{\mathcal{S}} \mu(J(S))\, ds = 0.$$

Hence for μ-almost all ε in $[0, 1]$ we must have $\int_{\mathcal{S}} f(\varepsilon, S)\, ds = 0$, or $s(\{S: \varepsilon \text{ belongs to } J(S)\}) = 0$ completing the proof.

THEOREM 1. *For the search game on three arcs (without the nonloitering assumption) the value is* 3.

Proof. The existence of a value V and an optimal searcher mixed strategy $\bar{s}$ is guaranteed by Gal's theorem [7, Appendix 1]. It was shown in Lemma 1 that $V \leqq 3$. We will now show that given any ε^* we can find a hider mixed strategy $\bar{h} = \bar{h}(\bar{s}, \varepsilon^*)$ such that $c(\bar{s}, \bar{h}) \geqq 3 - \varepsilon^*$. Since $\bar{s}$ is assumed optimal, we will then have $V \geqq c(\bar{s}, \bar{h})$, or $V \geqq 3 - \varepsilon^*$.

The hider strategy $\bar{h}$ is defined as follows. Choose a small positive ε which satisfies condition (4.1) for $\bar{s}$-almost all searcher pure strategies S. Lemma 3 ensures that this choice can always be made with arbitrarily small ε. Denote $t_i = i - \varepsilon$ for all integers i and let Z_i denote either A or B respectively, depending on whether i is odd or even. Let $\delta_1 = 0$ and for $i = 2, 3, \cdots$ choose $\delta_i > 0$ sufficiently small so that

$$\bar{s}(\{S: 0 < d(S(t_i), Z_i) \leqq 2\delta_i\}) < \varepsilon 2^{-i}. \tag{4.2}$$

This is always possible since for fixed i the sets with say $\delta_i = 1/n$ are decreasing and have empty intersection. To choose a pure hider strategy $\bar{H}$ according to $\bar{h}$, proceed

as follows (this procedure defines $\bar{h}$). First pick a pure strategy H using the oscillation strategy $h^*(\varepsilon)$ of staying at B until time $1-\varepsilon$ and then oscillating randomly as described in § 3. Let $t_i^- = t_i - \delta_i$ and $t_i^+ = t_i + \delta_i$. Define $\bar{H}$, given H, by $\bar{H}(t) = H(t_i^-) = H(t_i^+)$ for $t_i^- \leqq t \leqq t_i^+$ if $H(t_i^-) = H(t_i^+)$ and $\bar{H}(t) = H(t)$ otherwise. This is perhaps easier in words: If the same arc is chosen for the transit just before t_i and for just after t_i, then do not go all the way to $Z_i = H(t_i)$ but instead wait at distance δ_i from Z_i during the interval $t_i^- \leqq t \leqq t_i^+$.

Let $\hat{\mathcal{S}}$ denote the subset of $\mathcal{S}$ consisting of all S satisfying condition (4.1) with respect to the ε chosen above, and such that

(4.3) For all i, either $S(t_i) = Z_i$ or $d(S(t_i), Z_i) > 2\delta_i$.

Our choices of ε and the δ_i ensure that

(4.4) $$s(\hat{\mathcal{S}}) > 1 - \varepsilon/2.$$

We will show that

(4.5) $$c(S, \bar{h}) \geqq 3 - 2\varepsilon \quad \text{for all } S \text{ in } \hat{\mathcal{S}}.$$

It will then follow from (4.4) and (4.5) that $V \geqq c(S, \bar{h}) \geqq (\varepsilon/2)(0) + (1-\varepsilon/2) \times (3-2\varepsilon)$ for all S in $\mathcal{S}$. By choosing ε sufficiently small we thus have $V \geqq 3 - \varepsilon^*$. It remains only to demonstrate (4.5).

Fix any S in $\hat{\mathcal{S}}$ and define a vector $x = (x_1, x_2, \cdots)$, which depends on S, by $x_i = 1$ if $S(t_i) = Z_i$ and $x_i = 0$ otherwise. Observe that $x_1 = 0$ and that

(4.6) $$x_i x_{i+1} = 0 \quad \text{for all } i$$

because of condition (4.1) with $\delta = 1$. We shall use the notation Pr ( ) to denote the probability of various events assuming that the searcher is using the pure strategy S and the hider is employing the mixed strategy $\bar{h}$. In particular we will need the following two important equations, which we justify below.

(4.7) $$\Pr(T > t_{i+1}^- / T > t_i) = (\tfrac{2}{3})^{1-x_i-x_{i+1}},$$

(4.8) $$\Pr(T > t_i^+ / T > t_i^-) = (\tfrac{1}{3})^{x_i}.$$

Since the hider always chooses his next arc equiprobably out of the three choices, and independently of his current arc, the respective probabilities of switching arcs (and thus going through a vertex) and staying on the same arc (avoiding the vertex) are $\frac{2}{3}$ and $\frac{1}{3}$. To justify equation (4.7), suppose the hider is "alive" at time t_i. Since S satisfies (4.1) and (4.3) the hider will certainly still be alive at time t_i^+, i.e. $T > t_i^+$. Of the three possible paths that the hider may take from t_i^+ to t_{i+1} at most one will intersect S. If neither $S(t_i) = Z_i$ nor $S(t_{i+1}) = Z_{i+1}$, then exactly one will intersect S (otherwise none will intersect S). In the former case $\Pr(T > t_{i+1}^- / T > t_i^-)$ is equal to $\frac{2}{3}$; in the latter it is equal to 1. To establish (4.8), simply observe that condition (4.3) guarantees that the only way the hider can be caught between times t_i^- and t_i^+ is if the hider switches arcs at Z_i at time t_i (which has probability $\frac{2}{3}$) and the searcher is also at Z_i at time t_i (in which case $x_i = 1$). Equations (4.7) and (4.8) may be combined to give

(4.9) $$\Pr(T > t_{i+1}^- / T > t_i^-) = (\tfrac{1}{3})^{x_i} (\tfrac{2}{3})^{1-x_i-x_{i+1}}.$$

We also make the obvious remark,

(4.10) $$\Pr(T > t_1^-) = 1.$$

Let $p_i = \Pr(T > t_i^-)$ so that $p_1 = 1$ and $p_{i+1} = p_i r_i$, where $r_i = r_i(x) = (\frac{1}{3})^{x_i}(\frac{2}{3})^{1-x_i-x_{i+1}}$. It follows that $p_i = r_1 r_2 \cdots r_{i-1}$. We may estimate

$$
\begin{aligned}
c(S, \bar{h}) &\geqq \sum_{n=1}^{\infty} t_n^- \Pr(t_n^- < T \leqq t_{n+1}) \\
&= \sum_{n=1}^{\infty} (n - \varepsilon - \delta_n)(p_n - p_{n+1}) \qquad (4.11) \\
&\geqq (1 - \varepsilon - \delta_2) + \sum_{n=2}^{\infty} p_n \geqq (1 - 2\varepsilon) + \sum_{n=2}^{\infty} p_n.
\end{aligned}
$$

But

$$
\sum_{n=2}^{\infty} p_n(x) = \sum_{n=2}^{\infty} \prod_{i=1}^{n-1} r_i(x) = \sum_{n=1}^{\infty} \prod_{i=1}^{n} r_i(x) = \phi(x),
$$

where ϕ is defined as in Lemma 2, and hence $\phi(x) = 2$. Thus (4.11) implies (4.5) completing the proof.

COROLLARY 1. *The search game on three arcs (without the nonloitering assumption) does not have an equilibrium in distribution.*

Proof. Since $V = 3$ (Theorem 1) it is sufficient to find a $\delta > 0$ such that for any h in $\mathcal{H}^*$, $U(F^+(h)) \leqq 3 - \delta$. It follows from the definitions that for any h in $\mathcal{H}^*$, $(F^+(h))(t) \geqq \sup_s (F^-(s))(t)$ so that in particular $1 - (F^+(h))(t) \leqq \min[1 - (F^-(s^*))(t), 1 - (F^-(\hat{s}))(t)]$ where s^* is Gal's oscillation strategy (§ 3) and $\hat{s}$ is the strategy of Lemma 1. Recall that $1 - (F^-(s^*))(t) = (\frac{2}{3})^{[t]}$ so that $U(F^-(s^*)) = 3$. The estimate for $T > 2$ in Lemma 1 shows that for t in the interval $[2, 3)$, $1 - (F^-(\hat{s}))(t) = \frac{3}{7}$, while $1 - (F^-(s^*))(t) = \frac{4}{9}$. Therefore

$$
\begin{aligned}
U(F^+(h)) &= \int_0^{\infty} 1 - (F^+(h))(t)\, dt \leqq \int_0^{\infty} \min[1 - (F^-(s^*))(t), 1 - (F^-(\hat{s}))(t)]\, dt \\
&\leqq \int_0^{\infty} [1 - (F^-(s^*))(t)]\, dt - \int_2^3 [(F^-(\hat{s}))(t) - (F^-(s^*))(t)]\, dt \\
&= 3 - (\tfrac{4}{7} - \tfrac{5}{9}) = 3 - \tfrac{1}{63}.
\end{aligned}
$$

LIMITING DISTRIBUTION FOR RANDOM OPTIMIZATION METHODS*

CHANG C. Y. DOREA†

Abstract. Let f be a function defined on some domain $\Omega \subset R^d$. We consider the problem of finding the global minimum of f subjected to some constraints, say $g_i(x) \leqq 0$, $i = 1, \cdots, m$. When differentiability is not assumed random optimization methods provide an alternative way to estimate the minimum. For two such methods we study the existence of the limiting distribution and the estimation of the parameter of the limiting distribution.

Key words. random optimization, limiting distribution, order statistics

1. Introduction. Let f be a measurable function defined on some domain $\Omega \subset R^d$, we like to find the global minimum of f subjected to some constraints represented by a measurable set A. That is, find l such that

$$l = \lim_{x \in A} f(x), \qquad A = \{g_i(x) \leqq 0, i = 1, \cdots, k\}. \tag{1}$$

The standard methods such as the gradient method or the steepest descent method, all require that f satisfies some differentiability property. In the cases where differentiability is not assumed random optimization methods could well be applied. Consider the random procedures described below.

Method (A). Let $\eta^1, \eta^2, \cdots$ be iid random vectors with a common distribution G. Let $X_0, X_1, \cdots$ be defined by

step 0. $X_0 = f(U)$, where U is uniformly distributed over A.

step $k+1$. Having defined X_k, let X_{k+1} be defined by

(a1) $X_{k+1} = f(\eta^{k+1})$, if $\eta^{k+1} \in A$ and $f(\eta^{k+1}) < f(\eta^k)$.

(a2) $X_{k+1} = X_k$, otherwise.

Method (B). Let $\xi^1, \xi^2, \cdots$ be iid random vectors with a common distribution H. Let $W^0, W^1, W^2, \cdots$ be defined by

step 0. $W^0 = U$, where U is uniformly distributed over A.

step $k+1$. Having defined W^k, let W^{k+1} be defined by

(b1) $W^{k+1} = W^k + \xi^{k+1}$, if $(W^k + \xi^{k+1}) \in A$.

(b2) $W^{k+1} = W^k$, otherwise

For $n \geqq 0$ define $Y_n = \min\{f(W^0), \cdots, f(W^n)\}$.

Note that the upper indices have been used to denote sequences of random vectors and the lower indices to denote sequences of random variables. For related results on Method (B) see Baba [1], Dorea [2] and Solis-Wets [6]. In fact, Method (B) can be viewed as a particular setting of the conceptual random algorithm considered by Solis-Wets [6].

Now a confidence statement for l can be made if the limiting distribution of X_n (or Y_n) properly normalized exists and the parameters of this limiting distribution can be estimated.

Notice that $X_n = \min\{X_0, \cdots, X_n\} \geqq \min\{f(U), f(\eta^1), \cdots, f(\eta^n)\}$ with equality holding if $P(A) = 1$. Since the X_j's are not independent the usual extreme value theory cannot be directly applied. Also W^n is not exactly a random vector whose components are partial sums of independent random variables or randomly stopped subsequences

* Received by the editors June 14, 1983, and in revised from May 15, 1984. This research was supported in part by CNPq 200607/82 and CNPq 301508/84.

† Departameto de Matematica, Universidade de Brasilia, 70910 Brasilia-DF, Brazil. This research was carried out while the author was at Iowa State University, Ames, Iowa 50011.

of partial sums. And again the results on the minimum of functions of partial sums cannot be used. In fact, W^n can be regarded as a partial sum of randomly selected r.v.'s

$$W^n = U + \sum_{i=1}^{n} \xi^{\sigma(i)}$$

where $\xi^0 = 0$, $\sigma(i) = i$ if $W^{i-1} + \xi^i \in A$, otherwise $\sigma(i) = 0$.

Thus our problem reduces to finding conditions on f and G (or H) that assure weak convergence under this dependence setting. In the next section it will be shown that if Condition (A) (Condition (B)) is satisfied then $X_n(Y_n)$ properly normalized converges weakly to a distribution of type $1 - b \exp(-x^\alpha)$, where $0 < b \leqq 1$ and $\alpha > 0$. Finally in § 3, following the approach of de Haan [4], we provide an asymptotic estimate of the parameter α based on the limiting behavior of the ratio of the differences of small order statistics.

2. Limiting distribution. Our problem is to find conditions under which there exist norming constants $a_n > 0$ that will assure the existence of a nondegenerate limiting distribution for $(X_n - l)/a_n$ (or $(Y_n - l)/a_n$). The introduction of norming constants is made necessary since in general we have convergence to the degenerate distribution, that is, $\lim_{n\to\infty} P(X_n = l) = 1$ (see Dorea [2]).

Let $A \subset R^d$ be a bounded and measurable set, say $A \subset [-L, L]^d$, and f a measurable function defined on $\Omega \supset A$. Let

Condition (A). (a1) $G = \pi G_i$ is a distribution such that $P(A) > 0$.

(a2) There exists a positive function $v(t)$, $t > 0$, with $\lim_{t\downarrow 0} v(t) = 0$ and $\alpha > 0$ such that for all $y > 0$ we have

$$\begin{aligned} &m(A_t(y)) \to y^\alpha \quad \text{as } t \downarrow 0, \\ &A_t(y) = \{u\colon tu \in (0,1)^d,\ G^*(tu) \in \bar{A},\ f(G^*(tu)) \leqq l + yv(t)\}. \end{aligned} \tag{2}$$

where $G = \pi G_i$ indicates that G is the product of its marginal distributions; $tu = (tu_1, \cdots, tu_d)$; m stands for the Lebesgue measure; and for $s \in (0,1)^d$, $G^*(s) = \{G_i^*(s_i), 1 \leqq i \leqq d\}$ with $G_i^*(s_i) = \inf\{r\colon G_i(r) \geqq s_i\}$.

Condition (B). (b1) H has a density function $h(x) \geqq \delta > 0$ for $x \in [-2L, 2L]^d$.

(b2) There exists a positive function $v(t)$, $t > 0$, with

$$\lim_{t\downarrow 0} v(t) = 0$$

and $\alpha > 0$ such that for all $y > 0$ we have as $t \downarrow 0$,

$$m\{u\colon tu \in A, f(tu) \leqq l + yv(t)\} \to y^\alpha. \tag{3}$$

Although conditions (2) and (3) are not easy to verify, examples (a) and (b) below show that they are not too restrictive. Note that if $G'(x) > 0$ on A then (2) reduces to (3). And, for (3) f need not satisfy sided Lipschitz type conditions or even be continuous. In de Haan [4, p. 469] we can find sufficient conditions for f to satisfy (2) when G is the uniform distribution on A and there exists $x_0 \in A$, $f(x_0) = l$ and $f(x) > l$, $x \neq x_0$. Namely, there exists $v(t) > 0$, $v(t) \to 0$ such that

$$\lim_{t\downarrow 0} \frac{f(x_0 + t_x) - l}{v(t)} \tag{4}$$

exists and is positive for all $x \neq 0$.

Examples. (a) Let $A = [-1, 1]^2$ and $f(x, y) = \max(|x|, |y|)$. Then (4) is verified with $v(t) = t$.

(b) Let $A=[-1, 1]$ and Q be any distribution with density $q(x)>0$ on A. Let

$$f(x)=\begin{cases} x^2, & -1\leqq x\leqq 0, \\ x\left(\sin\dfrac{1}{x}+2\right), & 0<x\leqq 1 \end{cases}$$

and $v(t)=(t/g(0))^2$ then (2) is satisfied with $\alpha=\frac{1}{2}$. Let $\beta>0$ and $f(x)=1$, $-1\leqq x\leqq 0$, $f(x)=x^{\beta}$. $0<x\leqq 1$, then (3) is satisfied with $v(t)=t^{\beta}$ and $\alpha=1/\beta$. Note that in both cases de Haan's condition (4) is not satisfied.

Let $E=[-2L, 2L]^d$, $a_n=v(n^{-1/d})$,

$$\tilde{X}_n=a_n^{-1}(X_n-l) \quad \text{and} \quad \tilde{Y}_n=a_n^{-1}(Y_n-l). \tag{5}$$

THEOREM (A). *Let X_n be defined by Method* (A) *and assume that Condition* (A) *holds. Then*

$$\lim_{n\to\infty} P(\tilde{X}_n\leqq y)=1-b\exp(-y^{\alpha}), \qquad y>0. \tag{6}$$

THEOREM (B). *Let Y_n be defined by Method* (B) *and assume that Condition* (B) *holds. Then for $y>0$*

$$\begin{aligned} 1-\exp(-cy^{\alpha}) &\leqq \liminf_{n\to\infty} P(\tilde{Y}_n\leqq y) \\ &\leqq \limsup_{n\to\infty} P(\tilde{Y}_n\leqq y)\leqq 1-\exp(-Cy^{\alpha}), \end{aligned} \tag{7}$$

where $c=\inf_{x\in E} h(x)$ and $C=\sup_{x\in E} h(x)$.

COROLLARY (B). *If H is such that it is uniform on E then for $a_n=v(n^{-1/d})c^{-1/\alpha}$ we have for $y>0$*

$$\lim_{n\to\infty} P(\tilde{Y}_n\leqq y)=1-\exp(-y^{\alpha}). \tag{8}$$

Remarks. Although we were not able to find the limiting distribution for Method (B) except for those satisfying Corollary (B), it is worth pointing out that with respect to the expected number of steps required to reach an ε-neighborhood of l, the uniform distribution on E is the optimizing one and it satisfies Corollary (B) (see Dorea [2]). If general distributions are considered in Condition (A) by dropping the requirement $G=\pi G_i$, the results of Theorem (A) can still be obtained. In this case one needs to replace (2) by a condition on the distribution of $f(\eta)$:

$$P(\eta\in A, f(\eta)\leqq l+yv(t))\to y^{\alpha}.$$

An alternative approach is to express the required dependence of G by means of constraint functions g_i that determine A.

Proof of Theorem (A). Let η be a r.v. with distribution G and let

$$\begin{aligned} &P_A=P(\eta\in A), \qquad q_A=1-p_A, \\ &\beta_n=P(f(\eta)>l+a_n y,\ \eta\in A), \\ &\gamma_n=P(f(U)>l+a_n y). \end{aligned} \tag{9}$$

Then we can write

$$\begin{aligned} P(\tilde{X}_n>y) &= P(f(U)>l+a_n y,\ \eta_i\notin A,\ i=1,\cdots,n)+\cdots \\ &\quad +P(f(U)>l+a_n y, f(\eta_i)>l+a_n y,\ \eta_i\in A,\ i=1,\cdots,n) \\ &= \gamma_n(q_A+\beta_n)^n. \end{aligned} \tag{10}$$

(a1) Since U is uniformly distributed and $a_n \downarrow 0$ we have

$$\lim_{n\to\infty} \gamma_n = b, \qquad 0 < b \leqq 1. \tag{11}$$

Note that since (2) is satisfied we have $b = 1$ whenever $G'(x) > 0$ on A.

(a2) Let $F_t(y) = \{u\colon u \in A, f(u) \leqq l + yv(t)\}$ so that

$$\beta_n = p_A - P(\eta \in F_{n^{-1/d}}(y)).$$

Let $V = (V_1, \cdots, V_d)$ be uniformly distributed on $[0, 1]^d$. Then, since $G = \pi G_i$ we have η and $G^*(V) = \{G_1^*(V_1), \cdots, G_d^*(V_d)\}$ with the same probability distribution. Hence we can write

$$\begin{aligned} P(\eta \in F_t(y)) &= P(G^*(V) \in F_t(y)) \\ &= P(G^*(V) \in A, f(G^*(V)) \leqq l + yv(t)) = t^d m(A_t(y)). \end{aligned}$$

From (2) it follows that

$$\frac{1}{t^d} P(\eta \in F_t(y)) \to y^\alpha \quad \text{as } t \downarrow 0;$$

hence

$$n \log (1 - P(\eta \in F_{n^{-1/d}}(y)) \to -y^\alpha \quad \text{as } n \to \infty. \tag{12}$$

(a3) Finally from (10), (11) and (12) we have

$$P(\tilde{X}_n \leqq y) = 1 - \gamma_n (1 - P(\eta \in F_{n^{-1/d}}(y)))^n$$

and

$$\lim_{n\to\infty} P(\tilde{X}_n \leqq y) = 1 - b \exp(-y^\alpha).$$

Proof of Theorem (B). First notice that $Y_0 \geqq Y_1 \geqq \cdots \geqq Y_n$ and

$$P(\tilde{Y}_n > y) = P(\tilde{Y}_{n-1} > y) - P(\tilde{Y}_n \leqq y,\ \tilde{Y}_{n-1} > y). \tag{13}$$

(b1) By (3)

$$P(\tilde{Y}_0 > y) = P(f(U) > l + a_n y) = \gamma_n \xrightarrow[n\to\infty]{} 1. \tag{14}$$

(b2) Clearly for all $x \in A$ the conditional density of $W^k + \xi^{k+1}$ given W^k is

$$h_{W^k + \xi^{k+1} | W^k}(z|x) = h(z - x) \tag{15}$$

and

$$\begin{aligned} &\inf_{z\in A, x\in A} h(z - x) \geqq c \geqq \delta > 0, \\ &\sup_{z\in A, x\in A} h(z - x) \leqq C. \end{aligned} \tag{16}$$

Now let F_{j-1} denote the distribution of W^{j-1}. Then by (15)

$$P(\tilde{Y}_j \leqq y,\ \tilde{Y}_{j-1} > y) = \int_{A \setminus Q_n} \int_{Q_n} h(z - x)\, dz\, dF_{j-1}(x)$$

where $Q_n = \{u\colon u \in A, f(u) \leqq l + ya_n\}$.

By (16) we have

$$cm(Q_n) P(\tilde{Y}_{j-1} > y) \leqq P(\tilde{Y}_j \leqq y,\ \tilde{Y}_{j-1} > y) \leqq Cm(Q_n) P(\tilde{Y}_{j-1} > y). \tag{17}$$

From (13), (14) and (17) we have

$$\gamma_n(1-Cm(Q_n))^n \leqq P(\tilde{Y}_n > y) \leqq \gamma_n(1-cm(Q_n))^n.$$

Now from (3) it follows that $nm(Q_n) \to y^\alpha$, so that (7) follows.

3. Estimation of the parameter. Let $Z_1, Z_2, \cdots$ be iid r.v.'s with common distribution F and let $Z_{(1)} \leqq Z_{(2)} \leqq \cdots \leqq Z_{(n)}$ denote the order statistics from $(Z_1, \cdots, Z_n)$. From de Haan [4] it follows that if for some $\alpha > 0$ we have

$$\lim_{t \downarrow 0} \frac{F(l+tx)}{F(l+t)} = x^\alpha \quad \text{for all } x > 0, \tag{18}$$

then for

$$\varphi_Z(n) = \log \frac{Z_{(k(n))} - Z_{(3)}}{Z_{(2)} - Z_{(1)}} \Big/ \log k(n) \tag{19}$$

we have for all $\varepsilon > 0$

$$\lim_{n \to \infty} P(|\varphi_Z(n) - 1/\alpha| > \varepsilon) = 0 \tag{20}$$

provided $k(n) \to \infty$ and $k(n)/n \to 0$.

It is easy to verify that (20) remains true if (18) holds with a positive function $v(t)$ with $\lim_{t \downarrow 0} v(t) = 0$ in place of t. We shall adapt the above results to our dependence setting of Methods (A) and (B). For $j \geqq 1$ define the following stopping times

$$\sigma_j = \inf\{i: i > \sigma_{j-1}, \eta^i \in A\}, \qquad \sigma_0 = 0,$$

$$\tau_j = \inf\{i: i > \tau_{j-1}, W^{\tau_{j-1}} + \xi^i \in A\}, \qquad \tau_0 = 0.$$

For $k \geqq 1$ let $R_k = f(\eta^{\sigma_k})$ and $S_k = f(W^{\tau_k})$ and define $\varphi_R(n)$ and $\varphi_S(n)$ analogously as in (19).

PROPOSITION (A). *Suppose Condition* (A) *is satisfied. Then*

$$\lim_{n \to \infty} P(|\varphi_R(n) - 1/\alpha| \geqq \varepsilon) = 0 \quad \forall \varepsilon > 0. \tag{21}$$

PROPOSITION (B). *Suppose Condition* (B) *is satisfied and H has a density* $h(x)$ *with* $h(x) = c > 0$, $-2L \leqq x \leqq 2L$. *Then*

$$\lim_{n \to \infty} P(|\varphi_S(n) - 1/\alpha| \geqq \varepsilon) = 0 \quad \forall \varepsilon > 0. \tag{22}$$

Proof of Proposition (A). First we will show that $R_1, R_2, \cdots$ are iid with the distribution

$$F_R(x) = \frac{1}{P(A)} \int_{\{u: u \in A, f(u) \leqq x\}} dG(u).$$

This follows from the relation

$$P(\eta^{\sigma_1} \leqq x^1, \cdots, \eta^{\sigma_k} \leqq x^k) = \sum_{1 \leqq i_1 < i_2 < \cdots < i_k} P(\sigma_j = i_j, \eta^{i_j} \leqq x^j, j = 1, \cdots, k)$$

$$= \sum_{1 \leqq i_1 < i_2 < \cdots < i_k} q_A^{i_1 - 1} p_A(x^1) \cdots q_A^{i_k - i_{k-1} - 1} p_A(x^k)$$

where

$$q_A = 1 - P(A), \; p_A(x) = \int_{\{u \in A, u \leqq x\}} dG(u) \quad \text{and} \quad (\eta \leqq x) = \{\eta_i \leqq x_i, i = 1, \cdots, d\}.$$

It remains to show that F_R satisfies (18); now

$$F_R(l+yv(t)) = \frac{1}{P(A)} P(\eta^1 \in A, f(\eta^1) \leqq l+yv(t)).$$

Proceeding as in step (a2) of Theorem (A) we can write

$$F_R(l+yv(t)) = \frac{1}{P(A)} t^d m(A_t(y)).$$

Now from (2)

$$\lim_{t \downarrow 0} \frac{m(A_t(y))}{m(A_t(1))} = y^\alpha,$$

so that (18) follows.

Remark. If we assume F_R absolutely continuous we have

$$P(R_{(1)} < R_{(2)} < \cdots < R_{(n)}) = 1$$

and (21) can be translated in terms of X_n's of Method (A). Let $\rho_1 = n$, $\rho_j = \sup\{k: k < \rho_{j-1}, X_k \neq X_{\rho_{j-1}}\}$ and from (21) $\log((X_{\rho_{k(n)}} - X_{\rho_3})/(X_{\rho_3} - X_{\rho_2}))/\log k(n)$ converges in probability to $1/\alpha$. Analogous results hold for the Y_n's of Method (B).

Proof of Proposition (B). Notice that

$$P(W^{\tau_1} \leqq x) = \sum_{i=1}^{\infty} P(U + \xi^k \leqq x, \tau_1 = k)$$

and

$$P(U + \xi^k \leqq x, \tau_1 = k) = (1 - cm(A))^{k-1} P(U + \xi^k \leqq x, U + \xi^k \in A)$$

since

$$P(U + \xi^k \in A) = \int_A \int_{x \in A \setminus u} \frac{c}{m(A)} du\, dx = cm(A).$$

So we can write

$$P(W^{\tau_1} \leqq x) = \frac{1}{P(A)} P(\xi^1 : \xi^1 \in A, \xi^1 \leqq x).$$

Now proceeding as in Proposition (A) we can show that $W^{\tau_1}, W^{\tau_2}, \cdots$ are iid r.v.'s. Moreover

$$F_S(x) = \frac{c}{P(A)} m\{u: u \in A, f(u) \leqq x\}$$

and (18) follows from (3).

Acknowledgment. The author wishes to thank the referee for helpful comments and suggestions.

ON THE INTERPLAY OF SINGULAR PERTURBATIONS AND WIDE-BAND STOCHASTIC FLUCTUATIONS*

MOHAMED EL-ANSARY† AND HASSAN KHALIL‡

Abstract. A class of nonlinear singularly perturbed systems driven by wide-band noise is considered. The asymptotic behavior of the slow variables is studied when the fast variables are sufficiently fast (represented by $\mu \to 0$) and the wide-band noise is sufficiently wide (represented by $\varepsilon \to 0$). A reduced-order Markov model which represents the behavior of the slow variables is derived. It is shown that the slow variables converge weakly to the solution of this reduced-order model as ε and μ tend to zero. The coefficients of this reduced-order model depend, in general, on the speeds of ε and μ as they approach zero. The implication of such dependence on the engineering practice of neglecting parasitic elements is discussed. Special cases where the model is independent of the speeds of ε and μ are explored.

Key words. asymptotic methods, model order reduction, singular perturbation, wide-band stochastic fluctuations

1. Introduction. The purpose of this paper is to highlight the interplay of two asymptotic phenomena which arise in the analysis and design of control systems. The first phenomenon arises in singular perturbation analysis of deterministic systems containing parasitic elements while the second phenomenon arises in asymptotic stochastic analysis of systems driven by wide-band noise.

Consider the singularly perturbed system

$$\dot{x}(t) = f(x(t), y(t), u(t)), \tag{1.1}$$

$$\mu \dot{y}(t) = g(x(t), y(t), u(t)), \tag{1.2}$$

where μ is a small positive parameter representing parasitic elements. If the input $u(t)$ is smooth and deterministic, a reduced-order model of this system can be obtained by neglecting the parasitic elements, i.e. by setting $\mu = 0$. Assuming that the algebraic equation

$$0 = g(\bar{x}(t), \bar{y}(t), u(t)) \tag{1.3}$$

has a unique root

$$\bar{y}(t) = h(\bar{x}(t), u(t)), \tag{1.4}$$

the reduced-order model is given by

$$\dot{\bar{x}}(t) = f(\bar{x}(t), u(t)). \tag{1.5}$$

The literature on singular perturbation theory (see [1] for a survey) is full of analyses validating this order reduction procedure. In particular if both $x(t)$ and $\bar{x}(t)$ start from the same initial conditions, then under certain stability conditions imposed on the boundary layer system, $x(t) \to \bar{x}(t)$ as $\mu \to 0$, on compact time intervals.

Consider next a system described by the differential equation

$$\dot{x}(t) = f(x(t)) + G(x(t))v^{\varepsilon}(t) \tag{1.6}$$

* Received by the editors July 5, 1983, and in revised form July 10, 1984. A preliminary version of this paper was presented at the 21st IEEE Conference on Decision and Control, Orlando, Florida, 1982. The work of this paper was supported by the U.S. Department of Energy, Electric Energy Systems Division, under contract DE-AC01-80RA50425 with Michigan State University.

where $v^\varepsilon(t)$ is a wide-band stationary process in the sense that its spectrum is flat up to a frequency of order $1/\varepsilon$ where ε is a small positive parameter. The process $v^\varepsilon(t)$ is not white noise but it tends to white noise as $\varepsilon \to 0$. Asymptotic stochastic analysis (cf. [2]-[4]) shows that $x(t)$ converges weakly to a diffusion process $\bar{x}(t)$ as $\varepsilon \to 0$, where $\bar{x}(t)$ satisfies the Ito equation

$$d\bar{x}(t) = (f(\bar{x}(t)) + g(\bar{x}(t)))\, dt + G(\bar{x}(t))\, dw. \tag{1.7}$$

The vector $g(\bar{x})$, which is usually referred to as the correction term, is formed of the elements of G and their partial derivatives with respect to x. Since most of the stochastic stability and control results have been developed for systems driven by white noise [5], the importance of the above limit is in extending the range of those results to cases when the noise is not white but only approximately so (see [3] for details).

The study of systems where both parasitic parameters and wide-band noise are present has been initiated in [6], [7]. The first paper treated linear systems and the second one nonlinear systems. The results of [6] and [7] did not show the interaction between the two asymptotic phenomena in which we are interested in this paper. Such interaction could not appear in [6] anyway since, as it will be shown, it is tied in with nonlinearities. The approach adopted in [7] did not reveal such interaction because implicit in that approach there was a sequential ordering of the two asymptotic phenomena in the sense that order reduction as in singular perturbation methods was performed first, followed by asymptotic stochastic analysis to compute the diffusion limit. The interaction between the two asymptotic phenomena has been brought to attention after a paper by Razvig [8]. In that paper Razvig considered the second order equation

$$\mu\ddot{x}(t) + \dot{x}(t) = a(x(t)) + b(x(t))v^\varepsilon(t) \tag{1.8}$$

where $v^\varepsilon(t)$ is exponentially correlated noise with correlation time ε. He studied the asymptotic behavior of $x(t)$ as ε and μ tend to zero and suggested that for sufficiently small ε and μ, $x(t)$ can be approximated by a diffusion process $\bar{x}(t)$ defined by the Ito equation

$$d\bar{x}(t) = \left[a(\bar{x}(t)) + \frac{0.5}{1+\varepsilon/\mu} \frac{\partial b}{\partial x}(\bar{x}(t))b(\bar{x}(t))S(0) \right] dt + b(x(t))\sqrt{S(0)}\, dw(t) \tag{1.9}$$

where $S(\omega/\varepsilon)$ is the spectrum of v^ε. In deriving this reduced-order model Razvig employed a formal intuitive reasoning. He assumed that over a time interval Δt which is very small with respect to the relaxation time of $x(t)$ while very large with respect to μ and ε, the process $x(t)$ will behave like a Markov process. With that assumption he went on to compute the first and second moments of $x(t+\Delta t) - x(t)$ given $x(t) = x$ which resulted in the drift and diffusion coefficients of (1.9). Razvig did not prove that $x(t)$ converges to $\bar{x}(t)$ as $\varepsilon, \mu \to 0$ in any stochastic sense. The remarkable feature of the reduced order model (1.9) is its dependence on the ratio ε/μ hinting to the interaction between the two asymptotic phenomena. Our work has been motivated by Razvig's example. Our objective has been to generalize the reduced-order model of Razvig to a wider class of systems and to provide a rigorous proof of convergence of $x(t)$ to the diffusion process defined by the reduced-order model. Section 2 gives a reduced-order model and convergence proof for a class of nonlinear singularly perturbed systems driven by wide-band noise. The class of singularly perturbed systems considered is a special case of (1.1), (1.2) in which y appears linearly. The linearity in y is assumed to avoid technical complications; yet, it is a realistic assumption and parasitics in many physical systems appear in this form. The convergence proof adapts

a martingale method developed by Kushner [9] for proving weak convergence of a sequence of non-Markovian processes to a diffusion process. In § 3 we discuss the implication of the results of § 2 on the robustness of the well established engineering practice of reducing the order of physical systems by neglecting parasitic elements.

2. Reduced-order model and convergence result. Consider the singularly perturbed system

$$\dot{x}^{\varepsilon,\mu}(t) = a_1(x^{\varepsilon,\mu}(t)) + A_{12}(x^{\varepsilon,\mu}(t))y^{\varepsilon,\mu}(t) + B_1(x^{\varepsilon,\mu}(t))v^{\varepsilon}(t), \qquad x^{\varepsilon,\mu}(0) = x_0, \tag{2.1}$$

$$\mu\dot{y}^{\varepsilon,\mu}(t) = a_{21}(x^{\varepsilon,\mu}(t)) + A_2 y^{\varepsilon,\mu}(t) + B_2(x^{\varepsilon,\mu}(t))v^{\varepsilon}(t), \qquad y^{\varepsilon,\mu}(0) = y_0 \tag{2.2}$$

where $x \in R^n$, $y \in R^m$ and x_0, y_0 are bounded random vectors. The stochastic process $v^{\varepsilon} \in R^r$ is defined as

$$v^{\varepsilon}(t) = \frac{1}{\sqrt{\varepsilon}} v(t/\varepsilon) \tag{2.3}$$

where $v(t)$ satisfies:

(A1) $v(t)$ is a stationary, zero mean, right continuous, uniformly bounded process on $[0, \infty)$. The σ-algebras induced by $v(t)$ are assumed to have a mixing property with an exponential mixing rate [10],

$$\sup_{A_i, t} |P(A_2/A_1) - P(A_2)| \leqq K e^{-\alpha\tau} \tag{2.4}$$

for some $\alpha > 0$, where $A_1 \in \sigma\{v(s), s \leqq t\}$ and $A_2 \in \sigma\{v(s), s \geqq t+\tau\}$. The exponential mixing rate assumption is taken for convenience but can be replaced by a more general mixing rate as in [2]-[4]. The process $v^{\varepsilon}(t)$ is said to be wide-band noise since its power spectral density matrix $S^{\varepsilon}(\omega) = S(\omega/\varepsilon)$ will have a frequency band of ω_0/ε when $S(\omega)$, the spectral matrix of v, has a frequency band ω_0. Indeed, the process $v^{\varepsilon}(t)$ converges to Gaussian white noise by the central limit theorem [2].

We make the following assumptions:

(A2) The coefficients a_1, a_{21}, A_{12}, B_1 and B_2 are continuous in x and have continuous partial derivatives up to the second order which are bounded uniformly in x;

(A3) The constant matrix A_2 is Hurwitz, i.e. $\operatorname{Re} \lambda(A_2) < 0$;

(A4) The positive parameters ε and μ satisfy $\varepsilon > \mu\gamma_0$ where $\gamma_0 > 0$ is arbitrary but fixed.

Under the smoothness conditions spelled out in (A2), the usual existence and uniqueness theory for ordinary differential equations gives us a solution for (2.1) and (2.2) on $[0, T]$ for each sample path of $v(\cdot)$. Condition (A3) is needed to guarantee asymptotic stability of the boundary-layer phenomena associated with y. Condition (A4) excludes the case $\varepsilon/\mu \to 0$ as $\mu \to 0$. This technicality is needed in the convergence proof as it will be pointed out later.

Our objective is to study the asymptotic behavior of $x^{\varepsilon,\mu}(\cdot)$ as $\varepsilon \to 0$ and $\mu \to 0$. The main result of this paper shows that $x^{\varepsilon,\mu}(\cdot)$ converges weakly to a diffusion process $\bar{x}(\cdot)$ with initial condition $\bar{x}(0) = x_0$. The infinitesimal generator associated with $\bar{x}(\cdot)$, whose form will follow from the proof of the result, is given by

$$L^{\gamma} f(x) = \sum_{i=1}^{n} b_i(x) \frac{\partial f}{\partial x_i}(x) + \frac{1}{2} \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial^2 f}{\partial x_i \, \partial x_j}(x), \tag{2.5}$$

where

$$b(x) = a_0(x) + h_1(x) - A_{12}(x)A_2^{-1}h_2(x) + h_3(x), \tag{2.6}$$

$$A(x) = B_0(x)S(0)B_0^T(x) \triangleq [a_{ij}(x)], \tag{2.7}$$

$$a_0(x) = a_1(x) - A_{12}(x)A_2^{-1}a_{21}(x), \tag{2.8}$$

$$B_0(x) = B_1(x) - A_{12}(x)A_2^{-1}B_2(x), \tag{2.9}$$

$S(\omega)$ is the spectral matrix of v,

$$h_{1i} = \operatorname{tr}[D_i'B_0W' + D_i'A_{12}A_2^{-1}\Sigma]^1, \tag{2.10}$$

$$h_{2i} = \operatorname{tr}[E_i'B_0W' + E_i'A_{12}A_2^{-1}\Sigma], \tag{2.11}$$

$$h_{3i} = \operatorname{tr}[-F_i'B_0W'B_2'(A_2')^{-1} - F_i'B_0\Sigma'(A_2')^{-1} + F_i'A_{12}A_2^{-1}P], \tag{2.12}$$

$$D_i = \left[\nabla_x\psi_{i1} \mid \nabla_x\psi_{i2} \mid \text{-----} \mid \nabla_x\psi_{ir}\right]_{n\times r}, \qquad B_1 = [\psi_{ij}]_{n\times r}, \tag{2.13}$$

$$E_i = \left[\nabla_x\eta_{i1} \mid \nabla_x\eta_{i2} \mid \text{-----} \mid \nabla_x\eta_{ir}\right]_{n\times r}, \qquad B_2 = [\eta_{ij}]_{m\times r}, \tag{2.14}$$

$$F_i = \left[\nabla_x\xi_{i1} \mid \nabla_x\xi_{i2} \mid \text{-----} \mid \nabla_x\xi_{im}\right]_{n\times m}, \qquad A_{12} = [\xi ij]_{n\times m}, \tag{2.15}$$

$$W = \int_0^\infty R(\tau)\,d\tau, \quad R \text{ is the correlation matrix of } v,$$

$$\Sigma = \int_0^\infty e^{A_2\gamma\tau}B_2R'(\tau)\,d\tau \quad \text{for some } \gamma \in [\gamma_0, \infty),\ \gamma_0 > 0, \tag{2.16}$$

$$P = \int_0^\infty e^{A_2\lambda}(B_2\Sigma' + \Sigma B_2')\,e^{A_2'\lambda}\,d\lambda. \tag{2.17}$$

We require that

(A5) $b(x)$ and $B_0(x)$ satisfy the growth and Lipschitz conditions

$$|b(x)| + |B_0(x)| \leqq K(1+|x|) \qquad \forall x \in R^n,$$

$$|b(x) - b(z)| + |B_0(x) - B_0(z)| \leqq K|x - z| \qquad \forall x, z \in R^n.$$

Condition (A5) implies that the martingale problem corresponding to L^γ is well-posed [11]. Condition (A5) follows from the smoothness condition (A2) if A_{12} is independent of x or if a_{21} is bounded and B_2 is independent of x. It is, however, a restrictive requirement that eliminates some interesting problems. For example, it does not allow both A_{12} and B_2 to be linear in x simultaneously.

Our main result is the following theorem.

THEOREM 1. *Under the assumptions* (A1) *to* (A5), $x^{\varepsilon,\mu}(\cdot)$ *converges weakly to* $\bar{x}(\cdot)$ *as* $\varepsilon \to 0$, $\mu \to 0$ *and* $\varepsilon/\mu \to \gamma$.

Proof. We utilize a technique for proving weak convergence of a sequence of non-Markovian processes to a diffusion process which was introduced by Kurtz [12] and further developed by Kushner [4], [9], [13]. The version used here is due to Kushner [9]. Our proof, in fact, follows Kushner's method step-by-step as it was applied in [13]. There are, however, two additional levels of complexity in our proof. The first one is due to the singularly perturbed equation (2.2). The second one is in computing the explicit form of the operator L^γ, which required lengthy and detailed manipulations. Before we state Kushner's method we need to introduce some definitions and terminology which are recalled from [9].

[1] (') denotes transposition.

Truncated processes. For every positive integer N, let $S_N = \{x \in R^n, \|x\| \leqq N\}$ and define the truncated process $x_N^{\varepsilon,\mu}(t)$ to be the solution of (2.1), (2.2) with the right-hand side of (2.1) multiplied by $q_N(x)$, i.e.,

$$\dot{x}_N^{\varepsilon,\mu} = q_N(x_N^{\varepsilon,\mu})[a_1(x_N^{\varepsilon,\mu}) + A_{12}(x_N^{\varepsilon,\mu})y_N^{\varepsilon,\mu} + B_1(x_N^{\varepsilon,\mu})v^\varepsilon], \quad x_N^{\varepsilon,\mu}(0) = x_0, \tag{2.18}$$

$$\mu\dot{y}_N^{\varepsilon,\mu} = a_{21}(x_N^{\varepsilon,\mu}) + A_2 y_N^{\varepsilon,\mu} + B_2(x_N^{\varepsilon,\mu})v^\varepsilon, \quad y_N^{\varepsilon,\mu}(0) = y_0, \tag{2.19}$$

where $q_N(x) = 1$ for $x \in S_N$, $q_N(x) = 0$ for $x \in R^n - S_{N+1}$ and $q_N(x) \in [0, 1]$ and has third derivatives that are bounded uniformly in x and N. For each N, $\{x_N^{\varepsilon,\mu}(\cdot)\}$ is bounded uniformly in μ and ε. As it will be seen, the actual technical proof involves only the truncated processes $\{x_N^{\varepsilon,\mu}(\cdot)\}$. See [9], [13] for similar treatment.

Terminology. Let $(\Omega, P, \mathscr{F})$ be the probability space in which $v(\cdot)$ is defined and let $\mathscr{F}_{t,N}^{\varepsilon,\mu}$ be the σ-algebra induced by $\{x_N^{\varepsilon,\mu}(s), y_N^{\varepsilon,\mu}(s), v^\varepsilon(s), 0 \leqq s \leqq t\}$ and $E_{t,N}^{\varepsilon,\mu}$ the corresponding conditional expectation. Let $\mathscr{L}^0$ be the class of measurable (ω, t) real valued functions such that if $f(\cdot) \in \mathscr{L}^0$ then $E|f(t+s) - f(t)| \to 0$ as $s \to 0^+$, $\sup_t E|f(t)| < \infty$ and $f(t)$ is adapted to $\mathscr{F}_{t,N}^{\varepsilon,\mu}$. We say $p - \lim_{s\to 0} f^s = 0 \Leftrightarrow \sup_{s,t} E|f^s(t)| < \infty$ and $E|f^s(t)| \to 0$ as $s \to 0^+$. Define an operator $A_N^{\varepsilon,\mu}$ and its domain $D(A_N^{\varepsilon,\mu})$ as follows: $f \in D(A_N^{\varepsilon,\mu})$ and $A_N^{\varepsilon,\mu} f = g \Leftrightarrow f, g \in \mathscr{L}^0$ and

$$p - \lim_{r\to 0} \left| \frac{E_{t,N}^{\varepsilon,\mu} f(t+r) - f(t)}{r} - g(t) \right| = 0.$$

Let L_N^γ be a diffusion operator of the form (2.7) such that the coefficients of L_N^γ and L^γ are equal for $x \in S_N$. Let $\hat{\mathscr{C}}_0$ be the space of continuous functions $f: R^n \to R$ which have compact support and $\hat{\mathscr{C}}_0^3$ be the space of functions which belongs to $\hat{\mathscr{C}}_0$ together with its partial derivatives up to the third order.

The following lemma is Theorems (1) and (2) of [9] adapted to our case.

LEMMA 1. *Assume that the martingale problem associated with L^γ is well-posed. For each fixed N, let $\{x_N^{\varepsilon,\mu}(\cdot)\}$ be the solution of* (2.18) *and* (2.19). *Suppose that for each $f \in \hat{\mathscr{C}}_0^3$, there is a sequence $f_N^{\varepsilon,\mu}(\cdot) \in D(A_N^{\varepsilon,\mu})$ and a random variable $M_{N,T}^{\varepsilon,\mu}(f)$, for each $T > 0$, such that*

$$p - \lim_{\substack{\varepsilon,\mu\to 0 \\ \varepsilon/\mu\to\gamma}} [f_N^{\varepsilon,\mu}(t) - f(x_N^{\varepsilon,\mu}(t))] = 0, \tag{2.20}$$

$$p - \lim_{\substack{\varepsilon,\mu\to 0 \\ \varepsilon/\mu\to\gamma}} [A_N^{\varepsilon,\mu} f_N^{\varepsilon,\mu}(t) - L_N^\gamma f(x_N^{\varepsilon,\mu}(t))] = 0, \tag{2.21}$$

$$p\{\sup_{t\leqq T} |f_N^{\varepsilon,\mu}(t) - f(x_N^{\varepsilon,\mu}(t))| \geqq \eta\} \to 0 \quad \text{as } \varepsilon, \mu \to 0, \varepsilon/\mu \to \gamma, \tag{2.22}$$

$$\sup_{t\leqq T} |A_N^{\varepsilon,\mu} f_N^{\varepsilon,\mu}(t)| \leqq M_{N,T}^{\varepsilon,\mu}(f), \tag{2.23}$$

$$\sup_{\varepsilon,\mu} p\{M_{N,T}^{\varepsilon,\mu}(f) \geqq K\} \to 0 \quad \text{as } K \to \infty. \tag{2.24}$$

Then $\{x^{\varepsilon,\mu}(\cdot)\}$ converges weakly to $\bar{x}(\cdot)$ as $\varepsilon \to 0$, $\mu \to 0$ and $\varepsilon/\mu \to \gamma$.

For notational convenience we write $x(t)$, $y(t)$, $A^{\varepsilon,\mu}$, L^γ, $f_i(t)$ and E_t instead of $x_N^{\varepsilon,\mu}(t)$, $y_N^{\varepsilon,\mu}(t)$, $A_N^{\varepsilon,\mu}$, L_N^γ, $f_{i,N}^{\varepsilon,\mu}(t)$ and $E_{t,N}^{\varepsilon,\mu}$ respectively but we are always working with the truncated process $\{x_N^{\varepsilon,\mu}(\cdot)\}$. Moreover, we omit the q_N terms for further simplification. Now we proceed with the proof of the theorem. Let $f \in \mathscr{C}_0^3$ be given, then the test function $f^{\varepsilon,\mu}(t)$ is constructed in three steps as in [13]. First, we have

$$A^{\varepsilon,\mu} f(x(t)) = \frac{\partial f}{\partial x}(x(t))[a_1(x(t)) + A_{12}(x(t))y(t) + B_1(x(t))v^\varepsilon(t)]. \tag{2.25}$$

The last two terms on the right-hand side of (2.25) are not uniformly bounded in ε and μ and cannot be part of the operator L^γ, so they are averaged out by defining $f_1(x, t)$ as:

$$f_1(x,t)=\int_0^\infty E_t\frac{\partial f}{\partial x}(x)[A_{12}(x)[\hat{y}(t+s,x)+A_2^{-1}a_{21}(x)]+B_1(x)v^\varepsilon(t+s)]\,ds \tag{2.26}$$

where

$$\begin{aligned}\hat{y}(t+s,x)&=e^{A_2 s/\mu}y(t)+(e^{A_2 s/\mu}-I)A_2^{-1}a_{21}(x)\\&\quad+\frac{1}{\mu}\int_t^{t+s}e^{A_2(t+s-\tau)/\mu}B_2(x)v^\varepsilon(\tau)\,d\tau.\end{aligned} \tag{2.27}$$

Here, $\hat{y}(t+s, x)$ is the solution of the singularly perturbed equation (2.19) starting at $s=0$ from initial condition $y(t)$ with x, on the right-hand side of (2.19), being frozen at $x=x(t)$. Subtracting the term $-A_2^{-1}a_{21}(x)$ in (2.26), in a sense, centers $\hat{y}$ at its steady-state mean. Using (2.27), it is straightforward to show that $f_1(x, t)$ is given by

$$\begin{aligned}f_1(x,t)&=-\mu\frac{\partial f}{\partial x}(x)A_{12}(x)A_2^{-1}[y(t)+A_2^{-1}a_{21}(x)]\\&\quad+\frac{\partial f}{\partial x}B_0(x)\int_0^\infty E_t v^\varepsilon(t+s)\,ds.\end{aligned} \tag{2.28}$$

But direct solution of (2.19) starting at $t=0$ shows that $y(t)$ is given by

$$y(t)=e^{A_2 t/\mu}y_0+\frac{1}{\mu}\int_0^t e^{A_2(t-\tau)/\mu}\left[a_{21}(x(\tau))+B_2(x(\tau))\frac{1}{\sqrt{\varepsilon}}v(\tau/\varepsilon)\right]d\tau. \tag{2.29}$$

Using the boundedness of v and y_0, the boundedness of a_{21} and B_2, which follows from the boundedness of the truncated process, and the exponentially decaying nature of the transition matrix $\exp[A_2 t/\mu]$, it can be shown that $\sqrt{\varepsilon}\,y(t)$ is uniformly bounded in ε and μ. Hence, using the mixing property (2.4), the compact support of $(\partial f/\partial x)(x)$ and the boundedness of the truncated process $x(t)$, we get

$$|f_1(x,t)|\leqq C_1\sqrt{\varepsilon}+C_2\mu/\sqrt{\varepsilon}. \tag{2.30}$$

The restriction $\varepsilon/\mu\geqq\gamma_0>0$ guarantees that the right-hand side of (2.30) is bounded by $C_1\sqrt{\varepsilon}+C_3\sqrt{\mu}$; that is why this restriction has been imposed. Thus we have shown that

$$|f_1(t)|=|f_1(x(t),t)|\leqq K_1(\sqrt{\varepsilon}+\sqrt{\mu}). \tag{2.31}$$

$K_1>0$ is independent of ε, μ and ω.

Operating on $f_1(t)$ by $A^{\varepsilon,\mu}$, we get

$$\begin{aligned}A^{\varepsilon,\mu}f_1(t)&=-\frac{\partial f}{\partial x}(x)[A_{12}(x)y(t)+A_{12}(x)A_2^{-1}a_{21}(x)+B_1(x)v^\varepsilon(t)]\\&\quad+\frac{\partial f_1}{\partial x}(x,t)[a_1(x)+A_{12}(x)y(t)+B_1(x)v^\varepsilon(t)].\end{aligned} \tag{2.32}$$

Adding (2.25) to (2.32) yields

$$A^{\varepsilon,\mu}(f(x)+f_1(t))=\frac{\partial f}{\partial x}(x)a_0(x)+\frac{\partial f_1}{\partial x}(x,t)[a_1(x)+A_{12}(x)y(t)+B_1(x)v^\varepsilon(t)]. \tag{2.33}$$

The last two terms of (2.33) are, again, not uniformly bounded in ε and μ and cannot be part of L^γ, so we average them out by defining f_2 as

$$f_2(x,t)=\int_0^\infty \left[E_t \frac{\partial f_1}{\partial x}(x,t+s)(A_{12}(x)\hat{y}(t+s,x)+A_{12}(x)A_2^{-1}a_{21}(x)+B_1(x)v^\varepsilon(t+s)) \right.$$

(2.34)

$$\left. +\frac{\partial f}{\partial x}(x)a_0(x)-L^{(\varepsilon/\mu)}f(x) \right] ds.$$

The form of $L^{(\varepsilon/\mu)}$, as defined by (2.5)-(2.17) with ε/μ replacing γ, results as a by product of showing that $|f_2(x(t),t)|$ is $O(\mu+\varepsilon)$, i.e., by identifying the parts of the first three terms on the right-hand side of (2.34) which are not $O(\varepsilon)$ or $O(\mu)$. This involves lengthy calculations which are given in detail in [17]. Using the compact support of f_x and f_{xx}, the mixing property (2.4) and the boundedness of the truncated process, it can be shown that

$$|f_2(t)|=|f_2(x(t),t)|\leqq K_2\varepsilon+K_3\mu \tag{2.35}$$

where K_2 and K_3 are positive constants independent of ε, μ and ω. Operating on $f_2(t)$ by $A^{\varepsilon,\mu}$ yields

$$A^{\varepsilon,\mu}f_2(t)=L^{(\varepsilon/\mu)}f(x)-\frac{\partial f_1}{\partial x}(x,t)(A_{12}(x)y(t)+A_{12}(x)A_2^{-1}a_{21}(x)+B_1(x)v^\varepsilon(t))$$

(2.36)

$$-\frac{\partial f}{\partial x}(x)a_0(x)+\frac{\partial f_2}{\partial x}(x,t)(a_1(x)+A_{12}(x)y(t)+B_1(x)v^\varepsilon(t)).$$

Adding (2.33) to (2.36) we get

$$A^{\varepsilon,\mu}(f(x)+f_1(t)+f_2(t))$$

(2.37)

$$=L^{\varepsilon/\mu}f(x)+\frac{\partial f_1}{\partial x}(x,t)a_0(x)+\frac{\partial f_2}{\partial x}(x,t)[a_1(x)+A_{12}(x)y(t)+B_1(x)v^\varepsilon(t)].$$

We define

$$f^{\varepsilon,\mu}(t)=f(x(t))+f_1(x(t),t)+f_2(x(t),t) \quad \text{for } 0\leqq t\leqq T. \tag{2.38}$$

Then condition (2.20) of Lemma 1 follows directly from (2.31), (2.35) and (2.38).

From the mixing property, the compact supports of the partial derivatives of f up to the third order and the boundedness of the truncated process we can show that

$$\left|\frac{\partial f_1}{\partial x}(x,t)a_0(x)\right|+\left|\frac{\partial f_2}{\partial x}(x,t)(A_{12}(x)y(t)+B_1v^\varepsilon(t))\right|\leqq K_4\sqrt{\varepsilon}+K_5\sqrt{\mu} \tag{2.39}$$

and

$$\left|\frac{\partial f_2}{\partial x}(x,t)a_1(x)\right|\leqq K_6\varepsilon+K_7\mu, \tag{2.40}$$

where the positive constants K_i are independent of ε, μ and ω.

By the smooth dependence of L^γ on γ (see (2.16)), it follows that there exists a constant $c>0$ such that

$$|L^{(\varepsilon/\mu)}f(x)-L^\gamma f(x)|\leqq c\left|\frac{\varepsilon}{\mu}-\gamma\right|. \tag{2.41}$$

From (2.37), (2.38) we have:

$$
\begin{aligned}
&|A^{\varepsilon,\mu}f^{\varepsilon,\mu}(t) - L^{\gamma}f(x(t))| \\
&\leqq \left| \frac{\partial f_1}{\partial x}(x,t)a_0(x) + \frac{\partial f_2}{\partial x}(x,t)(a_1(x) + A_{12}(x)y(t) + B_1(x)v^{\varepsilon}(t)) \right. \\
&\qquad \left. + L^{(\varepsilon/\mu)}f(x(t)) - L^{\gamma}f(x(t)) \right|.
\end{aligned} \tag{2.42}
$$

Then (2.21) of Lemma (1) follows immediately from (2.39)-(2.42).

Now we need to verify (2.22)-(2.24) of Lemma 1. The limit (2.22) follows directly from (2.31) and (2.35). Also (2.23) and (2.24) follow easily from (2.39)-(2.42) and the compact support of f. Thus the proof of the theorem is completed by applying Lemma 1. Q.E.D.

From the proof of Theorem 1 it is apparent that if L^{γ} is independent of the parameter γ then the requirement $\varepsilon/\mu \to \gamma$ in Theorem 1 can be dropped.

COROLLARY 1. *Suppose that assumptions* (A1) *to* (A5) *hold and that* $L^{\gamma} = L$ (*independent of* γ). *Then* $x^{\varepsilon,\mu}(\cdot)$ *converges weakly to* $\bar{x}(\cdot)$ *as* $\varepsilon \to 0$ *and* $\mu \to 0$.

In Theorem 1 we employed the noise condition (A1) which requires the noise process $v(\cdot)$ to be a stationary, uniformly bounded, ϕ-mixing process. The use of ϕ-mixing processes is typical in asymptotic stochastic analysis (e.g. [2]-[4]), although in those references ϕ does not have to be exponentially decaying. It is obvious, however, from Kushner's work [4] that the noise process $v(\cdot)$ can be a stationary Gaussian process with rational spectra. Since this type of unbounded noise process very often is more important in applications, we extend our result to that case.

Suppose that the initial states x_0 and y_0 are Gaussian random vectors with bounded second moments. Assumption (A1) is replaced by

(A1)′ The process $v(t)$ is defined by

$$
\begin{aligned}
d\xi &= Q\xi\, dt + U\, dw, \\
v(t) &= \Gamma\xi(t),
\end{aligned} \tag{2.43}
$$

where $w(\cdot)$ is a vector Brownian motion, Q, U and Γ are constant matrices and Q is Hurwitz.

THEOREM 2. *Under the assumptions* (A1)′ *and* (A2)-(A5), $x^{\varepsilon,\mu}(\cdot)$ *converges weakly to a diffusion process* $\bar{x}(\cdot)$ *with initial condition* $\bar{x}(0) = x_0$ *and infinitesimal generator defined by* (2.5).

Remark. A corollary similar to Corollary 1 holds in this case as well.

Proof. The proof is almost the same as that of Theorem 1. The only difference is that instead of using the mixing property we use inequalities that follow directly from (2.43), e.g., $|E_t v(t+s)| \leqq K e^{-\alpha s}|\xi(t)$. Proceeding as in the proof of Theorem 1 we arrive at four inequalities similar to (2.31), (2.35), (2.39) and (2.40) with the left-hand side replaced by its expectation. For example, (2.31) is replaced by

$$E|f_1(t)| \leqq K_1(\sqrt{\varepsilon} + \sqrt{\mu}).$$

Conditions (2.20) and (2.21) of Lemma 1 follow immediately from these four inequalities. To verify conditions (2.22)-(2.24) of Lemma 1, we use the fact that there is a finite w.p.1 w-function C such that $|\xi(t)| \leqq C$ for all $t \in [0, T]$ w.p.1. This fact leads to four inequalities similar, again, to (2.31), (2.35), (2.39) and (2.40) which hold w.p.1 and the right-hand side constants (e.g., K_1 in (2.31)) are replaced by finite w.p.1 w-functions. These inequalities lead easily to (2.22)-(2.24). Q.E.D.

3. Discussion and conclusions. Our main motivation for studying the asymptotic behavior of singularly perturbed systems driven by wide-band noise has been to highlight the interplay of the two asymptotic phenomena involved in the problem. The explicit form of the limiting diffusion model derived in § 2 clearly shows such interaction through the dependence of the matrix Σ, defined by (2.14), on $\gamma = \lim_{\varepsilon,\mu\to 0} \varepsilon/\mu$. Such interplay becomes significant when we study its impact on the well-established engineering practice of neglecting parasitic elements when writing down differential equations representing electrical networks, mechanical systems, etc. According to that practice, in modeling the singularly perturbed system (2.1), (2.2), the parasitic elements represented by μ are neglected. This is equivalent to setting $\mu = 0$ in (2.2) replacing (2.2) by the algebraic equation

$$0 = a_{21}(x) + A_2 y + B_2(x)v^{\varepsilon}. \tag{3.1}$$

Since A_2 is nonsingular, (3.1) can be solved to get

$$y = -A_2^{-1}[a_{21}(x) + B_2(x)v^{\varepsilon}]. \tag{3.2}$$

Substituting (3.2) in (2.1) results in the reduced-order model

$$\dot{x} = a_0(x) + B_0(x)v^{\varepsilon} \tag{3.3}$$

where a_0 and B_0 are defined in (2.8) and (2.9). Although in deriving the reduced-order model (3.3) we started with the higher-dimensional model (2.1) and (2.2) and arrived at (3.3) through the formal procedure of setting $\mu = 0$, it is typical in practical modeling situations that such order reduction is done even before writing down any equations representing the system. Parasitic elements are usually neglected by omitting them from the physical description of the system (e.g., omitting parasitic inductances or capacitances from electrical networks descriptions). As a result of that it is not uncommon that the only available mathematical model to describe the system is the reduced-order model (3.3). Using (3.3) to characterize the behavior of x may lead to wrong conclusions. In particular, since our interest here is in the case when ε is sufficiently small, we can study the asymptotic behavior of x as $\varepsilon \to 0$ using well-established techniques (e.g. [2]-[4]). As $\varepsilon \to 0$ the solution of (3.3) converges weakly to a diffusion process with infinitesimal generator $\tilde{L}$ given by

$$\tilde{L}f(x) = \sum_{i=1}^{n} \tilde{b}_i(x)\frac{\partial f}{\partial x}(x) + \frac{1}{2}\sum_{i,j=1}^{n} \tilde{a}_{ij}(x)\frac{\partial^2 f(x)}{\partial x_i\, \partial x_j} \tag{3.4}$$

where

$$\tilde{b} = a_0 + \tilde{h}_1 - A_{12}A_2^{-1}\tilde{h}_2 + \tilde{h}_3, \tag{3.5}$$

$$\tilde{A} = B_0 S(0) B_0', \tag{3.6}$$

$$\tilde{h}_{1i} = \operatorname{tr}[D_i' B_0 W], \tag{3.7}$$

$$\tilde{h}_{2i} = \operatorname{tr}[E_i' B_0 W], \tag{3.8}$$

and

$$\tilde{h}_{3i} = \operatorname{tr}[-F_i' B_0 W B_2' A_2^{-1}]. \tag{3.9}$$

Obviously this diffusion limit is different from the right diffusion limit given in § 2. In fact, comparing (3.5)-(3.9) with (2.6)-(2.12) shows that the two operators coincide only as $\gamma \to \infty$ (i.e., $\mu/\varepsilon \to 0$), indicating that the use of the reduced-order model (3.3) is acceptable only if $\mu \ll \varepsilon$.

As a generic example that illustrates the above situation consider the feedback control system of Fig. 1. Our interest here is not in designing such a control system, although this is an interesting problem for which the order reduction results of this paper could be useful, but in analyzing the behavior of x once the system has been built. The singularly perturbed equation in the forward loop represents actuator dynamics, amplified dynamics or *RC* or *RL* sections, which typically have small time constants represented here by the small parameter μ. In modeling such feedback systems, it is the practice of engineers to simplify the model by neglecting the fast dynamics of actuators, amplifiers, etc., when the time constant μ is sufficiently small with respect to the relaxation time of the plant. Such simplification leads to the feedback system of Fig. 2 in which the dynamic equation $\mu\dot{y} = Hy + Ke$ is replaced by the algebraic equation $y = -H^{-1}Ke$. Readers who are not familiar with this engineering practice can realize how common that practice is by noticing that whenever an amplifier in a control system is modeled by a constant gain k, such model simplification has been already employed since a more realistic model of the amplifier would be the first-order transfer function $k/(1+s\tau)$ or even higher-order transfer functions. If the driving inputs r and n are smooth deterministic functions of time, neglecting parasitic elements is justified by invoking singular perturbation results [1]. To analyze the situation when n is wide-band noise that can be modeled as $n(t) = (1/\sqrt{\varepsilon})v(t/\varepsilon)$, we invoke the result of § 2. The feedback system of Fig. 1 is represented by

$$\dot{x} = f(x) + G(x)y, \tag{3.10}$$

$$\mu\dot{y} = K(r-x) + Hy + Kn, \tag{3.11}$$

which fits the structure of equations (2.1), (2.2). Suppose that $f(x)$ and $G(x)$ are smooth enough that our technical conditions are satisfied, H is a stability matrix, and r is a constant set point. Then, for sufficiently small ε and μ, the behavior of x can be approximated by a diffusion process with infinitesimal generator (2.5) which is dependent on γ. If the simplified feedback system of Fig. 2 is used to analyze the behavior of x, then for sufficiently small ε, x can be approximated by a diffusion process whose infinitesimal generator is given by (3.4). This shows the invalidity of

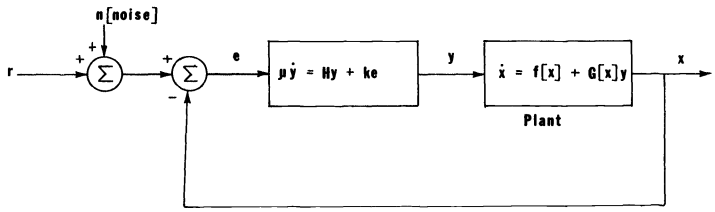

FIG. 1

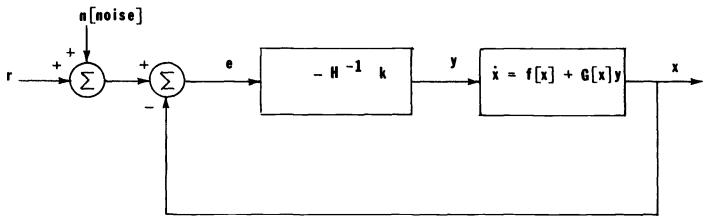

FIG. 2

the simplified feedback system of Fig. 2 as a model for analyzing x. To make the example more transparent, let us consider a specific situation where $x \in R$, $y \in R^2$,

$$G(x) = [c^{-x}, 1], \qquad H = \begin{bmatrix} -1 & 0 \\ 0 & -2 \end{bmatrix}, \qquad K = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

and suppose that the correlation function $R(\tau)$ is given by $R(\tau) = \sigma^2 e^{-|\tau|}$. Then, as $\varepsilon, \mu \to 0$, $x(\cdot)$ converges weakly to $\bar{x}(\cdot)$ which satisfies the Ito equation

$$d\bar{x} = \left[f(\bar{x}) + \left(\frac{1}{2} + e^{-\bar{x}}\right)(r - \bar{x}) - \frac{3\gamma^2 + 6\gamma + 2}{3(\gamma+1)(2\gamma+1)} \sigma^2 e^{-\bar{x}} - \sigma^2 e^{-2\bar{x}} \right] dt$$

$$+ \sqrt{2}\sigma^2 \left[\frac{1}{2} + e^{-\bar{x}} \right] dw, \qquad \bar{x}(0) = x_0$$

where $\gamma = \lim_{\varepsilon,\mu \to 0} (\varepsilon/\mu)$.

On the other hand, the diffusion process corresponding to (3.4) satisfies the Ito equation

$$d\tilde{x} = [f(\tilde{x}) + (\tfrac{1}{2} + e^{-\tilde{x}})(r - \tilde{x}) + \tfrac{1}{2}\sigma^2 e^{-\tilde{x}} - \sigma^2 e^{-2\tilde{x}}]\, dt + \sqrt{2}\sigma^2 [\tfrac{1}{2} + e^{-\tilde{x}}]\, dw, \qquad \tilde{x}(0) = x_0.$$

It is apparent that for all finite $\gamma > 0$, the two Ito equations are different. They coincide only as $\gamma \to \infty$.

The above discussions have shown that reducing the order of dynamic systems driven by wide-band stochastic inputs via neglecting parasitic elements is, in general, valid only when the frequency band of the neglected fast dynamics is much wider than the frequency band of the input. There are, however, several interesting special cases where neglecting parasitic elements is valid even when the frequency band of the input is of the same order of the frequency band of the fast dynamics. These are the special cases for which the operator L^γ is independent of γ. Using the explicit form of the operator L^γ given by (2.7)-(2.17), we can easily identify such special cases. For instance, it is apparent that for linear systems, as long as the behavior of the slow variable x is concerned, μ can be set to zero. This conclusion for linear systems can be interpreted in the following way. Although replacing the differential equation (2.2) by the algebraic equation (3.1) cannot be used to approximate y, it can be used as an input to the slow equation (2.1) since the error resulting from this approximation will be filtered out by the slow equation. The same conclusion holds even when the input is modeled as white noise [14]. From (2.7)-(2.17), we can see also that the nonlinearity of a_1 and a_{21} is not the source of the inconsistency encountered here. It is the nonlinearities in B_1, B_2 and A_{12} that give rise to the correction terms h_1, h_2 and h_3, respectively, bringing in the dependence on γ through the matrix Σ. Recall that

$$\Sigma = \int_0^\infty e^{A_2 \gamma \tau} B_2 R'(\tau)\, d\tau$$

and suppose, without loss of generality, that R is normalized in such a way that B_2 is proportional to the root-mean square of the noise input. It is apparent that if $B_2 = 0$ (no noise input to the singularly perturbed equation) or B_2 is sufficiently small (small noise input to the singularly perturbed equation), then the dependence of L^γ on γ will either vanish or be insignificant, respectively. The small noise case is particularly important and arises frequently in applications cf. [15]. For example, in the feedback system of Fig. 1, let $n(t)$ have a correlation function $\lambda^2 e^{-|\tau|/\theta}$ where λ is of order one and θ is sufficiently small. The power spectrum of $n(t)$ is $2\theta\lambda^2/(1 + \omega^2\theta^2)$ which is flat

over a frequency band of order $1/\theta$. As $\theta \to 0$, $n(t)$ does not tend to white noise but $n/\sqrt{\theta}$ tends to white noise. Taking $\varepsilon = \theta$, $n(t)$ can be modeled as $n(t) = v(t/\varepsilon)$ where $v(t)$ has $\lambda^2 e^{-\tau}$ as its correlation. For this $n(t)$, equation (3.10), (3.11) take the form

$$\dot{x} = f(x) + G(x)y,$$

$$\mu\dot{y} = K(r-x) + Hy + \sqrt{\varepsilon}\, Kv^{\varepsilon},$$

which is of the form (2.1), (2.2) except that B_2 is multiplied by $\sqrt{\varepsilon}$.

Checking the proof of Theorem 1, it can be easily seen that the following corollary holds for the small noise case.

COROLLARY 2. *Consider the system* (2.1), (2.2) *except that* B_2 *is replaced by* βB_2. *Assume that* (A1)-(A5) *hold. Let* $\hat{x}(\cdot)$ *be a diffusion process whose infinitesimal generator is given by* (2.7)-(2.17) *with* $B_2 = 0$ *and let* $x(0) = x_0$. *Then* $x^{\varepsilon,\mu,\beta}(\cdot)$ *converges weakly to* $\hat{x}(\cdot)$ *as* $\varepsilon \to 0$, $\mu \to 0$ *and* $\beta \to 0$.

A similar corollary holds for the Gaussian case of Theorem 2.

Finally, we conclude our discussions by pointing out that the restriction $\varepsilon/\mu \geqq \gamma > 0$ which has been imposed in this paper is purely technical and that the form of the operator L^{γ} derived in § 2 is actually valid as $\gamma \to 0$. This can be shown by studying the case $\varepsilon/\mu \to 0$ as two sequential limiting processes $\varepsilon \to 0$ followed by $\mu \to 0$, and employing asymptotic results from [3]-[5], [16]. The details of that are given in [17].

ON SEMINORMALITY OF INTEGRAL FUNCTIONALS AND THEIR INTEGRANDS*

E. J. BALDER†

Dedicated to E. J. McShane on the occasion of his 80th birthday.

Abstract. We present a definition of seminormality which extends classical notions due to Tonelli [Fondamenti di Calcolo delle Variazioni, 1921], McShane [Ann Scuola Norm. Sup. Pisa (2), 3 (1934), pp. 181-211, 287-315] and Cesari [Trans. Amer. Math. Soc., 124 (1966), pp. 369-412; J. Optim. Theory Appl., 6 (1970), pp. 114-137; SIAM J. Control Optim., 9 (1971), pp. 287-315], and applies to both integrands ("seminormality in the small") and their integral functionals ("seminormality in the large"). Our main result states that under very general hypotheses seminormality in the small and large are equivalent. By introducing a notion called Nagumo tightness, we show that the usual sufficient conditions for the lower semicontinuity of an integral functional also imply a form of seminormality of the integral functional. Necessary conditions for the lower semicontinuity of an integral functional can also be obtained from our results.

Key words. seminormality, integral functionals, lower semicontinuity, lower closure, tightness, property (Q).

1. Introduction. Let (X, d) be a metric space and $(V, P, \langle \cdot, \cdot \rangle)$ a pair of locally convex spaces paired by the strict duality (or nondegenerate bilinear form) $\langle \cdot, \cdot \rangle$ on $V \times P$. Let $\bar{\mathbb{R}} \equiv [-\infty, +\infty]$ denote the set of extended real numbers; we shall use the convention $(+\infty) - (+\infty) \equiv +\infty$ throughout.

A function $a: X \times V \to \bar{\mathbb{R}}$ is defined to be *simple seminormal* (on $X \times V$) if there exist a lower semicontinuous function $f: X \to \bar{\mathbb{R}}$ and $p \in P$ such that

$$a(x, v) = f(x) + \langle v, p \rangle.$$

A function $a: X \times V \to \bar{\mathbb{R}}$ is defined to be *seminormal* (on $X \times V$) if it is the (pointwise) supremum of a collection of simple seminormal functions on $X \times V$. An equivalent, more traditional definition of seminormality will be given in § 2, where this property will be studied in detail.

Now suppose in addition that X, V and P are Suslin spaces (Appendix B). Let $(T, \mathcal{T}, \mu)$ be a σ-finite measure space and let $\mathcal{X}$ be a decomposable set of equivalence classes of $(\mathcal{T}, \mathcal{B}(X))$-measurable functions, equipped with the essential supremum metric

$$d(x, y) \equiv \operatorname*{ess\,sup}_{t \in T} d(x(t), y(t)).$$

Also, let $(\mathcal{V}, \mathcal{P}, \langle \cdot, \cdot \rangle)$ be a pair of decomposable vector spaces of equivalence classes of scalarly μ-integrable functions (cf. Appendix B) going from T into V and P respectively, paired by the strict duality

$$\langle v, p \rangle \equiv \int_T \langle v(t), p(t) \rangle \mu(dt),$$

where it is assumed that for every $v \in \mathcal{V}$, $p \in \mathcal{P}$ the function $t \mapsto \langle v(t), p(t) \rangle$ is μ-integrable.

Let $l: T \times X \times V \to \bar{\mathbb{R}}$ be a function which is such that for some $p_0 \in \mathcal{P}$ and $\phi_0 \in \mathcal{L}^1_{\mathbb{R}}$

$$l(t, x, v) \geqq \langle v, p_0(t) \rangle + \phi_0(t) \text{ for all } x \in X \text{ and } v \in V \ \mu\text{-a.e.} \tag{1.1}$$

* Received by the editors August 16, 1983, and in final revised form February 4, 1985.
† Mathematical Institute, University of Utrecht, Utrecht, the Netherlands.

By means of outer integration (Appendix A) we define the integral functional $I_l: \mathscr{X} \times \mathscr{V} \to \bar{\mathbb{R}}$ as follows:

$$I_l(x, v) \equiv \tilde{\int}_T l(t, x(t), v(t)) \mu\,(dt).$$

We can now view seminormality at the following two levels:

(i) *Seminormality in the small*: seminormality of the function $l(t, \cdot, \cdot): X \times V \to \bar{\mathbb{R}}$ μ-a.e. (i.e., for μ-almost every $t \in T$). Here seminormality is defined with respect to the framework consisting of (X, d) and $(V, P, \langle \cdot, \cdot \rangle)$.

(ii) *Seminormality in the large*: seminormality of the integral functional $I_l: \mathscr{X} \times \mathscr{V} \to \bar{\mathbb{R}}$ of l. Here seminormality is defined with respect to the framework which is composed of $(\mathscr{X}, d)$ and $(\mathscr{V}, \mathscr{P}, \langle \cdot, \cdot \rangle)$, introduced above.

While seminormality in the small has a long history, starting with the seminal work by Tonelli [27] and McShane [21], seminormality in the large seems to be an entirely new concept. The main explanation for this rather surprising observation can undoubtedly be found in the traditional occupation with integral functionals of a single variable, such as exemplified by

$$I(x) \equiv \int_0^1 l(t, x(t), \dot{x}(t))\, dt$$

where x ranges over a set of smooth curves; e.g. cf. [10].

The principal result of this paper, which will be presented in § 3, states that under quite general hypotheses seminormality in the small and in the large are *equivalent.* There are essentially two ways in which this result can be used to shed new light on lower semicontinuity and lower closure questions for integral functionals (§ 4). The most important one is as follows. A function $h: V \to (-\infty, +\infty]$ is said to be of *Nagumo type* on V if h is convex and sequentially inf-compact on V for every slope. A subset $\mathscr{V}_0$ of $\mathscr{V}$ is defined to be *Nagumo tight* if there exists a $\mathscr{T} \times \mathscr{B}(X)$-measurable function $h: T \times V \to [0, +\infty]$ such that

$$h(t, \cdot) \text{ is of Nagumo type on } V \ \mu\text{-a.e.},$$

$$\sup_{v \in \mathscr{V}_0} I_h(v) < +\infty.$$

Also, $\mathscr{V}_0 \subset \mathscr{V}$ is defined to be *almost Nagumo tight* if there exists a nonincreasing sequence $\{B_i\}_1^\infty$ in $\mathscr{T}$, whose intersection is a μ-null set, such that for every $i \in \mathbb{N}$ the restrictions to $T \setminus B_i$ of all elements of $\mathscr{V}_0$ form a Nagumo tight set. Important examples of almost Nagumo tightness are the following. (a) A subset $\mathscr{V}_0$ of $\mathscr{V}$ is Nagumo tight if there exists a scalarly measurable multifunction $\Gamma: T \rightrightarrows V$ having (sequentially) compact convex values such that $v(t) \in \Gamma(t)$ μ-a.e. for every $v \in \mathscr{V}_0$. (b) In case V is a separable reflexive Banach space, P its topological dual V' and $\mathscr{V} \equiv \mathscr{L}^1_V$, $\mathscr{P} \equiv \mathscr{L}^\infty_{V'}$, a subset $\mathscr{V}_0$ of $\mathscr{L}^1_V$ is Nagumo tight if it is relatively (sequentially) compact for the weak topology $\sigma(\mathscr{L}^1_V, \mathscr{L}^\infty_{V'})$. (c) In the same case as in (b) a sequence in $\mathscr{V}_0$ has an almost Nagumo tight subsequence if it is uniformly bounded in L^1-norm.

Now suppose that $l: T \times X \times V \to \bar{\mathbb{R}}$ satisfies the following well-known sufficient conditions for sequential lower semicontinuity of I_l on $\mathscr{X} \times \mathscr{V}$:

$l(t, \cdot, \cdot)$ is sequentially lower semicontinuous on $X \times V$ μ-a.e.,

$l(t, x, \cdot)$ is convex on V for every $x \in X$ μ-a.e.

Define $l_1: T \times X \times V \times \mathbb{R} \to \bar{\mathbb{R}}$ by

$$l_1(t, x, v, \lambda) \equiv \max(l(t, v, x), \lambda).$$

Then it follows from the main result that for every $\mathcal{V}_0 \subset \mathcal{V}$, $\mathcal{L}_0 \subset \mathcal{L}^1_{\mathbb{R}}$ such that $\mathcal{V}_0$ is almost Nagumo tight and $\mathcal{L}_0^- \equiv \{\lambda^-: \lambda \in \mathcal{L}_0\}$ is uniformly integrable, I_{l_1} has the following *coincident seminormality* property:

$$I_{l_1} \text{ coincides on } \mathcal{X} \times \mathcal{V}_0 \times \mathcal{L}_0 \text{ with a seminormal function,}$$

where $I_{l_1}: \mathcal{X} \times \mathcal{V} \times \mathcal{L}^1_{\mathbb{R}} \to \bar{\mathbb{R}}$ is defined by

$$I_{l_1}(x, v, \lambda) \equiv \int_T^{\tilde{}} l_1(t, x(t), v(t), \lambda(t))\, \mu\,(dt),$$

and seminormality is considered with respect to the framework consisting of $(\mathcal{X}, d)$ and the pair $(\mathcal{V} \times \mathcal{L}^1_{\mathbb{R}}, \mathcal{P} \times \mathcal{L}^\infty_{\mathbb{R}})$, equipped with the duality

$$\langle\langle v, \lambda; p, q \rangle\rangle \equiv \int_T (\langle v(t), p(t) \rangle + \lambda(t) q(t)) \mu\,(dt).$$

Coincident seminormality being a much stronger property than relative lower semicontinuity, one thus generalizes a whole class of results. These ideas can be carried over to the subject of lower closure without much difficulty.

The second way in which the main result can be used concerns the usual necessary conditions for lower semicontinuity of integral functionals. This line of approach could be of some interest as a contribution to unifying necessary and sufficient conditions for lower semicontinuity of integral functionals. Although our result is quite general in most respects, the boundedness condition (1.1) makes it somewhat incomparable to similar results obtained elsewhere.

2. Seminormality. In this section we study several aspects of seminormality. We introduce the seminormal hull of a function and show it to be representable by semicontinuous hulls and Fenchel conjugation. Also, we give some sufficient conditions for seminormality to hold. Finally, we show the close relationship which exists between the notion of seminormality developed here and Cesari's property (Q) for multifunctions [8]. Let us note in advance that although this section is strictly treated in terms of the framework for seminormality in the small, most results obtained here can be used in connection with seminormality in the large by a simple substitution of framework.

Let (X, d) be a metric space. For every $x \in X$ and $\delta > 0$ the set of all $y \in X$ such that $d(x, y) < \delta$ ($d(x, y) \leqq \delta$) will be denoted by $B(x; \delta)$ ($\bar{B}(x; \delta)$). Also, let $(V, P, \langle \cdot, \cdot \rangle)$ be a pair of locally convex spaces, paired by the strict duality $\langle \cdot, \cdot \rangle: V \times P \to \mathbb{R}$. The topologies on V and P are understood to be compatible with the duality; note that strictness of the duality causes these topologies to be Hausdorff [9, 5.22].

Let $a: X \times V \to \bar{\mathbb{R}}$ be a given function. Following Tonelli [27] and McShane [21] (see also Cesari [8]), we introduce a notion of seminormality for extended real-valued functions by defining a to be *seminormal* at the point $(x, v) \in X \times V$ if for every $\alpha \in \mathbb{R}$, $\alpha < a(x, v)$, there exist $p \in P$, $\beta \in \mathbb{R}$, $\delta > 0$ such that

$$a \geqq \langle \cdot, p \rangle + \beta - \chi(\cdot; B(x, \delta)), \tag{2.1}$$

$$\alpha < \langle v, p \rangle + \beta. \tag{2.2}$$

As usual, the indicator function $\chi(\cdot; B)$ of a subset B of X is given by $\chi(y; B) \equiv 0$ if

$y \in B$, $\chi(y; B) \equiv +\infty$ if $y \notin B$. Also, we say that $a: X \times V \to \bar{\mathbb{R}}$ is *seminormal* (on $X \times V$) if a is seminormal at every point of $X \times V$. The following observation is obvious, but important.

Remark 2.1. The (pointwise) supremum of an arbitrary collection of seminormal functions on $X \times V$ is seminormal. Also, the sum of a finite collection of seminormal functions on $X \times V$ is seminormal, provided that no addition of values $+\infty$ and $-\infty$ takes place. □

As a consequence of this remark, it makes sense to define the *seminormal hull* $\tilde{\tilde{a}}: X \times V \to \bar{\mathbb{R}}$ of the function $a: X \times V \to \bar{\mathbb{R}}$ to be the supremum of the collection of all seminormal functions on $X \times V$ which are (pointwise) no larger than a; note that $\tilde{\tilde{a}}$ is seminormal on $X \times V$ by Remark 2.1 and that

$$\tilde{\tilde{a}} \leqq a. \tag{2.3}$$

By means of the hull concept we can take a different look at local seminormality.

PROPOSITION 2.2. *For every $x \in X$, $v \in V$ the following are equivalent*:

$$a \text{ is seminormal at } (x, v), \tag{2.4}$$

$$\tilde{\tilde{a}}(x, v) = a(x, v). \tag{2.5}$$

Proof. If (2.5) holds, then (2.3) and seminormality of $\tilde{\tilde{a}}$ imply (2.4) directly. Conversely, if (2.4) is true, then for every $\alpha \in \mathbb{R}$, $\alpha < a(x, v)$, there exist $p \in P$, $\beta \in \mathbb{R}$, $\delta > 0$ such that $e \leqq a$ and $e(x, v) > \alpha$, where e is the function on the right in (2.1). Since e is obviously seminormal on $X \times V$, we find $\tilde{\tilde{a}}(x, v) > \alpha$, which shows that $\tilde{\tilde{a}}(x, v) \geqq a(x, v)$. By (2.3) we thus have (2.5). □

Remark 2.3. The above proof shows that the seminormal hull of a is precisely the supremum of all functions $e \equiv \langle \cdot, p \rangle + \beta - \chi(\cdot; B(y; n^{-1}))$, $p \in P$, $\beta \in \mathbb{R}$, $n \in \mathbb{N}$, satisfying $e \leqq a$; note that the latter inequality implies

$$-\beta \geqq c(n, y, p) \equiv \sup_{z \in X, w \in V} [\langle w, p \rangle - a(z, w) - \chi(z; B(y; n^{-1}))].$$

Hence, we obtain

$$\tilde{\tilde{a}}(x, v) = \sup_{n \in \mathbb{N}, y \in X, p \in P} [\langle v, p \rangle - c(n, y, p) - \chi(x; B(y; n^{-1}))].$$

Further, note that e as above is evidently simple seminormal, as defined in § 1. Hence, it has been shown in the above proof that the seminormal hull of a is the supremum of the collection of all simple seminormal functions on $X \times V$ which are (pointwise) no larger than a. By Proposition 2.2 this shows the equivalence of the seminormality definitions given in § 1 and § 2.

Let us now express the seminormal hull a of $\tilde{\tilde{a}}$ in terms of the functions $b: X \times P \to \bar{\mathbb{R}}$ and $\bar{b}: X \times P \to \bar{\mathbb{R}}$, which we define as follows by Fenchel conjugation of a with respect to the variable v and semicontinuous hulls with respect to the variable x [7, I.4]:

$$b(y, p) \equiv a^*(y, p) \equiv \sup_{v \in V} [\langle v, p \rangle - a(y, v)],$$

$$\bar{b}(x, p) \equiv \limsup_{y \to x} b(y, p).$$

THEOREM 2.4. *For every $x \in X$, $v \in V$*

$$\tilde{\tilde{a}}(x, v) = \bar{b}^*(x, v) \equiv \sup_{p \in P} [\langle v, p \rangle - \bar{b}(x, p)]. \tag{2.6}$$

Proof. By definition of $\bar{b}$ we have $\bar{b} \geqq b$; this implies $\bar{b}^* \leqq b^* = a^{**} \leqq a$. From (2.6) it is clear that $\bar{b}^*$ is the supremum of a collection of simple seminormal functions.

Hence, $\bar{b}^*$ is seminormal (cf. Remark 2.3). By the above this implies $\tilde{\tilde{a}} \geqq \bar{b}^*$. On the other hand, let e be a simple seminormal function on $X \times V$ such that $e \leqq a$. For such a function one has trivially that $e^*: X \times P \to \bar{\mathbb{R}}$ is upper semicontinuous in the variable x. Hence the obvious inequality $e^* \geqq b$ implies $e^* \geqq \bar{b}$. By [7, I.4] (or ad hoc inspection) we have $e = e^{**}$. Combined, this gives $e \leqq \bar{b}^*$. By Remark 2.3 we conclude that $\tilde{\tilde{a}} \leqq \bar{b}^*$. This finishes the proof. □

Remark 2.5. It will be convenient to rewrite (2.6) in the following two ways:

$$\tilde{\tilde{a}}(x, v) = \sup_{p \in P} \lim_{n \to \infty} \uparrow \inf_{y \in X, w \in V} [\langle v - w, p \rangle + a(y, w) + \chi(y; B(x; n^{-1}))]$$

$$= \lim_{n \to \infty} \uparrow \sup_{p \in P} \inf_{y \in X, w \in V} [\langle v - w, p \rangle + a(y, w) + \chi(y; \bar{B}(x; n^{-1}))].$$

Remark 2.6. For every function $f: X \to \bar{\mathbb{R}}$, considered as a function on $X \times V$, we have that the seminormal hull $\tilde{\tilde{f}}$ of f is given by

$$\tilde{\tilde{f}}(x) = \liminf_{y \to x} f(y) \equiv \bar{f}(x).$$

Also, for every function $g: V \to \bar{\mathbb{R}}$, considered as a function on $X \times V$, we have that the seminormal hull $\tilde{\tilde{g}}$ of g is given by

$$\tilde{\tilde{g}}(v) = g^{**}(v).$$

Hence, the seminormal hull of $f: X \to \bar{\mathbb{R}}$ coincides with its lower semicontinuous hull $\bar{f}$, and the seminormal hull of $g: V \to \bar{\mathbb{R}}$ coincides with the Fenchel biconjugate g^{**}; the latter is known to be the lower semicontinuous convex hull of g, provided that g is affinely bounded from below [7, I.5]. Thus, the seminormal hull concept straddles two important hulls.

Let us observe that for every $x \in X$ seminormality of a at every point of $\{x\} \times V$ implies trivially that a is lower semicontinuous at every point of $\{x\} \times V$ and that $a(x, \cdot)$ is convex on V. We shall now establish a kind of converse to this implication, which in a somewhat less general form constitutes a classical sufficient condition for seminormality [8], [27]. Let us recall that a function $h: V \to (-\infty, +\infty]$ is said to be *sequentially inf-compact on V for every slope* if for every $p \in P$, $\gamma \in \mathbb{R}$ the set of all $v \in V$ such that $h(v) - \langle v, p \rangle \leqq \gamma$, is sequentially compact [7], [20]; of course then for every $p \in P$ there exists $\beta \in \mathbb{R}$ such that

$$h \geqq \langle \cdot, p \rangle + \beta \tag{2.7}$$

since the infimum of $h - \langle \cdot, p \rangle$ over V is attained somewhere (Weierstrass' theorem). A function from V into $(-\infty, +\infty]$ which is both convex and sequentially inf-compact on V for every slope will be called of *Nagumo type* on V in this paper; cf. [22].

Example 2.7. Suppose that $(V, P, \langle \cdot, \cdot \rangle)$ is specified as follows: V is a reflexive Banach space, whose norm we denote by $\| \cdot \|$, P is the topological dual V' of $(V, \| \cdot \|)$, $\langle \cdot, \cdot \rangle$ is the usual duality, and the topology on V is $\sigma(V, V')$. Then a function $h: V \to (-\infty, +\infty]$ is of Nagumo type if there exists a nondecreasing lower semicontinuous convex function $h' = [0, +\infty) \to (-\infty, +\infty]$ such that $h(v) \equiv h'(\|v\|)$ and

$$\lim_{\gamma \to \infty} \gamma^{-1} h'(\gamma) = +\infty. \tag{2.8}$$

Of course, this follows from the fact that every norm-bounded subset of V is relatively sequentially compact for the topology $\sigma(V, V')$ on V [16].

From now on until Remark 2.14 we make the additional assumption (cf. [14, p. 30 ff.]):

(C) V has countably determined compactness.

THEOREM 2.8. *For every $x \in X$ we have that if*

(2.9) *a is sequentially lower semicontinuous at every point of $\{x\} \times V$,*

(2.10) *$a(x, \cdot)$ is convex on V,*

and if there exist a function $h: V \to (-\infty, +\infty]$ and $\delta > 0$ such that

(2.11) *h is sequentially inf-compact on V for every slope,*

(2.12) *$a(y, \cdot) \geqq h$ for all $y \in B(x; \delta)$,*

then

a is seminormal at every point of $\{x\} \times V$.

COROLLARY 2.9. *For every $x \in X$ and $\varepsilon > 0$ we have that if* (2.9)-(2.10) *hold, if further there exist $p_0 \in P$, $\beta_0 \in \mathbb{R}$ and $\delta > 0$ such that*

(2.13) *$a(y, v) \geqq \langle v, p_0 \rangle + \beta_0$ for all $y \in B(x; \delta)$ and $v \in V$,*

and if $h: V \to (-\infty, +\infty]$ is of Nagumo type on V, then

$a + \varepsilon h$ is seminormal at every point of $\{x\} \times V$.

Proof. The conditions (2.9)-(2.12) of Theorem 2.8 are obviously satisfied if we substitute $a + \varepsilon h$ for a and $\langle \cdot, p_0 \rangle + \beta_0 + \varepsilon h$ for h. □

Remark 2.10. By assumption (C) any subset of V is (relatively) sequentially compact if and only if it is (relatively) compact. Hence, (2.9)-(2.12) in Theorem 2.8 imply

(2.10′) $a(x, \cdot)$ is lower semicontinuous and convex on V.

A similar observation holds for $a + \varepsilon h$ in Corollary 2.9.

We shall prepare the proof of Theorem 2.8 by giving a simple but very useful generalization of Dini's theorem. This result can also be regarded as a generalization of the well-known "theorem of the maximum" [2], [20, p. 358]; it is a special case of [29, Thm. 1].

LEMMA 2.11. *Let E be a topological Hausdorff space and $\{f_n\}_0^\infty$ a nondecreasing sequence of functions from E into $(-\infty, +\infty]$. If*

(2.14) $$\lim_{n \to \infty} \uparrow f_n(x) = f_0(x) \text{ for every } x \in E,$$

(2.15) $$\gamma_n \equiv \inf_{x \in E} f_n(x) > -\infty \text{ for every } n \in \mathbb{N},$$

and if there exists $\Omega \subset E$ such that for every $n \in \mathbb{N}$

(2.16) *f_n is sequentially lower semicontinuous at every point of Ω,*

and such that for every $\varepsilon > 0$ and every sequence $\{x_n\}_1^\infty \subset E$ which satisfies

(2.17) $$f_n(x_n) \leqq \gamma_n + \varepsilon \text{ for every } n \in \mathbb{N},$$

there exists a subsequence of $\{x_n\}_1^\infty$ which converges to some point in Ω. Then

$$\lim_{n \to \infty} \uparrow \gamma_n = \inf_{x \in \Omega} f_0(x).$$

Proof. Let us write $\gamma_0 \equiv \inf_\Omega f_0$; it is obvious that $\gamma_0 \geqq \lim_n \gamma_n$. Conversely, for arbitrary $\varepsilon > 0$ there exists by (2.15) a sequence $\{x_n\}$ satisfying (2.17). By hypothesis there exists a subsequence $\{x_{n'}\}$ of $\{x_n\}$ which converges to some point x_* in Ω. By using (2.14), (2.16) we find for every $k \in \mathbb{N}$

$$\liminf_{n'} f_{n'}(x_{n'}) \geqq \liminf_{n'} f_k(x_{n'}) \geqq f_k(x_*).$$

By (2.14), (2.17) this gives $\lim_n \gamma_n \geqq f_0(x_*) - \varepsilon$. It is now easy to finish the proof. □

Proof of Theorem 2.8. Let $v \in V$ be arbitrary. If $\tilde{\tilde{a}}(x, v) = +\infty$, then seminormality of a at (x, v) is a consequence of (2.3) and Proposition 2.2. So suppose now that $\tilde{\tilde{a}}(x, v) < +\infty$. Let $p \in P$ be arbitrary. We define

$$f_n(y, w) \equiv \langle v - w, p\rangle + a(y, w) + \chi(y; \bar{B}(x; n^{-1})),$$
$$f_0(y, w) \equiv \langle v - w, p\rangle + a(y, w) + \chi(y; \{x\}).$$

We shall apply Lemma 2.11 with $E \equiv X \times V$ and $\Omega \equiv \{x\} \times V$ (note that we could also have worked with open balls $B(x; n^{-1})$ in the definition of f_n). The conditions (2.14)-(2.16) obviously hold by virtue of (2.8)-(2.9) and (2.11)-(2.12). Let $\{(y_n, w_n)\}$ be as in (2.17) (viz., a sequence of ε-almost minimizers of $\{f_n\}$). Then by Remark 2.5, (2.12) and evident properties of indicator functions we have for every $n \in \mathbb{N}$

$$h(w_n) - \langle w_n, p\rangle \leqq \tilde{\tilde{a}}(x, v) - \langle v, p\rangle + \varepsilon,$$
$$y_n \in \bar{B}(x; n^{-1}).$$

From (2.11) and the above it follows that $\{(y_n, w_n)\}$ has a subsequence which converges to some point in $\{x\} \times V$. Hence we may apply Lemma 2.11 and we obtain

$$\lim_{n\to\infty} \uparrow \inf_{y \in X, w \in V} f_n(y, w) = \inf_{y \in X, w \in V} f_0(y, w).$$

By Remark 2.5 this gives

$$\tilde{\tilde{a}}(x, v) = \sup_{p \in P} [\langle v, p\rangle - b(x, p)] = a^{**}(x, v).$$

By [7, I.4] it follows from (2.10′) that $a^{**}(x, v) = a(x, v)$. In view of Proposition 2.2 this finishes the proof. □

Thus far, we studied seminormality of a in the framework composed of (X, d) and $(V, P, \langle \cdot, \cdot \rangle)$. Next to this, we shall now also consider the seminormality of functions from $X \times V \times \mathbb{R}$ into $\bar{\mathbb{R}}$ with respect to the framework which consists of (X, d) and $(V \times \mathbb{R}, P \times \mathbb{R}, \langle\langle \cdot; \cdot \rangle\rangle)$, where the duality $\langle\langle \cdot; \cdot \rangle\rangle$ is defined by

$$\langle\langle v, \lambda; p, q\rangle\rangle \equiv \langle v, p\rangle + \lambda q.$$

Let $a_1 : X \times V \times \mathbb{R} \to \bar{\mathbb{R}}$ correspond to a by the relation

$$a_1(x, v, \lambda) \equiv \max(a(x, v), \lambda).$$

We shall first present two analogues of Corollary 2.9. The first of these is straightforward and will not be used later on. The second analogue shows that it is possible to relinquish the boundedness condition (2.13) by adding to a_1 an additional growth term for the negative part of the variable λ.

PROPOSITION 2.12. *For every $x \in X$ and $\varepsilon > 0$ we have that if* (2.9)-(2.10) *and* (2.13) *hold and if $h : V \to (-\infty, +\infty]$ is of Nagumo type on V, then*

$$a_1 + \varepsilon h \text{ is seminormal at every point of } \{x\} \times V.$$

Proof. We have by definition of a_1

$$(a_1+\varepsilon h)(x, v, \lambda)=\max((a+\varepsilon h)(x, v), \varepsilon h(v)+\lambda).$$

By Corollary 2.9 the function $(x, v, \lambda)\mapsto(a+\varepsilon h)(x, v)$ is seminormal at every point of $\{x\}\times V\times\mathbb{R}$. The function $(x, v, \lambda)\mapsto\varepsilon h(v)+\lambda$ is simply seminormal. Hence, the result follows by Remark 2.1. □

THEOREM 2.13. *For every $x\in X$ and $\varepsilon>0$ we have that if* (2.9)-(2.10) *hold, if $h: V\to(-\infty, +\infty]$ is of Nagumo type on V and if $h': [0, +\infty)\to(-\infty, +\infty]$ is nondecreasing lower semicontinuous and convex, satisfying* (2.8), *then for the function $a_{1,\varepsilon}: X\times V\times\mathbb{R}\to\bar{\mathbb{R}}$, defined by*

$$a_{1,\varepsilon}(x, v, \lambda)\equiv a_1(x, v, \lambda)+\varepsilon h(v)+\varepsilon h'(\lambda^-),$$

where $\lambda^-\equiv\max(-\lambda, 0)$, we have

$$a_{1,\varepsilon} \text{ is seminormal at every point of } \{x\}\times V\times\mathbb{R}.$$

Proof. Let $v\in V$, $\lambda\in\mathbb{R}$ be arbitrary. Let $\tilde{\tilde{a}}_{1,\varepsilon}$ be the seminormal hull of $a_{1,\varepsilon}$. If $\tilde{\tilde{a}}_{1,\varepsilon}(x, v, \lambda)=+\infty$, then seminormality of $a_{1,\varepsilon}$ is immediate by (2.3) and Proposition 2.2. So suppose now that $\tilde{\tilde{a}}_{1,\varepsilon}(x, v, \lambda)<+\infty$. Let $p\in P$, $q\in\mathbb{R}$ be arbitrary and define

$$g_n(y, w, \kappa)\equiv\langle\langle v-w, \lambda-\kappa; p, q\rangle\rangle+a_{1,\varepsilon}(y, w, \kappa)+\chi(y; \bar{B}(x; n^{-1})),$$

$$g_0(y, w, \kappa)\equiv\langle\langle v-w, \lambda-\kappa; p, q\rangle\rangle+a_{1,\varepsilon}(y, w, \kappa)+\chi(y; \{x\}).$$

The first case to be considered is when $q<1$. We can then apply Lemma 2.11 with $E\equiv X\times V\times\mathbb{R}$, $\Omega\equiv\{x\}\times V\times\mathbb{R}$. Namely, conditions (2.14)-(2.16) hold obviously. Also, if $\{(y_n, w_n, \kappa_n)\}$ is a sequence of δ-almost minimizers of $\{g_n\}$ (cf. (2.17)), then by Remark 2.5 and obvious properties of indicator functions we have for every $n\in\mathbb{N}$

$$\varepsilon h(w_n)+\varepsilon h'(\kappa_n^-)+(1-q)\kappa_n-\langle w_n, p\rangle\leqq\tilde{\tilde{a}}_{1,\varepsilon}(x, v, \lambda)-\langle\langle v, \lambda; p, q\rangle\rangle+\delta,$$

$$y_n\in\bar{B}(x; n^{-1}).$$

From the Nagumo type property for h and h', and the inequality $q<1$ it follows then easily that $\{(y_n, w_n, \kappa_n)\}$ contains a subsequence converging to some point $\{x\}\times V\times\mathbb{R}$. By applying Lemma 2.11 we find

$$\lim_{n\to\infty}\uparrow\inf_{X\times V\times\mathbb{R}} g_n=\inf_{X\times V\times\mathbb{R}} g_0. \tag{2.18}$$

Next, we consider the case $q=1$. Then (2.18) continues to hold since for every $n\in\mathbb{N}\cup\{0\}$, $y\in X$ and $w\in V$ with $a(y, w)<+\infty$:

$$\inf_{\kappa\in\mathbb{R}} g_n(y, w, \kappa)=\langle v-w, p\rangle+\lambda+\varepsilon h(w)+\varepsilon h'(0)+\chi(y; \bar{B}(x; n^{-1})).$$

So this time we can apply Lemma 2.11 for $E\equiv X\times V$ and $\Omega\equiv\{x\}\times V$, in complete analogy to what was done in the proof of Theorem 2.8. It remains to consider the case when $q>1$. Then it is easy to see that $\inf_{X\times V\times\mathbb{R}} g_n=-\infty$ for every $n\in\mathbb{N}\cup\{0\}$; hence (2.18) continues to hold. We conclude that (2.18) holds in all three cases. By Remark 2.5 this leads to

$$\tilde{\tilde{a}}_{1,\varepsilon}(x, v, \lambda)=\sup_{p\in P, q\in\mathbb{R}}[\langle\langle v, \lambda; p, q\rangle\rangle-a_{1,\varepsilon}^*(x, p, q)]=a_{1,\varepsilon}^{**}(x, v, \lambda).$$

By [7, I.4] it follows from (2.10) and the properties of h and h' that $a_{1,\varepsilon}^{**}(x, v, \lambda)=a_{1,\varepsilon}(x, v, \lambda)$. The proof is finished by applying Proposition 2.2. □

Remark 2.14. The additional assumption (C) will now be dropped. For later reference we point out that (C) holds in either of the following two cases:

(i) P is separable (for example, Suslin).

(ii) V is normable for some topology for which P is its dual.

This follows from the Eberlein-Smulian theorem [14, p. 39].

The remainder of this section will be used to demonstrate the strong connections which exist between the notion of seminormality developed here and property (Q) for multifunctions, due to Cesari [8]. These connections can be phrased as follows: seminormality of a *finite-valued* function is equivalent to property (Q) of its epigraphic multifunction (cf. [8b, p. 134], [8d, p. 486] and Proposition 2.20 below) and property (Q) of a multifunction is equivalent to seminormality of the indicator function of the multifunction (cf. Proposition 2.15 below). Although these connections will not play a role further on, they do clarify the position of the present section in relation to a substantial part of the literature on lower semicontinuity and lower closure.

Let $Q: X \rightrightarrows V$ be a given multifunction; we shall not exclude the possibility that some or all values of Q are empty. Following Cesari [8] we say that the multifunction $Q: X \rightrightarrows V$ has *property* (Q) at $x \in X$ if

$$Q(x) = \bigcap_{\delta>0} \overline{\text{co}}\, Q(x; \delta), \tag{2.19}$$

where we denote the union of all sets $Q(y)$ with $d(y, x) < \delta$ by $Q(x; \delta)$. Note that one inclusion holds trivially in (2.19); as will soon be apparent, this corresponds precisely to (2.3) (note that the implicit hull concept thus given has not been used at all in the literature on property (Q)). We define the *indicator function* $\chi_Q: X \times V \to \bar{\mathbb{R}}$ of the multifunction Q by

$$\chi_Q(x, v) \equiv \begin{cases} 0 & \text{if } v \in Q(x), \\ +\infty & \text{if } v \notin Q(x). \end{cases}$$

In terms of our previous notation this means that $\chi_Q(x, v) = \chi(v; Q(x))$. Our next result states that property (Q) of Q is in fact a seminormality property of the indicator function χ_Q.

PROPOSITION 2.15. *For every $x \in X$ the following are equivalent:*

Q has property (Q) at x,

χ_Q is seminormal at every point of $\{x\} \times V$.

Proof. It is easy to see that

$$b_Q(y, p) \equiv \chi_Q^*(y, p) = \chi^*(p; Q(y)),$$
$$\bar{b}_Q(x, p) \equiv \limsup_{y \to x} b_Q(y, p) = \inf_{\delta>0} \chi^*(p; \overline{\text{co}}\, Q(x; \delta)).$$

For every closed convex subset C of V we have $\chi^{**}(\cdot; C) = \chi(\cdot; C)$ by [7, I.4]. Thus, by Theorem 2.4 the seminormal hull $\bar{\bar{\chi}}_Q$ of χ_Q is given by

$$\bar{\bar{\chi}}_Q(x, v) = \sup_{\delta>0} \chi(v; \overline{\text{co}}\, Q(x; \delta)) = \chi\Big(v; \bigcap_{\delta>0} \overline{\text{co}}\, Q(x; \delta)\Big).$$

Hence, the desired equivalence follows directly from Proposition 2.2 by obvious properties of indicator functions. □

We shall now work towards a characterization of seminormality in terms of property (Q). For this purpose, let $Q_1: X \rightrightarrows V \times \mathbb{R}$ be a given multifunction. Of course, the definition of property (Q) extends to Q_1 by an obvious substitution of framework. Following [1b], we define the *modified Lagrangian* $\zeta_{Q_1}: X \times V \times \mathbb{R} \to \bar{\mathbb{R}}$ of Q_1 by

$$\zeta_{Q_1}(x, v, \lambda) \equiv \inf\{\eta: \eta \geqq \lambda, (v, \eta) \in Q_1(x)\}.$$

It is useful to express ζ_{Q_1} differently. For every subset C of $V \times \mathbb{R}$ we define the function $\zeta(\cdot, \cdot; C): V \times \mathbb{R} \to \bar{\mathbb{R}}$ by

$$\zeta(v, \lambda; C) \equiv \inf_{\eta \geqq \lambda} [\eta + \chi(v, \eta; C)]; \tag{2.20}$$

then clearly we have $\zeta_{Q_1}(x, v, \lambda) = \zeta(v, \lambda; Q_1(x))$. For every subset C of $V \times \mathbb{R}$ we shall use the following terminology: the *section* of C at $v \in V$ is the set, denoted by C_v, which consists of all $\lambda \in \mathbb{R}$ such that $(v, \lambda) \in C$; we shall say that C_v is *closed from the right* if for every nonincreasing sequence $\{\lambda_k\}_1^\infty \subset C_v$ with $\lambda_0 \equiv \lim_{k\to\infty} \downarrow \lambda_k \in \mathbb{R}$, we have $\lambda_0 \in C_v$.

LEMMA 2.16. *If $C, C' \subset V \times \mathbb{R}$ are such that*

$$\zeta(\cdot, \cdot; C) = \zeta(\cdot, \cdot; C'),$$

$$C_v, C'_v \text{ are closed from the right for every } v \in V,$$

then $C = C'$.

Proof. The result follows directly from the fact that if C_v is closed from the right, the infimum in (2.20) is attained, provided that it is finite. □

Remark 2.17. Closedness from the right of the v-sections is an essential condition for the above lemma. Consider for instance the case where $C \equiv V \times \mathbb{Q}$, $C' \equiv V \times (\mathbb{R} \setminus \mathbb{Q})$, with $\mathbb{Q}$ denoting the set of rational numbers.

PROPOSITION 2.18. *For every $x \in X$ we have*

$$\zeta_{Q_1} \text{ is seminormal at every point of } \{x\} \times V \times \mathbb{R}, \tag{2.21}$$

$$(Q_1(x))_v \text{ is closed from the right for every } v \in V \tag{2.22}$$

if and only if

$$Q_1 \text{ has property } (Q) \text{ at } x. \tag{2.23}$$

Proof. An easy computation shows

$$\zeta^*(p, q; C) = \begin{cases} \chi^*(p, q-1; C) & \text{if } q \geqq 0, \\ +\infty & \text{otherwise.} \end{cases}$$

Since we have

$$b_{Q_1}(y, p, q) \equiv \zeta^*_{Q_1}(y, p, q) = \zeta^*(p, q; Q_1(y)),$$

this gives

$$\bar{b}_{Q_1}(x, p, q) \equiv \limsup_{y \to x} b_{Q_1}(y, p, q) = \inf_{\delta > 0} \zeta^*(p, q; \overline{\text{co}}\, Q_1(x; \delta)),$$

where $Q_1(x; \delta)$ stands for the union of all sets $Q_1(y)$ with $d(y, x) < \delta$. By [7, I.4] we have for every closed convex subset C of $V \times \mathbb{R}$ that $\zeta(\cdot, \cdot; C) = \zeta^{**}(\cdot, \cdot; C)$. Therefore, the seminormal hull $\tilde{\zeta}_{Q_1}$ of ζ_{Q_1} is given by

$$\tilde{\zeta}_{Q_1}(x, v, \lambda) = \sup_{\delta > 0} \zeta(v, \lambda; \overline{\text{co}}\, Q_1(x; \delta)), \tag{2.24}$$

as follows from applying Theorem 2.4. We can rewrite this as

$$\tilde{\tilde{\zeta}}_{Q_1}(x, v, \lambda) = \lim_{n\to\infty} \uparrow \inf_{\eta \geqq \lambda} [\eta + \chi(v, \eta; \overline{\text{co}}\, Q_1(x; n^{-1}))]. \tag{2.25}$$

If $\tilde{\tilde{\zeta}}_{Q_1}(x, v, \lambda) = +\infty$, then it follows trivially from (2.24) that

$$\tilde{\tilde{\zeta}}_{Q_1}(x, v, \lambda) = \zeta\Big(v, \lambda; \bigcap_{\delta>0} \overline{\text{co}}\, Q_1(x; \delta)\Big).$$

This identity remains valid if $\tilde{\tilde{\zeta}}_{Q_1}(x, v, \lambda) < +\infty$, since it then follows from (2.25) by an obvious application of Lemma 2.11 (or Dini's theorem). Taking into account the fact that (2.23) trivially implies (2.22), we conclude from Lemma 2.16 and Proposition 2.2 that (2.21)-(2.22) are equivalent to (2.23). □

Our next result states that seminormality for a and seminormality for a_1 are very closely related. Here we use the *effective domain multifunction* $D_a: X \rightrightarrows V$, defined by

$$D_a(x) \equiv \text{dom}\, a(x, \cdot) \equiv \{v \in V: a(x, v) < +\infty\}.$$

PROPOSITION 2.19. *The seminormal hull* $\tilde{\tilde{a}}_1$ *of* a_1 *is given by*

$$\tilde{\tilde{a}}_1(x, v, \lambda) = \max(\tilde{\tilde{a}}(x, v), \lambda + \tilde{\tilde{\chi}}_{D_a}(x, v)).$$

Proof. We define $b_1, \bar{b}_1: X \times P \times \mathbb{R} \to \bar{\mathbb{R}}$ by

$$b_1(y, p, q) \equiv a_1^*(y, p, q) \equiv \sup_{v\in V, \lambda\in\mathbb{R}} [\langle\langle v, \lambda; p, q\rangle\rangle - a_1(y, v, \lambda)],$$

$$\bar{b}_1(x, p, q) \equiv \limsup_{y\to x} b_1(y, p, q).$$

An easy computation shows

$$\bar{b}_1(x, p, q) = \begin{cases} (1-q)\bar{b}(x, p(1-q)^{-1}) & \text{if } 0 \leqq q < 1, \\ \bar{\chi}^*_{D_a}(x, p) & \text{if } q = 1, \\ +\infty & \text{if } q < 0 \text{ or } q > 1. \end{cases}$$

This yields directly

$$\bar{b}_1^*(x, v, \lambda) = \max(\bar{b}^*(x, v), \lambda + \tilde{\tilde{\chi}}_{D_a}(x, v)).$$

Hence, the result follows by applying Theorem 2.4. □

As a certain converse to Proposition 2.15 we can now demonstrate that seminormality of the function $a: X \times V \to \bar{\mathbb{R}}$ can be characterized in terms of property (Q) for the *epigraphic multifunction* $Q_a: X \rightrightarrows V \times \mathbb{R}$ of a, defined by

$$Q_a(x) \equiv \text{epi}\, a(x, \cdot) \equiv \{(v, \eta) \in V \times \mathbb{R}: \eta \geqq a(x, v)\}.$$

PROPOSITION 2.20. *For every* $x \in X$ *we have that if*

$$a \text{ is seminormal at every point of } \{x\} \times V, \tag{2.26}$$

then

$$Q_a \text{ has property } (Q) \text{ at } x. \tag{2.27}$$

Moreover, if $a(x, v) < +\infty$ *for all* $v \in V$, *then* (2.26) *and* (2.27) *are equivalent.*

Proof. The modified Lagrangian ζ_{Q_a} of Q_a is easily seen to be precisely the function a_1. Since Q_a obviously satisfies (2.22), the result follows immediately from combining Propositions 2.2, 2.18 and 2.19. □

We shall now briefly discuss the connections between the results of this section and work by others. Surprisingly enough, the adaptation of the seminormality concept of Tonelli and McShane to extended real-valued functions seems not to have been considered before. Hence, our results can only be compared to results which have been formulated in terms of property (Q) for multifunctions. Because of Propositions 2.2, 2.15, Theorem 2.4 generalizes [15, Thm. 3.1] (see also [8d, 17.6]). Also by Proposition 2.15 we can observe that Theorem 2.8 is well-known, albeit in slightly weaker forms [8d, 10.5i], [13, VIII.2.1], [26, Thm. 2.1], [3, Lemma 0.7]. It should be observed that Theorem 2.8 can also be extended as in [8d, 10.5ii] by the introduction of monotonicity in certain components of the variable v (the proof then follows again by Lemma 2.11 and Remark 2.5—this goes similar to the more subtle proof of Theorem 2.13). We also wish to point out that the result of [26, Thm. 2.1], which at first sight appears to belong to a class of more general results, is indeed covered by Theorem 2.8. This can be seen by invoking Proposition 2.20 and constructing a suitable minorant function h under the conditions given in [26]; the details are left to the reader.

Propositions 2.12, 2.19 and especially Theorem 2.13 all seem to be new. Proposition 2.15 is also a novel result; observe that it crucially depends on defining seminormality for extended real-valued functions. Finally, Propositions 2.18 and 2.20 are related to similar, more involved characterizations of seminormality in the sense of Tonelli and McShane, which were given in [8b], [8d, 17.3].

3. Seminormality in the small and in the large. In this section we shall establish the connections between seminormality in the small and in the large, announced in the introduction. We shall repeatedly use results involving outer integration and measurable selections; we refer to Appendices A and B for some basic definitions in this regard.

Let $(T, \mathcal{T}, \mu)$ be a σ-finite measure space. For the moment we shall also assume that the σ-algebra $\mathcal{T}$ is μ-complete; later, we will show how this assumption can be lifted. Let (X, d) be a metric Suslin space (Appendix B) and let $(V, P, \langle \cdot, \cdot \rangle)$ be a pair of locally convex Suslin spaces, paired by the strict duality $\langle \cdot, \cdot \rangle$ (i.e., V and P are Suslin for topologies compatible with $\langle \cdot, \cdot \rangle$).

Let $\mathcal{X}$ be a decomposable set of equivalence classes of $(\mathcal{T}, \mathcal{B}(X))$-measurable functions from T into X (the equivalence relation being equality μ-a.e.), which we equip with the essential supremum metric

$$d(x, y) \equiv \operatorname{ess\,sup}_{t \in T} d(x(t), y(t)).$$

Also, let $(\mathcal{V}, \mathcal{P}, \langle \cdot, \cdot \rangle)$ be a pair of decomposable vector spaces of equivalence classes of scalarly μ-integrable functions (Appendix B) going from T into V and P respectively, paired by the duality

$$\langle v, p \rangle \equiv \int_T \langle v(t), p(t) \rangle \mu(dt),$$

where it is assumed that for every $v \in \mathcal{V}$, $p \in \mathcal{P}$ the function $t \mapsto \langle v(t), p(t) \rangle$ belongs to $\mathcal{L}^1_{\mathbb{R}}$ (this function is certainly $\mathcal{T}$-measurable by [7, III.36]). As a consequence of the decomposability hypothesis, the duality $\langle \cdot, \cdot \rangle$ is strict [7, VII.5].

Let $l: T \times X \times V \to \bar{\mathbb{R}}$ be a given function. By means of outer integration (Appendix A) we define the integral functional $I_l: \mathcal{X} \times \mathcal{V} \to \bar{\mathbb{R}}$ as follows:

$$I_l(x, v) \equiv \tilde{\int_T} l(t, x(t), v(t)) \mu(dt).$$

We can now consider seminormality of the integrand l with respect to the framework consisting of (X, d) and $(V, P, \langle \cdot, \cdot \rangle)$ (*seminormality in the small*) and seminormality of the integral functional I_l with respect to the framework which consists of $(\mathscr{X}, d)$ and $(\mathscr{V}, \mathscr{P}, \langle \cdot, \cdot \rangle)$ (*seminormality in the large*). Our main result on the relationship between seminormality in the small and seminormality in the large can now be stated.

THEOREM 3.1. *For every $x \in \mathscr{X}$ such that there exist $p_0 \in \mathscr{P}$, $\varphi_0 \in \mathscr{L}^1_{\mathbb{R}}$ and $\delta > 0$ with*

$$l(t, y, v) \geqq \langle v, p_0(t) \rangle + \varphi_0(t) \text{ for all } y \in B(x(t); \delta) \text{ and } v \in V \quad \mu\text{-a.e.}, \tag{3.1}$$

we have that if

$$l(t, \cdot, \cdot) \text{ is seminormal at every point of } \{x(t)\} \times V \quad \mu\text{-a.e.}, \tag{3.2}$$

then

$$I_l \text{ is seminormal at every point of } \{x\} \times \mathscr{V}. \tag{3.3}$$

Moreover, if

$$l \text{ is } \mathscr{T} \times \mathscr{B}(X \times V)\text{-measurable}, \tag{3.4}$$

$$I_l(x, \cdot) \text{ is not identically equal to } +\infty \text{ on } \mathscr{V}, \tag{3.5}$$

then (3.2) *and* (3.3) *are equivalent.*

We shall avail ourselves of some lemmas to prove this main result.

LEMMA 3.2. *If* (3.4) *holds, then for every $n \in \mathbb{N}$ and $x \in \mathscr{X}$*

(a) *The function $l_{n,x}: T \times X \times V \to \bar{\mathbb{R}}$, defined by*

$$l_{n,x}(t, y, w) \equiv \begin{cases} l(t, y, w) & \text{if } d(y, x(t)) \leqq n^{-1}, \\ +\infty, \end{cases}$$

is $\mathscr{T} \times \mathscr{B}(X \times V)$-measurable.

(b) *The function $m_{n,x}: T \times P \to \bar{\mathbb{R}}$, defined by*

$$m_{n,x}(t, p) \equiv \sup_{y \in X, w \in V} [\langle w, p \rangle - l_{n,x}(t, y, w)],$$

is $\mathscr{T} \times \mathscr{B}(\mathscr{P})$-measurable.

(c) *The function $m^*_{n,x}: T \times V \to \bar{\mathbb{R}}$, defined by*

$$m^*_{n,x}(t, v) \equiv \sup_{p \in P} [\langle v, p \rangle - m_{n,x}(t, p)],$$

is $\mathscr{T} \times \mathscr{B}(V)$-measurable.

Proof. (a) A simple consequence of [7, III.36]. (b) (Compare with the proof of [7, VII.1].) By the von Neumann-Aumann theorem [7, III.22] the epigraphic multifunction $t \mapsto \operatorname{epi} l_{n,x}(t, \cdot, \cdot)$, whose graph is $\mathscr{T} \times \mathscr{B}(X \times V \times \mathbb{R})$-measurable by (a), has a sequence $\{(y_j, w_j, r_j)\}_1^\infty$ of measurable selections such that for every $t \in T$ the sequence $\{(y_j(t), w_j(t), r_j(t))\}$ is dense in $\operatorname{epi} l_{n,x}(t, \cdot, \cdot)$. By continuity of $\langle \cdot, p \rangle$ this gives

$$m_{n,x}(t, p) = \sup_{j \in \mathbb{N}} [\langle w_j(t), p \rangle - r_j(t)],$$

so measurability of $m_{n,x}$ is evident from [7, III.36]. (c) The proof here is entirely similar to that of (b). □

Let us introduce the function $l: T \times X \times V \to \bar{\mathbb{R}}$ by setting

$$\tilde{\tilde{l}}(t, \cdot, \cdot) \equiv \text{seminormal hull of } l(t, \cdot, \cdot).$$

LEMMA 3.3. *If* (3.4) *holds, then the function $\tilde{\tilde{l}}$ is $\mathscr{T} \times \mathscr{B}(X \times V)$-measurable.*

Proof. By Remark 2.3 we know

$$\tilde{\tilde{l}}(t, x, v) = \sup_{n\in\mathbb{N}, y\in X, p\in P} [\langle v, p\rangle - c(t, n, y, p) - \chi(x; B(y; n^{-1}))]$$

with $c: T\times\mathbb{N}\times X\times P\to\bar{\mathbb{R}}$ defined by

$$c(t, n, y, p) \equiv \sup_{z\in X, w\in V} [\langle w, p\rangle - l(t, z, w) - \chi(z; B(y; n^{-1}))].$$

Let us first show that $c(\cdot, n, \cdot, \cdot)$ is $\mathcal{T}\times\mathcal{B}(X\times P)$-measurable for arbitrary $n\in\mathbb{N}$. By the von Neumann-Aumann theorem [7, III.22] the epigraphic multifunction $t\mapsto$ epi $l(t, \cdot, \cdot)$ has a sequence $\{(z_j, w_j, r_j)\}$ of $(\mathcal{T}, \mathcal{B}(X\times V\times\mathbb{R}))$-measurable selections such that for every $t\in T$ the sequence $\{(z_j(t), w_j(t), r_j(t))\}$ is dense in epi $l(t, \cdot, \cdot)$. By continuity of $\langle\cdot, p\rangle$ and upper semicontinuity of the indicator function of an open set this gives

$$c(t, n, y, p) = \sup_{j\in\mathbb{N}} [\langle w_j(t), p\rangle - r_j(t) - \chi(z_j(t); B(y; n^{-1}))].$$

The desired measurability of $c(\cdot, n, \cdot, \cdot)$ is now obvious by [7, III.36]. The measurability proof for $\tilde{\tilde{l}}$ now proceeds by an obvious repetition of moves, which is left to the reader. □

Note that the crucial difference between Lemmas 3.2 and 3.3 is that Lemma 3.2 is concerned with closed balls in the space X, and Lemma 3.3 with open balls. The reasons for this distinction will be apparent in the proof of the following key result.

LEMMA 3.4. *If* (3.1), (3.4) *hold, then*

$$I_{\tilde{\tilde{l}}} \text{ is the seminormal hull of } I_l: \mathcal{X}\times\mathcal{V}\to\bar{\mathbb{R}}.$$

Proof. Let $x\in\mathcal{X}$ and $v\in V$ be arbitrary. By Remark 2.5 we have

$$\tilde{\tilde{I}}_l(x, v) = \lim_{n\to\infty} \uparrow \sup_{p\in\mathcal{P}} \alpha_{n,p},$$

where

$$\alpha_{n,p} \equiv \inf_{y\in\mathcal{X}, d(x,y)\leqq 1/n, w\in\mathcal{V}} [\langle v - w, p\rangle + I_l(y, w)].$$

By definition of the essential supremum metric d we have

$$\alpha_{n,p} = \inf_{y\in\mathcal{X}, w\in\mathcal{V}} [\langle v - w, p\rangle + I_{l_{n,x}}(y, w)],$$

with $l_{n,x}$ as defined in Lemma 3.2(a). If $\alpha_{n,p} > -\infty$, it follows from Lemma 3.2(b) and the decomposability of $\mathcal{X}$ and $\mathcal{V}$ by the reduction theorem (Theorem B.1) that

$$\alpha_{n,p} = \langle v, p\rangle - I_{m_{n,x}}(p).$$

Note that by (3.1) for n large enough

$$m_{n,x}(t, p_0(t)) \leqq -\varphi_0(t);$$

hence, it follows from the above, Lemma 3.2(c) and decomposability of $\mathcal{P}$ that

$$\sup_{p\in\mathcal{P}} \alpha_{n,p} = \sup_{p\in\mathcal{P}} [\langle v, p\rangle - I_{m_{n,x}}(p)] = I_{m^*_{n,x}}(v)$$

by yet another application of the reduction theorem. Note that by the above inequality

$$m^*_{n,x}(t, v(t)) \geqq \langle v(t), p_0(t)\rangle + \varphi_0(t)$$

for n large enough. Hence, it follows by the monotone convergence theorem that

$$\lim_{n\to\infty} \uparrow \sup_{p\in\mathscr{P}} \alpha_{n,p} = \int_T \lim_{n\to\infty} \uparrow m^*_{n,x}(t, v(t))\mu(dt).$$

By combination of the definitions leading up to that of $m^*_{n,x}$ in Lemma 3.2 and Remark 2.5 it is easily seen that

$$\lim_{n\to\infty} \uparrow m^*_{n,x}(t, w) = \tilde{\tilde{I}}(t, x(t), w).$$

Hence, we may conclude that $\tilde{\tilde{I}}_I = I^*_I$. □

At the present stage we can prove Theorem 3.1 under the additional hypothesis that (3.4) be valid throughout:

Proof of Theorem 3.1 (simplified version). Here we suppose that (3.4) is valid throughout. By Proposition 2.2, (3.2) is equivalent to

$$\tilde{\tilde{I}}(t, x(t), \cdot) = I(t, x(t), \cdot) \ \mu\text{-a.e.} \tag{3.6}$$

Thus, if (3.2) holds, Lemma 3.4 gives

$$\tilde{\tilde{I}}_I(x, \cdot) = I^*_I(x, \cdot) = I_I(x, \cdot).$$

Hence (3.3) follows by invoking Proposition 2.2. Conversely, if (3.3) holds, then Proposition 2.2 and Lemma 3.4 give

$$I_I(x, \cdot) = \tilde{\tilde{I}}_I(x, \cdot) = I^*_I(x, \cdot).$$

Hence, (3.6) follows by Theorem B.2 from (3.5), Lemma 3.3 and the decomposability of $\mathscr{V}$. □

We shall now introduce an additional lemma that will enable us to remove condition (3.4) in proving one of the implications in Theorem 3.1.

LEMMA 3.5. *There exists a* $\mathscr{T}\times\mathscr{B}(X\times V)$*-measurable function* $\hat{I}: T\times X\times V\to\bar{\mathbb{R}}$ *such that*

$$\hat{I}(t, \cdot, \cdot) \text{ is seminormal on } X\times V \ \mu\text{-a.e.}, \tag{3.7}$$

$$\hat{I}(t, \cdot, \cdot) \geqq \tilde{\tilde{I}}(t, \cdot, \cdot) \ \mu\text{-a.e.}, \tag{3.8}$$

$$I_{\hat{I}} = I^*_I. \tag{3.9}$$

Proof. Consider the set $\mathscr{G}$ of all normal integrands g on $T\times(\mathbb{N}\times X\times P)$ of the type

$$g(t, n, y, p) \equiv \langle v(t), p\rangle - \varphi(t) - \chi(x(t); B(y; n^{-1}))$$

for all $x\in\mathscr{X}$, $v\in\mathscr{V}$ and all $\mathscr{T}$-measurable functions $\varphi: T\to\bar{\mathbb{R}}$ satisfying $\varphi(t)\geqq \tilde{\tilde{I}}(t, x(t), v(t))$ μ-a.e. By Theorem B.3 there exists a countable subset $\mathscr{G}_0$ of $\mathscr{G}$ such that $\hat{g}\equiv\sup_{g\in\mathscr{G}_0} g$ satisfies the inequality $\hat{g}(t, \cdot)\geqq g(t, \cdot)$ μ-a.e. for every $g\in\mathscr{G}$. We define

$$\hat{I}(t, z, w) \equiv \sup_{n\in\mathbb{N}, y\in X, p\in P} [\langle w, p\rangle - \hat{g}(t, n, y, p) - \chi(y; B(z; n^{-1}))].$$

Since $\hat{I}(t, \cdot, \cdot)$ is the supremum of a collection of simple seminormal functions on $X\times V$, (3.7) follows immediately. Also, $\hat{g}$ is by its definition a normal integrand on $T\times(\mathbb{N}\times X\times P)$; hence the desired measurability of $\hat{I}$ is proven in complete analogy to what was done in Lemma 3.3. Also, it follows from the definition of $\hat{g}$ that

$$\hat{g}(t, n, y, p) \leqq \sup_{z\in X, w\in V} [\langle w, p\rangle - \tilde{\tilde{I}}(t, z, w) - \chi(z; B(y; n^{-1}))].$$

Therefore it follows by Remark 2.3 from the definition of $\hat{I}$ that for μ-a.e. $t\in T$ the

seminormal hull of $\tilde{\tilde{l}}(t,\cdot,\cdot)$, which is $\tilde{\tilde{l}}(t,\cdot,\cdot)$ itself, is no larger than $\hat{l}(t,\cdot,\cdot)$. This proves (3.8). Finally, let $x\in\mathscr{X}$ and $v\in\mathscr{V}$ be arbitrary. For every $\mathscr{T}$-measurable function $\varphi: T\to\bar{\mathbb{R}}$ such that $\varphi(t)\geqq\tilde{\tilde{l}}(t,x(t),v(t))$ μ-a.e. we have for μ-a.e. $t\in T$

$$\varphi(t)\geqq\langle v(t),p\rangle-\hat{g}(t,n,y,p)-\chi(y;B(x(t);n^{-1}))\text{ for all }n\in\mathbb{N},y\in X,p\in P,$$

by the essential supremum property of $\hat{g}$; this implies $\varphi(t)\geqq\hat{l}(t,x(t),v(t))$ μ-a.e. By definition of outer integration this means that $I_{\tilde{l}}(x,v)\geqq I_{\hat{l}}(x,v)$; the converse inequality follows directly from (3.8) and measurability of $\hat{l}$. We conclude that (3.9) has been shown to hold. □

Proof of Theorem 3.1 (remainder). Let $\hat{l}$ correspond to $\tilde{\tilde{l}}$ as in Lemma 3.5. Since (3.2) holds, we have (3.6). In view of (3.9) this gives

$$I_l(x,\cdot)=I_{\hat{l}}(x,\cdot).\tag{3.10}$$

As $\hat{l}$ is $\mathscr{T}\times\mathscr{B}(X\times V)$-measurable, substitution of $\hat{l}$ in lieu of l in Lemma 3.4 gives $\tilde{\tilde{I}}_{\hat{l}}=I_{\hat{l}}$ by using (3.7). This shows $I_{\hat{l}}$ to be seminormal on $\mathscr{X}\times\mathscr{V}$ (Proposition 2.2). By (3.9) and (2.3) we have $\tilde{\tilde{I}}_l\geqq I_{\hat{l}}$. By Proposition 2.2, (3.3) thus follows from (3.10). □

From the proof of Theorem 3.1 it is evident that the following result also holds; its proof will be left to the reader.

THEOREM 3.6. *For l such that there exist $p_0\in\mathscr{P}$ and $\varphi_0\in\mathscr{L}^1_{\mathbb{R}}$ with*

$$l(t,y,v)\geqq\langle v,p_0(t)\rangle+\varphi_0(t)\tag{3.11}$$

we have that if

$$l(t,\cdot,\cdot)\text{ is seminormal on }X\times V\ \mu\text{-a.e.},\tag{3.12}$$

then

$$I_l\text{ is seminormal on }\mathscr{X}\times\mathscr{V}.\tag{3.13}$$

Moreover, if (3.4) *holds and*

$$I_l\text{ is not identically equal to }+\infty\text{ on }\mathscr{X}\times\mathscr{V},$$

then (3.12) *and* (3.13) *are equivalent.*

We can rid Theorems 3.1 and 3.6 of the completeness assumption for the measure space $(T,\mathscr{T},\mu)$, hitherto in force.

Remark 3.7. Theorems 3.1 and 3.6 continue to hold if $(T,\mathscr{T},\mu)$ is not assumed to be complete. This follows from the fact that every equivalence class of $\mathscr{T}_\mu$-measurable functions in $\mathscr{X}$, $\mathscr{V}$ or $\mathscr{P}$ has a $\mathscr{T}$-measurable representant by [7, III.36] and elementary facts concerning completion. Here $\mathscr{T}_\mu$ stands for the μ-completion of the σ-algebra $\mathscr{T}$. Further details are left to the reader. □

4. Seminormality and semicontinuity of integral functionals. In this section we shall combine the results of §§ 2, 3 so as to obtain very general sufficient conditions for coincident seminormality, lower closure and lower semicontinuity of integral functionals (of course the point of these conditions is that they do not explicitly refer to seminormality). At the same time, a new approach is initiated to necessary conditions for the lower semicontinuity of integral functionals.

Let $(T,\mathscr{T},\mu)$ be a finite measure space; in contrast to § 3, this measure space is supposed to be finite, since we shall work with weak convergence in $\mathscr{L}^1$-spaces. Otherwise, the framework of this section is that of § 3: (X,d) is a metric Suslin space, $(V,P,\langle\cdot,\cdot\rangle)$ is a pair of locally convex spaces, paired by a strict duality $\langle\cdot,\cdot\rangle$, such

that V and P are Suslin spaces for topologies that are compatible with the duality. Further, $\mathscr{X}$ is a decomposable set of equivalence classes of $(\mathscr{T}, \mathscr{B}(X))$-measurable functions from T into X, and $(\mathscr{V}, \mathscr{P}, \langle \cdot, \cdot \rangle)$ is a pair of decomposable vector spaces of equivalence classes of scalarly $\mathscr{T}$-measurable functions, going from T into V and P respectively, equipped with the strict duality

$$\langle v, p \rangle \equiv \int_T \langle v(t), p(t) \rangle \mu(dt).$$

We recall from § 2 that a function $h: V \to (-\infty, +\infty]$ is said to be of *Nagumo type* if h is convex and sequentially inf-compact on V for every slope. A subset $\mathscr{V}_0$ of $\mathscr{V}$ is defined to be *Nagumo tight* if there exists a $\mathscr{T} \times \mathscr{B}(V)$-measurable function $h: T \times V \to [0, +\infty]$ such that

(4.1) $h(t, \cdot)$ is of Nagumo type on V μ-a.e.,

(4.2) $$\sup_{v \in \mathscr{V}_0} I_h(v) < +\infty.$$

Further, $\mathscr{V}_0$ is defined to be *almost Nagumo tight* if there exists a nonincreasing sequence $\{B_i\}_1^\infty$ in $\mathscr{T}$, whose intersection is a μ-null set, such that for every $i \in \mathbb{N}$ there exists a $\mathscr{T} \times \mathscr{B}(V)$-measurable function $h_i: T \times V \to [0, +\infty]$ with

$(4.1)_i$ $h_i(t, \cdot)$ is of Nagumo type on V μ-a.e.,

$(4.2)_i$ $$\sup_{v \in \mathscr{V}_0} \int_{T \setminus B_i} h_i(t, v(t)) \mu(dt) < +\infty.$$

The following examples show that (almost) Nagumo tightness occurs in some interesting cases.

Example 4.1. Every subset $\mathscr{V}_0$ of $\mathscr{V}$ for which there exists a scalarly $\mathscr{T}$-measurable multifunction $\Gamma: T \rightrightarrows V$ having (sequentially) compact convex values, such that for every $\varepsilon > 0$ there exists a set A_ε in $\mathscr{T}$, $\mu(A_\varepsilon) \leqq \varepsilon$, with

$$v(t) \in \Gamma(t) \quad \text{for all } v \in \mathscr{V}_0 \quad \text{for every } t \in T \setminus A_\varepsilon,$$

is almost Nagumo tight, as is seen by taking B_i to be the intersection of the sets $A_{1/j}$, $j \leqq i$, and h_i to be the indicator function χ_Γ of Γ; note that χ_Γ is $\mathscr{T} \times \mathscr{B}(V)$-measurable by [7, III.37].

Example 4.2. Suppose that $(V, P, \langle \cdot, \cdot \rangle)$ is specified as follows: V is a separable reflexive Banach space, whose norm we denote by $\| \cdot \|$, P is the topological dual V' of $(V, \| \cdot \|)$, $\langle \cdot, \cdot \rangle$ is the usual duality, V is equipped with the topology $\sigma(V, V')$ and P with the topology $\sigma(V', V)$ (in this case V and P are both locally convex Suslin [7, p. 202]). Suppose further that $(\mathscr{V}, \mathscr{P}, \langle \cdot, \cdot \rangle)$ is as follows: $\mathscr{V}$ is the usual L^1-space of $\mathscr{L}^1_V$ of equivalence classes of μ-integrable functions from T into V (note that strong and scalar μ-integrability coincide here by separability of $(V, \| \cdot \|)$), and $\mathscr{P}$ is the usual L^∞-space $\mathscr{L}^\infty_{V'}$ of equivalence classes of essentially bounded scalarly $\mathscr{T}$-measurable functions from T into V'.

Then every subset $\mathscr{V}_0$ of $\mathscr{L}^1_V$ which is relatively compact or relatively sequentially compact for the weak topology $\sigma(\mathscr{L}^1_V, \mathscr{L}^\infty_{V'})$, is Nagumo tight. Namely, by the Dunford–Pettis theorem [12, IV.2.1] the set of all functions $t \mapsto \|v(t)\|$, $v \in \mathscr{V}_0$, is uniformly integrable. Hence, there exists by the de la Vallée Poussin theorem [11, II.22] a nondecreasing continuous convex function $h': [0, +\infty) \to [0, +\infty)$ satisfying (2.8), such

that

$$\sup_{v\in\mathcal{V}_0}\int_T h'(\|v(t)\|)\mu(dt)<+\infty.$$

Setting $h(v)\equiv h'(\|v\|)$, we see that Nagumo tightness holds by Example 2.7.

Example 4.3. Suppose that $(V, P, \langle\cdot,\cdot\rangle)$ and $(\mathcal{V}, \mathcal{P}, \langle\cdot,\cdot\rangle)$ are as in Example 4.2. Then for every sequence $\{v_k\}_1^\infty$ in $\mathcal{V}$ such that

$$\sup_{k\in\mathbb{N}}\int_T \|v_k(t)\|\mu(dt)<+\infty,$$

there exists a subsequence $\{k'\}$ of $\{k\}$ such that $\{v_{k'}\}$ is almost Nagumo tight. Namely, the set of all functions $t\mapsto\|v_k(t)\|$, $k\in\mathbb{N}$, is uniformly bounded in $\mathcal{L}^1_{\mathbb{R}}$ in L^1-norm. Hence by the biting lemma of Chacon [4] there exist a nonincreasing sequence $\{B_i\}$ in $\mathcal{T}$, having a μ-null set as its intersection, and a subsequence $\{k'\}$ of $\{k\}$ such that for every $i\in\mathbb{N}$ the restrictions of the functions $t\mapsto\|v_{k'}(t)\|$ to $T\backslash B_i$ form a uniformly μ-integrable sequence. At this point the previous example can be taken up in an obvious way.

Let $l: T\times X\times V\to\bar{\mathbb{R}}$ be a given function; correspondingly we define the function $l_1: T\times X\times V\times\mathbb{R}\to\bar{\mathbb{R}}$ by

$$l_1(t, x, v, \lambda)\equiv\max(l(t, x, v), \lambda).$$

The integral functional $I_{l_1}: \mathcal{X}\times\mathcal{V}\times\mathcal{L}^1_{\mathbb{R}}\to\bar{\mathbb{R}}$, of course defined by

$$I_{l_1}(x, v, \lambda)\equiv\int_T l_1(t, x(t), v(t), \lambda(t))\mu(dt),$$

will be considered in connection with the seminormality framework which consists of $(\mathcal{X}, d)$ and the pair $(\mathcal{V}\times\mathcal{L}^1_{\mathbb{R}}, \mathcal{P}\times\mathcal{L}^\infty_{\mathbb{R}}, \langle\!\langle\cdot;\cdot\rangle\!\rangle)$ of decomposable vector spaces, whose duality (strict) is given by

$$\langle\!\langle v, \lambda; p, q\rangle\!\rangle\equiv\int_T(\langle v(t), p(t)\rangle+\lambda(t)q(t))\mu(dt).$$

THEOREM 4.4. *For every $x\in\mathcal{X}$ if*

(4.3) *$l(t,\cdot,\cdot)$ is sequentially lower semicontinuous at every point of $\{x(t)\}\times V$ μ-a.e.,*

(4.4) *$l(t, x(t),\cdot)$ is convex on V μ-a.e.,*

then for every $\mathcal{V}_0\subset\mathcal{V}$ and $\mathcal{L}_0\subset\mathcal{L}^1_{\mathbb{R}}$ satisfying

(4.5) *$\mathcal{V}_0$ is almost Nagumo tight,*

(4.6) *$\mathcal{L}_0^-\equiv\{\lambda^-: \lambda\in\mathcal{L}_0\}$ is uniformly μ-integrable,*

we have

(4.7) *I_{l_1} coincides on $\mathcal{X}\times\mathcal{V}_0\times\mathcal{L}_0$ with a function which is seminormal at every point of $\{x\}\times\mathcal{V}\times\mathcal{L}^1_{\mathbb{R}}$.*

Proof. To simplify matters, we shall first assume that $\mathcal{V}_0$ is Nagumo tight. Let h be as in (4.1)-(4.2). By (4.6) there exists a nondecreasing continuous convex function

$h'\colon[0,+\infty)\to[0,+\infty)$, satisfying (2.8), such that

$$\sup_{\lambda\in\mathscr{L}_0}\int_T h'(\lambda^-(t))\mu(dt)<+\infty, \tag{4.8}$$

as follows by the theorem of de la Vallée Poussin. For every $\varepsilon>0$ we define the function $l_{1,\varepsilon}\colon T\times X\times V\times\mathbb{R}\to\bar{\mathbb{R}}$ by

$$l_{1,\varepsilon}(t,y,v,\lambda)\equiv l_1(t,y,v,\lambda)+\varepsilon h(v)+\varepsilon h'(\lambda^-).$$

In view of (4.3)–(4.4) and the properties of h and h' we have by Theorem 2.13 that

$$l_{1,\varepsilon}(t,\cdot,\cdot,\cdot)\text{ is seminormal at every point of }\{x(t)\}\times V\times\mathbb{R}\ \mu\text{-a.e.}$$

Hence condition (3.2) of Theorem 3.1 holds. Also the boundedness condition (3.1)—in fact (3.11)—is valid, since we can take $p_0(t)\equiv 0$, $q_0(t)\equiv 1$ and $\varphi_0(t)\equiv 0$ for all $t\in T$. By Theorem 3.1 we obtain

$$I_{l_{1,\varepsilon}}\text{ is seminormal at every point of }\{x\}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}.$$

Let σ stand for the value of the supremum in (4.2) and σ' for the value of the supremum in (4.8). The function $J\colon\mathscr{X}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}\to\bar{\mathbb{R}}$ defined by

$$J\equiv\sup_{\varepsilon>0}(I_{l_{1,\varepsilon}}-\varepsilon\sigma-\varepsilon\sigma'),$$

is seminormal at every point of $\{x\}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}$, as follows from the above by Remark 2.1. It is also elementary to verify that

$$J(y,v,\lambda)=I_{l_1}(y,v,\lambda)\quad\text{for every } y\in\mathscr{X},\ v\in\mathscr{V}_0\text{ and }\lambda\in\mathscr{L}_0,$$

so the proof under the simplifying assumption has come to an end. Next, we suppose that merely (4.5) holds. Let $\{B_i\}_1^\infty$ be as asserted in the definition of almost Nagumo tightness. For every $i\in\mathbb{N}$ we define $I_i\colon\mathscr{X}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}\to\bar{\mathbb{R}}$ by

$$I_i(y,v,\lambda)\equiv\int_T 1_{T\setminus B_i}(t)l_1(t,y(t),v(t),\lambda(t))\mu(dt)+\int_{B_i}\lambda(t)\mu(dt). \tag{4.9}$$

From the above it follows by making an obvious substitution for the integrand that for every $i\in\mathbb{N}$, I_i coincides on $\mathscr{X}\times\mathscr{V}_0\times\mathscr{L}_0$ with a function $J_i\colon\mathscr{X}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}\to\bar{\mathbb{R}}$ which is seminormal at every point of $\{x\}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}$. By Proposition A.1 and the monotone convergence theorem we have $I_{l_1}=\lim_i\uparrow I_i$ on $\mathscr{X}\times\mathscr{V}\times\mathscr{L}^1_{\mathbb{R}}$ (pointwise), so the desired result now follows by Remark 2.1. □

In complete analogy to the derivation of Theorem 4.4 from Theorem 3.1 we can now obtain the following result from Theorem 3.6.

THEOREM 4.5. *If*

$l(t,\cdot,\cdot)$ *is sequentially lower semicontinuous on* $X\times V$ μ*-a.e.,*

$l(t,x,\cdot)$ *is convex on* V *for every* $x\in X$ μ*-a.e.,*

then for every $\mathscr{V}_0\subset\mathscr{V}$ *and* $\mathscr{L}_0\subset\mathscr{L}^1_{\mathbb{R}}$ *satisfying* (4.5)–(4.6) *we have*

I_{l_1} *coincides on* $\mathscr{X}\times\mathscr{V}_0\times\mathscr{L}_0$ *with a seminormal function.*

Remark 4.6. The coincident seminormality results obtained in Theorems 4.4 and 4.5 immediately imply lower semicontinuity results for I_{l_1}. For instance, (4.7) implies

I_{l_1} is lower semicontinuous at every point of $\{x\}\times\mathscr{V}_0\times\mathscr{L}_0$, relative to the set $\mathscr{X}\times\mathscr{V}_0\times\mathscr{L}_0$,

where $\mathscr{X}$ is equipped with the d-topology and $\mathscr{V} \times \mathscr{L}^1_{\mathbb{R}}$ with the weak topology $\sigma(\mathscr{V} \times \mathscr{L}^1_{\mathbb{R}}, \mathscr{P} \times \mathscr{L}^\infty_{\mathbb{R}})$.

Rather than the modes of convergence employed in the above remark, it is desirable to work with weaker modes of convergence. For this purpose we shall work from now on with given sequences $\{x_k\}_0^\infty$ in $\mathscr{X}$ and $\{v_k\}_1^\infty$ in $\mathscr{V}$ (formally we could consider generalized sequences, but with little effect—see our comments below). We shall say that the sequence $\{x_k\}_1^\infty$ *almost* converges in d to the function x_0 if there exists a nonincreasing sequence $\{B_i\}_1^\infty$ in $\mathcal{T}$, whose intersection is a μ-null set, such that for every $i \in \mathbb{N}$

$$\operatorname*{ess\,sup}_{t \in T \setminus B_i} d(x_k(t), x_0(t)) \to 0.$$

We shall also say that the sequence $\{v_k\}_1^\infty$ *almost* converges in $\sigma(\mathscr{V}, \mathscr{P})$ to $v \in \mathscr{V}$ if there exists a nonincreasing sequence $\{B_i\}_1^\infty$ in $\mathcal{T}$, whose intersection is a μ-null set, such that for every $i \in \mathbb{N}$

$$\int_{T \setminus B_i} \langle v_k(t), p(t) \rangle \mu(dt) \to \int_{T \setminus B_i} \langle v(t), p(t) \rangle \mu(dt) \text{ for every } p \in \mathscr{P}.$$

Example 4.7. If the sequence $\{x_k\}_1^\infty$ converges in measure μ to x_0 then there exists a subsequence $\{\ell\}$ of $\{k\}$ such that $\{x_k\}$ almost converges in d to x_0. Namely, $\{k\}$ contains a subsequence $\{\ell\}$ such that $\{x_\ell\}$ converges to x_0 μ-a.e. Therefore there exists by Egorov's theorem [23, II.4] a sequence $\{A_j\}_1^\infty$ in $\mathcal{T}$, $\mu(A_j) \leqq j^{-1}$, such that $\operatorname{ess\,sup}_{T \setminus A_j} d(x_\ell(t), x_0(t)) \to 0$ for every $j \in \mathbb{N}$. Now take B_i to be the intersection of the sets A_j, $j \leqq i$.

Example 4.8. Suppose that $(V, P, \langle \cdot, \cdot \rangle)$, $\langle \mathscr{V}, \mathscr{P}, \langle \cdot, \cdot \rangle \rangle$ and $\{v_k\}_1^\infty$ are as in Example 4.3. Then $\{k\}$ contains a subsequence $\{\ell\}$ such that $\{v_\ell\}$ almost converges in $\sigma(\mathscr{L}^1_V, \mathscr{L}^\infty_{V'})$ to some $v_* \in \mathscr{L}^1_V$. Namely, let $\{k'\}$ and $\{B_i\}^\infty$ be as in Example 4.3. For every $i \in \mathbb{N}$ the restrictions of the functions $t \mapsto \|v_{k'}(t)\|$ to $T \setminus B_i$ form a uniformly μ-integrable subset of $\mathscr{L}^1_{\mathbb{R}}$, so by the Dunford-Pettis theorem [12, IV.2.1] a subsequence of the sequence of restrictions of v_k to $T \setminus B_i$, $k \in \mathbb{N}$, converges in $\sigma(\mathscr{L}^1_V(T \setminus B_i), \mathscr{L}^\infty_{V'}(T \setminus B_i))$ to some element of $\mathscr{L}^1_V(T \setminus B_i)$. By the obvious extraction of a diagonal sequence one thus finds the desired $\{\ell\}$ and $v_* \in \mathscr{L}^1_V$ (μ-integrability of v_* follows from the uniform L^1-boundedness of the initial sequence).

Note that neither example above—nor any other of which we know—applies to generalized sequences. Thus, apart from Theorems 4.4, 4.5 and Remark 4.6, nothing new ensues for generalized sequences.

THEOREM 4.9. *If*

(4.10) $l(t, \cdot, \cdot)$ *is sequentially lower semicontinuous at every point of* $\{x_0(t)\} \times V$ μ-*a.e.*,

(4.11) $l(t, x_0(t), \cdot)$ *is convex on* V μ-*a.e.*,

if also

$\{x_k\}_1^\infty$ *almost converges in* d *to* x_0,

$\{v_k\}_1^\infty$ *almost converges in* $\sigma(\mathscr{V}, \mathscr{P})$ *to* $v \in \mathscr{V}$,

$\{v_k\}_1^\infty \cup \{v\}$ *is almost Nagumo tight,*

and if there exists a uniformly μ-*integrable sequence* $\{\lambda_k\}_1^\infty$ *in* $\mathscr{L}^1_{\mathbb{R}}$ *such that*

(4.12) $l(t, x_k(t), v_k(t)) \geqq \lambda_k(t)$ μ-*a.e. for every* $k \in \mathbb{N}$,

then

$$\liminf_{k\to\infty} I_l(x_k, v_k) \geqq I_l(x_0, v). \tag{4.13}$$

Proof. Suppose first that $\{x_k\}$ converges in d to x_0 and $\{v_k\}_1^\infty$ converges in $\sigma(\mathcal{V}, \mathcal{P})$ to v. Let α stand for the left side in (4.13). There exists a subsequence $\{k'\}$ of $\{k\}$ such that $\lim_{k'} I_l(x_{k'}, v_{k'}) = \alpha$. By the Dunford-Pettis theorem there exist a subsequence $\{k''\}$ of $\{k'\}$ and $\lambda_* \in \mathcal{L}^1_{\mathbb{R}}$ such that $\{\lambda_{k''}\}$ converges to λ_* in $\sigma(\mathcal{L}^1_{\mathbb{R}}, \mathcal{L}^\infty_{\mathbb{R}})$. Hence the sequence $\{(v_{k''}, \lambda_{k''})\}$ converges to (v, λ_*) in the topology $\sigma(\mathcal{V}\times\mathcal{L}^1_{\mathbb{R}}, \mathcal{P}\times\mathcal{L}^\infty_{\mathbb{R}})$. By Remark 4.6 this gives (4.13), in view of the definition of l_1. Next, we prove the result in full generality. Let $\{B_i\}_1^\infty$ be as in the definitions of almost d-convergence and almost $\sigma(\mathcal{V}, \mathcal{P})$-convergence; rather than taking unions pairwise, we may work with one such sequence. Since (4.9) is also valid here (admittedly with a different interpretation of the B_i), the result follows now from the above by imitating the final step in the proof of Theorem 4.4. □

COROLLARY 4.10. *If* (4.10)–(4.12) *hold, if also*

$$\{x_k\}_1^\infty \text{ converges in measure } \mu \text{ to } x_0,$$

$$\{v_k\}_1^\infty \text{ converges in } \sigma(\mathcal{V}, \mathcal{P}) \text{ to } v_0 \in \mathcal{V},$$

and if there exists a scalarly measurable multifunction $\Gamma: T \rightrightarrows V$ *having compact convex values, such that for every* $\varepsilon > 0$ *there exists* A_ε *in* $\mathcal{T}$, $\mu(A_\varepsilon) \leqq \varepsilon$, *with*

$$v_k(t) \in \Gamma(t) \text{ for all } k \in \mathbb{N}\cup\{0\} \text{ for every } t \in T\setminus A_\varepsilon,$$

then

$$\liminf_{k\to\infty} I_l(x_k, v_k) \geqq I_l(x_0, v_0).$$

Proof. Combine Examples 4.1, 4.7 and Theorem 4.9. □

COROLLARY 4.11. *Suppose that* $(V, P, \langle\cdot,\cdot\rangle)$, $(\mathcal{V}, \mathcal{P}, \langle\cdot,\cdot\rangle)$ *are as in Example* 4.2, *that* V *is the Cartesian product of two separable reflexive Banach spaces* U *and* W *and that* P *is the direct sum of their topological duals* U' *and* W'. *Correspondingly, we write* $v_k \equiv (u_k, w_k)$. *If* (4.10), (4.12) *hold and*

$$l(t, x_0(t), \cdot) \text{ is convex on } V \ \mu\text{-a.e.}, \tag{4.11'}$$

if also

$$\{x_k\}_1^\infty \text{ converges in measure } \mu \text{ to } x_0,$$

$$\{u_k\}_1^\infty \text{ converges in } \sigma(\mathcal{L}^1_U, \mathcal{L}^\infty_{U'}) \text{ to } u_0 \in \mathcal{L}^1_U,$$

$$\sup_{k\in\mathbb{N}} \int_T \|w_k(t)\|_W \mu(dt) < +\infty,$$

then there exists a function $w_* \in \mathcal{L}^1_W$ *such that*

$$\liminf_{k\to\infty} I_l(x_k, (u_k, w_k)) \geqq I_l(x_0, (u_0, w_*)).$$

Proof. By Examples 4.2–4.3 it is easy to see that the set $\mathcal{V}_0$ consisting of all (u_k, w_k), $k \in \mathbb{N}$, and (u_0, w_*) is almost Nagumo tight. Combine now Examples 4.7–4.8 with Theorem 4.9. □

It is a simple exercise to merge Corollaries 4.10–4.11 into one lower closure result, using Theorem 4.9; we shall leave this to the interested reader.

Our next subject concerns necessary conditions for the lower semicontinuity of the integral functional I_l. These will be derived in a very simple way from Theorem 3.1, which would seem to open up a new approach to the subject.

THEOREM 4.12. *Suppose that* $(V, P, \langle\cdot,\cdot\rangle)$, $(\mathcal{V}, \mathcal{P}, \langle\cdot,\cdot\rangle)$ *are as in Example* 4.2. *For every* $x \in \mathcal{X}$ *we have that if* (3.1) *and* (3.4)-(3.5) *hold, and if*

(4.14) I_l *is lower semicontinuous at every point of* $\{x\} \times \mathcal{V}$,

(4.15) *the measure* μ *is nonatomic,*

then

(4.16) $l(t,\cdot,\cdot)$ *is sequentially lower semicontinuous at every point of* $\{x(t)\} \times V$ μ*-a.e.,*

(4.17) $l(t, x(t), \cdot)$ *is convex* μ*-a.e.*

Proof. By (3.5) there exists $v_0 \in \mathcal{V}$ such that $I_l(x, v_0) < +\infty$. The singleton $\{v_0\}$ being compact for $\sigma(\mathcal{L}^1_V, \mathcal{L}^\infty_{V'})$, there exists a nondecreasing continuous convex function $h' : [0, +\infty) \to [0, +\infty)$, satisfying (2.8), such that $I_h(v_0) < +\infty$ where we have set $h \equiv h'(\|\cdot\|)$ (Example 4.2). It follows directly from the norm continuity and convexity of h that the integral functional I_h is lower semicontinuous and convex on $\mathcal{L}^1_V$ (for instance, directly by Theorem 3.1). For arbitrary $p \in \mathcal{L}^\infty_{V'}$ the function $\gamma \mapsto h'(\gamma) - \|p\|_\infty \gamma$ satisfies the growth condition (2.8). Hence, it follows by the Dunford Pettis theorem [12, IV.2.1] and the above that

$$I_h \text{ is of Nagumo type on } \mathcal{V}.$$

Also, it follows from (4.14)-(4.15) that

$$I_l(x,\cdot) \text{ is convex on } \mathcal{V}.$$

To see this, note that the epigraph epi $I_l(x,\cdot)$ of $I_l(x,\cdot)$ is closed in $\mathcal{L}^1_V \times \mathbb{R}$ by (4.14). Hence, for epi $I_l(x,\cdot)$ to be convex, it is enough that for every $m \in \mathbb{N}$ and $\{p_1, \cdots, p_m\} \subset \mathcal{L}^\infty_{V'}$ and every $\rho \in \mathbb{R}$ the set consisting of $(\langle v, p_1\rangle, \cdots, \langle v, p_m\rangle, \rho r) \in \mathbb{R}^{m+1}$, for all $(v, r) \in$ epi $I_l(x,\cdot)$, is convex. The latter is evident from (4.15) by Lyapunov's theorem [7]. Further, by (3.1) there exist $p_0 \in \mathcal{P}$, $\beta_0 \in \mathbb{R}$ and $\delta > 0$ such that

$$I_l(y, v) \geqq \langle v, p_0\rangle + \beta_0 \text{ for all } y \in \mathcal{X},\ d(y, x) < \delta, \text{ and all } v \in \mathcal{V},$$

where we take $\beta_0 \equiv \int_T \varphi_0\, d\mu$. Thus all conditions of Corollary 2.9 (cf. Remark 2.14) have been shown to hold. It follows that for every $\varepsilon > 0$

$$I_l + \varepsilon I_h \text{ is seminormal at every point of } \{x\} \times \mathcal{V}.$$

By Theorem 3.1 this implies that for every $\varepsilon > 0$

$$l_\varepsilon(t,\cdot,\cdot) \text{ is seminormal at every point of } \{x(t)\} \times V \ \mu\text{-a.e.}$$

where $l_\varepsilon : T \times X \times V \to \bar{\mathbb{R}}$ is defined by

$$l_\varepsilon(t, y, v) \equiv l(t, y, v) + \varepsilon h(v).$$

From this it follows obviously that (4.16)-(4.17) are valid with l replaced by l_ε; letting ε go to zero then gives (4.17). Also, since $h : V \to (-\infty, +\infty]$ is nondecreasing (4.16) follows directly by using the uniform boundedness principle, letting ε go to zero [16]. □

We shall now briefly discuss the main results of this section. The tightness concept introduced in the beginning is in the spirit of [1e], [1f]; nevertheless the difference

with the tightness concept given there, which does not require superlinear growth of the function h, is considerable. Also the way in which tightness is made to work here is completely different from the approach followed in [1e], [1f]. The coincident seminormality result of Theorem 4.4 is quite new. The abstract lower closure and lower semicontinuity result in Theorem 4.9 is also new (but well-known in less general forms, of course). The lower semicontinuity result of Corollary 4.10 generalizes [1a, Case 2] and [6, Thms. 4, 5, 7, 8, 9]; cf. [1f]. The lower closure and lower semicontinuity result of Corollary 4.11 generalizes a multitude of results, e.g. [8d, 10.6i–ii, 10.7i–ii, 10.8i–ii], [17, Thm. 1], and the sufficiency part of [24b, Thm.] (where the space V is finite dimensional) and [5, Thm. 4.1(ii)] and the sufficiency part of [3, 1.0] (the latter two results on semicontinuity deal with a separable reflexive Banach space V). Note that none of the above results deals with outer integration. More importantly, none of the lower closure results mentioned above—nor any other of which we know—has been formulated for infinite-dimensional V, the one exception being [1f, Thm. 3.1], due to the present author. This result coincides precisely with Corollary 4.11, even though it was derived by a totally different approach. The necessary conditions for sequential lower semicontinuity obtained in Theorem 4.12 are quite general but for the boundedness condition (3.1); this makes the result somewhat incomparable to similar results obtained by others; e.g., cf. [17, Thm. 2], [24b, Thm.].

Appendix A. Let $(T, \mathcal{T}, \mu)$ be a σ-finite measure space. For every $\mathcal{T}$-measurable function $\varphi: T \to \bar{\mathbb{R}}$ we define

$$\int_T \varphi \, d\mu \equiv \int_T \varphi^+ \, d\mu - \int_T \varphi^- \, d\mu, \tag{A.1}$$

where $\varphi^+ \equiv \max(\varphi, 0)$, $\varphi^- \equiv \max(-\varphi, 0)$. Note that we use the convention $(+\infty) - (+\infty) \equiv +\infty$. Next, we define for every function $\psi: T \to \bar{\mathbb{R}}$

$$\tilde{\int}_T \psi \, d\mu \equiv \inf\left\{\int_T \varphi \, d\mu : \varphi: T \to \bar{\mathbb{R}} \text{ is } \mathcal{T}\text{-measurable}, \ \varphi \geqq \psi\right\}. \tag{A.2}$$

This notion of *outer integration* can be seen as an extension of the outer measure of μ. Note that outer integration in the sense of (A.2) reduces to integration in the sense of (A.1) for $\mathcal{T}$-measurable functions.

PROPOSITION A.1. *For every function $\psi: T \to \bar{\mathbb{R}}$ there exists a $\mathcal{T}$-measurable function $\hat{\varphi}: T \to \bar{\mathbb{R}}$, $\varphi \geqq \psi$, such that*

$$\tilde{\int}_T 1_B \psi \, d\mu = \int_T 1_B \hat{\varphi} \, d\mu \text{ for every } B \in T. \tag{A.3}$$

Proof. Let $\hat{\varphi}$ be the essential infimum of the collection Φ of all $\mathcal{T}$-measurable functions $\varphi: T \to \bar{\mathbb{R}}$ such that $\varphi \geqq \psi$ [23, I]. Then $\hat{\varphi} \geqq \psi$ and $\hat{\varphi} \leqq \varphi$ μ-a.e. for every $\varphi \in \Phi$. Let $B \in \mathcal{T}$ be arbitrary. For every $\mathcal{T}$-measurable function $\varphi: T \to \bar{\mathbb{R}}$ with $\varphi \geqq 1_B \psi$ we have evidently that the function $\varphi': T \to \bar{\mathbb{R}}$, defined by $\varphi'(t) \equiv \varphi(t)$ if $t \in B$ and $\varphi'(t) \equiv \hat{\varphi}(t)$ if $t \notin B$, belongs to the set Φ. Hence $\varphi' \geqq \hat{\varphi}$ μ-a.e., and in particular $\varphi(t) \geqq \hat{\varphi}(t)$ for μ-a.e. $t \in B$. Since $\varphi(t) \geqq 0$ for every $t \notin B$, this proves that $\int_T \varphi \, d\mu \geqq \int_T 1_B \hat{\varphi} \, d\mu$. Thus one inequality in (A.3) has been proven, and the converse inequality holds trivially. □

Appendix B. Let S be a *Suslin* space; by definition this means that there exist a Polish space R and a continuous surjection π from R onto S. Let $\mathcal{B}(S)$ denote the Borel σ-algebra on S. Let $(T, \mathcal{T}, \mu)$ be a σ-finite complete measure space and let $\mathcal{M}_S$

be the set of all $(\mathcal{T}, \mathcal{B}(S))$-measurable functions $u: T \to S$ such that $u(T)$ is a relatively compact subset of S. A set $\mathcal{U}$ of $(\mathcal{T}, \mathcal{B}(S))$-measurable functions from T into S is said to be *decomposable* if for every $u \in \mathcal{U}$, $v \in \mathcal{M}_S$ and $A \in \mathcal{T}$, $\mu(A) < +\infty$, the function $u': T \to S$, defined by $u'(t) \equiv v(t)$ if $t \in A$, $u'(t) \equiv u(t)$ if $t \notin A$, belongs to $\mathcal{U}$. For every function $g: T \times S \to \bar{\mathbb{R}}$ and every set $\mathcal{V}$ of $(\mathcal{T}, \mathcal{B}(S))$-measurable functions the integral functional $I_g: \mathcal{V} \to \bar{\mathbb{R}}$ is defined by

$$I_g(v) \equiv \tilde{\int}_T g(t, v(t)) \mu(dt),$$

where we use outer integration (cf. Appendix A). Our first result is due to Ioffe-Tikhomirov and Rockafellar [18], [25]; its present general form can be gleaned from the work by Castaing-Valadier [7, VII].

THEOREM B.1 (reduction theorem). *For every $\mathcal{T} \times \mathcal{B}(S)$-measurable function $g: T \times S \to \bar{\mathbb{R}}$ and every decomposable set $\mathcal{U}$ of $(\mathcal{T}, \mathcal{B}(S))$-measurable functions from T into S we have*

$$\inf_{u \in \mathcal{U}} I_g(u) = \int_T \inf_{s \in S} g(t, s) \mu(dt), \tag{B.1}$$

provided that the left-hand side does not equal $+\infty$.

Proof. Define $\gamma: T \to \mathbb{R}$ by $\gamma(t) \equiv \inf_S g(t, s)$; then it follows immediately from a well-known projection theorem [7, III.23] that γ is $\mathcal{T}$-measurable. Evidently, one inequality in (B.1) is trivial; to prove the other, let $\alpha \in \mathbb{R}$ be arbitrary, $\alpha > \int_T \gamma \, d\mu$. We will show that there exists $u \in \mathcal{U}$ such that $I_g(u) < \alpha$. By hypothesis, there exists $u_0 \in \mathcal{U}$ such that $I_g(u_0) < +\infty$. As μ is a σ-finite measure, there exists a strictly positive function φ_0 in $\mathcal{L}^1_{\mathbb{R}}$. Define for every $\varepsilon > 0$ the function $\varphi_\varepsilon: T \to \mathbb{R}$ by

$$\varphi_\varepsilon(t) \equiv \varepsilon \varphi_0(t) + \max(\gamma(t), -\varepsilon^{-1}).$$

For $\varepsilon > 0$ small enough φ_ε will satisfy $\int_T \varphi_\varepsilon \, d\mu < \alpha$ by the monotone convergence theorem. Since $\varphi_\varepsilon(t) > \gamma(t)$ for all $t \in T$, the multifunction $\Gamma: T \rightrightarrows S$, defined by

$$\Gamma(t) \equiv \{s \in S: g(t, s) < \varphi_\varepsilon(t)\}$$

is nonempty-valued. By measurability of g, φ_0 and γ, the graph of Γ is $\mathcal{T} \times \mathcal{B}(S)$-measurable. Hence, it follows from the Von Neumann-Aumann theorem [7, III.22] that there exists a $(\mathcal{T}, \mathcal{B}(S))$-measurable function $v: T \to S$ such that $g(t, v(t)) < \varphi_\varepsilon(t)$ for every $t \in T$. Consider now the image μ^v of the measure μ under the mapping v. Since S is Suslin, every finite measure on $(S, \mathcal{B}(S))$ is Radon [11, III.69]; μ being σ-finite, this quickly gives the existence of a nondecreasing sequence $\{K_i\}_1^\infty$ of compact subsets of S such that $\mu^v(T \setminus \bigcup_{i=1}^\infty K_i) = 0$ and $\mu^v(K_i) < +\infty$ for every $i \in \mathbb{N}$. Define $T_i \in \mathcal{T}$ to be the inverse image of K_i under v. Then clearly $v(T_i)$ is relatively compact in S and $\mu(T_i) < +\infty$ for every $i \in \mathbb{N}$; also, $\mu(T \setminus \bigcup_{i=1}^\infty T_i) = 0$. Defining $u_i: T \to S$ by $u_i(t) \equiv v(t)$ if $t \in T_i$, $u_i(t) \equiv u_0(t)$ if $t \notin T_i$, we know that $u_i \in \mathcal{U}$ for every $i \in \mathbb{N}$ by the decomposability of $\mathcal{U}$. Now

$$I_g(u_i) \leqq \int_{T_i} \varphi_\varepsilon \, d\mu + \int_{T \setminus T_i} g(t, u_0(t)) \mu(dt),$$

so for $i \in \mathbb{N}$ sufficiently large it follows from the above that $I_g(u_i) < \alpha$. □

It is easy to see that the above result applies to taking suprema as well, mutatis mutandis.

THEOREM B.2. *For every pair of $\mathcal{T} \times \mathcal{B}(S)$-measurable functions $g_1, g_2: T \times X \to (-\infty, +\infty]$ and every decomposable set $\mathcal{U}$ of $(\mathcal{T}, \mathcal{B}(S))$-measurable functions from T into*

S such that $g_1 \leqq g_2$ *and*

$$I_{g_1}(u) = I_{g_2}(u) \quad \textit{for all } u \in \mathcal{U},$$

we have

$$g_1(t, \cdot) = g_2(t, \cdot) \ \mu\text{-a.e.}, \tag{B.2}$$

provided that there exists $u_0 \in \mathcal{U}$ *for which both* $t \mapsto g_1(t, u_0(t))$ *and* $t \mapsto g_2(t, u_0(t))$ *are* μ*-integrable.*

Proof. If (B.2) were false, there would exist a set B in $\mathcal{T}$, $0 < \mu(B) < +\infty$, such that for every $t \in B$ the set

$$\Delta(t) \equiv \{s \in S: g_1(t, s) < g_2(t, s)\}$$

is nonempty. By the von Neumann–Aumann theorem [7, III.22] there would exist a $\mathcal{T}$-measurable function $v: B \to S$ such that $v(t) \in \Delta(t)$ for all $t \in B$. Just as in the proof of Theorem B.1, the fact that S is Suslin implies the existence of a nondecreasing sequence $\{B_i^\infty\}_1$ of $\mathcal{T}$-measurable subsets of B, $\lim_i \mu(B_i) = \mu(B)$ and with $v(B_i)$ relatively compact in S for every $i \in \mathbb{N}$. We now define a nondecreasing sequence $\{B_i'\}^\infty$ of $\mathcal{T}$-measurable sets by

$$B_i' \equiv \{t \in B_i: -i \leqq g_1(t, v(t)) \leqq i\}.$$

It is easy to see that $\lim_i \mu(B_i') = \mu(B)$ and that $B_i' \subset B_i$ for every $i \in \mathbb{N}$. Defining $u_i: T \to S$ by $u_i(t) \equiv v(t)$ if $t \in B_i'$ and $u_i(t) \equiv u_0(t)$ if $t \notin B_i'$, we have $u_i \in \mathcal{U}$ by decomposability and the above. Finally, this gives $I_{g_1}(u_i) < I_{g_2}(u_i)$ for every $i \in \mathbb{N}$ such that $\mu(B_i') > 0$, since we obviously have $g_1(t, u_0(t)) = g_2(t, u_0(t))$ μ-a.e. Thus we have arrived at the desired contradiction. □

A function $g: T \times S \to \bar{\mathbb{R}}$ is defined to be a *normal integrand* on $T \times S$ if g is $\mathcal{T} \times \mathcal{B}(S)$-measurable and $g(t, \cdot)$ is lower semicontinuous on S for every $t \in T$. The following result can be found in [1d]; it is also known for multifunctions in a rather similar form [28].

THEOREM B.3. *For every collection* $\mathcal{G}$ *of normal integrands on* $T \times S$ *there exists a countable subset* $\mathcal{G}_0$ *of* $\mathcal{G}$ *such that* $\hat{g} \equiv \sup_{g \in \mathcal{G}_0} g$ *satisfies*

$$\hat{g}(t, \cdot) \geqq g(t, \cdot) \ \mu\textit{-a.e. for every } g \in \mathcal{G}.$$

Proof. In case S is a metric Suslin space, the result follows by [1d, Thm. 2.2, Example A.2]. In general, let the Polish space R and the continuous surjection $\pi: R \to S$ be as at the beginning of this appendix. Define a collection of normal integrands on $T \times R$ by setting $g^\pi(t, r) \equiv g(t, \pi(r))$, $g \in \mathcal{G}$; the result then follows directly from the preceding one. □

Let $(V, P, \langle \cdot, \cdot \rangle)$ be a pair of Suslin locally convex spaces, paired by a strict duality $\langle \cdot, \cdot \rangle$, equipped with topologies which are compatible with the duality and which make V and P into Suslin spaces. A $(\mathcal{T}, \mathcal{B}(V))$-measurable function $v: T \to V$ which is such that for every $p \in P$ the function $t \mapsto \langle v(t), p \rangle$—$\mathcal{T}$-measurable by [7, III.36]—is μ-integrable is said to be *scalarly* μ*-integrable.* Incidentally, note that the obvious notion of scalar $\mathcal{T}$-measurability coincides with $(\mathcal{T}, \mathcal{B}(V))$-measurability [7, III.36].

Acknowledgments. The author is indebted to Dr. Paulette Clauzure for pointing out an error in earlier versions of Propositions 2.19 and 2.20, and for suggesting a number of other improvements. He also wishes to thank the referees for their constructive comments and for providing useful references.

THE OPTIMAL PROJECTION EQUATIONS FOR FINITE-DIMENSIONAL FIXED-ORDER DYNAMIC COMPENSATION OF INFINITE-DIMENSIONAL SYSTEMS*

DENNIS S. BERNSTEIN† AND DAVID C. HYLAND†

Abstract. One of the major difficulties in designing implementable finite-dimensional controllers for distributed parameter systems is that such systems are inherently infinite dimensional while controller dimension is severely constrained by on-line computing capability. While some approaches to this problem initially seek a correspondingly infinite-dimensional control law whose finite-dimensional approximation may be of impractically high order, the usual engineering approach involves first approximating the distributed parameter system with a high-order discretized model followed by design of a relatively low-order dynamic controller. Among the numerous approaches suggested for the latter step are model/controller reduction techniques used in conjunction with the standard *LQG* result. An alternative approach, developed in [36], relies upon the discovery in [31] that the necessary conditions for optimal fixed-order dynamic compensation can be transformed into a set of equations possessing remarkable structural coherence. The present paper generalizes this result to apply directly to the distributed parameter system itself. In contrast to the pair of operator Riccati equations for the "full-order" *LQG* case, the optimal finite-dimensional fixed-order dynamic compensator is characterized by *four* operator equations (two modified Riccati equations and two modified Lyapunov equations) coupled by an oblique projection whose rank is precisely equal to the order of the compensator and which determines the optimal compensator gains. This "optimal projection" is obtained by a full-rank factorization of the product of the finite-rank nonnegative-definite Hilbert-space operators which satisfy the pair of modified Lyapunov equations. The coupling represents a graphic portrayal of the demise of the classical separation principle for the finite-dimensional reduced-order controller case. The results obtained apply to a semigroup formulation in Hilbert space and thus are applicable to control problems involving a broad range of specific partial and functional differential equations.

Key words. optimality conditions, finite-dimensional fixed-order dynamic compensator, infinite-dimensional system, distributed parameter system, semisimple operator, oblique projection, Drazin generalized inverse

1. Introduction.

One of the major difficulties in designing active controllers for distributed parameter systems is that such systems are inherently infinite dimensional while implementable controllers are necessarily finite dimensional with controller dimension severely constrained by on-line computing capability. As pointed out by Balas ([1], see also [2]), control design for distributed parameter systems entails the *practical constraints* of 1) finitely many sensors and actuators, 2) a finite-dimensional controller and 3) natural system dissipation. The validity of 2) is apparent from the fact that processing and transmitting electrical signals by conventional analog or digital components constitutes finite-dimensional action. Although distributed parameter devices can also be utilized, their fabrication and implementation can incorporate at most a finite number of design specifications.[1] Hence, although distributed parameter systems are most accurately represented by infinite-dimensional models, real-world

* Received by the editors December 6, 1983, and in revised form September 15, 1984. This work was performed at Lincoln Laboratory/MIT and was sponsored by the Department of the Air Force.

† Harris Corporation, Government Aerospace Systems Division, Controls Analysis and Synthesis Group, Melbourne, Florida 32901.

[1] Examples of such components include tapped delay lines and surface acoustic wave devices. Although acoustoelectric convolvers [3, p. 465] can perform continuous-time integration, synthesis of the desired impulse-response kernel can incorporate only finitely many specified parameters. The obvious fact should also be noted that physical limitations impose an upper bound on the number of design parameters that can be incorporated in the construction of *any* device. For an extensive treatment of this subject, see [72].

constraints require that implementable controllers be modelled as lumped parameter systems.

Clearly, the above observations effectively preclude the possibility of realizing infinite-dimensional controllers that involve full-state feedback or full-state estimation (see, e.g., [4]-[6] and the numerous references therein). Although finite-dimensional approximation schemes have been applied to optimal infinite-dimensional control laws ([7]-[9]), these results only guarantee optimality in the limit, i.e., as the order of the approximating controller increases without bound. Hence, there is no guarantee that a particular approximate (i.e., discretized) controller is actually optimal over the class of approximate controllers of a given order dictated by implementation constraints. Moreover, even if an optimal *approximate* finite-dimensional controller could be obtained, it would almost certainly be suboptimal in the class of *all* controllers of the given order.

Although the usual engineering approach to this problem is to replace the distributed parameter system with a high-order finite-dimensional model, analogous, fundamental difficulties remain since application of *LQG* leads to a controller whose order is identical to that of the high-order approximate model. Attempts to remedy this problem usually rely upon some method of open-loop model reduction or closed-loop controller reduction (see, e.g., [10]-[15]). Most of these techniques (with the exception of [11]) are ad hoc in nature, however, and hence guarantees of optimality and stability may be lacking.

A more direct approach that avoids both model and controller reduction is to fix the controller structure and optimize the performance criterion with respect to the controller parameters. Although much effort was devoted to this approach (see, e.g., [16]-[30]), progress in this direction was impeded by the extreme complexity of the nonlinear matrix equations arising from the first-order necessary conditions. What was lacking, to quote the insightful remarks of [24], was a "deeper understanding of the structural coherence of these equations." The key to unlocking these unwieldy equations was subsequently discovered by Hyland in [31] and developed in [32]-[36]. Specifically, it was found that these equations harbored the definition of an *oblique projection* (i.e., idempotent matrix) which is a consequence of optimality and *not* the result of an ad hoc assumption. By exploiting the presence of this "optimal projection," the originally *very* complex stationary conditions can be transformed without loss of generality into much simpler and more tractable forms. The resulting equations (see [36, (2.10)-(2.17)]) preserve the simple form of *LQG* relations for the gains in terms of covariance and cost matrices which, in turn, are determined by a coupled system of two modified Riccati equations and two modified Lyapunov equations. This coupling, by means of the optimal projection, represents a graphic portrayal of the demise of the classical separation principle for the reduced-order controller case. When, as a special case, the order of the compensator is required to be equal to the order of the plant, the modified Riccati equations immediately reduce to the standard *LQG* Riccati equations and the modified Lyapunov equations express the proviso that the compensator be minimal, i.e., controllable and observable. Since the *LQG* Riccati equations as such are nothing more than the necessary conditions for full-order compensation, the "optimal projection equations" appear to provide a clear and simple generalization of standard *LQG* theory.

The fact that the optimal projection equations consist of *four* coupled matrix equations, i.e., two modified Riccati equations and two modified Lyapunov equations, can readily be explained by the following simple reason. Reduced-order control-design methods often involve either *LQG* applied to a reduced-order model or model reduction

applied to a full-order *LQG* design, and hence both approaches require the solution of precisely four equations: two Riccati equations (for *LQG*) plus two Lyapunov equations (for system reduction via balancing, as in [12], [14]). The *coupled* form of the optimal projection equations is thus a strong reminder that the *LQG* and order-reduction operations *cannot* be iterated but must, in a precise sense, be performed *simultaneously*. This situation is partly due to the fact that the optimal projection matrix may not be of the form $\left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right]$ even in the basis corresponding to the "balanced" realization [12], [14]. This point is explored in [37], [37a] where the solution to the optimal model-reduction problem is characterized by a pair of modified Lyapunov equations which are also coupled by an oblique projection.

Returning now to the distributed parameter problem, it should be mentioned that notable exceptions to the previously mentioned work on distributed parameter controllers are the contributions of Johnson [38] and Pearson [39], [40] who suggest fixing the order of the finite-dimensional compensator while retaining the distributed parameter model. Progress in this direction, however, was impeded not only by the intractability of the optimality conditions that were available for the finite-dimensional problem (as in [16]–[30]), but also by the lack of a suitable generalization of these conditions to the infinite-dimensional case. The purpose of the present paper is to make significant progress in filling these gaps, i.e., by deriving explicit optimality conditions which directly characterize the optimal finite-dimensional fixed-order dynamic compensator for an infinite-dimensional system and which are exactly analogous to the highly simplified optimal projection equations obtained in [31]–[34], [36] for the finite-dimensional case. Specifically, instead of a system for four matrix equations we obtain a system of four *operator* equations whose solutions characterize the optimal finite-dimensional fixed-order dynamic compensator. Moreover, the optimal projection now becomes a bounded idempotent Hilbert-space operator whose rank is precisely equal to the order of the compensator.

The mathematical setting we use is standard: a linear time-invariant differential system in Hilbert space with additive white noise, finitely many controls and finitely many noisy measurements (thus satisfying the first practical constraint mentioned above). The input and output maps are assumed to be bounded. Since the only explicit assumption on the unbounded dynamics operator is that it generate a strongly continuous semigroup, the results are potentially applicable to a broad range of specific partial and functional differential equations. The *actual* applicability of our results is essentially limited by practical constraint 3). Since we are concerned with the steady-state problem, we implicitly assume that the distributed parameter system is stabilizable, i.e., that there exists a dynamic compensator of a given order such that the closed-loop system is uniformly stable. We note that stabilizing compensators do exist for the wide class of problems considered in [41] and [42] which includes delay, parabolic and damped hyperbolic systems. The question of *how much* damping is required for stabilizability of hyperbolic systems is a crucial issue in designing controllers for large flexible space structures [7], [43]–[49a].

It is important to point out that the results of this paper can immediately be specialized to finite-dimensional systems by requiring that the Hilbert space characterizing the dynamical system be finite-dimensional. Then all unboundedness considerations can be ignored, adjoints can be interpreted as transposes and other obvious simplifications can be invoked. The only mathematical aspect requiring attention is the treatment of white noise which, for general handling of the infinite-dimensional case, is interpreted according to [6].[2] For the finite-dimensional case, however, the standard

classical notions suffice and the results go through with virtually no modifications.

The contents of the paper are as follows. Section 2 contains preliminary notation in addition to particular results for use later in the paper. Section 3 presents the optimal steady-state finite-dimensional fixed-order dynamic-compensation problem and the Main Theorem gives the necessary conditions in the form of the optimal projection equations (3.15)-(3.18). We then develop a series of results which serve to elucidate several aspects of the Main Theorem. Section 4 is devoted to the proof of the Main Theorem. The reader is alerted to the two crucial steps required. The first step involves generalizing to the infinite-dimensional case the derivation of the necessary conditions in their "primitive" form (see (4.27)-(4.29) and (4.48)-(4.53)). The derivation in [31]-[33], [36] involving Lagrange multipliers is invalid in the infinite-dimensional case due to the presence of the unbounded system-dynamics operator. Instead, we use the gramian form of the closed-loop covariance operator to obtain a dual problem formulation and then proceed to derive the primitive necessary conditions by means of a lengthy, but direct, computation (Lemma 4.7). The second crucial step involves transforming the primitive form of the necessary conditions to the final form given in the Main Theorem. This laborious computation was first carried out in [31], [32] and was subsequently facilitated in [33], [36] by means of a judicious change of variables (see (4.32), (4.33)). Finally, some concluding remarks are given in § 5.

2. Preliminaries. In this section we introduce general notation along with basic definitions and results for use in later sections. Our principal references are [6], [50] and [51].

Throughout this section let $\mathscr{H}$, $\mathscr{H}'$ and $\mathscr{H}''$ denote real separable Hilbert spaces with norm $\|\cdot\|$ and inner product $\langle\cdot,\cdot\rangle$ and let $\mathscr{B}(\mathscr{H},\mathscr{H}')$ denote the space of bounded linear operators from $\mathscr{H}$ into $\mathscr{H}'$. For $L\in\mathscr{B}(\mathscr{H},\mathscr{H}')$, $\|L\|$ is the norm of L, $\mathscr{R}(L)$ is the range of L, $\mathscr{N}(L)$ is the null space of L, $\rho(L)$ is the rank of L (set $\rho(L)=\infty$ if L does not have finite rank), L^{-1} is the inverse of L when L is invertible, i.e., when L has a bounded inverse, L^* is the adjoint of L and $L^{-*}\triangleq(L^*)^{-1}$. Recall that $\|L\|=\|L^*\|$ and that $\rho(L)=\rho(L^*)$ [50, p. 161]. Now suppose that $\mathscr{H}=\mathscr{H}'$ so that $L\in\mathscr{B}(\mathscr{H})\triangleq\mathscr{B}(\mathscr{H},\mathscr{H})$. If $LL^*=L^*L$ then L is *normal* and if $L=L^*$ then L is *selfadjoint.* If L is selfadjoint and $\langle Lx,x\rangle\geqq 0$, $x\in\mathscr{H}$, then L is *nonnegative definite.* Note that the selfadjointness assumption is included in the definition since the Hilbert spaces are assumed real. If L is nonnegative definite then $L^{1/2}$ denotes the (unique) nonnegative-definite square root of L. Call L semisimple (resp., real semisimple, nonnegative semisimple) if there exists invertible $S\in\mathscr{B}(\mathscr{H})$ such that SLS^{-1} is normal (resp., selfadjoint, nonnegative definite). This implies that SLS^{-1} has a complete set of orthonormal eigenvectors and, in the real-semisimple or nonnegative-semisimple cases, has real or nonnegative eigenvalues.

Recall that if $L\in\mathscr{B}(\mathscr{H})$ is compact then L has at most a countable number of eigenvalues and all nonzero eigenvalues have finite multiplicity. Hence, for $L\in\mathscr{B}(\mathscr{H},\mathscr{H}')$ compact, let $\{\alpha_i\}$ be the (at most countable) sequence of eigenvalues of $(LL^*)^{1/2}$ with appropriate multiplicity and $\alpha_1\geqq\alpha_2\geqq\cdots>0$ [50, p. 261]. Then $\mathscr{B}_1(\mathscr{H},\mathscr{H}')$ denotes the set of *trace class* (or *nuclear*) operators, i.e., the set of compact

[2] Alternatively, we could have adopted the white noise formulation of [4]. The main difference between the two white noise formalisms is that Balakrishnan works with finitely additive rather than countably additive measures. Strictly speaking, then, even in finite dimensions Balakrishnan's white noise is different from the standard notion (see [6, pp. 307, 315]).

$L \in \mathcal{B}(\mathcal{H}, \mathcal{H}')$ for which $\sum_i \alpha_i < \infty$ [50, p. 521]. $\mathcal{B}_1(\mathcal{H}, \mathcal{H}')$ is a Banach space with norm

$$\|L\|_1 \triangleq \sum_i \alpha_i.$$

If $\sum_i \alpha_i^2 < \infty$ then $L \in \mathcal{B}_2(\mathcal{H}, \mathcal{H}')$, the set of Hilbert-Schmidt operators, which is a Banach space with norm

$$\|L\|_2 \triangleq \left[\sum_i \alpha_i^2\right]^{1/2}.$$

Note that $\|L\| \leqq \|L\|_2 \leqq \|L\|_1$, $\|L\| = \|L^*\|$, $\|L\|_1 = \|L^*\|_1$ and $\|L\|_2 = \|L^*\|_2$. If $\mathcal{H} = \mathcal{H}'$, then we write $\mathcal{B}_1(\mathcal{H})$ and $\mathcal{B}_2(\mathcal{H})$ for $\mathcal{B}_1(\mathcal{H}, \mathcal{H})$ and $\mathcal{B}_2(\mathcal{H}, \mathcal{H})$, respectively. Note that if nonnegative-definite $L \in \mathcal{B}_1(\mathcal{H})$ then $L^{1/2} \in \mathcal{B}_2(\mathcal{H})$.

If $L \in \mathcal{B}_1(\mathcal{H}, \mathcal{H}')$ and $S \in \mathcal{B}(\mathcal{H}', \mathcal{H}'')$ then

$$\|SL\|_1 \leqq \|S\| \, \|L\|_1$$

and hence $SL \in \mathcal{B}_1(\mathcal{H}, \mathcal{H}')$. Similarly, under suitable hypotheses,

$$\|LS\|_1 \leqq \|S\| \, \|L\|_1,$$

and

$$\|SL\|_1 \leqq \|S\|_2 \|L\|_2.$$

LEMMA 2.1. *Suppose $L \in \mathcal{B}_1(\mathcal{H})$ and let $\{\lambda_i\}$ denote the nonzero eigenvalues of L with appropriate multiplicity. Then* [51, *p.* 89]

$$\sum_i |\lambda_i| \leqq \|L\|_1.$$

If L is selfadjoint then [50, *p.* 522]

$$\sum_i |\lambda_i| = \|L\|_1.$$

If L is nonnegative definite then

$$\sum_i \lambda_i = \|L\|_1.$$

Let $L \in \mathcal{B}_1(\mathcal{H})$. Then define [50, p. 523] the trace functional tr: $\mathcal{B}_1(\mathcal{H}) \to \mathbb{R}$ by

$$\operatorname{tr} L \triangleq \sum_i \langle L\phi_i, \phi_i \rangle,$$

where the summation is independent of the choice of orthonormal basis $\{\phi_i\}$. The trace satisfies $\operatorname{tr} L = \operatorname{tr} L^*$, $\operatorname{tr} SL = \operatorname{tr} LS$ for all $S \in \mathcal{B}(\mathcal{H})$, $\operatorname{tr} ST = \operatorname{tr} TS$ for all $S, T \in \mathcal{B}_2(\mathcal{H})$ and $\operatorname{tr}(\alpha T + \beta S) = \alpha(\operatorname{tr} T) + \beta(\operatorname{tr} S)$ for all $\alpha, \beta \in \mathbb{R}$ and $S, T \in \mathcal{B}_1(\mathcal{H})$.

LEMMA 2.2. *Suppose $L \in \mathcal{B}_1(\mathcal{H})$ and let $\{\lambda_i\}$ denote the nonzero eigenvalues of L with appropriate multiplicity. Then* [51, *p.* 139]

$$\operatorname{tr} L = \sum_i \lambda_i$$

and hence (by Lemma 2.1)

$$|\operatorname{tr} L| \leqq \|L\|_1.$$

If L is nonnegative definite then

$$\operatorname{tr} L = \|L\|_1.$$

COROLLARY 2.1. *For each* $S \in \mathcal{B}(\mathcal{H})$ *the linear functionals*

$$L \to \operatorname{tr} SL\colon \mathcal{B}_1(\mathcal{H}) \to \mathbb{R},$$

$$L \to \operatorname{tr} LS\colon \mathcal{B}_1(\mathcal{H}) \to \mathbb{R}$$

are continuous. For each $L \in \mathcal{B}_1(\mathcal{H})$ *the linear functionals*

$$S \to \operatorname{tr} LS\colon \mathcal{B}(\mathcal{H}) \to \mathbb{R},$$

$$S \to \operatorname{tr} SL\colon \mathcal{B}(\mathcal{H}) \to \mathbb{R}$$

are continuous.

Although showing that a bounded linear operator is trace class is slightly more involved than the above characterizations of $\mathcal{B}_1(\mathcal{H})$, the following result will suffice for our purposes (see [52, p. 96], or [52a, p. 171]).

LEMMA 2.3. *Let* $L \in \mathcal{B}(\mathcal{H})$ *be nonnegative definite. Then*

$$\sum_i \langle L\phi_i, \phi_i \rangle,$$

whether finite or infinite, is independent of the orthonormal basis $\{\phi_i\}$. *The summation is finite if and only if* $L \in \mathcal{B}_1(\mathcal{H})$.

Many of the operators introduced in the following section have finite-dimensional domain or range space and hence are degenerate, i.e., have finite rank. Recall that degenerate operators are necessarily trace class. The following result, which generalizes [53, Thm. 2.1, p. 240] in certain respects, will be fundamental in decomposing finite-rank operators.

LEMMA 2.4. Suppose $L_1, \cdots, L_r \in B(\mathcal{H}, \mathcal{H}')$ have finite rank. Then there exists a finite-dimensional subspace $\mathcal{M} \subset \mathcal{H}$ such that $L_i\mathcal{M}^\perp = 0$, $i = 1, \cdots, r$. Furthermore, if $\mathcal{H} = \mathcal{H}'$ then $\mathcal{M}$ can be chosen such that $L_i\mathcal{M} \subset \mathcal{M}$, $i = 1, \cdots, r$.

Proof. It suffices to consider the case $r = 1$. Writing L for L_1, note that since $\rho(L^*) < \infty$, $\mathcal{N}(L)^\perp = \mathcal{R}(L^*)$ [50, p. 155] and $\mathcal{N}(L)$ is closed, the first statement holds with $\mathcal{M} = \mathcal{N}(L)^\perp$. When $\mathcal{H} = \mathcal{H}'$ set $\mathcal{M} = \mathcal{N}(L)^\perp + \mathcal{R}(L)$ and note that $\mathcal{M}^\perp = \mathcal{N}(L) \cap \mathcal{R}(L)^\perp \subset \mathcal{N}(L)$ and $L\mathcal{M} \subset \mathcal{R}(L) \subset \mathcal{M}$. □

The following generalization of Sylvester's inequality [54, p. 66] will be used repeatedly in handling finite-rank operators.

LEMMA 2.5. *Let* $L \in \mathcal{B}(\mathcal{H}, \mathcal{H}')$ *and* $S \in \mathcal{B}(\mathcal{H}', \mathcal{H}'')$. *Then*

$$\rho(SL) \leqq \min\{\rho(S), \rho(L)\}. \tag{2.1}$$

If $\dim \mathcal{H}' = \nu < \infty$, *then*

$$\rho(S) + \rho(L) - \nu \leqq \rho(SL). \tag{2.2}$$

Proof. If either S or L does not have finite rank then (2.1) is immediate. If both S and L have finite rank then the standard arguments [54] used to prove the finite-dimensional version of (2.1) remain valid. To prove (2.2), note that Lemma 2.4 implies that there exist orthonormal bases for $\mathcal{H}$ and $\mathcal{H}'$ with respect to which L has the matrix representation $[\tilde{L}\ 0]$, where $\tilde{L} \in \mathbb{R}^{\nu \times p}$. Similarly, there exist orthonormal bases for $\mathcal{H}'$ and $\mathcal{H}''$ with respect to which S has the matrix representation $\left[\begin{smallmatrix} \tilde{S} \\ 0 \end{smallmatrix}\right]$, where $\tilde{S} \in \mathbb{R}^{q \times \nu}$. Since the two cited bases for $\mathcal{H}'$ may be different, let orthogonal $U \in \mathbb{R}^{\nu \times \nu}$ be the matrix representation (with respect to either basis for $\mathcal{H}'$) for the change in orthonormal basis [6, p. 100]. Hence SL has the matrix representation $\left[\begin{smallmatrix} \tilde{S}U\tilde{L} & 0 \\ 0 & 0 \end{smallmatrix}\right]$ and (2.2) follows from the known result [54, p. 66]. □

As in the proof of Lemma 2.5, we shall utilize the infinite-matrix representation of an operator with respect to an orthonormal basis. All matrix representations given

here will consist of real entries since the Hilbert spaces involved are real. When the orthonormal bases are specified and no confusion can arise, we shall not differentiate between an operator and its matrix representation. We shall use the infinite identity matrix I_∞ interchangeably with the identity $I_{\mathscr{H}}$ on $\mathscr{H}$.

When dealing with finite-dimensional Euclidean spaces the notation and terminology introduced above will be utilized with only minor changes. For example, bounded linear operators will be represented by matrices whose elements are determined according to fixed orthonormal bases and hence we identify $\mathbb{R}^{m\times n} = \mathscr{B}(\mathbb{R}^n, \mathbb{R}^m)$. Note that if $L \in \mathscr{B}(\mathbb{R}^n, \mathscr{H})$ and $S \in \mathscr{B}(\mathscr{H}, \mathbb{R}^m)$ then SL is an $m \times n$ matrix which is independent of any particular orthonormal basis for $\mathscr{H}$. The transposes of $x \in \mathbb{R}^n \triangleq \mathbb{R}^{n\times 1}$ and $M \in \mathbb{R}^{m\times n}$ are denoted by x^T and M^T and $M^{-T} \triangleq (M^T)^{-1}$. Let I_n denote the $n \times n$ identity matrix.

To specialize some of the above operator terminology to matrices, let $M \in \mathbb{R}^{n\times n}$. We shall say M is *nonnegative* (resp., *positive*) *diagonal* if M is diagonal with nonnegative (resp., positive) diagonal elements. M is *nonnegative* (resp., *positive*) *definite* if M is symmetric and $x^TMx \geqq 0$ (resp., $x^TMx > 0$), $x \in \mathbb{R}^n$. Recall that M is symmetric (resp., nonnegative definite, positive definite) if and only if there exists orthogonal $U \in \mathbb{R}^{n\times n}$ such that UMU^T is diagonal (resp., nonnegative diagonal, positive diagonal). M is *semisimple* [55, p. 13], or *nondefective* [56, p. 375], if M has n linearly independent eigenvectors, i.e., M has a diagonal Jordan canonical form over the complex field. M is *real* (resp., *nonnegative, positive*) *semisimple* if M is semisimple with real (resp., nonnegative, positive) eigenvalues. Note that M is real (resp., nonnegative, positive) semisimple if and only if there exists invertible $S \in \mathbb{R}^{n\times n}$ such that SMS^{-1} is diagonal (resp., nonnegative diagonal, positive diagonal). Alternatively, M is real (resp., nonnegative, positive) semisimple if and only if there exists invertible $S \in \mathbb{R}^{n\times n}$ such that SMS^{-1} is symmetric (resp., nonnegative definite, positive definite).

LEMMA 2.6. *The product of two nonnegative- (resp., positive-) definite matrices is nonnegative (resp., positive) semisimple.*

Proof. If S, $L \in \mathbb{R}^{n\times n}$ are both nonnegative (resp., positive) definite then by [55, Thm. 6.2.5, p. 123] there exists invertible $\phi \in \mathbb{R}^{n\times n}$ such that $D_S \triangleq \phi^{-1}S\phi^{-T}$ and $D_L \triangleq \phi^TL\phi$ are nonnegative (resp., positive) diagonal. Hence, $SL = \phi D_S D_L \phi^{-1}$ is nonnegative (resp., positive) semisimple, as desired. Alternatively, if either S or L is positive definite, then the result follows from $SL = L^{-1/2}(L^{1/2}SL^{1/2})L^{1/2}$ if L is positive definite or $SL = S^{1/2}(S^{1/2}LS^{1/2})S^{-1/2}$ if S is positive definite. □

3. Problem statement and the Main Theorem. We consider the following steady-state fixed-order dynamic-compensation problem. Given the dynamical system on $[0, \infty)$

$$\dot{x}(t) = Ax(t) + Bu(t) + H_1w(t), \tag{3.1}$$

$$y(t) = Cx(t) + H_2w(t), \tag{3.2}$$

design a finite-dimensional fixed-order dynamic compensator

$$\dot{x}_c(t) = A_cx_c(t) + B_cy(t), \tag{3.3}$$

$$u(t) = C_cx_c(t) \tag{3.4}$$

which minimizes the steady-state performance criterion

$$J(A_c, B_c, C_c) \triangleq \lim_{t\to\infty} \mathbb{E}[\langle R_1x(t), x(t)\rangle + u(t)^TR_2u(t)]. \tag{3.5}$$

The following data are assumed. The state $x(t)$ is an element of a real separable Hilbert space $\mathcal{H}$ and the state differential equation is interpreted in the weak sense (see, e.g., [6, pp. 229, 317]). The closed, densely defined operator $A: \mathcal{D}(A) \subset \mathcal{H} \to \mathcal{H}$ generates a strongly continuous semigroup e^{At}, $t \geqq 0$. The control $u(t) \in \mathbb{R}^m$, $B \in \mathcal{B}(\mathbb{R}^m, \mathcal{H})$ and the operator $R_1 \in \mathcal{B}_1(\mathcal{H})$ and the matrix $R_2 \in \mathbb{R}^{m \times m}$ are nonnegative definite and positive definite, respectively. $w(\cdot)$ is a zero-mean Gaussian "standard white noise process" in $L_2((0, \infty), \mathcal{H}')$ (see [6, p. 314]), where $\mathcal{H}'$ is a real separable Hilbert space, $H_1 \in \mathcal{B}_2(\mathcal{H}', \mathcal{H})$, $H_2 \in \mathcal{B}(\mathcal{H}', \mathbb{R}^l)$ and "$\mathbb{E}$" denotes expectation. We assume that $H_1 H_2^* = 0$, i.e., the disturbance and measurement noises are independent,[3] and that $V_2 \triangleq H_2 H_2^* \in \mathbb{R}^l$ is positive definite, i.e., all measurements are noisy. Note that $V_1 \triangleq H_1 H_1^* \in \mathcal{B}_1(\mathcal{H})$ is nonnegative definite and trace class.[4] The initial state $x(0)$ is Gaussian and independent of $w(\cdot)$. The observation $y(t) \in \mathbb{R}^l$ and $C \in \mathcal{B}(\mathcal{H}, \mathbb{R}^l)$. The dimension of the compensator state $x_c(t)$ is of fixed, finite order $n_c \leqq \dim \mathcal{H}$ and the optimization is performed over $A_c \in \mathbb{R}^{n_c \times n_c}$, $B_c \in \mathbb{R}^{n_c \times l}$ and $C_c \in \mathbb{R}^{m \times n_c}$.

To handle the closed-loop system (3.1)-(3.4), we introduce the augmented state space $\tilde{\mathcal{H}} \triangleq \mathcal{H} \oplus \mathbb{R}^{n_c}$ which is a real separable Hilbert space with inner product $\langle \tilde{x}_1, \tilde{x}_2 \rangle \triangleq \langle x_1, x_2 \rangle + x_{c1}^T x_{c2}$, $\tilde{x}_i \triangleq (x_i, x_{ci})$. An operator $L \in \mathcal{B}(\tilde{\mathcal{H}})$ has a "decomposition" into operators $L_1 \in \mathcal{B}(\mathcal{H})$, $L_{12} \in \mathcal{B}(\mathbb{R}^{n_c}, \mathcal{H})$, $L_{21} \in \mathcal{B}(\mathcal{H}, \mathbb{R}^{n_c})$ and $L_2 \in \mathbb{R}^{n_c \times n_c}$ in the sense that for $\tilde{x} \triangleq (x, x_c) \in \tilde{\mathcal{H}}$, $L\tilde{x} = (L_1 x + L_{12} x_c, L_{21} x + L_2 x_c)$, or, in "block" form,

$$L = \begin{bmatrix} L_1 & L_{12} \\ L_{21} & L_2 \end{bmatrix}.$$

For later use note that

$$\|L\| \leqq \|L_1\| + \|L_{12}\| + \|L_{21}\| + \|L_{22}\|$$

and

$$L^* = \begin{bmatrix} L_1^* & L_{21}^* \\ L_{12}^* & L_2^T \end{bmatrix}.$$

We can similarly construct unbounded operators in $\tilde{\mathcal{H}}$. Hence, define the closed-loop dynamics operator $\tilde{A}: \mathcal{D}(\tilde{A}) \subset \tilde{\mathcal{H}} \to \tilde{\mathcal{H}}$ on the dense domain $\mathcal{D}(\tilde{A}) \triangleq \mathcal{D}(A) \times \mathbb{R}^{n_c}$ by $\tilde{A}\tilde{x} = (Ax + BC_c x_c, B_c C x + A_c x_c)$. Since $\tilde{A}$ can be represented by

$$\tilde{A} = \begin{bmatrix} A & BC_c \\ B_c C & A_c \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & BC_c \\ B_c C & A_c \end{bmatrix}$$

and since the closed-loop operator

$$\begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix} : \mathcal{D}(\tilde{A}) \to \tilde{\mathcal{H}}$$

generates the strongly continuous semigroup

$$\begin{bmatrix} e^{At} & 0 \\ 0 & I_{n_c} \end{bmatrix}, \qquad t \geqq 0,$$

it follows from [50, Thm., p. 497] that $\tilde{A}$ is also closed and generates a strongly continuous semigroup $e^{\tilde{A}t} \in \mathcal{B}(\tilde{\mathcal{H}})$, $t \geqq 0$. To guarantee that J is finite and independent

[3] This assumption and its analogue, the lack of a cross-weighting term $x(t)^T R_{12} u(t)$ in (3.5), are for convenience only. See § 5.

[4] We must require that R_1 and V_1 be nuclear since covariance operators in the white noise formulation of [6] are not necessarily trace class as they are in the formulation of [4].

of initial conditions we restrict our attention to the set of admissible stabilizing compensators

$$\mathscr{A} \triangleq \{(A_c, B_c, C_c): e^{\tilde{A}t} \text{ is exponentially stable}\}.$$

Hence if $(A_c, B_c, C_c) \in \mathscr{A}$ then there exist $\alpha > 0$ and $\beta > 0$ such that

$$\|e^{\tilde{A}t}\| \leqq \alpha e^{-\beta t}, \qquad t \geqq 0. \tag{3.6}$$

Since the value of J is independent of the internal realization of the compensator, we can further restrict our attention to

$$\mathscr{A}_+ \triangleq \{(A_c, B_c, C_c) \in \mathscr{A}: (A_c, B_c) \text{ is controllable and } (C_c, A_c) \text{ is observable}\}.$$

The following lemma is required for the statement of the Main Theorem.

LEMMA 3.1. *Suppose $\hat{Q}$, $\hat{P} \in \mathscr{B}(\mathscr{H})$ have finite rank and are nonnegative definite. Then $\hat{Q}\hat{P}$ is nonnegative semisimple. Furthermore, if $\rho(\hat{Q}\hat{P}) = n_c$ then there exist G, $\Gamma \in \mathscr{B}(\mathscr{H}, \mathbb{R}^{n_c})$ and positive-semisimple $M \in \mathbb{R}^{n_c \times n_c}$ such that*

$$\hat{Q}\hat{P} = G^* M \Gamma, \tag{3.7}$$

$$\Gamma G^* = I_{n_c}. \tag{3.8}$$

Proof. By Lemma 2.4 there exists a finite-dimensional subspace $\mathscr{M} \subset \mathscr{H}$ such that $\hat{Q}\mathscr{M} \subset \mathscr{M}$, $\hat{Q}\mathscr{M}^\perp = 0$, $\hat{P}\mathscr{M} \subset \mathscr{M}$ and $\hat{P}\mathscr{M}^\perp = 0$. Hence there exists an orthonormal basis for $\mathscr{H}$ with respect to which $\hat{Q}$ and $\hat{P}$ have the infinite-matrix representations

$$\hat{Q} = \begin{bmatrix} \hat{Q}_1 & 0 \\ 0 & 0 \end{bmatrix}, \qquad \hat{P} = \begin{bmatrix} \hat{P}_1 & 0 \\ 0 & 0 \end{bmatrix},$$

where $\hat{Q}_1, \hat{P}_1 \in \mathbb{R}^{r \times r}$ are nonnegative definite and $r \triangleq \dim \mathscr{M}$. Since by Lemma 2.6 there exists invertible $\Psi \in \mathbb{R}^{r \times r}$ such that $\tilde{\Lambda} = \Psi^{-1}\hat{Q}_1\hat{P}_1\Psi$ is nonnegative diagonal, we have

$$\hat{Q}\hat{P} = \begin{bmatrix} \Psi & 0 \\ 0 & I_\infty \end{bmatrix} \begin{bmatrix} \tilde{\Lambda} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \Psi^{-1} & 0 \\ 0 & I_\infty \end{bmatrix},$$

which shows that $\hat{Q}\hat{P}$ is nonnegative semisimple. If, furthermore, $\rho(\hat{Q}\hat{P}) = n_c$ then it is clear that Ψ can be chosen (i.e., modified by an orthogonal matrix) so that

$$\tilde{\Lambda} = \begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix},$$

where $\Lambda \in \mathbb{R}^{n_c \times n_c}$ is positive diagonal. Hence,

$$\hat{Q}\hat{P} = \begin{bmatrix} \Psi & 0 \\ 0 & I_\infty \end{bmatrix} \begin{bmatrix} \begin{bmatrix} I_{n_c} \\ 0 \end{bmatrix} \\ 0 \end{bmatrix} \Lambda \begin{bmatrix} [I_{n_c} & 0] & 0 \end{bmatrix} \begin{bmatrix} \Psi^{-1} & 0 \\ 0 & I_\infty \end{bmatrix},$$

which shows that (3.7) and (3.8) are satisfied with

$$G = \begin{bmatrix} [S^T & 0] & 0 \end{bmatrix} \begin{bmatrix} \Psi^T & 0 \\ 0 & I_\infty \end{bmatrix}, \qquad M = S^{-1}\Lambda S, \Gamma = \begin{bmatrix} [S^{-1} & 0] & 0 \end{bmatrix} \begin{bmatrix} \Psi^{-1} & 0 \\ 0 & I_\infty \end{bmatrix},$$

for all invertible $S \in \mathbb{R}^{n_c \times n_c}$. □

We shall refer to $G, \Gamma \in \mathscr{B}(\mathscr{H}, \mathbb{R}^{n_c})$ and positive-semisimple $M \in \mathbb{R}^{n_c \times n_c}$ satisfying (3.7) and (3.8) as a *(G, M, Γ)-factorization of $\hat{Q}\hat{P}$*. For convenience in stating the Main Theorem define

$$\sum \triangleq BR_2^{-1}B^*, \qquad \overline{\sum} \triangleq C^* V_2^{-1} C.$$

MAIN THEOREM. *Suppose* $(A_c, B_c, C_c) \in \mathscr{A}_+$ *solves the steady-state fixed-order dynamic-compensation problem. Then there exist nonnegative-definite* $Q, P, \hat{Q}, \hat{P} \in \mathscr{B}_1(\mathscr{H})$ *such that* A_c, B_c *and* C_c *are given by*

$$A_c = \Gamma(A - Q\bar{\Sigma} - \Sigma P)G^*, \tag{3.9}$$

$$B_c = \Gamma Q C^* V_2^{-1}, \tag{3.10}$$

$$C_c = -R_2^{-1} B^* P G^*, \tag{3.11}$$

for some (G, M, Γ)*-factorization of* $\hat{Q}\hat{P}$*, and such that, with* $\tau \triangleq G^*\Gamma$*, the following conditions are satisfied*:

$$Q: \mathscr{D}(A^*) \to \mathscr{D}(A), \qquad P: \mathscr{D}(A) \to \mathscr{D}(A^*), \tag{3.12a, b}$$

$$\hat{Q}: \mathscr{H} \to \mathscr{D}(A), \qquad \hat{P}: \mathscr{H} \to \mathscr{D}(A^*), \tag{3.13a, b}$$

$$\rho(\hat{Q}) = \rho(\hat{P}) = \rho(\hat{Q}\hat{P}) = n_c, \tag{3.14a, b, c}[5]$$

$$0 = (A - \tau Q\bar{\Sigma})Q + Q(A - \tau Q\bar{\Sigma})^* + V_1 + \tau Q\bar{\Sigma}Q\tau^*, \tag{3.15}$$

$$0 = (A - \Sigma P\tau)^* P + P(A - \Sigma P\tau) + R_1 + \tau^* P\Sigma P\tau, \tag{3.16}$$

$$0 = [(A - \Sigma P)\hat{Q} + \hat{Q}(A - \Sigma P)^* + Q\bar{\Sigma}Q]\tau^*, \tag{3.17}$$

$$0 = [(A - Q\bar{\Sigma})^* \hat{P} + \hat{P}(A - Q\bar{\Sigma}) + P\Sigma P]\tau. \tag{3.18}$$

The content of the Main Theorem is clearly a set of necessary conditions which characterize the optimal steady-state fixed-order dynamic compensator when it exists. These necessary conditions consist of a system of four operator equations including a pair of modified Riccati equations (3.15) and (3.16) and a pair of modified Lyapunov equations (3.17) and (3.18). The salient feature of these four equations is the coupling by the operator $\tau \in \mathscr{B}(\mathscr{H})$ which, because of (3.8), is idempotent, i.e., $\tau^2 = \tau$. In general, τ is an *oblique* projection and not an orthogonal projection since there is no requirement that τ be selfadjoint. Additional features of the Main Theorem will be discussed in the remainder of this section. For convenience, let G, M, Γ, τ, Q, P, $\hat{Q}$ and $\hat{P}$ be as given by the Main Theorem and define $\Lambda \triangleq \operatorname{diag}(\lambda_1, \cdots, \lambda_{n_c})$, where $\lambda_1 \geqq \lambda_2 \geqq \cdots \geqq \lambda_{n_c} > 0$ are the eigenvalues of M.

We begin by noting that if x_c is replaced by Sx_c, where $S \in \mathbb{R}^{n_c \times n_c}$ is invertible, then an "equivalent" compensator is obtained with (A_c, B_c, C_c) replaced by $(SA_cS^{-1}, SB_c, C_cS^{-1})$.

PROPOSITION 3.1. *Let* $(A_c, B_c, C_c) \in \mathscr{A}_+$. *If* $S \in \mathbb{R}^{n_c \times n_c}$ *is invertible then* $(SA_cS^{-1}, SB_c, C_cS^{-1}) \in \mathscr{A}_+$ *and*

$$J(A_c, B_c, C_c) = J(SA_cS^{-1}, SB_c, C_cS^{-1}). \tag{3.19}$$

Proof. Although the result is obvious from system-theoretic arguments, we shall prove it analytically by utilizing elements of the development in § 4. Define

$$\tilde{S} \triangleq \begin{bmatrix} I_\infty & 0 \\ 0 & S \end{bmatrix} \in \mathscr{B}(\tilde{\mathscr{H}})$$

and note that replacing (A_c, B_c, C_c) by $(SA_cS^{-1}, SB_c, C_cS^{-1})$ is equivalent to replacing $\tilde{A}$, $\tilde{V}$ and $\tilde{R}$ by $\tilde{S}\tilde{A}\tilde{S}^{-1}$, $\tilde{S}\tilde{V}\tilde{S}^*$ and $\tilde{S}^{-*}\tilde{R}\tilde{S}^{-1}$, respectively. If $\alpha, \beta > 0$ satisfy (3.6) then a straightforward application of the Hille-Yosida theorem [57, pp. 153-5] shows that

[5] (3.14a) refers to $\rho(\hat{Q}) = n_c$, etc.

the strongly continuous semigroup generated by $\tilde{S}\tilde{A}\tilde{S}^{-1}$ satisfies $\|e^{\tilde{S}\tilde{A}\tilde{S}^{-1}t}\| \leqq \|\tilde{S}\|\,\|\tilde{S}^{-1}\|\alpha\, e^{-\beta t}$, which proves the first assertion. Since $\tilde{S}\,e^{\tilde{A}t}\tilde{S}^{-1}$, $t \geqq 0$, is also a strongly continuous semigroup with generator $\tilde{S}\tilde{A}\tilde{S}^{-1}$, it follows that $\tilde{S}\,e^{\tilde{A}t}\tilde{S}^{-1} = e^{\tilde{S}\tilde{A}\tilde{S}^{-1}t}$. Hence

$$\int_0^\infty e^{\tilde{S}\tilde{A}\tilde{S}^{-1}t}(\tilde{S}\tilde{V}\tilde{S}^*)\, e^{(\tilde{S}\tilde{A}\tilde{S}^{-1})^*t}\, dt = \tilde{S}\tilde{Q}\tilde{S}^*$$

and (3.19) follows from $\operatorname{tr}\tilde{Q}\tilde{R} = \operatorname{tr}(\tilde{S}\tilde{Q}\tilde{S}^*)(\tilde{S}^{-*}\tilde{R}\tilde{S}^{-1})$. □

In view of Proposition 3.1 one would expect the Main Theorem to apply also to $(SA_cS^{-1}, SB_c, C_cS^{-1})$. Indeed, it may be noted that no claim was made as to the uniqueness of the (G, M, Γ)-factorization of $\hat{Q}\hat{P}$ used to determine A_c, B_c and C_c in (3.9)-(3.11). These observations are reconciled by the following result which shows that a transformation of the compensator state basis corresponds to the alternative factorization $\hat{Q}\hat{P} = (S^{-T}G)^T(SMS^{-1})(S\Gamma)$ and, moreover, that all (G, M, Γ)-factorizations of $\hat{Q}\hat{P}$ are related by a nonsingular transformation. Note that τ remains invariant over the class of factorizations.

PROPOSITION 3.2. *If $S \in \mathbb{R}^{n_c \times n_c}$ is invertible then $\bar{G} \triangleq S^{-T}G$, $\bar{\Gamma} \triangleq S\Gamma$ and $\bar{M} \triangleq SMS^{-1}$ satisfy*

$$\hat{Q}\hat{P} = \bar{G}^*\bar{M}\bar{\Gamma}, \tag{3.7)'}$$

$$\bar{\Gamma}\bar{G}^* = I_{n_c}. \tag{3.8)'}$$

Conversely, if $\bar{G}, \bar{\Gamma} \in \mathcal{B}(\mathcal{H}, \mathbb{R}^{n_c})$ and invertible $\bar{M} \in \mathbb{R}^{n_c \times n_c}$ satisfy (3.7)′ *and* (3.8)′, *then there exists invertible $S \in \mathbb{R}^{n_c \times n_c}$ such that $\bar{G} = S^{-T}G$, $\bar{\Gamma} = S\Gamma$ and $\bar{M} = SMS^{-1}$.*

Proof. The first part of the proposition is immediate. The second part follows by taking $S \triangleq \bar{M}^{-1}\bar{\Gamma}G^*M^{-1}$, noting $S^{-1} = M\bar{\Gamma}\bar{G}^*\bar{M}^{-1}$ and using the identities $\bar{\Gamma}G^*M\Gamma\bar{G}^* = \bar{M}$ and $M\Gamma\bar{G}^* = \Gamma\bar{G}^*\bar{M}$. □

The next result shows that there exists a similarity transformation which simultaneously diagonalizes $\hat{Q}\hat{P}$ and τ.

PROPOSITION 3.3. *There exists invertible $\Phi \in \mathcal{B}(\mathcal{H})$ such that*

$$\hat{Q} = \Phi^{-1}\begin{bmatrix} \Lambda_{\hat{Q}} & 0 \\ 0 & 0 \end{bmatrix}\Phi^{-*}, \qquad \hat{P} = \Phi^*\begin{bmatrix} \Lambda_{\hat{P}} & 0 \\ 0 & 0 \end{bmatrix}\Phi, \tag{3.20a, b}$$

$$\hat{Q}\hat{P} = \Phi^{-1}\begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix}\Phi, \qquad \tau = \Phi^{-1}\begin{bmatrix} I_{n_c} & 0 \\ 0 & 0 \end{bmatrix}\Phi, \tag{3.21a, b}$$

where $\Lambda_{\hat{Q}}, \Lambda_{\hat{P}} \in \mathbb{R}^{n_c \times n_c}$ are positive diagonal and $\Lambda_{\hat{Q}}\Lambda_{\hat{P}} = \Lambda$. Consequently,

$$\hat{Q} = \tau\hat{Q}, \qquad \hat{P} = \hat{P}\tau. \tag{3.22a, b}$$

Proof. Proceeding as in the proof of Lemma 3.1, choose an orthonormal basis for $\mathcal{H}$ with respect to which

$$\hat{Q} = \begin{bmatrix} \hat{Q}_1 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad \hat{P} = \begin{bmatrix} \hat{P}_1 & 0 \\ 0 & 0 \end{bmatrix},$$

where $\hat{Q}_1, \hat{P}_1 \in \mathbb{R}^{r \times r}$ are nonnegative definite. By [55, Thm. 6.2.5, p. 123], there exists invertible $\Psi \in \mathbb{R}^{r \times r}$ such that $\tilde{\Lambda}_{\hat{Q}} \triangleq \Psi\hat{Q}_1\Psi^T$ and $\tilde{\Lambda}_{\hat{P}} = \Psi^{-T}\hat{P}_1\Psi^{-1}$ are nonnegative diagonal. Because of (3.14), it is clear that Ψ can be chosen so that

$$\tilde{\Lambda}_{\hat{Q}} = \begin{bmatrix} \Lambda_{\hat{Q}} & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad \tilde{\Lambda}_{\hat{P}} = \begin{bmatrix} \Lambda_{\hat{P}} & 0 \\ 0 & 0 \end{bmatrix},$$

where $\Lambda_{\hat{Q}}, \Lambda_{\hat{P}} \in \mathbb{R}^{n_c \times n_c}$ are positive diagonal. Thus (3.20) holds with

$$\Phi \triangleq \begin{bmatrix} \Psi & 0 \\ 0 & I_\infty \end{bmatrix}.$$

From (3.20) it follows that

$$\hat{Q}\hat{P} = \Phi^{-1} \begin{bmatrix} \Lambda_Q \Lambda_P & 0 \\ 0 & 0 \end{bmatrix} \Phi.$$

Now define $\bar{G} = [I_{n_c} \ 0]\Phi^{-*}$, $\bar{M} = \Lambda_{\hat{Q}}\Lambda_{\hat{P}}$ and $\bar{\Gamma} = [I_{n_c} \ 0]\Phi$ so that (3.7)′ and (3.8)′ are satisfied. By the second part of Proposition 3.2 there exists invertible $S \in \mathbb{R}^{n_c \times n_c}$ such that $G = S^T\bar{G}$, $M = S^{-1}\bar{M}S$ and $\Gamma = S^{-1}\bar{\Gamma}$. Since M and $\bar{M}$ have the same eigenvalues, $\bar{M} = \Lambda$ (modulo an ordering of the diagonal elements) and thus (3.21a) holds. Finally, (3.21b) follows from

$$\tau = G^*\Gamma = \bar{G}^*\bar{\Gamma} = \Phi^{-1} \begin{bmatrix} I_{n_c} & 0 \\ 0 & 0 \end{bmatrix} \Phi. \qquad \square$$

Remark 3.1. Proposition 3.3 shows that $\lambda_1, \cdots, \lambda_{n_c}$ are the positive eigenvalues of $\hat{Q}\hat{P}$.

Remark 3.2. The simultaneous diagonalization in (3.20) has been effected by a *contragredient transformation* [55], [58]. For applications of this type of transformation to model reduction and realization problems see [12], [59]–[61]. Simultaneous diagonalization of operators is discussed in [53, p. 181].

The following result validates the precise handling of the unbounded operator A in (3.9), (3.17) and (3.18).

PROPOSITION 3.4. *The following relations hold*:

(3.23a, b, c) $$\rho(G) = \rho(\Gamma) = \rho(\tau) = n_c,$$

(3.24a, b) $$\tau: \mathscr{H} \to \mathscr{D}(A), \qquad \tau^*: \mathscr{H} \to \mathscr{D}(A^*),$$

(3.25a, b) $$G^*: \mathbb{R}^{n_c} \to \mathscr{D}(A), \qquad \Gamma^*: \mathbb{R}^{n_c} \to \mathscr{D}(A^*).$$

Proof. From (3.8) and (2.1) it follows that $n_c = \rho(\Gamma G^*) \leqq \min\{\rho(\Gamma), \rho(G^*)\}$. Since $\rho(\Gamma) \leqq n_c$, $\rho(G) = \rho(G^*)$ and $\rho(G) \leqq n_c$, (3.23a) and (3.23b) hold. To show (3.23c) either note (3.21b) or use (3.14a) and (3.22) to obtain

$$n_c = \rho(\hat{Q}) = \rho(\tau\hat{Q}) \leqq \rho(\tau) = \rho(G^*\Gamma) \leqq \rho(\Gamma) = n_c.$$

To prove (3.24a) note that (3.22a) implies $\mathscr{R}(\hat{Q}) \subset \mathscr{R}(\tau)$ and thus $\rho(\hat{Q}) = \rho(\tau)$ implies $\mathscr{R}(\hat{Q}) = \mathscr{R}(\tau)$, and similarly for (3.24b). Finally, (3.25) follows from (3.23), (3.24), the definition $\tau = G^*\Gamma$ and the fact that $\tau^* = \Gamma^*G$. $\square$

Since the domain of A may not be all of $\mathscr{H}$, expressions involving A require special interpretation. First note that because of the range condition (3.25a), the expression (3.9) indeed represents an $n_c \times n_c$ matrix (see, e.g., [6, p. 80]). Similarly, because of (3.25b), A_c^T is given by

(3.26) $$A_c^T = G(A^* - \bar{\Sigma}Q - P\Sigma)\Gamma^*.$$

With regard to (3.15), note that because of (3.12a), the right-hand side of (3.15) is a linear operator with domain $\mathscr{D}(A^*)$. Since $\Theta \triangleq -\tau Q\bar{\Sigma}Q - Q\bar{\Sigma}Q\tau^* + V_1 + \tau Q\bar{\Sigma}Q\tau^*$ is continuous on $\mathscr{D}(A^*)$, $AQ + QA^*$ has a continuous extension on $\mathscr{H}$ given precisely by $-\Theta$. Similar remarks apply to (3.16). Analogous domain conditions were obtained in [5] for a deterministic infinite-dimensional linear-quadratic control problem with

full-state feedback. Finally, because of (3.24) the right-hand sides of (3.17) and (3.18) denote bounded linear operators on all of $\mathscr{H}$.

It is useful to present an alternative form of the optimal projection equations (3.15)-(3.18). For convenience define the notation

$$\tau_\perp \triangleq I_{\mathscr{H}} - \tau.$$

PROPOSITION 3.5. *Equations* (3.15)-(3.18) *are equivalent, respectively, to*

$$0 = AQ + QA^* + V_1 - Q\bar{\Sigma}Q + \tau_\perp Q\bar{\Sigma}Q\tau_\perp^*, \tag{3.27}$$

$$0 = A^*P + PA + R_1 - P\Sigma P + \tau_\perp^* P\Sigma P\tau_\perp, \tag{3.28}$$

$$0 = (A - \Sigma P)\hat{Q} + \hat{Q}(A - \Sigma P)^* + Q\bar{\Sigma}Q - \tau_\perp Q\bar{\Sigma}Q\tau_\perp^*, \tag{3.29}$$

$$0 = (A - Q\bar{\Sigma})^*\hat{P} + \hat{P}(A - Q\bar{\Sigma}) + P\Sigma P - \tau_\perp^* P\Sigma P\tau_\perp. \tag{3.30}$$

Proof. The equivalence of (3.27) and (3.28) to (3.15) and (3.16) is immediate. Using (3.22a) in the form $\hat{Q} = \hat{Q}\tau^*$, we obtain (3.17) = (3.29)τ^*. Conversely, from (3.22a) and $[(A - \Sigma P)\hat{Q}]^* = \hat{Q}(A - \Sigma P)^*$ (see, e.g., [6, p. 80]) it follows that (3.29) = (3.17) + (3.17)* − τ(3.17). Similarly, (3.18) and (3.30) are equivalent. □

The form of the optimal projection equations (3.27)-(3.30) helps demonstrate the relationship between the Main Theorem and the classical *LQG* result when $\dim \mathscr{H} = n < \infty$. In this case we need only note that the (G, M, Γ)-factorization of $\hat{Q}\hat{P}$ in the "full-order" case $n_c = n$ is given by $G = \Gamma = I_n$ and $M = \hat{Q}\hat{P}$. Since $\tau = I_n$, and thus $\tau_\perp = 0$, (3.27) and (3.28) reduce to the standard observer and regulator Riccati equations and (3.9)-(3.11) yield the usual *LQG* expressions. Furthermore, note that in the full-order case

$$A_c = A + BC_c - B_cC \tag{3.31}$$

and (3.29) and (3.31) can be written as

$$0 = (A_c + B_cC)\hat{Q} + \hat{Q}(A_c + B_cC)^T + B_cV_2B_c^T, \tag{3.32}$$

$$0 = (A_c - BC_c)^T\hat{P} + \hat{P}(A_c - BC_c) + C_c^TR_2C_c. \tag{3.33}$$

Since, as is well known, the stability of $\tilde{A}$ corresponds to the stability of $A + BC_c = A_c + B_cC$ and $A - B_cC = A_c - BC_c$, it follows from standard results (e.g., [62, pp. 48, 277]) that the positive-definiteness conditions (3.14a, b) are equivalent to the assumption that (A_c, B_c, C_c) is controllable and observable.

To obtain a geometric intepretation of the optimal projection we introduce the quasi-full-state estimate

$$\hat{x}(t) \triangleq G^*x_c(t) \in \mathscr{H}$$

so that $\tau\hat{x}(t) = \hat{x}(t)$ and $x_c(t) = \Gamma\hat{x}(t)$. Now, the closed-loop system (3.1)-(3.4) can be written as

$$\dot{x}(t) = Ax(t) - B\hat{C}_c\tau\hat{x}(t) + H_1w(t), \tag{3.34}$$

$$\dot{\hat{x}}(t) = \tau(A + B\hat{C}_c - \hat{B}_cC)\tau\hat{x}(t) + \tau\hat{B}_c(Cx(t) + H_2w(t)), \tag{3.35}$$

where (3.35) is interpreted in the sense of (3.34) since $\hat{x}(t) \in \mathscr{H}$ and where

$$\hat{B}_c \triangleq QC^*V_2^{-1}, \qquad \hat{C}_c \triangleq -R_2^{-1}B^*P.$$

It can thus be seen that the geometric structure of the quasi-full-order compensator is entirely dictated by the projection τ. In particular, control inputs $\tau\hat{x}(t)$ determined by

(3.35) are contained in $\mathcal{R}(\tau)$ and sensor inputs $\tau\hat{B}_c y(t)$ are annihilated unless they are contained in $[\mathcal{N}(\tau)]^\perp = \mathcal{R}(\tau^*)$. Consequently, $\mathcal{R}(\tau)$ and $\mathcal{R}(\tau^*)$ are the control and observation subspaces, respectively, of the compensator. Since τ is not necessarily an orthogonal projection, these (finite-dimensional) subspaces may be different.

From the form of (3.35) it is tempting to suggest that the optimal fixed-order dynamic compensator can be obtained by projecting the full-order (infinite-dimensional) *LQG* compensator. However, this is generally impossible for the following simple reason. Although the expressions for A_c, B_c and C_c in (3.9)-(3.11) have the *form* of a projection of the full-order *LQG* compensator, the operators Q and P in (3.9)-(3.11) are *not* the solutions of the usual *LQG* Riccati equations but instead must be obtained by simultaneously solving all four coupled equations (3.15)-(3.18). This observation reinforces the statement made in § 1 that the optimal fixed-order dynamic compensator cannot in general be obtained by *LQG* followed by closed-loop controller reduction as in [14] and [15].

We now give an explicit characterization of the optimal projection in terms of $\hat{Q}$ and $\hat{P}$. Since $\hat{Q}\hat{P}$ has finite rank, its Drazin inverse $(\hat{Q}\hat{P})^D$ exists (see [63, Thm. 6, p. 108]) and, since $(\hat{Q}\hat{P})^2 = G^*M^2\Gamma$, and hence $\rho(\hat{Q}\hat{P})^2 = \rho(\hat{Q}\hat{P})$, the "index" of $\hat{Q}\hat{P}$ (see [63], [64]) is 1. In this case the Drazin inverse is traditionally called the group inverse and is denoted by $(\hat{Q}\hat{P})^\#$ (see, e.g., [64, p. 124] or [65]).

PROPOSITION 3.6. *The optimal projection τ is given by*

$$\tau = \hat{Q}\hat{P}(\hat{Q}\hat{P})^\#. \tag{3.36}$$

Proof. It is easy to verify that the conditions characterizing the Drazin inverse [63] for the case that $\hat{Q}\hat{P}$ has index 1 are satisfied by $G^*M^{-1}\Gamma$. Hence $(\hat{Q}\hat{P})^\# = G^*M^{-1}\Gamma$ and (3.8) implies (3.36). □

We now give an alternative characterization of the optimal projection by introducing the following notation from [51, p. 73]. For $\phi, \psi \in \mathcal{H}$ define the operator $\phi \otimes \psi \in \mathcal{B}(\mathcal{H})$ by

$$(\phi \otimes \psi)x \triangleq \langle x, \phi\rangle\psi, \qquad x \in \mathcal{H},$$

and note that $\rho(\phi \otimes \psi) = 1$ if ϕ and ψ are both nonzero and $(\phi \otimes \psi)^* = \psi \otimes \phi$. Using this notation, (3.21a) can be written as

$$\Phi\hat{Q}\hat{P}\Phi^{-1} = \sum_{i=1}^{n_c} \lambda_i \xi_i \otimes \xi_i, \tag{3.37}$$

where $\{\xi_i\}_{i=1}^\infty$ is an orthonormal basis for $\mathcal{H}$. In terms of the Riesz bases (see e.g., [52, p. 309])

$$\phi_i \triangleq \Phi^*\xi_i, \qquad \psi_i \triangleq \Phi^{-1}\xi_i, \qquad i = 1, 2, \cdots,$$

(3.37) is equivalent to

$$\hat{Q}\hat{P} = \sum_{i=1}^{n_c} \lambda_i \phi_i \otimes \psi_i, \tag{3.38}$$

which can be regarded as a specialized spectral decomposition of a semisimple operator. We emphasize that, in contrast to the singular value decomposition for compact nonnormal operators (see, e.g., [50, p. 261]), the λ_i in (3.38) are *eigenvalues* of $\hat{Q}\hat{P}$ (see Remark 3.1), not singular values. Moreover, although $\{\phi_i\}_{i=1}^\infty$ and $\{\psi_i\}_{i=1}^\infty$ are bases for $\mathcal{H}$, they are not necessarily orthogonal. They are, however, biorthonormal, i.e., $\langle \phi_i, \psi_j\rangle = \delta_{ij}$, and hence $\phi_i \otimes \psi_i$ is a rank-one projection and $(\phi_i \otimes \psi_i)(\phi_j \otimes \psi_j) = 0$, $i \neq j$.

Since τ is a rank-n_c projection, it is not surprising that τ is given precisely by

$$\tau = \sum_{i=1}^{n_c} \phi_i \otimes \psi_i. \tag{3.39}$$

The following result summarizes the above observations.

PROPOSITION 3.7. *There exist biorthonormal linearly independent sets* $\{\psi_i\}_{i=1}^{n_c} \subset \mathscr{D}(A)$ *and* $\{\phi_i\}_{i=1}^{n_c} \subset \mathscr{D}(A^*)$ *such that* (3.38) *and* (3.39) *hold. Furthermore, if the* (G, M, Γ)*-factorization of* $\hat{Q}\hat{P}$ *is chosen such that* $M = \Lambda$, *then, for all* $x \in \mathscr{H}$,

$$Gx = (\langle x, \psi_1 \rangle, \cdots, \langle x, \psi_{n_c} \rangle)^T,$$

$$\Gamma x = (\langle x, \phi_1 \rangle, \cdots, \langle x, \phi_{n_c} \rangle)^T.$$

Remark 3.3. Note that $\hat{P}\hat{Q}$ and τ^* are given by

$$\hat{P}\hat{Q} = \sum_{i=1}^{n_c} \lambda_i \psi_i \otimes \phi_i, \qquad \tau^* = \sum_{i=1}^{n_c} \psi_i \otimes \phi_i,$$

and, for all $y \triangleq (y_1, \cdots, y_{n_c})^T \in \mathbb{R}^{n_c}$, G^* and Γ^* satisfy

$$G^* y = \sum_{i=1}^{n_c} y_i \psi_i, \qquad \Gamma^* y = \sum_{i=1}^{n_c} y_i \phi_i.$$

4. Proof of the Main Theorem. We state and prove a series of lemmas which allow us to compute the Frechet derivatives of J with respect to A_c, B_c and C_c. Requiring that these derivatives vanish leads to the necessary conditions in their "primitive" form. A transformation of variables then leads to the form of the necessary conditions (3.9)-(3.18).

Let "u-lim" denote the uniform limit (i.e., limit in operator norm) for bounded linear operators [50, p. 150] and, for strongly continuous $S(t) \in \mathscr{B}(\mathscr{H})$, $t \geqq 0$, interpret the strong integral $\int_{t_1}^{t_2} S(t)\, dt$ according to $\int_{t_1}^{t_2} S(t) z\, dt$, $z \in \mathscr{H}$ [50, p. 152]. Also recall the standard fact [6, p. 186] that $(e^{At})^* = e^{A^* t}$ and similarly for $\tilde{A}$. Throughout this section let $(A_c, B_c, C_c) \in \mathscr{A}_+$ and let $\alpha, \beta > 0$ satisfy (3.6).

To begin, note that the closed-loop system (3.1)-(3.4) can be written as

$$\dot{\tilde{x}}(t) = \tilde{A}\tilde{x}(t) + \tilde{H}w(t), \tag{4.1}$$

where

$$\tilde{H} \triangleq \begin{bmatrix} H_1 \\ B_c H_2 \end{bmatrix} \in \mathscr{B}_2(\mathscr{H}' \oplus \mathbb{R}^l).$$

For convenience define the nonnegative-definite operator

$$\tilde{V} \triangleq \tilde{H}\tilde{H}^* = \begin{bmatrix} V_1 & 0 \\ 0 & B_c V_2 B_c^T \end{bmatrix} \in \mathscr{B}_1(\tilde{\mathscr{H}}).$$

In terms of the augmented state $\tilde{x}(t)$, the performance criterion (3.5) becomes

$$J(A_c, B_c, C_c) = \lim_{t \to \infty} \mathbb{E}\langle \tilde{R}\tilde{x}(t), \tilde{x}(t) \rangle, \tag{4.2}$$

where the nonnegative-definite operator $\tilde{R}$ is defined by

$$\tilde{R} \triangleq \begin{bmatrix} R_1 & 0 \\ 0 & C_c^T R_2 C_c \end{bmatrix} \in \mathscr{B}_1(\tilde{\mathscr{H}}).$$

To write (4.2) in terms of the covariance of $\tilde{x}(t)$, recall [6, p. 308] that the covariance "$\mathbb{E}[(\xi-\mathbb{E}\xi)(\xi-\mathbb{E}\xi)^*]$" of a Hilbert-space-valued weak random variable ξ is defined to be the nonnegative-definite operator S which satisfies

$$\langle Sy, z\rangle = \mathbb{E}\langle \xi-\mathbb{E}\xi, y\rangle\langle \xi-\mathbb{E}\xi, z\rangle$$

for all y, z in the Hilbert space. Hence define [6, p. 317]

$$\tilde{Q}(t) \triangleq \mathbb{E}[(\tilde{x}(t)-\mathbb{E}\tilde{x}(t))(\tilde{x}(t)-\mathbb{E}\tilde{x}(t))^*].$$

LEMMA 4.1. *$\tilde{Q} \triangleq u\text{-}\lim_{t\to\infty} \tilde{Q}(t)$ exists and is given by*

$$\tilde{Q} = \int_0^\infty e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^*t}\,dt. \tag{4.3}$$

Furthermore,

$$J(A_c, B_c, C_c) = \operatorname{tr}\tilde{Q}\tilde{R}. \tag{4.4}$$

Proof. First compute (as in [6, p. 317])

$$\begin{aligned}
\langle \tilde{Q}(t)\tilde{y}, \tilde{z}\rangle &= \mathbb{E}\langle \tilde{x}(t) - e^{\tilde{A}t}\mathbb{E}\tilde{x}(0), \tilde{y}\rangle\langle \tilde{x}(t) - e^{\tilde{A}t}\mathbb{E}\tilde{x}(0), \tilde{z}\rangle \\
&= \mathbb{E}\left\langle \int_0^t e^{\tilde{A}(t-s)}\tilde{H}\tilde{w}(s)\,ds, \tilde{y}\right\rangle\left\langle \int_0^t e^{\tilde{A}(t-\sigma)}\tilde{H}\tilde{w}(\sigma)\,d\sigma, \tilde{z}\right\rangle \\
&\quad + \langle \tilde{Q}(0)\, e^{\tilde{A}^*t}\tilde{y}, e^{\tilde{A}^*t}\tilde{z}\rangle \\
&= \mathbb{E}\int_0^t\int_0^t \langle \tilde{w}(s), \tilde{H}^*\, e^{\tilde{A}^*(t-s)}\tilde{y}\rangle\langle \tilde{w}(\sigma), \tilde{H}^*\, e^{\tilde{A}^*(t-\sigma)}\tilde{z}\rangle\,ds\,d\sigma \\
&\quad + \langle e^{\tilde{A}t}\tilde{Q}(0)\, e^{\tilde{A}^*t}\tilde{y}, \tilde{z}\rangle \\
&= \int_0^t \langle e^{\tilde{A}(t-s)}\tilde{V}e^{\tilde{A}^*(t-s)}\tilde{y}, \tilde{z}\rangle\,ds + \langle e^{\tilde{A}t}\tilde{Q}(0)\, e^{\tilde{A}^*t}\tilde{y}, \tilde{z}\rangle,
\end{aligned}$$

which shows that $\tilde{Q}(t)$ is given by

$$\tilde{Q}(t) = e^{\tilde{A}t}\tilde{Q}(0)\, e^{\tilde{A}^*t} + \int_0^t e^{\tilde{A}s}\tilde{V}e^{\tilde{A}^*s}\,ds.$$

Clearly, (4.3) makes sense as a strong integral since

$$\|\tilde{Q}\| \leqq \int_0^\infty \|e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^*t}\|\,dt \leqq \alpha^2\|\tilde{V}\|\int_0^\infty e^{-2\beta t}\,dt < \infty.$$

To demonstrate uniform convergence it need only be noted that

$$\begin{aligned}
\|\tilde{Q} - \tilde{Q}(t)\| &= \sup_{\|\tilde{y}\|=1}\|(\tilde{Q}-\tilde{Q}(t))\tilde{y}\| \\
&= \sup_{\|\tilde{y}\|=1}\left\|\int_t^\infty e^{\tilde{A}s}\tilde{V}e^{\tilde{A}^*s}\tilde{y}\,ds - e^{\tilde{A}t}\tilde{Q}(0)\, e^{\tilde{A}^*t}\tilde{y}\right\| \\
&\leqq \int_t^\infty \|e^{\tilde{A}s}\tilde{V}e^{\tilde{A}^*s}\|\,ds + \|e^{\tilde{A}t}\tilde{Q}(0)\, e^{\tilde{A}^*t}\| \\
&\leqq \tfrac{1}{2}\alpha^2\|\tilde{V}\|\beta^{-1}\, e^{-2\beta t} + \|\tilde{Q}(0)\|\, e^{-2\beta t}.
\end{aligned}$$

Next, let $\{\phi_i\}_{i=1}^{\infty}$ be an orthonormal basis for $\tilde{\mathscr{H}}$ and use Parseval's equality to obtain

$$J(A_c, B_c, C_c) = \lim_{t\to\infty} \mathbb{E}\|\tilde{R}^{1/2}\tilde{x}(t)\|^2 = \lim_{t\to\infty} \mathbb{E} \sum_{i=1}^{\infty} \langle \tilde{R}^{1/2}\tilde{x}(t), \phi_i\rangle^2.$$

Since

$$f_n(t) \triangleq \sum_{i=1}^{n} \langle \tilde{R}^{1/2}\tilde{x}(t), \phi_i\rangle^2, \qquad t \geqq 0,$$

is nonnegative for each n and is increasing in n for each t with limit $\langle \tilde{R}\tilde{x}(t), \tilde{x}(t)\rangle$, monotone convergence permits expectation-limit interchange. Hence using $\mathbb{E}\tilde{x}(t) = e^{\tilde{A}t}\mathbb{E}\tilde{x}(0)$ we have

$$\begin{aligned} J(A_c, B_c, C_c) &= \lim_{t\to\infty} \sum_{i=1}^{\infty} \mathbb{E}\langle \tilde{x}(t), \tilde{R}^{1/2}\phi_i\rangle^2 \\ &= \lim_{t\to\infty} \sum_{i=1}^{\infty} [\langle \tilde{Q}(t)\tilde{R}^{1/2}\phi_i, \tilde{R}^{1/2}\phi_i\rangle + \langle e^{\tilde{A}t}\mathbb{E}\tilde{x}(0), \tilde{R}^{1/2}\phi_i\rangle^2] \\ &= \lim_{t\to\infty} \{\operatorname{tr}[\tilde{R}^{1/2}\tilde{Q}(t)\tilde{R}^{1/2}] + \|\tilde{R}^{1/2} e^{\tilde{A}t}\mathbb{E}\tilde{x}(0)\|^2\} \end{aligned}$$

which by Corollary 2.1 yields (4.4). □

We shall also require the "dual" of $\tilde{Q}$ given by

$$\tilde{P} = \int_0^{\infty} e^{\tilde{A}^* t}\tilde{R}\, e^{\tilde{A}t}\, dt. \tag{4.5}$$

Since $\tilde{V}$ and $\tilde{R}$ are nonnegative definite it is readily seen that $\tilde{Q}$ and $\tilde{P}$ are also nonnegative definite.

LEMMA 4.2. $\tilde{Q}, \tilde{P} \in \mathscr{B}_1(\tilde{\mathscr{H}})$.

Proof. It suffices to consider $\tilde{Q}$ only since the situation for $\tilde{P}$ is exactly analogous. Since $\tilde{Q}$ is nonnegative definite, Lemma 2.3 can be used. Letting $\{\phi_i\}_{i=1}^{\infty}$ be an orthonormal basis for $\tilde{\mathscr{H}}$, we have

$$\begin{aligned} \operatorname{tr}\tilde{Q} &= \sum_{i=1}^{\infty} \langle \tilde{Q}\phi_i, \phi_i\rangle = \sum_{i=1}^{\infty} \left\langle \int_0^{\infty} e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^* t}\phi_i\, dt, \phi_i \right\rangle \\ &= \lim_{n\to\infty} \int_0^{\infty} \sum_{i=1}^{n} \langle \tilde{V}e^{\tilde{A}^* t}\phi_i, e^{\tilde{A}^* t}\phi_i\rangle\, dt. \end{aligned}$$

Let $f_n(t)$ denote the above integrand. Since $\tilde{V}$ is nonnegative definite, $\{f_n(\cdot)\}$ is a monotonically increasing sequence of nonnegative functions such that $f_n(t) \to \operatorname{tr} e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^* t}$, $t \geqq 0$. Hence, by monotone convergence and Lemma 2.2,

$$\begin{aligned} \operatorname{tr}\tilde{Q} &= \int_0^{\infty} \operatorname{tr}[e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^* t}]\, dt \\ &= \int_0^{\infty} \|e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^* t}\|_1\, dt \leqq \alpha^2\|\tilde{V}\|_1 \int_0^{\infty} e^{-2\beta t}\, dt < \infty. \end{aligned}$$

□

LEMMA 4.3. *With $\tilde{Q}$ and $\tilde{P}$ given by* (4.3) *and* (4.5) *it follows that*

$$\operatorname{tr}\tilde{Q}\tilde{R} = \operatorname{tr}\tilde{V}\tilde{P}. \tag{4.6}$$

Proof. For any orthonormal basis $\{\phi_i\}_{i=1}^{\infty}$ of $\tilde{\mathscr{H}}$ we have

$$\operatorname{tr} \tilde{Q}\tilde{R} = \operatorname{tr} \tilde{R}\tilde{Q} = \sum_{i=1}^{\infty} \left\langle \tilde{R} \int_0^{\infty} e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t} \phi_i \, dt, \phi_i \right\rangle$$

$$= \lim_{n\to\infty} \int_0^{\infty} \sum_{i=1}^{n} \langle \tilde{R} e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t} \phi_i, \phi_i \rangle \, dt.$$

Letting $f_n(t)$ denote the above integrand it follows that $f_n(t) \to \operatorname{tr} \tilde{R} e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t}$, $t \geqq 0$, and

$$|f_n(t)| \leqq \sum_{i=1}^{\infty} |\langle e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t} \phi_i, \tilde{R}\phi_i \rangle| \leqq \alpha^2 \|\tilde{V}\| \, e^{-2\beta t} \sum_{i=1}^{\infty} \|\tilde{R}\phi_i\|.$$

If $\{\phi_i\}_{i=1}^{\infty}$ is chosen to be the set of orthonormal eigenvectors of $\tilde{R}$ then Lemma 2.1 implies $\sum_{i=1}^{\infty} \|\tilde{R}\phi_i\| = \|\tilde{R}\|_1$ and thus $|f_n(t)|$ is bounded on $[0, \infty)$ by an integrable function. Hence by dominated convergence,

$$\operatorname{tr} \tilde{Q}\tilde{R} = \int_0^{\infty} \operatorname{tr} [\tilde{R} e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t}] \, dt = \int_0^{\infty} \operatorname{tr} [e^{\tilde{A}^* t} \tilde{R} e^{\tilde{A}t} \tilde{V}] \, dt = \int_0^{\infty} \sum_{i=1}^{\infty} \langle \tilde{V}\phi_i, e^{\tilde{A}^* t} \tilde{R} e^{\tilde{A}t} \rangle \, dt.$$

And again using dominated convergence,

$$\operatorname{tr} \tilde{Q}\tilde{R} = \sum_{i=1}^{\infty} \int_0^{\infty} \langle \tilde{V}\phi_i, e^{\tilde{A}^* t} \tilde{R} e^{\tilde{A}t} \phi_i \rangle \, dt = \sum_{i=1}^{\infty} \left\langle \tilde{V}\phi_i, \int_0^{\infty} e^{\tilde{A}^* t} \tilde{R} e^{\tilde{A}t} \phi_i \, dt \right\rangle = \operatorname{tr} \tilde{V}\tilde{P}. \qquad \square$$

The next result is important in that it allows us to treat $\tilde{Q}$ and $\tilde{P}$ as solutions of dual algebraic Lyapunov equations. For a similar result involving groups rather than semigroups see [50, pp. 555–557].

LEMMA 4.4. *$\tilde{Q}$ is given by* (4.3) *if and only if $\tilde{Q} \in \mathscr{B}(\tilde{\mathscr{H}})$ satisfies*

$$\tilde{Q}\colon \mathscr{D}(\tilde{A}^*) \to \mathscr{D}(\tilde{A}), \tag{4.7}$$

$$0 = \tilde{A}\tilde{Q} + \tilde{Q}\tilde{A}^* + \tilde{V}, \tag{4.8}$$

where (4.8) *holds in the sense discussed in* § 3. *Furthermore, $\tilde{P}$ is given by* (4.5) *if and only if $\tilde{P} \in \mathscr{B}(\tilde{\mathscr{H}})$ satisfies*

$$\tilde{P}\colon \mathscr{D}(\tilde{A}) \to \mathscr{D}(\tilde{A}^*), \tag{4.9}$$

$$0 = \tilde{A}^*\tilde{P} + \tilde{P}\tilde{A} + \tilde{R}. \tag{4.10}$$

Proof. We consider $\tilde{Q}$ only. To prove necessity let $t' > 0$. Then for all $t \in [0, t')$ and $\tilde{x} \in \mathscr{D}(\tilde{A}^*)$ we can write

$$e^{\tilde{A}t} \tilde{Q} e^{\tilde{A}^* t'} \tilde{x} = \int_0^{\infty} e^{\tilde{A}(t+s)} \tilde{V} e^{\tilde{A}^*(t'+s)} \tilde{x} \, ds$$

$$= \int_t^{\infty} e^{\tilde{A}\sigma} \tilde{V} e^{\tilde{A}^*\sigma} \, e^{\tilde{A}^*(t'-t)} \tilde{x} \, d\sigma.$$

Hence,

$$\frac{d}{dt} e^{\tilde{A}t} \tilde{Q} e^{\tilde{A}^* t'} \tilde{x} = -\int_t^{\infty} e^{\tilde{A}\sigma} \tilde{V} e^{\tilde{A}^*\sigma} \, e^{\tilde{A}^*(t'-t)} \tilde{A}^* \tilde{x} \, d\sigma - e^{\tilde{A}t} \tilde{V} e^{\tilde{A}^* t'} \tilde{x}, \tag{4.11}$$

which shows that $e^{\tilde{A}t} \tilde{Q} e^{\tilde{A}^* t'}$ is strongly differentiable with respect to t for all $t \in [0, t')$. In particular, setting $t = 0$ it follows that $\tilde{Q} e^{\tilde{A}^* t'} \tilde{x} \in \mathscr{D}(\tilde{A})$ for all $\tilde{x} \in \mathscr{D}(\tilde{A}^*)$ (see, e.g., [6, p. 173] or [50, p. 485]). Performing the differentiation on the left-hand side of

(4.11) and setting $t=0$ yields

$$\tilde{A}\tilde{Q}\,e^{\tilde{A}^*t'}\tilde{x} = -\int_0^\infty e^{\tilde{A}\sigma}\tilde{V}\,e^{\tilde{A}^*\sigma}\,e^{\tilde{A}^*t'}\tilde{A}^*\tilde{x}\,d\sigma - \tilde{V}\,e^{\tilde{A}^*t'}\tilde{x}. \tag{4.12}$$

Now fix $\tilde{x}\in\mathcal{D}(\tilde{A}^*)$. Then for $\{t_i\}_{i=1}^\infty$, $t_i>0$, $t_i\to 0$, we have

$$\tilde{Q}\,e^{\tilde{A}^*t_i}\tilde{x}\in\mathcal{D}(\tilde{A}), \qquad i=1,2,3,\cdots,$$
$$\tilde{Q}\,e^{\tilde{A}^*t_i}\tilde{x}\xrightarrow[i\to\infty]{}\tilde{Q}\tilde{x}.$$

Now consider the sequence $\{\tilde{A}\tilde{Q}\,e^{\tilde{A}^*t_i}\tilde{x}\}_{i=1}^\infty$. Letting $t'=t_i$ in (4.12) and using dominated convergence to interchange limit and integration ($\tilde{A}^*\tilde{x}$ is a fixed element of $\tilde{\mathscr{H}}$), it follows that

$$\lim_{i\to\infty}\tilde{A}\tilde{Q}\,e^{\tilde{A}^*t_i}\tilde{x} = -\int_0^\infty e^{\tilde{A}\sigma}\tilde{V}\,e^{\tilde{A}^*\sigma}\tilde{A}^*\tilde{x}\,d\sigma - \tilde{V}\tilde{x}. \tag{4.13}$$

Since $\tilde{A}$ is closed, $\tilde{Q}\tilde{x}\in\mathcal{D}(\tilde{A})$. This proves (4.7). Also, since $\tilde{A}$ is closed we have

$$\lim_{i\to\infty}\tilde{A}\tilde{Q}\,e^{\tilde{A}^*t_i}\tilde{x} = \tilde{A}\tilde{Q}\tilde{x},$$

which with (4.13) implies

$$\tilde{A}\tilde{Q}\tilde{x} = -\tilde{Q}\tilde{A}^*\tilde{x} - \tilde{V}\tilde{x},$$

and hence

$$(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*+\tilde{V})\tilde{x}=0, \qquad \tilde{x}\in\mathcal{D}(\tilde{A}^*),$$

as desired.

To prove sufficiency let $\tilde{x}\in\mathcal{D}(\tilde{A})$. Then $e^{\tilde{A}^*t}\tilde{x}\in\mathcal{D}(\tilde{A}^*)$, $t\geqq 0$, and hence

$$\frac{d}{dt}\,e^{\tilde{A}t}\tilde{Q}\,e^{\tilde{A}^*t}\tilde{x} = e^{\tilde{A}t}(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)\,e^{\tilde{A}^*t}\tilde{x}.$$

Thus

$$e^{\tilde{A}t}\tilde{Q}\,e^{\tilde{A}^*t}\tilde{x} - \tilde{Q}\tilde{x} = \int_0^t e^{\tilde{A}s}(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)\,e^{\tilde{A}^*s}\tilde{x}\,ds, \qquad \tilde{x}\in\mathcal{D}(\tilde{A}^*).$$

Extending $\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*$ to all of $\tilde{\mathscr{H}}$ we obtain

$$e^{\tilde{A}t}\tilde{Q}\,e^{\tilde{A}^*t}\tilde{x} - \tilde{Q}\tilde{x} = -\int_0^t e^{\tilde{A}s}\tilde{V}\,e^{\tilde{A}^*s}\tilde{x}\,ds, \qquad \tilde{x}\in\tilde{\mathscr{H}}.$$

Letting $t\to\infty$ yields (4.3). □

We now introduce some notation which will prove to be most convenient in the following results. For $(A_c', B_c', C_c')\in\mathbb{R}^{n_c\times n_c}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c}$ define

$$\delta_{A_c}\triangleq A_c'-A_c, \qquad \delta_{B_c}\triangleq B_c'-B_c, \qquad \delta_{C_c}\triangleq C_c'-C_c$$

and

$$\|(\delta_{A_c},\delta_{B_c},\delta_{C_c})\|\triangleq\|\delta_{A_c}\|+\|\delta_{B_c}\|+\|\delta_{C_c}\|.$$

Furthermore, let $\tilde{A}'$, $\tilde{V}'$ and $\tilde{R}'$ denote $\tilde{A}$, $\tilde{V}$ and $\tilde{R}$ with (A_c, B_c, C_c) replaced by

(A_c', B_c', C_c') and define

$$\delta_{\tilde{A}} \triangleq \tilde{A}' - \tilde{A} = \begin{bmatrix} 0 & B\delta_{C_c} \\ \delta_{B_c} C & \delta_{A_c} \end{bmatrix},$$

$$\delta_{\tilde{V}} \triangleq \tilde{V}' - \tilde{V} = \begin{bmatrix} 0 & 0 \\ 0 & B_c V_2 \delta_{B_c}^T + \delta_{B_c} V_2 B_c^T + \delta_{B_c} V_2 \delta_{B_c}^T \end{bmatrix},$$

$$\delta_{\tilde{R}} \triangleq \tilde{R}' - \tilde{R} = \begin{bmatrix} 0 & 0 \\ 0 & C_c^T R_2 \delta_{C_c} + \delta_{C_c}^T R_2 C_c + \delta_{C_c}^T R_2 \delta_{C_c} \end{bmatrix}.$$

We shall also write $\tilde{Q}'$, $\tilde{P}'$ for $\tilde{Q}$, $\tilde{P}$ as given by (4.3) and (4.5) with $\tilde{A}$, $\tilde{V}$, $\tilde{R}$ replaced by $\tilde{A}'$, $\tilde{V}'$, $\tilde{R}'$ and define

$$\delta_{\tilde{Q}} \triangleq \tilde{Q}' - \tilde{Q}, \qquad \delta_{\tilde{P}} \triangleq \tilde{P}' - \tilde{P}.$$

LEMMA 4.5. $\mathscr{A}$ is open.

Proof. Let $(A_c, B_c, C_c) \in \mathscr{A}$ be arbitrary and consider the open set

$$N \triangleq \{(A_c', B_c', C_c') \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c} : \|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\| < \beta/2\alpha\gamma\}, \tag{4.14}$$

where $\gamma \triangleq \max\{1, \|B\|, \|C\|\}$. Then, since $\tilde{A}' = \tilde{A} + \delta_{\tilde{A}}$ and $\delta_{\tilde{A}} \in \mathscr{B}(\tilde{\mathscr{H}})$ it follows from Theorem 2.1, p. 497 of [50], that for all $(A_c', B_c', C_c') \in N$ and $t \geqq 0$,

$$\|e^{\tilde{A}'t}\| \leqq \alpha\, e^{(-\beta + \alpha\|\delta_{\tilde{A}}\|)t} \leqq \alpha\, e^{-\beta t/2}.$$

Hence, $N \subset \mathscr{A}$, as desired. □

LEMMA 4.6. *There exists $c > 0$ such that*

$$\|\delta_{\tilde{Q}}\| \leqq c\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|, \tag{4.15}$$

$$\|\delta_{\tilde{P}}\| \leqq c\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|, \tag{4.16}$$

for all $(A_c', B_c', C_c') \in N$, where $N \subset \mathscr{A}$ is the open neighborhood of (A_c, B_c, C_c) defined by (4.14).

Proof. We consider (4.15) only. Since $\|e^{\tilde{A}'t}\| \leqq \alpha e^{-\beta t/2}$, $t \geqq 0$, $(A_c', B_c', C_c') \in N$, it follows that

$$\begin{aligned} \|\delta_{\tilde{Q}}\| &\leqq \int_0^\infty \|e^{\tilde{A}'t}\tilde{V}'e^{\tilde{A}'^*t} - e^{\tilde{A}t}\tilde{V}e^{\tilde{A}^*t}\|\, dt \\ &\leqq \int_0^\infty \{\|e^{\tilde{A}'t}\|\,\|\tilde{V}'\|\,\|e^{\tilde{A}'^*t} - e^{\tilde{A}^*t}\| + \|e^{\tilde{A}'t}\|\,\|\delta_{\tilde{V}}\|\,\|e^{\tilde{A}^*t}\| + \|e^{\tilde{A}'t} - e^{\tilde{A}t}\|\,\|\tilde{V}\|\,\|e^{\tilde{A}^*t}\|\}\, dt \\ &\leqq \alpha(\|\tilde{V}\| + \|\delta_{\tilde{V}}\|) \int_0^\infty \|e^{(\tilde{A}^* + \delta_{\tilde{A}}^*)t} - e^{\tilde{A}^*t}\|\, e^{-\beta t/2}\, dt \qquad (4.17) \\ &\quad + \alpha^2\|\delta_{\tilde{V}}\| \int_0^\infty e^{-3\beta t/2}\, dt + \alpha\|\tilde{V}\| \int_0^\infty \|e^{(\tilde{A} + \delta_{\tilde{A}})t} - e^{\tilde{A}t}\|\, e^{-\beta t/2}\, dt \\ &= \alpha(2\|\tilde{V}\| + \|\delta_{\tilde{V}}\|) \int_0^\infty \|e^{(\tilde{A} + \delta_{\tilde{A}})t} - e^{\tilde{A}t}\| e^{-\beta t/2}\, dt + \frac{2\alpha^2}{3\beta}\|\delta_{\tilde{V}}\|. \end{aligned}$$

From [50, p. 497], it follows that the perturbed semigroup $e^{(\tilde{A} + \delta_{\tilde{A}})t}$ has an expansion

$$e^{(\tilde{A} + \delta_{\tilde{A}})t} = e^{\tilde{A}t} + \sum_{i=1}^{\infty} U_i(t), \qquad t \geqq 0,$$

where $U_i(t) \in \mathcal{B}(\tilde{\mathcal{H}})$, $t \geq 0$, satisfy the estimates

$$\|U_i(t)\| \leq \alpha^{i+1} \|\delta_{\tilde{A}}\|^i e^{-\beta t} t^i / i!.$$

Hence, for all $(A_c', B_c', C_c') \in N$,

$$\|e^{(\tilde{A}+\delta_{\tilde{A}})t} - e^{\tilde{A}t}\| \leq \sum_{i=1}^{\infty} \|U_i(t)\| \leq \alpha e^{-\beta t}[e^{\alpha\|\delta_{\tilde{A}}\|t} - 1]. \tag{4.18}$$

From (4.17), (4.18) and the relations $\|\delta_{\tilde{A}}\| \leq \gamma\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\| < \beta/2\alpha$ and

$$\int_0^{\infty} [e^{\alpha\|\delta_{\tilde{A}}\|t} - 1]\, e^{-3\beta t/2}\, dt < \frac{\alpha\gamma}{3\beta^2} \|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|$$

it follows that

$$\|\delta_{\tilde{Q}}\| \leq \frac{2\alpha^3\gamma}{3\beta^2}(2\|\tilde{V}\| + \|\delta_{\tilde{V}}\|)\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|$$

$$+ \frac{2\alpha^2}{3\beta}(2\|B_c V_2\|\, \|\delta_{B_c}\| + \|V_2\|\, \|\delta_{B_c}\|^2),$$

which yields (4.15). □

Since $\tilde{Q}, \tilde{P} \in \mathcal{B}(\tilde{\mathcal{H}})$ we can write

$$\tilde{Q} = \begin{bmatrix} Q_1 & Q_{12} \\ Q_{12}^* & Q_2 \end{bmatrix}, \qquad \tilde{P} = \begin{bmatrix} P_1 & P_{12} \\ P_{12}^* & P_2 \end{bmatrix},$$

where $Q_1 \in \mathcal{B}(\mathcal{H})$, $Q_{12} \in \mathcal{B}(\mathbb{R}^{n_c}, \mathcal{H})$, $Q_2 \in \mathbb{R}^{n_c \times n_c}$ and similarly for P_1, P_{12} and P_2. Note that Q_1, Q_2, P_1 and P_2 are nonnegative definite. Also, define the notation

$$\tilde{P}\tilde{Q} = \begin{bmatrix} Z_1 & Z_{12} \\ Z_{21} & Z_2 \end{bmatrix},$$

where

$$Z_1 \triangleq P_1 Q_1 + P_{12} Q_{12}^*, \qquad Z_{12} \triangleq P_1 Q_{12} + P_{12} Q_2,$$
$$Z_{21} \triangleq P_{12}^* Q_1 + P_2 Q_{12}^*, \qquad Z_2 \triangleq P_{12}^* Q_{12} + P_2 Q_2,$$

and, for $(A_c', B_c', C_c') \in \mathcal{A}$, let

$$\delta_J(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) \triangleq J(A_c', B_c', C_c') - J(A_c, B_c, C_c).$$

LEMMA 4.7. *Let* $(A_c', B_c', C_c') \in \mathcal{A}$. *Then*

$$\delta_J(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) = \mathcal{L}(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) + o(\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|), \tag{4.19}$$

where

$$\mathcal{L}(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) \triangleq 2\,\mathrm{tr}\,[Z_2 \delta_{A_c}] + 2\,\mathrm{tr}\,[(V_2 B_c^T P_2 + C Z_{21}^*)\delta_{B_c}] + 2\,\mathrm{tr}\,[Q_2 C_c^T R_2 + Z_{12}^* B)\delta_{C_c}] \tag{4.20}$$

and

$$\lim_{(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) \to 0} \|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|^{-1} o(\|(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})\|) = 0. \tag{4.21}$$

Proof. Combining (4.8) and (4.10) with (4.6), J can be written as

$$J(A_c, B_c, C_c) = \mathrm{tr}\,[\tilde{Q}\tilde{R} + \tilde{P}\tilde{V}] + \tfrac{1}{2}\,\mathrm{tr}\,[\tilde{Q}\,\mathrm{cl}\,(\tilde{A}^*\tilde{P} + \tilde{P}\tilde{A}) + \tilde{P}\,\mathrm{cl}\,(\tilde{A}\tilde{Q} + \tilde{Q}\tilde{A}^*)],$$

and likewise for (A_c', B_c', C_c'), where "cl" denotes closure (i.e., extension) of a bounded operator to all of $\mathscr{H}$. Now using the identity

$$\operatorname{tr}[\tilde{Q}'\tilde{R}'+\tilde{P}'\tilde{V}']-\operatorname{tr}[\tilde{Q}\tilde{R}+\tilde{P}\tilde{V}]=\operatorname{tr}[\tilde{Q}\delta_{\tilde{R}}+\tilde{P}\delta_{\tilde{V}}]+\operatorname{tr}[\delta_{\tilde{Q}}\tilde{R}'+\delta_{\tilde{P}}\tilde{V}']$$

we can compute

$$\begin{aligned}\delta_J(\delta_{A_c}, \delta_{B_c}, \delta_{C_c}) &= \operatorname{tr}[\tilde{Q}\delta_{\tilde{R}}+\tilde{P}\delta_{\tilde{V}}]+\tfrac{1}{2}\operatorname{tr}[\tilde{Q}\ \operatorname{cl}(\tilde{A}^*(\tilde{P}+\delta_{\tilde{P}})+(\tilde{P}+\delta_{\tilde{P}})\tilde{A}')]\\ &\quad+\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\ \operatorname{cl}(\tilde{A}'^*\tilde{P}'+\tilde{P}'\tilde{A}')]\\ &\quad+\tfrac{1}{2}\operatorname{tr}[\tilde{P}\ \operatorname{cl}(\tilde{A}'(\tilde{Q}+\delta_{\tilde{Q}})+(\tilde{Q}+\delta_{\tilde{Q}})\tilde{A}'^*)]\\ &\quad+\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{P}}\ \operatorname{cl}(\tilde{A}'\tilde{Q}'+\tilde{Q}'\tilde{A}'^*)]\\ &\quad-\tfrac{1}{2}\operatorname{tr}[\tilde{Q}\ \operatorname{cl}(\tilde{A}^*\tilde{P}+\tilde{P}\tilde{A})+\tilde{P}\ \operatorname{cl}(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)]\\ &\quad+\operatorname{tr}[\delta_{\tilde{Q}}\tilde{R}'+\delta_{\tilde{P}}\tilde{V}'].\end{aligned}$$

Using $\tilde{A}'=\tilde{A}+\delta_{\tilde{A}}$ and combining the second, fourth and sixth terms yields

$$\delta_J(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})=\Lambda+\Omega,$$

where

$$\begin{aligned}\Lambda &\triangleq \operatorname{tr}[\tilde{Q}\delta_{\tilde{R}}+\tilde{P}\delta_{\tilde{V}}]+\tfrac{1}{2}\operatorname{tr}[\tilde{Q}(\delta_{\tilde{A}}^*\tilde{P}+\tilde{P}\delta_{\tilde{A}})+\tilde{P}(\delta_{\tilde{A}}\tilde{Q}+\tilde{Q}\delta_{\tilde{A}}^*)]\\ &=\operatorname{tr}[\tilde{Q}\delta_{\tilde{R}}+\tilde{P}\delta_{\tilde{V}}]+2\operatorname{tr}[\delta_{\tilde{A}}\tilde{Q}\tilde{P}]\end{aligned}$$

and

$$\begin{aligned}\Omega &\triangleq \tfrac{1}{2}\operatorname{tr}[\tilde{Q}\ \operatorname{cl}(\tilde{A}'^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A}')+\tilde{P}\ \operatorname{cl}(\tilde{A}'\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\tilde{A}'^*)]\\ &\quad+\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\ \operatorname{cl}(\tilde{A}'^*\tilde{P}'+\tilde{P}'\tilde{A}')+\delta_{\tilde{P}}\ \operatorname{cl}(\tilde{A}'\tilde{Q}'+\tilde{Q}'\tilde{A}'^*)]+\operatorname{tr}[\delta_{\tilde{Q}}\tilde{R}'+\delta_{\tilde{P}}\tilde{V}'].\end{aligned}$$

Computing

$$\operatorname{tr}[\tilde{Q}\delta_{\tilde{R}}+\tilde{P}\delta_{\tilde{V}}]=2\operatorname{tr}[V_2B_c^TP_2\delta_{B_c}]+2\operatorname{tr}[Q_2C_c^TR_2\delta_{C_c}]+\operatorname{tr}[P_2\delta_{B_c}V_2\delta_{B_c}^T+Q_2\delta_{C_c}^TR_2\delta_{C_c}]$$

and

$$2\operatorname{tr}[\delta_{\tilde{A}}\tilde{Q}\tilde{P}]=2\operatorname{tr}[Z_2\delta_{A_c}]+2\operatorname{tr}[CZ_{21}^*\delta_{B_c}]+2\operatorname{tr}[Z_{12}^*B\delta_{C_c}]$$

and retaining first-order terms, we obtain (4.20).

To evaluate Ω, use (4.8) and (4.10) to replace $\tilde{R}'$ and $\tilde{V}'$ in the last term in Ω and write $\tilde{A}'=\tilde{A}+\delta_{\tilde{A}}$, to obtain

$$\begin{aligned}\Omega &= \tfrac{1}{2}\operatorname{tr}[\tilde{Q}\ \operatorname{cl}(\tilde{A}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A})+\tilde{P}\ \operatorname{cl}(\tilde{A}\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\tilde{A}^*)]\\ &\quad+\tfrac{1}{2}\operatorname{tr}[\tilde{Q}(\delta_{\tilde{A}}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\delta_{\tilde{A}})+\tilde{P}(\delta_{\tilde{A}}\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\delta_{\tilde{A}}^*)]\\ &\quad-\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\ \operatorname{cl}(\tilde{A}'^*\tilde{P}'+\tilde{P}'\tilde{A}')+\delta_{\tilde{P}}\ \operatorname{cl}(\tilde{A}'\tilde{Q}'+\tilde{Q}'\tilde{A}'^*)].\end{aligned}\tag{4.22}$$

Next we note that

$$\operatorname{tr}[\tilde{Q}\ \operatorname{cl}(\tilde{A}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A}^*)]=\operatorname{tr}[\delta_{\tilde{P}}\ \operatorname{cl}(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)].\tag{4.23}$$

To see this we observe that by arguments similar to those used in the proof of Lemma 4.4 and the fact that $\delta_{\tilde{P}}\colon \mathscr{D}(\tilde{A})\to\mathscr{D}(\tilde{A}^*)$ it follows that

$$\delta_{\tilde{P}}=-\int_0^\infty e^{\tilde{A}^*t}\ \operatorname{cl}(\tilde{A}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A})\ e^{\tilde{A}t}\,dt.$$

Now, using the technique of Lemma 4.3 with the role of $\tilde{R}$ played by $-\operatorname{cl}(\tilde{A}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A})$,

we see that

$$\operatorname{tr}[\tilde{Q}\,\mathrm{cl}\,(\tilde{A}^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A})]=-\operatorname{tr}[\delta_{\tilde{P}}\tilde{V}]=\operatorname{tr}[\delta_{\tilde{P}}\,\mathrm{cl}\,(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)].$$

Similarly, it can be shown that

$$\operatorname{tr}[\tilde{P}\,\mathrm{cl}\,(\tilde{A}\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\tilde{A}^*)]=\operatorname{tr}[\delta_{\tilde{Q}}\,\mathrm{cl}\,(\tilde{A}^*\tilde{P}+\tilde{P}\tilde{A})]. \tag{4.24}$$

Now substitute (4.23) and (4.24) into (4.22) and rearrange the second term in (4.22) so that

$$\begin{aligned}\Omega&=\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\,\mathrm{cl}\,(\tilde{A}^*\tilde{P}+\tilde{P}\tilde{A})+\delta_{\tilde{P}}\,\mathrm{cl}\,(\tilde{A}\tilde{Q}+\tilde{Q}\tilde{A}^*)]\\&\quad+\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}(\delta_{\tilde{A}}^*\tilde{P}+\tilde{P}\delta_{\tilde{A}})+\delta_{\tilde{P}}(\delta_{\tilde{A}}\tilde{Q}+\tilde{Q}\delta_{\tilde{A}}^*)]\\&\quad-\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\,\mathrm{cl}\,(\tilde{A}'^*\tilde{P}'+\tilde{P}'\tilde{A}')+\delta_{\tilde{P}}\,\mathrm{cl}\,(\tilde{A}'\tilde{Q}'+\tilde{Q}'\tilde{A}'^*)]\\&=-\tfrac{1}{2}\operatorname{tr}[\delta_{\tilde{Q}}\,\mathrm{cl}\,(\tilde{A}'^*\delta_{\tilde{P}}+\delta_{\tilde{P}}\tilde{A}')+\delta_{\tilde{P}}\,\mathrm{cl}\,(\tilde{A}'\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\tilde{A}'^*)].\end{aligned}$$

Using (4.8) to obtain

$$0=\tilde{A}'\delta_{\tilde{Q}}+\delta_{\tilde{Q}}\tilde{A}'^*+\delta_{\tilde{A}}\tilde{Q}+\tilde{Q}\delta_{\tilde{A}}^*+\delta_{\tilde{V}}$$

and (4.10) to obtain a similar relation involving $\tilde{P}$, we have

$$\Omega=\operatorname{tr}[\delta_{\tilde{Q}}(\delta_{\tilde{A}}^*\tilde{P}+\tilde{P}\delta_{\tilde{A}}+\delta_{\tilde{R}})]+\operatorname{tr}[\delta_{\tilde{P}}\tilde{Q}+\tilde{Q}\delta_{\tilde{A}}^*+\delta_{\tilde{V}})].$$

Restricting (A_c', B_c', C_c') to N (see (4.14)), using Lemma 4.6 and noting that $\delta_{\tilde{A}}$ and $\delta_{\tilde{R}}$ have finite rank, it follows that there exists $c_1>0$ such that

$$\|\Omega\|\leqq c_1\|(\delta_{A_c},\delta_{B_c},\delta_{C_c})\|^2. \tag{4.25}$$

Combining Ω with the second-order terms in Λ yields the desired result. □

LEMMA 4.8. $\mathscr{A}_+$ is open.

Proof. From the "generic" property of controllability and observability [62, p. 44] there exists an open neighborhood of (A_c, B_c, C_c) each of whose elements is minimal. Combining this fact with Lemma 4.5 yields the desired result. □

LEMMA 4.9. *Q_2 and P_2 are positive definite.*

Proof. First note that expanding the $\mathbb{R}^{n_c\times n_c}$-component of the Lyapunov equation (4.8) yields (4.50) below. By a minor extension of results from [66] or [67], (4.50) can be rewritten as

$$0=(A_c+B_cCQ_{12}Q_2^+)Q_2+Q_2(A_c+B_cCQ_{12}Q_2^+)^T+B_cV_2B_c^T,$$

where Q_2^+ is the Moore-Penrose or Drazin generalized inverse of Q_2. Next note that since (A_c, B_c) is controllable then so is $(A_c+B_cCQ_{12}Q_2^+, B_cV_2^{1/2})$. Now, since Q_2 and $B_cV_2B_c^T$ are nonnegative definite, it follows from [62, Lemma 12.2] that Q_2 is positive definite. Similar arguments show that P_2 is positive definite. □

Having established Lemmas 4.1-4.9, we can now proceed with the proof of the Main Theorem. Let $(A_c, B_c, C_c)\in\mathscr{A}_+$ be as in the Main Theorem and consider (4.19) with (A_c', B_c', C_c') confined to $\mathscr{A}_+$. Because $\mathscr{L}\colon \mathbb{R}^{n_c\times n_c}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c}\to\mathbb{R}$ is a bounded linear functional and $\mathscr{A}_+$ is open, the convergence in (4.21) implies that $\mathscr{L}$ is precisely the Frechet derivative of J with respect to (A_c, B_c, C_c). Since $\mathscr{A}_+$ is open, the optimality of (A_c, B_c, C_c) implies

$$\mathscr{L}(\delta_{A_c},\delta_{B_c},\delta_{C_c})=0 \tag{4.26}$$

for all $(\delta_{A_c}, \delta_{B_c}, \delta_{C_c})$. Clearly, (4.26) is equivalent to

$$Z_2=0, \tag{4.27}$$

(4.28) $$V_2 B_c^T P_2 + C Z_{21}^* = 0,$$

(4.29) $$Q_2 C_c^T R_2 + Z_{12}^* B = 0.$$

Thus, B_c and C_c are given by

(4.30) $$B_c = -P_2^{-1} Z_{21} C^* V_2^{-1},$$

(4.31) $$C_c = -R_2^{-1} B^* Z_{12} Q_2^{-1}.$$

Although B_c and C_c are now determined in terms of $\tilde{Q}$ and $\tilde{P}$, A_c remains to be found. Moreover, $\tilde{Q}$ and $\tilde{P}$ themselves depend (via (4.8) and (4.10)) on B_c and C_c. Hence our task now is to consolidate and simplify (4.7)-(4.10), (4.27), (4.30) and (4.31) to obtain the more tractable conditions (3.9)-(3.18). To this end let us define new variables

(4.32a, b) $$Q \triangleq Q_1 - Q_{12} Q_2^{-1} Q_{12}^*, \qquad P \triangleq P_1 - P_{12} P_2^{-1} P_{12}^*,$$

(4.33a, b) $$\hat{Q} \triangleq Q_{12} Q_2^{-1} Q_{12}^*, \qquad \hat{P} \triangleq P_{12} P_2^{-1} P_{12}^*.$$

Clearly, $\hat{Q}$ and $\hat{P}$ are nonnegative definite and have finite rank. Since by Lemma 4.2 $\tilde{Q}, \tilde{P} \in \mathscr{B}_1(\tilde{\mathscr{H}})$, it can be seen that $Q_1, P_1 \in \mathscr{B}_1(\mathscr{H})$, which implies $Q, P \in \mathscr{B}_1(\mathscr{H})$. To show that Q and P are nonnegative definite, note that Q is the $\mathscr{B}(\mathscr{H})$-component of the nonnegative-definite operator $\mathscr{Q}\tilde{Q}\mathscr{Q}^* \in \mathscr{B}(\tilde{\mathscr{H}})$, where

$$\mathscr{Q} \triangleq \begin{bmatrix} I_{\mathscr{H}} & -Q_{12} Q_2^{-1} \\ 0 & -I_{n_c} \end{bmatrix}.$$

Similarly, P is nonnegative definite.

From the domain conditions (4.7) and (4.9) it follows that

(4.34a, b) $$Q_1 : \mathscr{D}(A^*) \to \mathscr{D}(A), \qquad P_1 : \mathscr{D}(A) \to \mathscr{D}(A^*),$$

(4.35a, b) $$Q_{12} : \mathbb{R}^{n_c} \to \mathscr{D}(A), \qquad P_{12} : \mathbb{R}^{n_c} \to \mathscr{D}(A^*),$$

which lead to (3.12) and (3.13).

Next note that (4.27) is equivalent to (3.8) with

(4.36a, b) $$G \triangleq Q_2^{-1} Q_{12}^*, \qquad \Gamma \triangleq -P_2^{-1} P_{12}^*$$

and that (3.7) holds with

(4.37) $$M \triangleq Q_2 P_2.$$

Since Q_2 and P_2 are positive definite, Lemma 2.6 implies that M is positive semisimple. We can also define $\tau = G^* \Gamma$ which, by (3.8) satisfies $\tau^2 = \tau$. It is helpful to note the identities

(4.38a, b) $$\hat{Q} = Q_{12} G = G^* Q_{12}^*, \qquad \hat{P} = -P_{12} \Gamma = -\Gamma^* P_{12}^*,$$

(4.39a, b) $$\hat{Q} = G^* Q_2 G, \qquad \hat{P} = \Gamma^* P_2 \Gamma,$$

(4.40a, b) $$\tau G^* = G^*, \qquad \Gamma \tau = \Gamma,$$

(4.41a, b) $$\hat{Q} = \tau \hat{Q}, \qquad \hat{P} = \hat{P} \tau,$$

(4.42) $$\hat{Q} \hat{P} = -Q_{12} P_{12}^*.$$

From (3.8) and (2.1) it follows that

(4.43a, b) $$\rho(G) = \rho(\Gamma) = n_c,$$

(4.44a, b) $$\rho(Q_{12}) = \rho(P_{12}) = n_c.$$

Hence, (2.2) and (4.38) imply $n_c = \rho(Q_{12}) + \rho(G) - n_c \leqq \rho(\hat{Q}) \leqq \rho(Q_{12}) = n_c$, which yields (3.14a). Similarly, (3.14b) holds and (3.14c) follows from (2.2) and (4.42).

Using (4.38) and (4.39), the components of $\tilde{Q}$ and $\tilde{P}$ can be written in terms of G, Γ, Q, P, $\hat{Q}$ and $\hat{P}$ as

$$Q_1 = Q + \hat{Q}, \qquad P_1 = P + \hat{P}, \tag{4.45}$$

$$Q_{12} = \hat{Q}\Gamma^*, \qquad P_{12} = -\hat{P}G^*, \tag{4.46}$$

$$Q_2 = \Gamma\hat{Q}\Gamma^*, \qquad P_2 = G\hat{P}G^*. \tag{4.47}$$

Now (3.10) and (3.11) can be obtained by substituting (4.45)-(4.47) into (4.30) and (4.31).

Expanding the $\mathscr{B}(\mathscr{H})$, $\mathscr{B}(\mathbb{R}^{n_c}, \mathscr{H})$ and $\mathbb{R}^{n_c \times n_c}$ components of (4.8) and (4.10) yields

$$0 = AQ_1 + Q_1A^* + BC_cQ_{12}^* + Q_{12}(BC_c)^* + V_1, \tag{4.48}$$

$$0 = AQ_{12} + Q_{12}A_c^T + BC_cQ_2 + Q_1(B_cC)^*, \tag{4.49}$$

$$0 = A_cQ_2 + Q_2A_c^T + B_cCQ_{12} + Q_{12}^*(B_cC)^* + B_cV_2B_c^T, \tag{4.50}$$

$$0 = A^*P_1 + P_1A + (B_cC)^*P_{12}^* + P_{12}B_cC + R_1, \tag{4.51}$$

$$0 = P_{12}A_c + A^*P_{12} + (B_cC)^*P_2 + P_1BC_c, \tag{4.52}$$

$$0 = A_c^TP_2 + P_2A_c + (BC_c)^*P_{12} + P_{12}^*BC_c + C_c^TR_2C_c. \tag{4.53}$$

Substituting (4.45)-(4.47) into (4.48)-(4.53), using the identities

$$B_cC = \Gamma Q\bar{\Sigma}, \qquad BC_c = -\Sigma PG^*,$$

$$B_cV_2B_c^T = \Gamma Q\bar{\Sigma}Q\Gamma^*, \qquad C_c^TR_2C_c = GP\Sigma PG^*,$$

and defining

$$A_Q \triangleq A - Q\bar{\Sigma}, \qquad A_P \triangleq A - \Sigma P,$$

we obtain

$$0 = AQ + QA^* + A_P\hat{Q} + \hat{Q}A_P + V_1, \tag{4.54}$$

$$0 = [A_P\hat{Q} + Q\bar{\Sigma}Q + \hat{Q}(\Gamma^*A_c^TG + \bar{\Sigma}Q)]\Gamma^*, \tag{4.55}$$

$$0 = \Gamma[G^*A_c\Gamma\hat{Q} + Q\bar{\Sigma}\hat{Q} + Q\bar{\Sigma}Q + \hat{Q}(\Gamma^*A_c^TG + \bar{\Sigma}Q)]\Gamma^*, \tag{4.56}$$

$$0 = A^*P + PA + A_Q^*\hat{P} + \hat{P}A_Q + R_1, \tag{4.57}$$

$$0 = -[A_Q^*\hat{P} + P\Sigma P + \hat{P}(G^*A_c\Gamma + \Sigma P)]G^*, \tag{4.58}$$

$$0 = G[\Gamma^*A_c^TG\hat{P} + P\Sigma\hat{P} + P\Sigma P + \hat{P}(G^*A_c\Gamma + \Sigma P)]G^*. \tag{4.59}$$

We are now in a position to determine A_c by computing (4.56) $-\Gamma$(4.55) which yields (3.9). Alternatively, A_c can be obtained by computing (4.59) $+ G$(4.58). As mentioned in § 3, (3.9) is valid since $G^*: \mathbb{R}^{n_c} \to \mathscr{D}(A)$ and A_c^T is given by (3.26).

Next we substitute the expressions for A_c and A_c^T into (4.55), (4.56), (4.58) and (4.59) and compute the relations (4.55)G, G^*(4.56)G, $-$(4.58)Γ and Γ^*(4.59)Γ to obtain, respectively,

$$0 = [A_P\hat{Q} + \hat{Q}A_P^* + Q\bar{\Sigma}Q]\tau^*, \tag{4.60}$$

$$0 = \tau[A_P\hat{Q} + \hat{Q}A_P^* + Q\bar{\Sigma}Q]\tau^*, \tag{4.61}$$

$$0 = [A_Q^*\hat{P} + \hat{P}A_Q + P\Sigma P]\tau, \tag{4.62}$$

$$0 = \tau^*[A_Q^*\hat{P} + \hat{P}A_Q + P\Sigma P]\tau. \tag{4.63}$$

Note that (4.60)-(4.63) are *equivalent* to (4.55), (4.56), (4.58) and (4.59) since G and Γ have full rank. Since $(4.61) = \tau(4.60)$ and $(4.63) = \tau^*(4.62)$, (4.61) and (4.63) are superfluous and can be omitted. Thus we have derived (3.17) and (3.18).

To obtain (3.15) and (3.16) we need only compute the relations $(4.54) + \tau(4.60) - (4.60) - (4.60)^*$ and $(4.57) + \tau^*(4.62) - (4.62) - (4.62)^*$ and use (4.41).

Finally, to show that the preceding development entails no loss of generality in the optimality conditions we now use (3.9)-(3.18) to obtain (4.7)-(4.10) and (4.27)-(4.29). Let A_c, B_c, C_c, G, Γ, τ, Q, P, $\hat{Q}$, $\hat{P}$ be as in the theorem statement and define Q_1, Q_{12}, Q_2, P_1, P_{12}, P_2 by (4.45)-(4.47). Note that (3.12) and (3.13) imply (4.34) and (4.35) and hence (4.7) and (4.9). Using (3.8), (3.10), (3.11) and (3.22) it is easy to verify (4.27)-(4.29). Finally, substitute (4.32), (4.33) and (4.36) into (3.15)-(3.18), reverse the steps taken earlier in the proof and use (3.9)-(3.11) to obtain (4.8) and (4.10), which completes the proof. □

5. Concluding remarks. This paper has considered the problem of quadratically optimal, steady-state, fixed-order dynamic compensation for linear infinite-dimensional systems. The Main Theorem presents the stationarity conditions of the optimization problem in a highly simplified and rigorous form. The "optimal projection equations" (3.15)-(3.18) (or, equivalently, (3.27)-(3.30)) of the Main Theorem reveal the essential structure of the first-order necessary conditions and display the central role played by the optimal projection τ. The relationship of the Main Theorem to the standard finite-dimensional steady-state *LQG* problem can be demonstrated by replacing τ with the identity matrix and noting that (3.27) and (3.28) reduce immediately to the familiar pair of operator Riccati equations and that (3.29) and (3.30) yield the controllability and observability gramians of the controller.

Inasmuch as the Main Theorem is a fundamental generalization of classical steady-state *LQG* theory, a number of issues must be reexamined. Hence, in conclusion we should like to point out some possible extensions of the Main Theorem along with directions for further research.

1. *Sufficiency theory.* Although sufficient conditions for the existence of an optimal compensator were not investigated in this paper, auxiliary conditions based upon the structure of (3.15)-(3.18) could perhaps be imposed upon Q, P, $\hat{Q}$ and $\hat{P}$ to single out the global optimum from amongst the local minima. This would be similar to the situation in *LQG* theory where, under stabilizability and detectability hypotheses, optimal stabilizing Q and P are identified as the unique nonnegative-definite solutions of the pair of algebraic Riccati equations.

2. *Stabilizability.* Just as in the full-order *LQG* problem, one would expect a natural relationship between the structure of the optimal solution and stabilizability/detectability hypotheses. The results of [41], [42] and [68] could serve as a starting point in this regard.

3. *Numerical algorithms.* In practical situations, the distributed parameter system would be replaced by a high-order discretized model for which the matrix version (rather than the operator version) of the optimal projection equations could be solved numerically. A numerical algorithm for solving the matrix version of the optimal projection equations has been developed in [32] and [34]. The proposed computational scheme is fundamentally quite different from gradient search algorithms [17], [18], [21], [22], [24], [25], [28], [30] in that it operates through direct solution of the optimal projection equations by iterative refinement of the optimal projection.

4. *Convergence.* One of the principal uses for the optimal projection equations will be to understand the relationship between fixed-order dynamic-compensator

designs which are optimal with respect to approximate models and the optimal fixed-order dynamic compensator for the distributed parameter system itself. By considering a sequence of nth-order approximate models which converge to the distributed parameter system, conditions would be sought guaranteeing that the sequence of fixed-order compensators based on each approximate model approach the optimal dynamic compensator based upon the distributed parameter system (see [38]-[40]). This approach is analogous to the convergence results obtained in [7], [8] with the major difference being that the optimal projection equations permit the order of the compensator to remain fixed in accordance with real-world implementation constraints whereas in [7]-[9] the order of the compensator increases without bound.

5. *Unbounded control and observation.* An important generalization of the problem considered in this paper involves the case in which the input and output operators B and C are unbounded. The mathematical details for this problem are considerably more complex (see, e.g., [69]).

6. Singular observation noise/singular control weighting. As pointed out in [22], [33], [36] the assumptions of nonsingular control weighting and nonsingular observation noise preclude the use of direct output feedback as in

$$u(t) = C_c x_c(t) + D_c y(t) \tag{5.1}$$

since J is undefined unless

$$\operatorname{tr}[D_c^T R_2 D_c V_2] = 0 (\Leftrightarrow R_2 D_c V_2 = 0).$$

Although with due attention to (5.1) direct output feedback can be used in the singular case, the nature of the problem forebodes all of the difficulties associated with the singular *LQG* problem. Note that the deterministic output feedback problem [70], when viewed in this context, is highly singular.

7. *Discrete-time system/discrete-time compensator.* Digital implementation can be modelled by a discrete-time compensator with control of a continuous-time system facilitated by sampling and reconstruction devices. See [71], [73] for results in this direction.

8. *Cross weighting/correlated disturbance and observation noise.* This extension is straightforward and entirely analogous to the *LQG* case (see, e.g., [18, p. 351]).

Acknowledgments. We wish to thank Ardeth P. Grant for excellent and careful typing of the original manuscript version of this paper. Word processing and revision support was provided by Harris Corporation, GASD.

AN EXAMPLE ON THE EFFECT OF TIME DELAYS IN BOUNDARY FEEDBACK STABILIZATION OF WAVE EQUATIONS*

R. DATKO†, J. LAGNESE†‡ AND M. P. POLIS§‡

Abstract. This note is concerned with the effect of time delays in boundary feedback stabilization schemes for wave equations. The question to be addressed is whether such delays can destabilize a system which is uniformly asymptotically stable in the absence of delays.

Key words. boundary stabilization, delay systems

AMS(MOS) subject classification. 93D15

This note is concerned with the effect of time delays in boundary feedback stabilization schemes for wave equations. The question to be addressed is whether such delays can destabilize a system which is uniformly asymptotically stable in the absence of delays. It will be shown by example that for "almost" arbitrary delays such destabilization can indeed occur in certain otherwise stable boundary feedback schemes for both undamped and damped wave equations. Although the examples involve only one spatial dimension, it is to be expected that a similar phenomenon occurs in higher dimensions. This suggests that certain boundary stabilization schemes which have been proposed for various classes of hyperbolic systems [1]-[2], [5]-[7] may not be robust to the small delays which might well occur in computing feedback controls.

Consider the equation

$$u_{tt} - u_{xx} + 2au_t + a^2u = 0, \qquad 0 < x < 1, \quad t > 0, \tag{1}$$

with boundary conditions

$$u(0, t) = 0, \qquad t > 0, \tag{2}$$

$$u_x(1, t) = -ku_t(1, t), \qquad t > 0, \tag{3}$$

where $a \geqq 0$ and $k \geqq 0$. The question to be treated is the effect on the stability of (1)-(3) of a time delay in the right side of (3) when $k > 0$. If $k = 0$ and $a > 0$ Datko [3] has shown that the system (1)-(3) will be destabilized by a time delay in the velocity term of (1).

When $a > 0$, (1) contains both viscous damping and a restoring force proportional to displacement. If $k > 0$, (3) represents boundary damping in the system. It is known that (1)-(3) is uniformly asymptotically stable as long as $a^2 + k^2 > 0$ (see e.g. [1]) and that

$$E(u, t) \leqq C e^{-\alpha t} E(u, 0) \tag{4}$$

for some positive constant α, where E is the usual energy functional for (1) defined by

$$E(u, t) = \int_0^1 (u_t^2 + u_x^2 + a^2u^2)\, dx.$$

A necessary condition for (4) is that spectrum of (1)-(3) lie in a half-plane $\operatorname{Re}\omega \leqq \text{Const.} < 0$. The spectrum can be exhibited by setting $u = e^{\omega t}\phi(x)$. The eigenvalues ω and eigenfunctions ϕ are then determined by the problem

$$\phi''(x) - (a+\omega)^2\phi(x) = 0, \qquad 0 < x < 1, \tag{5}$$

$$\phi(0) = 0, \qquad \phi'(1) + k\omega\phi(1) = 0. \tag{6}$$

From (5), (6), the eigenvalues are the solutions of

$$e^{2(\omega+a)} = \frac{(k-1)\omega - a}{(k+1)\omega + a}. \tag{7}$$

If $a = 0$ and $k \neq 1$, (7) can be solved explicitly to yield

$$\operatorname{Re}\omega = \frac{1}{2}\log\left|\frac{k-1}{k+1}\right| < 0.$$

When $a = 0$ and $k = 1$, all solutions of (1)-(3) can be shown to vanish identically for $t > 2$. When $a \neq 0$ the solutions ω_n of (7) can be shown to lie in a half-plane $\operatorname{Re}\omega \leqq \alpha < 0$ and to satisfy $|\operatorname{Im}\omega_n| \to +\infty$.

Now let $\varepsilon > 0$ and suppose the boundary condition (3) is replaced by

$$u_x(1, t) = -ku_t(1, t-\varepsilon), \qquad t > \varepsilon. \tag{8}$$

The following result will be established.

THEOREM. *Let $K = e^{-2a}$. The system* (1), (2), (8) *has the following stability properties*:

(i) *If $0 < k < (1-K)/(1+K)$, for each $\varepsilon > 0$ there exists $\beta(\varepsilon) > 0$ such that the spectrum of the system lies in* $\operatorname{Re}\omega \leqq -\beta$.

(ii) *If $k = (1-K)/(1+K)$, for each $\varepsilon > 0$ the spectrum lies in* $\operatorname{Re}\omega < 0$, *but there is a countably dense set R in $(0, \infty)$ such that for each ε in R there is a sequence $\{\omega_n\}$ in the spectrum such that*

$$\lim_{n\to\infty} \operatorname{Re}\omega_n = 0.$$

(iii) *If $k > (1-K)/(1+K)$, there is dense open set D in $(0, \infty)$ such that for each ε in D the system admits exponentially unstable solutions.*

To prove the theorem, two lemmas will be needed. The first lemma is a special case of [4, Lemma 2.3].

LEMMA 1. *Let*

$$\begin{aligned} h(\varepsilon, \omega) &= \omega[1 + K e^{-2\omega} + k e^{-\varepsilon\omega}(1 - K e^{-2\omega})] + a(1 + K e^{-2\omega}) \\ &= \omega f(\varepsilon, \omega) + a(1 + K e^{-2\omega}). \end{aligned} \tag{9}$$

If, for fixed ε, $f(\varepsilon, \omega)$ has a zero at $\omega_0 = \xi_0 + i\eta_0$, then for any $\delta > 0$ the vertical strip $\{\omega: \xi_0 - \delta < \operatorname{Re}\omega < \xi_0 + \delta\}$ has an infinite number of zeros of both $f(\varepsilon, \omega)$ and $h(\varepsilon, \omega)$.

LEMMA 2. *Let $K = e^{-2a}$ and $k > (1-K)/(1+K)$. Then there exists for each such k an open dense set, $\mathcal{D}$, in $(0, \infty)$ such that for every ε in $\mathcal{D}$, $f(\varepsilon, \omega) = 0$ has at least one solution with* $\operatorname{Re}\omega > 0$.

Proof of Lemma 2. Let K and k satisfying the hypotheses of the lemma be fixed. Consider the mapping from the complex ω-plane into the complex ε-plane defined implicitly by

$$k = \frac{1 + K e^{-2\omega}}{K e^{-2\omega} - 1} e^{\varepsilon\omega}. \tag{10}$$

For $\omega \neq 0$ solutions of equation (10) can be found among the infinite family of meromorphic functions given by the equations

$$\varepsilon = \frac{1}{\omega}\left[\log k + \log\left(\frac{K e^{-2\omega} - 1}{K e^{-2\omega} + 1}\right) + 2m\pi i\right], \tag{11}$$

where log is the principal value of the logarithm (see e.g. [9]) and m is a positive integer.

Now let n be a fixed positive integer and

$$\omega = \omega_1 + \frac{(2n+1)}{2}\pi i, \qquad \omega_1 > 0. \tag{12}$$

Then ε in (11) has the form

$$\varepsilon = \frac{\log k + \log\left((K e^{-2\omega_1} + 1)/(1 - K e^{-2\omega_1})\right) + (2m+1)\pi i}{\omega_1 + ((2n+1)/2)\pi i}. \tag{13}$$

When ω_1 satisfies the equation

$$\omega_1 = \frac{2n+1}{2(2m+1)}\left[\log k + \log\left(\frac{K e^{-2\omega_1} + 1}{1 - K e^{-2\omega_1}}\right)\right], \tag{14}$$

equation (13) satisfies

$$\varepsilon = \frac{2(2m+1)}{2n+1}. \tag{15}$$

Equation (14) always has a solution for some $\omega_1 > 0$. To see this, notice that because $k > (1-K)/(1+K)$ the right side of (14) is positive for $\omega_1 = 0$ and as ω_1 tends to infinity the right side tends to $(2n+1)/(2(2m+1)) \log k$.

Next observe that points of the form (15) are dense on $(0, \infty)$. Furthermore because of the open mapping property of meromorphic functions (see e.g. [9, p. 116] about each point of the form (15) there is an open interval, with $2(2m+1)/(2n+1)$ as its center which is contained in the image, under the mapping (11), of some open ball in $\operatorname{Re} \omega > 0$. This completes the proof of the lemma.

Remark. It is tempting, and indeed it is probably correct, to state that the dense set $\mathcal{D}$ in Lemma 2 is $(0, \infty)$. However the proof of the lemma does not justify this statement.

Proof of the theorem. The spectrum of (1), (2), (8) is determined by the eigenvalue problem consisting of equation (5) together with the boundary condition $\phi(0) = 0$, $\phi'(1) + k\omega e^{-\varepsilon\omega}\phi(1) = 0$. The equation for the eigenvalues is therefore obtained by replacing k in (7) by $k e^{-\varepsilon\omega}$. The result is equivalent to

$$h(\varepsilon, \omega) = 0 \tag{16}$$

where h is defined by (9) and $K = e^{-2a}$.

(i) Suppose $k \leqq (1-K)/(1+K)$ and $\varepsilon > 0$. Since $\omega = 0$ is not a solution of (16), that equation can be rewritten as

$$1 = k e^{-\varepsilon\omega}\frac{K e^{-2\omega} - 1}{K e^{-2\omega} + 1} - \frac{a}{\omega}. \tag{17}$$

If (17) has a solution $\omega = \xi + i\eta$ with $\xi > 0$, then

$$1 = k \operatorname{Re}\left[e^{-\varepsilon\omega}\frac{K e^{-2\omega} - 1}{K e^{-2\omega} + 1}\right] - \frac{a\xi}{\xi^2 + \eta^2} < k\frac{1 + K e^{-2\xi}}{1 - K e^{-2\xi}} < k\frac{1+K}{1-K} \leqq 1 \tag{18}$$

which is a contradiction. Thus (16) has no solution with $\operatorname{Re}\omega > 0$, for any $\varepsilon > 0$, provided $k \leqq (1-K)/(1+K)$. Also, if $k < (1-K)/(1+K)$ the string of inequalities in (18) again leads to a contradiction whenever $\xi = \operatorname{Re}\omega \geqq 0$, so that all zeros of (16) must satisfy $\operatorname{Re}\omega < 0$ when $k < (1-K)/(1+K)$. Moreover, in this case it is not possible for a sequence of such zeros to accumulate at the imaginary axis. For suppose there were a sequence $\omega_n = \xi_n + i\eta_n$ of zeros such that $\lim \xi_n = 0$, $\underline{\lim}\,|\eta_n| > 0$. From (17)

$$1 \leqq \overline{\lim}\left\{k \operatorname{Re}\left[e^{-\varepsilon\omega_n}\frac{K e^{-2\omega_n}-1}{K e^{-2\omega_n}+1}\right] - \frac{a\xi_n}{\xi_n^2+\eta_n^2}\right\}$$

$$\leqq \lim k\frac{1+K e^{-2\xi_n}}{1-K e^{-2\xi_n}} = k\frac{1+K}{1-K} < 1,$$

a contradiction. Thus for $\varepsilon > 0$ and $k < (1-K)/(1+K)$, the spectrum of (1), (2), (8) must lie in a half-plane $\operatorname{Re}\omega \leqq -\beta$, $\beta > 0$.

(ii) From the proof of (i), if $k = (1-K)/(1+K)$ and $\varepsilon > 0$ the spectrum lies in $\operatorname{Re}\omega \leqq 0$. If (16) has a zero $\omega = i\eta$, $\eta \neq 0$, then from (17)

$$1 + \frac{a}{i\eta} = k e^{-i\varepsilon\eta}\left(\frac{K e^{-2i\eta}-1}{K e^{-2i\eta}+1}\right). \tag{19}$$

Taking the modulus of each side of (19) results in the contradiction

$$1 + \frac{a^2}{\eta^2} = k^2\frac{1+K^2-2K\cos 2\eta}{1+K^2+2K\cos 2\eta} \leqq k^2\left(\frac{1+K}{1-K}\right)^2 = 1.$$

However, it is easily seen that

$$f\left(\frac{2(2m+1)}{2n+1}, \frac{(2n+1)\pi i}{2}\right) = 0$$

where f is defined in (9) and m, n are arbitrary. Thus, by Lemma 1, given any $\delta > 0$ the vertical strip $\{\omega: -\delta < \operatorname{Re}\omega < 0\}$ contains an infinite number of points of the spectrum of (1), (2), (8).

(iii) Let $k > (1-K)/(1+K)$. By Lemmas 1 and 2 it follows that for each such k there is an open dense set, $\mathcal{D}$, in $(0, \infty)$ such that (16) is satisfied for each ε in $\mathcal{D}$ and some ω with $\operatorname{Re}\omega > 0$. This completes the proof.

Remark. One possible interpretation of the destabilizing effect of arbitrarily small time delays is that a delay ε will excite a high frequency mode (i.e., a mode with frequency $\approx 1/\varepsilon$) by causing the control force to be in phase rather than out of phase with the velocity of the mode in question. That is, time delays cause phase shifts in the control force which can have the effect of exciting rather than damping the high frequency modes of the system.

OPTIMAL INTERPOLATION WITH CONVEX SPLINES OF SECOND DEGREE*

LAKSHMAN S. THAKUR†

Abstract. Estimation of a convex function interpolating its known values and satisfying certain smoothness properties is needed in some applications and has been investigated in many studies from various perspectives. Without the convexity assumption, Karlin's theorem characterizes the solution to the problem studied here while under convexity, the analogous result is due to Smith and Ward. The aim of this paper is to give a convex programming characterization that can be used to calculate an optimal spline which solves a given problem of degree 2. Specifically, our aim is to determine a smooth ($f, f^{(1)}$ absolutely continuous) convex spline f of second degree, which interpolates $(r+2)$ given points in $[a, b]$, and minimizes the Tchebycheff norm $\|f^{(2)}\|_\infty$, with $f^{(2)}$ essentially bounded in $[a, b]$. The convexity of the formulation enables us to calculate an optimal spline using widely available computer routines for nonlinear optimization. The approach is illustrated by providing the convex programming formulations and the computer-obtained optimal solutions for two numerical examples.

1. Introduction.

Let $F_\infty^{(n)}[a, b]$ be a subset of the real Sobolev space

$$W_\infty^{(n)}[a, b] = \{f \in C^{(n-1)}[a, b] \mid f^{(n-1)} \text{ abs.cont.}; f^{(n)} \in L_\infty[a, b]\}$$

defined by

$$F_\infty^{(n)}[a, b] = \{f \in W_\infty^{(n)}[a, b] \mid f \text{ convex}; f(x_i) = y_i, i = 1, \cdots, n+r\}$$

where $\{x_i\}_1^{n+r}, \{y_i\}_1^{n+r} \in R^{n+r}$; $r \geqq 1$; $\{x_i\}_1^{n+r}$ is a strictly increasing sequence with $x_1 = a$, $x_{n+r} = b$, $x_i \in [a, b]$ for all i. Then the problem of *degree n* can be defined as

$$\text{Minimize } \{\|f^{(n)}\|_\infty : f \in F_\infty^{(n)}[a, b]\}. \tag{1}$$

Without the convexity condition on the functions, the work of Karlin [23], [24] and others [9], [14], [15] has established the existence of a perfect spline solution of (1). Under the convexity constraint, Smith and Ward [43] have given a natural analogue (given in § 3, for $n = 2$) of Karlin's theorem.

For $n = 2$, the case treated in this paper, Iliev and Pollul [22] have independently used a similar approach and have shown that the problem has a quadratic spline solution, characterized by the existence of a core interval [15] where all solutions must be the same and where the second derivative of the solution is the positive part of a perfect spline. Though not giving any computational results, they also state briefly an algorithm to find an optimal solution of (1). However, it uses their Lemma 3 and Lemma 4 [22, pp. 52-53]—("with Lemma 3a), 3b) define . . . , with the help of Lemma 4 . . . try to decrease . . ." [22, p. 55])—which involve 21 different graphs given in their descriptions, several graphs having 3-4 different cases in turn. Thus some 20-30 different situations may have to be considered, and the algorithm, as given, does not seem to be easily implementable.

Two further remarks about this work also deserve mention. First, their Theorem 3, giving the number of knots of the quadratic spline solution, (a) is not the tightest $(r+2)$ knots, vs. $(r-1)$ given in Theorem 2 here); and (b) does not assert the "perfectness" of the spline, as is done in our theorem. When "perfectness" is enforced in Remark 6, the knot count jumps to a much larger value: $(2r+2)$. Theorem 2 here combines the tightest knot count with "perfectness" and presents a much stronger result. Second, [22] considers the data which is *strictly* convex ($d_1 < d_2 < \cdots < d_{r+1}$, where $d_i = (y_{i+1} - y_i)/(x_{i+1} - x_i)$, $i = 1, \cdots, r+1$) whereas we assume only nondecreasing d_i's: $d_1 \leqq d_2 \leqq \cdots \leqq d_{r+1}$ (see Lemma 2 and Theorem 1). Inclusion of this data may require some changes in the analysis of [22].

In this paper, for degree $n = 2$, a concrete nonlinear convex programming formulation of the problem is given, enabling us to determine an optimal convex spline by the use of easily available computer-based optimization techniques [26], [42], [48].

There is a great deal of other work on related problems. Therefore, a brief review may be appropriate in order to differentiate the results presented here from this work. The main differences arise from the numerous combinations of differences in (i) problem definition, (ii) the norms considered, (iii) the emphasis on existence and characterization rather than computation, (iv) the emphasis on approximation rather than interpolation, (v) the lack of the convexity requirement, or (vi) the methods used in the computational scheme. We will refer to the most pertinent literature and point out these differences.

In [49] optimal convex splines are characterized but the norm considered is L_2-norm, and the suggested quadratic programming approach, based mainly on [25] (and [39], [46], [47]), is for the L_2-norm. The joint work of Passow, Roulier, and McAllister [30], [32], [38] (and the references there) on the shape preserving, monotone, and convex interpolating splines, deals with the existence and construction of such splines with given, prechosen smoothness, with no attempt to minimize $\|f^{(2)}\|_\infty$, as is the case with our problem. Regarding the lower order derivatives, in [40] Roulier and McAllister present estimates of $\max_{x_1 \leqq x \leqq x_{r+2}} |f^{(j)}(x) - s^{(j)}(x)|$, $j = 0, 1$, where s is the spline produced by the algorithm in [32]. Such results as in [34], [35], [36], [37], and [50] require the monotonicity of the spline, but not its convexity. Therefore, they are related but different. In [2], [3], [16], and [41], where conditions on derivatives (which can be used to imply convexity) are considered, the emphasis is on the question of the existence of certain polynomials (not splines) and on the degree of approximation.

Among the papers on "optimal recovery" of smooth functions, parallel results given in [6], [17], and [33] deal with the related problem of finding the smallest interval of possible values of $f(x_0)$, when a point x_0, the function values $f(x_1), \cdots, f(x_m)$, and a bound on $\|f^{(k)}\|_\infty$ $(k \leqq m)$ is given. The computational routines for optimal recovery (based on Newton's method) are given in [10], and [11]. Spline computations involve numerical evaluation of B-splines, which can be carried out by the use of divided differences, or by a more stable, efficient (and essentially the same) method presented in [7], [8], and [27].

Thus, many related problems have been studied in the literature. The use of mathematical programming techniques in the study of an optimal spline is also not new. For example, linear programming is used for best spline function approximation in [13], and for a discrete approximation problem with constraints in [1]. The Kuhn-Tucker conditions are used in [28], cubic and bicubic spline interpolation is studied via dynamic programming in [4], [5], and the use of quadratic programming in [25] has already been mentioned.

Finally, the literature dealing with the application of an optimal convex spline should be mentioned. It is easy to show (use [44, p. 706]) that if $\hat{f}$ is the piecewise linear function obtained by connecting the adjacent points $\{(x_i, y_i)\}_1^{r+2}$, then a solution f^* of (1) for $n=2$ gives the following bound E_{f^*} on the function error

$$\max_{a\leqq x\leqq b} |f^*(x)-\hat{f}(x)| \leqq E_{f^*} = K_{f^*}\delta^2/8$$

where $K_{f^*} = \|f^{*(2)}\|_\infty$, $\delta = \max_{1\leqq i\leqq r+1}(x_{i+1}-x_i)$. And, since we obviously have $E_{f^*} \leqq E_f \ \forall f \in F_\infty^{(2)}[a, b]$, one specific use of such a solution f^* is in investigating minimal error bounds on piecewise linear approximations in the error analysis of convex separable programs [44], [45]. But the major impetus to this paper, besides the perfect spline literature cited above, is provided by the same underlying motivations of such other work as: a quadratic programming formulation for obtaining a nonnegative, nondecreasing, or convex *piecewise linear* function minimizing the *least-square* norm [12]; its recent generalization to n variables via a variant of generalized programming formulation [18]; and an algorithm where the function is assumed, in addition, to have a polynomial form [21].

2. Preliminary analysis. If we define $G_\infty^{(n)}[a, b]$ for degree n, and p given points $\{x_i\}_1^p$, $\{y_i\}_1^p \in R^p$, $p \geqq n+1$ as

$$G_\infty^{(n)}[a, b] = \Big\{ g(x) \in W_\infty^{(n)}[a, b] \,\Big|\, g(x) \text{ nondecreasing in } [a, b];$$
$$\int_{x_i}^{x_{i+1}} g(x)\,dx = (y_{i+1}-y_i),\ i=1, \cdots, p-1 \Big\},$$

then it is easy to verify that for $n=2$, a solution of (1), if it exists for the given data, can be obtained by integrating the solution of

$$\text{Minimize } \{\|g^{(1)}\|_\infty : g(x) \in G_\infty^{(1)}[a, b]\}. \tag{2}$$

If $g^*(x)$ is the solution of (2), a solution $f^*(x)$ of (1) for $n=2$ is given by $f^*(x) = \int_{x_1}^x g^*(x)\,dx + y_1$. In addition, $\|f^{*(2)}\|_\infty = \|g^{*(1)}\|_\infty$. Now problem (2) is simpler than (1), in that it can be attacked directly as shown below. We begin by obtaining the optimal solution of a problem closely related to (2) in a single interval, i.e., for $p=2$.

LEMMA 1. *For degree $n=1$ and $p=2$ points $\{x_i\}_1^2$, $\{y_i\}_1^2 \in R^2$, $x_1 < x_2$, let*

$$\Omega = \{h(x) \in G_\infty^{(1)}[a, b] \,|\, h(x_1) = z_1,\ h(x_2) = z_2\}. \tag{3}$$

Then: (i) *There exists a nondecreasing continuous function $g(x) \in \Omega$ iff* (a) $(x_2-x_1)z_1 = (y_2-y_1) = (x_2-x_1)z_2$, *if $z_2 = z_1$, or* (b) $(x_2-x_1)z_1 < (y_2-y_1) < (x_2-x_1)z_2$ *if $z_2 > z_1$.*

(ii) *The value of* $\min\{\|g^{(1)}\|_\infty : g(x) \in \Omega\}$ *is given by* $\|g^{*(1)}\|_\infty$ *defined as follows* (*when* (i)(a) *or* (i)(b) *above is satisfied*):

$$\|g^{*(1)}\|_\infty = \begin{cases} 0 & \text{if } s_1 = s_2 = 0, \\ (s_1+s_2)^2/4s_1 & \text{if } 0 < s_1 \leqq s_2, \\ (s_1+s_2)^2/4s_2 & \text{if } s_1 \geqq s_2 > 0, \end{cases} \tag{4}$$

where $\Delta x = x_2-x_1$, $\Delta y = y_2-y_1$, $\Delta z = z_2-z_1$, $s_1 = 2[(\Delta y/\Delta x)-z_1]/\Delta x$, $s_2 = 2[z_2-(\Delta y/\Delta x)]/\Delta x$.

Proof. (i) *Necessity.* Due to the the nondecreasing property, we cannot have $z_2 < z_1$. If $z_2 = z_1$, the nondecreasing property implies that $g(x)$ is constant in $[x_1, x_2]$: $g(x) = z_1 = z_2$, and (a) follows immediately. For $z_2 > z_1$, let us take an arbitrary $g(x) \in$

$G_\infty^{(1)}[a, b]$. Since $g(x)$ is nondecreasing, we have $\min\{g(x): x \in [x_1, x_2]\} = g(x_1) = z_1$, and we get $(y_2 - y_1) = \int_{x_1}^{x_2} g(x)\,dx \geqq \int_{x_1}^{x_2} z_1\,dx = (x_2 - x_1)z_1$. But the center *equality* is impossible since it leads to a contradiction as follows. $\int_{x_1}^{x_2} g(x)\,dx = \int_{x_1}^{x_2} z_1\,dx$ implies $\int_{x_1}^{x_2} (g(x) - z_1)\,dx = 0$, and since $g(x)$ is nondecreasing (thus $(g(x) - z_1) \geqq 0$), this means $g(x) - z_1 = 0$ a.e. in $[x_1, x_2]$. Now by the continuity of $g(x)$, this implies that $g(x)$ is constant in $[x_1, x_2]$, giving $g(x_1) = z_1 = g(x_2) = z_2$, which is contrary to our assumption $z_2 > z_1$. Thus $(y_2 - y_1) > (x_2 - x_1)z_1$, the left inequality in (b). Similarly, considering $\max\{g(x): x \in [x_1, x_2]\} = g(x_2) = z_2$, we can show the right inequality: $(y_2 - y_1) < (x_2 - x_1)z_2$, completing the proof of (b).

Sufficiency. (a), the case for $z_2 = z_1$, is obvious since the function $g^*(x) = (y_2 - y_1)/(x_2 - x_1)$, $x_1 \leqq x \leqq x_2$ satisfies all the requirements. For (b), the $z_2 > z_1$ case, it is lengthy but easy to construct a nondecreasing continuous function $g^*(x)$, given below, and to check that it belongs to Ω.

If $s_1 < s_2$:

$$g^*(x) = \begin{cases} z_1, & x_1 \leqq x \leqq \tilde{x}, \\ l_1(x), & \tilde{x} \leqq x \leqq x_2, \end{cases} \tag{5}$$

where $l_1(x)$ is defined by $l_1(\tilde{x}) = z_1$, $l_1(x_2) = z_2$, $l_1^{(1)}(x) = \Delta z/(x_2 - \tilde{x})\ \forall x \in R$, and $\tilde{x} = x_2 - [2\Delta x s_1/(s_1 + s_2)]$.

If $s_1 \geqq s_2$:

$$g^*(x) = \begin{cases} l_2(x), & x_1 \leqq x \leqq \tilde{x}, \\ z_2, & \tilde{x} \leqq x \leqq x_2, \end{cases} \tag{6}$$

where $l_2(x)$ is defined by $l_2(x_1) = z_1$, $l_2(\tilde{x}) = z_2$, $l_2^{(1)}(x) = \Delta z/(\tilde{x} - x_1)\ \forall x \in R$, and $\tilde{x} = (2x_2 - x_1) - [2\Delta x s_1/(s_1 + s_2)]$.

(ii) By noting that $\Delta z/(x_2 - \tilde{x}) = (s_1 + s_2)^2/4s_1$, $\Delta z/(\tilde{x} - x_1) = (s_1 + s_2)^2/4s_2$, we can check directly that $\|g^{*(1)}\|_\infty$ is given by (4) for the functions defined by (5) and (6). What remains to be shown is that $\|g^{*(1)}\|_\infty$ is $\min\{\|g^{(1)}\|_\infty: g(x) \in \Omega\}$. There are two cases to be considered.

Case $s_1 < s_2$. Note that for this case $g^*(x)$ is given by (5). Take any $g(x) \neq g^*(x)$, $g(x) \in \Omega$. Then either $g(x) = g^*(x)$ in $[x_1, \tilde{x}]$, or $g(x) \neq g^*(x)$ in $[x_1, \tilde{x}]$. First, let $g(x) = g^*(x)$ in $[x_1, \tilde{x}]$. Considering points $(\tilde{x}, z_1)$, (x_2, z_2) through which both the functions pass, we see that $\|g^{(1)}(x)\|_\infty \geqq \|g^{*(1)}(x)\|_\infty$ in $(\tilde{x}, x_2)$, because $g^{*(1)}(x) = [(z_2 - z_1)/(x_2 - \tilde{x})]$, the minimum possible $\|f^{(1)}\|_\infty$ for any function f passing through $(\tilde{x}, z_1)$, (x_2, z_2). Now let $g(x) \neq g^*(x)$ in $[x_1, \tilde{x}]$. Since (i) g and g^* are nondecreasing, (ii) they are continuous, (iii) $g(x) = g^*(x) = z_1$, the minimum value of $g(x)$, $g^*(x)$ in $[x_1, x_2]$, and (iv) $g^*(x) = z_1$, $\forall x \in [x_1, \tilde{x}]$, we must have some $\hat{x} \in (x_1, \tilde{x})$ such that $g(x) > g^*(x)\ \forall x \in [\hat{x}, \tilde{x}]$ and in particular $g(\tilde{x}) > g^*(\tilde{x})$. This gives $\int_{x_1}^{\tilde{x}} g(x)\,dx > \int_{x_1}^{\tilde{x}} g^*(x)\,dx$, implying that $\int_{\tilde{x}}^{x_2} g(x)\,dx < \int_{\tilde{x}}^{x_2} g^*(x)\,dx$, which shows that there exists a $c \in (\tilde{x}, x_2)$ such that $g(c) < g^*(x)$. Thus, at $\tilde{x}$, $g(\tilde{x}) > g^*(\tilde{x})$, and at c, $g(c) < g^*(c)$, which together imply that there is a $d \in (\tilde{x}, c) \subset (\tilde{x}, x_2)$ such that $g(d) = g^*(d)$. Now considering points $(d, g^*(d))$, (x_2, z_2) through which both the functions pass, we see that $\|g^{(1)}(x)\|_\infty \geqq \|g^{*(1)}(x)\|_\infty$ in $(\tilde{x}, x_2)$ because $g^{*(1)}(x) = (z_2 - z_1)/(x_2 - \tilde{x}) = (z_2 - g^*(d))/(x_2 - d)$, the minimum possible $\|f^{(1)}\|_\infty$ for any function f passing through $(d, g^*(d))$, (x_2, z_2). Thus for $s_1 < s_2$, $\|g^{*(1)}\|_\infty \leqq \|g^{(1)}\|_\infty$ for any $g(x) \in \Omega$. The case $s_1 \geqq s_2$ can be proved similarly.

The following lemma considers several intervals together. Since the result is intuitive, for brevity, we will omit its proof, which involves many seemingly unavoidable details. The basic arguments used are clear: since d_i's are the first divided differences of the data, condition (a) is true if and only if $g(x) \in G_\infty^1[a, b]$ is nondecreasing, and

any i $(1 \leqq i \leqq r-2)$ such that $d_i = d_{i+1} \neq d_{i+2} = d_{i+3}$, forces a discontinuity of $g(x)$ at x_{i+2}, justifying condition (b). Note that in Lemma 2, there is no attempt to minimize $\|g^{(1)}\|_\infty$. It only considers the existence of a nondecreasing, continuous function in $G_\infty^{(1)}[a, b]$. For a related result for strictly convex data $(d_i < d_{i+1},\ i = 1, \cdots, r+1)$ see [36, Thm. 1], [38, Thm. A].

LEMMA 2. *For $n = 1$ and $p = (r+2)$ points $\{x_i\}_1^{r+2}$, $\{y_i\}_1^{r+2} \in R^{r+2}$, $x_i < x_{i+1}$, $1 \leqq i \leqq r+1$, there exists a nondecreasing, continuous function $g(x) \in G_\infty^{(1)}[a, b]$ iff* (a) *the sequence $\{d_i = (y_{i+1} - y_i)/(x_{i+1} - x_i)\}_1^{r+1}$ is nondecreasing, and* (b) *there is no i $(1 \leqq i \leqq r-2)$ for which $d_i = d_{i+1} \neq d_{i+2} = d_{i+3}$ holds.*

For the following main results, we will employ similar notation, especially the s_i's of Lemma 1 and $z_{1,i}$, $z_{2,i+1}$, where for each interval $[x_i, x_{i+1}]$, $1 \leqq i \leqq r+1$, $z_{1,i}$, $z_{2,i+1}$ represent the values corresponding to the z_1, z_2 values of Lemma 1, satisfying conditions (i)(a) or (b) given *there*. Theorem 1 combines the ideas of Lemma 1 (minimization of $\|g^{(1)}\|_\infty$ in a single interval), and Lemma 2 (problem data over several intervals) to provide a framework for solving problem (1) for $n = 2$.

3. Convex programming characterization: the main results.

THEOREM 1. *For $n = 2$ and $(r+2)$ given points $\{x_i\}_1^{r+2}$, $\{y_i\}_1^{r+2} \in R^{r+2}$, $x_i < x_{i+1}$, $i = 1, \cdots, r+1$; if $\{d_i = (y_{i+1} - y_i)/(x_{i+1} - x_i)\}_1^{r+1}$ is a nondecreasing sequence such that there is no i $(1 \leqq i \leqq r-2)$ for which $d_i = d_{i+1} \neq d_{i+2} = d_{i+3}$ holds then a solution $f^*(x)$ of* (1) *exists and can be found by solving the following convex programming problem* (7). *Problem* (7) *has a linear objective function, $(r+1)$ variables $(t_0, t_1, \cdots, t_r)$, $2r$ main constraints* ((a), (b), (c)), *and r lower and r upper bounds on the variables* (d). *The optimal value of $\|f^{*(2)}\|_\infty$ is given by the optimal value of t_0, and the optimal convex function can be constructed from the optimal values of t_i, $i = 1, \cdots, r$ (as shown in Corollary* 1):

Minimize t_0

Subject to:

$$
\begin{aligned}
&\text{(a)}\quad t_0 - t_1 \geqq 0, \qquad t_0 - (\hat{a}_r k_r - \hat{b}_r t_r) \geqq 0,\\
&\text{(b)}\quad t_0 - [(\hat{a}_i k_i - \hat{b}_i t_i + t_{i+1})^2 / 4(\hat{a}_i k_i - \hat{b}_i t_i)] \geqq 0,\\
&\text{(c)}\quad t_0 - [(\hat{a}_i k_i - \hat{b}_i t_i + t_{i+1})^2 / 4 t_{i+1}] \geqq 0,\\
&\text{(d)}\quad (\hat{a}_i / \hat{b}_i) k_i \geqq t_i \geqq 0, \qquad i = 1, \cdots, r.
\end{aligned}
\qquad \left.\begin{aligned}\\ \\ \\ \end{aligned}\right\} \quad i = 1, \cdots, r-1, \tag{7}
$$

The constants $\hat{a}_i$, $\hat{b}_i$ and k_i, $i = 1, \cdots, r$ are calculated from the data as follows:

$$
\begin{aligned}
&\hat{a}_i = (\Delta x_i + \Delta x_{i+1}) / \Delta x_{i+1}, \qquad \hat{b}_i = (\Delta x_i / \Delta x_{i+1}),\\
&k_i = 2(\Delta y_i \Delta x_{i+1} - \Delta x_i \Delta y_{i+1}) / [(x_{i+1}^2 - x_i^2)\Delta x_{i+1} - (x_{i+2}^2 - x_{i+1}^2)\Delta x_i],\\
&\Delta x_i = x_{i+1} - x_i, \qquad \Delta y_i = y_{i+1} - y_i.
\end{aligned}
$$

Proof. Lemma 2 implies that a convex function $f \in F_\infty^{(2)}[a, b]$ through the $(r+2)$ given points exists. As noted before, if $g^*(x)$ is the solution of (2), $\|f^{*(2)}\|_\infty = \|g^{*(1)}\|_\infty$. Therefore, the optimal value $\|f^{*(2)}\|_\infty$ can be determined by finding the optimal values of $\{z_{1,i}, z_{2,i+1}\}_1^{r+1}$ such that $\max\{\|g_i^{(1)}\|_\infty : 1 \leqq i \leqq r+1\}$ is minimized under the constraints

$$
\begin{aligned}
&(x_{i+1} - x_i) z_{1,i} \leqq y_{i+1} - y_i \leqq (x_{i+1} - x_i) z_{2,i+1},\\
&(z_{2,i+1} \geqq z_{1,i}),
\end{aligned}
\qquad \left.\begin{aligned}\\ \end{aligned}\right\} \quad i = 1, \cdots, r+1, \tag{8}
$$

where $\|g_i^{(1)}\|_\infty$ in the ith interval is given by (4) of Lemma 1. Note that the first constraint

implies the conditions (i)(a) if $z_{2,i+1} = z_{1,i}$, or (i)(b) if $z_{2,i+1} > z_{1,i}$, of Lemma 1. This insures that $\{z_{1,i}, z_{2,i+1}\}_1^{r+1}$ values chosen will be such that we have an appropriate convex function within each interval $[x_i, x_{i+1}]$, $1 \leqq i \leqq r+1$. The second condition insures that when these intervals are considered together this convexity extends to the entire domain $[x_1, x_{r+2}]$. Thus, a solution of (1) can be obtained by solving:

$$\text{Minimize } t_0 = \max_{i=1,3,5,\cdots,2r+1} [\max \{((s_i + s_{i+1})^2/4s_i), ((s_i + s_{i+1})^2/4s_{i+1})\}]$$

under the above constraints. Note that for the minimization of $\|g_1^{(1)}\|_\infty$, an optimal value of $z_{2,2}$ implies that $s_1 = s_2 = \|g_1^{(1)}\|_\infty$ in the *first* interval. Similarly, we have $s_{2r+2} = s_{2r+1} = \|g_{r+1}^{(1)}\|_\infty$ in the *last* interval. Hence, eliminating s_2, s_{2r+2} and renumbering the s_i's ($[(s_1, s_2), s_3, \cdots, (s_{2r+1}, s_{2r+2})] \equiv [s_1, s_2, \cdots, s_{2r}]$), the objective function can be written as:

$$\text{Minimize } t_0 = \max_{i=2,4,\cdots,2r-2} [\max \{s_1, ((s_i + s_{i+1})^2/4s_i), ((s_i + s_{i+1})^2/4s_{i+1}), s_{2r}\}].$$

Now we can directly check by their definitions that

$$s_i \Delta x_{j(i)} + s_{i+1} \Delta x_{j(i)+1} = (\Delta x_{j(i)} + \Delta x_{j(i)+1}) k_{j(i)}, \qquad i = 1, 3, \cdots, 2r-1, \quad j(i) = (i+1)/2, \tag{9}$$

or

$$s_{i+1} = \hat{a}_{j(i)} k_{j(i)} - \hat{b}_{j(i)} s_i, \qquad i = 1, 3, \cdots, 2r-1,$$

where $k_{j(i)}$ is a constant representing $f^{(2)}$ of *the* second degree polynomial through three consecutive points $(x_{j(i)}, y_{j(i)})$, $(x_{j(i)+1}, y_{j(i)+1})$, $(x_{j(i)+2}, y_{j(i)+2})$. We can also check that constraints (8) hold iff $s_i \geqq 0$, $i = 1, \cdots, 2r$.

Now if we give the name t_i for the variable $s_{(2i-1)}$, $i = 1, \cdots, r$ and use (9) to eliminate $s_2, s_4, \cdots, s_{2r}$, we can write the problem (after some simplification) as

$$\begin{aligned} &\text{Minimize } t_0 = \max_{1 \leqq i \leqq r-1} [\max \{t_1, ((\hat{a}_i k_i - \hat{b}_i t_i + t_{i+1})^2/4(\hat{a}_i k_i - \hat{b}_i t_i)), \\ &\qquad ((\hat{a}_i k_i - \hat{b}_i t_i + t_{i+1})^2/4t_{i+1}), (\hat{a}_r k_r - \hat{b}_r t_r)\}] \\ &\text{Subject to: } \hat{a}_i k_i \geqq \hat{b}_i t_i \geqq 0 \qquad i = 1, \cdots, r. \end{aligned} \tag{10}$$

Problem (10) can now be written in the form (7) given in the theorem.

To show that a minimizing problem given by (7) is convex, we need to demonstrate that its constraints are concave and the objective is convex [29]. Being linear, the objective of (7) is convex, and constraints (a) and (d) are concave. Therefore, we have only to show that (b) and (c) are concave for all $i = 1, \cdots, r-1$. Since the form of the constraints (b) and (c) is the same for all i, it is, obviously, sufficient to show concavity for a single value of i. If H is the Hessian of constraint (b) for $i = 1$, we see that

$$H = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \dfrac{-\hat{b}_1^2 t_2^2}{2(\hat{a}_1 k_1 - \hat{b}_1 t_1)^3} & \dfrac{-\hat{b}_1 t_2}{2(\hat{a}_1 k_1 - \hat{b}_1 t_1)^2} \\ 0 & \dfrac{-\hat{b}_1 t_2}{2(\hat{a}_1 k_1 - \hat{b}_1 t_1)^2} & \dfrac{-1}{2(\hat{a}_1 k_1 - \hat{b}_1 t_1)} \end{pmatrix}.$$

Let $G = -H$. Then it is easy to see that G is symmetric, all its diagonal elements are nonnegative, and all its leading principal determinants are also nonnegative for all

values of t_2, $(\hat{a}_1 k_1 - \hat{b}_1 t_1) \geqq 0$. Thus G is semipositive definite, implying that function $(-b)$ is convex, and therefore, (b) is concave for $i=1$. Similarly, the Hessian for (c), $i=1$, is

$$H = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \dfrac{-\hat{b}_1^2}{2t_2} & \dfrac{-\hat{b}_1(\hat{a}_1 k_1 - \hat{b}_1 t_1)}{2t_2^2} \\ 0 & \dfrac{-\hat{b}_1(\hat{a}_1 k_1 - \hat{b}_1 t_1)}{2t_2^2} & \dfrac{-(\hat{a}_1 k_1 - \hat{b}_1 t_1)^2}{2t_2^3} \end{pmatrix},$$

which implies that function (c) is also concave for $i=1$. This completes the proof of the theorem.

It should be noted that the convexity of this formulation is very valuable for numerical computations, since it implies that any local minimum of the problem is also its global minimum.

We can use the following corollary to calculate an optimal convex spline $f^*(x)$. In view of Lemma 1 and 2, the corollary is evident by noting that t_i^*'s here correspond to the s_i's of Lemma 1.

COROLLARY 1. *Let optimal values $z_{1,i}^*$, $z_{2,i+1}^*$, $i=1, \cdots, r+1$ be given in terms of the optimal values of the variables t_i^*, $i=1, \cdots, r$ of Theorem 1 as follows*:

$$\left.\begin{aligned} z_{1,1}^* &= (\bar{\Delta} y_2/\bar{\Delta} x_2) - t_1^*(\bar{\Delta} x_2/2), \\ z_{1,i}^* &= (\bar{\Delta} y_i/\bar{\Delta} x_i) + t_{i-1}^*(\bar{\Delta} x_i/2), \\ z_{2,i}^* &= z_{1,i}^*, \end{aligned}\right\} \quad i=2, \cdots, r+1,$$
$$z_{2,r+2}^* = (\bar{\Delta} y_{r+2}/\bar{\Delta} x_{r+2}) - t_r^*(\bar{\Delta} x_{r+1}/2) + k_r[(\bar{\Delta} x_{r+2} + \bar{\Delta} x_{r+1})/2], \tag{11}$$

where $\bar{\Delta} y_i = (y_i - y_{i-1})$, $\bar{\Delta} x_i = (x_i - x_{i-1})$, $i=2, \cdots, r+2$. Let g^* be defined in each interval $[x_i, x_{i+1}]$, $i=1, \cdots, r+1$, by (5) and (6) (of Lemma 1) with $z_1 = z_{1,i}^*$, $z_2 = z_{2,i+1}^*$. Then an optimal convex spline, solving the problem (1) for $n=2$, is given by $f^*(x) = \int_{x_1}^{x} g^*(x)\, dx + y_1$.

Now we mention two common special cases. If $\{d_i = (y_{i+1} - y_i)/(x_{i+1} - x_i)\}_1^{r+1}$ is *strictly increasing*, obviously, there is no i such that $d_i = d_{i+1} \neq d_{i+2} = d_{i+3}$ $(1 \leqq i \leqq r-2)$, so that a solution of $f^*(x)$ of (1) exists and can be found by solving the convex programming problem (7) and using Corollary 1. For *equidistant* data, it is easy to check that $\hat{a}_i$ and $\hat{b}_i$ values simplify to $\hat{a}_i = 2$, $\hat{b}_i = 1$, $i=1, \cdots, r$, in formulation (7).

The above results help find any solution $f^* \in F_\infty^{(2)}[a, b]$ which minimizes $\|f^{*(2)}\|_\infty$. There is no emphasis on determining the maximum number of knots f^* may need, or on finding an f^* analogous to the perfect spline of Karlin's theorem [23] which characterizes f^* without the convexity requirement on f^*. Under convexity, it is natural that a perfect spline f^* (which has by definition a single value for $|f^{*(2)}|$ with $f^{*(2)}$ having opposite signs on the different sides of a knot) should be replaced by a spline where $f^{*(2)}$ takes only two values, either $f^{*(2)} > 0$ or 0, with different values on the different sides of a knot. For completeness, the following theorem is given which states the result analogous to Karlin's theorem for $n=2$. It is due to Smith and Ward [43] who prove it for general n. We give it in our notation for $n=2$.

THEOREM 2 (Smith and Ward). *For $n=2$ and $(r+2)$ points $\{x_i\}_1^{r+2}, \{y_i\}_1^{r+2} \in R^{r+2}$, $x_i < x_{i+1}$, $i=1, \cdots, r+1$, if there is some $f(x) \in F_\infty^{(2)}[a, b]$, then there exist a solution f^* of (1) and values $\xi_1, \cdots, \xi_k$ with $k \leqq r-1$, such that $a = x_1 = \xi_0 < \xi_1 < \cdots < \xi_k < \xi_{k+1} =$*

$x_{r+2} = b$, *and either*

$$f^{*(2)}(x) = \begin{cases} \|f^{*(2)}\|_\infty & \text{for } x \in (\xi_{2i}, \xi_{2i+1}), \quad (2i+1) \leqq k+1, \\ 0 & \text{for } x \in (\xi_{2i+1}, \xi_{2i+2}), \quad (2i+2) \leqq k+1, \end{cases}$$

or

$$f^{*(2)}(x) = \begin{cases} 0 & \text{for } x \in (\xi_{2i}, \xi_{2i+1}), \quad (2i+1) \leqq k+1, \\ \|f^{*(2)}\|_\infty & \text{for } x \in (\xi_{2i+1}, \xi_{2i+2}), \quad (2i+2) \leqq k+1, \end{cases}$$

for $i = 0, \cdots, i(k)$, *where* $i(k) = k/2$ *if* k *is even, and* $i(k) = (k-1)/2$ *if it is odd.*

Proof. We will prove the theorem by showing that if g^* is any solution of (1) for $n = 2$ with $\|g^{*(2)}\| = \beta$, then, as described in the statement, there is also a "perfect" convex spline solution f^* of (1) having less than or equal to $(r-1)$ knots with $\|f^{*(2)}\|_\infty = \beta$. This is done by considering the following related problem:

(1)′ Minimize $\{\|f^{(2)}\|_\infty : f \in W_\infty^{(2)}[a, b], f(x_i) = y_i - (\beta/2)(x_i^2/2), i = 1, \cdots, r+2\}$,

whose perfect spline solution can be used to obtain $f^*(x)$. Note that problem (1)′ does not have the convexity requirement, therefore by Karlin's theorem [23] there is a perfect spline solution F^* of (1)′ with number of knots $\leqq (r-1)$. Now we can show that (i) $\|F^{*(2)}\|_\infty = \beta/2$, and (ii) then the desired f^* is given by $f^*(x) = F^*(x) + (\beta/2)(x^2/2)$.

(i) Let $G^*(x) = g^*(x) - (\beta/2)(x^2/2)$. Then $G^*(x) \in W_\infty^{(2)}[a, b]$, it interpolates the data of problem (1)′: $G^*(x_i) = g^*(x_i) - (\beta/2)(x_i^2/2) = y_i - (\beta/2)(x_i^2/2)$, and since $G^{*(2)}(x) = g^{*(2)}(x) - \beta/2$, we get $\|G^{*(2)}\|_\infty = \|g^{*(2)}\|_\infty - \beta/2 = \beta/2$. Thus, $G^*(x)$ would be a solution of (1)′ if $\|F^{*(2)}\|_\infty = \beta/2$, that is, $\|F^{*(2)}\|_\infty$ is not *less than* $\beta/2$. We will prove this by showing that $\|F^{*(2)}\|_\infty < \beta/2$ leads to the contradiction that g^*, an assumed solution of (1), is not a solution of (1). Let $\|F^{*(2)}\|_\infty < \beta/2 = \beta/2 - \varepsilon$, where $(\beta/2) \geqq \varepsilon > 0$. Consider $h(x) = F^*(x) + (\beta/2)(x^2/2)$. Then $h(x) \in W_\infty^{(2)}[a, b]$, it interpolates the data of problem (1): $h(x_i) = F^*(x_i) + (\beta/2)(x_i^2/2) = y_i - (\beta/2)(x_i^2/2) + (\beta/2)(x_i^2/2) = y_i$, and since $h^{(2)}(x) = F^{*(2)} + \beta/2$, we get $h^{(2)}(x) \geqq 0$ (hence $h(x)$ is convex), and $\|h^{(2)}\|_\infty = \|F^{*(2)}\|_\infty + \beta/2 = \beta/2 - \varepsilon + \beta/2 = \beta - \varepsilon$. Thus $h(x)$ is a solution of (1) with $\|h^{(2)}\|_\infty < \beta$, which contradicts the fact that $g^*(x)$ is a solution of (1) with $\|g^{*(2)}\|_\infty = \beta$. Therefore, $\|F^{*(2)}\|_\infty = \beta/2$.

(ii) As shown for $h(x)$ above, $f^*(x)$ defined by $f^*(x) = F^*(x) + (\beta/2)(x^2/2)$ is a solution of (1). Now since $f^{*(2)}(x) = F^{*(2)}(x) + \beta/2$ and $F^*(x)$ is a perfect ($F^{*(2)}(x) = \beta/2$, or $(-\beta/2)$) spline of degree 2 with number of knots $\leqq (r-1)$, we see that $f^*(x)$ has the same number of knots with $f^{*(2)}(x) = 0$ or β. This proves the theorem.

4. Numerical examples and a computer implementation. Since the capability of available computer software to find a local minimum far exceeds that of finding a global one, convexity of the formulation is very helpful in actual calculations. Here, we provide two examples for illustration and initial numerical validation. Each example is such that its optimal value $\|f^{*(2)}\|_\infty$ can also be directly found. This allows a comparison with the optimal value obtained by computer routines using our formulation.

(i) Consider a 4-point problem, $p = 4$, $n = 2$, $r = 2$:

$$\{x_i\}_1^4 \equiv \{0, 1, 2, 3\}, \qquad \{y_i\}_1^4 \equiv \{0, 10, 28, 54\}.$$

We can calculate $k_1 = k_2 = 8$, using the easily derived expression

$$k_i = 2\frac{(y_i - y_{i+1})(x_{i+1} - x_{i+2}) - (y_{i+1} - y_{i+2})(x_i - x_{i+1})}{(x_i^2 - x_{i+1}^2)(x_{i+1} - x_{i+2}) - (x_{i+1}^2 - x_{i+2}^2)(x_i - x_{i+1})}. \tag{12}$$

Recall that the constant k_i represents $f^{(2)}$ of the second degree polynomial through these consecutive points: (x_i, y_i), (x_{i+1}, y_{i+1}), and (x_{i+2}, y_{i+2}). Since the points lie on a second degree polynomial $g(x) = 4x^2 + 6x$, it is obvious that the optimal value $\|f^{*(2)}\|_\infty$ is $g^{(2)} = 8$. The formulation (7) with $\hat{a}_i = 2$, $\hat{b}_i = 1$ for equidistant data gives

Minimize t_0

Subject to:

$$
\begin{aligned}
& g_1 \equiv t_0 - t_1 \geqq 0, \\
& g_2 \equiv t_0 - [(16 - t_1 + t_2)^2/4(16 - t_1)] \geqq 0, \\
& g_3 \equiv t_0 - [(16 - t_1 + t_2)^2/4t_2] \geqq 0, \\
& g_4 \equiv t_0 - (16 - t_2) \geqq 0, \\
& g_5 \equiv 16 - t_1 \geqq 0, \\
& g_6 \equiv 16 - t_2 \geqq 0, \\
& g_7 \equiv t_1 \geqq 0, \\
& g_8 \equiv t_2 \geqq 0.
\end{aligned} \tag{13}
$$

It is easy to check that (13) has an optimal solution at $(t_0^* = 8 = \|f^{*(2)}\|_\infty$, $t_1^* = 8$, $t_2^* = 8)$. This can be done (as follows) by verifying that the Kuhn-Tucker conditions sufficient for a solution to be an optimal solution of a convex program are satisfied at $(t_0 = 8, t_1 = 8, t_2 = 8)$ with dual variable values $\lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = 1/4$, $\lambda_5 = \lambda_6 = \lambda_7 = \lambda_8 = 0$. Substituting $t_0 = t_1 = t_2 = 8$, we see that this is a feasible solution since all the constraints g_1 through g_8 are satisfied. Since $g_1 = g_2 = g_3 = g_4 = 0$, and $g_5 = g_6 = g_7 = g_8 > 0$ at this solution, we have the complementary slackness conditions: $g_i\lambda_i = 0$ for $i = 1, \cdots, 8$. Finally using * to denote the value at $(t_0 = t_1 = t_2 = 8)$, we see that the following gradient conditions are also satisfied:

$$
\begin{aligned}
\frac{\partial t_0^*}{\partial t_0} &= \sum_{i=1}^{8} \lambda_i \frac{\partial g_i^*}{\partial t_0} \equiv 1 = \lambda_1 + \lambda_2 + \lambda_3 + \lambda_4, \\
\frac{\partial t_0^*}{\partial t_1} &= \sum_{i=1}^{8} \lambda_i \frac{\partial g_i^*}{\partial t_1} \equiv 0 = -\lambda_1 + \lambda_3, \\
\frac{\partial t_0^*}{\partial t_2} &= \sum_{i=1}^{8} \lambda_i \frac{\partial g_i^*}{\partial t_2} \equiv 0 = -\lambda_2 + \lambda_4.
\end{aligned}
$$

Thus our formulation solves the problem, and its optimal value t_0^* gives the optimal value of $\|f^{*(2)}\|_\infty$.

Now using a computer routine for constrained optimization given in [26, pp. 386-398, Constrained Rosenbrock HILL ALGORITHM] we obtain the same solution. Several initial (starting) solutions were tried, all converging to the optimal values shown in Table 1.

(ii) We take a 7-point problem for our second example, $p = 7$, $n = 2$, $r = 5$:

$$
\begin{aligned}
\{x_i\}_1^7 &\equiv \{0, 1, 2, 3, 4, 5, 6\}, \\
\{y_i\}_1^7 &\equiv \{16, 12, 10, 9.5, 10, 12.5, 18\}.
\end{aligned}
$$

We can calculate $k_1 = 2$, $k_2 = 1.5$, $k_3 = 1$, $k_4 = 2$, $k_5 = 3$ as before. It is easy to verify, this time geometrically, that there *is* a convex function $f^* \in F_\infty^{(2)}[a, b]$ such that $\|f^{*(2)}\|_\infty = 3$. This implies that f^* is an optimal solution with $\|f^{*(2)}\|_\infty = 3$, since for

TABLE 1

Initial solution		Optimal values		
t_1	t_2	t_0^*	t_1^*	t_2^*
1.0	1.0	8.0000000	8.000009	7.999994
5.0	5.0	8.0000010	8.000009	7.999993
12.0	12.0	8.0000000	7.999999	8.000001

any $f \in F_\infty^{(2)}[a, b]$, obviously, $\|f^{(2)}\|_\infty \geqq \max_{1 \leqq i \leqq 5} \{k_i\} = 3$. Thus, the formulation, with 6 variables in this case, must have optimal $t_0^* = 3$. Note that optimal values of $t_1, \cdots, t_5$ are not unique for this example.

The computer routine mentioned above (Rosenbrock HILL ALGORITHM) again gives the desired optimal values shown in Table 2 from several initial solutions. For brevity, explicit formulation is not given for this problem.

TABLE 2

Initial solution					Optimal values					
t_1	t_2	t_3	t_4	t_5	t_0^*	t_1^*	t_2^*	t_3^*	t_4^*	t_5^*

ON THE REGULARITY OF THE KUHN-TUCKER CURVE*

A. L. DONTCHEV† AND H. TH. JONGEN‡

Abstract. We consider twice continuously differentiable finite dimensional optimization problems, depending on a real parameter. Besides a discussion of (local) Lipschitz continuity of the Kuhn-Tucker curve, we present conditions under which the Kuhn-Tucker curve is piecewise continuously differentiable. Throughout the paper we assume the linear independence of the gradients of the binding constraint functions. We use Kojima's concept of strongly stable Kuhn-Tucker points and present a new equivalent formulation of this concept.

Key words. Kuhn-Tucker curve, Lipschitz continuity, piecewise continuous differentiability, strongly stable Kuhn-Tucker points, critical points

1. Introduction. Let $C^2(R^n, R)$ denote the space of real valued twice continuously differentiable functions on the n-dimensional Euclidean space R^n. By z we denote a vector in R^{n+1}, and z will always be partitioned as $z=(x, t)$, where $x\in R^n$, $t\in R$. The real number t will be considered as a parameter. Let I, J be finite index sets, $I=\{1, \cdots, m\}$, $J=\{1, \cdots, s\}$, and let $f, h_i, g_j \in C^2(R^{n+1}, R)$, $i\in I, j\in J$.

We define

$$M(t)=\{x\in R^n \mid h_i(x, t)=0,\ g_j(x, t)\geqq 0,\ i\in I, j\in J\}, \tag{1.1}$$

$$J_0(z)=\{j\in J \mid g_j(z)=0\}. \tag{1.2}$$

For every $t\in R$ we have the following optimization problem $P(t)$:

$$P(t):\quad \text{Minimize } f(\cdot, t) \text{ on } M(t). \tag{1.3}$$

In the sequel we denote by $D\phi(z)$ the $(n+1)$-row vector of the first partial derivatives of ϕ evaluated at z, and by $D^2\phi(z)$ the $(n+1)\times(n+1)$-matrix of the second partial derivatives. Similarly, $D_x\phi(z)$, $D_t\phi(z)$, $D_{xt}\phi(z)$ will correspond to the partial derivatives with respect to x and t.

For an $r\times q$-matrix A, the set Ker A will be:

$$\text{Ker } A=\{\xi\in R^q \mid A\xi=0\}. \tag{1.4}$$

If B is a symmetric $n\times n$-matrix and L a linear subspace of R^n, then by $B_{|L}$ we mean some matrix of the family $\mathcal{V}$, $\mathcal{V}=\{V^TBV \mid V$ is a matrix with n rows, whose columns form a basis for $L\}$. In view of Sylvester's theorem (cf. [12]) the number of negative (resp. zero, positive) eigenvalues of V^TBV does not depend on the incidental choice of V. We say that $B_{|L}$ is (non)singular (resp. positive) (semi-) definite if V^TBV is so, where $V^TBV\in\mathcal{V}$.

In this paper we are concerned with a *local* analysis thereby assuming the linear independence of the gradients of the binding constraint functions. In this spirit we simply assume throughout the whole paper that the following Condition A is satisfied.

Condition A. The set $\{D_xh_i(z), D_xg_j(z), i\in I, j\in J_0(z)\}$ is linearly independent at all $z=(x, t)$ for which $x\in M(t)$.

DEFINITION 1.1 [8]. A point $\bar{x}$ is called a *critical point* for $P(\bar{t})$ if $\bar{x} \in M(\bar{t})$ and if there exist (unique) real numbers $\bar{\lambda}_i$, $\bar{\mu}_j$, $i \in I$, $j \in J_0(\bar{z})$ satisfying

$$D_x f = \sum_{i \in I} \bar{\lambda}_i D_x h_i + \sum_{j \in J_0(\bar{z})} \bar{\mu}_j D_x g_{j|z=\bar{z}}. \tag{1.5}$$

The numbers $\bar{\lambda}_i$, $\bar{\mu}_j$ are called Lagrange parameters. A critical point $\bar{x}$ is a *Kuhn–Tucker point* (KT-point) if $\bar{\mu}_j \geqq 0$ for all $j \in J_0(\bar{z})$.

A critical point $\bar{x}$ is called *nondegenerate* if the following two conditions hold:

ND1. $\bar{\mu}_j \neq 0, j \in J_0(\bar{z})$.

ND2. $D_x^2 L(\bar{z})_{|T}$ is nonsingular,

where the (Lagrange) function L and the linear subspace $T \subset R^n$ are defined as follows:

$$L(z) = f(z) - \sum_{i \in I} \bar{\lambda}_i h_i(z) - \sum_{j \in J_0(\bar{z})} \bar{\mu}_j g_j(z), \tag{1.6}$$

$$T = \bigcap_{i \in I} \operatorname{Ker} D_x h_i(\bar{z}) \cap \bigcap_{j \in J_0(\bar{z})} \operatorname{Ker} D_x g_j(\bar{z}). \tag{1.7}$$

A point $\bar{z} = (\bar{x}, \bar{t})$ is called a (nondegenerate) critical point if $\bar{x}$ is a (nondegenerate) critical point for $P(\bar{t})$. Let $\Sigma \subset R^{n+1}$ denote the set of critical points and Σ_{KT} be the subset of Σ consisting of the KT-points.

Remark 1.1. If one would like to drop Condition A, then there are two possibilities. Either one imposes a weaker constraint qualification guaranteeing that local minima are Kuhn–Tucker points (for example the Mangasarian–Fromowitz constraint qualification, as used by Kojima [9] and Kojima and Hirabayashi [11]). Or one studies generic one-parameter families, but then the whole concept of critical points has to be weakened (cf. [6], [7]). □

If in some neighborhood of $\bar{z} = (\bar{x}, \bar{t})$ the Kuhn–Tucker set Σ_{KT} can be parametrized by t, t ranging in some interval, then we will speak about "the Kuhn–Tucker curve." In this paper we discuss the regularity properties of the KT-curve (local Lipschitz continuity, piecewise C^1-differentiability). We emphasize that this kind of investigation is important for sensitivity analysis, which is basic in optimization. Therefore, we feel that every new insight in this area has its own relevance. A basic tool in sensitivity analysis is the idea of implicit function theorems. This was already recognized by Fiacco and so, let us start with the following profound result (a similar result holds for all nondegenerate critical points, cf. [8]).

THEOREM 1.1 (Fiacco [1]). *Let $\bar{z} = (\bar{x}, \bar{t})$ be a nondegenerate critical point, $\bar{\mu}_j \geqq 0$ for all $j \in J_0(\bar{z})$ and $D_x^2 L(\bar{z})_{|T}$ positive definite. Then in some open neighborhood $\mathcal{O}$ of $\bar{z}$ the Kuhn–Tucker curve depends C^1 on the parameter t, $\Sigma_{KT} \cap \mathcal{O} = \{(x(t), t), t \in (a, b)\}$. Every $x(t)$ is a strict local minimum for $P(t)$ and the corresponding Lagrange parameters $\lambda_i(t)$, $\mu_j(t)$ depend C^1 on t.*

The paper is organized as follows. In § 2 we apply a beautiful abstract theorem of Hager in order to obtain Lipschitz continuity for a curve which is continuously selected from a finite number of Lipschitz continuous curves. In § 3 we prove an equivalent formulation for Kojima's concept of strong stability. In § 4 we show that local Lipschitz continuity of the Kuhn–Tucker curve is a direct consequence of Kojima's continuity result and a continuous curve selection (here the result of § 2 is used). Finally, in § 5 we deduce fairly weak conditions for piecewise C^1-differentiability of the Kuhn–Tucker curve. Under these conditions it might be possible to adapt appropriately numerical schemes, as used in solving ordinary differential equations, for tracing the Kuhn–Tucker curve. Such an analysis would be relevant especially in optimal control computations. The latter fact will be the basis for future research.

2. On the Lipschitz continuity of a continuous selection. The idea of the result in this section is based on Hager's theorem which we will state first. Let $\mathcal{S}$ be a Banach space, $\mathcal{D}$ be a convex subset of a Banach space, and $z: \mathcal{D} \to \mathcal{S}$ be continuous. Moreover, let $c: \mathcal{D} \to 2^{\{1,\cdots,m\}}$ = power set of $\{1, \cdots, m\}$ have the following property:

(2.1) If $\{d_k\} \subset \mathcal{D}$, $d_k \to d \in \mathcal{D}$ as $k \to \infty$, and $I \subset c(d_k)$ for all k, then $I \subset c(d)$.

Given $d, e \in \mathcal{D}$, let (d, e) denote the ordered pair and define the segment:

$$[d, e] = \{(1-\lambda)d + \lambda e | 0 \leqq \lambda \leqq 1\}.$$

The points $d, e \in \mathcal{D}$ are called compatible if $c(d) = c(e)$ and $c(\delta) \subset c(d)$ for all $\delta \in [d, e]$.

THEOREM 2.1 (Hager [3]). *If γ satisfies*

$$\|z(d) - z(e)\|_{\mathcal{S}} \leqq \gamma \|d - e\|_{\mathcal{D}} \tag{2.2}$$

for all compatible $d, e \in \mathcal{D}$, then γ satisfies (2.2) *for all $d, e \in \mathcal{D}$.*

As a consequence of Theorem 2.1 we obtain the following result.

THEOREM 2.2. *Let $[a, b] \subset R$ be an interval and let $y_i: [a, b] \to R^n$ be a Lipschitz continuous function with Lipschitz constant α_i, $i = 1, \cdots, r$. Let $y: [a, b] \to R^n$ be a continuous function having the property that for all $t \in [a, b]$: $y(t) = y_i(t)$ for some $i \in \{1, \cdots, r\}$.*

Then y is Lipschitz continuous with Lipschitz constant $\alpha := \max_{i=1,\cdots,r} \alpha_i$.

Proof. We reformulate Theorem 2.2 in terms of Hager's theorem. Put $\mathcal{D} = [a, b]$, $\mathcal{S} = R^n$. The map c is defined as follows. Put $m = r$ and $c(t) = \{i \in \{1, \cdots, r\} | y(t) = y_i(t)\}$. Let $\{t_k\} \subset [a, b]$ be a sequence and suppose that for some j, $y_j(t_k) = y(t_k)$ for all k. If $t_k \to \bar{t}$, then by continuity, $y_j(t_k) \to y_j(\bar{t})$ and $y(t_k) \to y(\bar{t})$. This establishes (2.1). The map y plays the role of the map z. Finally, it suffices to show the inequality $\|y(t_1) - y(t_2)\| \leqq \alpha |t_1 - t_2|$ for all $t_1, t_2 \in [a, b]$ with $c(t_1) = c(t_2)$. But the latter fact is obvious since $\alpha = \max_{i=1,\cdots,r} \alpha_i$. □

3. An equivalent formulation of Kojima's strong stability concept. In [9] Kojima introduced strongly stable Kuhn-Tucker points. In fact, Kojima states the concept of strong stability in a more or less topological way (which incorporates continuous dependence on the data) and then he shows the equivalence of it with a condition on corresponding partial derivatives. We take this equivalent formulation as a definition.

DEFINITION 3.1 (cf. [9]). Let $\bar{x}$ be a critical point for $P(\bar{t})$ with Lagrange parameters $\bar{\lambda}_i$, $\bar{\mu}_j$ satisfying (1.5) and suppose that $\bar{x}$ is a Kuhn-Tucker point (i.e. $\bar{\mu}_j \geqq 0$, $j \in J_0(\bar{z})$). Put $J_0^+(\bar{z}) = \{j \in J_0(\bar{z}) | \bar{\mu}_j > 0\}$. Let L be the Lagrange function (cf. (1.6)) and for all $\tilde{J}$ with $J_0^+(\bar{z}) \subset \tilde{J} \subset J_0(\bar{z})$ define

$$T(\tilde{J}) = \bigcap_{i \in I} \operatorname{Ker} D_x h_i(\bar{z}) \cap \bigcap_{j \in \tilde{J}} \operatorname{Ker} D_x g_j(\bar{z}). \tag{3.1}$$

Then $\bar{x}$ is strongly stable if for all $\tilde{J}$ with $J_0^+(\bar{z}) \subset \tilde{J} \subset J_0(\bar{z})$:

K1. $D_x^2 L(\bar{z})_{|T(\tilde{J})}$ is nonsingular

K2. sign det $(D_x^2 L(\bar{z})_{|T(\tilde{J})})$ is constant.

We will present a new condition which is equivalent with K1, K2. In fact, this condition clarifies some ideas behind Kojima's work, such as the stationary index, introduced in [9]. We show that $D_x^2 L(\bar{z})_{|T(J_0^+(\bar{z}))}$ is in a certain sense a "positive extension" of $D_x^2 L(\bar{z})_{|T(J_0(\bar{z}))}$:

THEOREM 3.1. *Let $\bar{x}$ be a Kuhn-Tucker point for $P(\bar{t})$. In the terminology of Definition* 3.1, *let V be a matrix whose columns form a basis for $T(J_0^+(\bar{z}))$. Moreover,*

let $T(J_0^+(\bar z)/J_0(\bar z))$ *denote the orthogonal complement in* $T(J_0^+(\bar z))$ *of* $T(J_0(\bar z))$. *Then,* $\bar x$ *is strongly stable iff* K1*, K2* *hold*:

K1*. $V^T D_x^2 L(\bar z) V$ *is nonsingular.*

K2*. $(V^T D_x^2 L(\bar z) V)^{-1}_{|T(J_0^+(\bar z)/J_0(\bar z))}$ *is positive definite.*

The proof of Theorem 3.1 is a direct consequence of Theorem 3.2 below. But first, we need the following lemma (cf. [6], [7] for a proof).

Let Ind (index) denote "the number of negative eigenvalues" and let $\perp$ denote the orthogonal complement.

LEMMA 3.1. *Let A be a nonsingular symmetric $n\times n$-matrix, L be a linear subspace of R^n. If $A^{-1}_{|L^\perp}$ is nonsingular, then we have*:

a. $A_{|L}$ *is nonsingular.*

b. $\operatorname{Ind}(A) = \operatorname{Ind}(A_{|L}) + \operatorname{Ind}(A^{-1}_{|L^\perp})$.

Let L_a, L_b be linear subspaces of R^n, $L_a \subset L_b$ and $L_a \neq L_b$. A finite sequence of linear subspaces $L_1, L_2, \cdots, L_p$ of R^n is called a simple chain from L_a to L_b if $L_1 = L_a$, $L_p = L_b$, $L_i \subset L_{i+1}$ and $\dim(L_{i+1}) = \dim(L_i) + 1$ for $i = 1, \cdots, p-1$.

THEOREM 3.2. *Let A be a nonsingular symmetric $n \times n$-matrix and $L \subset R^n$ a linear subspace. Then $A^{-1}_{|L^\perp}$ is positive definite iff there is some simple chain $L_1, \cdots, L_r$ from L to R^n such that*:

S1. $A_{|L_i}$ *is nonsingular for* $i = 1, \cdots, r$.

S2. $\operatorname{sign\,det}(A_{|L_i})$ *is constant,* $i = 1, \cdots, r$.

Proof. The theorem in the cases $\dim(L) = 0, n$ being obvious, we assume that $0 < \dim(L) < n$.

The "only if" part. Suppose that $A^{-1}_{|L^\perp}$ is positive definite and let $L_1, \cdots, L_r$ be any simple chain from L to R^n. Since $L_i^\perp \subset L^\perp$ it follows that $A^{-1}_{|L_i^\perp}$ is positive definite as well. From Lemma 3.1 we conclude that $A_{|L_i}$ is nonsingular and

$$\operatorname{Ind}(A) = \operatorname{Ind}(A_{|L_i}) + \operatorname{Ind}(A^{-1}_{|L_i^\perp}) = \operatorname{Ind}(A_{|L_i}). \tag{3.2}$$

But (3.2) and the fact that both A and $A_{|L_i}$ are nonsingular imply that $\operatorname{sign\,det}(A) = \operatorname{sign\,det}(A_{|L_i})$.

The "if part". Let $L_1, \cdots, L_r$ be a simple chain from L to R^n such that S1, S2 hold. From S1 and Lemma 3.1a we conclude that $A^{-1}_{|L_i^\perp}$ is nonsingular. If we can show that $\operatorname{Ind}(A_{|L_i}) = \operatorname{Ind}(A_{|L_{i+1}})$, $i = 1, \cdots, r-1$, then we are done. In fact, in that case, it follows that $\operatorname{Ind}(A_{|L_1}) = \operatorname{Ind}(A_{|L_r})$; hence, $\operatorname{Ind}(A_{|L}) = \operatorname{Ind}(A)$.

Now we can apply Lemma 3.1b and conclude that $\operatorname{Ind}(A^{-1}_{|L^\perp}) = 0$. This implies that A^{-1} is positive semi-definite on $L^\perp$. But since we already know that $A^{-1}_{|L^\perp}$ is nonsingular, it follows that $A^{-1}_{|L^\perp}$ is positive definite.

So it remains to show that $\operatorname{Ind}(A_{|L_i}) = \operatorname{Ind}(A_{|L_{i+1}})$. Let V_i, V_{i+1} be a matrix whose columns form a basis for L_i, L_{i+1} (V_{i+1} extending V_i), and let T_i be the one-dimensional linear subspace of L_{i+1} orthogonal to L_i. From S_1 we see that both $V_i^T A V_i$ and $V_{i+1}^T A V_{i+1}$ are nonsingular. Now we replace in Lemma 3.1 the matrix A by $(V_{i+1}^T A V_{i+1})^{-1}$, the linear space L by T_i and obtain from Lemma 3.1a, in view of the nonsingularity of $V_i^T A V_i$, that $(V_{i+1}^T A V_{i+1})^{-1}_{|T_i}$ is nonsingular. Keeping this result in mind, we replace in Lemma 3.1 the matrix A by $V_{i+1}^T A V_{i+1}$, the linear subspace L by L_i and we obtain:

$$\operatorname{Ind}(V_{i+1}^T A V_{i+1}) = \operatorname{Ind}(V_i^T A V_i) + \operatorname{Ind} \underbrace{((V_{i+1}^T A V_{i+1})^{-1}_{|T_i})}_{\delta_i}. \tag{3.3}$$

Since T_i is one-dimensional, we see that δ_i in (3.3) is a number which is either equal to one or zero. If δ_i equals one, then $\operatorname{Ind}(V_{i+1}^T A V_{i+1})$ is even (resp. odd) whenever

Ind $(V_i^T A V_i)$ is odd (resp. even). Consequently, we obtain:

$$\text{sign det}\,(V_{i+1}^T A V_{i+1}) = -\text{sign det}\,(V_i^T A V_i). \tag{3.4}$$

However, (3.4) is in contradistinction to S2. Hence, we obtain $\delta_i = 0$ and (3.3) yields the desired result. □

Remark 3.1. From the proof of Theorem 3.2 we see that we may replace in the formulation of Theorem 3.2 "iff there is some simple chain $\cdots$" by "iff for every simple chain $L_1, \cdots, L_r$ from L to R^n the conditions S1, S2 hold:".

Remark 3.2. A special case of Lemma 3.1 is obtained as follows: A nonsingular symmetric $n \times n$-matrix A is positive definite iff for some (and hence every) linear subspace $L \subset R^n$ we have: $A_{|L}$ and $A_{|L^\perp}^{-1}$ are positive definite. This particular case has been proved by Fujiwara et al. [2] by means of tools from optimization theory. Finally, we mention the following: at the level of positive (semi-) definiteness there is an interesting extension proved by Han and Mangasarian [4] where linear subspaces are replaced by certain cones.

4. On the local Lipschitz continuity of the Kuhn–Tucker curve. Strong stability of a Kuhn-Tucker point implies continuity of the Kuhn-Tucker curve. This is an immediate consequence of Kojima's theory [9]. We show by means of application of Hager's theorem to certain canonical curves, that local Lipschitz continuity of the KT-curve is then automatically true. We mention that local Lipschitz continuity is also established by means of two different approaches, in fact by Kojima and Hirabayashi [10] and Robinson [13].

THEOREM 4.1. *Let $\bar{x}$ be a Kuhn-Tucker point for $P(\bar{t})$ which is strongly stable. Then, in some neighborhood $\mathcal{O}$ of $\bar{z} = (\bar{x}, \bar{t})$ the Kuhn-Tucker set can be parametrized as a continuous function of the parameter t, say $\{(x(t), t), t \in (a, b)\}$. Moreover, the function $t \to x(t)$ is locally Lipschitz continuous. The same holds w.r.t. the corresponding Lagrange parameters $\lambda_i(t)$, $\mu_j(t)$ under the convention that $\mu_j(t) = 0$ if $g_j(x(t), t) \neq 0$.*

For the proof of Theorem 4.1 we need the following simple lemma (see for example [5]).

LEMMA 4.1. *Let A be a symmetric $n \times n$-matrix, B be an $n \times k$-matrix, and let V be a matrix whose columns form a basis for* Ker B^T. *Then the matrix Q,*

$$Q = \begin{pmatrix} A & B \\ B^T & 0 \end{pmatrix},$$

is nonsingular iff rank $B = k$ *and $V^T A V$ is nonsingular.*

Proof of Theorem 4.1. As we mentioned in the beginning of this section we only show that the continuity of the Kuhn-Tucker curve [9] automatically implies local Lipschitz continuity. Note that for every $\tilde{J}$, $J_0^+(\bar{z}) \subset \tilde{J} \subset J_0(\bar{z})$, the point $\bar{x}$ is a critical point for $\tilde{P}(\bar{t})$:

$$\tilde{P}(\bar{t}): \quad \text{Minimize } f(x, \bar{t}) \text{ subject to } h_i(x, \bar{t}) = 0,\ i \in I,\ g_j(x, \bar{t}) = 0,\ j \in \tilde{J}.$$

Otherwise stated, $(\bar{x}, \bar{t}, \bar{\lambda}_i, i \in I, \bar{\mu}_j, j \in \tilde{J})$ is a zero point of the C^1-map $\tilde{\mathcal{F}}$:

$$\tilde{\mathcal{F}}: \begin{pmatrix} x \\ t \\ \lambda_i,\ i \in I \\ \mu_j,\ j \in \tilde{J} \end{pmatrix} \to \begin{pmatrix} D_x^T f(x, t) - \sum_{i \in I} \lambda_i D_x^T h_i(x, t) - \sum_{j \in \tilde{J}} \mu_j D_x^T g_j(x, t) \\ -h_i(x, t),\ i \in I \\ -g_j(x, t),\ j \in \tilde{J} \end{pmatrix}$$

where $\bar{\lambda}_i$, $i \in I$, $\bar{\mu}_j$, $j \in J_0(\bar{z})$ are the Lagrange parameters corresponding to $\bar{x}$ as a critical point for $P(\bar{t})$.

The map $\tilde{\mathcal{F}}$ is of class C^1. Since $\bar{x}$ is strongly stable, we see that the Jacobian matrix of $\tilde{\mathcal{F}}$ w.r.t. $(x, \lambda_i, i \in I, \mu_j, j \in \tilde{J})$ at $(\bar{x}, \bar{t}, \bar{\lambda}_i, i \in I, \bar{\mu}_j, j \in \tilde{J})$ is nonsingular, thereby using Lemma 4.1. By means of the implicit function theorem we obtain locally a unique C^1-curve $(\tilde{x}(t), t, \tilde{\lambda}_i(t), i \in I, \tilde{\mu}_j(t), j \in \tilde{J})$ along which $\tilde{\mathcal{F}}$ vanishes identically. In particular, $\tilde{x}(t)$, $\tilde{\lambda}_i(t)$, $i \in I$, $\tilde{\mu}_j(t)$, $j \in \tilde{J}$, are locally Lipschitz continuous. For t in some open neighborhood (a, b) of $\bar{t}$ the Kuhn-Tucker curve $\{(x(t), t) \mid t \in (a, b)\}$ obviously has the property that $x(t) = \tilde{x}(t)$, where $\tilde{x}(t)$ corresponds to some $\tilde{J}$, $J_0^+(\bar{z}) \subset \tilde{J} \subset J_0(\bar{z})$. But then, Theorem 2.2 implies that $t \to x(t)$ is locally Lipschitz continuous. With the convention that $\tilde{\mu}_j(t) = 0$ if $j \notin \tilde{J}$, the corresponding result for the Lagrange parameters follows in a similar way. □

5. On the piecewise C^1-differentiability of the Kuhn–Tucker curve. In general, under the assumptions of Theorem 4.1, local Lipschitz continuity of the Kuhn-Tucker curve will not imply piecewise C^1-differentiability (shortly PC^1). So, we need an additional condition in order to guarantee the latter fact. The idea behind such an additional condition comes from the recent investigations of Jongen et al. [7] where generic properties of (generalized) critical point sets are studied. On the other hand and independently from [7], this is also connected with assumptions on regular values of certain maps used by Kojima and Hirabayashi [11]. Let us start with an illustrating simple example.

Example 5.1. Consider $f(x, t) := x^2 - \phi(t)x \to \min$, $x \geqq 0$. Put $\phi(t) = t^6 \sin(1/t)$, $t \neq 0$ and $\phi(0) = 0$. Then, f is of class C^2. Clearly, $\bar{x} = 0$ is the unique minimum as the parameter t equals zero. Moreover, $\bar{x} = 0$ is then strongly stable, but the Kuhn-Tucker curve is merely local Lipschitz continuous and not PC^1. A similar example can be constructed with ϕ (and hence f) being of class C^∞. So, smoothness of the data is not sufficient for guaranteeing the KT-curve to be PC^1. Note, on the other hand, that a similar example cannot be constructed with ϕ analytic. □

Let $\bar{x}$ be a Kuhn-Tucker point for $P(\bar{t})$ which is strongly stable. In view of Theorem 4.1 the Kuhn-Tucker curve is locally Lipschitz continuous in a neighborhood of $\bar{z} = (\bar{x}, \bar{t})$. In order to study the local PC^1-differentiability we obviously may restrict ourselves to the case that $J_0^+(\bar{z}) \neq J_0(\bar{z})$, i.e. the strict complementarity is violated. In fact, if $J_0^+(\bar{z}) = J_0(\bar{z})$, then the KT-curve is locally already of class C^1. Now, we introduce the following conditions B1, B2.

Condition B1. $J_0(\bar{z}) \backslash J_0^+(\bar{z})$ is a singleton (i.e. the strict complementarity is violated for exactly one binding inequality constraint).

Without loss of generality, we put (if Condition B1 holds):

$$J_0(\bar{z}) = \{1, \cdots, p\}, \qquad J_0^+(\bar{z}) = \{1, \cdots, p-1\}, \tag{5.1}$$

$$B(\bar{z}) = -[D_x^T h_1, \cdots, D_x^T g_p]_{|\bar{z}}. \tag{5.2}$$

Condition B2. Adopting the notation of (5.1), (5.2) the matrix H is nonsingular, where

$$H = \begin{pmatrix} D_x^2 L & B & D_t D_x^T L \\ B^T & 0 & D_t \begin{Bmatrix} -h_i, i \in I \\ -g_j, j = 1, \cdots, p \end{Bmatrix} \\ 0 & (0, \cdots, 0, 1) & 0 \end{pmatrix}_{|\bar{z}}.$$

We need the following simple lemma (without proof).

LEMMA 5.1. *Let A be a nonsingular $n \times n$-matrix, $k > n$ and Q a $k \times k$-matrix:*

$$Q = \begin{pmatrix} A & C \\ E & D \end{pmatrix}.$$

Then Q is nonsingular iff $D - EA^{-1}C$ is nonsingular.

THEOREM 5.1. *Let $\bar{x}$ be a Kuhn-Tucker point for $P(\bar{t})$ which is strongly stable. If Conditions* B1, B2 *hold at $\bar{z} = (\bar{x}, \bar{t})$, then the Kuhn-Tucker curve is locally PC^1-differentiable.*

Proof. Let $\bar{\lambda}_i$, $i \in I$, $\bar{\mu}_j$, $j \in J_0(\bar{z})$ be the Lagrange parameters corresponding to $\bar{x}$. From B1 and the convention (5.1) we see that $\bar{\mu}_p = 0$ and $\bar{\mu}_j > 0$ for $j = 1, \cdots, p-1$. Let $\tilde{P}(t)$ be a problem the only difference of which from $P(t)$ is that the constraint g_p is considered as an equality constraint. Then, $\bar{x}$ is a Kuhn-Tucker point for $\tilde{P}(\bar{t})$ which is nondegenerate as a critical point. But then, in some open neighborhood of $\bar{z}$ the KT-curve w.r.t. $\tilde{P}(t)$ is of class C^1 (cf. proof of Theorem 4.1), say $t \to [\tilde{x}(t), t, \tilde{\lambda}_i(t), i \in I, \tilde{\mu}_j(t), j \in J_0(\bar{z})]$. For t in some neighborhood of $\bar{t}$ we observe: $(\tilde{x}(t), t)$ is a critical point for $P(t)$ as well and it is a Kuhn-Tucker point for $P(t)$ iff $\tilde{\mu}_p(t) \geqq 0$. Since $\tilde{\mu}_p(\bar{t}) = \bar{\mu}_p = 0$, a moment of reflection shows that we are done if we can show that $\dot{\tilde{\mu}}_p(\bar{t}) = d\mu_p(\bar{t})/dt \neq 0$.

The derivatives $\dot{\tilde{x}}(\bar{t})$, $\dot{\tilde{\lambda}}_i(\bar{t})$, $\dot{\tilde{\mu}}_j(\bar{t})$ are obtained as the solution of the system:

$$\begin{pmatrix} D_x^2 L & B \\ B^T & 0 \end{pmatrix}_{\bar{z}} \begin{pmatrix} \dot{\tilde{x}} \\ \dot{\tilde{\lambda}}_i,\ i = 1, \cdots, m \\ \dot{\tilde{\mu}}_j,\ j = 1, \cdots, p \end{pmatrix}_{\bar{t}} + \begin{pmatrix} D_t D_x^T L \\ -D_t h_i,\ i = 1, \cdots, m \\ -D_t g_j,\ j = 1, \cdots, p \end{pmatrix}_{\bar{z}} = 0, \tag{5.3}$$

with B as in (5.2). The system (5.3) is determined by means of the implicit function theorem, introducing a corresponding map $\tilde{\mathcal{T}}$ as in the proof of Theorem 4.1. We denote:

$$\begin{pmatrix} D_x^2 L & B \\ B^T & 0 \end{pmatrix}_{\bar{z}} = \begin{pmatrix} A & b \\ b^T & 0 \end{pmatrix}, \quad b \text{ the last column of } B(\bar{z}), \tag{5.4}$$

$$\begin{pmatrix} D_t D_x^T L \\ -D_t h_i,\ i \in I \\ -D_t g_j,\ j \in J_0(\bar{z}) \end{pmatrix}_{\bar{z}} = \begin{pmatrix} v \\ -D_t g_p(\bar{z}) \end{pmatrix}. \tag{5.5}$$

From Lemma 4.1, Condition B1 and the fact that $\bar{x}$ is a strongly stable KT-point it follows that in (5.4) both A and $\left(\begin{smallmatrix} A & b \\ b^T & 0 \end{smallmatrix}\right)$ are nonsingular.

Now we can compute:

$$\dot{\tilde{\mu}}_p(\bar{t}) = (b^T A^{-1} b)^{-1}(-D_t g_p(\bar{z}) - b^T A^{-1} v).$$

However, using Lemma 5.1, it follows that the matrix H (cf. Condition B2) is nonsingular iff $(b^T A^{-1} b)^{-1}(-D_t g_p(\bar{z}) - b^T A v) \neq 0$. This completes the proof of Theorem 5.1. □

Remark 5.1. In the proof of Theorem 5.1 we used the fact that $\dot{\tilde{\mu}}_p(\bar{t})$ is unequal to zero. It is easily seen that the corresponding derivative in Example 5.1 actually vanishes!

Acknowledgments. We would like to thank Bruno Brosowski who invited both of us to Oberwolfach where this work was initiated. Moreover, we are grateful to the anonymous referees. Their precise and positive criticism improved the quality and readability of our manuscript.

THE GENERIC LOCAL TIME-OPTIMAL STABILIZING CONTROLS IN DIMENSION 3*

ALBERTO BRESSAN†

Abstract. This paper studies the control system

$$\dot{x}(t) = X(x(t)) + Y(x(t))u(t), \qquad X(p_0) = 0, |u(t)| \leqq 1,$$

where X and Y are $\mathscr{C}^\infty$ vector fields on a 3-dimensional manifold $\mathcal{M}$. Under generic assumptions on X, Y, the structure of the time-optimal stabilizing controls is completely determined in a neighborhood of p_0. The proofs rely on a systematic use of a local asymptotic approximation of X and Y by means of vector fields which generate a nilpotent Lie algebra.

Key words. nonlinear control system, time optimal trajectory, asymptotic nilpotent approximation

AMS(MOS) subject classifications. 49B10, 93C10

1. Introduction. Let $\mathcal{M}$ be a 3-dimensional manifold, $p_0 \in \mathcal{M}$ and let X, Y be smooth vector fields on $\mathcal{M}$ with $X(p_0) = 0$. Consider the control system

$$\begin{aligned} \dot{y}(t) &= X(y(t)) + Y(y(t))u(t), \\ y(0) &= p_0, \end{aligned} \tag{1.1}$$

where the scalar control $u(\cdot)$ is measurable and satisfies $|u(t)| \leqq 1$ almost everywhere. This paper provides a description of all admissible controls that steer the system (1.1) in minimum time from p_0 to any point p in a neighborhood of p_0. We show that the structure of the local time-optimal trajectories is completely determined by the Lie brackets up to order three of X and Y at p_0, under the generic assumptions

(A1) The vectors Y, $[Y, X]$ and $[[Y, X], X]$ are linearly independent at p_0,

(A2) $[Y, [Y, X]](p_0) = \bar{k}_1 Y(p_0) + \bar{k}_2 [Y, X](p_0) + \bar{k}_3 [[Y, X], X](p_0)$ with $|\bar{k}_3| \neq 1$.

For the system (1.1), a numerical algorithm yielding a stabilizing control was studied in [7]. Sussmann [12] provided a complete description of time-optimal trajectories for analytic systems in the plane. The present work is part of a general program of research whose goal is to determine the local properties of control systems of the form (1.1) from the linear relations among the Lie brackets of X and Y at p_0. Our main technique is the local approximation of (1.1) by means of a nilpotent system defined on the same state space [1]. Somewhat different approximations were discussed in [3], [6] and applied in [8], [11] to obtain results on local controllability. From (1.1), a suitable rescaling of time and space coordinates leads us to the system

$$\begin{aligned} (\dot{x}_1, \dot{x}_2, \dot{x}_3) &= (u, x_1, x_2 + kx_1^2/2) + h(x), \\ (x_1, x_2, x_3)(0) &= (0, 0, 0), \qquad t \in [0, 1], \end{aligned} \tag{1.2}$$

where $k = \bar{k}_3$, and the vector field $h(\cdot)$ is as small as we please, together with all of its high-order partial derivatives. In the special case $h \equiv 0$, the trajectories of (1.2) are easily computed as integrals of the control. The time-optimal controllability problem can therefore be explicitly solved applying Pontryagin's maximum principle. We use the directional convexity of the reachable set and a global necessary condition [2] to rule out the optimality of bang-bang controls with more than two switchings. In the

† Istituto di Matematica Applicata, Università di Padova, Padova 35100, Italy.

general case, h can be regarded as a small perturbation. Repeated applications of the implicit function theorem complete the proof. The asymptotic approximation technique used here appears to be quite general and might be effective in the study of higher dimensional systems as well.

2. The main theorem. As a preliminary, note that if (A1) holds, by the implicit function theorem the equation

$$[Y,[Y,X]](y) = k_1(y)\,Y(y) + k_2(y)[Y,X](y) + k(y)[[Y,X],X](y) \tag{2.1}$$

uniquely defines the smooth functions $k_i(y)$ in a neighborhood V of p_0. If (A2) holds with $|\bar{k}_3| > 1$, we can also assume $|k_3(y)| > 1$ for all $y \in V$. Two special families of trajectories will be considered.

DEFINITION. Let $y(\cdot)$ be an absolutely continuous map from $[0, T]$ into $\mathcal{M}$ with $y(0) = p_0$. We say that y is a BBB-trajectory for the system (1.1) if there exist $0 \leqq \tau_1 \leqq \tau_2 \leqq T$ such that

$$\dot{y} = X(y) + Y(y) \quad \text{or} \quad \dot{y} = X(y) - Y(y) \tag{2.2}$$

on each one of the (possibly empty) subintervals $(0, \tau_1)$, (τ_1, τ_2), (τ_2, T). We call $y(\cdot)$ a BSB-trajectory if there exist $0 \leqq \tau_1 < \tau_2 \leqq T$ such that (2.2) holds on $(0, \tau_1)$ and on (τ_2, T), while

$$\dot{y} = X(y) + k_3^{-1}(y)\,Y(y) \tag{2.3}$$

on (τ_1, τ_2).

Our main result states that the bang-bang and the partially singular trajectories just defined are locally the only optimal ones.

THEOREM 1. *Consider the system* (1.1) *and let* (A1), (A2) *hold.*

i) *If* $|\bar{k}_3| < 1$, *then there exists a neighborhood* V *of* p_0 *in* $\mathcal{M}$ *such that every time-optimal trajectory steering* p_0 *to a point* $p \in V$ *is a BBB-trajectory.*

ii) *If* $|\bar{k}_3| > 1$, *then there exists a neighborhood* V *of* p_0 *such that every trajectory steeering* p_0 *to a point* $p \in V$ *in minimum time is either a BBB- or a BSB-trajectory.*

By inverting time and the vector fields X, Y, Theorem 1 thus yields the solution of the generic local time-optimal stabilization problem in dimension three. A noteworthy consequence is that, at least for analytic X and Y, this solution can be written in regular feedback form [13]. When $|\bar{k}| < 1$, (1.1) behaves essentially like a linear system. Part i) in Theorem 1 could already be deduced from [10]. When $|\bar{k}_3| > 1$, the nonlinearities begin to play a major role, and a careful analysis is required. In §§ 3, 4 we prove that Theorem 1 is a consequence of an analogous result (Theorem 2) concerning the system (1.2). The main steps in the proof of Theorem 2 are collected in § 5. Technical details are then worked out in §§ 6–10, which may be skipped in a first reading.

3. An equivalent result. By introducing a suitable set of coordinates, (1.1) will be transformed into a more tractable system on $\mathbb{R}^3$. In the following, the variable in $\mathbb{R}^3$ is $x = (x_1, x_2, x_3)$ and $\{e_1, e_2, e_3\}$ denotes the canonical orthonormal basis. Given a smooth vector field $g = (g_1, g_2, g_3)$ on $\mathbb{R}^3$, its partial derivatives are written

$$g_{i,j} = \frac{\partial g_i}{\partial x_j}, \quad g_{i,jk} = \frac{\partial^2 g_i}{\partial x_j\,\partial x_k}, \quad \cdots;$$

∇g denotes the 3×3 matrix $(g_{i,j})$ of first order partials of g. Consider the map

$$\theta\colon (s_1, s_2, s_3) \to (\exp s_1 Y) \cdot (\exp s_2 [Y,X]) \cdot (\exp s_3 [[Y,X],X])(p_0), \tag{3.1}$$

where $(\exp sZ)(p)$ is the value at time s of the solution of the Cauchy problem

$$\dot{y}(t) = Z(y(t)), \qquad y(0) = p \in \mathcal{M}.$$

Because of (A1), θ defines a local chart of a neighborhood of p_0. In this chart, the system (1.1) becomes

$$\dot{x} = f(x) + e_1 u, \qquad x(0) = 0 \in \mathbb{R}^3. \tag{3.2}$$

The vector field f can be written in the form

$$f(x) = (\bar{k}_1 x_1^2/2,\ x_1 + \bar{k}_2 x_1^2/2,\ x_2 + \bar{k}_3 x_1^2/2) + \tilde{f}(x) \tag{3.3}$$

with $\tilde{f}_{i,j}(0) = \tilde{f}_{i,11}(0) = 0$ for $i = 1, 2, 3$, $j = 1, 2$.

Since the problem is local, we can assume that θ is defined on some open ball $B_r \subseteq \mathbb{R}^3$ centered at the origin with radius r, and that f can be extended outside B_r to a $\mathcal{C}^\infty$ vector field, still called f, with compact support. We now apply to (3.2) the asymptotic rescaling procedure discussed in [1]. Consider the orthogonal decomposition $\mathbb{R}^3 = W_1 \oplus W_2 \oplus W_3$ with $W_i = \{\xi e_i;\ \xi \in \mathbb{R}\}$. Let $\pi_i : \mathbb{R}^3 \to W_i$ be the canonical projections. Given an admissible control $u(\cdot)$, let $t \to x(u, t)$ be the corresponding trajectory of (3.2). If u is defined on the time-interval $[0, \varepsilon]$, construct the rescaled control $u_\varepsilon : [0, 1] \to \mathbb{R}$ by setting $u_\varepsilon(t) = u(\varepsilon t)$. Moreover, set

$$x^\varepsilon(u_\varepsilon, t) = \sum_{i=1}^{3} \varepsilon^{-i} \pi_i(x(u, \varepsilon t)). \tag{3.4}$$

A direct computation shows that x^ε is the response of the system

$$\dot{x}(t) = f^\varepsilon(x(t)) + e_1 u_\varepsilon(t), \qquad x(0) = 0 \in \mathbb{R}^3 \tag{3.5}$$

with $f^\varepsilon = (f_1^\varepsilon, f_2^\varepsilon, f_3^\varepsilon)$,

$$f_i^\varepsilon(x) = \varepsilon^{1-i} f_i\left(\sum_{j=1}^{3} \varepsilon^j \pi_j(x)\right). \tag{3.6}$$

For every $\varepsilon > 0$, (3.5) is merely a linear rescaling of (3.2). Therefore, a control u is time-optimal for (3.2) on $[0, \varepsilon]$ if and only if the corresponding u_ε is time-optimal for (3.5) on $[0, 1]$. Because of (3.3), the main result proved in [1] now implies that, as $\varepsilon \to 0$, f^ε converges to the vector field

$$\bar{f}(x) = (0,\ x_1,\ x_2 + \bar{k}_3 x_1^2/2) \tag{3.7}$$

together with all partial derivatives, uniformly on bounded sets. Theorem 1 thus becomes a consequence of the following result concerning the system (1.2). If $k \geqq 0$, we write Ω_k for the open box $(-2, 2) \times (-1, 1) \times (-1 - k, 1 + k) \subset \mathbb{R}^3$, $\mathcal{C}^3(\Omega_k)$ for the Banach space of three times continuously differentiable vector fields on Ω_k, and we let $\mathcal{F}$ be the family of all neighborhoods of the null vector field in $\mathcal{C}^3(\Omega_k)$.

THEOREM 2. a) *If $0 \leqq k < 1$, then there exists $\mathcal{V} \in \mathcal{F}$ such that for all $h \in \mathcal{V}$, $0 \leqq T \leqq 1$, every time-optimal control $u(\cdot)$ for (1.2) on $[0, T]$ is bang-bang with at most two switchings.*

b) *If $k > 1$, then there exists $\mathcal{V} \in \mathcal{F}$ such that, given any $h \in \mathcal{V}$, every time-optimal control u for (1.2) on $[0, T] \subseteq [0, 1]$ has the following property. Either u is bang-bang with finitely many switchings on $[0, T]$, or there exists $0 \leqq t_1 < t_2 \leqq T$ such that $u(t)$ is constantly equal to $+1$ or -1 on $[0, t_1]$ and on $[t_2, T]$, while $u(t) = k_3^{-1}(x(t))$ on (t_1, t_2). Here $k_3(x)$ is the third coefficient in the linear relation*

$$[e_1, [e_1, g]](x) = k_1(x) e_1 + k_2(x)[e_1, g](x) + k_3(x)[[e_1, g], g](x), \tag{3.8}$$

with $g = \bar{f} + h$.

c) *If $k>1$, then there exists $\mathcal{V}\in\mathcal{F}$ such that, if $h\in\mathcal{V}$ and u is a bang-bang control with initial switchings at times $0<t_1<t_2<t_3=1$, then u is not time-optimal for* (1.2) *after time* 1.

As usual, statements concerning controls in $\mathcal{L}^1$ are always meant "up to $\mathcal{L}^1$-equivalence."

4. Proof of Theorem 1. Let Theorem 2 hold. By possibly replacing Y with $-Y$ in (A2) we can assume $\bar{k}_3\geqq 0$. Consider the case $0\leqq\bar{k}_3<1$ first. Set $k=\bar{k}_3$ and choose the neighborhood $\mathcal{V}\in\mathcal{F}$ according to a) in Theorem 2. Choose $\varepsilon>0$ so small that the reachable set at time ε for the sytem (1.1) is contained within the range of the chart θ, i.e. $R(\varepsilon)\subset\theta(B_r)$, and such that $\varepsilon\Omega\subset B_r$, $h=f^\varepsilon-\bar{f}\in\mathcal{V}$. This is possible because, as $\varepsilon\to 0$, the convergence of f^ε to $\bar{f}$ in (3.6), (3.7) is uniform on the bounded set Ω_k [1]. If the control u steers the system (1.1) from p_0 to some point $p\in R(\varepsilon)$ in minimum time $\eta\leqq\varepsilon$, then the control $t\to u_\varepsilon(t)=u(\varepsilon t)$ is time optimal for the system (1.2) on the interval $[0,\eta\varepsilon^{-1}]\subseteq[0,1]$. By a) in Theorem 2, u_ε is bang-bang with at most two switchings, hence the same holds for u. Taking $V=R(\varepsilon)$, this proves i) in Theorem 1.

The proof of ii) is similar. If $\bar{k}_3>1$, set $k=\bar{k}_3$ and choose $\mathcal{V}\in\mathcal{F}$ according to b) and c) in Theorem 2. Choose $\varepsilon>0$ such that $R(\varepsilon)\subset\theta(B_r)$, $\varepsilon\Omega_k\subset B_r$, $f^\eta-\bar{f}\in\mathcal{V}$ for every $\eta\in[0,\varepsilon]$. If $0<\eta\leqq\varepsilon$ and the control u is time-optimal for (1.1) on $[0,\eta]$, then, setting $h=f^\varepsilon-\bar{f}$, the control $t\to u_\varepsilon(t)=u(\varepsilon t)$ is optimal for (1.2) on $[0,\eta\varepsilon^{-1}]\subseteq[0,1]$. By b) in Theorem 2, either u_ε is partly singular, or u_ε is bang-bang with finitely many switchings, hence the same holds for u. In the first case, comparing (3.8) with (2.1) one concludes that u generates a BSB-trajectory, because the linear relations among the Lie brackets of the vector fields f, e_1 are preserved under the transformation (3.6). In the second case, if u has more than two switchings inside $[0,\eta]$, let $0<t_1<t_2<t_3=\eta'<\eta$ be its first three switching times. The control $t\to u_{\eta'}(t)=u(\eta' t)$ has then its third switch at $t=1$. Since $f^{\eta'}-\bar{f}\in\mathcal{V}$, using c) we see that $u_{\eta'}$ is not optimal after time 1, hence u is not optimal at time $\eta>\eta'$, a contradiction. Taking $V=R(\varepsilon)$, this completes the proof of part ii).

5. Sketch of the proof of Theorem 2. In the following, we denote $\bar{f}(x)$ the vector field with components $(0, x_1, x_2+kx_1^2/2)$; h is the small perturbation and $g=\bar{f}+h$. We write B_ε for the open ball centered at the origin with radius ε. When $h\equiv 0$, the exact solution of (1.2) is

$$
\begin{aligned}
x_1(u,t)&=\int_0^t u(s)\,ds,\\
x_2(u,t)&=\int_0^t (t-s)u(s)\,ds,\\
x_3(u,t)&=\frac{1}{2}\int_0^t (t-s)^2u(s)\,ds+\frac{k}{2}\int_0^t\left(\int_0^s u(r)\,dr\right)^2 ds.
\end{aligned}
\tag{5.1}
$$

If u is an admissible control, i.e. if $|u(t)|\leqq 1$ almost everywhere, then for $t\in[0,1]$ the trajectory $t\to x(u,t)$ is contained inside the closed box $[-1,1]\times[-\frac{1}{2},\frac{1}{2}]\times[-(k+1)/6,(k+1)/6]$. By a classical perturbation theorem [5], there exists a bounded neighborhood $\mathcal{V}_0\in\mathcal{F}$ such that, if $h\in\mathcal{V}_0$, every admissible trajectory for (1.2) remains inside Ω_k during the time interval $[0,1]$. The neighborhood $\mathcal{V}_0$ now chosen will be kept fixed throughout. The first part of our proof will single out all solutions of the

Pontryagin's equations for (1.2) on any interval $[0, T] \subseteq [0, 1]$.

$$(5.2)_1 \quad (\dot{x}_1, \dot{x}_2, \dot{x}_3) = \left(u + h_1(x), x_1 + h_2(x), x_2 + \frac{k}{2}x_1^2 + h_3(x)\right),$$

$$(5.2)_2 \quad (\dot{\lambda}_1, \dot{\lambda}_2, \dot{\lambda}_3) = -\left(\lambda_2 + kx_1\lambda_3 + \sum_{i=1}^{3} h_{i,1}\lambda_i, \lambda_3 + \sum_{i=1}^{3} h_{i,2}\lambda_i, \sum_{i=1}^{3} h_{i,3}\lambda_i\right),$$

$$(5.2)_3 \quad (x_1, x_2, x_3)(0) = (0, 0, 0), \qquad (\lambda_1, \lambda_2, \lambda_3)(T) = (\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3),$$

$$(5.2)_4 \quad u(t) \in \operatorname{sgn} \lambda_1(t) \quad \text{a.e. on } [0, T],$$

where $\bar{\lambda} = (\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3) \neq (0, 0, 0)$, $0 < T \leqq 1$ and the convention $\operatorname{sgn} 0 = [-1, 1]$ is used. Notice that for every data $\bar{\lambda}$ and T, $(5.2)_{1\text{-}4}$ has at least one solution. Indeed, the compactness of the reachable set $R(T)$ implies the existence of a control $\tilde{u}$ for which $x(\tilde{u}, T) = \max\{\langle \bar{\lambda}, x\rangle; x \in R(T)\}$. Such $\tilde{u}$ clearly yields a solution of (5.2). Different types of extremal controls arise, depending on the direction of $\bar{\lambda}$.

PROPOSITION 1. *There exists $\mathcal{V}_1 \in \mathcal{F}$ such that, if $h \in \mathcal{V}_1$ and $\bar{\lambda}_3^2 \leqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$, then the solution (u, x, λ) of (5.2) is unique and the corresponding control u is bang-bang with at most one switching.*

PROPOSITION 2. *For every $\varepsilon > 0$ there exists $\mathcal{V}_2 \in \mathcal{F}$ such that, if $h \in \mathcal{V}_2$ and $\bar{\lambda}_3^2 \geqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$, then any solution (u, x, λ) of (5.2) satisfies*

$$\ddot{\lambda}_1(t) \in [(1 - k \operatorname{sgn} \lambda_1(t)) + B_\varepsilon]\bar{\lambda}_3 \quad \text{a.e. on } [0, T]. \tag{5.3}$$

The two above results together imply part a) of Theorem 2. Indeed, let $0 \leqq k < 1$ and choose the neighborhoods $\mathcal{V}_1$, $\mathcal{V}_2$ according to Propositions 1 and 2 with $\varepsilon = (1-k)/2$. If $h \in \mathcal{V}_1 \cap \mathcal{V}_2$ and if (u, x, λ) is a solution of (5.2), then either $\bar{\lambda}_3^2 \leqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$ and by Proposition 1 u is bang-bang with at most one switching, or $\bar{\lambda}_3^2 \geqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$. In this case, by (5.3) and the choice of ε, $\ddot{\lambda}_1(t)$ has a.e. the same sign of $\lambda_3(T) = \bar{\lambda}_3 \neq 0$. Hence λ_1 is either strictly concave or strictly convex on $[0, T]$ and can vanish at most at two distinct points. The corresponding control u is therefore bang-bang with no more than two switchings. Next, we assume $k > 1$ and study the case where the third component of $\bar{\lambda}$ is large compared with the others.

PROPOSITION 3. *If $k > 1$, there exists $\mathcal{V}_3 \in \mathcal{F}$ such that every solution (u, x, λ) of (5.2) with $h \in \mathcal{V}_3$, $\bar{\lambda}_3^2 \geqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$, $\bar{\lambda}_3 < 0$, has the following property. There exist $0 \leqq \tau_1 \leqq \tau_2 \leqq T$ such that u is constantly equal to $+1$ or -1 on $[0, \tau_1]$ and on $[\tau_2, T]$, while $u(t) = k_3^{-1}(x(t))$ on (τ_1, τ_2). Here $k_3(x)$ is the scalar function defined at (3.8).*

PROPOSITION 4. *If $k > 1$, there exists $\mathcal{V}_4 \in \mathcal{F}$ such that, for every solution (u, x, λ) of (5.2) with $h \in \mathcal{V}_4$, $\bar{\lambda}_3^2 \geqq (12k+16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$ and $\bar{\lambda}_3 > 0$, either the control u is bang-bang with finitely many switchings on $[0, T]$, or $u(t) = k_3^{-1}(x(t))$ throughout $[0, T]$.*

Propositions 1, 3 and 4 clearly imply part b) of Theorem 2. To prove c), define the set of vectors

$$\Lambda = \{w = (w_1, w_2, w_3) \in \mathbb{R}^3;\ w_3^2 \geqq (12k+16)^2(w_1^2 + w_2^2)\}.$$

Choose $\mathcal{V}_1 \in \mathcal{F}$ according to Proposition 1. An application of Theorem 2 in [2] yields

COROLLARY 1. *If $h \in \mathcal{V}_1$, then the reachable set $R(1)$ for the system (1.2) is Λ-convex, i.e. $R(1)$ contains the point $\xi p + (1-\xi)q$ whenever $p, q \in R(1)$, $\xi \in [0, 1]$ and $p - q \in \Lambda$.*

Let now u be a bang-bang control satisfying Pontryagin's conditions and having a third switch at time $t = 1$. To prove that the value $x(u, 1)$ of the corresponding trajectory at time 1 lies in the interior of $R(1)$, it suffices to exhibit a second admissible control, say u', such that

$$x_i(u', 1) = x_i(u, 1) \quad \text{for } i = 1, 2, \qquad x_3(u', 1) > x_3(u, 1). \tag{5.4}$$

Indeed, if (u, x, λ) is a solution of (5.2) and if the vector field $h(\cdot)$ is sufficiently small, then $\lambda_3(1) > 0$ because of Propositions 1 and 3. The vector $w = x(u', 1) - x(u, 1) = (0, 0, x_3(u', 1) - x_3(u, 1))$ therefore has a positive inner product with $\lambda(1)$ and lies in the interior of Λ. By [2, Thm. 1], $x(u, 1) \in \text{int } R(1)$. To complete the proof, we only need to show that such a control u' always exists. For $a, b, c \geqq 0$ define the control $u^+ = u^+(a, b, c)$ by setting

$$
\begin{aligned}
&u^+(a, b, c)(t) = 1 \qquad \text{for } t \in [0, a) \cup [a+b, a+b+c),\\
&u^+(a, b, c)(t) = -1 \quad \text{for } t \in [a, a+b) \cup [a+b+c, \infty).
\end{aligned} \tag{5.5}
$$

If $\alpha, \beta, \gamma \geqq 0$, define $u^-(\alpha, \beta\, \gamma)(t) = -u^+(\alpha, \beta, \gamma)(t)$. Call $x^+ = x^+(a, b, c)$ the point reached by the system (1.2) at time $T = a+b+c$, subject to the control $u^+(a, b, c)$ and define $x^- = x^-(\alpha, \beta, \gamma)$ similarly. In the special case $h \equiv 0$, the components of x^+, x^- can be explicitly computed from (5.1):

$$
\begin{aligned}
&x_1^+ = a - b + c, \qquad x_2^+ = (a+b+c)^2/2 - (b+c)^2 + c^2,\\
&x_3^+ = \tfrac{1}{3}\{\tfrac{1}{2}(a+b+c)^3 - (b+c)^3 + c^3 + k[a^3 + (b-a)^3 + \tfrac{1}{2}(c-b+a)^3]\},\\
&x_1^- = -\alpha + \beta - \gamma, \qquad x_2^- = -(\alpha+\beta+\gamma)^2/2 + (\beta+\gamma)^2 - \gamma^2,\\
&x_3^- = \tfrac{1}{3}\{-\tfrac{1}{2}(\alpha+\beta+\gamma)^3 + (\beta+\gamma)^3 - \gamma^3 + k[\alpha^3 + (\beta-\alpha)^3 + \tfrac{1}{2}(\gamma-\beta+\alpha)^3]\}.
\end{aligned} \tag{5.6}
$$

The three conditions

$$
x_1^+ = x_1^-, \quad x_2^+ = x_2^-, \quad a+b+c = \alpha+\beta+\gamma = T \tag{5.7}
$$

imply the relations

$$
\alpha = bc/(a+c), \quad \beta = a+c, \quad \gamma = ab/(a+c), \tag{5.8}
$$

$$
a = \beta\gamma/(\alpha+\gamma), \quad b = \alpha+\gamma, \quad c = \alpha\beta/(\alpha+\gamma). \tag{5.9}
$$

When these are satisfied, we have $\Delta x = x^+(a, b, c) - x^-(\alpha, \beta, \gamma) = (0, 0, x_3^+ - x_3^-)$ and a direct calculation (see Appendix) shows that

$$
\begin{aligned}
x_3^+ - x_3^- &= [(a+b+c) - k(a-b+c)]abc/(a+c)\\
&= [(\alpha+\beta+\gamma) + k(\alpha-\beta+\gamma)]\alpha\beta\gamma/(\alpha+\gamma).
\end{aligned} \tag{5.10}
$$

If $a, b, c > 0$ and $u^+(a, b, c)$ satisfies the maximum principle on $[0, T+\varepsilon]$ for some $\varepsilon > 0$, then the corresponding adjoint variable λ in (5.2) satisfies

$$
\begin{aligned}
&\lambda_3(t) = \bar{\lambda}_3 > 0 \quad \forall t \in [0, T],\\
&\lambda_1(a) = \lambda_1(a+b) = \lambda_1(a+b+c) = 0,\\
&\ddot{\lambda}_1(t) = (1+k)\bar{\lambda}_3 \quad \text{for } t \in (a, a+b),\\
&\ddot{\lambda}_1(t) = (1-k)\bar{\lambda}_3 \quad \text{for } t \in (a+b, a+b+c).
\end{aligned}
$$

The above relations imply $(k+1)b = (k-1)c$. Using this equality in (5.10) we obtain

$$
x_3^+ - x_3^- = (1-k)a^2bc/(a+c) < 0. \tag{5.11}
$$

If $u = u^+(a, b, c)$, consider the control $u' = u^-(\alpha, \beta, \gamma)$ with α, β, γ defined at (5.8). When $T = a+b+c = 1$, (5.7) and (5.11) imply (5.4). Therefore u cannot be optimal after time $T = 1$. The case where the bang-bang control u takes initially the value -1 can be treated similarly. Let $u = u^-(\alpha, \beta, \gamma)$ for some $\alpha, \beta, \gamma > 0$. If Pontryagin's equations (5.2) are satisfied, then $(k-1)\beta = (k+1)\gamma$. Consider the control $u' =$

$u^+(a, b, c)$ with a, b, c defined in terms of α, β, γ at (5.9). From (5.10) and the above equality we now obtain

$$x_3^+ - x_3^- = (k+1)\alpha^2\beta\gamma/(\alpha+\gamma) > 0. \tag{5.12}$$

When $T = \alpha+\beta+\gamma = 1$, (5.7) and (5.12) imply (5.4). Therefore $u = u^-$ cannot be optimal after time $T = 1$. This establishes part c) of Theorem 2 in the case $h \equiv 0$. Thanks to the implicit function theorem, the above arguments remain valid when a small perturbation h is added to the vector field $\bar{f}$ in (1.2).

PROPOSITION 5. *There exists $\mathcal{V}_5 \in \mathcal{F}$ such that, if $h \in \mathcal{V}_5$ and if u is a bang-bang control with initial switchings at time t_i: $0 < t_1 < t_2 < t_3 = 1$ which satisfies Pontryagin's equations* (5.2) *on* $[0, 1]$ *with* $\lambda_1(1) = 0$, *then there exists a second admissible control u' such that* (5.4) *holds.*

This will complete the proof of Theorem 2.

6. Proof of Proposition 1.

LEMMA 1. *Let $k \geqq 0$, $\lambda \in \mathbb{R}^3$ with $|\lambda| = (\lambda_1^2+\lambda_2^2+\lambda_3^2)^{1/2} = 1$. Set $\eta = (12k+16)^{-1}$ and assume $\lambda_3^2 \leqq \eta^2(\lambda_1^2+\lambda_2^2)$. Then at least one of the following holds*

i) $|\lambda_1| \geqq |\lambda_2| + (2k+1)|\lambda_3| + (2k+4)\eta$;

ii) $|\lambda_2| \geqq (2k+1)|\lambda_3| + (2k+4)\eta$.

Indeed, if ii) fails, since $|\lambda_3| \leqq \eta$ we have

$$\begin{aligned} |\lambda_1| &\geqq 1 - |\lambda_2| - |\lambda_3| \geqq 1 - [(2k+1)|\lambda_3| + (2k+4)\eta] - \eta \\ &\geqq (8k+10)\eta \geqq |\lambda_2| + (2k+1)|\lambda_3| + (2k+4)\eta. \end{aligned}$$

LEMMA 2. *There exists a constant $M > 0$ such that every solution (u, x, λ) of $(5.2)_{1\text{-}4}$ with $|\bar{\lambda}| = 1$, $h \in \mathcal{V}_0$, satisfies*

$$M^{-1} \leqq |\lambda(t)| \leqq M \quad \forall t \in [0, T], \tag{6.1}$$

$$|\dot{x}_i(t)| \leqq M, \qquad |\dot{\lambda}_i(t)| \leqq M, \qquad i = 1, 2, 3, \quad t \in [0, T]. \tag{6.2}$$

Proof. Since $\mathcal{V}_0$ is bounded in $\mathcal{C}^3(\Omega_k)$, the operator norms of the matrices $\nabla g(x)$ of first order partial derivatives of $g = \bar{f} + h$ satisfy a uniform bound, say $|\nabla g(x)| \leqq N$, for all $h \in \mathcal{V}_0$, $x \in \Omega_k$.

By $(5.2)_2$, (6.1) holds with $M = e^N$. The bounds in (6.2) follows from $(5.2)_{1\text{-}2}$ and (6.1), with a possibly larger constant M.

To prove Proposition 1, it clearly suffices to consider the case $|\bar{\lambda}| = 1$. Set $\eta = (12k+16)^{-1}$ and define $\eta' = \eta/3M$, with M being the constant in (6.1), (6.2). Choose a neighborhood $\mathcal{V}_1 \subseteq \mathcal{V}_0$ in $\mathcal{F}$ such that $|h_{i,j}(x)| < \eta'$ for all $x \in \Omega_k$, $h \in \mathcal{V}_1$, $i, j \in \{1, 2, 3\}$. By Lemma 1, two cases must be considered.

Case 1. Let $|\bar{\lambda}_1| \geqq |\bar{\lambda}_2| + (2k+1)|\bar{\lambda}_3| + (2k+4)\eta$. Then for $t \in [0, T] \subseteq [0, 1]$, using $(5.2)_2$ we obtain

$$|\dot{\lambda}_3(t)| \leqq 3\eta' M = \eta,$$

$$|\lambda_3(t)| \leqq |\bar{\lambda}_3| + \eta, \tag{6.3}$$

$$|\dot{\lambda}_2(t)| \leqq |\bar{\lambda}_3| + \eta + 3\eta' M, \tag{6.4}$$

$$|\lambda_2(t)| \leqq |\bar{\lambda}_2| + |\bar{\lambda}_3| + 2\eta,$$

$$|\dot{\lambda}_1(t)| \leqq |\bar{\lambda}_2| + |\bar{\lambda}_3| + 2\eta + 2k(|\bar{\lambda}_3| + \eta) + 3\eta' M,$$

$$|\lambda_1(t)| \geqq |\bar{\lambda}_1| - (|\bar{\lambda}_2| + |\bar{\lambda}_3| + 2\eta) - 2k(|\bar{\lambda}_3| + \eta) - \eta \geqq \eta > 0.$$

Therefore $\lambda_1(t) \neq 0$ throughout the interval $[0, T]$. From $(5.2)_4$ we deduce $u(t) =$

sgn $\lambda_1(t) = \text{sgn}\,\bar\lambda_1$. The control u is thus uniquely determined and constant throughout $[0, T]$.

Case 2. Let $|\bar\lambda_2| \geqq (2k+1)|\bar\lambda_3| + (2k+4)\eta$. From $(5.2)_{1\text{-}2}$, using (6.3) and (6.4) we now obtain

$$\begin{aligned} &|\lambda_2(t)| \geqq |\bar\lambda_2| - |\bar\lambda_3| - 2\eta, \\ &|\dot\lambda_1(t)| \geqq (|\bar\lambda_2| - |\bar\lambda_3| - 2\eta) - 2k(|\bar\lambda_3| + \eta) - 3\eta' M \geqq \eta > 0. \end{aligned} \tag{6.5}$$

By (6.5), $\lambda_1(\cdot)$ is a strictly monotone function, with at most one zero. By $(5.2)_4$, the corresponding control $u(\cdot)$ is bang-bang with at most one switching inside $[0, T]$. We claim that such a control u is unique, whenever $h \in \mathscr{V}_1$, for a suitably small neighborhood $\mathscr{V}_1 \in \mathscr{F}$. To set the ideas, assume $\bar\lambda_2 > 0$, the case $\bar\lambda_2 < 0$ being entirely analogous. Define the set

$$\Gamma = \{\lambda \in \mathbb{R}^3;\ |\lambda| = 1,\ \lambda_3^2 \leqq \eta^2(\lambda_1^2 + \lambda_2^2),\ \lambda_2 \geqq (2k+1)|\lambda_3| + (2k+4)\eta\}$$

and fix $\bar\lambda \in \Gamma$, $0 < T \leqq 1$. For $\tau \in [0, T]$ define the control $u(\tau, \cdot)$ by setting $u(\tau, t) = 1$ when $t \in [0, \tau]$, $u(\tau, t) = -1$ when $t \in (\tau, T]$, and let $x(\tau, \cdot)$, $\lambda(\tau, \cdot)$ be the solutions of $(5.2)_{1\text{-}3}$ corresponding to the control $u(\tau, \cdot)$. Since $\bar\lambda \in \Gamma$, we already know that any solution of $(5.2)_{1\text{-}4}$ is of the form $(u(\tau, \cdot), x(\tau, \cdot), \lambda(\tau, \cdot))$ for some $\tau \in [0, T]$. Notice that $(5.2)_4$ holds iff either $\tau = 0$ and $\lambda_1(0, 0) \leqq 0$, or $0 < \tau < T$ and $\lambda_1(\tau, \tau) = 0$, or $\tau = T$ and $\lambda_1(T, T) \geqq 0$. Uniqueness will be established by proving that

$$\frac{d}{d\tau}\lambda_1(\tau, \tau) < 0 \quad \forall \tau \in [0, T]. \tag{6.6}$$

When $h \equiv 0$ in (1.2), a direct calculation yields

$$\begin{aligned} &x_1(\tau, s) = 2\tau - s \quad \forall s \in [\tau, T], \\ &\lambda_3(\tau, s) = \bar\lambda_3, \qquad \lambda_2(\tau, s) = \bar\lambda_2 + (T-s)\bar\lambda_3, \\ &\lambda_1(\tau, t) = \bar\lambda_1 + \int_t^T [\bar\lambda_2 + (T-s)\bar\lambda_3 + k(2\tau - s)\bar\lambda_3]\, ds, \\ &\frac{d}{d\tau}\lambda_1(\tau, \tau) = -\bar\lambda_2 - (T-\tau)\bar\lambda_3 - k\tau\bar\lambda_3 + 2k(T-\tau)\bar\lambda_3 \\ &\qquad\qquad \leqq -\bar\lambda_2 + (1+2k)|\bar\lambda_3| + k\eta \leqq -(k+3)\eta < 0. \end{aligned} \tag{6.7}$$

This proves (6.6) when $h \equiv 0$. To cover the general case, notice that (6.7) holds uniformly as $(\tau, T, \bar\lambda)$ range in the compact set $\{\tau, T \in \mathbb{R};\ 0 \leqq \tau \leqq T \leqq 1\} \times \Gamma$. Moreover, by the implicit function theorem, the total derivative of $\lambda_1(\tau, \tau)$ w.r.t. τ depends continuously on τ, T, $\bar\lambda$ and on the partial derivatives of order $\leqq 2$ of the vector field h. Therefore, if the neighborhood $\mathscr{V}_1 \in \mathscr{F}$ is suitably small, (6.6) still holds for any $h \in \mathscr{V}_1$. This completes the uniqueness proof.

7. Proof of Proposition 2. Again it is not restrictive to assume $|\bar\lambda| = 1$. In this case, $\bar\lambda_3^2 \geqq (12k+16)^{-2}(\bar\lambda_2^2 + \bar\lambda_3^2)$ implies $|\bar\lambda_3| \geqq (24k+32)^{-1}$. Let M be the constant in (6.1), (6.2) and choose some $\sigma > 0$ for which

$$(24k+32)(9+9M+10k)M\sigma \leqq \varepsilon. \tag{7.1}$$

Choose $\mathscr{V}_2 \in \mathscr{F}$ contained in $\mathscr{V}_0$ such that

$$|h_{i,j}(x)| \leqq \sigma, \quad |h_{i,jl}(x)| \leqq \sigma, \quad |h_1(x)| \leqq \sigma \tag{7.2}$$

for all $h \in \mathcal{V}_2$, $x \in \Omega_k$, $i, j, l \in \{1, 2, 3\}$. Since the right-hand side of $(4.3)_2$ is absolutely continuous, we can differentiate $(4.3)_2$ once more:

$$\ddot{\lambda}_1 = -\dot{\lambda}_2 - k\dot{x}_1\lambda_3 - kx_1\dot{\lambda}_3 - \sum_{i=1}^{3}\sum_{j=1}^{3} h_{i,1j}(x)\dot{x}_j\lambda_i - \sum_{i=1}^{3} h_{i,1}(x)\dot{\lambda}_i. \tag{7.3}$$

Using the bounds (6.1), (6.2), (7.1), (7.2) and the relations

$$\begin{aligned} &-\dot{\lambda}_2 - k\dot{x}_1\lambda_3 = \lambda_3 + \sum_{i=1}^{3} h_{i,2}(x)\lambda_i - ku\lambda_3 - kh_1(x)\lambda_3, \\ &|\dot{\lambda}_3| = \left|\sum_{i=1}^{3} h_{i,3}\lambda_i\right| \leqq 3\sigma M, \qquad |\lambda_3(t) - \bar{\lambda}| \leqq 3\sigma M, \qquad |x_1| \leqq 2, \end{aligned} \tag{7.4}$$

we obtain

$$|\ddot{\lambda}_1(t) - (1 - ku(t))\bar{\lambda}_3| \leqq (9 + 10k + 9M)M\sigma \leqq \varepsilon(24k + 32)^{-1} \leqq \varepsilon|\bar{\lambda}_3|.$$

8. Proof of Proposition 3. Set $\varepsilon = (k-1)/2$ and choose $\mathcal{V}' \in \mathcal{F}$ according to Proposition 2. Choose $\mathcal{V}'' \in \mathcal{F}$ so small that, whenever $h \in \mathcal{V}''$ and $g \in \bar{f} + h$, the following conditions hold at every point $x \in \Omega_k$.

i) The vectors e_1, $[e_1, g](x)$ and $[[e_1, g], g](x)$ are linearly independent.

ii) In (3.8), $k_3(x) > 1$.

Such a $\mathcal{V}''$ exists. Indeed, when $h \equiv 0$ we have $g \equiv \bar{f}$ and $[e_1, \bar{f}](x) = (0, 1, kx_1)$, $[[e_1, \bar{f}], \bar{f}](x) = (0, 0, 1)$, $[e_1, [e_1, \bar{f}]](x) = (0, 0, k)$. In this case the coefficients of the linear combination (3.8) are $k_1(x) = k_2(x) = 0$, $k_3(x) = k > 1$. By continuity, the conditions i) and ii) remain valid when h ranges within a suitably small neighborhood of the null vector field in $\mathcal{C}^3(\Omega_k)$. Now set $\mathcal{V}_3 = \mathcal{V}' \cap \mathcal{V}''$ and let (u, x, λ) be a solution of (5.2) with $\bar{\lambda}_3^2 \geqq (12k + 16)^{-2}(\bar{\lambda}_1^2 + \bar{\lambda}_2^2)$, $\bar{\lambda}_3 < 0$. We claim that $S = \{t \in [0, T];\ \lambda_1(t) = 0\}$ is a closed interval, possibly empty. If $t_1, t_2 \in S$, let $|\lambda_1(\tau)| = \max\{|\lambda_1(t)|;\ t_1 \leqq t \leqq t_2\}$. If $\lambda_1(\tau) \neq 0$, then $u(t) = \operatorname{sgn} \lambda_1(t)$ is constant on a neighborhood of τ, hence λ_1 is twice differentiable at τ. Since $\bar{\lambda}_3 < 0$, (5.3) and the choice of ε imply that $\operatorname{sgn} \ddot{\lambda}_1(\tau) = \operatorname{sgn} \lambda_1(\tau)$, a contradiction that proves our claim. If S is empty, Proposition 3 trivially holds by setting $\tau_1 = \tau_2 = 0$. If S contains a single point τ, set $\tau_1 = \tau_2 = \tau$. Finally, let S be a nondegenerate interval, say $[\tau_1, \tau_2]$. We need to show that $u(t) = k_3^{-1}(x(t))$ a.e. on S. The relations $\lambda_1(t) = \dot{\lambda}_1(t) = \ddot{\lambda}_1(t) = 0$ imply

$$\begin{aligned} &\langle \lambda(t), e_1 \rangle = 0, \\ &\langle -\dot{\lambda}(t), e_1 \rangle = \langle \lambda(t), \nabla g(x(t)) e_1 \rangle = \langle \lambda(t), [e_1, g](x(t)) \rangle = 0, \\ &\langle \ddot{\lambda}_1(t), e_1 \rangle = -\frac{d}{dt}\langle \lambda(t), [e_1, g](x(t)) \rangle \\ &\qquad = \langle \lambda(t), \nabla g(x(t)) \cdot [e_1, g](x(t)) - \nabla [e_1, g](x(t)) \cdot (g(x(t)) + u(t)e_1) \rangle \\ &\qquad = \langle \lambda(t), [[e_1, g], g](x(t)) - u(t)[e_1[e_1, g]](x(t)) \rangle = 0. \end{aligned}$$

Since $\lambda(t)$ never vanishes, for $t \in (\tau_1, \tau_2)$ the vectors e_1, $[e_1, g](x(t))$ and $[[e_1, g], g](x(t)) - u(t)[e_1, [e_1, g]](x(t))$, being orthogonal to $\lambda(t)$, are linearly dependent. Because of the assumption i), $u(t)$ is uniquely determined and thus coincides with $k_3^{-1}(x(t))$, defined by (3.8).

9. Proof of Proposition 4. Some preliminary technical results are needed.

LEMMA 4. *Let $\tau > 0$ and let ϕ be a twice differentiable concave scalar function, with $\phi(0) = \phi(\tau) = 0$, $\dot{\phi}(0) > 0$, and let σ, m_1, m_2 be positive constants such that*

$$-m_2 \leqq \ddot{\phi}(t) \leqq -m_1 < 0, \quad |\ddot{\phi}(t) - \ddot{\phi}(t')| \leqq \sigma|t - t'| \tag{9.1}$$

for all $t, t' \in [0, \tau]$. *Then*

$$|\dot\phi(\tau)| \geqq \dot\phi(0) - 4\sigma(m_1+2m_2)m_1^{-3}\dot\phi^2(0). \tag{9.2}$$

Proof. The first assumption in (9.1) implies $\tau \in [2\dot\phi(0)/m_2, 2\dot\phi(0)/m_1]$. Let $a = -\ddot\phi(0) > 0$ and define the energy $E(t) = \dot\phi^2(t)/2 + a\phi(t)$. Then

$$\left|\frac{dE(t)}{dt}\right| = |\dot\phi(t)(\ddot\phi(t)+a)| \leqq \dot\phi(0)\left(1+\frac{2m_2}{m_1}\right)\sigma t.$$

Integrating from 0 to τ we obtain

$$|E(\tau) - E(0)| \leqq 2\sigma(m_1+2m_2)m_1^{-3}\dot\phi^3(0). \tag{9.3}$$

This implies (9.2) because

$$\begin{aligned}|\dot\phi(\tau)| - |\dot\phi(0)| &= (\dot\phi^2(\tau) - \dot\phi^2(0))(|\dot\phi(\tau)| + |\dot\phi(0)|)^{-1} \\ &\leqq 2|E(\tau) - E(0)||\dot\phi(0)|^{-1}.\end{aligned}$$

LEMMA 5. *Let* $(d_n)_{n\geqq 1}$ *be a sequence of strictly positive numbers such that* $d_{n+1} \geqq d_n - Cd_n^2$ *for some constant* $C > 1$ *and all* $n \geqq 1$. *Then* $\sum_{n=1}^{\infty} d_n = +\infty$.

Proof. If the series converges, then $d_n \to 0$, hence $d_n \leqq 1/2C$ for all $n \geqq N$, with N suitably large. We claim that $d_{N+n} \geqq n^{-1}d_{N+1}$ for all $n \geqq 1$. Indeed, if this inequality holds for some n, then

$$\begin{aligned}d_{N+n+1} &\geqq \min\{x - Cx^2;\ d_{N+1}/n \leqq x \leqq 1/2C\} \\ &= \frac{1}{n}d_{N+1} - \frac{C}{n^2}d_{N+1}^2 \geqq \left(\frac{1}{n} - \frac{C}{n^2}\cdot\frac{1}{2C}\right)d_{N+1} \geqq d_{N+1}/(n+1).\end{aligned}$$

By induction, our claim holds for every $n \geqq 1$, showing that the series diverges, a contradiction.

LEMMA 6. *Let* $h \in \mathscr{V}_0$ *and let* $t \to (x(t), \lambda(t))$ *be any local solution of the autonomous differential equation on* $\mathbb{R}^6$:

$$\dot x(t) = g(x(t)) + e_1, \qquad \dot\lambda(t) = -\lambda(t)\cdot\nabla g(x(t))$$

obtained by setting $u(t) \equiv 1$ *in* $(5.2)_{1\text{-}2}$. *There exists a constant* σ' *such that*

$$\left|\frac{d^3}{dt^3}\lambda_1(t)\right| \leqq \sigma'|\lambda(t)|, \qquad \left|\frac{d}{dt}\lambda_3(t)\right| \leqq \sigma'|\lambda(t)| \tag{9.4}$$

whenever $x(t) \in \Omega_k$. *The smallest possible constant* σ' *in* (9.4) *approaches zero as the vector field* $h = g - \bar f$ *tends to zero in* $\mathscr{C}^3(\Omega_k)$. *The same holds for the system*

$$\dot x(t) = g(x(t)) - e_1, \qquad \dot\lambda(t) = -\lambda(t)\cdot\nabla g(x(t)).$$

All of the above is clear because the left-hand sides in (9.4) depend continuously on x, λ and on the vector field $h \in \mathscr{C}^3(\Omega_k)$, and vanish identically when $h \equiv 0$.

Proposition 4 can now be proved. Fix $\varepsilon = (k-1)/2$, choose $\mathscr{V}_2, \mathscr{V}_3 \in \mathscr{F}$ according to Propositions 2 and 3 and set $\mathscr{V}_4 = \mathscr{V}_2 \cap \mathscr{V}_3$. Let $h \in \mathscr{V}_4$ and let (u, x, λ) be a solution of (5.2) with $|\bar\lambda| = 1$, $\bar\lambda$ satisfying the assumptions made in Proposition 4. If $\lambda_1(t) = 0$ for all $t \in [0, T]$, then $(u, x, -\lambda)$ is another solution of (5.2); hence by Proposition 3 $u(t) = k_3^{-1}(x(t))$ for all t. Now assume $\lambda_1(\tau) \neq 0$ for some $\tau \in [0, T]$. Then $[\tau, T]$ contains only finitely many zeros of λ_1. To see this, set $m_1 = (k-1-\varepsilon)\bar\lambda_3$, $m_2 = (k+1+\varepsilon)\bar\lambda_3$. Whenever $\lambda_1(t) \neq 0$, u is constantly equal to $\operatorname{sgn}\lambda_1(t)$ on a neighborhood of t; hence

λ_1 is three times differentiable at t. By (5.3)

$$-m_2 \leqq \frac{d^2}{dt^2}|\lambda_1(t)| \leqq -m_1 < 0. \tag{9.5}$$

If λ_1 vanishes infinitely many times inside $[\tau, T]$, let τ_0 be the smallest time. Recursively, set $\tau_{n+1} = \inf\{t \in (\tau_n, T];\ \lambda_1(t) = 0\}$. By (9.5), $\dot\lambda_1(\tau_0) \neq 0$ and τ_0 is an isolated zero of λ_1. By induction, one easily checks that the same holds for every n; hence the sequence $(\tau_n)_{n \geqq 1}$ is strictly increasing. We now apply Lemma 4 to the function $\phi(t) = |\lambda_1(\tau_n + t)|$ for each interval $[\tau_n, \tau_{n+1}]$. The second estimate in (9.1) is obtained from (9.4) and (6.1), setting $\sigma = M\sigma'$. Using (9.2) we deduce

$$|\dot\lambda_1(\tau_{n+1})| \geqq |\dot\lambda_1(\tau_n)| - 4\sigma(m_1 + 2m_2)m_1^{-3}|\dot\lambda_1(\tau_n)|^2.$$

If infinitely many τ_n were defined, by Lemma 5 $\sum_{n=0}^{\infty} |\dot\lambda_1(\tau_n)| = +\infty$. From (9.5) it follows that $\tau_{n+1} - \tau_n \geqq 2|\dot\lambda_1(\tau_n)|m_2^{-1}$, hence $\lim_{n\to\infty} \tau_n = +\infty$, providing a contradiction. An analogous argument shows that λ_1 can have only finitely many zeros inside $[0, \tau]$. Hence the corresponding control u is bang-bang with finitely many switchings.

10. Proof of Proposition 5. We restrict the analysis to the case where $u(t) = +1$ on the initial interval $[0, t_1)$. When $u(t) = -1$ on $[0, t_1)$ an entirely analogous argument applies.

LEMMA 7. *For every h in a suitably small neighborhood $V \in \mathcal{F}$, there exists a unique one-parameter family of bang-bang controls $u(\xi) = u^+(a(\xi), b(\xi), c(\xi))$, $\xi \in [0, 1/2]$, having a first switch at time $t = \xi$ and a third switch at $t = 1$, which satisfy Pontryagin's equations* (5.2) *on the time interval $[\xi, 1]$ with $\lambda_1(\xi) = \lambda_1(1) = 0$.*

Proof. Whenever $h \in \mathcal{V}$ is small enough, the proofs of Propositions 1 to 3 show that the adjoint variable $\lambda(\cdot)$ in (5.2) corresponding to a bang-bang control with at least two switchings inside $[0, 1]$ must satisfy

$$\lambda_3(t) > 0, \quad |\ddot\lambda_1(t)/\lambda_3(1) - (1 - ku(t))| \leqq (k-1)/2 \tag{10.1}$$

a.e. on $[0, 1]$. To construct the one-parameter family $u(\xi)$, for a fixed $h \in \mathcal{C}^3(\Omega_k)$, $g = \bar f + h$ and $\xi \in [0, \frac{1}{2}]$, let $u = u^+(\xi, t_2 - \xi, 1 - t_2)$ be the control whose value is initially $+1$ and has switchings at times ξ, t_2, 1, as in (5.5). Consider the Cauchy problem on $\mathbb{R}^6$, starting at time $t = \xi$:

$$\begin{aligned} &\dot x(t) = g(x(t)) + e_1 u(t), \qquad \dot\lambda(t) = -\lambda(t)\nabla g(x(t)), \\ &x(\xi) = (\exp \xi(g + e_1))(0), \quad \lambda(\xi) = (0, \nu, 1) \end{aligned} \tag{10.2}$$

for some $\nu \in \mathbb{R}$. The above data determine uniquely a trajectory $t \to (x(t), \lambda(t))$. From (10.1) it is clear that the control $u = u^+(\xi, t_2 - \xi, 1 - t_2)$ satisfies the Maximum Principle (5.2) on a neighborhood of the interval $[\xi, 1]$ iff $\lambda_1(t_2) = \lambda_1(1) = 0$. We claim that for $\mathcal{V} \in \mathcal{F}$ suitably small, the conditions

$$\lambda_1(t_2) = \lambda_1(1) = 0, \qquad \xi < t_2 < 1 \tag{10.3}$$

implicitly define t_2, ν uniquely as functions of h, ξ, for all $h \in \mathcal{V}$, $\xi \in [0, 1/2]$. Indeed, when $h \equiv 0$, the equations (10.1), (10.3) can be solved explicitly, first for ν as a function of t_2 and ξ, then for t_2 in terms of ξ:

$$\lambda_1(t_2) = (t_2 - \xi)(-\nu - k\xi) + (t_2 - \xi)^2(1 - k)/2. \tag{10.4}$$

The right-hand side of (10.4) vanishes at the point $t_2 \in (\xi, 1)$ iff $\nu = (t_2 - \xi)(1 - k)/2 - k\xi$.

In this case

$$\lambda_1(1) = (1-t_2)(t_2-\xi)(1+k)/2 + (1-t_2)^2(1-k)/2. \tag{10.5}$$

Hence $\lambda_1(1) = 0$ iff

$$(t_2-\xi)/(1-t_2) = (k-1)/(k+1). \tag{10.6}$$

The exact value of t_2 as a function of ξ is immediately obtained from (10.6). From (10.6) it also follows that

$$(t_2-\xi) > (k-1)/4(k+1), \quad 1+\xi-2t_2 > 0, \quad 1-t_2 \geqq 1/4 \tag{10.7}$$

for all $\xi \in [0, 1/2]$. Differentiating (10.4) and (10.5) w.r.t ν and t_2 respectively and using (10.7) we obtain

$$\frac{\partial \lambda_1(t_2)}{\partial \nu} = \xi - t_2 < -\frac{k-1}{4(k+1)} < 0, \tag{10.8}$$

$$\frac{\partial \lambda_1(1)}{\partial t_2} = (1+\xi-2t_2)(k+1)/2 + (k-1)(1-t_2) > (k-1)/4 > 0. \tag{10.9}$$

By the implicit function theorem, there exists a neighborhood $\mathcal{V} \in \mathcal{F}$ such that (10.2), (10.3) determine (t_2, ν) uniquely as $\mathcal{C}^3$ functions of (h, ξ) in $\mathcal{V} \times [0, 1/2]$. This proves Lemma 7, by setting $a(\xi) = \xi$, $b(\xi) = t_2(\xi) - \xi$, $c(\xi) = 1 - t_2(\xi)$.

Next, it will be shown that Proposition 5 holds if the bang-bang control u belongs to the one-parameter family $u^+(a(\xi), b(\xi), c(\xi))$ just defined. To this purpose we need a technical result, whose proof is straightforward.

LEMMA 8. *Let $\mathcal{V} \in \mathcal{F}$ and let $(h, \xi) \to \phi(h, \xi)$ be a $\mathcal{C}^2$ map from $\mathcal{V} \times [0, 1/2]$ into $\mathbb{R}$ such that $\phi(h, 0) = 0$ for all $h \in \mathcal{V}$ and $\phi(0, \xi) > 0$ for all $\xi \in (0, 1/2]$. Assume that either* i) $(\partial\phi/\partial\xi)(0, 0) > 0$ *or* ii) $(\partial\phi/\partial\xi)(h, 0) = 0$ *for all $h \in \mathcal{V}$ and $(\partial^2\phi/\partial\xi^2)(0, 0) > 0$. Then $\phi(h, \xi) > 0$ for all $\xi \in (0, 1/2]$ and all h in some neighborhood of the null vector field in $\mathcal{C}^3(\Omega_k)$.*

For $h \in \mathcal{V}$ suitably small, we now construct a second one-parameter family of bang-bang controls $u'(\xi) = u^-(\alpha(\xi), \beta(\xi), \gamma(\xi))$, choosing α, β, γ such that $\alpha + \beta + \gamma = 1$ and the equalities in (5.4) hold, i.e.

$$\begin{aligned} &\pi_i(\exp \gamma(\xi)(g-e_1))(\exp \beta(\xi)(g+e_1))(\exp \alpha(\xi)(g-e_1))(0) \\ &\quad = \pi_i(\exp c(\xi)(g+e_1))(\exp b(\xi)(g-e_1))(\exp a(\xi)(g+e_1))(0) \end{aligned} \tag{10.10}$$

for $i = 1, 2$. When $h \equiv 0$, (10.6) implies

$$a(\xi) = \xi, \qquad b(\xi) = (k-1)(1-\xi)/2k, \qquad c(\xi) = (k+1)(1-\xi)/2k \tag{10.11}$$

and $\alpha(\xi)$, $\beta(\xi)$, $\gamma(\xi)$ are obtained substituting the values (10.11) in (5.8). By the implicit function theorem, the condition $\alpha(\xi) + \beta(\xi) + \gamma(\xi) = 1$ together with (10.10) defines a $\mathcal{C}^3$ map $(h, \xi) \to (\alpha, \beta, \gamma)$ on $\mathcal{V} \times [0, 1/2]$, for a suitably small neighborhood $\mathcal{V} \in \mathcal{F}$. Notice that when $h \equiv 0$ and ξ ranges inside $[0, 1/2]$, $\alpha(\xi)$ and $\beta(\xi)$ are strictly positive, while $\gamma(\xi) > 0$ for $\xi > 0$. Moreover, $(d\gamma/d\xi) = (k-1)/(k+1) > 0$ at $\xi = 0$. Setting $\phi = \gamma$ in Lemma 8, we deduce $\gamma(\xi) > 0$ for all $(h, \xi) \in \mathcal{V} \times [0, 1/2]$ with $\mathcal{V}$ small enough. Therefore the bang-bang control $u'(\xi) = u^-(\alpha(\xi), \beta(\xi), \gamma(\xi))$ is well defined. To prove the last inequality in (5.4), set $\phi(h, \xi) = x_3(u'(\xi), 1) - x_3(u(\xi), 1)$. For any fixed h, when $\xi = 0$ (10.10) has the obvious solution $\alpha(0) = b(0)$, $\beta(0) = c(0)$, $\gamma(0) = a(0) = 0$. Call $\tilde{u}$ the control $u^+(a(0), b(0), c(0))$, which coincides with $u^-(\alpha(0), \beta(0), \gamma(0))$ for all $t \in [0, 1]$, and let $t \to (\tilde{x}(t), \tilde{\lambda}(t))$ be the corresponding trajectory and adjoint variable in (10.2). Since $\tilde{\lambda}_1$ vanishes at times 0, $t_2 = b(0)$, 1, as $\xi \to 0$ we have

$$\langle\tilde{\lambda}(1), x(u^+(a(\xi), b(\xi), c(\xi)), 1) - \tilde{x}(1)\rangle\xi^{-1}$$
$$= \left[\int_0^1 \tilde{\lambda}_1(t)[u^+(a(\xi), b(\xi), c(\xi))(t) - u^+(a(0), b(0), c(0))(t)]\, dt + O(\xi^2)\right]\xi^{-1}$$
$$= o(\xi).$$

The same holds for $u^-(\alpha(\xi), \beta(\xi), \gamma(\xi))$, therefore

$$\lim_{\xi\to 0}\langle\tilde{\lambda}(1), x(u'(\xi), 1) - x(u(\xi), 1)\rangle\bar{\xi}^{-1} = \tilde{\lambda}_3(1)(\partial\phi/\partial\xi)(h, 0) = 0. \tag{10.12}$$

From (10.12) we deduce $(\partial\phi/\partial\xi)(h, 0) = 0$. When $h \equiv 0$, (5.10) and (10.11) imply

$$\phi(0, \xi) = \frac{(k-1)^2(k+1)(1-\xi)^2}{2k[2k\xi + (k+1)(1-\xi)]},$$

hence $(\partial^2\phi/\partial\xi^2)(0, 0) = (k-1)^2/k > 0$. By Lemma 8, $x_3(u'(\xi), 1) - x_3(u(\xi), 1) > 0$ for all $\xi \in (0, 1/2]$ and h in a neighborhood of the null vector field.

To conclude the proof of Proposition 5, notice that for every constant $\varepsilon' > 0$, in (5.3) we can choose $\varepsilon > 0$ so small that the conditions

$$|\ddot{\lambda}_1(t)/\bar{\lambda}_3 - (1-k)| \leqq \varepsilon \quad \text{for } t \in (0, t_1) \cup (t_2, 1),$$
$$|\ddot{\lambda}_1(t)/\bar{\lambda}_3 - (1+k)| \leqq \varepsilon \quad \text{for } t \in (t_1, t_2)$$

together with $\lambda_1(t_1) = \lambda_1(t_2) = \lambda_1(1) = 0$, $\lambda_1(t) > 0$ on $(0, t_1)$ imply

$$|(t_2 - t_1)/(1 - t_2) - (k-1)/(k+1)| \leqq \varepsilon', \qquad t_1 \leqq (1 - t_2) + \varepsilon'. \tag{10.13}$$

For $\varepsilon' > 0$ suitably small, (10.13) implies $t_1 \in [0, 1/2]$. Therefore, if $h \in \mathcal{V}$ is small enough, a bang-bang control u, which is initially positive and has switchings at times $0 < t_1 < t_2 < t_3 = 1$, can satisfy Pontryagin's equations (5.2) only if $t_1 \leqq 1/2$. But in this case u is the member of the one-parameter family of control functions $u^+(a(\xi), b(\xi), c(\xi))$ obtained by setting $\xi = t_1$. Hence Proposition 5 holds for u.

Appendix. The equalities (5.10) are obtained from (5.6) to (5.9), using the relations $ab = \beta\gamma$, $\alpha\beta = bc$, as follows.

$$\begin{aligned}
3(x_3^+ - x_3^-) &= (a+b+c)^3 - (b+c)^3 + c^3 - (\beta+\gamma)^3 + \gamma^3 \\
&\quad + k[a^3 + (b-a)^3 - \alpha^3 - (\beta-\alpha)^3 + (a-b+c)^3] \\
&= a^3 + 3a^2(b+c) + 3a(b+c)^2 + (b+c)^3 - (b+c)^3 + c^3 - \beta^3 - 3\beta^2\gamma \\
&\quad - 3\beta\gamma^2 - \gamma^3 + \gamma^3 + k[a^3 + (b-a)^3 - \alpha^3 - \beta^3 + 3\beta^2\alpha - 3\beta\alpha^2 \\
&\qquad\qquad + \alpha^3 + c^3 - 3c^2(b-a) + 3c(b-a)^2 - (b-a)^3] \\
&= a^3 + 3a^2b + 3a^2c + 3ab^2 + 6abc + 3ac^2 + c^3 - (a^3 + 3a^2c + 3ac^2 + c^3) \\
&\quad - 3a^2b^2/(a+c) - 3(a^2b + abc) \\
&\quad + k[a^3 - (a^3 + 3a^2c + 3ac^2 + c^3) + 3(abc + bc^2) - 3b^2c^2/(a+c) \\
&\qquad\qquad + c^3 - 3bc^2 + 3ac^2 + 3b^2c - 6abc + 3a^2c] \\
&= 3ab^2 + 3abc - 3a^2b^2/(a+c) + k[-3abc - 3b^2c^2/(a+c) + 3b^2c],
\end{aligned}$$

$$\begin{aligned}
x_3^+ - x_3^- &= (a^2b^2 + ab^2c + a^2bc + abc^2 - a^2b^2)/(a+c) \\
&\quad - k(a^2bc + abc^2 + b^2c^2 - ab^2c - b^2c^2)/(a+c) \\
&= \frac{abc}{a+c}[a+b+c-k(a-b+c)] = \frac{\alpha\beta\gamma}{\alpha+\gamma}[\alpha+\beta+\gamma+k(\alpha-\beta+\gamma)].
\end{aligned}$$

AN OPTIMIZATION PROBLEM WITH VOLUME CONSTRAINT*

N. AGUILERA†, H. W. ALT‡ AND L. A. CAFFARELLI§

Abstract. We consider the optimization problem of minimizing Dirichlet integral $\int_\Omega |\nabla u|^2$ with volume constraint on the set $\{u>0\}$. We use a penalization method which for small values of the penalization parameter leads to a solution of the original problem.

Key words. partial differential equations, free boundary, optimization, optimum design

AMS(MOS) subject classifications. 35A15, 35J65, 49A22

1. Introduction. A classical variational problem asks for the properties of the following optimal configuration:

Given a perfect conductor $\Gamma_0=\partial\Omega$, Ω a bounded or unbounded domain, find a second one $\Gamma_1=\Omega\cap\partial D$, D a subdomain of Ω containing Γ_0 as boundary, such that their mutual energy is minimized among all bodies D with a prescribed volume ω_0.

Mathematically the problem under consideration is the following:

Let $\Omega\subset\mathbb{R}^n$ be a domain with bounded Lipschitz boundary $\partial\Omega$, Ω being bounded or unbounded, and $u_0\in H^{1,2}(\Omega)$ nonnegative. We assume that u_0 is strictly positive in a neighborhood of at least one C^2-regular point of $\partial\Omega$. Furthermore let $0<\omega_0<\mathcal{L}^n(\Omega)$, where $\mathcal{L}^n$ denotes the n-dimensional Lebesgue measure. We look for a function $u\in H^{1,2}(\Omega)$ with

$$u=u_0 \quad \text{on } \partial\Omega \quad \text{and} \quad \mathcal{L}^n(\{u>0\})=\omega_0$$

minimizing Dirichlet integral among all functions with these properties, that is,

$$\mathcal{J}(u)\leqq\mathcal{J}(v) \quad \text{for all } v\in K_0,$$

where

$$\mathcal{J}(v):=\int_\Omega |\nabla v|^2,$$

$$K_0:=\{v\in L^1_{\text{loc}}(\Omega);\ \nabla v\in L^2(\Omega),\ v=u_0 \text{ on } \partial\Omega,\ v\geqq 0, \text{ and } \mathcal{L}^n(\{v>0\})=\omega_0\}.$$

Although the existence of a weak solution is not hard to prove, the regularity properties of such a solution and its free boundary $\partial\{u>0\}\cap\Omega$ are not easy to establish, mainly because it is hard, at this stage, to make volume preserving perturbations.

Formally, by Hadamard's variational formula (see [3]), the solution u satisfies the free boundary condition

$$-\partial_\nu u=\lambda \quad \text{on } \partial\{u>0\}\cap\Omega$$

for some $\lambda>0$. Solution to such a free boundary problem can be obtained by minimizing the energy functional

$$\tilde{\mathcal{J}}_\lambda(v):=\int_\Omega (|\nabla v|^2+\lambda^2\chi(\{v>0\}))$$

on the convex set

$$K:=\{v\in L^1_{\text{loc}}(\Omega);\ \nabla v\in L^2(\Omega),\ v=u_0 \text{ on } \partial\Omega, \text{ and } v\geqq 0\}.$$

A complete mathematical description has been given by two of the authors ([A−C]), who proved that a minimizer $\tilde{u}_\lambda$ of $\tilde{\mathcal{J}}_\lambda$ is Lipschitz continuous. Furthermore, the free boundary $\partial\{\tilde{u}_\lambda > 0\} \cap \Omega$ is, if $n \geqq 3$ except for a closed set of $n-1$ Hausdorff dimension zero, an analytic hypersurface, on which $-\partial_\nu \tilde{u}_\lambda = \lambda$ is satisfied.

The relation between solutions of the original functional $\mathcal{J}$ and solutions of $\tilde{\mathcal{J}}_\lambda$ is clear. If, for a choice of the parameter λ, we have $\mathcal{L}^n(\{\tilde{u}_\lambda > 0\}) = \omega_0$, then $\tilde{u}_\lambda$ becomes a minimizer of $\mathcal{J}$. Unfortunately, given a value of ω_0, it is not clear that a corresponding value of λ exists, even if Ω is the unit ball (see [A-C, 2.6]). However for the exterior problem, for instance if $\mathbb{R}^n \backslash \Omega$ is starlike, the existence of λ is guaranteed (see [A]).

To solve the original problem in a way that will allow us to perform nonvolume preserving variations, we will use a penalization technique. Therefore for $\varepsilon > 0$ we consider the functional

$$\mathcal{J}_\varepsilon(v) := \int_\Omega |\nabla v|^2 + f_\varepsilon(\mathcal{L}^n(\{v > 0\})) \quad \text{for } v \in K$$

with

$$f_\varepsilon(s) := \begin{cases} \dfrac{1}{\varepsilon}(s - \omega_0) & \text{for } s \geqq \omega_0, \\ \varepsilon(s - \omega_0) & \text{for } s \leqq \omega_0. \end{cases}$$

We will show that minimizers u_ε of $\mathcal{J}_\varepsilon$ are weak solutions of the free boundary problem $-\partial_\nu u_\varepsilon = \lambda_\varepsilon$ for some λ_ε in the sense of [A-C] and therefore the theory established there can be applied.

Finally, we like to fetch from u_ε a solution u to our original variational problem for $\mathcal{J}$. Perhaps the most interesting feature of this note is the fact that it is not necessary to pass to the limit in ε to obtain u, since for ε small enough the volume of $\{u_\varepsilon > 0\}$ automatically adjusts to ω_0.

The reason is that by a simple comparison argument λ_ε stays away from zero and infinity independently of ε, that is,

$$0 < c \leqq \lambda_\varepsilon \leqq C < \infty \quad \text{for all small } \varepsilon.$$

Then using the fact that $f'_\varepsilon(s)$ jumps from a small to a large number at $s = \omega_0$ we conclude that $\mathcal{L}^n(\{u_\varepsilon > 0\}) = \omega_0$. In fact, if we assume that $\mathcal{L}^n(\{u_\varepsilon > 0\}) > \omega_0$, then an inward perturbation of $\{u_\varepsilon > 0\}$ with volume change δV will induce a change $\delta f_\varepsilon = -(1/\varepsilon)\delta V$, while the Dirichlet integral will change by $\lambda_\varepsilon^2 \delta V \leqq C^2 \delta V$, for $(1/\varepsilon) > C^2$ a contradiction to u_ε being a minimizer. If $\mathcal{L}^n(\{u_\varepsilon > 0\}) < \omega_0$ we argue similarly.

2. Solution for the functional $\mathcal{J}_\varepsilon$.

THEOREM. *There exists a minimizer $u_\varepsilon \in \mathcal{K}$ of $\mathcal{J}_\varepsilon$ with the following properties:*

1) *Lipschitz continuity*: $u_\varepsilon \in C^{0,1}_{\text{loc}}(\Omega)$.

2) *Nondegeneracy*: $c\ \text{dist}\,(x, \partial\{u_\varepsilon > 0\}) \leqq u_\varepsilon(x) \leqq C\ \text{dist}\,(x, \partial\{u_\varepsilon > 0\})$ *for* $x \in D$.

3) *Positive density*: $c \leqq \mathcal{L}^n(B_r(x) \cap \{u_\varepsilon > 0\}) / \mathcal{L}^n(B_r(x)) \leqq 1 - c$ *for* $B_r(x) \subset D$.

Here D is any relative compact subdomain of Ω, and the constants c, C depend on D and ε.

Proof. The proofs follow exactly those in [A-C, §§ 1-3]. Here are some details: If we choose u_0 with $\mathcal{L}^n(\{u_0 > 0\}) \leqq \omega_0$ we get $\mathcal{J}_\varepsilon(u_0) \leqq C$ (uniformly in ε). Also $\mathcal{J}(v) \geqq -\omega_0$ for all $v \in \mathcal{K}$. Therefore a minimizing sequence u_k exists, and

$$\int_\Omega |\nabla u_k|^2 \leqq C, \qquad \mathcal{L}^n(\{u_k > 0\}) \leqq C.$$

Hence for some $u_\varepsilon \in \mathcal{K}$ and a subsequence

$$\nabla u_k \to \nabla u_\varepsilon \quad \text{weakly in } L^2(\Omega),$$

$$u_k \to u_\varepsilon \quad \text{almost everywhere in } \Omega.$$

Consequently

$$\mathcal{L}^n(\{u_\varepsilon > 0\}) \leqq \liminf_{k\to\infty} \mathcal{L}^n(\{u_k > 0\}),$$

$$\int_\Omega |\nabla u_\varepsilon|^2 \leqq \liminf_{k\to\infty} \int_\Omega |\nabla u_k|^2,$$

so that u_ε is a minimizer.

Using the fact that

$$\varepsilon(s_2 - s_1) \leqq f_\varepsilon(s_2 - s_1) \leqq \frac{1}{\varepsilon}(s_2 - s_1) \quad \text{for } s_1 \leqq s_2,$$

we obtain the properties 1)-3) as in [A-C, § 3].

This puts our solution u_ε under the hypothesis of [A-C, § 4] and therefore representation Theorem 4.5 and Theorem 4.8 are valid.

THEOREM 2. 1) $\mathcal{H}^{n-1}(D \cap \partial(u_\varepsilon > 0)) < \infty$ *for* $D \Subset \Omega$.

2) *There is a Borel function* q_{u_ε} *such that in the sense of distributions*

$$\Delta u_\varepsilon = q_{u_\varepsilon} \mathcal{H}^{n-1} \llcorner \partial\{u_\varepsilon > 0\},$$

that is, for $\zeta \in C_0^\infty(\Omega)$ *we have*

$$-\int_\Omega \nabla u_\varepsilon \nabla \zeta = \int_{\Omega \cap \partial\{u_\varepsilon > 0\}} \zeta q_{u_\varepsilon} \, d\mathcal{H}^{n-1}.$$

3) *For* $D \Subset \Omega$ *there are constants* $0 < c \leqq C < \infty$ *depending on* u_ε, Ω, D *such that for balls* $B_r(x_0) \subset D$ *with center* $x_0 \in \partial\{u_\varepsilon > 0\}$

$$c \leqq q_{u_\varepsilon}(x_0) \leqq C,$$

$$cr^{n-1} \leqq \mathcal{H}^{n-1}(B_r(x_0) \cap \partial\{u_\varepsilon > 0\}) \leqq Cr^{n-1}.$$

4) *For* $\mathcal{H}^{n-1}$ *almost all* $x_0 \in \partial_{\text{red}}\{u_\varepsilon > 0\}$

$$\text{Tan}\,(\partial\{u_\varepsilon > 0\}, x_0) = \{x;\, x \cdot \nu_{u_\varepsilon}(x_0) = 0\},$$

which determines the outward normal ν_{u_ε} *of* $\{u_\varepsilon > 0\}$ *at* x_0, *and*

$$u_\varepsilon(x_0 + x) = q_{u_\varepsilon}(x_0) \max(-x \cdot \nu_{u_\varepsilon}(x_0), 0) + o(x) \quad \text{as } x \to 0.$$

5) $\mathcal{H}^{n-1}(\partial\{u_\varepsilon > 0\} \setminus \partial_{\text{red}}\{u_\varepsilon > 0\}) = 0$.

The last statement is a consequence of the positive density property (see proof of [A-C, 5.5]).

With this theorem at hand it is not difficult to identify q_{u_ε}.

THEOREM 3. *For some positive constant* $\lambda_\varepsilon > 0$

$$q_{u_\varepsilon} = \lambda_\varepsilon \qquad \mathcal{H}^{n-1} \text{ almost everywhere on } \partial_{\text{red}}\{u_\varepsilon > 0\}.$$

Proof. We write u instead of u_ε. Let x_0, x_1 be two points in $\partial_{\text{red}}\{u > 0\}$ at which u behaves as in Theorem 2.4.

Assume that $q_u(x_0) > q_u(x_1)$. We construct a perturbation outwards to $\{u > 0\}$ at x_0, inwards at x_1 that preserves volume up to higher order terms. That is, we replace

u for small ρ by the function

$$v_\rho(\tau_\rho(x)) := u(x),$$

where

$$\tau_\rho(x) := \begin{cases} x + \kappa\rho\phi\left(\dfrac{|x-x_0|}{\rho}\right)\nu_u(x_0) & \text{for } x \in B_\rho(x_0), \\ x - \kappa\rho\phi\left(\dfrac{|x-x_1|}{\rho}\right)\nu_u(x_1) & \text{for } x \in B_\rho(x_1), \\ x & \text{elsewhere.} \end{cases}$$

κ is a small positive constant and ϕ is a nonnegative C_0^∞ function, $\phi \not\equiv 0$, supported in the unit interval. If κ is small enough (independent of ρ) then τ_ρ is a diffeomorphism with

$$D\tau_\rho(x) = I + \kappa D\eta_i\left(\frac{x-x_i}{\rho}\right) \quad \text{in } B_\rho(x_i),$$

$$\eta_i(y) := (-1)^i\phi(|y|)\nu_u(x_i).$$

Introducing the normalized functions

$$u_{i\rho}(y) := \frac{1}{\rho}\,u(x_i + \rho y),$$

the first part of Theorem 2.4 says that the set $B_1(0) \cap \{u_{i\rho} > 0\}$ approaches

$$\{y \in B_1(0);\ y \cdot \nu_i < 0\}, \qquad \nu_i := \nu_u(x_i),$$

as $\rho \to 0$. Therefore

$$\rho^{-n}\mathcal{L}^n(B_\rho(x_i) \cap \{v_\rho > 0\}) = \rho^{-n}\int_{B_1(0)\cap\{u_{i\rho}>0\}} \det D\tau_\rho(x_i + \rho y)\,dy$$

$$\to \int_{\{y\cdot\nu_i<0\}} \left(1 + (-1)^i\kappa\phi'(|y|)\frac{y}{|y|}\cdot\nu_i\right)dy.$$

Since the last integral is independent of the direction of ν_i, we conclude

$$\rho^{-n}(\mathcal{L}^n(\{v_\rho > 0\}) - \mathcal{L}^n(\{u > 0\})) \to 0;$$

therefore

$$f_\varepsilon(\mathcal{L}^n(\{v_\rho > 0\})) - f_\varepsilon(\mathcal{L}^n(\{u > 0\})) \leqq \frac{1}{\varepsilon}\,o(\rho^n).$$

We now compute the change in the Dirichlet integral. Again we normalize to the unit ball and obtain

$$\rho^{-n}\int_{B_\rho(x_i)} (|\nabla v_\rho|^2 - |\nabla u|^2) = \int_{B_1(0)\cap\{u_{i\rho}>0\}} (|\nabla u_{i\rho}(I + \kappa D\eta_i)^{-1}|^2 \det(I + \kappa D\eta_i) - |\nabla u_{i\rho}|^2)$$

$$= \kappa\int_{B_1(0)\cap\{u_{i\rho}>0\}} (|\nabla u_{i\rho}|^2\nabla\cdot\eta_i - 2\nabla u_{i\rho} D\eta_i \nabla u_{i\rho}) + o(\kappa).$$

From Theorem 2.4 we know that

$$u_{i\rho}(y) \to q_u(x_i)\max(-y\cdot\nu_i, 0)$$

uniformly in any bounded domain. Also for any $\delta > 0$

$$u_{i\rho}(y) > 0 \quad \text{for } y \in B_2(0), \quad y \cdot \nu_i < -\delta/2,$$

$$u_{i\rho}(y) = 0 \quad \text{for } y \in B_2(0), \quad y \cdot \nu_i > \delta/2,$$

provided ρ is small enough. Hence

$$\nabla u_{i\rho} \to -q_u(x_i)\nu_i$$

uniformly in $B_1(0) \cap \{y \cdot \nu_i < -\delta\}$. Since $\nabla u_{i\rho}$ are uniformly bounded, we conclude

$$\nabla u_{i\rho} \to -q_u(x_i)\nu_i \chi(B_1(0) \cap \{y \cdot \nu_i < 0\})$$

in $L^p(B_1(0))$ for any $p < \infty$. Therefore the above expression converges to

$$\kappa \int_{B_1(0)\cap\{y\cdot\nu_i<0\}} q_u(x_i)^2(\nabla \cdot \eta_i - 2\nu_i D\eta_i \nu_i) + o(\kappa)$$

$$= -\kappa q_u(x_i)^2 \int_{B_1(0)\cap\{y\cdot\nu_i<0\}} \partial_{\nu i}\eta_i \cdot \nu_i + o(\kappa)$$

$$= -\kappa(-1)^i q_u(x_i)^2 \int_{B_1(0)\cap\{y\cdot\nu_i=0\}} \phi(|y|)\, d\mathcal{H}^{n-1}(y) + o(\kappa),$$

or

$$\int_\Omega |\nabla v_\rho|^2 - \int_\Omega |\nabla u|^2 = \rho^n \left(\kappa(q_u(x_1)^2 - q_u(x_0)^2) \int_{B_1(0)} \phi(|y|)\, d\mathcal{L}^{n-1}(y) + o(\kappa) \right) + o(\rho^n).$$

If $q_u(x_1) < q_u(x_0)$ then the main term becomes negative if we choose κ small enough. For small ρ this contradicts the minimum property of u. This proves the theorem.

With the last theorem we complete the proof of the fact that u_ε satisfies the properties of a weak solution in [A-C, Def. 5.1]. Therefore [A-C, Thms. 8.3, 8.4] apply to it: The free boundary of u_ε is a locally smooth surface, except possibly for a closed set of $n-1$ Hausdorff measure zero. Along the regular part of it

$$-\partial_\nu u_\varepsilon = \lambda_\varepsilon.$$

3. Behavior of the solution for small ε. To complete our study we will now show that for ε small enough

$$\mathcal{L}^n(\{u_\varepsilon > 0\}) = \omega_0.$$

Remark. $0 < c \leqq \mathcal{L}^n(\{u_\varepsilon > 0\}) \leqq \omega_0 + C\varepsilon$.

Proof. In the proof of Theorem 1 we saw that

$$\mathcal{J}_\varepsilon(u_\varepsilon) \leqq \mathcal{J}_\varepsilon(u_0) \leqq C,$$

where C is independent of ε. Hence

$$f_\varepsilon(\mathcal{L}^n(\{u_\varepsilon > 0\})) \leqq C,$$

which proves the estimate from above. Also

$$\int_\Omega |\nabla u_\varepsilon|^2 \leqq C.$$

Since u_ε takes values u_0 on $\partial\Omega$ we obtain integrating along lines with $D := \Omega \cap B_\delta(\partial\Omega)$

$$\left(\int_{\partial\Omega} u_0\right)^2 \leqq C(\delta)\cdot \mathcal{L}^n(D\cap\{u_\varepsilon>0\})\int_D (|\nabla u_\varepsilon|^2+u_\varepsilon^2),$$

the last integral being bounded uniformly in ε; hence the estimate from below is proved.

As a consequence we obtain

LEMMA 5. *$\lambda_\varepsilon \leqq C$, where C is independent of ε.*

Proof. First we consider the case that Ω is bounded, and let w be the harmonic function in Ω with boundary values u_0. Then $w>0$ in Ω. Next choose $\delta>0$ so that the measure ω_1 of the set

$$D := \Omega\setminus\bar{B}_\delta(\partial\Omega)$$

exceeds ω_0, and $\mathcal{L}^n(\Omega\setminus D)$ is smaller than the constant c in Remark 4. Then for small ε

$$\mathcal{L}^n(D\cap\{u_\varepsilon>0\}) \leqq \omega_0 + C\varepsilon \leqq \frac{\omega_0+\omega_1}{2} < \omega_1 = \mathcal{L}^n(D)$$

and

$$\mathcal{L}^n(D\cap\{u_\varepsilon>0\}) \geqq \mathcal{L}^n(\{u_\varepsilon>0\}) - \mathcal{L}^n(\Omega\setminus D) \geqq c - \mathcal{L}^n(\Omega\setminus D) > 0.$$

Therefore by the isoperimetric inequality

$$\mathcal{H}^{n-1}(D\cap\partial\{u_\varepsilon>0\}) \geqq c(\mathcal{L}^n(D\cap\{u_\varepsilon>0\}))^{(n-1)/n} \geqq c>0.$$

Since u_ε have bounded Dirichlet integrals, we conclude using Theorem 2.2

$$\begin{aligned} C &\geqq \int_\Omega \nabla(u_\varepsilon - w)\nabla u_\varepsilon = \int_{\Omega\cap\partial\{u_\varepsilon>0\}} w\lambda_\varepsilon \, d\mathcal{H}^{n-1} \\ &\geqq \lambda_\varepsilon \inf_D w\cdot \mathcal{H}^{n-1}(D\cap\partial\{u_\varepsilon>0\}) \geqq c\lambda_\varepsilon. \end{aligned}$$

In the unbounded case we choose a fixed ball $B_R(0)$ containing $\partial\Omega$ with $\mathcal{L}^n(\Omega\cap B_R(0)) > \omega_0$. We argue with $\Omega\cap B_R(0)$ instead of Ω, let $w=0$ on $\partial B_R(0)$, and compute

$$\int_\Omega \nabla \min(u_\varepsilon - w, 0)\nabla u_\varepsilon.$$

Furthermore we use the fact that in Remark 4 the measure of $\{u_\varepsilon>0\}$ was estimated from below near $\partial\Omega$.

We remark that if u_0 is strictly positive on $\partial\Omega$ and $\partial\Omega$ is smooth, the proof can be performed as follows:

$$\begin{aligned} C &\geqq \int_\Omega |\nabla u_\varepsilon|^2 = \int_{\partial\Omega} u_0\,\partial_\nu u_\varepsilon \\ &\geqq \inf_{\partial\Omega} u_0\cdot \int_{\partial\Omega} \partial_\nu u_\varepsilon = \inf_{\partial\Omega} u_0 \int_{\Omega\cap\partial\{u_\varepsilon>0\}} \partial_{-\nu} u_\varepsilon \, d\mathcal{H}^{n-1} = \lambda_\varepsilon \inf_{\partial\Omega} u_0\, \mathcal{H}^{n-1}(\Omega\cap\partial\{u_\varepsilon>0\}). \end{aligned}$$

LEMMA 6. *$\lambda_\varepsilon \geqq c>0$, where c is independent of ε.*

Proof. Let $B_{\rho_0}(y_0)$, $y_0\in\partial\Omega$ be a ball such that $B_{\rho_0}(y_0)\cap\partial\Omega$ is C^2 and $u_0 \geqq c_0>0$ in $B_{\rho_0}(y_0)$. First let us assume that $u_\varepsilon>0$ in a neighborhood of y_0. Let y_1 be any free boundary point of u_ε in $\Omega\setminus B_\delta(\partial\Omega)$, δ independent of ε (see proof of Lemma 5; in the exterior case y_1 also should be bounded uniformly in ε). Choose a smooth family of

smooth domains $D_t \subset \Omega \cup B_{\rho_0}(y_0)$ such that $D_0 \subset B_{\rho_0}(y_0)\backslash\Omega$ touching $\partial\Omega$ at y_0 and $y_1 \subset D_1$, the smoothness not depending on ε. Let t be the first value for which D_t touches a free boundary point $x_0 \in \partial D_t \cap \partial\{u_\varepsilon > 0\}$.

Consider the harmonic function w in $D_t\backslash\bar{D}_0$ with boundary values c_0 on ∂D_0 and 0 on ∂D_t. Then

$$\partial_{-\nu} w(x_0) \geqq c c_0,$$

where c depends only on n and the geometry of D_0 and D_t, therefore c is independent of ε. Since $u \geqq w$ on $\partial(D_t \cap \Omega)$ we have $u \geqq w$ in $D_t \cap \Omega$. Hence if x_0 is a regular free boundary point

$$\lambda_\varepsilon = \partial_{-\nu} u_\varepsilon(x_0) \geqq \partial_{-\nu} w(x_0) \geqq c > 0,$$

where c is independent of ε, proving the lemma. However since we do not know it, we have to work more.

For small $r > 0$ we have writing u instead of u_ε

$$⨍_{\partial B_r(x_0)} u \geqq ⨍_{\partial B_r(x_0)} w \geqq cr.$$

Here ⨍ denotes the mean value. Let v_0 be the harmonic extension of u on $\partial B_r(x_0)$ into $B_r(x_0)$. Then (see [A-C, 3.2])

$$\int_{B_r(x_0)} (|\nabla u|^2 - |\nabla v_0|^2) = \int_{B_r(x_0)} |\nabla(u - v_0)|^2 \geqq c\mathcal{L}^n(B_r(x_0) \cap \{u = 0\}) \left(\frac{1}{r} ⨍_{\partial B_r(x_0)} u\right)^2$$
$$\geqq c\mathcal{L}^n(B_r(x_0) \cap \{u = 0\}),$$

where c is independent of ε. Consider now a free boundary point x_1 away from x_0. We can choose x_1 to be regular, say, $\partial\{u > 0\}$ is smooth in $B_{r_0}(x_1)$ for some small r_0. Near x_1 we make a smooth perturbation of the set $\{u > 0\}$ decreasing its volume by δ_r where

$$\delta_r := \mathcal{L}^n(B_r(x_0) \cap \{u = 0\}).$$

Let v_1 be the harmonic function in the perturbed set vanishing on its boundary and equal to u on $\partial B_{r_0}(x_1)$. Then

$$\int_{B_{r_0}(x_1)} (|\nabla v_1|^2 - |\nabla u|^2) = \lambda_\varepsilon^2 \delta_r + o(\delta_r).$$

Since the function

$$v := \begin{cases} v_0 & \text{in } B_r(x_0), \\ v_1 & \text{in } B_{r_0}(x_1), \\ u & \text{elsewhere,} \end{cases}$$

satisfies $\mathcal{L}^n(\{v > 0\}) = \mathcal{L}^n(\{u > 0\})$ we obtain

$$0 \leqq \mathcal{J}_\varepsilon(v) - \mathcal{J}_\varepsilon(u)$$
$$= \int_{B_r(x_0)} (|\nabla v_0|^2 - |\nabla u|)^2 + \int_{B_{r_0}(x_1)} (|\nabla v_1|^2 - |\nabla u|^2)$$
$$\leqq -c\delta_r + \lambda_\varepsilon^2 \delta_r + o(\delta_r),$$

that is, $\lambda_\varepsilon \geqq c$.

To prove that u is positive near y_0 we remark that the above estimate

$$\left(\frac{1}{r}\int_{\partial D_r} u\right)^2 \mathcal{L}^n(D_r \cap \{u=0\}) \leqq C \int_{D_r} |\nabla(u-v_0)|^2$$

is true for any domain D_r with smooth boundary, where v_0 is the harmonic extension of u on ∂D_r into D_r. The constant C depends only on the geometry and C^2 smoothness of the set

$$\frac{1}{r} D_r := \{x \in \mathbb{R}^n;\ rx \in D_r\}.$$

If we choose D_r with $\Omega \cap B_r(y_0) \subset D_r \subset B_{2r}(y_0)$ we obtain using the minimum property of u

$$\left(\frac{c_0}{r}\right)^2 \mathcal{L}^n(D_r \cap \{u=0\}) \leqq C\left(\int_{D_r} |\nabla u|^2 - \int_{D_r} |\nabla v_0|^2\right)$$

$$\leqq \frac{C}{\varepsilon} \mathcal{L}^n(D_r \cap \{u=0\});$$

hence $u>0$ in $\Omega \cap B_r(y_0)$ for small r (depending on ε).

We are now ready to prove

THEOREM 7. *For ε small, $\mathcal{L}^n(\{u_\varepsilon > 0\}) = \omega_0$, that is, u_ε minimizes our original functional $\mathcal{J}$ on K_0.*

Proof. By Lemmas 5 and 6

$$c \leqq \lambda_\varepsilon \leqq C.$$

Choose a regular point of the free boundary $\partial\{u_\varepsilon > 0\}$. Since the solution is smooth in a neighborhood of it, we can make regular perturbations as pointed out in the introduction.

We should remark that our results also apply if we replace the volume $\mathcal{L}^n(\{u>0\})$ by

$$\int_\Omega \rho\chi(\{u>0\})$$

with a smooth positive function ρ.

THE DIRICHLET–NEUMANN BOUNDARY CONTROL PROBLEM ASSOCIATED WITH MAXWELL'S EQUATIONS IN A CYLINDRICAL REGION*

D. L. RUSSELL†

Abstract. In a cylindrical region we consider electromagnetic fields independent of the axial coordinate: controlling the time evolution of such fields by means of boundary currents, likewise independent of the axial direction, is equivalent to controlling, simultaneously, two wave equations; one with boundary control of Dirichlet type, the other of Neumann type. In this paper we provide a preliminary study of control problems of this type and indicate what is necessary for extensions of our work.

AMS (MOS) subject classifications. 93B05, 93C20, 78A25, 35L15, 35L20

Key words. hyperbolic PDE, control, boundary value control, distributed parameter systems, Maxwell equations, electromagnetic equations

1. Background. In this paper we consider a region $\Omega \subseteq R^3$, not necessarily bounded, having piecewise smooth boundary Γ and almost everywhere uniquely defined unit exterior normal vector $\vec{\nu} = \vec{\nu}(x, y, z)$, $(x, y, z) \in \Gamma$. It is assumed that the region Ω is occupied by a medium having constant electrical permittivity ε and constant magnetic permeability μ. We have then, in Ω, the paired electric and magnetic fields

$$\vec{E} = \vec{E}(x, y, z, t),$$
$$\vec{H} = \vec{H}(x, y, z, t),$$

having finite *energy*

$$\mathbf{E}(t) = \frac{1}{2}\int\int\int_{\Omega} (\varepsilon \|\vec{E}\|^2 + \mu \|\vec{H}\|^2)\, dv, \tag{1.1}$$

where $\|\cdot\|$ denotes the usual Euclidean norm in R^3. As is well known ([4], [9]), $\vec{E}$ and $\vec{H}$ satisfy, in Ω, Maxwell's equations

$$\operatorname{curl} \vec{H} = \varepsilon \frac{\partial \vec{E}}{\partial t}, \tag{1.2}$$

$$\operatorname{curl} \vec{E} = -\mu \frac{\partial \vec{H}}{\partial t}, \tag{1.3}$$

$$\operatorname{div} \vec{E} = \rho, \tag{1.4}$$

$$\operatorname{div} \vec{H} = 0, \tag{1.5}$$

where $\rho = \rho(x, y, z, t)$ is the electrical charge density in Ω—which is zero throughout this paper. (That (1.5) might eventually have to be modified to account for magnetic monopoles will trouble us not at all here!)

Control problems associated with Maxwell's equations have been of interest primarily in connection with nuclear fusion applications—in which case ρ is not

† Department of Mathematics, University of Wisconsin, Madison, Wisconsin 53706.

identically equal to zero and the Maxwell equations are coupled with the dynamical equations governing the plasma evolution. In this connection we cite the work of P. K. C. Wang [29], [30], [31]. The point of view which we take here is that we cannot hope to treat these more complicated problems until we have a firmer grasp on the control theory of Maxwell's system in its own right. In this direction some work on controllability with control influence distributed throughout Ω has been carried out by G. Chen [2], [3]. We are primarily concerned here with the possibility of influencing the evolution of the fields $\vec{E}$ and $\vec{H}$ by means of an externally determined current $\vec{J}(x, y, z, t)$ flowing tangentially in Γ so that

$$\vec{J}(x, y, z, t) \cdot \vec{\nu}(x, y, z) = 0, \tag{1.6}$$

for $(x, y, z) \in \Gamma$ where $\vec{\nu}(x, y, z)$ is defined. Then we have the boundary condition (see e.g. [4], [28])

$$\mu \vec{H}_\tau(x, y, z, t) = \vec{\nu}(x, y, z) \times \vec{J}(x, y, z, t) \tag{1.7}$$

for $(x, y, z) \in \Gamma$ such that $\vec{\nu}(x, y, z)$ is well defined. Here, and subsequently, the subscript τ refers to the component of the vector in question which is tangential to Γ. Similarly, the subscript ν will denote the normal component. Writing

$$\vec{H} = \vec{H}_\nu + \vec{H}_\tau,$$
$$\vec{J} = \vec{J}_\nu + \vec{J}_\tau = \vec{J}_\tau \quad \text{on } \Gamma,$$

we see that (1.7) becomes $\mu \vec{H}_\tau = \vec{\nu} \times \vec{J}_\tau$, so that $\vec{H}_\tau$ is a vector tangential to Γ and perpendicular to $\vec{J} = \vec{J}_\tau$.

The state space in which we study solutions of the above system will be denoted by $H_{\mathbf{E},d}(\Omega)$; it is a closed subspace of the space $H_{\mathbf{E}}(\Omega)$ of square integrable six-dimensional fields $(\vec{E}(x, y, z, t), \vec{H}(x, y, z, t))$ with the inner product and norm

$$\langle (\vec{E}_1, \vec{H}_1); (\vec{E}_2, \vec{H}_2) \rangle \equiv \iiint_\Omega (\varepsilon \vec{E}_1 \cdot \vec{E}_2 + \mu \vec{H}_1 \cdot \vec{H}_2)\, dv, \tag{1.8}$$

$$\| (\vec{E}, \vec{H}) \|^2 = \langle (\vec{E}, \vec{H}); (\vec{E}; \vec{H}) \rangle. \tag{1.9}$$

Clearly $H_{\mathbf{E}}(\Omega)$ is a real Hilbert space with this inner product. Where a complex space is required, we employ conjugation as usual. The state space $H_{\mathbf{E},d}(\Omega)$ is the closed span in $H_{\mathbf{E}}(\Omega)$ of those continuously differentiable fields $(\vec{E}(x, y, z, t), \vec{H}(x, y, z, t))$ for which

$$\operatorname{div} \vec{E} = \frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y} + \frac{\partial E_z}{\partial z} = 0,$$

$$\operatorname{div} \vec{H} = \frac{\partial H_x}{\partial x} + \frac{\partial H_y}{\partial y} + \frac{\partial H_z}{\partial z} = 0.$$

If $\vec{E}_0, \vec{H}_0$ and $\vec{E}_1, \vec{H}_1$ are two smooth solution pairs for (1.2)-(1.5), (1.7), the first corresponding to $\vec{J} \equiv 0$ on Γ, we see easily that

$$\frac{d}{dt} \langle (\vec{E}_0, \vec{H}_0); (\vec{E}_1, \vec{H}_1) \rangle$$

$$= \iiint_\Omega \left(\varepsilon \left[\vec{E}_0 \cdot \frac{\partial \vec{E}_1}{\partial t} + \frac{\partial \vec{E}_0}{\partial t} \cdot \vec{E}_1 \right] + \mu \left[\vec{H}_0 \cdot \frac{\partial \vec{H}_1}{\partial t} + \frac{\partial \vec{H}_0}{\partial t} \cdot \vec{H}_1 \right] \right) dv$$

$$= (\text{using (1.2), (1.3)})$$

$$= \iiint_{\Omega} (\vec{E}_0 \cdot \operatorname{curl} \vec{H}_1 - \operatorname{curl} \vec{E}_0 \cdot \vec{H}_1 + \operatorname{curl} \vec{H}_0 \cdot \vec{E}_1 - \vec{H}_0 \cdot \operatorname{curl} \vec{E}_1)\, dv$$

$$= (\text{using } \operatorname{div}(E \times H) = \operatorname{curl} \vec{E} \cdot \vec{H} - \vec{E} \cdot \operatorname{curl} \vec{H})$$

$$= -\iiint_{\Omega} [\operatorname{div}(\vec{E}_0 \times \vec{H}_1) + \operatorname{div}(\vec{E}_1 \times \vec{H}_0)]\, dv \tag{1.10}$$

$$= -\iint_{\Gamma} (\vec{E}_0 \times \vec{H}_1 + \vec{E}_1 \times \vec{H}_0) \cdot \nu\, ds$$

$$= -\iint_{\Gamma} (\vec{E}_{0\tau} \times \vec{H}_{1\tau} + \vec{E}_{0\tau} \times \vec{H}_{1\nu} + \vec{E}_{1\tau} \times \vec{H}_{0\tau} + \vec{E}_{1\tau} \times \vec{H}_{0\nu}) \cdot \nu\, ds$$

$$= -\iint_{\Gamma} (\vec{E}_{0\tau} \times \vec{H}_{1\tau} + \vec{E}_{1\tau} \times \vec{H}_{0\tau}) \cdot \nu\, ds$$

$$= (\text{using (1.7) and noting that } \vec{J} \equiv 0 \text{ for } \vec{E}_0, \vec{H}_0)$$

$$= -\iint_{\Gamma} (\vec{E}_{0\tau} \cdot \vec{J})\, ds.$$

If we go through the same computation with $\vec{E}_0$, $\vec{H}_0$, $\vec{E}_1$, $\vec{H}_1$ both replaced by the same $\vec{E}$, $\vec{H}$ satisfying (1.2)-(1.5), (1.7), (1.8), we find that

$$\frac{d\mathbf{E}}{dt} = -\iint_{\Gamma} (\vec{E} \times \vec{H}) \cdot \vec{v}\, ds = -\iint_{\Gamma} \vec{E}_{\tau} \cdot \vec{J}\, ds. \tag{1.11}$$

For $\vec{J} \equiv 0$ generalized solutions of (1.2)-(1.5), (1.7), (1.8) can be discussed in the general context of partial differential equations and strongly continuous semigroups. The generator

$$A(\vec{E}, \vec{H}) = \left(\frac{1}{\varepsilon} \operatorname{curl} \vec{H}, -\frac{1}{\mu} \operatorname{curl} \vec{E}\right) \tag{1.12}$$

with domain consisting of $\vec{E}$, $\vec{H}$ in the Sobolev space $H^1_{\mathbf{E},d}(\Omega)(= H_{\mathbf{E},d}(\Omega) \cap H^1(\Omega))$ having zero divergence and satisfying (cf. (1.7))

$$\vec{H}_{\tau}|_{\Gamma} = 0, \tag{1.13}$$

is antisymmetric and generates a group of isometries in $H_{\mathbf{E},d}(\Omega)$. (See [32], [33], [34] for related work.) Sufficient conditions on $\vec{J}$ so that solutions of the inhomogeneous system (1.2)-(1.5), (1.7), (1.8) lie in $H_{\mathbf{E},d}(\Omega)$ and are strongly continuous there may be obtained much as in [18], [19] but it is not easy to specify necessary and sufficient conditions. Indeed, this is already difficult for the much simpler, but related, wave

equation

$$\mu\varepsilon\frac{\partial^2 w}{\partial t^2}=\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}+\frac{\partial^2 w}{\partial z^2}$$

with boundary forcing terms. We will make some comments related to this in § 6.

2. Control problems in a cylindrical region. The main point in this paper is to study the question of controllability of the electromagnetic field $\vec{E}$, $\vec{H}$ by means of the boundary current $\vec{J}=\vec{J}_\tau$. By controllability we mean the possibility of transferring an initial field $\vec{E}(x, y, z, 0)$, $\vec{H}(x, y, z, 0)\in H_{\mathbf{E},d}(\Omega)$, given at time $t=0$, to a prescribed terminal field $\vec{E}(x, y, z, T)$, $\vec{H}(x, y, z, T)\in H_{\mathbf{E},d}(\Omega)$, specified at $t=T>0$, by means of a suitable control current $\vec{J}(x, y, z, t)$ defined for $(x, y, z)\in\Gamma$, $t\in[0, T]$. Because the homogeneous Maxwell equations correspond to a group of isometries in $H_{\mathbf{E},d}(\Omega)$, it is enough to consider the special case wherein

$$\vec{E}(x, y, z, 0)\equiv 0, \tag{2.1}$$

$$\vec{H}(x, y, z, 0)\equiv 0. \tag{2.2}$$

For a given space, $\mathbf{J}$, of admissible control currents $\vec{J}(x, y, z, t)=\vec{J}_\tau(x, y, z, t)$ defined on $\Gamma\times[0, T]$ we define the reachable set $R(T, \mathbf{J})$ to be the subspace of $H_{\mathbf{E},d}(\Omega)$ consisting of states reachable from the zero initial state using controls $\vec{J}\in\mathbf{J}$. Following earlier definitions [26] our system is *approximately controllable in time* T if $R(T, \mathbf{J})$ is dense in $H_{\mathbf{E},d}(\Omega)$ and *exactly controllable in time* T if $R(T, \mathbf{J})=H_{\mathbf{E},d}(\Omega)$ (or some precisely designated subspace of $H_{\mathbf{E},d}(\Omega)$).

At this writing we are not able to discuss the general three-dimensional problem wherein the vector fields $\vec{E}$ and $\vec{H}$ are unrestricted and Ω has a general geometry. We hope in later work to consider at least some three-dimensional cases which arise for special domains Ω. For the present we must content ourselves with an analysis of certain cases in which Ω is a cylinder:

$$\Omega=\mathbf{R}\times(-\infty, \infty)=\{(x, y, z)\,|\,(x, y)\in R\quad R^2,\ z \text{ real}\}$$

$\mathbf{R}$ being an open connected region in R^2 with piecewise smooth boundary $\mathbf{B}$. Thus

$$\partial\Omega=\partial\mathbf{R}\times(-\infty, \infty)=\mathbf{B}\times(-\infty, \infty).$$

Even here we can give results only for special two-dimensional regions $\mathbf{R}$.

The two-dimensional problem in the cylinder $\Omega=\mathbf{R}\times(-\infty, \infty)$ occurs when we confine attention to fields

$$\vec{E}=\vec{E}(x, y, t),\qquad \vec{H}=\vec{H}(x, y, t)$$

which do not depend on the coordinate z corresponding to the axial, or longitudinal, direction of the cylinder. (Note that this is not at all the same thing as requiring that E_z, H_z, the field components in the z direction, should be zero.) We correspondingly consider only control currents

$$\vec{J}=\vec{J}(x, y, t)$$

which do not depend upon z.

We will see in § 3 that the only "interesting" control problems occur in the case where $\vec{J}$ is not permitted to be an arbitrary vector tangent to $\partial\Omega$ but, rather, has a preassigned direction in the tangent space (but arbitrary sign and magnitude). In this section and § 3 we will see that this case reduces to control of two separate wave equations with a single control function entering into both of them.

Then, in §§ 5 and 6 we will investigate the case where Ω is a rectangle and the control boundary is one side and the case where Ω is a disc and control is applied on the whole boundary, respectively. In the first instance we obtain an approximate controllability result and in the second, an exact controllability result relative to transfer between finite energy states. In each case the minimum time for control turns out to be twice the time required for control of a single wave equation under comparable circumstances. It is our expectation that this will turn out to be a general rule but, for the present, this can only be offered as a conjecture.

It is relatively easy to replace the requirement that the fields should be constant relative to the z-direction by the requirement that they should be periodic in the z-direction. This work will appear separately.

Of course the energy $\mathbf{E}$ in the cylinder Ω is infinite if $\vec{E}, \vec{H}$ are not identically zero. We redefine $\mathbf{E}$ to be the energy per unit length of cylinder:

$$\mathbf{E}(t) = \frac{1}{2}\int\int_{\mathbf{R}} (\varepsilon \|\vec{E}(x, y, t)\|^2 + \mu \|\vec{H}(x, y, t)\|^2)\, dx\, dy. \tag{2.3}$$

The space $H_{\mathbf{E},d}(\Omega)$ is now replaced by $H_{\mathbf{E},d}(\mathbf{R})$. Because

$$\frac{\partial E_z(x, y, t)}{\partial z} \equiv 0, \qquad \frac{\partial H_z(x, y, t)}{\partial z} \equiv 0,$$

we have

$$\operatorname{div} \vec{E} = \frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y}, \qquad \operatorname{div} \vec{H} = \frac{\partial H_x}{\partial x} + \frac{\partial H_y}{\partial y}. \tag{2.4}$$

The curl expressions simplify to

$$\operatorname{curl} \vec{E} = \left(\frac{\partial E_z}{\partial y}, -\frac{\partial E_z}{\partial x}, \frac{\partial E_y}{\partial x} - \frac{\partial E_x}{\partial y}\right),$$

$$\operatorname{curl} \vec{H} = \left(\frac{\partial H_z}{\partial y}, -\frac{\partial H_z}{\partial x}, \frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y}\right),$$

so that the equations (1.2), (1.3) become

$$\begin{aligned}
&\text{(i)} \quad \varepsilon \frac{\partial E_x}{\partial t} = \frac{\partial H_z}{\partial y}, && \text{(iv)} \quad \mu \frac{\partial H_x}{\partial t} = -\frac{\partial E_z}{\partial y}, \\
&\text{(ii)} \quad \varepsilon \frac{\partial E_y}{\partial t} = -\frac{\partial H_z}{\partial x}, && \text{(v)} \quad \mu \frac{\partial H_y}{\partial t} = \frac{\partial E_z}{\partial x}, \\
&\text{(iii)} \quad \varepsilon \frac{\partial E_z}{\partial t} = \frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y}, && \text{(vi)} \quad \mu \frac{\partial H_z}{\partial t} = -\frac{\partial E_y}{\partial x} + \frac{\partial E_x}{\partial y}.
\end{aligned} \tag{2.5}$$

It is clear from (2.5) (i)-(vi), that if $\vec{E}(x, y, 0)$, $\vec{H}(x, y, 0)$ are given, then the subsequent evolution of $E_z(x, y, t)$, $H_z(x, y, t)$ determine all of the other components. As for these components themselves, differentiating (2.5)(iii) and (2.5)(vi) with respect to t and then substituting (2.5)(iv), (v) and (2.5)(i), (ii) into the respectively resulting expressions, we obtain the familiar wave equations

$$\mu\varepsilon \frac{\partial^2 E_z}{\partial t^2} = \frac{\partial^2 E_z}{\partial x^2} + \frac{\partial^2 E_z}{\partial y^2}, \tag{2.6}$$

$$\mu\varepsilon\frac{\partial^2 H_z}{\partial t^2}=\frac{\partial^2 H_z}{\partial x^2}+\frac{\partial^2 H_z}{\partial y^2}, \tag{2.7}$$

valid for $(x, y)\in\mathbf{R}$, $t\in[0,\infty)$, provided E_z, H_z have enough derivatives, or provided the equations are interpreted in the distributional sense. Assuming the initial states $\vec{E}(x, y, 0)$, $\vec{H}(x, y, 0)$ are divergence-free, we compute (cf. (2.4))

$$\varepsilon\frac{\partial}{\partial t}\left(\frac{\partial E_x}{\partial x}+\frac{\partial E_y}{\partial y}\right)=(\text{using (2.5)(i), (ii)})=\varepsilon\left(\frac{\partial^2 H_z}{\partial x\,\partial y}-\frac{\partial^2 H_z}{\partial y\,\partial x}\right)=0$$

and similarly

$$\mu\frac{\partial}{\partial t}\left(\frac{\partial H_x}{\partial x}+\frac{\partial H_y}{\partial y}\right)=0$$

and we conclude that the fields remain divergence-free for all time.

Suppose, then, that divergence-free initial states $\vec{E}(x, y, 0)$, $\vec{H}(x, y, 0)$ are given. Then $E_z(x, y, 0)$, $H_z(x, y, 0)$ are known and (2.5)(iii), (vi) determine $(\partial E_z/\partial t)(x, y, 0)$ and $(\partial H_z/\partial t)(x, y, 0)$. If (2.6), (2.7) are then solved with these initial conditions, and appropriate boundary conditions, the complete solution of Maxwell's equations (2.5)(i)-(vi), can be obtained by integrating (2.5)(i), (ii), (iv), (v). Thus it is enough to work with (2.6), (2.7), and it should be noted that the divergence condition does not have any bearing on E_z, H_z; it can be ignored henceforth.

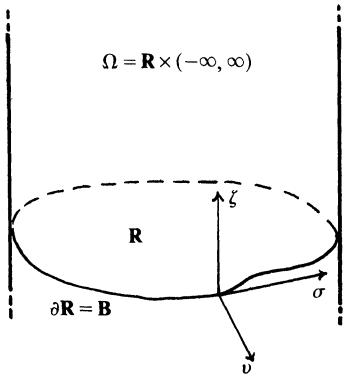

FIG. 1. *The region* **R**.

It is important to recast the boundary condition (1.7) so that it provides boundary conditions for (2.6), (2.7). We ask the reader to consult Fig. 1, where the region **R** with boundary $\partial\mathbf{R}=\mathbf{B}$ is shown. At a point $(x, y)\in\mathbf{B}$ we let $\vec{\nu}=\vec{\nu}(x, y)$ denote the unit exterior normal to **B** and we let $\vec{\sigma}=\vec{\sigma}(x, y)$ denote the positively oriented unit tangent vector to **B** there. With $\vec{\zeta}$, the unit vector in the positive z direction, $\vec{\nu}$, $\vec{\sigma}$, $\vec{\zeta}$ form a positively oriented orthogonal triple of unit vectors. Given an arbitrary vector w, we can decompose it as

$$\vec{w}=(w_\nu, w_\sigma, w_\zeta(=w_z)),$$
$$\|\vec{w}\|^2=w_\nu^2+w_\sigma^2+w_z^2.$$

The tangential part of $\vec{H}$, which we have designated as $\vec{H}_\tau$, may now be represented as

$$\vec{H}_\tau=H_z\vec{\zeta}+H_\sigma\vec{\sigma} \tag{2.8}$$

and the current $\vec{J}=\vec{J}_\tau$ may likewise be represented as

$$\vec{J}_\tau=J_z\vec{\zeta}+J_\sigma\vec{\sigma}.$$

Then

$$\vec{\nu} \times \vec{J} = \vec{\nu} \times \vec{J}_\tau = \vec{\nu} \times (J_z \vec{\zeta} + J_\sigma \vec{\sigma}) = -J_z \vec{\sigma} + J_\sigma \vec{\zeta}. \tag{2.9}$$

Combining (1.8), (2.8), (2.9), we see that on $\mathbf{B}$

$$H_z(x, y, t) = J_\sigma(x, y, t), \tag{2.10}$$

$$H_\sigma(x, y, t) = -J_z(x, y, t). \tag{2.11}$$

Represent $\vec{\nu}$, $\vec{\sigma}$ as

$$\vec{\nu} = \nu_x \vec{\xi} + \nu_y \vec{\eta}, \tag{2.12}$$

$$\vec{\sigma} = \sigma_x \vec{\xi} + \sigma_y \vec{\eta} = -\nu_y \vec{\xi} + \nu_x \vec{\eta}. \tag{2.13}$$

Then compute

$$\begin{aligned} \frac{\partial E_z}{\partial \nu} &= \frac{\partial E_z}{\partial x} \nu_x + \frac{\partial E_z}{\partial y} \nu_y \\ &= (\text{using (1.3)}) \\ &= \mu \frac{\partial H_y}{\partial t} \sigma_y + \mu \frac{\partial H_x}{\partial t} \sigma_x = \mu \frac{\partial H_\sigma}{\partial t} \\ &= (\text{using (2.11)}) = -\frac{\partial J_z}{\partial t}. \end{aligned} \tag{2.14}$$

The equations (2.10), (2.14) provide the needed boundary conditions for (2.6), (2.7) respectively. For H_z we have the Dirichlet-type boundary condition (2.10) while for E_z we have the Neumann-type boundary condition (2.14). If we let

$$\vec{U}(x, y, t) = \frac{\partial \vec{J}}{\partial t}(x, y, t),$$

$$\vec{U} = \vec{U}_\tau = U_\sigma \vec{\sigma} + U_z \vec{\zeta},$$

and differentiate (2.10), we have the more symmetric form

$$\frac{\partial H_z}{\partial t}(x, y, t) = U_\sigma(x, y, t), \quad \frac{\partial E_z}{\partial \nu} = -U_z(x, y, t), \quad (x, y) \in \mathbf{B}. \tag{2.15}$$

We complete this section by discussing the question of expression of the energy per unit cylinder length, (2.3), solely in terms of H_z and E_z.

We consider the equations (2.6), (2.7) with homogeneous boundary conditions

$$\frac{\partial H_z}{\partial t}(x, y, t) = 0, \quad \frac{\partial E_z}{\partial \nu}(x, y, t) = 0, \quad (x, y) \in \mathbf{B}.$$

We use the symbol Δ for the Laplacian:

$$\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}.$$

Initially we take H_z, E_z to lie in the Sobolev space $H^2(\mathbf{R})$. This space must be decomposed in order to attach a meaning to Δ^{-1}.

The boundary condition for H_z may be rewritten as

$$H_z(x, y, t) = h(x, y), \qquad (x, y) \in \mathbf{B},$$

where, by the trace theorem, $h \in H^{3/2}(\mathbf{B})$. Then we can write

$$H_z(x, y, t) = \hat{H}_z(x, y, t) + \tilde{H}_z(x, y)$$

where $\tilde{H}_z(x, y)$ is the solution of

$$\Delta \tilde{H}_z(x, y) = 0, \quad \tilde{H}_z(x, y) = h(x, y), \quad (x, y) \in \mathbf{B}$$

and

$$\hat{H}_z(x, y, t) = 0, \qquad (x, y) \in \mathbf{B}.$$

The inverse Laplacian Δ^{-1} is well defined on the functions $\hat{H}_z$. For E_z we may write

$$E_z(x, y, t) = \hat{E}_z(x, y, t) + \tilde{E}_z(t)$$

where $\tilde{E}_z$, as indicated, is constant with respect to $(x, y) \in \mathbf{R}$ and

$$\int_{\mathbf{B}} \hat{E}_z(x, y, t)\, ds = 0.$$

It is well known that Δ^{-1} is well defined on the functions $\hat{E}_z$.

We proceed first on the assumption that

$$H_z(x, y, t) = \hat{H}_z(x, y, t), \qquad E_z(x, y, t) = \hat{E}_z(x, y, t).$$

We form new solutions of (2.6), (2.7) by setting

$$\mu \frac{\partial G_z}{\partial t} = -E_z, \qquad \varepsilon \frac{\partial F_z}{\partial t} = H_z,$$

$$G_z = \varepsilon \Delta^{-1} \frac{\partial E_z}{\partial t}, \qquad F_z = \mu \Delta^{-1} \frac{\partial H_z}{\partial t}.$$

We then determine G_x, G_y, F_x, F_y, using the equations (2.5) with $\vec{G}$ replacing $\vec{H}$, $\vec{F}$ replacing $\vec{E}$, so that $\vec{F}$ and $\vec{G}$ satisfy Maxwell's equations:

$$\mu \frac{\partial \vec{G}}{\partial t} = -\operatorname{curl} \vec{F}, \qquad \varepsilon \frac{\partial \vec{F}}{\partial t} = \operatorname{curl} \vec{G}.$$

It will then be found that

$$\vec{E} = \operatorname{curl} \vec{F}, \qquad \vec{H} = \operatorname{curl} \vec{G}.$$

Following this, (2.3) can be written as

$$\mathbf{E}(t) = \frac{1}{2} \iint_{\mathbf{R}} (\varepsilon \|\operatorname{curl} \vec{F}\|^2 + \mu \|\operatorname{curl} \vec{G}\|^2)\, dx\, dy$$

$$= \frac{1}{2} \iint_{\mathbf{R}} \varepsilon \left[\left(\frac{\partial F_z}{\partial x} \right)^2 + \left(\frac{\partial F_z}{\partial y} \right)^2 + \left(\frac{\partial F_y}{\partial x} - \frac{\partial F_x}{\partial y} \right)^2 \right] \tag{2.16}$$

$$+ \mu \left[\left(\frac{\partial G_z}{\partial x} \right)^2 + \left(\frac{\partial G_z}{\partial y} \right)^2 + \left(\frac{\partial G_y}{\partial x} - \frac{\partial G_x}{\partial y} \right)^2 \right] dx\, dy.$$

Then from (2.16) we have

$$\mathbf{E}(t)=\frac{1}{2}\iint_{\mathbf{R}}\left\{\varepsilon\left[\left(\frac{\partial F_z}{\partial x}\right)^2+\left(\frac{\partial F_z}{\partial y}\right)^2+\left(\mu\frac{\partial G_z}{\partial t}\right)^2\right]\right.$$
$$\left.+\mu\left[\left(\frac{\partial G_z}{\partial x}\right)^2+\left(\frac{\partial G_z}{\partial y}\right)^2+\left(\varepsilon\frac{\partial F_z}{\partial t}\right)^2\right]\right\}dx\,dy$$
$$=\frac{1}{2}\iint_{\mathbf{R}}\varepsilon\left[\left(\frac{\partial F_z}{\partial x}\right)^2+\left(\frac{\partial F_z}{\partial y}\right)^2+(E_z)^2\right]+\mu\left[\left(\frac{\partial G_z}{\partial x}\right)^2+\left(\frac{\partial G_z}{\partial y}\right)^2+(H_z)^2\right]dx\,dy.$$

Now consider the quadratic form, for $E_z=\hat{E}_z$ and $(\ ,\ )$ the inner product in $L^2(\mathbf{R})$,

$$\left(\frac{\partial E_z}{\partial t},-\Delta^{-1}\frac{\partial E_z}{\partial t}\right)=\left(\mu\frac{\partial^2 G_z}{\partial t^2},-\Delta^{-1}\frac{\partial^2 G_z}{\partial t^2}\right)$$
$$=(\text{since } G_z \text{ satisfies the wave equation } \mu\varepsilon\,\partial^2 G_z/\partial t^2=\Delta G_z$$
$$\text{and the boundary conditions } G_z(x,y,t)=0,\ (x,y)\in\mathbf{B})$$
$$=\frac{1}{\mu\varepsilon^2}(-\Delta G_z,G_z)=\frac{1}{\mu\varepsilon^2}\iint_{\mathbf{R}}\left[\left(\frac{\partial G_z}{\partial x}\right)^2+\left(\frac{\partial G_z}{\partial y}\right)^2\right]dx\,dy.$$

Similarly

$$\left(\frac{\partial H_z}{\partial t},-\Delta^{-1}\frac{\partial H_z}{\partial t}\right)=\frac{1}{\varepsilon\mu^2}\iint_{\mathbf{R}}\left[\left(\frac{\partial F_z}{\partial x}\right)^2+\left(\frac{\partial F_z}{\partial y}\right)^2\right]dx\,dy$$

from which it follows that

$$\mathbf{E}(t)=\frac{(\mu\varepsilon)^2}{2}\left[\left(\frac{\partial E_z}{\partial t},-\Delta^{-1}\frac{\partial E_z}{\partial t}\right)+\left(\frac{\partial H_z}{\partial t},-\Delta^{-1}\frac{\partial H_z}{\partial t}\right)\right]+\frac{1}{2}\iint_{\mathbf{R}}\left[\varepsilon(E_z)^2+\mu(H_z)^2\right]dx\,dy.$$

It is necessary to modify this expression for general E_z, H_z. We begin with

$$E_z(x,y,t)=\tilde{E}_z(t).$$

The only possible solutions of the wave equation (2.6) satisfying $\partial E_z/\partial\nu|_B=0$ and having this form are

$$E_z(x,y,t)=e_0+e_1t$$

where e_0 and e_1 are constants. (Such solutions are consistent with a constant boundary current J for which $J_\sigma\equiv 0$.) The corresponding E_x, E_y, H_z are zero but

$$\varepsilon e_1=\varepsilon\frac{\partial E_z}{\partial t}=\frac{\partial H_y}{\partial x}-\frac{\partial H_x}{\partial y}.$$

It is not possible to express this quantity in terms of E_z itself or H_z. It is better to leave it in the form $\varepsilon\,\partial E_z/\partial t$. Solutions of Maxwell's equations with E_z having this form have energy expressible as a quadratic form in E_z and $\partial E_z/\partial t$.

Next we consider $H_z=\tilde{H}_z$ as described earlier. Such a solution is consistent with a boundary current for which $J_\tau=0$, constant with respect to time but possibly varying

with $(x, y) \in B$. We may take H_x, H_y, E_z all zero. However,

$$\varepsilon \frac{\partial E_x}{\partial t} = \frac{\partial H_z}{\partial y}, \qquad \varepsilon \frac{\partial E_y}{\partial t} = -\frac{\partial H_z}{\partial x}$$

so we may not assume that E_x and E_y are equal to zero. The energy associated with solutions of this type is expressible in terms of

$$\iint_{\mathbf{R}} \left[\left(\frac{\partial H_z}{\partial x} \right)^2 + \left(\frac{\partial H_z}{\partial y} \right)^2 \right] dx\, dy$$

if integration with respect to t is permitted. In the sequel we will not explicitly consider the timewise linear electric fields satisfying the above equations.

We see then that a norm involving only E_z and H_z and compatible with the energy (2.3) may be expressed as

$$|(E_z, H_z)|^2 = (\mu\varepsilon)^2 \left[\left(\frac{\partial \hat{E}_z}{\partial t}, -\Delta^{-1} \frac{\partial \hat{E}_z}{\partial t} \right) + \left(\frac{\partial \hat{H}_z}{\partial t}, -\Delta^{-1} \frac{\partial \hat{H}_z}{\partial t} \right) \right]$$

$$+ \iint_{\mathbf{R}} \left[\varepsilon (\hat{E}_z)^2 + \mu (\hat{H}_z)^2 + \rho_0 (\tilde{E}_z)^2 \right. \tag{2.17}$$

$$\left. + \rho_1 \left(\frac{\partial \tilde{E}_z}{\partial t} \right)^2 + \sigma_0 \left(\frac{\partial \tilde{H}_z}{\partial x} \right)^2 + \sigma_1 \left(\frac{\partial \tilde{H}_z}{\partial y} \right)^2 \right] dx\, dy$$

where ρ_0, ρ_1, σ_0, σ, are positive numbers. It will be seen that this is a weaker norm than the one associated with a pair of wave equations, viz.:

$$|(E_z, H_z)|^2 = \iint_{\mathbf{R}} \left\{ \mu\varepsilon \left[\left(\frac{\partial E_z}{\partial t} \right)^2 + \left(\frac{\partial H_z}{\partial t} \right)^2 \right] + |\nabla E_z|^2 + |\nabla H_z|^2 \right\} dx\, dy. \tag{2.18}$$

We will denote the Hilbert space of states E_z, H_z, $\partial E_z/\partial t$, $\partial H_z/\partial t$ lying in $H^1(\mathbf{R})$, $H^1(\mathbf{R})$, $L^2(\mathbf{R})$, $L^2(\mathbf{R})$, respectively, by $\hat{H}$. This space will be very convenient for use in the remainder of this paper. In some cases we will add boundary conditions to the specification of H, the space with norm $|\cdot|$, without changing the symbol, to correspond to an agreed specification of the states in $\hat{H}$ by similar boundary conditions.

3. Some control configurations. We describe here two possible realizations of the control problem which we have posed and indicate why we have chosen the mathematically more interesting (i.e., more difficult) one to work with in this paper.

Let us assume that $\Gamma = \partial\Omega = B \times (-\infty, \infty)$ is covered by one or more layers of conducting bars, arranged in rows as shown in Fig. 3.1. In the case of a single layer of conducting bars shown in Fig. 2(b), the bars are arranged so that they make an angle θ, $0 < |\theta| < \pi/2$, with the vector $\vec{\sigma}$ (cf. Fig. 1), while in the double layer case (Fig. 2(a)) they are arranged so that the bars in the second layer make an angle ψ, $0 < |\psi| < \pi/2$, $\psi \neq \theta$, with the vector $\vec{\sigma}$. The current in any row of bars parallel to the z-axis is independent of z; i.e., constant for all bars in that row. As we consider successively smaller bars we obtain, as an idealization, the boundary current vector

$$\vec{J}(x, y, t) = J(x, y, t)(\cos\theta \vec{\sigma} + \sin\theta \vec{\zeta}) \tag{3.1}$$

in the single layer case, $J(x, y, t)$ denoting the current strength with the sign determined

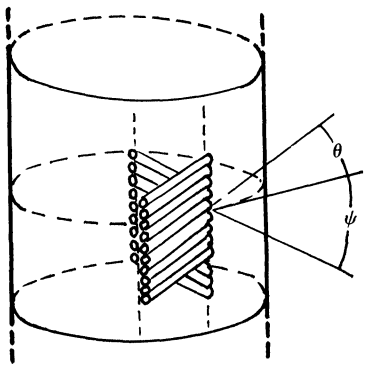

FIG. 2(a). *Double layer control.*

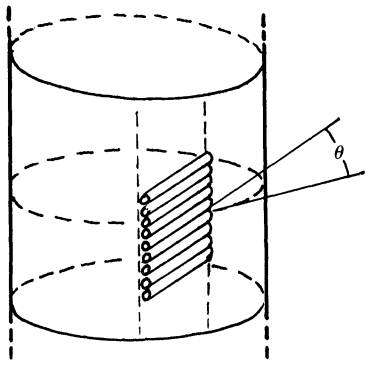

FIG. 2(b). *Single layer control.*

so that J positive yields a positive current component in the $\vec{\sigma}$ direction. The corresponding formula in the double layer case is

$$\vec{J}(x, y, t) = J_1(x, y, t)(\cos\theta\vec{\sigma} + \sin\theta\vec{\zeta}) + J_2(x, y, t)(\cos\psi\vec{\sigma} + \sin\psi\vec{\zeta}). \tag{3.2}$$

The current components are, in the single layer case

$$J_\sigma(x, y, t) = J(x, y, t)\cos\theta,$$

$$J_z(x, y, t) = J(x, y, t)\sin\theta,$$

and in the double layer case,

$$\begin{pmatrix} J_\sigma(x, y, t) \\ J_z(x, y, t) \end{pmatrix} = \begin{pmatrix} \cos\theta & \cos\psi \\ \sin\theta & \sin\psi \end{pmatrix} \begin{pmatrix} J_1(x, y, t) \\ J_2(x, y, t) \end{pmatrix}. \tag{3.3}$$

The determinant of the matrix in (3.3) is $\sin(\psi - \theta) \neq 0$ if $\psi \neq \theta$ in the range $0 < |\theta| < \pi/2$, $0 < |\psi| < \pi/2$. Thus in the double layer case J_σ and J_z are independent if J_1 and J_2 are independent while in the single layer case J_σ and J_z are fixed nonzero multiples of each other.

The double layer case is easily disposed of in the light of earlier work on boundary control of the wave equation. Referring back to (2.10), (2.11), we now have, for $(x, y) \in \mathbf{B} = \partial\mathbf{R}$, $t \in [0, \infty)$,

$$\frac{\partial H_z}{\partial t}(x,y,t) = U_\sigma(x, y, t) = \cos\theta u_1(x, y, t) + \cos\psi u_2(x, y, t),$$

$$\frac{\partial E_z}{\partial \nu}(x, y, t) = -U_z(x, y, t) = -\sin\theta u_1(x, y, t) + \cos\psi u_2(x, y, t),$$

$$u_1(x, y, t) = \frac{\partial J_1}{\partial t}(x, y, t), \qquad u_2(x, y, t) = \frac{\partial J_2}{\partial t}(x, y, t).$$

Since U_σ and U_z are independent if u_1 and u_2 are, the control problem splits into two uncoupled wave-equation problems, one for E_z and one for H_z. These have been discussed thoroughly in [2], [3], [15], [16], [22], [23], [25] with affirmative controllability results for various control configurations and will not concern us further here.

In the remainder of this paper we study the single layer case. If we let

$$u(x, y, t) = \frac{\partial J}{\partial t}(x, y, t) \tag{3.4}$$

we now have the wave equations (2.6), (2.7) for E_z, H_z and the boundary conditions

$$\frac{\partial H_z}{\partial t}(x, y, t) = \cos\theta \frac{\partial J}{\partial t}(x, y, t) \equiv \alpha u(x, y, t), \tag{3.5}$$

$$\frac{\partial E_z}{\partial \nu}(x, y, t) = -\sin\theta \frac{\partial J}{\partial t}(x, y, t) \equiv \beta u(x, y, t). \tag{3.6}$$

The control problems for E_z and H_z are now coupled because the single control function, $u(x, y, t)$, appears in the boundary conditions for both E_z and H_z; we have to control both systems simultaneously using the same control function.

If we rely on experience in a single space dimension, which has proved generally quite helpful in the control theory of a single wave equation, we are led to believe that systems like (2.6), (2.7), (3.5), (3.6) may, in fact, be controllable. Replacing $u(x, y, t)$ by $u_0(t)$, $u_1(t)$ and taking $0 \leqq x \leqq 1$, the one-dimensional equations are, using variables v, w,

$$\rho \frac{\partial^2 v}{\partial t^2} - \frac{\partial^2 v}{\partial x^2} = 0, \tag{3.7}$$

$$\frac{\partial v}{\partial t}(0, t) = \alpha u_0(t), \qquad \frac{\partial v}{\partial t}(1, t) = \alpha u_1(t), \tag{3.8}$$

$$\rho \frac{\partial^2 w}{\partial t^2} - \frac{\partial^2 w}{\partial x^2} = 0, \tag{3.9}$$

$$\frac{\partial w}{\partial x}(0, t) = -\beta u_0(t), \qquad \frac{\partial w}{\partial x}(1, t) = \beta u_1(t), \tag{3.10}$$

(note that $-\partial w/\partial x$ corresponds to the exterior normal derivative at 0). Letting

$$\tilde{v} = \frac{\partial v}{\partial x}, \tag{3.11}$$

$$\tilde{w} = \frac{\partial w}{\partial t}, \tag{3.12}$$

we find that

$$\rho \frac{\partial^2 \tilde{v}}{\partial t^2} - \frac{\partial^2 \tilde{v}}{\partial x^2} = 0, \tag{3.13}$$

and

$$\rho \frac{\partial^2 \tilde{w}}{\partial t^2} - \frac{\partial^2 \tilde{w}}{\partial x^2} = 0. \tag{3.14}$$

Differentiating (3.11) with respect to t and using (3.8), we have

$$\frac{1}{\rho}\frac{\partial^2 v}{\partial x^2}(0, t) = \frac{1}{\rho}\frac{\partial \tilde{v}}{\partial x}(0, t) = \frac{\alpha}{\rho} u_0'(t), \tag{3.15}$$

$$\frac{1}{\rho}\frac{\partial^2 v}{\partial x^2}(1, t) = \frac{1}{\rho}\frac{\partial \tilde{v}}{\partial x}(1, t) = \frac{\alpha}{\rho} u_1'(t), \tag{3.16}$$

while differentiation of (3.12) along with (3.10) yields

$$\frac{\partial^2 w}{\partial t\, \partial x}(0, t) = \frac{\partial \tilde{w}}{\partial x}(0, t) = -\beta u_0'(t), \tag{3.17}$$

$$\frac{\partial^2 w}{\partial t\,\partial x}(1,t)=\frac{\partial \tilde{w}}{\partial x}(1,t)=\beta u_1'(t). \tag{3.18}$$

Combining (3.13) with (3.14), (3.15), (3.16), (3.17), (3.18), we see that $\beta\tilde{v}+\alpha\tilde{w}/\rho$, $\beta\tilde{v}-\alpha\tilde{w}/\rho$ both satisfy the wave equation and

$$\frac{\partial}{\partial x}\left(\beta\tilde{v}+\frac{\alpha}{\rho}\tilde{w}\right)(0,t)=0, \qquad \frac{\partial}{\partial x}\left(\beta\tilde{v}+\frac{\alpha}{\rho}\tilde{w}\right)(1,t)=\frac{2\alpha\beta}{\rho}u_1'(1),$$

$$\frac{\partial}{\partial x}\left(\beta\tilde{v}-\frac{\alpha}{\rho}\tilde{w}\right)(0,t)=\frac{2\alpha\beta}{\rho}u_0'(t), \qquad \frac{\partial}{\partial x}\left(\beta\tilde{v}-\frac{\alpha}{\rho}\tilde{w}\right)(1,t)=0.$$

Thus the control problems for $\beta\tilde{v}+\alpha\tilde{w}/\rho$ and $\beta\tilde{v}-\alpha\tilde{w}/\rho$ are both of Neumann type and are *uncoupled.* Affirmative controllability results are then available from [20], [21], [24].

If we replace $u_0(t)$ (or $u_1(t)$ by 0 in the above, then $\beta\tilde{v}-\alpha\tilde{w}/\rho$ (or $\beta\tilde{v}+\alpha\tilde{w}/\rho$) will become completely uncontrollable and our original system must therefore be uncontrollable. This result at first seems to predict failure for the enterprise which we now undertake for the two-dimensional case.

4. Approximate boundary controllability. By a simple change of scale in the t variable, and renaming of the independent variables, we may assume that the system of interest is

$$\left.\begin{aligned} \frac{\partial^2 v}{\partial t^2}&=\frac{\partial^2 v}{\partial x^2}+\frac{\partial^2 v}{\partial y^2}, \qquad (4.1)\\ \frac{\partial^2 w}{\partial t^2}&=\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}, \qquad (4.2)\end{aligned}\right\} \quad t\geqq 0, \quad (x,y)\in\mathbf{R},$$

with boundary conditions

$$\left.\begin{aligned} \frac{\partial v}{\partial t}(x,y,t)&=\alpha u(x,y,t), \qquad (4.3)\\ \frac{\partial w}{\partial \nu}(x,y,t)&=\beta u(x,y,t), \qquad (4.4)\end{aligned}\right\} \quad t\geqq 0, \quad (x,y)\in\mathbf{B}=\partial\Omega.$$

We will not, in general, assume that $u(x,y,t)$ can be selected at will for all values of (x,y,t) shown. More on this later.

Because the system is time reversible, it is sufficient to analyze controllability in terms of control from the zero initial state

$$\left.\begin{aligned} v(x,y,0)=\frac{\partial v}{\partial t}(x,y,0)&=0, \qquad (4.5)\\ w(x,y,0)=\frac{\partial w}{\partial t}(x,y,0)&=0, \qquad (4.6)\end{aligned}\right\} \quad (x,y)\in\mathbf{R},$$

to a final state

$$\left.\begin{aligned} v(x,y,T)=v_0(x,y), \quad \frac{\partial v}{\partial t}(x,y,T)&=v_1(x,y), \qquad (4.7)\\ w(x,y,T)=w_0(x,y), \quad \frac{\partial w}{\partial t}(x,y,T)&=w_1(x,y), \qquad (4.8)\end{aligned}\right\} \quad (x,y)\in\mathbf{R}.$$

We have noted in § 2 that the $\|\cdot\|$-finite states are dense in the $|\cdot|$-finite states. In the present context this means that we can work with the Hilbert space of states v, $\partial v/\partial t$, w, $\partial w/\partial t$ with the inner product

$$\left(\left(v, \frac{\partial v}{\partial t}, w, \frac{\partial w}{\partial t}\right); \left(\tilde{v}, \frac{\partial \tilde{v}}{\partial t}, \tilde{w}, \frac{\partial \tilde{w}}{\partial t}\right)\right)$$

$$= \int\int_{\mathbf{R}} \left[\frac{\partial v}{\partial t}\frac{\partial \tilde{v}}{\partial t} + \frac{\partial w}{\partial t}\frac{\partial \tilde{w}}{\partial t} + \frac{\partial v}{\partial x}\frac{\partial \tilde{v}}{\partial x} + \frac{\partial w}{\partial x}\frac{\partial \tilde{w}}{\partial x} + \frac{\partial v}{\partial y}\frac{\partial \tilde{v}}{\partial y} + \frac{\partial w}{\partial y}\frac{\partial \tilde{w}}{\partial y}\right] dx\, dy, \tag{4.9}$$

the space which we refer to as $\hat{H}$. The norm is $\|\cdot\|$ (cf. (2.18)) with $\mu\varepsilon = 1$. As we have indicated, this is a dense subspace of H, the Hilbert space obtained by use of the norm $|\cdot|$ (cf. (2.17)).

The final states (4.7), (4.8) are not quite arbitrary in $\hat{H}$ if the control u is restricted so that its support is contained in a proper relatively closed subset $B_1 \subset B$. Since the condition

$$\frac{\partial v}{\partial t}(x, y, t) = \alpha u(x, y, t), \qquad (x, y) \in \mathbf{B}$$

applies, we may as well adjoin the additional condition

$$v_0(x, y) = 0, \qquad (x, y) \in \mathbf{B} - \mathbf{B}_1 \equiv \mathbf{B}_0. \tag{4.10}$$

The trace theorem [1], [19] assures us that this describes a closed subspace of $\hat{H}$, which we will call $\hat{H}_1$. The only restriction on $\hat{H}_1$ is (4.10); v_0 is permitted to have arbitrary values in $H^{1/2}(\mathbf{B}_1)$ and w_0, w_1 are unrestricted in $H^1(\mathbf{B})$, $H^0(\mathbf{R}) = L^2(\mathbf{R})$, respectively.

Let U be a given space of admissible control functions, about which we will shortly have more to say. For each control $u \in U$ we assume the existence of a unique solution v_u, w_u of (4.1)–(4.6) for $t \geqq 0$, $(x, y) \in \mathbf{R}$. Very general sufficient conditions for this to be the case are given in [19]. We define the reachable set at time T, $R(U, T)$, to be the set of all final states $v_u(x, y, T)$, $(\partial v_u/\partial t)(x, y, T)$, $w_u(x, y, T)$, $(\partial w_u/\partial t)(x, y, T)$ which may be realized in this way. The set $R(U, T)$ is a subspace of $\hat{H}_1$ if U is a linear space, which we will assume, and our system is approximately controllable in time T if $R(U, T)$ is dense in $\hat{H}_1$ (then $R(U, T)$ is also dense in H because $|\cdot|$ is a weaker norm than $\|\cdot\|$ and $\hat{H}_1$ is dense in H). Evidently $R(U, T)$ is dense in $\hat{H}_1$ just in case, given an arbitrary state $(\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1)$ in $\hat{H}_1$,

$$\left\{\left(\left(v_u(x, y, T), \frac{\partial v_u}{\partial t}(x, y, T), w_u(x, y, T), \frac{\partial w_u}{\partial t}(x, y, T)\right); (\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1)\right) = 0, u \in U\right\}$$

$$\Rightarrow (\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1) = 0. \tag{4.11}$$

Let $\tilde{v}(x, y, t)$, $\tilde{w}(x, y, t)$ be the unique solution of (4.1), (4.2) satisfying the terminal conditions at time T:

$$\tilde{v}(x, y, T) = \tilde{v}_0, \quad \frac{\partial \tilde{v}}{\partial t}(x, y, T) = \tilde{v}_1, \quad \tilde{w}(x, y, T) = \tilde{w}_0, \quad \frac{\partial \tilde{w}}{\partial t}(x, y, T) = \tilde{w}_1, \tag{4.12}$$

and the homogeneous boundary conditions

$$\left.\begin{aligned} &\frac{\partial \tilde{v}}{\partial t}(x, y, t) = 0, \qquad (4.13)\\ &\frac{\partial \tilde{w}}{\partial \nu}(x, y, t) = 0, \qquad (4.14)\end{aligned}\right\} \quad (x, y) \in \mathbf{B}, \quad t \geqq 0.$$

Computing the quantity

$$\frac{d}{dt}\left(\left(v_u(x, y, t), \frac{\partial v_u}{\partial t}(x, y, t), w_u(x, y, t), \frac{\partial w_u}{\partial t}(x, y, t)\right);\right.$$
$$\left.\left(\tilde{v}(x, y, t), \frac{\partial \tilde{v}}{\partial t}(x, y, t), \tilde{w}(x, y, t), \frac{\partial \tilde{w}}{\partial t}(x, y, t)\right)\right),$$

using familiar duality theorems involving the Laplacian and integrating from 0 to T (see [22], [23], [26] for details in the case of a single wave equation) we see that

$$\left(\left(v_u(x, y, T), \frac{\partial v_u}{\partial t}(x, y, T), w_u(x, y, T), \frac{\partial w_u}{\partial t}(x, y, T)\right); (\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1)\right)$$

$$= \int_0^T \int_{\mathbf{B}} \left[\frac{\partial \tilde{v}}{\partial t}(x, y, t)\frac{\partial v_u}{\partial \nu}(x, y, t) + \frac{\partial \tilde{v}}{\partial \nu}(x, y, t)\frac{\partial v_u}{\partial t}(x, y, t)\right. \tag{4.15}$$
$$\left. + \frac{\partial \tilde{w}}{\partial t}(x, y, t)\frac{\partial w_u}{\partial \nu}(x, y, t) + \frac{\partial \tilde{w}}{\partial \nu}(x, y, t)\frac{\partial w_u}{\partial t}(x, y, t)\right] ds\, dt.$$

Then using the boundary conditions (4.3), (4.4), (4.13), (4.14), we see that the above reduces to

$$\int_0^T \int_{\mathbf{B}} \left[\alpha \frac{\partial \tilde{v}}{\partial \nu}(x, y, t) + \beta \frac{\partial \tilde{w}}{\partial t}(x, y, t)\right] u(x, y, t)\, ds\, dt. \tag{4.16}$$

If, as discussed above, we suppose that $\mathbf{B}$ has the disjoint decomposition

$$\mathbf{B} = \mathbf{B}_0 \cup \mathbf{B}_1,$$

with $\mathbf{B}_1$ relatively open in $\mathbf{B}$, and that $u(x, y, t) \equiv 0$, $(x, y) \in \mathbf{B}_0$ while on $\mathbf{B}_1$ u is unrestricted save for the specification of the admissible space (e.g., we might take

$$U = C(\mathbf{B}_1 \times [0, T]), \qquad U = L^2(\mathbf{B}_1 \times [0, T]), \tag{4.17}$$

or any of many other possibilities), and if we suppose the first equation in (4.11) to hold, we conclude that (4.16) vanishes for all $u \in U$. We know from the trace theorem ([1], [19]) that the partial derivatives

$$\frac{\partial \tilde{v}}{\partial t}, \frac{\partial \tilde{v}}{\partial \nu}, \frac{\partial \tilde{w}}{\partial t}, \frac{\partial \tilde{w}}{\partial \nu},$$

restricted to $\mathbf{B}$, all lie in $H^{1/2}(\mathbf{B})$ for $t \in [0, T]$ and vary, with respect to the norm in that space, continuously with respect to t, i.e. they lie in $C(H^{1/2}(\mathbf{B}); [0, T])$. We suppose, as is the case for (4.17), e.g., that U includes a total subspace of the dual space of $C(H^{1/2}(\mathbf{B}_1); [0, T])$. Then the fact that (4.17) is zero for all $u \in U$ implies

$$\alpha \frac{\partial \tilde{v}}{\partial \nu}(x, y, t) + \beta \frac{\partial \tilde{w}}{\partial t}(x, y, t) = 0, \qquad (x, y) \in \mathbf{B}_1, \quad t \in [0, T]. \tag{4.18}$$

We also have (cf. (4.13), (4.14))

$$\frac{\partial \tilde{v}}{\partial t}(x, y, t) = 0, \quad \frac{\partial \tilde{w}}{\partial \nu}(x, y, t) = 0, \quad (x, y) \in \mathbf{B}_1, \quad t \in [0, T]. \tag{4.19}$$

The boundary values of $\tilde{v}$ and $\tilde{w}$ are therefore *overspecified* on $\mathbf{B}_1 \times [0, T]$. The proof of approximate controllability, where it can be carried through, depends upon being able to use this overspecification to show that

$$\tilde{v}(x, y, t) \equiv 0, \quad \tilde{w}(x, y, t) \equiv 0, \quad (x, y) \in \mathbf{R}, \quad t \in [0, T],$$

and therefore to conclude that the implication (4.11) is indeed valid so that $R(U, T)$ is dense in $\hat{H}_1$ and hence in H. We carry this argument out for the case in which $\mathbf{R}$ is a rectangle and $\mathbf{B}_1$ is one of its sides in § 5.

Following the development in [6], it may be seen that our system is exactly controllable in $\hat{H}_1$, using the control space $U = L^2(\mathbf{B}_1 \times [0, T])$, just in case

$$\left\| \alpha \frac{\partial \tilde{v}}{\partial \nu} + \beta \frac{\partial \tilde{w}}{\partial t} \right\|_{L^2(\mathbf{B}_1 \times [0,T])} \geqq K \| (\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1) \|_{\hat{H}} \tag{4.20}$$

for some $K > 0$. In general this is a very difficult result to obtain but we are able to obtain exact controllability, by other means, for the case where $\mathbf{R}$ is a disc in R^2 and $\mathbf{B}_1 = \mathbf{B}$ is its boundary, a circle. This result is developed in § 6 where it will be seen that it is heavily dependent on certain properties of the Bessel functions.

5. The case $\mathbf{R}$ = a rectangle, $\mathbf{B}_1$ = one side. The work here can be carried out for a rectangle with arbitrary dimensions, but all essential ideas are contained in the notationally simpler case

$$\mathbf{R} = \{(x, y) \mid 0 \leqq x \leqq \pi, 0 \leqq y \leqq \pi\}$$

to which attention is restricted henceforth. We will assume that $\mathbf{B}_1$, the portion of the boundary on which control is exercised, is one side of $\mathbf{R}$; without loss of generality it is the set

$$\mathbf{B}_1 = \{(\pi, y) \mid 0 \leqq y \leqq \pi\}. \tag{5.1}$$

We consider then $\tilde{v}$, $\tilde{w}$ satisfying (4.1), (4.2) in $\mathbf{R} \times [0, T]$ for some $T > 0$, and also satisfying boundary conditions

$$\frac{\partial \tilde{v}}{\partial t}(x, y, t) = 0, \quad \frac{\partial \tilde{w}}{\partial \nu}(x, y, t) = 0, \quad (x; y) \in \mathbf{B} = \partial \mathbf{R}, \quad t \in [0, T], \tag{5.2}$$

$$\begin{aligned} &\alpha \frac{\partial \tilde{v}}{\partial \nu}(\pi, y, t) + \beta \frac{\partial \tilde{w}}{\partial t}(\pi, y, t) \\ &\quad = -\alpha \frac{\partial \tilde{v}}{\partial x}(\pi, y, t) + \beta \frac{\partial \tilde{w}}{\partial t}(\pi, y, t) = 0, \qquad 0 \leqq y \leqq \pi, \quad t \in [0, T]. \end{aligned} \tag{5.3}$$

We may assume without loss of generality, since the wave equation is time reversible with either Dirichlet or Neumann boundary conditions, that $\tilde{v}$ and $\tilde{w}$ are extended to satisfy (4.1), (4.2) on $-\infty < t < \infty$ and that the boundary conditions (5.2) hold for $(x, y) \in \mathbf{B}$, $t \in (-\infty, \infty)$. We may not assume that the boundary condition (5.3) is applicable beyond $[0, T]$, however, if controls are restricted to have support in $\mathbf{B}_1 \times [0, T]$. Let $\delta > 0$ and let $s(t)$ be an arbitrary function in $C^\infty(-\infty, \infty)$ with support in

$(-\delta, \delta)$. Define

$$\hat{v}(x, y, t) = \int_{-\infty}^{\infty} s(t-\tau)\tilde{v}(x, y, \tau)\, d\tau, \tag{5.4}$$

$$\hat{w}(x, y, t) = \int_{-\infty}^{\infty} s(t-\tau)\tilde{w}(x, y, \tau)\, d\tau. \tag{5.5}$$

Then $\hat{v}$, $\hat{w}$ are solutions of the wave equations (4.1), (4.2) satisfying boundary conditions

$$\frac{\partial \hat{v}}{\partial t}(x, y, t) = 0, \quad \frac{\partial \hat{w}}{\partial \nu}(x, y, t) = 0, \quad (x, y) \in \mathbf{B} = \partial\mathbf{R}, \quad -\infty < t < \infty, \tag{5.6}$$

while

$$\alpha\frac{\partial \hat{v}}{\partial x}(\pi, y, t) + \beta\frac{\partial \hat{w}}{\partial t}(\pi, y, t) = 0, \quad 0 \leqq y \leqq \pi, \quad t \in [\delta, T-\delta]. \tag{5.7}$$

Moreover, it can be shown that $\hat{v}$, $\hat{w}$ are of class C^∞ for $(x, y) \in \mathbf{R}$, $-\infty < t < \infty$. If we can show $\hat{v} \equiv 0$, $\hat{w} \equiv 0$ for any such choice of s, then $\tilde{v} \equiv 0$, $\tilde{w} \equiv 0$.

Let us define, for $(x, y) \in \mathbf{R}$, $-\infty < t < \infty$,

$$\phi(x, y, t) = \alpha\frac{\partial \hat{v}}{\partial x}(x, y, t) + \beta\frac{\partial \hat{w}}{\partial t}(x, y, t). \tag{5.8}$$

From (5.7) we have

$$\phi(\pi, y, t) = 0, \quad 0 \leqq y \leqq \pi, \quad t \in [\delta, T-\delta]. \tag{5.9}$$

Since α and β are constants, we have

$$\frac{\partial^2 \phi}{\partial t^2} = \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}, \qquad (x, y) \in \mathbf{R}, \quad -\infty < t < \infty. \tag{5.10}$$

Let us note that, since $\hat{v}$ satisfies the wave equation in $\mathbf{R} \cup \mathbf{B}$,

$$\begin{aligned} &\alpha\frac{\partial^2 \hat{v}}{\partial t^2}(x, y, t) + \beta\frac{\partial^2 \hat{w}}{\partial t\, \partial x}(x, y, t) \\ &\quad = \alpha\left[\frac{\partial^2 \hat{v}}{\partial x^2}(x, y, t) + \frac{\partial^2 \hat{v}}{\partial y^2}(x, y, t)\right] + \beta\frac{\partial^2 \hat{w}}{\partial t\, \partial x}(x, y, t). \end{aligned} \tag{5.11}$$

Setting $x = \pi$ in (5.11) and differentiating the identities in (5.6) with respect to t, we see that the left-hand side vanishes. Then, comparing (5.11) with (5.8)

$$\frac{\partial \phi}{\partial x}(\pi, y, t) = -\alpha\frac{\partial^2 \hat{v}}{\partial y^2}(\pi, y, t) \equiv \alpha(y), \qquad 0 \leqq y \leqq \pi, \quad \delta \leqq t \leqq T-\delta, \tag{5.12}$$

the last identity being valid as a consequence of the first condition in (5.6).

The two conditions, (5.8) and (5.12), satisfied by ϕ at the boundary $x = \pi$ enable us to use Holmgren's uniqueness theorem (see [5] or [13], e.g.) in much the same way as it was used in the proof of the approximate controllability of the wave equation in [22], [23] to see that if

$$T > 2 + 2\delta \tag{5.13}$$

then ϕ must be independent of t for $1 + \delta \leqq t \leqq T - 1 - \delta$, i.e.

$$\phi(x, y, t) = \phi(x, y), \qquad (x, y) \in \mathbf{R}, \quad 1 + \delta \leqq t \leqq T - 1 - \delta. \tag{5.14}$$

Because $\hat{v}$ and $\hat{w}$ satisfy the wave equation in $\mathbf{R}$ with the homogeneous boundary conditions (5.6), and are of class C^∞ in $\mathbf{R}\cup\mathbf{B}$, we have C^∞-convergent expansions

$$\hat{v}(x, y, t) = \hat{v}_0(x, y) + \sum_{k=1}^{\infty}\sum_{j=1}^{\infty} (v_{kj}\, e^{i\omega_{kj}t} + \bar{v}_{kj}\, e^{-\omega_{kj}t}) \sin kx \sin jy, \tag{5.15}$$

$$\hat{w}(x, y, t) = \hat{w}_0 + \sum_{k=1}^{\infty}\sum_{j=1} (w_{kj}\, e^{i\omega_{kj}t} + \bar{w}_{kj}\, e^{-i\omega_{kj}t}) \cos kx \cos jy, \tag{5.16}$$

where

$$w_{kj} = \sqrt{k^2+j^2}, \tag{5.17}$$

$\hat{v}_0(x, y)$ is a C^∞ function in $\mathbf{R}\cup\mathbf{B}$ such that (cf. (4.10))

$$\hat{v}_0(x, y) = 0, \qquad (x, y)\in \mathbf{B}-\{(\pi, y)\,|\,0\leqq y\leqq \pi\} \tag{5.18}$$

and $\hat{w}_0$ is a constant. Then, from (5.8),

$$\begin{aligned}\phi(x, y, t) - \alpha\frac{\partial \hat{v}_0(x, y)}{\partial x} &= \sum_{k=1}^{\infty} \cos kx \Bigg[\sum_{j=1}^{\infty} (\alpha k v_{kj} \sin jy + i\beta\omega_{kj} w_{kj} \cos jy)\, e^{i\omega_{kj}t} \\ &\qquad + \sum_{j=1}^{\infty} (\alpha k \bar{v}_{kj} \sin jy - i\beta\omega_{kj}\bar{w}_{kj} \cos jy)\, e^{-i\omega_{kj}t}\Bigg],\end{aligned} \tag{5.19}$$

still C^∞-convergent for $(x, y)\in\mathbf{R}\cup\mathbf{B}$, $-\infty<t<\infty$. Noting (5.14), we see that the left-hand side takes the form

$$\phi(x, y, t) - \alpha\frac{\partial \hat{v}_0(x, y)}{\partial x} = \phi(x, y) - \alpha\frac{\partial \hat{v}_0(x, y)}{\partial x} \equiv \hat{\phi}(x, y), \qquad 1+\delta\leqq t\leqq T-1-\delta. \tag{5.20}$$

We now strengthen (5.13) to

$$T > 4+2\delta \tag{5.21}$$

and we see that the time interval in (5.14), (5.20) has length >2, i.e.

$$T-1-\delta-(1+\delta) = T-(2+2\delta) > 2.$$

Since the functions $\sqrt{2/\pi}\cos kx$ are orthonormal on $0\leqq x\leqq\pi$, we conclude from (5.19), (5.20) that for $k = 1, 2, 3, \cdots$

$$\begin{aligned}&\sum_{j=1}^{\infty} (\alpha k v_{kj} \sin jy + i\beta\omega_{kj} w_{kj} \cos jy)\, e^{i\omega_{kj}t} \\ &\qquad + \sum_{j=1}^{\infty} (\alpha k \bar{v}_{kj} \sin jy - i\beta\omega_{kj}\bar{w}_{kj} \cos jy)\, e^{-i\omega_{kj}t} \\ &= \frac{2}{\pi}\int_0^{\pi} \hat{\phi}(x, y) \cos kx\, dx \equiv \Phi_k(y), \qquad 1+\delta\leqq t\leqq T-1-\delta.\end{aligned} \tag{5.22}$$

Classical results of Levinson and Schwartz ([17], [27]), which have frequently been used in control studies of this type (see, e.g., [12], [21]), can now be used to show that for each fixed k, the exponential functions

$$\exp(\pm i\omega_{kj}t) = \exp(\pm\sqrt{k^2+j^2}\,t), \qquad j = 1, 2, 3, \cdots,$$

together with the constant function 1 are strongly independent in $L^2(I)$ for any t-interval I of length >2. This clearly contradicts (5.22) unless we have

$$\Phi_k(y) \equiv 0, \qquad 0 \leqq y \leqq \pi \tag{5.23}$$

and

$$\alpha k v_{kj} \sin jy + i\beta\omega_{kj} w_{kj} \cos jy = 0, \qquad 0 \leqq y \leqq \pi, \quad j = 1, 2, 3, \cdots.$$

Since, for each j, $\sin jy$ and $\cos jy$ are independent on $0 \leqq y \leqq \pi$ and since none of α, k, β, ω_{kj} are zero, we conclude that

$$v_{kj} = 0, \quad w_{kj} = 0, \quad k = 1, 2, 3, \cdots, \quad j = 1, 2, 3, \cdots. \tag{5.24}$$

Since (5.22), (5.23) show that

$$\hat{\phi}(x, y) = \sum_{k=1}^{\infty} \Phi_k(y) \cos kx = 0,$$

(5.19) gives

$$\phi(x, y, t) = \phi(x, y) = \alpha \frac{\partial \hat{v}_0(x, y)}{\partial x}, \qquad (x, y) \in \mathbf{R}, \quad 1 + \delta \leqq t \leqq T - 1 - \delta. \tag{5.25}$$

Noting (5.15) and (5.16) and the fact that $\hat{v}(0, y, t) \equiv 0$, we conclude from (5.23) that

$$\left.\begin{aligned} \hat{v}(x, y, t) &\equiv \hat{v}_0(x, y) \\ \hat{w}(x, y, t) &\equiv \hat{w}_0 \end{aligned}\right\} \qquad 1 + \delta \leqq t \leqq T - 1 - \delta. \tag{5.26}$$

Since $v(x, y, t) \equiv v_0(x, y)$ is a solution of the wave equation with (cf. (5.18))

$$\hat{v}_0(x, y) = 0, \qquad (x, y) \in \mathbf{B} - \{(\pi, y) \mid 0 \leqq y \leqq \pi\}$$

it must in fact be a solution of Laplace's equation there. Then we compute

$$\begin{aligned} &\int_{\mathbf{R}} \left[\left(\frac{\partial \hat{v}_0}{\partial x}(x, y) \right)^2 + \left(\frac{\partial \hat{v}_0}{\partial y}(x, y) \right)^2 + \hat{v}_0(x, y) \left(\frac{\partial^2 \hat{v}_0}{\partial x^2}(x, y) + \frac{\partial^2 \hat{v}_0}{\partial y^2}(x, y) \right) \right] dx\, dy \\ &= \int_{\mathbf{R}} \operatorname{div} (\hat{v}_0(x, y) \operatorname{grad} \hat{v}_0(x, y))\, dx\, dy \\ &= \int_{\mathbf{B}} \hat{v}_0(x, y) \operatorname{grad} \hat{v}_0(x, y) \cdot \nu(x, y)\, ds = \int_0^{\pi} \hat{v}_0(\pi, y) \frac{\partial \hat{v}_0}{\partial x}(\pi, y)\, dy. \end{aligned} \tag{5.27}$$

Combining (5.9) and (5.25) with the fact that $\hat{v}_0$ satisfies Laplace's equation, we conclude from (5.27) that

$$\int_{\mathbf{R}} \left[\left(\frac{\partial \hat{v}_0}{\partial x}(x, y) \right)^2 + \left(\frac{\partial \hat{v}_0}{\partial y}(x, y) \right)^2 \right] dx\, dy = 0$$

and this, together with (5.18), implies

$$\hat{v}_0(x, y) \equiv 0. \tag{5.28}$$

Combining (5.26) and (5.28), we conclude that

$$\left.\begin{aligned} \hat{v}(x, t, t) &\equiv 0 \\ \hat{w}(x, y, t) &\equiv \hat{w}_0 \end{aligned}\right\} \qquad (x, y) \in \mathbf{R}, \quad -\infty < t < \infty, \tag{5.29}$$

the result for $-\infty < t < \infty$ being an immediate consequence of the result for $1 + \delta \leqq t \leqq T - 1 - \delta$. Since this is true for every $\delta > 0$ and every $s(t)$ in (5.4), (5.5), we conclude

that a comparable result obtains for $\hat{v}$, $\hat{w}$ in (4.11), (5.2), (5.3). It follows (since $w=$ constant is a zero state in $\hat{H}$ and in H) that (cf. (4.9) ff.)

$$\|(\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1)\|_{\hat{H}} = \|(\tilde{v}_0, \tilde{v}_1, \tilde{w}_0, \tilde{w}_1)\|_H = 0$$

and, from the discussion in § 4, the approximate controllability result follows for $u \in L^2(\mathbf{B}_1 \times [0, T])$, $T > 4$. The comparable result for a single wave equation appears in [22], [23] where a control time $T > 2$ (in the same geometrical context) is seen to be required. Thus the "critical control time" for the combined Dirichlet-Neumann problem, which we have seen to be equivalent to the Maxwell system under the restrictions which we have imposed, is exactly twice the critical control time for the (single) wave equation.

The approximate controllability just established cannot be strengthened to exact controllability when the controlled portion of the boundary, $\mathbf{B}_1$, is just one side of the rectangle. This follows from the result [8] of Fattorini who has shown that only a very weak form of approximate controllability obtains for the (single) wave equation under these circumstances. It is known from [2], [3], [25] that exact controllability of finite energy states for the (single) wave equation is obtained with control on at least two sides of the rectangle. The question as to whether this remains the case for Maxwell's equations, with the doubled time interval again, is not completely clear at this time but seems likely to be answered in the affirmative.

The difficulty in such work, which would be approached in much the same manner as Graham and the present author treated the wave equation in [12], lies in the imperfect state of the literature as regards the eigenfunctions of the Maxwell system in three-dimensional regions. No definitive description of the complete set of eigenfunctions appears to exist for such a basic region as the three-dimensional ball. The nature of the eigenfunctions in the case of a rectangle can be sorted out with some difficulty and work on the control problem is under way in this direction. Results for general regions, comparable to those in [2], [3], [15], [16], [25] are hampered by the lack of a general energy decay result similar to what is available for the (single) wave equation. We see in the next section, however, that we can obtain exact controllability results for the two-dimensional problem corresponding to the circular cylinder.

6. Some exact controllability results in the case of a circular cylinder. We consider now the case $\Omega = \mathbf{R} \times (-\infty, \infty)$ with

$$\mathbf{R} = \{(x, y) \mid x^2 + y^2 < 1\},$$
$$\mathbf{B} = \partial\mathbf{R} = \{(x, y) \mid x^2 + y^2 = 1\}.$$

With introduction of the usual polar coordinates r, θ, the equations (4.1), (4.2) now become

$$\frac{\partial^2 v}{\partial t^2} = \frac{\partial^2 v}{\partial r^2} + \frac{1}{r}\frac{\partial v}{\partial r} + \frac{1}{r^2}\frac{\partial^2 v}{\partial \theta^2}, \tag{6.1}$$

$$\frac{\partial^2 w}{\partial t^2} = \frac{\partial^2 w}{\partial r^2} + \frac{1}{r}\frac{\partial w}{\partial r} + \frac{1}{r^2}\frac{\partial^2 w}{\partial \theta^2} \tag{6.2}$$

and the boundary conditions (4.3), (4.4) are transformed to

$$\frac{\partial v}{\partial t}(1, \theta, t) = \alpha u(\theta, t), \tag{6.3}$$

$$\frac{\partial w}{\partial r}(1, \theta, t) = \beta u(\theta, t). \tag{6.4}$$

Writing

$$v(r,\theta,t)=\sum_{k=-\infty}^{\infty} v_k(r,t)\,e^{ik\theta}, \qquad v_{-k}=\bar{v}_k, \tag{6.5}$$

$$w(r,\theta,t)=\sum_{k=-\infty}^{\infty} w_k(r,t)\,e^{ik\theta}, \qquad w_{-k}=\bar{w}_k, \tag{6.6}$$

$$u(\theta,t)=\sum_{k=-\infty}^{\infty} u_k(t)\,e^{ik\theta}, \tag{6.7}$$

we arrive at an infinite collection of control problems in the single space dimension, r:

$$\frac{\partial^2 v_k}{\partial t^2}=\frac{\partial^2 v_k}{\partial r^2}+\frac{1}{r}\frac{\partial v_k}{\partial r}-\frac{k^2}{r^2}v_k=0, \qquad -\infty<k<\infty, \tag{6.8}$$

$$\frac{\partial^2 w_k}{\partial t^2}=\frac{\partial^2 w_k}{\partial r^2}+\frac{1}{r}\frac{\partial w_k}{\partial r}-\frac{k^2}{r^2}w_k=0, \qquad -\infty<k<\infty, \tag{6.9}$$

$$\frac{\partial v_k}{\partial t}(1,t)=\alpha u_k(t), \qquad -\infty<k<\infty, \tag{6.10}$$

$$\frac{\partial w_k}{\partial r}(1,t)=\beta u_k(t), \qquad -\infty<k<\infty. \tag{6.11}$$

We will first treat the equation (4.1) with the boundary condition (4.3) which, as we have seen, reduces to the set of problems (6.8), (6.10), $-\infty<k<\infty$. With

$$z(r,\theta,t)=\sum_{k=-\infty}^{\infty} z_k(r,t)\,e^{ik\theta}=\sum_{k=-\infty}^{\infty}\frac{\partial v_k(r,t)}{\partial t}\,e^{ik\theta}=\frac{\partial v}{\partial t}(r,\theta,t)$$

we have the equivalent first order systems

$$\frac{\partial}{\partial t}\begin{pmatrix} v_k(r,t)\\ z_k(r,t)\end{pmatrix}=\begin{pmatrix} 0 & I\\ L_{|k|} & 0\end{pmatrix}\begin{pmatrix} v_k(r,t)\\ z_k(r,t)\end{pmatrix}=L_{|k|}\begin{pmatrix} v_k(r,t)\\ z_k(r,t)\end{pmatrix} \tag{6.12}$$

where $L_{|k|}$ is the differential operator on the right-hand side of (6.8). The boundary conditions (6.10) become

$$z_k(1,t)=\alpha u_k(t), \qquad -\infty<k<\infty. \tag{6.13}$$

The eigenvalues of the operator $L_{|k|}$ with the corresponding homogeneous boundary condition

$$z_k(1,t)=0 \tag{6.14}$$

are

$$0,\ \pm i\omega_{|k|,l}, \qquad l=1,2,3,\cdots,$$

where $\omega_{|k|,l}$ is the lth positive zero of the Bessel function $J_{|k|}(r)$ of order $|k|$. The corresponding vector eigenfunctions are

$$\begin{pmatrix}\phi_{|k|,0}(r)\\ 0\end{pmatrix},\begin{pmatrix}\phi_{|k|,l}(r)\\ \pm i\omega_{|k|,l}\phi_{|k|,l}(r)\end{pmatrix}, \qquad -\infty<k<\infty, \quad l=1,2,3,\cdots,$$

where

$$\begin{aligned}&\phi_{|k|,0}(r)=A_{|k|,0}r^{|k|}, \qquad -\infty<k<\infty,\\ &\phi_{|k|,l}(r)=A_{|k|,l}J_{|k|}(\omega_{|k|,l}r), \qquad -\infty<k<\infty, \quad l=1,2,3,\cdots.\end{aligned} \tag{6.15}$$

The normalization coefficients $A_{|k|,0}$, $A_{|k|,l}$ are chosen so that

$$\int_0^1 r|\phi_{|k|,0}(r)|^2\,dr=\frac{1}{2\pi},\qquad \int_0^1 r|\phi_{|k|,l}(r)|^2\,dr=\frac{1}{2\pi},\qquad l=1,2,3,\cdots. \tag{6.16}$$

Thus

$$A_{|k|,0}=\sqrt{\frac{|k|+1}{\pi}},\qquad -\infty<k<\infty, \tag{6.17}$$

while, as may be seen from [5], e.g.

$$A_{|k|,l}=\frac{\omega_{|k|,l}}{\sqrt{\pi}J_{|k|,l}(\omega_{|k|,l})}. \tag{6.18}$$

The state space in which we wish to work, for the present at least, is (cf. (2.18))

$$\tilde{H}=\left\{\begin{pmatrix}v\\z\end{pmatrix}\,\middle|\, v\in H^1(\mathbf{R}),\ z\in L^2(\mathbf{R})\right\}$$

with the inner product

$$\left(\begin{pmatrix}v_1\\z_1\end{pmatrix},\begin{pmatrix}v_2\\z_2\end{pmatrix}\right)=\int_{\mathbf{R}}(\nabla v_1\cdot\overline{\nabla v_2}+z_1\overline{z_2})\,dx\,dy$$

and associated norm. Since the $\phi_{|k|,l}$ satisfy the homogeneous boundary condition (6.14), one easily sees that

$$\begin{aligned}\left\|\begin{pmatrix}\phi_{|k|,0}\,e^{ik\theta}\\0\end{pmatrix}\right\|_{\tilde{H}}^2&=-\int_{\mathbf{R}}\phi_{|k|,0}\,e^{ik\theta}\overline{\Delta(\phi_{|k|,0}\,e^{ik\theta})}\,dx\,dy\\&\quad+\int_{\partial\mathbf{R}}\phi_{|k|,0}\,e^{ik\theta}\overline{\frac{\partial\phi_{|k|,0}}{\partial r}}\,e^{-ik\theta}\,d\theta+\frac{|k|+1}{\pi}\int_0^{2\pi}|k|\,d\theta\\&=2|k|(|k|+1),\qquad -\infty<k<\infty,\end{aligned} \tag{6.19}$$

while

$$\begin{aligned}\left\|\begin{pmatrix}\phi_{|k|,l}\\\pm i\omega_{|k|,l}\phi_{|k|,l}\end{pmatrix}\right\|_{\tilde{H}}^2&=\lambda_{|k|,l}\int_{\mathbf{R}}|\varepsilon_{|k|,l}|^2\,dx\,dy\\&\quad+\int_{\mathbf{R}}\nabla\phi_{|k|,l}\cdot\overline{\nabla\phi_{|k|,l}}\,dx\,dy=2\lambda_{|k|,l}\int_{\mathbf{R}}|\phi_{|k|,l}|^2\,dx\,dy=2\lambda_{|k|,l},\end{aligned} \tag{6.20}$$

where

$$\lambda_{|k|,l}=(\omega_{|k|,l})^2,\qquad -\infty<k<\infty,\quad l=1,2,3,\cdots.$$

The state $\binom{\phi_{0,0}}{0}$ has zero norm in $\tilde{H}$. Nevertheless we will not neglect this component.

If v, $\tilde{v}$ both satisfy the wave equation and (6.3), (4.13) on ∂R with initial state (4.5) for v we have (cf. (4.16))

$$\left(\begin{pmatrix}v(\cdot,\cdot,T)\\z(\cdot,\cdot,T)\end{pmatrix},\begin{pmatrix}\tilde{v}(\cdot,\cdot,T)\\\tilde{z}(\cdot,\cdot,T)\end{pmatrix}\right)_{\tilde{H}}=\alpha\int_0^T\int_{\mathbf{B}=\partial\mathbf{R}}u(x,y,t)\overline{\frac{\partial\tilde{v}}{\partial\nu}}(x,y,t)\,ds\,dt. \tag{6.21}$$

It may be shown that this result is valid for all u for which the solution (in the generalized sense) v lies in $\tilde{H}$ and varies continuously with respect to t. This class of controls u is discussed in [19] and is known to include, e.g., $u\in C([0,T];H^{1/2}(\mathbf{B}))$.

If we assume $\binom{v}{z}$ given by the $\tilde{H}$-convergent series

$$\begin{pmatrix} v(\cdot,\cdot,t) \\ z(\cdot,\cdot,t) \end{pmatrix} = \sum_{k=-\infty}^{\infty} v_{k,0}(t)(\phi_{|k|,0}\, e^{ik\theta}) + \sum_{k=-\infty}^{\infty}\sum_{l=1}^{\infty}\left[v_{k,l}^{+}(t)\begin{pmatrix} \phi_{|k|,l}\, e^{ik\theta} \\ i\omega_{|k|,l}\phi_{|k|,l}\, e^{ik\theta} \end{pmatrix} + v_{k,l}^{-}(t)\begin{pmatrix} \phi_{|k|,l}\, e^{ik\theta} \\ -i\omega_{|k|,l}\phi_{|k|,l}\, e^{ik\theta} \end{pmatrix}\right]$$

and successively let

$$\begin{pmatrix} \tilde{v}(\cdot,\cdot,t) \\ \tilde{z}(\cdot,\cdot,t) \end{pmatrix} = \begin{pmatrix} \phi_{|k|,0}\, e^{ik\theta} \\ 0 \end{pmatrix}, \exp(i\omega_{|k|,l}(t-T))\begin{pmatrix} \phi_{|k|,l}\, e^{ik\theta} \\ i\omega_{|k|,l}\phi_{|k|,l}\, e^{ik\theta} \end{pmatrix}, \exp(-i\omega_{|k|,l}(t-T))\begin{pmatrix} \phi_{|k|,l}\, e^{ik\theta} \\ -i\omega_{|k|,l}\phi_{|k|,l}\, e^{ik\theta} \end{pmatrix}, \quad -\infty < k < \infty, \quad l = 1, 2, 3, \cdots \tag{6.22}$$

for $T > 0$ we arrive at the equations

$$\begin{aligned} 2|k|(|k|+1)v_{k,0}(T) &= \alpha \int_0^T \int_0^{2\pi} u(\theta, t)\overline{\frac{\partial \phi_{|k|,0}}{\partial r}(1)}\, e^{-ik\theta}\, d\theta\, dt \\ &= 2\pi\alpha \overline{\frac{\partial \phi_{|k|,0}}{\partial r}(1)} \int_0^T u_k(t)\, dt, \end{aligned} \tag{6.23}$$

$$\begin{aligned} 2\lambda_{|k|,l}v_{k,l}^{+}(T) &= \alpha \int_0^T \int_0^{2\pi} u(\theta, t)\exp(i\omega_{|k|,l}(T-t))\overline{\frac{\partial \phi_{|k|,l}}{\partial r}(1)}\, e^{-ik\theta}\, d\theta\, dt \\ &= 2\pi\alpha \overline{\frac{\partial \phi_{|k|,l}}{\partial r}(1)} \int_0^T \exp(i\omega_{|k|,l}(T-t))u_k(t)\, dt, \end{aligned} \tag{6.24}$$

$$\begin{aligned} 2\lambda_{|k|,l}v_{k,l}^{-}(T) &= \alpha \int_0^T \int_0^{2\pi} u(\theta, t)\exp(-i\omega_{|k|,l}(T-t))\overline{\frac{\partial \phi_{|k|,l}}{\partial r}(1)}\, e^{-ik\theta}\, d\theta\, dt \\ &= 2\pi\alpha \overline{\frac{\partial \phi_{|k|,l}}{\partial r}(1)} \int_0^T \exp(-i\omega_{|k|,l}(T-t))u_k(t)\, dt. \end{aligned} \tag{6.25}$$

Thus the Dirichlet boundary control problem for (6.8), (6.10) is reduced to a moment problem (6.23), (6.24), (6.25) for which $u_k(t)$ must be a solution. We proceed in much the same way with the Neumann boundary control problem for (6.9), (6.11). We let

$$\zeta(r, \theta, t) = \sum_{k=-\infty}^{\infty} \zeta_k(r, t)\, e^{ik\theta} = \sum_{k=-\infty}^{\infty} \frac{\partial w_k(r, t)}{\partial t}\, e^{ik\theta} = \frac{\partial w}{\partial t}(r, \theta, t)$$

and obtain, in place of (6.12),

$$\frac{\partial}{\partial t}\begin{pmatrix} w_k(r, t) \\ \zeta_k(r, t) \end{pmatrix} = \begin{pmatrix} 0 & I \\ M_{|k|} & 0 \end{pmatrix}\begin{pmatrix} w_k(r, t) \\ \zeta_k(r, t) \end{pmatrix} = M_{|k|}\begin{pmatrix} v_k(r, t) \\ z_k(r, t) \end{pmatrix}. \tag{6.26}$$

The boundary conditions are now

$$\frac{\partial w_k}{\partial r}(1, t) = \beta u_k(t), \qquad -\infty < k < \infty.$$

The eigenvalues of $M_{|k|}$ with the corresponding homogeneous boundary condition

$$\frac{\partial w_k}{\partial r}(1, t) = 0$$

are, for $k=0$,

$$0, \quad \pm i\nu_{0,l} \quad l=1,2,3,\cdots,$$

where $\nu_{0,l}$ is the lth zero of the differentiated Bessel function, $j_0'(r)$, of order 0, and, for $k\neq 0$,

$$\pm i\nu_{|k|,l}, \qquad l=1,2,3,\cdots,$$

where $\nu_{k,l}$ is the lth zero of $J_k'(r)$. In the case $k=0$ the eigenvalue 0 has double multiplicity. The special solutions taking the place of (6.22) in this case are

$$\begin{pmatrix}\tilde{w}(\cdot,\cdot,t)\\ \tilde{\zeta}(\cdot,\cdot,t)\end{pmatrix}=\begin{pmatrix}\psi_{00}\\ 0\end{pmatrix},\begin{pmatrix}(t-T)\psi_{00}\\ \psi_{00}\end{pmatrix} \tag{6.27}$$

where ψ_{00} is such that (cf. (6.16))

$$\int_0^1 r\psi_{00}^2\,dr=\frac{1}{2\pi}, \quad \text{i.e.,} \quad \psi_{00}=\frac{1}{\sqrt{\pi}}.$$

In all of the other cases the vector eigenfunctions take the form

$$\begin{pmatrix}\psi_{|k|,l}(r)\\ \pm i\nu_{|k|,l}\psi_{|k|,l}(r)\end{pmatrix}, \qquad -\infty<k<\infty, \quad l=1,2,3,\cdots$$

where

$$\psi_{|k|,l}(r)=B_{|k|,l}J_{|k|}(\nu_{|k|,l}r), \qquad -\infty<k<\infty, \quad l=1,2,3,\cdots,$$

the normalization coefficients

$$B_{|k|,l}=\frac{\nu_{|k|,l}}{\sqrt{\pi}\,(\mu_{|k|,l}-k^2)^{1/2}J_{|k|}(\nu_{|k|,l})} \tag{6.28}$$

selected so that

$$\int_0^{\mathbf{R}} r|\psi_{|k|,l}(r)|^2\,dr=\frac{1}{2\pi}.$$

The corresponding special solutions of the homogeneous equation are

$$\begin{aligned}\begin{pmatrix}\tilde{w}(\cdot,\cdot,t)\\ \tilde{\zeta}(\cdot,\cdot,t)\end{pmatrix}&=\exp\left(i\nu_{|k|,l}(t-T)\right)\begin{pmatrix}\psi_{|k|,l}\,e^{ik\theta}\\ i\nu_{|k|,l}\psi_{|k|,l}\,e^{ik\theta}\end{pmatrix},\\ &\exp\left(-i\nu_{|k|,l}(t-T)\right)\begin{pmatrix}\psi_{|k|,l}\,e^{ik\theta}\\ -i\nu_{|k|,l}\psi_{|k|,l}\,e^{ik\theta}\end{pmatrix}.\end{aligned} \tag{6.29}$$

As in (6.20) it may be seen that

$$\left\|\begin{pmatrix}\psi_{|k|,l}\\ \pm i\nu_{|k|,l}\psi_{|k|,l}\end{pmatrix}\right\|_{\tilde{H}}^2=2\mu_{|k|,l}, \qquad \mu_{|k|,l}=(\nu_{|k|,l})^2.$$

Let w satisfy the wave equation and (6.4) with $w(x,y,0)\equiv 0$, $\zeta(x,y,0)=(\partial w/\partial t)(x,y,0)\equiv 0$ in $\mathbf{R}$. We expand $\binom{w}{\zeta}$ in the form

$$\begin{aligned}\begin{pmatrix}w(\cdot,\cdot,t)\\ \zeta(\cdot,\cdot,t)\end{pmatrix}&=w_{00}(t)\begin{pmatrix}\psi_{00}\\ 0\end{pmatrix}+\zeta_{00}(t)\begin{pmatrix}0\\ \psi_{00}\end{pmatrix}\\ &+\sum_{k=-\infty}^{\infty}\sum_{l=1}^{\infty}\left[w_{k,l}^{+}(t)\begin{pmatrix}\psi_{|k|,l}\,e^{ik\theta}\\ i\nu_{|k|,l}\psi_{|k|,l}\,e^{ik\theta}\end{pmatrix}+w_{k,l}^{-}(t)\begin{pmatrix}\psi_{|k|,l}\,e^{ik\theta}\\ -i\nu_{|k|,l}\psi_{|k|,l}\,e^{ik\theta}\end{pmatrix}\right].\end{aligned}$$

If $\tilde{w}$ satisfies the wave equation and the homogeneous boundary condition (cf. (4.14))

$$\frac{\partial \tilde{w}}{\partial \nu}(x, y, t) = 0, \qquad (x, y) \in \mathbf{B}, \quad t \geqq 0,$$

we find (cf. (4.16), (6.21)) that

$$\left(\begin{pmatrix} w(\cdot, \cdot, T) \\ \zeta(\cdot, \cdot, T) \end{pmatrix}, \begin{pmatrix} \tilde{w}(\cdot, \cdot, T) \\ \tilde{\zeta}(\cdot, \cdot, T) \end{pmatrix} \right)_{\tilde{H}} = \beta \int_0^T \int_{\mathbf{B}=\partial\mathbf{R}} u(x, y, t) \overline{\frac{\partial \tilde{w}}{\partial t}(x, y, t)}\, ds\, dt. \tag{6.30}$$

Employing (6.29), (6.3) successively for $\binom{w}{\zeta}$, we arrive at the equations, for $-\infty < k < \infty$, $l = 1, 2, 3, \cdots$,

$$\begin{aligned} 2\mu_{|k|,l} w^+_{k,l}(T) &= \beta \int_0^T \int_0^{2\pi} u(\theta, t) i\nu_{|k|,l} \exp\left(i\nu_{|k|,l}(T-t)\right) \psi_{|k|,l}(1)\, e^{-ik\theta}\, d\theta\, dt \\ &= 2\pi\beta i \nu_{|k|,l} \overline{\psi_{|k|,l}(1)} \int_0^T \exp\left(i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt, \end{aligned} \tag{6.31}$$

$$\begin{aligned} 2\mu_{|k|,l} w^-_{k,l}(T) &= -\beta \int_0^T \int_0^{2\pi} u(\theta, t) i\nu_{|k|,l} \exp\left(-i\nu_{|k|,l}(T-t)\right) \psi_{|k|,l}(1)\, e^{-ik\theta}\, d\theta\, dt \\ &= -2\pi\beta i \nu_{|k|,l} \overline{\psi_{|k|,l}(1)} \int_0^T \exp\left(-i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt. \end{aligned} \tag{6.32}$$

We find also, taking $\begin{pmatrix} \tilde{w} \\ \tilde{\zeta} \end{pmatrix}$ in the second form given in (6.27), that

$$\zeta_{00}(T) = \beta \int_0^T \int_0^{2\pi} u(\theta, t) \overline{\psi_{00}}\, d\theta\, dt = 2\pi\beta \overline{\psi_{00}} \int_0^T u_0(t)\, dt. \tag{6.33}$$

Since this must be true for all T and $(d/dt) w_{00}(t) = \zeta_{00}(t)$, we have also

$$w_{00}(T) = 2\pi\beta \overline{\psi_{00}} \int_0^T (T-t) u_0(t)\, dt. \tag{6.34}$$

Since $\mu_{|k|,l} = (\nu_{|k|,l})^2$, (6.31), (6.32) become

$$\begin{aligned} \frac{\nu_{|k|,l}}{\pi\beta i} w^+_{k,l}(T) &= \overline{\psi_{|k|,l}(1)} \int_0^T \exp\left(i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt \\ &= B_{|k|,l} J_{|k|,l}(\nu_{|k|,l}) \int_0^T \exp\left(i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt, \end{aligned} \tag{6.35}$$

$$\frac{\nu_{|k|,l}}{\pi\beta i} w^-_{k,l}(T) = -B_{|k|,l} J_{|k|,l}(\nu_{|k|,l}) \int_0^T \exp\left(-i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt. \tag{6.36}$$

Taking account of the fact that

$$\overline{\frac{\partial \phi_{|k|,l}}{\partial r}(1)} = \omega_{|k|,l} A_{|k|,l} \frac{\partial J_{|k|,l}}{\partial r}(\omega_{|k|,l}),$$

(6.24) and (6.25) yield

$$\frac{\omega_{|k|,l}}{\pi\alpha} v^+_{k,l}(T) = A_{|k|,l} \frac{\partial J_{|k|,l}}{\partial r}(\omega_{|k|,l}) \int_0^T \exp\left(i\omega_{|k|,l}(T-t)\right) u_k(t)\, dt, \tag{6.37}$$

$$\frac{\omega_{|k|,l}}{\pi\alpha} v^-_{k,l}(T) = A_{|k|,l} \frac{\partial J_{|k|,l}}{\partial r}(\omega_{|k|,l}) \int_0^T \exp\left(-i\omega_{|k|,l}(T-t)\right) u_k(t)\, dt. \tag{6.38}$$

On the other hand

$$\frac{\partial \phi_{|k|,0}}{\partial r}(1) = A_{|k|,0}|k|$$

so (6.23) gives

$$\frac{|k|+1}{\pi\alpha} v_{k,0}(T) = A_{|k|,0} \int_0^T u_k(t)\, dt. \tag{6.39}$$

Using the formula (6.18) and (6.28) for $A_{|k|,l}$ and $B_{|k|,l}$ we have

$$\frac{\nu_{|k|,l}}{\pi\beta i} w^+_{k,l}(T) = \frac{\nu_{|k|,l}}{\sqrt{\pi}(\mu_{|k|,l}-k^2)^{1/2}} \int_0^T \exp\left(i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt, \tag{6.40}$$

$$\frac{\nu_{|k|,l}}{\pi\beta i} w^-_{k,l}(T) = \frac{-\nu_{|k|,l}}{\sqrt{\pi}(\mu_{|k|,l}-k^2)^{1/2}} \int_0^T \exp\left(-i\nu_{|k|,l}(T-t)\right) u_k(t)\, dt, \tag{6.41}$$

$$\frac{\omega_{|k|,l}}{\pi\alpha} v^+_{k,l}(T) = \frac{1}{\sqrt{\pi}} \int_0^T \exp\left(i\omega_{|k|,l}(T-t)\right) u_k(t)\, dt, \tag{6.42}$$

$$\frac{\omega_{|k|,l}}{\pi\alpha} v^-_{k,l}(T) = \frac{1}{\sqrt{\pi}} \int_0^T \exp\left(-i\omega_{|k|,l}(T-t)\right) u_k(t)\, dt. \tag{6.43}$$

The equations (6.39) become, in view of (6.17),

$$\frac{\sqrt{2}\sqrt{|k|(|k|+1)}}{\pi\alpha} v_{k,0}(T) = \frac{\sqrt{2|k|}}{\sqrt{\pi}} \int_0^T u_k(t)\, dt. \tag{6.44}$$

This is valid, but meaningless, for $k=0$. It is easy to see that in the case $k=0$ we should use

$$\frac{1}{\sqrt{\pi}\alpha} v_{00}(T) = \int_0^T u_k(t)\, dt. \tag{6.45}$$

The equations (6.33) and (6.34) are left as they appear. We note that all of the coefficients

$$\frac{\nu_{|k|,l}}{\sqrt{\pi}(\mu_{|k|,l}-k^2)^{1/2}}, \quad \frac{1}{\sqrt{\pi}}, \quad \frac{\sqrt{2|k|}}{\sqrt{\pi}}, \quad k \neq 0, \quad 2\pi\beta$$

are bounded away from zero, uniformly with respect to k.

It is also possible to show, using the work [10], [11] of K. D. Graham, that the numbers

$$0, \nu_{|k|,1}, \omega_{|k|,1}, \nu_{|k|,2}, \omega_{|k|,2}, \cdots, \nu_{|k|,j}, \omega_{|k|,j}, \cdots$$

are separated by a gap at least equal to $\pi/2$, again uniformly with respect to k. Applying the result [14] of A. E. Ingham along with the work of Duffin and Schaeffer [7], much as in [12], [2], [3], we conclude the existence of functions $u_k(t)$ in $L^2[0, T]$, for any fixed $T>4$, solving the above moment problems, $-\infty<k<\infty$. Moreover, the result of Ingham implies as explained in [12], [26], that for each k

$$c^{-2}N_k^2 \leqq \int_0^T |u_k(t)|^2\, dt \leqq C^2 N_k^2$$

where

$$N_k^2 = 2|k|(|k|+1)|v_{k,0}(T)|^2 + \sum_{l=1}^{\infty} \lambda_{|k|,l}|v_{k,l}^+(T)|^2 + \sum_{l=1}^{\infty} \lambda_{|k|,l}|v_{k,l}^-(T)|^2$$
$$+ \sum_{l=1}^{\infty} \mu_{|k|,l}|w_{k,l}^+(T)|^2 + \sum_{l=1}^{\infty} \mu_{|k|,l}|w_{k,l}^-(T)|^2$$

$k = \pm 1, \pm 2, \cdots$. For $k = 0$ we must add $|\zeta_{00}(T)|^2 + |w_{00}(T)|^2$. Since

$$\int_0^T \int_0^{2\pi} |u(\theta, t)|^2 \, d\theta \, dt = \sum_{k=-\infty}^{\infty} \int_0^T |u_k(t)|^2 \, dt \tag{6.46}$$

we see that the above moment problems, equivalent to the control problem, can be solved with (6.46) finite, provided that

$$\sum_{k=-\infty}^{\infty} N_k^2 < \infty,$$

which is the same as saying that the norm of the final state in $\hat{H}$ should be finite. We have, then, the exact controllability result that any $\hat{H}$ state may be controlled to any other $\hat{H}$ state during a time interval of length $T > 4$ with the control configuration we have described here. As discussed in connection with the wave equation in [2], [3], and [12], one cannot be sure that the state of the system remains in $\hat{H}$ for all $t \in [0, T]$. However, in the present case of the Maxwell equations one can show that these states do lie in $H = H_{\mathbf{E},d}(\mathbf{R})$. Again this is exactly twice the critical control time for the (single) wave equation under the same circumstances, as established in [10], [12].

7. Concluding remarks. The approximate controllability results of § 5 would appear to be extendable to domains other than rectangular ones but the precise method of extension remains to be worked out. We will indicate some aspects of this problem which are clear from our current work.

First of all, the result of § 5 is almost trivially extended to the case where control is exercised only on a subset $\{(\pi, y) | 0 \leqq a \leqq y \leqq b \leqq \pi\}$, $b > a$, of $\{(\pi, y) | 0 \leqq y \leqq \pi\}$. The only change is that the interval $1 + \delta \leqq t \leqq T - 1 - \delta$ appearing in (5.14) and subsequently must be modified to $d + \delta \leqq t \leqq T - d - \delta$ where

$$d = \inf_{a \leqq y \leqq b} \left\{ \sup_{\substack{0 \leqq \xi \leqq \pi \\ 0 \leqq \eta \leqq \pi}} \{[(\pi - \xi)^2 + (\eta - y)^2]^{1/2}\} \right\}.$$

If $\phi(\pi, y, t) \equiv (\partial\phi/\partial x)(\pi, y, t) \equiv 0$ for $\delta \leqq t \leqq T - \delta$, $a \leqq y \leqq b$, the Holmgren theorem will still apply to show that $\phi(x, y, t) \equiv 0$, $(x, y) \in \mathbf{R}$, $d + \delta \leqq t \leqq T - d - \delta$. After that the remainder of the proof is the same: the same eigenfunctions and frequencies must be dealt with, the functions $\sin jy$, $\cos jy$ are still independent on $a \leqq y \geqq b$ and $b > a$ and the conditions

$$\hat{v}_0(x, y) = 0, \qquad (x, y) \in \mathbf{B} - \{(\pi, y) | a \leqq y \leqq b\}$$
$$\frac{\partial \hat{v}_0}{\partial x}(\pi, y) = 0, \qquad a \leqq y \leqq b,$$

still show $\hat{v}_0(x, y) \equiv 0$ in $\mathbf{R}$.

The first limitation of the method which we have used in § 5 lies in its dependence on the construction of $\phi(x, y, t)$ as a linear combination of partial derivatives of $\hat{v}$ and $\hat{w}$. It is necessary to have *a solution of the wave equation to which Holmgren's theorem*

may be applied. This part of the proof can still be used for nonrectangular domains as long as a portion of the boundary on which control is applied is a straight line segment. Assuming the segment parallel to the y-axis, one can construct ϕ by the formula (5.8) again and show that ϕ and $\partial\phi/\partial x$ both vanish on the straight line segment in question, allowing subsequent application of the Holmgren theorem to show $\phi(x, y, t) \equiv 0$ for $(x, y) \in \mathbf{R}$ and t in some interval $d + \delta \leqq t \leqq T - d - \delta$, with d depending on the geometry of $\mathbf{R}$. But then we are faced with a second limitation.

The second limitation of the method which we have used lies in its reliance on the specific form of the eigenfunctions and frequencies to pass from $\phi(x, y, t) \equiv 0$ to the conclusion that both $\hat{v}(x, y, t)$ and $\hat{w}(x, y, t)$ are likewise identically zero. It needs to be emphasized that no local analysis will suffice here. In the one-dimensional case (see our remarks at the end of § 3) if the control problem is stated for boundary conditions

$$v(0, t) = 0, \qquad \frac{\partial v}{\partial t}(1, t) = \alpha u(t), \tag{7.1}$$

$$\frac{\partial w}{\partial x}(0, t) = 0, \qquad \frac{\partial w}{\partial x}(1, t) = \beta u(t) \tag{7.2}$$

the $\tilde{v}$, $\tilde{w}$ constructed as in § 4 will satisfy the wave equation and

$$\tilde{v}(0, t) = 0, \qquad \frac{\partial \tilde{v}}{\partial t}(1, t) = 0, \tag{7.3}$$

$$\frac{\partial \tilde{w}}{\partial x}(0, t) = 0, \qquad \frac{\partial \tilde{w}}{\partial x}(1, t) = 0, \tag{7.4}$$

$$\alpha \frac{\partial \tilde{v}}{\partial x}(1, t) + \beta \frac{\partial \tilde{w}}{\partial t}(1, t) \equiv \phi(1, t) = 0. \tag{7.5}$$

Here if we take $\tilde{w}$ to be a nonzero solution of the wave equation satisfying (7.4) and take

$$\tilde{v}(x, t) = -\frac{\beta}{\alpha} \int_0^x \frac{\partial \tilde{w}}{\partial t}(\xi, t)\, d\xi,$$

we clearly have $\tilde{v}(0, t) = 0$,

$$\begin{aligned}
\frac{\partial \tilde{v}}{\partial t}(1, t) &= \frac{\beta}{\alpha} \int_0^1 \frac{\partial^2 \tilde{w}}{\partial t^2}(\xi, t)\, d\xi \\
&= -\frac{\beta}{\alpha} \int_0^1 \frac{\partial^2 \tilde{w}}{\partial \xi^2}(\xi, t)\, d\xi = \frac{\beta}{\alpha}\left(\frac{\partial \tilde{w}}{\partial x}(0, t) - \frac{\partial \tilde{w}}{\partial x}(1, t)\right) = 0, \\
\frac{\partial^2 \tilde{v}}{\partial t^2}(x, t) &= -\frac{\beta}{\alpha} \int_0^x \frac{\partial^3 \tilde{w}}{\partial t^3}(\xi, t)\, d\xi \\
&= -\frac{\beta}{\alpha} \int_0^x \frac{\partial^3 \tilde{w}}{\partial t\, \partial \xi^2}(\xi, t)\, d\xi = -\frac{\beta}{\alpha} \frac{\partial^2 \tilde{w}}{\partial t\, \partial x}(x, t) = \frac{\partial^2 \tilde{v}}{\partial x^2}(x, t)
\end{aligned}$$

so that $\tilde{v}$ satisfies the wave equation and, clearly, (7.5) is also satisfied. Thus the wave equation with (7.1), (7.2) is not approximately controllable; $\phi(x, t) \equiv \alpha(\partial\tilde{v}/\partial x)(x, t) + \beta(\partial\tilde{w}/\partial t)(x, t) \equiv 0$ but this does not imply that $\tilde{v}$ or $\tilde{w}$ are identically equal to zero. The additional condition which makes this work in (3.7)ff. is the fact

that one can show there that

$$-\alpha\frac{\partial\tilde{v}}{\partial x}(0,t)+\beta\frac{\partial\tilde{w}}{\partial t}(0,t)=0.$$

It seems likely that the question of whether or not $\phi=0$ implies that both $\hat{v}$ and $\hat{w}$, equivalently $\tilde{v}$ and $\tilde{w}$, are both zero must eventually reduce to a boundary value problem of an as yet unidentified type.

At the present writing there is only one, rather curious, result which we can offer which yields approximate controllability for a domain $\mathbf{R}$ of rather general shape. We suppose that the "control boundary" $\mathbf{B}_1\subset\mathbf{B}=\partial\mathbf{R}$ includes two nonparallel line segments, l_1 and l_2, with unit exterior normals ν_1 and ν_2. Proceeding as before we can show, applying the Holmgren theorem together with

$$\frac{\partial\hat{v}}{\partial t}=0 \quad \text{on } l_1, l_2,$$

$$\frac{\partial\hat{w}}{\partial\nu_i}=0, \quad i=1,2 \quad \text{on } l_1, l_2, \text{ respectively,}$$

$$\alpha\frac{\partial\hat{v}}{\partial\nu_i}+\beta\frac{\partial\hat{w}}{\partial t}=0, \quad i=1,2 \quad \text{on } l_1, l_2, \text{ respectively,}$$

that both

$$\phi_1=\alpha\frac{\partial\hat{v}}{\partial\nu_1}+\beta\frac{\partial\hat{w}}{\partial t}, \tag{7.6}$$

$$\phi_2=\alpha\frac{\partial\hat{v}}{\partial\nu_2}+\beta\frac{\partial\hat{w}}{\partial t}, \tag{7.7}$$

must vanish identically in $\mathbf{R}$ for $d+\delta\leqq t\leqq T-d-\delta$, $\delta>0$ arbitrary, $d>0$ depending on the geometry of $\mathbf{R}$ and $\mathbf{B}$, the location of l_1 and l_2 within $\mathbf{B}$, etc. But then both ϕ_1 and ϕ_2 must vanish on l_1 (say) for these values of t. Subtracting (7.6) from (7.7), we see that

$$\alpha\left(\frac{\partial\hat{v}}{\partial\nu_1}-\frac{\partial\hat{v}}{\partial\nu_2}\right)=0 \quad \text{on } l_1\times[d+\delta, T-d-\delta].$$

This shows, since l_1 and l_2 are not parallel, that a nontangential derivative of $\hat{v}$ vanishes on $l_1\times[d+\delta, T-d-\delta]$. Combining this with $\partial\hat{v}/\partial t=0$ on l_1 and applying the Holmgren theorem to $\hat{v}$ alone, much as in [5], [13], we are able to conclude $\hat{v}\equiv 0$, provided T is appropriately large. Then one easily has the same result for $\hat{w}$ and approximate controllability follows.

This result gives approximate controllability for $\mathbf{R}$ equal to the interior of any closed polyhedron in R^2 with control on at least two sides.

Further inspection of this argument shows that only l_2 needs to be assumed to be a line segment. That is needed in order to identify ϕ_2 as a solution of the wave equation. We may then take l_1 to be any smooth portion of $\mathbf{B}_1$ which is never parallel to l_1 and achieve the same result.

Finally, let us indicate that we are very much aware of the limitations, from the point of view of actual implementation, of the control configuration discussed in this paper. In principle, at least, the boundary conditions (1.7), (1.8), along with the further "single layer" condition discussed in connection with (3.1), could be achieved with conducting bars attached to terminals as shown in Fig. 3.

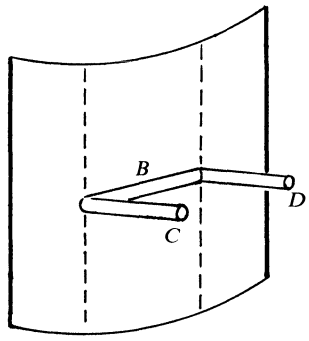

FIG. 3. *Conducting bar and busses.*

We have not considered any effects of propagation delays in the controlling circuits—i.e., we have not assumed that these are distributed parameter systems. This assumption, and evident limitations on the speed with which prescribed currents can be computed and established in the controlling circuits together with sensing limitations, place admittedly severe limitations on what can be done "open loop." It is likely that the eventual significance of our results will be most evident in connection with closed loop behavior wherein time varying magnetic fields $\vec{H}$ near the boundary of Ω induce currents in the bars B which, being resistive, will then act as energy dissipators. We hope to discuss this topic in later work.

Another control configuration may be obtained by supposing the boundary of Ω to be a sheet of material to which electromagnets are attached in a dense array as shown in Fig. 4. If J denotes the current through, the windings of the electromagnets, then we shall have

$$H_\nu = \alpha J$$

where α is dependent on the electromagnet's configuration. The theory in this case will take much the same form as the one discussed in this paper.

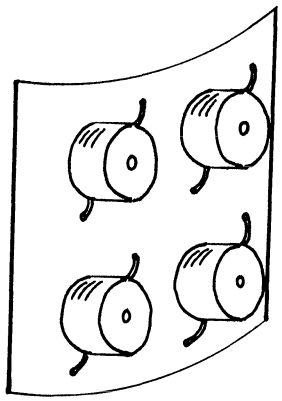

FIG. 4. *Electromagnet array.*

LOCAL REALIZATIONS OF NONLINEAR CAUSAL OPERATORS*

BRONISŁAW JAKUBCZYK†

Abstract. We give necessary and sufficient conditions for a causal operator to have a local realization of class $C^k(k=1,\cdots,\infty,\omega)$ of the form

$$\dot{x}=f(x,u),\qquad y=h(x).$$

We show that two minimal local realizations of the same response map are locally diffeomorphic.

Key words. causal operators, nonlinear systems, nonlinear realization theory, existence and uniqueness of realizations

1. Introduction. Let Ω, Y be sets and let $\mathcal{U}$, $\mathcal{Y}$ be sets of functions $[0,T)\to\Omega$ and $[0,T]\to Y$, respectively. We shall assume that $\mathcal{U}$ contains all piecewise constant functions and $Y=R^r$. An operator $F:\mathcal{U}\to\mathcal{Y}$ is called (strictly) causal if $u|_{[0,t)}=v|_{[0,t)}$ implies $(F(u))(t)=(F(v))(t)$ for any $u,v\in\mathcal{U}$ and $0\leqq t\leqq T$ (here t has interpretation of time).

In this paper, for general classes of functions $\mathcal{U}$, $\mathcal{Y}$ we give necessary and sufficient conditions for the operator $u\to y=F(u)$ to be locally represented by a system of the form

$$\dot{x}=f(x,u),\quad x(0)=x_0,\quad y=h(x), \tag{1}$$

where $x(t)\in V$ and V is an open subset of R^n for some $n>0$. "Locally" means "for small times" here.

The problem arises in the system theory, where Ω, Y are input and output spaces, respectively; u, y are input and output signals; and F is an operator describing input-output behavior of a system (black box). Then (1) is a desired internal description of the system (called realization), which is to be found.

A solution of a global version of the problem was given in [14] (uniqueness) and [8] (existence). Related results may be found in [1]-[7] and [9]-[13]. In the global version of [8] the time horizon is infinite, $T=\infty$, the realization is sought with the state space V being any differentiable manifold and system (1) obtained is complete (has solutions forward and backward for all times). In this case the response map is required to have an extension to an "input group". The construction of the realization is obtained via a certain factorization (Nerode equivalence) of this group.

The main difficulty of the local problem is that it is hard to localize the group argument. Therefore, another construction has to be used. The construction used in this paper is completely elementary and given explicitly in terms of functions, which is an advantage from the point of view of possible practical computations. Another advantage of the approach presented in this paper is that it requires minimal hypotheses on the response map, only regularity and finiteness of the response map (the extension assumption of [8] is dropped). However, under these assumptions it is not possible to obtain a realization which is good for all inputs, at least in the C^∞ case. Thus, we construct a realization which is good after some transient behavior. In the analytic case this transient behavior can be dropped.

* Received by the editors February 2, 1984, and in revised form December 1, 1984.
† Institute of Mathematics, Polish Academy of Sciences, 00-950 Warsaw, Sniadeckich 8, Poland.

Another approach to the local problem was presented in [5], where the operator F is given by a series with iterated integrals and f is analytic of the form $f(x, u) = f_0(x) + \sum_i u_i g_i(x)$. The analytic version of our result (Theorem 2) can be used to derive the existence result in [5].

A strictly causal operator F can be uniquely represented by a map $P: \mathcal{S} \to Y$ (called "response map", "input-output map" or "causal functional" if $Y = R$), where $\mathcal{S}$ is the set of all functions being restrictions to $[0, t)$, $0 \leqq t \leqq T$ of functions in $\mathcal{U}$, and

$$P(a) = (F(u))(t), \qquad a = u|_{[0, t)}.$$

We shall formulate our results in terms of the map P. Note that P defines F by the formula $(F(u))(t) = P(u|_{[0, t)})$, $u \in \mathcal{U}$.

In the paper we use the norm $|x| = |x_1| + \cdots + |x_n|$ in R^n and the norm $\|A\|$ of a matrix A denotes the norm of the corresponding operator in such normed spaces. Composition of functions is denoted by $\circ$.

2. Main results. Assume that $\mathcal{U} = \mathcal{U}_{pc}$, where $\mathcal{U}_{pc}$ consists of all piecewise constant functions $[0, T) \to \Omega$, with $T > 0$ fixed, and let $\mathcal{S}_{pc}$ be the corresponding class of restricted function. Let $R_+ = [0, \infty)$. For $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_p)$, $\mathbf{t} = (t_1, \cdots, t_p)$ we denote by

$$a = \boldsymbol{\alpha}(\mathbf{t}) = (t_1, \alpha_1) \cdots (t_p, \alpha_p), \qquad p \geqq 1, \quad t_i \in R_+, \quad \alpha_i \in \Omega, \tag{2}$$

the function in $\mathcal{S}_{pc}$ given by $a(t) = \alpha_i$ for $t \in [t_1 + \cdots + t_{i-1}, t_1 + \cdots + t_i)$. Denote $|a| = t_1 + \cdots + t_p$.

The elements $a, b \in \mathcal{S}_{pc}$ can be multiplied; by ab we mean the concatenation of a and b (writing one sequence (2) after the other). If $|a| + |b| \leqq T$, then $ab \in \mathcal{S}_{pc}$. We include the function e with empty domain (empty sequence (2)) in $\mathcal{S}_{pc}$, it plays the role of identity.

DEFINITION 1. Let $P = (P_1, \cdots, P_r)$ be a map $P: \mathcal{S}_{pc} \to R^r$. We say that $\Sigma = (V, f, h, x_0)$ is a *local realization of P of class C^k after function $c \in \mathcal{S}_{pc}$* if

(i) $x_0 \in V \subset R^n$ and $h: V \to R^r$ is a function of class C^k,

(ii) $f(\cdot, \alpha)$, $\alpha \in \Omega$, are vector fields on V of class C^{k-1} and their local flows $\Phi^f_{(t, \alpha)}(x)$ are of class C^k with respect to (t, x),

(iii) $P(ca) = h \circ \Phi^f_a(x_0)$

for $a = \boldsymbol{\alpha}(\mathbf{t})$ with any sequence $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_p)$ and $\mathbf{t}$ in a neighborhood of $0 \in R^p_+$. Here

$$\Phi^f_a = \Phi^f_{(t_p, \alpha_p)} \circ \cdots \circ \Phi^f_{(t_1, \alpha_1)}.$$

We also say that Σ is a *local realization around function $c = \boldsymbol{\beta}(\mathbf{s}^*)$* if (iii) is satisfied for all $c = \boldsymbol{\beta}(\mathbf{s})$ and $a = \boldsymbol{\alpha}(\mathbf{t})$ with $\mathbf{s}, \mathbf{t}$ in a neighborhood of $(\mathbf{s}^*, 0) \in R^m \times R^p_+$ where $x_0 = x_0(\mathbf{s})$. Finally, Σ is called a *realization of P on an interval* $[0, \sigma]$ if (iii) is satisfied for all $a \in \mathcal{S}_{pc}$ with $|a| \leqq \sigma$.

In case $k = 1$ one should read in (ii) "there exist local flows $\Phi^f_{(t, \alpha)}(x)$ of class C^1 of $f(\cdot, \alpha)$". The number n is called dimension of the realization, $n = \dim \Sigma$.

Let E_δ be the simplex $E_\delta = \{\mathbf{t} \in R^p_+ \mid |\mathbf{t}| < \delta\}$. We shall use the following assumptions on P.

(A1) Functions $\mathbf{t} \to P(\boldsymbol{\alpha}(\mathbf{t}))$ are of class C^k on E_T for any sequence $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_p)$, $\alpha_i \in \Omega$, and $p \geqq 1$.

Here and below a function defined on a (partially) closed polyhedron W is called of class C^k if all partial derivatives (directional partial derivatives) up to order k exist and are continuous on W. For $k = \omega$ we require that the Taylor series taken at any point of W is convergent in a neighborhood of this point.

(A2) The functions $P(\boldsymbol{\alpha}(\mathbf{t}))$ and their partial derivatives $(\partial/\partial t_i)P(\boldsymbol{\alpha}(\mathbf{t}))$ satisfy the Lipschitz conditions

$$|P(\boldsymbol{\alpha}(\mathbf{t}))-P(\boldsymbol{\alpha}(\mathbf{t}'))|\leqq L|\mathbf{t}-\mathbf{t}'|,$$

$$\left|\frac{\partial}{\partial t_i}P(\boldsymbol{\alpha}(\mathbf{t}))-\frac{\partial}{\partial t_i}P(\boldsymbol{\alpha}(\mathbf{t}'))\right|\leqq M|\mathbf{t}-\mathbf{t}'|,\qquad i=1,\cdots,p,$$

on E_T with constants L, M independent of the sequence $\boldsymbol{\alpha}$.

Let $\mathbf{b}=(b_1,\cdots,b_q)$, $b_i\in\mathcal{S}_{pc}$ and take $\delta=T-\max\{|b_1|,\cdots,|b_q|\}$. Define a map $\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}\colon E_\delta\to R^{rq}$,

$$\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}(\mathbf{t})=(P(\boldsymbol{\alpha}(\mathbf{t})b_1),\cdots,P(\boldsymbol{\alpha}(\mathbf{t})b_q)).$$

Define

$$\operatorname{rank} P=\sup_{\boldsymbol{\alpha},\mathbf{b},\mathbf{t}}\operatorname{rank} d\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}(\mathbf{t}),$$

where $d\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}$ denotes the Jacobian of the map $\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}$ and the supremum is taken over all finite sequences $\boldsymbol{\alpha}$, $\mathbf{b}$, $\mathbf{t}$ such that $\Psi^{\mathbf{b}}_{\boldsymbol{\alpha}}(\mathbf{t})$ makes sense.

We say that the *rank of P is attained at function $c\in\mathcal{S}_{pc}$* if there exist a representation $c=\boldsymbol{\beta}(\mathbf{s})=(s_1,\beta_1)\cdots(s_m,\beta_m)$ of c and a sequence $\mathbf{b}$ such that $\operatorname{rank} d\Psi^{\mathbf{b}}_{\boldsymbol{\beta}}(\mathbf{s})=\operatorname{rank} P$.

THEOREM 1. *If the map $P:\mathcal{S}_{pc}\to R^r$ satisfies condition* (A1) *and rank P is finite, then there exists a local realization Σ of P of class $C^k(k=1,2,\cdots,\infty,\omega)$, with* $\dim\Sigma=\operatorname{rank} P$, *after (as well as around) any function c at which the rank is attained.*

If, additionally, condition (A2) *is satisfied, then Σ is a realization on an interval $[0,\sigma]$ and $f(x,u)$ is bounded on $V\times\Omega$ and Lipschitzian with respect to x.*

Remark 1. From regularity properties of solutions of differential equations one can see that, if the map P is defined by a realization Σ via formula (iii), then (A1) is satisfied and $\operatorname{rank} P\leqq\dim\Sigma$.

In the (real) analytic case, $k=\omega$, we can strengthen condition (A1).

(A1)′ There exist a function $\rho:\Omega\to(0,\infty)$ and a $\delta>0$ such that the functions $\mathbf{t}\to\mathbf{P}(\boldsymbol{\alpha}(\mathbf{t}))$ are of class C^ω on E_T and have analytic extensions to $E^\rho_{\delta,\boldsymbol{\alpha}}=\{\mathbf{t}\in R^p\,|\,\rho(\alpha_1)|t_1|+\cdots+\rho(\alpha_p)|t_p|<\delta\}$.

THEOREM 2. *The map P has a local realization of class C^ω (after the identity e) if it satisfies condition* (A1)′ *and rank P is finite. If P satisfies also* (A2), *then it has a realization on an interval $[0,\sigma]$, $\sigma>0$. Conversely, if P is given by a C^w realization via* (iii) *with $c=e$, then* (A1)′ *is satisfied and* rank P *is finite.*

Remark 2. This theorem is a generalization of the analytic version of the existence theorem of Fliess [4], [5] (one can prove that our rank is equivalent to the rank used in [4], [5]).

To formulate a uniqueness result, we introduce the following definitions. Let $\mathcal{S}^\tau_{pc}$ denote the set of all $a\in\mathcal{S}_{pc}$ such that $|a|\leqq\tau$. For a map $P:\mathcal{S}_{pc}\to R^r$ define a local rank by

$$\operatorname{rank}_{\mathrm{loc}} P=\inf_{0<\tau\leqq T}\operatorname{rank} P|\mathcal{S}^\tau_{pc}.$$

The maximal value of τ at which the infimum is attained is denoted by τ^*; then $\operatorname{rank}_{\mathrm{loc}} P=\operatorname{rank} P|\mathcal{S}^{\tau^*}_{pc}$.

Any quadruple $\Sigma=(V,f,h,x_0)$ defines a map P_Σ given by

$$P_\Sigma(a)=h\circ\Phi^f_{(t_p,\alpha_p)}\circ\cdots\circ\Phi^f_{(t_1,\alpha_1)}(x_0),$$

for all $a=(t_1,\alpha_1)\cdots(t_p,\alpha_p)\in\mathcal{S}_{pc}$ such that the right-hand side makes sense. Assume

that P_Σ is well defined for all $a \in \mathscr{S}_{pc}^{\delta}$. Then $\operatorname{rank}_{\mathrm{loc}} P_\Sigma$ is well defined, with the infimum taken over $\tau \in [0, \delta]$.

DEFINITION 2. A realization Σ is called *locally minimal* if $\dim \Sigma = \operatorname{rank}_{\mathrm{loc}} P_\Sigma$.

DEFINITION 3. Realizations Σ and $\hat{\Sigma}$ are called *locally diffeomorphic* at points $x_1 \in V$ and $\hat{x}_1 \in \hat{V}$ if there is a local diffeomorphism χ of a neighborhood $U \subset V$ of the point x_1 onto a neighborhood $\hat{U} \subset \hat{V}$ of the point $\hat{x}_1$ such that $\chi(x_1) = \hat{x}_1$ and

$$h(x) = \hat{h} \circ \chi(x), \qquad d\chi(x) f(x, \alpha) = \hat{f}(\chi(x), \alpha), \tag{3}$$

for $x \in U$ and $\alpha \in \Omega$.

THEOREM 3. *Let Σ and $\hat{\Sigma}$ be realizations of class $C^k (k = 1, \cdots, \infty, \omega)$ on an interval $[0, \sigma]$ of a map $P: \mathscr{S}_{pc} \to R^r$ (after the identity e). If Σ and Σ are locally minimal, then they are locally diffeomorphic (of class C^k) at the points $x_1 = \Phi_c^f(x_0)$ and $\hat{x}_1 = \Phi_c^{\hat{f}}(\hat{x}_0)$, where $c \in \mathscr{S}_{pc}$ is any function at which the rank of the map $P|\mathscr{S}_{pc}^{\delta}$ is attained with $\delta = \min\{\sigma, \tau^*\}$.*

Let us formulate an existence result for a general class of functions $\mathscr{U}$. Assume that Ω is a metric space. Let $\mathscr{U}$ be a subfamily of $\mathscr{M}_c([0, T]; \Omega)$ (the space of measurable functions the image of each is contained in a compact subset of Ω a.e.) and contains all piecewise constant functions $\mathscr{U}_{pc} \subset \mathscr{U}$. As before, $\mathscr{S}$ denotes the set of restrictions to the intervals $(0, t)$, $0 \leqq t \leqq T$, of functions in $\mathscr{U}$. For $a = u|_{[0, t)}$ we denote $|a| = t$.

The term "realization on the interval $(0, \sigma]$" means now that (iii) is satisfied for all $a \in \mathscr{S}$ such that $|a| \leqq \sigma$, where $\Phi_a^f(x)$ denotes the point after time $t = |a|$ of the trajectory of system (1) starting from x, with $u = a$.

Additional problems which appear now are to guarantee that the function $f(x, u)$ is continuous with respect to u in order to (1) have a solution and to guarantee that (iii) is satisfied for nonpiecewise constant a. Thus we put the following additional conditions.

(A3) Functions $(\mathbf{t}, \boldsymbol{\alpha}) \to P(\boldsymbol{\alpha}(\mathbf{t}))$ are continuous as maps $E_T \times \Omega^p \to R^r$ together with partial derivatives $(\partial/\partial t_i) P(\boldsymbol{\alpha}(\mathbf{t}))$, $i = 1, \cdots, p$.

(A4) If $|a| = |a_1| = |a_2| = \cdots$, where $a, a_i \in \mathscr{S}$, the images of a and a_i are in a common compact subset of Ω and $a_i \to a$ pointwise on $[0, |a|)$, a.e., then $P(a_i) \to P(a)$.

THEOREM 4. *If the function $P: \mathscr{S} \to R^r$ satisfies assumptions* (A1), (A2), (A3), (A4) *and* rank P *is finite, then there exists a realization Σ of P of class $C^k (k = 1, \cdots, \infty, \omega)$ on an interval $[0, \sigma]$ after any function $c \in \mathscr{S}_{pc}$ at which the rank is attained. Additionally,* $\dim \Sigma = \operatorname{rank} P$ *and the function $f(x, u)$ is bounded, continuous with respect to (x, u) and satisfies the Lipschitz condition with respect to x uniformly on $u \in \Omega$.*

If $k = \omega$ and assumption (A1) *is replaced by* (A1)′, *then we can take $c = e$. If, additionally, Ω is compact then assumption* (A2) *can be replaced by* (A3) *strengthened to second order partial derivatives.*

3. Proofs.

Proof of Theorem 1. Let $c = \boldsymbol{\beta}(\mathbf{s}^*)$, $\mathbf{s}^* = (s_1^*, \cdots, s_m^*)$, $\boldsymbol{\beta} = (\beta_1, \cdots, \beta_m)$ and $\mathbf{b} = (b_1, \cdots, b_q)$ be such that $\operatorname{rank} d\Psi_{\boldsymbol{\beta}}^{\mathbf{b}}(\mathbf{s}^*) = \operatorname{rank} P = n$. Enlarging, possibly, the number of b_i in $\mathbf{b}$ we can assume that one of the b_i is identity e.

There exists a $n \times n$, nonsingular submatrix A of the Jacobian $J = d\Psi_{\boldsymbol{\beta}}^{\mathbf{b}}(\mathbf{s}^*)$. Assume that A consists of the first n rows and the first n columns of J. Define functions $\eta: R^n \to R^m$, $\P: R^\nu \to R^n$, $\nu = rq$, by

$$\eta(\tau_1, \cdots, \tau_n) = (\tau_1, \cdots, \tau_n, s_{n+1}^*, \cdots, s_m^*),$$

$$\P(y_1, \cdots, y_\nu) = (y_1, \cdots, y_n).$$

Then the composition

$$\Psi(\tau) = \P \circ \Psi^{\mathbf{b}}_{\boldsymbol{\beta}} \circ \eta(\tau) \tag{4}$$

has a nonsingular Jacobian at $\tau = \tau^*$ such that $\eta(\tau^*) = \mathbf{s}^*$. Thus, there exists a neighborhood V of τ^* such that Ψ is a diffeomorphism of V onto an open subset U of R^n, rank $d\Psi(\tau) = n$ for $\tau \in \operatorname{cl} V$ and Ψ is a homeomorphism $\Psi: \operatorname{cl} V \to \operatorname{cl} U$. For technical reasons it will be convenient to take V of the form

$$V = (\tau \in R^n \,|\, |\tau - \tau^*| < C\} \subset R^n_+ \tag{5}$$

where $0 < C < \min\{\tau_1^*, \cdots, \tau_n^*\}$ (the further construction can be also carried out for more general V).

If the submatrix A consists of the columns $i_1, \cdots, i_n$ and the rows $j_1, \cdots, j_n$ of J, then one defines η by putting the variables $\tau_1, \cdots, \tau_n$ in place of $s^*_{i_1}, \cdots, s^*_{i_n}$ and $\P$ is the projection onto the coordinates $y_{j_1}, \cdots, y_{j_n}$.

Now we can define our realization $\Sigma = (V, f, h, x_0)$. We take as the state space the set V defined above. Take $x_0 = \tau^* \in V$. We shall denote the state by τ instead of x. Define

$$h(\tau) = \mathbf{P}(\boldsymbol{\beta}(\eta(\tau))), \qquad \tau \in V.$$

From (A1) it follows that h is of class C^k. For $a = (t_1, \alpha_1) \cdots (t_p, \alpha_p) = \boldsymbol{\alpha}(t)$ define

$$\Phi_a(\tau) = \Psi^{-1} \circ \P \circ \Psi^{\mathbf{b}}_{\boldsymbol{\beta}, a} \circ \eta(\tau),$$

where

$$\Psi^{\mathbf{b}}_{\boldsymbol{\beta}, a}(\mathbf{s}) = (\mathbf{P}(\boldsymbol{\beta}(\mathbf{s}) a b_1), \cdots, \mathbf{P}(\boldsymbol{\beta}(\mathbf{s}) a b_q)). \tag{6}$$

Note that $\Psi^{\mathbf{b}}_{\boldsymbol{\beta}, e} = \Psi^{\mathbf{b}}_{\boldsymbol{\beta}, \boldsymbol{\alpha}(0)} = \Psi^{\mathbf{b}}_{\boldsymbol{\beta}}$.

The expression $\Phi_a(\tau) = \Phi_{\boldsymbol{\alpha}(\mathbf{t})}(\tau)$ is well defined for $(\tau, \mathbf{t})$ in a neighborhood W of the set $V \times \{0\} \subset R^n \times R^p_+$, defined by the condition $\P \circ \Psi^{\mathbf{b}}_{\boldsymbol{\beta}, a} \circ \eta(\tau) \subset \Psi(V)$. In particular, $\Phi_{\boldsymbol{\alpha}(0)}$ is the identity on V. The function $(\tau, \mathbf{t}) \to \Phi_{\boldsymbol{\alpha}(t)}(\tau)$ is of class C^k on W since $\Psi^{-1}, \P$ are of class C^k and the function $(\mathbf{t}, \mathbf{s}) \to \Psi^{\mathbf{b}}_{\boldsymbol{\beta}, \boldsymbol{\alpha}(\mathbf{t})}(\mathbf{s})$ is of class C^k (this follows from assumption (A1)).

Assume that we have proved that

$$\Phi_{a'} \circ \Phi_a(\tau) = \Phi_{aa'}(\tau) \tag{7}$$

for $a = \boldsymbol{\alpha}(\mathbf{t})$, $a' = \boldsymbol{\alpha}'(\mathbf{t}')$ and $(\tau, \mathbf{t}, \mathbf{t}')$ in a neighborhood of the set $V \times \{0\} \times \{0\}$ in $R^n \times R^p_+ \times R^{p'}_+$. Then we obtain that

$$\Phi_{(t, \alpha)} \circ \Phi_{(t', \alpha)}(\tau) = \Phi_{(t', \alpha)(t, \alpha)}(\tau) = \Phi_{(t'+t, \alpha)}(\tau)$$

for (τ, t, t') in a neighborhood of the set $V \times \{0\} \times \{0\}$ in $R^n \times R_+ \times R_+$. This together with $\Phi_{(0, \alpha)} = \mathrm{id}_V$ implies that $\Phi_{(t, \alpha)}$ is a local (semi) flow of class C^k. Thus, we can define the corresponding vector field

$$f(\tau, \alpha) = \frac{d}{dt} \Phi_{(t, \alpha)}(\tau)\big|_{t=0^+}, \qquad \tau \in V, \tag{8}$$

which is of class C^{k-1}. This completes the construction of the realization Σ.

From the construction it follows that $\Phi^f_{(t, \alpha)}(\tau) = \Phi_{(t, \alpha)}(\tau)$ for (τ, t) in a neighborhood of the set $V \times \{0\} \subset R^n \times R_+$. This and successive application of (7) gives that

$$\Phi^f_{(t_p, \alpha_p)} \circ \cdots \circ \Phi^f_{(t_1, \alpha_1)}(\tau) = \Phi_{(t_1, \alpha_1) \cdots (t_p, \alpha_p)}(\tau) \tag{9}$$

for $(\tau, \mathbf{t})$ in a neighborhood of the set $V \times \{0\} \subset R^n \times R^p_+$.

To prove that Σ is a local realization of P after the function c and to show (7) we use the following lemma.

LEMMA 1. *For any α, α' there exists a neighborhood N of the set $V\times\{0\}\times\{0\}$ in $R^n\times R_+^p\times R_+^{p'}$ such that for $a=\alpha(\mathbf{t})$, $a'=\alpha'(\mathbf{t}')$ and $(\tau,\mathbf{t},\mathbf{t}')\in N$ we have that*

$$\Psi^{\mathbf{b}}_{\beta,a'}\circ\eta\circ\Phi_a(\tau)=\Psi^{\mathbf{b}}_{\beta,aa'}\circ\eta(\tau), \tag{10}$$

$$\Psi^{\mathbf{b}}_{\beta,a'}\circ\eta\circ\Phi_a(\tau(\mathbf{s}))=\Psi^{\mathbf{b}}_{\beta,aa'}(\mathbf{s}). \tag{10}'$$

To show (7) it is enough to compose both sides of (10) with $\Psi^{-1}\circ\P$ on the left and use the definition of Φ_a.

Taking $\tau=\tau^*$, $a'=e$ in (10) and considering the component of the functions $\Psi^{\mathbf{b}}_{\beta}$ and $\Psi^{\mathbf{b}}_{\beta,a}$ corresponding to $b_i=e$, we obtain from the lemma that

$$\mathbf{P}(\beta(\eta(\Phi_a(\tau^*)))=\mathbf{P}(\beta(\eta(\tau^*))a) \tag{11}$$

i.e. $h\circ\Phi_a(\tau^*)=\mathbf{P}(ca)$ for $a=\alpha(\mathbf{t})$ and $\mathbf{t}$ in a neighborhood of $0\in R_+^p$. This together with (9) means that Σ is a local realization of P after the function c. The realization around c is obtained using equality (10)′ instead of (10). We postpone the proof of the second claim in Theorem 1 after the proof of Lemma 1.

Remark 2. In the above construction we used the lengths of time intervals of the input for the local coordinates of our realization. One can also use components of the output for the local coordinates, taking $\hat{V}=\Psi(V)$, $\hat{x}_0=\Psi(\tau^*)$ and

$$\hat{h}(x)=\mathbf{P}(\beta(\eta(\Psi^{-1}(x)))),$$

$$\hat{\Phi}_a(x)=\P\circ\Psi^{\mathbf{b}}_{\beta,a}\circ\eta\circ\Psi^{-1}(x).$$

Then $\hat{\Sigma}=(\hat{V},\hat{f},\hat{h},\hat{x}_0)$ is also a realization of P after the function c, where $\hat{f}$ is obtained from $\hat{\Phi}_a$ via (8). This construction is, perhaps, more natural when P is given by results of experiments which are points in the output space $Y=R^r$.

Lemma 1 will follow from the following lemma. For $C>0$, $\delta>0$ define the sets

$$W_{C,\delta}=\{(z,x,y)\in R^n\times R_+^p\times R_+^{p'}\,|\,|z-z_0|+\delta|x|+\delta|y|\leqq C\},$$

$$V_{C,\delta}=\{(z,x)\in R^n\times R_+^p\,|\,|z-z_0|+\delta|x|\leqq C\},\qquad V_C=\{z\in R^n\,|\,|z-z_0|\leqq C\}.$$

LEMMA 2. *Let $\varphi\colon W_{C,\delta}\to R^m$ be a function of class C^k, $k=1,2,\cdots,\infty,\omega$. Assume that*

$$\operatorname{rank} d\varphi=\operatorname{rank}\frac{\partial\varphi}{\partial z}=n=\operatorname{rank}\left(\frac{\partial\Psi}{\partial z},\frac{\partial\Psi}{\partial x}\right) \tag{12}$$

on $W_{C,\delta}$, where $\Psi\colon W_{C,\delta}\to R^{2m}$ is the function

$$\Psi(z,x,y)=(\varphi(z,x,0),\ \varphi(z,x,y))$$

and $(\partial\Psi/\partial z,\partial\Psi/\partial x)$ denotes its partial Jacobian with respect to z and x. Then, there exists a constant $0<\lambda\leqq\delta$ and a function $\gamma\colon V_{C,\lambda}\to R^n$ such that the equation

$$\varphi(\tilde{z},0,y)=\varphi(z,x,y) \tag{13}$$

has the solution $\tilde{z}=\gamma(z,x)$ for all $(z,x,y)\in W_{C,\lambda}$. If the function $z\to\varphi(z,0,0)$ is injective on V_C, then the function γ is unique and of class C^k.

Additionally, if each component φ_i, $i=1,\cdots,m$, of φ satisfies the Lipschitz condition on $W_{C,\delta}$

$$|\varphi_i(z,x,y)-\varphi_i(z',x',y')|\leqq L(|z-z'|+|x-x'|+|y-y'|) \tag{14}$$

and the same condition is satisfied for the partial derivatives $(\partial/\partial z_j)\varphi_i(z, x, y)$, $j = 1, \cdots, n$, *with constant* M, *then* λ *can be taken*

$$\lambda = \max\left\{\delta, (\Delta_{\min})^{-1}(n!)^2 L^{2n}\binom{m}{n} n(1+2CML^{-1})\right\}, \tag{15}$$

where $\Delta_{\min}$ *is the infimum of the sum of squares of all* n*-minors of* $(\partial/\partial z)\varphi(z, 0, 0)$ *over* $z \in V_C$.

The same result holds for the spaces R^p_+, $R^{p'}_+$ *replaced by* R^p *and* $R^{p'}$. *The lemma also holds if the condition* $\operatorname{rank} \partial\varphi/\partial z = n$ *is satisfied on* $W_{C,\delta} \cap \{(z, x, y) | x = 0, y = 0\}$ *only.*

Proof. Let $I = (i_1, \cdots, i_n)$ be any sequence of numbers $1 \leqq i_1 < \cdots < i_n \leqq m$. Denote all such sequences by $I_1, \cdots, I_\mu$, $\mu = \binom{m}{n}$. Define a function $\varphi_I : W_{C,\delta} \to R^n$,

$$\varphi_I(z, x, y) = \varphi_I(z, x) = (\varphi_{i_1}(z, x, 0), \cdots, \varphi_{i_n}(z, x, 0)). \tag{16}$$

Let $V_i \subset W_{C,\delta}$ be the set of points on which the function $\Delta_i = \det(\partial/\partial z)\varphi_{I_i}$ is different from zero. From the last equality of (12) and the definition of Ψ it follows that, on V_i,

$$\frac{\partial\Psi}{\partial z}\left(\frac{\partial}{\partial z}\varphi_{I_i}\right)^{-1}\frac{\partial}{\partial x}\varphi_{I_i} - \frac{\partial\Psi}{\partial x} = 0, \qquad i = 1, \cdots, \mu. \tag{17}$$

The second equality in (12) gives that the function $\Delta = \Delta_1^2 + \cdots + \Delta_\mu^2$ is nonzero on $W_{C,\delta}$. Define $\tilde{\Delta}_i = \Delta_i^2\Delta^{-1}$. Then we have that $\tilde{\Delta}_1 + \cdots + \tilde{\Delta}_\mu = 1$. Note that $\tilde{\Delta}_i((\partial/\partial z)\varphi_{I_i})^{-1}$ is well defined and of class C^k on $W_{C,\delta}$. Multiplying equations (17) by $\tilde{\Delta}_i$ and summing them up over i, we obtain that

$$\frac{\partial\Psi}{\partial z}A - \frac{\partial\Psi}{\partial x} = 0,$$

on $W_{C,\delta}$, where A is the matrix

$$A = \{A_{ij}\} = \sum_{r=1}^{\mu}\tilde{\Delta}_r\left(\frac{\partial}{\partial z}\varphi_{I_r}\right)^{-1}\frac{\partial}{\partial x}\varphi_{I_r}.$$

In particular, we have that

$$\sum_{i=1}^{n}\frac{\partial\Psi}{\partial z_i}A_{ij} - \frac{\partial\Psi}{\partial x_j} = 0, \qquad j = 1, \cdots, p.$$

This means that the function Ψ is constant along trajectories of the vector fields

$$g_j = \sum_{i=1}^{n} A_{ij}\frac{\partial}{\partial z_i} - \frac{\partial}{\partial x_j}, \qquad j = 1, \cdots, p.$$

which are of class C^{k-1} on $W_{C,\delta}$. Denote the local flow of g_j by Φ^j_t. Denote

$$D_j = \sup_{V_{C,\delta}}(|A_{1j}| + \cdots + |A_{nj}|), \qquad D = \max\{D_1, \cdots, D_p\}, \tag{18}$$

where the supremum over $V_{C,\delta}$ equals the supremum over $W_{C,\delta}$ since the functions φ_I given by (16) do not depend on y. Take $\lambda = \max\{D, \delta\}$. The vector fields g_j point in the set $W_{C,\lambda}$ (or are tangent to the boundary) at the boundary points (z, x, y) such that $|z - z_0| + \lambda|x| + \lambda|y| = C$ and $x_i \neq 0 \neq y_i$. Thus the trajectory $\Phi^j_t(z, x, y)$ of g_j starting in $W_{C,\delta}$ does not leave $W_{C,\lambda}$ until $t = x_j$. Combining p trajectories, we obtain, by the form of g_j, that

$$\Phi^p_{x_p} \circ \cdots \circ \Phi^1_{x_1}(z, x, y) = (\tilde{z}, 0, y) \tag{19}$$

where $(\tilde{z}, 0, y) \in W_{C,\lambda}$. So defined $\tilde{z}$ gives the solution $\tilde{z} = \tilde{\gamma}(z, x, y)$ of (13) for $(z, x, y) \in W_{C,\lambda}$ since the function Ψ is constant along the trajectories of g_j and in particular, $\Psi(\tilde{z}, 0, y) = \Psi(z, x, y)$. The function $\tilde{\gamma}$ is independent of y as the vector fields g_j do not depend on y.

The function $\gamma(z, x) = \tilde{\gamma}(z, x, 0)$ gives the desired solution. If the function $z \to \varphi(z, 0, 0)$ is injective, then the solution of $\varphi(\tilde{z}, 0, 0) = \varphi(z, x, 0)$ determines the function $\gamma(z, x)$ uniquely and assures that it is of class C^1 because, locally, $\gamma(z, x) = \Lambda_I^{-1} \circ \varphi_I(z, x, 0)$, where $\Lambda_I(z) = \varphi_I(z, 0, 0)$.

To prove the last part of the lemma, it is enough to majorize the constant D in (18) using constants L and M. The constant D defined as a supremum (18) over $V_{C,\lambda}$ (instead of $V_{C,\delta}$) is also good and we shall majorize such D computing at the same time λ. We have that

$$D \leqq n \max_{i,j} \sup_{V_{C,\lambda}} |A_{ij}| \tag{20}$$

and $\lambda = \max\{D, \delta\}$. From the definition of A it follows that

$$A = \Delta^{-1} \sum_{r=1}^{\mu} \Delta_r \left(\frac{\partial}{\partial z} \varphi_{I_r}\right)^* \frac{\partial}{\partial x} \varphi_{I_r},$$

where by B^* we denote the adjoint matrix of B (it consists of $(n-1)$-minors of B^T). From inequality (14) it follows that $|(\partial/\partial z_j)\varphi_i| \leqq L$ and $(\partial/\partial x_j)\varphi_i| \leqq L$, on $V_{C,\lambda}$. Therefore, from the definition of determinant it follows that $|\Delta_r| \leqq n! L^n$. Thus, we obtain easily that

$$|A_{ij}| \leqq \mu \Delta^{-1} n! L^n n(n-1)! L^{n-1} L = \mu (n!)^2 L^{2n} \Delta^{-1}. \tag{21}$$

To majorize Δ^{-1}, we shall compute the Lipschitz constant for $\Delta = \Delta_1^2 + \cdots + \Delta_\mu^2$. Note that nKN^{n-1} is the Lipschitz constant for the product $f_1 f_2 \cdots f_n$, if K is the Lipschitz constant for $f_1, \cdots, f_n$ and $N = \max_i \sup |f_i|$. Thus the definition of determinant and $|(\partial/\partial z_j)\varphi_i| \leqq L$ gives that the Lipschitz constant for Δ_r can be taken $n! nML^{n-1}$. Therefore, the Lipschitz constant for Δ is

$$L_\Delta = \mu 2n! nML^{n-1} n! L^N = 2\mu n (n!)^2 ML^{2n-1}.$$

Now we can majorize Δ^{-1} over $V_{C,\lambda}$ for $\lambda > \Delta_{\min}^{-1} L_\Delta C$

$$\sup_{V_{C,\lambda}} \Delta^{-1} = \left(\inf_{V_{C,\lambda}} \Delta\right)^{-1} \leqq \left(\inf_{V_C} \Delta - L_\Delta C \lambda^{-1}\right)^{-1} = (\Delta_{\min} - L_\Delta C \lambda^{-1})^{-1}. \tag{22}$$

Taking into account (20), (21) and (22), we obtain that

$$D \leqq n\mu (n!)^2 L^{2n} (\Delta_{\min} - C\lambda^{-1} 2\mu n (n!)^2 ML^{2n-1})^{-1}.$$

If we put $\lambda = D$, we obtain

$$D \leqq \Delta_{\min}^{-1} (n!)^2 L^{2n} \binom{m}{n} n(1 + 2CML^{-1}).$$

This means that λ given by (15) satisfies the assertions of the lemma.

The proof in case of R_+^p, $R_+^{p'}$ replaced by R^p, $R^{p'}$ is analogous.

If the condition $\operatorname{rank} \partial\varphi/\partial z = n$ is satisfied on $W_{C,\delta} \cap \{(z, x, y) | x = 0, y = 0\}$ only, then Δ is positive on this set. From its compactness it follows that Δ is also positive on a set $W_{C,\delta'}$ with a $\delta' \geqq \delta$. Thus (12) is satisfied on $W_{C,\delta'}$. In the Lipschitzian case it is enough to take any $\delta' \geqq \delta$ such that $\delta' > \Delta_{\min}^{-1} CL_\Delta$.

Proof of Lemma 1. Consider the function

$$\varphi(\tau, \mathbf{t}, \mathbf{t}') = \Psi^{\mathbf{b}}_{\beta, \alpha(\mathbf{t})\alpha'(\mathbf{t}')} \circ \eta(\tau). \tag{23}$$

We shall see that φ satisfies the assumptions of Lemma 1 with $z=\boldsymbol{\tau}$, $x=\mathbf{t}$, $y=\mathbf{t}'$ and $z_0=\boldsymbol{\tau}^*$. In fact, φ is well defined on the set $W_{C,\delta}$, where C is taken as in the definition (5) of the set V and $\delta=1$. Since $\varphi(\boldsymbol{\tau},0,0)=\Psi^{\mathbf{b}}_{\boldsymbol{\beta}}\circ\eta(\boldsymbol{\tau})$, then it follows from the choice of V that $\operatorname{rank}\partial\varphi/\partial\boldsymbol{\tau}(\boldsymbol{\tau},\mathbf{t},\mathbf{t}')=n$ for $\boldsymbol{\tau}\in\operatorname{cl}V$, $\mathbf{t}=0$, $\mathbf{t}'=0$ and so for $(\boldsymbol{\tau},\mathbf{t},\mathbf{t}')\in W_{C,\delta}$ with some $\delta\geqq 1$.

From condition (A1) it follows that φ is of class C^k.

We have that $\operatorname{rank}\partial\varphi/\partial\boldsymbol{\tau}\leqq\operatorname{rank}d\varphi\leqq\operatorname{rank}P$ and $\operatorname{rank}\partial\varphi/\partial\boldsymbol{\tau}\leqq\operatorname{rank}(\partial\Psi/\partial\boldsymbol{\tau},\partial\Psi/\partial\mathbf{t})\leqq\operatorname{rank}P$, where Ψ is defined as in Lemma 2. The last inequality above follows from the definition of rank P and the equality

$$\Psi(\boldsymbol{\tau},\mathbf{t},\mathbf{t}')=\Psi^{\mathbf{bb}'}_{\boldsymbol{\beta}\boldsymbol{\alpha}}(\eta(\boldsymbol{\tau}),\mathbf{t}),$$

where $\mathbf{bb}'=(b_1,\cdots,b_q,a'b_1,\cdots,a'b_q)$, $a'=\boldsymbol{\alpha}'(\mathbf{t}')$ and $\boldsymbol{\beta}\boldsymbol{\alpha}=(\beta_1,\cdots,\beta_m,\alpha_1,\cdots,\alpha_p)$. The above inequalities together with $\operatorname{rank}\partial\varphi/\partial\boldsymbol{\tau}=\operatorname{rank}P$ on $W_{C,\delta}$ imply that φ satisfies condition (12) in Lemma 2.

From Lemma 2 we deduce that there exists a unique function $\gamma(\boldsymbol{\tau},\mathbf{t})$ such that

$$\Psi^{\mathbf{b}}_{\boldsymbol{\beta},\boldsymbol{\alpha}'(\mathbf{t}')}\circ\eta(\gamma(\boldsymbol{\tau},\mathbf{t}))=\Psi^{\mathbf{b}}_{\boldsymbol{\beta},\boldsymbol{\alpha}(\mathbf{t})\boldsymbol{\alpha}'(\mathbf{t}')}\circ\eta(\boldsymbol{\tau}) \tag{24}$$

for $(\boldsymbol{\tau},\mathbf{t},\mathbf{t}')$ in a neighborhood of the set $U\times\{0\}\times\{0\}$ in $R^n\times R^p_+\times R^{p'}_+$. Taking $\mathbf{t}'=0$, we obtain a simpler equality

$$\Psi^{\mathbf{b}}_{\boldsymbol{\beta}}\circ\eta(\gamma(\boldsymbol{\tau},\mathbf{t}))=\Psi^{\mathbf{b}}_{\boldsymbol{\beta},a}\circ\eta(\boldsymbol{\tau}),\qquad a=\boldsymbol{\alpha}(\mathbf{t}). \tag{25}$$

Composing both sides with $\Psi^{-1}\circ\P$ on the left and taking into account the definitions of Ψ and Φ_a, we find that

$$\gamma(\boldsymbol{\tau},\mathbf{t})=\Phi_a(\boldsymbol{\tau})$$

and so formula (10) is proved.

The proof of formula (10)′ is analogous, except that we take the function φ of the form

$$\varphi(\boldsymbol{\tau},\boldsymbol{\tau}',\mathbf{t},\mathbf{t}')=\Psi^{\mathbf{b}}_{\boldsymbol{\beta},\boldsymbol{\alpha}(\mathbf{t})\boldsymbol{\alpha}'(\mathbf{t}')}(\boldsymbol{\tau},\boldsymbol{\tau}'+s'^*),$$

where $\boldsymbol{\tau}'=\mathbf{s}'-\mathbf{s}'^*$ and $z=\boldsymbol{\tau}$, $x=(\boldsymbol{\tau}',\mathbf{t})$, $y=\mathbf{t}'$, $z_0=\boldsymbol{\tau}^*$, where $\mathbf{s}'$ denotes the $m-n$ variables in $\mathbf{s}$ complementary to $\boldsymbol{\tau}$ (see the definition of the function η at the beginning of the proof of Theorem 1). Then instead of equality (25) we obtain

$$\Psi^{\mathbf{b}}_{\boldsymbol{\beta}}\circ\eta(\gamma(\boldsymbol{\tau},\boldsymbol{\tau}',\mathbf{t}))=\Psi^{\mathbf{b}}_{\boldsymbol{\beta},a}(\boldsymbol{\tau},\boldsymbol{\tau}'+\mathbf{s}'^*),\qquad a=\boldsymbol{\alpha}(\mathbf{t}),$$

and so

$$\begin{aligned}\gamma(\boldsymbol{\tau},\boldsymbol{\tau}',\mathbf{t})&=\Psi^{-1}\circ\pi\circ\Psi^{\mathbf{b}}_{\boldsymbol{\beta},a}(\boldsymbol{\tau},\boldsymbol{\tau}'+\mathbf{s}'^*)\\&=\Psi^{-1}\circ\pi\circ\Psi^{\mathbf{b}}_{\boldsymbol{\beta},a}(\boldsymbol{\tau}(\mathbf{s}),\mathbf{s}'^*)\\&=\Phi_a(\boldsymbol{\tau}(\mathbf{s})),\qquad \mathbf{s}=(\boldsymbol{\tau},\boldsymbol{\tau}'+\mathbf{s}'^*).\end{aligned}$$

Here the implicit function $\boldsymbol{\tau}(\mathbf{s})$ exists since the function $\Psi^{-1}\circ\pi\circ\Psi^{\mathbf{b}}_{\boldsymbol{\beta},a}$ is regular (of full rank) with respect to the first argument. The proof of Lemma 1 is complete.

Now we shall prove the second claim in Theorem 1. Condition (A2) implies that the function φ in (23) satisfies the Lipschitz condition with constant L and the partial derivatives $\partial\varphi/\partial\tau_i$ satisfy this condition with constant M. Therefore, we can apply formula (15) in Lemma 2 to deduce that λ does not depend on the sequences $\boldsymbol{\alpha}$ and $\boldsymbol{\alpha}'$ in (23). Therefore, equality (10) in Lemma 1 holds for $(\boldsymbol{\tau},\mathbf{t},\mathbf{t}')$ in $W_{C,\lambda}$, in particular, for $(\boldsymbol{\tau}^*,\mathbf{t},\mathbf{t}')$ such that $|\mathbf{t}|+|\mathbf{t}|'\leqq C\lambda^{-1}=\sigma$ where C is taken as in (5). This implies that (7) holds for such $\mathbf{t},\mathbf{t}'$ with $\mathbf{a}=\boldsymbol{\alpha}(\mathbf{t})$, $a'=\boldsymbol{\alpha}'(\mathbf{t}')$ and $\boldsymbol{\tau}=\boldsymbol{\tau}^*$. A successive application of

(7) together with $\Phi^f_{(t,\alpha)} = \Phi_{(t,\alpha)}$ give (9) with $t_1 + \cdots + t_p \leqq \sigma$ and $\tau = \tau^*$. We have also that (11) holds for $|a| \leqq \sigma = C\lambda^{-1}$, so we obtain that the realization Σ constructed in the course of proving Theorem 1 is a realization of P on the interval $[0, \sigma]$, where $\sigma = C\lambda^{-1}$. If we take into account that $\varphi(\tau, 0, 0) = \Psi^b_\beta \circ \eta(\tau)$, then formula (15) gives the following formula for σ

$$\sigma = \min\{C, \sigma_1\}$$

where

$$\sigma_1 = \Delta_{min}(n(n!)^2\binom{m}{n}L^{2n})^{-1}(C^{-1} + 2ML^{-1})^{-1}, \qquad n = \operatorname{rank} P,$$

where $\Delta_{\min}$ is the infimum over cl V of the sum of squares of all the n-minors of the Jacobian matrix $d(\Psi^b_\beta \circ \eta)$.

Condition (A2) and the definition of Φ_a imply also that the map $\Phi_{(t,\alpha)}(\tau)$ satisfies the Lipschitz condition with respect to t with a constant independent of α and $\tau \in V$ (note that Ψ^{-1} and $\P$ are Lipschitzian with the constants $L_1 = \sup_{x \in \operatorname{cl} V} \|(d\Psi(x))^{-1}\|$ and $L_2 = 1$). Thus, definition (8) of $f(\tau, \alpha)$ gives that f is bounded by the constant qLL_1. The Lipschitz property of f can be proved analogously. The proof of Theorem 1 is complete.

Remark 3. In the proof of Theorem 1 we did not use any other property of the expression Φ_a besides the properties following from Lemma 1. Therefore, (10) can be used for the definition of Φ_a. Also, due to Lemma 2 and the proof of Lemma 1, the following simpler equation

$$\Psi^b_\beta \circ \eta(\Phi_a(\tau)) = \Psi^b_{\beta,a} \circ \eta(\tau)$$

determines uniquely $\Phi_a(\tau)$. The definition of Φ_a by the above equation gives, in general, a bigger domain V for our realization. Namely, here τ should be in a set V on which the map $\Psi^b_\beta \circ \eta$ is injective (to have uniqueness), while previously we required that there exists a projection $\P$ such that $\P \circ \Psi^b_\beta \circ \eta$ is a diffeomorphism on V.

Proof of Theorem 2. *Necessity.* Let (V, f, h, x_0) be a realization of P of class C^ω and dimension n. Let $\sigma > 0$ be a constant such that V contains the closed ball B of radius σ and the center at x_0. Define

$$\rho(\alpha) = \sup_{x \in B} \|f(x, \alpha)\|,$$

where $\|\cdot\|$ is the Euclidean norm in R^n. Then the solution of the equation

$$\dot{x} = f(x, a), \qquad x(0) = x_0$$

is well defined and stays in B for $t \leqq |a|$, for any $a = (t_1, \alpha_1) \cdots (t_p, \alpha_p)$ such that

$$|a|_\rho = \rho(\alpha_1)|t_1| + \cdots + \rho(\alpha_p)|t_p| < \sigma.$$

Moreover, $\Phi^f_a(x_0) \in B$ for such a and $h \circ \Phi^f_a(x_0) = h \circ \Phi^f_{(t_p,\alpha_p)} \circ \cdots \circ \Phi^f_{(t_1,\alpha_1)}(x_0)$ is analytic with respect to $(t_1, \cdots, t_p)$. Thus condition (A1)′ is satisfied.

Define functions Ψ_α and Ψ^b by $\Psi_\alpha(\mathbf{t}) = \Phi^f_{\alpha(\mathbf{t})}(x_0)$, $\Psi^b(x) = (h \circ \Phi^f_{b_1}(x), \cdots, h \circ \Phi^f_{b_q}(x))$. One can easily see that $\Psi^b_\alpha(\mathbf{t}) = \Psi^b \circ \Psi_\alpha$. Thus, $\operatorname{rank} d\Psi^b_\alpha(\mathbf{t}) \leqq \operatorname{rank} d\Psi_\alpha(\mathbf{t}) \leqq n$ and we conclude that rank P is finite.

Sufficiency. If (A1)′ is satisfied, then the expressions

$$P((t_1, \alpha_1) \cdots (t_p, \alpha_p)) \tag{26}$$

are well defined for $\mathbf{t} = (t_1, \cdots, t_p) \in E^\rho_{\sigma,\alpha}$. Now the argument $(t_1, \alpha_1) \cdots (t_p, \alpha_p) = \boldsymbol{\alpha}(\mathbf{t})$ is not treated as a function but as a finite sequence with values in $R \times \Omega$. We multiply

such sequences by concatenation. Before constructing the realization we note that

$$(27)\qquad P(a'(t_1, \alpha_1)\cdots(t_p, \alpha_p)(-t_p, \alpha_p)\cdots(-t_p, \alpha_p)\cdots(-t_1, \alpha_1)a'') = P(a'a'')$$

where $a' = \boldsymbol{\alpha}'(\mathbf{t}')$, $a'' = \boldsymbol{\alpha}''(\mathbf{t}'')$, and $\mathbf{t}' \in R^{p'}$, $\mathbf{t}'' \in R^{p''}$, $\mathbf{t} = (t_1, \cdots, t_p)$ are such that $2|\boldsymbol{\alpha}(\mathbf{t})|_\rho + |a'|_\rho + |a''|_\rho < \delta$. For $p = 1$ this follows from the following equalities, by taking $\hat{t}_1 = -t_1$ in the first one,

$$P(a'(t_1, \alpha_1)(\hat{t}_1, \alpha_1)a'') = P(a'(t_1 + \hat{t}_1, \alpha_1)a''),$$

$$P(a'(0, \alpha)a'') = P(a'a'').$$

Each of these equalities is true for $\mathbf{t}' \in R_+^{p'}$, $\mathbf{t}'' \in R_+^{p''}$ and $t_1, \hat{t}_1 \geqq 0$ since both arguments represent the same functions. They extend to all $\mathbf{t}'$, $\mathbf{t}''$, t_1, $\hat{t}_1$ by the analyticity. The proof of (27) for general p follows by induction with respect to p.

The extension of the domain of the expressions (26) gives that the functions $\Psi_\alpha^{\mathbf{b}}$ are well defined on the sets $E_{\lambda,\alpha}^\rho \subset R^p$, $\lambda = \delta - \max\{|b_1|_\rho, \cdots, |b_q|_\rho\}$, where b_i are finite sequences with values in $R \times \Omega$ such that $|b_i|_\rho < \delta$. The function $\Psi_{\beta,a}^{\mathbf{b}}(\mathbf{s})$ given by (6) is well defined for $a = \boldsymbol{\alpha}(\mathbf{t})$ and $\mathbf{s} \in R^m$, $\mathbf{t} \in R^p$ such that $|a|_\rho + |\boldsymbol{\beta}(\mathbf{s})|_\rho \leqq \delta - \max\{|b_1|_\rho, \cdots, |b_q|_\rho\}$. Thus, the whole construction in the proof of Theorem 1 can be carried out with replacing R_+ by R, and replacing the positive cones by the whole spaces.

Let rank $d\Psi_\beta^{\mathbf{b}}(s^*) = \text{rank } P$, $\boldsymbol{\beta} = (\beta_1, \cdots, \beta_m)$. From the analyticity of the function $\Psi_\beta^{\mathbf{b}}$ it follows that this equality is satisfied for $\mathbf{s}^* \in R_+^m$ arbitrarily close to 0, in particular, we can assume that $|\boldsymbol{\beta}(\mathbf{s}^*)|_\rho < \frac{1}{3}\lambda$. Take the sequences $\boldsymbol{\beta}' = (\beta_1, \cdots, \beta_m, \beta_m, \cdots, \beta_1)$ and $\mathbf{b}' = (cb_1, \cdots, cb_q)$, where $c = (s_1^*, \beta_1)\cdots(s_m^*, \beta_m)$. Consider the function $\Psi_{\beta'}^{\mathbf{b}'} = \Psi_{\beta'}^{\mathbf{b}'}(\mathbf{s}, \hat{\mathbf{s}})$. From (27) and the definition of the function $\Psi_{\beta'}^{\mathbf{b}'}$ it follows that

$$\Psi_{\beta'}^{\mathbf{b}'}(\mathbf{s}, \hat{\mathbf{s}}^*) = \Psi_\beta^{\mathbf{b}}(\mathbf{s}),$$

where $\hat{\mathbf{s}}^* = (-s_m^*, \cdots, -s_1^*)$. Therefore,

$$\text{rank } d\Psi_{\beta'}^{\mathbf{b}'}(\mathbf{s}^*, \hat{\mathbf{s}}^*) = \text{rank } d\Psi_\beta^{\mathbf{b}}(\mathbf{s}^*) = \text{rank } P.$$

Now we can construct our realization Σ as in the proof of Theorem 1, starting with the function $\Psi_{\beta'}^{\mathbf{b}'}$ instead of $\Psi_\beta^{\mathbf{b}}$ and taking the sequence

$$c' = (s_1^*, \beta_1)\cdots(s_m^*, \beta_m)(-s_m^*, \beta_m)\cdots(-s_1^*, \beta_1)$$

instead of $c = (s_1^*, \beta_1)\cdots(s_m^*, \beta_m)$. From the form of c' and property (27) it follows that $P(c'a) = P(a)$, so such realization Σ is a realization after the identity e. The proof is complete.

Remark 4. From the analyticity it follows that condition (iii) is satisfied for $a = \boldsymbol{\alpha}(\mathbf{t})$ for all $\mathbf{t} \in R^p$ such that $P(a)$ and $\Phi_a^f(x_0)$ are well defined.

Proof of Theorem 3. Consider the map $P_\sigma = P|_{\mathscr{S}_{pc}^\sigma}$ and restrict all further considerations to the domain $\mathscr{S}_{pc}^\sigma$. Let $c = \boldsymbol{\beta}(s^*)$ and $\mathbf{b}$ be such that $|c| + |b_i| \leqq \sigma$ and rank $d\Psi_\beta^{\mathbf{b}}(\mathbf{s}^*) = \text{rank } P_\sigma$. Define functions η and $\P$ as at the beginning of the proof of Theorem 1. Then the function

$$\Psi = \P \circ \Psi_\beta^{\mathbf{b}} \circ \eta$$

is a local diffeomorphism defined on a neighborhood of the point $\boldsymbol{\tau}^* \in R^n$, where $\eta(\boldsymbol{\tau}^*) = \mathbf{s}^*$ and $n = \text{rank } P_\sigma = \text{rank}_{\text{loc}} P$. Define functions Ψ_β and $\Psi^{\mathbf{b}}$ by

$$\Psi_\beta(\mathbf{s}) = \Phi_{\beta(\mathbf{s})}^f(x_0), \qquad \Psi^{\mathbf{b}}(x) = (h \circ \Phi_{b_1}^f(x), \cdots, h \circ \Phi_{b_q}^f(x))$$

and, analogously, functions $\hat{\Psi}_\beta$ and $\hat{\Psi}^{\mathbf{b}}$ corresponding to the second realization $\hat{\Sigma}$.

Then $\Psi_{\beta}(\mathbf{s}^*) = x_1 = \Phi_c^f(x_0)$, $\hat{\Psi}_{\beta}(\mathbf{s}^*) = \hat{x}_1 = \Phi_c^{\hat{f}}(\hat{x}_0)$ and we have that

$$\Psi^{\mathbf{b}} \circ \Psi_{\beta}(\mathbf{s}) = \Psi_{\beta}^{\mathbf{b}}(\mathbf{s}) = \hat{\Psi}^{\mathbf{b}} \circ \hat{\Psi}_{\beta}(\mathbf{s}),$$

and so

$$\P \circ \Psi^{\mathbf{b}} \circ \Psi_{\beta} \circ \eta(\tau) = \Psi(\tau) = \P \circ \hat{\Psi}^{\mathbf{b}} \circ \hat{\Psi}_{\beta} \circ \eta(\tau)$$

for τ in a neighborhood of $\tau^* \in R^n$. From the minimality of $\sum$ it follows that $\dim \sum = n$, i.e. the maps $\Psi_{\beta} \circ \eta$ and $\P \circ \Psi^{\mathbf{b}}$ are "into R^n" and "from a subset of R^n". Since their composition Ψ is a local diffeomorphism of R^n, they are local diffeomorphisms too. Define the local diffeomorphism

$$\chi = \hat{\Psi}_{\beta} \circ \eta \circ (\Psi_{\beta} \circ \eta)^{-1} = (\P \circ \hat{\Psi}^{\mathbf{b}})^{-1} \circ \P \circ \Psi^{\mathbf{b}}.$$

Then we have that $\chi(x_1) = \hat{x}_1$. From the definition of functions $\Psi^{\mathbf{b}}$, Ψ_{β}, $\hat{\Psi}^{\mathbf{b}}$, $\hat{\Psi}_{\beta}$ and definition (6) of $\Psi_{\beta,a}^{\mathbf{b}}$ it follows that

$$\P \circ \Psi^{\mathbf{b}} \circ \Phi_a^f \circ \Psi_{\beta} \circ \eta = \P \circ \Psi_{\beta,a}^{b} \circ \eta = \P \circ \hat{\Psi}^{\mathbf{b}} \circ \Phi_a^{\hat{f}} \circ \hat{\Psi}_{\beta} \circ \eta$$

locally around τ^*, for $a = \alpha(\mathbf{t})$ with $\mathbf{t}$ sufficiently small. Composing the above expressions with $(\P \circ \hat{\Psi}^{\mathbf{b}})^{-1}$ on the left and $(\Psi_{\beta} \circ \eta)^{-1}$ on the right, we obtain

$$\chi \circ \Phi_a^f = \Phi_a^{\hat{f}} \circ \chi.$$

Putting $a = (t, \alpha)$ and taking the derivative of both sides with respect to t at $t = 0$ gives the second equality in (3).

We have also that

$$h \circ \Psi_{\beta} \circ \eta(\tau) = P(\beta(\eta(\tau))) = \hat{h} \circ \hat{\Psi}_{\beta} \circ \eta(\tau)$$

for τ in a neighborhood of τ^*. Composing both sides with $(\Psi_{\beta} \circ \eta)^{-1}$ on the right gives that $h = \hat{h} \circ \chi$ in a neighborhood of x_1. The proof is complete.

Proof of Theorem 4. Assumptions (A1), (A2) and Theorem 1 imply that there exists a realization Σ of class C^k of the map $P|_{\mathscr{S}_{pc}}$ after a function c, on an interval $[0, \delta]$. From the definition of Φ_a in the proof of Theorem 1 and from (A3) it follows that the function $\Phi_{(t,\alpha)}(\tau)$ is continuous with respect to (τ, t, α) together with the partial derivative with respect to t. This and definition (8) of $f(\tau, \alpha)$ imply that f is continuous with respect to (τ, α).

Condition (A2) implies, additionally, that $f(\tau, \alpha)$ is bounded and Lipschitzian with respect to τ. To see the latter, it is enough to use the definitions of Φ_a and $f(\tau, \alpha)$ and to note that the maps Ψ^{-1}, $\P$ and η are Lipschitzian together with the first derivatives.

From the continuity and the Lipschitz property of f it follows that, if functions a_i, a have values in a compact subset of Ω and $a_i \to a$ pointwise almost everywhere, then $\Phi_{a_i}^f(\tau) \to \Phi_a^f(\tau)$ provided all the terms are well defined. Let $a \in \mathscr{S}$ be any function such that $|a| \leqq \delta$. There exists a sequence of functions $a_i \in \mathscr{S}_{pc}$, $|a_i| = |a|$ such that $a_i \to a$ pointwise. From the fact that Σ is a realization of $P|_{\mathscr{S}_{pc}}$, the continuity property mentioned above and condition (A4) it follows that $P(ca) = h \circ \Phi_a^f(\tau^*)$. Thus Σ is a realization of P after the function c, on the internal $[0, \delta]$.

The proof of the second claim in Theorem 4 is analogous to the proof of Theorem 2. If condition (A3) is strengthened to the second order partial derivatives, then $f(\tau, \alpha)$ is continuous together with the first order partial derivatives with respect to τ. This and the compactness of Ω implies the Lipschitz property of f.

THE VALUE FUNCTION IN OPTIMAL CONTROL: SENSITIVITY, CONTROLLABILITY, AND TIME-OPTIMALITY*

FRANK H. CLARKE† AND PHILIP D. LOEWEN†

Abstract. We consider a general optimal control problem in which the constraints depend on a parameter α, and the resulting value function $V(\alpha)$. A formula for the generalized gradient of V is proven and then used to obtain results on stability and controllability of the problem. A special study is made of the time-optimal control problem, one consequence of which is a new criterion assuring local null-controllability of the system and continuity of the minimal time function at the origin.

Key words. sensitivity analysis, perturbation, generalized gradients, time-optimality, controllability

1. Introduction. The value function plays a central role in optimization. To illustrate this, let us consider a standard problem $\mathrm{P}(\alpha)$ in optimal control theory, indexed by a parameter α as follows:

$$\mathrm{P}(\alpha)\qquad \begin{aligned} &\text{minimize} && \int_0^1 L(x(t), u(t), \alpha)\, dt \\ &\text{subject to} && \dot{x}(t) = \varphi(x(t), u(t), \alpha), \\ & && u(t) \in U(\alpha), \\ & && x(0) \in C_0(\alpha), \quad x(1) \in C_1(\alpha). \end{aligned}$$

The minimum in the problem $\mathrm{P}(\alpha)$ defines $V(\alpha)$. The first role of V is evident: it measures the sensitivity of the problem (more precisely, of the problem's optimal outcome) to perturbations of the objective function and the various constraints. Knowledge of how V behaves is therefore useful in problems of design or error analysis. Particularly interesting is the derivative of V, a measure of what has been called "differential stability." In the quest for differential properties of V, however, we must face the fact that not only will V not generally be differentiable, it can easily fail to be continuous or even everywhere finite. (By the usual convention, the minimum over the empty set is $+\infty$, so that $V(\alpha) = +\infty$ whenever $\mathrm{P}(\alpha)$ admits no feasible (x, u).) The very fact that V is finite near a given α is in many cases a coveted conclusion, implying as it does a type of local controllability of the constraints.

In studying differential properties of V then, whether for sensitivity analysis, or to explain results such as the maximum principle geometrically, or in connection with the well-known role that V plays in verification techniques (i.e., the Hamilton-Jacobi equation as a sufficient condition, see [4, § 3.7]), or in constructing feedback laws (as in dynamic programming), one must consider derivatives in other than the classical sense.

Following a seminal paper by Gauvin [6], a great deal of progress has recently been made in studying the value function V of a perturbed mathematical programming problem based on its generalized gradient ∂V. (See [2], [4, § 6.5], [7], and especially Rockafellar [20], in which the issue is surveyed.) In [4, § 3.4], Clarke obtains a formula for ∂V for a general fixed-time control problem, subject however only to additive

perturbations of the endpoint constraints. See [1], [3], [5], [13], [15], [18], [19] for results related to stability of control problems.

Our first purpose in this article is to obtain a formula for the generalized gradient of the value function of a general fixed- or free-time control problem in which all of the constraints (including the dynamics) are subject to (nonadditive) peturbation. Secondly, we will explore some of the major consequences of this characterization. In § 3 we derive a series of conditions under which, successively, V is locally finite (which, as mentioned above, has implications for controllability), locally Lipschitz, admits directional derivatives, or actually differentiable. Section 4 is devoted to an example illustrating the main theorem. In § 5 we undertake a special study of the time-optimal control problem. The special case of this problem in which the dynamics are linear and V reduces to the minimal time function T has been extensively studied [8], [9], [11], [16], [17]. Using the general theorem of § 3, we are able to extend to nonlinear systems the main results of the linear theory. In particular, we derive a new criterion assuring the continuity of T at the origin and the local null-controllability of the system.

We now proceed to describe the context in which we shall work.

The Problem. The object of our study is a relative of the standard optimal control problem known as the *differential inclusion problem*:

$$\text{(P)}\quad \min\{f(T, x(0), x(T)):\ \dot{x}(t)\in F(x(t)) \text{ a.e. on } [0, T], \text{ and } (T, x(0), x(T))\in S\}.$$

The objective of problem (P) is to choose a (nondegenerate) time interval $[0, T]$ and an arc (i.e. an absolutely continuous function) $x:[0, T]\to X\subseteq \mathbf{R}^n$ satisfying the endpoint constraints $(T, x(0), x(T))\in S$ and the dynamic constraint $\dot{x}(t)\in F(x(t))$ a.e. on $[0, T]$, and providing a minimum for the function $f(T, x(0), x(T))$. Here $F: X\to \mathbf{R}^n$ is a *multifunction*, a mapping which carries a point x in $\mathbf{R}^n$ into a nonempty compact subset $F(x)\subseteq \mathbf{R}^n$. To see the relationship between (P) and a more conventional optimal control problem, suppose the Mayer problem below is given:

$$\text{(Q)}\quad \begin{aligned}\min\{f(T, x(0), x(T)):\ &\dot{x}(t)=\varphi(x(t), u(t)) \text{ a.e. on } [0, T],\\ &\text{where } u(t)\in U \text{ a.e. on } [0, T], \text{ and } (T, x(0), x(T))\in S\}.\end{aligned}$$

We may then define a version of (P) with the same f and S, and with $F(x) := \varphi(x, U)$. Any arc admissible for (Q) is also admissible for (P), where it is assigned the same value. Conversely, reasonable hypotheses on φ imply that if $x:[0, T]\to \mathbf{R}^n$ is an admissible arc for (P), then there is a measurable function $u:[0, T]\to U$ such that $\dot{x}(t)=\varphi(x(t), u(t))$ a.e. on $[0, T]$. (This is Filippov's lemma. In the sequel, any φ and U for which $F(x)=\varphi(x, U)$ for all $x\in X$, will be termed a *classical representation* of F.) Thus the Mayer problem (Q) is a special case of (P). Of course, nonautonomous versions of both problems exist. The techniques presented below require very few modifications to be applied to such problems: we have chosen the simple form of (P) to ease the exposition.

Hypotheses. The following mild conditions govern the data comprising problem (P). Throughout this paper, B denotes the open unit ball of the appropriate Euclidean space.

(h_1) There are a closed set $X\subseteq \mathbf{R}^n$ and an $\varepsilon>0$ such that the multifunction F is defined on $X+\varepsilon B$; the values of F are nonempty compact convex subsets of $\mathbf{R}^n$.

(h_2) F is locally Lipschitz on $X+\varepsilon B$. (A multifunction $\Gamma:\mathbf{R}^m\to\mathbf{R}^m$ is *Lipschitz of rank* K on a set $C\subseteq \mathbf{R}^m$ if $\Gamma(x_2)\subseteq \Gamma(x_1)+K|x_2-x_1|B$ for all x_1, x_2 in C.)

(h_3) F obeys a linear growth condition: for some $c\geqq 0$, $k\geqq 0$, one has $F(x)\subseteq (k|x|+c)B$ for all $x\in X+\varepsilon B$.

(h_4) The constraint set $S \subseteq \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^n$ is a closed set, and $\{(t, x) : (t, x, y) \in S\}$ is compact.

(h_5) The objective function $f : S \to \mathbf{R}$ is locally Lipschitz on S.

Remark. The requirement in (h_1) that F be convex-valued means that we are working in this article with the "relaxed" problem in the sense of Warga [22]. (See also [4, § 5.5], in which classical representations of standard relaxed problems are discussed.) The state constraint $x(t) \in X$ is admitted to allow consideration of local minima. Our hypotheses will limit attention to arcs lying in int X, hence excluding binding "unilateral" state constraints.

The growth condition (h_3) allows us to use Gronwall's inequality to estimate the modulus of continuity of any trajectory for F. Here is the result.

LEMMA 1.1. *Suppose $x : [0, T] \to \mathbf{R}^n$ is an arc with $\dot{x}(t) \in F(x(t))$ a.e. on $[0, T]$. Then*

$$|x(t) - x(a)| \leqq \left(|x(a)| + \frac{c}{k}\right)(e^{k(t-a)} - 1)$$

for all $0 \leqq a \leqq t \leqq T$.

The following result concerning the sequential compactness of trajectories is crucial to the theory of existence of solutions to (P) and to the sensitivity analysis of Part 3. It is the autonomous case of [4, Thm. 3.1.7].

PROPOSITION 1.2. *Let $\Gamma : \mathbf{R}^m \to \mathbf{R}^m$ be an upper semicontinuous multifunction with nonempty compact convex values defined on a set of the form $C + \varepsilon B$, where $C \subseteq \mathbf{R}^m$ is closed and $\varepsilon > 0$. Let $x_j : [0, T_j] \to \mathbf{R}^m$ be a sequence of arcs for which $T_j \to T > 0$, and satisfying the following hypotheses*:

(i) *$x_j(t) \in C$ for all $t \in [0, T_j]$;*

(ii) *there is a constant $M > 0$ such that $\Gamma(x_j(t)) \subseteq M\bar{B}$ for all $t \in [0, T_j]$, and $|\dot{x}_j(t)| \leqq M$ a.e. on $[0, T_j]$;*

(iii) *$\dot{x}_j(t) \in \Gamma(x_j(t)) + r_j(t)B$ a.e. on $[0, T] \cap [0, T_j]$, where $\{r_j\}$ is a sequence of measurable functions on $[0, T]$ converging uniformly to zero*;

(iv) *the sequence $\{x_j(0)\}$ is bounded.*

There there is a subsequence of $\{x_j\}$ along which $x_j|_{[0,T]}$ converges uniformly to an arc $x : [0, T] \to C$ obeying $\dot{x}(t) \in \Gamma(x(t))$ a.e. on $[0, T]$. Along this subsequence, $x_j(T_j) \to x(T)$. (If $T_j < T$, then $x_j|_{[0,T]}$ should be interpreted as the extension $\tilde{x}_j$ of x_j which obeys $\tilde{x}_j(t) := x_j(T_j)$ for $t \in (T_j, T]$.)

Proof. Conditions (ii) and (iv) imply that $\tilde{x}_j = x_j|_{[0,T]}$ is a uniformly bounded equicontinuous family of functions, whence it has a uniformly convergent subsequence. By (i), the limit function x lies in C. Moreover, the Dunford-Pettis criterion applies (along the subsequence) to show that $\{\dot{\tilde{x}}_j\}$ is weakly compact in $L^1[0, T]$, so that x is actually an arc. Finally, a support function argument shows that $\dot{x}(t) \in F(x(t))$ a.e. on $[0, T]$, just as in [4]. □

The existence theory for problem (P) is a simple consequence of Proposition 1.2.

PROPOSITION 1.3. *Suppose that the data of problem* (P) *satisfy* (h_1)-(h_5), *and that there is at least one feasible arc for* (P). *Suppose also that degenerate arcs are ruled out, i.e.*

$$(h_6) \qquad S \cap \{(0, x, x) : x \in \mathbf{R}^n\} = \varnothing.$$

Then problem (P) *has a solution.*

Proof. Let $x_j : [0, T_j] \to \mathbf{R}^n$ be a sequence of feasible arcs for (P) such that

$$f(T_j, x_j(0), x_j(T_j)) \to \inf (\mathrm{P}) < +\infty.$$

Then $\{(T_j, x_j(0))\}$ lies in a compact set by (h_4), so we may pass to a subsequence if necessary and assume that $x_j(0) \to x_0 \in \mathbf{R}^n$ and $T_j \to T \geqq 0$.

Note that $T = 0$ is impossible, since Lemma 1.1 implies that

$$|x_j(T_j) - x_0| \leqq |x_j(T_j) - x_j(0)| + |x_j(0) - x_0| \leqq \left(|x_j(0)| + \frac{c}{k}\right)(e^{kT_j} - 1) + |x_j(0) - x_0|.$$

So if $T_j \to 0$, then $x_j(T_j) \to x_0$ and the sequence $\{(T_j, x_j(0), x_j(T_j))\}$ in the closed set S would converge to a point $(0, x_0, x_0)$ outside S by (h_6). This is absurd: we must have $T > 0$.

Hypotheses (i), (ii), (iv) of Proposition 1.2 are now evident; condition (iii) follows readily from Lemma 1.1 and the growth condition (h_3). We deduce that a subsequence of $\{x_j\}$ converges to a feasible arc $x: [0, T] \to \mathbf{R}^n$ which solves (P). □

2. Techniques. This section summarizes the techniques of nonsmooth analysis which are central to the sensitivity results of § 3.

Generalized gradients. The calculus of generalized gradients, presented in detail in [4], has a well-developed geometric aspect which is the foundation of the arguments in § 3.

Let C be a nonempty closed subset of $\mathbf{R}^m$, with $x \in C$. The vector $v \in \mathbf{R}^m$ is *perpendicular to C at x*, written $v \perp C$ at x, if $|(x+v) - x| \leqq |(x+v) - c|$ for all $c \in C$, with strict inequality for $c \neq x$. (I.e. the closed ball of radius $|v|$ and centre $x+v$ meets C in the single point x.) In terms of the Euclidean distance function $d_C(z) := \inf\{|z - c| : c \in C\}$, $v \perp C$ at x if x is the unique point of C at which the infimum defining $d_C(x+v)$ is attained. This hints at a profitable link between perpendicularity and a problem of minimization.

LEMMA 2.1. *Let C be a nonempty closed subset of $\mathbf{R}^m$, with $x \in C$. If $v \perp C$ at x, then $\langle v, c - x\rangle \leqq \frac{1}{2}|c - x|^2$ for all c in C.*

Proof. Write the definition of $v \perp C$ at x in terms of the inner product. □

The collection of all perpendiculars to C at base points near x defines the *normal cone to C at x*, denoted $N_C(x)$, as follows: $N_C(x)$ is the closed convex cone generated by the set

$$\left\{\lim_{i \to \infty} \frac{v_i}{|v_i|} : v_i \to 0,\ v_i \perp C \text{ at } x_i \to x\right\} \cup \{0\}.$$

The first set in this union consists of all unit vectors which can be obtained by computing limits of normalized perpendiculars: the perpendiculars must diminish in length and their corresponding base points x_i in C must converge to the given point x.

Now let an extended-real-valued function f be defined on $\mathbf{R}^m$. Suppose $f(x)$ is finite, and that epi f is locally closed near $(x, f(x))$. Then the *generalized gradient of f at x* is the (closed, convex) set

$$\partial f(x) = \{\zeta \in \mathbf{R}^m : (\zeta, -1) \in N_{\text{epi } f}(x, f(x))\}.$$

Extremely bad behaviour of f near x is captured by the *asymptotic generalized gradient of f at x*, namely

$$\partial^\infty f(x) = \{\zeta \in \mathbf{R}^m : (\zeta, 0) \in N_{\text{epi } f}(x, f(x))\}.$$

Note that $\partial^\infty f(x)$ is a closed convex cone containing the origin. It reduces to $\{0\}$ if and only if f is Lipschitz near x ([4, Prop. 2.9.7]).

Necessary conditions. The calculus of generalized gradients allows the formulation of general first-order necessary conditions for problem (P) without any assumptions

of smoothness or differentiability beyond (h_1)-(h_5). The principal figure in these conditions is the *Hamiltonian* $H: \mathbf{R}^n \times \mathbf{R}^n \to \mathbf{R}$, defined by

$$H(x, p) := \sup \{\langle p, v\rangle : v \in F(x)\}.$$

When $F(x)$ admits a classical representation $\varphi(x, U)$, H is a function sometimes referred to as the "maximized Hamiltonian" in the literature:

$$H(x, p) := \sup \{\langle p, \varphi(x, u)\rangle : u \in U\}.$$

THEOREM 2.2 (Necessary Conditions). *Suppose that the arc* $x: [0, T] \to \operatorname{int} X$ *solves* (P). *Then for all* r *sufficiently large, there exist a scalar* $\lambda \in \{0, 1\}$, *an arc* $p: [0, T] \to \mathbf{R}^n$, *and a vector* $\zeta \in \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^n$ *such that conclusions* (a)-(d) *below hold with* $\lambda + \|p\| > 0$.

(a) $(-\dot{p}(t), \dot{x}(t)) \in \partial H(x(t), p(t))$ *a.e. on* $[0, T]$.

(b) *There is a constant* h *such that* $H(x(t), p(t)) = h$ *for all* $t \in [0, T]$.

(c) $\zeta \in \partial f(T, x(0), x(T))$.

(d) $(h, p(0), -p(T)) \in \lambda\zeta + r\, \partial d_S(T, x(0), x(T))$.

Proof. Evidently $x: [0, T] \to \mathbf{R}^n$ is an interior solution for (P) if and only if the arc $(x(0), x(\cdot)): [0, T] \to \mathbf{R}^n \times \mathbf{R}^n$ is an interior solution for the related problem

$$\min \{f(\tau, y_0(\tau), y(\tau)) : (\dot{y}_0(t), \dot{y}(t)) \in \{0\} \times F(y) \text{ a.e. on } [0, \tau],$$
$$(y_0(0), y(0)) \in D \cap M\bar{B}, (\tau, y_0(\tau), y(\tau)) \in S\},$$

where $D = \{(y, y) : y \in \mathbf{R}^n\}$ and $M > 0$ is chosen so large that MB includes the whole second component of S (which can be done by (h_4)). This related problem has precisely the form for which [4, Thm. 3.6.1, Corollary], provides necessary conditions. A straightforward translation of terms yields the version of the result stated above. □

Remarks. Since (in general notation) $N_C(z)$ is the closed convex cone generated by $\partial d_C(z)$, condition (c) is often replaced at very slight expense by

$$(c') \qquad (h, p(0), -p(T)) \in \lambda\zeta + N_S(T, x(0), x(T)).$$

The pair (p, ζ) satisfying conditions (a), (b), and (c') is called an *index* λ *multiplier* corresponding to x. The multiplier is *normal* if $\lambda = 1$ and *abnormal* if $\lambda = 0$; if no solution of (P) admits a nontrivial abnormal multiplier, we say that problem (P) itself is *normal.* It follows from condition (a) [4, Prop. 3.2.4(b)] that the arc p satisfies $|\dot{p}(t)| \leqq K|p(t)|$ for some constant K. This observation, together with Gronwall's lemma, implies that an arc p satisfying (a) is either identically zero or else nonvanishing on $[0, T]$.

We refer to [4] for a complete discussion of the relationship between this theorem and the celebrated Maximum Principle of Pontryagin.

3. General sensitivity analysis. We are now prepared to investigate the sensitivity of the differential inclusion problem (P) to small changes in its objective function, dynamics, and constraints. Specifically, we will compute the generalized gradient at 0 of the *value function* $V: \mathbf{R}^m \to \mathbf{R} \cup \{+\infty\}$ defined in terms of the following perturbed optimization problem:

$$\text{P}(\alpha) \qquad V(\alpha) := \min\{f(T, x(0), x(T), \alpha) : \dot{x}(t) \in F(x(t), \alpha) \quad \text{a.e. on } [0, T],$$
$$\text{and } (T, x(0), x(T), \alpha) \in S\}.$$

The main result, presented in Theorem 3.3 below, is that $\partial V(0)$ is captured by an extension of the multiplier rule, Theorem 2.2, which incorporates elements which monitor the effects of the perturbation along the optimal arc.

Multipliers. An *index* λ *multiplier* corresponding to an admissible arc $x: [0, T] \to \operatorname{int} X$ for P(0) is a triple (p, q, ζ) satisfying conditions (a)-(d) below.

(a) $(p, q): [0, T] \to \mathbf{R}^n \times \mathbf{R}^m$ is an arc obeying the *Hamiltonian inclusion*

$$(-\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial \mathscr{H}(x(t), 0, p(t)) \quad \text{a.e. on } [0, T],$$

where the *Hamiltonian* for the perturbed problem $\mathrm{P}(\alpha)$ is

$$\mathscr{H}(x, \alpha, p) := \sup \{\langle p, v\rangle : v \in F(x, \alpha)\}.$$

(b) There is a constant h such that $\mathscr{H}(x(t), 0, p(t)) = h$ for all t in $[0, \mathrm{T}]$.

(c) $\zeta \in \partial f(T, x(0), x(T), 0)$.

(d) $(h, p(0), -p(T), -q(T)) \in \lambda\zeta + N_S(T, x(0), x(T), 0)$.

The collection of all such triples is the set $M^\lambda(x)$, the *index* λ *multiplier set corresponding to* x. We shall later be concerned with the set Y of all solutions to P(0) and the corresponding collection of multipliers

$$M^\lambda(Y) = \bigcup_{x \in Y} M^\lambda(x).$$

Hypotheses. The following modifications of hypotheses (h_1)-(h_6) above ensure that for each $\alpha \in \mathbf{R}^n$ near the nominal value $\alpha = 0$, problem $\mathrm{P}(\alpha)$ is amenable to the techniques of §§ 1 and 2. In particular, they imply that whenever $V(\alpha) < +\infty$, then $\mathrm{P}(\alpha)$ has a solution. We retain them throughout § 3.

(H1) The $\mathbf{R}^n$-valued multifunction F is defined on $X \times \varepsilon B \subseteq \mathbf{R}^n \times \mathbf{R}^m$ for some $\varepsilon > 0$, where $X \subseteq \mathbf{R}^n$ is closed. The values of F are nonempty compact convex sets.

(H2) The multifunction F is (jointly) locally Lipschitz on $X \times \varepsilon B$.

(H3) There are constants $c \geqq 0$, $k \geqq 0$ such that $F(x, \alpha) \subseteq (k|x| + c)B$ for all $(x, \alpha) \in X \times \varepsilon B$.

(H4) The constraint set $S \subseteq \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^n \times \mathbf{R}^m$ is closed, and its projection $\{(t, x) : (t, x, y, \alpha) \in S\}$ is compact.

(H5) The objective function $f: S \to \mathbf{R}$ is locally Lipschitz on S.

(H6) Degenerate arcs are inadmissible, i.e.

$$S \cap \{(0, x, x, \alpha) : x \in X, \alpha \in \varepsilon \bar{B}\} = \varnothing.$$

In addition to the hypotheses stating that $\mathrm{P}(\alpha)$ is well-behaved for each fixed α, we demand that the perturbation structure of the problem vary reasonably as α changes. This requires three more hypotheses.

(H7) Problem P(0) has a feasible arc. By Proposition 1.2, it follows that P(0) has a solution. We also assume that every arc solving P(0) lies entirely inside int X.

(H8) For every arc $x: [0, T] \to \mathbf{R}^n$ in Y, the multifunction $(t, x, y, \alpha) \to N_S(t, x, y, \alpha)$ is closed at the point $(T, x(0), x(T), 0)$.

(H9) The perturbation structure is *nondegenerate*, i.e. every triple (p, q, ζ) in $M^0(Y)$ with $q(0) = 0$ also has $p \equiv 0$.

To understand (H9), suppose first that the unperturbed data f, F, and S of problem (P) in § 1 are forced into the shape of $\mathrm{P}(\alpha)$ by imposing trivial α-dependence. Then an arc $x: [0, T] \to \mathbf{R}^n$ is admissible for P(0) if and only if it is admissible for (P), and every index λ multiplier (p, q, ζ_0) corresponding to x must have $q \equiv 0$ and $\zeta_0 = (\zeta, 0) \in \partial f(T, x(0), x(T)) \times \{0\}$. These multipliers are in one-to-one correspondence with the mulipliers (p, ζ) for (P) defined by conclusions (a), (b), (c'), (d) of Theorem 2.2. Hence in the case of trivial α-dependence, (H9) reduces to the assumption that P(0) is normal. If $\mathrm{P}(\alpha)$ has nontrivial α-dependence, (H9) is strictly weaker than the assumption that P(0) is normal because of the additional condition $q(0) = 0$. Indeed, there are perturba-

tion schemes (such as the additive endpoint perturbation studied in [4, § 3.4]) which are always nondegenerate but in which the normality of p(0) is determined by other features of the problem's data.

Hypothesis (H8) is a mild condition which is satisfied automatically if,for example, the cone $N_S(T, x(0), x(T), 0)$ is pointed. In many cases, such as the additive endpoint perturbations studied in [4, § 3.4] or the minimal time problem of § 5, (H8) can be verified directly. A detailed discussion of conditions which imply (H8) is given in [14].

Hypothesis (H7) is required because problems whose solution arcs spend some time on the boundary of X obey a more complicated multiplier rule than that described by Theorem 2.2. (This amounts to allowing abstract state constraints in problem (P): the interested reader may consult [4, Thm. 3.6.1].) The proof techniques presented below can be extended to this setting, but (H7) eases the exposition considerably. Proposition 3.2 below shows that (H7) implies that the perturbed problem is *tame* in the sense of [20].

LEMMA 3.1. *Assume* (H1)-(H6). *Then there exists a positive constant* T_0 *such that if* $x:[0, T]\to\mathbf{R}^n$ *is admissible for some* $\mathrm{P}(\alpha)$, $\alpha\in\varepsilon B$, *then* $T\geqq T_0$.

Proof. If this statement were false, then there would be a sequence $\{\alpha_i\}$ in εB with corresponding trajectories $x_i:[0, T_i]\to\mathbf{R}^n$ admissible for $\mathrm{P}(\alpha_i)$ while $T_i\to 0$. By passing to a subsequence if necessary, we may assume $x_i(0)\to x_0$ (by (H4)) and $\alpha_i\to\alpha\in\varepsilon\bar{B}$. But then Lemma 1.1 would imply that $x_i(T_i)\to x_0$, and we would reach the absurd conclusion that the sequence $\{(T_i, x_i(0), x_i(T_i), \alpha_i)\}$ in the closed set S converges to a point $(0, x_0, x_0, \alpha)$ which lies outside S by (H6). □

PROPOSITION 3.2. *Assume* (H1)-(H7). *Then there is some* $\delta\in(0, \varepsilon)$ *such that* $\alpha\in\delta B$ *and* $V(\alpha)<V(0)+\delta$ *imply that all solutions of* $\mathrm{P}(\alpha)$ *lie in* int X.

Proof. Suppose not. Then there is a sequence $\{\alpha_j\}$ with $|\alpha_j|<\frac{1}{j}$ and $V(\alpha_j)<V(0)+\frac{1}{j}$ for which there exist corresponding solutions $x_j:[0, T_j]\to\mathbf{R}^n$ of $\mathrm{P}(\alpha_j)$ which all fail to lie in int X. By passing to a subsequence if necessary, we may assume that $x_j(0)\to x_0$ and $T_j\to T>0$. According to Proposition 1.2 (with $\Gamma(x):=F(x, 0)$ and $r_j(t):=K|\alpha_j|$ for some fixed $K>0$), a further subsequence (which we do not relabel) converges uniformly to an arc $x:[0, T]\to\mathbf{R}^n$ admissible for P(0) and obeying

$$V(0)\leqq f(T, x(0), x(T), 0)\leqq\lim_{j\to\infty} f(T_j, x_j(0), x_j(T_j), \alpha_j)$$

$$=\lim_{j\to\infty} V(\alpha_j)\leqq\lim_{j\to\infty}\left(V(0)+\frac{1}{j}\right)=V(0).$$

Hence the arc x is a solution of P(0). But this contradicts (H7), since any arc which is the uniform limit of arcs not contained in int X cannot lie in int X. □

Theorem 3.3 below is the main result of this section. It relates the differential properties of V to the arcs q in the multiplier sets introduced above. For any index λ multiplier (p, q, ζ) corresponding to an arc $x:[0, T]\to\mathbf{R}^n$ for P(0), we define $Q(p, q, \zeta):=-q(0)$. The notation $Q[M^\lambda(x)]$ designates the set of all possible values of $-q(0)$ obtained in this way, and $Q[M^\lambda(Y)]$ denotes $\cup_{x\in Y} Q[M^\lambda(x)]$. The proof of Theorem 3.3 occupies the remainder of § 3.

THEOREM 3.3. *Under hypotheses* (H1)-(H9), *the function* V *is lower semicontinuous near* 0, *and one has*

$$\partial V(0)=\overline{\mathrm{co}}\,\{Q[M^1(Y)]\cap\partial V(0)+Q[M^0(Y)]\cap\partial^\infty V(0)\}.$$

If the cone $Q[M^0(Y)]$ *is pointed, the closure operation is superfluous and one also has*

$$\partial^\infty V(0)=\mathrm{co}\,\{Q[M^0(Y)]\cap\partial^\infty V(0)\}.$$

(*A subset of* $\mathbf{R}^m$ *is* pointed *if zero cannot be obtained as a positive linear combination of its nonzero elements.*)

COROLLARY 1 (Lipschitz behaviour of V). *If* $Q[M^0(Y)]=\{0\}$, *then* V *is finite and Lipschitz near* 0. *In particular, if* P(0) *is normal* (*i.e.*, $Q[M^0(Y)]=\{0\}$) *then* P(0) *is locally controllable, in the sense that* P(α) *admits feasible arcs for all* α *near* 0.

Proof. The cone $\{0\}$ is certainly pointed, so $\partial^\infty V(0)=\{0\}$ by Theorem 3.3. This implies that V is finite and Lipschitz near 0 [4, Prop. 2.9.7]. □

COROLLARY 2 (Existence of nontrivial multipliers). *If* $x:[0, T]\to\mathbf{R}^n$ *solves* P(0) *then it has an index* λ *multiplier* (p, q, ζ) *with* $\lambda+|q(0)|>0$.

Proof. If $Y=\{x\}$ the proof is simple: either $Q[M^0(x)]$ is different from $\{0\}$, whence the conclusion is immediate, or $Q[M^0(x)]=\{0\}$. In the latter case, $\partial^\infty V(0)=\{0\}$ implies that $\partial V(0)$ is nonempty [4, Prop. 2.9.7]: thus

$$\varnothing\neq\partial V(0)=\operatorname{co}\{Q[M^1(x)]\cap\partial V(0)\},$$

and we find $M^1(x)\neq\varnothing$.

If x is not the only solution to P(0), a bookkeeping device allows the formulation of a problem related to P(0) for which x is the unique solution. Transposition of the preceding argument into this case yields the desired result, as in [4, Thm. 3.5.2]. □

The following immediate consequences of the formulas in the theorem are proven just as in [4, Thm. 6.5.2, Corollaries 2, 3]. As in that reference, we use the notation V', V^+, V_+ to denote (respectively) the usual one-sided directional derivative, upper right and lower right Dini derivatives (see [4, p. 242]).

COROLLARY 3 (Directional derivatives of V). *Suppose that* $Q[M^0(Y)]=\{0\}$. *Then one has for each* u *in* $\mathbf{R}^m$:

$$V^+(0; u)\leq\inf_{x\in Y}\sup\langle u, Q[M^1(x)]\rangle,$$

$$V_+(0; u)\geqq\inf_{x\in Y}\inf\langle u, Q[M^1(x)]\rangle.$$

If $Q[M^1(x)]$ *is a singleton* $Q(x)$ *for each* x *in* Y, *then* $V'(0; u)$ *exists for each* u *in* $\mathbf{R}^m$ *and one has*

$$V'(0; u)=\inf_{x\in Y}\langle Q(x), u\rangle.$$

COROLLARY 4 (Differentiability of V). *If* Y *is a singleton* $\{x\}$, *and if for this* x *one has* $Q[M^0(x)]=\{0\}$ *and* $Q[M^1(x)]=\{\zeta\}$, *then* V *is strictly differentiable at* 0 *with* $DV(0)=\zeta$. (*Strict differentiability is defined in* [4, § 2.2].)

Proof of Theorem 3.3. To prove Theorem 3.3, we will calculate the generalized gradients of V by appealing to the definitions given in § 2. The first step is to establish that epi V is locally closed near $(0, V(0))$.

LEMMA 3.4. *The function* V *is lower semicontinuous on* δB, *where* δ *is given by Proposition* 3.2.

Proof. Fix any α in δB. Given any sequence $\alpha_j\to\alpha$, we must show that $V(\alpha)\leqq\liminf_{j\to\infty}V(\alpha_j)$. If the right side is $+\infty$, there is nothing to prove; otherwise, we may pass to a subsequence if necessary and assume that $\lim_{j\to\infty}V(\alpha_j)$ exists. Let $x_j:[0, T_j]\to\mathbf{R}^n$ solve P(α_j): Proposition 1.2 implies that a subsequence of these arcs converges to an F-trajectory $x:[0, T]\to\mathbf{R}^n$ admissible for P(α), with $T\geqq T_0>0$ by Lemma 3.1. Then

$$V(\alpha)\leqq f(T, x(0), x(T), \alpha)=\lim_{j\to\infty}f(T_j, x_j(0), x_j(T_j), \alpha_j)=\lim_{j\to\infty}V(\alpha_j),$$

as required. □

The proof of Theorem 3.3 is built on the following geometric proposition of Rockafellar [20, Prop. 15].

PROPOSITION 3.5. *Let D and D^∞ be closed subsets of $\mathbf{R}^m$ such that D^∞ is a cone containing the point 0 and the recession cone of D. For the closed cone*

$$N := \{r(\zeta, -1) : r > 0,\ \zeta \in D\} \cup \{(\zeta, 0) : \zeta \in D^\infty\}$$

in $\mathbf{R}^m \times \mathbf{R}$, one has

$$\{\zeta : (\zeta, -1) \in \overline{\text{co}}\ N\} = \overline{\text{co}}\ (D + D^\infty).$$

If the cone D^∞ is pointed, the closure operation on the right-hand side is superfluous, and one also has

$$\{\zeta : (\zeta, 0) \in \overline{\text{co}}\ N\} = \text{co}\ D^\infty.$$

To complete the proof, we must successfully identify D with $Q[M^1(Y)] \cap \partial V(0)$ and D^∞ with $Q[M^0(Y)] \cap \partial^\infty V(0)$. Both these sets are closed, being the intersections of closed sets. ($Q[M^\lambda(Y)]$ is closed by Proposition 1.2.) Moreover, D^∞ is the intersection of two cones containing 0, and is therefore such a cone itself. Thus we only need to show that

$$N_{\text{epi}\, V}(0, V(0)) = \overline{\text{co}}\ (N_1 \cup N_2),$$

where

$$N_1 := \{r(\zeta, -1) : r > 0,\ \zeta \in Q[M^1(Y)] \cap \partial V(0)\}$$
$$N_2 := \{(\zeta, 0) : \zeta \in Q[M^0(Y)] \cap \partial^\infty V(0)\},$$

and then check that D^∞ is the recession cone of D.

The definitions of $\partial V(0)$ and $\partial^\infty V(0)$ imply that

$$N_{\text{epi}\, V}(0, V(0)) \supseteq \overline{\text{co}}\ (N_1 \cup N_2).$$

To prove the reverse inclusion, we will use the definition of the normal cone in terms of limits of normalized perpendicular vectors given in § 2. It motivates the following lemma.

LEMMA 3.6. *Suppose $(\beta, -u) \perp \text{epi}\ V$ at (α, v), where $v < V(0) + \delta$ and $\alpha \in \delta B$. Then there exists a solution $x : [0, T] \to \mathbf{R}^n$ to $\text{P}(\alpha)$ (for some $T \geqq T_0$) to which there correspond a scalar $\lambda \in \{0, 1\}$, an arc $(p, q) : [0, T] \to \mathbf{R}^n \times \mathbf{R}^m$, and a vector $\zeta \in \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^n \times \mathbf{R}^m$ such that $\|(p, q)\| + \lambda / |(\beta, -u)| > 0$ and* (a)-(e) *hold.*

(a) $(-\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial \mathcal{H}(x(t), \alpha, p(t))$ *a.e. on* $[0, T]$.

(b) *There is a constant h such that $\mathcal{H}(x(t), \alpha, p(t)) = h$ on* $[0, T]$.

(c) $\zeta = (\tau, \xi, \eta, \eta_1) \in \partial f(T, x(0), x(T), \alpha)$.

(d) $(h, p(0), -p(T), -q(T)) \in \lambda (u / |(\beta, -u)|) \zeta + N_S(T, x(0), x(T), \alpha)$.

(e) $q(0) = -\lambda (\beta / |(\beta, -u)|)$.

Proof. By Proposition 3.2, $V(\alpha) \leqq v < V(0) + \delta$ implies that problem $\text{P}(\alpha)$ has a solution $x : [0, T] \to \mathbf{R}^n$ lying entirely inside int X. Now for any $\alpha' \in \delta \bar{B}$, every F-trajectory $y : [0, T'] \to \mathbf{R}^n$ admissible for $\text{P}(\alpha')$ obeys

$$\begin{aligned} V(\alpha') &\leqq f(T', y(0), y(T'), \alpha') \\ &\leqq f(T', y(0), y(T'), \alpha') + v - f(T, x(0), x(T), \alpha), \end{aligned}$$

i.e. $(\alpha', f(T', y(0), y(T'), \alpha') + v - f(T, x(0), x(T), \alpha)) \in \text{epi } V$. Replacing c in Lemma 2.1 with the left side of this expression yields the inequality

$$uf(T, x(0), x(T), \alpha) - \langle \alpha, \beta \rangle \leqq uf(T', y(0), y(T'), \alpha') - \langle \alpha', \beta \rangle + \tfrac{1}{2}|(\alpha - \alpha', f(T', y(0), y(T'), \alpha') - f(T, x(0), x(T), \alpha))|^2.$$

Note that equality holds when $\alpha' = \alpha$ and $y = x$ (so $T' = T$). Thus $(x(\cdot), \alpha)$ is an interior solution for the (unperturbed) problem in which

$$\tilde{f}(t, x, x_1, y, y_1) := uf(t, x, y, y_1) - \langle \beta, x_1 \rangle + \tfrac{1}{2}|(y_1 - \alpha, f(t, x, y, y_1) - f(T, x(0), x(T), \alpha))|^2,$$

$$\tilde{F}(x, x_1) := F(x, x_1) \times \{0\},$$

$$\tilde{S} := \{(t, x, x_1, y, y_1) : (t, x, y, y_1) \in S, x_1 \in \delta \bar{B}\}.$$

The Hamiltonian for this new problem is

$$\tilde{H}(x, x_1, p, q) = \sup \{\langle (p, q), (v, 0) \rangle : v \in F(x, x_1)\} = \mathcal{H}(x, x_1, p).$$

Hypotheses (h_1)-(h_5) of § 1 are easy to verify, so by Theorem 2.2, there exist a scalar $\lambda \in \{0, 1\}$, an arc $(p, q) : [0, T] \to \mathbf{R}^n \times \mathbf{R}^m$, and a vector $\tilde{\zeta} \in \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^m \times \mathbf{R}^n \times \mathbf{R}^m$ such that $\lambda + \|(p, q)\| > 0$ and conclusions (i)-(iv) below hold.

(i) $(-\dot{p}(t), -\dot{q}(t), \dot{x}(t), 0) \in \mathcal{H}(x(t), \alpha, p(t)) \times \{0\}$ a.e. on $[0, T]$.

(ii) There is a constant h such that $\mathcal{H}(x(t), \alpha, p(t)) = h$ on $[0, T]$.

(iii) $\tilde{\zeta} = u(\tau, \xi, 0, \eta, \eta_1) + (0, 0, -\beta, 0, 0)$ for some $(\tau, \xi, \eta, \eta_1)$ in $\partial f(T, x(0), x(T), \alpha)$.

(iv) $(h, p(0), q(0), -p(T), -q(T)) \in \lambda \tilde{\zeta} + N_{\tilde{S}}(T, x(0), \alpha, x(T), \alpha)$.

Condition (iv) implies that $q(0) = -\lambda\beta$ and

(iv′) $(h, p(0), -p(T), -q(T)) \in \lambda u(\tau, \xi, \eta, \eta_1) + N_S(T, x(0), x(T), \alpha)$.

Replacing the arc (h, p, q) by the scaled version $(h, p, q)/|(\beta, -u)|$ yields the desired conclusions. □

Suppose now that a sequence $(\beta_i, -u_i)$ of vectors perpendicular to epi V at corresponding points (α_i, v_i) is given, where $(\beta_i, -u_i) \to (0, 0)$, $(\alpha_i, v_i) \to (0, V(0))$, and the limit of $(\beta_i, -u_i)/|(\beta_i, -u_i)|$ exists and equals (say) (β_0, u_0). Since $N_{\text{epi } V}(0, V(0))$ is precisely the closed convex cone generated by such limit vectors, we need only prove $(\beta_0, -u_0) \in N_1 \cup N_2$. This is a consequence of the following lemma.

LEMMA 3.7. *Let $(\beta, -u_0)$ be the unit vector introduced above. Then there is a solution $x : [0, T] \to \mathbf{R}^n$ to* P(0), *an arc (p, q), and a vector $\zeta \in \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^n \times \mathbf{R}^m$ such that*

(a) $(-\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial \mathcal{H}(x(t), 0, p(t))$ *a.e. on* $[0, T]$,

(b) *there is a constant h such that $\mathcal{H}(x(t), 0, p(t)) = h$ on* $[0, T]$.

(c) $\zeta = (\tau, \xi, \eta, \eta_1) \in \partial f(T, x(0), x(T), 0)$,

(d) $(h, p(0), -p(T), -q(T)) \in u_0 \zeta + N_S(T, x(0), x(T), 0)$,

(e) $q(0) = -\beta_0$.

Proof. For all i sufficiently large, Lemma 3.6 applies to the perpendicular vectors $(\beta_i, -u_i)$ to provide solutions $x_i : [0, T_i] \to \mathbf{R}^n$ (with $T_i \geqq T_0 > 0$) for $\text{P}(\alpha_i)$ with corresponding quantities $\lambda_i, (h_i, p_i, q_i)$, and ζ_i satisfying Lemma 3.6(a)-(e): note that

$$f(T_i, x_i(0), x_i(T_i), \alpha_i) = V(\alpha_i) \leqq v_i \to V(0).$$

Observe that $\lambda_i \neq 0$ for all i sufficiently large. For if this were false, then there would be a subsequence with $\lambda_i = 0$ for all i (we do not relabel). Then condition (d) implies $q_i(0) = 0$ for all i and the nontriviality condition forces $p_i(0) \neq 0$ for all i. We may therefore scale the arcs (h_i, p_i, q_i) by $|p_i(0)|^{-1}$: the result is a sequence of arcs

$(h_i, p_i, q_i): [0, T] \to \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^m$ such that

$$(-\dot{p}_i(t), -\dot{q}_i(t), \dot{x}_i(t)) \in \partial \mathcal{H}(x_i(t), \alpha_i, p_i(t)) \quad \text{a.e. on } [0, T],$$

$$\mathcal{H}(x_i(t), \alpha_i, p_i(t)) = h_i \quad \text{on } [0, T],$$

$$(h_i, p_i(0), -p_i(T_i), -q_i(T_i)) \in N_S(T_i, x_i(0), x_i(T_i), \alpha_i), \quad \text{and}$$

$$|p_i(0)| = 1 \quad \text{while } q_i(0) = 0.$$

For these arcs, $\{(p_i(0), q_i(0), x_i(0))\}$ is a bounded set (by (h_4)). Since $\partial \mathcal{H}$ is a multifunction satisfying the hypotheses of Proposition 1.2, a subsequence (which we do not relabel) of $\{(p_i, q_i, x_i)\}$ converges uniformly to an arc (p, q, x) on some interval $[0, T]$ $(T \geqq T_0)$ such that x is admissible for P(0) and $(-\dot{p}, -\dot{q}, \dot{x}) \in \partial \mathcal{H}(x, 0, p)$ a.e. on $[0, T]$. Thus the sequence h_i also converges to some constant h such that $\mathcal{H}(x(t), 0, p(t)) = h$ on $[0, T]$. The note above implies that $f(T, x(0), x(T), 0) \leqq V(0)$, so that x actually solves problem P(0): the problem with this is that hypothesis (H8) allows us to take the limit of the transversality condition above and deduce that

$$(h, p(0), -p(T), q(T)) \in N_S(T, x(0), x(T), 0).$$

This contradicts the nondegeneracy of problem P(α), since $|p(0)| = 1$ while $q(0) = 0$ and $\lambda = 0$. So we must indeed have $\lambda_i = 1$ for all i sufficiently large.

Likewise, the sequence $\{p_i(0)\}$ must be bounded. Otherwise, there would be a subsequence along which $|p_i(0)| \to +\infty$ (we do not relabel). Scaling the arcs (h_i, p_i, q_i) by the factor $|p_i(0)|^{-1}$ gives a sequence of solutions and "multipliers" obeying

$$(-\dot{p}_i(t), -\dot{q}_i(t), \dot{x}_i(t)) \in \partial \mathcal{H}(x(t), \alpha_i, p_i(t)) \quad \text{a.e. on } [0, T],$$

$$\mathcal{H}(x_i(t), \alpha_i, p_i(t)) = h_i \quad \text{on } [0, T_i],$$

$$(h_i, p_i(0), -p_i(T_i), -q_i(T_i)) \in \lambda \frac{u_i}{|(\beta_i, u_i)|} \frac{\zeta_i}{|p_i(0)|} + N_S(T_i, x_i(0), x_i(T_i), \alpha_i),$$

$$|p_i(0)| = 1 \quad \text{and} \quad q_i(0) = \frac{-\lambda u_i}{|(\beta_1, -u_i)|} \frac{1}{|p_i(0)|} \to 0.$$

Passing to a uniformly convergent subsequence of $\{(p_i, q_i, x_i)\}$ by Proposition 1.2 leads once again to a solution $x: [0, T] \to \mathbf{R}^n$ for problem P(0) and an arc (p, q) with $|p(0)| = 1$ but $q(0) = 0$. The limit of the transversality condition above shows that (H9) is violated. Thus $\{p_i(0)\}$ is bounded.

Therefore the sequence $\{(p_i(0), q_i(0), x_i(0))\}$ is bounded as it stands, and $\lambda_i = 1$ for all sufficiently large i. A final application of Proposition 1.2 yields a subsequence of $\{(p_i, q_i, x_i)\}$ which converges uniformly to a solution x for problem P(0), and the adjoint arc (p, q) described in the conclusions of the lemma. (This last limiting argument depends upon the fact that since f is locally Lipschitz, the multifunction ∂f is upper semicontinuous, hence closed. See [4, Prop. 2.1.5].) □

Lemma 3.7 allows us to prove that $(\beta_0, -u_0)$ lies in $N_1 \cup N_2$. Suppose first that $u_0 \neq 0$. Upon scaling the arc (h, p, q) by $1/u_0$ in conclusions (a)-(e) and renaming the resulting adjoint arcs as (h, p, q), we obtain a multiplier of index 1 for the solution $x(\cdot)$, with $-q(p) = \beta_0/u_0$. But by construction,

$$u_0\left(\frac{\beta_0}{u_0}, -1\right) = (\beta_0, -u_0) \in N_{\text{epi } V}(0, V(0)),$$

so $-q(0) = \beta_0/u_0$ lies in $\partial V(0)$. In other words,

$$\frac{\beta_0}{u_0} \in Q[M^1(Y)] \cap \partial V(0),$$

i.e. $(\beta_0, -u_0) \in N_1$.

Second, assume $u_0 = 0$. Then (h, p, q) is an adjoint arc associated with an index 0 multiplier for the solution $x(\cdot)$, and $-q(0) = \beta_0$. Since $(\beta_0, 0)$ lies in $N_{\text{epi } V}(0, V(0))$ by construction, we also have $\beta_0 \in \partial^\infty V(0)$. Hence $\beta_0 \in Q[M^0(Y)] \cap \partial^\infty V(0)$ and $(\beta_0, 0) \in N_2$.

We have finally established that $N_{\text{epi } V}(0, V(0)) \subseteq \overline{\text{co}}(N_1 \cup N_2)$. Since the reverse inclusion is obvious, equality holds. Only one technical verification remains in the proof of Theorem 3.3.

LEMMA 3.8. *The set* $Q[M^0(Y)] \cap \partial^\infty V(0)$ *contains the recession cone of the set* $Q[M^1(Y)] \cap \partial V(0)$.

Proof. Recall that the recession cone of a set C in $\mathbf{R}^m$ is the cone

$$0^+C := \left\{ \lim_{i\to\infty} \delta_i y_i : y_i \in C, \delta_i \downarrow 0 \right\}.$$

Since $\partial^\infty V(0)$ automatically contains $0^+ \partial V(0)$, it suffices to prove that $Q[M^0(Y)]$ contains $0^+Q[M^1(Y)]$. Any element q of the latter set must be obtained as $q = \lim_{i\to\infty} -\delta_i q_i(0)$ for a sequence of solutions $x_i : [0, T_i] \to \mathbf{R}^n$ for P(0) with corresponding multipliers (p_i, q_i, ζ_i) of index 1 and a sequence of scalars $\delta_i \downarrow 0$. When we replace $(\delta_i h_i, \delta_i p_i, \delta_i q_i)$ by (h_i, p_i, q_i) in conditions (a)-(d) defining a multiplier, the Hamiltonian inclusion is unchanged and the transversality condition takes the form

$$(h_i, p_i(0), -p_i(T_i), -q_i(T_i)) \in \lambda \delta_i \zeta_i + N_S(T_i, x_i(0), x_i(T_i), 0).$$

Under this scaling, we have $q = \lim_{i\to\infty} -q_i(0)$. In particular, $\{q_i(0)\}$ is a bounded sequence. Now the sequence $\{x_i(0)\}$ is bounded by (H4), and the sequence $\{p_i(0)\}$ is bounded by an argument identical to that of Lemma 3.7. Hence the arcs $\{(p_i, q_i, x_i)\}$ have a uniformly convergent subsequence by Proposition 1.2. Since $\delta_i \downarrow 0$, the limit of this subsequence is an arc (p, q, x) on some interval $[0, T]$ for which x solves P(0) and (p, q) is an adjoint pair satisfying the limiting transversality condition

$$(h, p(0), -p(T), -q(T)) \in N_S(T, x(0), x(T), 0).$$

Moreover, one has $q = \lim_{i\to\infty} -q_i(0) = -q(0)$. That is, q lies in $Q[M^0(Y)]$ as required. □

The proof of Theorem 3.3 is complete.

4. Example: sensitivity to discount rate. In this section we apply Theorem 3.3 to a well-known optimal control problem. The discussion illustrates the theorem's utility and also demonstrates how it can be applied to many nonautonomous, fixed-time problems by introducing auxiliary state variables.

The model. Consider a factory whose productive capacity at time t is $x(t)$. At each instant, a certain fraction $u(t)$ of the factory's output may be reinvested to increase its capacity for production: the capacity then grows according to the law $\dot{x}(t) = u(t)x(t)$. The remaining output is to be sold at a fixed price: hence the total profits over the preassigned time interval $[0, \tau]$ amount to $\int_0^\tau (1 - u(t))x(t)\, dt$. The manager's objective is to maximize his company's profit over the time period $[0, \tau]$ by judicious choice of

the fraction $u(t)$ in $[0, 1]$. It can be posed as follows:

$$\min\left\{\int_0^\tau (u(t)-1)x(t)\,dt : \dot{x}(t)=u(t)x(t) \text{ a.e. on } [0,\tau],\right.$$
$$\left. 0\leqq u(t)\leqq 1 \text{ on } [0,\tau],\ x(0)=c>0\right\}.$$

To keep the problem interesting, we assume the given stopping time t exceeds 1.

We will use Theorem 3.3 to investigate the marginal loss of revenue incurred when a discount rate $\alpha>0$ forces the inclusion of the factor $e^{-\alpha t}$ in the objective integrand. This loss is measured by the function

$$V(\alpha) := \min\left\{\int_0^\tau e^{-\alpha t}(u(t)-1)x(t)\,dt : \dot{x}(t)=u(t)x(t) \text{ a.e. on } [0,\tau],\right.$$
$$\left. 0\leqq u(t)\leqq 1,\ x(0)=c>0\right\},$$

which measures the negative of the factory's profit under the optimal reinvestment policy.

Sensitivity analysis. The control problem defining $V(\alpha)$ can be solved directly by the Maximum Principle. After some calculation, one can define a switching time $\tau_s=\tau+1/\alpha \log(1-\alpha)$ and discover the optimal strategy $u(t)=1_{[0,\tau_s]}(t)$. The value of the optimal policy comes to $V(\alpha)=-c(1-\alpha)^{(1-\alpha)/\alpha}\,e^{(1-\alpha)\tau}$. L'Hospital's rule gives $V(0)=-c\,e^{\tau-1}$ and $V'(0)=c(\tau-\frac{1}{2})\,e^{\tau-1}$.

To calculate $\partial V(0)$ using Theorem 3.3, we must express V as the value function of a differential inclusion problem. This can be done by introducing new states x_0 (which measures the time) and x_1 (which accumulates the objective integral) so that the state space is $X=[-1,\tau+1]\times\mathbf{R}^2\subseteq\mathbf{R}^3$, and defining

$$F(x_0,x_1,x,\alpha) := \{(1, e^{-\delta x_0}(1-v)x, vx) : v\in[0,1]\},$$
$$f(T,x_0,x_1,x,y_0,y_1,y,\alpha) := -y_1,$$
$$S := \{\tau\}\times\{(0,0,c)\}\times\mathbf{R}^3\times\mathbf{R}.$$

Then clearly

$$V(\alpha)=\min\{f(T,x_0(0),x_1(0),x(0),x_0(T),x_1(T),x(T),\alpha):$$
$$(\dot{x}_0,\dot{x}_1,\dot{x})\in F(x_0,x_1,x,\alpha) \text{ a.e. on } [0,T],$$
$$(T,x_0(0),x_1(0),x(0),x_0(T),x_1(T),x(T),\alpha)\in S\}.$$

Hypotheses (H1)-(H8) are evidently satisfied by these data, and (H9) will be verified shortly. The Hamiltonian for this perturbed problem is

$$\mathcal{H}(x_0,x_1,x,\alpha,p_0,p_1,p)=\max\{\langle(p_0,p_1,p),(1,e^{-\alpha x_0}(1-v)x,vx)\rangle : 0\leqq v\leqq 1\}$$
$$=p_0+\max\{px, p_1 x\,e^{-\alpha x_0}\}.$$

At any base point $s\in S$, $N_S(s)=\mathbf{R}\times\mathbf{R}^3\times\{(0,0,0)\}\times\{0\}$; also $\partial f(r)=(0,0,0,0,0,-1,0,0)$ for all r.

The formula for $\partial V(0)$ given by Theorem 3.3 involves only multipliers corresponding to solutions of P(0)—the easy problem in which $\alpha=0$. Suppose, therefore, that $(x_0,x_1,x):[0,\tau]\to\mathbf{R}^3$ is an admissible arc for P(0) with a corresponding index λ

multiplier (p_0, p_1, p, q, ζ). Then the transversality condition

$$(h, p_0(0), p_1(0), p(0), -p_0(\tau), -p_1(\tau), -p(\tau), -q(\tau))$$
$$\in \lambda(0, 0, 0, 0, 0, -1, 0, 0) \times \mathbf{R} \times \mathbf{R}^3 \times \{(0, 0, 0)\} \times \{0\}$$

implies that $p_1(\tau) = \lambda$ while $p_0(\tau) = p(\tau) = q(\tau) = 0$. Since $\mathscr{H}$ has no x_1-dependence, the Hamiltonian inclusion implies that $\dot{p}_1 = 0$ a.e. on $[0, \tau]$, whence $p_1 \equiv \lambda$ on $[0, \tau]$. Thus the Hamiltonian inclusion becomes

$$(-\dot{p}_0, -\dot{p}_1, -\dot{p}, -\dot{q}, \dot{x}_0, \dot{x}_1, \dot{x}) \in \begin{cases} (0, 0, \lambda, -\lambda x_0 x, 1, x, 0) & \text{if } p < \lambda, \\ (0, 0, p, 0, 1, 0, x) & \text{if } p > \lambda, \\ \text{convex hull of these} & \text{if } p = \lambda. \end{cases}$$

Hence $p_0(t) \equiv p_0(\tau) = 0$.

Note that $\lambda = 0$ implies $\dot{q} = 0$ so $q \equiv 0$; also, $p_1 \equiv \lambda = 0$. By Gronwall's inequality, $p \equiv 0$ when $\lambda = 0$. Thus $\lambda = 0$ implies $(p_0, p_1, p) \equiv 0$ for any arc x: in particular, (H9) holds and $Q[M^0(Y)] = \{0\}$.

Now that (H1)-(H9) are verified, Theorem 3.3 applies. Corollary 2 asserts that any solution for P(0) has an index λ multiplier with $\lambda + |q(0)| > 0$. We have just seen that this condition must fail if $\lambda = 0$, so any multiplier corresponding to a solution must have $\lambda = 1$. Then $p(\tau) = 0 < \lambda$ implies that $\dot{p} = -1$ on $(\tau - 1, \tau]$ and $\dot{p} = -p$ on $[0, \tau - 1)$. Consequently $\dot{x} = x$ on $[0, \tau - 1)$ and $\dot{x} = 0$ on $(\tau - 1, \tau]$, while $\dot{x}_1 = 0$ on $[0, \tau - 1)$ and $\dot{x}_1 = x(\tau)$ on $(\tau - 1, \tau]$. We also obtain $\dot{q} = 0$ on $[0, \tau - 1)$ and $\dot{q} = tx(t)$ on $(\tau - 1, \tau]$. Integrating these equations gives the unique multiplier of index 1 for problem P(0):

$$p(t) = \begin{cases} e^{(\tau-1)-t} & \text{on } [0, \tau - 1), \\ \tau - t & \text{on } [\tau - 1, \tau], \end{cases}$$

$$q(t) = \begin{cases} c(\tfrac{1}{2} - \tau)\, e^{\tau-1} & \text{on } [0, \tau - 1), \\ \tfrac{1}{2} c\, e^{\tau-1}(t^2 - \tau^2) & \text{on } [\tau - 1, \tau]. \end{cases}$$

Thus multiplier corresponds to an arc (x_0, x_1, x) which must be the unique solution to P(0), where $x_0(t) = t$ and

$$x_1(t) = \begin{cases} 0 & \text{on } [0, \tau - 1), \\ c\, e^{\tau-1}(t - \tau + 1) & \text{on } [\tau - 1, \tau], \end{cases}$$

$$x(t) = \begin{cases} c\, e^{t} & \text{on } [0, \tau - 1), \\ c\, e^{\tau-1} & \text{on } [\tau - 1, \tau]. \end{cases}$$

Hence $V(0) = -x_1(\tau) = -c\, e^{\tau-1}$ and $Q[M^1(Y)] = \{-q(0)\} = \{c(\tau - \frac{1}{2})\, e^{\tau-1}\}$. Theorem 3.3 asserts that $\partial V(0) = \{c(\tau - \frac{1}{2})\, e^{\tau-1}\}$, as expected.

5. The minimal time function.

The problem. The standard minimum time problem in optimal control theory requires that the state of a given dynamical system be steered to its nominal value, say 0, from some given initial state $\alpha \neq 0$ in the least possible time. Of course, different initial values α generally require different control strategies and take different times to reach the origin. In a differential inclusion formulation, this variation defines a function $T: \mathbf{R}^n \to \mathbf{R} \cup \{+\infty\}$ via

$$T(\alpha) := \min \{T : \dot{x}(t) \in F(x(t)) \text{ a.e. on } [0, T],\ x(0) = \alpha,\ x(T) = 0\}.$$

$T(\alpha)$ assumes the value $+\infty$ iff there is no possibility of steering α to 0. Thus the very

finiteness of T is related to controllability properties of the system, a fact which we shall exploit presently. The other issues we shall discuss are the differential properties of T (or equivalently, the sensitivity of the problem with respect to the initial state), and the behaviour of T at the origin.

The function T has received attention especially in the *linear case* [1], [8], [9], [16], [17], in which $F(x)$ is of the form $Ax+BU$ for an $n\times n$ matrix A, an $n\times m$ matrix B, and a compact convex subset U of $\mathbf{R}^m$ (i.e., the case of a standard linear control system $\dot{x}=Ax+Bu$, $u\in U$). We shall recover in this section many of the results for the linear problem, but more importantly we shall develop a methodology for the much more complex nonlinear case. (See [3], [11], [18], [19], [21] for somewhat related results in a nonlinear setting.) An important issue here is the continuity of T at the origin. It is possible for T to be finite everywhere and yet not go to zero as α approaches zero.

An example of this situation can be based upon the vector field $\psi:\mathbf{R}^2\to\mathbf{R}^2$ defined by $\psi(x,y)=(\theta(y),0)$, where

$$\theta(y):=\max\{0,\min(1,2-y)\};$$

the nature of ψ is indicated in Fig. 1. We define a multifunction consistent with our hypotheses via

$$F(x,y):=\{\psi(x,y)+(u,v):|u|\leqq 1,|v|\leqq 1\}.$$

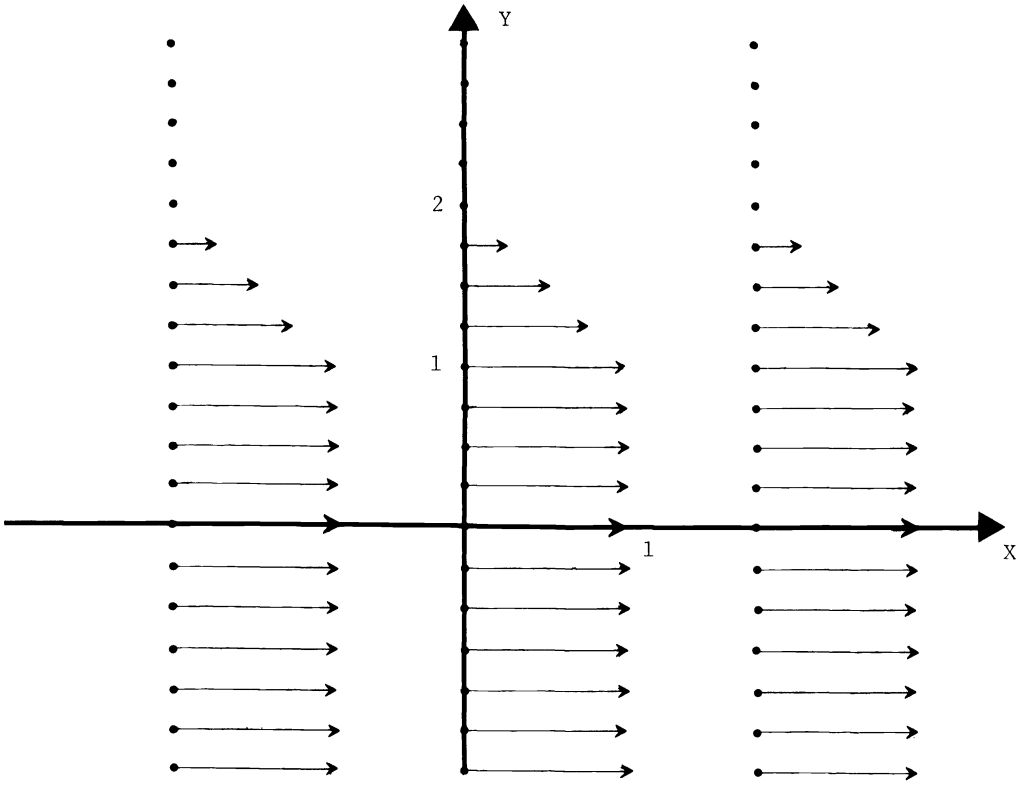

FIG. 1

We can think of ψ as the current in a river, and of (u, v) as the natural velocity of a boat; thus $F(x, y)$ is the set of possible resultant velocities depending on the steering angle. It is easy to see that starting from points $(0, -r)$ (for $r > 0$) the origin can be reached in time r, whereas, for some positive m, it is the case that from points $(\varepsilon, -r)$, for any $\varepsilon > 0$, it will require time in excess of $r + m$ to reach the origin. Thus T is discontinuous at 0 despite being finite everywhere. (Note also that $0 \in F(0)$: this hypothesis figures in some of the results below.)

The generalized gradient of T. Let us fix $\alpha_0 \in \mathbf{R}^n \backslash \{0\}$ with the property that $T(\alpha_0) < +\infty$. We posit the usual hypotheses (H1)-(H3) regarding F; these simplify somewhat because now F does not depend on α. Upon fixing any $M > T(\alpha_0)$, we may define

$$S := \{(m, \alpha_0 + \alpha, 0, \alpha) : m \in [0, M],\ \alpha \in \bar{B}\}$$

and in doing so recognize that the minimal time problem is a special case of P(0) for (H4)-(H6) are satisfied. The problem defining $T(\alpha_0)$ (namely, P(0)) admits a solution by Proposition 1.3; we adopt the hypothesis that all solutions lie in the interior of X, which gives (H7) (and implies that $0 \in \operatorname{int} X$ necessarily). It turns out that (H8) is automatically satisfied for this problem, since $N_S(s)$ is given by $\{(0, \beta, v, -\beta) : v \in \mathbf{R}^n, \beta \in \mathbf{R}^n\}$ for any s in rel int S.

Let us now examine multipliers corresponding to a trajectory $x: [0, T] \to \mathbf{R}^n$ obeying $x(0) = \alpha_0$, $x(T) = 0$. A multiplier of index λ corresponding to x consists of a triple (p, q, ζ) obeying

(a) $\dot{q}(t) = 0$ and $(-\dot{p}(t), \dot{x}(t)) \in \partial H(x(t), p(t))$ a.e. on $[0, T]$, where $H(x, p) := \sup\{\langle p, v\rangle : v \in F(x)\}$;

(b) $H(x(t), p(t)) = h$ on $[0, T]$, for some constant h;

(c) $\zeta \in \{(1, 0, 0, 0)\} = \partial f(T, \alpha_0, 0, 0)$;

(d) $(h, p(0), -p(T), -q(T)) \in \lambda(1, 0, 0, 0) + \{(0, \beta, v, -\beta) : \beta \in \mathbf{R}^n,\ v \in \mathbf{R}^n\}$.

Condition (d) implies $h = \lambda$ and $q(T) = p(0)$, so we have $q \equiv p(0)$ by (a). Moreover, $q = 0$ implies $p(0) = 0$, whence $p \equiv 0$ by Gronwall's inequality: thus (H9) holds.

We have now shown that an element of $M^\lambda(x)$, a multiplier of index λ corresponding to x, is in essence an arc p satisfying

$$(-\dot{p}(t), \dot{x}(t)) \in \partial H(x, p) \quad \text{a.e. on } [0, T], \tag{1}$$

$$H(x(t), p(t)) = \lambda \quad \text{on } [0, T]. \tag{2}$$

Since we have verified all the hypotheses, we may deduce from Theorem 3.3 the following result.

THEOREM 5.1. *One has*

$$\partial T(\alpha_0) = \overline{\operatorname{co}}\{Q[M^1(Y)] \cap \partial T(\alpha_0) + Q[M^0(Y)] \cap \partial^\infty T(\alpha_0)\},$$

where Y is the set of solutions to the minimal time problem beginning at α_0, and where $Q[M^\lambda(Y)]$ signifies the set

$$\bigcup_{x \in Y} \{-p(0) : \text{the arc } (x, p) \text{ satisfies (1) and (2)}\}.$$

If $Q[M^0(Y)]$ is pointed, the closure operation is unnecessary and one also has

$$\partial^\infty T(\alpha_0) = \operatorname{co}\{Q[M^0(Y)] \cap \partial^\infty T(\alpha_0)\}.$$

Normality. As in the case of Theorem 3.3, a variety of consequences can be drawn from these formulas. We shall limit ourselves here to those bearing upon the Lipschitz character of T. An arc x admissible for P(α_0) is temed *normal* if whenever conditions (1) and (2) hold with $\lambda = 0$, then $p \equiv 0$; i.e. if the only multiplier of index 0 for x is

the trivial one. The problem $P(\alpha_0)$ itself is termed *normal* if every solution x in Y is normal; i.e., if $Q[M^0(Y)] = \{0\}$. Theorem 5.1 then yields the following.

COROLLARY 1. *If* $P(\alpha_0)$ *is normal, then* T *is Lipschitz near* α_0, *and* $\partial T(\alpha_0)$ *is a compact convex set obeying*

$$\operatorname{ext}\{\partial T(\alpha_0)\} \subseteq Q[M^1(Y)].$$

(In the terminology of [4], [5], this implies that "normal problems are calm.")

DEFINITION 5.2. The *abnormal set* S is the set of all points $x(\tau)$ where, for some $\tau > 0$, there exists an arc $(x, p):[0, \tau] \to \mathbf{R}^n \times \mathbf{R}^n$ with p not identically zero, such that

(i) $x(0) = 0$, $x(t) \in \operatorname{int} X$;

(ii) $(-\dot{p}(t), \dot{x}(t)) \in -\partial H(x(t), p(t))$ a.e. on $[0, \tau]$;

(iii) $H(x(t), p(t)) = 0$ on $[0, \tau]$.

By convention, we shall also allow $\tau = 0$ above, so that S always contains the origin. Observe that after time reversal, S is the set of states reachable from the origin via abnormal F-trajectories (condition (ii) implies $\dot{x}(t) \in -F(x(t))$ a.e.).

COROLLARY 2. *If the point* α_0 *of Theorem* 5.1 *lies in the complement of* S, *then* T *is Lipschitz near* α_0.

Proof. The problem $P(\alpha_0)$ is normal, for if x on $[0, T]$ were any abnormal solution to $P(\alpha_0)$ and p its associated multiplier, then the arc $(\tilde{x}(t), \tilde{p}(t)) := (x(T-t), p(T-t))$ would satisfy the conditions of Definition 5.2, contradicting $\alpha_0 \notin S$. The result follows from Corollary 1. □

The set S thus provides an estimate of the initial conditions for which T is badly behaved (i.e., non-Lipschitz). We shall be able to study the "smallness" of S following a discussion of the behaviour of T at the origin.

Behaviour at the origin. We shall henceforth assume that $0 \in F(0)$. This implies that the zero arc is an F-trajectory.

DEFINITION 5.3. We shall say *the origin is normal* if for all positive T sufficiently small, the zero arc on $[0, T]$ is normal.

To paraphrase, the origin is normal if for T small enough, it is not possible to find a nontrivial arc p satifying on $[0, T]$ the conditions

$$(-\dot{p}(t), 0) \in \partial H(0, p(t)) \quad \text{a.e.,} \tag{3}$$

$$H(0, p(t)) = 0. \tag{4}$$

(By reversing time, it is equivalent to consider $(\dot{p}, 0) \in \partial H(0, p)$ in (3).) We recall [4] that a locally Lipschitz function φ is called *regular* at u provided that for all v the usual one-sided directional derivative $\varphi'(u; v)$ exists and coincides with the generalized directional derivative $\varphi^\circ(u; v)$. Among others, smooth and convex functions are regular. It follows from [4, Thm. 2.8.2] that H is regular when F admits a smooth classical relaxed representation.

The following result asserts that by and large the abnormal set will be nontrivial unless 0 lies in the interior of $F(0)$.

PROPOSITION 5.4. *If* $0 \in \operatorname{int} F(0)$, *then* $S = \{0\}$ *and the origin is normal*; *moreover,* T *is Lipschitz on a neighbourhood of* 0. *Conversely, when the origin is normal and* H *is regular on* $\{0\} \times \mathbf{R}^n$, *then* $S = \{0\}$ *implies* $0 \in \operatorname{int} F(0)$.

Proof. Suppose that $0 \in \operatorname{int} F(0)$. Then $H(0, p(0)) = 0$ implies $p(0) = 0$, so that (since $|\dot{p}| \leqq K|p|$) any arc (x, p) satisfying (i)-(iii) of Definition 5.2 has p identically zero. Thus $S = \{0\}$ and the origin is normal.

To verify that T is Lipschitz near 0, observe that the Lipschitz character of F implies that there exists $\delta > 0$ for which $\delta \bar{B} \subseteq F(\alpha)$ for all α in δB. Hence there is a

constant $M>0$ such that for all α in δB, $H(\alpha, p(0))=1$ implies $|-p(0)| \leqq M$. By Theorem 5.1, $\partial T(\alpha) \subseteq M\bar{B}$ for all nonzero α in δB. We will see below (Thm. 5.6) that T is continuous at 0. This allows us to verify that T is Lipschitz of rank $M+1$ throughout δB.

For the converse, suppose that 0 fails to lie in int $F(0)$. We need to show that S does not reduce to $\{0\}$. The normal cone to $F(0)$ contains a nonzero element ζ: $H(0, \zeta)=0$. Consider the differential inclusion initial-value problem

$$(-\dot{p}(t), \dot{x}(t)) \in -\partial H(x(t), p(t)), \qquad (x(0), p(0))=(0, \zeta).$$

Since ∂H is compact convex-valued and upper semicontinuous [4], standard existence results imply the local existence of a solution (x necessarily remains in int X for t near 0.) Then the regularity of H applies [4, Prop. 7.7.1] to yield $H(x, p)=$ *constant* $=H(0, p(0))=H(0, \zeta)=0$. But the origin is normal, so $x(t) \neq 0$ for $t>0$: this proves that S contains nonzero points. □

The following shows that under certain smoothness hypotheses S can be shown to consist of a curve through the origin. (It seems that S often coincides with the "switching curve" of an optimal synthesis of the prolem, but no formal result of that type is yet known to us.) A function is said to be C^{1+} if it is differentiable and its derivative is locally Lipschitz. Zeidan [23, Thm. 3] has given conditions assuring that the Hamiltonian of a control problem be C^{1+}.

PROPOSITION 5.5. *Suppose that $H(x, p)$ is C^{1+} on $X \times (\mathbf{R}^n \backslash \{0\})$, and that the normal cone to $F(0)$ at 0 is contained in the line $\mathbf{R}\zeta$ for some ζ in $\mathbf{R}^n$. Then for some (non-degenerate) interval $[a, b]$ containing 0, S is of the form*

$$\{s(t): a \leqq t \leqq b\},$$

where $s(0)=0$, s is continuous at 0, and s is C^1 in (a, b) except perhaps at 0. (We allow the cases $a=-\infty$ and $b=+\infty$.)

Proof. Consider (x, p) as in Definition 5.2. (If no such (x, p) exist, then $S=\{0\}$ and we simply take $s \equiv 0$.) Since $H(0, p(0))=0$, we can assume (by scaling p) that $p(0)$ is either ζ or $-\zeta$. If $\zeta=0$ then $0 \in$ int $F(0)$, which implies $S=\{0\}$ (Prop. 5.4). So suppose $\zeta \neq 0$, and consider first the possible case $p(0)=\zeta$. Then there exists a local solution to the initial-value problem

$$(-\dot{p}(t), \dot{x}(t))=\nabla H(x(t), p(t)), \qquad (x(0), p(0))=(0, \zeta).$$

Since the Hamiltonian has the constant value $H(0, \zeta)=0$ along such a solution, the curve $x(t)$ traces out points of S until it leaves X (if ever). In a similar fashion, the case $p(0)=-\zeta$ may produce another branch of S. The required representation of S now follows readily. □

We now see that normality of the origin rules out the type of behaviour exhibited by the example illustrated by Fig. 1.

THEOREM 5.6. *If the origin is normal, then T is finite in a neighbourhood of* 0, *and continuous at* 0.

Proof. We shall define a new family of problems P(α) of the type discussed in § 3, one for which x belongs to $\mathbf{R}^{n+1}$. We shall use the notation (y, z) to express x as a point in $\mathbf{R}^n \times \mathbf{R}$. The data of problem (P) are:

$f(T, x_0, x_T) := z_T+(T-b)^2$, where $x_T=(y_T, z_T)$ and b is a given positive number chosen so small that the zero is normal on $[0, b]$;

$\tilde{F}(x) := F(y) \times \{|y|\}, \qquad \tilde{X}=X \times \mathbf{R},$

$S := \{(T, \alpha, 0, 0, \beta, \alpha) \in \mathbf{R} \times \mathbf{R}^{n+1} \times \mathbf{R}^{n+1} \times \mathbf{R}^n : \frac{1}{2}b \leqq T \leqq 2b, |\alpha| \leqq 1, \text{any } \beta\}.$

(The reader may find it helpful to view the problem $P(\alpha)$ in an equvalent form: to minimize $(b-T)^2+\int_0^T |y(t)|\,dt$ over the trajectories y for F on an interval $[0, T]$ satisfying $y(0)=\alpha$, $y(T)=0$.) It is evident that the unique solution to $P(0)$ is $x\equiv 0$ on $[0, b]$.

We now claim that this arc is normal. We calculate (for $p=(r, s)$ in $\mathbf{R}^n\times\mathbf{R}$)

$$\tilde{H}(x, \alpha, p)=H(y, r)+s|y|.$$

A multiplier of index 0 corresponding to the zero arc on $[0, b]$ therefore consists of an arc (r, s, q) satisfying on $[0, b]$ the conditions:

$$(-\dot{r}(t), 0)\in\partial H(0, r(t))+s\bar{B}\times\{0\},\quad \dot{s}(t)=0,\quad \dot{q}(t)=0 \quad \text{a.e.},$$

$$H(0, r(t))=h,\qquad (h, r(0), s(0), -r(b), -s(b), -q(b))\in N_S(b, x(0), x(b), 0).$$

The last of these conditions gives $h=0$, $r(0)=q(b)$, $s(b)=0$. It follows that s is identically zero, so that r satisfies on $[0, b]$

$$(-\dot{r}(t), 0)\in\partial H(0, r) \quad \text{a.e.},\qquad H(0, r(t))=0.$$

Since the origin is normal, our choice of b implies that r is zero on $[0, b]$. Then $q(b)=r(0)=0$, which together with $\dot{q}=0$ a.e. implies that q is 0 too. Hence (r, s, q) is zero, which confirms that the only multiplier of index 0 is the trivial one, as stated. (This incidentally implies hypothesis (H9) of § 3; the other hypotheses are readily confirmed.) We now apply Corollary 1 of Theorem 3.3 to deduce that the value function $V(\alpha)$ corresponding to the above problem is finite and Lipschitz near 0. For some $\delta>0$, this certainly implies the existence, for all $|\alpha|\leqq\delta$, of an admissible trajectory y for F on an interval $[0, \tau]$ satisfying $\tau\leqq 2b$, $y(0)=\alpha$, $y(\tau)=0$, whence we deduce $T(\alpha)\leqq 2b$. (Of course, δ depends on b.) Given $\varepsilon>0$, choose any b in $(0, \varepsilon/2)$, and let the above conclusions hold for that b, for all $|\alpha|\leqq\delta$. Then $|\alpha|<\delta$ implies $T(\alpha)\leqq 2b<\varepsilon$ and we have shown that T is continuous at 0. □

Remark. A simple example in which the origin is normal yet for which T is not Lipschitz at 0 (albeit continuous) is the well-known instance of the linear case $F(x)=Ax+BU$ in which

$$A=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix},\quad B=\begin{pmatrix}0\\ 1\end{pmatrix},\quad U=[-1, 1].$$

The origin is normal by Corollary 2 below; calculation shows

$$T(x, y)=\begin{cases}-y+[2y^2-4x]^{1/2} & \text{if } 2x\leqq -y|y|,\\ y+[2y^2+4x]^{1/2} & \text{if } 2x\geqq -y|y|.\end{cases}$$

This function fails to be Lipschitz along

$$S=\{(x, y)\colon 2x+y|y|=0\},$$

the abnormal set and also the switching curve for the optimal synthesis.

Controllability. We now proceed to explore some controllability implications of Theorem 5.6. The proof showed that T is finite near 0, whence:

COROLLARY 1. *If the origin is normal, then there is a neighbourhood of* 0 *all of whose points can be steered to* 0 *in finite time.*

We now show that Corollary 1 can be viewed as an extension of the well-known result in linear control theory (see for example [12]) that gives a criterion for controllability in terms of the rank of the controllability matrix

$$C=[B\quad AB\quad A^2B\quad \cdots\quad A^{n-1}B].$$

Suppose that $F(x)$ is of the form $\varphi(x)+BU$, where $\varphi: \mathbf{R}^n \to \mathbf{R}^n$ is C^1, $\varphi(0)=0$, B is $n \times m$, and U is a compact convex subset of $\mathbf{R}^m$ containing 0 in its interior. Construct the $n \times mn$ matrix C as indicated above, where $A = D\varphi(0)$.

COROLLARY 2. *The controllability matrix C has full rank (i.e., n) if and only if the origin is normal. When this is the case, all points in a neighbourhood of 0 can be steered to 0 in finite time, and T is continuous at 0.*

Proof. The origin fails to be normal if and only if there is a nonvanishing arc p defined on some interval $[0, T]$ and obeying

$$(-\dot{p}(t), 0) \in \partial H(0, p(t)) \quad \text{a.e.}, \qquad H(0, p(t)) = 0.$$

Since $H(x, p)$ is given by $\langle \varphi(x), p\rangle + \max\{\langle p, Bu\rangle : u \in U\}$ in this setting, these conditions are equivalent to

$$-\dot{p}(t) = A^* p(t) \quad \text{a.e.}, \qquad B^* p(t) \equiv 0.$$

Defining $p_0 = p(0)$, we find that the origin fails to be normal if and only if there is a nonzero vector p_0 such that for some $T > 0$,

$$B^* e^{-A^* t} p_0 \equiv 0 \quad \text{on } [0, T]. \tag{5}$$

Now if the origin is not normal, then alternately setting $t = 0$ and computing d/dt in (5) shows that $p_0^* C = 0$, i.e. rank $(C) < n$. Conversely, if rank $(C) < n$ then there exists a nonzero vector p_0 such that $p_0^* C = 0$. This implies (5) via the Cayley-Hamilton theorem. □

Normality of the origin has been seen to be a useful property of a system; it is one that can often be confirmed on an ad hoc basis in specific cases. We now give an example of a criterion applicable to fully nonlinear systems. We suppose that $F(x)$ has a classic representation $\varphi(x, U)$, where $D_x\varphi(x, u)$ exists, φ and $D_x\varphi$ are continuous in (x, u), and U is compact.

COROLLARY 3. *Suppose that the normal cone to $F(0)$ at 0 is contained in the line $\mathbf{R}\zeta$ for some ζ, that 0 is an extreme point of $F(0)$, and that a unique $\hat{u} \in U$ exists such that $\varphi(0, \hat{u}) = 0$. Then, if ζ is not an eigenvector for $D_x^* \varphi(0, \hat{u})$, the origin is normal. Thus T is finite near 0 and continuous at 0. If in addition H is C^{1+} for $p \neq 0$, then T is Lipschitz near 0 except perhaps on a curve through the origin.*

Proof. If the origin is not normal, then there exists on some interval $[0, T]$ a nonvanishing arc p satisfying

$$(-\dot{p}(t), 0) \in \partial H(0, p(t)) \quad \text{a.e.}, \qquad H(0, p(t)) = 0.$$

Here we have $H(x, p) = \max\{\langle p, \varphi(x, u)\rangle : u \in U\}$, and by [4, Thm. 2.8.2] we deduce the existence of $n+1$ points u_i in U such that

$$0 = \sum_{i=1}^{n+1} \lambda_i \varphi(0, u_i),$$

$$-\dot{p}(t) = \sum_{i=1}^{n+1} \lambda_i D_x^* \varphi(0, u_i) p(t),$$

$$\langle p(t), \varphi(0, u_i)\rangle = H(0, p(t)) = 0 \text{ for each } i,$$

where the λ_i are nonnegative and sum to 1. Since each $\varphi(0, u_i)$ belongs to $F(0)$ and 0 is an extreme point, each $\varphi(0, u_i)$ equals 0, whence each u_i equals $\hat{u}$. The condition $H(0, p(t)) = 0$ implies that $p(t)$ belongs to $N_{F(0)}(0)$ for each t, whence $p(t) = \alpha(t)\zeta$

for some nonvanishing scalar function α. These conclusions lead to

$$\alpha(t)A^*\zeta = -\dot{\alpha}(t)\zeta,$$

which contradicts the hypothesis that ζ is not an eigenvector for A^*. The final assertion follows from Proposition 5.5. □

When F is globally defined (i.e., $X = \mathbf{R}^n$), we can combine Lyapunov stability and controllability near 0 in the usual way (see for example [12]) to obtain a global conclusion as follows.

COROLLARY 4. *Let there be a locally Lipschitz selection $f(x)$ for $F(x)$ such that $f(x) \cdot \nabla L(x) < 0$ for $x \neq 0$, where $L: \mathbf{R}^n \to \mathbf{R}$ is differentiable for $x \neq 0$ and the level sets $\{x: L(x) \leqq \alpha\}$ are compact for each α. Suppose in addition that the origin is normal. Then any point $\mathbf{R}^n$ can be steered to the origin in finite time.*

STRONG CONTROLLABILITY OF NONLINEAR SYSTEMS*

RONALD M. HIRSCHORN†

Abstract. The shape of the reachable set for an affine control system is studied by introducing trace vector fields, freely-controlled and semi-controlled vector fields. Properties of these classes of vector fields are established and they are related to the structure of the reachable set of states at time t. A method for generating semi-controlled vector fields from a trace vector fields and a freely-controlled vector field is presented.

Key words. controllability, affine systems

1. Introduction. The purpose of this paper is to study the shape of the reachable set for system models of the form

$$\frac{dx}{dt}(t) = A(x(t)) + \sum_{i=1}^{m} u_i(t) B_i(x(t)), \qquad x(0) = x_0 \in M \tag{1.1}$$

where M is a real analytic manifold, $A, B_1, \cdots, B_m$ are real analytic vector fields and the controls u_i are piecewise constant functions from $R^+ = [0, \infty)$ into $R = (-\infty, \infty)$. A state x_1 is said to be *reachable from* x_0 *at time* t_1 if for some choice of controls there is a solution $x_u(t)$ to (1.1) with $x_u(0) = x_0$ and $x_u(t_1) = x_1$. Let $\mathcal{R}_t(x_0)$ denote the set of states reachable from x_0 at time t, and set $\mathcal{R}(x_0) = \cup_{t \geqq 0} \mathcal{R}_t(x_0)$. In order to investigate the shape of the reachable set $\mathcal{R}(x_0)$, we introduce the idea of a *trace vector field* X, a vector field with the property that $X_t(x) \in \overline{\mathcal{R}_t(x)} \forall x \in M$ and $\forall t > 0$ where $X_t(x)$ is defined, i.e., the integral curve for X at time t is in the closure of reachable set at time t. The set $\mathcal{T}$ of trace vector fields of the system (1.1) yields information about the shape of the reachable set. The standard linear controllability results asserts that for the system $\dot{x} = Ax + Bu$ a vector field X belongs to $\mathcal{T}$ iff $X(x) = Ax + d(x)$ where $d(x) \in \text{range}\,[B \mid AB \mid \cdots \mid A^{n-1}B]$. It follows that $\mathcal{R}_t(x_0)$ includes $e^{tA}x_0 + \text{range}\,[B \mid AB \mid \cdots \mid A^{n-1}B]$.

For the system (1.1) it is clear that the "drift term" A belongs to $\mathcal{T}$, and the "controlled" vector fields B_i have the property that $A + \alpha B_i$ belongs to $\mathcal{T}$ for all real α (i.e., set $u_i \equiv \alpha_i$ and $u_j \equiv 0$ for $j \neq i$). The purpose of this paper is to describe a method for generating more vector fields in $\mathcal{T}$ by finding more "controlled" vector fields. A vector field X is said to be a *freely-controlled* vector field for the system (1.1) if $A + \alpha X$ belongs to $\mathcal{T}$ for all real α and *semi-controlled* if $A + \alpha X$ belongs to $\mathcal{T}$ for all $\alpha \geqq 0$. Thus in the linear case X is freely-controlled iff $X(x) \in \text{range}\,[B \mid AB \mid \cdots \mid A^{n-1}B]$ for all x in $M = R^n$, and every semi-controlled vector field is also freely controlled. In the nonlinear case there are often semi-controlled vector fields which are not freely-controlled. The problem of finding the reachable set for nonlinear systems has been studied by a number of authors (cf. Brockett [1], Hirschorn [5], Kunita [8], Sussmann and Jurdjevic [12], Jurdjevic and Kupka [9]). The work of Kunita [8] provided the motivation for this paper.

In § 2 some of the basic properties of semi and freely-controlled vector fields and their connections with the reachable set are presented. In § 3 a technique is described for generating semi-controlled vector fields from a freely-controlled vector field and a trace vector field.

2. Controlled vector fields and controllability. Let $V(M)$ denote the set of all real-analytic vector fields on M and $C^\omega(M)$ the ring of real analytic functions on M. We regard $V(M)$ as a Lie algebra over R with the Lie bracket $[X, Y] = XY - YX$ and let ad_X denote the linear operator on $V(M)$ defined by $\mathrm{ad}_X Y = [X, Y]$. If X is a vector field on M and $x \in M$, then $t \to X_t(x)$ denotes the *integral curve* of X through x, i.e., $X_0(x) = x$ and $(d/dt)X_t(x) = X(X_t(x))$. If $X_t(x)$ is defined for all t in R and for all $x \in M$, then X is said to be *complete*. If D is a subset of $V(M)$ then $\{D\}_{LA}$ will denote the smallest Lie subalgebra of $V(M)$ containing D and $D(x)$ is the subset $\{X(x) | X \in D\}$ of the tangent space of M at x.

The system (1.1) gives rise to the triple of Lie subalgebras $(\mathscr{L}, \mathscr{L}_0, \mathscr{B})$ where $\mathscr{B} = \{B_1, \cdots, B_m\}_{LA}$, $\mathscr{L} = \{A, B_1, \cdots, B_m\}_{LA}$ and $\mathscr{L}_0$ is the smallest ideal in $\mathscr{L}$ which contains $\mathscr{B}$. In [12] Sussmann and Jurdjevic relate some of basic qualitative properties of the reachable set to these Lie algebras. Let $\mathscr{D}$ be a Lie subalgebra of $V(M)$. Then $x \to \mathscr{D}(x)$ defines an involutive distribution on M and $I(\mathscr{D}, x)$ will denote the unique maximal connected integral manifold for this distribution containing x. The existence of $I(\mathscr{D}, x)$ is a consequence of a global version of Frobenius' theorem (cf. [11]). Sussmann and Jurdjevic [12] showed that the reachable set $\mathscr{R}(x)$ is contained in $I(\mathscr{L}, x)$ and, with respect to the topology of $I(\mathscr{L}, x)$, $\mathscr{R}(x)$ is contained in the closure of its interior. Also $\mathscr{R}_t(x)$ is contained in $I(\mathscr{L}_0, A_t(x))$ and $\mathscr{R}_t(x)$ is contained in the closure of its interior relative to the topology of $I(\mathscr{L}_0, A_t(x_0))$. This means that the closure of the reachable set has basically the same shape as the reachable set. The system (1.1) will be called *controllable* if $\mathscr{R}(x) = I(\mathscr{L}, x)$ for all $x \in M$ and *strongly controllable* if $\mathscr{R}_t(x) = I(\mathscr{L}_0, A_t(x))$ for all $x \in M$ and for all $t > 0$. For linear systems $I(\mathscr{L}_0, x) = x + \mathrm{range}\,[B \vdots AB \vdots \cdots \vdots A^{n-1}B]$, $A_t(x) = e^{tA}x$, so that every time-invariant linear system is strongly-controllable. A few nonlinear systems are known to be strongly-controllable (cf. [5], [8]) but this is not the usual case. In fact for most systems little is known about $\mathscr{R}_t(x)$ beyond the fact that the interior of $\mathscr{R}_t(x)$ is nonempty in $I(\mathscr{L}_0, A_t(x))$.

A more detailed picture of $\mathscr{R}_t(x)$ and $\mathscr{R}(x)$ is possible. A vector field $Y \in V(M)$ is called a *trace vector field* for the system (1.1) if $Y_t(x) \in \overline{\mathscr{R}_t(x)}$ for all $x \in M$ and for all $t > 0$ such that $Y_t(x)$ is defined, where $\overline{\mathscr{R}_t(x)}$ is the closure of $\mathscr{R}_t(x)$ relative to the topology of $I(\mathscr{L}_0, A_t(x))$. A vector field X is *semi (freely)-controlled* if $A + \alpha X$ is a trace vector field for all $\alpha > 0$ ($\alpha \in R$).

Let $\mathscr{T}$ denote the collection of all trace vector fields for (1.1), $\mathscr{F}$ the collection of freely-controlled vector fields, and $\mathscr{F}^+$ the semi-controlled vector fields for (1.1). One can obtain more quantitative information about the reachable set by examining the triple $(\mathscr{T}, \mathscr{F}^+, \mathscr{F})$. Some of the basic properties of $\mathscr{T}$, $\mathscr{F}^+$ and $\mathscr{F}$ are derived in the following:

LEMMA 2.1. *Consider the system* (1.1). *Then*:

a) *A vector field X belongs to $\mathscr{F}^+$ ($\mathscr{F}$) if and only if $A_t(X_s(x))$ is in the closure of $\mathscr{R}_t(x)$ for all $t > 0$, $s > 0$ ($s \in R$) and for all $x \in M$.*

b) *If $f_1, f_2, \cdots, f_k \in C^\omega(M)$ and $X_1, \cdots, X_k \in \mathscr{F}$ then $\sum_{i=1}^k f_i X_i \in \mathscr{F}$.*

c) *If $f_1, \cdots, f_k \in C^\omega(M)$ are nonnegative and $X_1, \cdots, X_k \in \mathscr{F}^+$ then $\sum_{i=1}^k f_i X_i \in \mathscr{F}^+$.*

d) *If $c_1, c_2, \cdots, c_k$ are nonnegative real numbers with $\sum_{i=1}^k c_i = 1$ and if $Y_1, \cdots, Y_k \in \mathscr{T}$ then $\sum_{i=1}^k c_i Y_i \in \mathscr{T}$.*

Proof. a) Let ε, $t > 0$ and let $X \in \mathscr{F}^+$. Then $(A + \alpha X)_t(x) \in \overline{\mathscr{R}_t(x)}$ for all $\alpha > 0$ so for $\alpha = s/\varepsilon$ one has $(A + sX/\varepsilon)_\varepsilon(x) \in \overline{\mathscr{R}_\varepsilon(x)}$ and $A_{t-\varepsilon} \circ (A + sX/\varepsilon)_\varepsilon(x) \in \overline{\mathscr{R}_t(x)}$. Letting ε tend to zero, one has $A_t \circ X_s(x) \in \overline{\mathscr{R}_t(x)}$. Suppose $A_t \circ X_s(x) \in \overline{\mathscr{R}_t(x)}$ for s, $t > 0$ and

for all $x \in M$. The Campbell-Baker-Hausdorff formula asserts that if $F, G \in V(M)$ then

$$F_{t_1} \circ G_{t_2}(x) = Z_1(x) \quad \text{where } Z = t_1 F + t_2 G + \frac{t_1 t_2}{2}[F, G] + \cdots$$

is a formal power series which converges for t_1 and t_2 in some neighbourhood of 0 in R^2. Thus $(A_{t/n} \circ X_{\alpha t/n})^n(x) = (t/nA + \alpha t/nX + t^2\alpha/2n^2[A, X] + \cdots)_1^n(x) \in \overline{\mathcal{R}_t(x)}$ where n is a positive integer and $\alpha > 0$. Letting $n \to \infty$, one has $(A + \alpha X)_t(x) \in \overline{\mathcal{R}_t(x)}$ so that $X \in \mathcal{F}^+$. If $X \in \mathcal{F}$, then $-X \in \mathcal{F}^+$ and the case where $X \in \mathcal{F}$ follows from the above.

b) The integral curve for $f_i X_i$ is a reparametrization of the integral curve of X_i, so using part a) it is clear that $f_i X_i \in \mathcal{F}$. Thus it is enough to check that if $X_1, \cdots, X_k \in \mathcal{F}$ then $\sum_{i=1}^k X_i \in \mathcal{F}$. For $\alpha \in R$ the well-known results on bang-bang controls (cf. [7]) assert that the integral curves for $A + \alpha(\sum_{i=1}^k X_i)$ can be approximated by compositions of integral curves for $\{A + \alpha X_i | i = 1, \cdots, k\}$ and it follows that $A + \alpha \sum_{i=1}^k X_i \in \mathcal{T}$, hence $\sum_{i=1}^k X_i \in \mathcal{F}^+$.

c) and d) are proved using the same method of proof as is used in part b).

THEOREM 2.2. *Consider the system* (1.1) *with associated triples* $(\mathcal{L}, \mathcal{L}_0, \mathcal{B})$ *and* $(\mathcal{T}, \mathcal{F}^+, \mathcal{F})$. *Then*:

a) $\mathcal{F}$ *is a Lie subalgebra of* $V(M)$ *containing* $\mathcal{B}$.

b) $\mathcal{T} + \mathcal{F}^+ \subset \mathcal{T}$.

c) $\mathcal{F}^+ \supset \mathcal{F}$ *and* $\mathcal{F}(x) \subset \mathcal{F}^+(x) \subset \mathcal{L}_0(x)$ *for all* $x \in M$.

Proof. a) $\mathcal{F}$ is a vector space by Lemma 2.1 part b). Let $X, Y \in \mathcal{F}$. To show that $[X, Y] \in \mathcal{F}$, one can proceed as follows: For $X^1, \cdots, X^k \in \mathcal{F}$, $s_1, \cdots, s_k \in R$ one can use Lemma 2.1 part a) to see that $A_{t-\varepsilon k} \circ (A_\varepsilon \circ X^1_{s_1}) \circ \cdots \circ (A_\varepsilon \circ X^k_{s_k})(x) \in \overline{\mathcal{R}_t(x)}$ for all $\varepsilon > 0$. Letting $\varepsilon \to 0$ it follows that $A_t \circ X^1_{s_1} \circ \cdots \circ X^k_{s_k}(x) \in \overline{\mathcal{R}_t(x)}$. From Chow's theorem (cf. [7]) one can see that for each $t > 0$ and n a positive integer one can express $([X, Y])_{t/n}(x)$ as $X_{r_1} \circ Y_{r_2} \circ \cdots \circ X_{r_{l-1}} \circ Y_{r_l}(x)$ for some set of real numbers $r_1, \cdots, r_l$ and thus $A_{t/n} \circ ([X, Y])_{t/n}(x) \in \overline{\mathcal{R}_{t/n}(x)}$. It follows that $(A_{t/n} \circ ([X, Y])_{t/n})^n(x) \in \overline{\mathcal{R}_t(x)}$, and letting $n \to \infty$ the Campbell-Baker-Hausdorff formula can be used to show that $(A + [X, Y])_t(x) \in \overline{\mathcal{R}_t(x)}$. If X is replaced by a multiple αX, one has $(A + \alpha[X, Y])_t(x) \in \overline{\mathcal{R}_t(x)}$ or $[X, Y] \in \mathcal{F}$.

b) Let $X \in \mathcal{F}^+$ and $Y \in \mathcal{T}$ so that from Lemma 2.1 $A_t \circ X_s(x) \in \overline{\mathcal{R}_t(x)}$ for $t, s > 0$ and by definition $Y_t(x) \in \overline{\mathcal{R}_t(x)}$ for $t > 0$. Thus $(A_\varepsilon \circ X_s) \circ (Y_{t-\varepsilon})(x) \in \overline{\mathcal{R}_t(x)}$ for all $\varepsilon > 0$ and in the limit as $\varepsilon \to 0$ one sees that $X_s \circ Y_t(x) \in \overline{\mathcal{R}_t(x)}$ for all $s > 0$. In particular $X_{t/n} \circ Y_{t/n}(x) \in \overline{\mathcal{R}_t(x)}$ for n a positive integer, and using the Campbell-Baker-Hausdorff formula one sees that $(X_{t/n} \circ Y_{t/n})^n(x) \to (X + Y)_t(x) \in \overline{\mathcal{R}_t(x)}$. This means that $X + Y \in \mathcal{T}$.

c) Clearly $\mathcal{F}^+ \supset \mathcal{F}$. Fix $x \in M$ and $X \in \mathcal{F}^+$. Then $A_t \circ X_s(x) \in \overline{\mathcal{R}_t(x)}$ for $s > 0$. Now $\overline{\mathcal{R}_t(x)} \subset I(\mathcal{L}_0, A_t(x))$ and in [12] it is shown that $I(\mathcal{L}_0, A_t(x)) = A_t(I(\mathcal{L}_0, x))$. This means that $A_t \circ X_s(x) \subset A_t(I(\mathcal{L}_0, x))$ so that $X_s(x) \subset I(\mathcal{L}_0, x)$ for all $s > 0$, and thus $X(x) \subset \mathcal{L}_0(x)$, which completes the proof.

The next results show that a knowledge of $\mathcal{F}^+$ translates into information on the structure of the reachable set at time t.

DEFINITION. Let $\mathcal{S}$ be a subset of $V(M)$ and let $t > 0$. An *integral curve of* $\mathcal{S}$ *on* $[0, t]$ is a continuous mapping $\alpha : [0, t] \to M$ such that there exists a partition $0 = t_0 < t_1 < \cdots < t_k = t$ and vector fields $X_1, \cdots, X_k \in \mathcal{S}$ with the property that on $[t_{i-1}, t_i]$ the curve α is an integral curve of X_i for $i = 1, 2, \cdots, k$. A point y in M is $\mathcal{S}$*-reachable* from $x \in M$ if $\exists$ a $t > 0$ and an integral curve α of $\mathcal{S}$ on $[0, t]$ such that $\alpha(0) = x$ and $\alpha(t) = y$. By Theorem 2.7 $\mathcal{F}^+(x) \subset \mathcal{L}_0(x)$ for all $x \in M$ so that points in M which are

$\mathcal{F}^+$-reachable from x will be contained in $I(\mathcal{L}_0, x)$. Note that $I(\mathcal{L}_0, x)$ is precisely the set of points in M which are $\mathcal{L}_0$-reachable from x_0 (cf. [14]).

THEOREM 2.3. *Consider the system* (1.1) *with triples* $(\mathcal{L}, \mathcal{L}_0, \mathcal{B})$ *and* $(\mathcal{T}, \mathcal{F}^+, \mathcal{F})$. *Suppose that* $Y \in \mathcal{T}$ *is a trace vector field and that* y *is* $\mathcal{F}^+$*-reachable from* x. *Then* $Y_t(y)$ *is contained in* $\overline{\mathcal{R}_t(x)}$ *for all* $t>0$ *and for all* $x \in M$, *where* $\overline{\mathcal{R}_t(x)}$ *is the closure of* $\mathcal{R}_t(x)$ *relative to the topology of* $I(\mathcal{L}_0, A_t(x))$.

COROLLARY 1. *The system* (1.1) *is strongly controllable if and only if* $\mathcal{F}^+(x) = \mathcal{L}_0(x)$ *for all* $x \in M$ *if and only if* $\mathcal{F}(x) = \mathcal{F}^+(x) = \mathcal{L}_0(x)$ *for all* $x \in M$.

COROLLARY 2. *The system* (1.1) *is strongly controllable if and only if for each* $x \in M \exists$ *vector fields* $X_1, \cdots, X_k \in \mathcal{F}^+$ *whose positive linear span at* x *is all of* $\mathcal{L}_0(x)$ (i.e. *for each* $v \in \mathcal{L}_0(x)$ $\exists$ *nonnegative constants* $c_1, \cdots, c_k$ *such that* $v = \sum_{i=1}^k c_i X_i(x)$).

Proof. (Theorem 2.3). Let y be $\mathcal{F}^+$-reachable from x so that $y = X^1_{s_1} \circ X^2_{s_2} \circ \cdots \circ X^k_{s_k}(x)$ for some $X^i \in \mathcal{F}^+$ and $s_i > 0$. Then $(A_\varepsilon \circ X^1_{s_1}) \circ \cdots \circ (A_\varepsilon \circ X^k_{s_k})(x) \in \overline{\mathcal{R}_{k\varepsilon}(x)}$ by Lemma 2.1, and if $Y \in \mathcal{T}$ than $Y_{t-k\varepsilon} \circ (A_\varepsilon \circ X^1_{s_1}) \circ \cdots \circ (A_\varepsilon \circ X^k_{x_k})(x) \in \overline{\mathcal{R}_t(x)}$. Letting $\varepsilon \to 0$, one finds that $Y_t(y) \in \overline{\mathcal{R}_t(x)}$, which completes the proof.

Proof. (Corollary 1). Suppose that (1.1) is strongly controllable. Then $\mathcal{R}_t(x) = I(\mathcal{L}_0, A_t(x)) = A_t(I(\mathcal{L}_0, x))$ and if $X \in \mathcal{L}_0$ then $A_t \circ X_s(x) \in \mathcal{R}_t(x)$ for $s>0$. From Lemma 2.1 $X \in \mathcal{F}^+$, so that $\mathcal{F}^+ \supset \mathcal{L}_0$. From Theorem 2.2 $\mathcal{F}^+(x) \subset \mathcal{L}_0(x)$ so $\mathcal{F}^+(x) = \mathcal{L}_0(x)$. Suppose $\mathcal{L}_0(x) = \mathcal{F}^+(x)$ for all $x \in M$. Then the points in M which are $\mathcal{F}^+$-reachable from x will be $I(\mathcal{L}_0, x)$, and Theorem 2.3 implies that for $y \in I(\mathcal{L}_0, x)$, $A_t(y) \in \overline{\mathcal{R}_t(x)}$, so $\overline{\mathcal{R}_t(x)} = I(\mathcal{L}_0, A_t(x))$ for all $t>0$ and $x \in M$. This implies that $\mathcal{R}_t(x) = I(\mathcal{L}_0, A_t(x))$ (cf. [5]).

Proof. (Corollary 2). This result follows from Corollary 1 and part c) of Lemma 2.1.

THEOREM 2.4. *Consider the system* (1.1) *and suppose that the vector field* $A \in \mathcal{F}^+$. *Then* $\overline{\mathcal{R}_t(x)} = \overline{\mathcal{R}(x)}$ *for all* $t>0$ *and for all* $x \in M$. *In particular the system is strongly controllable if and only if it is controllable.*

Proof. In [5] it is shown that the closure of $\mathcal{R}_t(x)$ is equal to the closure of the set

$$\left\{ A_{t_1} \circ B_{s_1} \circ \cdots \circ A_{t_k} \circ B_{s_k}(x) \mid k = 1, 2, \cdots;\ t_i > 0;\ s_i \in R;\ \sum_{i=1}^{k} t_i = t \right\}$$

and $\overline{\mathcal{R}(x)}$ is equal to the closure of

$$\{A_{t_1} \circ B_{s_1} \circ \cdots \circ A_{t_k} \circ B_{s_k}(x) \mid k = 1, 2, \cdots;\ t_i > 0;\ s_i \in R\}.$$

If $A \in \mathcal{F}^+$ then $A_t \circ A_s(x) \in \overline{\mathcal{R}_t(x)}$ for all $s>0$ so that $A_{t+s}(x) \in \overline{\mathcal{R}_t(x)}$ for all $s>0$. This implies that $\overline{\mathcal{R}_t(x)} = \overline{\mathcal{R}(x)}$ for all $t>0$.

COROLLARY 1. *If* (1.1) *is a right-invariant system on a compact Lie group* G (cf. [13]) *and* $A \in \mathcal{F}^+$, *then the system is strongly controllable.*

Proof. For systems which are described by right-invariant vector fields and whose state space is a compact Lie group G it is known that $\mathcal{R}(x) = I(\mathcal{L}, x)$ (cf. [13]). If $A \in \mathcal{F}^+$ then $\mathcal{L} = \mathcal{L}_0$ and Theorem 2.4 implies that $\overline{\mathcal{R}_t(x)} = \overline{I(\mathcal{L}_0, x)} = I(\mathcal{L}_0, x) = I(\mathcal{L}_0, A_t, x)$ so that the system is strongly controllable.

To take advantage of the above results, one needs a way to find vector fields in $\mathcal{F}^+$ for the system (1.1). At this stage one knows that

$$\mathcal{F}^+ \supset \mathcal{F} \supset \mathcal{B}$$

and that $\mathcal{T} \supset \{A + \mathcal{F}^+\} \supset \{A + \mathcal{B}\}$. The next section provides a way of generating more vector fields in $\mathcal{F}^+$ given a complete vector field $X \in \mathcal{F}$ and a vector field $Y \in \mathcal{T}$.

3. Construction of controlled vector fields. Suppose that $X \in \mathcal{F}$ is a complete vector field and $Y \in \mathcal{T}$ is a trace vector field. Since X is complete, the map $x \to X_s(x)$ is a

diffeomorphism from M onto itself for each fixed $s \in R$. If $\phi(x) = X_s(x)$, then $d\phi$ is a linear isomorphism of tangent spaces and $x \to (\phi_* Y)(x) = d\phi_{\phi^{-1}(x)} Y(\phi^{-1}(x))$ defines a real analytic vector field on M which will be denoted by $dX_s Y$. Furthermore $dX_s Y \in \mathcal{T}$ for all $s \in R$. To see this, note that $t \to X_s \circ Y_t \circ X_{-s}(x)$ is the integral curve for $dX_s Y$ through x. If $y = X_{-s}(x)$, then y is $\mathcal{F}^+$-reachable from x (here $X \in \mathcal{F} \subset \mathcal{F}^+$) so that $Y_t(X_{-s}(x)) \in \overline{\mathcal{R}_t(x)}$ by Theorem 2.3. If $0 < \varepsilon < t$, then it follows that $z = Y_{t-\varepsilon}(X_{-s}(x)) \in \overline{\mathcal{R}_{t-\varepsilon}(x)}$, $Y_\varepsilon(X_s(z)) \in \overline{\mathcal{R}_\varepsilon(z)}$ so that $Y_\varepsilon \circ X_s \circ Y_{t-\varepsilon} \circ X_{-s}(x) \in \overline{\mathcal{R}_t(x)}$ for all ε between zero and t. Letting $\varepsilon \to 0$, one finds that $X_s \circ Y_t \circ X_{-s}(x)$ is in the closure of $\mathcal{R}_t(x)$ for any $t > 0$ and any $s \in R$, and thus $dX_s Y \in \mathcal{T}$ for all real s.

The observation that if $X \in \mathcal{F}$ is complete and $Y \in \mathcal{T}$ then $dX_s Y \in \mathcal{T}$ for real s forms the basis for many of the results of Kunita in [8]. In the case where $\mathcal{L} = \mathcal{L}_0$ his results can be used to show that if, for some positive integer k, one has $\operatorname{ad}_X^{k+1} Y = Z \in \mathcal{F}$ then $\operatorname{ad}_X^k Y \in \mathcal{F}^+$. More generally one knows that, at least locally, $\exists$ some positive integer k and functions $a_0, a_1, \cdots, a_k \in C^\omega(M)$ such that

$$\operatorname{ad}_X^{k+1} Y = a_0 Y + a_1 \operatorname{ad}_X Y + \cdots + a_k \operatorname{ad}_X^k Y + Z \tag{3.1}$$

where $Z \in \mathcal{F}$ (i.e., take $Z = 0$ and $k = n-1$ where $n = \dim M$). The case where the functions a_i vary with x but are constant along the integral curves of X is considered later in this section. For now it will be assumed that X and Y are such that $a_0, \cdots, a_k$ are constants. In this case the least positive integer k for which (3.1) holds with a_i constant functions on M and $Z \in \mathcal{F}$ is called the *controllability index of* (X, Y), $k(X, Y)$. If (3.1) never holds with a_i constants then we set $k(X, Y) = \infty$.

If $k(X, Y) < \infty$ then one can construct from $dX_s Y$ a new family of vector fields W^s with the property that $W^s \in \mathcal{T}$ for all real s and $\operatorname{span}\{W^s | s \in R\}$ is a finite dimensional subspace of $V(M)$. Since X, Y are real analytic vector fields one can expand $dX_{-s} Y$ in a Taylor series about $s = 0$. It is well known that $dX_{-s} Y = \sum_{j=0}^{\infty} (s^j/j!) \operatorname{ad}_X^j Y$ for all s in R, where ad_X is a linear operator on $V(M)$, an infinite dimensional real vector space. For $k = k(X, Y)$ it is not difficult to verify that

$$V = \operatorname{span}\{Y, \operatorname{ad}_X Y, \cdots, \operatorname{ad}_X^k Y\}$$

is a $(k+1)$-dimensional subspace of $V(M)$ and that

$$T(\operatorname{ad}_X^i Y) = \begin{cases} \operatorname{ad}_X^{i+1} Y & \text{for } 1 \leqq i < k, \\ \sum_{i=0}^{k} a_i \operatorname{ad}_X^i Y & \text{for } i = k \end{cases} \tag{3.2}$$

define a linear operator on V. It follows that $\exp sT = I + sT + (s^2/2!) T^2 + \cdots$ defines a linear operator on V for all real s, and

$$W^s = (\exp sT)(Y) = \sum_{i=0}^{\infty} \frac{s^i}{i!} T^i(Y) \tag{3.3}$$

defines a vector field which is in V for all real s. To see that $W^s \in \mathcal{T}$, note that the power series expansions for $dX_{-s} Y$ and W^s have the same coefficients for $1, s, \cdots, s^k$ as a consequence of (3.2). For $dX_{-s} Y$ the coefficient of $s^{k+1}/(k+1)!$ is

$$\operatorname{ad}_X^{k+1} Y = a_0 Y + a_1 \operatorname{ad}_X Y + \cdots + a_k \operatorname{ad}_X^k Y + Z$$

and for W^s the coefficient of $s^{k+1}/(k+1)!$ is

$$T^{k+1}(Y) = a_0 Y + a_1 \operatorname{ad}_X Y + \cdots + a_k \operatorname{ad}_X^k Y$$

by (3.2). These coefficients differ by Z, a freely-controlled vector field in $\mathcal{F}$. Similarly

the coefficients of $s^{k+2}/(k+2)!$ in the power series expansions for $dX_{-s}Y$ and W^s differ by $(\mathrm{ad}_X Z + a_k Z)$, which is also freely controlled, since $X, Z \in \mathcal{F}$ and $\mathcal{F}$ is a Lie algebra by Theorem 2.2. A simple induction argument shows that the coefficients of an arbitrary power of s in the series expansions for $dX_{-s}Y$ and W^s differ by a vector field in $\mathcal{F}$. Thus $W^s = dX_{-s}Y + Z^s$ where $Z^s \in \mathcal{F}$, $dX_{-s}Y \in \mathcal{T}$. By Theorem 2.2 $\mathcal{F} \subset \mathcal{F}^+$ and $\mathcal{F}^+ + \mathcal{T} \subset \mathcal{T}$ so that $W^s \in \mathcal{T}$ for all real s.

The fact that $W^s \in \mathcal{T}$ for all real s can be used to construct semi-controlled vector fields for the system (1.1).

Since $W^s \in \mathcal{T}$ and $A \in \mathcal{T}$, then by Theorem 2.2 it follows that $(1-b)A + bW^s \in \mathcal{T}$ for all $b > 0$. It turns out that one can choose s to be a function of b in such a way that as b approaches 0, the vector field $bW^{s(b)}$ approaches a nonzero vector field W. This means that $A + W$ will be in $\mathcal{T}$, and if $s(b)$ is replaced by a positive multiple $\alpha s(b)$, then $A + \alpha W \in \mathcal{T}$ for all $\alpha \geqq 0$. In other words W is, by definition, a semi-controlled vector field in $\mathcal{F}^+$. The method for extracting W from W^s will now be explained.

LEMMA 3.1. *Suppose that X is a complete freely-controlled vector field for the system* (1.1) *and Y is a trace vector field such that $k(X, Y) < \infty$. Then for each s in R*

$$W^s = \sum_{i=0}^{k} b_i^s \, \mathrm{ad}_X^i \, Y \tag{3.4}$$

is a trace vector field for (1.1) *and the real numbers b_i^s are the entries in the first column of the matrix exponential $e^{sQ(X,Y)}$ where $Q(X, Y)$ is the $(k+1)\times(k+1)$ matrix*

$$Q(X, Y) = \begin{bmatrix} 0 & 0 & \cdots & 0 & a_0 \\ 1 & 0 & \cdots & 0 & a_1 \\ 0 & 1 & \cdots & 0 & a_2 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & 1 & a_k \end{bmatrix} \tag{3.5}$$

with $k = k(X, Y)$ and $a_0, a_1, \cdots, a_k$ defined by (3.1).

Proof. By definition $W^s = (\exp sT)(Y) \in V$ for all $s \in R$ where $V = \mathrm{span}\{Y, \mathrm{ad}_X Y, \cdots, \mathrm{ad}_X^k Y\}$. Thus $\beta = \{Y, \mathrm{ad}_X Y, \cdots, \mathrm{ad}_X^k Y\}$ is an ordered basis for V and from the definition of T, equation (3.2), it follows that the matrix representation for T with respect to β is $Q(X, Y)$. Thus, in β-coordinates, one can represent W^s by the $(k+1)$ by 1 coordinate matrix $[W^s]_\beta$ with entries b_i^s (i.e. $W^s = \sum_{i=0}^k b_i^s \, \mathrm{ad}_X^i \, Y$). Since $W^s = (\exp sT)(Y)$, one has

$$[W^s]_\beta = [(\exp sT)\, Y]_\beta = [\exp sT]_\beta [Y]_\beta.$$

Now $[Y]_\beta$ is the transpose of $[1, 0, \cdots, 0]$ and $[\exp sT]_\beta = e^{s[T]_\beta} = e^{sQ(X,Y)}$ so that the coordinate matrix of W^s with respect to β is the first column of the matrix $e^{sQ(X,Y)}$. This completes the proof.

The rate at which the terms b_i^s from (3.4) grow with respect to s can be studied by using the Cauchy integral formula to evaluate $e^{sQ(X,Y)}$ (cf. [2]). If $\lambda_1, \lambda_2, \cdots, \lambda_d$ are the distinct eigenvalues of $Q(X, Y)$ with multiplicities $m_1, m_2, \cdots, m_d$, then

$$e^{sQ(X,Y)} = \sum_{j=1}^{d} \sum_{l=0}^{m_j - 1} s^l \, e^{s\lambda_j} Q_{jl} \tag{3.6}$$

where

$$Q_{j,l} = \frac{1}{l!(m_j - 1 - l)!} \frac{d^{m_j - 1 - l}}{dz^{m_j - 1 - l}} [(z - \lambda_j)^{m_j} (Iz - Q(X, Y))^{-1}]_{z = \lambda_j}.$$

Let a_{MAX} (a_{MIN}) denote the maximum (minimum) real part of the eigenvalues $\lambda_1, \lambda_2, \cdots, \lambda_d$. Relabel these eigenvalues so that among those eigenvalues with real part a_{MAX} the ones with maximum multiplicity are $\lambda_1, \cdots, \lambda_q$. Then among all eigenvalues of $Q(X, Y)$ with real part a_{MAX} the maximum multiplicity is m_1 which is the multiplicity of $\lambda_1, \lambda_2, \cdots, \lambda_q$. The remaining eigenvalues are relabelled so that among those with real part a_{MIN} the ones with maximum multiplicity are $\lambda_p, \cdots, \lambda_d$. Then the sum (3.6) for $e^{sQ(X,Y)}$ can be rewritten as

$$e^{sQ(X,Y)} = \sum_{j=1}^{q} s^{m_1-1} e^{s\lambda_j} Q_{j(m_1-1)} + \sum_{j=p}^{d} s^{m_d-1} e^{s\lambda_j} Q_{j(m-1)} + R(s)$$

where $R(s)$ is the matrix formed by the remaining double sums in (3.6). The first two sums in the above expression can be simplified by noting that $\lambda_1, \cdots, \lambda_q$ are of the form $\lambda_j = a_{\mathrm{MAX}} + ib_j$ and $\lambda_p, \cdots, \lambda_d$ are of the form $\lambda_j = a_{\mathrm{MIN}} + ib_j$. Since

$$e^{s\lambda_1} = e^{s(a_{\mathrm{MAX}}+ib_1)} = e^{sa_{\mathrm{MAX}}} e^{sib_1}$$

the above sum can be written as

$$e^{sQ(X,Y)} = s^{m_1-1} e^{sa_{\mathrm{MAX}}} D_{\mathrm{MAX}}(s) + s^{m_d-1} e^{sa_{\mathrm{MIN}}} D_{\mathrm{MIN}}(s) + R(s) \tag{3.7}$$

where

$$D_{\mathrm{MAX}}(s) = \sum_{j=1}^{q} e^{sib_j} Q_{j(m_1-1)} \quad \text{and} \quad D_{\mathrm{MIN}}(s) = \sum_{j=P}^{d} e^{sib_j} Q_{j(m_d-1)}.$$

Note that $D_{\mathrm{MAX}}(s)$, $D_{\mathrm{MIN}}(s)$ and $R(s)$ are periodic with respect to s with period 2π because $e^{sib_j} = \cos sb_j + i \sin sb_j$. This decomposition results in a corresponding decomposition for W^s as a consequence of Lemma 3.1.

LEMMA 3.2. *Suppose that X is a complete, freely-controlled vector field for the system* (1.1) *and Y is a trace vector field with $k(X, Y) < \infty$. Then for each real s the trace vector field W^s can be decomposed as the sum*

$$W^s = s^{m_1-1} e^{sa_{\mathrm{MAX}}} W^s_{\mathrm{MAX}} + s^{m_d-1} e^{sa_{\mathrm{MIN}}} W^s_{\mathrm{MIN}} + R^s \tag{3.8}$$

where W^s_{MAX} and W^s_{MIN} are vector fields which are periodic in s with period 2π. The vector fields W^s_{MAX}, W^s_{MIN}, and R^s are defined by $\sum_{j=0}^{k(X,Y)} c_j^s \operatorname{ad}_X^j Y$ where the scalars c_j^s are the first columns of the matrices $D_{\mathrm{MAX}}(s)$, $D_{\mathrm{MIN}}(s)$, and $R(s)$ respectively.

Proof. $W^s = \sum_{i=0}^{k} b_i^s \operatorname{ad}_X^i Y$ by Lemma 3.1, where $k = k(X, Y)$, and b_i^s are the entries in the first column of $e^{sQ(X,Y)}$. Using (3.7) to decompose $e^{sQ(X,Y)}$ results in (3.8). The next theorem shows that the vector fields W^s_{MAX} and W^s_{MIN} are semi-controlled.

THEOREM 3.3. *Suppose that X is a complete, freely-controlled vector field for the system* (1.1) *and Y is a trace vector field with $k(X, Y) < \infty$. Consider the trace vector field W^s decomposed in* (3.8) *as the sum*

$$s^{m_1-1} e^{sa_{\mathrm{MAX}}} W^s_{\mathrm{MAX}} + s^{m_d-1} e^{sa_{\mathrm{MIN}}} W^s_{\mathrm{MIN}} + R^s.$$

Then,

(i) *If $a_{\mathrm{MAX}} > 0$ then $W^s_{\mathrm{MAX}} \in \mathcal{F}^+$ for all $s \in R$.*
(ii) *If $a_{\mathrm{MIN}} < 0$ then $(-1)^{m_d-1} W^s_{\mathrm{MIN}} \in \mathcal{F}^+$ for all $s \in R$.*
(iii) *If $a_{\mathrm{MAX}} = 0$ and $m_1 > 1$ then $W^s_{\mathrm{MAX}} \in \mathcal{F}^+$ for all $s \in R$.*
(iv) *If $a_{\mathrm{MIN}} = 0$ and $m_d > 1$ then $(-1)^{m_d+1} W^s_{\mathrm{MIN}} \in \mathcal{F}^+$ for all $s \in R$.*

Proof. Set $k = k(X, Y) < \infty$ and suppose $a_{\mathrm{MAX}} > 0$. Let $r_1, \cdots, r_l$ denote the distinct real parts of the eigenvalues $\lambda_1, \cdots, \lambda_d$ of $Q(X, Y)$ in decreasing order, so that

$r_1 = a_{\text{MAX}}$ and $r_l = a_{\text{MIN}}$. Using (3.8) for W^s one sees that

$$s^{1-m_1} e^{(-sa_{\text{MAX}})} W^s - W^s_{\text{MAX}} = s^{m_d-m_1} e^{s(a_{\text{MIN}}-a_{\text{MAX}})} W^s_{\text{MIN}} + s^{1-m_1} e^{-sa_{\text{MAX}}} R^s.$$

Set $\alpha(s) = s^{1-m_1} e^{-sa_{\text{MAX}}}$ and set $\hat{W}^s = \alpha(s) W^s$. Since $a_{\text{MIN}} - a_{\text{MAX}} < 0$ here and W^s_{MIN} is periodic in s, it follows that

$$\lim_{s\to\infty} s^{m_d-m_1} e^{s(a_{\text{MIN}}-a_{\text{MAX}})} W^s_{\text{MIN}} = 0$$

and similarly $\lim_{s\to\infty} \alpha(s) R^s = 0$. Thus as s tends to infinity, $\hat{W}^s(x)$ approaches $W^s_{\text{MAX}}(x)$ uniformly with respect to x. Also since $\hat{W}^s$ is a multiple of W^s by $\alpha(s)$, it follows that for $\tau > 0$, the integral curve $\hat{W}^s_\tau(x) = W^s_{\sigma(\tau,s)}(x)$ for some real analytic function $\sigma(\tau, s)$ on $R^+ \times R$. Because $\alpha(s) \to 0$ as $s \to \infty$, the function $\sigma(\tau, s) \to 0$ uniformly in τ as $s \to \infty$, and because $W^s \in \mathcal{T}$, $W^s_{\sigma(\tau,s)}(x) \in \overline{\mathcal{R}_{\sigma(\tau,s)}(x)}$. This means that $\hat{W}^s_\tau(x) \in \overline{\mathcal{R}_{\sigma(\tau,s)}(x)}$ and

$$A_{t-\sigma(\tau,s)} \circ \hat{W}^s_\tau(x) \in \overline{\mathcal{R}_t(x)} \quad \text{for } \sigma(\tau, s) < t. \tag{3.9}$$

Because $\hat{W}^s(x)$ approaches $W^s_{\text{MAX}}(x)$ uniformly in x as $s \to \infty$, the integral curves for $\hat{W}^s$ and W^s_{MAX} approach one another as $s \to \infty$. Fix $s_0 \in R$ and set $s_n = s_0 + 2\pi n$ for n a positive integer. Since W^s_{MAX} is periodic with respect to s with period 2π, it follows that $W^{s_n}_{\text{MAX}} = W^{s_0}_{\text{MAX}}$ and $\lim_{n\to\infty} \hat{W}^{s_n}_\tau(x) = (W^{s_0}_{\text{MAX}})_\tau(x)$ for $\tau > 0$. From (3.9) $A_{t-\sigma(\tau,s_n)} \circ \hat{W}^{s_n}_\tau(x) \in \overline{\mathcal{R}_t(x)}$ for $\alpha(\tau, s_n) < t$, and since $\lim_{n\to\infty} \sigma(\tau, s_n) = 0$ it follows that

$$A_t \circ \lim_{n\to\infty} \hat{W}^{s_n}_\tau(x) = A_t \circ (W^{s_0}_{\text{MAX}})_\tau(x) \in \overline{\mathcal{R}_t(x)}$$

for all $x \in M$ and for all $\tau > 0$. Lemma 2.1 implies that $W^{s_0}_{\text{MAX}} \in \mathcal{F}^+$. This completes the proof of part (i).

Assume $a_{\text{MIN}} < 0$. Using (3.8) one sees that

$$s^{1-m_d} e^{-sa_{\text{MIN}}} W^s - W^s_{\text{MIN}} = s^{m_1-m_d} e^{s(a_{\text{MAX}}-a_{\text{MIN}})} W^s_{\text{MAX}} + s^{1-m_d} e^{-sa_{\text{MIN}}} W^s.$$

Set $\alpha(s) = s^{1-m_d} e^{-sa_{\text{MAX}}}$ and set $\hat{W}^s = \alpha(s) W^s$. Here $a_{\text{MAX}} - a_{\text{MIN}}$ is positive so $\lim_{s\to-\infty} s^{m_1-m_d} e^{s(a_{\text{MAX}}-a_{\text{MIN}})} W^s_{\text{MAX}} = 0$ and the proof of part (i) can be repeated with $s \to -\infty$ instead of $+\infty$. If $m_d - 1$ is odd then for s negative $\hat{W}^s$ and W^s will have the opposite signs which accounts for the $(-1)^{m_d+1}$ term in (ii).

Suppose $a_{\text{MAX}} = 0$ and $m_1 > 0$. Since $r_1 = 0$, the numbers $r_2, \cdots, r_l$ must be negative so that $s^{m_d-m_1} e^{s(a_{\text{MIN}}-a_{\text{MAX}})}$ tends to zero as $s \to +\infty$ and the proof used in part (i) can be repeated.

Finally, suppose $a_{\text{MIN}} = 0$ and $m_d > 1$. Then

$$\lim_{s\to-\infty} s^{m_1-m_d} e^{s(a_{\text{MAX}}-a_{\text{MIN}})} = 0$$

and the proof of part (ii) can be used. This completes the proof.

Remark 1. If M is a Lie group and $X \in \mathcal{F}$ and $Y \in \mathcal{T}$ are both right (left)-invariant vector fields on M then $k(X, Y) < \infty$ because $\{X, Y\}_{LA}$ is a finite dimensional Lie algebra over R.

Remark 2. Suppose $X \in \mathcal{F}$ is complete, $Y \in \mathcal{T}$, $k(X, Y) = k < \infty$ and the eigenvalues of $Q(X, Y)$ are all identically 0 (this is a situation where the results of Kunita [8] can be used to show that $\text{ad}^k_X Y$ and $(-1)^k \text{ad}^k_X Y$ are semi-controlled). In this case Theorem 3.3 part (iii) results in $W^s_{\text{MAX}} = \text{ad}^k_X Y \in \mathcal{F}^+$ and part (iv) yields $(-1)^k \text{ad}^k_X Y \in \mathcal{F}^+$.

Remark 3. The assumption that X be complete in this theorem and in Theorem 3.5 cannot be omitted. For example the systems

$$\dot{x}_1 = u \text{ with } x_1, x_2 \in R \quad \text{and} \quad \dot{y}_1 = u \text{ with } y_1 \in (-1, 1),$$
$$\dot{x}_2 = x_1, \qquad\qquad \dot{y}_2 = y_1 \text{ and } y_2 \in R$$

have identical algebraic properties. They generate isomorphic Lie algebras but only the first is strongly controllable. This is because the vector field $B(x) = (1, 0)$ is not complete when y_1 is restricted to $(-1, 1)$.

Remark 4. If $\hat{K}$ is any positive integer greater than or equal to $K(X, Y)$, then one could replace $K(X, Y)$ by $\hat{K}$ and repeat Lemmas 3.1 and 3.2 to generate $\hat{W}^s$, $\hat{a}_{\text{MAX}}$, $\hat{a}_{\text{MIN}}$ and $\hat{W}^s_{\text{MAX}}$, $\hat{W}^s_{\text{MIN}}$. Then Theorem 3.3 is still true. This means that one does not need to use the smallest k such that (3.1) holds.

Example 3.4. Consider the system modelled by

$$\dot{x} = A(x) + uB(x), \qquad x \in M$$

where $M = (0, \infty) \times S^1 = \{(x_1, x_2, x_3) \in R^3 | x_1 > 0, x_2^2 + x_3^2 = 1\}$, $A(x_1, x_2, x_3) = (1, 0, 0)$, and $B(x_1, x_2, x_3) = (x_1, x_3, -x_2)$. Since A is a trace vector field and B is a complete freely-controlled vector field one can set $X = B$, $Y = A$ and compute $k(X, Y)$. Here $\text{ad}_X\, Y(x) = (dA)_x B(x) - (dB)_x A(x) = -A(x) = -Y(x)$. Using (3.1) $a_0 = -1$, $k(X, Y) = 0$ and $Q(X, Y) = [a_0] = [-1]$ from (3.5). The eigenvalues for $Q(X, Y)$ consist of $\lambda_1 = -1$ so $d = 1$, $a_{\text{MAX}} = a_{\text{MIN}} = -1$, $m_1 = 1$, and (3.8) becomes $W^s = e^{-s} Y = e^{-s} A = (e^{-s}, 0, 0)$ where one can consider $W^s_{\text{MAX}} = A$, $W^s_{\text{MIN}} = 0$, $R^s = 0$ or take $W^s_{\text{MAX}} = 0$, $W^s_{\text{MIN}} = A$, $R^s = 0$. In the latter case Theorem 3.3 part (ii) asserts $(-1)^2 W^s_{\text{MIN}} = A \in \mathcal{F}^+$. Thus $A + \alpha A$ is a trace vector field for all $\alpha \in [0, \infty)$, which means that $((1+\alpha)A)_t(x)$ is in the closure of $\mathcal{R}_t(x)$ for all $\alpha > 0$ or equivalently $A_s(x) \in \overline{\mathcal{R}_t(x)}$ for all $s \geqq t$. Usually one knows that $A_t(x) \in \overline{\mathcal{R}_t(x)}$, but in this case even as t approaches zero, one can travel arbitrarily far along the A-integral curve. Geometrically one sees this since the leaves of the B distribution crowd together as $s \to -\infty$ and for "small t" $A_t(x)$ passes through "many B leaves", see Fig. 1.

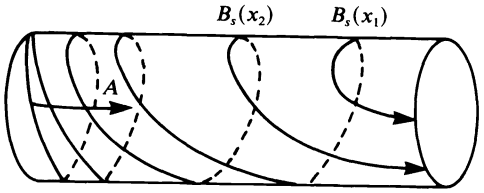

FIG. 1

Example 3.5. Consider the system (1.1) with $A(x) = (x_1 x_2, x_1, e^{x_1} x_2)$ and $B(x) = (x_2^2, 0, 0)$ where $M = R^3$. Here the triple of Lie algebras $(\mathcal{L}, \mathcal{L}_0, \mathcal{B})$ has $\mathcal{L}_0$ infinite-dimensional, $\mathcal{B}$ one-dimensional and we know that $X = B \in \mathcal{F}$ is complete and $Y = A \in \mathcal{T}$. In order to use Theorem 3.3 to find new semi-controlled vector fields, the controllability index $k(X, Y)$ must be finite. Here $\text{ad}_X\, Y = (x_2^3 - 2x_1 x_2, x_2^2, x_2^3 e^{x_1})$, $\text{ad}_X^2\, Y = (-4x_2^3, 0, x_2^5 e^{x_1})$, $\text{ad}_X^3\, Y = (0, 0, x_2^7 e^{x_1})$ and it is easy to see that there is no positive constant k such that $\text{ad}_X^{k+1}\, Y$ is a *constant* linear combination of $Y, \text{ad}_X\, Y, \cdots, \text{ad}_X^k\, Y$ so that $k(X, Y) = \infty$. It is true, however, that $\text{ad}_X^3\, Y(x) = x_2^2\, \text{ad}_X^2\, Y(x) - 4x_2 X(x)$. From Theorem 2.1 $Z = -4x_2 X \in \mathcal{F}$, and if $a_2(x) = x_2^2$ then

$$\text{ad}_X^3\, Y(x) = a_2(x)\, \text{ad}_X^2\, Y + Z$$

where $Z \in \mathcal{F}$. It is true that a_2 is not a constant, but $Xa_2(x) = (da_2)_x X(x) = 0$ for all

$x \in M$ so that a_2 is *constant along integral curves for* X. This case is considered in Theorem 3.5, and this example will be continued after Theorem 3.5.

Suppose that $X \in \mathcal{F}$ is complete, $Y \in \mathcal{T}$ and for some positive integer k

$$\operatorname{ad}_X^{k+1} Y = a_0 Y + \cdots + a_k \operatorname{ad}_X^k Y + Z \tag{3.10}$$

where $Z \in \mathcal{F}$, $a_i \in C^\omega(M)$, and $(Xa_i)(x) = (da_i)_x X(x) = 0$ for all $x \in M$ (i.e. the functions a_i are constant along the integral curves of the vector field X). The least positive integer k for which (3.10) holds is called the *local controllability index of* (X, Y), $k_*(X, Y)$. If (3.10) never holds, then $k_*(X, Y) = \infty$. Clearly $k_*(X, Y) < k(X, Y)$ and in Example 3.5 $k_*(X, Y) = 2$ while $k(X, Y) = \infty$.

Following the steps used before, let $k = k_*(X, Y)$, set $V = \operatorname{span}\{Y, \cdots, \operatorname{ad}_X^k Y\}$, and for a fixed $y \in M$ let T^y be the linear operator on V defined by

$$T^y(\operatorname{ad}_X^i Y) = \begin{cases} \operatorname{ad}_X^{i+1} Y & \text{for } 1 \leqq i < k, \\ \sum_{i=0}^{k} a_i(y) \operatorname{ad}_X^i Y & \text{for } i = k \end{cases}$$

so that $(\exp sT^y)(Y)$ is a vector field in V. This means that $x \to (\exp sT^y)(Y)(x)$ defines a vector field on M and it follows that $x \to (\exp sT^x)(Y)(x)$ defines a vector field in $V(M)$ which will be called W_*^s. Because $Xa_i \equiv 0$ one can repeat the same argument which was used earlier in this section to show that the W_*^s is a trace vector field for all real s. As in Lemma 3.1 $W_*^s(x) = \sum_{i=0}^{k_*(X,Y)} b_i^s(x) \operatorname{ad}_X Y(x)$ where $b_i^s(x)$ is the first column of the matrix exponential $e^{sQ_x(X,Y)}$ with

$$Q_x(X, Y) = \begin{bmatrix} 0 & 0 & \cdots & 0 & a_0(x) \\ 1 & 0 & \cdots & 0 & a_1(x) \\ 0 & 1 & & & \\ \vdots & & \ddots & & \vdots \\ 0 & & \cdots & 1 & a_k(x) \end{bmatrix}. \tag{3.11}$$

One can get a decomposition for $e^{sQ_x(X,Y)}$ similar to the expression (3.7) for $e^{sQ(X,Y)}$ by restricting x to an open dense submanifold of M. Let $d(x)$ denote the number of distinct eigenvalues of $Q_x(X, Y)$ and $l(x)$ the number of distinct real parts of the eigenvalues of $Q_x(X, Y)$. Define d and l to be the maximum values of $d(x)$ and $l(x)$ respectively as x varies over M and set

$$M(X, Y) = \{x \in M \mid d(x) = d \text{ and } l(x) = l\}.$$

Because the entries in $Q_x(X, Y)$ are real analytic in x, it follows that $M(X, Y)$ is an open dense submanifold of M. For each $x \in M(X, Y)$ let $a_{\mathrm{MAX}}(x)(a_{\mathrm{MIN}}(x))$ denote the maximum (minimum) real part of the eigenvalues $\lambda_1(x), \cdots, \lambda_d(x)$ of $Q_x(X, Y)$ which have multiplicities $m_1(x), \cdots, m_d(x)$. Relabel these eigenvalues so that among those with real part $a_{\mathrm{MAX}}(x)$ the ones with maximum multiplicity are $\lambda_1(x), \cdots, \lambda_{q(x)}(x)$ and among those eigenvalues with real part $a_{\mathrm{MIN}}(x)$ the ones with minimum multiplicity are $\lambda_{p(x)}, \cdots, \lambda_d(x)$. While $p(x)$, $q(x)$ and $m_i(x)$ may vary with x, it is straightforward to show that these functions are constant on the connected components of $M(X, Y)$. Thus the decomposition (3.7) for $e^{sQ(X,Y)}$ can be used on the connected components of $M(X, Y)$. Thus on $M(X, Y)$

$$e^{sQ_x(X,Y)} = s^{m_1(x)-1} e^{sa_{\mathrm{MAX}}(x)} D_{\mathrm{MAX}}(s, x) + e^{m_d(x)-1} e^{sa_{\mathrm{MIN}}(x)} D_{\mathrm{MIN}}(s, x) + R(s, x) \tag{3.12}$$

where D_{MAX} and D_{MIN} are defined as in (3.7) but are x-dependent as $Q_x(X, Y)$ varies with x.

LEMMA 3.4. *Suppose that X is a complete, freely-controlled vector field for the system* (1.1) *and Y is a trace vector field with $k_*(X, Y) < \infty$. Then on the open dense submanifold $M(X, Y)$ of M the trace vector field W^s_* can be decomposed as the sum*

$$W^s_*(x) = s^{m_1(x)-1} e^{sa_{\mathrm{MAX}}(x)} W^s_{*\mathrm{MAX}}(x) + s^{m_d(x)-1} e^{sa_{\mathrm{MIN}}(x)} W^s_{*\mathrm{MIN}}(x) + R^s(x). \tag{3.13}$$

The real analytic vector fields $W^s_{*\mathrm{MAX}}$ and $W^s_{*\mathrm{MIN}}$ are periodic with respect to s with period 2π, and $W^s_{*\mathrm{MAX}}(x)$, $W^s_{*\mathrm{MIN}}(x)$ and $R^s(x)$ are defined by $\sum_{j=0}^{k_*(X,Y)} c^s_j(x)\, \mathrm{ad}^j_X\, Y(x)$ where the scalars $c^s_j(x)$ are the first columns of the matrices $D_{\mathrm{MAX}}(s, x)$, $D_{\mathrm{MIN}}(s, x)$ and $R(x, s)$ respectively.

Proof. The proof is the same as the proof for Lemma 3.2.

THEOREM 3.5. *Suppose that X is a complete, freely-controlled vector field for the system* (1.1) *and Y is a trace vector field with $k_*(X, Y) < \infty$. Consider the trace vector field W^s_* decomposed as in* (3.13) *as the sum $s^{m_1-1} e^{sa_{\mathrm{MAX}}} W^s_{*\mathrm{MAX}} + s^{m_d-1} e^{sa_{\mathrm{MIN}}} W^s_{*\mathrm{MIN}} + R^s$ on $M(X, Y)$, an open dense submanifold of M. Then for the system* (1.1) *restricted to $M(X, Y)$*

(i) *if $a_{\mathrm{MAX}} > 0$ then $W^s_{*\mathrm{MAX}} \in \mathcal{F}^+$ for all $s \in R$,*

(ii) *if $a_{\mathrm{MIN}} < 0$ then $(-1)^{m_d+1} W^s_{*\mathrm{MIN}} \in \mathcal{F}^+$ for all $s \in R$,*

(iii) *if $a_{\mathrm{MAX}} \equiv 0$ and $m_1 > 1$ then $W^s_{*\mathrm{MAX}} \in \mathcal{F}^+$ for all $s \in R$,*

(iv) *if $a_{\mathrm{MIN}} \equiv 0$ and $m_d > 1$ then $(-1)^{m_d+1} W^s_{*\mathrm{MIN}} \in \mathcal{F}^+$ for all $s \in R$.*

Proof. It suffices to prove the theorem on a connected component M_0 of $M(X, Y)$. Set $k = k_*(X, Y)$. To prove (i) the proof of Theorem 3.3 will be modified to take account of the fact that while m_1 and m_d are constant in M_0 the eigenvalues $\lambda_1, \cdots, \lambda_d$ of $Q_x(X, Y)$ vary with x. Fix $y \in M$ and choose a compact *nbhd* U_y of y and $\varepsilon_y > 0$ so that $r_1(x) = a_{\mathrm{MAX}}(x) > \varepsilon_y$ for $x \in U_y$ and $r_1(x) - r_j(x) > \varepsilon_y$ for all $x \in U_y$ and $j = 1, \cdots, l$. Here $\{r_i\}$ are the real parts of $\{\lambda_i\}$. Now let V_y be an open *nbhd* of y contained in U_y such that the integral curve of the vector field $\hat{W}^s$, which is defined in the proof of Theorem 3.3, has the property that for some $b_y > 0$, $\hat{W}^s_\tau(x) \in U_y$ $\forall x \in V_y$ $\forall s > 0$ and $\forall \tau \in [0, b_y)$. For $x \in V_y$ the proof of Theorem 3.3 can be repeated exactly to conclude that $A_t \circ (W^s_{\mathrm{MAX}})_\tau(x) \in \overline{\mathcal{R}_t(x)}$ for all $x \in V_y$, $t > 0$ and $\tau \in [0, b_y)$. To complete the proof of part (i) let $\sigma > 0$ and choose an open covering of the curve $\{(W^s_{\mathrm{MAX}})_\tau(x) | 0 \leqq \tau \leqq \sigma\}$ by sets of the form U_y defined above. Choose a finite subcover. Use the above result on each U_y in the subcover to conclude $A_t \circ (W^s_{\mathrm{MAX}})_\tau(x) \in \overline{\mathcal{R}_t(x)}$ for all $\tau > 0$ (where the integral curve is defined). This completes the proof of (i). The same modification works for parts (ii), (iii) and (iv).

Example 3.5 (*continued*). In this example $\mathrm{ad}^3_X\, Y(x) = a_2(x)\, \mathrm{ad}^2_X\, Y + Z$ where $a_2(x) = x_2^2$ and $Xa_2(x) = (da_2)_x X(x) = [0 \;\; 2x_2 \;\; 0]X(x) = 0$ so that $k_*(X, Y) = 2$. The characteristic polynomial for $Q_x(X, Y)$ is $\lambda^3 - x_2^2\lambda^2$ so that the distinct eigenvalues are $\lambda_1(x) = x_2^2$ and $\lambda_2(x) = 0$ with multiplicities $m_1(x) = 1$ and $m_2(x) = 2$ for $x_2 \neq 0$. When $x_2 = 0$ $d(x) = 1$ and $l(x) = 1$ but when $x_2 \neq 0$ $l(x) = d(x) = 2$ so that $l = d = 2$ and $M(X, Y) = \{(x_1, x_2, x_3) \in R^3 | x_2 \neq 0\}$. In this example (3.12) becomes

$$e^{sQ_x(X,Y)} = e^{sx_2^2} \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1/x_2^4 & 1/x_2^2 & 1 \end{bmatrix} + s \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ -1/x_2^2 & 0 & 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -1/x_2^4 & -1/x_2^2 & 0 \end{bmatrix}$$

and (3.13) becomes

$$W^s_*(x) = e^{sx_2^2} W^s_{*\mathrm{MAX}}(x) + s W^s_{*\mathrm{MIN}}(x) + R^s(x)$$

where

$$W^s_{*\mathrm{MAX}}(x) = \left(\frac{-4}{x_2}, 0, x_2\, e^{x_1}\right), \qquad W^s_{*\mathrm{MIN}}(x) = (x_2^3 + 4x_2 - 2x_1x_2, x_2^2, 0)$$

and $R^s(x)=(x_1x_2-4/x_2, x_1, 0)$. Since $a_{\mathrm{MAX}}(x)=x_2^2>0$ on $M(X, Y)$ Theorem 3.5 (i) implies that $W^s_{*\mathrm{MAX}}\in\mathscr{F}^+$ on $M(X, Y)$. Since $a_{\mathrm{MIN}}(x)\equiv 0$ and $m_2(x)=m_d(x)=2>1$ Theorem 3.5 (iv) implies that $(-1)^{m_d+1}W^s_{*\mathrm{MIN}}=-W^s_{*\mathrm{MIN}}\in\mathscr{F}^+$. Since $\pm B\in\mathscr{F}^+$ one can use Lemma 2.1 to show

$$e^{-x_1}\left(\frac{4}{x_2^3}B(x)+W^s_{*\mathrm{MAX}}(x)\right)=(0, 0, x_2)\in\mathscr{F}^+;$$

$$\frac{1}{x_2^2}\left(\frac{x_2^2+4-2x_1}{x_2}B(x)-W^s_{*\mathrm{MIN}}(x)\right)=(0, -1, 0)\in\mathscr{F}^+.$$

Thus on $M(X, Y)=\{(x_1, x_2, x_3)\in R|x_2\neq 0\}$ the vector fields $(\pm 1, 0, 0)$, $(0, 0, x_2)$, $(0, -1, 0)$ and positive linear combinations of these vector fields are in $\mathscr{F}^+$. This increases our knowledge of the shape of the reachable set for this system. Without Theorem 3.5 it is only evident that $(\pm 1, 0, 0)$ are in $\mathscr{F}^+$.

Acknowledgment. The author wishes to thank the anonymous referee for helpful suggestions and in particular for Remark 3 following the proof of Theorem 3.3.

ON LIMIT CYCLES OF FEEDBACK SYSTEMS WHICH CONTAIN A HYSTERESIS NONLINEARITY*

R. K. MILLER†, A. N. MICHEL‡ AND G. S. KRENZ†

Abstract. In this paper, we concern ourselves with the stability of limit cycles in feedback systems which have hysteresis nonlinearities. Although the quasi-static analysis of limit cycles (Loeb criterion) predicts, in most cases correctly, the stability properties of limit cycles, it is well known that analyses which are based on the method of describing functions may lead to erroneous conclusions. In this paper, we show to what extent the describing function method can be given a rigorous mathematical basis. We show that for a specific example, the main result of this paper predicts correctly the stability of a limit cycle while the Loeb criterion yields an incorrect result. Also, we show that our analysis explains to a certain extent the presence of distortions in solutions of the class of feedback systems considered herein.

In arriving at the main result of this paper, use is made of several known facts for functional differential equations and of a result on integral manifolds.

Key words. functional differential equations, periodic solutions, feedback control systems, describing functions, Galerkin's method, hysteresis nonlinearity, delay differential equations, stability, orbital asymptotic stability, Loeb criterion, quasi-static stability analysis, limit cycles

1. Introduction.

The analysis of limit cycle behavior in nonlinear feedback systems is of great practical importance. Questions which arise in this connection concern the existence or nonexistence of limit cycles, estimates of amplitude and frequency of limit cycles, and the stability or instability of limit cycles. The sinusoidal describing function has been found to be a useful tool for answering questions of this type, particularly when the feedback system in question is endowed with one nonlinearity.

The purpose of the present paper is to show to what extent the method of describing functions can be given a rigorous mathematical basis. Our analysis here is an extension of earlier work [1], [30], [31] to the case where the nonlinearity in the feedback system is allowed to exhibit hysteresis. Hysteresis nonlinearities abound in applications. Some of the common types of such nonlinearities include iron core inductors, relays, gears with backlash, and the like. For an extensive discussion of the qualitative characteristics of such nonlinearities, refer, e.g., to the text by Gelb and Van der Velde [2].

It will be seen that the extension of the results in [1], [30], [31] to hysteresis nonlinearities involves considerable complications in the mathematical analysis. This is to be expected, since systems with memory are necessarily more complicated than those which are memoryless. The following example illustrates one such complication. Consider the feedback system

$$y^{(6)}+0.58y^{(5)}+11.6y^{(4)}+4.8648y^{(3)}+35.5y''+7.28y'+24.5y+5n(y)=0, \tag{1.1}$$

where $n(y)$ is the nonlinearity whose graph is given in Fig. 1. The sinusoidal-input describing function of this nonlinearity is given by

$$N(A)=2-\frac{2}{\pi}\left\{\sin^{-1}\left(\frac{2}{A}\right)+\left(\frac{2}{A}\right)\sqrt{1-4A^{-2}}\right\}-\frac{8i}{\pi A^2}.$$

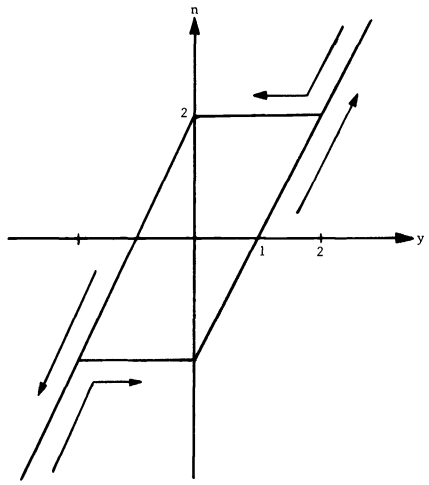

FIG. 1. *Nonlinear element for* (1.1).

A routine application of the describing function method [2] yields the prediction of a stable limit $y_0(t)$, which is approximately equal to

$$y_0(t) \cong A_0 \sin(\omega_0 t + \theta) \tag{1.2}$$

where $A_0 = 2.75$ and $\omega = 1.21$. (Without loss of generality, we take $\theta = 0$.) Numerical simulations of (1.1) verify that $y_0(t)$ does indeed exist and is approximately given by (1.2). These numerical solutions were also used to check whether or not (1.2) can be differentiated, i.e., whether or not it is true that, e.g.,

$$y_0'(t) \cong \omega_0 A_0 \cos \omega_0 t, \qquad y_0'' \cong -\omega_0^2 A_0 \sin \omega_0 t, \cdots. \tag{1.3}$$

It was found that (1.3) is not always valid. Specifically, Fig. 2 depicts the graphs of $y_0(t)$ and $y_0^{(5)}(t)$, computed numerically by simulating (1.1), as well as the predicted derivative $\omega_0^5 A_0 \cos \omega_0 t$. Clearly, (1.3) is not valid. This is curious, since (1.3) is found

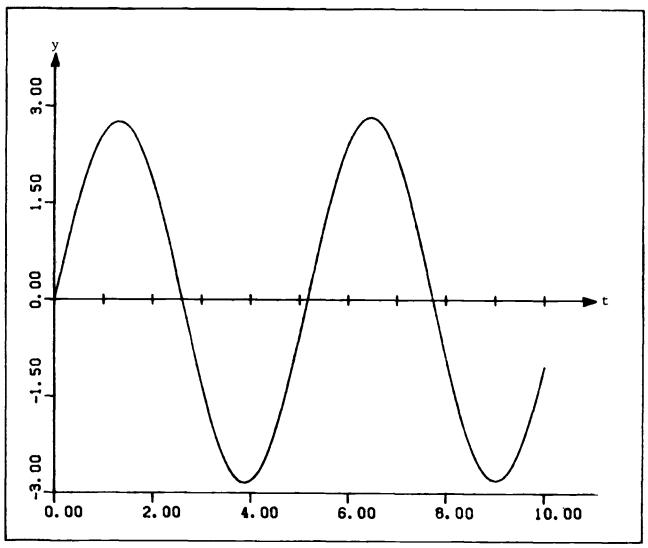

FIG. 2a. $y(t) \cong A_0 \sin \omega_0 t$.

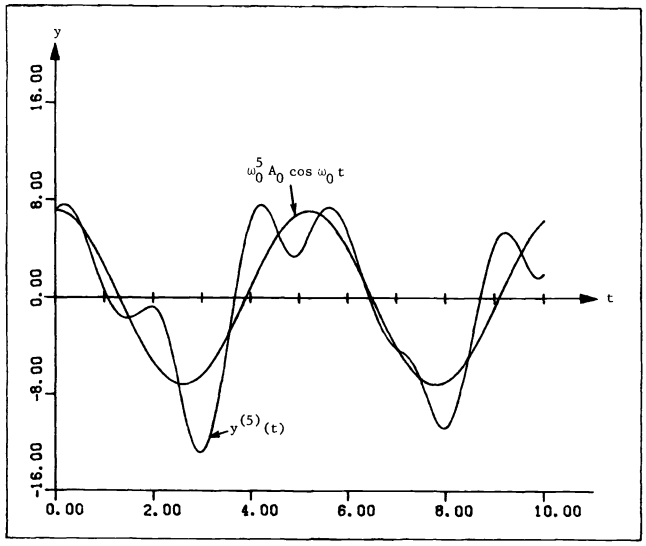

FIG. 2b. $y^{(5)}(t)$ *and* $\omega_0^5 A_0 \cos \omega_0 t$.

to be true to rather high accuracy for feedback systems where the nonlinearity $n(y)$ in (1.1) is memoryless.

Several third through sixth order equations with a variety of nonlinearities were simulated. The result was always the same: For stable limit cycles (1.3) accurately predicts the values of derivatives when $n(y)$ is memoryless and is inaccurate when $n(y)$ exhibits hysteresis. Our results will provide an explanation of this curious phenomenon. Furthermore, our results will also explain why a limit cycle can sometimes be unstable, even though the method of describing functions yields a prediction of stability.

Recently, the method of describing functions and other generalized Galerkin procedures have been studied extensively. Many of these results are concerned with *existence* of a limit cycle (e.g., Holtzman [7], Mees [8], Mees and Chua [10], Miller and Michel [11], Sandberg [12], [13], Cesari [14], Urabe [15] and Stokes [16]). *Nonexistence* results for limit cycles can be found in Mees and Bergen [9], Skar, Miller and Michel [17] and Urabe [15]. Also, *stability* results for limit cycles can be found in Mees and Chua [10], and in [1], [30], [31]. The method of analysis and results in [10], which are obtained by using Hopf bifurcation, are quite different from the results and methods of [1], [30], [31] and of this paper. Specifically, in the present paper we employ linearization about an approximate periodic solution, we make use of several appropriate transformations, and we utilize some results from the theory of integral manifolds (cf. [1], [4, Chap. 4], [5] or [6]). Our results contain a justification and correction of the popular quasi-static stability analysis (or Loeb criterion) developed by Cahen [18] (see also Loeb [19], Gibson [3], or Gelb and Van der Velde [2, pp. 120–125]). This quasi-static analysis is based on the sinusoidal-input describing function and has a well-known graphical interpretation. Furthermore, it has been established by a great deal of experience that the quasi-static stability analysis of limit cycles will usually yield correct predictions. However, we shall see that in certain situations this stability prediction can be incorrect. An example of such an incorrect prediction will be given at the end of this paper.

2. Main results. Consider the linear differential operators

$$Ly = \alpha_0 y^{(J)} + \alpha_1 y^{(J-1)} + \cdots + \alpha_{J-1} y' + \alpha_J y$$

and

$$Qy = \gamma_1 y^{(J-1)} + \gamma_2 y^{(J-2)} + \cdots + \gamma_{J-1} y' + \gamma_J y$$

where all α_j and γ_j are real numbers, $\alpha_0 = 1$ and at least one $\gamma_j \neq 0$. Let $n(y)$ denote a real valued, odd nonlinearity with hysteresis. Moreover, we assume that $n(y)$ is determined by an "upper" function, $n_U(y)$, which is used to define $n(y)$ as y decreases from $+\infty$ to $-\infty$, and a "lower" function, $n_L(y)$, which is used to define $n(y)$ as y increases from $-\infty$ to $+\infty$. For example, if $n(y)$ represents a relay with hysteresis as depicted in Fig. 3a, then $n_U(y)$ and $n_L(y)$ are the functions whose graphs are as shown in Figs. 3b and 3c, respectively.

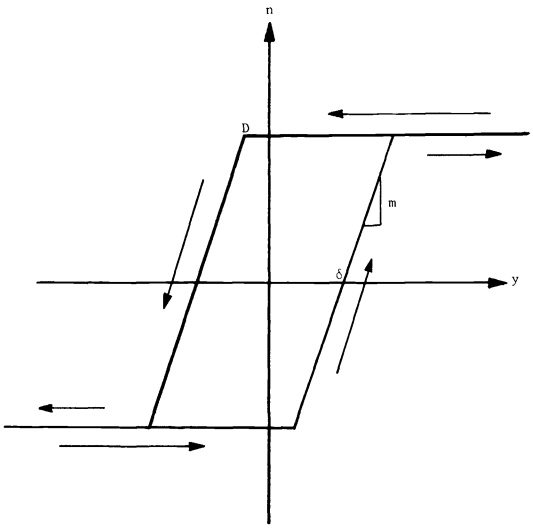

FIG. 3a. *The functional* $n(y)$.

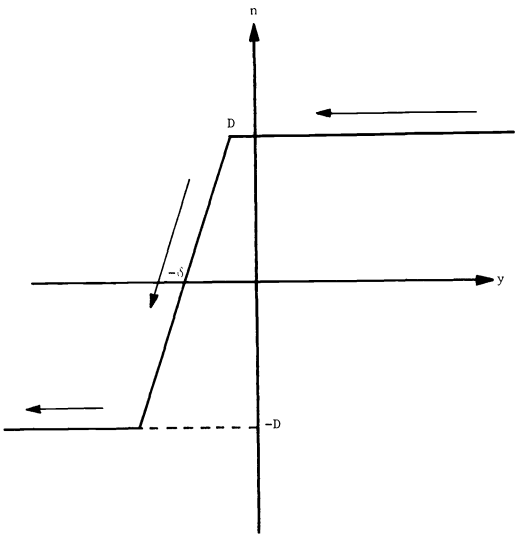

FIG. 3b. *The function* $n_U(y)$.

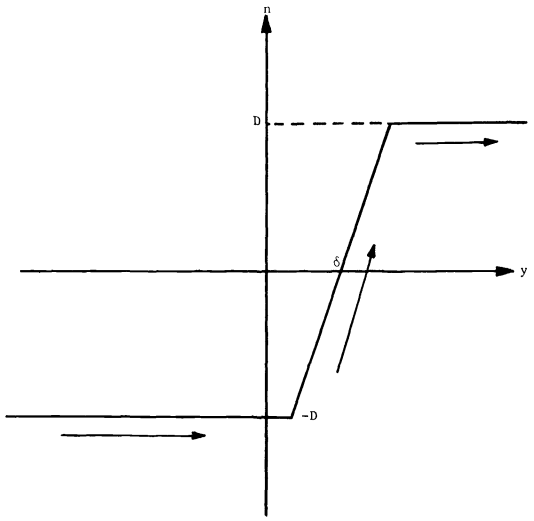

FIG. 3c. *The function* $n_L(y)$.

The *hysteresis region* of a hysteresis nonlinearity $n(y)$ is defined as the set $\{y \in R: n_U(y) \neq n_L(y)\}$. We assume that the hysteresis region is bounded. We also assume that n_U (resp., n_L) is a piecewise continuously differentiable function and that n_U'' (resp., n_L'') exists and is uniformly continuous on all intervals of the form (a, b) on which $n_U'(y)$ (resp., $n_L'(y)$) exists and is continuous.

Consider now the *feedback system*

$$Ly + n(Qy) = 0. \tag{2.1}$$

Suppose that the method of describing functions predicts a $2\pi/\omega_0$-periodic solution with amplitude A_0 (where A_0 and ω_0 are positive numbers). Thus, if

$$p(s) \triangleq \alpha_0 s^J + \alpha_1 s^{J-1} + \cdots + \alpha_{J-1} s + \alpha_J, \qquad q(s) \triangleq \gamma_1 s^{J-1} + \gamma_2 s^{J-2} + \cdots + \gamma_J$$

and if $N(A) = N_R(A) + iN_I(A)$ is the describing function for $n(y)$, then

$$p(i\omega_0) + q(i\omega_0) N(A_0 E) = 0, \qquad E = |q(i\omega_0)|. \tag{2.2}$$

We assume that $A_0 E$ is not in the hysteresis region of $n(y)$ nor is $y = A_0 E$ a value where $n'(y)$ does not exist. For example, if the graph of $n(y)$ is as shown in Fig. 4, then we assume that $A_0 E$ is not in the interval $[\delta_1, \delta_2]$ and $A_0 E$ is not equal to δ_3.

We expect that (2.1) will have a periodic solution $\phi(t)$ which is approximately equal to $A_0 \cos \omega_0 t$. In this case, ϕ will generate an integral manifold of (2.1), namely the set of points $\{(\phi(t+\theta), \phi'(t+\theta), \cdots, \phi^{(J-1)}(t+\theta)): -\infty < t, \theta < \infty\}$. We will show that a typical equation of the form (2.1) will have an associated integral manifold S whose stability type can be readily determined. The existence of S is independent of existence or nonexistence of a periodic solution ϕ. Hence, if (2.1) does not have a periodic solution $\phi(t) \cong A_0 \cos \omega_0 t$, it will still have the integral manifold S with the same type of behavior as the solutions of (2.1).

Our stability analysis depends on first finding a certain linear differential-difference equation of the form

$$\begin{aligned} &\alpha_0 y^{(J)}(t) + \alpha_1 y^{(J-1)}(t) + \cdots + \alpha_{J-1} y^{(1)}(t) + \alpha_J y(t) \\ &\quad + |N(A_0 E)|[\gamma_1 y^{(J-1)}(t-\alpha) + \gamma_2 y^{(J-2)}(t-\alpha) + \cdots + \gamma_J y(t-\alpha)] = 0. \end{aligned} \tag{2.3}$$

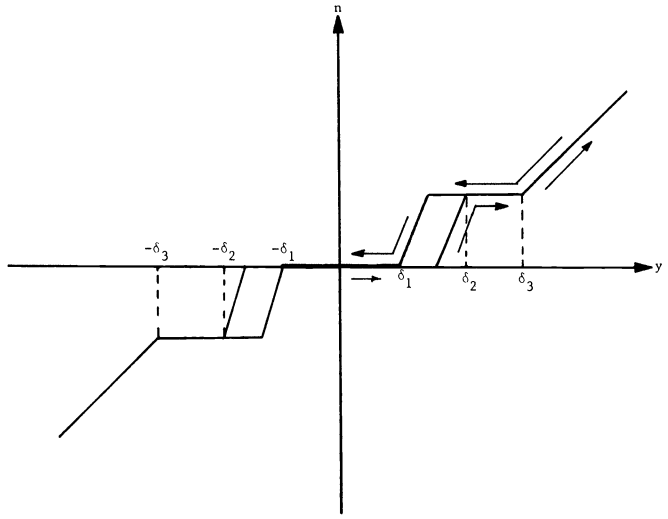

FIG. 4

The number $\alpha \geqq 0$ is computed by first writing $N(A_0E)$ in the polar form

$$N(A_0E) = |N(A_0E)|\, e^{-i\theta_0}$$

where $\theta_0 = \arg N(A_0E)$ satisfies $0 \leqq \theta_0 < 2\pi$. Define

$$\alpha \triangleq \frac{\theta_0}{\omega_0} \geqq 0.$$

The characteristic equation for (2.3) has the form $P(s) = 0$ where

$$P(s) \triangleq p(s) + |N(A_0E)|\, e^{-\alpha s} q(s) \tag{2.4}$$

and where $p(s)$ and $q(s)$ are defined as for (2.2). From (2.2) we know that $s_1 = i\omega_0$ and $s_2 = -i\omega_0$ are roots of $P(s)$. We label the remaining roots as $s_3, s_4, s_5, \cdots$.

We are now in a position to enumerate the assumptions for our main result:

(A-1) The numbers α_k and γ_k are real, $\alpha_0 = 1$, and not all γ_j are zero.

(A-2) $n(y)$ is a real functional determined by an "upper" function $n_U(y)$ and a "lower" function $n_L(y)$. The functions n_U and n_L are real valued, piecewise continuous, differentiable functions whose second derivatives are uniformly continuous on all intervals (a, b) where their first derivatives exist. Moreover, $n(y)$ is odd in the sense that

$$n_U(y) = -n_L(-y)$$

for all real numbers y. Also $n_U(y) = n_L(y)$ for $|y|$ sufficiently large.

(A-3) For some $A_0 > 0$ and $\omega_0 > 0$ equation (2.2) is true and $N(A_0E) \neq 0$. Moreover, EA_0 is not in the hysteresis region of n nor does EA_0 lie at a discontinuity of n'_U or n'_L.

(A-4) $s_1 = i\omega_0$ and $s_2 = -i\omega_0$ are simple roots of the function $P(s)$ defined by (2.4). The remaining roots $s_3, s_4, \cdots$ have nonzero real parts.

(A-5) For $k = 3, 4, \cdots$, s_k is a simple root of $P(s)$.

The main result of the present paper follows.

THEOREM 1. *Assume that* (A-1)-(A-5) *are true and define*

$$D \triangleq \operatorname{Re}\{N'(A_0E)q(i\omega_0)/P'(i\omega_0)\}.$$

If the numbers $|P'(s_k)^{-1}|$ *are sufficiently small for* $k = 1, 2, 3, \cdots$, *then* (2.1) *has, in a*

small neighborhood of the set

$$S_0 = \{(t, A_0 \cos(\omega_0 t + \theta), -A_0\omega_0 \sin(\omega_0 t + \theta), -A_0\omega_0^2 \cos(\omega_0 t + \theta), \cdots)^T: -\infty < t < \infty, 0 \leqq \theta \leqq 2\pi\} \subset R^{J+1}$$

a unique integral manifold S. This integral manifold is stable if $D > 0$ *and if* $\operatorname{Re} s_k < 0$ *for all* $k \geqq 3$. *This integral manifold is unstable if* $D < 0$ *or if* $\operatorname{Re} s_k > 0$ *for some* $k \geqq 3$.

Observe that the conclusion of the theorem is the existence of an integral manifold S which lies near the integral manifold generated by the approximate solution $A_0 \cos \omega_0 t$. The manifold S corresponds to a deformed torus fitted tightly around the predicted state-space limit cycle. While we cannot prove that solutions on S are periodic, these solutions will *appear* to the eye to be periodic and nearly sinusoidal with frequency near ω_0 and amplitude near A_0. If S is stable, then the apparent periodic solutions will appear to be orbitally asymptotically stable with asymptotic phase. If S is unstable, they will appear to be unstable in the sense of Lyapunov. This is the sense in which the theorem justifies the use of the describing function.

We remark that the hypothesis (A-5) concerning the simplicity of the roots s_k could be relaxed. In this case, the assumption that $|P'(s_k)^{-1}|$ is small must be replaced by other more complicated conditions. All of this can be accomplished only by making an already complicated analysis even more complicated. Hence, we shall retain (A-5). It will be shown later that if (A-5) is not true, then there is an $\varepsilon_0 > 0$ such that when α_J is replaced by $\alpha_J + \varepsilon$ and $0 < |\varepsilon| < \varepsilon_0$ hypothesis (A-5) is true. Hence, (A-5) does not appear to be a severe restriction.

Theorem 1 has the disadvantage that it is difficult to obtain the roots s_k for $k \geqq 3$, and hence, it is difficult to obtain the numbers $|P'(s_k)^{-1}|$. In addition, we cannot specify precisely how small the numbers $|P'(s_k)^{-1}|$ should be. However, this difficulty is partially offset by our knowledge that

$$\lim_{k \to \infty} |P'(s_k)^{-1}| = 0.$$

Moreover, for a typical equation (2.1) of degree $J \geqq 3$, these constants seem to be rather small. In all the examples which we considered, the size of the one number $|P'(i\omega_0)^{-1}|$ was a good indication of whether Theorem 1 would apply. We conjecture that in Theorem 1 only $|P'(i\omega_0)^{-1}|$ need be small while the smallness of $|P'(s_j)^{-1}|$ for $j \geqq 3$ is unnecessary. This conjecture is known to be true when $n(y)$ is a function rather than a functional which exhibits hysteresis (cf. [30], [31]).

The remainder of this paper is organized as follows. in § 3 we provide some necessary material concerning differential-delay equations; in § 4 we present some required background material on integral manifolds; in §§ 5 and 6 we prove the main result of this paper; in § 7 we discuss situations for which the quasi-static stability analysis yields incorrect results; in § 8 we present some specific examples; finally, the paper is concluded with several concluding remarks in § 9.

3. Some background material on differential-delay equations. Let R^J denote the real J-dimensional Euclidean space of column vectors with any convenient norm. Let R_J be the corresponding real J-dimensional space of row vectors. Consider a linear differential-difference equation of the form

$$z'(t) = B_0 z(t) + B_1 z(t - \alpha), \tag{3.1}$$

where $z(t)$ is an R^J-vector valued function, B_0 and B_1 are real and constant $J \times J$ matrices and α is a fixed nonnegative constant. An initial condition for (3.1) consists of specifying the value of $z(t)$ over the initial interval $-\alpha \leqq t \leqq 0$.

We shall view (3.1) as a functional differential equation with initial values in an appropriate Banach space. Our discussion follows Hale [22], [23]. Define

$$C[-\alpha, 0] = \{\phi: [-\alpha, 0] \to R^J;\ \phi \text{ is continuous}\}$$

and define a norm on $C[-\alpha, 0]$ by

$$\|\phi\| = \max\{|\phi(\theta)|, -\alpha \leqq \theta \leqq 0\}$$

where $|\cdot|$ denotes the norm on R^J. Similarly, define

$$C^*[0, \alpha] = \{\psi: [0, \alpha] \to R_J;\ \psi \text{ is continuous}\}$$

and define

$$\|\psi\| = \max\{|\psi(s)|: 0 \leqq s \leqq \alpha\}.$$

Given a continuous function $z: [-\alpha, a) \to R^J$ with $a > 0$, define an element z_t of $C[-\alpha, 0]$ by the formula

$$z_t(\theta) = z(t+\theta), \qquad -\alpha \leqq \theta \leqq 0,$$

for any $t \in [0, a)$. With the aid of this notation, (3.1) can now be written as

$$z'(t) = L_0 z_t, \tag{3.2}$$

where L_0 is the linear map from $C[-\alpha, 0]$ into R^J defined by

$$L_0\phi = B_0\phi(0) + B_1\phi(-\alpha).$$

This linear map can also be written as a Stieltjes integral, i.e.,

$$L_0\phi = \int_{-\alpha}^{0} d\eta(\theta)\phi(\theta) \tag{3.3}$$

where

$$\eta(\theta) = \begin{cases} 0 & \text{if } \theta = -\alpha, \\ B_1 & \text{if } -\alpha < \theta < 0, \\ B_0 + B_1 & \text{if } \theta = 0. \end{cases}$$

The *adjoint equation* corresponding to (3.1) is the equation

$$y'(t) = -y(t)B_0 - y(t+\alpha)B_1$$

where $y(t) \in R_J$ is a row vector valued function.

The initial value problem for (3.2) takes the form

$$z'(t) = L_0 z_t, \qquad z_0 = \phi \tag{3.4}$$

where the initial function ϕ is chosen from the set $C[-\alpha, 0]$. The initial value problem (3.4) has a unique solution defined for all $t \geqq 0$. We denote this solution by $z(t, \phi)$ if we think of z as R^J-valued and by $z_t(\phi)$ if we view z as assuming values in $C[-\alpha, 0]$.

We shall also require the notation

$$T(t)\phi \triangleq z_t(\phi)$$

for all $t \geqq 0$ and for all ϕ in $C[-\alpha, 0]$. For any fixed $t \geqq 0$, $T(t)$ is a bounded linear map from $C[-\alpha, 0]$ into itself with the usual operator norm

$$\|T(t)\| = \sup\{\|T(t)\phi\|;\ \phi \in C[-\alpha, 0] \text{ and } \|\phi\| = 1\}.$$

$T(t)$ determines a C_0-semigroup on $C[-\alpha, 0]$. The infinitesimal generator of this semigroup is the operator A_0 whose domain is

$$D(A_0) = \{\phi \in C[-\alpha, 0];\ \phi' \text{ exists},\ \phi' \in C[-\alpha, 0] \text{ and } \phi'(0) = L_0(\phi)\}.$$

For any ϕ in $D(A_0)$, A_0 is defined by the relation

$$(A_0\phi)(\theta) = \begin{cases} \phi'(\theta), & -\alpha \leqq \theta < 0, \\ L_0(\phi), & \theta = 0. \end{cases}$$

The set $D(A_0)$ is a dense subset of $C[-\alpha, 0]$. Refer, e.g., to Krein [25] or Hille and Phillips [26] for a discussion of C_0-semigroups.

The *characteristic equation* associated with (3.1) is

$$P(s) \triangleq \det (sI - B_0 - B_1 e^{-\alpha s}) = 0,$$

where I denotes the $J \times J$ identity matrix. The *eigenvalues* associated with (3.1) are the solutions of the characteristic equation. If $B_1 \neq 0$ and if $\alpha > 0$, then it is known that there is a countably infinite set

$$\sigma(L_0) = \{\lambda_n : n = 1, 2, 3, \cdots\}$$

of eigenvalues for (3.1). Each eigenvalue has finite multiplicity. These eigenvalues can be indexed so that $\operatorname{Re} \lambda_1 \geqq \operatorname{Re} \lambda_2 \geqq \operatorname{Re} \lambda_3 \geqq \cdots$ and we shall assume that this has in fact been done. It is known that $\operatorname{Re} \lambda_k$ will tend to $-\infty$ as $k \to \infty$.

Given any real number μ, define $\Lambda(\mu) = \{\lambda \in \sigma(L_0) : \operatorname{Re} \lambda \geqq -\mu\}$. There is a set $\{\phi_1, \phi_2, \cdots, \phi_V\}$ in $C[-\alpha, 0]$, called the *bases for the generalized eigenspace of* (3.1) for $\Lambda(\mu)$, and a set $\{\psi_1, \psi_2, \cdots, \psi_V\}$ in $C^*[0, \alpha]$, called the *bases for the generalized eigenspace of the adjoint of* (3.1) *for* $\Lambda(\mu)$, with the following special properties. Let Φ_μ be the $J \times V$ matrix whose columns are the vectors $\phi_1, \phi_2, \cdots, \phi_V$, i.e.,

$$\Phi_\mu = [\phi_1, \phi_2, \cdots, \phi_V].$$

Let Ψ_μ be that $V \times J$ matrix whose rows are the vectors $\psi_1, \psi_2, \cdots, \psi_V$, i.e.,

$$\Psi_\mu = \text{column}\,[\psi_1, \psi_2, \cdots, \psi_V].$$

Define a bilinear map by

$$(\psi, \phi) \triangleq \psi(0)\phi(0) - \int_{-\alpha}^{0} \left[\int_0^\theta \psi(\xi - \theta)\, d\eta(\theta) \right] \phi(\xi)\, d\xi,$$

for all $\psi \in C^*[0, \alpha]$ and for all $\phi \in C[-\alpha, 0]$. Then, Φ_μ and Ψ_μ can be chosen so that $(\psi_i, \phi_j) = \delta_{ij}$, the Kronecker delta. Define

$$P_\mu = \{\phi \in C[-\alpha, 0];\ \phi = \Phi_\mu b \text{ for some } b \in R^V\}$$

and

$$Q_\mu = \{\phi \in C[-\alpha, 0];\ (\Psi_\mu, \phi) = 0\}.$$

Then $C[-\alpha, 0]$ is the direct sum of P_μ and Q_μ. Indeed, if

$$\phi_P = \Phi_\mu(\Psi_\mu, \phi) \quad \text{and} \quad \phi_Q = \phi - \phi_P,$$

then $\phi_P \in P_\mu$, $\phi_Q \in Q_\mu$ and $\phi = \phi_P + \phi_Q$. The two subspaces P_μ and Q_μ are invariant under $T(t)$, i.e.,

$$T(t)P_\mu \subset P_\mu \quad \text{and} \quad T(t)Q_\mu \subset Q_\mu$$

for all $t \geqq 0$. There is a matrix B_μ (cf., e.g., [23, pp. 170-171] or [22]) such that

$$[T(t)\Phi_\mu b](\theta) = \Phi_\mu(0)\, e^{B_\mu(t+\theta)}b \tag{3.5}$$

for all $b \in R_V$, for all $t \geqq 0$, and for all $\theta \in [-\alpha, 0]$, while

$$\|T(t)\phi\| \leqq K_\mu\, e^{-\mu t}\|\phi\| \tag{3.6}$$

for all $\phi \in Q_\mu$ and for all $t \geqq 0$.

Consider also the nonhomogeneous initial value problem

$$z'(t) = L_0 z_t + F_0(t), \qquad z_0 = \phi \tag{3.7}$$

where $\phi \in C[-\alpha, 0]$, $F_0 : [0, \infty) \to R^J$ is continuous, and $L_0\phi$ is defined by (3.3). We again fix μ and obtain $\Lambda(\mu)$, B_μ, P_μ and Q_μ. Define

$$H_0(\theta) = \begin{cases} 0 & \text{if } -\infty \leqq \theta < 0, \\ I & \text{if } \theta = 0. \end{cases}$$

Then the solution $z_t(\phi)$ of (3.7) can be written in the form

$$z_t(\phi) = \Phi_\mu y(t) + z_{1t}$$

where

$$\begin{aligned} &y' = B_\mu y + \Psi_\mu(0)F_0(t), \qquad y(0) = (\Psi_\mu, \phi), \\ &z_{1t} = T(t)\phi_Q + \int_0^t T(t-s)[H_0 - \Phi_\mu\Psi_\mu(0)]F_0(s)\, ds. \end{aligned} \tag{3.8}$$

Here $\phi_Q = \phi - \Phi_\mu(\Psi_\mu, \phi) \in Q_\mu$ and $z_{1t} \in Q_\mu$ for all $t \geqq 0$.

All of the above results concerning (3.1) and (3.7) can be found in Hale [23, especially Chapter 7] or [22, especially pp. 94-130].

We now specialize to the equation

$$\alpha_0 y^{(J)}(t) + \alpha_1 y^{(J-1)}(t) + \cdots + \alpha_J y(t) + N[\gamma_1 y^{(J-1)}(t-\alpha) + \cdots + \gamma_J y(t-\alpha)] \tag{3.9}$$

where $\alpha_0 = 1$, $\alpha \geqq 0$, N, α_k and γ_i are real numbers, $N \neq 0$, and at least one $\gamma_i \neq 0$. As usual, if we set $z_1 = y$, $z_2 = y'$, etc., in (3.9), then that equation is equivalent to an equation of the form (3.1). Hence, the foregoing analysis concerning (3.1) will apply to (3.9). If we define

$$\Delta(\lambda) = \begin{bmatrix} \lambda & -1 & \cdots & 0 \\ 0 & \lambda & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots \\ N\gamma_J e^{-\alpha\lambda} + \alpha_J & N\gamma_{J-1} e^{-\alpha\lambda} + \alpha_{J-1} & \cdots & N\gamma_1 e^{-\alpha\lambda} + \alpha_1 \end{bmatrix}$$

then the characteristic equation associated with (3.1) is seen to be

$$P(\lambda) = \det \Delta(\lambda) = \sum_{j=0}^{J-1} \lambda^j(\alpha_{J-j} + N\gamma_{J-j} e^{-\lambda\alpha}) + \lambda^J. \tag{3.10}$$

If A_0 is the infinitesimal generator of the corresponding semigroup and if λ is not an eigenvalue, then $(A_0 - \lambda I)\phi = \psi$ can be solved for $\phi = R(\lambda)\psi$ where $R(\lambda) = (A_0 - \lambda I)^{-1}$.

A lengthy but straightforward calculation shows that

$$\phi(\theta) = -\Delta(\lambda)^{-1}\left[\psi(0)\, e^{\lambda\theta} - e^{\lambda\theta}\int_{-\alpha}^{0} d\eta(u)\left(\int_0^u e^{\lambda(u-s)}\psi(s)\, ds\right)\right] + \int_0^\theta e^{\lambda(\theta-s)}\psi(s)\, ds \tag{3.11}$$

(see, e.g., Hale [22] or [23]).

Now fix a large positive μ. If $\phi \in Q_\mu \cap D(A_0)$, then for some $\sigma > 0$ it will be true that for $t > \alpha$,

$$T(t)\phi = -\frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{\lambda t} R(\lambda)\phi\, d\lambda, \tag{3.12}$$

where the integral is taken in the principal value sense (cf., e.g., [25, Thm. 13, p. 31] or [26, § 11.6]). If x^* is any linear functional on $C[-\alpha, 0]$, then by (3.12) it follows that

$$x^*(T(t)\phi) = -\frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{\lambda t} x^*(R(\lambda)\phi)\, d\lambda. \tag{3.13}$$

In particular, we pick x^* in (3.13) so that $x^*(\phi) = \phi(0)$. This yields

$$z(t, \phi) = [T(t)\phi](0) = -\frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{\lambda t}[R(\lambda)\phi](0)\, d\lambda.$$

The above relation, together with (3.11) results in the equation

$$z(t, \phi) = \frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{\lambda t}\Delta(\lambda)^{-1}\left[\phi(0) - \int_{-\alpha}^{0} d\eta(u)\left(\int_0^u e^{\lambda(u-s)}\phi(s)\, ds\right)\right] d\lambda. \tag{3.14}$$

The function F defined by

$$F(\lambda) \triangleq \Delta(\lambda)^{-1}\left[\phi(0) - \int_{-\alpha}^{0} d\eta(u)\left(\int_0^u e^{\lambda(u-s)}\phi(s)\, ds\right)\right]$$

is meromorphic and its poles can occur only at the eigenvalues $\lambda \in \sigma(L_0)$. Since $\phi \in Q_\mu$, it follows that $(\Psi_\mu, \phi) = 0$. Hence, the points $\lambda \in \Lambda(\mu)$ are removable singularities of F. The poles of $F(\lambda)$ must be in the set $\sigma(L_0) \cap \{\lambda : \operatorname{Re}\lambda < -\mu\}$. Thus, the contour of integration in (3.14) can be shifted to the left to the line $\operatorname{Re}\lambda = -\mu$, i.e.,

$$z(t, \phi) = \frac{1}{2\pi i}\int_{-\mu-i\infty}^{-\mu+i\infty} e^{\lambda t} F(\lambda)\, d\lambda. \tag{3.15}$$

Since (3.1) is now the Jth order equation (3.9), written in system form, the following result is true (cf. [24, § 12.8, especially p. 423, Thm. 12.15]).

THEOREM 2. (a) *The roots of* $P(\lambda) = \det\Delta(\lambda)$ *lie in a half plane* $\operatorname{Re}\lambda \leqq a_0$. *This set of roots is countable, the multiplicity of any root is at most J, and there can be at most J multiple roots. If* $\alpha > 0$, *then the (infinite) set of roots asymptotically approaches the curve*

$$|\lambda^M e^{\alpha\lambda}| = |N\gamma_M| \tag{3.16}$$

as $\operatorname{Re}\lambda \to -\infty$ *where M is the smallest integer j such that* $\gamma_j \neq 0$. *Moreover, there exists a number* $k > 0$ *such that the roots lie along the curve* (3.16) *an asymptotic distance of k apart.*

(b) *There exist* $M \geqq 1$ *and* $c_0 > 0$ *and for any* $c_1 > 0$ *there exists a number* $K > 0$ *such that if* $|\lambda| \geqq c_0$ *and if* λ *is at least a distance* c_1 *away from the set* $\sigma(L_0)$, *then* $|\Delta(\lambda)^{-1}| \leqq K|\lambda|^{-M}$.

Figure 5 shows the general shape of the curve (3.16). The x's indicate a typical set $\sigma(L_0)$. For $\alpha > 0$, Theorem 2 could also be applied to $\Delta'(\lambda)$. For $\Delta'(\lambda)$, the equation corresponding to (3.16) is $|\lambda^{M-1}\varepsilon^{\alpha\lambda}| = |\alpha N\gamma_M / M|$. Since the graph of this equation will not intersect the curve described by (3.16) for $|\lambda|$ sufficiently large, then there exists $c_1 > 0$ such that the roots of $P(\lambda)$ and $P'(\lambda)$ are separated by a distance of at least one when $|\lambda| \geqq c_1$ and such that $P(\lambda)$ has no roots on the circle $|\lambda| = c_1$. The number c_1 can be chosen independently of small changes in the coefficients $(\alpha_0, \alpha_1, \cdots, \alpha_J) \in R^{J+1}$, e.g. see [24]. Hence, any multiple roots of $P(\lambda)$ must lie in the disk $|\lambda| < c_1$. An elementary complex variable argument shows that if $P(\lambda)$ has multiple roots in the disk $|\lambda| < c_1$, then there is an $\delta_0 > 0$ such that if δ is a real number with $0 < |\delta| < \delta_0$ then $P(\lambda) + \delta$ has only simple roots. Hence, we can always arrange things so that assumption (A-5) is true by an arbitrarily small change in the parameter α_J of the differential equation (2.1).

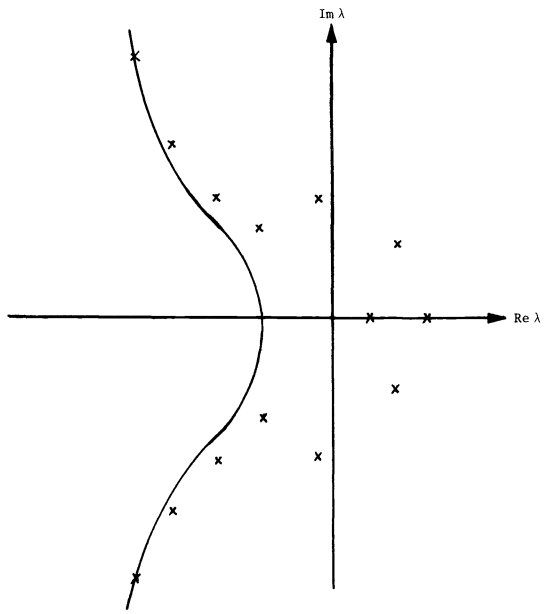

FIG. 5. *Typical curve* $|\lambda^M e^{\alpha\lambda}| = |N\gamma_M|$ *and set* $\sigma(L_0)$.

Let c_0 and k be the numbers defined in Theorem 2. Choose ε in the interval $0 < \varepsilon < k$. Since the choice of μ is at our disposal, we may pick $\mu > c_0 + k$, and so large, that all points of the set $\sigma(L_0) \cap \{\lambda : \operatorname{Re}\lambda < -\mu\}$ lie within $\varepsilon/10$ of the curve (3.16) and are located at a distance greater than $0.8k$ from each other. Define $c_2 \triangleq \inf\{\operatorname{Im}\lambda - \varepsilon/10 : \lambda \in \sigma(L_0) \text{ and } \operatorname{Re}\lambda < -\mu\}$. Define

$$S_0(\varepsilon) = \{\lambda : \lambda \text{ lies within } \varepsilon/10 \text{ of the set } \sigma(L_0)\}.$$

Let K be the number given in Theorem 2, corresponding to $c_1 = \varepsilon/10$. Define

$$\Gamma_1 = \{-\mu + i\tau;\ 0 \leqq \tau \leqq c_2\},$$

$$\Gamma_2 = \{\sigma + ic_2;\ -\mu \leqq \sigma \leqq -\mu + \varepsilon\},$$

and

$$\Gamma_3 = \{-\mu + \varepsilon + i\tau;\ c_2 \leqq \tau \leqq \infty\}.$$

Let Γ denote the upward directed curve made up of $\Gamma_1 \cup \Gamma_2 \cup \Gamma_3$ and its symmetric image below the real axis (see Fig. 6). By its construction, the contour Γ misses the set $S_0(\varepsilon)$. Hence, $|\Delta(\lambda)^{-1}| \leqq K|\lambda|^{-1}$ on Γ. The contour in (3.15) can be shifted so that

$$z(t, \phi) = \frac{1}{2\pi i} \int_{\Gamma} e^{\lambda t} F(\lambda)\, d\lambda.$$

Now

$$\begin{aligned} \frac{1}{2\pi i} \int_{\Gamma_1} e^{\lambda t} F(\lambda)\, d\lambda &= \frac{1}{2\pi} \int_0^{c_2} e^{(-\mu + i\tau)t} F(-\mu + i\tau)\, d\tau \\ &= \frac{e^{-\mu t}}{2\pi} \int_0^{c_2} e^{-i\tau t} F(-\mu + i\tau)\, d\tau. \end{aligned} \tag{3.17}$$

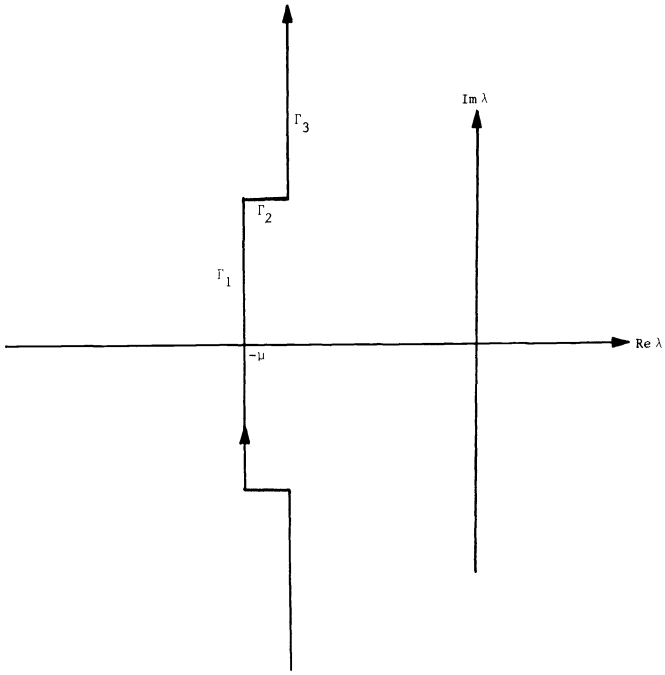

FIG. 6. *The contour* Γ.

The last integral above on the right is the Fourier transform of a function whose L^2-norm can be estimated by

$$\int_0^{c_2} |F(-\mu + i\tau)|^2\, d\tau \leqq \int_{-\infty}^{\infty} K^2 |-\mu + i\tau|^{-2}\, d\tau \triangleq K_1(\mu)^2.$$

By the Parseval relation, the last integral on the right in (3.17) defines a function of t whose L_2-norm over $(0, \infty)$ is at most $\sqrt{2\pi}\, K_1(\mu)$. Similarly, the function f defined by the integral

$$\frac{1}{2\pi i} \int_{\Gamma_3} e^{\lambda t} F(\lambda)\, d\lambda = e^{-(\mu+\varepsilon)t} f(t)$$

has L^2-norm over $(0,\infty)$ which is at most $\sqrt{2\pi}\,K_1(\mu)$. The corresponding contour integrals below the real axis satisfy identical estimates.

Now consider the integral

$$\frac{1}{2\pi i}\int_{\Gamma_2} e^{\lambda t}F(\lambda)\,d\lambda = \frac{1}{2\pi i}\int_0^{\varepsilon} e^{(-\mu+\sigma+ic_2)t}F(-\mu+\sigma+ic_2)\,d\sigma.$$

The magnitude of this integral is at most

$$\frac{e^{-\mu t}}{2\pi}\int_0^{\varepsilon} e^{\sigma t}K|-\mu+\sigma+ic_2|^{-1}\,d\sigma.$$

The corresponding integral below the real axis satisfies an identical estimate.

From these estimates we see that if $\|\phi\| \leqq 1$, then there is a constant $K_2(\mu)$ such that $K_2(\mu)\to 0$ as $\mu\to\infty$ and

$$z(t,\phi) = [g_\mu(t)+f_\mu(t)]\,e^{(-\mu+\varepsilon)t} \tag{3.18}$$

where

$$\int_0^{\infty} |f_\mu(t)|^2\,dt \leqq K_2(\mu)^2, \qquad |g_\mu(t)| \leqq K_2(\mu).$$

Since $z=(y, y', y'', \cdots, y^{(J-1)})^T$ where y solves (3.9), then we see that $y^{(J)}(t)$ satisfies a similar estimate. Hence, $z'(t,\phi)$ also satisfies a similar estimate, i.e.,

$$z'(t,\phi) = [g(t)+f(t)]\,e^{(-\mu+\varepsilon)t}, \tag{3.19}$$

with $|g(t)| \leqq K_2(\mu)$ and $\|f\|_{L^2} \leqq K_2(\mu)$. From (3.18) and (3.19) we see that

$$z(t,\phi) = -\int_t^{\infty} [g(s)+f(s)]\,e^{(-\mu+\varepsilon)s}\,ds,$$

or

$$z(t,\phi) = e^{(-\mu+\varepsilon)t}\int_t^{\infty} [g(s)+f(s)]\,e^{(-\mu+\varepsilon)(s-t)}\,ds. \tag{3.20}$$

We can obtain an estimate for the integral (3.20) as follows:

$$\begin{aligned}\int_t^{\infty} [g(s)+f(s)]\,e^{(-\mu+\varepsilon)(s-t)}\,ds &\leqq \int_t^{\infty} [K_2(\mu)+|f(s)|]\,e^{(-\mu+\varepsilon)(s-t)}\,ds\\ &= K_2(\mu)(\mu-\varepsilon)^{-1} - \int_t^{\infty} |f(s)|\,e^{(-\mu+\varepsilon)(s-t)}\,ds\\ &\leqq K_2(\mu)(\mu-\varepsilon)^{-1} + \left(\int_0^{\infty} e^{2(-\mu+\varepsilon)s}\,ds\right)^{1/2}\|f\|_{L^2}\\ &\leqq K_2(\mu)(\mu-\varepsilon)^{-1} + [2(\mu-\varepsilon)]^{-1/2}K_2(\mu) \triangleq K(\mu).\end{aligned}$$

Since $K(\mu)\to 0$ as $\mu\to\infty$, we can prove the following result.

THEOREM 3. *If y solves* (3.9), *$z=(y, y', \cdots, y^{(J-1)})^T$, and ε is any small positive constant, then for all sufficiently large μ there is a constant $K(\mu)$ such that $K(\mu)\to 0$ as $\mu\to\infty$ and*

$$\|T(t)\phi\| \leqq K(\mu)\,e^{(-\mu+\varepsilon)t}\|\phi\|$$

for all $t>\alpha$ and for all $\phi\in Q_\mu$.

Proof. We have proved the result when $\phi \in Q_\mu \cap D(A_0)$ and $\alpha > 0$. Since this set is dense in Q_μ, the theorem follows by continuity. The case $\alpha = 0$ is trivial. □

Remark 1. We note that $T(t)\phi_0$ makes sense for the piecewise continuous function $\phi_0 \triangleq H_0 - \Phi_\phi \Psi_\mu(0)$ given in (3.8). Since $T(t)\phi_0$ is bounded for $0 \leqq t \leqq \alpha$ and since $T(t)\phi_0 \in Q_\mu$ for $t \geqq \alpha$, then $T(t)\phi_0 = T(t-\alpha)T(\alpha)\phi_0$ for $t > \alpha$ and we have

$$\begin{aligned}\|T(t)\phi_0\| &= \|T(t-\alpha)T(\alpha)\phi_0\| \leqq K(\mu)\, e^{-\mu(t-\alpha)} \|T(\alpha)\phi_0\| \\ &= (K(\mu)\|T(\alpha)\phi_0\|\, e^{\mu\alpha})\, e^{-\mu t}.\end{aligned}$$

This inequality will be needed later.

4. Some background material on integral manifolds. Consider a real-valued coupled system of integrodifferential equations of the form

$$\begin{aligned}\theta' &= \varepsilon\theta(t, \theta, r, v_1, v_{2t}, \varepsilon), \\ r' &= \varepsilon\beta r + \varepsilon R(t, \theta, r, v_1, v_{2t}, \varepsilon), \\ v_1' &= Cv_1 + \varepsilon V_1(t, \theta, r, v_1, v_{2t}, \varepsilon), \\ v_{2t}'(\tau) &= F_1(t)(\tau) + \varepsilon \int_{t_0}^{t} F_2(t-s)(\tau)\, V_2(s, \theta(s), r(s), v_1(s), v_{2s}, \varepsilon)\, ds\end{aligned} \tag{4.1}$$

defined on a set

$$\begin{aligned}D_1 = \{(t, \theta, r, v_1, \phi, \varepsilon)&: t, \theta, r \in R^1, 0 < \varepsilon \leqq \varepsilon_0, v_1 \in R^m, \\ &\phi \in C_\mu[-\alpha, 0], |r| \leqq \eta_1, |v_1| \leqq \eta_2, \|\phi\| \leqq \eta_3\}.\end{aligned}$$

Here $C_\mu[-\alpha, 0]$ is a closed subspace of $C[-\alpha, 0]$. We assume $\beta \neq 0$, C is a constant, noncritical $m \times m$ matrix, θ and R are real-valued, V_2 is R^J-valued, and V_1 is R^m-valued. Assume that θ, R, V_1 and V_2 are $2\pi/\omega_0$-periodic in t for some $\omega_0 > 0$, 2π-periodic in θ, and continuous on D_1. Assume that F_1 maps $[0, \infty)$ into $C_\mu[-\alpha, 0]$, F_1 is continuous and $\|F_1(t)\| \leqq K_1\, e^{-\mu t}$ for some $K_1 > 0$ and $\mu > 0$. Assume that $F_2(t)(\theta)$ is a piecewise continuous matrix-valued map such that each column of F_2 is a continuous map from $[\alpha, \infty)$ to $C_\mu[-\alpha, 0]$ and $\|F_2(t)\| \leqq K_1\, e^{-\mu t}$ for all $t \geqq \alpha$.

We assume that V_i is a Lipschitz continuous function of (θ, r, v, ϕ) on D_1 for $i = 1, 2$. Also, there is a continuous and nonnegative function $M_1(\theta, a_1, a_2, a_3, \varepsilon)$ such that M_1 is 2π-periodic in θ, piecewise continuous in θ, and such that

$$\int_0^{2\pi} M_1(\theta, a_1, a_2, a_3, \varepsilon)\, d\theta \to 0 \tag{4.2}$$

as $\varepsilon \to 0$, $a_1 \to 0$, $a_2 \to 0$ and $a_3 \to 0$. Moreover, for all points $(t, \theta_i, r_j, v_k, \phi_m, \varepsilon)$ in D_1 with $|r_j| \leqq a_1$, $|v_k| \leqq a_2$ and $\|\phi_m\| \leqq a_3$, we have

$$|R(t, \theta_1, r_0, v_0, \phi_0, \varepsilon) - R(t, \theta_2, r_0, v_0, \phi_0, \varepsilon)| \leqq M_1(\omega_0 t - \theta_1, a_1, a_2, a_3, \varepsilon)|\theta_1 - \theta_2|,$$

$$|R(t, \theta_0, r_1, v_0, \phi_0, \varepsilon) - R(t, \theta_0, r_2, v_0, \phi_0, \varepsilon)| \leqq M_1(\omega_0 t - \theta_0, a_1, a_2, a_3, \varepsilon)|r_1 - r_2|,$$

$$|R(t, \theta_0, r_0, v_1, \phi_0, \varepsilon) - R(t, \theta_0, r_0, v_2, \phi_0, \varepsilon)| \leqq M_1(\omega_0 t - \theta_0, a_1, a_2, a_3, \varepsilon)|v_1 - v_2|,$$

and

$$|R(t, \theta_0, r_0, v_0, \phi_1, \varepsilon) - R(t, \theta_0, r_0, v_0, \phi_2, \varepsilon)| \leqq M_1(\omega_0 t - \theta_0, a_1, a_2, a_3, \varepsilon)\|\phi_1 - \phi_2\|.$$

We assume that θ satisfies these same four Lipschitz conditions using the same Lipschitz function M_1.

We shall require the notion of an integral manifold of (4.1).

DEFINITION 4. A surface S_ε in $(t, \theta, r, v, \phi, \varepsilon)$-space is an integral manifold of system (4.1) for a fixed ε if given any point $(t_0, \theta_0, r_0, v_0, \phi_0, \varepsilon)$ in $S_\varepsilon \cap D_1$, the solution of (4.1) which satisfies $\theta(t_0) = \theta_0$, $r(t_0) = r_0$, $v_1(t_0) = v_0$ and $v_{2t_0} = \phi$ is defined for all times t and $(t, \theta(t), r(t), v_1(t), v_{2t}, \varepsilon) \in D \cap S_\varepsilon$ for all $t \in R$.

For example, in (4.1) if $\theta \equiv R = V_1 \equiv V_2 \equiv F_1 \equiv 0$, then there is an integral manifold, namely

$$S = \{(t, \theta, 0, 0, 0, \varepsilon);\ 0 \leqq t < \infty,\ -\infty < \theta < \infty\}.$$

This integral manifold is stable if $\beta < 0$ and C is a stable matrix, and it is unstable if $\beta > 0$ or if C has an eigenvalue with positive real part. Intuitively, since θ, R, V_1 and V_2 are small, then one might expect that for ε small there will exist an integral manifold S_ε of (4.1) which is close to S and which has the same stability properties as S. This conjecture is correct. Indeed, the following result is true.

THEOREM 5. *Suppose that θ, R, V_1 and V_2 have the periodicity and continuity properties enumerated above, that M_1 satisfies* (4.2), *that $\beta \neq 0$, and that C is noncritical. There is an $\eta > 0$ such that if $K_1 < \eta$ then in the region*

$$D(\eta) = \{(t, \theta, r, v_1, \phi, \varepsilon) D_1 \colon |r| \leqq \eta, |v_1| \leqq \eta, \|\phi\| \leqq \eta \text{ and } 0 < \varepsilon \leqq \eta\}$$

there is a unique integral manifold S_ε of (4.1). *This integral manifold will have the same stability properties as S.*

One can show that S_ε is determined by three functions f_1, f_2 and f_3 with

$$S_\varepsilon = \{(t, \theta, r, v, \phi, \varepsilon) \in D(\eta);\ r = f_1(t, \theta, \varepsilon),\ v = f_2(t, \theta, \varepsilon) \text{ and } \phi = f_3(t, \theta, \varepsilon)\}.$$

The functions f_i, $i = 1, 2, 3$, are continuous in (t, θ, ε), $2\pi/\omega_0$-periodic in t, 2π-periodic in θ, and $f_i(t, 0, 0) \equiv 0$. The proof of Theorem 5 is long and detailed but involves standard techniques. It follows the same outline as used by Hale [4, Chap. 7].

5. Transformation of the feedback system. In this section, we shall prove our main result, Theorem 1. This will be accomplished by using several transformations to reduce (2.1) to an integral manifold problem. We assume that the hypotheses of § 2 are true and we employ the notation established in that section. Assume for now that $\alpha > 0$. The case $\alpha = 0$ will be handled later. Since the limit cycle predicted by the method of describing functions is $A_0 \cos \omega_0 t$, where $A_0 E$ is not in a hysteresis region of $n(y)$, then by restricting our attention to functions $y(t)$ for which

$$|y(t+\theta) - A_0 \cos \omega_0 t| + |y'(t+\theta) + A_0 \omega_0 \sin \omega_0 t|$$

is small over $0 \leqq t \leqq 2\pi/\omega_0$ for some phase shift θ (which may depend on y), there will be no problem in defining $n(y(t))$ given $y(t+s)$ over $-\alpha \leqq s \leqq 0$. Hence, we can assume that $n(y)$ is a functional with domain in $C[-\alpha, 0]$.

Given the values A_0, ω_0 and α such that $E = |q(i\omega_0)|$, $p(i\omega_0) + N(A_0 E) q(i\omega_0) = 0$ while $N(A_0 E) = |N(A_0 E)|\, e^{-i\alpha\omega_0}$, we define an operator L_1 and a nonlinearity $n_1(y)$ by the relations

$$L_1 y(t) \triangleq Ly(t) + NQy(t-\alpha), \qquad N = |N(A_0 E)|$$

and

$$n_1(y_t) \triangleq NQy(t-\alpha) - n(Qy).$$

Thus (2.1) can be written as

$$L_1 y(t) = n_1(y_t). \tag{5.1}$$

As usual, we let $z=(y, y', y'', \cdots, y^{(J-1)})^T$ and we represent (5.1) equivalently as

$$z'(t)=L_0 z_t+e_J n_1(y_t), \tag{5.2}$$

where

$$e_J=(0,0,\cdots,0,1)^T\in R^J,$$

$$L_0\phi \triangleq \int_{-\alpha}^{0} d\eta(\theta)\phi(\theta)\triangleq B_0\phi(0)+B_1\phi(-\alpha),$$

and

$$B_0=\begin{bmatrix} 0 & 1 & 0 & \cdots & 0\\ 0 & 0 & 1 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & 0 & 0 & \cdots & 1\\ -\alpha_J & -\alpha_{J-1} & -\alpha_{J-2} & \cdots & -\alpha_1 \end{bmatrix}$$

$$B_1=\begin{bmatrix} 0 & 0 & \cdots & 0\\ \vdots & \vdots & & \vdots\\ 0 & 0 & \cdots & 0\\ -N\gamma_J & -N\gamma_{J-1} & \cdots & -N\gamma_1 \end{bmatrix}.$$

Fix μ, a large positive number and let $\Lambda(\mu)$ be the set of eigenvalues s_k of $z'=L_0 z$ such that $\operatorname{Re} s_k \geqq -\mu$. We enumerate $\Lambda(\mu)=\{s_1, s_2, \cdots, s_{N(\mu)}\}$ in such a way that $s_1=i\omega_0$, $s_2=-i\omega_0$ and in such a way that complex conjugate pairs are ordered as s_k, s_{k+1} where $\operatorname{Im} s_k>0$ and $\operatorname{Im} s_{k+1}=\operatorname{Im}\bar{s}_k<0$. We wish to think of $F_0(t)=e_J n_1(y(t))$ and then write a decomposition of the form (3.8). Hence, we shall need to compute the generalized eigenspaces of the linear problem $z'=L_0 z_t$ and of its adjoint. A sample calculation of the type which we must perform can be found in [23, pp. 182-184] or [22, pp. 116-119].

Let $\xi(s)\in R^J$ be the vector defined by $\xi(s)=(1, s, s^2, \cdots, s^{J-1})^T$. Define $\eta(s)=(s^{J-1}+[\alpha_1+\gamma_1 N e^{-\alpha s}]s^{J-2}+\cdots+[\alpha_{J-1}+\gamma_{J-1}N e^{-\alpha s}], \cdots, s+[\alpha_1+N\gamma_1 e^{-\alpha s}], 1)$. Let s_k be a real root of $\Delta(s)$. It is easy to check that $\phi_k(\theta)\triangleq e^{s_k\theta}\xi(s_k)$ is the corresponding eigenfunction and that $\hat{\psi}_k(\theta)\triangleq e^{-s_k\theta}\eta(s_k)$ is an eigenfunction of the adjoint. Then $\hat{\psi}(0)\phi(0)=\eta(s_k)\xi(s_k)=Js^{J-1}+(J-1)s^{J-2}[\alpha_1+\gamma_1 N e^{-\alpha s}]+\cdots+[\alpha_{J-1}+N\gamma_{J-1}]e^{-\alpha s}$ and

$$\begin{aligned}\int_{-\alpha}^{0}\int_{0}^{\theta} &\eta(s_k)\, e^{-s_k(u-\theta)}\, d\eta(\theta)\xi(s_k)\, e^{s_k u}\, du\\ &=\eta(s_k)\left[\int_{-\alpha}^{0}\int_{0}^{\theta} e^{-s_k\theta}\, d\eta(\theta)\, du\right]\xi(s_k)=\eta(s_k)\int_{-\alpha}^{0}\theta\, e^{-s_k\theta}\, d\eta(\theta)\xi(s_k)\\ &=\alpha|N(A_0)|q(s_k)\, e^{-\alpha s_k}.\end{aligned}$$

Hence $(\hat{\psi}_k, \phi_k)=P'(s_k)\neq 0$. Define $\psi_k(\theta)=\hat{\psi}_k(\theta)/P'(s_k)$ so that $\psi_k(0)e_J=P'(s_k)^{-1}$. Then $(\psi_k, \phi_k)=1$ as required. Let $z_t(\phi)$ be the solution of (5.2) which satisfies the initial condition $z_0(\phi)=\phi$ and let $\psi_k^*=\psi_k$. Then $y_k(t)\triangleq(\psi_k^*, z_t(\phi))$ solves

$$y_k'=s_k y_k+\frac{P'(s_k)}{|P'(s_k)|^2}n_1(y_t), \qquad y_k(0)=(\psi_k^*, \phi). \tag{5.3}$$

Now consider an eigenvalue s_k such that $\operatorname{Im} s_k > 0$. From the ordering of the eigenvalues which we have employed, we know that $s_{k+1} = \bar{s}_k$. Then $u_k(\theta) \triangleq e^{s_k\theta}\xi(s_k)$ is an eigenfunction corresponding to the eigenvalue s_k and $v_k(\theta) \triangleq e^{-s_k\theta}\eta(s_k)$ is an eigenfunction for the adjoint problem. Hence

$$\phi_{1k}(\theta) \triangleq \operatorname{Re} u_k(\theta), \qquad \phi_{2k}(\theta) \triangleq \operatorname{Im} u_k(\theta)$$

generates the generalized eigenspace for the eigenvalues $\{s_k, s_{k+1}\}$ while

$$\hat{\psi}_{1k}(\theta) = \operatorname{Re} v_k(\theta), \qquad \hat{\psi}_{2k}(\theta) = \operatorname{Im} v_k(\theta)$$

will generate the generalized eigenspace for the adjoint. Since $s_k \neq s_{k+1}$, then from general considerations in Hale [22] or [23] we know that $(\bar{v}_k, u_k) = (v_k, \bar{u}_k) = 0$. By a computation similar to the case where s_k is real, we can compute

$$(v_k, u_k) = P'(s_k), \qquad (\bar{v}_k, \bar{u}_k) = P'(\bar{s}_k) = \overline{P'(s_k)}.$$

Since $\phi_{1k} = (u_k + \bar{u}_k)/2$ and ϕ_{2k}, $\hat{\psi}_{1k}$ and $\hat{\psi}_{2k}$ can be similarly expressed, then

$$D_k = \begin{bmatrix} (\hat{\psi}_{1k}, \phi_{1k}) & (\hat{\psi}_{1k}, \phi_{2k}) \\ (\hat{\psi}_{2k}, \phi_{1k}) & (\hat{\psi}_{2k}, \phi_{2k}) \end{bmatrix}$$

is easily evaluated. Indeed,

$$D_k = \frac{1}{2}\begin{bmatrix} \operatorname{Re} P'(s_k) & \operatorname{Im} P'(s_k) \\ \operatorname{Im} P'(s_k) & -\operatorname{Re} P'(s_k) \end{bmatrix}.$$

Hence, the pair ψ_{1k} and ψ_{2k} defined by

$$\begin{bmatrix} \psi_{1k} \\ \psi_{2k} \end{bmatrix} \triangleq D_k^{-1}\begin{bmatrix} \hat{\psi}_{1k} \\ \hat{\psi}_{2k} \end{bmatrix} = 2\begin{bmatrix} \operatorname{Re}[P'(\bar{s}_k)^{-1}v_k] \\ -\operatorname{Im}[P'(\bar{s}_k)^{-1}v_k] \end{bmatrix}$$

will generate the generalized eigenspace for the adjoint and in addition will satisfy the relations $(\psi_{nk}, \phi_{mk}) = \delta_{mn}$. Moreover,

$$\begin{bmatrix} \psi_{1k}(0) \\ \psi_{2k}(0) \end{bmatrix} e_J = \begin{bmatrix} \psi_{1k}(0)e_J \\ \psi_{2k}(0)e_J \end{bmatrix} = 2\begin{bmatrix} \operatorname{Re} P'(\bar{s}_k)^{-1} \\ -\operatorname{Im} P'(\bar{s}_k)^{-1} \end{bmatrix}.$$

Let $z_t(\phi)$ be the solution of (5.2) which satisfies the initial condition $z_0(\phi) = \phi$. If we define $w_{1k}(t) = (\psi_{1k}, z_t(\phi))$ and $w_{2k}(t) = (\psi_{2k}, z_t(\phi))$ then

$$\begin{bmatrix} w_{1k}' \\ w_{2k}' \end{bmatrix} = \begin{bmatrix} \operatorname{Re} s_k & -\operatorname{Im} s_k \\ \operatorname{Im} s_k & \operatorname{Re} s_k \end{bmatrix}\begin{bmatrix} w_{1k} \\ w_{2k} \end{bmatrix} + \begin{bmatrix} \operatorname{Re} P'(\bar{s}_k)^{-1} \\ -\operatorname{Im} P'(\bar{s}_k)^{-1} \end{bmatrix}[2n_1(y_t)]. \tag{5.4}$$

Equivalently, we can define $y_k = (w_{1k} + iw_{2k})/2$, $y_{k+1} = \bar{y}_k$, $\psi_k^* = (\psi_{1k} + i\psi_{2k})/2$ and $\psi_{k+1}^* = \bar{\psi}_k^*$. Then

$$y_k' = s_k y_k + \frac{P'(s_k)}{|P'(s_k)|^2} n_1(y_t), \qquad y_k(0) = (\psi_k^*, \phi)$$

and

$$y_{k+1}' = \bar{s}_k y_{k+1} + \frac{P'(\bar{s}_k)}{|P'(\bar{s}_k)|^2} n_1(y_t), \qquad y_{k+1}(0) = (\psi_{k+1}^*, \phi).$$

Since $s_{k+1} = \bar{s}_k$, both of these equations have the form (5.3).

Given the set $\Lambda(\mu) = \{s_1, s_2, s_3, \cdots, s_{N(\mu)}\}$ we have seen that for $k = 3, 4, \cdots, N(\mu)$, there is an eigenvector ψ_k^* of the adjoint problem and a function $y_k(t)$ which satisfies (5.3). (For $k = 1, 2$ we choose to leave the solution in the form (5.4).)

The solution $z_t(\phi)$ of (5.2) which satisfies $z_0(\phi)=\phi$ can be written in the form

$$z_t(\phi)=\phi_{11}w_{11}(t)+\phi_{21}w_{21}(t)+\operatorname{Re}\left[\sum_{j=3}^{N(\mu)}u_k y_k(t)\right]+z_{1t}(\mu,\phi).$$

Since $z_t(\phi)(0)=z(t,\phi)=(y(t),y'(t),\cdots,y^{(J-1)}(t))$, this is equivalent to

$$\begin{aligned}(y(t),\cdots,y^{(J-1)}(t))^T=\phi_{11}(0)w_{11}(t)+\phi_{21}(0)w_{21}(t)+\operatorname{Re}\left[\sum_{j=3}^{N}\xi(s_k)y_k(t)\right]\\ +z_{1t}(\mu,\phi)(0)\end{aligned}\tag{5.5}$$

where w_{11}, w_{21}, y_k and z_{1t} satisfy the equations

$$\begin{bmatrix}w_{11}\\ w_{21}\end{bmatrix}'=\begin{bmatrix}0 & -\omega_0\\ \omega_0 & 0\end{bmatrix}\begin{bmatrix}w_{11}\\ w_{21}\end{bmatrix}+2\begin{bmatrix}\operatorname{Re}P'(i\omega_0)^{-1}\\ -\operatorname{Im}P'(i\omega_0)^{-1}\end{bmatrix}n_1(y_t),\tag{5.6}$$

$$y_k'=s_k y_k+(P'(\bar{s}_k))^{-1}n_1(y_t),\qquad 3\leqq k\leqq N(\mu)\tag{5.7}$$

and

$$z_{1t}(\phi)=T(t)\phi_Q+\int_0^t T(t-s)[H_0-\Phi_\mu\Psi_\mu(0)]n_1(y_t)\,ds.\tag{5.8}$$

Moreover, by Theorem 3 we have $\|T(t)\phi_Q\|\leqq K(\mu)c^{-\mu t}\|\phi\|$ for all $\phi\in C[-\alpha,0]$ and $\|T(t)[H_0-\Phi_\mu\Psi_\mu(0)]\|\leqq K(\mu)\,e^{-\mu t}$ for some constant $K(\mu)$ such that $K(\mu)\to 0$ as $\mu\to\infty$.

Equation (5.6) will now be further transformed in the manner used in [1], [30]. Define $y_1(t)\triangleq y(t)-\phi_{11}(0)w_{11}(t)-\phi_{21}(0)w_{21}(t)$,

$$\Phi(t)\triangleq\begin{bmatrix}\cos\omega_0 t & \sin\omega_0 t\\ -\sin\omega_0 t & \cos\omega_0 t\end{bmatrix}\quad\text{and}\quad\begin{bmatrix}w_{11}\\ w_{21}\end{bmatrix}\triangleq\Phi(t)\begin{bmatrix}x_1\\ x_2\end{bmatrix}$$

so that

$$\begin{bmatrix}x_1\\ x_2\end{bmatrix}'=\Phi(-t)\begin{bmatrix}2\operatorname{Re}P'(i\omega_0)^{-1}\\ -2\operatorname{Im}P'(i\omega_0)^{-1}\end{bmatrix}n_1(y(t))\triangleq f(t,x_1,x_2,y_1).\tag{5.9}$$

Since we are assuming that $|P'(i\omega_0)|^{-1}$ is small, then averaging can be applied to (5.9). Let $f_0(x_1,x_2)$ be the mean value with respect to t of $f(t,x_1,x_2,0)$, i.e.,

$$f_0(x_1,x_2)=\frac{\omega_0}{2\pi}\int_0^{2\pi/\omega_0}f(t,x_1,x_2,0)\,dt.$$

Define

$$U(t,x_1,x_2)=\int_0^t[f(t,x_1,x_2,0)-f_0(x_1,x_2)]\,dt$$

and

$$\begin{bmatrix}x_1\\ x_2\end{bmatrix}=w+U(t,w),\qquad w=\begin{bmatrix}w_1\\ w_2\end{bmatrix}.\tag{5.10}$$

Clearly U is $(2\pi/\omega_0)$-periodic in t. We shall later show that U is continuously differentiable in x_1 and x_2 and that $\partial U/\partial x_i$ is Lipschitz continuous in (x_1,x_2) uniformly in t. In particular, the 2×2 Jacobian matrix $U_w=[\partial U_i/\partial x_j]$ exists and is continuous. Thus, the change in variables (5.10) can be used to see that

$$w' = f_0(w) + [I + U_w(t, w)]^{-1}[f(t, w + U(t, w), y_1) - f(t, w, 0) - U_w(t, w) f_0(w)]$$
$$\triangleq f_0(w) + f_1(t, w, y_1).$$

Here f_1 is the two-dimensional column vector whose components are f_{11} and f_{12}.

We shall now compute the averaged term $f_0(w)$. Recall that by the definition of the sinusoidal input describing function, if $n_0(z) = Nz(t-\alpha) - n(z)$,

$$\frac{\omega_0}{2\pi}\int_0^{2\pi/\omega_0} n_0(A\cos(\omega_0 t + \theta))\, e^{i\omega_0 t}\, dt = \frac{A}{2} e^{i\theta} N_0(A, \omega_0) \tag{5.11}$$

for any $A > 0$ and for any real number θ. Let $N_0(A, \omega_0) = N_{0R}(A) + iN_{0I}(A)$. On equating the real and imaginary parts of (5.11), we find that

$$\frac{\omega_0}{2\pi}\int_0^{2\pi/\omega_0} n_0(A\cos(\omega_0 t + \theta))\cos\omega_0 t\, dt = \frac{A}{2}[N_{0R}(A)\cos\theta - N_{0I}(A)\sin\theta)]$$

and

$$\frac{\omega_0}{2\pi}\int_0^{2\pi/\omega_0} n_0(A\cos(\omega_0 t + \theta))\sin\omega_0 t\, dt = \frac{-A}{2}[N_{0I}(A)\cos\theta + N_{0R}(A)\sin\theta].$$

Since $(y, y', \cdots, y^{(J-1)})^T = \phi_{11}(0)w_{11} + \phi_{21}(0)w_{21}$, then

$$Qy = \sum_{j=1}^{J} \gamma_{J-j} y^{(j)} = \operatorname{Re} q(i\omega_0) w_{11} + \operatorname{Im} g(i\omega_0) w_{21}.$$

Let $q(i\omega_0) = E e^{i\theta_1}$ where $E = |q(i\omega_0)|$. Let $x_1 = A\cos\theta_2$ and $x_2 = -A\sin\theta_2$. Then

$$\begin{aligned} Qy &= E\cos\theta_1(x_1\cos\omega_0 t + x_2\sin\omega_0 t) + E\sin\theta_1(-x_1\sin\omega_0 t + x_2\cos\omega_0 t) \\ &= E\cos\theta_1(A\cos(\omega_0 t + \theta_2)) + E\sin\theta_1(-A\sin(\omega_0 t + \theta_2)) \\ &= EA\cos(\omega_0 t + \theta) \end{aligned}$$

where $\theta = \theta_1 + \theta_2$. Then

$$f(t, x_1, x_2, 0) = \begin{bmatrix} \cos\omega_0 t & -\sin\omega_0 t \\ \sin\omega_0 t & \cos\omega_0 t \end{bmatrix} \begin{bmatrix} \operatorname{Re} P'(i\omega_0)^{-1} \\ -\operatorname{Im} P'(i\omega_0)^{-1} \end{bmatrix} n_0(EA\cos(\omega_0 t + \theta)).$$

Hence

$$f_0(x_1, x_2) = \begin{bmatrix} \frac{AE}{2}[N_{0R}(AE)\cos\theta - N_{0I}(AE)\sin\theta] & \frac{AE}{2}[N_{0I}(AE)\cos\theta + N_{0R}(AE)\sin\theta] \\ -\frac{AE}{2}[N_{0I}(AE)\cos\theta + N_{0R}(AE)\sin\theta] & \frac{AE}{2}[N_{0R}(AE)\cos\theta - N_{0I}(AE)\sin\theta] \end{bmatrix} \times \begin{bmatrix} \operatorname{Re} P'(i\omega_0)^{-1} \\ -\operatorname{Im} P'(i\omega_0)^{-1} \end{bmatrix}$$

or

$$f_0(x_1, x_2) = \frac{1}{2}\begin{bmatrix} N_{2R}(A)x_1 + N_{21}(A)x_2 & N_{2I}(A)x_1 - N_{2R}(A)x_2 \\ -N_{21}(A)x_1 + N_{2R}(A)x_2 & N_{2R}(A)x_1 + N_{2I}(A)x_2 \end{bmatrix} \times \begin{bmatrix} \operatorname{Re} P'(i\omega_0)^{-1} \\ -\operatorname{Im} P'(i\omega_0)^{-1} \end{bmatrix} \tag{5.12}$$

where $x_1^2 + x_2^2 = A^2$ and $N_2(A) = N_0(AE)q(i\omega_0)$.

We introduce polar coordinates $w_1 = (r+A_0)\cos\theta$, $w_2 = (r+A_0)\sin\theta$ so that

$$\begin{bmatrix} (r+A_0)\theta' \\ r' \end{bmatrix} = \frac{1}{(r+A_0)} \begin{bmatrix} w_1' w_2 - w_2' w_1 \\ w_1' w_1 + w_2' w_2 \end{bmatrix}.$$

Then (5.9) and (5.12) yield

$$\begin{aligned} r' = {} & \tfrac{1}{2}[N_{2R}(r+A_0)\ \mathrm{Re}\ P'(i\omega_0)^{-1}(r+A_0) - N_{2I}(r+A_0)\ \mathrm{Im}\ P'(i\omega_0)^{-1}(r+A_0)] \\ & + \cos\theta f_{11}(t, (r+A_0)\cos\theta, (r+A_0)\sin\theta, y) \\ & + \sin\theta f_{12}(t, (r+A_0)\cos\theta, (r+A_0)\sin\theta, y) \end{aligned}$$

and

$$\begin{aligned} \theta' = {} & \tfrac{1}{2}[N_{2R}(r+A_0)\ \mathrm{Im}\ P'(i\omega_0)^{-1} + N_{2I}(r+A_0)\ \mathrm{Re}\ P'(i\omega_0)^{-1}] \\ & + \{-\sin\theta f_{11} + \cos\theta f_{12}\}/(r+A_0). \end{aligned}$$

These two equations are more conveniently written in the form

$$\begin{aligned} r' = {} & \frac{(r+A_0)}{2}\ \mathrm{Re}\ \{N_0(E(r+A_0))q(i\omega_0)/P'(i\omega_0)\} + \cos\theta f_{11} + \sin\theta f_{12}, \\ \theta' = {} & \tfrac{1}{2}\ \mathrm{Im}\ \{N_0(E(r+A_0))q(i\omega_0)/P'(i\omega_0)\} + \{-\sin\theta f_{11} + \cos\theta f_{12}\}/(r+A_0). \end{aligned} \tag{5.13}$$

Let $K(\mu)$ be the constant associated with (5.8) and let $\varepsilon = \max\{|P'(s_k)|^{-1}: k = 1, 2, 3, \cdots, \}$. Define $\hat{y}_k = \varepsilon^{-1/2} y_k$ and $\hat{z}_{1t}(\phi) = K(\mu)^{-1/2} z_{1t}(\phi)$. Then (5.7) and (5.8) can be written in the form

$$\hat{y}_k' = s_k \hat{y}_k + (P'(\bar{s}_k)\sqrt{\varepsilon})^{-1} n_1(y(t)), \qquad 3 \leqq k \leqq N(\mu) \tag{5.14}$$

and

$$\hat{z}_{1t}(\phi) = T(t)\phi_Q K(\mu)^{-1/2} + \int_0^t T(t-s)[H_0 - \Phi_\mu \Psi_\mu(0)] K(\mu)^{-1/2} n_1(y(s))\, ds. \tag{5.15}$$

Here

$$z(t, \phi) = \phi_{11}(0) w_{11}(t) + \phi_{21}(0) w_{21}(t) + \sqrt{\varepsilon}\ \mathrm{Re}\left[\sum_{j=3}^{N(\mu)} u_k(0)\hat{y}_k(t)\right] + K(\mu)^{1/2}\hat{z}_{1t}(\phi)(0)$$

where $\phi_{11}(0) = \mathrm{Re}\ \xi(i\omega_0)$, $\phi_{21}(0) = \mathrm{Im}\ \xi(i\omega_0)$ and $u_k(0) = \xi(s_k)$. Now

$$\begin{aligned} & \phi_{11}(0) w_{11}(t) + \phi_{21}(0) w_{21}(t) \\ & \quad = \phi_{11}(0)[x_1 \cos\omega_0 t + x_2 \sin\omega_0 t] + \phi_{21}(0)[-x_1 \sin\omega_0 t + x_2 \cos\omega_0 t] \\ & \quad = \phi_{11}(0)[(w_1 + U_1(t, w))\cos\omega_0 t + (w_2 + U_2(t, \omega))\sin\omega_0 t] \\ & \qquad + \phi_{21}(0)[-(w_1 + U_1(t, \omega))\sin\omega_0 t + (w_2 + U_2(t, w))\cos\omega_0 t] \\ & \quad = \phi_{11}(0)[w_1 \cos\omega_0 t + w_2 \sin\omega_0 t] + \phi_{21}[-w_1 \sin\omega_0 t + w_2 \cos\omega_0 t] + \mathcal{O}(\varepsilon) \\ & \quad = \phi_{11}(0)[(r+A_0)\cos\theta\cos\omega_0 t - (r+A_0)\sin\theta\sin\omega_0 t] \\ & \qquad + \phi_{21}(0)[-(r+A_0)\cos\theta\sin\omega_0 t - (r+A_0)\sin\theta\cos\omega_0 t] + \mathcal{O}(\varepsilon) \\ & \quad = \phi_{11}(0)(r+A_0)\cos(\omega_0 t + \theta) - \phi_{21}(0)(r+A_0)\sin(\omega_0 t + \theta) + \mathcal{O}(\varepsilon). \end{aligned}$$

Hence, for $t \geqq 0$ we have

$$z(t, \phi) = \phi_{11}(0)(r + A_0)\cos(\omega_0 t + \theta) - \phi_{21}(0)(r + A_0)\sin(\omega_0 t + \theta)$$
$$+ \sqrt{\varepsilon}\,\mathrm{Re}\sum_{k=3}^{N(\mu)} \xi(s_k)\hat{y}_k(t) + \mathcal{O}(\varepsilon) + \mathcal{O}(K(\mu)^{1/2}).$$

In particular,

$$y(t) = (r(t) + A_0)\cos(\omega_0 t + \theta) + \sqrt{\varepsilon}\,\mathrm{Re}\left(\sum_{k=3}^{N(\mu)} \hat{y}_k(t)\right) + \mathcal{O}(\varepsilon) + \mathcal{O}(K(\mu)^{1/2}) \tag{5.16}$$

and

$$y^{(j)} = (r(t) + A_0)\frac{d^j}{dt^j}(\cos(\omega_0 t + \theta))$$
$$+ \sqrt{\varepsilon}\,\mathrm{Re}\left(\sum_{k=3}^{N(\mu)} s_k^j \hat{y}_k(t)\right) + \mathcal{O}(\varepsilon) + \mathcal{O}(K(\mu)^{1/2}). \tag{5.17}$$

The terms $\mathcal{O}(\varepsilon)$ and $\mathcal{O}(K(\mu)^{1/2})$ are small, independently of j, when ε and $K(\mu)$ are small, and these terms have small Lipschitz constants. Hence, if we take into account the smoothness results for $U(t, w)$ which are proved in the next section, we see that Theorem 5 can be applied to (5.13), (5.14), (5.15) and (5.16) with $C_\mu[-\alpha, 0] = Q_\mu$ to complete the proof of Theorem 1 when $\alpha > 0$.

We also note that by taking μ large we can make $K(\mu)$ as small as desired without affecting the constant ε. Hence, the necessary assumption for system (5.13)-(5.16) is not that $K(\mu)$ and ε be small, but only that ε be small. We conjecture that it is really only necessary to assume that $|P'(i\omega_0)|^{-1}$ is small but we have no proof as yet.

Finally, we note that the distortions from a sinusoidal curve for the high derivatives $y^{(j)}(t)$ can readily be explained by using (5.17). Since $\mathcal{O}(\varepsilon)$ and $\mathcal{O}(K(\mu)^{1/2})$ are small independently of j, then to good approximation solutions near the integral manifold S which was obtained in Theorem 1 have the form

$$y^{(j)}(t) \cong (r(t) + A_0)\frac{d^j}{dt^j}\left(\cos(\omega_0 t + \theta) + \sqrt{\varepsilon}\,\mathrm{Re}\left(\sum_{k=3}^{N(\mu)} s_k^j \hat{y}_k(t)\right)\right).$$

When $\sqrt{\varepsilon}$ is small, $r(t)$ is small and the $\hat{y}_k$'s are small. Thus $y(t) \cong A_0 \cos(\omega_0 t + \theta)$. However, the numbers s_k are complex numbers and Im s_k grows rapidly as k increases. Hence, for moderate sized integers j the quantity

$$\mathrm{Re}\left[\sqrt{\varepsilon}\sum_{k=3}^{N(\mu)} s_k^j \hat{y}_k(t)\right] \tag{5.18}$$

can be large, even though $\sqrt{\varepsilon}$ and $\hat{y}_k(t)$ are small. This is the source of the distortions discussed in § 1. We note that in the stable case $\hat{y}_k(t) \to 0$ as $t \to \infty$. Hence, the distortions are not usually too severe. On the other hand, if for some k $\hat{y}_k(t)$ is growing, then (5.18) seems to predict the possibility of very severe distortions. Several numerical simulations indicate that this does indeed happen.

When $\alpha = 0$, the proof is almost the same. Replace $C[-\alpha, 0]$ by $C[-\alpha_1, 0]$ for any $\alpha_1 > 0$. Since in this case L_1 is an ordinary differential operator (with no delay), there will be only a finite number (i.e. J) eigenvalues. This means that μ can be taken so large that the ϕ_Q and $H_0 - \Phi_\mu \Psi_\mu$ in (5.15) are zero. Hence, Theorem 5 can again be applied but now with $C_\mu[-\alpha_1, 0]$ equal to the zero subspace.

When $\alpha = 0$, it is really only necessary to assume that β_1 and β_2 are small. A different proof is needed to see this. The transformations used in [30], [31] can be used to reduce (5.1) to the form

$$\begin{aligned}
\frac{dr}{d\tau} &= \frac{r+A_0}{2}\operatorname{Re}\{N_0(EA)q(i\omega_0)(\beta_1 - i\beta_2)\} + \cos\theta f_{11} + \sin\theta f_{12}, \\
\frac{d\theta}{d\tau} &= \frac{1}{2}\operatorname{Im}\{N_0(EA)q(i\omega_0)(\beta_1 - i\beta_2)\} + \{-\sin\theta f_{11} + \cos\theta f_{12}\}/(r+A_0), \\
\frac{dx_4}{dt} &= C_1 x_4 - [\beta_1\hat{\xi}_1 + \beta_2\hat{\xi}_2]n_1(y_t).
\end{aligned} \tag{5.19}$$

Here $\tau = \omega_0 t$, $\beta_1 - i\beta_2 = 2/\omega_0 P'(i\omega_0)$, $\varepsilon = |\beta_1 - i\beta_2|$, C_1 is the companion matrix for the $(J-2)$-degree polynomial

$$\prod_{j=3}^{J}(s - s_j/\omega_0),$$

and $\hat{\xi}_1$ and $\hat{\xi}$, are the $J-2$ vectors

$$\hat{\xi}_1 = (1, 0, -1, 0, 1, 0, -1, \cdots)^T, \qquad \hat{\xi}_2 = (0, 1, 0, -1, 0, 1, \cdots)^T.$$

Moreover, $y(t) = y(\tau/\omega_0)$ has the form

$$y(\tau/\omega_0) = (r+A_0)\cos(\tau + \theta + \theta_1) + \sqrt{\varepsilon}\, B_2 x_4 + \mathcal{O}(\varepsilon)$$

where $\theta_1 = \arg q(i\omega_0)$. For ε small (i.e. for β_1 and β_2 small), Theorem 5 can be applied to (5.19) with $C_\mu[-\alpha, 0]$ equal to the zero subspace. This proves the assertion.

6. Smoothness of U. It was shown in [1, § 5] that if $n(y)$ is a function (i.e., $n(y)$ exhibits no hysteresis), then the function $U(t, w)$ defined in § 5 has continuous derivatives $\partial U/\partial w_1$ and $\partial U/\partial w_2$ which are Lipschitz continuous in w. The integral used to define $U(t, w)$ can be decomposed into pieces of the form

$$\int_0^t [\cos\omega_0 s]n_1(r\cos(\theta + \omega_0 s))\, ds$$

and

$$\int_0^t [\sin\omega_0 s]n_1(r\cos(\theta + \omega_0 s))\, ds$$

where $w_1 = r\cos\theta$ and $w_2 = -r\sin\theta$. These two integrals can be decomposed into pieces on which $\cos(\theta + \omega_0 s)$ is either strictly increasing or strictly decreasing. When $y = \cos(\theta + \omega_0 s)$ is increasing $n_1(y)$ can be replaced by $n_{1L}(y)$ (and when decreasing it can be replaced by $n_{1U}(y)$). Since n_{1L} and n_{1U} are ordinary functions, the results in [1] still apply.

7. The incorrectness of the quasi-static stability analysis. Given the feedback equation (2.1) and the solution ω_0 and A_0 of (2.2), the quasi-static stability analysis proceeds as follows (cf., e.g., [2, pp. 120–125]). Define $V(a, s)$ by the relation

$$V(a, s) = 1 + N(a)G(s), \qquad G(s) = q(s)/p(s).$$

It is required that all roots s_j of the polynomial $p(s) + N(A_0)q(s)$ with $s_j \neq \pm i\omega_0$ have

negative real parts and, in addition

$$\text{Im}\left(\overline{\frac{\partial V}{\partial a}}\frac{\partial V}{\partial s}i\right)=\text{Re}\left(\overline{\frac{\partial V}{\partial a}}\frac{\partial V}{\partial s}\right)>0 \tag{7.1}$$

at $a=A_0E$ and $s=i\omega_0$. Condition (7.1) has a well-known graphical interpretation. An equivalent statement is that for some A_1 and A_2 with $A_1<A_0<A_2$ the polynomial $p(s)+N(A)q(s)$ is stable when $A_0<A<A_2$ and is unstable when $A_1<A<A_0$.

Condition (7.1) can be written in terms of N, p and q as follows. Since $1+N(A_0E)G(i\omega_0)=0$, then at $a=A_0E$, $s=i\omega_0$ we have

$$G'=\frac{q'}{p}-\frac{qp'}{p^2}=\frac{q'}{p}+\frac{p'}{NP}=\frac{p'+Nq'}{NP}.$$

Hence, at $a=A_0E$ and $s=i\omega_0$

$$\begin{aligned}\overline{\frac{\partial V}{\partial a}}\frac{\partial V}{\partial s}&=\bar{N}'\bar{G}NG'=\left(\overline{\frac{N'}{G'}}\right)\bar{G}N|G'|^2\\&=\left(\overline{\frac{N'}{p'+Nq'}}\right)(\overline{Np})\bar{G}N|G'|^2\\&=\left(\overline{\frac{N'q}{p'+Nq'}}\right)|N|^2|G'|^2,\end{aligned}$$

so that (7.1) reduces to

$$\text{Re}\left\{\frac{N'(A_0E)q(i\omega_0)}{p'(i\omega_0)+N(A_0)q'(i\omega_0)}\right\}>0. \tag{7.2}$$

The stability condition corresponding to (7.2) which was obtained from Theorem 1 of the paper is that

$$\text{Re}\left\{\frac{N'(A_0E)q(i\omega_0)}{P'(i\omega_0)}\right\}>0, \tag{7.3}$$

or equivalently that the real part of

$$N'(A_0E)q(i\omega_0)/(p'(i\omega_0)+N(A_0E)q'(i\omega_0)-\alpha N(A_0E)q(i\omega_0))$$

is positive. It is also required that all roots of

$$P(s)=p(s)+|N(A_0E)|\,e^{-\alpha s}q(s)$$

other than $\pm i\omega_0$ have negative real parts. Our stability criterion can be interpreted in the following way. We write (2.1) in the form

$$Ly(t)+|N(A_0E)|Qy(t-\alpha)+n_2(y)=0, \tag{7.4}$$

where $n_2(y)=n(Qy)-|N(A_0E)|Qy(t-\alpha)$. We now apply the quasi-static stability analysis to (7.4). In doing so, we define

$$V_1(a,s)=1+[N(a)-|N(A_0E)|q(s)\,e^{-\alpha s}]q(s)/P(s).$$

We require that all roots of $P(s)=0$ other than $\pm i\omega_0$ have negative real parts and that at $a=A_0E$, $s=i\omega_0$

$$\text{Re}\left\{\overline{\frac{\partial V_1}{\partial a}}\frac{\partial V_1}{\partial s}\right\}>0. \tag{7.5}$$

Inequalities (7.3) and (7.5) are equivalent and can be graphically verified. The condition that all roots of $P(s)$ have negative real parts (or that one has positive real part) can also be graphically verified.

This situation is rather interesting. The quasi-static stability analysis usually seems to yield correct predictions for the stability of limit cycles. However, our stability criteria do not agree with this well-known method. It follows that one of the two methods of prediction must be incorrect. In the next section, we discuss a sixth order equation whose periodic solution is predicted to be stable according to the quasi-static analysis and is predicted to be unstable according to Theorem 1 of this paper. Numerical simulations show that this periodic solution is unstable.

8. An example. The quasi-static stability analysis will usually yield a correct stability prediction. This is because the number α is normally rather small. When α is small enough, (7.2) will imply (7.3). The condition that all roots of $P(s)$ except $\pm i\omega_0$ have negative real parts is equivalent to the condition that the graph

$$\left\{\frac{q(i\omega)}{p(i\omega)}\, e^{-i\alpha(\omega-\omega_0)}\colon -\infty<\omega<\infty\right\}$$

does not touch the point $-1/N(A_0E)$ (except at $\pm i\omega_0$) and does not encircle this point. When $|\omega|$ is large, then $|q(i\omega)/p(i\omega)|$ will be less than $|N(A_0E)|^{-1}$. Hence, for α small, this graphical condition is not very different from the same graphical condition for $\{q(i\omega)/p(i\omega)\colon -\infty<\omega<\infty\}$. However, it is possible to find examples with α so large that the quasistatic stability analysis gives an incorrect prediction while Theorem 1 of the present paper yields a correct prediction of limit cycle stability. We shall now present one such example.

Let $q(s)=1$ while

$$p(s)=(s^2+0.5s+0.09)(s^2+0.8s+9)(s^2+0.03s+31)$$

or

$$p(s)=s^6+1.33s^5+40.529s^4+45.1567s^3+295.13716s^2+141.7563s+25.11.$$

Consider the sixth order equation

$$P(D)y+250n(y)=0 \tag{8.1}$$

where $n(y)$ is the hysteresis nonlinearity depicted in Fig. 7. The describing function for this nonlinearity is known to be

$$N(A)=2-\frac{2}{\pi}\left\{\sin^{-1}\left(\frac{2}{A}\right)+\frac{2}{A}\sqrt{1-\frac{4}{A^2}}\right\}-\frac{8i}{\pi A^2}.$$

For the given $p(s)$ and $N(A)$ the equation $p(i\omega)+250N(A)=0$ has a solution ω_0 and A_0 with $A\cong 2.91$ and $\omega_0\cong 1.293$. (Refer to the polar plot in Fig. 8.) It is clear from Fig. 8 that the quasistatic stability analysis yields the prediction that the limit cycle of (8.1), which is approximately equal to $A_0\cos\omega_0 t$, is stable.

Given A_0 and ω_0 we can compute $\mathrm{Re}\,[N'(A_0)/P'(i\omega_0)]$. This number is positive as required for stability. Fig. 9 depicts a polar plot of

$$100P(i\omega)^{-1}=100[p(i\omega)+|N(A_0)|\,e^{i\alpha\omega}]^{-1}.$$

We see that the curve of $100P(i\omega)^{-1}$ encircles the point $-(2.5|N(A_0)|)^{-1}$. Hence, $P(s)=0$ has a root s_3 with positive real part, i.e., Theorem 1 predicts that the limit

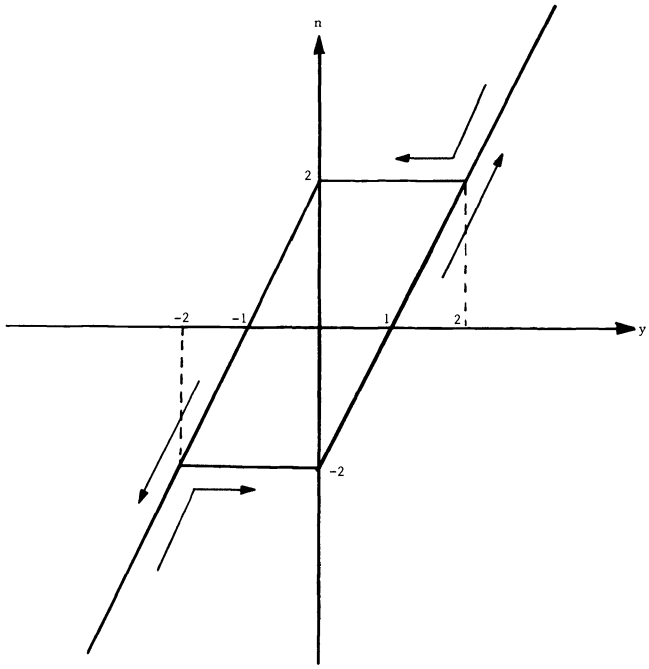

FIG. 7. *A hysteresis nonlinearity.*

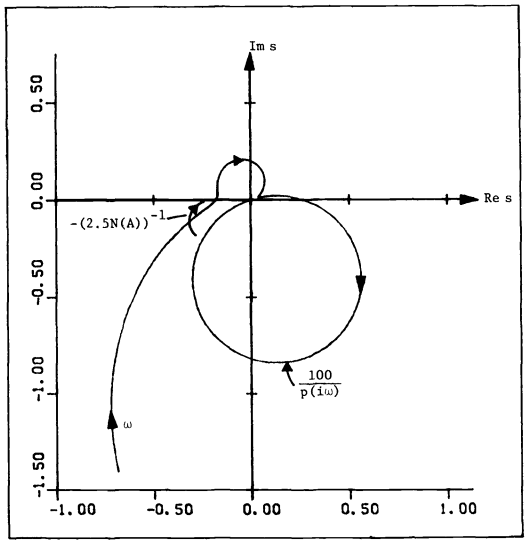

FIG. 8. *Polar plot of* $100/p(i\omega)$ *and* $-(2.5N(A))^{-1}$.

cycle is unstable. A few calculations show that the unstable root s_3 is approximately equal to $0.022+5.575i$. Moreover, since

$$\frac{1}{P'(i\omega_0)} \cong -0.0000689+0.0020285i$$

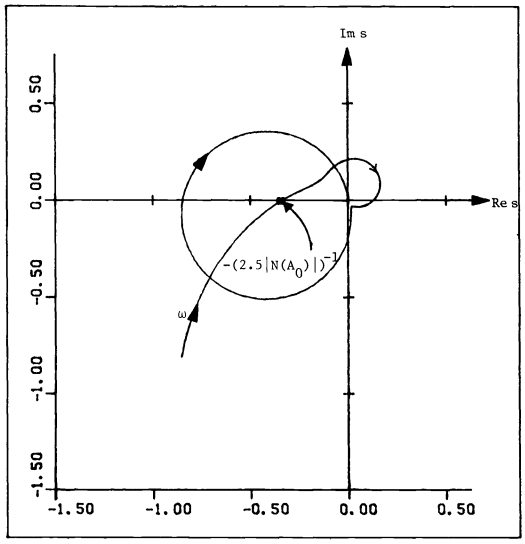

FIG. 9. *Polar plot of* $100/P(i\omega)$.

and

$$\frac{1}{P'(s_3)} \cong -0.000038515 + 0.00010724i$$

then the first four of the parameters $|P'(s_i)|^{-1}$ are certainly small. Hence, it seems likely that Theorem 1 will yield the correct stability prediction.

Solutions of (8.1) were simulated using initial conditions near the predicted periodic solution. These numerical simulations verify our theoretical predictions. Only one (apparent) periodic solution $y(t)$ was found anywhere near the predicted periodic solution. This periodic solution appears to be nearly sinusoidal with frequency and amplitude very near the predicted values $A_0 = 2.91$ and $\omega_0 = 1.293$. Some of the results of our simulations are displayed in Fig. 10 for $0 \leqq t \leqq 6$. Clearly $y(t)$ is unstable. The

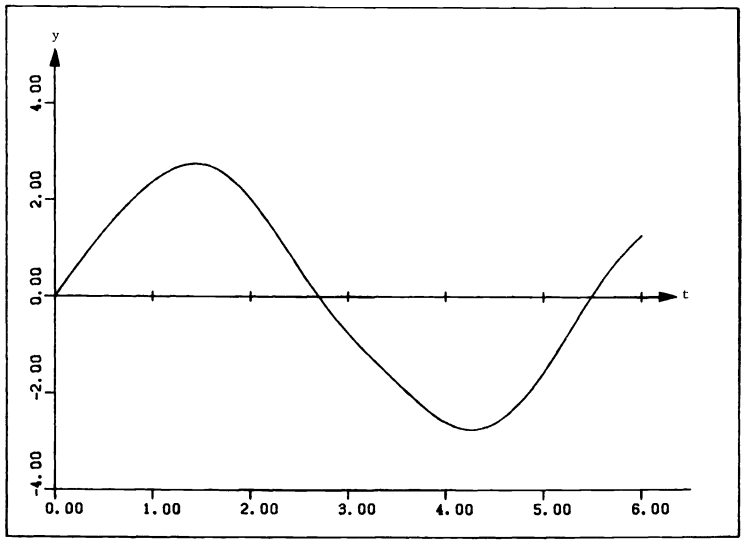

FIG. 10a. *Solution* $y(t)$.

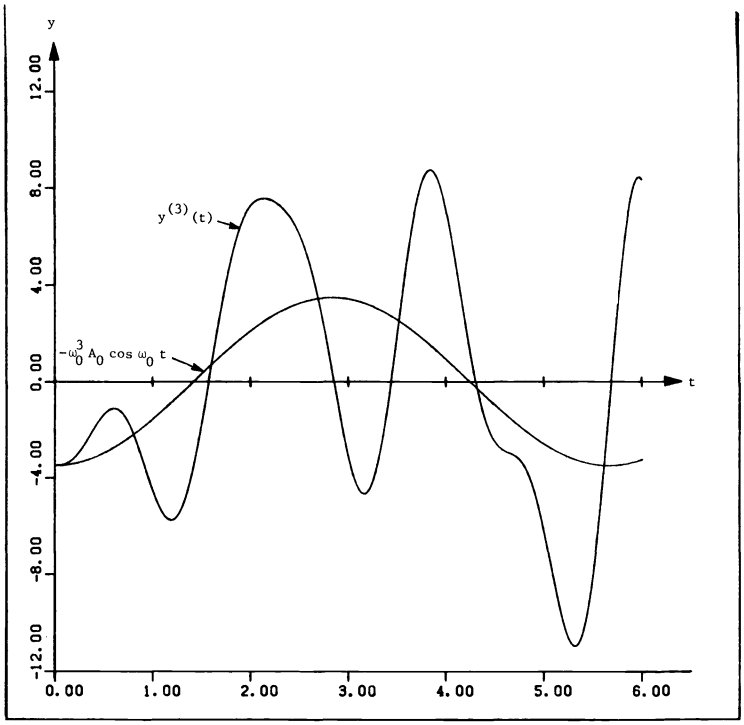

FIG. 10b. $y^{(3)}(t)$ *and* $-\omega_0^3 A_0 \cos \omega_0 t$.

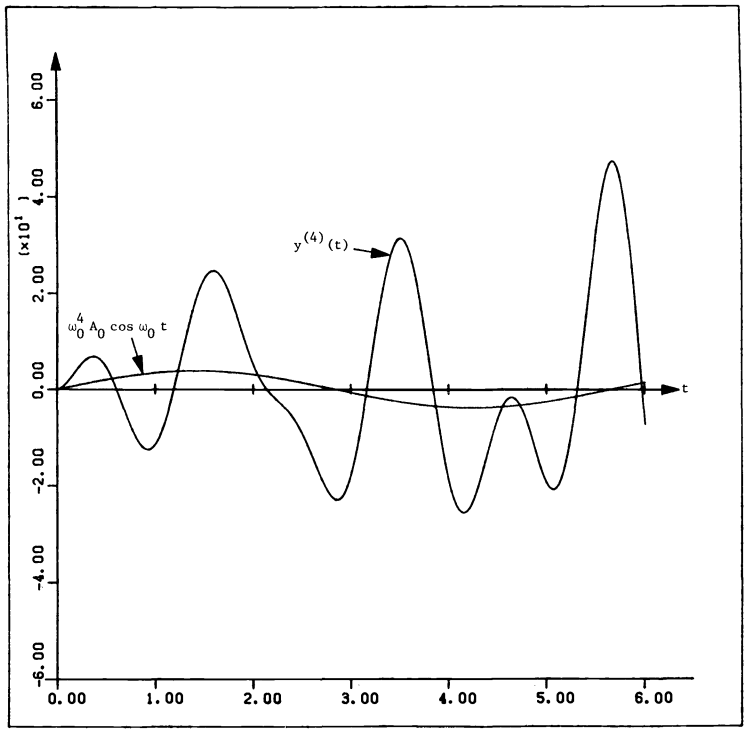

FIG. 10c. $y^{(4)}(t)$ *and* $-\omega_0^4 A_0 \cos \omega_0 t$.

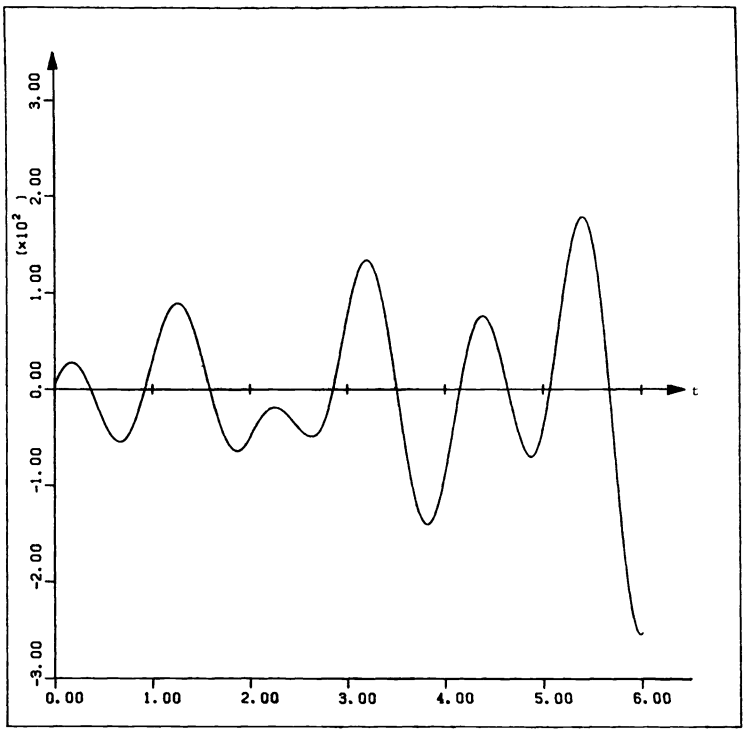

FIG. 10d. $y^{(5)}(t)$.

instability shows up first in the high derivatives of $y(t)$ and then is exhibited in the lower order derivatives. The unstable behavior becomes even more pronounced for $t > 6$.

From the present example we can conclude that the quasistatic stability analysis is not always correct. From the simulation of this example and from several other simulations of third through sixth order equations (not included here) we feel that Theorem 1 does provide a reliable stability analysis when $|P'(i\omega_0)|^{-1}$ is small.

9. Concluding remarks. We have presented an analysis (Theorem 1) for the stability of limit cycles for feedback systems with hysteresis nonlinearities. To obtain these results, we have made use of certain results for functional differential equations and of a result for integral manifolds. Theorem 1 constitutes a generalization of a result for feedback systems with nonlinearities which do not exhibit hysteresis.

A specific example was included for which Loeb's criterion does not predict correctly the stability of a limit cycle while Theorem 1 predicts correctly the stability of the limit cycle.

Like most stability criteria obtained via linearization, our result is local, that is, certain parameters must be "sufficiently small". Nevertheless, Theorem 1 will allow the analyst to proceed with much more confidence when using the method of describing functions. Moreover, our results also correctly predict in remarkable detail the behavior of solutions which are near the (apparent) sinusoidal periodic solution, e.g., the rate of approach to the periodic solution, the speed-up or slow-down of the phase as the periodic solution is approached, and the distortions in derivatives.

GENERALIZED QUASICONVEX MAPPINGS AND VECTOR OPTIMIZATION*

J. JAHN† AND E. SACHS‡

Abstract. Quasiconvexity for mappings is generalized in such a way that this notion gives the sufficiency of necessary optimality conditions such as multiplier rules. One can show that it is the weakest type of generalized convexity notions in the sense that this generalized quasiconvexity holds if certain multiplier rules are sufficient for optimality. It also yields the equivalence of local and global minima. The theory is applied to a multi-objective programming problem and a vector approximation problem.

Key words. multi-objective programming, necessary optimality conditions, quasiconvexity, vector approximation

AMS(MOS) subject classification. 49B27

1. Introduction. In optimization theory the notion of convexity plays an important role for the development of powerful theorems concerning existence of optimal points, their characterization and numerical computation. In this paper we focus mainly on the characterization of optimal points using convexity conditions. According to the particular class of problems treated, there are various generalizations of the definition of a convex function which are already discussed in several textbooks on optimization theory, e.g. Mangasarian [16], Avriel [1] and Krabs [12]. In addition, a number of studies on the comparison of different convexity definitions have been published, see e.g. Ponstein [23] among the earliest and for most recent surveys Schaible/Ziemba [25].

Let us recall the most widely used generalizations of a convex real-valued function in optimization theory: A function $f:\mathbb{R}^n \to \mathbb{R}$ is called *quasiconvex* if for all $\lambda \in [0,1]$, $x, \bar{x} \in \mathbb{R}^n$ the inequality $f(x) \leqq f(\bar{x})$ implies $f(\lambda x + (1-\lambda)\bar{x}) \leqq f(\bar{x})$ or if the level sets $L_\alpha = \{x \in \mathbb{R}^n | f(x) \leqq \alpha\}$ are convex sets for all $\alpha \in \mathbb{R}$.

In the context with optimization and game theory this definition of quasiconvexity is mostly credited to Nikaidô [19], but it is worthwhile to mention that twenty-six years earlier von Neumann [18] introduced the same class of functions using the definition with the level sets. He applied it to prove a saddlepoint theorem in game theory and called them "functions with the property (K)".

A differentiable function $f:\mathbb{R}^n \to \mathbb{R}$ is called *pseudoconvex* if for all $x, \bar{x} \in \mathbb{R}^n$ with $\langle \nabla f(\bar{x}), x - \bar{x} \rangle \geqq 0$ we also have $f(x) \geqq f(\bar{x})$. This definition can be found in Mangasarian [15] and Tuy [26].

These definitions and stronger or weaker versions can be used to prove for example that local minima are global ones or that necessary conditions for minima are also sufficient.

For vector optimization problems extensions of these definitions have been introduced by Hartwig [5] for finite-dimensional problems and by Craven [4], Nehse [17] and Peemöller [21] for problems in infinite-dimensional spaces. In some of these papers it is shown that under certain convexity assumptions the Karush-Kuhn-Tucker multiplier rule as a necessary optimality condition is also sufficient for optimal points.

Since the notion of a convex set or a convex function is purely geometric and does not require any topological properties, we formulate most of the results in linear

spaces. The second section deals with generalizations of quasiconvex mappings. Quasiconvexity as defined earlier is described by a convexity requirement in the domain of the mapping. We define an extension of this concept and also its differentiable version. The relation to pseudoconvexity is discussed together with examples.

The third section begins with the formulation of minimal and weakly minimal points in vector optimization. In § 3.2 we consider problems with equality and inequality constraints in infinite-dimensional spaces where it is shown that a certain type of convexity for the function involved is characteristic for the sufficiency of the generalized Karush-Kuhn-Tucker multiplier rule. In this sense, the convexity condition for the functions of the vector optimization problem cannot be relaxed. Also for this problem we show the equivalence of two types of Lagrange multiplier rules for vector optimization problems under a convex-likeness condition. These results extend the approaches by Hartwig [5] and Craven [4] for vector optimization problems because the C-quasiconvexity is characteristic for the sufficiency of multiplier rules. For scalar-valued objectives a similar condition has been given by Krabs [12]. However, when his almost-pseudoconvexity condition is applied to a finite-dimensional nonlinear programming problem with inequality constraints then all functions describing the inequalities have to be quasiconvex, not only those with active indices as we obtain from our general theory and as one can find in e.g. Mangasarian [16, p. 151].

Since for strictly quasiconvex functions local and global minima coincide, e.g. Mangasarian [16, p. 139], we treat this question in § 3.3. We show that the cor (C_Y)-quasiconvexity is necessary and sufficient for the property that local weakly minimal points are also global weakly minimal. A statement of this type holds for minimal points in vector optimization. In the scalar-valued case, similar characterizations have been obtained in Zang and Avriel [29].

In a final subsection we consider a nonlinear multi-objective programming problem and show which "classical" condition on the functions describing the optimization problem yield the C-quasiconvexity as defined in (16). A second application is a vector approximation problem. Under a certain representation condition for the family of functions which defines the approximation problem we prove that the differentiable C-quasiconvexity is satisfied. This applies to rational vector approximation with the maximum norm and extends a result by Krabs [11] for the real-valued case. Finally we present a generalized Kolmogorov condition.

In the following we list some symbols and notations which are used in this paper. Let X, Y be real linear spaces and let A, B, C be nonempty subsets of X, then:

$X' := \{l: X \to \mathbb{R} | l \text{ is linear on } X\}$,
$A + B := \{a + b | a \in A, b \in B\}$,
$[a, b] := \{\lambda a + (1-\lambda) b | \lambda \in [0, 1]\}$ for all $a, b \in X$
(and $(a, b), [a, b), (a, b]$ are defined in the same way),
$\operatorname{cor}(A) := \{a \in A | \text{for each } x \in X \text{ there exists some } \alpha > 0 \text{ with } [a, a + \alpha x] \subset A\}$
denotes the algebraic interior of A,
$\operatorname{lin}(A) := \{x \in X | \text{there is some } x \neq a \in A \text{ with } [a, x) \subset A\} \cup A$
denotes the algebraic closure of A,
$\operatorname{cone}(A) := \{\alpha x | \alpha \geqq 0, x \in A\}$,
$f(A) := \{f(a) | a \in A\}$ for a function $f: A \to Y$,
$\operatorname{span}(A) :=$ smallest linear subspace of X containing A.

The set A is called *algebraically open* (or *algebraically closed*), if $\operatorname{cor} A = A$ (or $\operatorname{lin}(A) = A$). The set C is said to be a *cone*, if $\operatorname{cone}(C) \subset C$. It is well known that $C = C + C$ for a convex cone C and $\operatorname{cor}(C) = \operatorname{cor}(C) + C$ for a convex cone C with nonempty

algebraic interior. A cone C is called pointed, if $C \cap (-C) = \{0_X\}$. A convex cone C induces a partial ordering $\geqq$ in X by $x \geqq 0_X$ being equivalent to $x \in C_X$. This implies a partial ordering also for the dual space X' by the *dual cone*

$$C_{X'} := \{l \in X' | l(c) \geqq 0 \text{ for all } c \in C\}.$$

The obvious extension of convex functions to partially ordered real linear spaces is the following.

DEFINITION 1.1. Let E, F be real linear spaces, C a convex cone in F, S a nonempty convex subset of E and $v: S \to F$ a mapping. v is called *convex* if $s_1, s_2 \in S$ and $\lambda \in [0, 1]$ imply

$$\lambda v(s_1) + (1-\lambda) v(s_2) - v(\lambda s_1 + (1-\lambda) s_2) \in C. \tag{1}$$

Recall the following generalization of the convexity notion (e.g., see Vogel [27] and Nehse [17]).

DEFINITION 1.2. Let E, F be real linear spaces, C a convex cone in F, S a nonempty subset of E and $v: S \to F$ a mapping. v is called *convex-like* if $v(S) + C$ is convex.

It can be shown that each convex mapping is also convex-like.

2. Generalized quasiconvex mappings. In this section we investigate some generalizations of the quasiconvexity notion. The definition of quasiconvex functionals on $\mathbb{R}^n$ given in the previous section can be carried over easily to the vector-valued case (e.g., see Hartwig [5, p. 304] and Peemöller [21, p. 134] among others).

DEFINITION 2.1. Let E, F be real linear spaces, C a convex cone in F, S a nonempty convex subset of E and $v: S \to F$ a mapping. v is called *quasiconvex* if

$$s_1, s_2 \in S \quad \text{with} \quad v(s_1) - v(s_2) \in C \tag{2}$$

implies that

$$v(s_1) - v(\lambda s_1 + (1-\lambda) s_2) \in C \quad \text{for all } \lambda \in [0, 1]. \tag{3}$$

Every convex mapping $v: S \to F$ is also quasiconvex, because (2) and C being a convex cone imply for any $\lambda \in [0, 1]$

$$d := (1-\lambda)(v(s_1) - v(s_2)) \in C.$$

Therefore, from (1) we obtain

$$v(s_1) - v(\lambda s_1 + (1-\lambda) s_2) \in C + \{d\} \subset C.$$

John von Neumann's definition (see [18, p. 307]) using the level sets is sufficient for this type of quasiconvexity.

LEMMA 2.2. *Let E, F be real linear spaces, C a convex cone in F, S a nonempty convex subset of E and $v: S \to F$ a mapping. Then the mapping v is quasiconvex if and only if for all $\bar{s} \in S$ the sets*

$$L_{\bar{s}} := \{s \in S | s \neq \bar{s},\ v(\bar{s}) - v(s) \in C\} \tag{4}$$

contain $[s, \bar{s})$ whenever $s \in L_{\bar{s}}$.

The proof of Lemma 2.2 follows immediately from Definition 2.1.

2.1. *C*-quasiconvexity. In this subsection we extend the class of quasiconvex mappings considerably by the following definition.

DEFINITION 2.3. Let E, F be real linear spaces, S and C nonempty subsets of E and F, respectively, $v: S \to F$ a mapping and $\bar{s} \in S$ a given element. v is called C-

quasiconvex at $\bar{s}$ if the following holds: Whenever there is some $s \in S$ with

$$s \neq \bar{s} \quad \text{and} \quad v(\bar{s}) - v(s) \in C, \tag{5}$$

then there exists some $\tilde{s} \in S$ with

$$\tilde{s} \neq \bar{s}, \quad s_\lambda := \lambda \tilde{s} + (1-\lambda)\bar{s} \in S \quad \text{and} \quad v(\bar{s}) - v(s_\lambda) \in C \quad \text{for all } \lambda \in (0, 1]. \tag{6}$$

Example 2.4.

(a) Clearly, every quasiconvex mapping $v: S \to F$ is C-quasiconvex at all $\bar{s} \in S$ where C is the ordering cone in F.

(b) Let the mapping $v: \mathbb{R} \to \mathbb{R}^2$ be given by

$$v(\alpha) = (\alpha, \sin \alpha) \quad \text{for all } \alpha \in \mathbb{R}$$

where $\mathbb{R}^2$ is partially ordered in the componentwise sense. The mapping v is $\mathbb{R}^2_+$-quasiconvex at 0 but it is not quasiconvex (at 0).

The following lemma shows that C-quasiconvexity of v at $\bar{s}$ can also be characterized by a property of the level set $L_{\bar{s}}$ in (4).

LEMMA 2.5. *Let E, F be real linear spaces, S and C nonempty subsets of E and F, respectively, $v: S \to F$ a mapping and $\bar{s} \in S$ a given element. The mapping v is C-quasiconvex at $\bar{s} \in S$ if and only if the set $L_{\bar{s}}$ defined by* (4) *is empty or it contains a half-open line segment starting at $\bar{s}$, excluding $\bar{s}$.*

Proof. Rewrite (6) as

$$[\tilde{s}, \bar{s}) \subset L_{\bar{s}}$$

and the statement of the lemma is clear. □

As seen from Lemma 2.5 the relaxation of the requirement (3) to (6) by allowing $\tilde{s} \neq s_2$ extends the class of quasiconvex mappings considerably.

2.2. Differentiable C-quasiconvexity. For several applications it is necessary to investigate C-quasiconvex mappings which are differentiable in a certain sense. For such mappings it is reasonable to introduce an appropriate framework for differentiable C-quasiconvexity. Before we present this definition we introduce the following weak differentiability notion which extends the usual notion of Gâteaux variations to real linear spaces which are not equipped with any topology along the lines of Kirsch/Warth/Werner [10, p. 33].

DEFINITION 2.6. Let E, F be real linear spaces, S and A nonempty subsets of E and F, respectively, $v: S \to F$ a mapping and $\bar{s} \in S$ a given element. A mapping $v'(\bar{s}): S - \{\bar{s}\} \to F$ is called a *Gâteaux variation of v at $\bar{s}$ with respect to A* if the following holds: Whenever there is an element $s \in S$ with

$$s \neq \bar{s} \quad \text{and} \quad v'(\bar{s})(s - \bar{s}) \in A,$$

then there exists some $\bar{\tau} > 0$ with

$$s_\tau := \bar{s} + \tau(s - \bar{s}) \in S \quad \text{and} \quad \frac{1}{\tau}(v(s_\tau) - v(\bar{s})) \in A \quad \text{for all } \tau \in (0, \bar{\tau}].$$

Example 2.7. In addition, let F be a linear topological space and let $v'(\bar{s}): S - \{\bar{s}\} \to F$ represent the directional derivative, i.e. assume that for each $s \in S$ there exists $\bar{\tau} > 0$ with $[s, s_{\bar{\tau}}] \subset S$ and

$$v'(\bar{s})(s - \bar{s}) = \lim_{\tau \downarrow 0} \frac{1}{\tau}(v(\bar{s} + \tau(s - \bar{s})) - v(\bar{s})).$$

Then $v'(\bar{s})$ is a Gâteaux variation of v at $\bar{s}$ with respect to all open sets of F. Suppose $A \subset F$ is open and for some $s \in S$

$$w = v'(\bar{s})(s - \bar{s}) \in A,$$

then $A - \{w\}$ is an open 0_F-neighborhood and there exists $\bar{\tau} > 0$ with

$$\frac{1}{\tau}(v(s_\tau) - v(\bar{s})) - w \in A - \{w\} \quad \text{for all } \tau \in (0, \bar{\tau}],$$

which yields the desired relation. If v is an affine mapping, a Gâteaux variation exists with respect to all sets A.

Next we present the notion of differentiable C-quasiconvexity.

DEFINITION 2.8. Let E, F be real linear spaces, S a nonempty subset of E, C_1 and $C_2 \subset C_3$ nonempty subsets of F, $\bar{s} \in S$ a given element and $v: S \to F$ a mapping which has a Gâteaux variation at $\bar{s}$ with respect to C_3. v is called *differentiably C_1-C_2-quasiconvex at $\bar{s}$* if the following holds: Whenever there is some $s \in S$ with

$$s \neq \bar{s} \quad \text{and} \quad v(s) - v(\bar{s}) \in C_1 \tag{7}$$

then there exists some $\tilde{s} \in S$ with

$$\tilde{s} \neq \bar{s}, \quad [\tilde{s}, \bar{s}] \subset S \quad \text{and} \quad v'(\bar{s})(\tilde{s} - \bar{s}) \in C_2. \tag{8}$$

In the case of $C_1 = C_2 =: C$ the mapping v is simply called *differentiably C-quasiconvex at $\bar{s}$.*

Example 2.9. Let E, F be normed linear spaces, S a subset of E with a nonempty topological interior $\operatorname{int}(S)$, C a convex cone in F, $\bar{s} \in \operatorname{int}(S)$ a given element and $v: S \to F$ a mapping which is Fréchet-differentiable at $\bar{s}$. Then the mapping v is called *pseudoconvex at $\bar{s}$* (for similar definitions, compare Hartwig [5, p. 305] and Craven [4, p. 665] among others), if for all $s \in S$ the following holds:

$$v'(\bar{s})(s - \bar{s}) \in C \Rightarrow v(s) - v(\bar{s}) \in C.$$

This implication is equivalent to

$$v(s) - v(\bar{s}) \notin C \Rightarrow v'(\bar{s})(s - \bar{s}) \notin C.$$

Therefore, each mapping v which is pseudoconvex at $\bar{s}$ is also differentiably $(F \setminus C)$-quasiconvex at $\bar{s}$. This shows that the class of pseudoconvex mappings is contained in the larger class of differentiably $C_1 - C_2$-quasiconvex mappings.

Example 2.10. Let E, F be Banach spaces, S a nonempty convex subset of E, C a closed convex cone in F and $v: S \to F$ a Fréchet-differentiable mapping at a point $\bar{s} \in S$. Nehse [17, p. 484] defines v to be *strong pseudoconvex at $\bar{s}$ with respect to C* if there exists a functional $p_v: S \times S \to \{\delta \in \mathbb{R} : \delta > 0\}$ such that

$$p_v(s, \bar{s})(v(s) - v(\bar{s})) - v'(\bar{s})(s - \bar{s}) \in C \quad \text{for all } s \in S.$$

It is easy to verify that these mappings are also differentiably $(-C)$-quasiconvex and differentiably $(-\operatorname{cor}(C))$-quasiconvex provided $\operatorname{cor}(C) \neq \emptyset$.

With the next theorem we investigate some relations between C-quasiconvexity and differentiable C-quasiconvexity.

THEOREM 2.11. *Let E, F be real linear spaces, S a nonempty subset of E, $C \subset \hat{C}$ nonempty subsets of F such that $C \cup \{0_F\}$ is a cone, $\bar{s} \in S$ a given element and $v: S \to F$ a mapping.*

(a) *If v is $(-C)$-quasiconvex at $\bar{s}$ and has a Gâteaux variation at $\bar{s}$ with respect to $\hat{C}$ and $F \setminus C$, then v is differentiably C-quasiconvex at $\bar{s}$.*

(b) *If v is differentiably C-quasiconvex at $\bar{s}$ with a Gâteaux variation of v at $\bar{s}$ with respect to C, then v is $(-C)$-quasiconvex at $\bar{s}$.*

Proof. (a) Let some $s \in S$ be given with (7). Since v is assumed to be $(-C)$-quasiconvex at $\bar{s}$ there exists some $\tilde{s} \in S$ such that for all $\lambda \in (0, 1]$

$$\tilde{s} \neq \bar{s}, \quad s_\lambda = \lambda\tilde{s} + (1-\lambda)\bar{s} \in S \quad \text{and} \quad v(\bar{s}) - v(s_\lambda) \in -C. \tag{9}$$

Suppose that for all Gâteaux variations of v at $\bar{s}$ with respect to $\hat{C}$ and $F \setminus C$

$$v'(\bar{s})(\tilde{s} - \bar{s}) \notin C.$$

Then, from the definition of a Gâteaux variation with respect to $F \setminus C$ there exists some $\bar{\tau} > 0$ with

$$s_\tau := \bar{s} + \tau(\bar{s} - \tilde{s}) \quad \text{and} \quad \frac{1}{\tau}(v(s_\tau) - v(\bar{s})) \notin C \quad \text{for all } \tau \in (0, \bar{\tau}].$$

By assumption $C \cup \{0_F\}$ is a cone, and therefore we conclude

$$v(\bar{s}) - v(s_\tau) \notin -C \quad \text{for all } \tau \in (0, \bar{\tau}].$$

But this contradicts (9) and shows that for some Gâteaux variation of v at $\bar{s}$ with respect to $F \setminus C$ and $\hat{C}$

$$v'(\bar{s})(\tilde{s} - \bar{s}) \in C,$$

which shows that (7) implies (8) in Definition 2.8 with $C_1 = C_2 = C$ and $C_3 = \hat{C}$.

(b) Let $s \in S$ be given with $s \neq \bar{s}$ and $v(s) - v(\bar{s}) \in C$. Then differentiable C-quasiconvexity of v at $\bar{s}$ implies that there exists some $\tilde{s} \in S$ and a Gâteaux variation of v at $\bar{s}$ with respect to C with the property

$$\tilde{s} \neq \bar{s}, [\tilde{s}, \bar{s}] \subset S \quad \text{and} \quad v'(\bar{s})(\tilde{s} - \bar{s}) \in C.$$

Then by Definition 2.6 there exists some $\bar{\tau} > 0$ with

$$s_\tau := \bar{s} + \tau(\tilde{s} - \bar{s}) \in S \quad \text{and} \quad \frac{1}{\tau}(v(s_\tau) - v(\bar{s})) \in C \quad \text{for all } \tau \in (0, \bar{\tau}].$$

Observing that $C \cup \{0_F\}$ is a cone, we arrive at (6) and the proof of the $(-C)$-quasiconvexity at $\bar{s}$ is complete. □

If one considers Gâteaux variations with respect to algebraically open sets, in the previous theorem under (a) and (b), one should assume that C is algebraically closed and that $F \setminus C$ and $\hat{C}$ are algebraically open, respectively.

3. Application to vector optimization problems. This section is aimed to show the applicability and the usefulness of the notions of generalized convexity introduced in § 2 to vector optimization problems. The generalized Karush-Kuhn-Tucker multiplier rule with a real-valued or vector-valued Lagrangian is examined and we prove that this multiplier rule is a sufficient optimality condition for a substitute problem if and only if the corresponding mappings are generalized quasiconvex. We show also that the local optima are global optima if and only if the objective mapping is in some sense generalized convex. In the last subsection we discuss some examples.

3.1. Problem formulation. In this subsection we consider the vector optimization problem

$$\text{“}\min_{x \in S}\text{”} f(x)$$

where f is a mapping whose domain is a subset of a real linear space and whose range is a subset of a partially ordered real linear space. S is a subset of the domain of f. The set S is called the *constraint set* or *feasible set* and f is called the *objective mapping.*

There are several possibilities to define minima of f on S. We restrict ourselves to the following two optimality notions.

DEFINITION 3.1. Let X, Y be real linear spaces where Y is partially ordered by a convex cone C_Y. Furthermore, let S be a nonempty subset of X and $f: S \to Y$ be a given mapping.

(a) An element $\bar{x} \in S$ is called a *minimal point of f on S,* if

$$(\{f(\bar{x})\} - C_Y) \cap f(S) = \{f(\bar{x})\}.$$

(b) In addition, let $\operatorname{cor}(C_Y) \neq \emptyset$. An element $\bar{x} \in S$ is called a *weakly minimal point of f on S,* if

$$(\{f(\bar{x})\} - \operatorname{cor}(C_Y)) \cap f(S) = \emptyset.$$

The following lemma gives a relation between the two types of optimal points.

LEMMA 3.2. *Let X, Y be real linear spaces, $C_Y \subsetneq Y$ a convex cone with* $\operatorname{cor}(C_Y) \neq \emptyset$, *$S$ a nonempty subset of X and $f: S \to Y$ a mapping. Then each minimal point of f on S is a weakly minimal point of f on S.*

For a special case, a proof of this lemma and an example which shows that the reverse implication does not hold can be found in Lin [14, pp. 49, 47]. From a theoretical point of view the notion of weak minimality is more elegant than the notion of minimality but in the applications the notion of minimality is more desirable.

3.2. Sufficiency of the generalized Karush–Kuhn–Tucker multiplier rule. In this subsection vector optimization problems are considered where the set S of feasible points is given by inequality and equality constraints. In connection with a regularity condition necessary conditions can be established, the so-called generalized Karush-Kuhn-Tucker conditions, which generalize the well-known Lagrange multiplier rule (for a discussion of these necessary conditions for vector optimization problems we refer to Kuhn/Tucker [13], Hurwicz [7], Borwein [2], Vogel [28], Kirsch/Warth/Werner [10], Sachs [24], Hartwig [5], Oettli [20], Borwein [3], Craven [4], among others). It is our aim to give a characterization of these conditions in terms of the definition of generalized convexity as previously given. The generalized Karush-Kuhn-Tucker conditions are investigated in a vector-valued and in a real-valued form.

The vector optimization problem which is under investigation is given as follows:

$$\begin{aligned} &\text{"min"}\ f(x) \\ &\text{subject to} - g(x) \in C_{Z_1}, \\ &\qquad h(x) = 0_{Z_2}, \\ &\qquad x \in S_0. \end{aligned} \tag{10}$$

For this problem we assume the following:

$$\begin{aligned} &\text{Let } X, Y, Z_1, Z_2 \text{ be real linear spaces;} \\ &\text{let } C_Y \subset Y, C_{Z_1} \subset Z_1 \text{ and } C_{Z_2} \subset Z_2 \text{ be convex cones where} \\ &\qquad \operatorname{cor}(C_Y) \neq \emptyset \text{ and } C_{Z_2} \text{ is pointed;} \\ &\text{let } S_0 \text{ be a nonempty subset of } X; \\ &\text{let } f: S_0 \to Y,\ g: S_0 \to Z_1 \text{ and } h: S_0 \to Z_2 \text{ be mappings,} \\ &\text{let the feasible set } S \text{ be defined by} \\ &\qquad S := \{x \in S_0 \mid -g(x) \in C_{Z_1},\ h(x) = 0_{Z_2}\}. \end{aligned} \tag{11}$$

THEOREM 3.3. *Let the vector optimization problem* (10) *with* (11) *be given and suppose that for some* $\bar{x} \in S$ *there exist sets* G_i, $i = 0, 1, 2$ *with* $\operatorname{cor}(C_Y) \subset G_0 \subset Y$, $C_{Z_1} + \operatorname{cone}(g(\bar{x})) \subset G_1 \subset Z_1$, $(C_{Z_2} \cup (-C_{Z_2})) \subset G_2 \subset Z_2$, *such that the mappings* f, g, h *have Gâteaux variations at* $\bar{x}$ *with respect to* G_0, G_1, *and* G_2, *respectively. Assume that there exist some*

$$t \in C_{Y'} \setminus \{0_{Y'}\}, \quad u \in C_{Z_1'}, \quad v \in Z_2' \tag{12}$$

with

$$(t \circ f'(\bar{x}) + u \circ g'(\bar{x}) + v \circ h'(\bar{x}))(x - \bar{x}) \geqq 0 \quad \text{for all } x \in S_0 \tag{13}$$

and

$$(u \circ g)(\bar{x}) = 0. \tag{14}$$

Then $\bar{x}$ *is a weakly minimal point of* f *on*

$$\bar{S} := \{x \in S_0 \mid -g(x) \in C_{Z_1} + \operatorname{cone}(g(\bar{x})),\ h(x) = 0_{Z_2}\}$$

if and only if

$$(f, g, h, h) : S_0^4 \to Y \times Z_1 \times Z_2 \times Z_2 \tag{15}$$

is differentiably $(-C)$*-quasiconvex at* $\bar{x}$ *with*

$$C := \operatorname{cor}(C_Y) \times (C_{Z_1} + \operatorname{cone}(g(\bar{x}))) \times C_{Z_2} \times (-C_{Z_2}). \tag{16}$$

Proof. Assume that the multiplier rule (12)-(14) holds at some $\bar{x} \in S$. Then we assert that

$$(f'(\bar{x})(x - \bar{x}), g'(\bar{x})(x - \bar{x}), h'(\bar{x})(x - \bar{x}), h'(\bar{x})(x - \bar{x})) \notin -C \quad \text{for all } x \in S_0. \tag{17}$$

For the proof of this assertion assume that there exists some $x \in S_0$ with

$$f'(\bar{x})(x - \bar{x}) \in -\operatorname{cor}(C_Y),$$
$$g'(\bar{x})(x - \bar{x}) \in -C_{Z_1} - \operatorname{cone}(g(\bar{x})),$$
$$h'(\bar{x})(x - \bar{x}) \in -C_{Z_2},$$
$$h'(\bar{x})(x - \bar{x}) \in C_{Z_2}.$$

Because C_{Z_2} is a pointed cone we obtain

$$h'(\bar{x})(x - \bar{x}) \in C_{Z_2} \cap (-C_{Z_2}) = \{0_{Z_2}\}$$

and together with (12) we conclude for some $\alpha \geqq 0$

$$(t \circ f'(\bar{x}) + u \circ g'(\bar{x}) + v \circ h'(\bar{x}))(x - \bar{x}) < -\alpha(u \circ g)(\bar{x}).$$

But this inequality contradicts (13) and (14). Hence (17) holds and with the generalized quasiconvexity requirement we deduce that for all $x \in S_0$

$$(f(x) - f(\bar{x}), g(x) - g(\bar{x}), h(x) - h(\bar{x}), h(x) - h(\bar{x})) \notin -C. \tag{18}$$

Condition (18) means that there is no $x \in S_0$ with

$$f(x) \in \{f(\bar{x})\} - \operatorname{cor}(C_Y),$$
$$-g(x) \in \{-g(\bar{x})\} + C_{Z_1} + \operatorname{cone}(g(\bar{x})) = C_{Z_1} + \operatorname{cone}(g(\bar{x})),$$
$$h(x) \in C_{Z_2} \cap (-C_{Z_2}) = \{0_{Z_2}\}.$$

So (18) is equivalent with the statement that

$$(\{f(\bar{x})\} - \operatorname{cor}(C_Y)) \cap f(\bar{S}) = \emptyset,$$

i.e. $\bar{x}$ is a weakly minimal point of f on $\bar{S}$.

Conversely, if in addition to (12)-(14) $\bar{x}$ is a weakly minimal point of f on $\bar{S}$, then (18) holds and the differentiable C-quasiconvexity of (15) at $\bar{x}$ is trivial. □

In the previous theorem we showed the equivalence of the generalized quasiconvexity with the sufficiency of the generalized Karush-Kuhn-Tucker conditions for optimality of a substitute problem where S is replaced by $\bar{S}$. For the original problem the following conclusion holds.

COROLLARY 3.4. *Let the assumptions of Theorem* 3.3 *be satisfied and let the mapping* (15) *be differentiably* $(-C)$*-quasiconvex at* $\bar{x} \in S$ *with* C *given by* (16); *then* $\bar{x}$ *is a weakly minimal point of* f *on* S.

Proof. By Theorem 3.3 $\bar{x} \in S$ is a weakly minimal point of f on $\bar{S}$, i.e.

$$(\{f(\bar{x})\} - \operatorname{cor}(C_Y)) \cap f(\bar{S}) = \emptyset.$$

But $S \subset \bar{S}$ implies that $\bar{x}$ is also a weakly minimal point of f on S. □

Corollary 3.4 extends results of Vogel [28, p. 100], Hartwig [5, p. 313-314] (for another optimality notion) and Craven [4, p. 666-667]. In Theorem 3.3 a real-valued Lagrangian $t \circ f + u \circ g + v \circ h$ is considered implicitly. For a vector-valued Lagrangian $f + L_1 \circ g + L_2 \circ h$ where L_1 and L_2 are appropriate linear mappings we obtain a similar result as in Theorem 3.3 without using a separate approach (as in Craven [4]). Under a convex-likeness assumption there is no difference if we use a real-valued or a vector-valued Lagrangian. This result is formulated in

THEOREM 3.5. *Let the vector optimization problem* (10) *with* (11) *be given. For some* $\bar{x} \in S$ *we assume that* $f'(\bar{x})\colon S_0 - \{\bar{x}\} \to Y$, $g'(\bar{x})\colon S_0 - \{\bar{x}\} \to Z_1$ *and* $h'(\bar{x})\colon S_0 - \{\bar{x}\} \to Z_2$ *are arbitrary mappings. Then for the two statements,*

(19) *there exist* $t \in C_{Y'} \setminus \{0_{Y'}\}$, $u \in C_{Z_1'}$, *and* $v \in Z_2'$
with the properties $(t \circ f'(\bar{x}) + u \circ g'(\bar{x}) + v \circ h'(\bar{x}))(x - \bar{x}) \geqq 0$ *for all* $x \in S_0$
and $(u \circ g)(\bar{x}) = 0$,

and

(20) *there exist a linear mapping* $L_1\colon Z_1 \to Y$ *with*
$L_1(C_{Z_1}) \subset (\operatorname{cor}(C_Y) \cup \{0_Y\})$ *and a linear mapping*
$L_2\colon Z_2 \to Y$ *with the properties*
$(f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x}))(x - \bar{x}) \notin -\operatorname{cor}(C_Y)$ *for all* $x \in S_0$
and $(L_1 \circ g)(\bar{x}) = 0_Y$,

the following holds:

(a) *The statement* (19) *implies the statement* (20).

(b) *If the statement* (20) *holds and the mapping* $f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x})$ *is convex-like, then the statement* (19) *is true.*

Proof.

(a) We assume that the statement (19) is true. Because of $t \in C_{Y'} \setminus \{0_{Y'}\}$ and $\operatorname{cor}(C_Y) \neq \emptyset$ there exists a $\tilde{y} \in \operatorname{cor}(C_Y)$ with $t(\tilde{y}) = 1$. Then, following an idea due to Borwein [2, p. 62], we define the mappings $L_1\colon Z_1 \to Y$ and $L_2\colon Z_2 \to Y$ by

$$L_1(z_1) = u(z_1)\tilde{y} \quad \text{for all } z_1 \in Z_1 \tag{21}$$

and

$$L_2(z_2) = v(z_2)\tilde{y} \quad \text{for all } z_2 \in Z_2.$$

Obviously, L_1 and L_2 are linear mappings, and we have

$$L_1(C_{Z_1}) \subset \operatorname{cor}(C_Y) \cup \{0_Y\}.$$

Furthermore, we obtain $t \circ L_1 = u$ and $t \circ L_2 = v$. Consequently, the inequality in the statement (19) can be rewritten as

$$(t \circ (f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x})))(x - \bar{x}) \geqq 0 \quad \text{for all } x \in S_0.$$

Then we conclude with a scalarization result (e.g., compare [9, Cor. 2.3(c)])

$$(f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x}))(x - \bar{x}) \notin -\operatorname{cor}(C_Y) \quad \text{for all } x \in S_0.$$

Finally, with the equality (21) we get

$$(L_1 \circ g)(\bar{x}) = (u \circ g)(\bar{x})\tilde{y} = 0_Y.$$

So the statement (20) is true.

(b) Now we assume that the statement (20) is true. Then we have

$$(f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x}))(x - \bar{x}) \notin -\operatorname{cor}(C_Y) \quad \text{for all } x \in S_0,$$

and if we notice that $\operatorname{cor}(C_Y) = \operatorname{cor}(C_Y) + C_Y$, this implies

$$(S + C_Y) \cap (-\operatorname{cor}(C_Y)) = \varnothing$$

where S is defined as

$$S := \{(f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x}))(x - \bar{x}) | x \in S_0\}.$$

Since the mapping $f'(\bar{x}) + L_1 \circ g'(\bar{x}) + L_2 \circ h'(\bar{x})$ is assumed to be convex-like, the set $S + C_Y$ is convex. By a known separation theorem (e.g., see Holmes [7, § 4.B]) there exists a linear functional $t \in C_{Y'} \backslash \{0_{Y'}\}$ with

$$(t \circ f'(\bar{x}) + t \circ L_1 \circ g'(\bar{x}) + t \circ L_2 \circ h'(\bar{x}))(x - \bar{x}) \geqq 0 \quad \text{for all } x \in S_0.$$

If we define $u := t \circ L_1$ and $v := t \circ L_2$ we obtain

$$(t \circ f'(\bar{x}) + u \circ g'(\bar{x}) + v \circ h'(\bar{x}))(x - \bar{x}) \geqq 0 \quad \text{for all } x \in S_0$$

and

$$(u \circ g)(\bar{x}) = (t \circ L_1 \circ g)(\bar{x}) = 0.$$

Furthermore, for any $z_1 \in C_{Z_1}$ we obtain

$$u(z_1) = (t \circ L_1)(z_1) \geqq 0$$

which implies $u \in C_{Z_1'}$. This completes the proof. □

Although we use the notation of a derivative, Theorem 3.5 holds for arbitrary mappings $f'(\bar{x})$, $g'(\bar{x})$ and $h'(\bar{x})$. The "multiplier" L_1 in (20) is (in a stronger sense) a monotone mapping.

If the generalized quasiconvexity assumption in Theorem 3.3 is strengthened, then a similar theorem holds for minimal points of f on $\bar{S}$.

THEOREM 3.6. *Let all the assumptions of Theorem* 3.3 *be satisfied. Then* $\bar{x}$ *is a minimal point of* f *on* $\bar{S}$ *if and only if the composite mapping* (f, g, h, h) *is differentiably* $(-C_1)-(-C_2)$*-quasiconvex at* $\bar{x}$ *with*

$$C_1 := (C_Y \backslash \{0_Y\}) \times (C_{Z_1} + \operatorname{cone}(g(\bar{x}))) \times C_{Z_2} \times (-C_{Z_2})$$

and

$$C_2 := \operatorname{cor}(C_Y) \times (C_{Z_1} + \operatorname{cone}(g(\bar{x}))) \times C_{Z_2} \times (-C_{Z_2}).$$

The proof of this theorem is almost identical to the one of Theorem 3.3 and it is therefore omitted. A result which is similar to that of Corollary 3.4 can also be obtained.

3.3. Local and global minima. It is well-known that a real-valued strictly quasiconvex function on a convex subset of $\mathbb{R}^n$ has the property that all its local minima are also global minima (e.g., see Mangasarian [16, p. 139]). We show in this subsection that this fact extends to hold under C-quasiconvexity and it is even characteristic for it.

DEFINITION 3.7. Let X, Y be real linear spaces, S a nonempty subset of X, C_Y a convex cone in Y and $f: S \to Y$ a mapping.

(a) An element $\bar{x} \in S$ is called a *local minimal point of f on S*, if there is a set $U \subset X$ with $\bar{x} \in \operatorname{cor}(U)$ such that $\bar{x}$ is a minimal point of f on $S \cap \operatorname{cor}(U)$.

(b) In addition, let $\operatorname{cor}(C_Y) \neq \emptyset$. An element $\bar{x} \in S$ is called a *local weakly minimal point of f on S*, if there is a set $U \subset X$ with $\bar{x} \in \operatorname{cor}(U)$ such that $\bar{x}$ is a weakly minimal point of f on $S \cap \operatorname{cor}(U)$.

The following two theorems state a necessary and sufficient condition under which local minima are even global minima.

THEOREM 3.8. *Let X, Y be real linear spaces, S a nonempty subset of X, C_Y a convex cone in Y with $C_Y \neq \{0_Y\}$ and $f: S \to Y$ a mapping. Let $\bar{x} \in S$ be a local minimal point of f on S. Then $\bar{x}$ is a (global) minimal point of f on S if and only if f is $(C_Y \setminus \{0_Y\})$-quasiconvex at $\bar{x}$.*

Proof. Suppose that $\bar{x} \in S$ is a local minimal point of f on S. If $\bar{x}$ is not a minimal point of f on S, then there exists some $x \in S$ with

$$f(\bar{x}) - f(x) \in C_Y \setminus \{0_Y\}.$$

Assume f is $(C_Y \setminus \{0_Y\})$-quasiconvex at $\bar{x}$; then there exists some $\tilde{x} \in S$ with

$$x_\lambda := \lambda \tilde{x} + (1-\lambda)\bar{x} \in S, \ \tilde{x} \neq \bar{x}$$

and

$$f(\bar{x}) - f(x_\lambda) \in C_Y \setminus \{0_Y\} \quad \text{for all } \lambda \in (0, 1]. \tag{22}$$

Since $\bar{x} \in \operatorname{cor}(U)$ there exists some $\bar{\lambda} \in (0, 1]$ with

$$x_\lambda \in \operatorname{cor}(U) \quad \text{for all } \lambda \in (0, \bar{\lambda}]. \tag{23}$$

(22) and (23) together contradict the assumption that $\bar{x}$ is a local minimal point of f on S. On the other hand if $\bar{x}$ is a minimal point of f on S, then there is no $x \in S$ with

$$f(\bar{x}) - f(x) \in C_Y \setminus \{0_Y\}$$

and the $(C_Y \setminus \{0_Y\})$-quasiconvexity of f at $\bar{x}$ holds trivially. □

The following theorem can be proven similarly.

THEOREM 3.9. *Let X, Y be real linear spaces, S a nonempty subset of X, C_Y a convex cone in Y with $\operatorname{cor}(C_Y) \neq \emptyset$ and $f: S \to Y$ a mapping. Let $\bar{x} \in S$ be a local weakly minimal point of f on S. Then $\bar{x}$ is a (global) weakly minimal point of f on S if and only if f is $\operatorname{cor}(C_Y)$-quasiconvex at $\bar{x}$.*

Zang and Avriel [29] characterized functions on $\mathbb{R}^n$ whose local minima are also global by a lower semicontinuity property of the corresponding level sets.

3.4. Examples. In this last section we consider two special problems, namely a nonlinear multi-objective programming problem and a vector approximation problem.

For both problems we present conditions under which the generalized quasiconvexity assumption in Theorem 3.3 is fulfilled.

The vector optimization problem (10) reduces to a nonlinear multi-objective programming problem, if we set

$$
\begin{aligned}
&X=\mathbb{R}^n, \quad Y=\mathbb{R}^m, \quad Z_1=\mathbb{R}^k, \quad Z_2=\mathbb{R}^l,\\
&C_Y=\{y\in\mathbb{R}^m \mid y_i\geqq 0 \text{ for all } i=1,\cdots,m\},\\
&C_{Z_1}=\{z\in\mathbb{R}^k \mid z_i\geqq 0 \text{ for all } i=1,\cdots,k\},\\
&C_{Z_2}=\{z\in\mathbb{R}^l \mid z_i\geqq 0 \text{ for all } i=1,\cdots,l\}.
\end{aligned}
\tag{24}
$$

For this special case we obtain

LEMMA 3.10. *Let the nonlinear multi-objective programming problem* (10) *with* (11) *and the special assumption* (24) *be given and assume that at some* $\bar{x}\in S$ *the vector functions* f, g, h *have partial derivatives at* $\bar{x}$. *If the functions* $f_1,\cdots,f_m$ *are pseudoconvex at* $\bar{x}$ *and the functions* $h_1,\cdots,h_l,-h_1,\cdots,-h_l$ *and* g_i *for all* $i\in I(\bar{x})$ *with*

$$I(\bar{x}):=\{i\in\{1,\cdots,k\} \mid g_i(\bar{x})=0\}$$

are quasiconvex at $\bar{x}$, *then the composite vector function* (f, g, h, h) *is differentiably* $(-C)$*-quasiconvex at* $\bar{x}$ *with* C *defined by* (16).

Proof. Let some $x=s\in S$ be given with (7), i.e. $\bar{x}\neq x$ and

$$
\begin{aligned}
&f_i(\bar{x})-f_i(x)>0 \quad \text{for all } i=1,\cdots,m,\\
&g_i(\bar{x})-g_i(x)\geqq \alpha g_i(\bar{x}) \quad \text{for all } i=1,\cdots,k \text{ and some } \alpha\geqq 0,\\
&h_i(\bar{x})-h_i(x)=0 \quad \text{for all } i=1,\cdots,l.
\end{aligned}
\tag{25}
$$

The inequality (25) implies

$$g_i(\bar{x})-g_i(x)\geqq 0 \quad \text{for all } i\in I(\bar{x}).$$

Using the characterization of differentiable quasiconvex functions and the definition of pseudoconvex functions (e.g., compare Mangasarian [16, ch. 9]) the previous inequalities imply

$$
\begin{aligned}
&f_i'(\bar{x})(\bar{x}-x)>0 \quad \text{for all } i=1,\cdots,m,\\
&g_i'(\bar{x})(\bar{x}-x)\geqq 0 \quad \text{for all } i\in I(\bar{x}),\\
&h_i'(\bar{x})(\bar{x}-x)=0 \quad \text{for all } i=1,\cdots,l.
\end{aligned}
$$

Since $g_i(\bar{x})<0$ for all $i\notin I(\bar{x})$ there is an $\alpha>0$ with

$$g_i'(\bar{x})(\bar{x}-x)\geqq \alpha g_i(\bar{x}) \quad \text{for all } i\in\{1,\cdots,m\}.$$

Hence $\tilde{s}=x$ satisfies (8). □

Lemma 3.10 shows in particular that the convexity type conditions are only imposed on the active constraints. This is for example not the case if one applies the condition of a function being "almost pseudoconcave" in Krabs [12, p. 172] to this standard problem of optimization. However, the almost pseudoconcavity was introduced in order to obtain the sufficiency of necessary optimality conditions for problems in Chebyshev approximation.

Next we consider a special Chebyshev vector approximation problem under the following assumption:

Let A be a nonempty convex subset of $\mathbb{R}^n$;
let A_0 be an open superset of A;
let Q be a compact space with at least $n+2$ elements;
(26) let $C(Q)$ denote the real linear space of real-valued continuous functions on Q equipped with the maximum norm $\|\cdot\|_\infty$;
let $F_1, \cdots, F_m: A_0 \to C(Q)$ be mappings which are Fréchet differentiable on A_0;
let $z_1, \cdots, z_m \in C(Q)$ be given functions.

Then the Chebyshev vector approximation problem is formalized as

$$\text{(27)} \qquad \text{"min"}_{a \in A} \begin{pmatrix} \|F_1(a) - z_1\|_\infty \\ \vdots \\ \|F_m(a) - z_m\|_\infty \end{pmatrix}$$

where the partial ordering in $\mathbb{R}^m$ is understood in the natural sense. For our investigations we replace this problem by the following:

$$\text{"min"} (\gamma_1, \cdots, \gamma_m)^T$$

subject to

$$\text{(28)} \qquad \left.\begin{aligned} F_i(a)(t) - z_i(t) - \gamma_i &\leqq 0 \\ -F_i(a)(t) + z_i(t) - \gamma_i &\leqq 0 \end{aligned}\right\} \text{for all } i = 1, \cdots, m \text{ and all } t \in Q$$

$$a \in A.$$

The vector optimization problem (28) is a special type of (10) without equality constraints. Then (11) reduces to:

$$X = \mathbb{R}^{n+m}, \quad Y = \mathbb{R}^m, \quad Z_1 = C(Q)^{2m}, \quad S_0 = A \times \mathbb{R}^m,$$
$$C_Y = \{y \mid y_i \geqq 0 \text{ for all } i = 1, \cdots, m\},$$
$$C_{Z_1} = C_{C(Q)}^{2m} \text{ with } C_{C(Q)} = \{u \in C(Q) \mid u(t) \geqq 0 \text{ for all } t \in Q\},$$
$$f: A \times \mathbb{R}^m \to Y \text{ with } f(x) = (\gamma_1, \cdots, \gamma_m)^T \text{ for all } x = (a, \gamma_1, \cdots, \gamma_m) \in A \times \mathbb{R}^m,$$
$$g: A \times \mathbb{R}^m \to Z_1 \text{ with}$$

$$\text{(29)} \qquad g(x) = \begin{pmatrix} F_1(a) - z_1 - \gamma_1 \mathbb{1} \\ -F_1(a) + z_1 - \gamma_1 \mathbb{1} \\ \vdots \\ F_m(a) - z_m - \gamma_m \mathbb{1} \\ -F_m(a) + z_m - \gamma_m \mathbb{1} \end{pmatrix} \text{ for all } x = (a, \gamma_1, \cdots, \gamma_m) \in A \times \mathbb{R}^m$$

where $\mathbb{1} \in C(Q)$ denotes the function which equals 1.

The equivalence of both problems (27) and (28) can be derived from the following lemma.

LEMMA 3.11. *Let X, Y be real linear spaces, C_Y a convex cone in Y with* cor $(C_Y) \neq \emptyset$, *S a nonempty subset of X and $f: S \to Y$ a mapping. In the space $X \times Y$ we define $S_1 = \{(x, y) \in S \times Y: y \in \{f(x)\} + C_Y\}$ and $\phi: S_1 \to Y$ by $\phi(x, y) = y$ for all $(x, y) \in S_1$. Then*

the problems

$$\text{"min"}_{x\in S} f(x) \quad \textit{and} \quad \text{"min"}_{(x,y)\in S_1} \phi(x, y)$$

are equivalent in the following sense:

If $\bar{x} \in S$ is a weakly minimal point of f on S, then $(\bar{x}, f(\bar{x}))$ is a weakly minimal point of ϕ on S_1. On the other hand, suppose $(\bar{x}, \bar{y}) \in S_1$ is a weakly minimal point of ϕ on S_1; then $\bar{x} \in S$ is a weakly minimal point of f on S.

The proof of this lemma is a consequence from the equality $C_Y = C_Y + \operatorname{cor}(C_Y)$ and the definition of the problems.

The same statement on the equivalence of minimal points holds if the condition $\operatorname{cor}(C_Y) \neq \emptyset$ is replaced by C_Y being pointed.

For the real-valued case (i.e., $m = 1$) Krabs [11] gave a condition on F_1 which assures the sufficiency of necessary conditions for the previous problem. It is also sufficient for the almost pseudo-concavity. We show that an extension of this condition, a representation condition, as well implies the differentiable C-quasiconvexity of the mapping (15) at each $\bar{x} \in S$ with C given by (16).

LEMMA 3.12. *Let the vector optimization problem* (28) *with the assumptions* (26) *and* (29) *be given. Let $(F_1, \cdots, F_m)$ satisfy the representation condition, i.e., for every $a_1, a_2 \in A$ there exist positive functions $\psi_1(a_1, a_2), \cdots, \psi_m(a_1, a_2) \in C(Q)$ and some $\tilde{a} \in A$ with*

$$F_i(a_1) - F_i(a_2) = \psi_i(a_1, a_2) F_i'(a_2)(\tilde{a} - a_2) \quad \textit{for all } i = 1, \cdots, m. \tag{30}$$

Then the composite mapping (f, g) is differentiably $(-C)$-quasiconvex at each $\bar{x} \in S$ with $C := \operatorname{cor}(C_Y) \times (C_{Z_1} + \operatorname{cone}(g(\bar{x})))$.

Proof. Let some $(\bar{a}, \bar{\gamma}_1, \cdots, \bar{\gamma}_m), (a, \gamma_1, \cdots, \gamma_m) \in S$ be given with

$$\bar{\gamma}_i - \gamma_i > 0 \quad \text{for all } i = 1, \cdots, m,$$

$$F_i(\bar{a}) - \bar{\gamma}_i - F_i(a) + \gamma_i \mathbb{1} \geqq \alpha(F_i(\bar{a}) - z_i - \bar{\gamma}_i \mathbb{1}) \tag{31}$$

$$-F_i(\bar{a}) - \bar{\gamma}_i + F_i(a) + \gamma_i \mathbb{1} \geqq \alpha(-F_i(\bar{a}) + z_i - \bar{\gamma}_i \mathbb{1}) \tag{32}$$

for all $i = 1, \cdots, m$ and some $\alpha \geqq 0$,

Then there exist positive functions $\psi_1(a, \bar{a}), \cdots, \psi_m(a, \bar{a}) \in C(Q)$ and some $\bar{a} \in A$ with (30). Furthermore there exist positive real numbers $\alpha_1, \cdots, \alpha_m, \beta_1, \cdots, \beta_m$ with

$$0 < \alpha_i \leqq \psi_i(a, \bar{a})(t) \leqq \beta_i \quad \text{for all } i = 1, \cdots, m \text{ and all } t \in Q,$$

and we define

$$\tilde{\alpha} := \frac{\alpha}{\min\{\alpha_1, \cdots, \alpha_m\}}$$

and

$$\tilde{\gamma}_i := \bar{\gamma}_i - \frac{1}{\beta_i}(\bar{\gamma}_i - \gamma_i) < \bar{\gamma}_i \quad \text{for all } i = 1, \cdots, m.$$

Then (31) implies with (30) and the feasibility of $(\bar{a}, \bar{\gamma}_1, \cdots, \bar{\gamma}_m)$

$$\begin{aligned} -F_i'(\bar{a})(\tilde{a} - \bar{a}) &= F_i'(\bar{a})(\bar{a} - \tilde{a}) \\ &= \frac{1}{\psi_i(a, \bar{a})}(F_i(\bar{a}) - F_i(a)) \\ &\geqq \frac{\alpha}{\alpha_i}(F_i(\bar{a}) - z_i - \bar{\gamma}_i \mathbb{1}) + \frac{\bar{\gamma}_i - \gamma_i}{\beta_i} \\ &\geqq \tilde{\alpha}(F_i(\bar{a}) - z_i - \bar{\gamma}_i \mathbb{1}) + (\bar{\gamma}_i - \tilde{\gamma}_i) \quad \text{for all } i = 1, \cdots, m. \end{aligned}$$

Similarly (32) implies

$$F_i'(\bar{a})(\tilde{a}-\bar{a}) = \frac{1}{\psi_i(a,\bar{a})}(F_i(a)-F_i(\bar{a}))$$

$$\geqq \frac{\alpha}{\alpha_i}(-F_i(\bar{a})+z_i-\gamma_i\mathbb{1})+\frac{\bar{\gamma}_i-\gamma_i}{\beta_i}$$

$$\geqq \tilde{\alpha}(-F_i(\bar{a})+z_i-\gamma_i\mathbb{1})+(\bar{\gamma}_i-\tilde{\gamma}_i) \quad \text{for all } i=1,\cdots,m.$$

Hence (8) holds with $\tilde{s}=(\tilde{a},\tilde{\gamma})$. □

The representation condition (30) is satisfied for rational approximating families: Let functions $p_j^i \in C(Q)$, $i=1,\cdots,m$, $j=1,\cdots,n$ be given and define for some $n_i \in \{1,2,\cdots,n-1\}$, $i=1,\cdots,m$

$$F_i(a) = \frac{\sum_{j=1}^{n_i}\alpha_j p_j^i}{\sum_{j=n_i+1}^{n}\alpha_j p_j^i} \quad \text{for } a=(\alpha_1,\cdots,\alpha_n)\in\mathbb{R}^n,$$

$$A = \left\{ a\in\mathbb{R}^n : \sum_{j=n_i+1}^{n}\alpha_j p_j^i(t)>0 \quad \text{for all } t\in Q \right\}.$$

An easy computation shows that (30) holds with

$$\psi_i(a_1,a_2) = \sum_{j=n_i+1}^{n}\alpha_j^{(1)}p_j^i \Big/ \sum_{j=n_i+1}^{n}\alpha_j^{(2)}p_j^i,$$

$$a_k = (\alpha_1^{(k)},\cdots,\alpha_n^{(k)}), \qquad k=1,2.$$

For further discussion of these types of condition for the case $m=1$ see Krabs [11].

For real-valued Chebyshev approximation problems the multiplier rule (12)-(14) can be formulated more precisely taking into account the special structure of approximation problems. This is extended to the Chebyshev vector approximation problem in the following lemma.

LEMMA 3.13. *Let the assumptions* (26) *and* (29) *be satisfied, and let a vector* $(\bar{a},\bar{\gamma})\in A\times\mathbb{R}^m$ *with* $\bar{\gamma}_i = \|F_i(\bar{a})-z_i\|_\infty$, $i=1,\cdots,m$, *be given. For each* $i=1,\cdots,m$ *let the Fréchet-derivative of* F_i *at* $\bar{a}$ *be given by*

$$F_i'(\bar{a})(a) = \sum_{k=1}^{n} a_k v_{ik} \quad \textit{for all } a\in A$$

with certain functions $v_{ik}\in C(Q)$. *The vector* $(\bar{a},\bar{\gamma})$ *satisfies the multiplier rule* (12)-(14) *for problem* (28) *if and only if there exist nonnegative numbers* $\tau_1,\cdots,\tau_m$ *where at least one* τ_i *is nonzero with the following property: For each* $i=1,\cdots,m$ *with* $\tau_i>0$ *there exist* p_i *points* $t_{ij}\in E_i(\bar{a})$ *with*

$$1\leqq p_i \leqq \dim \operatorname{span}\{v_{i1},\cdots,v_{in},\mathbb{1},F_i(\bar{a})-z_i\}\leqq n+2,$$

$$E_i(\bar{a}) := \{t\in Q \,|\, |(F_i(\bar{a})-z_i)(t)| = \|F_i(\bar{a})-z_i\|_\infty\}$$

and there are $\lambda_{ij}\in\mathbb{R}$, $j=1,\cdots,p_i$, *such that*

$$\sum_{j=1}^{p_i}|\lambda_{ij}| = 1, \tag{33}$$

$$\sum_{k=1}^{n}(a_k-\bar{a}_k)\sum_{\substack{i=1\\ \tau_i>0}}^{m}\tau_i\sum_{j=1}^{p_i}\lambda_{ij}v_{ik}(t_{ij})\geqq 0 \quad \textit{for all } a\in A, \tag{34}$$

and

$$(\operatorname{sgn} \lambda_{ij})(F_i(\bar{a}) - z_i)(t_{ij}) = \|F_i(a) - z_i\|_\infty \quad \text{if } \lambda_{ij} \neq 0. \tag{35}$$

Proof. A short calculation shows that (12)-(14) are equivalent to the existence of $\tau_1, \cdots, \tau_m \geqq 0$ where at least one τ_i is nonzero and $u_i, w_i \in C_{C(Q)'}$, $i = 1, \cdots, m$, with

$$\tau_i = u_i(\mathbb{1}) + w_i(\mathbb{1}), \tag{36}$$

$$\sum_{i=1}^{m} (u_i - w_i)(F_i'(\bar{a})(a - \bar{a})) \geqq 0 \quad \text{for all } a \in A, \tag{37}$$

and

$$u_i(F_i(\bar{a}) - z_i - \bar{\gamma}_i \mathbb{1}) = 0 \quad \text{and} \quad w_i(-F_i(\bar{a}) + z_i - \bar{\gamma}_i \mathbb{1}) = 0 \quad \text{for } i = 1, \cdots, m. \tag{38}$$

$\tau_i = 0$ implies $u_i = w_i = 0_{C(Q)'}$ and nothing needs to be shown. Otherwise define $\bar{u}_i = (1/\tau_i)u_i$, $\bar{w}_i = (1/\tau_i)w_i$ and a representation theorem for linear functionals (see Krabs [12, IV 2.3-4]) on finite-dimensional subspaces of $C(Q)$ gives the existence of q_i points $t_{ij}^+ \in Q$ and numbers $\bar{\lambda}_{ij}^+ \geqq 0$, $i = 1, \cdots, m$, $j = 1, \cdots, q_i$, with

$$\bar{u}_i(y) = \sum_{j=1}^{q_i} \bar{\lambda}_{ij}^+ y(t_{ij}^+).$$

In a similar way there exist r_i points $t_{ij}^- \in Q$ and numbers $\bar{\lambda}_{ij}^- \geqq 0$, $i = 1, \cdots, m$, $j = 1, \cdots, r_i$, with

$$\bar{w}_i(y) = \sum_{j=1}^{r_i} \bar{\lambda}_{ij}^- y(t_{ij}^-).$$

If we define for each $i = 1, \cdots, m$

$$\lambda_{ij} := \bar{\lambda}_{ij}^+ \quad \text{for } j = 1, \cdots, q_i$$

and

$$\lambda_{i\,j+q_i} := -\bar{\lambda}_{ij}^- \quad \text{for } j = 1, \cdots, r_i,$$

and if we set $p_i := q_i + r_i$, then (36) is equivalent to (33), and (37) is equivalent to (34). The analogous application of a known result from optimization (e.g., compare Krabs [13, Thm. I.5.2]) leads to $p_i \leqq \dim \operatorname{span}\{v_{i1}, \cdots, v_{in}, \mathbb{1}, F_i(\bar{a}) - z_i\}$. For $i = 1, \cdots, m$ the equations (38) can be written as

$$\sum_{j=1}^{q_i} \lambda_{ij}[(F_i(\bar{a}) - z_i)(t_{ij}^+) - \|F_i(\bar{a}) - z_i\|_\infty] = 0$$

and

$$\sum_{j=1}^{r_i} \lambda_{ij}[(F_i(\bar{a}) - z_i)(t_{ij}^-) + \|F_i(\bar{a}) - z_i\|_\infty] = 0,$$

which is equivalent to (35). □

With the aid of Lemma 3.13 the multiplier result in Theorem 3.3 leads to an alternation theorem which generalizes the well-known Kolmogorov condition to vector approximation problems. This result extends also an alternation theorem for linear Chebyshev vector approximation problems given in [8, p. 585].

4. Conclusion. In this paper, generalized quasiconvex mappings such as C-quasiconvex and differentiable C-quasiconvex mappings are presented. C-quasiconvex

mappings subsume the classes of quasiconvex, strictly quasiconvex and pseudoconvex functions. It turns out that these notions are very useful in vector optimization and can be applied to optimality conditions and the investigation of local minima. It is one of the main results that the differentiable C-quasiconvexity is characteristic for the sufficiency of a certain multiplier rule for optimal points.

SINGULAR OPTIMAL CONTROL: A GEOMETRIC APPROACH*

J. C. WILLEMS†, A. KİTAPÇI† AND L. M. SILVERMAN‡

Abstract. Linear quadratic singular optimal control problem is solved for nonminimum phase and noninvertible systems. A state space decomposition is obtained and a reduced order nonsingular subproblem is solved. The optimal stabilizing input of the singular problem has been found when there are no transmission zeros on the imaginary axis.

Key words. optimal control, singular optimal control, geometric control, distributions

1. Introduction. This paper is concerned with linear quadratic problems in which the cost functional is not positive definite in the control. These are called singular problems. In [1], the finite horizon problem and the infinite horizon problem have been solved when the system is minimum phase. It was also shown that the regular part of the optimal input is feedback implementable.

The geometric theory of linear systems added a great deal of insight into the structure of the solution of such singular problems. In fact, it could be claimed that the theory of (almost) controlled invariant and controllable subspaces are the generic tools for studying this class of problems as demonstrated in [1].

In the present paper, we will investigate the problem further and obtain algorithms for actually computing the optimal control. The nonminimum phase case is also considered and results are found by solving reduced order algebraic Riccati equations. As is well known, the optimal control may not exist in the class of regular control functions and indeed, our optimal trajectory and the ensuing state trajectory lies in the class of distributions. In addition, for positive times, the optimal trajectory is smooth and lies on a predetermined linear subspace of the state space.

We will be using standard notation: $\mathbb{R}^m$ for m-dimensional Euclidean space, $\mathbb{R}^+ := [0, \infty)$, $\mathscr{D}'$ for the distributions with support on $\mathbb{R}^+$, $A \backslash B$ for $A \cap B^{\text{complement}}$, $\langle A | \mathscr{L} \rangle$ for the largest A-invariant subspace containing the subspace $\mathscr{L}$, and $\langle \mathscr{L} | A \rangle$ for the smallest A-invariant subspace contained in $\mathscr{L}$. Of course, for the familiar $\dot{x} = Ax + Bu$, $y = Cx$, $\langle A | \text{im } B \rangle$ is the reachable subspace, while $\langle \ker C | A \rangle$ is the nonobservable subspace.

2. Problem statement. In this paper we will study the full linear quadratic problem with nonnegative cost functional. The usual formulation is to consider, for the system $\dot{x} = Ax + Bu$, the cost functional $\int q(x, u)\, dt$ with q a quadratic form (in x and u jointly). However, since we will only be concerned with the situation in which $q \geqq 0$, we can always introduce the output $y = Cx + Du$ such that $\|y\|^2 = q(x, u)$. As in [1] we are thus led to consider the linear system

$$\Sigma \quad \dot{x} = Ax + Bu, \qquad y = Cx + Du \tag{1}$$

with state space $\mathscr{X}=\mathbb{R}^n$, input space $\mathscr{U}=\mathbb{R}^m$, and output space $\mathscr{Y}=\mathbb{R}^p$, and with cost $\int \|\underline{y}\|^2\,dt$.

Consider the following spaces of inputs:

(i) *Regular inputs*:

$$\mathscr{U}^{\text{reg}}=\mathscr{L}_2^{\text{loc}}(\mathbb{R}^+;\mathbb{R}^m)$$
$$=\left\{\underline{u}:\mathbb{R}^+\to\mathbb{R}^m \;\middle|\; \underline{u} \text{ is measurable and } \int_0^T \|\underline{u}\|^2\,dt<\infty \text{ for all } T\in\mathbb{R}^+\right\}.$$

(ii) *Distributional inputs*: Even though we could consider general distributions on $\mathbb{R}^+$, we will, as in [1], restrict our attention to Bohl type distributions (those whose Laplace transform is rational). Thus

$$\mathscr{U}^{\text{dist}}:=\{\underline{u}\in\mathscr{D}'_+ \mid \underline{u}=\underline{u}^{\text{imp}}+\underline{u}^{\text{reg}} \text{ with } \underline{u}^{\text{imp}} \text{ an impulsive distribution, and } \underline{u}^{\text{reg}}\in\mathscr{U}^{\text{reg}}\}.$$

An impulsive distribution is one with support in 0, i.e., a distribution of the form $\sum_{i=0}^{N} a_i\underline{\delta}^{(i)}$ with $a_i\in\mathbb{R}^m$, $\underline{\delta}$ the Dirac delta, and (i) the i-th derivative.

Let $\mathscr{X}^{\text{reg}}$, $\mathscr{X}^{\text{dist}}$, $\mathscr{Y}^{\text{reg}}$ and $\mathscr{Y}^{\text{dist}}$ be similarly defined. Obviously $\mathscr{U}^{\text{dist}}\supset\mathscr{U}^{\text{reg}}$. Now for any given initial condition $\underline{x}(0)=x_0$ and any $\underline{u}\in\mathscr{U}^{\text{dist}}$, Σ generated in the standard way unique solutions $\underline{x}\in\mathscr{X}^{\text{dist}}$ and $\underline{y}\in\mathscr{Y}^{\text{dist}}$ (for details, see [1, § 3]). In order to display the dependence on x_0 and $\underline{u}$ we will denote these unique solutions by $\underline{x}(x_0,\underline{u})$ and $\underline{y}(x_0,\underline{u})$. Of course, if $\underline{u}\in\mathscr{U}^{\text{reg}}$ then also $\underline{x}(x_0,\underline{u})\in\mathscr{X}^{\text{reg}}$ and $\underline{y}(x_0,\underline{u})\in\mathscr{Y}^{\text{reg}}$. However, it is important to observe that some $\underline{u}\in\mathscr{U}^{\text{dist}}\backslash\mathscr{U}^{\text{reg}}$ may lead to solutions $\underline{y}(x_0,\underline{u})\in\mathscr{Y}^{\text{reg}}$.

Now consider the cost function $\int_0^\infty \|\underline{y}\|^2\,dt$. Formally, define

$$\mathscr{J}:\mathscr{X}\times\mathscr{U}^{\text{dist}}\to\mathbb{R}^e$$

by

$$\mathscr{J}(x_0,\underline{u}):=\int_0^\infty \|\underline{y}(x_0,\underline{u})\|^2\,dt \tag{2}$$

where we will agree to set $\mathscr{J}(x_0,\underline{u})=\infty$ when

$$\underline{y}(x_0,\underline{u})\in\mathscr{Y}^{\text{dist}}\backslash\mathscr{Y}^{\text{reg}} \quad \text{or when} \quad \underline{y}(x_0,\underline{u})\in\mathscr{L}_2^{\text{loc}}\backslash\mathscr{L}_2.$$

We will be interested in minimizing $\mathscr{J}$ with or without stability conditions on the state. Let

$$\mathscr{U}^{\text{dist}}_{\text{stab}}(x_0):=\{\underline{u}\in\mathscr{U}^{\text{dist}} \mid \lim_{t\to\infty}\underline{x}(x_0,\underline{u})(t)=0\}$$

and let $\mathscr{U}^{\text{reg}}_{\text{stab}}(x_0)$ be similarly defined. Now define

$$\mathscr{J}^*(x_0):=\operatorname*{infimum}_{\underline{u}\in\mathscr{U}^{\text{dist}}}\mathscr{J}(x_0,\underline{u})$$

and

$$\mathscr{J}^*_{\text{stab}}(x_0):=\operatorname*{infimum}_{\underline{u}\in\mathscr{U}^{\text{dist}}_{\text{stab}}(x_0)}\mathscr{J}(x_0,\underline{u}).$$

We will study a number of aspects of the cost minimization problem introduced above. In particular we shall answer the following questions:

(i) How can $\mathscr{J}^*$ and $\mathscr{J}^*_{\text{stab}}$ be evaluated? When are $\mathscr{J}^*(x_0)$ and $\mathscr{J}^*_{\text{stab}}(x_0)$ finite? When are they zero?

(ii) Find, if it exists, $\underline{u}^*\in\mathscr{U}^{\text{dist}}$ such that $\mathscr{J}(x_0,\underline{u}^*)=\mathscr{J}^*(x_0)$. Is $\underline{u}^*$ unique? When is $\underline{u}^*\in\mathscr{U}^{\text{reg}}$?

(iii) Same questions for $\underline{u}^*\in\mathscr{U}^{\text{dist}}_{\text{stab}}(x_0)$ and $\mathscr{J}^*_{\text{stab}}(x_0)$.

Example. Before jumping into the details of the analysis, let us consider the special case in which we consider the controllable system Σ: $\dot{x} = Ax + Bu$ and are asked to minimize $\int_0^\infty \|\underline{x}\|^2\, dt$, i.e., $y = x$. Now set $\mathscr{X} = \mathscr{X}_1 \oplus \mathscr{X}_2$ with $\mathscr{X}_1 := \text{im } B$ and $\mathscr{X}_2 := (\text{im } B)^\perp$ In this basis, Σ becomes:

$$\dot{x}_1 = A_{11}x_1 + A_{12}x_2 + u,$$

$$\dot{x}_2 = A_{21}x_1 + A_{22}x_2,$$

and

$$\mathscr{J}(x_0) = \int_0^\infty (\|\underline{x}_1\|^2 + \|\underline{x}_2\|^2)\, dt,$$

where we have chosen also the basis in $\mathscr{U}$ suitably and we have assumed that B is injective.

Note that (A, B) controllable implies (A_{22}, A_{21}) controllable. Let $x_0 = (x_{1,0}, x_{2,0})$ be given. Now solve the classical linear quadratic problem which asks to minimize

$$\int_0^\infty (\|\underline{v}\|^2 + \|\underline{x}_2\|^2)\, dt$$

with $\underline{v}$ as control, for $\dot{x}_2 = A_{22}x_2 + A_{21}v$, $\underline{x}_2(0) = x_{2,0}$. This yields $v^* = Fx_2$ as the optimal control law and $x_{2,0}^T K x_{2,0}$ as the minimal cost. There K is the unique positive definite symmetric solution of the appropriate algebraic Riccati equation and $F = -A_{21}^T K$. Now it is easy to see that $\mathscr{J}(x_{1,0}, x_{2,0}) \geqq x_{2,0}^T K x_{2,0}$, and that $\mathscr{J}^*(x_{1,0}, x_{2,0}) = \mathscr{J}^*_{\text{stab}}(x_{1,0}, x_{2,0}) = x_{2,0}^T K x_{2,0}$ provided $x_{1,0} = Fx_{2,0}$. If, however, $x_{1,0} \neq Fx_{2,0}$ then we can use the impulsive control $\underline{u} = (Fx_{2,0} - x_{1,0})\underline{\delta}$ in order to obtain $\underline{x}_1(0^+) = F\underline{x}_2(0^+) = Fx_{2,0}$. This impulse derives the state to the desired subspace.

The optimal control law then looks like

$$\underline{u} = (Fx_{2,0} - x_{1,0})\underline{\delta} \quad \text{for } t = 0,$$

$$\underline{u} = F(A_{21}x_1 + A_{22}x_2) - A_{11}x_1 - A_{12}x_2 \quad \text{for } t > 0.$$

Our purpose is to generalize this picture: the optimal control consists of an impulse part at $t = 0$. This brings us to a subspace where the rest of the motion takes place and where a classical LQ problem needs to be solved. This surface (a linear subspace) in $\mathscr{X}$ is the *regular subspace.* The computation of this subspace and the control law to be used on it can be carried out by solving a classical algebraic Riccati equation. The computation of the impulses which bring us on this surface involves linear equations only.

3. Some notions from geometric control. The analysis of the singular LQ-problem defined by Σ via (1) and (2) needs the full power of the geometric theory of linear systems as exposed in [2], generalized to "almost" versions and distributional inputs in [3], and further generalized and made relevant to linear quadratic problems in [1]. In this section we will introduce these notions in a self-contained way and recall some relevant facts regarding them.

Consider for the system

$$\Sigma: \dot{x} = Ax + Bu, \qquad y = Cx + Du.$$

The following line-up of subspaces:

(i) $\mathscr{V}^*$, the output nulling subspace, defined as

$$\mathscr{V}^* := \{x_0 \in \mathscr{X} | \exists \underline{u} \in \mathscr{U}^{\text{reg}} \text{ such that } \underline{y}(x_0, \underline{u}) = \underline{0}\};$$

(ii) $\mathscr{R}^*$, the controllable output nulling subspace, defined as

$$\mathscr{R}^* := \{x_0 \in \mathscr{X} | \exists \underline{u} \mathscr{U}^{\text{reg}} \text{ such that } \underline{y}(x_0, \underline{u}) = \underline{0} \text{ and such that } \underline{u}(x_0, \underline{u}) \text{ has compact support}\};$$

(iii) $\mathscr{V}^*_{\mathscr{D}}$, the distributional output nulling subspace, defined as

$$\mathscr{V}^*_{\mathscr{D}} := \{x_0 \in \mathscr{X} | \exists \underline{u} \in \mathscr{U}^{\text{dist}} \text{ such that } \underline{y}(x_0, \bar{u}) = \underline{0} \text{ distribution}\};$$

(iv) $\mathscr{R}^*_{\mathscr{D}}$, the controllable distributional output nulling subspace, defined as

$$\mathscr{R}^*_{\mathscr{D}} := \{x_0 \in \mathscr{X} | \exists \underline{u} \in \mathscr{U}^{\text{dist}} \text{ such that } \underline{y}(x_0, \underline{u}) = \underline{0} \text{ and } \underline{x}(x_0, \underline{u}) \text{ has compact support}\};$$

(v) $\mathscr{V}^*_a$, the L_∞-almost output nulling subspace, defined as

$$\mathscr{V}^*_a := \{x_0 \in \mathscr{X} | \forall \varepsilon > 0, \exists \underline{u} \in \mathscr{U}^{\text{reg}} \text{ such that } \|\underline{y}(x_0, \underline{u})\|_{L_\infty} \leqq \varepsilon\};$$

(vi) $\mathscr{R}^*_a$, the controllable L_∞-almost output nulling subspace, defined as

$$\mathscr{R}^*_a := \{x_0 \in \mathscr{X} | \exists T > 0 \text{ such that } \forall \varepsilon > 0, \exists \underline{u} \in \mathscr{U}^{\text{reg}}, \text{ such that } \|\underline{y}(x_0, u)\|_{L_\infty} \leqq \varepsilon \text{ and support } \underline{x}(x_0, \underline{u}) \subset [0, T]\};$$

(vii) $\mathscr{V}^*_b$, the L_2-almost output nulling subspace, defined as

$$\mathscr{V}^*_b := \{x_0 \in \mathscr{X} | \forall \varepsilon > 0, \exists \underline{u} \in \mathscr{U}^{\text{reg}}, \text{ such that } \|\underline{y}(x_0, \underline{u})\|_{L_2} \leqq \varepsilon\};$$

(viii) $\mathscr{R}^*_b$, the controllable L_2-almost output nulling subspace, defined as

$$\mathscr{R}^*_b := \{x_0 \in \mathscr{X} | \exists T > 0 \text{ such that } \forall \varepsilon > 0, \exists \underline{u} \in \mathscr{U}^{\text{reg}}, \text{ such that } \|\underline{y}(x_0, \underline{u})\|_{L_2} \leqq \varepsilon \text{ and support } \underline{x}(x_0, \underline{u}) \subset [0, T]\}.$$

These subspaces have been studied in [3] for the case $D = 0$, and much of it has been generalized to the case $D \neq 0$ in [1]. Actually the case $D \neq 0$ is easily reduced to the case $D = 0$. Indeed, by choosing the bases in $\mathscr{U}$ and $\mathscr{Y}$ properly, we may always write Σ as

$$\dot{x} = Ax + B_1 u_1 + B_2 u_2, \qquad y_1 = C_1 x + u_1, \qquad y_2 = C_2 x$$

with $\mathscr{U} = \mathscr{U}_1 \oplus \mathscr{U}_2$, $\mathscr{U}_2 = \ker D$, $\mathscr{Y} = \mathscr{Y}_1 \oplus \mathscr{Y}_2$, $\mathscr{Y}_1 = \text{im } D$. Now define

$$\Sigma' : \dot{x} = A'x + B_2 u_2, \qquad y_2 = C_2 x$$

with $A' := A - B_1 C_1$. It is easy to see that the subspaces (i)-(viii) are identical for Σ (with input u and output y) and for Σ' (with input u_2 and output y_2). The properties desired below are easily obtained from this observation and the results of [3]. However, it is convenient to express the relations in terms of Σ directly.

PROPOSITION 1. *There holds*

1. $\mathscr{V}^*_b = \mathscr{V}^*$, $\mathscr{R}^*_b = \mathscr{R}^*_{\mathscr{D}}$;
2. $\mathscr{V}^*_a = \mathscr{V}^* + \mathscr{R}^*_a$, $\mathscr{V}^*_b = \mathscr{V}^* + \mathscr{R}^*_b$;
3. $\mathscr{R}^* = \mathscr{V}^* \cap \mathscr{R}^*_a = \mathscr{V}^* \cap \mathscr{R}^*_b$;
4. $\mathscr{R}^*_a = \mathscr{R}^*_b \cap C^{-1} \text{ im } D$, $\mathscr{R}^*_b = [A|_1 B]((\mathscr{R}^*_a \oplus \mathscr{U}) \cap \ker [C|_1 D])$.

We particularly draw attention to property 4 which yields a simple way of deriving $\mathscr{R}^*_a$ from $\mathscr{R}^*_b$ and vice versa.

In [1], [3] simple algorithms have been derived for the computation of the subspaces (i)-(viii). For the situation at hand, these are

$$\mathscr{V}_0 := \mathscr{K}, \qquad \mathscr{V}_{i+1} = \left[\begin{matrix} A \\ \hline C \end{matrix}\right]^{-1} \left((\mathscr{V}_i \oplus \{0\}) + \operatorname{im} \left[\begin{matrix} B \\ \hline D \end{matrix}\right] \right);$$

$$\mathscr{R}_0 := \{0\}, \mathscr{R}_{i+1} = (C^{-1} \operatorname{im} D) \cap [A_{\mid}^{\mid} B]((\mathscr{R}_i \oplus \mathscr{U}) \cap \ker [C_{\mid}^{\mid} D]),$$

$$\mathscr{S}_0 := \{0\}, \mathscr{S}_{i+1} = [A_{\mid}^{\mid} B]((\mathscr{S}_i \oplus \mathscr{U}) \cap \ker [C_{\mid}^{\mid} D]).$$

These recursive algorithms compute the desired subspaces. In fact,

$$\mathscr{V}_i \downarrow \mathscr{V}_n = \mathscr{V}^*,$$

$$\mathscr{R}_i \uparrow \mathscr{R}_n = \mathscr{R}_a^*,$$

$$\mathscr{S}_i \uparrow \mathscr{S}_n = \mathscr{R}_b^*,$$

$$(\mathscr{V}_i \cap \mathscr{R}_i) \uparrow (\mathscr{V}_n \cap \mathscr{R}_n) = \mathscr{R}^*,$$

$$(\mathscr{V}_i \cap \mathscr{J}_i) \uparrow (\mathscr{V}_n \cap \mathscr{J}_n) = \mathscr{R}^*.$$

These algorithms immediately yield the following.

PROPOSITION 2. *There hold*

1. $\mathscr{R}_a^* = (C^{-1} \operatorname{im} D) \cap [A_{\mid}^{\mid} B]((\mathscr{R}_a^* \oplus \mathscr{U}) \cap \ker [C_{\mid}^{\mid} D])$;
2. $\mathscr{R}_b^* = [A_{\mid}^{\mid} B]((\mathscr{R}_b^* \oplus \mathscr{U}) \cap \ker [C_{\mid}^{\mid} D])$.

The subspaces introduced allow to decide invertibility of Σ. We quote some results to this effect from [1]. We will say that Σ is *right invertible* if for every $\underline{y} \in \mathscr{Y}^{\text{dist}}$ there exists an $\underline{u} \in \mathscr{U}^{\text{dist}}$ such that $\underline{y}(0, \underline{u}) = \underline{y}$. (In [1] it is actually assumed in the definition that $\underline{y} \in \mathscr{Y}^{\text{reg}}$, but the above definition defines an equivalent and perhaps a more natural property.)

PROPOSITION 3. *The following statements are equivalent*:

(i) Σ *is right invertible.*

(ii) $\mathscr{V}_b^* = \mathscr{K}$ *and* $\operatorname{im} [C_{\mid}^{\mid} D] = \mathscr{Y}$.

(iii) *The transfer function* $T(s) = D + C(Is - A)^{-1} B$ *is right invertible over the field of rational functions.*

Also, left invertibility is readily desired from the notions introduced above. The system Σ is called *left invertible* if $\{0 \neq u \in \mathscr{U}^{\text{dist}}\} \Rightarrow \{\underline{y}(0, \underline{u}) \neq \underline{0}\}$. (In [1] it is actually assumed in the definition that $\underline{y}(0, \underline{u}) \in \mathscr{Y}^{\text{reg}}$ but the above definition defines an equivalent and perhaps a more natural property.)

PROPOSITION 4. *The following statements are equivalent*:

(i) Σ *is left invertible.*

(ii) $\mathscr{R}^* = \{0\}$ *and* $\ker \left[\begin{matrix} B \\ \hline D \end{matrix}\right] = \{0\}$.

(iii) *The transfer function* $T(s) = D + C(Is - A)^{-1} B$ *is left invertible over the field of rational functions.*

Note that left invertibility immediately implies that $\{\underline{y}(0, \underline{u}_1) = \underline{y}(0, \underline{u}_2)\} \Rightarrow \{\underline{u}_1 = \underline{u}_2\}$.

Actually, using the results of [4] we can also classify the transfer functions with a polynomial inverse.

PROPOSITION 5. *The following statements are equivalent*:

(i) $\mathscr{R}_b^* = \mathscr{K}$.

(ii) $T(s) = D + C(Is - A)^{-1} B$ *has a right inverse which is a polynomial matrix.*

Finally, the equivalence of the open loop definitions of the spaces (i)-(viii) and their feedback counterparts lies at the basis of many control theoretic applications of these notions. We will only need the following here.

PROPOSITION 6. *There exist a feedback matrix* $F: \mathscr{X} \to \mathscr{U}$ *and a chain* $B_i \subset B$ *such that*

(i) $(A+BF)\mathscr{V}^* \subset \mathscr{V}^*$ *and* $(C+DF)\mathscr{V}^* = \{0\}$;

(ii) $(A+BF)\mathscr{R}^* \subset \mathscr{R}^*$;

(iii) $\mathscr{R}_b^* = B_1 \oplus A_F B_2 \oplus \cdots \oplus A_F^{n-1} B_n$.

Proof. The proof follows from [6, Thm. 1] where the subspaces $\mathscr{R}_b^*$ and $\mathscr{V}^*$ are called strongly reachable and weakly unobservable subspaces and denoted as $\mathscr{W}$ and $\mathscr{V}$.

4. A suitable basis choice and preliminary feedback. By means of an appropriate choice of the basis in the input, state, and output space, and by applying a preliminary feedback, it is possible to simplify the analysis considerably.

Decompose $\mathscr{Y} = \mathscr{Y}_1 \oplus \mathscr{Y}_2$ with $\mathscr{Y}_1 = \operatorname{im} D$ and $\mathscr{Y}_2 = \mathscr{Y}_1^{\perp}$. Now choose $\mathscr{U}_2 = \ker D$ and $\mathscr{U}_1$ such that $\mathscr{U}_1 = \mathscr{U}_1 \oplus \mathscr{U}_2$. By suitably choosing the basis we obtain $D = \left[\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right]$. This yields for Σ:

$$\dot{x} = Ax + B_1 u_1 + B_2 u_2, \quad y_1 = C_1 x + u_1, \quad y_2 = C_2 x,$$

with $\|y\|^2 = \|y_1\|^2 + \|y_2\|^2$. It is easy to see that the spaces (i)-(viii) introduced in § 3 are identical for the system Σ as for

$$\dot{x} = A'x + B_2 u_2, \qquad y_2 = C_2 x \text{ with } A' := A - B_1 C_1$$

where we consider u_2 as input and y_2 as output.

Now decompose the state space as follows:

$$\mathscr{X} = \mathscr{X}_1 \oplus \mathscr{X}_2 \oplus \mathscr{X}_3 \oplus \mathscr{X}_4 \oplus \mathscr{X}_5$$

with

$$\mathscr{X}_3 = \mathscr{R}^*, \quad \mathscr{X}_2 \oplus \mathscr{X}_3 = \mathscr{V}^*, \quad \mathscr{X}_3 \oplus \mathscr{X}_4 = \mathscr{R}_a^*,$$

and

$$\mathscr{X}_3 \oplus \mathscr{X}_4 \oplus \mathscr{X}_5 = \mathscr{R}_b^*.$$

Now choose feedback F such that $(A'+B_2F)\mathscr{V}^* \subset \mathscr{V}^*$, $C_2\mathscr{V}^* = \{0\}$, $(A'+B_2F)\mathscr{R}^* \subset \mathscr{R}^*$ and $\mathscr{R}_b^* = B_{20} \oplus (A'+B_2F)B_{21} \oplus (A'+B_2F)^2 B_{22} \oplus \cdots \oplus (A'+B_2F)^{n-1} B_{2n}$ where $B_{20} = B_2$ and B_{2i} is a chain in B_2 (see Proposition 5). This yields $\mathscr{V}^* \cap \operatorname{im} B_2 \subset \mathscr{R}^*$. Also from Proposition 1.4 we know that $\mathscr{R}_a^* = \mathscr{R}_b^* \cap \ker C_2$ and $\mathscr{R}_b^* = (A'+B_2F)\mathscr{R}_1^* + \operatorname{im} B_2$.

The choice of basis indicated and the feedback

$$u_1 = u_1' - C_1 x, \tag{3a}$$

$$u_2 = u_2' + Fx, \tag{3b}$$

reduces our system to $\bar{\Sigma}$

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \end{bmatrix} = \begin{bmatrix} A_{11} & 0 & 0 & 0 & A_{15} \\ A_{21} & A_{22} & 0 & 0 & A_{25} \\ A_{31} & A_{32} & A_{33} & A_{34} & A_{35} \\ A_{41} & 0 & 0 & A_{44} & A_{45} \\ A_{51} & 0 & 0 & A_{54} & A_{55} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} + \begin{bmatrix} B_{11} \\ B_{12} \\ B_{13} \\ B_{14} \\ B_{15} \end{bmatrix} u_1' + \begin{bmatrix} 0 \\ 0 \\ B_{23} \\ B_{24} \\ B_{25} \end{bmatrix} u_2',$$

$$y_1 = u_1', \qquad y_2 = [C_{21}\ 0\ 0\ 0\ C_{25}] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix}. \tag{4}$$

The problem is to

$$\text{minimize} \int_0^\infty (\|u_1'\|^2 + \|y_2\|^2)\, dt. \tag{5}$$

We have the following.

PROPOSITION 7.

1. $\ker C_{25} = \{0\}$.
2. *The transfer function associated with*

$$\left\{ \begin{bmatrix} A_{33} & A_{34} & A_{35} \\ 0 & A_{44} & A_{45} \\ 0 & A_{54} & A_{55} \end{bmatrix}, \begin{bmatrix} B_{23} \\ B_{24} \\ B_{25} \end{bmatrix}, [0\ 0\ I] \right\}$$

has a right inverse which is a polynomial matrix.

3. *The system*

$$\left\{ \begin{bmatrix} A_{44} & A_{45} \\ A_{54} & A_{55} \end{bmatrix}, \begin{bmatrix} B_{24} \\ B_{25} \end{bmatrix}, [0\ I] \right\}$$

is left invertible.

4. (A_{33}, B_{23}) *is a controllable pair.*

Proof.

1. It follows from $\mathscr{R}_b^* \cap \ker C_2 = \mathscr{R}_a^*$.

2. It follows from Proposition 4 that this transfer function with the output matrix replaced by $[0\ 0\ C_{25}]$ has a polynomial right inverse. The result then follows using 1.

3. By Proposition 4 we need to show that the controllability output nulling subspace associated with this system is zero. Assume that this is not the case and add this subspace to $\mathscr{X}_3$. Clearly the subspace obtained in this way will be in the controllability output nulling subspace for the original system Σ, proving the claim.

4. Follows from $\langle A' + B_2F | \operatorname{im} B_2 \cap \mathscr{R}^* \rangle = \mathscr{R}^*$. □

We will use the feedback F and the chain B_{2i} to simplify the system representation given in (4). We obtain

PROPOSITION 8. *There exists a coordinate transformation such that* $\bar{\Sigma}_T = \Sigma^*$ *where*

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \end{bmatrix} = \begin{bmatrix} A_{11}^* & 0 & 0 & 0 & A_{15} \\ A_{21}^* & A_{22} & 0 & 0 & A_{25} \\ 0 & A_{32} & A_{33} & A_{34} & A_{35} \\ 0 & 0 & 0 & A_{44} & A_{45} \\ 0 & 0 & 0 & A_{54} & A_{55} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} + \begin{bmatrix} B_{11} \\ B_{12} \\ B_{13} \\ B_{14} \\ B_{15} \end{bmatrix} u_1' + \begin{bmatrix} 0 \\ 0 \\ B_{23} \\ B_{24} \\ B_{25} \end{bmatrix} u_2',$$

$$y_2 = [C_{21}^*\ 0\ 0\ 0\ C_{25}]\underline{x}, \qquad y_1 = u_1'$$

where (C_{21}^*, A_{11}^*) *is an observable pair.*

Proof. Follows from Lemma 1 and the Column Elimination Algorithm given in [6]. □

5. Regular *LQ* problems. Our approach in studying singular LQ-problems will be to reduce them to regular LQ-problems. Regular LQ-problems are those for which distributional inputs are not candidates for optimal controls since they always lead to infinite cost:

DEFINITION. The LQ problem Σ (as defined by (1), (2)) will be called *regular* if $\{x_0 \in \mathscr{X},\ \underline{u} \in \mathscr{U}^{\text{dist}} \setminus \mathscr{U}^{\text{reg}}\} \Rightarrow \{\mathscr{J}(x_0, \underline{u}) = \infty\}$.

It is easy to decide regularity as follows.

THEOREM 1. *The following conditions are equivalent*:

(i) Σ *defines a regular LQ-problem.*

(ii) $\{x_0 \in \mathscr{X},\ \underline{u} \in \mathscr{U}^{\text{dist}} \setminus \mathscr{U}^{\text{reg}}\} \Rightarrow \{\underline{y}(x_0, \underline{u}) \in \mathscr{Y}^{\text{dist}} \setminus \mathscr{Y}^{\text{reg}}\}$.

(iii) $\ker D = \{0\}$.

Proof. (i)$\Rightarrow$(ii): Since $\underline{y}(x_0, \underline{u}) = \underline{y}(x_0, 0) + \underline{y}(0, \underline{u})$, (ii) is equivalent to

$$\{\underline{u} \in \mathscr{U}^{\text{dist}} \setminus \mathscr{U}^{\text{reg}}\} \Rightarrow \{\underline{y}(0, \underline{u}) \in \mathscr{Y}^{\text{dist}} \setminus \mathscr{Y}^{\text{reg}}\}.$$

Now, if this were not the case, $\exists \underline{u} \in \mathscr{U}^{\text{dist}} \setminus \mathscr{U}^{\text{reg}}$ such that $\underline{y}(0, \underline{u}) \in \mathscr{Y}^{\text{reg}}$. The corresponding $\underline{x}(0, \underline{u})$ will satisfy $\underline{x}(0, \underline{u})(t) \in \langle A | \text{im } B \rangle$ for all $t > 0$. In particular, $\underline{x}(0, \underline{u})(1) \in \langle A | \text{im } B \rangle$. Hence since $\underline{x}(0, u)(1)$ belongs to the controllable subspace of Σ, we can modify, if needed, $\underline{u}(t)$ to $\underline{u}^{\text{new}}(t)$ for $t \geqq 1$ such that $y(0, \underline{u}^{\text{new}}) \in \mathscr{L}(0, \infty)$. This $\underline{u}^{\text{new}}$ is still in $\mathscr{U}^{\text{dist}} \setminus \mathscr{U}^{\text{new}}$, but $\mathscr{J}(x_0, \underline{u}^{\text{new}}) < \infty$. Hence {not (ii)}$\Rightarrow${not (i)}. The implication (ii)$\Rightarrow$(i) is obvious.

To show the equivalence of (ii) and (iii), observe that by a suitable choice of the basis in $\mathscr{U}$ and $\mathscr{Y}$, Σ may be represented as

$$\dot{x} = Ax + B_1 u_1 + B_2 u_2, \quad y_1 = C_1 x + u_1, \quad y_2 = C_2 x,$$

$$u = (x_1, u_2), \qquad y = (y_1, y_2)$$

with $u_1 \in \mathbb{R}^{m_1}$, $m_1 = \text{codim ker } D = \dim \text{im } D$ and $u_2 \in \mathbb{R}^{m_2}$, $m_2 = m - m_1$. Now (ii)$\Leftrightarrow$ $\{m_2 = 0\} \Leftrightarrow$ (iii) is obvious. □

Regular LQ problems may thus be reduced by a simple basis change and a feedback transformation to the standard LQ problems.

Recall the LQ problem standard if it is regular and if the associated $\mathscr{V}^* = \{0\}$, i.e., if $\ker D = \{0\}$ and if $\langle C^{-1} \text{ im } D | A - (D^T D)^{-1} D^T C \rangle = \{0\}$.

Let Σ define a regular LQ-problem. By Theorem 1 this is equivalent to $\ker D = \{0\}$. By choosing the basis in $\mathscr{U}$ appropriately and making an orthogonal basis change in $\mathscr{Y}$ we can then bring D into the form $\begin{bmatrix} I \\ 0 \end{bmatrix}$. Σ becomes

$$\dot{x} = Ax + Bu, \quad y_1 = C_1 x_2 + u, \quad y_2 = C_2 x, \quad y = (y_1, y_2).$$

Now use the preliminary feedback $u = v - C_1 x_2$. This yields the system

$$\dot{x} = A' x + Bv, \qquad y_2 = C_2 x$$

with $A' := A - B_1 C_1$ and $\mathscr{J} = \int_0^\infty (\|\underline{y}\|^2 + \|\underline{y}_2\|^2)\, dt$.

We obtain the familiar standard LQ problem

$$\text{minimize} \int_0^\infty (\|\tilde{u}\|^2 + \|\tilde{y}\|^2)\, dt$$

for $\dot{\tilde{x}} = \tilde{A}\tilde{x} + \tilde{B}\tilde{u}$; $\tilde{y} = \tilde{C}\tilde{x}$ with the simple basis change such that $\tilde{C} = C/L$ where $L = (\mathscr{V}^*)^\perp$.

6. The singular *LQ*-problem without stability constraints. At this point it is convenient to study the LQ-problem introduced in § 2 with and without stability separately.

We will reduce the general singular problem to regular ones, and regular problems to standard ones. In addition, we will assume throughout that (A, B) is asymptotically stabilizable. We have the well-known proposition as follows.

PROPOSITION 9. *Let (A, B) be asymptotically stabilizable and assume that Σ defines a standard LQ-problem. Then the control law $u^* = F_0 x$ generates $\mathcal{J}(x_0, \underline{u}^*) = \mathcal{J}^*(x_0)$. Here*

$$F_0 = -(D^T D)^{-1}(B^T P_0 + D^T C) \tag{6}$$

and P_0 is the unique positive semi-definite solution of the algebraic Riccati equation

$$A^T P + PA - (PB + C^T D)^T (D^T D)^{-1}(PB + C^T D) + C^T C = 0. \tag{7}$$

In fact, $P_0 > 0$ and $\mathcal{J}^*(x_0) = x_0^T P_0 x_0$. Moreover, the closed loop system $\dot{x} = (A + BF_0)x$ is asymptotically stable.

It is easy to extend Proposition 9 to the regular case.

PROPOSITION 10. *Let (A, B) be asymptotically stabilizable and assume that Σ defines a regular LQ-problem. Then the control law (6) with P_0 the infimal positive semidefinite solution of the algebraic Riccati equation (7) generates $\mathcal{J}(x_0, u^*) = \mathcal{J}^*(x_0)$, and $\mathcal{J}^*(x_0) = x_0^T P_0 x_0$. Further $\{\mathcal{J}^*(x_0) = 0\} \Leftrightarrow \{x_0 \in \ker P_0\} \Leftrightarrow \{x_0 \in \mathcal{V}^* = \langle C^{-1} \operatorname{im} D | (D^T D)^{-1} D^T C \rangle\}$. Finally, the closed loop system $\dot{x} = (A + BF_0)x$ will be asymptotically stable if and only if $\mathcal{V}^* \subset \mathcal{L}^-(A - B(D^T D)^{-1} D^T C)$ (i.e., detectability).*

Proof. See [1] with the sign change on (6.2) at page 23, [7].

Note that in order to solve for P_0 and F_0 in Proposition 10 it suffices to solve a standard algebraic Riccati equation of dimension = the codimension of $\mathcal{V}^*$, since $P_0 = P_0^T \geqq 0$ and $\ker P_0 = \mathcal{V}^*$.

We now have all the preliminary results which go into the solution of the general singular *LQ* problem *without* stability. We will assume that the problem is already in the form (4)-(5).

THEOREM 2. *Assume that (A, B) is asymptotically stabilizable and consider the singular LQ-problem (4)-(6). Then*

(i) $\mathcal{J}^*(x_0) < \infty$. *In fact,*

$$\mathcal{J}^*((x_{1,0}, x_{2,0}, x_{3,0}, x_{4,0}, x_{5,0})) = x_{1,0}^T P_0 x_{1,0}$$

with P_0 the unique positive semidefinite solution of the algebraic Riccati equation

$$\begin{aligned} A_{11}^T P + PA_{11} - (PA_{15} + C_{21}^T C_{25})^T (C_{25}^T C_{25})^{-1}(PA_{15} + C_{21}^T C_{25}) \\ - PB_{11} B_{11}^T P + C_{21}^T C_{21} = 0. \end{aligned} \tag{8}$$

Moreover, $P_0 > 0$.

(ii) *$\forall x_0 \in \mathcal{X}$, there exists an $u^* \in \mathcal{U}^{\text{dist}}$ such that $\mathcal{J}(x_0, u^*) = \mathcal{J}^*(x_0)$. This optimal control is generated as follows*

$$u_1'^* = -B_{11}^T P_0 x_1 \tag{9}$$

and $\underline{u}_2'^*$ such that $\underline{x}_5^*$ is regular and satisfies

$$x_5^* = -(C_{25}^T C_{25})^{-1}(A_{15}^T P_0 + C_{25}^T C_{21}) x_1. \tag{10}$$

There always exists a distribution $\underline{u}_2'^*$ such that (10) will be satisfied as a distribution.

(iii) *The optimal trajectory lies on the linear subspace*

$$x_5 = -(C_{25}^T C_{25})^{-1}(A_{15}^T P_0 + C_{25}^T C_{21}) x_1$$

for $t > 0$.

(iv) *The optimal trajectory*

$$\underline{x}_1^*, \underline{x}_2^*, \underline{x}_3^*, \underline{x}_4^*, \underline{x}_5^*$$

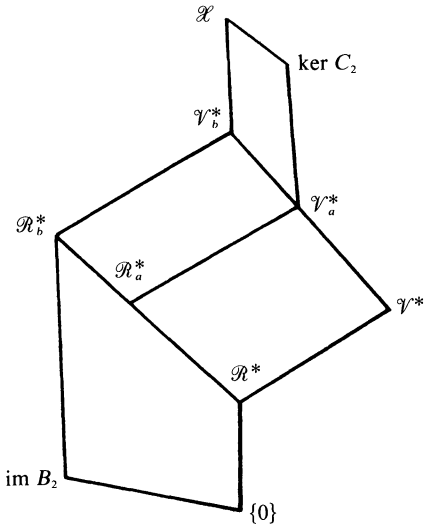
is such that

$$\underline{x}_1^* \text{ and } \underline{x}_2^* \text{ are regular}$$

and $\underline{x}_3^*$, $\underline{x}_4^*$, *and* $\underline{x}_5^*$ *may be distributions. Moreover,* $\underline{x}_1^*$, $\underline{x}_2^*$, $\underline{x}_4^*$ *and* $\underline{x}_5^*$ *are uniquely defined, while* $\underline{x}_3^*$ *is not.*

The proof of this theorem is given in Appendix A.

Theorem 1 allows us to recognize several interesting special cases of the singular LQ-problem. Recall the following lattice diagram (B_2 and C_2 are as defined in § 4):



The problem is *standard*:
$\Leftrightarrow$ {the optimal control is a regular function and $\mathscr{J}^*(x_0) > 0$ for $x_0 \neq 0$}
$\Leftrightarrow \{\mathscr{V}_b^* = \{0\}\}$.

The problem is *regular*:$\Leftrightarrow$ {the optimal control is a regular function}
$\Leftrightarrow \{\mathscr{R}_b^* = \{0\}\}$
$\Leftrightarrow$ {Ker $D = \{0\}$}.

The problem is *cheap*:$\Leftrightarrow \{\mathscr{J}^*(x_0) = 0$ for all $x_0\}$
$\Leftrightarrow \{\mathscr{V}_b^* = \mathscr{X}\}$.

The problem is *totally singular*:$\Leftrightarrow$ {the optimal control has zero regular part}
$\Leftrightarrow \{\mathscr{R}_b^* = \mathscr{X}$ and $\mathscr{R}^* = \{0\}\}$.

The problem is *potentially singular*:
$\Leftrightarrow$ {there always is an optimal control with regular part zero}
$\Leftrightarrow \{\mathscr{R}_b^* = \mathscr{X}\}$.

7. The singular LQ-problem with stability. In this section we will generalize the ideas of § 6 in order to study the singular LQ-problem with the stability constraint $\lim_{t\to\infty} \underline{x}(t) = 0$ as a side condition. We start by analyzing the geometric structure of Σ as given in § 2 in still a bit more detail and derive a refinement of the decomposition (4).

7.1. A further decomposition of $\mathscr{V}^*$. Our approach to solve the singular LQ-problem with stability needs a further decomposition of the output nulling subspace

$\mathcal{V}^*$. Consider $\mathcal{V}^-$, $\mathcal{V}^0$, and $\mathcal{V}^+$ the output nulling subspaces with respectively asymptotic stability, neutral stability, and exponential instability. These are defined and computed as follows.

Take any F such that $(A+BF)\mathcal{V}^* \subset \mathcal{V}^*$ (solutions converge neither for $t \to \pm\infty$) and $(C+DF)\mathcal{V}^* = \{0\}$. Then $(A+BF)\mathcal{R}^* \subset \mathcal{R}^*$. Now there exists such an F with the property that the characteristic polynomial of $(A+BF)|\mathcal{R}^*$ is equal to any given monic polynomial of suitable degree. However, the eigenvalues of $(A+BF)$ (mod $\mathcal{R}^*$) are independent of the F which we choose. Now choose an F such that the spectra of $(A+BF)|\mathcal{R}^*$ and $(A+BF)$ (mod $\mathcal{R}^*$) are disjoint. This yields a decomposition of $\mathcal{V}^*$ into $\mathcal{V}^* = \mathcal{V}_1 \oplus \mathcal{V}_2 \oplus \mathcal{V}_3 \oplus \mathcal{R}^*$ with $\mathcal{V}_1$, $\mathcal{V}_2$ and $\mathcal{V}_3$ $(A+BF)$-invariant and such that $(A+BF)|\mathcal{V}_1$, $(A+BF)|\mathcal{V}_2$ and $(A+BF)|\mathcal{V}_3$ have their spectra in the open right half plane, on the imaginary axis, and in the open left half plane, respectively. In terms of these, set $\mathcal{V}^+ = \mathcal{R}^* \oplus \mathcal{V}_1$, $\mathcal{V}^0 = \mathcal{R}^* \oplus \mathcal{V}_2$, and $\mathcal{V}^- = \mathcal{R}^* \oplus \mathcal{V}_3$.

Using such an F and the above decomposition of $\mathcal{X}_2 \oplus \mathcal{X}_3$ in (4) yields a decomposition of $\mathcal{X}_2$ into $\mathcal{X}_2 = \mathcal{X}_{21} \oplus \mathcal{X}_{22} \oplus \mathcal{X}_{23}$ with an associated partitioning of A_{22}, A_{25}, and B_{12} into

$$(11) \qquad A_{22} = \begin{bmatrix} A_{22,1} & 0 & 0 \\ 0 & A_{22,2} & 0 \\ 0 & 0 & A_{22,3} \end{bmatrix} \quad A_{25} = \begin{bmatrix} A_{25,1} \\ A_{25,2} \\ A_{25,3} \end{bmatrix} \quad B_{12} = \begin{bmatrix} B_{12,1} \\ B_{12,2} \\ B_{12,3} \end{bmatrix}$$

with $\sigma(A_{22,1})$, $\sigma(A_{22,2})$, and $\sigma(A_{22,3})$ in the open right half plane, on the imaginary axis, and in the open left half plane, respectively. Furthermore, $A_{32} = 0$.

7.2. The regular *LQ*-problem with stability. In the *standard* problem we obtain asymptotic stability of the closed loop system as a consequence of the minimization of $\mathcal{J}$. This shows that the standard problem has the same solution with or without the side constraint $\lim_{t\to\infty} \underline{x}(t) = 0$. The difference starts when we consider the regular problem.

Consider now the regular *LQ* problem: Σ with $\ker D = \{0\}$. By Theorem 1 we may restrict attention to $\mathcal{U}^{\text{reg}}$. Now consider the subspaces $\mathcal{V}^+$, $\mathcal{V}^0$, and $\mathcal{V}^-$ introduced in § 7.1. Because of regularity, these may be computed in more detail:

$$\mathcal{V}^* = \langle C^{-1} \operatorname{im} D | A' \rangle \quad \text{with } A' := A - (D^T D)^{-1} D^T C$$

and, also because of regularity, $\mathcal{R}^* = \{0\}$. Now make a spectral decomposition of $\mathcal{V}^*$ corresponding to the decomposition of the spectrum of $A'|\mathcal{V}^*$ into its open right half plane, its imaginary axis, and its open left half plane parts. This yields $\mathcal{V}^+$, $\mathcal{V}^0$, and $\mathcal{V}^-$ respectively.

We obtain the following proposition.

PROPOSITION 11. *Consider the regular LQ-problems*: Σ *with* $\ker D = \{0\}$, *with the stability condition* $\lim_{t\to\infty} \underline{x}(t) = 0$. *Then*

(i) *For all* $x_0 \in \mathcal{X}$, *there exists a control* $\underline{u} \in \mathcal{U}^{\text{reg}}_{\text{stab}}(x_0)$ *such that* $\mathcal{J}(x_0, \underline{u}) < \infty$ *if and only if* (A, B) *is asymptotically stabilizable. Assume this to be the case.*

(ii) *There exists a supremal nonnegative definite symmetric solution,* P_+, *to the algebraic Riccati equation* (7). *We have* $\inf_{u\in\mathcal{U}^{\text{reg}}_{\text{stab}}} \mathcal{J}(x_0, \underline{u}) = \inf_{u\in\mathcal{U}^{\text{dist}}_{\text{stab}}} \mathcal{J}(x_0, \underline{u}) = x_0^T P_+ x_0$.

(iii) *For all* $x_0 \in \mathcal{X}$ *there exists an optimal control* $u^* \in \mathcal{U}^{\text{reg}}_{\text{stab}}(x_0)$ (*hence* $\mathcal{J}(\underline{u}^*, x_0) = \underline{x}_0^T P_+ x_0$) *if and only if* $\mathcal{V}^0 = \{0\}$.

(iv) *Assuming this to be the case, then* $u^* = F_+ x$ *with* $F_+ := -(D^T D)^{-1}(B^T P_+ + D^T C)$ *generates the optimal control.*

(v) $\{\inf_{u\in\mathcal{U}^{\text{reg}}_{\text{stab}}} \mathcal{J}(x_0, \underline{u}) = 0\} \Leftrightarrow \{x_0 \in \ker P_+\} \Leftrightarrow \{x_0 \in \mathcal{V}^0 + \mathcal{V}^-\}$.

(vi) $P_+ = P_0$ (*and consequently the nonnegative definite solution of* (7) *is unique*) *if and only if* $\mathcal{V}^+ = \{0\}$ (*i.e., exponential detectability*).

(vii) $u^* = F_0 x$ *will yield also asymptotic stability if and only if* $\mathcal{V}^+ + \mathcal{V}^0 = \{0\}$. *In this case, the LQ problem* Σ *with and without stability give identical answers.*

Proof. Of course, part (i) is obvious. Assume thus that (A, B) is asymptotically stabilizable using the representation derived at the end of § 5. It follows that we should prove this proposition for the LQ-problem in which we are asked to minimize $\int_0^\infty (\|u\|^2 + \|y\|^2)\, dt$ for the system $\dot{x} = Ax + Bu$; $y = Cx$. Then $\mathcal{V}^* = \langle \ker C | A \rangle$, while $\mathcal{V}^+$, $\mathcal{V}^0$, $\mathcal{V}^-$ correspond to the decomposition of $\mathcal{V}^*$ associated with the partition of the spectrum of $A|\mathcal{V}^*$ into its components in the open right half plane, on the imaginary axis, and in the open left half plane, respectively. The associated algebraic Riccati equation is

$$A^T P + PA - PBB^T P + C^T C = 0.$$

Let P_0 be the infimal nonnegative definite symmetric solution of this algebraic Riccati equation. Since (A, B) is asymptotically stabilizable, such a solution exists. Using standard calculations, it is easy to see that, whenever $\lim_{t\to\infty} \underline{x}(t) = 0$, then $\mathcal{J}(x_0, \underline{u}) = x_0^T P_0 x_0 + \int_0^\infty \|\underline{u} + B^T P_0 \underline{x}(x_0, \underline{u})\|^2\, dt$. Now use the preliminary feedback $u = v - B^T P_0 x$. The problem then requires the minimization of $\int_0^\infty \|\underline{v}\|^2\, dt$ for $\dot{x} = A_0 x + Bv$ with $A_0 := A - BB^T P_0$, under the stability constraint $\lim_{t\to\infty} \underline{x}(x_0, \underline{v})(t) = 0$. Let $\mathcal{L}^+$, $\mathcal{L}^0$, $\mathcal{L}^-$ be the decomposition of $\mathcal{X}$ corresponding to the partition of the spectrum of A_0 into its components in the open right half plane, on the imaginary axis, and in the open left half plane. By Proposition 9, we know that $\ker P_0 = \mathcal{V}^* = \langle \ker C | A \rangle$. Further $\mathcal{V}^*$ is A_0-invariant and $A_0 \pmod{\mathcal{V}^*}$ has its eigenvalues in the open left half plane.

Now minimize $\mathcal{J}(\underline{x}_0, \underline{u}) = \int_0^\infty \|\underline{v}\|^2\, dt$ subject to $\dot{x} = A_0 x + Bv$, $\underline{x}(0) = x_0$, and $\lim_{t\to\infty} \underline{x}(x_0, \underline{v})(t) = 0$. Clearly if $x_0 \in \mathcal{L}^-$, the optimal control $\underline{v}^* = 0$, and $\min \mathcal{J}'(x_0, \underline{v}^*) = 0$. Next, if $0 \neq x_0 \in \mathcal{L}^0$, $\inf \mathcal{J}'(x_0, \underline{v}^*) = 0$ (see [5, Lemma 3.2]) but no optimal control exists since $\underline{v}^* = 0$ does not meet the condition $\lim_{t\to\infty} \underline{x}(x_0, \underline{v}^*) = 0$. Consider now the situation $x_0 \in \mathcal{L}^+$.

Define $A_+ := A_0|\mathcal{L}^+$ and $B_+ := QB$ with Q the projection of π onto $\mathcal{L}^+$ along $\mathcal{L}^0 \oplus \mathcal{L}^-$. Note that the stabilizability of (A, B) implies that (A_+, B_+) is controllable. Further the eigenvalues of A_+ are in the open right half plane. Now solve the minimization of $\int_0^\infty \|\underline{v}\|^2\, dt$ for $\dot{x}_+ = A_+ x_+ + B_+ v$ with $\underline{x}_+(0) = x_{+,0}$ and $\lim_{t\to\infty} \underline{x}_+(t, \underline{v}) = 0$. The optimal control for this problem is $v^* = -B^T W_+^{-1} x_+$ with W_+, related to the controllability Grammian, defined as the unique solution of $A_+ W_+ + W_+ A_+^T = B_+ B_+^T$. Clearly $W_+ = W_+^T > 0$, and hence $\pi_+ = W_+^{-1}$ is the supremal (alternatively, the unique positive definite) symmetric solution of $\pi_+ A_+ + A_+^T \pi_+ - \pi_+ B_+ B_+^T \pi_+ = 0$. Now combine the solution which we obtained for $\mathcal{L}^-$, $\mathcal{L}^0$, and $\mathcal{L}^+$. Define

$$\pi = \begin{bmatrix} \pi_+ & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

to conform with the partition of $\mathcal{X}$ into $\mathcal{X} = \mathcal{L}^+ \oplus \mathcal{L}^0 \oplus \mathcal{L}^-$. This yields $x_0^T \pi x_0$ as $\inf \mathcal{J}'(x_0, \underline{v})$. If $\mathcal{X} = \mathcal{L}^+ \oplus \mathcal{L}^-$ then $v^* = -B^T \pi x$ is the optimal control law.

Combining this solution with the preliminary feedback yields $x_0^T (P_0 + \pi) x_0$ for $\inf \mathcal{J}(x_0, \underline{u})$ and $u^* = -B^T (P_0 + \pi) x$. Define now $P_+ = P_0 + \pi$ and unify all the statements of Proposition 11.

7.3. The singular case with stability. We are now in a position to state the solution of the general singular LQ problems with stability. We will assume that the problem

is already in the form (4)-(5) with the refinement of $\mathscr{X}_1$ leading to the partition of A_{22} as given in (11).

THEOREM 3. *Consider the singular LQ-problem* (2) *with the stability constraint* $\lim_{t\to\infty} \underline{x}(t) = 0$. *Assume that by a preliminary feedback and a proper choice of the bases,* Σ *is already in the form* (4)-(5), *with* $\mathscr{X}_2$ *further decomposed so as to induce the form* (11). *Then*

(i) *For all* $x_0 \in \mathscr{X}$, *there exists a control* $\underline{u} \in \mathscr{U}_{\text{stab}}^{\text{dist}}(x_0)$ *with* $\mathscr{J}(x_0, \underline{u}) < \infty$ *if and only if* (A, B) *is asymptotically stabilizable. Assume this to be the case.*

(ii) *Let* P_0 *be as defined in Theorem* 2 (i). *Now let* W_+ *be the solution of*

$$A_{22,1} W_+ + W_+ A_{22,1}^T = B_{12,1} B_{12,1}^T + A_{25,1} A_{25,1}^T. \tag{12}$$

Then $W_+ = W_+^T > 0$, *and* $\mathscr{J}_{\text{stab}}^*(x_0) = x_{1,0}^T P_0 x_{1,0} + x_{21,0}^T W_+^{-1} x_{21,0}$.

(iii) *For all* $x_0 \in \mathscr{X}$, *there exists an optimal control* $\underline{u}^* \in \mathscr{U}_{\text{stab}}^{\text{dist}}(x_0)$ *if and only if* $\mathscr{X}_{22} = 0$ (*in the notation of* § 7.1 *this means* $\mathscr{V}^* = \mathscr{V}^+ + \mathscr{V}^-$). *This optimal control is generated as follows*

$$u_1^* = -B_{11}^T P_0 x_1 - B_{21,1}^T W_+^{-1} x_{21} \tag{13}$$

and $u_2'^*$ *such that* x_5^* *is regular and satisfies*

$$x_5^* = -(C_{25}^T C_{25})^{-1} (A_{15}^T P_0 + C_{25}^T C_{21}) x_1 - A_{21,1}^T W_+^{-1} x_{21}. \tag{14}$$

7.4. Computation of optimal input. In this part we will discuss the computation of the optimal input. Using Theorem 3 (iii), we will obtain $u_1'^*$, x_5^*, x_1^*, x_{21}^* for initial conditions x_{10} and $x_{21,0}$. To compute $u_2'^*$ we consider the differential equation

$$\begin{bmatrix} \dot{x}_{2,3} \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \end{bmatrix} = \begin{bmatrix} A_{22,3} & 0 & 0 & A_{25} \\ 0 & A_{33} & A_{34} & A_{35} \\ 0 & 0 & A_{44} & A_{45} \\ 0 & 0 & A_{54} & A_{55} \end{bmatrix} \begin{bmatrix} x_{2,3} \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} + \begin{bmatrix} B_{12,3} \\ B_{13} \\ B_{14} \\ B_{15} \end{bmatrix} u_1' + \begin{bmatrix} 0 \\ B_{23} \\ B_{24} \\ B_{25} \end{bmatrix} u_2'.$$

We will first compute $\bar{x}_{2,3}$, $\bar{x}_3$, $\bar{x}_4$, $\bar{x}_5$ by taking $u_1' = u_1^*$ and $u_2' = 0$. Since from Theorem 3 part (iii) $\mathscr{X}_{22} = 0$ we can conclude

$$\left\langle \begin{bmatrix} A_{22,3} & 0 & 0 & A_{25} \\ 0 & A_{33} & A_{34} & A_{35} \\ 0 & 0 & A_{44} & A_{45} \\ 0 & 0 & A_{54} & A_{55} \end{bmatrix}, \begin{bmatrix} 0 \\ B_{23} \\ B_{24} \\ B_{25} \end{bmatrix} \right\rangle$$

$$\begin{bmatrix} 0 & 0 & 0 & I \end{bmatrix}$$

has $\mathscr{V}^* + \mathscr{R}_b^* = \mathscr{X}$ (see Proposition 6.2). Therefore, we will compute $u_2'^*$ such that $\Delta x_5(t) = \bar{x}_5(t) - x_5^*(t)$ will be zero. If $\Delta x_5(0) \neq 0$, $u_2'^*$ contains impulses. Using the results of [6] one can directly compute the impulsive and regular parts of $u_2'^*$. We will first find the feedback F and chain B_i which are defined by Proposition 5 by using [6, Theorem 1] for $A' = A - B_1 C_1$, B_2 and C_2. By applying the nested version of the left structure algorithm one can find output transformation Q, input transformation G and feedback F such that $A_F = A' + B_2 F$, $C_2^T = [(C_1^*)^T \cdots (C_\alpha^*)^T]$ and $B_2 = [B_{21} \cdots B_{2\alpha+1}]$ where $(C_i^*)^T$, $B_{2i} \in \mathscr{R}^{nx(q_i - q_{i-1})}$. If $Q \neq I$ one has to introduce Q into *ARE* in Theorem 3. We will choose $[T_3 \ T_4] = \text{Im}\,[B_{22} \ B_{23} \ A_F B_{23} \cdots B_{\alpha+1} \cdots A_F^{\alpha-2} B_{\alpha+1}]$ and $T_5 = [B_{21} \ A_F B_{22} \cdots A_F^{\alpha-1} B_{2\alpha}]$ where columns of $[T_3 \ T_4]$ and T_5 are basis vectors for x_3, x_4 and x_5 respectively. With this

special basis selection we will obtain the matrix

$$N = \begin{bmatrix} A_{33} & A_{34} & A_{35} & B_{23} \\ 0 & A_{44} & A_{45} & B_{24} \\ 0 & A_{54} & A_{55} & B_{25} \end{bmatrix}$$

where

$$N = \begin{bmatrix} N_{11} & \cdots & N_{1\theta_1} \\ \vdots & & \vdots \\ N_{\theta_2 1} & \cdots & N_{\theta_2\theta_1} \end{bmatrix}$$

and for each $i \exists aj^*(i)$ such that $N_{i,j^*(i)} = I$ where $j^*(i) < i$. Then we will apply the column elimination algorithm [6] to eliminate nonzero elements of each row. Let $J = \{j | \exists i \ni j^*(i) = j\}$. For each $j \in J$, $\dot{x}_{j^*(i)} + A_{55}\Delta x_5(t)$. We start the procedure with $i = \theta_2$, at each step we know x_i and compute $x_{j^*(i)}$ since $j^*(i) < i$. Recursively one can find $x_i(t)$ $\forall i$ and $u_2'(t)$. From the special selection of the basis vectors in $\mathscr{X}_5$ it is not hard to prove that the impulsive part of u_2' has the following property: $u_{2i}' = [\zeta_1^T\delta(t)\ \zeta_2^T\dot{\delta}(t) \cdots \zeta_{\alpha-1}^T\delta^{\alpha-1}(t)]$. The numerical aspects of the computations are investigated in [6].

Appendix A. Proof of Theorem 2. We start with the system in the form (4)-(5). The idea is now to consider the subsystem

$$\mathscr{J}' = \int_0^\infty (\|\underline{u}_1'\|^2 + \|C_{21}\underline{x}_1 + C_{25}\underline{x}_5\|^2)\, dt$$

with x_5 considered as a control (i.e., as being unconstrained). Obviously

$$\inf \mathscr{J}'(x_{1,0}) \leqq \inf \mathscr{J}(x_{1,0}, x_{2,0}, x_{3,0}, x_{4,0}, x_{5,0}).$$

Since the LQ-problem thus obtained is regular, we can apply Proposition 10. Observe that asymptotic stabilizability of (A, B) implies asymptotic stabilizability of $(A_{11}, (A_{15}^{\dagger}B_{11}))$. The resulting optimal control $(u_1'^*, x_5^*)$ is then given by (9)-(10) and consequently in order to prove statements (i), (ii), and (iii) of Theorem 2 it suffices to show that there always exists a distribution $\underline{u}_2^*$ such that (10) will be satisfied. More explicitly, define $L := -(C_{25}^TC_{25})^{-1}(A_{15}^TP_0 + C_{25}^TC_{21})$. Then we should generate $\underline{x}_5^* = L\underline{x}_1^*$ with $\underline{x}_1^*$ defined by

$$\dot{x}_1^* = (A_{11} + A_{15}L - B_{11}B_{11}^TP_0)\underline{x}_1^*, \qquad \underline{x}_1^*(0) = x_{1,0}.$$

The fact that the desired $\underline{u}_2'^*$ exists is an immediate consequence of Proposition 7.2. Note that since in particular $x_{5,0}$ may be unequal to $-Lx_{1,0}$, we obtain in general distributions for $u_2'^*$ and hence for $\underline{x}_3^*$, $\underline{x}_4^*$, and $\underline{x}_5^*$. The uniqueness claim (iv) of Theorem 2 may be shown as follows. From the original construction of $\underline{x}_5^*$ and $\underline{u}_1'^*$ it follows that they are unique. From Proposition 4 it follows that $\underline{x}_3^*$ is not unique, while from Proposition 7.5 it follows that $\underline{x}_4^*$ and $\underline{x}_5^*$ are unique.

Appendix B. Proof of Theorem 3. We start with the problem in the form (4)-(5)-(11) and consider first the subsystem

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} A_{11} & 0 \\ A_{12} & A_{22} \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} A_{15} \\ A_{25} \end{bmatrix}x_5 + \begin{bmatrix} B_{11} \\ B_{12} \end{bmatrix}x_1'$$

for which we will minimize

$$\mathcal{J}'_{\text{stab}} = \int_0^\infty (\|\underline{u}'_1\|^2 + \|C_{21}\underline{x}_1 + C_{25}\underline{x}_5\|^2)\, dt$$

with x_5 considered as a control and with the constraint $\lim_{t\to\infty}(\underline{x}_1(t), \underline{x}_2(t)) = a$. Since this is a regular problem, we can apply Proposition 9. This yields the optimal trajectory $\underline{x}_1^*, \underline{x}_2^*, \underline{x}_5^*$ which converges to zero at $t \to \infty$. Using the ideas of Appendix A, this will yield Theorem 3 provided we can show that there exists a $\underline{u}_2'^*$ which generates $\underline{x}_3^*, \underline{x}_4^*$ which also converge to zero. This, however, immediately follows from the fact that in Proposition 7.2 a right inverse with a polynomial transfer function is obtained.

ON THE HESSIAN OF LAGRANGIAN AND SECOND ORDER OPTIMALITY CONDITIONS*

S.-P. HAN†

Abstract. For a constrained minimization problem, the restriction of a Hessian of Lagrangian to a tangent space of the feasible set can be used to detect whether a Karush-Kuhn-Tucker point is a local minimum, maximum or saddle point of the problem. It is shown in this paper that the restriction of the Hessian to a normal space with respect to the indefinite inner product induced by the Hessian can be used to characterize a Karush-Kuhn-Tucker point for the Wolfe dual. From this result and by an inertia theorem in [S.-P. Han and O. Fujiwara, *An inertia theorem and its application to nonlinear programs*, manuscript March 1984], we deduce that, under a regularity condition, the Hessian is positive semidefinite if and only if the considered Karush-Kuhn-Tucker point satisfies the second order necessary condition for a local minimum point of the primal problem and, at the same time, satisfies the second order necessary condition for a local maximum point of the dual. Similar results on the positive definiteness of the Hessian are also discussed, which strengthen some results given in [O. Fujiwara, S.-P. Han and O. L. Mangasarian, *Local duality of nonlinear programs*, SIAM J. Control Optim., 22 (1984) pp. 162-169], [S.-P. Han and O. L. Mangasarian, *Characterization of positive definite and semidefinite matrices via quadratic programming duality*, SIAM J. Alg. Disc. Meth., 5 (1984) pp. 26-32].

1. Introduction. The inertia of a symmetric $n \times n$ real matrix H, denoted here by $\pi(H)$, is the triple (ρ, η, θ) where ρ, η and θ are the numbers of positive, negative and zero eigenvalues of H, respectively, with multiplicities counted. When H is the Hessian of a real-valued function at a stationary point, the inertia $\pi(H)$ provides useful information about the stationary point being a local maximum, minimum or saddle point of the function. In the case of the constrained optimization problem:

$$\text{(P)} \qquad \begin{aligned} &\text{Minimize } f(x) \\ &\text{subject to } h(x) = 0 \end{aligned}$$

where $f: R^n \to R$ and $h: R^n \to R^k$ are twice continuously differentiable at a Karush-Kuhn-Tucker point x^*, such characterization of the Karush-Kuhn-Tucker point x^* and its Lagrange multiplier v^* can be done through the Hessian of the Lagrangian $L(x, v) := f(x) + v^T h(x)$. To be more specific, let H be the $n \times n$ Hessian matrix of the Lagrangian L with respect to x at (x^*, v^*) and let $S := \ker(J)$ where J is the $k \times n$ Jacobian matrix of h at x^*. Notice that S is just the tangent space of the constraint surface $h(x) = 0$ at x^* when the Jacobian J has full row rank. The relative inertia $\pi(H/S)$ of H with respect to S is defined to be the triple:

$$\pi(H/S) := (\rho(H/S), \eta(H/S), \theta(H/S))$$

where $\rho(H/S)$, $\eta(H/S)$ and $\theta(H/S)$ are the numbers of positive, negative and zero eigenvalues of the matrix $B^T H B$, respectively, and B is any matrix with its columns forming a basis of the subspace S. The notation is justified because it follows from Sylvester's law of inertia that the triple $\pi(H/S)$ is independent of the choice of a basis for the subspace S. Recall that the Karush-Kuhn-Tucker point x^* and its Lagrange

† Department of Mathematics, University of Illinois, Urbana, Illinois 61801.

multiplier v^* satisfy the second order sufficient condition for a local minimum point of the problem (P) if H is positive definite on S [5]; that is,

$$x^T H x > 0 \quad \text{for any nonzero } x \text{ in } S. \tag{1.1}$$

This condition can be paraphrased in terms of the inertia $\pi(H/S)$ as follows:

$$\pi(H/S) = (\dim(S), 0, 0). \tag{1.2}$$

Similarly, under a constraint qualification, the standard second order necessary condition in [5] is that H is positive semidefinite on S; that is,

$$x^T H x \geqq 0 \quad \text{for any } x \in S. \tag{1.3}$$

This can also be written simply as:

$$\eta(H/S) = 0. \tag{1.4}$$

Consequently, when $\rho(H/S)$ and $\eta(H/S)$ are positive and a constraint qualification is satisfied, x^* is only a saddle point of (P). A more complete characterization of the Karush-Kuhn-Tucker point x^* by the relative inertia $\pi(H/S)$ is possible by further imposing a nondegeneracy condition such as the one given in [3].

For the Wolfe dual [11], [12] of (P):

$$\text{(D)} \qquad \begin{aligned} &\text{Maximize } L(x, v) \\ &\text{subject to } \nabla_x L(x, v) = 0, \end{aligned}$$

it will be shown that the Karush-Kuhn-Tucker pair (x^*, v^*) can be characterized also as a stationary point of the dual problem (D) by the inertia $\pi(H/(HS)^\perp)$. The subspace $(HS)^\perp$ is given by:

$$(HS)^\perp = \{x : x^T H y = 0 \text{ for any } y \in S\}$$

and is the orthogonal complement of S with respect to the indefinite inner product defined by $\langle x, y\rangle_H := x^T H y$ (see, for example, [1], [9]). When S is the tangent space of the constraint surface, the set $(HS)^\perp$ can be viewed as its normal space with respect to the inner product at x^*. In this sense, the Karush-Kuhn-Tucker pair (x^*, v^*) can be analyzed as a solution to both the primal and the dual problems by restricting the Hessian H to the tangent space S and the normal space $(HS)^\perp$, respectively.

We further use an inertia theorem in [6] to show that, under a regularity condition, the Hessian matrix H is positive semidefinite if and only if the Karush-Kuhn-Tucker pair (x^*, v^*) satisfies the second order necessary conditions for a local minimum point of the primal problem (P) and, at the same time, satisfies the second order necessary condition for a local maximum point of the dual problem (D). Similar results on the positive definiteness of the Hessian are also given, which strengthen some results in [4], [8].

For the simplicity of our presentation, we only consider the equality constraints here. We note that, since all the results are local, we can extend them to an inequality constrained problem by treating active inequality constraints as equalities and under the conditions of the strict complementarity and the linear independence of the gradients of active constraints.

In § 2, we characterize a Karush-Kuhn-Tucker point for Problem (D) by the inertia $\pi(H/(HS)^\perp)$. In § 3, we analyze the definiteness of the Hessian matrix H through the second order optimality conditions of (P) and (D).

2. Inertia of Hessian. For the Wolfe dual (D), the Lagrangian is given by:

$$\Psi(x, v, w) := L(x, v) + w^T \nabla_x L(x, v).$$

It is known [11], [12] that a Karush-Kuhn-Tucker pair (x^*, v^*) of Problem (P) is also a Karush-Kuhn-Tucker point of Problem (D) with its associated Lagrange multiplier $w^* = 0$. For this reason, we will consider only the Karush-Kuhn-Tucker point (x^*, v^*) of (D) that has a Lagrange multiplier $w^* = 0$. To characterize such a vector $(x^*, v^*, 0)$ as a solution of (D), we need the $(n+k)\times(n+k)$ Hessian matrix of Ψ with respect to (x, v) at $(x^*, v^*, 0)$; that is,

$$M = \begin{pmatrix} H & J^T \\ J & 0 \end{pmatrix} \tag{2.1}$$

where the matrices H and J are defined as in § 1. In this case the counterpart of the set S for (D) at (x^*, v^*) is given by:

$$T := \{(x, y): Hx + J^T y = 0\} \tag{2.2}$$

which is the tangent space of the feasible set of (D) at (x^*, v^*) when the rows of the matrix $[H \quad J^T]$ are linearly independent. Therefore, as in the primal case, the Karush-Kuhn-Tucker point (x^*, v^*) of (D) and its Lagrange multiplier $w^* = 0$ can be analyzed by the inertia $\pi(M/T)$. Similar to conditions (1.2) and (1.4), the second order sufficient condition for (x^*, v^*) to be a local maximum point of the dual problem (D) is:

$$\pi(M/T) = (0, \dim(T), 0), \tag{2.3}$$

and, under a constraint qualification such as the matrix $[H \quad J^T]$ having full rank, the second order necessary condtion is:

$$\rho(M/T) = 0. \tag{2.4}$$

It will be shown below that conditions (2.3) and (2.4) can, in turn, be rewritten in terms of the inertia $\pi(H/(HS)^\perp)$. For establishing this result, we first deduce a relation between the two subspaces S and T.

LEMMA 2.1. *Let T be the subspace in R^{n+k} defined by* (2.2) *and S be the kernel of the matrix J; then (x, y) is in T if and only if*

$$x \in (HS)^\perp \quad \textit{and} \quad y \in -(J^T)^\dagger Hx + \ker(J^T)$$

where $(J^T)^\dagger$ is the Moore-Penrose inverse of J^T.

Proof. For any x in R^n, let $y^* := -(J^T)^\dagger Hx$. We first note that $S^\perp = \text{image}(J^T)$ and if Hx is in $S^\perp$ then $Hx + J^T y^* = 0$.

If $(x, y) \in T$ then $Hx = -J^T y \in S^\perp$. Hence, we have that $x \in (HS)^\perp$ and $Hx = -J^T y = -J^T y^*$. Therefore, it follows that $x \in (HS)^\perp$ and $y \in y^* + \ker(J^T)$.

Conversely, if $x \in (HS)^\perp$ and $y \in y^* + \ker(J^T)$, then $Hx \in S^\perp = \text{image}(J^T)$ and $Hx + J^T y^* = 0$, which implies that $Hx + J^T y = 0$. □

We can now relate the inertia $\pi(H/(HS)^\perp)$ to the inertia $\pi(M/T)$ as follows.

THEOREM 2.2. *Let M be a $(n+k)\times(n+k)$ matrix of the form* (2.1), *S be the kernel of the matrix J, and T be the subspace determined by* (2.2); *then*

$$\pi(M/T) = \pi(-H/(HS)^\perp) + (0, 0, m)$$

where $m = \dim(\ker(J^T))$.

Proof. Let X be a matrix with its columns forming a basis of $(HS)^\perp$ and let $Y := -(J^T)^\dagger HX$. Hence, we have the $HX + J^T Y = 0$. We also let Z be a matrix with

its columns being a basis of $\ker(J^T)$, and let

$$P := \begin{pmatrix} X & 0 \\ Y & Z \end{pmatrix}.$$

Then by Lemma 2.1 the columns of P form a basis of the subspace T. Therefore, the inertia $\pi(M/T) = \pi(P^T M P)$. Now, by using the equations $HX + J^T Y = 0$ and $J^T Z = 0$ we have that

$$P^T M P = \begin{pmatrix} Y^T J X & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} -X^T H X & 0 \\ 0 & 0 \end{pmatrix}.$$

Thus, we have that

$$\pi(M/T) = \pi(-X^T H X) + (0, 0, m) = \pi(-H/(HS)^{\perp}) + (0, 0, m). \qquad \square$$

COROLLARY 2.3. *Let M, T, S and m be defined as in Theorem* 2.2. *If H is nonsingular then* $\pi(M/T) = \pi(-H^{-1}/S^{\perp}) + (0, 0, m)$.

Proof. Let X be a matrix with its columns forming a basis of $(HS)^{\perp}$; then by the nonsingularity of H we have that the columns of HX form a basis of the subspace $S^{\perp}$. The corollary then follows directly from $X^T H X = (HX)^T H^{-1} (HX)$. $\square$

With Theorem 2.2 we now can characterize a Karush-Kuhn-Tucker point for the dual problem (D) as follows.

THEOREM 2.4. *If (x^*, v^*) is a Karush-Kuhn-Tucker point of the dual problem* (D) *with Lagrange multiplier $w^* = 0$, then*

(1). *the vector $(x^*, v^*, 0)$ satisfies the second order sufficient condition* (2.3) *for a local maximum point of* (D) *if and only if the Jacobian J of h at x^* has full row rank and*

$$\pi(H/(HS)^{\perp}) = (\dim((HS)^{\perp}), 0, 0);$$

(2). *the vector $(x^*, v^*, 0)$ satisfies the second order necessary condition* (2.4) *for a local maximum point of* (D) *if and only if*

$$\eta(H/(HS)^{\perp}) = 0.$$

Proof. We notice that it follows from Theorem 2.2 that

$$\begin{aligned} \pi(M/T) &= \pi(-H/(HS)^{\perp}) + (0, 0, m) \\ &= (\eta(H/(HS)^{\perp}), \rho(H/(HS)^{\perp}), \theta(H/(HS)^{\perp}) + m), \end{aligned}$$

where $m = \dim(\ker(J^T))$. The results follow immediately from (2.3) and (2.4). $\square$

The following corollary is a direct consequence of Theorem 2.4 and Corollary 2.3.

COROLLARY 2.5. *Let x^* and v^* be defined as in Theorem* 2.4. *The vector $(x^*, v^*, 0)$ satisfies the second order necessary condition* (2.4) *for a local maximum point of the dual problem* (D) *if and only if*

$$x^T H x \geqq 0 \quad \textit{for any } x \in (HS)^{\perp}. \tag{2.5}$$

If, in addition, H is nonsingular then condition (2.5) *is equivalent to*

$$x^T H^{-1} x \geqq 0 \quad \textit{for any } x \in S^{\perp}. \tag{2.6}$$

Because $\ker(H) \subset (HS)^{\perp}$, the positive definiteness of H on the subspace $(HS)^{\perp}$ implies the nonsingularity of H. Therefore, from Corollary 2.3, we can rewrite the dual second order sufficient condition in terms of the inverse of the Hessian H as in the following corollary, which is a result also given in [4].

COROLLARY 2.6. *Let x^* and v^* be defined as in Theorem* 2.4. *The vector $(x^*, v^*, 0)$ satisfies the second order sufficient condition for a local maximum point of the dual*

problem (D) *if and only if the Jacobian J has full row rank, the Hessian H is nonsingular and*

$$x^T H^{-1} x > 0 \quad \textit{for any nonzero } x \in S^{\perp}. \tag{2.7}$$

We can also characterize a saddle point of (D) as in the following theorem.

THEOREM 2.7. *Let* (x^*, v^*) *be defined as in Theorem* 2.4. *A sufficient condition for* (x^*, v^*) *to be a saddle point of* (D) *is that the matrix* $[H\ J^T]$ *has full rank and*

$$\rho(H/(HS)^{\perp}) > 0 \quad \textit{and} \quad \eta(H/(HS)^{\perp}) > 0. \tag{2.8}$$

Furthermore, condition (2.8) *is also a necessary condition if H is nonsingular on* $(HS)^{\perp}$ *and J has full rank.*

Proof. Under the constraint qualification that the $n \times (n+k)$ matrix $[H\ J^T]$ has full row rank, the vector (x^*, v^*) being a local minimum point implies $\rho(H/(HS)^{\perp}) = 0$; and it being a local maximum point implies $\eta(H/(HS)^{\perp}) = 0$. Therefore, the vector (x^*, v^*) can only be a local saddle point of (D) if (2.8) holds.

Conversely, it follows from Theorem 2.2 that if H is nonsingular on $(HS)^{\perp}$ and J has full rank then

$$\pi(M/T) = \pi(-H/(HS)^{\perp}) \quad \text{and} \quad \theta(M/T) = 0.$$

Therefore, $\eta(H/(HS)^{\perp}) = 0$ implies that (x^*, v^*) is a maximum point; while $\rho(H/(HS)^{\perp}) = 0$ implies that (x^*, v^*) is a minimum point. Hence, condition (2.8) is necessary for (x^*, v^*) to be a saddle point of (D). □

3. Definiteness of Hessian. In § 2 it was shown that the triples $\pi(H/S)$ and $\pi(H/(HS)^{\perp})$ can be used to characterize a solution of the primal problem (P) and the dual problem (D), respectively. Interestingly, by an inertia theorem in [6], $\pi(H/S)$ and $\pi(H/(HS)^{\perp})$ can be closely related to the inertia $\pi(H)$ of the Hessian H itself. We give the theorem below; its proof can be found in [6].

THEOREM 3.1. *Let H be a symmetric* $n \times n$ *matrix and S be a subspace in* R^n *that satisfy the condition*:

$$S \cap (HS)^{\perp} \subset \ker(H); \tag{3.1}$$

then

$$\pi(H) = \pi(H/S) + \pi(H/(HS)^{\perp}) - (0, 0, \dim(S \cap (HS)^{\perp})).$$

As before, let the vector x^* be a Karush-Kuhn-Tucker point of (P) and v^* be its Lagrange multiplier. Consequently, the pair (x^*, v^*) is also a Karush-Kuhn-Tucker point of the dual problem (D) with it Lagrange multiplier $w^* = 0$. Let the matrices H and J also be defined as in § 1. For simplicity, we use (PN), (PS), (DN) and (DS) to denote the primal second order necessary condition (1.3), the primal second order sufficient condition (1.1), the dual second order necessary condition (2.4) and the dual second order sufficient condition (2.3), respectively. Therefore, from the results given in §§ 1 and 2, we have

(PN) $\eta(H/S) = 0,$

(PS) $\pi(H/S) = (\dim(S), 0, 0),$

(DN) $\eta(H/(HS)^{\perp}) = 0,$

(DS) $\pi(H/(HS)^{\perp}) = (\dim(HS)^{\perp}, 0, 0) \quad \text{and} \quad \operatorname{rank}(J) = k.$

We can now use Theorem 3.1 to deduce a result on the positive semidefiniteness of the Hessian H as follows.

THEOREM 3.2. *If the Hessian matrix H satisfies condition* (3.1) *then*

$$\text{(PN) and (DN)} \Leftrightarrow H \text{ is positive semidefinite.}$$

Proof.

$$\begin{aligned}\text{(PN) and (DN)} &\Leftrightarrow \eta(H/S)=0 \text{ and } \eta(H/(HS)^{\perp})=0\\ &\Leftrightarrow \eta(H)=\eta(H/S)+\eta(H/(HS)^{\perp})=0\\ &\Leftrightarrow H \text{ is positive semidefinite.}\end{aligned}$$

□

We note that condition (3.1) is essential in Theorem 3.2. Consider the example given in [4]:

$$\text{Minimize } -x_1x_2$$

$$\text{subject to } x_1=0.$$

The vector $x^*=(0, 1)$ together with $v^*=1$ constitute a Karush-Kuhn-Tucker point. Both the primal and dual second order necessary conditions are satisfied at (x^*, v^*); but the Hessian H, which is given by

$$H=\begin{pmatrix}0 & -1\\ -1 & 0\end{pmatrix},$$

is not positive semidefinite. In this case, condition (3.1) does not hold and the theorem cannot apply.

We also note here that condition (3.1) is closely related to the following often used but more restrictive ccondition in mathematical programming [2], [7], [10]:

$$x^THx=0 \quad \text{and} \quad x\in S \Rightarrow Hx=0. \tag{3.2}$$

It is clear that (3.2) implies (3.1); however, the converse is not true. This can be seen from the following example:

$$H=\begin{pmatrix}0 & 1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 1\end{pmatrix} \qquad S=\{x: x_3=0\}.$$

Obviously, condition (3.1) is satisfied for this particular case; but condition (3.2) is violated at the vector $(1, -1, 0)$. Nevertheless, condition (3.1) is no longer needed when either (PS) or (DS) is assumed.

THEOREM 3.3. (PS) *and* (DN)$\Rightarrow$ *H is positive semidefinite.*

Proof. We first show that (PS) implies condition (3.1). If x is any vector in $S\cap(HS)^{\perp}$ then $x^THx=0$. Notice that if (PS) holds then H is positive definite on S. Therefore, we have $x=0$. This proves $S\cap(HS)^{\perp}=\{0\}$ and condition (3.1) is trivially satisfied. The theorem then follows directly from Theorem 3.2. □

THEOREM 3.4. (PN) *and* (DS)$\Rightarrow$*H is positive definite.*

Proof. By the similar argument as in the proof of the Theorem 3.3, we can show that (DS) implies condition (3.1). Therefore, by Theorem 3.2, we have that H is positive semidefinite. On the other hand, if (DS) holds then, by Corollary 2.6, H is also nonsingular. Thus, H is actually positive definite. □

From Theorems 3.3 and 3.4, we notice that (P) and (D) are not interchangeable and the results are not perfectly symmetric with respect to (P) and (D). This is because

the dual second order sufficient condition is a much stronger condition, which implies the nonsingularity of the Hessian H. Under the nonsingularity assumption on the Hessian H and by the fact that any nonsingular positive semidefinite matrix is actually positive definite, the statement of Theorem 3.4 will still hold when (P) and (D) are interchanged; this is also a result given in [4].

We make a last remark that the implications of Theorems 2.4 and 3.1 are certainly not limited to the characterization of the definiteness of the Hessian H as in Theorems 3.2, 3.3 and 3.4. They can also be used in analyzing a Karush-Kuhn-Tucker point for solving both the primal and the dual problems. For instance, under condition (3.1) and a constraint qualification, if it is known that $\eta(H) > \dim(S)$ then we can immediately conclude that the considered Karush-Kuhn-Tucker point is not a local maximum point of the dual problem (D). Similarly, if $\eta(H) > \dim((HS)^{\perp})$ then the Karush-Kuhn-Tucker point cannot be a local minimum point of the primal problem (P).

Acknowledgment. The author would like to thank one of the referees for his suggestions concerning Theorem 2.7.

NECESSARY CONDITIONS FOR A DOMAIN OPTIMIZATION PROBLEM IN ELLIPTIC BOUNDARY VALUE PROBLEMS*

NOBUO FUJII†

Abstract. This paper deals with a domain optimization problem suggested by a real physical problem, the shape optimization problem for high-beta plasmas in nuclear fusion research. The function of the space dependent variable, which is the solution of an elliptic boundary value problem defined on a variable domain, should be optimized. The fundamental equation which evaluates the variation of the solution according to the boundary variation is given. From this equation, a variational equation and its equivalent which relate the variation of the solution to the variation of the boundary are derived. This variational equation is exploited to derive a necessary condition for the optimality of the domain. The necessary condition is composed of the Euler-Lagrange equation in the wider sense and the transversality condition. Another form of the necessary condition is also obtained from the equivlaent variational equation.

Key words. domain optimization, variational equation, boundary value problem, partial differential equation

1. Introduction. In research on nuclear fusion the investigation of the high-beta plasma has received attention in these years [4], [7], [11], [13], [20] [21]. In particular, Miller and Moore [11] and others [13] investigated the optimal shape of the cross-section of plasmas in axisymmetric toroids. Here "optimal" means the highest possible β-value, the ratio of the kinetic pressure to the magnetic pressure, of equilibrium plasmas. The β-value varies with the shape of the cross-section as well as the current profile of the plasma ring. Their approaches are intuitive and heuristic, though their results are very valuable. These investigations suggest that we develop a more systematic way for designing the shape of plasma cross-sections.

In this paper we shall consider a domain optimization problem which is suggested by the above physical problem. Our problem to be considered is, however, abstract, simplified, and only a step for solving the real physical problem.

Let us consider an elliptic boundary value problem:

$$\begin{aligned} &\Delta u(x) - (\mathbf{v}(x)\cdot\nabla)u(x) = f(x, u(x)), && x\in\Omega, \\ &u(x) = \kappa(\text{const.}), && x\in\Gamma. \end{aligned} \tag{1.1}$$

Here the symbol Δ denotes the Laplacian operator in R^2, the two-dimensional Euclidean space, and ∇, the gradient operator in R^2. The given nonlinear function $f(x, \xi)$ satisfies suitable conditions which will be clear in the next section. The domain Ω, which is bounded and has a sufficiently smooth boundary Γ, is assumed to be free to vary within a larger domain Ω_0. We want to determine Ω such that the functional $J(\Omega; u)$ defined by

$$J(\Omega; u) = \int_\Omega g(x, u)\, d\Omega \tag{1.2}$$

takes the largest (or smallest) value subject to (1.1) and

$$\int_\Omega h(x)\, d\Omega = M \text{ (const.)}, \tag{1.3}$$

* Received by the editors August 9, 1983, and in revised form January 7, 1985.

† Department of Control Engineering, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560, Japan.

where the functions $g(x, \xi)$ and $h(x)$ are suitably defined. Note that the elliptic boundary value problem (1.1) is a generalization of the Grad-Shafranov equation [1, p. 66] which the equilibrium plasma must obey.

Pironneau studied similar problems in fluid mechanics, namely, the minimum-drag problems [15], [16]. In these problems the system of partial differential equations, Stokes or Navier-Stokes equations, is the main constraint, and the objective function is the energy dissipation in the fluid. He derived a necessary optimality condition for each problem with subsidiary constraints; he dealt with not the genuine (classical) but the weak solution of the system of partial differential equations, however. Other authors studied the related or similar problems [9], [17], [18], [19], [22]. Cea [3] enumerated various examples of the domain optimization problems. In particular, Zolesio [22] proposed in the general framework the method for calculating the first variation of objective functions. These authors, except Zolesio, never introduced the variation of the solution of the boundary value problem. Introduction of this notion seems to be natural in the context of the theory of variation.

We shall define the variation of the solution of the boundary value problem and derive a necessary condition for the solution Ω of the domain optimization problem (1.1)-(1.3), assuming the existence of the solution. In order to obtain the necessary condition, we must derive a variational equation which relates the first order variation δu of the solution of (1.1) to the variation δn of the boundary Γ. In § 2, the existence of the well defined δu will be shown first. The equation of variation and its equivalent will, then, be given. Using these results, in § 3 we shall derive the necessary condition for the optimal domain Ω. An equivalent form of the necessary condition will be given as well.

2. Equation of variation. The solution of the boundary value problem (1.1) is, of course, dependent on the domain Ω. If the domain varies (slightly), then the solution is forced to vary even in the common part of the domains. In this section, we shall derive an equation of variation, i.e. a relation between the first-order variation δu of the solution and the variation δn of the domain. We shall show an equivalent form of the equation, too. As far as the author knows, these formulae do not seem to be known in the literature. Once these formulae are obtained, it is not so difficult to derive a necessary condition which the optimal domain must satisfy.

Let Ω be a bounded domain in R^2 whose boundary Γ is sufficiently smooth; we henceforth fix it. Consider another domain Ω_0 large enough to contain Ω in its interior. Let the function $f(x, \xi)$ be defined on $\Omega_0 \times R$, continuous in x, and twice continuously differentiable with respect to ξ. Furthermore let us assume that $f(x, \xi)$ satisfies

$$|f(x, \xi)| \leqq c_0, \qquad \frac{\partial f(x, \xi)}{\partial \xi} \geqq 0, \qquad (x, \xi) \in \Omega_0 \times R, \tag{2.1}$$

where c_0 is a constant. The vector valued function $\mathbf{v}(x)$ is assumed to be defined on Ω_0 and is continuously differentiable. We assume that

$$\operatorname{div} \mathbf{v}(x) \leqq 0; \tag{2.2}$$

note that this condition is always satisfied in the Grad-Shafranov equation. Let us define on Γ a continuous function $\rho(s)$ of arclength s which is piecewise continuously differentiable. We erect at each point on Γ the normal and plot on it normal segments $\varepsilon\rho(s)$ such that the positive segment lies on the exterior normal. If ε is sufficiently small, the endpoints of the segments will form a continuous curve Γ_ε. Obviously Γ_ε is piecewise continuously differentiable. Let Ω_ε be the domain bounded by Γ_ε. We obtain

a sequence of domains which converges to Ω as ε tends to zero; we may, hence, assume that each Ω_ε is contained in Ω_0.

Let us consider the following sequence of elliptic boundary value problems:

$$\begin{aligned} &\Delta u_\varepsilon - (\mathbf{v}(x)\cdot\nabla)u_\varepsilon = f(x, u_\varepsilon), && x\in\Omega_\varepsilon, \\ &u_\varepsilon = \kappa, && x\in\Gamma_\varepsilon, \end{aligned} \tag{2.3}$$

and the boundary value problem

$$\begin{aligned} &\Delta u - (\mathbf{v}(x)\cdot\nabla)u = f(x, u), && x\in\Omega, \\ &u = \kappa, && x\in\Gamma. \end{aligned} \tag{2.4}$$

As is well known [5, Chap. IV], [14], each of these nonlinear boundary value problems has, owing to (2.1), a unique solution which is continuous on $\Omega_\varepsilon+\Gamma_\varepsilon(\Omega+\Gamma)$ and is twice continuously differentiable in $\Omega_\varepsilon(\Omega)$. Let us denote the solution of (2.3) by u_ε and denote that of (2.4) by u. What can we say about the difference between u and u_ε? In response to this question, we have the following

THEOREM 1. *Let $\rho(s)$ be a continuous variation of the boundary Γ of Ω and be piecewise continuously differentiable. Then there exists a well defined function $\phi(x)$ which is continuous in Ω such that*

$$u(x)-u_\varepsilon(x)=\varepsilon\phi(x)+o(\varepsilon), \qquad x\in\Omega\cap\Omega_\varepsilon, \tag{2.5}$$

where $o(\varepsilon)$ is a quantity such that $\varepsilon^{-1}o(\varepsilon)\to 0$ $(\varepsilon\to 0)$ and is uniformaly bounded.

If $f(x, u)$ does not depend on u and $\mathbf{v}(x)\equiv 0$, Theorem 1 is immediately proven (see Appendix 1), since we know the following lemma [2], [6, p. 292]:

LEMMA 1. *Let $G(x, y)$ be Green's function on Ω and $G_\varepsilon(x, y)$ be Green's function on Ω_ε. Then we have*

$$\begin{aligned} G(x, y)-G_\varepsilon(x, y) &= \frac{\varepsilon}{2\pi}\oint_\Gamma \frac{\partial G(z, x)}{\partial n_z}\frac{\partial G(z, y)}{\partial n_z}\rho\, d\Gamma_z+\varepsilon^2\gamma(x, y; \varepsilon) \\ &\equiv \varepsilon\delta G(x, y)+\varepsilon^2\gamma(x, y; \varepsilon), \qquad x, y\in\Omega\cap\Omega_\varepsilon, \end{aligned} \tag{2.6}$$

where, of course, $\partial/\partial n_z$ stands for the normal derivative and $\gamma(x, y; \varepsilon)$ is uniformly bounded in $\Omega\cap\Omega_\varepsilon$.

Unfortunately, however, our equations are nonlinear; it is never obvious that (2.5) holds. In the rest of this section we shall prove Theorem 1 step by step. In § 2.1, we shall assume that $\rho(s)$ is nonnegative to show (2.5). In § 2.2, we shall then show (2.5) in the general case. At the same time an equation of variation and its equivalent will be derived.

2.1. Convergence from above. Let $\rho(s)$ be nonnegative, i.e. $\rho(s)\geqq 0$. Then each Ω_ε contains Ω. Furthermore $\{\Omega_\varepsilon\}$ converges monotonically to Ω as ε approaches zero. In view of these, we may assume from the outset that ε is bounded, say $0<\varepsilon\leqq\varepsilon_1$.

Let us define a function $\phi_\varepsilon(x)$ which depends not only on $x\in\Omega$ but also on ε by

$$\phi_\varepsilon(x)=\frac{1}{\varepsilon}(u(x)-u_\varepsilon(x)). \tag{2.7}$$

Now we can assert the following proposition which will play a fundamental role for showing (2.5). In what follows, all the constants do not depend on ε.

PROPOSITION 1. (i) *There exist constants K_1 and K_2 such that*

$$|u_\varepsilon|\leqq K_1, \qquad x\in\Omega_\varepsilon, \tag{2.8}$$

$$|\phi_\varepsilon| < K_2, \qquad x \in \Omega_\varepsilon. \tag{2.9}$$

As a consequence of (2.9)

$$u_\varepsilon \to u \quad \textit{uniformly on } \Omega(\varepsilon \to 0). \tag{2.10}$$

(ii) *There exists a constant* K_3 *such that*

$$|\nabla u_\varepsilon| \leqq K_3, \qquad x \in \Omega_\varepsilon. \tag{2.11}$$

Furthermore,

$$\nabla u_\varepsilon \to \nabla u \quad \textit{for every } x \in \Omega(\varepsilon \to 0). \tag{2.12}$$

Proof. There evidently exists a constant c_1 such that $|u_1(x) - \kappa| \leqq c_1$, $u_1(x)$ being the solution corresponding to Ω_{ε_1}. It is immediate to show that $u_\varepsilon - u_1$ satisfies

$$\Delta(u_\varepsilon - u_1) - \mathbf{v} \cdot \nabla(u_\varepsilon - u_1) = \int_0^1 \frac{\partial f}{\partial \xi}(x, tu_\varepsilon + (1-t)u_1)\, dt (u_\varepsilon - u_1), \qquad x \in \Omega_\varepsilon.$$

Assumption (2.1) and the celebrated maximum principle [5, p. 326] tell us that

$$\max_{x \in \Omega_\varepsilon} |u_\varepsilon - u_1| \leqq \max_{x \in \Gamma_\varepsilon} |u_\varepsilon - u_1| = \max_{\Gamma_\varepsilon} |u_1 - \kappa| \leqq c_1.$$

From this estimate (2.8) follows at once.

Again we easily obtain, for $x \in \Omega$,

$$\Delta \phi_\varepsilon - \mathbf{v}(x) \cdot \nabla \phi_\varepsilon - \left(\int_0^1 \frac{\partial f}{\partial \xi}(x, tu + (1-t)u_\varepsilon)\, dt \right) \phi_\varepsilon = 0,$$

where ϕ_ε is defined by (2.7). From this it follows that

$$\max_{x \in \Omega} |\phi_\varepsilon| \leqq \max_{x \in \Gamma} \left| \frac{1}{\varepsilon}(u - u_\varepsilon) \right|. \tag{2.13}$$

To proceed further, the following lemma is useful. This lemma is a version of the assertion found in Courant and Hilbert [5, p. 370]; the proof of it may hence be omitted.

LEMMA 2. (i) *Let* $V_\varepsilon(x)$ *be a continuous function on* $\Omega_\varepsilon + \Gamma_\varepsilon$ *and be twice continuously differentiable in* Ω_ε. *If* $V_\varepsilon(x) \equiv 0$ *on* Γ_ε, *then there exist constants* c_2 *and* c_3 *such that*

$$\sup_{x \in \Omega_\varepsilon} \left| \frac{\partial V_\varepsilon}{\partial x_i} \right| \leqq c_2 \sup_{\Omega_\varepsilon} |\Delta V_\varepsilon - \mathbf{v}(x) \cdot \nabla V_\varepsilon| + c_3 \sup_{\Omega_\varepsilon} |V_\varepsilon(x)|, \qquad i = 1, 2. \tag{2.14}$$

(ii) *Let* $V(x)$ *be continuous on* $\Omega + \Gamma$ *and be twice continuously differentiable in* Ω. *Then, for any closed subdomain* G *in* Ω, *there exist constants* $\bar{c}_2$ *and* $\bar{c}_3$ *such that*

$$\max_{x \in G} \left| \frac{\partial V}{\partial x_i} \right| \leqq \bar{c}_2 \sup_{\Omega} |\Delta V - \mathbf{v}(x) \cdot \nabla V| + \bar{c}_3 \sup_{\Omega} |V(x)|, \qquad i = 1, 2. \tag{2.15}$$

The constants $\bar{c}_2$ *and* $\bar{c}_3$ *may depend on* G.

Going back to (2.13), we want to estimate the right-hand side. For each point $x(s)$ on Γ, let $x(s) + a\rho(s)$ denote a point of distance $a\rho(s)$ from $x(s)$ along the normal. Thanks to the mean value theorem, we can obtain

$$\begin{aligned} u(x(s)) - u_\varepsilon(x(s)) &= u_\varepsilon(x(s) + \varepsilon\rho(s)) - u_\varepsilon(x(s)) \\ &= \mathbf{n} \cdot \operatorname{grad} u_\varepsilon(x(s) + \alpha\varepsilon\rho(s))\varepsilon\rho(s), \end{aligned}$$

where $\mathbf{n}$ is the unit outward normal and α satisfies $0 < \alpha < 1$. In view of Lemma 2, the

following estimate is easy:

$$|\mathbf{n}\cdot\operatorname{grad} u_\varepsilon(x(s)+\alpha\varepsilon\rho(s))|\leqq 2c_2\sup_{\Omega_\varepsilon}|\Delta u_\varepsilon-\mathbf{v}\cdot\nabla u_\varepsilon|+2c_3\sup_{\Omega_\varepsilon}|u_\varepsilon-\kappa|$$
$$\leqq 2c_2\sup_{\Omega_\varepsilon}|f(x,u_\varepsilon)|+2c_3\{\sup_{\Omega_\varepsilon}|u_\varepsilon|+|\kappa|\}.$$

From (2.8) and the fact that $f(x,\xi)$ is bounded, it readily follows that for a constant c_4

$$\max_\Gamma\left|\frac{1}{\varepsilon}(u-u_\varepsilon)\right|\leqq c_4\max_\Gamma|\rho(s)|.$$

This and (2.13) yield (2.9) at once. From Lemma 2, we easily obtain (2.11) in the same fashion as above.

Applying the second part of Lemma 2 to $V(x)=u-u_\varepsilon$, we obtain

$$\max_{x\in G}|\operatorname{grad}(u-u_\varepsilon)|\leqq 2\bar{c}_2\sup_\Omega|\Delta(u-u_\varepsilon)-\mathbf{v}\cdot\nabla(u-u_\varepsilon)|$$
$$+2\bar{c}_3\sup_\Omega|u-u_\varepsilon|.$$

The second term of the right-hand side converges to zero due to (2.10). As to the first term, we can estimate as follows

$$|\Delta(u-u_\varepsilon)-\mathbf{v}\cdot\nabla(u-u_\varepsilon)|\leqq\left|\int_0^1\frac{\partial f}{\partial\xi}(x,tu+(1-t)u_\varepsilon)\,dt\right||u-u_\varepsilon|.$$

Thus, in view of (2.10), the first term approaches zero as ε tends to zero. Since G is an arbitrary closed subdomain in Ω, (2.12) follows from these facts. Proposition 1 is thereby proved.

We now wish to show (2.5). First we shall show $\phi_\varepsilon(x)$ converges to a function as ε tends to zero. In what follows we can assume that $\kappa=0$ without loss of generality. In fact, by setting $u_\varepsilon=v_\varepsilon+\kappa$ $(u=v+\kappa)$ we have a new boundary value problem with zero boundary data for v_ε (resp. v). Doing this affects neither the definition of ϕ_ε nor the properties of $f(x,\xi)$ stated above.

It is possible to represent u and u_ε by integral equations with the help of Green's functions, i.e.

$$u(x)=-\frac{1}{2\pi}\left\{\int_\Omega G(x,y)(\mathbf{v}\cdot\nabla)_y u(y)\,d\Omega_y\right.$$
$$\left.+\int_\Omega G(x,y)f(y,u)\,d\Omega_y\right\},\qquad x\in\Omega, \tag{2.16}$$

$$u_\varepsilon(x)=-\frac{1}{2\pi}\left\{\int_{\Omega_\varepsilon}G_\varepsilon(x,y)(\mathbf{v}\cdot\nabla)_y u_\varepsilon(y)\,d\Omega_y\right.$$
$$\left.+\int_{\Omega_\varepsilon}G_\varepsilon(x,y)f(y,u_\varepsilon)\,d\Omega_y\right\},\qquad x\in\Omega_\varepsilon. \tag{2.17}$$

From these we easily obtain

$$\phi_\varepsilon(x)=-\frac{1}{2\pi}\int_\Omega\left\{G(x,y)\frac{\partial f(y,u)}{\partial\xi}-\operatorname{div}_y(\mathbf{v}(y)G(x,y))\right\}\phi_\varepsilon\,d\Omega_y$$
$$-\frac{1}{2\pi\varepsilon}\int_\Omega\{G(x,y)-G_\varepsilon(x,y)\}\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y$$

$$+\frac{1}{2\pi\varepsilon}\int_{\Omega_\varepsilon-\Omega} G_\varepsilon(x,y)\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y \tag{2.18}$$
$$+\frac{1}{4\pi}\int_\Omega G(x,y)\frac{\partial^2 f(y,u^*)}{\partial\xi^2}\phi_\varepsilon(u-u_\varepsilon)\,d\Omega_y,$$

where u^* lies between u and u_ε.

Let us introduce the integral kernel by

$$K(x,y)\equiv -\frac{1}{2\pi}\left\{G(x,y)\frac{\partial f(y,u)}{\partial\xi}-\mathrm{div}_y\,(\mathbf{v}(y)G(x,y))\right\},\qquad x,y\in\Omega, \tag{2.19}$$

and introduce functions $F(x,\varepsilon)$ etc. by

$$\begin{aligned}F(x,\varepsilon)=&-\frac{1}{2\pi\varepsilon}\int_\Omega\{G(x,y)-G_\varepsilon(x,y)\}\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y\\&+\frac{1}{2\pi\varepsilon}\int_{\Omega_\varepsilon-\Omega} G_\varepsilon(x,y)\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y\\&+\frac{1}{4\pi}\int_\Omega G(x,y)\frac{\partial^2 f(y,u^*)}{\partial\xi^2}\phi_\varepsilon(u-u_\varepsilon)\,d\Omega_y\\&\equiv F_1(x,\varepsilon)+F_2(x,\varepsilon)+F_3(x,\varepsilon).\end{aligned} \tag{2.20}$$

Then (2.18) is rewritten as an integral equation on Ω:

$$\phi_\varepsilon(x)=\int_\Omega K(x,y)\phi_\varepsilon(y)\,d\Omega_y+F(x,\varepsilon). \tag{2.21}$$

In order to investigate (2.21), let us examine the properties of the integral kernel $K(x,y)$. Noting that $G(x,y)$ is the Green's function in two-dimensional domain Ω, we can easily conclude that the kernel has the following properties:

(i) $K(x,y)$ is continuous in both variables x and y except at the points $x=y$;

(ii) there exist constants c_5, c_6 and c_7 such that

$$|K(x,y)|\leqq\frac{c_5}{|x-y|}+c_6\ln\frac{c_7}{|x-y|},\qquad x,y\in\Omega. \tag{2.22}$$

Here we used the assumptions for $f(x\cdot\xi)$, $\mathbf{v}(x)$, and used the fact that $G(x,y)$ has a logarithmic singularity. The estimate (2.22) enables us to make an argument along the classical potential theory [8, Chap. 11], [12, Chap. 8]. Thus, we can say that the new integral kernel defined by $K(x,y;\lambda)\equiv\lambda K(x,y)$ has the resolvent kernel $R(x,y;\lambda)$ which satisfies

$$K(x,y;\lambda)=R(x,y;\lambda)-\int_\Omega K(x,z;\lambda)R(z,y;\lambda)\,d\Omega_z,$$

λ being a (complex) parameter. Of course, $R(x,y;\lambda)$ is expressed by [8, Chap. 11], [12, Chap. 8]

$$R(x,y;\lambda)=K(x,y;\lambda)+K_1(x,y;\lambda)+\frac{M_1(x,y;\lambda)}{\eta(\lambda)},\qquad x,y\in\Omega. \tag{2.23}$$

Here $K_1(x,y;\lambda)$ is the first iterated kernel of $K(x,y;\lambda)$, $M_1(x,y;\lambda)$ is continuous in

x, y and analytic in λ, and $\eta(\lambda)$ is an analytic function of λ. The poles of $R(x, y; \lambda)$ are just the poles of M_1/η.

Now we have the following lemma; the proof will be given in Appendix 2.

LEMMA 3. *The resolvent* $R(x, y; \lambda)$ *does not have pole* $\lambda = 1$. *Hence, the kernel* $K(x, y)$ *has the resolvent* $R(x, y) = R(x, y; 1)$.

As is well known in the classical potential theory, the resolvent has the same singularity as that of the kernel $K(x, y)$; more precisely, $R(x, y)$ has the following estimate

$$|R(x, y)| \leqq c_8 \frac{1}{|x-y|} + c_9 \ln \frac{c_{10}}{|x-y|}, \tag{2.24}$$

c_8, c_9 and c_{10} being constants.

Thus, the solution ϕ_ε of the integral equation (2.21) can be expressed by

$$\phi_\varepsilon(x) = F(x, \varepsilon) + \int_\Omega R(x, z) F(z, \varepsilon)\, d\Omega_z. \tag{2.25}$$

If we show that each term of $F(x, \varepsilon)$ converges to a certain function and is bounded, then, thanks to (2.24), $\phi_\varepsilon(x)$ is shown to approach a function.

Let us examine each term of $F(x, \varepsilon)$ in turn. In view of Lemma 1, (2.10) and (2.12) it is obvious that

$$F_1(x, \varepsilon) \to F_0(x) \equiv \frac{1}{2\pi} \int_\Omega \delta G(x, y)\{f(y, u) + (\mathbf{v} \cdot \nabla)_y\}\, d\Omega_y \quad (\varepsilon \to 0), \quad \text{for every } x \in \Omega. \tag{2.26}$$

Since the logarithmic singularities of Green's functions are eliminated by subtraction and u_ε is uniformly bounded, $F_1(x, \varepsilon)$ is uniformly bounded; i.e. for a constant c_{11}

$$|F_1(x, \varepsilon)| \leqq c_{11}. \tag{2.27}$$

Obviously,

$$F_2(x, \varepsilon) \to 0 \quad (\varepsilon \to 0) \quad \text{for every } x \in \Omega, \tag{2.28}$$

because $G_\varepsilon(x, y) = 0$ provided $y \in \Gamma_\varepsilon$. The modulus of $F_2(x, \varepsilon)$ can be bounded by

$$\begin{aligned} |F_2(x, \varepsilon)| &\leqq \frac{1}{\varepsilon}(c_0 + \max_{\Omega_0} |\mathbf{v}(x)| K_3) \int_{\Omega_\varepsilon - \Omega} |G_\varepsilon(x, y)|\, d\Omega_y \\ &\leqq \Big\{ (c_0 + K_3 \max_{\Omega_0} |\mathbf{v}(x)|) c_{12} \ln \frac{c_{13}}{\zeta} \oint_\Gamma \rho(s)\, ds \\ &\qquad + 2c_g \max_\Gamma |\rho(s)|(\zeta - \zeta \ln \zeta) + c_{14} \Big\}, \end{aligned}$$

where c_{12}, c_{13}, c_{14} are constants, ζ is a sufficiently small fixed number, and c_g is a geometric factor dependent on only Ω. This estimate shows that $F_2(x, \varepsilon)$ is uniformly bounded; i.e., for a constant c_{15},

$$|F_2(x, \varepsilon)| \leqq c_{15}. \tag{2.29}$$

Finally, since $\partial^2 f/\partial \xi^2$ is continuous and u_ε converges uniformly to u, we obtain for a constant c_{16}

$$\left| \frac{\partial^2 f}{\partial \xi^2}(y, u^*) \right| \leqq c_{16}.$$

This, (2.9) and (2.10) yield

$$|F_3(x, \varepsilon)| \leqq c_{17} \tag{2.30}$$

and at the same time

$$F_3(x, \varepsilon) \to 0 \quad (\varepsilon \to 0) \quad \text{for } x \in \Omega, \tag{2.31}$$

c_{17} being a constant.

Combining (2.26)-(2.31), we can conclude that

$$\phi_\varepsilon(x) \to \phi(x) \equiv F_0(x) + \int_\Omega R(x, z) F_0(z)\, d\Omega_z, \qquad x \in \Omega. \tag{2.32}$$

In other words, we established (2.5) for the case where every Ω_ε contains Ω.

An easy but tedious examination of the above derivation shows that the term $o(\varepsilon)$ in (2.5) is uniformly bounded.

2.2. Convergence in the general case and the equation of variation. We have just proved (2.5) in the case of nonnegative $\rho(s)$. From this result, it is possible to prove Theorem 1 in the general case, by using the Hadamard's device [6, p. 295], [2]. However this procedure calls for very tedious calculations, since domain dependent quantites appear in this procedure. So we shall prove the theorem along the argument in the former subsection, which will be a great help for reading this subsection.

Let $\rho(s)$ be an arbitrary, piecewise continuously differentiable function. In this case, the boundary curves Γ and Γ_ε may intercross each other. We can assert the following proposition in this case, too. The proof is almost similar to that of Proposition 1; it may therefore be omitted.

PROPOSITION 2. *Let the positive ε be bounded.*

(i) *Then, there exist constants K_4, K_5 and K_6 such that*

$$|u_\varepsilon(x)| \leqq K_4, \quad |\nabla u_\varepsilon| \leqq K_5, \quad |\phi_\varepsilon(x)| \leqq K_6, \qquad x \in \Omega_\varepsilon, \tag{2.33}$$

where, of course, ϕ_ε is defined by (2.7). *The last inequality of* (2.33) *implies that u_ε converges to u uniformly in every compact subdomain of Ω.*

(ii) *For every $x \in \Omega$, ∇u_ε converges to ∇u.*

Let us define Ω_ε^0, Ω_ε^1 and Ω_ε^2 by

$$\Omega_\varepsilon^0 = \Omega \cap \Omega_\varepsilon, \quad \Omega_\varepsilon^1 = \Omega - \Omega_\varepsilon^0, \quad \Omega_\varepsilon^2 = \Omega_\varepsilon - \Omega_\varepsilon^0. \tag{2.34}$$

Obviously, when ε approaches zero,

$$\Omega_\varepsilon^0 \to \Omega, \quad \Omega_\varepsilon^1 \to \varnothing, \quad \Omega_\varepsilon^2 \to \varnothing,$$

$\varnothing$ being the empty set. It is obvious that there exists a positive $\varepsilon(x)$ for any $x \in \Omega$ such that $x \in \Omega_\varepsilon^0$ $(0 < \varepsilon < \varepsilon(x))$. Therefore, in what follows, we shall understand that x belongs to Ω_ε^0 unless otherwise stated. We may assume that $\kappa = 0$ in this subsection, too. From (2.6), (2.16) and (2.17) we can easily obtain

$$u(x) - u_\varepsilon(x) = -\frac{1}{2\pi} \int_{\Omega_\varepsilon^0} \left\{ G(x, y) \frac{\partial f(y, u)}{\partial \xi} - \operatorname{div}_y (\mathbf{v}(y) G(x, y)) \right\} (u - u_\varepsilon)\, d\Omega_y$$

$$-\frac{1}{2\pi} \int_{\Omega_\varepsilon^0} \varepsilon \delta G(x, y) \{ f(y, u) + (\mathbf{v} \cdot \nabla)_y u \}\, d\Omega_y$$

$$-\frac{1}{2\pi} \int_{\Omega_\varepsilon^0} \varepsilon^2 \gamma(x, y; \varepsilon) \{ f(y, u) + (\mathbf{v} \cdot \nabla)_y u \}\, d\Omega_y$$

$$
\begin{aligned}
(2.35)\qquad & -\frac{1}{2\pi}\int_{\Omega_\varepsilon^0}(G-G_\varepsilon)\{f(y,u_\varepsilon)-f(y,u)+(\mathbf{v}\cdot\nabla)_y(u_\varepsilon-u)\}\,d\Omega_y \\
& -\frac{1}{2\pi}\Bigg[\int_{\Omega_\varepsilon^1}G(x,y)\{f(y,u)+(\mathbf{v}\cdot\nabla)_y u\}\,d\Omega_y \\
& \qquad -\int_{\Omega_\varepsilon^2}G_\varepsilon(x,y)\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y\Bigg] \\
& +\frac{1}{4\pi}\int_{\Omega_\varepsilon^0}G(x,y)\frac{\partial^2 f(y,u^*)}{\partial\xi^2}(u-u_\varepsilon)^2\,d\Omega_y \\
& -\frac{1}{2\pi}\int_{\Gamma_\varepsilon\cap\Omega}G(x,y)u(y)\mathbf{v}\cdot\mathbf{n}\,d\Gamma_y,
\end{aligned}
$$

where u^* lies between u and u_ε. If we introduce $\bar{r}(x,\varepsilon)$ by

$$
\begin{aligned}
& \bar{r}(x,\varepsilon)\equiv\sum_{i=1}^{5}r_i(x,\varepsilon), \\
& r_1(x,\varepsilon)\equiv-\frac{1}{2\pi}\int_{\Omega_\varepsilon^0}\varepsilon\gamma(x,y;\varepsilon)\{f(y,u)+(\mathbf{v}\cdot\nabla)_y u\}\,d\Omega_y, \\
& r_2(x,\varepsilon)\equiv-\frac{1}{2\pi\varepsilon}\int_{\Omega_\varepsilon^0}(G-G_\varepsilon)\{f(y,u_\varepsilon)-f(y,u)+(\mathbf{v}\cdot\nabla)_y(u_\varepsilon-u)\}\,d\Omega_y, \\
(2.36)\qquad & r_3(x,\varepsilon)\equiv-\frac{1}{2\pi\varepsilon}\Bigg[\int_{\Omega_\varepsilon^1}G(x,y)\{f(y,u)+(\mathbf{v}\cdot\nabla)_y u\}\,d\Omega_y \\
& \qquad -\int_{\Omega_\varepsilon^2}G_\varepsilon(x,y)\{f(y,u_\varepsilon)+(\mathbf{v}\cdot\nabla)_y u_\varepsilon\}\,d\Omega_y\Bigg], \\
& r_4(x,\varepsilon)\equiv\frac{1}{4\pi\varepsilon}\int_{\Omega_\varepsilon^0}G(x,y)\frac{\partial^2 f(y,u^*)}{\partial\xi^2}(u-u_\varepsilon)^2\,d\Omega_y, \\
& r_5(x,\varepsilon)\equiv-\frac{1}{2\pi\varepsilon}\int_{\Gamma_\varepsilon\cap\Omega}G(x,y)u(y)\mathbf{v}\cdot\mathbf{n}\,d\Gamma_y,
\end{aligned}
$$

we can obtain, from (2.35) and (2.19),

$$
\begin{aligned}
(2.37)\qquad & \phi_\varepsilon(x)=\int_{\Omega_\varepsilon^0}K(x,y)\phi_\varepsilon(y)\,d\Omega_y \\
& \qquad -\frac{1}{2\pi}\int_{\Omega_\varepsilon^0}\delta G(x,y)\{f(y,u)+(\mathbf{v}\cdot\nabla)_y u\}\,d\Omega_y+\bar{r}(x,\varepsilon).
\end{aligned}
$$

Equation (2.37) can be regarded as an integral equation for ϕ_ε. This integral equation is, however, difficult to be handled, since the domain of definition varies with ε. We shall therefore use a little device instead of dealing directly with (2.37).

Consider the following integral equation for ϕ:

$$
\begin{aligned}
(2.38)\qquad & \phi(x)=\int_{\Omega}K(x,y)\phi(y)\,d\Omega_y \\
& \qquad -\frac{1}{2\pi}\int_{\Omega}\delta G(x,y)\{f(y,u)+(\mathbf{v}\cdot\nabla)_y u\}\,d\Omega_y, \qquad x\in\Omega.
\end{aligned}
$$

It is seen from Lemma 3 that this integral equation admits a unique solution $\phi(x)$ which is a continuous function on Ω. Let $\Phi_\varepsilon(x)$ be defined by

$$\Phi_\varepsilon(x) \equiv \phi(x) - \phi_\varepsilon(x). \tag{2.39}$$

Subtracting (2.37) from (2.38), we obtain the following integral equation for $\Phi_\varepsilon(x)$:

$$\begin{aligned}\Phi_\varepsilon(x) = &\int_{\Omega_\varepsilon^0} K(x, y)\Phi_\varepsilon(y)\, d\Omega_y + \int_{\Omega-\Omega_\varepsilon^0} K(x, y)\phi(y)\, d\Omega_y \\ &- \frac{1}{2\pi}\int_{\Omega-\Omega_\varepsilon^0} \delta G(x, y)\{f(y, u) + (\mathbf{v}\cdot\nabla)_y u\}\, d\Omega_y - \bar{r}(x, \varepsilon).\end{aligned} \tag{2.40}$$

Let $r(x, \varepsilon)$ be given by

$$\begin{aligned} r(x, \varepsilon) &= -\bar{r}(x, \varepsilon) + r_6(x, \varepsilon) + r_7(x, \varepsilon), \\ r_6(x, \varepsilon) &= \int_{\Omega-\Omega_\varepsilon^0} K(x, y)\phi(y)\, d\Omega_y, \\ r_7(x, \varepsilon) &= -\frac{1}{2\pi}\int_{\Omega-\Omega_\varepsilon^0} \delta G(x, y)\{f(y, u) + (\mathbf{v}\cdot\nabla)_y u\}\, d\Omega_y. \end{aligned} \tag{2.41}$$

Integral equation (2.40) is then rewritten as

$$\Phi_\varepsilon(x) = \int_{\Omega_\varepsilon^0} K(x, y)\Phi_\varepsilon(y)\, d\Omega_y + r(x, \varepsilon). \tag{2.42}$$

If the resolvent $R_\varepsilon(x, y)$ of $K(x, y)$ on Ω_ε^0 exists, the solution of (2.42) can be given by

$$\Phi_\varepsilon(x) = r(x, \varepsilon) + \int_{\Omega_\varepsilon^0} R_\varepsilon(x, z) r(z, \varepsilon)\, d\Omega_z. \tag{2.43}$$

Let us show that $R_\varepsilon(x, y)$ really exists provided that ε is small enough. Consider the resolvent $R(x, y; \lambda; \varepsilon)$ of $K(x, y; \lambda) \equiv \lambda K(x, y)$ on Ω_ε^0. By the discussion similar to that in § 2.1, we see that $R(x, y; \lambda; \varepsilon)$ is expressed by

$$R(x, y; \lambda; \varepsilon) = K(x, y; \lambda) + K_1(x, y; \lambda; \varepsilon) + \frac{M(x, y; \lambda; \varepsilon)}{\eta(\lambda; \varepsilon)}. \tag{2.44}$$

Here, $K_1(x, y; \lambda; \varepsilon)$ is the first iterated kernel of $K(x, y; \lambda)$ on Ω_ε^0, and $M(x, y; \lambda; \varepsilon)$ is continuous in both x and y. The analytic function $\eta(\lambda; \varepsilon)$ is given by a series each term of which is the iterated integral of the Fredholm determinant on Ω_ε^0 [8, Chap. 11], [12, Chap. 8]. As is easily seen, the Fredholm determinant is continuous with respect to ε, and hence the integral of it is continuous in ε. While the series is uniformly convergent, $\eta(\lambda; \varepsilon)$ is continuous in ε. Since $\eta(\lambda; \varepsilon)$ is not only continuous in ε but also analytic with respect to λ, it follows immediately from Lemma 3 that $M(x, y; \lambda; \varepsilon)/\eta(\lambda; \varepsilon)$ does not have pole $\lambda = 1$ provided that ε is small enough. This means that $R_\varepsilon(x, y)$ exists and is given by $R_\varepsilon(x, y) = R(x, y; 1; \varepsilon)$ if ε is sufficiently small. Moreover, it is easy to show that there exist constants c_{17}, c_{18} and c_{19} such that

$$|R_\varepsilon(x, y)| \leqq c_{17}\frac{1}{|x-y|} + c_{18}\ln\frac{c_{19}}{|x-y|}. \tag{2.45}$$

In view of Proposition 2, it is possible to show that $r(x, \varepsilon)$ is uniformly bounded and converges to zero; more precisely, for a constant K_7 and for every $x \in \Omega$,

$$|r(x, \varepsilon)| \leqq K_7 \quad \text{and} \quad r(x, \varepsilon) \to 0 \qquad (\varepsilon \to 0). \tag{2.46}$$

In fact, it is obvious from Lemma 1 and Proposition 2 that $r_1(x, \varepsilon)$, $r_2(x, \varepsilon)$ are bounded and approach zero, respectively. As for $r_3(x, \varepsilon)$ and $r_4(x, \varepsilon)$, we can employ the same argument as that in § 2.2; hence, they are bounded and converge to zero. Noting that $G(x, y)$, $u(y)$ are zero at $y \in \Gamma$ and that $\Gamma_\varepsilon \cap \Omega$ is close to Γ, we can conclude that $r_5(x, \varepsilon)$ is bounded and approaches zero. Finally, it is easy to see that $r_6(x, \varepsilon)$, $r_7(x, \varepsilon)$ are bounded and converge to zero, since $K(x, y)$, $\delta G(x, y)$ are integrable and the measure of $\Omega - \Omega_\varepsilon^0$ approaches zero. Thus, (2.46) has been established.

From (2.43), (2.45) and (2.46), it readily follows that $\Phi_\varepsilon \to 0$ $(\varepsilon \to 0)$. This means that $\phi_\varepsilon \to \phi$ $(\varepsilon \to 0)$ for every $x \in \Omega$; i.e. we have proved (2.5) for arbitrary $\rho(s)$. Again, it is possible to show that the term $o(\varepsilon)$ in (2.5) is uniformly bounded in this case, too. The proof of Theorem 1 is thereby completed.

Now we wish to derive the relation between the first variation $\phi(x)$ of the solution and the boundary variation $\rho(s)$. In what follows and in the next section, we shall rewrite $\rho(s)$ as $\delta n(s)$ (or simply δn) and rewrite $\phi(x)$ as $\delta u(x)$ (or δu). As an immediate corollary to Theorem 1, we have

COROLLARY 1. *The variation $\delta u(x)$ is related to $\delta n(s)$ through*

$$\delta u(x) = \int_\Omega K(x, y)\delta u(y)\, d\Omega_y - \frac{1}{2\pi} \oint_\Gamma \frac{\partial u(y)}{\partial n_y} \delta n(y) \frac{\partial G(x, y)}{\partial n_y}\, d\Gamma_y, \qquad x \in \Omega. \tag{2.47}$$

Proof. We give only the outline of the proof. Using a fundamental solution $U(x, y)$ of the Laplacian, we can represent $u = u_\varepsilon$ by an integral equation similar to (2.18). The formula (2.5) helps us to obtain an integral equation for $\delta u(x)$ by the limiting process. After replacing $U(x, y)$ by $G(x, y)$ we obtain (2.47). This completes the proof.

Note that we can obtain (2.47) also from (2.38) by changing the order of integration, and that (2.47) admits a unique solution owing to Lemma 3.

From Corollary 1, we can easily derive an equivalent characterization for $\delta u(x)$.

COROLLARY 2. *The variation $\delta u(x)$ is the solution of the following boundary value problem:*

$$\begin{aligned} &(\Delta - \mathbf{v}(x) \cdot \nabla)\delta u(x) = \frac{\partial f(x, u)}{\partial \xi} \delta u(x), && x \in \Omega, \\ &\delta u(x) = \frac{\partial u(x)}{\partial n} \delta n(x), && x \in \Gamma. \end{aligned} \tag{2.48}$$

Proof. First note that (2.48) has a unique solution owing to (2.1). On the other hand, the solution of (2.47) is unique. Thus the solution of (2.48) is just the variation $\delta u(x)$ determined by (2.47). This completes the proof.

3. Multiplier rule. In this section we shall derive a necessary condition, which is, so to speak, a multiplier rule, for optimality of the domain in the optimization problem posed in § 1, assuming that the problem has a solution. This condition is based on (2.47). Another form of the necessary condition will be obtained from (2.48), too.

Let the domain Ω with the sufficiently smooth boundary Γ be an optimal domain. Let $u(x)$ be the corresponding solution of (1.1). Thanks to (2.5), it is possible to calculate the first order variation δJ of the functional J defined by (1.2). In fact, let δn be the boundary variation with the properties stated in the previous section and let δu be the corresponding variation of u. It is easy, with the help of (2.5), to obtain

$$\delta J = \int_\Omega \frac{\partial g(x, u)}{\partial \xi} \delta u\, d\Omega_x + \oint_\Gamma g(x, u)\delta n\, d\Gamma_x, \tag{3.1}$$

where we supposed that $g(x, \xi)$ is continuous in x and continuously differentiable in ξ.

Let us define a function $\lambda(x)$ by

$$\lambda(x) - \int_\Omega \lambda(y) K(y, x)\, d\Omega_y = \frac{\partial g(x, u)}{\partial \xi}, \qquad x \in \Omega \tag{3.2}$$

In view of Lemma 3, (3.2) has the unique solution $\lambda(x)$ for given $u(x)$; the equation (3.2), thus, really defines the continuous function $\lambda(x)$. Substitution of (3.2) into (3.1) yields

$$\delta J = \int_\Omega \lambda(x) \left\{ \delta u(x) - \int_\Omega K(x, y) \delta u(y)\, d\Omega_y \right\} d\Omega_x + \oint_\Gamma g(x, u) \delta n\, d\Gamma_x. \tag{3.3}$$

Again, substituting (2.47) into (3.3), we obtain

$$\delta J = \oint_\Gamma \left\{ \frac{1}{2\pi} \frac{\partial u(x)}{\partial n_x} \left(\int_\Omega \lambda(y) \frac{\partial G(y, x)}{\partial n_x}\, d\Omega_y \right) + g(x, u) \right\} \delta n(x)\, d\Gamma_x. \tag{3.4}$$

Thus $\delta u(x)$ has been eliminated from δJ. From the constraint (1.3), $\delta n(x)$ should satisfy

$$\oint_\Gamma h(x) \delta n(x)\, d\Gamma_x = 0. \tag{3.5}$$

Combining (3.4) and (3.5), we can conclude that there exists a constant λ_0 such that

$$\frac{1}{2\pi} \frac{\partial u(x)}{\partial n} \left(\int_\Omega \lambda(y) \frac{\partial G(y, x)}{\partial n_x}\, d\Omega_y \right) + g(x, u) = \lambda_0 h(x), \qquad x \in \Gamma. \tag{3.6}$$

In summary, we obtained the following necessary condition for the optimality of Ω.

THEOREM 2. *If Ω is an optimal domain and $u(x)$ is the corresponding solution of* (1.1), *then there exist a continuous function $\lambda(x)$ and a constant λ_0 such that*

$$\lambda(x) - \int_\Omega \lambda(y) K(y, x)\, d\Omega_y = \frac{\partial g(x, u)}{\partial \xi}, \qquad x \in \Omega, \tag{3.2}$$

$$\frac{1}{2\pi} \frac{\partial u(x)}{\partial n} \left(\int_\Omega \lambda(y) \frac{\partial G(y, x)}{\partial n_x}\, d\Omega_y \right) + g(x, u) = \lambda_0 h(x), \qquad x \in \Gamma. \tag{3.6}$$

We may call (3.2) an Euler-Lagrange equation in the wider sense. Equation (3.6) is the transversality condition.

From (2.48) we can obtain another form of the necessary condition.

THEOREM 3. *If Ω is an optimal domain and $u(x)$ is the corresponding solution of* (1.1), *then there eixst a function $p(x)$ and a constant λ_0 such that*

$$\begin{aligned} &\Delta p(x) + \operatorname{div}(\mathbf{v}(x) p(x)) - \frac{\partial f(x, u)}{\partial \xi} p(x) = \frac{\partial g(x, u)}{\partial \xi}, \qquad x \in \Omega, \\ &p(x) = 0, \qquad x \in \Gamma, \end{aligned} \tag{3.7}$$

$$-\frac{\partial u}{\partial n} \frac{\partial p}{\partial n} + g(x, u) = \lambda_0 h(x), \qquad x \in \Gamma. \tag{3.8}$$

Proof. Boundary value problem (3.7) admits a unique solution $p(x)$ due to (2.2). Substitution of (3.7) into (3.1) and integration by parts yield

$$\delta J = \oint_{\Gamma} \left\{ -\frac{\partial u}{\partial n}\frac{\partial p}{\partial n} + g(x, u) \right\} \delta n(x)\, d\Gamma_x. \tag{3.9}$$

From this and (3.5) we obtain (3.8). The proof is thereby completed.

We derived a necessary condition and its equivalent, which will play an important role in the investigation of the properties of the optimal domain as well as in the development of numerical methods for the optimization problem.

Recently, Zolesio [22] has pointed out that the first variation of the objective function takes the form similar to (3.9) in the case of linear boundary value problems, assuming the existence of $\delta u(x)$. As far as the author knows, no author showed the existence of $\delta u(x)$, especially in the case of the nonlinear boundary value problem.

4. Concluding remarks. We have derived the variational equations (2.47) and (2.48), each of which relates the first order variation δu of the solution of the elliptic boundary value problem to the variation of the domain. These equations are based on the relation (2.5), which also plays a fundamental role for deriving the first order variation δJ of the functional J. From the variational equation (2.47) and the expression for δJ a necessary condition for optimality of the domain Ω is obtained. This condition is composed of the Euler-Lagrange equation in the wider sense and the transversality condition. Another equivalent form of the necessary condition is derived from (2.48), too.

These necessary conditions are expected to be used in the investigation of the properties of the optimal domain and to be useful for developing the numerical method to seek the optimal domain. Our results are, however, only the first step for dealing with the real physical problem stated in § 1. The application of our results to this physical problem will be reported in a further paper.

From the theoretical point of view, there remain various problems. Namely, the existence of an optimal domain should be made clear. Lions [10] gives an existence result for a domain optimization problem which is different from that considered in this paper. We must give a sufficient condition, too. Further necessary conditions will be important for the investigation of the properties of the optimal domain as well as for the development of the numerical method. Our method and results are to be extended to a wider class of problems including optimal designs of vibrating plates or rods in structural mechanics and even to the dynamical problems described by, e.g., parabolic partial differential equations.

Appendix 1. Let us prove (2.5) for the case where $f(x, u)$ does not depend on u and $\mathbf{v}(x) \equiv 0$. Let u and u_ε be the solutions of the boundary value problems:

$$\begin{aligned} &\Delta u = f(x), && x \in \Omega, \\ &u = \kappa, && x \in \Gamma, \end{aligned} \tag{A.1}$$

$$\begin{aligned} &\Delta u_\varepsilon = f(x), && x \in \Omega_\varepsilon, \\ &u = \kappa, && x \in \Gamma_\varepsilon, \end{aligned} \tag{A.2}$$

respectively. Also in this case we can assume that $\kappa = 0$ without loss of generality. The solutions u and u_ε are expressed by

$$u(x) = -\frac{1}{2\pi}\int_G G(x, y) f(y)\, d\Omega_y, \tag{A.3}$$

$$u_\varepsilon(x) = -\frac{1}{2\pi}\int_{\Omega_\varepsilon} G_\varepsilon(x, y) f(y)\, d\Omega_y, \tag{A.4}$$

respectively. Let Ω_ε^0, Ω_ε^1 and Ω_ε^2 be as in the text (§ 2.2). Subtracting (A.4) from (A.3), we readily obtain

$$\begin{aligned} u(x) - u_\varepsilon(x) = &-\frac{1}{2\pi}\int_{\Omega_\varepsilon^0} (G - G_\varepsilon) f(y)\, d\Omega_y \\ &-\frac{1}{2\pi}\left[\int_{\Omega_\varepsilon^1} G(x, y) f(y)\, d\Omega_y - \int_{\Omega_\varepsilon^2} G_\varepsilon(x, y) f(y)\, d\Omega_y\right]. \end{aligned}$$

From this and Lemma 1, it follows that

$$\begin{aligned} \phi_\varepsilon(x) = &-\frac{1}{2\pi}\int_{\Omega_\varepsilon^0} \delta G(x, y) f(y)\, d\Omega_y \\ &-\frac{1}{2\pi}\varepsilon\int_{\Omega_\varepsilon^0} \gamma(x, y; \varepsilon) f(y)\, d\Omega_y \\ &-\frac{1}{2\pi\varepsilon}\left[\int_{\Omega_\varepsilon^1} G(x, y) f(y)\, d\Omega_y - \int_{\Omega_\varepsilon^2} G_\varepsilon(x, y) f(y)\, d\Omega_y\right]. \end{aligned} \tag{A.5}$$

Let ε approach zero in (A.5). It is easy to see that

$$-\frac{1}{2\pi}\int_{\Omega_\varepsilon^0} \delta G(x, y) f(y)\, d\Omega_y \to -\frac{1}{2\pi}\int_{\Omega} \delta G(x, y) f(y)\, d\Omega_y.$$

The second term of the right-hand side of (A.5) obviously tends to zero. As for the third term, we can see by the same reasoning as in the text that it approaches zero. These facts show that (2.5) for the case where $f(x, u)$ does not depend on u and $\mathbf{v}(x) \equiv 0$.

Appendix 2.

Proof of Lemma 3. We shall give the outline of the proof. Suppose that $\lambda = 1$ were a pole of $R(x, y; \lambda)$. Then there would be a function $\phi(x)$, continuous, not identically zero, which satisfies

$$\phi(x) = \int_\Omega K(x, y; 1)\phi(y)\, d\Omega_y = \int_\Omega K(x, y)\phi(y)\, d\Omega_y. \tag{A.6}$$

From the definition (2.19) of $K(x, y)$ and by integration by parts, (A.6) turns out to be

$$\phi(x) = -\frac{1}{2\pi}\int_\Omega G(x, y)\left\{\frac{\partial f(y, u)}{\partial \xi}\phi + (\mathbf{v}\cdot\nabla)_y\phi\right\} d\Omega_y. \tag{A.7}$$

Thus, the function $\phi(x)$ would satisfy

$$\Delta\phi(x) - (\mathbf{v}\cdot\nabla)\phi(x) - \frac{\partial f(x, u)}{\partial \xi}\phi(x) = 0, \qquad x \in \Omega. \tag{A.8}$$

By letting $x \to z \in \Gamma$ in (A.7), the boundary values of $\phi(x)$ would be zero, i.e.,

$$\phi(x) = 0, \qquad x \in \Gamma. \tag{A.9}$$

In view of (2.1), the solution of the boundary value problem (A.8), (A.9) is unique; $\phi(x) \equiv 0$ is the solution. This is contrarry to the assumption, and hence $\lambda = 1$ is not a pole of $R(x, y; \lambda)$. Lemma 3 is thereby proved.

Acknowledgments. The author thanks the reviewers for their critical readings and helpful comments. He wishes to express his thanks to Professor Y. Sakawa of Osaka University and to Mr. A. Myslinski of System Research Institute of Polish Academy of Science for their comments.

DIFFERENTIAL GAMES OF GENERALIZED PURSUIT AND EVASION*

LEONARD D. BERKOVITZ†

Abstract. Differential games of generalized pursuit and evasion are studied by comparing them with differential games of fixed duration, for which a theory already has been established. It is shown that if the Isaacs condition holds and the data satisfy reasonable hypotheses, then the games have values which are continuous functions of the initial time and state. If the data satisfy appropriate Lipschitz conditions, then the value is Lipschitz continuous and satisfies the Isaacs equation at all points of differentiability of the value.

Key words. differential games, generalized pursuit and evasion, value, Isaacs equation

1. Introduction. In [1] we developed a theory of differential games of fixed duration in which the existence of value and saddle point in the presence of the Isaacs condition was obtained by relatively elementary methods, without recourse to arguments involving stochastic processes and partial differential equations. In [1], the definition of strategy followed that of Friedman [2], [3], while the definition of payoff followed that of Krasovskii and Subbotin [4]. In this paper we shall study differential games of generalized pursuit and evasion under these notions of strategy and payoff. We assume that the reader is familiar with [1] and shall freely use concepts, notations, definitions, etc. introduced there.

Formulated intuitively, the game that we shall study here has its state $x(t)$ at time t determined by the system of differential equations

$$\frac{dx}{dt} = f(t, x, u(t), v(t)), \qquad x(t_0) = x_0, \tag{1.1}$$

where $u(t) \in Y$ is chosen by Player I at each instant of time t and $v(t) \in Z$ is chosen by Player II at each instant of time t. The payoff is

$$\int_{t_0}^{t_f} f^0(s, \phi(s), u(s), v(s))\, ds, \tag{1.2}$$

where ϕ is the solution of (1.1) and t_f is the first time that $(t, \varphi(t))$ reaches some preassigned terminal set $\mathcal{T}$. Note that if we adjoin a coordinate x^0 to x and a differential equation $dx^0/dt = f^0(t, x, u(t), v(t))$ to (1.1), then if $\hat{x} = (x^0, x)$, we can write the payoff as $\varphi^0(t_f)$.

We shall show that under appropriate conditions on the data of the problem, if the Isaacs condition holds, then the game of generalized pursuit and evasion has a continuous value. We shall obtain these results by comparing our game with a family of games of fixed duration, adapting the idea introduced in Friedman [3] to our definition of the game. Many details will be simpler than in [3]. We shall also show that if we further require the data of the problem to be Lipschitz, then the value function will be Lipschitz continuous and will satisfy the Isaacs equation at points of differentiability.

2. Assumptions and notation. As noted in the introduction we shall use the notation established in [1, § 2]. In addition, we shall let $\hat{x} = (x^0, x)$ and shall let $\hat{f} = (f^0, f^1, \cdots, f^n)$. Concerning $\hat{f}$, we assume the following.

* Received by the editors June 27, 1984, and in revised form December 18, 1984.
† Department of Mathematics, Purdue University, West Lafayette, Indiana 47907.

Assumption I. Statements (i) to (iii) of Assumption I of [1] hold with f replaced by $\hat{f}$.

(iv): $f^0(t, x, y, z) \geqq 0$ for all (t, x, y, z) in $\mathscr{D}$, where $\mathscr{D}$ is as in (2.1) of [1].

In the sequel we shall only need to consider the function f^0 evaluated at points (t, x, y, z) of the form $(t, \varphi(t), u(t), v(t))$ where $\varphi(\cdot) = \varphi(\cdot, t_0, x_0, u, v)$ is an nth state trajectory of (1.1) corresponding to the controls u and v. It follows from (i)-(iii) of Assumption I that for all initial conditions (t_0, x_0) in a given compact set in (t, x)-space, the set of all possible nth stage trajectories resulting from all possible strategies is such that all points $(t, \varphi(t), u(t), v(t))$ lie in a compact subset of $\mathscr{D}$. Hence, since f^0 is continuous, f^0 is bounded below on this set by some constant $-C$, $C > 0$. Hence there is no loss of generality in assuming that $f^0(t, x, y, z) \geqq 0$ on $\mathscr{D}$, for we may replace f^0 by $f^0 + C$.

Assumption I′. Statements (i)-(iii) are as in Assumption I′ of [1] with f replaced by $\hat{f}$.

Assumption II is concerned with the terminal set.

Assumption II. Let F_1 be a closed domain in $(T_0, \infty) \times R^n$ with $C^{(2)}$ boundary ∂F_1. At each point $(t, x) \in \partial F_1$ let

$$\min_z \max_y [\nu_0 + \langle \nu, f(t, x, y, z) \rangle] < 0, \tag{2.1}$$

where (ν_0, ν) is the normal to ∂F_1 at (t, x) pointing to the exterior of F_1, the min is taken over $z \in Z$ and the max over y in Y. Let F denote the intersection of F_1 with the slab $T_0 \leqq t \leqq T$, and let F be bounded. Let the terminal set $\mathscr{T}$ be given by $\mathscr{T} = F \cup ([T, \infty) \times R^n)$.

Assumption II′. Let F_1 be as in Assumption I and let F_1 further satisfy the condition $F_1 \supset ([T, \infty) \times R^n)$. Let $F = F_1$ and let $\mathscr{T} = F$.

3. Definition of game. Let (t_0, x_0) with $(t_0, x_0) \notin \mathscr{T}$ be an initial point of the game. Let Γ be a strategy for Player I on the interval $[t_0, T]$ and Δ a strategy for Player II on the interval $[t_0, T]$, where strategies are defined as in [1]. Corresponding to (Γ, Δ) we obtain a sequence of controls (u_n, v_n) and a sequence of nth stage trajectories $\hat{\varphi}_n(\cdot, t_0, x_0, u_n, v_n)$, where $\hat{\varphi}_n = (\varphi_n^0, \varphi_n)$ satisfies

$$\begin{aligned} \varphi_n^{0\prime}(t) &= f^0(t, \varphi_n(t), u_n(t), v_n(t)), \qquad \varphi_n^0(t_0) = x_n^0, \\ \varphi_n'(t) &= f(t, \varphi_n(t), u_n(t), v_n(t)), \qquad \varphi_n(t_0) = x_n, \end{aligned} \tag{3.1}$$

where $(x_n^0, x_n) \to (0, x_0)$. Note that to determine φ_n we must solve a system of differential equations. Once φ_n is determined, the zeroth component φ_n^0 is determined by a quadrature. A motion $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ is a limit of nth stage trajectories $\hat{\varphi}_n(t_0, x_{0n}, u_n, v_n)$, where (u_n, v_n) are the controls resulting from (Γ_n, Δ_n).

Let $\mathscr{T}$ be either as in Assumption II or Assumption II′. By the *capture time* $t_{f,n}$ of the nth stage trajectory $\hat{\varphi}_n(\cdot)$, we mean the first time such that $(t, \varphi_n(t))$ belongs to $\mathscr{T}$. More precisely, let $C_{t_0,n} = \{t\colon t_0 < t \leqq T\colon (t, \varphi_n(t)) \in \mathscr{T}\}$. Clearly $C_{t_0,n}$ is not empty. Let $t_{f,n} = \inf\{t\colon t \in C_{t_0,n}\}$. The *capture time* t_f of a motion $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ is defined similarly. Note that all points $(t_{f,n}, \varphi_n(t_{f,n}))$ and $(t_f, \varphi[t_f])$ belong to $\mathscr{T}$.

We now define the payoff $P(t_0, x_0, \Gamma, \Delta)$ resulting from a pair of strategies (Γ, Δ) as follows:

$$P(t_0, x_0, \Gamma, \Delta) \equiv \cup\, \varphi^0[t_f, t_0, x_0, \Gamma, \Delta], \tag{3.2}$$

where the union is taken over all motions $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ resulting from (Γ, Δ). Note that t_f in general will be different for different motions. Having defined the strategies

and payoff, the definition of the game is complete. We shall designate this game as "the game G" or "the game $G(t_0, x_0)$", when we wish to call attention to the initial position. We shall let $W^+(t_0, x_0)$ denote the upper value of $G(t_0, x_0)$ and let $W^-(t_0, x_0)$ denote the lower value of $G(t_0, x_0)$. Thus:

$$W^+(t_0, x_0) = \inf_{\Delta} \sup_{\Gamma} P(t_0, x_0, \Gamma, \Delta)\, W^-(t_0, x_0) = \sup_{\Gamma} \inf_{\Delta} P(t_0, x_0, \Gamma, \Delta).$$

4. Comparison with game of fixed duration. We make two simple observations that we shall use. First, since $f^0 \geqq 0$, we have that for any nth stage trajectory $\hat{\varphi}_n(\cdot)$, the zeroth component $\varphi_n^0(\cdot)$ is a nondecreasing function. Similarly, the zeroth component $\varphi^0[\cdot]$ of any motion $\hat{\varphi}[\cdot]$ is nondecreasing. The second observation we state as a Lemma.

LEMMA 4.1. *Let $\{\hat{\varphi}_n(\cdot)\}$ be a sequence of nth stage trajectories converging uniformly to a motion $\hat{\varphi}[\cdot]$. Let $\{t_{f,n}\}$ be the corresponding sequence of capture times for the trajectories and let t_f be the capture time of $\hat{\varphi}[\cdot]$. Then* $\liminf_n \varphi_n^0(t_{f,n}) \geqq \varphi^0[t_f]$. *A similar conclusion holds for any sequence of motions $\{\hat{\varphi}_n[\cdot]\}$ with capture times $\{t_{f,n}\}$ converging uniformly to a motion $\varphi[\cdot]$ with capture time t_f.*

We prove the first statement; the proof of the second is similar. Let $\lambda = \liminf_n \varphi_n^0(t_{f,n})$. Then there exists a subsequence, which we again label as $\hat{\varphi}_n(\cdot)$, such that $\varphi_n^0(t_{f,n}) \to \lambda$ and $t_{f,n} \to \bar{t}$ for some $\bar{t}$ in $[t_0, T]$. Since $\hat{\varphi}_n(\cdot)$ converges uniformly to $\hat{\varphi}[\cdot]$, we have that $\hat{\varphi}_n(t_{f,n}) \to \hat{\varphi}[\bar{t}]$. Since each point $(t_{f,n}, \varphi_n(t_{f,n}))$ belongs to $\mathcal{T}$, and $\mathcal{T}$ is closed, we have that $(\bar{t}, \varphi[\bar{t}]) \in \mathcal{T}$. Hence by the definition of t_f, $\bar{t} \geqq t_f$, and by the monotonicity of φ^0, $\lambda = \varphi^0[\bar{t}] \geqq \varphi^0[t_f]$, which is the desired conclusion.

COROLLARY. *Let $\{t_{f,n}\}$ and t_f be as in the lemma. Then* $\liminf_n t_{f,n} \geqq t_f$.

Let Assumption II hold. Let $\hat{\partial}F$ denote the boundary points of F that are not interior to F_1, i.e.

$$\hat{\partial}F = (\partial F) \cap (\partial F_1).$$

For a point (t, x) with $T_0 \leqq t \leqq T$, let $\rho(t, x)$ denote the signed distance of (t, x) to $\hat{\partial}F$, with negative values assigned to points (t, x) in the interior of F.

For $\varepsilon > 0$, let $(\hat{\partial}F)_\varepsilon = \{(t, x)\colon T_0 \leqq t \leqq T,\ |\rho(t, x)| < \varepsilon\}$. Then since $\hat{\partial}F$ is a $C^{(2)}$ manifold and since F is bounded, it follows that there exists an $\varepsilon_0 > 0$ such that ρ is C' on $(\hat{\partial}F)_{\varepsilon_0}$. Moreover, if (τ, ξ) is a point of $\hat{\partial}F$ with $\tau < T$ and if (ν^0, ν) is the unit normal to $\hat{\partial}F$ at (τ, ξ) pointing to the exterior of F, then

$$\lim_{(t,x)\to(\tau,\xi)} (\rho_t(t, x), \rho_x(t, x)) = (\nu^0, \nu). \tag{4.1}$$

Let Assumption II′ hold. For a point (t, x) let $\rho(t, x)$ now denote the signed distance of (t, x) to ∂F, with negative values assigned to points interior to F. Let $(\partial F)_\varepsilon = \{(t, x)\colon |\rho(t, x)| < \varepsilon\}$. Then for each $R > 0$ there exists an $\varepsilon_0 > 0$ such that ρ is C' in $(\partial F)_{\varepsilon_0} \cap \{(t, x)\colon |x| < R\}$ and (4.1) holds for all (τ, ξ) in $(\partial F)_{\varepsilon_0} \cap \{(t, x)\colon |x| < R\}$.

Let Assumption II or II′ hold. Let $F_\mu = \{(t, x)\colon (t, x) \in F, |\rho(t, x)| < \mu\}$. If Assumption II holds, there exists a $\mu_0 > 0$ such that for all $0 < \mu < \mu_0$, $F - F_\mu \neq \phi$. If Assumption II′ holds, there exists a μ_0 such that for all $0 < \mu < \mu_0$, $(F - F_\mu) \cap \{(t, x)\colon |x| < R\} \neq \phi$.

We now define a family of games of fixed duration. Let Assumption II or II′ hold. Let $\gamma(r) = 1 - r$ if $0 \leqq r \leqq 1$ and let $\gamma(r) = 0$ if $r > 1$. For each $0 < \mu < \mu_0$ let

$$f_\mu^0(t, x, y, z) = \begin{cases} f^0(t, x, y, z)\gamma(|\rho(t, x)|/\mu) & \text{if } (t, x) \in F, \\ f^0(t, x, y, z) & \text{if } (t, x) \notin F. \end{cases}$$

The function f_μ^0 is continuous on $[T_0, T_1] \times R^n \times Y \times Z \times (0, \mu_0)$, and $f_\mu^0(t, x, y, z) = 0$ if $(t, x) \in F - F_\mu$. For each μ in $(0, \mu_0)$ we consider the game G_μ of fixed duration with

terminal time T, with dynamics given by (1.1) and with payoff

$$P_\mu(t_0, x_0, \Gamma, \Delta) = \int_{t_0}^{T} f_\mu^0(s, \varphi(s), u(s), v(s))\, ds.$$

If we introduce a zeroth coordinate x^0 by means of the state equation $dx^0/dt = f_\mu^0(t, x, y, z)$, then the games of fixed duration G_μ will be in the format of [1] with $g(\hat{x}) = x^0$. It is readily verified that Assumption I or I′ of [1] holds for the games G_μ whenever the corresponding assumption holds for the generalized pursuit evasion game G.

Let $W^+(t_0, x_0, \mu)$ and $W^-(t_0, x_0, \mu)$ denote the upper and lower values respectively of the games G_μ, $0 < \mu < \mu_0$, with initial position (t_0, x_0). Let

$$R = (([T_0, \infty) \times R^n) - \mathcal{T}) \cup (\partial \mathcal{T}). \tag{4.2}$$

LEMMA 4.2. *Let Assumption* I *and either Assumption* II *or* II′ *hold. Then for each* (t_0, x_0) *in* R *and each* $0 < \mu < \mu_0$

$$W^-(t_0, x_0) \leqq W^-(t_0, x_0, \mu), \qquad W^+(t_0, x_0) \leqq W^+(t_0, x_0, \mu).$$

For $(t_0, x_0) \in \partial \mathcal{T}$ the result is immediate, since $W^-(t_0, x_0)$ and $W^+(t_0, x_0)$ are equal to zero, and $f_\mu^0 \geqq 0$. We henceforth suppose that $(t_0, x_0) \notin \partial \mathcal{T}$.

Let $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ be a motion in the game $G(t_0, x_0)$ and let $\{\hat{\varphi}_n(\cdot, t_0, x_0, u_n, v_n)\}$ be the sequence of nth stage trajectories converging uniformly to $\hat{\varphi}[\cdot]$. The sequence $\hat{\varphi}_n(\cdot)$ determines a sequence $\{\hat{\varphi}_{\mu,n}(\cdot, t_0, x_0, u_n, v_n)\}$ of nth stage trajectories in the game $G_\mu(t_0, x_0)$ where

$$\begin{aligned}
\varphi_{\mu,n}(t) &= \varphi_n(t), \qquad t_0 \leqq t \leqq T, \\
\varphi_{\mu,n}^0(t) &= \varphi_n^0(t), \qquad t_0 \leqq t \leqq t_{f,n}, \\
&= \varphi_n^0(t_{f,n}) + \int_{t_{f,n}}^{t} f_\mu^0(s, \varphi_n(s), u_n(s), v_n(s))\, ds
\end{aligned}$$

for $t_{f,n} \leqq t \leqq T$. The capture time of $\hat{\varphi}_{\mu,n}(\cdot)$ is obviously also $t_{f,n}$. There exists a subsequence of $\{\hat{\varphi}_{\mu,n}(\cdot)\}$, which we again label as $\{\hat{\varphi}_{\mu,n}(\cdot)\}$ which converges uniformly to a motion $\hat{\varphi}_\mu[\cdot, t_0, x_0, \Gamma, \Delta]$ in the game G_μ, where

$$\varphi_\mu[t, t_0, x_0, \Gamma, \Delta] = \varphi[t, t_0, x_0, \Gamma, \Delta], \qquad t_0 \leqq t \leqq T.$$

Thus $\hat{\varphi}_\mu[\cdot]$ and $\hat{\varphi}[\cdot]$ have the same capture time t_f.

Let $t_n = \min(t_f, t_{f,n})$. Using the corollary to Lemma 4.1, we conclude that $t_n \to t_f$. For $t_0 \leqq t \leqq t_n$, $\varphi_{\mu,n}^0(t) = \varphi_n^0(t)$ and for $t_n \leqq t \leqq T$

$$\varphi_{\mu,n}^0(t) = \varphi_n^0(t_n) + \int_{t_n}^{t} f_\mu^0(s, \varphi_n(s), u_n(s), v_n(s))\, ds.$$

If we now set $t = T$ in the preceding equation and then let $n \to \infty$, we get that $\varphi_\mu^0[T] = \varphi^0[t_f] + E$, where $E \geqq 0$. To summarize, we have shown that for every motion $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ in the game G, there is a motion $\hat{\varphi}_\mu[\cdot, t_0, x_0, \Gamma, \Delta]$ (same Γ, Δ) in the game G_μ such that

$$\varphi^0[t_f, t_0, x_0, \Gamma, \Delta] \leqq \varphi_\mu^0[T, t_0, x_0, \Gamma, \Delta]. \tag{4.3}$$

In a similar fashion we can show that for every motion $\hat{\varphi}_\mu[\cdot, t_0, x_0, \Gamma, \Delta]$ in the game G_μ there is a motion $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ in the game G such that (4.3) holds. Hence for

each fixed Γ,

$$\inf_{\Delta} P(t_0, x_0, \Gamma, \Delta) \leqq \inf_{\Delta} P_\mu(t_0, x_0, \Gamma, \Delta),$$

and for each fixed Δ

$$\sup_{\Gamma} P(t_0, x_0, \Gamma, \Delta) \leqq \sup_{\Gamma} P_\mu(t_0, x_0, \Gamma, \Delta).$$

The conclusion of the lemma follows from these inequalities and from the definitions of W^+ and W^-.

LEMMA 4.3. *Let Assumption* I *and either Assumption* II *or* II′ *hold. Let $\mathscr{C}$ be a compact set in R. Then there exists a constant $C>0$ such that for all μ sufficiently small and all (t_0, x_0) in $\mathscr{C}$*

$$W^-(t_0, x_0) \geqq W^-(t_0, x_0, \mu) - C\mu.$$

The proof of the lemma involves an adaptation to our definition of the game of ideas used by Friedman [2], [3]. The proof will be given in several steps and will be carried out under the supposition that $(t_0, x_0) \notin \partial\mathscr{T}$ and that Assumption II holds. The reader will see that the proof is also valid for $(t_0, x_0) \in \partial\mathscr{T}$ if he keeps in mind that if $(t_0, x_0) \in \partial\mathscr{T}$ then $W^-(t_0, x_0) = 0$, that $t_f = t_0$, and consequently that $\varphi[t_f, t_0, x_0, \Gamma, \Delta] = x_0$, $\varphi^0[t_f, t_0, \Gamma, \Delta] = 0$. He should also look upon the strategy Δ^* to be defined below as being a strategy over $[t_0, T]$ in the game $G_\mu(t_0, x_0)$, rather than a modification of Δ. He will have to change the definition of $\Delta^*_{n,1}$ to be any control u_1 in I_1. The proof if Assumption II′ holds is then the same as that if Assumption II holds, except that for $\hat{\partial}F$ one should read ∂F.

We noted earlier that there exists an $\varepsilon_0 > 0$ such that ρ is C' on $(\hat{\partial}F)_{\varepsilon_0}$. Define a function on $(\hat{\partial}F)_{\varepsilon_0} \times Y \times Z$ as follows:

$$\Lambda(t, x, y, z) = \frac{\partial \rho}{\partial t}(t, x) + \sum_{i=1}^{n} \frac{\partial \rho}{\partial x^i}(t, x) f^i(t, x, y, z). \tag{4.4}$$

Let

$$\Lambda_1(t, x) = \min_z \max_y \Lambda(t, x, y, z),$$

where the min is taken over Z and the max over Y. From the continuity of (ρ_t, ρ_x) on $(\hat{\partial}F)_{\varepsilon_0}$, from the compactness of $\hat{\partial}F$, from (2.1) and from (4.1) it follows that there exists an $\varepsilon_1 < \varepsilon_0$ and a constant $A > 0$ such that

$$\Lambda_1(t, x) \leqq -A_1 \qquad (t, x) \in (\hat{\partial}F)_{\varepsilon_1}. \tag{4.5}$$

Let $\Lambda_0(t, x, z) = \max_y \Lambda(t, x, y, z)$ and let $z^*(t, x)$ be an element in Z such that

$$\Lambda_0(t, x, z^*(t, x)) = \min_z \Lambda_0(t, x, z) = \min_z \max_y \Lambda(t, x, y, z)$$

$$= \Lambda_1(t, x).$$

Now,

$$\Lambda(t, x, y, z^*(t, x)) \leqq \max_y \Lambda(t, x, y, z^*(t, x)) = \Lambda_0(t, x, z^*(t, x)).$$

Thus, for all $(t, x) \in (\hat{\partial}F)_{\varepsilon_0}$ and y in Y

$$\Lambda(t, x, y, z^*(t, x)) \leqq \Lambda_1(t, x). \tag{4.6}$$

The function Λ is uniformly continuous on the closure of $(\hat{\partial}F)_{\varepsilon_1} \times Y \times Z$. Hence there exists an $\varepsilon_2 < \varepsilon_1$ and a $\delta > 0$ such that for all (t, x) in $(\hat{\partial}F)_{\varepsilon_2}$ and all (t', x') with

$|(t', x')-(t, x)|<\delta$ we have $(t', x')\in(\hat{\partial}F)_{\varepsilon_1}$ and $|\Lambda(t', x', y, z)-\Lambda(t, x, y, z)|\leqq A/2$ for all $y\in Y$ and $z\in Z$. From this and from (4.6) and (4.5) we get that for all (t, x) in $\operatorname{cl}[(\hat{\partial}F)_{\varepsilon_2}]$ and all $|(t', x')-(t, x)|<\delta$,

$$\Lambda(t', x', y, z^*(t, x))\leqq\Lambda(t, x, y, z^*(t, x))+A/2\leqq -A/2. \tag{4.7}$$

Since ρ is C' on $(\hat{\partial}F)_{\varepsilon_0}$, it follows that for any absolutely continuous function θ whose graph lies in $(\hat{\partial}F)_{\varepsilon_0}$ the mapping $t\to\rho(t, \theta(t))$ is absolutely continuous and

$$\frac{d}{dt}\rho(t, \theta(t))=\rho_t(t, \theta(t))+\langle\rho_x(t, \theta(t)), \theta'(t)\rangle \quad \text{a.e.}$$

(See [2, Lemma 3.2.2].) In particular if φ is a trajectory of (1.1), then

$$\frac{d}{dt}\rho(t, \varphi(t))=\Lambda(t, \varphi(t), u(t), v(t)) \quad \text{a.e.} \tag{4.8}$$

as long as the trajectory lies in $(\hat{\partial}F)_{\varepsilon_0}$.

LEMMA 4.4. *Let (Γ, Δ) be a pair of strategies and let $\{\hat{\varphi}_n(\cdot)=\hat{\varphi}_n(\cdot, t_0, x_{0n}, \Gamma, \Delta)\}$ be a corresponding sequence of nth stage trajectories. Let $\bar{t}\in(t_0, T)$. Then there exists a strategy Δ^*, depending on Δ and $\bar{t}$, and a sequence $\varepsilon(n)\to 0$ as $n\to\infty$ such that if $\{\hat{\varphi}_n^*(\cdot)\}=\{\hat{\varphi}_n^*(\cdot, t_0, x_{0n}, u_n^*, v_n^*)\}$ is the sequence of nth state trajectories resulting from (Γ, Δ^*) and $\{x_{0n}\}$, then the following are true.*

(i) *$\hat{\varphi}_n^*(t)=\hat{\varphi}_n(t)$ for $t_0\leqq t\leqq\bar{t}$.*

(ii) *If $\{t_n\}$ is a sequence converging to $\bar{t}$ and if for all sufficiently large n, $t_n\leqq\bar{t}$ and $(\bar{t}, \varphi_n(\bar{t}))\in(\hat{\partial}F)_{\varepsilon_2}$, then the inequality*

$$\rho(t, \varphi_n^*(t))-\rho(t_n, \varphi_n^*(t_n))\leqq\varepsilon(n)-A(t-t_n)/2 \tag{4.9}$$

holds for these values of n and for all t such that the graph of φ_n^* on the interval $[\bar{t}, t]$ lies in $(\hat{\partial}F)_{\varepsilon_2}$.

Let $\{\pi_n\}$ be a sequence of partitions of $[t_0, T]$ and let π_n have partition points $t_0=\tau_0<\tau_1<\cdots<\tau_n=T$. Let $I_i=[\tau_{i-1}, \tau_i)$, $i=1, \cdots, n$. Let $k=k(n)$ denote the integer such that $\bar{t}\in I_{k+1}$. We define the strategy $\Delta^*=\{\Delta_n^*\}$. Let $\Delta_{n,1}^*=\Delta_{n,1}$. For $2\leqq j\leqq k+1$, let

$$\Delta_{n,j}^*(\mathcal{Y}_1\times\mathcal{Z}_1\times\cdots\times\mathcal{Y}_{j-1}\times\mathcal{Z}_{j-1})=\Delta_{n,j}(\mathcal{Y}_1\times\mathcal{Z}_1\times\cdots\times\mathcal{Y}_{j-1}\times\mathcal{Z}_{j-1}).$$

Let $j>k+1$. For $i=1, \cdots, j-1$, let $u_{n,i}\in\mathcal{Y}_i$, $v_{n,i}\in\mathcal{Z}_i$, and for $t\in I_i$, let $u_n'(t)=u_{n,i}(t)$ and $v_n'(t)=v_{n,i}(t)$. Then u_n' and v_n' are controls on $[t_0, \tau_{j-1})$ and they determine an nth stage trajectory $\hat{\varphi}_n^*(\cdot)=\hat{\varphi}_n^*(\cdot, t_0, x_{0n}, u_n', v_n')$ on $[t_0, \tau_{j-1}]$. We now define $\Delta_{n,j}^*$. If $(\tau_{j-1}, \varphi^*(\tau_{j-1}))\in(\hat{\partial}F)_{\varepsilon_2}$, let

$$(\Delta_{n,j}^*(u_{n,1}, v_{n,1}, \cdots, u_{n,j-1}, v_{n,j-1}))(t)=z^*(\tau_{j-1}, \varphi_n^*(\tau_{j-1}))$$

for all $t\in I_j$. If $(\tau_{j-1}, \varphi_n^*(\tau_{j-1}))\notin(\hat{\partial}F)_{\varepsilon_2}$ let

$$\begin{aligned}&\Delta_{n,j}^*(u_{n,1}, v_{n,1}, \cdots, u_{n,j-1}, v_{n,j-1})\\&\quad=\Delta_{n,j}(u_{n,1}, v_{n,1}, \cdots, u_{n,j-1}, v_{n,j-1}).\end{aligned}$$

By construction $\hat{\varphi}_n^*(t)=\hat{\varphi}_n(t)$ for $t_0\leqq t\leqq\bar{t}$. By assumption $(\bar{t}, \varphi_n(\bar{t}))\in(\hat{\partial}F)_{\varepsilon_2}$ for n sufficiently large, so that for each n there is an interval $[\bar{t}, \bar{t}+\alpha_n)$ on which the graph

of $\hat{\varphi}_n^*(\cdot)$ lies in $(\hat{\partial}F)_{\varepsilon_2}$. It now follows from (4.8) that for $t \in [\bar{t}, \bar{t}+\alpha_n)$

$$
\begin{aligned}
&\rho(t, \varphi_n^*(t)) - \rho(t_n, \varphi_n^*(t_n)) \\
&\quad = \int_{t_n}^{t} \Lambda(s, \varphi_n^*(s), u_n^*(s), v_n^*(s))\, ds \\
&\quad = \int_{t_n}^{\tau_{k+1}} \Lambda(s, \varphi_n(s), u_n^*(s), v_n^*(s))\, ds \\
&\qquad + \sum_{j=1}^{J} \int_{\tau_{k+1}}^{\tau_{k+j+1}} \Lambda(s, \varphi_n^*(s), u_n^*(s), z_j^*)\, ds + \int_{\tau_{k+J}}^{t} \Lambda(s, \varphi_n^*(s), u_n^*(s), z_J^*)\, ds,
\end{aligned} \tag{4.10}
$$

where $J = J(n, t)$ and $z_j^* = z^*(\tau_{k+j}, \varphi_n^*(\tau_{k+j}))$.

We now estimate each of the terms on the right. It follows from Assumption I that there exists a constant $K > 0$, independent of controls u, v and depending only on the compact set $\mathscr{C}$ of initial values such that for all trajectories φ of the system (1.1) we have $|\varphi(t) - \varphi(t')| \leqq K|t - t'|$. Hence the first integral on the right is bounded by $K|\tau_{k+1} - t_n|$, which $\to 0$ as $n \to \infty$. It also follows that there exists an integer n_0 which depends only on $\mathscr{C}$ such that for all partition points τ_i, all nth stage trajectories, $n \geqq n_0$, $\hat{\varphi}_n^*(\cdot)$ resulting from all strategies Γ, Δ^*, we have $|(t, \varphi_n^*(t)) - (\tau_i, \varphi_n^*(\tau_i))| < \delta$, for all t in I_{i+1}, where δ is as in (4.7). Applying this and (4.7) to each integrand in (4.10) other than the first, gives $\Lambda(s, \varphi_n^*(s), u_n^*(s), z_j^*) \leqq -A/2, j = k+1, \cdots, k+J$. Combining this with the bound $K|\tau_{k+1} - t_n|$ on the first integral in (4.10) establishes (4.9) and the lemma.

Remark 4.1. We shall refer to the strategy Δ^* defined above as the modification of Δ by means of the forcing function z^*.

COROLLARY 4.4.1. *Let $\tilde{t} > \bar{t}$. For all n sufficiently large let $(\tilde{t}, \varphi_n^*(\tilde{t})) \in (\hat{\partial}F)_{\varepsilon_2}$ and let the graph of $\varphi_n^*(\cdot)$ on $[\tilde{t}, t]$ lie in $(\hat{\partial}F)_{\varepsilon_2}$. Then for sufficiently large n,*

$$
\rho(t, \varphi_n^*(t)) - \rho(\tilde{t}, \varphi_n^*(\tilde{t})) \leqq -A(t - \tilde{t})/2. \tag{4.11}
$$

Since $\bar{t} < \tilde{t}$, for n sufficiently large, $\tau_{k+1} < \tilde{t}$. Thus, if in (4.10) we replace t_n by $\tilde{t}$, we obtain that the integrand on the right in (4.10) is $\leqq -A/2$ for all $\tilde{t} \leqq s \leqq t$.

LEMMA 4.5. *Let μ satisfy $0 < \mu \leqq \varepsilon_2/2$ and let (Γ, Δ) be strategies in G. Let $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$ be a motion with capture time t_f. Then there exists a $\Delta^* = \Delta^*(\Gamma, \Delta, \hat{\varphi}[\cdot])$ and a motion $\hat{\varphi}_\mu[\cdot, t_0, x_0, \Gamma, \Delta^*]$ in the game G_μ such that for $t_0 \leqq t \leqq t_f$,*

$$
\hat{\varphi}[t, t_0, x_0, \Gamma, \Delta] = \hat{\varphi}_\mu[t, t_0, x_0, \Gamma, \Delta^*], \tag{4.12}
$$

and

$$
\varphi^0[t_f, t_0, x_0, \Gamma, \Delta] \geqq \varphi_\mu^0[T, t_0, x_0, \Gamma, \Delta^*] - C\mu, \tag{4.13}
$$

where C is a constant independent of Γ, Δ, μ and the motion $\hat{\varphi}[\cdot]$, but dependent on the set $\mathscr{C}$ of initial conditions.

We first note that if $t_f = T$, then $\varphi^0[T] = \varphi^0[t_f] = \varphi_\mu^0[t_f] = \varphi_\mu^0[T]$. Thus we can take $\Delta^* = \Delta$ and (4.12) and (4.13) hold for any $C \geqq 0$. Hence we need only consider the case $t_f < T$.

Let $\{\hat{\varphi}_n(\cdot)\} = \{\hat{\varphi}_n(\cdot, t_0, x_{0n}, u_n, v_n)\}$ be the sequence (after relabelling) of nth stage trajectories converging to the motion $\hat{\varphi}[\cdot, t_0, x_0, \Gamma, \Delta]$. Let $t_{f,n}$ be the capture time of $\hat{\varphi}_n(\cdot)$ and let $t_n = \min(t_{f,n}, t_f)$. Then $t_n \leqq t_f$ and, as was seen in the proof of Lemma 4.1, $t_n \to t_f$. Applying Lemma 4.4 with $\bar{t} = t_f$ and $\{t_n\}$ as above, we obtain a strategy Δ^*, a sequence of nth stage trajectories $\{\hat{\varphi}_n^*(\cdot)\} = \{\hat{\varphi}_n^*(\cdot, t_0, x_{0n}, u_n^*, v_n^*)\}$ resulting from (Γ, Δ^*) and a motion $\hat{\varphi}^*[\cdot]$ having the properties stated in Lemma 4.4.

Let

$$\varphi_{\mu,n}(t, t_0, x_0, u_n^*, v_n^*) = \varphi_n^*(t, t_0, x_0, u_n^*, v_n^*) \tag{4.14}$$

for all $t_0 \leqq t \leqq T$. Since for $t_0 \leqq t \leqq t_n$, $\hat{\varphi}_n^*(t) = \hat{\varphi}_n(t)$, we have that

$$\varphi_{\mu,n}(t, t_0, x_0, u_n^*, v_n^*) = \varphi_n(t, t_0, x_0, u_n, v_n) \tag{4.15}$$

for $t_0 \leqq t \leqq t_n$. For $t_0 \leqq t \leqq t_n$, let

$$\varphi_{\mu,n}^0(t, t_0, x_0, u_n^*, v_n^*) = \varphi_n^{*0}(t, t_0, x_0, u_n^*, v_n^*) = \varphi_n^0(t, t_0, x_0, u_n, v_n). \tag{4.16}$$

For $t_n \leqq t \leqq T$, let

$$\varphi_{\mu,n}^0(t) = \varphi_n^0(t_n) + \int_{t_n}^{t} f_\mu^0(s, \varphi_n^*(s), u_n^*(s), v_n^*(s))\, ds. \tag{4.17}$$

The sequence $\{\hat{\varphi}_{\mu,n}(\cdot)\}$ thus defined is clearly a sequence of nth stage trajectories in the game G_μ corresponding to the strategies (Γ, Δ^*). We select a further subsequence so that we may assume that $\hat{\varphi}_{\mu,n}(\cdot)$ converges to a motion $\hat{\varphi}_\mu[\cdot, t_0, x_0, \Gamma, \Delta^*]$ of the game G_μ.

We shall show that the motion $\hat{\varphi}_\mu[\cdot]$ of the previous paragraph has the desired properties. First, we conclude immediately from (4.15) and (4.16) that (4.12) holds.

Now suppose that $t_f < T - (3\mu/A)$. Let $\varepsilon(n)$ be as in Lemma 4.4 and let

$$t_{\mu,n} = t_n + 2[\varepsilon(n) + \rho(t_n, \varphi_n^*(t_n)) + \mu]/A. \tag{4.18}$$

Then for n sufficiently large $t_{\mu,n} < T$. We assert that for each sufficiently large n, there exists an s_n in $[t_n, t_{\mu,n}]$ such that

$$\rho(s_n, \varphi_n^*(s_n)) < -\mu. \tag{4.19}$$

First we suppose that on the interval $[t_n, t_{\mu,n}]$ the graph of $\varphi_n^*(\cdot)$ lies entirely in $(\hat{\partial}F)_{\varepsilon_2}$. We can then set $t = t_{\mu,n}$ in (4.9) and obtain that $\rho(t_{\mu,n}, \varphi_n^*(t_{\mu,n})) < -\mu$.

For those n such that the graph of $\varphi_n^*(\cdot)$ on $[t_n, t_{\mu,n}]$ does not lie entirely in $(\hat{\partial}F)_{\varepsilon_2}$ we proceed as follows. We first note that by virtue of (4.12) we can find a $\tilde{t} > t_f$ such that for all n sufficiently large, the graph of $\varphi_n^*(\cdot)$ on $[t_f, \tilde{t}]$ will lie in $(\hat{\partial}F)_{\varepsilon_2}$. Let $\bar{t} = t_f$ and apply Corollary 4.4.1 to observe that if $t > \tilde{t}$ and if the graph of $\varphi_n^*(\cdot)$ on $[\tilde{t}, t]$ lies in $(\hat{\partial}F)_{\varepsilon_2}$, then $\rho(t, \varphi_n^*(t)) < \rho(\tilde{t}, \varphi_n^*(\tilde{t}))$. From this we conclude that when the trajectory $\varphi_n^*(\cdot)$ leaves $(\hat{\partial}F)_{\varepsilon_2}$, it will do so in the interior of F. Since $\mu < \varepsilon_2/2$, (4.19) follows.

From (4.19) and (4.14) we see that for all n sufficiently large we are assured that the trajectories $\varphi_{\mu,n}(\cdot)$ will eventually leave the set $F_\mu = (\hat{\partial}F)_\mu \cap F$ at some time $t_n < \bar{s}_n < t_{\mu,n}$. If we use Corollary 4.41 with $\bar{t} = t_f$, we can easily show that for sufficiently large n, once the trajectory $\varphi_{\mu,n}(\cdot)$ leaves F_μ, then it will never reenter F_μ and will remain in $F - F_\mu$. Hence for $t_{\mu,n} \leqq t \leqq T$, $f_\mu^0(t, \varphi_{\mu,n}(t), u_n^*(t), v_n^*(t)) = 0$. From this and from (4.17) we get

$$\varphi_{\mu,n}^0(T) = \varphi^0(t_n) + \int_{t_n}^{t_{\mu,n}} f_\mu^0(s, \varphi_n^*(s), u_n^*(s), v_n^*(s))\, ds. \tag{4.20}$$

Recall that $f_\mu^0 \geqq 0$. The integral in (4.20) is bounded above by $K(t_{\mu,n} - t_n)$, where K is a positive constant which depends only on the set $\mathscr{C}$ of initial data. Therefore, if we let $n \to \infty$ in (4.20) and take into account (4.18), we get $\varphi_\mu^0[T] \leqq \varphi^0[t_f] + C\mu$, for some constant C depending only on $\mathscr{C}$. But this is precisely (4.13).

If $t_f \geqq T-(3\mu/A)$ then $T-t_f \leqq 3\mu/A$. In (4.17) replace t by T. Then the resulting integral will be bounded above by $L(T-t_n)$. The result again follows on letting $n\to\infty$, Lemma 4.5 is thus proved.

We now can easily establish Lemma 4.3. Fix Γ. From (4.13) we have

$$\begin{aligned}\inf_{\Delta}\varphi^0[t_f, t_0, x_0, \Gamma, \Delta] &\geqq \inf_{\Delta}\varphi^0_\mu[T, t_0, x_0, \Gamma, \Delta^*(\Delta)] - C_\mu \\ &\geqq \inf_{\tilde{\Delta}}\varphi^0_\mu[T, t_0, x_0, \Gamma, \tilde{\Delta}] - C_\mu,\end{aligned}$$

where $\tilde{\Delta}$ is an arbitrary strategy in G_μ over $[t_0, T]$. If we now take the supremum over Γ, we obtain the conclusion of Lemma 4.3.

5. Properties of W^-.

LEMMA 5.1. *Let Assumption* I *and Assumption* II *or* II′ *hold. Then for each* (t, x) *in* R

$$\lim_{\mu\to 0} W^-(t, x, \mu) = W^-(t, x), \tag{5.1}$$

and the convergence is uniform on compact subsets $\mathscr{C}$ *of* R. *The function* W^- *is continuous on* R.

Proof. The second statement is a consequence of the first. Let $\mathscr{C}$ be a compact subset of R. Then by Lemmas 4.2 and 4.3 there exists a constant C such that for all (t, x) in R and μ sufficiently small

$$W^-(t, x, \mu) - C\mu \leqq W^-(t, x) \leqq W^-(t, x, \mu).$$

The first statement follows from this.

Let

$$\tilde{R} \equiv R - \partial\mathscr{T} \equiv ([T_0, \infty)\times R^n) - \mathscr{T}.$$

LEMMA 5.2. *Let Assumptions* I′ *and* II′ *hold. Then the function* W^- *is Lipschitz continuous on compact subsets of* $\tilde{R}$.

Let (τ, ξ) and (τ', ξ') be two points in $\tilde{R}$. The crux of the proof is Lemma 5.3 below, which relates the payoff resulting from a motion with initial point (τ, ξ) to the payoff resulting from a motion with initial point (τ', ξ'). In [1, § 6] we showed that to each pair of strategies (Γ, Δ) in the game with initial point (τ, ξ) there corresponds a pair of strategies $(\theta\Gamma, \theta\Delta)$ in the game with initial point (τ', ξ'). Moreover the mappings $\theta\colon \Gamma\to\theta\Gamma$ and $\theta\colon \Delta\to\theta\Delta$ are one-to-one and onto.

LEMMA 5.3. *Let* X *be a compact subset of* $\tilde{R}$ *and let* (τ, ξ) *be a point in* X. *Then there exists a* $\delta_0 > 0$ *and a* $K > 0$, *both depending on the set* X *but not on the point* (τ, ξ), *such that for all* (τ', ξ') *satisfying* (τ', ξ') *in* X,

$$|(\tau', \xi') - (\tau, \xi)| \leqq \delta_0 \tag{5.2}$$

the following is true. Given a pair of strategies (Γ, Δ) *in* $G(\tau, \xi)$ *and a motion* $\hat{\varphi}[\cdot, \tau, \xi, \Gamma, \Delta]$ *with capture time* t_f, *then there exists a strategy* Δ^* *in* $G(\tau', \xi')$ *and a motion* $\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \Delta^*]$ *with capture time* s_f^* *such that*

$$\varphi^0[t_f, \tau, \xi, \Gamma, \Delta] \geqq \varphi^0[s_f^*, \tau', \xi', \theta\Gamma, \Delta^*] + E(\tau, \xi, \tau', \xi'), \tag{5.3}$$

where

$$|E(\tau, \xi, \tau', \xi')| \leqq K[|\tau-\tau'| + |\xi-\xi'|] \tag{5.4}$$

for all (τ, ξ, τ', ξ') *satisfying* (5.2).

Proof. Let $\{\hat{\varphi}_n\} = \{\hat{\varphi}_n(\cdot, \tau, \xi_n, u_n, v_n)\}$ denote the sequence of nth stage trajectories converging uniformly to the motion $\varphi[\cdot, \tau, \xi, \Gamma, \Delta]$ and let $\{t_{f,n}\}$ denote the corresponding sequence of capture times of the trajectories. Let $\{\theta\hat{\varphi}_n\} = \{\theta\hat{\varphi}_n(\cdot, \tau', \xi'_n, \theta u_n, \theta v_n)\}$ denote the sequence of nth stage trajectories resulting from $(\theta\Gamma, \theta\Delta)$ and let $\{s_{f,n}\}$ denote the corresponding sequence of capture times. We suppose, after choosing a subsequence if necessary, that $\{\theta\hat{\varphi}_n\}$ converges to a motion $(\theta\hat{\varphi}[\cdot]) = \hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \theta\Delta]$ with capture time s_f. Recall that the mapping θ utilizes the relationship $s = s(t)$ between the time variable t on $[\tau, T]$ and the time variable s on $[\tau', T]$ given by (6.5) of [1]. It follows from (6.5) of [1] that for $\tau \leqq t \leqq T$, $|s(t) - t| \leqq |\tau - \tau'|$.

We consider three cases. First we suppose that $s(t_f) < s_f$. Let $t_n = \min(t_f, t_{f,n})$, and let $s_n = \min(s_f, s_{f,n})$. Then $t_n \to t_f$ and $s_n \to s_f$. Hence $s(t_n) \leqq s(t_f)$ and $s(t_n) \to s(t_f)$. Thus for n sufficiently large, $s(t_n) < s_n$, and consequently $\rho(s(t_n), \theta\varphi(s(t_n))) > 0$. From the preceding, the triangle inequality and Lemma 6.4 of [1] we see that there exists a constant K_1, which depends on X, such that

$$\begin{aligned} \rho(s(t_n), \theta\varphi_n(s(t_n))) &\leqq |(s(t_n), \theta\varphi_n(s(t_n))) - (t_f, \varphi[t_f])| \\ &\leqq |(s(t_n), \theta\varphi_n(s(t_n))) - (t_n, \varphi_n(t_n))| + |(t_n, \varphi_n(t_n)) - (t_f, \varphi[t_f])| \\ &\leqq K_1[|\tau - \tau'| + |\xi - \xi'|] + \varepsilon_n, \end{aligned} \tag{5.5}$$

where $\varepsilon_n \to 0$ as $n \to \infty$, uniformly for (τ, ξ), (τ', ξ') in X. It follows that there exists a $\delta_0 > 0$, which depends on X, such that whenever $(\tau', \xi') \in X$ and $|(\tau', \xi') - (\tau, \xi)| \leqq \delta_0$, then $(s(t_n), \theta\varphi_n(s(t_n))) \in (\partial F)_{\varepsilon_2}$ for all n sufficiently large. Thus $(s(t_f), \theta\varphi[s(t_f)]) \in (\partial F)_{\varepsilon_2}$.

Let $(\theta\Delta_n)^*$ denote the modification of $\theta\Delta_n$ after $s(t_f)$ by means of the forcing function $z^*(t, x)$. Let $(\theta\hat{\varphi}_n)^*(\cdot)$ denote the corresponding nth stage trajectory and let $(\theta\hat{\varphi})^*[\cdot]$ denote any motion $(\theta\hat{\varphi})^*[\cdot, \tau', \xi', \theta\Gamma, (\theta\Delta)^*]$. Note that for $0 \leqq s \leqq s(t_n)$ we have $(\theta\hat{\varphi}_n)(s) = (\theta\hat{\varphi}_n)^*(s)$, and for $0 \leqq s \leqq s(t_f)$ we have $(\theta\hat{\varphi})[s] = (\theta\hat{\varphi})^*[s]$. It follows from (4.9) that for each n there exists a maximal interval $[s(t_f), st_f) + \alpha_n)$ such that for s in this interval,

$$\rho(s, (\theta\varphi_n)^*(s)) - \rho(s(t_n), (\theta\varphi_n)^*(s(t_n))) \leqq \varepsilon_n - A(s - s(t_n))/2. \tag{5.6}$$

Since for $s > s(t_f)$, $d\rho/ds < 0$ along $(\theta\varphi_n)^*(s)$, and since $s(t_n) \to s_f$, it follows that for n sufficiently large the trajectory $(\theta\varphi_n)^*(s)$ has a capture time $s^*_{f,n} \in [s(t_f), s(t_f) + \alpha_n)$. Let s^*_f denote the capture time of $(\theta\hat{\varphi})^*[\cdot]$, and let $s^*_n = \min(s^*_f, s^*_{f,n})$. If we now set $s = s^*_n$ in (5.6), note that $(\theta\varphi_n)^*(s_n) \to (\theta\varphi)^*[s^*_f]$ and use (5.5) we get that

$$s^*_n - s(t_n) \leqq \varepsilon'_n + (2K_1/A)[|\tau - \tau'| + |\xi - \xi'|], \tag{5.7}$$

where $\varepsilon'_n \to 0$ as $n \to \infty$, uniformly with respect to (Γ, Δ) and (τ, ξ, τ', ξ') satisfying (5.2).

If we denote the outcomes of $(\theta\Gamma_n(\theta\Delta_n)^*)$ by $((\theta u_n)^*, (\theta v_n)^*)$, then for n sufficiently large we have

$$\begin{aligned} &(\theta\varphi^0_n)^*(s^*_n, \tau', \xi'_n, (\theta u_n)^*(\theta v_n)^*) \\ &\quad = \varphi^0_n(s(t_n), \tau', \xi'_n, \theta u_n, \theta v_n) \\ &\qquad + \int_{s(t_n)}^{s^*_n} f^0(s, (\theta\varphi_n)^*(s), (\theta u_n)^*(s), (\theta v_n)^*(s))\, ds. \end{aligned}$$

It now follows from Lemma 6.5 of [1], from (5.7) and from the fact that the integrand on the right is bounded that

$$(\theta\varphi^0_n)^*(s^*_n, \tau', \xi'_n, (\theta u_n)^*, (\theta v_n)^*) = \varphi^0_n(t_n, \tau, \xi_n, u_n, v_n) + E'(\tau, \xi, \tau', \xi') + \varepsilon''_n,$$

where E' is as in (5.4) and $\varepsilon_n'' \to 0$ uniformly with respect to (Γ, Δ) and (τ, ξ, τ', ξ') satisfying (5.2). If we now let $n \to \infty$, and take subsequences, if necessary, we obtain

$$\varphi^0[t_f, \tau, \xi, \Gamma, \Delta] = (\theta\varphi^0)^*[s_f^*, \tau', \xi', \theta\Gamma, (\theta\Delta)^*] + E(\tau, \xi, \tau', \xi'),$$

where $E = -E'$. If we now set $\Delta^* \equiv (\theta\Delta)^*$ and set $\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \Delta^*] = (\theta\hat{\varphi})^*[\cdot, \tau', \xi', \theta\Gamma, (\theta\Delta)^*]$ we obtain (5.3) and (5.4) in the case under consideration.

Let us now suppose that $s_f < s(t_f)$. Then $t_f > t(s_f)$ and also $t_n > t(s_n)$ for n sufficiently large. Hence, since $f^0 \geqq 0$, we have that $\varphi^0(t_n, \tau, \xi_n, u_n, v_n) \geqq \varphi^0(t(s_n), \tau, \xi_n, u_n, v_n)$. If we now use Lemma 6.4 of [1] we get

$$\varphi^0(t_n, \tau, \xi_n, u_n, v_n) \geqq \theta\varphi^0(s_n, \tau', \xi_n', \theta u_n, \theta v_n) + E,$$

where E is as in (5.4). If we let $n \to \infty$ we get

$$\varphi^0[t_f, \tau, \xi, \Gamma, \Delta] \geqq \theta\varphi^0[s_f, \tau', \xi', \theta\Gamma, \theta\Delta] + E.$$

If we set $s_f^* = s_f$, $\Delta^* = \theta\Delta$ and $\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \Delta^*] = \theta\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \theta\Delta]$, we obtain statements (5.3) and (5.4).

If $s_f = s(t_f)$, the lemma follows immediately from Lemma 6.4 of [1] with $s_f^* = s_f$ and $\Delta^* = \theta\Delta$.

We return to the proof of Lemma 5.2. Since W^- is continuous on R, to prove that it is Lipschitz continuous on a compact subset X of R it suffices to show that there exists a $\delta_0 \geqq 0$ and a constant K such that if (τ, ξ) and (τ', ξ') are as in (5.2) then

$$|W^-(\tau, \xi) - W^-(\tau', \xi')| \leqq K[|\tau - \tau'| + |\xi - \xi'|]. \tag{5.8}$$

Let $(\tau, \xi) \in X$, let $\varepsilon > 0$ be arbitrary and let Γ be arbitrary. Then there exists a Δ_Γ and a motion $\hat{\varphi}[\cdot, \tau, \xi, \Gamma, \Delta_\Gamma]$ such that $\varepsilon + W^-(\tau, \xi) \geqq \varphi^0[t_f, \tau, \xi, \Gamma, \Delta_\Gamma]$. Let (τ', ξ') be as in (5.2). Then by Lemma 5.3, there exists a strategy Δ^* in $G(\tau', \xi')$ and a motion $\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \Delta^*]$ with capture time s_f^* such that

$$\varepsilon + W^-(\tau, \xi) \geqq \varphi^0[s_f^*, \tau', \xi', \theta\Gamma, \Delta^*] + E(\tau, \xi, \tau', \xi'),$$

where E is as in (5.4). Hence

$$\varepsilon + W^-(\tau, \xi) \geqq \inf_{\Delta} \varphi^0[s_f, \tau', \xi', \theta\Gamma, \Delta] + E(\tau, \xi, \tau', \xi'),$$

where the infinimum is taken over all strategies Δ on $[\tau', T]$ and all motions $\hat{\varphi}[\cdot, \tau', \xi', \theta\Gamma, \Delta]$. Since $\varepsilon > 0$ is arbitrary and the mapping $\theta: \Gamma \to \theta\Gamma$ is one-to-one onto, it now follows that $W^-(\tau, \xi) \geqq W^-(\tau', \xi') + E$. We may also start with (τ', ξ') and obtain that $W^-(\tau', \xi') \geqq W^-(\tau, \xi) + E'$. From the last two inequalities (5.8) follows.

6. Existence of value. Let

$$H(t, x, \lambda^0, \lambda, y, z) = \lambda^0 f^0(t, x, y, z) + \langle \lambda, f(t, x, y, z) \rangle. \tag{6.1}$$

DEFINITION 6.1. The Isaacs condition holds at a point (t, x) for the game G if

$$\min_z \max_y H(t, x, 1, \lambda, y, z) = \max_y \min_z H(t, x, 1, \lambda, y, z) \tag{6.2}$$

for all $\lambda \in R^n$, where the max is taken over y in Y and the min is taken over $z \in Z$. The Isaacs condition holds on a set in R^{n+1} if it holds at each point of the set.

The Isaacs condition (6.2) holds if and only if for all $\lambda^0 \geqq 0$

$$\min_z \max_y H(t, x, \lambda^0, \lambda, y, z) = \max_y \min_z H(t, x, \lambda^0, \lambda, y, z). \tag{6.3}$$

If (6.3) holds for all $\lambda^0 \geqq 0$, then (6.2) surely holds. Since for $\lambda^0 > 0$, $H(t, x, \lambda^0, \lambda, y,$

$z) = \lambda^0 H(t, x, 1, \lambda/\lambda^0, y, z)$, it follows that if (6.2) holds, then (6.3) holds for $\lambda^0 > 0$. To obtain (6.3) for $\lambda^0 = 0$, write (6.3) in the equivalent form of a saddle point inequality and let $\lambda^0 \to 0$.

Assumption III. The Isaacs condition (6.2) holds at all points of $[T_0, T_1] \times R^n$.

At each point (t, x) of $[T_0, T_1] \times R^n$, let

$$\min_z \max_y [s^0 f_\mu^0 + \langle s, f \rangle] = \max_y \min_z [s^0 f_\mu^0 + \langle s, f \rangle], \tag{6.4}$$

for all $\hat{s} = (s^0, s)$, where the argument of f_μ^0 and f is (t, x, y, z). It then follows from [1] that each game G_μ has a value and saddle point. We shall show in the appendix that we only need (6.4) to hold for those vectors $\hat{s}$ with $s^0 \geqq 0$ in order for G_μ to have a value and saddle point.

For fixed (t, x), $f_\mu^0(t, x, y, z) = \alpha(t, x) f^0(t, x, y, z)$, where $0 \leqq \alpha(t, x) \leqq 1$. It follows from the equivalence of (6.3) and (6.2) that if the Isaacs condition (6.2) holds for the game G, then (6.4) holds for all vectors $\hat{s}$ with $s^0 \geqq 0$. Thus, if Assumption III holds then each game G_μ has a value and a saddle point.

THEOREM 6.1. *Let Assumptions* I, II *or* II′ *and* III *hold. Then for each* (t, x) *in* R *the game* $G(t, x)$ *has value* $W(t, x)$ *and the function* W *is continuous on* r. *If Assumptions* I′, II′ and III *hold, then* W *is Lipschitz continuous on compact subsets of* $\tilde{R}$.

Let (t, x) be fixed in R. Then by Lemma 4.2, $W^+(t, x) \leqq W^+(t, x, \mu)$. Since each game $G_\mu(t, x)$ has value, we have $W^+(t, x, \mu) = W^-(t, x, \mu)$ and so $W^+(t, x) \leqq W^-(t, x, \mu)$. It now follows from (5.1) that $W^+(t, x) \leqq W^-(t, x)$, and thus $G(t, x)$ has value. The continuity of W now follows from Lemma 5.1 and the Lipschitz property from Lemma 5.2.

7. The Isaacs equation. In studying the game G we have essentially converted the game in $[T_0, T_1] \times R^n$ with integral payoff (1.2) into a game in $[T_0, T_1] \times R^{n+1}$ with terminal payoff $g(t_f, \hat{x}_f) = x_f^0$. For the game in $[T_0, T_1] \times R^{n+1}$ we have always taken the initial condition $(t_0, \hat{x}_0)$ to be such that $\hat{x}_0 = (0, x_0)$, where $(t_0, x_0) \in R$. In developing the Isaacs equation it will be necessary to consider initial conditions with $\hat{x}_0 = (x_0^0, x_0)$, where x_0^0 is arbitrary. If we consider such arbitrary initial conditions, then it is easy to see that if $\hat{W}^+(t_0, \hat{x}_0)$ denotes the upper value of this game and if $\hat{W}^-(t_0, \hat{x}_0)$ denotes the lower value, then $\hat{W}^\pm(t_0, \hat{x}_0) = x_0^0 + W^\pm(t_0, x_0)$. Thus, if the value $W(t_0, x_0)$ exists, then for any $\hat{x}_0$ so does $\hat{W}(t_0, \hat{x}_0)$ and

$$\hat{W}(t_0, \hat{x}_0) = x_0^0 + W(t_0, x_0). \tag{7.1}$$

The principal result of this section is Theorem 7.1 below, which states that if the data of the problem is Lipschitz then the value function W satisfies the Isaacs equation. The first step in the proof of this result is to establish the following modification of Lemma 8.3 of [1].

Let $(t_0, \hat{x}_0)$ be fixed, let $v_0 = \hat{W}^-(t_0, \hat{x}_0)$ and let $v^0 = \hat{W}^+(t_0, \hat{x}_0)$. Let $\hat{C}(v_0) = \{(\tau, \hat{\xi}) : (\tau, \xi) \notin \mathcal{T},\ \hat{W}^-(\tau, \hat{\xi}) \leqq v_0\}$ and let $\hat{C}(v^0) = \{(\tau, \hat{\xi}) : (\tau, \xi) \notin \mathcal{T},\ \hat{W}^+(\tau, \hat{\xi}) \geqq v^0\}$.

LEMMA 7.1. *Let* $(\tau, \hat{\xi})$ *be a point of* $\hat{C}(v_0)$. *Let* t_1 *satisfy* $\tau < t_1 < T$ *and let* u *be any control for Player I on* $[\tau, t_1]$. *Then either there exists a relaxed control* $\zeta' = \zeta'(u)$ *such that the relaxed trajectory* $\hat{\psi}(\cdot, \tau, \hat{\xi}, u, \zeta')$ *has the property that* $(t_f, \psi(t_f)) \in \mathcal{T}$ *for some* $t_f \in [\tau, t_1]$ *or there exists a relaxed control* $\zeta = \zeta(u)$ *such that* $(t, \psi(t)) \notin \mathcal{T}$ *for all* $t \in [\tau, t_1]$ *and* $(t_1, \psi(t_1)) \in \hat{C}(v_0)$.

The proof is a modification of the proof of Lemma 8.3 of [1] and will be omitted.

Using Lemma 7.1 in the way Lemma 8.3 of [1] was used to establish Lemma 13.1 of [1], we can establish the analogue of Lemma 13.1 for $\hat{W}^+$ and $\hat{W}^-$. From this we obtain Theorem 7.1.

THEOREM 7.1. *Let Assumptions* I′, II′ *and* III *hold. then at almost every point of* $\tilde{R}$:

$$\begin{aligned} -W_t(t,x) &= H(t,x,1,W_x(t,x),y^*,z^*) \\ &= \min_z \max_y H(t,x,1,W_x(t,x),y,z) \\ &= \max_y \min_z H(t,x,1,W_x(t,x),y,z), \end{aligned}$$

where H is as in (6.1), *the* max *is taken over Y, the* min *is taken over Z, and* $y^* = y^*(t,x)$, $z^* = z^*(t,x)$ *is the saddle point for the game over* $Y \times Z$ *with payoff* $H(t,x,1,W_x(t,x),y,z)$.

Appendix. Games $G(t_0, x_0)$ in $[T_0, T_1] \times R^n$ with fixed terminal time T and payoffs of the form $g(x_f) + \int_{t_0}^{T} f^0(t,x,u,v)\,dt$ can be written as games $\hat{G}(t_0, \hat{x}_0)$ in $[T_0, T_1] \times R^{n+1}$ with terminal payoff $g(x_f) + x_f^0$ by adjoining a zeroth coordinate as in (3.1). If we let $\hat{W}^-(\tau, \hat{\xi})$ with $\hat{\xi} = (\xi^0, \xi)$ denote the upper value of the game $\hat{G}(\tau, \hat{\xi})$ and let $W^-(\tau, \xi)$ denote the lower value of the game $G(\tau, \xi)$ then $\hat{W}^-(\tau, \hat{\xi}) = \xi^0 + W^-(\tau, \xi)$. A similar relationship holds for $\hat{W}^+(\tau, \xi)$.

We now refer to [1, § 10], interpreted for the game $\hat{G}(t_0, \hat{x}_0)$. In constructing the extremal aiming strategies for this game the Isaacs condition is required to hold only for those vectors $\hat{s} = (s^0, s)$ of the form $\hat{s} = \hat{s}^* = \hat{x}^* - \hat{w}^*$, where $(t^*, \hat{x}^*) \notin \hat{C}(v_0)$ (or $\notin \hat{C}(v^0)$) and $(t^*, \hat{w}^*)$ is a point of $S(t^*) = H(t^*) \cap \hat{C}(v_0)$ of minimum distance to $(t^*, \hat{x}^*)$. We shall now show that for $\hat{s}^*$ we always have $s^{*0} \geqq 0$.

Let $(\tau, \hat{\xi})$ be a point $\notin \hat{C}(v_0)$. Let $(\tau, \hat{\xi}^*)$ be a point of $S(\tau) = H(\tau) \cap \hat{C}(v_0)$ at which the distance from $S(\tau)$ to $(\tau, \hat{\xi})$ is achieved. We first note that $\hat{W}^-(\tau, \hat{\xi}^*) = v_0$. For if $\hat{W}^-(\tau, \hat{\xi}^*) < v_0$, then since W^- is continuous there would exist points of $\hat{C}(v_0)$ closer to $(\tau, \hat{\xi})$ than $(\tau, \hat{\xi}^*)$. Thus, $W^-(\tau, \xi^*) + \xi^{*0} = v_0$. Now $\hat{s}^* = \hat{\xi} - \hat{\xi}^*$, so if $s^{*0} < 0$, we must have $\xi^0 < \xi^{*0}$. But if this were the case, then $W^-(\tau, \xi^*) + \xi^0 < v_0$. Hence $(\xi^*, \xi^0) \in S(\tau)$. Clearly, $|(\xi^*, \xi^0) - (\xi, \xi^0)| < |(\xi^*, \xi^{*0}) - (\xi, \xi^0)|$. But this contradicts the definition of (ξ^*, ξ^{*0}). Hence $s^{*0} < 0$ is not possible.

DYNAMICAL REALIZATIONS OF HOMOGENEOUS HAMILTONIAN SYSTEMS*

P. E. CROUCH† AND M. IRVING‡

Abstract. In this work we consider homogeneous input-output systems defined by a single Volterra kernel, which have an internal state space realization in the form of a Hamiltonian system. Previous work by one of the authors considered the state space realization of input-output maps determined by finite Volterra series, the homogeneous case being characterized by an internal homogeneity. The present paper shows that minimal Hamiltonian realizations exist which exhibit the same polynomic structure whilst simultaneously displaying the canonical symplectic structure. The homogeneity is conveniently handled by extensive use of graded vector spaces, and their relation with nilpotent Lie algebras. The additional relation with symplectic structures is also utilized here. The work also provides a specialized version of the Darboux-Weinstein theorem, which is globally valid.

Key words. Hamiltonian, symplectic, Volterra series, realization theory, canonical form

1. Introduction.

1.1. One of the authors has previously considered minimal state space representations of input-output systems defined by finite Volterra series [4]. These dynamical realizations, or controlled dynamical systems with outputs, are characterized by certain polynomic vector fields on a vector space generating solvable Lie algebras, with codimension one nilpotent ideal. When the Volterra series consists of a single term this external homogeneity is reflected in a particular type of internal homogeneity.

Such input-output systems also determine an intrinsic graded vector space structure on the state space which may be exploited to describe the nilpotent Lie algebras which occur. The relationship between graded vector spaces and nilpotent Lie algebras is well understood; see, for example, [7].

A controlled dynamical system on a symplectic manifold may take a special form, being defined by Hamiltonian vector fields, with associated output maps being the Hamiltonian functions. The input-output maps of such Hamiltonian systems therefore represent a subclass of all input-output systems, and in particular those with finite Volterra series form a subclass of finite Volterra series. In Crouch and Irving [5] necessary and sufficient conditions are given for a finite Volterra series to be the input-output map of a Hamiltonian system. However, the state space representation used there for such systems was that of the bilinear system. The problem of obtaining minimal representations, as for arbitrary finite Volterra series in Crouch [4] had remained unanswered. That minimal Hamiltonian realizations exist at all have been answered affirmatively by van der Schaft [17], and under more restrictive conditions in Goncalves [6], although in this latter work a technique is exploited which to some extent is used in this paper.

In this paper we obtain minimal Hamiltonian realizations in the form of [4] but only in the restricted case of homogeneous Volterra series. The case of Volterra series consisting of only the term linear in "u" corresponds to minimal linear systems. Realizability and structural questions for minimal Hamiltonian systems within this class are dealt with in van der Schaft [22]. This paper can be viewed as a partial generalization of that work. The general case remains a formidable problem.

Symplectic geometry has already exposed much of the structure in transitive Lie group actions on symplectic manifolds where the corresponding Lie algebra is represented by Hamiltonian vector fields. We review some of this material briefly in § 2. See also Souriau [15], Kostant [10], Kirillov [9], and the work of Wallach [18]. In this work we are obviously interested in the case of nilpotent and solvable group actions on noncompact manifolds. In fact such a transitive, nilpotent group action on a compact symplectic manifold implies that the group is Abelian, Zwart and Boothby [20]. The results most clearly allied to ours are contained in Pukansky [14] and again Wallach [18]. However there is a lot of work on the associated algebraic and representation problems in Kirillov [9] and Auslander and Kostant [1]. In fact we use a few of the results in this latter reference to a large extent. We feel that although the problem studied here is motivated by a problem in control theory, it is of independent mathematical interest, and as such we give both control theoretic and abstract mathematical interpretations of the results.

Two main techniques are used to derive the results. The first, studied in § 4, relies on the decomposition of systems with nilpotent Lie algebras, as in Crouch [4], and itself based on earlier work of Krener [11] and Chen [3]. This gives a coordinate representation of the abstract system on a graded vector space with compatible symplectic structure. This defines a graded symplectic vector space which we analyze in § 2.

The second technique depends on a new and global version of the Darboux-Weinstein theorem in [19], and is described in § 5.

Many of the ideas here evolved during the Ph.D. thesis of M. Irving [5]. However the approach taken by Irving is somewhat different, and the main aim is to produce local results but in the more general case of arbitrary finite Volterra series.

In the remainder of the section we make the structure and problems raised here more specific.

1.2. We assume all data is real analytic and introduce the class of systems defined by the equations

$$\begin{aligned} &\dot{x}(t) = X_0(x(t)) + \sum_{i=1}^{m} u_i(t) X_i(x(t)), \qquad x(0) = x_0, \\ &y_j(t) = h_j(x(t)), \qquad 1 \leqq j \leqq p, \quad X_0(x_0) = 0, \end{aligned} \tag{1}$$

where the state x belongs to a manifold M and $X_0, X_1, \cdots, X_m$ are complete vector fields on M with $h_1, \cdots, h_p$ real valued functions on M. In this paper we are interested in the subclass of systems which exhibit the following relation between the output functions $t \mapsto y_i(t)$, and the input or control functions $t \mapsto u_i(t)$, called the input-output map.

$$y_j(t) = \int_0^t \cdots \int_0^{\sigma_{N-1}} \sum_{i_1, \cdots, i_N} W_N^{j i_1 \cdots i_N}(t, \sigma_1, \cdots, \sigma_N) u_{i_1}(\sigma_1) \cdots u_{i_N}(\sigma_N)\, d\sigma_N \cdots d\sigma_1 \tag{2}$$

for suitable continuously differentiable, and hence analytic functions $W_N^{j i_1 \cdots i_N}$ in the variables $t, \sigma_1, \cdots, \sigma_N$. To describe a natural class of systems which exhibit such input-output maps we briefly recall some results from graded vector spaces; see Goodman [7].

Let V be an n-dimensional real vector space viewed as a direct sum of N vector spaces V_i, $V = V_1 \oplus V_2 \oplus \cdots \oplus V_N$ and write $x \in V$ as $(x_1, x_2, \cdots, x_N)$ where $x_i \in V_i$. We define for each $t > 0$ a dilation δ_t by

$$\delta_t(x_1, x_2, \cdots, x_N) = (t x_1, t^2 x_2, \cdots, t^N x_N).$$

We call the pair (V, δ_t) a graded vector space of degree N. We say a function h on V is homogeneous of degree k if

$$h \circ \delta_t = t^k h.$$

Let Q^k denote the vector space of all homogeneous polynomials of degree k on V. A vector field X on V with polynomial coefficients is said to be homogeneous of degree m, $0 \leqq m \leqq N$, if for each $k \geqq 0$ and $h \in Q^k$

$$L_X(h) \in Q^{k-m}$$

where L denotes the Lie derivative, and $Q^k = \{0\}$ for $k < 0$. Equivalently, a vector field X is homogeneous of degree m if

$$\delta_{t*} X = (X \circ \delta_t) t^m.$$

We denote the space of all vector vector fields homogneeous of degree m by P^m. We easily deduce that

$$[P^k, P^m] \subset p^{m+k}, \qquad Q^k \otimes P^m \subset P^{m-k}$$

where $[\cdot, \cdot]$ denotes Lie bracket.

From the results of Crouch [4] one may deduce the following result.

THEOREM 1. *If there exists a system* (1) *whose input-output map coincides with a given input-output map as in* (2), *then there exists another system defined on a graded vector space V and represented by*

$$\begin{aligned} &\dot{z}(t) = Z_0(z(t)) + \sum_{i=1}^{m} u_i(t) Z_i(z(t)), \qquad z(0) = 0, \\ &y_j(t) = H_j(z(t)), \qquad 1 \leqq j \leqq p, \quad Z_0(0) = 0, \end{aligned} \tag{3}$$

with $z \in V = V_1 \oplus V_2 \oplus \cdots \oplus V_N$ satisfying

(i) $Z_0 \in P^0$, $Z_i \in P^1$, $1 \leqq i \leqq m$ $\quad H_j \in Q^N$, $1 \leqq j \leqq p$.

(ii) *The input-output map relating the y_j and u_i functions coincides with the given one.*

(iii) *The system is accessible; that is the Lie algebra $\mathcal{L}$ generated by $Z_0, Z_1, \cdots, Z_m$ is transitive on V, and in particular the subalgebra $\mathcal{S} \subset \mathcal{L}$ defined as the ideal generated by $Z_1, \cdots, Z_m$ in $\mathcal{L}$ is also transitive on V.*

(iv) *The system is locally observable; that is the smallest linear space $\mathcal{H}$ of functions on V containing H_j, $1 \leqq j \leqq p$ and closed under Lie derivatives by $Z_0, Z_1, \cdots, Z_m$ satisfies $d\mathcal{H}(x) = \{dh(x); h \in \mathcal{H}\} = T_x^* V = V$ for all $x \in V$.*

We also have the following result which includes a partial converse to Theorem 1.

THEOREM 2. *Any system* (3) *defined on a graded vector space (V, δ_t) of degree N, which satisfies condition* (i) *of Theorem* 1, *has an input-output map in the form of equation* (2). *The Lie algebra $\mathcal{L}$ is solvable, finite-dimensional and the ideal $\mathcal{S}$ is nilpotent and has a codimension at most one in $\mathcal{L}$. The descending central series of $\mathcal{S}$ has length less than or equal to N. That is $\mathcal{S}^{N+1} = \{0\}$ where $\mathcal{S}^1 = \mathcal{S}$, $\mathcal{S}^k = [\mathcal{S}, \mathcal{S}^{k-1}]$.*

Proof. For general systems (1) the input-output map can be expanded in a Volterra series, Brockett [2], Lesiak and Krener [12], the Nth term of which is given by (2). From Krener and Lesiak [12], it can be shown that the kernel $W_r^I(t, \sigma_1, \cdots, \sigma_r)$ defining the rth term is given by

$$\sum_J \sigma_r^{j_r}/j_r! \cdots \sigma_1^{j_1}/j_1!\, t^{j_0}/j_0!\, \alpha_r^{J,I}(x_0), \tag{4}$$

where

$$\alpha_r^{J,I} = L_{adX_0^{j_r}(X_{i_r})} \cdots L_{adX_0^{j_1}(X_{i_1})} L_{X_0}^{j_0}(h_j),$$
$$J = (j_0, j_1, \cdots, j_r), \qquad I = (j, i_1, \cdots, i_r).$$

Here $ad\, X_0(X) = [X_0, X]$ and $ad\, X_0^j(X) = ad\, X_0(ad\, X_0^{j-1}(X))$ with a similar definition for the repeated Lie derivative $L_{X_0}^j(h)$.

By using this formula in the case of system (3) under conditions (i) of Theorem 1 it is clear that W_r^I vanishes for each r except $r = N$ for each I. It follows that the input-output map in this case is an expression as in equation (2). The remaining results follow directly from the properties of the spaces P^i and Q^i. □

1.3. If now M is a symplectic manifold with symplectic form ω, denote by X_h the Hamiltonian vector field on M with Hamiltonian h, that is

$$i(X_h)\omega = dh$$

where i is the inner product. Let β be the map $h \to X_h$ the Lie algebra homomorphism of functions on M under Poisson bracket, also denoted $[\cdot, \cdot]$, into the Lie algebra of vector fields on M under the Lie bracket.

Consider a controlled differential equation with outputs, on the symplectic manifold (M, ω)

$$\begin{aligned} &\dot{x}(t) = X_{h_0}(x(t)) + \sum_{i=1}^{m} u_i(t) X_{h_i}(x(t)), \qquad x(0) = x_0, \\ &y_i(t) = h_i(x(t)), \qquad 1 \leqq i \leqq m, \quad X_{h_0}(x_0) = 0. \end{aligned} \tag{5}$$

We call such a system a Hamiltonian system. Motivation for such a definition is made in van der Schaft [23], see also Brockett [24]. For example, if one takes a set of Lagrangian equations with generalized inputs u_i and observations $y_i = q_i$, the configuration space generalized coordinates, we obtain

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{q}_i} - \frac{\partial L}{\partial q_i} = -u_i, \qquad 1 \leqq i \leqq n, \qquad y_i = q_i.$$

Under suitable conditions the Legendre transformation then yields a set of Hamiltonian equations in R^{2n} of the form

$$\begin{aligned} \dot{q}_i &= \frac{\partial H}{\partial p_i} + \sum_{j=1}^{n} u_j \frac{\partial H_j}{\partial p_i}, \qquad 1 \leqq i \leqq n, \\ \dot{p}_i &= -\frac{\partial H}{\partial q_i} - \sum_{j=1}^{n} u_j \frac{\partial H_j}{\partial q_i}, \qquad 1 \leqq i \leqq n, \\ y_i &= H_i, \end{aligned}$$

where $H_i(p, q) = q_i$. This is just a specific case of the system (5).

If system (5) exhibits an input-output map as in equation (2), we may use the results of van der Schaft [17], or Goncalves [6] to deduce that there exists another Hamiltonian system defined on another symplectic manifold (M', ω') denoted

$$\begin{aligned} &\dot{z}(t) = Z_{H_0}(z(t)) + \sum_{i=1}^{m} u_i(t) Z_{H_i}(z(t)), \qquad z(0) = z_0, \\ &y_i(t) = H_i(z(t)), \qquad 1 \leqq i \geqq m, \quad Z_{H_0}(z_0) = 0, \end{aligned} \tag{6}$$

satisfying conditions (ii)-(iv) of Theorem 1. Thus we define corresponding spaces $\mathscr{H}'$, $\mathscr{S}'$, $\mathscr{L}'$. Note that conditions (ii) and (iv) are equivalent in this case because β maps $\mathscr{H}'$ onto $\mathscr{S}'$, and ω' is nondegenerate. This motivates the question which we answer in this paper: can we reproduce condition (i) whilst simultaneously retaining the symplectic structure, and conditions (ii), (iii) and (iv) of Theorem 1.

Before posing the corresponding abstract mathematical question we comment on the added structure possessed by system (6) by virtue of its Hamiltonian nature. The isomorphism theorem of Sussmann [16] ensures that system (6) and the system (3) obtained by applying Theorem 1 are isomorphic. In particular M' is diffeomorphic to a Cartesian space, and the Lie algebras $\mathscr{S}'$ and $\mathscr{L}'$ are isomorphic to $\mathscr{S}$ and $\mathscr{L}$, respectively. In particular by Theorem 2 $\mathscr{S}'$ is a nilpotent ideal of codimension one in $\mathscr{L}'$, which has step length less than or equal to N and is finite-dimensional. If the Poisson Lie algebra of functions on M generated by $H_0, H_1, \cdots, H_m$ is denoted $\mathscr{K}'$, then $\mathscr{H}'$ is the codimension one ideal in $\mathscr{K}'$ generated by $H_1, \cdots, H_m$, such that β maps $\mathscr{K}'$ onto $\mathscr{L}'$ and $\mathscr{H}'$ onto $\mathscr{S}'$. Since the kernel of β consists of the one-dimensional space of constant functions, $\mathscr{K}'$ and $\mathscr{H}'$ are solvable and nilpotent Lie algebras, respectively.

Using the identities for Hamiltonian vector fields

$$[Z_H, Z_G] = Z_{[H,G]}, \qquad L_{Z_H}(G) = [G, H],$$

we may rewrite the coefficients $\alpha_r^{J,I}(x_0)$ up to a choice in sign by

$$\alpha_r^{J,I} = [ad\, H_0^{j_r}(H_{i_r}), [\cdots [ad\, H_0^{j_1}(H_{i_1}), ad\, H_0^{j_0}(H_j)] \cdots]. \tag{7}$$

Since system (6) has the input-output map in (2) we see that $\alpha_r^{J,I}(z_0)$ are zero for all J, I and r except $r = N$. We also deduce [4, Thm. 3.2] that the functions $\alpha_r^{J,I}$ are identically zero for $r > N$ and constant for $r = N$. It follows that $\mathscr{H}'$ has descending central series of length exactly $N+1$, denoted $\mathscr{H}'^k$, $k = 0, \cdots, N$, $\mathscr{H}'^0 = \mathscr{H}'$, with $\mathscr{H}'^N$ consisting of constant functions only.

1.4. The discussion in the previous subsection motivates consideration of the following abstract system of data:

A symplectic manifold (M, ω), a specific point $x_0 \in M$, a solvable Lie algebra $\mathscr{K}$ of functions on M generated by the functions $H_0, H_1, \cdots, H_m$ with a codimension one nilpotent ideal $\mathscr{H}$ generated by $H_1, \cdots, H_m$ and additionally satisfying:

Assumption (i). $\beta(H_i)$ are complete vector fields $0 \leqq i \leqq m$.

Assumption (ii). $\beta(H_0)(x_0) = 0$, $d\mathscr{H}(x) = T_x^\infty M$, $\quad x \in M$.

Assumption (iii). $\mathscr{H}$ has a descending central series of length $N+1$, and in particular there exist multi-indices J and I such that $\alpha_N^{J,I}(x_0) \neq 0$ ($\alpha_r^{J,I}$ defined in (7)).

Assumption (iv). $\alpha_r^{J,I}(x_0) = 0$ for $r < N$.

We make some prelminary deductions about such a situation. Clearly this situation allows us to define a Hamiltonian system (6) satisfying conditions (ii)-(iv) of Theorem 1, for an input-output map (2) defined by the coefficients $\alpha_N^{J,I}(x_0)$. Thus as in § 1.3 we deduce that Lie algebra $\mathscr{L} = \beta(\mathscr{K})$ is finite-dimensional, and the Lie algebra $\mathscr{S} = \beta(\mathscr{H})$ is a finite-dimensional nilpotent ideal, with descending central series of length N (if it had length less than N then $\mathscr{H}$ would necessarily have step length less then $N+1$ which is a contradiction). Moreover M is diffeomorphic to a Cartesian space, and $\alpha_N^{J,I}$ are all constant functions on M.

Since $\mathscr{L}$ is finite-dimensional and generated by complete vector fields, we may assume that $\mathscr{L}$ is the infinitesimal generator of a Lie transformation group L acting on M, Palais [13]. Since $\mathscr{L}$ is transitive on M, L is transitive on M and then so too

is the nilpotent ideal $S \subset L$ with Lie algebra $\mathscr{S}$. Let K, $H \subset K$ be the simply connected Lie groups with algebras $\mathscr{K}$ and $\mathscr{H}$, respectively. The homomorphism β extends to a homomorphism of groups $b: K \to L$, which in turn exhibits both K and H as Lie transformation groups of M.

2. Graded symplectic vector spaces. Let (V, δ_t) be a graded vector space of degree N, and assume that ω is a symplectic form on V. If ω satisfies $\delta_t^* \omega = t^{N+1}\omega$, or for vector fields X and Y on V we have $\omega(\delta_{t*}X \circ \delta_t^{-1}, \delta_{t*}Y \circ \delta_t^{-1}) = \omega(X, Y)t^{N+1}$; then we say ω is homogeneous symplectic form on V, and the triple (V, δ_t, ω) is a homogeneous graded symplectic vector space. We only deal with homogeneous structures in this paper so we shall not use the term homogeneous from now on. The motivation for considering such a definition comes from the following result.

LEMMA 1. *Given a graded symplectic vector space* (V, δ_t, ω) *then a function* $H \in Q^k$ *if and only if the Hamiltonian vector field* $X_H \in P^{N+1-k}$.

Proof. Assume $H \in Q^k$ is given. Then for any vector field Z on V we have

$$\begin{aligned} t^k\, dH(Z) &= d(H \circ \delta_t)(Z) = dH \circ \delta_t \delta_{t*} Z \\ &= \omega(X_H \circ \delta_t, \delta_{t*}Z) = \omega(\delta_{t*}\delta_{t*}^{-1}X_H \circ \delta_t, \delta_{t*}Z) \\ &= t^{N+1}\omega(\delta_{t*}^{-1}X_H \circ \delta_t, Z). \end{aligned}$$

Thus $dH(Z) = \omega(X_H, Z) = t^{N+1-k}\omega(\delta_{t*}^{-1}X_H \circ \delta_t, Z)$.

Since Z is arbitrary we deduce that

$$\delta_{t*}X_H = t^{N+1-k}X_H \circ \delta_t$$

and hence $X_H \in P^{N+1-k}$. The converse is completely analogous. □

As special cases we see that $X_H \in P^0(P^1)$ if and only if $H \in Q^{N+1}(Q^N)$. Thus in the case of $N = 1$, $X_H \in P^0$ if and only if $H \in Q^2$, and in this case $\delta_t^* \omega = t^2\omega$. It follows that ω is a constant symplectic form, X_H is a linear vector field and H is a quadratic function on V.

Given a vector space V which has the particular form

$$V = V_1 \oplus V_2 \oplus \cdots \oplus V_N \oplus W_N \oplus W_{N-1} \oplus \cdots \oplus W_1$$

with $\operatorname{Dim}(W_i) = \operatorname{Dim}(V_i) = n_i$, $1 \leqq i \leqq N$, we may select linear isomorphisms $\Omega_i: W_i \to V_i^*$ where V_i^* is the dual space of V_i and construct a symplectic form on V by setting

$$\begin{aligned} &\omega(p_i, p_j) = \omega(q_i, q_j) = 0, \qquad 1 \leqq i, j \leqq N, \\ &\omega(q_i, p_j) = \omega(p_j, q_i) = 0, \qquad i \neq j, \\ &\omega(q_i, p_i) = -\omega(p_i, q_i) = \Omega_i p_i(q_i), \qquad 1 \leqq i \leqq N, \end{aligned}$$

where $p_i \in W_i$, $q_i \in V_i$ are also identified with vectors in V all components of which are zero except those of $p_i \in W_i$ and $q_i \in V_i$, respectively. If we define a graded structure on V by setting

$$\delta_t(q_1, q_2, \cdots, q_N, p_N, p_{N-1}, \cdots, p_1) = (tq_1, \cdots, t^N q_N, tp_N, t^2 P_{N-1}, \cdots, t^N p_1)$$

then it is clear that ω is a constant symplectic form on V which satisfies $\delta_t^* \omega = t^{N+1}\omega$. It follows that (V, ω, δ_t) forms a graded symplectic vector space. By identifying W_i and V_i with R^{n_i} and Ω_i with the identity matrix on R^{n_i}, ω is represented in its canonical form which we denote by

$$\Omega_c = \sum_{i=1}^{N} dq_i \wedge dp_i.$$

THEOREM 3. *Given the graded symplectic vector space* $(R^n, \delta_t, \Omega_c)$ *of degree* N *where* R^n *has the form*

$$R^n = R^{n_1} \oplus R^{n_2} \oplus \cdots R^{n_N} \oplus \cdots \oplus R^{n_1}$$

and the dilation δ_t *has the form*

$$\delta_t(q_1, q_2, \cdots, q_N, p_N, \cdots, p_1) = (tq_1, t^2 q_2, \cdots, t^N q_N, tp_N, t^2 p_{N-1}, \cdots, t^N p_1)$$

then if N *is even* $N = 2r$ *there exists a symplectic diffeomorphism* Φ_1 *which intertwines the graded structures* $\Phi_1 : (R^n, \delta_t, \Omega_c) \to (R^n, \delta_t^1, \Omega_c)$ *where the graded structure on* (R^n, δ_t^1) *is defined by*

$$R^n = R^{n_1} \oplus R^{n_N} \oplus R^{n_2} \oplus R^{n_{N-1}} \cdots \oplus R^{n_N} \oplus R^{n_1}$$

$$\begin{aligned} (8) \qquad & \delta_t^1(q_1, q_2, \cdots, q_N, p_N, \cdots, p_1) \\ & = (tq_1, tq_2, \cdots, t^r q_{N-1}, t^r q_N, t^{r+1} p_N, t^{r+1} p_{N-1}, \cdots, t^N p_2, t^N p_1); \end{aligned}$$

if N *is odd* $N = 2r+1$ *there exists a symplectic diffeomorphism* Φ_2 *which intertwines the graded structures* $\Phi_2 : (R^n, \delta_t, \Omega_c) \to (R^n, \delta_t^2, \Omega_c)$ *where the graded structure on* (R^n, δ_t^2) *is defined by*

$$R^n = R^{n_1} \oplus R^{n_N} \oplus R^{n_2} \oplus R^{n_{N-1}} \oplus \cdots \oplus R^{n_N} \oplus R^{n_1}$$

$$\begin{aligned} (9) \qquad & \delta_t^2(q_1, q_2, \cdots, q_N, p_N, \cdots, p_1) \\ & = (tq_1, tq_2, \cdots, t^r q_{N-2}, t^r q_{N-1}, t^{r+1} q_N, t^{r+1} p_N, \cdots, t^N p_2, t^N p_1). \end{aligned}$$

Proof. If $N = 2r$ take Φ_1 to be the map

$$\begin{aligned} & q_i \to q_{2i-1}, \\ & p_{N-i+1} \to -q_{2i}, \qquad 1 \leqq i \leqq r, \\ & q_{N-i+1} \to p_{2i}, \\ & p_i \to p_{2i-1}. \end{aligned}$$

If $N = 2r+1$ take Φ_2 to be the map

$$\begin{aligned} & p_{N-i+1} \to -q_{2i}, \qquad 1 \leqq i \leqq r, \\ & q_{N-i+1} \to p_{2i}, \\ & q_i \to q_{2i-1}, \qquad 1 \leqq i \leqq r+1, \\ & p_i \to p_{2i-1}, \end{aligned}$$

Φ_1 and Φ_2 are clearly diffeomorphisms, and $\delta_t^1 = \Phi_1 \circ \delta_t \circ \Phi_1^{-1}$ satisfies (8) whilst $\delta_t^2 = \Phi_2 \circ \delta_t \circ \Phi_2^{-1}$ satifies (9). That Φ_i preserves Ω_c we take $N = 2r$, $i = 1$ and write

$$\Omega_c = \sum_{i=1}^{r} dq_i \wedge dp_i + \sum_{i=1}^{r} dq_{N-i+1} \wedge dp_{N-i+1}.$$

Thus

$$(\Phi_1^{-1})^* \Omega = \sum_{i=1}^{r} dq_{2i-1} \wedge dp_{2i-1} - \sum_{i=1}^{r} dp_{2i} \wedge dq_{2i} = \Omega_c.$$

The proof in the case $i = 2$, $N = 2r+1$ follows similarly. □

It is interesting to look at the effect of the maps Φ_1 and Φ_2 on functions on the graded vector space (R^n, δ_t). In the case N even all functions in P^N and P^{N+1} with

respect to (R^n, δ_t^1) are affine in the "p" variables, but certainly not with respect to (R^n, δ_t). In the case N odd all functions in P^N with respect to (R^n, δ_t^2) are affine in the "p" variables, but certainly not with respect to (R^n, δ_t). However functions in P^{N+1} with respect to (R^n, δ_t^2) are affine with respect to "p_1" $\cdots$ "p_{N-1}" variables and quadratic with respect to "p_N" variables. Again this is not the case with respect to (R^n, δ_t).

In the remaining sections we shall construct examples of the graded vector spaces $(R^n, \delta_t^1, \Omega_c)$ and $(R^n, \delta_t^2, \Omega_c)$, but by use of Theorem 3 we see that these are equivalent to (R^n, δ_t, Ω) graded vector spaces.

3. Symplectic geometry.

3.1. We briefly recall some facts from symplectic geometry as found in Souriau [15], Pukansky [14], Kostant [10] and nicely summarized in Wallach [18]. Let (M, ω) be a symplectic manifold, and let $\psi: K \times M \to M$ be the action of a Lie transformation group K on M, with Lie algebra $\mathcal{K}$. Let $X^{\#}$ denote the vector field on M induced by the action of K on M, and corresponding to the vector field $X \in \mathcal{K}$. Thus for $x \in M$.

$$X^{\#}(x) = \frac{d}{dt}\psi(\exp tX, x)\Big|_{t=0}.$$

The action of ψ of K on M is said to be Hamiltonian if (i) $X^{\#}$ is infinitesimally symplectic for each $X \in \mathcal{K}$, that is $L_{X^{\#}}\omega = 0$, (ii) there exists a Lie algebra homomorphism λ from $\mathcal{K}$ into the Lie algebra of functions on M under Poisson bracket satisfying $\beta \circ \lambda(X) = X^{\#}$, $X \in \mathcal{K}$.

Let $\mathcal{K}^*$ denote the dual space of $\mathcal{K}$, $k \to Ad\, k$ the adjoint representation of K on $\mathcal{K}$, and $k \to Ad\, k^*$ the coadjoint representation of K on $\mathcal{K}^*$ defined by

$$Ad\, k^* f(X) = f(Ad\, k^{-1} X), \qquad f \in \mathcal{K}^*, \quad X \in \mathcal{K}.$$

Denote the action of K on $\mathcal{K}^*(k, f) \to Ad\, k^* f$ by $\phi: K \times \mathcal{K}^* \to \mathcal{K}^*$. If O_f denotes the orbit of f under K in $\mathcal{K}^*$ then O_f has a symplectic manifold structure with symplectic form Ω^f. If $X \in \mathcal{K}$ let X^* denote the vector field on O_f induced by the action of K on O_f, then

$$\Omega^f(X^*(f), Y^*(f)) = f([X, Y]).$$

If the action of K on M is Hamiltonian, then we define the "moment" map $\tau: M \to \mathcal{K}^*$ by

$$\tau(x)(X) = \lambda(X)(x), \qquad X \in \mathcal{K}, \quad x \in M.$$

The moment map τ is equivariant for the actions ψ and ϕ of K on M and $\mathcal{K}^*$, respectively

$$\tau(\psi(k, x)) = \phi(k, \tau(x)).$$

In the case where K acts transitively on M and we specify $x_0 \in M$ with $f = \tau(x_0)$, then $\tau: M \to O_f$ is a covering map which preserves the symplectic structure, $\tau^* \Omega^f = \omega$.

In the case where K is a nilpotent Lie group then as shown in Wallach [18, p. 302], O_f is diffeomorphic to a cartesian space, and so in this case τ is a diffeomorphsim and M is diffeomorphic to a cartesian space also.

3.2. We now recall some results on polarizations of nilpotent Lie algebras from Kirillov [9] and Auslander and Kostant [1], and conclude by giving implications for solvable and nilpotent Hamiltonian group actions on symplectic manifolds.

If $\mathcal{H}$ is a real Lie algebra and $f \in \mathcal{H}^*$ then we define a subalgebra $\mathcal{H}_f$ by

$$\mathcal{H}_f = \{X \in \mathcal{H}; f([X, Y]) = 0, Y \in \mathcal{H}\}.$$

A real polarization for $\mathcal{H}$ at f is a subalgebra $\mathcal{P} \subset \mathcal{H}$ such that

$\mathcal{P}_R$ (i) $\quad \operatorname{Dim}\left(\frac{\mathcal{H}}{\mathcal{P}}\right) = \frac{1}{2}\operatorname{Dim}\left(\frac{\mathcal{H}}{\mathcal{H}_f}\right),$

$\mathcal{P}_R$ (ii) $\quad f([\mathcal{P}, \mathcal{P}]) = 0.$

Alternatively $\mathcal{P}$ is described as a maximal subspace of $\mathcal{H}$ satisfying $\mathcal{P}_R$ (ii). In particular $\mathcal{P} \supset \mathcal{H}_f$.

A fundamental result of Kirillov [9] is that nilpotent Lie algebras $\mathcal{H}$ admit polarizations for every $f \in \mathcal{H}^*$.

In the case of interest in this paper the nilpotent Lie algebra $\mathcal{H}$ is a codimension one ideal in $\mathcal{K}$ a solvable Lie algebra. If $X \in \mathcal{K}$ is such that $\mathcal{H}$ and X span $\mathcal{K}$ then $t \to \exp t \operatorname{ad} X$ defines a one parameter group Γ of automorphisms of $\mathcal{H}$. In general, given $f \in \mathcal{H}^*$ there may not exist any polarization for $\mathcal{H}$ at f which is invariant under Γ. To deal with this case we introduce complex polarizations, as in Auslander and Kostant [1].

Let $\mathcal{H}_c = \mathcal{H} + i\mathcal{H}$ be the complexification of the real Lie algebra $\mathcal{H}$, and extend $f \in \mathcal{H}^*$ to a linear functional on $\mathcal{H}_c$. A complex polarization for $\mathcal{H}$ at f is a complex subalgebra $\mathcal{P}_c \subset \mathcal{H}_c$ satisfying

$\mathcal{P}_c$ (i) $\quad \mathcal{H}_f \subset \mathcal{P}_c,$

$\mathcal{P}_c$ (ii) $\quad \operatorname{Dim}_{\mathbb{C}} \frac{\mathcal{H}_c}{\mathcal{P}_c} = \frac{1}{2}\operatorname{Dim}_{\mathbb{R}} \frac{\mathcal{H}}{\mathcal{H}_f},$

$\mathcal{P}_c$ (iii) $\quad f([\mathcal{P}_c, \mathcal{P}_c]) = 0,$

$\mathcal{P}_c$ (iv) $\quad \mathcal{P}_c + \bar{\mathcal{P}}_c$ is a Lie subalgebra of $\mathcal{H}_c$

(where $\bar{\mathcal{P}}_c$ denotes complex conjugate of $\mathcal{P}_c$). If θ_f is the bilinear form on $\mathcal{H}$ defined by $\theta_f(X, Y) = f([X, Y])$, then θ_f extends to a bilinear form on $\mathcal{H}_c$ by extending f to $\mathcal{H}_c$. A complex polarization $\mathcal{P}_c \subset \mathcal{H}_c$ may be defined as a maximal subspace of $\mathcal{H}_c$ satisfying $\mathcal{P}_c$ (iii), that is $\theta_f(\mathcal{P}_c, \mathcal{P}_c) = 0$.

If we set $\mathcal{D} = \mathcal{P}_c \cap \mathcal{H}$ and $\mathcal{E} = (\mathcal{P}_c + \bar{\mathcal{P}}_c) \cap \mathcal{H}$ then $\mathcal{D}$ and $\mathcal{E}$ are real subalgebras of $\mathcal{H}$ such that $\mathcal{D}$ is the orthogonal complement of $\mathcal{E}$ with respect to θ_f. Note that since $\mathcal{H}_f \subset \mathcal{D} \subset \mathcal{E}$, $\theta_f(\mathcal{D}, \mathcal{D}) = 0$ so θ_f induces a nondegenerate bilinear form on $\mathcal{E}/\mathcal{D}$. If $\mathcal{E} = \mathcal{D}$ then $\mathcal{P}_c = \mathcal{P} + i\mathcal{P}$ where $\mathcal{P}$ is a real polarization for $\mathcal{H}$ at f. Finally a complex polarization is said to be positive if either $\mathcal{E} = \mathcal{D}$ or

$$-i\theta_f(z, z) \geqq 0 \quad \forall z \in \mathcal{P}_c.$$

When $\mathcal{H}$ is a nilpotent Lie algebra given any $f \in \mathcal{H}^*$ and one parameter group of automorphisms Γ of $\mathcal{H}$ there exists a positive complex polarization for $\mathcal{H}$ at f which is invariant under Γ, ([1, Lem. II.3.1]). Moreover, $\mathcal{D}$ is an ideal in $\mathcal{E}$ such that $\mathcal{E}/\mathcal{D}$ is abelian ([1, Thm. 1.4.10]). We note that since Γ is real and $\mathcal{P}_c$ is invariant under Γ, both of the real subalgebras $\mathcal{D}$ and $\mathcal{E}$ are also invariant under Γ.

3.3. We now show how this structure may be introduced into the situation described in § 1.4. Let $\phi: K \times M \to M$ be the transitive action of the simply connected Lie group K on the symplectic manifold (M, ω), where K has Lie algebra $\mathcal{K}$. The action is clearly Hamiltonian since $\beta(\mathcal{K})$ consists of Hamiltonian vector fields, and

$\beta(X) = X^{\#}$ for each vector field $X \in \mathcal{K}$ by the construction of the action ψ. Clearly ψ restricts to the nilpotent ideal H also giving a transitive Hamiltonian action on M. Let $\phi: K \times \mathcal{K}^* \to \mathcal{K}^*$ be the corresponding action of K on $\mathcal{K}^*$ under the coadjoint representation. Notice that since $\mathcal{H}$ is an ideal in $\mathcal{K}$, ϕ restricts to an action $\phi: K \times \mathcal{H}^* \to \mathcal{H}^*$. If $\tau: M \to \mathcal{H}^*$ is the moment map, $f = \tau(x_0)$ and O_f the orbit of f under $H \subset K$, then since $\mathcal{H}$ is nilpotent $\tau: M \to O_f$ is a diffeomorphism with M and O_f diffeomorphic to cartesian spaces. This of course is in agreement with the observation in § 1.4.

Since τ is equivalent for the actions ψ and ϕ of K on M and $\mathcal{H}^*$, respectively, and $\beta(H_0)(x_0) = 0$, the one parameter group generated by H_0 is in the isotropy group $\{k \in K;\ \phi(k, f) = f\} = \{k \in K;\ \psi(k, x_0) = x_0\}$. In particular, the orbit of f under K coincides with O_f. Let $H_f = \{k \in H;\ \phi(k, f) = f\} = \{k \in H;\ \psi(k, x_0) = x_0\}$. Since H_f is a closed subgroup of a simply connected nilpotent group H, H_f is a simply connected subgroup with Lie algebra $\mathcal{H}_f$. Hence M and O_f may be viewed as the homogeneous space H/H_f with

$$\operatorname{Dim}\left(\frac{H}{H_f}\right) = \operatorname{Dim}\left(\frac{\mathcal{H}}{\mathcal{H}_f}\right) = \operatorname{Dim} O_f = \operatorname{Dim} M.$$

LEMMA 2.

$$ad\, H_0(\mathcal{H}_f) \subset \mathcal{H}_f.$$

Proof. If $X \in \mathcal{H}_f$ and $Y \in \mathcal{H}$ then $f([[H_0, X], Y]) = -f[[X, Y], H_0]) - f([[Y, H_0], X])$. Since $X \in \mathcal{H}_f$ and $\mathcal{H}$ is an ideal in $\mathcal{K}$, $f([[Y, H_0], X]) = 0$. Since the one parameter group generated by H_0 is in the isotropy group $\{k \in K;\ \phi(k, f) = f\} f([[X, Y], H_0]) = 0$. Thus $f([[H_0, X], Y]) = 0$ and since X and Y are arbitrary the result follows. □

Since τ preserves the symplectic structures on M and O_f, for each $X, Y \in \mathcal{H}$ we have

$$\omega(X^{\#}(x_0), Y^{\#}(x_0)) = \Omega^f(X^*(f), Y^*(f)) = \theta_f(X, Y). \tag{10}$$

Note that $X^{\#}(x_0)$ vanishes if and only if $X^*(f)$ vanishes, since then $X \in \mathcal{H}_f$. Now θ_f is in general a degenerate bilinear form on $\mathcal{H}$ whilst ω defines a nondegenerate bilinear form on $T_{x_0}M$. We define an orthogonal complement of subspaces of a vector space V with respect to a bilinear form Ω, degenerate or not, in the usual manner $W^{\perp} = \{X \in V;\ \Omega(X, W) = 0\}$. We than define isotropic (coisotropic) subspaces by $W \subset W^{\perp}$ ($W^{\perp} \subset W$). A Lagrangian subspace W is a maximally isotropic subspace or $W = W^{\perp}$.

We define the linear map $\beta_0: \mathcal{H} \to T_{x_0}M$ by setting $\beta_0(X) = X^{\#}(x_0)$. Thus β_0 has kernel $\mathcal{H}_f$ and gives the following easily verified result.

LEMMA 3. *With respect to the alternating bilinear form on $T_{x_0}M$ defined by ω and θ_f on $\mathcal{H}$ we have for any subspace $W \subset \mathcal{H}$*

$$(\beta_0(W))^{\perp} = \beta_0(W^{\perp}).$$

We deduce that if $\mathcal{P}$ is a polarization for $\mathcal{H}$ at f then $\beta_0(\mathcal{P})$ is a Lagrangian subspace of $T_{x_0}M$ with respect to ω, and if $\mathcal{P}_c$ is a complex polarization for $\mathcal{H}$ at f with corresponding real subalgebras $\mathcal{D} \subset \mathcal{E}$, then $\beta_0(D)^{\perp} = \beta_0(\mathcal{E})$ as subspaces of T_xM with respect to ω. We actually use a more sophisticated version of these results in the next section.

Finally we state for future reference, the following result which summarizes the invariance properties of polarizations described in § 3.2.

LEMMA 4. *Given the situation described in* § 1.4 *set $f = \tau(x_0)$ then either there exists a real polarization $\mathcal{P}$ for $\mathcal{H}$ at f, $\mathcal{P} = \mathcal{P}^{\perp}$, which is invariant under ad H_0, or there exists*

a complex polarization $\mathcal{P}_c$ for $\mathcal{H}$ at f, and associated real subalgebras $\mathcal{D} \subset \mathcal{E} \subset \mathcal{H}$ such that $\mathcal{D}^\perp = \mathcal{E}$ and both $\mathcal{D}$ and $\mathcal{E}$ are invariant under ad H_0.

4. Decompositions.

4.1. In this section we construct global coordinates for a Hamiltonian system constructed from the data described in § 1.4.

We must make definitions before we state the main result that we use. Assume that T is a transitive Lie algebra of vector fields on a manifold M, and a specific point $x_0 \in M$ is given. Let $\mathcal{N} \subset T$ be the subalgebra of vector fields on M which vanish at x_0. Let $\{T^k\}_{k=1}^{N+1}$ be a sequence of subspaces of T with

$$T = T^1 \supset T^2 \supset \cdots \supset T^N \supset \mathcal{N} = T^{N+1}$$

with $T^i(x_0)/T^{i+1}(x_0) \cong R^{n_i}$, $1 \leqq i \leqq N-1$, $T^N(x_0) \cong R^{n_N}$. Choose vector fields X_{ij} in T as follows: $X_{ij} \in T^i$ for $j = 1 \cdots n_i$, $X_{i1}(x_0) \cdots X_{in_i}(x_0)$ are linearly independent and together with $T^{i+1}(x_0)$ span $T^i(x_0)$.

Let $(t, x) \to \gamma_{ij}(t)(x)$ be the flow of X_{ij} and define a local coordinate chart (U, ϕ) for M about x_0 on a suitable neighbourhood U of x_0 where ϕ^{-1} is the map

$$(x_{11}, x_{12} \cdots x_{1n_1}, x_{21} \cdots x_{Nn_N}) \to \gamma_{11}(x_{11}) \circ \gamma_{12}(x_{12}) \circ \cdots \gamma_{1n_1}(x_{1n_1}) \circ \gamma_{21}(x_{21}) \circ \cdots \gamma_{Nn_N}(x_{Nn_n}).$$

We call (U, ϕ) a system of coordinates adapted to the sequence $\{T^k\}_{k=1}^{N+1}$.

In the situation of § 1.4 we have a solvable Lie algebra $\mathcal{L} = \beta(\mathcal{H})$ generated by vector fields $X_{H_i} = \beta(H_i)$ $0 \leqq i \leqq m$, and a nilpotent ideal $\mathcal{S} = \beta(\mathcal{H})$ generated by $X_{H_i} = \beta(H_i)$, $1 \leqq i \leqq m$. Let $\mathcal{O}$ be the subspace of $\mathcal{H}$ spanned by $H_1 \cdots H_m$ and closed under Poisson bracket with H_0. We set $\mathcal{O}^0 = \mathcal{O}$, $\mathcal{O}^k = [\mathcal{O}, \mathcal{O}^{k-1}]$. Thus $\mathcal{H}^k = \mathcal{O}^k + \mathcal{H}^{k+1}$ for $k = 0, \cdots, N$ where $\mathcal{H}^k$ is the descending central series of $\mathcal{H}$. Now $\beta(\mathcal{O}) = \mathcal{R}$, the subspace of $\mathcal{S}$ spanned by $X_{H_1} \cdots X_{H_m}$ and closed under Lie bracket with X_{H_0}. Setting $\mathcal{R}^{k+1} = \beta(\mathcal{O}^k)$ for $k = 0, \cdots, N-1$, $\mathcal{R} = \mathcal{R}^1$, $\mathcal{R}^k = [\mathcal{R}, \mathcal{R}^{k-1}]$ and $\mathcal{S}^k = \mathcal{R}^k + \mathcal{S}^{k+1}$ where $\mathcal{S}^k$ is the descending central seires of $\mathcal{S}$. (The indexing is chosen to coincide with that in Crouch [4]). Note that $\mathcal{R}^{N+1} = \{0\}$ which corresponds to the fact that $\mathcal{H}^N$ consists of constant functions. The following result, to which the above situation will be applied, follows from Crouch [4].

THEOREM 4. *Let $X_0, X_1, \cdots, X_m$ be complete vector fields on a manifold M which generate a solvable transitive Lie algebra, with nilpotent ideal $\mathcal{S}$ of codimension one generated by $X_1 \cdots X_m$. Assume $X_0(x_0) = 0$ for $x_0 \in M$. Let $\{\mathcal{R}^k\}$ be the sequence of subspaces of $\mathcal{S}$ as defined above, $\{\mathcal{S}^k\}$ the descending central series of $\mathcal{S}$ of length N, and the $\mathcal{N} \subset \mathcal{S}$ the subalgebra consisting of vector fields vanishing at x_0. Assume that $\mathcal{R}^k \cap \mathcal{N} = \mathcal{R}^k \cap (\mathcal{S}^{k+1} + \mathcal{N})$ for $k = 1 \cdots N-1$. Then there exists a global system of coordinates (M, Φ) adapted to the sequence of subalgebras*

$$\mathcal{S} = \mathcal{S}^1 \supset \mathcal{S}^2 + \mathcal{N} \supset \mathcal{S}^3 + \mathcal{N} \supset \cdots \supset \mathcal{S}^N + \mathcal{N} \supset \mathcal{N}$$

such that $\Phi(M) = R^n$ can be given a graded vector space structure $(R^n, \delta_t) R^n = R^{n_1} \oplus \cdots \oplus R^{n_N}$ $\delta_t(x_1 \cdots x_N) = (tx_1, t^2x_2, \cdots, t^N x_N)$ satisfying

(i) $\Phi_* X_0 \circ \Phi^{-1} \in P^0$.

(ii) $\Phi_* X_i \circ \Phi^{-1} \in P^1$, $\quad 1 \leqq i \leqq m$.

(iii) $\Phi(x_0) = 0$, Φ_* *maps the subspace $\mathcal{S}^k(x_0) \subset T_{x_0}M$ onto the subspace $R^{n_k} \oplus \cdots \oplus R^{n_N}$ of R^n.*

(iv) *The linear part of $\Phi_* X_0 \circ \Phi^{-1}$ is just the block diagonal matrix representation of $-\text{ad}\, X_0$ on S/N induced by the coordinate system and corresponding to the invariant subspaces $R^i + \mathcal{N}/\mathcal{N}$.*

The significance of the condition $R^k \cap \mathcal{N} = \mathcal{R}^k \cap \mathcal{S}^{k+1} + \mathcal{N})$ is indicated by the following result.

LEMMA 5. *In the situation of* § 1.4 *we have* $\mathcal{H}_f + \mathcal{H}^{n-k} = \mathcal{H}^{k\perp}$ *for* $k = 0, \cdots, N$ *and* $\mathcal{R}^k \cap \mathcal{N} = \mathcal{R}^k \cap (\mathcal{S}^{k+1} + \mathcal{N})$ *for* $k = 1, \cdots, N-1$. *Equivalently,* $T_{x_0}M$ *is the direct sum decomposition* $T_{x_0}M = R^1(x_0) \oplus \cdots \oplus R^N(x_0)$, *with* $\operatorname{Dim}(R^i(x_0)) = \operatorname{Dim}(R^{N+1-i}(x_0))$, *and* $\omega(R^i(x_0), R^j(x_0)) = 0$ *for* $i + j \neq N+1$.

Proof. By taking appropriate linear combinations and applying the Jacobi relation to the functions $\alpha_r^{J,I}$ defined in (7), it is clear that Assumption (iv) in § 1.4 is equivalent to

$$\theta_f(\mathcal{O}^j, \mathcal{O}^k) = 0 \quad \text{for } j + k \leqq N-2,$$

since $f = \tau(x_0)$ with $\tau(x_0)(X) = X(x_0)$ for $X \in \mathcal{H}$. Now Assumption (iii) in § 1.4 implies that $\theta_f(\mathcal{O}^j, \mathcal{O}^k) = 0$ for $j + k \geqq N$. In particular $\theta_f(\mathcal{O}^j, \mathcal{O}^k) \neq 0$ if and only if $j + k = N-1$.

From (10) we see that

$$\theta_f(X, Y) = \omega(\beta_0(X), \beta_0(Y)), \qquad X \in \mathcal{O}^j, \quad Y \in \mathcal{O}^k$$

so $\omega(\mathcal{R}^k(x_0), R^j(x_0)) = 0$ for $j + k \neq N+1$. By Assumption (ii) in § 1.4 $\beta_0(\mathcal{H}) = \mathcal{S}(x_0)$ spans $T_{x_0}M$. Thus by the nondegeneracy of ω given $Z \in \mathcal{O}^{N-j-1}$ such that $\beta_0(Z) \neq 0$ there exists $Y \in \mathcal{O}^j$ such that

$$\omega(\beta_0(Z), \beta_0(Y)) = \theta_f(Z, Y) \neq 0 \quad \text{for } j = 0, \cdots, N-1.$$

In particular, $\mathcal{R}^i(x_0) \cap \mathcal{R}^j(x_0) = \{0\}$ for $i \neq j$ since $\mathcal{R}^i(x_0) = \beta_0(\mathcal{O}^{i-1})$. It follows that $\mathcal{R}^i(x_0) \cap \mathcal{S}^{i+1}(x_0) = \{0\}$. That is

$$\{0\} = (\mathcal{R}^i + \mathcal{N}/\mathcal{N} \cap (\mathcal{S}^{i+1} + \mathcal{N})/\mathcal{N} = \frac{\mathcal{R}^i \cap (\mathcal{S}^{i+1} + \mathcal{N}) + \mathcal{N}}{\mathcal{N}}.$$

Hence $\mathcal{R}^i \cap (\mathcal{S}^{i+1} + \mathcal{N}) \subset \mathcal{N} \cap \mathcal{R}^i$. It is clear that this is equivalent to the direct sum decomposition of $T_{x_0}M$ by the spaces $R^i(x_0)$.

We must show $\mathcal{H}_f + \mathcal{H}^{N-k} = \mathcal{H}^{k\perp}$. Since $[\mathcal{H}^j, \mathcal{H}^k] \subset \mathcal{H}^{j+k+1}$, by definition of the descending central series, and $\mathcal{H}^{N+1} = \{0\}$ it is clear that $\mathcal{H}_f + \mathcal{H}^{N-k} \subset \mathcal{H}^{k\perp}$. Conversely, if $Z \in \mathcal{H}^{k\perp}$ then $\theta_f(Z, \mathcal{O}^j) = 0$ for $j \geqq k$. If $Z \notin \mathcal{H}_f + \mathcal{H}^{N-k}$, then $Z \in \mathcal{O}^0 + \cdots + \mathcal{O}^{N-k-1}$ and $\beta_0(Z) \neq 0$. If $Z = \sum_{i=0}^{N-k-1} Z_i$ with $Z_i \in \mathcal{O}^{N-k-i}$, then $0 = \theta_f(Z, \mathcal{O}^j) = \theta_f(Z_{N-j-1}, \mathcal{O}^j) = \omega(\beta_0(Z_{N-j-1}), \beta_0(\mathcal{O}^j))$ for $j \geqq k$. Now not all $\beta_0(Z_{N-j-1}) = 0$ since $\beta_0(Z) \neq 0$. But this contradicts our previous statement. Thus $\mathcal{H}_f + \mathcal{H}^{N-k} = \mathcal{H}^{k\perp}$. □

Remark 1. In the original context of Theorem 5 in Crouch [4], a less specific version of Lemma 5 is valid, but still yields the equivalence of $\mathcal{R}^k \cap \mathcal{N} = \mathcal{R}^k \cap (\mathcal{S}^{k+1} + \mathcal{N})$ with the direct sum decomposition of $T_{x_0}M$ by spaces $\mathcal{R}^k(X_0)$. The choice of coordinate system adapted to $\{\mathcal{S}^k + \mathcal{N}\}_{k=1}^{N+1}$ in Theorem 5 is characterized by the selection of the vector fields $X_{ij} \in \mathcal{R}^i$, which is possible by the above property.

4.2. We now construct certain sequences of subspaces of the Lie algebra $\mathcal{H}$, using the subalgebras $\mathcal{P}$, $\mathcal{D}$, $\mathcal{E}$ and $\mathcal{H}_f$ constructed in § 3. As in Assumption (iii) of § 1.4 we assume H has a descending central series of length $N+1$ and hence

$$\mathcal{H} = \mathcal{H}^0 \supset \mathcal{H}^1 \supset \cdots \supset \mathcal{H}^{N-1} \supset \mathcal{H}_f \supset \{0\};$$

here $\mathcal{H}^N$ consists of constant functions so $\mathcal{H}^N \subset \mathcal{H}_f$. We also have the orthogonal complement sequence, with respect to θ_f

$$\mathcal{H} = \mathcal{H}_f^{\perp} \supset \mathcal{H}^{N-1\perp} \supset \cdots \supset \mathcal{H}^{1\perp} \supset \mathcal{H}^{0\perp} = \mathcal{H}_f.$$

We must consider four cases.

Case 1. $N=2r$ there exists real polarization $\mathcal{P}$ at f invariant under $ad\, H_0$.

Case 2. $N=2r+1$ there exists real polarization $\mathcal{P}$ at f invariant under $ad\, H_0$.

Case 3. $N=2r$ there exists a complex polarization $\mathcal{P}_c$ at f invariant under $ad\, H_0$.

Case 4. $N=2r+1$ there exists a complex polarization $\mathcal{P}_c$ at f invariant under $ad\, H_0$.

In Cases 1 and 2 we have the following inclusions:

$$\mathcal{P}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-K}\supset\mathcal{P}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k+1}\supset\mathcal{P}\cap\mathcal{H}^{k-1\perp}+\mathcal{H}^{N-k+1} \tag{11}$$

for $k=1,2,\cdots,N$.

In Case 3 we have the following inclusions:

$$E\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k}\supset\mathcal{E}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k+1}\supset\mathcal{E}\cap\mathcal{H}^{k-1\perp}+\mathcal{H}^{N-k+1}$$

for $k=N,\ N-1,\cdots,r+1$,

$$\begin{gathered}\mathcal{E}\cap\mathcal{H}^{r\perp}+\mathcal{H}^{r}\supset\mathcal{D}\cap\mathcal{H}^{r\perp}+\mathcal{H}^{r},\\ \mathcal{D}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k}\supset\mathcal{D}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k+1}\supset\mathcal{D}\cap\mathcal{H}^{k-1\perp}+\mathcal{H}^{N-k+1}\end{gathered} \tag{12}$$

for $k=1,2,\cdots,r$.

In Case 4 we have the following inclusions:

$$\mathcal{E}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{n-k}\supset\mathcal{E}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k+1}\supset\mathcal{E}\cap\mathcal{H}^{k-1\perp}+\mathcal{H}^{N-k+1}$$

for $k=N,\ N=1,\cdots,r+2$,

$$\begin{gathered}\mathcal{E}\cap\mathcal{H}^{r+1\perp}+\mathcal{H}^{r}\supset\mathcal{E}\cap\mathcal{H}^{r+1\perp}+\mathcal{H}^{r+1}\supset\mathcal{D}\cap\mathcal{H}^{r+1\perp}+\mathcal{H}^{r+1}\supset\mathcal{D}\cap\mathcal{H}^{r\perp}+\mathcal{H}^{r+1},\\ \mathcal{D}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k}\supset\mathcal{D}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k+1}\supset\mathcal{D}\cap\mathcal{H}^{k-1\perp}+\mathcal{H}^{N-k+1}\end{gathered} \tag{13}$$

for $k=1,2,\cdots,r$.

LEMMA 6. *For $N=2r$ and $1\leqq k,j\leqq r$ or for $N=2r+1$ and $1\leqq k\leqq r$, $1\leqq j\leqq r+1$ we have the following identities concerning subalgebras of $\mathcal{H}$.*

$$\begin{aligned}(\mathcal{P}\cap\mathcal{H}^{N-k\perp}+\mathcal{H}^{k})^{\perp}&=\mathcal{P}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k},\\ (\mathcal{P}\cap\mathcal{H}^{N-j+1\perp}+\mathcal{H}^{j})^{\perp}&=\mathcal{P}\cap\mathcal{H}^{j\perp}+\mathcal{H}^{N-j+1},\\ (\mathcal{E}\cap\mathcal{H}^{N-k\perp}+\mathcal{H}^{k})^{\perp}&=\mathcal{D}\cap\mathcal{H}^{k\perp}+\mathcal{H}^{N-k},\\ (\mathcal{E}\cap\mathcal{H}^{N-j+1\perp}+\mathcal{H}^{j})^{\perp}&=\mathcal{D}\cap\mathcal{H}^{j\perp}+\mathcal{H}^{N-j+1}.\end{aligned}$$

Proof. As in Lemma 5 $\mathcal{H}^{N-k}\subset\mathcal{H}^{k\perp}$, so $\mathcal{H}^{N-k+1}\subset\mathcal{H}^{k\perp}$ also. If $X,\ Y\in\mathcal{H}^{k\perp}$ and $Z\in\mathcal{H}^{k-1}$ then

$$\theta_f([X,Y],Z)=f([[X,Y],Z])=-f([[Y,Z],X])-f([[Z,X],Y]).$$

Since $[Y,Z]$ and $[Z,X]$ belong to $\mathcal{H}^{k}$ and $X,\ Y\in\mathcal{H}^{k\perp}$ the last two terms vanish. Thus $[\mathcal{H}^{k\perp},\mathcal{H}^{k\perp}]\subset\mathcal{H}^{k-1\perp}\subset\mathcal{H}^{k\perp}$. The lemma is now obvious once it is observed that $\mathcal{D}$, $\mathcal{E}$ and $\mathcal{P}$ are all subalgebras of $\mathcal{H}$ satisfying $\mathcal{P}=\mathcal{P}^{\perp}$, $\mathcal{D}=\mathcal{E}^{\perp}$. □

We may now apply Lemma 5 to the expressions in (11), (12) and (13), whilst remembering that $\mathcal{H}_f\subset\mathcal{P}$ and $\mathcal{H}_f\subset\mathcal{D}\subset\mathcal{E}$.

In Cases 1 and 2 we have the following inclusions:

$$\mathcal{H}^{N-k}+\mathcal{H}_f\supset\mathcal{P}\cap\mathcal{H}^{n-k}+\mathcal{H}^{N-k+1}+\mathcal{H}_f\supset\mathcal{H}^{N-k+1}+\mathcal{H}_f \tag{14}$$

for $k=1,2,\cdots,N$.

In Case 3 we have the following inclusions:

$$\mathcal{H}^{N-k}+\mathcal{H}_f \supset \mathcal{E}\cap\mathcal{H}^{N-k}+\mathcal{H}^{N-k+1}+\mathcal{H}_f \supset \mathcal{H}^{N-k+1}+\mathcal{H}_f \tag{15}$$

for $k=N,\ N-1,\cdots,r+1$,

$$\mathcal{H}^{N-k}+\mathcal{H}_f \supset \mathcal{D}\cap\mathcal{H}^{N-k}+\mathcal{H}^{N-k+1}+\mathcal{H}_f \supset \mathcal{H}^{N-k+1}+\mathcal{H}_f$$

for $k=1,2,\cdots,r$.

In Case 4 we have the following inclusions:

$$\mathcal{H}^{N-k}+\mathcal{H}_f \supset \mathcal{E}\cap\mathcal{H}^{N-k}+\mathcal{H}^{N-k+1}+\mathcal{H}_f \supset \mathcal{H}^{N-k+1}+\mathcal{H}_f$$

for $k=N,\ N-1,\cdots,r+2$,

$$\begin{aligned}&\mathcal{H}^{r}+\mathcal{H}_f \supset \mathcal{E}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{D}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{H}^{r+1}+\mathcal{H}_f,\\ &\mathcal{H}^{N-k}+\mathcal{H}_f \supset \mathcal{D}\cap\mathcal{H}^{N-k}+\mathcal{H}^{N-k+1}+\mathcal{H}_f \supset \mathcal{H}^{N-k+1}+\mathcal{H}_f\end{aligned} \tag{16}$$

for $k=1,2,\cdots,r$.

We may now use these sequences of subalgebras to obtain our initial coordinate representation of the situation described in § 1.4.

THEOREM 5. *In the situation of* § 1.4 *we meet the hypotheses of Theorem* 4 *by setting* $\beta(H_i)=X_i,\ 0\leqq i\leqq m,\ \mathcal{S}^{k+1}=\beta(\mathcal{H}^k)k=0,\cdots,N-1,\ \mathcal{N}=\beta(\mathcal{H}_f)$. *We obtain a diffeomorphism from M onto a graded vector space* (R^n,δ_t) *of degree N with the properties listed in Theorem* 4. *The graded vector space structure may be refined by adapting the coordinates to the homomorphic images under* β *of the sequences of subalgebras of* $\mathcal{H}$ *in* (14)-(16), *depending on whether N is even or odd, and whether or not there exists a real ad* H_0 *invariant polarization for* $\mathcal{H}$ *at f. This distinguishes the four cases listed above. In Cases* 1 *and* 3 *the resulting graded structure corresponds to that defined in equation* (8). *In Cases* 2 *and* 4 *the resulting graded structure corresponds to that defined in equation* (9). *In Case* 4, *however, we must add an extra subspace.*

Proof. The only hypotheses of Theorem 4 not trivially satisfied by the situation described in § 2.4 are the assumptions $\mathcal{R}^k\cap\mathcal{N}=\mathcal{R}^k\cap(\mathcal{S}^{k+1}+\mathcal{N})$. However, these are shown to be satisfied in Lemma 5. It is clear that in refining the coordinates to the homomorphic images under β of the sequences of subspaces in (14) and (15) we may define correspondingly refined graded vector spaces, which in Cases 1 and 3 is that defined in (8) and in Case 2 is that defined in (9), whilst retaining properties (i)-(iii) in Theorem 4.

In Case 4, which defines the sequences of subspaces in (16), there is an added inclusion

$$\mathcal{H}^{r}+\mathcal{H}_f \supset \mathcal{E}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{D}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{H}^{r+1}+\mathcal{H}_f.$$

By Lemma 6 we have (with respect to θ_f)

$$(\mathcal{E}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f)^{\perp}=\mathcal{D}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f.$$

Thus by standard symplectic algebra there exists a subspace $\mathcal{P}_L\subset H$ such that $\mathcal{P}_L^{\perp}=\mathcal{P}_L$ and

$$\mathcal{H}^{r}+\mathcal{H}_f \supset \mathcal{E}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{P}_L \supset \mathcal{D}\cap\mathcal{H}^{r}+\mathcal{H}^{r+1}+\mathcal{H}_f \supset \mathcal{H}^{r+1}+\mathcal{H}_f. \tag{17}$$

It is now clear that we can also refine the coordinates in Case 4, using the homomorphic images under β of the sequences of subspaces in (16) and (17), to give the graded vector space structure defined in equation (9), whilse also retaining properties (i)-(iii) of Theorem 4.

The dimensional constraints on the graded vector spaces defined in (8) and (9) are also valid in this case. To see this we simply apply Lemma 3 to the identities in Lemma 6, (whilst remembering that $\mathcal{H}^{N-k}+\mathcal{H}_f=\mathcal{H}^{k\perp}$ from Lemma 5), and use the non-degeneracy of the bilinear form ω on $T_{x_0}M$.

It remains to consider to what extent we may retain property (iv) of Theorem 4. By Lemmas 2 and 4 the subalgebras $\mathcal{H}_f$, $\mathcal{P}$, $\mathcal{D}$, and $\mathcal{E}$ may be invariant under $ad\, H_0$. Note also that $\mathcal{H}^k$ is invariant under $ad\, H_0$ also. It follows that all subalgebras encountered in the sequences of subalgebras (14), (15), (16) are therefore invariant under $ad\, H_0$. It is not true however that the subspace $\mathcal{P}_L$ in (17) is invariant under $ad\, H_0$. Indeed it is this noninvariance which causes us to seek complex polarizations $\mathcal{P}_c$ which are invariant.

Notice that each block A^k in the matrix representation of $-ad\,\beta(H_0)$ on $\mathcal{S}/\mathcal{N}$, where A^k is its representation on $\mathcal{R}^k+\mathcal{N}/\mathcal{N}$, $1\leqq k\leqq N$ by (iv) of Theorem 4, is also equal to the induced representation on $((\mathcal{S}^k+\mathcal{N})/\mathcal{N}/(\mathcal{S}^{k+1}+\mathcal{N})/\mathcal{N}$ since $\mathcal{R}^k\cap\mathcal{N}=\mathcal{R}^k\cap(\mathcal{S}^{k+1}+\mathcal{N})$, and hence is also equal to the induced representation of $-ad\, H_0$ on

$$\frac{(\mathcal{H}^{k-1}+\mathcal{H}_f)/\mathcal{H}_f}{(\mathcal{H}^k+\mathcal{H}_f)/\mathcal{H}_f}.$$

Since all of the extra subspaces introduced in (14)-(16), are "sandwiched" between subspaces $\mathcal{H}^{k+1}+\mathcal{H}_f$ for some k, and these are invariant under $-ad\, H_0$, it follows that A^k has a block triangular form. In all but Case 4 we have

$$A^k=\begin{pmatrix}A^k_{11} & 0\\ A^k_{21} & A^k_{22}\end{pmatrix}$$

for each k but in Case 4 and $k=r+1$, $N=2r+1$ corresponding to the subspaces in (17) we have

$$A^k=\begin{pmatrix}A^k_{11} & 0 & 0 & 0\\ A^k_{21} & A^k_{22} & A^k_{23} & 0\\ A^k_{21} & A^k_{32} & A^k_{33} & 0\\ A^k_{41} & A^k_{42} & A^k_{43} & A^k_{44}\end{pmatrix}.$$

□

4.3. In this subsection we work out further details concerning the coordinate representation of the situation in § 1.4 obtained in Theorem 5.

LEMMA 7. *Let $\Phi: M\to R^n$ be the diffeomorphism obtained in Theorem 5 from the symplectic manifold (M,ω) onto the graded vector space (R^n,δ_t). Then $\sigma=\Phi^{-1*}\omega$ defines a symplectic form on R^n, such that (R^n,δ_t,σ) is a graded symplectic vector space.*

Proof. In this lemma the initial graded vector space structure obtained in Theorem 5 supplies sufficient structure for the proof of the result. Using the notation at the beginning of § 4.1, we abbreviate the map Φ^{-1} by $(x^1,x^2,\cdots,x^N)\to\gamma^1(x^1)\circ\cdots\circ\gamma^N(x^N)=\phi(x)(x_0)$ where x^i represents each component of the coordinates $(x_{i1}),\cdots,(x_{in_i})$ and γ^i represents each of the flows $\gamma_{i1},\cdots,\gamma_{in_i}$. In this case each flow γ_{ij} corresponds to a Hamiltonian vector field $X_{h_{ij}}$ which belongs to $\mathcal{R}^i$ by Remark 1 in § 4.1; thus h_{ij} belongs to $\mathcal{O}^{i-1}$. Abbreviate $X_{h_{ij}}$ by X^i and h_{ij} by h^i.

It now follows that

$$\begin{aligned}\sigma_x\left(\frac{\partial}{\partial x^i},\frac{\partial}{\partial x^j}\right)&=((\Phi^{-1})^*\omega)_x\left(\frac{\partial}{\partial x^i},\frac{\partial}{\partial x^j}\right)\\&=\omega_{\Phi^{-1}(x)}\left((\Phi^{-1})_*\frac{\partial}{\partial x^i},\Phi_*^{-1}\frac{\partial}{\partial x^j}\right)\\&=\omega_{\phi(x)(x_0)}\left(\frac{\partial}{\partial x^i}\phi(x)(x_0),\frac{\partial}{\partial x^i}\phi(x)(x_0)\right).\end{aligned}$$

Now

$$\frac{\partial}{\partial x^i}\phi(x)(x_0) = \gamma^1(x^1)_* \cdots \gamma^{i-1}(x^{i-1})_* X^i(\gamma^i(x^i) \circ \cdots \circ \gamma^N(x^N)(x_0))$$

$$= \phi(x)_* \gamma^N(-x^N)_* \cdots \gamma^i(-x^i)_* X^i(\gamma^i(x^i) \circ \cdots \circ \gamma^N(x^N)(x_0)).$$

Since $p \to \phi(x)(p)$, $\phi(x): M \to M$ is a composition of symplectic maps $p \to \gamma_{ij}(x_{ij})(p)$ for each $x \in R^n$, it follows that $\phi(x)^*\omega = \omega$. Moreover by Jacobi's theorem, Abraham and Marsden [21], if $\psi: M \to M$ is a symplectic map and X_h is a Hamiltonian vector field with Hamiltonian h, then $\psi_*^{-1} X_h \circ \psi = X_{h \circ \psi}$. It follows that

$$\sigma_x\left(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right) = \omega_{x_0}(X_{h^i \circ \gamma^i(x^i) \circ \cdots \circ \gamma^N(x^N)}, X_{h^j \circ \gamma^j(x^j) \circ \cdots \circ \gamma^N(x^N)}).$$

By definition of the Poisson bracket we may express this as

$$[h^i \circ \gamma^i(x^i) \circ \cdots \circ \gamma^N(x^N), h^j \circ \gamma^j(x^j) \circ \cdots \circ \gamma^N(x^N)](x_0).$$

Up to sign we may represent this as a sum of iterated Poisson brackets

$$\sum_{\substack{k_N, \cdots, k_i \\ l_N, \cdots, l_i}} [(ad\, h^N)^{k_N} \cdots (ad\, h^i)^{k_i}(h^i), (ad\, h^N)^{l_N} \cdots (ad\, h^j)^{l_j}(h^j)](x_0)$$

$$\times \frac{(x^N)^{k_N}}{k_N!} \cdots \frac{(x^i)^{k_i}}{k_i!} \frac{(x^N)^{l_N}}{l_N!} \cdots \frac{(x^j)^{l_j}}{l_j!}.$$

Since each $h^k \in \mathscr{H}$, a nilpotent Lie algebra this is a polynomial on $x^N, \cdots, x^{\min(i,j)}$.

We must verify that σ whose i,jth component is given above satisfies $\delta_t^* \sigma = t^{N+1}\sigma$, where the dilation δ_t is defined in our abbreviated terminology by

$$\delta_t(x^1, \cdots, x^N) = (tx^1, \cdots, t^N x^N).$$

This is equivalent to showing that the above polynomial expression lies in $\mathscr{O}^{N+1-i-j}$. However by construction each $h^j \in \mathscr{O}^{j-1}$, and Lemma 5 Assumptions (iii) and (iv) in § 1.4 imply that $\theta_f(\mathscr{O}^l, \mathscr{O}^k) = 0$ unless $l+k = N-1$ or $l-1+k-1 = N+1$, from which the required result follows. □

COROLLARY 1. *In the situation of Lemma 7 the components of the symplectic form σ on R^n evaluated at zero are given by*

$$\sigma_0\left(\frac{\partial}{\partial x_{il}}, \frac{\partial}{\partial x_{jk}}\right) = \omega_{x_0}(X_{il}, X_{jk})$$

for $1 \leqq i \leqq n_l$, $1 \leqq j \leqq n_k$, $1 \leqq k, l \leqq N$.

Proof. Evaluate the expression in (19) at $x = 0$ and replace the abbreviations for the nomenclature used at the beginning of § 4.1. □

LEMMA 8. *In the situation of Theorem 5 the coordinate system for the refined graded vector space may be chosen so that $\sigma = (\Phi^{-1^*}\omega)$ takes its canonical form at $x = 0$.*

Proof. By Corollary 1 and Remark 1 it is clear that special attention must be paid to the choice of the vector fields $X_{ij} \in \mathscr{R}^i$.

We use the following result which can be found in Irving [8], and is derived using standard technqiues of symplectic linear algebra. Let (V, ω) be a symplectic vector space, with a sequence of subspaces $\{V_k\}_{k=1}^{2q+1}$

$$V = V_1 \supset V_2 \supset \cdots \supset V_{q+1} \supset \cdots \supset V_{2q-1} \supset V_{2q} \supset \{0\} = V_{2q+1}$$

satisfying $V_{2q-k+2}^{\perp} = V_k$ for $k = 1, \cdots, 2q+1$.In particular $V_{q+1} = V_{q+1}^{\perp}$ is a Lagrangian subspace. Assume that $V_k = U_k \oplus V_{k+1}$ is a direct sum decomposition for $k = 1, \cdots, 2q$.

Then we may choose a basis for V consisting of vectors selected only from the spaces U_k such that the resulting coordinate system for V displays ω in the form

$$\left(\begin{array}{c|c} 0 & I \\ \hline -I & 0 \end{array}\right)$$

and

$$I = \begin{pmatrix} & & & I_{n_q} \\ & 0 & \iddots & \\ & I_{n_2} & & \\ & & 0 & \\ I_{n_1} & & & \end{pmatrix} \qquad n_k = \text{Dim } U_k,\ k = 1, \cdots, q.$$

The partitioning obviously corresponds to the subspaces V_k. By suitable labelling of the coordinates, as in (8) and (9), we obtain the canonical representation of a symplectic form.

In the situation considered here we apply Lemmas 3, 6 and 5 in turn to the sequences of subspaces in (14)-(16), adding the subspace $\mathscr{P}_L$ defined in (17) to the sequence in (16). This defines sequences of subspaces of $T_{x_0}M$ as above, in each of the cases one to four, which satisfy the required orthogonality conditions. Although the corresponding subspaces U_k are not uniquely defined, we have the expression

$$T_{x_0}M = \mathscr{R}^1(x_0) \oplus \mathscr{R}^2(x_0) \oplus \cdots \oplus \mathscr{R}^N(x_0).$$

In the situation above either V_k coincides with a direct sum $\mathscr{R}^j(x_0) \oplus \cdots \oplus \mathscr{R}^N(x_0) = \mathscr{S}^j(x_0)$ or $\mathscr{S}^j(x_0) \supsetneq V_k \supsetneq \mathscr{S}^{j+1}(x_0)$. Moreover, in this latter case we have $\mathscr{S}^j(x_0) \supset V_{k-1} \supset V_k \supset V_{k+1} \supset \mathscr{S}^{j+1}(x_0)$. It follows that each subspace U_k may be defined as a subspace of some $\mathscr{R}^j(x_0)$ subspace. We deduce that there exists a basis of $T_{x_0}M$ with each element contained in the intersection of some $\mathscr{R}^j(x_0)$ subspace and some V_k subspace, such that in the coordinate system defined by this basis ω_{x_0} is in its canonical form. We now select the vector fields X_{ij} so as to coincide with this basis when evaluated at x_0. This choice meets all the conditions imposed in Theorem 5, and by Corollary 1 ensures that σ evaluated at $x = 0$ is in canonical form. □

Combining these results we obtain the main result of this section.

THEOREM 6. *In the situation of* § 1.4 *there exists a symplectic diffeomorphism* Φ *from* M *onto a graded symplectic vector space* (R^n, δ_t, σ), $\Phi(x_0) = 0$, *with* δ_t *defined in* (8) *or* (9) *and* $\sigma(0)$ *in canonical form.*

Further, with respect to this graded structure $H_0 \circ \Phi^{-1} \in Q^{N+1}$ *and* $H_i \circ \Phi^{-1} \in Q^N$, $1 \leqq i \leqq m$.

Proof. We apply Theorem 5 to obtain an initial diffeomorphism Φ from M onto a graded vector space (R^n, δ_t) with δ_t defined in (8) or (9), and such that $\Phi_* \beta(H_0) \circ \Phi^{-1} \in P^0$, $1 \leqq i \leqq m$, $\Phi_* \beta(H_i) \circ \Phi^{-1} \in P^{-1}$, and $\Phi(x_0) = 0$. By Lemma 7 ${\Phi^{-1}}^* \omega = \sigma$ makes (R^n, δ_t, σ) into a graded symplectic vector space, with Φ a symplectic map. By Lemma 8 we modify our initial choice of Φ so that $\sigma(0)$ is in canonical form. Since Φ is symplectic $\Phi_* \beta(H_i) \circ \Phi^{-1} = \beta(H_i \circ \Phi^{-1})$, $0 \leqq i \leqq m$ with respect to σ. By Lemma 1 we deduce that $H_0 \circ \Phi^{-1} \in Q^{N+1}$, $H_i \circ \Phi^{-1} \in Q^N$. □

5. A Darboux–Weinstein theorem. In this section we are given a graded symplectic vector space of degree N, (R^n, δ_t, ω), where ω is a nonconstant form on R^n. We wish to show that there is a global diffeomorphism ϕ of R^n such that

(i) $\phi^* \bar{\omega} = \omega$ where $\bar{\omega}$ is the constant symplectic form on R^n which is equal to $\omega(0)$.

(ii) ϕ preserves the graded structure of (R^n, δ_t). That is ϕ commutes with the dilation δ_t, $\phi \circ \delta_t = \delta_t \circ \phi$.

We note that if X is a vector field on (R^n, δ_t) such that $X \in P^0$, then $\delta_{t*}X = X \circ \delta_t$. Therefore, if $(s, x) \to \psi(s)(x)$ is the flow of X we have

$$\delta_t \circ \psi(s) = \psi(s) \circ \delta_t.$$

Therefore we may synthesize diffeomorphisms ϕ as above from the flows of vector fields in P^0.

We need a technical result before showing that we can in fact achieve such a result.

LEMMA 9. *If $(s, x) \to X(s)(x)$ is a time varying vector field on a graded vector space (R^n, δ_t) of degree N such that for each s $X(s) \in P^0$ and for each $x \in R^n$ the map $s \to X(s)(x)$ is continuous then X is complete. That is its flow*

$$(s, u, x) \to \phi(s, u)(x) \qquad \phi(u, u)(x) = x$$

$$\frac{d\phi}{ds}(s, u)(x) = X(s)(\phi(s, u)(x))$$

is C^1 and defined on $R \times R \times R^n$. Moreover each map $x \to \phi(s, u)(x)$ commutes with δ_t.

Proof. The fact that $X(s) \in P^0$ implies that we may write $X(s)$ in the coordinates of $\mathbb{R}^n$ as

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \vdots \\ \dot{x}_N \end{bmatrix} = \begin{bmatrix} A_1(t)x_1 \\ A_2(t)x_2 + a_2(t, x_1) \\ \vdots \\ A_N(t)x_N + a_N(t, x_1 \cdots x_{N-1}) \end{bmatrix}$$

where $a_k(s, \delta_t x) = t^k a_k(s, x) = t^k a_k(s, x_1 \cdots x_{k-1})$. Each of the components of the matrices $A_k(t)$ and the coefficients of the polynomials $a_k(t, x)$ are continuous in t by assumption. This implies that the fundamental solution of $\dot{x}_k(s) = A_k(s)x_k(s)$, $x_k(u) = x_k^0$, is C^1, $x_k(s) = \Phi(s, u)x_k^0$, and defined for all $(s, u) \in \mathbb{R} \times \mathbb{R}$. This in turn implies by successive integration of the equations above that the vector field X is complete. That $\delta_t(\phi(s, u)(x)) = \phi(s, u)(\delta_t(x))$ follows as before from $\delta_{t*}X(s)(x) = X(s)(\delta_t(x))$. □

To prove the Darboux-Weinstein result we need the following construction, on a graded vector space of degree $N(R^n, \delta_t)$ with closed two form ω, satisfying $\delta_t^* \omega = t^{N+1}\omega$. We note that nondegeneracy is not required of ω.

If $Z(t)$ is the vector field $d\delta_s/ds|_{s=t}$ along δ_t then

$$\frac{d}{ds}(\delta_s^* \omega)_{s=t} = \delta_t^* L_{Z(t)}\omega = \delta_t^* i(Z(t))\, d\omega + d\delta_t^*(i(Z(t))\omega).$$

Since $d\omega = 0$, δ_0 is the zero map and δ_1 is the identity map we may integrate this equation with respect to t on $[0, 1]$ to obtain $\omega = dI(\omega)$ where

$$I(\omega) = \int_0^1 \delta_s^*(i(Z(s))\omega)\, ds.$$

We note that $\delta_s \circ \delta_t = \delta_t \circ \delta_s$ for $t, s > 0$, and hence $\delta_{t*}Z(s) = Z(s) \circ \delta_t$. Thus

$$\delta_t^* I(\omega) = \int_0^1 \delta_s^*(i(\delta_{t*}^{-1}Z(s) \circ \delta_t)\delta_t^* \omega)\, ds$$

$$= \int_0^1 \delta_s^*(i(Z(s))t^{N+1}\omega)\, ds = t^{N+1} I(\omega).$$

Thus $I(\omega)$ also satisfies $\delta_t^* I(\omega) = t^{N+1} I(\omega)$. We prove our version of the Darboux-Weinstein theorem in Weinstein [19].

THEOREM 7. *Given a graded symplectic vector space* (R^n, δ_t, ω) *with polynomic symplectic form* ω, *there exists a diffeomorphism* ϕ *of* R^n, *which preserves the graded structure and satisfies* $\phi^*\omega = \bar{\omega}$, *where* $\bar{\omega}$ *is the constant symplectic form defined by* $\omega(0)$. *Moreover the linear part of* ϕ *is the identity map.*

Proof. Let $\Omega = \omega - \bar{\omega}$ and $\Omega_t = \bar{\omega} + t\Omega$. Now $d\Omega = O$ and $\delta_t^*\Omega = t^{N+1}\Omega$. It follows by the preceding argument that $\sigma = I(\Omega)$ satisfies $d\sigma = \Omega$ and $\delta_t^*\sigma = t^{N+1}\sigma$. We also claim that for any t, Ω_t is a nondegenerate bilinear form on the whole of R^n. Consider the matrix representation of ω with respect to the coordinate system of the graded vector space. It therefore has a corresponding block structure corresponding to the decomposition $R^n = R^{n_1} \oplus \cdots \oplus R^{n_N}$. Identifying $\partial/\partial x^i$ with any vector field $\partial/\partial x_{ij}$ as in the proof of Lemma 7 we may write

$$\omega = \sum_{k=-(N-1)}^{N-1} \omega_k, \quad \text{where } \omega_k\left(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right) = \delta_{i+j,N+1-k}\omega\left(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right)$$

for $-(N-1) \leqq k \leqq (N-1)$.

It follows that the components α_k of ω_k are polynomials which satisfy

$$\alpha_k \circ \delta_t = t^k \alpha_k.$$

Since ω is polynomic in these coordinates, we must have $\omega_{-1} = \cdots = \omega_{-(N-1)} = 0$ and ω_0 constant. Moreover, since ω_k for $k > 0$ vanish at $x = 0$ we see that $\omega_0 = \bar{\omega}$.

It follows that $\Omega_t = \bar{\omega} + \sum_{k=1}^{N-1} t\omega_k$ where $\bar{\omega}$ has the block form

$$\begin{pmatrix} & & & A_N \\ & 0 & \iddots & \\ & A_2 & & 0 \\ A_1 & & & \end{pmatrix}$$

and ω_k has the block form

$$\begin{pmatrix} 0 & & B_{N-k}(x) & 0 \\ & \ddots & & \ddots \\ B_1(x) & 0 & & \\ \vdots & \ddots & & \\ 0 & & & 0 \end{pmatrix}.$$

Since $\bar{\omega}$ is invertible it follows that Ω_t is also invertible for any t and any $x \in R^n$. Thus Ω_t defines an isomorphism $\Omega_t^\# : T_x R^n \to T_x R^n$.

We define a time varying vector field on R^n by $Y(t) = -\Omega_t^{\#-1}(\sigma)$. Clearly $\Omega_t^{\#-1}$ is continuous (even linear) in t. We claim that $Y(t) \in P^0$ for each t, also. However, by definition $\Omega_t(Y(t), Z) = -\sigma(Z)$ and $\delta_s^*\Omega_t = s^{N+1}\Omega_t$, $\delta_s^*\sigma = s^{N+1}\sigma$. Thus it is clear that $\delta_{s*}Y(t) = Y(t) \circ \delta_s$ which simply states that $Y(t) \in P^0$ for each t as claimed.

We may now apply Lemma 9 to see that $Y(t)$ is complete. Let $(t, x) \to \phi(t, x)$ denote the map $(t, x) \to \phi(t, 0)(x)$ where ϕ is the flow of Y. It follows that

$$\begin{aligned} \frac{d}{dt}\phi_t^*\Omega_t &= \phi_t^* \frac{d\Omega_s}{ds}\bigg|_{s=t} + \phi_t^* L_{Y(t)}\Omega_t \\ &= \phi_t^*\Omega + \phi_t^* d(i(Y(t))\Omega_t) + \phi_t^* i(Y(t))\, d\Omega_t \end{aligned}$$

$$= \phi_t^* \Omega - \phi_t^* \, d\sigma \quad \text{since } d\Omega_t = 0$$

$$= 0 \quad \text{since } \Omega = d\sigma.$$

Therefore by integrating with respect to t for $t \in [0, 1]$ we obtain $\phi_1^* \Omega_1 = \Omega_0$. Thus the required diffeomorphism ϕ is just ϕ_1.

Now $\Omega = \omega - \bar{\omega} = \sum_{k=1}^{N-1} \omega_k$, where the components of ω_k belong to Q^k. Since $\Omega = d\sigma$ we may write $\sigma = \sum_{k=1}^{N-1} \sigma_k$ where the components of σ belong to Q^{k+1}. In particular, σ contains no components with linear terms. On the other hand, $\Omega_t^{\#^{-1}} = \bar{\omega}^{\#^{-1}} + t\alpha$ for some matrix α, with polynomial coefficients. It follows that $Y(t) = -\Omega_t^{\#^{-1}}(\sigma)$ is a vector field with polynomial coefficients containing no linear, or constant terms. This shows that the linear part of the map $x \to \phi(1, 0)(x)$, is the identity map as desired. □

6. Summary.

6.1. In this final section we draw together the results of the previous sections, and give some examples.

By combining Theorems 6 and 7 we obtain the following abstract result.

THEOREM 8. *Given a symplectic manifold* (M, ω), *a specific point* $x_0 \in M$, *a solvable Lie algebra* $\mathcal{H}$ *of functions on* M *generated by* $H_1 \cdots H_m$, *satisfying the assumptions* (i)-(iv) *of* § 1.4, *then there exists a diffeomorphsim* $\Phi : M \to R^n$ *onto a graded symplectic vector space* (R^n, δ_t, σ) *such that* $\Phi(x_0) = 0$, $\Phi^* \sigma = \omega$, σ *is in its canonical representation, and with respect to the graded structure*

$$H_0 \circ \Phi^{-1} \in Q^{N+1}, \quad H_i \circ \Phi^{-1} \in Q^N, \quad 1 \leqq i \leqq m.$$

We may also give the following control theoretic version of this result.

THEOREM 9. *Given an homogeneous Volterra series* (2) *which is realizable by a Hamiltonian system* (5), *there exists another Hamiltonian realization on a graded symplectic vector space, with the symplectic form exhibited in canonical form, which satisfies all of the conditions* (i)-(iv) *to Theorem* 1.

This result completely answers the problem posed in § 1.3. The partial converse of Theorem 9 is also true and mimics Theorem 2. By employing Theorem 3 we can also ensure linearity in the "p" variables.

THEOREM 10. *Given a Hamiltonian system* (5) *on a graded symplectic vector space* $(R^n, \delta_t, \Omega_c)$ *of degree* N, *defined by* $H_0 \in Q^{N+1}$ *and* $H_i \in Q^N$, $1 \leqq i \leqq m$, *then the input-output map is a homogeneous Volterra series* (2). *By symplectic change of coordinates onto another graded symplectic vector space* $(R^n, \delta_t', \Omega_c)$ *we can assume that all functions* H_i, $1 \leqq i \leqq m$ *are affine in the "*p*" coordinates and polynomial in the "*q*" variables.*

Linearity in the "p" coordinates for the function H_0 is discussed in § 2.

Of course it is this representation with linearity in the "p" coordinates which is obtained in Theorems 8 and 9. Moreover, the discussion about linearity in the "p" coordinates for the function H_0 is concerned eventually with the four cases described in § 4.2. Indeed the discussion concerns most importantly the quadratic terms in the H_0 function, or equivalently the linear terms in the corresponding Hamiltonian vector field X_{H_0}. This is discussed at length in Theorem 5, and results are also valid for the representation obtained in Theorem 6. In the Darboux-Weinstein Theorem 7 it is shown that the final coordinate change is the identity in its linear component which in turn shows that this structure for the linear part of X_{H_0}, or quadratic part of H_0 is still valid in the final representations presented in Theorems 8 and 9. The interested reader should have no difficulty in writing down explicit forms for each of the four cases described in § 4.2. See also Irving [8] for more details concerning these systems.

We conjecture that similar results are also true in the nonhomogeneous case, where we consider arbitrary finite Volterra series, or equivalently dispense with Assumption (iv) in § 1.4. Indeed, most of the results in § 4 can be carried out successfully using inclusions (11)-(13). We do, however, lose linearity on the "p" variables. It has not been possible to obtain a corresponding global version of the Darboux-Weinstein theorem however.

6.2. In this subsection we present some examples of accessible Hamiltonian systems all with respect to the canonical symplectic structure.

Example 1. $R^4 = R^2 \oplus R^2$, is a graded vector space of degree $N = 2$.

$$H_0 = p_2 q_1 + q_2 q_1^2, \qquad H_1 = p_1,$$
$$\dot{q}_1 = u, \qquad \dot{q}_2 = q_1,$$
$$\dot{p}_1 = -p_2 - 2q_2 q_1, \qquad \dot{p}_2 = -q_1^2,$$
$$y = p_1.$$

In this example there exists an $ad\, H_0$ invariant polarization for $\mathcal{H}$.

Example 2. $R^6 = R^2 \oplus R^2 \oplus R^2$, is a graded vector space of degree $N = 3$,

$$H_1 = p_1, \qquad H_0 = p_2 q_1 + p_3 q_1^2 + q_2 q_1^3$$
$$\dot{q}_1 = u, \quad \dot{q}_2 = q_1, \quad \dot{q}_3 = q_1^2,$$
$$\dot{p}_3 = -q_2^2, \quad \dot{p}_2 = -q_1^3 - 2q_2 q_3, \quad \dot{p}_1 = -2p_3 q_1 - p_2 - 3q_2 q_1^2,$$
$$y = p_1.$$

In this example there exists an $ad\, H_0$ invariant polarization for H.

Example 3. R^2 is a graded vector space of degree $N = 1$.

$$H_1 = p_1, \qquad H_0 = \tfrac{1}{2}(p_1^2 + q_1^2),$$
$$\dot{q}_1 = p_1 + u, \qquad \dot{p}_1 = -q_1,$$
$$y = p_1.$$

In this example there is no real $ad\, H_0$ invariant polarization for $\mathcal{H}$.

Example 4. $R^4 = R \oplus R^2 \oplus R$ is a graded vector space of degree

$$N = 3, \quad H_1 = p_1, \quad H_0 = p_2 q_1^2 + \tfrac{1}{2}(p_2^2 + q_2^2),$$
$$\dot{q}_1 = u, \quad \dot{q}_2 = q_1^2 + p_2, \quad \dot{p}_2 = -q_2, \quad \dot{p}_1 = -2p_2 q_1,$$
$$y = p_1.$$

In this example there is no real $ad\, H_0$ invariant polarization for $\mathcal{H}$.

MINIMUM VARIANCE CONTROL OF DISCRETE TIME MULTIVARIABLE ARMAX SYSTEMS*

U. SHAKED† AND P. R. KUMAR‡

Abstract. We consider multivariable ARMAX stochastic systems. These systems can incorporate the following complicating features: general delay structures, nonminimum phase transfer functions, different dimensions for input and output vectors. We obtain the control laws which minimize the variance of the output process while maintaining system stability.

Key words. minimum variance control, vector ARMAX systems, nonminimum phase systems

1. Introduction. We consider multivariable linear stochastic systems in an ARMAX format:

$$A(z)y(t) = z^d B(z)u(t) + C(z)w(t). \tag{1}$$

Here z is the *backward* shift operator: $zy(t) := y(t-1)$. $y(t) \in \mathbb{R}^m$ is the output, $u(t) \in \mathbb{R}^l$ is the input and $w(t) \in \mathbb{R}^m$ is a white noise process, i.e. it is wide sense stationary, $Ew(t) = 0$ and covariance $Ew(t)w^T(s) = Q\delta_{ts}$.

$$A(z) = I + \sum_{i=1}^{n} A_i z^i. \tag{2i}$$

$$B(z) = B_0 + \sum_{i=1}^{n} B_i z^i, \qquad B_0 \neq 0, \quad B(z) \text{ is of full rank.} \tag{2ii}$$

$$C(z) = C_0 + \sum_{i=1}^{n} C_i z^i, \qquad C^{-1}(z) \text{ is analytic inside the closed unit disc.} \tag{2iii}$$

(2iv) d, the delay, is an integer with $d \geqq 1$.

We shall define as "admissible", control laws which are of the form $u(t) = M(z)y(t)$ where

(3i) $M(z)$ is a matrix of rational functions;

(3ii) $M(z)$ is analytic at $z = 0$.

The condition (3ii) restricts us to the set of nonanticipative control laws, while (3i) is imposed merely for convenience.

We shall further say that an admissible control law $u(t) = M(z)y(t)$ is "stabilizing" if the four transfer functions

$$\begin{aligned} &M(z)[I - z^d A^{-1}(z)B(z)M(z)]^{-1}, \qquad [I - z^d A^{-1}(z)B(z)M(z)]^{-1}, \\ &[I - z^d M(z)A^{-1}(z)B(z)]^{-1}, \qquad z^d A^{-1}(z)B(z)[I - z^d M(z)A^{-1}(z)B(z)]^{-1} \end{aligned} \tag{4}$$

are all analytic inside the closed unit disc. The restrictions in (4) are imposed so that the resulting closed-loop system is internally stable.

Our goal in this paper is to find a control law, from among the set of all admissible stabilizing control laws, which minimizes the variance $Ey^T(t)y(t)$ of the output process in steady state.

For single-input, single-output (i.e., $m = l = 1$) minimum phase systems, the problem has been solved by Astrom [1]. The minimum variance control law is shown to be

$$u(t) = -\frac{-G(z)}{B(z)F(z)}\, y(t) \tag{5i}$$

where $F(z)$, a polynomial of degree $d-1$, and $G(z)$, a polynomial, satisfy

$$C(z) = A(z)F(z) + z^d G(z). \tag{5ii}$$

If the system is of nonminimum phase, then while the above control law still minimizes the variance of the output process from among the set of all admissible control laws, it is *not* however stabilizing. To satisfy stability, one must "sacrifice" some variance. This constrained optimization problem of obtaining a control law which minimizes the output variance over the set of all admissible, stabilizing control laws, for single-input, single-output systems has been solved by Peterka [2]. It is shown to be

$$u(t) = -\frac{S(z)}{R(z)}\, y(t) \tag{6i}$$

where $R(z)$, a polynomial of degree $(n+d-1)$, and $S(z)$, a polynomial, satisfy

$$B^*(z)C(z) = A(z)R(z) + z^d B(z)S(z). \tag{6ii}$$

Here, $B^*(z)$ is the minimum phase spectral factor of $B(z)B(z^{-1})$.

In the multi-input, multi-output case, Borison [3] has considered the situation where (i) the number of inputs is equal to the number of outputs, (5ii) B_0 is invertible and (iii) $B(z)$ is of minimum phase, i.e. $\det B(z) \neq 0$ for $0 < |z| \leqq 1$. Under these conditions, the optimal solution is given by multivariable analog of (5i, ii). This treatment is not fully general from several points of view. Firstly, conditions (i) and (iii) are restrictive. Secondly, the restriction that B_0 is invertible, condition (ii), means that by defining a new control $\bar{u}(t) := B_0 u(t)$, we really have a system where for each output variable there is one special input variable which influences that output variable after other input variables have ceased to influence it. Moreover, the different output variables will be influenced by their special input variables with the same delay. This simplifies the problem considerably and in fact one outgrowth of this restriction is that the control law really minimizes, separately, the variance of each output variable, or equivalently, the same control law simultaneously minimizes $Ey^T(t)Ry(t)$ for all $R \geqq 0$. We shall see that this situation is not true in general.

In another treatment of the multi-input, multi-output case, Goodwin, Ramadge, and Caines [4] assume that $A(z) = (1 + \alpha_1 z + \cdots + \alpha_n z^n)I$ where $\alpha_1, \cdots, \alpha_n$ are scalars. Stability of the solution is not considered, but use is made of the solution only when $d = 1$, the number of inputs is equal to the number of outputs, B_0 is invertible, and the system is of minimum phase, i.e. $\det B(z) \neq 0$ for $0 < |z| \leqq 1$, in which situation there are no problems. Recently Dugard, Goodwin, and Xianya [6] have studied the minimum variance problem through an examination of the role of the interactor matrix, and have obtained the minimum variance control law when the interactor matrix is diagonal.

We also refer the reader to Bayoumi and El Bagoury [5] for some errors in previous attempts to deal with the problem of minimum variance control of multi-variable systems.

In this paper, our goal is to treat all the complications caused by (i) B_0 possibly singular, i.e. general delay structures, (ii) nonminimum phase systems, i.e. det $B(z)$ possibly vanishing in $0<|z|<1$ and (iii) rectangular systems where the number of inputs is different from the number of outputs. Throughout, we address the problem of minimizing $Ey^T(t)y(t)$ while maintaining system stability.

If one wishes to minimize $Ey^T(t)Ry(t)$ for some positive definite R, then this is easily accomplished by defining $\bar{y}(t) := R^{1/2}y(t)$, $\bar{A}(z) := R^{1/2}A(z)R^{-1/2}$, $\bar{B}(z) := R^{1/2}B(z)$, $\bar{C}(z) := R^{1/2}C(z)$ and considering the system $\bar{A}(z)\bar{y}(t) = z^d\bar{B}(z)u(t) + \bar{C}(z)w(t)$, which satisfies assumptions (2i-iv).

Our treatment proceeds in the order of increasing generality. In § 2 we treat systems with general delay structures, with the solution given by Theorems 2.1, 2.2 and 2.3. In § 3 we treat nonminimum phase systems, with the solution given in Theorem 3.1 and finally in § 4 we treat rectangular systems, with the solution provided in Theorem 4.1.

2. Nonuniform delay systems. In this section we obtain the admissible, stabilizing, minimum variance control law for the multivariable ARMAX system (1), when it has a general delay structure. For this reason we allow det $B(z)$ to have zeros at the origin, because such zeros correspond to nonuniform transmission delays in different input-output channels.

Except for such zeros at the origin, we assume that the system is of a minimum phase, i.e., det $B(z) \neq 0$ for $0<|z|<1$. The system is also assumed to have the same number of inputs and outputs, i.e. it is square.

The complete solution for this problem is furnished by the following three Theorems.

THEOREM 2.1. *Suppose there exist $F(z)$ and $G(z)$ which satisfy*:

(7i) $F(z) = \sum_{i=0}^{d+p-1} F_i z^i$ *for some p, and F_0 is invertible.*

(7ii) $G(z)$ *is a matrix of rational functions which are analytic at $z=0$.*

(7iii) $\lim_{z\to 0} z^d F^T(z^{-1})A^{-1}(z)B(z) = 0.$

(7iv) $C(z) = A(z)F(z) + z^d B(z)G(z).$

Then, the admissible, stabilizing control law which minimizes the variance $Ey^T(t)y(t)$ of the output, is

$$u(t) = -G(z)F^{-1}(z)y(t).$$

The resulting minimum variance is

$$Ey^T(t)y(t) = \operatorname{tr} \sum_{i=0}^{d+p-1} F_i^T F_i Q.$$

THEOREM 2.2. *Define the following*:

(8i) *Let $\sum_{i=0}^{\infty} D_i z^i$ be a power series expansion of $A^{-1}(z)B(z)$.*

(8ii) *Let p be the largest power of z^{-1} in $B^{-1}(z)A(z)$.*

(8iii) *Let $E_0, E_1, \cdots, E_p$ be matrices satisfying*

$$B^{-1}(z)A(z) = E_p z^{-p} + E_{p-1}z^{-p+1} + \cdots + E_0 + o(1).$$

(8iv) *Let*

$$\mathcal{W}_m^n := \begin{bmatrix} 0 & \cdots & 0 & D_m \\ \vdots & & D_m & D_{m+1} \\ 0 & \cdots & \vdots & \vdots \\ D_m & \cdots & D_{n-1} & D_n \end{bmatrix} \quad \text{and} \quad \mathcal{E}_m^n := \begin{bmatrix} E_n & 0 & \cdots & 0 \\ E_{n-1} & E_n & & \vdots \\ \vdots & \vdots & \ddots & 0 \\ E_m & E_{m+1} & \cdots & E_n \end{bmatrix}.$$

Then, the matrix

$$[\mathcal{W}_0^{p-1}, \mathcal{E}_1^{pT}]$$

has full rank.

THEOREM 2.3. *Define the following*:

(9i) *Define* $F_0, \cdots, F_{d-1}$ *recursively by* $F_0 := C_0$ *and*

$$F_k := C_k - \sum_{i=1}^{k} A_i F_{k-i} \quad \text{for } k = 1, \cdots, d-1.$$

(9ii) *Define* $H_d, H_{d+1}, \cdots$ *as the coefficient matrices in the power series expansion*

$$A^{-1}(z)C(z) - \sum_{i=0}^{d-1} F_i z^i =: \sum_{i=d}^{\infty} H_i z^i.$$

(9iii) *Let* K *and* J *be matrices which satisfy the linear system of equations*

$$[\mathcal{W}_0^{p-1}, \mathcal{E}_1^{pT}][K^T, J^T]^T = [H_d^T, \cdots, H_{d+p-1}^T]^T.$$

(9iv) *Define* $F_d, \cdots, F_{d+p-1}$ *by* $[F_d^T, \cdots, F_{d+p-1}^T] := \mathcal{E}_1^{pT} J$.

(9v) *Define* $F(z) := \sum_{i=0}^{d+p-1} F_i z^i$ *and* $G(z) := z^{-d} B^{-1}(z)[C(z) - A(z)F(z)]$.

Then, $F(z)$ *and* $G(z)$ *satisfy* (7i-iv).

The significance of the three Theorems 2.1, 2.2 and 2.3 is the following. Theorem 2.1 gives sufficient conditions for the solution $u(t) = -G(z)F^{-1}(z)y(t)$ to be optimal. Theorem 2.2 asserts that a certain matrix is of full rank. Theorem 2.3 uses the solution of a system of linear equations, guaranteed to exist by Theorem 2.2, to construct $F(z)$ and $G(z)$ which satisfy the sufficient conditions of Theorem 2.1. Thus, we have a constructive procedure for obtaining an admissible, stabilizing, minimum variance control law.

One useful property of the minimum variance control law is that it does *not* depend on the noise covariance Q. Thus, the *same* control law is optimal irrespective of the noise covariance.

As we have mentioned earlier at the end of § 1, the above theorems can be employed to solve the problem of minimizing $Ey^T(t)Ry(t)$ for any positive definite R. However, in general, the solution will depend on R. This means, in particular, that the control law of Theorems 2.1, 2.2 and 2.3 does not separately minimize the variance of each output variable. This differentiates the case $\det B_0 \neq 0$, considered in [3], from the general delay structures considered here.

The minimum variance $\operatorname{tr} \sum_{i=0}^{d+p-1} F_i^T F_i Q$ can be decomposed into two parts. $\operatorname{tr} \sum_{i=d}^{d+p-1} F_i^T F_i Q$ can be regarded as the increase in variance resulting from the singularity of B_0, while the remaining part $\sum_{i=0}^{d-1} F_i^T F_i Q$ is the variance due to the delay of d time units. In the case considered in [3], only the latter part is present.

The proofs of Theorems 2.1, 2.2 and 2.3 follow immediately from Lemmas 2.4–2.10 below.

LEMMA 2.4. *Suppose $F(z)$ is a matrix of polynomials, which, together with a certain $G(z)$ satisfies* (7ii, iii *and* iv). *Let $u(t)=M(z)y(t)$ be any admissible control law which is applied to the system* (1). *Then, the output $y(t)$ of the closed loop system can be decomposed as $y(t)=y_1(t)+y_2(t)$ with*

$$y_1(t)=F(z)w(t), \qquad y_2(t)=z^dA^{-1}(z)B(z)[G(z)+T(z)A^{-1}(z)C(z)]w(t)$$

where

$$T(z):=M(z)[I-z^dA^{-1}(z)B(z)M(z)]^{-1}.$$

Furthermore, the two components $y_1(t)$ and $y_2(t)$ are uncorrelated.

Proof. The closed loop system is clearly $Ay=z^dBMy+Cw$, and so $y=(I-z^dA^{-1}BM)^{-1}A^{-1}Cw$ and $u=TA^{-1}Cw$. Substituting for u, we therefore get $Ay=z^dBTA^{-1}Cw+Cw$. Using (7iv) for C gives the required decomposition for the closed-loop output y. Throughout this paper we shall evaluate variances of processes by contour integration along the unit circle. This is possible, since by our stability assumption (4), the control laws considered give a stable closed loop system. To see that the two components are uncorrelated, note first that

$$\operatorname{cor}(Fw, z^dA^{-1}B[G+TA^{-1}C]w)$$
$$=\frac{\operatorname{tr}}{2\pi i}\oint F^T(z^{-1})z^dA^{-1}(z)B(z)[G(z)+T(z)A^{-1}(z)C(z)]Q\frac{dz}{z}$$

where, here and in the sequel, the contour is a circle centered at the origin and with unit radius. Note that $F^T(z^{-1})$ has a singularity only at the origin. Now $G(z)$ is analytic at the origin, by assumption. Also, because $M(z)$ is analytic at the origin, so is $T(z)$, and therefore also $T(z)A^{-1}(z)C(z)$. Utilizing (7iii), we see that the integrand vanishes at the origin. Moreover, the integrand also has no singularities elsewhere in the unit disc since the control is stabilizing, and so the above integral vanishes. □

LEMMA 2.5. *Suppose that $F(z)$ and $G(z)$ satisfy* (7i–iv). *Then, the control law which minimizes $Ey^T(t)y(t)$ over the set of all admissible control laws is $u(t)=M(z)y(t)$, where*

$$M(z)=-G(z)F^{-1}(z)$$

and the resulting minimum variance is

$$Ey^T(t)y(t)=\operatorname{var}(F(z)w(t))=\operatorname{tr}\sum_{i=0}^{p+d-1}F_i^TF_iQ.$$

Proof. From Lemma 2.4 it follows that for an admissible choice of M,

$$Ey^T(t)y(t)=\operatorname{var}(F(z)w(t))$$
$$+\frac{\operatorname{tr}}{2\pi_i}\oint[G(z^{-1})+T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^TB^T(z^{-1})A^{-T}(z^{-1}) \tag{10}$$
$$\cdot A^{-1}(z)B(z)[G(z)+T(z)A^{-1}(z)C(z)]Q\frac{dz}{z}.$$

Since $F(z)$ does not depend on the choice of $M(z)$, the best that one can hope to do, if one wishes to minimize the variance, is to choose $M(z)$ so that the integral

on the right-hand side above is zero. One way to do this is to choose $M(z)$ so as to make $G(z)+T(z)A^{-1}(z)C(z)=0$, i.e. $T(z)=-G(z)C^{-1}(z)A(z)$. Since $T=M[I-z^dA^{-1}BM]^{-1}$, M would have to be chosen so that $T^{-1}=M^{-1}-z^dA^{-1}B$, i.e.

$$\begin{aligned} M &= [(I+z^dA^{-1}BT)T^{-1}]^{-1} \\ &= T(I+z^dA^{-1}BT)^{-1} \\ &= -GC^{-1}A(I-z^dA^{-1}BGC^{-1}A)^{-1} \\ &= -GC^{-1}A[I-A^{-1}(C-AF)C^{-1}A]^{-1} \\ &= -GF^{-1}. \end{aligned}$$

It remains to be seen whether this choice of M is admissible. Clearly it is a matrix of rational functions and so (3i) is satisfied. So we need to only check that (3ii), i.e. nonanticipativity, is satisfied. Now $G(z)$ is analytic at the origin, by assumption, and also $F^{-1}(0)=F_0^{-1}=C_0^{-1}$ exists by assumption, showing that $M(z)$ is analytic at the origin. □

LEMMA 2.6. *Suppose $F(z)$ and $G(z)$ satisfy* (7i, ii, iv). *Then, the control law*

$$u(t)=-G(z)F^{-1}(z)y(t)$$

is stabilizing.

Proof. To determine that the control law is stabilizing, we need to check that the four transfer functions in (4) are all analytic inside the closed unit disc, with M given by $M=-GF^{-1}$. Simple calculation using (7iv) shows that

(11i) $$M[I-z^dA^{-1}BM]^{-1}=-GC^{-1}A=-z^{-d}B^{-1}(C-AF)C^{-1}A,$$

(11ii) $$[I-z^dA^{-1}BM]^{-1}=FC^{-1}A,$$

(11iii) $$[I-z^dMA^{-1}B]^{-1}=B^{-1}AFC^{-1}B=I+[-z^{-d}B^{-1}(C-AF)C^{-1}A][z^dA^{-1}B],$$

(11iv) $$z^dA^{-1}B[I-z^dMA^{-1}B]^{-1}=z^dFC^{-1}B.$$

B^{-1} is analytic inside the closed unit disc, except possibly at the origin, by assumption. $(C-AF)$ is a polynomial by (7i). Also C^{-1} is analytic inside the closed unit disc by (2iii). Hence $z^{-d}B^{-1}(C-AF)C^{-1}A$ is analytic inside the closed unit disc, except perhaps at the origin. However $z^{-d}B^{-1}(C-AF)C^{-1}A=GC^{-1}A$ and since G is analytic at the origin, so is $GC^{-1}A$. Hence (11i) is analytic inside the closed unit disc. (11ii) and (11iv) are both analytic inside the closed unit disc since $C^{-1}(z)$ is so and A, B, F are all matrices of polynomials. Examining (11iii), $B^{-1}AFC^{-1}B$ is analytic inside the closed unit disc, except perhaps at the origin. However $z^dA^{-1}B$ is analytic at the origin, and (11i) has also been shown to be so. Hence $B^{-1}AFC^{-1}B=I+[z^{-d}B^{-1}(C-AF)C^{-1}A][z^dA^{-1}B]$ is also analytic at the origin, thus showing that (11iii) is analytic inside the closed unit disc. □

It may be noted that at this stage Theorem 2.1 has been proved. Now we need to establish Theorems 2.2 and 2.3

LEMMA 2.7. *Let*

(12) $$\tilde{\mathscr{E}}_0^p=\begin{bmatrix} \tilde{E}_p & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & 0 \\ \tilde{E}_0 & \cdots & \cdots & \tilde{E}_p \end{bmatrix}$$

for some matrices $\tilde{E}_0, \cdots, \tilde{E}_p$. If $\tilde{\mathscr{E}}_0^p \mathscr{W}_0^p=\operatorname{diag}(0, \cdots, 0, I)$ then there exists a square

matrix N of the form

$$N=\begin{bmatrix} I & & 0 & 0 \\ \alpha_1 & & & \vdots \\ \vdots & \ddots & & \vdots \\ \vdots & & & 0 \\ \alpha_p & \cdots & \alpha_1 & I \end{bmatrix} \tag{13}$$

such that $\tilde{\mathscr{E}}_0^p = N\mathscr{E}_0^p$.

Proof. Since $\tilde{\mathscr{E}}_0^p \mathscr{W}_0^p = \operatorname{diag}(0, \cdots, 0, I)$ it follows that

$$(\tilde{E}_p z^{-p} + \tilde{E}_{p-1} z^{-p+1} + \cdots + \tilde{E}_0)(D_0 + D_1 z + \cdots) = I + O(z)$$

where $O(z) = \alpha_1 z + \alpha_2 z^2 + \cdots$ for some matrices $\alpha_1, \alpha_2, \cdots$. Hence

$$\begin{aligned}(\tilde{E}_p z^{-p} + \cdots + \tilde{E}_0) &= (I + O(z))(D_0 + D_1 z + \cdots)^{-1} \\ &= (I + O(z))(E_p z^{-p} + E_{p-1} z^{-p+1} + \cdots + E_0 + o(1)).\end{aligned}$$

Equating coefficients of identical powers of z^{-1}, we get

$$\tilde{E}_p = E_p, \quad \tilde{E}_{p-i} = E_{p-i} + \sum_{k=1}^{i} \alpha_k E_{p+k-i} \quad \text{for } i = 1, \cdots, p.$$

Hence the suggested N suffices.

LEMMA 2.8.

$$N(\mathscr{W}_0^{(p-1)T}) = R(\mathscr{E}_1^{pT}).$$

Here $N(\cdot)$ denotes the null space and $R(\cdot)$ the range space.

Proof. Consider $(\beta_1^T, \cdots, \beta_p^T)^T \in N(\mathscr{W}_0^{(p-1)T})$. Suppose to the contrary that $(\beta_1^T, \cdots, \beta_p^T)^T \notin R(\mathscr{E}_1^{pT})$. Since $D_0 \neq 0$ we can find a row vector β_0^T so that $(\beta_0^T, \cdots, \beta_p^T)[D_0^T, \cdots, D_p^T]^T \neq 0$. Since $(\beta_1^T, \cdots, \beta_p^T)^T \notin R(\mathscr{E}_1^{pT})$, it follows that $(\beta_1^T, \cdots, \beta_p^T)^T \notin R([E_1, \cdots, E_p]^T)$. Hence $(\beta_0^T, \cdots, \beta_p^T)^T \notin R([E_0, \cdots, E_p]^T)$. Since $[E_0, \cdots, E_p][D_0^T, \cdots, D_p^T]^T = I$, as is easily checked, it follows that by choosing $(m-1)$ rows from $[E_0, \cdots, E_p]$ (if I above is $m \times m$) and the row $(\beta_0^T, \cdots, \beta_p^T)$ we can build a matrix $[\bar{E}_0, \bar{E}_1, \cdots, \bar{E}_p]$ with m rows and such that $[\bar{E}_0, \cdots, \bar{E}_p][D_0^T, \cdots, D_p^T]^T$ is of full rank. Premultiplying by an appropriate non-singular matrix we can obtain $[\tilde{E}_0, \cdots, \tilde{E}_p]$ such that $[\tilde{E}_0, \cdots, \tilde{E}_p][D_0^T, \cdots, D_p^T]^T = I$ and the rows of $[\tilde{E}_0, \cdots, \tilde{E}_p]$ span the row-space of $[\bar{E}_0, \cdots, \bar{E}_p]$. Now let $\tilde{\mathscr{E}}_0^p$ be defined from $\tilde{E}_0, \cdots, \tilde{E}_p$ as in the statement of Lemma 2.7. It is easily checked that $\tilde{\mathscr{E}}_0^p \mathscr{W}_0^p = \operatorname{diag}(0, \cdots, 0, I)$. Lemma 2.7 now applies and shows that the rows of $[\tilde{E}_0, \cdots, \tilde{E}_p]$ are linear combinations of the rows of $\mathscr{E}_0^p$. But then the rows of $[\tilde{E}_1, \cdots, \tilde{E}_p]$ are linear combinations of the rows of $\mathscr{E}_1^p$, which contradicts our assumption that $(\beta_1^T, \cdots, \beta_p^T)^T \notin R(\mathscr{E}_1^{pT})$. This shows that $N(\mathscr{W}_0^{(p-1)T}) \subseteq R(\mathscr{E}_1^{pT})$. The reverse containment $R(\mathscr{E}_1^{pT}) \subseteq N(\mathscr{W}_0^{(p-1)T})$ follows trivially from the relationship $\mathscr{E}_0^p \mathscr{W}_0^p = \operatorname{diag}(0, \cdots, 0, I)$. □

LEMMA 2.9. $[\mathscr{W}_0^{p-1}, \mathscr{E}_1^{pT}]$ *is a full rank matrix.*

Proof. Suppose $\rho^T[\mathscr{W}_0^{p-1}, \mathscr{E}_1^{pT}]=0$ for some vector ρ. Since $\rho \in N(\mathscr{W}_0^{(p-1)T})$ it follows by Lemma 2.8 that $\rho = \mathscr{E}_1^{pT}\gamma$ for some γ. But $\rho^T\mathscr{E}_1^{pT}\gamma = 0$, and so $\gamma^T\mathscr{E}_1^p\mathscr{E}_1^{pT}\gamma = 0$. Hence $\rho = \mathscr{E}_1^{pT}\gamma = 0$. □

Thus we have also proved Theorem 2.2. Now we complete the proof of Theorem 2.3.

LEMMA 2.10. *If* $F(z)$ *and* $G(z)$ *are defined as in Theorem* 2.3, *then* (7i-iv) *of Theorem* 2.1 *are satisfied.*

Proof. (7i) is trivial since $F(0) = F_0 = C_0$ is invertible by assumption. (7iv) follows from the definition of $G(z)$. So we need to check only (7ii) and (7iii). Now

$$(7\text{iii}) \Leftrightarrow \lim_{z\to 0} z^d[F_0^T + F_1^T z^{-1} + \cdots + F_{d+p-1}^T z^{-d-p+1}][D_0 + D_1 z + \cdots + D_{p-1}z^{p-1}] = 0$$

$$\Leftrightarrow \lim_{z\to 0} [F_d^T + F_{d+1}^T z^{-1} + \cdots + F_{d+p-1}^T z^{-p+1}][D_0 + D_1 z + \cdots + D_{p-1}z^{p-1}] = 0$$

$$\Leftrightarrow \text{coefficients of nonpositive powers of } z \text{ vanish in}$$

$$[F_d^T + \cdots + F_{d+p-1}^T z^{-p+1}][D_0 + D_1 z + \cdots + D_{p-1}z^{p-1}]$$

$$\Leftrightarrow [F_d^T, \cdots, F_{d+p-1}^T]^T \in N(\mathscr{W}_0^{(p-1)T})$$

$$\Leftrightarrow [F_d^T, \cdots, F_{d+p-1}^T] \in R(\mathscr{E}_1^{pT})$$

$$\Leftrightarrow [F_d^T, \cdots, F_{d+p-1}^T] = \mathscr{E}_1^{pT}J \text{ for some matrix } J.$$

Similarly

$$(7\text{iv}) \Leftrightarrow z^{-d}B^{-1}(z)[C(z) - A(z)F(z)] = O(1)$$

$$\Leftrightarrow z^{-d}B^{-1}(z)A(z)[A^{-1}(z)C(z) - F(z)] = O(1)$$

$$\Leftrightarrow z^{-d}B^{-1}(z)A(z)[A^{-1}(z)C(z) - F_0 - F_1 z - \cdots - F_{d+p-1}z^{d+p-1}] = O(1)$$

$$\Leftrightarrow z^{-d}B^{-1}(z)A(z)[H_d z^d + H_{d+1}z^{d+1} + \cdots - F_d z^d - F_{d+1}z^{d+1} \cdots - F_{d+p-1}z^{d+p-1}]$$

$$= O(1),$$

$$\Leftrightarrow B^{-1}(z)A(z)[(H_d - F_d) + \cdots + (H_{d+p-1} - F_{d+p-1})z^{p-1} + O(z^p)] = O(1)$$

$$\Leftrightarrow \text{coefficients of strictly negative powers of } z \text{ vanish in}$$

$$[E_p z^{-p} + \cdots + E_1 z^{-1} + O(1)][(H_d - F_d) + \cdots + (H_{d+p-1} - F_{d+p-1})z^{p-1} + O(z^p)]$$

$$\Leftrightarrow [(H_d - F_d)^T, \cdots, (H_{d+p-1} - F_{d+p-1})^T]^T \in N(\mathscr{E}_1^p)$$

$$\Leftrightarrow [(H_d - F_d)^T, \cdots, (H_{d+p-1} - F_{d+p-1})^T]^T \in R(\mathscr{W}_0^{p-1})$$

$$\Leftrightarrow [(H_d - F_d)^T, \cdots, (H_{d+p-1} - F_{d+p-1})^T]^T \in \mathscr{W}_0^{p-1}K \text{ for some matrix } K.$$

Thus if $[\mathscr{W}_0^{p-1}, \mathscr{E}_1^{pT}][K^T, J^T]^T = [H_d^T, \cdots, H_{d+p-1}^T]^T$ and $\mathscr{E}_1^{pT}J = [F_d^T, \cdots, F_{d+p-1}^T]$, as we have assumed, then both (7ii) and (7iii) are satisfied. □

The proofs of Theorems 2.1, 2.2 and 2.3 are now complete.

3. Square nonminimum phase systems. We now turn to the problem of minimizing the variance over the set of admissible, stabilizing control laws for systems which have nonminimum phase transfer functions besides those caused by pure delays.

Thus we consider systems for which $\det B(z)$ may vanish in $\{z: 0 < |z| < 1\}$ besides possible vanishing in $\{z: z = 0 \text{ or } |z| > 1\}$. We do not allow $\det B(z)$ to vanish in $\{z: |z| = 1\}$ since we have imposed the requirement in (4) that our closed-loop systems

should be *strictly* stable as opposed to just stable, i.e. we have required analyticity of the four transfer functions in (4) in the *closed* unit disc and not just the *open* unit disc. If we are willing to admit such a relaxation, then our solution is valid even for det $B(z)$ vanishing on the unit circle $\{z: |z|=1\}$.

In this section, we also assume that the number of inputs is equal to the number of outputs, i.e. the system is square with $m=l$ in (1).

By Lemma 2.5 we see that we have already solved the problem of obtaining the admissible control law which minimizes the variance of the output, and the control law which does this is just the control law of Theorems 2.1, 2.2 and 2.3. However, this control law is *not* stabilizing, i.e. it does not satisfy (4), when det $B(z)$ vanishes in $\{z: 0<|z|\leqq 1\}$. The reason is that Lemma 2.6 is no more valid, as can be seen from an examination of (11).

For single-input, single-output systems, Peterka [2] has solved the problem of obtaining the control law which minimizes the output variance over the class of all admissible, stabilizing control laws. We now solve this problem for the multivariable case.

We will obtain the solution by reducing the problem to the type considered in the previous section. Accordingly we will denote the $F(z)$ and $G(z)$ generated by Theorem 2.3 by $F(A(\cdot), B(\cdot), C(\cdot), d)(z)$ and $G(A(\cdot), B(\cdot), C(\cdot), d)(z)$ in order to explicity display the functional arguments on which they depend. We note here that the algorithms of Theorems 2.2 and 2.3 can be employed even when $d=0$ to generate F and G.

THEOREM 3.1. *We assume that $A^{-1}(z)$ and $B^{-1}(z)$ have no poles in common inside the closed unit disc, $A^{-1}(z)$ and $B^{-1}(z^{-1})$ have no poles in common inside the closed unit disc and $A^{-1}(z)$ and $A^{-1}(z^{-1})$ have no poles in common. In the above and what follows, by a zero of $X(z)$ we shall mean a singularity of $X^{-1}(z)$, and by a pole of $X(z)$ we mean a singularity of $X(z)$.*

(14i) *Let $\Delta(z)$ be a spectral factor which satisfies*

$$\Delta^T(z^{-1})\Delta(z) = B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z)B(z)$$

and is such that its poles are those of $A^{-1}(z)B(z)$, while its nonzero zeros are outside the closed unit disc images of the nonzero zeros of $A^{-1}(z)B(z)$. By an "outside the closed unit disc image of z", we mean η such that $\eta=z$ if $|z|>1$ and $\eta=z^{-1}$ if $|z|<1$.

(14ii) *Let $\alpha(z)$ and $\beta(z)$ be matrices of polynomials such that*

$$\alpha^{-1}(z)\beta(z) = \Delta(z)$$

is a left coprime representation of $\Delta(z)$, and such that the zeros of $\beta(z)$ are the zeros of $\Delta(z)$, while the poles of $\alpha^{-1}(z)$ are the poles of $\Delta(z)$.

(14iii) *Let $\theta(z) := \alpha^{-1}(z)\beta(z)B^{-1}(z)[C(z)-A(z)F(z)]z^{-d}$, where*

$$F(z) := F(A(\cdot), B(\cdot), C(\cdot), d)(z) \text{ and}$$

$$G(z) := G(A(\cdot), B(\cdot), C(\cdot), d)(z).$$

(14iv) *Let $\theta_+(z)$ and $\theta_-(z)$ satisfying $\theta(z)=\theta_+(z)+\theta_-(z)$ be such that $\theta_+(z)$ is the sum of all the partial fraction terms of $\theta(z)$ which have poles either outside the closed unit disc (including infinity) or coinciding with the poles of $A^{-1}(z)$ inside the closed unit disc, and constant terms, if any.*

(14v) *Let* $\gamma(z)$ *be a polynomial matrix such that*

$$\theta_+(z) = \alpha^{-1}(z)\gamma(z).$$

(*The existence of such a polynomial matrix* $\gamma(z)$ *will be proved.*)

(14vi) *Let* $\tilde{F}(z) := F(\alpha(\cdot), \beta(\cdot), \gamma(\cdot), 0)(z)$ *and*

$$\tilde{G}(z) := G(\alpha(\cdot), \beta(\cdot), \gamma(\cdot), 0)(z).$$

Then, the control law which minimizes $Ey^T(t)y(t)$ *over the class of all admissible, stabilizing control laws is given by*

$$u(t) = -\tilde{G}(z)[F(z) + z^d A^{-1}(z)B(z)(G(z) - \tilde{G}(z))]^{-1} y(t). \tag{15}$$

The resulting minimum variance is

$$\begin{aligned} Ey^T(t)y(t) &= \operatorname{tr} \sum_j F_j^T F_j Q + \operatorname{tr} \sum_j \tilde{F}_j^T \tilde{F}_j Q \\ &+ \frac{\operatorname{tr}}{2\pi i} \oint \{\alpha^{-1}(z)\beta(z)[G(z) - \tilde{G}(z)] - \tilde{F}(z)\} \\ &\quad \cdot \{\alpha^{-1}(z^{-1})\beta(z^{-1})[G(z^{-1}) - \tilde{G}(z^{-1})] - \tilde{F}(z^{-1})\}^T Q \frac{dz}{z} \end{aligned} \tag{16}$$

where

$$F(z) =: \sum_j F_j z^j \quad \text{and} \quad \tilde{F}(z) =: \sum_j \tilde{F}_j z^j.$$

Proof. Let $u(t) = M(z)y(t)$. From (10), it follows that

$$\begin{aligned} Ey^T(t)y(t) &= \operatorname{tr} \sum_j F_j^T F_j Q \\ &+ \frac{\operatorname{tr}}{2\pi i} \oint B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z)B(z) \\ &\quad \cdot [G(z) + T(z)A^{-1}(z)C(z)] \\ &\quad \cdot Q[G(z^{-1}) + T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}. \end{aligned}$$

Since $\beta^T(z^{-1})\alpha^{-T}(z^{-1})\alpha^{-1}(z)\beta(z) = B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z)B(z)$ from (14i, ii), it follows that

$$\begin{aligned} Ey^T(t)y(t) &= \operatorname{tr} \sum_j F_j^T F_j Q + \frac{\operatorname{tr}}{2\pi i} \oint \beta^T(z^{-1})\alpha^{-T}(z^{-1}) \\ &\quad \cdot [\alpha^{-1}(z)\beta(z)G(z) + \alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)] \\ &\quad \cdot Q[G(z^{-1}) + T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}. \end{aligned}$$

Substituting $G(z)=B^{-1}(z)[C(z)-A(z)F(z)]z^{-d}$, and using (14iii), (14iv) gives

$$Ey^T(t)y(t)=\operatorname{tr}\sum_j F_j^T F_j Q + \frac{\operatorname{tr}}{2\pi i}\oint [\theta_+(z)+\theta_-(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)] \cdot Q[\theta_+(z^{-1})+\theta_-(z^{-1})+\alpha^{-1}(z^{-1})\beta(z^{-1}) \cdot T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}.$$

Since $y_2=z^dA^{-1}B(G+TA^{-1}C)w$, in the notation of Lemma 2.4, our assumption that the control law is stabilizing shows that $A^{-1}B(G+TA^{-1}C)$ has no singularities inside the closed unit disc, and in particular that it has no singularities inside the closed unit disc coinciding with those of $A^{-1}(z)$. Hence the residues of $[\theta_+(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]$ evaulated at the zeros of $A(z)$ or $\alpha(z)$ which are inside the closed unit disc are zero. Since therefore $[\theta_+(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]$ and $(\theta_-^T(z^{-1}))/z$ are both analytic inside the closed unit disc, where we have also used the fact that $\theta_-(z)$ is a matrix of strictly proper rational functions, we deduce that the cross term

$$\frac{\operatorname{tr}}{2\pi i}\oint [\theta_+(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]Q\theta_-^T(z^{-1})\frac{dz}{z}$$

vanishes. Hence

$$Ey^T(t)y(t)=\operatorname{tr}\sum_j F_j^T F_j Q+\frac{\operatorname{tr}}{2\pi i}\oint \theta_-(z)Q\theta_-^T(z^{-1})\frac{dz}{z} + \frac{\operatorname{tr}}{2\pi i}\oint [\theta_+(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)] \cdot Q[\theta_+(z^{-1})+\alpha^{-1}(z^{-1})\beta(z^{-1}) \cdot T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}. \tag{17}$$

The first two terms in the right-hand side of (17) do not depend on the choice of $T(z)$ and, therefore, on the choice of $M(z)$. Hence to minimize $Ey^T(t)y(t)$, we need to only minimize

$$\frac{\operatorname{tr}}{2\pi i}\oint [\theta_+(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)] \cdot Q[\theta_+(z^{-1})+\alpha^{-1}(z^{-1})\beta(z^{-1})T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}. \tag{18}$$

Now let us examine $\theta_+(z)$. From (14i, ii) we see that

$$\alpha^{-1}(z)\beta(z)B^{-1}(z)=\alpha^T(z^{-1})\beta^{-T}(z^{-1})B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z). \tag{19}$$

An examination of the right-hand side of (19) shows that the only poles of (19) which do not coincide with those of $A^{-1}(z)$ are either at the origin or coincide with the poles of $\beta^{-T}(z^{-1})$, and so all the poles of the left-hand side of (19) which do not coincide with the poles of $A^{-1}(z)$ are inside the closed unit disc. Substituting (19) in the

expression for $\theta(z)$ in (14iii), we obtain

$$\theta(z)=\alpha^T(z^{-1})\beta^{-T}(z^{-1})B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z)[C(z)-A(z)F(z)]z^{-d}.$$

Utilizing the definition of $\theta_+(z)$, we see therefore that

$$\theta_+(z)=\alpha^{-1}(z)\gamma(z)$$

for some polynomial matrix $\gamma(z)$. This proves the existence of $\gamma(z)$ claimed in (14v). Now substituting for $\theta_+(z)$ in (18) shows that to minimize $Ey^T(t)y(t)$, we need to minimize

$$\frac{\operatorname{tr}}{2\pi i}\oint[\alpha^{-1}(z)\gamma(z)+\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]$$

$$\cdot\, Q[\alpha^{-1}(z^{-1})\gamma(z^{-1})+\alpha^{-1}(z^{-1})\beta(z^{-1})T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T\frac{dz}{z}.$$

Define $S(z):=T(z)A^{-1}(z)C(z)$ and our problem now is how to choose $S(z)$, analytic at the origin, so as to minimize

$$\frac{\operatorname{tr}}{2\pi i}\oint[\alpha^{-1}(z)\gamma(z)+\alpha^{-1}(z)\beta(z)S(z)]$$

$$\cdot\, Q[\alpha^{-1}(z^{-1})\gamma(z^{-1})+\alpha^{-1}(z^{-1})\beta(z^{-1})S(z^{-1})]^T\frac{dz}{z}. \tag{20}$$

But this resembles the problem of § 2, where since we had

$$\begin{aligned}y(t)&=[A^{-1}(z)C(z)+z^dA^{-1}(z)B(z)T(z)A^{-1}(z)C(z)]w(t)\\&=[A^{-1}(z)C(z)+z^dA^{-1}(z)B(z)S(z)]w(t)\end{aligned}$$

we had to choose $S(z)$, analytic at the origin, so as to minimize

$$\frac{\operatorname{tr}}{2\pi i}\oint[A^{-1}(z)C(z)+z^dA^{-1}(z)B(z)S(z)]$$

$$\cdot\, Q[A^{-1}(z^{-1})C(z^{-1})+z^{-d}A^{-1}(z^{-1})B(z^{-1})S(z^{-1})]^T\frac{dz}{z}. \tag{21}$$

Making the obvious identifications between (20) and (21), we can apply the results of § 2 and see that the optimal choice for $S(z)$ is

$$S(z)=-\tilde{G}(z) \tag{22}$$

where $\tilde{G}(z)$ is as in (14vi). Furthermore the minimum value of (20) is

$$\sum_j \tilde{F}_j^T\tilde{F}_jQ. \tag{23}$$

Since (23) is the minimum value of the third term in the right-hand side of (17), it follows by substituting in (17) that the resulting variance is

$$Ey^T(t)y(t)=\operatorname{tr}\sum_j F_j^TF_jQ+\operatorname{tr}\sum_j\tilde{F}_j^T\tilde{F}_jQ+\frac{\operatorname{tr}}{2\pi i}\oint\theta_-(z)Q\theta_-^T(z^{-1})\frac{dz}{z}. \tag{24}$$

Since $C(z)=A(z)F(z)+z^dB(z)G(z)$ and $\gamma(z)=\alpha(z)\tilde{F}(z)+\beta(z)\tilde{G}(z)$, which follow from the definitions of F, G, $\tilde{F}$ and $\tilde{G}$ in (14iii, vi) we obtain $G(z)=B^{-1}(z)[C(z)-A(z)F(z)]z^{-d}$ and $\alpha^{-1}(z)\gamma(z)=\tilde{F}(z)+\alpha^{-1}(z)\beta(z)\tilde{G}(z)$. Substituting

these two expressions in the definitions of $\theta(z)$ and $\theta_+(z)$ in (14iii, v), we get

$$\begin{aligned}\theta_-(z) &= \theta(z) - \theta_+(z) \\ &= \alpha^{-1}(z)\beta(z)G(z) - \tilde{F}(z) - \alpha^{-1}(z)\beta(z)\tilde{G}(z) \\ &= \alpha^{-1}(z)\beta(z)[G(z) - \tilde{G}(z)] - \tilde{F}(z).\end{aligned} \tag{25}$$

Substituting (25) in (24) gives the expression (16) claimed as the minimum variance. We still need to determine that the choice of $S(z)$ in (22) corresponds to (15) and also that it is stabilizing. Since $S(z) = T(z)A^{-1}(z)C(z)$, we obtain that the choice of $T(z)$ is $T(z) = -\tilde{G}(z)C^{-1}(z)A(z)$ and since $T = M[I - z^d A^{-1}BM]^{-1}$ it follows that

$$\begin{aligned}M(z) &= T(z)[I + z^d A^{-1}(z)B(z)T(z)]^{-1} \\ &= T(z)[I - z^d A^{-1}(z)B(z)\tilde{G}(z)C^{-1}(z)A(z)]^{-1} \\ &= -\tilde{G}(z)[A^{-1}(z)C(z) - z^d A^{-1}(z)B(z)\tilde{G}(z)]^{-1} \\ &= -\tilde{G}(z)[F(z) + z^d A^{-1}(z)B(z)(G(z) - \tilde{G}(z))]^{-1}\end{aligned}$$

which coincides with the control law of (15). It remains to be shown that this choice of $M(z)$ is stabilizing, i.e. it satisfies (4). Simple calculations show that two of the transfer functions in (4) are

$$\begin{aligned}M[I - z^d A^{-1}BM]^{-1} &= -\beta^{-1}(\gamma - \alpha\tilde{F})C^{-1}A, \\ [I - z^d MA^{-1}B]^{-1} &= I - z^d\tilde{G}C^{-1}A = I - z^d\beta^{-1}(\gamma - \alpha\tilde{F})C^{-1}B\end{aligned} \tag{26}$$

which are both analytic inside the closed unit disc, since β^{-1} and C^{-1} are. The third transfer function in (4) is $[I - z^d A^{-1}(z)B(z)M(z)]^{-1}$ which can, by simple calculation, be seen to be equal to $I - z^d A^{-1}(z)B(z)\tilde{G}(z)C^{-1}(z)A(z)$, which in turn is $I - z^d A^{-1}(z)B(z)\beta^{-1}(z)[\gamma(z) - \alpha(z)\tilde{F}(z)]C^{-1}(z)A(z)$. Except for the term $A^{-1}(z)$, all other quantities are analytic inside the closed unit disc, and so if this transfer function has any singularities inside the closed unit disc, they must coincide with those of $A^{-1}(z)$. However, we also have

$$\begin{aligned}[I - z^d A^{-1}(z)B(z)M(z)]^{-1} &= [F(z) + z^d A^{-1}(z)B(z)(G(z) - \tilde{G}(z))]C^{-1}(z)A(z) \\ &= \{F(z) + z^d A^{-1}(z)B(z)\beta^{-1}(z)\alpha(z)[\theta_-(z) - \tilde{F}(z)]\} \\ &\quad \cdot C^{-1}(z)A(z)\end{aligned}$$

which, if it has any singularities inside the closed unit disc coinciding with those of $A^{-1}(z)$, can only be singularities of $A^{-1}(z)B(z)\beta^{-1}(z)\alpha(z)$ inside the closed unit disc coinciding with those of $A^{-1}(z)$. However, by (14i, ii), we have $A^{-1}(z)B(z)\beta^{-1}(z)\alpha(z) = A^T(z^{-1})B^{-T}(z^{-1})\beta^T(z^{-1})\alpha^{-T}(z^{-1})$. The only poles of the right-hand side inside the closed unit disc are either at the origin or coincident with the poles of $\alpha^{-1}(z^{-1})$ or $B^{-1}(z^{-1})$. By our assumptions, there can however be no poles of $A^{-1}(z)$ in any of these locations, showing that $[I - z^d A^{-1}BM]^{-1}$ is analytic inside the closed unit disc. The last transfer function of (14) we need to check is $z^d A^{-1}B[I - z^d MA^{-1}B]^{-1}$. Since (26), which is a factor, has no poles inside the closed unit disc, it follows that if there are poles of $z^d A^{-1}B[I - z^d MA^{-1}B]^{-1}$ inside the closed unit disc, they must be poles of A^{-1}. Simple calculation shows that $z^d A^{-1}B[I - z^d MA^{-1}B]^{-1} = z^d FC^{-1}B + z^d A^{-1}B\beta^{-1}\alpha(\theta_- + \tilde{F})C^{-1}B$. The first term is analytic inside the closed unit disc, and so is $(\theta_- + \tilde{F})C^{-1}B$. Hence we only need to show that $A^{-1}(z)B(z)\beta^{-1}(z)\alpha(z)$ has no poles inside the closed unit disc which coincide with those of $A^{-1}(z)$. But we have already done this. □

If the system is of minimum phase, i.e. $B^{-1}(z)$ is analytic in $\{z: 0<|z|\leqq 1\}$, then $\alpha = A$, $\beta = B$ and so $\theta = A^{-1}[C - AF]z^{-d}$, thus showing that $\gamma = [C - AF]z^{-d}$. Hence $\tilde{F} = 0$ and $\tilde{G} = G$. Thus the control law (15) above reduces to what it is in the minimum phase case of Theorem 2.1. Moreover the minimum variance (16) also reduces to what it is in Theorem 2.1.

The additional cost of stably controlling a nonminimum phase system is therefore

$$\operatorname{tr} \sum_j \tilde{F}_j^T \tilde{F}_j Q + \frac{\operatorname{tr}}{2\pi i} \oint \{\alpha^{-1}(z)\beta(z)[G(z) - \tilde{G}(z)] - \tilde{F}(z)\} \cdot Q\{\alpha^{-1}(z^{-1})\beta(z^{-1})[G(z^{-1}) - \tilde{G}(z^{-1})] - \tilde{F}(z^{-1})\}^T \frac{dz}{z}.$$

This is the "sacrifice" in variance that must be made to obtain a stable system. If one just wants to minimize the variance without paying attention to stability, then this sacrifice need not be made.

One useful property of the control law (15) is that it does not depend on the noise covariance $Ew(t)w^T(t)$. Thus, the same control law is optimal irrespective of the covariance $Ew(t)w^T(t)$.

4. Rectangular systems. Now we consider rectangular systems, i.e. systems where the number of inputs is not equal to the number of outputs.

If the system has more inputs than outputs, then the previous results can still be used if we replace $B^{-1}(z)$ by $B^{\#}(z)$, any right inverse of $B(z)$. The proofs proceed as before.

So we turn our attention to systems where the number of inputs is less than the number of outputs. Before describing the solution, we first discuss some pitfalls. One way of proceeding, it might appear, is to make the system "square" by adding fictitious inputs with small "gains" ε which are then driven to zero. This can, however, result in matrices $M(z)$ and $T(z)$ which become unbounded as $\varepsilon \to 0$. Another way of making the system square is to add fictitious inputs which have *delays* which are then driven to infinity. However, the resulting solution for $F(z)$ will be a power series, at best.

We therefore adopt the more fruitful approach of the following Theorem. As in previous sections, we assume that the system has no zeros exactly on the unit circle $\{z: |z| = 1\}$, or more precisely, $B^T(z^{-1})A^{-T}(z^{-1})A^{-1}(z)B(z)$ has no zeros on the unit circle $\{z: |z| = 1\}$.

THEOREM 4.1. *We assume that $A^{-1}(z)$ and $A^{-1}(z^{-1})$ have no poles in common and also that for every pole t_k of $A^{-1}(z)$ inside the closed unit disc, its residue R_k in the partial fraction expansion of $A^{-1}(z)B(z)$ satisfies the condition* $\lim_{z \to t_k} B^T(z^{-1})A^{-T}(z^{-1})R_k \neq 0$.

(27i) *Let $\delta(z) := A^{-1}(z)B(z)$.*

(27ii) *Let $\Delta(z) = \alpha^{-1}(z)\beta(z)$ be a square minimum phase spectral factor satisfying $\Delta^T(z^{-1})\Delta(z) = \delta^T(z^{-1})\delta(z)$ and such that the nonzero zeros of the polynomial matrix $\beta(z)$ are outside the unit circle images of the nonzero zeros of $\delta^T(z^{-1})\delta(z)$ while the poles of the polynomial matrix $\alpha^{-1}(z)$ are those of $\delta(z)$.*

(27iii) *Define $\tilde{\theta}(z) := \Delta^{-T}(z^{-1})\delta^T(z^{-1})A^{-1}(z)C(z)$ and decompose $\tilde{\theta}(z)$ as $\tilde{\theta}(z) =: \tilde{\theta}_+(z) + \tilde{\theta}_-(z)$ where $\tilde{\theta}_-(z)$ consists of those partial fraction terms with poles which are inside the unit circle and not coinciding with those of $A^{-1}(z)$.*

(27iv) *Let $\tilde{\theta}_+(z) = \tilde{\alpha}^{-1}(z)\tilde{\gamma}(z)$ where $\tilde{\alpha}(z)$ is a square polynomial matrix with zeros corresponding to those of $A(z)$ and $\tilde{\gamma}(z)$ is a rectangular matrix of polynomials with more columns than rows.*

(27v) *Let* $\tilde{F}(z) =: F(\tilde{\alpha}(\cdot), \beta(\cdot), \tilde{\gamma}(\cdot), d)(z)$ *and* $\tilde{G}(z) := G(\tilde{\alpha}(\cdot), \beta(\cdot), \tilde{\gamma}(\cdot), d)(z)$. *Then, the control law which minimizes the output variance* $Ey^T(t)y(t)$ *over the set of all admissible stabilizing control laws is*

$$u(t) = -\tilde{G}(z)[C(z) - z^d B(z)\tilde{G}(z)]^{-1}A(z)y(t).$$

Proof. Let $\tilde{\delta}(z)$ be a full rank left annihilator of $\delta(z)$. Clearly

$$\begin{bmatrix} \tilde{\delta}(z) \\ [\delta^T(z^{-1})\delta(z)]^{-1}\delta^T(z^{-1}) \end{bmatrix} [\tilde{\delta}^T(z^{-1})[\tilde{\delta}(z)\tilde{\delta}^T(z^{-1})]^{-1}, \delta(z)] = I$$

and so each of the matrices on the left-hand side of the above is the inverse of the other. Multiplying the two matrices above in the reverse order gives

$$\tilde{\delta}^T(z^{-1})[\tilde{\delta}(z)\tilde{\delta}^T(z^{-1})]^{-1}\tilde{\delta}(z) + \delta(z)[\delta^T(z^{-1})\delta(z)]^{-1}\delta^T(z^{-1}) = I.$$

Hence, for any admissible $u(t) = M(z)y(t)$, we can decompose $y(t) = y_1(t) + y_2(t)$ where

$$\begin{aligned} y_1(t) &= \tilde{\delta}^T(z^{-1})[\tilde{\delta}(z)\tilde{\delta}^T(z^{-1})]^{-1}\tilde{\delta}(z)A^{-1}(z)C(z)w(t), \quad \text{and} \\ y_2(t) &= \delta(z)\{[\delta^T(z^{-1})\delta(z)]^{-1}\delta^T(z^{-1})A^{-1}(z)C(z) + z^d T(z)A^{-1}(z)C(z)\}w(t) \end{aligned} \tag{28}$$

where $T(z)$ is as in Lemma 2.4. By integrating along the unit circle, it can be seen that $Ey_1^T(t)y_2(t) = 0$. So $Ey^T(t)y(t) = Ey_1^T(t)y_1(t) + Ey_2^T(t)y_2(t)$. The first term on the right-hand side does not depend on the choice of $M(z)$. Hence, to minimize $Ey^T(t)y(t)$ we need to minimize only $Ey_2^T(t)y_2(t)$. Now

$$\begin{aligned} Ey_2^T(t)y_2(t) = \frac{\text{tr}}{2\pi i}\oint \delta^T(z^{-1})\delta(z)\{[\delta^T(z^{-1})\delta(z)]^{-1}\delta^T(z^{-1}) + z^d T(z)\} \\ \cdot A^{-1}(z)C(z)QC^T(z^{-1})A^{-T}(z^{-1}) \\ \cdot \{[\delta^T(z)\delta(z^{-1})]^{-1}\delta^T(z) + z^{-d}T(z^{-1})\}^T \frac{dz}{z} \end{aligned}$$

and so, using $\Delta^T(z^{-1})\Delta(z) = \delta^T(z^{-1})\delta(z)$, we get

$$\begin{aligned} Ey_2^T(t)y_2(t) &= \frac{\text{tr}}{2\pi i}\oint [\Delta^{-T}(z^{-1})\delta^T(z^{-1}) + z^d\Delta(z)T(z)] \\ &\quad \cdot A^{-1}(z)C(z)QC^T(z^{-1})A^{-T}(z^{-1}) \\ &\quad \cdot [\Delta^{-T}(z)\delta^T(z) + z^{-d}\Delta(z^{-1})T(z^{-1})]^T \frac{dz}{z} \\ &= \frac{\text{tr}}{2\pi i}\oint [\tilde{\theta}_-(z) + \tilde{\theta}_+(z) + z^d\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)] \\ &\quad \cdot Q[\tilde{\theta}_-(z^{-1}) + \tilde{\theta}_+(z^{-1}) + z^{-d}\alpha^{-1}(z^{-1})\beta(z^{-1}) \\ &\quad \cdot T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T \frac{dz}{z}. \end{aligned}$$

As in Theorem 3.1, the cross term

$$\frac{\text{tr}}{2\pi i}\oint [\tilde{\theta}_+(z) + z^d\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]Q\tilde{\theta}_-^T(z^{-1})\frac{dz}{z}$$

vanishes. Also, the term $(\text{tr}/2\pi i)\oint \tilde{\theta}_-(z)Q\tilde{\theta}_-^T(z^{-1})dz/z$ can be ignored since it does

not depend on $M(z)$. Hence, the problem becomes one of minimizing

$$\begin{aligned}(29)\quad &\frac{\mathrm{tr}}{2\pi i}\oint [\tilde{\theta}_+(z)+z^d\alpha^{-1}(z)\beta(z)T(z)A^{-1}(z)C(z)]\\ &\qquad\cdot Q[\tilde{\theta}_+(z^{-1})+z^{-d}\alpha^{-1}(z^{-1})\beta(z^{-1})T(z^{-1})A^{-1}(z^{-1})C(z^{-1})]^T\frac{dz}{z}\\ &=\frac{\mathrm{tr}}{2\pi i}\oint [\tilde{\alpha}^{-1}(z)\tilde{\gamma}(z)+z^d\alpha^{-1}(z)\beta(z)S(z)]\\ &\qquad\cdot Q[\tilde{\alpha}^{-1}(z^{-1})\tilde{\gamma}(z^{-1})+z^{-d}\alpha^{-1}(z^{-1})\beta(z^{-1})S(z^{-1})]^T\frac{dz}{z}.\end{aligned}$$

The slight difference, because $\alpha \neq \tilde{\alpha}$, between the problem of minimizing (29) and the problem of minimizing (20) is unimportant, and the rest of the proof proceeds as in the proof of Theorem 3.1. □

The variance of (28) represents an additional cost due to the nonsquareness of the system. The cost term $(\mathrm{tr}/2\pi i)\oint \tilde{\theta}_-(z)Q\tilde{\theta}_-^T(z^{-1})(dz/z)$ is also affected by the nonsquareness and will be positive even if the system is of minimum phase.

EXISTENCE THEOREMS FOR OPTIMAL CONTROL AND CALCULUS OF VARIATIONS PROBLEMS WHERE THE STATES CAN JUMP*

J. M. MURRAY†

Abstract. We examine optimal control and calculus of variations problems where the states can be discontinuous. In the control theory setting this is caused by allowing impulse controls. Conditions under which optimal solutions will exist for these problems are determined after we derive suitable objective functionals that can handle the jump terms.

Key words. control theory, calculus of variations, existence, impulse controls, jumps

1. Introduction. In this paper the question of existence of an optimal solution for optimal control and calculus of variations problems is investigated. For the usual class of problems where the state vector x must be absolutely continuous, current existence theory requires that the Hamiltonian $H(t, x, p)$ nowhere has the value of $+\infty$. This is equivalent to $P(t, x)$, the effective domain of $H(t, x, \cdot)$, being the whole space $\mathbb{R}^n$. In many economic applications this is undesirable since the elements of $P(t, x)$ have the interpretation of price vectors, which may be subject to constraints; the case $P(t, x) \equiv \mathbb{R}^n_+$, the nonnegative orthant, is often encountered.

Dealing with these problems requires replacing the original space of absolutely continuous functions with the space of functions of bounded variation for the state vectors x. Jumps in the state can occur when the costate vector p strikes the boundary of $P(t, x)$. In the control theory setting these jumps arise from using impulse controls. To incorporate the cost of any jumps in the state and the use of impulses, the objective functional must be extended, and in such a way so that it reduces to the usual case when jumps and impulses are not present. Rockafellar [13] has derived such an extension and obtained existence results for his problem but with the assumption that the Lagrangian $L(t, x, v)$ is convex in (x, v) for each t. This implies that $P(t, x)$ is independent of x.

In this paper, calculus of variations and optimal control problems are extended to allow jumps in the state and impulse controls and existence theorems are derived for these problems. These results differ from Rockafellar's in that the Lagrangian $L(t, x, v)$ is merely convex in v for each (t, x) as is the case for existence theorems for problems where the state must be absolutely continuous.

Other results in this area can be found in [2], [6], [7], [14], [15], and [16].

2. Notation and definitions. We will only consider calculus of variations and optimal control problems over a fixed time interval $[t_0, t_1]$. To simplify notation we will denote this interval by T.

Let $\mathcal{A}_1(D)$ be the space of absolutely continuous functions over the interval D. By $\mathcal{A}_m(D)$ we will mean the space of vector-valued functions $f = (f_1, \cdots, f_m)$ where $f_i \in \mathcal{A}_1(D)$, $i = 1, \cdots, m$. Since we mostly deal with the interval T and the case where n is the dimension of the state space, we will often shorten $\mathcal{A}_n(T)$ to $\mathcal{A}$, with the time interval and the number of components understood to be the above.

This paper formed part of the author's doctoral dissertation completed at the University of Washington, Seattle, Washington, under the supervision of Professor R. T. Rockafellar. That work was partially supported by the Air Force Office of Scientific Research, under grant F49620-82-K-0012.

Let $\mathscr{C}_1(D)$ be the space of continuous functions on the interval D. We will also use $\mathscr{C}_m(D)$ and $\mathscr{C}$.

For $D=[s_0, s_1]$ let $\mathscr{NB}_1(D)$ be the space of functions of bounded variation that are right continuous on $(s_0, s_1]$.

Two functions of bounded variation, f and g, will be called *equivalent* if $f=g$ except on a countable subset of (s_0, s_1). Let $\mathscr{B}_1(D)$ be the space of equivalence classes of functions of bounded variation on D. Belonging to each equivalence class is a unique element of $\mathscr{NB}_1(D)$, and corresponding to this function is a unique Borel measure. This measure then determines the particular equivalence class of $\mathscr{B}_1(D)$. As above, $\mathscr{B}_m(D)$ will denote the space of vector valued functions $f=(f_1, \cdots, f_m)$ where each f_i belongs to $\mathscr{B}_1(D)$ and for ease of notation we will write $\mathscr{B}_n(T)$ as $\mathscr{B}$.

Let $\mathscr{M}(D)$ be the space of one-dimensional, nonnegative regular Borel measures on D. Where D is obvious from the context we will simply write $\mathscr{M}$.

Let $g \in \mathscr{B}_m(D)$, where $D=[s_0, s_1]$. Then $dg(t)=\dot{g}(t)\,dt+\gamma(t)\,d\theta(t)$ for some $\theta \in \mathscr{M}$, and Borel measurable function γ, and we can define

$$\|g\|_{m,V} \triangleq |g(s_0)|+\int_D |\dot{g}(t)|\,dt+\int_D |\gamma(t)|\,d\theta(t)$$

whose value is independent of the choice of θ and γ.

In what follows, B_d^m denotes the m-dimensional closed ball with radius d and centred at the origin. As above, we will often omit the superscript m when it equals n the dimension of the state space, and simply write B_d.

Let $L_1(D)$ be the class of Lebesgue measurable functions on D. By $L_m(D)$ we will mean the space of vector-valued functions $f=(f_1, \cdots, f_m)$ where $f_i \in L_1(D)$, $i=1, \cdots, m$. Where the interval involved is obvious we will often write L_m instead of $L_m(D)$.

The *effective domain* of the function f is the set $\operatorname{dom} f \equiv \{y: f(y)<\infty\}$.

When the minimum of a function g may not be attained we write $\inf_y g(y)$ in place of $\min_y g(y)$, and, for the latter statement, there is the implicit understanding that the minimum is attained.

The generalized problem of Bolza in calculus of variations has the following form

$$\underset{x \in \mathscr{A}}{\text{minimize}}\ J(x)=l(x(t_0), x(t_1))+\int_T L(t, x(t), \dot{x}(t))\,dt \tag{2.1}$$

where l and L have values in $\mathbb{R} \cup \{+\infty\}$.

An example where $J(x)$ has a finite infimum over all $x \in \mathscr{A}$ but no such x attains the infimum, is the following:

Example 1. minimize $J(x)=l(x(0), x(1))+\int_0^1 (1-t)|\dot{x}(t)|\,dt$ where

$$l(a, b)=\begin{cases} 0 & \text{if } a=0,\ b=\pi, \\ +\infty & \text{otherwise.} \end{cases}$$

This has a minimizing sequence $\{\bar{x}_n\}$ where

$$\bar{x}_n(t)=\begin{cases} 0, & i \in \left[0, 1-\dfrac{1}{n}\right], \\ n\left(t-1+\dfrac{1}{n}\right)\pi, & t \in \left(1-\dfrac{1}{n}, 1\right], \end{cases}$$

but no minimum in the space $\mathscr{A}$ since the limit function is discontinuous at $t=1$. In

order to include such problems in the general framework, we wish to extend problem (2.1) to states x that have discontinuities, which we can perhaps consider as arising from the use of impulse controls in the control theory setting. The larger class of functions we will use will be $\mathcal{B}$. If we so wanted, we could manage this by using a limiting process of the kind evident in the example. However, it is our purpose here to actually derive a new objective functional for $\mathcal{B}$ which is equivalent to (2.1) when the two overlap. In [13] where the Lagrangian, $L(t, x, v)$, was convex in (x, v) for each t, a suitable extension of (2.1) turned out to be

$$(2.2) \qquad \underset{x\in\mathcal{B}}{\text{minimize}}\ I(x) = l(x(t_0), x(t_1)) + \int_T L(t, x(t), \dot{x}(t))\, dt + \int_T \bar{r}(t, \xi(t))\, d\theta(t)$$

where $dx(t) = \dot{x}(t)\, dt + \xi(t)\, d\theta(t)$, $\theta \in \mathcal{M}$ and $\bar{r}$ is the recession function for L (this is defined later).

The suitability of the extension (2.2) of (2.1) arises from the ability to derive existence results for it and its compatibility with (2.1) when $x \in \mathcal{A}$. Also it agrees with the limiting process mentioned above and one has under certain conditions $\inf_{\mathcal{A}} J = \min_{\mathcal{B}} I$.

It is our task in this paper to obtain existence theorems for extensions of the problem (2.1) when L is merely convex in v for each (t, x). These will then give some idea on how to properly formulate problems when the states can jump.

Our desire to consider the case when L is only convex in v is partly in an attempt to mirror existence theory when the states must belong to $\mathcal{A}$. In some cases it turns out that we can use the same extension (2.2) when the convexity condition is relaxed. However at other times we cannot and must resort to a more complicated formula that reflects the underlying situation. We will separate the two situations and show when the simpler formula may be used and, in that case, the other formula actually reduces to it.

The need for something subtler than (2.2) can be seen from the following.

Example 2. Let $x, v \in \mathbb{R}^2$ and define the matrix function R by

$$R(x) = \begin{pmatrix} \cos|x| & \sin|x| \\ -\sin|x| & \cos|x| \end{pmatrix}.$$

Let

$$L(t, x, v) = \begin{cases} (1-t)|v| & \text{if } (0,1)\cdot R(x)\cdot \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} \leqq 0, \\ +\infty & \text{otherwise.} \end{cases}$$

This L is not convex in (x, v), but, is convex in v for each (t, x). Consider the problem

$$\underset{x\in\mathcal{A}}{\text{minimize}}\ J(x) = \int_0^1 L(t, x(t), \dot{x}(t))\, dt$$

subject to $x(0) = (0, 0)^T$, $x(1) = (0, \pi)^T$. Obviously, for any $x \in \mathcal{A}$, $J(x) > 0$. From the form of L it would seem that we would want to delay our departure from the origin as long as possible and hence it might be profitable to attempt to use a generalization of the sequence $\{\bar{x}_n\}$ of Example 1. However this turns out to be prohibitively expensive since

$$\dot{\bar{x}}_n(t) = \begin{pmatrix} 0 \\ n\pi \end{pmatrix}$$

is not feasible for $t \in (1-1/n, 1-1/2n)$. Consider, instead, the more roundabout sequence $\{\tilde{x}_n\}$ where

$$\tilde{x}_n(t) = \begin{cases} \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & t \in \left[0, 1-\frac{1}{n}\right], \\ \begin{pmatrix} n\pi\left(t-1+\frac{1}{n}\right) \\ 0 \end{pmatrix}, & t \in \left(1-\frac{1}{n}, 1-\frac{1}{2n}\right], \\ \begin{pmatrix} \pi/2 \\ 4n\pi\left(t-1+\frac{1}{n}\right)-2\pi \end{pmatrix}, & t \in \left(1-\frac{1}{2n}, 1-\frac{1}{4n}\right], \\ \begin{pmatrix} 2n\pi(1-t) \\ \pi \end{pmatrix}, & t \in \left(1-\frac{1}{4n}, 1\right]. \end{cases}$$

Then it can be verified that each $\tilde{x}_n$ is feasible and

$$J(\tilde{x}_n) = \frac{31\pi}{16n} \quad \text{which implies } \{\tilde{x}_n\} \text{ is a minimizing sequence.}$$

The important point here is that although $\{\bar{x}_n\}$ and $\{\tilde{x}_n\}$ have the same discontinuous limit, the cost that we want to attribute to the limit depends on how we arrive at that limit. This is the reason why the expression (2.2) does not apply here: the $\bar{r}$ term is not capable of handling the many different ways we can jump from one point to another. In the totally convex case it is cheapest to jump "in a straight line" following the pattern of $\{\bar{x}_n\}$ but this is often not so when L is only convex in v as this example demonstrates. We must look for a more discerning extension of J.

In the latter sections of this paper, we will use the existence result obtained for calculus of variations problems to determine when a solution exists for certain generalized problems in optimal control.

We will assume that the following hold throughout this paper.

General assumptions. $L: T \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is a Lebesgue normal integrand. This is equivalent to the epigraph of L,

$$\text{epi } L(t, \cdot, \cdot) = \{(x, v, \alpha) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}: \alpha \geqq L(t, x, v)\}$$

being closed and depending Lebesgue measurably on t, in the sense that for each closed $D \subset \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$, the set

$$\{t \in T: D \cap \text{epi } L(t, \cdot, \cdot) \neq \varnothing\}$$

is Lebesgue measurable. Normality implies that $L(t, x(t), v(t))$ is Lebesgue measurable in t whenever $(x(t), v(t))$ is and that $L(t, \cdot, \cdot)$ is lower semicontinuous for each $t \in T$. These results may be found in [12].

$$L(t, x, \cdot) \text{ is convex for each } (t, x),$$

$$l: \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\} \text{ is lower semicontinuous.}$$

DEFINITIONS. The *state constraint* multifunction $X: T \rightrightarrows \mathbb{R}^n$ is given by $X(t) = \{x: \exists v \text{ with } L(t, x, v) < \infty\}$. Since $X(t)$ may not be the whole space, we include problems with constraints.

The *Hamiltonian* $H: T \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{\pm\infty\}$ is defined by $H(t, x, p) = \sup_v \{p \cdot v - L(t, x, v)\}$.

The *adjoint state constraint* multifunction $P: T \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is given by

$$P(t, x) = \{p: H(t, x, p) < \infty\} = \operatorname{dom} H(t, x, \cdot).$$

The *recession function* for L is

$$r: T \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\},$$

$$r(t, x, \xi) = \lim_{\lambda \to +\infty} \frac{L(t, x, v + \lambda\xi) - L(t, x, v)}{\lambda}$$

where $v \in \operatorname{dom} L(t, x, \cdot)$. The function r is independent of v since $L(t, x, \cdot)$ is convex (see [8, Thm. 8.5]). Using [8, Thm. 13.3], we can also write

$$r(t, x, \xi) = \sup\{p \cdot \xi: p \in P(t, x)\} = \sup\{p \cdot \xi: p \in \operatorname{cl} P(t, x)\}.$$

If $r(t, x_1, \xi) = r(t, x_2, \xi)$ for all $x_1, x_2 \in X(t)$ then we can define $\bar{r}(t, \xi)$ to be this common value. This is the function that appears in (2.2).

A multifunction $S: T \rightrightarrows \mathbb{R}^n$ is upper semicontinuous if whenever K is a compact subset of $\mathbb{R}^n$, the set $\{t \in T: K \cap S(t) \neq \varnothing\}$ is closed.

A multifunction $S: T \rightrightarrows \mathbb{R}^n$ is *lower semicontinuous* if the set $\{t \in T: U \cap S(t) \neq \varnothing\}$ is open relative to T for every open $U \subset \mathbb{R}^n$.

A multifunction $S: T \rightrightarrows \mathbb{R}^n$ is *fully lower semicontinuous* if S is lower semicontinuous and one has $x_0 \in \operatorname{cl} S(\tau)$ whenever there are neighbourhoods U and V of x_0 and τ such that the set $\{t \in V: S(t) \supset U\}$ is dense in V. (This definition is taken from [9, p. 457].)

For the two cases, where (2.2) is valid and where it is not, we will have slightly different sets of hypotheses. For the former, they will be labelled (*A*), and for the latter, (*B*).

Assumptions (A).

Assumption (A1). There exists a multifunction $\bar{P}: T \rightrightarrows \mathbb{R}^n$ such that for all $x \in X(t)$, we have

$$\operatorname{cl} P(t, x) = \bar{P}(t) \quad \text{for all } t \in T.$$

If this holds, the recession function r will be independent of $x \in X(t)$, so we can define the function $\bar{r}$ such that

$$\bar{r}(t, \xi) = r(t, x, \xi) \quad \text{where } x \text{ is any element of } X(t).$$

This is the function that appears in (2.2). In that case, r was independent of x because L was totally convex, that is $L(t, \cdot, \cdot)$ was convex for all t.

Assumption (A2). $\bar{P}$ is fully lower semicontinuous on T and $\operatorname{int} \bar{P}(t) \neq \varnothing$ for any $t \in T$. Here $\operatorname{int} D$ denotes the interior of the set D.

Assumption (A3). The multifunction $X: T \rightrightarrows \mathbb{R}^n$ is upper semicontinuous and $X(t)$ is closed for each $t \in T$.

Assumption (A4). For each $x \in \mathscr{B}$ such that $x(t) \in X(t)$ a.e. one has

$$\int_V |H(t, x(t), p)|\, dt < \infty$$

whenever V is an open subset of T and p is a point of $\mathbb{R}^n$ having a neighbourhood U such that $U \subset \bar{P}(t)$, $\forall t \in V$.

This assumption is needed for the proof of Theorem 5 of [9], which we require. It is used to prove the following proposition. Define for $x \in \mathscr{B}$,

$$E_x = \left\{p \in \mathscr{C}: \int_T H(t, x(t), p(t))\, dt < \infty\right\}.$$

PROPOSITION 1. *Assume* (A1), (A2) *and* (A4) *hold. Then, if* $x(t) \in X(t)$ *a.e., one has*

$$\operatorname{int} E_x = \{p \in \mathscr{C}: p(t) \in \operatorname{int} \bar{P}(t), \forall t \in T\} \neq \varnothing.$$

(To simplify notation, we will call the right-hand side of the above equation, $\mathscr{E}$.)

Proof. Fix an $x \in \mathscr{B}$ such that $x(t) \in X(t)$ a.e. and let $f(t, \cdot) = H(t, x(t), \cdot)$. Then f is a normal convex integrand since it is the conjugate of $L(t, x(t), \cdot)$ (see [12]). The required result then follows from [9, Thm. 5]. Q.E.D.

Assumption (A5). For each $M \geqq 0$ and function $p \in \mathscr{E}$, there exists an integrable function $\Gamma: T \to \mathbb{R}$ such that whenever $x \in \mathscr{B}$ satisfies $x(t) \in X(t)$ a.e. and $\|x\|_V \leqq M$, then

$$H(t, x(t), p(t)) \leqq \Gamma(t) \quad \text{a.e.}$$

Note that the following simpler, but more restrictive assumption would imply both (A4) and (A5):

For each $M \geqq 0$ there exists a summable function $\Gamma: T \to \mathbb{R}$ such that

$$|H(t, x, p)| \leqq \Gamma(t)$$

when $x \in X(t)$, $p \in \bar{P}(t)$, $|x| \leqq M$ and $|p| \leqq M$.

Assumptions (B).

Assumption (B1).

$$0 \in \operatorname{cl} P(t, x) \quad \text{for all } (t, x).$$

This is equivalent to saying that $r(t, x, \xi) \geqq 0$ for all (t, x, ξ) and it implies $q(t, a, a) = 0$ so that the only contributions to the summation in (2.3) are from the atoms of dx, that is, where $x(t^-)$ and $x(t^+)$ differ. Since a function of bounded variation only has countably many atoms, the summation will be over a countable number of t values.

We will need the following bounded forms of P and r. Let $K > 0$ and define

$$P_K(t, x) = P(t, x) \cap B_K,$$

$$r_K(t, x, \xi) = \sup\{p \cdot \xi: p \in P_K(t, x)\}.$$

Of course, $r_K \leqq r$ (B_K is the closed ball of radius K).

Assumption (B2). For $x \in X(t)$, $\operatorname{int} P(t, x) \neq \varnothing$ for any $t \in T$.

Assumption (B3). For any K, M and ε all greater than zero, there exists a $\gamma_{K\varepsilon} > 0$ such that for all $x \in B_M$, $t \in T$, $\tilde{\gamma} \geqq \gamma_{K\varepsilon}$ and $\xi \in \mathbb{R}^n$ with $|\xi| \geqq 1$ we have $L(t, x, \tilde{\gamma}\xi)/\tilde{\gamma} \geqq r_K(t, x, \xi) - \varepsilon|\xi|$.

Assumption (B4). For any K, $M > 0$, $x \in X(t)$, $x' \in X(t')$ with $x, x' \in B_M$ there exist γ_3 and γ_4 such that

$$|r_K(t', x', \xi) - r_K(t, x, \xi)| \leqq \gamma_3|\xi| \cdot |t - t'| + \gamma_4|\xi| \cdot |x - x'|$$

for all $\xi \in \mathbb{R}^n$.

Assumption (B5). The multifunction $X: T \rightrightarrows \mathbb{R}^n$ is upper semicontinuous and $X(t)$ is closed for each $t \in T$.

Assumption (B6). For each $x \in \mathscr{A}$ such that $x(t) \in X(t)$ we have

$$\int_V |H(t, x(t), p)|\, dt < \infty$$

whenever V is an open subset of T and p is a point of $\mathbb{R}^n$ having a neighbourhood U such that $U \subset P(t, x(t))$, for all $t \in V$.

Assumption (B7). For each $M \geqq 0$ and set $D \subset \{x \in \mathscr{A}: \|x\|_V \leqq M \text{ and } x(t) \in X(t) \text{ for all } t \in T\}$, if there exists a function $\bar{p} \in \mathscr{C}$ such that

$$\bar{p}(t) \in \operatorname{int} \bigcap_{x \in D} P(t, x(t)),$$

then there exists an integrable function Γ, depending on M, D and $\bar{p}$ such that

$$H(t, x(t), \bar{p}(t)) \leqq \Gamma(t) \quad \text{a.e.}$$

for all $x \in D$. Assumption (B7), (or (A5) for its class of problems), is required in the proof of Proposition 2. Notice that assumptions (A) and (B) overlap, which is not surprising since one problem, and its proof, is a generalization of the other.

There is much correspondence between the two sets of assumptions. Assumption (B4) says that the multifunction $P(t, x)$ has some sort of Lipschitz property and when combined with (B2) would imply the weaker assumptions (A2) for $\bar{P}$. Assumptions (B5) and (A3) are the same, whereas (B6) and (B7) are generalizations of (A4) and (A5) respectively. Apart from (B1) whose inclusion has already been explained the only assumption in (B) that is not in (A) is (B3). This is some sort of uniformity condition on the Lagrangian. We know, because of convexity, that for fixed (t, x) the Lagrangian will, for large v, essentially behave like its recession function, but in the proof of the theorem we need to ensure this property, not only for a fixed (t, x), but for a whole range of them.

If assumptions (A) are satisfied, which imply the recession function is independent of x, then we will use the functional I as expressed in (2.2). However if the recession function is not independent of x for our problem, then we must resort to the functional Φ defined in the following manner.

Let $x \in \mathscr{B}$ and

$$dx(t) = \dot{x}(t)\, dt + \xi_s(t)\, d\theta_s(t) + \xi_a(t)\, d\theta_a(t)$$

where $\xi_s(t)\, d\theta_s(t)$ represents the smooth or nonatomic singular part of $dx(t)$ and $\xi_a(t)\, d\theta_a(t)$ represents the atomic singular part. Then, for the general problem where the adjoint state constraint $P(t, x)$, and hence the recession function r, can depend on x we will take for the extended functional the following

$$\begin{aligned} \Phi(x) = l(x(t_0), x(t_1)) &+ \int_T L(t, x(t), \dot{x}(t))\, dt \\ &+ \int_T r(t, x(t), \xi_s(t))\, d\theta_s(t) + \sum_{t \in T} q(t, x(t^-), x(t^+)) \end{aligned} \tag{2.3}$$

where $x \in \mathscr{B}$ and

$$q(t, a, b) = \inf_{y \in \mathscr{A}[0,1]} \left\{ \int_0^1 r(t, y(s), \dot{y}(s))\, ds: y(0) = a, y(1) = b \right\}. \tag{2.4}$$

It can be shown [5, Prop. II.2] that Φ reduces to the functional I in (2.2), when r is independent of $x \in X(t)$, and it is obviously equivalent to J of (2.1) when x belongs to $\mathscr{A}$. The problem associated with (2.3) is

$$\min_{x \in \mathscr{B}} \Phi(x). \tag{2.5}$$

To show that we can find an optimal solution for the problems (2.2) and (2.5), we will prove that under certain conditions the level sets

$$\begin{aligned} &\{x \in \mathcal{B}\colon I(x) \leqq \alpha\}, \\ &\{x \in \mathcal{B}\colon \Phi(x) \leqq \alpha\} \end{aligned} \tag{2.6}$$

where $\alpha \in \mathbb{R}$, are compact in an appropriate topology. The topology that we will be using is the weak* topology on $\mathcal{B}$. A neighbourhood of $\bar{x} \in \mathcal{B}$ in this topology is by definition any subset of $\mathcal{B}$ which contains a set of the form

$$V(\bar{x}, F, \delta) = \left\{ x \in \mathcal{B}\colon |\bar{x}(t_0) - x(t_0)| + \left| \int_T p(t)[d\bar{x}(t) - dx(t)] \right| < \delta, p \in F \right\}$$

where $\delta > 0$ and F is a finite subset of $\mathcal{C}$.

This topology is based on the pairing

$$\langle x, (a, p) \rangle = x(t_0) \cdot a + \int_T p(t)\, dx(t)$$

between $\mathcal{B}$ and $\mathbb{R}^n \times \mathcal{C}$. The latter is a Banach space under the norm $\|(a, p)\| = \max\{|a|, \|p\|\}$ and in this way $\mathcal{B}$ can be identified with the dual Banach space $(\mathbb{R}^n \times \mathcal{C})^*$.

Notation. If $\bar{x}$ is the limit of the generalized sequence x_ν in the weak* topology on $\mathcal{B}$, we shall write it as $x_\nu \to^{w^*} \bar{x}$.

Theorem 1 will be the basis for our general existence theorem. It shows that the functional Φ is weak* lower semicontinuous over sets that are bounded by the norm $\|\cdot\|_V$. We will later place other conditions on the problem which ensure that the level sets (2.6) are bounded with this norm. Then the level sets will be compact so that a minimum will exist, if the problem is feasible.

Theorem 1A provides the same sort of results for the functional I and problem (2.2).

DEFINITIONS. Let $M \geqq 0$. Then define

$$\Phi_M(x) = l(x(t_0), x(t_1)) + \int_T L(t, x(t), \dot{x}(t))\, dt + \int_T r(t, x(t), \xi_s(t))\, d\theta_s(t) + Q_M(x)$$

where

$$Q_M(x) = \inf_{\{m_i\}} \sum_{t_i \in T} \inf_y \left\{ \int_0^1 r(t_i, y(s), \dot{y}(s))\, ds\colon y(0) = x(t_i^-), \; y(1) = x(t_i^+), y \in \mathcal{A}[0, 1], \int_0^1 |\dot{y}(s)|\, ds \leqq m_i \right\}$$

where the $\{t_i\}$ consist of the atoms of dx and

$$\sum_i m_i = M - \left[|x(t_0)| + \int_T |\dot{x}(t)|\, dt + \int_T |\xi_s(t)|\, d\theta_s(t) \right]$$

where $m_i \geqq 0$ for all i. The first infimum in the definition of $Q_M(x)$ is over all such $\{m_i\}$. Notice that if $\|x\|_V > M$ then $Q_M(x)$ and hence $\Phi_M(x)$ are positively infinite.

THEOREM 1. *Let assumptions* (B) *hold. Also assume there exist constants* $\gamma_1, \gamma_2 \in \mathbb{R}$ *such that* $L(t, x, v) \geqq -\gamma_1|x| + \gamma_2$. *Then for all real numbers* α *and* M, *the set*

$$S_{\alpha,M} = \{x \in \mathcal{B}\colon \Phi_M(x) \leqq \alpha\} \tag{2.7}$$

is compact in the weak topology of* $\mathcal{B}$.

THEOREM 1A. *Let assumptions* (A) *hold. Then for all real numbers* α *and* M, *the set*

$$\tilde{S}_{\alpha,M} = \{x \in \mathcal{B}: I(x) \leqq \alpha, \|x\|_V \leqq M\}$$

is compact in the weak topology of* $\mathcal{B}$.

We will suffice ourselves here in proving Theorem 1. The proof of Theorem 1A (see [5]) follows similar, but simpler steps which we will later outline.

It will turn out useful to have an alternate form of Φ_M. This involves "fitting together" the various pieces of x and the y to form a new state vector $\tilde{x}$ which is absolutely continuous. This follows the approach used by Rishel in [5] to obtain necessary conditions. We will now construct this alternate form.

Fix a $\theta \in \mathcal{M}$. Define the function $\hat{\psi}: T \to \mathbb{R}$ by

$$\begin{aligned} &\hat{\psi}(t_0) = t_0, \\ &\hat{\psi}(\tau) = \int_{[t_0,\tau]} dt + \int_{[t_0,\tau]} d\theta(t) \quad \text{for } t_0 < \tau \leqq t_1. \end{aligned} \tag{2.8}$$

Let $\eta_0 = \hat{\psi}(t_0) = t_0$ and $\eta_1 = \hat{\psi}(t_1)$.

Define the multifunction ψ by

$$\begin{aligned} &\psi(t_0) = [\hat{\psi}(t_0), \hat{\psi}(t_0^+)], \\ &\psi(t) = [\hat{\psi}(t^-), \hat{\psi}(t)] \quad \text{for } t_0 < t \leqq t_1. \end{aligned}$$

Since $\hat{\psi}$ is strictly increasing, the inverse multifunction of ψ is actually a function, which we shall call ζ

$$\zeta: [\eta_0, \eta_1] \to \mathbb{R}.$$

We also have for $\eta_\alpha < \eta_\beta$,

$$0 \leqq \zeta(\eta_\beta) - \zeta(\eta_\alpha) \leqq \eta_\beta - \eta_\alpha.$$

So ζ is absolutely continuous and

$$0 \leqq \frac{d\zeta}{d\eta} \leqq 1.$$

Define $h: [\eta_0, \eta_1] \to \mathbb{R}$ by

$$h(\eta) = 1 - \frac{d\zeta}{d\eta}(\eta).$$

Then if $t \in T$ and $\bar{\eta}$ is such that $t = \zeta(\bar{\eta})$, we have

$$t = \zeta(\bar{\eta}) = \eta_0 + \int_{\eta_0}^{\bar{\eta}} \frac{d\zeta}{d\eta}(\eta)\, d\eta = \eta_0 + \int_{\eta_0}^{\bar{\eta}} (1 - h(\eta))\, d\eta. \tag{2.9}$$

From (2.8), (2.9) and the definition of ζ, we deduce that $(d\zeta/d\eta)(\eta) \in \{0, 1\}$, and likewise $h(\eta)$, $\forall \eta \in [\eta_0, \eta_1]$. If $t \in T$ corresponds to an $\bar{\eta} \in [\eta_0, \eta_1]$ via ζ, and $d\zeta(\bar{\eta})/d\eta = 0$, then t belongs to the support of θ almost always.

Now suppose that we are given an $x \in \mathcal{B}$ with

$$dx(t) = \dot{x}(t)\, dt + \xi(t)\, d\theta(t), \qquad \theta \in \mathcal{M}.$$

Although the choice of θ is not unique, we can choose a suitable one relative to x and fix it. This then determines a ζ and h.

DEFINITION.

$$\mathscr{A}_\theta(x)=\{\tilde{x}\in\mathscr{A}[\eta_0,\eta_1]:\ \tilde{x}(\eta_0)=x(t_0),\ \tilde{x}(\eta_1)=x(t_1) \text{ and } \tilde{x}(\eta)=x(\zeta(\eta)) \text{ a.e. when } h(\eta)=0\}.$$

Let us consider the following functional for $\tilde{x}\in\mathscr{A}_\theta(x)$

$$\Phi_\theta(\tilde{x},x)=l(\tilde{x}(\eta_0),\tilde{x}(\eta_1))+\int_{\eta_0}^{\eta_1}L\left(\zeta(\eta),\tilde{x}(\eta),\frac{d\tilde{x}}{d\eta}(\eta)\right)(1-h(\eta))\,d\eta + \int_{\eta_0}^{\eta_1}r\left(\zeta(\eta),\tilde{x}(\eta),\frac{d\tilde{x}}{d\eta}(\eta)\right)h(\eta)\,d\eta. \tag{2.10}$$

This can be rewritten as

$$\Phi_\theta(\tilde{x},x)=l(x(t_0),x(t_1))+\int_T L(t,x(t),\dot{x}(t))\,dt + \int_{\eta_0}^{\eta_1}r\left(\zeta(\eta),\tilde{x}(\eta),\frac{d\tilde{x}}{d\eta}(\eta)\right)h(\eta)\,d\eta.$$

DEFINITION.

$$\mathscr{A}_{M\theta}(x)=\{\tilde{x}\in\mathscr{A}_\theta(x):\ \|\tilde{x}\|_V\leqq M\}.$$

Using this definition and the positive homogeneity of $r(t,x,\cdot)$, we find that

$$\begin{aligned}\Phi_M(x)&=\inf_{\tilde{x}\in\mathscr{A}_{M\theta}(x)}\Phi_\theta(\tilde{x},x)\\&=l(x(t_0),x(t_1))+\int_T L(t,x(t)\dot{x}(t))\,dt\\&\quad+\inf_{\tilde{x}\in\mathscr{A}_{M\theta}(x)}\int_{\eta_0}^{\eta_1}r\left(\zeta(\eta),\tilde{x}(\eta),\frac{d\tilde{x}}{d\eta}(\eta)\right)h(\eta)\,d\eta.\end{aligned} \tag{2.11}$$

From the above we see that the choice of θ has no real effect on the value of Φ_M provided of course

$$dx(t)=\dot{x}(t)\,dt+\xi(t)\,d\theta(t).$$

So the size of $[\eta_0,\eta_1]$ can be chosen for any purpose we have in mind, subject to the constraint $[t_0,t_1]\subset[\eta_0,\eta_1]$. The formula in (2.11) is the alternate form for Φ_M.

PROPOSITION 2. *Let assumption* (B7) *hold. Let* $M\geqq 0$ *and* $D\subset\{x\in\mathscr{A}:\ \|x\|_V\leqq M$ *and* $x(t)\in X(t)$ *for all* $t\in T\}$. *For each* t *let* $\mathscr{D}(t)=\{x(t):\ x\in D\}$. *If there exists a* $p\in\mathscr{C}$ *such that* $p(t)\in\operatorname{int}\bar{P}(t)\equiv\operatorname{int}\bigcap_{y\in\mathscr{D}(t)}P(t,y)$ *then* $H(t,\cdot,p(t))$ *is upper semicontinuous on* $\mathscr{D}(t)$.

Proof. Write $L_0=-H$ and $K_0(t,x,p,v)=L(t,x,v)-pv$. Then $L_0(t,x,p)=\inf K_0(t,x,p,v)$ where $K_0(t,\cdot,\cdot,\cdot)$ is lower semicontinuous. Using the equivalence theorem of [11] it suffices to show that for fixed $t\in T$, $\alpha\in\mathbb{R}$ and $N\geqq 0$ the set

$$s=\{v:\ x\in\mathscr{D}(t) \text{ with } |x|\leqq N \text{ and } L(t,x,v)-pv\leqq\alpha\}$$

is bounded.

Since $p(t)\subset\operatorname{int}\bar{P}(t)$, $\exists\delta>0$ and $p_i\in\operatorname{int}\bar{P}(t)$, $i=1,\cdots,k$ such that

$$p(t)+B_\delta\subset\operatorname{co}\{p_1,\cdots,p_k\}\subset\operatorname{int}\bar{P}(t).$$

By (B7), $\exists \Gamma_i$ such that

$$H(t, x, p_i) \leqq \Gamma_i(t), \qquad i = 1, \cdots, k, \forall x \in \mathscr{D}(t).$$

By the convexity of $H(t, x, p)$ in p, we have

$$H(t, x, \tilde{p}) \leqq \Gamma(t) = \max_{i=1,\cdots,k} \Gamma_i(t) \quad \forall \tilde{p} \in p(t) + B_\delta, \forall x \in \mathscr{D}(t).$$

Then on $\mathscr{D}(t)$,

$$\tilde{p}v - L(t, x, v) \leqq \Gamma(t) \quad \forall \tilde{p} \in p(t) + B_\delta.$$

Hence

$$L(t, x, v) \geqq \sup_{\tilde{p} \in p(t)+B_\delta} \{\tilde{p}v - \Gamma(t)\} = p(t)v + \delta|v| - \Gamma(t).$$

Therefore on $\mathscr{D}(t)$

$$\alpha \geqq L(t, x, v) - p(t)v \geqq p(t)v + \delta|v| - \Gamma(t) - p(t)v = \delta|v| - \Gamma(t)$$

$$\Rightarrow |v| \leqq \frac{\alpha + \Gamma(t)}{\delta}$$

and S is bounded. Q.E.D.

PROPOSITION 3. *Let assumptions* (B5) *and* (B7) *hold. Define*

$$\psi(x, p) = \int_S H(t, x(t), p(t))\, dt$$

where S is a compact subset of T. Suppose $\bar{x} \in \mathscr{A}(S)$, $x_j \to \bar{x}$ uniformly on S and

$$\{x_j\}_{j=1}^{\infty} \subset \{x \in \mathscr{A}(S): \|x\|_V \leqq M, x(t) \in X(t), t \in S\}.$$

Let $\bar{p} \in \mathscr{C}(S)$. If $\bar{p}$ is such that $\exists \varepsilon > 0$ and k with

$$\bar{p}(t) + B_\varepsilon \subset P(t, x_j(t)) \quad \forall j \geqq k,$$

then

$$\limsup_{j \to \infty} \psi(x_j, \bar{p}) \leqq \psi(\bar{x}, \bar{p}).$$

Proof. Using Proposition 2 and Fatou's lemma, we have

$$\limsup \psi(x_j, \bar{p}) \leqq \int_S \limsup_{j \to \infty} H(t, x_j(t), \bar{p}(t))\, dt$$

$$\leqq \int_S H(t, \bar{x}(t), \bar{p}(t))\, dt = \psi(\bar{x}, \bar{p}). \qquad \text{Q.E.D.}$$

3. Proof of Theorem 1. Fix $\alpha \in \mathbb{R}$ and $M > 0$. To avoid the trivial, we will assume that $S_{\alpha,M}$ is nonempty.

Since $S_{\alpha,M} \subset \{x \in \mathscr{B}: \|x\|_V \leqq M\}$ and this last set is bounded in the strong topology, to show weak* compactness we only need to show that $S_{\alpha,M}$ is closed in the weak* topology. This task is made simpler by realizing that the boundedness of $S_{\alpha,M}$ causes it to be metrizable so it suffices to look at sequences to prove the weak* closure of $S_{\alpha,M}$.

Let $\{x_j\}_{j=1}^{\infty} \subset S_{\alpha,M}$ and $x_j \to^{w^*} \bar{x}$, where $\bar{x} \in \mathscr{B}$. By [4, Thm. 33, p. 291], $\|\bar{x}\|_V \leqq M$. Let

$$dx_j(t) = \dot{x}_j(t)\, dt + \xi_j(t)\, d\theta_j(t), \qquad j = 1, \cdots$$

and

$$d\bar{x}(t) = \dot{\bar{x}}(t)\, dt + \bar{\xi}(t)\, d\bar{\theta}(t).$$

Choose the θ_j and $\bar{\theta}$ so that the corresponding reparametrizations in the alternate form of Φ_M, (2.11), have the same endpoints η_0 and η_1. Since each of the θ_j and $\bar{\theta}$ has support whose Lebesgue measure is zero in T, then for any $\delta > 0$ we can find a relatively open set $A \subset T$ such that

$$m(A) < \delta \quad \text{and} \quad A \supset \bigcup_{j=1}^{\infty} \operatorname{supp}\{\theta_j\} \cup \operatorname{supp}\{\bar{\theta}\}$$

where $\operatorname{supp}\{\theta_j\}$ = the support set of θ_j and m is the Lebesgue measure.

Our mode of attack will be to show, separately, that on $T \backslash A$ and A, Φ_M is approximately weak* lower semicontinuous with respect to this sequence. As we make A smaller, the approximation improves until we obtain the required results.

Firstly, we will investigate the behaviour of Φ_M on a set similar to A. Fix $\varepsilon > 0$. For each j, choose an $\tilde{x}_j \in \mathscr{A}_{M\theta_j}(x_j)$ such that

$$|\Phi_M(x_j) - \tilde{\Phi}(\tilde{x}_j)| < \varepsilon \tag{3.1}$$

where $\tilde{\Phi}(\tilde{x}_j) = \Phi_{\theta_j}(\tilde{x}_j, x_j)$ (see (2.10)).

Although each of the $\tilde{x}_j$ are absolutely continuous, it may happen that as $j \to \infty$ they will approach a function that is not absolutely continuous, which is exactly the type of behaviour we are trying to model. To see how this limit behaves, we will reparametrize the problem yet again so that the derivatives involved are bounded and the limit functions will be absolutely continuous. In this endeavour, we will follow the approach of Warga [16].

For each j, define

$$\rho_j(\eta) = \max\left\{1, \left|\frac{d\tilde{x}_{j1}}{d\eta}(\eta)\right|, \cdots, \left|\frac{d\tilde{x}_{jn}}{d\eta}(\eta)\right|\right\}.$$

Because each of the $\tilde{x}_{ji}$, $i = 1, \cdots, n$ are integrable over $[\eta_0, \eta_1]$, ρ_j is integrable for each j. For each j, define

$$\alpha_j(\eta) = \eta_0 + \int_{\eta_0}^{\eta} \rho_j(s)\, ds.$$

Since $\rho_j(\eta) \geqq 1$ for all $\eta \in [\eta_0, \eta_1]$, α_j is strictly increasing. As α_j is also continuous, it has an inverse ω_j and

$$\omega_j(\tau) = \tau_0 + \int_{\tau_0}^{\tau} \beta_j(s)\, ds, \qquad \tau \in [\tau_0, \tau_{j1}]$$

where

$$0 \leqq \beta_j(\tau) \leqq \frac{1}{\rho_j(\omega_j(\tau))} \leqq 1$$

and $\tau_0 = \eta_0$, $\tau_{j1} = \alpha_j(\eta_1) \leqq M + (\eta_1 - \eta_0) \equiv \tau_1$. Let

$$\chi_j(\tau) = \tilde{x}_j(\omega_j(\tau)).$$

Then for $i = 1, \cdots, n$

$$0 \leqq \left|\frac{d\chi_{ji}}{d\tau}(\tau)\right| = \left|\frac{d\tilde{x}_{ji}}{d\eta}(\omega_j(\tau))\right| \beta_j(\tau) = \left|\frac{d\tilde{x}_{ji}}{d\eta}(\omega_j(\tau))\right| \Big/ \rho_j(\omega_j(\tau)) \leqq 1.$$

Let

$$z_j(\tau) = \zeta_j(\omega_j(\tau)),$$

where ζ_j corresponds to the metatime for x_j (see (2.9) and its derivation).

Then

$$0 \leqq \frac{dz_j}{d\tau}(\tau) = \frac{d\zeta_j}{d\eta}(\omega_j(\tau))\beta_j(\tau) \leqq \beta_j(\tau) \leqq 1.$$

Since $d\zeta_j/d\eta \in \{0, 1\}$, we also have $(dz_j/d\tau)(\tau) \in \{0, \beta_j(\tau)\}$. To ease the burden of notation, let us denote "$d/d\tau$" by "$'$". So, for example $dz_j/d\tau$ is replaced by $z_j'(\tau)$.

Although the triple (z_j, χ_j, ω_j) is defined on the interval $[\tau_0, \alpha_j(\eta_1)]$, we can extend it to $[\tau_0, \tau_1]$ by defining

$$\begin{aligned}(z_j(\tau), \chi_j(\tau), \omega_j(\tau) &= (z_j(\alpha_j(\eta_1)), \chi_j(\alpha_j(\eta_1)), \omega_j(\alpha_j(\eta_1)) \\ &= (t_1, \tilde{x}_j(\eta_1), \eta_1) \quad \text{when } \tau \in (\alpha_j(\eta_1), \tau_1].\end{aligned}$$

By the Arzela-Ascoli theorem, the sequence $\{(z_j, \chi_j, \omega_j)\}_{j=1}^{\infty}$ has a subsequence, which we shall again label in the same manner, that converges uniformly on $[\tau_0, \tau_1]$ to a triple $(\bar{z}, \bar{\chi}, \bar{\omega}) \in \mathscr{A}_{n+2}[\tau_0, \tau_1]$ that has the same bounds on its derivatives.

Our objective functional in the η variable was

$$\begin{aligned}\tilde{\Phi}(\tilde{x}_j) = l(\tilde{x}_j(\eta_0), \tilde{x}_j(\eta_1)) + \int_{\eta_0}^{\eta_1} \Bigg[& L\left(\zeta_j(\eta), \tilde{x}_j(\eta), \frac{d\tilde{x}_j}{d\eta}(\eta)\right)\frac{d\zeta_j}{d\eta}(\eta) \\ & + r\left(\zeta_j(\eta), \tilde{x}_j(\eta), \frac{d\tilde{x}_j}{d\eta}(\eta)\right)\left(1 - \frac{d\zeta_j}{d\eta}(\eta)\right)\Bigg] d\eta.\end{aligned}$$

Transforming the problem into the τ variable, we obtain

$$\begin{aligned}\hat{\Phi}(z_j, \chi_j, \omega_j) = {} & l(\chi_j(\tau_0), \chi_j(\tau_1)) \\ & + \int_{\tau_0}^{\tau_1} \Bigg[L\left(z_j(\tau), \chi_j(\tau), \frac{1}{\beta_j(\tau)}\chi_j'(\tau)\right)\frac{1}{\beta_j(\tau)} z_j'(\tau) \\ & + r\left(z_j(\tau), \chi_j(\tau), \frac{1}{\beta_j(\tau)}\chi_j'(\tau)\right)\left(1 - \frac{1}{\beta_j(\tau)} z_j'(\tau)\right)\Bigg]\beta_j(\tau)\, d\tau.\end{aligned}$$

Let

$$g_j(\tau) = \begin{cases} 0 & \text{when } z_j'(\tau) = 0, \\ 1 & \text{otherwise.} \end{cases}$$

Then

$$g_j(\tau) = z_j'(\tau)/\beta_j(\tau)$$

and

$$\begin{aligned}\hat{\Phi}_j \equiv {} & \hat{\Phi}(z_j, \chi_j, \omega_j) \\ = {} & l(\chi_j(\tau_0), \chi_j(\tau_1)) + \int_{\tau_0}^{\tau_1} \Bigg[L\left(z_j(\tau), \chi_j(\tau), \frac{1}{\beta_j(\tau)}\chi_j'(\tau)\right) g_j(\tau)\beta_j(\tau) \\ & + r(z_j(\tau), \chi_j(\tau), \chi_j'(\tau))(1 - g_j(\tau))\Bigg] d\tau.\end{aligned}$$

Define

$$D = \{\tau: \bar{g}(\tau) = 0\} \quad \text{and} \quad D_0 = \{\tau \in D: \bar{\beta}(\tau) = 0\}$$

where $\bar{\omega}'(\tau) = \bar{\beta}(\tau)$ and

$$\bar{g}(\tau) = \begin{cases} 0 & \text{when } \bar{z}'(\tau) = 0, \\ 1 & \text{otherwise.} \end{cases}$$

Since $\bar{\omega}$ is nondecreasing on $[\tau_0, \tau_1]$, there exist a countable number of distinct intervals D_i, $i = 1, 2, \cdots$ such that $m(D_0 \backslash \cup_{i=1}^{\infty} D_i) = 0$. As $\omega_j \to \bar{\omega}$ uniformly on $[\tau_0, \tau_1]$, for every $\varepsilon' > 0$ $\exists k$ such that $\forall j \geqq k$

$$|\omega_j(\tau) - \bar{\omega}(\tau)| < \varepsilon'. \tag{3.2}$$

There also exists an integer $\bar{n}$ such that, for some $\bar{\varepsilon}'$, $m(\cup_{i=1}^{\bar{n}} D_i) \geqq m(D_0) - \bar{\varepsilon}'$ and on each of the D_i we will have, using (3.2)

$$\int_{D_i} \beta_j(\tau)\, d\tau < 2\varepsilon', \qquad j \geqq k.$$

Therefore, for $j \geqq k$

$$\int_{D_0} |\beta_j(\tau)|\, d\tau = \int_{D_0} \beta_j(\tau)\, d\tau < \bar{\varepsilon}' + 2\bar{n}\varepsilon'.$$

Fixing $\bar{\varepsilon}'$ and hence $\bar{n}$, we can make ε' as small as we like and show that

$$\lim_{j \to \infty} \int_{D_0} |\beta_j(\tau)|\, d\tau < \bar{\varepsilon}'.$$

As $\bar{\varepsilon}'$ is arbitrary, we see that

$$\beta_j \xrightarrow{L_1^1} \bar{\beta} \quad \text{on } D_0.$$

So there is a subsequence which we shall still call $\{\beta_j\}_{j=1}^{\infty}$ such that

$$\beta_j(\tau) \to \bar{\beta}(\tau) \quad \text{a.e. on } D_0.$$

By Egorov's theorem,

$$\beta_j \to \bar{\beta} \quad \text{almost uniformly on } D_0.$$

Similarly $g_j \to \bar{g}$ almost uniformly on $D \backslash D_0$ (or more precisely, a subsequence of $\{g_j\}_{j=1}^{\infty}$) so for any $\varepsilon' > 0$, $\delta' > 0$, $\exists k$ (since the particular value of k is of no interest to us we will not worry that the same symbol k appears above) and a $D_{\varepsilon'}$ such that $\forall j \geqq k$

$$\beta_j(\tau) < \delta' \quad \text{or} \quad g_j(\tau) = 0 \quad \text{on } D_{\varepsilon'},$$
$$m(D \backslash D_{\varepsilon'}) < \varepsilon'.$$

Hence for $j \geqq k$, we have by the above and the assumption on L in the statement of the theorem, that the functional $\hat{\Phi}_j$ evaluated over D is,

$$\hat{\Phi}_j|_D \geqq \int_{D_{\varepsilon'}} \Big[L\Big(z_j(\tau), \chi_j(\tau), \frac{1}{\beta_j(\tau)} \chi_j'(\tau)\Big) \beta_j(\tau) g_j(\tau) + r(z_j(\tau), \chi_j(\tau), \chi_j'(\tau))(1 - g_j(\tau)) \Big]\, d\tau + (\gamma_2 - \gamma_1 M)\varepsilon' \tag{3.3}$$

where we have assumed, to simplify the expression, that $\tau_0, \tau_1 \notin D$ so that l does not appear.

Choosing a K and ε'', we obtain a $\gamma_{K\varepsilon''}$ from assumption (B3) such that

$$L\left(z_j, \chi_j, \frac{|\chi_j'|}{\beta_j}\cdot\frac{\chi_j'}{|\chi_j'|}\right)\frac{B_j}{|\chi_j'|} \geqq r_K\left(z_j, \chi_j, \frac{\chi_j'}{|\chi_j'|}\right) - \varepsilon'' \tag{3.4}$$

whenever $|\chi_j'|/\beta_j \geqq \gamma_{K\varepsilon''}$ which occurs for $j \geqq k$ on $D_{\varepsilon'}$ if

$$|\chi_j'| \geqq \delta'\gamma_{K\varepsilon''}.$$

We can rewrite (3.4) as,

$$L\left(z_j, \chi_j, \frac{\chi_j'}{\beta_j}\right)\beta_j \geqq r_K(z_j, \chi_j, \chi_j') - \varepsilon''|\chi_j'|$$

when $|\chi_j'| \geqq \delta'\gamma_{K\varepsilon''}$ on $D_{\varepsilon'}$. Therefore (4.3) gives

$$\begin{aligned}\hat{\Phi}_j|_D \geqq \int_{D_{\varepsilon'}} & [r_K(z_j(\tau), \chi_j(\tau), \chi_j'(\tau))g_j(\tau) \\ & + r(z_j(\tau), \chi_j(\tau), \chi_j'(\tau))(1-g_j(\tau))]\, d\tau \\ & + \delta'(\gamma_2 - \gamma_1 M)m(D_{\varepsilon'}) - \varepsilon'' M - K\delta'\gamma_{K\varepsilon''}m(D_{\varepsilon'}) + (\gamma_2 - \gamma_1 M)\varepsilon'\end{aligned}$$

(where the second last term appears because when $|\chi_j'| < \delta'\gamma_{K\varepsilon''}$ we have $r_K \leqq K|\chi_j'| < K\delta'\gamma_{K\varepsilon''}$. For ease of notation, let the last line of the above inequality be denoted by ν).

$$\geqq \int_{D_{\varepsilon'}} r_K(z_j(\tau), \chi_j(\tau), \chi_j'(\tau))\, d\tau + \nu.$$

Now X is a closed, upper semicontinuous multifunction by assumption (B5), so $\bar{\chi}(\tau) \in X(\bar{z}(\tau))$ because (z_j, χ_j) converges uniformly to $(\bar{z}, \bar{\chi})$, and $\chi_j(\tau) \in X(z_j(\tau))$. By assumption (B4), for any $\varepsilon''' > 0$, $\exists k$ such that $\forall j \geqq k$,

$$\hat{\Phi}_j|_D \geqq \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \chi_j'(\tau))\, d\tau - \varepsilon''' M(\gamma_3 + \gamma_4) + \nu. \tag{3.5}$$

By the properties of the χ_j' and χ_j and Theorem 3.1 of [1] we see that χ_j' converges weakly to $\bar{\chi}'$. So by Mazur's theorem [1, Thm. 3.2] there exists a sequence of convex combinations of the χ_j' that converges almost everywhere to $\bar{\chi}'$, that is

$$\sum_{i=1}^{\bar{k}(j)} \lambda_{ij}\chi'_{s(j)+i}(\tau) \to \bar{\chi}'(\tau) \quad \text{a.e.}$$

where $\sum_{i=1}^{\bar{k}(j)} \lambda_{ij} = 1$, $\lambda_{ij} \geqq 0$ and $s(j) + \bar{k}(j) < s(j+1) + 1$. Therefore, by (3.5) and Fatou's lemma

$$\begin{aligned}\liminf_j & \sum_{i=1}^{\bar{k}(j)} \lambda_{ij}\hat{\Phi}_{s(j)+i}|_D \\ & \geqq \int_{D_{\varepsilon'}} \liminf_j \sum_{i=1}^{\bar{k}(j)} \lambda_{ij} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \chi'_{s(j)+i}(\tau))\, d\tau - \varepsilon''' M(\gamma_3 + \gamma_4) + \nu \\ & \geqq \int_{D_{\varepsilon'}} \liminf_j r_K\left(\bar{z}(\tau), \bar{\chi}(\tau), \sum_{i=1}^{\bar{k}(j)} \lambda_{ij}\chi'_{s(j)+i}(\tau)\right) d\tau \\ & \quad - \varepsilon''' M(\gamma_3 + \gamma_4) + \nu \quad \text{(since } r_K(t, x, \cdot) \text{ is convex)} \\ & \geqq \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau))\, d\tau \\ & \quad - \varepsilon''' M(\gamma_3 + \gamma_4) + \nu \quad \text{(since } r_K(t, x, \cdot) \text{ is lower semicontinuous).}\end{aligned}$$

Therefore

$$\liminf_j \hat{\Phi}_j|_D \geqq \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau))\, d\tau - \varepsilon''' M(\gamma_3+\gamma_4) + \nu.$$

Let $\bar{\varepsilon} > 0$. Then for our fixed K and ε' such that

$$-(\gamma_2 - \gamma_1 M)\varepsilon' < \frac{\bar{\varepsilon}}{5}$$

we can choose, in order,

$$\varepsilon''' M(\gamma_3+\gamma_4) < \frac{\bar{\varepsilon}}{5},$$

$$\varepsilon'' M < \frac{\bar{\varepsilon}}{5},$$

$$K\delta'\gamma_{K\varepsilon''} m(D_{\varepsilon'}) < \frac{\bar{\varepsilon}}{5},$$

$$-\delta'(\gamma_2 - \gamma_1 M) m(D_{\varepsilon'}) < \frac{\bar{\varepsilon}}{5}.$$

Hence,

$$\liminf_j \hat{\Phi}_j|_D \geqq \int_{D_{\varepsilon'}} r_K(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau))\, d\tau - \bar{\varepsilon}.$$

Since K and ε' were arbitrary,

$$\begin{aligned}\liminf_j \hat{\Phi}(z_j, \chi_j, \alpha_j^{-1})|_D &\geqq \int_D r(\bar{z}(\tau), \bar{\chi}(\tau), \bar{\chi}'(\tau))\, d\tau - \bar{\varepsilon} \\ &= \hat{\Phi}(\bar{z}, \bar{\chi}, \bar{\alpha}^{-1})|_D - \bar{\varepsilon}.\end{aligned}$$

Therefore,

$$\liminf_j \hat{\Phi}(z_j, \chi_j, \alpha_j^{-1})|_D \geqq \hat{\Phi}(\bar{z}, \bar{\chi}, \bar{\alpha}^{-1})|_D. \tag{3.6}$$

Let us define an x^* such that

$$x^*(\bar{z}(\tau)) = \bar{\chi}(\tau), \qquad \tau \notin D.$$

Then x^* (or more precisely, its equivalence class) belongs to $\mathcal{B}$. What we wish to show is that x^* and $\bar{x}$ are equivalent and that from $\bar{\chi}$ we can construct an $\tilde{x} \in \mathcal{A}_{M\bar{\theta}}(\bar{x})$ so that (3.6) implies a corresponding result for the $\Phi(x_j)$ and $\Phi(\bar{x})$. Firstly let us show the equivalence of x^* and $\bar{x}$. The function $\bar{z}$ represents the original time variable t. We want to show that $x^*(\bar{z}(\tau)) = \bar{x}(\bar{z}(\tau))$ for almost all $\tau \notin D$ since the times $z(\tau)$, $\tau \in D$, correspond to the singular part of dx^*.

Fix $\varepsilon > 0$; then there exists an open set $A \subset T$ with $m(A) < \varepsilon$ such that $A \supset \bigcup_{j=1}^{\infty} z_j(D_j) \cup \bar{z}(D)$ where $D_j = \{\tau\colon z_j'(\tau) = 0\}$. Since $(z_j, \chi_j) \to (\bar{z}, \bar{\chi})$ uniformly, for every $\delta > 0$ $\exists k$ such that for $j \geqq k$

$$|z_j(\tau) - \bar{z}(\tau)| < \delta \quad \text{and} \quad |\chi_j(\tau) - \bar{\chi}(\tau)| < \delta \quad \forall \tau.$$

But on $T\backslash A$, $\bar{z}^{-1}$ and z_j^{-1}, $j = 1, 2, \cdots$ exist since we have $\bar{z}'(\tau) = 1$ when $\bar{z}(\tau) \in T\backslash A$ and $z_j'(\tau) = 1$ when $z_j(\tau) \in T\backslash A$. We will then have for $j \geqq k$ and $t \in T\backslash A$

$$|z_j^{-1}(t) - \bar{z}^{-1}(t)| < \delta. \tag{3.7}$$

Since $\bar{\chi}$ is uniformly continuous, given $\varepsilon' > 0$, we can choose the above δ sufficiently small such that

$$|\bar{\chi}(z_j^{-1}(t)) - \bar{\chi}(\bar{z}^{-1}(t))| < \varepsilon', \qquad t \in T \backslash A. \tag{3.8}$$

Therefore given $\varepsilon' > 0$ and a δ sufficiently small so that (3.7) and (3.8) are satisfied, there will exist a k such that for $j \geqq k$ and a.a. $t \in T \backslash A$

$$|x_j(t) - x^*(t)| < |\chi_j(z_j^{-1}(t)) - \bar{\chi}(z_j^{-1}(t))| + |\bar{\chi}(z_j^{-1}(t)) - \bar{\chi}(\bar{z}^{-1}(t))| < \delta + \varepsilon'.$$

In other words $x_j(t) \to x^*(t)$ a.e. on $T \backslash A$. Since A can be made arbitrarily small, we have that $x_j(t) \to x^*(t)$ a.e. on T. But $x_j(t) \to \bar{x}(t)$ a.e. so $\bar{x}(t) = x^*(t)$ a.e. and they belong to the same equivalence class.

Now we can use $\bar{\chi}$ to construct an $\bar{\bar{x}} \in A_{M\bar{\theta}}(\bar{x})$. It may have happened that over some interval $[\alpha, \beta]$ in D that $\bar{\chi}(\alpha) = \bar{\chi}(\beta)$. If this is the case, we can remove that portion of $\bar{\chi}$ and replace it with $\bar{\chi} = \bar{\chi}(\alpha)$ a constant value on $[\alpha, \beta]$ and make the corresponding objective functional no worse, and possibly better since on D the integrand is r and $r(\bar{z}, \bar{\chi}, 0) = 0$. This is equivalent to removing that portion of $[\tau_0, \tau_1]$ that corresponds to $[\alpha, \beta]$ and joining up the endpoints $\bar{\chi}(\alpha)$ and $\bar{\chi}(\beta)$. So suppose we have gone through this last procedure and we can find no subinterval of D that has equal $\bar{\chi}$ endpoints.

From $\bar{x}$ we can generate a function $\hat{\psi}$ which effectively produces a new time variable η. For every subinterval $D^i = [\tau_{i1}, \tau_{i2}]$ of D we can produce a corresponding interval $\bar{\omega}(D^i)$. Each D^i also corresponds to a time $\bar{z}(D^i)$ in T. An $\bar{\bar{x}} \in A_{M\bar{\theta}}(x)$ that will suffice is one that on the η interval $\nu_i = [\hat{\psi}(\bar{z}(D^i)^-), \hat{\psi}(\bar{z}(D^i)^+)]$ has

$$\bar{\bar{x}}(\eta) = \bar{\chi}\left(\tau_i^- + \frac{m(D^i)}{m(\nu_i)}(\eta - \hat{\psi}(\bar{z}(D^i)^-))\right)$$

where $\hat{\psi}$ is given by (2.8) for a $\bar{\theta}$ such that

$$d\bar{x}(t) = \dot{x}(t)\, dt + \bar{\xi}(t) d\bar{\theta}(t).$$

$m(\nu_i)$ will not be zero in the above because we have removed all subintervals $[\alpha, \beta]$ of D where $\bar{\chi}(\alpha) = \bar{\chi}(\beta)$. The rest of $\bar{\bar{x}}$ is given uniquely by $\bar{x}$ and hence $\bar{\chi}$. The positive homogeneity of r and the fact that the recession function of r is r will ensure that

$$\tilde{\Phi}(\bar{\bar{x}})|_{\bar{\omega}(D)} \leqq \hat{\Phi}(\bar{\chi})|_D.$$

Then (3.6) and the above imply

$$\liminf_j \tilde{\Phi}(\bar{\bar{x}}_j)|_{\bar{\omega}(D)} \geqq \tilde{\Phi}(\bar{\bar{x}})|_{\bar{\omega}(D)}.$$

As before, for any $\bar{\varepsilon} > 0$ we can find a set $A \supset \bar{z}(D)$ such that $m(A) < \bar{\varepsilon}$. By the assumption on L in the statement of the Theorem,

$$\int_A L(t, x_j(t), \dot{x}_j(t))\, dt \geqq \bar{\varepsilon}(\gamma_2 - \gamma_1 M).$$

If the following holds:

$$\int_T L(t, \bar{x}(t), \dot{\bar{x}}(t))\, dt < \infty, \tag{3.9}$$

then using (3.1) and the above, we find

$$\begin{aligned}\liminf_j \Phi(x_j)|_A &\geqq \liminf_j \tilde{\Phi}(\tilde{x}_j)|_{\bar{\omega}(D)} - \varepsilon + \bar{\varepsilon}(\gamma_2 - \gamma_1 M)\\ &\geqq \tilde{\Phi}(\bar{\tilde{x}})|_{\bar{\omega}(D)} - \varepsilon + \bar{\varepsilon}(\gamma_2 - \gamma_1 M)\\ &\geqq \Phi(\bar{x})|_A - \varepsilon + \bar{\varepsilon}(\gamma_2 - \gamma_1 M) - \int_A L(t, \bar{x}(t), \dot{\bar{x}}(t))\, dt.\end{aligned}$$

So if (3.9) holds, then for any $\varepsilon' > 0$ we can find an A containing the singular parts of $d\bar{x}$ and the dx_j, $j = 1, 2, \cdots$ such that

$$\liminf_j \Phi(x_j)|_A \geqq \Phi(\bar{x})|_A - \varepsilon'. \tag{3.10}$$

To finish the proof, we need to display similar behaviour on $T\backslash A$, and to verify (3.9).

Suppose (3.9) does not hold. Then we can replace it in the following with some arbitrarily large number. Then for some comparable number N, we can use the lower bound assumed on L in the statement of the theorem to show that

$$\liminf \Phi(x_j)|_{T\backslash A} \geqq N$$

in contradiction to $\{x_j\}_{j=1}^{\infty} \subset S_{\alpha,M}$. So we can assume that (3.9) does hold.

Let $\hat{x}$ be an arbitrary element of $\{x_j\}_{j=1}^{\infty} \cup \{\bar{x}\}$. On $T\backslash A$, $\hat{x}$ is absolutely continuous. Define

$$\hat{P}(t) = P(t, \hat{x}(t)) \quad \forall t \in T\backslash A.$$

Using [9, Thm. 5], we can write (where we have omitted the l term for convenience. Its lower semicontinuity ensures the corresponding results apply when it is included)

$$\begin{aligned}\Phi(\hat{x})|_{T\backslash A} &= \int_{T\backslash A} L(t, \hat{x}(t), \dot{\hat{x}}(t))\, dt\\ &= \sup_{p \in \mathscr{C}_{\hat{x}}} \left\{ \int_{T\backslash A} p(t)\dot{\hat{x}}(t)\, dt - \int_{T\backslash A} H(t, \hat{x}(t), p(t))\, dt \right\} \qquad (3.11)\\ &\equiv \sup_{p \in \mathscr{C}_{\hat{x}}} \phi(\hat{x}, p)|_{T\backslash A}\end{aligned}$$

where

$$\mathscr{C}_{\hat{x}} = \{p \in \mathscr{C}: p(t) \in \operatorname{int} \hat{P}(t), \forall t \in T\backslash A\}.$$

In light of (3.11) and the lower bound on $L(\cdot, \cdot, \cdot)$ for $|x| \leqq M$, we can find a $\bar{p} \in \mathscr{C}_{\bar{x}}$ such that

$$|\Phi(\bar{x})|_{T\backslash A} - \phi(\bar{x}, \bar{p})|_{T\backslash A}| < \varepsilon.$$

Suppose $x_j \to \bar{x}$ uniformly on $T\backslash A$ (this need not be the case, but we will show later that it is approximately true). By assumption (B4)

$$P_K(t, x') \subset P_K(t, x) + B_{\gamma_4|x-x'|}.$$

For K sufficiently large,

$$\bar{p}(t) \in \operatorname{int} P_K(t, \bar{x}(t)) \quad \forall t \in T\backslash A.$$

So $\exists \bar{\delta} > 0$ such that

$$\bar{p}(t) + B_{\bar{\delta}} \subset \operatorname{int} P_K(t, \bar{x}(t)) \quad \forall t \in T\backslash A.$$

Since $x_j \to \bar{x}$ uniformly on $T\backslash A$, there exists a k such that $\forall j \geqq k$

$$|x_j(t) - \bar{x}(t)| \leqq \frac{\bar{\delta}}{2\gamma_4} \quad \forall t \in T\backslash A.$$

Hence for $j \geqq k$, $\bar{p}(t) + B_{\bar{\delta}/4} \subset P(t, x_j(t))$. By Proposition 3

$$\liminf_j \phi(x_j, \bar{p})|_{T\backslash A} \geqq \phi(\bar{x}, \bar{p})|_{T\backslash A}.$$

But

$$\liminf_j \Phi(x_j)|_{T\backslash A} \geqq \liminf (\phi(x_j, \bar{p})|_{T\backslash A} \geqq \phi(\bar{x}, \bar{p})|_{T\backslash A} \geqq \Phi(\bar{x})|_{T\backslash A} - \varepsilon.$$

That is,

$$\liminf_j \Phi(x_j)|_{T\backslash A} \geqq \Phi(\bar{x})|_{T\backslash A} - \varepsilon \tag{3.12}$$

which is analogous to (3.10). However, in the above, we assumed that $x_j \to \bar{x}$ uniformly on $T\backslash A$. In general this is not implied by sequential weak* convergence, but we may do the following.

As we stated earlier, there exists a subsequence which we shall also call $\{x_j\}$ such that

$$x_j(t) \to \bar{x}(t) \quad \text{a.e.}$$

By Egorov's theorem, for given $\hat{\varepsilon} > 0$, there exists a relatively open set $V \subset T\backslash A$ such that $m(V) < \hat{\varepsilon}$ and

$$x_j \to \bar{x} \quad \text{uniformly on } (T\backslash A)\backslash V.$$

By choosing $\hat{\varepsilon}$ sufficiently small we have for $\varepsilon' > 0$

$$\Phi(\bar{x})|_V < \varepsilon' \quad \text{and} \quad \Phi(x_j)|_V \geqq \hat{\varepsilon}(\gamma_2 - \gamma_1 M).$$

These become negligible for small enough $\hat{\varepsilon}$, and we are left with $x_j \to \bar{x}$ uniformly on $(T\backslash A)\backslash V$, where we apply the previous reasoning. Thus (3.12) holds.

Combining (3.12) and (3.10) and realizing that ε is arbitrary, we obtain

$$\liminf_j \Phi(x_j) \geqq \Phi(\bar{x})$$

and the proof of Theorem 1 is complete. Q.E.D.

Remark. If we let $x_j = \bar{x}$ for all j and we choose a minimizing sequence of $\tilde{\Phi}$, (see (3.1)), we find that the above proof implies that the infimum in (2.11), and hence the infima in the definition of Φ_M, are attained.

Let a function $g: T \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be such that $g(t, x, \cdot)$ is nonnegative, convex, positively homogeneous and lower semicontinuous for all (t, x). Then we can define the set

$$G(t, x) = \{\zeta: \zeta \cdot \xi \leqq g(t, x, \xi) \text{ for all } \xi \in \mathbb{R}^n\}$$

and following the guidance of r_k and P_K, we can also define g_K and G_K.

Let us define the functional Φ_g on $\mathcal{B}$ by

$$\Phi_g(x) = l(x(t_0), x(t_1)) + \int_T L(t, x(t), \dot{x}(t))\, dt$$

$$+ \int_T g(t, x(t), \xi_s(t))\, d\theta_s(t) + \sum_{t \in T} q_g(t, x(t^-), x(t^+))$$

where

$$q_g(t, a, b) = \inf\left\{\int_0^1 g(t, y(s), \dot{y}(s))\, ds\colon y(0) = a,\ y(1) = b \text{ and } y \in \mathcal{A}[0, 1]\right\}.$$

We can also define Φ_{gM} analogously to Φ_M.

COROLLARY 1. *Let g have the properties stated above and let the assumptions of Theorem* 1 *be met but with g_K in place of r_K in assumption* (B4). *If $g \leqq r$ then*

$$Z_{\alpha,M} = \{x \in \mathcal{B}\colon \Phi_{g,M} \leqq \alpha\}$$

is compact in the weak topology on $\mathcal{B}$.*

Proof. This follows by making the appropriate substitutions in the proof of Theorem 1. Q.E.D.

What happens if we define a functional Φ_g as above but where $g(t, x, \xi) > r(t, x, \xi)$ for some (t, x, ξ)? If this were the case, we could not be certain that an optimal solution exists, for it may happen that if $\{x_j\} \subset \mathcal{A}$ and $x_j \to^{w^*} \bar{x}$ with $\bar{x} \in \mathcal{B}\backslash\mathcal{A}$, then

$$\lim_j \Phi_g(x_j) = \Phi(\bar{x}) < \Phi_g(\bar{x}).$$

So Theorem 1 and Corollary 1 show that the functional Φ with its terms containing the recession function for L gives an upper-limit on the well defined extensions of the original functional over $\mathcal{A}$.

Outline of proof of Theorem 1*A.* The major simplifying factor in the proof of Theorem 1A is that the "straight line" is the cheapest way to go between two points although this fact is more of an outcome of the theorem rather than the basis for its proof. Not only does this simplify the form of the functional, but in the proof, one does not have to divide the interval into two components A and $T\backslash A$, one only has to follow the argument on the $T\backslash A$ section. Then, the fact that the adjoint state constraint multifunction P is independent of x simplifies the process even further in as much as Propositions 1 and 2 become easier and the set $\mathcal{E}_{\hat{x}}$ is the same for all $\hat{x}$. The details of this argument can be found in [5].

4. An existence theorem for calculus of variations. To obtain an existence theorem, we need to place conditions on the problem so that

$$\{x \in \mathcal{B}\colon I(x) \leqq \alpha\} \quad \text{and} \quad \{x \in \mathcal{B}\colon \Phi(x) \leqq \alpha\}$$

will be compact in the weak* topology.

Assumptions (G).

Assumption (G1). There exists a function $\bar{p}$ which is continuously differentiable on T constants γ_1 and γ_2 with γ_1 nonnegative, and a $\delta > 0$ with $\delta \geqq \|\bar{p}\|_\infty$ such that for all (t, x)

$$H(t, x, p) \leqq \gamma_1|x| - \dot{\bar{p}}(t)x - \gamma_2 \quad \text{when } |p - \bar{p}(t)| \leqq \delta.$$

Notice that assumptions (B1), (B2) and the assumption in the statement of Theorem 1 are implied by (G1).

Assumption (G2). For the function $\bar{p}$ above, the following holds for all a, b in $\mathbb{R}^n$

$$l(a, b) \geqq k(|a|) - \bar{p}(t_1)b - \rho|b|$$

where $\rho \geqq 0$ and $k\colon [0, \infty) \to \mathbb{R} \cup \{+\infty\}$ is a nondecreasing function such that

$$\lim_{s \to +\infty} \frac{k(s)}{s} = +\infty.$$

Assumption (G3). The parameters δ, ρ and γ_1 in assumptions (G1) and (G2) can be chosen such that $\delta - \rho - \gamma_1$ is greater than zero.

THEOREM 2. *Let assumptions* (G) *hold. Then for each* $\alpha \in \mathbb{R}$, *there exists an* $M > 0$ *such that*

$$\{\tilde{x} \in \mathscr{A}_\theta(x): x \in \mathscr{B} \text{ and } \Phi_\theta(\tilde{x}, x) \leqq \alpha\} \subset \{\tilde{x} \in \mathscr{A}_\theta(x): x \in \mathscr{B} \text{ and } \|\tilde{x}\|_V \leqq M\}.$$

Using this result we can replace Φ_M with Φ in (2.7) and thereby obtain an existence theorem for the extended calculus of variations problem.

Proof. Because $L(t, x, \cdot)$ is convex and lowersemicontinuous, the inequality in (G1) is equivalent to

$$\begin{aligned} L(t, x, v) &= \sup\{pv - H(t, x, p)\} \\ &= \sup\{(p + \bar{p}(t))v - H(t, x, p + \bar{p}(t))\} \\ &\geqq \bar{p}(t)v + \delta|v| - \gamma_1|x| + \bar{p}(t)x + \gamma_2. \end{aligned}$$

Fix $\alpha \in \mathbb{R}$ and choose an $x \in \mathscr{B}$ and an $\tilde{x} \in \mathscr{A}_\theta(x)$ such that $\Phi_\theta(\tilde{x}, x) \leqq \alpha$ where Φ_θ is defined in (2.10)

$$\begin{aligned} \alpha &\geqq l(\tilde{x}(\eta_0), \tilde{x}(\eta_1)) + \int_{\eta_0}^{\eta} L\left(\zeta(\eta), \tilde{x}(\eta), \frac{d\tilde{x}}{d\eta}(\eta)\right)(1 - h(\eta))\, d\eta \\ &\quad + \int_{\eta_0}^{\eta_1} r\left(\zeta(\eta), \tilde{x}(\eta), \frac{d\tilde{x}}{d\eta}(\eta)\right)h(\eta)\, d\eta \\ &\geqq l(\tilde{x}(\eta_0), \tilde{x}(\eta_1)) + \int_{\eta_0}^{\eta_1} \bar{p}(\zeta(\eta))\frac{d\tilde{x}}{d\eta}(\eta)\, d\eta + \delta\int_{\eta_0}^{\eta_1}\left|\frac{d\tilde{x}}{d\eta}(\eta)\right| d\eta \\ &\quad - \gamma_1\int_{\eta_0}^{\eta_1}|\tilde{x}(\eta)|\, d\eta + \int_{\eta_0}^{\eta_1}\frac{d\bar{p}}{d\eta}(\zeta(\eta))\tilde{x}(\eta)\, d\eta + \gamma_2 T \\ &\geqq k(|\tilde{x}(\eta_0)|) - \bar{p}(\zeta(\eta_1))\tilde{x}(\eta_1) - \rho|\tilde{x}(\eta_1)| + \int_{\eta_0}^{\eta_1}\bar{p}(\zeta(\eta))\frac{d\tilde{x}}{d\eta}(\eta)\, d\eta \\ &\quad + \delta\int_{\eta_0}^{\eta_1}\left|\frac{d\tilde{x}}{d\eta}(\eta)\right| d\eta - \gamma_1\int_{\eta_0}^{\eta_1}|\tilde{x}(\eta)|\, d\eta + \int_{\eta_0}^{\eta_1}\frac{d\bar{p}}{d\eta}(\zeta(\eta))\tilde{x}(\eta)\, d\eta + \gamma_2 T \\ &= k(|\tilde{x}(\eta_0)|) - \rho|\tilde{x}(\eta_1)| - \bar{p}(\zeta(\eta_0))\tilde{x}(\eta_0) \\ &\quad + \delta\int_{\eta_0}^{\eta_1}\left|\frac{d\tilde{x}(\eta)}{d\eta}\right| d\eta - \gamma_1\int_{\eta_0}^{\eta_1}|\tilde{x}(\eta)|\, d\eta + \gamma_2 T \\ &\geqq k(|\tilde{x}(\eta_0)|) - |\tilde{x}(\eta_0)|(\rho + |\bar{p}(\zeta(\eta_0))| + \gamma_1) \\ &\quad - (\rho + \gamma_1 - \delta)\int_{\eta_0}^{\eta_1}\left|\frac{d\tilde{x}(\eta)}{d\eta}\right| d\eta + \gamma_2 T. \end{aligned}$$

By the definition of k there exists a $\lambda \in \mathbb{R}$ such that for $s \geqq 0$

$$k(s) - (|\bar{p}(\eta_0)| + \delta)s \geqq \lambda.$$

Hence

$$\alpha - \lambda - \gamma_2 T \geqq (\delta - \rho - \gamma_1)\left(|\tilde{x}(\eta_0)| + \int_{\eta_0}^{\eta_1}\left|\frac{d\tilde{x}}{d\eta}(\eta)\right| d\eta\right).$$

By (G3), $\delta - \rho - \gamma_1$ is positive and we can choose our M in the theorem to be

$$\frac{\alpha - \lambda - \gamma_2 T}{\delta - \rho - \gamma_1}.$$ Q.E.D.

Combining Theorems 1 and 2, we obtain the following existence theorem.

THEOREM 3. *Let assumptions* (B) *and* (G) *hold. Then for each* $\alpha \in \mathbb{R}$, *the level sets*

$$S_\alpha = \{x \in \mathscr{B}: \Phi(x) \leqq \alpha\}$$

are compact in the weak topology. In particular, an optimal solution exists for problem* (2.5) *if there is a feasible solution.*

Remark. Theorem 2 and the remark following the proof of Theorem 1 imply that under the above conditions the infima in the definition of Φ are attained so that we can replace inf with min. Applying similar reasoning to Theorem 1A, we obtain

THEOREM 3A. *Let assumptions* (A) *and* (G) *hold. Then for each* $\alpha \in \mathbb{R}$, *the level sets*

$$\tilde{S}_\alpha = \{x \in \mathscr{B}: I(x) \leqq \alpha\}$$

are compact in the weak topology. In particular, an optimal solution exists for problem* (2.2) *if there is a feasible solution.*

Remark. As far as Theorem 3A is concerned, one can make do with a weaker version of assumption (G). For example we only need $\bar{p} \in \mathscr{A}$ and it is not necessary that $\|\bar{p}\|_\infty \leqq \delta$.

Although the optimal solution will, in general, not be absolutely continuous, there are cases when it is. The most obvious of these is when the recession function is trivial.

COROLLARY 2. *Let assumptions* (A) *and* (G) *hold, and*

$$\bar{r}(t, \xi) = \begin{cases} 0 & \text{if } \xi = 0, \\ +\infty & \text{otherwise.} \end{cases}$$

If problem (2.2) is feasible, then an optimal solution will exist and will belong to $\mathscr{A}$.

Note. The condition in the above corollary is equivalent to

$$H(t, x, p) < \infty \ \forall p, \quad \text{or} \quad P(t, x) \equiv \mathbb{R}^n.$$

An example of a class of problems that has an optimal solution belonging to $\mathscr{A}$ although other optimal solutions will exist that belong to $\mathscr{B} \setminus \mathscr{A}$, is contained in the following corollary to Theorem 3.

COROLLARY 3. *Let assumptions* (B) *and* (G) *hold. Also assume that L is parametric, in other words, that L is independent of t and* $L(x, \lambda \dot{x}) = \lambda L(x, \dot{x})$ *for* $\lambda \geqq 0$. *If problem* (2.4) *is feasible, then an optimal solution that belongs to* $\mathscr{A}$ *will exist.*

Proof. If $(x, \dot{x}) \in \operatorname{dom} L$ then $(x, 0) \in \operatorname{dom} L^\infty$ and

$$r(x, \xi) = \lim_{\lambda \to \infty} \frac{L(x, \lambda \xi)}{\lambda} = L(x, \xi).$$

Because of this, assumption (B3) will automatically be satisfied and

$$\Phi(x) = \min_{\tilde{x} \in \mathscr{A}_\theta(x)} \left\{ l(\tilde{x}(\eta_0), \tilde{x}(\eta_1)) + \int_{\eta_0}^{\eta_1} \left[L\left(\tilde{x}(\eta), \frac{d\tilde{x}}{d\eta}(\eta)\right)(1 - h(\eta)) + r\left(\tilde{x}(\eta), \frac{d\tilde{x}}{d\eta}(\eta)\right) h(\eta) \right] d\eta \right\}$$

$$= \min_{\tilde{x} \in \mathscr{A}_\theta(x)} \left\{ l(\tilde{x}(\eta_0), \tilde{x}(\eta_1)) + \int_{\eta_0}^{\eta_1} L\left(\tilde{x}(\eta), \frac{d\tilde{x}}{d\eta}(\eta)\right) d\eta \right\}.$$

Since an optimal solution $\bar{x}$ of (2.5) exists if the problem is feasible, we can find an $\tilde{\bar{x}} \in \mathscr{A}_{\tilde{\theta}}(\bar{x})$ that achieves the minimum in the above. Reparametrizing $\tilde{\bar{x}}$, we can find an $\hat{x} \in \mathscr{A}$ such that

$$\Phi(\bar{x}) = l(\hat{x}(t_0), \hat{x}(t_1)) + \int_T L(\hat{x}(t), \dot{\hat{x}}(t))\, dt$$

and so $\hat{x}$ is optimal. Q.E.D.

Example 3. Consider the model of a fishery with irreversible investment (see [3]). Its description is as follows

$$\text{minimize } \mathscr{J} = \int_0^\infty e^{-\delta t}[\pi I(t) + cE(t) - pqE(t)x(t)]\, dt$$

subject to

$$\dot{x}(t) = F(x(t)) - qE(t)x(t), \qquad x(0) = x_0,$$
$$\dot{K}(t) = I(t) - \gamma K(t), \qquad K(0) = K_0,$$

and

$$0 \leqq E(t) \leqq K(t), \qquad 0 \leqq I(t), \qquad 0 \leqq x(t)$$

where

$x(t)$ = fish population biomass at time t

$K(t)$ = capital at time t

$E(t)$ = fishing effort at time t

$I(t)$ = investment rate at time t

$F(\cdot)$ = natural growth function of the biomass

π = price of capital

c = operating cost per unit effort

p = price of landed fish

q = catchability coefficient

δ = instantaneous rate of discount

γ = rate of depreciation.

The above problem is not a simple one to solve for several reasons. It is over an infinite interval, it has mixed control and state constraints ($0 \leqq E \leqq K$) and it allows unbounded investment rate without the objective function penalizing it via a growth condition, as would be necessary to apply the usual existence theorems. In fact, the optimal solution, as calculated in [3] can have jumps in K, brought about by an infinite investment rate. So attempting to minimize J over $\mathscr{A}$ will be a fruitless search. If we were to replace the infinite time interval with a finite one, we could analyse the problem via one of our extended problems. In that case, what would be the extended functional? The next section deals with transforming control problems to calculus of variations problems but in this case we can do it more directly.

Replace I with $\dot{K}+\gamma K$ and E with $(F(x)-\dot{x})/qx$. Then the corresponding calculus of variations problem is

$$\text{minimize } J=\int_0^\infty e^{-\delta t}\left[\pi(K(t)+\gamma K(t))+\left(\frac{c}{qx(t)}-p\right)(F(x(t))-\dot{x}(t))\right]dt$$

subject to $x(0)=x_0$, $K(0)=K_0$

$$0\leqq\frac{F(x)-\dot{x}}{qx}\leqq K, \qquad 0\leqq x, \quad 0\leqq\dot{K}.$$

Let $y=(x, K)^T$, $v=(\dot{x}, \dot{K})^T$; then the Lagrangian is convex in v for each (t, y) and the recession function is independent of y and has the form

$$\bar{r}(t, \xi)=\begin{cases} e^{-\delta t}\pi\xi_2 & \text{if } \xi=(\xi_1, \xi_2)^T \text{ with } \xi_1=0,\ \xi_2\geqq 0,\\ +\infty & \text{otherwise.}\end{cases}$$

Extending the problem to $\mathcal{B}$ then leads to

$$\text{minimize } \hat{J}=\int_0^\infty e^{-\delta t}\left[\pi(\dot{K}(t)+\gamma K(t))+\left(\frac{c}{qx(t)}-p\right)(F(x(t))-\dot{x}(t))\right]dt + \int_0^\infty e^{-\delta t}\pi\xi_2(t)\,d\theta(t)$$

where

$$dK(t)=\dot{K}(t)\,dt+\xi_2(t)\,d\theta(t), \qquad x(0)=x_0, \quad \theta\in\mathcal{M},$$
$$K(0)=K_0,$$
$$0\leqq\frac{F(x)-\dot{x}}{qx}\leqq K, \qquad 0\leqq x, \quad 0\leqq\dot{K}, \quad 0\leqq\xi_2.$$

This is essentially the extension of J to arcs in $\mathcal{B}$ that is used in [3].

5. An existence theorem for optimal control. Many optimal control problems can be stated in the following compact form

$$\text{minimize } \tilde{\Psi}(x, u)=l(x(t_0), x(t_1))+\int_T K(t, x(t), \dot{x}(t), u(t))\,dt \tag{5.1}$$

over all $x\in\mathcal{A}$ and $u\in L^1_m$, where

$$K: T\times\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}^m\to\mathbb{R}\cup\{+\infty\}.$$

We will assume that K is a Lebesgue normal integrand and $K(t, x, \cdot, \cdot)$ is convex for each (t, x); l will have the same properties as it did for the calculus of variations problem.

To see how the problem (5.1) and the corresponding assumptions relate to an optimal control problem in the usual form, we refer the reader to [10].

We can convert (5.1) to a calculus of variations problem, by defining

$$L(t, x, v)=\inf_u K(t, x, v, u). \tag{5.2}$$

The convexity of $K(t, x, \cdot, \cdot)$ ensures the convexity of $L(t, x, \cdot)$. If K satisfies assumption (U1) below, we will then have a problem with the same form as (2.1).

We wish to extend the functional in (5.1) so that it can evaluate any $x \in \mathcal{B}$. Let $\hat{r}$ be the recession function of K, that is

$$\hat{r}(t, x, \xi, \mu) = \lim_{\lambda \to \infty} \left\{ \frac{K(t, x, v+\lambda\xi, u+\lambda\mu) - K(t, x, v, u)}{\lambda} \right\}$$

where $(x, v, u) \in \operatorname{dom} K(t, \cdot, \cdot, \cdot)$.

Our extension of (5.1) is then

$$\begin{aligned} \text{minimize } \Psi(x, \nu) = l(x(t_0), x(t_1)) &+ \int_T K(t, x(t), \dot{x}(t), u(t))\, dt \\ &+ \int_T \hat{r}(t, x(t), \xi_s(t), \mu_s(t))\, d\theta_s(t) \\ &+ \sum_{t \in T} \hat{q}(t, x(t^-), x(t^+)) \end{aligned} \tag{5.3}$$

where

$$\hat{q}(t, a, b) = \inf \left\{ \int_0^1 \hat{r}(t, y(s), \dot{y}(s), z(s))\, ds : y(0) = a,\ y(1) = b,\ y \in \mathcal{A}[0, 1] \text{ and } z \in L^1_m[0, 1] \right\}$$

and $x \in \mathcal{B}$, $\nu \in \mathcal{B}_m$ and

$$\begin{aligned} dx(t) &= \dot{x}(t)\, dt + \xi_s(t)\, d\theta_s(t) + \xi_a(t)\, d\theta_a(t), \\ d\nu(t) &= u(t)\, dt + \mu_s(t)\, d\theta_s(t) + \mu_a(t)\, d\theta_a(t) \end{aligned}$$

where, as before, the subscripts s and a denote, respectively, the smooth (nonatomic) and atomic parts of the singular measure. Let us also define

$$r(t, x, \xi) = \inf_{\mu} \hat{r}(t, x, \xi, \mu). \tag{5.4}$$

Assumption (U1) (inf-boundedness). For each fixed $t \in T$, $\alpha \in \mathbb{R}$ and bounded set $D \subset \mathbb{R}^n \times \mathbb{R}^n$, the set $\{u \in \mathbb{R}^m : (x, v) \in D \text{ with } K(t, x, v, u) \leqq \alpha\}$ is bounded.

Under this assumption $L(t, \cdot, \cdot)$ is lower semicontinuous and the r in (5.4) is the recession function for L (see [5]). In the following theorem, the assumptions on L and r apply to those functions as obtained above.

THEOREM 4. *Let assumptions* (B), (G) *and* (U1) *hold. Then if problem* (5.3) *has a feasible solution, it has an optimal solution.*

Proof. This result is shown by first proving that the problems (5.3) and (2.5) are in some sense equivalent, by a modified version of the Equivalence Theorem of [11]. Then we may use Theorem 3. Q.E.D.

Thus we can obtain existence results for the extended optimal control problem of (5.3), as well as the simpler versions that correspond to the calculus of variation problems in Corollaries 2 and 3, and those modified problems satisfying the conditions of Corollary 1.

As is true for the calculus of variations problem, the analogue of the functional I for optimal control has a much simpler form than (5.3).

Before we introduce this extension, we need to make the following definitions and assumptions. Define the multifunction $X : T \rightrightarrows \mathbb{R}^n$ by

$$X(t) = \{x : \exists (v, u) \text{ with } K(t, x, v, u) < \infty\}.$$

Using (5.2), we can re-express this as

$$X(t) = \{x: \exists v \text{ with } L(t, x, v) < \infty\}$$

which is the same as our earlier X. Define

$$\tilde{H}(t, x, p, w) = \sup_{v,u} \{p \cdot v + w \cdot u - K(t, x, v, u)\}.$$

Let

$$\tilde{F}(t, x) = \operatorname{dom} \tilde{H}(t, x, \cdot, \cdot) = \{(p, w): \tilde{H}(t, x, p, w) < \infty\}.$$

The following will imply assumption (A1), so that the recession function for the control problem will be independent of x.

Assumption (U2). There exists a multifunction $F: T \rightrightarrows \mathbb{R}^n$ such that for all $x \in X(t)$

$$\operatorname{cl} \tilde{F}(t, x) = F(t) \quad \text{for all } t \in T.$$

We can define the recession function $\hat{r}$ by

$$\hat{r}(t, \xi, \mu) = \sup \{p \cdot \xi + w \cdot \mu: (p, w) \in F(t)\}.$$

Assumption (U2). The extension of the functional in (2.2) to optimal control problems is then given by,

$$\begin{aligned} \text{minimize } \bar{\Psi}(x, v) = l(x(t_0), x(t_1)) &+ \int_T K(t, x(t), \dot{x}(t), u(t))\, dt \\ &+ \int_T \hat{r}(t, \xi(t), \mu(t))\, d\theta(t) \end{aligned} \tag{5.5}$$

where $x \in \mathcal{B}$, $v \in \mathcal{B}_m$ and

$$dx(t) = \dot{x}(t)\, dt + \xi(t)\, d\theta(t),$$
$$dv(t) = u(t)\, dt + \mu(t)\, d\theta(t)$$

and $\theta \in \mathcal{M}$.

Finally, we have the analogue of Theorem 4 for the simpler case.

THEOREM 4A. *Let assumptions* (A), (G), (U1) *and* (U2) *hold. Then if problem* (5.5) *has a feasible solution, it has an optimal solution.*

6. Discussion. One of the purposes in developing these existence theorems was to give foundation to the functionals Φ, I and Ψ and $\bar{\Psi}$ being valid extensions of the functionals J and $\tilde{\Psi}$ which only cover cases where $x \in \mathcal{A}$. We are not implying that they are the only extensions to problems where the states can jump and the controls can exhibit impulsive behaviour, but from Corollary 1 and the resulting discussion we can say with some justification that they form "upper bounds" for such extensions. If we look at it from an economic viewpoint, this should not be surprising. Thinking of the L and g terms of Corollary 1 as two producers, the difference being that the second producer g, can supply any amount of product instantaneously whereas the first needs some amount of time to do so, if g charges more than the limit that L charges when the period over which it supplies the product goes to zero, we would buy the product from L. But this limit of L is none other than the recession function r. So g must charge less than this limit to sell its goods, that is, for there to be any instantaneous change in the product x, we must have g less than or equal to r.

In many problems that one encounters in the economic literature where the states are allowed to have jumps, the term involving the nonatomic singular part of dx is

absent. However it is not difficult to construct a sequence of functions that are absolutely continuous and where the limit of the sequence is a continuous function of bounded variation with a nontrivial singular term. Therefore, such problems may not be well defined.

Acknowledgment. The author is deeply grateful to Professor R. T. Rockafellar for his guidance and assistance.

OPTIMAL CONTROL FOR VARIATIONAL INEQUALITIES*

AVNER FRIEDMAN†

Abstract. Consider the problem of maximizing a functional which depends on a control function k and on the solution of an elliptic variational inequality with k appearing in the data. The variational problem for k is nondifferentiable and nonconvex. We obtain necessary conditions on a maximizer k_0 and then use them to determine the structure of k_0 in some cases.

Key words. optimal control, variational inequality

AMS(MOS) subject classification. 93C20

Introduction. Consider an elliptic variational inequality with control k appearing either as an inhomogeneous term on the right-hand side or in the boundary data. Denote the corresponding solution by u and consider the functional

$$J(k)=\int F(x, u)\,dx+\int \Phi(k). \tag{0.1}$$

We are interested in studying the solutions k_0 of the optimization problem

$$J(k_0)=\max_{k\in\mathcal{A}} J(k), \qquad k_0\in\mathcal{A}, \tag{0.2}$$

where $\mathcal{A}$ is the class of controls.

This problem differs significantly for similar problems for solutions of linear or quasilinear elliptic (or parabolic) equations (as dealt with by Lions [10], [11] and the references given there) in that the functional $J(k)$ is generally nondifferentiable in the case of a variational inequality. Although some necessary conditions for k_0 have been derived by Barbu [1] and Mignot and Puel [12] (see also the references in [1], [12]), these conditions seem too implicit for extracting from them significant properties of the maximizer. In some specific elliptic and parabolic variational inequalities [4], [5], [7] the structures of the optimal controls have been determined; however the corresponding functionals $J(k)$ in these instances are actually differentiable.

In this paper we consider a large class of optimal control problems for elliptic variational inequalities with nondifferentiable $J(k)$; the main assumption regarding F is that $F_u\geqq 0$. In § 1 we shall derive an effective necessary condition for the maximizer, and in § 2 we use it to determine the structure of k_0 for a certain class $\mathcal{A}$. In § 3 we give several extensions.

1. A necessary condition. Let Ω be a bounded domain in $\mathbb{R}^n$ with C^2 boundary $\partial\Omega$ and let p be a positive number satisfying

$$p>\frac{n}{2}, \qquad p\geqq 2. \tag{1.1}$$

Let U^0 be a given function satisfying

$$U^0\in W^{2,p}(\Omega), \qquad U^0>0 \quad \text{in } \bar{\Omega}, \tag{1.2}$$

† Department of Mathematics, Northwestern University, Evanston, Illinois 60201.

and let f be a given function satisfying

$$f \in L^p(\Omega). \tag{1.3}$$

We introduce a class $\mathscr{A}$ of control functions $k(x)$ with the properties

(1.4) $\mathscr{A}$ is a closed, bounded and convex subset of $L^p(\Omega)$.

For any $k \in \mathscr{A}$ consider the variational inequality

$$\int_\Omega \nabla u \cdot \nabla(\psi - u) \geqq -\int_\Omega (f+k)(\psi - u) \quad \forall \psi \in K,\ u \in K, \tag{1.5}$$

where

$$K = \{\psi \in H^1(\Omega),\ \psi \geqq 0 \text{ a.e.},\ \psi - U^0 \in H_0^1(\Omega)\}, \tag{1.6}$$

and the functional

$$J(k) = \int_\Omega F(x, u)\, dx + \int_\Omega \Phi(k)\, dx, \tag{1.7}$$

we assume that

(1.8) $\int_\Omega \Phi(k)$ is upper semicontinuous under weak convergence in $L^p(\Omega)$, i.e., if $k_m \to k$ weakly in $L^p(\Omega)$ where $k_m, k \in \mathscr{A}$ then

$$\int_\Omega \Phi(k) \geqq \limsup_{m\to\infty} \int_\Omega \Phi(k_m),$$

and that

(1.9) $F(x, u)$ is continuous in $\bar{\Omega} \times \mathbb{R}^1$.

Consider the problem

$$J(k_0) = \max_{k \in \mathscr{A}} J(k), \qquad k_0 \in \mathscr{A}. \tag{1.10}$$

By general theory for variational inequalities [3], [8] the solutions u of (1.5) belong to a bounded set of $W^{2,p}(\Omega)$ and, therefore, by (1.1) and Sobolev's imbedding,

$$|u|_{C^\alpha(\bar{\Omega})} \leqq C, \quad \text{where } \alpha = 2 - \frac{n}{p}, \qquad C < \infty. \tag{1.11}$$

Taking a maximizing sequence k_m and their corresponding solutions $u = u_m$ and using (1.8), (1.9) and (1.11), we find that, for a subsequence,

$$k_m \to k_0 \quad \text{weakly in } L^p(\Omega), \qquad k_0 \in \mathscr{A},$$
$$u_m \to u_0 \quad \text{in } C^\beta(\bar{\Omega}) \quad \text{for any } 0 < \beta < \alpha,$$

and k_0 is the solution of (1.10); u_0 is the solution of (1.5) corresponding to k_0.

In order to derive necessary conditions on k_0 we further assume that

$$\begin{aligned} &F_u(x, u) \text{ is continuous in } \bar{\Omega} \times \mathbb{R}^1, \\ &F_u(x, u) \geqq 0, \end{aligned} \tag{1.12}$$

and that $\Phi(k)$ has a derivative $\Phi'(k)$, that is,

(1.13) for any $k \in \mathscr{A}$ there is a function in $L^q(\Omega)$ $(1/q+1/p=1)$ denoted by $\Phi'(k)$ such that for any $l \in L^p(\Omega)$ with $k+\varepsilon l \in \mathscr{A}$ if $0<\varepsilon<1$ there holds

$$\frac{1}{\varepsilon}\int_\Omega [\Phi(k+\varepsilon l)-\Phi(k)]\,dx \to \int_\Omega \Phi'(k) l\,dx$$

if $\varepsilon \to 0$.

Let k_0 be a solution of (1.10) and denote by u_0 the corresponding solution of (1.5). Introduce the noncoincidence set

$$\Omega_0 = \{x \in \Omega,\ u_0(x) > 0\},$$

(which is an open set since u_0 is continuous in $\bar{\Omega}$) and let Q be the solution of the Dirichlet problem

$$\int_\Omega \nabla Q \cdot \nabla \psi = \int_\Omega F_u(x, u_0)\psi\,dx \quad \forall \psi \in H_0^1(\Omega_0), \quad Q \in H_0^1(\Omega_0). \tag{1.14}$$

By elliptic regularity $Q \in W^{2,p}(G)$ for any open set G with $\bar{G} \subset \Omega_0 \cup \partial\Omega$. Since the free boundary

$$\Gamma = \partial\Omega_0 \cap \Omega$$

is not regular, in general, one cannot assert that Q is continuous up to the free boundary Γ with $Q=0$ on Γ.

Taking $\psi = Q^-$ in (1.14) and using (1.12) we easily find that

$$\int_{\Omega_0} |\nabla Q^-|^2 = 0,$$

which implies (since $Q^- \in H_0^1(\Omega_0)$) that $Q^- = 0$, i.e., $Q \geqq 0$. By the strong maximum principle we further infer that

$$Q > 0 \quad \text{in } \Omega_0. \tag{1.15}$$

By comparison with the solution Q^1 of $\Delta Q^1 = -A$ in Ω, $Q^1 = 0$ on $\partial\Omega$ where $A > F_u(x, u_0)$, we find that $Q < Q^1$ in Ω_0, so that

$$Q \leqq C < \infty \quad \text{in } \Omega_0. \tag{1.16}$$

We can now state the main result of this section.

THEOREM 1.1. *Let k_0 be a solution of* (1.10) *and suppose that $k_0+\varepsilon l \in \mathscr{A}$ for all $0<\varepsilon<\varepsilon_0$, for some $\varepsilon_0>0$, and* supp $l \subset \Omega_0$. *Then*

$$\int_{\Omega_0} (Q-\Phi'(k_0))l\,dx \geqq 0. \tag{1.17}$$

Proof. Let U^1 be a nonnegative function in $W^{2,p}(\Omega)$ such that $U^1 = U^0$ in a neighborhood of $\partial\Omega$ and $U^1 = 0$ in a neighborhood of $\Omega \setminus \Omega_0$.

Denote by U_ε the solution of the Dirichlet problem

$$\begin{aligned} &\int_{\Omega_0} \nabla U_\varepsilon \cdot \nabla(\phi - U_\varepsilon) = -\int_{\Omega_0} (f+k_0+\varepsilon l)(\phi - U_\varepsilon) \quad \text{for any } \phi, \\ &\qquad \phi - U^1 \in H_0^1(\Omega_0), \quad U_\varepsilon - U^1 \in H_0^1(\Omega_0). \end{aligned} \tag{1.18}$$

Denote by u_ε the solution of the variational inequality (1.5) corresponding to $k_0+\varepsilon l$, i.e.,

$$\int_\Omega \nabla u_\varepsilon \cdot \nabla(\psi - u_\varepsilon) \geqq -\int_\Omega (f+k_0+\varepsilon l)(\psi - u_\varepsilon) \quad \text{for any } \psi \in K, \qquad u_\varepsilon \in K. \tag{1.19}$$

Taking $\psi = u_\varepsilon + (U_\varepsilon - u_\varepsilon)^+$ in (1.19) (where $U_\varepsilon = 0$ outside Ω_0) and $\phi = U_\varepsilon - (U_\varepsilon - u_\varepsilon)^+$ in (1.18) and adding, we obtain

$$-\int_{\Omega_0} \nabla(U_\varepsilon - u_\varepsilon)\cdot\nabla(U_\varepsilon - u_\varepsilon)^+ \geqq 0,$$

so that $\nabla(U_\varepsilon - u_\varepsilon)^+ = 0$; consequently

$$U_\varepsilon \leqq u_\varepsilon \quad \text{in } \Omega_0. \tag{1.20}$$

LEMMA 1.2. *There holds*

$$u_0 - U^1 \in H_0^1(\Omega_0), \tag{1.21}$$

and, for a subsequence $\varepsilon \to 0$,

$$\frac{U_\varepsilon - u_0}{\varepsilon} \to z \quad \textit{weakly in } H_0^1(\Omega_0), \tag{1.22}$$

where $z \in H_0^1(\Omega_0)$, *and* $\Delta z = l$ *in* Ω_0.

Proof. For any small $\delta > 0$, the function $(u_0 - \delta)^+ - (U^1 - \delta)^+$ has compact support in Ω_0 and hence belongs to $H_0^1(\Omega_0)$. Taking $\delta \to 0$ it follows that $u_0 - U^1$ is also in $H_0^1(\Omega_0)$.

To prove (1.22) notice that since $\Delta u_0 = f + k_0$ in Ω_0,

$$\int_{\Omega_0} \nabla u_0 \cdot \nabla \phi = -\int_{\Omega_0} (f+k_0)\phi,$$

for any $\phi \in C_0^1(\Omega_0)$ and, by approximation, also for any $\phi \in H_0^1(\Omega_0)$. Recalling (1.21) we then have

$$\int_{\Omega_0} \nabla u_0 \cdot \nabla(\psi - u_0) = -\int_{\Omega_0} (f+k_0)(\psi - u_0) \quad \text{if } \psi - U^1 \in H_0^1(\Omega_0).$$

Taking $\psi = U_\varepsilon$ and taking $\phi = u_0$ in (1.18) we obtain, by adding,

$$\int \Omega_0 |\nabla(u_0 - U_\varepsilon)|^2 \leqq \varepsilon \int_{\Omega_0} |l(u_0 - U_\varepsilon)| \leqq C\varepsilon \left\{ \int_{\Omega_0} |u_0 - U_\varepsilon|^2 \right\}^{1/2},$$

since $l \in L^p(\Omega)$, $p \geqq 2$. It follows that

$$\left\| \frac{u_0 - U_\varepsilon}{\varepsilon} \right\|_{H_0^1(\Omega_0)} \leqq C, \tag{1.23}$$

and the assertion (1.22) follows. Clearly $z \in H_0^1(\Omega_0)$. Also, since $\Delta(U_\varepsilon - u_0) = \varepsilon l$ in Ω_0, $\Delta z = l$ in Ω_0.

Having proved Lemma 1.2, we now proceed to establish the assertion (1.17). We begin with the inequality

$$J(k_0 + \varepsilon l) \leqq J(k_0),$$

or

$$\frac{1}{\varepsilon}\int_\Omega [F(x, u_\varepsilon) - F(x, u_0)] + \frac{1}{\varepsilon}\int_\Omega [\Phi(k_0 + \varepsilon l) - \Phi(k_0)] \leqq 0. \tag{1.24}$$

By the mean value theorem,

$$\frac{1}{\varepsilon}[F(x, u_\varepsilon) - F(x, u_0)] = F_u(x, \tilde{u}_\varepsilon(x))(u_\varepsilon - u_0)/\varepsilon,$$

where $\tilde{u}_\varepsilon(x)$ lies in the interval $(u_0(x), u_\varepsilon(x))$. Recalling (1.20) and the assumption $F_u(x, u) \geqq 0$, we obtain

$$\frac{1}{\varepsilon}[F(x, u_\varepsilon) - F(x, u_0)] \geqq F_u(x, \tilde{u}_\varepsilon(x))(U_\varepsilon - u_0)/\varepsilon. \tag{1.25}$$

Since $u_\varepsilon \to u_0$ uniformly in $\bar{\Omega}$, we also have

$$F_u(x, \tilde{u}_\varepsilon(x)) \to F_u(x, u_0(x)) \quad \text{uniformly with respect to } x \in \Omega. \tag{1.26}$$

Let Q_ε be the solution of the Dirichlet problem

$$\int_{\Omega_0} \nabla Q_\varepsilon \cdot \nabla \psi = \int_{\Omega_0} F_u(x, \tilde{u}_\varepsilon(x))\psi, \qquad \forall \psi \in H_0^1(\Omega_0), \quad Q_\varepsilon \in H_0^1(\Omega_0). \tag{1.27}$$

Taking $\psi = Q_\varepsilon - Q$ in (1.14) and $\psi = Q - Q_\varepsilon$ in (1.27) and adding we easily deduce, using (1.26), that

$$\|Q_\varepsilon - Q\|_{H_0^1(\Omega_0)} \to 0. \tag{1.28}$$

Substituting (1.25) into (1.24) and using (1.27) with $\psi = (U_\varepsilon - u_0)/\varepsilon$, we get

$$\int_{\Omega_0} \nabla Q_\varepsilon \cdot \nabla \frac{U_\varepsilon - u_0}{\varepsilon} + \frac{1}{\varepsilon} \int_\Omega (\Phi(k_0 + \varepsilon l) - \Phi(k_0)) \leqq 0.$$

Taking $\varepsilon \to 0$ and using (1.28), (1.22) and (1.13), we obtain

$$\int_{\Omega_0} \nabla Q \cdot \nabla z + \int_{\Omega_0} \Phi'(k_0) l \leqq 0. \tag{1.29}$$

Let $Q_j \in C_0^1(\Omega_0)$, $Q_j \to Q$ in $H_0^1(\Omega_0)$. Then

$$\int_{\Omega_0} \nabla Q_j \cdot \nabla z = -\int_{\Omega_0} Q_j \Delta z = -\int_{\Omega_0} Q_j l.$$

Taking $j \to \infty$ we obtain

$$\int_{\Omega_0} \nabla Q \cdot \nabla z = -\int_{\Omega_0} Q l.$$

Substituting this into (1.29), the assertion (1.17) follows.

Remark 1.1. Consider the case of a general obstacle g; that is, u is a solution of (1.5) with K replaced by

$$K_g = \{\psi \in H_0^1(\Omega), \psi \geqq g \text{ a.e.}, \psi - U^0 \in H_0^1(\Omega)\}. \tag{1.30}$$

Taking $\tilde{u} = u - g$, $\tilde{U}^0 = U^0 - g$ the problem is reduced to the one studied before with f replaced by $\tilde{f} = f - \Delta g$. Thus Theorem 1.1 can immediately be applied.

Remark 1.2. Theorem 1.1 can obviously be extended to general elliptic variational inequalities with variable coefficients (with K defined by (1.6) or (1.30)).

Remark 1.3. One can prove that, for a subsequence $\varepsilon \to 0$,

$$\frac{u_\varepsilon - u_0}{\varepsilon} \to \tilde{z} \text{ weakly in } H^1(\Omega_0),$$

but we cannot assert that $(u_\varepsilon - u_0)/\varepsilon \in H_0^1(\Omega_0)$ or even that $\tilde{z} \in H_0^1(\Omega_0)$ (unless the free

boundary is known to be smooth). It is for this reason that we have introduced the auxiliary solution U_ε; fortunately, replacing u_ε by U_ε does not change the inequality (1.24).

2. An application. Consider the case

$$\mathscr{A} = \left\{ 0 \leqq k(x) \leqq N, \int_\Omega k(x)\, dx = M \right\}, \tag{2.1}$$

where M, N are positive constants. We assume that

$$N \cdot \text{meas}\,(\Omega) > M \tag{2.2}$$

so that $\mathscr{A}$ is nontrivial. We take the functional

$$J(k) = \int_\Omega F(x, u)\, dx \tag{2.3}$$

and assume in addition to (1.9), (1.12) that

$$F_u(x, u) > 0 \quad \text{if } u > 0. \tag{2.4}$$

We also assume that (1.2) and (1.3) hold, as before.

Let k_0 be a solution of (1.10) and u_0 the solution of (1.5) and (1.6) corresponding to k_0. Set $\Omega_0 = \{x \in \Omega, u_0(x) > 0\}$ and define Q as in (1.14).

Notice that on any level set $\{Q = \lambda\}$ there holds $\Delta Q = 0$ a.e. and, therefore, also $F_u(x, u_0) = 0$. In view of (2.4) we conclude that

$$\text{meas}\,\{Q = \lambda\} = 0 \quad \text{for any } \lambda. \tag{2.5}$$

THEOREM 2.1. *For any maximizer k_0 there is a $\lambda \geqq 0$ such that*

$$\begin{aligned} &k_0 = N \text{ a.e. in the set } \Omega_0 \cap \{Q < \lambda\}, \\ &k_0 = 0 \text{ a.e. in the set } \Omega_0 \cap \{Q > \lambda\}. \end{aligned} \tag{2.6}$$

Proof. We first claim that

$$\text{meas}\,\{x \in \Omega_0, 0 < k_0(x) < N\} = 0. \tag{2.7}$$

Indeed, otherwise there exists a Lebesgue point x_0 of k_0, $x_0 \in \Omega_0$, such that

$$2\delta < k(x_0) < N - 2\delta, \qquad 0 < 4\delta < N.$$

Hence for any $\varepsilon > 0$ there is a set G of positive measure in the ball $B_\varepsilon(x_0) = \{|x - x_0| < \varepsilon\}$ such that

$$\delta < k(x) < N - 2\delta \quad \text{in } G.$$

Let $l(x)$ be any bounded function with support in G such that $\int l(x) = 0$. Then $k_0 \pm \varepsilon l \in \mathscr{A}$ if ε is small enough, and Theorem 1.1 gives

$$\int_G Ql = 0.$$

It follows that $Q = \text{const}$ in G, which contradicts (2.5).

From (2.7) we see that

$$k_0 = N\chi_A \quad \text{in } \Omega_0$$

where χ_A denotes the characteristic function of a set A. Let x_0 be any Lebesgue point

of A and of $k(x)$, and let y_0 be any Lebesgue point of $\Omega_0 \backslash A$ and of $k(x)$. Then we have

$$Q(x_0) \leqq Q(y_0). \tag{2.8}$$

Indeed, otherwise there is a $\lambda_0 > 0$ such that

$$k_0(x) = N, \quad k_0(y) = 0, \quad Q(x) > \lambda_0, \quad Q(y) < \lambda_0 \tag{2.9}$$

for $x \in G$, $y \in G'$ where $G \subset B_\varepsilon(x_0)$, $G' \subset B_\varepsilon(y_0)$ for some small $\varepsilon > 0$ and meas $(G) =$ meas $(G') > 0$. Take $l = -1$ in G, $l = 1$ in G' and $l = 0$ elsewhere. Then $k_0 + \varepsilon l \in \mathscr{A}$ if $\varepsilon > 0$, ε small, and Theorem 1.1 gives

$$\int_G Ql + \int_{G'} Ql \geqq 0$$

or $\int_{G'} Q \geqq \int_G Q$, a contradiction to (2.9).

Having proved (2.8) we conclude that $Q(x) < Q(y)$ a.e. for $x \in A$, $y \in \Omega_0 \backslash A$. This yields the assertion of the lemma for some $\lambda \geqq 0$.

THEOREM 2.2. *If*

$$\text{meas } \{x \in \Omega_0, k_0(x) > 0\} > 0 \tag{2.10}$$

then

$$k_0 = N \quad \text{a.e. in } \Omega \backslash \Omega_0. \tag{2.11}$$

Theorems 2.1 and 2.2 exhibit the bang-bang nature of the optimal controls.

Proof. Suppose (2.11) is not true. Then for any small $\varepsilon > 0$ one can find a set $G \subset (\Omega \backslash \Omega_0)$ with small positive measure such that $k(x) < N - \delta$ in G.

By (2.10) there exists a set G' in Ω_0 such that $k(x) > \delta$ in G' and meas $G' =$ meas G. Define $l = 1$ in G, $l = -1$ in G' and $l = 0$ elsewhere. Then $k_0 + \varepsilon l \in \mathscr{A}$ if $\varepsilon < \delta$. Denoting the corresponding solution of (1.5) by u_ε, we claim that

$$u_\varepsilon \geqq u_0, \qquad u_\varepsilon \not\equiv u_0. \tag{2.12}$$

Indeed, we substitute $\psi = u_0 - (u_0 - u_\varepsilon)^+$ in the variational inequality for u_0 and $\psi = u_\varepsilon + (u_0 - u_\varepsilon)^+$ in the variational inequality for u_ε. Adding the two inequalities we get

$$\int_\Omega |\nabla (u_0 - u_\varepsilon)^+|^2 \leqq \varepsilon \int_\Omega l(u_0 - u_\varepsilon)^+ = -\varepsilon \int_{G'} (u_0 - u_\varepsilon)^+ \leqq 0.$$

Hence $(u_0 - u_\varepsilon)^+ = 0$ and, since $\Delta u \not\equiv \Delta u_\varepsilon$ on G', (2.12) follows.

From (2.12) we conclude that $J(k_0 + \varepsilon l) > J(k_0)$, a contradiction.

Remark 2.1. If $f \leqq 0$ then the condition (2.10) is satisfied. Indeed, otherwise we have $\Delta u_0 = f \leqq 0$ in Ω_0. Take a ball B in Ω_0 with $\partial B \cap \Gamma = \{x_0\}$ (Γ is the free boundary). Since $u_0 > 0$ in B and $u_0(x_0) = 0$, the maximum principle gives $\nabla u(x_0) \neq 0$, a contradiction.

THEOREM 2.3. *If $f \geqq -N$ then, for any maximizer k_0,*

$$\text{meas } \{x \in \Omega_0, k_0(x) = N\} < \text{meas } \Omega_0. \tag{2.13}$$

Proof. Suppose (2.13) is not true. Then

$$-\Delta u_0 = -f - N \quad \text{in } \Omega_0.$$

Since also $-\Delta u_0 = 0 \geqq -f - N$ a.e. in $\Omega \backslash \Omega_0$, it follows that

$$-\Delta u_0 \geqq -f - N \quad \text{a.e. in } \Omega.$$

Also

$$u_0 \geqq 0, \quad u_0(-\Delta u_0 + f + N) = 0 \quad \text{a.e. in } \Omega.$$

Since $-(f+k) \geqq -(f+N)$ for any $k \in \mathscr{A}$, we then have, by comparison of u_0 with the solution u of (1.5), that $u \geqq u_0$. Since $u > 0$ (and, therefore, $\Delta u = f + k$) in some Ω-neighborhood $\tilde{\Omega}$ of $\partial\Omega$, if we choose k with $k \not\equiv N$ in $\tilde{\Omega}$ we then have $u \not\equiv u_0$ so that, by (2.4), $J(k) > J(k_0)$, a contradiction.

Remark 2.2. For any component T in Ω_0 of $\{Q < \lambda\}$ there holds

$$\partial T \cap \partial\Omega_0 \neq \varnothing. \tag{2.14}$$

Indeed, otherwise $Q = \lambda$ on ∂T and, since $-\Delta Q = F_u(x, u_0) > 0$ in T, the maximum principle gives $Q > \lambda$ in T, a contradiction. One of the components of $\{Q < \lambda\}$ must contain an Ω-neighborhood of $\partial\Omega$. If the free boundary $\partial\Omega_0 \cap \Omega$ consists of a finite number m of smooth surface Γ_i then the set $\{Q < \lambda\}$ has at most $m+1$ components: for each component T we have that either $\partial T \supset \partial\Omega$ or $\partial T \supset \Gamma_i$ for some i.

Remark 2.3. In case Ω is a one-dimensional interval $\{0 < x < a\}$ and $f \geqq 0$, the coincidence set consists of a single interval (which may be empty) and $k_0 = N$ on precisely three intervals: $0 \leqq x \leqq \gamma_1$, $\gamma_2 \leqq x \leqq \gamma_3$, $\gamma_4 \leqq x \leqq a$ (provided the coincidence set consists of a nonzero interval). When $f = 0$ and $F(x, u) \equiv u$ the γ_i can be computed explicitly; this special case was analyzed by Yaniro [13] by a method which is strictly one-dimensional.

Remark 2.4. The results of §§ 1 and 2 extend to the case where $U^0 \geqq 0$ on $\partial\Omega$.

3. Various extensions. In this section we give additional applications of the methods of §§ 1 and 2.

We begin by considering the same problem (1.10) associated with (1.5) and (1.6) where $\mathscr{A}$ is given by

$$\mathscr{A} = \left\{ k \in L^p(\Omega),\ k \geqq 0 \text{ a.e.},\ \int_\Omega k^p \leqq M \right\}, \tag{3.1}$$

and

$$J(k) = \int_\Omega F(x, u)\, dx + \int_\Omega \Phi(k); \tag{3.2}$$

here p, F and Φ are as in § 1. For any maximizer k_0 we introduce the corresponding u_0, Ω_0 and Q as before.

THEOREM 3.1. *For any maximizer k_0 there exists a real number μ such that*

$$Q - \Phi'(k_0) = \mu k_0^{p-1} \quad \textit{a.e. in } \Omega_0 \cap \{k_0 > 0\}, \tag{3.3}$$

$$Q - \Phi'(k_0) \geqq 0 \quad \textit{a.e. in } \Omega_0 \cap \{k_0 = 0\}. \tag{3.4}$$

Proof. To prove (3.3) we may assume that $\Omega_0 \cap \{k_0 > 0\}$ has positive measure. Take any $\delta > 0$ such that the set $A_\delta = \{x \in \Omega_0,\ k_0(x) > \delta\}$ has positive measure and let l be any bounded measurable function with support in A_δ such that

$$\int k_0^{p-1} l = 0. \tag{3.5}$$

Let $\tilde{k}_0 = k_0$ if $x \in A_\delta$, $\tilde{k}_0 = 0$ if $x \in \Omega \setminus A_\delta$. The function

$$k_\varepsilon = k_0 + \varepsilon((\pm l) - \gamma \tilde{k}_0), \qquad \gamma > 0$$

is nonnegative if ε is small enough and

$$\int k_\varepsilon^p = \int k_0^p + \varepsilon p \int k_0^{p-1}((\pm l) - \gamma \tilde{k}_0) + O(\varepsilon^2)$$

$$\leqq M - \varepsilon p \gamma \int_{A_\delta} k_0^p + O(\varepsilon^2) < M,$$

if ε is small enough. Thus $k_\varepsilon \in \mathscr{A}$ and Theorem 1.1 gives

$$\int_{A_\delta} (Q - \Phi'(k_0))((\pm l) - \gamma \tilde{k}_0) \geqq 0.$$

Taking $\gamma \to 0$ we get

$$\int_{A_\delta} (Q - \Phi'(k_0)) l = 0. \tag{3.6}$$

We have thus proved that (3.5) implies (3.6) when l is any bounded measurable function with support in A_δ. Consequently,

$$Q - \Phi'(k_0) = \mu k_0^{p-1} \quad \text{in } A_\delta,$$

where μ is some real number. Since obviously μ is independent of δ, the assertion (3.3) follows.

To prove (3.4) let S be any compact subset of Ω_0 contained in $\{k_0(x) = 0\}$ and let l_0 be a bounded measurable function with support in $S \cup A_\delta$ (for some small $\delta > 0$) satisfying

$$l_0 \geqq 0 \quad \text{on } S, \qquad l_0 = -1 \quad \text{on } A_\delta.$$

Let $l = Dl_0$ in S, $l = l_0$ elsewhere. Then, for any large $D > 0$, the function $k_0 + \varepsilon l$ is in $\mathscr{A}$ if ε is small enough. Applying Theorem 1.1, we get

$$D \int_S (Q - \Phi'(k_0)) l_0 \geqq \int_{A_\delta} (Q - \Phi'(k_0)).$$

Dividing by D and letting $D \to \infty$, we find that

$$\int_S (Q - \Phi'(k_0)) l_0 \geqq 0.$$

Since l_0 and S are arbitrary, (3.4) follows.

Remark 3.1. If $\Phi(k) \equiv 0$ then the proof of Theorem 2.2 shows that supp k_0 is contained in the coincidence set of u_0, provided the latter has positive measure.

We next study problems with control on the boundary. Consider the variational inequality

$$\begin{aligned} &\int_\Omega \nabla u \cdot \nabla(\psi - u) \geqq -\int_\Omega f(\psi - u) \quad \text{if } \psi - u \in H_0^1(\Omega), \quad \psi \geqq 0 \quad \text{a.e.,} \\ &u \in H^1(\Omega), \quad u \geqq 0 \quad \text{a.e.,} \quad u = U^0 + k \quad \text{on } \partial\Omega \text{ in the sense of trace class,} \end{aligned} \tag{3.7}$$

where U^0 is as in § 1 and k is the control function varying in the class, say,

$$\mathscr{B} = \left\{ k \in L^\infty(\partial\Omega),\ 0 \leqq k \leqq N,\ \int_{\partial\Omega} k = M \right\}.$$

We associate with (3.7) a functional, say,

$$J(k)=\int_\Omega F(x,u)\,dx+\int_{\partial\Omega}\Phi(k)\,dS,$$

where F and Φ are as in §§ 1 and 2 (with Ω replaced by $\partial\Omega$ in (1.8) and (1.13)).

Let k_0 be a maximizer, i.e.,

$$J(k_0)=\max_{k\in\mathcal{B}} J(k),\qquad k_0\in\mathcal{B}, \tag{3.8}$$

and denote by u_0 the corresponding solution of (3.7). Set $\Omega_0=\{x\in\Omega,\ u_0(x)>0\}$ and define Q, as before, by (1.14).

THEOREM 3.2. *Let k_0 be a solution of* (3.8) *and suppose $k_0+\varepsilon l\in\mathcal{B}$ for all $0<\varepsilon<\varepsilon_0$, for some $\varepsilon_0>0$. Then*

$$\int_{\partial\Omega}\left(\frac{\partial Q}{\partial\nu}-\Phi'(k_0)\right)l\geqq 0, \tag{3.9}$$

where ν is the outward normal to $\partial\Omega$.

Proof. Denote by u_ε the solution of (3.7) corresponding to $k_0+\varepsilon l$ and let $\tilde{U}_\varepsilon$ be a function in $H^1(\Omega)$ such that $\tilde{U}_\varepsilon=u_0$ in a neighborhood of $\Omega\setminus\Omega_0$, $\tilde{U}_\varepsilon=u_0+\varepsilon l$ on $\partial\Omega$. Denote by U_ε the solution of

$$\Delta U_\varepsilon=f\quad\text{in }\Omega_0,$$
$$U_\varepsilon-\tilde{U}_\varepsilon\in H_0^1(\Omega_0).$$

Then we again have that $u_\varepsilon\geqq U_\varepsilon$. Proceeding as in the proof of Theorem 1.1 we can show that

$$\frac{U_\varepsilon-u_0}{\varepsilon}\to z\quad\text{weakly in } H^1(\Omega_0),$$
$$\Delta z=0\quad\text{in }\Omega_0,$$
$$z-U^*\in H_0^1(\Omega_0),$$

where U^* is a function in $H^1(\Omega)$ such that $U^*=l$ on $\partial\Omega$ (in the sense of trace class) and $U^*=0$ in a neighborhood of $\partial\Omega_0\cap\Omega$. Further

$$-\int_{\partial\Omega_0\cap\partial\Omega}\frac{\partial Q}{\partial\nu}z+\int_\Omega\nabla z\cdot\nabla Q+\int_{\partial\Omega}\Phi'(k_0)l\leqq 0.$$

Since the middle integral on the left-hand side vanishes, (3.9) follows.

Remark 3.2. From Theorem 3.2 we can easily deduce that there exists a λ such that

$$k_0=N\text{ on }\left\{x\in\partial\Omega;\ \frac{\partial Q}{\partial\nu}-\Phi'(k_0)>\lambda\right\},$$
$$k_0=0\text{ on }\left\{x\in\partial\Omega;\ \frac{\partial Q}{\partial\nu}-\Phi'(k_0)<\lambda\right\}.$$

Remark 3.3. Theorem 3.2 extends to the case where $U^0\geqq 0$ on $\partial\Omega$.

Remark 3.4. There are several difficulties in trying to extend the method of this paper to parabolic variational inequalities: (i) although the existence of a solution U_ε to the parabolic analogue of (1.18) is known, uniqueness does not seem to be known (see [9, p. 63]) since no a priori regularity properties of the free boundary are assumed;

thus the inequality $U_\varepsilon \leqq u_\varepsilon$ is not obvious; (ii) the same problem occurs for Q_ε, although in the case of increasing sets $S(t) \equiv \{x;\ u(x, t) > 0\}$ uniqueness is known; see [9, p. 63]; (iii) the regularity of U_ε and Q in t does not seem to be sufficient to justify the integration by parts steps needed to extend the proof of Theorem 1.1. In what follows we briefly give one example in which the free boundary is smooth so that our method can be applied.

Consider the one-phase exterior Stefan problem with inner core S for the water region. We impose the boundary condition

$$\frac{\partial \theta}{\partial \nu} = \gamma + k(t) \quad \text{on } S \qquad \theta = \text{temperature}, \tag{3.10}$$

where γ is a positive constant and k varies in the class

$$\mathcal{B}_0 = \left\{ o \leqq k(t) \leqq N, \int_0^T k(t) \leqq M \right\}.$$

It is well known that the problem for θ can be formulated as a variational inequality for u ($u_t = \theta$ and $u = 0$ on the free boundary); see [3], [8].

We assume that

$$S \text{ is a ball}, \qquad N < \gamma. \tag{3.11}$$

Introducing polar coordinates (r, φ) about the center of S (φ is $(n-1)$-dimensional), we have that $\partial u/\partial \varphi = 0$ on $S \times (0, T)$. From this we deduce, by a standard argument that $|\partial u/\partial \varphi| \leqq C$ in the entire domain $\Omega \times (0, T)$. Recalling (3.10) and (3.11), we deduce that

$$\frac{\partial u}{\partial l} > 0 \quad \text{on } S,$$

for any direction l close enough to the radial direction $-r$. This enables us to deduce, as in [6], that the free boundary is Lipschitz continuous and, by [2], it is C^1 (or, in fact, C^∞).

We are now in a position to be able to study maximization or minimization problems. Consider the problem of maximizing the volume of ice which has melted by time T. This translates into the problem of minimizing

$$J_0(k) = \int u_t(x, T)\, dx. \tag{3.12}$$

Since this functional is not very regular, we replace it by an average

$$\frac{1}{T - T_0} \int_{T_0}^{T} \int_\Omega u_t(x, t)\, dx\, dt, \qquad 0 < T_0 < T,$$

or by

$$J(k) = \int_\Omega u(x, T)\, dx - \int_\Omega u(x, T_0)\, dx. \tag{3.13}$$

We also replace $\mathcal{B}_0$ by

$$\mathcal{B} = \{k \in \mathcal{B}_0 \text{ and } k(t) = 0 \text{ if } t > T_0\}. \tag{3.14}$$

Denote by Q^s the solution of

$$\begin{aligned} &Q_t+\Delta Q=0 && \text{in } \{u_0>0\}\cap\{t<s\}\equiv\Omega_0^s,\\ &Q=1 && \text{on } \{t=s\},\\ &\frac{\partial Q}{\partial \nu}=0 && \text{if } x\in S,\quad 0<t<s,\\ &Q=0 && \text{on the free boundary in } \{0<t<s\}. \end{aligned}$$

Proceeding as in § 1, we find that

$$\int_0^{T_0}\int_S (Q^T-Q^{T_0})L(\tau)\,dS\,d\tau\geqq 0,$$

where

$$\frac{\partial z}{\partial \nu}=L(\tau)=\int_0^\tau l(\sigma)\,d\sigma \quad \text{on } S\times(0,T_0).$$

Hence the function

$$W(\tau)=\int_\tau^T\int_S Q^T-\int_\tau^{T_0}\int_S Q^{T_0}$$

satisfies

$$\int_0^{T_0} W(\tau)l(\tau)\geqq 0.$$

Since

$$W_\tau=-\int_S (Q^T-Q^{T_0})$$

and $Q^T<Q^{T_0}$ by the maximum principle, we find, as in the proof of Theorem 1.1, that

$$k_0(t)=\begin{cases} N, & \text{if } 0<t<t_0,\\ 0, & \text{if } t_0<t<T. \end{cases}$$

For $n=1$ the same result was obtained in [5] for the original functional (3.12); the restriction $N<\gamma$ is not needed in this case.

ON THE EFFICIENCY AND OPTIMALITY OF ALLOCATIONS II*

NIKOLAOS S. PAPAGEORGIOU†

Abstract. In this work we study the problem of characterizing efficient, price efficient and optimal allocations in a very general economic model with a continuum of agents and an infinite-dimensional commodity space. We do that using the theory of concave normal integrands and Clarke's theory of generalized gradients, as well as certain results from geometric functional analysis. We also consider approximations of those notions and study their properties using the theory of ε-subdifferentiation and Ekeland's variational principal. Then we examine those concepts in the context of a particular sector of the enonomy using single valued and multivalued conditional expectations and martingale theory. Finally we study stability questions using the Kuratowski-Mosco convergence of sets and the epi-convergence (τ-convergence) of closed functions.

Key words. normal integrand, generalized gradient, measurable multifunction, conditional expectation, subdifferential, ε-subdifferential, Kuratowski-Mosco convergence

1. Introduction. A central problem in economics is the characterization of efficient programs of resource allocation by a price system and the use of a price mechanism to attain such an allocation in economies where decision making is decentralized. Previous work in this area was done by Majumdar [23], [24], Peleg [31]–[34], Peleg-Yaari [35] and Radner [37]. However, their models were quite restrictive (one agent-discrete time models) and their assumptions were quite strict from a mathematical viewpoint because they did not address the problem in the framework of nonsmooth analysis. Also their work, when it was infinite-dimensional, was concentrated on the dual pair (commodity space-price space) (l^∞, l^1). Our work aims at overcoming the limitations of those papers, providing a more general and natural framework for addressing those issues and presenting several new results that, even when we put them in the context of the earlier models, are novel. Furthermore in this work, we are the first to introduce and study approximate efficiency and optimality, which provide a strong insight into the properties of complete efficiency and optimality. Also, since our model corresponds to a multisector economy, we study what happens when we restrict our attention to a specific sector and finally—and in this respect we believe that our work is pioneering—we examine the stability of all the concepts that we introduce, under perturbations of the data on which they depend.

2. Background material and basic notions. We start with a description of our model. We postpone the precise mathematical definitions until later in this section.

Our model is a very general and flexible one and so it admits several economic interpretations. We will briefly outline all of them. The mathematical objects that constitute our model are the following: A (nonatomic) finite measure space (Ω, Σ, μ), a separable Banach space X ordered by a nonempty, closed, convex, pointed cone X_+, a measurable multifunction $F: \Omega \to 2^X$ and a function $u: \Omega \times X \to \bar{\mathbb{R}}$. Now we will give their economic interpretation.

If we view our economy as a producer's economy, (Ω, Σ, μ) is the measure space of agents (producers); Ω is the set of agents, Σ is the family of all possible coalitions and $\mu(\cdot)$ gives the relative size of the coalitions. The idea of a continuum of agents

† Department of Mathematics, University of Illinois, Urbana, Illinois 61801.

was first introduced by Aumann [1] as a device to capture the spirit of pure competition; in other words the economic situation where each individual agent cannot alone influence the outcome of the collective activity, but can do so through coalitions. We put the word nonatomic in parenthesis because it is not always necessary. When the measure space is atomic we interpret the atoms as large traders who constitute the oligopolistic participants of the economic process. The space X is the commodity space. The assumption that commodities are not finite in number agrees with many classical situations for economic theory: intertemporal equilibrium with an infinite horizon, a world of uncertainty with an infinite number of states or differentiation of commodities. The multifunction $F(\cdot)$ describes the production feasibility set for each producer $\omega \in \Omega$. So we call $F(\cdot)$ the production multifunction. The function $u(\omega, \cdot)$ specifies the profit function for each producer $\omega \in \Omega$. Finally a function $p(\cdot) \in [L_X^1(\Omega)]_+^*$ will be called a "price system" and then $p(\omega)$ represents the price established by agent $\omega \in \Omega$ for his production. From the viewpoint of optimization theory prices can be identified with "Lagrange multipliers" or "dual variables".

We can also view the mathematical model as representing a consumer's economy with only public goods. Then (Ω, Σ, μ) is the measure space of consumers, X is again the commodity space, $F: \Omega \to 2^X$ is the consumption multifunction, i.e., for each agent $\omega \in \Omega$, $F(\omega)$ represents the set of his feasible consumption bundles and $u(\omega, \cdot)$ gives the utility function of agent $\omega \in \Omega$. Finally $p(\cdot) \in [L_X^1(\Omega)]_+^*$ assigns a different price (tax rate) for each consumer.

We can also have a probabilistic interpretation of our model. Namely, think of a world of uncertainty with only one agent. Then (Ω, Σ, μ) is the probability space of all possible outcomes, $F(\omega)$ is the agent's consumption set when the state of affairs is ω, $u(\omega, \cdot)$ is his utility function when the outcome is $\omega \in \Omega$ and finally $p(\omega)$ is the price system that he faces when the state of nature is ω.

Finally we can give a "dynamic" interpretation to our mathematical model. In that case we have that $\Omega = T$ is a closed interval in $\mathbb{R}_+$, Σ is the Lebesgue subsets of T and $\mu = \lambda$ is the Lebesgue measure. Think of $t \in T$ as a time variable. Then $F(t)$ is the set of all feasible consumption plans for the community at time t, $u(t, \cdot)$ is the utility function at that same instant of time and finally $p(t)$ is the price system prevailing in the market at time $t \in T$.

In general $F(\cdot)$ will be a closed valued, integrably bounded multifunction. In that case the set S_F^1 of feasible resource allocations is nonempty. For the function $u: \Omega \times X \to \bar{\mathbb{R}}$ we will assume initially that it is a concave, normal integrand (in the sense of Rockafellar [40]) which is monotone increasing. So we will rely heavily on Rockafellar's powerful theory of normal integrands. Then we generalize to functions which are not necessarily concave in the x variable, but they are locally Lipschitz. Here our main tool will be Clarke's theory of generalized gradients [7]–[9].

The three basic concepts that are central in this work are the following:

(1) We will say that $f(\cdot) \in L_X^1(\Omega)$ is an efficient allocation if and only if $f \in S_F^1$ and $(f(\omega) + \dot{X}_+) \cap F(\omega) = \varnothing$ μ-a.e. where $\dot{X}_+ = X_+ \backslash \{\varnothing\}$.

So efficient allocations are those under which no nonnull coalition can find another feasible redistribution of resources so as to improve the well being of all its members and at the same time keep the welfare status of the rest of the society at the same level. Viewed in another way an efficient allocation is one which to μ-almost all agents assigns a commodity bundle which is maximal within their feasibility set for the partial ordering on X induced by X_+.

(2) We will say that $f(\cdot) \in L_X^1(\Omega)$ is an optimal allocation if and only if $f \in S_F^1$ and $u(\omega, g(\omega)) \leqq u(\omega, f(\omega))\mu$-a.e. for all $g \in S_F^1$.

So an optimal allocation is one which maximizes the profit (or utility) of μ-almost all agents among all other feasible allocations.

We know that prices suggest how economic decisions can be decentralized. But in addition to that the study of price systems associated with efficient allocations (programs) can be used to provide qualitative information about such programs (like existence results, topological properties of the set of efficient allocations etc.) So it is natural to make the following definition.

(3) If $p(\cdot) \in [L_X^1(\Omega)]_+^* \setminus \{0\}$ we will say that $f(\cdot) \in L_X^1(\Omega)$ is a "$p(\cdot)$-efficient" (or "price efficient for $p(\cdot)$") allocation if and only if $\langle p, f \rangle = \sigma_{S_F^1}(p)$ where $\sigma_{S_F^1}(\cdot)$ is the support function of the set S_F^1 and $\langle \cdot, \cdot \rangle$ denotes the duality brackets between $L_X^1(\Omega)$ and $[L_X^1(\Omega)]^*$.

In [28] the author obtained some first relations between the above three concepts. Here we will extend those results and prove new ones.

Sometimes mathematical economists prefer to have resource allocation functions that belong in $L_X^\infty(\Omega)$. We therefore conduct a parallel investigation for this case. The main technical difficulty that we face in this case is that $[L_X^\infty(\Omega)]^*$ is not $L_{X^*}^1(\Omega)$ but a much larger Banach space. If we attempt to define price systems as elements of $[L_X^\infty(\Omega)]_+^*$, we cannot have a satisfactory economic interpretation for them. So we are forced to confine ourselves to price systems in $L_{X^*}^1(\Omega) \subsetneq [L_X^\infty(\Omega)]^*$. However this calls for trouble, because as our work in [28] suggests, the arguments that guarantee the existence of a value maximizing price system are classical duality arguments (separation theorems) which produce elements in $[L_X^\infty(\Omega)]^*$ which may not be in $L_{X^*}^1(\Omega)$. To overcome this difficulty we will use Levin's generalization of the Yosida–Hewitt theorem [22] and the work of Rockafellar [41], [42], which examined normal integral functionals within the dual system $(L_X^\infty(\Omega), L_{X^*}^1(\Omega))$.

When int $X_+ \neq \varnothing$ we can have a weaker notion of efficiency.

(4) We say that $f(\cdot) \in L_X^1(\Omega)$ is a "weakly efficient allocation" if and only if $f \in S_F^1$ and $(f(\omega) + \text{int } X_+) \cap F(\omega) = \varnothing$ μ-a.e.

Intuitively we can think of weakly efficient allocations as those allocations for which no nonnegligible coalition can find an alternative feasible redistribution of goods that will make all of its members strictly better without affecting the well being of the rest of the society. Clearly every efficient allocation is weakly efficient, but the converse is not true in general.

In certain cases it is quite difficult to determine efficient and optimal allocations. We want then to be able to get arbitrarily close to such allocations. This leads to the following two notions.

(1a) Given $\varepsilon(\cdot) \in [L^1(\Omega)]_+$ we say that $f(\cdot) \in L_X^1(\Omega)$ is "$\varepsilon(\cdot)$-optimal" if and only if $f \in S_F^1$ and $u(\omega, g(\omega)) - \varepsilon(\omega) \leqq u(\omega, f(\omega))$ μ-a.e. for all $g \in S_F^1$.

(2a) If $p(\cdot) \in [L_X^1(\Omega)]_+^* \setminus \{0\}$ and $\varepsilon > 0$, then $f(\cdot) \in L_X^1(\Omega)$ is "ε-$p(\cdot)$-efficient" if and only if $f \in S_F^1$ and $\langle p, f \rangle \geqq \sigma_{S_F^1}(p) - \varepsilon$.

If we are within the producer's or consumer's model and we want to examine only a sector of the economy, we model that by passing to a sub-σ-field Σ_0 of Σ. Then the profit (resp. utility) function is given by $E^{\Sigma_0} u(\cdot, \cdot)$ and the production (resp. consumption) multifunction by $E^{\Sigma_0} F(\cdot)$. In the context of the probabilistic model this means that we have only partial information about the underlying uncertainty.

Now we will pass to the mathematical definitions and we will recall very briefly some basic facts from the theory of measurable multifunctions. For details the reader can refer to Castaing–Valadier [6], Himmelberg [14] and Rockafellar [39], [40].

So let $F: \Omega \to 2^X \setminus \{\varnothing\}$ be a multivalued function (multifunction). We introduce the set $\text{Gr } F = \{(\omega, x) \in \Omega \times X: x \in F(\omega)\}$ which we will call the graph of $F(\cdot)$. If $V \subseteq X$, we define $F^-(V) = \{\omega \in \Omega: F(\omega) \cap V \neq \varnothing\}$.

When X is a topological vector space, by $P_f(X)$ (resp. $P_k(X)$) we will denote the nonempty closed (resp. compact) subsets of X. A w in front of f (resp. k) will mean that the closedness (resp. compactness) is with respect to the weak topology $w(X, X^*)$. Finally a c after f or k will mean that the set is in addition convex.

The next theorem summarizes the major results existing on the measurability of closed valued multifunctions.

THEOREM 2.1. *Let (Ω, Σ) be a measurable space and X a separable metric space. Let $F:\Omega \to P_f(X)$ be a multifunction.*

Consider the following statements:

(1) $F^-(B) \in \Sigma$ *for every* $B \in B(X) =$ *the Borel* σ*-field of* X.

(2) $F^-(C) \in \Sigma$ *for every* C *a closed subset of* X.

(3) $F^-(U) \in \Sigma$ *for every* U *an open subset of* X.

(4) $\omega \to d_{F(\omega)}(x) = \inf_{z \in F(\omega)} \|x - z\|$ *is measurable for all* $x \in X$.

(5) *There exists a sequence of measurable selectors* $f_n(\cdot)$ *of* $F(\cdot)$ *s.t.* $F(\omega) = \operatorname{cl}\{f_n(\omega)\}_{n \geq 1}$ (*Castaing representation*).

(6) $\operatorname{Gr} F \in \Sigma \times B(X)$.

Then we have the following results:

(i) (1)$\Rightarrow$(2)$\Rightarrow$(3)$\Leftrightarrow$(4)$\Rightarrow$(6).

(ii) *If X is a Polish space (i.e., in addition is complete) then* (3)$\Leftrightarrow$(5).

(iii) *If X is Polish and there is a complete σ-finite measure on Σ then* (1)-(6) *are all equivalent.*

Following Himmelberg [14], we say that a multifunction $F:\Omega \to P_f(X)$ satisfying (1) (resp. (2), (3)) is Borel (resp. strongly, weakly) measurable.

Let X be a separable Banach space. For any multifunction $F:\Omega \to 2^X$ we can define the set

$$S_F^1 = \{f(\cdot) \in L_X^1(\Omega): f(\omega) \in F(\omega) \mu\text{-a.e.}\},$$

i.e., S_F^1 contains all the integrable selectors of $F(\cdot)$. Clearly S_F^1 may be empty. If it is nonempty and $F(\cdot)$ is closed valued then it is easy to check that it is a closed subset of $L_X^1(\Omega)$.

Using this set we can define an integral for $F(\cdot)$:

$$\int_\Omega F(\omega)\, d\mu(\omega) = \left\{ \int_\Omega f(\omega)\, d\mu(\omega): f \in S_F^1 \right\}.$$

This was first introduced by Aumann [2] for $X = \mathbb{R}^n$. It is a natural generalization of both the integral of single valued functions and of the Minkowski sum of sets. It turned out to be a very powerful tool in several areas of applied mathematics especially in optimal control and mathematical economics.

In our case the integrals $\int_\Omega f(\omega)\, d\mu(\omega) f \in S_F^1$ are taken in the sense of Bochner [10]. Clearly if $S_F^1 = \varnothing$ then $\int_\Omega F(\omega)\, d\mu(\omega) = \varnothing$.

We will say that a measurable multifunction $F:\Omega \to P_f(X)$ is integrably bounded if there is a $\varphi(\cdot) \in L^1(\Omega)$ s.t.

$$|F(\omega)| = \sup_{x \in F(\omega)} \|x\| \leqq \varphi(\omega) \mu\text{-a.e.}$$

Using the Kuratowski-Ryll-Nardzewski selection theorem [21] we can see that for an integrably bounded multifunction $S_F^1 \neq \varnothing$ and so $\int_\Omega F(\omega)\, d\mu(\omega) \neq \varnothing$.

According to Hiai-Umegaki [13] for Σ_0 a sub-σ-field of Σ and $F:\Omega \to P_f(X)$ an integrably bounded multifunction, there exists a unique Σ_0-measurable multifunction $E^{\Sigma_0}F:\Omega \to P_f(X)$ which is integrable bounded also and for which we have that

$$S_{E^{\Sigma_0}F}^1 = \operatorname{cl}\{E^{\Sigma_0} f: f \in S_F^1\}$$

where the closure is taken in the $L^1_X(\Omega)$-norm topology. From here on for simplicity we will write $S^1_{E^{\Sigma_0}F} = S^1(\Sigma_0)$. The multifunction $E^{\Sigma_0}F(\cdot)$ is called the set valued conditional expectation of $F(\cdot)$ with respect to the sub-σ-field Σ_0.

Finally we will introduce a notion of convergence of closed sets, which is different from the convergence in the Hausdorff metric and which is more appropriate in the study of the stability of optimization and variational problems. This mode of set convergence was first introduced by Mosco [26], [27] and was extensively studied by Salinetti-Wets [45]-[47]. So let X be a Banach space and let $\{A_n\}_{n\geq 1}$ be a sequence of nonempty, closed subsets of X. Let t be a topology on X. We will say that A_n t-converges in the Kuratowski-Mosco sense to A if

$$t\text{-}\overline{\lim_{n\to\infty}} A_n \subseteq A \subseteq t\text{-}\underline{\lim_{n\to\infty}} A_n,$$

where

$$t\text{-}\overline{\lim_{n\to\infty}} A_n = \{x = t\text{-}\lim_{m\to\infty} x_m : x_m \in A_m,\ m \in M \subseteq N\}$$

and

$$t\text{-}\underline{\lim_{n\to\infty}} A_n = \{x = t\text{-}\lim_{n\to\infty} x_n : x_n \in A_n,\ n \in N\}.$$

Since we always have that

$$t\text{-}\underline{\lim_{n\to\infty}} A_n \subseteq t\text{-}\overline{\lim_{n\to\infty}} A_n,$$

we deduce that $\{A_n\}_{n\geq 1}$ t-converges to A in the Kuratowski-Mosco sense if and only if $t\text{-}\underline{\lim}_{n\to\infty} A_n = A = t\text{-}\overline{\lim}_{n\to\infty} A_n$. In that case we write that

$$A_n \xrightarrow{t\text{K-M}} A \quad \text{as } n \to \infty.$$

When $w\text{-}\overline{\lim}_{n\to\infty} A_n = A = s\text{-}\underline{\lim}_{n\to\infty}$ (where w denotes the weak topology and s the strong topology on X), we say that A_n converges to A in the Kuratowski-Mosco sense and we write

$$A_n \xrightarrow{\text{K-M}} A \quad \text{as } n \to \infty.$$

Finally if $\{f_n, f\}_{n\geq 1}$ is a sequence of $\bar{\mathbb{R}}$-valued closed convex functions on X, we say that $f_n \xrightarrow{\tau} f$ as $n \to \infty$ if and only if

$$\operatorname{epi} f_n \xrightarrow{\text{K-M}} \operatorname{epi} f \quad \text{as } n \to \infty.$$

We have defined price systems to be functions in $[L^1_X(\Omega)]^*_+$. We know that in general $[L^1_X(\Omega)]^* = L^\infty_{X^*_{w^*}}(\Omega)$ (see [20]) where $X^*_{w^*}$ is the space X^* with the w^*-topology. If X^* has the Radon-Nikodym property then $[L^1_X(\Omega)]^* = L^\infty_{X^*}(\Omega)$.

Throughout this work (Ω, Σ, μ) will be a complete probability space and X a separable Banach space. Additional hypotheses will be introduced as needed. Since we will be dealing with concave functions all the notions and results of convex analysis will be used in a "concave-context". Thus if $f: X \to \bar{\mathbb{R}}$ ($\bar{\mathbb{R}} = \mathbb{R} \cup \{-\infty\}$) is concave, we take $\partial_\varepsilon f(x) = \{x^* \in X^* : f(z) - f(x) \leqq (x^*, z - x) + \varepsilon \text{ for all } z \in X\}$, $\varepsilon \geqq 0$. The conjugate $f^*: X^* \to \bar{\mathbb{R}}$ of $f(\cdot)$ is defined by $f^*(x^*) = \inf_{x\in X} \{(x^*, x) - f(x)\}$.

Briefly the organization of the paper is as follows: In the next section we study the properties of efficient, price efficient and weakly efficient allocations. In § 4 we conduct an analogous study for optimal allocations. In § 5 we deal with the approximate

versions of those concepts. Finally in § 6 we examine the stability (robustness) of those notions under perturbations of the data and we also examine what happens to them when we restrict our attention to a particular economic sector.

We believe that our work illustrates in a rather convincing way, how some elegant mathematical theories, like Rockafellar's theory of normal integrands, Clarke's theory of generalized gradients and the Kuratowski-Mosco convergence of sets and functions can have nontrivial applications in mathematical economics.

3. Efficient and price efficient allocations. We will start with an existence result concerning efficient allocations. For that purpose assume that $\operatorname{int} X_+^* \neq \varnothing$, $F: \Omega \to P_{fc}(X)$ is integrably bounded and S_F^1 is locally w-compact in $L_X^1(\Omega)$. Then we have:

THEOREM 3.1. *Under the above hypotheses the set of efficient allocations is nonempty.*

Proof. Since by hypothesis $F(\cdot)$ is integrably bounded we have that S_F^1 is nonempty, bounded, closed and convex. So $\operatorname{As}(S_F^1) = \{0\}$ where $\operatorname{As}(\cdot)$ denotes the asymptotic cone of the set under consideration.

For any $g(\cdot) \in S_F^1$ we have that

$$(*) \qquad \operatorname{As}[S_F^1 \cap (g + (L_X^1)_+] = \operatorname{As}(S_F^1) \cap \operatorname{As}(g + (L_X^1)_+) = \operatorname{As} S_F^1 \cap (L_X^1)_+ = \{0\}.$$

By hypothesis S_F^1 is locally w-compact. Then so is $(S_F^1 \cap (g + (L_X^1)_+))$. Hence using (*) and Theorem I-9 of Castaing-Valadier [6] we conclude that $K_g = S_F^1 \cap (g + (L_X^1)_+)$ is w-compact in $L_X^1(\Omega)$.

Since $\operatorname{int} X_+^* \neq \varnothing$, we can see that $\operatorname{int}(L_{X^*}^\infty)_+ \neq \varnothing$. So let $p(\cdot) \in \operatorname{int}(L_{X^*}^\infty)_+$. Because K_g is w-compact, there exists $f(\cdot) \in K_g$ where $p(\cdot)$ achieves its supremum on K_g. We claim that $f(\cdot)$ is an efficient allocation. Suppose not. Then we can find $\hat{f} \in S_F^1$ s.t. $\hat{f} > f$ (i.e. $\mu\{\omega \in \Omega: \hat{f}(\omega) - f(\omega) \in \dot{X}_+\} > 0$). Clearly then $\hat{f} \in K_g$ and furthermore since $p(\cdot) \in \operatorname{int}(L_{X^*}^\infty)_+$, we have that

$$\langle p, \hat{f} - f \rangle > 0 \Rightarrow \langle p, f \rangle > \sigma_{K_g}(p),$$

a blatant contradiction.

So indeed $f(\cdot)$ is an efficient allocation. Q.E.D.

Remark. In [30] Theorem 3.4 gives us a necessary and sufficient condition for S_F^1 to be locally w-compact. This is the following:

> S_F^1 is a locally w-compact subset of $L_X^1(\Omega)$ if and only if the polar $(S_F^1)^0$ has a nonempty relative interior for the Mackey topology $m(L_{X^*_{w^*}}, L_X^1)$ and span $(S_F^1)^0$ is closed and of finite codimension.

Now we turn to the study of the geometric properties of the efficient and price efficient allocations.

We will start with a topological property of efficient allocations. So assume that $F: \Omega \to P_f(X)$ is integrably bounded.

PROPOSITION 3.1. *If $f(\cdot) \in L_X^1(\Omega)$ is an efficient allocation then $f(\omega) \in \operatorname{bd} F(\omega)$, $\omega \in \Omega$.*

Proof. Without any loss of generality we may assume that $\operatorname{int} F(\omega) \neq \varnothing$ for all $\omega \in \Omega$. Suppose that for $A \in \Sigma$ with $\mu(A) > 0$ and for $\omega \in A$ we have that $f(\omega) \in \operatorname{int} F(\omega)$. This means that there exists an $\varepsilon > 0$ depending on ω s.t.

$$[f(\omega) + B_\varepsilon^X(0)] \subseteq F(\omega),$$

where $B_\varepsilon^X(0) = \{x \in X: \|x\| \leqq \varepsilon\}$.

Consider the following multifunction defined on $A \subseteq \Omega$:

$$R(\omega) = \{\varepsilon > 0: f(\omega) + B_\varepsilon^X(0) \subseteq F(\omega)\} = \{\varepsilon > 0: \|f(\omega) - \operatorname{bd} F(\omega)\| \geqq \varepsilon\}.$$

From Theorem 4.6 of Himmelberg [14] we know that $\omega \to \operatorname{bd} F(\omega)$ is a $P_f(X)$-valued, measurable multifunction. So by Castaing's representation theorem there exist $\{u_n(\cdot)\}_{n\geq 1} \subseteq S^1_{\operatorname{bd} F}$ s.t.

$$\operatorname{cl}\{u_n(\omega)\}_{n\geq 1} = \operatorname{bd} F(\omega).$$

Then $\|f(\omega) - \operatorname{bd} F(\omega)\| = \inf_{n\geq 1} \|f(\omega) - u_n(\omega)\|$. But note that for all $n \geq 1$, $\omega \to \|f(\omega) - u_n(\omega)\|$ is measurable. Hence $\omega \to \|f(\omega) - \operatorname{bd} F(\omega)\|$ is measurable.

Let $\varphi(\omega, \varepsilon) = \|f(\omega) - \operatorname{bd} F(\omega)\| - \varepsilon$. Clearly this is a Caratheodory function and so is jointly measurable. Observe that

$$\operatorname{Gr} R = \{(\omega, \varepsilon) \in \Omega \times \mathbb{R}_+ \colon \varphi(\omega, \varepsilon) \geq 0\}.$$

Hence $\operatorname{Gr} R \in \Sigma_A \times B(\mathbb{R})$ where $\Sigma_A = \Sigma \cap A$. So we can apply Aumann's measurable selection theorem and find $\varepsilon : A \to \mathbb{R}_+$ measurable s.t. $\varepsilon(\omega) \in R(\omega)\omega \in A$. Therefore,

$$f(\omega) + B^X_{\varepsilon(\omega)}(0) \subseteq F(\omega) \quad \text{for } \omega \in A.$$

Now consider the multifunction $\Gamma(\omega) = B_{\varepsilon(\omega)}(0) \subseteq X_+$. Theorem 2.4 of Himmelberg [14] tells us that $\Gamma(\cdot)$ is measurable and closed valued. Applying the Kuratowski-Ryll-Nardzewski measurable section theorem we can find $e : A \to X_+$ measurable s.t. $e(\omega) \in \Gamma(\omega)$ for all $\omega \in A$. Then $g(\omega) = f(\omega) + e(\omega) \in F(\omega)$ for $\omega \in A$.

Define

$$\hat{g}(\omega) = \begin{cases} g(\omega) & \text{if } \omega \in A, \\ f(\omega) & \text{if } \omega \in \Omega \backslash A. \end{cases}$$

Clearly $\hat{g} \in S^1_F$ and $\hat{g} > f$, contradicting the hypothesis that $f(\cdot)$ is an efficient allocation. Q.E.D.

The next result provides an interesting global geometric characterization of efficient allocations. Recall that in a topological vector space a closed, convex subset is said to be rotund if every boundary point of the set is an extreme point.

PROPOSITION 3.2. *If $F : \Omega \to P_f(X)$ is an integrably bounded multifunction with rotund values and $f(\cdot) \in L^1_X(\Omega)$ is an efficient allocation then $f(\cdot) \in \operatorname{ext} S^1_F$.*

Proof. From Proposition 3.1 we know that $f(\omega) \in \operatorname{bd} F(\omega)$, $\omega \in \Omega$. Because of the rotundity of the set $F(\omega)$ we have that $f(\omega) \in \operatorname{ext} F(\omega)$, $\omega \in \Omega$. Using the work of Benamara [3], we then conclude that

$$f \in S^1_{\operatorname{ext} F} = \operatorname{ext} S^1_F. \qquad \text{Q.E.D.}$$

We can have something similar for price efficient allocations. First we need to introduce a new piece of terminology. If $f(\cdot) \in L^1_X(\Omega)$ and we have that $f(\omega) \in \operatorname{ext} F(\omega)$ μ-a.e. we will say that $f(\cdot)$ is an extremal allocation.

The next result tells us that any price efficient allocation can be substituted by an extremal allocation which is still price efficient for the same price system.

We will need an auxiliary lemma, which actually is interesting in its own right. This result first appeared in [29] and we repeat it here for the convenience of the reader.

LEMMA I. *If $F : \Omega \to P_{wkc}(X)$ is integrably bounded then S^1_F is a w-compact convex subset of $L^1_X(\Omega)$.*

Proof. We know that S^1_F is a nonempty, bounded, closed and convex subset of $L^1_X(\Omega)$. Let $q(\cdot) \in [L^1_X(\Omega)]^*$. From the Dinculeanu-Foias theorem (see [20]) we know that $[L^1_X(\Omega)]^* = L^\infty_{X^*_{w^*}}(\Omega)$. So $q(\cdot) \in L^\infty_{X^*_{w^*}}(\Omega)$. Then

$$\sup_{f \in S^1_F} \langle q, f \rangle = \sup_{f \in S^1_F} \int_\Omega (q(\omega), f(\omega))\, d\mu(\omega).$$

Using Theorem 2.2 of [13] we get that

$$\sup_{f\in S_F^1}\langle q,f\rangle=\int_\Omega \sup_{y\in F(\omega)}(q(\omega),y)\,d\mu(\omega).$$

Consider the multifunction

$$\Gamma(\omega)=\{h\in G(\omega):(q(\omega),h)=\sigma_{F(\omega)}(p(\omega))\}.$$

Because $F(\cdot)$ is $P_{wkc}(X)$-valued we can see that $\Gamma(\cdot)$ takes values in $P_f(X)$. Furthermore for the same reason $\sigma_{F(\cdot)}(\cdot)$ is a Caratheodory function. Hence $\omega\to\sigma_{F(\omega)}(q(\omega))$ is measurable. Then $\varphi(\omega,h)=(q(\omega),h)-\sigma_{F(\omega)}(q(\omega))$ being a Caratheodory function is jointly measurable. Observe that

$$\Gamma(\omega)=\{h\in F(\omega):\varphi(\omega,h)=0\}.$$

So $\operatorname{Gr}\Gamma\in\Sigma\times B(X)$. Applying Aumann's selection theorem we can find $h:\Omega\to X$ measurable s.t. $\sigma_{F(\omega)}(q(\omega))=(q(\omega),h(\omega))$, $\omega\in\Omega$. Therefore we have that

$$\sup_{f\in S_F^1}\langle q,f\rangle=\int_\Omega (q(\omega),h(\omega))\,d\mu(\omega)=\langle q,h\rangle.$$

Since $h(\cdot)\in S_F^1$ we conclude using James' theorem (see [19]) that S_F^1 is w-compact as claimed. Q.E.D.

Now we can proceed and state our result on price efficient allocations.

PROPOSITION 3.3. *If $F:\Omega\to P_{wkc}(X)$ is integrably bounded then for any $p(\cdot)\in[L^\infty_{X^*_{w^*}}]\backslash\{0\}$ we can find an extremal allocation which is price efficient for that price system $p(\cdot)$.*

Proof. From the previous lemma we know that S_F^1 is a w-compact subset of $L_X^1(\Omega)$. So $\sup_{f\in S_F^1}\langle p,f\rangle$ is attained at some element of S_F^1. From Bauer's maximum principle we know that this element can be taken to belong in ext S_F^1. So for some $\hat f(\cdot)\in\operatorname{ext} S_F^1$, $\langle p,\hat f\rangle=\sigma_{S_F^1}(p)$. On the other hand, from Benamara [3] we know that ext $S_F^1=S^1_{\operatorname{ext} F}$. Hence $\hat f(\cdot)\in S^1_{\operatorname{ext} F}$ which means that $\hat f(\cdot)$ is an extremal allocation. Q.E.D.

Now let $F:\Omega\to P_{fc}(X)$ be an integrably bounded multifunction and consider the following set

$$G(F)=\{(f,p)\in L_X^1(\Omega)\times[L^\infty_{X^*_{w^*}}(\Omega)]_+:f(\cdot)\text{ is }p\text{-efficient}\},$$

i.e., $G(F)$ contains all pairs of allocations and price systems s.t. the allocation is price efficient for that price system.

PROPOSITION 3.4. (1) *$G(F)$ is closed in $(L_X^1(\Omega),s)\times(L^\infty_{X^*_{w^*}}(\Omega),w^*)$.*

(2) *If X has the Schur property then $G(F)$ is closed in $(L_X^1(\Omega),w)\times(L^\infty_{X^*_{w^*}},w)$.*

Proof. (1) Let (f_a,p_a) be a net in $G(F)$ s.t. $(f_a,p_a)\xrightarrow{s\times w^*}(f,p)$. Then by definition we have that

$$\langle p_a,f_a\rangle=\sigma_{S_F^1}(p_a).$$

Because

$$f_a\xrightarrow{s\text{-}L_X^1}f\quad\text{and}\quad p_a\xrightarrow{w^*\text{-}L^\infty_{X^*_{w^*}}}p$$

we have that $\langle p_a,f_a\rangle\to\langle p,f\rangle$. On the other hand, $\underline{\lim}_a\,\sigma_{S_F^1}(p_a)\geqq\sigma_{S_F^1}(p)$. So $\sigma_{S_F^1}(p)\leqq\langle p,f\rangle$. But note that $f\in S_F^1$. Hence $\sigma_{S_F^1}(p)=\langle p,f\rangle$ which means that $f(\cdot)$ is p-efficient, i.e., $(f,p)\in G(F)$.

(2) If X has the Schur property, then we know from Khurana [49] that $L^1_X(\Omega)$ has the Dunford-Pettis property. So if

$$f_a \xrightarrow{w\text{-}L^1_X} f \quad \text{and} \quad p_a \xrightarrow{w\text{-}L^\infty_{X^*_{w^*}}} p$$

then $\langle p_a, f_a\rangle \to \langle p, f\rangle$. Again we can get that $\sigma_{S^1_F}(p) \leqq \langle p, f\rangle$ and since $f \in S^1_F$ equality holds. So $(f, p) \in G(F)$. Q.E.D.

Now we will pass to a series of results that compare efficiency and price efficiency.

Although a price efficient allocation is not necessarily efficient the next result tells us that price efficient allocations are w-dense in the set of efficient allocations. For that purpose assume that Σ is countably generated and int $X^*_+ \neq \varnothing$.

THEOREM 3.2. *If $F: \Omega \to P_{wkc}(X)$ is integrably bounded then the $w(L^1_X(\Omega), L^\infty_{X^*_{w^*}}(\Omega))$-closure of the set of all price efficient allocations contains the set of efficient allocations.*

Proof. Observe that if $f(\cdot) \in S^1_F$ is efficient for $F(\cdot)$ it is also efficient for $(F(\cdot) - X_+)$ and vice versa. So from Proposition 3.1 we know that $f(\omega) \in bd(F(\omega) - X_+)\omega \in \Omega$, which implies that $f(\cdot) \in bd(S^1_{F-X_+})$.

From the Bishop-Phelps theorem (see [12]) we know that there exist $\{f_n\}_{n\geqq 1} \subseteq bd(S^1_{F-X_+})$ s.t. $f_n(\cdot)$ is $p_n(\cdot)$-efficient with $\|p_n\|_{L^\infty_{X^*_{w^*}}} \leqq 1$ and

$$f_n \xrightarrow{s\text{-}L^1_X} f \quad \text{as } n \to \infty.$$

Hence

$$\langle p_n, f_n\rangle = \sigma_{S^1_{F-X^+}}(p_n) \Rightarrow \langle p_n, f_n\rangle \geqq \langle p_n, f_n - e\rangle$$

for all $e(\cdot) \in [L^1_X(\Omega)]_+$. So $\langle p_n, e\rangle \geqq 0$ for all $e(\cdot) \in [L^1_X(\Omega)]_+$ which means that $p_n(\cdot) \in [L^\infty_{X^*_{w^*}}(\Omega)]_+$ for all $n \geqq 1$.

Because Σ is countably generated $L^1_X(\Omega)$ is separable and so we can assume that

$$p_n \xrightarrow{w^*\text{-}L^\infty_{X^*_{w^*}}} p \quad \text{as } n \to \infty$$

and for all $n \geqq 1 \langle p_n, f_n\rangle = \sigma_{S^1_{F-X^+}}(p_n) = \sigma_{S^1_F}(p_n)$.

For $n \geqq 1$ define $\Delta(f_n) = \{g(\cdot) \in S^1_F : g \geqq f_n\}$. Since $\Delta(f_n)$ is a closed, convex subset of S^1_F and S^1_F is w-compact we deduce that $\Delta(f_n)$ is w-compact for all $n \geqq 1$. Our claim is that $\Delta(f_n)$ has a maximal element with respect to the cone $[L^1_X(\Omega)]_+$. Suppose not. Then for every $g(\cdot) \in \Delta(f_n)$ we can find $g'(\cdot) \in \Delta(f_n)$ s.t. $g' > g$. Since by hypothesis int $X^*_+ \neq \varnothing$ we can see that int $[L^\infty_{X^*_{w^*}}(\Omega)]_+ \neq \varnothing$. Let $\hat{p}(\cdot) \in$ int $(L^\infty_{X^*_{w^*}}(\Omega))_+$. Because $\Delta(f_n)$ is w-compact, there exists $\hat{g}(\cdot) \in \Delta(f_n)$ s.t. $\sigma_{\Delta(f_n)}(\hat{p}) = \langle \hat{p}, \hat{g}\rangle$. From what we said above we can find $\hat{\hat{g}} \in \Delta(f_n)$ s.t. $\hat{\hat{g}} > \hat{g}$. Then $\langle \hat{p}, \hat{\hat{g}} - \hat{g}\rangle > 0$ which means that $\langle \hat{p}, \hat{\hat{g}}\rangle > \sigma_{\Delta(f_n)}(\hat{p})$, a contradiction.

So let $g_n(\cdot) \in \Delta(f_n)$ be maximal. Then clearly $g_n(\cdot)$ is maximal in S^1_F. But then this means that $g_n(\cdot)$ is efficient. Because of the w-compactness of S^1_F and the Eberlein-Smulian theorem (see [11, p. 430]) we may assume, without loss of generality, that

$$g_n \xrightarrow{w\text{-}L^1_X} g \in S^1_F \quad \text{as } n \to \infty.$$

Then $g \geqq f$ and since $f(\cdot)$ is by hypothesis efficient we may conclude (after changing $g(\cdot)$ on a μ-null set) that $g(\omega) = f(\omega)$ for all $\omega \in \Omega$. Q.E.D.

We can have an analogue of Theorem 3.2 for $L^\infty_X(\Omega)$ allocations. Assume that X is reflexive and int $X^*_+ \neq \varnothing$.

THEOREM 3.3. *If $F:\Omega \to P_{wkc}(X)$ is integrably bounded by $\varphi(\cdot) \in L^{\infty}(\Omega)$ then the norm-closure of the set of price efficient allocations with price systems in $[L^1_{X^*}(\Omega)]_+$ contains the set of efficient allocations.*

The proof of this result follows the pattern of the proof of the previous theorem, but instead of the Bishop-Phelps theorem we use a generalization of it due to Phelps [36, Thm. 1].

We can now go further and determine a situation where price efficiency implies efficiency.

So again assume that $\operatorname{int} X_+^+ \neq \varnothing$. Then we have the following result.

PROPOSITION 3.5. *If $F:\Omega \to P_f(X)$ is integrably bounded and $f(\cdot) \in L^1_X(\Omega)$ is price efficient for the price system $p(\cdot) \in \operatorname{int}[L^{\infty}_{X^*_{w^*}}(\Omega)]_+$ then $f(\cdot)$ is efficient.*

Proof. Suppose not. Then as before we can find $\hat{f}(\cdot) \in S^1_F$ s.t. $(\hat{f}-f)(\cdot) \in [L^1_X(\Omega)]_+ \backslash \{0\}$. Then from Borwein [5] we know that

$$\langle p, \hat{f}-f\rangle > 0 \Rightarrow \langle p, \hat{f}\rangle > \sigma_{S^1_F}(p),$$

a contradiction. Q.E.D.

Once again we turn our attention to $L^{\infty}_X(\Omega)$ allocations. As we already mentioned in § 2, the difficulty that we encounter in this case is that $L^1_{X^*}(\Omega) \subsetneq [L^{\infty}_X(\Omega)]^*$ and the elements of $[L^{\infty}_X(\Omega)]^*$ outside $L^1_{X^*}(\Omega)$ do not have in general a satisfactory economic interpretation. So the natural question to ask, is whether we can always choose our price system to belong in $L^1_{X^*}(\Omega)$. The next theorem gives us conditions that produce an affirmative answer to this question.

Before going into the theorem we would like to recall a few facts about $L^{\infty}_X(\Omega)$. Details can be found in Levin [22] and Rockafellar [41]. A functional $x^* \in [L^{\infty}_X(\Omega)]^*$ is said to be "absolutely continuous" relative to μ if $\langle x^*, x(\cdot)\rangle = \int_{\Omega} (x^*(\omega), x(\omega))\, d\mu(\omega)$ for all $x(\cdot) \in L^{\infty}_X(\Omega)$, where $x^*(\cdot) \in L^1_{X^*}(\Omega)$. In this case we call $x^*(\cdot)$ the density of the functional x^*. The absolutely continuous functionals form a closed subspace of $[L^{\infty}_X(\Omega)]^*$ which is isometrically isomorphic to $L^1_{X^*}(\Omega)$. This subspace has a natural complement in $[L^{\infty}_X(\Omega)]^*$, the subspace of singular functionals. A functional $x^* \in [L^{\infty}_X(\Omega)]^*$ is said to be "singular" relative to μ if there exists a sequence of sets $A_n \in \Sigma$ s.t. $A_{n+1} \subseteq A_n$ for all $n \geqq 1$, $\mu(A_n) \downarrow 0$ as $n \to \infty$ and $\langle x^*, x(\cdot)\rangle = 0$ for every $x(\cdot) \in L^{\infty}_X(\Omega)$ which vanishes on some A_n. Then each element $x^* \in [L^{\infty}_X(\Omega)]^*$ has a unique decomposition of the form $x^* = x^*_a + x^*_s$ where x^*_a is absolutely continuous relative to μ and x^*_s is singular relative to μ. Moreover $\|x^*\| = \|x^*_a\| + \|x^*_s\|$.

Assume that $\operatorname{int} X_+ \neq \varnothing$.

THEOREM 3.4. *If $F:\Omega \to P_{fc}(X)$ is integrably bounded by $\varphi(\cdot) \in L^{\infty}(\Omega)$ and $f(\cdot) \in S^{\infty}_F$ is an efficient allocation then there exists $p(\cdot) \in [L^1_{X^*}(\Omega)]_+$ s.t. $f(\cdot)$ is price efficient for that price system $p(\cdot)$.*

Proof. Since by hypothesis $f(\cdot)$ is efficient we know that

$$(f + [\dot{L}^{\infty}_X(\Omega)]_+) \cap S^{\infty}_F = \varnothing \qquad ([\dot{L}^{\infty}_X(\Omega)]_+ = [L^{\infty}_X(\Omega)]\backslash\{0\}).$$

Recall that $\operatorname{int}[L^{\infty}_X]_+ \neq \varnothing$ and that S^{∞}_F is convex. So we can apply the first separation theorem for convex sets and find $p(\cdot) \in [L^{\infty}_X(\Omega)]^* \backslash \{0\}$ s.t.

$$\langle p, f+e\rangle \geqq \langle p, g\rangle$$

for all $e(\cdot) \in [L^{\infty}_X(\Omega)]_+$ and all $g(\cdot) \in S^{\infty}_F$. (Here $\langle \cdot, \cdot \rangle$ denotes the duality brackets between $L^{\infty}_X(\Omega)$ and $[L^{\infty}_X(\Omega)]^*$.) Taking $g = f$ we get that $\langle p, e\rangle \geqq 0$ and since $e(\cdot) \in [L^{\infty}_X(\Omega)]_+$ is arbitrary we conclude that $p(\cdot) \in [L^{\infty}_X(\Omega)]^*_+$.

Next note that $\langle p, f\rangle = \sigma_{S^{\infty}_F}(p)$. We claim that $\langle p_a, f\rangle = \sigma_{S^{\infty}_F}(p_a)$ where p_a is the absolutely continuous part of the functional $p \in [L^{\infty}_X(\Omega)]^*$. Let $\{A_n\}_{n \geqq 1} \subseteq \Sigma$ be the sets

that have, relative to p_s, the property described in the definition of the singular part of p. So $A_{n+1} \subseteq A_n n \geqq 1$ and $\mu(A_n) \downarrow 0$ as $n \to \infty$ while $\langle p_s, g \rangle = 0$ if $g|_{A_n} = 0$ for some $n \geqq 1$. Define

$$g_n(\omega) = \begin{cases} f(\omega) & \text{for } \omega \in A_n, \\ g(\omega) & \text{for } \omega \in \Omega \backslash A_n, \end{cases}$$

where $g(\cdot) \in S_F^\infty$ arbitrary. Clearly $g_n(\cdot) \in S_F^\infty$.

Note that

$$g_n(\cdot) \xrightarrow{\mu} g(\omega) \quad \text{as } n \to \infty.$$

By passing to a subsequence, if necessary, we may assume that $g_n(\omega) \to g(\omega)$ μ-a.e. as $n \to \infty$. Also note that $\langle p_s, g_n - f \rangle = 0$. So we have that

$$\langle p, g_n - f \rangle = \langle p_a + p_s, g_n - f \rangle = \langle p_a, g_n - f \rangle \leqq 0.$$

Applying Lebesgue's dominated convergence theorem we get that $\langle p_a, g_n - f \rangle \to \langle p_a, g - f \rangle \leqq 0$ as $n \to \infty$ and since $g(\cdot) \in S_F^\infty$ was arbitrary we conclude that $\langle p_a, f \rangle = \sigma_{S_F^\infty}(p_a)$ which proves that $f(\cdot)$ is price efficient for the price system $p_a(\cdot) \in L_{X^*}^1(\Omega)$. Q.E.D.

In the next result we examine what happens to price efficient allocations when we have two consumption (or production) multifunctions and we pass to their intersection.

PROPOSITION 3.6. *If $F_1 : \Omega \to P_{kc}(X)$ and $F_2 : \Omega \to P_{fc}(X)$ are integrably bounded, $\operatorname{int} S_{F_2}^1 \neq \varnothing$, $S_{F_1}^1 \cap \operatorname{int} S_{F_2}^1 \neq \varnothing$ and $f(\cdot)$ is price efficient for the multifunction $(F_1 \cap F_2)(\cdot)$ and for the price system $p(\cdot)$ then $f(\cdot)$ is price efficient for $(p(\cdot), F_1(\cdot))$ and $(p(\cdot), F_2(\cdot))$.*

Proof. Because by hypothesis $f(\cdot)$ is price efficient for $p(\cdot)$ and $(F_1 \cap F_2)(\cdot)$ we have that $\langle p, f \rangle = \sigma_{S_{F_1 \cap F_2}^1}(p) = \sigma_{S_{F_1}^1 \cap S_{F_2}^1}(p)$. Since $S_{F_1}^1 \cap \operatorname{int} S_{F_2}^1 \neq \varnothing$ from Moreau [25] we know that

$$\begin{aligned} \sigma_{S_{F_1}^1 \cap S_{F_2}^1}(p) &= [\sigma_{S_{F_1}^1} \square \sigma_{S_{F_2}^1}](p) \\ &= \inf_{p' \in L_{X^{**}(\Omega)}^\infty} [\sigma_{S_{F_1}^1}(p - p') + \sigma_{S_{F_2}^1}(p')] \\ &\geqq \langle p - p', f \rangle + \langle p', f \rangle = \langle p, f \rangle. \end{aligned}$$

Since $\langle p, f \rangle = \sigma_{S_{F_1}^1 \cap S_{F_2}^1}(p)$, we get that the above infimal convolution is exact at $p = p + 0$ and $p = 0 + p$. So $f(\cdot)$ is $(p(\cdot), F_1(\cdot))$ and $(p(\cdot), F_2(\cdot))$ efficient. Q.E.D.

Now we will study the concepts of efficiency and price efficiency for a particular sector of the economy. Recall that we model sectors by sub-σ-fields of Σ.

For that we will need the following lemma, the proof of which can be found in [28, § 5].

LEMMA II. *If $p(\cdot) \in L_{X^*}^\infty(\Omega, \Sigma_0)$ and $f(\cdot) \in L_X^1(\Omega)$ then $\langle p, f \rangle = \langle p, E^{\Sigma_0} f \rangle$.*

For the next theorem assume that X^* is separable. Then from the Dunford-Pettis theorem (see [10]) we know that X^* has the Radon-Nikodym property and so $[L_X^1(\Omega)]^* = L_{X^*}^\infty(\Omega)$. Also assume that X_+^* is generating.

THEOREM 3.5. (i) *If $F : \Omega \to P_{wkc}(X)$ is integrably bounded and $v(\cdot) \in S_{E^{\Sigma_0} F}^1$ is efficient for $E^{\Sigma_0} F(\cdot)$ then there exists $f(\cdot) \in S_F^1$ which is efficient for $F(\cdot)$ and such that $v(\cdot) = E^{\Sigma_0} f(\cdot)$.*

(2) *Suppose $F(\cdot)$ is as above and $p(\cdot) \in [L_{X^*}^\infty(\Omega, \Sigma_0)]_+$. Then: $f(\cdot) \in S_F^1$ is price efficient for $p(\cdot)$, $F(\cdot)$ if and only if $E^{\Sigma_0} f(\cdot) \in S^1(\Sigma_0)$ is price efficient for $p(\cdot)$, $E^{\Sigma_0} F(\cdot)$.*

Proof. (1) From Hiai-Umegaki [13] we know that

$$S^1(\Sigma_0) = \operatorname{cl} E(S_F^1 | \Sigma_0)$$

where the closure is taken in the $L_X^1(\Omega, \Sigma_0)$-norm.

But from Lemma I we know that S_F^1 is w-compact and convex in $L_X^1(\Omega)$. So $E(S_F^1|\Sigma_0) = S^1(\Sigma_0)$. Therefore $v(\cdot) = E^{\Sigma_0} f(\cdot)$ for some $f(\cdot) \in S_F^1$. Our claim is that $f(\cdot)$ is efficient for $F(\cdot)$. Suppose not. Then there exists $A \in \Sigma$ with $\mu(A) > 0$ s.t.

$$G(\omega) = (f(\omega) + \dot{X}_+) \cap F(\omega) \neq \varnothing$$

for all $\omega \in A$. Note that the multifunction $\omega \to f(\omega) + \dot{X}_+$ has a measurable graph. To see that consider $h: (\omega, x) \to (\omega, x - f(\omega))$. Then $h^{-1}(\Omega \times \dot{X}_+) = \operatorname{Gr} G_1$ where $G_1(\omega) = f(\omega) + \dot{X}_+$, and $h(\cdot, \cdot)$ is $(\Sigma \cap A) \times B(X)$-measurable. So $\operatorname{Gr} G = \operatorname{Gr} G_1 \cap \operatorname{Gr} F \in (\Sigma \cap A) \times B(X)$. Hence we can apply Aumann's measurable selection theorem and find $g: A \to X$ measurable s.t. $g(\omega) \in (f(\omega) + X_+) \cap F(\omega) \omega \in A$. Next define

$$\tilde{g}(\omega) = \begin{cases} g(\omega) & \text{for } \omega \in A, \\ f(\omega) & \text{for } \omega \in \Omega \backslash A. \end{cases}$$

Clearly $\tilde{g} > f$. Then for all $p(\cdot) \in [L_{X^*}^{\infty}(\Omega, \Sigma_0)]^*$ we have that

$$\langle p, \tilde{g} - f \rangle \geqq 0 \Rightarrow \langle p, E^{\Sigma_0}(g - f) \rangle \geqq 0 \quad \text{(by Lemma II)}$$

$$\Rightarrow E^{\Sigma_0} \tilde{g} \geqq E^{\Sigma_0} f.$$

We claim that $E^{\Sigma_0} \tilde{g} > E^{\Sigma_0} f$. Because if $E^{\Sigma_0} \tilde{g}(\omega) = E^{\Sigma_0} f(\omega)$ μ-a.e. then $\int_\Omega E^{\Sigma_0} \tilde{g}(\omega)\, d\mu(\omega) = \int_\Omega E^{\Sigma_0} f(\omega)\, d\mu(\omega)$. Hence

$$\int_\Omega \tilde{g}(\omega)\, d\mu(\omega) = \int_\Omega f(\omega)\, d\mu(\omega)$$

$$\Rightarrow \left(x^*, \int_\Omega \tilde{g}(\omega)\, d\mu(\omega) \right) = \left(x^*, \int_\Omega f(\omega)\, d\mu(\omega) \right) \quad \text{for all } x \in X_+^*$$

$$\Rightarrow \int_\Omega (x^*, \tilde{g}(\omega))\, d\mu(\omega) = \int_\Omega (x^*, f(\omega))\, d\mu(\omega)$$

$$\Rightarrow \int_\Omega (x^*, \tilde{g}(\omega) - f(\omega))\, d\mu(\omega) = 0.$$

Recall that $(x^*, \tilde{g}(\omega) - f(\omega)) \geqq 0$ μ-a.e. Hence $(x^*, \tilde{g}(\omega) - f(\omega)) = 0$ μ-a.e. for $x^* \in X_+^*$. Since by hypothesis X_+^* is generating, we get that for all $x^* \in X^*(x^*, \tilde{g}(\omega) - f(\omega)) = 0$ μ-a.e. and so $\tilde{g}(\omega) = f(\omega)$ μ-a.e., a contradiction. So $E^{\Sigma_0} f < E^{\Sigma_0} \tilde{g}$ which in turn contradicts the efficiency of $E^{\Sigma_0} f(\cdot) = v(\cdot)$ because $E^{\Sigma_0} \tilde{g} \in E^{\Sigma_0} S_F^1 = S_{E^{\Sigma_0} F}^1$. Therefore $f(\cdot)$ is indeed efficient for $F(\cdot)$.

(2) Suppose $f(\cdot) \in S_F^1$ is price efficient for $p(\cdot)$ and $F(\cdot)$, with $p(\cdot) \in [L_{X^*}^{\infty}(\Omega, \Sigma_0)]_+$. This means that

$$\langle p, f \rangle = \sigma_{S_F^1}(p)$$

$$\Rightarrow \int_\Omega (p(\omega), f(\omega))\, d\mu(\omega) = \sup_{g(\cdot) \in S_F^1} \int_\Omega (p(\omega), g(\omega))\, d\mu(\omega)$$

$$= \int_\Omega \sup_{y \in F(\omega)} (p(\omega), y)\, d\mu(\omega)$$

$$= \int_\Omega \sigma_{F(\omega)}(p(\omega))\, d\mu(\omega).$$

Using Lemma II and Bismut [4] we get that

$$\int_\Omega (p(\omega), E^{\Sigma_0} f(\omega))\, d\mu(\omega) = \int_\Omega E^{\Sigma_0} \sigma_{F(\omega)}(p(\omega))\, d\mu(\omega).$$

From [13, Thm. 5.5] (see also Valadier [48]) we know that

$$\int_\Omega E^{\Sigma_0}\sigma_{F(\omega)}(p(\omega))\,d\mu(\omega)=\int_\Omega \sigma_{\Sigma_0(\omega)}(p(\omega))\,d\mu(\omega)=\sigma_{S^1(\Sigma_0)}(p)$$

where $\sigma_{\Sigma_0(\omega)}(\cdot)=\sigma_{E^{\Sigma_0}F(\omega)}(\cdot)$.

Hence $\langle p, E^{\Sigma_0}f\rangle=\sigma_{S^1(\Sigma_0)}(p)$ which proves that $E^{\Sigma_0}f(\cdot)$ is price efficient for $p(\cdot)$ and $E^{\Sigma_0}F(\cdot)$.

Now suppose that $E^{\Sigma_0}f\in S^1(\Sigma_0)$ is price efficient for $p(\cdot)$ and $E^{\Sigma_0}F(\cdot)$. Then we have

$$\langle p, E^{\Sigma_0}f\rangle=\sigma_{S^1(\Sigma_0)}(p)=\int_\Omega \sigma_{\Sigma_0(\omega)}(p(\omega))\,d\mu(\omega)=\int_\Omega E^{\Sigma_0}\sigma_{F(\omega)}(p(\omega))\,d\mu(\omega).$$

Again by Lemma II and [4] we get that

$$\langle p, f\rangle=\int_\Omega \sigma_{F(\omega)}(p(\omega))\,d\mu(\omega)=\sigma_{S^1_F}(p).$$

which proves that $f(\cdot)$ is price efficient for $p(\cdot)$ and $F(\cdot)$. Q.E.D.

We will conclude this section by studying the topological properties of the set of weakly efficient allocations. We will denote that set by $wE(F)$.

Our first result is the following.

THEOREM 3.6. *If $F:\Omega\to P_f(X)$ is integrably bounded then $wE(F)$ is a w-closed subset of $L^1_X(\Omega)$.*

Proof. Let $\{f_\delta(\cdot)\}_{\delta\in\Delta}$ be a net in $wE(F)$ and suppose that $f_\delta \xrightarrow{w\text{-}L^1_X} f$. We will show that $f(\cdot)\in wE(F)$. Suppose not. Then there exists $B\in\Sigma$ with $\mu(B)>0$ s.t. for all $\omega\in B(f(\omega)+\operatorname{int} X_+)\cap F(\omega)\neq\varnothing$. For $\omega\in B$ let $R(\omega)=(f(\omega)+\operatorname{int} X_+)\cap F(\omega)$. Note that $\operatorname{Gr} R=\operatorname{Gr}(f(\cdot)+\operatorname{int} X_+)\cap \operatorname{Gr} F$ and as in the proof of Theorem 3.5 we can show that $\operatorname{Gr} R\in\Sigma_B\times B(X)$. Applying Aumann's measurable selection theorem we can find $r:B\to X$ measurable s.t. $r(\omega)\in R(\omega)\omega\in B$. So $r(\omega)\gg f(\omega)\in B$ (i.e., $r(\omega)-f(\omega)\in \operatorname{int} X_+$ for all $\omega\in B$). Therefore for every $A\in\Sigma$, $A\subseteq B$ and every $x^*\in X^*_+$ we have that

$$\int_A (x^*, r(\omega))\,d\mu(\omega)>\int_A (x^*, f(\omega))\,d\mu(\omega).$$

Since by hypothesis $f_\delta \xrightarrow{w\text{-}L^1_X} f$ we can find $\delta_0\in\Delta$ s.t. for $\delta\in\Delta$ $\delta\geqq\delta_0$ we have that

$$\int_A (x^*, r(\omega))\,d\mu(\omega)>\int_A (x^*, f_\delta(\omega))\,d\mu(\omega)\Rightarrow\int_A (x^*, r(\omega)-f_\delta(\omega))\,d\mu(\omega)>0$$

and this is true for all $A\in\Sigma$, $A\subseteq B$, $x^*\in X^*_+$ and $\delta\geqq\delta_0$. So we have that

$$(x^*, r(\omega)-f_\delta(\omega))>0\quad \mu_{\hat{A}}\text{-a.e.}$$

for some $\hat{A}\in\Sigma$, $\hat{A}\subseteq B\mu(\hat{A})>0$ and for all $x^*\in \dot{X}^*_+$. Hence $r(\omega))\gg f_\delta(\omega)$ $\mu_{\hat{A}}$-a.e. From that we get that

$$(f_\delta(\omega)+\operatorname{int} X_+)\cap F(\omega)\neq\varnothing$$

for all $\omega\in\hat{A}$ and all $\delta\geqq\delta_0$, a contradiction. So $f(\cdot)\in wE(F)$ and so $wE(F)$ is w-closed in $L^1_X(\Omega)$. Q.E.D.

If we strengthen our hypotheses on $F(\cdot)$ and X we can deduce even more about $wE(F)$. So assume that X is finite-dimensional and that $wE(F)\neq\varnothing$.

THEOREM 3.7. *If $F:\Omega\to P_k(X)$ is integrably bounded and for all $\omega\in\Omega$ $\operatorname{int} F(\omega)\neq\varnothing$ then $wE(F)$ is a w-compact subset of $L^1_X(\Omega)$.*

Proof. We already know that $wE(F)$ is w-closed. Clearly it is also bounded. So if we can show that every element in $[L_X^1(\Omega)]^* = L_{X^*}^\infty(\Omega)$ achieves its supremum on $wE(F)$, by James' theorem we are done.

So let $x^*(\cdot) \in L_{X^*}^\infty(\Omega)$. Then we have that

$$\sup_{f(\cdot)\in wE(F)} \langle x^*, f\rangle = \sup_{f(\cdot)\in wE(F)} \int_\Omega (x^*(\omega), f(\omega))\, d\mu(\omega).$$

Consider the multifunction $\omega \to wE(\omega) = \{x \in F(\omega): (x + \operatorname{int} X_+) \cap F(\omega) = \varnothing\}$. Clearly this is nonempty. We will show that it is also closed valued. Let $\{x_n\} \subseteq wE(\omega)$ and $x_n \to x$ and $n \to \infty$. Then $x \in F(\omega)$. Also for all $n \geqq 1$ $(x_n + \operatorname{int} X_+) \cap F(\omega) = \varnothing$. So $(x + \operatorname{int} X_+) \cap \operatorname{int} F(\omega) = \varnothing$. Suppose $x \notin wE(F)$. Then $(x + \operatorname{int} X_+) \cap F(\omega) \neq \varnothing$ and so $(x + \operatorname{int} X_+) \cap \operatorname{int} F(\omega) \neq \varnothing$. Since $(x_n + \operatorname{int} X_+) \to (x + \operatorname{int} X_+)$ in the Kuratowski sense, from Theorem 2.2 of Salinetti-Wets [47] we have that $(x_n + \operatorname{int} X_+) \cap \operatorname{int} F(\omega) \neq \varnothing$ for all $n \geqq n_0$, a contradiction. Hence for all $\omega \in \Omega$, $wE(\omega)$ is closed. Now observe that

$$\operatorname{Gr} wE(\cdot) = [\operatorname{dom} \Phi]^c \cap \operatorname{Gr} F,$$

where $\Phi(\omega, x) = (x + \operatorname{int} X_+) \cap F(\omega)$. It is easy to see that the graph of $\Phi(\cdot, \cdot)$ is $\Sigma \times B(X) \times B(X)$-measurable. So by Theorem 3.4 and Propositions 2.1 and 2.2 of Himmelberg [14] we have that $\operatorname{dom} \Phi \in \Sigma \times B(X)$. Therefore $\operatorname{Gr} wE(\cdot) \in \Sigma \times B(X)$ and then this tells us that $\omega \to wE(\omega)$ is measurable. Applying [13, Thm. 2.2] we get that

$$\sup_{f(\cdot)\in wE(F)} \langle x^*, f\rangle = \int_\Omega \sup_{x\in wE(\omega)} (x^*(\omega), x)\, d\mu(\omega).$$

Since $wE(\omega)$ is a closed subset of $F(\omega)$ it is compact. Hence if we define

$$M(\omega) = \{\hat{x} \in wA(\omega): (x^*(\omega), \hat{x}) = \sup_{x\in wE(\omega)} (x^*(\omega), x)\}$$

this set is nonempty and closed for all $\omega \in \Omega$. Also from [14, Thm. 6.4] we have that $\omega \to M(\omega)$ is measurable. Then by the Kuratowski-Ryll Nardzewski selection theorem we can find $\hat{x}: \Omega \to X$ measurable s.t. $\hat{x}(\omega) \in wE(\omega)\omega \in \Omega$. So $\hat{x}(\cdot) \in wE(F)$ and

$$\sup_{f\in wE(F)} \langle x^*, f\rangle = \langle x^*, \hat{x}\rangle$$

which means that $wE(F)$ is w-compact in $L_X^1(\Omega)$. Q.E.D.

Remark. If $F(\cdot)$ is also convex valued then we know that automatically we have $\operatorname{rint} F(\omega) \neq \varnothing$ for all $\omega \in B$. So the interiority assumption on $F(\cdot)$ is redundant.

4. Optimal allocations. In this section we focus our attention on optimal allocations. We will start with a powerful existence result. For that purpose we need to introduce the following notion:

a function $\varphi: X \to \bar{\mathbb{R}}$ is said to be quasi-sup-w-compact if and only if there exists $\hat{\beta} \in \mathbb{R}$ s.t. for $\beta \geqq \hat{\beta}$ we have that $U_\beta^\varphi = \{x \in X: \varphi(x) \geqq \beta\}$ is w-compact.

Using this concept we can have the following existence result.

THEOREM 4.1. *If $u: \Omega \times X \to \bar{\mathbb{R}}$ is an integrand s.t.*

(i) *$u(\cdot, \cdot)$ is $\Sigma \times B(X)$-measurable and as a function of x is weakly upper semicontinuous,*

(ii) *$u(\omega, \cdot)$ is μ-a.e. quasi-sup-w-compact, and if $F: \Omega \to P_{fc}(X)$ is integrably bounded then there exists an optimal allocation.*

Proof. Let $\beta \geqq \hat{\beta}$. Then for all $\omega \in \Omega$ we have that

$$\begin{aligned} U^{u(\omega,\cdot)} &= \{x \in X: u(\omega, x) \geqq \beta\} \\ &\supseteq \{x \in X: u(\omega, x) - \delta_{F(\omega)}(x) \geqq \beta\} \\ &= U_{\beta}^{[u(\omega,\cdot)-\delta_{F(\omega)}(\cdot)]} = \Lambda_{\beta}(\omega). \end{aligned}$$

So for μ-almost all $\omega \in \Omega$ and for $\beta \geqq \hat{\beta}$ we have that $\Lambda_{\beta}(\omega)$ is w-compact. Now observe that

$$\sup_{x \in X} [u(\omega, x) - \delta_{F(\omega)}(x)] = \sup_{x \in \Lambda_{\beta}(\omega)} [u(\omega, x) - \delta_{F(\omega)}(x)] = \sup_{x \in \Lambda_{\beta}(\omega)} u(\omega, x).$$

By the Weierstrass theorem we know that the above supremum is attained for μ-almost all $\omega \in \Omega$. Define

$$G(\omega) = \{\hat{x} \in F(\omega): u(\omega, \hat{x}) = m(\omega)\}$$

where $m(\omega) = \sup_{x \in F(\omega)} u(\omega, x)$. Using Castaing's representation theorem and the weak upper-semicontinuity of $u(\omega, \cdot)$, it is easy to see that $m(\cdot)$ is measurable. By redefining $G(\cdot)$ on a μ-null set (if necessary) we may assume that $G(\omega) \neq \varnothing$ for all $\omega \in \Omega$. Also note that $\operatorname{Gr} G = \{(\omega, \hat{x}) \in \Omega \times X: u(\omega, \hat{x}) = m(\omega)\} \cap \operatorname{Gr} F \in \Sigma \times B(X)$. Hence we can apply Aumann's measurable selection theorem to find $f: \Omega \to X$ measurable s.t. $f(\omega) \in G(\omega) \omega \in \Omega$. So $f(\cdot) \in S_F^1$ and

$$u(\omega, g(\omega)) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

for all $g(\cdot) \in S_F^1$. Thus $f(\cdot)$ is an optimal allocation. Q.E.D.

The next result is another existence result. It provides a set of conditions on $u(\cdot, \cdot)$ and $F(\cdot)$ under which there exists an optimal allocation which is also price efficient. Such an allocation is sometimes called "competitive optimal allocation".

THEOREM 4.2. *If $F: \Omega \to P_{wkc}(X)$ is integrably bounded and $u: \Omega \times X \to \bar{\mathbb{R}}$ is such that*

(i) *$u(\cdot, \cdot)$ is a $\Sigma \times B(X)$-measurable,*

(ii) *$u(\omega, \cdot)$ is monotone increasing and concave for all $\omega \in \Omega$,*

(iii) *for every $g(\cdot) \in S_F^1 \left| \int_{\Omega} u(\omega, g(\omega))\, d\mu(\omega) \right| < +\infty$,*

(iv) *there exists $x^*(\cdot) \in L_{X^*}^{\infty}(\Omega)$ s.t. $\int_{\Omega} u^*(\omega, x^*(\omega))\, d\mu(\omega) > -\infty$,*

then there exists a competitive optimal allocation.

Remark. Here $u^*(\cdot, \cdot)$ denotes the concave conjugate of $u(\omega, \cdot)$.

Proof. From Lemma I of § 3 we know that S_F^1 is a w-compact subset of $L_X^1(\Omega)$. Also from hypothesis (iii) and using the results of Rockafellar [42, Thm. 21] applied in this case to concave functions, we get that

$$(I_u)^*(\cdot) = I_{u^*}(\cdot).$$

Furthermore hypothesis (iv) allows us to apply once more that result of Rockafellar and get that

$$(I_{u^*})^*(\cdot) = I_{u^{**}}(\cdot).$$

But recall that $u^{**}(\cdot) = u(\cdot)$. Hence

$$(I_u)^{**}(\cdot) = I_u(\cdot)$$

which means $I_u(\cdot)$ is continuous with respect to any topology on $L_X^1(\Omega)$ compatible with the duality $(L_X^1(\Omega), L_{X_{w^*}^*}^{\infty}(\Omega))$. So the Weierstrass theorem tells us that $I_u(\cdot)$ achieves its supremum on the w-compact set S_F^1. Let $\hat{f}(\cdot) \in S_F^1$ s.t.

$$I_u(\hat{f}) = \sup_{g(\cdot) \in S_F^1} I_u(g).$$

Also because of the monotonicity of $u(\omega, \cdot)$ for all $\omega \in \Omega$ we can easily see that

$$I_u(\hat{f}) = \sup_{g(\cdot) \in [S_F^1 - (L_X^1)_+]} I_u(g).$$

If we set

$$\hat{\delta}(g) = \begin{cases} 0 & \text{if } g \in S_F^1 - (L_X^1)_+, \\ -\infty & \text{otherwise,} \end{cases}$$

(it is easy to see that this is concave and u.s.c.) then from the well-known extremality condition of convex analysis (applied to concave functions and their "superdifferential" $\partial(\cdot)$) we have that

$$0 \in \partial[I_u + \tilde{\delta}](\hat{f}).$$

Now apply the Moreau-Rockafellar theorem [38] and get that

$$0 \in \partial I_u(\hat{f}) + \partial \tilde{\delta}(\hat{f}).$$

So there exists $p(\cdot) \in \partial I_u(\hat{f})$ s.t. $-p(\cdot) \in \partial \tilde{\delta}(\hat{f})$. This second fact implies that

$$\langle p, \hat{f} \rangle \geqq \langle p, g \rangle$$

for all $g(\cdot) \in [S_F^1 - (L_X^1)_+]$. Hence

$$\langle p, \hat{f} \rangle \geqq \langle p, g \rangle - \langle p, e \rangle$$

for all $g(\cdot) \in S_F^1$ and all $e(\cdot) \in (L_X^1)_+$. Take $g = \hat{f}$ to conclude that $p(\cdot) \in [L_{X_w^*}^\infty(\Omega)]_+$. Also from Rockafellar [42] we know that $p(\cdot) \in \partial I_u(\hat{f})$ implies that $p(\omega) \in \partial u(\omega, \hat{f}(\omega))$ μ-a.e. and so

$$(*) \qquad u(\omega, g(\omega)) - u(\omega, \hat{f}(\omega)) \leqq (p(\omega), g(\omega) - \hat{f}(\omega)) \quad \mu\text{-a.e.}$$

for all $g(\cdot) \in S_F^1$. Also it is easy to see that

$$\tilde{\delta}_{S_F^1}(g) = \int_\Omega \tilde{\delta}_{F(\omega)}(g(\omega))\, d\mu(\omega)\, g(\cdot) \in S_F^1.$$

Since $-p(\cdot) \in \partial \tilde{\delta}_{S_F^1}(\hat{f})$ we get that $-p(\omega) \in \partial \tilde{\delta}_{F(\omega)}(\hat{f}(\omega))$, u-a.e. which means that $(p(\omega), \hat{f}(\omega)) \geqq (p(\omega), g(\omega))$ μ-a.e. for all $g(\cdot) \in S_F^1$. Using this fact and (*) we conclude that

$$u(\omega, g(\omega)) \leqq u(\omega, \hat{f}(\omega)) \quad \mu\text{-a.e.}$$

for all $g(\cdot) \in S_F^1$. So $\hat{f}(\cdot)$ is a competitive optimal allocation. Q.E.D.

Now we will pass to utility (profit) functions $u(\cdot, \cdot)$ that are not concave.

We start with a result that gives us a necessary condition for the optimality of an allocation.

THEOREM 4.3. *If $F: \Omega \to P_f(X)$ is integrably bounded $u: \Omega \times X \to \mathbb{R}$ is an integrand s.t.*

(i) *$u(\omega, \cdot)$ is Lipschitz and increasing for all $\omega \in \Omega$,*

(ii) *$u(\cdot, x)$ is measurable for all $x \in X$,*

and if $f(\cdot) \in S_F^1$ is an optimal allocation then there exists $p(\cdot) \in [L_{X_{w^*}^*}^\infty(\Omega)]_+$ s.t. $p(\omega) \in \partial u(\omega, f(\omega))$ μ-a.e.

Remark. Here ∂ denotes Clarke's generalized subdifferential. For details we refer to Clarke [7], [9] and Rockafellar [43].

Proof. Because $f(\cdot) \in S_F^1$ is by hypothesis an optimal allocation we have that

$$u(\omega, g(\omega)) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

for all $g(\cdot) \in S_F^1$. Since $u(\omega, \cdot)$ is by hypothesis increasing we have that

$$I_u(g) \leqq I_u(f)$$

for all $g(\cdot) \in S_F^1 - (L_X^1(\Omega))_+$. Hence

$$\sup_{g(\cdot) \in S_F^1 - (L_X^1)_+} I_u(g) = I_u(f).$$

Note that if $A = S_F^1 - (L_X^1)_+$ for some $k > 0$ large enough

$$\sup_{g(\cdot) \in A} I_u(g) = \sup_{g(\cdot) \in L_X^1} [I_u(g) - kd_A(g)] = I_u(f).$$

We know that $d_A(\cdot)$ is Lipschitz. Then from Clarke [9] we know that $0 \in \partial[I_u - kd_A](g)$. Recall that Clarke's generalized subdifferential is subadditive and $\partial(-kd_A)(\cdot) = -\partial kd_A(\cdot)$ (see [9]). So we get that

$$0 \in \partial I_u(f) - \partial kd_A(F) \Rightarrow \partial I_u(f) \cap \partial kd_A(f) \neq \varnothing.$$

Let $p(\cdot) \in \partial I_u(f) \cap \partial kd_A(f)$. Then we have that

$$\langle p, \tilde{g} - f \rangle \leqq kd_A^0(f; \tilde{g} - f)$$

for all $\tilde{g}(\cdot) \in L_X^1(\Omega)$. Fix $e(\cdot) \in (L_X^1)_-$, otherwise arbitrary. Then

$$\langle p, f + e - f \rangle = \langle p, e \rangle \leqq kd_A^0(f; e).$$

From Hiriart-Urruty [15] we know that

$$d_A^0(f; e) = \overline{\lim_{\substack{g' \to f \\ g' \in A \\ \lambda \downarrow 0}}} \frac{d_A(g' + \lambda e)}{\lambda} = 0 \Rightarrow \langle p, e \rangle \leqq 0$$

$$\Rightarrow p(\cdot) \in [L_{X_{w^*}^*}^{\infty}(\Omega)]_+.$$

Also from Clarke [9] we know that if $p(\cdot) \in \partial I_u(f)$ then $p(\omega) \in \partial u(\omega, f(\omega))$ μ-a.e. Q.E.D.

Remark. If $F(\cdot)$ is also convex valued, then S_F^1 is convex and so is $d_A(\cdot)$. In this case generalized and convex subdifferentials coincide and so $\partial kd_A(f) = N_A(f)$. This means that $\langle p, f \rangle = \sigma_A(p) = \sigma_{S_F^1}(p)$. So we obtain the following extension of Theorem 4.3.

COROLLARY. *If all hypotheses of Theorem* 4.3 *hold and* $F(\cdot)$ *is, in addition, convex valued then* $f(\cdot)$ *is a competitive optimal allocation.*

We will conclude this section with another necessary condition for optimality in the absence of concavity. Now take $u(\omega, \cdot)$ to be locally Lipschitz $\omega \in \Omega$.

THEOREM 4.4. *If* $u(\cdot, \cdot)$ *and* $F(\cdot)$ *are as in Theorem* 4.3 *and* $f(\cdot) \in S_F^1$ *is an optimal allocation then for all* $e \in X_+$, $u^0(f(\omega); e) \geqq 0$ μ-*a.e.*

Proof. Using the Castaing representation of $F(\cdot)$ and the continuity of $u(\omega, \cdot)$ we can easily see that for all $x \in F(\omega)$

$$u(\omega, x) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

Let $v(\omega, x) = -u(\omega, x)$. Then for all $x \in F(\omega)$ we have that

$$v(\omega, x) \geqq v(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

So $f(\omega)$ is μ-a.e. the minimum of the locally Lipschitz function $v(\omega, \cdot)$ on the set $F(\omega)$. Furthermore because of the monotonicity of $u(\omega, \cdot)$ we can say that $f(\omega)$ is

μ-a.e. the minimum of $v(\omega, \cdot)$ on $F(\omega) - X_+$. From Hiriart-Urruty [16] we deduce that

$$v^0(\omega, f(\omega); h) \geqq 0 \quad \mu\text{-a.e.}$$

for all $h \in \tau_{F(\omega)-X_+}(f(\omega))$ (where τ denotes Clarke's tangent cone (see [7], [16], [43])). So

$$(-u)^0(\omega, f(\omega); h) = u^0(\omega, f(\omega); -h) \geqq 0 \quad \mu\text{-a.e.}$$

Note that $X_- \subseteq \tau_{F(\omega)-X_+}(f(\omega))$. Hence for all $e \in X_+$ we have that

$$u^0(\omega, f(\omega); e) \geqq 0 \quad \mu\text{-a.e.} \qquad \text{Q.E.D.}$$

5. Approximate efficiency and optimality. Sometimes price efficient and optimal allocations may not exist or it may be difficult to obtain them. In cases like these our objective is to approximate as closely as possible those ideal situations. This motivated the introduction of the $\varepsilon(\cdot)$-optimal and the ε-price efficient allocations. In this section we examine such allocations.

Naturally enough we will start with an existence result. Clearly from their definition, ε-price efficient allocations always exist. Let us see what is the situation with $\varepsilon(\cdot)$-optimal allocations.

PROPOSITION 5.1. *If $u: \Omega \times X \to \bar{\mathbb{R}}$ is a $\Sigma \times B(X)$-measurable integrand and $F: \Omega \to P_f(X)$ is an integrably bounded multifunction then for any $\varepsilon(\cdot) \in [L^1(\Omega)]_+$ s.t. $\varepsilon(\omega) > 0$ μ-a.e. $\varepsilon(\cdot)$-optimal allocation always exist.*

Proof. Consider the following multifunction

$$G(\omega) = \{\bar{x} \in F(\omega): \sup_{x \in F(\omega)} u(\omega, x) - \varepsilon(\omega) \leqq u(\omega, \bar{x})\}.$$

Clearly $G(\omega) \neq \varnothing$. By appropriately redefining $G(\cdot)$ on the exceptional μ-null set we may assume that $G(\cdot)$ is nonempty and closed valued. Also if $m(\omega) = \sup_{s \in F(\omega)} u(\omega, x)$ then we have that $m(\omega) > \lambda$ if and only if there exists $x \in F(\omega)$ s.t. $u(\omega, x) > \lambda$. So we see that

$$\{\omega \in \Omega;\ m(\omega) > \lambda\} = \mathrm{pr}_\Omega [\{(\omega, x) \in \Omega \times X: u(\omega, x) > \lambda\} \cap \mathrm{Gr}\, F].$$

From Saint-Beuve's projection theorem [44] we know that $\mathrm{pr}_\Omega [\{(\omega, x) \in \Omega \times X: u(\omega, x) > \lambda\} \cap \mathrm{Gr}\, F] \in \Sigma$. So $m(\cdot)$ is Σ-measurable. Let $\psi(\omega, x) = m(\omega) - \varepsilon(\omega) - u(\omega, x)$. Clearly this integrand is $\Sigma \times B(X)$-measurable and also $G(\omega) = \{x \in F(\omega): \psi(\omega, x) \leqq 0\}$. So

$$\mathrm{Gr}\, G = \{(\omega, x) \in \Omega \times X: \psi(\omega, x) \leqq 0\} \cap \mathrm{Gr}\, F \in \Sigma \times B(X).$$

This allows us to apply Aumann's measurable selection theorem and get $f: \Omega \to X$ measurable s.t. $f(\omega) \in G(\omega) \omega \in \Omega$. Hence

$$m(\omega) - \varepsilon(\omega) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

$$\Rightarrow u(\omega, g(\omega)) - \varepsilon(\omega) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

for all $g(\cdot) \in S_F^1$. This means that $f(\cdot) \in S_F^1$ is $\varepsilon(\cdot)$-optimal. Q.E.D.

Now we will compare $\varepsilon(\cdot)$-optimal allocations with ε-price efficient allocations.

PROPOSITION 5.2. *If $u: \Omega \times X \to \mathbb{R}$ is a Caratheodory, concave, increasing integrand s.t. for all $x \in X |u(\omega, x)| \leqq \varphi(\omega)$ μ-a.e. where $\varphi(\cdot) \in L^1(\Omega)$ and if $F: \Omega \to P_{fc}(X)$ is integrably bounded then every $\varepsilon(\cdot)$-optimal allocation is ε'-price efficient where $\varepsilon' \leqq \int_\Omega \varepsilon(\omega)\, d\mu(\omega) = \varepsilon$.*

Proof. Since by hypothesis $f(\cdot) \in S_F^1$ is $\varepsilon(\cdot)$-optimal we have for all $g(\cdot) \in S_F^1$ that

$$u(\omega, g(\omega)) - u(\omega, f(\omega)) \leqq \varepsilon(\omega) \quad \mu\text{-a.e.}$$

$$\Rightarrow \int_\Omega u(\omega, g(\omega))\, d\mu(\omega) - \int_\Omega u(\omega, f(\omega))\, d\mu(\omega) \leqq \int_\Omega \varepsilon(\omega)\, d\mu(\omega)$$

$$\Rightarrow I_u(g) - I_u(f) \leqq \varepsilon.$$

Because $u(\omega, \cdot)$ is monotone increasing for all $\omega \in \Omega$, we can also say that

$$I_u(g') - I_u(f) \leqq \varepsilon$$

for all $g'(\cdot) \in S_F^1 - (L_X^1)_+$. This means that

$$0 \in \partial_\varepsilon (I_u + \tilde{\delta}_{S_F^1 - (L_X^1)_+})(f).$$

From Hiriart-Urruty [18, Thm. 2.1] we know that there exist $\varepsilon_1, \varepsilon_2 \geqq 0$ s.t. $\varepsilon_1 + \varepsilon_2 = \varepsilon$ and

$$0 \in \partial_{\varepsilon_1} I_u(f) + \partial_{\varepsilon_2} \tilde{\delta}(f).$$

Hence there exists $p(\cdot) \in \partial_{\varepsilon_1} I_u(f)$ s.t. $-p(\cdot) \in \partial_{\varepsilon_2} \tilde{\delta}(f)$. This last fact tells us that

$$\langle -p, g' \rangle - \varepsilon_2 \leqq \langle -p, f \rangle$$

for all $g'(\cdot) \in S_F^1 - (L_X^1)_+$. Let $e(\cdot) \in (L_X^1)_+$ be arbitrary and set $g' = f - e$. Then we have that

$$\langle -p, -e \rangle \leqq \varepsilon_2 \Rightarrow \langle p, e \rangle \leqq \varepsilon_2$$

$$\Rightarrow p(\cdot) \in -(L_X^1)_+.$$

Next observe that for all $g(\cdot) \in S_F^1$

$$\langle -p, g \rangle - \varepsilon_2 \leqq \langle -p, f \rangle, \quad (-p(\cdot) \in (L_X^1)_+)$$

which means that $f(\cdot)$ is ε_2-price efficient and $\varepsilon_2 \leqq \varepsilon$. Q.E.D.

The next result tells us that given an approximately optimal allocation and any number $\delta > 0$, we can find another, at least as good allocation, which is within a distance δ from the original one for the sup-norm.

THEOREM 5.1. *If $u: \Omega \times X \to \mathbb{R}$ is a Caratheodory integrand $F: \Omega \to P_f(X)$ is integrably bounded, $f(\cdot) \in S_F^1$ is $\varepsilon(\cdot)$-optimal and $\lambda > 0$ then we can find $\hat{f}(\cdot) \in S_F^1$ which is $\hat{\varepsilon}(\cdot)$-optimal with $\hat{\varepsilon}(\omega) \leqq \varepsilon(\omega)$ μ-a.e. and $\|\hat{f}(\omega) - f(\omega)\| \leqq \lambda$ μ-a.e.*

Proof. Consider the following multifunction

$$\Gamma(\omega) = \Big\{ x \in F(\omega) : u(\omega, f(\omega)) \leqq u(\omega, x), \|f(\omega) - x\| \leqq \lambda$$

$$u(\omega, z) < u(\omega, x) + \frac{\varepsilon(\omega)}{\lambda} \|x - z\| \text{ for all } z \neq x z \in F(\omega) \Big\}.$$

From the Ekeland variational principle [12] we know that for all $\omega \in \Omega$, $\Gamma(\omega) \neq \varnothing$. Also recalling that $\operatorname{Gr} F \in \Sigma \times B(X)$ and that $u(\cdot, \cdot)$ being a Caratheodory integrand is $\Sigma \times B(X)$-measurable, we can easily conclude that $\operatorname{Gr} \Gamma \in \Sigma \times B(X)$.

Apply Aumann's measurable selection theorem to find $\hat{f}: \Omega \to X$ measurable s.t. $\hat{f}(\omega) \in \Gamma(\omega)$, $\omega \in \Omega$. So we have that

$$u(\omega, z) - \varepsilon(\omega) \leqq u(\omega, f(\omega)) \leqq u(\omega, \hat{f}(\omega)) \quad \mu\text{-a.e.} \qquad z \in F(\omega), \tag{5.1}$$

$$\|\hat{f}(\omega)-f(\omega)\| \leqq \lambda \quad \mu\text{-a.e.}, \tag{5.2}$$

$$u(\omega, z)-\frac{\varepsilon(\omega)}{\lambda}\|z-\hat{f}(\omega)\| \leqq u(\omega, f(\omega)) \quad \text{for all } z \in F(\omega)\backslash\{\hat{f}(\omega)\}. \tag{5.3}$$

From (5.3) we get that

$$u(\omega, z)-\frac{\varepsilon(\omega)}{\lambda}\operatorname{diam} F(\omega) \leqq u(\omega, \hat{f}(\omega)). \tag{5.3'}$$

Note that diam $F(\omega)<\infty$ μ-a.e. Set

$$\hat{\varepsilon}(\omega)=\min\left[\varepsilon(\omega), \frac{\varepsilon(\omega)}{\lambda}\operatorname{diam} F(\omega)\right].$$

Using Castaing's representation it is easy to see that $\omega \to \operatorname{diam} F(\omega)$ is measurable. So $\omega \to \hat{\varepsilon}(\omega)$ is measurable. From (5.1), (5.2) and (5.3') we get that

$$\|\hat{f}(\omega)-f(\omega)\| \leqq \lambda \quad \mu\text{-a.e.}$$

and

$$u(\omega, z)-\hat{\varepsilon}(\omega) \leqq u(\omega, \hat{f}(\omega)) \quad \mu\text{-a.e.}$$

which tells us that $\hat{f}(\cdot) \in S_F^1$ is the desired allocation. Q.E.D.

Sometimes ε-price efficient allocations are called ε-profit maximizing allocations. Using this concept of ε-profit maximization we can have a necessary and sufficient condition for efficiency. Recall that a set $V \subseteq X$ is said to be X_+-convex if and only if $V-X_+$ is convex. Assume that int $X_+^* \neq \varnothing$ and denote by $E(F)$ the set of efficient allocations of $F(\cdot)$.

THEOREM 5.2. *Assume that $F:\Omega \to 2^X$ is an integrably bounded multifunction with nonempty, w-compact and X_+-convex values. Then we have: $f(\cdot) \in S_F^1$ is an efficient allocation if and only if for every $e(\cdot) \in [L_X^1(\Omega)]_+$ there exists a price system $p(\cdot) \in [L_{X^*}^\infty(\Omega)]_+$ s.t. $f(\cdot)$ is ε-price efficient for $p(\cdot)$ with $\varepsilon=\langle p, e\rangle$.*

Proof (*Necessity*). Suppose $f(\cdot) \in S_F^1$ is an efficient allocation.

Consider the multifunction $G(\omega)=F(\omega)-X_+$. Clearly this is closed, convex valued and measurable. Also S_G^1 is nonempty, closed and convex. Note that $E(F)=E(G)$. So $f(\cdot)$ is efficient for $G(\cdot)$. For $e(\cdot) \in [L_X^1(\Omega)]_+$ consider the function

$$g(\omega)=f(\omega)+e(\omega).$$

Because $f(\cdot) \in E(G)$, $g(\omega) \notin G(\omega)$ μ-a.e. So far $\omega \in \Omega\backslash N$ where $\mu(N)=0$, we can apply the second separation theorem. According to that there exists $p \in B_1^{X^*}(0)=\{x^* \in X^*: \|x^*\| \leqq 1\}$, $p \neq 0$ depending on $\omega \in \Omega$ s.t. $\sigma_{G(\omega)}(p)<(p, g(\omega))$. From the nature of $G(\cdot)$ we get that $p \in \dot{X}_+ = X_+\backslash\{0\}$. Consider the multifunction

$$\Gamma(\omega)=\{p \in B_1^{X^*}(0) \cap X_+^*: \sigma_{G(\omega)}(p)<(p, g(\omega))\}.$$

For $\omega \in \Omega\backslash N$ we know that $\Gamma(\omega) \neq \varnothing$. For $\omega \in N$ let $\Gamma(\omega)=\{0\}$. Then for all $\omega \in \Omega$ $\Gamma(\omega) \neq \varnothing$. Define $\varphi(\omega, p)=\sigma_{G(\omega)}(p)-(p, g(\omega))$. Observe that $\varphi(\omega, \cdot)$ is l.s.c. for all $\omega \in \Omega$ and $\varphi(\cdot, p)$ is measurable for all $p \in B_1^{X^*}(0)$. Furthermore dom $\varphi(\omega, \cdot) \supseteq B_1^{X^*}(0) \cap X_+^*$ and so int (dom $\varphi(\omega, \cdot)) \supseteq$ int $(B_1^X(0) \cap X_+^*)=$ int $B_1^X(0) \cap$ int $X_+^* \neq \varnothing$. Hence from Corollary 2E of Rockafellar [40] we deduce that $\varphi(\cdot, \cdot)$ is a $\Sigma \times B(X^*)$-measurable function. Next observe that

$$\operatorname{Gr} \Gamma=\{(\omega, p) \in \Omega \times B_1^{X^*}: \varphi(\omega, p)<0\} \cup (N \times \{0\}).$$

So $\operatorname{Gr}\Gamma \in \Sigma \times B(X^*)$. This means that we can find $P: \Omega \to B_1^{X^*} \cap X_+^*$ s.t. $p(\omega) \in \Gamma(\omega)$ $\omega \in \Omega$. Hence

$$(p(\omega), g(\omega)) > \sigma_{G(\omega)}(p(\omega)) \quad \mu\text{-a.e.}$$

$$\Rightarrow \int_\Omega (p(\omega), g(\omega))\, d\mu(\omega) > \int_\Omega \sigma_{G(\omega)}(p(\omega))\, d\mu(\omega)$$

$$\Rightarrow \int_\Omega (p(\omega), f(\omega))\, d\mu(\omega) + \int_\Omega (p(\omega), e(\omega))\, d\mu(\omega) > \int_\Omega \sigma_{G(\omega)}(p(\omega))\, d\mu(\omega).$$

Since $p(\cdot) \in L_{X^*}^\infty(\Omega))_+$ from the definition of $G(\cdot)$ we see that

$$\sigma_{G(\omega)}(p(\omega)) = \sigma_{F(\omega)}(p(\omega)) \omega \in \Omega.$$

Furthermore we know that

$$\int_\Omega \sigma_{F(\omega)}(p(\omega))\, d\mu(\omega) = \sigma_{S_F^1}(p).$$

So finally we have that

$$\langle p, f \rangle > \sigma_{S_F^1}(p) - \varepsilon$$

where $\varepsilon = \langle p, e \rangle = \int_\Omega (p(\omega), e(\omega))\, d\mu(\omega)$ which shows that indeed $f(\cdot)$ is ε-price efficient with $\varepsilon = \langle p, f \rangle$.

Sufficiency. Suppose that $f(\cdot)$ was not an efficient allocation. This means that there exists $A \in \Sigma$ with $\mu(A) > 0$ s.t. for $\omega \in A$

$$G(\omega) = [f(\omega) + X_+] \cap F(\omega) \neq \varnothing.$$

Clearly $\operatorname{Gr} G \in (\Sigma \cap A) \times B(X)$. So we can find $g: A \to X$ measurable s.t. $g(\omega) \in G(\omega)$ $\omega \in A$.

Define

$$\hat{g}(\omega) = \begin{cases} g(\omega) & \text{for } \omega \in A, \\ f(\omega) & \text{for } \omega \in \Omega \backslash A. \end{cases}$$

Clearly $\hat{g}(\cdot) \in S_F^1$ and $\hat{g} > f$. Let $e(\omega) = \hat{g}(\omega) - f(\omega)$. Then $e(\cdot) \in (L_X^1)_+ \backslash \{0\}$. So we can find $p(\cdot) \in (L_{X^*}^\infty)_+$ s.t.

$$\langle p, f \rangle > \sigma_{S_F^1}(p) - \langle p, e \rangle \Rightarrow \langle p, f \rangle > \langle p, \hat{g} \rangle - \langle p, e \rangle$$

$$\Rightarrow \langle p, f \rangle > \langle p, \hat{g} - e \rangle = \langle p, f \rangle$$

a contradiction. So $f(\cdot)$ has to be efficient. Q.E.D.

6. Stability results. In this final section of our work we examine the variation of the sets of efficient and optimal allocations as we perturb the data on which those notions depend.

We will start with a stability result for the set of efficient allocations $E(F)$, when the consumption (production) multifunction varies in the Kuratowski-Mosco sense described in § 2. For that purpose we need the following lemma. Assume that $\operatorname{int} X_+^* \neq \varnothing$.

LEMMA III. *If $F: \Omega \to P_{fc}(X)$ is integrably bounded and S_F^1 is locally w-compact then $E(F) - (L_X^1)_+ = S_F^1 - (L_X^1)_+$.*

Proof. Clearly $E(F) - (L_X^1)_+ \subseteq S_F^1 - (L_X^1)_+$. Let $g(\cdot) \in S_F^1 - (L_X^1)_+$. Then we have that $g(\cdot) \in g'(\cdot) - (L_X^1)_+$ where $g'(\cdot) \in S_F^1$. Consider the set $(g' + (L_X^1)_+) \cap S_F^1$ and

let $z(\cdot)\in E((g'+(L^1_X)_+)\cap S^1_F)$. Such an element exists by Theorem 3.1. We claim that $z(\cdot)\in E(F)$. Suppose not. Then $(z(\cdot)+(L^1_X)_+)\in S^1_F\neq\varnothing$. So there are $\hat{g}(\cdot)\in S^1_F$ and $e(\cdot)\in(L^1_X)_+$ s.t. $\hat{g}(\cdot)=z(\cdot)+e(\cdot)$. But note that $z(\cdot)=g'(\cdot)+e'(\cdot)$ for some $e'(\cdot)\in(L^1_X)_+$. So $\hat{g}(\cdot)=g'(\cdot)+e'(\cdot)+e(\cdot)\in g'(\cdot)+(L^1_X)_+$. Therefore $z(\cdot)\notin E((g'+(L^1_X)_+)\in S^1_F)$ a contradiction. Hence $z(\cdot)\in E(F)$ and $z(\cdot)=g'(\cdot)+e''(\cdot)(e''(\cdot)=e'(\cdot)+e(\cdot))$. Thus $z(\cdot)=g(\cdot)+e''(\cdot)+e'''(\cdot)(e'''(\cdot)\in(L^1_X)_+)$ which means that $z(\cdot)-e''(\cdot)-e'''(\cdot)-g\in E(F)-(L^1_X)_+$. Q.E.D.

Now we are ready for the stability result we promised.

THEOREM 6.1. *If F_n, $F:\Omega\to P_{fc}(X)$ are measurable multifunctions for all $n\geqq 1$ and $F_n(\omega)\subseteq W(\omega)$ μ-a.e. with $W:\Omega\to P_{wkc}(X)$ integrably bounded and if $F_n(\omega)\xrightarrow{K\text{-}M}F(\omega)$ μ-a.e. then*

$$E(F)\subseteq w\text{-}\limsup_{n\to\infty}E(F_n).$$

Proof. Let $f(\cdot)\in E(f)$. Then $f(\cdot)\in S^1_F$ and so $f(\omega)\in F(\omega)$ μ-a.e. Since by hypothesis

$$F_n(\omega)\xrightarrow{K\text{-}M}F(\omega)\quad\mu\text{-a.e.}$$

we know that

$$\|f(\omega)-F_n(\omega)\|\to 0\quad\mu\text{-a.e.}$$

as $n\to\infty$. Let $G_n(\omega)=\{x_n\in F_n(\omega)\colon\|f(\omega)-x_n\|=\|f(\omega)-F_n(\omega)\|\}$. Clearly for all $n\geqq 1$, $\omega\to G_n(\omega)$ is nonempty, closed valued and measurable. Apply the Kuratowski-Ryll Nardzewski measurable selection theorem to find $g_n:\Omega\to X$ measurable s.t. $g_n(\omega)\in G_n(\omega)$ for all $\omega\in\Omega$ and all $n\geqq 1$. Then $g_n(\cdot)\in S^1_{F_n}$ for all $n\geqq 1$ and

$$\|f(\omega)-g_n(\omega)\|\to 0\quad\mu\text{-a.e.}$$

as $n\to\infty$. From Lemma III we know that

$$g_n(\cdot)=f_n(\cdot)-e_n(\cdot)$$

where $f_n(\cdot)\in E(F_n)$ and $e_n(\cdot)\in(L^1_X)_+(n\geqq 1)$. Then

$$f_n(\omega)-e_n(\omega)\to f(\omega)\quad\mu\text{-a.e.}$$

as $n\to\infty$. Applying Lebesgue's dominated convergence theorem for Bochner integrals we get that

$$f_n-e_n\xrightarrow{s\text{-}L^1_X(\Omega)}f$$

as $n\to\infty$. Note that $S^1_{F_n}\subseteq S^1_W$ for all $n\geqq 1$ and from Lemma I we know that S^1_W is w-compact in $L^1_X(\Omega)$. From the Eberlein-Smulian theorem we can find a subsequence $\{n_k\}\subseteq\{n\}$ s.t.

$$f_{n_k}\xrightarrow{w\text{-}L^1_X}f'\in S^1_F\quad\text{as } k\to\infty.$$

Also

$$f_{n_k}-e_{n_k}\xrightarrow{s\text{-}L^1_X}f\quad\text{as } k\to\infty.$$

Then for all $p(\cdot)\in L^\infty_{X^*}(\Omega)$ we have that

$$\langle p, e_{n_k}+f-f'\rangle-\langle p, e_{n_k}-f_{n_k}+f\rangle+\langle p, f_{n_k}-f'\rangle\to 0$$

as $k \to \infty$. So we deduce that

$$e_{n_k} \xrightarrow{w\text{-}L^1_X} f' - f \quad \text{as } k \to \infty.$$

Since $(L^1_X)_+$ is closed, convex we get that $f' \geqq f$. Since $f(\cdot) \in E(F)$ and $f'(\cdot) \in S^1_F$ we must have $f' = f$. Hence

$$f(\cdot) \in w\text{-}\limsup_n E(F_n)$$

and since $f(\cdot) \in E(F)$ was arbitrary we conclude that

$$E(F) \subseteq w\text{-}\limsup_{n \to \infty} E(F_n). \qquad \text{Q.E.D.}$$

Now we pass to approximately price efficient allocations. In the next result we prove that the set of approximately price efficient allocations is continuous in the Hausdorff metric with respect to both the level of approximation $\varepsilon > 0$ and the efficient price system $p(\cdot)$.

Let X be reflexive (always separable). If $A \subseteq L^1_X(\cdot)$ then by $\partial_\varepsilon \sigma_A(\cdot)$ we will mean the $L^1_X(\Omega)$-subgradients of σ_A: $[L^1_X(\Omega)]^* = L^\infty_{X^*}(\Omega) \to \bar{\mathbb{R}}$. So we will be interested only in the absolutely continuous parts of the ε-subgradients in $\partial^*_\varepsilon \sigma_A(\cdot) \subseteq [L^\infty_{X^*}(\Omega)]^*$. We will denote the set of ε-price efficient allocations, with approximately efficient price system $p(\cdot)$ by $PE_F(\varepsilon, p)$. Then we have

PROPOSITION 6.1. *If $F: \Omega \to P_{fc}(X)$ is integrably bounded $\{\varepsilon_n, \varepsilon\}_{n \geqq 1} \subseteq \mathbb{R}_+ \setminus \{0\}$, $\{p_n, p\}_{n \geqq 1} \subseteq L^\infty_{X^*}(\Omega) \setminus \{0\}$ $\varepsilon_n \to \varepsilon$ and $p_n \xrightarrow{s\text{-}L^\infty_X} p$ as $n \to \infty$ then $PE_F(\varepsilon_n, p_n) \xrightarrow{h} PE_F(\varepsilon, p)$ as $n \to \infty$ (here $h(\cdot, \cdot)$ denote the Hausdorff metric).*

Proof. From the definition of approximate price efficiency and [8, Lemma 2] we can easily deduce that

$$PE_F(\varepsilon_n, p_n) = \partial_{\varepsilon_n}[\langle p_n, \cdot \rangle - d_{S^1_F}(\cdot)], \qquad PE_F(\varepsilon, p) = \partial_\varepsilon[\langle p, \cdot \rangle - d_{S^1_F}(\cdot)].$$

Both sets are nonempty, convex, closed in $L^1_X(\cdot)$. We know that $h(\cdot, \cdot)$ defines a metric on those sets. Also recall that since S^1_F is convex $d_{S^1_F}(\cdot)$ is convex. So $-d_{S^1_F}(\cdot)$ is a concave, Lipschitz function. Hence from Hiriart-Urruty [17] we know that for all $n \geqq 1$

$$h(\partial_{\varepsilon_n} d\langle p_n, \cdot \rangle - d_{S^1_F}(\cdot)], \partial_\varepsilon[\langle p, \cdot \rangle - d_{S^1_F}(\cdot)]) \leqq \frac{1}{\min(\varepsilon_n, \varepsilon)}[\|p_n - p\|_\infty + |\varepsilon_n - \varepsilon|]$$

$$\Rightarrow h(PE_F(\varepsilon_n, p_n), PE_F(\varepsilon, p)) \leqq \frac{1}{\min(\varepsilon_n, \varepsilon)}[\|p_n - p\|_\infty + |\varepsilon_n - \varepsilon|].$$

Let $n \to \infty$. We conclude that $PE_F(\varepsilon_n, p_n) \xrightarrow{h} PE_F(\varepsilon, p)$. Q.E.D.

So the above result tells us that: the nonempty, closed, convex valued multifunction $PE_F(\cdot, \cdot)$ is Hausdorff continuous on $L^1_X(\Omega) \times \dot{\mathbb{R}}_+ (\dot{\mathbb{R}}_+ = \mathbb{R}_+ \setminus \{0\})$ with the strong product topology.

When $\varepsilon = 0$, the result of Hiriart-Urruty [17] on which the proof of the previous proposition was based is not any more applicable. So in that case we cannot have any more convergence in the Hausdorff metric. However we can prove convergence in the Kuratowski-Mosco sense for a fixed price system $p(\cdot)$.

PROPOSITION 6.2. *If $F: \Omega \to P_{fc}(X)$ is integrably bounded, $p(\cdot) \in [L^\infty_{X^*}(\Omega)]_+ \setminus \{0\}$ and $\varepsilon_n \downarrow 0$ as $n \to \infty$ then $PE_F(\varepsilon_n, p) \xrightarrow{K\text{-}M} PE_F(\varepsilon, p)$ as $n \to \infty$.*

Proof. Let $f_m(\cdot) \in PE_F(\varepsilon_m, p)$ $m \in M \subseteq N$ and suppose that $f_m \xrightarrow{w\text{-}L^1_X} f$. Since $f_m(\cdot) \in S^1_F$ and S^1_F is closed and convex in $L^1_X(\Omega)$ we get that $f(\cdot) \in S^1_F$.

By definition for all $m \in M$ we have that

$$\sigma_{S_F^1}(p) - \varepsilon_m \leqq \langle p, f_m \rangle.$$

Passing to the limit as $m \to \infty$ we get that

$$\sigma_{S_F^1}(p) \leqq \langle p, f \rangle$$

and since $f(\cdot) \in S_F^1$ we get that $\sigma_{S_F^1}(p) = \langle p, f \rangle$. So $f(\cdot) \in PE_F(p)$. Hence we see that

$$w\text{-}\limsup_{n \to \infty} PE_F(\varepsilon_n, p) \subseteq PE_F(p). \tag{6.1}$$

Next let $f(\cdot) \in PE_F(p)$. Then for all $n \geqq 1$ $f(\cdot) \in PE_F(\varepsilon_n, p)$. Applying Ekeland's variational principle we can find $f_n(\cdot) \in S_F^1$ s.t.

$$\sigma_{S_F^1}(p) - \varepsilon_n \leqq \langle p, f_n \rangle, \tag{6.2}$$

$$\|f_n - f\|_1 \leqq \sqrt{\varepsilon_n}. \tag{6.3}$$

From (2) we have that $f_n(\cdot) \in PE_F(\varepsilon_n, p)$ and from (6.3) we get that

$$f_n \xrightarrow{s\text{-}L_X^1} f \quad \text{as } n \to \infty.$$

Hence we deduce that

$$PE_F(p) \subseteq s\text{-}\liminf_{n \to \infty} PE_F(\varepsilon_n, p). \tag{6.4}$$

From (6.1) and (6.4) above we finally conclude that

$$PE_F(\varepsilon_n, p) \xrightarrow{\text{K-M}} PE_F(\varepsilon, p) \quad \text{as } n \to \infty. \qquad \text{Q.E.D.}$$

In the remaining part of this section we examine the behavior of optimality, price efficiency and efficiency for a sector as the sector gets larger.

So let $\{\Sigma_n\}_{n \geqq 1}$ be a sequence of sub-σ-fields of Σ and suppose that $\bigvee_{n=1} \Sigma_n = \Sigma$. Also assume that X is finite-dimensional. Denote by $A(u, F)$ the set of all optimal allocations determined by the consumption (production) multifunction $F(\cdot)$ and the utility (profit) functions $u(\cdot, \cdot)$. Then we have

THEOREM 6.2. *If $u: \Omega \times X \to \mathbb{R}$ is a Caratheodory integrand s.t. $|u(\omega), x)| \leqq \varphi(\omega)$ μ-a.e. for all $x \in X$ where $\varphi(\cdot) \in L^1(\omega)$ and if $F: \Omega \to P_{fc}(X)$ is integrably bounded then*

$$s\text{-}\limsup_{n \to \infty} A(E^{\Sigma_n} u, E^{\Sigma_n} F) \subseteq A(u, F).$$

Proof. Let

$$f(\cdot) \in s\text{-}\limsup_{n \to \infty} A(E^{\Sigma_n} u, E^{\Sigma_n} F).$$

Then this means that there exist $r_m(\cdot) \in A(E^{\Sigma_m} u, E^{\Sigma_m} F)$, $m \in M \subseteq N$ s.t. $r_m \xrightarrow{s\text{-}L_X^1} f$ as $m \to \infty$.

Recall that $r_m(\cdot) \in S^1(\Sigma_m)$. From Hiai-Umegaki [13] (see also Valadier [48]) we know that $S^1(\Sigma_m) = \text{cl}\{E^{\Sigma_m} S_F^1\}$ with the closure taken in the $L_n^1(\Omega)$-norm. Since X is finite-dimensional, from Lemma I of § 3 we know that S_F^1 is a w-compact, convex subset of $L_X^1(\Omega)$. Hence $S^1(\Sigma_m) = E^{\Sigma_m} S_F^1$. So $r_m = E^{\Sigma_m} f_m$ where $f_m(\cdot) \in S_F^1$ $m \in M$. By passing from the beginning to a subsequence, if necessary, we may assume that

$$E^{\Sigma_m} f_m(\omega) \to f(\omega) \quad \mu\text{-a.e.}$$

as $m \to \infty$. Since $r_m(\cdot) \in A(E^{\Sigma_m} u, E^{\Sigma_m} g)$ and $S^1(\Sigma_m) = E^{\Sigma_m} S_F^1$ we have that for every

$g(\cdot) \in S_F^1$

$$E^{\Sigma_m} u(w, E^{\Sigma_m} g(\omega)) \leqq E^{\Sigma_m} u(\omega, E^{\Sigma_m} f(\omega)) \quad \mu\text{-a.e.}$$

Since $F(\cdot)$ is integrably bounded from martingale theory we know that $E^{\Sigma_m} g(\omega) \to g(\omega)$ μ-a.e. as $m \to \infty$. Furthermore from Bismut [4, Thm. 1, p. 668] we know that

$$E^{\Sigma_m} u(\omega, \cdot) \to u(\omega, \cdot) \quad \mu\text{-a.e.}$$

and the convergence is uniform on compact sets.

Hence we deduce that

$$E^{\Sigma_m} u(\omega, E^{\Sigma_m} g(\omega)) \to u(\omega, g(\omega)) \quad \mu\text{-a.e.}$$

and

$$E^{\Sigma_m} u(\omega, E^{\Sigma_m} f(\omega)) \to u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

Since for all $m \in M \subseteq N$, $E^{\Sigma_m} u(\omega, E^{\Sigma_m} g(\omega)) \leqq E^{\Sigma_m} u(\omega, E^{\Sigma_m} f(\omega))$ μ-a.e. we conclude that

$$u(\omega, g(\omega)) \leqq u(\omega, f(\omega)) \quad \mu\text{-a.e.}$$

and since this is true for all $g(\cdot) \in S_F^1$, we have that $f(\cdot) \in A(u, F)$. Q.E.D.

We have an analogous stability result for price efficient allocations. For that purpose assume that X is finite-dimensional and Σ is a countably generated σ-field. Then we have

THEOREM 6.3. *If $F: \Omega \to P_{fc}(X)$ is integrably bounded then*

$$w\text{-}\limsup_{n \to \infty} PE(E^{\Sigma_n} F) \subseteq PE_1(F).$$

Proof. Let

$$f(\cdot) \in w\text{-}\limsup_{n \to \infty} PE(E^{\Sigma_n} F).$$

This means that there exist

$$g_m(\cdot) \in PE(E^{\Sigma_m} F) m \in M \subseteq N \text{ s.t. } g_m \xrightarrow{w\text{-}L_n^1(\Omega)} f \quad \text{as } m \to \infty.$$

So $g_m(\cdot) \in S^1(\Sigma_m)$ and there exist $p_m(\cdot) \in B^{L_n^\infty(\Omega, \Sigma_m)}(0)$

$$\langle p_m, g_m \rangle = \sigma_{S^1(\Sigma_m)}(p_m) m \in M.$$

Recall that

$$\sigma_{S^1(\Sigma_m)}(p_m) = \int_\Omega \sigma_{\Sigma_m(\omega)}(p_m(\omega))\, d\mu(\omega).$$

From Valadier [48] we know that $\sigma_{\Sigma_m(\omega)}(p_m(\omega)) = E^{\Sigma_m} \sigma_{F(\omega)}(p_m(\omega))$ μ-a.e. But then from Bismut [4] we get that

$$\int_\Omega E^{\Sigma_n} \sigma_{F(\omega)}(p_n(\omega))\, d\mu(\omega) = \int_\Omega \sigma_{F(\omega)}(p_n(\omega))\, d\mu(\omega) = \sigma_{S_F^1}(p_n).$$

Because Σ is countably generated, $L_n^1(\Omega)$ is separable and so $B_1^{L_n^\infty(\Omega)}(0)$ is metrizable with the w^*-topology and so w^*-sequentially compact. Hence we can find

$$\{m_k\} \subseteq \{m\} \text{ s.t. } p_{m_k} \xrightarrow{w^*\text{-}L_n^\infty} p \quad \text{as } k \to \infty$$

and $p(\cdot) \in B^{L_n^\infty(\Omega)}(0)$. At this point use Mazur's theorem to find

$$z_{m_k}(\cdot) \in \text{conv} \bigcup_{n \geq k} g_{m_n}(\cdot) \text{ s.t. } z_{m_k}(\cdot) \xrightarrow{s\text{-}L_n^1} f(\cdot) \quad \text{as } k \to \infty.$$

So we have that

$$\langle p_{m_k}, z_{m_k} \rangle \to \langle p, f(\cdot) \rangle \quad \text{as } k \to \infty. \tag{6.5}$$

Also note that since S_F^1 is bounded, $\sigma_{S_F^1}(\cdot)$ is finite and so because of convexity we conclude that it is continuous on $(B^{L_n^\infty(\Omega)}(0), w^*)$. Hence we have that

$$\sigma_{S^1(\Sigma_m)}(p_{m_k}) = \sigma_{S_k^1}(p_{m_k}) \to \sigma_{S_F^1}(p) \quad \text{as } k \to \infty. \tag{6.6}$$

Since $\sigma_{S^1(\Sigma_m)}(p_{m_k}) = \langle p_{m_k}, z_{m_k} \rangle$ from (6.5) and (6.6) above we conclude that $\langle p, f \rangle = \sigma_{S_F^1}(p)$. Because S_F^1 is a closed, convex subset of $L_n^1(\Omega)$, Hormander's theorem tells us that $f(\cdot) \in S_F^1$. Therefore, $f(\cdot) \in PE(F)$. Q.E.D.

Remark. A careful examination of the above proof can convince the reader that if X is a general separable Banach space then

$$s\text{-}\limsup_{n \to \infty} PE(E^{\Sigma_n} F) \subseteq PE(F).$$

We will conclude the paper with a similar stability analysis for the set $E(F)$ of efficient allocations. Assume that X is finite-dimensional Banach space.

THEOREM 6.4. *If $F: \Omega \to P_{fc}(X)$ is integrably bounded by $\varphi(\cdot) \in L^1(\Omega, \Sigma_1)$ then $E(F) \subseteq w\text{-}\limsup_{n \to \infty} E(E^{\Sigma_n} F)$.*

Proof. From Valadier [48] we know that for all $x^* \in X^*$ we have

$$\sigma_{E^{\Sigma_n} F(\omega)}(x^*) = E^{\Sigma_n} \sigma_{F(\omega)}(x^*) \quad \mu\text{-a.e.}$$

the exceptional set independent of x^* because of continuity. From Bismut [4] we know that for all $x^* \in X^*$

$$E^{\Sigma_n} \sigma_{F(\omega)}(x^*) \to \sigma_{F(\omega)}(x^*) \quad \mu\text{-a.e.}$$

As in the proof of Theorem 6.2 we can get that $S^1_{E^{\Sigma_n} F} = E^{\Sigma_n} S_F^1$. Hence

$$|E^{\Sigma_n} F(\omega)| = \sup_{f \in S_F^1} \|E^{\Sigma_n} f(\omega)\| \leq \sup_{f \in S_F^1} E^{\Sigma_n} \|f(\omega)\| \leq E^{\Sigma_n} \varphi(\omega) = \varphi(\omega) < +\infty \ \mu\text{-a.e.}$$

So we can write that

$$\text{dom } \sigma_{E^{\Sigma_n} F(\omega)}(\cdot) = \text{dom } \sigma_{F(\omega)}(\cdot) = X^* \quad \mu\text{-a.e.}$$

Then Corollary 2E of Salinetti-Wets [45] tells us that

$$\sigma_{E^{\Sigma_n} F(\omega)}(\cdot) = E^{\Sigma_n} \sigma_{F(\omega)}(\cdot) \xrightarrow{\tau} \sigma_{F(\omega)}(\cdot) \quad \mu\text{-a.e.}$$

as $n \to \infty$. But then from Theorem 3.1 of Mosco [27] we deduce that $E^{\Sigma_n} F \xrightarrow{sK} F$ as $n \to \infty$. Now recall that for all $n \geq 1$ we have $|E^{\Sigma_n} F(\omega)| \leq \varphi(\omega)$ μ-a.e. So

$$|E^{\Sigma_n} F(\omega)| \leq B^X_{\varphi(\omega)}(0) = \{x \in X : \|x\| \leq \varphi(\omega)\}.$$

It is easy to see that $\omega \to B^X_{\varphi(\omega)}(0)$ is integrably bounded. Therefore we can apply Theorem 6.1 and get that

$$E(F) \subseteq w\text{-}\limsup_{n \to \infty} E(E^{\Sigma_n} F). \qquad \text{Q.E.D.}$$

If we impose more restrictions on $F(\cdot)$ we can have a stronger version of Theorem 6.4. Assume that X is a reflexive Banach space (always separable).

THEOREM 6.5. *If $F: \Omega \to P_{fc}(X)$ is measurable and $F(\omega) \subseteq W$ μ-a.e. with W a weakly compact, convex subset of X then*

$$E(E^{\Sigma_n}F) \overset{sK}{\to} E(F) \quad \text{as } n \to \infty.$$

Proof. From Theorem 6.1 of Hiai-Umegaki [13] we have that

$$h(E^{\Sigma_n}F(\omega), F(\omega)) \to 0 \quad \mu\text{-a.e.} \quad \text{as } n \to \infty.$$

Also since $F(\omega) \subseteq W$ μ-a.e., we have that $E^{\Sigma_n}F(\omega) \subseteq E^{\Sigma_n}W = W$ μ-a.e. Hence we can apply Theorem 5.4 of [28] to conclude that

$$E(E^{\Sigma_n}F) \overset{sK}{\to} E(F) \quad \text{as } n \to \infty. \qquad \text{Q.E.D.}$$

Concluding our work, we would like to point out that it will be interesting to consider also risk-aversely efficient allocations (see [33]), study their properties and compare them with the notions introduced and studied in this paper. Risk-aversely efficient allocations are important in economic theory.

Acknowledgment. The author is very grateful to the referee for reading the paper carefully and making several comments and suggestions that improved the presentation considerably.

AN APPROACH TO SIMULTANEOUS SYSTEM DESIGN, I. SEMIALGEBRAIC GEOMETRIC METHODS*

BIJOY K. GHOSH†

Abstract. This paper introduces semialgebraic parameterization as an approach to analyze simultaneous stabilization and pole placement problems. Rational families of plants of a given McMillan degree, that are simultaneously stabilizable by a fixed family of compensators, are parameterized. For a discrete family of plants, the parameterization problem reduces to the simultaneous stabilization or the pole placement problem of a r-tuple of multi input multi output plants by a nonswitching compensator. It is shown that by removing a semialgebraic subset of a proper algebraic set, the "space of plants" can be decomposed into components that are either simultaneously stabilizable or simultaneously unstabilizable. Under special cases, explicit parameterization of the semialgebraic set is obtained. Finally a necessary condition for the simultaneous stabilization of single input or single output plants is obtained.

Key words. plant, compensator, semialgebraic-set, decision-theory

AMS(MOS) subject classifications. 93, 14

1. Introduction. Classically, in control theory one considers a lumped, linear, time-invariant, proper or strictly proper plant and one of the design objectives is to construct an output feedback scheme that would stabilize the plant. Not all plants have a compensator that satisfies the specified design constraints and it is of interest to parameterize those plants that do. In this paper, the semialgebraic properties of the parameterization problem is studied. In a related part II we study this problem via algebraic geometric methods.

In order to introduce the class of problems to be investigated, we consider a $p \times m$ rational, transfer function matrix $G(s)$ modelling a m input p output plant and address the following problem:

Problem 1.1. Let S be a topological space. Consider a family of plants $G_\lambda(s)$ parameterized by $\lambda \in S$. Does there exist a compensator $K_{f(\lambda)}(s)$ where

$$f: S \to S_1 \subset S \tag{1.1}$$

such that the closed loop systems $G_\lambda[I + K_{f(\lambda)}(s)G_\lambda(s)]^{-1}$ are stable for all $\lambda \in S$.

If the answer to Problem 1.1 is "yes", one asks the following parameterization problem.

Problem 1.2. Let f be fixed. Describe the family of plants $G_\lambda(s)$ for which there exists a family of compensators $K_{f(\lambda)}(s)$ such that the closed loop system $G_\lambda(s)[I + K_{f(\lambda)}(s)G_\lambda(s)]^{-1}$ is stable for all $\lambda \in S$.

If $S = S_1$ and f is the identity map, an adaptive control problem, called the "switching compensator problem" is obtained. If f is a constant map, the so-called "nonswitching compensator problem" also known as the "blending problem" is obtained. An important class of the noswitching compensator problem, called the "simultaneous stabilization problem" arises when the set S is discrete. The problem is to describe the set of r-tuples of plants $G_1(s), \cdots, G_r(s)$ that admit a stabilizing compensator. Let us now consider the following two examples.

* Received by the editors August 21, 1984, and in revised form on February 11, 1985.

† Department of Systems Science and Mathematics, Washington University, St. Louis, Missouri 63130. This research was partially supported by National Aeronautics and Space Administration grant NSG 2265 while the author was at Harvard University, Cambridge, Massachusetts. This paper is part of the author's Ph.D. thesis at Harvard University, Cambridge, Massachusetts.

Example 1.1 (*a switching compensator paroblem*). Let S be the set of real numbers $\mathbb{R}$. Consider $G_\lambda(s)$ to be a family of plants of degree 1 given by $G_\lambda(s)=1/(s+\lambda^2)$, where $\lambda \in \mathbb{R}$. Let K_λ be a family of feedback gains given by $K_\lambda = k_1\lambda + k_2$ where $k_1, k_2, \lambda \in \mathbb{R}$. Let us now ask the following question: Does there exist some values of $k_1, k_2 \in \mathbb{R}^2$ such that the closed loop system $G_\lambda(s)[1+K_\lambda G_\lambda(s)]^{-1}$ is stable for all $\lambda \in \mathbb{R}$?

Of course it is easy to see that K_λ stabilizes $G_\lambda(s)$ for all $\lambda \in \mathbb{R}$ iff

$$\lambda^2 + k_1\lambda + k_2 > 0. \tag{1.2}$$

Clearly, for

$$k_1^2 < 4k_2, \tag{1.3}$$

the inequality (1.2) is satisfied for all $\lambda \in \mathbb{R}$. Therefore, the family of plants $G_\lambda(s)$ is stabilizable by the family of switching compensators $K_\lambda(s)$ provided (1.3) is satisfied.

Example 1.2 (*a parameterization problem*). As a continuation of Example 1.1, let $G_\lambda(s)=a/(bs+\lambda^2)$, $K_\lambda = k_1\lambda + k_2$. Let us now ask the following question: For which $a, b \in \mathbb{R}^2$ does there exist $k_1, k_2 \in \mathbb{R}^2$ such that the closed loop system $G_\lambda(s)[1+K_\lambda G_\lambda(s)]^{-1}$ is stable for all $\lambda \in \mathbb{R}$?

Once again, K_λ stabilizes $G_\lambda(s)$ for all $\lambda \in \mathbb{R}$ iff

$$b(\lambda^2 + ak_1\lambda + ak_2) > 0. \tag{1.4}$$

Eliminating the variables $k_1, k_2 \in \mathbb{R}^2$ from the above inequation, we may check that the set of $a, b, \lambda \in \mathbb{R}^3$ for which there exists some $k_1, k_2 \in \mathbb{R}^2$ satisfying (1.4) is given by

$$(b>0 \text{ and } a=0 \text{ and } \lambda \neq 0) \quad \text{or} \quad (a \neq 0). \tag{1.5}$$

The set of $(a, b) \in \mathbb{R}^2$ for which (1.5) is satisfied for all $\lambda \in \mathbb{R}$ is given by

$$\{(a, b) | a \neq 0\}, \tag{1.6}$$

which is also the required solution to the parameterization problem.

As pointed out in [15], the compensator problem 1.1 and the parameterization Problem 1.2 is encountered in reliability studies. One frequently encounters situations when it is desirable to stabilize a plant with multiple modes of operation. For example, if $G_1(s)$ models a plant in its nominal mode, one might consider $G_2(s), \cdots, G_r(s)$ as the models of the plant in the faulted mode. It might be desirable to construct a feedback nonswitching compensator that simultaneously stabilizes $G_1(s), \cdots, G_r(s)$. In another situation, for example in considering an adaptive control problem, one considers a parameterized family of plants $G_\lambda(s)$ and wishes to construct a stabilizing compensator $K_\lambda(s)$ such that $(G_\lambda(s), K_\lambda(s))$ is stable for all λ in a parameter set. If $K_\lambda(s)$ is independent of λ, then the problem reduces to the blending problem, i.e. of constructing a fixed compensator for a family of plants. For details on the motivation and other references we refer to [1], [12].

The main idea of this paper is now summarized. First of all, the space of proper plants of McMillan degree n and the space of proper compensators of McMillan degree q have been described as a quasi-affine variety. In particular the plants and the compensators under consideration are parameterized as semialgebraic subsets of the affine spaces $\mathbb{R}^N$ and $\mathbb{R}^M$, respectively. By using the Routh-Hurwitz criterion [11], the set of plants and the set of compensators that correspond to a stable system in the closed loop is described by a set of semialgebraic conditions in the product space $\mathbb{R}^N \times \mathbb{R}^M$. The stabilizable plants are now described by the application of the decision method [2] which utilizes a rational procedure of eliminating the compensator variables from the above semialgebraic sets of conditions. By Tarski [26] and Seidenberg [22]

(see also Cohen [7]) this results in a semi-algebraic parameterization of the set of stabilizable plants in $\mathbb{R}^N$.

Of course the above argument continues to hold if one considers the pole-placement problem instead of the stabilization problem and a r-tuple of plants or more generally a rational family of plants of a fixed McMillan degree instead of a single plant. It may be noted, however, that the above parameterization may not be obtained by an efficient algorithm since it is known [10] that the Tarski-Seidenberg algorithms are computationally inefficient. However, a recent improvement by Collins [8] and by Arnon [3] have considerably improved the efficiency.

The organization of this paper is as follows. In § 2 a parameterization of the space of input output systems of a fixed McMillan degree has been described. In § 3 the set of stabilizable/pole assignable plants have been parameterized by the application of the Routh-Hurwitz condition [11] and the decision theory [2]. The parameterization problem of § 3 is generalized in § 4 to a family of plants, rather than one. Specifically, a simultaneously stabilizable family of plants has been parameterized. In § 5, the path component properties of the pole placement problem is described. In §§ 6 and 7 we restrict our attention to the case of a r-tuple of single input or single output plants (in particular $1 \times m$ plants). In § 6, an explicit solution to the parameterization problem is obtained under the hypothesis that $(q+1)(m+1) = \sum n_i + rq$ where n_i, $i = 1, \cdots, r$ and q are the McMillan degrees of the plants and the compensator, respectively. Especially when the above hypothesis is not satisfied, in § 7 we parameterize a set of unstabilizable r-tuples of plants, thereby obtaining a necessary condition to the simultaneous stabilization problem. The paper concludes in § 8 with a discussion on the possibility of parameterizing the set of stabilizable/pole assignable r-tuples of plants by a dynamic compensator of finite but a priori unbounded McMillan degree. This new problem serves to give some measure of the relative depth of the parameterization questions posed and solved in this paper.

2. A parameterization of the space of systems. Let k be either $\mathbb{R}$ or $\mathbb{C}$. We now parameterize the set of $p \times m$ proper, rational, matrix valued transfer functions over k as a subset of k^N where $N = n(m+p) + mp$. Let (A, B, C, D) be a 4-tuple of matrices in k^N of orders $n \times n$, $n \times m$, $p \times n$ and $p \times m$, respectively. Let us consider the following.

DEFINITION. A tuple of matrices (A, B, C, D) is defined to be a minimal system of degree n if the proper $p \times m$ transfer function

$$G(s) = \sum_{i=1}^{\infty} CA^{i-1}B/s^i + D \tag{2.1}$$

is of McMillan degree n.

It is well known that a tuple (A, B, C, D) is minimal iff it is observable and reachable. The space of minimal systems of degree n is denoted by $\tilde{S}^n_{m,p}$. Let us consider the following proposition.

LEMMA 2.1. *$\tilde{S}^n_{m,p}$ is an irreducible subset of k^N.*

Proof. The affine space k^N is irreducible. $\tilde{S}^n_{m,p}$ is a nonempty Zariski open subset of k^N since it contains observable and reachable 4-tuples of matrices. Hence $\tilde{S}^n_{m,p}$ is irreducible. (See Hartshorne [16].) Q.E.D.

It is quite possible that two 4-tuples of matrices (A_1, B_1, C_1, D_1) and (A_2, B_2, C_2, D_2) correspond via (2.1) to the same transfer function $G(s)$. The above is indeed the case iff there exist a nonsingular $n \times n$ matrix $g \in Gl(n, k)$ such that

$$A_2 = gA_1g^{-1}, \quad B_2 = gB_1, \quad C_2 = C_1g^{-1}, \quad D_2 = D_1. \tag{2.2}$$

Thus there exists an action of $Gl(n, k)$ on the space $\tilde{S}^n_{m,p}$ and the problem is to parameterize the moduli space $\tilde{S}^n_{m,p}/Gl(n, k)$. This is done as follows.

LEMMA 2.2. *$\tilde{S}^n_{m,p}/Gl(n, k)$ is an analytic manifold of dimension $n(m+p)+mp$. Moreover, there exists a set of local co-ordinate charts with rational co-ordinate functions.*

Remark. The proof of Lemma 2.2 is an adaptation from Clark [6], Hazewinkel and Kalman [18], Byres and Hurt [4] and Hazewinkel [17]. We choose to restate this well-known fact since the algebraic structure of the moduli space is important in what we derive later on in this paper.

Proof. Let $\tilde{\Sigma}_0$ denote the set of reachable pairs of matrices (A, B) and denote

$$\Sigma_0 = \tilde{\Sigma}_0/Gl(n, k). \tag{2.3}$$

It is well known (see [4], [18]) that Σ_0 is an analytic manifold of dimension nm which admits a rational atlas. Let $\tilde{\Sigma}^n_{m,p}$ be the observable and reachable triples (A, B, C) and define

$$\Sigma^n_{m,p} = \tilde{\Sigma}^n_{m,p}/Gl(n, k). \tag{2.4}$$

Using a result due to Byrnes and Hurt [4], $\Sigma^n_{m,p} \to \Sigma_0$ is canonically an algebraic vector bundle of rank pn. Hence $\Sigma^n_{m,p}$ is a $n(m+p)$-dimensional analytic manifold having rational coordinate functions. Finally the proof of this lemma follows from the observation that

$$\tilde{S}^n_{m,p}/Gl(n, k) = \Sigma^n_{m,p} \times k^{mp}. \tag{2.5}$$

Q.E.D.

Alternatively, it is also possible to parameterize $\tilde{S}^n_{m,p}/Gl(n, k)$ in the following way.

Let $H^n_{m,p}$ be the affine $(2n-1)mp$-dimensional space of $p \times m$ block Hankel matrices of the type

$$H = \begin{bmatrix} H_1 & H_2 & \cdots & H_n \\ H_2 & H_3 & \cdots & H_{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ H_n & H_{n+1} & & H_{2n-1} \end{bmatrix} \tag{2.6}$$

where H_i, $i = 1, \cdots, 2n-1$ are $p \times m$ matrices. Consider the affine space

$$H^n_{m,p} \times k^{mp} \times k^{mp}, \tag{2.7}$$

and define the subset

$$S^n_{m,p} \subset H^n_{m,p} \times k^{mp} \times k^{mp} \tag{2.8}$$

given by

$$\begin{aligned} S^n_{m,p} &= \{(H, H_{2n}, H_0) | \text{rank } H = n \text{ and col } (H_{n+1}, \cdots, H_{2n}) \\ &= \sum_{i=1}^{n} [\alpha_i I_p] \text{ col } (H_i, \cdots, H_{n+i-1}) \text{ for some } \alpha_1, \cdots, \alpha_n \in k\}. \end{aligned} \tag{2.9}$$

There is an algebraic map

$$\Phi: \tilde{S}^n_{m,p} \to S^n_{mp} \tag{2.10}$$

defined by

$$\Phi(A, B, C, D) = \left(\begin{bmatrix} CB & \cdots & CA^{n-1}B \\ CA^{n-1}B & \cdots & CA^{2n-2}B \end{bmatrix}, CA^{2n-1}B, D \right). \tag{2.11}$$

We now consider the following lemma.

LEMMA 2.3. *$S^n_{m,p}$ is a quasi affine algebraic variety in the affine space $k^{(2n+1)mp}$.*

Proof. By (2.9), $S^n_{m,p}$ is an open subset of a closed algebraic subset in $k^{(2n+1)mp}$. Moreover, $S^n_{m,p}$ is irreducible, since $\tilde{S}^n_{m,p}$ is, and the map Φ is algebraic (see Shaferavich [23]). Q.E.D.

A topology on $S^n_{m,p}$ is induced from the Zariski topology [16] on $k^{(2n+1)mp}$. It is well known, by realization theory [19], that every element of $S^n_{m,p}$ corresponds with a $p \times m$ proper plant of McMillan degree n. Hence $S^n_{m,p}$ is isomorphic to the moduli space $\tilde{S}^n_{m,p}/Gl(n, k)$.

3. A parameterization of the space of stabilizable/pole assignable systems. Let k be the real field $\mathbb{R}$. To begin with, we consider the product space of $p \times m$ proper plants of degree n and $m \times p$ proper compensators of degree q, given by

$$S^n_{m,p} \times S^q_{p,m}, \tag{3.1}$$

which is of course a quasi affine variety. (See [12]). We now consider the following two problems

Problem 3.1. Describe the set of plants $G(s)$ in $S^n_{m,p}$ and compensators $K(s)$ in $S^q_{p,m}$ such that the pair $(G(s), K(s))$ is stable in the closed loop.

Problem 3.2. Describe the set of plants $G(s)$ in $S^n_{m,p}$ and compensators $K(s)$ in $S^q_{p,m}$ such that the closed loop system $G(s)[I+K(s)G(s)]^{-1}$ has poles in a prescribed $n+q$ tuple of self-conjugate complex points $s_1, \cdots, s_{n+q}$.

We now show that there exists a semialgebraic parameterization to the set of plants and compensators satisfying the properties stipulated in Problems 3.1 and 3.2.

THEOREM 3.1. *The subset U_1 of* (3.1) *given by*

$$U_1 = \{(G(s), K(s)) | K(s) \text{ stabilizes } G(s)\}, \tag{3.2}$$

is semialgebraic.

In order to prove Theorem 3.1 we need the following lemma.

LEMMA 3.1. *Let Φ be the map*

$$\Phi: S^n_{m,p} \times S^q_{p,m} \to \mathbb{R}^{n+q} \tag{3.3}$$

defined by

$$\begin{aligned} \Phi(G(s), K(s)) = {} & \text{coefficients of the monic characteristic polynomial} \\ & \pi(s) \text{ of the closed loop system } G(s)[I+K(s)G(s)]^{-1}. \end{aligned} \tag{3.4}$$

Then Φ is rational.

Proof. Consider the affine spaces

$$H_n = H^n_{m,p} \times \mathbb{R}^{mp} \times \mathbb{R}^{mp} \tag{3.5}$$

and

$$H_q = H^q_{p,m} \times \mathbb{R}^{mp} \times \mathbb{R}^{mp} \tag{3.6}$$

associated with $S^n_{m,p}$ and $S^q_{p,m}$, respectively. By realization theory [19], every point in the quasi-affine algebraic variety $S^n_{m,p} \times S^q_{p,m}$ of $H_n \times H_q$ corresponds to a plant-compensator pair $(G(s), K(s))$, and therefore corresponds to the closed loop plant $\underline{G}(s) = G(s)[I+K(s)G(s)]^{-1}$. Moreover, the coefficients of the characteristic polynomial of $\underline{G}(s)$ is rational in the parameters of $H_n \times H_q$ since $G(s)$ and $K(s)$ are of fixed degrees n and q, respectively. By restriction to $S^n_{m,p} \times S^q_{p,m}$, Φ is clearly rational. Q.E.D.

LEMMA 3.2. *Consider the real $n+q(th)$ degree polynomial*

$$p(s) = s^{n+q} + a_{n+q-1}s^{n+q-1} + \cdots + a_0 \tag{3.7}$$

parameterized as points in $\mathbb{R}^{n+q}$. *Then the set*

$$S=\{(a_0,\cdots,a_{n+q-1})|p(s)\ \textit{is stable}\} \tag{3.8}$$

is semialgebraic in $\mathbb{R}^{n+q}$.

Proof. The proof is omitted as it is the well-known Routh–Hurwitz condition [11]. Q.E.D.

Theorem 3.1 now follows trivially from the Lemmas 3.1 and 3.2. Note that the compensator $K(s)$ stabilizes the plant $G(s)$ just in case the associated characteristic polynomial $\pi(s)$ is stable. Note also that the coefficients of $\pi(s)$ are rational in the plant and the compensator parameters. Q.E.D.

The proof of the following theorem is analogous and is omitted.

THEOREM 3.2. *The subset* U_2 *of* (3.1) *given by*

$$U_2=\{(G(s),K(s))|\textit{the poles of } G(s)(I+K(s)G(s))^{-1} \textit{ are at a given set of self conjugate complex points } s_1,\cdots,s_{n+q}\} \tag{3.9}$$

is semialgebraic.

We now state the stabilizability problem as follows.

Problem 3.3. Describe the set of plants in $S^n_{m,p}$ for which there exists a compensator $K(s)$ in $S^q_{p,m}$ such that the closed loop system $G(s)[I+K(s)G(s)]^{-1}$ is stable.

We also state the pole assignability problem as follows.

Problem 3.4. Describe the set of plants in $S^n_{m,p}$ for which there exists a compensator $K(s)$ in $S^q_{p,m}$ such that the closed loop system $G(s)[I+K(s)G(s)]^{-1}$ has poles in an arbitrary $n+q$ set of self-conjugate complex points.

The following theorem reveals the semialgebraic nature of the sets described in Problems 3.3 and 3.4.

THEOREM 3.3. *The subset* U_s *of* U_1 *given by*

$$U_s=\{G(s)|\exists K(s)\in S^q_{p,m} \textit{ and } G(s)[I+K(s)G(s)]^{-1} \textit{ is stable}\} \tag{3.10}$$

is semialgebraic. The subset U_p *of* U_2 *given by*

$$U_p=\{G(s)|\textit{for all self conjugate set } s_1,\cdots,s_{n+q} \textit{ of complex numbers, } \exists K(s)\in S^q_{p,m} \textit{ and } G(s)[I+K(s)G(s)]^{-1} \textit{ has poles at } s_1,\cdots,s_{n+q}\} \tag{3.11}$$

is semialgebraic.

Proof. Consider the product space (3.1) and consider the projection

$$\text{proj: } S^n_{m,p}\times S^q_{p,m}\to S^n_{m,p}. \tag{3.12}$$

It is clear that

$$U_s=\text{proj } U_1. \tag{3.13}$$

By Theorem 3.1, U_1 is semialgebraic and proj is a rational map. Thus by the Tarski [26], Seidenberg [22] theory of elimination over $\mathbb{R}$, U_s is semialgebraic. In order to show that U_p is semialgebraic consider the product space

$$S^n_{m,p}\times S^q_{p,m}\times\mathbb{R}^{n+q}, \tag{3.14}$$

and its subset U_2' given by

$$U_2'=\{(G(s),K(s),(c_0,\cdots,c_{n+q-1}))|\text{ the poles of } G(s)[I+K(s)G(s)]^{-1} \text{ are at the zeros of } \pi(s)=s^n+c_{n+q-1}s^{n+q-1}+\cdots+c_0\}. \tag{3.15}$$

Consider now the following two projections:

$$\text{proj}_1\text{: } S^n_{m,p}\times S^q_{p,m}\times\mathbb{R}^{n+q}\to S^n_{m,p}\times\mathbb{R}^{n+q} \tag{3.16}$$

and

$$\text{proj}_2 : S^n_{m,p} \times \mathbb{R}^{n+q} \to S^n_{m,p}. \tag{3.17}$$

It is easy to see that

$$U_p = \text{proj}_2 [\overline{\text{proj}_1 (U_2')}], \tag{3.18}$$

where $\bar{\Omega}$ denotes the complement of Ω in the respective ambient space. Since the complement of a semialgebraic set is semialgebraic, by Tarski-Seidenberg [26], [22], U_p is semialgebraic. Q.E.D.

Example 3.1. Consider the single input single output plant $g(s)$ and the compensator $k(s)$ given by

$$g(s) = 1/(s^2 + bs + c), \tag{3.19}$$

$$k(s) = k/(s + \alpha). \tag{3.20}$$

The characteristic polynomial is given by

$$(s^2 + bs + c)(s + \alpha) + k, \tag{3.21}$$

which vanishes in the left half-plane iff

$$\alpha + b > 0 \text{ and } \alpha c + k > 0 \text{ and } (\alpha + b)(\alpha b + c) - (\alpha c + k) > 0. \tag{3.22}$$

The above inequalities (3.22) have been obtained by the application of the Routh-Hurwitz condition to the characteristic polynomial (3.21). In order to describe the set of stabilizable plants, we need to eliminate the variables k, α from (3.22) and obtain

$$b > 0 \text{ or } c - b^2 > 0. \tag{3.23}$$

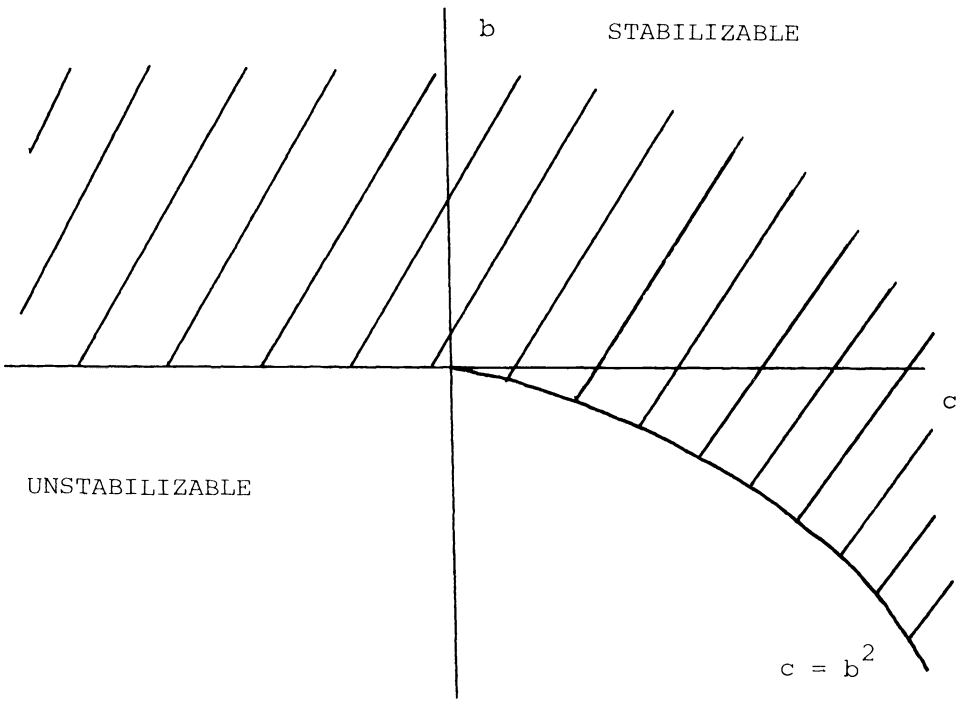

FIG. 3.1. *The set of stabilizable and unstabilizable plants of Example* 3.1.

In other words, for every b, c satisfying (3.23) there exists $k, \alpha \in \mathbb{R}$ such that (3.22) is satisfied. Thus the set of stabilizable plants are given by the shaded region in Fig. 3.1.

4. Semialgebraic path component properties of families of systems. Consider the space of r-tuples of plants

$$W = S_{m,p}^{n_1} \times \cdots \times S_{m,p}^{n_r} \tag{4.1}$$

of McMillan degrees of $n_1, \cdots, n_r$ respectively. We now define a family of r-tuples of plants and a family of compensators as follows. Let $\Lambda_1 \subset \mathbb{R}^{s_1}$, $\Lambda_2 \subset \mathbb{R}^{s_2}$ be a pair of semialgebraic subsets. A collection of families of r-tuple of plants in W, parameterized by a semialgebraic subset W_1 of W is given by an algebraic function

$$\phi_1 : \Lambda_1 \times W_1 \to W. \tag{4.2}$$

Similarly, a collection of families of compensators in $S_{p,m}^q$ parameterized by a semialgebraic subset W_2 of W is given by the algebraic function

$$\phi_2 : \Lambda_2 \times W_2 \to S_{p,m}^q. \tag{4.3}$$

Note that a given element $w_1 \in W_1$ indeed defines a family of r-tuples of plants given by

$$\phi_1(\cdot, w_1) : \Lambda_1 \to W. \tag{4.4}$$

Similarly,

$$\phi_2(\cdot, w_2) : \Lambda_2 \to S_{p,m}^q \tag{4.5}$$

for $w_2 \in W_2$, defines a family ofcompensators. For notational simplicity, we would denote by $w_1 \in W_1$, the family of r-tuples of plants given by $\phi_1(\cdot, w_1)$. Similarly, $w_2 \in W_2$ will be used to denote the family of compensators $\phi_2(\cdot, w_2)$. We now define the notion of σ-stabilizability. Let h be a fixed algebraic function

$$h : \Lambda_1 \to \Lambda_2. \tag{4.6}$$

Let f_i, $i = 1, \cdots, r$ respectively, be the projections

$$f_i : W \to S_{m,p}^{n_i}. \tag{4.7}$$

DEFINITION (σ-*stabilizability*). The family of r-tuples of plants $w_1 \in W_1$, is said to be σ-stabilizable by a family of compensators $w_2 \in W_2$, if the closed loop systems

$$f_i \phi_1(\lambda, w_1)[I + \phi_2(h(\lambda), w_2) f_i \phi_1(\lambda, w_1)]^{-1} \tag{4.8}$$

have poles with real part less than $-\sigma$, for all $\lambda \in \Lambda_1$ and for all $i = 1, \cdots, r$.

In order to introduce the main result of this section we consider the following problem.

Problem. Describe the subset W_1' of W_1 given by

$$W_1' = \{w_1 \in W_1 | \exists \sigma > 0, w_2 \in W_2 \text{ and } w_1 \text{ is } \sigma\text{-stabilizable by } w_2\}. \tag{4.9}$$

The main result is now summarized as follows.

THEOREM 4.1. *For a fixed algebraic function h described by* (4.6), *the set W_1' of σ-stabilizable families of r-tuple of plants for $\sigma > 0$, is open, semialgebraic. There exists a semialgebraic subset X of a proper algebraic set, where X consists of non-σ stabilizable families of r-tuples of plants in W_1, such that $W_1 - X$ has finitely many path components with the property that—if w_1 and w_1' are in the same path component of $W_1 - X$ then the*

family w_1 is σ-stabilizable iff the family w_1' is σ-stabilizable by some family of compensators $w_2 \in W_2$.

Proof. To see that W_1' is open, let $w_1 \in W_1'$. By assumption, there exists a $\sigma_0 > 0$ such that w_1 is σ_0-stabilizable by some $w_2 \in W_2$. Equivalently, the closed loop systems $f_i\phi_1(\lambda, w_1)[I + \phi_2(h(\lambda), w_2), f_i(\phi_1(\lambda, w_1))]^{-1}$ have poles with real part less than $-\sigma_0$, for all $\lambda \in \Lambda_1$ and for all $i = 1, \cdots, r$. Since $\sigma_0 > 0$, every element w_1' sufficiently close to w_1 in W_1', is σ_0'-stabilizable for σ_0' sufficiently close to σ_0. Hence $\sigma_0' > 0$. Hence W_1' is open.

To see that W_1' is semialgebraic, consider the space

$$W_1 \times W_2 \times \Lambda_1 \times \mathbb{R}^-, \tag{4.10}$$

where $\mathbb{R}^-$ is the open negative real axis. Consider the subset U in (4.10) given by

$$U = \{(w_1, w_2, \lambda_1, \sigma) | f_i(\phi_1(\lambda_1, w_1)) \text{ is } \sigma\text{-stabilizable by } \phi_2(h(\lambda_1), w_2)\}. \tag{4.11}$$

By the Routh–Hurwitz condition [11], U is semialgebraic. Let p be the projection

$$\text{proj}_1 \colon W_1 \times W_2 \times \Lambda_1 \times \mathbb{R}^- \to W_1 \times \Lambda_1 \tag{4.12}$$

by the Tarski–Seidenberg [26], [22] theory of elimination over R, $U_1 = \text{proj}_1 U$ is semialgebraic in $W_1 \times \Lambda_1$. Moreover $\bar{U}_1$, the complement of U_1 in $W_1 \times \Lambda_1$ is also semialgebraic. Consider the projection

$$\text{proj}_2 \colon W_1 \times \Lambda_1 \to W_1. \tag{4.13}$$

The set $U_2 = \overline{\text{proj}_2(\bar{U}_1)}$ is semialgebraic in W_1. Moreover, U_2 precisely corresponds to those families of r tuples of plants that are σ-stabilizable. Hence $W_1' = U_2$ is semialgebraic.

Thus W_1' is open, semialgebraic and by Delzell's theorem [9], is described by conjunction and disjunction of strict inequalities.

$$h_j(\cdot) > 0 \tag{4.14}$$

for $j = 1, \cdots, t$, where t is some positive integer. Let us now define a proper, algebraic subset X_1 of W_1 given by

$$X_1 = \bigcup_j \{h_j(\cdot) = 0\} \tag{4.15}$$

for $j = 1, \cdots, t$. Since X_1 is algebraic, by Whitney [20], $W_1 - X_1$ has finitely many path components. Let X be defined by

$$\begin{aligned} X &= \bigcup_j [\{h_j(\cdot) = 0 \cap \bar{W}_1'] \\ &= X_1 \cap \bar{W}_1'. \end{aligned} \tag{4.16}$$

Clearly X is semialgebraic and is a subset of the proper algebraic set X_1. Moreover

$$W_1 - X = (W_1 - X_1) \cup (X_1 - \bar{W}_1'). \tag{4.17}$$

Since $W_1 - X_1$ has finitely many path components with the property that every component either contains simultaneously σ-stabilizable family of plants for some $\sigma > 0$ or simultaneously σ-unstabilizable family of plants, it is clear $W_1 - X$ also has the same property. This is because a σ-stabilizable component and a σ-unstabilizable component cannot be separated by a boundary of σ-stabilizable family of plants, σ-stabilizability being an open condition. Q.E.D.

Let us now consider a refinement of Theorem 4.1 under the hypothesis that Λ_1 is compact.

THEOREM 4.2. *Let the parameter space Λ_1 be compact. For a fixed algebraic function h described by* (4.6), *the set W_1' of stabilizable families of r-tuple of plants is open, semialgebraic. There exists a semialgebraic subset X of a proper algebraic set, where X consists of nonstabilizable families of r-tuples of plants in W_1, such that $W_1 - X$ has finitely many path components with the property that—if w_1 and w_1' are in the same path components of $W_1 - X$, then the family w_1 is stabilizable iff the family w_1' is stabilizable by some family of compensators $w_2 \in W_2$.*

Remark. Note first of all that in Theorem 4.2 we are discussing stabilizability (or zero stabilizability) as opposed to Theorem 4.1 where we have σ-stabilizability, for $\sigma > 0$.

An important corollary of Theorem 4.2, follows in the special case when $\Lambda_1 = \{1, 2, \cdots, r\}$ and h is a constant function.

COROLLARY 4.1. *There exists a semi-algebraic subset of a proper algebraic set X, consisting of nonstabilizable r-tuples of plants such that $W_1 - X$ has finitely many components with the property that—if $(G_1(s), \cdots, G_r(s))$ and $(G_1'(s), \cdots, G_r'(s))$ are in the same path component then $(G_1(s), \cdots, G_r(s))$ is simultaneously stabilizable by a fixed nonswitching compensator iff $(G_1'(s), \cdots, G_r'(s))$ is so.*

If on the other hand Λ_2 the compensator parameter space is a single point, so that the algebraic function h described by (4.6) is a constant function, we have the simultaneous version of the "blending problem" originally addressed by Tannenbaum [24], [25].

Finally we come to the proof of Theorem 4.2.

Proof. The proof of this theorem is analogous to Theorem 4.1. However, one has to show that the set W_1' given by (4.18) is open.

$$W_1' = \{w_1 \in W_1 | \exists w_2 \in W_2 \text{ and } w_1 \text{ is stabilizable by } w_2\}. \tag{4.18}$$

Let $w_1 \in W_1'$. By hypothesis, there exists a $w_2 \in W_2$ with the following property—if $\pi_i(s, \lambda_1)$ is the characteristic polynomial of the closed loop system for $\lambda_1 \in \Lambda_1$ and $i \in \{1, \cdots, r\}$, then $\pi_i(s, \lambda_1)$ has roots in the open left half of the complex plane for all $\lambda_1 \in \Lambda_1$ and $i \in \{1, \cdots, r\}$. Let $s_{i,j}^{(\lambda_1)}$, $j = 1, \cdots, n_i + q$ be the roots of $\pi_i(s, \lambda_1)$, for a fixed $i \in \{1, \cdots, r\}$, $\lambda_1 \in \Lambda_1$. Define

$$r^{(\lambda_1)} = \max_{i,j} \operatorname{Re} s_{i,j}^{(\lambda_1)}, \tag{4.19}$$

where $r^{(\lambda_1)}$ is clearly a continuous function of λ_1. Since Λ_1 is compact, $r^{(\lambda_1)}$ attains a maximum value r where $r < 0$, since $w_1 \in W_1'$. Consider w_1' in a sufficiently small open neighborhood N_{w_1} of w_1 in W_1, together with w_2 in W_2. By repeating the above argument, there exists $r' < 0$ sufficiently close to r, such that the real parts of the roots of the associated characteristic polynomials $\pi_1'(s, \lambda_1)$ for all $i \in \{1, \cdots, r\}$ and $\lambda_1 \in \Lambda_1$ is less than or equal to r'. Hence $N_{w_1} \subset W_1'$. Q.E.D.

Remark. A semialgebraic subset of a proper algebraic set is automatically of Lebesgue measure zero. Thus, roughly speaking, one is deleting a "thin" set of nonstabilizable plants (family of plants) so that the remaining set has a "component" property. This, we remark, is conceptually significant since we now have to analyze big pieces of components rather than an individual family of plants.

5. Path component properties of the simultaneous pole placement problem. In this section we want to generalize the pole assignability Problem 3.4 to the simultaneous pole placement problem described as follows.

Problem 5.1. Parameterize the set of r-tuples of m input p output plants, $G_1(s), \cdots, G_r(s)$ each of a given McMillan degree n_i, $i=1, \cdots, r$, respectively, for which there exist a nonswitching p input m output proper compensator $K(s)$ of McMillan degree q that arbitrarily assigns all the poles of the closed loop systems $G_i(s)[I+K(s)G_i(s)]^{-1}$; $i=1, \cdots, r$.

Generalizing the technique used in the proof of Theorem 3.3, we now show the following.

THEOREM 5.1. *The set W_p of simultaneously pole assignable (by a proper compensator of Mcmillan degree q) r-tuples of plants $G_1(s), \cdots, G_r(s)$, in $W = S^{n_1}_{m,p} \times \cdots \times S^{n_r}_{m,p}$ is semialgebraic. There exists a proper algebraic set X in W such that $W-X$ has finitely many path components with the property that—if $(G_1(s), \cdots, G_r(s))$ and $(G'_1(s), \cdots, G'_r(s))$ are in the same path component, then $(G_1(s), \cdots, G_2(s))$ is simultaneously pole assignable by a proper compensator of McMillan degree q iff $(G'_1(s), \cdots, G'_r(s))$ is so.*

Remark. We do not claim in Theorem 5.1 that the set W_p is open.

Proof. The fact that W_p is semialgebraic is an immediate generalization of Theorem 3.3 (see [12] for details). Thus W_p is described by conjunction and disjunction of inequalities and equalities of the type

$$h_j(\cdot) > 0, \qquad g_k(\cdot) = 0 \tag{5.1}$$

for $j=1, \cdots, t_1$, $k=1, \cdots, t_2$ where t_1, t_2 are some positive integers. Define X to be the proper algebraic set given by

$$X = \bigcup_j \{h_j(\cdot)=0\} \bigcup_k \{g_k(\cdot)=\}. \tag{5.2}$$

It is clear that X is the proper algebraic set with the required path component property. Q.E.D.

For the rest of this section, our aim is to refine Theorem 5.1. First of all we claim that the set W_p, of pole assignable r-tuple of plants is not open in general. This we show by considering the following example.

Example 5.1. Consider a single input single output plant of McMillan degree 1 given by $(p_1 s+p_2)/(s+p_3)$ parameterized in $\mathbb{R}^3$ by the point (p_1, p_2, p_3). Consider the gain feedback c_1/c_2. To say that the gain places the poles of the system at $s=-\alpha$ is to say that the following matrix equation

$$[c_1 \quad c_2]\begin{bmatrix} p_1 & p_2 \\ 1 & p_3 \end{bmatrix} = [1 \quad \alpha] \tag{5.3}$$

has a solution. The set of all p_1, p_2, p_3 for which (5.3) has a solution is given by $\mathcal{S}_1 \cup \mathcal{S}_2$ where

$$\mathcal{S}_1 = \{(p_1, p_2, p_3) | p_2 \neq p_1 p_3\},$$

$$\mathcal{S}_2 = \{(p_1, p_2, p_3) | p_2 = p_1 p_3, p_3 = \alpha\}.$$

Note that although $\mathcal{S}_1$ is an open set, $\mathcal{S}_2$ is a proper Zariski closed subset of $\mathbb{R}^3$. Note also that the set

$$\mathbb{R}^2 - \{(p_1, p_2, p_3) | p_2 = p_1 p_3\} \tag{5.4}$$

has finitely many components that are pole assignable.

6. An explicit solution of the parameterization problem. In this section, we consider an r-tuple of $p \times m$, $\min(m, p) = 1$ strictly proper plants of McMillan degrees n_i, $i=$

$1, \cdots, r$, respectively. The problem is to parameterize explicitly the set of r-tuples of plants that can be stabilized by a proper compensator of McMillan degree q. In this section we obtain the parameterization under the assumption $(q+1)(m+1)=\Sigma n_i + rq$. Without any loss of generality we can assume that $m \geqq p$, for if $K(s)$ stabilizes $G_i^T(s)$, then $K^T(s)$ stabilizes $G_i(s)$. A given set of r, m input 1 output plants of McMillan degree $\leqq n_i$ may be represented as

$$\left[\sum_{j=0}^{n_i} p_{m+1,j}^i s^j\right]^{-1}\left[\sum_{j=0}^{n_i} p_{1,j}^i s^j, \cdots, \sum_{j=0}^{n_i} p_{m,j}^i s^j\right] \tag{6.1}$$

for $i=1,2,\cdots,r$, where $p_{m+1,n_i}^i=1$, $i=1,\cdots,r$ and $p_{k,n_i}^i=0$, $k=1,\cdots,m$, $i=1,\cdots,r$. Similarly, a 1 input m output proper compensator of McMillan degree $\leqq q$ is represented as

$$\left[\sum_{j=0}^{q} a_{1,j}s^j, \cdots, \sum_{j=0}^{q} a_{m,j}s^j\right]^T\left[\sum_{j=0}^{q} a_{m+1,j}s^j\right]^{-1}. \tag{6.2}$$

The associated return difference equation, $\det[I+K(s)G_p(s)]=0$ is given by

$$\begin{aligned}\pi_i(s) &= \sum_{k=1}^{m+p}\left[\sum_{j=0}^{n_i} p_{k,j}^i s^j\right]\left[\sum_{j=0}^{q} a_{k,j}s^j\right] \\ &\triangleq \sum_{j=0}^{n_i+q} c_{i,j}s^j \quad \forall i=1,\cdots,r,\end{aligned} \tag{6.3}$$

where $c_{i,n_i+q}=1\ \forall i=1,\cdots,r$. A generic r-tuple of plants defines a linear mapping χ, via (6.3), between the compensator parameters and the coefficient of the return difference polynomials given by

$$\chi: \mathbb{R}^{q(m+1)+m+1} \to \mathbb{R}^{\Sigma n_i + rq + 1}, \tag{6.4}$$

where χ may be defined as

$$\chi(\underline{a}) = \underline{a}S = (c_{1,0}, \cdots, c_{1,n_1+q-1}, \cdots, c_{r,n_r+q-1}, c_{1,n_1+q}), \tag{6.5}$$

where $\underline{a}$ is the $q(m+1)+m+1$ compensator parameters $a_{i,j}$ and S is the associated Sylvestor's matrix (see [12], [15] for details). It is known [12] that for a generic r-tuple of plants, the rows of S are independent. Thus the image of χ given by (6.4) is a subspace of codimension 1 in $\mathbb{R}^{\Sigma n_i + rq + 1}$. Let us now define

$$\begin{aligned}\mathcal{D} = \Bigg\{(c_{i,j}, j=0,\cdots,n_i+q;\ i=1,\cdots,r) \Bigg| &\sum_{j=0}^{n_i+q} c_{i,j}s^j \text{ has roots in the open} \\ &\text{left half of the complex plane, for } i=1,\cdots,r\Bigg\}\end{aligned} \tag{6.6}$$

and its convex hull $\Omega(\mathcal{D}) \subset R^{n_1+q} \times \cdots \times \mathbb{R}^{n_r+q}$. It was shown by Chen [5] that

LEMMA 6.1 (Chen [5]). *The convex hull of $\mathcal{D}$ is given by*

$$\Omega(\mathcal{D}) = \{(c_{i,j}) | c_{i,j} > 0\}. \tag{6.7}$$

Moreover if image χ is an affine hyperplane then

$$\text{image}\,(\chi) \cap \Omega(\mathcal{D}) \neq \varnothing \text{ iff } \text{image}\,(\chi) \cap \mathcal{D} \neq \varnothing. \tag{6.8}$$

Thus the stabilizability of the r-tuple of plants (6.1) is equivalent to solving (6.5) for some $c_{i,j} > 0\ \forall i,j$. We now prove the following lemma.

LEMMA 6.2. *Assume* $(q+1)(m+1)=\sum n_i+rq$. *For a given r-tuple of plants (chosen generically) let* $\underline{\alpha}$ *be a vector orthogonal to image* χ. *Then the r-tuple of plants is simultaneously unstabilizable iff* $\underline{\alpha}\in\Omega(\mathscr{D})$.

Proof. (if) By assumption $\underline{\alpha}\in\Omega(\mathscr{D})$ so that

$$\text{image}\,(\chi)\cap\Omega(\mathscr{D})=\varnothing. \tag{6.9}$$

Thus by Lemma 6.1,

$$\text{image}\,\chi\cap\mathscr{D}=\varnothing. \tag{6.10}$$

(only if) Assume that $\underline{\alpha}\notin\Omega(\mathscr{D})$. Then clearly there exists $\underline{\alpha}_1\in\Omega(\mathscr{D})$ such that $\underline{\alpha}\perp\underline{\alpha}_1$. Hence $\underline{\alpha}_1\in$ image χ so that

$$\text{image}\,\chi\cap\Omega(\mathscr{D})\neq\varnothing$$

or equivalently by Lemma 6.1,

$$\text{image}\,\chi\cap\mathscr{D}\neq\varnothing. \qquad \text{Q.E.D.}$$

We now use Lemma 6.2 to obtain a parameterization of the set of unstabilizable r-tuples of plants. Let us represent the Sylvestor matrix S in (6.5) as

$$S=\begin{bmatrix} s_{11} & \cdots & s_{1,t} \\ s_{t-1,1} & \cdots & s_{t-1,t}\end{bmatrix}, \tag{6.11}$$

where $t=\sum n_i+rq+1$. Let

$$v_1\bar{i}_1+v_2\bar{i}_2+\cdots+v_t\bar{i}_t \tag{6.12}$$

be a vector orthogonal to image χ, where $\bar{i}_j, j=1,\cdots,t$ is the standard basis of $\mathbb{R}^t$. Then clearly

$$v_i=(-1)^{i+1}\det S_i,\ i=1,\cdots,t, \tag{6.13}$$

where S_i is obtained from S by deleting its ith column. The set of stabilizable r-tuples of plants is now obtained by the semialgebraic condition

$$(v_1<0 \text{ or } \cdots \text{ or } v_t<0) \tag{6.14}$$

and

$$(v_1>0 \text{ or } \cdots \text{ or } v_t>0).$$

Example 6.1. Assume $q=0$, $r=2$, $m=2$, $p=1$, $n_1=1$, $n_2=2$. The Sylvestor matrix S is given by

$$S=\begin{bmatrix} p^1_{1,0} & p^2_{1,0} & p^2_{1,1} & 0 \\ p^1_{2,0} & p^2_{2,0} & p^2_{2,1} & 0 \\ p^1_{3,0} & p^2_{3,0} & p^2_{3,1} & 1\end{bmatrix}. \tag{6.15}$$

Thus,

$$\begin{aligned} v_1&=p^2_{1,0}p^2_{2,1}-p^2_{2,0}p^2_{1,1}\\ v_2&=p^1_{2,0}p^2_{1,1}-p^1_{1,0}p^2_{2,1},\\ v_3&=p^1_{1,0}p^2_{2,0}-p^1_{2,0}p^2_{1,0},\\ v_4&=\det\begin{bmatrix} p^1_{1,0} & p^2_{1,0} & p^2_{1,1} \\ p^1_{2,0} & p^2_{2,0} & p^2_{2,1} \\ p^1_{3,0} & p^2_{3,0} & p^2_{3,1}\end{bmatrix}.\end{aligned} \tag{6.16}$$

The simultaneously unstabilizable plants are given by

$$v_i v_j > 0 \quad \text{for } i, j \in \{1, 2, 3, 4\}. \tag{6.17}$$

7. A necessary condition for simultaneous stabilization of min $(m, p) = 1$ plants. We begin this section with the remark that the process of parameterizing the simultaneously stabilizable/unstabilizable r-tuples of plants (as described in §§ 2, 3 and 4) is computationally inefficient since it involves eliminating the set of compensator coefficients using decision algebra [2]. Thus we view §§ 2, 3 and 4 to be qualitative.

In [15], Ghosh and Byrnes have obtained sufficient conditions for the generic simultaneous stabilization of a r-tuple of plants. Furthermore the techniques described in [15] can be used to construct a simultaneously stabilizing compensator. In this section we obtain a necessary condition to the following simultaneous stabilization problem.

Problem 7.1. Given an r-tuple of $1 \times m$ proper plants $G_1(s), \cdots, G_r(s)$ of McMillan degrees n_i, $i = 1, \cdots, r$, respectively, does there exist a compensator $K(s)$ of McMillan degree q such that the closed-loop systems $G_i(s)[I + K(s)G_i(s)]^{-1}$, $i = 1, \cdots, r$ are (internally) stable?

Note that in the above Problem 7.1, the McMillan degree q of the compensator is held fixed. In order to illustrate the main idea of this section we consider the following example.

Example 7.1. Consider a triplet of single input single output plants $p_i(s)/q_i(s)$, $i = 1, 2, 3$ of McMillan degrees n_1, n_2, n_3 respectively. Let $c(s)/d(s)$ be the corresponding stabilizing compensators. Thus there exist Hurwitz polynomials $\Delta_1(s)$, $\Delta_2(s)$, $\Delta_3(s)$ such that

$$p_i(s)c(s) + q_i(s)d(s) = \Delta_i(s), \qquad i = 1, 2, 3, \tag{7.1}$$

or equivalently,

$$\begin{bmatrix} p_1(s) & q_1(s) \\ p_2(s) & q_2(s) \\ p_3(s) & q_3(s) \end{bmatrix} \begin{bmatrix} c(s) \\ d(s) \end{bmatrix} = \begin{bmatrix} \Delta_1(s) \\ \Delta_2(s) \\ \Delta_3(s) \end{bmatrix}. \tag{7.2}$$

A necessary condition for (7.2) to be satisfied is given by

$$\Delta_1(s)\eta_{32}(s) + \Delta_2(s)\eta_{13}(s) + \Delta_3(s)\eta_{21}(s) = 0, \tag{7.3}$$

where $\eta_{ij}(s) = p_i(s)q_j(s) - q_i(s)p_j(s)$.

In fact if the triplet of plants is chosen generically, then (7.3) is also a sufficient condition for the existence of $c(s)$, $d(s)$ satisfying 7.2 (see [13] for details). Now if we assume $n_1 = n_2 = n_3 = 1$ and $q = 0$, then generically we may write

$$\Delta_i(s) = \Delta_{i0} + \Delta_{i1}s, \tag{7.4}$$

and

$$\begin{aligned} \eta_{13}(s) &= \xi_{10} + \xi_{11}s + \xi_{12}s^2, \\ \eta_{13}(s) &= \xi_{20} + \xi_{21}s + \xi_{22}s^2, \\ \eta_{21}(s) &= \xi_{30} + \xi_{31}s + \xi_{32}s^2, \end{aligned} \tag{7.5}$$

so that (7.3) can be written as

$$[\Delta_{10}\,\Delta_{11}\,\Delta_{20}\,\Delta_{21}\,\Delta_{30}\,\Delta_{31}]\begin{bmatrix}\xi_{10} & \xi_{11} & \xi_{12} & 0\\ 0 & \xi_{10} & \xi_{11} & \xi_{12}\\ \xi_{20} & \xi_{21} & \xi_{22} & 0\\ 0 & \xi_{20} & \xi_{21} & \xi_{22}\\ \xi_{30} & \xi_{31} & \xi_{32} & 0\\ 0 & \xi_{30} & \xi_{31} & \xi_{32}\end{bmatrix} = [0\,0\,0\,0]. \tag{7.6}$$

A necessary and sufficient condition that $\Delta_i(s)$ defined in (7.4) is stable is given by the following:

$$\Delta_{i0} \text{ and } \Delta_{i1} \text{ have the same sign, for all } i = 1, 2, 3.$$

Assume for the purpose of illustration that every entry of the vector

$$[\Delta_{10}\,\Delta_{11}\,\Delta_{20}\,\Delta_{21}\,\Delta_{30}\,\Delta_{31}] \tag{7.7}$$

is positive. Thus to say that (7.6) is satisfied is to say that the polytope generated by the 6 points $p_1, p_2, p_3, p_4, p_5, p_6$ contain the origin, where

$$\begin{aligned} p_1 &= (\xi_{10}\,\xi_{11}\,\xi_{12}\,0), & p_2 &= (0\,\xi_{10}\,\xi_{11}\,\xi_{12}),\\ p_3 &= (\xi_{20}\,\xi_{21}\,\xi_{22}\,0), & p_4 &= (0\,\xi_{20}\,\xi_{21}\,\xi_{22}),\\ p_5 &= (\xi_{30}\,\xi_{31}\,\xi_{32}\,0), & p_6 &= (0\,\xi_{30}\,\xi_{31}\,\xi_{32}). \end{aligned} \tag{7.8}$$

Thus a necessary and sufficient condition that the triplet of single input single output plants of McMillan degree 1 is stabilizable by a feedback gain is that the polytope generated by

$$\begin{aligned} &p_1, p_2, p_3, p_4, p_5, p_6 \quad \text{or} \quad p_1, p_2, p_3, p_4, -p_5, -p_6 \quad \text{or}\\ &p_1, p_2, -p_3, -p_4, p_5, p_6 \quad \text{or} \quad p_1, p_2, -p_3, -p_4, -p_5, -p_6 \end{aligned} \tag{7.9}$$

contains the origin.

We would now like to generalize the argument presented in Example 7.1. Note first of all that for $n_1 = n_2 = n_3 = q = 1$ or for $n_1 = n_2 = n_3 = 2$, $q = 0$ one can mimic the argument of Example 7.1 to obtain a necessary and sufficient condition for the simultaneous stabilization of a triplet of plants.

The proof relies on the fact that a quadratic polynomial $\Delta_i(s)$, $i = 1, 2, 3$ is stable iff every coefficient of $\Delta_i(s)$ has the same sign. However, in general, a polynomial $\Delta(s)$ of degree n is stable only if every coefficient of $\Delta(s)$ is of the same sign. This idea is now applied as follows.

Consider a $m+2$ tuple of $1 \times m$ proper plants represented as

$$G_i(s) = \left[\frac{n_{i1}(s)}{n_{i,m+1}(s)} \quad \frac{n_{i2}(s)}{n_{i,m+1}(s)} \quad \cdots \quad \frac{n_{im}(s)}{n_{i,m+1}(s)}\right] \tag{7.10}$$

for $i = 1, 2, \cdots, m+2$. Consider a $m \times 1$ proper compensator represented as

$$k(s) = \left[\frac{c_1(s)}{c_{m+1}(s)} \quad \cdots \quad \frac{c_m(s)}{c_{m+1}(s)}\right]^T. \tag{7.11}$$

The compensator (7.11) stabilizes each one of the plants (7.10) iff there exists Hurwitz polynomials $\Delta_1(s), \cdots, \Delta_{m+2}(s)$ such that

$$n_{i1}(s)c_1(s) + \cdots + n_{i,m+1}(s)c_{m+1}(s) = \Delta_i(s) \tag{7.12}$$

for $i=1,\cdots,m+2$. Writing (7.12) in the matrix notation as

$$\begin{bmatrix} n_{11}(s) & \cdots & n_{1,m+1}(s) \\ n_{m+1,1}(s) & \cdots & n_{m+1,m+1}(s) \\ n_{m+2,1}(s) & \cdots & n_{m+2,m+1}(s) \end{bmatrix} \begin{bmatrix} c_1(s) \\ c_{m+1}(s) \end{bmatrix} = \begin{bmatrix} \Delta_1(s) \\ \Delta_{m+1}(s) \\ \Delta_{m+2}(s) \end{bmatrix}, \tag{7.13}$$

a necessary condition for the existence of $c_1(s),\cdots,c_{m+1}(s)$ that satisfy (7.13) is given by the condition

$$\det \begin{bmatrix} n_{11}(s) & \cdots & n_{1,m+1}(s) & \Delta_1(s) \\ n_{m+2,1}(s) & \cdots & n_{m+2,m+1}(s) & \Delta_{m+2}(s) \end{bmatrix} = 0. \tag{7.14}$$

The equation (7.14) can be viewed as a generalization of (7.3). Using the necessary condition for the stability of a polynomial, viz that every coefficient is of the same sign, one obtains the required necessary condition.

8. Conclusion and future developments. In this paper we describe an approach to simultaneous system design using semialgebraic geometric methods. The procedure described in this paper relies heavily on the fact that the McMillan degree of the compensator under consideration is bounded. Although this might be a reasonable assumption under most practical situations, it is also of interest to consider Problems 1.1 and 1.2 with the assumption that the McMillan degree of the compensator is not a priori bounded. We remark that the "space of compensators" under the above hypothesis is not finite-dimensional and semialgebraic geometric methods using decision algebra [2] are therefore not applicable. Using transcendental and interpolation methods, we have obtained (see [14]) semialgebraic parameterization of the simultaneously stabilizable and pole assignable collections of plants. Complete solution to the parameterization Problems 1.1 and 1.2 where the compensators are of unbounded McMillan degree is a subject of future research.

As an additional remark, it may be interesting to point out a recent research work by Richter and DeCarlo [21] on eigenvalue assignment by decentralized feedback and the fact the simultaneous system design problem may be viewed as a decentralized feedback problem with special structure.

Acknowledgments. Encouragement and constructive criticisms of Prof. Chris. I. Byrnes during the research work is gratefully acknowledged. Suggestions and comments of the referees are also gratefully acknowledged.

STATE ESTIMATION AND CONTROL OF CONDITIONALLY LINEAR SYSTEMS*

WOJCIECH J. KOLODZIEJ† AND RONALD R. MOHLER†‡

Abstract. The filtering problem for a partially observable stochastic system, with linear-in-unobservable state dynamics and non-Gaussian initial conditions is studied here. It is shown that the conditional expected value of the unobservable states, given the past and present observations, can be expressed in terms of a finite dimensional set of statistics. This result, which generalizes the conditionally Gaussian filter, is used to derive a separation principle for a linear-quadratic control problem.

Key words. optimal filtering, stochastic control, non-Gaussian stochastic systems

Introduction. Stochastic, partially observable systems, with linear-in-unobservable state dynamics are termed *conditionally linear systems* here. It is well-known that the solution of a state estimation problem for a conditionally linear system with Gaussian distribution of the initial state is given in terms of two sets of sufficient statistics, satisfying stochastic differential equations [4].

Discussed here is the state estimation problem which generalizes the above result for the case of an arbitrary a priori distribution of the initial state. The method applied in this study is based on the derivation of an explicit formula for the conditional characteristic function of the state, given the past and present observations. This approach, as opposed to the one presented in [1], avoids the use of Zakai's equation.

It is shown here that the conditional characteristic function of the present and past states, given the present and past observations, is parametrically determined by a finite number of sufficient statistics. This result leads to the derivation of a filter, in the form of a finite set of stochastic differential equations which extends the result of [1] in a similar manner as a conditionally Gaussian filter generalizes a Kalman filter.

Also discussed here and illustrated by the examples, is the suitability of the filter structure for the study of stochastic control and parameter estimation.

1. Problem formulation and the main result. Given the following system of stochastic differential equations

$$dx_t = (f_0(t, y) + f_1(t, y)x_t)\,dt + g_0(t, y)\,dw_t + q_0(t, y)\,dv_t, \tag{1.1}$$

$$dy_t = (h_0(t, y) + h_1(t, y)x_t)\,dt + dv_t, \qquad 0 \leqq t \leqq T, \tag{1.2}$$

where f_0, f_1, g_0, q_0, h_0, h_1 are $\mathbf{Y}_t$ measurable functionals of y, with $\mathbf{Y}_t = \sigma\text{-alg}\{y_s, 0 \leqq s \leqq t\}$, and w_t, v_t are independent Wiener processes.

The objective is to find $\hat{x}_t = \mathbf{E}(x_t|\mathbf{Y}_t)$, assuming that x_t, y_t satisfy (1.1) and (1.2), and that the conditional distribution of the initial states $F(a) = P(x_0 \leqq a|y_0)$ is given.

The organization of this section starts with Lemma 1, whereby it is shown that the conditional characteristic function of $(x_{t_0}, x_{t_1}, \cdots, x_{t_n})|\mathbf{Y}_t$, for arbitrary partition $0 \leqq t_0 < t_1 < \cdots < t_n \leqq t \leqq T$, of the interval $[0, T]$ is of a particular form. Results from the theory of conditionally Gaussian processes are used here.

Next, in Lemma 2, the explicit formula for the characteristic function of $x_t|\mathbf{Y}_t$ is derived, and finally, in Lemma 3, all the results are organized to yield the recursive, finite-dimensional set of filter equations.

The assumptions used in the proof of Lemma 1 and 2 are listed below: Let C_T denote the space of continuous functions $\eta = \{\eta_t, 0 \leqq t \leqq T\}$. It is assumed that for each $\eta \in C_T$

$$\int_0^T \left(\sum_{k=0}^{1} (|f_k(t, \eta)| + |h_k(t, \eta)|) + |g_0(t, \eta)|^2 + |q_0(t, \eta)|^2 \right) dt < \infty. \tag{1.3}$$

The above assumption assures the existence of the Ito integrals in (1.1) and (1.2) [3]. In order to use the results for conditionally Gaussian processes it is also assumed that [4]:

$$\text{for all } \eta \in C_T, \quad t \in [0, T], \quad |f_1(t, \eta)| + |h_1(t, \eta)| \leqq \text{const}, \tag{1.4}$$

and

$$\int_0^T \mathbf{E}(|f_0(t, y)|^4 + |g_0(t, y)|^4 + |q_0(t, y)|^4)\, dt < \infty, \mathbf{E}(|x_0|^4) < \infty. \tag{1.5}$$

LEMMA 1. *Let*

$$\phi_t = \exp\left(i \sum_{k=0}^{n} z_k x_{t_k} \right), \quad z = \begin{bmatrix} z_1 \\ \vdots \\ z_n \end{bmatrix} \in R^n, \quad 0 \leqq t_0 < t_1 < \cdots < t_n \leqq t \leqq T.$$

Then the conditional characteristic function of $(x_{t_0}, x_{t_1}, \cdots, x_{t_n})|\mathbf{Y}_t$ *is given by*

$$\mathbf{e}_t(z) = \mathbf{E}(\phi_t|\mathbf{Y}_t) = \int_{-\infty}^{\infty} \exp\,(Q(t, a, z, y))\, dF(a) \tag{1.6}$$

where $Q(t, a, z, y)$ *is quadratic in the variables* a *and* z.

Proof of Lemma 1. First notice that (1.1) solves as

$$x_t = \Phi_t \left(x_0 + \int_0^t \Phi_s^{-1}(f_0 - q_0 h_0)\, ds + \int_0^t \Phi_s^{-1} q_0\, dy_s + \int_0^t \Phi_s^{-1} g_0\, dw_s \right) \tag{1.7}$$

where

$$\Phi_t = \exp\left(\int_0^t (f_1 - q_0 h_1)\, ds \right).$$

Rewrite (1.7) in the symbolic way as

$$x_t = \psi_t(x_0, w, y). \tag{1.8}$$

Now, the following version of the Bayes formula will be used [2, p. 8]: Let $\phi_t(x_0, w, y)$ be a nonanticipative functional of its arguments with $\mathbf{E}(|\phi_t|) < \infty$ for all $t \in [0, T]$. Then

$$\mathbf{E}(\phi_t|\mathbf{Y}_t) = \int_{-\infty}^{\infty} \int_{C_T} \phi_t(a, \eta, y) \rho_t(a, \eta, y)\, d\mu_w(\eta)\, dF(a) \tag{1.9}$$

where μ_w is a Wiener measure on the measurable space of continuous functions η on $[0, T]$,

$$\rho_t(a, \eta, y) = \exp\left(\int_0^t h_1(\psi_s(a, \eta, y) - \hat{x}_s(y))\, d\nu_s \right. \tag{1.10}$$

$$\left. - \frac{1}{2} \int_0^t h_1^2(\psi_s(a, \eta, y) - \hat{x}_s(y))^2\, ds \right)$$

with $d\nu_s = dy_s - (h_0 + h_1\hat{x}_s)\,ds$, and $\psi_s(a, \eta, y)$ defined by (1.8). The innovations process ν_t can be represented by

$$\nu_t = \int_0^t (dy_s - (h_0(s, y) + h_1(s, y)\hat{x}_s(y))\,ds) = v_t + \int_0^t h_1(s, y)(x_s - \hat{x}_s(y))\,ds.$$

Now using the Ito formula we have

$$e^{iz\nu_t} = e^{iz\nu_s} + iz\int_s^t h_1(\tau, y)\, e^{iz\nu_\tau}(x_\tau - \hat{x}_\tau(y))\,d\tau$$
$$+ iz\int_s^t e^{iz\nu_\tau}\,dv_\tau - \frac{z^2}{2}\int_s^t e^{iz\nu_\tau}\,d\tau.$$

Multiplying both sides of the above equation by $e^{iz\nu_s}$ and taking the conditional expectation $\mathbf{E}(\cdot|\mathbf{Y}_s)$ gives

$$\mathbf{E}(e^{iz(\nu_t - \nu_s)}|\mathbf{Y}_s) = 1 - \frac{z^2}{2}\int_s^t \mathbf{E}(e^{iz(\nu_\tau - \nu_s)}|\mathbf{Y}_s)\,d\tau.$$

Solving the last equation yields

$$\mathbf{E}(e^{iz(\nu_t - \nu_s)}|\mathbf{Y}_s) = e^{-z^2(t-s)/2}, \tag{1.11}$$

which shows that $(\nu_t, \mathbf{Y}_t)$ is a Wiener process. Now rewrite $\rho_t(a, \eta, y)$ in a more convenient form. To this end introduce the following notation:

$$A_1(t, y) = h_1\left(\Phi_t\left(\int_0^t \Phi_s^{-1}(f_0 - q_0h_0)\,ds + \int_0^t \Phi_s^{-1}q_0\,dy_s\right) - \hat{x}_t\right),$$

$$A_2(t, y) = h_1\Phi_t,$$

$$A_3(t, y) = \Phi_t^{-1}g_0,$$

$$C_1(t, y) = \int_0^t A_1(s, y)\,d\nu_s - \tfrac{1}{2}\int_0^t A_1^2(s, y)\,ds,$$

$$C_2(t, y) = \int_0^t A_2(s, y)\,d\nu_s - \int_0^t A_1(s, y)A_2(s, y)\,ds,$$

$$C_3(t, y) = \int_0^t A_2^2(s, y)\,ds,$$

$$C_4(t, y, w) = \int_0^t A_2(s, y)\int_0^s A_3(\tau, y)\,dw_\tau\,d\nu_s$$
$$- \int_0^t A_1(s, y)A_2(s, y)\int_0^s A_3(\tau, y)\,dw_\tau\,ds,$$

$$C_5(t, y, w) = -\int_0^t A_2^2(s, y)\int_0^s A_3(s, y)\,dw_\tau\,ds.$$

Note also that $C_4(t, y, w)$ and $C_5(t, y, w)$ can be rewritten with the use of the Ito formula as follows:

$$C_4(t, y, w) = \int_0^t A_4(t, s, y)\,dw_s,$$

$$C_5(t, y, w) = \int_0^t A_5(t, s, y)\,dw_s,$$

where

$$A_4(t, s, y) = \left(\int_s^t A_2(\tau, y)\, d\nu_\tau - \int_s^t A_1(\tau, y) A_2(\tau, y)\, d\tau \right) A_3(s, y),$$

$$A_5(t, s, y) = -\left(\int_s^t A_2^2(\tau, y)\, d\tau \right) A_3(s, y).$$

Now, using the above notation, we have from (1.8) and (1.10)

$$\begin{aligned} \rho_t(a, w, y) &= \exp\left(C_1 + a(C_2 + C_5) + C_4 - \frac{a^2}{2} C_3 - \frac{1}{2} \int_0^t A_2^2 \left(\int_0^s A_3\, dw_\tau \right)^2 ds \right) \\ &= \exp\left(C_1 + aC_2 - \frac{a^2}{2} C_3 + \int_0^t (aA_5 + A_4)\, dw_s - \frac{1}{2} \int_0^t A_2^2 \left(\int_0^s A_3\, dw_\tau \right)^2 ds \right). \end{aligned} \tag{1.12}$$

The arguments in (1.12) were omitted for brevity. From (1.8) it follows that

$$x_t = \psi_t(x_0, w, y) = \Phi_t \left(x_0 + A_6(t, y) + \int_0^t A_3(s, y)\, dw_s \right)$$

where

$$A_6(t, y) = \int_0^t \Phi_s^{-1}(f_0 - q_0 h_0)\, ds + \int_0^t \Phi_s^{-1} q_0\, dy_s.$$

Combining (1.12) and the above,

$$\begin{aligned} \exp(Q(t, a, z, y)) &= \int_{C_T} \phi_t(a, \eta, y) \rho_t(a, \eta, y)\, d\mu_w(\eta) \\ &= \exp\left(C_1 + aC_2 - \frac{a^2}{2} C_3 + a \left(\sum_{k=1}^n \Phi_{t_k} i z_k \right) + \sum_{k=1}^n \Phi_{t_k} A_6(t_k, y) i z_k \right) \\ &\quad \cdot \int_{C_T} \exp\left(\int_0^t (aA_5 + A_4)\, d\eta_s + \sum_{k=1}^n i z_k \Phi_{t_k} \int_0^{t_k} A_3\, d\eta_s \right. \\ &\qquad \left. - \tfrac{1}{2} \int_0^t A_2^2 \left(\int_0^s A_3\, d\eta_\tau \right)^2 ds \right) d\mu_w(\eta). \end{aligned} \tag{1.13}$$

In order to evaluate the integral in (1.13), the following results will be used:

(i) Since the above integral represents a conditional expected value of its integrand, under the condition that y_s, $s \in [0, t]$ and $x_0 = a$ are given, the resulting distributions are of conditionally Gaussian type [4]. Note that this fact does *not* depend on the $F(a)$.

(ii) With all the variables in (1.13) being conditionally Gaussian we can use a convenient theorem:

THEOREM [4, pp. 12–13]. *Let w_t, $t \in [0, T]$ be a Wiener process and let $R(t)$, $G(t)$, and $H(t) \geqq 0$ be such that*

$$\int_0^T (|R(t)| + G(t)^2 + H(t))\, dt < \infty.$$

Then for all $t \in [0, T]$

$$\begin{aligned} &\mathbf{E}\left(\exp\left(\int_0^t R(s) G(s)\, dw_s - \int_0^t H(s) \left(\int_0^s G(\tau)\, dw_\tau \right)^2 ds \right) \right) \\ &\qquad = \exp\left(\frac{1}{2} D(t) + \frac{1}{2} \int_0^t G(s)^2 \Gamma(s)\, ds \right) \end{aligned} \tag{1.14}$$

where

$$d\Gamma(s) = (2H(s) - \Gamma(s)^2 G(s)^2)\, ds, \qquad \Gamma(t) = 0,$$

and $D(t)$ *is the covariance of* $\int_0^t R(s)\, d\xi_s$, *where*

$$d\xi_s = G(s)^2 \Gamma(s) \xi_s\, ds + G(s)\, dw_s, \qquad \xi_0 = 0.$$

Comparing the last integral in (1.13) with the equation given by (1.14), we note that the corresponding $R(t)$ is a linear function of a and z. Now (1.9), (1.13), (1.14), and the definition of $D(t)$ conclude the proof of Lemma 1.

From Lemma 1 it follows in particular that for $z \in R$, the characteristic function of $x_t|\mathbf{Y}_t$ is given by

$$\begin{aligned}\mathbf{e}_t(z) = C(t, y) \int_{-\infty}^{\infty} \exp\,(a^2 F_1(t, y) + aF_2(t, y) \\ + izaF_3(t, y) + izF_4(t, y) + z^2 F_5(t, y))\, dF(a),\end{aligned} \tag{1.15}$$

where F_1, F_2, F_3, F_4, F_5 do not depend on $F(a)$. Normalizing $\mathbf{e}_t(z)$ (i.e., requiring that $\mathbf{e}_t(0) = 1$) yields

$$\mathbf{e}_t(z) = \exp\,(izF_4 + z^2 F_5) \frac{\int_{-\infty}^{\infty} \exp\,(a^2 F_1 + a(F_2 + izF_3))\, dF(a)}{\int_{-\infty}^{\infty} \exp\,(a^2 F_1 + aF_2)\, dF(a)}. \tag{1.16}$$

Then from the general properties of the characteristic function, it follows that

$$\frac{1}{i} \frac{d\mathbf{e}_t(z)}{dz}\bigg|_{z=0} = \hat{x}_t, \qquad \left(\frac{1}{i}\right)^2 \frac{d^2 \mathbf{e}_t(z)}{dz^2}\bigg|_{z=0} = P_t + \hat{x}_t^2,$$

where $P_t = \mathbf{E}((x_t - \hat{x}_t)^2|\mathbf{Y}_t)$ i.e., the conditional variance of $x_t|\mathbf{Y}_t$. From the above and (1.16)

$$\hat{x}_t = F_3 I_t(1) + F_4, \tag{1.17}$$

$$P_t = -2F_5 + F_3^2 (I_t(2) - I_t^2(1)), \tag{1.18}$$

where

$$I_t(n) = \frac{\int_{-\infty}^{\infty} a^n \exp\,(a^2 F_1 + aF_2)\, dF(a)}{\int_{-\infty}^{\infty} \exp\,(a^2 F_1 + aF_2)\, dF(a)}, \qquad n = 1, 2. \tag{1.19}$$

The following Lemma defines F_i, $i = 1, 2, 3, 4, 5$ in (1.16).

LEMMA 2. *The characteristic function of* $x_t|\mathbf{Y}_t$ *is given by*

$$\mathbf{e}_t(z) = \exp\,(-\tfrac{1}{2} z^2 \bar{P}_t(0)) \frac{\int_{-\infty}^{\infty} \exp\,(a^2 F_1 + aF_2 + iz\bar{x}_t(a, 0))\, dF(a)}{\int_{-\infty}^{\infty} \exp\,(a^2 F_1 + aF_2)\, dF(a)}, \tag{1.20}$$

where $\bar{x}_t(a, 0)$, $\bar{P}_t(0)$ *are given as the solutions to the following set of differential equations with* $\sigma = 0$

$$\begin{aligned}&d\bar{x}_t(a, \sigma) = (f_0 + f_1 \bar{x}_t(a, \sigma))\, dt + (q_0 + \bar{P}_t(\sigma) h_1)(dy_t - (h_0 + h_1 \bar{x}_t(a, \sigma))\, dt), \\ &\bar{x}_0(a, \sigma) = a,\end{aligned} \tag{1.21}$$

$$d\bar{P}_t(\sigma) = (2f_1 \bar{P}_t(\sigma) + g_0^2 + q_0^2 - (q_0 + \bar{P}_t(\sigma) h_1)^2\, dt, \qquad \bar{P}_0(\sigma) = \sigma^2, \tag{1.22}$$

and

$$F_1 = -\frac{1}{2} \int_0^t h_1^2 \phi_s^2\, ds, \tag{1.23}$$

$$F_2 = \int_0^t \phi_s h_1 (d\nu_s + h_1 \phi_s I_s(1)\, ds), \tag{1.24}$$

$$\phi_t = \exp\left(\int_0^t (f_1 - h_1(q_0 + \bar{P}_s(0) h_1))\, ds \right). \tag{1.25}$$

Proof of Lemma 2. Since the F_i do not depend on $F(a)$ (see Lemma 1), take

$$dF(a) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(a-m)^2}{2\sigma^2} \right) da, \qquad \sigma > 0. \tag{1.26}$$

In this case the resulting conditionally Gaussian distribution allows for explicit $\mathbf{e}_t(z)$ calculation [4]. Accordingly,

$$\mathbf{e}_t(z) = \exp\left(iz\bar{x}_t(m, \sigma) - \tfrac{1}{2} z^2 \bar{P}_t(\sigma) \right), \tag{1.27}$$

where $\bar{x}_t(m, \sigma)$ and $\bar{P}_t(\sigma)$ satisfy (1.21) and (1.22) respectively. With $F(a)$ given by (1.26) it follows from (1.16) that

$$\mathbf{e}_t(z) = \exp\left(iz\left(F_4 + \hat{\sigma}^2\left(F_2 + \frac{m}{\sigma^2} \right) F_3 \right) + z^2\left(F_5 - \frac{1}{2}\hat{\sigma}^2 F_3^2 \right) \right), \tag{1.28}$$

where

$$\hat{\sigma}^{-2} = \sigma^{-2} - 2F_1.$$

Comparing (1.27) and (1.28), we have

$$\bar{x}_t(m, \sigma) = F_4 + \hat{\sigma}^2\left(F_2 + \frac{m}{\sigma^2} \right) F_3, \tag{1.29}$$

and

$$\bar{P}_t(\sigma) = \hat{\sigma}^2 F_3^2 - 2F_5. \tag{1.30}$$

Letting now $\sigma \to 0$ in (1.29) and (1.30), it follows that

$$F_4 + mF_3 = \bar{x}_t(m, 0), \tag{1.31}$$

and

$$F_5 = -\tfrac{1}{2}\bar{P}_t(0). \tag{1.32}$$

The above allows $\mathbf{e}_t(z)$ to be of the form of (1.20) with F_1 and F_2 yet to be defined. Using now (1.17) and (1.18) and explicitly calculating $I_t(n)$, $n = 1, 2$, we have

$$\Delta_t(\sigma^{-2} - 2F_1) = F_3^2 \tag{1.33}$$

and

$$\Delta_t\left(\frac{m}{\sigma^2} + F_2 \right) = F_3(\hat{x}_t - F_4), \tag{1.34}$$

with

$$\Delta_t = P_t - \bar{P}_t(0).$$

The formulae for F_1 and F_2 will be obtained by differentiating (1.33) and (1.34). However, before this is done, recall from the theory of nonlinear filtering [3] that in

general, for x_t, y_t given as a solution to (1.1) and (1.2) $\hat{x}_t$, P_t satisfy

$$d\hat{x}_t = (f_0 + f_1\hat{x}_t)\,dt + (q_0 + P_t h_1)\,d\nu_t, \qquad \hat{x}_0 = \int_{-\infty}^{\infty} a\,dF(a), \tag{1.35}$$

$$\begin{aligned} dP_t &= (2f_1P_t + g_0^2 + q_0^2 - (q_0 + P_t h_1)^2)\,dt + h_1 R_t\,d\nu_t \\ P_0 &= \int_{-\infty}^{\infty} (a - \hat{x}_0)^2\,dF(a), \end{aligned} \tag{1.36}$$

where

$$R_t = \mathbf{E}((x_t - \hat{x}_t)^3 | \mathbf{Y}_t).$$

Remark. Direct application of (1.35) and (1.36) meets the difficulty of infinite coupling between the subsequent moments. From (1.22), (1.35), and (1.36), and the fact that for conditionally Gaussian processes $R_t = 0$,

$$d\Delta_t = \Delta_t(2f_1 - h_1(2q_0 + h_1(P_t + \bar{P}_t(0))))\,dt, \qquad \Delta_0 = \sigma^2. \tag{1.37}$$

Now from (1.33) and (1.34) (upon differentiation) and using (1.35), (1.37), it follows that

$$dF_1 = -\tfrac{1}{2}h_1^2 F_3^2\,dt, \qquad F_1(0) = 0, \tag{1.38}$$

and

$$dF_2 = F_3 h_1(d\nu_t + h_1 F_3 I_t(1)\,dt), \qquad F_2(0) = 0. \tag{1.39}$$

To define F_3, notice that (1.21) solves as

$$\begin{aligned} \bar{x}_t(a, \sigma) = \phi_t\Big(a + \int_0^t \phi_s^{-1}(f_0 - h_0(q_0 + \bar{P}_s(\sigma)h_1))\Big)\,ds \\ + \int_0^t \phi_s^{-1}(q_0 + \bar{P}_s(\sigma)h_1)\,dy_s), \end{aligned} \tag{1.40}$$

where

$$\phi_t = \exp\Big(\int_0^t (f_1 - h_1(q_0 + \bar{P}_s(\sigma)h_1))\Big)\,ds. \tag{1.41}$$

Comparing the above with (1.31) shows that $F_3 = \phi_t$ for $\sigma = 0$, which ends the proof of Lemma 2.

Lemma 3 below merely organizes all the results into the filter equations and the final form of the conditional characteristic function.

LEMMA 3. *Given the system* (1.1) *and* (1.2) *together with the a priori distribution* $F(a) = P(x_0 \leqq a | y_0)$. *The following are the* <u>*filter*</u> *equations* (*i.e., formulae of the recursive type, which calculate* $\hat{x}_t = \mathbf{E}(x_t | \mathbf{Y}_t)$).

$$d\hat{x}_t = (f_0 + f_1\hat{x}_t)\,dt + (q_0 + P_t h_1)\,d\nu_t, \; \hat{x}_0 = \int_{-\infty}^{\infty} a\,dF(a), \tag{1.42}$$

$$d\nu_t = dy_t - (h_0 + h_1\hat{x}_t)\,dt, \tag{1.43}$$

$$P_t = \bar{P}_t + \phi_t^2(I_t(2) - I_t^2(1)), \tag{1.44}$$

$$d\bar{P}_t = (2f_1\bar{P}_t + g_0^2 + q_0^2 - (q_0 + \bar{P}_t h_1)^2)\,dt, \qquad \bar{P}_0 = 0, \tag{1.45}$$

$$I_t(n) = \frac{\int_{-\infty}^{\infty} a^n \exp(a^2F_1 + aF_2)\,dF(a)}{\int_{-\infty}^{\infty} \exp(a^2F_1 + aF_2)\,dF(a)}, \qquad n = 1, 2, \tag{1.46}$$

$$dF_1 = -\tfrac{1}{2}h_1^2\phi_t^2\,dt, \qquad F_1(0)=0, \tag{1.47}$$

$$dF_2 = \phi_t h_1(dv_t + \phi_t h_1 I_t(1)\,dt), \qquad F_2(0)=0, \tag{1.48}$$

$$d\phi_t = (f_1 - h_1(q_0 + \bar{P}_t h_1))\phi_t\,dt, \qquad \phi_0 = 1. \tag{1.49}$$

The characteristic function of $x_t|\mathbf{Y}_t$ is given by:

$$\mathbf{e}_t(z) = \exp\left(ix(\hat{x}_t - \phi_t I_t(1)) - \tfrac{1}{2}z^2\bar{P}_t\right)\frac{\int_{-\infty}^{\infty}\exp\left(a^2F_1 + a(F_2 + iz\phi_t)\right)dF(a)}{\int_{-\infty}^{\infty}\exp\left(a^2F_1 + aF_2\right)dF(a)}. \tag{1.50}$$

2. Special cases and control problems. Two special cases of (1.1) and (1.2) result in significant simplification of the filter equations. The first case occurs when $g_0(t, y) = 0$, $0 \leqq t \leqq T$. From (1.7) it follows then that x_t is of the form

$$x_t = A_t(y)x_0 + B_t(y).$$

Using the above equation in (1.2), we have the following estimation problem: Let x_0 be a random variable with distribution $F(a) = P(x_0 \leqq a|y_0)$. Assume that the observation process y_t, $0 \leqq t \leqq T$, admits a differential

$$dy_t = (h_0(t, y) + h_1(t, y)x_0)\,dt + dv_t,$$

where the notation stays the same as in (1.2) and h_0, h_1 satisfy (1.3) and (1.4). From Lemma 2 it follows now that the conditional characteristic function of x_0 given $\mathbf{Y}_t$ is of the form

$$\mathbf{e}_t(z) = \frac{\int_{-\infty}^{\infty}\exp\left(a^2F_1 + aF_2 + iza\right)dF(a)}{\int_{-\infty}^{\infty}\exp\left(a^2F_1 + aF_2\right)dF(a)}. \tag{2.1}$$

The above results from the fact that $dx_0 = 0$ replaces (1.1) implying $\bar{P}_t(0) = 0$ and $\bar{x}_t(a, 0) = a$, as defined by (1.21) and (1.22). Now

$$\left.\frac{d\mathbf{e}_t(z)}{dz}\right|_{z=0} = i\hat{x}_t,$$

where $\hat{x}_t = \mathbf{E}(x_0|\mathbf{Y}_t)$, combined with the general filter equations (1.42) ÷ (1.50) yields

$$\hat{x}_t = \frac{\int_{-\infty}^{\infty} a\exp\left(-\tfrac{1}{2}a^2\int_0^t h_1^2\,ds + a\int_0^t h_1(dy_s - h_0\,ds)\right)dF(a)}{\int_{-\infty}^{\infty}\exp\left(-\tfrac{1}{2}a^2\int_0^t h_1^2\,ds + a\int_0^t h_1(dy_s - h_0\,ds)\right)dF(a)}. \tag{2.2}$$

In particular if

$$dF(a) = \frac{1}{\sqrt{2\pi}\,\sigma_0}\exp\left(-\frac{(a-m_0)^2}{2\sigma_0^2}\right)da,$$

(2.2) results in

$$\hat{x}_t = \frac{m_0 + \sigma_0^2\int_0^t h_1(dy_s - h_0\,ds)}{1 + \sigma_0^2\int_0^t h_1^2\,ds}. \tag{2.3}$$

The above agrees with the result presented in [4, pp. 22-24].

The second special case for which the filter takes a simple form follows if $h_1(t, y) = 0$ (i.e., the state is not observable directly), $0 \leqq t \leqq T$. Now the filter equations (1.42) ÷

(1.50) reduce to

$$
\begin{aligned}
&d\hat{x}_t = (f_0 + f_1\hat{x}_t)\,dt + q_0(dy_t - h_0\,dt),\\
&\hat{x}_0 = \int_{-\infty}^{\infty} a\,dF(a),\\
&dP_t = (2f_1P_t + g_0^2)\,dt,\\
&P_0 = \int_{-\infty}^{\infty} (a-\hat{x}_0)^2\,dF(a).
\end{aligned}
\tag{2.4}
$$

In order to discuss a control problem using the results obtained here, assume that all the coefficients in (1.1) and (1.2), except $f_0(t, y)$ which is denoted here by $u_t(y)$, are functions of time only. If $u_t(y)$ satisfies the assumption (1.5), we say that $u = \{u_t(y), 0 \leqq t \leqq T\}$ is an admissible control and write $u \in \mathbf{U}$.

Let x_t^u, $\hat{x}_t^u$ denote the solutions to (1.1) and (1.42) respectively, for some $u \in \mathbf{U}$, and let x_t^0, $\hat{x}_t^0$ correspond to $u_t \equiv 0, 0 \leqq t \leqq T$.

Define $e_t^u = x_t^u - \hat{x}_t^u$, $e_0^u = x_0 - \hat{x}_0 = e_0^0$, $e_t^0 = x_t^0 - \hat{x}_t^0$. Subtracting (1.42) from (1.1), we have

$$
de_t^u = f_1e_t^u dt + g_0dw_t + q_0dv_t - (q_0 + P_t(e^u)h_1)(h_1e_t^u + dv_t),
\tag{2.5}
$$

where $P_t = P_t(e^u)$ shows that P_t depends only on e_s^u, $0 \leqq s \leqq t$ which is seen from (1.48) rewritten as:

$$
dF_2 = \phi_t h_1(e_t^u h_1\,dt + dv_t + \phi_t h_1 I_t(1))\,dt.
\tag{2.6}
$$

From (2.5) it follows that with probability one the values of e_t^u and e_t^0 coincide for all $u \in \mathbf{U}$. Now, since

$$
d\nu_t^u = dy_t^u - (h_0 + h_1\hat{x}_t^u)\,dt = h_1e_t^u\,dt + dv_t = h_1e_t^0\,dt + dv_t = d\nu_t^0
\tag{2.7}
$$

ν_t^u and ν_t^0 coincide with probability one. From (2.7) it follows that (1.42) can be rewritten as

$$
d\hat{x}_t^u = (f_1\hat{x}_t^u + u_t)\,dt + (q_0 + h_1P_t(e_t^0))\,d\nu_t^0, \qquad \hat{x}_0^u = \hat{x}_0 = \int_{-\infty}^{\infty} a\,dF(a).
\tag{2.8}
$$

Now let $\tilde{u}_t = F_t(\hat{x}^{\tilde{u}})$, where F_t is a nonanticipative functional of $\hat{x}_s^{\tilde{u}}$, $0 \leqq s \leqq t$, and satisfies

$$
E\left(\int_0^T |F_t|^4\,dt\right) < \infty.
\tag{2.9}
$$

From (2.8) it follows that $\tilde{u}_t$ is σ-alg $\{\nu_s^0, 0 \leqq s \leqq t\}$ measurable. Now, let $\bar{u}_t$ be any admissible control and let $y_t^{\bar{u}}$ be an observation process associated with $\bar{u}_t$. From (2.7),

$$
\mathbf{Y}_t^{\bar{u}} = \sigma\text{-alg}\,\{y_s^{\bar{u}}, 0 \leqq s \leqq t\} \supseteq \sigma\text{-alg}\,\{\nu_s^{\bar{u}}, 0 \leqq s \leqq t\} = \sigma\text{-alg}\,\{\nu_s^0, 0 \leqq s \leqq t\}.
\tag{2.10}
$$

The above shows that $\tilde{u}_t$ is $\mathbf{Y}_t^{\bar{u}}$ measurable. This fact combined with (2.9) states that $\tilde{u}_t \in \mathbf{U}$, and that we can expect the separation of the stochastic control of $\tilde{u}_t$ type and the filtering problem. As an illustration of the statement, consider the following control problem.

Linear-quadratic control problem with non-Gaussian initial distributions. The partially observable controlled process (x_t, y_t), $0 \leqq t \leqq T$, is given by the stochastic equations

$$
\begin{aligned}
&dx_t = (f_1(t)x_t + u_t)\,dt + g_0(t)\,dw_t,\\
&dy_t = h_1(t)x_t\,dt + dv_t, \qquad y_0 = 0.
\end{aligned}
\tag{2.11}
$$

The independent Wiener processes w_t and v_t entering into (2.11) are also independent of the random variable x_0 (the initial state). x_0 is assumed to have distribution function $F(a) = P(x_0 \leqq a)$ with $\int_{-\infty}^{\infty} a^4\, dF(a) < \infty$ (finite fourth order moment).

The $\mathbf{Y}_t = \sigma\text{-alg}\{y_s, 0 \leqq s \leqq t\}$ measurable, stochastic process u_t is called a control at time t and is assumed to satisfy

$$\mathbf{E}\left(\int_0^T |u_t|^4\, dt\right) < \infty.$$

For $u = \{u_t, 0 \leqq t \leqq T\}$, satisfying the above we write $u \in \mathbf{U}$, where $\mathbf{U}$ is the class of admissible controls. It is also assumed that f_1, g_0, h_1 satisfy the deterministic version of (1.3) ÷ (1.5).

Consider now the performance functional

$$J(u) = \mathbf{E}\left(x_T^2 h_T + \int_0^T (x_t^2 H(t) + u_t^2 R(t))\, dt\right) \tag{2.12}$$

where $h_T \geqq 0$, $H(t) \geqq 0$, $0 \leqq R^{-1}(t) \leqq \text{const.}$, $0 \leqq t \leqq T$. The admissible control $\hat{u} \in \mathbf{U}$ is called optimal if

$$J(\hat{u}) = \inf_{u \in \mathbf{U}} J(u).$$

LEMMA. *The optimal control for the process* (2.11) *and the performance index* (2.12) *exists and is defined by*

$$\hat{u}_t = -R^{-1}(t) Q(t) \hat{x}_t, \qquad 0 \leqq t \leqq T \tag{2.13}$$

where $Q(t) \geqq 0$ *satisfies the Riccati equation*

$$-\frac{dQ(t)}{dt} = 2f_1(t) Q(t) + H(t) - Q^2(t) R^{-1}(t), \qquad Q(T) = h_T, \tag{2.14}$$

and $\hat{x}_t$ *is defined by*

$$\begin{aligned}
&d\hat{x}_t = (f_1(t) - R^{-1}(t) Q(t)) \hat{x}_t\, dt + P_t(\nu) h_1(t)\, d\nu_t,\\
&\hat{x}_0 = \int_{-\infty}^{\infty} a\, dF(a),\\
&d\nu_t = dy_t - h_1(t) \hat{x}_t\, dt,\\
&P_t = \bar{P}(t) + \phi(t)^2 (I_t(2) - I_t^2(1)),\\
&\frac{d\bar{P}(t)}{dt} = 2f_1(t) \bar{P}(t) + g_0^2(t) - h_1^2(t) \bar{P}^2(t), \qquad \bar{P}(0) = 0,\\
&\phi(t) = \exp\left(\int_0^t (f_1(s) - h_1^2(s) \bar{P}(s))\, ds\right),\\
&F_1(t) = -\tfrac{1}{2} \int_0^t h_1^2(s) \phi^2(s)\, ds,\\
&F_2(t, \nu) = \int_0^t \phi(t) h_1(t) (d\nu_t + \phi(t) h_1(t) I_t(1)\, dt),\\
&I_t(n) = \frac{\int_{-\infty}^{\infty} a^n \exp(a^2 F_1(t) + a F_2(t, \nu))\, dF(a)}{\int_{-\infty}^{\infty} \exp(a^2 F_1(t) + a F_2(t, \nu))\, dF(a)}, \qquad n = 1, 2.
\end{aligned} \tag{2.15}$$

Remark. The structure of the optimal control law is identical with the optimal controller for *LQG* problem.

Proof of the lemma. First note that the assumptions made in the control problem statement assure well-defined filter for the system (2.11) and $u \in \mathbf{U}$. Next rewrite the performance index as follows:

$$
\begin{aligned}
J(u) &= \mathbf{E}(\mathbf{E}(x_T^2 h_T | \mathbf{Y}_T) + \int_0^T \mathbf{E}(x_t^2 H(t) + u_t^2 R(t) | \mathbf{Y}_t)\, dt) \\
&= \mathbf{E}((\hat{x}_T^u)^2 h_T + \int_0^T ((\hat{x}_t^u)^2 H(t) + u_t^2 R(t))\, dt) \qquad (2.16) \\
&\quad + \mathbf{E}(h_T P_T^u + \int_0^T P_t^u H(t)\, dt).
\end{aligned}
$$

From (2.6) we conclude that P_t^u does not depend on the control u and coincides with the function P_t^0 obtained from the filter equations for $u_t \equiv 0$, $0 \leqq t \leqq T$. The process $\hat{x}_t^u$ entering (2.15) satisfies equation (see (2.8))

$$
d\hat{x}_t^u = (f_1(t)\hat{x}_t^u + u_t)\, dt + h_1(t) P_t^0\, d\nu_t^0, \qquad (2.17)
$$

where $\nu_t^0 = \nu_t^u = \int_0^t (dy_s^u - h_1(s)\hat{x}_s^u\, ds)$, according to (2.7), and ν_t^0 is a Wiener process (see (1.11)). Introduce now the function

$$
V(t, \xi) = \xi^2 Q(t) + \int_t^T Q(\tau) h_1^2(\tau) (P_\tau^0)^2\, d\tau \qquad (2.18)
$$

where $0 \leqq t \leqq T$, $-\infty < \xi < \infty$, and $Q(t)$ satisfies (2.14). It is easy to verify that $V(t, \xi)$ satisfies the following Bellman equation:

$$
\begin{aligned}
&\xi^2 H(t) + \xi f_1(t) \frac{\partial V(t, \xi)}{\partial \xi} + \frac{1}{2} (P_t^0)^2 h_1^2(t) \frac{\partial^2 V(t, \xi)}{\partial \xi^2} + \frac{\partial V(t, \xi)}{\partial t} \\
&\qquad + \min_\eta \left(\eta^2 R(t) + \eta \frac{\partial V(t, \xi)}{\partial \xi} \right) = 0, \qquad (2.19)
\end{aligned}
$$

and that $V(T, \xi) = \xi^2 h_T$. Note that $\hat{\eta}$ which minimizes the above for positive definite $R(t)$, is given by

$$
\hat{\eta} = -R^{-1}(t) Q(t) \xi. \qquad (2.20)
$$

Calculate now, with the use of the Ito formula,

$$
\begin{aligned}
V(T, \hat{x}_T^u) - V(0, \hat{x}_0) = \int_0^T \Bigg(\Bigg(\frac{\partial V(t, \xi)}{\partial t}\Bigg|_{\xi = \hat{x}_t^u} + \frac{1}{2} h_1^2(t) (P_t^0)^2 \frac{\partial^2 V(t, \xi)}{\partial \xi^2}\Bigg|_{\xi = \hat{x}_t^u} \Bigg) dt \\
+ \frac{\partial V(t, \xi)}{\partial \xi}\Bigg|_{\xi = \hat{x}_t^u} d\hat{x}_t^u \Bigg).
\end{aligned}
$$

Taking into account (2.8) and (2.19), we obtain

$$
V(T, \hat{x}_T^u) - V(0, \hat{x}_0) \geqq - \int_0^T ((\hat{x}_t^u)^2 H(t) + u_t^2 R(t))\, dt + 2 \int_0^T \hat{x}_t^u Q(t) P_t^0 h_1(t)\, d\nu_t^0.
$$

After taking the expectation of both sides of the above inequality,

$$
V(0, \hat{x}_0) \leqq \mathbf{E}((\hat{x}_T^u)^2 h_T + \int_0^T ((\hat{x}_t^u)^2 H(t) + u_t^2 R(t))\, dt). \qquad (2.21)
$$

The equality in (2.21) holds, according to (2.20), only if

$$\tilde{u}_t = -R^{-1}(t)Q(t)\hat{x}_t^{\tilde{u}}. \tag{2.22}$$

Comparing (2.21) with (2.16),

$$J(\tilde{u}) \leqq J(u) \quad \text{for all } u \in \mathbf{U}.$$

The admissibility of $\tilde{u}$ defined by (2.22) follows from (2.10) and the fact that

$$\mathbf{E}\left(\sup_{0 \leqq t \leqq T} (\hat{x}_t^{\tilde{u}})^4\right) < \infty.$$

The above can be proven in the same way as in the derivation of a conditionally Gaussian filter [4, Lemma 12.1; pp. 18-19]. This ends the proof of the lemma.

It seems to be possible, (following e.g. [2]) to show that the separation principle holds also for nonquadratic performance functionals. Obviously, the construction of the optimal control law might, in general, entail considerable analytical difficulties.

GLOBAL REALIZATIONS OF ANALYTIC INPUT-OUTPUT MAPPINGS*

J. P. GAUTHIER† AND G. BORNARD†

Abstract. A sufficient condition is presented for the existence and the uniqueness of a global minimal analytic realization of a nonlinear analytic input-output mapping, when the latter is defined on an open subset of the semigroup of the inputs defined for positive times.

The state space of this realization is exhibited as a quotient space of a Riemann surface on a Lie group.

Key words. nonlinear systems, realization, Lie groups, sheaves

AMS(MOS) subject classifications. 93C10, 93B15, 93B20, 22E99

1. Introduction. This paper deals with the problem of finding a finite dimensional minimal analytic realization of a given analytic input-output mapping (precise definitions will be given in § 2).

Conditions of existence and uniqueness of a global realization have been given by Jakubczyck [3], in the case where the input-output mapping is defined on the whole group of the inputs, i.e. for all positive and negative times.

Here we are interested in the case where the given input-output mapping is defined only on a subset of the semigroup S of the inputs corresponding to positive times. This case seems to be of importance from a control point of view.

The following small example points out the kind of difficulties that arise when considering uncompletely defined input-output mappings. Consider the input-output mapping P generated by the following equations:

Example 1.

$$\dot{x} = \frac{1}{x+u}, \qquad x \in R, \quad u \in R^{+}*,$$

$$y = x, \qquad y \in R \quad \text{(output)}.$$

$$x(0) = 0,$$

Clearly P is defined for every piecewise constant input function and every positive time i.e., P is defined on S. Remark also that the rank defined by Jakubczyk is 1.

However, it is not possible to find an analytic manifold and a family of everywhere defined analytic vector fields on it that realizes P: on any neighborhood of 0, there exists some $u > 0$ such that $\dot{x}$ is not defined.

In the present paper, sufficient conditions are given for the existence of local and global realizations when P is defined on a subset of S.

When the input-output mapping is defined for all positive and negative times, the global condition becomes necessary and sufficient for the existence of a "right invariant" realization on Lie Group.

Section 2 is devoted to general definitions and notations, § 3 presents two technical lemmas and a local realization one. The main result is developed in § 4, and an illustrative example is detailed in § 5.

2. Definitions and notation. Let U be the set of the values of the input (U is any set, with no structure needed), and $\mathcal{G}$ be the monoïd generated by ε, the empty sequence,

* Received by the editors January 24, 1984, and in revised form April 3, 1985.

† Laboratoire d'Automatique de Grenoble, ENSIEG-INPG, CNRS LA 228, 38402 Saint-Martin d'Hères, France.

and all the sequences with elements in $U \times R$, under the operation of concatenation. $\mathcal{G}$ can be endowed with the natural topology induced by the topology of R^∞.

The notation $\underline{u}(\underline{t}) = (u_k, t_k) \cdots (u_1, t_1)$, $\underline{u} \in U^k$, $\underline{t} \in R^k$, $k \in N$, will be used throughout the paper for the elements of $\mathcal{G}$.

Let G be the group obtained as the quotient of $\mathcal{G}$ through the equivalence relation $R_{\mathcal{G}}$ defined by:

$$\left.\begin{array}{l}(v,0)R_{\mathcal{G}}\varepsilon \\ \underline{u}(\underline{r})(v,0)\underline{w}(s)R_{\mathcal{G}}\underline{u}(\underline{r})\underline{w}(\underline{s}) \\ \underline{u}(\underline{r})(v,t)(v,t')\underline{w}(\underline{s})R_{\mathcal{G}}\underline{u}(\underline{r})(v,t+t')\underline{w}(\underline{s})\end{array}\right\} \begin{array}{l}\text{for every } \underline{u}(\underline{r}) \in \mathcal{G},\ \underline{w}(\underline{s}) \in \mathcal{G}, \\ v \in U,\ t \in R,\ t' \in R.\end{array}$$

An element $\underline{u}(\underline{t})$, $\underline{u} \in U^k$, $\underline{t} \in R^k$, is said to be minimal when k is minimal among all the elements of the class of $\underline{u}(\underline{t})$ for $R_{\mathcal{G}}$. Each class has exactly one minimal element.

The notation $\underline{u}^{-1}(\underline{t}) = (u_1, -t_1) \cdots (u_k, -t_k)$ will also be used for denoting the inverse of the element $\underline{u}(\underline{t}) = (u_k, t_k) \cdots (u_1, t_1)$.

G is given the quotient topology. It can also be given a natural analytic structure (in the sense given in the remark below).

Replacing R, R^∞, $\mathcal{G}$, G, R by R^+, $R^{+\infty}$, $\mathcal{S}$, S, $R_{\mathcal{S}}$ respectively in the previous definitions, one obtains the monoïd $\mathcal{S}$, the semigroup $S = \mathcal{S}/R_{\mathcal{S}}$.

Remarks. (a) For the topology so defined on S, a subset W of S is open iff, for every $k \in N$, $\underline{u} \in U^k$, the subset $W_{\underline{u}} = \{\underline{t} \in R^{+k} | \underline{u}(\underline{t}) \in W\}$ is open in R^{+k}.

Let W be an open subset of S, Y an analytic manifold. The analytic structure of S is defined in the following way: a mapping $P: W \to Y$ is analytic iff, for every $k \in N$, $\underline{u} \in U^k$, the mapping $P_{\underline{u}}(\underline{t}) = P(\underline{u}(\underline{t})): W_{\underline{u}} \to Y$ is analytic.

(b) $\mathcal{S}$ is a subset of $\mathcal{G}$, $R_{\mathcal{S}}$ is the restriction to $\mathcal{S}$ of $R_{\mathcal{G}}$. This defines a canonical inclusion of S in G. It can be shown that the topology of S is exactly that which is induced by the topology of G through this inclusion.

From a control point of view, G and S are the group and semigroup of piecewise-constant inputs for all times and for only positive times respectively.

In the paper, an analytic input-output mapping P will be an analytic mapping from D_P to some analytic manifold Y, where D_P is either G or a connected open subset of S.

It will be useful to define the action $*$ of R^+ on $R^{+\infty}$ and S:

$$t * \underline{s} = \begin{cases} (s_1, \cdots, s_i, t - \eta_i, 0, \cdots, 0) & \text{for } \eta_i \leqq t \leqq \eta_{i+1}, \\ (s_1, \cdots, s_k) & \text{for } \eta_k \leqq t, \end{cases}$$

$$t * \underline{u}(\underline{s}) = \underline{u}(t * \underline{s}),$$

where

$$t \in R^+, \quad \underline{s} = (s_1, \cdots, s_k) \in R^{+k}, \quad \underline{u} \in U^k, \qquad k \in N,$$

$$\eta_i = \sum_{j=1}^{i} s_j, \qquad i = 1, \cdots, k.$$

A subset W of S is said to be "truncation-closed" if $R^+ * W \subset W$.

Remarks.

- In the literature, an input-output mapping is often defined in an alternate way, (as a "system" for example), which implicitly insures that D_P is truncation-closed.
- S is truncation-closed.
- A truncation-closed subset of S is connected.

• When D_P is a truncation-closed open subset of S, the mapping $P_{\underline{u}}(\underline{t}) = P(\underline{u}(\underline{t}))$ is defined on a connected neighborhood of 0 in R^{+k} for every $k \in N$, $\underline{u} \in U^k$.

Consider some analytic input-output mapping $P: D_P \to Y$. The following standard notation will be used throughout the paper:

$$a \in D_P, \quad a' \in D_P, \quad \underline{b} \in D_P^q, \quad \underline{b}' \in D_P^{q'},$$

$$a = \underline{u}(\underline{t}) \in D_P, \quad \underline{u} \in U^k, \quad \underline{t} \in R^k,$$

$$\underline{b} = (b_1, \cdots, b_q) = (\underline{v}_1(\underline{s}_1), \cdots, \underline{v}_q(\underline{s}_q)) = \underline{\underline{v}}(\underline{s}), \qquad q \in N, \underline{b} \in D_P^q,$$

$$\underline{v}_i \in U^{q_i}, \underline{s}_i \in R^{q_i}, i = 1, \cdots, q,$$

$$\underline{\underline{v}} \in U^{\bar{q}}, \underline{s} \in R^{\bar{q}}, \bar{q} = \sum_{i=1}^{q} q_i,$$

$$\Psi_{a,a'}^{\underline{b},\underline{b}'} = (\Psi_{a,a'}^{b_1,b_1'}, \Psi_{a,a'^2}^{b_1,b_2'}, \cdots, \Psi_{a,a'}^{b_q,b_q'})$$

where $\Psi_{a,a'}^{b_i,b_j'} = P(b_i a b_j' a')$.

$\Psi_{\underline{u}(\underline{t}),\underline{u}'(\underline{t}')}^{\underline{b},\underline{b}'}$ is an analytic mapping from an open subset of $R^k \times R^{k'}$ to $Y^{qq'}$, when considered as a function of $\underline{t}$ and $\underline{t}'$.

The notation $\Psi_a^{\underline{b},\underline{b}'}$ will also be used for $\Psi_{a,\varepsilon}^{\underline{b},\underline{b}'}$ and $\Psi_a^{\underline{b}}$ for $\Psi_a^{\underline{b},\varepsilon}$.

Let Ψ_0 be the family of analytic mappings:

$$\Psi_0 = \{\Psi_{\underline{u}(\underline{t})}^{\underline{b},\underline{b}'} | \underline{b}, \underline{b}' \in G^\infty, \underline{u}(\underline{t}) \in G \text{ such that } b_i \underline{u}(\underline{t}) b_j' \in D_P, \forall i, j\},$$

and Ψ_1 the family Ψ_0 restricted to $\underline{b}' = \varepsilon$. The rank n_0 of the family Ψ_0 is the maximum of the ranks of the Jacobian matrices $(\partial/\partial \underline{t})(\Psi_{\underline{u}(\underline{t})}^{b_i,b_j'})$ when the arguments cross the domain.

The rank n_1 is defined in the same way on Ψ_1. Clearly, n_1 is the rank defined by Jakubczyk [3].

This notation will also be used, depending on the context, when replacing G by S, R by R^+.

An analytic system defined on the input space U and the output analytic manifold Y is a 4-tuple:

$$Q = \{M, x_0, F = \{X_u | u \in U\}, h\}$$

where M is a finite dimensional connected manifold, $x_0 \in M$, F a family of analytic vector fields on M, h an analytic mapping from M to Y. Q defines in an obvious way, considering positive times, an input-output mapping P_Q, with domain D_Q truncation-closed and open in S.

A local analytic realization of an input-output mapping P, "after a," for some element $a \in D_P$, is an analytic system Q such that:

• $P(ba) = P_Q(b)$ for every $b \in D_Q$ such that $ba \in D_P$.

• The ranks n_1 (and n_0 if n_0 is finite) are the same for P and P_Q.

A (global) analytic realization of P is an analytic system Q such that $D_P \subset D_Q$ and that $P = P_Q | D_P$.

A (local or global) analytic realization Q is said to be minimal when Q is weakly controllable, and observable (see Sussmann [5]).

3. Lemmas. Let M be an analytic connected manifold and $F = \{X_u | u \in U\}$ a family of analytic vector fields on M. Consider the following notations:

$$M^1 = M, \quad X_u^1 = X_u, \quad u \in U, \quad F^1 = F,$$

$$M^{k+1} = M^k \times M^k, \; X_u^{k+1} = X_u^k \oplus X_u^k, \; u \in U, \; F^{k+1} = \{X_u^{k+1} | u \in U\} \text{ for } k = 2, 3, \cdots.$$

The Lie algebras $L(F)$ and $L(F^k)$ generated by F and F^k respectively, considered as subalgebras of the Lie algebras of vector fields on M and M^k, are naturally isomorphic.

Let n^k be the maximal dimension of the orbits of F^k in M^k (see Sussmann [6]). The sequence n^k is increasing, since every orbit of M^k identifies with the corresponding orbit in the diagonal of M^{k+1}.

LEMMA 1 (orbits of finite dimension). *The following two statements are equivalent.*

(a) *$L(F)$ is a Lie algebra of finite dimension.*

(b) *The sequence n^k is stationary, with limit n.*

Proof. (a) $\rightarrow$ (b). $L(F^k)$ being a Lie algebra of finite dimension n, $L(F^k)$ evaluated at $x_0 \in M^k$ can be only of dimension $n' \leqq n$. Then, because of the analyticity, the orbit through x_0 is of dimension $n' \leqq n$. The sequence n^k, being increasing and bounded is stationary. The fact that its limit is exactly n is proved later.

(b) $\rightarrow$ (a). Assume that for some k, $n^{k+1} = n^k$. Let x_0 belong to an orbit of M^k of dimension n^k, let $\{Y_i^k \in L(F^k),\ i = 1, \cdots, n^k\}$ be a set of n^k vector fields, linearly independent at x_0, and let V^k be a connected neighborhood of x_0 in M^k, such that the Y_i^k are linearly independent on V^k, and the $Y_i^{k+1} = Y_i^k \oplus Y_i^k$ are also linearly independent on the neighborhood $V^{k+1} = V^k \times V^k$ of (x_0, x_0) in M^{k+1}.

Consider Z^k, any vector field in $L(F^k)$ and the corresponding vector field $Z^{k+1} = Z^k \oplus Z^k$ in $L(F^{k+1})$. Because $n^{k+1} = n^k$, Z^{k+1} expresses linearly, by analytic functions, as a function of $(Y_i^{k+1},\ i = 1, \cdots, n^k)$. If not, there would exist an orbit of dimension $n'' > n^{k+1}$ in M^{k+1}, which contradicts the definition of n^{k+1}. Then:

$$Z^{k+1}(x, y) = \sum_{i=1}^{n^k} \gamma_i(x, y)\, Y_i^{k+1}(x, y) \quad \text{for } x \in V^k, \quad y \in V^k$$

and in particular by projections on the first factor:

$$Z^k(x) = \sum_{i=1}^{n^k} \gamma_i(x, y)\, Y_i^k(x).$$

In some local coordinate system, one obtains:

$$\frac{\partial Z(x)}{\partial y_j} = \sum_{i=1}^{n^k} \frac{\partial \gamma_i(x, y)}{\partial y_j}\, Y_i^k(x) = 0$$

and then $\partial \gamma_i(x, y)/\partial y_j = 0$ for $j = 1, \cdots, n^k$, since the vector fields $Y_i^k(x)$ are linearly independent. x and y playing the same role, it follows that the $\gamma_i(x, y)$ are constant functions. In particular, one has

$$[Y_i^k, Y_j^k] = \sum_{m=1}^{n^k} \gamma_{ij}^m\, Y_m^k$$

with constant γ_{ij}^m.

Since this is true on a neighborhood of x_0, it must be true everywhere on M^k, by analyticity and connectedness. The γ_{ij}^m are the structure constants of the Lie algebra $L(F)$ which is then of dimension n^k.

Clearly one has $n^i = n^k$ for $i > k$, and then $n^k = n$. This completes the proof of Lemma 1.

LEMMA 2 (lift on a Lie group). *Let $F = \{X_u | u \in U\}$ be a family of analytic vector fields on some connected open set $V_0 \subset R^n$, $x_0 \in V_0$ and assume that:*

- *$L(F)$ the Lie algebra generated by F has dimension n;*
- *$L(F)(x_0)$ spans $T_{R^n}(x_0)$.*

Then there exist a real simply connected Lie group $\tilde{G}$ of dimension n, with identity e, and an analytic diffeomorphism Ψ from $V_1 \subset V_0$ on some neighborhood W of e in $\tilde{G}$, such that $x_0 \in V_1$ and:

- $\Psi(x_0) = e$.
- *For every $u \in U$, $\tilde{X}_u = d\Psi X_u$ is the restriction to W of some right invariant vector field on $\tilde{G}$.*

Proof. The proof, not given here, is a consequence of the third Lie's theorem ([9, p. 551] for example).

LEMMA 3 (local realization). *Let P be an analytic input-output mapping from a truncation-closed open subset D_P of S to an analytic manifold Y. Assume that the rank n_1 of the associated family Ψ_1 is finite (see notation in § 2).*

Then there exists a local minimal analytic realization Q of P, of dimension n_1, after a, for some element $a \in D_P$.

Proof. In the following, all the mappings under consideration are analytic. Assume that n_0 is finite. By hypothesis there exist $\underline{u}_1(t_1) \in S$, $\underline{u}_2(t_2) \in S$, $\underline{v}(\underline{s}_1) \in S^{q_1}$, $\underline{v}_2(\underline{s}_2) \in S^{q_2}$, $\underline{v}'(\underline{s}'_1) \in S^{q'}$, $q_1, q_2, q' \in N$, such that:

- The rank of $\Psi^{\underline{v}_1(\underline{s}_1), \underline{v}'(\underline{s}'_1)}_{\underline{u}_1(\underline{t})}$ with respect to $\underline{t}$ is n_0 at $\underline{t} = \underline{t}_1 \in R^{+k_1}$.
- The rank of $\Psi^{\underline{v}_2(\underline{s}_2)}_{\underline{u}_2(\underline{t})}$ with respect to $\underline{t}$ is n_1 at $\underline{t} = \underline{t}_2 \in R^{+k_2}$.

Denote $\underline{u} = (\underline{u}_1, \underline{u}_2) \in U^k$, $\underline{v} = (\underline{v}_1, \underline{v}_2) \in U^{\bar{q}}$, and consider the mappings:

$$\Omega_0(\underline{s}, \underline{s}', \underline{t}', \underline{t}) = \Psi^{\underline{v}(\underline{s}), \underline{v}'(\underline{s}')}_{\underline{u}(\underline{t}'), \underline{u}(\underline{t})} : R^{+\bar{q}} \times R^{+\bar{q}'} \times R^{+k} \times R^{+k} \to Y^{qq'},$$

$$\Omega_1(\underline{s}, \underline{t}', \underline{t}) = \Omega_0(\underline{s}, 0, \underline{t}', \underline{t}) : R^{+\bar{q}} \times R^{+k} \times R^{+k} \to Y^q,$$

$$\Omega_2(\underline{s}, \underline{t}) = \Omega_1(\underline{s}, 0, \underline{t}) : R^{+\bar{q}} \times R^{+k} \to Y^q.$$

By construction, the ranks of Ω_0, Ω_1 with respect to $\underline{t}'$ and the rank of Ω_2 with respect to $\underline{t}$ are n_0, n_1, n_1 at $((\underline{s}_1, 0), \underline{s}'_1, (\underline{t}_1, 0), 0)$, $((0, \underline{s}_2), (0, \underline{t}_2), 0)$, $((0, \underline{s}_2), (0, \underline{t}_2))$ respectively.

Since D_P is truncation-closed, the domains of $\Omega_0, \Omega_1, \Omega_2$ are connected neighborhoods of 0 in the corresponding spaces. Moreover, the ranks n_0, n_1, n_1 are maximal. Then, by analyticity the ranks n_0, n_1, n_1 are reached almost everywhere on the domains of $\Omega_0, \Omega_1, \Omega_2$.

It is then possible to find $\underline{s}_0, \underline{s}'_0, \underline{t}_0$ such that:

- The rank of Ω_2 is n_1 at $(\underline{s}_0, \underline{t}_0)$.
- There exists $\underline{t}'_0$ arbitrarily small, such that the ranks of Ω_0, Ω_1 are n_0, n_1 at $(\underline{s}_0, \underline{s}'_0, \underline{t}'_0, \underline{t}_0)$, $(\underline{s}_0, \underline{t}'_0, \underline{t}_0)$ respectively.

In the case where n_0 is infinite, the same argument applies for the choice of $\underline{s}_0, \underline{t}_0$, considering only Ω_1, Ω_2 and n_1.

Denoting $\underline{b} = (\underline{v}(\underline{s}_0))$, the rank of $\Psi^{\underline{b}}_{\underline{u}(\underline{t})}$ is n_1 at $\underline{t}_0$. It is then possible to find two analytic connected submanifolds V_0, Y_0, of R^{+*k}, Y^q respectively, of dimension n_1, such that the restriction of $\Psi^{\underline{b}}_{\underline{u}(\underline{t})}$ to V_0 is a diffeomorphism of V_0 on Y_0. The canonical immersion of V_0 in R^k will be denoted $\underline{t} = \underline{t}(\underline{\tau})$.

Consider the mapping

$$\bar{\Phi}^{\underline{b}}_{\underline{u}}(\theta, \underline{\tau}) = \Psi^{\underline{b}}_{(u,\theta)\underline{u}(\underline{t}(\underline{\tau}))},$$

which is defined on some connected neighborhood $\bar{W}_0$ of $(0, V_0)$ in $R^+ \times V_0$, since D_P is open. There exists a connected neighborhood W_0 of $(0, V_0)$ in $R \times V_0$ such that

- $\bar{\Phi}^{\underline{b}}_{\underline{u}}$ extends in a unique way in $\Phi^{\underline{b}}_{\underline{u}}$ on W_0.
- $\Phi^{\underline{b}}_{\underline{u}}(\theta, \underline{\tau}) \in Y_0$ for every $(\theta, \underline{\tau}) \in W_0$, since n_1 is maximal.

Consider, on W_0, the equality

$$\Phi_u^b(0, \underline{\tau}) = \Phi_u^b(\theta, \underline{\gamma}). \tag{L1}$$

For any $\underline{\gamma}_0 \in V_0$, this equality holds for $\underline{\tau} = \underline{\gamma} = \underline{\gamma}_0$, $\theta = 0$, and the rank of $\Phi_u^b(0, \underline{\tau})$ with respect to $\underline{\tau}$, and the rank of $\Phi_u^b(\theta, \underline{\gamma})$ with respect to $(\theta, \underline{\gamma})$ are both n_1 at this point.

From the implicit function theorem, there exists a connected neighborhood W_1 of $(0, \underline{\gamma}_0)$ in W_0, and a unique analytic mapping σ: $W_1 \to V_0$ such that:

$$\Phi_u^b(0, \sigma(\theta, \underline{\gamma})) = \Phi_u^b(\theta, \underline{\gamma}) \quad \text{for every } (\theta, \underline{\gamma}) \in W_1. \tag{L2}$$

Denote $V_1 = \{\underline{\gamma} \in V_0 | (0, \underline{\gamma}) \in W_1\}$.

For any $\underline{w} \in U^p$, $p \in N$, there exist $\underline{r} \in R^{+p}$ small enough, and a connected neighborhood V_2 of $\underline{\gamma}_0$ in V_1, such that $\underline{w}(\underline{r})\underline{u}(\underline{t}(\underline{\gamma})) \in D_P$ for every $\underline{\gamma} \in V_2$. Denote $c = \underline{w}(\underline{r})$ and consider the mapping:

$$\Phi_u^c(\theta, \underline{\gamma}) = \Psi^c_{(u,\theta)\underline{u}(\underline{t}(\underline{\gamma}))}$$

which is defined on some connected neighborhood W_2 of $(0, \underline{\gamma}_0)$ in $R \times V_2$, through a small extension of $\Psi^c_{(u,\theta)\underline{u}(\underline{t}(\underline{\gamma}))}$ for $\theta < 0$. An intermediate step is to show that:

$$\Phi_u^c(0, \sigma(\theta, \underline{\gamma})) = \Phi_u^c(\theta, \underline{\gamma}), \tag{L3}$$

for $(\theta, \underline{\gamma}) \in W_3$, some neighborhood of $(0, \underline{\gamma}_0)$ in W_2.

Consider now the equality:

$$\begin{aligned} &\text{(a)} \quad \Phi_u^b(0, \underline{\tau}) = \Phi_u^b(\theta, \underline{\gamma}), \\ &\text{(b)} \quad \Phi_u^c(0, \underline{\tau}) = \Phi_u^c(\theta, \underline{\gamma}). \end{aligned} \tag{L4}$$

(L4) holds for $\underline{\tau} = \underline{\gamma} = \underline{\gamma}_0$, $\theta = 0$. Denoting $\Phi_u^{b,c}$ for (Φ_u^b, Φ_u^c), the rank of $\Phi_u^{b,c}(0, \underline{\tau})$ with respect to $\underline{\tau}$ and the rank of $\Phi_u^{b,c}(\theta, \underline{\gamma})$ with respect to $(\theta, \underline{\gamma})$ are both n_1 at this point (since n_1 is maximal).

From the implicit function theorem there exist a connected neighborhood $W_3 \subset W_2$ of $(0, \underline{\gamma}_0)$ and a unique mapping $\bar{\sigma}$: $W_3 \to V_0$ such that:

$$\Phi_u^{b,c}(0, \bar{\sigma}(\theta, \underline{\gamma})) = \Phi_u^{b,c}(\theta, \underline{\gamma}) \quad \text{for every } (\theta, \underline{\gamma}) \in W_3.$$

But the solution of (L4a), unique on $W_3 \subset W_2$, is already given by σ. Then $\bar{\sigma} = \sigma|_{W_3}$, and (L3) holds.

Considering now the case $c = b_i(u, \delta)$, $i = 1, \cdots, q$ and using the fact that $(u, \delta)(u, \theta) = (u, \delta + \theta)$, an easy calculation based upon the preceding results shows that $\sigma(\delta, \sigma(\theta, \underline{\gamma})) = \sigma(\delta + \theta, \underline{\gamma})$ for $\underline{\gamma}$ near $\underline{\gamma}_0$ and δ, θ small enough. Moreover it is clear that $\sigma(0, \underline{\gamma}) = \underline{\gamma}$.

Consequently σ defines an analytic local one parameter subgroup on a neighborhood of $\underline{\gamma}_0$ in V_0. The same process can be achieved for every $\underline{\gamma} \in V_0$, and it is straightforward to see that all these local subgroups fit conveniently and define an analytic local one parameter subgroup on V_0.

Note X_u for the corresponding vector fields on V_0. The same construction can be performed for every $u \in U$.

A family of analytic vector fields has been defined on the n_1-dimensional analytic manifold V_0. Consider the output mapping h: $V_0 \to Y$ defined by:

$$h(\underline{\tau}) = P(\underline{u}, \underline{t}(\underline{\tau})).$$

Then the system:

$$Q = \{V_0, \underline{\tau}_0, F = \{X_u | u \in U\}, h\}$$

is a candidate to realize P locally after $\underline{u}(\underline{t}_0)$.

One has to show that, for any $p \in N$, $\underline{w} \in U^p$, one has

$$\text{(L5)} \qquad h(\exp X_{w_p} r_p \circ \cdots \circ \exp X_{w_1} r_1(\tau_0)) = P((w_p, r_p) \cdots (w_1, r_1)\underline{u}(\underline{t}(\tau_0)))$$

for every $\underline{r} \in R^{+p}$ such that both members are defined.

In (L2) and (L3) one can now replace $\sigma(\theta, \gamma)$ by $\exp X_u \theta(\gamma)$, which is defined on V_0, for small θ. From (L3) with $c = (w_p, r_p) \cdots (w_2, r_2)$, and for r_1 small enough, one obtains:

$$P((u_p, r_p) \cdots (u_2, r_2)(u_1, r_1)\underline{u}(\underline{t}(\tau_0))) = P((u_p, r_p) \cdots (u_2, r_2)\underline{u}(\underline{t}(\exp X_{u_1} r_1(\tau_0)))).$$

Iterating this operation, and using the definition of h, one obtains (L5) for small times.

Consider any $\underline{r}_0 \in R^{+p}$ such that $\underline{w}(\underline{r}_0) \in D_Q$ and $\underline{w}(\underline{r}_0)\underline{u}(t_0) \in D_P$. D_P and D_Q are both truncation-closed and both members of (L5) are defined along the same truncation-closed path from $\underline{r}_0$ to 0 in R^{+p}. It follows that they are defined on a connected open subset of R^{+p} containing $\underline{r}_0$ and 0. Since (L5) holds on a neighborhood of 0 in R^{+p}, then it holds also at $\underline{r}_0$.

The rank n_1' associated to P_Q cannot be greater than n_1. Moreover, from the choice of $\underline{s}_0$ and $\underline{t}_0$ at the beginning of the proof, there exists $\underline{t}_0' \in R^{+p}$ such that $\underline{u}(\underline{t}_0') \in D_Q$ and that Ω_1 is of rank n_1 at $(\underline{s}_0, \underline{t}_0', \underline{t}_0)$. Then $n_1' = n_1$. The same applies for n_0 when it is finite.

By construction, Q is weakly controllable, observable. This ends the proof of Lemma 3.

4. Main result: global realization.

THEOREM 1. *Let P be an analytic input-output mapping from an open truncation-closed subset D_P of S to an analytic manifold Y. Assume that the rank n_0 of the family Ψ_0 of mappings associated to P is finite, and let n_1 be of the rank of the associated family Ψ_1.*

Then there exists a global minimal analytic realization of P, of dimension n_1.

Proof. The proof is achieved in three steps.

(a) *Finite dimensional orbits and lift on a Lie group.* The rank $n_1 \leqq n_0$ is finite. From Lemma 3 there exists a local realization $Q = \{V_0, x_0 = \tau_0, F = \{X_u | u \in U\}, h\}$ associated to the sequences $\underline{u}_0(\underline{t}(\tau_0))$, $\underline{b} = \underline{v}(\underline{s}_0)$, where V_0 can be restricted to be relatively compact. Consider, for the system Q, the following notation:

$$\hat{b}(x) = \exp X_{v_p} s_p \circ \cdots \circ \exp X_{v_1} s_1(x) \quad \text{for } x \in V_0, \quad b = \underline{v}(\underline{s}) \in G,$$

$$\underline{\hat{b}}(x)(\hat{b}_1(x), \cdots, \hat{b}_q(x)) \quad \text{for } \underline{b} \in G^q,$$

$$\bar{\Phi}^{\underline{x}}_{\underline{u}(\underline{t})} = (\hat{\underline{u}}(\underline{t})(x_1), \cdots, \hat{\underline{u}}(\underline{t})(x_{q'})) : R^k \to V_0^{q'} \quad \text{for} \begin{cases} k \in N, \\ \underline{u} \in U^k, \\ \underline{t} \in R^k, \\ \underline{x} \in V_0^{q'}, \end{cases}$$

$$\bar{\Psi}^{\underline{b}}(\underline{x}) = (h(\hat{b}_1(x_1)), \cdots, h(\hat{b}_q(x_1)), \cdots, h(\hat{b}_q(x_{q'}))) : V_0^{q'} \to Y^{qq'},$$

$$\bar{\Psi}^{\underline{b},\underline{x}}_{\underline{u}(\underline{t})} = \bar{\Psi}^{\underline{b}} \circ \bar{\Phi}^{\underline{x}}_{\underline{u}(\underline{t})}.$$

Clearly, one has:

$$\bar{\Psi}^{\underline{b},\underline{x}}_{\underline{u}(\underline{t})} = \Psi^{\underline{b},(\underline{u}_0(\underline{t}(x_1)), \cdots, \underline{u}_0(\underline{t}(x_{q'})))}_{\underline{u}(\underline{t})} \quad \text{for } \underline{x} \in V_0^{q'}, \quad \underline{b} = \underline{v}(\underline{s}), \quad \underline{t} \text{ and } \underline{s} \text{ small.}$$

The rank of $\Psi^{\underline{b}\underline{x}}_{\underline{u}(\underline{t})}$ with respect to $\underline{t}$ is then $\leqq n_0$.

Consider now, for $q'=2^p$, $F^{q'}$, the lift of the family F in $V_0^{q'}=V_0\times\cdots\times V_0$, and $O(\underline{x})$, the orbit of $F^{q'}$ through $\underline{x}\in V_0^{q'}$. One has:

$$O(\underline{x})=\{\underline{x}'\in V_0^{q'}|\underline{x}'=\bar{\Phi}^{\underline{x}}_{\underline{u}(t)} \text{ for } \underline{u}(t)\in G\}.$$

Denote by n the maximal dimension of the orbit $O(x)$ when $\underline{x}$ crosses $V_0^{q'}$, which has dimension $q'n_1$. This dimension is reached almost everywhere on $V_0^{q'}$, and for any $\underline{x}$ such that this dimension is reached, there exists $\underline{u}\in U^k$, $k\in N$, such that the rank of $\bar{\Phi}^{\underline{x}}_{\underline{u}(t)}$ with respect to $\underline{t}$ is n almost everywhere on a neighborhood of 0 in R^k. Meanwhile, there exists $\underline{b}\in G^\infty$ such that $\bar{\Psi}^{\underline{b}}$ has rank $q'n_1$ almost everywhere on some connected open subset of $V_0^{q'}$. Then one can find $\underline{x}\in V_0^{q'}$, k, $q\in N$, $\underline{u}\in U^k$, $\underline{t}_1\in R^k$, $\underline{b}\in G^q$, such that:

- $O(\underline{x})$ has maximal dimension n in $V_0^{q'}$.
- $\bar{\Phi}^{\underline{x}}_{\underline{u}(t)}$ has rank n (maximal) at $\underline{t}_1$ and then on some neighborhood W_1 of $\underline{t}_1$ in R^k.
- $\bar{\Psi}^{\underline{b}}$ has rank $q'n_1$.

The situation is as follows:

$$W_1 \xrightarrow{\bar{\Phi}^{\underline{x}}_{\underline{u}(t)}} V_0^{q'} \xrightarrow{\bar{\Psi}^{\underline{b}}} Y^{qq'}.$$

Sylvester's inequality applied to some Jacobian matrices, states that

$$\operatorname{rank}\bar{\Phi}^{\underline{x}}_{\underline{u}(t)}+\operatorname{rank}\bar{\Psi}^{\underline{b}}-\dim V_0^{q'}\leqq\operatorname{rank}\bar{\Psi}^{\underline{b},\underline{x}}_{\underline{u}(t)}.$$

Then $n\leqq n_0$.

Since the maximal rank n_0 of $\bar{\Psi}^{\underline{b}\underline{x}}_{\underline{u}(t)}$ is reached for some $\underline{x}_1\in V_0^{q'}$, $\underline{b}_1\in G^\infty$, $\underline{u}_1(\underline{t}_1)\in G$, the same applies necessarily for $\bar{\Phi}^{\underline{x}}_{\underline{u}(t)}$, and then $O(\underline{x}_1)$ has dimension n_0. The maximal dimension of all the orbits $O(\underline{x})$ is exactly n_0. Then from Lemma 1, the Lie algebra generated by F has finite dimension n_0.

Consider the orbit $O(\underline{x}_0)$, of dimension n_0, with $\underline{x}_0\in\Pi_1^{-1}(x_0)\cap O(\underline{x}_0)$, where Π_1 is the projection on the first factor in $V_0^{q'}$. This is possible since the system Q is weakly controllable on V_0. Clearly the system $\tilde{Q}'=(O(\underline{x}_0), \underline{x}_0, F^{q'}=\{X_u^{q'}|u\in U\}, h\circ\Pi_1)$ is a realization of P_Q, and then a local realization of P, generally not observable.

The Lie algebra generated by F has finite dimension n_0. From Lemma 2, there exist a Lie group $\tilde{G}$, simply connected, and an analytic diffeomorphism ν from some connected neighbourhood $\tilde{V}'$ of $\underline{x}_0$ in $O(\underline{x}_0)$ to a neighborhood $\tilde{V}$ of the identity e of $\tilde{G}$, such that:

- $\nu(\underline{x}_0)=e$.
- $d\nu X_u^{q'}=\tilde{X}_u$, $u\in U$, the restriction to $\tilde{V}$ of a right invariant vector field $\tilde{X}_u$ on $\tilde{G}$.

Let $\tilde{h}$ be the analytic mapping from $\tilde{V}$ to Y defined by $\tilde{h}=h\circ\Pi_1\circ\nu^{-1}$. Then $\tilde{Q}=(\tilde{V}, e, \tilde{F}=\{\tilde{X}_u|u\in U\}, \tilde{h})$ is a local realization of P.

(b) *Global realization on a Riemann surface.* Let M be the sheaf of germs of analytic mappings from $\tilde{G}$ to $\tilde{Y}$. Consider $\bar{M}$ the connected component of M containing the germs of $\tilde{h}$ at the points of $\tilde{V}$, and π the canonical projection from $\bar{M}$ to $\tilde{G}$. $\bar{M}$ is an analytic manifold, paracompact if Y is so (when Y is R, $\bar{M}$ is nothing but a Riemann surface without ramification on $\tilde{G}$), and π is a local diffeomorphism from $\bar{M}$ to $\tilde{G}$.

Then the vector fields $\tilde{X}_u$ on $\tilde{G}$ can be lifted in vector fields $\bar{X}_u$ on $\bar{M}$, not complete in general. Let $\bar{x}_0^u\in\bar{M}$ be the germ at e of $\tilde{h}$, and $\bar{h}$ be the analytic mapping from $\bar{M}$ to Y defined by $\bar{h}(\bar{x})=\tilde{f}(\tilde{x})$ where $\bar{x}$ is the germ at $\tilde{x}\in\tilde{G}$ of the mapping $\tilde{f}$. Clearly, the system $\bar{Q}=\{\bar{M}, \bar{x}_0, \bar{F}=\{\bar{X}_u|u\in U\}, \bar{h}\}$ is a local realization of P_Q.

One has now to show that, with a change of origin, $\bar{Q}$ is also a global realization of P.

Consider the following notation:

$$\tilde{\underline{u}}(\underline{t}) = (\exp \tilde{X}_{u_k} t_k \circ \cdots \circ \exp \tilde{X}_{u_1} t_1(\cdot)), \quad \text{for } k \in N, \quad \underline{u} \in N^k, \quad \underline{t} \in R^k,$$

$$\bar{\underline{u}}(\underline{t}) = (\exp \bar{X}_{u_k} t_k \circ \cdots \circ \exp \bar{X}_{u_1} t_1(\cdot)), \quad \text{on its domain.}$$

From now on, the sequence $\underline{u}_0(\underline{t}_0)$ supporting the local realization will be denoted $\underline{u}(\underline{t}_0)$, for simplicity.

Let $\underline{w}(\underline{r}_0)$, $\underline{w} \in U^p$, $p \in N$, be an arbitrary element of D_P, let $\underline{v} \in U^q$, $q \in N$, be such that $\tilde{v}(\underline{s})$ has rank n_0 almost everywhere on R^q, and consider the mapping:

$$\Omega(\underline{s}', \underline{s}, \underline{r}, \underline{t}) = P(\underline{w}(\underline{r})\underline{v}^{-1}(\underline{s}')\underline{v}(s)\underline{u}(\underline{t})).$$

Since P is defined on a truncation-closed open subset D_P of S, Ω is defined on an open connected subset W^+ of $R^{-q} \times R^{+q} \times R^{+p} \times R^{+k}$ which contains the points $(0, 0, 0, 0)$, $(0, 0, 0, \underline{t}_0)$ and $(0, 0, \underline{r}_0, 0)$. Then it can be analytically extended to some connected open subset W or $R^q \times R^q \times R^p \times R^k$ which contains the same three points. Moreover W can be restricted to be of the form: $W = W_s \times W_s \times W_{tr}$ where $W_s \subset R^q$, $W_{tr} \subset R^p \times R^k$. By abuse it will be said "$\underline{r} \in W_{tr}$" for "$\underline{r}$ is such that $(\underline{r}, \underline{t}) \in W_{tr}$ for some $\underline{t} \in R^k$."

There exists a submanifold W_λ of W_s, of dimension n_0, with the canonical immersion denoted by $\underline{s}$, such that, for some $\underline{s}_0 = \underline{s}(\underline{\lambda}_0)$, $\underline{\lambda}_0 \in W_\lambda$, the mapping:

$$\sigma(\underline{\lambda}) = \tilde{\underline{v}}^{-1}(\underline{s}_0)\tilde{\underline{v}}(\underline{s}(\underline{\lambda}))(e)$$

restricted to W_λ, is a diffeomorphism of W_λ on a neighborhood $\tilde{W}_\lambda$ of e in $\tilde{G}$.

Consider now the mapping:

$$h_{\underline{r},\underline{t}'}(\tilde{x}) = P(\underline{w}(\underline{r})\underline{v}^{-1}(\underline{s}_0)\underline{v}(\underline{s}(\sigma^{-1}(\tilde{\underline{w}}^{-1}(\underline{r})\tilde{x}\tilde{\underline{u}}(\underline{t}_0 - \underline{t}')(e))))\underline{u}(\underline{t}'))$$

$$= \Omega(\underline{s}_0, \underline{s}(\sigma^{-1}(\tilde{\underline{w}}^{-1}(\underline{r})\tilde{x}\tilde{\underline{u}}(\underline{t}_0 - \underline{t}')(e))), \underline{r}, \underline{t}').$$

Since $\sigma^{-1}(\tilde{\underline{w}}^{-1}(\underline{r})\tilde{w}(\underline{r})\tilde{\underline{u}}^{-1}(\underline{t}_0 - t')\tilde{\underline{u}}(\underline{t}_0 - \underline{t}')(e)) = \underline{\lambda}_0$, $h_{\underline{r},\underline{t}'}(\tilde{x})$ is defined along the two paths in $W_{tr} \times \tilde{G}$:

$$\zeta \in R^+, \quad \underline{t}' = \zeta * \underline{t}_0, \quad \underline{r} = 0, \quad \tilde{x} = \tilde{\underline{w}}(\underline{r})\tilde{\underline{u}}^{-1}(\underline{t}_0 - \underline{t}')(e),$$

$$\zeta \in R^+, \quad \underline{t}' = 0, \quad \underline{r} = \zeta * \underline{r}_0, \quad \tilde{x} = \tilde{\underline{w}}(\underline{r})\tilde{\underline{u}}^{-1}(\underline{t}_0 - \underline{t}')(e),$$

linking $(0, \underline{t}_0, e)$ to $(0, 0, \tilde{\underline{u}}^{-1}(\underline{t}_0)(e))$, and $(0, 0, \tilde{\underline{u}}^{-1}(\underline{t}_0)(e))$ to $(\underline{r}_0, 0, \tilde{\underline{w}}(\underline{r}_0)\tilde{u}^{-1}(\underline{t}_0)(e)$ respectively. Then $h_{\underline{r},\underline{t}'}(\tilde{\underline{x}})$ is defined on a connected open subset W_h of $W_{tr} \times \tilde{G}$ which contains the three upper mentioned points. For $\tilde{x}$ near e, $h_{\underline{r},\underline{t}'}$ fits with $\tilde{h}$, by construction and from an argument of analyticity. It follows, by analyticity and connectedness, that it does not depend locally on $\underline{r}$ and $\underline{t}'$, everywhere on W_{tr}. Then the germs of $h_{\underline{r},\underline{t}'}$, at points $\tilde{x}$ where it is defined, are elements of $\bar{M}$.

In particular, at $(\underline{r}_0, 0, \tilde{\underline{w}}(\underline{r}_0)\tilde{\underline{u}}^{-1}(\underline{t}_0)(e))$, this gives:

$$\bar{h}(\bar{\underline{w}}(\underline{r}_0)\bar{\underline{u}}^{-1}(\underline{t}_0)(\bar{x}_0)) = P(\underline{w}(\underline{r}_0)\underline{v}^{-1}(\underline{s}_0)\underline{v}(\underline{s}_0)\underline{u}(0)).$$

The mapping

$$\Lambda(\underline{s}', \underline{s}) = P(\underline{w}(\underline{r})\underline{v}^{-1}(\underline{s}')\underline{v}(\underline{s})\underline{u}(0)), \quad \text{for any } \underline{r} = \zeta * \underline{r}_0, \zeta \in R^+,$$

is defined on $W_s \times W_s$. For the open subset $\underline{s}' < 0$, $\underline{s} > 0$, one has:

$$\Lambda(\underline{s}', \underline{s}) = P(\underline{w}(\underline{r})(v_1, -s_1') \cdots (v_{q-1}, -s_{q-1}')(v_q, s_q - s_q')(v_{q-1}, s_{q-1}) \cdots (v_1, s_1)\underline{u}(0)).$$

Then this relation holds also on $W_s \times W_s$, and in particular for every $\underline{s}', \underline{s}$ such that

$s'_q = s_q$. The same process can be iterated for $q-1, \cdots, 1$. This gives:

$$\bar{h}(\bar{\underline{w}}(\underline{r})\bar{u}^{-1}(\underline{t}_0)(\bar{x}_0)) = P(\underline{w}(\underline{r})\underline{u}(0)) = P(\underline{w}(\underline{r})) \quad \text{for any } \underline{r} = \zeta * \underline{r}_0,\ \zeta \in R^+.$$

Taking the new origin in M the point $\bar{x}'_0 = \bar{u}^{-1}(\underline{t}_0)(\bar{x}_0)$, one obtains finally:

$$\bar{h}(\bar{\underline{w}}(\underline{r})(\bar{x}'_0)) = P(\underline{w}(\underline{r})) \quad \text{for every } \underline{w}(\underline{r}) \in D_P.$$

Then the system

$$\bar{Q} = (\bar{M}, \bar{x}'_0, \bar{F} = \{\bar{X}_u | u \in U\}, \bar{h})$$

is a global realization of P.

(c) *Minimality and uniqueness.* $\bar{Q}$ is an analytic system. Then from Sussmann's theory [4], [5], [6], there exists a (global) minimal realization

$$Q^m = (M^m, x_0^m, F^m = \{X_u^m | u \in U\}, h^m)$$

of $\bar{Q}$, then also of P. The minimal realization of P is not unique. However the realization Q^m which has been built is a maximal one in the sense that, if

$$Q = (M, x_0, F = \{X_u | u \in U\}, h)$$

is another minimal realization of P, then there exists a mapping $\tau: M \to M^m$ such that:

- τ is a diffeomorphism of M on its image in M^m,
- $d\tau(X_u) = X_u^m$,
- $h = h_0^m \tau$.

Consider $x \in M$, and some $\underline{u}(\underline{t})$ such that $x = \hat{\underline{u}}(\underline{t})(x_0)$. To the path $\gamma = (R^+) * \hat{u}(t)(x_0)$ between x_0 and x in M corresponds the uniquely defined path $\tilde{\gamma} = (R^+) * \hat{\underline{u}}(\underline{t})(\tilde{x}_0)$ in $\tilde{G}$, where $\tilde{x}_0$ is the point of $\tilde{G}$ corresponding to $\bar{x}'_0$ of $\bar{M}$, since the vector fields $\tilde{X}_u$ are complete in $\tilde{G}$. Applying (like in the last part of (b)) a strategy of identification of the germs of the analytic mapping along $\tilde{\gamma}$, it is clear that to γ and $\tilde{\gamma}$ corresponds the uniquely defined paths $\bar{\gamma} = (R^+) * \hat{\underline{u}}(\underline{t})(\bar{x}'_0)$ in the Riemann surface $\bar{M}$ and $\gamma^m = (R^+) * \hat{\underline{u}}(\underline{t})(x_0^m)$ in M^m. Let $\tau: M \to M^m$ be defined by: $\tau(\bar{u}(\underline{t})(x_0)) = \hat{\underline{u}}(\underline{t})(x_0^m)$. τ is well defined. Clearly x and $\tau(x)$ are indistinguishable, and since Q^m and Q are two minimal analytic realizations, τ is everywhere on M a local diffeomorphism. Moreover the indistinguishability equivalence relation on M^m restricts to the identity. Then τ is a diffeomorphism of M on its image in M^m, with the required proprieties.

This ends the proof of Theorem 1.

COROLLARY 1. *Complete case. Assume that P, analytic, is defined on $D_P = G$. Then the following two propositions are equivalent*:

(a) *The rank n_0 associated to P is finite.*

(b) *There exists a global realization of P on a Lie group $\tilde{G}$, by a family of right-invariant vector fields on $\tilde{G}$.*

Proof. $a \to b$. *n_0 is finite.* From Theorem 1, there exists a (global) realization $\bar{Q} = (\bar{M}, \bar{x}_0, \bar{F} = \{\bar{X}_u | \in U\}, \bar{h})$ where $\bar{M}$ is a Riemann surface on a Lie group $\tilde{G}$ and the $\bar{X}_u$ are the lifts of right-invariant vector fields on $\tilde{G}$.

Since $D_P = G$, the $\bar{X}_u$ are complete on $\bar{M}$. F is a transitive family of complete symmetry vector fields for the closed equivalence relation $\sim$ defined on $\bar{M}$ by: $\bar{x}_1 \sim \bar{x}_2$ when $\pi(\bar{x}_1) = \pi(\bar{x}_2)$, π being the canonical mapping from $\bar{M}$ to G. Then from Sussmann [4, Thm. 11], π defines a locally trivial fibration on $\bar{M}$, of basis $\tilde{G}$ and fiber $\pi^{-1}(\tilde{x})$. Since π is a local diffeomorphism, the fiber is discrete, and $\bar{M}$ is then a covering space of $\tilde{G}$, which is itself a simply connected Lie group. Then $\bar{M}$ and $\tilde{G}$ are essentially the same object and P realizes on $\tilde{G}$, by the right-invariant vector fields $\tilde{X}_u$.

$b \to a$. *Straightforward.* This ends the proof of Corollary 1.

Remark. When $D_P = G$, Jakubczyk's technique is equivalent to the following manipulation. Consider the subset H_1 of G:

$$H_1 = \{h_1 \in G | P(ch_1) = P(c) \text{ for every } c \in G\}.$$

H_1 is a closed subgroup of G, and Jakubczyk's rank condition expresses that H_1 has finite codimension in G. Then the quotient G/H_1, interpreted as the state space of the minimal realization, is a manifold.

Again with $D_P = G$, consider now the subset H_0 of G:

$$H_0 = \{h_0 \in G | P(ch_0 d) = P(cd) \text{ for every } c, d \in G\}.$$

H_0 is a closed subgroup of G, and moreover it is a *normal* subgroup. The quotient $G_0 = G/H_0$ is then a group. The finiteness of n_0 expresses that H_0 has finite codimension. Then G_0 is a Lie group.

This group G_0 interprets as the group of diffeomorphisms of the minimal realization of P. Moreover, the group $\tilde{G}$ which was exhibited above is nothing but the universal covering of G_0.

5. Examples.

Example 1 (*continued*). The rank r_0 of the system described in Example 1 is not finite, and Theorem 1 does not apply.

Example 2. Consider $M = R^2$ with coordinates ρ, h and the vector fields:

$$X_1 = e^{-\rho} \cosh \frac{\partial}{\partial \rho} - e^{-\rho} \sinh \frac{\partial}{\partial h},$$

$$X_2 = e^{-\rho} \sinh \frac{\partial}{\partial \rho} + e^{-\rho} \cosh \frac{\partial}{\partial h};$$

take $x_0 = (\rho_0, h_0) = (\log 2/2, 5\pi/4)$ and the function $r(\rho, h) = h$. This mapping defines a realization Q of an input-output mapping P (whose domain is an open star-shaped subset of S):

$$Q = (M, x_0, \{X_1, X_2\}, r).$$

It will be shown that this input-output mapping P so defined leads to a maximal use of the main theorem (in the sense that the conflicts appearing in analytic extensions of mappings make necessary the use of sheaves of analytic germs).

Consider R^3 with coordinates (x, y, z) and the regular imbedding ψ of R^2 into R^3 so defined:

$$\psi(\rho, h) = \begin{cases} 1 + e^{\rho} \cosh = \psi_1(\rho, h), \\ 1 + e^{\rho} \sinh = \psi_2(\rho, h), \\ h = \psi_3(\rho, h). \end{cases}$$

$\psi(\rho, h)$ is the helicoïd H represented at Fig. 1. On R^2, (imbedded in R^3 as the subspace $z = 0$), consider the two vector fields $\tilde{X}_1 = \partial/\partial x$, $\tilde{X}_2 = \partial/\partial y$, and the point $\tilde{x}_0 = (0, 0)$. R^2, with its additive structure, is a Lie group, and $\tilde{X}_1$ and $\tilde{X}_2$ are right-invariant vector fields on R^2 (as a Lie group).

Denote π for the canonical map; from R^2 to R^2:

$$\pi(\rho, h) \to \begin{cases} x = \psi_1(\rho, h), \\ y = \psi_2(\rho, h). \end{cases}$$

π is a local diffeomorphism from H to $R^2(z = 0)$.

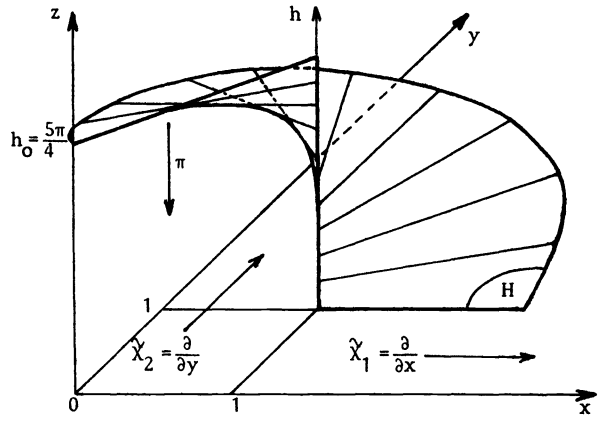

FIG. 1

It is not hard to check that X_1, X_2 are the lifts (through π) of the vector fields $\tilde{X}_1, \tilde{X}_2$ and that the point $x_0 = (\rho_0, h_0)$ belongs to $\pi^{-1}(0, 0)$.

We claim that:

(1) Q is a minimal realization of P.

(2) The Lie algebra generated by X_1 and X_2 (which is the same than the Lie algebra generated by $\tilde{X}_1, \tilde{X}_2$) is isomorphic to the (trivial) Lie algebra of the Lie group R^2 (with its additive structure).

(3) For P, $n_0 = 2$.

(4) $H = \psi(R^2)$ is a Riemann surface on the Lie group $R^2(z = 0)$ associated to the analytic mapping $\tilde{r}$ from $R^2(z = 0)$ to R,

$$\tilde{r}(x, y) = \pi - \arcsin\left(\frac{y-1}{\sqrt{(x+1)^2+(y-1)^2}}\right),$$

$\tilde{r}$ being defined for (x, y) near $(0, 0)$.

(5) π is nothing but the canonical mapping from H (as a Riemann surface on the Lie group R^2) to R^2 (as a Lie group).

(6) The realization

$$\tilde{Q} = (R^2, (0, 0), \{\tilde{X}_1, \tilde{X}_2\}, \tilde{r}(x, y)\},$$

R^2 being considered as a Lie group and $\tilde{X}_1, \tilde{X}_2$ as right-invariant vector fields, realizes locally P for small times.

There is then a maximal use of the theorem, since π is a diffeomorphism of the realizations $\tilde{Q}$, Q for small times, and is not global.

Associate to X_1 and $\tilde{X}_1$ the value u_1 for the control, and to X_2 and $\tilde{X}_2$ the value u_2, and consider the sequences of S:

$$\underline{u}(\underline{t}_0) = (u_2, 2)(u_1, 2) \quad \text{and} \quad \underline{v}(\underline{t}_0) = (u_1, 2)(u_2, 2).$$

Starting from $(x = 0, y = 0)$ with vector fields $\tilde{X}_1, \tilde{X}_2$, wth controls $\underline{u}(\underline{t}_0)$ and $\underline{v}(\underline{t}_0)$ clearly leads to the same point $(x, y) = (2, 2)$,

However, to ensure analyticity, $\tilde{r}$ cannot have the same value for these two sequences of control (along one path, $\tilde{r}$ is increasing, along other one it decreases). On the contrary, starting from x_0 in H with the vector fields X_1, X_2, (that is to say "lifting" the preceding manipulation on H) anything is all right.

IDENTIFIABILITY OF SPATIALLY-VARYING CONDUCTIVITY FROM POINT OBSERVATION AS AN INVERSE STURM–LIOUVILLE PROBLEM*

COSTAS KRAVARIS† AND JOHN H. SEINFELD‡

Abstract. This paper discusses identifiability of the spatially varying parameter $\alpha(x)$ in the heat equation $u_t-(\alpha u_x)_x=f$ from measurement of u at a single point. The identifiability problem is formulated as an inverse Sturm–Liouville problem for $(\alpha y')'+\lambda y=0$. It is proved that the eigenvalues and the normalizing constants determine the above Sturm–Liouville operator uniquely. Identifiability and nonidentifiability results are obtained for three heat conduction problems.

Key words. identifiability, distributed parameter systems, inverse Sturm–Liouville problem, system identification

1. Introduction.

The partial differential equation

$$\frac{\partial u}{\partial t}-\frac{\partial}{\partial x}\left(\alpha(x,y)\frac{\partial u}{\partial x}\right)-\frac{\partial}{\partial y}\left(\alpha(x,y)\frac{\partial u}{\partial y}\right)=f(x,y,t) \tag{1.1}$$

governs the temperature distribution in a nonhomogeneous isotropic solid or the pressure distribution in a fluid-containing porous medium. The conductivity $\alpha(x, y)$ is inaccessible to direct measurement and, consequently, its value must be inferred from measurements of u at a finite number of points. A fundamental question arising in such problems is that of *identifiability*, namely, do the measurements provide sufficient information to determine α uniquely.

Relatively little work has been carried out on the identifiability of $\alpha(x)$ in (1.1). Early work by Cannon and coworkers [3–5] is concerned with the steady-state version of (1.1) and identifiability given the temperature u and the heat flux along the boundary. Kitamura and Nakagiri [11] have studied the identifiability of $\alpha(x)$ in the one-dimensional version of (1.1) given measurements of $u(x, t)$ at all x and t. Nakagiri [17] has considered the identifiability of the operator in general first and second order evolution equations in Hilbert spaces given whole domain measurements of the state.

The most relevant measurement configuration is that of one or more point measurements of the state u and we concentrate on that situation here. Specifically, we consider the problem of identifying $\alpha(x)$ in the one-dimensional version of (1.1),

$$\frac{\partial u}{\partial t}-\frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right)=f(x,t) \tag{1.2}$$

given a measurement of u at a single point x_p, $u(x_p, t)$. The appropriate method of attack to obtain uniqueness and nonuniqueness results is to formulate the problem as an inverse Sturm–Liouville problem.

2. Inverse Sturm–Liouville problems. Their relation to identifiability problems.

The inverse Sturm–Liouville problem was first posed in 1946 by Borg [2] as follows: *Given the eigenvalues λ_n of the Sturm–Liouville problem*

$$y''+[\lambda-q(x)]y=0, \tag{2.1}$$

* Received by the editors June 14, 1983, and in revised form March 15, 1985.

‡ Department of Chemical Engineering, California Institute of Technology, Pasadena, California 91125.

$$y'(0) - hy(0) = 0, \tag{2.2}$$

$$y'(l) + Hy(l) = 0, \tag{2.3}$$

determine $q(x)$. Borg showed that knowledge of the spectrum alone is not sufficient to determine $q(x)$ uniquely. Since that early work, two not altogether equivalent inverse Sturm-Liouville problems have been considered.

One approach, which has become associated with Gel'fand and Levitan [10], uses the spectral function $\sigma(\lambda)$ as a starting point. If $\phi(x; \lambda)$ denotes the solution of (2.1) satisfying $y(0) = 1$ and $y'(0) = h$ and if we define

$$E_f(\lambda) = \int_0^l f(x)\phi(x; \lambda)\, dx$$

where $f(x)$ is an arbitrary element of $L^2(0, l)$, then by Parseval's theorem,

$$\int_0^l f^2(x)\, dx = \int_{-\infty}^{\infty} E_f^2(\lambda)\, d\sigma(\lambda)$$

where

$$\sigma(\lambda) = \sum_{\lambda_n < \lambda} \frac{1}{\xi_n}$$

and

$$\xi_n = \int_0^l \phi^2(x; \lambda_n)\, dx.$$

Gel'fand and Levitan have shown that knowledge of $\sigma(\lambda)$, or equivalently, of the spectrum $\{\lambda_n\}$ and the normalizing constants $\{\xi_n\}$, determine the potential $q(x)$ uniquely. Furthermore, they provided a method of constructing $q(x)$ from $\sigma(\lambda)$, as well as necessary and sufficient conditions for existence. Note that since $\xi_n = [y_n(0)]^{-2}$, where $y_n(x)$ are the normalized eigenfunctions of the Sturm-Liouville problem (2.1)-(2.3), the results of Gel'fand and Levitan can be interpreted as applicable to the problem of constructing a Sturm-Liouville operator of the form (2.1) given $\{\lambda_n\}$ and $\{|y_n(0)|\}$.

The other approach to the inverse Sturm-Liouville problem consists in using two spectra, such as $\{\lambda_n\}$ associated with (2.1)-(2.3) and $\{\mu_n\}$ associated with (2.1) and a different set of boundary conditions, to determine $q(x)$ [15]. Krein [12], [13] provided a method of constructing $q(x)$ from two spectra as well as necessary and sufficient conditions for existence. The issue of existence was investigated further by Levitan [16] who showed how the normalizing constants ξ_n can be evaluated from $\{\lambda_n\}$ and $\{\mu_n\}$.

It is noteworthy that the prior work on inverse Sturm-Liouville theory is based on the Liouville normal form (2.1)-(2.3). As we shall see shortly, the problem of interest in the present work requires us to consider inverse Sturm-Liouville problems that are not in normal form.

Consider for a moment the parabolic system,

$$\begin{aligned}
&\frac{\partial u}{\partial t} - \frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right) + q(x)u = f(x, t) \quad \text{in }]0, l[\times]0, T], \\
&u(x, 0) = u_0(x) \quad \text{in }]0, l[, \\
&\frac{\partial u}{\partial x}(0, t) - hu(0, t) = g(t) \quad \text{in }]0, T], \\
&\frac{\partial u}{\partial x}(l, t) + Hu(l, t) = G(t) \quad \text{in }]0, T],
\end{aligned} \tag{2.4}$$

where $f(x, t)$, $u_0(x)$, $g(t)$, $G(t)$, h and H are known. Given the point measurement $z_d(t) = u(x_p, t)$, $t \in]0, T]$, at some $x_p \in [0, l]$, the question is can $\alpha(x)$ and $q(x)$ be uniquely determined.

Note that the solution[1] of (2.4) can be expressed in terms of the eigenvalues λ_n and the eigenfunctions $y_n(x)$ of

$$\begin{aligned} &\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right)+[\lambda - q(x)]y = 0, \\ &y'(0) - hy(0) = 0, \\ &y'(l) + Hy(l) = 0, \end{aligned} \tag{2.5}$$

as follows

$$\begin{aligned} u(x, t) = &\sum_{n=1}^{\infty}\left[\int_0^l u_0(x)y_n(x)\,dx\right]y_n(x)\,e^{-\lambda_n t} \\ &+\int_0^t\int_0^l\left\{\sum_{n=1}^{\infty} y_n(x)y_n(x')\,e^{-\lambda_n(t-\tau)}\right\}f(x', \tau)\,dx'\,d\tau \\ &-\int_0^t\left\{\sum_{n=1}^{\infty}\alpha(0)y_n(0)y_n(x)\,e^{-\lambda_n(t-\tau)}\right\}g(\tau)\,d\tau \\ &+\int_0^t\left\{\sum_{n=1}^{\infty}\alpha(l)y_n(l)y_n(x)\,e^{-\lambda_n(t-\tau)}\right\}G(\tau)\,d\tau \end{aligned} \tag{2.6}$$

and thus the measurement

$$\begin{aligned} z_d(t) = u(x_p, t) = &\sum_{n=1}^{\infty} y_n(x_p)\left[\int_0^l u_0(x)y_n(x)\,dx\right]e^{-\lambda_n t} \\ &+\int_0^t\int_0^l\left\{\sum_{n=1}^{\infty} y_n(x_p)y_n(x')\,e^{-\lambda_n(t-\tau)}\right\}f(x', \tau)\,dx'\,d\tau \\ &-\int_0^t\left\{\sum_{n=1}^{\infty}\alpha(0)y_n(0)y_n(x_p)\,e^{-\lambda_n(t-\tau)}\right\}g(\tau)\,d\tau \\ &+\int_0^t\left\{\sum_{n=1}^{\infty}\alpha(l)y_n(l)y_n(x_p)\,e^{-\lambda_n(t-\tau)}\right\}G(\tau)\,d\tau. \end{aligned} \tag{2.7}$$

Kitamura and Nakagiri [11] (see also [8]) considered (2.4) with $\alpha(x)$ and $q(x)$ both being constant. Using (2.7), they have shown that (under certain assumptions) in the following special cases

(i) $f(x, t) = 0$, $g(t) = G(t) = 0$,

(ii) $f(x, t) = 0$, $u_0(x) = 0$, one of $g(t)$ or $G(t)$ vanishes,

(iii) $u_0(x) = 0$, $g(t) = G(t) = 0$, $f(x, t) = f_1(x)f_2(t)$,

the eigenvalues λ_n can be uniquely determined. Thus the constants α and q can be easily obtained.

When α and q are spatially varying, one can still (under certain assumptions) determine the eigenvalues λ_n as well as some information on the eigenfunctions $y_n(x)$ for the cases (i)-(iii) [18]. Thus the identifiability problem reduces to an inverse Sturm-Liouville problem related to (2.5).

[1] With $\alpha(x)$ strictly positive and $\alpha(x)$, $q(x)$, $f(x, t)$, $u_0(x)$, $g(t)$ and $G(t)$ sufficiently regular, there exists a unique strong solution of (2.4). See [14, pp. 320-321] for appropriate Hölder continuity and compatibility conditions.

Pierce [18] has considered the identifiability of $q(x)$ in (2.4) when $\alpha(x) \equiv 1$. In this case the Sturm-Liouville system (2.5) is in normal form (it is identical to (2.1)-(2.3)). He obtained a number of identifiability results in very special cases, as an immediate consequence of the Gel'fand and Levitan [10] and Levinson [15] theories. Some complementary results to [18] were obtained by Suzuki and Murayama [20] and Suzuki [21]; these results do not rely directly on the Gel'fand-Levitan or the Levinson-Krein theories, but rather on the Povzner representation theorem [19] (this is Lemma 2 in [21, p. 302]).

In the present work we are going to consider the case $q(x) = 0$, i.e.

$$
\begin{aligned}
&\frac{\partial u}{\partial t} - \frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right) = f(x, t) \quad \text{in }]0, l[\times]0, T], \\
&u(x, 0) = u_0(x) \quad \text{in }]0, l[, \\
&\frac{\partial u}{\partial x}(0, t) - hu(0, t) = g(t) \quad \text{in }]0, T], \\
&\frac{\partial u}{\partial x}(l, t) + Hu(l, t) = G(t) \quad \text{in }]0, T],
\end{aligned} \tag{2.8}
$$

the general problem being to determine $\alpha(x)$ knowing $f(x, t)$, $u_0(x)$, $g(t)$, $G(t)$, h and H and given the point measurement

$$
z_d(t) = u(x_p, t), \qquad t \in]0, T] \tag{2.9}
$$

at some $x_p \in [0, l]$. The Sturm-Liouville system associated wth (2.8) is

$$
\begin{aligned}
&\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right) + \lambda y = 0, \\
&y'(0) - hy(0) = 0, \\
&y'(l) + Hh(l) = 0,
\end{aligned} \tag{2.10}
$$

and the eigenfunction expansion of the solution of (2.8) is still given by (2.6).

In § 3 we define three special cases of (2.8) corresponding to models of physical systems and formulate identifiability problems as inverse Sturm-Liouville problems. In § 4 we state and prove the analogue of Gel'fand and Levitan's result for the Sturm-Liouville problem (2.10). In § 5 we obtain uniqueness and nonuniqueness results for the identification problems of § 3.

3. Problem statement. In the previous section we have stated a general identifiability problem associated with the system (2.8) and the measurement (2.9). With the available tools it does not appear to be possible to attack the problem in its full generality; rather, it is necessary to consider special cases. It will, however, be very important to select cases that are physically relevant and of practical significance. Our selection is based on the following considerations:

(i) In practice one generally has point actuators and thus boundary control and/or point control at some interior point(s) exist as opposed to distributed control.

(ii) Before performing a heat conduction experiment, it is natural to assume that the system is at ambient temperature, i.e. u = constant. Thus, the most important special case for $u_0(x)$ is $u_0(x)$ = constant.

In the present work the analysis will be restricted to the SISO case. In other words, we are going to assume either that only one of $g(t)$, $G(t)$ is nonzero and $f(x, t) = 0$

or $g(t)=G(t)=0$ and $f(x,t)=Q(t)\delta(x-x_p)$. Also, we will restrict ourselves to the special case of $u_0(x)=u_0$ (constant).

We consider

$$
\begin{aligned}
&\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right) \quad \text{in }]0,l[\times]0,T],\\
&u(x,0)=u_0 \quad \text{in }]0,l[,\\
&\alpha(0)\frac{\partial u}{\partial x}(0,t)=Q(t) \quad \text{in }]0,T],\\
&\frac{\partial u}{\partial x}(l,t)=0 \quad \text{in }]0,T],
\end{aligned}
\tag{3.1}
$$

where

$$
\begin{aligned}
&\alpha\in C^1([0,l]) \quad \text{and} \quad \exists\alpha_0>0\colon \alpha(x)\geqq\alpha_0 \quad \forall x\in[0,l],\\
&Q\in H^1(0,T) \quad \text{and} \quad \nexists\varepsilon>0\colon Q(t)=0 \quad \forall t\in]0,\varepsilon[,\\
&u_0\in\mathbb{R}.
\end{aligned}
$$

PROBLEM 1. *To a known input $Q(t)$, a known initial state u_0 and a given measurement $z_d(t)=u(0,t)$, $t\in]0,T]$, does there correspond a unique $\alpha(x)$?*

PROBLEM 2. *To a known input $Q(t)$, a known initial state u_0 and a given measurement $z_d(t)=u(l,t)$, $t\in]0,T]$, does there correspond a unique $\alpha(x)$?*

Now consider

$$
\begin{aligned}
&\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right)+Q(t)\delta(x-x_p) \quad \text{in }]0,l[\times]0,T],\\
&u(x,0)=u_0 \quad \text{in }]0,l[,\\
&\frac{\partial u}{\partial x}(0,t)=\frac{\partial u}{\partial x}(l,t)=0 \quad \text{in }]0,T],
\end{aligned}
\tag{3.2}
$$

where

$$
\begin{aligned}
&\alpha\in C^1([0,l]) \quad \text{and} \quad \exists\alpha_0>0\colon \alpha(x)\geqq\alpha_0 \quad \forall x\in[0,l],\\
&Q\in H^1(0,T) \quad \text{and} \quad \nexists\varepsilon>0\colon Q(t)=0 \quad \forall t\in]0,\varepsilon[,\\
&u_0\in\mathbb{R},\\
&x_p\in]0,l[.
\end{aligned}
$$

PROBLEM 3. *To a known input $Q(t)$, a known initial state u_0 and a given measurement $z_d(t)=u(x_p,t)$, $t\in]0,T]$, does there correspond a unique $\alpha(x)$?*

To be able to formulate Problems 1-3 as inverse Sturm-Liouville problems, we will need the following lemmata:

LEMMA 1. *Let $\{\lambda_n\}$ and $\{\hat{\lambda}_n\}$ be strictly increasing sequences tending to infinity and let $\sum_{n=1}^{\infty}c_ne^{-\lambda_nt}$, $\sum_{n=1}^{\infty}\hat{c}_ne^{-\hat{\lambda}_nt}$ be uniformly convergent on $[\delta,+\infty)$ for every $\delta>0$. Suppose*

$$
\sum_{n=1}^{\infty}c_n\,e^{-\lambda_nt}=\sum_{n=1}^{\infty}\hat{c}_n\,e^{-\hat{\lambda}_nt} \quad \forall t\in]0,T].
\tag{3.3}
$$

If $c_n\neq0$ and $\hat{c}_n\neq0$ $\forall n\in\mathbb{N}$, then $\lambda_n=\hat{\lambda}_n$ and $c_n=\hat{c}_n$ $\forall n\in\mathbb{N}$.

Proof. By analytic continuation we see that (3.3) should hold for all $t>0$. The result follows from the uniqueness of the expansion in Dirichlet series (see for example proof of Lemma 3 in [9]).

LEMMA 2 [22, p. 325]. *Let* Ψ, $Q\in L^1(0, T)$ *and assume*

$$\exists \varepsilon>0\colon Q(t)=0 \quad \text{a.e. in } [0, \varepsilon[.$$

If

$$\int_0^t \Psi(t-\tau)Q(\tau)\,d\tau=0 \quad \text{a.e. in }]0, T[,$$

then

$$\Psi(t)=0 \quad \text{a.e. in }]0, T[.$$

COROLLARY. *Let* $Q\in L^1(0, T)$ *and assume*

$$\exists \varepsilon>0\colon Q(t)=0 \quad \text{a.e. in }]0, \varepsilon[.$$

If the integral equation

$$\int_0^t \Psi(t-\tau)Q(\tau)\,d\tau=R(t)$$

admits a solution $\Psi\in L^1(0, T)$ *then* Ψ *is unique.*

Next consider

$$\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right)+\lambda y=0, \quad y'(0)=0, \quad y'(l)=0, \tag{3.4}$$

where $\alpha\in C^1([0, l])$ and $\exists\alpha_0\colon \alpha(x)\geqq\alpha_0\,\forall x\in[0, l]$ and denote by λ_n the eigenvalues of the above Sturm-Liouville problem and by $y_n(x)$ its normalized eigenfunctions.

PROBLEM 1′. *Referring to* (3.4), *is knowledge of* $\{\lambda_n\}_{n=1}^{\infty}$ *and* $\{|y_n(0)|\}_{n=1}^{\infty}$ *sufficient to determine* $\alpha(x)$ *uniquely*?

Proof of equivalence of Problems 1 *and* 1′. We will show that knowing $Q(t)$ and u_0,

(i) $z_d(t)$ is sufficient to determine $\{\lambda_n\}_{n=1}^{\infty}$ and $\{|y_n(0)|\}_{n=1}^{\infty}$ uniquely and

(ii) $\{\lambda_n\}_{n=1}^{\infty}$ and $\{|y_n(0)|\}_{n=1}^{\infty}$ are sufficient to determine $z_d(t)$ uniquely.

The eigenfunction expansion of the solution of (3.1) is given by

$$u(x, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} y_n(0)y_n(x)\,e^{-\lambda_n(t-\tau)}\right\}Q(\tau)\,d\tau.$$

Hence

$$z_d(t)=u(0, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} |y_n(0)|^2\,e^{-\lambda_n(t-\tau)}\right\}Q(\tau)\,d\tau. \tag{3.5}$$

Now given $Q(t)$, u_0 and $z_d(t)$, it follows from the Corollary of Lemma 2 that the function

$$\Psi(t)=\sum_{n=1}^{\infty} |y_n(0)|^2\,e^{-\lambda_n t}$$

is uniquely determined. But by Lemma 1 $\{\lambda_n\}$ and $\{|y_n(0)|\}$ are uniquely determined by $\Psi(t)$. This proves (i). Part (ii) is an obvious consequence of (3.5).

PROBLEM 2′. *Referring to* (3.4), *is knowledge of* $\{\lambda_n\}_{n=1}^{\infty}$ *and* $\{y_n(0)y_n(l)\}_{n=1}^{\infty}$ *sufficient to determine* $\alpha(x)$ *uniquely*?

Proof of equivalence of Problems 2 *and* 2′. The eigenfunction expansion of the solution of (3.1) is given by

$$u(x, t) = u_0 - \int_0^t \left\{ \sum_{n=1}^{\infty} y_n(0) y_n(x)\, e^{-\lambda_n (t-\tau)} \right\} Q(\tau)\, d\tau.$$

Hence

$$z_d(t) = u(l, t) = u_0 - \int_0^t \left\{ \sum_{n=1}^{\infty} y_n(0) y_n(l)\, e^{-\lambda_n (t-\tau)} \right\} Q(\tau)\, d\tau. \tag{3.6}$$

Using (3.6) and repeating the same argument as with Problems 1 and 1′, we conclude that Problems 2 and 2′ are equivalent.

PROBLEM 3′. *Referring to* (3.4), *is knowledge of* $\{\lambda_n\}_{n=1}^{\infty}$ *and* $\{|y_n(x_p)|\}_{n=1}^{\infty}$ *sufficient to determine* $\alpha(x)$ *uniquely*?

Problem 3 *is equivalent to Problem* 3′ *provided that* $y_n(x_p) \neq 0\ \forall n \in \mathbb{N}$. Indeed, using the eigenfunction expansion of the solution of (3.2),

$$u(x, t) = u_0 + \int_0^t \left\{ \sum_{n=1}^{\infty} y_n(x_p) y_n(x)\, e^{-\lambda_n (t-\tau)} \right\} Q(\tau)\, d\tau$$

we have

$$z_d(t) = u(x_p, t) = u_0 + \int_0^t \left\{ \sum_{n=1}^{\infty} |y_n(x_p)|^2\, e^{-\lambda_n (t-\tau)} \right\} Q(\tau)\, d\tau. \tag{3.7}$$

Thus, repeating the same argument as with Problems 1 and 1′, we conclude that Problems 3 and 3′ are equivalent, provided that $y_n(x_p) \neq 0\ \forall n \in \mathbb{N}$.

4. An associated inverse Sturm–Liouville problem. As mentioned in § 2, Gel'fand and Levitan ([10]) have solved the inverse Sturm-Liouville problem for a Sturm-Liouville operator in *normal* form. Their result (as applied to a finite interval) can be stated as follows:

THEOREM 1 (Gel'fand and Levitan). *Let* $\{\lambda_n\}$ *and* $\{\xi_n\}$ *be two sequences of positive real numbers obeying the asymptotic formulas*

$$\sqrt{\lambda_n} = \frac{\pi}{l} n + \frac{b_1}{n} + \frac{b_3}{n^3} + O\left(\frac{1}{n^4}\right), \qquad \xi_n = \frac{l}{2} + \frac{a_1}{n^2} + O\left(\frac{1}{n^4}\right)$$

where a_1, b_1, b_3 *are constants. Then there exists a unique differential operator, defined by a differential expression of the form*

$$L(y) = y'' - q(x)y, \qquad 0 \leqq x \leqq l$$

with $q \in C([0, l])$ *and by boundary conditions of the form*

$$y'(0) - hy(0) = 0, \qquad y'(l) + Hy(l) = 0$$

which has $\{\lambda_n\}$ *as eigenvalues and* $\{\xi_n\}$ *as normalizing constants. The function* $q(x)$ *and the number* h *can be computed via*

$$q(x) = \frac{1}{2} \frac{\partial K(x, x)}{\partial x}, \qquad h = K(0, 0)$$

where $K(x, t)$ *is the solution of the linear integral equation*

$$F(x, t) + K(x, t) + \int_0^x K(x, s) F(s, t)\, ds = 0$$

and where

$$F(x,t)=\frac{1}{\xi_0}\cos(\sqrt{\lambda_0}x)\cdot\cos(\sqrt{\lambda_0}t)-\frac{1}{l}$$
$$+\sum_{n=1}^{\infty}\left[\frac{\cos(\sqrt{\lambda_n}x)\cos(\sqrt{\lambda_n}t)}{\xi_n}-\frac{2}{l}\cos\left(\frac{n\pi}{l}x\right)\cos\left(\frac{n\pi}{l}t\right)\right].$$

Note that the above theorem gives at the same time existence, uniqueness and method of construction of the differential operator from its eigenvalues and its normalizing constants. For the purpose of studying identifiability problems, one needs only uniqueness. With this in mind, and the fact that $\xi_n=[y_n(0)]^{-2}$, where $y_n(x)$ are the normalized eigenfunctions of the Sturm-Liouville operator, what we wish to retain is

THEOREM 1′ (Gel'fand and Levitan). *Consider*

$$\begin{aligned} &y''+[\lambda-q(x)]y=0,\\ &y'(0)-hy(0)=0,\\ &y'(l)+Hy(l)=0, \end{aligned}\tag{4.1}$$

where $q\in C([0,l])$ and denote by λ_n its eigenvalues and $y_n(x)$ its normalized eigenfunctions. Also, consider

$$\begin{aligned} &y''+[\lambda-r(x)]y=0,\\ &y'(0)-\hat{h}y(0)=0,\\ &y'(l)+\hat{H}y(l)=0, \end{aligned}\tag{4.2}$$

where $r\in C([0,l])$ and denote by μ_n its eigenvalues and $z_n(x)$ its normalized eigenfunctions. If

$$\lambda_n=\mu_n,\qquad |y_n(0)|=|z_n(0)|\quad \forall n\in\mathbb{N},\tag{4.3}$$

then

$$q(x)=r(x),\quad h=\hat{h},\quad H=\hat{H}.$$

The purpose of this section will be to obtain a similar result for the Sturm-Liouville problem (3.4). Note that (3.4) can be reduced to (4.1) via the so-called Liouville transform [1]. Therefore, it is natural to try to "back Liouville transform" the result of Gel'fand and Levitan. In fact, this is possible and it leads to the following result:

Given $\alpha(0)$, λ_n and $|y_n(0)|$ for a differential operator of the form (3.4), *there corresponds a unique $\alpha(x)$.*

Using an entirely different approach than that of Gel'fand and Levitan, we will show that λ_n and $|y_n(0)|$ are sufficient to determine $\alpha(x)$ uniquely. In fact, we will prove the following theorem:

THEOREM 2. *Consider*

$$\begin{aligned} &\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right)+\lambda y=0,\\ &y'(0)-hy(0)=0,\\ &y'(l)+Hy(l)=0, \end{aligned}\tag{4.4}$$

with $\alpha\in C^1([0,l])$, and $\exists\alpha_0>0$: $\alpha(x)\geqq\alpha_0$ $\forall x\in[0,l]$ and denote by λ_n its eigenvalues

and $y_n(x)$ its normalized eigenfunctions. Also, consider

$$\frac{d}{dx}\left(\beta(x)\frac{dy}{dx}\right)+\lambda y=0,$$

$$y'(0)-\hat{h}y(0)=0, \tag{4.5}$$

$$y'(l)+\hat{H}y(l)=0,$$

with $\beta\in C^1([0,l])$, and $\exists\beta_0>0$: $\beta(x)\geqq\beta_0$ $\forall x\in[0,l]$ and denote by μ_n its eigenvalues and $z_n(x)$ its normalized eigenfunctions. If

$$\lambda_n=\mu_n, \qquad |y_n(0)|=|z_n(0)| \quad \forall n\in\mathbb{N}, \tag{4.6}$$

then

$$\alpha(x)=\beta(x), \quad h=\hat{h}, \quad H=\hat{H}.$$

Before proving Theorem 2, we will first prove a number of lemmata. The key to the proof of Theorem 2 will be Lemma 6 which is an analogue of the Povzner representation theorem (see [19] or [21, Lemma 2, p. 302]) for the differential operator $(d/dx)\,(\alpha(x)d/dx)$. An immediate consequence of Lemma 6 will be that we can relate $z_n(x)$ to $y_n(x)$ by

$$\frac{z_n(x)}{z_n(0)}=\frac{U(y_n(x))}{y_n(0)}$$

where U is a bounded linear operator defined by (4.24). Note that U has to relate functions defined on $[0,l]$ to functions defined on $[0,l]$; this is guaranteed by Lemmata 3 and 4. Taking into account that $|z_n(0)|=|y_n(0)|$ we will conclude that U has to be unitary. Lemma 5 will provide the appropriate conditions for U to be unitary. Using these conditions we will finally conclude that $z_n(x)=y_n(x)$.

LEMMA 3. *Consider the class $\mathcal{M}$ of differential operators of the form*

$$A=\frac{d}{dx}\left(\alpha(x)\frac{d}{dx}\right)$$

densely defined in $L^2(0,l)$, where $\alpha\in C^1([0,l])$ bounded below by a positive constant. If $A_1\in\mathcal{M}$ and $A_2\in\mathcal{M}$ have the same spectrum, then

$$\int_0^l\frac{dx}{\sqrt{\alpha_1(x)}}=\int_0^l\frac{dx}{\sqrt{\alpha_2(x)}}.$$

Proof. For every $A\in\mathcal{M}$, the eigenvalues λ_n satisfy the following asymptotic formula (see for example [7])

$$\sqrt{\lambda_n}=\frac{n\pi}{\int_0^l(dx/\sqrt{\alpha(x)})}+O(1).$$

Now if the operators $A_1=(d/dx)\,(\alpha_1(x)d/dx)$ and $A_2=(d/dx)\,(\alpha_2(x)d/dx)$ have

the same eigenvalues λ_n, then

$$\sqrt{\lambda_n}\int_0^l \frac{dx}{\sqrt{\alpha_1(x)}} = n\pi + O(1) = \sqrt{\lambda_n}\int_0^l \frac{dx}{\sqrt{\alpha_2(x)}}$$

$$\Rightarrow \sqrt{\lambda_n}\left(\int_0^l \frac{dx}{\sqrt{\alpha_1(x)}} - \int_0^l \frac{dx}{\sqrt{\alpha_2(x)}}\right) = O(1)$$

$$\Rightarrow \int_0^l \frac{dx}{\sqrt{\alpha_1(x)}} - \int_0^l \frac{dx}{\sqrt{\alpha_2(x)}} = O\left(\frac{1}{\sqrt{\lambda_n}}\right) = O\left(\frac{1}{n}\right) \quad \forall n \in \mathbb{N}.$$

Hence

$$\int_0^l \frac{dx}{\sqrt{\alpha_1(x)}} = \int_0^l \frac{dx}{\sqrt{\alpha_2(x)}}.$$

Q.E.D.

LEMMA 4. *Let $\alpha, \beta \in C^1([0, l])$ bounded below by positive constants and satisfying*

$$\int_0^l \frac{dx}{\sqrt{\alpha(x)}} = \int_0^l \frac{dx}{\sqrt{\beta(x)}}.$$

Denote $\rho \in C^2([0, l])$ the solution of

$$\frac{d\rho}{dx} = [\beta(x)]^{-1/2}[\alpha(\rho)]^{1/2}, \qquad \rho(0) = 0.$$

Then $\rho(x)$ is a bijection of $[0, l]$ onto itself.

Proof. Since $d\rho/dx > 0$, ρ is strictly increasing. Furthermore, from the definition of ρ, we have

$$\frac{d\rho}{[\alpha(\rho)]^{1/2}} = \frac{dx}{[\beta(x)]^{1/2}}$$

which upon integration gives

$$\int_0^{\rho(l)} \frac{dx}{\sqrt{\alpha(x)}} = \int_0^l \frac{dx}{\sqrt{\beta(x)}}.$$

Hence

$$\int_0^{\rho(l)} \frac{dx}{\sqrt{\alpha(x)}} = \int_0^l \frac{dx}{\sqrt{\alpha(x)}} \Leftrightarrow \int_l^{\rho(l)} \frac{dx}{\sqrt{\alpha(x)}} = 0.$$

But since $\alpha(x)$ is strictly positive, $\int_0^x (dx'/\sqrt{\alpha(x')})$ is a strictly increasing function. Hence $\rho(l) = l$. So ρ is a strictly increasing continuous mapping of $[0, l]$ onto $[0, l]$. Hence ρ is a bijection.

LEMMA 5. *Let $\alpha(x)$, $\beta(x)$, $\rho(x)$ as in Lemma 4 and let $U: L^2(0, l) \to L^2(0, l)$ be defined by*

$$U(f) = \kappa\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} f(\rho(x)) + \int_0^x K(x, t) f(\rho(t))\, dt$$

where $\kappa \in \mathbb{R}^+$ and $K \in C([0, l] \times [0, l])$. U will be unitary iff $\kappa = 1$ and $K = 0$.

Proof. Let

$$T(f)=\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} f(\rho(x)), \qquad V(f)=\int_0^x K(x,t)f(\rho(t))\,dt$$

so that

$$U=\kappa T+V.$$

To prove the "if" part of the lemma, we need to show that T is unitary. A straightforward calculation gives the adjoint of T

$$T^*(f)=\left[\frac{\beta(\rho^{-1}(x))}{\alpha(x)}\right]^{1/4} f(\rho^{-1}(x))$$

and thus $TT^*=T^*T=I$.

To prove the "only if" part of the lemma, we will first show that the spectral radius of V is zero. To see this, observe that

$$|(V^n f)(x)|^2 \leqq \frac{\gamma\Gamma^{(n-1)^2}M^n}{2^{n-1}(n-1)!}\|f\|_{L^2}^2 x^{2n-1} \quad \forall x\in[0,l], \tag{4.7}$$

where

$$\gamma=\sup_{0\leqq x\leqq l}\left[\frac{\beta(x)}{\alpha(\rho(x))}\right]^{1/2},$$

$$\Gamma=\sup_{0\leqq x\leqq l}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/2},$$

$$M=\sup_{0\leqq t\leqq x\leqq l}[K(x,t)]^2.$$

(See Appendix A for a proof). Hence

$$\|V^n\|_{L^2}\leqq\frac{\gamma^{1/2}}{\sqrt{n!}}\Gamma^{(n-1)^2/2}\left(\frac{Ml^2}{2}\right)^{n/2}, \qquad r(V)=\lim_{n\to\infty}\|V^n\|^{1/n}=0.$$

Now

$$V=U-\kappa T.$$

Since U and T are unitary, it is easy to show that $(U-\kappa T)$ and $(U-\kappa T)^*$ commute, i.e. $V=U-\kappa T$ is normal. But for every normal operator, the spectral radius equals the norm of the operator. Hence $\|V\|_{L^2}=0\Rightarrow K(x,t)=0$. So

$$U=\kappa T$$

and since they are both unitary and $\kappa>0$, it follows that $\kappa=1$. This completes the proof of the lemma.

LEMMA 6. *Let $\alpha(x)$ and $\beta(x)$ be C^1-functions bounded below by positive constants. Furthermore, let $\phi(x;\lambda)$ be the solution of*

$$\frac{d}{dx}\left(\alpha(x)\frac{dw}{dx}\right)+\lambda w=0, \qquad x\geqq 0,$$

$$w(0)=1, \tag{4.8}$$

$$w'(0)=h,$$

$\psi(x;\lambda)$ be the solution of

$$\frac{d}{dx}\left(\beta(x)\frac{dw}{dx}\right)+\lambda w=0, \qquad x\geqq 0,$$

$$w(0)=1, \tag{4.9}$$

$$w'(0)=\hat{h}.$$

Then there exists a continuous kernel $K(x,t)$ such that

$$\psi(x;\lambda)=\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\phi(\rho(x);\lambda)+\int_0^x K(x,t)\phi(\rho(t);\lambda)\,dt \quad \forall x\geqq 0, \tag{4.10}$$

where $\rho(x)$ is the solution of

$$\frac{d\rho}{dx}=[\beta(x)]^{-1/2}[\alpha(\rho)]^{1/2}, \qquad \rho(0)=0. \tag{4.11}$$

Proof. Let $u(x,y;\lambda)=\phi(x;\lambda)\psi(y;\lambda)$.

It can be easily seen that u satisfies the hyperbolic P.D.E.

$$\frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right)-\frac{\partial}{\partial y}\left(\beta(y)\frac{\partial u}{\partial y}\right)=0 \tag{4.12}$$

and the initial conditions

$$u|_{y=0}=\phi(x;\lambda) \tag{4.13}$$

$$\left.\frac{\partial u}{\partial y}\right|_{y=0}=\hat{h}\phi(x;\lambda). \tag{4.14}$$

The Cauchy problem (4.12)-(4.14) admits a unique solution which can be computed by Riemann's method (See Appendix B for details). First, we make the change of variable

$$X=\int_0^x \frac{dx'}{\sqrt{\alpha(x')}}=\mathscr{A}(x), \qquad Y=\int_0^y \frac{dy'}{\sqrt{\beta(y')}}=\mathscr{B}(y).$$

Then, applying (B.9) we find

$$\begin{aligned}\tilde{u}(X,Y;\lambda)=\frac{1}{2}\left[\frac{\beta(0)}{\tilde{\beta}(Y)\tilde{\alpha}(X)}\right]^{1/4}&\{[\tilde{\alpha}(X-Y)]^{1/4}\tilde{\phi}(X-Y;\lambda)\\ &+[\tilde{\alpha}(X+Y)]^{1/4}\tilde{\phi}(X+Y;\lambda)\}\\ &+\frac{1}{2}\int_{X-Y}^{X+Y}\tilde{W}(X,Y,t)\tilde{\phi}(t;\lambda)\,dt\end{aligned} \tag{4.15}$$

where $\tilde{W}(X,Y,t)=W_1(X,Y,t)+\hat{h}W_2(X,Y,t)$. Applying (4.15) at $X=0$ we obtain

$$\begin{aligned}\tilde{\psi}(Y;\lambda)=\tilde{u}(0,Y;\lambda)=\frac{1}{2}\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}&\frac{[\tilde{\alpha}(-Y)]^{1/4}\tilde{\phi}(-Y;\lambda)+[\tilde{\alpha}(Y)]^{1/4}\tilde{\phi}(Y;\lambda)}{[\tilde{\beta}(Y)]^{1/4}}\\ &+\frac{1}{2}\int_{-Y}^{Y}\tilde{W}(0,Y,t)\tilde{\phi}(t;\lambda)\,dt.\end{aligned} \tag{4.16}$$

Now, if the function $\alpha(x)$ is continued so as to be even, it is easy to see that

$\phi(x;\lambda)=\phi(-x;\lambda)$. Thus we easily deduce that

$$\tilde{\alpha}(Y)=\tilde{\alpha}(-Y), \qquad \tilde{\phi}(Y;\lambda)=\tilde{\phi}(-Y;\lambda). \tag{4.17}$$

Furthermore

$$\begin{aligned}\int_{-Y}^{Y}\tilde{W}(0,Y,t)\tilde{\phi}(t;\lambda)\,dt &= \int_{0}^{Y}\tilde{W}(0,Y,t)\tilde{\phi}(t;\lambda)\,dt+\int_{0}^{Y}\tilde{W}(0,Y,-t)\tilde{\phi}(t;\lambda)\,dt \\ &= \int_{0}^{Y}\{\tilde{W}(0,Y,t)+\tilde{W}(0,Y,-t)\}\tilde{\phi}(t;\lambda)\,dt. \end{aligned} \tag{4.18}$$

Thus setting

$$\tilde{K}(Y,t)=\frac{1}{2}\{\tilde{W}(0,Y,t)+\tilde{W}(0,Y,-t)\}$$

it follows from (4.16), (4.17) and (4.18) that

$$\tilde{\psi}(Y;\lambda)=\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\tilde{\alpha}(Y)}{\tilde{\beta}(Y)}\right]^{1/4}\tilde{\phi}(Y;\lambda)+\int_{0}^{Y}\tilde{K}(Y;t)\tilde{\phi}(t,\lambda)\,dt. \tag{4.19}$$

It remains to back-transform to the original variables. It is easy to see that

$$\rho=\mathscr{A}^{-1}\circ\mathscr{B}.$$

Also recall (from Appendix B) the notation $\tilde{\alpha}=\alpha\circ\mathscr{A}^{-1}$, $\tilde{\beta}=\beta\circ\mathscr{B}^{-1}$, $\tilde{\phi}=\phi\circ\mathscr{A}^{-1}$ etc. Thus (4.19) becomes

$$\psi(y,\lambda)=\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(y))}{\beta(y)}\right]^{1/4}\phi(\rho(y);\lambda)+\int_{0}^{y}K(y,t)\phi(\rho(t);\lambda)\,dt$$

where

$$K(y,t)=\frac{\tilde{K}(\mathscr{B}(y),\mathscr{B}(t))}{\sqrt{\beta(t)}}. \qquad \text{Q.E.D.}$$

Proof of Theorem 2. Let $\phi(x;\lambda)$ be the solution of

$$\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right)+\lambda y=0, \quad y(0)=1, \quad y'(0)=h, \tag{4.20}$$

and $\psi(x;\lambda)$ the solution of

$$\frac{d}{dx}\left(\beta(x)\frac{dy}{dx}\right)+\lambda y=0, \quad y(0)=1, \quad y'(0)=\hat{h}. \tag{4.21}$$

Clearly,

$$y_n(x)=y_n(0)\phi(x;\lambda_n), \quad z_n(x)=z_n(0)\psi(x;\lambda_n) \quad \forall n\in\mathbb{N}.$$

From Lemma 6 we have

$$\psi(x;\lambda)=\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\phi(\rho(x);\lambda)+\int_{0}^{x}K(x,t)\phi(\rho(t);\lambda)\,dt. \tag{4.22}$$

Hence,

$$\frac{z_n(x)}{z_n(0)}=\frac{[\beta(0)/\alpha(0)]^{1/4}[\alpha(\rho(x))/\beta(x)]^{1/4}y_n(\rho(x))+\int_{0}^{x}K(x,t)y_n(\rho(t))\,dt}{y_n(0)}. \tag{4.23}$$

Now define the operator $U: L^2(0, l) \to L^2(0, l)$ by

$$U(f) = \left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} f(\rho(x)) + \int_0^x K(x, t) f(\rho(t))\, dt. \tag{4.24}$$

Since every $f \in L^2(0, l)$ can be expanded as

$$f(x) = \sum_{n=1}^{\infty} f_n y_n(x)$$

where

$$f_n = \int_0^l f(x) y_n(x)\, dx,$$

we have

$$\begin{aligned}(Uf)(x) &= \left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} f(\rho(x)) + \int_0^x K(x, t) f(\rho(t))\, dt \\ &= \left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} \sum_{n=1}^{\infty} f_n y_n(\rho(x)) + \int_0^x K(x, t) \sum_{n=1}^{\infty} f_n y_n(\rho(t))\, dt \\ &= \sum_{n=1}^{\infty} f_n \left\{\left[\frac{\beta(0)}{\alpha(0)}\right]^{1/4}\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} y_n(\rho(x)) + \int_0^x K(x, t) y_n(\rho(t))\, dt\right\}\end{aligned}$$

and taking into account (4.23),

$$(Uf)(x) = \sum_{n=1}^{\infty} f_n \frac{y_n(0)}{z_n(0)} z_n(x).$$

Thus, from Parseval's theorem we obtain

$$\|Uf\|_{L^2}^2 = \sum_{n=1}^{\infty} f_n^2 \left|\frac{y_n(0)}{z_n(0)}\right|^2$$

and since $|y_n(0)| = |z_n(0)|\ \forall n \in \mathbb{N}$ (by (4.6)),

$$\|Uf\|_{L^2}^2 = \sum_{n=1}^{\infty} f_n^2 = \|f\|_{L^2}^2,$$

which means that U is unitary. But from Lemma 5, this implies $[\beta(0)/\alpha(0)]^{1/4} = 1$ and $K(x, t) = 0$. So

$$\alpha(0) = \beta(0), \tag{4.25}$$

$$\psi(x; \lambda) = \left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4} \phi(\rho(x); \lambda). \tag{4.26}$$

Now, due to (4.26), we have

$$\begin{aligned}\frac{d}{dx}\left(\beta(x)\frac{d\psi}{dx}\right) + \lambda\psi = [\alpha(\rho(x))]^{1/4}[\beta(x)]^{3/4}\frac{d^2\phi(\rho(x); \lambda)}{dx^2} \\ + \frac{1}{2}\left\{\left[\frac{\beta(x)}{\alpha(\rho(x))}\right]^{3/4}\frac{d}{dx}[\alpha(\rho(x))]\right. \\ \left. + \left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\beta'(x)\right\}\frac{d\phi(\rho(x); \lambda)}{dx}\end{aligned}$$

$$+\left\{\frac{d}{dx}\left(\beta(x)\frac{d}{dx}\left(\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\right)\right)\right\}\phi(\rho(x);\lambda)$$

$$+\lambda\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\phi(\rho(x);\lambda)$$

$$=\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\left\{\frac{d}{d\rho(x)}\left(\alpha(\rho(x))\frac{d\phi(\rho(x);\lambda)}{d\rho(x)}\right)+\lambda\phi(\rho(x);\lambda)\right\}$$

$$+\left\{\frac{d}{dx}\left(\beta(x)\frac{d}{dx}\left(\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\right)\right)\right\}\phi(\rho(x);\lambda).$$

Since $\phi(x;\lambda)$ and $\psi(x;\lambda)$ are solutions of (4.20) and (4.21) respectively, it follows that

$$\frac{d}{dx}\left(\beta(x)\frac{d}{dx}\left(\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}\right)\right)=0.$$

Integrating and taking into account (4.25) we find

$$\left[\frac{\alpha(\rho(x))}{\beta(x)}\right]^{1/4}=1+c\int_0^x\frac{d\xi}{\beta(\xi)};$$

hence

$$\rho(x)=\int_0^x\left(1+c\int_0^\xi\frac{d\xi'}{\beta(\xi')}\right)^2 d\xi.$$

Finally, since $\rho(l)=l$ and $\int_0^x(d\xi/\beta(\xi))$ is a strictly increasing positive function, it easily follows that $c=0$. So $\rho(x)=x$, hence $\alpha(x)=\beta(x)$, hence $\psi(x;\lambda)=\phi(x;\lambda)$, hence $h=\hat{h}$ and $H=\hat{H}$. This completes the proof.

5. Identifiability and nonidentifiability results. Using Theorem 2 we can now solve completely Problems 1 and 2, which were posed in § 3. Also we can solve a special case of Problem 3, namely that for which $x_p=l/2$.

RESULT 1. *Consider Problem* 1. *To a known input* $Q(t)$, *a known initial state* u_0 *and a given measurement,* $z_d(t)=u(0,t)$, $t\in]0,T]$ *there corresponds a unique* $\alpha(x)$.

Proof. Immediate consequence of Theorem 2.

The next result will establish the fact that Problem 2 has in general a nonunique solution. We first establish the following lemma:

LEMMA 7. *Consider* (3.4) *with eigenvalues* λ_n *and normalized eigenfunctions* $y_n(x)$. *Also consider*

$$\frac{d}{dx}\left(\alpha(l-x)\frac{dy}{dx}\right)+\lambda y=0,\quad y'(0)=0,\quad y'(l)=0, \tag{5.1}$$

with eigenvalues $\bar{\lambda}_n$ *and normalized eigenfunctions* $\bar{y}_n(x)$. *Then*

$$\bar{\lambda}_n=\lambda_n,\qquad \bar{y}_n(x)=y_n(l-x)\quad \forall n\in\mathbb{N}. \tag{5.2}$$

Proof. Under the affine transformation

$$\bar{x}=l-x$$

(5.1) reduces to (3.4). Equation (5.2) follows immediately.

RESULT 2. *If* $u(x, t)$ *is the solution of* (3.1) *and* $\bar{u}(x, t)$ *is the solution of*

$$
\begin{aligned}
&\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\left(\alpha(l-x)\frac{\partial u}{\partial x}\right) \quad \text{in }]0, l[\times]0, T],\\
&u(x, 0)=u_0 \quad \text{in }]0, l[,\\
&\alpha(0)\frac{\partial u}{\partial x}(0, t)=Q(t) \quad \text{in }]0, T],\\
&\frac{\partial u}{\partial x}(l, t)=0 \quad \text{in }]0, T],
\end{aligned}
\tag{5.3}
$$

then

$$
\bar{u}(l, t)=u(l, t). \tag{5.4}
$$

Proof. We have

$$
u(l, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} y_n(0)y_n(l)\, e^{-\lambda_n(t-\tau)}\right\}Q(\tau)\, d\tau,
$$

$$
\bar{u}(l, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} \bar{y}_n(0)\bar{y}_n(l)\, e^{-\bar{\lambda}_n(t-\tau)}\right\}Q(\tau)\, d\tau.
$$

Using Lemma 7, we immediately conclude that

$$
\lambda_n=\bar{\lambda}_n, \quad y_n(0)y_n(l)=\bar{y}_n(0)\bar{y}_n(l) \quad \forall n\in\mathbb{N}.
$$

Hence the result.

LEMMA 8. *Consider again* (3.4). *If* $\alpha(x)$ *is symmetric, i.e.* $\alpha(x)=\alpha(l-x)$, *then*

$$
y_n(x)=y_n(l-x). \tag{5.5}
$$

Proof. Immediate consequence of Lemma 7.

RESULT 3. *Consider again* (3.1) *and assume that* $\alpha(x)$ *is symmetric. Then to a known* $Q(t)$, *a known* u_0 *and a given measurement*

$$
z_d(t)=u(l, t)
$$

there corresponds a unique $\alpha(x)$.

Proof. We have

$$
u(l, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} y_n(0)y_n(l)\, e^{-\lambda_n(t-\tau)}\right\}Q(\tau)\, d\tau.
$$

From (5.5) we have $y_n(0)=y_n(l)$, hence

$$
z_d(t)=u(l, t)=u_0-\int_0^t\left\{\sum_{n=1}^{\infty} |y_n(0)|^2\, e^{-\lambda_n(t-\tau)}\right\}Q(\tau)\, d\tau.
$$

Thus the problem of identifying $\alpha(x)$ from $Q(t)$, u_0 and $z_d(t)$ reduces to the one of identifying $\alpha(x)$ from $\{\lambda_n\}$ and $\{|y_n(0)|\}$. Hence by Theorem 2 $\alpha(x)$ is unique.

The next two results solve the special case $x_p=l/2$ for Problem 3.

RESULT 4. *If $u(x, t)$ is the solution of* (3.2) *for $x_p = l/2$ and $\bar{u}(x, t)$ is the solution of*

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x}\left(\alpha(l-x)\frac{\partial u}{\partial x}\right) + Q(t)\delta\left(x - \frac{l}{2}\right) \quad \text{in }]0, l[\times]0, T],$$

$$u(x, 0) = u_0 \quad \text{in }]0, l[, \tag{5.6}$$

$$\frac{\partial u}{\partial x}(0, t) = \frac{\partial u}{\partial x}(l, t) = 0 \quad \text{in }]0, T],$$

then

$$\bar{u}\left(\frac{l}{2}, t\right) = u\left(\frac{l}{2}, t\right).$$

Proof. We have

$$u\left(\frac{l}{2}, t\right) = u_0 + \int_0^t \left\{\sum_{n=1}^{\infty}\left[y_n\left(\frac{l}{2}\right)\right]^2 e^{-\lambda_n(t-\tau)}\right\} Q(\tau)\, d\tau,$$

$$\bar{u}\left(\frac{l}{2}, t\right) = u_0 + \int_0^t \left\{\sum_{n=1}^{\infty}\left[\bar{y}_n\left(\frac{l}{2}\right)\right]^2 e^{-\lambda_n(t-\tau)}\right\} Q(\tau)\, d\tau.$$

Using Lemma 7, we immediately conclude that

$$y_n\left(\frac{l}{2}\right) = \bar{y}_n\left(\frac{l}{2}\right) \quad \forall n \in \mathbb{N}.$$

Hence the result.

RESULT 5. *Consider again* (3.2) *with $x_p = l/2$ and assume that $\alpha(x)$ is symmetric. Then to a known $Q(t)$, a known u_0 and a given measurement*

$$z_d(t) = u\left(\frac{l}{2}, t\right)$$

there corresponds a unique $\alpha(x)$.

Proof. Since $\alpha(x)$ is symmetric, $y_n(x)$ are symmetric $\forall n \in \mathbb{N}$ by Lemma 8. Hence,

$$y_n'\left(\frac{l}{2}\right) = 0 \quad \forall n \in \mathbb{N}.$$

Now consider the Sturm–Liouville problem

$$\frac{d}{dx}\left(\alpha(x)\frac{dy}{dx}\right) + \lambda y = 0, \quad y'(0) = 0, \quad y'\left(\frac{l}{2}\right) = 0, \tag{5.7}$$

and observe that (3.4) and (5.7) have the same eigenvalues λ_n and the same normalized eigenfunctions $y_n(x)$, $x \in [0, l/2]$. Thus the problem of identifying $\alpha(x)$ from $Q(t)$, u_0 and $z_d(t)$ reduces to the one of identifying $\alpha(x)$ in (5.7) from $\{\lambda_n\}$ and $\{|y_n(l/2)|\}$. Hence by Theorem 2 $\alpha(x)$ is unique.

6. Conclusions and significance. In this paper the problem of identifiability of spatially varying conductivity from point measurement of temperature in the linear, one-dimensional heat equation is addressed. Uniqueness and nonuniqueness results are derived referring to special cases of the above general problem. More specifically, in Problem 1 (system (3.1)) we have shown that in a rod, which is insulated at one

end and heated at the other end (with known heat flux), measurement of the temperature as a function of time at the heated end determines uniquely the conductivity as a function of position. Uniqueness is not obtained, however, when in the above physical system the measurement is placed at the insulated end (Problem 2). In Problem 3 (system (3.2)) we have addressed the case of a rod, which is insulated at both ends, with a known heat source at the point $x = x_p$ and a temperature measurement as a function of time at x_p. We have shown that in the special case where both the heat source and the sensor are placed in the middle of the rod ($x_p = l/2$), there corresponds in general a nonunique conductivity. Only in the highly exceptional case where the conductivity is a symmetric function (with respect to the middle of the rod) Problems 2 and 3 can have a unique solution.

There are still important questions that remain unanswered, such as: (i) Is the system described by (3.1) identifiable if $0 < x_p < l$? In other words, is uniqueness the "rule" or the "exception"? (ii) In the system described by (3.2), is the point $x_p = l/2$ an "exceptional" or a "typical" point? What happens for other x_p's?

The above questions reduce to inverse Sturm-Liouville problems for which, at the moment, results are not available. However, we intuitively expect that uniqueness will be the case for all x_p's, except for a set of measure zero.

The motivation of undertaking this work is to establish identifiability conditions for (1.1). Since, for example, (1.1) governs the pressure distribution in petroleum reservoirs and subsurface aquifers, and since the identification of $\alpha(x, y)$ is a key problem in describing these systems, elucidation of the fundamental question of identifiability will have a significant impact on the estimation of such parameters. It should be pointed out, however, that we are far from being able to make the extension from one to two spatial dimensions. Although the work of Nakagiri [17] has established that the identification of eigenvalues from point observation is possible for n-dimensional parabolic systems, the existing inverse Sturm-Liouville theories are still one-dimensional.

Appendix A. Proof of (4.7). We will first prove (4.7) for $n = 1$. We have

$$|(Vf)(x)|^2 = \left| \int_0^x K(x, t) f(\rho(t))\, dt \right|^2$$

$$= \left| \int_0^x \left[\frac{\beta(t)}{\alpha(\rho(t))} \right]^{1/4} K(x, t) \left[\frac{\alpha(\rho(t))}{\beta(t)} \right]^{1/4} f(\rho(t))\, dt \right|^2$$

$$\leqq \left(\int_0^x \left[\frac{\beta(t)}{\alpha(\rho(t))} \right]^{1/2} [K(x, t)]^2\, dt \right) \left(\int_0^x \left[\frac{\alpha(\rho(t))}{\beta(t)} \right]^{1/2} [f(\rho(t))]^2\, dt \right)$$

$$\text{First integral} \leqq \int_0^x \gamma M\, dt = \gamma M x$$

$$\text{Second integral} = \int_0^{\rho(x)} f^2(\zeta)\, d\zeta \leqq \int_0^l f^2(\zeta)\, d\zeta = \|f\|_{L^2}^2$$

and thus $|(Vf)(x)|^2 \leqq \gamma M \|f\|_{L^2}^2 x$.

Suppose now that (4.7) is true for $n = k$, i.e.

$$|(V^k f)(x)|^2 \leqq \frac{\gamma \Gamma^{(k-1)^2} M^k}{2^{k-1}(k-1)!} \|f\|_{L^2}^2 x^{2k-1}.$$

We have

$$|(V^{k+1}f)(x)|^2 = \left|\int_0^x K(x,t)(V^k f)(\rho(t))\right|^2 \leqq \left(\int_0^x [K(x,t)]^2\,dt\right)\left(\int_0^x [(V^k f)(\rho(t))]^2\,dt\right)$$

$$\text{First integral} \leqq \int_0^x M\,dt = Mx$$

$$\text{Second integral} \leqq \frac{\gamma\Gamma^{(k-1)^2}M^k}{2^{k-1}(k-1)!}\|f\|_{L^2}^2\int_0^x [\rho(t)]^{2k-1}\,dt$$

$$\leqq \frac{\gamma\Gamma^{(k-1)^2}M^k}{2^{k-1}(k-1)!}\|f\|_{L^2}^2\Gamma^{2k-1}\int_0^x t^{2k-1}\,dt$$

$$= \frac{\gamma\Gamma^{k^2}M^k}{2^{k-1}(k-1)!}\|f\|_{L^2}^2\frac{x^{2k}}{2k} = \frac{\gamma\Gamma^{k^2}M^k}{2^k k!}\|f\|_{L^2}^2 x^{2k}.$$

Hence

$$|(V^{k+1}f)(x)|^2 \leqq \frac{\gamma\Gamma^{k^2}M^{k+1}}{2^k k!}\|f\|_{L^2}^2 x^{2k+1}.$$

So (4.7) is also true for $n = k+1$. This completes the proof.

Appendix B. Solution of the Cauchy problem for $(\alpha u_x)_x - (\beta u_y)_y = 0$ by Riemann's method. Consider

$$\frac{\partial}{\partial x}\left(\alpha(x)\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(\beta(y)\frac{\partial u}{\partial y}\right) = 0,$$

(B.1)
$$u|_{y=0} = f(x),$$

$$\left.\frac{\partial u}{\partial y}\right|_{y=0} = g(x).$$

By making the change of variable

(B.2)
$$X = \int_0^x \frac{dx'}{\sqrt{\alpha(x')}} = \mathscr{A}(x), \qquad Y = \int_0^y \frac{dy'}{\sqrt{\beta(y')}} = \mathscr{B}(y),$$

(B.1) becomes

$$\frac{\partial^2\tilde{u}}{\partial X^2} - \frac{\partial^2\tilde{u}}{\partial Y^2} + 2\tilde{a}(X)\frac{\partial\tilde{u}}{\partial X} + 2\tilde{b}(Y)\frac{\partial\tilde{u}}{\partial Y} = 0,$$

(B.3)
$$\tilde{u}|_{Y=0} = \tilde{f}(X),$$

$$\left.\frac{\partial\tilde{u}}{\partial Y}\right|_{Y=0} = \sqrt{\beta(0)}\tilde{g}(X),$$

where

(B.4)
$$a(x) = \frac{d\alpha(x)/dx}{4\sqrt{\alpha(x)}}, \qquad b(y) = -\frac{d\beta(y)/dy}{4\sqrt{\beta(y)}}$$

and where we have used the symbols $\tilde{u}(X, Y)$, $\tilde{a}(X)$, $\tilde{b}(Y)$, $\tilde{f}(X)$, $\tilde{g}(X)$ in place of $u(\mathscr{A}^{-1}(X), \mathscr{B}^{-1}(Y))$, $a(\mathscr{A}^{-1}(X))$, $b(\mathscr{B}^{-1}(Y))$, $f(\mathscr{A}^{-1}(X))$, $g(\mathscr{A}^{-1}(X))$ respectively.

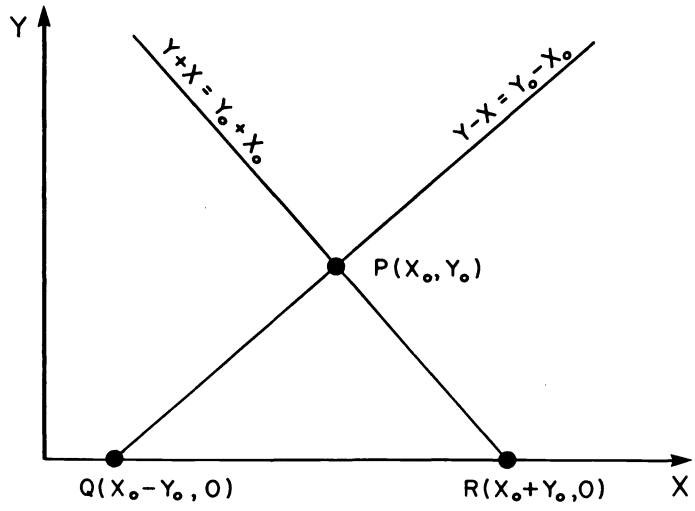

FIG. 1

For the solution of (B.3) we make use of Riemann's formula [6, p. 81] (see Fig. 1),

$$\tilde{u}(P)=\frac{1}{2}[\tilde{u}(Q)\tilde{v}(Q)+\tilde{u}(R)\tilde{v}(R)]+\frac{1}{2}\int_{QR}\left(\tilde{v}\frac{\partial\tilde{u}}{\partial Y}-\tilde{u}\frac{\partial\tilde{v}}{\partial Y}-2\tilde{b}\tilde{u}\tilde{v}\right)dX$$

(B.5)

$$+\left(\tilde{v}\frac{\partial\tilde{u}}{\partial X}-\tilde{u}\frac{\partial\tilde{v}}{\partial X}+2\tilde{a}\tilde{u}\tilde{v}\right)dY$$

where $\tilde{v}(X, Y; X_0, Y_0)$ is the solution of

$$\frac{\partial^2\tilde{v}}{\partial X^2}-\frac{\partial^2\tilde{v}}{\partial Y^2}-2\tilde{a}(X)\frac{\partial\tilde{u}}{\partial X}-2\tilde{b}(Y)\frac{\partial\tilde{v}}{\partial Y}-\left(\frac{d\tilde{a}}{dX}+\frac{d\tilde{b}}{dY}\right)\tilde{v}=0,$$

(B.6)

$$\frac{\partial\tilde{v}}{\partial X}-\frac{\partial\tilde{v}}{\partial Y}=(\tilde{a}+\tilde{b})\tilde{v} \quad \text{on } Y+X=Y_0+X_0,$$

$$\frac{\partial\tilde{v}}{\partial X}+\frac{\partial\tilde{v}}{\partial Y}=(\tilde{a}-\tilde{b})\tilde{v} \quad \text{on } Y-X=Y_0-X_0,$$

$$\tilde{v}(X_0, Y_0)=1.$$

It can be easily seen that the boundary conditions in (B.6) are equivalent to

$$\text{(B.7)}\quad \tilde{v}=\exp\left[\int_{X_0}^{X}\tilde{a}(X')\,dX'-\int_{Y_0}^{Y}\tilde{b}(Y')\,dY'\right] \quad \text{on the lines}\begin{cases} Y+X=Y_0+X_0 \\ Y-X=Y_0-X_0 \end{cases}$$

Thus (B.5) gives

$$\tilde{u}(X_0, Y_0)=\frac{1}{2}\exp\left[\int_0^{Y_0}\tilde{b}(Y')\,dY'\right]$$

$$\cdot\left\{\tilde{f}(X_0-Y_0)\exp\left[\int_{X_0}^{X_0-Y_0}\tilde{a}(X')\,dX'\right]\right.$$

(B.8)

$$\left.+\tilde{f}(X_0+Y_0)\exp\left[\int_{X_0}^{X_0+Y_0}\tilde{a}(X')\,dX'\right]\right\}$$

$$+\frac{1}{2}\int_{X_0-Y_0}^{X_0+Y_0}W_1(X_0, Y_0, t)\tilde{f}(t)\,dt+\frac{1}{2}\int_{X_0-Y_0}^{X_0+Y_0}W_2(X_0, Y_0, t)\tilde{g}(t)\,dt$$

where

$$W_1(X_0, Y_0, t) = -\frac{\partial \tilde{\nu}}{\partial Y}(t, 0; X_0, Y_0) - 2b(0)\tilde{\nu}(t, 0; X_0, Y_0),$$

$$W_2(X_0, Y_0, t) = \sqrt{\beta(0)}\,\tilde{\nu}(t, 0; X_0, Y_0).$$

Finally, taking into account (B.4), the integrals of the first term of (B.8) can be easily evaluated. Thus (B.8) (dropping the subscript 0) gives

$$\tilde{u}(X, Y) = \frac{1}{2}\left[\frac{\beta(0)}{\tilde{\beta}(Y)\tilde{\alpha}(X)}\right]^{1/4}\{[\tilde{\alpha}(X-Y)]^{1/4}\tilde{f}(X-Y) + [\tilde{\alpha}(X+Y)]^{1/4}\tilde{f}(X+Y)\}$$
$$+\frac{1}{2}\int_{X-Y}^{X+Y} W_1(X, Y, t)\tilde{f}(t)\,dt + \frac{1}{2}\int_{X-Y}^{X+Y} W_2(X, Y, t)\tilde{g}(t)\,dt \tag{B.9}$$

where $\tilde{\alpha}(\cdot) = \alpha(\mathscr{A}^{-1}(\cdot))$ and $\tilde{\beta}(\cdot) \equiv \beta(\mathscr{B}^{-1}(\cdot))$.

HYPERBOLIC STATE SPACE DECOMPOSITION FOR A LINEAR STOCHASTIC DELAY EQUATION*

S. MOHAMMED†, M. SCHEUTZOW‡ AND H. v. WEIZSÄCKER‡

Abstract. We consider the equation $dX(t)=(\int_{-r}^{0}X(s+t)\,d\mu(s))\,dt+G\,dW(t)$ where $r>0$, μ is a matrix-valued signed measure on $[-r,0]$, W is an n-dimensional Wiener process and G is a fixed $n\times n$ matrix. Using the known decomposition $C=S\oplus U$ of $C=C[-r,0]$ into a stable closed subspace S and a finite dimensional unstable subspace U for the analogous deterministic equation, we prove that the projection of the solution X onto S converges exponentially fast to a stationary Gaussian process. Also the speed of explosion of the projection onto U is exhibited.

Key words. asymptotic stationarity, infinite dimensional diffusion, stochastic functional DE, hyperbolic decomposition, stochastic variation of constants

AMS(MOS) subject classifications. Primary 60H10; secondary 34K20, 60G10, 93E03

1. Introduction. Let F be an $\mathbb{R}^n$-valued continuous linear map on the Banach space $C=C([-r,0],\mathbb{R}^n)$ of continuous functions from $[-r,0]$ to $\mathbb{R}^n$ $(r>0)$. For any $t\geqq 0$ and any continuous function $x:[-r,+\infty)\to\mathbb{R}^n$ we define $x_t\in C$ by $x_t(u)=x(t+u)$, $u\in[-r,0]$. Let $(f(t))_{t\geqq 0}$ be an $\mathbb{R}^n$-valued, locally (in t) integrable function.

Deterministic functional differential equations of the form

$$\begin{aligned} &x'(t)=F(x_t)+f(t), \qquad t\geqq 0,\\ &x_0=\eta \end{aligned} \tag{1}$$

with a "hyperbolic" linear functional $F:C\to\mathbb{R}^n$ have frequently been studied. It is known [3, p. 187] that there exists a decomposition $C=U\oplus S$ where U is a finite dimensional linear subspace, such that the projection x_t^U of x_t on U behaves like an unstable finite system of ordinary differential equations and x_t^S converges to 0 as $t\to\infty$ for any initial condition. This decomposition is uniquely determined by the functional F.

In this paper we establish an analogous result if f is replaced by "white noise", i.e., we consider the equation

$$\begin{aligned} &dX(t)=F(X_t)\,dt+G\,dW(t),\\ &X_0=\eta \end{aligned} \tag{2}$$

where $(W(t))_{t\geqq 0}$ is an n-dimensional Wiener process and G is a fixed element of the space $L(\mathbb{R}^n)$ of all $n\times n$ matrices.

Although in general no solution of (2) converges to a stationary process, we show that the projection X_t^S of the solution X_t of (2) on the space S associated with (1) does so. The complementary projection X_t^U is a solution of a purely unstable finite system of stochastic differential equations without delay; in particular on every non-degenerated subspace V of U the variance of the induced probability distribution converges to infinity exponentially.

Our aim was to show how in a specific infinite dimensional situation a stochastic hyperbolic decomposition makes sense. The result could be extended to more general

situations like time dependent G with appropriate regularity conditions. A more interesting challenge is the formulation of some general principles about infinite dimensional linear stochastic equations from which our results could be derived.

2. The variation of constants. First we want to write down a stochastic variation-of-constants formula of the solution of (2) which looks the same as for equation (1) (cf. [3, pp. 80–87] and Theorems 1 and 2a below). In this section $F: C \to \mathbb{R}^n$ is any continuous linear functional. The assumption of hyperbolicity will appear only in Theorem 4.

LEMMA 1. *Let μ be a finite signed measure on $[a, b]$. Let $\varphi: [a, b] \times [c, d] \to \mathbb{R}$ be in $L_2([a, b] \times [c, d], \lambda \otimes |\mu|)$. Then for every 1-dimensional Brownian motion W*

$$\int_c^d \int_a^b \varphi(s, u)\, dW(s)\, d\mu(u) = \int_a^b \int_c^d \varphi(s, u)\, d\mu(u)\, dW(s) \quad a.s.$$

Proof. If $\varphi = 1_{]\alpha, \beta] \times]\gamma, \delta]}$ then this is the obvious equality

$$\int_\gamma^\delta W(\beta) - W(\alpha)\, d\mu = (W(\beta) - W(\alpha))(\mu]\gamma, \delta]).$$

Both sides of the equation to be proved are linear and are easily seen to be continuous on $L^2([a, b] \times [c, d], \lambda \otimes |\mu|)$. The step functions with rectangular steps being dense in this space, the lemma follows. □

Let $\tilde{C}$ (resp. $\bar{C}$) be the Banach space of all bounded Borel measurable $\mathbb{R}^n$ (resp. $\mathbb{R}^{n \times n}$-) valued functions on $[-r, 0]$ given the sup norm.

For $D \in \bar{C}$ and a linear operator R on $\tilde{C}$ define $RD := (Rd_1, \cdots, Rd_n)$ where d_j is the jth column of D. Define $\bar{\tilde{C}}$ as the set of all functions $B: [a, b] \to \bar{C}$ such that $B(\cdot)(\cdot)$ is a product measurable $\mathbb{R}^{n \times n}$-valued bounded function. For $B \in \bar{\tilde{C}}$ and an n-dimensional Brownian motion we define Wiener integrals of the form $\int_a^b B(s)\, dW(s)$ by

$$\left(\int_a^b B(s)\, dW(s)\right)(u) = \int_a^b B(s)(u)\, dW(s) = \sum_{j=1}^n \int_a^b (B(s)(u))_j\, dW_j(s)$$

$$= \sum_{j=1}^n \int_a^b (b_j(s))(u)\, dW_j(s), \qquad u \in [-r, 0].$$

LEMMA 2. *Let $L: C \to \mathbb{R}^n$ be continuous, linear and $B \in \bar{\tilde{C}}$. Then*

$$\tilde{L}\left(\int_a^b B(s)\, dW(s)\right) = \int_a^b \tilde{L}(B(s))\, dW(s) = \sum_{j=1}^n \int_a^b \tilde{L}(b_j(s))\, dW_j(s) \quad a.e.$$

where $\tilde{L}$ is the canonical extension of L to $\tilde{C}$ using the Riesz representation theorem.

Proof. Follows from Lemma 1. □

For every initial condition $\eta \in \tilde{C}$ there is a unique solution of

$$x'(t) = \tilde{F}(x_t), \qquad x_0 = \eta \tag{3}$$

where $\tilde{F}$ is the canonical extension of F to the space $\tilde{C}$. This can be seen by a straightforward extension of the usual contraction argument. The resulting semigroup $(T(t), t \geqq 0)$ of linear operators on $\tilde{C}$ where $T(t)\eta = x_t$ as in (3), however, is not strongly continuous in contrast to the analogous semigroup on C.

Let $\Delta: [-r, 0] \to L(\mathbb{R}^n)$ be defined by

$$\Delta(u) = 0, \qquad u \in [-r, 0[,$$

$$\Delta(0) = I \qquad (I = \text{identity matrix on } \mathbb{R}^n).$$

THEOREM 1. (variation-of-constant formula). *The solution of* (2) *can be written in the form* $X_t = T(t)\eta + \int_0^t T(t-s)\Delta G\, dW(s)$.

Proof. Define $Y_t = T(t)\eta + \int_0^t T(t-s)\Delta G\, dW(s)$, $t \geqq 0$. For $u \geqq -t$, $u \in [-r, 0]$ we get

$$Y_t(u) = (T(t)\eta)(u) + \int_0^t (T(t-s)\Delta G)(u)\, dW(s)$$

$$= (T(t+u)\eta)(0) + \int_0^{t+u} (T(t+u-s)\Delta G)(0)\, dW(s) = Y_{t+u}(0)$$

as $T(t-s)\Delta G(u) = (T(t+u-s)\Delta G)(0)$ for $0 \leqq s \leqq t+u$ and $(T(t-s)\Delta G)(u) = 0$ for $t+u < s \leqq t$. Also $Y_t(u) = \eta(t+u) = Y_0(t+u)$ if $-r \leqq t+u < 0$. Therefore Y_t corresponds to a stochastic process on $[-r, \infty[$,

$$Y(t) = Y_t(0) = (T(t)\eta)(0) + \int_0^t (T(t-s)\Delta G)(0)\, dW(s)$$

$$= (T(t)\eta)(0) + \sum_{j=1}^n \int_0^t (T(t-s)(\Delta G)_j)(0)\, dW_j(s).$$

Lemma 1 implies the general identity

$$\int_0^t f(t-s)\, dW(s) - \int_0^t f(0)\, dW(s) = \int_0^t \int_s^t \frac{\partial}{\partial u} f(u-s)\, du\, dW(s)$$

$$= \int_0^t \int_0^u \frac{\partial}{\partial u} f(u-s)\, dW(s)\, du.$$

Hence

$$dY(t) = F(T(t)\eta)\, dt + \sum_{j=1}^n \left((\Delta G)_j(0)\, dW_j(t) + \int_0^t \frac{\partial T(t-s)(\Delta G)_j(0)}{\partial t}\, dW_j(s) \right) dt$$

$$= F(T(t)\eta)\, dt + G\, dW(t) + \sum_{j=1}^n \left(\int_0^t F(T(t-s)(\Delta G)_j)\, dW_j(s) \right) dt$$

$$= F\left(T(t)\eta + \int_0^t T(t-s)\Delta G\, dW(s) \right) dt + G\, dW(t) = F(Y_t)\, dt + G\, dW(t)$$

i.e., $Y(t)$ satisfies (2) which proves the assertion as (2) has a unique solution. □

Let A be the unbounded operator on $\tilde{C}$ defined by $D(A) = \{\phi : \phi \in C^1[-r, 0]$ and $\phi'(0) = F(\phi)\}$ and

$$(A\phi)(u) = \begin{cases} \dfrac{d\phi}{du}(u), & -r \leqq u < 0, \\ F(\phi) = \displaystyle\int_{-r}^0 \phi(s)\, d\mu(s), & u = 0, \end{cases}$$

where we have represented F by a matrix-valued signed measure (or function of bounded variation in each component) μ on $[-r, 0]$ (see [3, p. 167]).

We now define U to be the sum of the generalized eigenspaces of the eigenvalues of A with nonnegative real part. The set of eigenvalues of A coincides with the solutions of the characteristic equation $\det(\lambda I - \int_{-r}^0 e^{\lambda u}\, d\mu(u)) = 0$ [3, p. 168]. One can choose a closed complementary subspace S such that $T(t)(S) \subseteq S$ for all $t \geqq 0$. U is finite-dimensional with $T(t)U \subseteq U$ for all t [3, p. 171].

The projection π^U of C onto U corresponding to the decomposition $C = U \oplus S$ is a continuous linear map since S is closed. Thus, U being finite dimensional, it has a representation by a $L(\mathbb{R}^n, U)$-valued, signed measure (or function of bounded variation) ρ^U. This induces a canonical extension of π^U to a continuous linear functional π^U on $\tilde{C}$ by the formula $\pi^U(\phi) = \int_{-r}^{0} \phi \, d\rho^U$, $\phi \in \tilde{C}$. Then $\tilde{C} = U \oplus \tilde{S}$ where $\tilde{S} = \{\phi : \pi^U(\phi) = 0\}$. The associated projection onto $\tilde{S}$ is given by the formula $\pi^{\tilde{S}}(\phi) = \phi - \pi^U(\phi)$, or shortly: $\pi^{\tilde{S}} = 1 - \pi^U$ where 1 is the identity on $\tilde{C}$. We write η^U and $\eta^{\tilde{S}}$ instead of $\pi^U \eta$ and $\pi^{\tilde{S}} \eta$ respectively.

LEMMA 3. *$(T(t)\eta)^U = T(t)(\eta^U)$ and $(T(t)\eta)^{\tilde{S}} = T(t)(\eta^{\tilde{S}})$ holds for every $\eta \in \tilde{C}$.*

Proof. For $\eta \in C$ this follows immediately from the invariance of U and S under $T(t)$; e.g.,

$$(T(t)\eta)^U = (T(t)\eta^U + T(t)\eta^S)^U = (T(t)\eta^U)^U + (T(t)\eta^S)^U = T(t)\eta^U + 0.$$

Let us consider the following continuity property of linear operators $R : \tilde{C} \to \tilde{C}$:

(**) If η^k is a uniformly bounded sequence in $\tilde{C}$ such that $\eta^k(u) \to 0$ for all $u \in [-r, 0]$, then $R\eta^k(u) \to 0$ for all $u \in [-r, 0]$.

From the uniqueness part in the Riesz representation theorem for every continuous linear $R : C \to U$ there is exactly one extension $R : \tilde{C} \to U$ with (**). Hence for the first part of the lemma it is sufficient to show that $\pi^U \circ T(t)$ and $T(t) \circ \pi^U$ both have (**) (we have seen already that they coincide on C). From the definition of $\pi^U : \tilde{C} \to U$, π^U has (**). Thus it remains to prove (**) for $T(t)$. This follows from Lemma 4.

The statement concerning S now follows algebraically:

$$(T(t))\eta^{\tilde{S}} = T(t)\eta + (T(t)\eta)^U = T(t)\eta - T(t)\eta^U = T(t)(\eta - \eta^U) = T(t)\eta^{\tilde{S}}. \qquad \square$$

LEMMA 4. *$T(t)$ has the continuity property (**) for every $t > 0$.*

Proof. Let $|\mu|$ be the variation measure associated with the matrix valued measure μ on $[-r, 0]$ defined by the functional F. Fix η. Define ${}^{\eta}g$ by ${}^{\eta}g(t) := \|T(t)\eta\|_{1,|\mu|} + |(T(t)\eta)(0)|$. We have

$$(T(t)\eta)(u) = \begin{cases} \eta(0) + \int_0^{t+u} F(T(s)\eta)\, ds & \text{for } t \geqq -u, \\ \eta(t+u) & \text{for } t < -u. \end{cases}$$

Thus

$$\begin{aligned}
{}^{\eta}g(t) &= \int_{-r}^{0} |(T(t)\eta)(u)| d|\mu|(u) + |(T(t)\eta)(0)| \\
&= \int_{-r}^{\max(-r,-t)} |\eta(t+u)| d\mu|(u) \\
&\quad + \int_{\max(-r,-t)}^{0} \left| \eta(0) + \int_0^{t+u} F(T(s)\eta)\, ds \right| d|\mu|(u) \\
&\quad + \left| \eta(0) + \int_0^{t} F(T(s)\eta)\, ds \right| \\
&\leqq \int_{-r}^{\max(-t,-r)} |\eta(t+u)| d|\mu|(u) + (\|\mu\|_1 + 1)\left(|\eta(0)| + \int_0^t \|T(s)\eta\|_{1,|\mu|}\, ds \right) \\
&\leqq {}^{\eta}h(t) + C \int_0^t {}^{\eta}g(s)\, ds
\end{aligned}$$

where

$$ {}^{\eta}h(t) = \int_{-r}^{\max(-t,-r)} |\eta(t+u)|d|\mu|(u) + (|||\mu|||_1 + 1)|\eta(0)|, $$

$$ C = |||\mu|||_1 + 1 \quad \text{and} \quad |||\mu|||_1 = |\mu|[-r, 0]. $$

Then Gronwall's lemma [2, p. 393] implies

$$ {}^{\eta}g(t) \leqq {}^{\eta}h(t) + C \int_0^t {}^{\eta}h(s)\, e^{C(t-s)}\, ds. $$

Now suppose (η^k) is a uniformly bounded sequence which converges to 0 pointwise. Then the sequence $({}^{\eta^k}h)$ is also uniformly bounded on bounded intervals and converges to 0 for every t by dominated convergence. The Gronwall estimate then implies again by dominated convergence ${}^{\eta^k}g(t) \to 0$ for all t. In particular $|(T(t)\eta^k)(0)| \to 0$ for all t. Because of

$$ (T(t)\eta^k)(u) = \begin{cases} \eta^k(t+u), & -r \leqq t+u \leqq 0, \\ (T(t+u)\eta^k)(0), & t+u > 0, \end{cases} $$

we get finally that $(T(t)\eta_k)(u)$ converges for every u to 0. □

As in [3, p. 173] define $C^* = C([0, r], \mathbb{R}^{n^*})$, where $\mathbb{R}^{n^*}$ is the n-dimensional space of row vectors. For α in C^* and ϕ in C define

$$ (\alpha, \phi) = \alpha(0)\phi(0) - \int_{-r}^{0} \int_0^{\theta} \alpha(\xi - \theta)\phi(\xi)\, d\xi\, d\mu(\theta) \tag{4} $$

where μ is the matrix-valued measure representing the functional F. Let A^* be the (formal) adjoint operator of A defined by

$$ A^*\alpha(s) = \begin{cases} -\dfrac{d\alpha(s)}{ds}, & 0 < s \leqq r, \\ \displaystyle\int_{-r}^{0} \alpha(-\theta)\, d\mu(\theta), & s = 0, \end{cases} $$

where $D(A^*)$ consists of all functions α in C^* which have a continuous derivative such that

$$ -\frac{d\alpha(0)}{ds} = \int_{-r}^{0} \alpha(-\theta)\, d\mu(\theta) \qquad ([3, p. 174]). $$

According to [3, p. 175] the spectra of A and A^* consist only of eigenvalues and coincide (including multiplicity).

Let U^* be the sum of the generalized eigenspaces of A^* corresponding to the eigenvalues with nonnegative real part. Suppose dim $U = d$ (=dim U^*). Take a basis $\Phi = (\Phi_1, \cdots, \Phi_d)$ for U and a basis

$$ \Psi = \begin{pmatrix} \Psi_1 \\ \vdots \\ \Psi_d \end{pmatrix} $$

for U^* satisfying $(\Phi_i, \Psi_j) = \delta_{ij}$ $(i, j = 1, \cdots, d)$ and let $B \in L(\mathbb{R}^d)$ satisfy $A\Phi = \Phi B$ and $A^*\Psi = B\Psi$ where $A\Phi = (A\Phi_1, \cdots, A\Phi_d)$, $A^*\Psi = (A\Psi_1, \cdots, A\Psi_d)^T$ and ΦB and $B\Psi$ are defined like matrix multiplication. According to [3, p. 186] such a B exists and is unique and its eigenvalues coincide with those of A (or A^*) having nonnegative real

part (including multiplicity). For any $\phi \in C$ the projection of ϕ on U can be written explicitly as

$$\phi^U = \Phi(\Psi, \phi) \tag{5}$$

([3, p. 186]). Now the right-hand side of the last equation also make sense for $\phi \in \tilde{C}$ by defining the bilinear form (4) as above. Both sides are continuous with respect to pointwise convergence of uniformly bounded sequences. For the left side this was stated before Lemma 3, and for the right side it follows from dominated convergence. As $\tilde{C}$ is the smallest class of functions containing C which is closed under pointwise limits of uniformly bounded sequences, the identity also holds for $\phi \in \tilde{C}$.

THEOREM 2. (a) *The projection of X_t on U and $\tilde{S}$ can be written as*

$$X_t^U = T(t)\eta^U + \int_0^t T(t-s)\Delta^U G\, dW(s),$$

$$X_t^{\tilde{S}} = T(t)\eta^{\tilde{S}} + \int_0^t T(t-s)\Delta^{\tilde{S}}\, G\, dW(s).$$

Furthermore

$$\Delta^U = \Phi(\Psi(0)), \qquad \Delta^{\tilde{S}} = \Delta - \Delta^U$$

and

$$X_t^U = \Phi(Y(t)), \qquad t \geqq 0$$

where $Y(t) = (\Psi, X_t)$ is a continuous process on $\mathbb{R}^d$ satisfying the equation

$$dY(t) = BY(t)\, dt + \Psi(0) G\, dW(t), \qquad Y(0) = (\Psi, \eta).$$

(b) *There exist numbers $\alpha < 0$ and $M > 0$ such that*

$$\| T(t)\eta^{\tilde{S}} \| \leqq M e^{\alpha t} \| \eta^{\tilde{S}} \|$$

and

$$\| T(t)\Delta^{\tilde{S}} \| \leqq M e^{\alpha t}, \qquad t \geqq 0$$

where

$$\| T(t)\Delta^{\tilde{S}} \| := \left(\sum_{j=1}^{n} \| T(t)\delta_j^{\tilde{S}} \|^2 \right)^{1/2}$$

and $\delta_j^{\tilde{S}}$ is the jth column of $\Delta^{\tilde{S}}$.

Proof. (a) The representations of X_t^U and $X_t^{\tilde{S}}$ follow from Lemma 2, Theorem 1 and Lemma 3. The formula $\Delta^U = \Phi(\Psi(0))$ is an application of (5). The representation $X_t^U = \Phi Y(t)$ follows exactly like the proof in the deterministic case in [3, p. 186] with $f(s)\, ds$ replaced by $G\, dW(s)$.

(b) [3, p. 187]. □

3. Asymptotics for X^U and X^S.

THEOREM 3. *Let $W(t)$ be an n-dimensional Wiener process defined for all $t \in \mathbb{R}$, normalized by $W(0) = 0$. Then for every distribution of $X_0 = \eta$ with $E\|\eta\|^2 < \infty$, the process $X_t^{\tilde{S}}$ converges to the stationary continuous Gaussian process $Z_t = \int_{-\infty}^t T(t-s)\Delta^{\tilde{S}}\, G\, dW(s)$ in L^2 with exponential speed. In particular the distribution of $X_t^{\tilde{S}}$ converges weakly to the Gaussian distribution of the stationary process $(Z_t)_{t \geqq 0}$.*

Proof. As in the proof of Theorem 1 one can easily show that $(Z_t)_{t\geqq 0}$ corresponds to a process on $[-r,\infty[$ having values in $\mathbb{R}^n$ where

$$Z(t)=Z_t(0)=\int_{-\infty}^{t}(T(t-s)\Delta^{\tilde{S}}G)(0)\,dW(s),\qquad t\geqq 0,$$
$$Z(t)=Z_0(t),\qquad -r\leqq t\leqq 0.$$

$Z(t)$ is well defined as

$$\begin{aligned}E\|Z(t)\|_2^2&=E\left\|\int_{-\infty}^{t}(T(t-s)\Delta^{\tilde{S}}G)(0)\,dW(s)\right\|_2^2\\&=E\sum_{i=1}^{n}\left(\sum_{j=1}^{n}\int_{-\infty}^{t}(((T(t-s)\Delta^{\tilde{S}}G)(0))_j)_i\,dW_j(s)\right)^2\\&=\sum_{i=1}^{n}\sum_{j=1}^{n}\int_{-\infty}^{t}((((T(t-s)\Delta^{\tilde{S}}G)(0))_j)_i)^2\,ds\\&\leqq m_1\int_{-\infty}^{t}\|(T(t-s)\Delta^{\tilde{S}}G)(0)\|^2\,ds\\&\leqq m_2\|G\|^2\int_{-\infty}^{t}\|T(t-s)\Delta^{\tilde{S}}\|^2\,ds\\&\leqq m_2\|G\|^2M^2\int_{-\infty}^{t}e^{2\alpha(t-s)}\,ds=\frac{-m_2\|G\|^2M^2}{2\alpha}<\infty.\end{aligned}$$

Obviously $Z(t)$, $t\geqq -r$ is Gaussian and has continuous sample paths (almost surely). $Z(t)$ is stationary since

$$Z(t)=\int_{-\infty}^{t}(T(t-s)\Delta^{\tilde{S}}G)(0)\,dW(s)=\int_{0}^{\infty}(T(s)\Delta^{\tilde{S}}G)(0)\,dW(t-s).$$

Now

$$E\|X_t^{\tilde{S}}-Z_t\|_C^2\leqq 2E\|T(t)\eta^{\tilde{S}}\|_C^2+2E\left\|\int_{-\infty}^{0}T(t-s)\Delta^{\tilde{S}}G\,dW(s)\right\|_C^2$$

and

$$E\|T(t)\eta^{\tilde{S}}\|_C^2\leqq E(Me^{\alpha t}\|\eta^{\tilde{S}}\|_C)^2=M^2e^{2\alpha t}E\|\eta^{\tilde{S}}\|_C^2\to 0\quad\text{as } t\to\infty.$$

Also, for $t>2r$, we have

$$\begin{aligned}&E\left\|\int_{-\infty}^{0}T(t-s)\Delta^{\tilde{S}}G\,dW(s)\right\|_C^2\\&\quad=E\sup_{-r\leqq u\leqq 0}\lim_{v\to-\infty}\left\|\int_{v}^{0}\sum_{j=1}^{n}T(t-s)(\Delta^{\tilde{S}}G)_j(u)\,dW_j(s)\right\|^2\\&\quad=E\sup_{-r\leqq u\leqq 0}\lim_{v\to-\infty}\sum_{i=1}^{n}\left(\sum_{j=1}^{n}\int_{v}^{0}(T(t-s)(\Delta^{\tilde{S}}G)_j(u))_i\,dW_j(s)\right)^2\\&\quad=E\sup_{-r\leqq u\leqq 0}\lim_{v\to-\infty}\sum_{i=1}^{n}\left(\sum_{j=1}^{n}(T(t-s)(\Delta^{\tilde{S}}G)_j(u))_iW_j(s)\Big|_{v}^{0}\right.\\&\qquad\left.-\int_{v}^{0}\frac{\partial(T(t-s)(\Delta^{\tilde{S}}G)_j(u))_i}{\partial s}W_j(s)\,ds\right)^2\end{aligned}$$

$$\leqq E \lim_{v\to-\infty} 2n \sum_{k=1}^{n} (W_k(v))^2 \sup_{-r\leqq u\leqq 0} \sum_{j=1}^{n} \sum_{i=1}^{n} (T(t-v)(\Delta^{\tilde{S}}G)_j(u))_i^2$$

$$+E \lim_{v\to-\infty} 2n \sup_{-r\leqq u\leqq 0} \sum_{i=1}^{n} \sum_{j=1}^{n} \left(\int_v^0 F_i(T(t-s+u)(\Delta^{\tilde{S}}G)_j) |W_j(s)|\, ds \right)^2.$$

Now

$$E \lim_{v\to-\infty} 2n \sum_{k=1}^{n} (W_k(v))^2 \sup_{-r\leqq u\leqq 0} \sum_{j=1}^{n} \sum_{i=1}^{n} (T(t-v)(\Delta^{\tilde{S}}G)_j(u))_i^2$$

$$\leqq E \lim_{v\to-\infty} m_3 \sum_{k=1}^{n} (W_k(v))^2 \sup_{-r\leqq u\leqq 0} \|T(t-v)\Delta^{\tilde{S}}G(u)\|^2$$

$$\leqq E \lim_{v\to-\infty} m_3 \sum_{k=1}^{n} (W_k(v))^2 \sup_{-r\leqq u\leqq 0} \|T(t-v)\Delta^{\tilde{S}}(u)\|^2 \|G\|^2$$

$$\leqq E \lim_{v\to-\infty} m_4 \sum_{k=1}^{n} (W_k(v))^2 \|G\|^2 \|T(t-v)\Delta^{\tilde{S}}\|_C^2$$

$$\leqq E \lim_{v\to-\infty} m_4 \sum_{k=1}^{n} (W_k(v))^2 \|G\|^2 M^2 e^{2\alpha(t-v)}$$

where m_3 and m_4 are suitable constants.

The limit is 0 almost surely as

$$\overline{\lim_{v\to-\infty}} \frac{W_k(v)}{\sqrt{2|v|\log\log|v|}} = 1 \quad \text{a.s.}$$

Using the fact that $T(t-s+u)(\Delta^{\tilde{S}}G)_j \in C$ for $t > 2r$, the second limit is estimated as follows:

$$E \lim_{v\to-\infty} 2n \sup_{-r\leqq u\leqq 0} \sum_{i=1}^{n} \sum_{j=1}^{n} \left(\int_v^0 |F_i(T(t-s+u)(\Delta^{\tilde{S}}G)_j)\| W_j(s)|\, ds \right)^2$$

$$\leqq E \lim_{v\to-\infty} (2n)^2 \sup_{-r\leqq u\leqq 0} \sum_{j=1}^{n} \left(\int_v^0 \|F(T(t-s+u)(\Delta^{\tilde{S}}G)_j)\|\, |W_j(s)|\, ds \right)^2$$

$$\leqq E \lim_{v\to-\infty} (2n)^2 \|F\|^2 \sup_{-r\leqq u\leqq 0} \sum_{j=1}^{n} \left(\int_v^0 \|T(t-s+u)(\Delta^{\tilde{S}}G)_j\|\, |W_j(s)|\, ds \right)^2$$

$$\leqq E(2n)^2 \|F\|^2 \|G\|^2 m_5 \lim_{v\to-\infty} \sup_{-r\leqq u\leqq 0} \sum_{j=1}^{n} \left(\int_v^0 \|T(t-s+u)\Delta^{\tilde{S}}\|\, |W_j(s)|\, ds \right)^2$$

$$\leqq E(2n)^2 \|F\|^2 \|G\|^2 m_5 e^{2\alpha t} e^{-2\alpha r} \lim_{v\to-\infty} \sum_{j=1}^{n} \left(\int_v^0 M e^{-\alpha s} |W_j(s)|\, ds \right)^2.$$

The limit is finite almost surely because of the law of the iterated logarithm and its expectation is finite:

$$E\left(\int_{-\infty}^0 e^{-\alpha s} |W_j(s)|\, ds \right)^2 = \int_{-\infty}^0 \int_{-\infty}^0 e^{-\alpha s} e^{-\alpha t} E|W_j(s) W_j(t)|\, ds\, dt$$

$$\leqq -\frac{1}{\alpha} \int_{-\infty}^0 e^{-\alpha s}\, ds < \infty. \qquad \square$$

According to Theorem 2, X_t^U is completely characterized by the finite-dimensional process $Y(t)$. In the next theorem we will describe the growth of $Y(t)$ by looking at its projections on one-dimensional subspaces. Let d be the dimension of the state space of $Y(t)$. Define $C := \psi(0) \cdot G$. Applying the well-known formulas for the mean and covariance of the solution of a linear stochastic differential equation (see e.g. [1, p. 143]),

$$EY(t) = e^{Bt} EY(0) \tag{6}$$

and

$$K(t) = e^{Bt}\left(K(0) + \int_0^t (e^{-Bu}C)(e^{-Bu}C)^T\,du\right)(e^{Bt})^T \tag{7}$$

where $K(t)$ is the covariance matrix of the components of Y, we get

THEOREM 4. *Assume all eigenvalues of B have strictly positive real parts.*

a) *If $EY(0) \neq 0$ then $EY(t)$ grows with exponential speed i.e. there exists some $a > 0$ such that for any $\varepsilon > 0$ there exist positive constants D_1 and D_2 such that*

$$D_1 e^{at} \leqq |EY(t)| \leqq D_2 e^{(a+\varepsilon)t} \quad \text{for all } t \geqq 0.$$

b) *If the "variance of $Y(t)$ in direction z", given by $z^T K(t) z / \|z\|^2$ is strictly positive for some $t_0 > 0$, then it is also strictly positive for all $t \geqq t_0$ and it grows with exponential speed.*

Proof. The proofs follow from (6) and (7) and from the fact that $K(0) + \int_0^t (e^{-Bu}C)(e^{-Bu}C)^T\,du$ is nondecreasing in t in the sense of positive definite matrices. □

Remark. If either $K(0)$ is positive definite or (B, C) is completely controllable i.e. rank $(C, BC, B^2C, \cdots, B^{d-1}C) = d$, then $(z^T K(t) z)/\|z\|^2 > 0$ for all $t > 0$ and for all $z \in \mathbb{R}^d \setminus \{0\}$. The second condition is equivalent to the positive definiteness of the integral in (7) for some (and then for all) $t > 0$ (see [4], p. 39).

The assumption on B means that the operator A has no purely imaginary eigenvalues, i.e., that F is "hyperbola".

Final remark. After submission the essential results of this paper have been incorporated into [6]. Related, but somewhat different questions have been treated in [5] and [7].

OPTIMAL CONTROL WITH STATE-SPACE CONSTRAINT I*

HALİL METE SONER†

Abstract. We investigate the optimal value of a deterministic control problem with state space constraint. We show that the optimal value function is the only viscosity subsolution, on the open domain, and the viscosity supersolution, on the closed domain, of the corresponding Bellman equation. Finally, the uniform continuity of the optimal value function is obtained under an assumption on the vector field.

Key words. optimal control, viscosity solutions, Hamilton-Jacobi-Bellman equations, state-space constraint

AMS(MOS) subject classifications. 93E20, 35J65, 35K60, 60J60

Introduction. This paper is concerned with the optimal control of deterministic trajectories given a state-space constraint. The dynamics of the controlled process are (0.1) below. More precisely, let the control u be a Borel measurable map from $[0, \infty)$ into a compact, separable, metric space U and $y(x, \cdot, u)$ be the controlled process. The trajectories $y(x, t, u)$ are the solutions of

$$\frac{d}{dt}y(x, t, u) = b(y(x, t, u), u(t)) \tag{0.1}$$

with initial data $y(x, 0, u) = x$. Let θ be an open subset of R^n and $\mathcal{A}_x$ be the set of strategies under which $y(x, t, u)$ lies in $\bar{\theta}$ (bar denotes the closure). In this paper we refer to $\mathcal{A}_x$ as the set of admissible controls. The structure of $\mathcal{A}_x$ constitutes a state-space constraint. We now associate a discounted cost to every admissible control u and x in $\bar{\theta}$. Given these the optimal value function is

$$v(x) = \inf_{u \in \mathcal{A}_x} \int_0^\infty e^{-t} f(y(x, t, u), u(t))\, dt. \tag{0.2}$$

Note that v is not necessarily continuous. This is caused by the complicated structure of the set valued function $x \to \mathcal{A}_x$. However, as will be shown in § 3 the optimal value function is uniformly continuous on $\bar{\theta}$ given that at every point x on $\partial\theta$ (boundary of θ) there is an $\alpha(x)$ in U such that $b(x, \alpha(x)) \cdot \nu(x) \leqq -\beta < 0$. Here $\nu(x)$ is the exterior normal vector.

If v is uniformly continuous one can make use of the notion of weak (or so-called viscosity) solution of Hamilton-Jacobi equations introduced by M. G. Crandall and P.-L. Lions [2]. In [2] they proved the uniqueness of the viscosity solutions of Hamilton-Jacobi equations in a wide-class of cases. In [1], M. G. Crandall, L. C. Evans, P.-L. Lions provide a simpler introduction to the subject. The book by P.-L. Lions [5] and the review paper by M. G. Crandall and P. E. Souganidis [3] provide a view of the scope of the theory and the references to much of the recent literature. Finally, P.-L. Lions in [6] states results related to constrained problems and viscosity solutions. He proves that under an assumption, stronger than the one above, the optimal value function is locally Lipschitz. Then by using the "everywhere characterization"

† Lefschetz Center for Dynamical Systems, Division of Applied Mathematics, Brown University, Providence, Rhode Island, 02912.

of Lipschitz viscosity solutions [7], he obtains an existence and uniqueness result for the Bellman equation $v+H(x, Dv)=0$.

Let $H \in C(\bar{\theta} \times R^n; R)$ be given by

$$H(x, p)=\sup_{\alpha \in U}\{-b(x, \alpha) \cdot p-f(x, \alpha)\}. \tag{0.3}$$

In § 2, the optimal value function is characterized as the only viscosity solution of $v(x)+H(x, Dv(x))=0$ on θ given the appropriate boundary conditions. Note that v is not a priori defined on $\partial\theta$. The only information at the boundary is given by the state-space constraint. To motivate the boundary condition assume that there is a continuous optimal feedback strategy $\alpha^*(x)$ and v is continuously differentiable on $\bar{\theta}$. The constraint imposes the inequality $b(x, \alpha^*(x)) \cdot \nu(x) \leqq 0$ at the boundary of θ. Also, the optimality of α^* yields $H(x, \nabla v(x))=-b(x, \alpha^*(x)) \cdot \nabla v(x)-f(x, \alpha^*(x))$. Given these, one can show

$$H(x, \nabla v(x)) \leqq H(x, \nabla v(x)+\beta \nu(x)) \quad \text{for all } \beta \geqq 0 \text{ and } x \in \partial\theta. \tag{0.4}$$

Moreover if ψ is differentiable and $v-\psi$ has a minimum on $\bar{\theta}$ at $x \in \partial\theta$, then $\nabla\psi(x)=\nabla v(x)+\beta\nu(x)$ for some positive β. In view of (0.4),

$$v(x)+H(x, \nabla v(x)) \leqq v(x)+H(x, \nabla\psi(x)). \tag{0.5}$$

Since v is smooth, it is easy to show that $v(x)+H(x, \nabla v(x))=0$ on $\bar{\theta}$. Hence $v(x)+H(x, \nabla\psi(x)) \geqq 0$ whenever ψ is smooth and $v-\psi$ has a minimum, relative to $\bar{\theta}$, at $x \in \partial\theta$. In fact, it is proved that v is the only solution of the Bellman equation with this property (Theorem 2.2).

One can view the inequality (0.4) as a constraint on the normal derivative of v at the boundary. Suppose the Hamiltonian $H(x, p)$ is differentiable with respect to p. Then (0.4) reads as $H_p(x, \nabla v(x)) \cdot \nu(x) \geqq 0$. This implicitly imposes a constraint on $\nabla v(x)$ at the boundary. We give the following simple example to clarify this point.

Example. Let $\theta=(0, 1)$, $U=[-1, 1]$, $b(x, u)=u$, $f(x, u)=-u$ if $u \in [0, 1]$ and $f(x, u)=0$ otherwise. The corresponding Hamiltonian $H(x, p)$ is given by

$$H(x, p)=\begin{cases} 1-p & \text{if } p \leqq \frac{1}{2}, \\ p & \text{if } p > \frac{1}{2}. \end{cases}$$

At $x=1$ the condition (0.4) implies that $v_x(1) \geqq \frac{1}{2}$ and at $x=0$ we have $v_x(0) \leqq \frac{1}{2}$. For this example $v(x)=\frac{1}{2}e^{x-1}-1$ is the only solution of $v(x)+H(x, v_x(x))=0$ on $x \in (0, 1)$ satisfying the inequalities $v_x(0) \leqq \frac{1}{2}$ and $v_x(1) \geqq \frac{1}{2}$.

1. Statement of the problem. Let θ be an open subset of $\mathbb{R}^n$ with a connected boundary satisfying:

(A1) There are positive constants h, r and an R^n-value bounded, uniformly continuous map η of $\bar{\theta}$ satisfying

$$B(x+t\eta(x), rt) \subset \theta \quad \text{for all } x \in \bar{\theta} \quad \text{and } t \in (0, h].$$

Here $B(x, r)$ denotes the ball with center x and radius r.

Remark. If θ is bounded and $\partial\theta$ is C^1, then it satisfies (A1). Also boundaries with isolated corners may satisfy (A1), for example, $\theta=\{(x, y) \in R^2: x>0, y>0\}$.

We assume the following throughout the paper:

(1.0) The controls take values in a compact metric space U.

For all $x, y \in R^n$, $u \in U$ the functions

$$b: R^n \times U \to R^n,$$

$$f: R^n \times U \to R$$

satisfy

$$\sup_{\alpha \in U} |b(x, \alpha) - b(v, \alpha)| \leqq L(b)|x - y| \quad \text{for all } x, y, \tag{1.1}$$

$$\sup_{a \in U} |b(x, \alpha)| \leqq K(b) \quad \text{for all } x, \tag{1.2}$$

$$\sup_{a \in U} |f(x, \alpha) - f(y, \alpha)| \leqq \omega_f(|x - y|) \quad \text{for all } x, y, \tag{1.3}$$

$$\sup_{\alpha \in U} |f(x, \alpha)| \leqq K(f) \quad \text{for all } x \tag{1.4}$$

where ω_f is a nondecreasing continuous function with $\omega_f(0) = 0$.

Consider $\mathcal{A}$, the set of all measurable maps of $[0, \infty)$ into U. For any $u \in \mathcal{A}$ and $x \in \bar{\theta}$ let $y(x, \cdot, u)$ be the solution of (0.1) with initial data $y(x, 0, u) = x$. The associated discounted cost $J(x, u)$ is

$$J(x, u) = \int_0^\infty e^{-t} f(y(x, t, u), u(t))\, dt. \tag{1.5}$$

We allow only the controls which leave $y(x, \cdot, u)$ in $\bar{\theta}$. To have a feasible problem, we assume that the set of admissible controls is nonempty, i.e.

$$\mathcal{A}_x = \{u \in \mathcal{A}: y(x, t, u) \in \bar{\theta} \text{ for all } t \geqq 0\} \neq \varnothing \quad \text{for all } x \in \bar{\theta}. \tag{A2}$$

Under these assumptions the optimal value function

$$v(x) = \inf_{u \in \mathcal{A}_x} J(x, u), \qquad x \in \bar{\theta} \tag{1.6}$$

is bounded.

2. Hamilton–Jacobi–Bellman equation. We begin by recalling the notion of viscosity solutions [1], [2]. Let K be a subset of R^n. We will use the notations $C^1(K)$ and $BUC(\bar{\theta})$ to mean the set of continuously differentiable functions in a neighborhood of K and the set of bounded uniformly continuous functions on $\bar{\theta}$, respectively.

DEFINITIONS 1.1. Let K be a subset of R^n and $v \in BUC(\bar{K})$.

(i) We say v is a *viscosity subsolution* of $v(x) + H(x, Dv(x)) = 0$ on K if

$$v(x_0) + H(x_0, \nabla\psi(x_0)) \leqq 0$$

whenever $\psi \in C^1(\bar{K})$ and $v - \psi$ has a maximum, relative to K, at $x_0 \in K$.

(ii) We say v is a *viscosity supersolution* of $v(x) + H(x, Dv(x)) = 0$ on K if

$$v(x_0) + H(x_0, \nabla\psi(x_0)) \geqq 0$$

whenever $\psi \in C^1(\bar{K})$ and $v - \psi$ has a minimum, relative to K, at $x_0 \in K$.

If v is both subsolution and supersolution, then v is called a viscosity solution.

Remark. A viscosity solution v satisfies the equation at every point where v is differentiable.

In order to consider the state space constraint problem, we extend the definition as follows.

DEFINITION 2.1. $v \in BUC(\bar{\theta})$ is said to be a *constrained viscosity solution* of $v(x) + H(x, Dv(x)) = 0$ on $\bar{\theta}$ if it is a subsolution on θ and a supersolution on $\bar{\theta}$.

Remark. The fact that v is a supersolution on the closed domain imposes a boundary condition. To demonstrate this, suppose $v \in C^1(\bar{\theta})$ is a constrained viscosity solution; then $v(x)+H(x, \nabla v(x))=0$ for all $x \in \bar{\theta}$. But also $v(x)+H(x, \nabla v(x)+\alpha\nu(x)) \geqq 0$, for all $x \in \partial\theta$ and α positive, because if $v-\psi$ has a minimum at $x_0 \in \partial\theta$, then $\nabla\psi(x_0)=\nabla v(x_0)+\alpha\nu(x_0)$ for some $\alpha \geqq 0$. Hence v satisfies (0.5).

THEOREM 2.1. *Suppose that* (A1), (A2), (1.0)-(1.4) *hold and that the optimal value function v is in $BUC(\bar{\theta})$. Then v is the only constrained viscosity solution of $v(x)+H(x, \nabla(x))=0$ on $\bar{\theta}$.*

Proof. First recall that the optimal value satisfies the dynamic programming principle, i.e.: for any positive T

$$v(x)=\inf_{u \in \mathscr{A}_x}\left\{\int_0^T e^{-t} f(y(x, t, u), u(t))\, dt + e^{-T} v(y(x, T, u))\right\}. \tag{2.1}$$

Let $\psi \in C^1(\bar{\theta})$, $x_0 \in \theta$ and $(v-\psi)(x_0)=\max[(v-\psi)(x): x \in \bar{\theta}]=0$. Then, for any $u \in \mathscr{A}_{x_0}$ and t positive, the dynamic programming relation yields:

$$\psi(x_0) \leqq \int_0^t e^{-s} f(y(x_0, s, u), u(s))\, ds + e^{-t}\psi(y(x_0, t, u))$$

which implies

$$\begin{aligned}\frac{1}{t}\int_0^t [\psi(y(x_0, s, u))-b(y(x_0, s, u), u(s)) \\ \cdot \nabla\psi(y(x_0, s, u))-f(y(x_0, s, u), u(s))]\, e^{-s}\, ds \leqq 0.\end{aligned} \tag{2.2}$$

Use (1.1), (1.3) and the fact $|y(x_0, s, u)-x_0| \leqq K(b)s$ to obtain:

$$\psi(x_0)-\frac{1}{t}\int_0^t b(x_0, u(s))\, ds \cdot \nabla\psi(x_0)-\frac{1}{t}\int_0^t f(x_0, u(s))\, ds \leqq h(t). \tag{2.3}$$

Here $h(t)$ denotes a continuous function of $[0, \infty)$ into R with value zero at the origin. Put $t_0=\operatorname{dist}(x_0, \partial\theta)/K(b)$ and for any $\alpha \in U$ define u as follows:

$$u(t)=\alpha\chi_{[0, t_0)}(t)+\tilde{u}(t-t_0)\chi_{[t_0, \infty)}(t) \tag{2.4}$$

where $\tilde{u}$ is any control in $\mathscr{A}_{y(x_0, t_0, u)}$. Then u is in $\mathscr{A}_{x_0}$. Use u in (2.3) to get:

$$\psi(x_0)-b(x_0, \alpha)\cdot\nabla\psi(x_0)-f(x_0, \alpha) \leqq h(t) \quad \text{for all } \alpha \in U \text{ and } t \leqq t_0. \tag{2.5}$$

Send t to zero to prove v is a subsolution on θ. Now let $\psi \in C^1(\bar{\theta})$ and $(v-\psi)(x_0)=\min_{x \in \bar{\theta}}[(v-\psi)(x)]=0$ for some $x_0 \in \bar{\theta}$. Then we have

$$\psi(x_0)=\inf_{u \in \mathscr{A}_{x_0}}\left[\int_0^T f(y(x_0, t, u), u(t))\, e^{-t}\, dt + e^{-T} v(y(x_0, T, u))\right] \quad \text{for } T \geqq 0. \tag{2.6}$$

Thus there is a sequence $\{u^m\}_{m=1}^{\infty} \subset \mathscr{A}_{x_0}$ such that

$$\psi(x_0)+\frac{1}{m^2} \geqq \int_0^{1/m} e^{-t} f(y(x_0, t, u^m), u^m(t))\, dt + e^{-1/m}\psi\left(y\left(x_0, \frac{1}{m}, u^m\right)\right). \tag{2.7}$$

Use (1.1) and (1.3) and proceed as in (2.3) and (2.4) to obtain

$$\psi(x_0)-m\int_0^{1/m} b(x_0, u^m(t))\, dt \cdot \nabla\psi(x_0)-m\int_0^{1/m} f(x_0, u^m(t))\, dt \geqq -K(m) \tag{2.8}$$

where $K(m)$ denotes a sequence of numbers which converges to zero as m tends to

infinity. Observe that $(b^m, f^m) = (m\int_0^{1/m} b(x_0, u^m(t))\,dt,\ m\int_0^{1/m} f(x_0, u^m(t))\,dt)$ lies in the closed convex hull of $BF(x_0) = \{(b(x_0, \alpha), f(x_0, \alpha)),\ \alpha \in U\}$ which is compact. Thus there is a subsequence denoted by m again and $(b, f) \in \overline{co}\,BF(x_0)$ such that (b^m, f^m) converges to (b, f). Send m to infinity in (2.8) to get

$$\psi(x_0) - b \cdot \nabla\psi(x_0) - f \geqq 0: \tag{2.9}$$

hence

$$\psi(x_0) + \sup\{-b \cdot \nabla\psi(x_0) - f: (b, f) \in \overline{co}\,BF(x_0)\} \geqq 0. \tag{2.10}$$

But $H(x_0, \nabla\psi(x_0)) = \sup\{-b \cdot \nabla\psi(x_0) - f: (b, f) \in \overline{co}\ BF(x_0)\}$. This proves that the optimal value v is a constrained viscosity solution. The uniqueness is an immediate consequence of the following theorem. □

Consider two running costs $\{f_i;\ i = 1, 2\}$ and the corresponding Hamiltonians H_i defined as in (0.3).

THEOREM 2.2. *Suppose v_1 is a viscosity subsolution of $v(x) + H_1(x, Dv(x)) = 0$ on θ and v_2 is a viscosity supersolution of $v(x) + H_2(x, Dv(x)) = 0$ on $\bar{\theta}$. Let* (A1), (1.1), (1.2) *hold and f_i satisfy* (1.3) *and* (1.4) *for $i = 1, 2$. Then*

$$\sup_{x \in \bar{\theta}} [v_1(x) - v_2(x)] \leqq \sup_{\substack{x \in \bar{\theta} \\ \alpha \in U}} [f_1(x, \alpha) - f_2(x, \alpha)]. \tag{2.11}$$

Before we give the proof, we briefly sketch the technique introduced by Crandall, Evans and Lions [1] and point out the modification we need. Let ξ be a smooth bump function ξ, for example, $\xi(r) = 1 - r^2$. Let $m = \max\{\|v_1\|_\infty, \|v_2\|_\infty\}$ and define

$$\Phi(x, y) = v_1(x) - v_2(y) + 3m\xi\left(\frac{x - y}{\varepsilon}\right). \tag{2.12}$$

Suppose Φ attains its maximum at $(x_0, y_0) \in \bar{\theta} \times \bar{\theta}$. It follows that $|x_0 - y_0| \leqq \varepsilon$. Now consider the map $x \to v_1(x) - v_2(y_0) + 3m\xi(x - y_0/\varepsilon)$. It has a maximum at x_0. If $x_0 \in \theta$, the viscosity property yields

$$v_1(x_0) + H_1(x_0, p_\varepsilon) \leqq 0, \tag{2.13}$$

$$p_\varepsilon = \frac{3m}{\varepsilon}\nabla\xi\left(\frac{x_0 - y_0}{\varepsilon}\right). \tag{2.14}$$

Similarly, consider the map $y \to v_1(x_0) - v_2(y) + 3m\xi(x_0 - y/\varepsilon)$. At $y_0 \in \bar{\theta}$ it has a maximum. The viscosity property implies

$$v_2(y_0) + H_2(y_0, p_\varepsilon) \geqq 0. \tag{2.15}$$

Subtract (2.15) from (2.13) and use the fact $|x_0 - y_0| \leqq \varepsilon$ to obtain

$$\begin{aligned} v_1(x_0) - v_2(y_0) &\leqq H_2(y_0, p_\varepsilon) - H_1(x_0, p_\varepsilon) \\ &\leqq 0(\varepsilon) + \sup_{x \in \theta \alpha \in U} [f_1(x, \alpha) - f_2(x, \alpha)]. \end{aligned} \tag{2.16}$$

This will give (2.11) since one can estimate $\sup_{x \in \theta}[v_1(x) - v_2(x)]$ by $v_1(x_0) - v_2(y_0)$. In general, however, x_0 may lie on $\partial\Omega$. To complete the proof of the theorem, we have to modify Φ so that x_0 lies in θ.

Proof of Theorem 2.1. Let η, r be as in (A1), pick $z_\delta \in \bar{\theta}$ and ρ positive such that

$$|\eta(x) - \eta(y)| \leqq \frac{r}{2} \quad \text{for all } x, y \in \bar{\theta} \text{ and } |x - y| < \rho, \tag{2.17}$$

$$v_1(z_\delta) - v_2(z_\delta) \geqq \sup_{x \in \bar{\theta}} [v_1(x) - v_2(x)] - \frac{\delta}{2}. \tag{2.18}$$

Define $\Phi^\varepsilon : \bar{\theta} \times \bar{\theta} \to R$ as follows:

$$\Phi^\varepsilon(x, y) = v_1(x) - v_2(y) - \left| \frac{x-y}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 - \left| \frac{y - z_\delta}{\rho} \right|^2. \tag{2.19}$$

Note that $z_\delta + (\varepsilon 2/r)\eta(z_\delta)$ is in θ for small ε. Use these to obtain

$$\begin{aligned} \Phi^\varepsilon\left(z_\delta + \frac{2\varepsilon}{r}\eta(z_\delta), z_\delta \right) &\geqq v_1(z_\delta) - v_2(z_\delta) - \omega_1(c\varepsilon) \\ &\geqq \sup_{x \in \theta} [v_1(x) - v_2(x)] - \frac{\delta}{2} - \omega_1(c\varepsilon) \end{aligned} \tag{2.20}$$

where $\omega_1(r)$ is the modulus of continuity and c is a positive constant. We also have

$$\Phi^\varepsilon(x, y) \leqq v_1(x) - v_2(x) + \omega_1(|x-y|) - \left| \frac{x-y}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 - \left| \frac{y - z_\delta}{\rho} \right|^2. \tag{2.21}$$

Suppose $\Phi^\varepsilon(x, y) \geqq \Phi^\varepsilon(z_\delta + (2\varepsilon/r)\eta(z_\delta), z_\delta)$. Use (2.20) and (2.21) to obtain

$$\left| \frac{y - z_\delta}{\rho} \right|^2 + \left| \frac{x-y}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 \leqq \omega_1(c\varepsilon) + \frac{\delta}{2} + \omega_1(|x-y|). \tag{2.22}$$

Since ω_1 is bounded it follows that $\Phi^\varepsilon(x, y) \leqq \Phi^\varepsilon(z_\delta + (2\varepsilon/r)\eta(z_\delta), z_\delta)$ for $x, y \notin B(z_\delta, K)$ for sufficiently large K. Hence Φ^ε achieves its maximum, say at x_0, y_0. Also (2.22) yields that there is m positive such that $|x_0 - y_0| \leqq m\varepsilon$. We use this in (2.22) to obtain

$$\left| \frac{y_0 - z_\delta}{\rho} \right|^2 + \left| \frac{x_0 - y_0}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 \leqq \omega_1(c\varepsilon) + \frac{\delta}{2} + \omega_1(m\varepsilon). \tag{2.23}$$

Pick ε and δ so that the right-hand side of (2.23) is less than one. Hence $|y_0 - z_\delta| \leqq \rho$, (2.17) implies there in e is the unit ball such that $\eta(y_0) = \eta(z_\delta) + (r/2)e$. Also, there is e' again in the unit ball such that $x_0 = y_0 + (\varepsilon 2/r)\eta(z_\delta) + \varepsilon e'$. Combining these yields

$$x_0 = y_0 + \frac{2\varepsilon}{r}\left(\eta(y_0) + r\left[-\frac{e}{2} + \frac{e'}{2} \right] \right) \in B(y_0 + t\eta(y_0), tr) \tag{2.24}$$

with $t = 2\varepsilon/r$. Thus, (A1) implies $x_0 \in \theta$ if ε is small. Now consider the maps

$$\bar{\psi}(x) = v_2(y_0) + \left| \frac{x - y_0}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 + \left| \frac{y_0 - z_\delta}{\rho} \right|^2, \tag{2.25}$$

$$\psi(y) = v_1(x_0) - \left| \frac{x_0 - y}{\varepsilon} - \frac{2}{r}\eta(z_\delta) \right|^2 - \left| \frac{y - z_\delta}{\rho} \right|^2. \tag{2.26}$$

Then $v_1 - \bar{\psi}$ has a maximum at $x_0 \in \theta$ and $v_2 - \psi$ has a minimum at $y_0 \in \bar{\theta}$. The viscosity property yields

$$v_1(x_0) + H_1(x_0, p_\varepsilon) \leqq 0, \tag{2.27}$$

$$v_2(y_0) + H_2(y_0, p_\varepsilon + q_\varepsilon) \geqq 0 \tag{2.28}$$

where

$$p_\varepsilon = 2\left(\frac{x_0 - y_0}{\varepsilon} - \frac{2}{r}\eta(z_\delta)\right)\frac{1}{\varepsilon}, \qquad q_\varepsilon = -2\left(\frac{y_0 - z_\delta}{\rho^2}\right).$$

Subtract (2.28) from (2.27),

$$\begin{aligned} v_1(x_0) - v_2(y_0) &\leqq [H_2(y_0, p_\varepsilon + q_\varepsilon) - H_2(x_0, p_\varepsilon)] \\ &\quad + [H_2(x_0, p_\varepsilon) - H_1(x_0, p_\varepsilon)] := I(\varepsilon) + J(\varepsilon), \end{aligned} \tag{2.29}$$

$$J(\varepsilon) \leqq \sup_{\alpha \in U} [f_1(x_0, \alpha) - f_2(x_0, \alpha)]. \tag{2.30}$$

Using (1.2) and (1.3) yields

$$I(\varepsilon) \leqq \omega_{f_2}(|x_0 - y_0|) + |p_\varepsilon| L(b)|x_0 - y_0| + K(b)|q_\varepsilon|. \tag{2.31}$$

(2.23) yields $|q_\varepsilon| \leqq h(\varepsilon) + \delta/2$, $\varepsilon|p_\varepsilon| \leqq h(\varepsilon) + \delta/2$, and $|x_0 - y_0|\varepsilon^{-1} \leqq C$ for some C independent of ε. Here $h(\varepsilon)$ denotes a continuous function of ε which has value zero at the origin. Thus, we have

$$I(\varepsilon) \leqq \omega_{f_2}(C\varepsilon) + L(b)h(\varepsilon)C + K(b)h(\varepsilon) \leqq h(\varepsilon) + C\delta. \tag{2.32}$$

Substitute (2.30), (2.32) into (2.29) to get

$$v_1(x_0) - v_2(y_0) \leqq h(\varepsilon) + \sup_{\alpha \in U} [f_1(x_0, \alpha) - f_2(x_0, \alpha)] + C\delta. \tag{2.33}$$

Also we have,

$$\begin{aligned} \max_{x \in \bar{\theta}} \{v_1(x) - v_2(x)\} &\leqq v_1\left(z_\delta + \frac{2\varepsilon}{r}\eta(z_\delta)\right) - v_2(z_\delta) + \delta + \omega_1(c\varepsilon) \\ &\leqq \max\{\phi^\varepsilon(x, y) : x, y \in \bar{\theta}\} + \delta + \omega_1(c\varepsilon). \end{aligned}$$

Using (2.23) and (2.33), one can show that

$$\max\{\phi^\varepsilon(x, y) : x, y \in \bar{\theta}\} \leqq h(\varepsilon) + c\delta + \sup_{x \in \bar{\theta}, \alpha \in U} \{f_1(x, \alpha) - f_2(y, \alpha)\}. \tag{2.34}$$

Now send first ε then δ to zero. □

In fact, using the fact that x_0 is close to z_δ in (2.33), one can improve the result as follows:

COROLLARY 2.3. *Let $z_\delta \in \bar{\theta}$ be as in* (2.18); *then under the hypothesis of Theorem* 2 *we have*

$$v_1(z_\delta) - v_2(z_\delta) \leqq \sup_{\alpha \in U} [f_1(z_\delta, \alpha) - f_2(z_\delta, \alpha)] + C\delta + \omega_{f_1}(C\delta) + \omega_{f_2}(C\delta)$$

where C is a positive constant depending on $K(b)$, $L(b)$.

3. Uniform continuity of the value function. In this section we prove the continuity of the value function under the following assumptions.

(A3) There is a positive constant β such that for any $x \in \partial\theta$ there is $\alpha(x) \in U$ satisfying $b(x, \alpha(x)) \cdot \nu(x) \leqq -\beta < 0$, where ν is the exterior normal vector.

(A4) The boundary $\partial\theta$ is of class C^2.

(A5) If $\partial\theta$ is not compact there are positive constants ρ and l such that, for any $x \in \partial\theta$ there is a $T \in C^2(B(x, \rho)$ with inverse $T^{-1} \in C^1(B(x, \rho))$ satisfying

$$\begin{aligned} &\text{(i)} \quad T(B(x,\rho) \cap \theta) \subset \{y \in R^n, y_n > 0\}, \\ (3.1) \quad &\text{(ii)} \quad T(B(x,\rho) \cap \partial\theta) \subset \{y \in R^n, y_n = 0\}, \\ &\text{(iii)} \quad \|T\|_{C^2(B(x,\rho))} + \|T^{-1}\|_{C^1(B(x,\rho))} \leqq l. \end{aligned}$$

The subscript n denotes the nth component.

Remark. The condition (3.1) is satisfied locally if (A4) holds. By using a technique similar to the one indicated below, one can prove the continuity of the optimal value function under (A3) and (A4). Instead of this we use (A5) together with (A3) and (A4) to obtain a uniform modulus of continuity for the optimal value function.

LEMMA 3.1. *Suppose* (A3)-(A5) *hold. Then, for all* $x \in \partial\theta$, $\bar{b}(x, \alpha(x))_n \geqq l\beta$ *where*

$$(3.2) \qquad \bar{b}(y, \alpha) = \nabla T(T^{-1}(y)) \cdot b(T^{-1}(y), \alpha), \; y \in B(x, \rho) \text{ and } \alpha \in U.$$

Proof. Given $x_0 \in \partial\theta$ pick T as in (A5). Observe $\partial\theta \cap B(x_0, \rho) \subset \{x: T_n(x) = 0\}$. Hence $\nu(x_0) = -\nabla T_n(x_0)/|\nabla T_n(x_0)|$.

$$\begin{aligned} \bar{b}(T(x_0), \alpha(x_0))_n &= \nabla T_n(x_0) \cdot b(x_0, \alpha(x_0)) \\ &= -|\nabla T_n(x_0)| \nu(x_0) \cdot b(x_0, \alpha(x_0)) \geqq l\beta. \end{aligned} \tag{3.3}$$

□

Remark. The vector field $\bar{b}$ is the image of b under the transformation T.

Let u be an admissible control for $x_0 \in \bar{\theta}$. Then u is not necessarily admissible at any point x, regardless how close that point is to x_0. The following lemma provides a way to project it into $\mathcal{A}_x$ by changing the cost proportionally to $|x - x_0|$.

LEMMA 3.2. *Assume that* (A3)-(A5), (1.1)-(1.4) *hold. Then there exist* $t^* > 0$ *and* $L > 0$ *such that for any* $x \in \bar{\theta}$ *and* $u \in \mathcal{A}$ *there is* $\bar{u}$ *in* $\mathcal{A}_x$ *satisfying*

$$(3.4) \qquad |J_{t^*}(x, \bar{u}) - J_{t^*}(x, u)| \leqq L \sup_{t \in [0, t^*]} [\operatorname{dist}(y(x, t, u), \bar{\theta})]$$

where

$$(3.5) \qquad J_{t^*}(x, u) = \int_0^{t^*} e^{-t} f(y(x, t, u), u(t))\, dt.$$

Proof. In the proof we shall determine t^*, sufficiently small. Let t_0 be the first entrance to $\partial\theta$, i.e.,

$$\begin{aligned} t_0 &= \inf\{0 < t \leqq t^*, y(x, t, u) \in \partial\theta\} \\ &\quad \text{or } t^* \text{ if } y(x, t, u) \in \theta \text{ for all } t \leqq t^*. \end{aligned} \tag{3.6}$$

Let $\varepsilon = \sup\{\text{dist. } (y(x, t, u), \bar{\theta}); t \in [0, t^*]\}$. Define $\bar{u}$ as follows

$$(3.7) \qquad \bar{u}(t) = u(t)\chi_{[0, t_0) \cup (t_0 + k\varepsilon, \infty)}(t) + \alpha(y(x, t_0, u))\chi_{[t_0, t_0 + k\varepsilon]}(t)$$

where k is to be chosen and $\alpha(x)$ is as in (A3). We claim that $y(x, t, \bar{u}) \in \bar{\theta}$ for $t \leqq t^*$. At $y(x, t_0, u) \in \partial\theta$ there is a map T satisfying (3.1). Set $z(x, t, u) = T(y(x, t, u))$ for any u in $\mathcal{A}$, then z obeys the differential equation

$$(3.8) \qquad \frac{d}{dt} z(x, t, u) = \bar{b}(z(x, t, u), u(t))$$

where $\bar{b}$ is as in (3.2). The vector field $\bar{b}$ is Lipschitz continuous on $N = T(B(y(x, t_0, u), \rho))$. Moreover, on N it is bounded by $K(\bar{b}) = lK(b)$ and its Lipschitz

constant $L(\bar{b})$ is no more than $l^2K(b)+l^2L(b)$. (Here l is as in (A5).) If we choose t^* less than $\rho(K(b))^{-1}$, then $y(x, t, \bar{u})$ lies in $B(y(x, t_0, u), \rho)$ for all $t \leqq t^*$. Hence, $z(x, t, \bar{u}) \in N$ for all $t \leqq t^*$ and without loss of generality we assume $\bar{b}$ is Lipschitz continuous with Lipschitz constant $l^2K(b)+l^2L(b)$. To prove the claim, it suffices to show $(z(x, t, \bar{u}))_n \geqq 0$ on $t \in [0, t^*]$. Consider

$$\psi(t) = (z(x, t+k\varepsilon, \bar{u}) - z(x, t, u))_n \quad \text{for } t \geqq t_0. \tag{3.9}$$

Then

$$\begin{aligned}
\psi(t) &= \psi(t_0) + \int_{t_0}^{t} [\bar{b}(z(x, s+k\varepsilon, \bar{u}), u(t) - \bar{b}(z(x, s, u), u(t))]_n \, ds \\
&\geqq \psi(t_0) - L(\bar{b})|z(x, t_0+k\varepsilon, \bar{u}) - z(x, t_0, u)| \int_{t_0}^{t} e^{L(\bar{b})(s-t_0)} \, ds \qquad (3.10) \\
&\geqq \psi(t_0) - K(\bar{b})k\varepsilon(e^{L(\bar{b})(t-t_0)} - 1) \\
&\geqq \psi(t_0) - K(\bar{b})k\varepsilon(e^{L(\bar{b})(t^*-t_0)} - 1) \quad \text{for } t \in [t_0, t^*].
\end{aligned}$$

Now choose t^* less than $(L(\bar{b}))^{-1} \ln(1+\beta l/4K(\bar{b}))$, where β is as in (A3). We have

$$\psi(t) \geqq \psi(t_0) - k\varepsilon\beta l_4^1 \quad \text{for } t \in [t_0, t^*]. \tag{3.11}$$

We need an estimate for $\psi(t_0)$. To simplify the notation, let $\bar{b}_0 = \bar{b}(z(x, t_0, u))$, $\alpha(y(x, t_0, u))$ and $\omega(t) = z(x, t_0, u) + (t-t_0)\bar{b}_0$. Then, Lemma 3.1 yields that $(\bar{b}_0)_n \geqq \beta l$ and hence,

$$\omega(t)_n \leqq \beta l(t-t_0) \quad \text{for } t \geqq t_0. \tag{3.12}$$

Using standard O.D.E. estimates, one can obtain

$$|z(x, t, \bar{u}) - \omega(t)| \leqq \tfrac{1}{2}L(\bar{b})K(\bar{b})(t-t_0)^2 \quad \text{for } t \geqq t_0. \tag{3.13}$$

Thus

$$z(x, t_0+k\varepsilon, \bar{u})_n \geqq \beta lk\varepsilon - \tfrac{1}{2}L(\bar{b})K(\bar{b})(k\varepsilon)^2. \tag{3.14}$$

Since $y(x, t_0, u) \in \partial\theta$, we have $\psi(t_0) = z(x, t_0+k\varepsilon, \bar{u})_n$. Substitute (3.14) into (3.11) to get

$$\psi(t) \geqq k\varepsilon(\beta l_4^3 - \tfrac{1}{2}L(\bar{b})K(\bar{b})k\varepsilon). \tag{3.15}$$

Choose k to be the minimum of $\beta l/2\varepsilon L(\bar{b})K(\bar{b})$ and $2/\beta$. Then for $t \leqq t^*$

$$\psi(t) \geqq \varepsilon l = \sup\{[-z(x, t, u)_n], t \in [0, t^*]\}. \tag{3.16}$$

Hence, $z(x, t+k\varepsilon, \bar{u})_n = \psi(t) + z(x, t, u)_n \geqq 0$ for all $t \in [t_0, t^*]$. One can prove (3.4) by using the standard estimates. □

THEOREM 3.3. *Suppose* (A3)-(A5), (1.1), (1.2) *and* (1.4) *hold. Then the value function v is in $BUC(\bar{\theta})$.*

Proof. Without loss of generality one can assume f is Lipschitz in x uniformly with respect to α. If not, we take a sequence f^n of Lipschitz continuous functions converging to f uniformly. Let $x, y \in \bar{\theta}$ and $|x-y| < r$. For any positive δ, pick a δ-optimal control u in $\mathcal{A}_y$, i.e.

$$J_{t^*}(y, u) + e^{-t^*}v(y(y, t^*, u)) \leqq v(y) + \delta \tag{3.17}$$

where t^* is as in Lemma 3.2. Construct $\bar{u} \in \mathcal{A}_x$ as in Lemma 3.2, and set $\varepsilon = \sup[\text{dist}(y(x, t, u), \bar{\theta}), t \in [0, t^*]]$. Using standard estimates, one can get $\varepsilon \leqq Cr$ for

some C positive. Thus, we have

$$|J_{t^*}(x, u) - J_{t^*}(x, \bar{u})| \leqq LCr. \tag{3.18}$$

Also the construction of $\bar{u}$ yields

$$|y(x, t^*, u) - y(x, t^*, \bar{u})| \leqq \bar{C}r \quad \text{for some } \bar{C} > 0. \tag{3.19}$$

Also

$$|y(x, t^*, \bar{u}) - y(y, t^*, u)| \leqq \bar{C}r + |y(x, t^*, u) - y(y, t^*, u)| \leqq \tilde{C}r \quad \text{for some } \tilde{C} > 1. \tag{3.20}$$

And

$$|J_{t^*}(x, \bar{u}) - J_{t^*}(y, u)| \leqq LCr + |J_{t^*}(x, u) - J_{t^*}(y, u)| \leqq Cr \quad \text{for some } C > 0. \tag{3.21}$$

Let $\omega(r) = \sup\{|v(x) - v(y)|, x, y \in \bar{\theta}, |x - y| < r\}$ for $r > 0$. At the origin $\omega(0) = \lim_{r \downarrow 0} \omega(r)$. Combine (3.17), (3.20) and (3.21) and use the dynamic programming principle to obtain

$$\begin{aligned} v(x) - v(y) &\leqq J_{t^*}(x, \bar{u}) + e^{-t^*} v(y(x, t^*, \bar{u})) \\ &\quad - J_{t^*}(y, u) - e^{-t^*} v(y(y, t^*, u)) + \delta \\ &\leqq Cr + e^{-t^*} \omega(\tilde{C}r) + \delta \quad \text{for all } \delta > 0. \end{aligned} \tag{3.22}$$

Hence we have

$$\omega(r) \leqq Cr + e^{-t^*} \omega(\tilde{C}r) \quad \text{and} \quad \tilde{C} > 1. \tag{3.23}$$

Assume $\tilde{C} e^{-t^*} \neq 1$ and iterate (3.23) to obtain

$$\begin{aligned} \omega(0) &= \lim_{n \to \infty} \omega(\tilde{C}^{-n}) \leqq \lim_{n \to \infty} \left[C\tilde{C}^{-n} \sum_{l=0}^{n-1} [\tilde{C} e^{-t^*}]^l + e^{-nt^*} \omega(1) \right] \\ &= C \lim_{n \to \infty} \left[\frac{e^{-nt^*} - \tilde{C}^{-n}}{\tilde{C} e^{-t^*} - 1} \right] = 0. \end{aligned}$$

□

Acknowledgments. Finally, I would like to express thanks to Professor P. E. Souganidis for introducing me to the notion of viscosity solutions and their applications to control problems and to Professor W. H. Fleming for suggesting the problem, helpful converstations and good advice. This paper comprises part of the author's dissertation written under the direction of Professor W. H. Fleming at Brown University.

DECOUPLAGE DES SYSTEMES NON LINEAIRES, SERIES GENERATRICES NON COMMUTATIVES ET ALGEBRES DE LIE*

DANIEL CLAUDE†

Résumé. L'utilisation conjointe des séries génératrices et des algèbres de Lie rend possible une approche algébrique du découplage des systèmes non linéaires. On présente une méthode de découplage cohérente grâce à la notion supplémentaire d'immersion d'un système dans un autre, concept qui formalise la notion de même comportement entrée-sortie. Ainsi, un choix judicieux des lois de bouclage assurant le découplage permet d'immerger un système dans un système défini sur $\mathbb{R}^\eta$, avec η dépendant des nombres caractéristiques du système.

Abstract. The joint use of noncommutative generating power series and Lie algebras gives an algebraic approach for decoupling problem of nonlinear systems. We produce a coherent decoupling method using the additional notion of the immersion of a system into another, a concept which makes clear the fact that two systems have a same input-output behaviour. Thus, a judicious choice of feedback which gives decoupling is able to immerse a system into a system defined on $\mathbb{R}^\eta$, with η depending on the characteristic numbers of the system.

Key words. nonlinear systems, decoupling, noninteracting control, disturbance rejection, noncommutative generating series, Lie algebras

On considère des fonctionnelles causales, en temps continu, associant une entrée vectorielle $\mathbf{e}$ à une sortie vectorielle y par l'intermédiaire d'une dynamique donnée par un système différentiel. Ces systèmes dynamiques multivariables sont de la forme:

$$\begin{aligned} &\frac{dq}{dt} = \dot{q}(t) = f(q) + \mathbf{e}(t)g(q), \\ &y(t) = h(q) \end{aligned} \tag{1}$$

où l'état q est de dimension N.

La commande d'un système de type (1) pose immédiatement à tout utilisateur le problème suivant: comment éviter qu'une entrée perturbe une sortie ou bien, à cause des couplages inhérents à ces systèmes, affecte plusieurs sorties simultanément? Par exemple, dans le pilotage d'un avion, que faire pour qu'une action sur le gouvernail d'altitude ne modifie pas en même temps le vecteur instantané de rotation et les angles d'attaque, de roulis, de virage et de tangage (cf. Singh et Schy [33])? La réponse à ces interrogations est donnée par la théorie du découplage qui consiste à rendre les sorties d'un système indépendantes de certaines entrées. Pour y parvenir, un système ayant rarement les propriétés souhaitées, on utilisera ici des bouclages ou "feedbacks", statiques par retour d'état du type:

$$\mathbf{e}(t) = \alpha(q) + \mathbf{v}(t)\beta(q) \tag{2}$$

où $\mathbf{v}$ indique une nouvelle entrée vectorielle permettant la commande du système.

Le système (1) bouclé devient:

$$\begin{aligned} &\dot{q} = [f(q) + \alpha(q)g(q)] + \mathbf{v}(t)\beta(q)g(q), \\ &y = h(q) = (h_1(q), \cdots, h_r(q)). \end{aligned} \tag{3}$$

* Received by the editors September 14, 1983, and in final revised form January 13, 1985.

† Laboratoire des Signaux et Systèmes, C.N.R.S.-E.S.E., Plateau du Moulon, 91190 Gif-sur-Yvette, France.

On cherche alors les bouclages donnant le découplage désiré entre l'entrée $\mathbf{v}$ et la sortie y.

La solution du problème pour les systèmes linéaires[1]—systèmes où l'espace d'état Q est un espace vectoriel de dimension finie N, où f et g sont respectivement des champs de vecteurs linéaire et constant, et où la fonction de sortie $h: Q \to \mathbb{R}^r$ est linéaire—a été donnée simultanément autour des années soixante-dix, grâce à l'approche géométrique, par Basile et Marro [1] et par Wonham et Morse [39].

Pour les systèmes non linéaires, ce problème, important par ses applications pratiques, restait ouvert.

Les progrès récents dus à l'usage de la géométrie différentielle, introduite en automatique non linéaire par Hermann [18] et Lobry [24][2], ont suggéré à Hirschorn [20] et Isidori, Krener, Gori-Giorgi et Monaco [22] l'utilisation d'un certain type de distributions, dites (f, g)-invariantes, pour attaquer le découplage en non linéaire. Cette approche géométrique, dans laquelle la notion de sous-espace vectoriel, utilisée en linéaire, est remplacée par celle de distribution, se révèle fructueuse et apparaît dans l'étude de systèmes très généraux (cf. Nijmeijer et van der Schaft [28]).

Cependant, seules les distributions de rang constant présentent un réel intérêt géométrique par les changements de coordonnées qu'elles permettent (cf. Isidori [21], Respondek [32], Nijmeijer [27], Bournonville [2]) et l'existence de singularités conduit, contrairement au cas linéaire, à des difficultés redoutables (cf. Byrnes et Krener [3]). Comme le montre Isidori [21], le découplage peut être assuré par l'existence d'une carte locale dans laquelle la dynamique du système se décompose en deux parties dont une est inobservable. Mais, pour avoir une valeur globale, cela impose des conditions restrictives incompatibles avec la présence des singularités les plus communes. Tout ceci nous amène à retenir, pour le non linéaire, deux types de découplage d'un système, le découplage structurel lié à une décomposition de la dynamique (cf. Isidori [21]) et le découplage fonctionnel, déterminé uniquement par le comportement externe (entrée-sortie), comportement lui-même caractérisé par la série génératrice non commutative du système (cf. Fliess [11]). Ce dernier découplage a l'avantage de permettre des solutions sans les conditions de régularité nécessaires au découplage structurel qu'il redonne en plus facilement. Mais les difficultés évoquées plus haut demeurent et la recherche de bouclages donnant un découplage fonctionnel conduit en général à travailler sur un ouvert dense de la variété d'état (cf. Hirschorn [20]). Dans beaucoup d'exemples concrets définis sur $\mathbb{R}^N$, cet ouvert est le complémentaire d'un hyperplan (cf. Singh et Schy [33]) dont la simple approche peut entraîner des instabilités numériques rédhibitoires.

L'utilisation des séries génératrices non commutatives, inséparablement liées à la géométrie différentielle (cf. Fliess [13]), permet de traiter sous un aspect plus algébrique le découplage des systèmes non linéaires. L'emploi d'algèbres de Lie, sur l'anneau des fonctions analytiques sur la variété d'état, fournit alors un équivalent algébrique aux distributions analytiques. Cela conduit de façon naturelle aux lois de bouclage cherchées et complète la méthode géométrique tout en généralisant une méthode bien connue des ingénieurs (cf. Porter [30]). Il est alors possible de tenir compte de nouvelles données comme par exemple les contraintes physiques (cf. Gauthier, Bornard, Bacha et Idir [16]). De plus, la notion de découplage fini qui implique la nullité d'un nombre fini de premiers termes de la série génératrice du système au lieu d'une infinité pour

[1] On pourra consulter le livre de Wonham [38] pour une étude complète du découplage des systèmes linéaires.

[2] On pourra consulter un cours avancé de Sussmann [35] pour un "survey" récent.

le découplage fonctionnel, permet des procédés algorithmiques nouveaux (cf. Claude et Dufresne [7] et Kasinski et Lévine [23]). Le découplage fonctionnel, complété par le découplage fini, rend possible la présentation d'une méthode de découplage cohérente grâce à la notion dernière d'immersion d'un système dans un autre. Ce concept d'immersion (cf. Fliess [12] et Fliess et Kupka [14]) qui formalise la notion de même comportement entrée-sortie, offre une solution intéressante. Ainsi, un choix judicieux de lois de bouclage assurant le découplage permet d'immerger le système dans un système défini sur $\mathbb{R}^\eta$, avec η dépendant des nombres caractéristiques du système.

Il est à noter que nos démonstrations restent dans un cadre strictement algébrique.

La plupart des résultats de cet article ont déjà été publiés sous une forme souvent succincte en [4], [5], [6].

Table des Matières

1. Séries génératrices et découplage. Le découplage d'un système consistant à rendre les sorties d'un système indépendantes de certaines entrées, on est conduit dans le système (3) à associer à chaque sortie une partition de l'entrée $\mathbf{v}$ en deux sous-ensembles: les commandes admissibles et les perturbations. Ainsi, tout découplage se ramène à une association de rejets de perturbations, et nous ne traitons que ce dernier problème.

Nous considérons des systèmes à coefficients analytiques où les entrées apparaissent au premier degré, de la forme:

$$\text{(I)} \qquad \begin{aligned} \dot{q}(t) &= A^0(q) + \sum_{l=1}^{d} \mathbf{u}_l(t) A^l(q) + \sum_{j=1}^{k} \mathbf{p}_j(t) P^j(q), \\ y &= h(q). \end{aligned}$$

L'état q appartient à une variété analytique réelle Q connexe et de dimension N; les champs de vecteurs $A^0, A^1, \cdots, A^d, P^1, \cdots, P^k: Q \to TQ$ (fibré tangent) et la fonction vectorielle $h = (h_1, \cdots, h_r)$ de Q dans $\mathbb{R}^r$, sont analytiques; les entrées $\mathbf{u}_1, \cdots, \mathbf{u}_d, \mathbf{p}_1, \cdots, \mathbf{p}_k$ sont des fonctions réelles continues par morceaux. On désire que la sortie vectorielle $y = (y_1, \cdots, y_r)$ ne dépende pas de l'entrée $\mathbf{p} = (\mathbf{p}_1, \cdots, \mathbf{p}_k)$, au moyen de bouclages du genre:

$$(*) \qquad \begin{aligned} \mathbf{u}_l(t) &= \alpha_l(q) + \sum_{i=1}^{n} \beta_l^i(q) \mathbf{a}_i(t) \quad \text{avec } l = 1, \cdots, d, \\ \mathbf{p}_j(t) &= \mathbf{p}_j(t) \quad \text{avec } j = 1, \cdots, k. \end{aligned}$$

Les fonctions α_l et β_l^i sont analytiques et $\mathbf{a}_1, \cdots, \mathbf{a}_n$ désignent de nouvelles entrées permettant la commande du système bouclé.

En prenant $\alpha_l = 0$ et $\beta_l^i = \delta_l^i$ (symbole de Kronecker) avec $l = 1, \cdots, d$ et $i = 1, \cdots, n$, on retrouve le système (I).

Le système bouclé peut s'écrire:

$$\text{(II)} \qquad \begin{aligned} \dot{q} &= \hat{A}^0 + \sum_{i=1}^{n} \mathbf{a}_i \hat{A}^i + \sum_{j=1}^{k} \mathbf{p}_j P^j, \\ y &= h(q) \end{aligned}$$

avec

$$\hat{A}^0 = A^0 + \sum_{l=1}^{d} \alpha_l A^l \quad \text{et} \quad \hat{A}^i = \sum_{l=1}^{d} \beta_l^i A^l \qquad (i = 1, \cdots, n).$$

Comme l'a montré Fliess [11], la sortie $y(t)$ du système différentiel (II), initialisé en $q(0)$, est une fonctionnelle causale analytique des entrées $\mathbf{a}_1, \cdots, \mathbf{a}_n, \mathbf{p}_1, \cdots, \mathbf{p}_k$ définie par une série génératrice. Cette série génératrice $\mathfrak{h}|q(0) = (\mathfrak{h}_1|q(0), \cdots, \mathfrak{h}_r|q(0))$ et la sortie vectorielle $y = (y_1, \cdots, y_r)$ sont données par:

$$\text{(4)} \qquad \mathfrak{h}_s|q(0) = h_s|q(0) \cdot 1 + \sum_{\nu \geqq 0} \sum_{j_0, \cdots, j_\nu = 0}^{n+k} C^{j_0} \cdots C^{j_\nu} \cdot h_s|q(0) \cdot \mathbf{c}_{j_\nu} \cdots \mathbf{c}_{j_0} \qquad (s = 1, \cdots, r),$$

$$\text{(5)} \qquad y_s(t) = h_s|q(0) + \sum_{\nu \geqq 0} \sum_{j_0, \cdots, j_\nu = 0}^{n+k} C^{j_0} \cdots C^{j_\nu} \cdot h_s|q(0) \cdot \int_0^t d\xi_{j_\nu} \cdots d\xi_{j_0} \qquad (s = 1, \cdots, r).$$

Cette dernière série n'étant convergente en général que pour des temps courts et de petites entrées.

Chaque $\mathbf{c}_j$ appartient à l'alphabet

$$\begin{aligned} \mathbf{c} &= \{\mathbf{a}_0, \mathbf{a}_1, \cdots, \mathbf{a}_n, \mathbf{p}_1, \cdots, \mathbf{p}_k\} \\ &= \{\mathbf{c}_0, \mathbf{c}_1, \cdots, \mathbf{c}_n, \mathbf{c}_{n+1}, \cdots, \mathbf{c}_{n+k}\} \\ &= \mathbf{a} \cup \mathbf{p} \quad \text{avec } \mathbf{a} = \{\mathbf{a}_0, \cdots, \mathbf{a}_n\} \quad \text{et} \quad \mathbf{p} = \{\mathbf{p}_1, \cdots, \mathbf{p}_k\}. \end{aligned}$$

Chaque C^j appartient à l'ensemble des champs de vecteurs du système

$$\begin{aligned} \mathscr{C} &= \{\hat{A}^0, \cdots, \hat{A}^n, P^1, \cdots, P^k\} = \{C^0, C^1, \cdots, C^n, C^{n+1}, \cdots, C^{n+k}\} \\ &= \mathscr{A} \cup \mathscr{P} \quad \text{avec } \mathscr{A} = \{\hat{A}^0, \cdots, \hat{A}^n\} \quad \text{et} \quad \mathscr{P} = \{P^1, \cdots, P^k\}. \end{aligned}$$

La barre $|q(0)$ désigne l'évaluation en $q(0)$.

L'intégrale itérée $\int_0^t d\xi_{j_\nu} \cdots d\xi_{j_0}$ est définie par récurrence:

$$\xi_0(t) = t, \qquad \xi_j(t) = \int_0^t \mathbf{a}_i(\tau)\, d\tau \qquad (i = 1, \cdots, n),$$

$$\xi_l(t) = \int_0^t \mathbf{p}_{l-n}(\tau)\, d\tau \qquad (l = n+1, \cdots, n+k)$$

avec

$$\int_0^t d\xi_j = \xi_j(t) \qquad (j = 0, \cdots, n+k),$$

$$\int_0^t d\xi_{j_\nu} \cdots d\xi_{j_0} = \int_0^t d\xi_{j_\nu}(\tau) \int_0^\tau d\xi_{j_{\nu-1}} \cdots d\xi_{j_0},$$

la dernière intégrale étant prise au sens de Stieltjes.

Nous avons montré en [6] que pour les systèmes initialisés, le découplage peut seulement s'exprimer à l'aide des séries génératrices. L'initialisation ne permet pas de formuler des conditions équivalentes de découplage liées aux champs de vecteurs du système, ni de calculer aisément les lois de bouclages nécessaires au découplage. Aussi, considérons-nous des systèmes de type (II) sans initialisation préalable.

Pour un système de type (II) non initialisé, on peut encore associer une série génératrice vectorielle $\mathfrak{h} = (\mathfrak{h}_1, \cdots, \mathfrak{h}_r)$ dans laquelle les coefficients de $\mathfrak{h}_s$ $(s = 1, \cdots, r)$ sont des éléments de $C^\omega(Q)$, l'anneau des fonctions analytiques sur la variété Q. $\mathfrak{h}$ est définie par:

$$\mathfrak{h}_s = h_s \cdot 1 + \sum_{\nu \geqq 0} \sum_{j_0, \cdots, j_\nu = 0}^{n+k} C^{j_0} \cdots C^{j_\nu} \cdot h_s \cdot \mathbf{c}_{j_\nu} \cdots \mathbf{c}_{j_0} \qquad (s = 1, \cdots, r).$$

On peut maintenant préciser la notion de découplage que nous utilisons.

Découplage total (fonctionnel). La sortie y d'un système de type (II) est découplée totalement par rapport à l'entrée $\mathbf{p}$, si et seulement si chaque sortie $y_1, \cdots, y_r$ ne dépend pas des entrées $\mathbf{p}_1, \cdots, \mathbf{p}_k$, quelle que soit l'initialisation $q(0)$ du système.

L'utilisation des séries génératrices éclaire le concept de découplage d'un système en le reliant à la nullité de certains coefficients.

PROPOSITION 1. *La sortie y d'un système de type* (II) *est totalement découplée par rapport à* $\mathbf{p}$ *si et seulement si tous les coefficients* $C^{j_0} \cdots C^{j_\nu} \cdot h_s$ $(s = 1, \cdots, r)$ *sont nuls dès qu'il existe au moins un* C^j *appartenant à* $\mathcal{P} = \{P^1, \cdots, P^k\}$, *l'ensemble des champs de vecteurs liés aux perturbations* $\mathbf{p}_1, \cdots, \mathbf{p}_k$.

Preuve. L'utilisation de la formule (5) montre que la condition est évidemment suffisante. Réciproquement, l'unicité de la série génératrice, montrée par Fliess [11] dans le cas de coefficients réels, s'étend bien évidemment au cas de coefficients analytiques et permet de conclure. En effet, si la sortie y du système (II) est totalement découplée par rapport à $\mathbf{p}$, elle représente une fonctionnelle causale analytique des entrées $\mathbf{a}_1, \cdots, \mathbf{a}_n$. Par conséquent, cette fonctionnelle est définie par une série génératrice $\mathfrak{h} = (\mathfrak{h}_1, \cdots, \mathfrak{h}_r)$ où $\mathfrak{h}_s$ $(s = 1, \cdots, r)$ est élément de $C^\omega(Q)\langle\langle \mathbf{a} \rangle\rangle$, la $C^\omega(Q)$-algèbre des séries formelles, à coefficients dans $C^\omega(Q)$, en les variables associatives $\mathbf{a}_0, \cdots, \mathbf{a}_n$. Comme chaque série $\mathfrak{h}_s$ $(s = 1, \cdots, r)$ est aussi par définition élément de $C^\omega(Q)\langle\langle \mathbf{c} \rangle\rangle$, la $C^\omega(Q)$-algèbre des séries formelles à coefficients dans $C^\omega(Q)$, en les indéterminées associatives $\mathbf{a}_0, \cdots, \mathbf{a}_n, \mathbf{p}_1, \cdots, \mathbf{p}_k$, on a bien la nullité des coefficients $C^{j_0} \cdots C^{j_\nu} \cdot h_s$ $(s = 1, \cdots, r)$ pour lesquels il existe au moins un C^j appartenant à $\mathcal{P}$. □

De la même manière, la valeur d'une fonctionnelle analytique dépendant d'intégrales itérées, nous voyons (cf. Fliess [11], formules de majoration) que la contribution des termes apparaissant dans la série génératrice décroît avec la longueur et est négligeable, en pratique, à partir d'un certain rang. Nous allons appliquer cette propriété au découplage. On note $\mathbf{c}^*$ le monoïde libre engendré par l'alphabet $\mathbf{c}$. $\mathbf{c}^*$ est l'ensemble des mots formés avec les lettres de $\mathbf{c}$ et est muni de la multiplication non commutative définie par la concaténation de deux mots, l'élément neutre étant le mot vide noté 1. On a ainsi, pour tout mot $\mathbf{w}$ de $\mathbf{c}^*$:

$$1 \cdot \mathbf{w} = \mathbf{w} \cdot 1 = \mathbf{w}$$

$$\text{et si, } \mathbf{w}_1 = \mathbf{c}_{j_\nu} \cdots \mathbf{c}_{j_0};\ \mathbf{w}_2 = \mathbf{c}_{j'_{\nu'}} \cdots \mathbf{c}_{j'_0} \text{ alors } \mathbf{w}_1 \cdot \mathbf{w}_2 = \mathbf{c}_{j_\nu} \cdots \mathbf{c}_{j_0} \mathbf{c}_{j'_{\nu'}} \cdots \mathbf{c}_{j'_0}.$$

$\mathbf{c}^*\mathbf{p}\mathbf{c}^*$ désigne l'ensemble des mots de $\mathbf{c}^*$ contenant au moins une occurrence de $\mathbf{p}_j$ $(j = 1, \cdots, k)$. En notant W l'expression obtenue en remplaçant $\mathbf{a}_0$ par $\hat{A}^0$, $\mathbf{a}_i$ par $\hat{A}^i$ $(i = 1, \cdots, n)$ et $\mathbf{p}_j$ par P^j $(j = 1, \cdots, k)$ dans chaque mot $\mathbf{w}$ de $\mathbf{c}^*$, on peut énoncer:

Découplage fini. Un système de type (II) a sa sortie y_s $(s=1,\cdots,r)$ découplée par rapport à l'entrée **p**, à l'ordre μ si et seulement si l'une des conditions suivantes est satisfaite:

(i) $\mathscr{P}\cdot h_s \not\equiv 0$;

(ii) $W\cdot h_s = C^{j_0}\cdots C^{j_\nu}\cdot h_s \equiv 0$

pour tout $\mathbf{w}\in(\mathbf{c^*pc^*})_\mu$, l'ensemble des mots de **c*pc*** de longueur inférieure ou égale à μ avec $\mu \geqq 1$.

L'ordre μ est nul dans le premier cas alors qu'il est supérieur ou égal à un dans le second.

Si une sortie y_s du système (II) n'est pas découplée totalement par rapport à **p**, on peut définir *l'ordre de découplage fini maximal* auquel est découplée y_s par rapport à **p**, c'est le plus grand des ordres de découplage fini de y_s par rapport à **p**.

2. Algèbres de découplage. Les systèmes (II) étant pris non initialisés, on va pouvoir donner, à l'aide des propositions qui suivent, des conditions de découplage liées aux champs de vecteurs du système et aux opérateurs différentiels qu'ils définissent.

Soient $\mathscr{D}_{\mathscr{A}}$ et $\mathfrak{L}_{\mathscr{A}}$, respectivement, la $\mathbb{R}$-algèbre des opérateurs différentiels et la $C^\omega(Q)$-algèbre de Lie engendrées par $\mathscr{A}$. On peut énoncer:

PROPOSITION 2. *Les conditions suivantes sont équivalentes*:

1. *Tous les coefficients* $C^{j_0}\cdots C^{j_\nu}\cdot h_s$ $(s=1,\cdots,r)$ *contenant au moins un élément de* $\mathscr{P}$ *sont identiquement nuls.*

2. $\mathscr{P}\cdot f\equiv 0$ *pour les fonctions* f *du* $\mathscr{D}_{\mathscr{A}}$*-module à gauche engendré par les fonctions* h_s $(s=1,\cdots,r)$.

3. *Les opérateurs différentiels* D *du* $\mathscr{D}_{\mathscr{A}}$*-module bilatère engendré par* $\mathscr{P}$ *vérifient* $D\cdot h_s\equiv 0$ $(s=1,\cdots,r)$.

4. *Les opérateurs différentiels* D *du* $\mathscr{D}_{\mathscr{A}}$*-module à droite engendré par* $\mathscr{P}$ *satisfont à* $D\cdot h_s\equiv 0$ $(s=1,\cdots,r)$.

5. *La plus petite* $C^\omega(Q)$*-algèbre de Lie de champs de vecteurs contenant* $\mathscr{P}$ *et normalisée par* $\mathfrak{L}_{\mathscr{A}}$*, annihile les fonctions* h_s $(s=1,\cdots,r)$. *On note cette algèbre* $\mathfrak{T}_{\mathbf{p}}$.

Preuve. On a immédiatement les équivalences $1\Leftrightarrow 2$, $2\Leftrightarrow 3$ et $3\Leftrightarrow 4$. D'autre part, $\mathfrak{T}_{\mathbf{p}}$ est engendrée par $\mathscr{T}$, l'ensemble des champs de vecteurs de la forme

$$\operatorname{ad}\hat{A}^{i_1}\circ\cdots\circ\operatorname{ad}\hat{A}^{i_\nu}(P^j)\quad \text{avec } j\in\{1,\cdots,k\}$$

et $i_1,\cdots,i_\nu\in\{0,\cdots,n\}$. On va montrer que $5\Rightarrow 4$ par récurrence.

Prenons un élément $C\cdot\hat{A}^{i_1}\cdots\hat{A}^{i_\nu}\cdot h_s$ avec $C\in\mathscr{T}$, $\nu\geqq 0$ et $s=1,\cdots,r$. On a:

$$C\cdot\hat{A}^{i_1}\cdots\hat{A}^{i_\nu}\cdot h_s=[C,\hat{A}^{i_1}]\cdot\hat{A}^{i_2}\cdots\hat{A}^{i_\nu}\cdot h_s+\hat{A}^{i_1}\cdot C\cdot\hat{A}^{i_2}\cdots\hat{A}^{i_\nu}\cdot h_s.$$

Mais, $-[C,\hat{A}^{i_1}]=\operatorname{ad}\hat{A}^{i_1}(C)$ appartient à $\mathscr{T}$ et d'après l'hypothèse de récurrence,

$$[C,\hat{A}^{i_1}]\cdot\hat{A}^{i_2}\cdots\hat{A}^{i_\nu}\cdot h_s\equiv 0\quad\text{et}\quad C\cdot\hat{A}^{i_2}\cdots\hat{A}^{i_\nu}\cdot h_s\equiv 0;$$

donc:

$$\hat{A}^{i_1}\cdot C\cdot\hat{A}^{i_2}\cdots\hat{A}^{i_\nu}\cdot hs\equiv 0\quad\text{et ainsi}\quad C\cdot\hat{A}^{i_1}\cdots\hat{A}^{i_\nu}\cdot h_s\equiv 0.$$

La propriété étant vérifiée pour $\nu=0$, l'implication annoncée est bien démontrée si on prend $C\in\mathscr{P}$. Il est clair de plus que $4\Rightarrow 5$. □

Nous allons maintenant énoncer le pendant des résultats bien connus en automatique linéaire (cf. Wonham [38]).

On désigne par $\mathfrak{H}$, la $C^\omega(Q)$-algèbre de Lie des champs de vecteurs associés à h par:

$$\mathfrak{H}=\bigcap_{s=1}^{r}\mathfrak{H}_s\quad\text{avec } C\in\mathfrak{H}_s \text{ ssi } C\cdot h_s\equiv 0.$$

THÉORÈME 1. *La sortie y d'un système noninitialisé de type* (II) *est totalement découplée par rapport à l'entrée* **p**, *si et seulement si, il existe une sous-algèbre* $\mathfrak{D}$ *de la* $C^\omega(Q)$*-algèbre de Lie* $\mathfrak{Q}$ *des champs de vecteurs sur* Q, *telle que*:

$$[\mathscr{A}, \mathfrak{D}] \subset \mathfrak{D} \quad \text{et} \quad \mathscr{P} \subset \mathfrak{D} \subset \mathfrak{H}. \tag{6}$$

Preuve. D'après la définition de l'algèbre $\mathfrak{T}_{\mathbf{p}}$ on a

$$\mathscr{P} \subset \mathfrak{T}_{\mathbf{p}} \quad \text{et} \quad [\mathscr{A}, \mathfrak{T}_{\mathbf{p}}] \subset \mathfrak{T}_{\mathbf{p}}.$$

Des propositions 1 et 2, si le système (II) a sa sortie y totalement découplée par rapport à **p**, on a aussi:

$$\mathfrak{T}_{\mathbf{p}} \subset \mathfrak{H}.$$

Réciproquement, s'il existe une sous-algèbre $\mathfrak{D}$ de l'algèbre de Lie $\mathfrak{Q}$ telle que:

$$[\mathscr{A}, \mathfrak{D}] \subset \mathfrak{D} \quad \text{et} \quad \mathscr{P} \subset \mathfrak{D} \subset \mathfrak{H}$$

alors, on a bien $\mathscr{T} \subset \mathfrak{H}$ et $\mathfrak{T}_{\mathbf{p}} \subset \mathfrak{H}$. Les propositions 1 et 2 donnent la conclusion. □

Nous appelons *algèbre de découplage* du système (II) toute sous-algèbre $\mathfrak{D}$ de l'algèbre de Lie $\mathfrak{Q}$ vérifiant (6).

On note $\mathfrak{D}_h^{\mathbf{a}}$, la $C^\omega(Q)$-algèbre de Lie des champs de vecteur sur Q qui annihilent les fonctions du $\mathscr{D}_{\mathscr{A}}$-module à gauche engendré par les fonctions h_s ($s = 1, \cdots, r$). On a alors:

COROLLAIRE. *Une condition nécessaire et suffisante pour qu'un système non initialisé de type* (II) *ait sa sortie y totalement découplée par rapport à l'entrée* **p** *est que l'une des conditions équivalentes suivantes soit vérifiée*:

(i) $\mathfrak{T}_{\mathbf{p}} \subset \mathfrak{H}$;

(ii) $\mathscr{P} \subset \mathfrak{D}_h^{\mathbf{a}}$.

Pour un bouclage de type (*) donné, $\mathfrak{T}_{\mathbf{p}}$ est *la plus petite algèbre de découplage* de la sortie y du système (II) par rapport à **p** et $\mathfrak{D}_h^{\mathbf{a}}$ *la plus grande.*

Preuve. Pour un bouclage de type (*) tel que le système non initialisé de type (II) ait sa sortie y totalement découplée par rapport à l'entrée **p**, nous avons vu au cours de la démonstration du théorème 1 que $\mathfrak{T}_{\mathbf{p}}$ est la plus petite algèbre de découplage.

D'après les définitions, on a:

$$\mathfrak{D}_h^{\mathbf{a}} \subset \mathfrak{H} \quad \text{et} \quad [\mathscr{A}, \mathfrak{D}_h^{\mathbf{a}}] \subset \mathfrak{D}_h^{\mathbf{a}}$$

et la condition $\mathscr{P} \subset \mathfrak{D}_h^{\mathbf{a}}$ est ainsi une condition nécessaire et suffisante de découplage. De plus, si $\mathfrak{M}$ est un $C^\omega(Q)$-module de champs de vecteurs sur Q tel que $\mathfrak{M} \subset \mathfrak{H}$ et $[\mathscr{A}, \mathfrak{M}] \subset \mathfrak{M}$ alors $\mathfrak{M} \subset \mathfrak{D}_h^{\mathbf{a}}$.

On fait une démonstration par récurrence. Prenons un élément $C \cdot \hat{A}^{i_1} \cdots \hat{A}^{i_\nu} \cdot h_s$ où $C \in \mathfrak{M}$, $\nu \geqq 0$ et $s = 1, \cdots, r$.

On a, comme dans la démonstration de la proposition 1:

$$C \cdot \hat{A}^{i_1} \cdots \hat{A}^{i_\nu} \cdot h_s = [C, \hat{A}^{i_1}] \cdot \hat{A}^{i_2} \cdots \hat{A}^{i_\nu} \cdot h_s + \hat{A}^{i_1} \cdot C \cdot \hat{A}^{i_2} \cdots \hat{A}^{i_\nu} \cdot h_s$$

mais, $[C, \hat{A}^{i_1}] \in \mathfrak{M}$ et d'après l'hypothèse de récurrence,

$$[C, \hat{A}^{i_1}] \cdot \hat{A}^{i_2} \cdots \hat{A}^{i_\nu} \cdot h_s \equiv 0 \quad \text{et} \quad C \cdot \hat{A}^{i_2} \cdots \hat{A}^{i_\nu} \cdot h_s \equiv 0,$$

d'où la nullité de $C \cdot \hat{A}^{i_1} \cdots \hat{A}^{i_\nu} \cdot h_s$ et l'implication désirée puisque la propriété est vérifiée pour $\nu = 0$. □

Remarque 1. Le corollaire explique pourquoi dans le théorème 1 nous avons préféré la structure de $C^\omega(Q)$-algèbre de Lie à celle de $C^\omega(Q)$-module qui aurait suffi.

Remarque 2. En prenant les distributions associées aux algèbres de découplage on retrouve les résultats de Hirschorn [20] et de Isidori, Krener, Gori-Giorgi et Monaco [22]. On peut se reporter aux articles d'Isidori [21], d'Hirschorn [20] ou à [6] pour comprendre qu'il s'agit bien d'une extension du linéaire au non linéaire.

3. Nombres caractéristiques. Le découplage d'un système linéaire peut être caractérisé par des considérations sur l'ordre de ses zéros infinis (cf. Descusse et Dion [10]). De même, l'étude du découplage du système non linéaire de type (I) nécessite tout d'abord le calcul de ce que nous nommons ses *nombres caractéristiques* φ_s $(s = 1, \cdots, r)$.

On note $\mathfrak{L}_f$ la $C^\omega(Q)$-algèbre de Lie des champs de vecteurs associés à la fonction f, élément de $C^\omega(Q)$. Elle est définie par:

$$C \in \mathfrak{L}_f \quad \text{ssi} \quad C \cdot f \equiv 0 \quad \text{avec} f \in C^\omega(Q).$$

Si $L^m_{A^0} h_s$ représente l'itérée m-ième de la dérivée de Lie L_{A^0}, avec $L^0_{A^0} = Id$, φ_s est le nombre entier tel que:

$$\forall l \, A^l \in \bigcap_{0 \leqq m < \varphi_s} \mathfrak{L}_{L^m_{A^0} h_s} \quad \text{et} \quad \exists l \, A^l \cdot L^{\varphi_s}_{A^0} h_s \not\equiv 0$$

où $l = 1, \cdots, d$; $s = 1, \cdots, r$.

Exemple. On prend le système de type (I), défini sur $\mathbb{R}^N$ par:

$$\dot{q} = A^0 + \mathbf{u} A^1, \qquad y = q_1 \tag{7}$$

avec

$$A^0 = q_2 \frac{\partial}{\partial q_1} + \cdots + q_{n+1} \frac{\partial}{\partial q_n} \quad \text{où } 1 \leqq n \leqq N-1,$$

$$A^1 = \frac{\partial}{\partial q_{n+1}}.$$

On a $A^1 \cdot L^m_{A^0} q_1 \equiv 0$ pour $0 \leqq m \leqq n-1$ et $A^1 \cdot L^n_{A^0} q_1 = 1 \not\equiv 0$.

Ainsi, le système (7) a pour nombre caractéristique:

$$\varphi_1 = n.$$

Les nombres caractéristiques jouent un rôle fondamental dans l'étude des systèmes non linéaires de type (I). On les retrouve dans tous les travaux de découplage comme par exemple dans Sinha [34] et Isidori et al. [22]. Ainsi, en vue d'une commande non interactive (partition scalaire de l'entrée et de la sortie, une entrée agissant sur une seule sortie), Porter [30] définit un *index*, noté ici od_s, d'une sortie y_s d'un système de type (I). Cet ordre différentiel donne l'ordre de dérivation minimal de y_s, permettant d'exprimer $y_s^{(od_s)}$ en fonction de l'entrée $\mathbf{u}$ et des dérivées de y_s d'ordre inférieur à od_s. De même, Tokumaru et al. [37] définissent *l'ordre relatif*, noté ici or_s, et qui est utilisé aussi par Hirschorn [19] dans l'étude de l'inversion des systèmes. Le lien entre les quatre nombres φ_s, i_s, od_s et or_s est donné par:

$$i_s = od_s = or_s = \varphi_s + 1.$$

Dans l'étude de l'inversion des systèmes non linéaires, le théorème I.3 de Rebhuhn [31] permet d'énoncer la propriété importante suivante:

PROPOSITION 3[3]. *Les nombres caractéristiques d'un système de type* (I) *sont toujours majorés strictement par la dimension de la variété d'état quand ils sont définis.*

[3] La démonstration simple et directe qui suit est due à une correspondance fructueuse avec Dominique Cerveau.

Preuve. 1. Il est immédiat que si $\boldsymbol{R}$ est un anneau intègre, le $\boldsymbol{R}$-module $\boldsymbol{R}^k$ ($k \in \mathbb{N}^*$) a la propriété que toute suite de $k+1$ éléments est liée. On peut appliquer cela à l'anneau des germes de fonctions analytiques en un point de la variété Q.

2. On va utiliser le résultat précédent pour montrer que pour chaque s ($s = 1, \cdots, r$) les champs des vecteurs A^{l_0}, $(\text{ad } A^0)(A^{l_0}), \cdots, (\text{ad } A^0)^{\varphi_s}(A^{l_0})$, avec A^{l_0} tel que $A^{l_0} \cdot L^{\varphi_s}_{A^0} h_s \not\equiv 0$, sont génériquement indépendants.

Si tel n'était pas le cas, il existerait sur un ouvert des fonctions analytiques $a_0, \cdots, a_{\varphi_s}$ telles que:

$$a_0 A^{l_0} + a_1(\text{ad } A^0)(A^{l_0}) + \cdots + a_{\varphi_s}(\text{ad } A^0)^{\varphi_s}(A^{l_0}) \equiv 0 \text{ les } a_i \text{ n'étant pas tous nuls.}$$

Soit n le plus grand indice tel que $a_i \not\equiv 0$; alors:

$$a_0 A^{l_0} + \cdots + a_n(\text{ad } A^0)^n(A^{l_0}) \equiv 0 \quad \text{et} \quad n \leqq \varphi_s.$$

On applique ce champ de vecteurs à la fonction $L^{\varphi_s - n}_{A^0} h_s$. Or, il est facilement démontrable par récurrence que $(\text{ad } A^0)^n(C)$ est une combinaison linéaire réelle d'éléments de type

$$(A^0)^\nu C (A^0)^\mu \quad \text{où } \nu + \mu = n \quad (\nu \text{ et } \mu \in \mathbb{N})$$

avec un seul terme $C(A^0)^n$.

De ce fait et en tenant compte de la définition de φ_s, on aurait $a_n A^{l_0} \cdot L^{\varphi_s}_{A^0} h_s \equiv 0$, ce qui est exclu. □

Cette propriété permet en particulier de prendre $N-1$ comme borne universelle dans le calcul algorithmique du découplage présenté dans [7].

Si s est tel que φ_s ne soit pas défini, la série génératrice du système (I) restreinte à la sortie y_s ne contient que des termes associés aux mots de $\mathbf{c^*pa^*} \cup \mathbf{a^*}$.

Les résultats qui suivent justifient le nom de nombres caractéristiques que nous avons choisi:

LEMME 1. *Pour un système bouclé de type* (II) *on a*:

(i) *Si φ_s est défini, alors pour tout $i = 1, \cdots, n$:*

$$\hat{A}^i \cdot L^m_{\hat{A}^0} h_s \equiv 0 \quad \textit{avec } 0 \leqq m < \varphi_s \textit{ soit } \hat{A}^i \in \bigcap_{0 \leqq m < \varphi_s} \mathfrak{L}_{L^m_{A^0} h_s}$$

et

$$L^m_{\hat{A}^0} h_s = L^m_{A^0} h_s \quad \textit{avec } 0 \leqq m \leqq \varphi_s,$$

quel que soit le bouclage de type (∗) *utilisé.*

(ii) *Si de plus, la matrice $\Phi = (\beta^i_l)$ ($l = 1, \cdots, d$, $i = 1, \cdots, n$) est inversible, alors φ_s est le nombre caractéristique de la sortie y_s du système bouclé* (II).

(iii) *Si φ_s n'est pas défini alors pour tout entier m*

$$\hat{A}^i \cdot L^m_{\hat{A}^0} h_s \equiv 0 \quad \textit{et} \quad L^m_{\hat{A}^0} h_s = L^m_{A^0} h_s \qquad (i = 1, \cdots, n).$$

Preuve. (i) 1. On montre d'abord par récurrence que

$$L^m_{\hat{A}^0} h_s = L^m_{A^0} h_s \quad \text{pour } 0 \leqq m \leqq \varphi_s.$$

C'est vrai pour $m = 0$ car $L^0_{\hat{A}^0} h_s = L^0_{A^0} h_s = h_s$. Si $L^m_{\hat{A}^0} h_s = L^m_{A^0} h_s$ avec $m < \varphi_s$ on a

$$L^{m+1}_{\hat{A}^0} h_s = \hat{A}^0 \cdot L^m_{\hat{A}^0} h_s = \hat{A}^0 \cdot L^m_{A^0} h_s = L^{m+1}_{A^0} h_s + \sum_{l=1}^{d} \alpha_l A^l \cdot L^m_{A^0} h_s$$

soit

$$L^{m+1}_{\hat{A}^0} h_s = L^{m+1}_{A^0} h_s$$

d'après la définition de φ_s.

2. D'après le paragraphe 1, on a: $\hat{A}^i \cdot L^m_{\hat{A}^0} h_s = \hat{A}^i \cdot L^m_{A^0} h_s$ pour $i = 1, \cdots, n$ et $0 \leqq m < \varphi_s$.

Soit

$$\hat{A}^i \cdot L^m_{\hat{A}^0} h_s = \sum_{l=1}^{d} \beta^i_l A^l \cdot L^m_{A^0} h_s \equiv 0$$

d'après la définition de φ_s.

(ii) Si $\mathbf{\Phi}$ est inversible et si $\forall i \, \hat{A}^i \cdot L^{\varphi_s}_{\hat{A}^0} h_s \equiv 0$ on a $d = n$ et $\sum_{l=1}^{n} \beta^i_l A^l \cdot L^{\varphi_s}_{A^0} h_s \equiv 0$ pour tout $i = 1, \cdots, n$.

En désignant par $\mathbf{\Omega}_s$ la matrice ligne

$$\mathbf{\Omega}_s = (A^1 \cdot L^{\varphi_s}_{A^0} h_s, \cdots, A^n \cdot L^{\varphi_s}_{A^0} h_s)$$

on peut écrire

$$\mathbf{\Omega}_s \cdot \mathbf{\Phi} = 0$$

d'où $\mathbf{\Omega}_s = 0$ ce qui est contradictoire avec la définition de φ_s.

(iii) Immédiat par récurrence. □

4. La plus grande algèbre de découplage. Les algèbres de découplage permettant par les distributions associées de retrouver localement le découplage structurel (cf. Isidori [21]), il convient de déterminer la plus grande algèbre de découplage $\mathfrak{D}^*$ qui existe au moins localement. Si les nombres caractéristiques φ_s $(s = 1, \cdots, r)$ sont définis, elle peut être donnée, comme on va le voir par:

$$\mathfrak{D}^0 = \bigcap_{s=1}^{r} \mathfrak{L}_s \quad \text{avec } \mathfrak{L}_s = \bigcap_{0 \leqq m \leqq \varphi_s} \mathfrak{L}_{L^m_{A^0} h_s}.$$

PROPOSITION 4. *Si les nombres caractéristiques φ_s $(s = 1, \cdots, r)$ du système* (I) *sont tous définis, on a*:

(a) $\mathfrak{D} \subset \mathfrak{D}^0$, *pour tout algèbre de découplage $\mathfrak{D}$ de la sortie y du système* (II) *par rapport à* **p**.

(b) *Une condition nécessaire pour que $\mathfrak{D}$ soit une algèbre de découplage est que*:

$$\mathfrak{D} \cdot g^i_s \equiv 0, \qquad i = 0, \cdots, n, \quad s = 1, \cdots, r$$

où $g^i_s = \hat{A}^i \cdot L^{\varphi_s}_{A^0} h_s$ avec $\hat{A}^i \in \mathscr{A} = \{\hat{A}^0, \cdots, \hat{A}^n\}$.

(c) *Une condition nécessaire et suffisante pour que $\mathfrak{D}^0$ soit une algèbre de découplage du système* (II) *est qu'il existe un bouclage de type* (*) *tel que*:

$$\mathscr{P} \subset \mathfrak{D}^0 \quad \text{et} \quad \mathfrak{D}^0 \cdot g^i_s \equiv 0, \qquad i = 0, \cdots, n, \quad s = 1, \cdots, r.$$

Preuve. (a) On procède par récurrence et on montre que pour tout $s = 1, \cdots, r$,

$$\mathfrak{D} \subset \mathfrak{L}_s.$$

Si $m = 0$, $\mathfrak{L}_{h_s} = \mathfrak{H}_s$ et on sait d'après le théorème 1 que $\mathfrak{D} \subset \mathfrak{H}_s$.

D'autre part, si $\mathfrak{D} \subset \mathfrak{L}_{L^m_{A^0} h_s}$ avec $m < \varphi_s$, comme $[\hat{A}^0, \mathfrak{D}] \subset \mathfrak{D}$ on a, en utilisant le lemme 1,

$$\mathfrak{D} \cdot L^{m+1}_{A^0} h_s = \mathfrak{D} \cdot \hat{A}^0 \cdot L^m_{A^0} h_s = [\mathfrak{D}, \hat{A}^0] \cdot L^m_{A^0} h_s \equiv 0$$

et ainsi

$$\mathfrak{D} \subset \mathfrak{L}_{L^{m+1}_{A^0} h_s}.$$

(b) Si $\mathfrak{D}$ est une algèbre de découplage par rapport à $\mathbf{p}$ de la sortie y du système non initialisé de type (II), on a bien, $\mathfrak{D} \subset \mathfrak{D}^0$ d'après le paragraphe (a) et pour tout $s = 1, \cdots, r$:

$$[\mathfrak{D}, \hat{A}^i] \cdot L_{A^0}^{\varphi_s} h_s \equiv 0 \equiv \mathfrak{D} \cdot g_s^i \quad \text{pour tout } i = 0, \cdots, n.$$

(c) 1. La condition est nécessaire d'après (b) et le théorème 1.

2. Si $\mathscr{P} \subset \mathfrak{D}^0$ et $\mathfrak{D}^0 \cdot g_s^i \equiv 0$, on va montrer que $\mathfrak{D}^0$ est une algèbre de découplage de la sortie y du système (II), par rapport à $\mathbf{p}$. D'après le paragraphe (a), $\mathfrak{D}^0$ sera la plus grande.

Par définition, $\mathfrak{D}^0 \subset \mathfrak{H}$ et de plus, d'après la définition de φ_s, on a pour tout $s = 1, \cdots, r$:

$$[\hat{A}^i, \mathfrak{D}^0] \cdot L_{A^0}^m h_s = -\mathfrak{D}^0 \cdot \hat{A}^i \cdot L_{A^0}^m h_s = -\delta_{\varphi_s}^m \cdot \mathfrak{D}^0 \cdot g_s^i$$

avec $0 \leqq m \leqq \varphi_s$, δ_k^j le symbole de Kronecker et $i = 0, \cdots, n$.

Ainsi, on a bien

$$[\mathscr{A}, \mathfrak{D}^0] \subset \mathfrak{D}^0 \quad \text{et} \quad \mathscr{P} \subset \mathfrak{D}^0 \subset \mathfrak{H}. \qquad \square$$

Dans le cas où le découplage n'est pas total on peut néanmoins, grâce au découplage fini, préciser le lien entre la perturbation $\mathbf{p}$ et les entrées admissibles.

Si une sortie y_s $(s = 1, \cdots, r)$ du système (I), non initialisé, n'est pas découplée totalement par rapport à $\mathbf{p}$. On considère (cf. fin du chapitre 1) l'ordre de découplage fini maximal δ_s auquel y_s est découplée par rapport à $\mathbf{p}$.

LEMME 2. *Soit un système non initialisé de type* (I) *et* y_s $(s = 1, \cdots, r)$ *une de ses sorties découplée à l'ordre fini maximal* δ_s *par rapport à* $\mathbf{p}$. *On a*

(a) *Si* φ_s *est défini, alors*:

(1) *Soit* $\delta_s \leqq \varphi_s$ *et le système bouclé* (II) *a sa sortie* y_s *découplée à l'ordre* δ_s *quel que soit le bouclage de type* (*) *considéré.*

(2) *Soit* $\delta_s > \varphi_s$ *et le système bouclé* (II) *à sa sortie* y_s *au moins découplée, par rapport à* $\mathbf{p}$, *à un ordre supérieur ou égal à* $\varphi_s + 1$, *quel que soit le bouclage de type* (*) *considéré.*

(3) *Soit* $\delta_s > \varphi_s$ *et une condition nécessaire et suffisante pour que la sortie* y_s *du système* (II) *soit découplée, par rapport à* $\mathbf{p}$, *à un ordre supérieur ou égal à* $\varphi_s + 1 + \mu$ $(\mu \geqq 1)$ *est qu'il existe un bouclage de type* (*) *tel que*:

$$W \cdot g_s^i \equiv 0 \quad \textit{pour tout } \mathbf{w} \in (\mathbf{c}^*\mathbf{p}\mathbf{c}^*)_\mu \textit{ avec } \mu \geqq 1,$$

où

$$g_s^i = \hat{A}^i \cdot L_{A^0}^{\varphi_s} h_s \qquad (i = 0, \cdots, n).$$

(b) *Si* φ_s *n'est pas défini, alors quel que soit le bouclage de type* (*) *utilisé, le système bouclé* (II) *a sa sortie* y_s *découplée à l'ordre maximal* δ_s *par rapport à* $\mathbf{p}$ *et* $\delta_s < N$.

Preuve. (a) φ_s étant défini, on sait d'après le lemme 1 que:

$$\hat{A}^i \cdot L_{\hat{A}^0}^m h_s \equiv 0 \quad \text{si } 0 \leqq m < \varphi_s \text{ avec } i = 1, \cdots, n$$

et

$$L_{\hat{A}^0}^m h_s = L_{A^0}^m h_s \quad \text{si } 0 \leqq m \leqq \varphi_s.$$

1. Si $\delta_s \leqq \varphi_s$, d'après les considérations ci-dessus, on voit que quel que soit le bouclage de type (*), le système bouclé (II) a sa sortie y_s découplée par rapport à $\mathbf{p}$ à l'ordre maximal δ_s puisque $\mathscr{P} \cdot L_{\hat{A}^0}^{\delta_s} h_s = \mathscr{P} \cdot L_{A^0}^{\delta_s} h_s$ n'est pas nul.

2. Si $\delta_s > \varphi_s$, $\mathscr{P} \cdot L_{A^0}^m h_s = \mathscr{P} \cdot L_{A^0}^m h_s \equiv 0$ pour $0 \leqq m \leqq \varphi_s$ et comme $\hat{A}^i \cdot L_{A^0}^m h_s \equiv 0$ pour $0 \leqq m < \varphi_s$ $(i = 1, \cdots, n)$ on a $W \cdot \hat{A}^i \cdot L_{A^0}^m h_s \equiv 0$ pour $\mathbf{w} \in \mathbf{c}^*\mathbf{pc}^*$.

Ainsi, quel que soit le bouclage de type (*) la sortie y_s du système (II) est découplée, par rapport à $\mathbf{p}$, à un ordre fini $\mu \geqq \varphi_s + 1$.

3. D'après le paragraphe 2 seuls sont à considérer les mots $\mathbf{w} = \mathbf{w}_1 \cdot \mathbf{w}_2$ avec $\mathbf{w}_1 \in (\mathbf{c}^*\mathbf{pc}^*)_\mu$ et $\mathbf{w}_2 \in \mathbf{a}^*$, $\mathbf{w}_2$ étant de longueur $\varphi_s + 1$. La conclusion vient alors aisément du Lemme 1 et de la définition des fonctions g_s^i.

(b) Evident d'après le lemme 1 et puisque $\mathscr{P} \cdot L_{\hat{A}^0}^{\delta_s} h_s = \mathscr{P} \cdot L_{A^0}^{\delta_s} h_s$ n'est pas nul.

D'autre, part, l'inégalité $\delta_s < N$ se démontre comme dans la proposition 3 car: $\delta_s = 0$ ou alors, $\delta_s \geqq 1$ et $\delta_s = \sup \{n | \forall m (m < n \Rightarrow \forall j P^j \cdot L_{A^0}^m h_s \equiv 0);$ $j = 1, \cdots, k\}$. □

Les résultats de ce chapitre vont nous permettre de proposer maintenant une méthode de découplage.

5. Méthode de découplage. Les égalités $\hat{A}^i \cdot L_{A^0}^{\varphi_s} h_s = g_s^i$ $(i = 0, \cdots, n,\ s = 1, \cdots, r)$ avec $\hat{A}^i \in \mathscr{A}$ sont équivalentes au système d'équations suivant:

$$(**) \qquad \mathbf{\Omega} \cdot \mathbf{\Delta} = \mathbf{\Gamma}^0; \qquad \mathbf{\Omega} \cdot \mathbf{\Phi} = \mathbf{\Gamma}^1$$

où $\mathbf{\Omega}, \mathbf{\Delta}, \mathbf{\Phi}, \mathbf{\Gamma}^0, \mathbf{\Gamma}^1$ sont des matrices respectivement éléments de ${}^r(C^\omega(Q))^d$, ${}^d(C^\omega(Q))^1$, ${}^d(C^\omega(Q))^n$, ${}^r(C^\omega(Q))^1$ et ${}^r(C^\omega(Q))^n$ avec

$$\mathbf{\Omega}_s^l = A^l \cdot L_{A^0}^{\varphi_s} h_s, \qquad \mathbf{\Delta}_l = \alpha_l, \qquad \mathbf{\Phi}_l^i = \beta_l^i,$$

$$\mathbf{\Gamma}_s^0 = g_s^0 - L_{A^0}^{\varphi_s + 1} h_s \quad \text{et} \quad \mathbf{\Gamma}_s^{1i} = g_s^i$$

avec $s = 1, \cdots, r$ et $i = 1, \cdots, n$.

Il s'agit donc de "forcer" le système (**) à avoir des solutions avec les g_s^i tels que $\mathfrak{D} \cdot g_s^i \equiv 0$ $(i = 0, \cdots, n;\ s = 1, \cdots, r)$ où $\mathfrak{D}$ est une algèbre de découplage.

Les bouclages de type (*) que nous rappelons:

$$(*) \qquad \begin{aligned} \mathbf{u}_l(t) &= \alpha_l(q) + \sum_{i=1}^{n} \beta_l^i(q) \mathbf{a}_i(t) \quad \text{avec } l = 1, \cdots, d, \\ \mathbf{p}_j(t) &= \mathbf{p}_j(t) \quad \text{avec } j = 1, \cdots, k \end{aligned}$$

assurant alors un découplage du système (II) avec l'algèbre de Lie $\mathfrak{D}_h^{\mathbf{a}}$ correspondante.

Notons que la matrice $\mathbf{\Omega}$ n'a pas en général un rang constant sur toute la variété Q et les solutions ont un caractère local (cf. Hirschorn [20]).

THEOREM 2. *Soit un système de type* (I) *pour lequel on souhaite voir sa sortie y indépendante de la perturbation* $\mathbf{p}$ *grâce à l'utilisation des bouclages de type* (*). *Alors*:

(A) *Soit s tel que le nombre caractéristique* φ_s *ne soit pas défini, on a*:

1. *Si* δ_s $(\delta_s < N)$ *est l'ordre maximum de découplage fini de la sortie* y_s *du système* (I) *par rapport à* $\mathbf{p}$, *la sortie* y_s *du système bouclé* (II) *reste découplée à l'ordre maximum* δ_s *par rapport à* $\mathbf{p}$ *et ceci quel que soit le bouclage de type* (*) *utilisé.*

2. *Si la sortie* y_s *du système* (I) *est découplée totalement par rapport à* $\mathbf{p}$, *il en est de même dans le système bouclé, quel que soit le bouclage et la plus grande algèbre de découplage est* $\mathfrak{D}_{h_s}^{\mathbf{a}}$, *où ici*:

$$C \in \mathfrak{D}_{h_s}^{\mathbf{a}} \quad ssi \quad \forall m \geqq 0 \quad C \cdot L_{A^0}^m h_s \equiv 0.$$

(B) *Soit s tel que le nombre caractéristique* φ_s *soit défini mais avec* $\mathscr{P} \not\subset \mathfrak{L}_s$. *La sortie* y_s *est alors découplée à un ordre maximal* $\delta_s \leqq \varphi_s$ *indépendamment du bouclage choisi.*

(C) *Les nombres caractéristiques* φ_s $(s = 1, \cdots, r)$ *sont définis et* $\mathscr{P} \subset \mathfrak{D}^0$.

1. Chaque sortie y_s du système (I) est alors découplée à l'ordre φ_s+1 par rapport à $\mathbf{p}$ et chaque bouclage de type (*) assure un découplage de y_s au moins à l'ordre φ_s+1 par rapport à $\mathbf{p}$.

2. Les relations de compatibilité que doivent satisfaire les g_s^i sont mises en évidence en abordant la résolution du système (**) par mise sous forme triangulaire de $\mathbf{\Omega}$ en se plaçant dans l'anneau intégre $C^\omega(Q)$.

Les bouclages de type (*) cherchés et les fonctions g_s^i correspondantes doivent aussi vérifier:

$$\mathscr{P}\cdot g_s^i=0, \qquad i=0,\cdots,n, \quad s=1,\cdots,r,$$

et

$$\mathscr{P}\cdot(\mathbf{\Omega}\cdot\mathbf{\Delta})=\mathbf{\Gamma}^2, \qquad \mathscr{P}\cdot(\mathbf{\Omega}\cdot\mathbf{\Phi})=0$$

avec Γ^2 une matrice de ${}^r(C^\omega(Q))^1$ définie par

$$\mathbf{\Gamma}_s^2=-\mathscr{P}\cdot L_{A^0}^{\varphi_s+1}h_s, \qquad s=1,\cdots,r.$$

3. Si on peut résoudre le système (**) en prenant pour les g_s^i $(i=0,\cdots,n;\ s=1,\cdots,r)$ des fonctions de la $\mathbb{R}$-algèbre $\mathscr{G}$ des fonctions analytiques sur Q, définie comme suit:

$$g\in\mathscr{G} \quad \text{ssi} \quad \exists\tilde{g}\in C^\omega(\mathbb{R}^\eta) \quad \text{avec } \eta=r+\sum_{s=1}^{r}\varphi_s,$$

et

$$g(q)=\tilde{g}(h_1(q),\cdots,L_{A^0}^{\varphi_1}h_1(q),\cdots,h_r(q),\cdots,L_{A^0}^{\varphi_r}h_r(q)),$$

alors toute solution donne un bouclage permettant de découpler totalement y par rapport à $\mathbf{p}$, avec pour algèbre de découplage $\mathfrak{D}^0$, la plus grande des algèbres de découplage possibles.

Preuve. Immédiat d'après les résultats précédents. □

Remarque 1. En prenant g_s^0 nul et g_s^i $(i=1,\cdots,n)$ constant, on a bien $\mathfrak{D}^0(g_s^i)=0$ $(i=0,\cdots,n;\ s=1,\cdots,r)$ et on retrouve les résultats d'Isidori et al. [22]. Cependant, en prenant l'exemple donné dans [4], on voit que cette classe de bouclages est par trop restreinte. En effet, on considère le système défini sur $\mathbb{R}^2$ par:

$$\begin{aligned}\dot{q}_1(t)&=(\mathbf{u}(t)+\mathbf{p}(t))q_1(t),\\ \dot{q}_2(t)&=-\mathbf{p}(t)q_2(t),\\ y(t)&=q_1q_2.\end{aligned}\tag{8}$$

On a

$$A^0=0, \quad A^1=q_1\frac{\partial}{\partial q_1}, \quad P^1=q_1\frac{\partial}{\partial q_1}-q_2\frac{\partial}{\partial q_2}, \quad h(q)=q_1q_2.$$

Une intégration élémentaire montre que le système est totalement découplé par rapport à $\mathbf{p}$ et ainsi la classe des bouclages $\mathbf{u}=\alpha+\beta\mathbf{a}$ donnant le découplage de y par rapport à $\mathbf{p}$ doit contenir le bouclage $\mathbf{u}=\mathbf{a}$!

Le nombre caractéristique φ est égal à 0 car $A^1\cdot h\not\equiv 0$ et ainsi $\mathfrak{D}^0=\mathfrak{H}$. On a $P^1\in\mathfrak{H}\cdot\mathfrak{H}$ est engendré par P^1 et les fonctions g^i $(i=0,1)$ vérifiant $\mathfrak{H}(g^i)\equiv 0$ sont les fonctions analytiques du genre $\tilde{g}\circ h$ avec $\tilde{g}\in C^\omega(\mathbb{R})$.

Les bouclages donnant un découplage sont donc solution de $\mathbf{\Omega}\cdot\mathbf{\Delta}=(g^0)$ et $\mathbf{\Omega}\cdot\mathbf{\Phi}=(g^1)$ avec $\mathbf{\Omega}=(h)$ soit $\alpha=g^0/h$ et $\beta=g^1/h$.

On voit ainsi que c'est le bouclage déterminé par $g^0 = 0$ et $g^1 = h$ qui redonne le système initial.

Remarque 2. Dans le cas de perturbations mesurables on peut compléter les lois de bouclages de type (*) en posant

$$\mathbf{u}_l = \alpha_l + \sum_{i=1}^{n} \beta_l^i \mathbf{a}_i + \sum_{j=1}^{k} \gamma_l^j \mathbf{p}_j \qquad (l = 1, \cdots, d).$$

Le système (I) bouclé s'écrit alors:

$$\begin{aligned} \dot{q} &= \hat{A}^0 + \sum_{i=1}^{n} \mathbf{a}_i \hat{A}^i + \sum_{j=1}^{k} \mathbf{p}_j \hat{P}^j, \\ y &= h(q), \end{aligned} \tag{9}$$

avec

$$\hat{P}^j = P^j + \sum_{l=1}^{d} \gamma_l^j A^l \qquad (j = 1, \cdots, k).$$

Les fonctions γ_l^j, éléments de $C^\omega(Q)$, sont destinées à permettre aux perturbations $\hat{P}^j$ $(j = 1, \cdots, k)$ de vérifier la condition $\hat{P}^j \in \mathfrak{D}^0$.

On peut voir en [6] une application de ceci à l'étude du rejet de perturbations dans un modèle non linéaire de colonne à distiller proposé par Gauthier et al. [16].

6. Immersion et découplage. Pour des raisons supplémentaires de calcul par l'algorithme introduit en [7] et complété par l'algorithme rapide de Kasinski et Lévine [23] explicité en [17], nous nous intéressons plus spécialement aux bouclages liés à l'algèbre $\mathfrak{D}^0$.

Nous allons maintenant indiquer ce que devient le système (II) quand $\mathfrak{D}^0$ est une algèbre de découplage. Nous donnons le dernier outil qui nous sera nécessaire: *l'immersion* (cf. Fliess [12] et Fliess et Kupka [14]). L'immersion a pour but de préciser la notion de même comportement entrée-sortie, notion qui ne vas pas de soi en non linéaire. On peut déjà voir à travers divers travaux récents, comme la linéarisation (cf. Claude, Fliess et Isidori [8] en temps continu et Monaco et Normand-Cyrot [26] en temps discret) et le préprocesseur (Monaco [25]), que l'immersion apparaît comme un concept bien utile en théorie des systèmes.

Soient Σ et Σ' deux systèmes de type (II) ayant comme espaces d'état respectifs Q et Q' et comme fonctions de sorties h et h'.

DÉFINITION. Une immersion de Σ dans Σ' est une application analytique $\tau: Q \to Q'$ telle que Σ et Σ', respectivement initialisés en q et $q' = \tau(q)$, aient même série génératrice et que $h(q_1) \neq h(q_2) \Rightarrow h'(\tau(q_1)) \neq h'(\tau(q_2))$.

Le théorème suivant précise et étend les résultats de Porter [30] et généralise les résultats sur l'immersion par bouclage dans un système linéaire (cf. [8]).

THÉORÈME 3. *Si les nombres caractéristiques* φ_s $(s = 1, \cdots, r)$ *du système* (I) *existent, si* $\mathscr{P} \subset \mathfrak{D}^0$ *et si le système* (**) *admet des solutions avec* Φ *inversible et les fonctions* g_s^i $(i = 0, \cdots, n)$ *éléments de* $\mathscr{G}$, *alors les bouclages de type* (*) *correspondants permettent, par l'application*

$$\tau: Q \to \mathbb{R}^\eta \quad \text{avec } \eta = r + \sum_{s=1}^{r} \varphi_s$$

et

$$\tau(q) = (h_1(q), \cdots, L_{A^0}^{\varphi_1} h_1(q), \cdots, h_r(q), \cdots, L_{A^0}^{\varphi_r} h_r(q)),$$

d'immerger le système bouclé (II) *dans le système* Λ *défini par*:

$$\Lambda \qquad s=1,\cdots,r \quad \begin{cases} \dot{x}_s^m = x_s^{m+1}, & 0 \leqq m < \varphi_s, \\ \dot{x}_s^{\varphi_s} = \tilde{g}_s^0 + \sum_{i=1}^{n} \tilde{g}_s^i \mathbf{a}_i, \\ z_s = x_s^0, \end{cases}$$

où $\tilde{g}_s^i$ *est une fonction analytique sur* $\mathbb{R}^\eta$ *associée à* g_s^i *par* $g_s^i = \tilde{g}_s^i \circ \tau$.

Preuve. L'application τ est bien analytique et nous allons montrer que la série génératrice du système bouclé (II), initialisé en $q(0)$, est identique à celle du système Λ initialisé en $\tau(q(0))$.

Le système (II) ayant sa sortie y découplée par rapport à $\mathbf{p}$, chaque série génératrice $\mathfrak{h}_s$ $(s=1,\cdots,r)$ est telle que

$$\operatorname{supp} \mathfrak{h}_s \subset \mathbf{a}^*$$

avec $\mathbf{a}^*$, le monoïde engendré par l'alphabet $\mathbf{a}=\{\mathbf{a}_0, \mathbf{a}_1, \cdots, \mathbf{a}_n\}$. D'autre part, le système Λ peut s'écrire:

$$\dot{x} = B^0 + \sum_{i=1}^{n} \mathbf{a}_i B^i, \qquad z = f(x) \tag{10}$$

avec $z=(z_1,\cdots,z_r)$; $f=(f_1,\cdots,f_r)$ et $z_s = f_s(x) = x_s^0$ $(s=1,\cdots,r)$;

où

$$B^0 = \sum_{s=1}^{r} \left(\sum_{m=0}^{\varphi_s - 1} x_s^{m+1} \frac{\partial}{\partial x_s^m} + \tilde{g}_s^0 \frac{\partial}{\partial x_s^{\varphi_s}} \right)$$

et

$$B^i = \sum_{s=1}^{r} \tilde{g}_s^i \frac{\partial}{\partial x_s^{\varphi_s}}$$

(étant entendu que le terme $\sum_{m=0}^{\varphi_s - 1}$ disparaît quand $\varphi_s = 0$).

Un calcul élémentaire montre que $L_{B^0}^m f_s = x_s^m$ pour $0 \leqq m \leqq \varphi_s$ et que $B^i \cdot L_{B^0}^{\varphi_s} f_s = \tilde{g}_s^i$ avec $i=0,\cdots,n$ et $s=1,\cdots,r$.

Ainsi, comme Φ est inversible, les nombres φ_s $(s=1,\cdots,r)$ sont aussi les nombres caractéristiques du système Λ.

De plus, si

$$\tilde{\mathfrak{L}}_s = \bigcap_{0 \leqq m \leqq \varphi_s} \mathfrak{L}_{L_{B^0}^m f_s}$$

on a

$$\tilde{\mathfrak{D}}^0 = \bigcap_{s=1}^{r} \tilde{\mathfrak{L}}_s = \{0\}.$$

Comme $g_s^i \in \mathcal{G}$ $(s=1,\cdots,r,\ i=0,\cdots,n)$, il est clair que $\mathcal{G}$ est stable pour les dérivations de $\mathcal{A}=\{\hat{A}^0,\cdots,\hat{A}^n\}$.

De plus, on a pour $i=0,\cdots,n$:

$$\hat{A}^i \cdot L_{A^0}^m h_s = B^i \cdot x_s^m \circ \tau \quad \text{avec } 0 \leqq m \leqq \varphi_s.$$

Ainsi, si $g \in \mathcal{G}$ on a pour tout $i=0,\cdots,n$

$$\hat{A}^i \cdot g = B^i \cdot \tilde{g} \circ \tau$$

ou, encore, quel que soit $q(0)$ et pour tout $i=0,\cdots,n$

$$\hat{A}^i \cdot g|q(0) = B^i \cdot \tilde{g}|\tau(q(0)).$$

On trouve donc bien pour tout $s=1,\cdots,r$ et pour toute initialisation $q(0)$:

$$h_s|q(0) = f_s|\tau(q(0))$$

$$\text{et si } w \in \mathbf{a}^*,\ W\cdot h_s = W\cdot f_s \circ \tau$$

le premier membre de l'égalité étant relatif au système (II) et le second au système Λ.

Ainsi on a, quel que soit $q(0)$

$$\mathfrak{h}_s|q(0) = \mathfrak{f}_s|\tau(q(0)) \qquad (s=1,\cdots,r)$$

($\mathfrak{f}_s$ désignant la série génératrice du système Λ de sortie z_s), et τ est bien une immersion du système (II) dans le système Λ. □

Cette méthode a été utilisée aussi bien pour le calcul de lois de commande pour le pilotage d'un hélicoptère[4] qu'en neuro-endocrinologie [9].

ON AN ALGORITHM FOR OPTIMAL CONTROL USING PONTRYAGIN'S MAXIMUM PRINCIPLE*

JOSEPH FRÉDÉRIC BONNANS†

Abstract. Y. Sakawa and Y. Shindo recently proposed an algorithm to solve open-loop optimal control problems, using Pontryagin's maximum principle. It is established here that, under some hypothesis, the algorithm is well-defined and globally converges in some weak sense. When the stepsize of the algorithm tends to zero, the displacements are equivalent to those of a gradient with projection method. If the control enters in a linear way in the state equation and in a quadratic way in the criterion, the algorithm can be interpreted as a gradient plus projection method in some new metric.

Key words. optimal control, optimization algorithms, Pontryagin's principle

AMS(MOS) subject classifications. 49D99, 93C10

1. Introduction. We are concerned with the open-loop optimal control of a system governed by an ordinary differential equation. We assume that there are no state constraints and that the control constraints are local with respect to the time. Y. Sakawa and Y. Shindo [4] proposed the following iterative algorithm: a control and its state being given, compute the associated costate, then compute simultaneously a new control and a new state such that the state equation holds and that, at each time, the new control minimizes some function. This function is the sum of the Hamiltonian and of a quadratic term penalizing the difference between the new and the old controls. It is proved in [4] that, under some hypothesis, the sequence of the criterion decreases and that, if a subsequence of the controls converges a.e. towards some control $\bar{u}$, then $\bar{u}$ satisfies the first-order necessary optimality conditions.

We obtain here the following results:

- Under some regularity hypothesis, the algorithm is well-defined.
- the norm of the projected gradients of the controls computed by the algorithm tends towards zero. If the problem is convex, we deduce from it the weak convergence towards some optimal control.
- If the step size tends towards zero, the controls computed by the algorithm are equivalent in some way to those computed by a gradient plus projection method.
- If the control enters in a linear way in the state equation and in a quadratic way in the criterion, the algorithm reduces to some gradient plus projection method in some new metric.

2. Definition and well-posedness of the algorithm. We consider the following system:

$$\begin{aligned} &\frac{dy}{dt}(t) = f(y(t), u(t), t), \quad \text{a.e. } t \in (0, T), \\ &y(0) = 0; \end{aligned} \tag{2.1}$$

with $T > 0$ given, $y(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^p$. We will denote y_u the solution of (2.1). To this system is associated the following criterion

$$J(u) = \int_0^T 1(y_u(t), u(t), t)\, dt + g(y_u(T)). \tag{2.2}$$

* Received by the editors January 24, 1984, and in revised form February 14, 1985.
† INRIA, Domaine de Voluceau, BP 105-Rocquencourt, 78153 Le Chesnay Cedex, France.

Let $\mathcal{U}_{ad}$ be a closed, bounded, convex subset of $\mathbb{R}^p$. The control problem is

$$\begin{aligned} &\text{Min } J(u), \\ &u(t) \in \mathcal{U}_{ad}, \quad \text{a.e. } t \in (0, T). \end{aligned} \tag{2.3}$$

A control u is said to be admissible if $u(t) \in \mathcal{U}_{ad}$, a.e. $t \in (0, T)$ and $J(u)$ makes sense.

The Hamiltonian of the problem is

$$\begin{aligned} &H: \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}, \\ &(y, u, p, t) \to 1(y, u, t) + (p, f(y, u, t)). \end{aligned} \tag{2.4}$$

The costate equation can be written as

$$\begin{aligned} &-\frac{dp}{dt} = \frac{\partial H}{\partial y}(y_u(t), u(t), p(t), t), \quad \text{a.e. } t \in (0, T), \\ &p(T) = \frac{\partial g}{\partial y}(y_u(T)). \end{aligned} \tag{2.5}$$

We denote by $\|\cdot\|$ the Euclidean norm. Define the augmented Hamiltonian

$$\begin{aligned} &K_\varepsilon: \mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^p \times \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}, \\ &(y, u, v, p, t) \to H(y, u, p, t) + \frac{1}{2\varepsilon}\|u - v\|^2. \end{aligned} \tag{2.6}$$

Here is the algorithm proposed by Y. Sakawa and Y. Shindo [4]:

ALGORITHM 1.

0) Let some admissible control $u^0(t)$ and a sequence $\{\varepsilon^k\}$ of positive numbers be given. Set $k = 0$. Compute y^0, the state associated to u^0.
1) Compute the costate associated to $u^k(t)$.
2) $k = k+1$. Compute u^k, y^k such that y^k is the state corresponding to u^k and

$$K_{\varepsilon^k}(y^k, u^k, u^{k-1}, p^{k-1}, t) \leqq K_{\varepsilon^k}(y^k, u, u^{k-1}, p^{k-1}, t) \quad \forall u \in \mathcal{U}_{ad}, \text{ a.e. } t \in (0, T).$$

3) Stop if some convergence test is satisfied. Otherwise, go to 1.

We now state the hypotheses made on f, 1, g:

(2.7) f is twice continuously differentiable.

(2.8) There exists $C_1 > 0$ such that u admissible $\Rightarrow \|y_u(t)\| < C_1 \forall t \in [0, T]$.

(2.9) $1, \dfrac{\partial 1}{\partial y}, \dfrac{\partial 1}{\partial u}, \dfrac{\partial^2 1}{\partial y^2}, \dfrac{\partial^2 1}{\partial y\, \partial u}$ are continuous on $\mathbb{R}^n \times \mathbb{R}^p \times [0, T]$.

(2.10) There exists $\mu > 0$ such that, C_1 being the constant in (2.8):

$$\|z\| < C_1$$

implies that the mapping

$$u \to 1(z, u, t) + \mu\|u\|^2$$

is convex for any t in $[0, T]$.

(2.11) g is twice continuously differentiable from $\mathbb{R}^n$ onto $\mathbb{R}$.

Remark 2.1. These hypotheses are less restrictive than those of [4] in which g is null and $\partial^2 H/\partial u^2$ is supposed to exist and to be a positive matrix.

We note that (see Sakawa and Shindo [4]) (2.8) holds if

$$\begin{aligned} &\exists C_2 > 0 \quad \text{such that} \\ &\|f(y, u, t)\| \leqq C_2(1+\|y\|) \quad \forall (y, u) \in \mathbb{R}^n \times \mathcal{U}_{\text{ad}}. \end{aligned} \tag{2.12}$$

We now give a mathematical sense to (2.1)-(2.5). As $\mathcal{U}_{\text{ad}}$ is bounded, (2.1), (2.7) and (2.8) imply that y is in

$$Y = \left\{ y \in L^\infty(0, T, \mathbb{R}^n); \frac{dy}{dt} \in L^\infty(0, T, \mathbb{R}^n) \right\}.$$

As $Y \subset \mathscr{C}(0, T, \mathbb{R}^n)$, the initial condition of (2.1) makes sense. So also does the criterion. We easily check that if y_u exists, (2.5) has a unique solution p_u in Y and that there exists $\delta > 0$ such that, for any admissible u:

$$\|y_u(t)\| < \delta, \qquad \|p_u(t)\| < \delta \quad \forall t \in [0, T].$$

We denote

$$E = \{(z, q) \in \mathbb{R}^n \times \mathbb{R}^n; \|z\| < \delta \text{ and } \|q\| < \delta\}.$$

THEOREM 2.1. *Under hypotheses* (2.7) *to* (2.11), *there exists* $\varepsilon_0 > 0$ *such that, if* $\varepsilon^k < \varepsilon_0$, *for all* $k = 1, 2, \cdots$, *Algorithm* 1 *defines a uniquely defined sequence* $\{u^k\}$ *of admissible controls.*

Before proving the theorem, we first give:

LEMMA 2.1. *Let* $t \in [0, T]$ *be given. Define the* (*a priori multivalued*) *mapping*

$$\begin{aligned} &E \times \mathcal{U}_{\text{ad}} \times [0, \mathrm{T}] \to \mathbb{R}^p, \\ &u_\varepsilon : (z, q, v, t) \to u_\varepsilon(z, q, v, t). \end{aligned}$$

defined by

$$\begin{aligned} &u_\varepsilon \in \mathcal{U}_{\text{ad}}, \\ &K_\varepsilon(z, u_\varepsilon, v, q, t) \leqq K_\varepsilon(z, u, v, q, t) \quad \forall u \in \mathcal{U}_{\text{ad}}. \end{aligned} \tag{2.13}$$

Under hypotheses (2.7) *to* (2.10), *there exist* $\varepsilon_0 > 0$ *and* $\alpha > 0$ *independent of* t, *such that, if* $\varepsilon < \varepsilon_0$, *problem* (2.13) *has a unique solution* u_ε *continuous with respect to* t *such that*:

$$\|u_\varepsilon(z_2, q_2, v_2, t) - u_\varepsilon(z_1, q_1, v_1, t)\| \leqq \alpha(\|z_2 - z_1\| + \|q_2 - q_1\| + \|v_2 - v_1\|). \tag{2.14}$$

Proof of Lemma 2.1. From (2.7), (2.9) and (2.10) we deduce the existence of $C_2 > 0$ such that, for any $(z, q) \in E$, $t \in [0, T]$, $v, u_1, u_2 \in \mathcal{U}_{\text{ad}}$:

$$\begin{aligned} K_\varepsilon(z, u_2, v, q, t) \geqq K_\varepsilon(z, u_1, v, q, t) + \left(\frac{\partial K_\varepsilon}{\partial u}(z, u_1, v, q, t), u_2 - u_1 \right) \\ + \left(\frac{1}{2\varepsilon} - C_2 \right) \|u_2 - u_1\|^2. \end{aligned} \tag{2.15}$$

Consequently, if $\varepsilon < 1/2C_2$, K_ε is strictly convex with respect to u: this implies that (2.13) then has a unique solution. From now on we suppose that $\varepsilon < \varepsilon_0$, with $\varepsilon_0 < 1/2C_2$.

From (2.15) we deduce that

$$\left(\frac{\partial K_\varepsilon}{\partial u}(z, u_2, v, q, t) - \frac{\partial K_\varepsilon}{\partial u}(z, u_1, v, q, t), u_2 - u_1 \right) \geqq \left(\frac{1}{\varepsilon} - 2C_2 \right) \|u_2 - u_1\|^2. \tag{2.16}$$

We write the first order optimality condition of (2.13):

$$\left(\frac{\partial K_\varepsilon}{\partial u}(z, u_\varepsilon, v, q, t), u - u_\varepsilon\right) \geqq 0 \quad \forall u \in \mathcal{U}_{\text{ad}}. \tag{2.17}$$

For $i = 1, 2$, take z_i, q_i, v_i in $E \times E \times \mathcal{U}_{\text{ad}}$ and denote $u_i = u_\varepsilon(z_i, q_i, v_i, t)$. The above inequality implies

$$\left(\frac{\partial K_\varepsilon}{\partial u}(z_i, u_i, v_i, q_i, t), u_{3-i} - u_i\right) \geqq 0, \qquad i = 1, 2.$$

Adding the inequalities for $i = 1, 2$, we get

$$\left(\frac{\partial K_\varepsilon}{\partial u}(z_2, u_2, v_2, q_2, t) - \frac{\partial K_\varepsilon}{\partial u}(z_1, u_1, v_1, q_1, t), u_2 - u_1\right) \leqq 0,$$

or equivalently

$$\left(\frac{\partial K_\varepsilon}{\partial u}(z_2, u_2, v_2, q_2, t) - \frac{\partial K_\varepsilon}{\partial u}(z_2, u_1, v_2, q_2, t), u_2 - u_1\right)$$
$$\leqq \frac{\partial K_\varepsilon}{\partial u}(z_1, u_1, v_1, q_1, t) - \frac{\partial K_\varepsilon}{\partial u}(z_2, u_1, v_2, q_2, t), u_2 - u_1.$$

Using (2.16) and arranging the right-side member, we get

$$\left(\frac{1}{\varepsilon} - 2C_2\right)\|u_2 - u_1\|^2 \leqq \frac{1}{\varepsilon}(v_2 - v_1, u_2 - u_1)$$
$$+ \left(\frac{\partial H}{\partial u}(z_1, u_1, q_1, t) - \frac{\partial H}{\partial u}(z_2, u_1, q_2, t), u_2 - u_1\right).$$

This implies

$$(1 - 2C_2\varepsilon)\|u_2 - u_1\| \leqq \|v_2 - v_1\| + \varepsilon\left\|\frac{\partial H}{\partial u}(z_1, u_1, q_1, t) - \frac{\partial H}{\partial u}(z_2, u_1, q_2, t)\right\|.$$

Hypotheses (2.7), (2.11) imply that $\partial H/\partial u$ is continuously differentiable with respect to (z, q) in E. This implies that for some $C_3 > 0$ independent of $t \in [0, T]$, we have:

$$(1 - 2C_1\varepsilon)\|u_2 - u_1\| \leqq \|v_2 - v_1\| + C_3(\|z_2 - z_1\| + \|q_2 - q_1\|).$$

This proves (2.14). The continuity with respect to t of u_ε is a consequence of the continuity of $\partial K_\varepsilon/\partial u$ with respect to t and of the sufficiency of the optimality condition (2.17) for $\varepsilon < \varepsilon_0$. □

Proof of Theorem 2.1. Let us define

$$\phi: \mathbb{R}^n \times [0, T] \to \mathbb{R}^n,$$
$$\phi(z, t) = f(x, u_\varepsilon(z, p(t), u^0(t), t), t).$$

Then as $\|p(t)\| < \delta$ and $u^0(t)$ is in $\mathcal{U}_{\text{ad}}$ a.e. $t \in [0, T]$, Lemma 2.1 implies that ϕ is Lipschitzian with respect to z in any bounded neighbourhood $\mathcal{U}$ of 0 in $\mathbb{R}^n$, the Lipschitz constant being independent of t, and uniformly bounded in $\mathcal{U}$. The mapping ϕ is obviously measurable. Then by a theorem of Caratheodory (see [7]) the differential equation

$$\frac{dz}{dt} = \phi(z, t), \qquad t \in [0, T], \qquad z(0) = 0,$$

admits a unique solution for $t \in [0, t_0]$ for some $t_0 > 0$. But condition (2.8) implies that $z(t)$ remain uniformly bounded. This implies that the equation above has a unique solution in $[0, T]$. As $z = y^1$ and $u_\varepsilon(z(t), p(t), u^0(t), t) = u^1$, this proves that u^1 is uniquely defined, and so is u^k by recurrence. □

3. Convergence of the algorithm. This paragraph studies the asymptotic behaviour of the sequences generated by the algorithm. We first state a result similar to one of [4].

THEOREM 3.1. *Under hypotheses* (2.7) *to* (2.11), *there exists* $\alpha > 0$ *such that any sequence generated by the algorithm satisfies*

$$J(u^k) - J(u^{k-1}) \leqq -\left(\frac{1}{\varepsilon^k} - \alpha\right) \|u^k - u^{k-1}\|^2_{L^2(0,T,\mathbb{R}^p)}. \tag{3.1}$$

Proof. We drop the variable t when there is no ambiguity. The decrease of the criterion can be written as

$$\begin{aligned} J(u^k) - J(u^{k-1}) = \int_0^T & [H(y^k, u^k, p^{k-1}, t) - H(y^{k-1}, u^{k-1}, p^{k-1}, t) \\ & - (p^{k-1}, f(y^k, u^k, t) - f(y^{k-1}, u^{k-1}, t))]\, dt \\ & + g(y^k(T)) - g(y^{k-1}(T)). \end{aligned}$$

Define

$$\delta y^k = y^k - y^{k-1}, \qquad \delta u^k = u^k - u^{k-1}.$$

Then, with (2.1):

$$\begin{aligned} J(u^k) - J(u^{k-1}) = & \int_0^T \left[H(y^k, u^k, p^{k-1}, t) - H(y^{k-1}, u^{k-1}, p^{k-1}, t) - \left(p^{k-1}, \frac{d}{dt}(\delta y^k)\right)\right] dt \\ & + g(y^k(T)) - g(y^{k-1}(T)). \end{aligned} \tag{3.2}$$

We obviously have

$$\begin{aligned} H(y^k, u^k, p^{k-1}, t) - H(y^{k-1}, u^{k-1}, p^{k-1}, t) = & H(y^k, u^k, p^{k-1}, t) \\ & - H(y^k, u^k - \delta u^k, p^{k-1}, t) + H(y^{k-1} + \delta y^k, u^{k-1}, p^{k-1}, t) - H(y^{k-1}, u^{k-1}, p^{k-1}, t). \end{aligned}$$

It is easy to check that the hypotheses made imply the existence of $C_4 > 0$, such that, $\forall t \in [0, T]$:

$$\begin{aligned} H(y^k, u^k - \delta u^k, p^{k-1}, t) \geqq & H(y^k, u^k, p^{k-1}, t) \\ & - \left(\frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t), \delta u^k\right) - C_4 \|\delta u^k\|^2. \end{aligned}$$

$$\begin{aligned} H(y^{k-1} + \delta y^k, u^{k-1}, p^{k-1}, t) \leqq & H(y^{k-1}, u^{k-1}, p^{k-1}, t) \\ & + \left(\frac{\partial H}{\partial y}(y^{k-1}, u^{k-1}, p^{k-1}, t), \delta y^k\right) + C_4 \|\delta y^k\|^2. \end{aligned}$$

These inequalities with (3.2) imply

$$\begin{aligned} J(u^k) - J(u^{k-1}) \leqq \int_0^T & \left[\left(\frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t), \delta u^k\right) + C_4 \|\delta u^k\|^2 \right. \\ & \left. + \left(\frac{\partial H}{\partial y}(y^{k-1}, u^{k-1}, p^{k-1}, t), \delta y^k\right)\right. \end{aligned}$$

$$+C_4\|\delta y^k\|^2-\left(p^{k-1},\frac{d}{dt}(\delta y^k)\right)\Big]\,dt \tag{3.3}$$
$$+g(y^k(T))-g(y^{k-1}(T)).$$

We note that

$$\left(\frac{\partial H}{\partial u}(y^k,u^k,p^{k-1},t),\delta u^k\right)=\left(\frac{\partial K_{\varepsilon^k}}{\partial u}(y^k,u^k,u^{k-1},p^{k-1},t),\delta u^k\right)-\frac{1}{\varepsilon^k}\|\delta u^k\|^2$$

and, by definition of u^k

$$\left(\frac{\partial K_{\varepsilon^k}}{\partial u}(y^k,u^k,u^{k-1},p^{k-1},t),\delta u^k\right)\leqq 0,\quad \text{a.e. } t\in(0,T).$$

On the other hand, using (2.5) and integrating by parts,

$$\int_0^T\left[\left(\frac{\partial H}{\partial y}(y^{k-1},u^{k-1},p^{k-1},t),\delta y^k\right)-\left(p^{k-1},\frac{d}{dt}(\delta y^k)\right)\right]dt$$
$$=-\int_0^T\left[\left(\frac{d}{dt}p^{k-1},\delta y^k\right)+\left(p^{k-1},\frac{d}{dt}(\delta y^k)\right)\right]dt$$
$$=-[(p^{k-1}(t),\delta y^k(t))]_0^T=-\left(\frac{\partial g}{\partial y}(y^{k-1}(T)),\delta y^k(T)\right).$$

As $y(T)$ is uniformly bounded in $\mathbb{R}^n$, we deduce from (2.11) that for some $C_5>0$:

$$g(y^k(T))-g(y^{k-1}(T))-\left(\frac{\partial g}{\partial y}(y^{k-1}(T)),\delta y^k(T)\right)\leqq C_5\|\delta y^k(T)\|^2.$$

Using (3.3), we deduce that

$$J(u^k)-J(u^{k-1})\leqq\int_0^T\left[\left(C_4-\frac{1}{\varepsilon^k}\right)\|\delta u^k(t)\|_p^2+C_4\|\delta y^k(t)\|^2\right]dt \tag{3.4}$$
$$+C_5\|\delta y^k(T)\|^2.$$

We end the proof as in [4]: we have

$$\frac{d}{dt}\|\delta y^k(t)\|\leqq\left\|\frac{d}{dt}\delta y^k(t)\right\|=\|f(y^k,u^k,t)-f(y^{k-1},u^{k-1},t)\|.$$

Hypothesis (2.7) and the fact that y and u are uniformly bounded imply the existence of $C_6>0$ such that

$$\frac{d}{dt}\|\delta y^k(t)\|\leqq C_6(\|\delta y^k(t)\|+\|\delta u^k(t)\|).$$

Using Gronwall's inequality, we deduce that for some $C_7>0$

$$\|\delta y^k(t)\|\leqq C_7\int_0^T\|\delta u^k(t)\|\,dt,$$

and with the Cauchy-Schwarz inequality:

$$\|\delta y^k(t)\|^2\leqq C_8T\int_0^T\|\delta u^k(t)\|^2\,dt.$$

This implies

$$\int_0^T \|\delta y^k(t)\|^2\, dt \leqq C_8(T)^2 \int_0^T \|\delta u^k(t)\|^2\, dt.$$

The two last inequalities with (3.4) yields (3.1). □

We denote by $P_{\mathcal{U}_{ad}}$ the map from $L^2(0, T, \mathbb{R}^p)$ onto itself such that $P_{\mathcal{U}_{ad}}(u)(t)$ is a.e. in t the projection of $u(t)$ on $\mathcal{U}_{ad}$. The gradient of J is denoted ∇J. We state a result of global convergence:

THEOREM 3.2. *We suppose that J is bounded from below and that hypotheses* (2.7) *to* (2.11) *hold. Then there exists $\varepsilon_0 > 0$ such that, if $\varepsilon^k < \varepsilon_0$, any sequence generated by the algorithm satisfies*:

$$J(u^k) \text{ decreases}, \tag{3.5}$$

$$\|u^k - u^{k-1}\|_{L^2(0,T,\mathbb{R}^p)} \to 0, \tag{3.6}$$

$$\|u^k - P_{\mathcal{U}_{ad}}(u^k - \varepsilon^k \nabla J(u^k))\|_{L^2(0,T,\mathbb{R}^p)} \to 0. \tag{3.7}$$

Proof. Relations (3.5) and (3.6) are an easy consequence of Theorem 3.1. Let us verify (3.7). From the definition of u^k we deduce that

$$\left(u^k - u^{k-1} + \varepsilon^k \frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t),\ v - u^k\right) \geqq 0 \quad \forall v \in \mathcal{U}_{ad}, \quad \text{a.e. } t \in (0, T).$$

This can be written as

$$u^k = P_{\mathcal{U}_{ad}}\left(u^{k-1} - \varepsilon^k \frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t)\right).$$

We note that

$$\nabla J(u^{k-1}) = \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t),$$

so that

$$u^{k-1} - P_{\mathcal{U}_{ad}}(u^{k-1} - \varepsilon^k \nabla J(u^{k-1})) = u^{k-1} - u^k + P_{\mathcal{U}_{ad}}\left(u^{k-1} - \varepsilon^k \frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t)\right)$$
$$- P_{\mathcal{U}_{ad}}\left(u^{k-1} - \varepsilon^k \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t)\right).$$

As $P_{\mathcal{U}_{ad}}$ is a contraction, we obtain

$$\|u^{k-1} - P_{\mathcal{U}_{ad}}(u^{k-1} - \varepsilon^k \nabla J(u^{k-1}))\|_{L^2(0,T,\mathbb{R}^p)} \leqq \|u^{k-1} - u^k\|_{L^2(0,T,\mathbb{R}^p)}$$
$$+ \varepsilon^k \left\| \frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t) - \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t) \right\|_{L^2(0,T,\mathbb{R}^p)}. \tag{3.8}$$

From (3.6) we deduce that

$$u^k(t) - u^{k-1}(t) \to 0,$$
$$y^k(t) - y^{k-1}(t) \to 0, \quad \text{a.e. } t \in (0, T).$$
$$p^k(t) - p^{k-1}(t) \to 0.$$

As $\partial H/\partial u$ is uniformly continuous on compact sets, this implies that

$$\frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t) - \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t) \to 0, \quad \text{a.e. } t \in [0, T].$$

Using Lebesgue's theorem, we see that the right side of (3.8) tends towards zero. □

The hypotheses we made do not allow us to prove the convergence of $\{u^k\}$: in fact they do not even insure the existence of an optimal control. However, stronger results are easily deduced from (3.8) under an additional hypothesis: here is an example:

THEOREM 3.3. *We suppose that $J(u)$ is an l.s.c. convex function, defined on a convex domain, and bounded from below, that hypotheses* (2.7) *to* (2.11) *hold, that ε is small enough so that* (3.5), (3.6) *and* (3.7) *hold and that* $\liminf \varepsilon^k > 0$. *Then some subsequence of $\{u^k\}$ (still denoted $\{u^k\}$) satisfies*

$$u^k \to \bar{u} \qquad L^2(0, T, \mathbb{R}^p) \text{ weak},$$

where $\bar{u}$ is an optimal control.

The proof of the theorem is a direct consequence of (3.7) and of the following lemma:

LEMMA 3.1. *Let U be an Hilbert space and K a closed convex subset of U. Let $J: U \to \mathbb{R}$ be an l.s.c. proper convex functional. Let $\{u^k\}$ be a bounded sequence such that J is Gâteaux differentiable on $\{u^k\}$ and $\{\nabla J(u^k)\}$ is bounded. We assume that there exists a sequence ρ^k of positive numbers such that* $\liminf \rho^k \geqq \rho > 0$ *and that*

$$\|u^k - P_K(u^k - \rho^k \nabla J(u^k))\|_U \to 0.$$

Then any weak limit point of $\{u^k\}$ (there exist some) satisfies

$$\bar{u} \in K,$$

$$J(\bar{u}) \leqq J(u) \quad \forall u \in K.$$

Proof of Lemma 3.1. Denote $g^k = \nabla J(u^k)$, and suppose that for some subsequence (still denoted k) $u^k \to \bar{u}$ in U. Then $\bar{u}$ is in K. Denote

$$v^k = P_K(u^k - \rho^k g^k).$$

We have

$$(v^k - u^k + \rho^k g^k, w - v^k) \geqq 0 \quad \forall w \in K,$$

i.e.

$$(v^k - u^k, w - v^k) + \rho^k (g^k, w - u^k) + \rho^k (g^k, u^k - v^k) \geqq 0 \quad \forall v \in K.$$

We made the hypothesis $\|v^k - u^k\|_U \to 0$. Then as $\{g^k\}$ is bounded and as $\rho^k \geqq \rho/2$ for k great enough:

$$\liminf_{k \to +\infty} (g^k, w - u^k) \geqq 0 \quad \forall w \in K. \tag{3.9}$$

As J is convex, we have

$$J(w) \geqq J(u^k) + (g^k, w - u^k) \quad \forall w \in H.$$

Hence with (3.9), for any $w \in K$:

$$J(w) \geqq \liminf \{J(u^k) + (g^k, w - u^k)\} \geqq \liminf J(u^k).$$

The weak lower semi-continuity of J gives the conclusion. □

Remark 3.1. Lemma 3.1. still holds if we only suppose that g^k is an element of the subdifferential of J at u^k.

4. Relations with the gradient plus projection method. We have seen in the proof of Theorem 3.2. that the algorithm can be written as

$$u^k = P_{\mathcal{U}_{ad}}\left(u^{k-1} - \varepsilon \frac{\partial H}{\partial u}(y^k, u^k, p^{k-1}, t)\right). \tag{4.1}$$

The gradient plus projection method (A. A. Goldstein [2]) for a control problem can be written as

$$\hat{u}^k = P_{\mathcal{U}_{ad}}\left(u^{k-1} - \varepsilon \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t)\right), \tag{4.2}$$

where ε is the step size. We fix u^{k-1} and show that the two points obtained by (4.1) and (4.2) are very near when ε is small.

PROPOSITION 4.1. *Let $u^{k-1} \in L^2(0, T, \mathbb{R}^p)$ be an admissible control. We denote u_ε^k and $\hat{u}_\varepsilon^k$ the new controls obtained by* (4.1) *and* (4.2). *Then, if $\hat{u}_\varepsilon^k \neq u^{k-1}$ for some $\varepsilon > 0$:*

$$\lim_{\varepsilon \to 0} \frac{\|u_\varepsilon^k - \hat{u}_\varepsilon^k\|_{L^2(0,T,\mathbb{R}^p)}}{\|\hat{u}_\varepsilon^k - u^{k-1}\|_{L^2(0,T,\mathbb{R}^p)}} \to 0.$$

Proof. As $P_{\mathcal{U}_{ad}}$ is a contraction, (4.1), (4.2) imply that (dropping the subscripts ε):

$$\|u^k - \hat{u}^k\|_{L^2(0,T,\mathbb{R}^p)} \leqq \varepsilon \left\| \frac{\partial H}{\partial u}(y^k, u^k, p^k, t) - \frac{\partial H}{\partial u}(y^{k-1}, u^{k-1}, p^{k-1}, t) \right\|_{L^2(0,T,\mathbb{R}^p)}.$$

The continuous function $\partial H/\partial u$ is uniformly continuous on the bounded set of admissible states, controls and costates, for $t \in [0, T]$, so that $\forall \alpha > 0$, there exists ε_1 such that

$$\varepsilon < \varepsilon_1 \Rightarrow \|u^k - \hat{u}^k\|_{L^2(0,T,\mathbb{R}^p)} \leqq \alpha\varepsilon. \tag{4.3}$$

Lemma 1 of D. P. Bertsekas, E. M. Gafni [1] states that

$$\frac{1}{\varepsilon}\|\hat{u}_\varepsilon^k - u^{k-1}\|_{L^2(0,T,\mathbb{R}^p)} \geqq \frac{1}{\varepsilon'}\|\hat{u}_{\varepsilon'}^k - u^{k-1}\|_{L^2(0,T,\mathbb{R}^p)} \quad \forall \varepsilon' > \varepsilon > 0;$$

hence

$$\|\hat{u}^k - u^{k-1}\|_{L^2(0,T,\mathbb{R}^p)} \geqq C_1\varepsilon$$

for some $C_1 > 0$. This with (4.3) proves the proposition. □

We now see that in an important particular case, the algorithm is equivalent to a gradient plus projection method in some metric.

THEOREM 4.1. *We assume that the control enters in a linear way into the state equation and in a quadratic way into the criterion, i.e.*

$$f(y, u, t) = f_1(y, t) + B(t)u, \qquad l(y, u, t) = \tfrac{1}{2}u^t N(t)u + l_1(y, t),$$

where $B(t)$ and $N(t)$ are time-dependent matrices of convenient dimension, and $N(t)$ is symmetric. We denote

$$M_\varepsilon(t) = I + \varepsilon N(t).$$

Then the algorithm reduces to the gradient plus projection method in $L^2(0, T, \mathbb{R}^p)$ endowed

with the new metric

$$((u, v))_{L^2(0,t,\mathbb{R}^p)} = \int_0^T (u(t), M_\varepsilon(t)v(t))\, dt. \tag{4.4}$$

Proof. From (4.1) written with $k=1$ we see that u^1 is characterized by

$$(u^1(t)-u^0(t)+\varepsilon(N(t)u^1(t)+B^*(t)p^0(t)), v-u^1(t))\geqq 0, \quad \forall v\in \mathcal{U}_{\text{ad}}, \text{ a.e. } t\in(0, T).$$

This is equivalent to

$$((I+\varepsilon N(t))u^1(t)-(I+\varepsilon N(t))u^0(t)+\varepsilon(N(t)u^0(t)+B^*(t)p^0(t)), v-u^1(t))\geqq 0$$
$$\forall v\in \mathcal{U}_{\text{ad}}, \text{ a.e. } t\in[0, T].$$

We note that $\nabla J(u^0)(t) = N(t)u^0(t)+B^*(t)p^0(t)$, so that

$$(M_\varepsilon(t)(u^1(t)-u^0(t)+\varepsilon(M_\varepsilon)^{-1}\nabla J(u^0)(t)), v-u^1(t))\geqq 0 \quad \forall v\in \mathcal{U}_{\text{ad}}, \text{ a.e. } t\in(0, T).$$

This is the characterization of the point obtained by the gradient plus projection method associated to the metric (4.4). □

5. Conclusion. In this study of an algorithm of resolution of optimal control problems, we establish some results of well-posedness and of convergence. In addition, we show that this algorithm is strongly related to the gradient plus projection method. For numerical experiments using this algorithm, see [4], [5], [6].

Acknowledgments. I thank Professor Y. Sakawa, from Osaka University, for an interesting discussion concerning the algorithm studied in this paper, and the editor and a referee for their useful remarks.

STOCHASTIC ADAPTIVE CONTROL FOR EXPONENTIALLY CONVERGENT TIME-VARYING SYSTEMS*

GRAHAM C. GOODWIN†, DAVID J. HILL† AND XIE XIANYA‡

Abstract. This paper shows that the standard stochastic adaptive control algorithms for time-invariant systems have an inherent robustness property which renders them applicable, without modification, to time-varying systems whose parameters converge exponentially. One class of systems satisfying this requirement is those having non-steady-state Kalman filter or innovations representations. This allows the usual assumption of a stationary ARMAX representation to be replaced by a more general state space model.

Key words. stochastic control, adaptive control, martingale convergence, passivity, time-varying systems

1. Introduction. A stochastic adaptive controller is an algorithm which combines on-line parameter estimation with on-line control to generate a control law applicable to systems having unknown parameters and random disturbances [1]. Control laws based on this philosophy have been studied for at least three decades [2], but it is only recently that rigorous convergence analyses have appeared. To gain insight into the operation of these algorithms, several special cases have been studied in detail. For example, the authors of [3] have examined the convergence properties of a particular scheme which combines a simple stochastic gradient parameter estimator with a minimum variance control law.

A number of interesting properties of these simple stochastic adaptive control laws have been established. For example, the tracking error is known to converge to a minimum (in a specific sense) in a sample mean square sense [3]. In the case of regulation about a zero desired output, then it has been shown [5] that the parameter estimates converge to a fixed multiple of the true parameter values. However, if the desired output sequence is continuously disturbed and an identifiability condition holds, then the parameters can be shown to converge to their true values [4]. Various extensions of the above results have also been studied. For example convergence results have been established in [7], for least squares based adaptive control algorithms.

The above papers deal with systems having constant parameters. However, in practice one is often confronted with systems whose parameters vary with time in some fashion. This has motivated several authors to investigate special classes of time-varying systems in an effort to gain insights into the convergence properties relevant to this case. For example, Caines [8] has analyzed the performance of the stochastic gradient algorithm of [3] applied to systems with (converging) martingale parameters. Further results for systems having random parameters are described in [9].

The current paper also deals with systems whose parameters are time-varying. Indeed, the work has much in common with the results in [8], [9]. All three papers reduce to treatment of a near-super-martingale equation of a particular form—see equation (3.28) later. However, here the parameter time variations are deterministic and thus a different method of analysis is necessary from that used in [8], [9].

Our analysis has three key steps: a proof that a system which is convergent toward a minimum phase system has an input which grows no faster than the output; a proof that a system which is exponentially convergent toward a strictly passive system is eventually strictly passive in a certain sense (where the strict passivity concepts are

* Received by the editors May 29, 1984, and in revised form February 28, 1985.

† Department of Electrical and Computer Engineering, University of Newcastle, New South Wales, 2308, Australia.

‡ Department of Computer Science, Shanghai University of Science and Technology, Shanghai, China.

defined later); and a martingale convergence proof along the lines of [3], but using a modified martingale result as first proposed in [10], [11] in a different context.

One application of the results developed here is to systems described by a state space model corresponding to a non-steady-state innovations representation. Subject to the assumption that the system has no uncontrollable modes (in the filtering sense [12]) on the unit circle, then it is known [13] that the parameters in the innovations model are time-varying and converge exponentially fast toward those of the steady-state optimal filter. Thus the results of this paper allow global convergence to be established for the standard adaptive control algorithms when applied to these systems. This represents a relaxation of the usual modelling assumption employed elsewhere in the literature (e.g. [3] to [9]) that the system is described by an ARMAX model or equivalently a steady-state Kalman filter model. This particular robustness to modelling assumption is often implicitly assumed in the literature, and it is thus interesting for technical completeness to have a formal proof that the results go through in this case.

2. Preliminary result on passive systems. We verify a result which will be needed in the subsequent proof of convergence of an adaptive control algorithm. This concerns a passivity property of a system which is exponentially convergent toward an asymptotically stable and input strictly passive system. The definitions of passivity concepts used correspond to those presented in [15, Appendix C]. Consider the extended Hilbert space $l_{2e}^n(\mathbb{Z}_+)$ of sequences $v:\mathbb{Z}_+\to\mathbb{R}^n$ with truncated inner product $\langle u, v\rangle_T := \sum_{k=0}^{T-1} u^T(k)v(k) < \infty$. The main definition for present purposes is as follows.

DEFINITION 2.1. Consider a dynamical system represented by mapping $G: l_{2e}^n(\mathbb{Z}_+)\to l_{2e}^n(\mathbb{Z}_+)$. The system is input strictly passive (ISP) iff $\exists \delta > 0$ and β such that

$$\langle y, u\rangle_T \geqq \delta\|u\|_T^2 + \beta \quad \forall u \in l_{2e}(\mathbb{Z}_+) \text{ and } T \geqq 0. \tag{2.1}$$

Consider the following special case of the time-varying linear system model (A.1), (A.2):

$$x(t+1) = A(t)x(t) + Bu(t), \tag{2.2}$$

$$y(t) = Cx(t). \tag{2.3}$$

Let $A(t)\to A$ exponentially fast and define $\{y^*(t)\}, \{x^*(t)\}$ by

$$x^*(t+1) = Ax^*(t) + Bu^*(t), \tag{2.4}$$

$$y^*(t) = Cx^*(t) \tag{2.5}$$

with (A, B) controllable and A asymptotically stable.

The following result establishes that if (2.4), (2.5) is also ISP then (2.2), (2.3) satisfies a property very close to ISP.

THEOREM 2.1. *Provided* (2.4), (2.5) *is input strictly passive then there exist* $\bar{n}_0$, β *and* $\delta > 0$ *such that*

$$\sum_{t=n_0}^{N} (y(t)u(t) - \delta u(t)^2) + \beta \geqq 0 \tag{2.6}$$

for all $N \geqq n_0 \geqq \bar{n}_0$ *and for all* $\{u(t)\} \in l_{2e}(\mathbb{Z}_+)$. β, δ *depend on* $u(t)$ *for* $t < n_0$.

Proof. Since (2.4), (2.5) is ISP, there exists $\delta^* < 0$ and $\beta^*(x^*(n_0))$ such that

$$\sum_{t=n_0}^{N} (y^*(t)u^*(t) - \delta^* u^*(t)^2) + \beta^*(x^*(n_0)) \geqq 0 \tag{2.7}$$

for all $N \geqq n_0$ and for all $u(t) \in l_{2_e}(\mathbb{Z}_+)$. From (2.7), we have

$$\sum_{t=n_0}^{N} (y^*(t)-y(t))u(t)+\sum_{t=n_0}^{N} y(t)u(t) \geqq \delta^* \sum_{t=n_0}^{N} u(t)^2-\beta^*(x^*(n_0)).$$

Let

$$\alpha(n_0, N) := \sum_{t=n_0}^{N} (y^*(t)-y(t))u(t).$$

Then

$$\sum_{t=n_0}^{N} y(t)u(t) \geqq \delta^* \sum_{t=n_0}^{N} u(t)^2-\alpha(n_0, N)-\beta^*(x^*(n_0)). \tag{2.8}$$

The remainder of the proof involves establishing a bound for $\alpha(n_0, N)$. Now

$$y^*(t) = C\Phi^*(t, n_0)x^*(n_0)+\sum_{i=n_0}^{t-1} C\Phi^T(t, i+1)Bu^*(i),$$

$$y(t) = C\Phi(t, n_0)x(n_0)+\sum_{i=n_0}^{t-1} C\Phi(t, i+1)Bu(i)$$

where $\Phi^*(t, n_0) = A^{t-n_0}$ and $\Phi(t, n_0)$ is given by (A.3). Then

$$\begin{aligned}\alpha(n_0, N) &= \sum_{t=n_0}^{N} u(t)C\left(A^{t-n_0}x^*(n_0)-\prod_{i=n_0}^{t-1} A(i)\right)x(n_0)\\ &\quad+\sum_{t=n_0}^{N} u(t)C\left(\sum_{i=n_0}^{t-1}\left(A^{t-i-1}-\prod_{j=i+1}^{t-1} A(j)\right)Bu(i)\right)\\ &:= \alpha_1(n_0, N)+\alpha_2(n_0, N).\end{aligned}$$

Now without loss of generality choose $u^*(t)$ so that

$$x^*(n_0) = x(n_0) \quad \text{and} \quad y^*(n_0) = y(n_0).$$

This is possible because (2.4), (2.5) is controllable. We can consider $u(t) = u^*(t)$ for $t \geqq n_0$. We have

$$|\alpha(n_0, N)| \leqq |\alpha_1(n_0, N)|+|\alpha_2(n_0, N)|.$$

The remainder of the proof involves bounding α_1 and α_2 in terms of $\|u(t)\|_{n_0}^N$.

We will use $|\cdot|$ for the Euclidean norm.

$$\begin{aligned}|\alpha_1(n_0, N)| &= \left|\sum_{t=n_0}^{N} u(t)C\left(A^{t-n_0}-\prod_{i=n_0}^{t-1} A(i)\right)x(n_0)\right|\\ &\leqq \|u(t)\|_{n_0}^N\left\|C\left(A^{t-n_0}-\prod_{i=n_0}^{t-1} A(i)\right)x(n_0)\right\|_{n_0}^N\end{aligned}$$

using the Schwarz inequality

$$\leqq \|u(t)\|_{n_0}^N \sum_{t=n_0}^{N}\left|C\left(A^{t-n_0}-\prod_{i=n_0}^{t-1} A(i)\right)x(n_0)\right|$$

since $\|\cdot\|_2 \leqq \|\cdot\|_1$

$$\leqq \|u(t)\|_{n_0}^N|C||x(n_0)|\sum_{t=n_0}^{N}\left|A^{t-n_0}-\prod_{i=n_0}^{t-1} A(i)\right|$$

$$\leqq \|u(t)\|_{n_0}^N|C||x(n_0)|\eta^{n_0-1}\sum_{t=n_0}^{N}\chi\eta^{t-n_0}$$

choosing $n_0 \geqq \bar{n}$ and using Lemma A.2

$$\leqq 2\varepsilon_1\|u(t)\|_{n_0}^N|x(n_0)|$$

where

$$\varepsilon_1 = \frac{|C|\chi\eta^{n_0-1}}{2(1-\eta)} \leqq \varepsilon_1(\|u(t)\|_{n_0}^N)^2 + \varepsilon_1|x(n_0)|^2.$$

So $|\alpha_1(n_0, N)| \leqq \varepsilon_1(\|u(t)\|_{n_0}^N)^2 + \varepsilon_1|x(n_0)|^2$.

Now turning to α_2, we have

$$|\alpha_2(n_0, N)| = \left| \sum_{t=n_0}^{N} u(t) C \left(\sum_{i=n_0}^{t-1} \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) Bu(i) \right) \right|$$

$$\leqq \|u(t)\|_{n_0}^N \left\| C \sum_{i=n_0}^{t-1} \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) Bu(i) \right\|_{n_0}^N.$$

Observe that

$$\left\| C \sum_{i=n_0}^{t-1} \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) Bu(i) \right\|_{n_0}^N$$

$$= \left\{ \sum_{t=n_0}^{N} \left(\sum_{i=n_0}^{t-1} C \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) Bu(i) \right)^2 \right\}^{1/2}$$

$$\leqq \left\{ \sum_{t=n_0}^{N} \left(\sum_{i=n_0}^{t-1} \left(C \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) B \right)^2 \right) \left(\sum_{i=n_0}^{t-1} u(i)^2 \right) \right\}^{1/2}$$

using the Schwarz inequality

$$\leqq \left\{ \sum_{t=n_0}^{N} \sum_{i=n_0}^{t-1} \left(C \left(A^{t-i-1} - \prod_{j=i+1}^{t-1} A(j) \right) B \right)^2 \right\}^{1/2} \|u(t)\|_{n_0}^N$$

$$\leqq |C||B| \|u(t)\|_{n_0}^N \left\{ \sum_{t=n_0}^{N} \sum_{i=n_0}^{t-1} \chi^2 \eta^{2(t-1)} \right\}^{1/2}$$

using Lemma A.2

$$= |C||B|\chi \|u(t)\|_{n_0}^N \left\{ \sum_{t=n_0}^{N} \sum_{i=n_0}^{t-1} \eta^{2(t-1)} \right\}^{1/2}.$$

Now

$$\sum_{t=n_0}^{N} \sum_{i=n_0}^{t-1} \eta^{2(t-1)} = \sum_{p=0}^{N-n_0} \sum_{q=0}^{p-1} \eta^{2(p+n_0-1)}$$

$$\leqq \eta^{2(n_0-1)} \sum_{p=0}^{N-n_0} p\eta^{2p}$$

$$\leqq \eta^{2(n_0-1)} \frac{\eta^2}{(1-\eta^2)^2}$$

since $|\eta| < 1$

$$= \frac{\eta^{2n_0}}{(1-\eta^2)^2}.$$

So we have

$$|\alpha_2(n_0, N)| \leqq (\|u(t)\|_{n_0}^N)^2 |C||B|\chi \frac{\eta^{2n_0}}{(1-\eta^2)^2}.$$

Let

$$\varepsilon_2 = |C||B|\chi \frac{\eta^{2n_0}}{(1-\eta^2)^2}.$$

So

$$|\alpha_2(n_0, N)| \leqq \varepsilon_2(\|u(t)\|_{n_0}^N)^2.$$

We then have

$$|\alpha(n_0, N)| \leqq (\varepsilon_1+\varepsilon_2)(\|u(t)\|_{n_0}^N)^2+\varepsilon_1|x(n_0)|^2.$$

Note that ε_1, ε_2 can be made arbitrarily small by taking n_0 large enough.

Let

$$\varepsilon := \varepsilon_1+\varepsilon_2.$$

Substituting into (2.8)

$$\sum_{t=n_0}^{N} y(t)u(t) \geqq (\delta^*-\varepsilon)(\|u(t)\|_{n_0}^N)^2-\beta^*(x(n_0))-\varepsilon_1|x(n_0)|^2.$$

Let

$$\delta := \delta^*-\varepsilon, \qquad \beta := \beta^*(x(n_0))+\varepsilon_1|x(n_0)|^2.$$

By taking n_0 large enough, it can be guaranteed that $\delta>0$. □

Remarks. 1. Since system (2.4), (2.5) is both input strictly passive and asymptotically stable, it is in fact very strictly passive (see [15, Appendix C]).

2. The system does not become input strictly passive as usually defined because δ is dependent on $x(n_0)$.

3. The adaptive control algorithm. We are concerned here with the adaptive control of a linear time-varying finite dimensional system admitting an autoregressive moving average representation of the form:

$$\begin{aligned} &y(t)+a_1(t)y(t-1)+\cdots+a_n(t)y(t-n)\\ &\quad=b_0(t)u(t-d)+\cdots+b_m(t)u(t-d-m)\\ &\qquad+\omega(t)+c_1(t)\omega(t-1)+\cdots+c_l(t)\omega(t-l). \end{aligned} \tag{3.1}$$

We shall express (3.1) in compact notation as

$$A(t, q^{-1})y(t) = \acute{B}(t, q^{-1})q^{-d}u(t)+C(t, q^{-1})\omega(t) \tag{3.2}$$

where q^{-1} represents the delay operator and $A(t, q^{-1}) = 1+a_1(t)q^{-1}+\cdots+a_n(t)q^{-n}$; $B(t, q^{-1}) = b_0(t)+b_1(t)q^{-1}+\cdots+b_m(t)q^{-m}$; $C(t, q^{-1}) = 1+c_1(t)q^{-1}+\cdots+c_l(t)q^{-l}$. The corresponding initial condition is $x_0 := \{y(0)\cdots y(1-k);\ u(1-d), \cdots, u(1-k);\ \omega(0), \cdots, \omega(1-k)\}$ where $k = \max\{n, m+d, l\}$.

The process $\{x_0, \omega(1), \omega(2), \cdots\}$ is defined on the underlying probability space $(\Omega, \mathcal{F}, P)$ and we define $\mathcal{F}_0$ to be the σ-algebra generated by x_0. Further, for all $t \geqq 1$ $\mathcal{F}_t$ shall denote the σ-algebra generated by the observations up to time t. The distributions of the random variables $x_0, \omega(1), \omega(2), \cdots$ are assumed mutually absolutely continuous with respect to Lebesgue measure.

We make the following assumptions on the process $\{\omega(t)\}$:

(3.3) N.1 $\quad E\{\omega(t)|\mathcal{F}_{t-1}\} = 0$ a.s. $t \geqq 1$.

(3.4) N.2 $\quad E\{\omega(t)^2|\mathcal{F}_{t-1}\} = \sigma_t^2 \leqq \sigma^2 < \infty, \qquad t \geqq 1.$

(3.5) N.3 $\quad \limsup_{N\to\infty} \frac{1}{N}\sum_{t=1}^{N} \|\omega(t)\|^2 < \infty$ a.s.

We wish to design an adaptive control law to cause $\{y(t)\}$ to track (in some sense) a given desired output sequence $\{y^*(t)\}$ and to ensure that $\{y(t)\}$, $\{u(t)\}$ remain bounded (in some sense). Reference [3] presents further background to this problem as well as giving a convergence analysis for a particular adaptive control algorithm for the case when $A(t, q^{-1})$, $B(t, q^{-1})$, $C(t, q^{-1})$ do not depend on t.

In order to specify the algorithm, we assume:

S.1. d is known.

S.2. Upper bounds for n, m, and l are known.

In addition, the following properties of system (3.2) will be assumed in the analysis of the algorithm:

S.3
$$a_i(t) \to a_i, \qquad i = 1, \cdots, n,$$
$$b_i(t) \to b_i, \qquad i = 0, \cdots, m,$$
$$c_i(t) \to c_i, \qquad i = 1, \cdots, l,$$

exponentially fast.

S.4. $B(z)$ and $C(z)$ have all zeros outside the closed unit circle, where

$$B(z) = b_0 + b_1 z + \cdots + b_m z^m,$$
$$C(z) = 1 + c_1 z + \cdots + c_l z^l.$$

S.5. The system $C(q^{-1})z(t) = b(t)$ is input strictly passive.

For simplicity we shall treat the single input single output unit delay ($d = 1$) case. However, natural extensions exist for the multi-input multi-output nonunit delay as explored for non-time-varying systems in [3], [15], etc.

The model (3.2) can be rearranged into the following predictor form:

$$C(t, q^{-1})[y(t) - \omega(t)] = \alpha(t, q^{-1})y(t-1) + \beta(t, q^{-1})u(t-1) \tag{3.6}$$

where

$$\alpha(t, q^{-1}) := [C(t, q^{-1}) - A(t, q^{-1})]q, \tag{3.7}$$

$$\beta(t, q^{-1}) := B(t, q^{-1})q. \tag{3.8}$$

The adaptive control algorithm which we propose to analyze is the following stochastic gradient minimum variance algorithm:

$$\text{A.1} \qquad \hat{\theta}(t) = \hat{\theta}(t-1) + \frac{\phi(t-1)}{r(t-2) + \phi(t-1)^T \phi(t-1)} e(t) \tag{3.9}$$

where $\hat{\theta}(t)$ is an estimate of $\theta(t)$ and $\theta^T(t) = (\alpha_1(t), \alpha_2(t), \cdots, \alpha_n(t), b_0(t), \cdots, b_m(t), c_1(t), \cdots, c_l(t))$. $\hat{\theta}(0)$ is given such that $\hat{\theta}_{n+1}(0) \neq 0$.

$$\text{A.2} \qquad r(t-1) = r(t-2) + \phi(t-1)^T \phi(t-1), \qquad r(0) > 0 \text{ given.} \tag{3.10}$$

$$\text{A.3} \qquad y^*(t) = \phi(t-1)^T \hat{\theta}(t-1).$$

$$\text{A.4} \qquad \phi(t-1)^T = (y(t-1), \cdots, y(t-\bar{n}), u(t-1), \cdots, u(t-\bar{n}), -\bar{y}(t-1), \cdots, -y(t-\bar{n})) \tag{3.11}$$

where $\bar{n}$ = upper bound on max $(n, m+1, l)$.

$$\text{A.5} \qquad \bar{y}(t) = \phi(t-1)^T \hat{\theta}(t).$$
$$\text{A.6} \qquad e(t) = y(t) - y^*(t). \tag{3.12}$$

This algorithm differs slightly from the time-invariant version in [3] by using a posteriori predictions. A discussion of the significance of this can be seen in [15].

The theoretical possibility of division by zero while evaluating $u(t)$ can be avoided since it can be argued inductively [3] that division by zero is a zero probability event. Since all the results in this paper are almost sure results, then division by zero can only affect the convergence on a set of measure zero. This argument depends on the above assumption of absolute continuity of the distribution functions. Hence, the algorithm is well-posed in the sense that all variables remain bounded in finite time (a.s.).

We then have the following global convergence result:

THEOREM 3.1. *Let Assumptions* N.1-N.3 *and* S.1-S.5 *hold for the system* (3.1) *and the algorithm* A.1-A.6. *Then with probability one, for any initial parameter estimate* $\hat{\theta}(0)$

$$\limsup_{N\to\infty} \frac{1}{N} \sum_{t=1}^{N} y(t)^2 < \infty, \tag{3.13}$$

$$\limsup_{N\to\infty} \frac{1}{N} \sum_{t=1}^{N} u(t)^2 < \infty, \tag{3.14}$$

$$\lim_{N\to\infty} \frac{1}{N} \sum_{t=1}^{N} [E\{(y(t)-y^*(t))^2 | \mathcal{F}_{t-1}\} - \sigma_t^2] = 0 \tag{3.15}$$

where σ_t^2 *is the minimum mean square control error achievable at time t by* $\mathcal{F}_{t-1}$ *measurable controls.*

Proof. We shall present an outline proof only, highlighting the key departures from the usual proofs for time-invariant systems as in [3], [15].

Set

$$\eta(t) = y(t) - \bar{y}(t). \tag{3.16}$$

We then have the following preliminary properties of the algorithm:

$$\text{P.1} \qquad \eta(t) = \frac{r(t-2)}{r(t-1)} e(t). \tag{3.17}$$

$$\text{P.2} \qquad \lim_{N\to\infty} \sum_{t=1}^{N} \frac{\phi(t-1)^T \phi(t-1)}{r(t-1)r(t-2)} < \infty. \tag{3.18}$$

$$\text{P.3} \qquad C(t, q^{-1}) z(t) = b(t) \tag{3.19}$$

where

$$z(t) = \eta(t) - \omega(t), \tag{3.20}$$

$$b(t) = -\phi(t-1)^T \tilde{\theta}(t), \tag{3.21}$$

$$\tilde{\theta}(t) = \hat{\theta}(t) - \theta(t). \tag{3.22}$$

$$\text{P.4} \qquad E\{b(t)\omega(t) | \mathcal{F}_{t-1}\} = -\frac{\phi(t-1)^T \phi(t-1)}{r(t-1)} \sigma_t^2. \tag{3.23}$$

The above properties are as in [3], [13].

Now subtracting $\theta(t)$ from both sides of (3.9) and using (3.10), (3.17), we have

$$\tilde{\theta}(t) = \tilde{\theta}(t-1) + \theta_e(t) + \frac{\phi(t-1)}{r(t-2)} \eta(t)$$

where

$$\theta_e(t) = \theta(t) - \theta(t-1),$$

$$\tilde{\theta}(t) - \frac{\phi(t-1)\eta(t)}{r(t-2)} = \tilde{\theta}(t-1) + \theta_e(t). \tag{3.24}$$

Define

$$V(t) = \tilde{\theta}(t)^T \tilde{\theta}(t).$$

Then squaring both sides of (3.24) and using (3.21) gives

$$V(t) + \frac{2b(t)\eta(t)}{r(t-2)} + \frac{\phi(t-1)^T\phi(t-1)}{r(t-2)^2}\eta^2(t) = V(t-1) + 2\tilde{\theta}(t-1)^T\theta_e(t) + \|\theta_e(t)\|^2.$$

Hence using (3.20), (3.23) we have

$$\begin{aligned} E\{V(t)|\mathcal{F}_{t-1}\} &= V(t-1) - \frac{2}{r(t-2)} E\{b(t)z(t)|\mathcal{F}_{t-1}\} \\ &\quad + \frac{2\phi(t-1)^T\phi(t-1)}{r(t-2)r(t-1)}\sigma_t^2 - E\left\{\frac{\phi(t-1)^T\phi(t-1)}{r(t-2)^2}\eta(t)^2|\mathcal{F}_{t-1}\right\} \\ &\quad + \|\theta_e(t)\|^2 + 2\tilde{\theta}(t-1)^T\theta_e(t). \end{aligned} \tag{3.25}$$

From Assumption S.3, there exists a G, λ with $0 < G < \infty$, $|\lambda| < 1$ such that

$$\|\theta_e(t)\|^2 \leqq G|\lambda|^t. \tag{3.26}$$

Also, for $0 < a(t) < \infty$, we have

$$2[\tilde{\theta}(t-1)^T\theta_e(t)] \leqq a(t)^2\|\tilde{\theta}(t-1)\|^2 + \frac{1}{a(t)^2}\|\theta_e(t)\|^2.$$

Thus selecting $a(t)^2 = |\lambda|^{t/2}$ and using (3.26), we have

$$\begin{aligned} 2[\tilde{\theta}(t-1)^T\theta_e(t)] &\leqq |\lambda|^{t/2}\|\tilde{\theta}(t-1)\|^2 + G|\lambda|^{t/2} \\ &= |\lambda|^{t/2}V(t-1) + G|\lambda|^{t/2}. \end{aligned} \tag{3.27}$$

Substituting (3.27) into (3.25) gives

$$\begin{aligned} E\{V(t)|\mathcal{F}_{t-1}\} &\leqq V(t-1)[1 + |\lambda|^{t/2}] - \frac{2}{r(t-2)} E\{b(t)z(t)|\mathcal{F}_{t-1}\} \\ &\quad + \frac{2\phi(t-1)^T\phi(t-1)}{r(t-1)r(t-2)}\sigma_t^2 - E\left\{\frac{\phi(t-1)^T\phi(t-1)}{r(t-2)^2}\eta(t)^2\,\middle|\,\mathcal{F}_{t-1}\right\} + 2G|\lambda|^{t/2}. \end{aligned} \tag{3.28}$$

Define

$$S(t) := 2\sum_{j=n_0}^{t}[b(j)z(j) - \delta z(j)^2] + K, \tag{3.29}$$

$$X(t) := V(t) + \frac{S(t)}{r(t-2)} + 2\delta\sum_{j=n_0}^{t}\frac{z(j)^2}{r(j-2)} + \sum_{j=n_0}^{t}\frac{\phi(j-1)^T\phi(j-1)}{r(j-2)^2}\eta(j)^2. \tag{3.30}$$

From Assumptions S.5, S.3, Property P.3 and Theorem 2.1, we know that there exist a n_0, $\delta > 0$ and a K (depending on the conditions at n_0) such that $S(t) \geqq 0$ for all $t \geqq n_0$. Under these conditions $X(t) \geqq 0$.

It is readily seen using (3.28), (3.30) that

$$E\{X(t)|\mathcal{F}_{t-1}\} \leqq X(t-1)[1+|\lambda|^{t/2}] + \frac{2\phi(t-1)^T\phi(t-1)}{r(t-2)r(t-1)}\sigma_t^2 + 2G|\lambda|^{t/2} \quad \text{for } t \geqq n_0.$$

From Property P.2, and Assumption N.2, we have that

$$\sum_{t=0}^{\infty}\left[\frac{\phi(t-1)^T\phi(t-1)}{r(t-2)r(t-1)}\sigma_t^2 + G|\lambda|^{t/2}\right] < \infty.$$

Thus we can apply the martingale convergence theorem (Appendix B) to conclude

$$X(t) \to X < \infty \quad \text{a.s.} \tag{3.31}$$

Using (3.30), we see that

$$\lim_{N\to\infty}\sum_{t=1}^{N}\frac{z(t)}{r(t-2)} < \infty \quad \text{a.s.}, \tag{3.32}$$

$$\lim_{N\to\infty}\sum_{t=1}^{N}\frac{\phi(t-1)^T\phi(t-1)}{r(t-2)^2}\eta(t)^2 < \infty \quad \text{a.s.} \tag{3.33}$$

The lower summation limits in (3.32), (3.33) can be extended from n_0 to 1 because the algorithm ensures all variables remain bounded in finite time (a.s.).

A simple argument by contradiction can now be used to conclude (3.13) to (3.15) using (3.32) together with Assumptions S.3, S.4 and Theorem A.1. The steps are exactly as in [3] and as explained in general in [15]. □

4. Adaptive control with general state space model. Consider a linear finite dimensional system described by the following time-invariant state space model:

$$x(t+1) = Fx(t) + Gu(t) + v_1(t), \tag{4.1}$$

$$y(t) = Hx(t) + v_2(t) \tag{4.2}$$

where $\{v_1(t)\}$, $\{v_2(t)\}$ are zero mean Gaussian white noise sequences satisfying:

$$E\{v_1(t)v_1(t)^T\} = Q = DD^T \geqq 0, \tag{4.3}$$

$$E\{v_2(t)v_2(t)^T\} = R \geqq 0. \tag{4.4}$$

The initial state $x(0)$ is also assumed to have a Gaussian distribution with mean $\bar{x}_0$ and covariance P_0. We make the following assumptions:

S.S.1: (H, F) is observable.

S.S.2(a): (F, D) has no uncontrollable modes on the unit circle and $P_0 > 0$

or

(b): (F, D) is stabilizable and $P_0 \geqq 0$.

Using standard Kalman filtering ideas [12], the innovations model for (4.1), (4.2) is

$$\hat{x}(t+1) = F\hat{x}(t) + Gu(t) + K(t)\omega(t), \qquad \hat{x}(0) = \bar{x}_0, \tag{4.5}$$

$$y(t) = H\hat{x}(t) + \omega(t). \tag{4.6}$$

Here $K(t)$ is obtained from the solution of the following matrix Riccati equation:

$$\Sigma(t+1) = F\Sigma(t)F^T - F\Sigma(t)H^T(H\Sigma(t)H^T + R)^{-1}H\Sigma(t)F^T + Q, \tag{4.7}$$

$$\Sigma(0) = P_0, \tag{4.8}$$

$$K(t) = F\Sigma(t)H^T(H\Sigma(t)H^T + R)^{-1}. \tag{4.9}$$

In view of Assumption S.S.1, we can transform the system state such that (H, F) are in observer canonical form, i.e. (4.5), (4.6) can be written as

$$\hat{x}(t+1)=\begin{bmatrix}-a_1 & 1 & & 0\\ \vdots & & \ddots & \\ \vdots & & & 1\\ -a_n & 0 & \cdots & 0\end{bmatrix}\hat{x}(t)+\begin{bmatrix}b_1\\ \vdots\\ \vdots\\ b_n\end{bmatrix}u(t)+\begin{bmatrix}k_1(t)\\ \vdots\\ \vdots\\ k_n(t)\end{bmatrix}\omega(t), \tag{4.10}$$

$$y(t)=[1 \quad 0 \quad \cdots \quad 0]\hat{x}(t)+\omega(t). \tag{4.11}$$

Using (4.11) in (4.10) gives the following *time varying* ARMAX model:

$$A(q^{-1})y(t)=B(q^{-1})u(t)+C(t, q^{-1})\omega(t) \tag{4.12}$$

where

$$\begin{aligned}A(q^{-1})&=1+a_1q^{-1}+\cdots+a_nq^{-n},\\ B(q^{-1})&=b_1q^{-1}+\cdots+b_nq^{-n},\\ C(t, q^{-1})&=1+(k_1(t-1)+a_1)q^{-1}+\cdots+(k_n(t-n)+a_n)q^{-n}.\end{aligned} \tag{4.13}$$

It is known [13] that Assumptions S.S.1, S.S.2 are sufficient to ensure:

$$K(t)\to\bar{K} \quad \text{exponentially fast} \tag{4.14}$$

and

$$C(q^{-1})=1+(\bar{k}+a_1)q^{-1}+\cdots+(\bar{k}_n+a_n)q^{-n} \text{ is asymptotically stable.} \tag{4.15}$$

We make the following additional assumptions:

S.S.3: $b_1\neq 0$ (corresponding to $d=1$ in § 3).

S.S.4: An upper bound for n is known. (As in S.2, this is an assumption on the data supplied to the algorithm.)

S.S.5: The system

$$C(q^{-1})z(t)=b(t)$$

is input strictly passive.

S.S.6: $B(z)$ has all zeros outside the unit circle and $b_1\neq 0$ (the latter for simplicity only).

We then have the following elementary corollary to Theorem 3.1:

COROLLARY 4.1. *Let Assumptions* S.S.1-S.S.6 *hold for the system* (4.1), (4.2) *and the algorithm* A.1-A.6. *Then with probability one, for any initial parameter estimate* $\hat{\theta}(0)$

$$\limsup_{N\to\infty}\frac{1}{N}\sum_{t=1}^{N}y(t)^2<\infty, \tag{4.16}$$

$$\limsup_{N\to\infty}\frac{1}{N}\sum_{t=1}^{N}u(t)^2<\infty, \tag{4.17}$$

$$\lim_{N\to\infty}\frac{1}{N}\sum_{t=1}^{N}E\{(y(t)-y^*(t))^2|\mathcal{F}_{t-1}\}=\sigma^2 \tag{4.18}$$

where

$$\sigma^2=H\bar{\Sigma}H^T+R \tag{4.19}$$

and $\bar{\Sigma}$ *is the steady state solution of* (4.7).

Proof. The result is immediate from Theorem 3.1 on noting that $\{\omega(t)\}$ is a Gaussian innovations sequence and therefore satisfies N.1–N.3. Also, $\sigma_t^2 \to \sigma^2$ exponentially fast [13]. Hence

$$\lim_{N\to\infty} \frac{1}{N} \sum_{t=1}^{N} \sigma_t^2 = \sigma^2. \tag{4.20}$$

□

Remarks. 1. It should be pointed out that this result can be obtained directly from the corresponding result for the steady-state ARMAX model [3], [15]. Firstly, note that the covariance P_0 for the Kalman filter (with $\bar{x}_0$) defines a Gaussian distribution for x_0. So use of the steady-state gain $\bar{K}$ corresponds to a particular choice of the initial condition distribution. Since the martingale convergence theorem leads to a sample path convergence result, modification of the initial state distribution does not affect this result. The proof for this comes by noting that once a.s. convergence has been established with respect to one distribution, then it is also true for any other distribution which is absolutely continuous with respect to the original one [18]. Thus, having proved global convergence for the distribution corresponding to a steady-state Kalman filter, it also holds for other distributions corresponding to the non-steady-state case. However, it should be realized that the original martingale properties will no longer apply.

2. If a general initial condition distribution is used and one replaces (4.12) by the corresponding steady state ARMAX model, then the prediction error so defined will not satisfy N.1.

3. The result in Corollary 4.1 also applies to degenerate distributions, i.e. when the initial state is exactly known. In this case the argument in Remark 1 above cannot be used and the more complicated machinery of § 3 is necessary to deal with this case.

5. Conclusions. This paper has analyzed a robustness property of the discrete time stochastic adaptive control algorithm based on gradient estimation and minimum variance control. The algorithm is shown to be globally convergent when the system parameters are exponentially convergent to values satisfying the conditions for a globally convergent time-invariant system. This result is applied to the special case where the time variation is derived from a non-steady-state Kalman filter.

Appendix A—Properties of convergent linear systems. We present some properties of time-varying linear systems which are convergent toward an asymptotically stable system.

We consider the following time-varying system:

$$x(t+1) = A(t)x(t) + B(t)u(t), \tag{A.1}$$

$$y(t) = C(t)x(t) + D(t)u(t) \tag{A.2}$$

and we introduce the notation:

$$\Phi(n, n_0) = \prod_{k=n_0}^{n-1} A(k) \tag{A.3}$$

for the state transition matrix.

We will use $|\cdot|$ for the Euclidean norm and $\|\cdot\|$ for the l_2 norm (similarly for the induced norms).

LEMMA A.1. *Let A be asymptotically stable. Suppose $A(k) \to A$. Then there exist $\bar{n}$, $v > 0$, and $0 < \beta < 1$ such that*

$$|\Phi(n, n_0)| \leqq v\beta^{n-n_0} \tag{A.4}$$

for all $n > n_0 \geqq \bar{n}$.

Proof. Since A is asymptotically stable, $\exists P>0$ such that

$$P-A^TPA=Q \quad \text{with } Q>0. \tag{A.5}$$

Now consider the autonomous time-varying system

$$x(k+1)=A(k)x(k) \tag{A.6}$$

and try the Lyapunov function

$$V(x)=x^TPx. \tag{A.7}$$

Then

$$\begin{aligned} V(x(k+1))-V(x(k)) &= x(k)^T[A^T(k)PA(k)-P]x(k) \\ &:= -x(k)^TQ(k)x(k). \end{aligned} \tag{A.8}$$

Now since $Q(k)\to Q>0$, then $\exists \bar{n}$ such that for $k\geqq \bar{n}$, we have some μ such that

$$V(x(k+1))-V(x(k))\leqq -\mu|x(k)|^2. \tag{A.9}$$

Introducing $|x|_P=(x^TPx)^{1/2}$, we have

$$M|x|_P\leqq |x| \quad \text{where } M=(1/\lambda_{\max}P)^{1/2}. \tag{A.10}$$

Hence from (A.9)

$$\begin{aligned} |x(k+1)|_P^2 &\leqq x(k)^TPx(k)-\mu|x(k)|^2 \\ &\leqq (1-\mu M^2)|x(k)|_P^2 \quad \text{for all } x(k). \end{aligned}$$

Thus

$$|A(k)|_P\leqq (1-\mu M^2):=\beta<1.$$

Hence for $n>n_0\geqq \bar{n}$

$$|\Phi(n,n_0)|_P=\left|\prod_{k=n_0}^{n-1}A(k)\right|_P\leqq \prod_{k=n_0}^{n-1}|A(k)|_P\leqq \beta^{n-n_0}.$$

So

$$|\Phi(n,n_0)|\leqq v\beta^{n-n_0} \quad \text{for all } n>n_0\geqq \bar{n}$$

where

$$v=(1/\lambda_{\min}P)^{1/2}. \qquad \square$$

The authors suspect that Lemma 2.1 has been established elsewhere though they have no specific reference. Fuchs [14] states a related (but differing in detail) result. We can now immediately establish:

THEOREM A.1. *Consider the system* (2.1), (2.2). *Then provided* $A(k) \to A$ *with* A *asymptotically stable and* $B(k)$, $C(k)$, $D(k)$ *are bounded*:

(a) *There exist* $\bar{n}$, $0 < K_1 < \infty$, $0 \leqq K_2 < \infty$ *independent of* N *such that*

$$\sum_{t=n_0}^{N} |y(t)|^2 \leqq K_1 \sum_{t=n_0}^{N} |u(t)|^2 + K_2 \quad \text{for all } N \geqq n_0 \geqq \bar{n}. \tag{A.11}$$

(b) *There exist* $0 \leqq m_3 \leqq \infty$, $0 \leqq m_4 < \infty$ *which are independent of* t *such that*

$$|y_i(t)| \leqq m_3 + m_4 \max_{n_0 \leqq \tau \leqq N} |u(\tau)| \quad \text{for all } N \geqq t \geqq n_0. \tag{A.12}$$

Proof. The proof mimics the corresponding proof for the time-invariant case given elsewhere (see for example [15, Appendix B]). □

In the sequel, we use the notation $\|x(t)\|_{n_0}^{N} := (\sum_{t=n_0}^{N} |x(t)|^2)^{1/2}$. If the sum is finite for all $N \geqq n_0$, we say $x(t) \in l_{2e}(\mathbb{Z}_+)$ where $\mathbb{Z}_+$ is the set of integers $n_0, n_0+1, \cdots$.

LEMMA A.2. *Consider a matrix* A *and sequence* $A(k)$ *as in Lemma* A.1. *Suppose* $A(k) \to A$ *exponentially. Then there exist* $\bar{n}$, $\chi > 0$, *and* $0 < \eta < 1$ *such that*

$$\left| A^{n-n_0} - \prod_{k=n_0}^{n-1} A(k) \right| \leqq \chi \eta^{n-1} \tag{A.13}$$

for all $n > n_0 \geqq \bar{n}$.

Proof. Let $K(k) := A - A(k)$. We find the following observation useful

$$\begin{aligned} A^{n-n_0} - \prod_{k=n_0}^{n-1} A(k) &= AA^{n-n_0-1} - (A - K(n-1)) \prod_{k=n_0}^{n-2} A(k) \\ &= A\left(A^{n-n_0-1} - \prod_{k=n_0}^{n-2} A(k) \right) + K(n-1) \prod_{k=n_0}^{n-2} A(k). \end{aligned}$$

Repeated application of this gives

$$\begin{aligned} A^{n-n_0} - \prod_{k=n_0}^{n-1} A(k) &= A^{n-n_0-1} K(n_0) + A^{n-n_0-2} K(n_0+1) A(n_0) \\ &\quad + A^{n-n_0-3} K(n_0+2) \prod_{k=n_0}^{n_0+1} A(k) \\ &\quad + \cdots + AK(n-2) \prod_{k=n_0}^{n-3} A(k) + K(n-1) \prod_{k=n_0}^{n-2} A(k). \end{aligned}$$

Now since A is stable, $\exists \gamma > 0$, $0 < \xi < 1$ such that

$$|A^k| \leqq \gamma \xi^k.$$

Lemma A.1 gives that for $n > n_0 \geqq \bar{n} \exists v > 0$, $0 < \beta < 1$ such that

$$\left| \prod_{k=n_0}^{n-1} A(k) \right| \leqq v \beta^{n-n_0}.$$

Further, exponential convergence of $A(k)$ to A gives that $\exists \Omega > 0$, $0 < \lambda < 1$ such that

$$|K(k)| \leqq \Omega \lambda^k.$$

Let

$$\psi := \max(\gamma, v, \Omega), \qquad \eta := \max(\xi, \beta, \lambda).$$

Then

$$\begin{aligned}\left|A^{n-n_0}-\prod_{k=n_0}^{n-1}A(k)\right| &\leqq |K(n_0)||A^{n-n_0-1}|+|A(n_0)||K(n_0+1)||A^{n-n_0-2}| \\ &\quad +\left|\prod_{k=n_0}^{n_0+1}A(k)\right||K(n_0+2)||A^{n-n_0-3}| \\ &\quad +\cdots+\left|\prod_{k=n_0}^{n-3}A(k)\right||K(n-2)||A| \\ &\quad +\left|\prod_{k=n_0}^{n-2}A(k)\right||K(n-1)| \\ &\leqq \psi^2\eta^{n-1}(1+\psi\eta+\psi\eta^2+\cdots+\psi\eta^{n-n_0-2}+\eta^{n-n_0-1}) \\ &\qquad \text{using the above exponential bounds} \\ &= \psi^2\eta^{n-1}\left(1+\eta^{n-n_0-1}+\psi\eta\sum_{k=0}^{n-n_0-3}\eta^k\right) \\ &\qquad \text{assuming that } n-n_0\geqq 3 \\ &\leqq \psi^2\eta^{n-1}\left(2+\frac{\psi\eta}{1-\eta}\right).\end{aligned}$$

Let

$$\chi := \phi^2\left(2+\frac{\psi\eta}{1-\eta}\right).$$

Then we have the required inequality. (It is easy to see that the result holds for $n>n_0$.) □

Appendix B—Modified martingale convergence theorem. Let $\{X(t)\}$ be a sequence of nonnegative random variables adapted to an increasing sequence of sub σ-algebras $\{\mathcal{F}_t\}$. If

$$E\{X(t+1)|\mathcal{F}_t\}\leqq(1+\gamma(t))X(t)-\alpha(t)+\beta(t) \quad \text{a.s.}$$

where $\alpha(t)\geqq 0$, $\beta(t)\geqq 0$ and $E\{X(0)\}<\infty$, $\sum_{j=1}^{\infty}|\gamma(t)|<\infty$, $\sum_{j=0}^{\infty}\beta(j)<\infty$ a.s. then $X(t)$ converges almost surely to a finite random variable and

$$\lim_{N\to\infty}\sum_{t=0}^{N}\alpha(t)<\infty \quad \text{a.s.}$$

Proof. See Neveu [16]. □

The above theorem was first employed in a stochastic adaptive control proof in [10], [11]. Other applications are given in [15].

QUASI-VARIATIONAL INEQUALITIES AND ERGODIC IMPULSE CONTROL*

P. L. LIONS† AND B. PERTHAME‡

Abstract. In this paper, we solve the general ergodic control problem for reflected diffusion processes and the associated quasi-variational inequalities. Our method relies on some a priori estimates for the solutions of quasi-variational inequalities where the "discount factor" (i.e., the zero order term) is set to 0.

Key words. quasi-variational inequalities, reflected diffusion processes, impulse control, variational inequalities, Neumann conditions, ergodic control

1. Introduction. It is well known that impulse control problems for reflected diffusion processes may be solved by considering the solution of quasi-variational inequalities with Neumann boundary conditions (we refer to A. Bensoussan and J. L. Lions [3], A. Bensoussan [1] for more details). A typical example of such a quasi-variational inequality (QVI in short) is the following

$$\int_\Omega \nabla u_\alpha \cdot \nabla(v-u_\alpha)\,dx+\alpha\int_\Omega u_\alpha(v-u_\alpha)\,dx \geqq \int_\Omega f(v-u_\alpha)\,dx, \tag{1}$$
$$\forall v\in H^1(\Omega),\quad v\leqq Mu_\alpha \text{ a.e.},\quad u_\alpha\in H^1(\Omega),\quad u_\alpha\leqq Mu_\alpha \text{ a.e.}$$

where Ω is a given bounded smooth open set in $\mathbb{R}^n$, $\alpha>0$, f is a given function and M is an operator defined (for example) on $C(\bar\Omega)$ by

$$Mu=k+\inf\{c_0(\xi)+u(x+\xi)/\xi\geqq 0,\ x+\xi\in\bar\Omega\}, \tag{2}$$

where $k>0$, c_0 is continuous, subadditive, nonnegative and $c_0(0)=0$. Of course $\xi\geqq 0$ means that all the coordinates of ξ are nonnegative. We will assume (see below for a more precise assumption) that M maps $C(\bar\Omega)$ into $C(\bar\Omega)$.

In this particular situation, our main result shows that: denoting by $\langle\varphi\rangle=\text{meas}\,(\Omega)^{-1}\int_\Omega v\,dx$, $(\alpha u_\alpha, u_\alpha-\langle u_\alpha\rangle)$ converge uniformly on $\bar\Omega$ to the unique solution (λ, v_0) of

$$\int_\Omega \nabla u_0\cdot\nabla(v-v_0)\,dx\geqq\int_\Omega (f-\lambda)(v-v_0)\,dx, \tag{3}$$
$$\forall v\in H^1(\Omega),\quad v\leqq Mv_0 \text{ a.e.},\ \lambda\in\mathbb{R},\quad v_0\in H^1(\Omega)\cap C(\bar\Omega),\quad \langle v_0\rangle=0,\quad v_0\leqq Mv_0 \text{ in } \bar\Omega.$$

This result is stated in § 2; the existence part is proved in §§ 3 and 4: in § 3 we obtain H^1 bounds on $u_\alpha-\langle u_\alpha\rangle$ while in § 4 we prove that $u_\alpha-\langle u_\alpha\rangle$ are equicontinuous on $\bar\Omega$. The uniqueness is proved in § 5 and extensions to general second-order operators and general oblique derivative conditions are given in § 6. Finally the interpretation of these results in terms of ergodic impulse control is presented in § 7. Some technical results are collected in the appendix.

The above result (and the extensions obtained in this paper) answers a longstanding question concerning ergodic impulse control theory. And even if we borrow some techniques used in other ergodic problems by P. L. Lions [12], F. Gimbert [7], the specificity of the implicit obstacle Mu requires a particular treatment. We would like to mention a few other works on ergodic stochastic control problems: J. M. Lasry [10];

2. The main result. We consider $u_\alpha \in H^1(\Omega) \cap C(\bar{\Omega})$, the solution of (1) (the existence and uniqueness is deduced from the results of [3], Hanouzet and Joly [8]). Recall that we assume:

$$\forall u \in C(\bar{\Omega}), \quad Mu \in C(\bar{\Omega}); \tag{4}$$

this is the case if Ω is convex or more generally (cf. Perthame [16], [17]) if Ω satisfies:

$$\forall x \in \bar{\Omega}, \quad \{\xi / \xi \geqq 0;\ \xi \neq 0;\ x+\xi \in \partial\Omega;\ \exists \varepsilon > 0, \forall y \geqq 0, \quad x+y \notin \Omega \text{ if } |y-\xi| \leqq \varepsilon\} = \varnothing. \tag{5}$$

We will assume:

$$f \in L^p(\Omega) \quad \text{for some } p > \frac{N}{2} \text{ if } N \geqq 2, \quad p \geqq 1 \text{ if } N = 1. \tag{6}$$

THEOREM 1. *We assume* (5) *and* (6). *Then* αu_α *converges uniformly on* $\bar{\Omega}$ *to some constant* λ, *and* $u_\alpha - \langle u_\alpha \rangle$ *converges uniformly on* $\bar{\Omega}$ *and strongly in* $H^1(\Omega)$ *to* v_0. *Finally* (λ, v_0) *is the unique solution of the system* (3).

Remark. We give below extensions of this result and its stochastic interpretation.

The uniqueness of (λ, v_0) is proved in § 5; we prove in §§ 3-4 that $v_\alpha = u_\alpha - \langle u_\alpha \rangle$ is bounded in $H^1(\Omega)$ and relatively compact in $C(\bar{\Omega})$. If we know that $\alpha \langle u_\alpha \rangle$ is bounded, the convergence of $(\alpha u_\alpha, v_\alpha)$ is then easily deduced from these bounds.

We prove next that αu_α is bounded in $L^\infty(\Omega)$. First of all let us mention that this is an obvious consequence of comparison arguments if $f \in L^\infty(\Omega)$; indeed in this case we have:

$$\alpha \|u_\alpha\|_{L^\infty} \leqq \|f\|_{L^\infty}.$$

In the general case (i.e. (6)) we need to find a supersolution $\bar{u}_\alpha$ and a subsolution $\underline{u}_\alpha$ of the QVI (1) such that $\alpha \bar{u}_\alpha$, $\alpha \underline{u}_\alpha$ are bounded in $L^\infty(\Omega)$. For the supersolution, we just need to take $\bar{u}_\alpha$, the solution of

$$-\Delta \bar{u}_\alpha + \alpha \bar{u}_\alpha = f^+ \text{ in } \Omega, \quad \frac{\partial \bar{u}_\alpha}{\partial n} = 0 \text{ on } \Gamma, \quad \bar{u}_\alpha \in W^{2,p}(\Omega)$$

(where n denotes the unit outward normal to $\partial\Omega = \Gamma$). For the subsolution we first consider v_α^m, the solution of

$$-\Delta v_\alpha^m + \alpha v_\alpha^m = f \wedge (-m) \text{ in } \Omega, \quad \frac{\partial v_\alpha^m}{\partial n} = 0 \text{ on } \Gamma, \quad v_\alpha^m \in W^{2,p}(\Omega).$$

As α goes to 0, it is well known that $v_\alpha^m - \langle v_\alpha^m \rangle$ goes uniformly to v^m, the solution of

$$-\Delta v^m = f \wedge (-m) - \langle f \wedge (-m) \rangle \quad \text{in } \Omega,$$

$$\langle v^m \rangle = 0, \quad \frac{\partial v^m}{\partial n} = 0 \text{ on } \Gamma, \quad v^m \in W^{2,p}(\Omega).$$

Remarking that v^m converges uniformly to 0 as m goes to ∞, we choose m such that $\|v^m\|_{L^\infty} \leqq k/4$. Hence for α small enough

$$|v_\alpha^m(x) - v_\alpha^m(y)| \leqq k \quad \forall x, y \in \bar{\Omega},$$

and thus $v_\alpha^m \leqq M v_\alpha^m$ on $\bar{\Omega}$; and we may take $\underline{u}_\alpha = v_\alpha^m$ for α small (since $v_\alpha^m \leqq 0$, we may

take $\underline{u}_\alpha = v_{\alpha_0}^m$ for $\alpha \geqq \alpha_0 \cdots$). In view of standard results on linear equations $\alpha \underline{u}_\alpha$ is bounded in $L^\infty(\Omega)$, and we conclude since we have

$$\underline{u}_\alpha \leqq u_\alpha \leqq \bar{u}_\alpha.$$

In what follows we set $\lambda_\alpha = \alpha\langle u_\alpha \rangle$. λ_α is bounded, and $v_\alpha = u_\alpha - \langle u_\alpha \rangle$ is the solution of the following QVI

$$\begin{aligned} &a(v_\alpha, v - v_\alpha) + \alpha(v_\alpha, v - v_\alpha) \geqq (f_\alpha, v - v_\alpha) \quad \forall v \in H^1(\Omega), \quad v \leqq M v_\alpha \text{ a.e.}, \\ &v_\alpha \in C(\bar{\Omega}) \cap H^1(\Omega), \quad v_\alpha \leqq M v_\alpha \text{ in } \bar{\Omega} \end{aligned} \tag{7}$$

where (f, g) denotes the L^2 scalar product, $a(\varphi, \psi) = \int_\Omega \nabla\varphi \cdot \nabla\psi \, dx$, $f_\alpha = f - \lambda_\alpha$.

3. Boundedness of v_α in $H^1(\Omega)$. The bounds in $H^1(\Omega)$ rely on the following crucial lemma.

LEMMA 2. *Let $m_\alpha = \min_{\bar{\Omega}} v_\alpha$; then there exists $C \geqq 0$ independent of $\alpha \in]0, 1[$ such that*

$$|m_\alpha| \leqq C \| v_\alpha^- \|_{L^1(\Omega)} + C. \tag{8}$$

Using this lemma (which is proved below), it is now easy to prove the H^1 bounds: indeed using $v \equiv m_\alpha$ as a test function in (7), we find

$$\begin{aligned} \int_\Omega |Dv_\alpha|^2 + \alpha v_\alpha^2 \, dx &\leqq \int_\Omega f_\alpha (v_\alpha - m_\alpha) + \alpha v_\alpha m_\alpha \, dx \\ &\leqq C m_\alpha + C \| v_\alpha \|_{H^1(\Omega)} \leqq C \| v_\alpha \|_{H^1(\Omega)} + C \quad \text{by (8).} \end{aligned}$$

Recalling that $\langle v_\alpha \rangle = 0$, we conclude using the Poincaré inequality.

We now turn to the proof of Lemma 2: we consider the sets

$$\begin{aligned} E &= \{x \in \bar{\Omega}, \, v_\alpha(x) < m_\alpha + k\}, \\ F &= \{x \in \bar{\Omega}, \, v_\alpha(x) < m_\alpha + 2k + C_0\}, \end{aligned}$$

where $C_0 = \sup \{c_0(\xi), \, \xi \geqq 0, \, |\xi| \leqq \operatorname{diam}(\bar{\Omega})\}$.

Since we may assume without loss of generality that $|m_\alpha| = -m_\alpha$ is as large as we wish, (8) will be proved if we show that

$$\operatorname{meas}(F) \geqq \gamma > 0 \tag{9}$$

for some γ independent of $\alpha \in]0, 1[$.

Letting $\delta > 0$, we set $\Gamma_\delta = \{x \in \bar{\Omega}, \operatorname{dist}(x, \Gamma) \leqq \delta\}$. We may assume that E is contained in Γ_δ. Indeed if this were not the case, there would exist $x_0 \in E \cap (\Omega - \Gamma_\delta)$ and for all $x \in \bar{\Omega}$, $x \leqq x_0$ we would have

$$v_\alpha(x) \leqq M v_\alpha(x) \leqq k + c_0(x_0 - x) + v_\alpha(x_0) < m_\alpha + 2k + C_0,$$

i.e., $\{x \in \bar{\Omega}, \, x \leqq x_0\} \subset F$, proving (9) since $x_0 \notin \Gamma_\delta$.

Now if $E \subset \Gamma_\delta$, we observe that on the open set E, $v_\alpha < M v_\alpha$ and thus we obtain easily

$$\begin{aligned} &-\Delta v_\alpha + \alpha v_\alpha = f_\alpha \quad \text{in } E, \qquad \frac{\partial v_\alpha}{\partial n} = 0 \quad \text{on } \partial E \cap \partial\Omega = \Gamma_1', \\ &v_\alpha = m_\alpha + k \quad \text{on } \partial E \cap \Omega, \qquad v_\alpha \in W^{2,p}_{\text{loc}}(E \cup \Gamma_1') \cap C(\bar{E}). \end{aligned}$$

Let $h \in L^p(\Omega)$ satisfy $h \leqq f_\alpha - \alpha k - \alpha m_\alpha$, $\forall \alpha \in]0, 1[$ and let z_α be the solution of

$$-\Delta z_\alpha + \alpha z_\alpha = h \quad \text{in } \Gamma_\delta, \qquad \frac{\partial z_\alpha}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

$$z_\alpha = 0 \quad \text{on } \partial\Gamma_\delta - \partial\Omega, \qquad z_\alpha \in W^{2,p}(\Gamma_\delta).$$

We have

$$\|z_\alpha\|_{L^\infty(\Gamma_\delta)} \leqq C \|h\|_{L^p(\Gamma_\delta)} \tag{10}$$

where C does not depend on α or δ. Thus $|z_\alpha| \leqq k$ for δ small enough and, by the maximum principle, $z_\alpha \leqq v_\alpha - k - m_\alpha$ on E. At the minimum point of v_α we thus have $z_\alpha \leqq -k$ and this contradicts (10). This shows that for δ small enough E cannot be contained in Γ_δ and thus (9) and (8) are proved.

4. Compactness in $C(\bar{\Omega})$. We first show that v_α is bounded in $L^\infty(\Omega)$: notice that we already know from (8) and the H^1 bound that v_α is bounded from below. To show that v_α is bounded from above, we observe that (7) yields

$$a(v_\alpha, \varphi) + (v_\alpha, \varphi) \leqq (f_\alpha + (1-\alpha)v_\alpha, \varphi) \quad \forall \varphi \in H^1(\Omega), \quad \varphi \geqq 0. \tag{11}$$

Hence $v_\alpha \leqq \bar{v}_\alpha^1$, where $\bar{v}_\alpha^1$ is the solution of

$$-\Delta \bar{v}_\alpha^1 + \bar{v}_\alpha^1 = f_\alpha^+ + (1-\alpha)v_\alpha^+ \text{ in } \Omega, \quad \frac{\partial \bar{v}_\alpha^1}{\partial u} = 0 \quad \text{on } \Gamma, \quad \bar{v}_\alpha^1 \in W^{2,p_1}(\Omega)$$

where $p_1 = \min(p, 2N/(N-2))$ (if $N \leqq 2$, $p_1 = p$). If $p_1 > N/2$, $N \geqq 3$ or if $N \leqq 2$, $\bar{v}_\alpha^1$ is bounded in $L^\infty(\Omega)$ and we conclude. Now if $p_1 < N/2$, we deduce that $\bar{v}_\alpha^1$ is bounded in $L^{p_2}(\Omega)$ where $p_2 = Np_1/(N-2p_1)$ and thus v_α is also bounded in $L^{p_2}(\Omega)$. By an easy bootstrap argument we then obtain the L^∞ bound.

Next, we observe that v_α is also a solution of the following QVI:

$$\begin{aligned} &a(v_\alpha, v - v_\alpha) + (v_\alpha, v - v_\alpha) \geqq (f_\alpha + (1-\alpha)v_\alpha, v - v_\alpha) \\ &\forall v \in H^1(\Omega), \quad v \leqq Mv_\alpha \text{ a.e.}, \quad v_\alpha \in C(\bar{\Omega}) \cap H^1(\Omega), \quad v_\alpha \leqq Mv_\alpha \text{ in } \bar{\Omega}. \end{aligned} \tag{12}$$

If we denote by $g_\alpha = f_\alpha + (1-\alpha)v_\alpha$, we observe that g_α is bounded in $L^p(\Omega)$ and thus we conclude that v_α is compact in $C(\bar{\Omega})$ by a simple application of the following result proved in the appendix.

PROPOSITION 3. *Under assumptions* (5)-(6) *we denote by* $Tf = w$ *the solution of the following* QVI:

$$\begin{aligned} &a(w, v - w) + (w, v - w) \geqq (f, v - w) \\ &\forall v \in H^1(\Omega), \quad v \leqq Mw \text{ a.e.}, \; w \in C(\bar{\Omega}) \cap H^1(\Omega), \quad w \leqq Mw \text{ in } \bar{\Omega}. \end{aligned} \tag{13}$$

Then T maps bounded sets of $L^p(\Omega)$ into compact sets of $C(\bar{\Omega})$.

Using Proposition 3 we may now prove our claim (Theorem 1) on the convergence of αu_α, v_α to a subsequence (uniqueness will prove that the whole sequence converges); we may assume that as $\alpha \to 0_+$

$$\lambda_\alpha = \alpha\langle u_\alpha \rangle \to \lambda, \qquad v_\alpha \to v_0 \text{ in } C(\bar{\Omega}) \text{ and weakly in } H^1,$$

(thus $\alpha u_\alpha \to \lambda$ uniformly). Of course we have

$$\langle v_0 \rangle = 0, \qquad Mv_\alpha \to Mv_0 \text{ in } C(\bar{\Omega}) \text{ as } \alpha \to 0_+;$$

and we let $\delta_\alpha = \|Mv_\alpha - Mv_0\|_\infty$. If $v \in H^1(\Omega)$, $v \leqq Mv_0$ a.e., $v - \delta_\alpha \leqq Mv_\alpha$ a.e. and

consequently is an admissible test function for problem (7). Thus we find

$$a(v_\alpha, v-v_\alpha)+\alpha(v_\alpha, v-\delta_\alpha-v_\alpha)\geqq(f-\lambda_\alpha, v-\delta_\alpha-v_\alpha)$$

and passing to the limit we find

$$a(v_0, v)\geqq(f-\lambda, v-v_0)+\overline{\lim_\alpha}\, a(v_\alpha, v_\alpha).$$

Since by weak convergence

$$\underline{\lim_\alpha}\, a(v_\alpha, v_\alpha)\geqq a(v_0, v_0)$$

we deduce that (λ, v_0) solves (3). But in addition choosing $v=v_0$ we obtain $a(v_\alpha, v_\alpha)\to a(v_0, v_0)$ and thus ∇v_α converges strongly in L^2 to $a(v_0, v_0)$, proving the strong convergence in H^1.

5. Uniqueness. We first prove the uniqueness of λ: thus let (λ, v_0), (μ, w_0) be two solutions of (3). If $\lambda\neq\mu$, assume for example $\lambda<\mu$; then for $\varepsilon>0$ small enough

$$\lambda-\varepsilon(v_0-C_1)<\mu-\varepsilon w_0 \quad \text{in } \bar{\Omega}$$

where $C_1>\|v_0-w_0\|_{L^\infty}$. Observe next that w_0 (resp. v_0-C_1) is the solution of the following QVI

$$a(w_0, v-w_0)+\varepsilon(w_0, v-w_0)\geqq(f-\mu+\varepsilon w_0, v-w_0)$$

$$\forall v\in H^1(\Omega), \quad v\leqq Mw_0 \text{ a.e.}, \qquad w_0\in C(\bar{\Omega})\cap H^1(\Omega), \quad w_0\leqq Mw_0 \text{ a.e.}$$

(resp. the same problem with $f-\mu+\varepsilon w_0$ replaced by $f-\lambda+\varepsilon(v_0-C_1)$). Standard comparison results then yield: $v_0-C_1\geqq w_0$ in $\bar{\Omega}$, but in view of the choice of C_1 this is not possible. Hence $\lambda=\mu$.

We now have to prove: $v_0\equiv w_0$. This is more delicate and we are first going to show that v_0-w_0 is constant on an open set ω (not empty) included in Ω. To prove this, we assume $v_0\not\equiv w_0$ and then we claim there exists one maximum point of v_0-w_0 denoted by $\bar{x}$ such that

$$w_0(\bar{x})<Mw_0(\bar{x}).$$

Indeed if x_0 is any maximum point of v_0-w_0 on $\bar{\Omega}$, then if the above inequality does not hold at x_0, there exists $\xi\geqq 0$ such that

$$w_0(x_0)=k+c_0(\xi)+w_0(x_1) \quad \text{where } x_1=x_0+\xi\in\bar{\Omega}.$$

Then necessarily we have also

$$v_0(x_0)=k+c_0(\xi)+v_0(x_1)=Mv_0(x_0)$$

since if it were not the case we would have

$$\max(v_0-w_0)<v_0(x_1)-w_0(x_1)$$

and this is obviously impossible. Now clearly x_1 is a new maximum point of v_0-w_0 and we may choose $\bar{x}=x_1$ since $Mw_0(x_1)>w_0(x_1)$.

Then there exists $\delta>0$ such that on $V=\overline{B(\bar{x}, \delta)}\cap\bar{\Omega}$ we have $w_0<Mw_0$ and thus

$$-\Delta w_0=f-\lambda \quad \text{in } \mathring{V}, \qquad \frac{\partial w_0}{\partial n}=0 \quad \text{on } V\cap\partial\Omega.$$

Two cases occur. If $\bar{x}\in\Omega$ then in a connected neighborhood ω of $\bar{x}$ we have

$$a(v_0-w_0, \varphi)\leqq 0 \quad \forall\varphi\in\mathcal{D}_+(\omega), \qquad v_0-w_0\in H^1(\Omega),$$

$$v_0-w_0 \text{ achieves its maximum at } \bar{x}\in\omega$$

and the strong maximum principle (for weak subsolutions) implies that $v_0 - w_0$ is constant on ω.

On the other hand if $\bar{x} \in \partial\Omega$, then for δ small enough $\omega = B(\bar{x}, \delta) \cap \Omega$ is connected and we have:

$$a(v_0 - w_0, \varphi) \leqq 0 \quad \forall \varphi \in H^1_{\Gamma_0}(\Omega), \quad \varphi \geqq 0,$$

$$\max_{\bar{\omega}} (v_0 - w_0) = (v_0 - w_0)(\bar{x}) > 0$$

where

$$H^1_{\Gamma_0}(\omega) = \{u \in H^1(\omega), u|_{\Gamma_0} = 0\}, \qquad \Gamma_0 = \partial B(\bar{x}, \delta) \cap \Omega.$$

Considering the solution $\bar{u}$ of

$$-\Delta \bar{u} = 0 \quad \text{in } \omega, \qquad \frac{\partial \bar{u}}{\partial n} = 0 \quad \text{on } \partial\Omega \cap B(\bar{x}, \delta),$$

$$\bar{u} - (v_0 - w_0) \in H^1_{\Gamma_0}$$

we have: $v_0 - w_0 \leqq \bar{u} \leqq \max_{\bar{\omega}} (v_0 - w_0) = (v_0 - w_0)(\bar{x})$. Thus $\max_{\bar{\omega}} \bar{u} = \bar{u}(\bar{x})$, and again by the strong maximum principle we conclude. Therefore in both cases we have proved that

$$v_0 - w_0 = \max_{\bar{\Omega}} (v_0 - w_0) \quad \text{in } B(y_0, \delta) \quad \overline{B(y_o, \delta)} \subset \Omega \text{ for some } y_0 \in \Omega, \ \delta > 0. \tag{14}$$

Using (14), we are going to prove that $v_0 \equiv w_0 + \max_{\bar{\Omega}} (v_0 - w_0)$ on $\bar{\Omega}$ and since $\langle v_0 \rangle = \langle w_0 \rangle = 0$ the proof of the uniqueness will be completed. To prove this last claim, we consider the problem in $\Omega_1 = \Omega - \overline{B(y_0, \delta)}$

$$\begin{aligned} &a(u, v - u) \geqq (f - \lambda, v - u) \quad \forall v \in H^1(\Omega_1), \\ &v \equiv \varphi_0 \quad \text{on } \partial B(y_0, \delta), \qquad v \leqq Mu \quad \text{a.e. on } \Omega_1, \\ &u \in C(\bar{\Omega}) \cap H^1(\Omega_1), \quad u \equiv \varphi_0 \text{ in } \overline{B(y_0, \delta)}, \quad u \leqq Mu \text{ a.e. on } \Omega_1 \end{aligned} \tag{15}$$

where $\varphi_0 \equiv w_0 + \max_{\bar{\Omega}} (v_0 - w_0)$. Clearly enough in view of (14) both v_0 and φ_0 are solutions of (15) and hence we just have to prove that (15) has a unique solution. And this will be done by an easy adaptation of the classical arguments on QVI due to A. Bensoussan and J. L. Lions [3], B. Hanouzet and J. L. Joly [8]. Indeed let $\underline{u}$ be a fixed solution of (15), if $v \in H^1(\Omega_1) \cap C(\bar{\Omega}_1)$, $v \geqq \underline{u}$ in $\bar{\Omega}_1$ we set $u = Sv$ the solution of the variational inequality

$$\begin{aligned} &a(u, w - u) \geqq (f - \lambda, w - u) \quad \forall w \in H^1(\Omega_1), \qquad w = \underline{u} \text{ on } \partial B(y_0, \delta), \\ &w \leqq M\tilde{v} \text{ in } \Omega_1, \quad u \in H^1(\Omega_1), \quad u = \underline{u} \text{ on } \partial B(y_0, \delta), \quad u \leqq M\tilde{v} \text{ in } \Omega_1 \end{aligned}$$

where $\tilde{v}, \tilde{u}$ are the extensions of v, u to $\bar{\Omega}$ by φ_0 on $\overline{B(y_0, \delta)}$. Then $u \in C(\bar{\Omega}_1)$ and thus $\tilde{u} \in C(\bar{\Omega})$. Finally we consider u_0 solution of

$$-\Delta u_0 = f - \lambda \text{ in } \Omega_1, \quad \frac{\partial u_0}{\partial n} = 0 \text{ on } \partial\Omega, \quad u_0 = \varphi_0 \text{ on } \partial B(y_0, \delta);$$

and we set $\bar{u} = u_0 + C$. Choosing C large enough, we find $\theta \in]0, 1[$ such that

$$\underline{u} \leqq u_0 \leqq \theta\bar{u} + (1 - \theta)\underline{u} \quad \text{in } \bar{\Omega}_1.$$

Observing that S is nondecreasing and concave, we deduce

$$\underline{u} \leqq u_1 = Su_0 \leqq \theta S\bar{u} + (1 - \theta)\underline{u} \leqq \theta u_0 + (1 - \theta)\underline{u};$$

and iterating this string of inequalities, we find for $n \geqq 1$

$$\underline{u} \leqq u_n = S^n u_0 \leqq \theta u_{n-1} + (1-\theta)\underline{u} \quad \text{in } \bar{\Omega}_1.$$

Therefore for $n \geqq 1$

$$0 \leqq u_n - \underline{u} \leqq \theta^n (u_0 - \underline{u}) \quad \text{in } \bar{\Omega}_1$$

and u_n converges uniformly on $\bar{\Omega}_1$ to $\underline{u}$; since $\underline{u}$ is an arbitrary solution of (15), the uniqueness is proved.

6. Extensions. We will only mention the extension to a general operator

$$A = -a_{ij}\partial_{ij} - b_i \partial_i$$

where we use the convention on repeated indices and where $\partial_i = \partial/\partial x_i$. We will assume (for example)

$$a_{ij} = a_{ji} \in W^{1,\infty}(\Omega), \qquad b_i \in L^\infty(\Omega), \qquad \exists \nu > 0, \forall x \in \bar{\Omega}, \quad (a_{ij}) \geqq \nu I_N. \tag{16}$$

We will also consider a general oblique derivative boundary condition determined by a smooth vector field (say C^2) on Γ denoted by γ satisfying

$$\exists \nu > 0, \quad \forall x \in \Gamma, \quad \gamma(x) \cdot n(x) \geqq \nu. \tag{17}$$

In view of (16) we may also write A in divergence form:

$$A = -\partial_i (a_{ij}\partial_j) - (b_j - \partial_i a_{ij})\partial_j;$$

and we will denote by n_A the conormal

$$(n_A)_i = a_{ij} n_j, \quad \forall i \in \{1, \cdots, N\}, \quad \forall x \in \Gamma;$$

and we decompose γ as follows:

$$n_A = c\gamma + \gamma', \qquad n \cdot \gamma' = 0 \quad \text{on } \Gamma \tag{18}$$

and (17) implies $c \geqq c_0 > 0$ on Γ.

The strong formulation (and essentially heuristic) of the analogue of (1) is now:

$$\begin{aligned} &\max\,(Au_\alpha + \alpha u_\alpha - f,\, u_\alpha - Mu_\alpha) = 0 \quad \text{in } \Omega, \\ &\max\left(u_\alpha - Mu_\alpha, \frac{\partial u_\alpha}{\partial \gamma}\right) = 0 \quad \text{on } \Gamma. \end{aligned} \tag{19}$$

The precise formulation of (19) is

$$\begin{aligned} &a(u_\alpha, v - u_\alpha) + \alpha(u_\alpha, v - u_\alpha) \geqq (f, v - u_\alpha) \quad \forall v \in H^1(\Omega), \quad v \leqq Mu_\alpha \text{ a.e.}, \\ &u_\alpha \in C(\bar{\Omega}) \cap H^1(\Omega), \qquad u_\alpha \leqq Mu_\alpha \quad \text{in } \bar{\Omega} \end{aligned} \tag{20}$$

where the bilinear form is now given by

$$a(u, v) = \int_\Omega a_{ij}\partial_i u \partial_j v - b_i \partial_i uv + \partial_i a_{ij} \partial_j uv \, dx + \int_\Gamma \partial_{\gamma'} u \cdot v \, dS$$

the last integral being well defined (by duality) on $H^1(\Omega)^2$ since γ' is tangential.

Adapting easily the arguments of A. Bensoussan and J. L. Lions [3], one finds that (20) has a unique solution (the fact that $u_\alpha \in C(\bar{\Omega})$ being deduced from the methods of the appendix). Mimicking the arguments of the preceding sections, we obtain:

THEOREM 4. *Under assumptions* (5), (6), (16), (17), αu_α *converges uniformly on* $\bar{\Omega}$ *to some constant* λ, *and* $u_\alpha - \langle u_\alpha \rangle$ *converges uniformly on* $\bar{\Omega}$ *and strongly in* $H^1(\Omega)$ *to*

v_0. *Finally* (λ, v_0) *is the unique solution of*

$$
\begin{aligned}
&a(v_0, v-v_0) \geqq (f-\lambda), v-v_0) \quad \forall v \in H^1(\Omega), \quad v \leqq Mv_0 \text{ a.e.},\\
&v_0 \in C(\bar{\Omega}) \cap H^1(\Omega), \qquad v_0 \leqq Mv_0 \text{ in } \bar{\Omega}.
\end{aligned} \tag{21}
$$

7. The ergodic impulse control of diffusion processes. All throughout this section, we assume (5), (6), (16), (17). We introduce $\sigma_{ij} = \sqrt{2}(a_{ij})^{1/2}$ (σ_{ij} is the positive definite symmetric square root) and we first recall the stochastic interpretation of u_α—the solution of (20). To simplify notation, we will assume that $b_i \in W^{1,\infty}(\Omega)$, $f \in C(\bar{\Omega})$.

We consider (a, F, F_t, P, B_t) a probability space with a F_t-adapted Brownian motion in $\mathbb{R}^N$. The control will consist of a sequence of stopping times $(\theta_n)_{n\geqq 0}$ satisfying

$$
\theta_0 = 0 < \theta_1 < \theta_2 < \cdots < \theta_n < \theta_{n+1} \leqq +\infty, \qquad \theta_n \underset{n}{\uparrow} \infty \quad \text{a.s.}
$$

and of a sequence of random variables $(\xi_n)_{n\geqq 1}$ such that

$$
\xi_n \text{ is } F_{\theta_n}\text{-measurable}, \quad \xi_n \geqq 0, \quad X^n_{\theta_n} + \xi_n \in \bar{\Omega} \quad \text{a.s.},
$$

where X^n_t is defined below. We define inductively X^n_t for $t \in [\theta_n, \theta_{n+1}]$ by the solution of the following stochastic differential equation with reflection:

$$
\begin{aligned}
&dX^n_t = \sigma(X^n_t)\, dB_t + b(X^n_t)\, dt - \gamma(X^n_t)\, dA^n_t \quad \text{for } \theta_{n-1} \leqq t \leqq \theta_n,\\
&X^n_{\theta_{n-1}} = X^{n-1}_{\theta_{n-1}} + \xi_{n-1}, \qquad X^n_t \in \bar{\Omega} \quad \forall t \in [\theta_{n-1}, \theta_n],\\
&A^n_t = \int_{\theta_{n-1}}^{t} 1_\Gamma(X^n_s)\, d|A^n|_s \quad \forall t \in [\theta_{n-1}, \theta_n]
\end{aligned}
$$

where X^n_t, A^n_t are continuous, F_t-adapted; A^n_t has bounded variations and $|A^n|_t$ is the total variation of A^n on $[\theta_{n-1}, t]$. Finally $X^0_{\theta_0} = x$, $\xi_0 = 0$.

For more details on stochastic differential equations with reflection we refer the reader to Gihman and Skorohod [6], Ikeda and Watanabe [9], A. Bensoussan and J. L. Lions [3], P. L. Lions and A. S. Sznitman [15].

In what follows we denote by $\mathcal{S}$ any admissible control system consisting of $(\theta_n)_{n\geqq 0}$, $(\xi_n)_{n\geqq 1}$ with the above conditions. If θ is any stopping time ($\theta \leqq \infty$), we define the cost functions:

$$
\begin{aligned}
&J_\alpha(x, \theta, \mathcal{S}) = E\int_0^\theta f(X_t)\, e^{-\alpha t}\, dt + \sum_{n\geqq 1} \{k + c(\xi_n)\} 1_{\theta_n < \theta}\, e^{-\alpha \theta_n},\\
&J_\alpha(x, \mathcal{S}) = J_\alpha(x, +\infty, \mathcal{S}),\\
&J(x, \theta, \mathcal{S}) = E\int_0^\theta f(X_t)\, dt + \sum_{n\geqq 1} \{k + c(\xi_n)\} 1_{\theta_n < \theta} \quad \text{if } \theta \text{ is bounded},
\end{aligned}
$$

where $X_t = X^n_t$ for $t \in [\theta_{n-1}, \theta_n[$, $X_0 = x$.

THEOREM 5. *With the above conditions and notation, we have*

$$
u_\alpha(x) = \inf_{\mathcal{S}} J_\alpha(x, S).
$$

In addition λ*—the limit of* $\alpha\langle u_\alpha\rangle$*—is given by*

$$
\lambda = \lim_{T\to\infty} \frac{1}{T} \inf_{\mathcal{S}} J(x, T, \mathcal{S}), \quad \textit{uniformly for } x \in \bar{\Omega},
$$

$$
\lambda = \lim_{\alpha\to 0+} \alpha \inf_{\mathcal{S}} J_\alpha(x, \mathcal{S}), \quad \textit{uniformly for } x \in \bar{\Omega}.
$$

Furthermore if $v \in C(\bar{\Omega})$, *we denote by*

$$v(x, t) = \inf_{\mathcal{S}} \{J(x, t, \mathcal{S}) + E(v(X_t))\} \quad \forall x \in \bar{\Omega}, \quad \forall t \geqq 0;$$

then $v(x, t) - \langle v(\cdot, t)\rangle$ *converges uniformly on* $\bar{\Omega}$ *to* v_0 *as* $t \to +\infty$. *In particular if* $v \in C(\bar{\Omega})$ *satisfies for some* $T > 0$

$$v(x) = \inf_{\mathcal{S}} \{J(x, T, \mathcal{S}) + E(v(X_t))\} \quad \forall x \in \bar{\Omega}$$

then $v - \langle v\rangle = v_0$; *in addition* v_0 *satisfies* (*where* θ *is any bounded stopping time which may depend on* $\mathcal{S}$):

$$v_0(x) = \inf_{\mathcal{S}} \{J(x, \theta, \mathcal{S}) + E(v_0(X_\theta))\}.$$

Finally (λ, v_0) *is the unique solution in* $\mathbb{R} \times C(\bar{\Omega})$ (*up to the addition of a constant to* v_0) *of*

$$v_0(x) = \lim_{T \to \infty} \inf_{\mathcal{S}} \left\{ E \int_0^T \{f(X_t) - \lambda\}\, dt + \sum_{n \geqq 1} (k + c(\xi_n)) 1_{\theta_n < T} + v_0(X_T) \right\}$$

or

$$v_0(x) = \lim_{\alpha \to 0+} \inf_{\mathcal{S}} \left\{ E \int_0^\infty \{f(X_t) - \lambda\}\, e^{-\alpha t}\, dt + \sum_{n \geqq 1} (k + c(\xi_n))\, e^{-\alpha \theta_n} \right\}.$$

We skip the proof of this result since it is a straightforward application of our results and methods and of the verification arguments given in A. Bensoussan and J. L. Lions [3]. Let us also mention that, as in [3], all infima above are achieved for "explicit" optimal control systems $\mathcal{S}$ obtained by considering the successive exit times of the open set $\{v_0 < Mv_0\}$ and by choosing at each x in $\{v_0 = Mv_0\}$ an optimal jump i.e. choosing (in a measurable way) $\xi \geqq 0$ such that

$$v_0(x) = k + c_0(\xi) + v_0(x + \xi) \quad \text{if } x \in \{v_0 = Mv_0\}.$$

Appendix. Continuity results for variational inequalities and quasivariational inequalities with general oblique derivative boundary conditions. We begin with results concerning variational inequalities. We thus assume (6), (16), (17) and we let $\psi \in C(\bar{\Omega})$. Then exactly as in [3], [4] (see also P. L. Lions [13]), denoting by

$$b(u, v) = \int_\Omega a_{ij} \partial_i u \partial_j v - b_i \partial_i u v + \partial_i a_{ij} \partial_j u v + cuv\, dx + \int_\Gamma \partial_{\gamma'} u \cdot v\, dS$$

where

$$c \in L^\infty(\Omega), \qquad c \geqq c_0 > 0, \tag{A.1}$$

there exists a unique solution u of

$$b(u, v - u) \geqq (f, v - u) \quad \forall v \in H^1(\Omega), \quad v \leqq \psi \text{ a.e.}, \quad u \in H^1(\Omega), \quad u \leqq \psi \text{ a.e.} \tag{A.2}$$

The following result extends and sharpens results of [3]; this result is proved by the method of P. L. Lions [12]—see also P. L. Lions [14], F. Gimbert [7] for similar results.

THEOREM A.1. *We assume* (6), (16), (17) *and* (A.1) *and* $\psi \in C(\bar{\Omega})$. *Then if* u *is the solution of* (A.2), $u \in C(\bar{\Omega})$. *Furthermore if* $\psi \in W^{1,\infty}(\Omega)$ *and* $f \in L^p(\Omega)$ *with* $p > N$, $u \in W^{1,\infty}(\Omega)$; *and if* $\psi \in C^{0,\alpha}(\bar{\Omega})$ *for some* $\alpha \in]0, 1[$, $f \in L^p(\Omega)$ *with* $p = N/(2 - \alpha)$ *if* $N \geqq 2$ ($p = 1$ *if* $N = 1$) *then* $u \in C^{0,\alpha}(\bar{\Omega})$. *Finally if* ψ *lies in a compact set of* $C(\bar{\Omega})$, f

remains bounded in $L^p(\Omega)$ *for some* $p > N/2$ ($p = 1$ *if* $N = 1$), *then* u *remains in a compact set of* $C(\bar{\Omega})$.

Proof. We just have to prove that if $\psi \in W^{1,\infty}(\Omega)$ and $f \in L^p(\Omega)$ for some $p > N$ then $u \in W^{1,\infty}(\Omega)$. Indeed the remainder then follows from the well-known inequality:

$$\|(u_1 - u_2)^+\|_{L^\infty} = \|(\psi_1 - \psi_2)^+\|_{L^\infty}$$

if u_1, u_2 are the solutions of (A.2) corresponding to ψ_1, ψ_2.

Now if $\psi \in W^{1,\infty}(\Omega)$, substracting the solution of the linear problem:

$$A\bar{u} + c\bar{u} = f \text{ in } \Omega, \quad \partial_\gamma \bar{u} = 0 \text{ on } \Gamma, \quad \bar{u} \in W^{2,p}(\Omega)$$

we may assume without loss of generality that $f \equiv 0$.

Next, we recall (cf. [3]) that u is the limit as ε goes to 0 of the solution u_ε of:

$$Au_\varepsilon + cu_\varepsilon + \beta_\varepsilon(u_\varepsilon - \psi) = 0 \text{ in } \Omega, \quad \partial_\gamma u_\varepsilon = 0 \text{ on } \Gamma, \quad u_\varepsilon \in W^{2,p}(\Omega),$$

where $\beta_\varepsilon(t) = (1/\varepsilon)\beta(t)$, $\beta \equiv 0$ if $t \leqq 0$, $\beta'(t) > 0$ if $t > 0$, β is convex, smooth on $\mathbb{R}$.

Since the bounds on $\|u_\varepsilon\|_{W^{1,\infty}}$ obtained below just depend on (16), (17) and $\|\psi\|_{W^{1,\infty}}$, we may assume that a_{ij}, b_i, c, are smooth and so is u_ε. By a simple use of the maximum principle, we find:

$$\|u_\varepsilon\|_{L^\infty(\Omega)} \leqq C$$

where C denotes various constants independent of ε.

We recall from [12], [14], [15] that there exists a smooth matrix valued function $(\alpha_{ij})_{1 \leqq i,j \leqq N}$ satisfying

$$\exists \nu, \mu > 0, \forall x \in \bar{\Omega}, \quad \nu I_N \leqq (\alpha_{ij}) \leqq \mu I_N, \qquad (\alpha_{ij}) = (\alpha_{ji}),$$

$$\partial_\gamma(\alpha_{ij}\partial_i v \partial_j v) \leqq 0 \text{ on } \Gamma, \quad \forall v \in C^2(\bar{\Omega}), \qquad \partial_\gamma v = 0 \text{ on } \Gamma,$$

and we set

$$w = \alpha_{ij}\partial_i u_\varepsilon \partial_j u_\varepsilon + \lambda(C_0 - u_\varepsilon)^2$$

where $\lambda < 0$ is determined below, and $C_0 \geqq 1 + \|u_\varepsilon\|_{L^\infty}$. To simplify notation, we omit below the subscript ε and we set $\varphi_i = \partial_i \varphi$. Then we compute easily Aw and using the equation we find for some $\delta > 0$

$$\begin{aligned} Aw + 2cw \leqq & -2\delta|D^2u|^2 - 2\lambda\delta|Du|^2 - 2\alpha_{ij}u_i\beta'(u-\psi)(u_j - \psi_j) \\ & + C|D^2u||Du| + C|Du|^2 + 2\alpha_{ij}u_i b_{k,j}u_k \\ & - 2\alpha_{ij}u_i c_j u + 2\lambda(C_0 - u)\beta(u-\psi) + C; \end{aligned}$$

choosing λ large enough we deduce

$$\begin{aligned} Aw + (2c + \lambda\delta)w \leqq & 2(\alpha_{ij}u_i b_k u_k)_j + 2(\alpha_{ij}u_i c)_j + C\lambda^2 \\ & + 2\lambda(C_0 - u)\beta(u-\psi) - \beta'(u-\psi)(\alpha_{ij}u_i u_j - \alpha_{ij}\psi_i\psi_j). \end{aligned}$$

Since β is convex, $\beta(t) = 0$ if $t \leqq 0$; $\beta(u-\psi) \leqq \beta'(u-\psi)(u-\psi)$ and we finally obtain

$$Aw + (2c + \lambda\delta)w \leqq 2(\alpha_{ij}u_i b_k u_k)_j + 2(\alpha_{ij}u_i uc)_j + C\lambda^2 - \beta'(u-\psi)(w - \tilde{w})$$

where $\tilde{w} = \alpha_{ij}\psi_i\psi_j + \lambda(C - \psi)^2 \leqq C$.

Using comparison arguments, we deduce

$$w \leqq C\lambda + \|z_\lambda\|_{L^\infty(\Omega)} \quad \text{in } \bar{\Omega}$$

where z_λ is the solution of

$$Az_\lambda + (2c + \lambda\delta)z = 2(\alpha_{ij}u_i b_k u_k)_j + 2(\alpha_{ij}u_i uc)_j \quad \text{in } \Omega,$$

$$\partial_\gamma z_\lambda = 0 \quad \text{on } \Gamma.$$

But classical bounds on linear equations yield

$$\|z_\lambda\|_{L^\infty} \leqq \mu(\lambda)[\|\nabla u\|^2_{L^\infty(\Omega)} + \|\nabla u\|_{L^\infty(\Omega)}]$$

where $\mu(\lambda) \to 0$ as $\lambda \to +\infty$. Hence we obtain finally

$$\|\nabla u\|^2_{L^\infty(\Omega)} \leqq C\lambda + \mu(\lambda)[\|\nabla u\|^2_{L^\infty(\Omega)} + \|\nabla u\|_{L^\infty(\Omega)}]$$

and we conclude choosing λ large.

Let us mention that if b_i, $c \in W^{1,\infty}$, we conclude directly without introducing z_λ. □

We next state the extension of Proposition 3 to the case of general operators A:

THEOREM A.2. *We assume* (5), (6), (16), (17) *and* (A.1). *Then we denote by u the solution of the* QVI

$$\text{(A.3)} \qquad \begin{aligned} &b(u, v-u) \geqq (f, v-u) \quad \forall v \in H^1(\Omega), \quad v \leqq Mu \text{ a.e.} \\ &u \in C(\bar{\Omega}) \cap H^1(\Omega), \qquad u \leqq Mu \quad \text{in } \bar{\Omega}. \end{aligned}$$

Then if f lies in a bounded set of $L^p(\Omega)$ *with* $p > (N/2)$ *if* $N \geqq 2$, $p = 1$ *if* $N = 1$; *u remains in a compact set of* $C(\bar{\Omega})$.

Proof. We recall first that there exists a subsolution $\underline{u}$ of (A.3) which remains in a compact set of $C(\bar{\Omega})$ if f stays bounded in $L^p(\Omega)$ (see for example the construction of $\underline{u}$ in § 2).

Clearly the usual supersolution $\bar{u}$, solution of the linear problem

$$A\bar{u} + c\bar{u} = f \text{ in } \Omega, \quad \partial_\gamma \bar{u} = 0 \text{ on } \Gamma, \quad \bar{u} \in W^{2,p}(\Omega),$$

has the same property. We let $u_0 = \bar{u}$, and we define a sequence u_n inductively as the solution of (A.2) corresponding to $\psi = Mu_{n-1}$. By induction we prove that u—for each fixed n—remains in a compact set of $C(\bar{\Omega})$ if f stays bounded in $L^p(\Omega)$. Indeed this is true for $n = 0$ and if it is true for u_{n-1}, since M maps $C(\bar{\Omega})$ into $C(\bar{\Omega})$ (assumption (4)) and

$$\|Mu - Mv\|_\infty \leqq \|u - v\|_\infty,$$

Mu_{n-1} remains in a compact set of $C(\bar{\Omega})$ and so does u_n by Theorem A.1. Hence by Ascoli's theorem

$$|u_n(x) - u_n(y)| \leqq \delta_n(|x-y|), \qquad \delta_n(t) \to 0 \quad \text{as } t \to 0_+$$

for all x, y $\bar{\Omega}$; where δ_n does not depend on f provided f remains bounded in L^p.

Next, the Hanouzet-Joly argument [8] shows that u_n converges uniformly to u solution of (A.3) and

$$\|u_n - u\|_\infty \leqq C\theta^n$$

for some $\theta \in]0, 1[$, $C \geqq 0$ independent of f provided f remains bounded in $L^p(\Omega)$.

In conclusion, we find if f is bounded in L^p

$$\underline{u} \leqq u \leqq \bar{u} \text{ in } \bar{\Omega} \text{ and thus } \|u\| \leqq C,$$

$$|u(x) - u(y)| \leqq \inf_{n \geqq 1} \{C\theta^n + \delta_n(|x-y|)\} \quad \forall x, y \in \bar{\Omega}.$$

And by Ascoli's theorem, our claim is proved. □

Acknowledgments. The authors would like to thank A. Bensoussan, M. Robin and J. L. Menaldi for calling their attention to the problem treated in this paper.
