Abstract. In the first part of the paper we study the pencil $(sE-A)$ by using some geometric concepts given by Bernhard [SIAM J. Control Optim., 20 (1982), pp. 612-633] and some new ones which are introduced here. Such concepts are then used to obtain an alternative characterization for the finite and infinite-zero structure of the pencil and to construct a polynomial basis for $\ker(sE-A)$. Necessary and sufficient conditions for the rows or/and the columns of the pencil to be linearly independent over the ring of the polynomials are also given. The main geometric properties of a regular pencil are presented, including the identification of the subspace in which the impulsive response of the autonomous generalized linear system $E\dot{x}=Ax$ takes place. In the second part we consider the generalized linear system $E\dot{x}=Ax+Bu$; $y=Cx$ and we give necessary and sufficient conditions for the infinite-zeros of the regular pencil $(sE-A)$ to be controllable and observable.

Key words. theory of pencils, linear systems, controllability and observability

AMS(MOS) subject classifications. 15A21, 58F19, 93B

1. Introduction. In the first part of the paper (§§ 2-4) we consider the pencil $(sE-A)$ where s is the complex variable and E and A are given maps.

The pencil $(sE-A)$ is said to be regular if E and A are square maps with $\det(sE-A)\neq 0$ and it is said to be singular otherwise.

Bernhard [3] and Wong [17] have introduced some geometric concepts (subspaces) which are important for a geometric approach to the theory of pencils. In § 2 we introduce some other subspaces and we obtain geometric relations which are very useful for the analysis undertaken in the subsequent sections.

In § 3 we study the singular pencil $(sE-A)$. Bernhard [3] has characterized the finite-zeros, also known as the finite elementary divisors [7], and the minimal column indices of $(sE-A)$ by an indirect method, namely, he has identified them with the control invariants of a certain pair of maps denoted here by (F, G).

It is shown that the above elements can be characterized directly from the geometric concepts introduced by him without resorting to notions of linear systems. A polynomial basis for $\ker(sE-A)$ is also constructed.

We then obtain a block triangular representation for $\ker(sE-A)$ from which we can extract the infinite-zero structure and a polynomial basis for the left kernel of $(sE-A)$. We also refer to [12], [14] for algebraic approaches to infinite-zeros of a pencil.

Necessary and sufficient conditions for the rows or the columns of the singular pencil to be linearly independent over the ring of the polynomials are also given.

The regular pencil is analysed in § 4. This kind of pencil is important in the theory of dynamical linear systems. As an example, in [1] is shown a connection between regular pencils, almost controlled invariant subspaces [16] and the proportional-derivative state feedback law, $u=F_1x+F_2\dot{x}$, for the linear system $\dot{x}=Ax+Bu$.

Associated with a regular pencil we have an autonomous generalized linear system $E\dot{x}=Ax$ which has a unique solution for an arbitrary initial condition $x(0-)$. It has been shown in [13] that the response of such a system to an arbitrary $x(0-)$ consists

† Department of Electrical Engineering, FEC-Unicamp, C.P. 6122, Campinas 13100 S.P., Brasil. Part of this work was carried out while the author was with the Department of Electrical Engineering, Imperial College, University of London, London, England.

of a combination of an exponential motion determined by the finite-zeros and an impulsive component due to the infinite-zeros of $(sE - A)$.

The subspace in which the exponential motion occurs has already been characterized in [3], [15], [5]. We identify here the subspace in which the impulsive response takes place and we also summarize the main geometric properties of a regular pencil.

In the second part of the paper (§ 5) we consider the generalized linear system $E\dot{x} = Ax + Bu$; $y = Cx$, such that the associated pencil $(sE - A)$ is regular.

We shall concentrate on the study of controllability and observability of the zeros of the pencil $(sE - A)$. Rosenbrock [10] has been the first author to study this subject and he has given conditions for the infinite-zeros to be controllable and observable. Verghese [13] has pointed out that Rosenbrock's conditions were correct only in a special case and he has then provided tests which are valid in any situation. We have built on such tests to obtain necessary and sufficient conditions for the controllability and observability of the infinite-zeros which are expressed in terms of the geometry of the maps E, A, B and C. Geometric interpretations for the controllable and unobservable finite-zeros are also given.

Notation. We shall use throughout lower case letters for vectors, capitals for matrices and maps, and script for subspaces and vector spaces.

Im and ker denote image (range) and kernel (null space), respectively.

If A is a map and $\mathscr{L}$ and $\mathscr{K}$ are subspaces such that $A\mathscr{L} \subset \mathscr{K}$ we then denote the restriction of A to $\mathscr{L}$ with codomain $\mathscr{K}$ by $\mathscr{K}|A|\mathscr{L}$. Mat A denotes the matrix of the map A.

If $\mathscr{L}$ and $\mathscr{K}$ are subspaces such that $\mathscr{L} \subset \mathscr{K}$ then $\mathscr{K}$ (mod $\mathscr{L}$) or $\mathscr{K}/\mathscr{L}$ denotes the quotient space $\{k + \mathscr{L}, k \in \mathscr{K}\}$, $\dim \mathscr{K}/\mathscr{L} = \dim \mathscr{K} - \dim \mathscr{L}$.

If $\mathscr{X}$ is a vector space then $\mathscr{X}'$ stands for the associated dual vector space.

R denotes the real line and C the complex plane.

If n is a positive integer, then $\underline{n}$ stands for the set of integers $\{1, 2, \cdots, n\}$.

$\sigma(A)$ denotes the spectrum of A, i.e., the eigenvalues of A counting multiplicities.

$R[s]$ denotes the ring of the polynomials.

2. Some fundamental subspaces for a geometric description of the pencil $(sE - A)$. This section defines some subspaces which play a vital role later and establishes useful connections between them.

Let E and A be maps from $\mathscr{X}$ to $\mathscr{Z}$, $\dim \mathscr{X} = n$, $\dim \mathscr{Z} = m$, and let $\mathscr{M}$ be any given subspace of $\mathscr{X}$. Consider the following family F_1 of subspaces

$$F_1 := \{\mathscr{V} \subset \mathscr{X} | A\mathscr{V} \subset E\mathscr{V}, \mathscr{V} \subset \mathscr{M}\}.$$

It can be easily seen that the above family is closed under addition and therefore it contains a supremal element $\mathscr{V}^* \subset \mathscr{M}$ which can be computed through the following nonincreasing sequence [3], [17]

$$\mathscr{V}^* := \mathscr{V}^n, \qquad \mathscr{V}^u = \mathscr{M} \cap A^{-1}(E\mathscr{V}^{u-1}), \quad u \in \underline{n}, \qquad \mathscr{V}^0 = \mathscr{X}. \tag{1}$$

Hereafter we shall assume that $\mathscr{M} = A^{-1}(\text{Im } E)$. Thus $\mathscr{V}^*$ is the supremal element of the family F_1 which is contained in $\mathscr{X}$.

It has been shown in [3], [17] that if λ is a finite-zero of the pencil $(sE - A)$ then there exists a vector $v \in \mathscr{V}^*$ such that $Av = \lambda Ev$.

Let $\mathscr{K}$ be any given subspace of $\mathscr{X}$ and define a family F_2 of subspaces according to

$$F_2 := \{\mathscr{W}_a \subset \mathscr{X} | \mathscr{W}_a = \mathscr{K} \cap E^{-1}(A\mathscr{W}_a)\}.$$

The next proposition states that the above family has a unique least element.

PROPOSITION 1. *There is a unique element* $\mathcal{W}_a^* \in F_2$ *such that* $\mathcal{W}_a^* \subset \mathcal{W}_a$ *for every* $\mathcal{W}_a \in F_2$. *Furthermore* $\mathcal{W}_a^*$ *can be computed by the following sequence*

$$\mathcal{W}_a^* := \mathcal{W}_a^n, \qquad \mathcal{W}_a^u = \mathcal{K} \cap E^{-1}(A\mathcal{W}_a^{u-1}), \quad u \in \underline{n}, \qquad \mathcal{W}_a^0 = 0. \tag{2}$$

Proof. First note that the sequence (2) is nondecreasing. We have $\mathcal{W}_a^1 \supset \mathcal{W}_a^0$ and if $\mathcal{W}_a^u \supset \mathcal{W}_a^{u-1}$, then $\mathcal{W}_a^{u+1} = \mathcal{K} \cap E^{-1}(A\mathcal{W}_a^u) \supset \mathcal{K} \cap E^{-1}(A\mathcal{W}_a^{u-1}) = \mathcal{W}_a^u$.

Thus there exists $k \in \underline{n}$ such that $\mathcal{W}_a^u = \mathcal{W}_a^k$, $u \geqq k$. So $\mathcal{W}_a^* = \mathcal{W}_a^k$ and $\mathcal{W}_a^* \in F_2$. To show that $\mathcal{W}_a^*$ is infimal let $\mathcal{W}_a \in F_2$. Then $\mathcal{W}_a \supset \mathcal{W}_a^0$ and if $\mathcal{W}_a \supset \mathcal{W}_a^u$ we obtain

$$\mathcal{W}_a = \mathcal{K} \cap E^{-1}(A\mathcal{W}_a) \supset \mathcal{K} \cap E^{-1}(A\mathcal{W}_a^u) = \mathcal{W}_a^{u+1}.$$

Thus $\mathcal{W}_a \supset \mathcal{W}_a^u$, $\forall u \in \underline{n}$, so that $\mathcal{W}_a \supset \mathcal{W}_a^*$. □

We shall consider three cases for the subspace $\mathcal{K}$:

(i) $\mathcal{K} = \mathcal{V}^*$. In this situation we denote the infimal element of F_2 by $\mathcal{T}^*$, which is then given by (see (2))

$$\mathcal{T}^* := \mathcal{T}^n, \qquad \mathcal{T}^u = \mathcal{V}^* \cap E^{-1}(A\mathcal{T}^{u-1}), \quad u \in \underline{n}, \qquad \mathcal{T}^0 = 0. \tag{3}$$

We shall see in § 3 that the subspace $\mathcal{T}^*$ is the subspace which gives rise to a polynomial basis for $\ker(sE - A)$.

(ii) $\mathcal{K} = \mathcal{X}$. In this case the infimal element of F_2 is denoted by $\mathcal{W}_b^*$ which in turn is given by

$$\mathcal{W}_b^* := \mathcal{W}_b^n, \qquad \mathcal{W}_b^u = E^{-1}(A\mathcal{W}_b^{u-1}), \quad u \in \underline{n}, \qquad \mathcal{W}_b^0 = 0. \tag{4}$$

It will be shown in §§ 3 and 4 that the subspace $\mathcal{W}_b^*$ is related to the infinite-zero structure of the pencil $(sE - A)$.

(iii) If $\mathcal{K} = A^{-1}(\operatorname{Im} E)$ we let $\mathcal{W}_a^*$ denote the infimum of F_2 (computed by the sequence (2)). It will be shown in § 4 that if $(sE - A)$ is a regular pencil then the subspace $\mathcal{W}_a^*$ defined this way is the subspace in which the impulsive response of the autonomous generalized linear system $E\dot{x} = Ax$ takes place.

The next lemma shows some geometric properties of the sequences (1-4) above defined.

LEMMA 1. *Let* $\mathcal{K} = A^{-1}(\operatorname{Im} E)$ *in the sequence* (2). *Then*

(a) $E\mathcal{T}^u = A\mathcal{T}^{u-1}$,

(b) $\mathcal{T}^u = \mathcal{V}^* \cap \mathcal{W}_b^u$,

(c) $\mathcal{W}_a^u = \mathcal{K} \cap \mathcal{W}_b^u$,

(d) $\mathcal{T}^u = \mathcal{V}^* \cap \mathcal{W}_a^u$,

(e) $E\mathcal{W}_b^u = A\mathcal{W}_a^{u-1}$.

Proof. See Appendix.

The relevance and motivation for the subspaces above defined will be better understood in the following sections.

3. The singular pencil. Let $(sE - A)$ be a singular pencil and let $x(s)$ be a polynomial solution of least degree for the equation

$$(sE - A)x(s) = 0 \tag{5}$$

with

$$x(s) = x_k + sx_{k-1} + s^2x_{k-2} + \cdots + s^kx_0.$$

Substituting the above solution in (5) and equating the coefficients of the same power in s we then obtain

$$Ax_k = 0, \quad Ex_k = Ax_{k-1}, \quad \cdots, \quad Ex_1 = Ax_0, \quad Ex_0 = 0. \tag{6}$$

It has been shown by Gantmacher [7] that the vectors x_i, $i \in \{0, 1, \cdots, k\}$ are linearly independent. Let $\mathscr{D} := \text{span}\{x_i\}$. Then from (6) it follows that $A\mathscr{D} = E\mathscr{D}$. This suggests that $\mathscr{T}^*$ (note that $E\mathscr{T}^* = A\mathscr{T}^*$ by Lemma 1a) is the subspace which provides vectors for a polynomial basis for $\ker(sE - A)$. In other words if $x_i(s)$, $i \in \underline{l}$, is a basis over $R[s]$ for $\ker(sE - A)$ with

$$x_i(s) = x_{i,k_i} + sx_{i,k_i-1} + s^2 x_{i,k_i-2} + \cdots + s^{k_i} x_{i,0},$$

for some set of nonnegative integers $\{k_i\}$, $i \in \underline{l}$, then $\mathscr{T}^* = \text{span}\{x_{i,j}\}$, $i \in \underline{l}$, $j \in \{0, 1, \cdots, k_i\}$.

In order to show this consider the following family of subspaces:

$$F_3 := \{\mathscr{T} | A\mathscr{T} = E\mathscr{T}\}$$

such that $\mathscr{T} = \text{span}\{t_{i,j}\}$ with

$$Et_{i,0} = 0, \quad Et_{i,j} = At_{i,j-1}, \quad At_{i,h_i} = 0, \qquad i \in \underline{r}, \quad j \in \underline{h}_i, \tag{7}$$

where $r := \dim(\ker E \cap \mathscr{T}) = \dim(\ker A \cap \mathscr{T})$ and h_i, $i \in \underline{r}$, is a set of nonnegative integers.

The following theorem states that $\mathscr{T}^*$ is the supremum of F_3.

THEOREM 1. *$\mathscr{T}^* = \sup F_3$ and*

$$\mathscr{T}^* = \bigoplus_{i=1}^{l} \mathscr{T}_i$$

with

$$\mathscr{T}_i = \text{span}\{x_{i,j}\}, \qquad \dim \mathscr{T}_i = k_i + 1$$

such that

$$Ex_{i,0} = 0, \quad Ex_{i,j} = Ax_{i,j-1}, \quad Ax_{i,k_i} = 0, \qquad j \in \underline{k}_i \tag{8}$$

where

$$l := \dim(\ker E \cap \mathscr{T}^*) = \dim(\ker A \cap \mathscr{T}^*)$$

and k_i, $i \in \underline{l}$, is a set of nonnegative numbers uniquely defined from the dimensions of the subspaces $\mathscr{T}^u$ in (3).

Furthermore, for any decomposition of $\mathscr{T}^*$ as the direct sum of independent subspaces such as in (8), it is necessarily true that $\dim \mathscr{T}_i = k_i + 1$, $i \in \underline{l}$.

Proof. See Appendix.

Consider the set $\{x_{i,j}\}$, $i \in \underline{l}$, $j \in \{0, 1, \cdots, k_i\}$ in (8). As an immediate consequence of Theorem 1 we now obtain the following result.

COROLLARY 1. *Let $(sE - A)$ be a singular pencil. Then*

$$\ker(sE - A) = \underset{R[s]}{\text{span}}\{x_i(s)\}, \qquad i \in \underline{l},$$

where

$$l := \dim(\ker E \cap \mathscr{T}^*) = \dim \ker(\ker A \cap \mathscr{T}^*)$$

and

$$x_i(s) = x_{i,k_i} + sx_{i,k_i-1} + \cdots + s^{k_i} x_{i,0}.$$

The set $\{k_i\}$, $i \in \underline{l}$ coincides with the set of minimal column indices defined in [7].

Proof. Since $\mathcal{T}^*$ is the supremum of the family F_3 it follows that $x_i(s)$, $i \in \underline{l}$, is indeed a basis over $R[s]$ for $\ker(sE-A)$. By using (8) we then have

$$\operatorname{Mat}[E\mathcal{T}^* | (sE-A) | \mathcal{T}^*] = P(s) = \operatorname{diag}[P_i(s)], \qquad i \in \underline{l}, \quad \text{where}$$

$$P_i(s) = \begin{bmatrix} s & -1 & \cdot & \cdot & 0 & 0 \\ 0 & s & \cdot & \cdot & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & \cdot & -1 & 0 \\ 0 & 0 & \cdot & \cdot & s & -1 \end{bmatrix}_{k_i \times (k_i+1)} \tag{9}$$

Thus $P(s)$ corresponds to the set of canonical blocks associated with the minimal column indices in Gantmacher's decomposition of a singular pencil. The set $\{k_i\}$, $i \in \underline{l}$, is the set of minimal column indices due to the uniqueness of the canonical form of a singular pencil under strict equivalence [7]. □

The next theorem contains a geometric characterization for the finite-zeros of the pencil $(sE-A)$.

THEOREM 2. *Let $(sE-A)$ be a singular pencil and consider the map A_f: $\mathcal{V}^*$ (mod $\mathcal{T}^*$) $\to E\mathcal{V}^*$ (mod $E\mathcal{T}^*$) such that $A_f P = QA_v$ where $A_v := E\mathcal{V}^* | A | \mathcal{V}^*$ and P: $\mathcal{V}^* \to \mathcal{V}^*$ (mod $\mathcal{T}^*$), Q: $E\mathcal{V}^* \to E\mathcal{V}^*$ (mod $E\mathcal{T}^*$) are the canonical projections. Then*

$$\sigma(A_f) = \{\textit{finite-zeros of the singular pencil } (sE-A)\}.$$

Proof. Let $\mathcal{V}_1$ be any subspace such that

$$\mathcal{V}^* = \mathcal{T}^* \oplus \mathcal{V}_1 \tag{10}$$

and note that $\mathcal{V}_1 \cap \ker E = 0$ since $\mathcal{V}^* \cap \ker E \subset \mathcal{T}^*$.

Next we show that $E\mathcal{T}^* \cap E\mathcal{V}_1 = 0$. Suppose that $Et = Ev$, for $t \in \mathcal{T}^*$, $0 \neq v \in \mathcal{V}_1$. Then $v - t \in \ker E \cap \mathcal{V}^*$ and thus $v \in \mathcal{T}^*$, which is impossible. Thus we may consider the direct sum

$$E\mathcal{T}^* \oplus E\mathcal{V}_1 \tag{11}$$

so that in the decompositions (10)-(11)

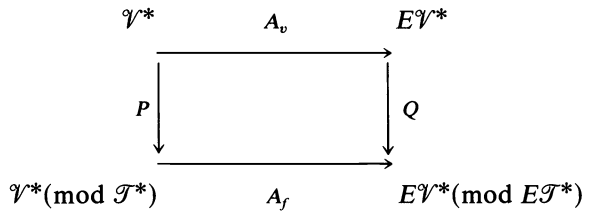
$$\operatorname{Mat}[E\mathcal{V}^* | (sE-A) | \mathcal{V}^*] = \begin{bmatrix} P(s) & -A_{12} \\ 0 & sI - A_{22} \end{bmatrix},$$

where $P(s)$ is as in Corollary 1 and

$$\begin{bmatrix} A_{12} \\ A_{22} \end{bmatrix} = \operatorname{Mat}[E\mathcal{V}^* | A | \mathcal{V}_1].$$

Since an eigenvector v associated with a finite-zero λ belongs to $\mathcal{V}^*$, i.e., $Av = \lambda Ev \Rightarrow v \in \mathcal{V}^*$, it follows that the finite-zeros of the pencil $(sE-A)$ coincide with the eigenvalues of A_{22}.

As a matter of fact, A_{22} is the representation of the map A_f defined above. The following commutative diagram illustrates the definition of A_f.



To show that the diagram commutes, note that $t \in \mathcal{T}^*$ implies $A_v t = Et_1$ for some $t_1 \in \mathcal{T}^*$. Thus $A_f P = QA_v$ and the map A_f is well defined.

Comment. As mentioned previously, in [3] the minimal column indices have been identified with the controllability indices of a certain pair of maps (F, G) while the finite-zeros have been associated with the eigenvalues of the uncontrollable map derived from the pair (F, G) [18]. The aim of Theorem 1, Corollary 1 and Theorem 2 has been to show that we can obtain this information (minimal column indices and finite-zeros) and a polynomial basis for $\ker (sE - A)$ by using only the geometric concepts introduced in the previous section.

We proceed with the geometric description of a singular pencil by identifying its infinite-zero structure and a polynomial basis for $\ker (sE^T - A^T)$ or, equivalently, a polynomial basis for the left kernel of $(sE - A)$.

From Gantmacher's decomposition of a singular pencil [7] it follows that to an infinite-zero of order g_i there corresponds a subspace $\mathcal{W}$, $\dim \mathcal{W} = g_i + 1$ such that

$$E\mathcal{W} \subset A\mathcal{W}, \qquad \mathcal{W} \cap \ker A = 0 \tag{12}$$

and such that the map $N := A\mathcal{W}|E|\mathcal{W}$ has all eigenvalues equal to zero, i.e., there exists a chain of linearly independent vectors $\{w_{i,j}\}$ which span $\mathcal{W}$ (see also [8, Thm. 6]) such that

$$\begin{aligned} &Ew_{i,1} = 0, \\ &Ew_{i,j} = Aw_{i,j-1}, \qquad j \in \{2, \cdots, g_i + 1\}. \end{aligned} \tag{13}$$

By using (13) we obtain the following representation:

$$\text{Mat}\,[A\mathcal{W}|(sE - A)|\mathcal{W}] = sN - I, \quad \text{where}$$

$$N = \begin{bmatrix} 0 & 1 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 1 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & \cdot & \cdot & 1 \\ 0 & \cdot & \cdot & \cdot & \cdot & 0 \end{bmatrix}_{(g_i+1)\times(g_i+1)} \tag{14}$$

Verghese [14] has shown that the pencil $(sN - I)$ has an infinite-zero of order g_i. The concept of an infinite-zero is a generalization of the concept of a finite-zero in the sense that the pencil $(sN - I)$ loses rank at $s = \infty$.

The next lemma contains some results which will allow us to proceed with the description of structural features of a singular pencil.

LEMMA 2. *Let $(sE - A)$ be a singular pencil for which $\mathcal{V}^* = 0$ in the sequence* (1). *Let $\mathcal{W}_b^*$ be given by the sequence* (4). *Then*:

(a) $\ker_{R[s]} (sE - A) = 0$ *and the pencil has no finite-zeros.*

(b) $E\mathcal{W}_b^* \subset A\mathcal{W}_b^*$ *and the map $N := A\mathcal{W}_b^*|E|\mathcal{W}_b^*$ has all eigenvalues equal to zero. The infinite-zero structure of $(sE - A)$ is determined from the Jordan decomposition*

of N. Moreover

$$\mathcal{W}_b^* = \sup\{\mathcal{W} | E\mathcal{W} \subset A\mathcal{W}\}. \tag{15}$$

(c) *Consider the maps*

$$\hat{E}: \mathcal{X}(\text{mod } \mathcal{W}_b^*) \to \mathcal{X}(\text{mod } A\mathcal{W}_b^*)$$

and

$$\hat{A}: \mathcal{X}(\text{mod } \mathcal{W}_b^*) \to \mathcal{X}(\text{mod } A\mathcal{W}_b^*)$$

such that

$$\hat{E}P = QE, \qquad \hat{A}P = QA,$$

where $P: \mathcal{X} \to \mathcal{X}(\text{mod } \mathcal{W}_b^*)$ *and* $Q: \mathcal{X} \to \mathcal{X}(\text{mod } A\mathcal{W}_b^*)$ *are the canonical projections.*

Then the pencil $(s\hat{E} - \hat{A})$ *has no finite and infinite-zeros and* $\ker_{R[s]}(s\hat{E} - \hat{A}) = 0$. *Furthermore, the rows of* $(s\hat{E} - \hat{A})$ *are linearly dependent over* $R[s]$.

Proof. It is intuitive that if $\mathcal{V}^* = 0$ for the pencil $(sE - A)$ then the structural invariants of such a pencil consist in general of infinite-zeros and minimal row indices only. Therefore $(sE - A)$ is in general a pencil with a number of rows greater or equal to the number of columns. A formal proof of the above theorem is given in the Appendix.

We are, finally, in a position to obtain the infinite-zero structure of the singular pencil $(sE - A)$ as well as a polynomial basis for the left kernel of $(sE - A)$. For this, let $\bar{A}$ and $\bar{E}$ be maps defined by

$$\bar{A}P = QA, \qquad \bar{E}P = QE, \tag{16}$$

where

$$P: \mathcal{X} \to \mathcal{X}(\text{mod } \mathcal{V}^*), \qquad Q: \mathcal{X} \to \mathcal{X}(\text{mod } E\mathcal{V}^*)$$

are the canonical projections. We then have the following theorem.

THEOREM 3. *Let* $(sE - A)$ *be a singular pencil. Then its infinite-zero structure coincides with that of* $(s\bar{E} - \bar{A})$. *Moreover, a polynomial basis for the left kernel of* $(s\bar{E} - \bar{A})$ *is also a polynomial basis for the left kernel of* $(sE - A)$.

Proof. Let $\bar{\mathcal{V}} := \sup\{\mathcal{V} | \bar{A}\mathcal{V} | \bar{E}\mathcal{V}\}$ and write $\mathcal{L} := P^{-1}\bar{\mathcal{V}}$. Then $\bar{A}P\mathcal{L} \subset \bar{E}P\mathcal{L}$, which implies $QA\mathcal{L} \subset QE\mathcal{L}$. Hence

$$A\mathcal{L} \subset E\mathcal{L} + E\mathcal{V}^*$$

which implies

$$A(\mathcal{L} + \mathcal{V}^*) \subset E(\mathcal{L} + \mathcal{V}^*)$$

so that

$$\mathcal{L} + \mathcal{V}^* \subset \mathcal{V}^* \Rightarrow \mathcal{L} \subset \mathcal{V}^* \Rightarrow \bar{\mathcal{V}} = 0.$$

Since $\bar{\mathcal{V}} = 0$ we then conclude from Lemma 2 that the pencil $(s\bar{E} - \bar{A})$ has no finite-zeros and its columns are linearly independent over $R[s]$. By using the results of Corollary 1, Theorem 2 and Lemma 2, it follows that the pencil $(sE - A)$ admits the following triangular decomposition

$$\text{Mat}(sE - A) = \begin{bmatrix} sE_1 - A_1 & x & x & x \\ 0 & sI - A_f & x & x \\ 0 & 0 & sN - I & x \\ 0 & 0 & 0 & sE_4 - A_4 \end{bmatrix} \tag{17}$$

where

$$\begin{bmatrix} sE_1 - A_1 & x \\ 0 & sI - A_f \end{bmatrix} = \text{Mat}\,[E\mathcal{V}^* | (sE - A) | \mathcal{V}^*]$$

and

$$\begin{bmatrix} sN - I & x \\ 0 & sE_4 - A_4 \end{bmatrix} = \text{Mat}\,(s\bar{E} - \bar{A}).$$

The pencil $(sE_1 - A_1)$ is given by $\text{diag}\,[P_i(s)]$, $i \in \underline{l}$, where $P_i(s)$ is as in (9). It can be easily seen that there exists a minor M in $(sE_1 - A_1)$ such that $\det M = s^{k_1 + \cdots + k_l}$, i.e. the rows of $(sE_1 - A_1)$ are linearly independent over $R[s]$.

The pencil $(sI - A_f)$ is regular and the eigenvalues of A_f coincide with the finite-zeros of $(sE - A)$.

The pencil $sN - I$ has only infinite-zeros. The Jordan decomposition of the map N (see Lemma 2b) determines the infinite-zero structure of $(sE - A)$.

By Lemma 2c, the pencil $(sE_4 - A_4)$ has no finite and infinite-zeros, $\ker_{R[s]} (sE_4 - A_4) = 0$ and its rows are linearly dependent over $R[s]$.

It now follows that a polynomial basis for the left kernel of $(sE_4 - A_4)$ is also a basis for the left kernel of $(sE - A)$. □

Comment. The triangular representation (17) is valid for any singular pencil. Van Dooren [11] has obtained a similar representation by means of algorithms which make use of the technique of singular value decomposition. His work is concerned with a stable numerical method which extracts the invariants of a singular pencil whereas this paper deals with the geometric structure of such a pencil.

In the remainder of this section we give geometric criteria for the rows or the columns of a singular pencil to be linearly independent over $R[s]$. First we need a preliminary result.

Consider the maps $\bar{A}$ and $\bar{E}$ in (16) and define the following sequence of subspaces

$$\bar{\mathcal{W}}_b := \bar{\mathcal{W}}_b^n, \qquad \bar{\mathcal{W}}_b^u = \bar{E}^{-1}(\bar{A}\bar{\mathcal{W}}_b^{u-1}), \quad u \in \underline{n}, \quad \bar{\mathcal{W}}_b = 0. \tag{18}$$

The next lemma establishes a relation between the sequence above defined and the sequence (4).

LEMMA 3. *$\bar{\mathcal{W}}_b^u = P\mathcal{W}_b^u$, where $P: \mathcal{X} \to \mathcal{X} (\text{mod } \mathcal{V}^*)$ is the canonical projection.*

Proof. See Appendix.

THEOREM 4. *Let $(sE - A)$ be a singular pencil. Then*:

(a) *Its columns are linearly independent over $R[s]$ if and only if $\mathcal{V}^* \cap \mathcal{W}_b^* = \mathcal{T}^* = 0$ (equivalently, $\mathcal{V}^* \cap \ker E = 0$).*

(b) *Its rows are linearly independent over $R[s]$ if and only if $\mathcal{V}^* + \mathcal{W}_b^* = \mathcal{X}$.*

Proof. (a) Immediate from Corollary 1.

(b) From (17) we have that the rows of $(sE - A)$ are linearly independent over $R[s]$ if and only if $\bar{\mathcal{W}}_b = \mathcal{X} (\text{mod } \mathcal{V}^*)$, i.e., if and only if $\mathcal{V}^* + \mathcal{W}_b^* = \mathcal{X}$ by using Lemma 3. □

4. The regular pencil. In this section we derive several geometric properties for regular pencils. An obvious necessary condition for a pencil $(sE - A)$ to be regular is that E and A are square maps. We then assume that E and A are maps from $\mathcal{X}$ to $\mathcal{X}$, $\dim \mathcal{X} = n$.

We first show geometric criteria for $(sE - A)$ to be regular.

THEOREM 5. *The following statements are equivalent*:

(i) *$(sE - A)$ is a regular pencil.*

(ii) $\mathcal{V}^* \oplus \mathcal{W}_b^* = \mathcal{X}$.

(iii) $\mathcal{V}^* \cap \ker E = 0$.

(iv) $E\mathcal{V}^* \oplus A\mathcal{W}_b^* = \mathcal{X}$.

Proof. (i)$\Leftrightarrow$(ii). From Theorem 4 we have that the rows and the columns of $(sE - A)$ are linearly independent over $R[s]$ if and only if $\mathcal{V}^* \oplus \mathcal{W}_b^* = \mathcal{X}$.

(ii)$\Rightarrow$(iii). Since $\mathcal{W}_b^* \supset \ker E$, we obviously have $\mathcal{V}^* \cap \ker E = 0$.

(iii)$\Rightarrow$(i). Since $\mathcal{V}^* \cap \ker E = 0$, then from Theorem 4 we obtain that the columns of $(sE - A)$ are linearly independent over $R[s]$. Since E and A are square maps it follows that the rows of $(sE - A)$ are also linearly independent over $R[s]$ and hence (i) follows.

(ii)$\Rightarrow$(iv). Note that $\mathcal{V}^* \cap \mathcal{W}_b^* = 0$ implies $\ker E \cap \mathcal{V}^* = 0$ and $\ker A \cap \mathcal{W}_b^* = 0$. Thus $\dim E\mathcal{V}^* = \dim \mathcal{V}^*$ and $\dim A\mathcal{W}_b^* = \dim \mathcal{W}_b^*$. Now suppose that

$$Ev = Aw, \quad v \in \mathcal{V}^*, \quad w \in \mathcal{W}_b^*.$$

This implies $w \in A^{-1}(E\mathcal{V}^*) = \mathcal{V}^*$, which is not possible. Thus $w = 0$ and hence $Ev = 0$. Since $\ker E \cap \mathcal{V}^* = 0$ we then have $v = 0$, so that (iv) is true.

(iv)$\Rightarrow$(i). Consider the decompositions (ii) and (iv) in the statement of the theorem and define the nonsingular map $M^{-1}: \mathcal{X} \to \mathcal{X}$ by

$$M^{-1}x = \begin{cases} Ex, & x \in \mathcal{V}^*, \\ Ax, & x \in \mathcal{W}_b^*. \end{cases} \tag{19}$$

Since $A\mathcal{V}^* \subset E\mathcal{V}^*$ and $E\mathcal{W}_b^* \subset A\mathcal{W}_b^*$ it now follows that the subspaces $\mathcal{V}^*$ and $\mathcal{W}_b^*$ are simultaneously MA- and ME-invariant, with

$$L := MA|\mathcal{V}^*, \qquad J := ME|\mathcal{W}_b^*, \tag{20}$$

$$ME|\mathcal{V}^* = I, \qquad MA|\mathcal{W}_b^* = I. \tag{21}$$

It now follows that in the decomposition (ii) the pencil $M(sE - A)$ admits the representation

$$\operatorname{Mat} M(sE - A) = \begin{bmatrix} sI - L & 0 \\ 0 & sJ - I \end{bmatrix}. \tag{22}$$

Since $\mathcal{V}^*$ is the supremum element of the family F_1 which is contained in $\mathcal{X}$ it follows that the map J is nilpotent ($MEw = \lambda w$, $0 \neq w \in \mathcal{W}_b^*$, $0 \neq \lambda \in C$ implies $Ew = \lambda M^{-1}w = \lambda Aw$, i.e. $w \in \mathcal{V}^*$ and hence $w = 0$).

Since J is nilpotent it follows that $\det(sJ - I) = (-1)^r$, $r := \dim \mathcal{W}_b^*$, and from (22) we conclude that the pencil is regular. □

Remarks. (i) The decomposition Theorem 5(ii) has also appeared in [9] and has been obtained by a different method.

(ii) The subspaces $\mathcal{V}^*$ and $\mathcal{W}_b^*$ in [5] have been described in terms of eigenspaces of $(\lambda E - A)^{-1}E$.

We now turn our attention to the autonomous generalized linear system

$$E\dot{x} = Ax \tag{23}$$

which is closely connected with the pencil $(sE - A)$. This is easily seen by taking the Laplace transform in (23) which yields

$$(sE - A)x(s) = Ex(0-)$$

where $x(0-)$ is the initial condition for (23).

When the pencil $(sE - A)$ is regular then the solution of (23) exists and is unique, namely

$$x(s) = (sE - A)^{-1}Ex(0-).$$

We shall concentrate on systems described by (23) whose associated pencil is regular.

Let M be the map defined from its inverse in (19) and consider the following maps:

$$Q_v: \mathscr{X} \to \mathscr{V}^*, \quad \text{the projection on } \mathscr{V}^* \text{ along } \mathscr{W}_b^* \tag{24}$$

and

$$Q_w: \mathscr{X} \to \mathscr{W}_b^*, \quad \text{the projection on } \mathscr{W}_b^* \text{ along } \mathscr{V}^*. \tag{25}$$

Premultiplying (23) by Q_vM and Q_wM, respectively, it follows that the system (23) can be decomposed as

$$\dot{x}_v = Lx_v, \qquad x_v \in \mathscr{V}^* \tag{26}$$

and

$$J\dot{x}_w = x_w, \qquad x_w \in \mathscr{W}_b^* \tag{27}$$

where L and J are as in (20).

The solution of (26) to an arbitrary initial condition $x_v(0^-)$ is well known and is determined by those finite-zeros of the pencil $(sE - A)$ which are excited (note in (22) that the eigenvalues of L coincide with the finite-zeros of $(sE - A)$).

The solution of (27) to an arbitrary initial condition $x_w(0^-) \in \mathscr{W}_b^*$ is a distribution (delta functional and its higher derivatives) and as pointed out in [13] we should consider the distributional differential equation

$$J\dot{x}_w = x_w + \delta x_w(0^-) \tag{28}$$

where δ denotes the delta functional.

Recall that J is a nilpotent map and let J be taken in the Jordan canonical form, i.e.,

$$J = \operatorname{diag}(J_1, \cdots, J_p, 0), \tag{29}$$

where

$$J_i = \begin{bmatrix} 0 & 1 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 1 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & \cdot & \cdot & 1 \\ 0 & \cdot & \cdot & \cdot & \cdot & 0 \end{bmatrix}_{(n_i+1)\times(n_i+1)}$$

In (29) the map J is decomposed into $p (p \geqq 0)$ blocks J_i of size $n_i + 1$ and a zero block of dimension $m (m \geqq 0)$ so that

$$\sum_{i \in \underline{p}} (n_i + 1) + m = \dim \mathscr{W}_b^*.$$

It is well known [14] that the pencil $sJ - I$ has p infinite-zeros of respective orders n_i, $i \in \underline{p}$. The integers p, n_i and m will be identified in a moment.

Let $x_w^T = [x_1, \cdots, x_p, x_{p+1}]^T$, where x_i is a column vector of size $n_i + 1$, $i \in \underline{p}$, and x_{p+1} is a column vector of size m.

The block diagonal structure of (29) implies that the equation (28) becomes decomposed as

$$J_i\dot{x}_i = x_i + \delta J_i x_i(0^-), \quad i \in \underline{p} \tag{30}$$

and a trivial equation $x_{p+1} = 0$.

The variables x_{p+1} are called static variables in the sense that they exhibit no dynamical behaviour. It has been shown in [13] that the distributional solution of (30) is given by

$$\begin{aligned} x_{i,1} &= -x_{i,2}(0^-)\delta - \cdots - x_{i,n_i+1}(0^-)\delta^{(n_i-1)}, \\ &\vdots \\ x_{i,n_i} &= -x_{i,n_i+1}(0^-)\delta, \\ x_{i,n_i+1} &= 0, \end{aligned} \tag{31}$$

where $\delta^{(h)}$ denotes the distributional derivative of order h of δ.

The subspace in which the distributional solution (31) takes place will be identified from a result of the next theorem which describes some structural features of the regular pencil $(sE-A)$.

THEOREM 6. *Let $(sE-A)$ be a regular pencil. Then:*

(a) *There are* $\dim \mathcal{V}^*$ *finite-zeros which are the eigenvalues of the map L defined in* (20).

(b) *There are* $p := \dim(\ker E \cap A^{-1}(\operatorname{Im} E))$ *infinite-zeros of respective orders* n_i, $i \in \underline{p}$, *which are determined from the dimensions of the subspaces* $\mathcal{W}_a^u$ *in* (2) (*with* $\mathcal{K} = A^{-1}(\operatorname{Im} E)$). *Further*

$$\sum_{i \in \underline{p}} n_i = \dim \mathcal{W}_a^*.$$

(c)

$$A^{-1}(\operatorname{Im} E) = \mathcal{V}^* \oplus \mathcal{W}_a^* \tag{32}$$

and

$$\operatorname{Im} E = E\mathcal{V}^* \oplus A\mathcal{W}_a^*. \tag{33}$$

(d) *Let* $\mathcal{N} \subset \ker E$ *be any subspace such that*

$$\mathcal{N} \oplus (\ker E \cap A^{-1}(\operatorname{Im} E)) = \ker E. \tag{34}$$

Then there are $m := \dim \mathcal{N}$ *static variables which do not play any role in the determination of the zero structure of* $(sE-A)$.

Proof. (a) See (22).

(b) Since the map J is nilpotent it follows that there exists a basis $\{w_{i,j}\}$ for $\mathcal{W}_b^*$ such that

$$Ew_{i,1} = 0; \quad Ew_{i,j} = Aw_{i,j-1},\ i \in \underline{p}, j \in \{2, \cdots, n_i+1\} \tag{35}$$

and

$$Ew_{i,1} = 0,\ i \in \{p+1, \cdots, p+m\}. \tag{36}$$

It is clear from (35) that for $i \in \underline{p}$, $\operatorname{span}\{w_{i,1}\} = \ker E \cap A^{-1}(\operatorname{Im} E)$. From (35) and (2) it also follows that $w_{i,j} \in \mathcal{W}_a^j$, $i \in \underline{p}$, $j \in \underline{n_i}$. Let $\mathcal{W}_a := \operatorname{span}\{w_{i,j}\}$, $i \in \underline{p}$, $j \in \underline{n_i}$. Hence $\mathcal{W}_a \subset \mathcal{W}_a^*$.

From (35) and (36) it is easy to see that $\dim \mathcal{W}_a = \dim \mathcal{W}_b^* - \dim \ker E$. From Lemma (1e) we obtain that $E\mathcal{W}_b^* = A\mathcal{W}_a^*$ and since the pencil is regular it follows that

$$\dim \mathcal{W}_a^* = \dim \mathcal{W}_b^* - \dim \ker E.$$

Therefore $\mathcal{W}_a = \mathcal{W}_a^*$ and since $w_{i,j} \in \mathcal{W}_a^j$, $i \in \underline{p}$, $j \in \underline{n}_i$, it follows that the orders of the infinite-zeros can be determined in the following way. Let

$$\phi_u := \dim \left[\frac{\mathcal{W}_a^u}{\mathcal{W}_a^{u-1}} \right], \quad u \in \underline{n}$$

and define

$$n_i := \text{number of integers in the set } \{\phi_1, \phi_2, \cdots, \phi_n\} \text{ which are } \geqq i.$$

Then

$$n_1 \geqq n_2 \geqq \cdots \geqq n_p \geqq 1 \quad \text{with} \sum_{i \in \underline{p}} n_i = \dim \mathcal{W}_a^*.$$

(c) First note that $\mathcal{V}^* \oplus \mathcal{W}_a^* \subset A^{-1}(\operatorname{Im} E)$ and let $\tilde{\mathcal{W}}_b$ be any subspace such that $\mathcal{W}_b^* = \mathcal{W}_a^* \oplus \tilde{\mathcal{W}}_b$. From Lemma 1(c), $\tilde{\mathcal{W}}_b \cap A^{-1}(\operatorname{Im} E) = 0$. Thus $\mathcal{X} = \mathcal{V}^* \oplus \mathcal{W}_a^* \oplus \tilde{\mathcal{W}}_b$ and then (32) follows.

To show (33), note from Theorem 5(ii), (iv) and Lemma 1(e), (c) that

$$\operatorname{Im} E = E\mathcal{X} = E\mathcal{V}^* + E\mathcal{W}_b^* = E\mathcal{V}^* \oplus A\mathcal{W}_a^*.$$

(d) It is clear from (36) that for $i \in \{p+1, \cdots, p+m\}$ we have that span $\{w_{i,1}\} = \mathcal{N}$, where $\mathcal{N}$ is as in (34).

Consider $\mathcal{W}_a^1 = \ker E \cap A^{-1}(\operatorname{Im} E)$ and let $\mathcal{C}_1$ be any subspace such that

$$\mathcal{X} = \mathcal{C}_1 \oplus \mathcal{W}_a^1 \oplus \mathcal{N}. \tag{37}$$

Note that $A\mathcal{W}_a^1 \subset \operatorname{Im} E$ and that $A\mathcal{N} \cap \operatorname{Im} E = 0$. Since the pencil is regular we also have that $\dim A\mathcal{N} = \dim \mathcal{N}$.

Let $\mathcal{C}_2$ be any subspace which yields a direct sum for the following decomposition

$$\mathcal{X} = \operatorname{Im} E \oplus \mathcal{C}_2 \oplus A\mathcal{N}. \tag{38}$$

Let $x \in \mathcal{X}$ be represented in the decomposition (37) and Ex and Ax be represented in the decomposition (38). Hence

$$\operatorname{Mat} E = \begin{bmatrix} I & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \qquad \operatorname{Mat} A = \begin{bmatrix} A_{11} & A_{12} & 0 \\ A_{21} & 0 & 0 \\ A_{31} & 0 & I \end{bmatrix} \tag{39}$$

where the identity matrix in Mat E has dim Im E and the identity matrix in Mat A has dim m.

Consider the pencil $(sE - A)$ with E and A as in (39) and postmultiply it by the nonsingular matrix

$$\begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ -A_{31} & 0 & I \end{bmatrix}.$$

This operation does not alter the zero structure of $(sE - A)$ [7] and the resulting pencil is represented as

$$\left[\begin{array}{cc|c} sI - A_{11} & -A_{12} & 0 \\ -A_{21} & 0 & 0 \\ \hline 0 & 0 & I \end{array}\right].$$

It is clear from the above block diagonal structure that the zero structure of $(sE-A)$ can be obtained from the reduced pencil

$$\begin{bmatrix} sI-A_{11} & -A_{12} \\ -A_{21} & 0 \end{bmatrix}. \qquad \square$$

COROLLARY 2. (a) *The number of zeros of the regular pencil is* $\dim E$.

(b) *The distributional response* (31) *belongs to* $\mathcal{W}_a^*$.

Proof. (a) This fact is well known [13], and follows from Theorem 6(a), (b), (c).

(b) By using (35) it follows that the components $x_{i,j}$, $i \in \underline{p}$, $j \in \underline{n}_i$ belong to $\mathcal{W}_a^*$.

Comment. From Corollary 2(b) and (26), it follows that the total response of (23) to an arbitrary $x(0^-)$ belongs to $A^{-1}(\operatorname{Im} E)$ (see (32)). This has a simple interpretation for a discrete time generalized linear system $Ex(k+1)=Ax(k)$, where $x(k)$ must belong to $A^{-1}(\operatorname{Im} E)$ in order for $x(k+1)$ to exist.

Other consequences are stated next.

COROLLARY 3. (a) *The regular pencil* $(sE-A)$ *has no infinite-zeros if and only if* $\ker E \cap A^{-1}(\operatorname{Im} E)=0$.

(b) *Suppose that the regular pencil* $(sE-A)$ *has infinite-zeros. Then there exist no static variables if and only if* $A \ker E \subset \operatorname{Im} E$.

Proof. (a) From Theorem 6(b) we have that $(sE-A)$ has no infinite-zeros if and only if $\mathcal{W}_a^*=0$, i.e. $\ker E \cap A^{-1}(\operatorname{Im} E)=0$.

(b) Since $(sE-A)$ has infinite-zeros then we must have $\ker E \cap A^{-1}(\operatorname{Im} E) \neq 0$. From (34) we then obtain that $(sE-A)$ has no static variables if and only if $\mathcal{N}=0$, i.e. $\ker E \cap A^{-1}(\operatorname{Im} E)=\ker E$, or equivalently $\ker E \subset A^{-1}(\operatorname{Im} E) \Leftrightarrow A \ker E \subset \operatorname{Im} E$. $\square$

Corollary 3 will be useful in the following section.

5. Controllability and observability for generalized linear systems. In this section we consider the generalized linear system Σ:

$$\Sigma: E\dot{x}=Ax+Bu, \qquad y=Cx, \tag{40}$$

such that the associated pencil $(sE-A)$ is regular, $x \in \mathcal{X} := R^n$, $u \in \mathcal{U} := R^m$, $y \in \mathcal{Y} := R^r$.

Consider the maps Q_v and Q_w in (24) and (25) and let M^{-1} be the map defined in (19).

Premultiplying (40) by Q_vM and Q_wM, respectively, it follows that in the decomposition of the Theorem 5(ii) the system (40) becomes decomposed as

$$\dot{x}_v = Lx_v + B_v u, \qquad x_v \in \mathcal{V}^*, \tag{41}$$

$$J\dot{x}_w = x_w + B_w u, \qquad x_w \in \mathcal{W}_b^*, \tag{42}$$

$$y = C_v x_v + C_w x_w,$$

where

$$B_v = Q_v MB, \qquad B_w = Q_w MB,$$

$$C_v = C|\mathcal{V}^*, \qquad C_w = C|\mathcal{W}_b^*.$$

In the following we describe the modal criterion for controllability and observability of the zeros of the pencil $(sE-A)$ [14]. Accordingly, we shall say that the system Σ is controllable or observable.

Test 1. The system Σ is controllable if and only if the pencil $[sE-A \;\; B]$ has no zeros (finite or infinite).

Test 2. The system Σ is observable if and only if the pencil $\begin{bmatrix} sE-A \\ C \end{bmatrix}$ has no zeros (finite or infinite).

From the above tests and the fact that J is nilpotent, it follows immediately that Σ is controllable and observable at its finite-zeros if and only if the pencils $[sI - L \;\; B_v]$ and $\begin{bmatrix} sI-L \\ C_v \end{bmatrix}$ have no finite zeros.

We first give a trivial interpretation for the reachable and unobservable subspaces corresponding to those controllable and unobservable finite-zeros.

PROPOSITION 2. *Let $\mathcal{V}^*$ be the subspace given by the sequence* (1). *Then*:

(a) *The reachable subspace is the least subspace $\mathcal{V}_c \subset \mathcal{V}^*$ such that*

$$A\mathcal{V}_c \subset E\mathcal{V}_c \quad \textit{and} \quad E\mathcal{V}_c \oplus A\mathcal{W}_b^* \supset \mathcal{B}.$$

(b) *The unobservable subspace is the largest subspace $\mathcal{V}_u \subset \mathcal{V}^*$ such that*

$$A\mathcal{V}_u \subset E\mathcal{V}_u \quad \textit{and} \quad \mathcal{V}_u \subset \ker C.$$

Proof. (a) Let $\mathcal{B} := \operatorname{Im} B$. It is well known that the reachable subspace is the least L-invariant subspace $\mathcal{V}_c$ which contains $\mathcal{B}_v = Q_v M\mathcal{B}$, i.e.,

$$L\mathcal{V}_c \subset \mathcal{V}_c \tag{43}$$

and

$$\mathcal{V}_c \supset Q_v M\mathcal{B}. \tag{44}$$

But (43) is equivalent to $A\mathcal{V}_c \subset E\mathcal{V}_c$ and by using (21) and (19) it follows from (44) that

$$Q_v M\mathcal{B} \subset Q_v ME\mathcal{V}_c \Leftrightarrow \mathcal{B} \subset (Q_v M)^{-1} Q_v ME\mathcal{V}_c = E\mathcal{V}_c + M^{-1}\mathcal{W}_b^* = E\mathcal{V}_c \oplus A\mathcal{W}_b^*.$$

(b) The unobservable subspace is the largest L-invariant subspace $\mathcal{V}_u$ which is contained in $\ker C_v$ which is equivalent to $A\mathcal{V}_u \subset E\mathcal{V}_u$ and $\mathcal{V}_u \subset \ker C$. □

Remark. Note that when $\mathcal{V}^* = \mathcal{X}$ (therefore $\mathcal{W}_b^* = 0$) and $E = I$, the above proposition merely gives the reachable and unobservable subspaces for the linear system $\dot{x} = Ax + Bu$; $y = Cx$.

Hereafter we shall concentrate on the study of controllability and observability of the infinite-zeros for the system Σ. Note that the infinite-zeros of the pencil $(sE - A)$ are situated in the pencil $(sJ - I)$. Thus the analysis of dynamic properties of the infinite-zeros, such as controllability, must be carried out on the subsystem

$$J\dot{x}_w = x_w + B_w u. \tag{45}$$

Let q be the index of nilpotency of J, namely, q is the least positive integer such that $J^q = 0$. Campbell [4] has shown that if the control u belongs to the class of the $q-1$ differentiable functions, then the unique solution of (45) in the class of functions is given by

$$x_w(t) = \sum_{i=0}^{q-1} J^i B_w u^{(i)}(t), \qquad t \geqq 0$$

where $u^{(i)}(t)$ denotes the ith derivative of $u(t)$.

Cobb [6] has shown that the reachable subspace $\mathcal{R}_w$ relative to the system (45) is given by

$$\mathcal{R}_w = \langle J | \mathcal{B}_w \rangle := \mathcal{B}_w + J\mathcal{B}_w + \cdots + J^{q-1}\mathcal{B}_w$$

with $\mathcal{B}_w = \operatorname{Im} B_w$. The reachability property implies that any point in $\mathcal{R}_w$ can be reached at any time t by using a suitable control u together with its derivatives.

It is shown next that we may have a situation where $\mathcal{R}_w \subset \mathcal{W}_b^*$ and yet all the infinite-zeros are controllable.

5.1. Controllability of the infinite-zeros. We shall show that controllability of the infinite-zeros is equivalent to reachability of certain quotient spaces. Let $J: \mathcal{W}_b^* \to \mathcal{W}_b^*$ be the map defined in (20) and let $\mathcal{W}_1 \subset \ker J$ be any space such that

$$\mathcal{W}_1 \oplus (\ker J \cap \operatorname{Im} J) = \ker J. \tag{46}$$

Note that $\mathcal{W}_1$ provides only simple eigenvectors to the nilpotent map J, in the sense that if $\{w_i\}$, $i \in \underline{t}$, $t := \dim \mathcal{W}_1$, is a basis for $\mathcal{W}_1$ then $Jw_i = 0$, $i \in \underline{t}$ and there exists no chain of eigenvectors starting from w_i, $i \in \underline{t}$. In other words, the subspace $\mathcal{W}_1$ can be associated with all the simple elementary divisors of J.

Let $\bar{\mathcal{W}} := \mathcal{W}_b^* (\operatorname{mod} \mathcal{W}_1)$ and let $P := \mathcal{W}_b^* \to \bar{\mathcal{W}}$ be the canonical projection. Let $\bar{J}$ be the unique map induced in $\bar{\mathcal{W}}$ such that $\bar{J}P = PJ$ and let $\bar{B}_w := B_w (\operatorname{mod} \mathcal{W}_1): \mathcal{U} \to \bar{\mathcal{W}}$.

Matrix representations for $\bar{J}$ and $\bar{B}_w$ can be readily obtained. For this, let $\mathcal{W}_2$ be any subspace such that $\mathcal{W}_b^* = \mathcal{W}_1 \oplus \mathcal{W}_2$. Then in this decomposition

$$\operatorname{Mat} J = \begin{bmatrix} 0 & J_{12} \\ 0 & J_{22} \end{bmatrix}, \qquad \operatorname{Mat} B_w = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}, \tag{47}$$

with $\operatorname{Mat} \bar{J} = J_{22}$ and $\operatorname{Mat} \bar{B}_w = B_2$.

Note from (46) that $J\mathcal{W}_1 = 0 \subset \mathcal{W}_1$ and there is a subspace $\hat{\mathcal{W}}_2$ such that $J\hat{\mathcal{W}}_2 \subset \hat{\mathcal{W}}_2$ and $\mathcal{W}_1 \oplus \hat{\mathcal{W}}_2 = \mathcal{W}_b^*$. The last statement can be readily verified by thinking of the eigenvector chains of J and (46). Thus by [18, Prop. 0.5], it follows that the elementary divisors of $J|\mathcal{W}_1$ with those of $\bar{J}$, together, give all the elementary divisors of J. Hence $\bar{J}$ is a map which possesses all the elementary divisors of order greater than one of J.

Let $\hat{\mathcal{W}}_2$ be a subspace as described above. Then $J_{12} = 0$ in (47) and the system (45) can be decomposed in the following way:

$$x_{w1} = -B_1 u \tag{48}$$

and

$$J_{22}\dot{x}_{w2} = x_{w2} + B_2 u \tag{49}$$

where $x_{w1} \in \mathcal{W}_1$ and $x_{w2} \in \hat{\mathcal{W}}_2$.

Note that the subsystem (48) is "static", in the sense that at each instant t, $x_{w1}(t)$ is a linear combination of the control variables $u(t)$. We recall that the variables x_{w1} have the same nature of the variables described in the previous section as static variables.

Test 4.2 in [13] gives a necessary and sufficient condition for the infinite-zeros to be observable. The dual of that test gives a necessary and sufficient condition for the controllability of those zeros and it is described next.

Test 3. Apply nonsingular transformations on the right of the pencil $[sE - A \;\; B]$ so as to bring it to the form $[sE_1 - A_1 \;\; A_2 \;\; B_2]$, where E_1 has full column rank and $A = [A_1 \;\; A_2]$. Then the system Σ is controllable at its infinite-zeros, i.e., the pencil $[sE - A \;\; B]$ has no infinite-zeros, if and only if

$$\operatorname{Im} E_1 + \operatorname{Im} A_2 + \mathcal{B} = \mathcal{X}. \tag{50}$$

We are now in a position to link the reachability concept described previously and the modal controllability concept introduced in Test 3.

THEOREM 7. *$\bar{\mathcal{W}}$ is reachable, namely $\langle \bar{J} | \bar{\mathcal{B}}_w \rangle = \bar{\mathcal{W}}$ if and only if the system* (45) *is controllable* (*at infinity*).

Proof. It is well known [18] that $\langle \bar{J} | \bar{\mathcal{B}}_w \rangle = \bar{\mathcal{W}}$ if and only if

$$\operatorname{Im} (\lambda I - \bar{J}) + \bar{\mathcal{B}}_w = \bar{\mathcal{W}} \quad \forall \lambda \in C. \tag{51}$$

Since $\bar{J}$ is nilpotent it is clear that (51) holds for $\lambda \neq 0$. Therefore

$$\langle \bar{J} | \bar{\mathcal{B}}_w \rangle = \bar{\mathcal{W}} \Leftrightarrow \operatorname{Im} \bar{J} + \bar{\mathcal{B}}_w = \bar{\mathcal{W}}. \tag{52}$$

Taking $\bar{J}$ in Jordan canonical form and applying Test 3 to the pencil $[s\bar{J} - I \ \bar{B}_w]$ it is readily seen that the condition (50) reduces to (52). □

Based on the result of Theorem 7, a procedure can be given to obtain the controllable subsystem of a system given by (45).

1. Choose any subspace $\mathcal{W}_1$ according to (46) and take any subspace $\mathcal{W}_2$ such that $\mathcal{W}_1 \oplus \mathcal{W}_2 = \mathcal{W}_b^*$.

2. Compute the pair (J_{22}, B_2).

3. Compute the least J_{22}-invariant subspace $\mathcal{W}_c$ which contains $\operatorname{Im} B_2$, i.e. $\mathcal{W}_c = \langle J_{22} | \operatorname{Im} B_2 \rangle$. By taking $\mathcal{W}_c$ as part of a basis for $\mathcal{W}_2$ we then obtain the following representations

$$\operatorname{Mat} J_{22} = \begin{bmatrix} \hat{J}_{11} & \hat{J}_{12} \\ 0 & \hat{J}_{22} \end{bmatrix}, \qquad \operatorname{Mat} B_2 = \begin{bmatrix} \hat{B}_1 \\ 0 \end{bmatrix},$$

so that the subsystem $J_{22}\hat{x} = \hat{x}_2$ is uncontrollable and $\hat{J}_{11}\hat{x}_1 = \hat{x}_1 + \hat{B}_1 u$ is controllable.

Remark. The procedure above described to obtain a controllable subsystem is not based on a canonical form as in reference [13] whose authors have pointed out the need for a geometric language to describe the concepts of controllability and observability of the infinite-zeros.

The next theorem contains a necessary and sufficient condition for the controllability of Σ at infinity.

THEOREM 8. *The system Σ is controllable at infinity if and only if*

$$\operatorname{Im} E + A \ker E + \mathcal{B} = \mathcal{X}. \tag{53}$$

Proof. Let $\mathcal{W}_1$ be a subspace as in (46) and let $\hat{\mathcal{W}}_2$ be a subspace such that $\mathcal{W}_1 \oplus \hat{\mathcal{W}}_2 = \mathcal{W}_b^*$ and $J\hat{\mathcal{W}}_2 \subset \hat{\mathcal{W}}_2$. This implies $J_{12} = 0$ in (47) and note that (J_{22}, B_2) is the pair induced in $\hat{\mathcal{W}}_2$. The space $\mathcal{X}$ is now decomposed as

$$\mathcal{X} = \mathcal{V}^* \oplus \mathcal{W}_1 \oplus \hat{\mathcal{W}}_2. \tag{54}$$

Let M^{-1} be the map defined in (19). Since $\operatorname{Im} E = E\mathcal{X}$ and $\mathcal{W}_1 \subset \ker J = \ker ME | \mathcal{W}_b^* = \ker E \subset \mathcal{W}_b^*$, it follows that the premultiplication of the left-hand side of (53) by M results in

$$ME(\mathcal{V}^* \oplus \hat{\mathcal{W}}_2) + MA \ker E + M\mathcal{B}.$$

By using (20)-(21) and (46)-(47) it follows that the above expression is equal to

$$\mathcal{V}^* \oplus \operatorname{Im} J_{22} + (\mathcal{W}_1 \oplus \ker J \cap \operatorname{Im} J) + \operatorname{Im} B_2. \tag{55}$$

But $\ker J \cap \operatorname{Im} J = \ker J_{22}$ and since J_{22} is nilpotent it follows that $\ker J_{22} \subset \operatorname{Im} J_{22}$. Thus (55) can be rewritten as

$$\mathcal{V}^* \oplus \mathcal{W}_1 \oplus (\operatorname{Im} J_{22} + \operatorname{Im} B_{22}).$$

Hence $M(\operatorname{Im} E + A \ker E + \mathcal{B}) = \mathcal{X}$ if and only if $\operatorname{Im} J_{22} + \operatorname{Im} B_2 = \hat{\mathcal{W}}_2$ or by (52) if and only if the infinite-zeros are controllable. □

Remarks. (a) Note that when the regular pencil has no infinite-zeros, then by Corollary 3(a), $A \ker E \cap \operatorname{Im} E = 0$ so that $\operatorname{Im} E \oplus A \ker E = \mathcal{X}$.

This simply means that absence of infinite-zeros in the pencil $(sE - A)$, obviously implies absence of infinite-zeros in the pencil $[sE - A \ B]$.

If $(sE-A)$ has infinite-zeros but has no static variables, then by using Corollary 3(b), the condition (53) reduces to $\operatorname{Im} E+\mathscr{B}=\mathscr{X}$, which is the condition given by Rosenbrock [10] and Cobb [5]. This shows that their condition is correct if no static variables are present.

(b) From (53) and (20)-(21) it follows that

$$\operatorname{Im} J+\ker J+\mathscr{B}_w=\mathscr{W}_b^*. \tag{56}$$

Thus conditions (52), (53) and (56) are equivalent necessary and sufficient conditions for controllability of Σ at infinity. The condition (56) has shown up in [5] in connection with the existence of a state feedback map that converts the infinite-zeros into finite ones. (See also [2] on this subject).

5.2. Observability of the infinite-zeros. Consider the system

$$J\dot{x}_w=x_w, \qquad y=C_w x_w. \tag{57}$$

Write again $\mathscr{W}_b^*=\mathscr{W}_1\oplus\hat{\mathscr{W}}_2$, where $\mathscr{W}_1$ is as in (46) and $\hat{\mathscr{W}}_2$ is such that $J\hat{\mathscr{W}}_2\subset\hat{\mathscr{W}}_2$. Then by using this decomposition for $\mathscr{W}_b^*$ it follows that (57) can be written as

$$\begin{bmatrix}0 & 0\\ 0 & J_{22}\end{bmatrix}\begin{bmatrix}\dot{x}_{w1}\\ \dot{x}_{w2}\end{bmatrix}=\begin{bmatrix}x_{w1}\\ x_{w2}\end{bmatrix}, \qquad y=[C_{w1} \quad C_{w2}]\begin{bmatrix}x_{w1}\\ x_{w2}\end{bmatrix}.$$

Hence $x_{w1}=0$ and $y=C_{w2}x_{w2}$. The system (57) is said to be observable at infinity if there are no impulsive motions in $\ker C_{w2}$. This is simply an extension of the observability criterion for exponential modes (caused by the finite-zeros).

Let $\langle\ker C_{w2}|J_{22}\rangle:=\ker C_{w2}\cap J_{22}^{-1}\ker C_{w2}\cap\cdots\cap J_{22}^{-q+1}\ker C_{w2}$, where q is the index of nilpotency of J_{22} (and of J). We then obtain:

THEOREM 9. $\langle\ker C_{w2}|J_{22}\rangle=0$ *if and only if the system* (57) *is observable* (*at infinity*).

Proof. Identical to the proof of Theorem 7 on considering the pair (J_{22}^T, C_{w2}^T) and noting that $\langle\ker C_{w2}|J_{22}\rangle=0$ if and only if $\langle J_{22}^T|\operatorname{Im} C_{w2}^T\rangle=\hat{\mathscr{W}}_2'$. □

Remark. By using a duality argument it follows that the subspace $\langle\ker C_{22}|J_{22}\rangle$ corresponds to those infinite-zeros which are unobservable and this fact can be used in a procedure to extract the observable infinite-zeros.

The next theorem shows how observability can be characterized directly in terms of the maps E, A and C.

THEOREM 10[1]. *The system* Σ *is observable at infinity if and only if*

$$\ker E\cap A^{-1}(\operatorname{Im} E)\cap\ker C=0. \tag{58}$$

Proof. Let $H(s):=\begin{bmatrix}sE-A\\ C\end{bmatrix}$. Since the zero structure of $H(s)$ coincides with the zero structure of $[sE^T-A^T \quad C^T]$ [14], we then obtain from Theorem 8 that the pencil $H(s)$ has no infinite-zeros if and only if

$$\operatorname{Im} E^T+A^T\ker E^T+\operatorname{Im} C^T=\mathscr{X}'.$$

By dualizing this last relation we then obtain (58). □

Remarks. (a) Note from Corollary 3(b) that if the pencil has no static variables then (58) reduces to $\ker E\cap\ker C=0$ and if the pencil has no infinite-zeros then by Corollary 3(a), $\ker E\cap A^{-1}(\operatorname{Im} E)=0$, which means that absence of infinite-zeros in the pencil $(sE-A)$ implies the same in the pencil $H(s)$.

[1] A referee has pointed out he believes that Theorems 8 and 10 are contained in a paper by D. J. Cobb (to appear in IEEE Trans. Automat. Control). Such theorems have appeared in the Ph.D. thesis (September, 1983) of the author of this paper, and since then the author has not been aware of any published work containing the mentioned theorems.

(b) Let $\{w_i\}$, $i \in \underline{p}$, be a basis for $\mathcal{W}_a^1 = \ker E \cap A^{-1}(\operatorname{Im} E)$. Then from (58) it follows that the system Σ is observable at infinity if and only if the vectors Cw_i, $i \in \underline{p}$, are linearly independent. This is equivalent to the test given by Verghese [14] which states that the columns of C corresponding to the first position of each Jordan block of order greater than one of J are linearly independent if and only if Σ is observable at infinity.

6. Appendix.

Proof of Lemma 1. (a) It is proven in [3].

(b) Note that $\mathcal{T}^1 = \mathcal{V}^* \cap \ker E = \mathcal{V}^* \cap \mathcal{W}_b^1$.

Assume that $\mathcal{T}^{u-1} = \mathcal{V}^* \cap \mathcal{W}_b^{u-1}$. Then

$$\begin{aligned}
\mathcal{T}^u &= \mathcal{V}^* \cap E^{-1}(A(\mathcal{V}^* \cap \mathcal{W}_b^{u-1})) \\
&= \mathcal{V}^* \cap E^{-1}(A(A^{-1}(E\mathcal{V}^*) \cap \mathcal{W}_b^{u-1})) \\
&= \mathcal{V}^* \cap E^{-1}(A\mathcal{W}_b^{u-1} \cap E\mathcal{V}^*) \\
&= \mathcal{V}^* \cap E^{-1}(A\mathcal{W}_b^{u-1}) \cap E^{-1}(E\mathcal{V}^*) \\
&= \mathcal{V}^* \cap (E^{-1}(A\mathcal{W}_b^{u-1}) \cap (\mathcal{V}^* + \ker E)) \\
&= \mathcal{V}^* \cap (E^{-1}(A\mathcal{W}_b^{u-1}) \cap \mathcal{V}^* + \ker E) \\
&= E^{-1}(A\mathcal{W}_b^{u-1}) \cap \mathcal{V}^* + \mathcal{V}^* \cap \ker E \\
&= E^{-1}(A\mathcal{W}_b^{u-1}) \cap \mathcal{V}^* = \mathcal{V}^* \cap \mathcal{W}_b^u.
\end{aligned}$$

(c) The proof is analogous to (b) if we replace $\mathcal{V}^*$ by $\mathcal{K} = A^{-1}(\operatorname{Im} E)$.

(d) From (b) and (c), $\mathcal{T}^u = \mathcal{V}^* \cap \mathcal{K} \cap \mathcal{W}_b^u = \mathcal{V}^* \cap \mathcal{W}_a^u$.

(e) By using (c) we obtain

$$A\mathcal{W}_a^{u-1} = A(A^{-1}(\operatorname{Im} E) \cap \mathcal{W}_b^{u-1}) = A\mathcal{W}_b^{u-1} \cap \operatorname{Im} E$$

and

$$E\mathcal{W}_b^u = E(E^{-1}(A\mathcal{W}_b^{u-1})) = A\mathcal{W}_b^{u-1} \cap \operatorname{Im} E. \qquad \square$$

Proof of Theorem 1. We first show that any subspace of the family F_3 is contained in $\mathcal{T}^*$.

Note that

$$t_{i,0} \in \ker E \cap \mathcal{T} \subset \ker E \cap \mathcal{V}^* \subset \mathcal{T}^*$$

and suppose that $t_{i,j-1} \in \mathcal{T}^*$, $j \in \{0, 1, \cdots, h_i - 1\}$. Then

$$t_{i,j} \in E^{-1}(A\mathcal{T}^*) \cap \mathcal{T} \subset E^{-1}(A\mathcal{T}^*) \cap \mathcal{V}^* = \mathcal{T}^*.$$

Finally,

$$t_{i,h_i} \in E^{-1}(A\mathcal{T}^*) \cap \ker A \subset E^{-1}(A\mathcal{T}^*) \cap \mathcal{V}^* = \mathcal{T}^*.$$

To show that the subspace $\mathcal{T}^*$ is the supremum of the family F_3 it then suffices to write $\mathcal{T}^*$ as in (8). For this, consider the sequence $\mathcal{T}^u$ in (3) and define

$$\rho_u := \dim\left[\frac{\mathcal{T}^u}{\mathcal{T}^{u-1}}\right], \qquad u \in \underline{n}. \tag{A.1}$$

By Lemma 1(a), $E\mathcal{T}^u = A\mathcal{T}^{u-1}$, which implies

$$\rho_u = \dim(\ker E \cap \mathcal{T}^u) - \dim(\ker A \cap \mathcal{T}^{u-1}). \tag{A.2}$$

From Lemma 1(b), it follows that $\ker E \cap \mathcal{T}^u = \ker E \cap \mathcal{V}^* = \ker E \cap \mathcal{T}^*$, so that $\dim(\ker E \cap \mathcal{T}^u) = l$, $u \in \underline{n}$. By using (A.2) we also obtain

$$\rho_u = \rho_{u+1} + \dim\left[\frac{\ker A \cap \mathcal{T}^u}{\ker A \cap \mathcal{T}^{u-1}}\right],$$

and since $\mathcal{T}^u \supset \mathcal{T}^{u-1}$, the result is $\rho_u \geqq \rho_{u+1}$.

Let $q \in \underline{n}$ be such that $\mathcal{T}^q \cap \ker A = \mathcal{T}^* \cap \ker A$. Since $\dim(\ker E \cap \mathcal{T}^*) = \dim(\ker A \cap \mathcal{T}^*)$ we then obtain from (A.1) and (A.2) that

$$\rho_1 + \rho_2 + \cdots + \rho_q = \dim \mathcal{T}^* \quad \text{and} \quad \rho_{q+1} = \rho_{q+2} = \cdots = \rho_n = 0.$$

Let $\mathcal{M}_u := \ker A \cap \mathcal{T}^u$, $u \in \underline{q}$. Since $\mathcal{T}^{u-1} \subset \mathcal{T}^u$, then $\mathcal{M}_1 \subset \mathcal{M}_2 \subset \cdots \subset \mathcal{M}_q$. Let $\mathcal{M}'_u \subset \mathcal{M}_u$ be such that

$$\mathcal{M}_{u-1} \oplus \mathcal{M}'_u = \mathcal{M}_u, \qquad u \in \{2, 3, \cdots, q\}.$$

Hence we can decompose $\mathcal{M}_u$ as

$$\mathcal{M}_u = \mathcal{M}'_1 \oplus \mathcal{M}'_2 \oplus \cdots \oplus \mathcal{M}'_u, \qquad u \in \underline{q} \tag{A.3}$$

with $\mathcal{M}'_1 := \mathcal{M}_1$.

Let $d_u := \dim \mathcal{M}'_u$, $u \in \underline{q}$ and let $X_{u,u-1}$ be a matrix of dimension $n \times d_u$ such that

$$\operatorname{Im} X_{u,u-1} = \mathcal{M}'_u, \qquad u \in \underline{q}. \tag{A.4}$$

Since $E\mathcal{T}^u = A\mathcal{T}^{u-1}$, it follows that the equations

$$EX_{u,j} = AX_{u,j-1}, \qquad u \in \{2, \cdots, q\}, \quad j \in \{1, \cdots, u-1\} \tag{A.5}$$

can be solved backwards for matrices $X_{u,j-1}$ of dimension $n \times d_u$ such that $\operatorname{Im} X_{u,j-1} \subset \mathcal{T}^{j-1}$ with

$$EX_{u,0} = 0 \quad \text{and} \quad AX_{u,u-1} = 0. \tag{A.6}$$

We need the following result.

LEMMA A. *The matrices $X_{u,j-1}$, $u \in \{2, \cdots, q\}$, $j \in \{1, \cdots, u-1\}$ are monic. The subspaces $\operatorname{Im} X_{u,j}$, $u \in \underline{q}$, $j \in \{0, \cdots, u-1\}$ are independent and*

$$\mathcal{T}^* = \sum_{u=1}^{q} \sum_{j=0}^{u-1} \operatorname{Im} X_{u,j}.$$

Proof. We shall show that $\ker E \cap \operatorname{Im} X_{u,j} = 0$. This will imply that the solution matrices $X_{u,j-1} = 0$ are monic and $\ker A \cap \operatorname{Im} X_{u,j-1} = 0$.

The proof is by induction. Suppose there exists $x_{u-1} \in \operatorname{Im} X_{u,u-1} = \mathcal{M}'_u$ such that $Ex_{u-1} = 0$.

Since $x_{u-1} \in \ker A$ we then obtain $x_{u-1} \in \ker E \cap \mathcal{T}^* \cap \ker A = \mathcal{M}_1$. But $x_{u-1} \in \mathcal{M}'_u$ and $\mathcal{M}_1 \cap \mathcal{M}'_u = 0$. Thus $x_{u-1} = 0$.

Now assume that $\ker E \cap \operatorname{Im} X_{u,j} = 0$, $j \in \{u-1, u-2, \cdots, 2\}$ and suppose there exists a vector $x_{j-1} \in \operatorname{Im} X_{u,j-1}$ such that $Ex_{j-1} = 0$. This implies that there exist vectors $x_j, \cdots, x_{u-1}$ such that

$$\begin{aligned} Ex_j &= Ax_{j-1}, \qquad x_j \in \operatorname{Im} \mathcal{X}_{u,j}, \\ &\vdots \\ Ex_{u-1} &= Ax_{u,2}, \\ Ax_{u-1} &= 0, \qquad x_{u-1} \in \mathcal{M}'_u, \end{aligned}$$

which implies $x_{u-1} \in \mathcal{M}'_u \cap \ker A \cap \mathcal{T}^{u-j+1} = \mathcal{M}'_u \cap \mathcal{M}_{u-j+1} = 0$. Thus $x_{u-1} = 0$ and therefore $x_{u-2} = x_{u-3} = \cdots = x_j = x_{j-1} = 0$.

In the following we prove that the subspaces $\operatorname{Im} X_{u,j}$, $u \in \underline{q}$, $j \in \{0, 1, \cdots, u-1\}$ are independent, i.e., that

$$\sum_{u=1}^{q} \sum_{j=0}^{u-1} X_{u,j}\alpha_{u,j} = 0$$

implies $\alpha_{u,j} = 0$, where $\alpha_{u,j}$ is a vector of dimension $d_u \times 1$ over the field of the reals.

Note that it suffices to prove that the subspaces $A \operatorname{Im} X_{u,j}$, $u \in \{2, 3, \cdots, q\}$, $j \in \{0, 1, \cdots, u-2\}$ are independent because $AX_{u,u-1} = 0$ and the subspaces $\operatorname{Im} X_{u,u-1} = \mathcal{M}'_u$, $u \in \underline{q}$, are independent.

Thus consider

$$\sum_{u=2}^{q} \sum_{j=0}^{u-2} AX_{u,j}\alpha_{u,j} = 0.$$

By using (A.5) we then obtain a sequence of vectors $(x_0, x_1, \cdots, x_{q-2})$ such that

$$\text{(A.7)} \qquad Ex_0 = 0, \quad Ex_1 = Ax_0, \quad \cdots, \quad Ex_{q-2} = Ax_{q-3}, \quad Ax_{q-2} = 0$$

with

$$\text{(A.8)} \quad \begin{aligned} x_{q-2} &= X_{q,q-1}\alpha_{q,0}, \\ x_{q-3} &= (X_{q-1,q-2}\alpha_{q-1,0}) + (X_{q,q-2}\alpha_{q,0} + X_{q,q-1}\alpha_{q,1}), \\ x_{q-4} &= (X_{q-2,q-3}\alpha_{q-2,0}) + (X_{q-1,q-3}\alpha_{q-1,0} + X_{q-1,q-2}\alpha_{q-1,1}) \\ &\quad + (X_{q,q-3}\alpha_{q,0} + X_{q,q-2}\alpha_{q,1} + X_{q,q-1}\alpha_{q,2}) \end{aligned}$$

$$\text{(A.9)} \quad \vdots$$

$$\begin{aligned} x_0 &= (X_{2,1}\alpha_{2,0}) + (X_{3,1}\alpha_{3,0} + X_{3,2}\alpha_{3,1}) + \cdots \\ &\quad + (X_{j,1}\alpha_{j,0} + X_{j,2}\alpha_{j,1} + \cdots + X_{j,j-1}\alpha_{j,j-2}) + \cdots \\ &\quad + (X_{q,1}\alpha_{q,0} + X_{q,2}\alpha_{q,1} + \cdots + X_{q,q-1}\alpha_{q,q-2}). \end{aligned}$$

Now (A.7) implies $x_{q-2} \in \ker A \cap \mathcal{T}^{q-1} = \mathcal{M}_{q-1}$ and from (A.8) we obtain $x_{q-2} \in \mathcal{M}_{q-1} \cap \mathcal{M}'_q = 0$. Since $X_{q,q-1}$ is monic we then have

$$\text{(A.10)} \qquad \alpha_{q,0} = 0.$$

Again from (A.7) we obtain $Ax_{q-3} = 0$, which implies

$$x_{q-3} \in \ker A \cap \mathcal{T}^{q-2} = \mathcal{M}_{q-2}.$$

By using (A.9), (A.10) and (A.4) we then obtain

$$x_{q-3} \in \mathcal{M}_{q-2} \cap (\mathcal{M}'_q \oplus \mathcal{M}'_{q-1}) = 0.$$

Since $\mathcal{M}'_q$ and $\mathcal{M}'_{q-1}$ are independent subspaces, the result is $\alpha_{q-1,0} = \alpha_{q,1} = 0$.

Proceeding this way, we obtain at the last step

$$x_0 \in \mathcal{M}_1 \cap (\mathcal{M}'_2 \oplus \mathcal{M}'_3 \oplus \cdots \oplus \mathcal{M}'_q) = 0$$

and consequently $\alpha_{u,j} = 0$, $u \in \{2, \cdots, q\}$, $j \in \{0, \cdots, u-2\}$, which implies that the subspaces $\operatorname{Im} X_{u,j}$, $u \in \underline{q}$, $j \in \{0, \cdots, u-1\}$ are independent.

Since the subspaces $\operatorname{Im} X_{u,0}$, $u \in \underline{q}$, are independent with $\dim \bigoplus_{u=1}^{q} \operatorname{Im} X_{u,0} = \sum_{u=1}^{q} d_u$ and since $\dim (\ker E \cap \mathcal{T}^*) = \dim (\ker A \cap \mathcal{T}^*)$, it follows that

$$\mathcal{T}^1 = \ker E \cap \mathcal{T}^* = \bigoplus_{u=1}^{q} \operatorname{Im} X_{u,0}.$$

From (A.2) we also obtain that for $c \in \underline{q}$

$$\mathcal{T}^c = \bigoplus_{u=1}^{q} \operatorname{Im} X_{u,0} \bigoplus_{u=2}^{q} \operatorname{Im} X_{u,1} \bigoplus \cdots \bigoplus_{u=c}^{q} \operatorname{Im} X_{u,c-1}$$

and then

$$\mathcal{T}^q = \mathcal{T}^* = \sum_{u=1}^{q} \sum_{j=0}^{u-1} \operatorname{Im} X_{u,j};$$

which concludes the proof. □

Continuation of Theorem 1. Let $\gamma_i := \sum_{u=i}^{q} d_u$ and consider the following set of vectors $\{x_{i,j}\}$, $j \in \{0, 1, \cdots, q-1\}$:

$$\begin{aligned}
\{x_{i,0}\} &:= [X_{1,0}; X_{2,0}; \cdots; X_{q,0}], \qquad i \in \underline{\gamma}_1, \\
\{x_{i,1}\} &:= [X_{2,1}; X_{3,1}; \cdots; X_{q,1}], \qquad i \in \underline{\gamma}_2, \\
&\vdots \\
\{x_{i,q-1}\} &:= [X_{q,q-1}], \qquad i \in \underline{\gamma}_q,
\end{aligned}$$

i.e., $\{x_{i,j}\}$, $i \in \underline{\gamma}_{j+1}$, is a set formed from the union of the columns of the matrices $[X_{j+1,j}; \cdots; X_{q,j}]$.

Analogously to the definition of the controllability indices of a pair (A, B) in [18], let

$$r_i := \text{number of integers in the set } \{\rho_1, \rho_2, \cdots, \rho_q\} \text{ which are } \geqq i.$$

Then

$$r_1 \geqq r_2 \geqq \cdots \geqq r_l \geqq 1.$$

Write $k_i := r_i - 1$, $i \in \underline{l}$, and note that $k_1 = q - 1$. Since the vectors $\{x_{i,j}\}$ above defined, constitute a basis for $\mathcal{T}^*$, it then follows that

$$\mathcal{T}^* = \bigoplus_{i=1}^{l} \mathcal{T}_i$$

with $\mathcal{T}_i = \operatorname{span}\{x_{i,j}\}$, $\dim \mathcal{T}_i = k_i + 1$, such that

$$Ex_{i,0} = 0, \quad Ex_{i,j} = Ax_{i,j-1}, \quad Ax_{i,k_i} = 0, \qquad j \in \underline{k}_i.$$

Now suppose that $\mathcal{T}^* = \bigoplus_{i=1}^{l} \mathcal{T}_i$, where $\mathcal{T}_i = \operatorname{span}\{x_{i,j}\}$, $\dim \mathcal{T}_i = m_i + 1$ and such that

$$Ex_{i,0} = 0, \quad Ex_{i,j} = Ax_{i,j-1}, \quad Ax_{i,m_i} = 0, \qquad j \in \underline{m}_i.$$

Fix an index $j \in \{0, 1, \cdots, n\}$ and let S_j be a subset of $\underline{l}$, such that $x_{i,j}$, $i \in S_j$ is a vector of the above basis. Then we must have $\dim \operatorname{span}\{x_{i,j}\} = \rho_{j+1}$, $i \in S_j$, which immediately implies that $m_i = k_i$, $i \in \underline{l}$. □

Proof of Lemma 2. (a) The statement of this item follows from Corollary 1 and Theorem 2. Also note that $\mathcal{V}^* = 0$ implies $\ker A = 0$.

(b) From (4) we have that $\mathcal{W}_b^* = E^{-1}(A\mathcal{W}_b^*)$ and thus $E\mathcal{W}_b^* \subset A\mathcal{W}_b^*$.

Suppose that N has an eigenvalue $\lambda \neq 0$. Then there exists a vector $0 \neq w \in \mathcal{W}_b^*$ such that $Ew = \lambda Aw$, i.e., $Aw = \lambda^{-1} Ew$ which implies $w \in \mathcal{V}^* = 0$.

Therefore all eigenvalues of N are equal to zero and N admits the following Jordan decomposition

$$\operatorname{Mat} N = \operatorname{diag}(N_1, \cdots, N_p, 0)$$

where N_i, $i \in \underline{p}$, is a matrix as in (14) with dim $N_i = g_i + 1$, $g_i \geqq 1$. It now follows that the pencil $(s\bar{E} - A)$ has p infinite-zeros of order g_i, $i \in \underline{p}$.

In order to show the statement (15) consider the family F_4 of all subspaces $\mathcal{W}$ described by (12), i.e.

$$F_4 = \{\mathcal{W} \subset \mathcal{X} | E\mathcal{W} \subset A\mathcal{W}\}$$

and such that the map $N := A\mathcal{W}|E|\mathcal{W}$ has all eigenvalues equal to zero.

We show next that $\mathcal{W}_b^*$ is the supremum of the above family. This can be easily seen by using induction in (13), i.e. $w_{i,1} \in \mathcal{W}_b^1$ and if $w_{i,j-1} \in \mathcal{W}_b^{j-1}$ then $w_{i,j} \in E^{-1}(A\mathcal{W}_b^{j-1}) = \mathcal{W}_b^j \subset \mathcal{W}_b^*$.

Next suppose that $\mathcal{W}_b^*$ is a proper subspace of $\tilde{\mathcal{W}}_b := \sup\{\mathcal{W} | E\mathcal{W} \subset A\mathcal{W}\}$. Then the map $A\tilde{\mathcal{W}}_b|E|\tilde{\mathcal{W}}_b$ has at least one eigenvalue $\lambda \neq 0$ which implies that there exists $0 \neq w \in \tilde{\mathcal{W}}$ but $w \notin \mathcal{W}_b^*$ such that $Ew = \lambda Aw$ which again implies $w \in \mathcal{V}^* = 0$, which proves (15).

(c) Note that for $w \in \mathcal{W}_b^*$ we have $Ew = Aw_1$, $w_1 \in \mathcal{W}_b^*$, and thus the map $\hat{E}$ is well defined.

We now show that the maps $\hat{E}$ and $\hat{A}$ are monic, i.e. $\ker \hat{E} = \ker \hat{A} = 0$. Suppose there exists $\hat{x} \in \mathcal{X} (\text{mod } \mathcal{W}_b^*) \in \ker \hat{E}$. Then

$$\hat{E}\hat{x} = \hat{E}Px = QEx = 0,$$

whence

$$Ex \in A\mathcal{W}_b^* \Rightarrow x \in E^{-1}(A\mathcal{W}_b^*) = \mathcal{W}_b^*$$

and then $\hat{x} = 0$. Analogously, suppose that $\hat{x} \in \ker \hat{A}$. Then

$$\hat{A}\hat{x} = \hat{A}Px = QAx = 0 \Rightarrow Ax \in A\mathcal{W}_b^*$$

and since A is monic, it follows that $x \in \mathcal{W}_b^*$ and hence $\hat{x} = 0$.

Since $\hat{E}$ and $\hat{A}$ are monic it follows that the pencil $(s\hat{E} - \hat{A})$ has no infinite-zeros (see (13)) and $\ker_{R[s]}(s\hat{E} - \hat{A}) = 0$, because the subspace $\mathcal{T}^*$ relative to the maps $\hat{E}$ and $\hat{A}$ is zero.

In the sequel we show (as expected) that the pencil $(s\hat{E} - \hat{A})$ has no finite-zeros. Note that since A is monic, then $\lambda = 0$ is not a finite-zero of $(sE - A)$. Now suppose there exist $0 \neq \lambda \in C$ and $\hat{v}$ such that $\hat{A}\hat{v} = \lambda \hat{E}\hat{v}$. Then

$$\hat{E}\hat{v} = \hat{E}Pv = QEv = \lambda^{-1}QAv. \tag{A.11}$$

Let $\nu := \text{span}\{v\}$. Then from (A.11) it follows that $E\nu \subset A\nu + A\mathcal{W}_b^*$ and hence

$$E(\nu + \mathcal{W}_b^*) \subset A(\nu + \mathcal{W}_b^*).$$

From (15) we then have $\nu + \mathcal{W}_b^* \subset \mathcal{W}_b^*$ whence $v \in \mathcal{W}_b^*$ and therefore $\hat{v} = 0$.

Since the pencil $(s\hat{E} - \hat{A})$ has no finite and infinite-zeros and $\ker_{R[s]}(s\hat{E} - \hat{A}) = 0$, it then follows that its rows must be linearly dependent over $R[s]$, i.e., there exists a vector $x^T(s)$ with components in $R[s]$ such that $x^T(s)(s\hat{E} - \hat{A}) = 0$. □

Remark. A polynomial basis for $\ker(sE^T - A^T)$ can be computed as indicated in the proof of Theorem 1.

Proof of Lemma 3. For $u = 1$, $\bar{\mathcal{W}}_b^1 = \ker \bar{E}$ and $\mathcal{W}_b^1 = \ker E$. We have to show that $\ker \bar{E} = P \ker E$.

Let $\bar{x} \in \mathcal{X} (\text{mod } \mathcal{V}^*) \in \ker \bar{E}$. Then by using (16) we obtain $0 = \bar{E}\bar{x} = \bar{E}Px = QEx$, which implies $Ex \in E\mathcal{V}^*$. Hence, $x \in \mathcal{V}^* + \ker E \Rightarrow \bar{x} = Px \in P \ker E$, i.e., $\ker \bar{E} \subset P \ker E$. Now, let $x \in \ker E$. Then $0 = QEx = \bar{E}Px$, so that $P \ker E \subset \ker \bar{E}$.

Assume that $\bar{W}_b^{u-1} = P\mathcal{W}_b^{u-1}$ and let $\mathcal{S} := P^{-1}\bar{\mathcal{W}}_b^u$. Hence from (18) we obtain $\bar{E}P\mathcal{S} \subset \bar{A}P\mathcal{W}_b^{u-1}$, or $QE\mathcal{S} \subset QA\mathcal{W}_b^{u-1}$, which implies, $E\mathcal{S} \subset A\mathcal{W}_b^{u-1} + E\mathcal{V}^*$. Hence

$$\mathcal{S} \subset E^{-1}(A\mathcal{W}_b^{u-1}) + \mathcal{V}^*$$

and then $P\mathcal{S} = \bar{\mathcal{W}}_b^u \subset P\mathcal{W}_b^u$.

Now consider the subspace $\mathcal{W}_b^u$ in (4). Then

$$QE\mathcal{W}_b^u \subset QA\mathcal{W}_b^{u-1} \Rightarrow \bar{E}P\mathcal{W}_b^u \subset \bar{A}P\mathcal{W}_b^{u-1}$$

which implies

$$P\mathcal{W}_b^u \subset \bar{E}^{-1}(\bar{A}\bar{\mathcal{W}}_b^{u-1}) = \bar{\mathcal{W}}_b^u. \qquad \square$$

INTRACTABLE PROBLEMS IN CONTROL THEORY*

CHRISTOS H. PAPADIMITRIOU† AND JOHN TSITSIKLIS†

Abstract. This paper is an attempt to understand the apparent intractability of problems in decentralized decision-making, using the concepts and methods of computational complexity. We first establish that the discrete version of an important paradigm for this area, proposed by Witsenhausen, is NP-complete, thus explaining the failures reported in the literature to attack it computationally. In the rest of the paper we show that the computational intractability of the discrete version of a control problem (the team decision problem in our particular example) can imply that there is no satisfactory (continuous) algorithm for the continuous version. To this end, we develop a theory of continuous algorithms and their complexity, and a quite general proof technique, which can prove interesting by themselves.

Key words. complexity, team theory, decentralized control

1. Introduction. Most classical problems arising in the fields of optimization and control are, in a very real sense, "easy to solve". By this we mean that there are computational procedures with satisfactory performance, which can be used to compute the solution of such problems. Naturally, a lot of effort is being devoted to finding more and more efficient algorithms which exploit any special structure present, but usually there is *no fundamental intractability* to be overcome. For example, in a nonlinear optimal control problem (under some smoothness assumptions) a solution can always be obtained by discretizing the problem with a dense enough grid and then using the discrete dynamic programming algorithm. Roughly speaking, the accuracy ε of the solution so obtained is inversely proportional to the number of points in the grid and such algorithms require time which is a polynomial function of $1/\varepsilon$. The situation is similar in many other classical problems such as nonlinear optimization or numerical integration of partial differential equations. In fact, in some extremely favorable cases (when, for example, the problem can be reduced to the evaluation of some analytic function), the computation time is polynomial in the *logarithm* of $1/\varepsilon$, or, even better, the solution can be expressed *in closed form.*

On the other hand, certain problems that arise in the field of decentralized decision making and control have defied all attempts for the development of realistic algorithms or representations of their solution. (It has been customary to refer to such problems as *nonclassical* control problems.) Witsenhausen's counterexample in decentralized control [Wi] is a paradigm. This problem can be viewed as a simple two-stage stochastic optimal control problem without perfect recall of the measurements. In contrast to related control problems with perfect recall, for which optimal decision rules are linear and easy to compute, the optimal decision rules for Witsenhausen's problem are provably nonlinear, and it is nontrivial to even show that they exist [Wi]. Despite persistent efforts, a representation of the optimal solution to this problem or an efficient algorithm to compute its solution has never been found. Ho and Chang [HC] took a closer look at the *discrete version* of this problem. They considered the "most reasonable" approaches to the construction of an efficient algorithm, and provided a discussion explaining why such approaches fail. However, this could not rule out the possibility that some other approach might lead to an efficient algorithm, or, more importantly, that an efficient solution for the continuous problem is possible.

This increase in difficulty in going from the centralized to the distributed problem is usually attributed to a loss of convexity; however, no formal explanation of this phenomenon had been attempted. On the other hand, some recent work has related the complexity of decentralized control, somewhat loosely, with the Theory of Computational Complexity [GJ], [PS]. These results indicate that the discrete versions of some seemingly simple problems in decentralized decision making (unfortunately, so far excluding Witsenhausen's counterexample) are computationally intractable (NP-complete or worse) [PT], [TA], [GJW], [Pa], [Ts], thus providing objective measures for the difficulty of the *discrete* problems. Nevertheless, the above research left open the issue of the intractability of the (more interesting) *original continuous problems.* In general, it is not automatically true that if a discrete version of a problem is hard, then the continuous problem is also hard. A classical example here could be linear programming, which can be solved in polynomial time, despite the fact that its discrete version—integer programming—is much harder.

In this paper we address and in many ways settle the issues raised above. In § 2 we discuss the few available results on the complexity of discrete nonclassical control problems. More importantly, we prove that the discrete version of Witsenhausen's counterexample is NP-complete, thus explaining the lack of progress on it, and the failures reported in [HC]. The goal of the remaining sections is to relate the complexity of discrete and continuous problems. In particular, we show that complexity results for a discrete problem can be used to prove the nonexistence of realistic (i.e., polynomial in the desired accuracy) algorithms for classes of continuous problems. We chose to proceed in terms of a specific example, the static team decision problem [MR], [Ra]; however, our proofs define a methodology by which similar results can be proved for other problems as well. In § 3 we make precise the notion of an algorithm that solves a continuous problem. We observe that there are several possible such notions. We also describe the main construction used in the rest of the paper, whereby from any instance of the discrete version of a decision problem we construct an instance of its continuous counterpart, which is provably closely related to the discrete one. In § 4 we show our main results, linking the difficulty of nonclassical control problems (the team problem in particular) to the theory of computational complexity. For three different notions of "efficiently solvable continuous problem" we present evidence that the team problem is not. These negative results depend on $P \neq NP$ and some related conjectures from Complexity Theory. Finally, in § 5 we discuss our results; we also place them into perspective by contrasting them to other theories of complexity for continuous problems [TW], [TWW], [YN], [Ko].

2. The complexity of discrete nonclassical problems. In this section we consider the computational complexity of the discrete versions of some representative nonclassical control problems: the static team decision problem [MT], [Ra], the discrete version of Witsenhausen's counterexample in stochastic control [Wi], as well as some nonclassical control problems in Markov chains. The main new result is that the discrete version of Witsenhausen's problem is NP-complete. For convenience, we restrict to problems involving two agents only; problems with more agents are bound to be at least as hard.

The discrete static team decision problem. We define below the discrete version of the team decision problem of Marschak and Radner, called DTEAM. The problem is the following: Each one of two agents observes a separate integer random variable k_i, $i = 1, 2$, $1 \leqq k_i \leqq N$ and makes a decision $u_i = \gamma_i(k_i)$, $u_i \in \{1, \cdots, M\}$ based on his own information only. Then a cost $c(k_1, k_2, \gamma_1(k_1), \gamma_2(k_2))$ is incurred. The problem consists

of finding decision rules that minimize the expected cost. For simplicity, we take all pairs (k_1, k_2) in the given range to be equiprobable.

An instance $I = (N, M, c, K)$ of DTEAM consists of positive integers N, M (the cardinalities of the observation and decision sets), a nonnegative integer K, and an integer valued cost function $c: \{1, \cdots, N\}^2 \times \{1, \cdots, M\}^2 \to Z$. For any pair γ_1, γ_2 of functions $\gamma_i: \{1, \cdots, N\} \to \{1, \cdots, M\}$, define their cost to be

$$J(\gamma_1, \gamma_2) = \sum_{k_1=1}^{N} \sum_{k_2=1}^{N} c(k_1, k_2, \gamma_1(k_1), \gamma_2(k_2)).$$

The optimal cost is defined to be

$$J^*(I) = \min_{\gamma_1, \gamma_2} J(\gamma_1, \gamma_2).$$

By "solving" this instance, we mean deciding whether $J^*(I) \leqq K$, or not.

We let SDTEAM (for *Simple* DTEAM) be the special case of DTEAM restricted to instances for which $K = 0$, $M = 4$ and the range of c is $\{0, 1\}$.

Complexity theory. At this point is seems appropriate to introduce some basic notions from complexity theory. See [GJ], [HU], [PS] for more complete and formal treatments.

Most of the discrete problems that we deal with in this paper will be of the *language recognition* kind, that is, problems of deciding whether a given string (encoding some combinatorial object) belongs to a fixed set of strings or not. In DTEAM, for example, the string encodes the integers M, N, and K, and the table of the cost function. The question is whether this string is in the set of strings (language) that encode instances of DTEAM in which the optimum cost is below K.

Our precise choice of a model of computation is not very critical. We could choose any variant of the Turing machine, or the random access machine models which appear to be much closer to actual computers [AHU]. All such choices are essentially equivalent (modulo a polynomial), as long as they are basically *realistic*. This latter clause excludes models which, for example, assume real arithmetic with infinite precision at unit cost per operation. Any model, whose units of computation can be achieved within a constant amount of time with constant hardware, is "realistic" in the above sense.

In the interest of differentiating between "easy" and "hard" problems, let us define P to be the class of all such problems that can be solved by an algorithm in a number of steps which is a polynomial in the length of the input string. Some well-known "hard" problems, including the satisfiability problem for Boolean formulas and the traveling salesman problem (with a limit on the cost of the tour, as in the definition of DTEAM), are not known, neither believed, to be in P; they belong, however, in another class, called NP (for nondeterministic polynomial). A problem is in NP if, whenever a string encodes a "yes" instance, there is a polynomially short and polynomially easy to check "certificate" that testifies to this. A "no" instance has no such certificate. For example, in the traveling salesman problem, the certificate is the shortest tour, of cost less than the set limit; in DTEAM the optimum decision rule that achieves cost K or less; and so on. Another, equivalent way to define NP is in terms of problems that can be solved in polynomial time by *nondeterministic* Turing machines (hence the name NP).

Is P = NP? This turns out to be the central open question in Complexity Theory today. It is widely believed that P $\neq$ NP, that is, that P is a proper subset of NP, but no proof exists (or is in sight). However, even in the absence of a definite answer to this question, for certain problems in NP we have quite convincing evidence that they

are indeed intractable. What has been shown is that these problems are NP-*complete.* This means that all problems in NP reduce in polynomial time to these. Hence, NP-complete problems are "the hardest problems in NP", in the sense that, if P is not NP, then the NP-complete problems will be the first to be intractable, of nonpolynomial complexity. A great variety of some of the hardest and most stubborn computational problems from combinatorics, optimization, logic, number theory and graph theory have been shown to be NP-complete (including the traveling salesman problem and the satisfiability of Boolean formulas; see [GJ] for a complete census, circa 1979). The usual way that a new problem is shown NP-complete is to reduce a known NP-complete problem to it. We shall see a rather involved example shortly.

Problem SDTEAM is known to be NP-complete [PT]. In fact, it follows easily from our proof that SDTEAM remains NP-complete even if the instances are restricted so that we know that the optimum cost is either zero or one, and we must decide which of the two. (This is done by taking any instance with $M = 3$—a case which is already NP-complete [PT]—and adding to each pair of observations a choice which can guarantee an overall cost of one). We shall use this fact in our proofs.

In our analysis of the complexity of nonclassical control problems, we shall also refer to complexity classes *above* P and NP. In analogy to polynomial-time computation, one can study the *exponential-time* analog, that is, problems solvable within a number of steps that grows as 2^{cn}, for some constant c. We let EXP and NEXP denote the corresponding deterministic and nondeterministic complexity classes. Also, we let DEXP and NDEXP be the analogous classes for *doubly exponential* complexities, that is, growths of the form 2^{c2^n}. These complexity classes are not, of course, nearly as practically important as P and NP, but they too are unresolved puzzles: It is not known whether EXP = NEXP or DEXP = NDEXP (although we expect that inequality holds). What *is* known, however, is that P = NP implies EXP = NEXP, which in turn implies DEXP = NDEXP (see [HU] for the standard arguments needed to show this).

Witsenhausen's counterexample revisited. Witsenhausen's counterexample is the following problem [Wi]:

$$\text{minimize } E[K(\gamma(x))^2+(\delta(x+\gamma(x)+v)+x+\gamma(x))^2],$$

with respect to all measurable real valued functions γ, δ of a single variable, where x, v are independent, normal, zero mean random variables (with given variance) and K a nonnegative constant. (Notice that this is not a (discrete) computational problem of the kind we introduced in the previous subsections. For more formal treatment of continuous computational problems, see the next section.) As was pointed out in the introduction, a representation of an optimal solution to this problem or an efficient algorithm has never been found. Of course, an algorithm can always be constructed as follows: discretize the densities of the random variables x, v and constrain the decision rules γ, δ to have finite range; then solve the discretized problem by exhaustive enumeration. However, this is unsatisfactory because the number of decision rules that have to be enumerated is exponential in the cardinality of the allowed range of the decision rules. It is this discrete problem that was studied by Ho and Chang [HC] with very little success. We explain this persistent record of failures by proving below that the discretized version of Witsenhausen's problem, as defined by Ho and Chang, is NP-complete.

Let us now define formally the discrete problem of interest:

Problem WITSENHAUSEN: Given probability mass functions f, $g: Z \to Q$ for integer variables x, v and integer constants K, B are there functions γ, $\delta: Z \to Z$ such

that

$$J(\gamma, \delta) = E[\gamma^2(x) + K(x + \gamma(x) + \delta(x + \gamma(x) + v))^2] \leqq B?$$

THEOREM 1. WITSENHAUSEN *is* NP-*complete.*

Proof. We first introduce a variation of the problem of three-dimensional matching (3DM) [GJ]:

3DM: Given a set S and a family F of subsets of S—of cardinality three—can we subdivide F into three subfamilies C_0, C_1, C_2 such that a) subsets in each family are disjoint; b) the union of the subsets in C_0 equals S?

LEMMA 1. 3DM *is* NP-*complete.*

Sketch. We basically use the construction in the standard proof that the (less restricted) version of 3DM, in which the sets in C_1, C_2 are not required to be disjoint, is NP-complete [GJ], [PS]. In that proof we construct, for each Boolean formula with three literals per clause, an instance of 3DM, such that there is a subfamily C_0 as described in 3DM iff the formula was satisfiable. It is not hard to observe, however, that, once a subfamily C_0 exists, the remaining sets of the instance can be subdivided into two subfamilies of disjoint sets. □

To prove Theorem 1, we reduce 3DM to WITSENHAUSEN. Suppose that we are given an instance S, F of 3DM, where $S = \{1, \cdots, m\}$, $F = \{S_1, \cdots, S_n\}$. Without loss of generality, assume that $n \leqq m$. We now construct an instance of WITSENHAUSEN. There will be $3n$ values of the random variable x with nonzero probability and $M = 1 + 4n\nu + 3n$ such values for v, where $\nu = \lceil \sqrt{3n - m + 1} \rceil$. All these values will be taken equiprobable. To complete the construction, we need to specify the sets $X = \{x_1, \cdots, x_{3n}\}$, $V = \{v_1, \cdots, v_M\}$ of values with nonzero probability. Concerning the constants B, K, we let $B = (3n - m)/3nM$, $K = 3nM(B + 1)$. To define the actual integers with nonzero probabilities, we need a lemma:

LEMMA 2. *There are n distinct integers* $0 \leqq z_1 \leqq \cdots \leqq z_n \leqq 3n^4$ *such that*

(a) *All the differences* $z_p - z_q$ *are distinct.*

(b) *Any difference* $(z_{i+1} - z_i) - (z_{j+1} - z_j)$ *is distinct from any difference in* (a).

Proof. We define z_k, $1 \leqq k \leqq n$, recursively. Let $z_1 = 0$ and assume that $z_1, \cdots, z_k$, $k < n$, have been constructed and $z_k \leqq 3k^4$. In order to pick a value for z_{k+1}, notice that it has to obey only the following constraints: (i) $z_{k+1} > z_k$, (ii) $z_{k+1} - z_p \neq z_i - z_j$, $(1 \leqq j, p, q \leqq k)$, (iii) $(z_{k+1} - z_k) - (z_{j+1} - z_j) \neq z_p - z_q$, $(1 \leqq j, p, q \leqq k + 1)$. (Some of the constraints in (iii) hold automatically.) So, z_{k+1} has to avoid at most $3k^4 + k^3 + (k+1)^3 < 3k^4 + 9k^3 < 3(k+1)^4$ values. Therefore, there exists an integer less than or equal to $3(k+1)^4$ whose value can be assigned to z_{k+1}. □

Notice that, given n, the integers $z_1, \cdots, z_n$ can be constructed recursively in polynomial time by means of the procedure suggested by the proof of Lemma 2. Let us assume that such a sequence $z_1, \cdots, z_{3n}$ has been constructed. Moreover, let us multiply each element of the sequence by 4, so that the expressions which are distinct by Lemma 2 are different by at least 4.

We now complete the construction of the sets X, V. The set X contains $3n$ elements; each element $x \in X$ is associated to a set $S_i \in F$ and an element $j_{ik} \in S_i$, where j_{ik} $(i = 1, \cdots, n; 1, 2, 3)$ denotes the kth element of S_i. We then let

$$x_{3(i-1)+k} = 3mz_{3(i-1)+k} + 3j_{ik}. \tag{2.1}$$

The set V contains the element 0; also for any consecutive elements x_i, x_{i+1} of X *corresponding to the same set* (that is, $i = 1, 2 \pmod 3$), V contains the numbers $x_{i+1} - x_i + \rho$, $\rho \in U = \{-\nu, -\nu + 1, \cdots, -2, -1, 1, 2, \cdots, \nu - 1, \nu\}$. Finally, V contains the numbers $3m(A + z_i)$, $i = 1, 2, \cdots, 3n$, where $A = 3z_{3n}$; this completes the construction.

Let us put together a few facts, for future reference:

LEMMA 3. (a) *If for some* γ, δ, *we have* $J(\gamma, \delta) \leqq B$, *then* $|\gamma(x)| \leqq \nu$, $\forall x \in X$.

(b) *The expressions* $|x_i - x_j|$, $|x_i - x_j + x_p - x_q|$, $|x_{i+1} - x_i - x_{j+1} + x_j + x_p - x_q|$, $(1 \leqq i - 1, j - 1, p, q \leqq n)$ *are either zero or no smaller than* $3m$. *For large enough* m, $3m > 4\nu + 2$.

(c) $|x_i - x_j| \leqq 3mA - 2 - \nu$, *for large enough* m.

Proof. (a) If for some $x \in X$ we have $|\gamma(x)| > \nu$, then

$$J(\gamma, \delta) > \frac{\nu^2}{3nM} \geqq \frac{3n - m}{3nM} = B.$$

(b) We use (2.1), the inequality $j_{ik} \leqq m$ and the fact that the magnitudes of the corresponding expressions involving the z's instead of the x's are either zero or at least four; we obtain in the second case, for example, $|x_{i+1} - x_i - x_{j+1} + x_j + x_p - x_q| \geqq 12m - 9m = 3m$. Finally notice that ν increases only as the square root of m, which also proves part (c). □

The following lemma completes the proof of the theorem.

LEMMA 4. (S, F) *is a "yes" instance of* 3DM *if and only if there exist* γ, δ *such that* $J(\gamma, \delta) \leqq B$ *for the above constructed instance of* WITSENHAUSEN.

Proof. If. Suppose that there exist γ, δ such that $J(\gamma, \delta) \leqq B$. Then, in particular, $K(x + \gamma(x) + \delta(x + \gamma(x) + v))^2 / 3Mn \leqq B$, $\forall x \in X$, $\forall v \in V$. Therefore, $|x + \gamma(x) + \delta(x + \gamma(x) + v)|^2 \leqq B/(B+1) < 1$, which implies that $x + \gamma(x) + \delta(x + \gamma(x) + v) = 0$, $\forall x \in X$, $\forall v \in V$. Let $x_i \neq x_j$. Then, using Lemma 3(a, b), we have

$$\begin{aligned} |\delta(x_i + \gamma(x_i) + v) - \delta(x_j + \gamma(x_j) + v')| &= |x_i + \gamma(x_i) - x_j - \gamma(x_j)| \\ &\geqq |x_i - x_j| - |\gamma(x_i) - \gamma(x_j)| \\ &\geqq 3m - 2\nu > 0, \end{aligned}$$

which shows that

$$x_i + \gamma(x_i) + v \neq x_j + \gamma(x_j) + v' \quad \forall v, v' \in V, \quad \forall x_i, x_j \in X, \quad x_i \neq x_j. \tag{2.2}$$

Let x_i, x_{i+1} be two consecutive elements of X corresponding to the same set S_j. Inequality (2.2) must hold for $v' = 0$ and $v = x_{i+1} - x_i + \rho$, $\forall \rho \in U$. Thus, $\gamma(x_i) + \rho \neq \gamma(x_{i+1})$, $\forall \rho \in U$. Consequently, either $\gamma(x_i) = \gamma(x_{i+1})$, or $|\gamma(x_i) - \gamma(x_{i+1})| > \nu$, which would contradict Lemma 3(a). Therefore γ takes the same value on those elements of X corresponding to the same set S_j. We denote this value by $\gamma(S_j)$.

Inequality (2.2) must also hold when x_i, x_j correspond to the same element $k \in S$ belonging to different subsets S_p, S_q; that is, $x_i = 3mz_i + 3k$, $x_j = 3mz_j + 3k$. Let $v = 3m(A + z_j)$, $v' = 3m(A + z_i)$. Inequality (2.2) becomes $\gamma(x_i) \neq \gamma(x_j)$, which implies $\gamma(S_p) \neq \gamma(S_q)$, whenever $S_p \neq S_q$, $S_p \cap S_q \neq \emptyset$.

Notice that (by our choice of B), $\gamma(x)$ can be nonzero for at most $3n - m$ elements of X. Moreover, at most one $\gamma(x)$ per element of $S = \{1, \cdots, m\}$ can be zero; thus, $\gamma(x)$ must be nonzero for exactly $3n - m$ elements; for those elements, $|\gamma(x)| = 1$. Let C_0 (respectively, C_1, C_2) be the family of subsets of F for which $\gamma(S_p) = 0$ (respectively, $\gamma(S_p) = 1$, $\gamma(S_p) = -1$). By the discussion in the last paragraph, subsets within the same family have to be disjoint. Moreover, $\gamma(x) = 0$ for exactly m elements, which shows that C_0 covers S exactly and we have a "yes" instance of 3DM.

Only If. Conversely, suppose that we have a "yes" instance of 3DM and let C_0, C_1, C_2 be the desired families of subsets. We construct γ by letting $\gamma(x_i) = 0$ (respectively, 1, -1) if x_i corresponds to an element of a subset $S_p \in C_0$ (respectively, C_1, C_2). Since C_0 is a cover to S, $\gamma(x) = 0$ for exactly m elements $x \in X$. Consequently, $E[\gamma^2(x)] = 1/(3nM)(3n - m) = B$. It remains to show that δ can be chosen so that

$x+\gamma(x)+\delta(x+\gamma(x)+v)=0$, $\forall x\in X$, $\forall v\in V$. For this it is sufficient to prove that $x_i+\gamma(x_i)+v\neq x_j+\gamma(x_j)+v'$, whenever $x_i\neq x_j$ and for all v, $v'\in V$. So, suppose that the desired inequality does not hold for some x_i, x_j, v, v'. We will derive a contradiction, but we will have to consider the various possible cases for v and v'.

(i) $v=v'=0$. If $x_i+\gamma(x_i)=x_j+\gamma(x_j)$, then $|x_i-x_j|\leqq 2$, which contradicts Lemma 3(b).

(ii) $v=0$, $v'=x_{l+1}-x_l+\rho$, $\rho\in U$. Then

$$|(x_i-x_j)-(x_{l+1}-x_l)|=|\gamma(x_j)-\gamma(x_i)+\rho|\leqq 2\nu+2<3m, \tag{2.3}$$

which implies, by Lemma 3(b), that $x_i-x_j=x_{l+1}-x_l$. It follows that $i=l+1$, $j=l$; therefore, $\gamma(x_i)=\gamma(x_j)$ and, using (2.3), $\rho=0$, which is a contradiction.

(iii) $v=x_{p+1}-x_p+\rho$, $v'=x_{l+1}-x_l+\rho'$, $\rho,\rho'\in U$. Then

$$|x_i-x_j+x_{p+1}-x_p-x_{l+1}+x_l|=|\gamma(x_j)-\gamma(x_i)-\rho+\rho'|<2\nu+2<3m,$$

which implies that $x_i-x_j+x_{p+1}-x_p-x_{l+1}+x_l=0$. So, one of the following must hold: $x_i=x_p$, $x_j=x_l$ or $x_p=x_l$. If $x_i=x_p$, it follows that $x_j=x_l$ (and conversely); in either case, we obtain $x_{p+1}=x_{l+1}$ and $x_p=x_l$; therefore, $x_i=x_j$, which is a contradiction.

(iv) $v=0$, $v'=3m(A+z_l)$. Then, $|x_i-x_j|=|\gamma(x_j)-\gamma(x_i)+3m(A+z_l)\geqq 3mA-2$, which contradicts Lemma 3(c).

(v) $v=x_{l+1}-x_l+\rho$, $\rho\in U$, $v'=3m(A+z_p)$. Then,

$$|x_i-x_j+x_{l+1}-x_l|=|\gamma(x_j)-\gamma(x_i)-\rho'+3m(A+z_p)|\geqq 3mA-2-\nu,$$

which contradicts Lemma 3(c).

(vi) $v=3m(A+z_p)$, $v'=3m(A+z_q)$. Let $x_i=3mz_i+k$, $x_j=3mz_j+k'$. Then, $3m|z_i-z_j+z_p-z_q|=|3(k'-k)+\gamma(x_j)-\gamma(x_i)|$. If $z_i-z_j+z_p-z_q=0$, then $2\geqq|\gamma(x_i)-\gamma(x_j)|=3|k-k'|$, which implies $k=k'$. Therefore, $\gamma(x_i)=\gamma(x_j)$, which is a contradiction because γ takes different values when x_i, x_j correspond to the same element of S. Therefore, $12m\leqq|z_i-z_j+z_p-z_q|\leqq 3m+2$, which is also a contradiction. This completes the proof of the lemma and the theorem. □

Decentralized and output control of imperfectly observed Markov chains. By simply observing that Witsenhausen's counterexample and the static team decision problem are at the root of several problems in decentralized control, we obtain some interesting Corollaries of Theorem 1. For example, one might be interested in formulating and studying problems of decentralized control of Markov chains. However, a single stage of such a problem would require the solution of a static team decision problem and NP-completeness (or worse) follows.

One could also formulate a problem of output control of a Markov chain, similar to the problem studied in [LA] under linear quadratic Gaussian assumptions: that is, the decision at time k would be constrained to be a function only of the observation made at time k (no recall). In fact, problem WITSENHAUSEN is a two-stage output control problem for a Markov chain and NP-completeness follows. The two-stage output control problem can be also easily seen to contain as a special case the problem of minimum distortion quantization which is also NP-complete [GJW]. Infinite horizon average cost versions of that problem can be also easily shown to be NP-complete. Finally, problems of causal coding and control of Markov chains, as defined in [WV], are also NP-complete for the same reasons.

3. Continuous problems and algorithms.

Continuous problems and their complexity. Our final aim is to derive complexity results for continuous problems. Unfortunately, there is no standard model of computa-

tion—or complexity measure—for such problems. In this subsection we shall discuss various notions of computation and complexity pertaining to continuous problems. A comparison of our framework and other existing work on the complexity of continuous problems appears in the last section.

In an instance of a typical continuous problem, we are given a finite set $F = \{f_1, \cdots, f_n\}$ of real functions (without loss of generality, with domains some power of the unit interval) and we are asked to evaluate (usually approximately) a functional $G(F) \in \Re$ of these functions. For example, $f_1, \cdots, f_n$ may be the boundary conditions for a partial differential equation and $G(f_1, \cdots, f_n)$ the value of the corresponding solution at a specific point. Closer to our concerns in this paper, we can define the continuous counterpart of the DTEAM problem mentioned in the previous section. In an instance of this problem, we are given a function $c: [0, 1]^4 \to [0, 1]$, assigning a cost to each combination of observations $y_1, y_2 \in [0, 1]$ and decisions $\gamma_1(y_1), \gamma_2(y_2) \in [0, 1]$. (Notice that we are assuming, for simplicity, that the probability distribution is uniform over $[0, 1]^2$.) The goal is to compute the functional $J^*(c)$ defined by

$$J^*(c) = \inf_{\gamma_1, \gamma_2} \int_0^1 \int_0^1 c(y_1, y_2, \gamma_1(y_1)\gamma_2(y_2))\, dy_1\, dy_2.$$

We shall be interested in the special case of this problem in which the function c is *Lipschitz continuous* with Lipschitz constant 1 (with respect to the max norm on $\Re^4$), as a representative of those special cases that we can hope to solve efficiently. Without such "smoothness" conditions, no realistic solution of continuous problems is possible, for simple information-theoretic considerations. We call the continuous version of the DTEAM problem with the Lipschitz condition the *Lipschitz continuous team problem*, or LCTEAM. That is, LCTEAM is the set of all instances, as described and restricted above. It should be obvious that a host of problems of continuous nature are amenable to similar formalization.

There are several possible notions of what it means for an algorithm to solve such a problem, and, equally important, the complexity of its operation. The subtle part is defining the sense in which the continuous functions f_i are "given". We examine a number of such approaches below.

Oracle algorithms. Continuous problems of the type defined above can often be solved by an algorithm which operates as follows: The input of the algorithm is a positive real ε, and the output is an approximation of the functional with error at most ε. Every time that the algorithm needs the value of a function f_i at some point x, this is done as follows: The algorithm submits x (a rational point), and an integer k to an *oracle* for f_i, and the oracle gives back the k most significant digits of the answer $f_i(x)$. The algorithm is "charged" for this service k steps, plus of course the time it took to construct x up to the desired precision. We say that an oracle algorithm solves a continuous problem Π in polynomial time if, for every instance I of Π there is a polynomial p_I such that the algorithm solves I within accuracy ε in time $p_I(1/\varepsilon)$.

Uniformly polynomial oracle algorithms. There is a stronger notion of efficiency, which requires that the polynomial be independent of the instance I. We call algorithms with this property *uniformly polynomial.* Notice that is a much stronger notion than that of plain polynomial-time oracle algorithms.

Note: The distinction between polynomial and uniformly polynomial algorithms has no counterpart in the context of combinatorial (discrete) problems, since in discrete problems the instance plays the role of both ε and I in the above definitions. It is, however, meaningful for continuous problems. For example, consider the problem in

which we are given one Lipschitz continuous function f over $[0, 1]$, and we are asked to compute $G(f) = \inf_{x\in[0,1]} f(x)$. A straightforward discretization leads to an algorithm with time requirements $O(K_f/\varepsilon)$, where K_f is the Lipschitz constant of f; so, this is a polynomial algorithm. On the other hand, $O(K_f/\varepsilon)$ is also a lower bound and since this problem contains instances with arbitrarily large Lipschitz constants, no uniformly polynomial algorithm exists.

Uniformly hard instances. One way to show that a continuous problem has no polynomial-time oracle algorithm at all is to exhibit an instance for which no polynomial-time oracle algorithm exists; such instances are called *uniformly hard.* Naturally, for discrete problems there are no hard single instances.

Instance-specific algorithms. We obtain an interesting variant of the concept of oracle algorithms by considering single instances of the problem Π. In each instance I, we just wish to compute a number, namely $G(F)$. We could ask the question, is this number *polynomial-time computable,* in the sense that we can compute it within accuracy ε in time polynomial in $1/\varepsilon$ by an ordinary algorithm (involving no oracles). This is a meaningful question only if the functions f_i are themselves polynomial-time computable, in that the value $f_i(x)$ can be computed in time which is polynomial in the accuracy in which x is given, and the desired accuracy.

Iterative algorithms. In numerical analysis or mathematical programming we are often interested in convergent *iterative algorithms.* These differ from the class of algorithms we introduced above in that they do not take ε as an input, and they never halt. Rather, from time to time they produce output values $G_i(F)$, $i = 1, 2, \cdots$ which are increasingly accurate approximations of $G(F)$. We may call an iterative algorithm *polynomial* if there is a polynomial p such that, for every instance, at time $p(1/\varepsilon)$, the most recent output value is accurate, within ε. It is clear that if a polynomial iterative algorithm exists, there also exists a uniformly polynomial algorithm for the problem. In fact the converse also holds [9]: take a uniformly polynomial algorithm and run it with $\varepsilon = 2^{-k}$, $k = 1, 2, \cdots$. The resulting algorithm is a polynomial iterative algorithm. For this reason, we shall not consider iterative algorithms any further.

3.7. The basic construction. Our method of connecting the complexity of the continuous version of the TEAM problem to the (much better understood) complexity of the discrete one, is based on the following lemma and construction:

LEMMA 5. *For each instance I of the* SDTEAM *problem we can define a function $c_I: [0, 1]^4 \to [0, 1]$ such that:*

(i) *Function c_I is Lipschitz continuous (with Lipschitz constant* 1*), and thus it defines an instance of* LCTEAM.

(ii) *The optimum $J^*(c_I)$ equals $1/20N^4$ if the optimum of I was* 1*, and* 0 *if it was* 0 *(recall for that instances of* SDTEAM *these are the only possibilities; N is the number of possible observations in I).*

(iii) *For any I and k-bit numbers y_1, y_2, u_1, u_2, and any $l > 0$, the l most significant bits of $c_I(y_1, y_2, u_1, u_2)$ can be computed in time polynomial in k, l, and the size of I.*

Proof. Let us first define a function $\alpha: [0, N] \to [0, 1/N]$ as follows:

$$\alpha(x) = \begin{cases} x - \lfloor x \rfloor & \text{if } x - \lfloor x \rfloor \leqq \dfrac{1}{N}, \\ \lceil x \rceil - x & \text{if } \lceil x \rceil - x \leqq \dfrac{1}{N}, \\ \dfrac{1}{N} & \text{otherwise} \end{cases}$$

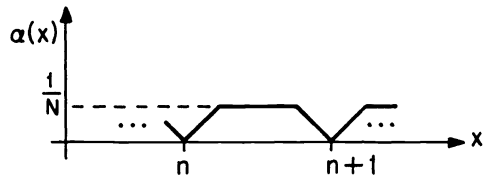

FIG. 1

(see Fig. 1), and define $q(y_1, y_2) = (1/(1-1/N)^2)\alpha(y_1)\alpha(y_2)$. Notice that q has Lipschitz constant $4/N$, and that its integral over $[0, N]^2$ is one.

Let us now recall the cost function of the discrete instance I, call it $d: \{1, 2, \cdots, N\} \times \{1, 2, 3, 4\} \to \{0, 1\}$. For $1 \leqq x_1, x_2 \leqq N$, integers, and $v_1, v_2 \in [1, 4]$, let $h(x_1, x_2, v_1, v_2)$ be the smallest $\delta \leqq 1$ such that there are u_1, u_2 with $|u_1 - v_1|, |u_2 - v_2| \leqq \delta$ and $d(x_1, x_2, u_1, u_2) = 0$, or 1 if no such δ exists. Then, define, for $0 \leqq y_1, y_2, u_1, u_2 \leqq 1$ the cost function $c_I(y_1, y_2, u_1, u_2)$ to be

$$\frac{q(Ny_1, Ny_2)}{20}[h(\lceil Ny_1 \rceil, \lceil Ny_2 \rceil, 3u_1+1, 3u_2+1) + 2p(3u_1+1) + 2p(3u_2+1)],$$

where $p(x)$ is the distance between x and its closest integer.

Let us verify the properties of c_I. To verify (i), function h has discontinuities at integral values of its first two arguments, but q is zero there, so c_I is continuous. To check that the Lipschitz constant is 1, recall that if the functions f_i have Lipschitz constants L_i and maxima m_i, $i = 1, 2$, then the function $f_1 f_2$ has Lipschitz constant $L_1 m_2 + L_2 m_1$. Within each "rectangle" of constant $\lceil Ny_1 \rceil$, $\lceil Ny_2 \rceil$ h has maximum 1 and Lipschitz constant 3, and $p(3u_1+1) + p(3u_2+1)$ has Lipschitz constant 6 and maximum 2, so their sum has maximum 3 and Lipschitz constant 9. Also, q has maximum $4/N^2$ and Lipschitz constant at most 8, and so their product has Lipschitz constant at most 20. It follows that c_I has indeed Lipschitz constant at most 1, as required.

For (ii), let us denote by $\mathcal{D}$ the set of all functions $\gamma: [0, 1] \to [0, 1]$ which are piecewise constant, with discontinuities at points i/N, and taking the values $\{0, \frac{1}{3}, \frac{2}{3}, 1\}$. We claim that, for fixed γ_2, the decision function $\gamma_1(y_1)$ which minimizes $J(\gamma_1, \gamma_2)$ is in $\mathcal{D}$. Notice that $\inf_\gamma J(\gamma_1, \gamma_2)$ is equal to

$$\frac{1}{(1-1/N)^2}\int_0^1 \alpha(Ny_1) \cdot \min_{u_1} \int_0^1 \alpha(Ny_2)[h + 2p(3u_1+1) + 2p(3\gamma_2(y_2)+1)]\, dy_2\, dy_1.$$

To carry out this minimization, it is sufficient to minimize, with respect to u_1,

$$\int_0^1 \alpha(Ny_2)[h(\lceil Ny_1 \rceil, \lceil Ny_2 \rceil, 3u_1+1, 3\gamma_2(y_2)+1)]\, dy_2 + \int_0^1 2p(3u_1+1)\, dy_2$$

for each y_1. The first term does not depend on y_1 within the interval $[i/N, (i+1)/N]$, and thus the optimum u_1 is indeed constant within this interval. Secondly, notice that the second term, together with the Lipschitz condition, ensures that the minimum is achieved at integer values of $3u_1+1$, that is, at values of γ_1 in $\{0, \frac{1}{3}, \frac{2}{3}, 1\}$.

The same argument shows that γ_2 may be constrained to be in $\mathcal{D}$ as well. Once we have shown that the optimizing decision functions are in $\mathcal{D}$, we have essentially shown that the continuous LCTEAM problem defined by c_I is in fact "isomorphic" to the discrete one I, and it has optimum which is $J^*(c_I) = (1/20N^4)J^*(I)$, where $J^*(I)$ is the optimum of I, either 0 or 1. Part (iii) is trivial. □

4. The main results. In this section we present our evidence that the Lipschitz continuous team problem is indeed intractable. We prove *three* such theorems, corresponding to three different notions of complexity of continuous problems introduced in the previous section, namely uniformly polynomial oracle algorithms, polynomial instance-specific algorithms, and uniformly hard instances. In all three cases, we show the intractability of LCTEAM, assuming that a very likely conjecture in Complexity Theory is true. Naturally, the stronger our notion of intractability of LCTEAM, the stronger the complexity-theoretic conjecture needed.

4.1. Nonexistence of uniformly polynomial algorithms.

THEOREM 2. *There is a uniformly polynomial algorithm for* LCTEAM *if and only if* P = NP.

Proof. If. Suppose that P = NP. We shall describe a uniformly polynomial algorithm for LCTEAM. The algorithm works by discretizing the problem, and obtaining appropriately approximate solutions by solving discrete instances of DTEAM (which is possible, once P = NP).

Let R correspond to a *truncation* operation: given some $x \in [0, 1]$ and some $\varepsilon > 0$, $R(x, \varepsilon)$ retains the $\lceil \log(1/\varepsilon) \rceil$ most significant bits of x; consequently, $|x - R(x, \varepsilon)| \leqq \varepsilon$ and if $\log(1/\varepsilon)$ is an integer, then $(1/\varepsilon)R(x, \varepsilon)$ is also an integer.

Given the cost function c of an instance of LCTEAM and some $\varepsilon > 0$ such that $\log(1/\varepsilon)$ is an integer, we construct an instance I of DTEAM by letting $\Delta = \varepsilon/8$, $N = 1/\Delta$, $M = 1/\Delta$ and cost function

$$d(i, j, k, l) = \frac{1}{\Delta} R(c(i\Delta, j\Delta, k\Delta, l\Delta), \Delta), \qquad (i, j, k, l) \in \left\{1, \cdots, \frac{1}{\Delta}\right\}^4. \tag{4.1}$$

Clearly, d is integer-valued and $C = \max d \leqq 1/\Delta$. Let $J^c(\gamma_1, \gamma_2)$, $J^d(\delta_1, \delta_2)$ denote the costs of pairs of decision rules for the continuous (c) and discrete (d) instances, respectively. J^{*c}, J^{*d} are the corresponding optimal costs.

LEMMA 6. $\|J^{*c} - \Delta^3 J^{*d}| \leqq \varepsilon$.

Proof. Let δ_1, δ_2 be the optimal for d. Let $\gamma_i(y_i) = \Delta\delta_i(k_i)$ for $y_i \in [(k_i - 1)\Delta, k_i\Delta]$, $k_i = 1, \cdots, N$, $i = 1, 2$. Using the definition of d and the Lipschitz continuity of c, we obtain

$$\begin{aligned} J^{*c} \leqq J(\gamma_1, \gamma_2) &= \sum_{k=1}^{N} \sum_{m=1}^{N} \int_{(k-1)\Delta}^{k\Delta} \int_{(m-1)\Delta}^{m\Delta} c(y_1, y_2, \gamma_1(y_1), \gamma_2(y_2))\, dy_1\, dy_2 \\ &\leqq \Delta^2 \sum_{k=1}^{N} \sum_{m=1}^{N} (\Delta d(k, m, \delta(k), \delta(m)) + 2\Delta) \qquad (4.2) \\ &= \Delta^3 J^d(\delta_1, \delta_2) + 2\Delta = \Delta^3 J^{*d} + 2\Delta \leqq \Delta^3 J^{*d} + \varepsilon. \end{aligned}$$

In order to prove the converse inequality, suppose that $\bar{\gamma}_1, \bar{\gamma}_2 : [0, 1] \to [0, 1]$, are such that $J^c(\bar{\gamma}_1, \bar{\gamma}_2) \leqq J^{*c} + \Delta$. Let $f(y_1, y_2) = \int_0^1 c(y_1, y_2, u_1, \bar{\gamma}_2(y_2))\, dy_2$. Then f is also Lipschitz continuous with Lipschitz constant 1. It follows that

$$|\inf_u f(y, u) - \inf_u f(y', y)| \leqq 2|y - y'| \quad \forall y, y' \in [0, 1].$$

Let $\hat{\gamma}_1(y_1) = \operatorname{argmin}_{u \in [0,1]} f(k\Delta, u)$, for $y_1 \in ((k-1)\Delta, k\Delta)$. Then,

$$\begin{aligned} J^c(\hat{\gamma}_1, \bar{\gamma}_2) &= \int_0^1 f(y_1, \hat{\gamma}_1(y_1))\, dy_1 \leqq \int_0^1 \left(\inf_{u \in [0,1]} f(y_1, u_1) + 2\Delta \right) dy_1 \\ &= \inf_{\gamma_1} \int_0^1 f(y_1, \gamma_1(y_1))\, dy_1 + 2\Delta = \inf_{\gamma_1} J^c(\gamma_1, \bar{\gamma}_2) + 2\Delta \\ &\leqq J^c(\bar{\gamma}_1, \bar{\gamma}_2) + 2\Delta \leqq J^{c*} + 3\Delta. \end{aligned}$$

In a similar way, we may construct a piecewise constant function $\hat{\gamma}_2: [0, 1] \to [0, 1]$ such that

$$J^c(\hat{\gamma}_1, \hat{\gamma}_2) \leqq J^c(\hat{\gamma}_1, \bar{\gamma}_2) + 2\Delta \leqq J^{c*} + 5\Delta.$$

The decision rules $\hat{\gamma}_i$, $i = 1, 2$, being piecewise constant determine corresponding decision rules $\hat{\delta}_i$, $i = 1, 2$, for the discrete cost function. Then, a chain of inequalities similar to (4.2) leads to

$$\Delta^3 J^{d*} \leqq \Delta^3 J^d(\hat{\delta}_1, \hat{\delta}_2) \leqq J^c(\hat{\gamma}_1, \hat{\gamma}_2) + 2\Delta \leqq J^{c*} + 7\Delta \leqq J^{c*} + \varepsilon. \qquad \square$$

Since P = NP there exists an algorithm for the problem of computing the optimal cost of any instance of DTEAM (based on the algorithm for DTEAM and binary search), which is polynomial in M, N, $\log C$, where C is the largest integer appearing in the cost function. Consider then the following algorithm for LCTEAM:

(i) Decrease ε (at most by a factor of 2) so that $\log(1/\varepsilon)$ is an integer.

(ii) Use the oracle to read the $\log(8/\varepsilon)$ most significant bits of $c(i\Delta, j\Delta, k\Delta, m\Delta)$, $1 \leqq i, j, k, m \leqq N$, where $N\Delta = 1$, $\Delta = \varepsilon/8$.

(iii) Run the assumed algorithm on the resulting instance of DTEAM, as defined by (4.1). Multiply the output by Δ^3 and return it.

This is clearly a uniformly polynomial algorithm, and the proof of the *if* part is complete.

Only If. If we had a uniformly polynomial algorithm for LCTEAM, we could solve any instance I of SDTEAM of size N as follows:

(i) Construct the corresponding instance c of LCTEAM, as in Lemma 5.

(ii) Simulate the assumed algorithm for LCTEAM on it, with desired accuracy $\varepsilon = 1/40N^4$. The time required is polynomial in N, including the computations of c, which, by Lemma 5(iii), are polynomially related to the "charges" for oracle calls of the corresponding computation of the algorithm.

(iii) If the result is less than $\varepsilon = 1/40N^4$, then the optimum cost of SDTEAM was 0, otherwise 1.

Since this is a polynomial-time algorithm for SDTEAM, an NP-complete problem, it follows that P = NP. $\square$

4.2. A hard instance with efficiently computable cost.

THEOREM 3. *If* DEXP $\neq$ NDEXP *then there exists an instance c of* LCTEAM *such that*

(i) *The cost* $c(y_1, y_1, u_1, u_2)$, *where* y_1, y_2, u_1, u_2 *are k-bit numbers between* 0 *and* 1 *can be computed with accuracy* ε *in time polynomial in* 2^k *and* $1/\varepsilon$, *whereas*

(ii) *The optimum value* J^* *is not polynomially computable; that is, it cannot be computed within accuracy* ε *in time polynomial in* $1/\varepsilon$.

Proof. We first need a lemma concerning the existence of certain "hard" sequences of instances of NP-complete problems, in the spirit of [HSI].

LEMMA 7. *If* DEXP $\neq$ NDEXP *then there is a sequence* $I_1, I_2, \cdots$ *of instances of* SDTEAM *such that*:

(a) *Instance* I_i *has size (that is,* N*) equal to* 2^i.

(b) *There is an algorithm which, given i, constructs* I_i *in time polynomial in* 2^i *(the size of the instance produced).*

(c) *There is no polynomial-time algorithm that solves all instances* I_i.

Sketch. Consider a problem L in NDEXP $-$ DEXP. Without loss of generality, instances of L are encoded in binary, and therefore an instance i also represents an integer, in binary. For each instance i of L, let $f(i)$ be the string of length 2^i which starts with the string i and has 0's in all other positions. The language $f(L) = \{f(i): i \in L\}$

is in NP (since L is in NDEXP), and thus there is a polynomial-time transformation that transforms each string $f(i)$ to an instance of SDTEAM such that the instance of SDTEAM is a "yes" instance if and only if $f(i) \in f(L)$. By "padding" these instances of SDTEAM to make them of size a power of two, and filling in the gaps with "null" instances, we obtain the sequence of the lemma. □

To show the theorem, consider a sequence of instances as constructed in the lemma. For each such instance I_i, we construct a continuous function $c_i: [0, 1]^4 \to [0, 1]$, as in Lemma 5. Consider now a *scaled, shifted* version of c_i, call it c_i', with support $[1-2^{-i}, 1-2^{-(i+1)}]^2 \times [0, 1]^2$ (see Fig. 2), defined in this range as

$$c_i'(y_1, y_2, u_1, u_2) = \frac{1}{2^{i+1}} c_i(2^{i+1}(y_1 - 1 + 2^{-i}), (2^{i+1}(y_2 - 1 + 2^{-i}), u_1, u_2)).$$

c_i is zero outside this domain. Finally, define the function c to be

$$c(y_1, y_2, u_1, u_2) = \sum_{i=1}^{\infty} c_i'(y_1, y_2, u_1, u_2).$$

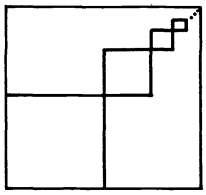

FIG. 2

This function is Lipschitz continuous with constant 1 (due to the scaling), as required by the theorem, and it is easy to see that it satisfies condition (i) (compare with (iii) of Lemma 5). To show (ii), notice that the optimum value J^* corresponding to c can be expressed in terms of the optima J_i^{*d} of the instances I_i that comprise it, as follows:

$$J^* = \sum_{i=1}^{\infty} J_i^{*d} \frac{1}{20 \cdot 2^{4i}} \frac{1}{2^{i+1}} \frac{1}{2^{2(i+1)}}.$$

The first term of the addend is the cost of the original discrete instance, known to be either 0 or 1 in SDTEAM. The second term was introduced by the construction of Lemma 5. The third is due to the scaling, whereas the last term represents the area of the support of instance c_i', as defined above. Thus, $J^* = \frac{1}{160} \sum_{i=1}^{\infty} J_i^{*d} 2^{-7i}$. From the form of the sum, it is evident that, if we could compute J^* within accuracy ε in time polynomial in $1/\varepsilon$, then we could compute the optimum cost of I_i in time polynomial in the size of I_i, contrary to Lemma 7. □

Theorem 3 has a weak converse. It can be shown that, if an instance of LCTEAM as described in Theorem 3 exists, then EXP $\neq$ NEXP. The argument goes as follows: If such a hard instance exists, then its *discretizations* (that is, the sequence of discrete problems resulting by subdividing the unit interval in 2^i equal intervals, and by defining the cost function on this grid by a restriction of the continuous cost function) are not all solvable by polynomial-time algorithms. Thus, we have a hard exponentially sparse sequence of *optimization* problems of the DTEAM type (in which we are asked to determine the optimum cost). Since each optimization problem in this sequence can be reduced to an exponential number of a *recognition* problems (asking whether the

cost of an instance is below some bound), say, by binary search, [PS], we obtain a hard polynomially sparse sequence of instances of this problem, known to be NP-complete. The existence of such hard sequences is known (see [HSI], or the argument above) to be equivalent to EXP $\neq$ NEXP.

A uniformly hard instance. If P $\neq$ NP we can show something stronger than the nonexistence of uniformly polynomial algorithms proved in Theorem 2. In particular, we can show that there is a uniformly hard instance of LCTEAM, which "fools" all polynomial-time oracle algorithms. Our construction has to use diagonalization arguments which are not polynomially constructive, and as a result the instance constructed is not one that can be computed efficiently. Since a complete proof of this result would require the introduction of machinery in a scale disproportional to the information added, we only present an outline of the proof.

THEOREM 4. *There is a uniformly hard instance of* LCTEAM *if and only if* P $\neq$ NP.

Sketch. One direction follows from Theorem 2. For the *if* direction, we first need to define a discrete analog of an oracle algorithm. One way to do this is to consider *sequence algorithms*, that is, algorithms which operate on infinite sequences of instances of a problem. Such an algorithm accepts as its input an infinite tape with the sequence, together with an integer i, and it returns the answer ("yes" or "no") of the ith instance of the sequence. To capture the charges due to precision of the queries and the answers of oracle machines, we require that the algorithm is charged $\lceil \log k \rceil$ to determine the value of the kth bit of its input tape.

We first show that, if P $\neq$ NP, there is a sequence of instances of the SDTEAM problem, of size exponentially increasing, which cannot be solved by any sequence algorithm. The construction is carried out by enumerating all polynomial-time sequence algorithms, and using the ith non-"null" instance in the sequence to rule out the ith sequence algorithm as a potential solver of the present instance (i.e., sequence). Since P $\neq$ NP, an instance on which the ith sequence algorithm does the wrong thing, and which is of size larger than some given bound, must exist. To avoid the possibility in which the ith algorithm takes "advice" from the previous or subsequent instances in solving the current instance, we interject a doubly exponential number of "null" instances between two such consecutive instances.

We finally construct an instance of the LCTEAM problem from the given sequence of SDTEAM problems, exactly as in the proof of Theorem 3. If this instance could be solved by some oracle algorithm, it can be argued that the sequence constructed in the previous paragraph can be solved by a sequence algorithm, which is impossible by its construction. □

5. Discussion. We have shown that the team decision problem with a Lipschitz continuous cost function and uniform probability distribution holds the same place in the continuous world that NP-complete problems do in the discrete world: it possesses an approximate algorithm which is polynomial in the desired accuracy if and only if P = NP. A similar result can be also proved if Lipschitz continuity is replaced by some other, possibly stronger, smoothness requirement such as once or twice differentiability, etc. Only the construction in Lemma 5 would have to be a little more elaborate. A similar result is also possible for Witsenhausen's counterexample in stochastic control if the assumption of normality of the underlying random variables is relaxed. Since the team decision problem is a basic component of (generally harder) problems in decentralized stochastic control, such problems (at least in the absence of any more special structure) are qualitatively different from the vast majority of traditional problems in continuous mathematics and classical control. Such problems,

including nonlinear optimization, filtering and control, as well as partial differential equations, possess algorithms which are polynomial in the desired accuracy, when some smoothness conditions are satisfied, and are solvable from a realistic point of view.

The proofs of our results are based on the fact that the discrete version of the team problem is NP-complete. In this sense, we demonstrate that NP-completeness results can be exploited to make inferences about the computational complexity of continuous problems. It should be noted, however, that the various notions of intractability used call for conjectures of varying strength from Complexity Theory, all of them implying $P \neq NP$.

The proofs of Theorems 2, 3, and 4 determine a methodology that can be applied to obtain similar negative complexity results concerning other continuous problems as well. Abstracting the main elements of the proofs, we see that the following properties of LCTEAM were heavily used:

(i) The discrete version of the problem of interest should be NP-complete.

(ii) We should be able to take an instance of the discrete problem and construct an instance of the continuous problem as in Lemma 5, while respecting certain smoothness requirements.

(iii) The above construction should be simple enough, so that the corresponding oracle calls can be efficiently simulated by a Turing machine.

(iv) Finally, it should be possible to take a sequence of increasingly large discrete instances and imbed them into a single one, while keeping the dimension of the continuous problem constant.

Finally, let us comment on the relation and some differences of our framework with other theories of complexity for continuous problems. The complexity of any algorithm solving a continuous problem can be roughly divided into two kinds of activities: oracle calls to obtain information about the instance to be solved and computations based on the values returned by the oracle. A lot of past research [TW], [TWW], [NY] has obtained lower bounds on the overall complexity by deriving lower bounds on the number of oracle calls necessary to obtain enough information so that an ε-approximate solution is possible. This is a valid approach for the types of problems emphasized in that research (mainly mathematical programming and numerical integration of partial differential equations) and has produced many interesting results; the main reason is that in such problems the amount of any further computation necessary can be bounded by a polynomial (and some times linear) function of the number of oracle calls. The team problem, however, is different: while $O(1/\varepsilon^4)$ oracle calls provide sufficient information for an ε-approximate solution, we have shown that further computations require time which is exponential in ε (unless $P = NP$). In other words, the structure of the team problem forces us to emphasize its computational complexity rather than its informational requirements.

Much closer to our approach are the very interesting recent results in [Ko]. In that paper, it is shown that there are ordinary differential equations which are given in terms of easily computable functions, but which cannot be integrated efficiently, unless P = PSPACE. In this sense, Ko's results are quite similar in spirit to Theorem 3. One of the differences is that Ko's notion of efficiency requires that algorithms operate in time polynomial in the *logarithm* of $1/\varepsilon$.

STOCHASTIC MINIMIZATION WITH CONSTANT STEP-SIZE: ASYMPTOTIC LAWS*

GEORG CH. PFLUG†

Abstract. The behavior of the stationary distribution of a Markovian process of the form

$$(*) \qquad X_{n+1}^a = \pi_S(X_n^a - aY_n^a)$$

as a tends to zero is studied. The process (*) is a constant step-size (constant gain) constrained stochastic approximation process, with π_S being the projection onto the convex set of constraints S. If the gains a are held constant, the process $\{X_n^a\}$ does not converge to the point of solution but the stationary distribution of $\{X_n^a\}$ converges to the unit mass at the solution, if $a \to 0$. Properly normalized the stationary distribution converges to a nondegenerated limit. This limit depends on the smoothness of the feasible set S in the neighborhood of the solution (in particular on the dimension of the largest linear subspace contained in the tangential cone).

Key words. stochastic optimization, stochastic approximation, constrained problems, constant gain, asymptotic distribution

1. Introduction and general results. The aim of this paper is to study the probabilistic behavior of stochastic recursions of the form

$$(1) \qquad X_{n+1}^a = \pi_S(X_n^a - aY_n^a), \qquad X_n^a \in \mathbb{R}^m, \quad n \geqq 1,$$

where π_S denotes the projection on the closed convex set S.

We assume that X_n^a, Y_n^a are random vectors in $\mathbb{R}^m$ and that the conditional distribution of Y_n^a given the history $X_1^a, \cdots, X_n^a$ depends only on X_n^a (and is in particular not explicitly dependent either on the iteration step n or on the real parameter $a > 0$). Thus $\{X_n^a\}$ is, for each fixed a, a *Markovian process.* In the interpretation given below, a is the *step-size parameter.* In this paper we shall be especially interested in the stationary distribution of (1) for small a.

Recursive processes of the form (1) are widely used to approximate the solution of the *stochastic program*

$$(2) \qquad \int_\Omega H(x, \omega)\, d\nu(\omega) = \min!, \qquad x \in S$$

where ν is a probability measure on some measurable space (Ω, A) and $H(\cdot, \cdot)$ is a known jointly measurable function $\mathbb{R}^m \times \Omega \to \mathbb{R}^1$. The set S is a closed, convex set of constraints in $\mathbb{R}^m$. The application $x \mapsto H(x, \omega)$ maps $\mathbb{R}^m$ into $L^1(\Omega, A, \nu)$. If $F(x) := \int H(x, \omega)\, d\nu(\omega)$ is known explicitly then the problem (2) can be viewed as a deterministic constrained minimization problem. In most cases of applications however $F(\cdot)$ is not known in an explicit manner. There are, in principle, three possible strategies for solution in this case:

(i) Try to calculate $F(\cdot)$ by numeric integration and proceed as in the deterministic case.

(ii) Try to approximate ν by a measure ν_0 such that $\int_\Omega H(x, \omega)\, d\nu_0(\omega)$ is close to $\int_\Omega H(x, \omega)\, d\nu(\omega)$ such that $\int_\Omega H(x, \omega)\, d\nu_0(\omega)$ is easily computed.

(iii) Use stochastic approximation.

* Received by the editors May 15, 1984, and in revised form April 3, 1985.

† Mathematical Institute, J. Liebig University, Arndtstrasse 2, Giessen D-6300, Federal Republic of Germany.

The first two approaches lead to deterministic procedures. Only the stochastic approximation method is stochastic in nature. This method will be considered here. To explain the idea behind this we have to introduce the notion of an L^1-derivative.

DEFINITION. A m-dimensional vector $\mathbf{H}_x(x^*, \omega)$ of L^1-functions is called the L^1-derivative of the function $x \mapsto H(x, \omega)$ at the point x^*, if

$$\int |H(x, \omega) - H(x^*, \omega) - (x - x^*)' \mathbf{H}_x(x^*, \omega)| \, d\nu(\omega) = o(\|x - x^*\|)$$

as x tends to x^*.

Suppose that the application $x \mapsto H(x, \omega)$ has for every x a L^1-derivative $\mathbf{H}_x(x, \cdot) = (H_{x,1}(x, \cdot), \cdots, H_{x,m}(x, \cdot))$. Then the random vector $\mathbf{H}_x$ is an unbiased estimate for the gradient(grad) of F, since

$$\int \mathbf{H}_x(x, \omega) \, d\nu(\omega) = \text{grad } F(x) =: f(x)$$

by componentwise integration.

The construction of a random sequence $\{X_n\}$ approximating the solution x_0 of the stochastic program (2) is done in a recursive way. Suppose X_1 is any starting value and assume that X_n is already constructed. Let Y_n be a random vector which is independent of $X_1, \cdots, X_{n-1}$ but not on X_n, such that its conditional distribution given $X_n = x_n$ coincides with the image measure of ν under $\mathbf{H}_x(x_n, \cdot)$, i.e.

$$P\{Y_n \in A | X_n = x_n\} := \nu\{\omega | \mathbf{H}_x(x_n, \omega) \in A\}.$$

By this construction

$$E(Y_n | X_1, \cdots, X_n) = E(Y_n | X_n) = f(X_n) = \text{grad } F(X_n).$$

The unknown solution point of (2) can be approximated by a stochastic version of the gradient method, using the *stochastic gradients* Y_n, namely

$$X_{n+1} = \pi_s(X_n - a_n Y_n). \tag{3}$$

Here a_n are appropriately chosen step-sizes. Many authors have considered such recursive procedures ([1], [3], [4] among others). It was shown that under some conditions—including $a_n \geqq 0$, $\sum a_n = \infty$, $\sum a_n^2 < \infty - X_n \to x_0$ a.s. where x_0 is the unique minimal point of (2).

For the practical implementation of algorithms of the type (3) asymptotic laws (for $a_n \to 0$) are of limited importance. The reason is that for the first iterations the absolute values of the step-size constants a_n are much more important than their speed of convergence to zero. For larger n however the constants $a_n = a/n$, which is the usual choice, converge very slowly to zero. Therefore we might as well take a_n to be constant, but small.

For this reason we shall consider in this paper the algorithm (1), i.e. the situation for fixed but small step size a. For the unconstrained process, a similar approach was used by Kushner and Hai Huang [5]. As we shall show, X_n^a converges in law to a *stationary sequence* fulfilling (1) irrespectively of the starting value. Let X^a be distributed according to this stationary distribution. We shall be especially interested in the limiting distribution of

$$\tilde{X}_n^a =: \frac{X^a - x_0}{g(a)} \tag{4}$$

as a tends to zero. $g(a)$ is a properly chosen normalization and x_0 is the point of

solution of the problem (2), which is assumed to be unique. Thus x_0 satisfies

$$x_0 \in S \qquad -f(x_0) \perp C_0 \quad \text{(i.e. } y' \cdot f(x_0) \geqq 0 \text{ for all } y \in C_0\text{)}$$

where C_0 is the *tangent cone* of S at x_0, i.e. C_0 is the closure of the set $\{\lambda(x - x_0) | x \in S, \lambda \geqq 0\}$.

We have assumed that the process X_n^a is a time-homogeneous Markov chain. Denote by $P^a(\cdot, \cdot)$ its transition probabilities, i.e.

$$P^a(x, A) = P\{X_{n+1}^a \in A | X_n^a = x\}$$

where $x \in S$ and $A \in \mathfrak{B}_S = \{\text{Borel sets}\} \cap S$. The transition probabilities can be chosen as Markov kernels, i.e.

(i) $x \mapsto P^a(x, A)$ is measurable for every $A \in \mathfrak{B}_S$,
(ii) $A \mapsto P^a(x, A)$ is a probability measure for every $x \in S$.

Markov kernels induce operations on the set of probability measures on $\mathfrak{B}_S$ by

$$P^a\mu\colon \quad A \mapsto \int P^a(x, A)\, d\mu(x)$$

and on the set of all bounded $\mathfrak{B}_S$ measurable functions by

$$P^a f\colon \quad x \mapsto \int f(y) P^a(x, dy).$$

The n-fold convolution of P^a is denoted by $P_n^a(\cdot, \cdot)$ and is again a Markov kernel.

We shall show that under some not very restrictive assumptions the chain X_n^a is recurrent (in the sense of Harris) and aperiodic. Hence there is a unique invariant measure μ^a and

$$\| P_n^a \gamma - \mu^a \| \to 0$$

for every "starting measure" γ, where $\| \ \|$ denotes the variational norm. μ^a is the distribution of the stationary random vector X^a. Moreover we shall be interested in the limit distribution of the normalized random vectors $\tilde{X}^a$ as $a \to 0$ (see (4)).

The analytic theory of Markov chains is used extensively in this paper. (A general reference is the book of Revuz [8].) In contrast to the unconstrained case it is not always possible to give a diffusion approximation for the process in the constrained case. (See § 3.) Therefore a discrete time Markovian process is used to describe also the asymptotic behavior.

We begin with stating the assumptions. We rewrite the algorithm (1) in the form

$$X_{n+1}^a = \pi_S(X_n^a - af(X_n^a) - aZ(X_n^a, \omega)) \tag{5}$$

where $Z(x, \omega) := Z(x) := \mathbf{H}_x(x, \omega) - f(x)$ are independent zero mean variables. Sometimes we write simply Z_n instead of $Z(X_n)$. When there is no ambiguity, we occasionally drop the superscript a, writing X_n instead of X_n^a. The inner product in $\mathbb{R}^m$ is denoted by $\langle \cdot, \cdot \rangle$. A' denotes the transpose of A and $\xrightarrow{w}$ means weak convergence. The starting value X_1 of the recursion may be an arbitrary random variable with finite second moment. We write P_{X_1} for the conditional probability given the starting value X_1. P_x means the law of the process started at $X_1 = x$. The corresponding expectation is denoted by E_x.

Assumptions (A).

(i) For every $\varepsilon > 0$ there is a $\delta_\varepsilon > 0$ such that

$$\inf_{\{x \in S \mid \|x - x_0\| \geqq \varepsilon\}} \frac{\langle x - x_0, f(x)\rangle}{\|x - x_0\|^2} \geqq \delta_\varepsilon.$$

(ii) $\|f(x)\| \leqq A + B\|x - x_0\|$ for some constants A, B.

(iii) $E(\|Z(x)\|^2) \leqq A_1 + B_1\|x + x_0\|^2$ for some constants A_1, B_1.

(iv) $x \mapsto f(x)$ is continuous for $x \in S$.

(v) $x \mapsto Z(x, \cdot)$ is continuous as a mapping

$$\mathbb{R}^m \to [L_2(\Omega, A, \nu)]^m.$$

(vi) The Lebesgue measure on $\mathbb{R}^m$ is absolutely continuous with respect to the disribution of $Z(x)$, for all $x \in S$.

Remark on the assumptions. The Assumption A(i) implies that $V(x) := \|x - x_0\|^2$ is a Lyapunov-type function. Likewise any function with similar properties could be used instead. Assumptions A(iv) and A(v) imply the Feller property of the transition probabilities. Indeed, if g is continuous and bounded on S then due to the continuity of the projection operator $E(g(X_2)|X_1 = x) = E(g(\pi_S(x - af(x) - aZ(x, \cdot))))$ is continuous in x. The condition A(vi) ensures the irreducibility of the process (Lemma 2) and is equivalent to: If $A \subseteq S$ has positive Lebesgue measure then $P(x, A) > 0$ for all x. This condition seems to be rather stringent, but in fact can always be easily fulfilled by adding to each random observation Y_n a small noise with nonvanishing density in $\mathbb{R}^m$ (e.g. a normally distributed noise).

LEMMA 1. *Let* $B_\varepsilon := \{x \in S \mid \|x - x_0\| \leqq \varepsilon\}$, *and let* τ_ε *be the first hitting time of* B_ε. *Then for every* $\varepsilon > 0$ *there is an* $a(\varepsilon) >$ *such that for* $0 < a \leqq a(\varepsilon)$

$$P_{X_1}\{\tau_\varepsilon > k\} \leqq \min\left(\varepsilon^{-2}(1 - a\beta_\varepsilon)^{k-1}\|X_1 - x_0\|^2, 1\right) \tag{6}$$

where $\beta_\varepsilon < 2\delta_\varepsilon$.

Proof. We denote by $\mathcal{F}_n$ the σ-algebra generated by $X_1, \cdots, X_n$. It follows from the assumptions that there are constants A_2, B_2 such that $\|f(x)\|^2 + E(\|Z(x)\|^2) \leqq A_2 + B_2\|x - x_0\|^2$. On the set $\{\tau_\varepsilon > n\} \in \mathcal{F}_n$ we have

$$\begin{aligned}
E(\|X_{n+1} - x_0\|^2|\mathcal{F}_n) &= E(\|\pi_S(X_n - af(X_n) - aZ_n) - x_0\|^2|\mathcal{F}_n) \\
&\leqq E(\|X_n - af(X_n) - aZ_n - x_0\|^2|\mathcal{F}_n) \\
&= \|X_n - x_0\|^2 + a^2\|f(X_n)\|^2 + a^2E(\|Z_n\|^2|\mathcal{F}_n) - 2a\langle f(X_n), X_n - x_0\rangle \\
&\leqq \|X_n - x_0\|^2 + a^2A_2 + a^2B_2\|X_n - x_0\|^2 - 2a\delta_\varepsilon\|X_n - x_0\|^2 \\
&\leqq \|X_n - x_0\|^2(1 - a\beta_\varepsilon)
\end{aligned}$$

for $\beta_\varepsilon < 2\delta_\varepsilon$ and sufficiently small a. It follows that $\|X_{n\wedge\tau_\varepsilon} + x_0\|^2(1 - a\beta_\varepsilon)^{-(n\wedge\tau_\varepsilon)}$ is a nonnegative supermartingale. Since for such supermartingales V_n

$$P_{V_1}\{V_n \geqq b\} \leqq \min\left(\frac{V_1}{b}, 1\right)$$

(cf. Neveu [6, Prop. II-2-7]) we conclude that

$$\begin{aligned}
P_{X_1}\{\tau_\varepsilon > k\} &\leqq P_{X_1}\{\|X_{k\wedge\tau_\varepsilon} - x_0\|^2 > \varepsilon^2\} \\
&\leqq P_{X_1}\{\|X_{k\wedge\tau_\varepsilon} - x_0\|^2(1 - \alpha\beta_\varepsilon)^{-(k\wedge\tau_\varepsilon)} \geqq \varepsilon^2(1 - a\beta_\varepsilon)^{-k}\} \\
&\leqq \min\left(\varepsilon^{-2}(1 - a\beta_\varepsilon)^{k-1}\|X_1 - x_0\|^2, 1\right).
\end{aligned}$$

LEMMA 2. *Let λ_S be the restriction of the Lebesgue measure λ to the set S. Then $\{X_n\}$ is λ_S-irreducible and aperiodic.*

Proof. For every fixed $x \in S$ we can decompose the transition probability $P(x, \cdot)$ in the absolute continuous part w.r.t. Lebesgue measure and the orthogonal part. According to the Assumption A(vi) the absolute continuous part has a nonvanishing density. Hence if $\lambda_S(A) > 0$ then $P(x, A) > 0$ whence the irreducibility and the aperiodicity follow.

LEMMA 3. *The process $\{X_n\}$ is recurrent in the sense of Harris and ergodic.*

Proof. By [8, Thms. 3.2.6, 3.2.7] we have to show that the potential kernel

$$G(x, A) = E\left(\sum_{n=1}^{\infty} 1_A(X_n) \,\middle|\, X_1 = x\right)$$

is not a proper kernel. We define an increasing sequence of stopping times by

$$\begin{aligned} \tau_1 &= \inf\{n > 0 | X_n \in B_\varepsilon\}, \\ &\vdots \\ \tau_{m+1} &= \inf\{n > \tau_m | X_n \in B_\varepsilon\}. \end{aligned}$$

We claim that $P(\tau_m < \infty) = 1$ for all m. Assume that there is a first $m \in \mathbb{N}$ such that $P(\tau_m = \infty) > 0$. Because of the strong Markov property and Lemma 1

$$P\{\tau_m - \tau_{m-1} > k\} \leqq E(\min(\varepsilon^{-2}(1 - \alpha\beta_\varepsilon)^{k-1} \| X_{\tau_{m-1}+1} - x_0 \|^2, 1))$$

which contradicts $P\{\tau_m = \infty\} > 0$. Let $g(\cdot) \not\equiv 0$ be a continuous nonnegative function with support in S. Due to the Feller property of the chain

$$h(x) := E(g(X_2) | X_1 = x)$$

is continuous in x. Because of Assumption A(vi) and the continuity of g, $h(x) > 0$. Hence $\inf_{x \in B_\varepsilon} h(x) \geqq \eta > 0$ since B_ε is compact. Therefore

$$E_x(g(X_{\tau_k+1})) \geqq \eta \quad \text{for all } x \in S$$

and

$$E_x\left(\sum_{n=1}^{\infty} g(X_n)\right) \geqq E_x\left(\sum_{k=1}^{\infty} g(X_{\tau_k+1})\right) = \infty.$$

Thus by considering a continuous $g \not\equiv 0$, $0 \leqq g \leqq 1_A$ we see that

$$G(x, A) := E\left(\sum_{n=1}^{\infty} 1_A(X_n) \,\middle|\, X_1 = x\right)$$

equals ∞ for every open set $A \subseteq S$ and this implies that the kernel is not proper.

The Markov chain is therefore recurrent in the sense of Harris. There is a unique (up to multiplicative constant) σ-finite invariant measure μ. It remains to show that μ is finite, which is equivalent to the ergodicity of the process.

Since on $\{\| X_n - x_0 \| \leqq \varepsilon\} \in \mathcal{F}_n$

$$E(\| X_{n+1} - x_0 \|^2 | \mathcal{F}_n) \leqq \| X_n - x_0 \|^2 + a^2(A_2 + B_2\varepsilon^2)$$

there are constants ξ_ε, $\eta_\varepsilon > 0$ such that

$$E(\| X_{n+1} - x_0 \|^2 | \mathcal{F}_n) \leqq \| X_n - x_0 \|^2 + a^2\xi_\varepsilon 1_{B_\varepsilon}(X_n) - a\eta_\varepsilon 1_{\bar{B}_\varepsilon}(X_n). \tag{7}$$

We consider the chain with $X_1 \equiv x_0$. Then (7) implies that $v_n := E(\| X_n - x_0 \|^2)$ is finite for every n. Moreover

$$0 \leqq v_{n+1} \leqq v_n + a^2\xi_\varepsilon P_{n-1}(x_0, B_\varepsilon) - a\eta_\varepsilon P_{n-1}(x_0, \bar{B}_\varepsilon). \tag{8}$$

If the chain were null recurrent, then $P_n(x_0, B_\varepsilon) \to 0$ (see [8, Theorem VI, 2.11]). In this case there exists a n_0 such that for $n \geqq n_0 P_n(x_0, B_\varepsilon) < \eta_\varepsilon / a\xi_\varepsilon + \eta_\varepsilon)$ which leads to a contradiction to (8). Hence the invariant measure μ^a can be chosen as a probability measure, and the Lemma is shown.

Integrating (7) with respect to μ^a we get

$$a\eta_\varepsilon \mu^a(\bar{B}_\varepsilon) \leqq a^2 \xi_\varepsilon \mu^a(B_\varepsilon).$$

Thus, for $a \to 0$ $\mu^a(\bar{B}_\varepsilon) \to 0$. This implies that the invariant measure μ^a of the process (1) satisfies

$$\mu_a \xrightarrow{w} \delta_{x_0} \quad \text{as } a \to 0$$

where δ_{x_0} denotes the Dirac measure at the point x_0. Nontrivial limit laws can be obtained by a proper normalization of the process. We shall consider first the smooth unconstrained case.

2. The smooth unconstrained case. In addition to the Assumptions (A) we impose the following conditions.

Assumptions (B).

(i) There are no constraints, i.e. $S = \mathbb{R}^m$.

(ii) f is differentiable at x_0 with Jacobian matrix A, i.e.

$$f(x) = A \cdot (x - x_0) + R(x - x_0)$$

where $\|R(y)\| = o(\|y\|)$ as $y \to 0$.

(iii) $\delta_\varepsilon \geqq \delta > 0$. (For the definition of δ_ε see Assumption A(i).)

THEOREM 1. (Kushner and Hai Huang). *Let the Assumptions* (A) *and* (B) *be fulfilled. Let* $\tilde{\mu}^a$ *be the distribution of* $a^{-1/2}(X^a - x_0)$ *where* X^a *is distributed according to* μ^a, *the stationary distribution of* (1). *Then*

$$\tilde{\mu}^a \xrightarrow{w} N(0, V) \quad \text{as } a \to 0,$$

a normal distribution with covariance matrix V fulfilling the equation

$$AV + VA' = \Sigma \tag{9}$$

where Σ *is the covariance matrix of* $Z(x_0, \omega)$.

Remark. By the vec-operation which transforms matrices to vectors by putting the columns one below the other the equation (9) can be made explicit for V:

$$\operatorname{vec} V = (I_m \otimes A + A' \otimes I_m)^{-1} \cdot \operatorname{vec} \Sigma$$

where $\otimes$ denotes the Kronecker product and I_m is the $m \times m$ unit matrix. (C.f. Graham [2].) There is still another representation of the solution, namely

$$V = \int_0^\infty \exp(uA) \cdot \Sigma \exp(uA')\, du.$$

This matrix-integral formula was found by Walk [9] in a slightly different context.

Proof of the Theorem. We show first that the measures μ^a are uniformly tight. From the proof of Lemma 1 we know that

$$E(\|X_{n+1} - x_0\|^2) \leqq E(\|X_n - x_0\|^2)(1 + a^2 B_2 - 2a\delta) + a^2 A_2.$$

We set $b_n := E(\|X_n - x_0\|^2)$. From

$$b_{n+1} \leqq b_n(1 + a^2 B_2 - 2a\delta) + a^2 A_2$$

it follows that for $a < \delta B_2^{-1}$

$$\limsup b_n \leqq a^2 A_2 (2a\delta - a^2 B_2)^{-1} \tag{10}$$

which shows that the variance of the stationary distribution is finite and $O(a)$.

Let $U_n := a^{-1/2}(X_n^a - x_0)$ where X_n^a is a stationary sequence of the process (1). We have to show that the distribution of U_n tends to a normal distribution as $a \to 0$. The U_n fulfill the recursion

$$U_{n+1} = U_n - a \cdot A \cdot U_n + \sqrt{a}\, R(\sqrt{a}\, U_n) + \sqrt{a} \cdot Z_n$$

where $Z_n = Z(\sqrt{a}\, U_n + x_0, \omega)$.

Let φ be a three times differentiable function on $\mathbb{R}^m$ with compact support. By an application of Taylor's theorem it may be shown that there is a constant C_1 such that φ satisfies for every u, x, y

$$\begin{aligned} &|\varphi(u+x+y) - \varphi(u) - \nabla\varphi(u)(x+y) - \tfrac{1}{2}(x+y)'\nabla^2\varphi(u)(x+y)| \\ &\quad \leqq C_1(\|x\|^3 + \|y\| \cdot \|x\|^2 + \|y\|^2). \end{aligned}$$

Let K be a sufficiently large constant. We use the above formula for

$$\begin{aligned} u &= U_n, \\ x &= a \cdot A \cdot U_n + \sqrt{a} \cdot R(\sqrt{a}\, U_n) + \sqrt{a} \cdot Z_n 1_{\{\|Z_n\| \leqq K\}}, \\ y &= \sqrt{a}\, Z_n 1_{\{\|Z_n\| > K\}}, \end{aligned}$$

and get by taking the conditional expectation w.r.t. $\mathcal{F}_n = \sigma(X_1, \cdots, X_n) = \sigma(U_1, \cdots, U_n)$:

$$\begin{aligned} E(\varphi(U_{n+1})|\mathcal{F}_n) &= \varphi(U_n) - \nabla\varphi(U_n)(a \cdot A \cdot U_n + \sqrt{a}\, R(\sqrt{a}\, U_n)) \\ &\quad + \tfrac{1}{2}(a \cdot A \cdot U_n + \sqrt{a}\, R(\sqrt{a}\, U_n)'\nabla^2\varphi(U_n)(aAU_n + \sqrt{a}\, R(\sqrt{a}\, U_n)) \\ &\quad + \tfrac{1}{2}a \operatorname{tr}(\nabla^2\varphi(U_n) \cdot \Sigma_K) + O(\|(a \cdot A \cdot U_n + \sqrt{a}\, R(\sqrt{a}\, U_n)\|^3) + O(a^{3/2}) \\ &\quad + O(\|a \cdot A \cdot U_n + \sqrt{a}\, R(\sqrt{a}\, R(a\sqrt{a}\, U_n)\|^2 \sqrt{a} \cdot E(\|Z_n\| \cdot 1_{\{\|Z_n\| > K\}})) \\ &\quad + O(aE(\|Z_n\|^2 \cdot 1_{\{\|Z_n\| > K\}}), \end{aligned} \tag{11}$$

where $\Sigma_K = E(Z_n Z_n' 1_{\{\|Z_n\| \leqq K\}} | \mathcal{F}_n)$. Let $\varepsilon > 0$. By taking a sufficiently small we may achieve that $\|R(\sqrt{a} \cdot u)\| \leqq \varepsilon \cdot \sqrt{a} \cdot \|u\|$ for all u belonging to the (bounded) support of φ. Since U_n is stationary $E(\varphi(U_{n+1})) = E(\varphi(U_n))$ and we get by taking the expectation on both sides of (11)

$$|-E(\nabla\varphi(U_n) \cdot a \cdot A \cdot U_n) + \tfrac{1}{2}aE(\operatorname{tr}(\nabla^2\varphi(U_n) \cdot \Sigma_K))| \leqq \varepsilon \cdot O(a) + O(a^{3/2}).$$

Dividing by a, we get

$$|E(\nabla\varphi(U_n)A \cdot U_n) - \tfrac{1}{2}E(\operatorname{tr}(\nabla^2\varphi(U_n) \cdot \Sigma_K))| \leqq \varepsilon \cdot 0(1) + o(1)$$

as $a \to 0$. Since μ^a tends to δ_{x_0} as $a \to 0$ and K was arbitrary it follows that Σ_K can be made arbitrarily close to $\Sigma := E(Z(x_0, \cdot)Z'(x_0, \cdot))$ by choosing K large and a small. Because of the uniform tightness, $\tilde{\mu}^a$ has cluster points as a tends to zero. Let U be distributed according to such a cluster point $\tilde{\mu}^0$. Then

$$|E(\nabla\varphi(U) \cdot A \cdot U) - \tfrac{1}{2}E(\operatorname{tr}(\nabla^2\varphi(U)\Sigma))| \leqq \varepsilon \cdot O(1)$$

for every ε and for every test function φ. Hence

$$\int [\nabla\varphi(u) \cdot A \cdot u - \tfrac{1}{2}\operatorname{tr}(\nabla^2\varphi(u) \cdot \Sigma)]\, d\tilde{\mu}^0(u) = 0 \tag{12}$$

for every φ. Let $M(A, \Sigma)$ be the set of probability measures satisfying (12) for all test functions φ. We have to show that $M(A, \Sigma)$ contains only the $N(0, V)$-distribution.

First, $N(0, V)$ is a member of $M(A, \Sigma)$ which can be seen by direct calculation. By simple algebra one also can show that $\tilde{\mu}_1 \in M(A, \Sigma_1)$ and $\tilde{\mu}_2 \in M(A, \Sigma_2)$ imply that the convolution $\tilde{\mu}_1 * \tilde{\mu}_2$ is an element of $M(A, \Sigma_1 + \Sigma_2)$. Thus convoluting any element $\tilde{\mu}$ of $M(A, \Sigma)$ with a $N(0, \varepsilon\Sigma)$ distribution we get an element of $M(A, (1+\varepsilon)\Sigma)$ which has an infinitely often differentiable density and is arbitrarily close to $\tilde{\mu}$. Therefore it suffices to show that the only element of $M(A, \Sigma)$ with C^∞-density is the normal $N(0, V)$ distribution.

Let $\tilde{\mu} \in M(A, \Sigma)$ have a C^∞-density $f(u)$. Then (12) can be written as

$$\int [\nabla\varphi(u) \cdot A \cdot u - \tfrac{1}{2} \operatorname{tr} (\nabla^2 \varphi(u)\Sigma)] f(u)\, du = 0.$$

By partial integration on $\mathbb{R}^m$ this is equivalent to

$$\int \varphi(u) [\operatorname{tr} (J_{A \cdot u \cdot f(u)}) + \tfrac{1}{2} \operatorname{tr} (\nabla^2 f(u) \cdot \Sigma)]\, du = 0$$

where $J_{Auf(u)}$ is the Jacobian of $u \mapsto A \cdot u \cdot f(u)$. Hence $f(u)$ must fulfill the differential equation $\operatorname{tr} (J_{Auf(u)}) + \frac{1}{2} \operatorname{tr} (\nabla^2 f(u)\Sigma) \equiv 0$ which has the unique solution

$$f(u) = \text{const} \cdot \exp\left(-\frac{u' V^{-1} u}{2}\right)$$

with $AV + VA' = \Sigma$. Thus $\tilde{\mu}^0$ must be the $N(0, V)$ distribution.

3. The constrained case—degenerate solution. Let C_0 be the tangent cone of S at x_0. It may happen that the cone C_0 contains no proper linear subspace. (Then evidently x_0 lies on the boundary of S.) This situation is investigated in detail in this section. We need some further assumptions.

Assumptions (C).

(i) $$\inf_{x \in S} \frac{\langle x - x_0, f(x) \rangle}{\|x - x_0\| \, \|f(x)\|} \geqq \delta > 0,$$

(ii) $$\|f(x)\| \geqq c > 0 \text{ for } x \in S.$$

Remark that Assumption C(i) implies that C_0 contains no proper linear subspace. Before we state the main result, we shall prove a lemma which is of interest for itself.

LEMMA 4. *Let $P^a(x, A)$, $a \geqq 0$ be a family of Markov kernels. Suppose that*

(i) *$P^a(x, \cdot)$ converges weakly to $P^0(x, \cdot)$ i.e. in bounded Lipschitz metric as $a \to 0$, uniformly on compact sets of x,*

(ii) *$P^0(x, \cdot)$ is Feller, i.e. $x \mapsto P^0(x, \cdot)$ is continuous in the weak topology.*

Then $\mu^a \xrightarrow{w} \mu^0$ implies that $P^a\mu^a \xrightarrow{w} P^0\mu^0$. In particular all limits of sequences of invariant laws for $P^a(\cdot, \cdot)$ are invariant laws for $P^0(\cdot, \cdot)$.

Proof. We have to show that for every bounded continuous function g

$$\int g(y) P^a(x, dy)\, d\mu^a(x) \to \int g(y) P^0(x, dy)\, d\mu^0(x) \tag{13}$$

as $a \to 0$.

Since $P^0(x, \cdot)$ is Feller, $x \mapsto \int g(y) P^0(x, dy)$ is bounded and continuous and hence

$$\int g(y) P^0(x, dy)\, d\mu^a(x) \to \int g(y) P^0(x, dy)\, d\mu^0(x). \tag{14}$$

Due to Assumption (i)

$$\int g(y)P^a(x, dy) \to \int g(y)P^0(x, dy)$$

uniformly on compact sets. If $\mu^a \xrightarrow{w} \mu^0$ then $\{\mu^a, a \geqq 0\}$ is uniformly tight. Hence

$$\int g(y)P^a(x, dy)\, d\mu^a(x) - \int g(y)P^0(x, dy)\, d\mu^a \to 0 \tag{15}$$

by uniformity and tightness. Putting together (14) and (15) we get (13).

THEOREM 2. *Let Assumptions* (A) *and* (C) *be fulfilled. Let* $\tilde{\mu}^a$ *be the distribution of* $a^{-1}(X^a - x_0)$, *where* X^a *is distributed according to* μ^a, *the stationary distribution of* (1). *Then*

$$\tilde{\mu}^a \xrightarrow{w} \tilde{\mu}^0$$

where $\tilde{\mu}^0$ *is the stationary distribution of the process*

$$X_{n+1} = \pi_{C_0}(X_n - f(x_0) - Z(x_0, \cdot)).$$

Thus the limiting law may be found by solving an integral equation.

Proof. Let $W_n^a = a^{-1}(X_n^a - x_0)$, X_n^a being stationary. Let $C_a = \{a^{-1}(x - x_0) | x \in S\}$. Clearly C_a is a closed convex set, $C_a \subseteq C_0$ and $C_a \uparrow C_0$ as $a \to 0$. Moreover $\pi_{C_a}(x) = a^{-1}(\pi_S(ax + x_0) - x_0)$. Hence W_n^a fulfills the relation

$$W_{n+1}^a = \pi_{C_a}(W_n^a - f(x_0 + aW_n^a) - Z(x_0 + aW_n^a, \cdot)). \tag{16}$$

Let $P^a(x, A)$ be the Markov kernel belonging to (16). We have to show that the assumptions of Lemma 4 are fulfilled. By Assumption A(v) $Z(x_0 + au, \cdot)$ converges in L^2 to $Z(x_0, \cdot)$ uniformly for each bounded set of u's. Consequently, by eventually passing to a subsequence, $\pi_{C_a}(u - f(x_0 + au) - Z(x_0 + au, \cdot))$ converges a.e. to $\pi_{C_0}(u - f(x_0) - Z(x_0, \cdot))$ uniformly on bounded sets, which implies the Assumption (i) of Lemma 4. The continuity of $u \mapsto \pi_{C_0}(u - f(x_0) + Z(x_0, \cdot))$ entails the Feller property of $P^0(x, \cdot)$.

The assertion of Theorem 2 is shown if we prove the tightness of the set $\{\mu^a, a \geqq 0\}$. By C(i) and C(ii) using A(i) with $\varepsilon = 1$ we may find constants $\beta < \min(2\delta \cdot c, \delta_1)$, A_3 and B_3 such that

$$\begin{aligned}
E(\|W_{n+1}^a\|^2) &\leqq E(\|W_n^a\|^2) - E(\langle W_n^a, f(x_0 + aW_n^a)\rangle) + E(\|Z(x_0 + aW_n^a, \cdot)\|^2) \\
&\leqq E(\|W_n^a\|^2) - \beta E(\|W_n^a\| \cdot 1_{\{\|W_n^a\| < 1/a\}}) - 2\delta_1 a E(\|W_n^a\|^2 1_{\{\|W_n^a\| \geqq 1/a\}}) \\
&\quad + A_3 + a^2 B_3 E(\|W_n^a\|^2 1_{\{\|W_n^a\| \geqq 1/a\}}) \\
&\leqq E(\|W_n^a\|^2) - \beta E(\|W_n^a\|) - \delta_1 a E(\|W_n^a\|^2 1_{\{\|W_n^a\| \geqq 1/a\}}) \\
&\quad + A_3 + a^2 B_3 E(\|W_n^a\|^2 1_{\{\|W_n^a\| \geqq 1/a\}}).
\end{aligned}$$

If W_n^a is distributed according to the stationary distribution and a is sufficiently small then it follows that

$$E(\|W_n^a\|) \leqq A_3 \beta^{-1}.$$

This implies tightness.

4. The constrained, nondegenerate situation. In this section we assume that the minimal point x_0 lies on the boundary of S and the tangent cone C_0 contains a p-dimensional subspace ($1 \leqq p \leqq m - 1$). Under some suitable assumptions, the limiting law is then, as we shall prove, concentrated on this subspace.

To begin with we consider the following special case. Suppose that the set of constraints S is of the form

$$S = \bar{S} \times \mathbb{R}^p \tag{17}$$

where $\bar{S}$ is a q-dimensional convex set ($p+q=m$) containing no proper subspace. Then the projection π_S is of the special form

$$\pi_S(x) = \begin{cases} \pi_{\bar{S}}(\bar{x}) \\ \bar{\bar{x}} \end{cases}$$

where $\binom{\bar{x}}{\bar{\bar{x}}}$ is the decomposition of the vector x in a q- (resp. p-) dimensional part. Suppose that $\bar{C}_0$ is tangent cone to $\bar{S}$ at $\bar{x}_0$. According to the above partition the recursion may be written in the form

$$\begin{aligned} \bar{X}^a_{n+1} &= \pi_{\bar{S}}(\bar{X}^a_n - a\bar{f}(X^a_n) - a\bar{Z}_n), \\ \bar{\bar{X}}^a_{n+1} &= \bar{\bar{X}}^a_n - a\bar{\bar{f}}(X^a_n) - a\bar{\bar{Z}}_n. \end{aligned} \tag{18}$$

For this system we make the following assumptions, which are a combination of Assumptions (B) and (C).

Assumptions (D).

(i) $\|f(x)\| \leqq c > 0$ for $x \in S$.

(ii)
$$\begin{pmatrix} \bar{x}_0 \\ \bar{\bar{x}} \end{pmatrix} \mapsto \bar{\bar{f}}\begin{pmatrix} \bar{x}_0 \\ \bar{\bar{x}} \end{pmatrix}$$

is differentiable at $\bar{\bar{x}}_0$ with the Jacobian matrix A, i.e.

$$\bar{\bar{f}}\begin{pmatrix} \bar{x}_0 \\ \bar{\bar{x}} \end{pmatrix} = A \cdot (\bar{\bar{x}} - \bar{\bar{x}}_0) + R(\bar{\bar{x}} - \bar{\bar{x}}_0)$$

where $\|R(\bar{\bar{y}})\| = o(\|\bar{\bar{y}}\|)$ as $\bar{\bar{y}} \to 0$.

(iii) $\langle x - x_0, f(x)\rangle \geqq \delta(\|\bar{x} - \bar{x}_0\| + \|\bar{\bar{x}} - \bar{\bar{x}}_0\|^2)$ for a $\delta > 0$.

(iv) f fulfills the Lipschitz condition

$$\left| f\begin{pmatrix} x \\ y \end{pmatrix} - f\begin{pmatrix} x \\ z \end{pmatrix} \right| = o(\|y - z\|^{1/2})$$

uniformly in x, y, z.

THEOREM 3. *Let Assumptions* (A) *and* (D) *be fulfilled. Let* $\tilde{\mu}^a$ *be the distribution of* $a^{-1/2}(X^a - x_0)$ *where* X^a *is distributed according to* μ^a, *the stationary distribution of* (16).

Then

$$\tilde{\mu}^a \xrightarrow{w} N(0, \bar{\bar{V}}) \quad \text{as } a \to 0,$$

a normal distribution (*concentrated on* $\mathbb{R}^p$) *with covariance matrix*

$$V = \begin{pmatrix} 0 & 0 \\ 0 & \bar{\bar{V}} \end{pmatrix}$$

satisfying

$$A\bar{\bar{V}} + \bar{\bar{V}}A' = \bar{\bar{\Sigma}}$$

where $\bar{\bar{\Sigma}}$ *is the covariance matrix of* $\bar{\bar{Z}}(x_0, \cdot)$.

Proof. Let $U^a_n := a^{-1/2}(X^a_n - x_0)$. U^a_n may be partitioned into the two parts $\bar{U}^a_n$ and $\bar{\bar{U}}^a_n$. Exactly as in Theorems 1 and 2 it can be shown using D(iii) that the distribution of $\{a^{-1/2}\bar{U}^a_n, \bar{\bar{U}}^a_n\}$ is uniformly tight. Thus $\bar{U}^a_n$ converges in distribution to zero.

Moreover with high probability $\bar{U}_n^a$ is smaller than $a^{1/2}K$ for a constant K and by D(iv) $a^{-1/2}|f(x_0+\sqrt{a}\,U_n^a)-f(x_0+\sqrt{a}\,\bar{U}_n^a)|\to 0$ in probability. The recursion for $\bar{U}_n^a$ is

$$\bar{U}_{n+1}^a=\bar{U}_n^a+\sqrt{a}\,\bar{f}(x_0+\sqrt{a}\,U_n^a)+\sqrt{a}\,\bar{\bar{Z}}(x_0+\sqrt{a}\,U_n^a).$$

On a set of arbitrary high probability

$$\bar{U}_{n+1}^a=\bar{U}_n^a+\sqrt{a}\,\bar{f}(\bar{x}_0+\sqrt{a}\,\bar{U}_n^a)+o(a)+\sqrt{a}\,\bar{\bar{Z}}(x_0+\sqrt{a}\,\bar{U}_n^a)$$

and the rest of the proof is identical to that of Theorem 2. The more general case of a convex set S with tangent cone C_0 at x_0 containing a p-dimensional subspace can be reduced to the above situation by a nonlinear local parameter transformation. We remark that once the global conditions for convergence are met the asymptotic behavior depends exclusively on local properties.

Instead of giving long and complicated formulas we illustrate this case by two examples.

Example 1. Suppose that S is the m-dimensional unit ball and $x_0=(1,0,\cdots,0)$. We may introduce polar coordinates $(r,\varphi_1,\cdots,\varphi_{m-1})$ in $\mathbb{R}^m$ such that $x_0=(1,0,\cdots,0)$ also in this coordinate system. Then

$$S=\bar{S}\times(\mathbb{R}^{m-1}\cap B)$$

where $\bar{S}=\{x\in\mathbb{R}_1\,|\,|x|\leqq 1\}$ and B is the set of possible values for $\varphi_1,\cdots,\varphi_{m-1}$; i.e. an open set which contains the point zero. Also the gradient function may be written in polar coordinates form $f(r,\varphi_1,\cdots,\varphi_{m-1})$. If this function is differentiable at x_0 and the other conditions are met then there is a limiting normal distribution, which is concentrated on a $(m-1)$-dimensional subspace, which corresponds to the hyperplane tangent to S at x_0.

It is worth noticing that the asymptotic distribution strongly depends on the "curvature" of the set S in a neighborhood of x_0. In particular not only the differentiability of f, but also the differentiability of the transformation into polar coordinates is needed in the above example to establish asymptotic normality. If the convex set S cannot be transformed in a differentiably way into the form (17) then asymptotic normality is not more valid. Let us consider the following example.

Example 2. Suppose that $S=\{\binom{x}{y}\in\mathbb{R}^2\,|\,y\leqq|x|^\alpha\}$, $1<\alpha<2$ and $f\binom{x}{y}\equiv\binom{0}{1}$. Then $x_0=\binom{0}{0}$. The tangent cone is $C_0=\{\binom{x}{y}|y\geqq 0\}$ and contains a 1-dimensional subspace. There is a reparametrization such that S is of the form (17) in the new coordinates (ξ,η) namely

$$\xi=\operatorname{sgn}x(\sqrt{u^*+|u^*|^{2\alpha}}),$$
$$\eta=\operatorname{sgn}(y-|x|^\alpha)\sqrt{(x-u^*)^2+(y-|u^*|^\alpha)^2}$$

where u^* is the solution of $(x-u)^2+(y-|u|^\alpha)^2=\min!$ This solution is unique in a neighborhood of $\binom{0}{0}$ if $x\neq 0$. If $x=0$ set $\xi=0$ and $\eta=y$. S may be expressed in these new coordinates

$$S=\left\{\begin{pmatrix}\xi\\ \eta\end{pmatrix}\in\mathbb{R}^2\,\middle|\,\eta\geqq 0\right\}$$

but the mapping $(x,y)\mapsto(\xi,\eta)$ is not differentiable in both directions in a neighborhood of $\binom{0}{0}$, since $\eta(x)=0(x^{2/(2\alpha-1)})$.

In order to cover also such cases it is necessary to investigate unconstrained systems for which

$$f(x-x_0)=\|x-x_0\|^{\gamma-1}A\cdot(x-x_0)+R(x-x_0)$$

with $\|R(y)\| = o(\|y\|^{\gamma})$, $\gamma \leqq 1$. The smooth case is included by setting $\gamma = 1$. It may be shown that in such cases the suitable normalization in (4) is $g(a) = a^{1/(1+\gamma)}$ and the asymptotic distribution is of the Weibull type. But this is beyond the scope of this paper. A related result for the one-dimensional case was shown by the author in [7].

AN EXACT FORMULA FOR A LINEAR QUADRATIC ADAPTIVE STOCHASTIC OPTIMAL CONTROL LAW*

RAYMOND RISHEL†

Abstract. For a Linear Quadratic Adaptive Stochastic Optimal Control Problem a formula for the optimal control is obtained by applying variational methods to an equivalent problem obtained from the Girsanov transformation. The formula does depend on a quantity defined through a martingale representation of the conditional remaining cost.

Key words. adaptive control, dual control, optimal adaptive stochastic control

AMS(MOS) classifications. 93C40, 93E20

Introduction. Linear quadratic adaptive stochastic problems are important in engineering and have a long history. Some very early papers on adaptive control are [7] where they are called dual control problems to emphasize the dual aspects of learning about the system and controlling it at the same time. Examples of more recent work are [1], [12], [10], [2]. These problems can be considered as partially observed stochastic control problems. However, probably because of the lack of theory they have not generally been approached from this point of view. Instead methods such as those in [1], [12], [10], [2] are used. There have been fundamental recent advances in the theory of partially observed stochastic control, for instance [8], [9], [3], [4]. The purpose of this paper is to apply methods such as these to a linear quadratic adaptive stochastic control problem to investigate their applicability. In particular, although the methods of [4] do not apply exactly, this paper uses methods which follow the spirit of [4] to obtain an explicit formula for the optimal control law for this linear quadratic stochastic adaptive control problem. The methods are also somewhat analogous to those of [6] although again these do not apply directly.

Unfortunately the formula for the optimal control involves a quantity which must be determined from a martingale representation theorem, and thus is not obtained in a constructive manner. However, it is hoped that knowing the explicit form of the optimal control law will lead to new methods for computing it or approximating it.

The linear quadratic adaptive stochastic optimal control problem considered is the minimization of

$$E\left[\int_0^T [x(t)'Mx(t)+u(t)'Nu(t)]\,dt\right] \tag{1}$$

where $x(t)$ is a solution of the controlled stochastic differential equation

$$dx=[A(z)x+B(z)u]\,dt+dW \tag{2}$$

with initial condition

$$x(0)=x_0 \tag{3}$$

in which the matrices $A(z)$ and $B(z)$ depend on a vector z of unknown parameters with given prior probability density $P(z)$.

* Received by the editors May 9, 1984, and in revised form April 11, 1985.

We shall show that necessary conditions that $u(t)$ be an optimal control based only on past measurements of x are that it have the form

$$u(t) = -\frac{N^{-1}}{2} \int B(z)'H(t, z)p(t, z)\, dz \tag{4}$$

where $p(t, z)$ is the conditional probability density of z given the past measurements of x up to time t and where $H(t, z)$ and $\theta(t, z)$ are uniquely determined as solutions of

$$d\theta(t, z) = -[x(t)'Mx(t) + u(t)'Nu(t)]\, dt + H(t, z)'\, dW \tag{5}$$

with terminal condition

$$\theta(T) \equiv 0. \tag{6}$$

An equivalent characterization of $H(t, z)$ is that it is uniquely determined from the representation

$$\begin{aligned} &\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt \\ &\quad = E\left\{\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt | x_0, z\right\} + \int_0^T H(t, z)'\, dW \end{aligned} \tag{7}$$

of the optimal criteria as a stochastic integral with respect to the Weiner process W.

The derivation begins by obtaining the linear quadratic control problem from an equivalent control problem through use of the Girsanov transformation; then variations are taken in the equivalent problem to obtain the optimality conditions.

1. Formulation. Consider formulating the adaptive control problem (1), (2), (3) through a change of probability measure. To do this, proceed as follows. Let $A(y)$ and $B(y)$ denote respectively $n \times n$ and $n \times m$ dimensional matrix valued Borel measurable functions of a q-dimensional vector variable y. Let $(\Omega, \mathcal{F}, P)$ denote a probability space Ω with σ-field of subsets $\mathcal{F}$ and probability measure P on Ω. Let $W(t)$ be an n-dimensional Weiner process defined on $(\Omega, \mathcal{F})$. Let x_0 and z denote n-dimensional and q-dimensional random vectors such that x_0, z, and $W(t)$ are mutually independent. Let z have probability density function $p(z)$. Define $x(t)$ by

$$x(t) = x_0 + W(t). \tag{8}$$

Define the σ-fields F_t and G_t by, F_t is the right continuous regularization of

$$\sigma[x(s);\ 0 \leqq s \leqq t] \tag{9}$$

and G_t is the right continuous regularization of

$$\sigma[z, x(s);\ 0 \leqq s \leqq t]. \tag{10}$$

Define an admissible control $u(t)$ to be an m-dimensional vector valued stochastic process satisfying I and II.

I. $u(t)$ is F_t adapted.

II. $E[\exp(\frac{1}{2}\int_0^T \|A(z)x(t) + B(z)u(t)\|^2\, dt)] < \infty$.

Define $q^u(t, z)$ by

$$\begin{aligned} q^u(t, z) \triangleq \exp\Bigg[&\int_0^t [A(z)x(s) + B(z)u(s)]'\, dW(s) \\ &-\frac{1}{2}\int_0^t \|A(z)x(s) + B(z)u(s)\|^2\, ds\Bigg]. \end{aligned} \tag{11}$$

It follows from II that

$$P\left(\int_0^T \|A(z)x(t)+B(z)u(t)\|^2\,dt<\infty\right)=1$$

and thus $q^u(t, z)$ is well defined.

Assumption II implies, [11, Thm. 6.1], that $q^u(t, z)$ is a G_t martingale and that

$$E[q^u(T, z)]=1. \tag{12}$$

If p^u is the probability measure whose Radon-Nikodym derivative with respect to P is $q^u(T, z)$, that is if

$$P^u=q^u(T, z)P, \tag{13}$$

then (12) asserts P^u is a probability measure. The Girsanov theorem, [11, Thm. 6.3], implies if $W^u(t)$ is defined by

$$W^u(t)=W(t)-\int_0^t [A(z)x(s)+B(z)u(s)]\,ds, \tag{14}$$

that $W^u(t)$ is a (P^u, G_t) Weiner process. Combining (8) and (14) gives

$$x(t)=x_0+\int_0^t [A(z)x(s)+B(z)u(s)]\,ds+W^u(t). \tag{15}$$

Denote taking expectations with respect to P^u by E^u and with respect to P by E. Thus

$$\begin{aligned} &E^u\left\{\int_0^T [x(t)'Mx(t)+u(t)'Nu(t)]\,dt\right\} \\ &\quad=E\left\{q^u(T, z)\int_0^T [x(t)'Mx(t)+u(t)'Nu(t)]\,dt\right\}. \end{aligned} \tag{16}$$

Thus the problem of minimizing the left-hand side of (16) subject to (15) holding over the class of admissible controls satisfying I and II is equivalent to the problem of minimizing the right side of (16), subject to (8) and (11), over the class of admissible controls satisfying I and II. Notice that Assumption I asserts the control $u(t)$ is F_t-measurable for each t, so that $u(t)$ depends only on the past of $x(t)$ and we can consider z as a vector of parameters unknown to the controller.

Define $J(u)$ by

$$J(u)=E\left\{q^u(T, z)\int_0^T [x(t)'Mx(t)+u(t)'Nu(t)]\,dt\right\}. \tag{17}$$

Motivated by these considerations we shall consider the problem of determining the optimal control for the problem of minimizing $J(u)$ subject to (8) and (11) over the class of controls satisfying I and II.

2. Variations. If $u(t)$ is an optimal control and $v(t)$ is a stochastic process which is bounded and F_t is adapted, then it can be shown that $u(t)+\varepsilon v(t)$ satisfies I and II for $-1\leqq\varepsilon\leqq 1$. Thus if

$$\delta J(u, v)\triangleq\frac{d}{dt}J(u+\varepsilon v)\Big|_{\varepsilon=0} \tag{18}$$

exists, then

$$\delta J(u, v)=0 \tag{19}$$

is a necessary condition for optimality.

LEMMA 1. *$\delta J(u, v)$ exists and is given by*

$$\delta J(u, v) = E\left\{ q^u(T, z)\left[\int_0^T (B(z)v(t))'\, dW^u \int_0^T (x(t)'Mx(t)+u(t)'Nu(t))\, dt + \int_0^T 2v(t)'Nu(t)\, dt\right]\right\}. \tag{20}$$

Proof. Since $v(t)$ is bounded it can be shown that

$$\left|q^{u+\varepsilon v}(T, z)\int_0^T [x(t)'Mx(t)+(u(t)+\varepsilon v(t))'N(u(t)+\varepsilon v(t))]\, dt - q^u(T, z)\int_0^T [x(t)'Mx(t)+u(t)'Nu(t)]\, dt\right| \leqq \varepsilon b, \tag{21}$$

where

$$E[b] < \infty. \tag{22}$$

This and Lebesgue's dominated convergence theorem justify computing (18) by differentiating with respect to ε under the expectation sign in

$$J(u+\varepsilon v) = E\left\{ q^{u+\varepsilon v}(T, z)\int_0^T [x(t)'Mx(t)+(u(t)+\varepsilon v(t))'N(u(t)+\varepsilon v(t))]\, dt\right\}. \tag{23}$$

Since

$$q^{u+\varepsilon v}(T, z) = \exp\left[\int_0^T [A(z)x(s)+B(z)(u(s)+\varepsilon v(s))]\, dW - \frac{1}{2}\int_0^T \|A(z)x(s)+B(z)(u(s)+\varepsilon v(s))\|^2\, ds\right], \tag{24}$$

$$\begin{aligned}\frac{d}{d\varepsilon} q^{u+\varepsilon v}(T, z)\Big|_{\varepsilon=0} &= q^u(T, z)\left[\int_0^T [B(z)v(s)]'\, dW - \int_0^T [B(z)v(s)]'[A(z)x(s)+B(z)u(s)]\, ds\right] \\ &= q^u(T, z)\int_0^T [B(z)v(s)]'\, dW^u.\end{aligned} \tag{25}$$

Thus (20) follows by differentiating under the expectation sign in (23) using (25) and the product rule for differentiation.

Remark. Let $\beta[0, T]$ and $\beta(E^q)$ denote the Borel fields on the respective spaces $[0, T]$ and E^q. Since $G_t = \sigma(z) \times F_t$ standard measure theoretic arguments imply for any G_t adapted process $\phi(t)$ there will be a function $\tilde{\phi}(t, y, \omega)$ which is $\beta[0, T] \times B(E^q) \times \mathcal{F}$ measurable and F_t measurable for each (t, y) such that

$$\phi(t)(\omega) = \tilde{\phi}(t, z(\omega), \omega). \tag{26}$$

Motivated by this we shall use the notation $\phi(t, z)$ to denote a G_t adapted process and interpret this to mean that

$$\phi(t, z)(\omega) = \tilde{\phi}(t, z(\omega), \omega). \tag{27}$$

THEOREM 1. *If R is a G_T measurable random variable for which*

$$E^u[R^2] < \infty, \tag{28}$$

there is a unique n-dimensional vector-valued G_t adapted process $\phi(t, z)$ for which

$$E^u\left[\int_0^t \|\phi(t, z)\|^2\, dt\right] < \infty \tag{29}$$

and

$$E^u[R|G_t] = E^u[R|z, x_0] + \int_0^t \phi(s, z)'\, dW^u. \tag{30}$$

Proof. By the representation theorem for square integrable martingales, [11, Thm. 5.4], the square integrable martingale $E^u[R|G_t]$ has the representation

$$E^u[R|G_t] = \int_0^t \phi(s, z)'\, dW^u + \mathcal{M}(t) \tag{31}$$

where $\mathcal{M}(t)$ is a martingale orthogonal to the stochastic integrals and $\phi(t, z)$ is a G_t adapted process for which

$$E^u\left[\int_0^T \|\phi(t, z)\|^2\, dt\right] < \infty. \tag{32}$$

It will follow that

$$\mathcal{M}(t) = \mathcal{M}(0) \tag{33}$$

if it can be shown that

$$E\left[(\mathcal{M}(t) - \mathcal{M}(0)) f(z) g(x_0) \prod_{j=1}^{n} F_j(W_{t_j}^u)\right] = 0 \tag{34}$$

for any bounded Borel measurable functions $f(y)$, $g(x)$, $F_j(x)$ and any t_j, $0 \leqq t_1 \leqq \cdots \leqq t_n \leqq t$. This can be done by repeating the proof of [11, Thm. 5.5] with minor changes. The crucial property needed is that if $t > s$ then the increment $W^u(t) - W^u(s)$ is independent of G_s. The theorem follows from (33) since

$$E^u[R|G_0] = E^u[R|z, x_0] = \mathcal{M}(0). \tag{35}$$

The uniqueness of $\phi(t, z)$ will follow exactly as the uniqueness argument in [11, Thm. 5.7, p. 170].

THEOREM 2. *If*

$$E^u\left[\left(\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt\right)^2\right] < \infty \tag{36}$$

and $H(t, z)$ is the G_t adapted process in the representation

$$\begin{aligned}\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt \\ = E^u\left[\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt | z, x_0\right] + \int_0^T H(t, z)'\, dW^u\end{aligned} \tag{37}$$

for which

$$E\left[\int_0^T \|H(t, z)\|^2\, dt\right] < \infty, \tag{38}$$

then $\delta J(u, v)$ is given by

$$\delta J(u, v) = E\left\{q^u(T, z) \int_0^T v(t)'[B(z)'H(t, z) - 2Nu(t)]\, dt\right\}. \tag{39}$$

Proof. Using (37), rules for expected values of products of stochastic integrals, and the orthogonality of stochastic integrals with respect to W^u and G_0 measurable functions gives

$$E\left\{q^u(T,z)\int_0^T [B(z)v(t)]'\,dW^u \int_0^T (x(t)'Mx(t)+u(t)'Nu(t))\,dt\right\}$$
$$= E\left\{q^u(T,z)\int_0^T v(t)'B(z)'H(t,z)\,dt\right\}. \tag{40}$$

Thus the theorem follows from (20) and (40).

Since we must have $\delta J(u,v)=0$ for every bounded F_t adapted process $v(t)$, a standard argument using (39) implies

$$E\{q^u(T,z)[B(z)'H(t,z)-2Nu(t)]|F_t\}=0 \tag{41}$$

for almost every t. Thus we have from (41) that a necessary condition for $u(t)$ to be an optimal control is that

$$u(t)=-\frac{1}{2}N^{-1}\frac{E[q^u(T,z)B(z)'H(t,z)|F_t]}{E[q^u(T,z)|F_t]} \tag{42}$$

holds for almost every t. Since $q^u(t,z)$ is a G_t martingale using conditioning first with respect to G_t and then with respect to F_t and using the law of iterated conditional expectations gives

$$u(t)=-\frac{1}{2}N^{-1}\frac{E[q^u(t,z)B(z)'H(t,z)|F_t]}{E[q^u(t,z)|F_t]}. \tag{43}$$

Since $G_t=\sigma(z)\times F_t$ and $\sigma(zr$ and F_t are independent σ-fields under P, taking the conditional expectation of a G_t measurable random variable given F_t under the measure P can be expressed by integrating the random variable with respect to the prior probability density $p(z)$ of z. Thus (43) can be rewritten as

$$u(t)=-\frac{1}{2}N^{-1}\frac{\int q^u(t,z)B(z)'H(t,z)p(z)\,dz}{\int q^u(t,z)p(z)\,dz}. \tag{44}$$

Similarly the conditional density of z given F_t under the measure P^u is given by

$$p^u(t,z)\triangleq\frac{q^u(t,z)p(z)}{\int q^u(t,z)p(z)\,dz}. \tag{45}$$

Thus (44) can also be expressed as

$$u(t)=-\frac{1}{2}N^{-1}\int p^u(t,z)B(z)'H(t,z)\,dz$$

where $p^u(t,z)$ is given by (45).

The quantity $H(t,z)$ can also be determined from an adjoint equation. To see this define $\theta(t,z)$ by

$$\theta(t,z)=-\int_0^t [x(s)'Mx(s)+u(s)'Nu(s)]\,ds$$
$$+E\left[\int_0^T [x(s)'Mx(s)+u(s)'Nu(s)]\,ds|x_0,z\right]+\int_0^t H(s,z)'\,dW^u. \tag{46}$$

Then from (37)

$$\theta(T, z) \equiv 0, \tag{47}$$

and (46) implies

$$d\theta(t, z) = -[x(t)'Mx(t) + u(t)'Nu(t)]\, dt + H(t, z)'\, dW^u \tag{48}$$

which are the desired adjoint equation and terminal boundary condition.

Solutions of (48) and (47) for which

$$E\left[\int_0^T \|H(t, z)\|^2\, dt\right] < \infty \tag{49}$$

holds are unique. To see this let $\tilde{\theta}(t, z)$ and $\tilde{H}(t, z)$ satisfy (48), (47) and (49). Then integrating (48) from 0 to T gives

$$\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt = \tilde{\theta}(0, z) + \int_0^T \tilde{H}(t, z)'\, dW^u. \tag{50}$$

Since the increments of W^u are independent of G_0 and (49) holds for $\tilde{H}(t, z)$, the conditional expectation of the stochastic integral given G_0 is zero and (50) implies

$$E\left[\int_0^T x(t)'Mx(t) + u(t)'Nu(t)]\, dt \,\middle|\, z, x_0\right] = \tilde{\theta}(0, z). \tag{51}$$

The uniqueness of the representation (37), (50) and (51) implies

$$\tilde{H}(t, z) = H(t, z). \tag{52}$$

Then $\tilde{\theta}(t, z) = \theta(t, z)$ follows by integrating (48) from 0 to t, using (51) and (52).

Collecting these results into a theorem, we have

THEOREM 3. *If $u(t)$ is an optimal control for the problem of minimizing*

$$E^u\left[\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt\right] \tag{53}$$

subject to $x(t)$ being a solution of

$$dx = [A(z)x + B(z)u]\, dt + dW^u, \qquad x(0) = x_0, \tag{54}$$

and

$$E^u\left[\left(\int_0^T [x(t)'Mx(t) + u(t)'Nu(t)]\, dt\right)^2\right] < \infty \tag{55}$$

is satisfied for the optimal control, then $u(t)$ must have the form

$$u(t) = -\frac{1}{2} N^{-1} \int p^u(t, z) B(z)' H(t, z)\, dz \tag{56}$$

where $\theta(t, z)$ and $H(t, z)$ are solutions of

$$d\theta(t, z) = -[x(t)'Mx(t) + u(t)'Nu(t)]\, dt + H(t, z)'\, dW^u, \qquad \theta(T, z) = 0 \tag{57}$$

where

$$p^u(t, z) = \frac{q^u(t, z)p(z)}{\int q^u(t, z)p(z)\, ds} \tag{58}$$

and

$$q^u(t,z)=\exp\left[\int_0^t [A(z)x(s)+B(z)u(s)]'\,dW^u - \frac{1}{2}\int_0^t \|A(z)x(s)+B(z)u(s)\|^2\,ds\right]. \tag{59}$$

3. Conclusions. Theorem 3 gives a stochastic two-point boundary value problem involving equations (54) and (56)-(59) with (54) and (57) being the primary equations of the two-point boundary value problem. *If* this could be solved to determine $H(t,z)$, then (56) would be an explicit representation of the optimal control.

It is natural to ask, "Is there a Riccati equation through which a solution of (54) and (56)-(59) can be expressed?" The existence of a Riccati equation solution in a corresponding linear quadratic control problem in [5] and the results derived there make this appear hopeful. A number of guesses can be made for the form of the solution; however, whether there is a solution of Riccati form is still an open question.

It is also natural to question whether an algorithm for approximating the optimal control could be based on equations (54) and (56)-(59) of Theorem 3. This is also an open question.

SUFFICIENT OPTIMALITY CONDITIONS FOR STRATIFIED CONTROL PROBLEMS*

STEFAN MIRICĂ†

Abstract. Sufficient optimality conditions of dynamic programming type avoiding the axioms of Boltyanskii's "regular synthesis" for control problems that have weakly stratified Hamiltonians are proved. An improved version of Boltyanskii's "fundamental lemma" is applied to the "value function" defined as the minimum of the cost functional along the solutions of a Hamiltonian inclusion which plays the role of a "system of characteristics" for the Hamilton-Jacobi-Bellman equation of dynamic programming.

Key words. optimal control problems, dynamic programming, sufficient optimality conditions, stratified sets and mappings, Hamiltonian systems

AMS(MOS) subject classification. 49C20

1. Introduction. The aim of this paper is to prove verifiable sufficient optimality conditions of dynamic programming type that avoid the axioms of Boltyanskii's regular synthesis ([1], [5]-[7], [17], [24]) for optimal control problems whose Hamiltonians are stratified functions in a very weak sense. As one may easily verify, a large number of classes of optimal control problems in the literature ([1], [7], [10], etc.) admit a stratified structure (as, for instance, the problems defined by subanalytic sets and mappings, [5], [6], [12], [22], [23]) so the approach based on the theory of stratified sets and mappings is by no means very restrictive.

The proofs of the main results in § 4 rely essentially on the preliminary results in § 2 concerning the behaviour of regular and absolutely continuous mappings with respect to stratified sets and mappings.

In § 3 we consider autonomous optimal control problems of Mayer type that have weakly stratified Hamiltonians and we introduce a generalized Hamiltonian system which is strongly connected with Pontryagin's maximum principle as well as with the theory of Hamiltonian vector fields on symplectic manifolds (e.g. [11]) and plays the role of a "system of characteristics" for the first order partial differential equation of dynamic programming often called the "Hamilton-Jacobi-Bellman equation". Under some additional hypotheses we prove that the solutions of the Hamiltonian inclusion (which we call *characteristics*) are extremals of the optimal control problem, i.e. their projections on the phase space are admissible trajectories satisfying maximum principle.

In § 4 we prove first a stronger version of Boltyanskii's "fundamental lemma" ([1], [5]-[7], [17], etc.); then we prove several theorems giving sufficient optimality conditions in terms of the "value function" defined as the minimum of the cost functional along the characteristics, separately, in the case of regulated (in particular, piecewise continuous) admissible controls and in the case of measurable bounded controls. We note that in the case of regulated admissible controls the Hamiltonian and the value function should be weakly C^1-stratified and continuous and the characteristics should be regular with respect to the stratification of the Hamiltonian while in the case of measurable bounded controls the Hamiltonian and the value function are required to be weakly C^1-stratified and locally Lipschitzian but the characteristics need only be absolutely continuous. The last theorem replaces a certain assumption on the value function with the easier verifiable property that the characteristics may be embedded in a family of "stratified flows".

* Received by the editors May 3, 1984, and in revised form January 24, 1985.
† Faculty of Mathematics, University of Bucharest, Academiei 14, 70109 Bucharest, Romania.

In § 5 we consider the well-known problem of "moon landing" ([7], [10], [16], etc.) in order to illustrate the way the above mentioned results may be used and their possible advantages over the usual approach involving necessary optimality conditions, uniqueness of the extremals and existence of optimal controls ([1], [7], [10], etc.). It is apparent that when applicable, the results in this paper may greatly simplify the arguments proving that the result of the computations (more or less the same in any approach) is indeed the optimal feedback control. Moreover, the intricate process of finding the extremals of the problem by the simultaneous operations of maximizing the Pontryagin function and integrating the adjoint system is replaced in this approach by the more systematized (if not easier) operation of finding the solutions of a differential inclusion which often turns out to be a piecewise smooth differential system (for which, it is conceivable that one may combine theoretical arguments with computer results).

The autonomous optimal control problems of Mayer type were preferred for the sake of simplicity of notations but it is obvious that similar results may be proved for general (nonautonomous) Bolza or Lagrange problems (which can always be written as autonomous Mayer problems, [7], [10]). Moreover, since one looks for optimal trajectories rather than for optimal controls, our approach is particularly suited for control problems defined by differential inclusions ([2], [8]). As far as the sufficient optimality conditions are concerned, the results in this paper may also be extended to optimal control problems in which the control space depends on the phase space variable.

It should be noted that the results in this paper considerably extend and improve the results in [19], at the same time correcting some errors in the statements and the proofs of Lemmas 2.2, 2.3 and 2.5 in [19] (which, however, do not affect the validity of the main results) which should be replaced by Lemmas 2.5 and 2.6 in this paper.

2. The behaviour of regular and absolutely continuous mappings with respect to stratified sets and functions. We shall use the following notations: Z—the set of integers, N—the set of positive integers, R^n—the real n-dimensional Euclidean space, $\langle \cdot, \cdot \rangle$ the scalar product in such a space; we identify a vector $x \in R^n$ with the corresponding linear functional $y \mapsto \langle x, y \rangle$ in $L(R^n, R)$. If X is a set, then $\mathcal{P}(X)$ ($\mathcal{P}_0(X)$) denotes the family of its (respectively, nonempty) subsets; if $X \subset R^n$, then $\mathrm{Cl}(X)$ denotes its closure in the usual topology; I, $[a, b]$, $[a, b) \subset R$ denote intervals of the real line; $[\![a, b]$ denotes one of the intervals $[a, b]$, $(a, b]$.

DEFINITION 2.1. A nonempty subset $X \subset R^n$ is said to be *weakly C^k-stratified* for some $k \in \{1, 2, \cdots \infty, \omega\}$ if it admits a locally finite partition $\mathcal{S}$ (i.e. any compact subset of X intersects only a finite number of members of $\mathcal{S}$) into connected regular submanifolds of R^n called strata.

We recall that X is said to be *C^k-stratified* ([5], [6], [12], [23], etc.) if $\mathcal{S}$ has the following additional property: for any $S_1, S_2 \in \mathcal{S}$ for which $S_1 \neq S_2$, $S_1 \cap \mathrm{Cl}(S_2) \neq \varnothing$ one has: $S_1 \subset \mathrm{Cl}(S_2)$ and $\dim(S_1) < \dim(S_2)$; we note that this property as well as the so called "Whitney property" of a stratification [5] are not needed in the proofs in this paper so we shall use only weakly stratified sets.

A weak stratification $\mathcal{S}$ of X is said to be *compatible* with a family $\mathcal{A} \subset \mathcal{P}(R^n)$ if any $A \in \mathcal{A}$ is either disjoint of any stratum of $\mathcal{S}$ or is a union of strata.

If $S \subset R^n$ is a submanifold of class C^k and $x \in S$, then T_xS denotes the *tangent space of S at x* and it will always be considered as a subspace of $R^n \cong T_xR^n$. We recall (e.g. [15]) that $\bar{x} \in T_xS$ iff there exists a C^k-mapping $c(\cdot) : (-a, a) \to S$, $a > 0$ such that: $c(0) = x$ and $c'(0) = \bar{x}$.

If $\mathcal{S}$ is a weak stratification of X, then one may define at each point $x \in X$ a *tangent space of X that corresponds to the* (weak) *stratification* $\mathcal{S}$ as follows: $T_x X = T_x S$ if $x \in S \in \mathcal{S}$; if the stratification $\mathcal{S}_1$ is compatible with the stratification $\mathcal{S}_2$ of the same subset $X \subset R^n$ and if for $x \in X$, $T_x^i X$ denotes the tangent space with respect to $\mathcal{S}_i$, $i = 1, 2$, then obviously: $T_x^1 X \subset T_x^2 X$.

DEFINITION 2.2. A mapping $f(\cdot): X \subset R^n \to R^m$ is said to be *weakly C^k-stratified* if there exists a weak C^k-stratification $\mathcal{S}_f$ of X such that for any $S \in \mathcal{S}_f$ the restriction $f_S(\cdot) = f(\cdot)|S$ is of class C^k; $f(\cdot)$ is said to be a *weak C^k-stratified submersion* if it has the following additional property; for any $S \in \mathcal{S}_f$ $f(S) \subset R^m$ is a regular submanifold and the restriction $f_S(\cdot): S \to f(S)$ is a submersion of class C^k (i.e. $\operatorname{rank}(Df_S(x)) = \dim(f(S))$ for any $x \in S$); $f(\cdot)$ is said to be stratified by $\mathcal{S}_f$.

We recall that $f(\cdot): X \subset R^n \to Y \subset R^m$ is said to be *C^k-stratified* ([5], [6], [22], etc.) if there exist a C^k-stratification $\mathcal{S}_X$ of X and a C^k-stratification $\mathcal{S}_Y$ of Y such that for any $S \in \mathcal{S}_X$ one has: $f(S) \in \mathcal{S}_Y$ and $f_S(\cdot): S \to f(S)$ is a submersion of class C^k.

We note that while any mapping $f(\cdot): X \subset R^n \to R^m$, of class C^1 on an open subset $X \subset R^n$ is weakly C^1-stratified, there obviously exist C^∞ mappings that are not C^1-stratified in the sense above. In this paper, with the only exception of the first component of the "stratified flow" in Definition 4.5 (which should be a weak C^1-stratified submersion) the functions involved need be only weakly C^1-stratified in the sense of Definition 2.2.

If $f(\cdot): X \subset R^n \to R^m$ is weakly C^1-stratified by the weak C^1-stratification $\mathcal{S}_f$ of X, then we define the *derivative of $f(\cdot)$ with respect to $\mathcal{S}_f$* as follows: $Df(x) = Df_S(x) \in L(T_x S, R^m)$ if $x \in S \in \mathcal{S}_f$. We note that if $\dim(S) = n$ (hence $S \subset R^n$ is open) then for any $x \in S$, $Df(x) \in L(R^n, R^m)$ is the usual (Fréchet) derivative of $f(\cdot)$ at x but if $\dim(S) < n$ then $f(\cdot)$ may be even discontinuous at the points in S; if $\dim(S) = 0$, hence $S = \{x\}$ is a singleton, then we take $T_x S = \{0\}$ and $Df(x) = 0$.

DEFINITION 2.3. An absolutely continuous mapping $x(\cdot): I \subset R \to R^n$ is said to be *regular* if its derivative, $x'(\cdot)$, is regulated ([3], § II.1) i.e. it has one-sided limits at each point in I and therefore it has a countable set of discontinuities, all of the first kind (at such points $x'(\cdot)$ may not even exist).

The mapping $x(\cdot)$ is said to be regular with respect to the weak stratification $\mathcal{S}$ of $X \subset R^n$ if there exists a countable partition $\{I_k; k \in N\}$ of I into subintervals such that for any $k \in N$ there exists $S_k \in \mathcal{S}$ such that $x(I_k) \subset S_k$, the restriction mapp $x_k(\cdot) = x(\cdot)|I_k$ is of class C^1 and its derivative has one-sided limits at the endpoints of the interval I_k.

We denote by $J_{x(\cdot)}$ the set of endpoints of the intervals I_k, $k \in N$, and we call them *switching points* of $x(\cdot)$; if $J_{x(\cdot)}$ is finite then $x(\cdot)$ is said to be *finitely regular* or *piecewise smooth* and its derivative is said to be *piecewise continuous.*

In what follows we shall use the following particular case of [4, Chap. XI, Corollary 4.2] (which is also a generalization of [3, § I.2, Prop. 2]):

LEMMA 2.4. *Let $f(\cdot): [a, b] \subset R \to R$ be continuous and such that there exists a countable subset $J_f \subset [a, b]$ with the following property: for any $t \in [a, b) \setminus J_f$ there exists a sequence $\{t_k\} \subset [a, b]$ such that $t_k \searrow t$* (i.e. $t_k > t$ for any $k \in N$) *and:*

$$\lim_{k \to \infty} \frac{f(t_k) - f(t)}{t_k - t} \geqq 0. \tag{2.1}$$

Then $f(b) \geqq f(a)$.

LEMMA 2.5. *Let $X \subset R^n$ be weakly C^1-stratified by $\mathcal{S}$, let $x(\cdot): [a, b] \subset R \to X$ be absolutely continuous and let $J_{x(\cdot)}$ be the set of points $t \in [a, b]$ at which either $x(\cdot)$ is*

not differentiable or t is isolated to the right in $x^{-1}(S)$ (i.e. there exists $r>0$ such that $(t, t+r)\cap x^{-1}(S)=\emptyset$) if $x(t)\in S\in\mathcal{S}$.

Then $J_{x(\cdot)}$ has zero Lebesgue measure and:

$$x'(t)\in T_{x(t)}X \quad \text{for any } t\in[a, b]\backslash J_{x(\cdot)}. \tag{2.2}$$

Moreover, if $x(\cdot)$ is regular, then $J_{x(\cdot)}\subset[a, b]$ is countable.

Proof. From its definition it follows that the set $J_{x(\cdot)}$ is the union $J_d\cup J_r$ where J_d is the null set of points $t\in[a, b]$ at which $x(\cdot)$ is not differentiable and J_r is the set of points $t\in[a, b]$ that are isolated to the right in $x^{-1}(S)\subset[a, b]$ if $x(t)\in S\in\mathcal{S}$. According to a known result (e.g. Problem $K(d)$ in [14, Chap. I]) the set of points that are isolated to the right in $x^{-1}(S)$ is countable for any $S\in\mathcal{S}$ and, on the other hand, since $\mathcal{S}$ is locally finite, the compact subset $x([a, b])\subset X$ intersects only a finite number of strata. It follows that the set J_r is countable; hence $J_{x(\cdot)}$ is a null set and if $x(\cdot)$ is regular, then $J_{x(\cdot)}=J_d\cup J_r$ is countable as J_d is also countable.

Further on, if $t\in[a, b]\backslash J_{x(\cdot)}$ then $x'(t)=\lim_{s\to t}(x(s)-x(t))/(s-t)$ exists and if $x(t)\in S\in\mathcal{S}$ then (since $t\notin J_r$) there exists a sequence $t_k\searrow t$ such that $x(t_k)\in S$ for any $k\in N$ and therefore $x'(t)=\lim_{k\to\infty}(x(t_k)-x(t))/(t_k-t)\in T_{x(t)}S=T_{x(t)}X$ as one may easily see taking a local coordinate chart with the submanifold property at $x(t)\in S$ (e.g. [15]).

LEMMA 2.6. *Let $f(\cdot): X\subset R^n\to R$ be continuous and weakly C^1-stratified, let $x(\cdot):[a, b]\subset R\to X$ be absolutely continuous and let $J_{x(\cdot)}$ be the set (defined in Lemma 2.5) of points in $[a, b]$ at which (2.2) does not hold.*

(i) *If $x(\cdot)$ is regular and the derivatives of $f(\cdot)$ and $x(\cdot)$ verify:*

$$Df(x(t))\cdot x'(t)\geqq 0 \quad \text{for any } t\in[a, b]\backslash J_{x(\cdot)}, \tag{2.3}$$

then $f(x(b))\geqq f(x(a))$.

(ii) *If $x(\cdot)$ is regular and satisfies:*

$$Df(x(t))\cdot x'(t)=0 \quad \text{for any } t\in[a, b]\backslash J_{x(\cdot)}, \tag{2.4}$$

then $t\mapsto f(x(t))$ is a constant function.

(iii) *If $f(\cdot)$ is, in addition, locally Lipschitzian (i.e. it is Lipschitzian on every compact subset of X) then the statements* (i) *and* (ii) *above hold for any absolutely continuous mapping $x(\cdot)$.*

Proof. Let $h(\cdot):[a, b]\to R$ be defined by: $h(t)=f(x(t))$, $t\in[a, b]$.

To prove (i), we note that if $x(\cdot)$ is regular, $t\in[a, b]\backslash J_{x(\cdot)}$ and $x(t)\in S\in\mathcal{S}_f$ then $x'(t)$ exists and $t\in x^{-1}(S)$ is not isolated to the right; hence there exists a sequence $t_k\searrow t$, $t_k\in x^{-1}(S)$ and therefore, since $f_S(\cdot)$ and $x(\cdot)$ are differentiable at $x(t)$ and, respectively, at t, it follows that

$$\lim_{k\to\infty}\frac{h(t_k)-h(t)}{t_k-t}=\lim_{k\to\infty}\frac{f(x(t_k))-f(x(t))}{t_k-t}=Df(x(t))\cdot x'(t)\geqq 0$$

since the local representative [15] $f_\alpha(\cdot): U\subset R^m\to R$ of $f_S(\cdot)$ at $x(t)\in S$ with respect to a local coordinate chart $(U, \alpha(\cdot))$, being Fréchet differentiable, has the property: $\lim_{u\to v, s\to 0}(f_\alpha(y+su)-f_\alpha(y))/s=Df_\alpha(y)\cdot v$ at any $y\in U$, $v\in R^m$, $m=\dim(S)$.

From (2.3) it follows now that $h(\cdot)=f(\cdot)ox(\cdot)$ satisfies the hypotheses in Lemma 2.4; hence $f(x(b))=h(b)\geqq h(a)=f(x(a))$.

The statement (ii) follows from (i) applied to the functions $f(\cdot)$ and $-f(\cdot)$ on every interval $[a, t]$, $t\in(a, b]$.

To prove (iii), we note that if $f(\cdot)$ is locally Lipschitzian and $x(\cdot)$ is absolutely continuous, then $h(\cdot)=f(\cdot)ox(\cdot)$ is absolutely continuous; hence at any point $t\in$

$[a, b]\backslash J_x(\cdot)$ at which $h(\cdot)$ is differentiable one has: $h'(t) = Df(x(t)) \cdot x'(t)$; since an absolutely continuous mapping is the indefinite integral of its derivative, (2.3) implies that $h(\cdot)$ is nondecreasing and (2.4) implies that $h(\cdot)$ is a constant function.

3. Generalized Hamiltonian systems for stratified optimal control problems. The optimal control problem we are considering is defined by the nonempty subsets: $X \subset R^n$ (*phase space*), $X_F \subset X$ (*target* or *terminal set*), $U \subset R^m$ (*control space*) and by the mappings: $g(\cdot): X_F \to R$ (*terminal payoff*) and $f(\cdot, \cdot): X \times U \to R^n$ (*controlled vector field*).

An optimal control problem is also defined by the set of admissible controls. Since in our approach Lemma 2.6 is essential and, on the other hand, it seems that the statements (i) and (ii) in this Lemma do not hold if $x(\cdot)$ is merely absolutely continuous (instead of being regular) unless $f(\cdot)$ is locally Lipschitzian, we shall consider separately the problem P_r in which the admissible controls are regulated mappings (the same type of results being valid for the problem P_{cp} in which the admissible controls are piecewise continuous) and the problem P_m in which the admissible controls are measurable and bounded.

For every $x_0 \in X\backslash X_F$ the set $\mathcal{U}_r(x_0)$ (respectively $\mathcal{U}_m(x_0)$) of *admissible controls with respect to x_0 for the problem P_r* (respectively, P_m) consists of all regulated (respectively, measurable bounded) mappings $u(\cdot): [0, t_F(u(\cdot))] \to U$ such that the (Carathéodory) solution $x(\cdot; x_0, u(\cdot))$ of the initial value problem:

$$x' = f(x, u(t)), \qquad x(0) = x_0 \tag{3.1}$$

is defined on $[0, t_F(u(\cdot))]$ and satisfies:

$$x_F(u(\cdot)) = x(t_F(\cdot); x_0, u(\cdot)) \in X_F, \tag{3.2}$$

$$x(t; x_0, u(\cdot)) \in X\backslash X_F \quad \text{for any } t \in [0, t_F(u(\cdot))). \tag{3.3}$$

The "terminal payoff," $g(\cdot)$, defines a "performance" $P(u(\cdot))$ for any admissible control $u(\cdot)$ as follows:

$$P(u(\cdot)) = g(x_F(u(\cdot)) \tag{3.4}$$

and an admissible control $\tilde{u}(\cdot) \in \mathcal{U}_r(x_0)$ (respectively, $\tilde{u}(\cdot) \in \mathcal{U}_m(x_0)$) is said to be *optimal with respect to the point $x_0 \in X\backslash X_F$ for the problem P_r* (respectively, P_m) if it satisfies:

$$P(\tilde{u}(\cdot)) \leqq P(u(\cdot)) \quad \text{for any } u(\cdot) \in \mathcal{U}_r(x_0) (u(\cdot) \in \mathcal{U}_m(x_0)). \tag{3.5}$$

An *optimal feedback control* for the problem P_r (respectively, P_m) is a mapping $v(\cdot): X_0 \subset X \to U$ such that for any $x_0 \in X_0\backslash X_F$ the initial value problem:

$$x' = f(x, v(x)), \qquad x(0) = x_0 \tag{3.6}$$

has a solution $\tilde{x}(\cdot; x_0)$ which is an *optimal trajectory* with respect to x_0 for the problem P_r (respectively, P_m) i.e. the mapping $\tilde{u}(t; x_0) = v(\tilde{x}(t; x_0))$ is optimal in $\mathcal{U}_r(x_0)$ (resp. in $\mathcal{U}_m(x_0)$).

If the control $\tilde{u}(\cdot)$ is optimal (in the sense of (3.5)), only among the admissible controls $u(\cdot)$ for which the corresponding trajectories $x(\cdot; x_0, u(\cdot))$ remain on a given subset $X_0 \subset X$ (i.e. $x(t; x_0, u(\cdot)) \in X_0\backslash X_F$ for any $t \in [0, t_F(u(\cdot))]$) we say that $\tilde{u}(\cdot)$ *solves the problem $P_r|X_0$* (respectively, $P_m|X_0$) at $x_0 \in X_0\backslash X_F$.

The so called "Pontryagin function" or "pseudo-Hamiltonian" [8] defined by:

$$\mathcal{H}(x, p, u) = \langle p, f(x, u)\rangle, \qquad p \in R^n\backslash\{0\} = R_0^n, \qquad (x, u) \in X \times U \tag{3.7}$$

as well as the Hamiltonian ("true Hamiltonian", [8]) defined by:

$$H(x,p)=\max\{\mathcal{H}(x,p,u);\ u\in U\},\qquad (x,p)\in A\subset X\times R_0^n \tag{3.8}$$

(where A denotes the set of all points $(x,p)\in X\times R_0^n$ for which $\mathcal{H}(x,p,\cdot)$ has a maximum on U) will play an essential role in what follows. We shall use also the corresponding marginal multifunction defined by:

$$\hat{U}(x,p)=\{u\in U;\ \mathcal{H}(x,p,u)=H(x,p)\},\qquad (x,p)\in A. \tag{3.9}$$

DEFINITION 3.1. The optimal control system $\Sigma=(X, X_F, U, f, g)$ is said to be *weakly stratified* if its data and the Hamiltonian have the following properties:

(i) $X\subset R^n$ is connected and $f(\cdot,\cdot)$ is continuous with respect to both variables and of class C^1 with respect to the first variable (i.e. if X is open, then the derivative $(x,u)\to D_1f(x,u)$ is continuous and if X is not open then $f(\cdot,\cdot)$ has an extension with this property on $X_1\times U$ where $X_1\supset X$ is open).

(ii) The terminal payoff $g(\cdot): X_F\to R$ is continuous and weakly C^1-stratified by a (weak) stratification $\mathcal{S}_g$ of X_F, of dimension $n_F<n$ (i.e. $\dim(S)\leqq n_F$ for any $S\in\mathcal{S}_g$).

(iii) The Hamiltonian, $H(\cdot,\cdot)$, is continuous and weakly C^1-stratified by a (weak) stratification $\mathcal{S}_H=\{A_j, j\in J\}$ of A.

We note that property (i) in Definition 3.1 implies the uniqueness of the solution $x(\cdot;x_0,u(\cdot))$ of (3.1) for any admissible control $u(\cdot)$ and also the fact that $x(\cdot;x_0,u(\cdot))$ is regular if $u(\cdot)$ is regulated. In fact, the uniqueness is implied by the weaker property of $f(\cdot,\cdot)$ being locally Lipschitzian with respect to the first variable but the class C^1 was assumed in view of property (iii). The existence of local solutions of (3.1) is given by Peano's theorem at any interior point $x_0\in X\setminus X_F$ and by Nagumo-type theorems [25], [26] requiring an additional tangency property of the controlled vector field, $f(\cdot,\cdot)$, at the boundary points of the subset $X\subset R^n$.

It should be noted also that the existence of admissible controls need not be assumed in this setting.

DEFINITION 3.2. Let $\Sigma=(X, X_F, U, f, g)$ be a weakly stratified control system and let $H(\cdot,\cdot)$ be its Hamiltonian.

The set-valued mapping $\xi_H(\cdot,\cdot)$ defined by

$$\xi_H(x,p)=\{(f(x,u),-pD_1f(x,u))\in T_{(x,p)}A;\ u\in\hat{U}(x,p)\},\qquad (x,p)\in A \tag{3.10}$$

is said to be the *controlled Hamiltonian orientor field* of $H(\cdot,\cdot)$ and the differential inclusion

$$(x',p')\in\xi_H(x,p) \tag{3.11}$$

is said to be the Hamiltonian inclusion of the control system Σ.

The set-valued mapping $\xi_H^{\#}(\cdot,\cdot)$ defined by:

$$\begin{aligned}\xi_H^{\#}(x,p)=\{&(\bar{x},\bar{p})\in T_{(x,p)}A;\ \langle\bar{x},\bar{q}\rangle-\langle\bar{p},\bar{y}\rangle\\ &=DH(x,p)\cdot(\bar{y},\bar{q})\text{ for any }(\bar{y},\bar{q})\in T_{(x,p)}A\},\qquad (x,p)\in A\end{aligned} \tag{3.12}$$

is said to be the natural Hamiltonian orientor field of $H(\cdot,\cdot)$.

Remark 3.3. We note that in the case a stratum $A_j\in\mathcal{S}_H$ is a *natural symplectic submanifold of* R^{2n} (i.e. the restriction $\Omega|A_j$ of the natural symplectic form Ω on R^{2n} is a symplectic form on A_j) the restriction $\xi_H^{\#}(\cdot,\cdot)|A_j$ coincides with the *Hamiltonian vector field* $(dH_j)^{\#}$ on A_j defined by $H_j(\cdot,\cdot)=H(\cdot,\cdot)|A_j$ [11], [20]. From (3.12) it follows [20] that at any point $(x,p)\in A$ the set $\xi_H^{\#}(x,p)$ is either a singleton (at "symplectic" points) or a linear manifold (at "singular" points) or the empty set (at "transversal" points).

The justification of Definition 3.2 as well as important properties of the solutions of (3.11) will follow from:

PROPOSITION 3.4. *If $\Sigma=(X, X_F, U, f, g)$ is a weakly stratified optimal control system then the derivatives of $H(\cdot,\cdot)$ and $\mathcal{H}_u(\cdot,\cdot)=\mathcal{H}(\cdot,\cdot,u)$, $u\in U$, are related as follows*:

$$DH(x,p)\cdot(\bar{x},\bar{p})=D\mathcal{H}_u(x,p)\cdot(\bar{x},\bar{p})=\langle pD_1f(x,u),\bar{x}\rangle+\langle f(x,u),\bar{p}\rangle \tag{3.13}$$
$$\text{for any } (x,p)\in A,\qquad (\bar{x},\bar{p})\in T_{(x,p)}A,\ u\in\hat{U}(x,p).$$

Proof. Let $(x,p)\in A_j\in\mathcal{S}_H$, $(\bar{x},\bar{p})\in T_{(x,p)}A$, $u\in\hat{U}(x,p)$ and let $c(\cdot):(-a,a)\to A_j$, $a>0$, be of class C^1 such that: $c(0)=(x,p)$, $c'(0)=(\bar{x},\bar{p})$; from the definition of the derivative of a mapping defined on a differentiable manifold (e.g. [15]) it follows: $DH(x,p)\cdot(\bar{x},\bar{p})=\lim_{t\to 0}(H(c(t))-H(c(0))/t$ and similarly for the derivative of $\mathcal{H}_u(\cdot,\cdot)$. The second part of (3.13) follows directly from (3.7). To prove the first part of (3.13), we note that from (3.8) it follows: $H(c(t))\geqq\mathcal{H}_u(c(t))$ for any $t\in(-a,a)$ and $H(c(0))=\mathcal{H}_u(c(0))$ and therefore for $t\searrow 0$ $(t>0)$ we have: $(H(c(t))-H(c(0)))/t\geqq(\mathcal{H}_u(c(t))-\mathcal{H}_u(c(0)))/t\to D\mathcal{H}_u(x,p)\cdot(\bar{x},\bar{p})$ and hence $DH(x,p)\cdot(\bar{x},\bar{p})\geqq D\mathcal{H}_u(x,p),(\bar{x},\bar{p})$; reasoning in the same way for $t\nearrow 0$, we obtain the reversed inequality; hence (3.13).

COROLLARY 3.5. *The multifunctions $\xi_H(\cdot,\cdot)$ and $\xi_H^{\#}(\cdot,\cdot)$ are related by*:

$$\xi_H(x,p)\subset\xi_H^{\#}(x,p)\quad \text{for any } (x,p)\in A. \tag{3.14}$$

Moreover, if the multifunction $\tilde{U}(\cdot,\cdot)$ is defined by:

$$\tilde{U}(x,p)=\{u\in\hat{U}(x,p);\ (f(x,u),-pD_1f(x,u))\in\xi_H(x,p)\},\qquad (x,p)\in A, \tag{3.15}$$

then $\xi_H(\cdot,\cdot)$ is given by:

$$\xi_H(x,p)=\{(f(x,u),-pD_1f(x,u));\ u\in\tilde{U}(x,p)\},\qquad (x,p)\in A \tag{3.16}$$

and the following property holds:

$$DH(x,p)\cdot(\bar{x},\bar{p})=0$$
$$\text{for any } (\bar{x},\bar{p})\in\xi_H(x,p),\qquad (x,p)\in A^0=\{(x,p)\in A;\ \tilde{U}(x,p)\neq\varnothing\}. \tag{3.17}$$

Proof. If $(\bar{x},\bar{p})\in\xi_H(x,p)$ and $(\bar{y},\bar{q})\in T_{(x,p)}A$ then from (3.10) it follows that there exists $u\in\hat{U}(x,p)$ such that $(\bar{x},\bar{p})=(f(x,u),-pD_1f(x,u))$; hence from (3.13) it follows: $\langle\bar{x},\bar{q}\rangle-\langle\bar{p},\bar{q}\rangle=\langle f(x,u),\bar{q}\rangle+\langle pD_1f(x,u),\bar{y}\rangle=D\mathcal{H}_u(x,p)\cdot(\bar{y},\bar{q})=DH(x,p)\cdot(\bar{y},\bar{q})$ i.e. $(x,p)\in\xi_H^{\#}(x,p)$ and (3.14) is proved.

If $u\in\tilde{U}(x,p)\subset\hat{U}(x,p)$, then from (3.15) and (3.12) it follows that $(\bar{x},\bar{p})=(f(x,u),-pD_1f(x,p))\in T_{(x,p)}A$; hence $(\bar{x},\bar{p})\in\xi_H(x,p)$ and (3.16) is proved.

Finally, if $(x,p)\in A^0$ (hence $\xi_H(x,p)\neq\varnothing$) and $(\bar{x},\bar{p})\in\xi_H(x,p)$, then from (3.14) it follows that $(\bar{x},\bar{p})\in\xi_H^{\#}(x,p)$ and from (3.12) it follows that $DH(x,p)\cdot(\bar{y},\bar{q})=\langle\bar{x},\bar{q}\rangle-\langle\bar{p},\bar{y}\rangle$ for any $(\bar{y},\bar{q})\in T_{(x,p)}A$; hence for $(\bar{y},\bar{q})=(\bar{x},\bar{p})$ we get (3.17).

The following sets of "terminal values" for the solutions of the Hamiltonian inclusion (3.11) are introduced in accordance with the *transversality conditions* in Pontryagin's maximum principle:

$$X^*_{F,n}=\{(x,p)\in A\cap(X_F\times R^n);\ H(x,p)=0,\langle p,\bar{x}\rangle=-Dg(x)\cdot\bar{x}(\forall)\bar{x}\in T_xX_F\}, \tag{3.18}$$

$$X^*_{F,a}=\{(x,p)\in A\cap(X_F\times R^n);\ H(x,p)=0,\langle p,\bar{x}\rangle=0(\forall)\bar{x}\in T_xX_F\}, \tag{3.19}$$

$$X^*_F=X^*_{F,n}\cup X^*_{F,a}. \tag{3.20}$$

The set $X^*_{F,n}$ corresponds to the "normal extremals" (in the sense of mathematical programming, [10]) of the optimal control system and the set $X^*_{F,a}$ corresponds to the "abnormal" ones. If $X^*_F=X^*_{F,n}$, then the optimal control system Σ is said to be *normal.*

DEFINITION 3.6. A mapping $x^*(\cdot)=(x(\cdot), p(\cdot)):[\![\tau, 0]\!]\to A$ which is regular with respect to the stratification $\mathcal{S}_H$ of A, satisfies:

$$x^*(0)=(x(0), p(0))\in X_F^*, \tag{3.21}$$

$$x(t)\in X\setminus X_F \quad \text{for any } t\in[\![\tau, 0) \tag{3.22}$$

and satisfies (3.11) everywhere except at its switching points is said to be a *regular characteristic* of the system Σ.

An absolutely continuous mapping $x^*(\cdot)=(x(\cdot), p(\cdot))$ satisfying (3.21) and (3.22) and satisfying (3.11) almost everywhere is said to be a *characteristic* of Σ.

We denote by $\mathcal{C}_r$ the set of all regular characteristics and by $\mathcal{C}_m$ the set of all characteristics of Σ. We denote also by $\mathcal{C}_r^n$ (respectively, $\mathcal{C}_m^n$) the set of regular characteristics that instead of (3.21) satisfy:

$$x^*(0)=(x(0), p(0))\in X_{F,n}^*, \tag{3.23}$$

and we call them *normal characteristics.*

PROPOSITION 3.7. *If $\Sigma=(X, X_F, U, f, g)$ is a weakly stratified optimal control system, then any regular characteristic $x^*(\cdot)=(x(\cdot), p(\cdot))\in\mathcal{C}_r$ satisfies*:

$$H(x(t), p(t))=0 \quad \textit{for any } t\in[\![\tau, 0], \tag{3.24}$$

$$\langle p(t), x'(t)\rangle=0 \quad \textit{for any } t\in[\![\tau, 0]\!]\setminus J_{x^*(\cdot)} \tag{3.25}$$

where $J_{x^*(\cdot)}$ denotes the set of the switching points of $x^*(\cdot)$.

If, in addition, $H(\cdot,\cdot)$ is locally Lipschitzian, then every characteristic $x^*(\cdot)\in\mathcal{C}_m$ satisfies (3.24) *and* (3.25) *where $J_{x^*(\cdot)}$ is the null set in Lemma* 2.5 *at which the relation*:

$$(x'(t), p'(t))\in T_{(x(t),p(t))}A \tag{3.26}$$

does not hold.

Proof. In both cases, (3.24) is an immediate consequence of (3.11), (3.17) and Lemma 2.6.

To prove (3.25), we note that from (3.10), (3.11) and (3.15) it follows that for any $t\in[\![\tau, 0]\!]\setminus J_{x^*(\cdot)}$ there exists $u(t)\in\tilde{U}(x(t), p(t))$ such that:

$$(x'(t), p'(t))=(f(x(t), u(t)), -p(t)D_1f(x(t), u(t))); \tag{3.27}$$

hence from (3.7), (3.8) and (3.24) it follows: $\langle p(t), x'(t)\rangle=\langle p(t), f(x(t), u(t))\rangle=\mathcal{H}(x(t), p(t), u(t))=H(x(t), p(t))=0$.

Remark 3.8. As it is apparent from the general idea of the approach in this paper, the projection, $x(\cdot)$, on the phase space of a characteristic, $x^*(\cdot)=(x(\cdot), p(\cdot))$, should be an admissible trajectory and we may, of course, introduce this requirement in the Definition 3.6 of the characteristics. In this case a regular characteristic need not be "regular with respect to the stratification $\mathcal{S}_H$" as it was asked in Definition 3.6. We prefer, however, to give some sufficient conditions implying that the projections on the phase space of the characteristics in Definition 3.6 are admissible trajectories.

We consider first the mapping $\xi(\cdot,\cdot,\cdot):X\times R^n\times U\to R^n$ defined by:

$$\xi(x, p, u)=(f(x, u), -pD_1f(x, u)), \qquad (x, p, u)\in X\times R^n\times U \tag{3.28}$$

and for any stratum $A_j\in\mathcal{S}_H$ for which $A_j\cap A^0\neq\varnothing$ (recall that $(x, p)\in A^0$ iff $\xi_H(x, p)\neq\varnothing$) we define:

$$V_j(x, p, v)=\begin{cases}\{u\in\tilde{U}(x, p);\ \xi(x, p, u)=v\} & \text{if } (x, p)\in A_j\cap A^0,\quad v\in R^{2n}\\ \limsup V_j(y, q, w) & \text{if } (x, p)\in A\cap Cl(A_j\cap A^0)\setminus(A_j\cap A^0)\\ (y, q, w)\to(x, p, v),\ (y, q, w)\in(A_j\cap A^0)\times R^{2n}\end{cases} \tag{3.29}$$

where $\limsup_{z\to z_0} V(z)=\{u;\ (\exists)z_k\to z_0,\ u_k\in V(z_k) \text{ such that } u_k\to u\}$.

DEFINITION 3.9. The optimal control system $\Sigma = (X, X_F, U, f, g)$ is said to be *regular* if it is weakly stratified and for any stratum $A_j \in \mathcal{S}_H$ for which $A_j \cap A^0 \neq \emptyset$, the set-valued mapping $V_j(\cdot,\cdot,\cdot)$ defined by (3.29) is compact-valued and is Lipschitzian with respect to the Hausdorff distance on any compact subset of its effective domain $\{(x, p, v);\ V_j(x, p, v) \neq \emptyset\}$.

The system Σ is said to be *Lipschitzian* if it is weakly stratified, the Hamiltonian $H(\cdot,\cdot)$ is locally Lipschitzian and the multifunction $\tilde{U}(\cdot,\cdot)$ defined by (3.15) is compact-valued and has closed graph.

We prove now that if Σ is either regular or Lipschitzian, then the projection on the phase space of any characteristic is an admissible trajectory:

PROPOSITION 3.10. *If Σ is a regular optimal control system, then for any regular characteristic $x^*(\cdot) = (x(\cdot), p(\cdot)) : [\tau, 0] \to A$ the projection, $\tilde{x}(\cdot)$, on the phase space, defined by*:

$$\tilde{x}(t) = x(t+\tau), \qquad t \in [0, -\tau] \tag{3.30}$$

is an admissible trajectory with respect to $x(\tau) \in X$ for the problem P_r.

If Σ is Lipschitzian, then the projection $\tilde{x}(\cdot)$ of any characteristic $x^*(\cdot) \in \mathcal{C}_m$ is an admissible trajectory with respect to $x(\tau) \in X$ for the problem P_m.

Proof. Let Σ be regular, $x^*(\cdot) = (x(\cdot), p(\cdot)) \in \mathcal{C}_r$ and let $\{I_k;\ k \in N\}$ be a partition of $[\tau, 0]$ into subintervals such that for any $k \in N$ there exists $A_k \in \mathcal{S}_H$ such that $x^*(I_k) \subset A_k$, the restriction $x_k^*(\cdot) = x^*(\cdot)|I_k$ is of class C^1 and its derivative has one-sided limits at the endpoints of I_k (Definition 2.3). From Definition 3.9 it follows that for any $k \in N$ the set-valued mapping $t \to V_k(x(t), p(t), (x'(t), p'(t)))$ is compact-valued and Lipschitzian on the compact interval $Cl(I_k)$; hence according to [13, Thm. 2] it has a continuous selection $u_k(\cdot)$; from (3.28) and (3.29) it follows that $u(\cdot) : [\tau, 0] \to U$ defined by: $u(t) = u_k(t)$ if $t \in I_k$, $k \in N$ and the first component, $x(\cdot)$, of $x^*(\cdot)$, verify (3.27) at any point $t \in [\tau, 0] \setminus J_{x(\cdot)}$; hence from (3.21) and (3.22) it follows that $\tilde{u}(\cdot)$ defined by: $\tilde{u}(t) = u(t+\tau)$ for $t \in [0, -\tau]$ is a regulated admissible control whose admissible trajectory is $\tilde{x}(\cdot)$ defined by (3.30).

If Σ is Lipschitzian and $x^*(\cdot) = (x(\cdot), p(\cdot)) \in \mathcal{C}_m$, then from the implicit function theorem for orientor fields (e.g. [7, § 8.2]) it follows that the multifunction $t \mapsto \tilde{U}(x(t), p(t))$ has a measurable selection $u(\cdot)$ satisfying (3.27) a.e.; hence $\tilde{u}(t) = u(t+\tau)$, and $t \in [0, -\tau]$ is a measurable bounded admissible control for the problem P_m whose trajectory is $\tilde{x}(\cdot)$ defined by (3.30).

Remark 3.11. The rather complicated property of a regular control system in Definition 3.9 was assumed in the absence of suitable theorems concerning the existence of continuous selections $u_k(t) \in \tilde{U}(x(t), p(t))$, $t \in I_k$ satisfying (3.27) (i.e. Filippov's lemmas for continuous implicit functions). This property may obviously be replaced by more restrictive but easier verifiable conditions like the following one: *for any $(x, p) \in A^0$* (for which $\xi_H(x, p) \neq \emptyset$) *$\xi_H(x, p)$ is a singleton and for stratum $A_j \in \mathcal{S}_H$ for which $A_j \cap A^0 \neq \emptyset$, the restriction $\tilde{U}(\cdot,\cdot)|(A_j \cap A^0)$ admits an extension to $Cl(A_j \cap A^0)$ that is either single-valued and continuous or compact-valued and locally Lipschitzian.*

4. Sufficient optimality conditions. As an easy corollary of Lemma 2.6 in § 2 we obtain the following improved version of Boltyanskii's "fundamental lemma" ([1, Chap. III, § 11], [5], etc.):

LEMMA 4.1. *Let $\Sigma = (X, X_F, U, f, g)$ be an optimal control system with properties* (i) *and* (ii) *in Definition* 3.1 *and let $W(\cdot) : X \to R$ be continuous and weakly C^1-stratified*

such that:

(4.1) $$W(x) = g(x) \quad \textit{for any } x \in X_F,$$

(4.2) $$DW(x) \cdot f(x, u) \geqq 0 \quad \textit{for any } x \in X \quad \textit{and any } u \in U \textit{ for which } f(x, u) \in T_x X.$$

Then for any $x_0 \in X \setminus X_F$ *and any admissible control* $u(\cdot) \in \mathcal{U}_r(x_0)$ *one has*:

(4.3) $$W(x_0) \leqq P(u(\cdot))$$

and therefore any admissible control $\tilde{u}(\cdot) \in \mathcal{U}_r(x_0)$ *for which*:

(4.4) $$W(x_0) = P(\tilde{u}(\cdot))$$

is optimal with respect to x_0 *for the problem* P_r.

If, in addition, $W(\cdot)|(X \setminus X_F)$ *is locally Lipschitzian, then the statements above hold for any measurable bounded admissible control.*

Proof. If $u(\cdot) \in \mathcal{U}_r(x_0)$ and $x(\cdot) = x(\cdot; x_0, u(\cdot))$ is the corresponding admissible trajectory then $x(\cdot)$ is regular and according to Lemma 2.5 there exists a countable subset $J_{x(\cdot)} \subset [0, t_F(u(\cdot))]$ such that $x'(t) = f(x(t), u(t)) \in T_{x(t)}X$ for any $t \in [0, t_F(u(\cdot))] \setminus J_{x(\cdot)}$ and therefore, since (4.2) implies: $DW(x(t)) \cdot x'(t) \geqq 0$, (4.3) follows from (4.1) and Lemma 2.6.

If $W(\cdot)|(X \setminus X_F)$ is locally Lipschitzian, $x_0 \in X \setminus X_F$ and $u(\cdot) \in \mathcal{U}_m(x_0)$ then from Lemma 2.5 it follows that there exists a null set $J_{x(\cdot)} \subset [0, t_F(u(\cdot))]$ such that $x'(t) = f(x(t), u(t)) \in T_{x(t)}X$ for any $t \in [0, t_F(u(\cdot))] \setminus J_{x(\cdot)}$ and (4.2) implies: $DW(x(t)) \cdot x'(t) \geqq 0$ for any $t \in [0, t_F(u(\cdot))] \setminus J_{x(\cdot)}$; since for any $t_1 \in (0, t_F(u(\cdot)))$, $x([0, t_1]) \subset X \setminus X_F$, the function $t \mapsto W(x(t))$ is absolutely continuous on $[0, t_1]$ and (4.3) follows in the same way as in the proof of the second part of Lemma 2.6.

Remark 4.2. We note that in Boltyanskii's fundamental lemma [1] and its other versions ([5], [6], etc.) the phase space $X \subset R^n$ is open, the terminal set X_F is a singleton, condition (4.2) is verified on $X \setminus M$ where $M \subset R^n$ is a "piecewise smooth" set of dimension less than n [1] or a Whitney-stratified set [5], [6] and the admissible controls are allowed to be only piecewise continuous (and the proof is very hard!). Apparently [Lemma 4.1, Condition 4.2] is more restrictive than the corresponding one in Boltyanskii's lemma since it must be verified also on lower dimensional strata of X but, on the other hand, Boltyanskii's lemma is used only in connection with the very complicated object called "regular synthesis" ([1], [5]–[7], [17], [24], etc.) for which, as it is shown in [17], condition (4.2) is necessarily verified on all the "cells" of the synthesis.

In what follows we use Lemma 4.1 in connection with the characteristics of the optimal control problem, hence before their projections on the phase space are "synthesized" into a precisely described global picture called "regular synthesis".

It should be noted, however, that the approach in this paper based on Lemmas 2.4–2.6 and 4.1 leaves out important classes of optimal control problems that have discontinuous value functions [9], [22].

We consider first the problem P_r for the optimal control system $\Sigma = (X, X_F, U, f, g)$ which is assumed to be regular (Definition 3.9) and we introduce the following notations: for any $\eta = (x_F, p_F) \in X_F^*$ we denote by $\mathcal{C}_r(\eta)$ the *set of all noncontinuable to the left regular characteristics* $x_k^*(\cdot; \eta) = (x_k(\cdot; \eta), p_k(\cdot; \eta)) : [\![\tau_k(\eta), 0] \to A$, $k \in \mathcal{H}_r(\eta)$, satisfying:

(4.5) $$x_k^*(0; \cdot) = \eta \in X_F^*,$$

(4.6) $$x_k(t) \in X \setminus X_F \quad \text{for any } t \in [\![\tau_k(\eta), 0).$$

As it is apparent from the definition of $\mathscr{C}_r(\eta)$ we allow the Hamiltonian system (3.11) to have more than one regular solution through the same points $(0, \eta)$ though this is not the case for significant classes of optimal control problems in the literature.

We define also the following sets and functions:

$$\chi_F(\eta) = y_F(t, \eta) = x_F, \quad \eta_F(t, \eta) = \eta \quad \text{if } \eta = (x_F, p_F) \in X_F^*, \quad t \in R, \tag{4.7}$$

$$Y_r^k(\eta) = [\![\tau_k(\eta), 0]\!] \times \{\eta\}, \qquad Y_r = \cup\{Y_r^k(\eta);\ \eta \in X_F^*,\ k \in \mathscr{K}_r(\eta)\} \tag{4.8}$$

$$X_r = \{x_k(t; \eta);\ (t, \eta) \in Y_r,\ k \in \mathscr{K}_r(\eta)\}, \tag{4.9}$$

$$W_r(x) = \min\{g(\chi_F(\eta));\ (t, \eta) \in Y_r,\ k \in \mathscr{K}_r(\eta),\ x_k(t; \eta) = x\}, \qquad x \in \tilde{X}_r \tag{4.10}$$

and we assume that the set $\tilde{X}_r \subset X_r$ on which $W_r(\cdot)$ is defined verifies:

$$\tilde{X}_r \setminus X_F \neq \varnothing. \tag{4.11}$$

The corresponding marginal multifunctions of (4.10) are given by:

$$\tilde{Y}_r(x) = \{(t, \eta) \in Y_r;\ g(\chi_F(\eta)) = W_r(x),\ x_k(t; \eta) = x,\ k \in \mathscr{K}_r(\eta)\}, \qquad x \in \tilde{X}_r, \tag{4.12}$$

$$\tilde{K}_r(x) = \{k \in \mathscr{K}_r(\eta);\ (t, \eta) \in \tilde{Y}_r(x),\ x_k(t; \eta) = x\}, \qquad x \in \tilde{X}_r, \tag{4.13}$$

THEOREM 4.3. *Let $\Sigma = (X, X_F, U, f, g)$ be a regular optimal control system and let $W_r(\cdot): \tilde{X}_r \to R$ defined by* (4.10) *be continuous and weakly C^1-stratified and such that for any $x_0 \in \tilde{X}_r \setminus X_F$ there exist $(t_0, \eta) \in \tilde{Y}_r(x_0)$, $k \in \tilde{K}_r(x_0)$ that verify*:

$$DW_r(x_0) \cdot \bar{x} = -\langle p_k(t_0; \eta), \bar{x}\rangle \quad \text{for any } \bar{x} \in T_{x_0}\tilde{X}_r. \tag{4.14}$$

Then for any such elements, the mapping $\tilde{x}(\cdot; x_0)$ defined by:

$$\tilde{x}(t; x_0) = x_k(t + t_0; \eta) \quad \text{for any } t \in [0, -t_0] \tag{4.15}$$

is an optimal trajectory with respect to x_0 for the problem $P_r|\tilde{X}_r$.

If, in addition $H(\cdot, \cdot)$ and $W_r(\cdot)|(\tilde{X}_r \setminus X_F)$ are locally Lipschitzian, then $\tilde{x}(\cdot; x_0)$ is optimal also for the problem $P_m|\tilde{X}_r$.

Proof. From Proposition 3.10 it follows that $\tilde{x}(\cdot; x_0)$ defined by (4.15) is a regular admissible trajectory realized by a (regulated) admissible control whose performance is given by: $P(\tilde{u}(\cdot)) = g(\chi_F(\eta)) = W_r(x_0)$. From (4.6) it follows that $W_r(\cdot)$ verifies (4.1) and from (4.14) it follows that $W_r(\cdot)$ verifies (4.2) since if $\bar{x} = f(x_0, u) \in T_{x_0}\tilde{X}_r$ then $\langle p_k(t_0; \eta), f(x_0, u)\rangle = \mathscr{H}(x_k(t_0; \eta), p_k(t_0; \eta), u) \leqq H(x_k(t_0; \eta), p_k(t_0; \eta)) = 0$ (Proposition 3.7) and therefore Theorem 4.3 follows from Lemma 4.1.

To state an analogous theorem for the problem P_m in which the admissible controls are measurable and bounded, we define $\mathscr{C}_m(\cdot)$, $\mathscr{K}_m(\cdot)$, Y_m, X_m, $\tilde{X}_m$, $W_m(\cdot)$, $\tilde{Y}_m(\cdot)$, $\tilde{K}_m(\cdot)$ as in (4.5)–(4.13) replacing the term "regular characteristics" by the term "characteristics". The proof of the next theorem is entirely similar to the proof of Theorem 4.3 so we omit it.

THEOREM 4.4. *Let $\Sigma = (X, X_F, U, f, g)$ be a Lipschitzian optimal control system (Definition* 3.9) *and let $W_m(\cdot): \tilde{X}_m \to R$ defined by* (4.10) *be continuous, weakly C^1-stratified and such that its restriction to $\tilde{X}_m \setminus X_F$ is locally Lipschitzian. If for any $x_0 \in \tilde{X}_m \setminus X_F$ there exist $(t_0, \eta) \in \tilde{Y}_m(x_0)$ and $k \in \tilde{K}_m(x_0)$ such that* (4.14) *holds, then $\tilde{x}(\cdot; x_0)$ defined by* (4.15) *is an optimal trajectory with respect to x_0 for the problem $P_m|\tilde{X}_m$.*

If, in addition, $\tilde{x}(\cdot; x_0)$ is realized by a regulated admissible control, then it is optimal also for the problem $P_r|\tilde{X}_m$.

Remark 4.5. If for any $x \in \tilde{X}_r$ we define: $V_r(x) = \cup\{\tilde{U}(x_k^*(t; \eta));\ (t, \eta) \in \tilde{Y}_r(x),\ k \in \tilde{K}_r(x)\}$, then obviously any mapping $v(\cdot): \tilde{X}_r \to U$ satisfying: $v(x) \in V_r(x)$ for any

$x \in \tilde{X}_r$ is an optimal feedback control for the problem $P_r|\tilde{X}_r$; a similar statement holds for the problem $P_m|\tilde{X}_m$.

We note that condition (4.14) together with the inequality: $DW_r(x(t)) \cdot f(x(t), u(t)) \geqq 0$ along any admissible pair $(u(\cdot), x(\cdot))$ of the problem $P_r|\tilde{X}_r$ obtained in the proof of Theorem 4.3 may be interpreted as a generalization of the well-known Hamilton-Jacobi-Bellman equation of dynamic programming:

$$\min \{DW_r(x) \cdot f(x, u); u \in U, f(x, u) \in T_x\tilde{X}_r\} = 0 \quad \text{for any } x \in \tilde{X}_r$$

for which the Hamiltonian inclusion (3.11) plays the role of a "system of characteristics".

We note also that Theorems 4.3 and 4.4 remain valid if in (4.5)-(4.13) one takes any family (not necessarily all) of (regular) characteristics but in this case the sets $\tilde{X}_r$ and $\tilde{X}_m$ may be too small and the optimal solutions of the problems $P_r|\tilde{X}_r$, $P_m|\tilde{X}_m$ may not be optimal solutions for the original problems, P_r and, respectively, P_m, since there may exist admissible trajectories that do not remain in $\tilde{X}_r$ ($\tilde{X}_m$).

One of the main difficulties in applying Theorems 4.3 and 4.4 to concrete problems is the verification of condition (4.14). The results to follow show that we can avoid condition (4.14) if we restrict ourselves to "normal" problems and assume that the characteristics may be embedded in a "stratified Hamiltonian flow" defined as follows:

DEFINITION 4.6. A continuous mapping $x^*(\cdot, \cdot) = (x(\cdot, \cdot), p(\cdot, \cdot)): Y \subset (-\infty, 0] \times X^*_{F,n} \to A$ is said to be a *stratified Hamiltonian flow* of (3.11) if it has the following properties:

(i) There exist the upper semicontinuous functions $\tau(\cdot)$, $\tau_i(\cdot): X^*_{F,n} \to [-\infty, 0]$, $i \in Z$, that are weakly C^1-stratified by a stratification $\mathcal{S}^*_F$ of $X^*_{F,n}$ and satisfy:

$$\tau(\eta) \leqq \cdots \leqq \tau_{i-1}(\eta) \leqq \tau_i(\eta) \leqq \cdots \leqq 0 \quad \text{for any } \eta \in X^*_{F,n}, \tag{4.16}$$

$$\lim_{i \to +\infty} \tau_i(\eta) = 0, \quad \lim_{i \to -\infty} \tau_i(\eta) = \tau(\eta) \quad \text{for any } \eta \in X^*_{F,n}, \tag{4.17}$$

$$Y = \{(t, \eta); \eta \in X^*_{F,n}, t \in [\![\tau(\eta), 0]\!]\} \tag{4.18}$$

and for any $\eta \in X^*_{F,n}$ the mapping $x^*(\cdot; \eta): [\![\tau(\eta), 0]\!] \to A$ is a regular characteristic of (3.11) satisfying (4.5)-(4.6), with the switching points $\{\tau_i(\eta); i \in Z\}$.

(ii) If Z_0 denotes the set of those $i \in Z$ for which the set:

$$Y_i = \{(t, \eta) \in Y; \tau_{i-1}(\eta) < t < \tau_i(\eta)\} \tag{4.19}$$

is not empty, then for any $i \in Z_0$ the "time-derivative" defined by:

$$x'(t; \eta) = D_1 x(t; \eta), \qquad (t, \eta) \in Y_i \tag{4.20}$$

has one-sided limits at $\tau_{i-1}(\eta)$, $\tau_i(\eta)$, and the restrictions $x^*_i(\cdot, \cdot)$, $x_i(\cdot, \cdot)$, $x'_i(\cdot, \cdot)$ of $x^*(\cdot, \cdot)$, $x(\cdot, \cdot)$, $x'(\cdot, \cdot)$, respectively, at $\bar{Y}_i$ defined by

$$\bar{Y}_i = \{(t, \eta) \in Y; \tau_{i-1}(\eta) < t < \tau_i(\eta)\} \tag{4.21}$$

are weakly C^1-stratified by a stratification $\mathcal{S}_i$ of $\bar{Y}_i$ such that $x_i(\cdot, \cdot)$ is a weakly C^1-stratified submersion and for any $S \in \mathcal{S}_i$ there exists $A_S \in \mathcal{S}_H$ such that $x^*(S) \subset A_S$.

(iii) For any $i \in Z_0$ the derivatives of $x_i(\cdot, \cdot)$ and $x'_i(\cdot, \cdot)$ verify:

$$Dx'_i(t; \eta) = D_1 Dx_i(t; \eta) \quad \text{for any } (t, \eta) \in \bar{Y}_i, \tag{4.22}$$

$$\begin{aligned} &Dx_i(\tau_i(\eta); \eta) \cdot (\bar{t}, \bar{\eta}) = (\bar{t} - D\tau_i(\eta) \cdot \bar{\eta}) x'_i(t; \eta) + \bar{x}_F \\ &\text{if } \bar{\eta} = (\bar{x}_F, \bar{p}_F) \subset T_\eta X^*_{F,n} \text{ and } \bar{t} \in R. \end{aligned} \tag{4.23}$$

(iv) For any $i \in Z_0$ and $S \in \mathcal{S}_i$ there exist $B_S^i \in \mathcal{S}_F^*$, $C_S^i \in \mathcal{S}_g$ such that for any $(t, (x_F, p_F)) \in S$ one has: $\eta = (x_F, p_F) \in B_S^i$, $x_F \in C_S^i$.

Remark 4.7. Since in the case $\tau_{-i}(\eta) = \tau(\eta) < 0 = \tau_0(\ ) = \tau_i(\eta)$ for any $i \in N$, $\eta \in R^{2n}$, (4.22) and (4.23) are the usual properties of the flow of a smooth vector field [15], the stratified Hamiltonian flow in Definition 4.6 is a generalization of such an object. In fact, the obvious way to obtain a stratified Hamiltonian flow is to "concatenate" a family, $\{x_i^*(\cdot;\cdot);\ i \in Z\}$, of smooth flows "via" a set, $\{\tau_i(\cdot);\ i \in Z\}$, of functions with property (i) in Definition 4.6 as follows [21]: $x^*(t;\eta) = x_i^*(t - \tau_i(\eta);\ x^*(\tau_i(\eta), \eta))$ for any $t \in [\tau_{i-1}(\eta), \tau_i(\eta)]$, $\eta \in X_{F,n}^*$.

We note that according to (4.16) and (4.17) we allow 0 and $\tau(\eta)$ to be cluster points of the set $\{\tau_i(\eta);\ i \in Z\}$ of the switching points of the regular characteristic $x^*(\cdot;\eta)$; obviously, the stratified Hamiltonian flow in Definition 4.6 may be generalized so as to contain even more pathological cases.

LEMMA 4.8. *If Σ is a weakly stratified optimal control system and $x^*(\cdot,\cdot) = (x(\cdot,\cdot), p(\cdot,\cdot))$ is a stratified Hamiltonian flow, then for any $i \in Z_0$, $(t,\eta) \in Y_i$ (Definition 4.6) and any $(\bar{t}, \bar{\eta}) \in T_{(t,\eta)}\bar{Y}_i$ one has:*

$$\langle p_i(t,\eta), Dx_i(t,\eta)\cdot(\bar{t},\bar{\eta})\rangle = -Dg(y_F(t,\eta))\cdot\bar{x}_F \quad \text{if } \bar{\eta} = (\bar{x}_F, \bar{p}_F). \tag{4.24}$$

Proof. According to (3.25) in Proposition 3.7 we have: $\langle p_i(t,\eta), x_i'(t,\eta)\rangle = 0$ for any $(t,\eta) \in \bar{Y}_i$ and therefore, since this is a stratified constant function, its derivative must vanish everywhere: using (4.22), (3.11) and (3.12), we obtain: $x_i'(t,\eta)\cdot Dp_i(t,\eta) + p_i(t,\eta)D_1Dx_i(t,\eta) = 0$ and therefore:

$$\begin{aligned} d/dt(p_i(t,\eta)Dx_i(t,\eta)) &= p_i'(t,\eta)Dx_i(t,\eta) + p_i(t,\eta)D_1Dx_i(t,\eta) \\ &= p_i'(t,\eta)Dx_i(t,\eta) - x_i'(t,\eta)Dp_i(t,\eta) \\ &= -DH(x_i^*(t,\eta))\cdot Dx_i^*(t,\eta) \\ &= -D(H(\cdot,\cdot)\circ x_i^*(\cdot,\cdot))(t,\eta) = 0 \end{aligned}$$

since from Proposition 3.7 and Definition 4.6 it follows that the function $(t,\eta) \mapsto H(x^*(t,\eta)) = 0$ is stratified and constant on $\bar{Y}_i$. From this formula we infer that for any $(t,\eta) \in \bar{Y}_i$, the mapping $s \mapsto p_i(s,\eta)Dx_i(s,\eta)$ is constant on the interval $[\tau_{i-1}(\eta), \tau_i(\eta)]$; hence $p_i(t,\eta)Dx_i(t,\eta) = p_i(\tau_i(\eta),\eta)Dx_i(\tau_i(\eta),\eta)$ for any $(t,\eta) \in \bar{Y}_i$ and therefore from (4.23) and (3.25) (Proposition 3.7) it follows that for any $(\bar{t},\bar{\eta}) \in T_{(t,\eta)}\bar{Y}_i$, $\bar{\eta} = (\bar{x}_F, \bar{p}_F)$ one has: $\langle p_i(t,\eta), Dx_i(t,\eta)\cdot(\bar{t},\bar{\eta})\rangle = \langle p_i(\tau_i(\eta),\eta), \bar{x}_F\rangle$. Since $p(\cdot,\eta)$ is continuous, from (4.17) and (3.18) it follows (4.24) and the Lemma is proved.

THEOREM 4.9. *Let $\Sigma = (X, X_F, U, f, g)$ be a regular optimal control system, let $x_k^*(\cdot,\cdot) = (x_k(\cdot,\cdot), p_k(\cdot,\cdot)) : Y_k \subset (-\infty, 0] \times X_{F,n}^* \to A$ $k \in \mathcal{K}$, be stratified Hamiltonian flows of (3.11) and let Y_r, X_r, $\tilde{X}_r$, $W_r(\cdot)$, $\tilde{Y}_r(\cdot)$, $\tilde{K}_r(\cdot)$ be defined as in (4.7)–(4.13) such that $W_r(\cdot) : \tilde{X}_r \to R$ is continuous and weakly C^1-stratified by $\mathcal{S}_r$ that is compatible with every family $\{x_{ki}(S);\ S \in \mathcal{S}_{ki}\}$, $k \in \mathcal{K}$, $i \in Z_0^k$ in Definition 4.6(ii).*

Then for any $x_0 \in \tilde{X}_r \setminus X_F$ and any $(t,\eta) \in \tilde{Y}_r(x_0)$, $k \in \tilde{K}_r(x_0)$, the mapping $\tilde{x}(\cdot; x_0)$ defined by (4.15) is an optimal trajectory with respect to x_0 for the problem $P_r|\tilde{X}_r$.

If Σ is a Lipschitzian optimal control system and $W_r(\cdot)|(\tilde{X}_r \setminus X_F)$ is locally Lipschitzian, then $\tilde{x}(\cdot; x_0)$ is optimal with respect to x_0 for the problem $P_m|\tilde{X}_r$.

Proof. The statements follow from Theorems 4.3 and 4.4, respectively, if we prove that for any $x \in \tilde{X}_r \setminus X_F$, $(t,\eta) \in \tilde{Y}_r(x)$, $k \in \tilde{K}_r(x)$, (4.14) is verified.

Let us consider $x \in S \in \mathcal{S}_r$ and $\bar{x} \in T_xS = T_x\tilde{X}_r$; since $x_k(t,\eta) = x$, from Definition 4.6 it follows that there exists $i \in Z_0^k$ (i.e. such that the set Y_{ki} defined by (4.19) is not empty) such that $(t,\eta) \in \bar{Y}_{ki}$. Since by Definition 4.6 restriction $x_{ki}(\cdot,\cdot) = x_k(\cdot,\cdot)|\bar{Y}_{ki}$ is a weakly stratified submersion (Definition 2.2), there exists $P \in \mathcal{S}_{ki}$ such that $x_{ki}(P) = S$

and $x_{ki}(\cdot,\cdot)|P$ is locally a projection [15]; hence for any $\bar{x}\in T_xS$ there exists $(\bar{t},\bar{\eta})\in T_{(t,\eta)}P = T_{(t,\eta)}\tilde{Y}_{ki}$ such that:

$$Dx_{ki}(t,\eta)\cdot(\bar{t},\bar{\eta}) = \bar{x}. \tag{4.25}$$

We shall prove next that in this case, if $y_F(\cdot,\cdot)$ is the projection defined in (4.7) then:

$$DW_r(x)\cdot\bar{x} = Dg(y_F(t,\eta))\cdot\bar{x}_F \quad \text{if } \bar{\eta}=(\bar{x}_F,\bar{p}_F). \tag{4.26}$$

Let $\gamma(\cdot):(-a,a)\to P$, $a>0$, be of class C^1 such that: $\gamma(0)=(t,\eta)$ and $\gamma'(0)=(\bar{t},\bar{\eta})$ and let $c(\cdot)$ be defined by: $c(s)=x_{ki}(\gamma(s))$, $s\in(-a,a)$; since $x_{ki}(\cdot,\cdot)|P$ is of class C^1 it follows that $c(\cdot)$ is of class C^1 and from (4.25) it follows: $c(0)=x$, $c'(0)=\bar{x}$ and hence the derivative of $W_r(\cdot)$ is given by: $DW_r(x)\cdot\bar{x}=\lim_{s\to 0}(W_r(c(s))-W_r(x))/s$. Further on, since $(t,\eta)\in\tilde{Y}_r(x)$, from (4.12) and (4.10) it follows that $W_r(c(s))\leqq g(y_F(\gamma(s)))$ for any $s\in(-a,a)$ and $W_r(x)=g(y_F(\gamma(0)))$ and since from the definition of $y_F(\cdot,\cdot)$ ($y_F(t,\eta)=x_F$ if $\eta=(x_F,p_F)$, $t\in R$) and the compatibility condition in Definition 4.6(iv), it follows $\lim_{s\to 0}(\gamma(s)-\gamma(0))/s=(\bar{t},\bar{\eta})$ and $\lim_{s\to 0}(y_F(\gamma(s))-y_F(\gamma(0)))/s=\bar{x}_F$ if $\bar{\eta}=(\bar{x}_F,\bar{p}_F)$, if $s\in(0,a)$ we have:

$$(W_r(c(s))-W_r(x))/s\leqq(g(y_F(\gamma(s)))-g(y_F(t,\eta)))/s\to Dg(y_F(t,\eta))\cdot\bar{x}_F.$$

Hence $DW_r(x)\cdot\bar{x}\leqq Dg(y_F(t,\eta))\cdot\bar{x}_F$. Reasoning in the same way for $s\in(-a,0)$, we obtain the reversed inequality hence (4.26).

To end the proof, it suffices now to note that from (4.24) in Lemma 4.8 applied to the stratified Hamiltonian flow $x_k^*(\cdot,\cdot)$ it follows: $Dg(y_F(t,\eta))\cdot\bar{x}_F=-\langle p_{ki}(t,\eta), Dx_{ki}(t,\eta)\cdot(\bar{t},\bar{\eta})\rangle$ and therefore from (4.25) and (4.26) it follows (4.14) and Theorem 4.9 is proved.

5. An example. The problem of a spacecraft attempting to make a soft landing on the moon using a minimum amount of fuel leads to the following optimal control problem ([7], [10], [16], etc.): *minimize* $(-x_3(t_F(u(\cdot))))$ *subject to*: $x_1'=x_2$, $x_2'=-g_0+u(t)/x_3$, $x_3'=-ku(t)$, $x_1(0)=x_1^0>0$, $x_2(0)=x_2^0\in R$, $x_3(0)=x_3^0\in I=[M,\alpha/g_0)$, $x_1(t_F(u(\cdot)))=x_2(t_F(u(\cdot)))=0$, $x_3(t_F(u(\cdot)))\in I$, $u(t)\in[0,\alpha]$ and $x_1(t)>0$, $x_3(t)\in I$ for any $t\in[0,t_F(u(\cdot)))$, where g_0, M, k, $\alpha>0$ are given constants satisfying the condition: $M<\alpha/g_0$.

Obviously this is a Mayer optimal control problem of the form (3.1)–(3.5) defined by the following elements:

$$X=X_0\cup X_F,\quad X_0=(0,\infty)\times R\times I,\quad X_F=\{0\}\times\{0\}\times I,\quad U=[0,\alpha], \tag{5.1}$$

$$f(x,u)=(x_2,-g_0+u/x_3,-ku),\quad g(0,0,x_3)=-x_3,\quad x_F=(0,0,x_3)\in X_F. \tag{5.2}$$

In view of the "physical" interpretations of the data of the problem it seems reasonable to look for optimal controls in the class of piecewise continuous admissible controls (i.e. to solve the problem P_{cp}) but we shall find piecewise continuous controls that are optimal in the class of measurable bounded admissible controls (i.e. for the problem P_m) solving thus also the problems P_r and P_{cp}.

The Pontryagin function and the Hamiltonian are given by:

$$\mathcal{H}(x,p,u)=p_1x_2-g_0p_2+uh(x,p),\qquad h(x,p)=p_2/x_3-kp_3, \tag{5.3}$$

$$\begin{aligned} &H(x,p)=p_1x_2-g_0p_2+\nu(h(x,p)),\\ &\nu(s)=s \quad \text{if } s>0,\qquad \nu(s)=0 \quad \text{if } s\leqq 0, \end{aligned} \tag{5.4}$$

$$\begin{aligned} &\hat{U}(x,p)=\{\alpha\} \quad \text{if } h(x,p)>0,\qquad \hat{U}(x,p)=\{0\} \quad \text{if } h(x,p)<0,\\ &\hat{U}(x,p)=U \quad \text{if } h(x,p)=0. \end{aligned} \tag{5.5}$$

It is easy to see that the data and the Hamiltonian have all the properties in Definition 3.9 so the optimal control system $\Sigma = (X, X_F, U, f, g)$ is at the same time regular and Lipschitzian. In fact the disjoint components, X_0 and X_F of X are C^ω-stratified by $\{X^1, X^2\}$ and $\{X^3, X^4\}$, respectively, where:

$$\begin{aligned} &X^1 = (0,\infty)\times R\times (M, \alpha/g_0), \qquad X^2 = (0,\infty)\times R\times\{M\},\\ &X^3 = \{0\}\times\{0\}\times(M, \alpha/g_0), \qquad X^4 = \{(0,0,M)\}. \end{aligned} \tag{5.6}$$

The set $A = X\times(R^3\backslash\{0\})$ on which $H(\cdot,\cdot)$ is defined is partitioned by the sets:

$$\begin{aligned} &A_+ = \{(x,p)\in A;\ h(x,p)>0\}, \qquad A_- = \{(x,p)\in A;\ h(x,p)<0\},\\ &A_0 = \{(x,p)\in A;\ h(x,p)=0\} \end{aligned} \tag{5.7}$$

each of them being C^ω-stratified by: $A_+^i = A_+\cap(X^i\times R^3)$, $A_-^i = A_-\cap(X^i\times R^3)$, $A_0^i = A_0\cap(X^i\times R^3)$, $i=1,2,3,4$, respectively.

Remark 5.1. For the verification of the above statements as well as for the computations to follow it is enough to recall that from the implicit functions theorem it follows that if $U\subset R^n$ is open, $F(\cdot): U\to R^m$ $(m<n)$ is of class C^k, $k\in\{1,2,\cdots\infty,\omega\}$, and the derivative $DF(x)\in L(R^n, R^m)$ is surjective for any $x\in U$ then the set $S=\{x\in U;\ F(x)=0\}$, if not empty, is a submanifold of class C^k, of dimension $n-m$, whose tangent space at each point is given by: $T_xS=\{\bar{x}\in R^n;\ DF(x)\cdot\bar{x}=0\}$. From the definition of a differentiable submanifold (e.g. [15]) it follows also that if $F(\cdot): U\to R^m$ is of class C^k, then its graph, $G_{F(\cdot)}=\{(x, F(x));\ x\in U\}$ is a submanifold of class C^k, of dimension n, of $U\times R^m$, whose tangent space is given by: $T_{(x,F(x))}G_{F(\cdot)} = \{(\bar{x}, DF(x)\cdot\bar{x});\ \bar{x}\in R^n = T_xU\}$.

To describe the controlled Hamiltonian orientor field defined by (3.10), we consider first the mapping $\xi(\cdot,\cdot,\cdot)$ defined by (3.28):

$$\xi(x,p,u) = (f(x,u), P(x,p,u)) = ((x_2, -g_0+u/x_3, -ku), (0, -p_1, up_2/(x_3)^2)) \tag{5.8}$$

and note that from (3.10), (5.5) and (5.7) it follows that $\xi_H(x,p)=\xi(x,p,\alpha)$ if $(x,p)\in A_+$ and $\xi(x,p,\alpha)\in T_{(x,p)}A_+$, $\xi_H(x,p)=\xi(x,p,0)$ if $(x,p)\in A_-$ and $\xi(x,p,0)\in T_{(x,p)}A_-$, $\xi_H(x,p)=\{\xi(x,p,u);\ u\in U,\ \xi(x,p,u)\in T_{(x,p)}A_0\}$, if $(x,p)\in A_0$ and $\xi_H(x,p)=\varnothing$ otherwise.

An easy computation using Remark 5.1 shows that we can refine the above-mentioned stratification of A_0 as follows: $A_0^i = A_{0+}^i\cup A_{0-}^i\cup A_{00}^i$ where $A_{0+}^i = \{(x,p)\in A_0^i;\ p_1>0\}$, $A_{0-}^i=\{(x,p)\in A_0^i;\ p_1<0\}$, $A_{00}^i=\{(x,p)\in A_0^i;\ p_1=0\}$, $i=1,2,3,4$, such that the Hamiltonian orientor field is given by:

$$\xi_H(x,p) = \begin{cases} \{\xi(x,p,\alpha)\} & \text{if } (x,p)\in A_+^1,\\ \{\xi(x,p,0)\} & \text{if } (x,p)\in A_-^1\cup A_-^2,\\ \xi(x,p,U) & \text{if } (x,p)\in A_{00}^1\cup A_{00}^2,\\ \varnothing & \text{otherwise.}\end{cases} \tag{5.9}$$

The set $X_{F,n}^*$ of the terminal values for normal characteristics (defined by (3.18)) contains the set $X_{F,a}^*$ (hence the problem is normal) and is given by: $X_{F,n}^* = X_F^* = \cup\{X_{+i}^*\cup X_{-i}^*\cup X_{0+}^*\cup X_{0-}^*;\ i=3,4\}$, where: $X_{+i}^* = \{(x,p)\in A_+^i,\ p_2 = q(x_3,p_3),\ p_3\in P_3^i\}$, $X_{-i}^* = \{(x,p)\in A_-^i;\ p_2=0,\ p_3\in P_3^i\}$, $X_{0+}^* = \{(x,p)\in A_{0+}^4;\ p_2=p_3=0\}$, $X_{0-}^* = \{(x,p)\in A_{0-}^4;\ p_2=p_3=0\}$, $i=3,4$, $P_3^3=\{1\}$, $P_3^4=(0,\infty)$, $q(x_3,p_3)=\alpha k x_3/(\alpha-g_0x_3)$.

Since the Hamiltonian cannot vanish on the sets A_{00}^i, $i=1,2,3,4$, from Proposition 3.7 and (5.9) it follows that for any $\eta=(x_F, p_F)\in X_F^*$ and any characteristic $x^*(\cdot,\eta)$ one has:

$$x^*(t,\eta)\in A_+^1\cup A_-^1\cup A_-^2 \quad \text{a.e. on } [\![\tau(\eta), 0]\!]. \tag{5.10}$$

From (5.7) it follows that the range of any characteristic is determined by the sign of the function $\chi(\cdot, \eta)$ defined by:

$$\chi(t, \eta) = h(x^*(t, \eta)), \qquad t \in [\![\tau(\eta), 0] \tag{5.11}$$

where $h(\cdot, \cdot)$ is defined by (5.3). Since $x^*(\cdot, \eta)$ is absolutely continuous, from (5.3) it follows that $\chi(\cdot, \eta)$ is absolutely continuous and from (5.9) it follows that the derivative of $\chi(\cdot, \eta)$ is given by: $\chi'(t, \eta) = -p_1^F / x_3(t, \eta)$ a.e. on $[\![\tau(\eta), 0]$, $\eta = (x_F, p_F) \in X_F^*$ and therefore, since $x_3(t, \eta) \in I = [M, \alpha/g_0)$, $\chi(\cdot, \eta)$ is a monotone function. It follows that any characteristic of the problem has at most one switching point and is finitely regular with respect to the C^ω-stratification $\mathcal{S}_H = \{A_+^i, A_-^i, A_{0+}^i, A_{0-}^i, A_{00}^i, i = 1, 2, 3, 4\}$.

We shall prove that all the characteristics are "integral curves" of a certain stratified Hamiltonian flow in the sense of Definition 4.6 and Remark 4.7.

From (5.8) and (5.9) it follows that no characteristic may terminate at a point $\eta \in X_{-3}^* \cup X_{-4}^* \cup X_{0+}^*$ since there exists $r > 0$ such that $\chi(t, \eta) < 0$ for any $t \in (-r, 0]$ but, on the other hand, the integral curve of $\xi(\cdot, \cdot, 0)$ through $(0, \eta)$ does not remain in A on the interval $(-r, 0)$; hence we take $\tau(\eta) = 0$ in this case.

From (5.8) and (5.9) it follows also that for any $\eta \in X_{+3}^* \cup X_{+4}^* \cup X_{0-}^*$ there exists a unique characteristic $x^*(\cdot, \eta)$ satisfying (3.21)-(3.22) and $\tau_1(\eta) < 0$ such that

$$x^*(t, \eta) = x_+^*(t, \eta) = (x^+(t, x^F), p^+(t, \eta)) \quad \text{for } t \in (\tau_1(\eta), 0], \quad \eta = (x^F, p^F) \tag{5.12}$$

where $x_+^*(\cdot, \cdot)$ is the flow of the smooth vector field $\xi(\cdot, \cdot, \alpha)$, its first component, $x^+(\cdot, \cdot)$, being the flow of $f(\cdot, \alpha)$ defined by (5.2) and $\tau_1(\eta) = \inf\{t < 0;\ \chi(t, \eta) < 0, x^+(t, x^F) \in X_0\}$. It is easy to see that if either $p_1^F \geqq 0$ or $p_1^F \leqq -\alpha k h(\eta)/\log(\alpha/g_0 x_3^F)$ then:

$$\tau_1(\eta) = T_0(x^F) = (x_3^F - \alpha/g_0)/\alpha k \tag{5.13}$$

and $x^*(\cdot, \eta)$ is not defined at $\tau_1(\eta)$ (since $x^*(t, \eta) \notin A$ for $t \leqq \tau_1(\eta)$); hence we must take $\tau_1(\eta) = \tau(\eta)$ in this case. For the remaining values of $\eta \in X_{+3}^* \cup X_{+4}^*$ (i.e. $-\alpha k h(\eta)/\log(\alpha/g_0 x_3^F) < p_1^F < 0$) we have $\tau_1(\eta) > T_0(x^F)$ and moreover, for every $x^F = (0, 0, x_3^F) \in X_F$ and any $t \in (T_0(x^F), 0)$ there exists $\eta = (x^F, p^F) \in X_{+3}^* \cup X_{+4}^*$ such that $\tau_1(\eta) = t$; further on, in this case $x^*(\cdot, \eta)$ is continuable on an interval $(\tau(\eta), \tau_1(\eta)]$ where it is given by:

$$x^*(t, \eta) = x_-^*(t - \tau_1(\eta), x_+^*(\eta)), \quad x_+^*(\eta) = x_+^*(\tau_1(\eta), \eta), \quad t \in (\tau(\eta), \tau_1(\eta)] \tag{5.14}$$

where $x_-^*(\cdot, \cdot) = (x^-(\cdot, \cdot), p^-(\cdot, \cdot))$ is the flow of the smooth vector field $\xi(\cdot, \cdot, 0)$ defined by (5.8), its first component, $x^-(\cdot, \cdot)$, being the flow of $f(\cdot, 0)$ defined by (5.2) and $\tau(\eta) = \inf\{t < \tau_1(\eta);\ x_1^-(t, x^+(\tau_1(\eta), x^F)) > 0\}$ which gives: $\tau(\eta) = \tau_1(\eta) + T_1(x^+(\eta))$ where: $T_1(x) = (x_2 - ((x_2)^2 + 2g_0 x_1)^{1/2})/g_0$, $x^+(\eta) = x^+(\tau_1(\eta), x^F)$. From these results it follows that any characteristic is an integral curve of the stratified Hamiltonian flow $x^*(\cdot, \cdot)$ defined by (5.12)-(5.14) and $X_m = X_r$, $W_m(\cdot) = W_r(\cdot)$, defined by (4.9) and (4.10), respectively, may be described "parametrically" as follows: $X_m = \{x^-(s - t, x^+(t, x^F));\ x^F \in X_F, t \in (T_0(x^F), 0], s \in (T_1(x^+(t, x^F)), t]\}$, $W_m(x) = -x_3^F$ if $x = x^-(s - t, x^+(t, x^F)) \in \tilde{X}_m = X_m$. Using implicit functions arguments, it follows easily that $\mathcal{S}_m = \{X_m^{i,j};\ i = 3, 4,\ j = 1, 2, 3\}$ where $X_m^{i,1} = X^i$, $X_m^{i,2} = \{x^+(t, x^F);\ x^F \in X^i,\ t \in (T_0(x^F), 0)\}$, $X_m^{i,3} = \{x^-(s - t, x^+(t, x^F));\ x^F \in X^i,\ t \in (T_0(x^F), 0),\ s \in (T_1(x^+(t, x^F)), t)\}$, is a C^1-stratification of $W_m(\cdot)$ which is continuous and its restriction $W_m(\cdot)|(X_m \setminus X_F)$ is locally Lipschitzian.

From Theorem 4.9 and Remark 4.5 it follows now that the function $v(\cdot): X_m \to U$ defined by:

$$v(x) = \begin{cases} \alpha & \text{if } x \in \cup\{X_m^{i,j};\ i=3,4, j=1,2\}, \\ 0 & \text{if } x \in X_m^{3,3} \cup X_m^{4,3} \end{cases}$$

is an optimal feedback control for the problems $P_m|X_m$, $P_r|X_m$ and $P_{cp}|X_m$.

Finally, using a tangency argument [25], [26], one may prove that any admissible trajectory (with respect to the original problem) that starts at a point in $X_m \setminus X_F$ remains on X_m and moreover, the points in $X \setminus X_m$ do not have admissible trajectories; hence $v(\cdot)$ is the optimal feedback control of the original problem.

THE GRADIENT PROJECTION METHOD USING CURRY'S STEPLENGTH*

R. R. PHELPS†

Abstract. It is shown that, using Curry's steplength, the gradient projection method for finding constrained stationary points of a real valued C^1 function on a closed convex subset C of Hilbert space can work for two rather different classes of convex sets: those with C^2 boundary and "orthogonal polyhedra". Both results are applications of Theorem 1, whose hypotheses require that the metric projection onto C possess directional derivatives which are continuous in a rather weak sense.

Key words. Hilbert space, gradient projection method, nonlinear optimization, Curry's steplength, orthogonal polyhedra

AMS(MOS) subject classification. 49D

1. Introduction. Let f be a real-valued C^1 function on the real Hilbert space H and suppose that C is a nonempty closed convex subset of H. The gradient projection minimization method is designed to produce a "constrained stationary point" of f in C. The method starts with any point $x_0 \in C$ and proceeds iteratively to define a sequence $\{x_n\}$ in C by

$$x_{n+1} = P[x_n - t_n \nabla f(x_n)], \qquad n = 0, 1, 2, \cdots, \tag{1}$$

where P is the metric projection of H onto C and the *steplengths* $t_n \geqq 0$ are chosen in some specified manner. If $C = H$, then P is just the identity map and one has the method of steepest descent for unconstrained minimization. In this case, that is, when $x_{n+1} = x_n - t_n \nabla f(x_n)$, there are at least two established ways of choosing the steplength. The *Cauchy steplength* is one for which t_n is a global minimum point for the C^1 function $g(t) = f(x_n - t_n \nabla f(x_n))$, $t \geqq 0$. (This assumes, of course, that such a minimum exists.) For the more general *Curry steplength* one chooses t_n to be the smallest stationary point of the same function. An historical account of these unconstrained methods (and a proof that Curry's method is valid in any normed linear space) is given by Byrd and Tapia [1]. Returning to the constrained method (1), one can analogously define the steplengths in terms of the functions

$$g_n(t) = f(P[x_n - t \nabla f(x_n)]), \qquad t \geqq 0. \tag{2}$$

In the case of Cauchy's steplength, the method works: any cluster point of $\{x_n\}$ is a constrained stationary point (defined below) of f in C. This was proved by McCormick and Tapia [7] for Hilbert space and by the author [9] for a reasonable class of Banach spaces. In this note we will examine the more general but more complicated case of Curry's steplength. The complications arise because, even in finite dimensional Euclidean space, P may fail to have directional derivatives (see [6], [10]), so that differentiability of the function g_n is at issue. In fact, even when P is analytic (outside of C), the function g_n may fail to be differentiable precisely at its global minimum point. (See the Example at the end of this paper). In order to avoid this difficulty, we modify slightly the definition of Curry's steplength; rather than defining t_n to be the smallest nonnegative stationary point of g_n we let

$$t_n = \inf\{t \geqq 0 \colon dg_n(t) \geqq 0\}, \tag{3}$$

* Received by the editors January 22, 1985, and in revised form May 17, 1985.

where dg_n denotes the right-hand derivative of g_n. This latter derivative will exist if P admits directional derivatives at every point, something we assume in our main theorem. When g_n is differentiable, definition (3) yields the smallest nonnegative stationary point of g_n. Moreover, it retains an important property of any reasonable steplength:

$$f(x_{n+1}) \leqq f(x_n) \quad \text{for all } n.$$

(To see this, note first that it is equivalent to $g_n(t_n) \leqq g_n(0)$. By definition, if $t_n > 0$, then for $t \in [0, t_n)$ we must have $dg_n(t) < 0$. By a standard monotonicity result (see, for instance, [3, p. 22]), the desired inequality holds.)

In order to say what we mean by a constrained stationary point for f, we first recall that the metric projection always has directional derivatives at points of C. To be precise, if $x \in C$, the *support cone* $S_C(x)$ (or simply $S(x)$) is defined to be the closure of the cone $\cup \{\lambda(C-x): \lambda > 0\}$. It is well-known that if $x \in C$ and $u \in H$, then $dP(x)u = P_{S(x)}u$, where

$$dP(x)u = \lim_{t \to 0^+} t^{-1}[P(x+tu) - P(x)]$$

and $P_{S(x)}$ is the metric projection of H onto $S(x)$. (See, for instance, [7] or [11, p. 300].) By combining this result with the chain rule one can compute the right-hand derivative at $t = 0$ of

$$g(t) = f(P[x - t\nabla f(x)]), \qquad t \geqq 0$$

whenever $x \in C$; since $Px = x$ we obtain

$$dg(0) = \langle \nabla f(x), P_{S(x)}[-\nabla f(x)] \rangle = \langle \nabla f(x), dP[x](-\nabla f(x)) \rangle.$$

As shown in the corollary in [9], this latter quantity equals $-\|P_{S(x)}[-\nabla f(x)]\|^2$. (Note that, in particular, we always have $dg(0) \leqq 0$.) We say that $x \in C$ is a *constrained stationary point* for f in C provided $P_{S(x)}[-\nabla f(x)] = 0$. This is obviously equivalent to requiring $dg(0) \geqq 0$. Our first result asserts that any cluster point x^* of the sequence (1) (using the steplength (3)) will be a constrained stationary point for f, provided dP exists in H and is continuous in a certain weak sense. Propositions 2 and 3 exhibit classes of sets C for which these latter hypotheses are satisfied.

As above, we define (when the limit exists)

$$dP(x)u = \lim_{t \to 0^+} t^{-1}[P(x+tu) - P(x)], \qquad x, u \in H.$$

The weak continuity property we use is the following. (It assumes that dP exists.)

(WSC) Suppose that $\{x_n\} \subseteq C$, $x \in C$ and $\|x_n - x\| \to 0$. Assume also that $\{u_n\} \subseteq H$, $t_n \to 0^+$, $x_n - t_n u_n \in H \backslash \operatorname{int} C$, $-u \in H \backslash \operatorname{int} S(x)$ and $\|u_n - u\| \to 0$. Then $\limsup_{n \to \infty} \langle u_n, dP[x_n - t_n u_n](-u_n) \rangle \leqq \langle u, dP[x](-u) \rangle$.

This property (which is more like a semi-continuity property) is clearly satisfied if $\{dP[x_n - t_n u_n](-u_n)\}$ converges weakly to $dP[x](-u)$, something which is true (Proposition 2) whenever C has a C^2 boundary. Weak convergence can fail, however, for the orthogonal polyhedra of Proposition 3, while the (WSC) holds.

2. Main theorem.

THEOREM 1. *Let C be a nonempty closed convex subset of the Hilbert space H and let P denote the metric projection of H onto C. Suppose that the directional derivative dP exists in H and satisfies the (WSC). If f is a real-valued C^1 function on H and $x_0 \in C$, inductively define g_n, t_n and x_n as in (1), (2) and (3). Then any cluster point x^* of the sequence $\{x_n\}$ is a constrained stationary point for f.*

Proof. If we define $g(t) = f(P[x^* - t\nabla f(x^*)])$, $t \geqq 0$, then the foregoing discussion shows that we want to prove that $dg(0) \geqq 0$. Let $\{x_i\}$ be a subsequence of $\{x_n\}$ converging to x^* and let t_i be the corresponding steplength used to define the successor to x_i. Let $t^* = \inf\{t_i\}$. Following a standard approach, we consider two cases.

Case 1. $t^* > 0$. Arguing by contradiction, suppose that $dg(0) < 0$. This implies that there exists $0 < \tau < t^*$ such that $\tau^{-1}[g[\tau) - g(0)] < 0$, that is,

$$f(P[x^* - \tau\nabla f(x^*)]) < f(P[x^*]) = f(x^*).$$

By continuity and the fact that x^* is the limit of $\{x_i\}$, there exists x_N such that

$$f(P[x_N - \tau\nabla f(x_N)]) < f(x^*).$$

Since $0 < \tau < t^* \leqq t_N$ and since, by definition of the steplength t_N, we have $dg_N(t) < 0$ for $\tau \leqq t < t_N$, the monotonicity of g_N in this latter interval implies that $g_N(t_N) \leqq g_N(\tau)$. This means that

$$f(x^*) > f(P[x_N - \tau\nabla f(x_N)]) = g_N(\tau) \geqq g_N(t_N) = f(x_{N+1}).$$

But $i > N+1$ for all but finitely many i, hence $f(x_i) \leqq f(x_{N+1}) < f(x^*)$. Since $f(x_i) \to f(x^*)$, this is a contradiction which completes the proof of Case 1.

Case 2. $t^* = 0$. Assume without loss of generality that $t_i \to 0$. By definition of t_i we can choose s_i for each i such that $t_i < s_i$, $dg_i(s_i) \geqq 0$ and $s_i \to 0$. Of course, $x_i \to x^*$. We consider several possibilities. Let

$$y_i = x_i - s_i\nabla f(x_i)$$

and suppose, first that $y_i \in \operatorname{int} C$ for infinitely many i. Since P is the identity map in C, this implies that

$$dP[y_i](-\nabla f(x_i)) = -\nabla f(x_i)$$

for infinitely many i. Also, $\nabla f(P[y_i]) = \nabla f(y_i)$. Since, for every i,

$$(\alpha) \qquad 0 \leqq dg_i(s_i) = \langle \nabla f(P[y_i]),\, dP[y_i](-\nabla f(x_i)) \rangle$$

we conclude that for infinitely many i the right side of (α) is $\langle \nabla f(y_i), -\nabla f(x_i) \rangle$, which converges to $\langle \nabla f(x^*), -\nabla f(x^*) \rangle = -\|\nabla f(x^*)\|^2$, and hence $\nabla f(x^*) = 0$.

Suppose, next, that $-\nabla f(x^*) \in \operatorname{int} S(x^*)$. This implies that $x^* - \tau\nabla f(x^*) \in \operatorname{int} C$ for some $\tau > 0$ and therefore $x_i - \tau\nabla f(x_i) \in \operatorname{int} C$ for all sufficiently large i. Since $s_i < \tau$ for all but finitely many i, the convexity of C implies that $y_i \equiv x_i - s_i\nabla f(x_i) \in \operatorname{int} C$ whenever $s_i < \tau$, which leads, as above, to $\nabla f(x^*) = 0$. Thus, we are reduced to examining the case where $-\nabla f(x^*) \in H \backslash \operatorname{int} S(x^*)$ and $y_i \in H \backslash \operatorname{int} C$ for all but finitely many i. (Assume that this holds for all i.) Since $y_i \to x^*$ and $x_i \to x^*$ we have $P[y_i] \to P[x^*] = x^*$ and $\nabla f(P[y_i]) - \nabla f(x_i) \to 0$. The sequence $\{dP[y_i](-\nabla f(x_i))\}$ is bounded, so $\langle \nabla f(x_i) - \nabla f(P[y_i]),\, dP[y_i](-\nabla f(x_i)) \rangle \to 0$. It follows from this and the inequality (α) above that

$$\limsup \langle \nabla f(x_i),\, dP[y_i](-\nabla f(x_i)) \rangle \geqq 0$$

and hence, by the (WSC), $dg(0) = \langle f(x^*),\, dP[x^*](-\nabla f(x^*)) \rangle \geqq 0$, which completes the proof.

The foregoing theorem can be formulated and proved in a more general class of Banach spaces, using the same definitions and hypotheses as were used in [9]. We have refrained from proving the more general result since our main application is to Hilbert space (via Proposition 2 below). (While Proposition 3 below could be proved in any l_p space, it applies to rather special subsets.)

3. Smooth bodies. Our next proposition shows that dP has the (WSC) if the boundary of C is sufficiently smooth; this is equivalent to smoothness of the Minkowski (or gauge) functional associated with C [2], [4].

PROPOSITION 2. *Suppose that C is a closed convex subset of Hilbert space H with $0 \in \operatorname{int} C$ and suppose that the Minkowski functional μ for C is of class C^2 (at nonzero points). Then the metric projection P of H onto C satisfies the following properties:*

(i) *The directional derivative $dP(x)u = \lim_{t \to 0^+} t^{-1}[P(x+tu) - P(x)]$ exists for all x, $u \in H$.*

(ii) *If $x \in C$, $\{y_n\} \subseteq H \backslash \operatorname{int} C$ and $\|y_n - x\| \to 0$, then $dP[y_n]u \to dP[x]u$ weakly for each $u \in H \backslash \operatorname{int} S_C(x)$.*

Proof. If $x \in \operatorname{int} C$, then the first assertion follows trivially from the fact that P is the identity mapping in C. If $x \in \partial C$, then it is well known (see McCormick and Tapia [7] or Zarantonello [11, p. 300]) that $dP(x)$ exists and is given by the metric projection $P_{S(x)}$ of H onto the support cone $S(x)$ of C at x. (In the present case, $S(x)$ is the translate to the origin of the closed half-space which contains C and supports it at x.) Finally, if $x \in H \backslash C$, then assertion (i) follows from Holmes' result [5] that since μ is C^2, we know that P is C^1 in $H \backslash C$. (See [2] for related results.) Thus, we need only prove assertion (ii), which implicitly assumes that $x \in \partial C$.

Since P is nonexpansive, we have $\|dP[y_n]u\| \leqq \|u\|$ for all n, so by the relative weak compactness of bounded sets, it suffices to prove that every weakly convergent subsequence of $\{dP[y_n]u\}$ has the same limit $w \in H$ and that $w = dP[x]u$. Without loss of generality we can assume that $\{dP[y_n]u\}$ converges weakly to w. Since the form of $dP[y_n]$ depends on whether $y_n \in C$, we consider first the case that y_n *is* in C—that is, $y_n \in \partial C$—for all but finitely many n. As we noted above, this implies that $dP[y_n]u = P_{S(y_n)}u$. Letting $\nabla\mu$ denote the gradient of μ (which exists at each point of ∂C), we have

$$S(y_n) = \{z \in H : \langle \nabla\mu(y_n), z\rangle \leqq 0\}.$$

We want, of course, to show that $w = P_{S(x)}u$. Suppose, first, that $\langle \nabla\mu(y_n), u\rangle > 0$ for infinitely many n. Then $\langle \nabla\mu(x), u\rangle \geqq 0$ and for infinitely many n the vector $P_{S(y_n)}u$ is the orthogonal projection of u onto the hyperplane

$$H(y_n) = \{z \in H : \langle \nabla\mu(y_n), z\rangle = 0\}.$$

For each such n we have the orthogonal decomposition

$$u = P_{S(y_n)}u + \langle \nabla\mu(y_n), u\rangle \|\nabla\mu(y_n)\|^{-2} \nabla\mu(y_n).$$

Since $\nabla\mu(y_n) \to \nabla\mu(x) \neq 0$ we conclude that u also has the decomposition

$$u = w + \langle \nabla\mu(x), u\rangle \|\nabla\mu(x)\|^{-2} \nabla\mu(x);$$

that is, $w = P_{S(x)}u$. Suppose, therefore, that $\langle \nabla\mu(y_n), u\rangle \leqq 0$ for all but finitely many n. It follows that $\langle \nabla\mu(x), u\rangle \leqq 0$ and $u \in S(y_n)$ for these n, so that $P_{S(y_n)}u = u$ and hence $u = w = P_{S(x)}u$.

We can thus assume that $y_n \in H \backslash C$ for infinitely many n. (For simplicity of notation, assume that it holds for all n.) We only have an implicit description of $dP[y]$ at points $y \in H \backslash C$; it is obtained from the identity

$$(\alpha) \qquad \langle y - Py, Py\rangle \nabla\mu(Py) = y - Py.$$

(See, for instance, [2] for a derivation of this relation. Always $\langle y - Py, y\rangle > 0$.) We can differentiate both sides of (α) in the direction $u \in H$ to obtain

$$(\beta) \qquad \begin{aligned} &\{\langle u - dP[y]u, Py\rangle + \langle y - Py, dP[y]u\rangle\} \nabla\mu(Py) + \langle y - Py, Py\rangle \, d\nabla\mu(Py)\{dP[y]\} \\ &\qquad = u - dP(y)u. \end{aligned}$$

If we now let $y = y_n$ and take limits as $n \to \infty$, we have $y_n - Py_n \to x - Px = 0$ and $dP[y_n]u \to w$ weakly; since μ is C^2 and P is C^1, we conclude that

$$(\gamma) \qquad \langle u - w, x\rangle \nabla\mu(x) = u - w, \qquad u \in H.$$

Now, it is known (see, again, [2]) that $\langle y - Py, dP[y]u\rangle = 0$ whenever $y \in H \setminus C$; from (α), this implies that $\langle \nabla\mu(Py), dP[y]u\rangle = 0$. Taking $y = x_n$, letting $n \to \infty$ and using the norm continuity of $\nabla\mu$ at boundary points of C, this yields $\langle \nabla\mu(x), w\rangle = 0$. We are interested in showing that $w = P_{S(x)}u$ whenever $u \in H \setminus \operatorname{int} S(x)$, that is, whenever $\langle \nabla\mu(x), u\rangle \geqq 0$. Certainly w will be the metric projection of u onto $S(x)$ if it is the metric projection $P_{H(x)}u$ of u onto $H(x) = \{z \in H: \langle \nabla\mu(x), z\rangle = 0\}$. We have just shown that $w \in H(x)$. Furthermore, if $z \in H(x)$, then from (γ) we obtain

$$\langle u - w, z - w\rangle = \langle u - w, x\rangle \langle \nabla\mu(x), z - w\rangle = 0$$

so w satisfies the defining inequality for $P_{H(x)}u$ and the proof is complete.

The fact that conclusion (ii) above implies (WSC) follows easily from the facts that $\|u - u_n\| \to 0$ and $\|dP[y]u_n - dP[y]u\| \leqq \|u - u_n\|$ for any y.

A word about the hypothesis that the boundary of C be C^2 smooth: it guaranteed that P would be C^1 in $H \setminus C$, while the *statement* of Proposition 2 requires merely that P have directional derivatives at each point. It is natural to suspect that a weaker smoothness hypothesis on the boundary of C would suffice for this, but C^1 smoothness is not enough. Zamfirescu [10] has shown that, for almost every (in the sense of Baire category, using the Hausdorff metric on compact convex sets) smooth convex body C in Euclidean n-space E, there is a dense G_δ set of points in $E \setminus C$ at which the associated metric projection fails to have a directional derivative (in at least one direction). (This is a very substantial improvement on Kruskal's well-known example [6].) Recall that for convex bodies in finite dimensional spaces, *smoothness*, that is, a unique supporting hyperplane at each boundary point, is equivalent to C^1 smoothness.

4. Orthogonal polyhedra. There is another class of convex sets C which contrasts sharply with the above; typical examples in the plane would be a rectangle with sides parallel to the coordinate axes, or a cone obtained by translating one of the four quadrants. Following McCormick and Tapia [7], we will call them orthogonal polyhedra. They can be defined in any $l_p(A)$ space (for an arbitrary set A and $1 \leqq p < \infty$) as follows.

For each $\alpha \in A$, let a_α be a real number or $-\infty$ and assume that the function a^+ (defined on A by $a_\alpha^+ = a_\alpha$ if $a_\alpha > 0$, $=0$ otherwise) is an element of $l_p(A)$. Similarly, let b_α be a real number or $+\infty$ and assume that $b^- \in l_p(A)$. Finally, suppose that $a_\alpha \leqq b_\alpha$ for each $\alpha \in A$. Define

$$I(a, b) = \{x \in l_p(A): a_\alpha \leqq x_\alpha \leqq b_\alpha \text{ for each } \alpha \in A\}.$$

It is obvious that $I(a, b)$ is closed, nonempty and convex. For each $\alpha \in A$ and $x \in l_p(A)$ we define

$$p_\alpha(x) = \min\{b_\alpha, \max\{a_\alpha, x_\alpha\}\};$$

this is a number between a_α and b_α which equals x_α if the latter is between these two limits (and equals one of the endpoints otherwise). It is elementary to verify that $Px \equiv (p_\alpha(x))_{\alpha \in A}$ is an element of $l_p(A)$; this uses the l_p-summability restrictions on a and b (and is equivalent to the latter). Moreover, *Px is the nearest point in $I(a, b)$ to x.* (For the uniqueness part of this assertion we require $1 < p < \infty$.) Indeed, one can

easily check cases to verify that if $y \in I(a, b)$, then for all $\alpha \in A$,

$$|x_\alpha - (Px)_\alpha| \equiv |x_\alpha - p_\alpha(x)| \leqq |y_\alpha - x_\alpha|$$

and hence $\|x - Px\|_p \leqq \|y - x\|_p$.

PROPOSITION. 3. *If $C = I(a, b) \subseteq l_p(A)$ (with a, b as above), then $dP[x]u$ exists for all x and u and (in the case $p = 2$) dP satisfies the* (WSC).

Proof. Given x, $u \in l_p(A)$ and $\alpha \in A$, let

$$dp_\alpha(x)u = \lim_{t \to 0^+} [p_\alpha(x + tu) - p_\alpha(x)]/t.$$

This limit exists; indeed, with some patience, it can easily be computed and is described as follows: First, one sees that $dp_\alpha(x)u = 0$ under the following conditions: If $a_\alpha = b_\alpha$, or if $x_\alpha > b_\alpha$ or $x_\alpha < a_\alpha$ or $x_\alpha = b_\alpha$ (and $u_\alpha > 0$) or $x_\alpha = a_\alpha$ (and $u_\alpha < 0$). In the remaining cases we have

$$(*) \qquad dp_\alpha(x)u = u_\alpha \text{ provided } a_\alpha < x_\alpha < b_\alpha \text{ or } a_\alpha < x_\alpha = b_\alpha \text{ (and } u_\alpha < 0) \text{ or } a_\alpha = x_\alpha < b_\alpha \text{ (and } u_\alpha > 0).$$

Since $|dp_\alpha(x)u| \leqq |u_\alpha|$, it is clear that $(dp_\alpha(x)u)_{\alpha \in A} \in l_p(A)$. By reviewing the above case-by-case computations, one obtains a bit more information, namely, that for $t > 0$

$$t^{-1}|p_\alpha(x + tu) - p_\alpha(x)| \leqq |u_\alpha| \quad \text{for each } \alpha.$$

Thus, for each α,

$$|t^{-1}[p_\alpha(x + tu) - p_\alpha(x)] - dp_\alpha(x)u|^p \leqq 2^p |u_\alpha|^p;$$

by dominated convergence, we conclude that

$$\|t^{-1}[P(x + tu) - P(x)] - (dp_\alpha(x)u)\|_p \to 0 \quad \text{as } t \to 0^+,$$

which means that *$dP[x]u$ exists and equals $(dp_\alpha(x)u)$ for each x, $u \in l_p(A)$.*

We now prove that, for $p = 2$, the directional derivative dP satisfies (WSC). Suppose, then, that $\{x^n\} \subseteq I(a, b)$ and $x \in I(a, b)$, that $-u \in l_2(A) \backslash \operatorname{int} S_I(x)$ and $\{u^n\} \subseteq l_2(A)$, and that $\|x^n - x\| \to 0$, $\|u^n - u\| \to 0$ and $t_n \to 0^+$. (We need not assume that $x^n - t_n u^n \in l_2(A) \backslash \operatorname{int} I(a, b)$.) We want to show that

$$(**) \qquad \limsup_{n \to \infty} \langle u^n, dP[x^n - t_n u^n](-u^n) \rangle \leqq \langle u, dP[x](-u) \rangle.$$

We use the coordinate-wise description of dP implicit in (*) to compute the relevant quantities. For instance, $\langle u, dP[x](-u) \rangle = -\sum (u_\alpha)^2$, where the sum is taken over the subset B of those indices $\alpha \in A$ for which x_α satisfies the inequalities described in (*). To compute, for each n, the inner-product term in the left side of (**), note that the α-th term is either zero or $-(u_\alpha^n)^2$, the later holding provided either (letting $y_\alpha^n = x_\alpha^n - t_n u_\alpha^n$) we have $a_\alpha < y_\alpha^n < b_\alpha$ or $a_\alpha < y_\alpha^n = b_\alpha$ (and $-u_\alpha^n < 0$) or $a_\alpha = y_\alpha^n < b_\alpha$ (and $-u_\alpha^n > 0$). The equalities in the latter two sets of inequalities cannot be satisfied: Since $x^n \in I(a, b)$, we have, for instance, $x_\alpha^n \leqq b_\alpha$, so if $-u_\alpha^n < 0$, then $y_\alpha^n < b_\alpha$. Similarly, we necessarily have $y_\alpha^n > a_\alpha$ whenever $-u_\alpha^n > 0$. Thus,

$$\langle u^n, dP[x^n - t_n u^n](-u^n) \rangle = -\sum (u_\alpha^n)^2,$$

where the sum is taken over the subset $B_n \subseteq A$ of all those α for which $a_\alpha < y_\alpha^n < b_\alpha$. Since $\|u^n - u\| \to 0$ and $\|x^n - x\| \to 0$ we have $u_\alpha^n \to u_\alpha$ and $x_\alpha^n \to x_\alpha$ for each α. Consider an index $\alpha \in B$. If $a_\alpha < x_\alpha < b_\alpha$, then since $t_n \to 0^+$, there exists n_α such that $a_\alpha < y_\alpha^n < b_\alpha$ for $n \geqq n_\alpha$, that is, $\alpha \in B_n$ for all sufficiently large n. If $a_\alpha < x_\alpha = b_\alpha$ and $-u_\alpha < 0$, then $-u_\alpha^n < 0$ for all sufficiently large n and $x_\alpha^n \leqq b_\alpha$ for all n, so again, $\alpha \in B_n$ for all

sufficiently large n. The same conclusion holds if $a_\alpha = x_\alpha < b_\alpha$ and $-u_\alpha > 0$. By using these computations and multiplying both sides of (**) by a minus sign, the latter becomes

$$(***) \qquad \sum_{\alpha \in B} (u_\alpha)^2 \leqq \liminf_{n\to\infty} \sum_{\alpha \in Bn} (u_\alpha^n)^2,$$

where $u_\alpha^n \to u_\alpha$ for all α and each $\alpha \in B$ is eventually in B_n. These last two conditions imply that, pointwise on the set A, we have

$$u^2\chi \leqq \liminf_{n\to\infty} (u^n)^2\chi_n,$$

where χ is the characteristic function of the set B and χ_n is the characteristic function of the set B_n. The inequality (***) is now seen to be a consequence of Fatou's lemma.

If, for each $\alpha \in A$, we let $b_\alpha = +\infty$, then we obtain the result for orthogonal polyhedra formulated by McCormick and Tapia [7]. (Actually, they chose an orthogonal system $\{\delta_\alpha: \alpha \in A\}$ in an arbitrary Hilbert space on which to base their polyhedra, but their version is canonically equivalent to the one just described.) One can obviously extend Proposition 3 by using the fact that if T is a linear isometry of $l_2(A)$ onto itself (or onto any other Hilbert space H), then the result is valid for the image $C = T[I(a, b)]$, since $P_C = TP_IT^{-1}$.

We remarked at the end of the introduction that, for orthogonal polyhedra, dP need not have the norm-to-weak continuity property exhibited in Proposition 2(ii) (which is valid for C^2 smooth bodies). This is shown by the following simple example: In l_2, let $C = I(a, b)$ be the positive cone (that is, $a \equiv 0$ and $b \equiv +\infty$); this has empty interior. From the description of dP given in the proof of Proposition 3, one sees readily that if $u \in l_2$ with $u_\alpha < 0$ for all α and if $\{y^n\}$ is a sequence which converges in norm to $x = 0$ and for which $y_\alpha^n > 0$ for all n and α, then for all α, we have $dp_\alpha(y^n)u = u_\alpha$ while $dp_\alpha(x)u = 0$. Thus, $x \in C$, $y^n \in l_2 \backslash \text{int } C$ and $u \in l_2 \backslash S_C(x)$ (this latter holding since $S_C(x) = C$), but $dP[y^n]u = u$ while $dP[x]u = 0$.

Proposition 3 is formulated and proved for $l_p(A)$ rather than for L_p (over a finite measure space, say) partly because this avoids the complications of working with equivalence classes of functions and equivalence classes of measurable sets. The proof given above for the existence of dP goes through without change in any L_p space, while the proof of the (WSC) property can be mimicked to provide a proof in L_2. Mignot [8] has proved the existence of directional derivatives for P_I for sets $I = \{f: a \leqq f \leqq b\}$ in certain Hilbert spaces of analytic functions. He has, in fact, obtained some fundamental results on metric projections and their directional derivatives in the more general context of Hilbert spaces provided with a nonsymmetric inner product. This has allowed him to give a number of applications to questions of optimal control.

5. An example. The following simple two-dimensional example shows that the composite function $g(t)$ may fail to be differentiable precisely at its unique minimum point in $t \geqq 0$, even when the set C has analytically smooth boundary.

Example. Let $C = \{(x, y) \in R^2: x^2 + y^2 \leqq 1\}$, let $f(x, y) = x^2y$ and let $\mathbf{x}^0 = (\frac{1}{2}, 0) \in C$. As usual, for $t \geqq 0$ define

$$g(t) = f(P_C[\mathbf{x}^0 - t\nabla f(\mathbf{x}^0)]).$$

Then $g(t)$ attains its minimum at $t = 2\sqrt{3}$, but is not differentiable there.

Proof. Since $\nabla f(x, y) = (2xy, x^2)$, we have $\mathbf{x}^0 - t\nabla f(\mathbf{x}^0) = (\frac{1}{2}, -t/4)$. For $0 \leqq t \leqq 2\sqrt{3}$, this is in C (where P_C is the identity), so $g(t) = -t/16$. For points x outside of C, we have $P_C(\mathbf{x}) = \mathbf{x}/\|\mathbf{x}\|$, so (with a little computation) we see that $g(t) = -4t(4 + t^2)^{-3/2}$ if $t \geqq 2\sqrt{3}$. It is readily calculated that $g'(t) > 0$ for $t \geqq 2\sqrt{3}$, while $g'(t) = -1/16$ for

$0 \leqq t \leqq 2\sqrt{3}$. (We take the appropriate one-sided derivatives at $t = 2\sqrt{3}$.) Thus, g has its minimum at $2\sqrt{3}$ but is not differentiable at this point. Note that the boundary of C is analytic, as is f; it is the nondifferentiability of P at the boundary which causes problems.

The referee has called our attention to the interesting paper of Gafni and Bertsekas [4], which presents a different and more complicated version of the gradient projection method. The complications are offset by the fact that any limit point of the sequence $\{x_n\}$ is a constrained stationary point, for *arbitrary* closed convex sets C. Briefly described, the differences are as follows: First, in the definition of x_{n+1}, the negative gradient $-\nabla f(x_n)$ is replaced by a vector g_n which is a somewhat complicated perturbed version of the latter. Second, an Armijo-like steplength rule is used which guarantees that $f(x_{n+1}) < f(x_n)$. There is considerable latitude in the choice of g_n: It is easy to construct specific examples for which Curry's steplength converges to an optimum in one iteration, while their method will either take an infinite sequence of iterations or, if g_1 is chosen carefully, a single iteration. They show that for the case when C is a polyhedral cone in a finite dimensional space, ∇f is locally Lipschitzian and f has a strict local minimum, then it is possible to guarantee superlinear convergence to the minimum point.

AN RKH SPACE APPROACH TO STATE FEEDBACK CONTROL FOR A CLASS OF LINEAR STOCHASTIC SYSTEMS*

R. B. MINTON† AND J. A. RENEKE‡

Abstract. Necessary and sufficient conditions are given for the solution of a linear-quadratic stochastic control problem, with the optimal control written explicitly as a function of the output. System dynamics are of the state-space form $h = \alpha Ch + z + u$, $h(0) = 0$, where h is an observable output, α is a constant matrix, C represents antiderivative, z is a random disturbance (e.g., Wiener process), and the control function $u = Dh$ for some Volterra integral operator D. A standard quadratic cost functional is defined in terms of a Hellinger integral, and the corresponding reproducing kernel Hilbert space is utilized to solve directly for the regulator

Key words. stochastic control theory, state-space system, reproducing kernel, Hellinger integral

AMS(MOS) subject classifications. 49, 60, 93

1. Introduction. In a linear-quadratic-Gaussian control problem, the goal is to find a control function which minimizes a quadratic cost functional subject to linear system dynamics with Gaussian noise and specified initial and terminal conditions. As discussed below, classical results in the literature on linear-quadratic-Gaussian problems require the solution of a matrix Riccati differential equation for complete determination of the optimal control law. In this paper, a necessary condition for solution of a general problem is found which gives the control function as an explicit, and uncomplicated, function of the output.

The function and operator spaces utilized in this paper allow consideration of a general linear system $h = Bh + u + z$ on a finite time interval $[-r, T]$, where B is a Volterra integral operator possibly containing delay and state-dependent noise terms, u is the control function to be determined, and z is a random disturbance. However, to facilitate the introduction of the "operator approach" being used in this paper, system dynamics will be restricted to the state-space format

$$h(t) = \int_0^t \alpha h(s)\, ds + u(t) + z(t), \qquad t \in [0, T]. \tag{1.1}$$

Here, h is an n-dimensional, directly observable output with $h(0) = 0$, and α is a constant $n \times n$ matrix. The control u is required to have the form

$$u(t) = [Dh](t), \tag{1.2}$$

where D is a Volterra integral operator. The disturbance $z(t)$ is a mean-zero second-order stochastic process with independent increments (e.g., n-dimensional Brownian motion). The cost functional J to be minimized has a standard form

$$J(u, h) = \frac{1}{2} E \int_0^T \left\{ c_1 h^*(t) h(t) + c_2 \frac{du^*}{dt}(t) \frac{du}{dt}(t) \right\} dt + \frac{1}{2} Eh^*(T) h(T), \tag{1.3}$$

where c_1 and c_2 are scalar constants and E denotes the expectation operator. The derivative du/dt appears in the cost functional because the control u is being added to the integral equation (1.1) rather than to the corresponding differential form (1.4).

A problem closely related to the control problem (1.1)-(1.3) is the so-called "linear regulator" problem. In this problem, system dynamics is described by

$$dx = [A(t)x(t) + B(t)u(t)]\,dt + \sigma(t)\,dW, \tag{1.4}$$

where $W(t)$ is a Wiener process. Solutions of (1.4) are interpreted as solutions of the corresponding stochastic (Ito) integral equation, since W is not of bounded variation. The cost functional to be minimized is

$$J = E\int_0^T \{x^*(t)M(t)x(t) + u^*(t)N(t)u(t)\}\,dt + Ex^*(T)Dx(T), \tag{1.5}$$

for positive definite matrices M, N, and D. This functional is similar to, but more general than, the cost functional (1.3). The optimal control can be found by the method of dynamic programming [1]. For the relatively simple problem (1.4)-(1.5) the partial differential equation describing the dynamic programming solution implies that the optimal control is given by

$$u(t) = -N(t)^{-1}B^*(t)K(t)x(t), \tag{1.6}$$

where $K(t)$ satisfies the matrix Riccati equation

$$K(t) = -K(t)A(t) - A^*(t)K(t) + K(t)B(t)N(t)^{-1}B^*(t)K(t) - M(t), \tag{1.7}$$
$$K(T) = D.$$

Because K depends on a terminal condition $K(T) = D$, the control (1.6) is not an admissible control in the sense of (1.2). To compute the control (1.6), it is necessary to solve the differential equation (1.7) separately for each t. Some aspects of the relationship between the above result and the result obtained in this paper are examined in an example presented in § 5.

The necessity of solving the auxiliary equation (1.7) provides part of the motivation for reworking the linear regulator problem. The control problem (1.1)-(1.3) is stated in terms of carefully chosen spaces of integral operators and the reproducing kernel Hilbert space induced by a Hellinger integral, and a necessary condition for the optimal control is found directly. These nonstandard spaces also allow consideration of control problems which are not currently in the literature, thus providing further motivation for the study of this approach. Similar spaces have been successfully employed to solve various problems involving deterministic hereditary systems, including system identification [2], parameter estimation [3], optimal control on a finite interval [4], and control of large-scale systems [5].

The spaces of integral operators are defined in § 2 of this paper. A Hellinger integral and its associated Hilbert space and reproducing kernel are introduced in § 3. The control problem (1.1)-(1.3) is solved in § 4. A necessary and sufficient condition for the minimum is given in Theorem 4.1, as well as a necessary condition giving the form of the optimal control. An example is given in § 5 to compare the controls from Theorem 4.1 and from the linear regulator problem.

2. Properties of the operator spaces. The following notation is used throughout the paper. Some definitions are stated in more generality than is required in this paper; in these cases, comments will be given to indicate the nature of the generality.

The underlying probability space is (Ω, F, P), where Ω is a set, F is a σ-algebra of subsets of Ω, and P is a probability measure on (Ω, F). The space $L_2(\Omega)$ contains all square-integrable (with respect to P) functions on Ω. The space $L_{2,n}(\Omega)$ of n-dimensional random variables consists of all functions from Ω into n-space for which

each component belongs to $L_2(\Omega)$. An inner product of elements $f(t)$ and $g(s)$ of $L_{2,n}(\Omega)$ is defined by

$$\langle f(t), g(s)\rangle = \int_\Omega \{f_1(t)g_1(s)+\cdots+f_n(t)g_n(s)\}\, dP,$$

where f_i and g_i are the components of $f(t)$ and $g(s)$, respectively. The corresponding norm satisfies $|f(t)|^2 = \langle f(t), f(t)\rangle$. The expected value of an element x of $L_{2,n}(\Omega)$ is $Ex = \int_\Omega x\, dP$; here, as elsewhere in the paper, Ω-dependence is suppressed in the notation.

The finite time interval to be considered is $S = [0, T]$, where T is a fixed positive constant. The space G of second-order n-dimensional stochastic processes consists of all functions from S into $L_{2,n}(\Omega)$ which are L_2-continuous in each component. The subspace G_0 of G consists of all functions $f \in G$ such that $f(0) = 0$ and $Ef(t) = 0$ for each $t \in S$. The subspace G_z of G_0 consists of all functions $z \in G_0$ such that z has independent increments: $z(t+\Delta t) - z(t)$ is stochastically independent of $z(s)$ for each $0 \leqq \Delta t \leqq T - t$ and $0 \leqq s \leqq t \leqq T$.

The disturbance z in the system equation (1.1) is taken to be a fixed but arbitrary element of G_z. The family of σ-algebras $\{F_t\}_{t\in S}$ corresponding to z is a fixed set of σ-algebras such that $F_s \subset F_t \subset F$ whenever $0 \leqq s \leqq t \leqq T$, and each F_t contains the σ-algebra generated by $\{z(s): 0 \leqq s \leqq t\}$. A canonical example is $z(t) = W(t)$, a Wiener process, and $F_t = \sigma(W(s): 0 \leqq s \leqq t)$. The conditional expectation of $x \in L_{2,n}(\Omega)$ relative to the σ-algebra F_t is denoted by $E(x|F_t)$. A function $f \in G$ is said to be nonanticipating if $E(f(s)|F_t) = f(s)$ whenever $0 \leqq s \leqq t \leqq T$.

For $f \in G$ and $v \in S$, the pseudonorm N_v on G is defined by

$$N_v(f) = \sup\{|f(x)|: 0 \leqq x \leqq v\}.$$

For $f \in G$ and $v \in S$, the projection $P_v f \in G$ is defined by

$$[P_v f](x) = \begin{cases} f(x), & 0 \leqq x \leqq v, \\ f(v), & v \leqq x \leqq T. \end{cases}$$

The above pseudonorms and projections are related by the identity $N_v(f) = N_T(P_v f)$ for each $f \in G$ and $v \in S$.

Integrations will be performed with respect to the measure $k(t) = 1 + t$, so that $dk(t) = dt$. However, all results in this paper hold with k being an arbitrary right continuous increasing function on S with $k(0) = 1$. The notation $k(t) = 1 + t$ will prove useful for writing formulas.

The operator space $\mathscr{A}$ consists of all functions $A: G \to G$ for which the following hold:

(i) A is linear;
(ii) $[Af](0) = f(0)$ for each $f \in G$;
(iii) A is deterministic: $EAf = AEf$ for each $f \in G$;
(iv) there exists a constant $c = c(A)$ such that if $f \in G$ and $0 \leqq u \leqq v \leqq T$,

$$|[Af](v) - f(v) - [Af](u) + f(u)| \leqq c \int_u^v N_t(f)\, dt.$$

The operator space $\mathscr{B}$ consists of all functions $B: G \to G$ for which the following hold:

(i) B is linear;
(ii) $[Bf](0) = 0$ for each $f \in G$;
(iii) B is deterministic: $EBf = BEf$ for each $f \in G$;

(iv) there exists a constant $c = c(B)$ such that if $f \in G$ and $0 \leqq u \leqq v \leqq T$,

$$|[Bf](v) - [Bf](u)| \leqq c \int_u^v N_t(f)\, dt.$$

The inequality $\int_u^v N_t(f)\, dt \geqq 0$ implies that $\mathscr{A}$ and $\mathscr{B}$ are nonempty; in particular, $0 \in \mathscr{B}$ and $I \in \mathscr{A}$, where 0 and I are the zero and identity operators on G, respectively. Another basic element of $\mathscr{B}$ is the operator C given by

$$[Cf](t) = \int_0^t f(s)\, ds, \qquad f \in G. \tag{2.1}$$

As will be shown in § 3, C has an adjoint C^*, with respect to the inner product space induced by a Hellinger integral, given by

$$[C^*f](t) = k(t)f(T) - f(0) - \int_0^t f(s)\, ds. \tag{2.2}$$

Since $[C^*f](0) = f(T) - f(0)$, C^* is not an element of $\mathscr{A}$ or $\mathscr{B}$. However, the quantity $k(t)[C^*Cf](0) - [C^*Cf](t)$ equals $[CCf](t)$, and $C^2 \in \mathscr{B}$ follows from part (vii) of Theorem 2.2. For similar operator spaces defined on $S_r = [-r, T]$, a fundamental element of $\mathscr{B}_r$ is the delay operator B_r given by

$$[B_r f](t) = \begin{cases} 0, & t \leqq 0, \\ \displaystyle\int_0^t b(s) f(s - r)\, ds, & t > 0, \quad f \in G. \end{cases}$$

Delay operators are not considered in this paper.

More examples of elements of $\mathscr{A}$ and $\mathscr{B}$ will be given in § 5. The most important tools for understanding the scope and nature of $\mathscr{A}$ and $\mathscr{B}$ are the fundamental relationship given in Theorem 2.1, and the algebraic structure detailed in Theorem 2.2. Using these results and the Laplace transform technique illustrated in § 5, many elements of $\mathscr{A}$ and $\mathscr{B}$ of practical interest can be computed.

THEOREM 2.1. *If $A \in \mathscr{A}$ and $B \in \mathscr{B}$, then the following hold*:

(i) *$I - B$ is* 1-1 *and onto G, and $(I - B)^{-1} \in \mathscr{A}$*;

(ii) *A is* 1-1 *and onto G, $A^{-1} \in \mathscr{A}$, and $I - A^{-1} \in \mathscr{B}$.*

The proof of Theorem 2.1 is given in § 7. In that proof, the inverse A of $I - B$ is constructed as

$$A = (I - B)^{-1} = I + B + B^2 + \cdots = \sum_{n=0}^{\infty} B^n. \tag{2.3}$$

On appropriate function spaces, (2.3) is identical to the series representation of Bharucha-Reid [3] for Volterra integral operators.

The two parts of Theorem 2.1 imply a 1-1 correspondence between elements of $\mathscr{A}$ and $\mathscr{B}$. The spaces are further related by a powerful algebraic structure, part of which is detailed in the following result.

THEOREM 2.2. *Let AB denote the composition of A and B: $(AB)f = A(Bf)$. If A, A_1, $A_2 \in \mathscr{A}$ and B, B_1, $B_2 \in \mathscr{B}$, then the following hold*:

(i) $-B \in \mathscr{B}$; (iv) $BA \in \mathscr{B}$; (vii) $B_1 B_2 \in \mathscr{B}$;

(ii) $A + B \in \mathscr{A}$; (v) $AB \in \mathscr{B}$; (viii) $P_t B \in \mathscr{B}$ *for* $t \in S$;

(iii) $B_1 + B_2 \in \mathscr{B}$; (vi) $A_1 A_2 \in \mathscr{A}$; (ix) *$\mathscr{A}$, $\mathscr{B}$ are convex.*

The proof of Theorem 2.2 is given in § 7. Theorems 2.1 and 2.2 will be used

extensively in solving equations. For example, the equation

$$x = y + [-B_1 + (I - B_2)^{-1}A]B_1 x$$

has the unique solution, as guaranteed by Theorems 2.1 and 2.2,

$$x = (I - [-B_1 + (I - B_2)^{-1}A]B_1)^{-1} y.$$

Although it is not a representation theorem, the following result provides some insight into the structure of elements of $\mathcal{A}$ and $\mathcal{B}$.

THEOREM 2.3. *Elements of $\mathcal{A}$ and $\mathcal{B}$ are causal; that is, if $f \in G$, $A \in \mathcal{A}$, and $B \in \mathcal{B}$, then $[Bf](t) = [BP_t f](t)$ and $[Af](t) = [AP_t f](t)$.*

Proof. Let $t \in S$ and $f \in G$ be fixed. It is first shown that $P_t B P_t = P_t B$. Clearly, $[P_t B P_t f](0) = [P_t B f](0) = 0$. Suppose that $0 = s_0 < s_1 < \cdots < s_q = t < \cdots < s_N = T$, and let $g = f - P_t f$. Consider $d = |[P_t B g](s_{p+1}) - [P_t B g](s_p)|$. If $p \geqq q$, then $s_{p+1} > s_p \geqq t$ and

$$d = |[Bg](s_{p+1}) - [BG](s_p)| \leqq c_B \int_{s_p}^{s_{p+1}} N_u(g)\, du = 0,$$

since $g(u) = 0$ for $u \leqq t$. Thus, $P_t B P_t = P_t B$, and

$$[Bf](t) = [P_t B f](t) = [P_t B P_t f](t) = [BP_t f](t).$$

Similarly, $P_t A P_t = P_t A$, and $[Af](t) = [AP_t f](t)$.

The above result indicates that the integral-like operators A and B do not use "future" values of their arguments. This property falls short of implying that A and B preserve the nonanticipating property. The operator D_N given in Lemma 4.1 indicates the type of operator that might not preserve nonanticipating functions.

3. The reproducing kernel Hilbert space. The types of integrals known as "Hellinger integrals" were introduced in 1907 in the dissertation of E. D. Hellinger [5]. Many properties of Hellinger integrals, including comparisons of spaces of Hellinger-integrable functions with the spaces of absolutely continuous functions and the functions of bounded variation, are given in [3] and [7], and reproducing kernels on spaces of Hellinger-integrable functions are introduced in [3] and [9].

An inner product space $\{G_H, Q\}$ of Hellinger-integrable functions is defined as follows, where $k(t) = 1 + t$.

The space G_H consists of all functions $f \in G$ for which there exists a constant $b = b(f)$ such that for each partition $\{s_p\}_{p=0,N}$ of $[0, T]$,

$$\sum_{p=1}^{N} |f(s_p) - f(s_{p-1})|^2 / (s_p - s_{p-1}) \leqq b.$$

The smallest such b is the Hellinger integral of f with respect to k, and is denoted $\int_0^T |df|^2 / dk$. The subspace G_{HO} consists of elements of $G_H \cap G_0$.

The functional Q is defined on $G_H \times G_H$ by

$$Q(f, g) = \langle f(0), g(0) \rangle + \int_0^T \langle df, dg \rangle / dk,$$

where the integral is the limit, through refinement of partitions, of the sums

$$\sum_{p=1}^{N} \langle f(s_p) - f(s_{p-1}), g(s_p) - g(s_{p-1}) \rangle / (s_p - s_{p-1}).$$

The corresponding norm is denoted N_H.

It is easy to verify that $\{G_H, Q\}$ is an inner product space. Furthermore, it is complete [3]. Elements of G_H are (in the mean-square sense) absolutely continuous, and G_H is dense with respect to the variation norm in the space of absolutely continuous functions [3]. The similarity of the N_H norm and a Sobolev space norm should be noted; in fact, with $k(t) = 1 + t$, G_H can be thought of as a mean-square Sobolev space.

A fundamental issue to be resolved is the effect of elements of $\mathscr{A}$ and $\mathscr{B}$ on elements of G and G_H. As seen in Theorem 2.1, A and $I - B$ map G onto G. The relationship of $\mathscr{A}$ and $\mathscr{B}$ to G_H is given in the following result.

THEOREM 3.1. *If $f \in G$, $B \in \mathscr{B}$, and $A \in \mathscr{A}$, then $Bf \in G_H$ and A maps G_H onto G_H.*

Proof. Let $0 = s_0 < s_1 < \cdots < s_N = T$, and let c be the constant corresponding to $B \in \mathscr{B}$. Then

$$\sum_{p=1}^{N} |[Bf](s_p) - [Bf](s_{p-1})|^2/(s_p - s_{p-1})$$

$$\leqq \sum_{p=1}^{N} c^2 \int_{s_{p-1}}^{s_p} N_t(f)\, dt^2/(s_p - s_{p-1})$$

$$\leqq c^2 N_T^2(f)\, T.$$

Thus, $Bf \in G_H$. Now, let $A = (I - B)^{-1}$, $g \in G_H$ be arbitrary, and $f = Ag$. Then $f - Bf = g$ and $f = g + Bf$. Since $g \in G_H$ and $Bf \in G_H$, it holds that $f \in G_H$. To show that A is onto G_H, let $f \in G_H$ be arbitrary and call $g = f - Bf$. Clearly, $g \in G_H$ and $f = Ag$.

A classical example of a reproducing kernel is the Green's function of a self-adjoint ordinary differential equation. For a discussion of the development and properties of reproducing kernels, see Aronszajn [1]. A reproducing kernel is defined as follows.

A function K from $S \times S$ into the linear transformations of $L_{2,n}(\Omega)$ is a reproducing kernel for $\{G_H, Q\}$ if for every $t \in S$, $x \in L_{2,n}(\Omega)$, and $f \in G_H$, the following hold:

(i) $K[\cdot, t]x \in G_H$;

(ii) $\langle f(t), x\rangle = Q(f, K[\cdot, t]x)$.

It is now shown that a reproducing kernel for $\{G_H, Q\}$ is given by

$$K(u, v) = \{\min(u, v)\}I, \tag{3.1}$$

where I is the identity transformation of $L_{2,n}(\Omega)$. If $x \in L_{2,n}(\Omega)$ and $t \in S$, it is clear that $K[\cdot, t]x \in G_H$. Let $f \in G$, $t \in S$, and $x \in L_{2,n}(\Omega)$ be arbitrary. Then

$$Q(f, K[\cdot, t]x) = \langle f(0), x\rangle + \int_S \langle df, d(K[\cdot, t]x)\rangle/dk$$

$$= \langle f(0), x\rangle + \int_0^t \langle df, x\, dk\rangle/dk$$

$$= \langle f(0), x\rangle + \int_0^t \langle df, x\rangle$$

$$= \langle f(t), x\rangle.$$

The reproducing kernel is now used to compute the adjoint C^* of C. Let $f \in G_H$ and

$g \in G_H$ be arbitrary. Since $[Cf](0) = 0$, it follows that

$$\begin{aligned} Q(Cf, g) &= \int_0^T \langle d(Cf), dg\rangle / dk = \int_0^T \langle f, dg\rangle \\ &= \langle f(T), g(T)\rangle - \langle f(0), g(0)\rangle - \int_0^T \langle df, g\rangle \\ &= Q(f, K[\cdot, T]g(T) - K[\cdot, 0]g(0) - Cg) \\ &= Q(f, C^*g) \end{aligned}$$

where $[C^*g](t) = k(t)g(T) - g(0) - \int_0^t g(s)\, ds$.

Three lemmas which will be needed to solve the control problem of § 4 are now presented. The first two lemmas are versions of the Hahn-Banach and Riesz representation theorems [11], respectively. The proof of Lemma 3.3. illustrates some of the power of the reproducing kernel.

LEMMA 3.1. *Let $L_0(\Omega)$ be the set of all $x \in L_{2,n}(\Omega)$ such that $Ex = 0$, and let $\{h_p\}_{p=1,N}$ and $\{c_p\}_{p=1,N}$ be sets of elements of $L_0(\Omega)$ such that the h_p's are linearly independent. Then there exists a continuous linear transformation M of $L_{2,n}(\Omega)$ such that $EM = ME$ and $Mh_p = c_p$ for $p = 1, \cdots, N$.*

LEMMA 3.2. *If λ is a continuous linear functional on G, then there exists a function λ of bounded variation (in S) such that for $f \in G$, $\lambda(f) = \int_S \langle f, d\lambda\rangle$.*

LEMMA 3.3. *If $f \in G_H$, $\lambda \in G$ has bounded variation, and $\lambda(T) = 0$, then $\int_S \langle f, d\lambda\rangle = Q(f, C_0\lambda)$, where $[C_0\lambda](t) = \lambda(0) - \int_S \lambda(s)\, ds$.*

Proof. Let $x \in L_{2,n}(\Omega)$, $t \in S$, and $f = K[\cdot, t]x$. Then integration by parts gives

$$\begin{aligned} \int_S \langle f, d\lambda\rangle &= \langle f(T), \lambda(T)\rangle - \langle f(0), \lambda(0)\rangle - \int_S \langle df, \lambda\rangle \\ &= -\langle K[0, t]x, \lambda(0)\rangle - \int_S \langle x dK[\ , t], \lambda\rangle \\ &= -\langle x, \lambda(0)\rangle - \int_S \langle x dk, \lambda\rangle \\ &= -\langle x, \lambda(0)\rangle - \left\langle x, \int_S \lambda(t)\, dt \right\rangle \\ &= Q(f, C_0\lambda). \end{aligned}$$

Thus, the conclusion holds for $f = K[\ , t]x$. For arbitrary $f \in G_H$, the theory of reproducing kernel Hilbert spaces [10] gives $f = \lim_{i\to\infty} f_i$, where f_i, where $f_i = \sum_{p=0}^{N(i)} K[\ , t_i(p)]x_i(p)$ where $x_i \in L_{2,n}(\Omega)$ and the partition $\{t_{i+1}(p)\}_{p=0,N(i+1)}$ is a refinement of the partition $\{t_i(p)\}_{p=0,N(i)}$. Since $\int_S \langle f_i, d\lambda\rangle = Q(f_i, C_0\lambda)$ for each i, it follows that

$$\int_S \langle f, d\lambda\rangle = \lim_{i\to\infty} \int_S \langle f_i, d\lambda\rangle = \lim_{i\to\infty} Q(f_i, C_0\lambda) = Q(f, C_0\lambda),$$

and the proof of the lemma is complete.

4. The control problem. In this section, a linear-quadratic stochastic control problem is stated and a necessary and sufficient condition is found for its solution. System

dynamics is given by the state-space form

$$h(t) = \int_0^t \alpha h(s)\, ds + u(t) + z(t) = \alpha[Ch](t) - + u(t) + z(t),$$

where α is an $n \times n$ constant matrix. The output h can be measured. State-independent noise in any part of the system is absorbed into the disturbance term z. It is assumed that $z \in G_z$, so that z could be Gaussian (i.e., z equals a multiple of a Wiener process on $[0, T]$), but is not required to be. The general nature of z allows a specific control problem to be formulated in terms of a "natural" model. That is, the state vector (and, in particular, its dimension) can be chosen without regard to the resulting form of the noise term, as long as the properties of G_z are retained. This modeling issue is discussed in more detail in § 5.

The objective of the control problem is to choose a feedback control $u = Dh$ for some $D \in \mathcal{B}$, such that a quadratic cost functional given by

$$\begin{aligned} J(D, h) &= \tfrac{1}{2}c_1 N_H^2(Dh) + \tfrac{1}{2}c_2 N_H^2(Ch) + \tfrac{1}{2}|h(T)|^2 \\ &= \tfrac{1}{2}E\left\{\int_0^T c_1 |du/dt|^2 + c_2 |h(t)|^2\, dt + |h(T)|^2\right\} \end{aligned}$$

is minimized.

To effectively apply the Lagrange multiplier theorem to this problem, it is necessary to have the following result.

LEMMA 4.1. *If $B \in \mathcal{B}$, $z \in G_z$, and $h = Bh + z$, then $\{f = Dh\colon D \in \mathcal{B}\}$ is dense in G_{HO}.*

Proof. By Theorem 3.1, each $f = Dh$ is in G_H, and since $f = DAz$, $Ef = 0$. Thus, $Dh \in G_{HO}$. Let $0 = t_0 < t_1 < \cdots < t_N = T$, and let $\{c_p\}_{p=1,N}$ be any sequence of elements of $L_0(\Omega)$. By Lemma 3.1, there exists a continuous linear transformation M of $L_{2,n}(\Omega)$ such that $Mh(t_p) = c_p$ for $p = 1, \cdots, N$. For this M, define a linear transformation D_N on G_H by

$$[D_N f](t) = \begin{cases} 0, & t = 0, \\ (t - t_{p-1})Mf(t_{p-1}) + [D_N f](t_{p-1}), & t_{p-1} < t \leqq t_p. \end{cases}$$

Note that $[D_N h](0) = [D_N h](t_1) = 0$, $[D_N h](t_2) = (t_2 - t_1)c_1$, etc. We show that $D_N \in \mathcal{B}$: if $t_{p-1} \leqq u \leqq v \leqq t_p$, then

$$|[D_N f](v) - [D_N f](u)| = |(v-u)Mf(t_{p-1})| \leqq (v-u)\|M\| N_{t_{p-1}}(f) \leqq \|M\| \int_u^v N_t(f)\, dt,$$

and $D_N E = E D_N$ follows from $EM = ME$. By definition, $D_N h$ is a K-polygon in G_{HO}: a K-polygon is any function that can be written in the form $\sum_{p=0}^{N} K[t, s_p]x_p$, where $\{x_p\}$ is a sequence of random variables in $L_{2,n}(\Omega)$, and $\{s_p\}$ is any sequence of numbers in $(0, T]$. As shown in [2], the set of K-polygons is dense in G_{HO}. Since N, $\{t_p\}$, and $\{c_p\}$ are arbitrary, $\{f = Dh\colon D \in \mathcal{B}\}$ contains all K-polygons in G_{HO}, and hence is dense in G_{HO}.

A complete statement of the control problem is now presented, followed by the main result of this paper. The control function is written explicitly as $u = Dh$ for some D.

Problem P. Let α be a constant $n \times n$ matrix, and let $z \in G_z$ be arbitrary but fixed. Let Γ be all pairs $(D, h) \in \mathcal{B} \times G_0$, and define a functional J on Γ by

$$J(D, h) = \tfrac{1}{2}c_1 N_H^2(Dh) + \tfrac{1}{2}c_2 N_H^2(Ch) + \tfrac{1}{2}|h(T)|^2$$

for fixed positive constants c_1 and c_2. Find the pair (D, h) that minimizes J over Γ subject to $h = \alpha Ch + Dh + z$.

THEOREM 4.1. *A necessary and sufficient condition for* $(D, h) \in \Gamma$ *to solve Problem* P *is that*

$$(I - P_0)\{c_2 C^* Ch + kh(T) + c_1(I - \alpha^* C^*)Dh\} = 0 \tag{4.1}$$

where C^* *is the adjoint of* C *in* $\{G_H, Q\}$ *and* α^* *is the transpose of* α. *Furthermore, if* (4.1) *holds, then*

$$Dh = (c_2/c_1)[I + \alpha^* C]^{-1} C^2 h. \tag{4.2}$$

Note that the expression (4.2) *is independent of the end-time* T.

Proof. It is first shown that (4.1) is necessary. The variation of the cost functional $J(D, h)$ in the direction of $(D, h) \in \Gamma$ is given by

$$\delta J(D, h; \tilde{D}, \tilde{h}) = c_1 Q(\tilde{D}h + D\tilde{h}, Dh) + c_2 Q(C\tilde{h}, Ch) + \langle \tilde{h}(T), h(T) \rangle.$$

The constraint is $K_1(D, h) = h - \alpha Ch - Dh - z = 0$, with variation $\delta K_1 = \tilde{h} - \alpha C\tilde{h} - \tilde{D}h - D\tilde{h}$. The Lagrange multiplier thorem [12] gives the following necessary condition for a minimizing pair (D, h): there exists a continuous linear functional $\tilde{\lambda}$ defined on G_0 such that for every $(\tilde{D}, \tilde{h}) \in \Gamma$,

$$c_1 Q(\tilde{D}h + D\tilde{h}, Dh) + c_2 Q(C\tilde{h}, Ch) + \langle \tilde{h}(T), h(T) \rangle + \tilde{\lambda}(\tilde{h} - \alpha C\tilde{h} - \tilde{D}h - D\tilde{h}) = 0.$$

By Lemmas 3.2 and 3.3, there exists a function λ_1 of bounded variation such that

$$\tilde{\lambda}(\tilde{h} - \alpha C\tilde{h} - \tilde{D}h - D\tilde{h}) = Q(\tilde{h} - \alpha C\tilde{h} - \tilde{D}h - \tilde{D}h, C_0\lambda_1) = Q(\tilde{h} - \alpha C\tilde{h} - \tilde{D}h - D\tilde{h}, \lambda)$$

where $\lambda = (I - P_0)C_0\lambda_1$. Furthermore, if $\tilde{h} \in G_H$, then

$$\langle \tilde{h}(T), h(T) \rangle = Q(\tilde{h}, K(\ , T)h(T)).$$

Thus, the necessary condition becomes: there exists $\lambda \in G_H$ such that

$$\begin{aligned} c_1 Q(\tilde{D}h + D\tilde{h}, Dh) + c_2 Q(C\tilde{h}, Ch) + Q(\tilde{h}, K(\ , T)h(T)) \\ + Q(\tilde{h} - \alpha C\tilde{h} - \tilde{D}h - D\tilde{h}, \lambda) = 0 \end{aligned} \tag{4.3}$$

for each $(\tilde{D}, \tilde{h}) \in \mathcal{B} \times \mathcal{G}_{HO}$. Letting $\tilde{h} = 0$, (4.3) implies that

$$Q(\tilde{D}h, c_1 Dh) - Q(\tilde{D}h, \lambda) = 0, \qquad \tilde{D} \in \mathcal{B}. \tag{4.4}$$

By Lemma 3.1, it follows that $c_1 Dh = \lambda$, since $[Dh](0) = \lambda(0) = 0$. Letting $\tilde{D} = 0$, (4.3) implies that

$$Q(\tilde{h}, c_1 D^* Dh) + Q(\tilde{h}, c_2 C^* Ch) + Q(\tilde{h}, K(\ , T)h(T)) + Q(h, (I - \alpha C - D)^* \lambda) = 0, \qquad \tilde{h} \in G_{HO}.$$

It follows that

$$(I - P_0)\{c_1 D^* Dh + c_2 C^* Ch + K(\ , T)h(T) + (I - \alpha^* C^* - D^*)\lambda\} = 0. \tag{4.5}$$

Combining (4.4) and (4.5) and setting $\lambda = c_1 Dh$ gives the desired equation (4.1). We now proceed to derive (4.2). Using the representations (2.2) and (3.1) of C^* and K, respectively, it is clear that (4.1) is equivalent to

$$c_2(k-1)[Ch](T) - c_2 C^2 h + (k-1)h(T) + \lambda - \alpha^*(k-1)\lambda(T) + \alpha^* C\lambda = 0.$$

Calling $\gamma = -c_2[Ch](T) - h(T) - h(T) + \alpha^*\lambda(T)$, it follows that

$$\lambda + \alpha^* C\lambda = c_2 C^2 h + (k-1)\gamma,$$

and $\alpha^* C \in \mathcal{B}$ implies that

$$\lambda = (I + \alpha^* C)^{-1}(c_2 D^2 h + (k-1)\gamma). \tag{4.6}$$

Intuitively, $\lambda = c_1 Dh$ for some $D \in \mathcal{B}$ implies that $\gamma = 0$. This is formalized below. Since $\lambda = c_1 Dh$, (4.6) and the constraint $h = (I - \alpha C - D)^{-1} z$ imply that

$$(I + \alpha^* C)^{-1}(k-1)\gamma = c_1 Dh - (I + \alpha^* C)^{-1} c_2 C^2 h = D_1 h = Bz,$$

where D_1 and B are the appropriately defined elements of $\mathcal{B}$. Solving for γ, we find that

$$\gamma = \frac{[(I + \alpha^* C)Bz](t)}{t}, \qquad t \in (0, T].$$

Taking a limit of the above equation as $t \to 0$, and observing that $(I + \alpha^* C)^{-1}(k-1)\gamma$, and hence Bz, is differentiable, l'Hôpital's rule gives

$$= \lim_{t \to 0} \frac{[(I + \alpha^* C)Bz](t)}{t} = \lim_{t \to 0} \{[Bz]'(t) + \alpha^* [Bz](t)\}$$

$$= [Bz]'(0) = \lim_{\varepsilon \to 0} \frac{[Bz](\varepsilon) - [Bz](0)}{\varepsilon} = \lim_{\varepsilon \to 0} \frac{[Bz](\varepsilon)}{\varepsilon}.$$

If c is the constant corresponding to $B \in \mathcal{B}$, then

$$\left| \frac{[Bz](\varepsilon)}{\varepsilon} \right| \leqq \frac{c}{\varepsilon} \int_0^{\varepsilon} N_t(z)\, dt \leqq c N_\varepsilon(z) \to 0 \quad \text{as } \varepsilon \to 0.$$

Thus, $\gamma = 0$, and (4.2) follows from (4.6). Finally, we show that (4.1) is sufficient. Clearly, (4.1) implies that (4.3) holds with $\lambda = c_1 Dh$. Suppose that (D, h) satisfies (4.3) with $h = \alpha C h + Dh + z$, and that $(\hat{D}, \hat{h}) \in \Gamma$ satisfies $\hat{h} = \alpha C \hat{h} + \hat{D}\hat{h} + z$. Then $h - \hat{h} \in G_{HO}$, and

$$0 = c_1 Q(\hat{D}h + D(h - \hat{h}), Dh) + c_2 Q(C(h - \hat{h}), Ch) + O(h - \hat{h}, kh(T))$$
$$+ Q(h - \hat{h} - \alpha C(h - \hat{h}) - \hat{D}h - D(h - \hat{h}), c_1 Dh).$$

Since $h - \hat{h} - \alpha C(h - \hat{h}) = Dh - \hat{D}\hat{h}$,

$$0 = c_1 Q(\hat{D}h + D(h - \hat{h}), Dh) + c_2 Q(C(h - \hat{h}), Ch) + Q(h - \hat{h} kh(T))$$
$$+ Q(-\hat{D}\hat{h} - \hat{D}h + D\hat{h}, c_1 Dh)$$
$$= c_1 N_H^2(Dh) + c_2 N_H^2(Ch) - c_1 Q(\hat{D}\hat{h}, Dh) - c_2 Q(C\hat{h}, Ch) + Q(h - \hat{h}, kh(T)).$$

Thus,

$$0 \leqq \tfrac{1}{2} c_1 N_H^2(\hat{D}\hat{h} - Dh) + \tfrac{1}{2} c_2 N_H^2(C\hat{h} - Ch) + \tfrac{1}{2} |\hat{h}(T) - h(T)|^2$$
$$= J(\hat{D}, \hat{h}) + J(D, h) - c_1 Q(\hat{D}\hat{h}, Dh) - c_2 Q(C\hat{h}, Ch) - \langle \hat{h}(T), h(T) \rangle$$
$$= J(\hat{D}, \hat{h}) + J(D, h) - c_1 N_H^2(Dh) - c_2 N_H^2(Ch) - Q(h, kh(T))$$
$$= J(\hat{D}, \hat{h}) - J(D, h).$$

Thus, the pair (D, h) satisfying (4.1) also satisfies $J(D, h) \leqq J(\hat{D}, \hat{h})$, with equality only if $\hat{h} = h$ and $\hat{D} = D$. This completes the proof of Theorem 4.1.

5. An application. In this section, the above result is applied to a pendulum model adapted from Russell [13]. His results are given to allow comparisons of some modeling and computational aspects of the approach taken in this paper and of Russell's more traditional approach.

The physical situation to be referred to is that of a pendulum which is constrained to move in a one-dimensional arc. The pendulum is thought of as a surveyor's instrument subjected to a random force w, which may represent wind or other disturbances. The connection of the pendulum to its housing causes friction, so that a simple linear model of the displacement angle $\theta(t)$ is

$$\theta''+\theta'+\theta=w, \quad \theta(0)=a, \quad \theta'(0)=b, \tag{5.1}$$

where a and b are mean-zero random variables. A control function is to be chosen as a function of θ and θ', and is allowed to affect θ and θ'.

To apply most state-space methods, it is necessary that the system noise be Gaussian; this requirement may play a large role in determining the state vector. For example, Russell uses the state vector $X=(\theta, \theta', w)^T$, because wind is not well modeled as white noise (the "derivative" of a Wiener process). If w is driven by white noise (that is, $w'+w=v=$ white noise), then the system is indeed linear and Gaussian:

$$X'=\begin{pmatrix} 0 & 1 & 0 \\ -1 & -1 & 1 \\ 0 & 0 & -1 \end{pmatrix} X+\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} v. \tag{5.2}$$

If w is not driven by white noise, further components (e.g., w') might be added to the state vector. The control only affects θ and θ', however, so components other than θ and θ' are in a practical sense superfluous.

The operator approach allows a more flexible approach to modeling, although it must be assumed that $a=b=0$ in (5.1). Equation (5.2) may be integrated to obtain an admissible 3-dimensional model, and equation (5.1) may be double-integrated to obtain an admissible 1-dimensional model. Since the control is 2-dimensional, the appropriate 2-dimensional model is presented below. Integrating (5.1) and identifying $h=(\theta, \theta')^*$ gives

$$h=\alpha Ch+z, \quad \alpha=\begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix}, \quad z(t)=\left(0 \cdot \int_0^t w(s)\,ds\right)^*, \tag{5.3}$$

The control function (4.2) and the resulting output $h=(I-\alpha C-D)^{-1}$ may be computed using Laplace transforms. If $g=(I+\alpha * C)^{-1}f$, $G=(g)$, and $F=(f)$, then $(I+\alpha */s)G=F$. Inverting the matrix $I+\alpha^*/s$ and taking inverse transforms gives

$$g(t)=f(t)+\int_0^t m(t-u)f(u)\,du,$$

$$m(x)=\exp(x/2)\begin{pmatrix} 1 \\ 3 \end{pmatrix}\sin\sqrt{3}/4\times\begin{pmatrix} -2 & 1 \\ -1 & -1 \end{pmatrix}+\cos\sqrt{3}/4\times\begin{pmatrix} 0 & 1 \\ -1 & 1 \end{pmatrix}.$$

A similar computation gives

$$\theta(t)=\int_0^t n(t-u)w(u)\,du,$$

$$n(x)=\cosh(\gamma x/2)[\cos\beta x-(1/2)\sin(\beta x)]$$

$$+\sinh(\gamma x/2)\left[\left(\frac{-1}{\gamma}\right)\cos(\beta x)+\left(\frac{5}{2\beta\gamma}\right)\sin(\beta x)\right],$$

$$\gamma^2=1+2\sqrt{5}, \qquad \beta^2=2\sqrt{5}-\tfrac{1}{2},$$

from which it is relatively easy to compute $E(\theta^2)$.

The corresponding calculations in Russell are done numerically. For the sake of comparison, it is assumed that the disturbance w in (5.1) is Gaussian, so that the covariance X of the optimal (Russell) output satisfies

$$X' = SX + XS* + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad X(0) = 0, \quad S = \alpha + K,$$

$$K' = -\alpha * K - K\alpha + I - K^2, \qquad K(T) = -I.$$

Some values of $E(\theta^2)$ for the two methods are given below for $T = 1$.

(5.4)

t	.25	.5	.75	1.0
Russell	.0013	.0128	.0519	.1391
Operator	.0024	.0197	.0671	.1491

Another comparison of the two methods can be made by differentiating the optimal Russell control $u_r = Kh$, and substituting for K' and h'. After integrating twice, it can be shown that $u_0 = u_r$ satisfies

$$u_0 = (I + \alpha * C)^{-1} C^2 h + (I + \alpha * C)^{-1} C^2 K z'.$$

The difference between u_0 and the optimal control (4.2), then, is the final term in the above expression. This difference is reflected in the table (5.4).

6. Conclusion. A general framework for the study of linear stochastic systems was presented, characterized by a reproducing kernel Hilbert space and the operator spaces $\mathscr{A}$ and $\mathscr{B}$. A state-space control problem was solved within this framework, and a necessary condition was found giving the optimal control explicitly as a function of the output. The function spaces used admit systems with delays and state-department noise, and it is hoped that results similar to Theorem 4.1 of this paper can be found in these more general settings.

7. Proofs of operator properties. The proofs of Theorems 2.1 and 2.2 are presented in this section.

Proof of Theorem 2.1. Let $f \in G$ be arbitrary, and c be the constant for fixed $B \in \mathscr{B}$. If $0 \leqq v \leqq T$, $Bf(0) = 0$ implies that

$$|Bf(v)| \leqq c \int_0^v N_t(f)\, dt. \tag{7.1}$$

Since $N_t(f)$ is increasing in t, it is clear from (7.1) that $N_v(Bf) \leqq c \int_0^v N_t(f)\, dt$. Applying this inequality to (7.1) and integrating by parts gives

$$|B^2 f(v)| \leqq c \int_0^v c \int_0^t N_s(f)\, ds\, dt = c^2 \int_0^v (v-t) N_t(f)\, dt.$$

By induction, we have that

$$|B^n f(v)| \leqq c^n \int_0^v \frac{(v-t)^{n-1}}{(n-1)!} N_t(f)\, dt \leqq \frac{c^n T^n}{(n-1)!} N_T(f).$$

Summing over n gives, for each p,

$$\left| \sum_{n=0}^{p} B^n f(v) \right| \leqq N_T(f) \sum_{n=1}^{\infty} c^n T^n / (n-1)!,$$

where the infinite series converges by the Ratio test. Thus, $\sum_{n=0}^{\infty} B^n f$ converges, and

$h = f + Bh$ has a unique solution. This establishes that $I - B$ is $1-1$ and onto, and hence has an inverse. Call $D = (I-B)^{-1}$. Then $D - I = BD$. Let $0 \leqq t \leqq T$. Since $B \in \mathscr{B}$,

$$|Df(t) - f(t)| \leqq c \int_0^t N_s(f) + N_s((D-I)f)\, ds. \tag{7.2}$$

Equation (7.2) implies $N_s((D-I)f) \leqq c \int_0^s N_u(f) + N_u((D-I)f)\, ds$, so that integration by parts gives

$$|Df(t) - f(t)| \leqq c \int_0^t (1 + c(t-s)) N_s(f) + c(t-s) N_s((D-I)f)\, ds.$$

Induction gives

$$|Df(t) - f(t)| \leqq c \int_0^t \left[1 + c(t-s) + \cdots + \frac{c^n (t-s)^n}{n!}\right] N_s(f) + \frac{c(t-s)^n}{n!} N_s(BDf)\, ds.$$

Letting $n \to \infty$ and simplifying, we get

$$|Df(t) - f(t)| \leqq c e^{ct} \int_0^t N_s(f)\, ds.$$

This inequality is used in the second of the inequalities below. Arguments similar to those given above yield

$$\begin{aligned} |((D-I)f)(v) - ((D-I)f)(u)| &\leqq c \int_u^v N_s(f) + N_s((D-I)f)\, ds \\ &\leqq c \int_u^v N_s(f) + c e^{ct} \int_0^s N_w(f)\, dw\, ds \\ &\leqq cT(1 + c e^{cT}) \int_u^v N_s(f)\, ds. \end{aligned}$$

Thus, $D = (I-B)^{-1} \in \mathscr{A}$, and part (i) is proven.

It is clear that $A \in \mathscr{A}$ implies $I - A \in \mathscr{B}$. From above, then, $A = I - (I - A)$ is $1-1$ and onto. If $A^{-1} \in \mathscr{A}$, it is clear that $I - A^{-1} \in \mathscr{B}$. It remains to show that $A^{-1} \in \mathscr{A}$.

Let c be the constant corresponding to $A \in \mathscr{A}$. Let $f \in G$ be arbitrary. Since A is onto, $f = Ag$ for some $g \in G$, and

$$|A^{-1} f(t) - f(t)| \leqq c \int_0^t N_s(g)\, ds \leqq c \int_0^t N_s(f) + N_s((A^{-1} - I)f)\, ds.$$

Replacing $N_s((A^{-1} - I)f)$ with its bound from the above inequality and integrating by parts, we get

$$|A^{-1} f(t) - f(t)| \leqq c \int_0^t (1 + c(t-s)) N_s(f) + c(t-s) N_s((A^{-1} - I)f)\, ds.$$

It follows that

$$|A^{-1} f(t) - f(t)| \leqq c e^{cT} \int_0^t N_s(f)\, ds.$$

The above inequality is used to show that

$$|A^{-1}f(v)-f(v)-A^{-1}f(u)+f(u)| \leqq c\int_u^v N_t(g)\,dt$$
$$\leqq c\int_u^v N_t(f)+ce^{cT}\int_0^t N_s(f)\,ds\,dt$$
$$\leqq c(1+cTe^{cT})\int_u^v N_t(f)\,dt.$$

Thus, $A^{-1}\in\mathscr{A}$, and the proof is complete.

Proof of Theorem 2.2. Let $f\in G$, and c_A, c_B, $\cdots$ be the constants corresponding to A, B, $\cdots$, respectively.

Part (i) is obvious.

Part (ii) follows from

$$|(A+B)f(v)-f(v)-(A+B)f(u)+f(u)| \leqq (c_A+c_B)\int_u^v N_t(f)\,dt.$$

Part (iii) follows from

$$|(B_1+B_2)f(v)-(B_1+B_2)f(u)| \leqq (c_{B_1}+c_{B_2})\int_u^v N_t(f)\,dt.$$

To prove (iv), let $A=I-B_1$. Then $A-I\in\mathscr{B}$. Let c_1 be the constant for $A-I$. Then

$$|BAf(v)-BAf(u)| \leqq c_B\int_u^v N_t(f)+N_t(B_1f)\,dt$$
$$\leqq c_B(1+c_1T)\int_u^v N_t(f)\,dt.$$

Part (v) follows from

$$|ABf(v)-ABf(u)| \leqq (c_Ac_BT+c_B)\int_u^v N_t(f)\,dt.$$

For (vi), let $A_1=(I-B_1)^{-1}$ and $A_2=(I-B_2)^{-1}$. Since $I-B\in\mathscr{A}$, (iv) gives $B_2(I-B_1)\in\mathscr{B}$, and (i), (ii) give $(I-B_1)-B_2(I-B_1)\in\mathscr{A}$. Then, Theorem 2.1(i) gives $A_1A_2\in\mathscr{A}$.

For (vii), $I-B_2\in\mathscr{A}$, so that (iv) gives $B_1(I-B_2)\in\mathscr{B}$, and (i), (iii) give $B_1B_2=B_1-B_1(I-B_2)\in\mathscr{B}$.

For (viii), it is sufficient to consider $0\leqq u\leqq t\leqq v\leqq T$. Then

$$|P_tBf(v)-P_tBf(u)|=|Bf(t)-Bf(u)| \leqq c_B\int_u^v N_s(f)\,ds.$$

For (ix), $cB\in\mathscr{B}$ for any constant c and (iii) imply that $\mathscr{B}$ is convex. If $a+b=1$, $A_1=I-B_1$, and $A_2=I-B_2$, then $aA_1+bA_2=I-aB_1-bB_2\in\mathscr{A}$, so that $\mathscr{A}$ is convex.

HIGHER ORDER CONDITIONS WITH AND WITHOUT LAGRANGE MULTIPLIERS*

J. WARGA†

Abstract. Let Q be a convex subset of a vector space, $\mathcal{U} \subset Q$, $\mathcal{Z}$ a topological vector space, C a convex subset of $\mathcal{Z}$ with a nonempty interior, $\phi = (\phi_1, \phi_2)$: $Q \to \mathbb{R}^m \times \mathcal{Z}$, $\bar{q} \in Q$ and $\phi_2(\bar{q}) \in C$. We assume that ϕ has a pth order Taylor approximation at $\bar{q}$ when it is restricted to an arbitrary finite-dimensional simplex in Q with a vertex at $\bar{q}$. In the case when $\mathcal{U}$ is a proper subset of Q we also assume that Q is a uniform space, ϕ continuous and $\mathcal{U}$ "abundant." We establish a number of higher order sufficient conditions, not involving any Lagrange multipliers, for the existence of neighborhoods G_1 and G_2 of the origins such that $\phi_1(\bar{q}) + G_1 \subset \{\phi_1(u) | u \in \mathcal{U}, \phi_2(u) + G_2 \subset C\}$. These sufficient conditions, involving nonconvex sets of variations, are shown by an example to be stronger than those in the literature. We also generalize prior "Lagrangian" conditions, more akin to the usual necessary conditions.

Key words. local controllability, inclusion restrictions, equality restrictions, Lagrange multipliers

AMS(MOS) subject classifications. 49B27, 49E15, 49E30

1. Introduction. The usual roles of first order and of higher order necessary conditions in optimization are quite different. First order conditions provide candidates for a restricted minimum. Higher order necessary conditions are applied in an attempt to eliminate some of these "first order" candidates from competition. These opposite tendencies also appear in the proofs of the necessary conditions. If we wish to minimize $\phi_0(x)$ on some convex set X subject to the restriction $\phi_1(x) = 0$ then the usual argument proceeds by contradiction: the assumption that the point $\phi(\bar{x}) = (\phi_0, \phi_1)(\bar{x})$ does not lie on the boundary of some "convex version" of the set $\phi(X)$ (that is, the denial of what is essentially the statement of necessary conditions) enables us to construct a set $X_1 \subset X$ such that $\phi(\bar{x})$ lies in the interior of $\phi(X_1)$.

Thus various necessary conditions, of first order and of higher orders, can be stated as (nonexclusive) alternatives [3], [4], [5]: either certain extremality relations hold at $\bar{x}$ or ϕ is controllable at $\bar{x}$, i.e., $\phi(\bar{x})$ belongs to the interior of $\phi(X)$. (We use the term "controllable" instead of "open" because of certain additional inclusion restrictions which are considered in the general problem.) The extremality conditions are formulated in terms of a Lagrange multiplier which represents a functional supporting some convex set of variations. In the case of first order conditions, the largest set of variations is convex and the conditions are quite general. However, in the case of higher order conditions [1], [5] that are also presented in a Lagrangian formulation, certain special convex subsets of the nonconvex set of nonlinear variations are effectively singled out and much information is sacrificed in the process.

In an attempt to discover stronger higher order conditions, we at first search directly for controllability theorems that involve possibly nonconvex sets of variations and do not involve Lagrange multipliers. We state such theorems in § 2 and then, in § 3, present more specialized "Lagrangian" conditions which generalize prior results [1], [5]. In § 4 we demonstrate by a simple example that the non-Lagrangian second order controllability conditions of § 2 are more powerful than their Lagrangian predecessors. The proofs are contained in § 5.

Our approach to non-Lagrangian controllability conditions is based on the observation (which follows from Brouwer's fixed point theorem) that if g is a homeomorphism

† Department of Mathematics, Northeastern University, Boston, Massachusetts 02115.

of some nhd (neighborhood) V of $\bar{x}$ in $\mathbb{R}^k$ into $\mathbb{R}^k$ then $(g+e)(V)$ contains a nhd of $(g+e)(\bar{x})$ provided e is continuous and its sup norm is sufficiently small. Now let Q be a convex subset of some vector space, $\bar{q} \in Q$, and $\phi_1 \colon Q \to \mathbb{R}^m$. We determine some finite-dimensional subset V of Q and a pth order Taylor approximation of $\phi_1|_V$ at $\bar{q}$ such that only the pth degree part of the Taylor approximation of $\phi_1 - \phi_1(\bar{q})|_V$ fails to vanish identically, and use that part, under appropriate conditions, to construct a related homeomorphism which plays the role of g. We use the error term to construct e and we can conclude that $\phi_1(V)$ contains a nhd of $\phi_1(\bar{q})$. This basic argument is suitably modified to take account of an additional "unilateral" restriction of the form $\phi_2(q) \in C$ in some topological vector space and to apply when we replace the convex set Q by a (possibly nonconvex) "abundant" subset $\mathcal{U}$. (In the case of optimal control, Q may be the set of relaxed controls or any convex set of ordinary controls and $\mathcal{U}$ any set of ordinary control functions in Q that contains concatenations ("splices") of any two of its elements [2, Thm. IV.3.9, p. 285].)

2. Higher order conditions without Lagrange multipliers. Let Q be a convex subset of a vector space, $\mathcal{U} \subset Q$, $\mathcal{Z}$ a topological vector space, $\mathcal{Z}^*$ the topological dual of $\mathcal{Z}$, C a convex subset of $\mathcal{Z}$ with a nonempty interior, $\phi = (\phi_1, \phi_2) \colon Q \to \mathbb{R}^m \times \mathcal{Z}$, $\bar{q} \in Q$ and $\phi_2(\bar{q}) \in C$. Let

$$\mathcal{T}_k = \left\{ (\theta_1, \cdots, \theta_k) \in \mathbb{R}^k \middle| \theta_j \geqq 0, \sum_j \theta_j \leqq 1 \right\}.$$

We shall say that ϕ has a *pth order finite Taylor approximation at* $\bar{q}$ if, for every choice of a positive integer k and of $q_1, \cdots, q_k \in Q$, the function

$$\theta \to \psi(\theta) \triangleq \phi\left(\bar{q} + \sum_{j=1}^{k} \theta_j (q_j - \bar{q})\right) \colon \mathcal{T}_k \to \mathbb{R}^m \times \mathcal{Z}$$

admits a pth order Taylor approximation at 0, i.e. there exists, for each $n = 1, 2, \cdots, p$, (a restriction of) an n-linear symmetric operator $\psi^{(n)}(0) \colon \mathcal{T}_k^n \to \mathbb{R}^m \times \mathcal{Z}$ such that

$$\lim |\theta|^{-p} \left(\psi(\theta) - \left[\psi(0) + \psi'(0)\theta + \cdots + \frac{1}{p!} \psi^{(p)}(0)\theta^p \right] \right) = 0 \quad \text{as } \theta \to 0, \quad \theta \in \mathcal{T}_k.$$

(Observe that this does not require the existence of higher order derivatives of ψ.) The existence of the operators $\psi^{(n)}(0)$ for each choice of k and $q_1, \cdots, q_k$ guarantees that for each $n = 1, \cdots, p$ there exists (a restriction of) an n-linear symmetric operator $\phi^{(n)}(\bar{q}) \colon (Q - \bar{q})^n \to \mathbb{R}^m \times \mathcal{Z}$ such that

$$\phi^{(n)}(\bar{q})(q_1 - \bar{q})^{\alpha_1} \cdots (q_k - \bar{q})^{\alpha_k} = \psi^{(n)}(0)\delta_1^{\alpha_1} \cdots \delta_k^{\alpha_k}$$

if $\alpha_i \geqq 0$, $\alpha_1 + \cdots + \alpha_k = n$ and δ_i is the ith column of the $k \times k$ unit matrix. As customary, we write ϕ', ϕ'', ϕ''' for $\phi^{(1)}$, $\phi^{(2)}$, $\phi^{(3)}$.

Our theorems will be applicable to a proper subset $\mathcal{U}$ of Q if the following condition is satisfied.

Condition 2.1. Q has a uniform structure, ϕ is continuous and, for every choice of a positive integer k, of $q_1, \cdots, q_k \in Q$ and of $\theta \in \mathcal{T}_k$, there exists a sequence $(u_n(\theta))$ in $\mathcal{U}$ such that

$$\lim_n u_n(\theta) = \bar{q} + \sum_{j=1}^{k} \theta_j (q_j - \bar{q}) \quad \text{uniformly for } \theta \in \mathcal{T}_k,$$

$$\theta \to u_n(\theta) \colon \mathcal{T}_k \to \mathcal{U} \text{ is continuous for } n = 1, 2, \cdots.$$

We write $\triangleq$ for "is defined as", A^0, co, A, $B(c, r)$, $\bar{B}(c, r)$ for the interior and the convex hull of A and the open and closed ball of center c and radius r, respectively. We identify $\mathbb{R}^k$ with its dual and write $l_1 x$ for $l_i \cdot x$ if $l_1, x \in \mathbb{R}^k$. We denote by $\mathcal{U}$ a subset of Q which is either Q itself or, if Q is a uniform space and ϕ continuous, one satisfying condition 2.1. We also write $\hat{C} \triangleq C - \phi_2(\bar{q})$.

We say that ϕ_1 is *strongly locally* $(\mathcal{U}, \phi_2, C)$*-controllable at* $\bar{q}$ if there exist nhds G_1, G_2 of 0 in $\mathbb{R}^m$, $\mathcal{Z}$ such that

$$\phi_1(\bar{q}) + G_1 \subset \{\phi_1(u) | u \in \mathcal{U},\ \phi_2(u) + G_2 \subset C\}.$$

Most of our specific second and third order conditions will follow from the following theorem.

THEOREM 2.2. *Let H be a nhd of some $\bar{x} \in \mathbb{R}^k$, $\alpha_1, c > 0$, $t \geqq 1$,*

$$I_n \triangleq \{1, 2, \cdots, i_n\}, \quad y_{ni} \in Q - \bar{q} \quad \forall n = 1, \cdots, p, \quad i \in I_n,$$

and let the functions

$$b_{ni}: H \to [0, c], \qquad f^n = (f_1^n, f_2^n): H \to \mathbb{R}^m \times \mathcal{Z}$$

be continuous. Assume that

(a) $f^n(x) \in \{0\} \times t\hat{C} \quad \forall n = 1, \cdots, p-1, \quad x \in H, \quad f^p(\bar{x}) \in \{0\} \times t\hat{C}^0,$

(b) $\sum_{n=1}^{p} \alpha_1^n \sum_{i \in I_n} b_{ni}(x) \leqq 1 \quad \forall x \in H$

so that

$$\tilde{q}(x, \alpha) \triangleq \bar{q} + \sum_{n=1}^{p} \alpha^n \sum_{i \in I_n} b_{ni}(x) y_{ni} \in Q \quad \forall x \in H, \quad \alpha \in [0, \alpha_1],$$

(c) $\phi(\tilde{q}(x, \alpha)) = \phi(\bar{q}) + \sum_{n=1}^{p} \frac{1}{n!} \alpha^n f^n(x) + \alpha^p d(x, \alpha),$

where $\lim_{\alpha \to 0+} d(x, \alpha) = 0$ *uniformly for* $x \in H$.

Assume, further, that either

(d) f_1^p *is continuously differentiable and the set* $\{\partial f_1^p(\bar{x})/\partial x_j | j = 1, \cdots, k\}$ *spans* $\mathbb{R}^m$,

or

(d′) *there exist a nhd V of 0 in $\mathbb{R}^{m+1}$ and a continuous function $a = (a_1, \cdots, a_k): V \to H$ such that the function*

$$\theta = (\theta_1, \cdots, \theta_{m+1}) \to \left(\sum_{\mu=1}^{m+1} \theta_\mu, f_1^p(a(\theta)) \right),$$

defined for $\theta \in V$, is a homeomorphism and $a(0) = \bar{x}$.

Then ϕ_1 is strongly locally $(\mathcal{U}, \phi_2, C)$-controllable.

Remark. In the special case where $k = m$ and there exists a nhd W of $\bar{x}$ such that $f_1^p|_W$ is a homeomorphism, condition (d′) is satisfied. Indeed, let $h_1, \cdots, h_{m+1}$ be the vertices of a simplex in $\mathbb{R}^m$ containing 0 in its interior and let V be such that

$$a(\theta) \triangleq (f_1^p)^{-1} \left(f_1^p(\bar{x}) + \sum_{\mu=1}^{m+1} \theta_\mu h_\mu \right) \in W \quad \forall \theta \in V.$$

Then $a(\theta)$ yields the function

$$\theta \to (\textstyle\sum \theta_\mu, f_1^p(a(\theta))) = \left(\sum_{\mu=1}^{m+1} \theta_\mu, f_1^p(\bar{x}) + \sum_{\mu=1}^{m+1} \theta_\mu h_\mu \right)$$

on V which is clearly a homeomorphism.

Second and third order conditions derived from Theorem 2.2 are presented below.

THEOREM 2.3. *Let* $I \triangleq \{1, 2, \cdots, i_1\}$, $J \triangleq \{1, 2, \cdots, j_1\}$ *and assume that* ϕ *has a second order finite Taylor approximation at* $\bar{q}$ *and there exist* $y_i, z_j \in Q - \bar{q}$ *for* $i \in I$, $j \in J$ *such that*

(a) $\phi'(\bar{q})y_i \in \{0\} \times \hat{C}$,

(b) $\phi''(\bar{q})\left(\sum_i y_i\right)^2 + 2\phi'(\bar{q})\sum_j z_j \in \{0\} \times \hat{C}^0$,

(c) *the vectors*

$$\phi_1''(\bar{q})\left(\sum_i y_i\right)y_s, \qquad \phi_1'(\bar{q})z_j \quad \text{for } s \in I, j \in J$$

span $\mathbb{R}^m$.

Then ϕ_1 *is strongly locally* $(\mathcal{U}, \phi_2, C)$*-controllable at* $\bar{q}$. *Furthermore, this conclusion remains valid if assumption* (c) *is replaced by*

(c′) *there exist a nhd* V *of* 0 *in* $\mathbb{R}^{m+1}$ *and continuous functions* $a_i, b_j: V \to (0, \infty)$ *such that the function*

$$\theta = (\theta_1, \cdots, \theta_{m+1}) \to \left(\sum_j \theta_j, \phi_1''(\bar{q})\left(\sum_i a_i(\theta)y_i\right)^2 + 2\phi_1'(\bar{q})\sum_j b_j(\theta)z_j\right)$$

is a homeomorphism and $a_i(0) = b_j(0) = 1$ $\forall i$ *and* j.

The following corollary of Theorem 2.3 can be used to rule out candidates for a restricted minimum.

THEOREM 2.4. *Let the assumptions of Theorem* 2.2 *be satisfied with* $\mathcal{Z}$, ϕ_2, C *replaced by* $\mathcal{Z} \times \mathbb{R}$, (ϕ_2, ϕ_0), $C \times (-\infty, \phi_0(\bar{q})]$. *Then there exists* $u \in \mathcal{U}$ *such that*

$$\phi_0(u) < \phi_0(\bar{q}), \quad \phi_1(u) = \phi_1(\bar{q}), \quad \phi_2(u) \in C.$$

Third order controllability conditions, analogous to those of Theorem 2.3, follow.

THEOREM 2.5. *Let* $I = \{1, 2, \cdots, i_1\}$, $J = \{1, \cdots, j_1\}$, $K = \{1, \cdots, k_1\}$, $R = \{1, \cdots, r_1\}$ *and* ϕ *have a third order finite Taylor approximation at* $\bar{q}$. *Assume that, for* $i, s \in I$, $j \in J$, $k \in K$ *and* $r \in R$, *there exist* $y_i, z_j, h_k \in Q - \bar{q}$ *and real numbers*

$$\chi_{isj} = \chi_{sij} \geqq 0, \quad \bar{\zeta}_j = \sum_{i,s} \chi_{isj} > 0 \quad \text{and } v_{rj}$$

such that

(a) $\phi'(\bar{q})y_i \in \{0\} \times \hat{C}$,

(b) $\sum_j v_{rj}\phi_1'(\bar{q})z_j = 0$,

(c) $\phi''(\bar{q})y_iy_s + 2\sum_j \chi_{isj}\phi'(\bar{q})z_j \in \{0\} \times \hat{C}^0$,

(d) $\phi'''(\bar{q})\left(\sum_i y_i\right)^3 + 6\phi''(\bar{q})\left(\sum_i y_i\right)\left(\sum_j \bar{\zeta}_j z_j\right) + 6\phi'(\bar{q})\left(\sum_k h_k\right) \in \{0\} \times \hat{C}^0$,

(e) *the set whose elements are the vectors*

$$3\phi_1'''(\bar{q})\left(\sum_i y_i\right)^2 y_s + 6\phi_1''(\bar{q})\left[\left(\sum_j \bar{\zeta}_j z_j\right)y_s + 2\left(\sum_i y_i\right)\left(\sum_{i,j} \chi_{isj} z_j\right)\right] \quad \text{for } s \in I,$$

$$\sum_j v_{rj}\phi_1''(\bar{q})\left(\sum_i y_i\right)z_j \quad \text{for } r \in R,$$

$$\phi_1'(\bar{q})h_k \quad \text{for } k \in K$$

spans $\mathbb{R}^m$.

Then ϕ_1 is strongly locally $(\mathcal{U}, \phi_2, C)$-controllable at $\bar{q}$. Furthermore, this conclusion remains valid if assumption (e) *is replaced by*

(e′) *there exist a nhd V of 0 in $\mathbb{R}^{m+1}$, continuous functions $a=(a_1, \cdots, a_{i_1})$: $V \to (0,\infty)^{i_1}$, $b=(b_1, \cdots, b_{r_1})$: $V \to \mathbb{R}^{r_1}$, $c=(c_1, \cdots, c_{k_1})$: $V \to (0,\infty)^{k_1}$, and a corresponding function*

$$\theta \to f_1^3(a(\theta), b(\theta), c(\theta)) \triangleq \phi_1'''(\bar{q})\left(\sum_i a_i(\theta) y_i\right)^3 + 6\sum_{i,j} a_i(\theta)\left[\sum_{s,t} \chi_{stij} a_s(\theta) a_t(\theta) + \sum_r v_{rj} b_r(\theta)\right] \phi_1''(\bar{q}) y_i z_j + 6\sum_k c_k(\theta)\phi_1'(\bar{q}) h_k$$

such that

$$\theta = (\theta_1, \cdots, \theta_k) \to \left(\sum_{\mu=1}^{m+1} \theta_\mu, f_1^3(a(\theta), b(\theta), c(\theta))\right)$$

is a homeomorphism and $a_i(0)=1$, $b_r(0)=0$, $c_k(0)=1 \forall i, r, k$.

As in the case of second order conditions, third order nonoptimality conditions analogous to Theorem 2.4 can be derived from Theorem 2.5 by replacing $\mathcal{Z}, \phi_2, C$ with $\mathcal{Z} \times \mathbb{R}, (\phi_2, \phi_0), C \times (-\infty, \phi_0(\bar{q})]$. Fourth and higher order controllability conditions can be similarly derived from Theorem 2.2 but they become progressively more complicated and unwieldy.

3. Lagrangian conditions. Let Y be an arbitrary set, $p \in \{1, 2, \cdots\}$ and $P \subset Y^p$. We refer to P as *symmetric* if $(y_1, \cdots, y_p) \in P$ implies $(y_{\pi(1)}, \cdots, y_{\pi(p)}) \in P$ for every permutation π of $(1, 2, \cdots, p)$.

THEOREM 3.1. *Let ϕ have a second order finite Taylor approximation at $\bar{q}$. Let $Y \subset Q - \bar{q}$, and let P be a symmetric subset of Y^2. Assume that*

(a) $$\phi'(\bar{q}) y \in \{0\} \times \hat{C} \quad \forall y \in Y$$

and, for every finite subset $\{y_1, \cdots, y_{i_1}\}$ of Y and for

$$S \triangleq \{(i,s) | (y_i, y_s) \in P\}, \quad N \triangleq \{1, 2, \cdots, i_1\}^2 \backslash S$$

there exist numbers α_{ab}^{is} $\forall (i,s) \in S$, $(a,b) \in N$ such that

(b) $$\phi''(\bar{q}) y_a y_b - \sum_{(i,s) \in S} \alpha_{ab}^{is} \phi''(\bar{q}) y_i y_s \in \{0\} \times \hat{C} \quad \forall (a,b) \in N,$$

(c) *for each $\sigma = (\sigma_{is})_{(i,s) \in S}$ with $\sigma_{is} = \sigma_{si} > 0$, the system*

$$\eta_i \eta_s + \sum_{(a,b) \in N} \alpha_{ab}^{is} \eta_a \eta_b = \sigma_{is} \quad \forall (i,s) \in S$$

has a solution $\eta(\sigma) = (\eta_1(\sigma), \cdots, \eta_{i_1}(\sigma))$ such that $\eta_i(\sigma) > 0$ and $\sigma \to \eta(\sigma)$ is continuous.

Then either

(d) *ϕ_1 is strongly locally $(\mathcal{U}, \phi_2, C)$-controllable at $\bar{q}$, or*

(e) *there exists $l = (l_1, l_2) \in \mathbb{R}^m \times \mathcal{Z}^*$ such that*

$$l \neq 0, \quad l\phi'(\bar{q}) z \geqq 0 \quad \forall z \in Q - \bar{q}, \qquad l_2[c - \phi_2(\bar{q})] \leqq 0 \quad \forall c \in C,$$

$$l\phi''(\bar{q}) y \bar{y} \geqq 0 \quad \forall (y, \bar{y}) \in P.$$

Somewhat stronger assumptions than in Theorem 3.1 provide some sufficiency criteria for verifying assumptions (b) and (c) above.

DEFINITION 3.2. Let Y be an arbitrary nonempty set and $P \subset Y^p$ symmetric. For any finite set $F \subset Y$ and any ordering $y_1, \cdots, y_{i_1}$ of elements of F, we denote by δ_i the ith row of the $i_1 \times i_1$ unit matrix, and set

$$S \triangleq \{(k_1, k_2, \cdots, k_p) | (y_{k_1}, \cdots, y_{k_p}) \in P\},$$

$$m_{(k_1,\cdots,k_p)} \triangleq \sum_{j=1}^{p} \delta_{k_j} \quad \forall (k_1, \cdots, k_p) \in S, \quad k_1 \leqq k_2 \leqq \cdots \leqq k_p.$$

We shall say that P is *independent* if the set $\{m_{(k_1,\cdots,k_p)} | (k_1, \cdots, k_p) \in S, k_1 \leqq k_2 \leqq \cdots \leqq k_p\}$ is either empty or linearly independent for every finite $F \subset Y$. (We observe that the particular ordering of elements of F does not affect the property of independence of P.)

Remark. Simple examples of independent sets are provided by:

the diagonal set $P \triangleq \{y, y, \cdots, y) | y \in Y\}$;

$p = 2$, $P \triangleq \{(y, p(y)) | y \in Y\}$, where p: $Y \to Y$ is its own inverse; or by

$Y \triangleq \{y_1, y_2, y_3\}$, $p = 2$, $P \triangleq \{(y_1, y_2), (y_2, y_1), (y_1, y_3), (y_3, y_1), (y_2, y_2)\}$.

THEOREM 3.3. *Let ϕ have a second order finite Taylor approximation at $\bar{q}$. Let $Y \subset Q - \bar{q}$ and $P \subset Y^2$ be symmetric and independent. Assume that*

(a) $\phi'(\bar{q})y \in \{0\} \times \hat{C} \quad \forall y \in Y$,

(b) $\phi''(\bar{q})y\bar{y} \in \{0\} \times \hat{C}$ *if* $y, \bar{y} \in Y$ *but* $(y, \bar{y}) \notin P$.

Then the conclusion of Theorem 3.1 *remains valid.*

Remark. Theorems 3.1 and 3.3 generalize [5, Thm. 2.2]. Indeed, the latter is a special case of Theorem 3.3 corresponding to the choice of $P \triangleq \{(y, y) | y \in Y\}$.

Third and higher order Lagrangian conditions with a generality analogous to that of Theorem 3.2 appear to be too complicated to be of much general interest. We therefore provide a third order analogue of Theorem 3.3. Higher order analogues can also be derived in a similar manner but they are more complicated.

THEOREM 3.4. *Let ϕ have a third order finite Taylor approximation at $\bar{q}$. Let $Y \subset Q - \bar{q}$ and $P \subset Y^3$ be symmetric and independent. For every choice of $u, v, w \in Q - \bar{q}$ and every function $(u, v, w) \to F(u, v, w)$: $(Q - \bar{q})^3 \to \mathbb{R}^m \times Z$, let $\mathcal{P}[F(u, v, w)]$ denote the sum $\sum_{(a,b,c)} F(a, b, c)$ over all distinct permutations (a, b, c) of (u, v, w). Assume that for every choice of $y_1, y_2 \in Y$ there exists a point $z(y_1, y_2) = z(y_2, y_1) \in Q - \bar{q}$ such that*

(a) $\phi'(\bar{q})y_1 \in \{0\} \times \hat{C}$,

(b) $\phi''(\bar{q})y_1y_2 + 2\phi'(\bar{q})z(y_1, y_2) \in \{0\} \times \hat{C}$,

(c) $\mathcal{P}[\phi'''(\bar{q})y_1y_2y_3 + 6\phi''(\bar{q})y_3z(y_1, y_2)] \in \{0\} \times \hat{C}$ *if* $y_3 \in Y$, $(y_1, y_2, y_3) \notin P$.

Then either

(d) ϕ_1 *is strongly locally* $(\mathcal{U}, \phi_2, C)$*-controllable at* $\bar{q}$, *or*

(e) *there exists* $l = (l_1, l_2) \in \mathbb{R}^m \times \mathcal{Z}^*$ *such that*

$$l \neq 0, \qquad l\phi'(\bar{q})h \geqq 0 \quad \forall h \in Q - \bar{q}, \qquad l_2[c - \phi_2(\bar{q})] \leqq 0 \quad \forall c \in C,$$

$$l\mathcal{P}[\phi'''(\bar{q})y_1y_2y_3 + 6\phi''(\bar{q})y_3z(y_1, y_2)] \geqq 0 \quad \forall (y_1, y_2, y_3) \in P.$$

Remark. In the special case where C is a cone, Y the singlet $\{y_1\}$, $P = \{(y_1, y_1, y_1)\}$ and ϕ_2 is replaced by (ϕ_2, ϕ_0) as in Theorem 2.4, the above results yield Bernstein's necessary condition III of [1, Thm. 6.1, pp. 231–232].

4. An example. Let $Q=\mathbb{R}^3$, $\bar{q}=(0,0,0)$, $q=(x_1,x_2,x_3)$ and

$$\phi_1(q)=(f_1,f_2)(q)+o(|q|^2),$$

where

$$f_1(q)=x_1^2+x_1x_2+x_2x_3+x_3^2,$$

$$f_2(q)=x_1x_3+x_2^2+2x_2x_3.$$

We shall first show that, by Theorem 2.3, $\phi_1(Q)$ contains a nhd of 0. Indeed, we can eliminate the references to ϕ_2, C by choosing $\mathscr{Z}=C=\mathbb{R}$ and $\phi_2=0$. We let

$$y_1=(1,0,0),\quad y_2=(0,-1,0),\quad y_3=(0,0,1)$$

which yields $\tilde{y}=y_1+y_2+y_3=(1,-1,1)$ and

$$\phi_1''(0)y^2=2(f_1,f_2)(\tilde{y})=(0,0).$$

Thus assumptions (a) and (b) of Theorem 2.3 are satisfied.

We have $\phi_1''(\bar{q})=(f_1'',f_2'')$ and

$$f_1''=\begin{pmatrix}2&1&0\\1&0&1\\0&1&2\end{pmatrix},\qquad f_2''=\begin{pmatrix}0&0&1\\0&2&2\\1&2&0\end{pmatrix},$$

and therefore

$$\phi_1''(\bar{q})\tilde{y}y_1=(1,1),\quad \phi_1''(\bar{q})\tilde{y}y_2=(-2,0),\quad \phi_1''(\bar{q})\tilde{y}y_3=(1,-1).$$

Thus assumption (c) is also satisfied and our conclusion follows from Theorem 2.3.

Next we shall show that prior second order conditions in the literature do not yield this result. The most general of these results appears to be [5, Thm. 2.2] (which generalizes the corresponding results of Bernstein [1]). For the present example, that theorem asserts that if $Y\subset Q-\bar{q}=\mathbb{R}^3$ and $\phi_1''(\bar{q})y_1y_2=0$ for $y_1\neq y_2$, $y_1,y_2\in Y$ then either $\phi_1(Q)$ contains a nhd of $(0,0)$ or there exists $l_1\neq 0$ such that

$$l_1\phi_1''(\bar{q})y^2\geqq 0\quad \forall y\in Y.$$

We shall show that such a vector l_1 exists for every admissible choice of Y which will prove that Theorem 2.2 of [5] cannot shed any light on our example. Indeed, if Y contains at most two distinct elements y_1, y_2 then we can always find some $l_1\neq 0$ in $\mathbb{R}^2$ such that

$$l_1\phi_1''(\bar{q})y_1^2\geqq 0\quad\text{and}\quad l_1\phi_1''(\bar{q})y_2^2\geqq 0.$$

Now if y_1, y_2 are two distinct nonzero elements of Y, then

$$\phi_1''(\bar{q})y_1y_2=(f_1'',f_2'')y_1y_2=(0,0)$$

and therefore $y_2\in\mathbb{R}^3$ is normal to the two vectors $f_1''y_1$ and $f_2''y_1$. If these vectors are not parallel, then y_2 is uniquely determined by y_1 except for a constant factor, and then Y cannot contain more than two distinct elements y for which $\phi_1''(\bar{q})y^2\neq 0$.

It remains, therefore, to consider the case when $f_1''y_1$ and $f_2''y_1$ are parallel. Since these two vectors differ from each other and from 0 if $y_1\neq 0$, they will be parallel if

$$(f_1''-\lambda f_2'')y_1=0$$

for some $\lambda\in\mathbb{R}$. Since $\det(f_1''-\lambda f_2'')=2\lambda^3-4\lambda^2-2\lambda-4$ has only one real root $\lambda_1\approx 2.6589672$ and the corresponding eigenvector $y_1=(1,-0.323812,0.630384)$ is unique,

all vectors normal to $f_1''y_1 = \lambda_1 f_2''y_1$ are linear combinations of two linearly independent vectors $u = (0, 1, -1.7400899)$ and $v = (0.5746829, 0, -1)$. Thus, if there are at least three nonzero vectors y_1, y_2, y_3 in Y, both y_2 and y_3 are linear combinations of u and v, say

$$y_2 = \alpha_1 u + \alpha_2 v, \qquad y_3 = \beta_1 u + \beta_2 v$$

and therefore the requirement $\phi_1''(\bar{q})y_2y_3 = 0$ yields

$$\alpha_1\beta_1\phi_1''(\bar{q})u^2 + (\alpha_1\beta_2 + \alpha_2\beta_1)\phi_1''(\bar{q})uv + \alpha_2\beta_2\phi_1''(\bar{q})v^2 = 0.$$

On the other hand, a direct calculation shows that $\phi_1''(\bar{q})u^2$, $\phi_1''(\bar{q})uv$ and $\phi_1''(\bar{q})v^2$ are each $\neq 0$ and

$$0.6018725\phi_1''(\bar{q})u^2 - 1.3783701\phi_1''(\bar{q})uv + \phi_1''(\bar{q})v^2 = 0,$$

where the first two coefficients are unique. Thus we may assume that $\alpha_2 = \beta_2 = 1$ and therefore

$$\alpha_1\beta_1 = 0.6018725, \qquad \alpha_1 + \beta_1 = -1.3783701$$

which cannot be satisfied by any real α_1, β_1. This shows that Y cannot contain more than two distinct nonzero elements.

5. Proofs. Let ϕ have a pth order finite Taylor approximation at $\bar{q}$, let $c > 0$ and $w_n \in Q - \bar{q}$, $b_n \in [0, c]$ $\forall n = 1, \cdots, p$, and let $\alpha_1 > 0$ be such that

$$c \sum_{n=1}^{p} \alpha_1^n \leqq 1.$$

Then

$$\hat{q}(\alpha) \triangleq \bar{q} + \sum_{n=1}^{p} b_n\alpha^n w_n \in Q \quad \forall \alpha \in [0, \alpha_1]$$

and

$$(*) \qquad \phi(\hat{q}(\alpha)) = \phi(\bar{q}) + \sum_{j=1}^{p} \frac{1}{j!}\phi^{(j)}(\bar{q})\left[\sum_{n=1}^{p} b_n\alpha^n w_n\right]^j + \alpha^p d_1(\alpha, b_1, \cdots, b_p)$$

where $\lim_{\alpha\to 0+} d_1(\alpha, b_1, \cdots, b_p) = 0$ uniformly for all choices of $b_1, \cdots, b_p \in [0, c]$ (because $\lim d_1(\alpha, b_1, \cdots, b_p) = 0$ as $|(b_1\alpha, b_2\alpha^2, \cdots, b_p\alpha^p)|$ converges to 0). If we rearrange the terms in (*), we obtain

$$(**) \qquad \phi(\hat{q}(\alpha)) = \phi(\bar{q}) + \sum_{n=1}^{p} \frac{1}{n!}\alpha^n f^n + \alpha^p d(\alpha, b_1, \cdots, b_p),$$

where $\lim_{\alpha\to 0+} d(\alpha, b_1, \cdots, b_p) = 0$ uniformly for all $b_1, \cdots, b_p \in [0, c]$ and, for $z_i \triangleq b_i w_i$,

$$f^n = \sum_{j=1}^{n} \frac{n!}{j!}\phi^{(j)}(\bar{q}) \sum_{m_1+m_2+\cdots+m_j=n} z_{m_1}z_{m_2}\cdots z_{m_j}$$

so that, in particular,

$$(***) \qquad \begin{aligned} f^1 &= \phi'(\bar{q})z_1, \qquad f^2 = \phi''(\bar{q})z_1^2 + 2\phi'(\bar{q})z_2, \\ f^3 &= \phi'''(\bar{q})z_1^3 + 6\phi''(\bar{q})z_1z_2 + 6\phi'(\bar{q})z_3, \end{aligned}$$

etc. We shall henceforth use the expansions in (**), (***) without any further reference to their derivation.

We shall use the notations 2.3(a), 3.1(c) etc. to denote statements (a) of Theorem 2.3, (c) of Theorem 3.1, etc.

LEMMA 5.1. *Let V be a nhd of 0 in $\mathbb{R}^{m+1}$, $t \geqq 1$, $\alpha_1 \geqq 0$ and, for $n = 1, 2, \cdots$,*

$$g = (g_1, g_2)\colon V \to \mathbb{R}^{m+1} \times \mathscr{Z},$$

$$e = (e_1, e_2)\colon V \times [0, \alpha_1] \to \mathbb{R}^{m+1} \times \mathscr{Z},$$

$$h^n = (h_1^n, h_2^n)\colon V \times [0, \alpha_1] \to \mathbb{R}^{m+1} \times \mathscr{Z}.$$

Assume that $g_1\colon V \to g_1(V)$ is a homeomorphism, that g_2, $e(\cdot, \alpha)$ and $h^n(\cdot, \alpha)$ are continuous for each α and n, and that

$$g(0) \in \{0\} \times t\hat{C}^0, \qquad \lim_{\alpha \to 0+} e(x, \alpha) = 0 \quad \textit{uniformly for } x \in V,$$

$$\forall \alpha > 0 \quad \lim_{n \to \infty} h^n(x, \alpha) = 0 \quad \textit{uniformly for } x \in V.$$

Then there exist $\alpha_0 \in (0, \log(1 + t^{-1})]$, $N \in \{1, 2, \cdots\}$ and nhds V_1, U_1, U_2 of 0 in $\mathbb{R}^{m+1}$, $\mathbb{R}^{m+1}$, $\mathscr{Z}$ such that

$$U_1 \subset \{g_1(x) + e_1(x, \alpha_0) + h_1^N(x, \alpha_0) \mid x \in V_1\},$$

$$g_2(x) + e_2(x, \alpha_0) + h_2^N(x, \alpha_0) + U_2 \subset t\hat{C}^0 \quad \forall x \in V_1.$$

Proof. Let $r, s > 0$ and a nhd U_2 of 0 in $\mathscr{Z}$ be such that $\bar{B}(0, r) \subset V$, $g_2^{-1}(\bar{B}(0, s)) \subset \bar{B}(0, r)$, $g_2(\bar{B}(0, r)) + U_2 + U_2 + U_2 \subset t\hat{C}^0$. Let $\alpha_0 \in (0, \min[\alpha_1, \log(1 + t^{-1})])$ be sufficiently small so that

$$|e_1(x, \alpha_0)| \leqq \tfrac{1}{3}s, \qquad e_2(x, \alpha_0) \in U_2 \quad \forall x \in V.$$

Finally, let $N \in \{1, 2, \cdots\}$ be sufficiently large so that

$$|h_1^N(x, \alpha_0)| \leqq \tfrac{1}{3}s, \qquad h_2^N(x, \alpha_0) \in U_2 \quad \forall x \in V.$$

Next we choose an arbitrary $u \in \mathbb{R}^{m+1}$ with $|u| \leqq \frac{1}{3}s$. The equation

$$g_1(x) + e_1(x, \alpha_0) + h_1^N(x, \alpha_0) = u \tag{1}$$

is equivalent to

$$x = g_1^{-1}(u - e_1(x, \alpha_0) - h_1^N(x, \alpha_0)). \tag{2}$$

Since the right-hand side in (2) is a continuous function of x mapping $\bar{B}(0, r)$ into itself, there exists a point $x = \bar{x} \in \bar{B}(0, r)$ satisfying (2) and therefore also (1). Thus

$$U_1 \triangleq \bar{B}(0, \tfrac{1}{3}s) \subset \{g_1(x) + e_1(x, \alpha_0) + h_1^N(x, \alpha_0) \mid x \in \bar{B}(0, r)\}.$$

Furthermore, for each $x \in \bar{B}(0, r)$, we have

$$g_2(x) + e_2(x, \alpha_0) + h_2^N(x, \alpha_0) + U_2 \subset g_2(x) + U_2 + U_2 + U_2 \subset t\hat{C}^0.$$

This shows that our conclusion is satisfied if we set $V_1 \triangleq \bar{B}(0, r)$. Q.E.D.

Proof of Theorem 2.2. We shall first assume that assumption (d) holds. Let $h_1, \cdots, h_{m+1}$ be the vertices of a simplex in $\mathbb{R}^m$ containing 0 in its interior. By assumption (d), there exist numbers $a_{\mu j}$ for $\mu = 1, \cdots, m+1$, $j = 1, \cdots, k$ such that

$$h_\mu = \sum_{j=1}^{k} a_{\mu j} \partial f_1^p(\bar{x}) / \partial x_j.$$

Let

$$\bar{x} \triangleq (\bar{x}_1, \cdots, \bar{x}_k), \qquad \theta \triangleq (\theta_1, \cdots, \theta_{m+1}),$$
$$a_j(\theta) \triangleq \bar{x}_j + \sum_{\mu} a_{\mu j}\theta_\mu, \qquad a(\theta) \triangleq (a_1, \cdots, a_{m+1})(\theta),$$

and let $\tilde{V}$ be a sufficiently small nhd of 0 in $\mathbb{R}^{m+1}$ so that $a(\theta) \in H$ for $\theta \in \tilde{V}$. We set

$$g_1(\theta) \triangleq \left(\sum_{\mu} \theta_\mu, f_1^p(a(\theta))\right) \quad \forall \theta \in \tilde{V}$$

and observe that

$$g_1(0) = (0, 0) \in \mathbb{R} \times \mathbb{R}^m, \qquad g_2(0) \in t\hat{C}^0.$$

We also have

$$\partial g_1(0)/\partial \theta_\mu = \left(1, \sum_{j=1}^{k} a_{\mu j}\partial f_1^p(\bar{x})/\partial x_j\right) = (1, h_\mu).$$

Thus the matrix $g_1'(0)$ is invertible and, by the inverse function theorem, $\theta \to g_1(\theta)$ is a homeomorphism of some nhd V of 0 in $\mathbb{R}^{m+1}$ onto $g_1(V)$. This shows that assumption (d) implies (d') so that we may assume in all cases that (d') is valid.

Next assume that Condition 2.1 holds. Since the functions b_{ni} are continuous, Condition 2.1 implies that, for all $(\theta, \alpha) \in V \times (0, \alpha_1]$, there exists a sequence $(u_\nu(\theta, \alpha))$ in $\mathcal{U}$ such that, for each α,

$$\lim_{\nu} u_\nu(\theta, \alpha) = \tilde{q}(a(\theta), \alpha) \text{ uniformly for } \theta \in V,$$

$$\theta \to u_\nu(\theta, \alpha) \text{ is continuous for each } \nu.$$

For $\theta \in V$ and $\alpha \in [0, \alpha_1]$, we set

$$h^\nu(\theta, \alpha) \triangleq (0, p!\alpha^{-p}[\phi(u_\nu(\theta, \alpha)) - \phi(\tilde{q}(a(\theta), \alpha))] \in \mathbb{R} \times \mathbb{R}^m \times \mathscr{Z},$$
$$g_2(\theta) \triangleq f_2^p(a(\theta)), \quad g \triangleq (g_1, g_2), \quad e_1(\theta, \alpha) \triangleq (0, p!d_1(a(\theta), \alpha)),$$
$$e_2(\theta, \alpha) \triangleq p!d_2(a(\theta), \alpha), \qquad e \triangleq (e_1, e_2)$$

and observe that t, g, e and h^ν satisfy the assumptions of Lemma 5.1. It follows that there exist $\alpha_0 \in (0, \log(1 + t^{-1})]$, $N \in \{1, 2, \cdots\}$ and nhds V_1, U_1, U_2 of 0 in $\mathbb{R}^{m+1}$, $\mathbb{R}^{m+1}$, $\mathscr{Z}$ such that

$$U_1 \subset \{g_1(\theta) + e_1(\theta, \alpha_0) + h_1^N(x, \alpha_0) | \theta \in V_1\}, \tag{1}$$

$$g_2(\theta) + e_2(\theta, \alpha_0) + h_2^N(\theta, \alpha_0) + U_2 \subset t\hat{C}^0 \quad \forall \theta \in V_1. \tag{2}$$

If we set $G_2 = (1/p!)\alpha_0^p U_2$, then relation (2) yields

$$p!\alpha_0^{-p}[\phi_2(u_N(\theta, \alpha_0)) - \phi_2(\bar{q}) - \sum_{n=1}^{p-1} \frac{1}{n!}\alpha_0^n f_2^n(a(\theta)) + G_2] \subset t\hat{C}^0 \quad \forall \theta \in V_1.$$

Since

$$\sum_{n=1}^{p} \frac{t}{n!}\alpha_0^n < t(e^{\alpha_0} - 1) \leqq 1 \quad \text{and} \quad f_2^n(a(\theta)) \in t\hat{C} \quad \forall n = 1, \cdots, p-1,$$

it follows that

$$\phi_2(u_N(\theta, \alpha_0)) + G_2 \subset C \quad \forall \theta \in V_1. \tag{3}$$

Now let

$$G_1 \triangleq \frac{1}{p!}\alpha_0^p\{(\tau_2, \cdots, \tau_{m+1}) | (\tau_1, \tau_2, \cdots, \tau_{m+1}) \in U_1\}.$$

Relation (1) and assumption (a) imply that

$$\phi_1(\bar{q}) + G_1 \subset \{\phi_1(u_N(\theta, \alpha_0)) | \theta \in V_1\}$$

which, together with (3), yields

$$\phi_1(\bar{q}) + G_1 \subset \{\phi(u) | u \in \mathcal{U}, \phi_2(u) + G_2 \subset C\}.$$

This completes the proof for the case when Condition 2.1 is satisfied. The proof when $\mathcal{U} = Q$ is even simpler; it is obtained by replacing each $u_\nu(\theta, \alpha)$ with $\tilde{q}(a(\theta), \alpha)$. Q.E.D.

Proof of Theorem 2.3. Let $\alpha_1 > 0$ be sufficiently small so that

$$2i_1\alpha_1 + 2j_1\alpha_1^2 \leqq 1, \tag{1}$$

and let

$$\hat{q}(x, \alpha) \triangleq \bar{q} + \alpha \sum_{i \in I} \eta_i y_i + \alpha^2 \sum_{j \in J} \zeta_j z_j,$$

where

$$k = i_1 + j_1, \qquad x = (x_1, \cdots, x_k) = (\eta_1, \cdots, \eta_{i_1}, \zeta_1, \cdots, \zeta_{j_1}),$$
$$x \in [0, 2]^{i_1+j_1}, \qquad \alpha \in [0, \alpha_1].$$

Thus $\alpha \sum \eta_i + \alpha^2 \sum \zeta_j \leqq 1$ and therefore $\hat{q}(x, \alpha) \in Q$. Since ϕ has a second order finite Taylor approximation, we have

$$\begin{aligned}\phi(\hat{q}(x, \alpha)) &= \phi(\bar{q}) + \alpha \sum_i \eta_i \phi'(\bar{q}) y_i \\ &\quad + \frac{1}{2}\alpha^2 \left[\sum_{i,s \in I} \eta_i \eta_s \phi''(\bar{q}) y_i y_s + 2 \sum_j \zeta_j \phi'(\bar{q}) z_j\right] + \alpha^2 d(x, \alpha),\end{aligned} \tag{2}$$

where $\lim_{\alpha \to 0+} d(x, \alpha) = 0$ uniformly for all $x \in [0, 2]^{i_1+j_1}$. Then Theorem 2.2 is applicable with $p = 2$, $c = 2$, $\bar{x} = (1, 1, \cdots, 1)$, $t = 1$ and obvious definitions of y_{ni}, b_{ni}, $f^n(y_{1i} = y_i, y_{2j} = z_j, b_{1i} = \eta_i, b_{2j} = \zeta_j$, $f^n(x)$ the coefficient of $\alpha^n/n!$ in (2), etc.). Indeed, if we choose H as a sufficiently small nhd of $\bar{x}$, then assumption 2.2(a) follows from 2.3(a)-(b) and assumptions 2.2(b)-(c) from (1) and (2). The partial derivatives $\partial f_1^2/\partial \eta_s$, $\partial f_1^2/\partial \zeta_j$ evaluated at $\bar{x} = (1, \cdots, 1)$ are

$$f^2_{1,\eta_s}(\bar{x}) = 2\phi_1''(\bar{q})\left(\sum_i y_i\right) y_s, \qquad f^2_{1,\zeta_j}(\bar{x}) = 2\phi'(\bar{q}) z_j,$$

so that assumption 2.2(d) follows from 2.3(c). Similarly, assumption 2.2(d') follows from 2.3(c'). Q.E.D.

Proof of Theorem 2.5. Let

$$\hat{q}(x, \alpha) \triangleq \bar{q} + \alpha \sum_i \eta_i y_i + \alpha^2 \sum_j \zeta_j z_j + \alpha^3 \sum_k \gamma_k h_k, \tag{1}$$

where

$$\kappa = i_1 + r_1 + k_1, \qquad x = (x_1, \cdots, x_\kappa) = (\eta_1, \cdots, \eta_{i_1}, \omega_1, \cdots, \omega_{r_1}, \gamma_1, \cdots, \gamma_{k_1})$$

and

$$\zeta_j = \sum_{i,s \in I} \chi_{isj} \eta_i \eta_s + \sum_{r \in R} v_{rj} \omega_r. \tag{2}$$

We restrict η_i and γ_k to the interval $[0, 2]$ and ω_r to the interval $[-\Omega, \Omega]$, where Ω is small enough so that $|\sum_r v_{rj}\omega_r| \leqq \frac{1}{2}\bar{\zeta}_j$. Thus $\zeta_j \in \frac{1}{2}\bar{\zeta}_j\,[1, 3]$. The corresponding set of values of x will be denoted by H_1. We then restrict α to the interval $[0, \alpha_1]$, where $\alpha_1 > 0$ is small enough so that

$$\alpha_1 \sum \eta_i + \alpha_1^2 \sum \zeta_j + \alpha_1^3 \sum \gamma_k \leqq 1 \quad \text{for } x \in H_1.$$

Thus $\hat{q}(x, \alpha) \in Q$ for $x \in H_1$ and $0 \leqq \alpha \leqq \alpha_1$ and

$$\begin{aligned}\phi(\hat{q}(x, \alpha)) = \phi(\bar{q}) &+ \alpha \sum_i \eta_i \phi'(\bar{q}) y_i \\ &+ \frac{1}{2}\alpha^2 \left[\sum_{i,s \in I} \eta_i \eta_s \phi''(\bar{q}) y_i y_s + 2 \sum_j \zeta_j \phi'(\bar{q}) z_j \right] \\ &+ \frac{1}{6}\alpha^3 \left[\sum_{i,s,t \in I} \eta_i \eta_s \eta_t \phi'''(\bar{q}) y_i y_s y_t \right. \\ &\left. + 6 \sum_{i,j} \eta_i \zeta_j \phi''(\bar{q}) y_i z_j + 6 \sum_k \gamma_k \phi'(\bar{q}) h_k \right] + \alpha^3 d(x, \alpha),\end{aligned} \tag{3}$$

where $\lim_{\alpha \to 0+} d(x, \alpha) = 0$ uniformly for $x \in H_1$. We denote by $f^1(x), f^2(x), f^3(x)$ the coefficients of $\alpha, \frac{1}{2}\alpha^2, \frac{1}{6}\alpha^3$ above.

We have $f_1^1(x) = 0$ by 2.5(a) and, by (2) and 2.5(b)-(c),

$$\begin{aligned}f_1^2(x) = &\sum_{i,s \in I} \eta_i \eta_s \left[\phi_1''(\bar{q}) y_i y_s + 2 \sum_j \chi_{isj} \phi_1'(\bar{q}) z_j \right] \\ &+ \sum_r \omega_r \sum_j v_{rj} \phi_1'(\bar{q}) z_j = 0 \quad \forall x \in H_1.\end{aligned}$$

Furthermore, we may choose a sufficiently small nhd H of $\bar{x} = (1, \cdots, 1, 0, \cdots 0, 1, \cdots, 1)$ contained in H_1 so that the assumption $f_2^2(\bar{x}) \in \hat{C}^0$ of 2.5(c) implies $f_2^2(x) \in \hat{C}^0$ for all $x \in H$. Thus assumptions 2.2(a)-(c) are satisfied with the obvious choice of b_{ni}. A straightforward computation shows that 2.2(d) is now equivalent to 2.5(e). Finally, 2.2(d') follows directly from (2), (3) and 2.5(e'). Q.E.D.

Proof of Theorem 3.1. Let

$$W \triangleq \{\phi''(\bar{q}) \sum{}' \tau_{uv} uv + 2\phi'(\bar{q}) z \,|\, (u, v) \in P, \tau_{uv} \in [0, 1], z \in Q - \bar{q}\},$$

where $\sum'$ denotes finite sums. The set W is convex and contains 0. Thus, by a variant of the convex separation theorem ([5, Proof of Lemma 4.1, pp. 55-56]), either there exists $l = (l_1, l_2) \in \mathbb{R}^m \times \mathcal{Z}^*$ such that

$$l \neq 0, \quad lw \geqq 0 \quad \forall w \in W, \qquad l_2[c - \phi_2(\bar{q})] \leqq 0 \quad \forall c \in C, \tag{1}$$

or there exist points $\xi^j = (\xi_1^j, \xi_2^j) \in W \,\forall j = 1, \cdots, m+1$ such that

$$0 \in [\text{co}\,\{\xi_1^1, \cdots, \xi_1^{m+1}\}]^0, \qquad \xi_2^j \in \hat{C}^0 \tag{2}$$

and therefore, for some $\beta_j > 0$,

$$\sum_j \beta_j = 1, \qquad \sum_j \beta_j \xi_1^j = 0. \tag{3}$$

If the first alternative holds, then relations (1) yield statement (e).

Now assume that the second alternative holds. Let $y_1, \cdots, y_{i_1}$ be the elements u, v of Y that appear in the expressions for ξ^j, and let S and N be correspondingly defined.

Then each ξ^j is of the form

$$\xi^j = \sum_{(i,s)\in S} \tau_{is}^j \phi''(\bar{q}) y_i y_s + 2\phi'(\bar{q}) z_j,$$

where $z_j \in Q - \bar{q}$ and $\tau_{is}^j \in [0, 1]$. Since $\phi''(\bar{q})$ is symmetric, we may assume that $\tau_{is}^j = \tau_{si}^j \ \forall j, i, s$. We can also assume that $\tau_{is}^j > 0 \ \forall j, i, s$ because a sufficiently small perturbation of the ξ^j will not affect the validity of relations (2).

Let

$$\sigma_{si}(\theta) = \sigma_{is}(\theta) \triangleq \sum_j (\beta_j + \theta_j)\tau_{is}^j \quad \forall (i, s) \in S, \quad \theta = (\theta_1, \cdots, \theta_{m+1}) \in \mathbb{R}^{m+1}.$$

Since $\sigma_{is}(0) > 0 \ \forall (i, s) \in S$, we may determine a compact nhd V of 0 in $\mathbb{R}^{m+1}$ such that

$$\tfrac{1}{2}\sigma_{is}(0) \leqq \sigma_{is}(\theta) \leqq 2\sigma_{is}(0), \qquad |\theta_j| \leqq \tfrac{1}{2}\beta_j \quad \forall (i, s) \in S, \quad \theta \in V.$$

Then, by assumption (c), there exist continuous functions

$$\theta \to \hat{\eta}_i(\theta) \triangleq \eta_i(\sigma(\theta)) \colon V \to \mathbb{R} \quad \forall i = 1, \cdots, i_1$$

such that

$$\hat{\eta}_i(\theta)\hat{\eta}_s(\theta) + \sum_{(a,b)\in N} \alpha_{ab}^{is} \hat{\eta}_a(\theta)\hat{\eta}_b(\theta) = \sigma_{is}(\theta) \quad \forall (i, s) \in S. \tag{4}$$

We deduce from (a)-(c) and (4) that there exist $t \geqq 1$ and continuous $v_1, v_2 \colon V \to t\hat{C}$ such that

$$\sum_{i=1}^{i_1} \hat{\eta}_i(\theta)\phi'(\bar{q}) y_i = (0, v_1(\theta)),$$

$$\begin{aligned}
&\sum_{i,s=1}^{i_1} \hat{\eta}_i(\theta)\hat{\eta}_s(\theta)\phi''(\bar{q}) y_i y_s + 2\sum_j (\beta_j + \theta_j)\phi'(\bar{q}) z_j \\
&\quad = \sum_{(a,b)\in N} \hat{\eta}_a(\theta)\hat{\eta}_b(\theta) \sum_{(i,s)\in S} \alpha_{ab}^{is} \phi''(\bar{q}) y_i y_s + (0, v_2(\theta)) \\
&\qquad + \sum_{(i,s)\in S} \hat{\eta}_i(\theta)\hat{\eta}_s(\theta)\phi''(\bar{q}) y_i y_s + 2\sum_j (\beta_j + \theta_j)\phi'(\bar{q}) z_j \\
&\quad = \sum_{(i,s)\in S} [\hat{\eta}_i(\theta)\hat{\eta}_s(\theta) + \sum_{(a,b)\in N} \alpha_{ab}^{is} \hat{\eta}_a(\theta)\hat{\eta}_b(\theta)]\phi''(\bar{q}) y_i y_s \\
&\qquad + 2\sum_j (\beta_j + \theta_j)\phi'(\bar{q}) z_j + (0, v_2(\theta)) \\
&\quad = \sum_{(i,s)\in S} \sigma_{is}(\theta)\phi''(\bar{q}) y_i y_s + 2\sum_j (\beta_j + \theta_j)\phi'(\bar{q}) z_j + (0, v_2(\theta)) \\
&\quad = \sum_j (\beta_j + \theta_j)\xi^j + (0, v_2(\theta)).
\end{aligned} \tag{5}$$

Now let

$$\tilde{q}(\theta, \alpha) \triangleq \bar{q} + \alpha \sum_i \hat{\eta}_i(\theta) y_i + \alpha^2 \sum_j (\beta_j + \theta_j) z_j, \tag{6}$$

where $\alpha \in [0, \alpha_1]$ and $\alpha_1 > 0$ is chosen sufficiently small so that

$$\alpha_1 \sum_i \hat{\eta}_i(\theta) + \alpha_1^2 \sum_j (\beta_j + \theta_j) \leqq 1 \quad \forall \theta \in V. \tag{7}$$

Then $\tilde{q}(\theta, \alpha) \in Q$ and, by (5),

$$\begin{aligned}
\phi(\tilde{q}(\theta, \alpha)) &= \phi(\bar{q}) + \alpha(0, v_1(\theta)) \\
&\quad + \frac{1}{2}\alpha^2 \left[\sum_j (\beta_j + \theta_j)\xi^j + (0, v_2(\theta)) \right] + \alpha^2 d(\theta, \alpha),
\end{aligned} \tag{8}$$

where $\lim_{\alpha\to 0+} d(\theta,\alpha)=0$ uniformly for $\theta\in V$. We can verify that Theorem 2.2 is applicable, with 0, θ, V replacing $\bar{x}$, x, H and with

$$p=2,\quad y_{1i}=y_i,\quad y_{2j}=z_j,\quad b_{1i}(\theta)\triangleq\hat{\eta}_i(\theta),\quad b_{2j}(\theta)\triangleq\beta_j+\theta_j,$$

$$f_2^1(\theta)=v_1(\theta),\qquad f^2(\theta)=\sum_j(\beta_j+\theta_j)\xi^j+(0,v_2(\theta)).$$

Indeed, assumption 2.2(a) follows from $v_i(\theta)\in t\hat{C}$, (2), (3) and 3.1(a); 2.2(b) from (6) and (7); 2.2(c) from (8); and 2.2(d) from the first relation of (2) which implies the linear independence of $\{(1,\xi_1^1),\cdots,(1,\xi_1^{m+1})\}$. Thus Theorem 2.2 implies alternative 3.1(d). Q.E.D.

Proof of Theorem 3.3. This theorem follows directly from Theorem 3.1. Indeed, let $\{y_1,\cdots,y_{i_1}\}$ be a finite subset of Y, and let S and N be defined as in Theorem 3.1 and $m_{(i,s)}$ as in Definition 3.2. Set $\alpha_{ab}^{is}=0$ for all $(i,s)\in S$, $(a,b)\in N$. Then assumptions 3.1(a), 3.1(b) follow from 3.3(a), 3.3(b), respectively. Furthermore, the system

$$\eta_i\eta_s=\sigma_{is}\quad\forall(i,s)\in S,\quad i\leqq s, \tag{1}$$

for arbitrary $\sigma_{is}>0$ is equivalent to

$$\log\eta_i+\log\eta_s=\log\sigma_{is}\quad\forall(i,s)\in S,\quad i\leqq s$$

which is a linear system in $\log\eta_i$ with a matrix whose rows are the $m_{(i,s)}$ and therefore independent. Thus system (1) has a solution $\eta(\sigma)=(\eta_1(\sigma),\cdots,\eta_{i_1}(\sigma))$ for all $\sigma=(\sigma_{is})$ with $\sigma_{is}=\sigma_{si}>0$ such that $\sigma\to\eta(\sigma)$ is continuous. This shows that assumption 3.1(c) is also satisfied. Q.E.D.

Proof of Theorem 3.4. Let P be partitioned into equivalence classes, two elements (u,v,w), (u_1,v_1,w_1) belonging to the same class if (u_1,v_1,w_1) is a permutation of (u,v,w). Let P' be formed by selecting one representative from each equivalence class. We set

$$W\triangleq\{\sum{}'\tau_{uvw}\mathcal{P}[\phi'''(\bar{q})uvw+6\phi''(\bar{q})wz(u,v)]+6\phi'(\bar{q})h\mid$$

$$(u,v,w)\in P',\ \tau_{uvw}\in[0,1],\ h\in Q-\bar{q}\},$$

where $\sum'$ denotes finite sums. The set W is convex and contains 0. Thus (as in the proof of Theorem 3.1) either there exists $l=(l_1,l_2)\in\mathbb{R}^m\times\mathcal{Z}^*$ such that

$$l\neq 0,\quad lw\geqq 0\quad\forall w\in W,\quad l_2[c-\phi_2(\bar{q})]\leqq 0\quad\forall c\in C, \tag{1}$$

or there exist points $\xi^\mu=(\xi_1^\mu,\xi_2^\mu)\in W\,\forall\mu=1,\cdots,m+1$ such that

$$0\in[c\{\xi_1^1,\cdots,\xi_1^{m+1}\}^0,\qquad \xi_2^\mu\in C^0-\phi_2(\bar{q})\subset\hat{C}^0 \tag{2}$$

and therefore, for some $\beta_\mu>0$,

$$\sum_\mu\beta_\mu=1,\qquad\sum_\mu\beta_\mu\xi_1^\mu=0. \tag{3}$$

If the first alternative holds, then relations (1) yield statement (e).

Now assume that the second alternative holds. Let $y_1, \cdots, y_{i_1}$ be the elements u, v, w of Y that appear in the expressions for ξ^μ. Let

$$S \triangleq \{(i, s, t) | (y_i, y_s, y_t) \in P'\}, \qquad z_{is} \triangleq z(y_i, y_s).$$

Then each ξ^μ can be written in the form

$$\xi^\mu = \sum_{(i,s,t)\in S} \tau^\mu_{ist} \mathscr{P}[\phi'''(\bar{q}) y_i y_s y_t + 6\phi''(\bar{q}) y_i z_{st}] + 6\phi'(\bar{q}) h_\mu,$$

where $h_\mu \in Q - \bar{q}$ and $\tau^\mu_{ist} \in [0, 1]$. We can also assume that all $\tau^\mu_{ist} > 0$ because small perturbations of the ξ^μ do not affect the validity of relations (2).

Let

$$\sigma_{ist}(\theta) \triangleq \sum_\mu (\beta_\mu + \theta_\mu) \tau^\mu_{ist} \quad \forall (i, s, t) \in S, \quad \theta = (\theta_1, \cdots, \theta_{m+1}) \in \mathbb{R}^{m+1}.$$

Since $\sigma_{ist}(0) > 0 \forall (i, s, t) \in S$, we may determine a compact nhd V of 0 in $\mathbb{R}^{m+1}$ such that

$$\tfrac{1}{2}\sigma_{ist}(0) \leqq \sigma_{ist}(\theta) \leqq 2\sigma_{ist}(0), \quad |\theta_\mu| \leqq \tfrac{1}{2}\beta_\mu \quad \forall \theta \in V.$$

Then, for each $\theta \in V$, the system

$$\eta_i \eta_s \eta_t = \sigma_{ist}(\theta) \quad \forall (i, s, t) \in S \tag{4}$$

is equivalent to the linear system in $\log \eta_i$,

$$\log \eta_i + \log \eta_s + \log \eta_t = \log \sigma_{ist}(\theta) \quad \forall (i, s, t) \in S$$

and, because of the independence of P, this last system has a matrix with the linearly independent rows $m_{(i,s,t)}$. Therefore, system (4) has a solution $\hat{\eta}(\theta) = (\hat{\eta}_1(\theta), \cdots, \hat{\eta}_{i_1}(\theta))$ which is continuous in θ.

Now let

$$\begin{aligned} \tilde{q}(\theta, \alpha) = \bar{q} &+ \alpha \sum_{i=1}^{i_1} \hat{\eta}_i(\theta) y_i + \alpha^2 \sum_{i,s=1}^{i_1} \hat{\eta}_i(\theta) \hat{\eta}_s(\theta) z_{is} \\ &+ \alpha^3 \sum_{\mu=1}^{m+1} (\beta_\mu + \theta_\mu) h_\mu \quad \forall \theta \in V, \quad \alpha \in [0, \alpha_1], \end{aligned} \tag{5}$$

where $\alpha_1 \in (0, \frac{1}{2}]$ is sufficiently small so that $\tilde{q}(\theta, \alpha) \in Q \forall \alpha \in [0, \alpha_1]$. Then, with the summations below carried out over all $i, s, t \in \{1, \cdots, i_1\}$, $j \in \{1, \cdots, j_1\}$ and $\mu \in \{1, \cdots, m+1\}$, we have

$$\begin{aligned} \phi(\tilde{q}(\theta, \alpha)) = \phi(\bar{q}) &+ \alpha \sum_i \phi'(\bar{q}) y_i \\ &+ \frac{1}{2}\alpha^2 \left[\phi''(\bar{q}) \left(\sum_i \hat{\eta}_i(\theta) y_i \right)^2 + 2\phi'(\bar{q}) \sum_{i,s} \hat{\eta}_i(\theta) \hat{\eta}_s(\theta) z_{is} \right] \\ &+ \frac{1}{6}\alpha^3 \left[\phi'''(\bar{q}) \left(\sum_i \hat{\eta}_i(\theta) y_i \right)^3 + 6\phi''(\bar{q}) \sum_{i,s,t} \hat{\eta}_i(\theta) \hat{\eta}_s(\theta) \hat{\eta}_t(\theta) z_{st} y_i \right. \\ &\qquad \left. + 6\phi'(\bar{q}) \sum_\mu (\beta_\mu + \theta_\mu) h_\mu \right] + \alpha^3 d(\theta, \alpha), \end{aligned}$$

where $\lim_{\alpha \to 0+} d(\theta, \alpha) = 0$ uniformly for $\theta \in V$. It follows, by (a)–(c) and (4) that there

exist $\tau \geqq 1$ and continuous v_1, v_2, v_3: $V \to \tau\hat{C}$ such that

$$\begin{aligned}
\phi(\tilde{q}(\theta,\alpha)) &= \phi(\bar{q}) + \alpha(0, v_1(\theta)) + \alpha^2(0, v_2(\theta)) \\
&\quad + \frac{1}{6}\alpha^3 \Bigg\{ \sum_{(i,s,t)\in S} \hat{\eta}_i(\theta)\hat{\eta}_s(\theta)\hat{\eta}_t(\theta)\mathcal{P}[\phi'''(\bar{q})y_i y_s y_t + 6\phi''(\bar{q})y_i z_{st}] \\
&\qquad\qquad + 6\phi'(\bar{q}) \sum_{\mu} (\beta_\mu + \theta_\mu) h_\mu \Bigg\} \\
&\quad + \alpha^3(0, v_3(\theta)) + \alpha^3 d(\theta,\alpha) \\
&= \phi(\bar{q}) + (0, \alpha v_1(\theta) + \alpha^2 v_2(\theta) + \alpha^3 v_3(\theta)) \\
&\quad + \frac{1}{6}\alpha^3 \sum_{(i,s,t)\in S} \sum_{\mu} (\beta_\mu + \theta_\mu)\tau_{ist}^{\mu}\mathcal{P}[\phi'''(\bar{q})y_i y_s y_t + 6\phi''(\bar{q})y_i z_{st}] \\
&\quad + 6\phi'(\bar{q}) \sum_{\mu} (\beta_\mu + \theta_\mu) h_\mu + \alpha^3 d(\theta,\alpha) \\
&= \phi(\bar{q}) + (0, \alpha v_1(\theta) + \alpha^2 v_2(\theta) + \alpha^3 v_3(\theta)) \\
&\quad + \frac{1}{6}\alpha^3 \sum_{\mu} (\beta_\mu + \theta_\mu)\xi^\mu + \alpha^3 d(\theta,\alpha).
\end{aligned}$$

It follows now from Theorem 2.2 (just as in the proof of Theorem 3.1) that ϕ_1 is strongly locally $(\mathcal{U}, \phi_2, C)$-controllable. Q.E.D.

NILPOTENT APPROXIMATIONS OF CONTROL SYSTEMS AND DISTRIBUTIONS*

HENRY HERMES†

Abstract. A constructive method is given to approximate the vector fields in a nonlinear control system, which is linear in the controls, by a system of similar form and on the same state space, with the describing vector fields of the approximating system generating a Lie algebra which has a certain, relevant, sub-algebra nilpotent. Given a k-dimensional distribution on R^n, say locally defined near zero, the method leads to an approximating k-distribution which has nilpotent basis, agrees with the original distribution at zero, and each derived distribution of the approximating distribution and original distribution also agree at zero.

Key words. nilpotent Lie algebras, system approximation

AMS(MOS) subject classifications. 93B10, 49E99

Introduction. The goal of this paper is to show how to constructively approximate (in a sense to be made precise) the vector fields $X^0, X^1, \cdots, X^k$ in a control system on R^n of the form

$$\dot{x} = X^0(x) + \sum_{i=1}^{k} u_i X^i(x), \quad x(0) = 0, \quad X^0(0) = 0, \tag{1}$$

by vector fields $Y^0, \cdots, Y^k$ for which either the Lie algebra, $L(Y^0, \cdots, Y^k)$, generated by $Y^0, \cdots, Y^k$ or a certain appropriate subalgebra of this algebra, is nilpotent.

Assume all vector fields are real analytic. For any set, $\mathcal{S}$, of vector fields on R^n (or an n-manifold M^n), $L(\mathcal{S})$ will denote the Lie algebra they generate, $\mathcal{S}(0)$ the elements of $\mathcal{S}$ evaluated at 0; $[X, Y] = (\text{ad } X, Y)$ the commutator, or Lie product, of the vector fields X, Y and, inductively, $(\text{ad}^{l+1} X, Y) = [X, (\text{ad}^l X, Y)]$.

For the vector fields of system (1), assign the weight $w_0 = 0$ to X^0 and $w_i = 1$ to X^i for $i = 1, \cdots, k$. The weight assigned to a commutator will be the sum of the weights of its constituent factors. For $i = 1, 2, \cdots$ let

$$\mathcal{S}_X^i \text{ be the set of commutators of } X^0, \cdots, X^k \text{ of weight } i. \tag{2}$$

Explicitly, $\mathcal{S}_X^1 = \{(\text{ad}^j X^0, X^i): j \geqq 0, i = 1, \cdots, m\}$. Recall [1] that dim span $\mathcal{S}_X^1(0) = n$ is the "first" order sufficient condition for local controllability of system (1) along the solution, denoted $(\exp tX^0)(0)$, of the uncontrolled equation $\dot{x} = X^0(x)$, $x(0) = 0$. The sets $\mathcal{S}_X^2, \cdots$ play a significant role in higher order local controllability conditions, [2], [3]. We shall assume, mainly for convenience,

$$\dim L(\mathcal{S}_X^1)(0) = n \tag{3}$$

which implies that for all $t > 0$ the attainable set of system (1) at time t has nonempty interior in R^n.

Assume dim span $\mathcal{S}_X^1(0) = n_1$, dim span $(\mathcal{S}_X^1 \cup \mathcal{S}_X^2)(0) = n_2$ and N is the smallest integer such that dim span $(\mathcal{S}_X^1 \cup \cdots \cup \mathcal{S}_X^N)(0) = n$. The notation X^π will denote a product of specific vector fields from the set $X^0, \cdots, X^k$ taken in a specific order. (If we deal with vector fields $Y^0, \cdots, Y^k$, $\mathcal{S}_Y^i$ will denote the equivalent set to $\mathcal{S}_X^i$ and Y^π the equivalent commutator to X^π.)

THEOREM 1. *Let* $X^{\pi_1}, \cdots, X^{\pi_{n_1}} \in \mathcal{S}_X^1$ *be such that* $X^{\pi_1}(0), \cdots, X^{\pi_{n_1}}(0)$ *are linearly independent. Adjoint* $X^{\pi_{n_1+1}}, \cdots, X^{\pi_{n_2}} \in \mathcal{S}_X^2$ *such that* $X^{\pi_1}(0), \cdots, X^{\pi_{n_2}}(0)$ *are independent and continue in this way until one has* $X^{\pi_1}, \cdots, X^{\pi_n}$ *with* $X^{\pi_1}(0), \cdots, X^{\pi_n}(0)$ *independent. Then there exist vector fields* $Y^0, \cdots, Y^k$ *on* R^n *which describe the approximating system*

$$\dot{x} = Y^0(x) + \sum_{i=1}^{k} u_i Y^i(x), \qquad x(0) = 0 \tag{4}$$

and satisfy (a) $Y^0(0) = 0$, (b) $Y^{\pi_i}(0) = X^{\pi_i}(0)$, $i = 1, \cdots, n$, (c) $L(\mathcal{S}_Y^1)$ *is nilpotent. Furthermore, the* Y^i *can be explicitly constructed and have polynomial coefficients relative to the preferred coordinates of the construction.*

Remark 1. It is well known (see Example 5) that one cannot, in general, find vector fields $Y^0, \cdots, Y^k$ with $L(Y^0, \cdots, Y^k)$ nilpotent and such that $Y^\pi(0) = X^\pi(0)$ for all commutators X^π of length $\leqq N$ (or, as seen in this example, even of length $\leqq 1$).

Remark 2. If one deals with distributions, say $D^k(x) = \operatorname{span}\{X^1(x), \cdots, X^k(x)\}$ defined in a neighborhood of zero in R^n, one would have $X^1(0), \cdots, X^k(0)$ independent. Then $X^{\pi_1} = X^1, \cdots, X^{\pi_k} = X^k$; $\mathcal{S}_X^1 = \{X^1, \cdots, X^k\}$ while $\mathcal{S}_X^2$ would consist of all products of pairs of elements of $\mathcal{S}_X^1$, etc. Let $D^{k,1}(x) = D^k(x)$, $D^{k,2}(x) = \operatorname{span}(\mathcal{S}_X^1 \cup \mathcal{S}_X^2)(x)$, etc. Theorem 1 then yields the existence of $Y^1, \cdots, Y^k$ such that if $E^k = E^{k,1}(x) = \operatorname{span}\{Y^1(x), \cdots, Y^k(x)\}$, $E^{k,2}(x) = \operatorname{span}(\mathcal{S}_Y^1 \cup \mathcal{S}_Y^2)(x)$, etc. then E^k is a k-distribution having a "nilpotent basis" $Y^1, \cdots, Y^k$ and which approximates D^k in the sense that $E^{k,i}(0) = D^{k,i}(0)$, $i = 1, \cdots, N$, i.e. the derived distributions agree to order N at 0.

Our main concern with Theorem 1 is its application to control systems of the form (1). The solution of (1) at time t for given control u can be expressed (see [4]) as

$$x(t, u) = (\exp tX^0) \circ y(t, u) \tag{5}$$

where $y(t, u)$ satisfies the auxiliary equation

$$\dot{y} = \sum_{i=1}^{k} u_i(t) \sum_{\nu=0}^{\infty} \frac{(-t)^\nu}{\nu!} (\operatorname{ad}^\nu X^0, X^i)(y), \qquad y(0) = 0. \tag{6}$$

If $L(\mathcal{S}_X^1)$ is nilpoent, the solution $y(t, u)$ of (6) can be constructively expressed ([5, § 3] or [3]) as a finite composition

$$y(t, u) = (\exp F_1(t, u) W^1) \circ \cdots \circ (\exp F_m(t, u) W^m)(0) \tag{7}$$

where $\{W^1, \cdots, W^m\}$ is an "ordered basis" for $L(\mathcal{S}_X^1)$. Substituting (7) in (5) yields an expression for the system output as a function of the control, analogous (equivalent) to the Volterra series expansion which is also finite when $L(\mathcal{S}_X^1)$ is nilpotent. Thus $L(\mathcal{S}_X^1)$ nilpotent implies local analysis of system (1) is greatly simplified. Theorem 1 yields $L(\mathcal{S}_Y^1)$ nilpotent for the approximating system (4).

From the assignment of weights, $\mathcal{S}_X^j$ consists of commutators containing j factors from $\{X^1, \cdots, X^k\}$. Each such factor has coefficient a control component so one can view an element of $\mathcal{S}_X^j$ as corresponding to a jth power of the control. In this sense, the approximation can loosely be considered as related to a truncation, to order N, of the expansion of the output $x(t, u)$ in terms of the control.

Nilpotent approximations have received a great deal of attention during the past decade. Krener [6] showed that for any integer $r \geqq 0$ there exists a bilinear system of the form

$$\dot{W} = A_0 W + \sum_{i=1}^{k} u_i A_i W, \qquad W(0) = \mathrm{id}, \tag{8}$$

on $Gl(m, R)$, for sufficiently large m depending on r, having $L(A_0, \cdots, A_k)$ nilpotent, and a linear map $l: gl(m, R) \to R$ such that for all $i_1, \cdots, i_s \in \{1, \cdots, k\}$ with $s \leqq r$, $l([A_{i_1}, [\cdots[A_{i_{s-1}}, A_{i_s}]\cdots]) = [X^{i_1}, [\cdots[X^{i_{s-1}}, X^{i_s}]\cdots](0)$. From this he deduces the existence of a smooth map $\lambda: Gl(m, R) \to R^n$, $\lambda(\mathrm{id}) = 0$, such that for any control u, $|(x(t, u) - \lambda(W(t, u))| \leqq Kt^{r+1}$. That is, the trajectories of the "lifted" nilpotent system (8) when mapped to R^n via λ, locally approximate those of system (1) to order $(r+1)$.

Rothschild and Stein [7] in their study of hypoelliptic operators of the form $L = \sum_{i=1}^{k} (X^i)^2$, again lift (or extend) the vector fields $X^1, \cdots, X^k$ to a sufficiently large space where their Lie algebra is "free to order r" and then achieve a nilpotent approximation theorem.

More recently, Crouch [8], [9], approximates the system (1) by a system of the same form, but on a space of dimension $\sum_{i=1}^{N} \dim \operatorname{span} \mathscr{S}_X^i(0)$, whose describing vector fields generate a solvable algebra containing $L(\mathscr{S}^1)$ as a nilpotent ideal. The input-output map of his "lifted" approximating system is the Nth order truncated Volterra series of the input-output map of system (1).

For computations, the liftings to a higher-dimensional manifold in the above papers create a problem since the map from this manifold back to R^n is, in general, difficult to explicitly obtain. Bressan [10], obtains a nilpotent approximation to a system of the form $\dot{x} = \sum_{i=1}^{k} u_i X^i(x)$ in which the approximating system (again of this form) lives on R^n. His results are closely related to those of this paper. Indeed, it is shown in Example 3 that our construction, when applied to Bressan's example [10] yields the same approximating system as obtained by Bressan. Many of the ideas and methods of this paper were greatly influenced by those in the aforementioned papers of Crouch and Bressan.

1. Dilations and their related nilpotent algebras. Consider R with coordinates $x = (x_1, \cdots, x_n)$. A dilation, δ_t, is a map $\delta_t: R^n \to R^n$ of the form $\delta_t x = (t^{r_1}x_1, \cdots, t^{r_n}x_n)$ where we assume all integers $r_1 \geqq 1$ and $r_1 \leqq r_2 \leqq \cdots r_n$. We first briefly review some standard definitions.

DEFINITION 1. A polynomial h on (R^n, δ_t) is homogeneous of degree j with respect to δ_t if $t^j h(x) = h(\delta_t x)$. Denote by H_j all polynomials homogeneous of degree j; $H_j = 0$ if $j < 0$.

Note that with $\delta_t x$ as above

$$h \in H_j \text{ implies } \frac{\partial h}{\partial x_i} \in H_{j-r_i}. \tag{9}$$

DEFINITION 2. A vector field X on (R^n, δ_t) is homogeneous of degree m if $Xh \in H_{j-m}$ whenever $h \in H_j$, $j = 0, 1, \cdots$. Thus if $X(x) = \sum_{i=1}^{m} a_i(x)\, \partial/\partial x_i$, X is homogeneous of degree m if $a_i \in H_{r_i - m}$, $i = 1, \cdots, n$.

Example 1. Consider R^3 with $\delta_t x = (tx_1, tx_2, t^3x_3)$. Then $h \in H_0$ implies $h(x) = c$, a constant; $h \in H_1$ implies $h(x) = c_1x_1 + c_2x_2$; $h \in H_2$ implies $h(x) = c_1x_1^2 + c_2x_1x_2 + c_3x_2^2$; $h \in H_3$ implies $h(x) = c_1x_1^3 + c_2x_1^2x_2 + c_3x_1x_2^2 + c_4x_2^3 + c_5x_3$, etc.

Remark 3. If X is homogeneous of degree m, Y homogeneous of degree l and $h \in H_j$, then $Xh \in H_{j-m}$, $Yh \in H_{j-l}$ so $[X, Y]h = Y(Xh) - X(Yh) \in H_{j-(m+l)}$ i.e. $[X, Y]$ is homogeneous of degree $(m+l)$.

PROPOSITION 1. *Let $\mathscr{L}_i$ denote the real linear span of all vector fields homogeneous of degree $\geqq i$ with respect to a given dilation $\delta_t x = (t^{r_1}x_1, \cdots, t^{r_n}x_n)$ on R^n. Then each $\mathscr{L}_i$ is a Lie algebra and $\mathscr{L}_1$ is a nilpotent ideal in $\mathscr{L}_0$.*

Indeed, $\mathscr{L}_0 \supset \mathscr{L}_1 \supset \cdots \supset \mathscr{L}_{r_n} \supset \mathscr{L}_{r_n+1} = \{0\}$ while Remark 3 shows $[\mathscr{L}_1, \mathscr{L}_i] \subset \mathscr{L}_{i+1}$ so the descending central series of $\mathscr{L}_1$ terminates showing that $\mathscr{L}_1$ is nilpotent.

Remark 4. If $Y^{\pi}(x)=\sum_{i=1}^{n} b_i(x)\,\partial/\partial x_i \in \mathscr{L}_j$, $1 \leqq j \leqq r_n$ relative to the dilation $\delta_t x = (t^{r_1}x_1, \cdots, t^{r_n}x_n)$, then $b_i(0)=0$ for $1 \leqq i \leqq k$, k the largest integer such that $r_k < j$.

Remark 5. Let $X(x)=\sum_{j=1}^{n} a_j(x)\,\partial/\partial x_j \in \mathscr{L}_1$ with $\mathscr{L}_1$ defined as above relative to the dilation $\delta_t x=(t^{r_1}x_1, \cdots, t^{r_n}x_n)$. Then $\partial^l a_j(x)/\partial x_{i_1}\cdots\partial x_{i_l}=0$ if $r_{i_1}+\cdots+r_{i_l} \geqq r_j$, $l=1, \cdots, n$. If $\alpha=(\alpha_1, \cdots, \alpha_n)$ is a multi-index and we define $|\alpha|=\sum_{i=1}^{n} r_i\alpha_i$ this means $X \in \mathscr{L}_1$ has the form

$$X(x)=\sum_{j=1}^{n}\left(\sum_{|\alpha|<r_j} c_{j,\alpha}x^{\alpha}\right)\frac{\partial}{\partial x_j}$$

where the $c_{j,\alpha}$ are constants and $x^{\alpha}=(x_1^{\alpha_1}\cdots x_n^{\alpha_n})$, Bressan [10] gives a direct (computational) proof that vector fields of this form generate a nilpotent algebra.

2. The constructive proof of Theorem 1.

A. Assume the vector fields $X^0, \cdots, X^k$ are given relative to some coordinates, say $y=(y_1, \cdots, y_n)$. We first make a linear change of coordinates to $x=(x_1, \cdots, x_n)$ such that relative to these coordinates, $X^{\pi_i}(0)=\partial/\partial x_i$, $i=1, \cdots, n$. Constructively, if in the original coordinates we had $X^{\pi_i}(y)=\sum_{j=1}^{n} a_{ij}(y)\,\partial/\partial y_j$, $i=1, \cdots, n$, let $a_i(y)$ denote the vector $a_i(y)=(a_{i1}(y), \cdots, a_{in}(y))$. Form the matrix, B, having columns $a_1(0), \cdots, a_n(0)$. Since $X^{\pi_1}(0), \cdots, X^{\pi_n}(0)$ are linearly independent, B is nonsingular. Make the linear coordinate change $x=B^{-1}y$ in which case $X^{\pi_i}(x)=\sum_{j=1}\alpha_{ij}(x)\,\partial/\partial x_j$ with $\alpha_i(x)=B^{-1}a_i(Bx)$, i.e. in these coordinates $X^{\pi_i}(0)=\partial/\partial x_i$.

B. Choose a dilation on R^n induced by system (1) as follows. Recall the assumption $\dim L(\mathscr{S}_X^1)(0)=n$ and notation $\dim \operatorname{span}(\mathscr{S}_X^1 \cup \cdots \cup \mathscr{S}_X^i)(0)=n_i$. This assumption implies $n_1 \geqq 1$ and there exists a smallest integer N such that $n_N=n$. Choose the dilation (in the preferred coordinates as above).

(i) $\delta_t x=(tx_1, \cdots, tx_{n_1}, t^2x_{n_1+1}, \cdots, t^2x_{n_2}, \cdots, t^N x_n)$ or, for future notational convenience,

(ii) $\delta_t x=(t^{r_1}x_1, \cdots, t^{r_{n_1}}x_{n_1}, t^{r_{n_1+1}}x_{n_1+1}, \cdots, t^{r_N}x_n)$ where r_i is the exponent of t in (i) of the coefficient of x_i.

C. Let $X^0(x)=\sum_{j=1}^{n} a_{0j}(x)\,\partial/\partial x_j$ be our vector field of weight zero. The approximating vector field $Y^0(x)=\sum_{j=0}^{n} b_{0j}(x)\,\partial/\partial x_j$ is obtained by letting b_{0j} be the truncation of the expansion of a_{0j} in homogeneous polynomials (relative to δ_t) of degree $\leqq r_j$. Specifically, if we expand $a_{0j}(x)=\sum_{l=0}^{\infty} a_{0j}^l(x)$ where $a_{0j}^l \in H_l$, then

$$b_{01}(x)=\sum_{l=0}^{r_1} a_{01}^l(x), \cdots, b_{0n}(x)=\sum_{l=0}^{r_n} a_{0n}^l(x). \tag{10}$$

If $X^i(x)=\sum_{j=1}^{n} a_{ij}(x)\,\partial/\partial x_j$, $1 \leqq i \leqq k$, is a vector field of weight one, the approximating vector field $Y^i(x)=\sum_{j=0}^{n} b_{ij}(x)\,\partial/\partial x_j$ where b_{ij} is the truncation of the expansion of a_{ij} in homogeneous polynomials of degree $\leqq r_j-1$. In the above notation

$$b_{i1}(x)=\sum_{l=0}^{r_1-1} a_{i1}^l(x), \cdots, b_{in}(x)=\sum_{l=0}^{r_n-1} a_{in}^l(x). \tag{11}$$

D. (a) From the construction, if $X^{\pi}(x)=\sum_{i=1}^{n} a_i(x)\,\partial/\partial x_i$ is any commutator of weight $j \geqq 1$, the corresponding "approximating" commutator $Y^{\pi}(x)=\sum_{i=1}^{n} b_i(x)\,\partial/\partial x_i$ satisfies $a_i(0)=b_i(0)$, $n_{j-1}+1 \leqq i \leqq n$.

(b) If $Y^{\pi}(x)=\sum_{i=1}^{n} b_i(x)\,\partial/\partial x_i$ is an approximating commutator of weight $j \geqq 1$, then $Y^{\pi} \in \mathscr{L}_j$ so (see Remark 4) $b_i(0)=0$, $1 \leqq i \leqq n_{j-1}$.

(c) Now consider the specifically chosen commutators X^{π_l}, $1 \leqq l \leqq n$, which, in our preferred coordinates, satisfy $X^{\pi_l}(0)=\sum_{i=1}^{n} a_i(0)\,\partial/\partial x_i=\partial/\partial x_l$. If X^{π_l} has weight

j, then $n_{j-1}+1 \leqq l \leqq n_j$ (see (i)) so if $Y^{\pi_l}(x) = \sum_{i=1}^n b_i(x)\,\partial/\partial x_i$ is the approximating commutator, from (b), $b_i(0) = 0$ for $1 \leqq i \leqq n_{j-1}$ while from (a), $b_i(0) = a_i(0)$ for the remaining indices. Thus $Y^{\pi_l}(0) = X^{\pi_l}(0)$.

Finally, $L(\mathscr{S}_Y^1)$ is nilpotent by Proposition 1, while $X^0(0) = 0$ certainly implies $Y^0(0) = 0$.

3. Examples. For notational and printing ease, throughout this section a vector field $X(x) = \sum_{i=1}^n a_i(x)\,\partial/\partial x_i$ will be written as $X(x) = (a_1(x), \cdots, a_n(x))$.

Example 2. The purpose of this example is to show that one cannot replace the statement $Y^{\pi_i}(0) = X^{\pi_i}(0)$, $i = 1, \cdots, n$ of Theorem 1 by $Y^{\pi_i}(0) = X^{\pi_i}(0)$ for all commutators X^π of length $\leqq N$.

Consider R^3 with $X^0(x) = (0, x_1, x_1^2/2)$, $X^1 = (1, 0, 0)$, $X^2(x) = (x_2, 0, 0)$. Then $(\mathrm{ad}X^0, X^1)(x) = (0, 1, x_1)$, $(\mathrm{ad}^2X^0, X^1) = 0$, $[[X^0, X^1], X^1] = (0, 0, 1)$, $[X^2, [X^0, X^1]](x) = (1, 0, -x_2)$. One can choose $X^{\pi_1} = X^1 \in \mathscr{S}_X^1$, $X^{\pi_2} = (\mathrm{ad}\,X^0, X^1) \in \mathscr{S}_X^1$ and $X^{\pi_3} = [[X^0, X^1], X^1] \in \mathscr{S}_X^2$. This system induces the dilation $\delta_t x = (tx_1, tx_2, t^2x_2)$ and the coordinates are already the preferred coordinates which make $X^{\pi_i}(0) = \partial/\partial x_i$, $i = 1, \cdots, 3$.

A polynomial $h \in H_0$ implies $h = c$, $h \in H_1$ implies $h(x) = c_1x_1 + c_2x_2$, $h \in H_2$ implies $h(x) = c_1x_1^2 + c_2x_1x_2 + c_3x_2^2 + c_4x_3$. The formulae (10), (11) then yield the approximating vector fields $Y^0 = X^0$, $Y^1 = X^1$, $Y^2 = 0$. Thus $Y^{\pi_i}(0) = X^{\pi_i}(0)$, $i = 1, 2, 3$, $Y^0(0) = X^0(0)$ but $[X^2, [X^0, X^1]](0) \neq [Y^2, [Y^0, Y^1]](0)$.

Example 3. (An example from [10].) Consider R^2 with $X^0(x) = 0$, $X^1 = (1, 0) \in \mathscr{S}_X^1$, $X^2(x) = (\sin(x_1 - x_2), 1 - \cos(x_1 + x_2)) \in \mathscr{S}_X^1$. Then $[X^1, X^2](x) = (\cos(x_1 - x_2)), \sin(x_1 - x_2)) \in \mathscr{S}_X^2$ and one finds $1 = n_1 = \dim \mathrm{span}\, \mathscr{S}_X^1(0) = \dim \mathrm{span}\, (\mathscr{S}_X^1 \cup \mathscr{S}_X^2)(0)$ so $n_2 = n_1$. Further computation gives $[[X^2, X^1], X^1](0) = (0, 1)$ and this product has weight 3. Thus $\delta_t x = (tx_1, t^3x_2) = (t^{r_1}x_1, t^{r_2}x_2)$ while $X^{\pi_1} = X^1$, $X^{\pi_2} = [[X^2, X^1], X^1]$ with coordinates already as desired.

A polynomial $h \in H_0$ implies $h(x) = c$, $h \in H_1$ implies $h(x) = c_1x_1$, $h \in H_2$ implies $h(x) = c_1x_1^2$, $h \in H_3$ implies $h(x) = c_1x_1^3 + c_2x_2$.

Expanding the components of X^2 in a Taylor series about zero gives $\sin(x_1 - x_2) = (x_1 - x_2) - (x_1 - x_2)^3/3! + \cdots$, $1 - \cos(x_1 + x_2) = (x_1 + x_2)^2/2 + \cdots$. The approximating vector fields are $Y^1 = X^1$; the first component of Y^2 consists of terms in $\sin(x_1 - x_2)$ which belong to $H_{r_1 - 1} = H_0$, the second component of Y^2 consists of terms in $(1 - \cos(x_1 + x_2))$ which are in H_j with $0 \leqq j \leqq r_2 - 1 = 2$. Thus $Y^2(x) = (0, x_1^2/2)$. This agrees with the nilpotent approximation in [10].

Example 4. The case $\dim \mathrm{span}\, \mathscr{S}_X^1(0) = n$, i.e. the system satisfies the first order, local controllability condition.

Consider the system (1) on R^n and assume $\dim \mathrm{span}\, \mathscr{S}_X^1(0) = n$. Then $X^{\pi_1}, \cdots, X^{\pi_n}$ can be chosen from $\mathscr{S}_X^1$, these all have weight 1, and in the preferred coordinates $x = (x_1, \cdots, x_n)$ satisfy $X^{\pi_i}(0) = \partial/\partial x_i$, $i = 1, \cdots, n$. The induced dilation is $\delta_t x = (tx_1, \cdots, tx_n)$; polynomials $h \in H_0$ are constants while $h(x) \in H_1$ implies $h(x) = \sum_{i=1}^n c_i x_i$. The approximation $Y^0(x) = X_x(0)x$ where $X_x(x)$ denotes the Jacobian matrix of partial derivatives. For $1 \leqq i \leqq k$, if $X^i(x) = \sum_{j=1}^n a_{ij}(x)\,\partial/\partial x_j$, then $Y^i = \sum_{j=1}^n b_{ij}\,\partial/\partial x_j$ where b_{ij} is the constant term in the Taylor series expansion of $a_{ij}(x)$ about zero. Thus, here, the approximating system is the "simplest" linearization of the original system.

Example 5. Let $X^0(x) = (x_1, x_1^2/2)$, $X^1 = (1, 0)$ on R^2. Then $(\mathrm{ad}\,X^0, X^1)(x) = (1, x_1)$ while $(\mathrm{ad}^\nu X^0, X^1)(0) = X^1(0)$ for all $\nu \geqq 0$; hence $L(X^0, X^1)$ is not nilpotent nor could one find vector fields Y^0, Y^1 whose commutators agree with those of X^0, X^1 at zero to order one and with $L(Y^0, Y^1)$ nilpotent. Further computation shows $[[X^0X^1], X^1] = (0, 1) \in \mathscr{S}_X^2$ so one may choose $X^{\pi_1} = X^1 \in \mathscr{S}_X^1$; $X^{\pi_2} = [[X^0, X^1], X^1]$

and the induced dilation is $\delta_t x = (tx_1, t^2x_2)$. The approximating vector fields are $Y^0 = X^0$, $Y^1 = X^1$; $L(Y^0, Y^1)$ is not nilpotent but $L(\mathcal{S}_Y^1)$ is nilpotent as promised.

LEGENDRE-TAU APPROXIMATIONS FOR FUNCTIONAL DIFFERENTIAL EQUATIONS*

KAZUFUMI ITO† AND RUSSELL TEGLAS‡

Abstract. In this paper we consider the numerical approximation of solutions to linear retarded functional differential equations using the so-called Legendre-tau method. The functional differential equation is first reformulated as a partial differential equation with a nonlocal boundary condition involving time-differentiation. The approximate solution is then represented as a truncated Legendre series with time varying coefficients which satisfy a certain system of ordinary differential equations. The method is very easy to code and yields very accurate approximations. Convergence is established, various numerical examples are presented, and comparison between the latter and cubic spline approximations is made.

Key words. Legendre-tau approximation, retarded systems, numerical convergence

AMS (MOS) subject classifications. Primary 65N20, 65R20; secondary 34K99, 93C20

1. Introduction. In this paper we consider Legendre-tau approximations of solutions of functional differential equations (FDEs). The tau method, invented by Lanczos in 1938 [12], is one of several approximation techniques which are referred to as a spectral method [9]. Spectral methods have been used in numerical computations for a wide class of partial differential equations (PDEs). In this paper, we view the original FDE as a PDE $u_t = u_x$ with boundary conditions which involve time differentiation. The Legendre-tau method is based upon representing the approximate solution as a truncated series of Legendre polynomials. The evolution equation for the expansion coefficients is then determined by substituting the series into the above PDE and by imposing the boundary conditions. To our knowledge, the use of the tau method in approximating solutions of FDEs and the specific manner in which it is used (i.e., applying the tau method to a reformulated PDE with boundary conditions involving time evolution) are new. The idea of formulating FDEs as Cauchy problems on an appropriate Hilbert space is not new. Within this framework, Banks and Kappel [2] make use of approximation results from linear semigroup theory (in particular, the Trotter-Kato theorem) to establish the convergence of numerical schemes based upon splines.

In this paper our considerations are restricted to linear autonomous FDEs of retarded type. Our ideas can be extended to (i) nonautonomous, (ii) nonlinear, (iii) neutral-type or (iv) integro-differential systems. We add here that the tau method should prove useful in dealing with partial differential equations with boundary conditions which involve time differentiation. Our main goal is the application of the tau method to optimal control and parameter estimation problems. As will be discussed in § 7 the tau method may offer considerable improvements over other methods (e.g., those discussed in [2], [3]) in many instances. One reason for this is that the semigroup $\{S(t): t \geqq 0\}$ associated with a retarded FDE has the property that the range of $S(t)$ is contained in $\mathcal{D}(\mathcal{A}^k)$ for each $t \geqq kr$ where $\mathcal{A}$ is the infinitesimal generator of $\{S(t): t \geqq 0\}$ with domain $\mathcal{D}(\mathcal{A})$ and r is the longest delay time appearing in the FDE. Thus, the regularity of solutions increases with time. In § 3, we will see that, in such a case, approximations by orthogonal polynomials are quite powerful.

The following is a brief summary of the contents of this paper. In § 2, we review the equivalence results between FDEs and abstract Cauchy problems on the product space $\mathbb{R}^n \times L_2$. In § 3, we recall various properties of Legendre polynomials including certain estimates which are needed to establish convergence. Section 4 is concerned with the development of the numerical scheme based upon the Legendre-tau approximation for solving the class of FDEs under consideration. In order to establish the numerical convergence of such approximations to the actual solution in the $\mathbb{R}^n \times L_2$ norm, we first show, in § 5, that convergence holds in a stronger norm under the special assumptions that the initial data is sufficiently regular and that the inhomogeneous forcing term f is identically zero. In § 6, we then extend our result to the inhomogeneous case wherein $f \in L_2^{\text{loc}}$ and show that the sequence obtained by truncating the last term in each of the Legendre-tau approximations converges to the actual solution in the $\mathbb{R}^n \times L_2$ norm whenever the initial data lies in $\mathbb{R}^n \times L_2$. Finally, in § 7, we present numerical results and compare these with results for cubic spline approximations discussed in [2].

Throughout this paper the following notation will be used. $r > 0$ stands for the longest delay time appearing in the FDE. The Hilbert space of $\mathbb{R}^n$-valued square integrable functions on the interval $[a, b]$ is denoted by $L_2([a, b]; \mathbb{R}^n)$. When the underlying space and interval can be understood from the context, we will abbreviate the notation and simply write L_2. $L_2^{\text{loc}}([0, \infty); \mathbb{R}^n)$, or L_2^{loc}, is the space of $\mathbb{R}^n$-valued locally square integrable functions on the semi-infinite interval $[0, \infty)$. H^k is the Sobolev space of $\mathbb{R}^n$-valued functions f on a compact interval with $f^{(k-1)}$ absolutely continuous and $f^{(k)} \in L_2$, with norm $\|f\|_{H^k} = (\sum_{i=0}^{k} \|f^{(i)}\|_{L_2}^2)^{1/2}$. The Banach space of $\mathbb{R}^n$-valued continuous functions on the interval $[-r, 0]$ is denoted by C. We denote by Z the product space $\mathbb{R}^n \times L_2([-r, 0]; \mathbb{R}^n)$. Given an element $z \in Z$, $\eta \in \mathbb{R}^n$ and $\phi \in L_2$ denote the two coordinates of z: $z = (\eta, \phi)$. The bracket $\langle \cdot, \cdot \rangle_H$ stands for the inner product in the Hilbert space H, and the subscript for the underlying Hilbert space will be omitted when understood from the context. $\|\cdot\|$ denotes the norm for elements of a Banach space and for operators between Banach spaces, while $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^n$.

If X and Y are Banach spaces, then the space of bounded operators from X to Y is denoted by $\mathscr{L}(X, Y)$. $\mathscr{D}(\mathscr{A})$ denotes the domain of a linear operator $\mathscr{A}$. χ_I denotes the characteristic function of the interval I. Given a measurable function $x: [-r, \infty) \to \mathbb{R}^n$ and $t \geqq 0$, the function $x_t: [-r, 0] \to \mathbb{R}^n$ is defined by $x_t(\theta) = x(t + \theta)$, $\theta \in [-r, 0]$. Finally, for any function ϕ of the independent variable θ, we shall use either $\dot{\phi}$ or $\partial\phi/\partial\theta$ to denote the derivative of ϕ with respect to θ.

2. Linear retarded differential equations. In this section, we state the type of equations to be considered and recall some results for such equations which are important for the discussion to follow.

Given $(\eta, \phi) \in Z$ and $f \in L_2^{\text{loc}}([0, \infty); \mathbb{R}^n)$, we consider the initial value problem

$$\begin{aligned} &\frac{d}{dt}x(t) = Dx_t + f(t), \qquad t \geqq 0, \\ &x(0) = \eta, \qquad x_0 = \phi, \end{aligned} \tag{2.1}$$

where $D: \mathscr{D}(D) \subseteq L_2([-r, 0]; \mathbb{R}^n) \to \mathbb{R}^n$ has the form

$$D\phi = \int_{-r}^{0} d\mu(\theta)\phi(\theta) \tag{2.2}$$

with μ a matrix-valued function of bounded variation on $[-r, 0]$. As an example, consider

$$\mu(\theta) = \sum_{i=0}^{m} A_i \chi_{(\theta_i, 0]}(\theta) + \int_{-r}^{\theta} A(s)\, ds, \tag{2.3}$$

where $-r = \theta_m < \cdots < \theta_0 = 0$ and A_i and $A(\cdot)$ are $n \times n$ matrices, the elements of the latter being integrable on $[-r, 0]$. Then

$$Dx_t = \sum_{i=0}^{m} A_i x(t+\theta_i) + \int_{-r}^{0} A(\theta) x(t+\theta)\, d\theta, \qquad t \geqq 0. \tag{2.4}$$

It is well known [3], [5], [8] that for $(\eta, \phi) \in Z$ and $f \in L_2^{\text{loc}}$, (2.1) admits a unique solution

$$x \in L_2([-r, T]; \mathbb{R}^n) \cap H^1([0, T]; \mathbb{R}^n)$$

for any $T \geqq 0$ such that

$$z(t) = (x(t), x_t) \tag{2.5}$$

is a Z-valued continuous function which depends continuously on $(\eta, \phi) \in Z$ and $f \in L_2^{\text{loc}}$ for each $t \geqq 0$.

For $t \geqq 0$, define $S(t): Z \to Z$ by $S(t)(\eta, \phi) = (x(t), x_t)$ whre x is the homogeneous solution of (2.1) (i.e., $f \equiv 0$). Then $\{S(t): t \geqq 0\}$ forms a strongly continuous semigroup on Z. The following results are now standard if one deals with FDEs in the state space Z ([3], [4], [15]).

LEMMA 2.1.

(i) *If $\mathcal{A}$ denotes the infinitesimal generator of $\{S(t): t \geqq 0\}$, then*

$$\mathcal{D}(A) = \{(\eta, \phi) \in Z: \dot{\phi} \in L_2 \text{ and } \eta = \phi(0)\}$$

and for $(\phi(0), \phi) \in \mathcal{D}(A)$

$$\mathcal{A}(\phi(0), \phi) = (D\phi, \dot{\phi}).$$

(ii) *The spectrum $\sigma(\mathcal{A})$ of $\mathcal{A}$ only consists of point spectrum and $\lambda \in \sigma(\mathcal{A})$ if and only if $\det \Delta(\lambda) = 0$ where*

$$\Delta(\lambda) = \lambda I - \int_{-r}^{0} e^{\lambda\theta}\, d\mu(\theta).$$

For each λ in the resolvent set $\rho(\mathcal{A})$ of $\mathcal{A}$, the resolvent of $\mathcal{A}$ is given by

$$(\lambda I - \mathcal{A})^{-1} z = (\psi(0), \psi) \quad \text{for } z = (\eta, \phi) \in Z, \tag{2.6}$$

with

$$\psi(\theta) = e^{\lambda\theta} b + \int_{\theta}^{0} e^{\lambda(\theta - s)} \phi(s)\, d\theta,$$

$$b = \Delta^{-1}(\lambda)\left[\eta + D\left(\int_{\cdot}^{0} e^{\lambda(\cdot - s)} \phi(s)\, ds\right)\right].$$

(iii) *If $z(0) = (\phi(0), \phi) \in \mathcal{D}(\mathcal{A})$ and $f \in L_2^{\text{loc}}$, then $z(t) = S(t)z(0) + \int_0^t S(t-s)\mathcal{B}f(s)\, ds$ satisfies the equation*

$$\frac{dz}{dt}(t) = \mathcal{A}z(t) + \mathcal{B}f(t), \qquad t \geqq 0, \tag{2.7}$$

in Z where $\mathcal{B}:\mathbb{R}^n \to Z$ is defined by

$$\mathcal{B}f = (f, 0) \in Z \quad \text{for } f \in \mathbb{R}^n.$$

(iv) *For $k \geqq 2$, the domain of the kth power of $\mathcal{A}$ is contained in the set*

$$\{(\phi(0), \phi) \in Z: \dot{\phi}(0) = D\phi \text{ and } \phi \in H^k\},$$

and is dense in Z.

Since $\mathcal{A}$ is closed, $\mathcal{D}(\mathcal{A})$ itself with the graph norm

$$\|z\|^2_{\mathcal{D}(\mathcal{A})} = \|z\|^2_Z + \|\mathcal{A}z\|^2_Z$$

is a Hilbert space. Then the restriction of the semigroup $\{S(t): t \geqq 0\}$ to $\mathcal{D}(\mathcal{A})$ also forms a C_0-semigroup on $\mathcal{D}(\mathcal{A})$. Let us denote by X the space $H^1[-r, 0]$ equipped with the norm

$$\|\phi\|_1^2 = |\phi(0)|^2 + \int_{-r}^{0} |\dot{\phi}|^2 \, d\theta$$

and inner product

$$\langle \phi, \psi \rangle_1 = \langle \phi(0), \psi(0) \rangle_{\mathbb{R}^n} + \int_{-r}^{0} \langle \dot{\phi}(\theta), \dot{\psi}(\theta) \rangle_{\mathbb{R}^n} \, d\theta.$$

It is readily established that X is isomorphic to $\mathcal{D}(\mathcal{A}) \subset Z$: consider the map $E: \mathcal{D}(\mathcal{A}) \to X$ defined by

$$E(\phi(0), \phi) = \phi \in X \quad \text{for } (\phi(0), \phi) \in \mathcal{D}(\mathcal{A}).$$

Then $E^{-1}: X \to \mathcal{D}(\mathcal{A}) \subset Z$ is given by

$$E^{-1}\phi = (\phi(0), \phi) \in \mathcal{D}(\mathcal{A}) \quad \text{for } \phi \in X,$$

and it is easy to show that there exists constants $0 < c \leqq C < \infty$ such that

$$c\|\phi\|_1 \leqq \|E^{-1}\phi\|_{\mathcal{D}(\mathcal{A})} \leqq C\|\phi\|_1, \tag{2.8}$$

i.e., E is an isomorphism.

Since $\mathcal{A}$ generates a C_0-semigroup $\{S(t): t \geqq 0\}$ on $\mathcal{D}(\mathcal{A})$ with graph norm, $E\mathcal{A}E^{-1}$ generates a C_0-semigroup $\{ES(t)E^{-1}: t \geqq 0\}$ on X. Moreover, it is easily seen that

$$\mathcal{D}(E\mathcal{A}E^{-1}) = \{\phi \in X: \dot{\phi} \in X \text{ and } \dot{\phi}(0) = D\phi\}$$

and for $\phi \in \mathcal{D}(E\mathcal{A}E^{-1})$.

$$E\mathcal{A}E^{-1}\phi = \dot{\phi}. \tag{2.9}$$

For the sake of convenience, we will use the notation

$$\tilde{S}(t) = ES(t)E^{-1} \quad \text{and} \quad \tilde{\mathcal{A}} = E\mathcal{A}E^{-1}. \tag{2.10}$$

3. Properties of Legendre polynomials. In this section, we review some properties of Legendre polynomials ([11], [13], e.g.).

The Legendre polynomial of degree k, $p_k(x)$, $-1 \leqq x \leqq 1$, can be defined as the solution of the differential equation

$$\frac{d}{dx}\left((1-x^2)\frac{dp}{dx}(x)\right) + k(k+1)p(x) = 0, \tag{3.1}$$

which satisfies $p(1) = 1$. Thus, $p_0(x) = 1$, $p_1(x) = x$, $p_2(x) = \frac{1}{2}(3x^2 - 1)$, and so on. The

Legendre polynomials $\{p_k\}_{k\geqq 0}$ satisfy the orthogonality relation

$$\int_{-1}^{1} p_k(x)p_l(x)\,dx = \frac{2}{2k+1}\delta_{kl}, \tag{3.2}$$

and they form a basis for $L_2(-1,1)$: any $f\in L_2(-1,1)$ can be written as

$$f=\sum_{k\geqq 0} f_k p_k$$

where

$$f_k=\frac{2k+1}{2}\int_{-1}^{1} f(x)p_k(x)\,dx$$

with

$$\|f\|_{L_2}^2=\sum_{k\geqq 0}\frac{2}{2k+1}f_k^2.$$

They possess the recursion formula

$$(k+1)p_{k+1}(x)=(2k+1)xp_k(x)-kp_{k-1}(x). \tag{3.3}$$

From this, we have

$$p_k(\pm 1)=(\pm 1)^k, \qquad |p_k(x)|\leqq 1, \quad |x|\leqq 1,$$

and

$$\dot{p}_k(\pm 1)=(\pm 1)^{k+1}k(k+1)/2.$$

If f is represented as

$$f=\sum_{k=0}^{N} f_k p_k,$$

then

$$\dot{f}=\sum_{k=0}^{N-1} b_k p_k \quad \text{where } b_k\equiv(2k+1)\sum_{\substack{j=k+1\\ j+k\,\text{odd}}}^{N} f_j. \tag{3.4}$$

For any positive integer N, let P^N be the orthogonal projection of L_2 onto the subspace spanned by $\{p_k\}_{k=0}^N$. Then we have the following error estimates [6].

LEMMA 3.1. *For any real $s\geqq 0$, there exists a constant K such that*

$$\|f-P^N f\|_{L_2}\leqq KN^{-s}\|f\|_{H^s}.$$

LEMMA 3.2. *For any real s and σ such that $1\leqq s\leqq\sigma$, there exists a constant K such that*

$$\|f-P^N f\|_{H^s}\leqq KN^{2s-\sigma-1/2}\|f\|_{H^\sigma}.$$

The next lemma gives an error estimate in the supremum norm.

LEMMA 3.3. *For any positive integer m there exists a constant K such that*

$$|f(x)-P^N f(x)|\leqq KN^{-2m+1}\|f\|_{H^{2m}}.$$

Proof. Let us denote by $\mathscr{L}$ the differential operator

$$(\mathscr{L}f)(x)=\frac{d}{dx}\left((1-x^2)\frac{df}{dx}(x)\right).$$

From (3.1), we have

$$\int_{-1}^{1} f(x)p_k(x)\,dx = \left(-\frac{1}{k(k+1)}\right)^m \int_{-1}^{1} (\mathscr{L}^m p_k)(x) f(x)\,dx, \qquad k \geqq 1.$$

Since $\mathscr{L}$ is symmetric,

$$\int_{-1}^{1} f(x)p_k(x)\,dx = \left(-\frac{1}{k(k+1)}\right)^m \int_{-1}^{1} (\mathscr{L}^m f)(x) p_k(x)\,dx, \qquad k \geqq 1.$$

It follows that if $\{f_n\}_{n\geqq 0}$ are the Legendre coefficients of f, then

$$f_k = \left(-\frac{1}{k(k+1)}\right)^m \frac{2k+1}{2} \int_{-1}^{1} (\mathscr{L}^m f)(x) p_k(x)\,dx \equiv \left(-\frac{1}{k(k+1)}\right)^m g_k,$$

where $\{g_k\}_{k\geqq 0}$ are the Legendre coefficients of $\mathscr{L}^m f$. Thus, for any $M > N$ and $|x| \leqq 1$,

$$\begin{aligned}
|P^M f(x) - P^N f(x)| &= \left| \sum_{k=N+1}^{M} f_k p_k(x) \right| \\
&\leqq \sum_{k=N+1}^{M} |f_k| = \sum_{j=N+1}^{M} \left(\frac{1}{k(k+1)}\right)^m |g_k| \\
&\leqq \left(\sum_{k=N+1}^{M} \left(\frac{1}{k(k+1)}\right)^{2m} \frac{2k+1}{2} \right)^{1/2} \left(\sum_{k=N+1}^{M} \frac{2}{2k+1} |g_k|^2 \right)^{1/2} \\
&\leqq \left(\int_N^{\infty} \left(\frac{1}{x(x+1)}\right)^{2m} \frac{2x+1}{2}\,dx \right)^{1/2} \|\mathscr{L}^m f\|_{L_2} \\
&= (4m-2)^{-1/2} \left(\frac{1}{N(N+1)}\right)^{m-1/2} \|\mathscr{L}^m f\|_{L_2}.
\end{aligned}$$

Here we have used $|p_k(x)| \leqq 1$ for $|x| \leqq 1$ and

$$\left(\frac{1}{k(k+1)}\right)^{2m} \frac{2k+1}{2} \leqq \int_{k-1}^{k} \left(\frac{1}{x(x+1)}\right)^{2m} \frac{2x+1}{2}\,dx.$$

It now follows that $\{P^N f\}_{N\geqq 0}$ is a Cauchy sequence in $C[-1, 1]$ and hence that $P^N f$ converges uniformly to f. Letting $M \to \infty$ above, we obtain

$$|f(x) - P^N f(x)| \leqq (4m-2)^{-1/2} \left(\frac{1}{N(N+1)}\right)^{m-1/2} \|\mathscr{L}^m f\|_{L_2}.$$

Since $\mathscr{L}^m$ is a differential operator of order $2m$ with continuous coefficients on $[-1, 1]$, there exists a constant C_m for each $m \geqq 0$ such that

$$\|\mathscr{L}^m f\|_{L_2} \leqq C_m \|f\|_{H^{2m}},$$

which completes the proof.

If f is C^∞, then from Lemma 3.1, the error $\|f - P^N f\|$ decreases more rapidly than any power of $1/N$. This is usually referred to as "infinite order" approximation.

4. Legendre–tau approximation. In this section, we discuss the Legendre-tau approximation of solutions to (2.1).

For simplicity of exposition, we assume that $r = 2$. See the remark at the end of the section for the general case. If $z(t, \theta) = x(t+\theta)$, $\theta \in [-2, 0]$, where x is the solution

to (2.1) with initial data $(\eta, \phi) \in \mathcal{D}(\mathcal{A})$, then, according to Lemma 2.1, z satisfies

$$\frac{\partial z}{\partial t}(t, \theta) = \frac{\partial z}{\partial \theta}(t, \theta), \qquad \theta \in [-2, 0], \tag{4.1}$$

$$\frac{dz}{dt}(t, 0) = \int_{-2}^{0} d\mu(\theta) z(t, \theta) + f(t). \tag{4.2}$$

The approximate solution $z^N(t, \theta)$ is assumed to be expanded in a Legendre series:

$$z^N(t, \theta) = \sum_{k=0}^{N} a_k^N(t) p_k(\theta + 1), \qquad a_k^N \in \mathbb{R}^n. \tag{4.3}$$

The tau approximation [9] of (4.1) and (4.2) is as follows. Note that from (3.4),

$$\frac{\partial z^N}{\partial \theta}(t, \theta) = \sum_{k=0}^{N-1} b_k^N(t) p_k(\theta),$$

where

$$b_k^N(t) \equiv (2k+1) \sum_{\substack{j=k+1 \\ j+k \text{ odd}}}^{N} a_j^N(t). \tag{4.4}$$

Equating $\partial/\partial t$ (z^N) with $\partial/\partial \theta$ (z^N) in the sense that

$$\left\langle \frac{\partial}{\partial t} z^N - \frac{\partial}{\partial \theta} Z^N, g \right\rangle_{L_2} = 0$$

for all polynomials g on $[-2, 0]$ of degree at most $N-1$ leads to the N equations

$$\frac{d}{dt} a_k^N(t) = b_k^N(t), \qquad 0 \leqq k \leqq N-1. \tag{4.5}$$

The essence of the tau method is that the boundary condition (4.2) is then imposed to determine an equation for a_N^N. From (4.2) we obtain

$$\frac{d}{dt}\left(\sum_{k=0}^{N} a_k^N(t) \right) = \int_{-2}^{0} d\mu(\theta) z^N(t, \theta) + f(t),$$

or

$$\frac{d}{dt} a_N^N(t) = -\sum_{k=0}^{N-1} b_k^N(t) + \int_{-2}^{0} d\mu(\theta) z^N(t, \theta) + f(t). \tag{4.6}$$

Hence, from (4.3)-(4.6), we obtain a system of ordinary differential equations for $a_0^N, \cdots, a_N^N$:

$$\frac{d}{dt} \alpha^N(t) = A^N \alpha^N(t) + B^N f(t), \tag{4.7}$$

where $\alpha^N = \operatorname{col}(a_0^N, \cdots, a_N^N)$ and

$$B^N = e_N \otimes I,$$

where $e_N \in \mathbb{R}^{N+1}$ is given by $e_N = \operatorname{col}(0, \cdots, 0, 1)$, I is the $n \times n$ identity matrix, and $\otimes$ denotes Kronecker product. For the case where N is even, A^N is given by

$$A^N = A_0^N + A_\mu^N,$$

where

$$A_0^N = \begin{bmatrix} 0 & 1 & 0 & 1 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 3 & 0 & 3 & \cdots & 0 & 3 \\ 0 & 0 & 0 & 5 & 0 & \cdots & 5 & 0 \\ \vdots & \vdots & & & & & \vdots & \vdots \\ & & & & & & 2N-3 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 2N-1 \\ 0 & -1 & -3 & -6 & -10 & \cdots & & -\dfrac{N(N+1)}{2} \end{bmatrix} \otimes I \tag{4.8}$$

and

$$A_\mu^N = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \\ D_0 & D_1 & \cdots & D_N \end{bmatrix} \tag{4.9}$$

with

$$D_k = \int_{-2}^{0} d\mu(\theta) p_k(\theta+1), \qquad 0 \leqq k \leqq N. \tag{4.10}$$

For N odd, only the last column of A_0^N is different.

For $N \geqq 1$, let

$$z^N(t) = (z^N(t,0), z^N(t,\cdot)) \in Z$$

where

$$z^N(t,\theta) = \sum_{k=0}^{N} a_k^N(t) p_k(\theta+1)$$

as in (4.3). Then the approximate solution $z^N(t)$ is the exact solution to the modified equation:

$$\frac{d}{dt} z^N(t) = \mathcal{A} z^N(t) + \mathcal{B} f(t) + \tau_N(t), \tag{4.11}$$

in Z, where

$$\tau_N(t) = \left(0, \frac{d}{dt} a_N^N(t) p_N\right) \in Z.$$

Indeed,

$$\frac{d}{dt} z^N(t) = \left(\frac{d}{dt} \sum_{k=0}^{N} a_k^N(t), \frac{d}{dt} \sum_{k=0}^{N} a_k^N(t) p_k\right)$$

and, using (4.5) and (4.6),

$$= \left(\frac{d}{dt} \sum_{k=0}^{N} a_k^N(t), \sum_{k=0}^{N-1} b_k^N(t) p_k\right) + \tau_N(t),$$

$$= \left(Dz^N(t,\cdot) + f(t), \sum_{k=0}^{N-1} b_k^N(t) p_k\right) + \tau_N(t).$$

But

$$\mathscr{A}z^N(t)+\mathscr{B}f(t)=\left(Dz^N(t,\cdot)+f(t),\ \sum_{k=0}^{N-1} b_k^N(t)p_k\right), \tag{4.12}$$

whence (4.11) follows. Note that

$$\begin{aligned}\frac{d}{dt}a_N^N(t)&=-\sum_{k=0}^{N-1} b_k^N(t)+Dz^N(t,\cdot)+f(t)\\&=-\dot{z}^N(t,0)+Dz^N(t,\cdot)+f(t).\end{aligned}$$

This fact suggests the introduction of the projection operator L^N on Z, defined as follows: for $z=(\eta,\phi)\in Z$.

$$L^N z=\left(\eta,\ \sum_{k=0}^{N} a_k^N p_k\right), \tag{4.13}$$

where, for $0\leqq k\leqq N-1$,

$$a_k^N=\frac{2k+1}{2}\int_{-2}^{0}\phi(\theta)p_k(\theta+1)\,d\theta,$$

and

$$a_N^N=\eta-\sum_{k=0}^{N-1} a_N^N p_k(1)=\eta-\sum_{k=0}^{N-1} a_k^N.$$

It is easy to show that L^N is a projection on Z (i.e., $L^NL^N=L^N$) and $L^NZ\subset\mathscr{D}(\mathscr{A})$. The tau method can now be interpreted as follows. The approximate solution $z^N(t)$ satisfies

$$\frac{d}{dt}z^N(t)=L^N\mathscr{A}z^N(t)+L^N\mathscr{B}f(t) \tag{4.14}$$

in Z. Indeed, applying L^N to both sides of (4.12) and using (4.6),

$$L^N\mathscr{A}z^N(t)+L^N\mathscr{B}f(t)=\mathscr{A}z^N(t)+\mathscr{B}f(t)+\tau_N(t).$$

Remark. For the general case, i.e., $r\neq 2$, the matrix A^N appearing in (4.7) is replaced by

$$A^N=\frac{2}{r}A_0^N+\tilde{A}_\mu^N,$$

where

$$\tilde{D}_k=\int_{-r}^{0} d\mu(\theta)p_k\left(\frac{2\theta+r}{r}\right),\qquad 0\leqq k\leqq N,$$

replaces D_k in (4.9). In particular, if the delay operator D is given by (2.3) and (2.4), then $\tilde{D}_k$ has the form

$$\tilde{D}_k=\sum_{i=0}^{m} A_i p_k\left(\frac{2\theta_i+r}{r}\right)+\int_{-r}^{0} A(\theta)p_k\left(\frac{2\theta+r}{r}\right)d\theta,$$

for $0\leqq k\leqq N$.

5. Convergence proof. Note that the projection operators L^N are neither orthogonal nor uniformly bounded and therefore do not converge strongly to the

identity operator in Z. This fact underlies an essential difficulty in trying to prove convergence in the space Z. To overcome this difficulty, we will begin with a convergence result in the space X which is isomorphic to $\mathcal{D}(\mathcal{A})$: our motivation here is the fact that (4.14) is also valid in $\mathcal{D}(\mathcal{A})$.

Without loss of generality, we can assume that $r=2$. For each $N\geqq 1$, let us define the orthogonal projection Π^N on Z by

$$\Pi^N(\eta,\phi)=(\eta,P^{N-1}\phi) \quad \text{for } (\eta,\phi)\in Z, \tag{5.1}$$

where P^N is the orthogonal projection on $L_2([-2,0];\mathbb{R}^n)$:

$$(P^N\phi)(\theta)=\sum_{k=0}^{N} a_k p_k(\theta+1) \tag{5.2}$$

with

$$a_k=\frac{2k+1}{2}\int_{-2}^{0}\phi(\theta)p_k(\theta+1)\,d\theta.$$

The orthogonality of Π^N follows from that of P^N. Since the projection operators L^N, $N\geqq 1$, given by (4.13), can be written as

$$L^N z=\Pi^N z+(0,(\eta-(P^{N-1}\phi)(0))p_N) \quad \text{for } z=(\eta,\phi)\in Z, \tag{5.3}$$

it follows immediately that

$$L^N\Pi^N=L^N \quad \text{and} \quad \Pi^N L^N=\Pi^N. \tag{5.4}$$

This fact, when combined with the convergence result for the space X, will lead to the result that the solution $z^N(t)$ to (4.14) with initial data $z^N(0)=L^N(\eta,\phi)$ converges to $z(t)$, the solution to (2.7) with initial data $z(0)=(\eta,\phi)$ in Z in the sense that

$$\|\Pi^N z^N(t)-z(t)\|_Z\to 0 \quad \text{as } N\to\infty. \tag{5.5}$$

For $N\geqq 1$, we define the finite-dimensional subspace $X^N\subset X$ by

$$X^N=\left\{\phi\in X:\ \phi(\theta)=\sum_{k=0}^{N} a_k p_k(\theta+1),\ a_k\in\mathbb{R}^n\right\},$$

and the orthogonal projection Q^N of X onto X^N by

$$(Q^N\phi)(\theta)=\phi(0)+\int_0^\theta (P^{N-1}\dot{\phi})(s)\,ds.$$

The orthogonality of Q^N with respect to the inner product $\langle\cdot,\cdot\rangle_1$, follows from that of P^N on $L_2(-2,0)$. If

$$Q^N\phi=\sum_{k=0}^{N} a_k p_k,$$

then

$$\frac{d}{d\theta}Q^N\phi=\sum_{k=0}^{N} a_k\dot{p}_k=P^{N-1}\dot{\phi},$$

so that, from (4.4), a_k, $1\leqq k\leqq N$, are uniquely determined. a_0 is then determined by

$$(Q^N\phi)(0)=\phi(0)=\sum_{k=0}^{N} a_k \Rightarrow a_0=\phi(0)-\sum_{k=1}^{N} a_k.$$

Let us define $\mathcal{A}^N : X \to X^N$ by

$$\mathcal{A}^N\phi = EL^N\mathcal{A}E^{-1}Q^N\phi \quad \text{for } \phi \in X, \tag{5.6}$$

where E is the isomorphism between X and $\mathcal{D}(\mathcal{A})$ defined in § 2. Then (4.14) can be written as

$$\begin{aligned} &\frac{d}{dt}z^N(t) = \mathcal{A}^N z^N(t) + \mathcal{B}^N f(t) \quad \text{in } X, \\ &z^N(0) = Q^N\phi, \end{aligned} \tag{5.7}$$

where, for $N \geqq 1$, $\mathcal{B}^N = EL^N\mathcal{B}$.

Our goal in this section is to prove the semigroup convergence of $S^N(t) = e^{\mathcal{A}^N t}$ to $\tilde{S}(t)$, defined by (2.10). The case where $f \neq 0$ and the initial data lies merely in Z will be dealt with in the following section. The principal result of this section is based upon the Trotter-Kato theorem (see [14, Thm. 4.6]).

THEOREM 5.1. *Let $S(t)$ and $S^N(t)$, $N \geqq 1$, be C_0-semigroups acting on a Banach space X, with infinitesimal generators $\mathcal{A}$ and $\mathcal{A}^N$ respectively. Assume that the following conditions are satisfied*:

(i) (*stability*) *There exists a constant ω such that*

$$\|S(t)\|_X \leqq e^{\omega t} \quad \text{and} \quad \|S^N(t)\|_X \leqq e^{\omega t}, \qquad t \geqq 0.$$

(ii) (*consistency*) *There exists a subset $\mathcal{D}$ contained in $\mathcal{D}(\mathcal{A}) \cap \bigcap_{N=1}^{\infty} \mathcal{D}(\mathcal{A}^N)$ which together with $(\lambda I - \mathcal{A})\mathcal{D}$ for some $\lambda > 0$ is dense in X and such that $\mathcal{A}^N\phi \to \phi$ for all $\phi \in \mathcal{D}$ as $N \to \infty$. Then for all $\phi \in X$, $\|S^N(t)\phi - S(t)\phi\|_X \to 0$ uniformly on bounded t-intervals.*

LEMMA 5.2 (stability). *There exists a constant $\omega \in \mathbb{R}$ such that, for all $N \geqq 1$, $\mathcal{A}^N - \omega I$ is dissipative on X, i.e.,*

$$\langle \mathcal{A}^N\phi, \phi\rangle_1 \leqq \omega\|\phi\|_1^2 \quad \text{for } \phi \in X.$$

Moreover, if $z^N(t)$ is the solution to (5.7) with $z^N(0) = Q^N\phi$ for $\phi \in X$, then

$$\|z^N(t)\|_1^2 \leqq e^{2\omega t}\|z^N(0)\|_1^2 + \int_0^t e^{2\omega(t-s)}|f(s)|^2\, ds. \tag{5.8}$$

Proof. For any $\phi^N \in X^N$ and $f \in \mathbb{R}^n$, it follows from (5.6) and (4.13) that

$$\langle \mathcal{A}^N\phi^N + \mathcal{B}^N f, \phi^N\rangle_1 = \langle D\phi^N + f, \phi^N(0)\rangle + \int_{-2}^{0} \langle \ddot{\phi}^N(\theta) + b_N\dot{p}_N(\theta), \dot{\phi}^N(\theta)\rangle\, d\theta \tag{5.9}$$

where

$$b_N = D\phi^N + f - \dot{\phi}^N(0). \tag{5.10}$$

Let I denote the integral term in (5.9). Then

$$\begin{aligned} I &= \int_{-2}^{0} \frac{1}{2}\frac{d}{d\theta}|\dot{\phi}^N(\theta)|^2\, d\theta + \int_{-2}^{0} \langle b_N, \dot{\phi}^N(\theta)\rangle\dot{p}_N(\theta+1)\, d\theta \\ &= \frac{1}{2}|\dot{\phi}^N(0)|^2 - \frac{1}{2}|\dot{\phi}^N(-2)|^2 + \langle b_N, \dot{\phi}^N(0) - (-1)^N\dot{\phi}^N(-2)\rangle \\ &\quad + \int_{-2}^{0} \langle \ddot{\phi}^N(\theta), b_N\rangle p_N(\theta+1)\, d\theta \end{aligned} \tag{5.11}$$

where we have used $p_N(\pm 1) = (\pm 1)^N$. Note that the last term on the right-hand side

vanishes because $\ddot{\phi}^N$ is a vector in $\mathbb{R}^N$ whose elements are polynomials of degree less than N and hence orthogonal to p_N. Thus, from (5.11),

$$\begin{aligned} I &= \tfrac{1}{2}|\dot{\phi}^N(0)|^2 - \tfrac{1}{2}|\dot{\phi}^N(-2)|^2 + \langle D\phi^N + f - \dot{\phi}^N(0), \dot{\phi}^N(0) - (-1)^N\dot{\phi}^N(-2)\rangle \\ &= -\tfrac{1}{2}|\dot{\phi}^N(0)|^2 + (-1)^N\langle \dot{\phi}^N(0), \dot{\phi}^N(-2)\rangle - \tfrac{1}{2}|\dot{\phi}^N(-2)|^2 \\ &\quad + \langle D\phi^N + f, \dot{\phi}^N(0) - (-1)^N\dot{\phi}^N(-2)\rangle \\ &\leqq \tfrac{1}{2}|D\phi^N + f|^2 \end{aligned}$$

where we have used the inequality $2\langle x, y\rangle_{\mathbb{R}^n} \leqq |x|^2 + |y|^2$. From this and (5.9), we find

$$\begin{aligned} \langle \mathscr{A}^N\phi^N + \mathscr{B}^N f, \phi^N\rangle_1 &\leqq \langle D\phi^N + f, \phi^N(0)\rangle + \tfrac{1}{2}|D\phi^N + f|^2 \\ &= \langle D\phi^N, \phi^N(0)\rangle + \langle f, D\phi^N + \phi^N(0)\rangle + \tfrac{1}{2}|f|^2 + \tfrac{1}{2}|D\phi^N|^2 \\ &= \langle D\phi^N, \phi^N(0)\rangle + \tfrac{1}{2}\{|f|^2 + 2\langle f, D\phi^N + \phi^N(0)\rangle + |D\phi^N + \phi^N(0)|^2\} \\ &\quad - \tfrac{1}{2}|D\phi^N + \phi^N(0)|^2 + \tfrac{1}{2}|D\phi^N|^2 \\ &= \tfrac{1}{2}|f + D\phi^N + \phi^N(0)|^2 - \tfrac{1}{2}|\phi^N(0)|^2 \\ &\leqq |D\phi^N + \phi^N(0)|^2 + |f|^2. \end{aligned}$$

Note that $D \in \mathscr{L}(X, \mathbb{R}^n)$ with

$$|D\phi| \leqq \beta\|\phi\|_1 \tag{5.12}$$

for some positive constant $\beta < \infty$. Thus

$$\langle \mathscr{A}^N\phi^N + \mathscr{B}^N f, \phi^N\rangle_1 \leqq \omega\|\phi^N\|_1^2 + |f|^2 \tag{5.13}$$

with $\omega = (1+\beta)^2$.

Since Q^N is symmetric with respect to $\langle\cdot,\cdot\rangle_1$, we have, for all $\phi \in X$,

$$\langle \mathscr{A}^N\phi, \phi\rangle_1 = \langle Q^N\mathscr{A}^NQ^N\phi, \phi\rangle_1 = \langle \mathscr{A}^NQ^N\phi, Q^N\phi\rangle_1.$$

It then follows from (5.13) that

$$\langle \mathscr{A}^N\phi, \phi\rangle_1 \leqq \omega\|Q^N\phi\|_1^2 \leqq \|\phi\|_1^2$$

which implies that $\mathscr{A}^N - \omega I$ is dissipative on X.

From (5.7) and (5.13),

$$\frac{1}{2}\frac{d}{dt}\|z^N(t)\|_1^2 = \langle \mathscr{A}^Nz^N(t) + \mathscr{B}^Nf(t), z^N(t)\rangle_1 \leqq \omega\|z^N(t)\|_1^2 + |f(t)|^2.$$

A standard argument using Gronwall's inequality then yields (5.8). Q.E.D.

If $\tilde{\mathscr{A}}$ is defined by (2.10), (i.e., the infinitesimal generator of the semigroup $\tilde{S}(t)$, on X), then Lemma 5.3 follows.

LEMMA 5.3 (consistency). *Let*

$$\mathscr{D}^k = \{\phi \in X: \phi \in H^k \text{ and } \dot{\phi}(0) = D\phi\}.$$

Then for $k \geqq 2$, $\mathscr{D}^k$ and $(\lambda I - \tilde{\mathscr{A}})\mathscr{D}^k$ for $\lambda \in \mathbb{R}$ sufficiently large are dense in X and, for $k \geqq 5$, $\mathscr{A}^N\phi \to \tilde{\mathscr{A}}\phi$ in X for $\phi \in \mathscr{D}^k$.

Proof. Since $\mathscr{D}^k$ densely contained in $\mathscr{D}(\tilde{\mathscr{A}})$ for $k \geqq 2$, the denseness of $\mathscr{D}^k$ follows from that of $\mathscr{D}(\tilde{\mathscr{A}})$. Since $\mathscr{D}^2 = \mathscr{D}(\tilde{\mathscr{A}})$ and, for $\lambda \in \mathbb{R}$ sufficiently large

$$(\lambda I - \tilde{\mathscr{A}})\mathscr{D}(\tilde{\mathscr{A}}) = X,$$

$(\lambda I - \tilde{\mathscr{A}})\mathscr{D}^k$ is dense in X for $k \geqq 2$.

For $\phi \in \mathcal{D}(\tilde{\mathcal{A}})$ and $Q^N\phi \equiv \phi^N$,

$$(\mathcal{A}^N - \tilde{\mathcal{A}})\phi = \dot{\phi}^N - \dot{\phi} + (D\phi^N - \dot{\phi}^N(0))p_N \tag{5.14}$$

in X. From (5.10), the definition of Q^N,

$$\dot{\phi}^N = p^{N-1}\dot{\phi} \quad \text{and} \quad \phi^N(0) = \phi(0).$$

Thus, from Lemma 3.3,

$$|\dot{\phi}^N(0) - \dot{\phi}(0)| \leqq KN^{-2m+1}\|\dot{\phi}\|_{H^{2m}}.$$

From Lemma 3.2,

$$\|\dot{\phi} - \dot{\phi}^N\|_{H^1} = \|\dot{\phi} - p^{N-1}\dot{\phi}\|_{H^1} \leqq KN^{-2m+3/2}\|\dot{\phi}\|_{H^{2m}}.$$

From (5.12),

$$|D(\phi^N - \phi)|_{\mathbb{R}^n} \leqq \beta\|\phi - \phi^N\|_1 = \beta\|\dot{\phi} - \dot{\phi}^N\|_{L_2} = \beta\|\dot{\phi} - p^{N-1}\dot{\phi}\|_{L_2};$$

so that, by Lemma 3.1,

$$\leqq \beta KN^{-2m}\|\dot{\phi}\|_{H^{2m}}.$$

Since $\dot{\phi}(0) = D\phi$ for $\phi \in \mathcal{D}(\tilde{\mathcal{A}})$,

$$\begin{aligned}|D\phi^N - \dot{\phi}^N(0)| &\leqq |\dot{\phi}^N(0) - \dot{\phi}(0)| + |D(\phi^N - \phi)| \\ &\leqq (1+\beta)KN^{-2m+1}\|\dot{\phi}\|_{H^{2m}}.\end{aligned}$$

Note that

$$\int_{-1}^{1} |\dot{p}_N(\theta)|^2 = p_N(\theta)\dot{p}_N(\theta)|_{-1}^{1} - \int_{-1}^{1} p_N(\theta)\ddot{p}_N(\theta)\, d\theta$$

where the second term vanishes as before. Hence

$$\int_{-1}^{1} |\dot{p}_N(\theta)|^2\, d\theta = N(N+1).$$

It now follows from these estimates and (5.14) that

$$\begin{aligned}\|(\mathcal{A}^N - \tilde{\mathcal{A}})\phi\|_1 &\leqq \|\dot{\phi}^N - \dot{\phi}\|_1 + |D\phi^N - \dot{\phi}^N(0)|(1+\sqrt{N(N+1)}) \\ &\leqq (2+\beta)KN^{-2m+2}\|\dot{\phi}\|_{H^{2m}}.\end{aligned}$$

Therefore, if $\phi \in \mathcal{D}^k$, $k \geqq 5$,

$$\|(\mathcal{A}^N - \tilde{\mathcal{A}})\phi\|_1 \leqq (2+\beta)KN^{-2}\|\phi\|_{H^5} \to 0,$$

since $|\dot{\phi}\|_{H^4} \leqq \|\phi\|_{H^5}$. Q.E.D.

Remark. Using the same "completing the square" argument as the one employed in the proof of Lemma 5.2, it is easily verified that $\tilde{\mathcal{A}} - \omega I$ is dissipative on X as well.

Combining Theorem 5.1 with Lemmas 5.2 and 5.3, we have the following theorem.

THEOREM 5.4. *If $\{S^N(t): t \geqq 0\}$ denotes the semigroup on X generated by $\mathcal{A}^N$, $N \geqq 1$, then, for all $\phi \in X$,*

$$\|S^N(t)\phi - \tilde{S}(t)\phi\|_1 \to 0$$

uniformly on bounded t-intervals.

6. Convergence proof (continued). In this section, we prove the convergence of our scheme for the cases where $f \neq 0$ and where the initial data (η, ϕ) is merely assumed to lie in Z.

Let us first consider the case where $f \in L_2^{\text{loc}}([0,\infty);\mathbb{R}^n)$ and $(\eta,\phi)\equiv 0$. The solution (2.1) is given by

$$z(t)=\int_0^t S(t-s)\mathscr{B}f(s)\,ds. \tag{6.1}$$

Recall that for any $f\in\mathbb{R}^n$, $\mathscr{B}f=(f,0)\in Z$. Using formula (2.6) for the resolvent of $\mathscr{A}$,

$$\mathscr{A}^{-1}\mathscr{B}f=(\Delta^{-1}f,\Delta^{-1}p_0)\in Z \tag{6.2}$$

provided that $\Delta=\Delta(0)=\int_{-r}^0 d\mu(\theta)$ is invertible.

When Δ is not invertible (i.e., $0\in\sigma(\mathscr{A})$), we can choose $\omega\in\rho(\mathscr{A})$ and consider $y(t)=e^{-\omega t}x(t)$, $x(t)$ being the solution to the initial value problem (2.1). Then $y(t)$ satisfies

$$\frac{d}{dt}y(t)=-\omega y(t)+\int_{-r}^0 e^{\omega\theta}\,d\mu(\theta)y(t+\theta)+e^{-\omega t}f(t)\equiv D_\omega y_t+e^{-\omega t}f(t)$$

with initial data $y(\theta)=e^{-\omega\theta}\phi(\theta)$, $-r\leqq\theta\leqq 0$. Clearly, this problem may be formulated as before on the product space Z; the corresponding generator $\mathscr{A}_\omega$ will, by construction, satisfy $0\in\rho(\mathscr{A}_\omega)$:

$$\Delta_\omega(\lambda)=(\lambda+\omega)I-\int_{-r}^0 e^{(\lambda+\omega)\theta}\,d\mu(\theta),$$

$$\det[\Delta_\omega(0)]=\det[\Delta(\omega)]\neq 0.$$

Thus, without loss of generality, we may consider (6.2) above.

Let us rewrite (6.1) as

$$z(t)=\int_0^t \mathscr{A}S(t-s)\mathscr{C}f(s)\,ds$$

where $\mathscr{C}f\equiv\mathscr{A}^{-1}\mathscr{B}f$. If f is continuously differentiable, it follows from [10, p. 487] that

$$z(t)=S(t)\mathscr{C}f(0)-\mathscr{C}f(t)+\int_0^t S(t-s)\mathscr{C}\dot{f}(s)\,d.$$

Since $\mathscr{C}f\in\mathscr{D}(\mathscr{A})$, $z(t)\in\mathscr{D}(\mathscr{A})$ for all $t\geqq 0$ and we can write

$$\begin{aligned} Ez(t)&=ES(t)E^{-1}E\mathscr{C}f(0)-E\mathscr{C}f(t)+\int_0^t ES(t)E^{-1}E\mathscr{C}\dot{f}(s)\,ds \\ &=\tilde{S}(t)E\mathscr{C}f(0)-E\mathscr{C}(t)+\int_0^t \tilde{S}(t-s)E\mathscr{C}\dot{f}(s)\,ds. \end{aligned} \tag{6.3}$$

LEMMA 6.1. *For $z=(\eta,\phi)\in Z$,*

$$(\mathscr{A}^N)^{-1}EL^Nz=E\mathscr{A}^{-1}\Pi^Nz.$$

Proof. Recall that the isomorphism $E:\mathscr{D}(\mathscr{A})\to X$ and that $\mathscr{A}^N=EL^N\mathscr{A}E^{-1}Q^N$: $X\to X^N\equiv Q^NX$; thus, there will in general be many solutions $w\in\mathscr{D}(\mathscr{A})$ to

$$\mathscr{A}^NEw=EL^Nz. \tag{6.4}$$

We shall interpret $(\mathscr{A}^N)^{-1}EL^Nz$ to be the unique solution of (6.4) lying in X^N. We must then show that a unique solution exists and has the indicated form.

For $z\in Z$, let

$$\Pi^Nz=\left(\eta,\sum_{k=0}^{N-1}b_kp_k\right)\equiv(\eta,\phi).$$

From (2.6), $\mathscr{A}^{-1}(\eta, \phi) = (\psi(0), \psi)$, where

$$\psi(\theta) = \Delta^{-1}\left(\eta + D\int_{\cdot}^{0} \phi(s)\,ds\right) - \int_{\theta}^{0} \phi(s)\,ds,$$

and thus, since ϕ is a polynomial of degree $N-1$, ψ has degree N. This shows that

$$E\mathscr{A}^{-1}\Pi^N z \in X^N.$$

Since $Q^N : X \to X^N$ is a projection,

$$\begin{aligned}\mathscr{A}^N E\mathscr{A}^{-1}\Pi^N z &= EL^N \mathscr{A} E^{-1} Q^N E\mathscr{A}^{-1}\Pi^N z \\ &= EL^N \Pi^N z \\ &= EL^N z \quad \text{by (5.4).}\end{aligned}$$

Thus, $Ew = E\mathscr{A}^{-1}\Pi^N z \in X^N$ is a solution of (6.4).

To establish uniqueness, we must show that

$$\mathscr{A}^N Ev = 0 \text{ and } Ev \in X^N \Rightarrow v = 0.$$

Let $Ev = \sum_{k=0}^{N} a_k p_k \equiv \phi$ so that

$$v = E^{-1}\phi = (\phi(0), \phi) \in \mathscr{D}(\mathscr{A}).$$

Thus, $\mathscr{A}v = (D\phi, \dot{\phi})$, and so

$$\begin{aligned}\mathscr{A}^N Ev = EL^N \mathscr{A} E^{-1} Q^N Ev = EL^N \mathscr{A} v &= E(D\phi, \dot{\phi} + (D\phi - \dot{\phi}(0))p_N) \\ &= \dot{\phi} + (D\phi - \dot{\phi}(0))p_N.\end{aligned}$$

Since $\dot{\phi}$ is a polynomial of degree $N-1$, $\mathscr{A}^N Ev = 0$ and the orthogonality of the Legendre polynomials yields the fact that $\phi \equiv \phi_0 = \text{constant}$ and $D\phi = 0$. But

$$D\phi = D(\phi_0 p_0) = \Delta\phi_0$$

whence (cf. (6.2)) $\phi_0 = 0$, or $v = 0$. Q.E.D.

From Lemma 6.1,

$$(\mathscr{A}^N)^{-1} EL^N \mathscr{B} f = E\mathscr{A}^{-1}\Pi^N \mathscr{B} f = E\mathscr{A}^{-1}\mathscr{B} f = E\mathscr{C} f \quad \text{for } f \in \mathbb{R}^n.$$

From the definition of $\mathscr{A}^N$ and $\mathscr{B}^N$, the same argument as above applied to

$$z^N(t) = \int_0^t \mathscr{A}^N S^N(t-s)(\mathscr{A}^N)^{-1}\mathscr{B}^N f(s)\,ds$$

yields

$$z^N(t) = S^N(t)E\mathscr{C} f(0) - E\mathscr{C} f(t) + \int_0^t S^N(t-s)E\mathscr{C}\dot{f}(s)\,ds. \tag{6.5}$$

It then follows from Theorem 5.4 that

$$S^N(t)E\mathscr{C} f \to \tilde{S}(t)E\mathscr{C} f \quad \text{in } X \text{ for } f \in \mathbb{R}^n.$$

Since $\dim(\mathbb{R}^n) < \infty$, this implies

$$\|(S^N(t) - \tilde{S}(t))E\mathscr{C}\|_{\mathscr{L}(\mathbb{R}^n, X)} \to 0.$$

Hence, from (6.3) and (6.5), if f is continuously differentiable,

$$\|z^N(t) - Ez(t)\|_1 \to 0, \tag{6.6}$$

uniformly on bounded t-intervals.

According to the stability result of Lemma 5.2 (c.f. (5.8)),

$$\left\| \int_0^t S^N(t-s)\mathcal{B}^N f(s)\, ds \right\|_1 \leqq e^{\omega t} \|f\|_{L_2([0,t];\mathbb{R}^n)}. \tag{6.7}$$

Using the same argument as that given in the proof of Lemma 5.2, the above estimate holds true for (2.7); i.e.,

$$\left\| E \int_0^t S(t-s)\mathcal{B}f(s)\, ds \right\|_1 \leqq e^{\omega t} \|f\|_{L_2([0,t];\mathbb{R}^n)}. \tag{6.8}$$

Since the space of continuously differentiable functions on $[0, t]$ is dense in $L_2(0, t)$ for all $t > 0$, it follows from the Banach-Steinhaus theorem that (6.6) holds true for any $f \in L_2^{\text{loc}}$ as well. Thus, combining the above with Theorem 5.4, we have the following theorem.

THEOREM 6.2. *For any initial data $(\phi(0), \phi) \in Z$ with $\phi \in H^1$ and $f \in L_2^{\text{loc}}$, the approximate solution $z^N(t)$ to (5.7) converges strongly to $Ez(t)$ in X, uniformly on bounded t-intervals.*

Remark. The theorem yields much stronger convergence results with regard to the nature of the inhomogeneous term than those stated in [2] and [3] where convergence results in Z are obtained by other methods.

Note that Theorem 6.2 is not applicable when the initial data (η, ϕ) is merely assumed to lie in Z. To complete our study of convergence, we thus need to consider the case $(\eta, \phi) \in Z$ and $f \equiv 0$.

THEOREM 6.3. *For any $z = (\eta, \phi) \in Z$,*

$$\|\Pi^N(E^{-1}S^N(t)EL^N z - S(t)z)\|_Z \to 0$$

uniformly on bounded t-intervals.

Proof. Let

$$d = d(t) = \Pi^N(E^{-1}S^N(t)EL^N z - S(t)z),$$

thus

$$d = \Pi^N E^{-1}\mathcal{A}^N S^N(t)(\mathcal{A}^N)^{-1}EL^N z - \Pi^N S(t)z.$$

It follows from Lemma 6.1 that

$$\begin{aligned} d &= \Pi^N E^{-1}\mathcal{A}^N S^N(t)E\mathcal{A}^{-1}\Pi^N z - \Pi^N S(t)z \\ &= \Pi^N(E^{-1}\mathcal{A}^N - \mathcal{A}E^{-1})S^N(t)E\mathcal{A}^{-1}\Pi^N z \\ &\quad + \Pi^N \mathcal{A}E^{-1}(S^N(t) - \tilde{S}(t))E\mathcal{A}^{-1}z + \Pi^N \mathcal{A}E^{-1}S^N(t)E\mathcal{A}^{-1}(\Pi^N z - z) \\ &\equiv d_1 + d_2 + d_3. \end{aligned}$$

Since $S^N(t)E\mathcal{A}^{-1}\Pi^N z \in X^N$,

$$\begin{aligned} d_1 &= \Pi^N(E^{-1}EL^N\mathcal{A}E^{-1}Q^N - \mathcal{A}E^{-1})S^N(t)E\mathcal{A}^{-1}\Pi^N z \\ &= \Pi^N(L^N - I)\mathcal{A}E^{-1}S^N(t)E\mathcal{A}^{-1}\Pi^N z = 0 \end{aligned}$$

as $\Pi^N L^N y = \Pi^N y$ for any $y \in Z$. Since Π^N is orthogonal on Z,

$$\begin{aligned} \|d_2\|_Z &\leqq \|\mathcal{A}E^{-1}(S^N(t) - \tilde{S}(t))E\mathcal{A}^{-1}z\|_Z \leqq \|E^{-1}(S^N(t) - \tilde{S}(t))E\mathcal{A}^{-1}z\|_{\mathcal{D}(\mathcal{A})} \\ &\leqq C\|(S^N(t) - \tilde{S}(t))E\mathcal{A}^{-1}z\|_1 \end{aligned}$$

by (2.8). Thus, by Theorem 5.4, $\|d_2(t)\|_Z \to 0$ uniformly on bounded t-intervals.

Likewise,

$$\|d_3\|_Z \leqq C\|S^N(t)E\mathscr{A}^{-1}(\Pi^N z - z)\|_1 \leqq C \cdot \|S^N(t)\|_{\mathscr{L}(X)} \cdot \|E\mathscr{A}^{-1}(\Pi^N z - z)\|_1$$
$$\leqq C e^{\omega t} \cdot c^{-1}\|\mathscr{A}^{-1}(\Pi^N z - z)\|_{\mathscr{D}(\mathscr{A})}$$

by Lemma 5.2 and the first inequality in (2.8). Thus

$$\|d_3\|_Z \leqq \left(\frac{C}{c}\right) e^{\omega t}\{\|\mathscr{A}^{-1}(\Pi^N z - z)\|_Z + \|\Pi^N z - z\|_Z\}$$
$$\leqq \left(\frac{C}{c}\right) e^{\omega t} \cdot (\|\mathscr{A}^{-1}\|_{\mathscr{L}(Z)} + 1)\|\Pi^N z - z\|_Z,$$

and thus $\|d_3(t)\|_Z \to 0$ uniformly on bounded t-intervals as well. This completes the proof of Theorem 6.3.

Remark. Theorem 6.3 would not hold without Π^N as pointed out in § 5: the sequence of projections $\{L^N\}_{N\geqq 1}$ does not converge strongly to the identity operator in Z. However, the theorem implies that the $\mathbb{R}^n$-component of $z^N(t)$ (i.e., $z^N(t, 0)$) does in fact converge to $x(t)$, the solution of (2.1), uniformly on bounded t-intervals, and this is all that is needed as far as numerical convergence of our scheme is concerned. Moreover, it follows from (5.4) that $\{\Pi^N E^{-1} S^N(t) E L^N, t \geqq 0\}$ forms a strongly continuous semigroup on $Z^N \equiv \Pi^N Z$ and its generator is given by

$$\Pi^N E^{-1}\mathscr{A}^N E L^N = \Pi^N E^{-1} E L^N \mathscr{A} E^{-1} Q^N E L^N = \Pi^N \mathscr{A} L^N$$

by (5.6).

7. Numerical results and conclusions. In this section we discuss some numerical examples which demonstrate the feasibility of the Legendre-tau approximation. For the purpose of comparison, we have also computed approximate solutions by using the cubic spline approximation (S_3) which is discussed in [2]. All computations were performed on a Control Data Corporation Cyber 170 model 730 at NASA Langley Research Center (LaRC) using software written in Fortran. The integration of the system of ordinary differential equations (ODEs) (4.6) was carried out by an IMSL routine (DVERK) employing the Runge-Kutta-Verner fifth and sixth order method.

For the Legendre-tau approximation, implementation of the algorithms is almost as easy for the averaging approximation (AV) which is discussed in [3] and the first-order spline approximation (S_1). In Table 1, we give the number of operations for each approximation to compute the right-hand side of (4.6) for the scalar system:

$$\frac{d}{dt}x(t) = ax(t) + bx(t-r) + f(t). \tag{7.1}$$

SP stands for the Legendre-tau approximation. For S_3, C_1 and C_2 are some positive constants (independent of N). Note that, for S_1 and S_3, the operations which are required in order to perform the Cholesky decomposition of Q_k^N (for the definition,

TABLE 1

Method	Number of additions	Number of multiplications
SP	$2N+4$	$N+2$
AV	$N+2$	$N+2$
S_1	$3N+4$	$3N+5$
S_3	$11N+C_1$	$9N+C_2$

see [2, p. 511]) are not included. However these numbers may not reflect directly the CPU time required to solve the approximating system of ODEs. According to our calculations, for the same value of N, the Legendre-tau approximation is about four times as fast as S_3. In addition, no storage space is necessary for the matrix A^N appearing in (4.6) for system (7.1) because of its simple structure. For the general system (2.6) in $\mathbb{R}^n$, the last n rows of A^N need to be stored in order to integrate the approximating system of ODEs using the DVERK routine.

As will be evident from the numerical results for the examples presented below, both approximation methods (SP and S_3) behave about the same initially. The typical feature of the Legendre-tau method is that the relative error decreases with increasing time. This is not unexpected due to two facts: (i) the regularity of the solution to a problem which has smooth inhomogeneous terms increases in time (as pointed out in the Introduction) and (ii) Lemma 3.1. For all examples, on the interval where the solution is infinitely differentiable, the rate of convergence seems to be infinite order. In contrast, spline approximation methods and AV yields finite-order rates of convergence, which is observed in our calculations for S_3.

In order to approximate the initial data, or, in the case when the system involves distributed delays, the expansion coefficients of certain functions need to be computed. For AV and spline approximations such computations are relatively easy, since each element has local support. In our calculations for S_3 we used a Gauss quadrature rule [7]. In contrast, the Legendre polynomials are supported on the whole interval $[-2, 0]$, and, for k large, $p_k(x)$ is a rapidly oscillating function. A feasible algorithm for computing Legendre coefficients will be discussed in a forthcoming paper. However for AV and spline approximations, the expansion coefficients must be recomputed if N is changed. For the Legendre-tau approximation we can use the values which have already been computed for smaller N.

In the tables below we will use the following notation. δ_{SP}^N is one of the differences

$$\left| \sum_{k=0}^{N} (a_k^N)_j(t) - x_j(t) \right|, \qquad j = 1, 2, \cdots, n,$$

where $a_k^N(t)$ is the kth segment of dimension n in the solution vector α^N of the approximating system of ODEs (4.6), and $x(t)$ is the true solution. Similarly, $\delta_{S_3}^N$ denotes one of the differences

$$|(\beta^N(0) w_j^N)(t) - x_j(t)|, \qquad j = 1, 2, \cdots, n.$$

Example 1 (Banks-Kappel [2, Example 1]). In this example we study the equation for a damped oscillator with delayed restoring force and constant external force,

$$\frac{d^2}{dt^2} x(t) + \frac{d}{dt} x(t) + x(t-1) = 10,$$

with initial conditions

$$x(\theta) = \cos\theta, \quad \frac{d}{dt} x(\theta) = -\sin\theta \quad \text{for } \theta \in [-1, 0].$$

Rewriting the above equation as a first order system we have

$$\frac{d}{dt}\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix}\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}\begin{bmatrix} x_1(t-1) \\ x_2(t-1) \end{bmatrix} + \begin{bmatrix} 0 \\ 10 \end{bmatrix},$$

where $x_1(t) = x(t)$ and $x_2(t) = dx(t)/dt$.

Table 2 and Table 3 show the numerical results for $x(t)$ and $dx(t)/dt$. For this example SP achieves the same accuracy with smaller N that S_3 does. For SP, it appears that the rate of convergence is infinite-order.

Example 2 ([2, Example 4]). Next we use an example due to Popov for a degenerate system where we have $(1, -2, -1)^T x(t) = 0$ for $t \geqq 2$ and all iniital data $(\eta, \phi) \in Z$. The equation is

$$\frac{d}{dt}x(t) = \begin{bmatrix} 0 & 2 & 0 \\ 0 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 2 & 0 \end{bmatrix} x(t-1).$$

We choose the initial data:

$$\eta = \operatorname{col}(1, 1, 1) \quad \text{and} \quad \phi(\theta) \equiv 0 \in \mathbb{R}^3 \quad \text{for } -1 \leqq \theta \leqq 0.$$

Note that $(\eta, \phi) \notin \mathcal{D}(\mathcal{A})$.

In Tables 4, 5, and 6 we give the numerical results. Here the initial function is not in the subspace Z^N for either method. With respect to $x_2(t)$ and $x_3(t)$ we can see that S_3 gives slightly better approximations than SP for $t \leqq 1$. This is because x_2 and x_3 have a jump discontinuity in the derivative at $t = 1$. For SP, the convergence of the approximate solutions to the asymptotic solution $(2, 0, 2)$ is quite rapid and seems to be infinite-order.

Example 3 ([2, Example 5]). We consider the scalar equation

$$\frac{d}{dt}x(t) = 5x(t) + x(t-1),$$

with initial function

$$x(\theta) = 5 \quad \text{for } \theta \in [-1, 0].$$

The numerical results for this example can be found in Tables 7 and 8. Again, we observe the quickness of the convergence of the approximate SP solution in this example.

Example 4. Here we deal with the equation which has multiple point delays

$$\frac{d}{dt}x(t) = x(t) + 2x(t-\tfrac{1}{2}) + x(t-1)$$

with initial function

$$x(\theta) = 1 \quad \text{for } \theta \in [-1, 0].$$

The numerical results in Table 9 show that both methods work equally well.

Example 5. This example is used in [1] for the identification problem which has a distributed delay and a discontinuous forcing function. This equation is

$$\frac{d}{dt}x(t) = -3x(t) - \int_1^0 x(t+\theta)\, d\theta + u_{.1}(t),$$

with initial function

$$x(\theta) \equiv 1 \quad \text{for } \theta \in [-1, 0],$$

where $u_{.1}(t)$ is defined by

$$u_{.1}(t) = \begin{cases} 1 & \text{on } [0, .1], \\ 0 & \text{otherwise.} \end{cases}$$

In Table 10 we give the numerical results. The approximations by S_3 seem to be slightly better initially than by SP. This is because the solution $x_t(\theta)$ has a discontinuous derivative with respect to θ for $t \leqq 1.1$. The superiority of SP on the interval where the solution is infinitely differentiable is again observed for $t \geqq 1.2$.

From the discussion and numerical results presented here we can conclude the following. For the Legendre-tau approximation, the effort in implementing the algorithm is as much as for AV. But the accuracy of approximation is as good as that which can be obtained using high order spline approximation. When the solution to a problem is infinitely differentiable, the rate of convergence is faster than any finite power of $(1/N)$. In addition, from our calculations, our method appears to be about four times as fast as the cubic spline approximation method. These properties are much more evident for examples (not presented in this paper) where optimal control and the approximation of eigenvalues were considered.

FINITE TIME CONTROLLERS*

V. T. HAIMO†

Abstract. Continuous finite time differential equations are introduced as fast accurate controllers for dynamical systems. These have qualities superior to controllers which are currently in use in such applications as robotics. The structure of the phase portrait for scalar second order finite time systems is determined. This characterization is used to develop a class of second order finite time systems which can be used as controllers.

Key words. control systems, nonlinear stability, finite time control, ordinary differential equations

1. Introduction. A standard problem in system theory is to develop controllers which drive a system to a given position as fast as possible. Consider

$$\dot{x} = f(x) + u(t)g(x), \qquad x \text{ in } R^n$$

where f models the natural dynamics of the system and g the effect of the control u. An example would be the positioning of a robotic manipulator at a set point in space.

There is a considerable body of research on linear feedback input for multi-dimensional systems, that is feedback control laws of the form

$$u(t)g(x) = Kx, \qquad K : R^n \to R^n.$$

This research has been concerned with finding K so that certain performance criteria are met by the feedback system (see e.g., [1] and [2]). Linear feedback may be quite good from the point of view of accuracy of tracking and placement. It has the disadvantage, however, that solutions of the feedback system are exponential functions of time if f is smooth, since the system behaves linearly in a neighborhood of the set point. Thus convergence can never occur in finite time. Whether or not this presents a serious practical problem will depend on the application.

One may ask whether it is possible to control a system to equilibrium in finite time using a bounded control. A standard textbook solution to this problem is to use a bang-bang control strategy (see, for example, [3]). Such controls optimize the time to reach equilibrium for trajectories of

$$\dot{x} = Ax + Bu, \qquad x \text{ in } R^n, \qquad u \text{ in } R, \quad |u| \leqq 1.$$

It turns out that the optimal control $u(x)$ is discontinuous, and switches from $u = 1$ to $u = -1$ on specific contours in x space.

The implementation of such a discontinuous control strategy leads to decreased response time. There may also be unwanted side effects such as introduced vibrations which arise because of repeated overshooting of the switching contour, caused by errors in the implementation of the discontinuous control. We are thus led to rephrase the question posed above. Can one control a system to equilibrium using a bounded and continuous control law? We will develop such finite time controllers.

2. Definitions. We will discuss qualitative properties of differential equations. Some vocabulary which arises in this context is herewith defined. Suppose that

$$\dot{x} = f(x), \qquad x \text{ in } R^n,$$

and that $x(t, x_0)$ denotes a solution which passes through x_0 at $t = 0$. We will often call solutions *trajectories.* When $x(t, x_0)$ is regarded as a map from R^{n+1} to R^n_i then it will be called the *flow* of $\dot{x} = f$. A set is *invariant with respect to the flow* if all solutions intersecting the set are contained in it.

An *equilibrium point* is a point, x, such that $f(x) = 0$.

An equilibrium point is *asymptotically stable* if

(i) for any $\varepsilon > 0$ there exists a $\delta > 0$ so that $\|x_0\| < \delta \to \|x(t, x_0)\| < \varepsilon$, for all $t \geqq 0$, and

(ii) there exists a neighborhood of 0, U, so that all trajectories which enter U converge to the origin.

Here we have used the double bar to denote the Euclidean norm, as we shall continue to do throughout the paper.

In studying stability Lyapunov theory is very useful. The idea is to find a function which when restricted to a trajectory is a strictly decreasing function of time. If the restricted function has a unique minimum which is at the origin, then the trajectory must converge to that equilibrium.

More formally: suppose there exists $v(x)$ so that $v(0)$ is the unique minimum of v in a neighborhood of $x = 0$. Suppose also that v is C^1 and $\dot{v} = \langle \text{grad } v, f(x) \rangle < 0$ except at 0 where it vanishes. (Here grad v denotes the gradient of v with respect to the standard Riemannian metric on E^n.) Such a function will be called a *Lyapunov function* for $\dot{x} = f(x)$. Since we are only interested in studying local stability properties of ordinary differential equations, we need only define such a function in a neighborhood of zero. A Lyapunov function is *positive definite* if it is positive except at zero where it vanishes.

3. Finite time systems. It is appropriate to limit discussion to differential equations with an isolated equilibrium point at the origin, and no other equilibria, because we are interested, for example, in the behavior of a robot arm in the neighborhood of a set point. This set point is modeled as an isolated equilibrium and, as we are studying local behavior, other equilibria are not of concern. We will call differential equations with the properties that the origin is asymptotically stable, and all solutions which converge to zero do so in finite time, *finite time differential equations.* Unless otherwise specified all right-hand sides of differential equations will be C^1 everywhere except at zero, where they will be assumed to be continuous, and to have an isolated equilibrium.

One notices immediately that finite time differential equations cannot be Lipschitz at the origin. As all solutions reach zero in finite time, there is nonuniqueness of solutions through zero in backwards time. This, of course, violates the uniqueness condition for solutions of Lipschitz differential equations.

In one dimension necessary and sufficient conditions for the finite time property may be found easily. We have

FACT 1. $\dot{x} = r(x)$, $r(0) = 0$, *x in R, is finite time iff*

(i) $xr(x) \leqq 0$ *and equals* 0 *only at* $x = 0$, *for x in a neighborhood of* 0, *and*

(ii) $\int_p^0 (dx/r(x)) < \infty$ *for all p in R.*

Here (i) determines the asymptotic stability of the origin and (ii) determines the finite time property.

The proof is left to the reader.

Let $\text{sig}^a z = (\text{sgn } z)|z|^a$, for z and a in R.

Example 1. $\dot{x} = -\text{sig}^{1/2} x$ is a finite time equation.

One may use Lyapunov theory to extend Fact 1 to the multidimensional case.

PROPOSITION 1. *Consider $\dot{x} = g(x)$ with x in R^n and g continuous. If v is a positive definite Lyapunov function for $\dot{x} = g$, and if $\dot{v} \leqq r(v)$, where $\dot{z} = r(z)$, z in R, is a finite time equation, then $\dot{x} = g$ is also finite time.*

Proof. $\dot{v} \leqq r(v)$ implies that $dv/r(v) \geqq dt$ since by Fact 1 $r(v) < 0$ for $v > 0$. We then have

$$\infty > \int_p^0 dv/r(v) \quad \text{(again by Fact 1)} \quad \text{and}$$

$$\int_p^0 dv/r(v) \geqq \int_0^T dt = T,$$

where the trajectory of $\dot{x} = g$ with initial condition $x(0) = p$ reaches the origin at $t = T$, for $T \leqq \infty$. Since this time to origin is finite, then $\dot{x} = g$ is finite time.

Example 2.

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} -1 & 1/2 \\ 1/2 & -1 \end{bmatrix} \begin{bmatrix} \text{sig}^{1/2} x_1 \\ \text{sig}^{1/2} x_2 \end{bmatrix}$$

is finite time.

Proof. Let $v = x_1^2 + x_2^2$. Then

$$\dot{v} = -|x_1|^{3/2} - |x_2|^{3/2} + 1/2(x_1 \text{ sig}^{1/2} x_2 + x_2 \text{ sig}^{1/2} x_1).$$

One may show this is negative definite as follows. Let

$$C = \{(x_1, x_2): -|x_1|^{3/2} - |x_2|^{3/2} = -1\}.$$

By symmetry one easily sees that $\dot{v}$ achieves its maximum on the set C when $x_1 = x_2$. But $\dot{v} < 0$ when $x_1 = x_2$ and so $\dot{v} < 0$ when $x \neq 0$.

We need to show that $\dot{v} < r(v)$ where r is the right-hand side of a finite time differential equation. Letting $r(z) = -z^{4/5}$, we note that $\dot{v} < r(v)$ because $h(v, \dot{v}) = v^{4/5} + \dot{v}$ is largest when $x_1 = x_2$, and there it is negative. Thus by Proposition 1 $\dot{x} = u$ is finite time.

4. Second order systems. Systems of particular interest in many control theoretic situations are second order systems, and one may ask whether it is possible to generate continuous finite time controllers for second order systems.

Second order systems may of course be represented as first order systems with a special structure. One notices immediately that second order systems have at least one Lipschitz component since if

$$\ddot{x} = w(x, \dot{x})$$

then letting $x = x_1$ and $\dot{x} = x_2$

$$\dot{x}_1 = x_2$$

and

$$\dot{x}_2 = w(x_1, x_2).$$

The following theorem describes the behavior of finite time systems which have at least one Lipschitz component.

THEOREM 1. *Suppose that $\dot{x} = g(x)$ is finite time, with x in R^n, $g(0) = 0$, and g in C^1 on $R^n - \{0\}$, and that $g_i(x)$ is Lipschitz at $x = 0$, for some i. If $x(t)$ is a solution which*

reaches zero at $t = T < \infty$ *then*

$$\lim_{t \to T} \frac{x_i(t)}{\|x(t)\|} = 0.$$

Proof. Suppose $x(t, p_0)$ is a solution of $\dot{x} = g$ with $x(0, p_0) = p_0$ and $x(T, p_0) = 0$. By the mean value theorem, there is some q in $[0, T]$ so that

$$0 = x_i(T, p_0) = x_i(0, p_0) + Tg_i(x(q, p_0))$$

or

$$\frac{g_i(x(q, p_0))}{x_i(0, p_0)} = -\frac{1}{T}.$$

T may be considered to be a function of the initial condition p, where $T(p)$ is the time to origin for the trajectory beginning at p. We then have

$$\frac{g_i(x(q(p), p))}{x_i(0, p)} = -\frac{1}{T(p)}.$$

One may take the limit as $p \to 0$ along the trajectory through the point p_0.

Since $x_i(t, p)$ is a smooth function of t and vanishes at $t = T(p)$ then

$$\lim_{p \to 0} \left| \frac{x_i(q, p)}{x_i(0, p)} \right| = 1.$$

Thus

$$\lim_{p \to 0} \frac{g_i(x(q, p))}{x_i(q, p)} \frac{x_i(q, p)}{x_i(0, p)} = \lim_{p \to 0} -\frac{1}{T(p)} = -\infty$$

and so

$$\lim_{p \to 0} \frac{g_i(x(q, p))}{x_i(q, p)} \to -\infty.$$

g_i is Lipschitz so $g_i / \|x\|$ is bounded. Thus

$$\lim_{p \to 0} \frac{g_i(x(q, p))}{\|x(q, p)\|} \frac{\|x(q, p)\|}{x_i(q, p)} = -\infty$$

which implies that

$$\lim_{p \to 0} \frac{x_i}{\|x\|} = 0.$$

This result tells us that the trajectories of a second order finite time system converge in the state space along a hyperplane $x_1 = 0$ (where x_1 denotes the position of the system as above) since such a system must have at least one non-Lipschitz component.

Theorem 1 implies that for the system to reach zero in finite time trajectories must enter the region where the non-Lipschitz terms dominate.

We restrict our search for second order finite time systems to scalar problems. By Theorem 1 we know that trajectories of finite time systems in the $(x, \dot{x})$ plane converge tangent to the line $x = 0$. This tells us (among other things) that finite time trajectories do not spiral around the origin infinitely often as they approach it.

In trying to generate examples of differential equations with certain asymptotic behavior one may frequently exploit the fact that there are contours which may only

be crossed in certain directions, or not at all (as in the case of contours which are invariant with respect to the flow) in order to trap the trajectory into some region. This is of course the heart of Lyapunov theory. If one wishes to show that a second order system is finite time, one could search for a contour that prevented trajectories from spiraling around the origin. It seems natural to search for a contour which is itself invariant. This idea lies at the core of the next two theorems.

THEOREM 2. *Consider the scalar differential equation* $\ddot{x} = g(x, \dot{x})$ *with* $g(0, 0) = 0$. *Let* g *be in* C^1 *except at the origin where it is only assumed to be continuous. Suppose that the origin is asymptotically stable. Then all trajectories which reach zero do so in finite time if and only if*

(i) *there exists a solution* q *to the scalar differential equation*

$$q(z)\frac{dq}{dz} = g(z, q(z)), \qquad q(0) = 0,$$

such that $\dot{z} = q(z)$ *is a finite time scalar differential equation,*

(ii) *every solution* p *to*

$$p(z)\frac{dp}{dz} = g(z, p(z)), \qquad p(0) = 0,$$

is such that $\dot{z} = p(z)$ *is a finite time differential equation.*

Proof. Note that the analysis may be restricted to a sufficiently small neighborhood of the origin, N, such that all solutions with initial conditions in N converge to zero.

To prove sufficiency, two Lemmas are required. The structure of the proof is

$$\text{Lemma 1} \rightarrow \text{Lemma 2} \rightarrow \text{sufficiency.}$$

LEMMA 1. *Suppose* $(x(t), \dot{x}(t))$ *is a solution of* $\ddot{x} = g(x, \dot{x})$ *with* $x(T) = \dot{x}(T) = 0$ *for* $T \leqq \infty$. *Then there is an* S, *with* $0 < S < T$ *such that for* $S < t < T$ $x(t)\dot{x}(t) < 0$.

Proof. If $x(t_1)\dot{x}(t_1) > 0$, for some $t_1 \geqq 0$, then there is a $t_2 > t_1$ such that $x(t_2)\dot{x}(t_2) < 0$. Otherwise $|x(t)|$ is always increasing for $t > t_1$ and thus $x(t)$ cannot converge to zero.

Suppose there is no S such that $x(t)\dot{x}(t) < 0$ for $S < t < T$. This implies that if $x(t)\dot{x}(t) < 0$ for $t \geqq 0$ there is an $s > t$ so that $x(s)\dot{x}(s) = 0$. This in turn implies that $x(s) = 0$ for the following reason: One may show fairly easily that $xg(x, 0) < 0$ for all nonzero x, since the origin is the unique equilibrium solution (in N) of $\ddot{x} = g$, and since the origin is asymptotically stable. Thus the vector field $(\dot{x}, g(x, \dot{x}))$ points into the region in $(x, \dot{x})$ space, $x\dot{x} < 0$, along the line $\dot{x} = 0$, and so trajectories leaving this region must exit through the line $x = 0$.

There is a sequence of times $\{t_i\}$, (with $i = 1, \cdots, \infty$ and $\lim t_i = T$) with $x(t_i) = 0$ and $\dot{x}(t_i) \neq 0$. Note that $\dot{x}(t_i)\dot{x}(t_{i+1}) < 0$. Thus

$$(\dot{x}(t_i))(\dot{x}(t_{i+1})) = (\dot{x}(t_i) - q(x(t_i))(\dot{x}(t_{i+1}) - q(x(t_{i+1})))) < 0.$$

(The equality holds since $q(0) = 0$ and $x(t_i) = 0$ for all i.)

This shows that the function on R^2, $H(x, \dot{x}) = \dot{x} - q(x)$ (here we are regarding x and $\dot{x}$ as variables in R^2 rather than as functions of t) passes through zero along the trajectory $x(t), \dot{x}(t)$. By assumption (i), however, the contour in R^2, $H(x, \dot{x}) = 0$, is invariant with respect to the flow. Thus $H(x, \dot{x})$ cannot change sign when it is evaluated along the trajectory $x(t), \dot{x}(t)$. This contradiction shows that Lemma 1 holds.

LEMMA 2. *Suppose* $(x(t), \dot{x}(t))$ *is a solution of* $\ddot{x} = g(x, \dot{x})$ *with* $x(T) = \dot{x}(T) = 0$ *for* $T \leqq \infty$. *There is an* $r \in R^+$, *and a function* h *which is continuous and smooth away from* 0, *such that for* $T \geqq t > r$

$$\dot{x}(t) = h(x(t)), \qquad h(0) = 0.$$

Proof. By Lemma 1 there is an S satisfying $0<S<T$ so that for $S<t<T$ $x(t)\dot{x}(t)<0$. Clearly x and $\dot{x}$ do not change sign for such t. If $x(t)$ is positive, then it decreases as a function of t, and increases if it is negative. Thus no value of x is reached twice along the trajectory $(x(t), \dot{x}(t))$ for $t>S$. This implies that $\dot{x}(t)$ may be expressed as a function of $x(t)$: $\dot{x}(t)=h(x(t))$ for $t>S$. $h(x)$ is smooth, except perhaps at $x=0$ because $\dot{x}=h(x)$, so $\ddot{x}=(dh/dx)\dot{x}$ or $dh/dx=\ddot{x}/\dot{x}$, and $\ddot{x}(t)/\dot{x}(t)$ is continuous (as a function of x and $\dot{x}$; not t) except perhaps at $\dot{x}=0$. $\dot{x}=0$ on the trajectory only when $x=0$.

h is continuous at zero: $\lim_{x\to 0} h(x)=0$. Lemma 2 is proved. We show that it implies sufficiency.

Let $(x(t), \dot{x}(t))$ be a solution of $\ddot{x}=g(x,\dot{x})$ with $x(T)=\dot{x}(T)=0$ for $T\leqq\infty$. By Lemma 2 there is a function h such that $\dot{x}(t)=h(x(t))$ for sufficiently large t. We thus have

$$\ddot{x}=g(x,h(x))=h(x)\frac{dh}{dx} \tag{1}$$

except at $x=0$. But by L'Hospital's rule

$$\lim_{x\to 0}\frac{h(x)}{x}=\lim_{x\to 0}\frac{g(x,h(x))}{h(x)}=\frac{dh}{dx} \quad \text{at } x=0,$$

showing that (1) is satisfied for $x=0$. Thus h satisfies the conditions of assumption (ii) implying that $\dot{x}=h(x)$ must be finite time. Under these conditions x reaches zero in finite time, and since $h(0)=0$ so does $\dot{x}$.

As we started with an arbitrary trajectory all solutions must reach zero in finite time.

We prove necessity. Suppose $\ddot{x}=g(x,\dot{x})$ is finite time. We know by Theorem 1 that $\lim_{t\to T}(\dot{x}/x)=\pm\infty$ for a solution $(x,\dot{x})$ with $x(T)=\dot{x}(T)=0$.

Consider the function $x\dot{x}$. If there is a sequence of times $\{t_i\}$, $i=1,\cdots,\infty$, with $\lim t_i=T$, where $(x\dot{x})(t_i)=0$ for all i, then there is a sequence of times $\{s_j\}$, $j=1,\cdots,\infty$, so that $\dot{x}(s_j)=0$, for all j. Suppose this were not true. Then there would be some I so that for $i>I$

$$x\dot{x}(t_i)=0\Rightarrow x(t_i)=0.$$

If $x(t_i)=0$ and $x(t_{i+1})=0$ then

$$\dot{x}(t_i)\dot{x}(t_{i+1})<0,$$

which indicates that $\dot{x}=0$ at some point between t_i and t_{i+1}. This contradicts our assumption.

Such a sequence, $\{s_j\}$, contradicts the fact that $\lim(\dot{x}/x)=\pm\infty$ as $t\to T$. Thus there is an $S<T$ so that for $S<t<T$ $x\dot{x}(t)<0$. If for instance $x<0$ then x is strictly increasing and so there is a functional relationship between x and $\dot{x}$:

$$\dot{x}(t)=q(x(t)), \quad \text{with } q(0)=0.$$

One may show that q is smooth except perhaps at $x=0$, so q clearly satisfies the relationship

$$q(x)\frac{dq}{dx}=g(x,q(x))$$

and also satisfies it in the limit as x goes to zero.

By assumption, the components of the solution to $\ddot{x} = g(x, \dot{x})$, x and $\dot{x}$, reach zero in finite time. Thus $\dot{x} = q(x)$ must be a finite time first order differential equation and so condition (i) is satisfied. Condition (ii) also holds since for every solution $p(z)$ to

$$p(z)\frac{dp}{dz} = g(z, p(z)), \qquad p(0) = 0,$$

one obtains a trajectory $(x, \dot{x})$ which satisfies $\dot{x} = p(x)$. Once again, since x and $\dot{x}$ reach zero in finite time then $\dot{x} = p$ must be a finite time differential equation.

One should note that associated to each second order scalar finite time equation, $\ddot{x} = g$, there is a first order discontinuous differential equation (described in condition (i) of Theorem 2). This equation has nonunique solutions through the initial condition $q(0) = 0$, and these solutions are nonzero for $z \neq 0$. This distinguishes them from the classical examples of nonunique solutions of such equations as $\dot{x} = \operatorname{sig}^{1/2} x$, with $x(0) = 0$.

Theorem 2 provides a qualitative description of the phase portraits of second order finite time scalar systems. It can also be used to generate examples as we shall see shortly.

The problem of determining the stability properties of an equilibrium point of a non-Lipschitz differential equation can be difficult. In Theorem 2, asymptotic stability of the origin is assumed. In the next theorem a special structure of g gives a Lyapunov function associated with g.

THEOREM 3. *Let $\ddot{x} = g(x, \dot{x}) = f(x) + d(\dot{x})$, where $f(0) = d(0) = 0$, g is C^1 except at zero where it is continuous, $(\dot{x}, g) = (0, 0)$ only at $(x, \dot{x}) = (0, 0)$, and f is monotone decreasing. Then $\ddot{x} = u$ is finite time if and only if*

(i) *there exists a solution $q(z)$ to the first order differential equation on R*

$$q(z)\frac{dq}{dz} = g(z, q(z)), \qquad q(0) = 0 \tag{2}$$

such that $\dot{z} = q(z)$ is a finite time differential equation, and

(ii) *any solution, h, to (2) is such that $\dot{z} = h(z)$ is a finite time equation.*

Proof. (Sufficiency). We need only prove that the origin is asymptotically stable, and then apply Theorem 2. This will be accomplished by using a Lyapunov function.

Consider the function defined in a neighborhood of the origin

$$v(x, \dot{x}) = (\tfrac{1}{2})\dot{x}^2 - \int_0^x f(z)\, dz.$$

This is positive definite since f is decreasing and $f(0) = 0$.

$$\dot{v} = \dot{x}(\ddot{x} - f(x)) = \dot{x}d(\dot{x}).$$

We will show that this is negative for sufficiently small $(x, \dot{x})$ except when $\dot{x} = 0$.

By condition (i) there is a solution $q(z)$ to

$$q(z)\frac{dq}{dz} = f(z) + d(q(z)),$$

with $q(0) = 0$. $\dot{z} = q$ is finite time, so by Fact 1, dq/dz is negative. If $z > 0$ then $q(z)(dq/dz) > 0$ and so $f(z) + d(q(z)) > 0$. This implies that $d(q(z)) > 0$. (The last inequality holds because $f(z) < 0$ for $z > 0$.) Thus $d(y) > 0$ for $y < 0$. Similarly one may show that $d(y) < 0$ if $y > 0$.

We note that all trajectories are bounded as $t \to \infty$, because if $v(x_0) = c (c \text{ in } R^+)$ then $v(x(t, x_0)) \leqq c$. Thus we may use LaSalle's theorem [4] to note that all trajectories converge to the origin.

Necessity is a tautology because the assumption that $\ddot{x} = g$ is finite time includes the asymptotic stability of the origin. Thus we are back in the situation of Theorem 2.

5. Examples of second order systems. With Theorem 3 we may generate a class of finite time second order systems. These are presented in the following corollary.

COROLLARY 1. *Let* $\ddot{x} = -\text{sig}^a x - \text{sig}^b \dot{x} = g$ *with* $a > 0, b > 0$. *If* (A) $b < 1$ *and* (B) $a > b/(2-b)$, *then* $\ddot{x} = g$ *is finite time.*

Proof. $-\text{sig}^a x$ is monotone decreasing. In order to apply Theorem 3, we must prove that

(i) there exists a finite time solution q to

$$q\frac{dq}{dx} = -\text{sig}^a x - \text{sig}^b q(x) \quad \text{with } q(0) = 0,$$

and

(ii) that all such solutions are finite time.

Suppose that

$$q\frac{dq}{dx} = -\text{sig}^a x - \text{sig}^b q(x), \qquad q(0) = 0. \tag{3}$$

We would like to find a solution to this differential equation. The first thing that one notices about it, however, is that it is discontinuous when $q = 0$. Thus the existence theorems for solutions of continuous differential equations are not applicable. We will generate some continuous differential equations from (3).

Consider $p(x) = (1/2)q(x)^2$. This gives

$$\frac{dp}{dx} = q(x)\frac{dq}{dx} = -\text{sig}^a x - \text{sig}^b q(x).$$

Suppose we knew that $xq(x) < 0$ for $x \neq 0$.

If $x \geqq 0$ and $p \geqq 0$ then

$$\frac{dp}{dx} = -\text{sig}^a x + rp(x)^{b/2}, \qquad p(0) = 0 \tag{4}$$

(where $r = 2^{1/2}$), and if $x \leqq 0, p \geqq 0$ then

$$\frac{dp}{dx} = -\text{sig}^a x - rp(x)^{b/2}, \qquad p(0) = 0. \tag{5}$$

Clearly if each of these equations has a positive solution, p, for $x \geqq 0, x \leqq 0$ respectively, and if $xq(x) < 0$ for nonzero x, then there is a solution to (3) for all x.

We first prove that $xq(x) < 0$ for nonzero x. Suppose that $x > 0$ and $q > 0$. Then

$$q\frac{dq}{dx} < 0 \quad \text{so} \quad \frac{dq}{dx} < 0.$$

If $q(0) = 0$, however, this means we have a function which vanishes at zero, is positive for $x > 0$, where it has a negative derivative. This contradiction leads us to conclude that any solution q of (3) is such that $xq(x) < 0$ for $x > 0$. One can show similarly that $xq(x) \leqq 0$ for all x and only vanishes at the origin.

Both differential equations (4) and (5) are defined on closed sets. In order to use existence theorems for continuous differential equations on open sets to show that these equations have solutions, we must extend their domains of definition. This may be done as follows.

Consider the differential equations

$$\frac{dp}{dx} = -\operatorname{sig}^a x + r|p(x)|^{b/2}, \qquad p(0)=0 \tag{6}$$

and

$$\frac{dp}{dx} = -\operatorname{sig}^a x - r|p(x)|^{b/2}, \qquad p(0)=0. \tag{7}$$

These differential equations are defined for all real x and p, and reduce to (4) and (5) when $p>0$. If (6) has a solution p which is positive for $x>0$, and if (7) has a solution p which is positive for $x<0$ then (4) and (5) have the required solutions.

Consider (6). If there is a positive solution p for $x>0$, with $p(0)=0$ then $dp/dx>0$ for $x>0$ if x is sufficiently small. This implies that either

(i) $\lim_{x\to 0} \frac{dp}{dx} = \lim_{x\to 0} p(x)^{b/2}$ (limits from $x>0$)

or that

(ii) $\lim_{x\to 0} x^a = \lim_{x\to 0} p(x)^{b/2}$ (limits from $x>0$).

In case (i) we have that

$$\lim_{x\to 0} \frac{dp}{dx} = \lim_{x\to 0} p/x = \lim_{x\to 0} p^{b/2},$$

which implies that

$$\lim_{x\to 0} p(x) = \lim_{x\to 0} x^{2/(2-b)}.$$

Since the $p^{b/2}$ term dominates the $-x^a$ term, then we must have $a>b/(2-b)$.

In case (ii) we have that

$$\lim_{x\to 0} x^a = \lim_{x\to 0} p(x)^{b/2} \quad \text{or} \quad \lim_{x\to 0} p(x) = \lim_{x\to 0} x^{2a/b}.$$

In this case we have $2a/b-1 \geqq a$ since the x^a term dominates near 0. But $2a/b-1 \geqq a$ implies $a \geqq b/(2-b)$. In order for there to be a negative solution $p(x)$ to (6) for $x>0$ one may show similarly that it is necessary that $a \leqq b/(2-b)$.

We know that there is a solution $p(x)$, with $p(0)=0$ to (6), for $x>0$, by the existence theorem for solutions of continuous differential equations on open sets. Thus if $a>b/(2-b)$ this solution must be positive.

One may show by the same method that (7) may have a positive solution for $x<0$ if and only if $a \geqq b/(2-b)$ and must have a positive solution if the inequality is strict. Thus if assumption (B) holds, then (3) has a solution q. It is also clear from the above analysis that if assumption (B) holds then

$$\lim_{x\to 0} \frac{q(x)}{-\operatorname{sig}^z x} = 1 \quad \text{for } z = 1/(2-b). \tag{8}$$

We claim that $\dot{x} = q(x)$ is finite time if $b<1$. Define $h(x)$ by the equation $q(x) = h(x) - \operatorname{sig}^z x$. Then

$$\lim_{x\to 0} \frac{h(x)}{\operatorname{sig}^z x} = 0.$$

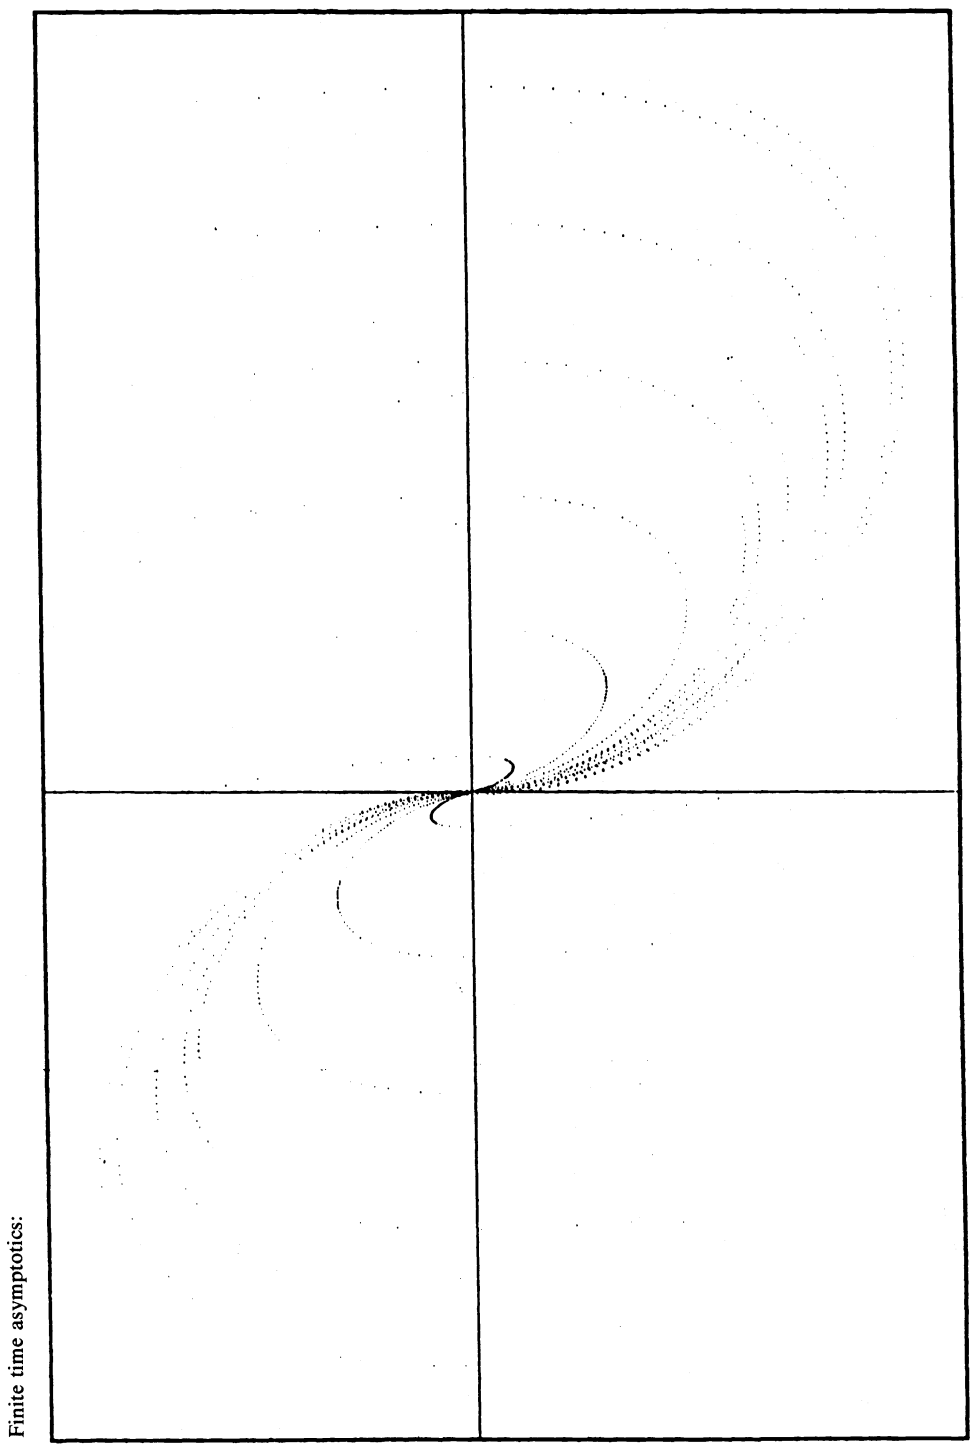

FIG. 1. *Finite time phase portrait.*

Consider the function $v(x) = |x|^{1-z}/1-z$, which is positive definite if $z<1$. Then

$$\dot{v} = \langle \operatorname{grad} v, q\rangle = (\operatorname{sig}^{-z} x)(h(x) - \operatorname{sig}^{z} x)$$

and

$$\lim_{x\to 0} \dot{v} = -1 \leqq -v^{1/2} \quad \text{near zero.}$$

Thus by Proposition 1 $\dot{x} = q$ is finite time if $z<1$, and $z<1$ implies that $b<1$. (Since the time to origin function v, for $\dot{x} = q$, is unbounded at zero if $b \geqq 1$ it follows that the equation $\dot{x} = q$ is finite time iff $b<1$.)

It only remains to show that all solutions of (3) are finite time. By the above analysis any solution of (3), q, satisfies (8). If $b<1$ then all such solutions are finite time.

Note that we have also shown that if $a < b/(2-b)$ or if $b \geqq 1$ then $\ddot{x} = g$ is not finite time. We have for instance

Example 3. $\ddot{x} = -\operatorname{sig}^{.4} x - \operatorname{sig}^{.5}\dot{x}$ is a finite time differential equation.

The phase portrait of this differential equation is displayed in Fig. 1.

It should be noted that this figure also displays the nonunique solutions of the scalar first order differential equation $q(x)(dq/dx) = -\operatorname{sig}^{.4} x - \operatorname{sig}^{.5} q(x)$, with $q(0) = 0$, where the x-axis is horizontal and the $q(x)$ axis is vertical.

A more cumbersome proof along the lines of the proof of Corollary 1 may be used to show that the following holds.

COROLLARY 2. *Let* $\ddot{x} = g = -\operatorname{sig}^{a} x - \operatorname{sig}^{b}\dot{x} + f(x) + d(\dot{x})$ *where* $a>0$, $1>b>0$, $a > b/(2-b)$, $f(0) = d(0) = 0, O(f) > O(|x|^{a})$ *and* $O(d) > O(|\dot{x}|^{b})$; *then* $\ddot{x} = g$ *is a finite time equation.*

The class of examples described in Corollary 2 is quite large. Theorem 2 describes the phase portrait of second order, finite time scalar systems, and also enables us to identify a class of these systems. These may in turn be used as finite time controllers.

For instance, the block design implementation for controlling a link of robot arm is displayed in Fig. 2. In this scheme I is the moment of inertia of the link.

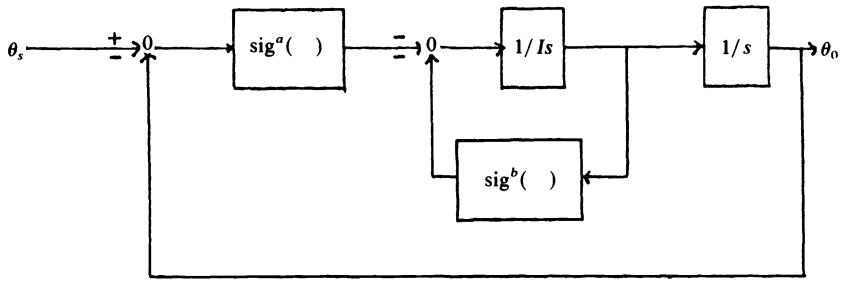

FIG. 2. *Second order servo-system with finite feedback.*

Acknowledgments. I would like to thank Roger Brockett for many helpful discussions on this material. John Baillieul also offered some interesting insights.

A MULTI-RESPONSE QUADRATIC CONTROL PROBLEM*

SUNG J. LEE†

Abstract. We consider a new class of regular quadratic control problem in a compact interval, which is associated with a first order system of ordinary differential equations and very general boundary operators. In particular the state is chosen to minimize a functional and there may be infinitely many minimizers. The theory of least-squares solutions of multi-valued operator equations is used in the investigation.

Key words. first-order differential equation, adjoint, generalized inverse, multi-valued operator, optimal controller

AMS(MOS) subject classification. 49A10

1. Introduction. The linear quadratic control problem with single responses generated by an ordinary differential equation has had an extensive study. The main objective of the problem is to establish the existence of an optimal controller and describe it by a system of differential equations. See a recent survey article [2]. Single responses are generated when an initial condition or a certain two-point condition is imposed in the state equation. But if an insufficient initial condition or a general or generalized boundary condition is imposed on the state equation, then a controller may generate multiple responses and so the associated cost functional becomes a multi-valued map, making the situation more complicated. This is a mathematically interesting case with a potential application, and has not yet been investigated in full in the literature. Thus we will consider a new class of quadratic control problem where the state is subject to a system of ordinary linear differential equations in a compact interval and is chosen to minimize a functional with possibly infinitely many minimizers. Because of the nature of multiple responses we will introduce a new method for the problem. The idea of the investigation is to change the control problem into a least-squares problem for a multi-valued operator equation in Hilbert space, and then characterize the result by Fredholm integro-differential equations and some side conditions. This process involves the recent results on least-squares solutions and generalized inverses for multi-valued linear operators developed in [7], [8], [9]. The main results of this paper are contained in Theorem 3.7 for the existence and Theorem 3.12 for the characterization.

2. Adjoint, least-squares solutions and generalized inverses of linear manifolds. In this section we will state some recent results on multi-valued linear operators which will be needed in the next section. In this paper we will not distinguish an operator (single-valued) from its graph. A vector space will be called a linear manifold. Let H_1, H_2, H_3 be Hilbert spaces over the real field $\mathbb{R}$ or the complex field $\mathbb{C}$. For notational convenience, the inner products of these spaces are denoted by $\langle \cdot, \cdot \rangle$ while their norms are denoted by $\| \cdot \|$. $H_1 \oplus H_2$ will denote the Hilbert space of all ordered pairs $\{x_1, x_2\} (x_1 \in H_1, x_2 \in H_2)$ with its inner product $\langle \cdot, \cdot \rangle$ defined by

$$\langle \{x_1, x_2\}, \{y_1, y_2\} \rangle := \langle x_1, y_1 \rangle + \langle x_2, y_2 \rangle,$$

and its norm $\| \cdot \|$ defined by

$$\| \{x_1, x_2\} \| := (\|x_1\|^2 + \|x_2\|^2)^{1/2}.$$

Let M be a linear manifold (also called a linear relation) in $H_1 \oplus H_2$. Then

$$\begin{aligned}
&\text{Dom } M := \{x: \{x, y\} \in M \text{ for some } y\},\\
&\text{Range } M := \{y: \{x, y\} \in M \text{ for some } x\},\\
&\text{Null } M := \{x: \{x, 0\} \in M\},\\
&M(x) := \{y: \{x, y\} \in M\},\\
&M^{-1} := \{\{x, y\}: \{y, x\} \in M\} \ (x \in \text{Dom } M),\\
&M^{\perp} \text{ (The orthogonal complement of } M)\\
&\quad := \{\{x, y\} \in H_1 \oplus H_2: \langle \{x, y\}, m\rangle = 0 \text{ for all } m \in M\},\\
&M^* \text{ (the adjoint of } M) := \{\{x, y\}: \{y, -x\} \in M^{\perp}\}.
\end{aligned}$$

One can show easily that M^* is a closed linear manifold, and M^* is an operator if Dom M is dense. Moreover, if M is a densely defined closed operator, then M^* is the graph of the usual adjoint operator of M. For this result and other related results, see [6] where related references may be found.

Suppose that $S \subset H_2 \oplus H_3$ is a linear manifold. Then

$$SM := \{\{x, y\} \in H_1 \oplus H_3: \{x, z\} \in M, \{z, y\} \in S \text{ for some } z\}.$$

Let P be the orthogonal projector from H_1 onto Null M, i.e., P is the bounded linear operator from H_1 onto Null M such that $P^2 = P$ and $P^* = P$. Let P^+ be the orthogonal projector from H_2 onto Null M^*. Define a linear manifold $M^\#$ in $H_2 \oplus H_1$ by

$$M^\# := [\text{graph } (I - P)]M^{-1}[\text{graph } (I - P^+)]$$

where I denotes the identity operator. $M^\#$ is called the orthogonal generalized inverse of M.

The following theorem can be found in [8] (see also [7]).

THEOREM 2.1. *Let M be a closed linear manifold in $H_1 \oplus H_2$. Then*

(i) *$M^\#$ is a closed linear operator with*

$$\text{Dom } M^\# = \text{Range } M \dotplus \text{Null } M^*,$$

$$\text{Range } M^\# = \text{Dom } M \cap (\text{Null } M)^{\perp},$$

where $\dotplus$ denotes an algebraic direct sum. In particular, Range M *is closed if and only if* Dom $M^\# = H_2$.

(ii) $M^\# = ((I - P)M^{-1}) \dotplus (\text{Null } M^* \oplus \{0\})$, *direct sum, where P is the orthogonal projector of H_1 onto* Null M. *In particular, $\{y, g\} \in M$ if and only if $g \in$* Range M *and $y = M^\#(g) + k$ for some $k \in$* Null M.

We remark here that if M is a densely defined closed linear operator, then $M^\#$ is precisely the Moore-Penrose generalized inverse of M. Moreover, $R \equiv (I - P)M^-$ is the operator such that $M^{-1} = R \dotplus (\{0\} \oplus \text{Null } M)$, orthogonal direct sum.

The conjugate transpose and the transpose of a matrix N are denoted by N^* and $N^{\mathbf{t}}$ (bold faced $\mathbf{t}$ to distinguish it from time t), respectively. $\mathbb{C}^k$ will denote the k-dimensional complex Euclidean space with its inner product $\langle \cdot, \cdot \rangle$ and its norm $\| \cdot \|$ defined by

$$\langle x, y\rangle = x^{\mathbf{t}}\bar{y}, \qquad \|x\| = (x^*x)^{1/2},$$

where $\bar{y}$ denotes the complex conjugate of y (where we have identified any element of $\mathbb{C}^k$ as a *column* vector).

Suppose T is a $m \times n$ constant complex matrix. Then the Moore-Penrose inverse matrix of T (which is a $n \times m$ matrix) is also denoted by $T^\#$. We can (and will) identify

T as a bounded operator from $\mathbb{C}^n$ into $\mathbb{C}^m$. Thus

$$\text{Null } T = \{x \in \mathbb{C}^n : Tx = 0\},$$

$$\text{Range } T = \{Tx : x \in \mathbb{C}^n\}.$$

When T is identified as an operator, its generalized inverse is an operator from $\mathbb{C}^m$ into $\mathbb{C}^n$, and this inverse can be identified as a $n \times m$ matrix with respect to the standard orthonormal bases of $\mathbb{C}^n$ and $\mathbb{C}^m$. This is precisely T^*. Hence the notation T^* is consistent with the general one given earlier.

We say that $u \in H_1$ is a least-squares solution, briefly LSS, of an inclusion $g \in M(x)$ (g is a given element in H_2) if $u \in \text{Dom } M$ and there exists $y \in M(u)$ such that

$$\|g - y\| = \text{Min}\{\|g - z\| : z \in \text{Range } M\}.$$

Notice that when M is an operator, this reduces to the usual definition of a least-squares solution.

The following can be found in [9].

THEOREM 2.2. *Let M be a linear manifold in $H_1 \oplus H_2$ and $g \in H_2$. Assume that M is closed. Then*

(i) *$g \in M(x)$ has a* LSS *if and only if $g \in \text{Dom } M^*$. In particular, if* Range *M is closed, then a* LSS *always exists.*

(ii) *u is a* LSS *of $g \in M(x)$ if and only if $u \in \text{Dom } M$ and $g \in M(u) \dotplus \text{Null } M^*$.*

(iii) *Assume that $g \in \text{Dom } M^*$. Then the set of all* LSS *are given by the coset*

$$M^*(g) \dotplus \text{Null } M.$$

In particular, $M^*(g)$ is the unique LSS *of smallest H_1-norm.*

3. Multi-response control problem. Let $[t_0, t_1]$ be a compact interval. For a natural number q, let X_q denote the Hilbert space of $x : [t_0, t_1] \to \mathbb{C}^q$ such that $\|x\| := (\int_{t_0}^{t_1} x^*(t)x(t)\,dt)^{1/2} < \infty$. The inner product $\langle \cdot, \cdot \rangle$ of X_q is defined by $\langle x, y \rangle := \int_{t_0}^{t_1} x^t(t)\overline{y(t)}\,dt$. In this paper all the analysis will take place within the field $\mathbb{C}$, but our results remain valid if $\mathbb{C}$ is replaced by the real field $\mathbb{R}$.

Let $A(t)(t \in [t_0, t_1])$ be an $n \times n$ continuous complex matrix-valued function. Let T_1 be the (graph of the) maximal differential operator contained in $X_n \oplus X_n$ defined by

$$T_1 x := \dot{x} - Ax \qquad (\dot{x} \equiv dx/dt)$$

for $x \in \text{Dom } T_1$, where $x \in \text{Dom } T_1$ if and only if $x \in X_n$, x is absolutely continuous entrywise in $[t_0, t_1]$ and $\dot{x} \in X_n$.

In this paper we will consider the problem (which will be referred to later as "the control problem"): Find $u^+ \in X_m$ (called an optimal controller), minimizing

$$\mathscr{C}(u, x) := \int_{t_0}^{t_1} (u^* Uu + (x - x_0)^* W(x - x_0))(t)\,dt + \|F_\Lambda(x)\|^2, \tag{3.1}$$

subject to

$$u \in X_m,\ x \in \text{Dom } T_1, \tag{3.2}$$

$$\dot{x}(t) = A(t)x(t) + B(t)u(t), \quad \text{almost all } t \in [t_0, t_1], \tag{3.3}$$

$$\|F_\Omega(x) - \gamma\| = \text{Min}\{\|F_\Omega(y) - \gamma\| : y \in \text{Dom } T_1,\ T_1 y = Bu\}. \tag{3.4}$$

Here

(i) $U(t)$, $W(t)$, $B(t)$ are $m \times m$, $n \times n$, $n \times m$ continuous complex matrix-valued functions of t. For each t, $U^*(t) = U(t)$, $W^*(t) = W(t)$, and $U(t)$ is positive definite and $W(t)$ is nonnegative definite.

(ii) x_0 is a given element of X_n and γ is a given element of $\mathbb{C}^d$.

(iii) F_Ω and F_Λ are the (boundary) operators defined on Dom T_1 by

$$F_\Omega(x) := \int_{t_0}^{t_1} (\Omega_1^*(t)x(t) + \Omega_2^*(t)\dot{x}(t))\, dt,$$

$$F_\Lambda(x) := \int_{t_0}^{t_1} (\Lambda_1^*(t)x(t) + \Lambda_2^*(t)\dot{x}(t))\, dt,$$

where $\Omega_1(t)(n\times d)$, $\Omega_2(t)(n\times d)$, $\Lambda_1(t)(n\times d_1)$, $\Lambda_2(t)(n\times d_1)$ are complex matrix-valued functions of $t\in[t_0, t_1]$ whose columns are X_n.

When $\{u^+, x^+\}$ minimizes $\mathscr{C}$, u^+ will be called an optimal controller and x^+ an optimal response corresponding to u^+.

We can say that the operator F_Ω (and hence F_Λ) is the most general boundary operator of finite-dimensional range generated by the formal expression $\dot{x} - Ax$ in the sense that F_Ω is a continuous linear operator from the Hilbert space Dom T_1 equipped with the T_1-norm defined by

$$\|x\|_{T_1} := (\|x\|^2 + \|T_1x\|^2)^{1/2}$$

into the finite-dimensional space $\mathbb{C}^d$ if and only if F_Ω has the representation as in the above. This can be proved easily using the Riesz–Fischer representation theorem. This operator can be a familiar general point-evaluation operator (see Lemma 3.4 below).

The main feature of this paper is: (i) the "most" general boundary operators are involved, (ii) the state is chosen to minimize $\|F_\Omega(x) - \gamma\|$ and there may be infinitely many minimizers. Consequently, the functional $\mathscr{C}$ becomes a multi-valued map of u. In particular, for a given control u, a response x is chosen so that $F_\Omega(x)$ is as close to the ideal target γ as possible. This idea becomes clearer if $F_\Omega(x)$ becomes a point-evaluation operator such as $x(t_0)$ or $x(t_1)$.

There are two obvious ways of treating $\mathscr{C}$: One is to treat it as a single-valued map of u and x and the other is to view it as a multi-valued map of u. We will present a new method of treating the problem by viewing $\mathscr{C}$ as a multi-valued map. This will be based on the recent theories [7], [8], [9] of the least-squares solutions and generalized inverses of a multi-valued linear operator.

Let us define our dynamical system $\mathscr{D}\subset X_m\oplus X_n$ by

$$\mathscr{D} = \{\{u, x\}: u \text{ and } x \text{ satisfy (3.2), (3.3), (3.4)}\}.$$

For $\{u, x\}\in\mathscr{D}$, u is called a control and x a response corresponding to u. First we will describe $\mathscr{D}$. To do this let Φ be the $n\times n$ fundamental matrix solution satisfying

$$\dot{\Phi}(t) = A(t)\Phi(t), \qquad t_0\leqq t\leqq t_1,$$

$$\Phi(t_0) = I_{n\times n}.$$

Define operators $\mathscr{H}: X_m\to X_n$ and $H_\Omega: X_m\to\mathbb{C}^d$ by

$$\mathscr{H}(u) := \Phi(t)\int_{t_0}^{t} (\Phi^{-1}Bu)(s)\, ds, \qquad t_0\leqq t\leqq t_1, \tag{3.5}$$

$$H_\Omega(u) := \int_{t_0}^{t_1} (\Omega_1^*\mathscr{H}(u) + \Omega_2^*(A\mathscr{H}(u) + Bu))(t)\, dt. \tag{3.6}$$

Let Q_Ω be the $d\times n$ matrix defined by

$$Q_\Omega := \int_{t_0}^{t_1} ((\Omega_1^* + \Omega_2^*A)\Phi)(t)\, dt. \tag{3.7}$$

We have the following description of $\mathscr{D}$.

LEMMA 3.1.

[I] *The following are equivalent*:

(i) $\{u, x\} \in \mathscr{D}$.

(ii) $u \in X_m$, $x = \mathscr{H}(u) + \Phi(\alpha - Q_\Omega^\# H_\Omega(u)) + \Phi Q_\Omega^\# \gamma$ *for some* $\alpha \in \text{Null } Q_\Omega$.

(iii) $u \in X_m$, $x = \mathscr{H}(u) + \Phi\alpha$ *for some* $\alpha \in \mathbb{C}^n$ *which is a least-squares solution of the matrix equation* (*for u fixed*)

$$Q_\Omega(\beta) = \gamma - H_\Omega(u).$$

[II] $\mathscr{D} = \{0, \Phi Q_\Omega^\# \gamma\} \dot{+} \mathscr{S}$, *where*

$$\mathscr{S} := \{\{u, \mathscr{H}(u) + \Phi(\alpha - Q_\Omega^\# H_\Omega(u))\} : u \in X_m, \alpha \in \text{Null } Q_\Omega\}.$$

In particular, Dom $\mathscr{D} = X_m$ *and* $\mathscr{D}$ *is a closed convex set in* $X_m \oplus X_n$.

Proof. Let $u \in X_m$, $y \in \text{Dom } T_1$ satisfy (3.3). Then $y = \mathscr{H}(u) + \Phi\beta$ for some $\beta \in \mathbb{C}^n$. Now $\mathscr{H}(u)$ is the solution of (3.3), subject to $x(t_0) = 0$. Thus using the definition of F_Ω,

$$F_\Omega(y) = Q_\Omega(\beta) + H_\Omega(u).$$

Thus $\{u, x\} \in \mathscr{D}$ if and only if $x = \mathscr{H}(u) + \Phi\alpha$ for some $\alpha \in \mathbb{C}^n$ such that $\|Q_\Omega(\beta) + H_\Omega(u) - \gamma\| = \text{Minimum } \{\|Q_\Omega(\beta) + H_\Omega(u) - \gamma\| : \beta \in \mathbb{C}^n\}$, or equivalently α is a least-squares solution of the matrix equation (for u fixed) $Q_\Omega(\beta) = \gamma - H_\Omega(u)$. Since Range Q_Ω is closed, the set of all such α is given by the coset

$$Q_\Omega^\#(\gamma - H_\Omega(u)) \dot{+} \text{Null } Q_\Omega.$$

This proves [I]. The first part of [II] follows from [I]. Clearly Dom $\mathscr{D} = X_m$. Since Null Q_Ω is finite-dimensional and the map $u \to \mathscr{H}(u) - \Phi Q_\Omega^\# H_\Omega(u)$ defines a bounded linear operator from X_m into X_n, we see that $\mathscr{S}$ is closed in $X_m \oplus X_n$. □

Remark. Let $\{u, x\} \in \mathscr{D}$ be as (I.ii) of the above lemma. Then

$$x(t_0) = \alpha - Q_\Omega^\# H_\Omega(u) + Q_\Omega^\# \gamma.$$

Thus the initial state of x depends on the control u. But if $H_\Omega(u) = 0$ (which is the case, for example, if $F_\Omega(x) = x(t_0)$), then $x(t_0)$ does not depend on u.

Remark. Minamide and Nakamura [10] considered an optimal control problem whose state is somewhat similar to ours in appearance: Minimize $\mathscr{C}$ (when $F_\Lambda \equiv 0$) over $u \in X_m$ such that

(1) $\dot{x} = Ax + Bu$ almost everywhere,

(2) $x(t_0) = \gamma$,

(3) $\|x(t_1) - x_0\| \leqq \|y(t_1) - x_0\|$ for *all* $v \in X_m$ and y such that $\dot{y} = Ay + Bv$, $y(t_0) = \gamma$.

Thus if we define an operator $\hat{\mathscr{H}} : X_m \to \mathbb{C}^n$ by $\hat{\mathscr{H}}(v) = (\mathscr{H}(v)(t_1)$, then this problem becomes: Minimize $\mathscr{C}$ over $u \in X_m$ such that u is a least-squares solution of $\hat{\mathscr{H}}(v) = x_0 - \Phi(t_1)\gamma$ and $\dot{x} = Ax + Bu$, $x(t_0) = \gamma$. This means that the state is subject to the usual initial condition (and hence generates a unique response), but the control space is restricted.

Thus there is no direct connection between the problems in [10] and ours. The condition (2) in the above corresponds to (3.4). Notice that the control space in [10] is the coset $\hat{\mathscr{H}}^\#(x_0 - \Phi(t_1)\gamma) \dot{+} \text{Null } \hat{\mathscr{H}}$ while our control space is the whole space X_m.

In [11] Minamide and Nakamura considered a problem which is somewhat similar in spirit to ours:

Find $u^+ \in X_m$ minimizing $\sum_{j=1}^m \int_{t_0}^{t_1} |u_j(t)|\, dt$, subject to $\dot{x} = Ax + Bu$, $x(t_0) = x_0$ and $\|x(t_1) - x_1\| < \varepsilon$, where x_0, x_1 are given constant vectors and $\varepsilon > 0$.

In [10], the closed forms of generalized inverses of (single-valued) operators are used to derive the differential equations for an optimal controller. This idea cannot be used in this paper as the "closed" forms of generalized inverses of multi-valued operators are not known in the literature. Instead, we use an abstract result for least-squares solutions to derive equations for the optimal controller for our problem.

In the following we will describe $\mathscr{S}$ and $\mathscr{D}$ in terms of equality constraints.

PROPOSITION 3.2.

(i) *Let $\mathscr{S}$ be as in the above lemma. Then $\{u, y\} \in \mathscr{S}$ if and only if $y \in \text{Dom } T_1$, $u \in X_m$ such that*

$$\dot{y} = Ay + Bu \quad \textit{almost everywhere},$$

$$F_\Omega(y) = (I - Q_\Omega Q_\Omega^\#) H_\Omega(u).$$

(ii) *$\{u, x\} \in \mathscr{D}$ if and only if $u \in X_m$, $x \in \text{Dom } T_1$ such that*

$$\dot{x} = Ax + Bu \quad \textit{almost everywhere},$$

$$F_\Omega(x) - \gamma = (Q_\Omega Q_\Omega^\# - I)(\gamma - H_\Omega(u)).$$

Proof. (i) The "only if" part is easy to check. Assume now that $y \in \text{Dom } T_1$ and $u \in X_m$ satisfy the above two equations. Write $y = \mathscr{H}(u) + \Phi\alpha$, $\alpha \in \mathbb{C}^n$. Then the second condition becomes

$$0 = Q_\Omega(\alpha + Q_\Omega^\# H_\Omega(u)).$$

Thus $\alpha = -Q_\Omega^\# Q_\Omega Q_\Omega^\# H_\Omega(u) + k = -Q_\Omega^\# H_\Omega(u) + k$ for some $k \in \text{Null } Q_\Omega$. Hence $y = \mathscr{H}(u) + \Phi[k - Q_\Omega^\# H_\Omega(u)]$, and so $\{u, y\} \in \mathscr{S}$. We now prove (ii). Take any $\{u, x\} \in \mathscr{D}$. Then by Lemma 3.1, $\{u, x\} = \{u, \Phi Q_\Omega^\# \gamma + y\}$ for some y such that $\{u, y\} \in \mathscr{S}$. Then using the definition of Q_Ω and part (i) above, $\dot{x} = Ax + Bu$ almost everywhere and $F_\Omega(x) - \gamma = (Q_\Omega Q_\Omega^\# - I)(\gamma - H_\Omega(u))$. This argument can be traced back. □

Remark. By the above proposition we can say that for $\{u, x\} \in \mathscr{D}$, the response x "misses" the target γ by $(Q_\Omega Q_\Omega^\# - I)(\gamma - H_\Omega(u))$.

Remark. Assume that $n = m$, $B = W = U = I_{n\times n}$ and Rank $Q_\Omega = d$. Then our problem can be stated equivalently (by taking $u^+ = T_1 x^+$ when x^+ is a minimizer):

Minimize $(\|x\|^2 + \|T_1 x\|^2)$, subject to $x \in \text{Dom } T_1 \cap F_\Omega^{-1}(\gamma)$.

Clearly $F_\Omega^{-1}(\gamma)$ is a closed convex set. Thus this particular case is a special case of the abstract problem considered in [1, Thm. 4.4]. However, the vector ξ appearing in this theorem vanishes in our case, and so his theorem does not give any new information to the above case. We thank J. Burns for drawing our attention to reference [1].

Since $Q_\Omega Q_\Omega^\#$ is the orthogonal projector on $\mathbb{C}^n$ onto Range Q_Ω, from Lemma 3.1 and Proposition 3.2 we have the following.

COROLLARY 3.3.

(i) *For each $u \in X_m$, u has a unique response if and only if* Dim Null $Q_\Omega = 0$.

(ii) *If* Rank $Q_\Omega = d$ *or* $\gamma - H_\Omega(u) \in \text{Range } Q_\Omega$ *for all* $u \in X_m$, *then* $\mathscr{D} = \{\{u, x\}: u \in X_m, x \in \text{Dom } T_1, T_1 x = Bu, F_\Omega(x) = \gamma\}$.

The following notation will be needed later. If x, y are $n \times p$ and $n \times q$ matrix-valued functions of t, then

$$\langle x, y \rangle := \int_{t_0}^{t_1} x^t(t) \bar{y}(t)\, dt, \qquad (p \times q).$$

In the following we find a necessary and sufficient condition for F_Ω to be a generalized two-point operator.

LEMMA 3.4. *Let M, N be $d \times n$ constant matrices and let f be a $d \times n$ matrix-valued function of t such that its rows are square-integrable over $[t_0, t_1]$. Then*:

(i) $$F_\Omega(x) = Mx(t_0) + Nx(t_1) + \int_{t_0}^{t_1} f(t)x(t)\,dt \quad \textit{for all } x \in \mathrm{Dom}\ T_1$$

if and only if $\Omega_2 \in \mathrm{Dom}\ T_1$ columnwise, $f^* + \dot{\Omega}_2 = \Omega_1$ almost everywhere, and

$$M = -\Omega_2^*(t_0), \qquad N = \Omega_2^*(t_1).$$

(ii) *If F_Ω has the form as the above, then*

$$Q_\Omega = \int_{t_0}^{t_1} f\Phi\,dt + M + N\Phi(t_1),$$

$$H_\Omega(u) = N^*(\mathscr{H}(u))(t_1) + \int_{t_0}^{t_1} f\mathscr{H}(u)\,dt, \qquad u \in X_m,$$

$$H_\Omega^*(\beta) = B^*(t)(\Phi^*)^{-1}(t)\left(\Phi^*(t_1)N^* + \int_t^{t_0} (\Phi^* f^*)(s)\,ds\right)\beta, \qquad \beta \in \mathbb{C}^d.$$

Proof. (i) Assume that F_Ω has the form as in the theorem. Then for all $x \in \mathrm{Dom}\ T_1$ with $x(t_0) = x(t_1) = 0$,

(*) $$\int_{t_0}^{t_1} (\Omega_1^* - f)x\,dt + \int_{t_0}^{t_1} \Omega_2^* \dot{x}\,dt = 0.$$

We now use the idea first used in [4]. For the above x, put $\dot{x} = g$. Then $g \in X_n$ and

(**) $$x(t) = \int_{t_0}^{t} g(s)\,ds.$$

Since $x(t_1) = 0$, this implies that g is orthogonal to $\mathbb{C}^n$ (after we have identified $\mathbb{C}^n$ as a subspace of X_n in the obvious manner). Conversely, if $g \in X_n$ and is orthogonal to $\mathbb{C}^n$, then the x defined by (**) belongs to Dom T_1 with $x(t_0) = x(t_1) = 0$. Now take any $g \in X_n$ orthogonal to $\mathbb{C}^n$ and define x as (**). Then (*) can be written (after interchanging the order of the integration) as

(*)′ $$\int_{t_0}^{t_1} \left(\int_t^{t_1} (\Omega_1^* - f)(s)\,ds + \Omega_2^*(t) \right) g(t)\,dt = 0.$$

Therefore

$$\int_t^{t_1} (\Omega_1^* - f)(s)\,ds + \Omega_2^*(t) = k \quad \text{a.e. } t \in [t_0, t_1]$$

for some $k \in \mathbb{C}^n$. Redefining Ω_2 in the set of measure zero if necessary, we see that the above is true for *all* t and hence Ω_2 is absolutely continuous on $[t_0, t_1]$. Differentiating the equality, we see that

$$\Omega_1^*(t) - f(t) = \dot{\Omega}_2^*(t), \quad \text{a.e. } t \in [t_0, t_1].$$

Returning to the representation of F_Ω, we have

$$\begin{aligned} Mx(t_0) + Nx(t_1) + \int_{t_0}^{t_1} f(t)x(t)\,dt &= \int_{t_0}^{t_1} [(f + \dot{\Omega}_2^*)x + \Omega_2^* \dot{x}]\,dx \\ &= \Omega_2^*(t_1)x(t_1) - \Omega_2^*(t_0)x(t_0) + \int_{t_0}^{t_1} f(t)x(t)\,dt \end{aligned}$$

for all $x \in \mathrm{Dom}\ T_1$. Thus $M = \Omega_2^*(t_0)$, $N = \Omega_2^*(t_1)$.

The above argument can be traced back. This proves (i). We now prove (ii). The first two parts follow directly from the definitions of Q_Ω and H_Ω together with part (i). The second part is easy to check as the general H_Ω^* is given by

$$H_\Omega^*(\beta) = B^*\Omega_2\beta + \mathscr{H}^*((\Omega_1 + A^*\Omega_2)\beta) \quad \text{all } \beta \in \mathbb{C}^d,$$

$$\mathscr{H}^*(x) = B^*(t)\Phi^{*-1}(t)\int_t^{t_1} \Phi^*(s)x(s)\,ds \quad \text{for all } x \in X_m.$$

This together with (i) gives the description of H_Ω^* as claimed. □

We will now describe $\mathscr{C}(u, x)$ in terms of the norms in X_m, X_n and $\mathbb{C}^{d_1}$. To do this it is convenient to introduce the following:

$$Q_\Lambda := \int_{t_0}^{t_1} ((\Lambda_1^* + \Lambda_2^* A)\Phi)(t)\,dt \qquad (d_1 \times n), \tag{3.8}$$

$$H_\Lambda(u) := \int_{t_0}^{t_1} (\Lambda_1^*\mathscr{H}(u) + \Lambda_2^*(A\mathscr{H}(u) + Bu))(t)\,dt, \qquad u \in X_m, \tag{3.9}$$

where $\mathscr{H}$ is defined in (3.5).

For each $t \in [t_0, t_1]$, let $U^{1/2}(t)$ denote the positive square root of $U(t)$, and $W^{1/2}(t)$ the nonnegative square root of $W(t)$.

The following will be needed later. We state it without a proof because it is easy to check.

LEMMA 3.5. *For $\{u, x\} \in \mathscr{D}$, write $x = \mathscr{H}(u) + \Phi q$, where*

$$q = \alpha - Q_\Omega^\# H_\Omega(u) + Q_\Omega^\# \gamma, \qquad \alpha \in \text{Null } Q_\Omega.$$

Then

$$\int_{t_0}^{t_1} (\Lambda_1^* x + \Lambda_2^* \dot{x})(t)\,dt = Q_\Lambda q + H_\Lambda(u),$$

$$\mathscr{C}(u, x) = \|\{U^{1/2}u,\ W^{1/2}(\mathscr{H}(u) + \Phi q - x_0),\ H_\Lambda(u) + Q_\Lambda q\}\|^2,$$

where $\|\{\cdot, \cdot, \cdot\}\|$ denotes the standard norm of $X_m \oplus X_n \oplus \mathbb{C}^{d_1}$.

We will now show that the control problem can be written as a least-squares problem for a multi-valued closed operator equation. We need the following definitions.

DEFINITION. ζ is the vector in $X_m \oplus X_n \oplus \mathbb{C}^{d_1}$ defined by

$$\zeta = \{0,\ W^{1/2}(x_0 - \Phi Q_\Omega^\# \gamma), -Q_\Lambda Q_\Omega^\# \gamma\}.$$

DEFINITION. $\mathscr{M}$ is a vector subspace of $X_m \oplus (X_m \oplus X_n \oplus \mathbb{C}^{d_1})$ defined by $\{u, g\} \in \mathscr{M}$ if and only if $u \in X_m$ and

$$g = \{U^{1/2}u,\ W^{1/2}(\mathscr{H}(u) + \Phi(\alpha - Q_\Omega^\# H_\Omega(u))),\ H_\Lambda(u) + Q_\Lambda(\alpha - Q_\Omega^\# H_\Omega(u))\},$$

for some $\alpha \in \text{Null } Q_\Omega$.

Since $U^{1/2}$ is invertible on $[t_0, t_1]$ and $\mathscr{H}$, H_Ω and H_Λ are bounded linear operators, we see easily that $\mathscr{M}$, Range $\mathscr{M}$ are closed and Null $\mathscr{M} = \{0\}$.

In the following theorem our control problem is changed to a least-squares problem.

THEOREM 3.6. *Let $u^+ \in X_m$. Then u^+ is an optimal controller if and only if u^+ is a least-squares solution of $\zeta \in \mathscr{M}(u)$.*

Proof. Note first that $\{u^+, x^+\}$ minimizes $\mathscr{C}$ subject to (3.2)-(3.4) if and only if it minimizes $\mathscr{C}$ over $\mathscr{D}$. Let $\{u^+, x^+\}$ be a minimizer of $\mathscr{C}$ and write it as

$$x^+ = \mathscr{H}(u^+) + \Phi q^+ \tag{1}$$

where

$$q^+ = \alpha^+ - Q_\Omega^\# H_\Omega(u^+) + Q_\Omega^\# \gamma, \qquad \alpha^+ \in \text{Null } Q_\Omega.$$

Take any $\{u, x\} \in \mathscr{D}$ and write it also as

$$x = \mathscr{H}(u) + \Phi q \tag{2}$$

where

$$q = \alpha - Q_\Omega^\# H_\Omega(u) + Q_\Omega^\# \gamma, \qquad \alpha \in \text{Null } Q_\Omega.$$

Then using Lemma 3.5, $\{u^+, x^+\}$ is a minimizer of $\mathscr{C}$ over $\mathscr{D}$ if and only if

$$\begin{aligned} \mathscr{C}(u^+, x^+) = \|\{U^{1/2}u^+,\ & W^{1/2}(\mathscr{H}(u^+) + \Phi\alpha^+ - \Phi Q_\Omega^\# H_\Omega(u^+)), \\ & H_\Lambda(u^+) + Q_\Lambda \alpha^+ - Q_\Lambda Q_\Omega^\# H_\Omega(u^+)\} - \zeta\|^2 \\ \leqq \mathscr{C}(u, x) = \|\{U^{1/2}u,\ & W^{1/2}(\mathscr{H}(u) + \Phi\alpha - \Phi Q_\Omega^\# H_\Omega(u)), \\ & H_\Lambda(u) + Q_\Lambda \alpha - Q_\Lambda Q_\Omega^\# H_\Omega(u)\} - \zeta\|^2 \end{aligned} \tag{3}$$

for all $u \in X_m$, $\alpha \in \text{Null } Q_\Omega$. Let us put

$$\begin{aligned} y^+ = \{U^{1/2}u^+,\ & W^{1/2}(\mathscr{H}(u^+) + \Phi\alpha^+ - \Phi Q_\Omega^\# H_\Omega(u^+)), \\ & H_\Lambda(u^+) + Q_\Lambda \alpha^+ - Q_\Lambda Q_\Omega^\# H_\Omega(u^+)\}. \end{aligned} \tag{4}$$

Then $y^+ \in \mathscr{M}(u^+)$, and so (3) becomes:

$$\|y^+ - \zeta\| = \text{Min}\,\{\|y - \zeta\| : y \in \text{Range } \mathscr{M}\}. \tag{5}$$

Thus if u^+ is an optimal controller for the control problem, then by definition there exists x^+ such that $\{u^+, x^+\} \in \mathscr{D}$ which minimizes $\mathscr{C}$ over $\mathscr{D}$. But then by (5), u^+ is a least-squares solution of $\zeta \in \mathscr{M}(u)$. Conversely, let u^+ be a least-squares solution of $\zeta \in \mathscr{M}(u)$. Then there exists $y^+ \in \mathscr{M}(u^+)$ satisfying (5). We now write y^+ as in (4) for some $\alpha^+ \in \text{Null } Q_\Omega$.

Define x^+ as in (1) and x as in (2) for some $u \in X_m$ and $\alpha \in \text{Null } Q_\Omega$. Then it follows from (5) that

$$\mathscr{C}(u^+, x^+) \leqq \mathscr{C}(u, x)$$

for all $\{u, x\} \in \mathscr{D}$. Thus $\{u^+, x^+\}$ minimizes $\mathscr{C}$ over $\mathscr{D}$, and hence u^+ is an optimal controller. □

Having identified an optimal controller as a least-squares solution, a general theorem, Theorem 2.2, is applicable.

THEOREM 3.7. *There always exists a unique optimal controller for the control problem. This is given by* $u^+ := \mathscr{M}^*(\zeta)$. *Moreover, the set of the responses corresponding to* u^+ *is given by*

$$\{\mathscr{H}(u^+) + \Phi(\alpha - Q_\Omega^\# H_\Omega(u^+) + Q_\Omega^\# \gamma) : \alpha \in \text{Null } Q_\Omega\}.$$

Proof. It was noted earlier that Null $\mathscr{M} = \{0\}$, and $\mathscr{M}$, Range $\mathscr{M}$ are closed. Thus the first part of the theorem follows from Theorem 3.6 together with (1), (3) of Theorem 2.2. By definition, x is a response corresponding to u^+ if and only if $\{u^+, x\} \in \mathscr{D}$. Thus the second part follows from (I.ii) of Lemma 3.1. □

A response x corresponding to $\mathscr{M}^*(\zeta)$ may not be an optimal response, i.e., $\{\mathscr{M}^*(\zeta), x\}$ may not minimize $\mathscr{C}$ over $\mathscr{D}$. Recall that when this element minimizes $\mathscr{C}$, x is called an optimal response (corresponding $\mathscr{M}^*(\zeta)$). Later we will characterize all

optimal responses. To do this, we introduce a linear operator R: Null $Q_\Omega \to X_m \oplus X_n \oplus \mathbb{C}^{d_1}$, and a function $p: X_m \to X_m \oplus X_n \oplus \mathbb{C}^{d_1}$ by

$$R(\beta) = \{0,\ W^{1/2}\Phi\beta,\ Q_\Lambda \beta\}, \qquad \beta \in \text{Null } Q_\Omega,$$

$$p(u) = \zeta - \{U^{1/2}u,\ W^{1/2}(\mathscr{H}(u) - \Phi Q_\Omega^{\#} H_\Omega(u)),\ H_\Lambda(u) - Q_\Lambda Q_\Omega^{\#} H_\Omega(u)\}.$$

Evidently, R is a bounded linear operator with closed range, and so Dom $R^{\#} = X_m \oplus X_n \oplus \mathbb{C}^{d_1}$.

First we have the following lemma.

LEMMA 3.8. $\|(RR^{\#} - I)(p(\mathscr{M}^{\#}(\zeta)))\| \leqq \|R(\beta) - p(u)\|$ *for all* $\beta \in$ Null Q_Ω, $u \in X_m$.

Proof. Put $u^+ = \mathscr{M}^{\#}(\zeta)$ and let x^+ be an optimal response corresponding to u^+. Then since $\{u^+, x^+\} \in \mathscr{D}$,

$$(1) \qquad x^+ = \mathscr{H}(u^+) + \Phi[\alpha^+ - Q_\Omega^{\#} H_\Omega(u^+) + Q_\Omega^{\#}\gamma]$$

for some $\alpha^+ \in$ Null Q_Ω, and since $\{u^+, x^+\}$ is a minimizer of $\mathscr{C}$,

$$(2) \qquad \mathscr{C}(u^+, x^+) \leqq \mathscr{C}(u, x) \quad \text{for all } \{u, x\} \in \mathscr{D}.$$

Take any $\{u, x\} \in \mathscr{D}$ and write x as

$$(3) \qquad x = \mathscr{H}(u) + \Phi[\alpha - Q_\Omega^{\#} H_\Omega(u^+) + Q_\Omega^{\#}\gamma]$$

for some $\alpha \in$ Null Q_Ω. Then using the definitions of R and p and Lemma 3.5 we have

$$(4) \qquad \mathscr{C}(u, x) = \|R(\alpha) - p(u)\|.$$

Thus (2) can be written equivalently as

$$(5) \qquad \|R(\alpha^+) - p(u^+)\| \leqq \|R(\alpha) - p(u)\|$$

for all $\alpha \in$ Null Q_Ω and $u \in X_m$.

This is true, in particular, for all $\alpha \in$ Null Q_Ω and $u = u^+$. Thus it follows from (4) that α^+ is a least-squares solution of $R(\beta) = p(u^+)$, and hence $\alpha^+ = R^{\#}(p(u^+)) + k$ for some $k \in$ Null R. Returning to (4), we have

$$\|R[R^{\#}(p(u^+)) + k] - p(u^+)\| = \|(RR^{\#} - I)(p(u^+))\| \leqq \|R(\alpha) - p(u)\|$$

for all $\alpha \in$ Null Q_Ω, $u \in X_m$. □

In the following theorem we find all optimal responses.

THEOREM 3.9. x^+ *is an optimal response corresponding to the optimal controller* $u^+ = \mathscr{M}^{\#}(\zeta)$ *if and only if*

$$x^+ = \mathscr{H}(u^+) + \Phi(\alpha^+ - Q_\Omega^{\#} H_\Omega(u^+) + Q_\Omega^{\#}\gamma)$$

for some $\alpha^+ \in$ Null Q_Ω *belonging to the coset*

$$R^{\#}(p(u^+)) \dotplus \text{Null } R,$$

or equivalently, for some $\alpha^+ \in$ Null Q_Ω *which is a least-squares solution of* $R(\beta) = p(u^+)$.

In particular, an optimal response is unique if and only if Dim Null $R = 0$.

Proof. Let x^+ be an optimal response corresponding to u^+. Then $\{u^+, x^+\}$ is a minimizer of $\mathscr{C}$ over $\mathscr{D}$. Thus

$$(1) \qquad x^+ = \mathscr{H}(u^+) + \Phi[\alpha^+ - Q_\Omega^{\#} H_\Omega(u^+) + Q_\Omega^{\#}\gamma]$$

for some $\alpha^+ \in$ Null Q_Ω, and

$$(2) \qquad \mathscr{C}(u^+, x^+) \leqq \mathscr{C}(u, x) \quad \text{for all } \{u, x\} \in \mathscr{D}.$$

Arguing similarly as in the proof of the above lemma, we see that α^+ must belong to the coset in the theorem. Suppose now that x^+ is defined as in (1) for some $\alpha^+ \in \text{Null } Q_\Omega$ such that

$$\alpha^+ = R^\#(p(u^+)) + k, \qquad k \in \text{Null } R. \tag{3}$$

Then by (4) of the above lemma,

$$\mathscr{C}(u^+, x^+) = \|R(\alpha^+) - p(u^+)\| = \|(RR^\# - I)(p(u^+))\|. \tag{4}$$

Take any $\{u, x\} \in \mathscr{D}$ and write x as

$$x = \mathscr{H}(u) + \Phi[\alpha - Q_\Omega^\# H_\Omega(u) + Q_\Omega^\# \gamma]$$

for some $\alpha \in \text{Null } Q_\Omega$. Then using (4) of the Lemma 3.8 again,

$$\mathscr{C}(u, x) = \|R(\alpha) - p(u)\|. \tag{5}$$

Thus by Lemma 3.8,

$$\mathscr{C}(u^+, x^+) = \|(RR^\# - I)(p(u^+))\| \leqq \|R(\alpha) - p(u)\| = \mathscr{C}(u, x).$$

Thus x^+ defined as (1) for some $\alpha^+ \in \text{Null } Q_\Omega$ defined as (3) is an optimal response. The second part of the theorem is clear. □

We have identified the optimal controller to the control problem as $\mathscr{M}^\#(\zeta)$. In a practical point of view this is not satisfactory as the "closed" form of $T^\#$ for a general multi-valued operator T is not known in the literature. Thus in the sequel of this paper we will characterize the optimal controller by integro-differential equations. The following is (ii) of Theorem 2.2 adopted to the present situation.

LEMMA 3.10. *u^+ is the optimal controller to the control problem if and only if*

$$\zeta \in \mathscr{M}(u^+) \dotplus \text{Null } \mathscr{M}^*.$$

We will replace the above inclusion by integro-differential equations. To do this, first we describe $\mathscr{M}^*$ which is a subspace of $(X_m \oplus X_n \oplus \mathbb{C}^{d_1}) \oplus X_m$.

LEMMA 3.11. *$\{\{v, f, \beta\}, u\} \in \mathscr{M}^*$ if and only if*

(i) $u \in X_m$, $\{v, f, \beta\} \in X_m \oplus X_n \oplus \mathbb{C}^{d_1}$,

(ii) $\overline{\langle W^{1/2}\Phi, f\rangle} + Q_\Lambda^* \beta \in (\text{Null } Q_\Omega)^\perp$,

(iii) $u = (U^{1/2})^* v + B^*(\Lambda_2 \beta - \Omega_2 l) + \mathscr{H}^*\big((W^{1/2})^* f + (\Lambda_1 + A^*\Lambda_2)\beta - (\Omega_1 + A^*\Omega_2) l\big)$

where

$$l := (Q_\Omega^\#)^*\big(Q_\Lambda^* \beta + \overline{\langle W^{1/2}\Phi, f\rangle}\big).$$

Proof. Take any $\{\{v, f, \beta\}, u\} \in \mathscr{M}^*$. Then for any $\{u_1, \{v_1, f_1, \beta_1\}\} \in \mathscr{M}$,

$$-\langle u, u_1\rangle + \langle v, v_1\rangle + \langle f, f_1\rangle + \langle \beta, \beta_1\rangle = 0. \tag{1}$$

By the definition $\mathscr{M}$,

$$v_1 = U^{1/2} u_1, \qquad f_1 = W^{1/2}[\mathscr{H}(u_1) + \Phi(\alpha - Q_\Omega^\# H_\Omega(u_1))],$$

$$\beta_1 = H_\Lambda(u_1) + Q_\Lambda[\alpha - Q_\Omega^\# H_\Omega(u_1)]$$

for $u_1 \in X_m$, $\alpha \in \text{Null } Q_\Omega$. Taking $u_1 = 0$ in (1), we see that

$$\langle f, W^{1/2}\Phi\alpha\rangle + \langle \beta, Q_\Lambda \alpha\rangle = 0 \tag{2}$$

for all $\alpha \in \text{Null } Q_\Omega$. Thus

$$\langle W^{1/2}\Phi, f\rangle + Q_\Lambda^* \beta \in (\text{Null } Q_\Omega)^\perp. \tag{3}$$

Returning to (1), we see that

$$(4)\qquad -\langle u, u_1\rangle+\langle v, U^{1/2}u_1\rangle+\langle f, W^{1/2}[\mathscr{H}(u_1)-\Phi Q_\Omega^{\#}H_\Omega(u_1)]\rangle$$
$$+\langle\beta, H_\Lambda(u_1)-Q_\Lambda Q_\Omega^{\#}H_\Omega(u_1)\rangle=0 \quad \text{for all } u_1\in X_m.$$

This then yields that

$$(5)\qquad u=(U^{1/2})^*v+\mathscr{H}^*((W^{1/2})^*f)-H_\Omega^*((Q_\Omega^{\#})^*\overline{\langle W^{1/2}\Phi, f\rangle})$$
$$+H_\Lambda^*(\beta)-H_\Omega^*((Q_\Lambda Q_\Omega^{\#})^*\beta).$$

Thus v, f, β, u satisfy (3) and (5). Conversely if these satisfy (3) and (5), then we see easily that (1) holds for all $\{u_1, \{v_1, f_1, \beta_1\}\}\in\mathscr{M}$. Now as was given in the proof of Lemma 3.4,

$$(6)\qquad H_\Omega^*(\delta)=B^*\Omega_2\delta+\mathscr{H}^*[(\Omega_1+A^*\Omega_2)\delta], \qquad \delta\in\mathbb{C}^d,$$

$$(7)\qquad H_\Lambda^*(\delta)=B^*\Lambda_2\delta+\mathscr{H}^*[(\Lambda_1+A^*\Lambda_2)\delta], \qquad \delta\in\mathbb{C}^{d_1}.$$

Thus since $\{\{v, f, \beta\}, u\}\in\mathscr{M}^*$ if and only if (3) and (5) hold, we see that using (6), (7) the result follows immediately. □

The following is a main result of this paper. Recall that $Q_\Omega(d\times n)$, $Q_\Lambda(d_1\times n)$ are defined in (3.7), (3.8), respectively, while $H_\Omega: X_m\to\mathbb{C}^d$, $H_\Lambda: X_m\to\mathbb{C}^{d_1}$ are defined in (3.6), (3.9), respectively.

THEOREM 3.12. *$u^+\in X_m$ is the optimal controller for the control problem if and only if*

$$u^+=U^{-1}B^*\eta \quad \textit{almost everywhere}$$

where η is an element of X_m for which there exists $z\in$ Dom T_1 such that

(i) $\dot z=Az+BU^{-1}B^*\eta$ *almost everywhere,*
(ii) $Q_\Omega(z(t_0)+Q_\Omega^{\#}H_\Omega(U^{-1}B^*\eta)-Q_\Omega^{\#}\gamma)=0$,
(iii) $\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt+Q_\Lambda^*(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0))\in$ Range (Q_Ω^*),
(iv) $\eta-\delta\in$ Dom T_1,
(v) $(\eta-\delta)(t_1)=0$,
(vi) $d(\eta-\delta)/dt=-A^*(\eta-\delta)+\psi$ *almost everywhere.*

Here δ and ψ are vector-valued functions of t (depending on η and z) defined by:

$$\delta=\Omega_2(Q_\Omega^{\#})^*\Big(Q_\Lambda^*H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda^*Q_\Lambda z(t_0)+\int_{t_0}^{t_1}\Phi^*W(z-z_0)\,dt\Big)$$
$$-\Lambda_2(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0)),$$
$$\psi=W(z-x_0)+(\Lambda_1+A^*\Lambda_2)(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0))$$
$$-(\Omega_1+A^*\Omega_2)(Q_\Omega^{\#})^*\Big(Q_\Lambda^*H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda^*Q_\Lambda z(t_0)+\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt\Big).$$

Proof. By Lemma 3.10, u is an optimal controller if and only if $u\in X_m$ and

$$(1)\qquad \zeta\in\mathscr{M}(u)\dot+\text{Null }\mathscr{M}^*.$$

Equivalently, there exists $g\in\mathscr{M}(u)$ such that

$$(2)\qquad g-\zeta\in\text{Null }\mathscr{M}^*.$$

Using the definition of ζ and $\mathscr{M}$, we can write

$$(3)\qquad g-\zeta=\{U^{1/2}u, W^{1/2}[\mathscr{H}(u)+\Phi(\alpha-Q_\Omega^{\#}H_\Omega(u)+Q_\Omega^{\#}\gamma)-x_0],$$
$$H_\Lambda(u)+Q_\Lambda[\alpha-Q_\Omega^{\#}H_\Omega(u)+Q_\Omega^{\#}\gamma]\},$$

for some $\alpha \in \text{Null } Q_\Omega$. Let

$$q = \alpha - Q_\Omega^* H_\Omega(u) + Q_\Omega^* \gamma, \tag{4}$$

$$z = \mathscr{H}(u) + \Phi q. \tag{5}$$

Then it is clear that $z \in \text{Dom } T_1$ and is the unique solution such that

(i) $\dot{z} = Az + Bu$ almost everywhere

and

$$z(t_0) = q. \tag{6}$$

Using (4), this initial condition is equivalent to

(ii) $Q_\Omega[z(t_0) + Q_\Omega^* H_\Omega(u) - Q_\Omega^* \gamma] = 0.$

Using (3), (4), (5) we can rewrite (2) as

$$\{U^{1/2}u,\ W^{1/2}(z - x_0),\ H_\Lambda(u) + Q_\Lambda q\} \in \text{Null } \mathscr{M}^*. \tag{7}$$

Since $(W^{1/2})^* W^{1/2} = W$, $(U^{1/2})^* U^{1/2} = U$, $z(t_0) = q$, by Lemma 3.11 the above inclusion is equivalent to (iii) and (8) below:

(iii) $\overline{\langle W\Phi,\ z - x_0\rangle} + Q_\Lambda^*(H_\Lambda(u) + Q_\Lambda z(t_0)) \in \text{Range } (Q_\Omega^*)$,

$$\begin{aligned} 0 = {} & Uu + B^*[\Lambda_2(H_\Lambda(u) + Q_\Lambda z(t_0)) - \Omega_2 l] \\ & + \mathscr{H}^*[W(z - x_0) + (\Lambda_1 + A^*\Lambda_2)(H_\Lambda(u) + Q_\Lambda z(t_0)) - (\Omega_1 + A^*\Omega_2) l], \end{aligned} \tag{8}$$

where

$$l = (Q_\Omega^*)^*[Q_\Lambda^*(H_\Lambda(u) + Q_\Lambda z(t_0)) + \overline{\langle W^{1/2}\Phi,\ W^{1/2}(z - x_0)\rangle}].$$

Let

$$\tilde{\delta} = \Omega_2 l - \Lambda_2(H_\Lambda(u) + Q_\Lambda z(t_0)), \tag{9}$$

$$\tilde{\psi} = W(z - x_0) + (\Lambda_1 + A^*\Lambda_2)(H_\Lambda(u) + Q_\Lambda z(t_0)) - (\Omega_1 + A^*\Omega_2) l. \tag{10}$$

Then using the characterization of $\mathscr{H}^*$ given in the proof of Lemma 3.4, we can rewrite (8) equivalently as

$$0 = U(t)u(t) - B^*(t)\left[\tilde{\delta}(t) - \int_t^{t_1} \Phi^{*-1}(t)\Phi^*(s)\tilde{\psi}(s)\, ds\right] \tag{11}$$

for almost all $t \in [t_0, t_1]$. Let

$$\eta(t) := \tilde{\delta}(t) - \int_t^{t_1} \Phi^{*-1}(t)\Phi^*(s)\tilde{\psi}(s)\, ds, \qquad t_0 \leqq t \leqq t_1. \tag{12}$$

Then, since $(d/dt)\Phi^{*-1} = -A^*\Phi^{*-1}$, we can rewrite (12) equivalently as the three statements below:

$$\eta - \tilde{\delta} \in \text{Dom } T_1, \tag{13}$$

$$\frac{d}{dt}(\eta - \tilde{\delta}) = -A^*(\eta - \tilde{\delta}) + \tilde{\psi}, \quad \text{almost all } t, \tag{14}$$

$$(\eta - \bar{\delta})(t_1) = 0. \tag{15}$$

Now (11) can be written as

$$u(t) = U^{-1}(t)B^*(t)\eta(t), \quad \text{almost all } t. \tag{16}$$

Thus $\tilde{\delta} = \delta$, $\tilde{\psi} = \psi$ and the statements in (13), (14) and (15) are equivalent to the statements (iv), (vi) and (v) in the theorem. □

Remark. In the above theorem η may not even be continuous. Thus we *cannot* write the condition (v) as $\eta(t_1)=\zeta(t_1)$ as they are meaningless. But we can if the columns of Ω_2 and Λ_2 are in Dom T_1. In fact, $\eta\in$ Dom T_1 if and only if $\zeta\in$ Dom T_1.

Remark. There always exists $\eta\in X_m$, and $z\in$ Dom T_1 satisfying (i)-(vi) of Theorem 3.12 as an optimal controller for the control problem always exists.

If Ω_2 and Λ_2 are sufficiently smooth, then Theorem 3.12 can be simplified further.

COROLLARY 3.13. *Assume that the columns of* Ω_2 *and* Λ_2 *are in* Dom T_1. *Then the optimal controller* u^+ *for the control problem is given by*

$$u^+ = U^{-1}B^*\eta \quad \textit{almost everywhere,}$$

where η *is an element of* Dom T_1 *for which there exists an element* $z\in$ Dom T_1 *satisfying* (i), (ii), (iii) *of Theorem* 3.12 *in addition to*

$$\text{(v)}\quad \eta(t_1)=\Omega_2(t_1)(Q_\Omega^\#)^*\Big(Q_\Lambda^*H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda^*Q_\Lambda z(t_0)+\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt\Big)$$
$$-\Lambda_2(t_1)\big(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0)\big),$$

$$\text{(vi)}\quad \dot\eta=-A^*\eta+W(z-x_0)+(\Lambda_1-\dot\Lambda_2)\big(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0)\big)$$
$$+(\dot\Omega_2-\Omega_1)(Q_\Omega^\#)^*\Big(Q_\Lambda^*H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda^*Q_\Lambda z(t_0)+\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt\Big)$$

almost everywhere.

Proof. Because of the assumption on Ω_2 and Λ_2, the condition (iv) of Theorem 3.12 is equivalent to $\eta\in$ Dom T_1. Thus (v) and (vi) of Theorem 3.12 can be written as (v) and (vi) of this corollary. □

If F_Ω is the usual two-point evaluation operator, then Corollary 3.13 becomes

COROLLARY 3.14. *Assume that* $\Lambda_2\in$ Dom T_1 (*columnwise*) *and there exist constant matrices* $M(d\times n)$, $N(d\times n)$ *such that*

$$F_\Omega(x)=Mx(t_0)+Nx(t_1)\quad \textit{for all } x\in \text{Dom } T_1.$$

Let u^+ *be the unique optimal controller for the control problem. Then it is given by*

$$u^+ = U^{-1}B^*\eta \quad \textit{almost everywhere}$$

where η *is an element of* Dom T_1 *for which there exists an element* $z\in$ Dom T_1 *satisfying the following*:

(i) $\dot z = Az+BU^{-1}B^*\eta$ *almost everywhere*;

(ii) $(M+N\Phi(t_1))(M+N\Phi(t_1))^\#(\gamma-N(\mathcal{H}(U^{-1}B^*\eta))(t_1))$
$=(M+N\Phi(t_1))z(t_0)$;

(iii) $\displaystyle\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt+Q_\Lambda^*\big(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0)\big)$

belongs to Range $((M+N\Phi(t_1))^*)$;

(iv) $\eta(t_1)=N^*\big((M+N\Phi(t_1))^\#\big)^*$
$$\cdot\Big(Q_\Lambda^*H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda^*Q_\Lambda z(t_0)+\int_{t_0}^{t_1}\Phi^*W(z-x_0)\,dt\Big)$$
$$-\Lambda_2(t_1)\big(H_\Lambda(U^{-1}B^*\eta)+Q_\Lambda z(t_0)\big);$$

(v) $\dot{\eta} = -A^*\eta + W(z - x_0) + (\Lambda_1 - \dot{\Lambda}_2)\big(H_\Lambda(U^{-1}B^*\eta) + Q_\Lambda z(t_0)\big)$

almost everywhere.

Proof. By Lemma 3.4, $\Omega_2 \in \text{Dom } T_1$ and $N^* = \Omega_2(t_1)$, $Q_\Omega = M + N\Phi(t_1)$, $\dot{\Omega}_2 = \Omega_1$, $H_\Omega(U^{-1}B^*\eta) = \mathcal{N}(\mathcal{H}(U^{-1}B^*\eta))(t_1)$. Thus the result follows from Corollary 3.14. □

If F_Λ is the usual two-point evaluation operator, then Corollary 3.13 (using Lemma 3.4) becomes.

COROLLARY 3.15. *Assume that* $\Omega_2 \in \text{Dom } T_1$ *and*

$$F_\Lambda = M_1 x(t_0) + N_1 x(t_1) \quad \textit{for all } x \in \text{Dom } T_1$$

for some constant matrices $M_1(d_1 \times n)$ *and* $N_1(d_1 \times n)$. *Let* u^+ *be the unique optimal controller for the control problem. Then it is given by*

$$u^+ = U^{-1}B^*\eta \quad \textit{almost everywhere,}$$

where η *is an element of* Dom T_1 *for which there exists an element* $z \in \text{Dom } T_1$ *satisfying the following*:

(i) $\dot{z} = Az + BU^{-1}B^*\eta$ *almost everywhere,*

(ii) $Q_\Omega\big(z(t_0) + Q_\Omega^* H_\Omega(U^{-1}B^*\eta) - Q_\Omega^*\gamma\big) = 0,$

(iii) $\displaystyle\int_{t_0}^{t_1} \Phi^* W(z - x_0)\, dt$

$$+ \big(M_1 + N_1\Phi(t_1)\big)^*\big(N_1(\mathcal{H}(U^{-1}B^*\eta))(t_1) + (M_1 + N_1\Phi(t_1))z(t_0)\big)$$

belongs to Range (Q_Ω^*),

(iv) $\eta(t_1) = -N_1^*\big(N_1(\mathcal{H}(U^{-1}B^*\eta))(t_1) + (M_1 + N_1\Phi(t_1))z(t_0)\big)$

$$+ \Omega_2(t_1)(Q_\Omega^*)^*\big((M_1 + N_1\Phi(t_1))^* N_1(\mathcal{H}(U^{-1}B^*\eta))(t_1)$$

$$+ (M_1 + N_1\Phi(t_1))^*(M_1 + N_1\Phi(t_1))z(t_0)\big),$$

(v) $\dot{\eta} = -A^*\eta + W(z - x_0) + (\dot{\Omega}_2 - \Omega_1)(Q_\Omega^*)^*$

$$\cdot \Big((M_1 + N_1\Phi(t_1))^*(\mathcal{H}(U^{-1}B^*\eta))(t_1)$$

$$+ (M_1 + N_1\Phi(t_1))^*(M_1 + N_1\Phi(t_1))z(t_0)$$

$$+ \int_{t_0}^{t_1} \Phi^* W(z - x_0)\, dt \Big) \quad \textit{almost everywhere.}$$

We have so far seen that if one of F_Ω and F_Λ is not a two-point evaluation operator, then the optimal controller is described by a Fredholm integro-differential equation. In the following, we will show that the optimal controller is described by a usual differential equation if F_Ω and F_Λ are point-evaluation operators.

COROLLARY 3.16. *Assume that*

$$F_\Omega(x) = Mx(t_0) + Nx(t_1),$$

$$F_\Lambda(x) = M_1 x(t_0) + N_1 x(t_1)$$

for all $x \in \text{Dom } T_1$, *where* $M(d \times n)$, $N(d \times n)$, $M_1(d_1 \times n)$, $N_1(d_1 \times n)$ *are constant matrices. Let* u^+ *be the optimal controller. Then it is described by*

$$u^+ = U^{-1}B^*\eta \quad \textit{almost everywhere,}$$

where $\eta \in \text{Dom } T_1$ *is such that there exists* $z \in \text{Dom } T_1$ *satisfying the following*:

(i) $\dot{z} = Az + BU^{-1}B^*\eta$ *almost everywhere,*

(ii) $(M + N\Phi(t_1))(M + N\Phi(t_1))^*\big(\gamma - N(\mathscr{H}(U^{-1}B^*\eta))(t_1)\big)$
$= (M + N\Phi(t_1))z(t_0),$

(iii) $\int_{t_0}^{t_1} \Phi^* W(z - x_0)\, dt + \big(M_1 + N_1\Phi(t_1)\big)^*\big(N_1(\mathscr{H}(U^{-1}B^*\eta))(t_1)$
$+ (M_1 + N_1\Phi(t_1))z(t_0)\big) \in \text{Range } ((M + N\Phi(t_1))^*),$

(iv) $\eta(t_1) = -N_1^*\big(N_1(\mathscr{H}(U^{-1}B^*\eta))(t_1) + (M_1 + N_1\Phi(t_1)z(t_0))\big)$
$+ N^*\big((M + N\Phi(t_1))^*\big)^*\big((M_1 + N_1\Phi(t_1))^* N_1(\mathscr{H}(U^{-1}B^*\eta))(t_1)$
$+ (M_1 + N_1\Phi(t_1))^*(M_1 + N_1\Phi(t_1))z(t_0)\big),$

(v) $\dot{\eta} = -A^*\eta + W(z - x_0)$ *almost everywhere.*

Proof. This follows from Corollaries 3.14 and 3.15. □

If $N = 0$ and $M_1 = 0$ then the above result reduces to a rather familiar result below.

COROLLARY 3.17. *Assume that*

$$F_\Omega(x) = Mx(t_0), \qquad F_\Lambda(x) = N_1 x(t_1)$$

for all $x \in \text{Dom } T_1$ *where* M *and* N_1 *are* $d \times n$ *and* $d_1 \times n$ *constant matrices, respectively. Then the unique optimal controller* u^+ *for the control problem is given by*

$$u^+ = U^{-1}B^*\eta \quad \textit{almost everywhere,}$$

where η *is an element of* Dom T_1 *for which there exists* $z \in \text{Dom } T_1$ *satisfying*:

(i) $\dot{z} = Az + BU^{-1}B^*\eta$ *almost everywhere,*

(ii) $MM^{\#}\gamma = Mz(t_0),$

(iii) $\int_{t_0}^{t_1} \Phi^* W(z - x_0)\, dt + (N_1\Phi(t_1))^*\big(N_1(\mathscr{H}(U^{-1}B^*\eta))(t_1) + N_1\Phi(t_1)z(t_0)\big)$
$\in \text{Range } (M^*\cdot),$

(iv) $\eta(t_1) = -N_1^*\big(N_1(\mathscr{H}(U^{-1}B^*\eta))(t_1) + N_1\Phi(t_1)z(t_0)\big),$

(v) $\dot{\eta} = -A^*\eta + W(z - x_0).$

Remark. When $M = I_{n\times n}$, the above result is well known in the literature. Notice that in this case the condition (iii) becomes redundant.

Example. In the control problem, take $[t_0, t_1] = [0, 1]$, $A = 0_{n\times n}$, $U = I_{m\times m}$, $W = I_{n\times n}$, $x_0 = 0_{n\times 1}$, $F_\Lambda = 0$, and

$$F_\Omega(x) = Mx(0) + Nx(1) + \int_0^1 f(t)x(t)\, dt, \qquad x \in \text{Dom } T_1,$$

where $M(d \times n)$, $N(d \times n)$ are constant matrices and $f(t)(d \times n)$ is a matrix-valued function of t such that f^*f is integrable in $[0, 1]$ entrywise.

Then the problem becomes:

Minimize $\int_0^1 (x^*x + u^*u)\, dt$, subject to $u \in X_m$, $x \in \text{Dom } T_1$, $\dot{x} = Bu$ almost everywhere, and the least-squares condition:

$$\left\| Mx(0) + Nx(1) + \int_0^1 fx\, dt - \gamma \right\|$$
$$= \text{Min}\left\{ \left\| My(0) + Ny(1) + \int_0^1 fy\, dt - \gamma \right\| : y \in \text{Dom } T_1, \dot{y} = Bu \text{ almost everywhere} \right\}.$$

Let $\mathcal{D}$ be the corresponding dynamical system, i.e., the set of all ordered pairs $\{u, x\}$ satisfying the above constraints. Then we see that the following are equivalent:

(1) $\{u, x\} \in \mathcal{D}$.

(2) $u \in X_m$, $x \in \text{Dom } T_1$, $\dot{x} = Bu$ almost everywhere,

and

$$\int_0^1 fx\,dt + Mx(0) + Nx(1) - \gamma = (QQ^* - I)\left(\gamma - \int_0^1 \left(N^* + \int_t^1 f(s)\,ds\right)B(t)u(t)\,dt\right).$$

(3) $u \in X_m$, $x = \int_0^t B(s)u(s)\,ds - \alpha$

$$- Q^* \int_0^1 \left(N^* + \int_t^1 f(s)\,ds\right)B(t)u(t)\,dt + Q^*\gamma$$

for some $\alpha \in \text{Null } Q$,

where Q (corresponds to Q_Ω) is the $d \times n$ matrix $M + N + \int_0^1 f\,dt$. Notice that for $\{u, x\} \in \mathcal{D}$,

$$x(0) = Q^*\gamma - \alpha - Q^* \int_0^1 \left(N^* + \int_t^1 f(s)\,ds\right)B(t)u(t)\,dt$$

for some $\alpha \in \text{Null } Q$.

Thus if $f = 0$, $N = 0$, then the least squares condition becomes a transversality condition:

$$x(0) - M^*\gamma \in \text{Null } M.$$

Since this condition does not depend on controls, even though $\mathcal{D}$ generates multi-responses, one can treat the control problem as a standard single response problem by eliminating "multi-responseness".

However, if $N \neq 0$, $f \neq 0$, and Null $Q \neq \{0\}$, then $x(0)$ depends directly on controls and Null Q, and so the least-squares condition is no longer a transversality condition. Thus it is not clear whether the maximum principle or the Bellman's dynamical programming method can even be useful in handling this case.

By Corollary 3.13 we have: The optimal controller u^+ is given by

$$u^+ = B^*\eta \quad \text{almost everywhere}$$

where η is an element of Dom T_1 for which there exists $z \in \text{Dom } T_1$ such that

(i) $\dot{z} = BB^*\eta$ almost everywhere,

(ii) $z(0) + Q^*\left(N^*(z(1) - z(0)) + \int_0^1 f(z - z(0))\,dt - \gamma\right) \in \text{Null } Q$,

(iii) $\int_0^1 z\,dt \in \text{Range } Q^*$,

(iv) $\eta(1) = N^*(Q^*)^* \int_0^1 z\,dt$,

(v) $\dot{\eta} = z - f^*(Q^*)^* \int_0^1 z\,dt$ almost everywhere.

Let $\mathcal{P}$ be the orthogonal projector of $\mathbb{C}^n$ onto Null Q, and let

$$g = Q^{\#}\gamma - Q^{\#}\int_0^1 \left(N^* + \int_t^1 f(s)\,ds\right)B(t)u(t)\,dt.$$

Then using Theorem 3.9 we see that

$$x^+ := \int_0^t B(s)u^+(s)\,ds + g + \mathcal{P}\left(\int_0^1 (s-1)B(s)u^+(s)\,ds\right)$$

is the unique optimal response corresponding to u^+, while for any $\alpha \in$ Null Q,

$$x := \int_0^t B(s)u^+(s)\,ds + g + \alpha$$

is a nonoptimal response corresponding to u^+.

Acknowledgment. The author thanks the referees for the constructive comments which led to improving this paper.

OPEN LOOP CONTROL OF WATER WAVES IN AN IRREGULAR DOMAIN*

RUSSELL M. REID†

Abstract. This paper considers open loop control of linear, small amplitude waves on a fluid surface. It extends the controllability results of Reid and Russell [4] to a two-dimensional domain with irregular bottom contour, constructing a null control via its Laplace transform, provided the bottom has finite arclength and no beaches. The domain may be multiply connected, i.e. contain fixed objects, provided they do not touch the surface.

Key words. water waves, small amplitude waves, linear waves

AMS(MOS) subject classification. 93

1. Introduction. This paper builds on results from an earlier paper by Reid and Russell [4], and relies heavily on that paper for background and comprehensibility. In [4], we developed a model for a controlled system of water waves on the surface of a two-dimensional region. The development of the model and the proofs of existence/uniqueness required no special assumptions about the shape of the region. The controllability result in [4], however, depended on knowledge of the eigenvalues of the underlying system, and thus applied only to a simple geometry for which the eigenvalues are known (infinitely deep tank with straight sides). The control result obtained was that an (essentially) arbitrary initial state can be steered to zero (surface is still) in infinite time, but not in any finite time, with the boundary control modeled. The rate of convergence to zero was not examined.

The current paper perturbs the argument in [4] to obtain the same result for variable, finite-depth regions. It constructs on open-loop, boundary null-control, i.e. one that steers an "arbitrary" initial state to zero in infinite time, and shows that no such control is possible in finite time.

This work begins with the evolution equation derived in [4] to describe linear waves controlled by a vibrating wall, and uses the existence/uniqueness results proved there. It also uses the result that the evolution operator A is self-adjoint with compact resolvent, and that an open loop null control must satisfy a certain moment equation involving exponentials of eigenvalues (equation (1.5) here). In [4], we solved the equation (1.5) for a simple geometry for which both eigenvalues and eigenfunctions are known, namely an infinitely deep, straight-sided tank. This work solves (1.5) for much more general geometries, following the same line of attack as [4]. It proceeds by perturbation of the work in [4], first by estimating the eigenvalues for a more general geometry, then by establishing functions which have zeros at those eigenvalues and which are recognizable as Laplace transforms of L^2 functions. Motivation for the perturbation techniques comes from equation (2.4) of this paper, which displays a potential function for the infinite depth tank. That potential decays exponentially with depth, leading one to expect that the effect of a bottom should also decay exponentially with depth. Such a guess is essentially correct, and is the key to eigenvalue estimation: one can estimate the influence of a bottom by looking in the infinite depth tank at the flow through the proposed bottom, then computing the influence of placing a bottom there. Calculating that surface influence is the same as computing the electric field at the surface due to a charge distribution placed on the bottom, where the charge

* Received by the editors April 1, 1984, and in revised form April 15, 1985.

† Department of Mathematical and Computer Sciences, Michigan Technological University, Houghton, Michigan 49931.

distribution equals the flow in the infinite depth tank through the proposed bottom; an integral form for such a potential is known.

In the proofs here, ideas and estimates are borrowed from the proofs in [4], so a reader must either recall key estimates from [4] or accept them without proof. If arguments duplicate those in [4], only necessary changes are supplied.

We begin the current work with a summary of the problem formulation, then give a brief overview of what follows.

Consider a fluid in a two-dimensional region Ω, with nonzero vertical walls at water level, i.e. no beaches. Denote the vertical segments by W_1 and W_2, the remaining fixed boundary (the bottom) by Γ, and the undisturbed surface ($z=0$) by S_0. Assume Γ has finite arc length. See Fig. 1.

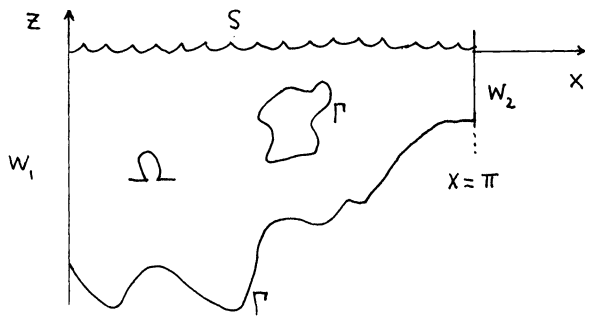

FIG. 1

The surface contour $\zeta(x, t)$ is a solution of

$$\ddot{\zeta} = -A\zeta, \tag{1.1}$$

where the evolution operator A is defined in terms of a harmonic "acceleration potential" ψ_ζ, which satisfies:

$$\begin{aligned} &\psi_\zeta = \zeta \quad \text{on } S_0, \\ &\frac{\partial \psi_\zeta}{\partial n} = 0 \quad \text{on } \Gamma \cup W_1 \cup W_2. \end{aligned} \tag{1.2}$$

(If fluid velocity is $-\nabla\phi$, then $\psi = \partial\phi/\partial t$, hence the name "acceleration potential.")

Then A is defined by

$$A\zeta = \left.\frac{\partial \psi_\zeta}{\partial z}\right|_{S_0}, \tag{1.3}$$

provided $\zeta \in D(A)$, i.e. $\zeta \in H^1 \cap L^2[0, \pi]$ and $\int_0^\pi \zeta(x)\,dx = 0$. (The last condition is needed to ensure volume conservation; hereafter we write it as $L_0^2(0, \pi)$.)

The controlled system, where wall W_2 oscillates with velocity $F(z)U(t)$, can be written

$$\frac{\partial}{\partial t}\begin{pmatrix} \zeta \\ \eta \end{pmatrix} = \begin{bmatrix} 0 & I \\ -A & 0 \end{bmatrix}\begin{pmatrix} \zeta \\ \eta \end{pmatrix} + \begin{pmatrix} 0 \\ d(x) \end{pmatrix} u(t) \tag{1.4}$$

or more briefly $(\partial/\partial t)\xi = A_0\xi + B(x)u(t)$, with $\eta = \partial\zeta/\partial t$, and $d(x)$ an L^2 control distribution function.

Existence, uniqueness, and regularity of solutions to (1.4) were established in [4], and an open loop null control $u(t)$ valid in infinite time was shown to satisfy

$$a_k + b_k \int_0^\infty e^{-w_k t} u(t)\, dt = 0, \qquad k = \pm 1, \pm 2, \pm 3, \cdots. \tag{1.5}$$

Here w_k are the eigenvalues of A_0; a_k and b_k are expansion coefficients of $\xi(x, 0)$ and $B(x)$ in terms of eigenfunctions of A_0. (It was shown in [4] that no such control can be hoped for in finite time, because wave propagation speeds approach zero as wavelength approaches zero.)

Existence of a control $u(t)$ satisfying (1.5) depends on the eigenvalues w_k. For a simple domain $\Omega_{\text{inf}} = \{(x, z): 0 \leqq x \leqq \pi,\ z \leqq 0\}$ (with straight sides and infinite depth), the operator $A \equiv A_{\text{inf}}$, its eigenvalues and eigenfunctions are known; solutions to (1.5) were constructed for this case in [4]. Here we prove similar results for a more general region Ω. In what follows, Ω_{inf}, A_{inf}, ψ_{inf} refer to the infinite depth domain, while Ω, A, ψ refer to the finite domain. The eigenvalues of A_{inf} were established in [4] as $\lambda_k = k$, $k = 0, 1, 2, \cdots$; here we establish and use estimates of the eigenvalues of A. We will use λ_k henceforth to denote eigenvalues of A, and w_k to denote eigenvalues of A_0 as above, specifically

$$w_{\pm k} = \pm i\sqrt{\lambda_k}, \qquad k = 1, 2, 3, \cdots. \tag{1.6}$$

Theorem 2.1 shows that the eigenvalues λ_k of the evolution operator A in the finite domain Ω are close to the eigenvalues of A_{inf} in the simpler domain Ω_{inf}, specifically $|\lambda_k - k| = O(1/k)$. Lemma 3.1 uses this closeness to show that a product analogous to $1/\Gamma(z)$, but with zeros at λ_k instead of k, is asymptotic to $1/\Gamma(z)$ in any sector lying in the right half plane. Using this product and a property similar to the reflection property of the Gamma function, Theorem 3.1 establishes a function $G_p(z)$ with zeros at $\pm i\sqrt{\lambda_k}$ and bounded in the right half plane. Theorem 3.2 shows that a control $u(t)$ can be constructed using $G_p(z)$ in the same way as for the simpler geometry Ω_{inf}. Smoothness conditions on the initial state which ensure convergence of the series defining $u(t)$ are the same as for the infinite depth case.

2. Eigenvalue estimates.

THEOREM 2.1. *The operator A has a discrete spectrum of eigenvalues $\lambda_k = k + \varepsilon_k/k$, where the $|\varepsilon_k|$ are bounded, and an associated complete orthonormal set of eigenfunctions $\phi_k(x)$.*

Proof. We prove three lemmas showing that the effect of a bottom is bounded: Define B and ψ_p by

$$A = A_{\text{inf}} + B, \qquad \psi = \psi_{\text{inf}} + \psi_p, \tag{2.1}$$

where B is a bottom perturbation operator and ψ_p is a harmonic function defined in Ω. The domain of B is that of A and A_{inf}, namely $H^1 \cap L_0^2(0, \pi)$, and B is related to ψ_p by (1.3), $B = \partial\psi_p/\partial z|_{S_0}$. Since both A and A_{inf} are self-adjoint (from [4]) and since

$$A^2 = A_{\text{inf}}^2 + A_{\text{inf}} \circ B + B \circ A_{\text{inf}} + B^2, \tag{2.2}$$

(where $D(A^2) = H^2 \cap L_0^2(0, \pi)$), we can display the eigenvalues of A as $(k^2 + O(1))^{1/2} = k + O(k^{-1})$ provided we can show that the last three terms in (2.2) are bounded. To this end, let

$$\zeta(x) = \sum_1^\infty a_n \cos(nx) \tag{2.3}$$

be the Fourier expansion of ζ ($a_0 = 0$ by conservation of volume). The potential

corresponding to $\zeta(x)$ in Ω_{inf} must satisfy $\psi(z=0)=\zeta(x)$, $\partial\psi/\partial x=0$ at $x=0$, $x=\pi$ and $\partial\psi/\partial z\to 0$ as $z\to-\infty$, and thus can be verified to be

$$\psi_{\text{inf}}(x, z)=\sum_{1}^{\infty} a_n e^{nz}\cos nx. \tag{2.4}$$

Therefore,

$$A_{\text{inf}}(\cos nx)=n\cos nx, \qquad n=1, 2, 3, \cdots. \tag{2.5}$$

Assume $\zeta\in H^1[0, \pi]$, so

$$\sum_{1}^{\infty} n^2 a_n^2<\infty. \tag{2.6}$$

To estimate B, we derive an integral representation for ψ_p as defined in (2.1). Construct an extended domain as shown, (see Fig. 2) so that the new domain is symmetric about $x=0$, $x=\pi$, and $z=0$. If $\Gamma(s)$ is a parametrization of the bottom contour, define a flux density $\sigma(s)$ on Γ by

$$\pi\sigma(s)\equiv\left.\frac{-\partial\psi_{\text{inf}}}{\partial n}\right|_{\Gamma(s)}, \tag{2.7}$$

defined on $\Gamma(s)$ and extended as in Fig. 2 to be symmetric about $x=0$, $x=\pi$, antisymmetric about $z=0$. $(\sigma(s, z)=-\sigma(s, -z))$

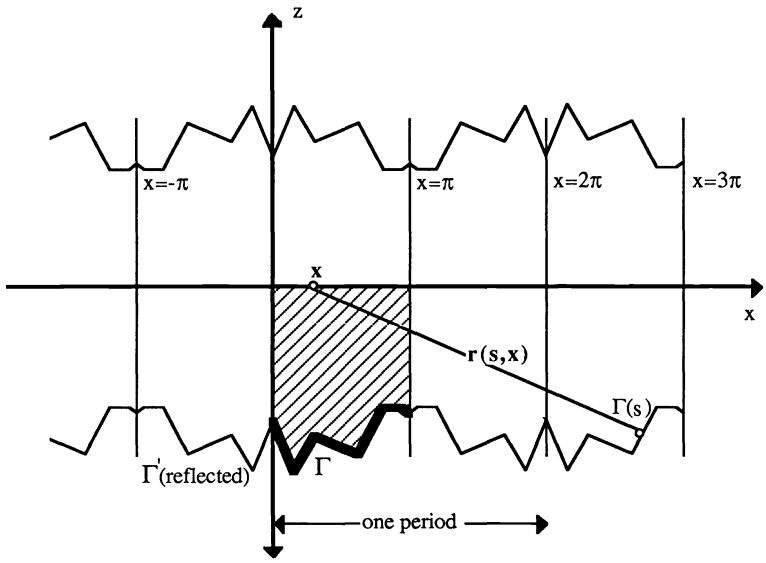

FIG. 2

Let Γ' represent the extension of Γ shown in Fig. 2, and hereafter $\sigma(s)$ refers to the extended domain although the notation is unchanged.

LEMMA 2.2. *The perturbation potential ψ_p and operator B of* (2.1) *are given by*

$$\psi_p(x, z)=\int_{\Gamma'}\sigma(s)\ln r(s, x, z)\,dx, \tag{2.8}$$

$$B\zeta(x)=\int_{\Gamma'}\frac{\sigma(s)h(s)}{[r(s, x, 0)]^2}\,ds \tag{2.9}$$

where $h(s)$ is the z coordinate at the point parametrized by s, and $r(s, x, z)$ is its distance from (x, z). (Dependence of ψ_p and B on $\zeta(x)$ comes from $\sigma(s)$ via (2.3), (2.4), (2.7).) *Note that $B = (\partial/\partial z)(\psi_p)|_{z=0}$, and that B is linear.*

Proof. ψ_p is the integral form of the two-dimensional potential whose normal derivative on $\Gamma'(s)$ is $\pi\sigma(s)$. Symmetry of the domain and the flux density $\sigma(s)$ shows that ψ_p has normal derivative zero on W_1 and W_2 and that $\psi_p = 0$ on $z = 0$, and equation (2.7) shows that $(\partial/\partial n)(\psi_{\text{inf}} + \psi_p) = 0$ on Γ. Thus $\psi_{\text{inf}} + \psi_p$ fulfills the requirements (1.2) for ψ_ζ (recall that $\psi_{\text{inf}} = \zeta$ on S_0), so ψ_p and $B\zeta \equiv (\partial/\partial z)\psi_p|_{z=0}$ satisfy (2.1). □

LEMMA 2.3. *$B \circ A_{\text{inf}}$ is bounded.*

Proof. Using (2.3), (2.5), we have

$$B \circ A_{\text{inf}}(\zeta) = \sum_1^\infty n a_n (B \cos nx). \tag{2.10}$$

Let $\sigma_n(s)$ be the flux density $\sigma(s)$ obtained by taking $\zeta(x) = \cos nx$ (compute ψ_{inf} with value $\cos nx$ on the surface S_0, and denote the result by ψ^n_{inf}. Use (2.7) to calculate $\sigma(s)$, and denote that result by $\sigma_n(s)$). Then $B(\cos nx)$ can be estimated by putting an estimate of $\sigma_n(s)$ into the integral form (2.9) for B. Since the potential ψ^n_{inf} is just that of a single term in (2.4),

$$\psi^n_{\text{inf}} = e^{nz} \cos nx, \tag{2.11}$$

and (2.7) implies

$$|\sigma_n(s)| \leqq \frac{1}{\pi} |\nabla \psi^n_{\text{inf}}| \leqq n\, e^{-nH} \tag{2.12}$$

where H is the minimum depth of the tank. If M is the maximum depth, we see from (2.9) that

$$|B \cos (nx)| \leqq \int_{\Gamma'} \frac{Mn\, e^{-nH}}{[r(s, x, 0)]^2}\, ds \leqq Kn\, e^{-nH} \tag{2.13}$$

for some k independent of n, provided Γ has finite arc length. Combining this with (2.10) we have, recalling (2.3),

$$\| B \circ A_{\text{inf}}(\zeta) \| \leqq K \sum_1^\infty n^2 a_n\, e^{-nH} \leqq C \| \zeta \|, \tag{2.14}$$

so that $B \circ A_{\text{inf}}$ is bounded. □

LEMMA 2.4. *$A_{\text{inf}} \circ B$ is bounded.*

Proof.

$$A_{\text{inf}} \circ B = \sum_1^\infty a_n A_{\text{inf}} \circ B \cos (nx), \tag{2.15}$$

so by the Schwarz inequality we need only a bound for

$$\sum_1^\infty |A_{\text{inf}} \circ B(\cos nx)|^2. \tag{2.16}$$

Use estimate (2.12) to define $|\hat{\sigma}_n(s)| \leqq 1$ by

$$\sigma_n(s) = n\, e^{-nH} \hat{\sigma}_n(s), \tag{2.17}$$

then consider an integral similar to (2.13):

$$A_{\text{inf}} \circ B(\cos nx) = n\, e^{-nH} \left[A_{\text{inf}} \circ \int_{\Gamma'} \frac{\hat{\sigma}_n(s) h(s)}{[r(s, x, 0)]^2}\, ds \right]. \tag{2.18}$$

The term in brackets may be shown to be bounded independent of n by estimating the derivative of the integral, and noting from (2.5) that

$$\|A_{\inf} f(x)\|_{L^2} = \|f_n'(x)\|_{L^2}.$$

The derivative of the integral can be estimated by:

$$\begin{aligned}\int_{\Gamma'} \frac{\hat{\sigma}_n(s)h(s)(\partial/\partial x)r(s,x,0)}{-2r(s,x,0)^3}\,dx &\leqq \frac{M}{2}\int_{\Gamma'} \frac{(\partial/\partial x)r(s,x,0)}{((x+H)/\sqrt{2})^3}\,ds \\ &\leqq \frac{M\sqrt{2}}{4}\int_{\Gamma'} \frac{1}{(x+H)^3}\,ds < \infty.\end{aligned} \tag{2.19}$$

Note that $|(\partial/\partial x)r(s,x,0)| \leqq 1$ because $r(s,x,0)$ is the distance from $(x,0)$ to the point parametrized by s, and that the arclength of Γ is finite. □

Finally, we note that $B \circ B$ is bounded, from (2.13), establishing Theorem 2.1.

We know from [14] that A is self-adjoint with compact resolvent, hence has a complete system of eigenfunctions. □

3. Construction of an open-loop control. Under some assumptions on a_k and b_k, (1.5) can be solved for a control $u(t) \in L^1 \cap L^2[0,\infty)$. Rewrite (1.5), recalling the w_k are eigenvalues of $A_0 = \left[\begin{smallmatrix} 0 & I \\ -A & 0 \end{smallmatrix}\right]$, and the λ_k the eigenvalues of A, as

$$\int_0^\infty e^{-w_k t} u(t)\,dt = c_k \equiv \frac{-a_k}{b_k}, \qquad k = \pm 1, \pm 2, \cdots, \tag{3.1}$$

with the convention $c_0 = 0$, and the approximate controllability assumption $b_k \neq 0$. Solve this moment problem for $u(t)$ in a way parallelling [4]: establish a function $G_p(z)$ which is uniformly bounded in the right half-plane and which has simple zeros at the $w_{\pm k} = \pm i\sqrt{\lambda_k}$, $k = 1, 2, 3, \cdots$. Then factor out zeros one at a time to establish a set of functions $p_k(z)$, $k = \pm 1, \pm 2, \cdots$, satisfying

$$\int_0^\infty e^{-w_k t} p_j(t)\,dt = \delta_{kj}, \qquad k, j = \pm 1, \pm 2, \pm 3, \cdots \tag{3.2}$$

so that $u(t)$ satisfying (3.1) is

$$u(t) = \sum_{-\infty}^{\infty} c_k p_k(t). \tag{3.3}$$

To construct $G_p(z)$ as noted above, let $\Gamma_p(z)$ be a "perturbed" gamma function with poles at $z = -\lambda_n$ instead of $z = -n$:

$$\frac{1}{\Gamma_p(z)} = z\, e^{\gamma z} \prod_{n=1}^{\infty} \left(1 + \frac{z}{\lambda_n}\right) e^{-z/n}. \tag{3.4}$$

The product converges absolutely since $\{\lambda_n - n\}$ is bounded (Theorem 2.1).

THEOREM 3.1. *The function*

$$G_p(z) = \frac{\Gamma[(z+1)^2]}{\Gamma_p(z^2)[e^{z+1}\Gamma(z+1)]^4} \tag{3.5}$$

is analytic for $\operatorname{Re}(z) > -1$, *uniformly bounded for* $\operatorname{Re}(z) \geqq 0$, *has bounded derivatives on the imaginary axis, and simple zeros at* $w_{\pm k} = \pm i\sqrt{\lambda_k}$.

Proof. Zeros and analyticity of $G_p(z)$ are clear; we establish boundedness by comparing $G_p(z)$ with the $G(z)$ discussed in [4], using the result from [4] that $G(z)$ is uniformly bounded in $\operatorname{Re}(z) \geqq 0$ with bounded derivatives on $\operatorname{Re}(z) = 0$.

LEMMA 3.1. *Let*

$$H(z)=\frac{\Gamma(z^2)}{\Gamma_p(z^2)}. \tag{3.6}$$

Then $H(z)$ and $1/H(z)$ are uniformly bounded for

$$|\arg z|\leqq\frac{\pi}{2}-\theta \quad \textit{for any } \theta>0. \tag{3.7}$$

Proof.

$$H(z)=\prod_{n=1}^{\infty}\frac{(1+z^2/(n+\varepsilon_n))}{(1+z^2/n)}=\prod_{n=1}^{\infty}\left(1-\frac{\varepsilon_n}{n+\varepsilon_n}+\frac{\varepsilon_n}{n+z^2}-\frac{\varepsilon_n^2}{(n+\varepsilon_n)(n+z^2)}\right) \tag{3.8}$$

where $\lambda_n=n+\varepsilon_n$ as in Theorem 2.1. Since $\varepsilon_n=\delta_n/n$ where $|\delta_n|\leqq C$,

$$\left|\frac{\varepsilon_n}{n+z^2}\right|\leqq\frac{C}{n^{3/2}}\csc(2\theta). \tag{3.9}$$

The product in (3.8) converges provided the sum of the last three terms converges, and

$$\sum_{n=1}^{\infty}\left|\frac{\varepsilon_n}{n+\varepsilon_n}\right|+\left|\frac{\varepsilon_n}{n+z^2}\right|+\left|\frac{\varepsilon_n}{(n+\varepsilon_n)(n+z^2)}\right|$$
$$\leqq\sum_{1}^{\infty}\frac{C}{(n+\varepsilon_n)\sqrt{n}}+\frac{C\csc(2\theta)}{n\sqrt{n}}+\frac{C\csc 2\theta}{(n+\varepsilon_n)n\sqrt{n}}.$$

The series on the right converges absolutely, and is bounded independent of z in the argument range (3.7). A similar analysis shows uniform boundedness of $1/H(z)$ in the same sector. □

Lemma 3.1 implies that $G_p(z)=H(z)G(z)$ is bounded in the argument range (3.7). In establishing boundedness of $G(z)$ when $|\arg z|=\pi/2$ in [4], we used the reflection principle

$$\frac{1}{\Gamma(z)}=\frac{-z\sin\pi z}{\pi}\Gamma(-z). \tag{3.10}$$

We need a similar reflection equation for $\Gamma_p(z)$; from (3.4) we see that

$$\frac{1}{\Gamma_p(z)}=-z^2\prod_{1}^{\infty}\left(1-\frac{z^2}{\lambda_n^2}\right)\Gamma_p(-z). \tag{3.11}$$

Let

$$p(z)=z\prod_{1}^{\infty}\left(1-\frac{z^2}{\lambda_n^2}\right). \tag{3.12}$$

Then we expect $p(z)$ to be related to $\sin\pi z$; in fact we can show:

LEMMA 3.2. *For some $\beta(s)\in L^2[-\pi,\pi]$, and some constant C,*

$$p(z)=z\prod_{1}^{\infty}\left(1-\frac{z^2}{\lambda_n^2}\right)=C\left[\sin\pi z-\int_{-\pi}^{\pi}\beta(s)\,e^{izs}\,ds\right]. \tag{3.13}$$

Proof. The exponentials $e^{\pm i\lambda_k s}$, together with 1, form a Riesz basis for $L^2[-\pi,\pi]$ because $\{\lambda_k-k\}$ is square summable (see [2]). In addition, $\{\sin\lambda_k\pi\}$ is square summable, so that there is a unique $\beta\in L^2[-\pi,\pi]$ with

$$\int_{-\pi}^{\pi}\beta(s)\,e^{i\lambda_k s}\,ds=\sin\lambda_k\pi, \qquad k=0,\pm1,\pm2,\pm3. \tag{3.14}$$

Therefore

$$g(z) = \sin \pi z - \int_{-\pi}^{\pi} \beta(s)\, e^{izs}\, ds \tag{3.15}$$

is entire, and has zeros precisely at $z = 0, \pm i\lambda_k$. The product (3.12) shows $p(z)$ to be entire with the same zeros. Choose α a zero of neither p nor g, define

$$p(\alpha) = Cg(\alpha),$$

then

$$\hat{\xi}(z) \equiv \frac{p(z) - Cg(z)}{z - \alpha}$$

is entire, L^2 on the real axis, and of exponential type π (see [3]). Therefore it is the Fourier transform of some $\xi(t) \in L^2[-\pi, \pi]$, which is orthogonal to 1, $e^{\pm\lambda_k t}$ and thus is zero. □

We complete the proof of Theorem 3.1 by noting that for $\pi/2 - \theta \leqq |\arg z| \leqq \pi/2$ (using estimates of $G(z)$ from [4],

$$G_p(z) = \frac{1}{4\pi^2 e} \cdot \left[1 - e^{-2\pi i z^2} - \int_{-\pi}^{\pi} \beta(s)\, e^{iz^2(s-\pi)}\, ds\right] C \frac{\Gamma_p(-z^2)}{\Gamma(-z^2)} \tag{3.16}$$

and thus is bounded and has bounded derivatives there.

THEOREM 3.2. *The functions $\hat{P}_k(z)$, defined by*

$$\hat{p}_k(z) = \frac{w_k G(z)}{z(z - w_k) G'(w_k)}, \qquad k = \pm 1, \pm 2, \pm 3, \cdots \tag{3.17}$$

are Laplace transforms of functions $p_k(t) \in L^1 \cap L^2[0, \infty)$ and satisfy biorthogonality relations

$$\hat{p}_k(w_j) = \delta_{kj}. \tag{3.18}$$

Proof. Estimates of $G(z)$ from [4] and the fact that $|w_k - i\sqrt{k}| = O(1/k^{3/2})$ allow the proof to follow the infinite depth case: $\hat{p}_k(z)$ is in $L^2(-\infty, \infty)$ as a function of y, uniformly in x and with estimates independent of k. Since y derivatives of $\hat{p}_k(iy)$ are in L^2, $tp_k(t)$ must be in L^1 and therefore $p_k(t) \in L^1 \cap L^2[0, \infty)$. □

The series (3.3) for a control $a(t)$ will converge provided the initial state is sufficiently smooth.

The a_k are the expansion coefficients of the initial state ξ_0 in terms of eigenfunctions of A_0 (see (1.5)). The b_k are coefficients of a control distribution function $B(x)$, and are design parameters of the control mechanism. Assume they were chosen to be slowly decaying, say $|b_k| \geqq 1/k^p$, where $p > \frac{1}{2}$ ensures that $\{b_k\}$ is square summable. Then (3.3) will converge to an admissible control provided $|a_k/b_k|$ is summable, for example if $|a_k| < 1/k^q$ for some $q > p + 1$.

FINITE DIMENSIONAL COMPENSATORS FOR INFINITE DIMENSIONAL SYSTEMS WITH UNBOUNDED INPUT OPERATORS*

R. F. CURTAIN† AND D. SALAMON†‡

Abstract. This paper contains a design procedure for constructing finite dimensional compensators for a class of infinite dimensional systems with unbounded input operators. Applications to retarded functional differential systems with delays in the input or the output variable and to partial differential equations with boundary input operators are discussed.

Key words. infinite dimensional systems, unbounded input operators, compensator, retarded functional differential equations, partial differential equations, boundary control

AMS(MOS) subject classifications. 34K20, 93C15, 93C25, 93D15

1. Introduction. In [15], [16], [17] Schumacher presented a design procedure for constructing stabilizing compensators for a class of infinite dimensional systems. The novel feature was that the compensators were finite dimensional and that they could be readily numerically calculated from finitely many system parameters. The class included those systems described by retarded functional differential and partial differential equations provided that the eigenvectors of the system operators were complete and provided that the input and output operators were bounded. In [3] Curtain presented an alternative compensator design which applied to essentially the same class of systems, except that for the special case of parabolic systems unbounded input and output operators were allowed. By means of enlarging the state space of the given distributed boundary control system, Curtain in [2] essentially transformed the original problem with unbounded control into one with bounded control action so that the techniques of either [16] or [3] could be applied. The resulting control, however, was of integral type. Neither of these two compensator designs are applicable to retarded systems with delays in the control or the observation.

In the present paper we make use of the abstract approach developed by Salamon [14] to extend the results of Schumacher [16] to allow for unbounded control action. This is done in a direct way without reformulating the original problem into one with a bounded input operator. In § 2 we outline the abstract formulation and prove a theorem on the existence of a finite dimensional compensator paralleling the development in [16]. In § 3 the general approach is then applied to retarded functional differential systems with delays in either the input or the output variables. The conditions are easy to check and they are quite reasonable, except for the assumption of completeness of the eigenfunctions which seems to be too strong. In a special case we are able to weaken this assumption.

Finally, in § 4, we show how boundary control systems fit into the abstract framework of § 2 and give an example. The results are compared with the approach in [3].

2. A general result. We consider the abstract Cauchy problem

$$\dot{x}(t) = Ax(t) + Bu(t), \qquad x(0) = x_0 \in X, \tag{2.1.1}$$

$$y(t) = Cx(t), \tag{2.1.2}$$

on the real, reflexive Banach space X where $A: \mathcal{D}(A) \to X$ is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on X and $C \in \mathcal{L}(X, \mathbb{R}^m)$.

In order to give a precise definition of what we mean by an unbounded input operator we need an extended state space $Z \supset X$. For this purpose let us first introduce the subspace

$$Z^* = \mathcal{D}_{X^*}(A^*) \subset X^*$$

endowed with the graph norm of A^*. Then Z^* becomes a real, reflexive Banach space and the injection of Z^* into X^* is continuous and dense. Defining Z to be the dual space of Z^*, we obtain by duality that

$$X \subset Z$$

with a continuous dense injection.

Remarks 2.1. (i) A^* can be regarded as a bounded operator from Z^* into X^* and $S^*(t)$ restricts to a strongly continuous semigroup on Z^*. By duality, A extends to a bounded operator from X into Z. This extension, regarded as an unbounded operator on Z, is the infinitesimal generator of the extended semigroup $S(t) \in \mathcal{L}(Z)$ (see [14, Lemma 1.3.2]).

(ii) If $\mu \notin \sigma(A) = \sigma(A^*)$, then the operator $\mu I - A: X \to Z$ is bijective. Furthermore, this operator commutes with the semigroup $S(t)$ so that it provides a similarity action between the semigroups $S(t) \in \mathcal{L}(X)$ and $S(t) \in \mathcal{L}(Z)$.

(iii) It follows from (ii) that the exponential growth rate of the semigroup $S(t)$ is the same on the state spaces X and Z, i.e.

$$\omega_0 = \lim_{t\to\infty} t^{-1} \log \|S(t)\|_{\mathcal{L}(X)} = \lim_{t\to\infty} t^{-1} \log \|S(t)\|_{\mathcal{L}(Z)}.$$

(iv) It also follows from (ii) that the spectrum of A on the state space X coincides with the spectrum of A on Z (see [14, Lemma 1.3.2]). Furthermore, the generalized eigenvectors for both operators are the same, since the eigenvectors of A and Z are contained in $\mathcal{D}_Z(A) = X$. Finally, the (generalized) eigenvectors of A are complete in X if and only if they are complete in Z.

We will always assume that B is a bounded, linear operator from R^l into Z. However, we want the solutions of (2.1.1) to be in the smaller space X on which the output operator is defined. Therefore we need the following hypothesis.

(H1) For every $T > 0$ there exists a constant $b_T > 0$ such that $\int_0^T S(T-s)Bu(s)\,ds \in X$ and

$$\left\| \int_0^T S(T-s)Bu(s)\,ds \right\|_X \leqq b_T \|u(\cdot)\|_{L^p[0,T;R^l]}$$

for every $u(\cdot) \in L^p[0, T; R^l]$ where $1 \leqq p < \infty$. In the following we collect some important consequences of (H1) which have been established in [14, § 1.3].

Remarks 2.2. (i) (H1) is satisfied if and only if the inequality

$$\|B^* S^*(\cdot)x^*\|_{L^q[0,T;R^l]} \leqq b_T \|x^*\|_{X^*}$$

holds for every $x^* \in Z^*$ and every $T > 0$ where $1/p + 1/q = 1$.

(ii) If (H1) is satisfied, then

$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds \in X \tag{2.2}$$

is the unique strong solution of (2.1.1) for every $x_0 \in X$ and every $u(\cdot) \in L^p[0, T; R^l]$. More precisely $x(t)$ is continuous in X on the interval $[0, T]$ and satisfies

$$x(t) = x_0 + \int_0^t [Ax(s) + Bu(s)]\,ds, \qquad 0 \leqq t \leqq T,$$

where the integral has to be understood is the state space Z. Thus (2.1.1) is satisfied in the space Z for almost every $t \in [0, T]$.

(iii) If (H1) is satisfied, then for every $w(\cdot) \in \mathscr{C}[0, T; X]$ there exists a unique $x(\cdot) \in \mathscr{C}[0, T; X]$ satisfying the equation

$$x(t) = w(t) + \int_0^t S(t-s)BFx(s)\,ds, \qquad t \geqq 0.$$

This solution $x(\cdot)$ depends continuously on $w(\cdot)$.

Moreover hypothesis (H1) implies the following important perturbation result.

THEOREM 2.3. *Let $F \in \mathscr{L}(X; \mathbb{R}^l)$ be given. Then the following statements hold.*

(i) *There exists a unique strongly continuous semigroup $S_F(t)$ on X satisfying*

$$S_F(t)x = S(t)x + \int_0^t S(t-s)BFS_F(s)\,x\,ds \tag{2.3}$$

for every $x \in X$ and every $t \geqq 0$. Its infinitesimal generator is given by

$$\mathscr{D}(A_F) = \{x \in X \mid Ax + BFx \in X\},$$

$$A_F x = Ax + BFx.$$

(ii) $A_F^* = A^* + F^*B^*: \mathscr{D}(A_F^*) = Z^* \to X^*$.

(iii) *$S_F(t)$ extends to a strongly continuous semigroup on Z and the infinitesimal generator of the extended semigroup is given by $A + BF: X \to Z$.*

(iv) *Let $x_0 \in X$ and $v(\cdot) \in L^p[0, T; \mathbb{R}^l]$ be given and let $x(\cdot) \in \mathscr{C}[0, T; X]$ be the unique solution of*

$$x(t) = S(t)x_0 + \int_0^t S(t-s)B[Fx(s) + v(s)]\,ds, \qquad 0 \leqq t \leqq T. \tag{2.4}$$

Then

$$x(t) = S_F(t)x_0 + \int_0^t S_F(t-s)Bv(s)\,ds, \qquad 0 \leqq t \leqq T. \tag{2.5}$$

(v) *Hypothesis* (H1) *is satisfied with $S(t)$ replaced by $S_F(t)$ and $S_F(t)$ satisfies*

$$S_F(t)x = S(t)x + \int_0^t S_F(t-s)BFS(s)x\,ds \tag{2.6}$$

for every $x \in X$ and every $t \geqq 0$.

(vi) *Let $x_0 \in X$ and $f(\cdot) \in L^p[0, T; X]$ be given and define*

$$x(t) = S_F(t)x_0 + \int_0^t S_F(t-s)f(s)\,ds, \qquad 0 \leqq t \leqq T. \tag{2.7}$$

Then

$$x(t) = S(t)x_0 + \int_0^t S(t-s)[BFx(s) + f(s)]\,ds, \qquad 0 \leqq t \leqq T. \tag{2.8}$$

Proof. Statement (i) has been shown in [14, Thm. 1.3.7] and (ii) follows from [14, Thm. 1.3.9] since the input space is finite-dimensional. By (ii), $S_F^*(t)$ restricts to a strongly continuous semigroup on $Z^* = \mathcal{D}(A_F^*)$ and hence $S_F(t)$ extends to a semigroup on Z. By Remark 2.1(i), the extended semigroup is generated by the adjoint operator of A_F^*, where A_F^* is regarded as a bounded operator from Z^* into X^*. This proves statement (iii).

In order to establish statement (iv), let us first assume that $v(\cdot) \in \mathscr{C}^1[0, T; \mathbb{R}^l]$ and let $x(\cdot) \in \mathscr{C}[0, T; X]$ be the unique solution of (2.4). Then it follows from Remark 2.2 (ii) that $x(\cdot) \in \mathscr{C}^1[0, T; Z]$ and

$$\frac{d}{dt} x(t) = (A + BF)x(t) + Bv(t), \qquad 0 \leqq t \leqq T.$$

Hence it follows from (iii) and a classical result in semigroup theory that $x(\cdot)$ is given by (2.5). In general, statement (iv) follows from the fact that the unique solutions of both (2.4) and (2.5), regarded as continuous functions with values in Z, depend continuously on $v(\cdot) \in L^p[0, T; \mathbb{R}^l]$.

It follows immediately from (iv) that (H1) is satisfied with $S(t)$ replaced by $S_F(t)$. Now let $x(t)$, $t \geqq 0$, be defined by the RHS of (2.6). Then it follows from (iv) that

$$\begin{aligned} x(t) &= S(t)x + \int_0^t S(t-s)B\left[F\int_0^s S_F(s-\tau)BFS(\tau)x\,d\tau + FS(s)x\right] ds \\ &= S(t)x + \int_0^t S(t-s)BFx(s)\,ds \end{aligned}$$

for $t \geqq 0$, and hence $x(t) = S_F(t)x$, by the definition of $S_F(t)$. This proves statement (v).

Statement (vi) can be established straightforwardly by inserting (2.3) into (2.7) and interchanging integrals. □

The aim of this section is to give sufficient conditions under which system (2.1) can be stabilized by a finite-dimensional compensator of the form

$$\dot{w}(t) = Mw(t) - Hy(t), \qquad w(0) = w_0, \tag{2.9.1}$$

$$u(t) = Kw(t) + v(t), \tag{2.9.2}$$

where $M \in \mathbb{R}^{N\times N}$, $H \in \mathbb{R}^{N\times m}$, $K \in \mathbb{R}^{l\times N}$ are suitably chosen matrices. To this end we need the following well-posedness result for the connected system (2.1), (2.9).

PROPOSITION 2.4. *Let* (H1) *be satisfied. Then for all* $x_0 \in X$, $w_0 \in \mathbb{R}^N$, $v(\cdot) \in L^p_{\mathrm{loc}}[0, \infty; \mathbb{R}^l]$ *there exists a unique solution pair* $x(t)$, $w(t)$ *of* (2.1) *and* (2.9). *This means that* $x(t)$ *is continuous in* X *and absolutely continuous in* Z, *that* (2.1.1) *is satisfied for almost every* $t \geqq 0$ *where* $u(t)$ *is given by* (2.9.2) *and that* $w(t) \in \mathbb{R}^N$ *is continuously differentiable and satisfies* (2.9.1) *where* $y(t)$ *is given by* (2.1.2).

Proof. Let us introduce the spaces $X_e = X \times \mathbb{R}^N$, $Z_e = Z \times \mathbb{R}^N$, $U_e = \mathbb{R}^l \times \mathbb{R}^m$ and the operators $S_e(t) \in \mathscr{L}(X_e)$, $B_e \in \mathscr{L}(U_e, Z_e)$, $F_e \in \mathscr{L}(X_e, U_e)$ by

$$S_e(t) = \begin{bmatrix} S(t) & 0 \\ 0 & e^{Mt} \end{bmatrix}, \quad B_e = \begin{bmatrix} B & 0 \\ 0 & -H \end{bmatrix}, \quad F_e = \begin{bmatrix} 0 & K \\ C & 0 \end{bmatrix}.$$

Then hypothesis (H1) is satisfied with X, Z, $S(t)$, B replaced by X_e, Z_e, $S_e(t)$, B_e, respectively. Moreover $x(t) \in X$ and $w(t) \in \mathbb{R}^N$ satisfy (2.1) and (2.9) in the above sense if and only if the following equation holds for every $t \geqq 0$

$$\begin{pmatrix} x(t) \\ w(t) \end{pmatrix} = S_e(t)\begin{pmatrix} x_0 \\ w_0 \end{pmatrix} + \int_0^t S_e(t-s)B_e\left[F_e\begin{pmatrix} x(s) \\ w(s) \end{pmatrix} + \begin{pmatrix} v(s) \\ 0 \end{pmatrix}\right] ds.$$

This proves the statement of the proposition. □

The following hypothesis together with (H1) will turn out to be sufficient for the existence of a stabilizing, finite dimensional compensator for system (2.1). It generalizes the approach of Schumacher [15], [16], [17] to systems with unbounded input operators.

(H2) Suppose that there exist operators $F \in \mathscr{L}(X, \mathbb{R}^l)$, $G \in \mathscr{L}(\mathbb{R}^m, X)$ and a finite dimensional subspace $W \subset X$ such that the following conditions are satisfied.

1. The feedback semigroup $S_F(t) \in \mathscr{L}(X)$, defined by (2.3), is exponentially stable.
2. The observer semigroup $S^G(t) \in \mathscr{L}(X)$, generated by $A+GC$ is exponentially stable.
3. $S_F(t)W \subset W$ for all $t \geqq 0$.
4. Range $G \subset W$.

If (H2) is satisfied and $N = \dim W$, then there exist linear maps $\iota: \mathbb{R}^N \to X$, $\pi: X \to \mathbb{R}^N$ satisfying

$$\pi\iota = \mathrm{id}, \quad \iota\pi x = x, \quad x \in W. \tag{2.10}$$

Moreover, $W \subset \mathscr{D}(A_F)$ and hence $\pi A_F \iota$ is a well defined linear map on $\mathbb{R}^N$. We will show that the system

$$\begin{aligned} \dot{w}(t) &= \pi(A_F + GC)\iota w(t) - \pi G y(t), \quad w(0) = w_0, \\ u(t) &= F\iota w(t), \end{aligned} \tag{2.11}$$

defines a stabilizing compensator for the Cauchy problem (2.1).

THEOREM 2.5. *If* (H1), (H2) *and* (2.10) *are satisfied, then the closed loop system* (2.1), (2.11) *is exponentially stable.*

Proof. By Proposition 2.4, the system (2.1), (2.11) is a well-posed Cauchy problem. Now let $x(t) \in X$, $w(t) \in \mathbb{R}^N$ be any solution pair of (2.1), (2.11) and define

$$z(t) = \iota w(t) - x(t) \in X, \qquad t \geqq 0. \tag{2.12}$$

Then

$$\dot{w}(t) = \pi A_F \iota w(t) + \pi G C z(t), \tag{2.13}$$

and hence, using $\pi S_F(t)\iota = e^{\pi A_F \iota t}$ and Theorem 2.3(vi) with $f(t) = GCz(t)$, we get

$$\begin{aligned} z(t) &= \iota\pi S_F(t)\iota w_0 + \int_0^t \iota\pi S_F(t-s)\iota\pi GCz(s)\, ds - x(t) \\ &= S_F(t)\iota w_0 + \int_0^t S_F(t-s)GCz(s)\, ds - x(t) \\ &= S(t)\iota w_0 + \int_0^t S(t-s)[BF\iota w(s) + GCz(s)]\, ds \\ &\quad - S(t)x_0 - \int_0^t S(t-s)Bu(s)\, ds \\ &= S(t)z(0) + \int_0^t S(t-s)GCz(s)\, ds, \qquad t \geqq 0. \end{aligned}$$

This implies $z(t) = S^G(t)z(0)$ and hence, by (2.13), stability of the pair $z(t)$, $w(t)$. Now the stability of the pair $x(t)$, $w(t)$ follows from (2.12). □

Clearly, the hypothesis (H2) is not very useful in the present form since it is rather difficult to check in concrete examples. Following the ideas of Schumacher [16], we transform (H2) into an easily verifiable criterion. The basic idea is to approximate G by generalized eigenvectors of A_F and to show that, if A has a complete set of

generalized eigenvectors and is stabilizable through B, then there exists a stabilizing feedback operator F which does not destroy the completeness property of A.

More precisely, we need the following assumptions on A.

(H3) The resolvent operator of A is compact and the set $\Lambda = \{\lambda \in P\sigma(A) | \operatorname{Re} \lambda \geqq -\omega\}$ is finite for some $\omega > 0$.

If (H3) is satisfied, then we may introduce the projection operator

$$P_\Lambda = \frac{1}{2\pi i} \int_\Gamma (\mu I - A)^{-1} \, d\mu$$

where Γ is a simple rectifiable curve surrounding Λ but no other eigenvalue of A. Clearly, P_Λ is a projection operator on both X and Z. Correspondingly we obtain the decomposition

$$X = X_\Lambda \oplus X^\Lambda, \qquad Z = X_\Lambda \oplus Z^\Lambda,$$

where $X_\Lambda = \text{range } P_\Lambda$, $Z^\Lambda = \ker P_\Lambda$, $X^\Lambda = Z^\Lambda \cap X$ are invariant subsapces under $S(t)$. If $N_\Lambda = \dim X_\Lambda$, we may identify X_Λ with $\mathbb{R}^{N_\Lambda}$ and obtain two maps

$$\iota_\Lambda : \mathbb{R}^{N_\Lambda} \to X_\Lambda, \qquad \pi_\Lambda : Z \to \mathbb{R}^{N_\Lambda}$$

with the properties

$$\pi_\Lambda \iota_\Lambda = \text{id}, \qquad \iota_\Lambda \pi_\Lambda = P_\Lambda. \tag{2.14}$$

Then the projection $x_\Lambda(t) = \pi_\Lambda x(t)$ of a solution to (2.1) satisfies the finite dimensional ODE

$$\begin{aligned} \dot{x}_\Lambda(t) &= A_\Lambda x_\Lambda(t) + B_\Lambda u(t), \qquad x_\Lambda(0) = \pi_\Lambda x_0, \\ y_\Lambda(t) &= C_\Lambda x_\Lambda(t) \end{aligned} \tag{2.15}$$

where

$$A_\Lambda = \pi_\Lambda A \iota_\Lambda, \quad B_\Lambda = \pi_\Lambda B, \quad C_\Lambda = C\iota_\Lambda. \tag{2.16}$$

Now we can replace (H2) by the following stronger conditions which can in many cases be easily verified. The result has been proved by Schumacher [16] for the case that range $B \subset X$ (bounded input operator).

PROPOSITION 2.6. *Let the operator A satisfy* (H3), *assume that the exponential estimate*

$$\| S(t)|_{X^\Lambda} \|_{\mathcal{L}(X^\Lambda)} \leqq M e^{-\omega t}, \qquad t \geqq 0, \tag{2.17}$$

holds for some $M \geqq 1$ and that the reduced finite dimensional system (2.15) *is controllable and observable. Furthermore, assume that the generalized eigenvectors of A are complete in X. Then* (H2) *is satisfied.*

Proof. Since (2.15) is controllable, there exists a matrix $F_\Lambda \in \mathbb{R}^{l \times N_\Lambda}$ such that the matrix $A_\Lambda + B_\Lambda F_\Lambda$ is stable. Furthermore, the estimate (2.17) implies that

$$\| S(t)|_{Z^\Lambda} \|_{\mathcal{L}(Z^\Lambda)} \leqq M e^{-\omega t}, \qquad t \geqq 0,$$

(Remark 2.1(iii)). It is a well-known result in infinite dimensional systems theory (see e.g. [5] or [16]) that under these assumptions the closed loop semigroup $S_F(t) \in \mathcal{L}(Z)$, generated by $A + BF : X \to Z$ with $F = F_\Lambda \pi_\Lambda : Z \to \mathbb{R}^l$ is exponentially stable. By Theorem 2.3, $S_F(t)$ restricts to a strongly continuous semigroup on X and the operator $\mu I - A - BF : X \to Z$ provides a similarity action between both semigroups (Remark 2.1(ii)). Hence the restricted semigroup $S_F(t) \in \mathcal{L}(X)$ is still exponentially stable (Remark 2.1(iii)).

By assumption, the generalized eigenvectors of A are complete in X and hence they are complete in Z (Remark 2.1(iv)). Therefore it is possible to choose the feedback matrix F_Λ such that $S_F(t)$ is exponentially stable and the generalized eigenvectors of $A+BF: X \to Z$ are complete in Z (Schumacher [16]). It follows again from the above similarity argument, that this completeness property carries over to the restricted operator $A_F: \mathcal{D}(A_F) \to X$ introduced in Theorem 2.3(i).

Now choose $G_\Lambda \in \mathbb{R}^{N_\Lambda \times m}$ such that $A_\Lambda + G_\Lambda C_\Lambda$ is stable and define $G = \iota_\Lambda G_\Lambda: \mathbb{R}^m \to X$. Then it is again a well-known fact from infinite-dimensional linear systems theory that $A+GC: \mathcal{D}(A) \to X$ generates an exponentially stable semigroup on X (see [5] or [16]). It is also well known that $A+\hat{G}C$ still generates an exponentially stable semigroup on X whenever $\|\hat{G}-G\|_{\mathcal{L}(\mathbb{R}^m,X)}$ is sufficiently small. Now we make use of the fact that the generalized eigenvectors of A_F are complete in X. This implies that $G: R^m \to X$ can be approximated arbitrarily close by an operator $\hat{G}: \mathbb{R}^m \to X$ whose range is spanned by finitely many generalized eigenvectors of A_F. We choose $\hat{G}$ in such a way that $A+\hat{G}C$ generates a stable semigroup and denote by W the finite dimensional subspace of X which is invariant under A_F and generated by those generalized eigenvectors which span the range of $\hat{G}$. Since W is a finite dimensional subspace contained in $\mathcal{D}(A_F)$ and invariant under A_F, the restriction of A_F to W is a bounded, linear operator generating a semigroup $S_W(t)$ on W. Since $d/dt\, S_W(t)x = A_F S_W(t)x$, the semigroup $S_W(t)$ coincides with $S_F(t)$ on W. Hence W is also invariant under the semigroup $S_F(t)$. We conclude that the operators $F: Z \to \mathbb{R}^l$ and $\hat{G}: \mathbb{R}^m \to X$ satisfy hypothesis (H2). □

Combining Proposition 2.6 with Theorem 2.5, we obtain a constructive procedure for designing a finite dimensional compensator for the Cauchy problem (2.1). The construction is based on the knowledge of the finite dimensional reduced system (2.15) and on the knowledge of sufficiently many eigenvalues and eigenvectors of the operator A_F. For the case of bounded input operators (range $B \subset X$) the procedure has been described in detail by Schumacher [16]. Precisely the same algorithm applies to the case where range $B \not\subset X$.

3. Retarded systems. In this section we apply the abstract result of the previous section to retarded functional differential equations (RFDE) with delays either in the input or in the output variable. If delays occur in the input and output variables at the same time, the RFDE can still be reformulated as an abstract Cauchy problem (see e.g. Pritchard-Salamon [12]) however, the completeness assumption will no longer be satisfied.

3.1. Retarded systems with output delays. We consider the linear RFDE

$$\begin{aligned} \dot{x}(t) &= Lx_t + B_0 u(t), \\ y(t) &= Cx_t, \end{aligned} \tag{3.1}$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^l$, $y(t) \in \mathbb{R}^m$ and x_t is defined by $x_t(\tau) = x(t+\tau)$ for $-h \leqq \tau \leqq 0$, $h > 0$. Correspondingly B_0 is a real $n \times l$-matrix and L and C are bounded linear functionals on $\mathcal{C} = \mathcal{C}[-h, 0; \mathbb{R}^n]$ with values in $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively. These can be written in the form

$$L\phi = \int_{-h}^{0} d\eta(\tau)\phi(\tau), \quad C\phi = \int_{-h}^{0} d\gamma(\tau)\phi(\tau), \quad \phi \in \mathcal{C},$$

where $\eta(\tau)$ and $\gamma(\tau)$ are normalized functions of bounded variation, i.e. they vanish for $\tau \geqq 0$, are constant for $\tau \leqq -h$ and left continuous for $-h < \tau < 0$.

It is well known that equation (3.1) admits a unique solution $x(\cdot) \in L^p_{\text{loc}}[-h, \infty; \mathbb{R}^n] \cap W^{1,p}_{\text{loc}}[0, \infty; \mathbb{R}^n]$ for every input $u(\cdot) \in L^p_{\text{loc}}[0, \infty; \mathbb{R}^l]$ and every initial condition of the form

$$x(0) = \phi^0, \quad x(\tau) = \phi^1(\tau), \quad -h \leqq \tau \leqq 0, \tag{3.2}$$

where $\phi = (\phi^0, \phi^1) \in \mathbb{R}^n \times L^p[-h, 0; \mathbb{R}^n] = M^p$. Moreover, in these spaces the solution $x(\cdot)$ of (3.1) and (3.2) depends continuously on ϕ and $u(\cdot)$. This has motivated the definition of the state of system (3.1) at time $t \geqq 0$ to be the pair

$$\hat{x}(t) = (x(t), x_t) \in M^p. \tag{3.3}$$

The evolution of $\hat{x}(t)$ can be described by the variation-of-constants formula

$$\hat{x}(t) = S(t)\phi + \int_0^t S(t-s)Bu(s)\, ds, \qquad t \geqq 0, \tag{3.4}$$

where $B \in \mathcal{L}(\mathbb{R}^l, M^p)$ maps $u \in \mathbb{R}^l$ into the pair $Bu = (B_0 u, 0)$ and $S(t) \in \mathcal{L}(M^p)$ is the strongly continuous semigroup generated by

$$\mathcal{D}(A) = \{\phi \in M^p \mid \phi^1 \in W^{1,p},\ \phi^1(0) = \phi^0\},$$
$$A\phi = (L\phi^1, \dot{\phi}^1).$$

Here $W^{1,p}$ denotes the Sobolev space $W^{1,p}[-h, 0, \mathbb{R}^n]$.

We will consider the evolution of the state (3.3) of system (3.1) in the dense subspace $\{(\phi(0), \phi) \mid \phi \in W^{1,p}\} \subset M^p$ which we shall identify with $W^{1,p}$. Then B becomes an "unbounded" operator ranging in the larger space M^p. However, it follows from the existence, uniqueness and continuous dependence result for the solutions of (3.1) and (3.2) that the state $\hat{x}(t)$ of (3.1), (3.2) defines a continuous function in $W^{1,p}$ provided that $\phi \in W^{1,p}$ and $u(\cdot) \in L^p_{\text{loc}}[0, \infty; \mathbb{R}^l]$. Hence, the operators A and B satisfy hypothesis (H1) with $Z = M^p$ and $X = W^{1,p}$. This implies that the state $\hat{x}(t) \in W^{1,p}$ of (3.1), (3.2) with $\phi \in W^{1,p}$ satisfies the Cauchy problem

$$\begin{aligned} &\frac{d}{dt}\hat{x}(t) = A\hat{x}(t) + Bu(t), \qquad \hat{x}(0) = \phi \in W^{1,p}, \\ &v(t) = C\hat{x}(t), \end{aligned} \tag{3.5}$$

in the sense of Remark 2.2(ii). Of course, the output operator $C: W^{1,p} \to \mathbb{R}^m$ is given by

$$C\phi = \int_{-h}^0 d\gamma(\tau)\phi^1(\tau), \qquad \phi \in W^{1,p}.$$

On the state space $W^{1,p}$ this operator is bounded.

Remarks 3.1. (i) If the equation

$$\eta(\tau) = \eta(-h) + A_1, \qquad -h < \tau \leqq \varepsilon - h, \tag{3.6}$$

holds for some $\varepsilon > 0$, then the generalized eigenfunctions of A are complete in M^p and in $W^{1,p}$ if and only if

$$\det A_1 \neq 0 \tag{3.7}$$

(see Manitius [9], Salamon [14, Chap. 3]).

(ii) It is well known that the operator A satisfies (H3).

(iii) The exponential growth of the semigroup $S(t)$ on the complementary subspace X^Λ corresponding to $\Lambda = \{\lambda \in \sigma(A) \mid \operatorname{Re} \lambda \geqq 0\}$ is determined by $\sup\{\operatorname{Re} \lambda \mid \lambda \in \sigma(A), \operatorname{Re} \lambda < 0\} < 0$.

(iv) Let (2.15) denote the reduced finite-dimensional system obtained by spectral projection of the solutions of (3.5) on the generalized eigenspace X_Λ. Then (2.15) is controllable iff

$$\operatorname{rank}[\lambda I - L(e^{\lambda \cdot}), B_0] = n \quad \forall \lambda \in \Lambda \tag{3.8}$$

(Pandolfi [10]) and observable iff

$$\operatorname{rank}\begin{bmatrix} \lambda I - L(e^{\lambda \cdot}) \\ C(e^{\lambda \cdot}) \end{bmatrix} = n \quad \forall \lambda \in \Lambda \tag{3.9}$$

(Bhat-Koivo [1], Salamon [13], [14]).

Combining these facts with Proposition 2.6 and Theorem 2.5, we obtain the following existence result for a finite dimensional compensator for system (3.1).

THEOREM 3.2. *If* (3.6)-(3.9) *are satisfied, then there exists a finite dimensional compensator of the form* (2.9) *such that the closed loop system* (3.1), (2.9) *is exponentially stable.*

3.2. Retarded systems with input delays. In this section we consider the RFDE

$$\begin{aligned} \dot{x}(t) &= Lx_t + Bu_t, \\ y(t) &= C_0 x(t), \end{aligned} \tag{3.10}$$

with general delays in the state and input and no delays in the output variable. This time C_0 is a real $m \times n$-matrix and B a bounded linear functional on $\mathscr{C}[-h, 0, \mathbb{R}^l]$ with values in $\mathbb{R}^n$ given by

$$B\xi = \int_{-h}^{0} d\beta(\tau)\xi(\tau), \qquad \xi \in \mathscr{C}[-h, 0, \mathbb{R}^l],$$

where $\beta(\tau)$ is an $n \times l$-matrix valued, normalized function of bounded variation. Of course, we can immediately get an existence result for a finite dimensional compensator for system (3.10) by dualizing Theorem 3.2. However, for reasons to become clear later, we make use of a direct approach for system (3.10), following the ideas of Vinter and Kwong [18] (see also Delfour [6], Salamon [14]).

First note that (3.10) admits a unique solution $x(\cdot) \in L^p_{\mathrm{loc}}[-h, \infty, \mathbb{R}^n] \cap W^{1,p}_{\mathrm{loc}}[0, \infty, \mathbb{R}^n]$ for every input $u(\cdot) \in L^p_{\mathrm{loc}}[0, \infty; \mathbb{R}^l]$ and every initial condition of the form

$$\begin{aligned} x(0) &= \phi^0, \qquad x(\tau) = \phi^1(\tau), \\ u(\tau) &= \xi(\tau), \qquad -h \leqq \tau < 0, \end{aligned} \tag{3.11}$$

where $\phi \in M^p$ and $\xi \in L^p[-h, 0; \mathbb{R}^l]$. In order to reformulate system (3.10) as an evolution equation in a product space, we rewrite (3.10)-(3.11) as

$$\begin{aligned} \dot{x}(t) &= \int_{-t}^{0} d\eta(\tau)x(t+\tau) + \int_{-t}^{0} d\beta(\tau)u(t+\tau) + f^1(-t), \\ y(t) &= C_0 x(t), \qquad x(0) = f^0, \end{aligned} \tag{3.12}$$

where the pair $f = (f^0, f^1) \in M^p$, given by

$$\begin{aligned} f^0 &= \phi^0, \\ f^1(\sigma) &= \int_{-h}^{\sigma} d\eta(\tau)\phi^1(\tau - \sigma) + \int_{-h}^{\sigma} d\beta(\tau)\xi(\tau - \sigma), \qquad -h \leqq \sigma \leqq 0, \end{aligned} \tag{3.13}$$

is regarded as the initial state of system (3.12). The corresponding state at time $t \geqq 0$ is given by

$$\begin{aligned} &\hat{x}(t) = (x(t), x^t) \in M^p, \\ &x^t(\sigma) = \int_{\sigma-t}^{\sigma} d\eta(\tau) x(t+\tau-\sigma) + \int_{\sigma-t}^{\sigma} d\beta(\tau) u(t+\tau-\sigma) + f^1(\sigma-t). \end{aligned} \tag{3.14}$$

It has been shown in [6], [14], [18] that the evolution of this state can be described by the variation-of-constants formula

$$\hat{x}(t) = S^{T^*}(t) f + \int_0^t S^{T^*}(t-s) B^{T^*} u(s)\, ds, \qquad t \geqq 0. \tag{3.15}$$

Here $S^{T^*}(t) \in \mathscr{L}(M^p)$ is the adjoint semigroup of $S^T(t) \in \mathscr{L}(M^q)$, $1/p + 1/q = 1$, which corresponds to the transposed equation $\dot{x}(t) = L^T x_t$ in the sense of § 3.1. Since $S^T(t)$ restricts to a semigroup on the dense subspace $W^{1,q} \subset M^q$, the adjoint semigroup $S^{T^*}(t)$ extends to the dual space $W^{-1,p} = (W^{1,q})^*$ which contains M^p as a dense subspace in a natural way. The input operator $B^{T^*} \in \mathscr{L}(\mathbb{R}^l, W^{-1,p})$ is the adjoint operator of $B^T \in \mathscr{L}(W^{1,q}, \mathbb{R}^l)$ given by

$$B^T \psi = \int_{-h}^{0} d\beta(\tau) \psi^1(\tau) \in \mathbb{R}^l, \qquad \psi \in W^{1,q} \subset M^q.$$

Since the infinitesimal generator A^{T^*} of $S^{T^*}(t)$ and the input operator B^{T^*} satisfy the hypothesis (H1) of § 2 with $X = M^p$ and $Z = W^{-1,p}$ (see Salamon [14]), the state $\hat{x}(t) \in M^p$ of system (3.12), given by (3.14), defines the unique solution of the abstract Cauchy problem

$$\begin{aligned} &\frac{d}{dt}\hat{x}(t) = A^{T^*}\hat{x}(t) + B^{T^*}u(t), \qquad \hat{x}(0) = f \in M^p, \\ &y(t) = C\hat{x}(t), \end{aligned} \tag{3.16}$$

in the sense of Remark 2.2(ii). Of course, the output operator $C: M^p \to \mathbb{R}^m$ is now given by

$$Cf = C_0 f^0 \in \mathbb{R}^m, \qquad f \in M^p.$$

In order to make the results of this section more precise, we briefly outline the construction of the reduced system (2.15). For this purpose let $X_\Lambda \subset W^{1,p}$ and $X_\Lambda^T \subset W^{1,q}$ denote the generalized eigenspaces of A and A^T, respectively, correspondig to $\Lambda = \{\lambda \in \sigma(A) | \operatorname{Re} \lambda \geqq 0\}$. Since Λ is a symmetric set, we can choose real bases $\{\phi_1, \cdots, \phi_{N_\Lambda}\}$ or X_Λ and $\{\psi_1, \cdots, \psi_{N_\Lambda}\}$ of X_Λ^T such that the matrices

$$\begin{aligned} \Phi &= [\phi_1 \cdots \phi_{N_\Lambda}] \in W^{1,p}[-h, 0; \mathbb{R}^{n \times N_\Lambda}], \\ \Psi &= [\psi_1 \cdots \psi_{N_\Lambda}] \in W^{1,q}[-h, 0; \mathbb{R}^{n \times N_\Lambda}], \end{aligned}$$

satisfy

$$\Psi^T(0)\Phi(0) + \int_{-h}^{0} \int_{\tau}^{0} \Psi^T(\sigma)\, d\eta(\tau) \Phi(\tau-\sigma)\, d\sigma = I \in \mathbb{R}^{N_\Lambda \times N_\Lambda}.$$

Then $\iota_\Lambda: \mathbb{R}^{N_\Lambda} \to M^p$ and $\pi_\Lambda: M^p \to \mathbb{R}^{N_\Lambda}$ may be defined by

$$[\iota_\Lambda x_\Lambda]^0 = \Phi(0) x_\Lambda, \quad [\iota_\Lambda x_\Lambda]^1(\sigma) = \int_{-h}^{\sigma} d\eta(\tau) \Phi(\tau-\sigma) x_\Lambda, \quad -h \leqq \sigma \leqq 0,$$

$$\pi_\Lambda f = \Psi^T(0) f^0 + \int_{-h}^{0} \Psi^T(\sigma) f^1(\sigma)\, d\sigma$$

for $x_\Lambda \in \mathbb{R}^{N_\Lambda}$ and $f \in M^p$, and the matrices $A_\Lambda \in \mathbb{R}^{N_\Lambda \times N_\Lambda}$, $B_\Lambda \in \mathbb{R}^{N_\Lambda \times l}$, $C_\Lambda \in \mathbb{R}^{m \times N_\Lambda}$ are given by

$$A(\Phi(0),\Phi) = (\Phi(0), \Phi)A_\Lambda, \quad B_\Lambda = \int_{-h}^{0} \Psi^T(\tau)\, d\beta(\tau), \quad C_\Lambda = C_0\Phi(0)$$

(see Salamon [14, § 2.4]).

Remarks 3.3. (i) If (3.6) is satisfied for some $\varepsilon > 0$, then the eigenfunctions of A^{T^*} are complete in M^P and in $W^{-1,p}$ if and only if (3.7) holds (see Manitius [9], Salamon [14, Chapter 3]).

(ii) If A_Λ, B_Λ, C_Λ are defined as above, then system (2.15) is controllable iff

$$\operatorname{rank}[\lambda I - L(e^{\lambda \cdot}), B(e^{\lambda \cdot})] = n \quad \forall \lambda \in \Lambda \tag{3.17}$$

and observable iff

$$\operatorname{rank}\begin{bmatrix} \lambda I - L(e^{\lambda \cdot}) \\ C_0 \end{bmatrix} = n \quad \forall \lambda \in \Lambda \tag{3.18}$$

(see Salamon [14]).

THEOREM 3.4. *If* (3.6)-(3.7) *and* (3.17)-(3.18) *are satisfied, then there exists a finite-dimensional compensator of the form* (2.9), *such that the closed loop system* (3.10), (2.9) *is exponentially stable.*

Remark 3.1(i) and Remark 3.3(i) show that the completeness property of A and A^{T^*} can be destroyed by arbitrarily small perturbations in the delays (compare Manitius [9]). However such perturbations would not affect the stability of the closed loop system (3.1), (2.9) respectively (3.10), (2.9). This indicates that the completeness assumption is somewhat artifical for the purpose of stabilization by a finite-dimensional compensator. This assumption can be weakened slightly in the special case of the RFDE

$$\begin{aligned} \dot{x}(t) &= A_0x(t) + A_1x(t-h) + B_0u(t), \\ y(t) &= C_0x(t), \end{aligned} \tag{3.19}$$

with a single point delay in the state variable if the state space is chosen to be

$$X = (f \in M^p \mid f^1(\tau) \in \text{range } A_1, -h \leqq \tau \leqq 0\}.$$

It has been shown by Manitius [9] that the completeness property for the operator A^{T^*} in this space is equivalent to the rank condition

$$\operatorname{rank}\begin{bmatrix} A_0 - \lambda I & A_1 \\ A_1 & 0 \end{bmatrix} = n + \operatorname{rank} A_1 \tag{3.20}$$

for some $\lambda \in \mathbb{C}$. Therefore we have the following result.

COROLLARY 3.5. *If* (3.8), (3.18) *and* (3.20) *are satisfied then there exists a finite dimensional compensator of the form* (2.9) *such that the closed loop system* (3.19), (2.9) *is exponentially stable.*

Remark 3.6. This result suggests that it should be possible to weaken the completeness assumption for the general RFDE which would be an important improvement. Another extension would be an existence result for RFDEs with delays in simultaneously the control and the observation. However, it is not obvious how this can be achieved with the present approach, the main difficulty being the completeness property.

Remark 3.7. Although the main results of this section, Theorems 3.2 and 3.4 are stated as existence results, we emphasize that the stabilizing compensator can in fact be constructed using exactly the same procedure as it is explained in detail in [16] for

RFDEs without delays in the external variables. The construction, as outlined in the proof of Proposition 2.6, involves calculating finitely many eigenvalues and eigenvectors of A and hence the projected system A_Λ, B_Λ, C_Λ as it is described in § 3.2. Then the matrices F_Λ and G_Λ can be calculated by standard finite dimensional procedures. The most difficult part of the design lies in finding eigenvectors of $A+BF$ to generate the subspace W. The approximation of $G=\iota_\Lambda G_\Lambda$ by an operator $\hat{G}$ with range in W then reduces to a finite-dimensional linear optimization procedure. This procedure has to be repeated—while increasing W—until $\hat{G}$ is close enough to G. The numerical example for a retarded system examined in [16] gives insight into the details of the design procedure.

4. Boundary control systems. The purpose of this section is to show how abstract boundary control systems in Hilbert spaces fit into the framework of § 2. When these results are applied to obtain finite-dimensional compensators for particular classes of partial differential equations (PDE), there is a considerable overlap with results of Curtain in [2], [3], [4]. The relation between both approaches will be discussed in detail at the end of this section.

Let W, X, U, Y be Hilbert spaces and suppose that

$$W \subset X$$

with a continuous, dense injection. Furthermore, let $\Delta \in \mathscr{L}(W, X)$, $\Gamma \in \mathscr{L}(W, U)$, $C \in \mathscr{L}(X, Y)$ be given. Then we consider the boundary control system

$$\begin{aligned} &\frac{d}{dt}x(t)=\Delta x(t), \qquad x(0)=x_0 \in W, \\ &\Gamma x(t)=u(t), \qquad t \geqq 0, \end{aligned} \tag{4.1}$$

with the output

$$y(t)=Cx(t), \qquad t \geqq 0. \tag{4.2}$$

DEFINITION 4.1 (*strong solution, well-posedness*).

(i) Let $u(\cdot) \in \mathscr{C}[0, T; U]$ and $x_0 \in W$ satisfy $\Gamma x_0 = u(0)$. Then a function $x(\cdot) \in \mathscr{C}[0, T; W]$ is said to be a (strong) solution of (4.1) if $x(\cdot) \in \mathscr{C}^1[0, T; X]$ and if (4.1) is satisfied for every $t \in [0, T]$.

(ii) The boundary control system (4.1) is said to be well-posed if the subspace $\{x \in W | \Gamma x = 0\}$ is dense in X, if the restriction of Λ to this subspace is a closed operator on X, and if for all $x_0 \in W$ and $u(\cdot) \in W^{1,2}[0, T; U]$ with $\Gamma x_0 = u(0)$ there exists a unique solution $x(\cdot) \in \mathscr{C}[0, t; W] \cap \mathscr{C}^1[0, T; X]$ of (4.1) depending continuously on x_0 and $u(\cdot)$. This means that there exists a constant $K > 0$ such that the inequality

$$\sup_{0 \leqq t \leqq T} \|x(t)\|_W + \sup_{0 \leqq t \leqq T} \|\dot{x}(t)\|_X \leqq K \left\{ \|x_0\|_W + \left[\int_0^T \|\dot{u}(t)\|_U^2 dt \right]^{1/2} \right\}$$

holds for every solution $x(t)$ of (4.1).

Remarks 4.2. Let system (4.1) be well posed.

(i) Taking $u(t) \equiv 0$, it follows from a classical result in semigroup theory (Phillips [11]) that the operator

$$Ax = \Delta x, \qquad \mathscr{D}(A) = \{x \in W | \Gamma x = 0\} \tag{4.3}$$

is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on X and that, for every $x_0 \in \mathscr{D}(A)$, the function $x(t) = S(t)x_0$ is the solution of (4.1) with $u(t) \equiv 0$.

(ii) As in § 2 we introduce the dense subspace $Z^* = \mathcal{D}_{X^*}(A^*) \subset X^*$. Then

$$X \subset Z$$

with a continuous, dense injection, A extends to a bounded operator from X to Z and $S(t)$ to a strongly continuous semigroup on Z.

(iii) It follows from [14, Lemma 1.3.2(i)] that

$$\{x \in W | \Gamma x = 0\} = \mathcal{D}_X(A) = \{x \in X = \mathcal{D}_Z(A) | Ax \in X\}$$

or in other words, if $x \in X$ and $Ax \in X$, then $x \in W$ and $\Gamma x = 0$. Furthermore, the W-norm on $\mathcal{D}_X(A)$ is equivalent to the graph norm of A [14, Remark 1.3.1(iii)]. This means that there exists a constant $K_1 > 0$ such that the inequality

$$\|x\|_W \leqq K_1[\|x\|_X + \|Ax\|_X]$$

holds for all $x \in W$ with $\Gamma x = 0$.

(iv) Γ is onto. Hence there exists a constant $K_0 > 0$ such that for every $u \in U$ there exists a $w \in W$ such that

$$\Gamma w = u, \qquad \|w\|_W \leqq K_0 \|u\|_U. \tag{4.4}$$

Let us now construct the input operator $B \in \mathcal{L}(U, Z)$.

1. Given $u \in U$ we may choose $w \in W$ such that $\Gamma w = u$ since Γ is onto (Remark 4.2(iv)). For this $w \in W$ we define $Bu := \Delta w - Aw \in Z$. This expression is well defined since $\Gamma w = 0$ if and only if $Aw = \Delta w$ (Remark 4.2(iii)). Hence the map $B: U \to Z$ satisfies, by definition, the equation

$$B\Gamma x = \Delta x - Ax, \qquad x \in W. \tag{4.5}$$

2. It is easy to see that B is a linear map.

3. Let $u \in U$ be given and choose $w \in W$ such that (4.4) holds. Then

$$\|Bu\|_Z \leqq \|\Delta - A\|_{\mathcal{L}(W,Z)} \|w\|_W \leqq K_0 \|\Delta - A\|_{\mathcal{L}(W,Z)} \|u\|_U$$

and therefore $B: U \to Z$ is bounded.

LEMMA 4.3. *Let the operators A and B be defined by* (4.3) *and* (4.5), *respectively. Furthermore, let $x \in X$ and $u \in U$ satisfy $Ax + Bu \in X$. Then*

$$x \in W, \quad \Gamma x = u, \quad \Delta x = Ax + Bu.$$

Furthermore there exists a constant $K > 0$ such that

$$\|x\|_W \leqq K[\|x\|_X + \|u\|_U + \|Ax + Bu\|_X]$$

for all $x \in X$, $u \in U$ with $Ax + Bu \in X$.

Proof. Let $x \in X$ and $u \in U$ satisfy $Ax + Bu \in X$ and choose $w \in W$ such that (4.4) holds. Then

$$A(x - w) = Ax + Bu - (A + B\Gamma)w = Ax + Bu - \Delta w \in X.$$

By Remark 4.2(iii), this implies that $x \in W$ and

$$\begin{aligned}
\|x\|_W &\leqq \|w\|_W + \|x - w\|_W \\
&\leqq \|w\|_W + K_1[\|x - w\|_X + \|A(x - w)\|_X] \\
&\leqq [1 + K_1\|\mathrm{id}\|_{\mathcal{L}(W,X)} + K_1\|\Delta\|_{\mathcal{L}(W,X)}]\|w\|_W \\
&\quad + K_1\|x\|_X + K_1\|Ax + Bu\|_X \\
&\leqq K[\|u\|_U + \|x\|_X + \|Ax + Bu\|_X].
\end{aligned}$$

Finally, we obtain again from Remark 4.2(iii) that $\Gamma x = \Gamma w = u$ and from (4.5) that $\Delta x = Ax + B\Gamma x = Ax + Bu$. □

The above operators A and B allow us to reformulate the boundary control system (4.1) as a Cauchy problem of the type (3.1). More precisely, we introduce the following concept of a weak solution for (4.1).

DEFINITION 4.4 (*weak solution*). Let the operators $A \in \mathscr{L}(X, Z)$ and $B \in \mathscr{L}(U, Z)$ be defined as above. Moreover, let $x_0 \in X$ and $u(\cdot) \in L^2[0, T, U]$ be given. Then $x(\cdot) \in \mathscr{C}[0, T; X] \cap W^{1,2}[0, T; Z]$ is said to be a weak solution of (4.1) if

$$\begin{aligned} &\frac{d}{dt} x(t) = Ax(t) + Bu(t), \qquad 0 \leqq t \leqq T, \\ &x(0) = x_0 \end{aligned} \tag{4.6}$$

is satisfied in Z (almost everywhere).

It follows from the definition of the operator B (Remark 4.2(iv)) that every strong solution $x(\cdot) \in \mathscr{C}[0, T; W] \cap \mathscr{C}^1[0, T; X]$ of (4.1) is a weak solution in the sense of Definition 4.4. Moreover we have the following result.

PROPOSITION 4.5. *Suppose that the operator A defined by* (4.3) *is the infinitesimal generator of a strongly continuous semigroup $S(t)$ on X and that $\Gamma \in \mathscr{L}(W, U)$ is onto. Furthermore let $B \in \mathscr{L}(U, Z)$ be defined by* (4.5). *Then the following statements are equivalent.*

(i) *System* (4.1) *is well posed.*

(ii) *The operators A and B satisfy hypothesis* (H1) *of* § 2 *with $p = 2$.*

(iii) *For every $x_0 \in X$ and every $u(\cdot) \in L^2[0, T; U]$ there exists a unique weak solution $x(\cdot) \in \mathscr{C}[0, T; X] \cap W^{1,2}[0, T; Z]$ of* (4.1) *depending continuously on x_0 and $u(\cdot)$. Moreover, the weak (and in particular the strong) solutions of* (4.1) *are given by*

$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\, ds \in X, \qquad 0 \leqq t \leqq T. \tag{4.7}$$

Proof. It is a well-known semigroup theoretic result that the solutions of (4.6), and therefore the weak solutions of (4.1), are given by (4.7). Furthermore, it follows from Remark 2.2(ii) that (ii) is equivalent to (iii).

In order to prove that (ii) implies (i), suppose that (H1) is satisfied and let $x(t)$ be given by (4.7) with $x_0 \in W$ and $u(\cdot) \in \mathscr{C}^1[0, T; U]$ satisfying $\Gamma x_0 = u(0)$. Then it is a well-known result from semigroup theory that $x(\cdot) \in \mathscr{C}[0, T; X] \cap \mathscr{C}^1[0, T; Z]$ satisfies

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) \\ &= S(t)[Ax_0 + Bu(0)] + \int_0^t S(t-s)B\dot{u}(s)\, ds \\ &= S(t)\Delta x_0 + \int_0^t S(t-s)B\dot{u}(s)\, ds, \qquad 0 \leqq t \leqq T. \end{aligned}$$

By (H1) and Remark 2.1(ii), this implies that $\dot{x}(\cdot) \in \mathscr{C}[0, T; X]$ and

$$\sup_{0 \leqq t \leqq T} \|\dot{x}(t)\|_X < \sup_{0 \leqq t \leqq T} \|S(t)\|_{\mathscr{L}(X)} \|\Delta\|_{\mathscr{L}(W,X)} \|x_0\|_W + b_T \|\dot{u}(\cdot)\|_{L^2[0,T;U]}.$$

Applying Lemma 4.3 to the term $Ax(t) + Bu(t) = \dot{x}(t) \in X$, we obtain that $x(\cdot) \in \mathscr{C}[0, T; W] \cap \mathscr{C}^1[0, T; X]$ satisfies (4.1). Since every strong solution of (4.1) is given

by (4.7), $x(t)$ is in fact the unique solution. Furthermore, we obtain from Lemma 4.3 that

$$\|x(t)\|_W \leqq K[\|x(t)\|_X + \|u(t)\|_U + \|\dot{x}(t)\|_X].$$

Since

$$\sup_{0\leqq t\leqq T} \|x(t)\|_X \leqq \sup_{0\leqq t\leqq T} \|S(t)\|_{\mathscr{L}(X)}\|\mathrm{id}\|_{\mathscr{L}(W,X)}\|x_0\|_W + b_T\|u(\cdot)\|_{L^2[0,T;U]}$$

and

$$\sup_{0\leqq t\leqq T} \|u(t)\|_U \leqq \|\Gamma\|_{\mathscr{L}(W,U)}\|x_0\|_W + \sqrt{T}\|\dot{u}(\cdot)\|_{\mathscr{L}^2[0,T;U]}$$

for $u(\cdot)\in \mathscr{C}^1[0, T; U]$ with $u(0)=\Gamma x_0$, this shows that system (4.1) is well posed.

Conversely, suppose that system (4.1) is well posed in the sense of Definition 4.1, let $v(\cdot)\in \mathscr{C}^1[0, T; U]$ and define

$$x(t)=\int_0^t S(t-s)B\int_0^s v(\tau)\,d\tau\,ds, \qquad u(t)=\int_0^t v(\tau)\,d\tau, \qquad 0\leqq t\leqq T.$$

Then $x(\cdot)\in C^1[0, T; Z]$ and

$$Ax(t)+Bu(t)=\dot{x}(t)=\int_0^t S(t-s)Bv(s)\,ds, \qquad 0\leqq t\leqq T.$$

Hence $x(\cdot)\in \mathscr{C}^1[0, T; X]$ and we obtain from Lemma 4.3 that $x(\cdot)\in \mathscr{C}[0, T; W]$, $\Gamma x(t)=u(t)$ and $\Delta x(t)=Ax(t)+Bu(t)$. Hence $x(t)$ is a strong solution of (4.1) in the sense of Definition 4.1(i) and satisfies the inequality

$$\left\|\int_0^T S(T-s)Bv(s)\,ds\right\|_X = \|\dot{x}(T)\|_X \leqq K\|v(\cdot)\|_{L^2[0,T;U]}.$$

This shows that the operators A and B satisfy the hypothesis (H1). □

Having established hypothesis (H1) we are now in a position to apply the perturbation result of § 2 (Theorem 2.2) to the boundary control system (4.1).

COROLLARY 4.6. *If system* (4.1) *is well posed, then the following statements hold.*

(i) *For every* $F\in \mathscr{L}(X, U)$ *the operator*

$$A_F x=\Delta x, \qquad \mathscr{D}(A_F)=\{x\in W \mid \Gamma x = Fx\} \tag{4.8}$$

is the infinitesimal generator of a strongly continuous semigroup $S_F(t)$ *on* X.

(ii) *For every* $x_0\in \mathscr{D}(A_F)$ *the function* $x(t)=S_F(t)x_0$, $t\geqq 0$, *is continuous in* W, *continuously differentiable in* X, *and satisfies the closed loop boundary control equations*

$$\begin{aligned} &\frac{d}{dt}x(t)=\Delta x(t), \qquad x(0)=x_0,\\ &\Gamma x(t)=Fx(t), \qquad t\geqq 0, \end{aligned} \tag{4.9}$$

where the derivative has to be understood in the space X.

(iii) *If* U *is finite dimensional, then* $S_F(t)$ *extends to a strongly continuous semigroup on* Z *whose infinitesimal generator is given by the extended operator* $A+BF: X\to Z$.

Proof. By Proposition 4.5, the operators A and B defined by (4.3) and (4.5), respectively, satisfy hypothesis (H1) of § 2. Hence it follows from Theorem 2.3(i) that the operator

$$A_F x=Ax+BFx, \qquad \mathscr{D}(A_F)=\{x\in X \mid Ax+BFx\in X\}$$

generates a strongly continuous semigroup of X (note that the proof of this result in

[14, Thm. 1.3.7] does not require U to be finite dimensional). Lemma 4.3 shows that this operator A_F coincides with the one defined by (4.8). This proves statement (i).

In order to prove statement (ii), let $x_0 \in \mathcal{D}(A_F)$ be given and define $u(t) = FS_F(t)x_0$, $t \geqq 0$. Then $u(t)$ is continuously differentiable for $t \geqq 0$ and satisfies $u(0) = Fx_0 = \Gamma x_0$. Hence (4.1) admits a unique strong solution $x(t)$, $t \geqq 0$, which by definition of the operators A and B also satisfies (4.6) and is therefore given by (4.7). This implies

$$x(t) = S(t)x_0 + \int_0^t S(t-s)BFS_F(s)x_0\, ds = S_F(t)x_0,$$

by definition of the semigroup $S_F(t)$.

Statement (iii) is an immediate consequence of Theorem 2.3(iii). □

So far we have shown that the general theory of § 2 also covers abstract boundary control systems. In particular, we have reformulated the boundary control system (4.1) in the semigroup theoretic framework with an unbounded input operator. A very similar approach has been developed by Ho and Russell in [8] under only slightly more restrictive assumptions. However, [8] does not contain any feedback results and also the above Proposition 4.5 seems to be new. Furthermore we point out that earlier results in this direction for various classes of partial differential equations can be found, e.g., in the classical work by Lions-Magenes [22], in the more recent papers by Washburn [19], Lasiecka-Triggiani [20], [21] and in the book by Curtain-Pritchard [5] (this list is by no means complete). Another general approach has been presented by Fattorini [7]. In [7] the input operator is bounded, however, there are derivatives in the input function which do not appear in our approach.

In [2] and [3] Curtain has used Fattorini's results for the construction of finite dimensional compensators which leads to integral terms in the loop. These integral terms will disappear if we apply the approach of this section to obtain existence results for finite dimensional compensators. More precisely, we have to assume that the operators A, B and C, introduced in this section, satisfy hypothesis (H2) of § 2, or respectively, hypothesis (H3) and the assumptions of Proposition 2.6. Under these conditions it follows readily from Theorem 2.5 that there exists a finite dimensional compensator of the form (2.9) such that the closed loop system (4.1), (4.2), (2.9) is exponentially stable.

Starting from (4.1), (4.2), the following problems have to be solved for the construction of the compensator.

1. Find the operators A and B.
2. Determine the spectrum of the operator A and the reduced subsystem (2.15).
3. Find the stabilizing operators $F: X \to U$ and $G: Y \to X$.
4. Determine the eigenvalues and eigenvectors of A_F to approximate G.

To illustrate this procedure, we consider the heat equation with Neumann boundary conditions and boundary control which has also been treated in [3] with different methods.

Example 4.7. Consider the parabolic PDE

$$z_t = \pi^{-2} z_{\xi\xi}, \qquad 0 < \xi < 1, \quad t > 0, \tag{4.10.1}$$

$$z_\xi(0, t) = u(t), \qquad z_\xi(1, t) = 0, \qquad t > 0, \tag{4.10.2}$$

$$z(\xi, 0) = z_0(\xi), \qquad 0 < \xi < 1, \tag{4.10.3}$$

$$y(t) = \int_0^1 c(\xi) z(\xi, t)\, d\xi, \qquad t > 0. \tag{4.10.4}$$

This system can be written in the abstract form (4.1) with

$$X = L^2[0,1], \quad W = \{\phi \in H^2[0,1] | \dot{\phi}(1) = 0\}, \quad U = \mathbb{R},$$
$$\Delta\phi = \pi^{-2}\ddot{\phi}, \qquad \Gamma\phi = \dot{\phi}(0),$$
$$Z^* = \mathcal{D}(A^*) = \mathcal{D}(A) = \{\psi \in H^2[0,1] | \dot{\psi}(0) = 0 = \dot{\psi}(1)\}.$$

The operator A satisfies (H3) and has a complete set of eigenvectors $\phi_0(\xi) \equiv 1$, $\phi_n(\xi) = \sqrt{2}\cos n\pi\xi$, corresponding to the eigenvalues $\lambda_0 = 0$, $\lambda_n = -n^2$, $n \in \mathbb{N}$. In order to determine the operator $B: \mathbb{R} \to Z$, let us choose any $\phi \in W$ such that $\Gamma\phi = 1$, e.g. $\phi(\xi) = -(\xi-1)^2/2$. Then, for every $\psi \in Z^*$, the following equation holds

$$\begin{aligned} B^*\psi &= \langle B^*\psi, \Gamma\phi\rangle = \langle \psi, B\Gamma\phi\rangle = \langle \psi, \Delta\phi - A\phi\rangle_{Z^*,Z} \\ &= \langle \psi, \Delta\phi\rangle_H - \langle A^*\psi, \phi\rangle_H \\ &= \frac{1}{\pi^2}\int_0^1 \psi(\xi)\ddot{\phi}(\xi)\,d\xi - \frac{1}{\pi^2}\int_0^1 \ddot{\psi}(\xi)\phi(\xi)\,d\xi \\ &= \frac{1}{\pi^2}\int_0^1 [\psi(\xi)\ddot{\phi}(\xi) + \dot{\psi}(\xi)\dot{\phi}(\xi)]\,d\xi \\ &= \frac{1}{\pi^2}[\psi(1)\dot{\phi}(1) - \psi(0)\dot{\phi}(0)] \\ &= -\frac{1}{\pi^2}\psi(0). \end{aligned}$$

It has been shown in Pritchard-Salamon [12] that these operators A and B satisfy hypothesis (H1) and therefore system (4.10) is well posed in $X = L^2[0,1]$ in the sense of Definition 4.1 (see Proposition 4.5). The spectral projection of $L^2[0,1]$ onto the eigenspace $X_\Lambda = \{\alpha\phi_0 | \alpha \in \mathbb{R}\}$ of A corresponding to the unstable part $\Lambda = \{0\}$ of the spectrum is given by

$$P_\Lambda\phi(\xi) = \int_0^1 \phi(\tau)\,d\tau, \qquad 0 < \xi < 1.$$

With the choice of $\{\phi_0\}$ as a basis of X_Λ, this operator splits into $P_\Lambda = \iota_\Lambda\pi_\Lambda$, where $\pi_\Lambda: L^2[0,1] \to R$ and $\iota_\Lambda: \mathbb{R} \to L^2[0,1]$ are given by

$$\pi_\Lambda\phi = \int_0^1 \phi(\tau)\,d\tau, \qquad \iota_\Lambda x_\Lambda(\xi) = x_\Lambda, \qquad 0 \leqq \xi \leqq 1.$$

Then the reduced finite dimensional system (2.15) is described by the "matrices"

$$A_\Lambda = 0, \quad B_\Lambda = -\pi^{-2}, \quad C_\Lambda = \int_0^1 c(\xi)\,d\xi.$$

This sytem is controllable and obervable if and only if

$$C_\Lambda = \int_0^1 c(\xi)\,d\xi \neq 0. \tag{4.11}$$

Stabilizing matrices are given e.g. by

$$F_\Lambda = \frac{\pi^2}{4}, \qquad G_\Lambda = -C_\Lambda^{-1}$$

so that $A_\Lambda + B_\Lambda F_\Lambda = -\frac{1}{4}$, $A_\Lambda + G_\Lambda C_\Lambda = -1$. Then the operator A_F with $F = F_\Lambda \pi_\Lambda$: $L^2[0,1] \to \mathbb{R}$ given by

$$\mathcal{D}(A_F) = \left\{ \phi \in H^2[0,1] \,|\, \dot{\phi}(1) = 0,\ \dot{\phi}(0) = \frac{\pi^2}{4} \int_0^1 \phi(\xi)\, d\xi \right\},$$

$$A_F \phi = \frac{1}{\pi^2} \ddot{\phi}.$$

The eigenvectors and eigenvalues of A_F coincide with those of A except for $\lambda_0 = 0$ which is now replaced by $\lambda_F = -\frac{1}{4}$. The corresponding normalized eigenfunction is

$$\phi_F(\xi) = \sqrt{2} \sin \frac{\pi}{2} \xi.$$

We will choose $W = \text{span}\{\phi_F\}$ and the maps

$$(\iota_F w)(\xi) = \phi_F(\xi) w, \qquad 0 < \xi < 1, \quad w \in \mathbb{R},$$

$$(\pi_F \phi)(\xi) = \int_0^1 \phi_F(\xi) \phi(\xi)\, d\xi, \qquad \phi \in L^2[0,1],$$

So that $\iota_F \pi_F : L^2[0,1] \to W$ is the orthogonal projection onto W and $\pi_F \iota_F = 1$.

Let us now consider the case that $c(\xi) = \xi$ for $0 \leqq \xi \leqq 1$. Then $C_\Lambda = \frac{1}{2}$ and we choose $G_\Lambda = -\pi g / 2\sqrt{2}$, $g > 0$. With this choice the operator $G : \mathbb{R} \to L^2[0,1]$ is given by

$$[Gy](\xi) = [\iota_\Lambda G_\Lambda y](\xi) = -\frac{\pi g}{2\sqrt{2}} y, \qquad 0 \leqq \xi \leqq 1.$$

We replace this operator by

$$[\hat{G}y](\xi) = [\iota_F \pi_F G y](\xi) = -gy\sqrt{2} \sin \frac{\pi}{2} \xi, \qquad 0 \leqq \xi \leqq 1,$$

whose range is in W. Since the perturbed operator $A + \hat{G}C$ generates an analytic semigroup it satisfies the "spectrum determined growth" assumption. Furthermore, its spectrum is given by

$$\sigma(A + \hat{G}C) = \{-\omega^2 \,|\, g[1 - \cos \omega\pi] = \omega^3 [8K + \pi^2/2\sqrt{2} - \sqrt{2}\pi^2\omega^2] \sin \omega\pi,\ \omega \neq 0\}$$

if $g > 0$. In the case $g < 0$ there is an additional positive eigenvalue $\lambda_0 = \omega^2 > 0$ where

$$-g \frac{e^{\omega\pi} + e^{-\omega\pi} - 2}{e^{\omega\pi} - e^{-\omega\pi}} = \omega^3 [8K + \pi^2/2\sqrt{2} + \sqrt{2}\pi^2\omega^2].$$

We conclude that $A + \hat{G}C$ generates an exponentially stable semigroup if and only if $g > 0$. Hence the operators F and $\hat{G}$ satisfy the hypothesis (H2) with the one-dimensional subspace $W = \text{span}\{\phi_F\}$. In this case the compensator (2.9) is described by the "matrices"

$$M = \pi_F (A_F + \hat{G}C) \iota_F = -\frac{1}{4} - \frac{4\sqrt{2}}{\pi^2} g,$$

$$H = \pi_F \hat{G} = -g,$$

$$K = F_\Lambda \pi_\Lambda \iota_F = \frac{\pi}{\sqrt{2}}.$$

Hence the first order system

$$\dot{w} = -\frac{1}{4} w - g\left[\frac{4\sqrt{2}}{\pi^2} w - y\right],$$
$$u = \frac{\pi}{\sqrt{2}} w, \tag{4.12}$$

defines a stablizing compensator for the parabolic PDE (4.10) with $c(\xi) \equiv \xi$ if and only if $g > 0$.

Remark 4.8. The results of this section show that the abstract framework of § 2 is general enough to cover both FDEs and PDEs. We mention that the approach of this section can also be applied to damped hyperbolic systems. Hence this paper represents a complete generalization of the compensator design of Schumacher [16] to infinite dimensional systems with unbounded control action. However, the degree of unboundedness which we can allow for the input/output operators is not as general as one would desire. For example, for the parabolic PDE (4.10) we cannot allow simultaneously Neumann boundary control and point observation. Also we cannot allow Dirichlet boundary control when the output operator is an arbitrary functional on $L^2[0, 1]$. A general theory which covers these cases would require the consideration of *unbounded output operators* as well. The extension of our theory to this case seems to involve some further difficulties and would be an interesting problem for future investigations.

Remark 4.9. Using the abstract approach outlined in § 2, it is possible to directly extend the results of Schumacher [15], [17] on tracking and regulation in infinite dimensions to unbounded control action. A different approach is to use the extended system formulation discussed in [2], which results in integral control action and this can be found in Curtain [4].

Note. Stronger results on finite dimensional compensators for some classes of functional differential equations have recently been developed by Kamen-Khargonekar-Tannenbaum [23], Nett [24], Logemann [25] using frequency domain methods.

MINIMAL ORDER ESTIMATION OF MULTIVARIABLE DISCRETE-TIME STOCHASTIC LINEAR SYSTEMS*

YORAM BARAM† AND URI SHAKED‡

Abstract. Minimal order estimation of the state of a discrete-time, multi-input, multi-output stochastic linear system is considered. The relationship between the given system structure and the order of the minimal estimator is investigated and a necessary and sufficient condition for order minimality is derived in terms of the internal system structure.

Key words. stochastic systems, estimation, filtering

AMS(MOS) subject classifications. 93E03, 93E10, 93E11

1. Introduction. This paper is concerned with the minimal order of the state estimator of a given state-space system. Order minimality of the estimator implies nonexistence of a lower order state estimator for the system. It is well known that an order reduction can be obtained when the observation noise is colored or when it is white with a singular covariance matrix [1]. In this paper we show that an order reduction may be obtained due to the internal structure of the system, even when the observation noise is white with a nonsingular covariance. In fact, we assume a nonsingular observation noise covariance and obtain a necessary and sufficient condition for the minimality of the state estimator in terms of the internal system structure and parameters.

Consider the system

$$x_{n+1} = Ax_n + Bw_n, \qquad x_n \in R^p, \tag{1.1a}$$

$$y_n = Cx_n + u_n, \qquad y_n \in R^q, \tag{1.1b}$$

with

$$E\{x_0\} = E\{w_n\} = E\{u_n\} = 0, \qquad E\{w_n x_0^T\} = E\{u_n x_0^T\} = 0,$$

and

$$E\{w_n w_k^T\} = Q\delta_{n,k}, \qquad E\{u_n u_k\} = P\delta_{n,k},$$

where

$$Q > 0, \qquad P > 0 \quad \text{and} \quad \delta_{n,k} = \begin{cases} 1 & n = k \\ 0 & n \neq k \end{cases}.$$

We further assume

$$E\{w_n u_k^T\} = 0.$$

Let us denote by $Y_n^- = \{y_{n-k}, k \geqq 0\}$ the space of past observations at time n and by $x_{n|k}$ the linear mean-square projection of x_n on Y_k^-. We assume that the system is asymptotically stable and that $E\{x_{n|n-1}x_{n|n-1}^T\}$ has a constant value Π and $E\{(x_n - x_{n|n-1})(x_n - x_{n|n-1})^T\}$ has a constant value Σ. It is well known that Π and Σ satisfy the

equations

$$\Pi - A\Pi A^T = AKRK^TA^T, \tag{1.2}$$

$$\Sigma - A\Sigma A^T + AKC\Sigma A^T = BQB^T, \tag{1.3}$$

where

$$K = \Sigma C^T R^{-1}, \qquad R = C\Sigma C^T + P.$$

The state predictions are obtained from the stationary Kalman filter

$$x_{n+1|n} = Ax_{n|n-1} + AK\nu_n \tag{1.4}$$

where $\nu_n = y_n - Cx_{n|n-1}$.

Let us denote by T the matrix whose columns are the eigenvectors of Π corresponding to nonzero eigenvalues and define

$$z_n = T^T x_{n|n-1}. \tag{1.5}$$

Then z_n has orthonormal components and dim z_n = rank Π. Furthermore, we have the inverse transformation

$$x_{n|n-1} = Tz_n. \tag{1.6}$$

Substituting (1.5) and (1.6) into (1.4) we get

$$z_{n+1} = T^TATz_n + T^TAK\nu_n \tag{1.7}$$

with $\nu_n = y_n - CTz_n$. Estimation updates can be obtained as

$$x_{n|n} = Tz_n + K\nu_n. \tag{1.8}$$

Since, clearly, there is no vector of dimension lower than that of z_n, from which $x_{n|n-1}$ can be obtained by a linear transformation, it seems justified to call (1.7) a minimal state estimator of the system (1.1).

2. Filter order minimality. Recall that to each Jordan block J_i, $i = 1, \cdots, t$, in the spectral decomposition of A there corresponds one eigenvalue α_i and one-eigenrow v_i^T (we note that α_i is not necessarily different from α_j for $i, j = 1, \cdots, t$). We have the following result.

THEOREM 1. *The filter* (1.4) *is of minimal order if and only if* (A, B) *is reachable,* A *is not singular and for any eigenrow* v_i^T *of* A

$$C(\alpha_i^{-1}I - A)^{-1}BQB^Tv_i \neq 0. \tag{2.1}$$

Proof. It follows from (1.3) that

$$(zI - A)\Sigma(z^{-1}I - A^T) + A\Sigma(z^{-1}I - A^T) + (zI - A)\Sigma A^T + \bar{K}C\Sigma A^T = BQB^T,$$

where z is the Z transform variable and where we have denoted

$$\bar{K} = AK.$$

We multiply both sides of this equation by $(zI - A)^{-1}$, on the left, and by $(z^{-1}I - A^T)^{-1}C^T$, on the right, and obtain

$$\begin{aligned}\Sigma C^T + (zI - A)^{-1}A\Sigma C^T + \Sigma A^T(z^{-1}I - A^T)^{-1}C^T \\ + (zI - A)^{-1}\bar{K}C\Sigma A^T(z^{-1}I - A^T)^{-1}C^T \\ = (zI - A)^{-1}BQB^T(z^{-1}I - A^T)^{-1}C^T.\end{aligned}$$

Since $A\Sigma C^T = \bar{K}R$, we readily find then that

$$\Sigma C^T + (zI - A)^{-1}\bar{K}R[I + \bar{K}^T(z^{-1}I - A^T)^{-1}C^T] = (zI - A)^{-1}BQB^T(z^{-1}I - A^T)^{-1}C^T. \tag{2.2}$$

We consider next the partial fraction expansion of the two sides of the last equation. Since the eigenstructure of A may consist of Jordan blocks of dimensions greater than one, we consider the contribution of each Jordan block to the partial fraction expansion separately. It is well known that the terms in the partial fraction expansion of $(zI - A)^{-1}$ that correspond to the Jordan block of dimension r_i of the eigenvalue α_i are

$$\vartheta_{i,k,j}(z) = u_i^{(k)}v_i^{(j)T}(z - \alpha_i)^{-(r_i - j - k)}, \qquad j, k = 0, 1, \cdots, r_i - 1, \tag{2.3}$$

where $u_i^{(0)}$ and $v_i^{(0)T}$ are the eigenvector and the eigenrow that correspond to this Jordan block and $u_i^{(k)}$ and $v_i^{(k)T}$ are the corresponding kth order pseudo-eigenvector and pseudo-eigenrows, respectively [2].

It follows from the asymptotic stability of the system (1.1) that the terms in the partial fraction expansion of $(zI - A)^{-1}BQB^T(z^{-1}I - A^T)^{-1}C^T$ that correspond to the eigenvalues of A are of the form $\vartheta_{i,k,j}(z)BQ \lim_{z\to\alpha_i} B^T(z^{-1}I - A^T)^{-1}C^T$. Obviously there may be terms in the expansion that correspond to $(z - \alpha_i)^{-r_i}$. These terms result from different Jordan blocks that correspond to α_i and α_j where $\alpha_i = \alpha_j$. They include $\vartheta_{j,0,0}(z)BQ \lim_{z\to\alpha_j} B^T(z^{-1}I - A^T)^{-1}C^T$, for all $\alpha_j = \alpha_i$ and $r_i = r_j$ and also other dyadic terms that result from Jordan blocks of $\alpha_j = \alpha_i$ which are of dimension greater than r_i (i.e., $\vartheta_{j,k,r_j - r_i - k}(z)BQ \lim_{z\to\alpha_i} B^T(z^{-1}I - A^T)^{-1}C^T$, $k \geqq r_j - r_i \geqq 0$). Since the eigenvectors and pseudo-eigenvectors of A are all independent, it is possible, given the matrix coefficient of $(z - \alpha_i)^{-r_i}$, in the partial fraction expansion of $(zI - A)^{-1}BQB^T(z^{-1}I - A^T)^{-1}C^T$, to find the term that corresponds to $(z - \alpha_i)^{-r_i}$ and the eigenrow $v_i^{(0)T}$ of the specific Jordan block of α_i, namely, $\vartheta_{i,0,0}(z)BQ \lim_{z\to\alpha_i} B^T(z^{-1}I - A^T)^{-1}C^T$. The corresponding term in the partial fraction expansion of $(zI - A)^{-1}\bar{K}R[I + \bar{K}^T(z^{-1}I - A^T)^{-1}C^T]$ in (2.2) is clearly $\vartheta_{i,0,0}(z)\bar{K}R \lim_{z\to\alpha_i} F^T(z^{-1})$, where $F(z) = I + C(zI - A)^{-1}\bar{K}$ is the return difference matrix of the one step ahead stationary Kalman filter. It follows therefore from (2.2) and (2.3) that

$$v_i^{(0)T}\bar{K}R \lim_{z\to\alpha_i} F^T(z^{-1}) = v_i^{(0)T}BQ \lim_{z\to\alpha_i} B^T(z^{-1}I - A^T)^{-1}C^T. \tag{2.4}$$

By the Popov-Belevitch-Hautus test for reachability [3, p. 135], $(A, \bar{K}R^{1/2})$ is reachable if and only if none of the eigenrows of A lie in the left annihilating subspace of $\bar{K}$. Since the zeros of $F^T(z^{-1})$ are the reciprocals of the poles of the Kalman filter, they lie outside the unit circle and $\lim_{z\to\alpha_i} F^T(z^{-1})$ is therefore nonsingular. The eigenrow $v_i^{(0)T}$ will lie then in the annihilating subspace of $\bar{K}$ if and only if

$$v_i^{(0)T}BQ \lim_{z\to\alpha_i} B^T(z^{-1}I - A^T)^{-1}C^T = 0. \tag{2.5}$$

It follows from (2.5) that the pair $(A, \bar{K}R^{1/2})$ is not reachable if and only if one of the following three cases holds.

(i) The matrix A is singular: The limit for $\alpha_i = 0$ will then yield the required zero in (2.5), independently of the specific structure of B and the eigenrows of A.

(ii) The pair (A, B) is nonreachable: In this case $v_i^{(0)T}B = 0$, which readily satisfies (2.5), independently of the specific structure of C.

(iii) The pair (A, B) is reachable and $\alpha_i \neq 0$ for each i, but (2.5) is satisfied for some i.

Since reachability of $(A, \bar{K}R^{1/2})$ implies that Π has a full rank [4, p. 64] and since $\dim z_n = \operatorname{rank}\Pi$, it follows that the state estimator (1.4) is minimal if and only if A is

nonsingular, (A, B) is reachable and none of the eigenrows of A satisfy (2.5). The proof is thus completed.

Let us now examine the conditions of Theorem 1. The matrix A is known to be nonsingular if the system is obtained by discretizing a continuous time linear system. Suppose that the pair (A, B) is reachable. Then by the Popov-Belevitch-Hautus test $B^T v_i \neq 0$ for all i. Suppose further that $r \geqq q$, i.e., that there are no less outputs than inputs. Then a sufficient condition for minimality of the filter is that the matrix $C(\alpha_i^{-1} I - A)^{-1} B$ is nonsingular. It follows that a sufficient condition for filter minimality in this case is that α_i^{-1} is not a zero of the system, i.e., that none of the system's zeros is a reciprocal of any of its poles. Reciprocal pole-zero pairs are known as all-pass elements as they represent a flat (unity) spectral density. In the single-input, single-output case, we immediately obtain that when the pair (A, B) is reachable, a necessary and sufficient condition for filter minimality is that the system contains no all-pass pairs. Condition (2.1) may then b regarded as a generalization of the no-all-pass condition to the multivariable case.

Finally, we note that the concept of filter order reduction, in the sense of this paper, is different from that of degeneracy of the Ricatti equation, which has received considerable attention in the literature (e.g. [5], [6]). The minimal filter order is equal to the rank of the matrix Π and not to that of the matrix Σ. Consequently, the filter order may not be minimal even when Σ is of full rank, as condition (2.1) need not be satisfied even if the system is reachable and observable. In the single-input, single-output case, when the system is reachable and observable and contains all-pass elements, Σ will be of full rank but Π will be rank deficient, yielding a state estimator of order lower than that of the given system.

3. Conclusion. This paper has investigated the relationships between a discrete time, stochastic linear system in state-space form and its minimal state estimator. A necessary and suffidient condition for the minimality of the Kalman filter as a state estimator has been obtained in terms of the internal system structure.

ITERATIVE TECHNIQUES FOR THE NASH SOLUTION IN QUADRATIC GAMES WITH UNKNOWN PARAMETERS*

G. P. PAPAVASSILOPOULOS†

Abstract. We study adaptive schemes for repeated quadratic Nash games in a deterministic and a stochastic framework. The convergence of the schemes is demonstrated under certain conditions.

Key words. Nash equilibrium, adaptive Games, stochastic approximation

AMS(MOS) subject classifications. 60G42, 62L20, 90D05, 90D15

1. Introduction. The object of this paper is the study of a static quadratic Nash game where the players do not have knowledge of the parameters involved in the description of the cost of their opponents and of their opponent's information. The game is played repeatedly and at each stage the players know the past actions of their opponents. The only dynamics involved are in the accumulation of the information on their opponent's previous actions; apart from this dynamic aspect, the problem considered is a repeated static game. We examine both the deterministic and stochastic case, consider some adaptive schemes for updating the players decisions, and we show convergence to the optimal decisions (in the mean square sense and with probability one for the stochastic case), under some conditions. The scheme for the stochastic case is actually a stochastic approximation algorithm of the Robbins-Monro type.

The underlying motivation for the present paper is to study situations of conflict where the players do not know some of the parameters involved in the description of the others' cost functionals, or in the state equation. Such situations have been and are being studied for the single player—i.e., control problem—case and come under the name of Adaptive Control; the corresponding problems for situations of conflict, i.e., Adaptive Games, has received very little attention up to now. The problem studied here can be considered as a very simple type of adaptive game where the players adapt their decisions as to converge in the limit to the solution of a static Nash game. It should be noted that the strategies exhibited in this paper do not constitute a Nash equilibrium pair for the construed dynamic—dynamic due to the dynamic information—game; but similarly, the adaptive control strategy in the self-tuning regulator problem [5], converges in the limit to the optimal solution without being necessarily optimal at each stage. Adaptive games are important for several reasons. For example, when two players are involved in a situation of conflict, it is reasonable to assume that each player knows his own objective, but not that of his opponent; in addition, he might not know several of the parameters of the dynamic system which couples him with the other. In decentralized control, we think of decentralization as a scheme according to which each controller knows his own objective and information but not those of the others. If each controller knew the objectives of the others—as is implicitly assumed in many existing decentralized schemes—then the notion of decentralization is weakened. Although considerable progress has been achieved for the centralized controller, single objective adaptive control [4]-[6], the area of adaptive games is in

† University of Southern California, Department of Electrical Engineering-Systems, Los Angeles, California 90089-0781.

its infancy. The only work that the author is familiar with in this area is [7] and [8]. In [7], adaptive schemes based on self-tuning for stochastic Nash and Stackelberg games are considered, where the players have the same information. (In the present paper the information of the players is different.) In [8] two adaptive schemes are studied for repeated Stackelberg games in a determinisitic framework.

The structure of the paper is as follows. In § 2 we consider the determinisitic case and study three simple adaptive schemes. In § 3 we consider an adaptive scheme for the stochastic case. The stochastic scheme is a Robbins-Monro type of stochastic approximation algorithm. Although several results exist for such algorithms, many of which can be used to provide convergence for the scheme considered here, the conditions of convergence that they would obtain for our scheme are more stringent than those that we prove here. In each section we provide several comments relating the results with previous work, expand on their meaning and provide appropriate motivation. Finally, we have a conclusions section.

2. Deterministic case. Let $J_1, J_2: R^{m_1} \times R^{m_2} \to R$ be two functions defined by:

$$J_i(u_1, u_2) = \tfrac{1}{2} u_i' u_i + u_i' R_i u_j + u_i' c_i, \qquad i \neq j, \quad i, j = 1, 2 \tag{1}$$

where $u_i \in R^{m_i}$, R_1, R_2 are real constant matrices and c_1, c_2 are real constant vectors of appropriate dimensions. A pair (u_1^*, u_2^*) is a Nash equilibrium if it satisfies ([1], [2]):

$$J_1(u_1^*, u_2^*) \leqq J_1(u_1, u_2^*) \quad \forall u_1 \in R^{m_1}, \tag{2}$$

$$J_2(u_1^*, u_2^*) \leqq J_2(u_1^*, u_2) \quad \forall u_2 \in R^{m_2}, \tag{3}$$

or equivalently if

$$R \begin{bmatrix} u_1^* \\ u_2^* \end{bmatrix} + c = 0, \quad R = \begin{bmatrix} 1 & R_1 \\ R_2 & 1 \end{bmatrix}, \quad c = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}. \tag{4}$$

J_i and u_i are the cost and the decision of player i.

Let us assume that player i knows R_i and c_i, but not R_j and c_j $(j \neq i)$; then he cannot solve (4) for u_i^*. Consider also that this game is played repeatedly at times $t = 1, 2, 3, \cdots$, that at time t, player i knows $I_t^i = \{u_{1,1}, \cdots, u_{1,t-1}, u_{2,1}, \cdots, u_{2,t-1}\}$ and plays u_{it} which is chosen as a function of I_t^i, i.e.,

$$u_{it} = F_i(I_t^i, t), \qquad i = 1, 2, \quad t = 2, 3, \cdots. \tag{5}$$

The question is: For what F_1, F_2 the recursion (5) will converge to a solution of (4). Let us now examine three possible choices of F_1, F_2.

CASE 1.

$$F_i(I_t^i, t) = -R_i u_{j,t-1} - c_i, \qquad i = 1, 2, \quad i \neq j. \tag{6}$$

The meaning of (6) is that player 1 minimizes $J_1(u_1, u_{2,t-1})$, i.e., he reacts only to the last announced decision of player 2. Recursion (5) assumes the form:

$$\begin{bmatrix} u_{1t} \\ u_{2t} \end{bmatrix} = \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} - \left(R \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} + c \right), \qquad t \geqq 2. \tag{7}$$

Recursion (7) will converge to a solution of (4) for any initial condition $(u_{1,1}, u_{2,1})$ if and only if all the eigenvalues of the matrix R lie within the open disc of radius 1 centered at the point 1 in the complex plane, i.e.,

$$|\lambda(R) - 1| < 1 \tag{8}$$

((8) is equivalent to $|\lambda(R_1, R_2)| < 1$). Condition (8) also guarantees that (4) has a unique solution.

CASE 2.

$$F_i(I_t^i, t) = -R_i[u_{j,t-1} + \theta u_{j,t-2} + \cdots + \theta^{t-2} u_{j,1}] \frac{1-\theta}{1-\theta^{t-1}} - c_i, \tag{9}$$

$$1 > \theta \geqq 0, \quad i = 1, 2, \quad i \neq j.$$

The meaning of (9) is that player 1 minimizes J_1 with respect to u_1, with u_2 fixed to a value that is a weighted average of $u_{2,t-1}, \cdots, u_{2,1}$ where more weight is put on the recent values of u_2. We assume that both players use the same θ. Recursion (9) can be written equivalently:

$$\begin{bmatrix} u_{1t} \\ u_{2t} \end{bmatrix} = \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} - \frac{1-\theta}{1-\theta^{t-1}} \left(R \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} + c \right), \qquad t \geqq 2. \tag{10}$$

Recursion (10) will converge to a solution of (4) for any initial condition $(u_{1,1}, u_{2,1})$ if and only if all the eigenvalues of the matrix R lie within the open disc of radius $(1-\theta)^{-1}$ centered at the point $(1-\theta)^{-1}$ in the complex plane, i.e.,

$$\left| \lambda(R) - \frac{1}{1-\theta} \right| < \frac{1}{1-\theta}. \tag{11}$$

Condition (11) also guarantees that (4) has a unique solution. (Notice that as $t \to +\infty$, $\theta^{t-1} \to 0$ and thus $(1-\theta)R$ in (10) assumes the role of R in (7).) Obviously, for $\theta = 0$, (11) reduces to (8) and (10) to (7).

CASE 3.

$$F_i(I_t^i, t) = -R_i[u_{j,t-1} + u_{j,t-2} + \cdots + u_{j,1}] \frac{1}{t-1} - c_i, \qquad i = 1, 2, \quad i \neq j. \tag{12}$$

The meaning of (12) is that player 1 minimizes J_1 with respect to u_1, with u_2 fixed to the arithmetic mean of $u_{2,t-1}, \cdots, u_{2,1}$. Recursion (12) can be written equivalently:

$$\begin{bmatrix} u_{1,t} \\ u_{2,t} \end{bmatrix} = \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} - \frac{1}{t-1} \left(R \begin{bmatrix} u_{1,t-1} \\ u_{2,t-1} \end{bmatrix} + c \right), \qquad t \geqq 2. \tag{13}$$

Recursion (13) will converge to a solution of (4), for any initial condition $(u_{1,1}, u_{2,1})$ if and only if all the eigenvalues of R has positive real parts, i.e.,

$$\operatorname{Re} \lambda(R) > 0 \tag{14}$$

(for proof see Appendix A, Lemma A3). Condition (14) also guarantees that (4) has a unique solution. Notice that as $\theta \to 1$, (11) reduces to (14).

Remark 1. Obviously (8)$\Rightarrow$(11)$\Rightarrow$(14). If (8) holds, (7) converges faster than (10) and if (11) holds, (10) converges faster than (13).

Remark 2. In all three cases we assumed that both players use the same scheme. Nonetheless, it might happen that they use different ones. It is easy to verify that if player 1 uses scheme 1 and player 2 uses scheme 2, the region of convergence is larger than if both were using scheme 1 and worse than if both were using scheme 2. Similar results holds for the other combinations.

Remark 3. If we consider (10) with $\theta > 1$, i.e., more weight is assigned to the old measurements, the scheme will not converge. This can be easily verified by considering the scalar version of (10) with $c = 0$:

$$u_t = u_{t-1} \left(1 - r \frac{1-\mu}{\mu} \frac{\mu^{t-1}}{1-\mu^{t-1}} \right), \qquad \mu = \frac{1}{\theta}$$

which for $t \to +\infty$ behaves like

$$y_t = y_{t-1}\left(1 - r\frac{1-\mu}{\mu}\mu^{t-1}\right)$$

(since $0 < \mu < 1$) and is easily seen to fail to converge.

Remark 4. Conditions (8), (11) and (14) can be expressed equivalently in terms of the eigenvalues of R_1R_2.

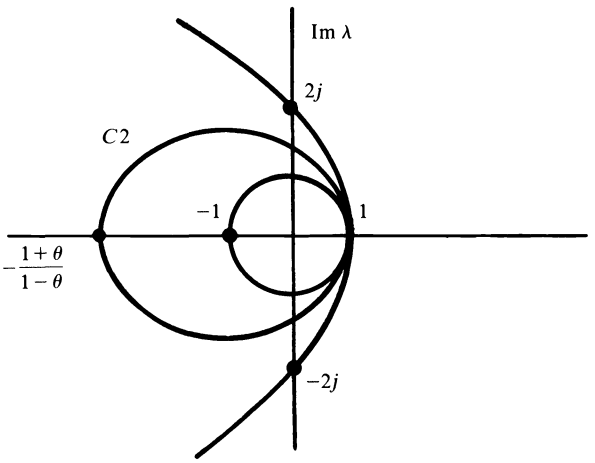

FIG. 1

Condition (8) corresponds to $|\lambda(R_1R_2)| < 1$, i.e., inside the unit disc, (11) corresponds to

$$(1-\theta)|\lambda| \pm 2\theta \cos\frac{\varphi}{2}|\lambda|^{1/2} - (1+\theta) < 0,$$

$$\lambda(R_1R_2) = |\lambda|e^{j\varphi},$$

i.e., inside the curve $C2$ of Fig. 1. Condition (14) corresponds to eigenvalues of R_1R_2 being inside the parabola defined by

$$\operatorname{Re}\lambda + \tfrac{1}{4}(\operatorname{Im}\lambda)^2 < 1, \qquad \lambda = \lambda(R_1R_2).$$

Remark 5. If (8) (or equivalently $|\lambda(R_1R_2)| < 1$) holds, the solution of (4) is called in game theory a stable equilibrium, and the game is called stable [1]. The reason is that if player i deviates from u_i^*, then player $j (j \neq i)$ responds according to scheme (6) and to that player i responds according to scheme (6) and so on and eventually they both converge back to (u_1^*, u_2^*). Obviously the notion of stable equilibrium depends on the reaction scheme that the players employ. If schemes (9) or (12) are used as reaction schemes, we have an enlarged class of stable games.

Remark 6. Since the scheme of Case 3 (12) has the best convergence region out of the three schemes, in the next section we will deal with the stochastic analogue of (12).

Remark 7. All three schemes considered can actually be viewed as schemes for solving $Ru + c = 0$ (see (4)), by using an iteration of the form:

$$u_{n+1} = u_n - D_n[Ru_n + c] \tag{15}$$

where D_n has to have the structure

$$D_n = \begin{bmatrix} D_n^1 & 0 \\ 0 & D_n^2 \end{bmatrix}.$$

(Iterative solutions of linear equations is a vast subject, see for e.g. [16].) Scheme (13) employed: $D_n^i = (1/n)I$. We can create new schemes which converge under weaker conditions than (14) by allowing $D_n^i = (1/n)D^i$ where D^1, D^2 are properly chosen constant matrices. For example, if R_1, R_2 are scalars, (14) is equivalent to $1 > r_1 r_2$; but if we use $D_n^i = (1/n)d_i$ in (15), the convergence condition becomes

$$\operatorname{Re}\lambda\left(\begin{bmatrix} d_1 & 0 \\ 0 & d_2 \end{bmatrix}\begin{bmatrix} 1 & r_1 \\ r_2 & 1 \end{bmatrix}\right) > 0$$

which is equivalent to:

$$d_1 + d_2 > 0, \qquad d_1 d_2 (1 - r_1 r_2) > 0,$$

and can always be satisfied for some d_1, d_2 as long as $1 \neq r_1 r_2$. Notice that $1 \neq r_1 r_2$ is the necessary and sufficient condition for solvability of (4) for any c.

Remark 8. Another way of going about the problem of this section is to consider that at each stage, each player uses a certain scheme to estimate the R and C of his opponent and then calculates his action by solving (4) wherein he employs the estimates of the R and c of his opponent. In such a scheme, each player should know at each stage not only the previous actions of his opponent—as in our scheme—but also the rationale according to which his opponent calculates his actions. This is necessary in order just to estimate his opponent's parameters at each stage. Nonetheless, such an additional knowledge can be permitted and the convergence of the resulting scheme studied. Finally, it should be noted that the problem considered here and the schemes proposed, besides having their own merit, provide a certain motivation for the scheme considered for the stochastic case of the next section.

3. The stochastic case. Let x be a Gaussian random vector in R^n with zero mean and unit covariance matrix. Let

$$y_i = C_i x, \qquad i = 1, 2 \tag{16}$$

represent the measurements of the two players, where C_1, C_2 are fixed real matrices of dimensions $n_1 \times n$, $n_2 \times n$ respectively. Let Γ_i be the set of all measurable γ_i: $R^{n_i} \to R^{m_i}$ functions with $E[\gamma_i(y_i)'\gamma_i(y_i)] < +\infty$. Set $u_i = \gamma_i(y_i)$ and let

$$J_i(\gamma_1, \gamma_2) = E[\tfrac{1}{2}u_i' u_i + u_i' R_i u_j + u_i' S_i x], \qquad i \neq j, \quad i, j = 1, 2 \tag{17}$$

represent the costs of the two players. R_1, R_2, S_1, S_2 are fixed real matrices of appropriate dimensions. A pair $(\gamma_1^*, \gamma_2^*) \in \Gamma_1 \times \Gamma_2$ is called a Nash equilibrium if it satisfies

$$\begin{aligned} &J_1(\gamma_1^*, \gamma_2^*) \leqq J_1(\gamma_1, \gamma_2^*) \quad \forall \gamma_1 \in \Gamma_1, \\ &J_2(\gamma_1^*, \gamma_2^*) \leqq J_2(\gamma_1^*, \gamma_2) \quad \forall \gamma_2 \in \Gamma_2. \end{aligned} \tag{18}$$

For background concerning the formulation of the stochastic Nash game see [18]. (18) is equivalent to (see [2], [3]):

$$\gamma_1^*(y_1) + R_1 E[\gamma_2^*(y_2)|y_1] + S_1 E[x|y_1] = 0, \tag{19a}$$

$$\gamma_2^*(y_2) + R_2 E[\gamma_1^*(y_1)|y_2] + S_2 E[x|y_2] = 0. \tag{19b}$$

It is known (see [3]) that if no eigenvalue of $R_1 R_2$ equals the inverse of any arbitrary but finite product of powers of the squares of the canonical correlation coefficients of

y_1, y_2 (i.e., of $\sigma_1, \sigma_2, \cdots$), then (19) has a unique solution which as to be linear in the information. The set of values where the eigenvalues of R_1R_2 should not lie is a countable isolated set of points in $[1, +\infty)$ and thus it is generically true that (19) admits a unique solution which has to be linear in the information. We can assume without loss of generality (see [3, Lemma 1]) that

$$n_1 \leqq n_2 C_1 C_1' = I_{n_1 \times n_1}, \quad C_2 C_2' = I_{n_2 \times n_2}, \quad C_1 C_2' = \begin{bmatrix} \sigma_1 & & 0 & \vdots & \\ & \sigma_2 & & \vdots & \\ & & \ddots & \vdots & 0 \\ 0 & & & \sigma_{n_1} \vdots & \end{bmatrix}_{n_1 \times n_2} \tag{20}$$

$$1 \geqq \sigma_1 \geqq \sigma_2 \geqq \sigma_{n_1} \geqq 0$$

and then $\gamma_i^*(y_i) = L_i y_i$ where L_1, L_2 are the solutions to the system:

$$\begin{aligned} L_1 + R_1 L_2 C_2 C_1' + S_1 C_1' &= 0, \\ L_2 + R_2 L_1 C_1 C_2' + S_2 C_2' &= 0. \end{aligned} \tag{21}$$

Let us assume that player i knows R_i, S_i, C_i, but not R_j, S_j, C_j, $i \neq j$; then he cannot solve (21) for L_i. Consider also that this game is played repeatedly at times $t = 1, 2, 3, \cdots$, that at time t player i knows

$$I_t^i = \{u_{1,1}, \cdots, u_{1,t-1}, u_{2,1}, \cdots, u_{2,t-1}, y_{i,1}, \cdots, y_{i,t}\} \tag{22}$$

where y_{it} is the measurement of player i at time t. We assume that

$$y_{it} = C_i x_t \tag{23}$$

where the x_t's are independent Gaussian vectors with zero mean and unit covariance. At time t, player 1 employs the following scheme for finding u_{1t}:

$$u_{1t} + R_1 \left(\frac{1}{t-1} \sum_{k=1}^{t-1} u_{2,k} y_{1,k}' \right) y_{1t} + S_1 C_1' y_{1t} = 0. \tag{24}$$

A justification of this scheme is the following: at time t player 1 has to solve (19a) for u_{1t} and thus he has to calculate $E[u_{2,t}|y_{1t}]$, $E[x|y_{1t}]$. If u_{2t} is linear in y_{2t}, then u_{2t}, y_{1t} are jointly Gaussian and thus

$$E[u_{2,t}|y_{1t}] = E[u_{2t} y_{1t}'](E[y_{1t} y_{1t}'])^{-1} y_{1,t}. \tag{25}$$

Player 1 approximates $E[u_{2t} y_{1t}']$ by $1/(t-1)\sum_{k=1}^{t-1}(u_{2,k} y_{1k}^T)$; a motivation for this approximation is the following: If player 1 knew all the parameters of (16), (17), he would then solve equation (19) at state t, employing (23); due to the independence of the x_t's, $1/(t-1)\sum_{k=1}^{t-1}(u_{2k} y_{1k}^T)$ would provide a reasonable approximation of $E[u_{2t}|y_{1t}]$, since u_{2k} would be independent of u_{2l}, y_{1l}, $l \neq k$. By overlooking the lack of independence of u_{2k} on u_{2l}, y_{1l}, $l \neq k$, he still employs the above approximation, hoping that things will work out. The convergence results of Theorems 1′ and 2′ provide a posterior justification for the reasonableness of this approximation.

By our assumption (20) $E[y_{1t} y_{1t}'] = I$ and $E[x_t|y_{1t}] = S_1 C_1' y_{1t}$. (24) yields that u_{1t} is linear in y_{1t}, i.e., $u_{1t} = L_{1t} y_{1t}$ where L_{1t} satisfies

$$L_{1t} + R_1 \left[\frac{1}{t-1} \sum_{k=1}^{t-1} u_{2k} y_{1k}' \right] + S_1 C_1' = 0. \tag{26}$$

A similar equation is satisfied by L_{2t}, if we consider that u_{2t} is calculated by an equation corresponding to (24) and $u_{2t} = L_{2t} y_{2t}$. The equations for L_{1t}, L_{2t} can be written

recursively as:

$$L_{1t} = L_{1,t-1} - \frac{1}{t-1}[L_{1,t-1} + R_1 L_{2,t-1} y_{2,t-1} y'_{1,t-1} + S_1 C'_1], \tag{27a}$$

$$L_{2t} = L_{2,t-1} - \frac{1}{t-1}[L_{2,t-1} + R_2 L_{1,t-1} y_{1,t-1} y'_{2,t-1} + S_2 C'_2]. \tag{27b}$$

Recursion (27) is the recursion that we intend to study and show that under some conditions converges to the solution of (21) in the q.m. sense and w.p.1. The initial condition L_{11}, L_{12} of (27) is taken to be an arbitrary pair of real constant matrices and we are interested in convergence for any initial condition. The recursion (27) defines a Markovian stochastic process (L_{1t}, L_{2t}) and is obviously a stochastic approximation algorithm of the Robbins-Monro type [9] for solving (21). Recursion (27) is a stochastic analogue of the scheme of Case 3 of the deterministic case.

Let us now study the convergence of (27). Let us call l_{it}, m_{it}, c_i, d_i the ith columns of L_{1t}, L_{2t}, $S_1C'_1$, $S_2C'_2$ respectively, i.e.,

$$\begin{aligned} L_{1t} &= [l_{1t}, \cdots, l_{n_1 t}], \qquad L_{2t} = [m_{1t}, \cdots, m_{n_2 t}], \\ S_1 C'_1 &= [c_1, \cdots, c_{n_1}], \qquad S_2 C'_2 = [d_2, \cdots, d_{n_2}]. \end{aligned} \tag{28}$$

Let

$$\bar{l}_{it} = E[l_{it}], \qquad \bar{m}_{it} = E[m_{it}]. \tag{29}$$

Using (20) and the fact that L_{1t} depends on $y_{11}, \cdots, y_{1t-1}, y_{21}, \cdots, y_{2,t-1}$, we obtain from (27):

$$\bar{l}_{it} = \bar{l}_{it-1} - \frac{1}{t-1}[\bar{l}_{i,t-1} + \sigma_i R_1 \bar{m}_{i,t-1} + c_i], \qquad i = 1, \cdots, n_1 \tag{30a}$$

$$\bar{m}_{it} = \bar{m}_{it-1} - \frac{1}{t-1}[\bar{m}_{i,t-1} + \sigma_i R_2 \bar{l}_{i,t-1} + d_i], \qquad i = 1, \cdots, n_1 \tag{30b}$$

and

$$\bar{m}_{it} = \bar{m}_{i,t-1} - \frac{1}{t-1}[\bar{m}_{i,t-1} + d_i], \qquad i = n_1 + 1, \cdots, n_2. \tag{30c}$$

Recursion (30c) converges for any initial condition (see Lemma A3). Recursions (30a) and (30b) can be written as

$$\begin{bmatrix} \bar{l}_{it} \\ \bar{m}_{it} \end{bmatrix} = \begin{bmatrix} \bar{l}_{i,t-1} \\ \bar{m}_{i,t-1} \end{bmatrix} - \frac{1}{t-1}\left(\begin{bmatrix} I & \sigma_i R_1 \\ \sigma_i R_2 & I \end{bmatrix} \begin{bmatrix} \bar{l}_{i,t-1} \\ \bar{m}_{i,t-1} \end{bmatrix} + \begin{bmatrix} c_i \\ d_i \end{bmatrix} \right) \tag{31}$$

and using Lemma A3 yields that (31) converges for any initial condition if and only if

$$\operatorname{Re} \lambda \left(\begin{bmatrix} I & \sigma_i R_1 \\ \sigma_i R_2 & I \end{bmatrix} \right) > 0. \tag{32}$$

It is easy to see that if (32) holds for σ_1 then it holds for any σ_i, $0 \leqq \sigma_i \leqq \sigma_1$. We thus have proven the following theorem.

THEOREM 1'. *The means of L_{1t}, L_{2t} as defined by the recursion* (27) *converge to a solution of* (21) *for any initial condition, if and only if*

$$\operatorname{Re} \lambda \left(\begin{bmatrix} I & \sigma_1 R_1 \\ \sigma_1 R_2 & I \end{bmatrix} \right) > 0. \tag{33}$$

It is easy to see that if (33) holds then (21) has a unique solution. If we want (27) to converge to a solution of (21) not only for any initial condition, but also for any pair of measurements, i.e., any C_1, C_2, we have to consider $\sigma_1 = 1$ in (33) which is exactly the condition for convergence of Case 3 of the deterministic case.

Next we will show that L_{1t}, L_{2t} converge to a solution of (21) in the mean square sense, under condition (33). For simplicity and w.l.o.g. we will assume $S_1 C_1' = 0$, $S_2 C_2' = 0$. We can write (27) component-wise in tems of l_{it}, m_{it} and then form the products $l_{it} l_{jt}'$, $i, j = 1, \cdots, n_1$, $m_{it} m_{jt}'$, $i, j = 1, \cdots, n_2$ and $l_{it} m_{mt}'$, $i = 1, \cdots, n_1$, $j = 1, \cdots, n_2$. These products satisfy recursions that can be easily calculated, and taking expectations of which result in a recursion which gives the evolution of $E(l_{it} l_{jt}')$, $E(m_{it} m_{jt}')$, $E(l_{it} m_{jt}')$ in terms of $E(l_{i,t-1} l_{j,t-1}')$, $E(m_{i,t-1}, m_{j,t-1}')$ $E(l_{i,t-1} m_{j,t-1}')$. Before writing down this recursion we introduce some notation:

$$\Lambda_{ij}^t = E[l_{it} l_{jt}'], \qquad i, j = 1, \cdots, n_1, \tag{34a}$$

$$M_{ij}^t = E[m_{it} m_{jt}'], \qquad i, j = 1, \cdots, n_2, \tag{34b}$$

$$K_{ij}^t = E[l_{it} m_{jt}'], \quad i = 1, \cdots, n_1, \quad j = 1, \cdots, n_2, \tag{34c}$$

$$N_t = \left[\begin{array}{ccc|ccc} \Lambda_{11}^t & \cdots & \Lambda_{1n_1}^t & K_{1,1}^t & \cdots & K_{1,n_2}^t \\ \vdots & & \vdots & \vdots & & \vdots \\ \Lambda_{n_1 1}^t & \cdots & \Lambda_{n_1 n_1}^t & K_{n_1,1} & \cdots & K_{n_1,n_2}^t \\ \hline (K_{11}^t)' & \cdots & (K_{n_1,1}^t)' & M_{11}^t & \cdots & M_{1,n_2}^t \\ \vdots & & \vdots & \vdots & & \vdots \\ (K_{1,n_2}^t)' & \cdots & (K_{n_1 n_2}^t)' & M_{n_2,1} & \cdots & M_{n_2,n_2}^t \end{array}\right], \tag{35}$$

$$Q = \left[\begin{array}{ccc|ccccc} I & & 0 & \sigma_1 R_1 & & 0 & 0 & 0 \\ & \ddots & & & \sigma_2 R_1 & & \vdots & \\ & & & & & \ddots & & \\ 0 & & I & 0 & & \sigma_{n_1} R_1 & 0 \cdots & 0 \\ \hline \sigma_1 R_2 & & 0 & I & & & & \\ & \ddots & & & & & & \\ & 0 & \sigma_{n_1} R_2 & & & & & 0 \\ 0 & \cdots & 0 & & 0 & & \ddots & \\ \vdots & & \vdots & & & & & \\ 0 & \cdots & 0 & & & & & I \end{array}\right]. \tag{36}$$

Then N_t satisfies

$$N_t = N_{t-1} - \frac{1}{t-1}[N_{t-1} Q' + Q N_{t-1}] + \frac{1}{(t-1)^2} \mathscr{L}(N_{t-1}). \tag{37}$$

where $\mathscr{L}(\cdot)$ denotes a linear time invariant function of its argument. (For details of this derivation, see Appendix B.)

Using Lemma A4 we conclude that N_t goes to zero for any initial condition if and only if the matrix Q has eigenvalues with positive real parts which is easily seen to be equivalent to (33). We thus have proven.

THEOREM 2'. *L_{1t}, L_{2t} as defined by recursion* (27) *converge to a solution of* (21) *for any initial condition, in the mean square sense, if and only if* (33) *holds.*

Next, we will show that (L_{1t}, L_{2t}) converges under (33) for any initial condition to the solution of (21) with probability 1 (i.e., a.s. convergence). We again assume for simplicity and w.l.o.g. that $S_1C_1'=0$, $S_2C_2'=0$. We will use the theorem in paragraph 3 of [11] (or [13, Lemma 3.5]) which we restate here and which is an easy consequence of the martingale convergence theorem of Doob.

LEMMA 1. *Let $\{V_t\}$ be a sequence of random variables such that $E(V_1)$ exists. Let A be a real number and suppose $V_t \geqq A$. Furthermore, assume that $\sum_{t=1}^{\infty} E(E[V_{t+1}-V_t|V_1, \cdots, V_t]^+)$ converges. Then the sequence $\{V_t\}$ converges with probability* 1.

(Recall that if x is a random variable: $x^+=\frac{1}{2}(|x|+x)$.) Let $x_t=(l_{1t}', \cdots, l_{n_1,t}', m_{1,t}', \cdots, m_{n_2,t}')'$. We will prove that x_t converges to 0 w.p.l. or equivalently that $V_t=\|x_t\|^2$ does. Let $A=0$. From (27) we can easily obtain (see Appendix C)

$$|E[V_{t+1}-V_t|V_1, \cdots, V_t]| \leqq \frac{\alpha}{t} V_t$$

for some positive number α and thus

$$E[V_{t+1}-V_t|V_1, \cdots, V_t]^+ \leqq \frac{\alpha}{t} V_t.$$

In order to fulfill the assumption of Lemma 1, it suffices to show that

$$\sum_{t=1}^{\infty} \frac{\alpha}{t} E(V_t) < +\infty. \tag{38}$$

$E[V_t]=\operatorname{tr} N_t$ holds, and thus it suffices to show that

$$\sum_{t=1}^{\infty} \frac{\operatorname{tr} N_t}{t} < +\infty. \tag{39}$$

From (37) we obtain

$$N_{t+1}=N_1-Q\left[\sum_{t=1}^{t} \frac{N_k}{k}\right]-\left[\sum_{k=1}^{t} \frac{N_k}{k}\right] Q'+\mathscr{L}\left(\sum_{k=1}^{t} \frac{N_k}{k^2}\right). \tag{40}$$

If we assume that Q has eigenvalues with real parts (40) can be solved for $\sum_{k=1}^{t}(N_k/k)$ to yield

$$\sum_{k=1}^{t} \frac{N_k}{k}=\mathscr{L}'\left(N_{t+1}, N_1, \sum_{k=1}^{t} \frac{N_k}{k^2}\right).$$

Since N_k converges, it is bounded and so is $\sum_{k=1}^{t}(N_k/k^2)$. Thus $\sum_{k=1}^{t}(N_k/k)$ is uniformly bounded and thus (39) and (38) are bounded. We thus conclude that $\|x_t\|^2=V_t$ converges with probability 1. $\|x_t\|^2$ converges to 0 in the mean square sense by Theorem 2′ and thus in probability and thus it has a subsequence converging to zero with probability one [17, Thms. 2, 5, 3, p. 93]. Since we just showed that $\|x_t\|^2$ converges with probability one, this limit has to be zero. Let us now summarize the results of this section in a theorem.

THEOREM. *L_{1t}, L_{2t} as defined by recursion* (27) *converge to a solution of* (21) *for any initial condition, in the mean square sense and with probability one if and only if*

$$\operatorname{Re} \lambda\left(\begin{bmatrix} I & \sigma_1 R_1 \\ \sigma_1 R_2 & I \end{bmatrix}\right) > 0$$

(*under this condition* (21) *admits a unique solution*).

Remark 1. N_t, (37), goes to zero but it does not have to converge monotonically.

Remark 2. One can construct the stochastic analogues of the deterministic schemes of Cases 1 and 2, if a different—appropriate—approximation is used for $E[u_{2t}|y_{1t}]$ in (25). A little reflection, though, will persuade the reader that these schemes will converge under conditions more stringent than (33).

Remark 3. For a repeated Stackelberg game one can consider schemes similar to those considered here, if one assumes that the Leader does not know the parameters involved in the Follower's cost. An idea of this sort was recently studied in a deterministic framework in [8].

Remark 4. It should be clear from (30) and (37) that the rate of convergence of the means and the covariances of l_{it}, m_{it} depend on the eigenvalues of the matrices in (32) for $\sigma_i = 1, \sigma_1, \cdots, \sigma_{n_1}$, or equivalently of Q. Actually, a recursion of the form (A1) with $\bar{\lambda} = \operatorname{Re}(\lambda) > 0$ goes to zero like $(n^{\bar{\lambda}})^{-1}$, (see [12]). Thus if λ_m denotes the real part of the eigenvalues of Q, $m = 1, \cdots, n_1 + n_2$ and $\bar{\lambda} = \min \operatorname{Re}(\lambda_m)$ the mean converges no slower than $(t^{\bar{\lambda}})^{-1}$, the covariances no slower than $(t^{2\bar{\lambda}})^{-1}$, the third moments no slower than $(t^{3\bar{\lambda}})^{-1}$ and so on. Thus if one were to consider whether $t^{\theta}[L_{1t}, L_{2t}]$ converges weakly to a Gaussian random variable as $t \to \infty$, θ should be chosen equal to $\bar{\lambda}$ so that the second moments converge to a nonzero constant, but then automatically all the moments will also do so. Thus in general one cannot have asymptotic normality of $n^{\theta}[L_{1t}, L_{2t}]$ for some $\theta > 0$. As a matter of fact, Theorem (1) of [12] cannot be applied since its assumption (A4) fails for the stochastic approximation algorithm (27), considered here, as should be expected from the above remarks. Finally, it should be pointed out that the fact that the rate of convergence of the algorithm is given by $t^{-\bar{\lambda}}$ and $t^{-2\bar{\lambda}}$ for the first and second moments, is a useful fact when implementing it, in deciding when to stop, what is the probability of error when stopping in a finite number of iterations, etc.

Remark 5. Stochastic approximation has been an object of intensive study (see [9]-[15]). Several of the results available can be used to prove convergence of the iteration (27) but they demand conditions stronger than (33), or they are not applicable to it. For example, in [9] it is required that in the scheme $x_{n+1} = x_n - (1/n)y_n$, y_n is uniformly bounded. Assumptions III and IV of [10] do not hold for (27). In proving asymptotic normality [12], he uses Assumption (A4) which does not hold for (27). Assumptions A5, A5′ of [11] do not hold for our scheme. Lemma 3.1 and Theorem 4.3 of [13] can be applied to (27) but result in more stringent conditions than (33). The convergence analysis of [15] demands boundness of the second term in (27) which is not applicable to our case. Assumption iii in [14, Problem 1, p. 92] does not hold for (27).

4. Conclusions. There are several directions in which this research can be continued. One of them is the corresponding problem for the Stackelberg game (see Remark 3 in § 3). The dynamic case where the players are also coupled through the evolution of a discrete time equation is obviously important and useful. We hope that the analysis presented here will be helpful in such further research.

Appendix A.

LEMMA A1. *Consider the scalar recursion*

$$x_{n+1} = \left(1 - \frac{\lambda}{n}\right) x_n, \qquad n = 1, 2, 3, \cdots \tag{A1}$$

where λ *and* x_1 *are complex numbers. Then* $x_n \to 0$ *for any* x_1 *if and only if* $\operatorname{Re}(\lambda) > 0$.

(*If we set* $t_n = 1 + \cdots + 1/n$, *we see that* (A1) *is a discrete approximation of* $\dot{x} = -\lambda x$ *and thus* $\operatorname{Re}(\lambda) > 0$ *is expected in order to have asymptotic stability of* (A1).)

LEMMA A2. *Consider the scalar recursion*

$$x_{n+1} = \left(1 - \frac{\lambda}{n} + O\left(\frac{1}{n^2}\right)\right) x_n, \qquad n = 1, 2, 3, \cdots \tag{A2}$$

where x *and* x_1 *are complex numbers. Then* $x_n \to 0$ *for any* x_1 *if and only if* $\operatorname{Re}(\lambda) > 0$.

Proof. It is an immediate consequence of Lemma A1 since λ/n dominates $O(1/n^2)$. □

LEMMA A3. *Consider the recursion*

$$x_{n+1} = \left(I - \frac{1}{n} A + O\left(\frac{1}{n^2}\right)\right) x_n, \qquad n = 1, 2, 3, \cdots \tag{A3}$$

where A *is a real square matrix and* x_1 *is a vector. Then* $x_n \to 0$ *for any* x_1 *if and only if* $\operatorname{Re} \lambda(A) > 0$.

Proof. We bring A to its Jordan form and apply Lemma A2. It is helpful to notice that if P is a real symmetric matrix

$$x'_{n+1} P x_{n+1} = x'_n P x_n - \frac{1}{n} x'_n [PA + A'P] x_n + x'_n O\left(\frac{1}{n^2}\right) x_n$$

and thus if A has $\operatorname{Re} \lambda(A) > 0$, we can find a positive definite P so that $A'P + PA > 0$. Therefore if n is sufficiently large

$$\frac{1}{n} x'_n [PA + A'P] x_n > x'_n O\left(\frac{1}{n^2}\right) x_n$$

and thus $x'_{n+1} P x_n < x'_n P x_n$ and consequently x_n is bounded. This justifies the fact that the $1/n$ term dominates in (A3). □

LEMMA A4. *Consider the recursion*

$$N_{t+1} = N_t - \frac{1}{t}[N_t Q' + Q N_t] + \frac{1}{t_2} \mathscr{L}(N_t), \qquad t = 1, 2, \cdots \tag{A4}$$

where N_t, Q *are square matrices.* $N_t \to 0$ *for any initial condition if and only if* $\operatorname{Re} \lambda(Q) > 0$.

Proof. Let x_t be the vector composed of the columns of N_t. We can write the recursion equivalently as

$$x_{t+1} = x_t - \frac{1}{t} A x_t + \frac{1}{t^2} \mathscr{L}(x_t).$$

It can be checked that $\operatorname{Re} \lambda(A) > 0$ if and only if $\operatorname{Re} \lambda(Q) > 0$ and thus Lemma A3 can be applied. □

It should be pointed out that if x_n evolves as in (A1), and λ is real, x_n behaves like $n^{-\lambda}$ (see 12, (2.3)). If λ is complex, then (A2) implies that $|x_n|^2$ behaves like n^{-2a} and thus $|x_n|$ behaves like n^{-a}, i.e., $n^{-\operatorname{Re}\lambda}$. Consequently x_{n+1} in (A3) behaves like $n^{-\bar{\lambda}}$, where $\bar{\lambda} = \min \operatorname{Re} \lambda\ (A)$ and N_t in (A4) behaves like $t^{-2\bar{\lambda}}$ where $\bar{\lambda} = \min \operatorname{Re} \lambda(Q)$.

Appendix B. Let l_{it}, m_{it}, c_i, d_i be as in (28). For convenience, let

$$y_{i,t-1} = \begin{bmatrix} y_1 \\ \vdots \\ y_{n_1} \end{bmatrix}, \qquad y_{2,t-1} = \begin{bmatrix} z_1 \\ \vdots \\ z_{n_2} \end{bmatrix}. \tag{B1}$$

Equation (27) can be written as

$$l_{it} = l_{i,t-1} - \frac{1}{t-1}\left[l_{i,t-1} + y_i R_1 \sum_{j=1}^{n_2} z_j m_{j,t-1} + c_i \right], \qquad i = 1, \cdots, n_1, \tag{B2}$$

$$m_{it} = m_{i,t-1} - \frac{1}{t-1}\left[m_{i,t-1} + z_i R_2 \sum_{j=1}^{n_1} y_j l_{j,t-1} + d_i \right], \qquad i = 1, \cdots, n_2. \tag{B3}$$

For convenience, let us drop the subscript $t-1$ from $l_{i,t-1}$, $m_{i,t-1}$. From (B2), (B3), we obtain:

$$\begin{aligned} l_{it}l'_{jt} = {} & l_i l'_j - \frac{1}{t-1}\left[2l_i l'_j + y_j \sum_{l=1}^{n_2} z_l l_i m'_l R'_1 + y_i R_1 \sum_{k=1}^{n_2} z_k m_k l'_j + l_i c'_j + c_i l'_j \right] \\ & + \frac{1}{(t-1)^2}\left[l_i l'_j + y_j \sum_{l=1}^{n_2} z_l l_i m'_l R'_1 + y_i R_1 \sum_{k=1}^{n_2} z_k m_k l'_j + y_i y_j R_1 \sum_{k,l=1}^{n_2} z_k z_l m_k m'_l R'_1 \right. \\ & \left. + y_i R_i \sum_{k=1}^{n_2} z_k m_k c'_j + y_j \sum_{l=1}^{n_2} z_l c_i m'_l R'_1 + l_i c'_j + c_i l'_j + c_i c'_j \right], \\ & i, j = 1, \cdots, n_1, \end{aligned} \tag{B4}$$

$$\begin{aligned} m_{it}m'_{jt} = {} & m_i m'_j - \frac{1}{t-1}\left[2m_i m'_j + z_j \sum_{l=1}^{n_1} y_l m_i l'_l R'_2 + z_i R_2 \sum_{k=1}^{n_1} y_k l_k m'_j + m_i d'_j + d_i m'_j \right] \\ & + \frac{1}{(t-1)^2}\left[m_i m'_j + z_j \sum_{l=1}^{n_1} y_l m_i l'_l R'_2 + z_i R_2 \sum_{k=1}^{n_1} y_k l_k m'_j + z_i z_j R_2 \sum_{k,l=1}^{n_1} y_k y_l l_k l'_l R'_2 \right. \\ & \left. + z_i R_2 \sum_{k=1}^{n_1} y_k l_k d'_j + z_j \sum_{l=1}^{n_1} y_l d_i l'_l R'_2 + m_i d'_j + d_i m'_j + d_i d'_j \right], \\ & i, j = 1, \cdots, n_2, \end{aligned} \tag{B5}$$

$$\begin{aligned} l_{it}m'_{jt} = {} & l_i m'_j - \frac{1}{t-1}\left[2l_i m_j + z_j \sum_{l=1}^{n_1} y_l l_i l'_l R'_2 + y_i R_1 \sum_{k=1}^{n_2} z_k m_k m'_j + l_i d'_j + c_i m'_j \right] \\ & + \frac{1}{(t-1)^2}\left[l_i m'_j + z_j \sum_{l=1}^{n_1} y_l l_i l'_l R'_2 + y_i R_1 \sum_{k=1}^{n_2} z_k m_k m'_j + y_i z_j R_1 \sum_{k=1}^{n_2} \sum_{l=1}^{n_1} z_k y_l m_k l'_l R'_2 \right. \\ & \left. + y_i R_1 \sum_{k=1}^{n_2} z_k m_k d'_j + z_j \sum_{l=1}^{n_2} y_l c_i l'_l R'_2 + l_i d'_j + c_i m'_j + c_i d'_j \right], \\ & i = 1, \cdots, n_1, \quad j = 1, \cdots, n_2. \end{aligned} \tag{B6}$$

Let Λ_{ij}^t, M_{ij}^t, K_{ij}^t be defined as in (34), let c_i, $d_i = 0$ for simplicity and w.l.o.g.. We take expectation in (B4)-(B6) and drop for convenience the superscript $t-1$ from Λ_{ij}^{t-1}, M_{ij}^{t-1}, K_{ij}^{t-1} in the right-hand side. (When taking expectations, we use the fact that l_i^{t-1}, m_i^{t-1} are independent of $y_{1,t-1}$, $y_{2,t-1}$.) We obtain:

$$\begin{aligned} \Lambda_{ij}^t = {} & \Lambda_{ij} - \frac{1}{t-1}\left[2\Lambda_{ij} + \sigma_j K_{ij} R'_1 + \sigma_i R_1 (K_{ij})' \right] \\ & + \frac{1}{(t-1)^2}\left[\Lambda_{ij} + \sigma_j K_{ij} R'_1 + \sigma_i R_1 (K_{ij})' \right. \\ & \left. + \begin{cases} \sigma_i \sigma_j R_1 (M_{ij} + M_{ji}) R'_1, & \text{if } i \neq j \\ R_1 \left(\sum_{\substack{k=1 \\ k \neq i}}^{n_2} M_{kk} + E(y_i^2 z_i^2) M_{ii} \right) R'_1, & \text{if } i \neq j \end{cases} \right], \\ & i, j = 1, \cdots, n_1, \end{aligned} \tag{B7}$$

$$M_{ij}^{t} = M_{ij} - \frac{1}{t-1}[2M_{ij} + \sigma_j K_{ij} R_2' + \sigma_i R_1 (K_{ij})'] + \frac{1}{(t-1)^2}\mathscr{L}_2(\Lambda_{ij}\text{'s})$$

(B8)

$$i, j = 1, \cdots, n_2 \text{ and } \sigma_i = 0 \quad \text{if } i > n_1,$$

$$\sigma_j = 0 \quad \text{if } j > n_1,$$

$$K_{ij}^{t} = K_{ij} - \frac{1}{t-1}[2K_{ij} + \sigma_j \Lambda_{ij} R_2' + \sigma_i R_1 M_{ij}] + \frac{1}{(t-1)^2}\mathscr{L}_3(\Lambda_{ij}, M_{ij}, K_{ij}\text{'s}),$$

(B9)

$$i = 1, \cdots, n_1, \quad \sigma_i = 0 \text{ if } i > n_1,$$

$$j = 1, \cdots, n_2, \quad \sigma_j = 0 \text{ if } j > n_2.$$

Defining N_t and Q as in (35), (36) we see that (B7)-(B9) can be written in compact form as in (37).

Appendix C. Let $x_t = (l_{it}', \cdots, l_{n_1,t}', m_{1,t}', \cdots, m_{n_2,t}')$. Using (27) or the equivalent (B2), (B3) we have

$$x_{t+1} = x_t - \frac{1}{t}[R(y_{1t}, y_{2t})x_t] \tag{C1}$$

where the definition of $R(y_{1t}, y_{2t}) = \bar{R}_t$ is obvious from (B2), (B3). From (C1) we obtain

$$\|x_{t+1}\|^2 = \|x_t\|^2 - \frac{2}{t} x_t' \bar{R}_t x_t + \frac{1}{t^2} x_t' \bar{R}_t' \bar{R}_t x_t. \tag{C2}$$

It holds

$$\begin{aligned} &E[\|x_{t+1}\|^2 - \|x_t\|^2 | \|x_1\|^2, \cdots, \|x_t\|^2] \\ &\quad = E[E[\|x_{t+1}\|^2 - \|x_t\|^2 | \|x_1\|^2, \cdots, \|x_t\|^2] | x_1, \cdots, x_t], \end{aligned} \tag{C3}$$

$$\begin{aligned} E[x_t' \bar{R}_t x_t | \|x_1\|^2, \cdots, \|x_t\|^2] &= E[E[x_t' \bar{R}_t x_t | \|x_1\|^2, \cdots, \|x_t\|^2] | x_1, \cdots, x_t] \\ &= E[E[x_t' \bar{R}_t x_t | x_1, \cdots, x_t] | x_1, \cdots, x_t] | \|x_1\|^2, \cdots, \|x_t\|^2] \\ &= E[x_t' E[\bar{R}_t | x_1, \cdots, x_t] x_t | \|x_1\|^2, \cdots, \|x_t\|^2] \\ &= E[x_t' R_1 x_t | \|x_1\|^2, \cdots, \|x_t\|^2], \end{aligned} \tag{C4a}$$

since R_t depends only on y_{1t}, y_{2t} which are independent of $x_1, \cdots, x_t$ and where R_1 is a constant matrix defined by

$$E[R(y_{1t}, y_{2t})] = R_1. \tag{C4b}$$

Similarly

$$E[x_t' \bar{R}_t \bar{R}_t x_t | \|x_1\|^2, \cdots, \|x_t\|^2] = E[x_t' R_2 x_t | \|x_1\|^2, \cdots, \|x_t\|^2] \tag{C4c}$$

where R_2 is a constant matrix defined by

$$E[R'(y_{1,t}, y_{2,t}) R(y_{1t}, y_{2t})] = R_2. \tag{C5}$$

From (C3)-(C5) we obtain

$$\begin{aligned} &E[\|x_{t+1}\|^2 - \|x_t\|^2 | \|x_1\|^2, \cdots, \|x_t\|^2] \\ &\quad = E\left[x_t' \left(-\frac{2}{t} R_1 + \frac{1}{t^2} R_2\right) x_t | \|x_1\|^2, \cdots, \|x_t\|^2\right]. \end{aligned} \tag{C6}$$

It holds

$$-\frac{\alpha}{t} I \leqq -\frac{2}{t} R_1 + \frac{1}{t^2} R_2 \leqq \frac{\alpha}{t} I \tag{C7}$$

for some positive constant α and thus

$$\begin{aligned} &\left| \left[E \left[x_t' \left(-\frac{2}{t} R_1 + \frac{1}{t^2} R_2 \right) x_t \middle| \|x_1\|^2, \cdots, \|x_t\|^2 \right] \right] \right| \\ &\leqq \frac{\alpha}{t} E[\|x_t\|^2 | \|x_1\|^2, \cdots, \|x_t\|^2] = \frac{\alpha}{t} \|x_t\|^2. \end{aligned} \tag{C8}$$

Let $V_t = \|x_t\|^2$; then from (C6) and (C7) we obtain

$$|E[V_{t+1} - V_t | V_1, \cdots, V_t]| \leqq \frac{\alpha}{t}. \tag{C9}$$

THE LINEAR-QUADRATIC OPTIMAL CONTROL PROBLEM WITH DELAYS IN STATE AND CONTROL VARIABLES: A STATE SPACE APPROACH*

M. C. DELFOUR†

Abstract. This paper generalizes the results of Vinter and Kwong to a control operator with a more general delay structure than the one in A. Ichikawa and to delay systems with both finite and infinite memories. The linear-quadratic optimal control problem over both finite and infinite time horizons is treated. Several forms of associated abstract Riccati differential and algebraic equations are presented. The properties of the kernel of the solution are studied and a coupled set of matrix ordinary and partial differential equations is obtained.

Key words. optimal control, delays, state space, state control

AMS(MOS) subject classifications. 34, 29, 93

1. Introduction. The linear quadratic optimal control theory of systems with delays in state and control variables has been studied by several authors from different view points (cf. A. Ichikawa [1], [2], [3], Koivo and Lee [1], R. H. Kwong [1], [2], [3], Kwong and Willsky [1], [2], L. Pandolfi [1], [2], Vinter and Kwong [1]). Recently state-space techniques have been emphasized and two concepts of state have been proposed: the first one by A. Ichikawa [1], [2], [3] and the second one by Vinter and Kwong [1]. Both approaches lead to some Riccati equations. The work of A. Ichikawa [3] aims at a general theory for a family of evolution equations with a control operator containing a *finite number of pure delays*; the work of Vinter and Kwong [1] deals with differential delay equations in $\mathbb{R}^n$ and a less general control operator which does not contain pure delays.

The object of this paper is to generalize the results of Vinter and Kwong [1] to a *control operator with a more general delay structure* than the one in A. Ichikawa [3] and to *delay systems with both finite and infinite memory.* Finite time and infinite time optimal control problems will be covered. We do not attempt to extend our result to abstract evolution equations in a Hilbert space. We emphasize the basic state space theory of a differential system with delays in state and control variables (§ 4). Three sets of differential equations are derived for the decoupling operator: the standard operator Riccati equation, a new weak form of the equation, and a coupled set of matrix ordinary and partial differential equations for the kernel of the decoupling operator. The first one is a generalization of the one of Vinter and Kwong [1] and several numerical methods are available to approximate its solution. The second one is new and can advantageously be used to construct direct Galerkin full discretization (in space and time variables) methods nicely incorporating the natural characteristics of delay systems. A detailed discussion of those methods is unfortunately beyond the scope of this paper. The last set of coupled matrix differential equations is a complement to the first two. In specific applications and for certain classes of delay systems, it can become a very useful tool in the analysis of the structure of the feedback law. A recent and striking example of this philosophy can be found in the recent work of A. Manitius

on the design of feedback controllers for a wind tunnel. He used this set of equations to obtain the structure of the feedback law. He then numerically adjusted the parameters to meet other design criteria. So it is not possible to priviledge a single tool in the analysis and solution of linear quadratic problems. The issue is not to play one method against another one. Those tools and others are available to the designer who uses his experience and judgment in specific applications.

The presence of pure delays in the control operator makes it an unbounded operator (in the state space formulation). This creates new difficulties in the modelling and the solution of this linear quadratic problem; it necessitates special techniques which bear a certain similarity with those encountered in the analysis of parabolic systems with boundary control through a Dirichlet condition (cf. Delfour and Sorine [1]). It must be stressed that the techniques of A. Ichikawa [3] only apply to control operators with a special delay structure (a finite number of pure delays and an integral term on the length of the memory); they do not apply to the general delay structure we shall consider in this paper.

In § 2, we give the fundamental lemma which asserts that the conditions of Borisovic and Turbabin [1] are always verified for linear time-invariant delay-differential equations with finite or infinite memory. This is a special case of M. Delfour [3]. We also extend the concepts of hereditary operators and state found in Vinter and Kwong [1].

In § 3, the statement and solution of the linear quadratic optimal control problem on $[0, T]$ are provided. It is shown that the decoupling operator $\Pi(t)$ is a linear continuous transformation of the space M^2 ($M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$, $0 < h \leqq +\infty$, cf. Notation). However this is not sufficient to obtain a Riccati differential equation for $\Pi(t)$ and it is necessary to embed our optimal control problem into a larger family with initial data and right-hand side in a "bigger" space.

In § 4, the method of transposition is used to make sense of the solution of the state equation for more general data. Fundamental isomorphisms are characterized and an *integration by parts formula* is obtained; perturbation theorems are also presented. To our knowledge the results contained in Theorem 4.5 are new.

In § 5, the original optimal control problem (OCP) is embedded in an enlarged class of OCP's. The solution of this new OCP leads to an optimality system, the use of decoupling techniques and the construction of a Riccati differential equation. It is interesting to notice that the decoupling operator is a "smoothing operator." We essentially follow the method of J. L. Lions [1].

In § 6, we construct the matrix function associated with the decoupling operator $P(t)$, study its properties and derive a set of coupled ordinary and partial differential equations for it. We recover as a special case the equations given by Koivo and Lee [1] and R. H. Kwong [3] for a single delay in the state and control variables. Our results also generalize the linear quadratic optimal control theory of delay systems without delays in the control variable (cf. M. C. Delfour [4] and [1], and Delfour, Lee and Manitius [1]).

In § 7, we solve the infinite time optimal control problem, derive a Riccati equation for the decoupling operator P and a set of coupled partial differential matrix equations for the kernel of P. To our knowledge the techniques used in that section are new.

Some of the results presented in this paper have been announced without proofs in M. C. Delfour [2], [5].

Notation. $\mathbb{R}$ will denote the field of real numbers and, for an arbitrary integer $n \geqq 1$, $\mathbb{R}^n$ will be the n-dimensional Euclidean space. The norm of x in $\mathbb{R}^n$ and the inner product of x and y in $\mathbb{R}^n$ will be written $|x|$ and $x \cdot y$, respectively.

Given $-\infty \leqq a \leqq b \leqq +\infty$, $I(a, b) = \mathbb{R} \cap [a, b]$. For a real Banach space X, $L^2(a, b; X)$ will denote the space of all equivalence classes of square integrable Lebesgue measurable functions on $I(a, b)$ into X. The derivative of a function x on $I(a, b)$ into X will be denoted by $\dot{x}$, dx/dt, Dx or $D_t x$ (in the distributional sense). The Sobolev space of all functions y in $L^2(a, b; X)$ with distributional derivatives $D_t^j y$, $j = 1, \cdots, m$, in $L^2(a, b; X)$ will be written $H^m(a, b; X)$.

$C(a, b; X)$ will be the Banach space of all bounded continuous functions x from $I(a, b)$ into X; when $a = -\infty$, $b = +\infty$, or both, $C_0(a, b; X)$ will be the Banach space of bounded continuous functions vanishing at infinity $C_0(a, b; X) = \{x \in C(a, b; X) | \forall \varepsilon > 0, \exists \text{ compact } K \subset I(a, b), \text{ such that } |x(t)| < \varepsilon, \forall t \in K^c\}$, where K^c is the complement of K with respect to $I(a, b)$,

$$K^c = \{t \in I(a, b) | t \notin K\};$$

when a and b are finite we define $C_0(a, b; X)$ as $C(a, b; X)$. $C_c(a, b; X)$ will be the subspace of functions of $C(a, b; X)$ with compact support in $]a, b[$. It is not to be confused with the space of bounded continuous functions with support in $I(a, b)$. In general, the two spaces do not coincide except on $I(-\infty, \infty)$. In addition to the above function spaces, we shall also use the notation

$$\mathscr{F}_{\text{loc}}(a, \infty; X) = \{y: I(a, \infty) \to X | \forall T > a, y|_{I(a,T)} \in \mathscr{F}(a, T; X)\}$$

for any function space $\mathscr{F}$ (for instance, $\mathscr{F}$ can be C, L^2, H^1, etc.).

Given a real measure μ on a σ-algebra of subsets of a set S, $|\mu|$ will denote the total variation of μ (cf. W. Rudin [1, pp. 117–118]). The total variation of an $n \times m$ matrix β of real measures $\{\beta_{ij} | 1 \leqq i \leqq n, 1 \leqq j \leqq m\}$ is defined as

$$|\beta| = \left\{ \sum_{i=1}^{n} \sum_{j=1}^{m} |\beta_{ij}|^2 \right\}^{1/2},$$

where $|\beta_{ij}|$ is the total variation of β_{ij}.

Given two real Banach spaces X and Y, $\mathscr{L}(X, Y)$ will denote the space of all bounded (or continuous) linear maps from X to Y. The topological dual of X will be written X' and the duality pairing $(x^*, x) \to \langle x^*, x \rangle_X : X' \times X \to \mathbb{R}$. The transpose of an operator T in $\mathscr{L}(X, Y)$ will be denoted $T^* \in \mathscr{L}(Y', X')$.

When X is a Hilbert space, the inner product in $L^2(a, b; X)$ will be denoted $(\ ,\ )_2$. The inner product of two elements $\phi = (\phi^0, \phi^1)$ and $\psi = (\psi^0, \psi^1)$ in the space $M^2 = X \times L^2(-h, 0; X)$, $0 < h \leqq +\infty$, will be defined and denoted as follows:

$$((\phi, \psi)) = \phi^0 \cdot \psi^0 + (\phi^1, \psi^2)_2.$$

$\mathscr{D}(]a, b[; \mathbb{R}^n)$ will denote the vector space of all infinitely continuously differentiable functions from $]a, b[$ into $\mathbb{R}^n$.

In the paper we shall introduce several continuous injections (typ. $L: X \to Y$). The same notation will be used to denote the injection of a space of functions from $I(a, b)$ to X into another space of functions from $I(a, b)$ to Y (typ. $L: L^2(a, b; X) \to L^2(a, b; Y)$, $(Lx)(t) = Lx(t)$ for almost all t in $I(a, b)$). Also the integral of a function $t \to f(t): I(a, b) \to X$ will often be written $\int_a^b f\, dt$ instead of $\int_a^b f(t)\, dt$. This notation is more economical.

Given a Hilbert space V, we shall say that an element T in $\mathscr{L}(V', V)$ is symmetrical if

$$\forall v, w \in V', \qquad \langle v, Tw \rangle_V = \langle w, Tv \rangle_V;$$

we shall say that T is positive if

$$\forall v \in V', \qquad \langle v, Tv\rangle_V \geqq 0.$$

Given an $n \times m$ matrix M ($n \geqq 1$, $m \geqq 1$, integers) the transposed of the $m \times n$ matrix M will be denoted M^T.

2. System description and basic theory. Let h, $0 < h \leqq +\infty$, be the length of the memory of our system. When h is finite, we say that it has *finite memory*; when $h = +\infty$, we say that it has *infinite memory*. Let $B: C_0(-h, 0; \mathbb{R}^m) \to \mathbb{R}^n$ and $L: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n$ be continuous linear maps. Consider the system of equations

$$\begin{aligned} &\frac{dx}{dt}(t) = Lx_t + Bu_t + f^0(t), \qquad t \geqq 0, \\ &x(0) = \phi^0, \quad x_0 = \phi^1, \quad u_0 = w, \end{aligned} \tag{2.1}$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, $(\phi^0, \phi^1) \in M^2$, $w \in L^2(-h, 0; \mathbb{R}^m)$, $f^0 \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^n)$, $u \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^m)$ and u_t and x_t are defined as follows:

$$u_t(\theta) = \begin{cases} u(t+\theta), & t+\theta \geqq 0, \\ w(t+\theta), & \text{otherwise}, \end{cases} \qquad x_t(\theta) = \begin{cases} x(t+\theta), & t+\theta \geqq 0, \\ \phi^1(t+\theta), & \text{otherwise}. \end{cases} \tag{2.2}$$

2.1. Existence and uniqueness theory. For a fixed real number $a > 0$ and a continuous function y in $C_0(-h, a; \mathbb{R}^n)$ (resp. v in $C_0(-h, a; \mathbb{R}^m)$), the functions $t \to (\mathscr{L}y)(t) = Ly_t$ (resp. $t \to (\mathscr{B}v)(t) = Bv_t$) belong to $C(0, a; \mathbb{R}^n)$. Though the function y (resp. v) does not have a pointwise meaning for a function y in $L^2(-h, a; \mathbb{R}^n)$ (resp. v in $L^2(-h, a; \mathbb{R}^m)$), we shall show that it globally makes sense as an element of $L^2(0, a; \mathbb{R}^n)$. This amounts to showing that the three conditions of Borisovic and Turbabin [1] are always verified for delay systems with both finite and infinite memories.

LEMMA 2.1. *Fix h, $0 < h \leqq +\infty$, and the continuous linear map $B: C_0(-h, 0; \mathbb{R}^m) \to \mathbb{R}^n$ (resp. $L: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n$).*

(i) *There exists a unique $n \times m$ (resp. $n \times n$) matrix β (resp. η) of real regular Borel measures such that*

$$\begin{aligned} &Bw = \int_{-h}^{0} d_\theta \beta w(\theta) \quad \forall w \in C_0(-h, 0; \mathbb{R}^m) \\ &\left(\text{resp. } L\phi = \int_{-h}^{0} d_\theta \eta \phi(\theta) \quad \forall \phi \in C_0(-h, 0; \mathbb{R}^n).\right. \end{aligned} \tag{2.3}$$

(ii) *Let $a > 0$ be a fixed real number. For each v in $C_c(-h, a; \mathbb{R}^m)$ (resp. y in $C_c(-h, a; \mathbb{R}^n)$) the function $\mathscr{B}v$ (resp. $\mathscr{L}y$),*

$$t \to (\mathscr{B}v)(t) = Bv_t : [0, a] \to \mathbb{R}^n \qquad (\text{resp. } t \to (\mathscr{L}y)(t) = Ly_t : [0, a] \to \mathbb{R}^n) \tag{2.4}$$

is continuous and the map

$$\begin{aligned} &v \to \mathscr{B}v : C_c(-h, a; \mathbb{R}^m) \to L^2(0, a; \mathbb{R}^n) \\ &(\text{resp. } y \to \mathscr{L}y : C_c(-h, a; \mathbb{R}^n) \to L^2(0, a; \mathbb{R}^n)) \end{aligned} \tag{2.5}$$

is linear and continuous.

(iii) *The map $\mathscr{B}$ (resp. $\mathscr{L}$) extends to a continuous linear map defined on $L^2(-h, a; \mathbb{R}^m)$ (resp. $L^2(-h, a; \mathbb{R}^n)$)*

$$\mathscr{B} : L^2(-h, a; \mathbb{R}^m) \to L^2(0, a; \mathbb{R}^n) \qquad (\text{resp. } \mathscr{L} : L^2(-h, a; \mathbb{R}^n) \to L^2(0, a; \mathbb{R}^n)). \tag{2.6}$$

Proof. Cf. Appendix to § 2. □

Remark 2.1. For convenience we shall often use the notation Bv_t (resp. Ly_t) instead of $(\mathcal{B}v)(t)$ (resp. $(\mathcal{L}y)(t)$) for v in $L^2(-h, a; \mathbb{R}^m)$ (resp. y in $L^2(-h, a; \mathbb{R}^n)$).

Remark 2.2. For h finite, Lemma 2.1 is essentially Theorem 2.1 in Delfour and Manitius [1]. However, to our knowledge, this result is new for $h = +\infty$.

Lemma 2.1 says that we can now make sense of the right-hand side of (2.1) for all:

$$T>0, \quad x \text{ in } L^2(0, T; \mathbb{R}^n), \quad u \text{ in } L^2(0, T; \mathbb{R}^m), \tag{2.7}$$
$$\phi^1 \text{ in } L^2(-h, 0; \mathbb{R}^n), \quad w \text{ in } L^2(-h, 0; \mathbb{R}^m).$$

Since the maps $\mathcal{B}$ and $\mathcal{L}$ are defined between spaces of L^2-functions, it is possible to rewrite (2.1) in a way which separates the solution x and the control u defined on $[0, \infty[$ from the initial functions ϕ^1 and w on $I(-h, 0)$,

$$\dot{x} = \mathcal{L}(e_+^0 x + e_-^0 \phi^1) + \mathcal{B}(e_+^0 u + e_-^0 w) + f^0, \qquad x(0) = \phi^0, \tag{2.8}$$

where for an arbitrary function z defined on $I(a, b)$, $-\infty \leqq a < b \leqq +\infty$, and an arbitrary $s \in I(a, b)$

$$(e_+^s z)(t) = \begin{cases} z(t), & t \in I(s, b), \\ 0, & \text{otherwise}, \end{cases} \quad \left(\text{resp. } (e_-^s z)(t) = \begin{cases} 0, & \text{otherwise} \\ z(t), & t \in I(a, s) \end{cases} \right). \tag{2.9}$$

Notice that the terms in ϕ^1 and w are zero outside the interval $I(0, h)$. This suggests the introduction of the following *structural operators*

$$H: L^2(-h, 0; \mathbb{R}^n) \to L^2(-h, 0; \mathbb{R}^n), \qquad K: L^2(-h, 0; \mathbb{R}^m) \to L^2(-h, 0; \mathbb{R}^n) \tag{2.10}$$

which are defined for each α in $I(-h, 0)$ as

$$(H\phi^1)(\alpha) = \mathcal{L}(e_-^0 \phi^1)(-\alpha), \qquad (Kw)(\alpha) = \mathcal{B}(e_-^0 w)(-\alpha). \tag{2.11}$$

It is readily seen that for ϕ^1 in $C_0(-h, 0; \mathbb{R}^n)$ and w in $C_0(-h, 0; \mathbb{R}^m)$

$$(H\phi^1)(\alpha) = \int_{-h}^{\alpha} d\eta(\theta)\phi^1(\theta - \alpha), \qquad (Kw)(\alpha) = \int_{-h}^{\alpha} d\beta(\theta) w(\theta - \alpha). \tag{2.12}$$

In Delfour and Manitius [1, Thm. 2.1, p. 470], the first identity (2.12) was used to define H on $C(-h, 0; \mathbb{R}^n)$, $h < +\infty$; then it was shown that H has a continuous extension to $L^2(-h, 0; \mathbb{R}^n)$ which coincides with the operator defined by the first identity (2.11).

In view of (2.8) and (2.11), (2.1) is of the form

$$\dot{x} = \mathcal{L}(e_+^0 x) + \mathcal{B}(e_+^0 u) + f^0 + \mathcal{E}(\xi^1), \qquad x(0) = \xi^0, \tag{2.13}$$

where

$$\xi = (\xi^0, \xi^1) = (\phi^0, H\phi^1 + Kw) \in M^2, \tag{2.14}$$

and $\mathcal{E}$ is the continuous linear map from $L^2(-h, 0; \mathbb{R}^n)$ into $L^2_{\text{loc}}(0, \infty; \mathbb{R}^n)$ defined as

$$\mathcal{E}(\xi^1)(t) = (e_+^{-h}\xi^1)(-t), \qquad t \in I(0, \infty). \tag{2.15}$$

But (2.13) still makes sense for arbitrary ξ^1 in $L^2(-h, 0; \mathbb{R}^n)$. We summarize our conclusions in the next theorem.

THEOREM 2.2. (i) *Equation* (2.1) (*or, more accurately,* (2.8)) *has a unique solution* x *in* $H^1_{\text{loc}}(0, \infty; \mathbb{R}^n)$ *and for each* $T > 0$ *there exists a constant* $c > 0$ *such that*

$$\|x\|_{H^1(0,T;\mathbb{R}^n)} \leqq c[\|u\|_{L^2(0,T;\mathbb{R}^m)} + \|f^0\|_{L^2(0,T;\mathbb{R}^n)} + \|(\phi^0, H\phi^1 + Kw)\|_{M^2}]. \tag{2.16}$$

(ii) *For arbitrary* $\xi=(\xi^0,\xi^1)$ *in* M^2 (ξ *not related to* ϕ), (2.13) *has a unique solution* x *in* $H^1_{\text{loc}}(0,\infty;\mathbb{R}^n)$ *and for each* $T>0$, *there exists a constant* $c>0$ *such that*

$$\|x\|_{H^1(0,T;\mathbb{R}^n)}\leqq c[\|u\|_{L^2(0,T;\mathbb{R}^m)}+\|f^0\|_{L^2(0,T;\mathbb{R}^n)}+\|\xi\|_{M^2}]. \tag{2.17}$$

Proof. By standard arguments. See also M. Delfour [3]. □

2.2. Associated semigroups. Let w, u and f^0 be zero in (2.1). The solution x of (2.1) generates a strongly continuous semigroup $\{S(t)\}$ of class C_0 on M^2

$$S(t)(\phi^0,\phi^1)=(x(t),x_t) \tag{2.18}$$

with infinitesimal generator

$$\begin{aligned} &A(\phi^0,\phi^1)=(L\phi^1, D_\theta\phi^1) \quad \forall\phi=(\phi^0,\phi^1)\in\mathcal{D}(A),\\ &\mathcal{D}(A)=\{(\phi^0,\phi^1)\colon \phi^1\in H^1(-h,0;\mathbb{R}^n),\ \phi^0=\phi^1(0)\}. \end{aligned} \tag{2.19}$$

Notice that the above characterization of the operator A implies the following lemma which can also be proved directly.

LEMMA 2.3. $H^1(-\infty,0;\mathbb{R}^n)\subset C_0(-\infty,0;\mathbb{R}^n)$ *and the injection is continuous.*

Proof. Cf. Appendix to § 2. □

Associate with system (2.1) the following "transposed" system

$$\frac{dz}{dt}(t)=L^Tz_t,\quad t\geqq 0,\quad z(0)=\psi^0,\quad z_0=\psi^1, \tag{2.20}$$

where the operator $L^T\colon C_0(-h,0;\mathbb{R}^n)\to\mathbb{R}^n$,

$$L^T\psi=\int_{-h}^{0}d\eta(\theta)^T\psi(\theta),\qquad \psi\in C_0(-h,0;\mathbb{R}^n), \tag{2.21}$$

is in some sense the "transpose" of L. As above the solution of system (2.20) generates a strongly continuous semigroup $\{S^T(t)\}$ of class C_0 on M^2

$$S^T(t)(\psi^0,\psi^1)=(z(t),z_t),\qquad t\geqq 0, \tag{2.22}$$

with infinitesimal generator

$$A^T(\psi^0,\psi^1)=(L^T\psi^1, D_\theta\psi^1),\quad \forall(\psi^0,\psi^1)\in\mathcal{D}(A^T),\quad \mathcal{D}(A^T)=\mathcal{D}(A). \tag{2.23}$$

From the theory of semigroups of class C_0 we know that for each ψ in $\mathcal{D}(A^T)$ the map $t\to S^T(t)\psi$ defined on $[0,\infty[$ belongs to $C^1(0,T;M^2)\cap C(0,T;\mathcal{D}(A^T))$ for all $T>0$, when $\mathcal{D}(A^T)$ is endowed with the graph topology of A^T.

We shall denote by V *the Hilbert space* $\mathcal{D}(A^T)$ *endowed with the norm*

$$\|\psi\|_V=[\|\psi\|^2_{M^2}+\|A^T\psi\|^2_{M^2}]^{1/2}. \tag{2.24}$$

The restriction of $S^T(t)$ to V also generates a strongly continuous semigroup $\{S^T_V(t)\}$ of class C_0 on V with infinitesimal generator

$$\begin{aligned} &A^T_V(\psi^0,\psi^1)=(L^T\psi^1, D_\theta\psi^1)\quad \forall(\psi^0,\psi^1)\in\mathcal{D}(A^T_V),\\ &\mathcal{D}(A^T_V)=\{(\psi^0,\psi^1)\colon \psi^1\in H^2(-h,0;\mathbb{R}^n),\ \psi^0=\psi^1(0),\ L^T\psi^1=D\psi^1(0)\}. \end{aligned} \tag{2.25}$$

The space V is isomorphic to the Sobolev space $H^1(-h,0;\mathbb{R}^n)$ since the map

$$\psi\to J\psi=(\psi(0),\psi)\colon H^1(-h,0;\mathbb{R}^n)\to V \tag{2.26}$$

is clearly a continuous bijection. In fact one could define the analogue $\{\bar S^T_V(t)\}$ of the

semigroup $\{S_V^T(t)\}$ directly on $H^1(-h, 0; \mathbb{R}^n)$ as follows:

$$[\bar{S}_V^T(t)]\psi](\theta) = y(t+\theta), \qquad \theta \in I(-h, 0), \tag{2.27}$$

where y is the solution of

$$\frac{dy}{dt} = L^T y_t, \qquad y_0 = \psi. \tag{2.28}$$

Its infinitesimal generator would be

$$(\bar{A}_V^T\psi)(\theta) = \begin{cases} L^T\psi, & \theta = 0, \\ D\psi(\theta), & \theta \neq 0, \end{cases} \qquad \mathcal{D}(\bar{A}_V^T) = \{\psi \in H^2(-h, 0; \mathbb{R}^n): L^T\psi = D\psi(0)\}. \tag{2.29}$$

2.3. Extension of the state space theory of Vinter and Kwong. We have seen that a knowledge of the pair $(\phi^0, H\phi^1 + Kw)$ at time 0 is sufficient to solve (2.1). So at time $t > 0$ it is sufficient to know

$$\hat{x}(t) = (x(t), Hx_t + Ku_t) \quad \text{in } M^2 \tag{2.30}$$

in order to solve (2.1) for all times greater than or equal to t. For the more general case of (2.13) with an arbitrary ξ^1, the definition of the L^2-component $\hat{x}^1(t)$ or $\hat{x}(t)$ must be modified as follows

$$[\hat{x}^1(t)](\theta) = (H(e_+^0 x)_t + K(e_+^0 u)_t)(\theta) + \mathcal{E}(\xi^1)(t-\theta). \tag{2.31}$$

More generally for arbitrary initial time $s \geqq 0$ and initial function ξ^1, (2.13) becomes

$$\dot{x}(t) = (\mathcal{L}(e_+^s x) + \mathcal{B}(e_+^s u) + f^0)(t) + \mathcal{E}(\xi^1)(t-s), \quad t \geqq s, \quad x(s) = \xi^0. \tag{2.32}$$

Denote by $x(t; s, \xi, u, f^0)$ the solution of (2.32) at time $t \geqq s$ and by $\hat{x}(t; s, \xi, u, f^0) = (\hat{x}^0(t), \hat{x}^1(t))$ in M^2 its state at time $t \geqq s$ defined as follows:

$$\begin{aligned} &\hat{x}^0(t) = x(t; s, \xi, u, f^0), \\ &\hat{x}^1(t)(\theta) = (H(e_+^s x)_t + K(e_+^s u)_t)(\theta) + \mathcal{E}(\xi^1)(t-s-\theta), \qquad \theta \in I(-h, 0). \end{aligned} \tag{2.33}$$

In their paper, Vinter and Kwong [1] have obtained an equation for the evolution of the state $\hat{x}(t) = \hat{x}(t; s, \xi, u, f^0)$ in M^2 in the case where the operator B is of the form

$$Bw = B_0 w(0) + \int_{-h}^{0} B_1(\theta) w(\theta)\, d\theta, \tag{2.34}$$

where B_0 and $B_1(\theta)$ are $n \times m$ matrices and the elements of the matrix $B_1(\theta)$ belong to $L^2(-h, 0; \mathbb{R})$. In this special situation, for any $T > 0$ and u in $L^2(-h, T; \mathbb{R}^m)$ the map $\mathcal{B}$ associated with B reduces to

$$(\mathcal{B}u)(t) = B_0 u(t) + \int_{-h}^{0} B_1(\theta) u(t+\theta)\, d\theta. \tag{2.35}$$

The object of this section is to extend the above mentioned results to all continuous linear $B: C_0(-h, 0; \mathbb{R}^m) \to \mathbb{R}^n$. This will be given in Theorem 2.7. It necessitates the following definition and technical lemmas.

DEFINITION 2.4. To fix h, $0 < h \leqq +\infty$, we fix the arbitrary continuous linear map $B: C_0(-h, 0; \mathbb{R}^m) \to \mathbb{R}^n$ (resp. $L: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n$) and its representation in terms of the $n \times m$ (resp. $n \times n$) matrix β (resp. η) of real regular Borel measures.

(i) We shall denote by B^T (resp. L^T) the following continuous linear map

$$\phi \to B^T\phi = \int_{-h}^{0} d_\theta \beta^T \phi(\theta) : C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^m, \tag{2.36}$$

$$\left(\text{resp. } \phi \to L^T\phi = \int_{-h}^{0} d_\theta \eta^T \phi(\theta) : C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n\right)$$

where β^T (resp. η^T) is the transposed $n \times m$ matrix β (resp. $n \times n$-matrix η) of real regular Borel measures.

(ii) For each ϕ in $C_0(-h, 0; \mathbb{R}^n)$ define the function

$$(K^T\phi)(\alpha) = \int_{-h}^{\alpha} d_\theta \beta^T \phi(\theta - \alpha) \qquad (\text{resp. } (H^T\phi)(\alpha) = \int_{-h}^{\alpha} d_\theta \eta^T \phi(\theta - \alpha)) \tag{2.37}$$

in $L^2(-h, 0; \mathbb{R}^m)$ (resp. $L^2(-h, 0; \mathbb{R}^n)$). As in Lemma 2.1 and in the discussion from (2.10) to (2.12), the linear map K^T (resp. H^T) extends to a continuous linear map $K^T : L^2(-h, 0; \mathbb{R}^n) \to L^2(-h, 0; \mathbb{R}^m)$ (resp. $H^T : L^2(-h, 0; \mathbb{R}^n) \to L^2(-h, 0; \mathbb{R}^n)$). □

LEMMA 2.5. *If H^* and K^* are the respective transposes of the maps $H : L^2(-h, 0; \mathbb{R}^n) \to L^2(-h, 0; \mathbb{R}^n)$ and $K : L^2(-h, 0; \mathbb{R}^m) \to L^2(-h, 0; \mathbb{R}^n)$, then $H^* = H^T$ and $K^* = K^T$.*

Proof. Cf. Delfour and Manitius [1, pp. 473-474]. □

LEMMA 2.6. *Let $a > 0$ be a fixed real number. For each z in $C_c(-h, a; \mathbb{R}^n)$ the function $\mathcal{B}^T z$ (resp. $\mathcal{L}^T z$) is defined as*

$$t \to (\mathcal{B}^T z)(t) = B^T z_t : [0, a] \to \mathbb{R}^m \tag{2.38}$$

$$(\text{resp. } t \to (\mathcal{L}^T z)(t) = L^T z_t : [0, a] \to \mathbb{R}^n).$$

(i) *The function $\mathcal{B}^T z$ (resp. $\mathcal{L}^T z)(t)$ is continuous and the continuous linear map*

$$z \to \mathcal{B}^T z : C_c(-h, a; R^n) \to L^2(0, a; \mathbb{R}^m) \tag{2.39}$$

$$(\text{resp. } z \to \mathcal{L}^T z : C_c(-h, a; \mathbb{R}^n) \to L^2(0, a; \mathbb{R}^n))$$

extends to a continuous linear map

$$\mathcal{B}^T : L^2(-h, a; R^n) \to L^2(-h, a; \mathbb{R}^m) \tag{2.40}$$

$$(\text{resp. } \mathcal{L}^T : L^2(-h, a; R^n) \to L^2(-h, a; \mathbb{R}^n)).$$

(ii) *For all $t > s$, z in $L^2(s, t; R^n)$ and x in $L^2(s, t; \mathbb{R}^n)$ (resp. u in $L^2(s, t; \mathbb{R}^m)$)*

$$\int_s^t z(t-r) \cdot (\mathcal{L} e_+^s x)(r)\, dr = \int_s^t (\mathcal{L}^T e_+^0 z)(t-r) \cdot x(r)\, dr, \tag{2.41}$$

$$(\text{resp. } \int_s^t z(t-r) \cdot (\mathcal{B} e_+^s u)(r)\, dr = \int_s^t (\mathcal{B}^T e_+^0 z)(t-r) \cdot u(r)\, dr).$$

Proof. Cf. Appendix to § 2. □

In the following theorem the map $j : V \to M^2$ is defined as the injection of V into M^2

$$j(\psi^0, \psi^1) = (\psi^0, \psi^1), \tag{2.42}$$

where V is endowed with the topology generated by the norm (2.24). *We shall also identify the elements of the topological dual $(M^2)'$ of M^2 with those of M^2.* This means that we obtain the following chain of continuous dense injections

$$V \xrightarrow{j} M^2 \equiv (M^2)' \xrightarrow{j^*} V'.$$

THEOREM 2.7. (i) *For each pair* $0 \leqq s \leqq t$,

$$j^*\hat{x}(t; s, \xi, u, f^0) = j^*S^T(t-s)^*\xi + \int_s^t S_V^T(t-r)^*[(B^TJ^{-1})^*u(r) + j^*(f^0(r), 0)]\, dr, \tag{2.43}$$

where $J: H^1(-h, 0; \mathbb{R}^n) \to V$ *is defined by* (2.26), *the same notation* B^T *is used for the restriction to the subspace* $H^1(-h, 0; \mathbb{R}^n)$ *of the map* $B^T: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^m$ ($H^1(-h, 0; \mathbb{R}^n)$ *is a subspace of* $C_0(-h, 0; \mathbb{R}^n)$, $0 < h \leqq +\infty$).

(ii) *For each pair* $0 \leqq s < T$, *the function* $\hat{x}(t) = \hat{x}(t; s, \xi, u, f^0)$, $s \leqq t \leqq T$, *is the unique solution in the space*

$$\mathcal{W}(s, T; M^2, V') = \left\{ y \in C(s, T; M^2) \,\middle|\, \frac{dj^*y}{dt} \in L^2(s, T; V') \right\} \tag{2.44}$$

of the equation

$$\frac{d}{dt}(j^*y(t)) = (A^T)^*y(t) + (B^TJ^{-1})^*u(t) + j^*(f^0(t), 0) \text{ in } V', \qquad y(s) = \xi, \tag{2.45}$$

where j^*, $(B^TJ^{-1})^*$ *and* $(A^T)^*$ *are the transposes of the maps* j, B^TJ^{-1} *and* $A^T: V \to M^2$.

(iii) *In weak form the first equation* (2.45) *is equivalent to*

$$\frac{d}{dt}((j\psi, y(t))) = ((A^T\psi, y(t))) + B^TJ^{-1}\psi \cdot u(t) + \psi^0 \cdot f^0(t), \qquad t \geqq s, \tag{2.46}$$

for all $\psi = (\psi^0, \psi^1)$ *in* V (*recall that for each* $\psi = (\psi^0, \psi^1) \in V$, $\psi^1 \in H^1(-h, 0; \mathbb{R}^n)$ *and* $\psi^0 = \psi^1(0)$).

(iv) *When* B *is of the form*

$$Bw = B_0w(0) + \int_{-h}^0 B_1(\theta)w(\theta)\, d\theta, \tag{2.47}$$

then

$$B^TJ^{-1}\phi = B_M^Tj\phi \quad \forall \phi \in V, \tag{2.48}$$

where $B_M^T: M^2 \to U$ *is the continuous linear map*

$$B_M^T(\phi^0, \phi^1) = B_0^T\phi^0 + \int_{-h}^0 B_1(\theta)^T\phi^1(\theta)\, d\theta. \tag{2.49}$$

For such a B, (2.43), (2.45) *and* (2.46) *reduce to*

$$\hat{x}(t; s, \xi, u, f^0) = S^T(t-s)^*\xi + \int_s^t S^T(t-r)^*[(B_M^T)^*u(r) + (f^0(r), 0)]\, dr, \tag{2.50}$$

$$\frac{d}{dt}(j^*y(t)) = (A^T)^*y(t) + j^*[(B_M^T)^*u(t) + (f^0(t), 0)] \text{ in } V', \qquad y(s) = \xi \text{ in } M^2, \tag{2.51}$$

$$\frac{d}{dt}((j\psi, y(t))) = ((A^T\psi, y(t))) + ((j\psi, (B_M^T)^*u(t) + (f^0(t), 0))), \tag{2.52}$$

for all ψ *in* V.

Proof. Cf. Appendix to § 2. □

Remark 2.3. Part (iv) of the theorem is precisely the special case covered by Vinter and Kwong [1]. It corresponds to the subfamily of all continuous linear operators

$B: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^m$ for which the operator $(B^T J^{-1})^*: U \to V'$ is continuous with values in M^2. This condition is equivalent to say that the continuous linear map $\psi \to B^T J^{-1} \psi: V \to U$ is continuous for the M^2-topology. So it can be extended to a continuous linear map $B_M^T: M^2 \to U$ such that $B^T J^{-1} = B_M^T j$.

3. The linear quadratic optimal control problem on [0, T]. Fix $T > 0$. Associate with the solution of (2.1) the quadratic cost function

$$J^T(u, \phi^0, \phi^1, w) = \int_0^T [Qx(t) \cdot x(t) + Nu(t) \cdot u(t)]\, dt, \tag{3.1}$$

where "$\cdot$" denotes the inner product in $\mathbb{R}^n$ or $\mathbb{R}^m$. Q and N are $n \times n$ and $m \times m$ symmetrical matrices. Q is positive semi-definite and N is positive definite:

$$Q^* = Q \geqq 0, \qquad N^* = N > 0. \tag{3.2}$$

The optimal control problem on the finite time horizon $[0, T]$ consists in finding a u^* in $L^2(0, T; \mathbb{R}^m)$ such that

$$J^T(u^*, \phi^0, \phi^1, w) = \operatorname{Inf}\{J^T(u, \phi^0, \phi^1, w): u \in L^2(0, T; \mathbb{R}^m)\}. \tag{3.3}$$

We have seen that system (2.1) can be expressed in state form by introducing the state $\hat{x}(t)$ which is a solution of (2.50) with $s = 0$ and ξ given by identity (2.14). The cost function (3.1) can be redefined in terms of $\hat{x}(t)$,

$$J^T(u, \phi^0, \phi^1, w) = \int_0^T [((\tilde{Q}\hat{x}(t), \hat{x}(t))) + Nu(t) \cdot u(t)]\, dt, \tag{3.4}$$

by introducing the linear transformation $\tilde{Q}$ of M^2

$$\tilde{Q}(\psi^0, \psi^1) = (Q\psi^0, 0). \tag{3.5}$$

The minimizing control u^* is completely characterized by the following optimality system

$$\frac{dj^*\hat{x}}{dt} = (A^T)^*\hat{x} + (B^T J^{-1})^* u^* + j^*(f^0, 0) \text{ in } V', \qquad \hat{x}(0) = (\phi^0, H\phi^1 + Kw), \tag{3.6}$$

$$u^*(t) = -N^{-1} B^T p(t), \tag{3.7}$$

$$\frac{djp}{dt} + A^T p + \tilde{Q}\hat{x} = 0, \qquad p(T) = 0, \tag{3.8}$$

where the solution p of (3.8) belongs to $C(0, T; V)$ since $\tilde{Q}\hat{x}(t) = (Qx(t), 0)$ and $p(T) = 0$. So (3.7) makes sense.

The next step consists in decoupling the Hamiltonian system

$$\frac{dj^*\hat{x}}{dt} = (A^T)\hat{x} - Rp + j^*(f^0, 0), \qquad \hat{x}(0) = (\phi^0, H\phi^1 + Kw), \tag{3.9}$$

$$R = (B^T J^{-1})^* N^{-1} B^T J^{-1},$$

$$\frac{djp}{dt} + A^T p + \tilde{Q}\hat{x} = 0, \qquad p(T) = 0. \tag{3.10}$$

To do that, we fix s, $0 \leqq s < T$, and consider the embedded problem

$$\operatorname{Inf}\{J_s^T(u, \xi): u \in L^2(s, T; \mathbb{R}^m)\}, \tag{3.11}$$

where

$$J_s^T(u,\xi)=\int_s^T [((\tilde{Q}y(t),y(t)))+Nu(t)\cdot u(t)]\,dt, \tag{3.12}$$

and y is the solution of

$$\frac{dj^*y}{dt}=(A^T)^*y+(B^TJ^{-1})^*u+j^*(f^0,0), \qquad y(s)=\xi. \tag{3.13}$$

The minimizing control is again completely characterized by the Hamiltonian system

$$\frac{dj^*y}{dt}=(A^T)^*y-Rq+j^*(f^0,0), \qquad y(s)=\xi, \tag{3.14}$$

$$\frac{djq}{dt}+A^Tq+\tilde{Q}y=0, \qquad q(T)=0. \tag{3.15}$$

Following the decoupling theory of J. L. Lions [1]

$$p(t)=\Pi(t)\hat{x}(t)+r(t) \text{ in } [0,T], \tag{3.16}$$

where $\Pi(t)$ is a continuous linear operator from M^2 into V and $r(t)$ a vector in V. $\Pi(t)$ and $r(t)$ are constructed from (3.14)-(3.15) as follows:

$$\frac{dj^*\beta}{dt}=(A^T)^*\beta-R\gamma, \qquad \beta(s)=\xi, \tag{3.17}$$

$$\frac{dj\gamma}{dt}+A^T\gamma+\tilde{Q}\beta=0, \qquad \gamma(T)=0, \tag{3.18}$$

$$\Pi(s)\xi=\gamma(s), \tag{3.19}$$

$$\frac{dj^*\phi}{dt}=(A^T)^*\phi-R\psi+j^*(f_0,0), \qquad \phi(s)=0, \tag{3.20}$$

$$\frac{dj\psi}{dt}+A^T\psi+\tilde{Q}\phi=0, \qquad \psi(T)=0, \tag{3.21}$$

$$r(s)=\psi(s). \tag{3.22}$$

The second step is the study of the properties of $\Pi(s)$ with respect to s. This is easy if $\Pi(s)$ is considered as an operator from M^2 into M^2. By standard arguments (cf. J. L. Lions [1]) it can be shown that for each ξ in M^2, the map $s\to j\Pi(s)\xi$ is at least weakly continuous, bounded and strongly measurable from $[0,T]$ into M^2. It is more difficult to obtain the same properties for the same map from $[0,T]$ with value in V.

To get around this technical problem, we are led to embed system (3.13) into a larger class of systems indexed by the initial time s in $[0,T[$, initial conditions ξ in V' and arbitrary functions f in $L^2(0,T;V')$ instead of $j^*(f^0,0)$. However, we must make sense of (3.13) and the cost function (3.12) for such data. The advantage of this approach is that with V' as space of initial data, the techniques of J. L. Lions [1] are available to show that the new decoupling operator, $P(s)$, is a continuous linear map from V' to V and that for all ξ in V' the map $s\to P(s)\xi:[0,T]\to V$ is weakly continuous bounded and strongly measurable.

The fundamental theory is given in § 4, used in § 5 to derive the Riccati differential equation for P, and, in § 6 to derive the differential equations for the kernel associated

with the decoupling operator. *In the sequel* $\Pi(t)$ *will denote the decoupling operator considered as a continuous linear operator from* M^2 *into* M^2 *and not from* M^2 *into* V. In particular the decoupling identity (3.16) will be rewritten in the form

$$jp(t) = \Pi(t)\hat{x}(t) + jr(t) \quad \text{in } [0, T]. \tag{3.23}$$

4. Fundamental isomorphisms. In this section we establish two fundamental isomorphisms, obtain an "integration by parts formula" and prove a perturbation theorem which will be used to obtain the Riccati differential equation. Since this section is rather technical, we summarize the notation which will be used. Define the space

$$W = R^n \times H^1(-h, 0; R^n) \tag{4.1}$$

endowed with the product norm

$$(\phi^0, \phi^1)_W^2 = |\phi^0|^2 + \|\phi^1\|_{H^1}^2. \tag{4.2}$$

Identify the elements of the dual $(M^2)'$ of M^2 with those of M^2 and define the chain of continuous dense injections:

$$H^1(-h, 0; \mathbb{R}^n) \underset{J^{-1}}{\overset{J}{\rightleftarrows}} V \xrightarrow{l} W \xrightarrow{i} M^2 \equiv (M^2)' \xrightarrow{i^*} W' \xrightarrow{l^*} V' \xrightarrow{J^*} (H^1)',$$

$$i(\phi^0, \phi^1) = (\phi^0, \phi^1), \quad l(\phi^0, \phi^1) = (\phi^0, \phi^1), \quad J(\phi) = (\phi(0), \phi), \quad J^{-1}(\phi^0, \phi^1) = \phi^1. \tag{4.3}$$

Given two spaces X, Y with canonical dense injection $i_X: X \to Y$, define for $T > 0$

$$\mathcal{W}(0, T; X, Y) = \{v \in C(0, T; X): D_t i_X v \in L^2(0, T; Y)\}. \tag{4.4}$$

4.1. Adjoint isomorphism. It is well known from semigroup theory that for $T > 0$, $\psi \in V$ and $g \in L^2(0, T; V)$ the function

$$v(t) = S_V^T(T-t)\psi + \int_t^T S_V^T(r-t)g(r)\, dr \tag{4.5}$$

is the unique solution in the space $\mathcal{W}(0, T; V, M^2)$ to the differential equation

$$D_t jv + A^T v + jg = 0, \qquad v(T) = \psi. \tag{4.6}$$

In addition for $T > 0$, $\psi \in V$ and $g^0 \in L^2(0, T; R^n)$ the function

$$v(t) = (p(t), p^t), \qquad t > 0, \tag{4.7}$$

constructed from the solution of the differential equation

$$\dot{p}(t) + L^T p^t + g^0(t) = 0, \qquad (p(T), p^T) = \psi \in V, \tag{4.8}$$

is the unique solution in $\mathcal{W}(0, T; V, M^2)$ to the differential equation

$$D_t jv + A^T v + (g^0(t), 0) = 0, \qquad v(T) = \psi. \tag{4.9}$$

We combine the two sets of results in one.

LEMMA 4.1. *Fix* $T > 0$. *For all* $\psi \in V$ *and* $g \in L^2(0, T; W)$, *there exists a unique solution* v *in* $\mathcal{W}(0, T; V, M^2)$ *to the differential equation*

$$D_t jv + A^T v + ig = 0, \qquad v(T) = \psi. \tag{4.10}$$

From the above lemma, the map

$$v \to (-(D_t jv + A^T v), v(T)): \mathcal{W}(0, T; V, M^2) \to L^2(0, T; M^2) \times V$$

is injective, linear and continuous. It is also surjective onto the subspace $L^2(0, T; W) \times V$. This suggests the definition of the space

$$\mathcal{V}(0, T) = \{v \in C(0, T; V) | -(D_t jv + A^T v) \in L^2(0, T; W)\} \tag{4.11}$$

endowed with the norm

$$\|v\|^2_{\mathcal{V}(0,T)} = \|v\|^2_{C(0,T;V)} + \|D_t jv + A^T v\|^2_{L^2(0,T;W)}. \tag{4.12}$$

The inclusion

$$-(D_t jv + A^T v) \in L^2(0, T; W)$$

is to be understood as follows

$$\exists w \in L^2(0, T; W) \quad \text{such that } -(D_t jv + A^T v) = iw.$$

Notation 4.1. It will be convenient to associate with each element v of $\mathcal{V}(0, T)$ the function

$$-[D_t + A^T]v \in L^2(0, T; W) \tag{4.13}$$

characterized by the identity

$$i[D_t + A^T]v = Djv + A^T v. \tag{4.14}$$

□

It can be shown by standard arguments that the space $\mathcal{V}(0, T)$ is a Banach space.

THEOREM 4.2. *The map*

$$v \to (-[D_t + A^T]v, v(T)) : \mathcal{V}(0, T) \to L^2(0, T; W) \times V \tag{4.15}$$

is an (algebraic and topological) isomorphism.

4.2. Transposed adjoint isomorphism. From standard semigroup theory we can always construct the continuous linear map

$$(f, \xi) \to x : L^2(0, T; V') \times V' \to C(0, T; V') \tag{4.16}$$

where

$$x(t) = S_V^T(t)^* \xi + \int_0^t S_V^T(t - r)^* f(r)\, dr, \qquad 0 \leqq t \leqq T. \tag{4.17}$$

We shall see in Lemma 4.3 that we can further characterize the image of the map (4.16) and construct an isomorphism between $L^2(0, T; V') \times V'$ and that image. This result is in fact completely general and independent of the special semigroup $S_V^T(t)^*$.

However it will not be sufficient four our purposes. We shall need the following additional property:

$$\exists z \in L^2(0, T; W') \quad \text{such that } l^* z(t) = x(t) \quad \text{a.e. in } [0, T], \tag{4.18}$$

where W' is the topological dual of the product space $W = \mathbb{R}^n \times H^1(-h, 0; \mathbb{R}^n)$. This property will be obtained with the help of the "method of transposition."

For the reader who is not familiar with the method of transposition, pertinent details will be given in Lemma 4.4. This method is widely used in the theory of partial differential equations to make sense of the solution of equations with "nonsmooth data." Its starting point is the construction of the so-called "adjoint isomorphism" which is an isomorphism between two Banach spaces of "smooth functions" for the associated "adjoint system." The transpose of that isomorphism is itself an isomorphism between the duals of the initial spaces of "smooth functions" endowed with their

respective norm topologies. It will be referred to as the "transposed adjoint isomorphism."

Coming back to our specific problem, the "transposed adjoint isomorphism" and the "integration by parts" formula will be given in Theorem 4.5. The first Lemma gives a general construction which applies to any strongly continuous semigroup of class C_0.

LEMMA 4.3. *Let $\mathcal{D}(A_V^T)$ be the domain of the operator $A_V^T: \mathcal{D}(A_V^T) \to V$ defined in* (2.25) *of* § 2.2. *With the topology defined by the norm*

$$\|v\|_{\mathcal{D}} = \{\|v\|_V^2 + \|A_V^T v\|_V^2\}^{1/2}, \tag{4.19}$$

$\mathcal{D}(A_V^T)$ is a Hilbert space. Denote by $j_V: \mathcal{D}(A_V^T) \to V$ the continuous linear injection of the subspace $\mathcal{D}(A_V^T)$ of V into V.

(i) *For all $T > 0$, ξ in V' and f in $L^2(0, T; V')$ the function*

$$x(t) = S_V^T(t)^*\xi + \int_0^t S_V^T(t-r)^* f(r)\, dr \tag{4.20}$$

is the unique solution in $\mathcal{W}(0, T; V', \mathcal{D}(A_V^T)')$ to the equation

$$\frac{dj_V^* x}{dt} - (A_V^T)^* x = j_V^* f, \qquad x(0) = \xi, \tag{4.21}$$

where $\mathcal{D}(A_V^T)'$ is the topological dual of the Hilbert space $\mathcal{D}(A_V^T)$ endowed with the norm (4.19) *and $(A_V^T)^*$ is the transpose of the continuous linear operator $A_V^T: \mathcal{D}(A_V^T) \to V$.*

(ii) *The subspace*

$$\mathcal{X}(0, T) = \{x \in \mathcal{W}(0, T; V', \mathcal{D}(A_V^T)') \mid D_t j_V^* x - (A_V^T)^* x \in L^2(0, T; V')\} \tag{4.22}$$

is a Banach space when it is endowed with the norm

$$\|x\|_{\mathcal{X}(0,T)}^2 = \|x\|_{C(0,T;V')}^2 + \|D_t j^* x - (A_V^T)^* x\|_{L^2(0,T;V')}^2. \tag{4.23}$$

(iii) *The map*

$$x \to ((D_t j_V^* - (A_V^T)^*)x, x(0)) : \mathcal{X}(0, T) \to L^2(0, T; V') \times V' \tag{4.24}$$

is an (algebraic and topological) isomorphism when the product space $L^2(0, T; V') \times V'$ is endowed with the norm

$$\|(f, \xi)\|_{L^2(0,T;V') \times V'} = \{\|f\|_{L^2(0,T;V')}^2 + \|\xi\|_{V'}^2\}^{1/2}. \tag{4.25}$$

Proof. By standard arguments. □

Notation 4.2. It will be convenient to associate with each element of the space $\mathcal{X}(0, T)$ the function

$$[D_t - (A_V^T)^*]x \in L^2(0, T; V') \tag{4.26}$$

which is characterized by the identity

$$j_V^*[D_t - (A_V^T)^*]x = D_t j_V^* x - (A_V^T)^* x. \tag{4.27}$$

With the above characterization

$$[D_t - (A_V^T)^*]j^* x = D_t j^* x - (A^T)^* x \quad \forall x \in \mathcal{W}(0, T; M^2, V'). \tag{4.28}$$ □

At this juncture it is useful to recall our twofold objective: to obtain property (4.18) and an "integration by parts formula." All this will be easily obtained by transposition of the adjoint isomorphism (4.15) of Theorem 4.2. The method of transposition uses the following lemma.

LEMMA 4.4. *Given an (algebraic and topological) isomorphism $T: X \to Y$ between two real Banach spaces X and Y, its transpose $T^*: Y' \to X'$ is also an isomorphism between the topological dual spaces Y' and X' of Y and X endowed with their respective norm topologies. Therefore for each x' in X' the "variational equation"*

$$\langle T^* y', x\rangle_X = \langle x', x\rangle_X \quad \forall x \in X \tag{4.29}$$

has a unique solution y' in Y' which is equal to $(T^*)^{-1}x'$. Moreover the solution y' is continuous with respect to the datum x'.

Proof. Cf. Dunford and Schwartz [1, Vol. I, p. 479, Lemma 7]. The existence of a unique solution to the variational equation (4.37) is a trivial consequence of the continuous invertibility of T^*. □

THEOREM 4.5. (i) *Given (f, ξ) in $L^2(0, T; V') \times V'$, the variational equation*

$$-\int_0^T \langle z(t), ([D_t + A^T]v)(t)\rangle_W \, dt + \langle z_T, v(T)\rangle_V = \int_0^T \langle f(t), v(t)\rangle_V \, dt + \langle \xi, v(0)\rangle_V \quad \forall v \in \mathcal{V}(0, T; V, W), \tag{4.30}$$

has a unique solution (z, z_T) in $L^2(0, T; W') \times V'$ and there exists a constant $c > 0$ such that

$$\|(z, z_T)\|_{L^2(0,T;W')\times V'} \leqq c \|(f, \xi)\|_{L^2(0,T;V')\times V'} \tag{4.31}$$

for all (f, ξ) in $L^2(0, T; V') \times V'$.

(ii) *The solution of* (4.30) *is given in terms of ξ and f by the formulae*

$$l^* z(t) = x(t) \quad \text{a.e. in } [0, T], \tag{4.32}$$

$$z_T = x(T), \tag{4.33}$$

where x is the function

$$x(t) = S_V^T(t)^* \xi + \int_0^t S_V^T(t - r)^* f(r) \, dr. \tag{4.34}$$

(iii) *The map*

$$z \to ([D_t - (A_V^T)^*]l^* z, (l^* z)(0)) : \mathcal{Z}(0, T) \to L^2(0, T; V') \times V' \tag{4.35}$$

is an isomorphism for the Banach space

$$\mathcal{Z}(0, T) = \{z \in L^2(0, T; W') \mid l^* z \in \mathcal{H}(0, T)\} \tag{4.36}$$

endowed with the norm

$$\|z\|^2_{\mathcal{Z}(0,T)} = \|z\|^2_{L^2(0,T;W')} + \|l^* z\|^2_{\mathcal{H}(0,T)}. \tag{4.37}$$

(iv) *For all v in $\mathcal{V}(0, T)$ and z in $\mathcal{Z}(0, T)$*

$$-\int_0^T \langle z(t), ([D_t + A^T]v)(t)\rangle_W \, dt + \langle (l^* z)(T), v(T)\rangle_V = \int_0^T \langle ([D_t - (A_V^T)^*]l^* z)(t), v(t)\rangle_V \, dt + \langle (l^* z)(0), v(0)\rangle_V. \tag{4.38}$$

Proof. Cf. Appendix to § 4. □

Remark 4.1. Part (iii) of Theorem 4.5 says that the spaces $\mathcal{H}(0, T)$ and $\mathcal{Z}(0, T)$ are isomorphic:

$$l^* \mathcal{Z}(0, T) = \mathcal{H}(0, T). \tag{4.39}$$

So for each element x of $\mathscr{X}(0, T)$

$$\exists z = (z^0, z^1) \in \mathscr{Z}(0, T) \subset L^2(0, T; W') \quad \text{such that } x = l^* z, \tag{4.40}$$

where W', the dual space of $W = \mathbb{R}^n \times L^2(0, T; \mathbb{R}^n)$, is identified with the product space $\mathbb{R}^n \times H^1(0, T; \mathbb{R}^n)'$. *This is a generalization of the familiar and convenient product space structure* $M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$. Therefore any element x in $\mathscr{X}(0, T)$ can be represented in terms of a pair (z^0, z^1) in $\mathbb{R}^n \times H^1(0, T; \mathbb{R}^n)'$ as follows:

$$\langle x(t), Jv\rangle_V = z^0(t) \cdot v(0) + \langle z^1(t), v\rangle_{H^1} \tag{4.41}$$

$$\forall v \in H^1(-h, 0; \mathbb{R}^n) \quad \text{almost everywhere in } [0, T].$$

4.3. Perturbation theorem.

THEOREM 4.6. (i) *Let* K, $t \to K(t) : [0, T] \to \mathscr{L}(V, V)$ *be a strongly measurable and bounded operator-valued map. For each* v *in* $C(0, T; V)$ *denote by* Kv *the function*

$$(Kv)(t) = K(t)v(t), \qquad 0 \leqq t \leqq T.$$

The continuous linear map

$$v \to \left(-\left[\frac{d}{dt} + A^T\right] v - lKv, v(T)\right) : \mathscr{V}(0, T) \to L^2(0, T; W) \times V \tag{4.42}$$

is an (algebraic and topological) isomorphism.

(ii) *Let* F, $t \to F(t) : [0, T) \to \mathscr{L}(V', V')$ *be a strongly measurable and bounded operator-valued map. For each* y *in* $C(0, T; V')$ *denote by* Fy *the function*

$$(Fy)(t) = F(t)y(t), \qquad 0 \leqq t \leqq T. \tag{4.43}$$

The continuous linear map

$$y \to \left(\left[\frac{d}{dt} - (A_V^T)^*\right] l^* y - Fl^* y, (l^* y)(0)\right) : \mathscr{Z}(0, T) \to L^2(0, T; V') \times V' \tag{4.44}$$

is an (algebraic and topological) isomorphism.

Proof. Cf. Appendix to § 4. □

5. The new embedding of the control problem and the operator Riccati differential equation. In § 3 we have considered the following problem:

$$\operatorname{Inf}\{J^T(u, \phi^0, \phi^1, w) : u \in L^2(0, T; \mathbb{R}^m)\}, \tag{5.1}$$

where

$$J^T(u, \phi^0, \phi^1, w) = \int_0^T [Qx(t) \cdot x(t) + Nu(t) \cdot u(t)]\, dt \tag{5.2}$$

and

$$\begin{aligned} &\frac{dx}{dt} = Lx_t + Bu_t + f^0(t) \text{ in } [0, T], \qquad x \in H^1(0, T; \mathbb{R}^n), \\ &(x(0), x_0, u_0) = (\phi^0, \phi^1, w) \in \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n) \times L^2(-h, 0; \mathbb{R}^m). \end{aligned} \tag{5.3}$$

By using the extended state space theory of Vinter and Kwong (cf. § 2.3), problem (5.1) to (5.3) was embedded in the following larger family of problems indexed by $s \in [0, T[$ and ξ in M^2:

$$\operatorname{Inf}\{J_s^T(u, \xi) : u \in L^2(s, T; \mathbb{R}^m)\}, \tag{5.4}$$

where

$$J_s^T(u,\xi)=\int_s^T [((\tilde{Q}y(t),y(t)))+Nu(t)\cdot u(t)]\,dt \tag{5.5}$$

and

$$\frac{d}{dt}j^*y=(A^T)^*y+(B^TJ^{-1})^*u+j^*(f^0,0) \text{ in } [s,T], \qquad y(s)=\xi\in M^2, \tag{5.6}$$

($\tilde{Q}$ is defined by (3.5)).

5.1. New embedding of the control problem. In § 4 we have seen that system (5.6) can be further embedded in the larger family of problems indexed by $s\in[0,T[$ with initial conditions ξ in V' and right-hand sides f in $L^2(0,T;V')$; there exists a unique y in $\mathscr{X}(0,T)$ such that

$$[D_t-(A_V^T)^*]l^*y=(B^TJ^{-1})^*u+f \text{ in } [s,T], \qquad (l^*y)(s)=\xi. \tag{5.7}$$

The critical property that $y\in\mathscr{X}(0,T)\subset L^2(0,T;W')$ makes it possible to also associate with ξ in V' and u in $L^2(s,T;\mathbb{R}^m)$ the cost function

$$\hat{J}_s^T(u,\xi)=\int_s^T [\langle y,\hat{Q}y+2q\rangle_W+Nu\cdot u]\,dt, \tag{5.8}$$

for q in $L^2(0,T;W)$ and $\hat{Q}$ a continuous linear map from $W'=\mathbb{R}^n\times(H^1)'$ into $W=\mathbb{R}^n\times H^1$ defined as

$$\hat{Q}(\psi^0,\psi^1)=(Q\psi^0,0), \qquad H^1=H^1(-h,0;\mathbb{R}^n). \tag{5.9}$$

When $q=0$ and ξ and f are of the form $\xi=j^*\bar{\xi}$ and $f=j^*(f^0,0)$, it is not too difficult to see that (5.7)-(5.8) reduce to (5.6)-(5.5). Indeed the solution y to (5.7) is of the form $y=i^*\bar{y}$ for some $\bar{y}$ in $\mathscr{W}(s,T;M^2,V')$ (cf. Theorem 2.7(ii)) and by identity (4.28)

$$[D_t-(A_V^T)^*]l^*y=[D_t-(A_V^T)^*]l^*i^*\bar{y}=[D_t-(A_V^T)^*]j^*\bar{y}=\frac{d}{dt}j^*\bar{y}-A^T\bar{y}.$$

Furthermore,

LEMMA 5.1. $\tilde{Q}=i\hat{Q}i^*$.

Proof. For all pairs (ϕ^0,ϕ^1) and (ψ^0,ψ^1) in M^2

$$(((\phi^0,\phi^1),\tilde{Q}(\psi^0,\psi^1)))=\phi^0\cdot Q\psi^0$$

and

$$\langle i^*(\phi^0,\phi^1),\hat{Q}i^*(\psi^0,\psi^1)\rangle_W=\phi^0\cdot Q\psi^0. \qquad \square$$

So by construction $\tilde{Q}=i\hat{Q}i^*$ and

$$\langle y(t),\hat{Q}y(t)\rangle_W=\langle i^*\bar{y}(t),\hat{Q}i^*\bar{y}(t)\rangle_W=((\bar{y}(t),i\hat{Q}i^*\bar{y}(t)))=((\bar{y}(t),\tilde{Q}\bar{y}(t))).$$

Thus problem (5.6)-(5.5) is indeed embedded in problem (5.7)-(5.8).

The new optimal control problem in $[s,T]$ consists in minimizing $\hat{J}_s^T(u,\xi)$ over all u in $L^2(s,T;\mathbb{R}^m)$

$$\operatorname{Inf}\{\hat{J}_s^T(u,\xi)\,|\,u\in L^2(s,T;\mathbb{R}^m)\}. \tag{5.10}$$

5.2. Solution of the optimal control problem. The techniques of J. L. Lions [1] directly apply to problem (5.7), (5.8) and (5.10) and the minimizing control u^* is

completely characterized by the equation

$$\int_s^T [\langle z, \hat{Q}y + q\rangle_W + Nu^* \cdot v]\, dt = 0 \tag{5.11}$$

for all v in $L^2(s, T; \mathbb{R}^n)$ where y is the solution of

$$[D_t - (A_V^T)^*]l^*z = (B^TJ^{-1})^*v \text{ in } [s, T], \qquad (l^*z)(s) = 0. \tag{5.12}$$

As usual we introduce the adjoint system

$$-[D_t + A^T]p = \hat{Q}y + q \text{ in } [s, T], \qquad p(T) = 0, \tag{5.13}$$

with solution p in $\mathcal{V}(0, T)$ (cf. Theorem 4.2 and Notation 4.1). By using identity (4.30) of Theorem 4.5 on the interval $[s, T]$, we readily obtain

$$\int_s^T (B^TJ^{-1}p + Nu^*) \cdot v\, dt = 0 \quad \forall v \in L^2(s, T; \mathbb{R}^m), \tag{5.14}$$

or since N is invertible

$$u^*(t) = -N^{-1}B^TJ^{-1}p(t) \text{ in } [s, T]. \tag{5.15}$$

The substitution of $u = u^*$ (given by expression (5.15)) into (5.7) leads to the following Hamiltonian system

$$[D_t - (A_V^T)^*](l^*y) = -Rp + f, \quad (l^*y)(s) = \xi, \quad R = (B^TJ^{-1})^*N^{-1}B^TJ^{-1}, \tag{5.16}$$

$$-[D_t + A^T]p = \hat{Q}y + q, \qquad p(T) = 0. \tag{5.17}$$

It is important to emphasize that the above and forthcoming results follow the standard arguments of J. L. Lions [1]. For this reason proofs will be omitted. The next theorem uses invariant embedding with one small difference with respect to J. L. Lions [1]. The space of initial conditions V' is a Hilbert space which has not been identified with its topological dual since we have already identified the elements of the dual $(M^2)'$ of M^2 with the elements of M^2. This difference does not affect the proofs but is very essential in our results.

THEOREM 5.2. (i) *For $s = 0$, there exists a family $\{P(t): 0 \leqq t \leqq T\}$ of continuous linear maps from V' into V and a family $\{r(t): 0 \leqq t \leqq T\}$ of vectors in V such that*

$$p(t) = P(t)(l^*y)(t) + r(t), \qquad 0 \leqq t \leqq T. \tag{5.18}$$

$P(t)$ and $r(t)$ are obtained by the following rules:

a) *Solve*

$$\begin{aligned} &[D_t - (A_V^T)^*](l^*\phi) = -R\psi \text{ in } [s, t], \qquad (l^*\phi)(s) = h, \\ &-[D_t + A^T]\psi = \hat{Q}\phi \text{ in } [s, T], \qquad \psi(T) = 0, \end{aligned} \tag{5.19}$$

$$P(s)h = \psi(s). \tag{5.20}$$

b) *Solve*

$$\begin{aligned} &[D_t - (A_V^T)^*](l^*\beta) = -R\gamma + f \text{ in } [s, T], \qquad (l^*\beta)(s) = 0, \\ &-[D_t + A^T]\gamma = \hat{Q}\beta + q \text{ in } [s, T], \qquad \gamma(T) = 0, \end{aligned} \tag{5.21}$$

$$r(s) = \gamma(s). \tag{5.22}$$

(ii) *The operator $P(s)$ is symmetrical and positive*

$$\begin{aligned} &\forall h, k \text{ in } V', \quad \langle h, P(s)k\rangle_V = \langle k, P(s)h\rangle_V \\ &\forall h \text{ in } V', \quad \langle h, P(s)h\rangle_V \geqq 0. \end{aligned} \tag{5.23}$$

For all h in V', the map

$$t \to P(t)h : [0, T] \to V \tag{5.24}$$

is weakly continuous, bounded and strongly measurable. In particular

$$\exists c > 0 \quad \text{such that } \forall t \in [0, T], \quad \|P(t)\| \leqq c. \tag{5.25}$$

The proof of this theorem uses standard arguments and will be omitted.

5.3. Riccati differential equation for P. The remaining considerations and the final results are based on the perturbation Theorem 4.6 and a lemma. Theorem 4.6 will be used to perturb the adjoint isomorphism (4.15) by the operator $K(t) = P(t)R$; the lemma will say that if $q(t)$ is chosen equal to $-lP(t)f(t)$ in (5.17), then the pair of solutions (y, p) to system (5.16)-(5.17) verifies the identity $p(t) = P(t)y(t)$, $0 \leqq t \leqq T$.

LEMMA 5.3. *Recall the Hamiltonian system* (5.16)-(5.17), *identity* (5.18) *and the characterization of r in Theorem* 5.2(i). *The following conditions are equivalent*:

(i) $\forall s, \quad 0 \leqq s \leqq T, \quad r(s) = 0,$

(ii) $\forall s, \quad 0 \leqq s \leqq T, \quad p(s) = P(s)(l^* y)(s),$

(iii) *for all h in V' and s, $0 \leqq s \leqq T$,*

$$\int_s^T [\langle \phi(t), q(t)\rangle_W + \langle f(t), \psi(t)\rangle_V]\, dt = 0, \tag{5.26}$$

where (ϕ, ψ) is the solution of system (5.19) *on $[s, T]$ with initial condition h at time s. In particular if*

$$q(t) = -lP(t)f(t), \qquad 0 \leqq t \leqq T, \tag{5.27}$$

condition (5.26) *is verified and $r(s) = 0$, $0 \leqq s \leqq T$.*

Proof. Cf. Appendix to § 5. □

THEOREM 5.4. (i) *For each x in $\mathscr{Z}(0, T)$ the function Pl^*x,*

$$(P(l^*x))(t) = P(t)[l^*x](t) = P(t)l^*x(t), \qquad 0 \leqq t \leqq T, \tag{5.28}$$

is the unique solution in $\mathscr{V}(0, T)$ to the equation

$$[D_t + A^T]Pl^*x - lP[D_t - (A_V^T)^*]l^*x - lPR(Pl^*x) + \hat{Q}x = 0, \qquad P(T) = 0. \tag{5.29}$$

The family $P = \{P(t) \in \mathscr{L}(V', V) | 0 \leqq t \leqq T\}$ is the unique family with the above property in the class $(\mathscr{P})$ of all families of weakly continuous symmetrical operators $Z = \{Z(t) \in \mathscr{L}(V', V) | 0 \leqq t \leqq T\}$.

(ii) *The map $Pl^* : \mathscr{Z}(0, T) \to \mathscr{V}(0, T)$ is linear and continuous.*

(iii) *The function r is the unique solution in $\mathscr{V}(0, T)$ to the equation*

$$-[D_t + A^T]r + PRr = Pf + q \text{ in } [0, T], \qquad r(T) = 0. \tag{5.30}$$

Proof. Cf. Appendix to § 5. □

Equation (5.29) is not the usual form of the Riccati equation. We now make this connection.

THEOREM 5.5. *The following statements are equivalent to each other and to Theorem* 5.4(i).

(i) *For each x in $\mathcal{W}(0, T; M^2, V')$, the function Pj^*x is the unique solution in $\mathcal{V}(0, T)$ to the equation*

$$\frac{d}{dt}(jPj^*x)+A^TPj^*x+jP[-D_t(j^*x)+(A^T)^*x-RPj^*x]+\tilde{Q}x=0, \qquad P(T)=0. \tag{5.31}$$

In the class $(\mathcal{P})$ the solution P is unique.

(ii) *For each h in M^2, the function $t\to P(t)j^*h$ is the unique solution in $\mathcal{V}(0, T; V, W)$ to the equation*

$$\frac{d}{dt}(jP(t)j^*h)+A^TP(t)j^*h+jP(t)(A^T)^*h-jP(t)RP(t)j^*h+\tilde{Q}h=0, \tag{5.32}$$

$$P(T)=0.$$

P is the unique solution in the class $(\mathcal{P})$.

Proof. Cf. Appendix to § 5. □

6. Differential equation for the kernel of the equation $P(t)$. In this section we construct the kernel $P(t, \alpha, \theta)$ associated with the operators Π and P and derive a set of coupled partial differential matrix equations for it. We recover, as a special case, the equations derived by H. N. Koivo and E. B. Lee [1] and R. H. Kwong [3] for a single delay.

Recall that

$$V=\{(\phi^0, \phi^1)\in M^2 | \phi^1\in H^1(-h, 0; \mathbb{R}^n) \text{ and } \phi^0=\phi^1(0)\}, \tag{6.1}$$

that J is the isomorphism

$$\phi\to J\phi=(\phi(0), \phi): H^1\to V, \qquad H^1=H^1(-h, 0; \mathbb{R}^n), \tag{6.2}$$

and that j, i and l are the continuous injections

$$(\phi^0, \phi^1)\to j(\phi^0, \phi^1)=(\phi^0, \phi^1): V\to M^2, \tag{6.3}$$

$$(\phi^0, \phi^1)\to l(\phi^0, \phi^1)=(\phi^0, \phi^1): V\to W, \tag{6.4}$$

$$(\phi^0, \phi^1)\to i(\phi^0, \phi^1)=(\phi^0, \phi^1): W\to M^2, \tag{6.5}$$

$$j=il,$$

where V is endowed with the norm (2.24).

6.1. Definition and properties of the matrix kernel $P(t, \alpha, \theta)$. Recall the definition of $P(t)$, the results of Theorem 5.1 and the definition of $\Pi(t)$ at the end of § 3.

PROPOSITION 6.1. *For all t in $[0, T]$*

$$\Pi(t)=jP(t)j^*. \tag{6.6}$$

Proof. From definitions. □

The subspace V of M^2 endowed with the norm (2.24) is essentially isomorphic to H^1. It will be convenient to introduce on H^1, an operator equivalent to $P(t)$ on V.

DEFINITION 6.2. For each t in $[0, T]$

$$P_J(t)=J^{-1}P(t)(J^*)^{-1}. \tag{6.7}$$

□

It is readily seen that for each t, $P_J(t)$ is a continuous linear operator from $(H^1)'$ into H^1 and that the family $\{P_J(t): 0\leqq t\leqq T\}$ has properties analogous to those of the

family $\{P(t): 0 \leqq t \leqq T\}$:

$$\forall h, k \in (H^1)', \qquad \langle h, P_J(t)k\rangle_{H^1} = \langle k, P_J(t)h\rangle_{H^1},$$

$$\forall h \in (H^1)', \qquad \langle h, P_J(t)h\rangle_{H^1} \geqq 0,$$

$$\exists c > 0, \quad \forall t \in [0, T], \quad \|P_J(t)\| \leqq c, \tag{6.8}$$

$$\forall h \in (H^1)', \qquad t \to P_J(t)h : [0, T] \to H^1$$

is weakly continuous, bounded and strongly measurable.

DEFINITION 6.3. For each $(t, \alpha, \theta) \in [0, T] \times I(-h, 0) \times I(-h, 0)$, let $P(t, \alpha, \theta)$ be the $n \times n$ matrix defined as follows:

$$(e, d) \to d \cdot P(t, \alpha, \theta)e = \langle \delta_\theta d, P_J(t)(\delta_\alpha e)\rangle_{H^1} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}, \tag{6.9}$$

where for each ζ in $I(-h, 0)$ δ_ζ is the continuous linear map

$$\delta_\zeta : \mathbb{R}^n \to (H^1)', \quad \langle \delta_\zeta c, \phi\rangle_{H^1} = c \cdot \phi(\zeta) \quad \forall c \in \mathbb{R}^n \quad \forall \phi \in H^1. \qquad \square$$

It is easy to check that $P(t, \alpha, \theta)$ is well defined. The following lemma will be useful in the study of the properties of $P(t, \alpha, \theta)$.

LEMMA 6.4. (i) *For each e in $\mathbb{R}^n$, the function*

$$\alpha \to \delta_\alpha e : [-h, 0] \to (H^1)' \tag{6.10}$$

is uniformly continuous,

$$\forall \theta, \alpha \in I(-h, 0), \qquad \|\delta_\theta e - \delta_\alpha e\|_{(H^1)'} \leqq |\theta - \alpha|^{1/2}|e| \tag{6.11}$$

and there exists a constant $c' > 0$ such that

$$\forall \alpha \in I(-h, 0), \qquad \|\delta_\alpha e\|_{(H^1)'} \leqq c'|e|. \tag{6.12}$$

(ii) *For all ψ in $L^2(-h, 0; \mathbb{R}^n)$*

$$\int_{-h}^{0} \delta_\theta \psi(\theta)\, d\theta = J^* j^*(0, \psi) \quad \text{in } (H^1)'. \tag{6.13}$$

Proof. (i) For each ϕ in H^1

$$\langle \delta_\theta e - \delta_\alpha e, \phi\rangle_{H^1} = e \cdot [\phi(\theta) - \phi(\alpha)] = e \cdot \int_\alpha^\theta D\phi(\xi)\, d\xi,$$

$$|\langle \delta_\theta e - \delta_\alpha e, \phi\rangle| \leqq |e||\theta - \alpha|^{1/2}\|D\phi\|_{L^2} \leqq |e||\theta - \alpha|^{1/2}\|\phi\|_{H^1}.$$

By definition of the norm in $(H^1)'$, we obtain (6.11). To prove (6.12) recall the definition of δ_α and the norm in $(H^1)'$:

$$\|\delta_\alpha e\|_{(H^1)'} = \sup\{|\langle \delta_\alpha e, v\rangle_{H^1}| : \|v\|_{H^1} = 1\} = \sup\{|e \cdot v(\alpha)| : \|v\|_{H^1} = 1\}$$
$$\leqq |e| \sup\{c'\|v\|_{H^1} : \|v\|_{H^1} = 1\} = c'|e|,$$

since the injection of $H^1(-h, 0; \mathbb{R}^n)$ into the space of bounded continuous functions $C(-h, 0; \mathbb{R}^n)$ is continuous.

(ii) For each v in $H^1(-h, 0; \mathbb{R}^n)$ and almost all θ in $I(-h, 0)$

$$\langle \delta_\theta \psi(\theta), v\rangle_{H^1} = \psi(\theta) \cdot v(\theta),$$

$$\int_{-h}^{0} \langle \delta_\theta \psi(\theta), v\rangle_{H^1}\, d\theta = \int_{-h}^{0} \psi(\theta) \cdot v(\theta)\, d\theta = (((0, \psi), jJv)) = \langle J^* j^*(0, \psi), v\rangle_{H^1}.$$

Therefore

$$\left\langle \int_{-h}^{0} \delta_\theta \psi(\theta)\, d\theta, v \right\rangle_{H^1} = \langle J^* j^*(0, \psi), v \rangle_{H^1}. \qquad \square$$

THEOREM 6.5. (i) *For all* (t, α, θ) *in* $[0, T] \times I(-h, 0) \times I(-h, 0)$

$$P(t, \alpha, \theta)^* = P(t, \theta, \alpha). \tag{6.14}$$

(ii) *The matrix function*

$$(t, \alpha, \theta) \to P(t, \alpha, \theta) : [0, T] \times I(-h, 0) \times I(-h, 0) \to \mathscr{L}(\mathbb{R}^n, \mathbb{R}^n) \tag{6.15}$$

is continuous and bounded.

(iii) *There exists a constant* $c > 0$ *such that*

$$\sup \left\{ \int_{-h}^{0} |P(t, \theta, \alpha)|^2\, d\theta \,|(t, \alpha) \in [0, T] \times I(-h, 0) \right\} \leqq c, \tag{6.16}$$

$$\sup \left\{ \int_{-h}^{0} |P(t, \theta, \alpha)|^2\, d\alpha \,|(t, \theta) \in [0, T] \times I(-h, 0) \right\} \leqq c, \tag{6.17}$$

$$\sup \left\{ \int_{-h}^{0} \left| \frac{\partial P}{\partial \alpha}(t, \theta, \alpha) \right|^2 d\alpha \,|(t, \theta) \in [0, T] \times I(-h, 0) \right\} \leqq c, \tag{6.18}$$

$$\sup \left\{ \int_{-h}^{0} \left| \frac{\partial P}{\partial \theta}(t, \theta, \alpha) \right|^2 d\theta \,|(t, \alpha) \in [0, T] \times I(-h, 0) \right\} \leqq c. \tag{6.19}$$

When h *is finite the matrix function*

$$\left.\begin{aligned} &(t, \alpha, \theta) \to P(t, \alpha, \theta), \\ &(t, \alpha, \theta) \to \frac{\partial P}{\partial \alpha}(t, \alpha, \theta), \\ &(t, \alpha, \theta) \to \frac{\partial P}{\partial \theta}(t, \alpha, \theta), \end{aligned}\right\} : [0, T] \times I(-h, 0) \times I(-h, 0) \to \mathscr{L}(\mathbb{R}^n, \mathbb{R}^n), \tag{6.20}$$

all belong to $L^2([0, T] \times I(-h, 0) \times I(-h, 0); \mathscr{L}(\mathbb{R}^n, \mathbb{R}^n))$.

(iv) *For each* ϕ *in* M^2 *the function*

$$t \to P_J(t) J^* j^* \phi : [0, T] \to H^1 = H^1(-h, 0; \mathbb{R}^n) \tag{6.21}$$

is continuous and the functions

$$t \to P_J(t) J^* j^* \phi : [0, T] \to L^2 = L^2(-h, 0; \mathbb{R}^n), \tag{6.22}$$

$$t \to (P_J(t) J^* j^* \phi)(0) : [0, T] \to \mathbb{R}^n, \tag{6.23}$$

belong to $H^1(0, T; L^2)$ *and* $H^1(0, T; \mathbb{R}^n)$, *respectively.*

(v) *For each* $\phi = (\phi^0, \phi^1)$ *in* M^2, t *in* $[0, T]$ *and* α *in* $I(-h, 0)$

$$(P_J(t) J^* j^* \phi)(\alpha) = P(t, 0, \alpha)\phi^0 + \int_{-h}^{0} P(t, \theta, \alpha)\phi^1(\theta)\, d\theta. \tag{6.24}$$

Moreover the following functions are continuous

$$t \to P(t, 0, \alpha)\phi^0 + \int_{-h}^{0} P(t, \theta, \alpha)\phi^1(\theta)\, d\theta : [0, T] \to \mathbb{R}^n, \tag{6.25}$$

$$t \to P(t, 0, \cdot)\phi^0 + \int_{-h}^{0} P(t, \theta, \cdot)\phi^1(\theta)\, d\theta : [0, T] \to L^2, \tag{6.26}$$

$$t \to DP(t,0,\cdot)\phi^0 + D\int_{-h}^{0} P(t,\theta,\cdot)\phi^1(\theta)\,d\theta : [0,T] \to L^2, \tag{6.27}$$

where

$$\left[DP(t,0,\cdot)\phi^0 + D\int_{-h}^{0} P(t,\theta,\cdot)\phi^1(\theta)\,d\theta\right](\alpha) = \frac{\partial P}{\partial \alpha}(t,0,\alpha)\phi^0 + \frac{\partial}{\partial \alpha}\int_{-h}^{0} P(t,\theta,\alpha)\phi^1(\theta)\,d\theta; \tag{6.28}$$

the functions

$$t \to \frac{\partial P}{\partial t}(t,0,0)\phi^0 + \frac{\partial}{\partial t}\int_{-h}^{0} P(t,\theta,0)\phi^1(\theta)\,d\theta : [0,T] \to \mathbb{R}^n, \tag{6.29}$$

$$t \to \frac{\partial P}{\partial t}(t,0,\cdot)\phi^0 + \frac{d}{dt}\int_{-h}^{0} P(t,\theta,\cdot)\phi^1(\theta)\,d\theta : [0,T] \to L^2, \tag{6.30}$$

belong to $L^2(0,T;\mathbb{R}^n)$ *and* $L^2(0,T;L^2)$, *respectively.*

(vi) *For each* ϕ^0 *in* $\mathbb{R}^n$ *and* α *in* $I(-h,0)$, *the following functions are continuous*

$$t \to P(t,\alpha,0)\phi^0 : [0,T] \to \mathbb{R}^n, \tag{6.31}$$

$$t \to P(t,\cdot,0)\phi^0 : [0,T] \to L^2, \tag{6.32}$$

$$t \to DP(t,\cdot,0)\phi^0 : [0,T] \to L^2, \tag{6.33}$$

where

$$[DP(t,\cdot,0)\phi^0](\alpha) = \frac{\partial P}{\partial \alpha}(t,\alpha,0)\phi^0; \tag{6.34}$$

the function

$$t \to \frac{\partial P}{\partial t}(t,\cdot,0)\phi^0 : [0,T] \to L^2 \tag{6.35}$$

belongs to $L^2(0,T;L^2)$. *Moreover for each* ϕ *and* ψ *in* $L^2(-h,0;\mathbb{R}^n)$

$$\int_{-h}^{0} \phi(\alpha)\cdot\frac{\partial}{\partial \alpha}\int_{-h}^{0} P(t,\theta,\alpha)\psi(\theta)\,d\theta\,d\alpha = \int_{-h}^{0}\int_{-h}^{0} \frac{\partial P}{\partial \alpha}(t,\alpha,\theta)\phi(\alpha)\,d\alpha\cdot\psi(\theta)\,d\theta. \tag{6.36}$$

When ψ *belongs to* $L^2(-h,0;\mathbb{R}^n)\cap L^1(-h,0;\mathbb{R}^n)$,

$$\int_{-h}^{0} \phi(\alpha)\cdot\frac{\partial}{\partial \alpha}\int_{-h}^{0} P(t,\theta,\alpha)\psi(\theta)\,d\theta\,d\alpha = \int_{-h}^{0} \phi(\alpha)\cdot\int_{-h}^{0} \frac{\partial P}{\partial \alpha}(t,\theta,\alpha)\psi(\theta)\,d\theta\,d\alpha; \tag{6.37}$$

in particular when h *is finite,* $L^2(-h,0;\mathbb{R}^n)\cap L^1(-h,0;\mathbb{R}^n) = L^2(-h,0;\mathbb{R}^n)$ *and the above identity is true for all* ϕ *and* ψ *in* $L^2(-h,0;\mathbb{R}^n)$.

(vii) *The continuous linear operator* $\Pi(t) = jP(t)j^*$ *on* M^2 *can be decomposed as a matrix of operators*

$$\Pi(t) = \begin{bmatrix} \Pi^{00}(t) & \Pi^{01}(t) \\ \Pi^{10}(t) & \Pi^{11}(t) \end{bmatrix} \tag{6.38}$$

where

$$\Pi^{00}(t)\in\mathscr{L}(\mathbb{R}^n,\mathbb{R}^n),\qquad \Pi^{01}(t)\in\mathscr{L}(L^2,\mathbb{R}^n),$$
$$\Pi^{10}(t)\in\mathscr{L}(\mathbb{R}^n,L^2),\qquad \Pi^{11}(t)\in\mathscr{L}(L^2,L^2). \tag{6.39}$$

For each t in $[0,T]$, α in $I(-h,0)$ and $\phi=(\phi^0,\phi^1)$ in M^2

$$\Pi^{00}(t)=P(t,0,0),\qquad [\Pi^{10}(t)\phi^0](\alpha)=P(t,0,\alpha)\phi^0, \tag{6.40}$$

$$\Pi^{01}(t)\phi^1=\int_{-h}^{0}P(t,\theta,0)\phi^1(\theta)\,d\theta=\int_{-h}^{0}P(t,0,\theta)^*\phi^1(\theta)\,d\theta, \tag{6.41}$$

$$[\Pi^{11}(t)\phi^1](\alpha)=\int_{-h}^{0}P(t,\theta,\alpha)\phi^1(\theta)\,d\theta=\int_{-h}^{0}P(t,\alpha,\theta)^*\phi^1(\theta)\,d\theta. \tag{6.42}$$

Proof. Cf. Appendix to § 6. □

Remark 6.1. The case $h=+\infty$ introduces additional difficulties since the matrix functions (6.20) need not be L^2 with respect to (t,α,θ). Moreover identity (6.37) is not necessarily true and only identity (6.36) can be used in the derivation of the differential equations for $P(t,\alpha,\theta)$.

6.2. Coupled differential equations for $P(t,\alpha,\theta)$. Knowing the properties of $P(t,\alpha,\theta)$ and its relation to $P(t)$, we can now use the Riccati differential equation (5.45) of Theorem 5.5 to obtain a set of differential equations for $P(t,\alpha,\theta)$.

THEOREM 6.6. *The matrix function $P(t,\alpha,\theta)$ satisfies the following set of differential equations (in the sense of distributions):*

$$\begin{aligned}&\frac{\partial P}{\partial t}(t,0,0)+\int_{-h}^{0}d_\theta\eta^T P(t,0,\theta)+\int_{-h}^{0}P(t,\theta,0)\,d_\theta\eta,\\ &-\int_{-h}^{0}P(t,\zeta,0)\,d_\zeta\beta N^{-1}\int_{-h}^{0}d_\xi\beta^T P(t,0,\xi)+Q=0,\\ &P(T,0,0)=0,\end{aligned} \tag{6.43}$$

$$\begin{aligned}&\left(\frac{\partial}{\partial t}+\frac{\partial}{\partial\theta}\right)P(t,\theta,0)+\int_{-h}^{0}d_\alpha\eta^T P(t,\theta,\alpha)\\ &-\int_{-h}^{0}P(t,\zeta,0)\,d_\zeta\beta N^{-1}\int_{-h}^{0}d_\xi\beta^T P(t,\theta,\xi)=0,\\ &P(T,\theta,0)=0,\qquad \theta\in I(-h,0),\end{aligned} \tag{6.44}$$

$$\begin{aligned}&\left(\frac{\partial}{\partial t}+\frac{\partial}{\partial\theta}+\frac{\partial}{\partial\alpha}\right)P(t,\alpha,\theta)-\int_{-h}^{0}P(t,\zeta,\theta)\,d_\zeta\beta N^{-1}\int_{-h}^{0}d_\xi\beta^T P(t,\alpha,\xi)=0,\\ &P(T,\alpha,\theta)=0\quad\forall\alpha,\theta\ \textit{in}\ I(-h,0),\end{aligned} \tag{6.45}$$

$$P(t,\alpha,\theta)^*=P(t,\theta,\alpha)\quad\forall t\in[0,T]\quad\forall\alpha,\theta\in I(-h,0). \tag{6.46}$$

The matrix function

$$(t,\theta)\to\frac{\partial P}{\partial t}(t,\theta,0):[0,T]\times I(-h,0)\to\mathscr{L}(\mathbb{R}^n,\mathbb{R}^n) \tag{6.47}$$

is an L^2-matrix function. When h is finite the matrix function

$$(t, \alpha, \theta) \to \frac{\partial P}{\partial t}(t, \alpha, \theta) : [0, T] \times I(-h, 0) \times I(-h, 0) \to \mathscr{L}(\mathbb{R}^n, \mathbb{R}^n) \tag{6.48}$$

is an L^2-matrix function.

Proof. Cf. Appendix to § 6. □

Remark 6.2. When $h = +\infty$ the matrix function $P(t, \alpha, \theta)$ is not necessarily an L^2-matrix function.

COROLLARY 6.7. *Let $a > 0$ and $b > 0$ be two finite real numbers and $h = \max\{a, b\}$. Let B and L be of the form*

$$Bw = B_0 w(0) + B_1 w(-a), \tag{6.49}$$

$$L\phi = A_0 \phi(0) + A_1 \phi(-b). \tag{6.50}$$

Then the system of equations (6.43) *to* (6.45) *reduces to*

$$\begin{aligned}
&\frac{\partial P}{\partial t}(t, 0, 0) + A_0^T P(t, 0, 0) + A_1^T P(t, 0, -b) + P(t, 0, 0) A_0 + P(t, -b, 0) A_1, \\
&-[P(t, 0, 0) B_0 + P(t, -a, 0) B_1] N^{-1} [B_0^T P(t, 0, 0) + B_1^T P(t, 0, -a)] = 0, \qquad (6.51) \\
&P(T, 0, 0) = 0,
\end{aligned}$$

$$\begin{aligned}
&\left(\frac{\partial}{\partial t} + \frac{\partial}{\partial \theta}\right) P(t, \theta, 0) + A_0^T P(t, \theta, 0) + A_1^T P(t, \theta, -b), \\
&-[P(t, 0, 0) B_0 + P(t, -a, 0) B_1] N^{-1} [B_0^T P(t, \theta, 0) + B_1^T P(t, \theta, -a)] = 0, \qquad (6.52) \\
&P(T, \theta, 0) = 0 \quad \forall \theta \in I(-h, 0),
\end{aligned}$$

$$\begin{aligned}
&\left(\frac{\partial}{\partial t} + \frac{\partial}{\partial \alpha} + \frac{\partial}{\partial \theta}\right) P(t, \alpha, \theta) - [P(t, 0, \theta) B_0 + P(t, -a, \theta) B_1] N^{-1} \\
&\cdot [B_0^T P(t, \alpha, 0) + B_1^T P(t, \alpha, -a)] = 0, \qquad (6.53) \\
&P(T, \alpha, \theta) = 0 \quad \forall \alpha, \theta \in I(-h, 0).
\end{aligned}$$

"Modulo" an appropriate change of variables, the above system of equations coincides with the one of Koivo and Lee [1] and R. H. Kwong [3, (2.29)-(2.31)].

7. The linear-quadratic optimal control problem on $[0, \infty[$. We now associate with equation (5.3) on $[0, \infty[$

$$\begin{aligned}
&\frac{dx}{dt}(t) = Lx_t + Bu_t \text{ in } [0, \infty[, \ x \in H^1_{\text{loc}}(0, \infty; \mathbb{R}^n), \\
&(x(0), x_0, u_0) = (\phi^0, \phi^1, w) \in \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n) \times L^2(-h, 0; \mathbb{R}^n),
\end{aligned} \tag{7.1}$$

the cost function

$$J(u, \phi^0, \phi^1, w) = \int_0^\infty [|C^0 x(t)|^2 + Nu(t) \cdot u(t)]\, dt, \tag{7.2}$$

where C^0 is an arbitrary $r \times n$ matrix ($r \geqq 1$, an integer).

Define $Q = (C^0)^T C^0$. The infinite time horizon optimal control problem consists in minimizing the functional (7.2) over all u in $L^2(0, \infty; \mathbb{R}^m)$:

$$\text{Inf}\{J(u, \phi^0, \phi^1, w) | u \in L^2(0, \infty; \mathbb{R}^m)\}. \tag{7.3}$$

7.1. Stabilizability. The fundamental hypothesis to ensure the existence of a unique solution to problem (7.3) is the stabilizability hypothesis with respect to the observation operator.

DEFINITION 7.1. The pair (L, B) is *stabilizable with respect to* C^0 if for each ϕ in M^2 and $w=0$, there exists $u \in L^2(0, \infty; \mathbb{R}^m)$ such that

$$\int_0^\infty |C^0 x(t)|^2 \, dt < \infty. \tag{7.4}$$

□

We have seen that system (7.1) can be reformulated in state space and embedded in a larger family of state equations

$$[D_t - (A_V^T)^*] l^* y = (B^T J^{-1})^* u, \text{ in } [0, \infty[, \qquad (l^* y)(0) = y^0 \text{ in } V'. \tag{7.5}$$

The cost function (7.2) becomes

$$\hat{J}(u, y^0) = \int_0^\infty |Cy(t)|^2 + Nu(t) \cdot u(t) \, dt \tag{7.6}$$

where $C: W' \to \mathbb{R}^r$ is defined as

$$C(w_0, w_1) = C^0 w_0. \tag{7.7}$$

Define $\hat{Q}: W' \to W$ as $\hat{Q}(w_0, w_1) = ((C^0)^T C^0 w_0, 0)$. So we can associate with problem (7.5)-(7.6), the following concept of stabilizability.

DEFINITION 7.2. The pair $((A_V^T)^*, (B^T)^*)$ is stabilizable with respect to the observation C if for each y^0 in V', there exists u in $L^2(0, \infty; \mathbb{R}^m)$ such that

$$\int_0^\infty |Cy(t)|^2 \, dt < \infty. \tag{7.8}$$

□

Remark 7.1. Definition 7.1 (resp. Definition 7.2) says that for each initial condition ϕ in M^2 (resp. y^0 in V'), there exists a control function u in $L^2_{\text{loc}}(0, \infty; \mathbb{R}^m)$ for which the cost function is finite or, equivalently,

$$\int_0^\infty |u(s)|^2 \, ds < \infty \quad \text{and} \quad \int_0^\infty |C^0 x(t)|^2 \, dt < \infty \left(\text{resp.} \int_0^\infty |Cy(t)|^2 \, dt < \infty \right).$$

At this stage we do not want to speculate on the properties of an eventual feedback operator and the well-posedness of the closed loop system. We shall later see (cf. Theorem 7.5) that the hypothesis of Definition 7.1 is equivalent to the existence of a closed-loop operator of the form

$$K = -N^{-1} B^T J^{-1} P: V' \to \mathbb{R}^m, \qquad P \in \mathcal{L}(V', V) \tag{7.9}$$

for which the closed-loop system

$$[D_t - (A_V^T)^* + (B^T J^{-1})^* N^{-1} B^T J^{-1} P] l^* y = 0, \qquad (l^* y)(0) = y^0 \in V' \tag{7.10}$$

is well posed and its solution is exponentially stable for all y^0 in V'. □

When h is finite we have the following extension of the result in Vinter and Kwong [1].

THEOREM 7.3. *When h is finite, Definitions* 7.1 *and* 7.2 *are equivalent.*

Proof. It is clear that Definition 7.2 implies Definition 7.1. It suffices to choose $y^0 = j^*(\phi^0, H\phi^1 + Kw)$. The converse of the theorem follows from the next lemma which is an extension of Proposition 7.2 in Vinter and Kwong [1]. □

LEMMA 7.4. *When h is finite, there exist $\bar{\phi} = (\bar{\phi}^0, \bar{\phi}^1)$ in M^2 such that*

$$(l^* y)(2h) = j^*(\bar{\phi}^0, H\bar{\phi}^1), \tag{7.11}$$

where y is the solution of (7.5) with initial condition y^0 in V' and $u(t) = 0$ in $[0, 2h]$.

7.2. The family of operators $P_T(s)$. In § 5 we have fixed the final time $T > 0$ and embedded our problem in an internal $[s, T]$, $0 \leqq s \leqq T$. More precisely we have minimized the cost function (5.5) associated with the state equation (5.6). In Theorem 5.2 we have defined a family of decoupling operators $\{P_T(s) | 0 \leqq s \leqq T\}$ which we shall now index with the superscript T. This family is completely characterized by Theorem 5.2(i)a):

$$\begin{aligned} &[D_t - (A_V^T)^*] l^* \phi = -R\psi \text{ in } [s, T], \qquad (l^*\phi)(s) = k, \\ &[D_t + A^T]\psi + \hat{Q}\phi = 0 \text{ in } [s, T], \qquad \psi(T) = 0, \\ &P_T(s)k = \psi(s). \end{aligned} \tag{7.12}$$

Denote by $(\bar{\phi}, \bar{\psi})$ the solution of (7.12) for the initial condition $\bar{k}$. Using the integration by parts formula (4.38)

$$\langle (l^*\phi)(s), \bar{\psi}(s)\rangle_V = \langle (l^*\phi)(T), \bar{\psi}(T)\rangle_V - \int_s^T [\langle \phi, [D_t + A^T]\bar{\psi}\rangle_W + \langle [D_t - (A_V^T)^*] l^*\phi, \bar{\psi}\rangle_V]\, dt$$

and

$$\langle k, P_T(s)\bar{k}\rangle_V = \int_s^T [\langle \phi, \hat{Q}\bar{\phi}\rangle_W + \langle R\psi, \bar{\psi}\rangle_V]\, dt. \tag{7.13}$$

But recall that the optimal controls are of the form

$$u = -N^{-1}B^T J^{-1}\psi, \qquad \bar{u} = -N^{-1}B^T J^{-1}\bar{\psi};$$

thus (7.13) can be rewritten in the form

$$\langle k, P_T(s)\bar{k}\rangle_V = \int_s^T [\langle \phi, \hat{Q}\bar{\phi}\rangle_W + u \cdot N\bar{u}]\, dt. \tag{7.14}$$

In particular

$$\langle k, P_T(s)k\rangle_V = \hat{J}_s^T(u, k) = \operatorname{Inf}\{\hat{J}_s^T(v, k) | v \in L^2(s, T; \mathbb{R}^m)\}. \tag{7.15}$$

It is not difficult but fundamental to notice that for all s in $[0, T[$ and all h in V'

$$\operatorname{Inf}\{\hat{J}_s^T(v, k) | v \in L^2(s, T; \mathbb{R}^m)\} = \operatorname{Inf}\{\hat{J}_0^{T-s}(w, k) | w \in L^2(0, T-s; \mathbb{R}^m)\}. \tag{7.16}$$

As a result for all $T_1 \geqq s_1 \geqq 0$ and all $T_2 \geqq s_2 \geqq 0$

$$T_2 - s_2 = T_1 - s_1 \Rightarrow P_{T_2}(s_2) = P_{T_1}(s_1), \tag{7.17}$$

$$T_2 - s_2 \geqq T_1 - s_1 \Rightarrow P_{T_2}(s_2) \geqq P_{T_1}(s_1). \tag{7.18}$$

7.3. Solution of the optimal control problem on $[0, \infty[$. We summarize our results in a single theorem.

THEOREM 7.5. *Assume that the pair (L, B) is stabilizable with respect to C^0.*

(i) *For each k in V' there exists a unique u in $L^2(0, \infty; \mathbb{R}^m)$ such that*

$$\hat{J}(u, k) = \operatorname{Inf}\{\hat{J}(v, k) | v \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^m)\}. \tag{7.19}$$

(ii) *There exists a positive symmetrical operator P in $\mathscr{L}(V', V)$,*

$$\forall k, \bar{k} \in V', \quad \langle k, P\bar{k}\rangle_V = \langle \bar{k}, Pk\rangle_V, \tag{7.20}$$

$$\forall k \in V', \quad \langle k, Pk\rangle_V \geqq 0, \tag{7.21}$$

such that

$$\forall t \geqq 0, \quad \forall k \in V', \quad P_T(t)k \to Pk \text{ in } V\text{-strong as } T \text{ goes to } +\infty. \tag{7.22}$$

(iii) *The optimal control is of the form*

$$u(t) = -N^{-1}B^T J^{-1} P(l^* y)(t), \qquad t \geqq 0, \tag{7.23}$$

where y is the solution in

$$\mathscr{Z}_{\text{loc}}(0, \infty) = \{v : [0, \infty[\to W' \mid \forall T > 0,\ v|_{[0,T]} \in \mathscr{Z}(0, T)\} \tag{7.24}$$

of the equation

$$[D_t - (A_V^T)^*](l^* y) + RP(l^* y) = 0, \quad 0 \leqq t, \quad (l^* y)(0) = k. \tag{7.25}$$

Moreover for all k and $\bar{k}$ in V'

$$\langle k, P\bar{k}\rangle_V = \int_0^\infty [Cy(t) \cdot C\bar{y}(t) + u(t) \cdot N\bar{u}(t)]\, dt, \tag{7.26}$$

$$\langle k, P\bar{k}\rangle_V = \int_0^\infty [Cy(t) \cdot C\bar{y}(t) + \langle RP(l^* y)(t), P(l^* \bar{y})(t)\rangle_V\, dt, \tag{7.27}$$

where $\bar{u}$ and $\bar{y}$ are the optimal control and the solution to (7.25) *corresponding to the initial condition $\bar{k}$.*

(iv) *P is a positive symmetrical solution of the Riccati equation*

$$A^T Pj^* + jP(A^T)^* - jPRPj^* + \tilde{Q} = 0 \text{ in } \mathscr{L}(M^2, M^2), \tag{7.28}$$

where $\tilde{Q} \in \mathscr{L}(M^2, M^2)$ is defined as $\tilde{Q}(\phi^0, \phi^1) = (Q\phi^0, 0)$.

(v) *P is the minimal positive symmetrical solution of* (7.28). *That is, any other positive symmetrical solution $\bar{P}$ of* (7.28) *is such that*

$$\forall k \in V', \quad \langle k, \bar{P}k\rangle_V \geqq \langle k, Pk\rangle_V. \tag{7.29}$$

Proof. The Proof will be given in the Appendix. □

It is also possible to give conditions to ensure the uniqueness of the minimum positive solution to the Riccati equation (7.28) in terms of the stabilizability of the pair $(L^T, C^0)^T)$ with respect to the identity matrix in $\mathbb{R}^n$ (when the length h of the memory is finite). The reader is referred to Vinter and Kwong [1] and L. Pandolfi [2]. Necessary and sufficient conditions can be obtained by using techniques developed by M. Sorine [1], [2].

7.4. Equations for the kernel of the operator P. We proceed exactly as in § 6.

DEFINITION 7.6. The operator P_J in $\mathscr{L}((H^1)', H^1)$ is defined as

$$P_J = J^{-1}P(J^*)^{-1}. \tag{7.30}$$

□

Its properties are analogous to those of P:

$$\begin{aligned} &\forall \bar{k}, k \in (H^1)', \quad \langle \bar{k}, P_J k\rangle_{H^1} = \langle k, P_J \bar{k}\rangle_{H^1}, \\ &\forall k \in (H^1)', \quad \langle k, P_J k\rangle_{H^1} \geqq 0. \end{aligned} \tag{7.31}$$

DEFINITION 7.7. For each $(\alpha, \theta) \in I(-h, 0) \times I(-h, 0)$, let $P(\alpha, \theta)$ be the $n \times n$ matrix function defined as follows:

$$(e, d) \to d \cdot P(\alpha, \theta)e = \langle \delta_\theta d, P_J(\delta_\alpha e)\rangle_{H^1} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}. \tag{7.32}$$

□

THEOREM 7.8. (i) *For all* $(\alpha, \theta) \in I(-h, 0) \times I(-h, 0) \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$

$$P(\alpha, \theta)^* = P(\theta, \alpha). \tag{7.33}$$

(ii) *The matrix function*

$$(\alpha, \theta) \to P(\alpha, \theta) : I(-h, 0) \times I(-h, 0) \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \tag{7.34}$$

is bounded and continuous.

(iii) *There exists a constant* $c > 0$ *such that*

$$\sup\left\{\int_{-h}^{0} |P(\theta, \alpha)|^2 \, d\theta \,|\, \alpha \in I(-h, 0)\right\} \leqq c, \tag{7.35}$$

$$\sup\left\{\int_{-h}^{0} |P(\alpha, \theta)|^2 \, d\alpha \,|\, \theta \in I(-h, 0)\right\} \leqq c, \tag{7.36}$$

$$\sup\left\{\int_{-h}^{0} \left|\frac{\partial P}{\partial \alpha}(\theta, \alpha)\right|^2 d\alpha \,|\, \theta \in I(-h, 0)\right\} \leqq c, \tag{7.37}$$

$$\sup\left\{\int_{-h}^{0} \left|\frac{\partial P}{\partial \theta}(\theta, \alpha)\right|^2 d\theta \,|\, \alpha \in I(-h, 0)\right\} \leqq c. \tag{7.38}$$

When h is finite the matrix functions

$$\left.\begin{aligned} &(\alpha, \theta) \to P(\alpha, \theta), \\ &(\alpha, \theta) \to \frac{\partial P}{\partial \alpha}(\alpha, \theta), \\ &(\alpha, \theta) \to \frac{\partial P}{\partial \theta}(\alpha, \theta), \end{aligned}\right\} : I(-h, 0) \times I(-h, 0) \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n), \tag{7.39}$$

all belong to $L^2(I(-h, 0) \times I(-h, 0); \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n))$.

(iv) *For each* $\phi = (\phi^0, \phi^1)$ *in* M^2 *and* α *in* $I(-h, 0)$

$$(P_J J^* j^* \phi)(\alpha) = P(0, \alpha)\phi^0 + \int_{-h}^{0} P(\theta, \alpha)\phi^1(\theta) \, d\theta. \tag{7.40}$$

For all ϕ *and* ψ *in* $L^2(-h, 0; \mathbb{R}^n)$

$$\int_{-h}^{0} \psi(\alpha) \cdot \frac{\partial}{\partial \alpha} \int_{-h}^{0} P(\theta, \alpha)\phi(\theta) \, d\theta \, d\alpha = \int_{-h}^{0} \int_{-h}^{0} \frac{\partial P}{\partial \alpha}(\alpha, \theta)\psi(\alpha) \, d\alpha \cdot \phi(\theta) \, d\theta. \tag{7.41}$$

When ϕ *belongs to* $L^2(-h, 0; \mathbb{R}^n) \cap L^1(-h, 0; \mathbb{R}^n)$

$$\int_{-h}^{0} \psi(\alpha) \cdot \frac{\partial}{\partial \alpha} \int_{-h}^{0} P(\theta, \alpha)\phi(\theta) \, d\theta \, d\alpha = \int_{-h}^{0} \psi(\alpha) \cdot \int_{-h}^{0} \frac{\partial P}{\partial \alpha}(\theta, \alpha)\phi(\theta) \, d\theta \, d\alpha; \tag{7.42}$$

in particular, when h is finite, $L^2(-h, 0; \mathbb{R}^n) \cap L^1(-h, 0; \mathbb{R}^n) = L^2(-h, 0; \mathbb{R}^n)$ *and the above identity is true for all* ϕ *and* ψ *in* $L^2(-h, 0; \mathbb{R}^n)$.

(v) *The continuous linear operator* $\Pi = jPj^*$ *in* $\mathcal{L}(M^2, M^2)$ *can be decomposed as a matrix of operators as in Theorem* 6.5(vi).

Proof. Similar to the proof of Theorem 6.5. □

THEOREM 7.9. *The matrix $P(\alpha, \theta)$ satisfies the following set of differential equations*

$$(7.43)\quad \int_{-h}^{0} d_\theta \eta^T P(0,\theta) + \int_{-h}^{0} P(\theta,0)\, d_\theta \eta - \int_{-h}^{0} P(\zeta,0)\, d_\zeta \beta N^{-1} \int_{-h}^{0} d_\xi \beta^T P(0,\xi) + Q = 0,$$

$$(7.44)\quad \frac{\partial P}{\partial \theta}(\theta,0) + \int_{-h}^{0} d_\alpha \eta^T P(\theta,\alpha) - \int_{-h}^{0} P(\zeta,0)\, d_\zeta \beta N^{-1} \int_{-h}^{0} d_\xi \beta^T P(\theta,\xi) = 0,$$

$$(7.45)\quad \left(\frac{\partial}{\partial \theta} + \frac{\partial}{\partial \alpha}\right) P(\alpha,\theta) - \int_{-h}^{0} P(\zeta,\theta)\, d_\zeta \beta N^{-1} \int_{-h}^{0} d_\xi \beta^T P(\alpha,\xi) = 0,$$

$$(7.46)\quad P(\alpha,\theta)^* = P(\theta,\alpha) \quad \forall \alpha, \theta \in I(-h,0).$$

When h is finite, the elements of the matrix function $(\alpha,\theta) \to \partial P/\partial\alpha(\alpha,\theta)$ and $\partial P/\partial\theta(\alpha,\theta)$ belong to L^2.

Proof. Similar to proof of Theorem 6.6 □

Appendix to Section 2.

Proof of Lemma 2.1. In the proof we shall use results from W. Rudin [1, Chap. 6] on complex measures which includes, as a special case, real measures. We only provide a proof for B; the argument for L is the same with obvious changes.

(i) By the Riesz representation theorem (cf. W. Rudin [1, p. 131, Thm. 6.19]).

(ii) The map $t \to v_t : [0,a] \to C_0(-h,0;\mathbb{R}^m)$,

$$v_t : I(-h,0) \to \mathbb{R}^m, \qquad v_t(\theta) = v(t+\theta),$$

is continuous since the functions v in $C_c(-h,a;\mathbb{R}^m)$ are uniformly continuous. So the function $\mathcal{B}u$ is continuous since B is continuous on $C_0(-h,0;\mathbb{R}^m)$. Hence the map (2.5) is linear and continuous.

(iii) For arbitrary functions f in $C(0,a;\mathbb{R}^n)$ and u in $C_c(-h,a;\mathbb{R}^m)$ consider the integral

$$(1)\qquad \int_0^a d_t m f(t) \cdot \int_{-h}^{0} d_\theta \beta u(t+\theta) = \sum_{i=1}^{n} \sum_{j=1}^{m} \int_0^a d_t m f_i(t)\, d_\theta \beta_{ij} u_j(t+\theta),$$

where the f_i's, β_{ij}'s and u_j's are the respective components of f, β and u and m denotes the Lebesgue measure on $[0,a]$. For each pair i,j the integrand is continuous in $[0,a]\times I(-h,0)$ and hence $(m\times\beta_{ij})$-measurable. Moreover it is also integrable since

$$\int_0^a d_t m \int_{-h}^{0} |f(t)|\, d_\theta|\beta|\, |u(t+\theta)| \leqq |\beta|([-h,0]\cap\mathbb{R})\|f\|_{L^1}\|u\|_C < \infty,$$

where $|\beta|$ is the total variation of the matrix of measures β. By the Riesz representation theorem and the definition of $|\beta|$, the quantity $|\beta|(I(-h,0))$ is finite. So the conditions of Fubini's theorem (cf. W. Rudin [1, p. 140, Thm. 7.8]) are met and the order of integration can be changed in (1):

$$(f, \mathcal{B}v) = \sum_{i=1}^{n} \sum_{j=1}^{m} \int_{-h}^{0} d_\theta \beta_{ij} \int_0^a d_t m f_i(t) v_j(t+\theta).$$

Each element in the above double summation can be estimated separately:

$$\left|\int_{-h}^{0} d_\theta \beta_{ij} \int_0^a d_t m f_i(t) v_j(t+\theta)\right| \leqq \int_{-h}^{0} d_\theta |\beta_{ij}| \int_0^a d_t m |f_i(t)|\,|v_j(t+\theta)|$$

$$\leqq \int_{-h}^{0} d_\theta |\beta_{ij}|\,\|f_i\|_{L^2(0,a)} \|v_j\|_{L^2(\theta,a+\theta)}$$

$$\leqq |\beta_{ij}|(I(-h,0))\|f_i\|_{L^2(0,a)} \|v_j\|_{L^2(-h,a)}.$$

Finally

$$|(f, \mathcal{B}v)| \leqq |\beta|(I(-h,0))\|f\|_2 \|v\|_2.$$

This new estimate combined with the density of $C(0, a; \mathbb{R}^n)$ in $L^2(0, a; \mathbb{R}^n)$ (cf. W. Rudin [1, p. 68, Thm. 3.14]) yields

$$\|\mathcal{B}v\|_{L^2(0,a)} \leqq |\beta|(I(-h,0))\|v\|_{L^2(-h,a)}.$$

Note that the L^2-norm of v is with respect to the Lebesgue measure. By density of $C_c(-h, a; \mathbb{R}^m)$ in $L^2(-h, a; \mathbb{R}^m)$ (cf. W. Rudin [1, p. 68, Thm. 3.14]) the map (2.5) extends by continuity to a continuous linear map on all $L^2(-h, a; \mathbb{R}^m)$. □

Proof of Lemma 2.3. We already know that an element x of $H^1(-\infty, 0; \mathbb{R}^n)$ is almost everywhere equal to a unique bounded continuous function $\bar{x}$ in $C(-\infty, 0; \mathbb{R}^n)$. We also know that the injection $x \to \bar{x}$ of $H^1(-\infty, 0; \mathbb{R}^n)$ into $C(-\infty, 0; \mathbb{R}^n)$ is continuous (cf. Adams [1, p. 97, Thm. 5.4]).

It remains to prove that $\bar{x}$ belongs to the closed subspace $C_0(-\infty, 0; \mathbb{R}^n)$ of $C(-\infty, 0; \mathbb{R}^n)$. For each pair $-\infty < s' \leqq t \leqq 0$

$$\bar{x}(t) = \bar{x}(s') + \int_{s'}^{t} Dx(r)\, dr$$

and

$$(t-s)^{1/2}|\bar{x}(t)| \leqq \|\bar{x}\|_{L^2(s,t;\mathbb{R}^n)} + (t-s)\|Dx\|_{L^2(s,t;\mathbb{R}^n)}.$$

But $\bar{x} = x$ in $L^2(s, t; \mathbb{R}^n)$ and for $s = t-1$

$$|\bar{x}(t)| \leqq \sqrt{2}\|x\|_{H^1(t-1,t;\mathbb{R}^n)} \leqq \sqrt{2}\|x\|_{H^1(-\infty,t;\mathbb{R}^n)}.$$

But for each $\varepsilon > 0$, there exists $T < 0$ such that

$$\forall t \leqq T, \qquad \|x\|_{H^1(-\infty,t;\mathbb{R}^n)} \leqq \varepsilon.$$

In view of the above two inequalities

$$\forall \varepsilon > 0, \exists t < 0 \quad \text{such that } \forall t \leqq T, \qquad |\bar{x}(t)| \leqq \varepsilon.$$

This shows that $\bar{x}(t)$ goes to zero as t goes to $-\infty$ and proves that $\bar{x}$ belongs to $C_0(-\infty, 0; \mathbb{R}^n)$. □

Proof of Lemma 2.6. (i) Same proof as in Lemma 2.1(ii).
(ii) Choose z and x in $C_c(s, t; \mathbb{R}^n)$

$$\begin{aligned}
\int_s^t z(t-r)\cdot(\mathscr{L}e_+^s x)(r)\,dr &= \int_s^t z(t-r)\cdot\int_{-h}^0 d_\theta\eta(e_+^s x)(r+\theta)\,dr\\
&= \int_{-h}^0\int_s^t z(t-z)\cdot d_\theta\eta(e_+^s x)(r+\theta)\,dr\\
&= \int_{-h}^0\int_s^t (e_+^0 z)(t-r)\cdot d_\theta\eta(e_+^s x)(r+\theta)\,dr\\
&= \int_{-h}^0\int_{s+\theta}^{t+\theta} (e_+^0 z)(t-r+\theta)\cdot d_\theta\eta(e_+^s x)(r)\,dr\\
&= \int_{-h}^0\int_s^t d_\theta\eta^T(e_+^0 z)_{t-r}(\theta)\cdot(e_+^s x)(r)\,dr\\
&= \int_s^t L^T(e_+^0 z)_{t-r}\cdot(e_+^s x)(r)\,dr\\
&= \int_s^t (\mathscr{L}^T e_+^0 z)(t-r)\cdot(e_+^s x)(r)\,dr. \qquad \square
\end{aligned}$$

Proof of Theorem 2.7. (i) For $t=s$ the result is obvious. Fix the pair $0\leqq s<t$. Let x be the solution of (2.32):

$$\begin{aligned}
&\frac{dx}{dr}(r) = [\mathscr{L}e_+^s x + \mathscr{B}e_+^s u + f^0](r) + (e_+^{-h}\xi^1)(s-r), \qquad s\leqq r\leqq t,\\
&x(s) = \xi^0.
\end{aligned} \tag{2}$$

For an arbitrary $\psi=(\psi^0,\psi^1)$ in $V=\mathscr{D}(A^T)$, let z be the solution in $H^1_{\mathrm{loc}}(0,\infty;\mathbb{R}^n)$ of the equation

$$\frac{dz}{dr}(r) = L^T z_r, \quad r\geqq 0, \quad (z(0), z_0)=\psi. \tag{3}$$

We know that for $r\geqq 0$

$$(z(r), z_r) = S^T(r)\psi. \tag{4}$$

Inner product (2) with $z(t-r)$ on $[s,t]$:

$$\int_s^t z(t-r)\cdot[-\dot{x}(r)+(\mathscr{L}e_+^s x)(r)+(\mathscr{B}e_+^s u)(r)+f^0(r)+(e_+^{-h}\xi^1)(s-r)]\,dr=0. \tag{5}$$

Integrate by parts and use identities (2.41)

$$\begin{aligned}
0 = &\int_{-s}^t [-\dot{z}(t-r)+(\mathscr{L}^T e_+^0 z)(t-r)]\cdot x(r)\,dr\\
&+\int_s^t [(\mathscr{B}^T e_+^0 z)(t-r)\cdot u(r)+z(t-r)\cdot f^0(r)]\,dr\\
&+\int_s^t z(t-r)\cdot(e_+^{-h}\xi^1)(s-r)\,dr - z(0)\cdot x(t)+z(t-s)\cdot x(s)
\end{aligned}$$

or

$$\int_s^t [(\mathscr{L}^T e_-^0 z)(t-r)\cdot x(r)+(\mathscr{B}^T e_-^0 z)(t-r)\cdot u(r)]\,dr+\psi^0\cdot x(t)$$

$$(6)\qquad =\int_s^t [(\mathscr{B}^T z)(t-r)\cdot u(r)+z(t-r)\cdot f^0(r)\,dr$$

$$+z(t-s)\cdot\xi^0+\int_s^t z(t-r)\cdot(e_+^{-h}\xi^1)(s-r)\,dr.$$

But $e_-^0 z=\psi^1$ and after a change of variable the left-hand side of the above inequality becomes

$$\psi^0\cdot x(t)+\int_{-(t-s)}^0 [(\mathscr{L}^T e_-^0\psi^1)(-\alpha)x(t+\alpha)+(\mathscr{B}^T e_-^0\psi^1)(-\alpha)\cdot u(t+\alpha)]\,d\alpha$$

$$(7)\qquad =\psi^0\cdot x(t)+(H^T\psi^1,(e_+^s x)_t)+(K^T\psi^1,(e_+^s u)_t).$$

In addition

$$\int_s^t z(t-r)\cdot(e_+^{-h}\xi^1)(s-r)\,dr=\int_{s-t}^0 (e_+^0 z)(t-s+\alpha)\cdot(e_+^{-h}\xi^1)(\alpha)\,d\alpha$$

$$(8)\qquad =((e_+^0 z)_{t-s},\xi^1)=(z_{t-s},\xi^1)-((e_-^0\psi^1)_{t-s},\xi^1)$$

and

$$((e_-^0\psi^1)_{t-s},\xi^1)=\int_{-h}^0 (e_-^0\psi^1)(t-s+\alpha)\cdot\xi^1(\alpha)\,d\alpha$$

$$(9)\qquad =\int_{-h}^0 \psi^1(\beta)(e_+^{-h}\xi^1)(s-t+\beta)\,d\beta=(\psi^1,\mathscr{E}(\xi^1)(t-s)).$$

By combining (6)-(9) we obtain

$$\psi^0\cdot x(t)+(\psi^1,H(e_+^s x)_t+K(e_+^s u)_t+\mathscr{E}(\xi^1)(t-s)$$

$$=\int_s^t [B^T z_{t-r}\cdot u(r)+z(t-r)\cdot f^0(r)]\,dr+z(t-s)\cdot\xi^0+(z_{t-s},\xi^1)$$

or using the definition (2.34) for $\hat{x}(t)$ and (2.42) for j

$$((\psi,\hat{x}(t))=((S^T(t-s)j\psi,\xi))$$

$$(10)\qquad +\int_s^t [B^T J^{-1}S_V^T(t-r)\psi\cdot u(r)+S^T(t-r)j\psi\cdot(f^0(r),0)]\,dr.$$

By definition of j in (2.42)

$$(11)\qquad S^T(t)j\psi=jS_V^T(t)\psi\quad\forall\psi\in V=\mathscr{D}(A^T),$$

and identity (2.43) can be obtained from identity (10) which is true for all ψ in V.

(ii) We first show that $\hat{x}$ belongs to $C(s,T;M^2)$. By construction, the $\mathbb{R}^n$-component of $\hat{x}(t)$ belongs to $H^1(s,T;\mathbb{R}^n)$ and, a fortiori, to $C(s,T;\mathbb{R}^n)$. We only need to show the continuity of the L^2-component of $\hat{x}(t)$. Pick any t' and t in $[s,t]$:

$$\|\hat{x}^1(t')-\hat{x}^1(t)\|_2\leqq\|H((e_+^s(x))_{t'}-(e_+^s(x))_t)\|_2+\|K((e^s(u))_{t'}-(e_+^s(u))_t)\|_2$$

$$+\left[\int_{-h}^0 |(\mathscr{E}(\xi^1))(t'-s-\theta)-(\mathscr{E}(\xi^1))(t-s-\theta)|^2\,d\theta\right]^{1/2}.$$

The function $e_+^{-h}\xi^1$ is the extension by 0 of the function ξ^1 defined on $I(-h,0)$ to $]-\infty,0]$. For all $r\geqq 0$ we define the right shift

$$(e_+^{-h}\xi^1)_{-r}: I(-h,0)\to\mathbb{R}^n,\quad (e_+^{-h}\xi^1)_{-r}(\theta)=(e_+^{-h}\xi^1)(\theta-r),\quad \theta\in I(-h,0).$$

As a result for all $r\geqq 0$ and $\theta\in I(-h,0)$

$$\mathscr{E}(\xi^1)(r-\theta)=(e_+^{-h}\xi^1)(\theta-r).$$

By continuity of H and K, we obtain the following first upper bound:

$$c[\|(e_+^s(x))_{t'}-(e_+^s(x))_t\|_2+\|(e_+^s(u))_{t'}-(e_+^s(u))_t\|_2+\|(\xi_-^1)_{s-t'}-(\xi_-^1)_{s-t}\|_2].$$

But the square bracket only contains terms which can be considered as right or left shifts of L^2-functions. The continuity of $\hat{x}^1(t)$ now follows from the continuity of the shift operator.

Next compute the vectorial distributional derivative of $j^*\hat{x}(t)$. For all ψ in V

$$\langle\psi, j^*\hat{x}(t)\rangle_V=\langle\psi, j^*①+②\rangle_V,$$

where

$$①=\left[S^T(t-s)^*\xi+\int_s^t S^T(t-r)^*(f^0(r),0)\,dr\right]\in M^2,$$

$$②=\int_s^t S_V^T(t-r)^*(B^TJ^{-1})^*u(r)\,dr\in V'.$$

In view of the definitions and results of § 2.2, the function $t\to\langle\psi, j^*①\rangle_V=((j\psi,①))$ belongs to $H^1(s,T;\mathbb{R})$ and

$$\frac{d}{dt}\langle\psi, j^*①\rangle_V=((A^T\psi,①))+((j\psi,(f^0(t),0)))$$

for all ψ in $\mathscr{D}(A^T)=V$. For all ψ in $\mathscr{D}(A_V^T)$, the function $t\to\langle\psi,②\rangle_V$ belongs to $H^1(s,T;\mathbb{R})$ and

$$\frac{d}{dt}\langle\psi,②\rangle_V=\int_s^t\langle S_V^T(t-r)A_V^T\psi,(B^TJ^{-1})^*u(r)\rangle_V\,dr+\langle\psi,(B^TJ^{-1})^*u(t)\rangle_V$$
$$=\langle A_V^T\psi,②\rangle_V+\langle\psi,(B^TJ^{-1})^*u(t)\rangle_V.$$

Finally for all ψ in $\mathscr{D}(A_V^T)$, $A^T\psi=jA_V^T\psi$ and

$$\frac{d}{dt}\langle\psi, j^*①+②\rangle_V=((jA_V^T\psi,①))+((j\psi,(f^0(t),0)))+\langle A_V^T\psi,②\rangle_V+\langle\psi,(B^TJ^{-1})^*u(t)\rangle_V$$
$$=\langle A_V^T\psi, j^*①+②\rangle_V+\langle\psi,(B^TJ^{-1})^*u(t)+j^*(f^0(t),0)\rangle_V.$$

But

$$\langle A_V^T\psi, j^*①+②\rangle_V=\langle A_V^T\psi, j^*\hat{x}(t)\rangle_V=((jA_V^T\psi,\hat{x}(t)))=((A^T\psi,\hat{x}(t))),$$

and

$$\frac{d}{dt}\langle\psi, j^*\hat{x}(t)\rangle_V=\langle\psi,(A^T)^*\hat{x}(t)+(B^TJ^{-1})^*u(t)+j^*(f^0(t),0)\rangle_V. \tag{12}$$

By density of $\mathscr{D}(A_V^T)$ in V the above equation is true for all ψ in V and the vectorial

distributional derivative $D_t j^*\hat{x}$ of $j^*\hat{x}$ is the element of $L^2(s, T; V')$ given by

$$\frac{d}{dt}(j^*\hat{x})(t) = (A^T)^*\hat{x}(t) + (B^T J^{-1})^* u(t) + j^*(f^0(t), 0). \tag{13}$$

At this stage we have shown that $\hat{x}$ belongs to $\mathcal{W}(s, t; M^2, V')$ and that $\hat{x}$ is a solution of (13) with $\hat{x}(s) = \xi$. The proof of uniqueness follows standard arguments and will be omitted.

(iii) Equation (2.49) follows from (12) (ii).

(iv) By definition of B, the map $B^T: C_0(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n$ is given by the expression

$$B^T\phi = B_0^T\phi(0) + \int_{-h}^{0} B_1(\theta)^T\phi(\theta)\, d\theta;$$

by definition of B_M^T and all ϕ in $H^1(-h, 0; \mathbb{R}^n)$

$$B^T J^{-1}\phi = B_M^T j\phi \Rightarrow B^T J^{-1} = B_M^T j.$$

Making use of the above identity, we get

$$S_V^T(t-r)^*(B^T J^{-1})^* = S_V^T(t-r)^*(B_M^T j)^* = S_V^T(t-r)^* j^*(B_M^T)^* = j^* S^T(t-r)^*(B_M^T)^*.$$

Then the substitution of the last identity in (2.46) yields

$$\hat{x}(t) = S^T(t-s)^*\xi + \int_s^t S^T(t-r)^*[(B_M^T)^* u(r) + (f^0(r), 0)]\, dr.$$

Identities (2.51) and (2.52) are obtained from identities (2.45) and (2.46) by a similar argument. □

Appendix to Section 4.

Proof of Theorem 4.5. (i) From Lemma 4.4 by transposing (4.15).

(ii) We first establish identity (4.33). For some arbitrary ψ in V, let v be the solution in $\mathcal{V}(0, T)$ of the equation

$$\frac{djv}{dt} + A^T v = 0, \quad v(T) = \psi \Rightarrow v(t) = S_V^T(T-t)\psi \quad \forall t \in [0, T].$$

Upon substitution in (4.30) we get

$$\langle z_T, \psi\rangle_V = \int_0^T \langle f(t), S_V^T(T-t)\psi\rangle_V\, dt + \langle \xi, S_V^T(T)\psi\rangle_V$$

$$= \left\langle S_V^T(T)^*\psi + \int_0^T S_V^T(T-t)^* f(t)\, dt, \psi \right\rangle_V.$$

Since ψ is arbitrary we obtain (4.33). To establish identity (4.32) fix an arbitrary g in $L^2(0, T; V)$ and construct the solution v in $\mathcal{V}(0, T)$ of the equation

$$\frac{djv}{dt} + A^T v + jg = 0, \qquad v(T) = 0 \Rightarrow v(t) = \int_t^T S_V^T(r-t)g(r)\, dr.$$

By direct substitution in (4.30)

$$\int_0^T \langle z(t), lg(t)\rangle_W\, dt = \int_0^T \left\langle f(t), \int_t^T S_V^T(r-t)g(r)\, dr \right\rangle_V dt + \left\langle \xi, \int_0^T S_V^T(r)g(r)\, dr \right\rangle_V$$

$$= \int_0^T \left\langle S_V^T(r)^*\xi + \int_0^r S_V^T(r-t)^* f(t)\, dt, g(r) \right\rangle_V dr.$$

Since the last identity is true for all g we necessarily obtain (4.32).

(iii) Denote by $\mathscr{A}$ the isomorphism (4.24) in Lemma 4.3. From parts (i) and (ii) for all (f, ξ) in $L^2(0, T; V') \times V'$ there exists a unique x in $\mathscr{Z}(0, T)$ such that

$$x(t) = l^* z(t), \quad \text{a.e. in } [0, T] \quad \text{and} \quad (f, \xi) = \mathscr{A}x = \mathscr{A}l^* z.$$

Moreover, always from parts (i) and (ii), the map

$$(f, \xi) \to z: L^2(0, T; V') \times V' \to \mathscr{Z}(0, T)$$

is linear, injective and continuous. As a result $\mathscr{A}l^*$ is surjective, linear and, from (4.31), $(\mathscr{A}l^*)^{-1}$ is continuous. Therefore $\mathscr{A}l^*$ is an isomorphism.

(iv) The integration by parts formula follows from parts (i) and (iii) by choosing

$$f = \left[\frac{d}{dt} - (A^T)^*\right](l^* z) \quad \text{and} \quad \xi = (l^* z)(0)$$

in the variational equation (4.30). □

Proof of Theorem 4.6. (i) Given v in $C(0, T; V)$, let $\tilde{v}$ be the unique solution in $\mathscr{V}(0, T) \subset C(0, T; V)$ of the differential equation

$$-\left[\frac{d}{dt} + A^T\right]\tilde{v} = lKv + g, \qquad \tilde{v}(T) = \psi$$

for arbitrary g in $L^2(0, T; W)$ and ψ in V. Denote by Γ the map

$$v \to \Gamma v = \tilde{v}; \qquad C(0, T; V) \to C(0, T; V).$$

By construction, it is linear and continuous. We show that the map Γ is a contraction and hence has a unique fixed point. Given v_1 and v_2 in $C(0, T; V)$, we obtain, by linearity, that $\tilde{v}_2 - \tilde{v}_1$ is the unique solution of the equation

$$-\left[\frac{d}{dt} + A^T\right](\tilde{v}_2 - \tilde{v}_1) = lK(v_2 - v_1), \qquad \tilde{v}_2(T) - \tilde{v}_1(T) = 0.$$

This last equation is equivalent to

$$\tilde{v}_2(t) - \tilde{v}_1(t) = \int_t^T S_V^T(s - t)K(s)[v_2(s) - v_1(s)]\, ds, \qquad 0 \leqq t \leqq T.$$

By uniform boundedness of the operators $\{K(t): 0 \leqq t \leqq T\}$ and $\{S_V^T(t): 0 \leqq t \leqq T\}$

$$\|\tilde{v}_2(t) - \tilde{v}_1(t)\|_V \leqq c \int_t^T \|v_2(s) - v_1(s)\|_V\, ds, \qquad 0 \leqq t \leqq T.$$

This is sufficient to conclude that Γ is a contraction (standard argument). In particular there exists a unique v in $C(0, T; V)$, and a fortiori in $\mathscr{V}(0, T)$, such that $\Gamma v = v$: v is the unique solution in $\mathscr{V}(0, T)$ of the equation

$$-\left[\frac{d}{dt} + A^T\right]v = lKv + g, \qquad v(T) = \psi.$$

From this we conclude that the continuous linear map (4.42) is bijective. By the Banach inverse mapping theorem, it is an isomorphism.

(ii) An argument similar to the one of part (i) can be used to prove that the map (4.44) is an isomorphism. □

Appendix to Section 5.

Proof of Lemma 5.3. The equivalence of (i) and (ii) is a direct consequence of identity (5.18). We show that (i) is equivalent to (iii). Substitute $v=\psi$ and $z=\beta$ in the integration by parts formula (4.38) of Theorem 4.5(iv) on the time interval $[s, T]$

$$\langle (l^*\beta)(s), \psi(s)\rangle_V = \langle (l^*\beta)(T), \psi(T)\rangle_V + \int_s^T \langle \beta, -[D_t + A^T]\psi\rangle_W \, dt$$

$$- \int_s^T \langle [D_t - (A_V^T)^*] l^*\beta, \psi\rangle_V \, dt.$$

In view of (5.19) and (5.21) the above identity reduces to

$$0 = \int_s^T [\langle \beta, \hat{Q}\phi\rangle_W + \langle R\gamma - f, \psi\rangle_V] \, dt. \tag{1}$$

Similarly substitute $v=\gamma$ and $z=\phi$ in (4.38) on the time interval $[s, T]$

$$\langle (l^*\phi)(s), \gamma(s)\rangle_V = \langle (l^*\phi)(T), \gamma(T)\rangle_V + \int_s^T \langle \phi, -[D_t + A^T]\gamma\rangle_W \, dt$$

$$- \int_s^T \langle [D_t - (A_V^T)^*] l^*\phi, \gamma\rangle_V \, dt$$

and

$$\langle h, r(s)\rangle_V = \int_s^T [\langle \phi, \hat{Q}\beta + q\rangle_W + \langle R\psi, \gamma\rangle_V] \, dt. \tag{2}$$

Using the symmetry of $\hat{Q}$ and R and substracting (1) from (2) we obtain

$$\langle h, r(s)\rangle_V = \int_s^T [\langle \phi, q\rangle_W + \langle f, \psi\rangle_V] \, dt \tag{3}$$

for all s in $[0, T]$ and all h in V'. This last identity proves the equivalence of (i) and (iii).

To complete the proof of the lemma, recall that ψ and ϕ are necessarily related as follows:

$$\psi(t) = P(t)(l^*\phi)(t), \qquad s \leqq t \leqq T,$$

(cf. identity (5.18) in Theorem 5.2 applied to system (5.19)-(5.20).) Thus

$$\langle f(t), \psi(t)\rangle_V = \langle f(t), P(t)(l^*\phi)(t)\rangle_V = \langle (l^*\phi)(t), P(t)f(t)\rangle_V$$

$$= \langle l^*\phi(t), P(t)f(t)\rangle_V = \langle \phi(t), lP(t)f(t)\rangle_W$$

and when $q(t) = -lP(t)f(t)$, the right-hand side of (3) is identically null for all h and s. This shows that $r=0$ and completes the proof of the lemma. □

Proof of Theorem 5.4. (i) Pick any x in $\mathscr{Z}(0, T)$ and consider the equation

$$-[D_t + A^T]p + lPRp = \hat{Q}x - lP[D_t - (A_V^T)^*]l^*x, \qquad p(T) = 0. \tag{4}$$

By the perturbation Theorem 4.6 there exists a unique solution p in $\mathscr{V}(0, T)$ since the right-hand side belongs to $L^2(0, T; W)$. Define the function f, q and the vector ξ

$$f = [D_t - (A_V^T)^*]l^*x + Rp, \quad q = -lPf, \quad \xi = (l^*x)(0).$$

Then the pair (x, p) is the solution of the system

$$-[D_t + A^T]p = \hat{Q}x + q, \quad p(T) = 0, \quad [D_t - (A_V^T)^*](l^*x) = -Rp + f, \quad (l^*x)(0) = \xi.$$

But this is precisely the Hamiltonian system where q and f are such that $q = -lPf$. By Lemma 5.3 this implies that

$$p(t) = P(t)(l^*x)(t).$$

The substitution of the right-hand side of the last identity into (4) yields (5.29).

To prove uniqueness, let Z be a family in the class $(\mathscr{P})$ such that for all x in $\mathscr{X}(0, T)$ the function Zl^*x is the unique solution in $\mathscr{V}(0, T)$ to the equation

$$(5)\quad [D_t + A^T]Zl^*x - lZ[D_t - (A_V^T)^*]l^*x - lZRZl^*x + \hat{Q}x = 0, \qquad (Zl^*x)(T) = 0.$$

By substracting (5.29) from (5) we obtain

$$(6)\quad \begin{aligned} &\{[D_t + A^T] - lPR\}(Z-P)l^*x - l(Z-P)\{[D_t - (A_V^T)^*] + RP\}l^*x \\ &\quad - l(Z-P)R(Z-P)l^*x = 0, \\ &[(Z-P)l^*x](T) = 0. \end{aligned}$$

For all x in $\mathscr{X}(0, T)$, $(Z-P)l^*x$ belongs to $\mathscr{V}(0, T)$. We use integration by parts formula (4.38) on $[t, T]$ to obtain

$$\begin{aligned} &\langle x, \{[D_t + A^T] - lPR\}(Z-P)l^*x\rangle_{L^2(t,T;W)} \\ &\quad = -\langle\{[D_t - (A_V^T)^*] + RP\}l^*x, (Z-P)l^*x\rangle_{L^2(t;T;V)} \\ &\qquad - \langle(l^*x)(t), (Z-P)(t)(l^*x)(t)\rangle_V. \end{aligned}$$

Finally from the last identity and (6)

$$(7)\quad \begin{aligned} &-2\langle\{[D_t - (A_V^T)^*] + RP\}l^*x, (Z-P)l^*x\rangle_{L^2(t,T;V)} \\ &\quad = \langle R(Z-P)l^*x, (Z-P)l^*x\rangle_{L^2(t,T;V)} \\ &\qquad + \langle(l^*x)(t), (Z-P)(t)(l^*x)(t)\rangle_V \end{aligned}$$

where we have used the fact that $Z(t)$ and $P(t)$ are symmetrical. For an arbitrary h in V', construct the solution x in $\mathscr{V}(t, T; W', V')$ to

$$\{[D_t - (A_V^T)^*] + RP\}l^*x = 0 \quad \text{in } [t, T], \qquad (l^*x)(t) = h$$

(this is possible by the perturbation Theorem 4.6). Substitute this x in (7) to obtain

$$(8)\quad \langle h, [Z(t) - P(t)]h\rangle_V \leqq 0 \quad \forall h \in V'.$$

Now repeat the same steps with P and Z interchanged. The end result will be

$$(9)\quad \langle h, [P(t) - Z(t)]h\rangle_V \leqq 0 \quad \forall h \in V'.$$

Since $P(t) - Z(t)$ is a positive symmetrical operator, for all h and k in V'

$$\begin{aligned} 4\langle h, [P(t) - Z(t)]k\rangle_V &= \langle h + k, [P(t) - Z(t)](h + k)\rangle_V - \langle h - k, [P(t) - Z(t)](h - k)\rangle_V \\ &= 0, \end{aligned}$$

since from (8) and (9)

$$\langle h, [P(t) - Z(t)]h\rangle_V = 0 \quad \forall h \in V'.$$

This shows that for all t in $[0, T]$, $Z(t) = P(t)$. Therefore P is unique in the class $(\mathscr{P})$.

(ii) The continuity of the linear map Pl^* defined by (5.28) is a direct consequence of the continuity of the solution p to (4) with respect to the data and the uniform boundedness of P in $[0, T]$.

(iii) From identity (5.18) in Theorem 5.2(i)

$$r(t) = p(t) - P(t)(l^*y)(t).$$

The function r belongs to $\mathcal{V}(0, T)$ since both p and Pl^*y do. Recall that

$$-[D_t + A^T]p = \hat{Q}y + q, \qquad p(T) = 0. \tag{10}$$

Substitute $x = y$ in (5.29)

$$-[D_t + A^T](Pl^*y) = \hat{Q}y - lPRPl^*y - lP[D_t - (A_V^T)^*]l^*y, \qquad (Pl^*y)(T) = 0. \tag{11}$$

By substracting (11) from (10)

$$-[D_t + A^T]r = lP\{[D_t - (A_V^T)^*]l^*y + RPl^*y\} + q, \qquad r(T) = 0. \tag{12}$$

But from identities (5.18) and (5.16)

$$RPl^*y = R(p - r), \qquad [D_t - (A_V^T)^*](l^*y) = -Rp + f,$$

the expression between curly brackets in (12) reduces to $f - Rr$ and (12) finally reduces to (5.30). By the perturbation Theorem 4.6, we know that the solution r to (5.30) is unique. □

Proof of Theorem 5.5. (i) When x belongs to $\mathcal{W}(0, T; M^2, V')$, $i^*x \in \mathcal{Z}(0, T)$ and $l^*(i^*x) = j^*x$ (since $j = il$). So $P(l^*i^*x) = P(j^*x)$ is the unique solution in $\mathcal{V}(0, T)$ to the equation

$$[D_t + A^T](Pj^*x) - lP[D_t - (A_V^T)^*]j^*x - lPRPj^*x + \hat{Q}i^*x = 0, \qquad (Pj^*x)(T) = 0. \tag{13}$$

Equation (5.31) is now obtained from (13) by having the map i act on each term of (13). The following identities are used

$$i\hat{Q}i^*x = \tilde{Q}x, \qquad ilP[\ ] = jP[\ ],$$

$$i[D_t + A^T](Pj^*x) = \frac{d}{dt}(jPj^*x) + A^TPj^*x,$$

$$[D_t - (A_V^T)^*]j^*x = \frac{d}{dt}j^*x - (A^T)^*x.$$

(Cf. Lemma 5.1, identities (4.14) and (4.28) and Lemma 4.3.) The uniqueness argument is similar to the one in the proof of Theorem 5.4(i).

So far we have proved that the statement of Theorem 5.4(i) implies part (i) of the theorem. Conversely we can go back from (5.31) to (13) and use the density of $\{i^*x | x \in \mathcal{W}(0, T; M^2, V')\}$ in $\mathcal{Z}(0, T)$ to recover (5.29). We just sketch the proof. The linear subspace $i^*C(0, T; M^2)$ of $L^2(0, T; W')$ is dense in $L^2(0, T; W')$. So the linear subspace

$$S = \{x \in \mathcal{Z}(0, T) | \exists z \in C(0, T; M^2) \text{ such that } i^*z = x\}$$

is dense in

$$E = \{x \in \mathcal{Z}(0, T) | \exists z \in L^2(0, T; W') \text{ such that } x = z\} = \mathcal{Z}(0, T).$$

But it is not too difficult to see that

$$S = i^*\mathcal{W}(0, T; M^2, V') \qquad \text{(as a topological vector space)}.$$

This is sufficient to prove the equivalence of part (i) and Theorem 5.4(i).

(ii) Equation (5.32) is obtained from (5.31) by choosing functions x of the form

$$x(t)=h, \quad 0\leqq t\leqq T, \quad h\in M^2.$$

We now show that the property

(I) $\qquad \forall h\in M^2, \qquad t\to P(t)j^*h$ belongs to $\mathcal{V}(0, T)$

implies the property

(II) $\quad \forall x\in \mathcal{W}(0, T; M^2, V'), \qquad t\to P(t)j^*x(t)$ belongs to $\mathcal{V}(0, T)$.

For each $x\in \mathcal{W}(0, T; M^2, V')\subset C(0, T; M^2)$ and from property (I) the function $t\to P(t)j^*x(t)$ belongs to $C(0, T; V)$. Moreover the function

$$t\to \frac{d}{dt}j^*x(t)$$

belongs to $L^2(0, T; V')$.

Therefore for almost all t in $[0, T]$

$$\frac{d}{dt}[jP(t)j^*x(t)]=\frac{d}{dt}[jP(t)j^*h]_{h=x(t)}+jP(t)\frac{d}{dt}(j^*x(t)). \tag{14}$$

But from (5.32)

$$-\frac{d}{dt}(jP(t)j^*h)|_{h=x(t)}=[A^TP(t)j^*+jP(t)(A^T)^*-jP(t)RP(t)j^*+\tilde{Q}]x(t)$$

and necessarily $d/dt(jPj^*x)$ belongs to $L^2(0, T; M^2)$. Furthermore

$$\frac{d}{dt}(jP(t)j^*x(t))+A^TP(t)j^*x(t)$$

$$=-[jP(t)(A^T)^*-jP(t)RP(t)j^*+\tilde{Q}]x(t)+jP(t)\frac{d}{dt}j^*x(t).$$

But $j=il$, $\tilde{Q}=i\hat{Q}i^*$ and

$$\frac{d}{dt}(jPj^*x)+A^TPj^*x=iF$$

where $F\in L^2(0, T; W)$ is given by the expression

$$F=l\left\{P\frac{d}{dt}(j^*x)-P[(A^T)^*-RPj^*]x\right\}-\hat{Q}i^*x.$$

There exists a unique $y\in \mathcal{V}(0, T; V, W)$ such that

$$[D_t+A^T]y=F, \qquad y(T)=0.$$

Therefore

$$\frac{d}{dt}(jPj^*x)+A^TPj^*x=i[D_t+A^T]y=\frac{d}{dt}jy+A^Ty, \qquad (Pj^*x)(T)=0=y(T).$$

By uniqueness of solution in $\mathcal{W}(0, T; V, M^2)$, $y=Pj^*x\in \mathcal{V}(0, T)$. This proves that (I) implies (II). The converse is obvious. Now to complete the proof we must show that for an arbitrary x in $\mathcal{W}(0, T; V, M^2)$ we can go from (5.32) to (5.31). Set $h=x(t)$ in

(5.32) and recall from (14) that

$$\frac{d}{dt}(jP(t)j^*h)|_{h=x(t)}=\frac{d}{dt}(jP(t)j^*x(t))-jP(t)\frac{d}{dt}[j^*x(t)].$$

This yields (5.31) and completes the equivalence of property (II) and (5.31) with property (I) and (5.32). The uniqueness property of P for (ii) follows from the uniqueness property for (i). This completes the proof of the theorem. □

Appendix to Section 6.

Proof of Theorem 6.5. (i) From the first property (6.8)

$$\forall e, d\in\mathbb{R}^n, \qquad \langle\delta_\theta d, P_J(t)\delta_\alpha e\rangle_{H^1}=\langle\delta_\alpha e, P_J(t)\delta_\theta d\rangle_{H^1},$$
$$d\cdot P(t,\alpha,\theta)e=e\cdot P(t,\theta,\alpha)d.$$

This proves identity (6.14).

(ii) For all $\bar t$ and t in $[0, T]$, $\bar h$, h, k and $\bar k$ in $(H^1)'$

$$\langle\bar h, P_J(\bar t)\bar k\rangle_{H^1}-\langle h, P_J(t)k\rangle_{H^1}=\langle\bar h-h, P_J(\bar t)[\bar k-k]\rangle_{H^1}+\langle h, [P_J(\bar t)-P_J(t)]k\rangle_{H^1}$$
$$+\langle\bar h-h, P_J(\bar t)k\rangle_{H^1}+\langle h, P_J(t)(\bar k-k)\rangle_{H^1}.$$

In particular for $\bar h=\delta_{\bar\theta}d$, $h=\delta_\theta d$, $\bar k=\delta_{\bar\alpha}e$, $k=\delta_\alpha e$,

$$|d\cdot P(\bar t,\bar\alpha,\bar\theta)e-d\cdot P(t,\alpha,\theta)e|$$
$$\leqq c\|(\delta_{\bar\theta}-\delta_\theta)d\|_{(H^1)'}\|(\delta_{\bar\alpha}-\delta_\alpha)e\|_{(H^1)'}+|\langle\delta_\theta d, P_J(\bar t)\delta_\alpha e\rangle-\langle\delta_\theta d, P_J(t)\delta_\alpha e\rangle|$$
$$+c\|(\delta_{\bar\theta}-\delta_\theta)d\|_{(H^1)'}\|\delta_\alpha e\|_{(H^1)'}+c\|\delta_\theta d\|_{(H^1)'}\|(\delta_{\bar\alpha}-\delta_\alpha)e\|_{(H^1)'}$$

where we have used the boundedness of $P_J(t)$ (cf. third property (6.8)). In view of Lemma 6.4,

$$\|(\delta_{\bar\theta}-\delta_\theta)d\|_{(H^1)'}\leqq|d||\bar\theta-\theta|^{1/2},$$
$$\|(\delta_{\bar\alpha}-\delta_\alpha)e\|_{(H^1)'}\leqq|e||\bar\alpha-\alpha|^{1/2},$$
$$\exists c'>0, \quad \forall\alpha\in I(-h,0), \quad \|\delta_\alpha e\|_{(H^1)'}\leqq c'|e|.$$

As a result

$$|d\cdot P(\bar t,\bar\alpha,\bar\theta)e-d\cdot P(t,\alpha,\theta)e|$$
$$\leqq|\langle\delta_\theta d, P_J(\bar t)\delta_\alpha e\rangle-\langle\delta_\theta d, P_J(t)\delta_\alpha e\rangle|+c|d||e||\bar\theta-\theta|^{1/2}|\bar\alpha-\alpha|^{1/2}$$
$$+c|d||e||\bar\theta-\theta|^{1/2}+c|d||e||\bar\alpha-\alpha|^{1/2},$$

where $c>0$ stands for a generic constant. From the last property (6.8) the function $t\to\langle\delta_\theta d, P_J(t)\delta_\alpha c\rangle_{H^1}$ is continuous. As $(\bar t,\bar\alpha,\bar\theta)$ goes to (t,α,θ) the right-hand side of the above inequality goes to zero. This shows that each component of the matrix $P(t,\alpha,\theta)$ and a fortiori the matrix $P(t,\alpha,\theta)$ itself is jointly continuous with respect to its arguments. To show it is bounded, consider

$$|d\cdot P(t,\alpha,\theta)e|=|\langle\delta_\theta d, P_J(t)\delta_\alpha e\rangle_{H^1}|.$$

We know that the norm of the operator $P_J(t)$ is uniformly bounded with respect to t (cf. third property (6.8)); we also know that

$$\exists c'>0 \text{ such that } \|\delta_\theta d\|_{(H^1)'}\leqq c'|d|, \qquad \|\delta_\alpha e\|_{(H^1)'}\leqq c'|e|$$

(cf. inequality (6.12) in Lemma 6.4). As a result there exists a constant $c>0$ (independent of t, α, θ, d and e) such that

$$\forall d, e \in \mathbb{R}^n, \qquad |d \cdot P(t, \alpha, \theta)e| \leqq c|d||e|.$$

(iii) In view of the symmetry (6.14) it is sufficient to prove (6.16) and (6.18): the estimates (6.17) and (6.19) will follow from (6.16) and (6.18), respectively. For each e in $\mathbb{R}^n$, t in $[0, T]$ and θ in $I(-h, 0)$ the function $P_J(t)\delta_\theta e$ belongs to $H^1 = H^1(-h, 0; \mathbb{R}^n)$. Moreover

$$\|P_J(t)\delta_\theta e\|_{H^1} \leqq \|P_J(t)\|_{\mathscr{L}((H^1)', H^1)} \|\delta_\theta e\|_{(H^1)'} \leqq cc'|e|$$

(from the fourth property (6.8) and inequality (6.12) in Lemma 6.4). But for all d in $\mathbb{R}^n$ and α in $I(-h, 0)$

$$d \cdot P(t, \theta, \alpha)e = \langle \delta_\alpha d, P_J(t)\delta_\theta e\rangle_{H^1} = d \cdot (P_J(t)\delta_\theta e)(\alpha)$$

and

$$(P_J(t)\delta_\theta e)(\alpha) = P(t, \theta, \alpha)e. \tag{1}$$

In particular

$$\|P_J(t)\delta_\theta e\|_{L^2}^2 + \|DP_J(t)\delta_\theta e\|_{L^2}^2 = \|P_J(t)\delta_\theta e\|_{H^1}^2 \leqq c''|e|^2$$

or in view of (1)

$$\int_{-h}^{0} |P(t, \theta, \alpha)e|^2 \, d\alpha + \int_{-h}^{0} \left|\frac{\partial P}{\partial \alpha}(t, \theta, \alpha)e\right|^2 d\alpha \leqq c''|e|^2. \tag{2}$$

Estimates (6.16) and (6.18) now follow through a chain of standard estimates

(iv) Recall that the following sequence of maps and injection is linear and continuous (cf. Theorem 5.4(ii))

$$\mathscr{W}(0, T; M^2, V') \xrightarrow{i^*} \mathscr{Z}(0, T) \xrightarrow{Pl^*} \mathscr{V}(0, T) \hookrightarrow \mathscr{W}(0, T; V, M^2).$$

In particular all functions x of the form

$$x(t) = (\phi^0, \phi^1), \qquad 0 \leqq t \leqq M^2,$$

for some $\phi = (\phi^0, \phi^1)$ in M^2, belong to $\mathscr{W}(0, T; M^2, V')$ and the function $Pj^*x = Pl^*i^*x$ belongs to $\mathscr{W}(0, T; V, M^2)$, that is

$$Pj^*x \in C(0, T; V), \qquad jPj^*x \in H^1(0, T; M^2).$$

By definition of $P_J(t)$, $P_J(t) = J^{-1}P(t)(J^*)^{-1}$,

$$P_J J^* j^* x = J^{-1} Pj^* x \in C(0, T; H^1), \tag{3}$$

$$jJP_J J^* j^* x \in H^1(0, T; M^2). \tag{4}$$

But for each t in $[0, T]$

$$jJP_J(t)J^*j^*\phi = ([P_J(t)J^*j^*\phi](0), P_J(t)J^*j^*\phi).$$

Therefore

$$P_J J^* j^* x \in H^1(0, T; L^2) \tag{5}$$

and the function

$$t \to [P_J(t)J^*j^*\phi](0) : [0, T] \to \mathbb{R}^n \tag{6}$$

belongs to $H^1(0, T; \mathbb{R}^n)$. The properties of the functions (6.21), (6.22) and (6.23) follow from (3), (5) and (6).

(v) We prove (6.24) and apply the results of part (iv) to obtain identities (6.25) to (6.30). For all d in $\mathbb{R}^n$ and α in $I(-h, 0)$

$$\begin{aligned} d \cdot (P_J(t)J^*j^*\phi)(\alpha) &= \langle \delta_\alpha d, P_J(t)J^*j^*\phi\rangle_{H^1} \\ &= \langle J^*j^*\phi, P_J(t)\delta_\alpha d\rangle_{H^1} \\ &= ((\phi, jJP_J(t)\delta_\alpha d)) \\ &= \phi^0 \cdot [P_J(t)\delta_\alpha d](0) + \int_{-h}^{0} \phi^1(\theta) \cdot [P_J(t)\delta_\alpha d](\theta)\, d\theta \\ &= \langle \delta_0\phi^0, P_J(t)\delta_\alpha d\rangle_{H^1} + \int_{-h}^{0} \langle \delta_\theta\phi^1(\theta), P_J(t)\delta_\alpha d\rangle_{H^1}\, d\theta \\ &= \phi^0 \cdot P(t, \alpha, 0)d + \int_{-h}^{0} \phi^1(\theta) \cdot P(t, \alpha, \theta)\, d\, d\theta \\ &= [P(t, 0, \alpha)\phi^0 + \int_{-h}^{0} P(t, \theta, \alpha)\phi^1(\theta)\, d\theta] \cdot d, \end{aligned}$$

where we have used Lemma 6.4 and the symmetry relationship (6.14). This proves (6.24). The continuity of the functions (6.25) to (6.27) is a consequence of the continuity of the function (6.21), and for (6.25), the continuity of the injection of $H^1(-h, 0; \mathbb{R}^n)$ into $C_0(-h, 0; \mathbb{R}^n)$.

The properties of the functions (6.29) and (6.30) are obtained from those of the functions (6.22) and (6.23).

(vi) The properties of the functions (6.31) to (6.33) and (6.35) are obtained from the properties of the functions (6.25) to (6.27) and (6.30) with $\phi^1 = 0$ and the symmetry property (6.14). To prove (6.36), we use (6.24) with $(\phi^0, \phi^1) = (0, \psi)$, the property of the function (6.27) and identity (6.28):

$$(7) \qquad (\phi, DP_J(t)J^*j^*(0, \psi))_2 = \int_{-h}^{0} \phi(\alpha) \cdot \frac{\partial}{\partial \alpha} \int_{-h}^{0} P(t, \theta, \alpha)\psi(\theta)\, d\theta\, d\alpha.$$

But from identity (6.13) in Lemma 6.4

$$J^*j^*(0, \psi) = \int_{-h}^{0} \delta_\theta\psi(\theta)\, d\theta$$

and by continuity of D and $P_J(t)$

$$DP_J(t)J^*j^*(0, \psi) = \int_{-h}^{0} DP_J(t)\delta_\theta\psi(\theta)\, d\theta.$$

Moreover, for ϕ in $L^2(-h, 0; \mathbb{R}^n)$

$$\begin{aligned} (\phi, DP_J(t)J^*j^*(0, \psi))_2 &= \int_{-h}^{0} (\phi, DP_J(t)\delta_\theta\psi(\theta))_2\, d\theta \\ &= \int_{-h}^{0} \int_{-h}^{0} \phi(\alpha) \cdot \frac{\partial P}{\partial \alpha}(t, \theta, \alpha)\psi(\theta)\, d\alpha\, d\theta \end{aligned}$$

and using (6.14)

$$(8)\qquad (\phi, DP_J(t)J^*j^*(0,\psi))_2 = \int_{-h}^{0}\left[\int_{-h}^{0}\frac{\partial P}{\partial\alpha}(t,\alpha,\theta)\phi(\alpha)\,d\alpha\right]\cdot\psi(\theta)\,d\theta.$$

Comparing (7) and (8) we obtain (6.36).

The proof of identity (6.37) amounts to justifying a change in the order of integration on the right-hand side of (6.36). In view of inequality (6.19) it is easy to check that the integrand

$$(\alpha,\theta)\to\frac{\partial P}{\partial\alpha}(t,\alpha,\theta)\phi(\alpha)\cdot\psi(\theta)$$

is an L^1-function when $\phi\in L^2(-h,0;\mathbb{R}^n)$ and $\psi\in L^2(-h,0;\mathbb{R}^n)\cap L^1(-h,0;\mathbb{R}^n)$. This proves (6.37). When h is finite $L^2(-h,0;\mathbb{R}^n)\subset L^1(-h,0;\mathbb{R}^n)$ and this justifies the remark following identity (6.37).

(vii) Recall that for all $\phi=(\phi^0,\phi^1)$ in M^2

$$\Pi(t)\phi = jP(t)j^*\phi = jJP_J(t)J^*j^*\phi = ([P_J(t)J^*j^*\phi](0), P_J(t)J^*j^*\phi).$$

Now from identity (6.24)

$$\Pi^{00}(t)\phi^0+\Pi^{01}(t)\phi^1 = [P_J(t)J^*j^*\phi](0) = P(t,0,0)\phi^0+\int_{-h}^{0}P(t,\theta,0)\phi^1(\theta)\,d\theta,$$

$$[\Pi^{10}(t)\phi^0+\Pi^{11}(t)\phi^1](\alpha) = [P_J(t)J^*j^*\phi](\alpha) = P(t,0,\alpha)\phi^0+\int_{-h}^{0}P(t,\theta,\alpha)\phi^1(\theta)\,d\theta.$$

Since ϕ^0 and ϕ^1 are independent, this is sufficient to obtain (6.40) to (6.42). The last part of identities (6.41) and (6.42) is again a direct consequence of (6.14). □

Proof of Theorem 6.6. Start with the Riccati equation (5.45) of Theorem 5.5. Take the inner product (5.45) with k in M^2. The first term is the derivative of

$$①=((jP(t)j^*h,k))=\left[P(t,0,0)h^0+\int_{-h}^{0}P(t,\alpha,0)h^1(\alpha)\,d\alpha\right]\cdot k^0$$
$$+\int_{-h}^{0}\left[P(t,0,\theta)h^0+\int_{-h}^{0}P(t,\alpha,\theta)h^1(\alpha)\,d\alpha\right]\cdot k^1(\theta)\,d\theta.$$

The second term is

$$②=((A^TP(t)j^*h,k))=((A^TJP_J(t)J^*j^*h,k))$$
$$=L^TP_J(t)J^*j^*h,k^0+(D_\theta P_J(t)J^*j^*h,k^1)$$
$$=\int_{-h}^{0}d_\theta\eta^T\left[P(t,0,\theta)h^0+\int_{-h}^{0}P(t,\alpha,\theta)h^1(\alpha)\,d\alpha\right]\cdot k^0$$
$$+\int_{-h}^{0}\frac{\partial}{\partial\theta}\left[P(t,0,\theta)h^0+\int_{-h}^{0}P(t,\alpha,\theta)h^1(\alpha)\,d\alpha\right]\cdot k^1(\theta)\,d\theta.$$

The third term is

$$③ = ((jP(t)(A^T)^*h, k)) = ((h, A^TP(t)j^*k))$$
$$= h^0 \cdot \int_{-h}^{0} d_\alpha \eta^T \left[P(t, 0, \alpha)k^0 + \int_{-h}^{0} P(t, \theta, \alpha)k^1(\theta)\, d\theta \right]$$
$$+ \int_{-h}^{0} h^1(\alpha) \cdot \frac{\partial}{\partial \alpha} \left[P(t, 0, \alpha)k^0 + \int_{-h}^{0} P(t, \theta, \alpha)k^1(\theta)\, d\theta \right] d\alpha.$$

In view of (6.36)

$$\int_{-h}^{0} h^1(\alpha) \cdot \frac{\partial}{\partial \alpha} \int_{-h}^{0} P(t, \theta, \alpha)k^1(\theta)\, d\theta\, d\alpha = \int_{-h}^{0} \left[\int_{-h}^{0} \frac{\partial P}{\partial \alpha}(t, \alpha, \theta)h^1(\alpha)\, d\alpha \right] \cdot k^1(\theta)\, d\theta.$$

Using property (6.16) we can change the order of integration in the term

$$h^0 \cdot \int_{-h}^{0} d_\alpha \eta^T \int_{-h}^{0} P(t, \theta, \alpha)k^1(\theta)\, d\theta = \int_{-h}^{0} d\theta \left[\int_{-h}^{0} P(t, \alpha, \theta) d_\alpha \eta h^0 \right] \cdot k^1(\theta).$$

The final result is

$$③ = \int_{-h}^{0} P(t, \alpha, 0)\, d_\alpha \eta h^0, k^0 + \int_{-h}^{0} d\theta \left[\int_{-h}^{0} P(t, \alpha, \theta)\, d_\alpha \eta h^0 \right] \cdot k^1(\theta)$$
$$+ \int_{-h}^{0} \frac{\partial P}{\partial \alpha}(t, \alpha, 0)h^1(\alpha)\, d\alpha \cdot k^0$$
$$+ \int_{-h}^{0} d\theta \left[\int_{-h}^{0} d\alpha \frac{\partial P}{\partial \alpha}(t, \alpha, \theta)h^1(\alpha) \right] \cdot k^1(\theta).$$

The fourth term is

$$④ = ((jP(t)RP(t)j^*h, k)) = N^{-1}B^TJ^{-1}P(t)j^*h \cdot B^TJ^{-1}P(t)j^*k.$$

But

$$B^TJ^{-1}P(t)j^*k = B^TJ^{-1}JP_J(t)J^*j^*k = B^TP_J(t)J^*j^*k$$
$$= \int_{-h}^{0} d_\zeta \beta^T \left[P(t, 0, \zeta)k^0 + \int_{-h}^{0} P(t, \alpha, \zeta)k^1(\alpha)\, d\alpha \right]$$

and in view of (6.16) the order of integration can be changed in the last term. Finally,

$$④ = N^{-1} \left\{ \int_{-h}^{0} d_\xi \beta^T P(t, 0, \xi)h^0 + \int_{-h}^{0} d\alpha \int_{-h}^{0} d_\xi \beta^T P(t, \alpha, \xi)h^1(\alpha) \right\}$$
$$\cdot \left\{ \int_{-h}^{0} d_\zeta \beta^T P(t, 0, \zeta)k^0 + \int_{-h}^{0} d\theta \int_{-h}^{0} d_\zeta \beta^T P(t, \theta, \zeta)k^1(\theta) \right\}.$$

The last and simplest term is

$$⑤ = ((\tilde{Q}h, k)) = Qh^0 \cdot k^0.$$

Equations (6.43), (6.44) and (6.45) are now obtained by special choice of the pair (h, k) in the equation

$$\frac{d}{dt}① + ② + ③ + ④ + ⑤ = 0. \tag{9}$$

For $h=(h^0,0)$ and $k=(k^0,0)$ we obtain (6.41). For $h=(0,h^1)$ and $k=(k^0,0)$ equation (9) reduces to

$$\begin{aligned}(10)\qquad &\frac{d}{dt}\int_{-h}^{0} P(t,\alpha,0)h^1(\alpha)\,d\alpha+\int_{-h}^{0} d_\theta\eta^T\int_{-h}^{0} d\alpha\,P(t,\alpha,\theta)h^1(\alpha)\\ &+\int_{-h}^{0}\frac{\partial P}{\partial\alpha}(t,\alpha,0)h^1(\alpha)\,d\alpha\\ &-\int_{-h}^{0} P(t,\zeta,0)\,d_\zeta\beta N^{-1}\int_{-h}^{0} d\alpha\int_{-h}^{0} d_\xi\beta^T P(t,\alpha,\xi)h^1(\alpha)=0.\end{aligned}$$

From Theorem 6.5(vi) the map $\alpha\to\partial P/\partial t(t,\alpha,0)$ belongs to L^2 and

$$\frac{d}{dt}\int_{-h}^{0} P(t,\alpha,0)h^1(\alpha)\,d\alpha=\int_{-h}^{0}\frac{\partial P}{\partial t}(t,\alpha,0)h^1(\alpha)\,d\alpha.$$

In view of (6.16), the order of integration can be changed in the second term of (10) and the map

$$\alpha\to\int_{-h}^{0} d_\theta\eta^T P(t,\alpha,\theta)$$

belongs to L^2. The same remark applies to the last part of the last term in (10). As a result we can regroup terms in (8) to obtain

$$\begin{aligned}\int_{-h}^{0}\Big\{&\frac{\partial P}{\partial t}(t,\alpha,0)+\int_{-h}^{0} d_\theta\eta^T P(t,\alpha,\theta)+\frac{\partial P}{\partial\alpha}(t,\alpha,0)\\ &-\int_{-h}^{0} P(t,\zeta,0)d_\zeta\beta N^{-1}\int_{-h}^{0} d_\xi\beta^T P(t,\alpha,\xi)\Big\}h^1(\alpha)\,d\alpha=0.\end{aligned}$$

As a function of α, all terms in the curly bracket belong to L^2 and are continuous with respect to t in $[0,T]$ with values in $L^2(-h,0;\mathscr{L}(\mathbb{R}^n,\mathbb{R}^n))$. Therefore the curly bracket is null almost everywhere. This establishes (6.44).

To obtain (6.45), we set $h=(0,\phi)$ and $k=(0,\psi)$ in (9)

$$\begin{aligned}&\frac{d}{dt}\int_{-h}^{0}\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha\cdot\psi(\theta)\,d\theta+\int_{-h}^{0}\frac{\partial}{\partial\theta}\Big[\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha\Big]\cdot\psi(\theta)\,d\theta\\ &+\int_{-h}^{0}\Big[\int_{-h}^{0}\frac{\partial P}{\partial\alpha}(t,\alpha,\theta)\phi(\alpha)\,d\alpha\Big]\cdot\psi(\theta)\,d\theta\\ &-N^{-1}\int_{-h}^{0}\Big[\int_{-h}^{0} d_\xi\beta^T P(t,\alpha,\xi)\Big]\phi(\alpha)\,d\alpha\int_{-h}^{0}\Big[\int_{-h}^{0} d_\zeta\beta^T P(t,\theta,\zeta)\Big]\psi(\theta)\,d\theta=0.\end{aligned}$$

But in view of (6.30) with $(\phi^0,\phi^1)=(0,\phi)$

$$\frac{d}{dt}\int_{-h}^{0}\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha\cdot\psi(\theta)\,d\theta=\int_{-h}^{0}\Big[\frac{\partial}{\partial t}\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha\Big]\cdot\psi(\theta)\,d\theta.$$

Moreover for all ϕ in $L^2(-h,0;\mathbb{R}^n)\cap L^1(-h,0;\mathbb{R}^n)$ and ψ in $L^2(-h,0;\mathbb{R}^n)$ (cf. (6.37))

$$\int_{-h}^{0}\frac{\partial}{\partial\theta}\Big[\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha\Big]\cdot\psi(\theta)\,d\theta=\int_{-h}^{0}\Big[\int_{-h}^{0}\frac{\partial P}{\partial\theta}(t,\alpha,\theta)\phi(\alpha)\,d\alpha\Big]\cdot\psi(\theta)\,d\theta.$$

By factoring ϕ and ψ

$$(11)\qquad \int_{-h}^{0}\left\{\frac{\partial}{\partial t}\int_{-h}^{0} P(t,\alpha,\theta)\phi(\alpha)\,d\alpha+\int_{-h}^{0} Z(t,\alpha,\theta)\phi(\alpha)\,d\alpha\right\}\cdot\psi(\theta)\,d\theta$$

where

$$(12)\quad Z(t,\alpha,\theta)=\left(\frac{\partial}{\partial\theta}+\frac{\partial}{\partial\alpha}\right)P(t,\alpha,\theta)-\int_{-h}^{0} P(t,\zeta,\theta)\,d_{\zeta}\beta N^{-1}\int_{-h}^{0} d_{\xi}\beta^{T}P(t,\alpha,\xi).$$

Since the above identity is true for all ϕ in $L^2(-h,0;\mathbb{R}^n)\cap L^1(-h,0;\mathbb{R}^n)$ and ψ in $L^2(-h,0;\mathbb{R}^n)$, the time distributional derivative of $P(t,\alpha,\theta)$ is given by

$$\frac{\partial P}{\partial t}(t,\alpha,\theta)+Z(t,\alpha,\theta)=0\quad\text{a.e.}$$

When h is finite the matrix function Z is L^2 with respect to its arguments hence $\partial P/\partial t$ also belongs to L^2. □

Appendix to Section 7.

Proof of Theorem 7.5. The proof of parts (i) and (ii) follows standard arguments given for instance in R. Datko [1]. Part (iii) also uses standard arguments.

(iv) Start with the Riccati differential equation (5.45) of Theorem 5.5: for all k in M^2

$$(1)\qquad -\frac{d}{dt}(jP_T(t)j^*k)=A^TP_T(t)j^*k+jP_T(t)(A^T)^*k-jP_T(t)RP_T(t)j^*k+\tilde{Q}k.$$

Denote by $Z_T(t)$ the right-hand side of (1). For all $t>0$ the operator $Z_T(t)$ strongly converges to some operator

$$(2)\qquad Z=A^TPj^*+jP(A^T)^*-jPRPj^*+\tilde{Q}$$

in $\mathcal{L}(M^2,M^2)$ as T goes to $+\infty$ and

$$\forall k\in V,\qquad \lim_{t\leqq T\to\infty}\frac{d}{dt}(jP_T(t)j^*k)=-Zk\quad\text{in } M^2.$$

For each arbitrary fixed $\tau>0$, define the sequence

$$f_n(t)=jP_n(t)j^*k,\quad 0\leqq t\leqq\tau,\quad n\geqq 1.$$

The sequence $\{f_n\}$ belongs to $H^1(0,\tau;M^2)$,

$$\lim_{n\to\infty} f_n=f,\quad f(t)=jPj^*k,\qquad 0\leqq t\leqq\tau,$$

$$\lim_{n\to\infty}\frac{d}{dt}f_n(t)=g(t)=-Zk,\qquad 0\leqq t\leqq\tau.$$

But $(d/dt)f_n$ and g belong to $L^2(0,\tau;M^2)$ and there exists $c>0$ such that for all $n\geqq 1$ and t in $[0,\tau]$

$$\left|\frac{d}{dt}f_n(t)\right|\leqq c\|k\|_{M^2},\qquad |g(t)|\leqq c\|k\|_{M^2}.$$

By the Lebesgue Dominated Convergence Theorem

$$\frac{df_n}{dt}\to g\quad\text{in } L^2(0,\tau;M^2).$$

Finally we have shown that $\{f_n\}$ converges in the H^1-norm, and that

$$f_n \to f, \qquad \frac{df_n}{dt} \to g.$$

By completeness of $H^1(0, \tau; M^2)$

$$\frac{df}{dt} = g \Rightarrow 0 = \frac{d}{dt}(jPj^*k) = -Zk.$$

Since the above is true for all k in M^2, we conclude that $Z = 0$. Equation (7.28) is finally obtained from (2) with $Z = 0$.

(v) Let $\bar{P}$ in $\mathscr{L}(V', V)$ be another positive symmetrical solution of (7.28). Rearrange (7.28) for $\bar{P}$:

$$[A^T - j\bar{P}R]\bar{P}j^* + j\bar{P}[A^T - j\bar{P}R]^* + j\bar{P}R\bar{P}j^* + \tilde{Q} = 0. \tag{3}$$

Let z in $\mathscr{W}_{\text{loc}}(0, \infty; M^2, V')$ be the solution of

$$\frac{d}{dt}j^*z(t) - (A^T)^*z(t) + R\bar{P}j^*z(t) = 0, \qquad z(0) = k \in M^2 \tag{4}$$

(by Theorem 4.6(ii) and Theorem 2.7(ii) by choosing $u = -B^TJ^{-1}Pj^*z$). From (3)

$$((z(t), \{[A^T - j\bar{P}R]\bar{P}j^* + j\bar{P}[A^T - j\bar{P}R]^* + j\bar{P}R\bar{P}j^* + \tilde{Q}\}z(t))) = 0 \tag{5}$$

and if w is defined as

$$w(t) = -N^{-1}B^TJ^{-1}\bar{P}z(t), \qquad t \geqq 0, \tag{6}$$

we obtain from (5)

$$2\langle [A^T - j\bar{P}R]^*z(t), \bar{P}j^*z(t)\rangle_V + Nw(t) \cdot w(t) + ((z(t), \tilde{Q}z(t))) = 0.$$

From (4) the above equation reduces to

$$\frac{d}{dt}\{\langle j^*z(t), \bar{P}j^*z(t)\rangle_V + Nw(t) \cdot w(t) + \langle i^*z(t), \hat{Q}i^*z(t)\rangle_W\} = 0$$

and for all $t > 0$

$$\langle j^*k, \bar{P}j^*k\rangle_V = \langle j^*z(t), \bar{P}j^*z(t)\rangle_V + \int_0^t [|Ci^*z(s)|^2 + Nw(s) \cdot w(s)]\, ds \geqq J_0^t(w, j^*k)$$

$$\geqq J_0^t(u_t, j^*k) = \langle j^*k, P_t(0)j^*k\rangle_V,$$

where u_t is the minimizing control on $[0, t]$. By letting t go to $+\infty$, we obtain

$$\langle j^*k, \bar{P}j^*k\rangle \geqq \langle j^*k, Pj^*k\rangle. \tag{7}$$

By density of j^*M^2 in V' and continuity of the symmetrical operator $\bar{P} - P$, inequality (7) extends to all of V'. □

RICCATI EQUATIONS FOR HYPERBOLIC PARTIAL DIFFERENTIAL EQUATIONS WITH $L_2(0, T; L_2(\Gamma))$—DIRICHLET BOUNDARY TERMS*

I. LASIECKA† AND R. TRIGGIANI†

Abstract. This paper studies the quadratic optimal control problem for second order (linear) hyperbolic partial differential equations defined on a bounded domain $\Omega \subset R^n$ with boundary Γ. Both the finite interval case $[0, T]$, $T < \infty$, and the infinite interval case $T = \infty$ (regulator problem) are considered. The distinguishing feature of the paper, which differentiates it from previous (scarce!) literature on the subject, is that the controls are only $L_2(0, T; L_2(\Gamma))$-functions which act in the Dirichlet B.C. and that the corresponding solutions are penalized in the $L_2(0, T; L_2(\Omega))$-norm (smoother controls, particularly in space, were taken in the few previous works on this subject). The well-posedness of this formulation stems from recent results by the authors about regularity of second order hyperbolic mixed problems [L-T.1], [L-T.3]. Under minimal assumptions, the optimal control is synthesized, in a pointwise feedback form, through an operator which is shown to satisfy in a suitable sense a Riccati differential equation for $T < \infty$ and a Riccati algebraic equation for $T = \infty$. Unlike most, if not all, of the literature on quadratic control problems (for different dynamics!), the algebraic Riccati equation is *not* derived as a limit process as $T \uparrow \infty$ of the Riccati differential (or integral) equation on $[0, T]$. This has a special advantage in the case of hyperbolic dynamics. Rather, the approach followed for the control problems is direct, in the sense that first an operator is defined in terms of the hyperbolic dynamics and only subsequently shown to satisfy a Riccati equation (differential for $T < \infty$, algebraic for $T = \infty$). Regularity results of the optimal pair are also included. A functional analytic model, based on cosine operator theory and introduced by the authors in [L-T.1], [L-T.3], is used throughout to describe the hyperbolic dynamics.

Key words. Riccati equations, boundary control, hyperbolic partial differential equations

AMS(MOS) subject classification. 35

1. Introduction, problem formulation and statement of main results.

1.1. Introduction and problem formulation. The aim of the present paper is a study of the quadratic optimal control problem on both a finite, fixed interval $[0, T]$, $T < \infty$, (§§ 2–4) and also on the infinite interval $T = \infty$ (§ 5) for second order (linear) hyperbolic partial differential equations, where L_2-boundary controls act in the Dirichlet Boundary Conditions (B.C.). In this introductory section, we shall first formulate the problems and point out their relationship to (scarce!) existing literature on the subject, and then present a general orientative statement of our main results. Complete formal statements and proofs are given in §§ 2–5.

Let Ω be an open bounded domain in R^n with boundary Γ, say (piecewise) of class C^2. Let $-A(\xi, \partial)$ be a partial differential operator of order two in Ω with smooth real coefficients

$$-A(\xi, \partial) = \sum_{i,j=1}^{n} \frac{\partial}{\partial \xi_i}\left(a_{ij}(\xi)\frac{\partial}{\partial \xi_j}\right) + \sum_{j=1}^{n} b_j(\xi)\frac{\partial}{\partial \xi_j} + c_0(\xi)$$

with principal part uniformly strongly elliptic in Ω

$$\sum_{i,j=1}^{n} a_{ij}(\xi)\eta_i\eta_j \geqq \alpha \sum_{j=1}^{n} \eta_j^2, \qquad a_{ij} \equiv a_{ji}, \quad \alpha > 0.$$

We consider the mixed hyperbolic problem

$$\begin{aligned} &\frac{\partial^2 y}{\partial t^2}(t,\xi) = -A(\xi,\partial)y(t,\xi) && \text{in } (0,T]\times\Omega \equiv Q, \\ &y(0,\xi) = y_0(\xi), \quad \frac{\partial y}{\partial t}(0,\xi) = y_1(\xi) && \xi\in\Omega, \\ &y(t,\sigma) = u(t,\sigma) && \text{in } (0,T]\times\Gamma \equiv \Sigma, \end{aligned} \tag{1.1}$$

where the control function $u(t,\sigma)$ acts in the Dirichlet B.C. and is assumed to belong to $L_2(0,T;L_2(\Gamma)) \equiv L_2(\Sigma)$. Let $L_2(0,T;L_2(\Omega)) \equiv L_2(Q)$. The *homogeneous problem* (i.e. (1.1) with $u\equiv 0$) is *uniformly well-posed in* $L_2(\Omega)$; equivalently [F1], the operator $-A$ consisting of $-A(\xi,\partial)$ plus homogeneous Dirichlet B.C. *is the generator of a strongly continuous* (s.c.) cosine operator $C(t)$ on $L_2(\Omega)$, $t\in R$. Thus, $Ah = A(\xi,\partial)h$, $h\in\mathcal{D}(A) = \{x\in L_2(\Omega)\colon A(\xi,\partial)h\in L_2(\Omega),\ h|_\Gamma = 0\}$. The self-adjoint principal part of $-A(\xi,\partial)$ generates a s.c. (self-adjoint) cosine operator on $L_2(\Omega)$, while the first order part of $-A(\xi,\partial)$ is a perturbation which preserves generation of a s.c. cosine operator [F.3, Thm. 2.1], [T-W.1, Prop. 4.1]. Similarly, $-A^*$ generates a s.c. cosine operator on $L_2(\Omega)$, given precisely by $C^*(t)$; see [N.2] for the general case. For the necessary background on cosine operators, we refer e.g. to [F.1, I, II], [F.3], [N.2], [S.1], [T-W.1] plus bibliography cited therein. Of this theory we shall recall below only a few facts that will be frequently needed in the sequel. The optimal control problem of penalizing on $[0,T]$ both the boundary input $u\in L_2(\Sigma)$ and the corresponding solution y in a suitable norm is, of course, intimately dependent on the problem of *regularity* of the mixed problem (1.1). In particular, does $u\in L_2(\Sigma)$ imply that the corresponding solution $y\in L_2(Q)$? Only very recently was this seemingly natural question given an affirmative answer [L-T.1]. (For instance, the regularity results of the fundamental treatise [L-M.1] do not answer the above question.) Even more recently, this $L_2(Q)$-regularity result was markedly improved to conclude that, in fact, for $u\in L_2(\Sigma)$ the corresponding solution $y\in C([0,T];L_2(\Omega))$ [L-T.3].[1] See also the rather comprehensive study on regularity of hyperbolic mixed problems in [L-L-T.1].

THEOREM 1.1 (Regularity for (1.1)). *Let* Ω *either have* C^1*-boundary* Γ *or else be a parallelepiped. Let* $y_0\in L_2(\Omega)$ *and* $y_1\in H^{-1}(\Omega)$. *Then*:

(i) *The map from the input* $u\to$ *corresponding solution* $[y,\dot y]$ *is a continuous operator*: $L_2(\Sigma)\to L_2(Q)\otimes L_2(0,T;H^{-1}(\Omega))$ [L-T.1].

(ii) *In fact, the map from the input* $u\to$ *corresponding solution* $[y,\dot y]$ *of* (1.1) *is a continuous operator* $L_2(\Sigma)\to C([0,T];L_2(\Omega))\otimes C([0,T];H^{-1}(\Omega))$ [L-T.3].

On the basis of the (weaker) regularity result (i), one can then associate with (1.1) the quadratic cost functional[2] on $[0,T]$,

$$J(u,y) \equiv \int_0^T \{(Ry(t),y(t))_\Omega + |u(t)|_\Gamma^2\}\,dt = |R^{1/2}y|_Q^2 + |u|_\Sigma^2 \tag{1.2a}$$

with R satisfying:

(1.3) (H.1) R is a nonnegative self-adjoint, bounded operator on $L_2(\Omega)$

so that R may be the identity on $L_2(\Omega)$.

[1] In January, 1983 Professor J. L. Lions has kindly informed us that he also had proved this result in 1982 with a proof "100% different" from ours. Paper [L-L-T.1] is the result of correspondence that followed.

[2] The norms are all L_2-norms over the indicated domains, unless otherwise stated. Also, our treatment can be directly extended as to include quadratic penalization of the velocity $\dot y(t)$ in $H^{-1}(\Omega)$.

The *optimal control problem* (O.C.P.) on the finite interval $[0, T]$ is now:

(O.C.P.) Minimize $J(u, y(u))$ over all $u \in L_2(\Sigma)$, where $y(u)$ is the solution to (1.1) corresponding to u.

In light of Theorem 1.1(i), the functional $J(u, y(u))$ is continuous on $L_2(\Sigma)$; since it is strictly convex, it follows by standard arguments in optimization theory, that the (O.C.P.) admits a unique solution, which we shall denote by u^0. The corresponding optimal solution is then denoted by y^0. Actually, in view of the stronger regularity statement (ii) in Theorem 1.1, there is no essential *extra difficulty* in penalizing also the final state $|y(T)|_\Omega$; i.e. in replacing J in (1.2*a*) with

$$J(u, y) = |y(T)|^2_\Omega + |y|^2_Q + |u|^2_\Sigma, \tag{1.2b}$$

since the operator $u \in L_2(\Sigma) \to y(T) \in L_2(\Omega)$ is bounded.[3] Thus:

THEOREM 1.2. *Under the conclusion of Theorem* 1.1, *the* (O.C.P.) *corresponding to* (1.2a) *or* (1.2b) *admits a unique solution*: $u^0 \in L_2(\Sigma)$ *and* $y^0 \in C([0, T]; L_2(\Omega))$.

In § 5, we study also the quadratic optimal control problem (1.2a) with $T = \infty$ (regulator problem), under the minimal assumption—verified in [L-T.5]—that for each initial data there is a pair of u and y such that the corresponding cost with $T = \infty$ be finite. Before turning to the statement and proof of our results, we review (the scarce) existing literature on the quadratic optimal problem for hyperbolic partial differential equations, under Dirichlet boundary control. As already explained, a basic preliminary difficulty encountered in the study of the (O.C.P.) is a question of regularity of the solutions to the mixed problem (1.1); in particular, whether the cost J in (1.2a) is well-set. Thus, the crux of the case that we study here is that we penalize both the Dirichlet boundary control and the corresponding solution in the L_2-norms; i.e., in $L_2(0, T; L_2(\Gamma))$ and $L_2(0, T; L_2(\Omega))$, respectively. This is the *distinguishing feature*, which differentiates our present results from those already existing in the literature, e.g., [C-P.1], [C-P.2], [L.1][4]; where, in face of this, smoother boundary controls were considered, e.g. $u \in H^2_0([0, T] \times \Gamma)$ as in [L.1, p. 325], or $u \in L_2(0, T; H^{1/2}(\Gamma))$ as in [C-P.1] and [C-P.2]. Moreover, Riccati's synthesis is not investigated in [L.1] in the hyperbolic boundary case, only in the distributed case, see [L.1, p. 348]. We also stress that our approach here to the Riccati's synthesis is "explicit" and "constructive" (in the style of [L-T.2] in the parabolic case) in the sense that an operator is first defined by an explicit formula in terms of the given dynamics (see (2.22a) or (2.24) below) and only subsequently proved to be a solution of a Riccati differential and integral equation. This way, the usual difficulty—encountered in all "indirect" approaches to Riccati synthesis of much of the literature (for different dynamics!)—of proving existence of a solution to the operator Riccati differential equation is automatically taken care of. As to the infinite interval case, $T = \infty$, we are not aware of any derivation of the algebraic Riccati equation for the hyperbolic dynamics (1.1) in the literature.

1.2. Statement of main results. While we refer to §§ 2–5 for the complete, technical statements of our results, we wish to give here a preliminary general description of them, which will help orient the reader. To do this, some preliminary background

[3] This fact is surprising in light of known results for parabolic equations, where the solution y to an $L_2(\Sigma)$-control acting in the Dirichlet B.C. may not have a well defined point $y(T)$ [L.1, p. 202]. This pathology adds extra difficulty in the corresponding quadratic cost problem with final state penalization in $L_2(\Omega)$ see [L-T.2].

[4] See also [V-J.1].

material is needed. It is well known that the operator

$$\begin{vmatrix} 0 & I \\ -A & 0 \end{vmatrix}, \quad \text{with domain} = \mathcal{D}(A) \otimes \mathcal{D}(A^{1/2}) \tag{1.4}$$

generates a strongly continuous (s.c.) group on $H_0^1(\Omega) \otimes L_2(\Omega)$, which is, in fact, unitary if A is self-adjoint. (We may assume without loss of generality that the fractional powers of A are well-defined.) With $H_0^1(\Omega) \equiv \mathcal{D}(A^{1/2})$ [F.2], [L.2] it follows quickly from Theorem 1.1 that the operator $\mathcal{A}$,

$$\mathcal{A} = \begin{vmatrix} 0 & I \\ -A & 0 \end{vmatrix}, \quad \text{with domain } \mathcal{D}(\mathcal{A}) = \mathcal{D}(A^{1/2}) \otimes L_2(\Omega) \tag{1.5}$$

generates a s.c. group, which will be denoted by $e^{\mathcal{A}t}$, also on the space

$$E \equiv L_2(\Omega) \times [\mathcal{D}(A^{1/2})]' \equiv L_2(\Omega) \times H^{-1}(\Omega), \tag{1.6}$$

$$\left\| \begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \right\|_E^2 = \|x_1\|_{L_2(\Omega)}^2 + \|x_2\|_{H^{-1}(\Omega)}^2, \qquad \|z\|_{H^{-1}(\Omega)} = \|z\|_{[\mathcal{D}(A^{1/2})]'} = \|A^{-1/2} z\|_{L_2(\Omega)}. \tag{1.7}$$

We next introduce the Dirichlet map D (natural "harmonic" extension of boundary data on Γ into the interior Ω), defined by

$$Du = y \quad \text{where} \begin{cases} -A(\xi, \partial) y = 0 & \text{in } \Omega, \\ y|_\Gamma = u & \text{in } \Gamma. \end{cases} \tag{1.8}$$

It is a well-known result of elliptic theory [L-M.1, I], [N.1] that

(1.9a) D is a continuous operator $H^\sigma(\Gamma) \to H^{\sigma+1/2}(\Omega)$, σ real.

We shall in particular use

$$\begin{aligned} &D\text{: continuous } L_2(\Gamma) \to H^{1/2-2\varepsilon}(\Omega) \equiv \mathcal{D}(A^{1/4-\varepsilon}), \qquad \varepsilon > 0, \\ &\|z\|_{H^{1/2-2\varepsilon}(\Omega)} = \|A^{1/4-\varepsilon} z\|_{L_2(\Omega)}, \end{aligned} \tag{1.9b}$$

where for the identification on the right of (1.9b) as well as for the identification

$$H_0^{3/2-2\varepsilon}(\Omega) \equiv \mathcal{D}(A^{3/4-\varepsilon}), \qquad \varepsilon > 0, \quad \varepsilon \neq \tfrac{1}{2}, \tag{1.9c}$$

we refer to [[F.2], [L.2, Appendix]. We shall also use freely that [L-M.1, p. 196 with Remark 2.6, p. 121], [L.3, Remark 5.1, p. 238]

$$\mathcal{D}(A) = \mathcal{D}(A^*), \quad \text{hence } \mathcal{D}(A^\theta) = \mathcal{D}(A^{*\theta}), \qquad 0 \leqq \theta < 1. \tag{1.9d}$$

Regarding cosine operator theory, we briefly recall that $C(t)$ is even and $C(0) = I$, thus $S(t)x = \int_0^t C(\tau)x\, d\tau$ is odd. Moreover $d^2C(t)x/dt^2 = -AC(t)x$, $x \in \mathcal{D}(A)$ and $dC(t)x/dt = -AS(t)x$, $x \in \mathcal{D}(A^{1/2})$. Also, [F.1, I, II]

(1.10) the map $t \to A^{1/2}S(t)x$, is well-defined and continuous for all $x \in L_2(\Omega)$ and $\|A^{1/2}S(t)\| \leqq M_\gamma e^{\gamma t}$.

It is important to note that [S.1] (see also [L-T.1, Prop. 2.1]

$$C(t)x - x = -A \int_0^t \tau C(t-\tau)x\, d\tau, \qquad x \in L_2(\Omega) \tag{1.11a}$$

which after integration by parts can be written as[5]

$$(1.11b)\qquad C(t)x - x = -A\int_0^t S(t-\tau)x\,d\tau = -A\int_0^t S(\sigma)x\,d\sigma, \qquad x \in L_2(\Omega).$$

A few other results on the cosine operator theory (e.g. identities (3.6) below) will be quoted when needed. Our main results on the Riccati's feedback synthesis of the optimal control are as follows (see §§ 2-4 for more complete results).

THEOREM 1.3. *Case* $T<\infty$: (i) *For* R *as in* (H.1), *see* (1.3), *the unique control* u^0 *of the optimal control problem* (O.C.P.) *on* $[0, T]$, $T<\infty$ *can be expressed in feedback form as* (*see* (2.28) *below*)

$$u^0(t) = u^0(t, t_0=0; y_0, y_1) = -\mathscr{B}^*\mathscr{P}(t)\begin{vmatrix} y^0(t) \\ \dot{y}^0(t)\end{vmatrix}$$

$$= -D^*A^*\int_t^T S^*(\tau - t)R\Phi_1(\tau, 0)\begin{vmatrix} y_0 \\ y_1\end{vmatrix} d\tau \quad \text{in } t \in [0, T].$$

$\Phi(\tau, t) = [\Phi_1(\ ,\ ), \Phi_2(\ ,\ )]$ *is the evolution operator of the optimal feedback system* (*see* (2.13)-(2.14) *below*), *while* $\mathscr{P}(t)$ *is defined* ((2.22a) *below*)

$$\mathscr{P}(t)x = \int_t^T e^{\mathscr{A}^*(\tau - t)}\begin{vmatrix} R & 0 \\ 0 & 0\end{vmatrix}\Phi(\tau, t)x\,d\tau.$$

(ii) *For* R *satisfying, in addition* (*see* (3.43) *below*) *the assumption*

$$(H.2)\qquad R\text{: continuous } H^{1/2-\delta}(\Omega) = \mathscr{D}(A^{1/4-\delta/2}) \to H_0^{1/2+\delta}(\Omega) \equiv \mathscr{D}(A^{1/4+\delta/2})$$

for some arbitrarily small $\delta > 0$, *henceforth kept fixed, then*:

(ii.1) *For initial data* $[y_0, y_1] \in Y_r \equiv H^{1/2-\delta}(\Omega) \times H^{-1/2-\delta}(\Omega)$ *we have* (*see more precise statement in Theorem* 3.11 *below*)[6]

$$u^0 \in H^{1/2+\delta, 1/2+\delta}(\Sigma), \text{ a fortiori } u^0 \in C([0, T]; L_2(\Gamma)),$$

$$y^0 \in C([0, T]; H^{1/2-\delta}(\Omega)) \cap H^{1/2-\delta}(0, T; L_2(\Omega)),$$

$$\dot{y}^0 \in C([0, T]; H^{-1/2-\delta}(\Omega)).$$

(ii.2) *The operator*

$$\mathscr{B}^*\mathscr{P}(t)x = D^*A^*\int_t^T S^*(\tau - t)R\Phi_1(\tau, t)x\,d\tau$$

is continuous $Y_r \to C([0, T]; L_2(\Gamma))$ (*Theorem* 4.1 *below*).

(ii.3) *The operator* $\mathscr{P}(t)$ *is a self-adjoint nonnegative definite operator on* E *and satisfies the following Riccati differential equation*:

$$(R.D.E.)\qquad \frac{d}{dt}(\mathscr{P}(t)x, y)_E = -(Rx_1, y_1)_\Omega - (\mathscr{P}(t)x, \mathscr{A}y)_E - (\mathscr{P}(t)\mathscr{A}x, y)_E$$

$$+(\mathscr{B}^*\mathscr{P}(t)x, \mathscr{B}^*\mathscr{P}(t)y)_\Gamma$$

[5] This last result (1.11) rigorously justifies for all $x \in L_2(\Omega)$ the following procedure—which however is only formal for $x \notin \mathscr{D}(A^{1/2})$:

$$-A\int_0^t S(\sigma)x\,d\sigma = \int_0^t -AS(\sigma)x\,d\sigma = \int_0^t \frac{dC(\sigma)}{d\sigma}x\,d\sigma = C(t)x - x.$$

[6] $H^{r,s}(\Sigma) = L_2(0, T; H^r(\Gamma)) \cap H^s(0, T; L_2(\Gamma))$, as usual [L-M.1, II] and similarly for $H^{r,s}(Q)$.

for all $x, y \in Y_r$ *and in* $t \in [0, T)$ *with terminal condition* $\mathscr{P}(T) = 0$ (*see Theorem* 4.3 *below*), *as well as the corresponding Riccati integral equation.*

Remark 1.1. A *direct* approach (i.e. with no reference to a control problem, in particular *without* using the preliminary optimality conditions available in the control problem) was carried out in [DaP-L-T.1] to study the well-posedness of the R.D.E. for hyperbolic dynamics. In particular, in the case of the present paper, this approach shows also *uniqueness* of a nonnegative self-adjoint solution of the R.D.E. (satisfying further properties), provided a stronger assumption is made on R, namely that $RA^{1/4+\varepsilon}$ is a bounded operator on $L_2(\Omega)$.

In § 5, we study the regulator problem, i.e. problem (1.2a) (or the corresponding version which penalizes quadratically also the velocity $\dot{y}$ in $H^{-1}(\Omega)$) for $T = \infty$, under the sole assumption (H.1) for R (which allows R to be, in particular, the identity on $L_2(\Omega)$) and under the usual minimal assumption of the finite cost (see Theorem 1.2 below). We then derive that:

(i) the optimal control of the regulator problem is given in feedback form by

$$-u^0(t) = \mathscr{B}^*\mathscr{P}\begin{vmatrix} y^0(t) \\ \dot{y}^0(t) \end{vmatrix} = \mathscr{B}^*\mathscr{P}\Phi(t)\begin{vmatrix} y_0 \\ y_1 \end{vmatrix};$$

(ii) here $\mathscr{P}$ is a nonnegative, self-adjoint operator on E satisfying the algebraic Riccati equation

$$(Rx_1, y_1)_\Omega + (\mathscr{P}x, \mathscr{A}y)_E + (\mathscr{P}\mathscr{A}x, y)_E = (\mathscr{B}^*\mathscr{P}x, \mathscr{B}^*\mathscr{P}y)_\Gamma, \qquad x, y \in \mathscr{D}(\mathscr{A});$$

(iii) moreover, the optimal solution $\Phi(t)|y_0/y_1|$ defines a s.c. semigroup on E generated by $\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P}$. Uniqueness of the algebraic Riccati equation for the problem which also penalizes $\dot{y}$ is discussed in Theorem 5.11.

The approach presented in § 5 is particularly simple, when applied to a special but physically important case, which includes, in particular, the canonical wave equation, see Remark 5.2. A main feature of this approach is that—contrary to much, if not all, of the existing literature (see e.g. [F3] for a recent contribution on the *parabolic* case with Dirichlet boundary control)—the algebraic Riccati equation is *not* derived as a limit of the differential Riccati equation on $[0, T]$ via the limit process $T \uparrow \infty$: this would have required the study of the limit $\mathscr{B}^*\mathscr{P}_T(t)$ to $\mathscr{B}^*\mathscr{P}(\mathscr{P}_T(t) =$ Riccati operator of the problem on $[0, T]$) a particularly delicate question in the case of hyperbolic dynamics. This way we can dispense of assumption (H.2) for R, used for the Riccati differential equation, and derive the algebraic Riccati equation with R satisfying only assumption (H.1).

2. Optimality, the operators $\mathscr{P}(t)$ and $\Phi(\cdot, \cdot)$ and their preliminary properties. As an abstract version of the mixed problem (1.1), we can take the input-solution formula (see [L-T.1]) with $y_0 \in L_2(\Omega)$, $y_1 \in H^{-1}(\Omega)$:

$$y(t) = y(t, t_0 = 0; y_0, y_1) = C(t)y_0 + S(t)y_1 + (Lu)(t), \tag{2.1a}$$

$$\frac{dy}{dt}(t) = \frac{dy}{dt}(t, t_0 = 0; y_0, y_1) = -AS(t)y_0 + C(t)y_1 + \frac{d}{dt}(Lu)(t), \tag{2.1b}$$

where $C(t)$ and $S(t)x = \int_0^t C(\tau)x\, d\tau$ are, respectively, the cosine and "sine" operators on $L_2(\Omega)$, $t \in R$, generated by $-A$, and where the linear operators L and dL/dt are defined by

$$(Lu)(t) = A\int_0^t S(t-\tau)Du(\tau)\, d\tau, \tag{2.2a}$$

$$\frac{d}{dt}(Lu)(t) = A\int_0^t C(t-\tau)Du(\tau)\,d\tau. \tag{2.2b}$$

In view of Theorem 1.1 (ii), we have that

$$L\text{: continuous } L_2(\Sigma)\to C([0,T];L_2(\Omega)), \tag{2.3a}$$

$$\frac{dL}{dt}\text{: continuous } L_2(\Sigma)\to C([0,T];H^{-1}(\Omega)). \tag{2.3b}$$

Thus, by duality of Theorem 1.1 (i), the operator L^* adjoint of L, defined by $(Lu, v)_Q = (u, L^*v)_\Sigma$, and hence given by

$$\begin{aligned}(L^*v)(t) &= D^*A^*\int_t^T S^*(\tau-t)v(\tau)\,d\tau\\ &= D^*A^*\int_T^t S^*(t-\tau)v(\tau)\,d\tau, \qquad 0\leqq t\leqq T\end{aligned} \tag{2.4}$$

satisfies the property

$$L^*\text{: continuous } L_2(Q)\to L_2(\Sigma) \tag{2.5a}$$

and, in fact, even the property

$$L^*\text{: continuous } L_1(0,T;L_2(\Omega))\to L_2(\Sigma) \tag{2.5b}$$

by duality of Theorem 1.1 (ii). (Here and throughout the paper, we extend an inner product by continuity into a corresponding duality pairing, without changing notation and with no explicit mention necessarily made).

In order to treat the (O.C.P.) corresponding to the cost $J(u, y)$ in (1.2a), we introduce the Lagrangian

$$\mathscr{L}(u,y,p)\equiv\tfrac{1}{2}\{|u|_\Sigma^2+(Ry,y)_Q\}+(p,y-C(\cdot)y_0-S(\cdot)y_1-Lu)_Q. \tag{2.6}$$

The optimality conditions: $\mathscr{L}_y(u^0,y^0,p^0)=\mathscr{L}_u(u^0,y^0,p^0)=0$ yield, respectively e.g. as in [L-T.2, below (2.7), p. 47]

$$p^0=-Ry^0, \qquad u^0=L^*p^0, \quad \text{hence } u^0=-L^*Ry^0. \tag{2.7}$$

By eliminating y^0 between (2.1a) and (2.7), we obtain

$$u^0=-[I+L^*RL]^{-1}L^*R\{C(\cdot)y_0+S(\cdot)y_1\}\in L_2(\Sigma) \tag{2.8a}$$

and hence, using this in (2.1a) and (H.1) = (1.3)

$$y^0=\{I-L[I+L^*RL]^{-1}L^*R\}\{C(\cdot)y_0+S(\cdot)y_1\}. \tag{2.8b}$$

Note that, in (2.8), the (self-adjoint) inverse operator is well-defined and bounded on $L_2(\Sigma)$. On the other hand, if we eliminate u^0 instead between (2.1a) and (2.7), we obtain

$$y^0=[I+LL^*R]^{-1}\{C(\cdot)y_0+S(\cdot)y_1\}, \tag{2.8c}$$

$$u^0=-L^*R[I+LL^*R]^{-1}\{C(\cdot)y_0+S(\cdot)y_1\}, \tag{2.8d}$$

where we have to show the existence and boundedness of the new inverse operator. Indeed

$$[I+LL^*R]^{-1}=I-L[I+L^*RL]^{-1}L^*R \tag{2.8e}$$

---

[7] Thus, $L^*v=\partial z/\partial\eta_{A^*}|_\Gamma$, where: $z_{tt}=-A^*(\xi,\partial)z+v$, in $(0,T]\times\Omega$, $z(T,\xi)=z_t(T,\xi)=0$, and $z(t,\zeta)\equiv 0$, in $(0,T]\times\Gamma$.

well-defined and bounded on $L_2(Q)$. In fact, first $[I+LL^*R]$ is (i) *injective* on $L_2(Q)$ (since $x+LL^*Rx=0$, $x\in L_2(Q)$, after $L_2(Q)$-inner product with Rx, yields $L^*Rx=0$ by (1.3), hence $x=0$) and (ii) has *range dense* in $L_2(Q)$, since its adjoint $[I+RLL^*]$ has trivial null-space here ($z+RLL^*z=0$, $z\in L_2(Q)$, after $L_2(Q)$-inner product with LL^*z, yields $L^*z=0$ by (1.3), hence $z=0$). Secondly, the identity $I=I+LL^*R-L[I+L^*RL]^{-1}[I+L^*RL]L^*R$, where $[I+L^*RL]L^*R=L^*R[I+LL^*R]$, yields that the two sides in (2.8e) coincide on the range of $[I+LL^*R]$ on $L_2(Q)$ and so, by (ii) and the boundedness of the right-hand side operator, on all of $L_2(Q)$. Equations (2.8c-e) are justified. Notice that (2.8) provides the optimal solution (u^0, y^0) as $L_2(0, T)$-*trajectories* with values in $L_2(\Gamma)$ and $L_2(\Omega)$, respectively, in terms of the initial data. Our goal, however, is to express the optimal control u^0 in "feedback form;" i.e. as an operator acting pointwise in time (or a.e. in t) on the "measured" solution $[y^0(t), \dot{y}^0(t)]$ (so called "on line," or real time implementation in the engineering literature), precisely as described in Theorem 1.3. To accomplish this, an evolution operator will be introduced to describe the dynamics of the feedback system. Let s be an arbitrary time $0\leqq s<T$. Henceforth we take s as the new initial time of our optimal control problem with corresponding initial datum $y_s=[y_{0s}, y_{1s}]\in E$; i.e. we consider the optimal control problem of the introduction, but over the time interval $[s, T]$ rather than over $[0, T]$. We shall denote the corresponding optimal solution by $y^0(t, s; y_s)$ and $u^0(t, s; y_s)$.[8] The same procedure leading to the expressions (2.8c-d), once applied to the new problem, gives then

$$-u^0(\cdot, s; y_s)=L_s^*R\{y^0(\cdot, s; y_s)\}, \tag{2.9a}$$

$$u^0(t, s; y_s)=-L_s^*R[I_s+L_sL_s^*R]^{-1}\{C(\cdot-s)y_{0s}+S(\cdot-s)y_{1s}\}, \tag{2.9b}$$

$$y^0(t, s; y_s)=[I_s+L_sL_s^*R]^{-1}\{C(\cdot-s)y_{0s}+S(\cdot-s)y_{1s}\}, \tag{2.9c}$$

as elements of $L_2(s, T; L_2(\Gamma))$ and $L_2(s, T; L_2(\Omega))$, respectively. Here (compare with (2.2a) and (2.4)), we have

$$(L_su)(t)\equiv A\int_s^t S(t-\tau)Du(\tau)\,d\tau, \qquad s\leqq t\leqq T, \tag{2.10}$$

$$(L_s^*v)(t)\equiv\begin{cases}(L^*v)(t), & s\leqq t\leqq T,\\ 0, & 0\leqq t<s,\end{cases} \quad \text{a.e.} \tag{2.11}$$

The optimal dynamics is

$$\begin{aligned} y^0(t, s; y_s)&=C(t-s)y_{0s}+S(t-s)y_{1s}+\{L_s[u^0(\cdot, s; y_s)]\}(t),\\ \dot{y}^0(t, s; y_s)&=-AS(t-s)y_{0s}+C(t-s)y_{1s}+A\int_s^t C(t-\tau)Du^0(\tau, s; y_s)\,d\tau, \end{aligned} \tag{2.12}$$

(in $C([s, T];L_2(\Omega))$ and $C([s, T]; H^{-1}(\Omega))$, respectively). We now wish to obtain an explicit expression for the operator $\Phi(t, s)$ defined by

$$\begin{vmatrix} y^0(t, s; y_s)\\ \dot{y}^0(t, s; y_s)\end{vmatrix}=\Phi(t, s)\begin{vmatrix} y_{0s}\\ y_{1s}\end{vmatrix}, \qquad 0\leqq s\leqq t\leqq T, \tag{2.13}$$

which describes the evolution of the optimal solution originating at the starting point y_s at the initial time s. Using (2.9c) and its time derivative, we arrive at the explicit

---

[8] In the new notation, the optimal solution on $[0, T]$, so far denoted by $y^0(t)$ and $u^0(t)$, will be $y^0(t, 0; y_0)$ and $u^0(t, 0; y_0)$, respectively.

expression of $\Phi(t, s)$, $(0 \leqq s \leqq t \leqq T)$

$$\Phi(t, s) = \begin{vmatrix} V_s C(\cdot - s) & V_s S(\cdot - s) \\ \cdot & \cdot \end{vmatrix} \equiv \begin{vmatrix} \Phi_1(t, s) \\ \Phi_2(t, s) \end{vmatrix} \tag{2.14}$$

where we have set $V_s \equiv [I_s + L_s L_s^* R]^{-1}$. For fixed s, by (2.13) and Theorem 1.1, $\Phi(\cdot, s)$ is a bounded operator $E \to C([s, T]; E)$. Note that L_s acts on functions defined after s (see (2.10)) and after s the actions of the operators L_s^* and L^* coincide (a.e.) (see (2.11)), thus

$$L_s L_s^* = L_s L^*. \tag{2.15}$$

Moreover, since obviously on $L_2(Q)$: $\|I_s + L_s^* R L_s\| \geqq 1$ and hence $\|[I_s + L_s^* R L_s]^{-1}\| \leqq 1$, uniformly in s, the version of (2.8e) corresponding to "s" gives $\|V_s\|_{\mathscr{L}(L_2(Q))} \leqq \text{const}_T$, for all $s \in [0, T]$ and hence from (2.14)

$$\|\Phi(\cdot, s)\|_{\mathscr{L}(E \to L_2(0, T; E))} \leqq M_T \quad \text{uniformly in } s \in [0, T]. \tag{2.16}$$

Actually, a stronger version of (2.16) is true. From (2.11) and (2.5a) we obtain $\|L_s^*\|_E = \|L^*\|_E$ and along with (2.9b) and the uniform bound on $\|V_s\|$ in the $\mathscr{L}(L_2(Q))$-norm we deduce

$$\|u^0(\cdot, s; x)\|_{L_2(s, T; L_2(\Gamma))} \leqq \text{const}_T \|x\|_E, \tag{2.17}$$

where the constant const_T depends on T but not on s. Moreover, if $u^0_{\text{ext}}(\tau, s; x)$ denotes the extension to $0 \leqq \tau < s$ by zero of the function $u^0(\tau, s; x)$, we have from (2.10)

$$\begin{aligned} \|\{L_s u^0(\cdot, s; x)\}(t)\|_{L_2(\Omega)} &\leqq \sup_{0 \leqq t \leqq T} \left\| A \int_0^t S(t-\tau) D u^0_{\text{ext}}(\tau, s; x)\, d\tau \right\|_{L_2(\Omega)}, \\ &\leqq C_T \|u^0_{\text{ext}}(\cdot, s; x)\|_{L_2(0, T; L_2(\Gamma))}, \qquad \text{(by (2.3a))} \\ &= C_T \|u^0(\cdot, s; x)\|_{L_2(s, T; L_2(\Gamma))} \leqq \text{const}_T \|x\|_E. \qquad \text{(by (2.17))} \end{aligned} \tag{2.18}$$

From (2.12)-(2.13), we then plainly obtain (by (2.18)):

$$\|\Phi_1(t, s)x\|_{L_2(\Omega)} = \|y^0(t, s; x)\|_{L_2(\Omega)} \leqq \text{const}_T \|x\|_E \tag{2.19a}$$

uniformly in s and t, $0 \leqq s \leqq t \leqq T$, which is the sought after improvement over (2.16). A similar argument gives

$$\|\Phi_2(t, s)x\|_{H^{-1}(\Omega)} \leqq \text{const}_T \|x\|_E \tag{2.19b}$$

uniformly in s and t, $0 \leqq s \leqq t \leqq T$. We can then collect some preliminary properties of $\Phi(t, s)$ in the next lemma.

LEMMA 2.1. *For the operator $\Phi(t, s)$, defined by* (2.13), $0 \leqq s \leqq t \leqq T$, *as a bounded operator from E into itself, the following properties hold true*:

(i) $\Phi(t, t) = I$ (*identity on E*), $0 \leqq t \leqq T$.

(ii) $\Phi(t, s)\Phi(s, \tau) = \Phi(t, \tau)$ (*transition*), $0 \leqq \tau \leqq s \leqq t \leqq T$.

(iii) *For each fixed s, the operator $\Phi(\cdot, s)$ is continuous $E \to C([s, T]; E)$ (strong continuity in the first variable).*

(iv) *The following uniform bound attains*:

$$\|\Phi(t, s)\|_{\mathscr{L}(E \to E)} \leqq \text{const}_T \quad \textit{for all } 0 \leqq s \leqq t \leqq T,$$

where const_T *depends only on T, but not on s.*

(v) *For t fixed, $0 < t \leqq T$, the operator $\Phi(t, \cdot)$ is continuous $E \to C([0, t]; E)$ (strong continuity in the second variable).*

Proof. (i) and (ii) above are obvious; (iii) and, in fact, (iv) were proved above (see (2.19a-b)). Moreover, strong continuity in the first variable (property (iii)) combined with the uniform bound in property (iv) yields strong continuity in the second variable in the usual way (see e.g. [L-T.2, p. 58]. □

In order to express the optimal control u^0 in a (pointwise, or a.e.) feedback form, as claimed in Theorem 1.3, we compute via (2.9a), (2.13), (2.11), and (2.4):

$$-u^0(t, s; y_s) = \{L_s^* R y^0(\cdot, s; y_s)\}(t) = \{L_s^* R \Phi_1(\cdot, s) y_s\}(t), \qquad s \leqq t \leqq T$$

$$= D^* A^* \int_t^T S^*(\tau - t) R \Phi_1(\tau, s) y_s \, d\tau.$$

If we now take the initial time $s = t$ with initial data $y_s = y_t = [y^0(t), \dot{y}^0(t)]$, we obtain the desired pointwise relation

$$-u^0(t) = D^* A^* \int_t^T S^*(\tau - t) R \Phi_1(\tau, t) \begin{vmatrix} y^0(t) \\ \dot{y}^0(t) \end{vmatrix} d\tau \tag{2.20}$$

$$= D^* A^* \int_t^T S^*(\tau - t) R \Phi_1(\tau, 0) y \, d\tau \tag{2.21}$$

with initial point $y = [y_1, y_2] \in E$ at $t = 0$, where in going from (2.20) to (2.21) we have used $[y^0(t), \dot{y}^0(t)] = \Phi(t, 0) y$, (see (2.13)), as well as $\Phi_1(\tau, t)\Phi(t, 0) y = [\Phi(\tau, t)\Phi(t, 0) y]_1 = [\Phi(\tau, 0) y]_1 = \Phi_1(\tau, 0) y$ by Lemma 2.1(ii). Indeed, we can see also directly the following.

PROPOSITION 2.2. *The expression* (2.21) *is well-defined as an* $L_2(\Sigma)$*-function for all* $y \in E$.

Proof. The proof will follow quickly from certain results to be established in § 3. It is therefore deferred to Appendix 1. □

Motivated by this, we now define an operator $\mathscr{P}(t)$ on E by

$$\mathscr{P}(t) x \equiv \int_t^T e^{\mathscr{A}^*(\tau - t)} \begin{bmatrix} R & 0 \\ 0 & 0 \end{bmatrix} \Phi(\tau, t) x \, d\tau, \qquad x \in E \tag{2.22a}$$

$$\equiv \int_t^T e^{\mathscr{A}^*(\tau - t)} \begin{vmatrix} R \Phi_1(\tau, t) x \\ 0 \end{vmatrix} d\tau.$$

For $y = [y_1, y_2]$ also in E, we compute

$$(\mathscr{P}(t) x, y)_E = \int_t^T \left(\begin{vmatrix} R \Phi_1(\tau, t) x \\ 0 \end{vmatrix}, e^{\mathscr{A}(\tau - t)} y \right)_E d\tau \tag{2.22b}$$

where, of course, from (2.1)

$$e^{\mathscr{A} t} = \begin{vmatrix} C(t) & S(t) \\ -AS(t) & C(t) \end{vmatrix} \quad \text{on } E, \tag{2.23}$$

to get that

$$(\mathscr{P}(t) x, y)_E = \int_t^T \{(C^*(\tau - t) R \Phi_1(\tau, t) x, y_1)_\Omega$$

$$+ (A^{*1/2} S^*(\tau - t) R \Phi_1(\tau, t) x, A^{-1/2} y_2)_\Omega\} \, d\tau.$$

We have written the last term so that, by (1.7b)

$$(A^{*1/2} S^*(\tau - t) R \Phi_1(\tau, t) x, A^{-1/2} y_2)_\Omega = (A^{1/2} A^{*1/2} S^*(\tau - t) R \Phi_1(\tau, t) x, y_2)_{H^{-1}(\Omega)}.$$

Thus, we obtain that $\mathscr{P}(t): E \to E$ is given alternatively by the more illuminating expression

$$\mathscr{P}(t)x = \int_t^T \begin{vmatrix} C^*(\tau - t)R\Phi_1(\tau, t)x \\ A^{1/2}A^{*1/2}S^*(\tau - t)R\Phi_1(\tau, t)x \end{vmatrix} d\tau, \qquad x \in E. \tag{2.24}$$

Now, by (1.9) with $\sigma = 0$, the Dirichlet map D is continuous: $L_2(\Gamma) \to H^{1/2}(\Omega) = H_0^{1/2}(\Omega)$ [L-M.1, I, p. 55]. Thus, D^* is continuous $H^{-1/2}(\Omega) \to L_2(\Gamma)$, ($L_2(\Gamma) =$ pivot space) where $(Du, y)_\Omega = (u, D^*y)_\Gamma$, for all $u \in L_2(\Gamma)$, and $y \in H^{-1/2}(\Omega)$. Next, we define an (unbounded) operator $\mathscr{B}^*: E \supset \mathscr{D}(\mathscr{B}^*) \to L_2(\Gamma)$ by

$$\mathscr{B}^*v = D^*A^{*1/2}A^{-1/2}v_2, \qquad v = [v_1, v_2] \in \mathscr{D}(\mathscr{B}^*). \tag{2.25}$$

Since $\mathscr{D}(\mathscr{B}^*) \supset L_2(\Omega) \otimes H^{-1/2}(\Omega)$, we conclude that $\mathscr{B}^*$ has domain dense in E. Also, we obtain from (2.24)-(2.25):

$$\mathscr{B}^*\mathscr{P}(t)x = D^*A^* \int_t^T S^*(\tau - t)R\Phi_1(\tau, t)x \, d\tau \tag{2.26}$$

$$= \{L^*R\Phi_1(\cdot, t)x\}(t) \tag{2.27}$$

for any $x \in E$ for which (2.26) is well-defined a.e. in t in $L_2(\Gamma)$. By comparison with (2.20), we see that this is certainly the case on the optimal points $[y^0(t), \dot{y}^0(t)]$ and, indeed, the optimal control u^0 in (2.21) can then be rewritten as an $L_2(\Sigma)$-function as

$$-u^0(t) = \mathscr{B}^*\mathscr{P}(t) \begin{vmatrix} y^0(t) \\ \dot{y}^0(t) \end{vmatrix} = \mathscr{B}^*\mathscr{P}(t)\Phi(t, 0) \begin{vmatrix} y_0 \\ y_1 \end{vmatrix}, \qquad [y_0, y_1] \in E \tag{2.28}$$

more desirable than (2.20), since now $\mathscr{P}(t)$ has range in, and $\mathscr{B}^*$ acts from, the basic space E. $\mathscr{P}(t)$ will be the Riccati operator. This completes the proof of part (i) in Theorem 1.3.

Some (to be expected) properties of $\mathscr{P}(t)$ are collected next.

LEMMA 2.3. *The operator $\mathscr{P}(t)$ defined by* (2.22) *or* (2.24) *satisfies the following properties*:

(i) *For each fixed $t \in [0, T]$, $\mathscr{P}(t)$ is a bounded linear operator on E, and, in fact, $\mathscr{P}(t)$ is continuous $E \to C([0, T]; E)$.*

(ii) *For each fixed $t \in [0, T]$, the following identity—which is symmetric in x and y (both in E)—holds*:

$$(\mathscr{P}(t)x, y)_E = \int_t^T (R\Phi_1(\tau, t)x, \Phi_1(\tau, t)y)_\Omega \, d\tau + \int_t^T (\mathscr{B}^*\mathscr{P}(\tau)\Phi(\tau, t)x, \mathscr{B}^*\mathscr{P}(\tau)\Phi(\tau, t)y)_\Gamma \, d\tau. \tag{2.29}$$

Thus,

1) *$\mathscr{P}(t) = \mathscr{P}^*(t)$ and $\mathscr{P}(t)$ is self-adjoint on E;*

2) *$\mathscr{P}(t)$ is nonnegative definite.*

(iii) *The minimal* (optimal) *value of the performance index J of the optimal control problem on $[s, t]$, $s < T$, that initiates at y_s at time s is*

$$J^0(u^0(\cdot, s; y_s), y^0(\cdot, s; y_s)) = (\mathscr{P}(s)y_s, y_s)_E. \tag{2.30}$$

Hence, for any $x \in E$, the map $t \to (\mathscr{P}(t)x, x)_E$ is monotone decreasing.

Proof. (i) That $\mathscr{P}(t)$ is bounded on E for fixed t, or that $\mathscr{P}(t)x \in L_\infty(0, T; E)$, $x \in E$, follows immediately from (2.24) using: (1) the uniform bound on Φ_1 in Lemma 2.1

(iv); (2) the norm (1.7c) on $H^{-1}(\Omega)$; and (3) the property (1.10) for $A^{*1/2}S^*(t)z$, $z \in L_2(\Omega)$. To show that, in fact, $\mathscr{P}(t)x \in C([0, T]; E)$, one adds and subtracts a same quantity and uses, in addition to the above, the Lebesgue's dominated convergence theorem [H-P.1, p. 83]. Details are omitted.

(ii) By combining (2.1a, b) and recalling the definition of $\Phi(\cdot, \cdot)$ in (2.12) and also (2.23), we can write for $x \in E$

$$\Phi(\tau, t)x = e^{\mathscr{A}(\tau-t)}x + A\int_t^\tau \begin{vmatrix} S(\tau-\sigma)Du^0(\sigma, \tau; x) \\ C(\tau-\sigma)Du^0(\sigma, \tau; x) \end{vmatrix} d\sigma,$$

i.e. in view of (2.28)

$$e^{\mathscr{A}(\tau-t)}x = \Phi(\tau, t)x + A\int_t^\tau \begin{vmatrix} S(\tau-\sigma)D\mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)x \\ C(\tau-\sigma)D\mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)x \end{vmatrix} d\sigma. \tag{2.31}$$

We next substitute the expression of $e^{\mathscr{A}(\tau-t)}$ given by (2.31) into the right-hand side of (2.22b) to get

$$(\mathscr{P}(t)x, y)_E = \int_t^T (R\Phi_1(\tau, t)x, \Phi_1(\tau, t)y)_\Omega \, d\tau + I \tag{2.32}$$

where, changing the order of integration on I (see Appendix 2), we can write

$$I = \int_t^T \int_t^\tau (\Phi_1(\tau, t)x, AS(\tau-\sigma)D\mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)y)_\Omega \, d\sigma \, d\tau$$

$$= \int_t^T \left(\int_\sigma^T D^*A^*S^*(\tau-\sigma)\Phi_1(\tau, t)x \, d\tau, \mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)y \right)_\Omega d\sigma$$

(since $\Phi(\tau, \sigma)\Phi(\sigma, t)x = \Phi(\tau, t)x$, by Lemma 2.1(ii), and thus $\Phi_1(\tau, \sigma)\Phi(\sigma, t)x = \Phi_1(\tau, t)x$)

$$= \int_t^T (\mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)x, \mathscr{B}^*\mathscr{P}(\sigma)\Phi(\sigma, t)y)_\Gamma \, d\sigma \tag{2.33}$$

where, in the last step, we have made use of (2.26). Setting $x = y$ in (2.32)-(2.33) yields (ii.1)-(ii.2). Property (iii) follows from (ii) via (2.12) and (2.28). □

3. Regularity results.

3.1. Further regularity results for the mixed problem (1.1) needed for the (O.C.P.). In order to establish appropriate regularity for the optimal pair u^0, y^0 of the (O.C.P.) and to derive a Riccati equation, it is necessary to obtain preliminary *certain* regularity results of the mixed problem (1.1). This will be done in the present section, since we cannot merely quote these results from our own, or others' previous work. The technique used is in the style of [L-T.1], [L-T.3]. To this end, we begin with an abstract lemma, which will be used repeatedly.

LEMMA 3.1. *With X and Y two given separable Hilbert spaces, let $F(t) \in \mathscr{L}(X, Y)$ a.e. in $t \in [0, T]$. Define a (linear) operator $F(\cdot)$ by: $F(\cdot)x = F(t)x \in Y$, a.e. in $t \in [0, T]$, $x \in X$ and assume that $F(\cdot)$ is continuous $X \to L_2(0, T; Y)$; i.e.*

$$\|F(\cdot)x\|^2_{L_2(0,T;Y)} \equiv \int_0^T \|F(t)x\|^2_Y \, dt \leqq C_T\|x\|^2_X. \tag{3.1}$$

Then, for any $x(t) \in L_1(0, T; X)$, the operator $\bar{F}$ defined by: $(\bar{F}x(\cdot))(t) \equiv F(t)\int_0^t x(\tau) \, d\tau$

is continuous $L_1(0, T; X) \to L_2(0, T; Y)$:

$$\int_0^T \left\| F(t) \int_0^t x(\tau)\, d\tau \right\|_Y^2 dt \leqq C_T \int_0^T \|x(t)\|_X\, dt. \tag{3.2}$$

Proof of Lemma 3.1. If $F^*(t) \in \mathscr{L}(Y, X)$ a.e. in t is the adjoint of $F(t)$: $(F(t)x, y)_Y = (x, F^*(t)y)_X$ a.e., $x \in X$, $y \in Y$, we compute for $g \in L_2(0, T; Y)$, through a change of the order of integration and Schwarz inequality

$$\begin{aligned}
(\bar{F}x(\cdot), g)_{L_2(0, T; Y)} &= \int_0^T (F(t) \int_0^t x(\tau)\, d\tau, g(t))_Y\, dt \\
&= \int_0^T \int_0^t (x(\tau), F^*(t)g(t))_X\, d\tau\, dt \\
&= \int_0^T \int_\tau^T (F(t)x(\tau), g(t))_Y\, dt\, d\tau \qquad (3.3) \\
&\leqq \|g\|_{L_2(0, T; Y)} \int_0^T \left\{ \int_0^T \|F(t)x(\tau)\|_Y^2\, dt \right\}^{1/2} d\tau \\
&\leqq C_T \|g\| \int_0^T \|x(\tau)\|_X\, d\tau < \infty \qquad \text{(by (3.1))}
\end{aligned}$$

and $\bar{F}$ is well-defined from all of $L_1(0, T; Y)$ into $L_2(0, T; Y)$. Moreover, from (3.3) the adjoint $\bar{F}^*$ of $\bar{F}$, given by

$$(\bar{F}^* g)(\tau) \equiv \textstyle\int_\tau^T F^*(t)g(t)\, dt \tag{3.4}$$

is certainly well-defined on a dense set (e.g. step functions) of $L_2(0, T; Y)$ into $L_1(0, T; X)$. Thus, $\bar{F}$ is closable [K.1, p. 168] and by the closed graph theorem, $\bar{F}$ is bounded as claimed. □

The next theorem was proved in [L-T.3] and has a trace theory interpretation for the mixed problem (1.1). It played a crucial role there in our argument that succeeded in strengthening the regularity of the operator L in Theorem 1.1 from statement (i) into statement (ii). For completeness, we shall also include a sketch of its proof.

THEOREM 3.2 [L-T.3, "only if" part of Theorem 2.1]. *The operators* J_1 *and* J_2

$$(J_1 x)(t) \equiv D^* A^* S^*(t)x;\ (J_2 x)(t) \equiv D^* A^{*1/2} C^*(t)x \tag{3.5}$$

are bounded linear operators $L_2(\Omega) \to L_2(\Sigma)$.

Proof (*sketch*). It makes crucial use of the boundedness of $L^*: L_2(Q) \to L_2(\Sigma)$ (statement (2.5a)), thus of statement (i) in Theorem 1.1. The following identities hold for cosine and sine operators [T-W.1], [F.1].

$$S(s+t) + S(s-t) = 2S(s)C(t), \tag{3.6a}$$

$$S(s+t) = S(s)C(t) + S(t)C(s), \tag{3.6b}$$

$$C(t+s) - C(t-s) = -2AS(t)S(s). \tag{3.6c}$$

For $x \in L_2(\Omega)$, we now compute directly $L^*C(\cdot)x$ via (2.4) and (3.6a) (see also (1.11))

$$
\begin{aligned}
L^*C^*(\cdot)x &= D^*A^* \int_t^T S^*(\tau - t)C^*(\tau)x \, d\tau \\
&= \frac{1}{2} D^*A^* \int_t^T [S^*(2\tau - t) - S^*(t)]x \, d\tau \\
&= -\frac{1}{2}\left[\frac{1}{2} D^*C^*(2\tau - t)x\right]_{\tau=t}^{\tau=T} - \frac{(T-t)}{2} D^*A^*S^*(t)x \\
&= -\frac{1}{4} D^*C^*(2T - t)x - \frac{1}{4} D^*C^*(t)x - \frac{(T-t)}{2} D^*A^*S^*(t)x.
\end{aligned} \tag{3.7}
$$

Since $L^*C^*(\cdot)x \in L_2(\Sigma)$, and the first and second terms on the right of (3.7) are in $C([0, T]; L_2(\Gamma))$, we deduce that $(T-t)D^*A^*S^*(t)x \in L_2(0, T; L_2(\Gamma))$ for *any* T, and hence that $D^*A^*S^*(t)x \in L_2(0, T; L_2(\Gamma))$. Next, one proves that J_1 is closable, since its dual J_1^* (given explicitly below in (3.8)) is densely defined. By the closed graph theorem J_1 is bounded $L_2(\Omega) \to L_2(\Sigma)$.

The proof for J_2 is similar, starting now with $L^*A^{*1/2}S^*(\cdot)x$. See [L-T.3] for details. (We also refer to [L-T.3] for the converse of this result, which is not needed here: i.e. if J_1 and J_2 are bounded $L_2(\Omega) \to L_2(\Sigma)$, then L^* is bounded $L_2(Q) \to L_2(\Sigma)$.)

Remark 3.1. Theorem 3.2 admits a trace theory interpretation of problem (1.1) with homogeneous B.C. $u \equiv 0$, since D^*A^* is nothing but the operator of the co-normal derivative on Γ

$$
\begin{aligned}
&-D^*A^* = \frac{\partial}{\partial \nu_{A^*}}\bigg|_\Gamma, \quad \text{in particular } -D^*A^* = \frac{\partial}{\partial \nu}\bigg|_\Gamma \\
&\qquad\qquad \text{in the Laplacian case } -A(\xi, \partial) = \Delta.
\end{aligned} \tag{3.8}
$$

See in [L-T.3, Remark 2.1] or in [L-L-T.1, (3.4)] for more details. □

By taking the dual operator to J_1 and J_2: $(J_i x, u)_\Sigma = (x, J_i^* u)_\Omega$, we obtain the following.

COROLLARY 3.3. *For* $u \in L_2(\Sigma)$, *the integrals*

$$
A \int_0^t S(\tau)Du(\tau) \, d\tau \quad \text{and} \quad A^{1/2} \int_0^t C(\tau)Du(\tau) \, d\tau, \qquad 0 \leqq t \leqq T \tag{3.9}
$$

are well-defined as $L_2(\Omega)$*-functions, which moreover, are continuous in* $t \in [0, T]$.

THEOREM 3.4. *For* $0 \leqq \theta \leqq 1$ *and with reference to* (1.9c) *the operators* J_i *of* (3.5)

$$
(J_1 x)(t) = D^*A^*S^*(t)x, \qquad (J_2 x)(t) = D^*A^{*1/2}C^*(t)x
$$

are continuous $\mathscr{D}(A^\theta) \equiv \mathscr{D}(A^{*\theta}) \to H^{2\theta, 2\theta}(\Sigma)$ (*footnote* 6).

Proof. It suffices to prove the case $\theta = 1$, and interpolate with Theorem 3.2 ($\theta = 0$). With $x \in \mathscr{D}(A^*)$, we compute

$$
\left.
\begin{aligned}
&\frac{d^2}{dt^2} D^*A^*S^*(t)x = \frac{d}{dt} D^*A^*C^*(t)x = -D^*A^*S^*(t)A^*x, \\
&\frac{d^2}{dt^2} D^*A^{*1/2}C^*(t)x = -\frac{d}{dt} D^*A^{*1/2}S^*(t)A^*x = -D^*A^{*1/2}C^*(t)A^*x,
\end{aligned}
\right\} \in L_2(\Sigma) \tag{3.10}
$$

continuously, by Theorem 3.2 and $J_i x \to H^2(0, T; L_2(\Gamma))$. To prove that

$$
J_i x \in L_2(0, T; H^2(\Gamma)), \qquad x \in \mathscr{D}(A^*), \tag{3.11}
$$

we introduce, as in [L-L-T.1], a second order operator

$$B=\sum_{i,j} b_{ij}\frac{\partial^2}{\partial\xi_i\,\partial\xi_j}$$

on $\bar{\Omega}$, *tangential* to Γ (i.e. without transversal derivatives to Γ, when expressed in local coordinates) and with smooth coefficients b_{ij} on $\bar{\Omega}$. For simplicity of notation (only), we take A self-adjoint. We argue only for J_1. The solution of the problem

$$\begin{aligned} &\phi_{tt}=-A(\xi,\partial)\phi && \text{in } Q,\\ &\phi|_{t=0}=0, \qquad \phi_t|_{t=0}=x\in\mathscr{D}(A)\subset H^2(\Omega) && \text{in } \Omega,\\ &\phi|_\Gamma=0 && \text{in } \Sigma, \end{aligned} \tag{3.12}$$

is $\phi(t)=S(t)x$ and by Remark 3.1 with $\partial/\partial\nu_A$ written as $\partial/\partial\nu$

$$(J_1x)(t)=D^*AS(t)x=\frac{\partial}{\partial\nu}S(t)x\bigg|_\Gamma=\frac{\partial\phi(t)}{\partial\nu}\bigg|_\Gamma. \tag{3.13}$$

If we introduce a new variable

$$w=B\phi, \tag{3.14}$$

then proving (3.11) for $i=1$ is equivalent to proving that

$$\frac{\partial}{\partial\nu}B\phi\bigg|_\Gamma=\frac{\partial w}{\partial\nu}\bigg|_\Gamma\in L_2(\Sigma). \tag{3.15}$$

Notice that, as is well known (e.g. [K-N.1]), the commutator

$$K\equiv -BA(\cdot,\cdot)+A(\cdot,\cdot)B \tag{3.16}$$

is an operator of order $2+2-1=3$ in ξ, with smooth coefficients in $\bar{\Omega}$. From (3.14) and (3.12), we obtain the problem for w

$$\begin{aligned} &w_{tt}=-A(\xi,\partial)w+f && \text{in } Q,\\ &w|_{t=0}=0, \qquad w_t|_{t=0}=Bx\in L_2(\Omega) && \text{in } \Omega\\ &w|_\Gamma=0 && \text{in } \Sigma, \end{aligned} \tag{3.17}$$

where we have set $f\equiv K\phi$. Thus, since $\phi(t)=S(t)x\in\mathscr{D}(A^{3/2})\subset H^3(\Omega)$ for $x\in\mathscr{D}(A)$, we have

$$f\equiv K\phi\in L_2(Q). \tag{3.18}$$

The solution of (3.17) is

$$w(t)=S(t)(Bx)+\int_0^t S(t-\tau)f(\tau)\,d\tau. \tag{3.19}$$

By Theorem 3.2, since $Bx\in L_2(\Omega)$, then

$$D^*AS(t)(Bx)\in L_2(\Sigma). \tag{3.20}$$

Using identity (3.6b), we can write

$$\begin{aligned} D^*A\int_0^t S(t-\tau)f(\tau)\,d\tau=D^*AS(t)\int_0^t C(\tau)f(\tau)\,d\tau\\ -D^*A^{1/2}C(t)\int_0^t A^{1/2}S(\tau)f(\tau)\,d\tau. \end{aligned} \tag{3.21}$$

Now, both integrands in (3.21) are in $L_2(0, T; L_2(\Omega))$ by (3.18) and (1.10). Thus, Theorem 3.2 allows us to apply the abstract Lemma 3.1 with $X = L_2(\Omega)$, $Y = L_2(\Gamma)$ and obtain that each of the two terms on the right-hand side of (3.21) is in $L_2(\Sigma)$. Thus, returning to (3.19), and using (3.20)-(3.21), we conclude that

$$\frac{\partial w}{\partial \nu} = D^*AS(t)(Bx) + D^*A\int_0^t S(t-\tau)f(\tau)\,d\tau \in L_2(\Sigma) \tag{3.22}$$

and (3.15) is proved. Thus, (3.11) holds true if $i = 1$. A similar argument proves (3.11) for $i = 2$. An application of the closed graph theorem completes the proof. □

The next theorem complements statement (2.5a) on the regularity of the operator L^*; in its proof, we shall use Theorem 3.4 for $\theta = 1$.

THEOREM 3.5. *With* $0 \leqq \theta \leqq 1$, *we have for the operator* L^* *in* (2.4)

$$L^*\text{: continuous } L_2(0, T; \mathscr{D}(A^\theta)) \to H^{2\theta,2\theta}(\Sigma); \tag{3.23a}$$

equivalently,

$$L^*A^{-\theta}\text{: continuous } L_2(Q) \to H^{2\theta,2\theta}(\Sigma). \tag{3.23b}$$

Proof. It suffices to prove the case $\theta = 1$ and interpolate with (2.5a). To prove

$$v \in L_2(0, T; \mathscr{D}(A) \equiv \mathscr{D}(A^*)) \to L^*v \in L_2(0, T; H^2(\Gamma)) \tag{3.24}$$

we use (2.4) and indentity (3.6b) to get

$$\begin{aligned}(L^*v)(t) &= D^*A^*\int_t^T S^*(\tau - t)v(\tau)\,d\tau \\ &= D^*C^*(t)A^{*-1/2}\int_t^T A^{*1/2}S^*(\tau)A^*v(\tau)\,d\tau \\ &\quad - D^*S^*(t)\int_t^T C^*(\tau)A^*v(\tau)\,d\tau.\end{aligned} \tag{3.25}$$

A fortiori from Theorem 3.4 with $\theta = 1$, we are authorized to apply the abstract Lemma 3.1 with $F(t)$ either $D^*C^*(t)A^{*-1/2}$ or $D^*S^*(t)$, while $X = L_2(\Omega)$ and $Y = H^2(\Gamma)$. We thus obtain that each term in (3.25) (right) is in $L_2(0, T; H^2(\Gamma))$, i.e. (3.24). To prove the remaining part

$$v \in L_2(0, T; \mathscr{D}(A^*)) \to \frac{d^2(L^*v)}{dt^2}(t) \in L_2(\Sigma) \tag{3.26}$$

we compute from (2.4)

$$\frac{d^2(L^*v)}{dt^2}(t) = -\frac{d}{dt}D^*A^*\int_t^T C^*(\tau - t)v(\tau)d\tau = D^*A^*v(t) - (L^*(A^*v))(t) \tag{3.27}$$

and (3.27) implies (3.26) via (2.5a). □

The following consequences, particularly Theorem 3.8 below, will be needed in § 3.2, in the study of the regularity of the optimal solutions of the O.C.P.

THEOREM 3.6.

(i)

$$\left.\begin{array}{l} u \in C([0, T]; H^{1/2}(\Gamma)) \cap H^1(0, T; L_2(\Gamma)) \\ u(0) = 0 \text{ (}\textit{compatibility relation}\text{)} \end{array}\right\} \to Lu \in C([0, T]; H^1(\Omega)). \tag{3.28}$$

(ii) *Moreover,*

$$\left.\begin{array}{l} u \in H^1(0, T; L_2(\Gamma)) \\ u(0) = 0 \end{array}\right\} \to \frac{dLu}{dt} \in C([0, T]; L_2(\Omega)). \tag{3.29}$$

Proof. (i) Integrating (2.2a) by parts with $\dot{u} \in L_2(\Sigma)$ and using the *compatibility relation* gives

$$\begin{aligned} (Lu)(t) &= A \int_0^t AS(t-\tau)A^{-1}Du(\tau)\, d\tau = A \int_0^t \frac{dC(t-\tau)}{d\tau} A^{-1}Du(\tau)\, d\tau \\ &= C(0)Du(t) - C(t)Du(0) - \int_0^t C(t-\tau)D\dot{u}(\tau)\, d\tau \\ &= Du(t) - \left(A^{-1}\frac{dL\dot{u}}{dt}\right)(t) \end{aligned} \tag{3.30}$$

where by (2.2b) and the identity

$$C(t+s) = C(t)C(s) + AS(t)S(s) \qquad s, t \in R \tag{3.31}$$

(obtained summing up identities (2.4) and (2.28) in [T-W.1]),

$$\begin{aligned} \left(A^{-1}\frac{dL\dot{u}}{dt}\right)(t) &= \int_0^t C(t-\tau)D\dot{u}(\tau)\, d\tau \\ &= C(t)\int_0^t C(\tau)D\dot{u}(\tau)\, d\tau - S(t)A^{1/2}\int_0^t A^{1/2}S(\tau)D\dot{u}(\tau)\, d\tau. \end{aligned} \tag{3.32}$$

By Corollary 3.3 and (1.10), each of the two terms on (3.32) (right) is in $C([0, T]; \mathcal{D}(A^{1/2})) = H_0^1(\Omega))$. Returning to (3.30), we have $Du \in C([0, T]; H^1(\Omega))$, by elliptic theory with $u \in C([0, T]; H^{1/2}(\Gamma))$, and (i) follows. (ii) Differentiating (3.30) (via the left-hand side of (3.32)) yields for $\dot{u} \in L_2(\Sigma)$

$$\left(\frac{dLu}{dt}\right)(t) = A\int_0^t S(t-\tau)D\dot{u}(\tau)\, d\tau = (L\dot{u})(t) \in C([0, T]; L_2(\Omega)) \tag{3.33}$$

by statement (2.3a). □

Theorem 3.6 states what is needed in the sequel: a more complete result is given in [L-L-T.1]. A fortiori, since [L-M.1, I, Thm. 3.1, p. 19]

$$u \in H^{1,1}(\Sigma) \Rightarrow u \in C([0, T]; H^{1/2}(\Gamma)) \tag{3.34}$$

we obtain part (i) of the following corollary.

COROLLARY 3.7. *We have*

(i)

$$\left.\begin{array}{l} u \in H^{1,1}(\Sigma) \\ u(0) = 0 \end{array}\right\} \to \begin{array}{l} Lu \in C([0, T]; H^1(\Omega)) \\ \dfrac{dLu}{dt} \in C([0, T]; L_2(\Omega)) \end{array} \to Lu \in H^{1,1}(\Omega), \tag{3.35}$$

(ii) *For* $0 \leqq \theta < \frac{1}{2}$

$$u \in H^{\theta,\theta}(\Sigma) \to \left\{\begin{array}{l} Lu \in C([0, T]; H^{\theta}(\Omega)) \\ \dfrac{dLu}{dt} \in C([0, T]; H^{\theta-1}(\Omega)) \end{array}\right. \to Lu \in H^{\theta,\theta}(Q). \tag{3.36}$$

(iii) *Indeed for* $0 \leqq \theta < \frac{1}{2}$

$$u \in H^{\theta}(0, T; L_2(\Gamma)) \to \frac{dLu}{dt} \in C([0, T]; H^{\theta-1}(\Omega)). \tag{3.37}$$

Proof. We interpolate with $0 \leqq \theta < \frac{1}{2}$, so that the C.R. (compatibility relation) $u(0) = 0$ is irrelevant, between (2.3) and part (i) to get part (ii); and between (2.3b) and Theorem 3.6(ii) to get part (iii), see [L-M.1, Thm. 14.2, p. 95]. □

THEOREM 3.8. *With reference to the operators* L *and* L^* *in* (2.2) *and* (2.4), *the following regularity results hold*:

(i) *For* $0 \leqq \beta < \frac{1}{4}$, *we have*

$$A^{\beta} LL^* A^{-\beta}\text{: continuous } L_2(Q) \to C([0, T]; L_2(Q)); \tag{3.38a}$$

equivalently, with $\mathcal{D}(A^{\beta}) = H^{2\beta}(\Omega)$ (*see* (1.9b))

$$LL^*\text{: continuous } L_2(0, T; \mathcal{D}(A^{\beta})) \to C([0, T]; \mathcal{D}(A^{\beta})). \tag{3.38b}$$

(ii) *Moreover, for any* $\varepsilon > 0$

$$\frac{d}{dt}(LL^*) = \frac{dL}{dt} L^*\text{: continuous } L_2(0, T; H^{1/2-\varepsilon}(\Omega)) \to C([0, T]; H^{-1/2-\varepsilon}(\Omega)). \tag{3.39}$$

Proof. (i) We have

$$L^* A^{-\beta}\text{: continuous } L_2(Q) \to H^{2\beta, 2\beta}(\Sigma) \tag{3.40}$$

by (3.23b) in Theorem 3.5, and restricting β to $0 \leqq \beta < \frac{1}{4}$ so that $H^{2\beta}(\Omega) = \mathcal{D}(A^{\beta})$, we have

$$A^{\beta} L\text{: continuous } H^{2\beta, 2\beta}(\Sigma) \to C([0, T]; L_2(\Omega)) \tag{3.41}$$

a fortiori from Corollary 3.7(ii).

(ii) Plainly,

$$\frac{d(LL^*)}{dt} = \frac{dL}{dt} L^* \tag{3.42}$$

from (2.2a) and (2.4). But, by (3.23) in Theorem 3.5

$$L^*\text{: continuous } L_2(0, T; \mathcal{D}(A^{1/4-\varepsilon/2}) = H^{1/2-\varepsilon}(\Omega)) \to H^{1/2-\varepsilon, 1/2-\varepsilon}(\Sigma)$$

and part (ii) follows a fortiori from Corollary 3.7(iii) with $\theta = \frac{1}{2} - \varepsilon$. □

3.2. Regularity of optimal pair u^0, y^0 of the (O.C.P.). Once in possession of the regularity results of the previous subsection for the general mixed problem (1.1), we can now proceed to obtain regularity results for the optimal pair (u^0, y^0) of the (O.C.P.). While throughout § 2, the penalization operator R was subject only to the general assumption (H.1), so that R could also be the identity I on $L_2(\Omega)$, it turns out that the regularity theory for the optimal pair u^0, y^0 is particularly rich, if R is subject to any one of various possible "rather minimal" assumptions of ε-regularity type for an arbitrary $\varepsilon > 0$. This will also help in the derivation of the Riccati equation. Of said possible choices, we opt here for the following two versions. In addition to the standing hypothesis (H.1), R is assumed to satisfy either

$$\text{(H.2) } R\text{: continuous } H^{1/2-\delta}(\Omega) \equiv \mathcal{D}(A^{1/4-\delta/2}) \to H_0^{1/2+\delta}(\Omega) \equiv \mathcal{D}(A^{1/4+\delta/2}) \tag{3.43}$$

or else, less restrictively,

$$\text{(H.2')} \; R\text{: continuous } H^{1/2-\delta}(\Omega) \equiv \mathcal{D}(A^{1/4-\delta/2}) \to \mathcal{D}(A^{1/4}) \tag{3.44}$$

for some *arbitrarily small* number $\delta > 0$. Henceforth kept *fixed*: as a result of (H.2) or (H.2'), we shall obtain two slightly different regularity results for u^0 in Theorem 3.11 below. As the injection $\mathscr{D}(A^{1/4})$ or $(\mathscr{D}(A^{1/4+\delta/2})) \to H^{1/2-\delta}(\Omega)$ is compact, we have that

$$\left.\begin{array}{r}\text{under either assumption (3.43)}\\ \text{or assumption (3.44)}\end{array}\right\} \quad R \text{ is compact } H^{1/2-\delta}(\Omega) \to \text{itself} \tag{3.45}$$

a property needed later. With T and $\delta > 0$ fixed once and for all, we next introduce a function space

$$W = \left\{ f : f \in L_2(0, T; H^{1/2-\delta}(\Omega)), \frac{df}{dt} \in L_2(0, T; H^{-1/2-\delta}(\Omega)) \right\}. \tag{3.46}$$

By interpolation, $f \in W$ implies $D_t^{1/2-\delta} f \in L_2(Q)$, i.e.

$$f \in W \Rightarrow f \in H^{1/2-\delta, 1/2-\delta}(Q). \tag{3.47}$$

We shall need below a well-known compactness result, which we find convenient to state explicitly for easy use in various situations.

LEMMA 3.9 [A.1]. *Let B_0, B, B_1 be three Banach spaces with* (i) $B_0 \subset B \subset B_1$, $B_i =$ *reflexive*, $i = 0, 1$ (*where* $\subset$ *means that the inclusion is algebraic and topological*) *and with* (ii) *injection $B_0 \to B$ compact. Define the Banach space*

$$X \equiv \left\{ v : v \in L^{p_0}(0, T; B_0),\ v' = \frac{dv}{dt} \in L^{p_1}(0, T; B_1) \right\}$$

$0 < T < \infty$, $1 < p_i < \infty$, $i = 0, 1$ *with norm*

$$\|v\|_{L^{p_0}(0, T; B_0)} + \|v'\|_{L^{p_1}(0, T; B_1)}.$$

Then, the injection $X \to L^{p_0}(0, T; B)$ is compact.

A first application of this Lemma 3.9 is in the following theorem, a first step toward the regularity of y^0 (refer to (2.8c)).

THEOREM 3.10. *Let R satisfy* (H.1) *and* (H.2') = (3.44). *Then*

(i) *the operator LL^*R is compact $W \to W$ (see* (3.46));

(ii) *the operator $[I + LL^*R]$ is invertible on W, with bounded inverse on W.*

Proof. (i) With reference to (3.46) and Y below, we have:

$$W \xrightarrow[\text{continuous}]{R} Y \xrightarrow[\text{compact}]{\text{injection}} L_2(0, T; H^{1/2-\delta}(\Omega)) \xrightarrow[\text{continuous}]{LL^*} W, \tag{3.48}$$

by Lemma 3.9 — by Theorem (3.8)(i), $\beta = \frac{1}{4} - \delta/2$

$$Y = \left\{ v : v \in L_2(0, T; \mathscr{D}(A^{1/4})), \frac{dv}{dt} \in L_2(0, T; H^{-1/2-\delta}(\Omega)) \right\}, \tag{3.49}$$

where in the second step we apply Lemma 3.9 with $B_0 = \mathscr{D}(A^{1/4})$, $B = H^{1/2-\delta}(\Omega)$, $B_1 = H^{-1/2-\delta}(\Omega)$, $p_0 = p_1 = 2$ and in the third step Theorem 3.8, (3.38b) with $\beta = \frac{1}{4} - \delta/2$. Diagram (3.48) proves (i).

(ii) Because of the compactness of part (i), it suffices to see that $\lambda = 1$ is not an eigenvalue of LL^*R as an operator $W \to W$, finite otherwise $\lambda = 1$ would be a fortiori an eigenvalue of LL^*R: $L_2(Q) \to L_2(Q)$, which we already know to be impossible (see injectivity below (2.8e)). □

THEOREM 3.11 (regularity of optimal control u^0 and optimal solution y^0). *Let the initial data be*

$$[y_0, y_1] \in H^{1/2-\delta}(\Omega) \times H^{-1/2-\delta}(\Omega) \equiv \mathscr{D}(A^{1/4-\delta/2}) \times [\mathscr{D}(A^{1/4+\delta/2})]' \tag{3.50}$$

and let R satisfy ((H.1) *and*) (H.2′) = (3.44). *Then*:

$$y^0 \in C([0, T]; H^{1/2-\delta}(\Omega)) \cap H^{1/2-\delta}(0, T; L_2(\Omega)), \tag{3.51 (i)}$$

$$\frac{dy^0}{dt} \in C([0, T]; H^{-1/2-\delta}(\Omega)) \tag{3.52}$$

and

$$u^0 \in H^{1/2,1/2}(\Sigma). \tag{3.53 (ii)}$$

Moreover, if R satisfies instead (H.2) = (3.43), *then*

$$u^0 \in H^{1/2+\delta,1/2+\delta}(\Sigma), \tag{3.54a (ii′)}$$

$$\textit{a fortiori } u^0 \in C([0, T]; L_2(\Gamma)). \tag{3.54b}$$

Proof. (i) By (2.8c) and (3.50), as a consequence of Theorem 3.10(ii), we have $y^0 \in W$ in (3.46) and by (3.47) $y^0 \in H^{1/2-\delta,1/2-\delta}(Q)$. From here, a bootstrap argument gives the full statement (3.51)-(3.52): we return to (2.8c), now rewritten as

$$y^0 = -LL^*Ry^0 + C(\cdot)y_0 + S(\cdot)y_1 \tag{3.55}$$

where, a fortiori, $Ry^0 \in L_2(0, T; H^{1/2-\delta}(\Omega))$. Thus, we can apply Theorem 3.8(i) [(3.38b), with $\beta = \frac{1}{4} - \delta/2$], and (ii), to obtain the regularity of LL^*Ry^0, while (3.50) (and (1.10)) determines the regularity of $C(\cdot)y_0 + S(\cdot)y_1$. We obtain

$$\begin{aligned} &LL^*Ry^0,\ C(\cdot)y_0 + S(\cdot)y_1 \in C([0, T]; H^{1/2-\delta}(\Omega)), \\ &\frac{d}{dt}(LL^*Ry^0), \frac{d}{dt}[C(\cdot)y_0 + S(\cdot)y_1] \in C([0, T], H^{-1/2-\delta}(\Omega)), \end{aligned} \tag{3.56}$$

and (3.51)-(3.52) now follow from (3.56) via (3.55).

(ii) To prove (3.53-(3.54), we use $u^0 = -L^*Ry^0$, (2.7), where, a fortiori from part (i),

$$Ry^0 \in \begin{cases} C([0, T]; \mathscr{D}(A^{1/4})) & \text{if } R \text{ satisfies (H.2′) = (3.44),} \\ C([0, T]; \mathscr{D}(A^{1/4+\delta/2})) & \text{if } R \text{ satisfies (H.2) = (3.43).} \end{cases} \tag{3.57}$$

The desired conclusions on u^0 now follow from (3.57), by invoking Theorem 3.5, (3.23a). □

3.3. Further regularity properties of $\Phi(t, s)$. In Lemma 2.1 we collected some preliminary properties of the evolution operator $\Phi(t, s)$ on E, which were valid for any penalization operator R satisfying only the general assumption (H.1). In § 3.2, we introduced some "minimal" regularity assumptions (H.2) or (H.2′) on R and deduced, in Theorem 3.11, corresponding regularity properties of y^0. These, via the definition (2.13), translate into analogous properties for $\Phi(t, s)$, with s fixed. The goal of the present subsection, which culminates in Theorem 3.16 below, is to deduce further regularity properties for $\Phi(t, s)$ in the case where R satisfies also assumption (H.2) = (3.43) or (H.2′) = (3.44): these will be *uniformly* on s and either on a space smoother than E or else on the space of distributions $H^{-1/2-\delta}(\Omega)$ for the first coordinate $\Phi_1(t, s)$. These properties will be needed in the derivation of the Riccati equation. To accomplish

our aim, we see through (2.14) that we must therefore study properties of the family of operators $I_s + L_s L_s^* R \equiv I_s + L_s L^* R$ (see (2.15)), $s \in [0, T]$. First, we shall extend the statement of Theorem 3.11(ii), uniformly in s. This is accomplished via the following lemma, which we give in a generality larger than our needs in the sequel will call for.

LEMMA 3.12. *Given a Banach space Z, $\|\cdot\|$, assume that:*

(a) *$\{K_t\}$ is a family of compact operators on Z, for each $t \in [0, T]$, $T < \infty$;*

(b) *the map $t \to K_t x$ is continuous for each $x \in Z$;*

(c) *for each fixed $t \in [0, T]$, the inverse $[I + K_t]^{-1}$ exists as a well-defined bounded operator on Z.*

Then, in fact

$$\|[I + K_t]^{-1}\|_{\mathscr{L}(Z)} \leqq C_T, \quad \text{uniformly in } t \in [0, T]. \tag{3.58}$$

Proof. From (a) and (b) it follows that the set

$$\mathscr{K} \equiv \bigcup_{0 \leqq t \leqq T} K_t \quad [\text{unit ball in } Z]$$

is precompact.[9] Next, by contradiction, let conclusion (3.58) be false so that there are sequences $\{t_n\}$, $\{x_n\}$, $t_n \in [0, T]$, $\|x_n\| = 1$ such that

$$[I + K_{t_n}]x_n \to 0 \quad \text{as } n \to \infty. \tag{3.59}$$

But plainly $\{K_{t_n} x_n\} \in K$ and thus, there is a convergent subsequence

$$K_{t_{n_k}} x_{n_k} \to y \in \bar{\mathscr{K}}. \tag{3.60}$$

Then, by (3.59)-(3.60)

$$x_{n_k} = (I + K_{t_{n_k}})x_{n_k} - K_{t_{n_k}} x_{n_k} \to -y \tag{3.61}$$

so that $\|y\| = 1$. Also, by (b), the Principle of Uniform Boundedness gives $\|K_t\|_{\mathscr{L}(Z)} \leqq C_T$, for all $t \in [0, T]$. Thus, by (3.61), $K_{t_{n_k}}(x_{n_k} + y) \to 0$. Also, at the price of extracting a further subsequence (denoted by the same symbol), we have $t_{n_k} \to t_0 \in [0, T]$. These last two conclusions, along with (b) give

$$K_{t_{n_k}} x_{n_k} = K_{t_{n_k}}(x_{n_k} + y) - K_{t_{n_k}} y \to -K_{t_0} y. \tag{3.62}$$

From (3.59), using (3.61) and (3.62), we then obtain

$$-(y + K_{t_0} y) = 0, \qquad \|y\| = 1$$

which contradicts assumption (c) at $t = t_0$. □

Our first application of Lemma 3.12 is a version of Theorem 3.10(ii), uniform in s.

THEOREM 3.13. *Let the operator R in* (H.1) *satisfy* (H.2′) = (3.44). *Then, with reference to the space W in* (3.46), *we have*[10]

$$\|I_s + L_s L_s^* R]^{-1}\|_{\mathscr{L}(W)} \leqq C_T \quad \text{uniformly in } 0 \leqq s \leqq T. \tag{3.63}$$

Proof. We shall apply Lemma 3.12 with $Z = W$; with $K_s = L_s L_s^* R = L_s L^* R$ (see (2.15)) compact on W and with $I_s + L_s L_s^* R$ boundedly invertible on W for each fixed s, as guaranteed by Theorem 3.10. To verify the remaining assumption (b) of Lemma

[9] We omit the details of this topological result: it is closely related to the concept of "a collectively compact family of operators" as in P. M. Anselone's *Collectively Compact Operator Approximation Theory*, Prentice-Hall, Englewood Cliffs, NJ, 1971. Our proof here is a modification of that of Thm. 1.6 in this reference.

[10] We embed $L_2(s, T; \cdot)$ into $L_2(0, T; \cdot)$ by extension by zero on $[0, s)$ uniformly in s, where, in the last step, a subset of diagram (3.66) was used.

3.12 that the map: $s \to L_s L^* Rf$ continuous in $W, f \in W$, it suffices to show that

$$f \in W \to L_s L^* Rf \underset{(\text{in } s)}{\in} L_\infty(0, T; W) \tag{3.64}$$

since then (3.64) combined with a standard approximating argument (to be made more precise at the end of the proof)

$$\begin{matrix} f_n \text{ smooth} \in W \\ f_n \to f \text{ in } W \end{matrix} \quad \text{while } s \to L_s L^* Rf_n \text{ continuous in } W, \quad \text{for each } n \tag{3.65}$$

will yield the required continuity in s of $L_s L^* Rf$. Let $Q_s = (s, T] \times \Omega$, and for $g \in L_2(s, T; \cdot)$, let g_{ext} be its extension by zero on $0 \leqq t \leqq s$, and for simplicity $H^r(\cdot) \equiv H^{r,r}(\cdot)$ with $\cdot$ either Q or Σ. We complement diagram (3.48) by

$$\begin{aligned} f \in W &\xrightarrow[(3.44)]{} Rf \in L_2(0, T; \mathcal{D}(A^{1/2})) \\ &\xrightarrow[(3.23a)]{} L^* Rf \in H^{1/2-\delta}(\Sigma) \to LL^* Rf \in H^{1/2-\delta}(Q), \end{aligned} \tag{3.66}$$

continuously at each step, where Corollary 3.7(ii), (3.36) was used in the last step. With $f \in W$, using diagram (3.66)

$$\|L_s L^* Rf\|_{H^{1/2-\delta}(Q_s)} = \|L[L^* Rf]_{\text{ext}}\|_{H^{1/2-\delta}(Q)} \leqq C_T \|L^* Rf\|_{H^{1/2-\delta}(\Sigma)} \leqq C_T \|f\|_W \tag{3.67}$$

uniformly in $0 \leqq s \leqq T$. Similarly, using $(d/dt)(L_s L^* Rf) = (dL_s/dt) L^* Rf$, [(3.42)], we have for $f \in W$, and invoking Corollary 3.7(iii) ((3.37)) with $\theta = \frac{1}{2} - \delta$:

$$\begin{aligned} \left\| \frac{d}{dt} L_s L^* Rf \right\|_{L_2(s,T;H^{-1/2-\delta}(\Omega))} &= \left\| \frac{dL}{dt} [L^* Rf]_{\text{ext}} \right\|_{L_2(0,T;H^{-1/2-\delta}(\Omega))} \\ &\leqq C_T \|L^* Rf\|_{H^{1/2-\delta}(0,T;L_2(\Gamma))} \leqq C_T \|f\|_W \end{aligned} \tag{3.68}$$

uniformly in s, where in the last step, a subset of diagram (3.66) was used. Conclusions (3.67)–(3.68) combined are stronger than the desired property (3.64). To make (3.65) more precise, note first that if, say, $g \in C([0, T]; L_2(\Gamma))$ with $\dot{g} \in L_2(\Sigma)$, then the same steps carried out in (3.30) give, after integration by parts

$$\begin{aligned} (L_s g)(t) &= A \int_s^t S(t-\tau) Dg(\tau)\, d\tau \\ &= Dg(t) - C(t-s) Dg(s) - \int_s^t C(t-\tau) D\dot{g}(\tau)\, d\tau \\ &\underset{(\text{in } s)}{\in} C([0, T]; H^{1/2-2\varepsilon}(\Omega)). \end{aligned}$$

Differentiating in t

$$\begin{aligned} \frac{d(L_s g)(t)}{dt} &= AS(t-s) Dg(s) + A \int_s^t S(t-\tau) D\dot{g}(\tau)\, d\tau \\ &\underset{(\text{in } s)}{\in} C([0, T]; H^{-1/2-2\varepsilon}(\Omega)), \qquad \varepsilon > 0 \end{aligned}$$

by (1.9b–c); i.e. taking $2\varepsilon = \delta$, we conclude that $s \to L_s g$ continuous in W. Next, with $f \in W$, choose $f_n \in W, f_n \to f$ in W with, say, $f_n \in L_2(0, T; \mathcal{D}(A))$. Then from (3.23a), we obtain $L^* Rf_n \in H^{2,2}(\Sigma)$ and the above argument with $g = L^* Rf_n$ works a fortiori, and (3.65) holds. The proof of Theorem 3.13 is complete. □

We need two more results, before collecting the properties of the evolution operator $\Phi(t, s)$ crucial in the sequel. They are a counterpart of Theorem 3.10 and, respectively, of its uniform version, Theorem 3.13 this time, however, on the space of distributions $H^{-1/2-\delta}(\Omega) = [H_0^{1/2+\delta}(\Omega)]' = [\mathscr{D}(A^{1/4+\delta/2})]'$, and for R satisfying (H.2).

THEOREM 3.14. *Let the operator R in* (H.1) *satisfy* (H.2) = (3.43). *Then*

(i) *The operator LL^*R is compact: $L_2(0, T; H^{-1/2-\delta}(\Omega)) \to$ itself.*

(ii) *The operator $[I + LL^*R]$ is invertible on $L_2(0, T; H^{-1/2-\delta}(\Omega))$, with bounded inverse here.*

Proof. For notational convenience, we set $\beta = \frac{1}{4} + \delta/2$ in this proof. The operator LL^*R on $L_2(0, T; H^{-1/2-\delta}(\Omega))$ is equivalent to the operator

$$A^{*-\beta} LL^* R A^{*\beta} \quad \text{on } L_2(Q). \tag{3.69}$$

(i) Compactness of the latter in (3.69) is equivalent to compactness of its adjoint, i.e. of

$$A^{\beta} R L L^* A^{-\beta} \quad \text{on } L_2(Q) \tag{3.70}$$

(as LL^* is self-adjoint on $L_2(Q)$ and R is self-adjoint on $L_2(\Omega)$). Now for $2\alpha = \frac{1}{2} - \delta < 2\beta = \frac{1}{2} + \delta$, we have the diagram

$$\begin{array}{ccccccc} L_2(Q) & \xrightarrow[\substack{\text{continuous}\\ \text{by (3.23b)}}]{L^*A^{-\beta}} & H^{2\beta,2\beta}(\Sigma) & \xrightarrow[\text{injection}]{\text{compact}} & H^{2\alpha,2\alpha}(\Sigma) & \xrightarrow[(3.36)]{L} & H^{2\alpha,2\alpha}(Q) \\ & & & & & & \Big\downarrow{\scriptstyle R\ (3.43)} \\ L_2(Q) \equiv L_2(0, T; L_2(\Omega)) & & \xleftarrow[\text{continuous}]{A^{\beta}} & & L_2(0, T; H_0^{1/2+\delta}(\Omega)) \equiv \mathscr{D}(A^{\beta})). & & \end{array} \tag{3.71}$$

From here, we deduce that the operator in (3.70) is compact, and hence so is the operator on (3.69).

(ii) Because of the compactness of part (i), it is enough to show that $\lambda = 1$ is not an eigenvalue of LL^*R on $L_2(0, T; H^{-1/2-\delta}(\Omega))$ equivalently, by (3.70), of RLL^* on $L_2(0, T; \mathscr{D}(A^{\beta}))$. Indeed, the latter statement is true, for otherwise $\lambda = 1$ would be a fortiori an eigenvalue of RLL^* on $L_2(Q)$, i.e. $x + RLL^*x = 0$, impossible, as it is seen by taking $L_2(Q)$-inner product on the right with LL^*x. □

The uniform version (in s) of Theorem 3.14(ii), in the style of Theorem 3.13 is now the following.

THEOREM 3.15. *Let the operator R in* (H.1) *satisfy* (H.2) = (3.43). *Then* (*see footnote* 10):

$$\|I_s + L_s L_s^* R]^{-1}\|_{\mathscr{L}(L_2(0, T; H^{-1/2-\delta}(\Omega)))} \leqq C_T, \quad \textit{uniformly in } s \in [0, T].$$

Proof. As in the proof of Theorem 3.13, we shall apply Lemma 3.12, this time with $Z = L_2(0, T; H^{-1/2-\delta}(\Omega))$, $K_s = L_s L_s^* R = L_s L^* R$, [(2.15)], compact on Z and $I_s + L_s L^* R$ invertible on Z for each fixed s, as guaranteed by Theorem 3.14. To verify the remaining assumption (b) of Lemma 3.12 that the map

$$s \to L_s L^* R g \text{ is continuous in } Z, \text{ for each } g \in Z \tag{3.72}$$

it will suffice to show, as is the proof of Theorem 3.13, that $L_s L^* R g \in L_\infty(0, T; Z)$ in s, indeed that

$$\|L_s L^* R g\|_Z \leqq C_T \|g\|_Z \quad \text{uniformly in } s \in [0, T], \tag{3.73}$$

equivalent to (see the paragraph containing (3.69) and (3.70))

$$\|A^{\beta} R L_s L^* A^{-\beta} v\|_{L_2(s, T; L_2(\Omega))} \leqq C_T \|v\|_{L_2(Q)} \quad \text{uniformly in } s \in [0, T] \tag{3.74}$$

with $\beta = \frac{1}{4} + \delta/2$. But (3.74) holds true: in fact, in the notation of g_{ext} used above (3.66), we have by diagram (3.71) ($2\alpha = \frac{1}{2} - \delta$)

$$\begin{aligned} \|A^{\beta} R L_s L^* A^{-\beta} v\|_{L_2(s,T;L_2(\Omega))} &= \|A^{\beta} R L [L^* A^{-\beta} v]_{\text{ext}}\|_{L_2(Q)} \\ &\leqq C_T \|L^* A^{-\beta} v\|_{H^{2\alpha,2\alpha}(\Sigma)} \leqq C_T \|v\|_{L_2(Q)} \end{aligned} \tag{3.75}$$

as desired. □

Remark 3.2. We sketch another proof of conclusion (3.72), i.e. of the statement that with $\beta = \frac{1}{4} + \delta/2$

$$\|[I_s + A^{\beta} R L_s L_s^* A^{-\beta}]^{-1}\|_{(L_2(0,T;L_2(\Gamma))} \leqq C_T \quad \text{uniformly in } s \in [0, T].$$

First, using the full strength of (3.36) in the diagram (corresponding to the initial time s) in the proof of Theorem 3.14, we have that the operator

(*) $G_s \equiv A^{\beta} R L_s L_s^* A^{-\beta}$: continuous $L_2(s, T; L_2(\Gamma)) \to C([s, T]; L_2(\Omega))$ with bound independent of s

due to the continuity in s. Next, we consider the interval $s \leqq t \leqq T$, where $T - s < h$, for some $h > 0$, and prove that $[I_s + G_s]^{-1}$: continuous $L_2(s, T; L_2(\Gamma)) \to$ itself with a bound *independent* of h. Indeed

$$\begin{aligned} \|G_s x\|^2_{L_2(s,T;L_2(\Omega))} &= \int_s^T |G_s x(\cdot, s)(t)|^2_{L_2(\Omega)}\, dt \\ &\leqq \{\sup_{T-h \leqq s \leqq t \leqq T} |G_s x(\cdot, s)(t)|^2_{L_2(\Omega)}\}(T - s) \\ &\leqq C_T h \int_s^T |x(t, s)|^2_{L_2(\Omega)}\, dt \qquad \text{(by (*))} \end{aligned}$$

where C_T is independent of h by (*). We then choose h so that, say, $C_T h < \frac{1}{2}$ and repeat the procedure. After a finite number of steps we obtain the desired conclusion (3.72). □

The following is the main result of the present subsection and complements Lemma 2.1. It is obtained as a corollary of the result given above, via (2.13)–(2.14). First, let Y_r denote for convenience the space of "regular" initial data, as in (3.50):

$$Y_r \equiv H^{1/2-\delta}(\Omega) \times H^{-1/2-\delta}(\Omega) = \mathcal{D}(A^{1/4-\delta/2}) \times [\mathcal{D}(A^{1/4+\delta/2})]'. \tag{3.76}$$

THEOREM 3.16. (i) *Let the operator R satisfy* ((H.1) *and*) (H.2)′ = (3.44). *Then*:

(a) *For each s fixed, $s < T$, the operator $\Phi(\cdot, s)$ is strongly continuous $Y_r \to C([s, T]; Y_r)$.*

(b) *Moreover, with W as in* (3.46)

$$\|\Phi(\cdot, s)\|_{\mathcal{L}(Y_r \to W)} \leqq C_T \quad \textit{uniformly in } s \in [0, T] \quad \text{i.e.,} \tag{3.77a}$$

$$\|\Phi_1(\cdot, s) y\|^2_{L_2(s,T;H^{1/2-\delta}(\Omega))} + \|\Phi_2(\cdot, s) y\|^2_{L_2(s,T;H^{-1/2-\delta}(\Omega))} \leqq C_T \|y\|^2_{Y_r}. \tag{3.77b}$$

(ii) *If R satisfies* (H.2) = (3.43), *then*

$$\|A^{1/4+\delta/2} R \Phi_1(\cdot, s) y\|_{L_2(s,T;L_2(\Omega))} \leqq C_T \|y\|_{Y_r} \quad \textit{uniformly in } s \in [0, T]. \tag{3.78 (a)}$$

(b) *for $y = [y_0, y_1] \in [\mathcal{D}(A^{1/4+\delta/2})]' \times [\mathcal{D}(A^{5/4+\delta/2})]'$, whose norm we indicate by $|||\cdot|||$, then*

$$\|\Phi_1(\cdot, s) y\|_{L_2(s,T;H^{-1/2-\delta}(\Omega))} \leqq C_T |||y||| \quad \textit{uniformly in } s \in [0, T]. \tag{3.79}$$

(*We shall use* (3.79) *with much smoother y, however.*)

Proof. Property (ia) is a restatement of Theorem 3.11(i), via (2.13). Property (ib) follows from Theorem 3.13 [(3.63)], via (2.14) (and (1.10)). Property (iia) follows a fortiori from (3.77b), with $A^{1/4+\delta/2}R$ continuous $H^{1/2-\delta}(\Omega) \to L_2(\Omega)$. Property (iib) follows a fortiori from Theorem 3.15 [(3.72)], via (2.14) (and (1.10)). □

4. Further properties of $\mathscr{P}(t)$ and derivation of a Riccati differential equation.

4.1. A fundamental result for $\mathscr{B}^*\mathscr{P}(t)$. We now proceed to show that the operator $\mathscr{P}(t)$ satisfies the Riccati differential equation, as claimed in part (ii) of Theorem 1.3. To this end, it is necessary, as a preliminary step, to give a meaning to the operator $\mathscr{B}^*\mathscr{P}(t)$ as a function of t, which appears there in the quadratic term. This point is the major *difficulty* that one encounters in deriving the Riccati equation (whether differential or integral) for the problem under study. A fundamental role in this direction is played by the following theorem.

THEOREM 4.1. *Let R satisfy* ((H.1) *and*) (H.2) = (3.43) *and recall the space Y_r of "regular" initial data from* (3.76). *Then, for the operator $\mathscr{B}^*\mathscr{P}(t)$ defined by* (2.26), *the following property in t holds*:

(4.1) *$\mathscr{B}^*\mathscr{P}(t)$ is a bounded linear operator*

$$Y_r \to C([0, T]; L_2(\Gamma)), \quad \text{i.e.} \quad \max_{0 \leq t \leq T} \|\mathscr{B}^*\mathscr{P}(t)x\|_\Gamma \leq \text{const}_T \|x\|_{Y_r}, \qquad x \in Y_r.$$

Remark 4.1. Most of the effort required to prove Theorem 4.1 has already been made at the level of proving certain properties of Φ (Theorem 3.16). Observe first that the weaker statement

$$\mathscr{B}^*\mathscr{P}(t) \text{ continuous operator } Y_r \to L_\infty(0, T; L_2(\Gamma)) \tag{4.2}$$

can be quickly obtained from Theorem 3.16: with x and R as assumed, we can write (2.26) as

$$\mathscr{B}^*\mathscr{P}(t)x = D^*A^{*1/4-\delta/2} \int_t^T A^{*1/2}S^*(\tau - t)A^{*1/4+\delta/2}R\Phi_1(\tau, t)x \, d\tau \tag{4.3}$$

from which, invoking (1.9b), (1.10) we obtain

$$\begin{aligned} \|\mathscr{B}^*\mathscr{P}(t)x\|_{L_2(\Gamma)} &\leq C_T \int_t^T \|A^{*1/4+\delta/2}R\Phi_1(\tau, t)x\|_{L_2(\Omega)} \, d\tau \\ &\leq C_T \int_t^T \|A^{*1/4+\delta/2}R\Phi_1(\tau, t)x\|^2_{L_2(\Omega)} \, d\tau \\ &\leq C_T \|x\|_{Y_r} \quad \text{uniformly in } t \in [0, T] \end{aligned} \tag{4.4}$$

where in the last step we have used Theorem 3.16, statement (iia), ((3.78)). Thus, (4.2) is proved. □

Proof of Theorem 4.1. *Right continuity.* Let $t_1 \in [0, T)$ and let $t > t_1$. From (2.26), we compute after a change of variable

$$\begin{aligned} \mathscr{B}^*\mathscr{P}(t)x - \mathscr{B}^*\mathscr{P}(t_1)x &= D^*A^* \int_0^{T-t} S^*(\sigma)R\Phi_1(t+\sigma, t)x \, d\sigma \\ &\quad - D^*A^* \int_0^{T-t_1} S^*(\sigma)R\Phi_1(t_1+\sigma, t_1)x \, d\sigma = I_1(t) - I_2(t), \end{aligned} \tag{4.5}$$

$$
\begin{aligned}
I_1(t) &= D^*A^* \int_0^{T-t} S^*(\sigma)R[\Phi_1(t+\sigma, t)x - \Phi_1(t_1+\sigma, t_1)x]\, d\sigma, \\
I_2(t) &= D^*A^{*1/4-\delta/2} \int_{T-t}^{T-t_1} A^{*1/2}S^*(\sigma)A^{*1/4+\delta/2}R\Phi_1(t_1+\sigma, t_1)x\, d\sigma.
\end{aligned} \tag{4.6}
$$

As to $I_2(t)$, proceeding as in going from (4.3) to (4.4), we have that its integrand is in $L_2(t_1, T; L_2(\Omega))$. Thus, as $t \downarrow t_1$, $I_2(t) \to \theta$. As to $I_1(t)$, in a similar fashion we obtain

$$
\|I_1(t)\|^2_{L_2(\Gamma)} \leqq C_T \int_0^{T-t} \|A^{*1/4+\delta/2}R[\Phi_1(t+\sigma, t)x - \Phi_1(t_1+\sigma, t_1)x]\|^2_{L_2(\Omega)}\, d\sigma
$$

(adding and subtracting $\Phi_1(t+\sigma, t_1)x$)

$$
\leqq C_T\left\{\int_0^{T-t} A(t, \sigma) + B(t, \sigma)\, d\sigma\right\}, \tag{4.7}
$$

$$
A(t, \sigma) \equiv \|A^{*1/4+\delta/2}R[\Phi_1(t+\sigma, t)x - \Phi_1(t+\sigma, t_1)x]\|^2_{L_2(\Omega)}, \tag{4.8a}
$$

$$
B(t, \sigma) = \|A^{*1/4+\delta/2}R[\Phi_1(t+\sigma, t_1)x - \Phi_1(t_1+\sigma, t_1)x]\|^2_{L_2(\Omega)}. \tag{4.8b}
$$

Since $t > t_1$, as below (2.21) we have $\Phi_1(t+\sigma, t_1)x = \Phi_1(t+\sigma, t)\Phi(t, t_1)x$ and

$$
A(t, \sigma) \leqq \|A^{*1/4+\delta/2}R\Phi_1(t+\sigma, t)[x - \Phi(t, t_1)x]\|_{L_2(\Omega)}. \tag{4.9}
$$

Returning to the integral of $A(t, \sigma)$, we use there the Schwarz inequality, (4.9), and Theorem 3.16(iia), [(3.78)]. We obtain

$$
\begin{aligned}
\int_0^{T-t} A(t, \sigma)\, d\sigma &\leqq C_T \int_0^{T-t} \|A^{*1/4+\delta/2}R\Phi_1(t+\sigma, t)[x - \Phi(t, t_1)x]\|^2_{L_2(\Omega)}\, d\sigma \\
&\leqq C_T\|x - \Phi(t, t_1)x\|^2_{Y_r} \to 0 \quad \text{as } t \downarrow t_1
\end{aligned} \tag{4.10}
$$

as desired, with the right-hand side going to zero, by Theorem 3.16(ia). As to $B(t, \sigma)$, the same Theorem 3.16(ia) implies that for $|t - t_1| = |(t+\sigma) - (t_1+\sigma)|$ sufficiently small, and all $\sigma \in [0, T]$, the difference in square brackets in (4.8b) is arbitrarily small in the norm of $H^{1/2-\delta}(\Omega)$. But $A^{*1/4+\delta/2}R$: continuous $H^{1/2-\delta}(\Omega) \to L_2(\Omega)$. Hence,

$$
\int_0^{T-t} B(t, \sigma)\, d\sigma \to 0 \quad \text{as } t \downarrow t_1. \tag{4.11}
$$

Returning to (4.7) with (4.10) and (4.11), we conclude $\|I_1(t)\|_{L_2(\Gamma)} \to 0$ as well as $t \downarrow t_1$.

Left continuity. We interchange the role of t and t_1 in the above proof, i.e. we keep t fixed and let t_1 run $\uparrow t$. The above proves $\mathscr{B}^*\mathscr{P}(t)x \in C([0, T]; L_2(\Gamma))$, $x \in Y_r$ and by (4.4), Theorem 4.1 follows.

Remark 4.2. From the pointwise relation (2.28), we obtain again, via Theorem 4.1 and Theorem 3.11(i), ((3.51)), that for $y \in Y_r$, the corresponding optimal control $u^0(t) = u^0(t, 0; y) \in C([0, T]; L_2(\Gamma))$, a regularity result contained a fortiori in (3.54a).

4.2. Derivation of the Riccati differential equation for $\mathscr{P}(t)$. With the help of the fundamental Theorem 4.1, we can now proceed to derive the Riccati differential equation. In fact, we can now assert that the quadratic term $(\mathscr{B}^*\mathscr{P}(t)x,\ \mathscr{B}^*\mathscr{P}(t)y)_\Gamma$ in the R.D.E. is in $C[0, T]$ for $x, y \in Y_r$, [(3.76)].

LEMMA 4.2. *Let R satisfy* ((H.1) *and*) (H.2) = (3.43). *Let $x, y \in Y_r$*, [(3.76)]. *Then, both E-inner products $(\mathscr{P}(t)x, \mathscr{A}y)_E$ and $(\mathscr{P}(t)\mathscr{A}x, y)_E$ are well-defined at each t and in $C[0, T]$.*

Proof. Because of self-adjointedness of $\mathscr{P}(t)$ (Lemma 2.3), it is enough to consider the first inner product. For fixed t, we use (2.24) with $R\Phi_1(\tau, t)x \in C([t, T]; \mathscr{D}(A^{1/4+\delta/2}))$ for $x \in Y_r$ along with (1.5). Details are omitted (see also Lemma 2.3(i)). □

THEOREM 4.3. *Let R satisfy* ((H.1) *and*) (H.2) = (3.43). *Then the operator $\mathscr{P}(t)$ defined by* (2.22a) *or* (2.24) *satisfies the following Riccati differential equation*

$$\frac{d}{dt}(\mathscr{P}(t)x, y)_E = -(x_1, y_1)_\Omega - (\mathscr{P}(t)\mathscr{A}x, y)_E - (\mathscr{P}(t)x, \mathscr{A}y)_E + (\mathscr{B}^*\mathscr{P}(t)x, \mathscr{B}^*\mathscr{P}(t)y)_\Gamma$$

for all $x, y \in Y_r = H^{1/2-\delta}(\Omega) \times H^{-1/2-\delta}(\Omega)$, $t \in [0, T)$ with terminal condition $\mathscr{P}(T) = 0$.

Proof. Step 1. From (2.22a),

$$(\mathscr{P}(t)x, y)_E = \int_t^T \left(\begin{vmatrix} R\Phi_1(\tau, t)x \\ 0 \end{vmatrix}, e^{\mathscr{A}(\tau - t)}y \right)_E d\tau$$

we compute with $x, y \in Y_r$ and $\Phi_1(t, t)x = [\Phi(t, t)x]_1 = x_1$; using Lemma 4.2

$$\begin{aligned} \frac{d}{dt}(\mathscr{P}(t)x, y)_E &= -\left(\begin{vmatrix} x_1 \\ 0 \end{vmatrix}, y \right)_E \\ &\quad + \int_t^T \left(\left| \frac{\partial \Phi_1(\tau, t)x}{\partial t} \right|, R[e^{\mathscr{A}(\tau - t)}y]_1 \right)_\Omega d\tau - (\mathscr{P}(t)x, \mathscr{A}y)_E \end{aligned} \tag{4.12}$$

where we have to justify and evaluate the second term on the right-hand side of (4.12). This will be done below.

We first recall the operator $\mathscr{B}^*: E \supset \mathscr{D}(\mathscr{B}^*) \to L_2(\Gamma)$ from (2.25):

$$\mathscr{B}^*v = D^*A^{*1/2}A^{-1/2}v_2, \qquad v = [v_1, v_2] \in \mathscr{D}(\mathscr{B}^*)$$

where $\mathscr{D}(\mathscr{B}^*) \supset L_2(\Omega) \otimes H^{-1/2}(\Omega)$. For $v \in \mathscr{D}(\mathscr{B}^*)$ and $u \in L_2(\Gamma)$, the inner product $(u, \mathscr{B}^*v)_\Gamma$ is well-defined on $L_2(\Gamma)$ and we then introduce an operator $\mathscr{B}$, through the duality pairing defined on E:

$$(\mathscr{B}u, v)_E = (u, \mathscr{B}^*v)_\Gamma, \qquad u \in L_2(\Gamma), \quad v \in \mathscr{D}(\mathscr{B}^*). \tag{4.13}$$

Thus, for $x \in Y_r$ and $y = [y_1, y_2] \in L_2(\Omega) \otimes L_2(\Omega) \subset \mathscr{D}(\mathscr{B}^*)$ we compute the following well-defined expression (see Theorem 4.1) via (1.7)

$$\begin{aligned} (\mathscr{B}^*\mathscr{P}(t)x, \mathscr{B}^*y)_\Gamma &= (\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x, y)_E \\ &= ([\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_1, y_1)_\Omega + (A^{-1/2}[\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_2, A^{-1/2}y_2)_\Omega \end{aligned} \tag{4.14a}$$

in $C[0, T]$ and on the other hand via (2.25) we have

$$\begin{aligned} (\mathscr{B}^*\mathscr{P}(t)x, \mathscr{B}^*y)_\Gamma &= (\mathscr{B}^*\mathscr{P}(t)x, D^*A^{*1/2}A^{-1/2}y_2)_\Gamma \\ &= (A^{1/2}D\mathscr{B}^*\mathscr{P}(t)x, A^{-1/2}y_2)_\Omega. \end{aligned} \tag{4.14b}$$

We compare (4.14a) and (4.14b), with $y_1 \in L_2(\Omega)$ and $A^{-1/2}y_2$ which exhausts all of $\mathscr{D}(A^{1/2}) = H_0^1(\Omega)$, as y_2 runs over $L_2(\Omega)$. We thus deduce

$$[\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_1 = 0, \tag{4.15a}$$

$$A^{-1/2}[\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_2 = A^{1/2}D\mathscr{B}^*\mathscr{P}(t)x \in H^{-1}(\Omega), \qquad x \in E. \tag{4.15b}$$

Step 2. We collect a few facts.

LEMMA 4.4. (1) *For $x \in Y_r \equiv H^{1/2-\delta}(\Omega) \times H^{-1/2-\delta}(\Omega) = \mathscr{D}(A^{1/4-\delta/2}) \times [\mathscr{D}(A^{1/4+\delta/2})]'$ and for each t fixed, we have*

$$\text{(a)} \quad S(\tau - t)AD\mathscr{B}^*\mathscr{P}(t)x \underset{(\text{in } \tau)}{\in} C([t, T]; H^{-1/2-\delta}(\Omega)) \tag{4.16}$$

where A can indifferently be moved in front of $S(\cdot)$

$$(4.17)\quad (b)\qquad [I_t + L_t L_t^* R]^{-1}\{S(\cdot - t)AD\mathscr{B}^*\mathscr{P}(t)x\}(\tau) = \Phi_1(\tau, t)\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x \in L_2(t, T; H^{-1/2-\delta}(\Omega)).$$

(2) *In addition, let* $y \in Y_r$ *as well, and let R satisfy* (H.2) = (3.43). *Then*

(a) *the following duality pairing on* $H^{-1/2-\delta}(\Omega) \times H_0^{1/2+\delta}(\Omega)$ *is well-defined in the sense that*

$$(4.18)\qquad ([I_t + L_t L_t^* R]^{-1}\{S(\cdot - t)AD\mathscr{B}^*\mathscr{P}(t)x\},\ R[e^{\mathscr{A}(\tau - t)}y]_1)_\Omega \in L_2(t, T),$$

(b) *the following expression is well-defined in the sense that*

$$(4.19)\qquad (\mathscr{B}^*\mathscr{P}(t)x,\ \mathscr{B}^*\mathscr{P}(t)y)_\Gamma = \int_t^T \Big([I_t + L_t L_t^* R]^{-1} S(\cdot - t)AD\mathscr{B}^*\mathscr{P}(t)x,\ R[e^{\mathscr{A}(\tau - t)}y]_1\Big)_\Omega d\tau \in C[0, T].$$

Proof of Lemma 4.4. (1) Use Theorem 4.1 and (1.10) to obtain (4.16) (where $A^{1/4+\delta/2}$ is viewed as the isomorphic extension $L_2(\Omega) \to [\mathscr{D}(A^{1/4+\delta/2})]'$). Then, (4.17) follows from (4.16), via Theorem 3.14(ii). (2) In turn, (4.18) follows from (4.17), since $R[e^{\mathscr{A}\cdot}y]_1 \in C([t, T]; H_0^{1/2+\delta}(\Omega))$. (2b) By selfadjointness of $\mathscr{P}(t)$ (Lemma 2.3(ii.1)) and by (2.22a), we compute for $x, y \in Y_r$ the following expression, where, by Theorem 4.1, the left-hand side, and thus the right-hand side also, is well-defined and in $C([0, T]$:

$$(\mathscr{B}^*\mathscr{P}(t)x,\ \mathscr{B}^*\mathscr{P}(t)y)_\Gamma = (\mathscr{P}(t)\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x, y)_E = \int_t^T (\Phi_1(\tau, t)\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x,\ R[e^{\mathscr{A}(\tau - t)}y]_1)_\Omega\, d\tau$$

[recalling from (2.9c) and (2.13),

$$\begin{aligned} y^0(\tau, t; x) = \Phi_1(\tau, t)x &= \{[I_t + L_t L_t^* R]^{-1}[C(\cdot - t)x_1 + S(\cdot - t)x_2]\}(\tau),\ x \in E] \\ &= \int_t^T (\{[I_t + L_t L_t^* R]^{-1} \times \{C(\cdot - t)[\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_1 \\ &\qquad + S(\cdot - t)[\mathscr{B}\mathscr{B}^*\mathscr{P}(t)x]_2\}\}(\tau),\ R[e^{\mathscr{A}(\tau - t)}y]_1)_\Omega\, d\tau \\ &= \int_t^T (\text{zero} + [I_t + L_t L_t^* R]^{-1} S(\cdot - t)AD\mathscr{B}^*\mathscr{P}(t)x,\ R[e^{\mathscr{A}(\tau - t)}y]_1)_\Omega\, d\tau \end{aligned} \qquad (4.20)$$

where in the last step we have used (4.15), and (4.19) follows. The correctness of these expressions is also asserted in (4.18). □

Step 3. If $x \in Y_r$, then $A^{1/2}S(\cdot - t)A^{1/2}x_1 - C(\cdot - t)x_2 \in C([t, T]; H^{-1/2-\delta}(\Omega))$ and via (1.5) and (4.20) we obtain

$$(4.21)\qquad \{I_t + L_t L_t^* R]^{-1}[A^{1/2}S(\cdot - t)A^{1/2}x_1 - C(\cdot - t)x_2]\}(\tau) = -\Phi_1(\tau, t)\mathscr{A}x \in L_2(t, T; H^{-1/2-\delta}(\Omega))$$

by Theorem 3.14(ii). Thus, for $x, y \in Y_r$, (4.19), (4.21) yield the well-defined expression

in $C[0, T]$ via Lemma 4.2

$$\int_t^T ([I_t + L_t L_t^* R]^{-1}[S(\cdot - t)AD\mathcal{B}^*\mathcal{P}(t)x + A^{1/2}S(\cdot - t)A^{1/2}x_1 - C(\cdot - t)x_2], R[e^{\mathcal{A}(\tau - t)}y]_1)_\Omega \, d\tau$$

$$= (\mathcal{B}^*\mathcal{P}(t)x, \mathcal{B}^*\mathcal{P}(t)y)_\Gamma - \int_t^T \left(\begin{vmatrix} R\Phi_1(\tau, t)\mathcal{A}x \\ 0 \end{vmatrix}, e^{\mathcal{A}(\tau - t)}y \right)_E d\tau \tag{4.22}$$

$$= (\mathcal{B}^*\mathcal{P}(t)x, \mathcal{B}^*\mathcal{P}(t)y)_\Gamma - (\mathcal{P}(t)\mathcal{A}x, y)_E$$

where, in the last step, we have used the definition (2.22a) of $\mathcal{P}(t)$.

Step 4. We now return to (4.20), with $L_t L_t^* = L_t L^*$ ((2.15)), and $x \in Y_r$, rewritten as

$$\Phi_1(\cdot, t)x + L_t L_t^* R\Phi_1(\cdot, t)x = C(\cdot - t)x_1 + S(\cdot - t)x_2 \tag{4.23}$$

and compute first the term

$$\frac{\partial}{\partial t}\{L_t L^* R\Phi_1(\cdot, t)x\} = \frac{\partial}{\partial t}\int_t^\tau AS(\tau - \sigma)D[L^* R\Phi_1(\cdot, t)x](\sigma)\, d\sigma$$

$$= -AS(\tau - t)D[L^* R\Phi_1(\cdot, t)x](t) + \left\{ L_t L_t^* R \frac{\partial \Phi_1}{\partial t}(\cdot, t)x \right\}(\tau)$$

$$= -AS(\tau - t)D\mathcal{B}^*\mathcal{P}(t)x + \left\{ L_t L_t^* R \frac{\partial \Phi_1}{\partial t}(\cdot, t)x \right\}(\tau) \quad \text{(by (2.26))}.$$

Hence by differentiating (4.23) in t with $x \in Y_r$

$$\left\{ [I_t + L_t L_t^* R] \frac{\partial \Phi_1}{\partial t}(\cdot, t)x \right\}(\tau) = AS(\tau - t)D\mathcal{B}^*\mathcal{P}(t)x + A^{1/2}S(\tau - t)A^{1/2}x_1 - C(\tau - t)x_2$$

$$\in L_2(t, T; H^{-1/2-\delta}(\Omega)) \tag{4.24}$$

which, in τ, belongs for each t to $L_2(t, T; H^{-1/2-\delta}(\Omega))$ by Lemma 4.4, ((4.16)) so that

$$\frac{\partial \Phi_1}{\partial t}(\cdot, t)x = [I_t + L_t L_t^* R]^{-1}\{AS(\cdot - t)D\mathcal{B}^*\mathcal{P}(t)x + A^{1/2}S(\cdot - t)A^{1/2}x_1 - C(\cdot - t)x_2\}$$

$$\in L_2(t, T; H^{-1/2-\delta}(\Omega)), \qquad x \in Y_r \tag{4.25}$$

is well-defined and in $L_2(t, T; H^{-1/2-\delta}(\Omega)$, as guaranteed by Lemma 4.4, [(4.17)].

Step 5. By (4.25) and (4.22), with $x, y \in Y_r$

$$\int_t^T \left(\left\{ \frac{\partial \Phi_1}{\partial t}(\cdot, t)x \right\}(\tau), R[e^{\mathcal{A}(\tau - t)}y]_1 \right)_\Omega d\tau$$

$$= (\mathcal{B}^*\mathcal{P}(t)x, \mathcal{B}^*\mathcal{P}(t)y)_\Gamma - (\mathcal{P}(t)\mathcal{A}x, y)_E \tag{4.26}$$

which is well-defined as an $C[0, T]$-function, Theorem 4.1 and Lemma 4.2. But the left-hand side of (4.26) is, in fact, the second term in (4.12) which we sought to compute. Hence, inserting (4.26) into (4.12) gives, finally, the claimed Riccati differential equation of the statement. □

We explicitly single out a result, which is essentially already contained in (4.25). Using (4.17) plus (4.21), we can rewrite (4.25) as

$$\frac{\partial \Phi_1(\cdot, t)x}{\partial t} = -\Phi_1(\cdot, t)[\mathcal{A} - \mathcal{B}\mathcal{B}^*\mathcal{P}(t)]x \in L_2(t, T; H^{-1/2-\delta}(\Omega)), \qquad x \in Y_r$$

as a well-defined expression, which is in $L_2(t, T; H^{-1/2-\delta}(\Omega))$ for each t. A similar result can be obtained for Φ_2. Thus, we obtain the following.

PROPOSITION 4.5. *For $x \in Y_r$, we have*

$$\frac{\partial \Phi(\cdot, t)x}{\partial t} = -\Phi(\cdot, t)[\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P}(t)]x$$

as a well-defined expression in $L_2(t, T; [\mathscr{D}(A^{1/4+\delta/2})]' \times [\mathscr{D}(A^{3/4+\delta/2})]')$ for each t.

As a corollary to Theorem 4.3, we obtain a Riccati integral equation for $\mathscr{P}(t)$ in a standard way.

COROLLARY 4.6. *The Riccati operator $\mathscr{P}(t)$ of Theorem 4.3 satisfies the following integral equation*:

$$(\mathscr{P}(t)x, y)_E = \int_t^T \left(\begin{bmatrix} R & 0 \\ 0 & 0 \end{bmatrix} e^{\mathscr{A}(\tau - t)}x, e^{\mathscr{A}(\tau - t)}y \right)_E d\tau + \int_t^T (\mathscr{B}^*\mathscr{P}(\tau)\, e^{\mathscr{A}(\tau - t)}x, \mathscr{B}^*\mathscr{P}(\tau)\, e^{\mathscr{A}(\tau - t)}y)_\Gamma \, d\tau \tag{R.I.E.}$$

for all $x, y \in Y_r$ and all $t \in [0, T]$.

Remark 4.3. Plainly, the solution (2.1a, b), (2.2a, b) of problem (1.1) can also be written as

$$\begin{vmatrix} y(t) \\ \dot{y}(t) \end{vmatrix} = e^{\mathscr{A}t} \begin{vmatrix} y_0 \\ y_1 \end{vmatrix} + (\mathscr{L}u)(t). \tag{4.27}$$

See (1.5), (2.23), where we have introduced the operator

$$(\mathscr{L}u)(t) = \begin{vmatrix} (Lu)(t) \\ \left(\dfrac{dLu}{dt}\right)(t) \end{vmatrix} = \mathscr{A} \int_0^t e^{\mathscr{A}(t-\tau)}\mathscr{A}^{-1}\mathscr{B}u(\tau)\, d\tau \tag{4.28}$$

$$: \text{continuous } L_2(0, T; L_2(\Gamma)) \to C([0, T]; E)$$

$\mathscr{B}$ as in (4.13) so that

$$\mathscr{A}^{-1}\mathscr{B}u = \begin{vmatrix} -Du \\ 0 \end{vmatrix}, \qquad \mathscr{A}^{-1}\mathscr{B} \in \mathscr{L}(L_2(\Gamma), E).$$

We shall find it convenient to use (4.27)-(4.28) in § 5 (below (5.3)), where, by convention, we shall write (4.28) more expediently as

$$(\mathscr{L}u)(t) = \int_0^t e^{\mathscr{A}(t-\tau)}\mathscr{B}u(\tau)\, d\tau.$$

See also [D-L-T.1], for a *direct* study of the Riccati integral equation for hyperbolic dynamics written in the form (4.27)-(4.28).

5. The quadratic regulator problem for (1.1). The present section is devoted to a quick study of the optimal quadratic control problem over an infinite time interval (quadratic regulator) for the hyperbolic dynamics (1.1). Our treatment, in particular, has the important advantage that it does *not* require the usual limit process—present in most, if not all, available literature, see e.g. [B.1]—of deriving the algebraic Riccati equation from the differential (or integral) Riccati equation on $[0, T]$, as $T \uparrow \infty$. This advantage pays off particularly in cases like the hyperbolic dynamics, where regularity

properties of $\mathscr{B}^*\mathscr{P}(\mathscr{P}$ = Riccati operator of problem on $[0, \infty])$ can be deduced directly with minimal assumptions on the observation operators, in particular, without passing through the limit of $\mathscr{B}^*\mathscr{P}_T(t)(\mathscr{P}_T(t)$ = Riccati operator of problem on $[0, T])$, whose very definition may require, by contrast, stronger assumptions on the observation operators. In line with problem (1.2a) on $[0, T]$, $T<\infty$ of the preceding sections, the problem that we study now is: minimize the cost

$$J_\infty(u, y(u)) = \int_0^\infty \{(Ry(t), y(t))_\Omega + |u(t)|^2_\Gamma\}\, dt \tag{5.1}$$

over all $u \in L_2(0, \infty; L_2(\Gamma)) \equiv L_2(\Sigma)$, with $y(u)$ solution of (1.1) corresponding to u. R satisfies *only* assumption (H.1) of nonnegative definiteness on $L_2(\Omega)$; in particular, R may be the identity. A minimal assumption which we must impose for the above problem to make sense is, as usual:

(H) For each initial data $[y_0, y_1] \in E$, there exists a $u \in L_2(\Sigma_\infty)$, whose corresponding solution gives Ry in $L_2(0, \infty; E)$, whereby the corresponding cost J_∞ is finite.

Remark 5.1. It is proved in [L-T.5] that, under some assumptions on the bounded domain Ω, the boundary feedback $u(t) = -D^*y_t(t)$, once inserted in (1.1) with $-A(\xi, \partial) = \Delta$, gives rise to a closed loop hyperbolic system with the following properties:

(i) The corresponding *closed loop feedback* dynamics $[y(t), y_t(t)]$ is a s.c. contraction semigroup $S_F(t)$ on $L_2(\Omega) \times H^{-1}(\Omega)$; i.e. it can be represented here by

$$\begin{vmatrix} y(t) \\ y_t(t) \end{vmatrix} = S_F(t) \begin{vmatrix} y_0 \\ y_1 \end{vmatrix}.$$

(ii) $u = -D^*y_t \in L_2(0, \infty; L_2(\Gamma))$.

(iii) The semigroup $S_F(t)$ in (i) is exponentially stable in the corresponding uniform operator topology; i.e. there are constants C, δ both positive, such that

$$\|S_F(t)\| \leqq C e^{-\delta t}, \qquad t \geqq 0$$

where $\|\ \|$ is here the uniform operator norm on $L_2(\Omega) \times H^{-1}(\Omega)$.

As a consequence of this result, for each initial piece of data $[y_0, y_1] \in E$, there exists a $u \in L_2(\Sigma)$—indeed $u = -D^*y_t$—such that the cost

$$\int_0^\infty \{(Ry(t), y(t))_{L_2(\Omega)} + (R'y_t(t), y_t(t))_{H^{-1}(\Omega)} + |u(t)|^2_{L_2(\Gamma)}\}\, dt. \tag{5.2}$$

R' nonnegative definite on $H^{-1}(\Omega)$ is *finite* and the corresponding regulator problem could be studied, indeed with the techniques of the present section modulo only minor additions. For sake of simplicity, and in line with §§ 2-4, we shall, however, concentrate on problem (5.1), rather than (5.2) (see also footnote 2). Thus, a fortiori, assumption (H) above is satisfied, indeed in a boundary feedback, constructive manner. Reference [L-T.5] gives a version of the *uniform* feedback stabilization problem, with feedback acting in the Dirichlet B.C. Treatment of the same problem, with feedback acting, instead, in the Neumann B.C. on the nontrivial portion Γ_1 or Γ, with homogeneous Dirichlet B.C. in the possibly empty portion Γ_0 of Γ, $\Gamma_0 \cup \Gamma_1 = \Gamma$, with $\bar{\Gamma}_0 \cap \bar{\Gamma}_1 = \phi$, was previously given, in its most general and complete version, in [L-4], improving upon [C.1].

It is a standard result that, as a consequence of assumption (H) being satisfied, there is a *unique optimal pair* u^0_∞, y^0_∞ of the quadratic problem (5.1).

We shall now proceed to obtain certain quantities of the optimal control problem (5.1) over $[0, \infty]$ (e.g. the Riccati operator $\mathscr{P}$, the optimal control and optimal solution, etc.) via a limit process as $T \uparrow \infty$ of the corresponding quantities of the corresponding optimal control problem (1.2a) over $[0, T]$. However, at the level of deriving the algebraic Riccati equation, we shall *not* take the limit of the differential Riccati equation, as done in much if not all, of the literature e.g. [B.1]. Rather, we shall first derive for $\mathscr{P}$ a relation (see (5.30) below), and then derive both the pointwise synthesis for the optimal control and the algebraic Riccati equation.

Relation (5.30) for $\mathscr{P}$ may be taken as a *defining* relation in the special but important case where the original s.c. (semi-) group $e^{\mathscr{A}t}$ is *uniformly bounded* on E, a situation large enough to include most physical systems, in particular, the canonical wave equation $-A(\xi, \partial) = \Delta$, where $e^{\mathscr{A}t}$ is indeed a unitary group on E. When $e^{\mathscr{A}t}$ is uniformly bounded on E, our treatment becomes particularly simple and direct, see Remark 5.2 below.

With $0 < T < \infty$ fixed, we shall henceforth indicate with a subscript "T" the quantities related to the optimal control problem (1.3a) on $[0, T]$ of §§ 2-4. Thus, $u_T^0(t) \equiv u_T^0(t, 0; x)$, $y_T^0(t) \equiv y_T^0(t, 0, x)$ and $\dot{y}_T^0(t) \equiv \dot{y}_T^0(t, 0; x)$ are the optimal control and solution of (1.3a) on $[0, T]$, starting at x, while $\mathscr{P}_T(t)$, $J_T(\cdot, \cdot)$, $\Phi_T(t, s)x = [y_T^0(t, s; x), \dot{y}_T^0(t; s; x)]$ are the corresponding Riccati operator, cost, and evolution operator. Extension by zero beyond T of f_T will be indicated by $\tilde{f}_T$. Thus, $\tilde{y}_T^0(t) \equiv y_T^0(t)$, $0 \leqq t \leqq T$, and $\tilde{y}_T^0(t) \equiv 0$, $t > T$ and similarly for $\tilde{u}_T^0(t)$ and $\tilde{\Phi}_T$. The same quantities with $T = \infty$ refer to the problem (5.1) over $[0, \infty]$. We begin by considering $\Phi_T(t, s)$.

Recalling Remark 4.3, we introduce the operators

$$\mathscr{R} \equiv \begin{vmatrix} R & 0 \\ 0 & 0 \end{vmatrix} \text{ nonnegative definite on } E, \tag{5.3}$$

$$\mathscr{L} \equiv \begin{vmatrix} L \\ \dfrac{dL}{dt} \end{vmatrix} : \text{continuous } L_2(0, T; L_2(\Gamma)) \to C([0, T]; E) \text{ by (2.3a, b).} \tag{5.4}$$

If $\mathscr{L}^* = [L^*, dL^*/dt]$ is the dual operator $(\mathscr{L}u, v)_{L_2(0, T; E)} = (u, \mathscr{L}^* v)_{L_2(0, T; L_2(\Gamma))}$, then $\mathscr{L}^*\mathscr{R} = [L^*R, 0]$ and

$$[I + \mathscr{L}\mathscr{L}^*\mathscr{R}] = \begin{vmatrix} I + LL^*R \\ I + + \dfrac{dL}{dt} L^*R \end{vmatrix} = \text{boundedly invertible on } L_2(0, T; E) \tag{5.5}$$

(same argument as below (2.8d)). Moreover, the optimal dynamics (2.31a) can be rewritten as

$$\begin{aligned} \Phi_T(t, s)x &= e^{\mathscr{A}(t-s)}x + \{\mathscr{L}_s u_T^0(\cdot, s; x)\}(t) \\ &= e^{\mathscr{A}(t-s)}x - \{\mathscr{L}_s\mathscr{L}_s^*\mathscr{R}\Phi_T(\cdot, s; x)\}(t) \end{aligned} \tag{5.6}$$

where, with $\mathscr{B}$ as in (4.13)

$$(\mathscr{L}_s u)(t) \equiv \int_s^t e^{\mathscr{A}(t-\tau)}\mathscr{B}u(\tau)\, d\tau, \tag{5.7}$$

$$(\mathscr{L}_s^* v)(t) \equiv \begin{cases} \mathscr{B}^* \displaystyle\int_s^T e^{\mathscr{A}^*(\tau - t)} v(\tau)\, d\tau, & s \leqq t \leqq T, \\ 0, & 0 \leqq t \leqq s, \end{cases} \tag{5.8}$$

using the same convention as in Remark 4.3.

LEMMA 5.1. *In the notation introduced above* (5.3), *we have*

$$\Phi_{T-t}(\sigma, 0) \equiv \Phi_T(t+\sigma, t) \quad \text{on } E, \quad 0 \leqq t < T, \quad 0 \leqq \sigma \leqq T-t.$$

Proof. From (5.6) we have for $x \in E$

$$\Phi_{T-t}(\sigma, 0)x + \{\mathscr{L}\mathscr{L}^* \mathscr{R} \Phi_{T-t}(\cdot, 0)x\}(\sigma) = e^{\mathscr{A}\sigma}x, \qquad 0 \leqq \sigma \leqq T-t$$

or explicitly, from (5.7), (5.8)

$$(5.9) \quad e^{\mathscr{A}\sigma}x = \Phi_{T-t}(\sigma, 0)x + \int_0^\sigma e^{\mathscr{A}(\sigma-\tau)}\mathscr{B}\left(\mathscr{B}^* \int_\tau^{T-t} e^{\mathscr{A}^*(r-\tau)}\mathscr{R}\Phi_{T-t}(r, 0)x\, dr\right) d\tau.$$

Similarly

$$\begin{aligned} e^{\mathscr{A}(t+\sigma-t)}x &= \Phi_T(t+\sigma, t)x + \{\mathscr{L}_t\mathscr{L}_t^*\mathscr{R}\Phi_T(\cdot, t)x\}(t+\sigma), \qquad 0 \leqq \sigma \leqq T-t \\ &= \Phi_T(t+\sigma, t)x + \int_t^{t+\sigma} e^{\mathscr{A}(t+\sigma-\tau)}\mathscr{B}(\mathscr{B}^* \int_\tau^T e^{\mathscr{A}^*(\alpha-\tau)}\mathscr{R}\Phi_T(\alpha, t)x\, d\alpha\, d\tau. \end{aligned}$$

Setting $\tau - t = \beta$ in the first integral and then $\alpha - t = r$ in the second integral yields

$$(5.10) \quad e^{\mathscr{A}\sigma}x = \Phi_T(t+\sigma, t)x + \int_0^\sigma e^{\mathscr{A}(\sigma-\beta)}\mathscr{B}\left(\mathscr{B}^* \int_\beta^{T-t} e^{\mathscr{A}^*(r-\beta)}\mathscr{R}\Phi_T(t+r, t)x\, dr\right) d\tau.$$

Comparison between (5.9) and (5.10) shows that both $\Phi_{T-t}(\sigma, 0)$ and $\Phi_T(t+\sigma, t)$ satisfy the same equation, say (5.10). But then the difference

$$(5.11) \qquad z(\sigma, t) \equiv \Phi_T(t+\sigma, t)x - \Phi_{T-t}(\sigma, 0)x \underset{(\text{in } \sigma)}{\in} C([0, T-t]; E)$$

satisfies $[I + \mathscr{L}\mathscr{L}^*\mathscr{R}]z(\cdot, t) = 0$. By (5.5), we deduce that $z(\sigma, t)$ is the zero element in $L_2(0, T-t; E)$ and by (5.11) the conclusion follows. □

THEOREM 5.2. *In the notation introduced above* (5.3), *we have*:

(i) *The* (*self-adjoint*) *nonnegative definite operator* $\mathscr{P}_T(0)$ *converges strongly on* E *to a* (*self-adjoint*) *nonnegative definite operator* $\mathscr{P}$ *as* $T \uparrow \infty$; *i.e.*

$$(5.12) \qquad \mathscr{P}x = \lim_{T \uparrow \infty} \mathscr{P}_T(0)x = \lim_{T \uparrow \infty} \int_0^T e^{\mathscr{A}^*\tau} \left| \begin{matrix} R\Phi_{T,1}(\tau, 0)x \\ 0 \end{matrix} \right| d\tau, \qquad x \in E.$$

(ii) $$\mathscr{P}_{T-t}(0) = \mathscr{P}_T(t), \quad 0 \leqq t < T.$$

(5.13)

(iii) $\mathscr{P}$ *in* (i) *can likewise be defined by*

$$(5.14) \qquad \mathscr{P}x = \lim_{T \uparrow \infty} \mathscr{P}_T(t)x = \lim_{T \uparrow \infty} \int_t^T e^{\mathscr{A}^*(\tau-t)} \left| \begin{matrix} R\Phi_{T,1}(\tau, t)x \\ 0 \end{matrix} \right| d\tau, \qquad x \in E$$

independently on t, $0 \leqq t < T$.

(iv) *For* $x \in E$

$$(5.15) \quad J_\infty^0 \equiv J_\infty^0(u_\infty^0(\cdot, 0; x), y_\infty^0(\cdot, 0; x)) = \int_0^\infty |u_\infty^0(t)|_\Gamma^2 + (Ry_\infty^0(t), y^0(t))_\Omega\, dt = (\mathscr{P}x, x)_E.$$

(v) *The optimal pair on* $[0, T]$ *for problem* (1.3a) *converges to the optimal pair on* $[0, \infty]$ *for problem* (5.1) *strongly in* L_2; *more precisely*

$$(5.16) \qquad \begin{aligned} &\tilde{u}_T^0 \to u_\infty^0 \quad \text{in } L_2(\Sigma_\infty), \\ &R^{1/2}\tilde{y}_T^0 \to R^{1/2}y_\infty^0 \quad \text{in } L_2(Q_\infty), \end{aligned}$$

for a suitable subsequence in $T \uparrow \infty$.

(vi) *For each t fixed, we have*

$$\left.\begin{aligned} &y_T^0(t) \to y_\infty^0(t) \text{ in } L_2(\Omega) \quad &(5.17a)\\ &\dot{y}_T^0(t) \to \dot{y}_\infty^0(t) \text{ in } H^{-1}(\Omega) \quad &(5.17b)\end{aligned}\right\} \textit{uniformly on bounded intervals}$$

as $T \uparrow \infty$, $t < T$. *Moreover, for* $x \in E$

$$\left|\begin{matrix} y_\infty^0(t, 0; x) \\ \dot{y}_\infty^0(t, 0; x)\end{matrix}\right| \equiv \left|\begin{matrix} y_\infty^0(t) \\ \dot{y}_\infty^0(t)\end{matrix}\right| \in C([0, T_0]; E) \quad \textit{for any } T_0 < \infty. \tag{5.17c}$$

Proof. Property (i). From the nonnegative definite operator $\mathscr{P}_T(0)$ satisfying

$$(\mathscr{P}_T(0)x, x)_E = J_T(u_T^0(\cdot, 0; x), y_T^0(\cdot, 0; x)) \equiv J_T^0, \qquad x \in E \tag{5.18}$$

(Lemma 2.3(iii)) one obtains, in a standard way (e.g. [B.1, p. 270]), the operator $\mathscr{P}$ as in (5.12) left; then (5.12) right follows from (2.22a).

Property (ii). Identity (5.13), which is intuitive in view of Lemma 2.3(iii), is a direct consequence of definition (2.22a) of $\mathscr{P}_T(t)$, via Lemma 5.1.

Property (iii) then follows by taking the limit in (5.13) as $T \to \infty$ and using (5.12) left, and (2.22a).

Property (iv). *Step* 1. As remarked below Remark 5.1, the existence of a unique optimal pair $u_\infty^0 \in L_2(\Sigma_\infty)$ and $y_\infty^0 \in L_2(Q_\infty)$ for problem (5.1) is a standard consequence of the assumption on the finiteness of the cost for some pair. Let $u_{\infty,T}^0$ and $y_{\infty,T}^0$ be the "cut" functions of u_∞^0 and y_∞^0 at $t = T$; i.e. $u_{\infty,T}^0(t)$ (resp. $y_{\infty,T}^0(t)$) coincides with $u_\infty^0(t)$ (resp. $y_\infty^0(t)$) over $0 \leqq t \leqq T$, and vanishes for $t > T$. From (5.18) with $x \in E$

$$\begin{aligned} (\mathscr{P}_T(0)x, x)_E &= \int_0^T |u_T^0(t)|_\Gamma^2 + (Ry_T^0(t), y_T^0(t))_\Omega \, dt \\ &\leqq \int_0^T |u_{\infty,T}^0(t)|_\Gamma^2 + (Ry_{\infty,T}^0(t), y_{\infty,T}^0(t))_\Omega \, dt \\ &\leqq J_\infty(u_\infty^0(\cdot, 0; x), y_\infty^0(\cdot, 0; x)) \equiv J_\infty^0 < \infty. \end{aligned} \tag{5.19}$$

Thus, the extended functions $\{\tilde{u}_T^0\}$ and $\{R^{1/2}\tilde{y}_T^0\}$ are contained in a fixed ball of $L_2(\Sigma_\infty)$ and $L_2(Q_\infty)$ respectively, for all T. Hence, we can extract subsequences

$$\tilde{u}_T^0 \text{ weakly convergent to, say, some } \tilde{u} \text{ in } L_2(\Sigma_\infty), \tag{5.20a}$$

$$R^{1/2}\tilde{y}_T^0 \text{ weakly convergent to, say, some } R^{1/2}\tilde{y} \text{ in } L_2(Q_\infty). \tag{5.20b}$$

Step 2. With reference to (5.20) we have, in fact, that $\tilde{y}$ is the solution of (1.1) due to $\tilde{u}$; i.e. for any $0 < T_0 < \infty$

$$\tilde{y} = C(\cdot)x_1 + S(\cdot)x_2 + L\tilde{u} \in C([0, T_0]; L_2(\Omega)). \tag{5.21}$$

Indeed, with $T > T_0$, $Lu_T^0 = L\tilde{u}_T^0$ converges weakly to $L\tilde{u}$ in $L_2(0, T_0; L_2(\Omega))$, while the extension by zero of $R^{1/2}$ applied to $y_T^0 = C(\ )x_1 + S(x)x_2 + Lu_T^0$ converges weakly to $R^{1/2}\tilde{y}$ in $L_2(0, T_0; L_2(\Omega))$. By uniqueness of the weak limit, (5.21) follows (first in $L_2(0, T_0; L_2(\Omega))$).

Step 3. Passing to the limit in (5.19) yields

$$(\mathscr{P}x, x)_E \leqq J_\infty^0 \tag{5.22}$$

by (5.12) left. On the other hand, the well-known lower semicontinuity of the quadratic cost J_∞ resulting from the weak convergence (5.20) [E-T.1, p. 11] completed with (5.21) gives the inequality in

$$(\mathscr{P}_T(0)x, x)_E = J_T(u_T^0, y_T^0) = J_\infty(\tilde{u}_T^0, \tilde{y}_T^0) \geqq J_\infty(\tilde{u}, \tilde{y})$$

from which, taking the limit via (5.12) left,

$$(\mathscr{P}x, x)_E \geqq J_\infty(\tilde{u}, \tilde{y}) \geqq J_\infty^0. \tag{5.23}$$

Then (5.22)-(5.23) yield (5.15):

$$(\mathscr{P}x, x)_E = J_\infty(\tilde{u}, \tilde{y}) = J_\infty^0 = J_\infty(u_\infty^0, y_\infty^0). \tag{5.24}$$

Property (v). By uniqueness of the optimal pair (*Step* 1), we conclude from (5.24) that

$$\tilde{u} = u_\infty^0 \quad \text{in } L_2(\Sigma_\infty), \qquad \tilde{y} = y_\infty^0 \quad \text{in } L_2(Q_\infty), \tag{5.25}$$

and thus, (5.20) becomes

(5.26a) $\tilde{u}_T^0$ converges weakly to u_∞^0 in $L_2(\Sigma_\infty)$,

(5.26b) $R^{1/2}\tilde{y}_T^0$ converges weakly to $R^{1/2}y_\infty^0$ in $L_2(Q_\infty)$.

On the other hand, the established convergence $J_T^0 \to J_\infty^0$ provides norm convergence:

$$\|\tilde{u}_T^0\|_{L_2(\Sigma_\infty)}^2 + \|R^{1/2}\tilde{y}_T^0\|_{L_2(Q_\infty)}^2 \to \|u_\infty^0\|_{L_2(\Sigma_\infty)}^2 + \|R^{1/2}y_\infty^0\|_{L_2(Q_\infty)}^2.$$

This, combined with the weak convergence in (5.26), yields the strong convergence (5.16) as desired.

Property (vi). For each fixed t, (5.16) implies $((Lu_T^0)(t) \to ((Lu_\infty^0)(t)$ in $L_2(\Omega)$ and $((dL/dt)u_T^0)(t) \to ((dL/dt)u_\infty^0)(t)$, by the continuity (2.3a, b) uniformly on bounded intervals. Then (5.17a, b) follow via the limit on the optimal dynamics on $[0, T]$. (5.17c) is a restatement of (5.21) via (5.25), used also for the corresponding dynamics of the velocity $\dot{y}_\infty^0$.

We next define the operator $\Phi_\infty(t)$ on E by

$$\Phi_\infty(t)x = \begin{vmatrix} \Phi_{\infty,1}(t)x \\ \Phi_{\infty,2}(t)x \end{vmatrix} = \begin{vmatrix} y_\infty^0(t, 0; x) \\ \dot{y}_\infty^0(t, 0; x) \end{vmatrix}, \qquad x \in E. \tag{5.27}$$

COROLLARY 5.3. *In the notation introduced above* (5.3) *and in* (5.27), *we have*:
(i)

$$\tilde{\Phi}_{T,1}(\cdot, 0)x \to \Phi_{\infty,1}(\cdot)x \quad \textit{in } L_2(Q_\infty), \qquad x \in E. \tag{5.28}$$

(ii) *For each fixed* $t > 0$, *as* $T \uparrow \infty$, $T > t$:

$$\Phi_T(t, 0)x \to \Phi_\infty(t)x,\ x \in E; \textit{ uniformly on bounded intervals.} \tag{5.29}$$

(iii) $\Phi_\infty(t)$ *is a strongly continuous semigroup on* E.
(iv) *The operator* $\mathscr{P}$ *defined on* E *by* (5.12) *or* (5.14) *satisfies*

$$\mathscr{P}x = \int_0^{t_0} e^{\mathscr{A}^* \tau} \begin{vmatrix} R\Phi_{\infty,1}(\tau)x \\ 0 \end{vmatrix} d\tau + e^{\mathscr{A}^* t_0}\mathscr{P}\Phi_\infty(t_0)x, \qquad x \in E \tag{5.30}$$

where t_0 *is an arbitrary point* $0 \leqq t_0 < \infty$.

Proof. The convergence properties (i) and (ii) are restatements of properties (5.16b) and (5.17a) in Theorem 5.2.

(iii) Recalling (5.27) and (5.17c), we see that $\Phi_\infty(t)$ is strongly continuous on E. The semigroup property of $\Phi_\infty(t)$ then follows from (5.29) via the evolution properties

of $\Phi_T(\ ,\ )$ and Lemma 5.1: indeed, for $x \in E$

$$\begin{aligned}\Phi_T(t+\tau, 0)x &= \Phi_T(t+\tau, \tau)\Phi_T(\tau, 0)x \quad \text{(by Lemma 2.1(ii))}\\ &= \Phi_{T-\tau}(t, 0)\Phi_T(\tau, 0)x \quad \text{(by Lemma 5.1)}\\ &= \Phi_{T-\tau}(t, 0)[\Phi_T(\tau, 0)x - \Phi_\infty(\tau, 0)x] + \Phi_{T-\tau}(t, 0)\Phi_\infty(\tau, 0)x.\end{aligned}$$

Taking the limit as $T \uparrow \infty$ we obtain by virtue of (5.29)

$$\Phi_\infty(t+\tau)x = \Phi_\infty(t, 0)\Phi_\infty(\tau, 0)x$$

as desired, since for fixed t, $\Phi_{T-\tau}(t, 0)$ is uniformly bounded in T in the operator norm of E by the Principle of Uniform Boundedness.

As to (iv), we have from (5.22) for an arbitrary $0 < t_0 < T$ and $x \in E$

$$\begin{aligned}\mathscr{P}x &= \lim_{T \uparrow \infty} \left\{ \int_0^{t_0} e^{\mathscr{A}^* \tau} \left| \begin{matrix} R\Phi_{T,1}(\tau, 0)x \\ 0 \end{matrix} \right| d\tau + e^{\mathscr{A}^* t_0} \int_{t_0}^{T} e^{\mathscr{A}^*(\tau - t_0)} \left| \begin{matrix} R\Phi_{T,1}(\tau, t_0)\Phi_T(t_0, 0)x \\ 0 \end{matrix} \right| d\tau \right\}\\ &= \int_0^{t_0} e^{\mathscr{A}^* \tau} \left| \begin{matrix} R\Phi_{\infty,1}(\tau, 0)x \\ 0 \end{matrix} \right| d\tau + e^{\mathscr{A}^* t_0} \lim_{T \uparrow \infty} \mathscr{P}_T(t_0)\Phi_T(t_0, 0)x\end{aligned}$$

where we have used (5.28) and (5.14). But

$$\begin{aligned}\lim_{T \uparrow \infty} \mathscr{P}_T(t_0)\Phi_T(t_0, 0)x &= \lim \{\mathscr{P}_T(t_0)[\Phi_T(t_0, 0)x - \Phi_\infty(t_0, 0)x] + \mathscr{P}_T(t_0)\Phi_\infty(t_0, 0)x\}\\ &= \mathscr{P}\Phi_\infty(t_0, 0)x = \mathscr{P}\Phi_\infty(t_0)x \qquad (5.31)\end{aligned}$$

by (5.29), the uniform boundedness of $\mathscr{P}_T(t_0)$ in T for t_0 fixed, and (5.14).

Remark 5.2. With reference to Remark 5.1, suppose that we are studying the minimization problem, over all $u \in L_2(\Sigma_\infty)$, of the cost functional (5.2), which penalizes also the velocity component. Let $\mathscr{R} = \left| \begin{matrix} R & 0 \\ 0 & R' \end{matrix} \right|$ be positive definite on E. Then, the same procedure culminating in Corollary 5.3 leads to the further conclusions that:

(i) The corresponding semigroup $\Phi_\infty(t)$ on E satisfies

$$\Phi_\infty(t)x \in L_2(0, \infty; E), \qquad x \in E.$$

(ii) The corresponding operator $\mathscr{P}$ satisfies

$$\mathscr{P}x = \int_0^{t_0} e^{\mathscr{A}^* \tau} \mathscr{R}\Phi_\infty(\tau)x\, d\tau + e^{\mathscr{A}^* t_0}\mathscr{P}\Phi_\infty(t_0)x, \qquad x \in E, \tag{5.32a}$$

a counterpart of (5.30). Suppose in addition, that the original semigroup $e^{\mathscr{A}t}$ is *uniformly bounded* on E: $\|e^{\mathscr{A}t}\|_{\mathscr{L}(E)} \leqq C$, $t \geqq 0$, a situation which includes many physical hyperbolic systems, in particular the canonical wave equation $-A(\xi, \partial) = \Delta$, where $e^{\mathscr{A}t}$ is indeed a unitary s.c. group on E. Then, by a well-known result [D.1], property (i) above: $\Phi_\infty(t)x \in L_2(0, \infty; E)$ implies that $\Phi_\infty(t)$ is indeed exponentially stable on E:

$$\|\Phi_\infty(t)\|_{\mathscr{L}(E)} \leqq M_\omega e^{-\omega t}, \qquad t \geqq 0, \quad \text{some } \omega > 0.$$

Then, in (5.32) we can let $t_0 \to \infty$, thereby obtaining

$$\mathscr{P}x = \int_0^{\infty} e^{\mathscr{A}^* \tau} \mathscr{R}\Phi_\infty(\tau)x\, d\tau, \qquad x \in E, \tag{5.32b}$$

a *defining* formula for $\mathscr{P}$. Thus, under the assumptions of the present remark, the procedure which follows simplifies considerably with $\Phi_\infty(t_0) = \Phi_\infty(\infty) = 0$. □

THEOREM 5.4. *With $\mathscr{P}$ and $\Phi_\infty(\ )$ defined by* (5.12) *and below* (5.27), *and $\mathscr{B}^*$ as in* (2.25):

$$-u_\infty^0(t,0;x) = -u_\infty^0(t) = \mathscr{B}^*\mathscr{P}\Phi_\infty(t)x, \qquad x \in E \tag{5.33a}$$

where

$$\mathscr{B}^*\mathscr{P}\Phi_\infty(t)\text{: continuous } E \to L_2(\Sigma_\infty). \tag{5.33b}$$

Proof. Recall

$$e^{\mathscr{A}^* t}y = \begin{vmatrix} C^*(t)y_1 - S^*(t)A^{*1/2}A^{-1/2}y_2 \\ A^{1/2}A^{*1/2}S^*(t)y_1 + A^{1/2}C^*(t)A^{-1/2}y_2 \end{vmatrix}, \qquad y \in E \tag{5.34}$$

computed as in obtaining (2.24). By (2.25)

$$\mathscr{B}^* e^{\mathscr{A}^* t}y = D^*A^*S^*(t)y_1 + D^*A^{*1/2}C^*(t)A^{-1/2}y_2 \tag{5.35a}$$

$$\text{: continuous } E \to L_2(0, T; L_2(\Gamma)) \tag{5.35b}$$

which follows from Theorem 3.2. Next, recall (2.28) and (2.22a)

$$-u_T^0(t,0;x) = -u_T^0(t) = \mathscr{B}^*\mathscr{P}_T(t)\Phi_T(t,0)x = I_{1T}(t) + I_{2T}(t), \tag{5.36}$$

$$I_{1T}(t) = \mathscr{B}^* \int_t^{t_0} e^{\mathscr{A}^*(\tau - t)} \begin{vmatrix} R\Phi_{T,1}(\tau,0)x \\ 0 \end{vmatrix} d\tau, \tag{5.37a}$$

$$I_{2T}(t) = \mathscr{B}^* e^{\mathscr{A}^*(t_0 - t)} \int_{t_0}^{T} e^{\mathscr{A}^*(\tau - t_0)} \begin{vmatrix} R\Phi_{T,1}(\tau, t_0)\Phi_T(t_0,0)x \\ 0 \end{vmatrix} d\tau. \tag{5.37b}$$

But by (5.35a) and (3.6b)

$$\begin{aligned} I_{1,T}(t) &= -D^*A^*S^*(t) \int_t^{t_0} C^*(\tau)R\Phi_{T,1}(\tau,0)x\, d\tau \\ &\quad + D^*A^{*1/2}C^*(t)A^{*1/2} \int_t^{t_0} S^*(\tau)R\Phi_{T,1}(\tau,0)x\, d\tau \\ &\equiv \{\bar{F}(\cdot)\Phi_{T,1}(\cdot,0)x\}(t) \end{aligned}$$

where, by Lemma 3.1, $\bar{F}(\cdot)$ is continuous $L_1(0, T_1; L_2(\Omega)) \to L_2(0, T_1; L_2(\Gamma))$ for any finite T_1. Thus, by (5.28) in Corollary 5.3, we conclude from (5.37a)

$$\begin{aligned} \lim_{T \uparrow \infty} I_{1T}(t) &= \mathscr{B}^* \int_t^{t_0} e^{\mathscr{A}^*(\tau - t)} \begin{vmatrix} R\Phi_{\infty,1}(\tau)x \\ 0 \end{vmatrix} d\tau \\ &= \mathscr{B}^* \int_0^{t_0 - t} e^{\mathscr{A}^*\sigma} \begin{vmatrix} R\Phi_{\infty,1}(\sigma)\Phi_\infty(t)x \\ 0 \end{vmatrix} d\sigma \end{aligned} \tag{5.38}$$

the limit being taken in the $L_2(0, T_1; L_2(\Gamma))$-topology. As to I_{2T} in (5.37b), recall (2.22a) and (5.31) to get

$$\lim_{T \uparrow \infty} I_{2T}(t) = \lim_{T \uparrow \infty} \mathscr{B}^* e^{\mathscr{A}^*(t_0 - t)}\mathscr{P}_T(t_0)\Phi_T(t_0,0)x = \mathscr{B}^* e^{\mathscr{A}^*(t_0 - t)}\mathscr{P}\Phi_\infty(t_0)x \tag{5.39}$$

by (5.35b), the limit being taken as in (5.38). We return to (5.36) and use (5.16a) on the left, and (5.38), (5.39), (5.30) (with t_0 in (5.30) replaced by $t_0 - t$ now) on the right, thus obtaining (5.33).

DEFINITION 5.1. Henceforth, we let $\mathscr{A}_F$ (F for "feedback") be the closed, densely defined infinitesimal generator of the s.c. semigroup $\Phi_\infty(t)$ on E of Corollary

5.3(iii): $\Phi_\infty(t) = e^{\mathscr{A}_F t}$:

$$\frac{d\Phi_\infty(t)}{dt}x = \mathscr{A}_F\Phi_\infty(t)x = \Phi_\infty(t)\mathscr{A}_F x,\ x \in \mathscr{D}(\mathscr{A}_F). \tag{5.40}$$

LEMMA 5.5. *With $\mathscr{P}$ defined by* (5.12), *we have $\mathscr{D}(\mathscr{B}^*\mathscr{P}) \supset \mathscr{D}(\mathscr{A}_F)$ and for $x \in \mathscr{D}(\mathscr{A}_F)$*

$$\begin{aligned}\mathscr{B}^*\mathscr{P}x = D^*Rx_1 + D^*\int_0^{t_0} C^*(\tau)R\Phi_{\infty,1}(\tau)\mathscr{A}_F x\,d\tau \\ -D^*C^*(t_0)R\Phi_{\infty,1}(t_0)x + \mathscr{B}^*\,e^{\mathscr{A}^*t_0}\mathscr{P}\Phi_\infty(t_0)x \in L_2(\Gamma)\end{aligned} \tag{5.41}$$

where t_0 (depending on x) is chosen so that the last term in (5.41) *is well-defined on $L_2(\Gamma)$. See the proof below (the measure of the set of all such t_0's contained in a finite interval is the length of this interval).*

Proof. We use now (5.30) complemented by (5.35a). Integration by parts on the integral term $\int_0^{t_0}$ of (5.30) produces the first three terms at the right of (5.41), for an arbitrary $0 < t_0$. Next, note that

$$\mathscr{B}^*\,e^{\mathscr{A}^*t_0}\mathscr{P}\Phi_\infty(t_0)x = \mathscr{B}^*\,e^{\mathscr{A}^*t_0}\mathscr{P}\int_0^{t_0}\Phi_\infty(t)\mathscr{A}_F x\,dt + \mathscr{B}^*\,e^{\mathscr{A}^*t_0}\mathscr{P}x \tag{5.42}$$

since $d\Phi_\infty(t)x/dt = \Phi_\infty(t)\mathscr{A}_F x$. But each of the two terms on the right of (5.42) are in $L_2(0, T_1; L_2(\Gamma))$ in the variable t_0, for any finite T_1, by (5.35a, b) and Lemma 3.1. For each x, the measure of all t_0 (depending on x) in $[0, T_1]$ for which both terms are in $L_2(\Gamma)$ is equal to T_1.

We next provide information on $\mathscr{A}_F$.

LEMMA 5.6. *For $x \in E$ and $t \geqq 0$*

$$\frac{d\Phi_\infty(t)x}{dt} = [\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P}]\Phi_\infty(t)x \in [\mathscr{D}(\mathscr{A}^*)]'. \tag{5.43}$$

Thus,

$$[\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P}]\Phi_\infty(t)x = \mathscr{A}_F\Phi_\infty(t)x = \Phi_\infty(t)\mathscr{A}_F x,\ x \in \mathscr{D}(\mathscr{A}_F),\qquad t > 0, \tag{5.44a}$$

$$[\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P}]x = \mathscr{A}_F x,\qquad x \in \mathscr{D}(\mathscr{A}_F). \tag{5.44b}$$

Proof. From the optimal dynamics and the optimal control in (5.33a),

$$(\Phi_\infty(t)x, z)_E = (e^{\mathscr{A}t}x, z)_E - \left(\int_0^t e^{\mathscr{A}(t-\tau)}\mathscr{B}\mathscr{B}^*\mathscr{P}\Phi_\infty(\sigma)x\,d\tau, z\right)_E. \tag{5.45}$$

We differentiate in t with $x \in E$ and $z \in \mathscr{D}(\mathscr{A})$

$$\begin{aligned}\left(\frac{d\Phi_\infty}{dt}(t)x, z\right)_E = (e^{\mathscr{A}t}x, \mathscr{A}^*z)_E - (\mathscr{B}\mathscr{B}^*\mathscr{P}\Phi_\infty(t)x, z)_E \\ -\left(\int_0^t e^{\mathscr{A}(t-\tau)}\mathscr{B}\mathscr{B}^*\mathscr{P}\Phi_\infty(\tau)x\,d\tau, \mathscr{A}^*z\right)_E\end{aligned} \tag{5.46}$$

where the second term on the right of (5.46) is well-defined as a duality pairing on $[\mathscr{D}(\mathscr{A}^*)]' \times \mathscr{D}(\mathscr{A}^*)$ by (5.33b) and, say $\mathscr{A}^{-1}\mathscr{B}$ being bounded on E. Re-using (5.45) with z replaced by $\mathscr{A}^*z$ inside (5.46) yields (5.43).

LEMMA 5.7. *With $\mathscr{P}$ defined by* (5.12), *we have*

(i) $\mathscr{A}^*\mathscr{P}: \mathscr{D}(\mathscr{A}_F) \to E$.

(ii) $\mathscr{A}_F^*\mathscr{P}: \mathscr{D}(\mathscr{A}) \to E$.

Proof. Again, we use (5.30).

(i) For $x \in \mathscr{D}(\mathscr{A}_F)$, we apply $\mathscr{A}^*$ to (5.30) and integrate both sides in t_0 (variable) on some $[0, T_0]$. Performing integration by parts on the right side, we easily see that $T_0\mathscr{A}^*\mathscr{P}x \in E$.

(ii) To show $\mathscr{P}\mathscr{A}_F: E \to [\mathscr{D}(\mathscr{A})]'$, we take $x \in E$, $z \in \mathscr{D}(\mathscr{A})$ and compute $(\mathscr{P}\mathscr{A}_F x, z)_E$ via (5.30). Integrating both sides of this expression in t_0 over some $[0, T_0]$, (the right side by parts) we likewise find that $T_0(\mathscr{P}\mathscr{A}_F x, z)_E$ is well-defined.

LEMMA 5.8. *With $\mathscr{P}$ defined by* (5.12), *we have*

$$\text{(i)} \qquad -\mathscr{A}^*\mathscr{P}x = \begin{vmatrix} Rx_1 \\ 0 \end{vmatrix} + \mathscr{P}\mathscr{A}_F x \in E, \qquad x \in \mathscr{D}(\mathscr{A}_F).$$

$$\text{(ii)} \qquad -\mathscr{A}_F^*\mathscr{P}z = \begin{vmatrix} Rz_1 \\ 0 \end{vmatrix} + \mathscr{P}\mathscr{A}z \in E, \qquad z \in \mathscr{D}(\mathscr{A}).$$

Proof. Differentiate in t_0 the expression $(\mathscr{P}x, z)_E$ with $\mathscr{P}$ given by (5.30) and then set $t_0 = 0$. We get

$$\text{(5.47)} \qquad \left(\begin{vmatrix} Rx_1 \\ 0 \end{vmatrix}, z \right)_E + (\mathscr{P}\mathscr{A}_F x, z)_E + (\mathscr{P}x, \mathscr{A}z)_E = 0, \quad x \in \mathscr{D}(\mathscr{A}_F), \quad z \in \mathscr{D}(\mathscr{A}).$$

From here, using the a priori regularity of $\mathscr{A}^*\mathscr{P}$ and $\mathscr{A}_F^*\mathscr{P}$ given by Lemma 5.7, we extend the above inner products by continuity to all $z \in E$ with $x \in \mathscr{D}(\mathscr{A}_F)$, and to all $x \in E$ with $z \in \mathscr{D}(\mathscr{A})$. Lemma 5.8 follows. □

COROLLARY 5.9. *For $\mathscr{P}$ defined by* (5.12)

$(\mathscr{B}^*\mathscr{P}x, \mathscr{B}^*\mathscr{P}y) =$ *well-defined for $x, y \in \mathscr{D}(\mathscr{A})$, or else $x, y \in \mathscr{D}(\mathscr{A}_F)$. Thus,*

$$\mathscr{B}^*\mathscr{P}: \begin{vmatrix} \mathscr{D}(\mathscr{A}) \\ \mathscr{D}(\mathscr{A}_F) \end{vmatrix} \to L_2(\Gamma).$$

Proof. From Lemma 5.6, (5.44b)

$$\text{(5.48)} \qquad -(\mathscr{B}^*\mathscr{P}x, \mathscr{B}^*\mathscr{P}y)_\Gamma = (\mathscr{P}\mathscr{A}_F x, y)_E - (\mathscr{P}\mathscr{A}x, y)_E$$

where the first term on the right is well-defined by Lemma 5.8(ii) for $x \in E$ and $y \in \mathscr{D}(\mathscr{A})$ (or $x \in \mathscr{D}(\mathscr{A}_F)$ and $y \in E$) and the second term is well-defined for $x \in \mathscr{D}(\mathscr{A})$ and $y \in E$ (or, by Lemma 5.8(i), for $x \in E$ and $y \in \mathscr{D}(\mathscr{A}_F)$). □

THEOREM 5.10. (i) *The operator $\mathscr{P}$ defined by* (5.12) *satisfies the following algebraic Riccati equation*

$$\text{(5.49)} \qquad (Rx_1, y_1)_\Omega + (\mathscr{P}x, \mathscr{A}y)_E + (\mathscr{P}\mathscr{A}x, y)_E = (\mathscr{B}^*\mathscr{P}x, \mathscr{B}^*\mathscr{P}y)_\Gamma$$

for $x, y \in \mathscr{D}(\mathscr{A})$, or else for $x, y \in \mathscr{D}(\mathscr{A}_F)$.

Proof. (i) Combine Lemma 5.8 and Corollary 5.9. □

Remark 5.3. In the study of the minimization of the functional cost (5.2) which penalizes also the velocity component, we have already noted in Remark 5.2 that, for $\mathscr{R} = \begin{vmatrix} R & 0 \\ 0 & R' \end{vmatrix}$ positive definite on E, the corresponding semigroup $\Phi_\infty(t)$ is *exponentially stable here*: $(\#)$ $\|\Phi_\infty(t)\|_{\mathscr{L}(E)} \leqq M_\omega e^{-\omega t}$, $t \geqq 0$, $\omega < 0$. From here, it then follows, via a standard argument along the lines of [B.1, Corollary 5.3.1, pp. 272–273] or the notes [DaP.1], that the corresponding algebraic Riccati equation ((5.48) with the first term replaced by $(\mathscr{R}x, z)_E$) admits a unique self-adjoint nonnegative definite solution within

the class of linear operators $\mathscr{P} \in \mathscr{L}(E)$ such that $\mathscr{B}^*\mathscr{P} \in \mathscr{L}(\mathscr{D}(\mathscr{A}_F), L_2(\Gamma))$. Indeed, a generalization of this uniqueness result is available, as stated by:

THEOREM 5.11. *With reference to the optimal problem* (5.2), *let* $\mathscr{R} = \left|\begin{smallmatrix} R & 0 \\ 0 & R' \end{smallmatrix}\right|$ *be nonnegative definite on E, so that the existence statement of the corresponding algebraic Riccati equation* ((5.48) *with the first term replaced by* $(\mathscr{R}x, z)_E$) *holds true, as in Theorem* 5.10. *Assume further that*[11] *there exists an operator* $\mathscr{K} = \left|\begin{smallmatrix} K & 0 \\ 0 & K' \end{smallmatrix}\right|$ *with* $K, K' \in \mathscr{L}(L_2(\Omega)) \cap \mathscr{L}(\mathscr{D}(A))$ *such that the s.c. group generator* $\mathscr{A}_K = \mathscr{A} + \mathscr{K}\mathscr{R}^{1/2}$ *is exponentially stable as* $t \to +\infty$: $\|e^{\mathscr{A}_K t}\|_{\mathscr{L}(E)} \leqq M_\delta e^{-\delta t}$, $t \geqq 0$ *for some* $\delta > 0$. *Then, said algebraic Riccati equation admits a unique self-adjoint nonnegative definite solution within the class of linear operators* $\mathscr{P} \in \mathscr{L}(E)$ *such that* $\mathscr{B}^*\mathscr{P}^* \in \mathscr{L}(\mathscr{D}(\mathscr{A}_F), L_2(\Gamma))$.

Proof. As noted in the first paragraph, it suffices to show inequality (#), i.e. the exponential stability of $\Phi_\infty(t)$ on E for $t \geqq 0$. To this end, we write as usual

$$\frac{d\Phi_\infty(t)}{dt}x = (\mathscr{A} - \mathscr{B}\mathscr{B}^*\mathscr{P})\Phi_\infty(t)x + \mathscr{K}\mathscr{R}^{1/2}\Phi_\infty(t)x - \mathscr{K}\mathscr{R}^{1/2}\Phi_\infty(t)x, \qquad x \in \mathscr{D}(\mathscr{A}_F)$$

on E, or else

$$\frac{d\Phi_\infty(t)x}{dt} = \mathscr{A}_K\Phi_\infty(t)x - \mathscr{K}\mathscr{R}^{1/2}\Phi_\infty(t)x - \mathscr{B}\mathscr{B}^*\mathscr{P}\Phi_\infty(t)x$$

on $[\mathscr{D}(\mathscr{A})]'$. Thus, for $x \in E$

$$\Phi_\infty(t)x = e^{\mathscr{A}_K t}x + \int_0^t e^{\mathscr{A}_K(t-\tau)}\mathscr{K}\mathscr{R}^{1/2}\Phi_\infty(\tau)x\,d\tau + \int_0^t e^{\mathscr{A}_K(t-\tau)}\mathscr{B}\mathscr{B}^*\mathscr{P}\Phi_\infty(\tau)x\,d\tau$$

where

$$\int_0^\infty \|e^{\mathscr{A}_K t}x\|_E^2\,dt + \int_0^\infty \left\| \int_0^t e^{\mathscr{A}_K(t-\tau)}\mathscr{K}\mathscr{R}^{1/2}\Phi_\infty(\tau)x\,d\tau \right\|^2 dt \leqq C\|x\|_E^2, \qquad x \in E$$

since $\mathscr{R}^{1/2}\Phi_\infty(t)x \in L_2(0, \infty; E)$, by the finiteness of the optimal cost, as usual. Thus, in order to apply [D.1] and conclude with exponential stability of $\Phi_\infty(t)$ on E, what is left is to show the following result, the *crux* of our proof. This is the counterpart of the regularity Theorem 1.1(i), via Remark 4.3, extended to the infinite time interval for exponentially stable $e^{\mathscr{A}_K t}$.

LEMMA 5.12. *The map*

$$(\mathscr{L}_K u)(t) \equiv \int_0^t e^{\mathscr{A}_K(t-\tau)}\mathscr{B}u(\tau)\,d\tau$$

is continuous $L_2(0, \infty; L_2(\Gamma)) \to L_2(0, \infty; E)$; *equivalently, the map* $\mathscr{L}_K^*$: $(\mathscr{L}_K u, v)_{L_2(0,\infty;E)} = (u, \mathscr{L}_K^* v)_{L_2(0,\infty;L_2(\Gamma))}$, *given by*

$$(\mathscr{L}_K^* v)(t) \equiv \mathscr{B}^* \int_t^\infty e^{\mathscr{A}_K^*(\tau - t)}v(\tau)\,d\tau$$

is continuous $L_2(0, \infty; E) \to L_2(0, \infty; L_2(\Gamma))$.

Proof. The proof for $\mathscr{L}_K^*$ is carried out by applying to an hyperbolic dynamics the same multiplier technique used in [L-L-T.1, see in particular Remark 3.1] for a

[11] This assumption is plainly satisfied with $\mathscr{K} = -k\mathscr{R}^{-1/2}$, k sufficiently large, when $\mathscr{R}$ is positive definite.

finite time interval or in [L-T.5, Prop. 3.1] on an infinite time interval with a decaying factor $e^{-\beta t}$, $\beta > 0$. To this end, use is made of the definition $\mathscr{B}^*[v_1, v_2] = D^* v_2$ ((2.25) in the self-adjoint case) along with $D^* v_2 = D^* A A^{-1} v_2 = (\partial/\partial \nu) A^{-1} v_2$ on Γ, see (3.8). We refer to these last two references for details. □

Appendix 1. Proof of Proposition 2.2. By identity (3.6b), we re-write (2.21) (as done a few times in § 3, e.g. in (3.21)) as

$$\begin{aligned}(2.21) = D^* A^* S^*(t) \int_t^T C^*(\tau)\Phi_1(\tau, 0) y \, d\tau \\ -D^* A^{*1/2} C^*(t) \int_t^T A^{*1/2} S^*(\tau)\Phi_1(\tau, 0) y \, d\tau, \qquad y \in E.\end{aligned} \tag{A1.1}$$

The abstract Lemma 3.1 can then be applied with $X = L_2(\Omega)$, $Y = L_2(\Gamma)$, the integrands of (A1.1) in $C([0, T]; X)$, by Lemma 2.1(iii) and (1.10)] and the operators outside the integrals continuous $X \to L_2(0, T; X)$, see Theorem 3.2. As a result, (A1.1) $\in$ $L_2(0, T; L_2(\Gamma))$. □

Appendix 2. Change of order of integration below (2.32) Lemma 2.3(ii). In order to justify the change of order of integration, one first considers the regularized problem; i.e. the same problem with J replaced by J_ε

$$J_\varepsilon = \int_0^T (R_\varepsilon y(t), y(t))_\Omega \, dt + \int_0^T |u(t)|_\Gamma^2 \, dt$$

where $R_\varepsilon \to R$ strongly, $\varepsilon \downarrow 0$, R_ε positive self-adjoint and $A^* R_\varepsilon$ bounded for each $\varepsilon > 0$ (for example, one can use the resolvent $R(\lambda, A)$ of A and take $R_\varepsilon = (1/\varepsilon) R(1/\varepsilon, A^*) R$). For the problem with R_ε, it can be readily shown that

$$\mathscr{B}^* \mathscr{P}_\varepsilon \text{: continuous } L_2(\Omega) \to C([0, T]; L_2(\Gamma)).$$

Then, absolute integrability holds

$$\int_t^T \int_t^\tau |(D^* A^* S^*(\tau - \sigma)\Phi_1(\tau, t)x, \mathscr{B}^* \mathscr{P}_\varepsilon(\sigma)\Phi(\sigma, t)y)_\Gamma| \, d\sigma \, d\tau$$

the function on the left of the inner product being in L_2 in the variable σ, the one on the right being continuous in σ. Hence, change of the order of integration is legal for the problem with ε, and one obtains

$$\begin{aligned}(\mathscr{P}_\varepsilon(t)x, y)_E = \int_t^T (R_\varepsilon \Phi_{1,\varepsilon}(\tau, t)x, \Phi_{1,\varepsilon}(\tau, t)y)_\Omega \, d\tau \\ + \int_t^T (\mathscr{B}^* \mathscr{P}_\varepsilon(\tau)\Phi_\varepsilon(\tau, t)x, \mathscr{B}^* \mathscr{P}_\varepsilon(\tau)\Phi_\varepsilon(\tau, t)y)_\Gamma \, d\tau.\end{aligned}$$

It is then straightforward to show that $\mathscr{P}_\varepsilon \to \mathscr{P}$, $\Phi_\varepsilon \to \Phi$; $u_\varepsilon \to u$ in $L_2(0, T; \cdot)$. Passing to the limit yields (2.29). □

ESTIMATION OF COEFFICIENTS AND BOUNDARY PARAMETERS IN HYPERBOLIC SYSTEMS*

H. T. BANKS† AND K. A. MURPHY‡

Abstract. We consider semi-discrete Galerkin approximation schemes in connection with inverse problems for the estimation of spatially varying coefficients and boundary condition parameters in second order hyperbolic systems typical of those arising in 1-D surface seismic problems. Spline based algorithms are proposed for which theoretical convergence results along with a representative sample of numerical findings are given.

Key words. hyperbolic systems, parameter estimation, spline approximations

AMS(MOS) subject classifications. 35R30, 41A15, 63N30

1. Introduction. In this paper we consider computational techniques for the following class of inverse problems: For the system

$$\rho(x)\frac{\partial^2 v}{\partial t^2}=\frac{\partial}{\partial x}\left(E(x)\frac{\partial v}{\partial x}\right), \quad t>0, \quad 0\leqq x\leqq 1, \tag{1.1}$$

$$\frac{\partial v}{\partial x}(t,0)+k_1 v(t,0)=s(t;\tilde{k}), \tag{1.2}$$

$$\frac{\partial v}{\partial t}(t,1)+k_2\frac{\partial v}{\partial x}(t,1)=0, \tag{1.3}$$

$$v(0,x)=\phi(x), \qquad v_t(0,x)=\psi(x), \tag{1.4}$$

given observations $\{\hat{y}_{ij}\}$ for $\{v(t_i, x_j)\}$, choose, from some admissible set, "best" estimates for the parameters ρ, E, k_1, k_2, $\tilde{k}$. These problems are motivated by certain versions of the so-called "1-D Seismic Inversion Problem" (see, e.g. [1], [9]). Roughly speaking, one has an elastic medium (e.g., the earth) with density ρ and elastic modulus E. A perturbation of the system (explosions, or vibrating loads from specially designed trucks) near the surface ($x=0$) produces a source s for particle disturbances v that travel as elastic waves, being partially reflected due to the inhomogeneous nature of the medium. An important but difficult problem involves using the observed disturbances at the surface or at points along a "bore hole" to determine properties (represented by parameters in the system) of the medium. In the highly idealized 1-D "surface seismic" problem, one assumes that data are collected at the same point ($x=0$) where the original disturbance or "source" is located. In addition to this hypothesis which cannot be true, other unrealistic special assumptions are made about the nature of the traveling and reflected waves. Although the standard 1-D formulations are far from reality, exploration seismologists have developed techniques for processing actual field data (performing a series of experiments and "stacking" the data) so that the 1-D

‡ Department of Mathematics, Southern Methodist University, Dallas, Texas 75275.

problems are generally accepted as useful and worthy subjects of investigation. Consequently, numerous papers (for some interesting references, see the bibliographies of [1], [9]) on the 1-D problems can be found in the research literature.

In many formulations of the seismic inverse problem, the medium is assumed to be the half-line $x>0$ (with $x=0$ the surface) while in others (especially some of those dealing with computational schemes) one finds the assumption of an artificial finite boundary (say at $x=1$) at which no downgoing waves are reflected (an "absorbing" boundary). While there are several ways to approximate such a condition in 2- or 3-dimensional problems (see [13], [23]), for the 1-D formulation this condition is embodied in a simple boundary condition of the form (1.3); here $k_2 \approx \sqrt{E(1)/\rho(1)}$ and one can view this boundary condition as resulting from factoring the wave equation (1.1) at $x=1$ and imposing the condition of "no upgoing waves" at $x=1$.

Equation (1.1) is a 1-D version of the equations for an isotropic elastic medium while (1.2) represents an "elastic" boundary condition at the surface $x=0$ (k_1 represents an elastic modulus for the restoring force produced by the medium).

As is the case in many inverse or "identification" problems, the problems described above tend to be ill-posed (including a computationally undesirable instability) unless careful restrictions are imposed on the admissible parameter class (for some discussions of these aspects, see [1], [11]). We shall not focus on this aspect here. Rather, the purpose of our presentation in this paper is to demonstrate the feasibility of a certain theoretical approach and certain approximations in developing computational schemes for problems in which there are (i) unknown boundary parameters and (ii) unknown spatially varying coefficients in the system equations. We are, to our knowledge, the first to develop a sound theoretical framework for problems such as those considered here. Certain technical difficulties arise when one includes unknown boundary parameters in the estimation problems and we demonstrate one means of successfully treating (both theoretically and computationally) these difficulties. Ideas for estimation of variable coefficients in parabolic equations were carefully developed in [6] and we show here that these same techniques can be readily employed to give a rather complete theory for efficient schemes for problems involving hyperbolic systems.

We choose the "1-D seismic inverse problem" involving (1.1)–(1.4) as a test example to exhibit the efficacy of our ideas. However the technical features and notions we present are of importance in a number of other applications. There are rather easily motivated and fundamental problems in dealing with large elastic structures (large space structures—e.g. beamlike structures with tip bodies) that involve estimation of boundary condition parameters. In these cases the models are often hybrid models with distributed system (Euler–Bernoulli, Timoshenko) state equations and ordinary differential equation boundary conditions (see, for example, [2], [10], [20], [22]). A second class of problems for which the techniques introduced in this paper have immediate use are related to bioturbation [8], [14]. This is the mixing of lake and deep-sea sediments by burrowing activities of organisms. Understanding of this phenomenon is fundamental to geologists in interpreting geologic records contained in sediment core samples. The best models to date involve parabolic state equations (for a nonuniform "mixing chamber") with unknown parameters in the boundary conditions describing the flux into and out of the chamber.

In our approach here we employ the Trotter–Kato theorem to obtain theoretical convergence results (assuming regularity of parameter sets to guarantee existence of solutions to the inverse problems) for spline approximation schemes for the states. Boundary parameter estimation is treated directly via mappings that iteratively change the parameter-dependent spline basis elements into "conforming" elements (i.e., ele-

ments which satisfy the appropriate boundary conditions). We deal only with estimation of regular spatially-varying coefficients in (1.1), where again splines are used for parameters in a secondary approximation. Estimation of discontinuous coefficients (including location of the discontinuities) in problems such as those that are the focus of our attention in this paper can be effectively treated theoretically and numerically in a framework similar to that here using, for example, tau-Legendre state approximation schemes [4].

We turn then to the estimation problem for (1.1)-(1.4). It is theoretically and numerically advantageous to deal with homogeneous boundary conditions by transforming the problem so that the source term s in (1.2) appears in the initial data and in a term in the state equation. We make the transformation $u = v + G$ where (here "$\cdot$" represents differentiation with respect to t)

$$G(t, x; q) = -\left(\frac{1}{k_1}\right)s(t; \tilde{k}) + \left(\frac{1}{k_1 k_2}\right)x^2(x-1)\dot{s}(t; \tilde{k})$$

and obtain the system

$$\begin{aligned} &q_1(x)\frac{\partial^2 u}{\partial t^2} = \frac{\partial}{\partial x}\left(q_2(x)\frac{\partial u}{\partial x}\right) + F(t, x; q), \\ &u_x(t, 0) + q_3 u(t, 0) = 0, \\ &u_t(t, 1) + q_4 u_x(t, 1) = 0, \\ &u(0, x) = \tilde{\phi}(x; q), \qquad u_t(0, x) = \tilde{\psi}(x; q). \end{aligned} \tag{1.5}$$

Here the forcing function F is given by

$$\begin{aligned} F(t, x; q) \equiv q_1(x)&\left\{-\left(\frac{1}{q_3}\right)\ddot{s}(t; \tilde{k}) + \left(\frac{1}{q_3 q_4}\right)x^2(x-1)\ddot{s}(t; \tilde{k})\right\} \\ &-\frac{\partial}{\partial x}\left\{q_2(x)\left(\frac{1}{q_3 q_4}\right)(3x^2 - 2x)\dot{s}(t; \tilde{k})\right\}, \end{aligned}$$

where here and throughout we adopt the notation $q = (q_1, q_2, q_3, q_4, \tilde{k})$ with $q_1 \equiv \rho$, $q_2 \equiv E$, $q_3 = k_1$, and $q_4 = k_2$. The transformed initial conditions have the form

$$\begin{aligned} \tilde{\phi}(x; q) &= \phi(x) - \left(\frac{1}{q_3}\right)s(0; \tilde{k}) + \left(\frac{1}{q_3 q_4}\right)x^2(x-1)\dot{s}(0; \tilde{k}), \\ \tilde{\psi}(x; q) &= \psi(x) - \left(\frac{1}{q_3}\right)\dot{s}(0; \tilde{k}) + \left(\frac{1}{q_3 q_4}\right)x^2(x-1)\ddot{s}(0; \tilde{k}). \end{aligned}$$

We assume henceforth that we have observations $\hat{y}_i = (\hat{y}_{i1}, \cdots, \hat{y}_{im})$, $i = 1, 2, \cdots, n$, corresponding to $w(t_i; q) = (u(t_i, x_1), \cdots, u(t_i, x_m))$ where u is the solution of (1.5). For a criterion in determining a best estimate $\hat{q}$ of the parameters we use a least-squares function

$$J(q) = \sum_{i=1}^{n} |\hat{y}_i - w(t_i; q)|^2 \tag{1.6}$$

which we seek to minimize as q ranges over some admissible parameter set Q. We remark that in the event our observations $\hat{\eta}_i = (\hat{\eta}_{i1}, \cdots, \hat{\eta}_{im})$ are for the original system (1.1)-(1.4), we may apply directly the theory and techniques of this paper by considering

in place of (1.6) the criterion

$$\tilde{J}(q)=\sum_{i=1}^{n}|\hat{\eta}_i+\tilde{G}(t_i;\,q)-w(t_i;\,q)|^2 \tag{1.7}$$

where $\tilde{G}(t_i;\,q)\equiv(G(t_i,x_1;\,q),\cdots,G(t_i,x_m;\,q))$.

We make some standing assumptions to facilitate consideration of our problem in subsequent discussions. We shall search for q in a set $Q\subset C(0,1)\times H^1(0,1)\times R\times R\times R^k$ (we shall sometimes write Q as $Q_1\times Q_2\times Q_3\times Q_4\times Q_5$). We further assume that Q is compact in the $C\times H^1\times R^{2+k}$ topology, and that there exist positive constants $\underline{q}_i$, $\bar{q}_i$, $i=1,2,3,4$ such that

$$\begin{aligned}
&\underline{q}_i\leqq q_i(x)\leqq\bar{q}_i \quad \text{for } q_i\in Q_i, \quad i=1,2,\\
&\underline{q}_3\leqq -q_3\leqq\bar{q}_3 \quad \text{for } q_3\in Q_3, \quad \text{and}\\
&\underline{q}_4\leqq q_4\leqq\bar{q}_4 \quad \text{for } q_4\in Q_4.
\end{aligned}$$

Finally, we assume $\phi\in H^1(0,1)$, $\psi\in H^0(0,1)$, and $s(\cdot\,;\tilde{k})\in H^3(0,T)$ for each $\tilde{k}\in Q_5$, where $t_i\in[0,T]$, $T<\infty$, and that $\tilde{k}\to s(\cdot\,;\tilde{k})$ is a continuous mapping from Q_5 to $H^3(0,T)$.

We turn next to the theoretical foundations of the approximation schemes we propose to use in solving our inverse problem of minimizing J over Q, subject to (1.5).

2. Abstract formulation. The object in this section is to lay the theoretical foundation for the problem. First, we shall write our partial differential equation as an abstract ordinary differential equation in a Hilbert space, then determine a set of approximating ordinary differential equations. Each of these abstract equations will have an associated identification problem; the original will be referred to as (ID), the Nth approximating problem will be referred to as (ID^N). We shall use the theory of semigroups to obtain existence and uniqueness of solutions to the differential equations. We can then fit our problem into the theoretical framework developed in [5], and deduce that, under conditions stated there (reiterated below for clarity), one can solve (ID^N) for each N, and these parameter estimates thus obtained will "lead to" a solution of (ID).

The equation (1.5) can be rewritten as a first order system, motivating the use of a product $(V(q)\times L^2(q))$ of two spaces to be our Hilbert space $X(q)$.

Define $V(q)$ to be $H^1(0,1)$ with inner product defined by $\langle v,w\rangle_{V(q)}=\int_0^1 q_2DvDw\,dx-q_2(0)q_3v(0)w(0)$. ($D$ denotes the spatial differentiation operator $\partial/\partial x$.) It can be readily shown that for any $q\in Q$, $V(q)$ is a Hilbert space, and moreover, the assumptions made about Q imply that the $V(q)$ norm is uniformly equivalent to the H^1 norm as q ranges over Q. Let $V_B(q)$ contain those elements of $V(q)$ which satisfy the elastic boundary condition, i.e., $V_B(q)=\{v\in V(q)\cap H^2(0,1)\,|\,Dv(0)+q_3v(0)=0\}$.

We define $L^2(q)$ to be $H^0(0,1)$ with inner product given by $\langle v,w\rangle_{0,q}=\int_0^1 q_1vw\,dx$, and note that for each $q\in Q$, $L^2(q)$ is a Hilbert space and its norm is uniformly equivalent to the standard H^0 norm as q ranges over Q.

As described earlier, we take $X(q)=V(q)\times L^2(q)$ with inner product given by $\langle x,y\rangle_q=\langle x_1,y_1\rangle_{V(q)}+\langle x_2,y_2\rangle_{0,q}$ (where $x=(x_1,x_2)^T$ and $y=(y_1,y_2)^T$). It is clear from our remarks above that for $q\in Q$, $X(q)$ is a Hilbert space, and the X norm is uniformly equivalent to the $H^1\times H^0$ norm as q ranges over Q. We can formally write (1.5) as an abstract equation in $X(q)$:

$$\begin{aligned}
&\dot{z}(t)=A(q)z(t)+G(t;\,q),\\
&z(0)=z_0(q),
\end{aligned} \tag{2.1}$$

where we have identified $z(t) \in X(q)$ with $\binom{u(t,\cdot)}{u_t(t,\cdot)}$. The boundary conditions are incorporated into the domain of $A(q)$ by defining $\operatorname{dom} A(q) = \{\binom{u}{v} \in V_B(q) \times H^1(0,1) \mid v(1) + q_4 Du(1) = 0\}$, and A is the unbounded linear operator given by

$$A(q) = \begin{pmatrix} 0 & I \\ (1/q_1)D(q_2 D) & 0 \end{pmatrix}.$$

The function G and the initial condition are given by

$$G(t; q) = \begin{pmatrix} 0 \\ F(t, \cdot; q) \end{pmatrix} \quad \text{and} \quad z_0(q) = \begin{pmatrix} \tilde{\phi}(\cdot; q) \\ \tilde{\psi}(\cdot; q) \end{pmatrix}.$$

It can be shown that for each $q \in Q$, $A(q)$ is the infinitesimal generator of a C_0-semigroup, $T(t; q)$ on $X(q)$, so that we have the existence of mild solutions to (2.1), given by

$$z(t; q) = T(t; q) z_0(q) + \int_0^t T(t-s; q) G(s; q)\, ds \tag{2.2}$$

with $z(\cdot; q) \in C(0, T; X(q))$. In this context, the inverse problem can be stated as:

(ID) Given observations $\hat{y} = \{\hat{y}_i\}_{i=1}^n$, minimize $J(z(\cdot; q), \hat{y})$ over $q \in Q$ subject to $z(\cdot; q)$ satisfying (2.2).

Here, $J(q) \equiv J(z(\cdot; q), \hat{y}) = \sum_{i=1}^n |\hat{y}_i - \xi(t_i, q)|^2$ where $\xi(t_i, q) = (z_1(t_i, x_1; q), \cdots, z_1(t_i, x_m; q))$ and z_1 denotes the first component of z.

To prove that for each q, $A(q)$ generates a C_0-semigroup, one can use the Lumer-Phillips theorem [17, p. 16]. To employ this theorem, one must show the operator is dissipative, densely defined, and satisfies a certain range statement. To demonstrate the dissipativity of $A(q)$, we take $f \in \operatorname{dom} A(q)$, $q \in Q$, and compute (with an integration by parts)

$$\begin{aligned}
\langle A(q)f, f\rangle_q &= \left\langle \begin{pmatrix} f_2 \\ (1/q_1)D(q_2 Df_1) \end{pmatrix}, \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \right\rangle_q \\
&= \langle f_2, f_1\rangle_{V(q)} + \langle (1/q_1)D(q_2 Df_1), f_2\rangle_{0,q} \\
&= \int_0^1 q_2 Df_1 Df_2\, dx - q_2(0)q_3 f_1(0)f_2(0) + \int_0^1 D(q_2 Df_1)f_2\, dx \\
&= -q_2(0)q_3 f_1(0)f_2(0) - q_2(0)Df_1(0)f_2(0) + q_2(1)Df_1(1)f_2(1) \\
&= -q_2(1)q_4(Df_1(1))^2 \leqq 0.
\end{aligned}$$

By relating $\operatorname{dom} A(q)$ to other subsets (see [16] for details) which are known to be dense in $H^1 \times H^0$, one can easily argue that for each $q \in Q$, $\operatorname{dom} A(q)$ is dense in $X(q)$. One can also argue that $\mathcal{R}(\lambda - A(q)) = X(q)$ for some $\lambda > 0$, by demonstrating that given $\binom{f_1}{f_2} \in X(q)$, there exists $\binom{u}{v} \in \operatorname{dom} A(q)$ such that

$$\begin{pmatrix} \lambda u - v \\ -(1/q_1)D(q_2 Du) + \lambda v \end{pmatrix} = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}.$$

This is equivalent to solving the following two point boundary value problem:

$$-(1/q_1)D(q_2Du)+\lambda^2 u=\lambda f_1+f_2,$$
$$Du(0)+q_3u(0)=0,$$
$$\lambda u(1)+q_4Du(1)=f_1(1),$$

for $u\in H^2(0,1)$, and setting $v(x)=\lambda u(x)-f_1(x)$.

If we let $y=u-(1/q_4)x^2(x-1)f_1(1)$ the above problem is transformed to an equivalent one with homogeneous boundary conditions:

$$(-1/q_1)D(q_2Dy)+\lambda^2 y=F,$$
$$Dy(0)+q_3y(0)=0,$$
$$q_4Dy(1)+\lambda y(1)=0,$$

where $F\in L^2(q)$. One can then use the theory of self-adjoint operators (again see [16]) to argue that a solution exists for any $F\in L^2(q)$.

We now turn to the approximation of our equation (2.1). We shall obtain a solution z^N to an approximating equation (to be discussed in detail below) in a finite dimensional subspace of $X(q)$, denoted $X^N(q)$. Specifically, let $S^3(\Delta^N)$ represent the standard subspace of C^2 cubic splines corresponding to the partition $\Delta^N=\{x_i\}_{i=0}^N$, $x_i=i/N$ (see [18, pp. 78-81]); then, given $q\in Q$, we take $X^N(q)$ to be that subspace of $S^3(\Delta^N)\times S^3(\Delta^N)$ whose elements satisfy the boundary conditions corresponding to q (i.e., $X^N(q)\subset \operatorname{dom} A(q)$). Let B_j^N, $j=-1,\cdots,N+1$, be the B-spline basis elements for $S^3(\Delta^N)$. Then $X^N(q)$ is the $(2N+3)$-dimensional subspace spanned by the following set of basis functions:

$$\beta_1^N=\begin{pmatrix}\frac{4q_3}{N}B_{-1}^N+\left(3-\frac{q_3}{N}\right)B_0^N\\ 0\end{pmatrix},\qquad \beta_2^N=\begin{pmatrix}-\frac{4q_3}{N}B_1^N+\left(3+\frac{q_3}{N}\right)B_0^N\\ 0\end{pmatrix},$$

$$\beta_3^N=\begin{pmatrix}B_2^N\\ 0\end{pmatrix},\quad\cdots,\quad \beta_{N-1}^N=\begin{pmatrix}B_{N-2}^N\\ 0\end{pmatrix},$$

$$\beta_N^N=\begin{pmatrix}B_{N-1}^N\\ \frac{3Nq_4}{4}B_N^N\end{pmatrix},\qquad \beta_{N+1}^N=\begin{pmatrix}B_N^N\\ 0\end{pmatrix},\qquad \beta_{N+2}^N=\begin{pmatrix}B_{N+1}^N\\ -\frac{3Nq_4}{4}B_N^N\end{pmatrix}$$

$$\beta_{N+3}^N=\begin{pmatrix}-1/(3Nq_4)B_{N+1}^N\\ B_{N+1}^N\end{pmatrix},\qquad \beta_{N+4}^N=\begin{pmatrix}-1/(3Nq_4)B_{N+1}^N\\ B_{N-1}^N\end{pmatrix},$$

$$\beta_{N+5}^N=\begin{pmatrix}0\\ B_{N-2}^N\end{pmatrix},\quad\cdots,\quad \beta_{2N+1}^N=\begin{pmatrix}0\\ B_2^N\end{pmatrix},$$

$$\beta_{2N+2}^N=\begin{pmatrix}0\\ \frac{-4q_3}{N}B_1^N+\left(3+\frac{q_3}{N}\right)B_0^N\end{pmatrix},\qquad \beta_{2N+3}^N=\begin{pmatrix}0\\ \frac{4q_3}{N}B_{-1}^N+\left(3-\frac{q_3}{N}\right)B_0^N\end{pmatrix}.$$

Let $P^N(q):X(q)\to X^N(q)$ denote the orthogonal projection of $X(q)$ onto $X^N(q)$, i.e., given $f\in X(q)$, $P^N(q)f$ is that element in $X^N(q)$ which satisfies $|P^N(q)f-f|_q\leqq |g-f|_q$ for all $g\in X^N(q)$. For each $q\in Q$, we define an operator $A^N(q)$ on $X(q)$ given

by $A^N(q) = P^N(q)A(q)P^N(q)$, and then the approximating equation to (2.1) is written as:

$$\begin{aligned} \dot{z}^N(t) &= A^N(q)z^N(t) + P^N(q)G(t; q), \\ z^N(0) &= P^N(q)z_0(q), \end{aligned} \tag{2.3}$$

where $z^N(t) \in X^N(q)$. Using the fact that $A(q)$ is closed, $P^N(q)$ is bounded, and the Closed Graph Theorem, one finds that $A^N(q)$ is bounded. The operator $A^N(q)$ inherits the dissipativity of $A(q)$, and therefore it follows that for each $q \in Q$, $A^N(q)$ is the infinitesimal generator of a C_0-semigroup of contractions $T^N(t; q)$ on $X(q)$. It is readily seen that $T^N(t; q)$ leaves $X^N(q)$ invariant. Thus, for each $q \in Q$ and each $N = 1, 2, \cdots$, there exists a unique mild solution $z^N(\cdot; q) \in C(0, T; X^N(q))$ of (2.3), which can be expressed as

$$z^N(t; q) = T^N(t; q)P^N(q)z_0(q) + \int_0^t T^N(t-s; q)P^N(q)G(s; q)\, ds. \tag{2.4}$$

The associated approximate identification problem is given by

(ID^N) Given observations $\hat{y} = \{\hat{y}_i\}_{i=1}^n$, minimize $J(z^N(\cdot; q), \hat{y})$ over $q \in Q$ subject to $z^N(\cdot; q)$ satisfying (2.4).

Here, $J^N(q) \equiv J(z^N(\cdot; q), \hat{y}) = \sum_{i=1}^n |\hat{y}_i - \xi^N(t_i, q)|^2$ where $\xi^N(t_i, q) = (z_1^N(t_i, x_1; q), \cdots, z_1^N(t_i, x_m; q))$ and z_1^N denotes the first component of z^N.

Since $X^N(q)$ is finite-dimensional, (2.3) is in fact a system of $2N+3$ ordinary differential equations, which can be solved using standard numerical packages. Similarly, there are numerical packages available to solve (ID^N), provided solutions exist and we have some computationally feasible representation for q_1 and q_2. A detailed description of our numerical implementation, including a discussion of possible representations of q_1 and q_2, will be deferred to subsequent sections. First, our concern is to determine under what conditions solutions of (ID^N) exist and how they relate to a solution of (ID). This is the subject of the next theorem, a slight modification of that given in [5, p. 820].

THEOREM 2.1. *Assume Q is compact in the $C \times H^1 \times R^{2+k}$ topology. If $q \to z_0(q)$, $q \to P^N(q)f$, $q \to T^N(t; q)f$, $f \in X = X(q)$ are continuous in this same Q-topology, with the latter uniformly in $t \in [0, T]$, then:*

(i) *There exists for each N a solution $\hat{q}^N$ of* (ID^N) *and the sequence $\{\hat{q}^N\}$ possesses a convergent subsequence $\hat{q}^{N_k} \to \hat{q}$.*

(ii) *If we further assume that, for any sequence $\{q^j\}$ in Q with $q^j \to \tilde{q}$, we have $|z^j(t; q^j) - z(t; \tilde{q})|_{q^j} \to 0$ as $j \to \infty$, uniformly in $t \in [0, T]$, then $\hat{q}$ is a solution of* (ID).

The reader may, at first glance, find the convergence statement of (ii) suspect in that $z^j(t; q^j) \in X^j(q^j)$ and $z(t; \tilde{q}) \in X(\tilde{q})$, but this statement is meaningful in view of the following observation. In defining the spaces $V(q)$, $L^2(q)$, and $X(q)$, it was noted that $V(q)$, $L^2(q)$, and $X(q)$ are uniformly equivalent to H^1, H^0, and $H^1 \times H^0$, respectively, as q ranges over Q. This implies that the $X(q)$ are setwise equal as q ranges over Q. To be technically precise, we should use the canonical isomorphism when relating an element of $X(q^j)$ to its counterpart in $X(\tilde{q})$, but to simplify our presentation, we shall throughout abuse notation and omit the isomorphism.

It is easily seen from the form of $z_0(q)$ that $q \to z_0(q)$ is continuous. It is also true that for our $P^N(q)$, $T^N(t; q)$ we have $q \to P^N(q)f$ and $q \to T^N(t; q)f$ continuous; this will be readily seen from the matrix representations for our approximating scheme, and so further discussion is postponed until § 5.

The next theorem gives sufficient conditions for the hypothesis of (ii) from Theorem 2.1 to hold.

THEOREM 2.2. *Let q^N, $\tilde{q}$ be arbitrary in Q such that $q^N \to \tilde{q}$ as $N \to \infty$ (recall convergence is in the $C \times H^1 \times R^{2+k}$ topology). Suppose that the projections $P^N(q)$ are such that $|(P^N(q^N) - I)f|_{q^N} \to 0$ as $N \to \infty$ for all $f \in X(\tilde{q})$, that $f \in X(\tilde{q})$ implies $|T^N(t; q^N)f - T(t; \tilde{q})f|_{q^N} \to 0$ as $N \to \infty$, uniformly in $t \in [0, T]$, and that $|z_0(q^N) - z_0(\tilde{q})|_{q^N} \to 0$ as $N \to \infty$. Then the mild solutions $z^N(t; q^N)$ of (2.3) converge to the mild solution $z(t; \tilde{q})$ of (2.1) uniformly in $t \in [0, T]$.*

The proof of this theorem, which is based on a standard "variation-of-constants" representation for solutions z and z^N in terms of the semigroups T and T^N, essentially follows immediately from [5, Thm. 3.1, p. 823]. One only needs to verify that our spaces, operators, etc. satisfy the conditions required in [5].

It is clear from the continuity of $q \to z_0(q)$ that $|z_0(q^N) - z_0(\tilde{q})|_{q^N} \to 0$ as $q^N \to \tilde{q}$. It remains only to show the convergence of the projections and the semigroups. The main result of the next section is the convergence of the semigroups; the convergence of the projections is obtained as an intermediate proposition. In summary then, at the end of the next section, we will be able to deduce from Theorem 2.2 that $z^N(t; q^N)$ converges to $z(t; \tilde{q})$ whenever $q^N \to \tilde{q}$, and hence by Theorem 2.1 we are assured that the sequence of iterates $\{\hat{q}^N\}$ we obtain by solving (ID^N), has a subsequence which converges to a solution, $\hat{q}$, of (ID).

3. Convergence arguments. This section will be devoted to establishing the result: For each convergent sequence $q^N \to \tilde{q}$ in Q, and for any $f \in X(\tilde{q})$, $|T^N(t; q^N)f - T(t; \tilde{q})f|_{q^N} \to 0$ as $N \to \infty$, uniformly in $t \in [0, T]$. As explained in the previous section, this convergence result is crucial in arguing that $z^N(t; q^N) \to z(t; \tilde{q})$ whenever $q^N \to \tilde{q}$, which in turn is necessary to ensure that our candidate (the limit of our approximating subsequence) is indeed a solution to our inverse problem.

We shall first prove a slightly different form of convergence of the semigroups using the following version of the Trotter–Kato Theorem [3].

THEOREM 3.1. *Let $(\mathcal{B}, |\cdot|)$ and $(\mathcal{B}^N, |\cdot|_N)$, $N = 1, 2, \cdots$, be Banach spaces and let $\Pi^N : \mathcal{B} \to \mathcal{B}^N$ be bounded linear operators. Further assume that $T(t)$ and $T^N(t)$ are C_0-semigroups on $\mathcal{B}$ and $\mathcal{B}^N$ with infinitesimal generators $\tilde{A}$ and $\tilde{A}^N$, respectively. If*

(i) $\lim_{N\to\infty} |\Pi^N f|_N = |f|$ *for all* $f \in \mathcal{B}$,

(ii) *there exist constants M, ω independent of N such that $|T^N(t)|_N \leqq M e^{\omega t}$, for $t \geqq 0$,*

(iii) *there exists a set $\mathcal{D} \subset \mathcal{B}$, $\mathcal{D} \subset \mathrm{dom}(\tilde{A})$, with $\overline{(\lambda_0 - \tilde{A})\mathcal{D}} = \mathcal{B}$ for some $\lambda_0 > 0$, such that for all $f \in \mathcal{D}$ we have*

$$|\tilde{A}^N \Pi^N f - \Pi^N \tilde{A} f|_N \to 0 \quad \text{as } N \to \infty,$$

then $|T^N(t)\Pi^N f - \Pi^N T(t) f|_N \to 0$ as $N \to \infty$, for all $f \in \mathcal{B}$, uniformly in t on compact intervals in $[0, \infty)$.

It will be a standing assumption throughout this section that $q^N \to \tilde{q}$ in Q with this convergence in the $C \times H^1 \times R^{2+k}$ topology. Let $\mathcal{B} = X(\tilde{q})$ with norm denoted by $|\cdot|_{\tilde{q}}$, $\mathcal{B}^N = X(q^N)$ with norm $|\cdot|_{q^N}$ for $N = 1, 2, \cdots$, $\tilde{A} = A(\tilde{q})$ with corresponding semigroup $T(t) = T(t; \tilde{q})$, and $\tilde{A}^N = A^N(q^N) = P^N(q^N)A(q^N)P^N(q^N)$ with corresponding semigroup $T^N(t) = T^N(t; q^N)$ (as described in § 2). For each N, $\Pi^N : X(\tilde{q}) \to X(q^N)$ will be a bounded linear operator which will map elements of $\mathrm{dom}\, A(\tilde{q})$ into elements of $\mathrm{dom}\, A(q^N)$. Define

$$g^N(x) = \exp([\tilde{q}_3 - q_3^N]x) - (x^2/2)[\tilde{q}_3 - q_3^N] \exp[\tilde{q}_3 - q_3^N];$$

given $f=\binom{f_1}{f_2}$, let Π^N be defined by

$$\Pi^N f=\begin{pmatrix} g^N f_1 \\ (q_4^N/\tilde{q}_4)g^N f_2 \end{pmatrix}.$$

The functions g^N are defined so that as $N\to\infty$, $g^N(x)\to 1$, and $D^j(g^N(x))\to 0$ for any positive integer j, where in each case the convergence is uniform in $x\in[0,1]$.

A simple computation demonstrates that if $f\in \operatorname{dom} A(\tilde{q})$, then $\Pi^N f\in \operatorname{dom} A(q^N)$. For each N, Π^N is a bounded linear operator from $X(\tilde{q})$ to $X(q^N)$, but moreover, the set of operators $\{\Pi^N\}$ is uniformly bounded. This statement can be proved using the assumptions on Q and the properties of g^N mentioned above. Similar comments apply to the proof of our first proposition.

PROPOSITION 3.1. *For any* $f\in X(\tilde{q})$, $|\Pi^N f-f|_{q^N}\to 0$ *as* $N\to\infty$.

In order to argue the convergence of the infinitesimal generators, we shall need error estimates for the spline approximations and their derivatives. These will be variations of estimates such as those found in [21], modified to take into account our q-dependent norm, and the presence of the operator Π^N.

The following notation will be used throughout this section. Given a vector function f, we shall use f_i or $(f)_i$ to denote the ith component of f. Given the scalar function h, $I^N h$ will denote the standard cubic spline interpolant of h (thus $I^N h\in S^3(\Delta^N)$). For a vector function $f=\binom{f_1}{f_2}$, $I^N f$ will be the vector whose components are the spline interpolants of the components of f, i.e.,

$$I^N f=\begin{pmatrix} I^N f_1 \\ I^N f_2 \end{pmatrix} \quad \text{and} \quad I^N f\in S^3(\Delta^N)\times S^3(\Delta^N).$$

The interpolant of f which satisfies the boundary conditions corresponding to q will be written as $I_B^N(q)f$. While $I^N f$ interpolates f_1 and f_2 at the values $\{i/N\}_{i=0}^N$ and the derivatives of f_1 and f_2 at 0 and 1, $I_B^N(q)f$ will interpolate f_1 and f_2 at the values $\{i/N\}_{i=0}^N$, and will additionally satisfy

$$[D(I_B^N(q)f)_i](0)+q_3[(I_B^N(q)f)_i](0)=0, \quad \text{or equivalently,}$$
$$[D(I_B^N(q)f)_i](0)=-q_3 f_i(0) \quad \text{for } i=1,2,$$

and

$$[(I_B^N(q)f)_2](1)+q_4[D(I_B^N(q)f)_1](1)=0, \quad \text{or equivalently,}$$
$$[D(I_B^N(q)f)_1](1)=-(1/q_4)f_2(1).$$

We note that if f satisfies the boundary conditions involving q, then $I_B^N(q)f=I^N f$.

The first estimates involve cubic interpolants for scalar functions.

LEMMA 3.1. *If* $h\in H^2$, *then*

$$|D^2(h-I^N h)|_0\to 0 \quad \text{as } N\to\infty,$$
$$|D(h-I^N h)|_0\leqq N^{-1}|D^2(h-I^N h)|_0\leqq N^{-1}|D^2 h|_0,$$
$$|h-I^N h|_0\leqq N^{-2}|D^2(h-I^N h)|_0\leqq N^{-2}|D^2 h|_0.$$

The convergence statement of this lemma follows immediately from the density of H^3 in H^2, the estimates of [21, Thm. 6.9], and the first integral relation (4.15) of [21]. The estimates follow from (4.24) and (4.25), respectively, of [21] and the first integral relation.

One can use the results of Lemma 3.1 and the equivalence of the $X(q)$ and $H^1\times H^0$ norms to derive similar statements for the interpolants in the $X(q)$ norm.

LEMMA 3.2. *If* $f \in H^2 \times H^2$ *and* $q \in Q \subset C \times H^1 \times R^{2+k}$, *then*

$$|I^N f - f|_q \leqq K_1 N^{-1}(|D^2(f_1 - I^N f_1)|_0^2 + |D^2(f_2 - I^N f_2)|_0^2)^{1/2}$$
$$\leqq K_1 N^{-1}(|D^2 f_1|_0^2 + |D^2 f_2|_0^2)^{1/2},$$
$$|D(I^N f - f)|_q \leqq K_2(|D^2(f_1 - I^N f_1)|_0^2 + |D^2(f_2 - I^N f_2)|_0^2)^{1/2}$$

where K_1, K_2 *are constants which are independent of* f, q, *and* N.

Again, due to the equivalence of norms, the Schmidt inequality of [21, Thm. 1.5] can be modified and used component-wise to give a Schmidt type inequality in the $X(q)$ norm.

LEMMA 3.3. *If* $f \in S^3(\Delta^N) \times S^3(\Delta^N)$ *and* $q \in Q$, *then* $|Df|_q \leqq K_3 N |f|_q$, *where* K_3 *is a constant independent of* f, N, *and* q.

The preceding estimates can be used to establish convergence properties for the canonical projections $P^N(q^N)$ where $q^N \to \tilde{q}$ in Q.

PROPOSITION 3.2. *If* $f \in X(\tilde{q})$, *then*

$$|P^N(q^N) f - f|_{q^N} \to 0 \quad \text{as } N \to \infty.$$

Proof. First consider $f \in \operatorname{dom} A(\tilde{q}) \cap (H^2 \times H^2)$. For such f, $\Pi^N f \in \operatorname{dom} A(q^N) \cap (H^2 \times H^2)$ and $I_B^N(q^N)\Pi^N f = I^N \Pi^N f$. We use Lemma 3.2 in the triangle inequalities below to derive

$$|P^N(q^N) f - f|_{q^N} \leqq |P^N(q^N)[f - \Pi^N f]|_{q^N} + |P^N(q^N)\Pi^N f - \Pi^N f|_{q^N} + |\Pi^N f - f|_{q^N}$$
$$\leqq 2|\Pi^N f - f|_{q^N} + |I_B^N(q^N)\Pi^N f - \Pi^N f|_{q^N}$$
$$= 2|\Pi^N f - f|_{q^N} + |I^N \Pi^N f - \Pi^N f|_{q^N}$$
$$\leqq 2|\Pi^N f - f|_{q^N} + K_1 N^{-1}(|D^2(\Pi^N f)_1|_0^2 + |D^2(\Pi^N f)_2|_0^2)^{1/2}.$$

Thus we have $|P^N(q^N) f - f|_{q^N}$ bounded by terms which we can show converge to zero using Proposition 3.1 and the properties of g^N.

The $P^N(q^N)$ are uniformly bounded, and the set $\operatorname{dom} A(\tilde{q}) \cap (H^2 \times H^2)$ is dense in $X(\tilde{q})$, hence one can use standard arguments to conclude that the statement of the proposition holds for all $f \in X(\tilde{q})$.

PROPOSITION 3.3. *For each* $f \in X(\tilde{q})$, $|(P^N(q^N) - I)\Pi^N f|_{q^N} \to 0$ *as* $N \to \infty$, *and for each* $f \in \operatorname{dom} A(\tilde{q}) \cap (H^2 \times H^2)$, $|D[(P^N(q^N) - I)\Pi^N f]|_{q^N} \to 0$ *as* $N \to \infty$.

Proof. The first statement is proved within the proof of Proposition 3.2; specifically, it was shown that $|P^N(q^N)\Pi^N f - \Pi^N f|_{q^N} \leqq K_1 N^{-1}(|D^2(\Pi^N f)_1|_0^2 + |D^2(\Pi^N f)_2|_0^2)^{1/2}$.

The proof of the second statement is obtained from the following triangle inequality (here we also use Lemmas 3.3, 3.2):

$$|D(P^N(q^N)\Pi^N f - \Pi^N f)|_{q^N} \leqq |D(P^N(q^N)\Pi^N f - I^N(\Pi^N f))|_{q^N} + |D(I^N(\Pi^N f) - \Pi^N f)|_{q^N}$$
$$\leqq K_3 N |P^N(q^N)\Pi^N f - I^N(\Pi^N f)|_{q^N}$$
$$+ |D(I^N(\Pi^N f) - \Pi^N f)|_{q^N}$$
$$\leqq K_3 N |(P^N(q^N) - I)\Pi^N f|_{q^N} + K_3 N |\Pi^N f - I^N \Pi^N f|_{q^N}$$
$$+ |D[I^N(\Pi^N f) - \Pi^N f]|_{q^N}$$
$$\leqq 2K_3 N |I^N \Pi^N f - \Pi^N f|_{q^N} + |D[I^N \Pi^N f - \Pi^N f]|_{q^N}$$
$$\leqq (2K_1 K_3 + K_2)(|D^2[(\Pi^N f)_1 - I^N(\Pi^N f)_1]|_0^2$$
$$+ |D^2[(\Pi^N f)_2 - I^N(\Pi^N f)_2]|_0^2)^{1/2}.$$

Thus the conclusion $|D[(P^N(q^N)-I)\Pi^N f]|_{q^N}\to 0$ as $N\to\infty$ follows from the observation that for $i=1,2$

$$\begin{aligned}|D^2[I^N(\Pi^N f)_i-(\Pi^N f)_i]|_0 &\leqq |D^2[I^N((\Pi^N f)_i-f_i)]|_0\\ &\quad +|D^2[I^N f_i-f_i]|_0+|D^2[f_i-(\Pi^N f)_i]|_0\\ &\leqq 2|D^2[(\Pi^N f)_i-f_i]|_0+|D^2[I^N f_i-f_i]|_0,\end{aligned}$$

with the latter terms approaching zero because of the properties of g^N and Lemma 3.1, respectively.

In later arguments, it will be helpful to have bounds (in the H^1 and H^0 norms) on one component of an element of X in terms of a bound (in the $X(q)$ norm) on the entire element. Thus, we consider for $f\in X(q)$, $|f|_q^2=|f_1|_{V(q)}^2+|f_2|_{0,q}^2$ which is equivalent to $|Df_1|_0^2+|f_1|_0^2+|f_2|_0^2$, so that there exist constants k_1 and k_2 such that $|Df_1|_0^2\leqq k_1|f|_q^2$ and $|f_2|_0^2\leqq k_2|f|_q^2$. Similarly, $|Df|_q^2=|Df_1|_{V(q)}^2+|Df_2|_{0,q}^2$ which is equivalent to $|D^2f_1|_0^2+|Df_1|_0^2+|Df_2|_0^2$ so we infer the existence of constants k_3 and k_4 such that $|D^2f_1|_0^2\leqq k_3|Df|_q^2$ and $|Df_2|_0^2\leqq k_4|Df|_q^2$. For future reference, we combine and label these observations as

$$\begin{aligned}&|Df_1|_0^2\leqq k_1|f|_q^2,\\ &|D^2f_1|_0^2\leqq k_3|Df|_q^2,\\ &|f_2|_1^2\leqq k_2|f|_q^2+k_4|Df|_q^2.\end{aligned}\tag{3.1}$$

It is now possible to state and prove the following convergence theorem.

THEOREM 3.2. *Suppose $q^N\to\tilde{q}$ in Q (convergence is in the $C\times H^1\times R^{2+k}$ topology). Then*

$$|T^N(t;q^N)\Pi^N f-\Pi^N T(t;\tilde{q})f|_{q^N}\to 0\quad \text{as } N\to\infty,$$

for all $f\in X(\tilde{q})$, uniformly in t on compact intervals in $[0,\infty)$.

Proof. The result is an immediate consequence of Theorem 3.1, once the hypotheses of that theorem have been shown to hold. Part (i) follows from Proposition 3.1, while part (ii) holds since $T^N(t;q)$ and $T(t;q)$ are contraction semigroups for each N and $q\in Q$. It remains only to verify (iii), for which we take $\mathcal{D}$ to be the set $\operatorname{dom} A(\tilde{q})\cap(H^2\times H^2)$. Let $f\in\mathcal{D}$. Then

$$\begin{aligned}|A^N(q^N)\Pi^N f-\Pi^N A(\tilde{q})f|_{q^N} &= |P^N(q^N)A(q^N)P^N(q^N)\Pi^N f-\Pi^N A(\tilde{q})f|_{q^N}\\ &\leqq |P^N(q^N)[A(q^N)P^N(q^N)\Pi^N f-\Pi^N A(\tilde{q})f]|_{q^N}\\ &\quad +|P^N(q^N)\Pi^N A(\tilde{q})f-\Pi^N A(\tilde{q})f|_{q^N}\\ &\leqq |A(q^N)P^N(q^N)\Pi^N f-\Pi^N A(\tilde{q})f|_{q^N}\\ &\quad +|(P^N(q^N)-I)\Pi^N A(\tilde{q})f|_{q^N}\\ &\equiv \varepsilon_1(N)+\varepsilon_2(N).\end{aligned}$$

It follows directly from Proposition 3.3 that $\varepsilon_2(N)\to 0$ as $N\to\infty$. We must work harder to establish that $\varepsilon_1(N)\to 0$. We begin by breaking the norm into its two components

and treat each separately. Thus

$$
\begin{aligned}
[\varepsilon_1(N)]^2 &= \left| \begin{pmatrix} 0 & 1 \\ (1/q_1^N)D(q_2^N D) & 0 \end{pmatrix} (P^N(q^N)\Pi^N f) - \Pi^N \begin{pmatrix} 0 & 1 \\ (1/\tilde{q}_1)D(\tilde{q}_2 D) & 0 \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \right|^2_{q^N} \\
&= |(P^N(q^N)\Pi^N f)_2 - g^N f_2|^2_{V(q^N)} \\
&\quad + |(1/q_1^N)D[q_2^N D(P^N(q^N)\Pi^N f)_1] - (q_4^N/\tilde{q}_4) g^N (1/\tilde{q}_1) D[\tilde{q}_2 D f_1]|^2_{0,q^N} \\
&\equiv [\delta_1(N)]^2 + [\delta_2(N)]^2.
\end{aligned}
$$

We first observe that

$$
\begin{aligned}
\delta_1(N) &\leqq |(P^N(q^N)\Pi^N f)_2 - (q_4^N/\tilde{q}_4) g^N f_2|_{V(q^N)} + |[(q_4^N/\tilde{q}_4) - 1] g^N f_2|_{V(q^N)} \\
&= |(P^N(q^N)\Pi^N f)_2 - (\Pi^N f)_2|_{V(q^N)} + |((q_4^N/\tilde{q}_4) - 1) g^N f_2|_{V(q^N)}.
\end{aligned}
$$

It is more convenient, and due to the equivalence of the norms, it is sufficient, to establish the convergence in the H^1 norm. This can easily be done for the first term by invoking Proposition 3.3 and the inequalities (3.1). An argument can be made for the second term based on the properties of the g^N and the convergence $q^N \to \tilde{q}$.

We turn now to the estimation of $\delta_2(N)$. Using the equivalence of the $L^2(q^N)$ and H^0 norms, and the inequalities (3.1), we establish the following chain of inequalities:

$$
\delta_2(N) = \left| \frac{1}{q_1^N} D[q_2^N D(P^N(q^N)\Pi^N f)_1] - \left(\frac{q_4^N}{\tilde{q}_4} g^N \right) \frac{1}{\tilde{q}_1} D(\tilde{q}_2 D f_1) \right|_{0,q^N}
$$

which is equivalent to

$$
\begin{aligned}
&\left| \frac{1}{q_1^N} q_2^N D^2(P^N(q^N)\Pi^N f)_1 + \frac{1}{q_1^N} D q_2^N D(P^N(q^N)\Pi^N f)_1 \right. \\
&\qquad \left. - \frac{q_4^N}{\tilde{q}_4} g^N \frac{1}{\tilde{q}_1} \tilde{q}_2 D^2 f_1 - \frac{q_4^N}{\tilde{q}_4} g^N \frac{1}{\tilde{q}_1} D\tilde{q}_2 D f_1 \right|_0 \\
&\leqq \left| \frac{q_2^N}{q_1^N} D^2(P^N(q^N)\Pi^N f)_1 - \frac{\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} g^N \right) D^2 f_1 \right|_0 \\
&\quad + \left| \frac{D q_2^N}{q_1^N} D(P^N(q^N)\Pi^N f)_1 - \frac{D\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} g^N \right) D f_1 \right|_0 \\
&\leqq \left| \frac{q_2^N}{q_1^N} D^2(P^N(q^N)\Pi^N f)_1 - \frac{q_2^N}{q_1^N} D^2(\Pi^N f)_1 \right|_0 + \left| \frac{q_2^N}{q_1^N} D^2(\Pi^N f)_1 - \frac{\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} \right) g^N D^2 f_1 \right|_0 \\
&\quad + \left| \frac{D q_2^N}{q_1^N} D(P^N(q^N)\Pi^N f)_1 - \frac{D q_2^N}{q_1^N} D(\Pi^N f)_1 \right|_0 \\
&\quad + \left| \frac{D q_2^N}{q_1^N} D(\Pi^N f)_1 - \frac{D\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} g^N \right) D f_1 \right|_0 \\
&\leqq \sqrt{k_3} \left| \frac{q_2^N}{q_1^N} \right|_\infty |D[(P^N(q^N) - I)\Pi^N f]|_{q^N} + \left| \frac{D q_2^N}{q_1^N} \right|_0 |D((P^N(q^N) - I)\Pi^N f)_1|_\infty \\
&\quad + \left| \frac{q_2^N}{q_1^N} D^2(\Pi^N f)_1 - \frac{\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} \right) g^N D^2 f_1 \right|_0 + \left| \frac{D q_2^N}{q_1^N} D(\Pi^N f)_1 - \frac{D\tilde{q}_2}{\tilde{q}_1} \left(\frac{q_4^N}{\tilde{q}_4} g^N \right) D f_1 \right|_0 .
\end{aligned}
$$

We thus see that $\delta_2(N)$ can be bounded by four terms which go to zero as $N \to \infty$; the convergence of the first two terms is the result of Proposition 3.3 and the convergence of q^N to $\tilde{q}$, while the convergence of the second two can be argued using the properties of g^N and $q^N \to \tilde{q}$.

We can use this theorem, the convergence properties of the operators Π^N (Proposition 3.1), and the semigroup properties of T^N and T, to establish the final result we need, as a corollary.

COROLLARY 3.1. *Suppose* $q^N \to \tilde{q}$. *Then*

$$|T^N(t; q^N)f - T(t; \tilde{q})f|_{q^N} \to 0 \quad \text{as } N \to \infty$$

for all $f \in X(\tilde{q})$, *uniformly in* t *on compact intervals in* $[0, \infty)$.

We can now invoke the results (see Theorems 2.1 and 2.2) stated in § 2 to conclude that $\hat{q}$ (obtained there as the limit of an approximating subsequence, $\{\hat{q}^{N_k}\}$) is a solution to the identification problem.

4. Parameter approximation. In § 2, we pose the problem of minimizing $J^N(q)$ over Q. The arguments underlying Theorem 2.1 yield that (under certain assumptions) each Nth (approximate) problem has a solution $\hat{q}^N$, and for any convergent subsequence $\{\hat{q}^{N_k}\}$, with $\hat{q}^{N_k} \to \hat{q}$, we have $\hat{q}$ is a solution of the original identification problem. Recall, however, that q_1 and q_2 are functional coefficients, and hence each of the approximate optimization problems is in fact infinite-dimensional in nature. In this section, we discuss some methods for approximating these infinite-dimensional optimization problems by finite-dimensional ones, thus providing numerically tractable problems. This, of course, results in a second, or parameter, approximation that must be considered.

In § 5, we shall present the results of several numerical test examples. To facilitate our presentation, we set $q_1 = \rho \equiv 1$ and search for $q_2 \equiv E$, q_3, q_4, $\tilde{k}$, with q_2 the only functional unknown. We therefore restrict our theoretical discussions here to this case. (We note however that in principle, our methods and ideas can be applied to the estimation of both ρ and E.)

An approach that one might take would be to assume an a priori parameterization for q_2. Thus the estimation of the unknown function becomes the estimation of a set of unknown constants appearing in the parameterization. The convergence theory developed thus far is directly applicable to this method. However, it would only yield results for best approximates (through the criterion on state observations) to q_2 *within the fixed a priori parameterization class.* Little can be said about convergence to a "best fit parameter" $\hat{q}_2$ from the original parameter set Q.

An alternate approach, which does not require qualitative (e.g., shape) assumptions about the parameter class, is to search for the unknown parameter in a sequence of sets Q^M which are finite dimensional approximations to the set Q. For example, one might search for the unknown parameter in sequences of classes of linear combinations of spline (or members of any other suitably chosen approximation family) basis elements. Such an approach was given a careful theoretical development for problems involving parabolic equations in [6] and elliptic equations in [15]. Since the basic ideas do not depend on the particular type (e.g. parabolic, hyperbolic, elliptic) of system, they are easily adapted to the problems under investigation here. We therefore shall only sketch the pertinent results, referring the reader to [6], [15] for further details and to [21] for the necessary technical estimates.

We shall consider here two cases: Q^M as a set of linear spline interpolants, and Q^M as a set of cubic spline interpolants. For both cases we need to generalize the

theory developed in § 2, since we now have a "double index" (reflecting approximations for both the parameter and the state space) sequence of iterates, which we would like to argue converges to a solution of the original identification problem.

To be specific, let $Q = Q_2 \times Q_3 \times Q_4 \times Q_5 \subset H^1 \times R^{2+k}$, and assume we have a mapping $i^M: Q_2 \to H^1$. For I the identity map, define $\mathcal{I}^M = i^M \times (I)^{2+k}$, i.e., for $q \in Q$, we have $\mathcal{I}^M(q) = (i^M(q_2), q_3, q_4, q_5)$.

Let $Q^M = \mathcal{I}^M(Q)$. We assume

(4.1) The set $(Q^M)_2 \equiv i^M(Q_2)$ is compact in H^1.

(4.2) For $q_2 \in Q_2$, $i^M(q_2) \to q_2$ in H^1 as $M \to \infty$, and this convergence is uniform in $q_2 \in Q_2$.

The original set Q is assumed to be compact in $H^1 \times R^{2+k}$, so it follows from (4.1), the definition of $\mathcal{I}^M$, and Theorem 2.1 that for each N and M, a solution $\hat{q}_M^N$ exists to the problem of minimizing J^N over Q^M. From the definition $Q^M = \mathcal{I}^M(Q)$, we see that there exists $\bar{q}_M^N \in Q$ such that $\mathcal{I}^M(\bar{q}_M^N) = \hat{q}_M^N$ for each N and M. But the compactness of the original set Q then implies the existence of some subsequence $\{\bar{q}_{M_k}^{N_j}\}$ and an element $\hat{q} \in Q$ such that $\bar{q}_{M_k}^{N_j} \to \hat{q}$ in Q; moreover, this subsequence may be chosen so that both $N_j \to \infty$ and $M_k \to \infty$. The limit $\hat{q}$ is in fact a solution to the problem of minimizing J over Q; this claim is verified as follows: From the definition $\hat{q}_{M_k}^{N_j}$ we have

$$J^{N_j}(\hat{q}_{M_k}^{N_j}) \leqq J^{N_j}(q) \quad \text{for } q \in Q^{M_k}.$$

This implies

$$J^{N_j}(\hat{q}_{M_k}^{N_j}) \leqq J^{N_j}(\mathcal{I}^{M_k}(q)) \quad \text{for } q \in Q. \tag{4.3}$$

But $|\hat{q}_{M_k}^{N_j} - \hat{q}| \leqq |\mathcal{I}^{M_k}(\bar{q}_{M_k}^{N_j}) - \bar{q}_{M_k}^{N_j}| + |\bar{q}_{M_k}^{N_j} - \hat{q}|$, and thus $\hat{q}_{M_k}^{N_j} \to \hat{q}$ in Q as $N_j \to \infty$, $M_k \to \infty$ follows from (4.2), the definition of $\mathcal{I}^{M_k}$, and $\bar{q}_{M_k}^{N_j} \to \hat{q}$. If we take the limit in (4.3) as N_j, $M_k \to \infty$, we see that $J(\hat{q}) \leqq J(q)$ for $q \in Q$. Here we have used Theorem 2.2 with the observation that the convergence statement $z^N(t; q^N) \to z(t; \tilde{q})$ for any $q^N \to \tilde{q}$ is still valid if replaced by $z^N(t; q^j) \to z(t; \tilde{q})$ as $j, N \to \infty$, for any $q^j \to \tilde{q}$; this can be seen using a reindexing argument. These remarks are summarized in the following theorem.

THEOREM 4.1. *Let $Q^M = \mathcal{I}^M(Q)$ where (4.1) and (4.2) are satisfied. Let $\hat{q}_M^N$ be a solution to the problem of minimizing J^N over Q^M. Then for any convergent subsequence $\{\hat{q}_{M_k}^{N_j}\}$ with $N_j, M_k \to \infty$ and $\hat{q}_{M_k}^{N_j} \to \hat{q}$, the limit $\hat{q}$ is a solution to the problem of minimizing J over Q.*

We first consider the above results applied to the case where the Q^M are sets of linear spline interpolants. Let $S^1(\Delta^M)$ represent the subspace of piecewise linear splines corresponding to the partition $\Delta^M = \{x_i\}_{i=0}^M$, $x_i = i/M$, and let $i^M: H^1 \to S^1(\Delta^M)$ denote the standard linear spline interpolating operator. If, in addition to assuming Q_2 is compact in H^1, we assume Q_2 satisfies $Q_2 \subset \{q_2 \in H^2 \,|\, |D^2 q_2|_0 \leqq K\}$, then it is not difficult to show that (4.1) and (4.2) are true for Q^M and i^M as defined above. From a standard representation result for linear interpolating splines [21, p. 12], we infer the continuity of the operator i^M as a mapping from H^1 to H^1, and the compactness of $(Q^M)_2 = i^M(Q_2)$ in H^1 follows immediately. To establish (4.2) we appeal to standard estimates such as [21, (2.17) and (2.18)]. Having verified (4.1) and (4.2), we now state

THEOREM 4.2. *Suppose $Q = Q_2 \times Q_3 \times Q_4 \times Q_5$ is a compact subset of $H^1 \times R^{2+k}$ with Q_2 additionally satisfying $Q_2 \subset \{q_2 \in H^2 \,|\, |D^2 q_2|_0 \leqq K\}$. Let $Q^M \in \mathcal{I}^M(Q)$ where $\mathcal{I}^M \equiv i^M \times (I)^{2+k}$ and i^M is the linear spline interpolating operator. If $\hat{q}_M^N$ represents a solution obtained from minimizing J^N over Q^M, then for any subsequence $\{\hat{q}_{M_k}^{N_j}\}$ of $\{\hat{q}_M^N\}$ such that as $N_j, M_k \to \infty$, $\hat{q}_{M_k}^{N_j} \to \hat{q}$ in Q, we have that $\hat{q}$ is a minimizer for J over Q.*

Under slightly stronger assumptions on the set Q, we can develop a similar convergence result using cubic spline approximations to q_2. Let $S^3(\Delta^M)$ be the subspace of C^2 cubic splines corresponding to the partition Δ^M, and let $i^M: C^1 \to S^3(\Delta^M)$ denote the standard cubic spline interpolating operator (see §§ 2 and 3 for details). We assume Q_2 is a compact subset of C^1 satisfying also $Q_2 \subset \{q_2 \in H^2 \,||D^2 q_2|_0 \leqq K\}$. We again may use standard interpolating spline representations (see [21, p. 45]) to conclude that i^M is a continuous operator from C^1 to H^1, from whence it follows that $(Q^M)_2$ is compact in H^1. To verify (4.2), we again refer to (4.19) and (4.20) in [21]. Thus we have the following theorem.

THEOREM 4.3. *Suppose $Q = Q_2 \times Q_3 \times Q_4 \times Q_5$ is a compact subset of $C^1 \times R^{2+k}$ with $Q_2 \subset \{q_2 \in H^2 \,||D^2 q_2|_0 \leqq K\}$. Let $Q^M = \mathcal{I}^M(Q)$ where $\mathcal{I}^M \equiv i^M \times (I)^{2+k}$, and i^M is the cubic spline interpolating operator. If $\hat{q}_M^N$ represents a solution obtained from minimizing J^N over Q^M, then there exists $\hat{q} \in Q$ which minimizes J over Q, and a subsequence $\{\hat{q}_{M_k}^{N_j}\}$ of $\{\hat{q}_M^N\}$ such that as $N_j, M_k \to \infty$, $\hat{q}_{M_k}^{N_j} \to \hat{q}$.*

In the next section we present numerical findings for double (state and parameter) approximation schemes such as those described here.

5. Numerical implementation and examples. Recall from § 2 that the approximating identification problem is:

Given $\hat{y}$, minimize $J^N(q) = \sum_{i=1}^n |\hat{y}_i - \xi^N(t_i, q)|^2$ over $q \in Q$ (where ξ^N involves point evaluations, in space, of the first component of z^N) subject to $z^N(\cdot\,; q)$ satisfying the following ordinary differential equation:

$$\dot{z}^N(t) = A^N(q) z^N(t) + P^N(q) G(t; q),$$
$$z^N(0) = P^N(q) z_0(q).$$

(We continue our discussions in terms of the transformed system (1.5) and criterion (1.6) even though the numerical examples summarized in this section involve "data" for the original system (1.1)-(1.4) used in conjunction with the criterion (1.7).) Since $z^N \in X^N(q)$, z^N has a representation in terms of the basis elements of $X^N(q)$, $z^N(t; q) = \sum_{i=1}^{2N+3} w_i^N(t; q) \beta_i^N(x; q)$. If we let $[A^N(q)]$ and $[f^N]$ be the matrix and vector representations, respectively of $A^N(q)$ and $P_N(q)f$ (where f is an arbitrary function in $X(q)$) with respect to the basis elements of $X^N(q)$, and let $w^N(t; q) \equiv \text{col}\,(w_1^N(t; q), \cdots, w_{2N+3}^N(t; q))$, then $w^N(t; q)$ solves the following system of ordinary differential equations:

$$\dot{w}^N(t; q) = [A^N(q)] w^N(t; q) + [G^N(t; q)],$$
$$w^N(0; q) = [z_0^N(q)].$$

As in [5], this can be written more explicitly as:

$$Q^N \dot{w}^N(t; q) = K^N w^N(t; q) + R^N G(t; q), \tag{5.1}$$
$$Q^N w^N(0; q) = R^N z_0(q),$$

where Q^N and K^N are matrices, with elements described by $(Q^N)_{i,j} = \langle \beta_i^N, \beta_j^N \rangle_q$, $(K^N)_{i,j} = \langle \beta_i^N, A(q)\beta_j^N \rangle_q$, and $(R^N f)_i = \langle \beta_i^N, f \rangle_q$ for $f \in X(q)$. Due to the form of the B-spline basis elements we have chosen (see § 2), Q^N can be stored as a banded symmetric matrix; this banded, symmetric structure permits more efficient computations and requires less storage space. The matrix K^N has a similar sparse (although not symmetric) structure.

Each element of the matrices Q^N and K^N, and of the vector $R^N f$ depends continuously on q, therefore the representations $[A^N(q)]$ and $[f^N]$ are continuous in q. The basis elements for $X^N(q)$ depend linearly on q, and hence are continuous in q, which implies $q \to P^N(q)f$ and $q \to T^N(t; q)f$ (we note $T^N(t; q) = \exp(A^N(q)t)$ since $A^N(q)$ is a bounded operator) are continuous mappings (recall this was a necessary condition in Theorem 2.1).

We note that in the case where q_1 and q_2 are assumed to be constant, or to have a representation as, for example, a linear combination of spline elements, then the computations can be done more efficiently; in such cases, the numerical quadratures required to compute the inner products which form Q^N and K^N need be performed only once for each N. Then, to construct Q^N and K^N the appropriate multiples or linear combinations of these stored values are computed.

Many of the computations in the software package used to generate the following examples were done with IMSL subroutines (for example, the optimization, and the solution of the differential equation in (5.1)). Although much modification was necessary for the present application, the core of the package was developed by James Crowley [12]. The examples were computed either on an IBM VM/370, or a CDC 6600.

The optimization is done using a Levenberg-Marquardt algorithm. For fixed N, each iteration in the optimization is performed as follows. Given q, beginning at time zero ($t_1 = 0$), a Cholesky decomposition method is used to solve (5.1) for $\dot{w}^N(t; q)$ and $w^N(t_1; q)$; this is then integrated using Gear's method to obtain $w^N(t_2; q)$. We use the components of the vector $w^N(t_2; q)$ to recover $z_1^N(t_2; q)$ as the linear combination of the first components of the basis elements. The vector $\xi^N(t_2, q)$ is $z_1^N(t_2; q)$ evaluated at each of the spatial observation points. Using $w^N(t_2; q)$ as the initial value, (5.1) is solved again for $t \in [t_2, t_3]$, $\xi^N(t_3, q)$ is obtained, and this procedure is repeated until $\xi^N(t_i, q)$ has been evaluated at all times t_i; then $J^N(q)$ can be computed as the sum of the residuals, $|\hat{y}_i - \xi^N(t_i, q)|^2$. The data $\{\hat{y}_i\}$ is read in and stored at the beginning.

In the selection of examples to follow, the "data" has been generated with an independent finite difference scheme (an implicit method [19] was modified for our boundary conditions and the variable coefficient, $q_2(x)$) applied to the model with a priori chosen "true" values q^* of the parameters. In all examples, $q_1(x)$ is taken to be identically one (this is done to reduce ill-posedness, as mentioned in § 1). We begin each example with an initial guess, and a value of N; we solve (ID^N), to get converged values, $\bar{q}^N$ (these are numerical approximations (to $\hat{q}^N$) that result from the Levenberg-Marquardt algorithm), which we then use as starting values for the next value of N. So, in Example 5.1 (below) we begin with $N = 4$ and a guess q^0, and generate $\bar{q}^4$. We then start with $\bar{q}^4$ at $N = 8$, and generate $\bar{q}^8$.

The examples we present here are simple and are chosen mainly to illustrate how the scheme we have discussed theoretically performs when one is attempting to estimate boundary parameters or spatially varying elastic modulus. We have carried out numerous other numerical experiments to test the efficacy of the ideas. For example, we have found the algorithms to be rather robust with regard to the initial parameter guess q^0. That is, the integrity of the method is preserved in examples similar to Examples 5.1, 5.2 even though one starts with initial guesses which are as much as 200% in error from the "true" values. The optimization algorithm requires more iterations, CPU time is increased, but we still obtain convergence to accurate estimates of the parameters. Moreover, our theoretical and computational considerations can be modified to treat more realistic problems in which one has to estimate discontinuities in the elastic modulus E. Some initial numerical findings on such problems are reported in [4].

We remind the reader that the computations reported on below were carried out using "data" for the system (1.1)-(1.4) with criterion (1.7) and an appropriate approximate criterion for the Nth problem. (We have also successfully tested the methods on similar examples with the transformed system (1.5) and criterion (1.6), although, of course, this is not the typical formulation of the inverse problem for which data will be available.)

Example 5.1. For our first example we used "data" consisting of observations at $x=0$ and times $t=.25, .5, .75, \cdots, 2.0$. This is meant to simulate the situation in "surface seismic" experiments where only data at the surface are available. The source term was chosen as $s(t;\tilde{k})=q_5(1-e^{-5t})\,e^{q_6 t}$, a function which rises to a peak quickly and then gradually diminishes to zero; again this attempts to mimic the situation in seismic experiments. We assume vanishing initial conditions and seek to estimate a constant elastic modulus q_2 as well as the boundary parameters q_3, q_4 and the source parameters $\tilde{k}=(q_5, q_6)$. True values along with our estimates are given in the results summarized in Table 5.1. Graphs comparing the true solution at the surface $u(t, 0; q^*)$ with the approximate solution $u^N(t, 0; \bar{q}^N)$ are shown in Fig. 5.1. We also tested the method on this example using "data" for more spatial observations (data at $x=0, .5, 1.0$ and $t=.5, 1.0, 1.5$) with our findings given in Table 5.2. Based on these computations and a number of other tests, we suggest that there appears to be little difficulty with our method in the case where only one spatial observation is available as long as a sufficient number of time observations are available.

Example 5.2. In this example we compared the performance of our method on problems with "noisy data" with that on those without noise in the data. We used the same source term as that in Example 5.1, zero initial conditions, but a "true" parameterized elastic modulus $E(x)=\frac{3}{2}+1/\pi \arctan[q_{21}(x-q_{22})]$. Data for observations at $x=$ 0.0, 0.5, 1.0 and $t=.416, .832, 1.248, 1.664, 2.08, 2.496$ were used. Results for the case of data without noise are summarized in Table 5.3, while findings employing data with a noise level of approximately 3% are given in Table 5.4. In both cases, the method converges nicely but as one might expect, the converged values of the parameters do

not agree with the true parameters in the case of noisy data. In Figs. 5.2, 5.3, 5.4 and 5.5, we graphically depicted the curves for $\bar{E}^N$ and E^* in several cases.

Example 5.3. In this example we illustrate the ideas discussed in § 4 regarding parameter approximation in the set of linear and cubic splines. We do not assume an a priori shape for the elastic modulus $E(x)$, the "true" value of which is given by $E^*(x)=\frac{3}{2}+\tanh[6(x-.5)]$. Rather we first search for E in the class of linear spline approximations to E^*. We then carry out the search using cubic splines. Initial conditions are $u(0,x)=e^x$, $u_t(0,x)=-3\,e^x$ and no source term was assumed (i.e., $s\equiv 0$). Data for observations at 3 spatial points ($x=0.0$, 0.5, 1.0) and 6 time points ($t=.16, .32, \cdots, 1.0$) were used. Figure 5.6 depicts graphs of the true modulus E^*, the initial guess E^0, and the converged estimate $\bar{E}^4$ where we used linear splines (with 4 basis elements—$M=3$ in the notation of § 4) to approximate E and cubic splines ($N=4$) to approximate the state. At the same time we searched for the boundary parameters q_3, q_4 (true values $q_3^*=-1.0$, $q_4^*=3.0$) and obtained converged estimates $\bar{q}_3^4=-1.05425$, $\bar{q}_4^4=3.3576$ with a CPU time of 38 seconds and R.S.S. $=0.255\times10^{-2}$.

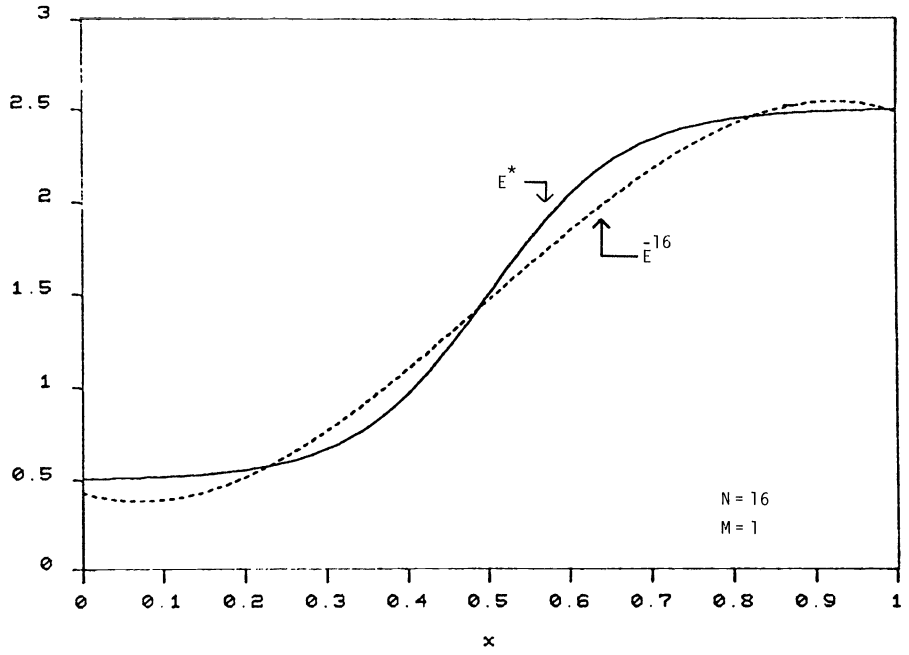

FIG. 5.8

Figure 5.7 contains graphs similar to those in Fig. 5.6 except $N = 16$ was used in the state approximations. Boundary parameter estimates corresponding to $\bar{E}^{16}$ were $\bar{q}_3^{16} = -1.10063$, $\bar{q}_4^{16} = 3.07049$ with CPU time of 118 seconds and R.S.S. $= 0.472 \times 10^{-4}$. The error (in the H^0 norm) in estimating E^* in each case was calculated to be $|E^* - \bar{E}^4| = .081$ and $|E^* - \bar{E}^{16}| = .030$.

We carried out similar calculations for the same example in which we employed cubic splines ($M = 1$ in the notation of § 4, i.e. 4 basis elements) for the parameter approximations. The graphs of E^*, E^0 and $\bar{E}^{16}$ are compared in Fig. 5.8. In this second test we did not search on the boundary parameters q_3, q_4 but rather held them fixed at their "true" values. The error at the converged parameter was $|E^* - \bar{E}^{16}| = .109$, with R.S.S. $= 0.293 \times 10^{-2}$ and a CPU time of 178 seconds.

6. Concluding remarks. We have presented in this paper both theoretical and numerical results using some of our ideas involving spline approximations for inverse or parameter estimation problems for hyperbolic systems. Among the novel features is the capability of estimating variable coefficients and boundary parameters with methods that are both theoretically sound and readily implementable. Our techniques (reported on earlier, [7]) involve the use of parameter dependent basis elements for the approximation subspaces in a Galerkin type semidiscrete scheme.

While we have focused on 1-dimensional space domain problems here, our ideas are in principle applicable to problems in 2- and 3-dimensional domains. We have devoted some thought to such problems in connection with use of basis elements that are tensor products of 1-D elements. These ideas offer some promise, given the parallelism that would be inherent in the resulting algorithms and given the emerging technology related to supercomputers and array processors. However, there are other ideas that also offer great promise; in particular, there are those involving spectral

methods such as the tau-Legendre for which we have reported preliminary findings in [4]. A fundamental difference between these techniques and those proposed in this paper is that in the tau-Legendre one does not require the approximation subspace basis elements to satisfy the boundary conditions. Instead the boundary conditions are essentially imposed as side constraints adjoined to the Galerkin type differential equations. This can offer significant computational advantages, especially in higher dimensional domain problems. We are currently pursuing investigations of these ideas.

The assumption of compactness on Q in our presentation was used to guarantee convergence results within our theoretical framework. It can also be used to establish stability results (i.e., a type of continuous dependence of parameter estimates $\hat{q}$ on the observations $\{\hat{y}_i\}$). When specifying a typical parameter set Q, this compactness requirement will often be manifested in terms of functional parameter constraints (e.g. bounds on certain derivatives) which can be important with regard to implementation. Thus, while we did not find it necessary to impose any such constraints in the algorithms used in producing the numerical results discussed in § 5 (this, we conjecture, was because the examples we considered here were relatively simple and rather well behaved—e.g. no other local extremals near the "true" values q^*), it is sometimes necessary to take them into consideration to obtain acceptable numerical performance. We have carried out numerical experiments with other problems for which this is a critical point, and satisfactory numerical performance will be guaranteed only if a constrained optimization procedure is employed. The compactness-related constraints can and should be implemented in certain cases. We are currently investigating further these questions and will report on our findings elsewhere. Here we just observe that the "compactness of Q" is an important computational as well as theoretical feature of our approach.

In closing we remark that the theoretical results presented above only guarantee convergence of subsequences $\{\hat{q}^{N_k}\}$ to a minimizer $\hat{q}$ for J. But for the class of problems investigated here and for a number of other types of inverse problems we have studied, we have in practice observed (numerically) convergence of the original sequence $\{\hat{q}^N\}$. This has been our experience even in examples with noisy data and may be due in many cases to the fact that the original problem of minimizing J over Q has a unique solution $\hat{q}$. In this situation, elementary and quite standard arguments can be employed to actually establish convergence of $\{\hat{q}^N\}$ itself to $\hat{q}$.

Acknowledgments. The authors would like to express their sincere appreciation to G. Moeckel (Mobil Oil Co.), R. Ewing (U. Wyoming), and K. Kunisch (U. Graz) for stimulating discussions during the course of some of the work reported above. They are also grateful for the support and hospitality received during their visit at Southern Methodist University where a substantial portion of the investigations reported on here were carried out.

GENERALIZED SOLUTIONS OF CONSTRAINED OPTIMIZATION PROBLEMS*

TOMÁŠ ROUBÍČEK†

Abstract. A constrained optimization problem on a uniform space X is considered. Under certain assumptions, the problem may be extended onto the completion of X with respect to the precompact modification of the original uniformity on X, which yields the generalized problem. It is shown that the solution of the perturbed classical problem (or of the penalized classical problem) converges to the solution of the generalized problem, which makes the generalized problem more convenient than the classical one. Finally, the general framework is demonstrated in special cases in normed linear spaces.

Key words. optimization, generalized solution, stability

1. Introduction and notation. In [6] the unconstrained optimization problem on a noncompact domain X was investigated with the aim to construct a "natural" extension of the domain, denoted $\bar{X}$, which guarantees the existence of the generalized solution (which is an element of $\bar{X}$) together with the stability of the set of the generalized solutions with respect to certain perturbations of the function to be minimized. The domain X was considered as a uniform space and the extended domain $\bar{X}$ was constructed as a completion of X with respect to another (admissible) uniformity. The existence and stability of the generalized solution is then guaranteed if the later uniformity is sufficiently coarse. Moreover, there exists such a uniformity which is optimal from the stability point of view.

In this paper the approach mentioned above is applied to a constrained optimization problem where the situation is more complicated than that in the unconstrained case. In this section the basic notation and some results from [6], required in what follows, are introduced. The "classical" constrained optimization problem, its perturbed version, the generalized problem, and basic relations between them are given in § 2. In the further sections, a characterization of the set of the generalized solutions using the level sets of the classical problem, some convergence results for the perturbed classical problem, and for the unconstrained problem arising from the use of the well-known penalty-function method are stated. The general framework exploiting the uniform-space theory, used in §§ 2–5, is somewhat unusual in optimization; in § 6 it is applied to two special cases, both employing the more usual normed-linear-space notation.

Now, we start with some definitions (see e.g. [1]). The filter $\mathcal{F}$ on a set M is a nonempty collection of the nonempty subsets of M such that $A \in \mathcal{F}$, $B \supset A \Rightarrow B \in \mathcal{F}$ and $A, B \in \mathcal{F} \Rightarrow A \cap B \in \mathcal{F}$. Let X be a completely regular Hausdorff topological space endowed with an admissible uniformity $\mathcal{U}_X$. It should be recalled that the uniformity $\mathcal{U}_X$ on X is a filter on $X \times X$ with the properties: $\forall U \in \mathcal{U}_X: \Delta \subset U$, $U^{-1} \in \mathcal{U}_X$ and $\exists V \in \mathcal{U}_X$, $V^2 \subset U$, where $\Delta = \{(x_1, x_2) \in X^2;\ x_1 = x_2\}$, $U^{-1} = \{(x_1, x_2) \in X^2;\ (x_2, x_1) \in U\}$ and $V^2 = \{(x_1, x_2) \in X^2;\ \exists x_3,\ (x_1, x_3) \in V,\ (x_3, x_2) \in V\}$. The elements of the uniformity are called entourages. The uniformity $\mathcal{U}_X$ is admissible iff it generates the topology of X. $\mathcal{U}_X$ is precompact iff $\forall U \in \mathcal{U}_X \exists$ a finite set $S \subset X$: $U(S) = X$, where $U(S) = \{x \in X;\ \exists x_1 \in S,\ (x, x_1) \in U\}$. Also, $\mathcal{U}_X$ is precompact iff the completion of X with

respect to $\mathcal{U}_X$ is compact. The finest from the precompact admissible uniformities on X which are coarser than $\mathcal{U}_X$, denoted $\mathcal{U}_X^*$, is called the precompact modification of $\mathcal{U}_X$. $\mathcal{U}_X^*$ is also the coarsest admissible uniformity on X which makes uniformly continuous all the functions $X \to [0, 1]$ which are uniformly continuous with respect to $\mathcal{U}_X$. A typical situation in most applications is the case when X is a normed linear space (with the norm denoted $\|\cdot\|_X$) and $\mathcal{U}_X$ is generated by means of the base $\{V_\varepsilon, \varepsilon > 0\}$, where $V_\varepsilon = \{(x_1, x_2) \in X^2; \|x_1 - x_2\|_X < \varepsilon\}$.

In [6] the minimization problem for a l.s.c. (lower semicontinuous) function $f: X \to \bar{R}$ is investigated; $\bar{R}$ denotes the usual two-point compactification of the real line, i.e. $\bar{R} = R \cup \{-\infty, +\infty\}$. As the extended domain $\bar{X}$ the completion of X with respect to $\mathcal{U}_X^*$ is taken. Obviously, since $\bar{X}$ is compact, there is a unique admissible uniformity on $\bar{X}$, denoted $\mathcal{U}_{\bar{X}}$, the entourages of which will be denoted with the bar, e.g. $\bar{U}$. Also elements of $\bar{X}$ will be denoted with the bar, e.g. $\bar{x}$. Note that the trace of $\mathcal{U}_{\bar{X}}$ on X is just $\mathcal{U}_X^*$, especially, $\bar{U} \cap X^2 \in \mathcal{U}_X^*$ for $\bar{U} \in \mathcal{U}_{\bar{X}}$. We can naturally extend f on $\bar{X}$ (the extension will be denoted again by f without any confusion) by the formula $f(\bar{x}) = \liminf_{x \to \bar{x}, x \in X} f(x)$; $x \to \bar{x}$ means, of course, the convergence in $\bar{X}$. Clearly, we have $\inf f(\bar{X}) = \inf f(X)$. An element $\bar{x} \in \bar{X}$ is said to be the generalized solution of the considered minimization problem iff $f(\bar{x}) = \inf f(X)$. The (nonempty) set of the generalized solutions is stable with respect to the perturbations of f in certain topology on the space of the functions $X \to \bar{R}$. This topology is induced by the uniformity on the space of the epigraphs which can be constructed by means of the uniformity $\mathcal{U}_X \times \mathcal{U}_{\bar{R}}$; for details see [6]. Moreover, the uniformity $\mathcal{U}_X^*$ is the finest uniformity by means of which the stable set of the generalized solutions can be constructed for arbitrary function f, see [6, Thm. 3]. The uniformity $\mathcal{U}_X^*$ has also the important property: $\forall A \subset X$, $\forall U \in \mathcal{U}_X$, $\exists V \in \mathcal{U}_X^*$: $V(A) \subset U(A)$; in other words, for every $A \subset X$ and $U \in \mathcal{U}_X$ there exists a $\mathcal{U}_X$-uniformly continuous function $\psi: X \to [0, 1]$ such that $\psi(A) = 0$ and $\psi(X \setminus U(A)) = 1$. This property of $\mathcal{U}_X^*$ enables us to describe certain sets in $\bar{X}$ by means of the original uniformity $\mathcal{U}_X$, which is remarkable because the uniformity $\mathcal{U}_X^*$ and the extended domain $\bar{X}$ have been defined in a somewhat nonconstructive manner, see also Remark in § 3.

For $\bar{x} \in \bar{X}$ we denote $\mathcal{N}(\bar{x})$ the filter on X which is the trace of the neighbourhood filter of $\bar{x}$ in $\bar{X}$. $\mathcal{N}(\bar{x})$ is a maximal $\mathcal{U}_X$-round filter on X, and the mapping $\bar{x} \mapsto \mathcal{N}(\bar{x})$ defines a one-to-one correspondence between the points in $\bar{X}$ and the filters of the mentioned property. Recall that the filter $\mathcal{F}$ on X is said to be $\mathcal{U}_X$-round (see [2]) iff $\forall A \in \mathcal{F} \exists B \in \mathcal{F} \exists V \in \mathcal{U}_X$: $V(B) \subset A$. Of course, $\mathcal{N}(\bar{x})$, being maximal in the class of the $\mathcal{U}_X$-round filters on X, can be constructed generally by means of the axiom of choice only. Still other characterizations of $\mathcal{N}(\bar{x})$ can be stated (see [6, Thm. 4]) but they use the uniformity $\mathcal{U}_X^*$ instead of the axiom of choice.

For $M \subset \bar{X}$ denote $\mathcal{N}(M) = \cap \{\mathcal{N}(\bar{x}); \bar{x} \in M\}$. Clearly, $\mathcal{N}(M)$ is again a filter on X. Moreover, let M_1, M_2 be closed subsets of $\bar{X}$, then $M_1 \neq M_2$ implies $\mathcal{N}(M_1) \neq \mathcal{N}(M_2)$. Thus the closed subsets of $\bar{X}$ are characterized by their filters $\mathcal{N}(\cdot)$, which will be employed in Theorem 3.

2. The classical and the generalized optimization problems. In the case of the constrained optimization problem, very little may be said under the condition that the mapping to the constraints is only continuous as usual in the classical theory of optimization. Here, the uniform continuity will be exploited. First, we will treat a general framework, and afterwards, in § 6, we will apply the obtained results to more usual and detailed structures.

Let X, Y be the uniform Hausdorff spaces endowed with the uniformities $\mathcal{U}_X$, $\mathcal{U}_Y$, respectively; $f: X \to \bar{R}$ be a l.s.c. function; $F: X \to Y$ be a uniformly continuous mapping; and C be a subset of Y. We shall deal with the classical optimization problem, denoted P_C:

$$P_C \quad \begin{array}{l} \text{minimize } f(x), \\ \text{subject to } x \in X, \qquad F(x) \in C. \end{array}$$

As usual, we define the admissible set $S_{ad}P_C = \{x \in X;\ F(x) \in C\}$, the value $\inf P_C = \inf f(S_{ad}P_C)$, and the set of the classical solutions $\operatorname{Arginf} P_C = \{x \in S_{ad}P_C;\ f(x) = \inf P_C\}$. Also we use the set of the approximate classical solutions $\operatorname{Arginf}_\varepsilon P_C = \{x \in S_{ad}P_C;\ f(x) \leqq \inf P_C + \varepsilon\}$, with $\varepsilon > 0$. From the "practical" or "engineering" point of view, some perturbed problems are very interesting. We employ the perturbations of the set C, namely in the form $\tilde{C} = V(C)$, $V \in \mathcal{U}_Y$. For the perturbed problem $P_{\tilde{C}}$ thus obtained, we can again define $S_{ad}P_{\tilde{C}}$, $\inf P_{\tilde{C}}$, and $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$ by replacing C by $\tilde{C}$ in the corresponding definitions for the problem P_C.

In most problems of "technical" origin, it suffices to find a solution from $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$, because such solution is "almost" optimal and, at the same time, the constraints are fulfilled with accuracy prescribed in advance, which is realistic in the technical problems. Similar approach has been already used in the book of J. Warga [7], in which, however, a specific structure of the optimal control problems on certain function spaces has been employed (our classical problems correspond to those which are named "original" in [7], and the generalized problems introduced below correspond roughly to the "extended" problems). There is, however, a fundamental difference between these two mentioned approaches because the extended problem in [7] is obtained by exploiting a topology which is weaker than the initial one, while our generalized problem will be obtained using the initial topology only.

Since the sets $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$ are of "technical" importance, there is naturally a question whether there exists a limit (in certain sense) when $\varepsilon \to 0$ and $\tilde{C} \to C$. Note that $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$ generally does not converge to $\operatorname{Arginf} P_C$. Thus we are motivated to introduce a generalized problem which is, in fact, a more natural setting of the classical problem P_C. To construct this generalized problem, denoted GP_C, we extend f and F on the space $\bar{X}$ (= the completion of X with respect to $\mathcal{U}_X^*$). The extension of f has been already defined in § 1. It is easy to see that F, being uniformly continuous with respect to $\mathcal{U}_X$ and $\mathcal{U}_Y$, is uniformly continuous with respect to $\mathcal{U}_X^*$ and $\mathcal{U}_Y^*$ as well. Denoting $\bar{Y}$ the completion of Y with respect to $\mathcal{U}_Y^*$, we may extend $F: \bar{X} \to \bar{Y}$ (the extended mapping is denoted again by F) in such a manner that F is continuous on $\bar{X}$. As X is dense in $\bar{X}$, this extension is unique. It should be emphasized that $\bar{X}$, $\bar{Y}$, $\bar{R}$ are compact, which together with the continuity of F and l.s.c. of f yields the base for most of the following results.

We introduce the generalized problem:

$$GP_C \quad \begin{array}{l} \text{minimize } f(\bar{x}) \\ \text{subject to } \bar{x} \in \bar{X}, \qquad F(\bar{x}) \in \bar{C} = \operatorname{cl}_{\bar{Y}} C, \end{array}$$

$\operatorname{cl}_{\bar{Y}} C$ denotes the closure of C in $\bar{Y}$. For this problem we define the admissible set, the value and the set of the generalized solutions by a straightforward manner, i.e. $S_{ad}GP_C = \{\bar{x} \in \bar{X};\ F(\bar{x}) \in \bar{C}\}$, $\inf GP_C = \inf f(S_{ad}GP_C)$ and $\operatorname{Arginf} GP_C = \{\bar{x} \in S_{ad}GP_C;\ f(\bar{x}) = \inf GP_C\}$.

The optimization problem is said to be nontrivial iff its value is less than $+\infty$. Especially, the nontrivial problem has a nonempty admissible set. Basic relationship between the optimization problems defined above is given in the following theorem.

THEOREM 1. *Let P_C be nontrivial, $\tilde{C} = V(C)$, $V \in \mathcal{U}_Y$, $\varepsilon > 0$. Then $P_{\tilde{C}}$ and GP_C are nontrivial, too*; $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$ *and* $\operatorname{Arginf} GP_C$ *are nonempty*; $\inf P_C \geqq \inf GP_C \geqq \inf P_{\tilde{C}}$; *and*

$$X \cap \operatorname{Arginf} GP_C = \begin{cases} \varnothing & \text{if } \inf P_C > \inf GP_C, \\ \operatorname{Arginf} P_{\mathrm{cl}_Y C} & \text{if } \inf P_C = \inf GP_C. \end{cases}$$

Proof. Clearly, $P_{\tilde{C}}$ and GP_C are nontrivial and $\operatorname{Arginf}_\varepsilon P_{\tilde{C}}$ is nonempty. $\operatorname{Arginf} GP_C$ is nonempty, as well, because f is l.s.c. on a compact set $S_{ad}GP_C$. Also the inequality $\inf P_C \geqq \inf GP_C$ is obvious. To prove $\inf GP_C \geqq \inf P_{\tilde{C}}$, we consider $\bar{x} \in \operatorname{Arginf} GP_C$ and $\bar{V} \in \mathcal{U}_{\bar{Y}}$ such that $V^2(C) \subset \tilde{C}$ with $V = \bar{V} \cap Y^2$. Since F is continuous on $\bar{X}$, there is $\bar{U} \in \mathcal{U}_{\bar{X}}$ such that $F(\bar{U}(\bar{x})) \subset \bar{V}(\bar{C})$. At the same time, $\inf f(X \cap \bar{U}(\bar{x})) \leqq f(\bar{x}) = \inf GP_C$. Thus for any $\varepsilon > 0$ there is $x \in X: f(x) \leqq \inf GP_C + \varepsilon$ and $F(x) \in \bar{V}(\bar{C}) \cap Y \subset V^2(C) \subset \tilde{C}$. As ε can be considered arbitrarily small, we have $\inf P_{\tilde{C}} \leqq \inf GP_C$. The last assertion of the theorem is straightforward. □

The situation in the constrained optimization problems differs essentially from that in the unconstrained problems, where the case $\inf P_C > \inf GP_C$ cannot appear (see [6]) and therefore the generalized solutions cannot be "better" than the classical ones. It will be shown in § 6.1 that certain "classical" conditions can guarantee that $\inf P_C = \inf GP_C$. Now, an example for the case $\inf P_C > \inf GP_C$ is given. An example of a similar nature has been given in [7, p. 247]. In our example, the problem P_C is even convex, but noncoercive. Problems which are coercive but nonconvex can be constructed, as well. To construct the example, we consider $X = l_2$, i.e. the Hilbert space of the squared summable sequences denoted $x = (x_1, x_2, \cdots)$; $Y = \bar{R}$; $f(x) = \sum_i -2^{-i}x_i$; $F(x) = \sum_i 2^{-5i}x_i^2$; and C is the set of nonpositive reals. Obviously, $S_{ad}P_C = \{0\}$ and $\inf P_C = 0$. Taking the sequence $x^{(j)}$, $j = 1, 2, \cdots$, where $x_i^{(j)} = 2^{2i}$ for $i = j$ and vanishes for $i \neq j$, we have $f(x^{(j)}) = -2^j$ and $F(x^{(j)}) = 2^{-j}$. In consequence of the compactness of $\bar{X}$, the sequence $\{x^{(j)}\}$ has a cluster point $\bar{x} \in \bar{X}$, for which we have $f(\bar{x}) = -\infty$ and $F(\bar{x}) = 0$; thus $\inf GP_C = -\infty$.

3. A characterization of $\inf GP_C$ and $\operatorname{Arginf} GP_C$ by the level sets. In what follows, we will consider the classical problem P_C to be nontrivial. For $a \in \bar{R}$ and $V \in \mathcal{U}_Y$, we denote the level set of the problem P_C: $\operatorname{lev}(a, V) = \{x \in X; f(x) \leqq a, F(x) \in V(C)\}$. By means of these level sets, a characterization of the value and of the set of the solutions of the generalized problem is given in Theorems 2 and 3, respectively.

THEOREM 2. *The collection* $\{\operatorname{lev}(a, V); a > a_0, V \in \mathcal{U}_Y\}$ *is a filter base on X iff* $a_0 \geqq \inf GP_C$.

Proof. For $a_0 < a < \inf f(X)$ the set $\operatorname{lev}(a, V)$ is empty, and therefore the collection in question is not a filter base. Now, consider $\inf f(X) \leqq a_0 < \inf GP_C$. Then the sets $\{\bar{x} \in \bar{X}; f(\bar{x}) \leqq a_0\}$ and $\{\bar{x} \in \bar{X}; F(\bar{x}) \in \bar{C}\}$ are disjoint and compact in $\bar{X}$, hence they have disjoint open neighbourhoods A_1, A_2, respectively. As $\bar{X} \setminus A_1$ is compact and f is l.s.c. on $\bar{X}$, $\inf f(\bar{X} \setminus A_1) > a_0$. As $\bar{X} \setminus A_2$ is compact, $F(\bar{X} \setminus A_2)$ is compact and disjoint with $\bar{C}$. Thus we see that for sufficiently small $\varepsilon > 0$ and $\bar{V} \in \mathcal{U}_{\bar{Y}}$, the sets $\{\bar{x} \in \bar{X}; f(\bar{x}) \leqq a_0 + \varepsilon\} \subset A_1$ and $\{\bar{x} \in \bar{X}; F(\bar{x}) \in \bar{V}(\bar{C})\} \subset A_2$ are disjoint, as well. Taking $V = \bar{V} \cap Y^2$, $\operatorname{lev}(a_0 + \varepsilon, V)$ is empty; thus the collection investigated cannot be a filter base.

On the other hand, for $a_0 \geqq \inf GP_C$, the considered level sets are nonempty, as it has been proved already in Theorem 1, and it is easy to see that they form a filter base. □

THEOREM 3. $\mathcal{N}(\operatorname{Arginf} GP_C) = \{U(\operatorname{lev}(a, V));\ U \in \mathcal{U}_X,\ V \in \mathcal{U}_Y,\ a > \inf GP_C\}$.

Proof. Due to Theorem 2 the collection in the right-hand side is a filter on X. First, consider any $A = U(\operatorname{lev}(a, V))$. Note that we may choose $U \in \mathcal{U}_X^*$ and $V \in \mathcal{U}_Y^*$ without any enlargement of A; cf. § 1. Taking symmetric $\bar{U} \in \mathcal{U}_{\bar{X}}$, $\bar{V} \in \mathcal{U}_{\bar{Y}}$, and a_1 such that $\bar{U}^2 \cap X^2 \subset U$, $\bar{V}^3 \cap Y^2 \subset V$, $\inf GP_C < a_1 < a$, we investigate the set $B = \bar{U}(\{\bar{x} \in \bar{X};\ f(\bar{x}) \leqq a_1,\ F(\bar{x}) \in \bar{V}(\bar{C})\})$. Clearly, $B \supset \bar{U}(\operatorname{Arginf} GP_C)$. Let $x \in B \cap X$. Then there is $\bar{x} \in \bar{X}$: $x \in \bar{U}(\bar{x})$, $f(\bar{x}) \leqq a_1$, $F(\bar{x}) \in \bar{V}(\bar{C})$. Due to the continuity of F on $\bar{X}$ and the definition of the extension of f, $\exists x_1 \in X$: $x_1 \in \bar{U}(\bar{x})$, $f(x_1) \leqq a$, $F(x_1) \in \bar{V}^2(\bar{C})$, and also $F(x_1) \in \bar{V}^3(C)$, hence $x \in A$. In other words, $B \cap X \subset A$ and B is a neighbourhood of $\operatorname{Arginf} GP_C$, thus $A \in \mathcal{N}(\bar{x})$ for every $\bar{x} \in \operatorname{Arginf} GP_C$.

Conversely, let $A \in \mathcal{N}(\operatorname{Arginf} GP_C)$. Then $\bar{A} = \operatorname{cl}_{\bar{X}} A$ is a neighbourhood of $\operatorname{Arginf} GP_C$. Since $\operatorname{Arginf} GP_C$ is compact, for a sufficiently small $\bar{U} \in \mathcal{U}_{\bar{X}}$, we have $\bar{A} \supset \bar{U}^2(\operatorname{Arginf} GP_C)$ and $A \supset \bar{U}^2(\operatorname{Arginf} GP_C) \cap X$. To prove the last inclusion, let us suppose the contradiction, i.e. that for every $\bar{U} \in \mathcal{U}_{\bar{X}}$ the set $N_{\bar{U}} = (X \setminus A) \cap \bar{U}^2(\operatorname{Arginf} GP_C)$ is nonempty. Consider the set $M_{\bar{U}} = \bar{U}^2(N_{\bar{U}}) \cap \operatorname{Arginf} GP_C$. For a symmetric entourage $\bar{U}$, $M_{\bar{U}}$ is nonempty. Note that it is generally not true if $\bar{U}$ is not symmetric. Furthermore, $\{M_{\bar{U}};\ \bar{U}$ be symmetric $\in \mathcal{U}_{\bar{X}}\}$ is the base of a filter on $\operatorname{Arginf} GP_C$ which has a cluster point $\bar{x} \in \operatorname{Arginf} GP_C$, because $\operatorname{Arginf} GP_C$ is compact. For this $\bar{x}$, $(X \setminus A) \cap \bar{U}^3(\bar{x})$ is nonempty for every $\bar{U} \in \mathcal{U}_{\bar{X}}$, which shows that $A \notin \mathcal{N}(\bar{x})$. This is, however, the desired contradiction.

To go on with the proof, we consider the sets $M = \bar{X} \setminus \bar{U}(\operatorname{Arginf} GP_C)$ and $L(\varepsilon, \bar{V}) = \{\bar{x} \in \bar{X};\ f(\bar{x}) \leqq \inf GP_C + \varepsilon,\ F(\bar{x}) \in \bar{V}(\bar{C})\}$. We may suppose $\bar{U}$ to be open, hence M is compact. We will prove that $\exists \varepsilon > 0$ and $\bar{V} \in \mathcal{U}_{\bar{Y}}$: $M \cap L(\varepsilon, \bar{V}) = \varnothing$. If it does not hold, $\{M \cap L(\varepsilon, \bar{V});\ \varepsilon > 0,\ \bar{V} \in \mathcal{U}_{\bar{Y}}\}$ will be the base of a filter on M which has a cluster point in M, say $\bar{x}$. For this $\bar{x}$ we have $f(\bar{x}) \leqq \inf GP_C$ and $F(\bar{x}) \in \bar{C}$, thus $\bar{x} \notin M$, which is, however, the contradiction. Hence for sufficiently small $\varepsilon > 0$ and $\bar{V} \in \mathcal{U}_{\bar{Y}}$ we have $L(\varepsilon, \bar{V}) \subset \bar{U}(\operatorname{Arginf} GP_C)$. Therefore $A \supset \bar{U}^2(\operatorname{Arginf} GP_C) \cap X \supset \bar{U}(L(\varepsilon, \bar{V})) \cap X = U(\operatorname{lev}(\inf GP_C + \varepsilon, V))$ with $U = \bar{U} \cap X^2 \in \mathcal{U}_X$, $V = \bar{V} \cap Y^2 \in \mathcal{U}_Y$. □

Remark. The filters $\mathcal{N}(\bar{x})$, being maximal $\mathcal{U}_X$-round, can be "constructed" either by means of the axiom of choice, at least if $\bar{x} \notin X$, or by means of the uniformity $\mathcal{U}_X^*$ (see [6, Thm. 4]), which is again of a nonconstructive nature. On the other hand, the characterization of $\mathcal{N}(\operatorname{Arginf} GP_C)$ by Theorem 3 may be considered as constructive because it does not use either the axiom of choice or the uniformity $\mathcal{U}_X^*$. Thus Theorem 3 gives certain "constructive" information about $\operatorname{Arginf} GP_C$, while there does not exist any possibility to give such a characterization for the element of $\operatorname{Arginf} GP_C$.

4. Some convergence results for the perturbed classical problem. In this section, it is shown that the value and the set of the approximate solutions of the perturbed classical problem $P_{\tilde{C}}$ converge just to the value and to the set of the generalized solutions of the problem GP_C, respectively. Thus the generalized problem GP_C may be considered as a more natural setting of the investigated optimization problem than its classical formulation P_C. The convergence results are summarized in the following theorem.

THEOREM 4. *Let $\delta > 0$ and $\bar{U} \in \mathcal{U}_{\bar{X}}$ be given. Then for sufficiently small $\varepsilon > 0$ and $V \in \mathcal{U}_Y$ it holds*

$\inf GP_C \geqq \inf P_{\tilde{C}} \geqq \inf GP_C - \delta$,

$\operatorname{Arginf}_\varepsilon P_{\tilde{C}} \subset \bar{U}(\operatorname{Arginf} GP_C)$,

$\operatorname{Arginf} GP_C \subset \bar{U}(\operatorname{Arginf}_\varepsilon P_{\tilde{C}})$, *where* $\tilde{C} = V(C)$.

Proof. Due to Theorem 1, we have $\inf GP_C \geqq \inf P_{\tilde{C}}$. As f is l.s.c. on $\bar{X}$ and $S_{ad} GP_C$ is compact, the set $\{\bar{x} \in \bar{X};\ f(\bar{x}) \geqq \inf GP_C - \delta\}$ is a neighbourhood of $S_{ad} GP_C$. Hence

there is an open entourage $\bar{U}_0 \in \mathcal{U}_{\bar{X}}$ such that $f(\bar{U}_0(S_{ad}GP_C)) \geqq \inf GP_C - \delta$. Using the compactness of $\bar{X} \setminus \bar{U}_0(S_{ad}GP_C)$ in the same manner as in the proof of Theorem 2, we obtain $\bar{V}_1 \in \mathcal{U}_{\bar{Y}}$ such that $\{\bar{x} \in \bar{X};\ F(\bar{x}) \in \bar{V}_1(\bar{C})\} \subset \bar{U}_0(S_{ad}GP_C)$. Taking $V_1 = \bar{V}_1 \cap Y^2$ and $\tilde{C} = V_1(C)$, we have $S_{ad}P_{\tilde{C}} \subset \bar{U}_0(S_{ad}GP_C)$, hence $\inf P_{\tilde{C}} \geqq \inf GP_C - \delta$.

Taking $\bar{V}_2 \in \mathcal{U}_{\bar{Y}}$ and $\varepsilon > 0$ such that $L(\varepsilon, \bar{V}_2) \subset \bar{U}(\operatorname{Arginf} GP_C)$, see the proof of Theorem 3, we obtain $\operatorname{Arginf}_\varepsilon P_{\tilde{C}} \subset \bar{U}(\operatorname{Arginf} GP_C)$ for $\tilde{C} = V_2(C)$ with $V_2 = \bar{V}_2 \cap Y^2$.

It is clear that the first two assertions of Theorem 4 are fulfilled if we choose $V \in \mathcal{U}_Y$ such that $V \subset V_1 \cap V_2$. Moreover, for a sufficiently small V, we have $\inf P_{\tilde{C}} \geqq \inf GP_C - \varepsilon/2$. Consider $\bar{x} \in \operatorname{Arginf} GP_C$ and $\bar{U}_1 \in \mathcal{U}_{\bar{X}}$, $\bar{U}_1 \subset \bar{U}^{-1}$. There is $x \in X$ such that $x \in \bar{U}_1(\bar{x})$, $F(x) \in V(C)$ and $f(x) \leqq \inf GP_C + \varepsilon/2$, and also $f(x) \leqq \inf P_{\tilde{C}} + \varepsilon$. Thus $\bar{x} \in \bar{U}(x)$ and $x \in \operatorname{Arginf}_\varepsilon P_{\tilde{C}}$, which completes the proof. □

5. The penalty-function method. In this section, a general setting of the well-known penalty-function method is investigated. Denoting φ a function $Y \to \bar{R}$ and $\{K_n\}$ an increasing sequence of positive constants tending toward the infinity, we can introduce the sequence of the unconstrained classical optimization problems, denoted $P_{C,n}$, which is created by applying the penalty-function method to the original problem P_C:

$$P_{C,n} \qquad \begin{array}{l} \text{minimize } f_n(x), \\ \text{with } f_n = f + K_n \cdot \varphi \circ F, \\ \text{subject to } x \in X. \end{array}$$

The expression $(-\infty)+(+\infty)$ in the definition of f_n will be avoided due to the assumptions in Theorem 5. As usual, we denote the value $\inf P_{C,n} = \inf f_n(X)$ and the set of the approximate classical solutions $\operatorname{Arginf}_\varepsilon P_{C,n} = \{x \in X;\ f_n(x) \leqq \inf P_{C,n} + \varepsilon\}$. In the classical framework, very little can be said about the convergence when $n \to \infty$, see e.g. [3]. The generalized problem GP_C, however, enables us to give some convergence results. Recall that P_C is supposed to be nontrivial.

THEOREM 5. *Let f be bounded from below by a constant $b > -\infty$; and let $\varphi : Y \to \bar{R}$ fulfill the assumptions: φ is uniformly continuous, $\varphi(C) = 0$, and $\forall V \in \mathcal{U}_Y \exists \delta > 0$: $\varphi(Y \setminus V(C)) \geqq \delta$. Then* $\inf P_{C,n} \nearrow \inf GP_C$ *(monotone convergence). Furthermore, let $x_n \in \operatorname{Arginf}_{\varepsilon(n)} P_{C,n}$ with $\varepsilon(n) \searrow 0$ for $n \to +\infty$. Then the sequence $\{x_n\}$ has a cluster point and each of such cluster points belongs to* $\operatorname{Arginf} GP_C$.

Proof. The sequence $\{\inf P_{C,n}\}$ is nondecreasing, because $f_n \leqq f_m$ for $n \leqq m$, and thus there exists its limit $\lim_{n\to\infty} \inf P_{C,n}$. Clearly, the assumptions imposed on φ guarantee that $\varphi(\bar{y}) = 0$ for $\bar{y} \in \bar{C}$ and $\varphi(\bar{y}) > 0$ for $\bar{y} \notin \bar{C}$. Let $\bar{x} \in \operatorname{Arginf} GP_C$. Then $f(\bar{x}) = \inf GP_C$ and $\varphi(F(\bar{x})) = 0$. Since $\varphi \circ F$ is continuous on $\bar{X}$, there is $\bar{U} \in \mathcal{U}_{\bar{X}}$ (depending on $\varepsilon > 0$) such that $\varphi(F(\bar{U}(\bar{x}))) \leqq \varepsilon$. Also there is $x \in X \cap \bar{U}(\bar{x})$ for which $f(x) \leqq \inf GP_C + \varepsilon$. Therefore, we have $f_n(x) \leqq \inf GP_C + \varepsilon(1 + K_n)$. Thus for every n, $\inf P_{C,n} \leqq \inf GP_C$, because ε has been arbitrarily positive, and obviously $\lim_{n\to\infty} \inf P_{C,n} \leqq \inf GP_C$.

Since $\bar{X}$ is compact, the sequence $\{x_n\}$ has at least one cluster point, say $\bar{x}$. We can easily obtain the estimate $\varphi(F(x_n)) \leqq (\inf P_C - b + \varepsilon(n))/K_n$, which gives $\varphi(F(x_n)) \to 0$ for $n \to \infty$. Thus $\varphi(F(\bar{x})) = 0$, and also $F(\bar{x}) \in \bar{C}$; in other words, $\bar{x} \in S_{ad}GP_C$. Obviously, $\inf P_{C,n} \geqq f(x_n) - \varepsilon(n)$, hence $\lim_{n\to\infty} \inf P_{C,n} \geqq f(\bar{x}) \geqq \inf GP_C$. This shows that $\lim_{n\to\infty} \inf P_{C,n} = \inf GP_C$ and $f(\bar{x}) = \inf GP_C$, i.e. $\bar{x} \in \operatorname{Arginf} GP_C$. □

6. Connections to the classical concepts. In this section two special cases are studied. In both of them, X is a normed linear space (not necessarily complete) with the norm $\|\cdot\|_X$. Naturally, the uniformity $\mathcal{U}_X$ is the norm uniformity, i.e. with the base $\{\{(x_1, x_2) \in X^2;\ \|x_1 - x_2\|_X \leqq \varepsilon\};\ \varepsilon > 0\}$.

6.1. Y is an ordered normed linear space. Let Y be an ordered normed linear space with the norm $\|\cdot\|_Y$ and the ordering $\leqq$. We suppose that the nonpositive cone $C=\{y\in Y;\ y\leqq 0\}$ has a nonempty interior; and $y>0$ will mean that $-y\in \operatorname{int} C$ (this notation is due to [3]). Of course, $\mathcal{U}_Y$ is the norm uniformity on Y.

In this framework the classical optimization problem P_C has the form

$$P_C^{(1)} \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } x\in X, \qquad F(x)\leqq 0. \end{array}$$

Since for $p>0$ $C+p$ is a uniform neighbourhood of C (i.e. $C+p=V(C)$ for some $V\in\mathcal{U}_Y$), the perturbed classical problem may have the form

$$P_{C+p}^{(1)} \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } x\in X, \qquad F(x)\leqq p, \end{array}$$

with $p>0$. Note that for every $V\in\mathcal{U}_Y$ we can choose a sufficiently small $p>0$ such that $C+p\subset V(C)$. Thus due to Theorem 3, the filter $\mathcal{N}(\operatorname{Arginf} GP_C^{(1)})$ has the base $\{A_{\varepsilon,p};\ \varepsilon>0, p>0\}$ with $A_{\varepsilon,p}=\{x\in X;\ \exists x_1\in X,\ \|x-x_1\|_X\leqq\varepsilon,\ f(x_1)\leqq\inf GP_C^{(1)}+\varepsilon,\ F(x_1)\leqq p\}$. Furthermore, Theorem 4 gives the convergence results for $p\searrow 0$ and $\varepsilon\searrow 0$, namely $\inf P_{C+p}^{(1)}\to\inf GP_C^{(1)}$ and $\operatorname{Arginf}_\varepsilon P_{C+p}^{(1)}\to\operatorname{Arginf} GP_C^{(1)}$ (in the sense of Theorem 4).

Now, we can investigate the penalty-function method in more detail. In the function spaces discussed in the sequel, C will be the cone of nonpositive functions on a measurable domain Ω in an Euclidean space. Using the usual quadratic penalty function and the projection onto the cone C, we obtain a special form of the function φ used in § 5, namely $\varphi: y\mapsto\inf_{y_1\leqq 0}\|y-y_1\|_Y^2$. Obviously, this function is uniformly continuous as a function $Y\to\bar{R}$, $\varphi(y)=0$ for $y\leqq 0$ and $\forall p>0\exists\delta>0$; $y\leqq p$ or $\varphi(y)\geqq\delta$. Thus we may apply Theorem 5 to obtain the convergence results. It should be emphasized that for the evaluation of φ we need not know the projection of y onto C. For example, for the case $Y=L_\infty(\Omega)$, i.e. the Banach space of the essentially bounded measurable functions, we can explicitly evaluate $\varphi(y)=((\operatorname{ess\,sup} y)^+)^2$ where $a^+=\max(a,0)$, while the projection of y onto C is generally nonunique. The same situation appears in the space $C^0(\Omega)$, i.e. the Banach space of the continuous functions on a compact domain Ω. On the other hand, the evaluation of φ may be very difficult even if the projection onto C is unique. This is the case $Y=H^1([0,1])$, i.e. the Sobolev space (of the Hilbert type) on the interval $[0,1]$, in which the projection is of very complicated nature, as it was shown in [5].

Remark. In applications, the interior of the cone C is often empty. For example, this is the case $Y=L_2(\Omega)$, i.e. the Hilbert space of the squared integrable functions. In such cases the notation used in this section cannot be employed because $C+p$ is not a uniform neighbourhood of C. However, the general theory may be applied. Using the function $\varphi: y\mapsto\inf_{y_1\in C}\|y-y_1\|_Y^2$, the filter $\mathcal{N}(\operatorname{Arginf} GP_C^{(1)})$ can be generated by the base $\{A_\varepsilon;\ \varepsilon>0\}$ with $A_\varepsilon=\{x\in X;\ \exists x_1\in X, \max(\|x-x_1\|_X; f(x_1)-\inf GP_C^{(1)};\ \varphi(F(x_1)))\leqq\varepsilon\}$. The perturbed problem can take the set $\tilde{C}=\{y\in Y;\ \varphi(y)\leqq\varepsilon\}$ with $\varepsilon>0$. Note that the sets $\tilde{C}$, having nonempty interiors, are quite large in comparison with C, but even such large perturbations are reasonable from the point of view of our theory because they still guarantee the convergence (in the sense of Theorem 4) of the perturbed problems. The penalty-function method can be applied in the same manner as in the case when C has a nonempty interior. If $Y=L_2(\Omega)$, then we can even evaluate $\varphi(y)=\|y^+\|_{L_2(\Omega)}^2$.

6.2. Classical dual problems. Now it will be shown that $\inf GP_C$ equals just to the extremal value of the classical dual problem obtained by the usual augmented-Lagrangian method (for a survey of the duality theory in optimization see [4]). Here C is a nonempty subset of a normed linear space Y endowed with a norm $\|\cdot\|_Y$. The dual problem can be constructed by the general duality theory of Lindberg when considered the generalized pairing $\psi: Y\times R^+\times Y^*\to R$ defined by $\psi(p, r, v)=\langle v, p\rangle + r\cdot\|p\|_Y^a$ where R^+ is the set of nonnegative reals, Y^* is the dual of Y, $\langle\cdot,\cdot\rangle$ is the pairing between Y^* and Y, and $a>0$. The perturbed objective $\Phi: X\times Y\to\bar R$ of the problem P_C is defined as $\Phi(x, p)=f(x)+\delta_C(F(x)-p)$ where $\delta_C: Y\to\bar R$ is the usual indicator function of C. The (augmented) Lagrangian $L: X\times R^+\times Y^*\to\bar R$ is then defined by

$$L(x, r, v)=\inf_{p\in Y}(\Phi(x, p)+\psi(p, r, v))=f(x)+\inf_{p\in C}\psi(F(x)-p, r, v),$$

and the dual objective $G: R^+\times Y^*\to\bar R$ has the form

$$G(r, v)=\inf_{x\in X}L(x, r, v)=\inf_{p\in Y}(h(p)+\psi(p, r, v)),$$

where $h: Y\to\bar R$ is the extremal-value function defined by

$$h(p)=\inf_{x\in X}\Phi(x, p).$$

The extremal value of the dual problem (i.e. the problem: maximize G over the domain $R^+\times Y^*$) is denoted β (i.e. $\beta=\sup G(R^+, Y^*)$).

We will prove that $\beta=\inf GP_C$ provided that f is bounded from below as required in Theorem 5. Denote

$$\varepsilon(r, v)=\inf_{p\in Y}\psi(p, r, v).$$

Clearly, $\varepsilon(r, v)\leqq 0$ and $\lim_{r\to+\infty}\varepsilon(r, v)=0$ for any $v\in Y^*$. As $\psi(p, r_1, v_1)+\psi(p, r_2, v_2)=\psi(p, r_1+r_2, v_1+v_2)$, for $r\geqq r_0\geqq 0$ we have $G(r, v)\geqq G(r_0, v_0)+\varepsilon(r-r_0, v-v_0)$. For any $\delta>0$ we can take r_0, v_0 such that $G(r_0, v_0)\geqq\beta-\delta/2$ and r such that $\varepsilon(r-r_0, -v_0)\geqq -\delta/2$, hence $G(r, 0)\geqq\beta-\delta$. Since the function $r\mapsto G(r, 0)$ is nondecreasing, we see that $\lim_{r\to+\infty}G(r, 0)=\beta$. However, using the notation of § 5 with $\varphi(y)=\inf_{y_1\in C}\|y-y_1\|_Y^a$, we have clearly $\inf P_{C,n}=G(K_n, 0)$, and employing Theorem 5, we come to $\inf GP_C=\beta$.

The problem P_C is called ψ-normal (with respect to the perturbations Φ) iff $\beta=\inf P_C$, see [4]. Thus we may use the usual criteria for ψ-normality which in our situation ensures that $\inf P_C=\inf GP_C$ and, due to Theorem 1, $\operatorname{Arginf} P_{\mathrm{cl}_Y C}=\operatorname{Arginf} GP_C\cap X$.

6.3. $\bar R$-valued constraints. Let I be an arbitrary index set. We will study the optimization problem

$$P_C^{(2)}\qquad \begin{aligned}&\text{minimize } f(x)\\ &\text{subject to } x\in X,\quad F_i(x)\leqq 0,\quad i\in I,\end{aligned}$$

where $F_i: X\to\bar R$ are uniformly continuous. To employ the general framework used above, we set $Y=\bar R^I$, $F=(F_i)_{i\in I}$ and $C=\{(y_i)_{i\in I}\in\bar R^I;\ \forall i\in I\ y_i\leqq 0\}$. If the uniformity on Y is considered as the product of the uniformities on $\bar R$ (i.e. $\mathcal{U}_Y=\prod_{i\in I}\mathcal{U}_{\bar R}$), then F is uniformly continuous, C is closed and, moreover, Y is compact. Therefore $\bar Y=Y$ and $\bar C=C$, which simplifies the generalized problem which can be explicitly written

in the form

$$GP_C^{(2)} \quad \begin{array}{l} \text{minimize } f(\bar{x}) \\ \text{subject to } \bar{x} \in \bar{X}, \quad F_i(\bar{x}) \leqq 0, \quad i \in I. \end{array}$$

The perturbed classical problem can now have the form

$$P_{\varepsilon,J}^{(2)} \quad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } x \in X, \quad F_i(x) \leqq \varepsilon, \quad i \in J, \end{array}$$

with $\varepsilon > 0$ and J is a finite subset of I. Obviously, the sets in the form $A_{\varepsilon,J} = \{x \in X; \exists x_1 \in X, \|x - x_1\|_X \leqq \varepsilon, f(x_1) \leqq \inf GP_C^{(2)} + \varepsilon, F_i(x_1) \leqq \varepsilon \text{ for } i \in J\}$ generate the filter $\mathcal{N}(\text{Arginf } GP_C^{(2)})$ when ε ranges the positive reals and J ranges the finite subsets of I. Furthermore, Theorem 4 gives the interesting result that $\inf GP_C^{(2)}$ and $\text{Arginf } GP_C^{(2)}$ can be obtained with prescribed accuracy when one fulfills (with certain accuracy) only a finite number of the constraints.

Supposing I to be finite, we can obtain the usual penalized problem by means of the function $\varphi: (y_i)_{i \in I} \mapsto \sum_{i \in I} (y_i^+)^2$ which clearly fulfills the properties required in Theorem 5. It is interesting that the penalty-function method can be generalized to the case when I is countable, say $I = \{1, 2, \cdots\}$. Then the penalized problem can be constructed by means of the function $\varphi: (y_i)_{i \in I} \mapsto \sum_{i \in I} 2^{-i} y_i^+ / (1 + y_i^+)$. The verification of the properties required for φ is again a simple matter.

Remark. The widely appearing case of a finite number of the constraints $F_i: X \to R$ can be treated by both of the mentioned special cases; however, the former case (§ 6.1) requires F_i to be uniformly continuous with respect to the additive uniformity on R, while for the later case F_i may be only uniformly continuous with respect to the uniformity induced from $\bar{R}$.

Remark. Let X be an Euclidean space, C be closed in Y, and the optimization problem P_C have certain coercive structure, namely either $f(x) \to +\infty$ for $\|x\|_X \to +\infty$ or $\exists V \in \mathcal{U}_Y$ such that the set $\{x \in X; F(x) \in V(C)\}$ is bounded. Then we can restrict our investigation to a sufficiently large closed ball B in X. Since B is compact, we have clearly $B \cap S_{ad} GP_C = B \cap S_{ad} P_C$, $\text{Arginf } GP_C = \text{Arginf } P_C$ and $\inf GP_C = \inf P_C$. Thus our theory is not too interesting for the coercive problems on a finite-dimensional domain.

7. Concluding remarks. If we accept the generalized problems as a realistic setting of the "technical" optimization problems, and thus avoid the classical problems, we can introduce also the perturbed generalized problems, which might be denoted as $GP_{\tilde{C}}$, for which we can investigate the convergence $\inf GP_{\tilde{C}} \to \inf GP_C$ and $\text{Arginf}_\varepsilon GP_{\tilde{C}} \to \text{Arginf } GP_C$ in a similar manner as it was made in § 4. Also the penalized classical problems can be extended on $\bar{X}$ in consequence of the uniform continuity of φ. Thus we can obtain the problems which might be denoted as $GP_{C,n}$, and similar convergence properties as in § 5 can be established.

Also, it should be pointed out that our concept is closely related with the notion of a proximity space, see e.g. [2]. For readers familiar with the proximity-space theory we recall that $\mathcal{U}_X^*$ induces not only the same topology as $\mathcal{U}_X$, but also the same proximity as $\mathcal{U}_X$. Moreover, $\mathcal{U}_X^*$ is the only precompact uniformity inducing this proximity. At the same time, $\mathcal{U}_X^*$ is the coarsest uniformity inducing the proximity in question. $\bar{X}$ is isomorphic to the so-called Smirnov compactification of X with respect to the proximity induced by $\mathcal{U}_X$.

Acknowledgment. The author would like to thank to J. Jarušek of the Institute of Information Theory and Automation, Czechoslovak Academy of Sciences for helpful advice and remarks in the course of preparing of this paper.

SIMILARITY AND REDUCTION FOR TIME VARYING LINEAR SYSTEMS WITH WELL-POSED BOUNDARY CONDITIONS*

I. GOHBERG† AND M. A. KAASHOEK‡

Abstract. The classical theory of similarity and reduction of causal and anti-causal systems is generalized and extended to time varying linear systems with well-posed boundary conditions. Two main problems are solved. The first is to determine to what extent a system with boundary conditions can be simplified by similarity and reduction. The second problem is to find the invariants of such a simplification. Special attention is given to the time invariant case.

Key words. time varying systems with boundary conditions, controllability, observability, irreducibility, weighting patterns, similarity, dilation, structure theorems, integral operators, semi-separable kernels

AMS(MOS) subject classifications. 93B10, 93B05, 93B07, 93B20, 45B05, 45E99, 93E10

0. Introduction and summary.

0.1. Introduction. On a finite time interval a multivariate time varying linear system with boundary conditions has the following state space representation:

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + B(t)u(t), && a \leqq t \leqq b, \\ &y(t) = C(t)x(t) + D(t)u(t), && a \leqq t \leqq b, \\ &N_1 x(a) + N_2 x(b) = 0. \end{aligned} \tag{0.1}$$

Here $A(t): X \to X$, $B(t): Z \to X$, $C(t): X \to Y$ and $D(t): Z \to Y$ are linear operators acting between finite dimensional linear spaces. As a function of t the main coefficient $A(t)$ is assumed to be integrable on $a \leqq t \leqq b$, the input coefficient $B(t)$ and the output coefficient $C(t)$ are square integrable and the external coefficient $D(t)$ is measurable and essentially bounded. The boundary conditions of the system (0.1), which are given in terms of two linear operators N_1 and N_2 acting on the state space X, are assumed to be well-posed, which means that $\det(N_1 + N_2 U(b)) \neq 0$. Here $U(t): X \to X$, $a \leqq t \leqq b$, is the fundamental operator of the system (0.1), i.e.,

$$\dot{U}(t) = A(t)U(t), \qquad a \leqq t \leqq b, \qquad U(a) = I_X.$$

The well-posedness of the boundary conditions implies that the input/output map of the system (0.1) can be written in the form of an integral operator:

$$y(t) = D(t)u(t) + \int_a^b k(t, s)u(s)\, ds, \qquad a \leqq t \leqq b,$$

the kernel $k(t, s)$ being given by

$$k(t, s) = \begin{cases} C(t)U(t)(N_1 + N_2 U(b))^{-1} N_1 U(s)^{-1} B(s), & a \leqq s < t \leqq b, \\ -C(t)U(t)(N_1 + N_2 U(b))^{-1} N_2 U(b) U(s)^{-1} B(s), & a \leqq t < s \leqq b. \end{cases}$$

Time varying linear systems with boundary conditions in state space representation appear for the first time explicitly in the work of A. J. Krener [17], [18], where he used such systems to model the problem of boundary value regulation. Later he analysed in this way the smoothing of non-Markovian linear processes [19]. More recently, also

in the linear estimation theory of stochastic processes governed by time varying systems with boundary conditions, further progress was made by M. B. Adams, A. S. Willsky and B. C. Levy [1], [2], [3]. Systems with boundary conditions appear implicitly in several earlier papers on linear estimation theory written by T. Kailath and his co-authors (see [11] and the references given there). In Kailath's papers the systems are hidden and only their input/output maps appear in the form of integral operators with semi-separable kernels. Let us mention in particular the paper of B. D. O. Anderson and T. Kailath [4], where these connections are seen more clearly.

Together with H. Bart the present authors came to systems with boundary conditions via an analysis of Wiener-Hopf integral equations and related convolution equations [6], [7]. To illustrate this, consider the equation

$$y(t) = u(t) - \int_0^\tau k(t-s)u(s)\,ds, \qquad 0 \leqq t \leqq \tau, \tag{0.2}$$

and assume that the matrix function $k(t)$, which is defined on $[-\tau, \tau]$, admits an extension to a function on the full real line which has a rational Fourier transform $\hat{k}(\lambda)$ with $\hat{k}(\infty) = 0$. Then, using the classical realization theory for rational matrix functions, $\hat{k}(\lambda)$ can be written in the form $\hat{k}(\lambda) = C(A-\lambda)^{-1}B$, and it turns out that the integral equation (0.2) describes the input/output map of the following boundary value system:

$$\begin{aligned} \dot{x}(t) &= -iAx(t) + iBu(t), \qquad 0 \leqq t \leqq \tau, \\ y(t) &= -Cx(t) + u(t), \qquad 0 \leqq t \leqq \tau, \\ (I-P)x(0) &+ Px(\tau) = 0, \end{aligned} \tag{0.3}$$

where P is the spectral projection corresponding to the eigenvalues of A in the upper half plane. The connection between Wiener-Hopf equations and systems with boundary conditions allows one to obtain explicit formulas for the solutions of the equations and for the factorizations of the corresponding symbols. These results are not restricted to systems with finite dimensional state spaces and are of interest also for various classes of infinite dimensional problems. In particular, in this way it is possible to solve for the non-conservative case the linear problem of energy transport in a semi-infinite or finite medium [5, Chap. 6], [16], [21]. Let us mention that for the transport problems the parameter t in the systems (0.1) and (0.3) is not the time but a spatial variable which characterizes the deepness in the medium.

We feel that the time has come now to find out the basic theory for systems with boundary conditions and to bring it up to the level of the classical theory of time varying causal systems which was developed in the sixties by R. E. Kalman, D. C. Youla, L. Weiss and others (see, e.g., [14], [24], [25] and the books [8], [12], [15], [22]). In particular, this means that a similarity and reduction theory for systems with boundary conditions has to be developed. To do this is the main aim of the present paper.

0.2. Summary. The main results about causal systems which we would also like to obtain for systems with boundary conditions can be described shortly as follows. First of all, a causal time varying system θ is irreducible if and only if it is controllable and observable. Here θ is called irreducible if among all causal time invariant systems with the same weighting pattern as θ the state space of θ is of minimal dimension. By definition the weighting pattern is the finite rank kernel

$$k_1(t,s) = C(t)U(t)U(s)^{-1}B(s), \qquad a \leqq t \leqq b, \quad a \leqq s \leqq b.$$

Secondly, after similarity any causal system can be reduced to a controllable and observable one in a canonical way and without changing the weighting pattern, and, thirdly, two irreducible causal time varying systems with the same external coefficient and the same weighting pattern are similar. From these results it is clear that the weighting pattern is the full invariant for similarity and reduction.

In our case for time varying systems with noncausal boundary conditions it is not always possible to transform a system by similarity and reduction into a controllable and observable one. Further, examples show that the weighting pattern is not the full invariant. In fact, in the general case the role of the weighting pattern is taken over by a sequence of finite rank kernels:

$$k_r(t, s) = C(t)U(t)P^{r-1}U(s)^{-1}B(s), \qquad a \leqq t \leqq b, \quad a \leqq s \leqq b,$$

where $r = 1, 2, \cdots$ and $P = (N_1 + N_2U(b))^{-1}N_2U(b)$. This sequence of kernels (or their associated finite rank operators) will be called the *sequence of weighting patterns* of the system (0.1). In the causal case (i.e., $N_1 = I$, $N_2 = 0$ and hence $P = 0$) all kernels in the sequence are identically zero except the first one which is the classical weighting pattern.

To characterize the noncausal irreducible systems, we need to introduce for each noncausal system an extended system which is obtained from the original one by adding in a standard way a number of new inputs and new outputs. For the system (0.1) the extension we have in mind is defined as follows:

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + \tilde{B}(t)\tilde{u}(t), && a \leqq t \leqq b, \\ &\tilde{y}(t) = \tilde{C}(t)x(t), && a \leqq t \leqq b, \\ &N_1x(a) + N_2x(b) = 0, \end{aligned} \tag{0.4}$$

where

$$\begin{aligned} \tilde{B}(t) &= [B(t)\ U(t)PU(t)^{-1}B(t) \cdots U(t)P^{n-1}U(t)^{-1}B(t)], \\ \tilde{C}(t) &= [C(t)\ C(t)U(t)PU(t)^{-1} \cdots C(t)U(t)P^{n-1}U(t)^{-1}]^T \end{aligned}$$

with $P = (N_1 + N_2U(b))^{-1}N_2U(b)$ and n equal to the state space dimension. (Here, as well as in the sequel, the symbol $[\cdots]^T$ means that one has to take the block transpose.) We prove that the original system (0.1) is irreducible if and only if the extended system (0.4) is controllable and observable, which means that the following block matrices have full rank:

$$[\mathscr{C} \quad P\mathscr{C} \quad \cdots \quad P^{n-1}\mathscr{C}], \qquad [\mathscr{O} \quad \mathscr{O}P \quad \cdots \quad \mathscr{O}P^{n-1}]^T,$$

where $\mathscr{C}$ and $\mathscr{O}$ are the controllability and observability Gramians of (0.1), respectively, i.e.,

$$\mathscr{C} = \int_a^b U(t)^{-1}B(t)B(t)^*(U(t)^{-1})^*\,dt, \qquad \mathscr{O} = \int_a^b U(t)^*C(t)^*C(t)U(t)\,dt.$$

Irreducibility of (0.1) means now that among all time varying systems with the same sequence of weighting patterns as (0.1) the state space of (0.1) is of minimal dimension. As in the causal case a canonical procedure allows one to reduce (after similarity) any time varying system with boundary conditions to an irreducible one. Further, we show that irreducible systems with the same external coefficient and the same sequence of weighting patterns are similar.

We specify and extend the theory of similarity and reduction for time invariant systems. The system (0.1) is time invariant if the coefficients $A=A(t)$, $B=B(t)$, $C=C(t)$ and $D=D(t)$ do not depend on t. In the time invariant case irreducibility means that the following block matrices have full rank:

$$[B\ AB\ \cdots\ A^{n-1}B\ PB\ PAB\ \cdots\ PA^{n-1}B\ \cdots\ P^{n-1}B\ P^{n-1}AB\ \cdots\ P^{n-1}A^{n-1}B],$$

$$[C\ CA\ \cdots\ CA^{n-1}\ CP\ CAP\ \cdots\ CA^{n-1}P\ \cdots\ CP^{n-1}\ CAP^{n-1}\ \cdots\ CA^{n-1}P^{n-1}]^{T},$$

where, as before, n is equal to the dimension of the state space. For time invariant systems with the extra property that the operator P commutes with the main coefficient A, which is true obviously in the causal case, our results concerning similarity and reduction resemble strongly the classical theorems for causal time invariant systems.

Let us make a few remarks about the extended system defined by (0.4). In the paper we actually work with a more refined type of extension which has a few additional properties. Namely, if θ denotes the original system and $E(\theta)$ the extension, then $E(E(\theta))=E(\theta)$ and $E(\theta)=\theta$ whenever θ is causal, anti-causal or θ is controllable and observable. In our opinion this notion of extension deserves to be studied further from the system theoretic point of view.

The theory of similarity and reduction developed in this paper has a natural analogue for discrete time systems with boundary conditions which we have set out fully in [10, Chap. IV]. In [10] one also finds a more detailed exposition of the present paper.

1. Preliminaries. This section has a preparatory character. We introduce some necessary terminology and we recall for systems with boundary conditions the notions of similarity, dilation and irreducibility.

In what follows the time varying boundary value system (0.1) will be denoted by

$$\theta=(A(t), B(t), C(t), D(t); N_1, N_2)_a^b. \tag{1.1}$$

Here $A(t):X\to X$, $B(t):Z\to X$, $C(t):X\to Y$ and $D(t):Z\to Y$ are linear operators acting between finite dimensional linear spaces. As a function of t the *main coefficient* $A(t)$ is integrable on $a\leqq t\leqq b$, the *input coefficient* $B(t)$ and the *output coefficient* $C(t)$ are square integrable, and the *external coefficient* $D(t)$ is measurable and essentially bounded. The spaces X, Y and Z are finite dimensional vector spaces over $\mathbb{C}$ endowed with a norm and an inner product. The boundary conditions of (1.1) are given in terms of two linear operators N_1 and N_2 acting on the *state space* X. In (1.1) the indices a, b will be omitted when it is clear on which time interval the system θ has to be considered. By definition the *fundamental operator* of θ is the unique absolutely continuous solution $U(t):X\to X$, $a\leqq t\leqq b$, of the operator differential equation

$$\dot{U}(t)=A(t)U(t),\quad a\leqq t\leqq b,\quad U(a)=I_X. \tag{1.2}$$

The boundary conditions of θ are said to be *well-posed* if the operator $N_1+N_2U(b)$ is invertible, in which case they can be rewritten in the following equivalent form:

$$(I-P)x(a)+PU(b)^{-1}x(b)=0, \tag{1.3}$$

where $P=(N_1+N_2U(b))^{-1}N_2U(b)$. The operator P is called the *canonical boundary value operator* of θ. For a system θ with well-posed boundary conditions the input-

output operator $T_\theta: L_2([a, b], Z) \to L_2([a, b], Y)$ is the bounded integral operator

$$(T_\theta\varphi)(t) = D(t)\varphi(t) + C(t)U(t)\Big\{(I-P)\int_a^t U(s)^{-1}B(s)\varphi(s)\,ds - P\int_t^b U(s)^{-1}B(s)\varphi(s)\,ds\Big\}, \qquad a \leqq t \leqq b.$$

Controllability and observability of a system with well-posed boundary conditions do not depend on the particular form of the boundary conditions (see [18]) and they are the same as for causal systems (i.e., $N_1 = I$, $N_2 = 0$). The operators

$$\mathscr{C}(\theta) = \int_a^b U(t)^{-1}B(t)B(t)^*(U(t)^{-1})^*\,dt, \qquad \mathscr{O}(\theta) = \int_a^b U(t)^*C(t)^*C(t)U(t)\,dt$$

are called the *controllability Gramian* and *observability Gramian* of θ, respectively, and as in the causal case a system θ with well-posed boundary conditions is controllable (resp., observable) if and only if $\mathscr{C}(\theta)$ (resp., $\mathscr{O}(\theta)$) is invertible.

Two time varying systems θ_1 and θ_2,

$$\theta_\nu = (A_\nu(t), B_\nu(t), C_\nu(t), D_\nu(t); N_1^{(\nu)}, N_2^{(\nu)}), \qquad \nu = 1, 2, \tag{1.4}$$

with state spaces X_1 and X_2, respectively, are called *similar* (notation: $\theta_1 \simeq \theta_2$) if θ_1 and θ_2 have the same external coefficient and there exist an invertible operator $E: X_1 \to X_2$ and an absolutely continuous function $S(t): X_1 \to X_2$, $a \leqq t \leqq b$, of which the values are invertible operators, such that

$$A_2(t) = S(t)A_1(t)S(t)^{-1} + \dot{S}(t)S(t)^{-1}, \tag{1.5}$$

$$B_2(t) = S(t)B_1(t), \tag{1.6}$$

$$C_2(t) = C_1(t)S(t)^{-1}, \tag{1.7}$$

$$N_1^{(2)} = EN_1^{(1)}S(a)^{-1}, \qquad N_2^{(2)} = EN_2^{(1)}S(b)^{-1}, \tag{1.8}$$

almost everywhere on $a \leqq t \leqq b$. This notion of similarity appears in a natural way when in (0.1) the state $x(t)$ is replaced by $z(t) = S(t)x(t)$ (see [9, § I.5]). We shall refer to $S(t)$, $a \leqq t \leqq b$, as a *similarity transformation* between θ_1 and θ_2. Formula (1.5) implies that the fundamental operators $U_1(t)$ and $U_2(t)$ of θ_1 and θ_2, respectively, are related in the following way:

$$U_2(t) = S(t)U_1(t)S(a)^{-1}, \qquad a \leqq t \leqq b. \tag{1.9}$$

Well-posedness of the boundary conditions is preserved under a similarity transformation and similar systems with well-posed boundary conditions have similar canonical boundary value operators. In fact, if P_1 and P_2 are the canonical boundary value operators of θ_1 and θ_2, respectively, then the above formulas imply that $P_2 = S(a)P_1S(a)^{-1}$. It follows that similar systems with well-posed boundary conditions have the same input-output operators.

For a system with well-posed boundary conditions we define $\theta_\square$ to be the system

$$\theta_\square = (0, U(t)^{-1}B(t), C(t)U(t), D(t); I-P, P)_a^b. \tag{1.10}$$

Here $U(t)$ is the fundamental operator of θ and P is its canonical boundary value operator. Obviously, $\theta \simeq \theta_\square$; in fact, to obtain $\theta_\square$ one applies to θ the similarity transformation $S(t) = U(t)^{-1}$, $a \leqq t \leqq b$. Note that, $(\theta_\square)_\square = \theta_\square$.

A system $\theta = (A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ will be called a *dilation* of the system $\theta_0 = (A_0(t), B_0(t), C_0(t), D_0(t); N_1^{(0)}, N_2^{(0)})_a^b$ if $D(t) = D_0(t)$ a.e. on $a \leqq t \leqq b$ and the state space X of θ admits a decomposition, $X = X_1 \oplus X_0 \oplus X_2$, such that relative to this decomposition the coefficients of θ and its boundary value operators are partitioned in the following way:

$$A(t) = \begin{pmatrix} * & * & * \\ 0 & A_0(t) & * \\ 0 & 0 & * \end{pmatrix}, \qquad B(t) = \begin{pmatrix} * \\ B_0(t) \\ 0 \end{pmatrix}, \tag{1.11}$$

$$C(t) = (0 \quad C_0(t) \quad *), \tag{1.12}$$

$$N_\nu = E \begin{pmatrix} * & * & * \\ 0 & N_\nu^{(0)} & * \\ 0 & 0 & * \end{pmatrix}, \qquad \nu = 1, 2. \tag{1.13}$$

Here (1.11) and (1.12) hold a.e. on $a \leqq t \leqq b$. The operator E appearing in (1.13) is some invertible operator on X. The symbols $*$ denote unspecified entries. The dilation is said to be *proper* whenever $\dim X > \dim X_0$. If the dilation θ has well-posed boundary conditions, then the same is true for θ_0 and the systems θ and θ_0 have the same input-output operator. To see this, one uses the fact that the fundamental operators $U(t)$ and $U_0(t)$ and the canonical boundary value operators P and P_0 of θ and θ_0 are related in the following way:

$$U(t) = \begin{pmatrix} * & * & * \\ 0 & U_0(t) & * \\ 0 & 0 & * \end{pmatrix}, \qquad P = \begin{pmatrix} * & * & * \\ 0 & P_0 & * \\ 0 & 0 & * \end{pmatrix}. \tag{1.14}$$

The system θ_0 is called a *reduction* of θ if θ is a dilation of θ_0, and θ_0 is said to be a *proper* reduction if, in addition, the state space dimension of θ_0 is strictly less than the state space dimension of θ. It is one of the classical results about causal systems that for a causal system θ the system $\theta_\square$ (see (1.10)) has a controllable and observable reduction (cf., [14], [24], [25]). Since $\theta \simeq \theta_\square$, it follows that a causal time varying system is similar to a dilation of a controllable and observable system (which is the main part of Kalman's canonical structure theorem [14]).

A time varying linear system θ with well-posed boundary conditions is called *irreducible* if none of the systems similar to θ admits a proper reduction. Since the system $\theta_\square$ has a proper reduction whenever θ (or any system similar to θ) has a proper reduction, one may conclude that θ is irreducible if and only if $\theta_\square$ does not have a proper reduction. For a causal system irreducibility is equivalent to controllability and observability (see [14]), but for systems with noncausal boundary conditions this is not true. In fact, in contrast to controllability and observability the notion of irreducibility depends heavily on the boundary conditions.

2. Main theorems. To state our main theorems, we use a standard procedure to add to a system new inputs and new outputs without changing the state space. Let $\theta = (A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ be a system with well-posed boundary conditions. Let $U(t)$ be the fundamental operator of θ and P its canonical boundary value operator. For r and q positive numbers we define the (r, q)-*extension* of θ (notation: $E_{rq}(\theta)$) to be the system

$$E_{rq}(\theta) \quad \begin{cases} \dot{x}(t) = A(t)x(t) + B^{(r)}(t)\tilde{u}(t), & a \leqq t \leqq b, \\ \tilde{y}(t) = C^{(q)}(t), & a \leqq t \leqq b, \\ N_1 x(a) + N_2 x(b) = 0, \end{cases}$$

of which the input space is equal to $Z^{(r)}$ (i.e., the direct sum of r copies of the input space Z of θ), the output space is $Y^{(q)}$ (i.e., the direct sum of q copies of the outspace Y of θ) and

$$B^{(r)}(t)=[B(t) \quad U(t)PU(t)^{-1}B(t) \quad \cdots \quad U(t)P^{r-1}U(t)^{-1}B(t)],$$
$$C^{(q)}(t)=[C(t) \quad C(t)U(t)PU(t)^{-1} \quad \cdots \quad C(t)U(t)P^{q-1}U(t)^{-1}]^{T}.$$

The definition of $E_{rq}(\theta)$ does not involve the external coefficient of θ. The system $E_{rq}(\theta)$ has well-posed boundary conditions, and $E_{rq}(\theta)$ and θ have the same canonical boundary value operator. The controllability and observability Gramians of $E_{rq}(\theta)$ are the following operators:

$$\mathscr{C}(E_{rq}(\theta))=\sum_{\nu=1}^{r} P^{\nu-1}\mathscr{C}(\theta)(P^{*})^{\nu-1}, \tag{2.1}$$

$$\mathscr{O}(E_{rq}(\theta))=\sum_{\nu=1}^{q} (P^{*})^{\nu-1}\mathscr{O}(\theta)P^{\nu-1}, \tag{2.2}$$

where $\mathscr{C}(\theta)$ and $\mathscr{O}(\theta)$ are the controllability and observability Gramians of θ, respectively. Obviously,

$$\operatorname{Im}\mathscr{C}(E_{rq}(\theta))=\operatorname{Im}[\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{r-1}\mathscr{C}(\theta)], \tag{2.3}$$

$$\operatorname{Ker}\mathscr{O}(E_{rq}(\theta))=\bigcap_{j=1}^{q} \operatorname{Ker}\mathscr{O}(\theta)P^{j-1}. \tag{2.4}$$

Let m and l be the smallest positive integers such that both $\mathscr{C}(E_{ml}(\theta))$ and $\mathscr{O}(E_{ml}(\theta))$ are of maximal rank. Note that the dimension of the right-hand side of (2.3) is maximal for $r=d$, where d is the degree of the minimal polynomial of P (which is less than the dimension of the state space of θ). It follows that $1\leqq m\leqq d$. Similarly, $1\leqq l\leqq d$. The system $E_{ml}(\theta)$ will be called the *standard extension* of θ (notation: STE (θ)). If θ is causal (i.e., $N_1=I$, $N_2=0$ and hence $P=0$) or if θ is anti-causal (i.e., $N_1=0$, $N_2=I$ and hence $P=I$), then the degree of the minimal polynomial of P is 1 and hence in those cases STE $(\theta)=\theta$. The equality STE $(\theta)=\theta$ also holds if the original system θ is controllable and observable. Finally, if the standard extension procedure is applied to the system STE (θ), then nothing new is obtained, i.e.,

$$\text{STE (STE }(\theta))=\text{STE }(\theta). \tag{2.5}$$

THEOREM 2.1. *Let $\theta=(A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ be a system with well-posed boundary conditions, and let $U(t)$ be its fundamental operator. The following statements are equivalent*:

(i) *θ is irreducible.*

(ii) *The standard extension of θ is controllable and observable.*

(iii) *The following block matrices have full rank*:

$$[\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{d-1}\mathscr{C}(\theta)], \qquad [\mathscr{O}(\theta) \quad \mathscr{O}(\theta)P \quad \cdots \quad \mathscr{O}(\theta)P^{d-1}]^{T};$$

(iv) $\operatorname{rank}[W_{j+k-1}(\theta)]_{j,k=1}^{d}=\dim X$.

Here $\mathscr{C}(\theta)$ and $\mathscr{O}(\theta)$ are the controllability and observability Gramians of θ, respectively, X is the state space of θ, the operator P is the canonical boundary value operator of θ, the number d is the degree of the minimal polynomial of P and $W_j(\theta)$ is the finite rank integral operator:

$$(W_j(\theta)\varphi)(t)=C(t)U(t)P^{j-1}\int_a^b U(s)^{-1}B(s)\varphi(s)\,ds, \qquad a\leqq t\leqq b. \tag{2.6}$$

The operator $W_j(\theta)$ defined by (2.6), which acts from $L_2([a, b], Z)$ into $L_2([a, b], Y)$, will be called the *jth weighting pattern* of the system $\theta (j = 1, 2, \cdots)$. For a causal system all weighting patterns are zero except the first one which is the classical weighting pattern. In case P is a projection only the first two weighting patterns are of interest. If the coefficients of θ are analytic functions in the time parameter t and P is a projection, then the weighting patterns are uniquely determined by the input-output operator and, conversely, the input-output operator is uniquely determined by (the first two) weighting patterns. The weighting patterns do not change under similarity, dilation and reduction.

THEOREM 2.2. *Two irreducible systems are similar if and only if they have the same external coefficient and the same sequence of weighting patterns, and in that case the similarity transformation is unique.*

THEOREM 2.3. *A time varying system θ with well-posed boundary conditions is irreducible if and only if among all time varying systems with well-posed boundary conditions and with the same sequence of weighting patterns as θ the system θ has the smallest state space dimension.*

THEOREM 2.4. *A time varying system θ with well-posed boundary conditions is similar to a dilation of an irreducible system. More precisely, let $\theta = (A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ have well-posed boundary conditions, let $U(t)$ be the fundamental operator of θ and P its canonical boundary value operator, and choose a direct sum decomposition, $X = X_1 \oplus X_0 \oplus X_2$, of the state space X of θ such that $X_1 = \operatorname{Ker} \mathcal{O}$ and X_0 is a direct complement of $X_1 \cap \operatorname{Im} \mathcal{C}$ in $\operatorname{Im} \mathcal{C}$, where $\mathcal{C}$ and $\mathcal{O}$ are the controllability and observability Gramians of the standard extension of θ, respectively. Then relative to the decomposition $X = X_1 \oplus X_0 \oplus X_2$ the following partitionings hold true:*

$$U(t)^{-1}B(t) = \begin{pmatrix} * \\ B_0(t) \\ 0 \end{pmatrix}, \qquad C(t)U(t) = (0 \quad C_0(t) \quad *), \qquad a \leqq t \leqq b, \quad a.e.,$$

$$P = \begin{pmatrix} * & * & * \\ 0 & P_0 & * \\ 0 & 0 & * \end{pmatrix},$$

the system $\theta_0 = (0, B_0(t), C_0(t), D(t); I - P_0, P_0)_a^b$ is irreducible and θ is similar to a dilation of θ_0.

COROLLARY 2.5. *Two time varying systems θ_1 and θ_2 with well-posed boundary conditions are similar to dilations of the same (irreducible) system if and only if θ_1 and θ_2 have the same external coefficient and the same sequence of weighting patterns.*

The theory developed in this section yields a general procedure to transform an arbitrary time varying system θ with well-posed boundary conditions into a controllable and observable system. First one applies (as in Theorem 2.4) a similarity and a reduction to transform θ into an irreducible system θ_0. Next, one adds to θ_0 inputs and outputs using the standard extension procedure defined in the beginning of this section. According to Theorem 2.1 the resulting system STE (θ_0) is controllable and observable.

In an earlier version of this paper (see [10]) we used the terms p-controllability and q-observability to describe irreducibility. Here p-controllability and q-observability of θ mean that the operators

$$\sum_{j=1}^{p} P^{j-1}\mathcal{C}(\theta)(P^*)^{j-1}, \qquad \sum_{j=1}^{q} (P^*)^{j-1}\mathcal{O}(\theta)P^{j-1}$$

are invertible. Thus θ is p-controllable and q-observable if and only if the (p, q)-extension $E_{pq}(\theta)$ is controllable and observable, and according to Theorem 2.1 the system θ is irreducible if and only if θ is p-controllable and q-observable for p and q sufficiently large.

3. Proofs of the main theorems. In this section we prove Theorems 2.1–2.4 and Corollary 2.5. We begin with a few general observations. In what follows $\theta = (A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ is a system with well-posed boundary conditions, $U(t)$ is the fundamental operator of θ and P its canonical boundary value operator.

LEMMA 3.1. *Assume that θ admits a reduction, i.e., the state space X of θ admits a decomposition $X = X_1 \oplus X_0 \oplus X_2$ such that relative to this decomposition* (1.11), (1.12) *and* (1.13) *hold true. Then*

$$\text{Im } P^{r-1}\mathscr{C}(\theta) \subset X_0 \oplus X_1, \quad \text{Ker } \mathscr{O}(\theta)P^{r-1} \supset X_1, \quad r \geqq 1. \tag{3.1}$$

Proof. From formula (1.11) it follows that the fundamental operator $U(t)$ of θ can be represented as in (1.14). This implies that $\text{Im } U(t)^{-1}B(t) \subset X_1 \oplus X_0$ and $\text{Ker } C(t)U(t) \supset X_1$ for almost all $a \leqq t \leqq b$. But then it is clear from the definitions of the Gramians $\mathscr{C}(\theta)$ and $\mathscr{O}(\theta)$ that $\text{Im } \mathscr{C}(\theta) \subset X_1 \oplus X_0$ and $\text{Ker } \mathscr{O}(\theta) \supset X_1$. Next, use the fact that P can be written as in (1.14). So the spaces $X_1 \oplus X_0$ and X_1 are invariant under P and (3.1) follows. □

Let $E_{ml}(\theta)$ be the standard extension of θ. Denote by $\mathscr{C}$ and $\mathscr{O}$ the controllability and observability Gramians of $E_{ml}(\theta)$. From the definition of the standard extension it follows (see (2.3) and (2.4)) that

$$\text{Im } \mathscr{C} = \text{Im } [\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{r-1}\mathscr{C}(\theta)], \qquad r \geqq m, \tag{3.2}$$

$$\text{Ker } \mathscr{O} = \bigcap_{j=1}^{q} \text{Ker } \mathscr{O}(\theta)P^{j-1}, \qquad q \geqq l. \tag{3.3}$$

This implies that $\text{Im } \mathscr{C}$ and $\text{Ker } \mathscr{O}$ are invariant under P.

Put $X_1 = \text{Ker } \mathscr{O}$, and let X_0 be a direct complement of $X_1 \cap \text{Im } \mathscr{C}$ in $\text{Im } \mathscr{C}$. Furthermore, let X_2 be a direct complement of $X_1 + X_0$ in the state space X of θ. Then $X = X_1 \oplus X_0 \oplus X_2$. The fact that P leaves invariant the spaces X_1 and $X_1 + X_0$ implies that relative to the decomposition $X = X_1 \oplus X_0 \oplus X_2$ the operator P admits the following partitioning:

$$P = \begin{pmatrix} * & * & * \\ 0 & P_0 & * \\ 0 & 0 & * \end{pmatrix}. \tag{3.4}$$

Let us consider the partitioning of $U(t)^{-1}B(t)$ and $C(t)U(t)$ relative to the decomposition $X = X_1 \oplus X_0 \oplus X_2$:

$$U(t)^{-1}B(t) = \begin{pmatrix} B_1(t) \\ B_0(t) \\ B_2(t) \end{pmatrix}, \qquad C(t)U(t) = (C_1(t) \quad C_0(t) \quad C_2(t)). \tag{3.5}$$

LEMMA 3.2. *In* (3.5) *the entries $B_2(t)$ and $C_1(t)$ are zero almost everywhere on $a \leqq t \leqq b$.*

Proof. Introduce the following auxiliary operators:

$$\Gamma: L_2([a, b], Z) \to X, \qquad \Gamma\varphi = \int_a^b U(s)^{-1}B(s)\varphi(s)\, ds, \tag{3.6}$$

$$\Lambda: X \to L_2([a, b], Y), \qquad (\Lambda x)(t) = C(t)U(t)x. \tag{3.7}$$

Note the $\Gamma\Gamma^* = \mathscr{C}(\theta)$ and $\Lambda^*\Lambda = \mathcal{O}(\theta)$. In particular, $\operatorname{Im}\Gamma = \operatorname{Im}\mathscr{C}(\theta)$ and $\operatorname{Ker}\Lambda = \operatorname{Ker}\mathcal{O}(\theta)$. Since $\operatorname{Im}\mathscr{C} \subset X_1 \oplus X_0$, we have $\operatorname{Im}\mathscr{C}(\theta) \subset X_1 \oplus X_0$ (see (3.2)), and it follows that $\Pi\Gamma = 0$, where Π is the projection of X along $X_1 \oplus X_0$ onto X_2. In other words

$$\int_a^b \Pi U(s)^{-1} B(s)\varphi(s)\, ds = 0 \qquad \forall \varphi \in L_2([a, b], Z).$$

But then we may conclude that $\Pi U(s)^{-1}B(s) = 0$ on $a \leqq s \leqq b$. This proves that $B_2(t) = 0$ a.e. Next observe that (3.3) implies that $\operatorname{Ker}\Lambda \subset X_1$, and thus $C(t)U(t)x = 0$ a.e. on $a \leqq t \leqq b$ for each $x \in X_1$. So $C_1(t) = 0$ a.e. □

Proof of Theorem 2.1. (i)⇒(ii). Assume θ is irreducible. Put

$$\theta_0 = (0, B_0(t), C_0(t), D(t); I - P_0, P_0)_a^b, \tag{3.8}$$

where $B_0(t)$ and $C_0(t)$ are defined by (3.5) and P_0 by (3.4). The triangular form of P (see (3.4)) and the fact that in (3.5) the entries $B_2(t)$ and $C_1(t)$ are zero a.e. imply that θ_0 is a reduction of the system $\theta_\square$ (which is defined by (1.10)). It follows that θ is similar to a dilation of θ_0. But θ is irreducible. So $X = X_0$, and we may conclude that $\operatorname{Ker}\mathcal{O} = (0)$ and $\operatorname{Im}\mathscr{C} = X$. In other words, the standard extension of θ is controllable and observable.

(ii)⇒(i). Assume that the standard extension of θ is controllable and observable. Let θ_1 be a system that is similar to θ. We want to prove that θ_1 does not have a proper reduction. First we show that the standard extension of θ_1 is also controllable and observable. Let X and X_1 be the state spaces of θ and θ_1, respectively, and let $S(t): X \to X_1$, $a \leqq t \leqq b$, be the similarity transformation between θ and θ_1. Then for any pair of positive numbers r and q the transformation $S(t)$ is a similarity between $E_{rq}(\theta)$ and $E_{rq}(\theta_1)$. This implies that the standard extension of θ and θ_1 are similar. Since controllability and observability are preserved under similarity, it follows that the standard extension of θ_1 is controllable and observable.

But then it suffices to show that θ does not have a proper reduction. Assume, as in Lemma 3.1, that θ has a reduction induced by the decomposition $X = X_1 \oplus X_0 \oplus X_2$. Then (3.1) implies that $\operatorname{Im}\mathscr{C} \subset X_0 \oplus X_1$ and $\operatorname{Ker}\mathcal{O} \supset X_1$. But θ is controllable and observable. So $\operatorname{Im}\mathscr{C} = X$ and $\operatorname{Ker}\mathcal{O} = (0)$. It follows that $X_0 = X$, and the reduction is not proper. So θ is irreducible.

(ii)⇔(iii). Let d be the degree of the minimal polynomial of P. Assume $E_{ml}(\theta)$ is the standard extension of θ. Then we know that $1 \leqq m \leqq d$ and $1 \leqq l \leqq d$. In particular (see (3.2) and (3.3)) we have

$$\operatorname{Im}\mathscr{C} = \operatorname{Im}[\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{d-1}\mathscr{C}(\theta)], \qquad \operatorname{Ker}\mathcal{O} = \bigcap_{j=1}^{d} \operatorname{Ker}\mathcal{O}(\theta)P^{j-1}. \tag{3.9}$$

Thus the standard extension of θ is controllable and observable if and only if

$$X = \operatorname{Im}[\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{d-1}\mathscr{C}(\theta)], \qquad \bigcap_{j=1}^{d} \operatorname{Ker}\mathcal{O}(\theta)P^{j-1} = (0). \tag{3.10}$$

This proves the equivalence of the statements (ii) and (iii).

(iii)⇔(iv). Using the auxiliary operators Γ and Λ defined by (3.6) and (3.7), respectively, one can rewrite the jth weighting pattern in the form: $W_j(\theta) = \Lambda P^{j-1}\Gamma$.

It follows that

$$[W_{j+k-1}(\theta)]_{j,k=1}^{d} = \begin{pmatrix} \Lambda \\ \Lambda P \\ \vdots \\ \Lambda P^{d-1} \end{pmatrix} [\Gamma \quad P\Gamma \quad \cdots \quad P^{d-1}\Gamma]. \tag{3.11}$$

Since $\Gamma\Gamma^* = \mathscr{C}(\theta)$ and $\Lambda^*\Lambda = \mathscr{O}(\theta)$, it is easily seen that

$$\operatorname{Im}[\mathscr{C}(\theta) \quad P\mathscr{C}(\theta) \quad \cdots \quad P^{d-1}\mathscr{C}(\theta)] = \operatorname{Im}[\Gamma \quad P\Gamma \quad \cdots \quad P^{d-1}\Gamma],$$

$$\bigcap_{j=1}^{d} \operatorname{Ker} \mathscr{O}(\theta)P^{j-1} = \bigcap_{j=1}^{d} \operatorname{Ker} \Lambda P^{j-1},$$

and thus the rank of the left-hand side of (3.11) is equal to dim X if and only if (3.10) holds. This proves the equivalence of (iii) and (iv). □

Proof of Theorem 2.4. Lemma 3.2 and the paragraph preceding this lemma show that $U(t)^{-1}B(t)$, $C(t)U(t)$ and P have the desired block matrix structure. It follows that the system $\theta_0 = (0, B_0(t), C_0(t), D(t); I - P_0, P_0)_a^b$ is a reduction of the system $\theta_\square$ (see (1.10)), and thus θ is similar to a dilation of θ_0. It remains to prove that θ_0 does not admit a proper reduction.

Let Γ and Λ be the operators defined by (3.6) and (3.7), and consider the following auxiliary operators

$$\Gamma_0 : L_2([a, b], Z) \to X_0, \qquad \Gamma_0 = \int_a^b B_0(s)\varphi(s)\, ds,$$

$$\Lambda_0 : X_0 \to L_2([a, b], Y), \qquad (\Lambda_0 x)(t) = C_0(t)x.$$

From the partitioning of $U(t)^{-1}B(t)$, $C(t)U(t)$ and P we may conclude that

$$P^{r-1}\Gamma = \begin{pmatrix} * \\ P_0^{r-1}\Gamma_0 \\ 0 \end{pmatrix}, \quad \Lambda P^{r-1} = (0 \quad \Lambda_0 P_0^{r-1} \quad *), \quad r \geqq 1. \tag{3.12}$$

Now recall that $X_0 \subset \operatorname{Im} \mathscr{C} = \operatorname{Im}[\Gamma \; P\Gamma \; \cdots \; P^{d-1}\Gamma]$, where d is the degree of the minimal polynomial of P. So the first identity in (3.12) implies that $X_0 = \operatorname{Im}[\Gamma_0 \; P_0\Gamma_0 \; \cdots \; P_0^{d-1}\Gamma_0]$. Furthermore, $X_1 = \bigcap_{j=1}^{d} \operatorname{Ker} \Lambda P^{j-1}$, and so the second identity in (3.12) shows that $\bigcap_{j=1}^{d} \operatorname{Ker} \Lambda_0 P_0^{j-1} = (0)$. Now apply Theorem 2.1 to conclude that θ_0 is irreducible. □

Proof of Theorem 2.2. It is easily seen that the weighting patterns are preserved under similarity. It follows that two similar systems have the same external coefficient and the same sequence of weighting patterns. We have to prove that for irreducible systems the converse statement is also true.

For $\nu = 1, 2$ let $\theta_\nu = (A_\nu(t), B_\nu(t), C_\nu(t), D_\nu(t); N_1^{(\nu)}, N_2^{(\nu)})_a^b$ be an irreducible system. Assume that $D_1(\cdot) = D_2(\cdot)$ and that θ_1 and θ_2 have the same sequence of weighting patterns. We want to prove that θ_1 and θ_2 are similar. For $\nu = 1, 2$ let X_ν be the state space of θ_ν, let $U_\nu(t)$ be the fundamental operator of θ_ν and P_ν its canonical boundary value operator. Take n to be the maximum of dim X_1 and dim X_2. Put

$$\tilde{B}_\nu(t) = [B_\nu(t) \quad U_\nu(t)P_\nu U_\nu(t)^{-1}B_\nu(t) \quad \cdots \quad U_\nu(t)P_\nu^n U_\nu(t)^{-1}B_\nu(t)],$$

$$\tilde{C}_\nu(t) = [C_\nu(t) \quad C_\nu(t)U_\nu(t)P_\nu U_\nu(t)^{-1} \quad \cdots \quad C_\nu(t)U_\nu(t)P_\nu^n U_\nu(t)^{-1}]^T,$$

and consider the causal system $\Delta_\nu = (A_\nu(t), \tilde{B}_\nu(t), \tilde{C}_\nu(t), 0; I, 0)_a^b$, where $\nu = 1, 2$. The

irreducibility of θ_1 and θ_2 implies that Δ_1 and Δ_2 are controllable and observable. Note that the first weighting pattern of Δ_ν is given by

$$W_1(\Delta_\nu) = [W_{j+k-1}(\theta_\nu)]_{j,k=1}^{n+1}.$$

Since θ_1 and θ_2 have the same sequence of weighting patterns, we conclude that Δ_1 and Δ_2 have the same first weighting pattern. But then we can apply the classical similarity theorem for (observable and controllable) causal systems (see, e.g., [25]) to show that $\Delta_1 \simeq \Delta_2$. So there exists an absolutely continuous function $S(t): X_1 \to X_2$, of which the values are invertible operators, such that

$$A_2(t) = S(t)A_1(t)S(t)^{-1} + \dot{S}(t)S(t)^{-1}, \tag{3.13}$$

$$\tilde{B}_2(t) = S(t)\tilde{B}_1(t), \qquad \tilde{C}_2(t) = \tilde{C}_1(t)S(t)^{-1}, \tag{3.14}$$

almost everywhere on $a \leqq t \leqq b$. Obviously, (3.14) implies that

$$B_2(t) = S(t)B_1(t), \qquad C_2(t) = C_1(t)S(t)^{-1}. \tag{3.15}$$

So to prove that θ_1 and θ_2 are similar, it remains to show that $P_2 = S(a)^{-1}P_1S(a)$. To do this, introduce

$$\hat{B}_\nu(t) = [B_\nu(t) \quad U_\nu(t)P_\nu U_\nu(t)^{-1}B_\nu(t) \quad \cdots \quad U_\nu(t)P^{n-1}U_\nu(t)^{-1}B_\nu(t)],$$

$$\hat{C}_\nu(t) = [C_\nu(t) \quad C_\nu(t)U_\nu(t)P_\nu U_\nu(t)^{-1} \quad \cdots \quad C_\nu(t)U_\nu(t)P^{n-1}U_\nu(t)^{-1}]^T,$$

for $\nu = 1, 2$. From (3.14) we may conclude that

$$\hat{B}_2(t) = S(t)\hat{B}_1(t), \tag{3.16}$$

$$U_2(t)P_2U_2(t)^{-1}\hat{B}_2(t) = S(t)(U_1(t)P_1U_1(t)^{-1})\hat{B}_1(t). \tag{3.17}$$

Now use that (3.13) implies that $U_2(t)S(a) = S(t)U_1(t)$, and insert this latter identity in the right-hand side of (3.17). So with (3.16) and (3.17) we come to:

$$(P_2 - S(a)P_1S(a)^{-1})U_2(t)\hat{B}_2(t) = 0, \quad a \leqq t \leqq b, \quad \text{a.e.}$$

But then

$$(P_2 - S(a)P_1S(a)^{-1})\left(\sum_{j=1}^{n} P_2^{j-1}\mathscr{C}(\theta_2)(P_2^*)^{j-1}\right)$$

$$= (P_2 - S(a)P_1S(a)^{-1})\int_a^b U_2(t)^{-1}\hat{B}_2(t)\hat{B}_2(t)^*(U_2(t)^{-1})^*\,dt = 0,$$

and we can use the controllability of the standard extension of θ_2 to show that $P_2 - S(a)P_1S(a)^{-1} = 0$.

The uniqueness of the similarity follows directly from the corresponding statement for causal systems. Indeed, let $S_0(t): X_1 \to X_2$, $a \leqq t \leqq b$, be a similarity transformation between θ_1 and θ_2. Then $U_2(t)S_0(a) = S_0(t)U_1(t)$ for $a \leqq t \leqq b$ and $P_2S_0(a) = S_0(a)P_1$. It follows that $S_0(t)$ is also a similarity transformation between Δ_1 and Δ_2. But Δ_1 and Δ_2 are causal systems, which are controllable and observable. Hence the similarity transformation is unique. □

Proof of Corollary 2.5. Similarity and dilation do not change the external coefficient and the sequence of weighting patterns. So we have only to prove the "if part" of Corollary 2.5.

To do this, assume that θ_1 and θ_2 have the same external coefficient and the same sequence of weighting patterns. We know (Theorem 2.4) that θ_1 is similar to a dilation

of an irreducible system, θ_{10} say. Also θ_2 is similar to a dilation of an irreducible system, θ_{20} say. Since similarity and dilation do not change the external coefficient and the sequence of weighting patterns, we conclude that θ_{10} and θ_{20} have the same external coefficient and the same sequence of weighting patterns. But then we can apply Theorem 2.2 to show that θ_{10} and θ_{20} are similar. Put $\theta_0 = \theta_{10}$. Then θ_0 is irreducible and θ_1 is similar to a dilation of θ_0. Further, since $\theta_{20} \simeq \theta_0$, we can use the next lemma to show that θ_2 is similar to a dilation of θ_0. □

LEMMA 3.3. *Let θ be a dilation of θ_0, and let $\tilde{\theta}_0$ be a system similar to θ_0. Then θ is similar to a dilation of $\tilde{\theta}_0$.*

Proof. Let $\theta = (A(t), B(t), C(t), D(t); N_1, N_2)_a^b$ and $\theta_0 = (A_0(t), B_0(t), C_0(t), D_0(t); N_1^{(0)}, N_2^{(0)})_a^b$. Further, let $S_0(t): X_0 \to \tilde{X}_0$, $a \leqq t \leqq b$, be a similarity between θ_0 and $\tilde{\theta}_0$. Thus the boundary value operators of $\tilde{\theta}_0$ are of the form

$$\tilde{N}_1^{(0)} = F_0 N_1^{(0)} S_0(a)^{-1}, \qquad \tilde{N}_2^{(0)} = F_0 N_2^{(0)} S_0(b)^{-1},$$

where $F_0: X_0 \to \tilde{X}_0$ is some invertible operator. Since θ is a dilation of θ_0, we may assume that (1.11), (1.12) and (1.13) hold true. Put $S(t) = I_{X_1} \oplus S_0(t) \oplus I_{X_2}$ and $F = I_{X_1} \oplus F_0 \oplus I_{X_2}$. Then $F, S(t): X_1 \oplus X_0 \oplus X_2 \to X_1 \oplus \tilde{X}_0 \oplus X_2$, $a \leqq t \leqq b$, are invertible operators. Consider $S(t)$, $a \leqq t \leqq b$, as a similarity transformation. When applied to θ, this transformation yields a new system $\tilde{\theta}$ of which the boundary value operators are given by

$$\tilde{N}_1 = FE^{-1} N_1 S(a)^{-1}, \qquad \tilde{N}_2 = FE^{-1} N_2 S(b)^{-1},$$

where E is the invertible operator appearing in (1.13). So $\theta \simeq \tilde{\theta}$, and it is easily checked that $\tilde{\theta}$ is a dilation of $\tilde{\theta}_0$. □

Proof of Theorem 2.3. Assume that among all systems with the same sequence of weighting patterns as θ the dimension of the state space of θ is as small as possible. Let θ_0 be the system introduced in Theorem 2.4. Since θ is similar to a dilation of θ_0, we know that θ and θ_0 have the same weighting patterns. So our hypotheses imply that the dimension of the state space X_0 of θ_0 is larger than or equal to the dimension of the state space X of θ. But from the construction of θ_0 it is clear that $X_0 \subset X$. Thus $X_0 = X$. But then $\theta \simeq \theta_0$, and we can use the irreducibility of θ_0 to conclude that θ is irreducible.

To prove the converse, assume that θ is irreducible. Let θ_1 be a system with well-posed boundary conditions and with the same sequence of weighting patterns as θ. Without loss of generality we assume that θ and θ_1 have the same external coefficient. Then, by Corollary 2.5, the systems θ and θ_1 are similar to dilations of the same irreducible system θ_0. The fact that θ is irreducible implies that $\theta \simeq \theta_0$. So the dimension of the state space of θ is equal to the dimension of the state space of θ_0 and the latter dimension is less than or equal to the dimension of the state space of θ_1. □

4. The time invariant case. In this section we review and specify the theory developed in §§ 2 and 3 for a time invariant system with boundary conditions:

$$\theta \quad \begin{cases} \dot{x}(t) = Ax(t) + Bu(t), & a \leqq t \leqq b, \\ y(t) = Cx(t) + Du(t), & a \leqq t \leqq b. \\ N_1 x(a) + N_2 x(b) = 0. \end{cases}$$

Such a system is characterized by the fact that the main coefficient, the input and output coefficients and the external coefficient do not depend on the time variable t. For brevity we write $\theta = (A, B, C, D; N_1, N_2)_a^b$.

The fundamental operator of the time invariant system θ is equal to $U(t) = e^{(t-a)A}$, $a \leqq t \leqq b$. Hence θ has well-posed boundary conditions if and only if $\det(N_1 e^{aA} + N_2 e^{bA}) \neq 0$, and in that case the canonical boundary value operator P of θ is given by

$$P = e^{aA}(N_1 e^{aA} + N_2 e^{bA})^{-1} N_2 e^{(b-a)A}. \tag{4.1}$$

For a time invariant system $\theta = (A, B, C, D; N_1, N_2)_a^b$ with well-posed boundary conditions, the (r, q)-extension $E_{rq}(\theta)$ is the system:

$$E_{rq}(\theta) \quad \begin{cases} \dot{x}(t) = Ax(t) + B^{(r)}(t)\tilde{u}(t), & a \leqq t \leqq b, \\ \tilde{y}(t) = C^{(q)}(t)x(t), & a \leqq t \leqq b, \\ N_1 x(a) + N_2 x(b) = 0, \end{cases}$$

where

$$B^{(r)}(t) = [B \quad e^{(t-a)A}Pe^{(a-t)A}B \quad \cdots \quad e^{(t-a)A}P^{r-1}e^{(a-t)A}B],$$
$$C^{(q)}(t) = [C \quad Ce^{(t-a)A}Pe^{(a-t)A} \quad \cdots \quad Ce^{(t-a)A}P^{q-1}e^{(a-t)A}]^T,$$

with P equal to the canonical boundary value operator of θ (see (4.1)). It follows that in general the (r, q)-extensions of θ are not time invariant, but depend on time. (An important special case when the (r, q)-extensions are time invariant systems will be discussed in the next section.) The fact that the (r, q)-extensions of θ (which include the standard extension) are not time invariant is probably one of the reasons that in many respects a time invariant system with well-posed boundary conditions behaves like a time varying system.

The rth weighting pattern of a time invariant system $\theta = (A, B, C, D; N_1, N_2)_a^b$ is the finite rank integral operator

$$(W_r(\theta)\varphi)(t) = Ce^{(t-a)A}P^{r-1}\int_a^b e^{(a-s)A}B\varphi(s)\,ds.$$

By expanding $e^{(t-a)A}$ and $e^{(a-s)A}$ into power series in $t-a$ and $s-a$, respectively, one sees that the weighting patterns are uniquely determined by the operators

$$CA^iP^{r-1}A^jB, \qquad i, j, r-1 = 0, 1, 2, \cdots. \tag{4.2}$$

The triple sequence (4.2) will be called the *sequence of moments* of θ.

Next we review the theorems of § 2 for the time invariant case. Let $\theta = (A, B, C, D; N_1, N_2)_a^b$ be a time invariant system with well-posed boundary conditions, and let P be its canonical boundary value operator. The condition of irreducibility for θ in Theorem 2.1(iii) may be replaced by the condition that the following block matrices have full rank:

$$[B \quad AB \quad \cdots \quad A^{n-1}B \quad PB \quad PAB \quad \cdots \quad PA^{n-1}B \quad \cdots \quad P^{d-1}B \quad P^{d-1}AB \quad \cdots \quad P^{d-1}A^{n-1}B],$$
$$[C \quad CA \quad \cdots \quad CA^{n-1} \quad CP \quad CAP \quad \cdots \quad CA^{n-1}P \quad \cdots \quad CP^{d-1} \quad CAP^{d-1} \quad \cdots \quad CA^{n-1}P^{d-1}]^T.$$

Here n is the dimension of the state space and (as before) d is the degree of the minimal polynomial of P.

In Theorem 2.2 (for time invariant systems) the weighting patterns can be replaced by the moments. Note, however, that the similarity transformation between two similar irreducible time invariant systems does not have to be time independent. For example,

consider the following two systems:

$$\theta_1 \quad \begin{cases} \dot{x}_1 = 0, \quad \dot{x}_2 = u, \quad 0 \leqq t \leqq 1, \\ y = x_2, \\ x_1(0) - x_2(0) + x_2(1) = 0, \qquad x_1(0) - x_1(1) - x_2(1) = 0; \end{cases}$$

$$\theta_2 \quad \begin{cases} \dot{x}_1 = x_1, \quad \dot{x}_2 = u, \quad 0 \leqq t \leqq 1, \\ y = x_2, \\ x_1(0) - x_2(0) + x_2(1) = 0, \qquad x_1(0) - x_1(1) - x_2(1) = 0. \end{cases}$$

One checks that

$$S(t) = \begin{pmatrix} e^t & 0 \\ 0 & 1 \end{pmatrix}, \qquad 0 \leqq t \leqq 1,$$

is a similarity transformation which transforms θ_1 into θ_2. Since the main coefficient of θ_1 is zero and the main coefficient of θ_2 is different from zero, there is no time independent similarity transforming θ_1 into θ_2. It is readily checked (using Theorem 2.1) that θ_1 and θ_2 are both irreducible.

In Theorem 2.3 for a time invariant system one may replace the weighting patterns by the moments. The same remark holds true for Corollary 2.5.

When applied to a time invariant system the similarity and reduction procedure of Theorem 2.4 does not always yield an irreducible system which is also time invariant. In fact, it may happen that a system θ is time invariant and that there is no irreducible time invariant system with the same sequence of weighting patterns as θ. For example, take

$$\Delta \quad \begin{cases} \dot{x}_1 = u, \quad \dot{x}_2 = x_1, \quad \dot{x}_3 = 0, \quad 0 \leqq t \leqq 1, \\ y = x_3, \\ x_1(0) = x_2(0) = 0, \qquad x_2(1) - x_3(1) = 0. \end{cases}$$

The first weighting pattern of the system Δ is the zero operator and all other weighting patterns are equal to the rank one integral operator

$$(W\varphi)(t) = \int_0^1 (s-1)\varphi(s)\, ds, \qquad 0 \leqq t \leqq 1.$$

It is not difficult to check that the following system Δ_0 has the same sequence of weighting patterns as Δ:

$$\Delta_0 \quad \begin{cases} \dot{x}_1 = (1-t)u, \quad \dot{x}_2 = (1-t)u, \quad 0 \leqq t \leqq 1, \\ y = -x_1 + x_2, \\ x_2(0) = 0, \qquad x_1(1) = 0. \end{cases}$$

Note that the state space of Δ has dimension three and that of Δ_0 is two-dimensional. Thus (see Theorem 2.3) the system Δ is not irreducible. On the other hand by applying Theorem 2.1 one easily sees that Δ_0 is an irreducible system. However, Δ_0 is time varying and one shows without difficulty that there is no time invariant system with a two-dimensional state space that has the same sequence of weighting patterns as Δ and Δ_0. So for the time invariant system Δ there is no irreducible time invariant system with the same sequence of weighting patterns as Δ.

5. Displacement systems. Deviating slightly from the terminology introduced in [9, § 1.6] we call a time invariant system θ with well-posed boundary conditions a

displacement system if the canonical boundary value operator P of θ commutes with the main coefficient A of θ. Causal (or anti-causal) time invariant systems are displacement systems. For a displacement system the kernel k of the input-output operator is a displacement kernel which means (see [13]) that k depends only on the difference of the arguments, i.e., $k(t, s) = h(t-s)$ for some function h. A similar remark holds true for the kernels of the weighting patterns of a displacement system. In fact, for a displacement system the kernel of the rth weighting pattern has the form

$$C e^{(t-a)A} P^{r-1} B, \qquad a \leqq t \leqq b, \quad a \leqq s \leqq b.$$

and its moments can be written as $CA^k P^{r-1} B$.

Let $\theta = (A, B, C, D; N_1, N_2)_a^b$ be a displacement system, and let P be its canonical boundary value operator. The (r, q)-extension $E_{rq}(\theta)$ of θ is the following system:

$$E_{rq}(\theta) \quad \begin{cases} \dot{x}(t) = Ax(t) + B^{(r)}\tilde{u}(t), & a \leqq t \leqq b, \\ \tilde{y}(t) = C^{(q)}x(t), & a \leqq t \leqq b, \\ N_1 x(a) + N_2 x(b) = 0, \end{cases}$$

where

$$B^{(r)} = [B \quad PB \quad \cdots \quad P^{r-1}B],$$
$$C^{(q)} = [C \quad CP \quad \cdots \quad CP^{q-1}]^T.$$

It follows that $E_{rq}(\theta)$ is again a displacement system. In particular, we see that the (r, q)-extensions (including the standard extension) of θ are time invariant. As a consequence for displacement systems the theory of similarity and reduction of § 2 resembles strongly the classical theory of causal time invariant systems.

THEOREM 5.1. *A similarity transformation between two irreducible displacement systems is time independent.*

Proof. For $\nu = 1, 2$ let $\theta_\nu = (A_\nu, B_\nu, C_\nu, D_\nu; N_1\ N_2)_a^b$ be an irreducible displacement system with state space X_ν. Let $S(t): X_1 \to X_2$, $a \leqq t \leqq b$, be a similarity transformation which transforms θ_1 into θ_2. We want to show that $S(t)$ does not depend on t. Put $F = S(a)$. Then $S(t) = e^{tA_2} F e^{-tA_1}$ and $P_2 F = F P_1$, where P_1 and P_2 are the canonical boundary value operators of θ_1 and θ_2, respectively. Since $P_1 A_1 = A_1 P_1$ and $P_2 A_2 = A_2 P_2$, it follows that

$$S(t) P_1 = P_2 S(t), \qquad a \leqq t \leqq b. \tag{5.1}$$

For $\nu = 1, 2$ consider the causal system $\Delta_\nu = (A_\nu, \tilde{B}_\nu, \tilde{C}_\nu, 0; I, 0)_a^b$, where

$$\tilde{B}_\nu = [B_\nu \quad P_\nu B_\nu \quad \cdots \quad P_\nu^{d-1} B_\nu],$$
$$\tilde{C}_\nu = [C_\nu \quad C_\nu P_\nu \quad \cdots \quad C_\nu P_\nu^{d-1}]^T.$$

Here d is the degree of the minimal polynomial of P_ν (which does not depend on ν). From (5.1) it follows that $S(t)$, $a \leqq t \leqq b$, is a similarity which transforms Δ_1 into Δ_2. The irreducibility of θ_1 and θ_2 implies that Δ_1 and Δ_2 are controllable and observable systems. Since, in addition, Δ_1 and Δ_2 are causal, we can use the classical theory of causal systems to show that $S(t)$ does not depend on t (see, e.g., [25, Thm. 2]). □

THEOREM 5.2. *A displacement system is a dilation of an irreducible displacement system.*

Proof. Let $\theta = (A, B, C, D; N_1, N_2)_a^b$ be a displacement system. Let P be the canonical boundary value operator of θ, and let n be the dimension of the state space

X of θ. Put

$$X_1 = \bigcap_{j,r=0}^{n-1} \operatorname{Ker} CA^jP^r, \qquad \tilde{X} = \bigvee_{j,r=0}^{n-1} \operatorname{Im} P^rA^jB, \tag{5.2}$$

where $\bigvee_{j=0}^{m} Z_j$ stands for the linear hull of the spaces $Z_0, \cdots, Z_m$. The operator P^n is a linear combination of the operators $I, P, \cdots, P^{n-1}$. So, if $x \in X_1$, then $CA^jP^nx = 0$ for $j = 0, \cdots, n-1$, and $Px \in X_1$. Also, $\operatorname{Im} P^nA^jB \subset \tilde{X}$, which implies that $P\tilde{X} \subset \tilde{X}$. Hence X_1 and $\tilde{X}$ are invariant under P. Since A commutes with P, we may interchange in (5.2) the positions of A and P. It follows that the spaces X_1 and $\tilde{X}$ are also invariant under A.

Let X_0 be a direct complement of $X_1 \cap \tilde{X}$ in $\tilde{X}$. Further, let X_2 be a direct complement of $X_1 \oplus X_0$ in X. So $X = X_1 \oplus X_0 \oplus X_2$ and $X_0 \subset \tilde{X} \subset X_1 \oplus X_0$. It follows that relative to the decomposition $X = X_1 \oplus X_0 \oplus X_2$ the operators A and P admit the following partitioning:

$$A = \begin{pmatrix} * & * & * \\ 0 & A_0 & * \\ 0 & 0 & * \end{pmatrix}, \qquad P = \begin{pmatrix} * & * & * \\ 0 & P_0 & * \\ 0 & 0 & * \end{pmatrix}. \tag{5.3}$$

Note that $\operatorname{Im} B \subset X_1 \oplus X_0$ and $X_1 \subset \operatorname{Ker} C$. So

$$B = \begin{pmatrix} * \\ B_0 \\ 0 \end{pmatrix}, \qquad C = [0 \quad C_0 \quad *] \tag{5.4}$$

relative to the decomposition $X = X_1 \oplus X_0 \oplus X_2$. Put

$$\theta_0 = (A_0, B_0, C_0, D; I - P_0, P_0 e^{-(b-a)A_0})_a^b.$$

Then θ is a dilation of θ_0. The fact that A commutes with P implies that A_0 commutes with P_0. Note that P_0 is the canonical boundary value operator of θ_0. Thus θ_0 is a displacement system. To prove that θ_0 is irreducible, it suffices to show that

$$\bigcap_{j,r=0}^{n-1} \operatorname{Ker} C_0A_0^jP_0^r = (0), \qquad \bigvee_{j,r=0}^{n-1} P_0^rA_0^jB_0 = X_0.$$

But these identities follow readily from the partitionings of A, P, B and C (see formulas (5.3) and (5.4)). □

Note that Theorem 5.2 implies that a displacement system is irreducible if and only if it does not admit a proper reduction. The next result is an immediate corollary of Theorem 5.2 and Theorem 2.2.

COROLLARY 5.3. *Two displacement systems θ_1 and θ_2 are dilations of similar irreducible systems if and only if θ_1 and θ_2 have the same external coefficient and the same sequence of moments.*

The results of this section can be extended to certain classes of time invariant systems with well-posed boundary conditions that are nondisplacement systems. For example, if $AP - PA = \alpha P + \beta A$ for some complex numbers α and β, then one can use the results of [20] (cf. [23]) to get the desired generalizations.

Acknowledgment. It is a pleasure to thank L. Lerer for useful discussions on the subject of this paper.

LARGE DEVIATIONS ESTIMATES FOR SYSTEMS WITH SMALL NOISE EFFECTS, AND APPLICATIONS TO STOCHASTIC SYSTEMS THEORY*

PAUL DUPUIS† AND HAROLD J. KUSHNER‡

Abstract. For typical stochastic systems (e.g., tracking systems), estimates of the behavior are hard to get. If the noise effects are small, then asymptotic methods are appealing (to get, for example, estimates of times required to lose track, etc.). In this paper, systems with small noise effects and wide bandwidth noise inputs are analyzed via large deviations methods. Inputs to many systems in control, communication or in physics are not "white noise", but of certain "wide bandwidth" types. Since large deviations results can be sensitive to the actual noise model used, working with a model that is close to the "physical" form is important. Several such models are dealt with, where the bandwidth is large, but the "intensity" small. For the models chosen, the action functionals turn out to be the same as for the "small Gaussian white noise" models. Thus, it is actually feasible to do computations with them. Estimates of the probability that the path lies in various sets are obtained. The formula for the mean escape time of the system from a set in which the "average dynamics" are stable is given, as are results on the most likely escape routes and the likely locations of the path on long time intervals. Such quantities, already available with small white noise model, are very helpful for understanding the long term systems behavior. The methods are applied to a detailed analysis of a phase locked loop tracking system (a special form of a nonlinear filter).

Key words. large deviations, phase locked loops, escape times, asymptotic analysis, wide bandwidth noise inputs, small noise effects

AMS(MOS) subject classifications. 60F10, 93E03, 94A05

1. Introduction.

The most common model used for large deviations (or small noise effects) asymptotic analysis in physics and engineering is the "small Gaussian white noise" model

$$dx^\varepsilon = b(x^\varepsilon)\,dt + \sqrt{\varepsilon}\sigma(x^\varepsilon)\Sigma^{1/2}\,dw, \qquad x \in R^n, \tag{1.1}$$

[1], [2], [3], [13], [14]. We insert the (nonsingular) matrix Σ in anticipation of future developments. Typically, the asymptotic analysis is used to estimate escape times from certain sets of interest, or the probability of inclusion of the path in a given set over some given time interval.

Suppose, in particular, that θ is an asymptotically stable point for $\dot{x} = b(x)$ and G is a neighborhood of θ, with a smooth boundary. Then we might be interested in an estimate of the probability of escape of $x^\varepsilon(\cdot)$ from G on a time interval $[0, T]$. Let $C_x[0, T]$ denote the set of continuous R^n-valued functions on $[0, T]$, with initial value x. Define the *H-function* (for (1.1)) and its *dual L* by

$$H(\alpha, x) = \alpha' b(x) + \alpha'\sigma(x)\Sigma\sigma'(x)\alpha/2, \tag{1.2}$$

$$L(\beta, x) = \sup_\alpha [\beta'\alpha - H(\alpha, x)] = \sup_\alpha [\alpha'(\beta - b(x)) + \alpha'\sigma(x)\Sigma\sigma'(x)\alpha/2]. \tag{1.3}$$

If $\sigma(x)\Sigma\sigma'(x) = \tilde{\Sigma}(x)$ is invertible, then

$$L(\beta, x) = (\beta - b(x))'\tilde{\Sigma}^{-1}(x)(\beta - b(x))/2. \tag{1.4a}$$

If

$$\tilde{\Sigma} = \begin{bmatrix} \tilde{\Sigma}_1 & 0 \\ 0 & 0 \end{bmatrix},$$

with $\tilde{\Sigma}_1$ invertible then (write $\beta = (\beta_1, \beta_2)$, $b = (b_1, b_2)$)

$$L(\beta, x) = \begin{cases} (\beta_1 - b_1(x))'\tilde{\Sigma}_1^{-1}(x)(\beta_1 - b_1(x))/2 & \text{for } \beta_2 = b_2(x), \\ \infty & \text{otherwise.} \end{cases} \tag{1.4b}$$

Define $\tau_G(\phi) = \inf\{t: \phi(t) \notin G\}$ for $\phi(\cdot) \in C_x[0, \infty)$. All $\phi(\cdot)$ below are in either $C_x[0, T]$ or $C_x[0, \infty)$. Define the action functional $S(\phi, T)$ by

$$S(\phi, T) = \begin{cases} \int_0^T L(\dot{\phi}(s), \phi(s))\, ds & \text{for } \phi(\cdot) \text{ absolutely continuous,} \\ \infty & \text{otherwise.} \end{cases}$$

Finally, define $S(\phi) = S(\phi, \tau_G(\phi))$. Let $A \subset C_x[0, T]$ with A^0 and $\bar{A}$ denoting the interior and closure of A, respectively. Let A_G denote the set of functions $\phi(\cdot)$ in $C_\theta[0, T]$ such that $\phi(t) \in \partial G$ for some $t < \infty$, and define $\tau_G^\varepsilon = \inf\{t: x^\varepsilon(t) \notin G\}$.

Typical results for (1.1) are (under broad conditions in G, $b(\cdot)$ *and* $\sigma(\cdot)$, there is equality in (1.5b)), for $x \in G$,

$$\lim_\varepsilon \varepsilon \log E_x \tau_G^\varepsilon = \inf_{\phi \in A_G} S(\phi), \tag{1.5a}$$

$$\begin{aligned} -\inf_{\phi \in A^0} S(\phi, T) &\leqq \underline{\lim}_\varepsilon \varepsilon \log P_x\{x^\varepsilon(\cdot) \in A\} \\ &\leqq \overline{\lim}_\varepsilon \varepsilon \log P_x\{x^\varepsilon(\cdot) \in A\} \leqq -\inf_{\phi \in \bar{A}} S(\phi, T). \end{aligned} \tag{1.5b}$$

Thus, obtaining the estimates in (1.5) requires solving a variational problem. With model (1.1), the integrand $L(\dot{\phi}, \phi)$ can be written explicitly, which is not usually the case for models which use other than "white noise". This simplicity underlies much of the popularity of (1.1).

By defining $u = (\sigma(\phi)\Sigma^{1/2})^{-1}(\dot{\phi} - b(\phi))$ in (1.3), we see that the variational problem of $\inf_{\phi \in A} \int_0^T L(\dot{\phi}, \phi)\, ds$ is equivalent to the "optimal control" problem:

$$\inf_{\phi \in A} \int_0^T |u(t)|^2\, dt, \qquad \dot{\phi} = b(\phi) + \sigma(\phi)\Sigma^{1/2}u. \tag{1.5c}$$

This equivalence will be useful in § 4.

From the point of view of applications to physical problems, the model (1.1) has several deficiencies. Owing to the small noise effects and the stability of $\dot{x} = b(x)$, the escape phenomena of interest requires a long time to occur, and escape depends on a burst of "unusual" noise. No physical noise is actually "white Gaussian", and the estimates can be quite sensitive to the actual noise model; e.g., let

$$\dot{x} = b(x^\varepsilon) + \sigma(x^\varepsilon)\xi^\varepsilon,$$

where $\int_0^t \xi^\varepsilon(s)\, ds/\sqrt{\varepsilon}$ converges to a Wiener process. Under quite reasonable conditions, the estimates for the quantities in (1.5) for this model can differ considerably from

those obtained for (1.1) [4]. See also [5] which presents some continuity results on the estimates with respect to the statistics of $\xi^\varepsilon(\cdot)$.

In this paper, we replace $w(\cdot)$ in (1.1) by more realistic noise processes—which are approximations to a Wiener process in an appropriate sense. We choose models such that the above action functional $S(\phi, T)$ can be used; i.e., the small Gaussian white noise approximation is valid. The treatment of applications with realistic noise processes (in, for example, stochastic systems theory) seems (to date) to require the type of analysis which we do here. The noise models are of the type which arise in numerous applications in control and communications theory, and in physics. A detailed application to a phase locked loop (a special form of nonlinear filter) problem is given in § 5. Owing to the possible sensitivity of the results to the model, we treat the system without simplifying it—and then show that the "Gaussian white noise" model for a simpler form is indeed valid, under the stated assumptions on the input noise.

We work with systems of the form

$$\dot{x}^\rho = b(x^\rho) + \varepsilon\sigma(x^\rho)\xi^\gamma(t) \tag{1.6}$$

where $\rho = (\varepsilon, \gamma)$, and $b(\cdot)$ and $\sigma(\cdot)$ are bounded, together with their first partial derivatives. Let τ_G^ρ denote the escape time of $x^\rho(\cdot)$ from G. Two specific stationary models will be used for the $\xi^\gamma(\cdot)$; in either case the integral of the driving noise $\int_0^t \xi^\gamma(s)\,ds$ converges weakly to a Wiener process $w(\cdot)$. In the phase locked loop example, we illustrate how the model might be easily modified to handle a variety of slightly different cases.

We will take limits as $\varepsilon \to 0$ and $\gamma \to 0$ simultaneously (i.e., as $\rho \to 0$). Thus $\xi^\gamma(t) \to$ "white noise" (loosely speaking) and its "weight" ε converges to zero. This allows a more realistic modelling than we could get with only a single parameter, since it allows us to vary the "bandwidth" and "intensity" of the noise more or less independently.

In [1, p. 132], the system $x^\varepsilon = b(x^\varepsilon, \varepsilon\xi)$ is dealt with, where $\xi(\cdot)$ is a fixed Gaussian process, and the analogue of (1.5a) is obtained, but the result or technique are not appropriate for our model or for applications such as those in § 5. In such cases, we are concerned with "small noise effects", and these can be caused by either (a) small noise (multiply a *fixed* process by ε), or (b) by using a process $\xi(t/\gamma)$, for small γ (wide bandwidth), or by a *combination* of both effects (e.g., use $\varepsilon\xi(t/\gamma)/\sqrt{\gamma}$). Such combinations are important in applications.

In § 2, we define the specific noise models which are to be used, and in § 3, the appropriate H-functionals are obtained. The basic limit theorems are stated and proved in § 4. Analogues of both (1.5a) and (1.5b) are obtained, as well as estimates of the locations of the points of escape from G.

The proofs depend on several (large derivations type) estimates for the noise processes—and for related dynamical systems, and these are derived in the appendices. We also obtain some results on the "jumping" of the process from invariant set to invariant set (of $\dot{x} = b(x)$), analogous to the results in [1, Chap. 6]. These results are useful for the problem of the asymptotic distribution of $x^\varepsilon(\cdot)$, for large t and small ε, when the system $\dot{x} = b(x)$ has several stable points or invariant sets.

In § 5, the techniques of § 4 are applied to a phase locked loop problem, and it is shown, under reasonable conditions, that a "small white noise" model is appropriate, and that the "high frequency" terms which appear in the actual dynamical equations can be neglected, in the sense that the correct action functionals are actually of the "small white noise" type, without the "high frequency" terms. These results validate the types of approximations and simplifications made in the PLL model analyzed in [3].

2. The noise models. The "wide-bandwidth" Gaussian noise process of Model I is a standard one in many applications. With Model II, we attempt to get close to the "physical" noise in many applications in control and communication theory, and in applications in physics. The idea is that the noise is "close to" impulsive but has a "short memory". Thus, we use a scaled and filtered impulsive noise process. Consider, for example, "shot" or "impulsive" noise in an electrical circuit. Owing to the sensitivity of the large deviations estimates to the noise model (see [4], for example), it is important to use a model which is as close to the "physical" situation as possible—even though for standard applications (not of a "large deviations" or "small noise" type) a Gaussian process approximation is usually adequate. With scalings other than that used in Model II below, the limit action functional would not be of the "small white noise" type.

Model I. Let $\xi^\gamma(t) = \xi(t/\gamma)/\sqrt{\gamma}$, where

$$d\xi = A\xi\, dt + B\, dw, \quad A \text{ stable}, \quad w(\cdot) \text{ standard}. \tag{2.1}$$

Then

$$W^\gamma(t) \equiv \int_0^t \xi^\gamma(s)\, ds$$

converges weakly to a Wiener process with covariance matrix

$$\tilde{\Sigma}_1 + \tilde{\Sigma}_1' = \Sigma_1 = \int_{-\infty}^{\infty} E\xi^\gamma(t)\xi^\gamma(0)\, dt = \int_{-\infty}^{\infty} E\xi(t)\xi(0)\, dt$$

where

$$\tilde{\Sigma}_1 = -A^{-1}\int_0^\infty (\exp At)BB'(\exp A't)\, dt.$$

An integration by parts yields $\Sigma_1 = (A^{-1}B)(A^{-1}B)'$.

Model II. $\xi^\gamma(t) = \bar{\xi}^\gamma(t/\gamma)/\gamma$, where

$$d\bar{\xi}^\gamma = A\bar{\xi}^\gamma\, dt + d\bar{J}^\gamma, \tag{2.2}$$

where $\bar{J}^\gamma(\cdot)$ is a jump Markov process with jump rate $\mu_\gamma\gamma$, and the jumps have the distribution of a random variable ψ^γ, where $E\psi^\gamma = 0$, $\operatorname{var}\psi^\gamma = \nu_\gamma$ and $\nu_\gamma\mu_\gamma = C_0$, a constant matrix. In order to obtain the desired "Gaussian" limit form for the H-functional an additional condition on the higher moments of ψ^γ, and on the relation between ε and γ is required: for some $\alpha > 0$ and $k < \infty$

$$\begin{aligned} &\mu_\gamma = O(\gamma^{-2-\alpha}), \qquad \nu_\gamma = O(\gamma^{2+\alpha})C_0, \\ &E|\psi_i^\gamma|^{2n} \leqq n!k^n|v_\gamma|^n, \\ &\gamma^{1+\alpha/2}/\varepsilon \to 0 \quad \text{as } \rho \to 0. \end{aligned} \tag{2.3}$$

Define

$$\tilde{\Sigma}_2 = \int_0^\infty (\exp At)\, dt \int_0^\infty (\exp As)C_0 \exp A's\, ds.$$

Then

$$W^\gamma(t) \equiv \int_0^t \xi^\gamma(s)\, ds$$

converges weakly to a Wiener process with covariance

$$\Sigma_2 = \int_{-\infty}^{\infty} E\xi^\gamma(t)\xi^\gamma(0)'\,dt = \tilde{\Sigma}_2 + \tilde{\Sigma}_2' = A^{-1}C_0(A')^{-1}.$$

Large deviations results for these noise models cannot be obtained directly from existing works. Freidlin and Ventsel [1] use (1.1), Ventsel [6] requires a Markov property for $x^\rho(\cdot)$, and other conditions which are not necessarily satisfied here. Azencott and Ruget [9] also require a Markov property on $x^\rho(\cdot)$. In Freidlin [7], a bounded noise process (and a single scaling parameter) is used. Except for a special case, we concentrate on the analogue of (1.5b) for $x^\rho(\cdot)$, and also obtain estimates of the type

$$\lim_\rho \varepsilon^2 \log E_x \tau_G^\rho = \inf_{\phi \in A_G} S(\phi). \tag{2.4}$$

The usual arguments for the equality in (2.4) (as in [1]) depend heavily on a Markov property and the use of Markov stopping times. In order to prove (2.4), we need various "large deviations" type estimates for $W^\gamma(\cdot)$, uniform in the initial condition $\xi^\gamma(0)$ in certain sets. Regrettably, this complicates the development.

3. The H-functions for the noise models.

Model I. Define

$$H(\alpha, x) = \alpha' b(x) + H_0(\alpha, x), \tag{3.1}$$

where H_0 is defined by (for any $t>0$ and with the *definition* $\lambda_\rho = \varepsilon^2$),

$$\begin{aligned} tH_0(\alpha, x) &= \lim_\rho \lambda_\rho \log E \exp \varepsilon \int_0^t \alpha'\sigma(x)\xi^\gamma(s)\,ds/\lambda_\rho \\ &= \alpha'\sigma(x)\int_{-\infty}^{\infty} E\xi^\gamma(s)\xi^\gamma(0)'\,ds\,\sigma'(x)\alpha/2 \\ &= \alpha'\sigma(x)\Sigma_1\sigma'(x)\alpha/2. \end{aligned} \tag{3.2}$$

If $\alpha(\cdot)$ is a piecewise constant function, then for each $T>0$,

$$\int_0^T H_0(\alpha(s), x)\,ds = \lim_\rho \lambda_\rho \log E \exp \varepsilon \int_0^T \alpha'(s)\sigma(x)\xi^\gamma(s)\,ds/\lambda_\rho. \tag{3.3}$$

The normalization sequence $\{\lambda_\rho\}$ does not depend on γ.

Model II. $H(\alpha, x)$ is defined by (3.1), and $H_0(\alpha, x)$ by the limit in (3.2), where also $\lambda_\rho = \varepsilon^2$; but here we have (for any $t>0$)

$$\begin{aligned} tH_0(\alpha, x) &= \lim_\rho \lambda_\rho \log E \exp \varepsilon\alpha' \int_0^t \sigma(x)\xi^\gamma(s)\,ds/\lambda_\rho \\ &= \lim_\rho \lambda_\rho \log E \exp \varepsilon\alpha'\sigma(x)\int_0^{t/\gamma} ds \int_\tau^{t/\gamma} \exp A(s-\tau)\,d\bar{J}^\gamma(\tau)/\lambda_\rho \\ &= \lim_\rho \lambda_\rho \log E \exp \varepsilon\alpha'\sigma(x)\Omega_0 \int_0^{t/\gamma} d\bar{J}^\gamma(\tau)/\lambda_\rho, \end{aligned} \tag{3.4}$$

where $\Omega_0 = \int_0^\infty \exp As\,ds = -A^{-1}$. Continuing, we have

$$H_0(\alpha, x) = \lim_\rho \lambda_\rho \mu_\gamma [E \exp \varepsilon\alpha'\sigma(x)\Omega_0\psi^\gamma/\lambda_\rho - 1]. \tag{3.5}$$

Under (2.3),

$$H_0(\alpha, x) = \alpha'\sigma(x)A^{-1}(\mu_\gamma\nu_\gamma)(A')^{-1}\sigma'(x)\alpha/2 = \alpha'\sigma(x)\Sigma_2\sigma'(x)\alpha/2, \tag{3.6}$$

(3.6) is of the Gaussian form, and it is the form which one would obtain if εdW were used in (1.6), where $W(\cdot)$ is the Wiener process limit (weak convergence sense) of $\{W^\gamma(\cdot)\}$. $H_0(\alpha, x)$ also satisfies (3.3) for any piecewise constant function $\alpha(\cdot)$.

Remark. By the above calculations, the H, L and S functionals are those of § 1, where the Σ there is either Σ_1 or Σ_2, depending on the noise model.

4. The limit theorems. Recall the definition of $L(\cdot,\cdot)$ in (1.3) and $S(\phi, T)$ in § 1.

THEOREM 4.1. *Under the assumptions in* §§ 1 *and* 2 *on the noise models and on* $\sigma(\cdot)$ *and* $b(\cdot)$,

$$\begin{aligned} -\inf_{\phi\in A^0} S(\phi, T) &\leqq \underline{\lim}_\rho \lambda_\rho \log P_x\{x^\rho(\cdot)\in A\} \\ &\leqq \overline{\lim}_\rho \lambda_\rho \log P_x\{x^\rho(\cdot)\in A\} \\ &\leqq -\inf_{\phi\in\bar{A}} S(\phi, T). \end{aligned} \tag{4.1}$$

Further, if $0<\delta<\frac{1}{2}$, *then* (4.1) *holds uniformly for* x *in a compact set and* $|\xi(0)|\leqq\gamma^{-\delta}\varepsilon^{-1}$ (*Model* I) *or* $|\bar{\xi}^\gamma(0)|\leqq\varepsilon^{-1}\gamma^{-\delta+1/2}$ (*Model* II).

The proof of this theorem is long, and is provided in Appendix I (Theorem A1.1 there).

Define $S^* = \inf_{\phi,T} S(\phi, T)$, where the infimum is over all T, $\phi\in C_\theta[0, T]$ satisfying $\phi(T)\in\partial G$. By (1.5c), this is equivalent to the optimal control problem

$$\inf \int_0^{\tau(\phi)} |u(t)|^2\, dt, \tag{4.2a}$$

$$\dot{\phi} = b(\phi)+\sigma(\phi)\Sigma^{1/2}u, \qquad \phi(0)=x, \tag{4.2b}$$

where $\tau(\phi)$ is the first hitting time of ∂G.

The mean exit time problem. We next prove a result for the mean exit time from a set G. The proof is an adaptation of that for the "white noise" case in [1], but is more complex since $x^\rho(\cdot)$ is neither Markovian, nor is the noise bounded. The proof in [1] requires that $\sigma(x)\Sigma\sigma'(x)$ be uniformly positive definite (the "nondegenerate" case). This is a very serious restriction in applications. In order to avoid it, we introduce the following controllability assumption for (4.2).

Assumption 4.1. There is an $M_1<\infty$ such that for small ε_1 and each x, $y\in N_{\varepsilon_1}(\theta)$ (ε_1-neighborhood of θ) there is a $u(\cdot)$ such that $|u(t)|\leqq M_1$ and for the *corresponding trajectory* (4.2b), $\phi(0)=x$, $\phi(t_1)=y$, *where* $t_1\to 0$ as $\varepsilon_1\to 0$.

This assumption always holds in the nondegenerate case. The assumption was used in [5, § 4 and elsewhere] to construct "approximately" optimal trajectories for certain "degenerate" problems.

THEOREM 4.2. *Let* θ *be an asymptotically stable equilibrium position of* $\dot{x}=b(x)$, *and assume* (*bounded*) G *is attracted to* θ. *Furthermore, assume that the boundary* ∂G *is smooth and* $(b(x), n(x))<0$ *for* $x\in\partial G$, *where* $n(x)$ *is the exterior normal of the boundary of* G, *and let* $S^*<\infty$. *Then, under Assumption* 4.1, *there exists a set with probability greater than* $1-\exp(-M_\rho/\lambda_\rho)$, *where* $M_\rho\to\infty$ *as* $\rho\to 0$ *such that*

$$\lim_\rho \lambda_\rho \log E_x\tau^\rho I_{A_\rho} = S^* \tag{4.3}$$

where τ^ρ *is the first exit time of* $x^\rho(\cdot)$ *from* G.

Remark. The proof of Theorem 4.2 is an adaptation of that for the "white noise" case in [1], but is more complex, since $x^\rho(\cdot)$ is not Markovian. Equation (4.3) differs slightly from the "usual" result, due to the presence of the "exceptional" set $\Omega - A_\rho$, of "exponentially small probability". This is hardly a restriction in applications.

Proof. Part I. First we show that for each $d>0$, there is a set A_ρ and a $\rho_0>0$ such that $P\{A_\rho\} \geqq 1-\exp(-M_\rho/\lambda_\rho)$, where $M_\rho \to \infty$ as $\rho \to 0$ and for $\rho < \rho_0$

$$\lambda_\rho \log E_x I_{A_\rho} \tau^\rho \leqq S^* + d \tag{4.4}$$

(d does not depend on $\xi(0)$ for $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$, $\delta \in (0, \frac{1}{2})$).

As is discussed in [1, p. 124], we may choose positive μ, h, T_1, T_2, $k<1$, such that the following conditions hold:

(a) All solutions of $\dot{x} = b(x)$ starting in $G \cup \partial G$ satisfy

$$|\theta - x(t)| \leqq k\mu$$

for $t \geqq T_1/2$.

(b) For every point in the set

$$D = \{x: |\theta - x| \leqq \mu\}$$

there is $\phi^x(\cdot) \in C_x[0, \infty)$ such that $\phi^x(0) = x$, $\phi^x(t)$ reaches the exterior of the h-neighborhood of G at time $T(x) \leqq T_2$ and

$$S(\phi^x, T(x)) < S^* + \frac{d}{2}.$$

In [1], the $\phi^x(\cdot)$ do not hit the $k\mu$-neighborhood of θ after exit from D, but this is not needed.

The construction of such $\phi^x(\cdot)$ is clear in the nondegenerate case. For the degenerate case, the controllability assumption is needed if the d-optimal for S^* are tangent to ∂G at the first hitting time. It also guarantees that the particular points in D to which the trajectories (in the cycles constructed below) return are irrelevant in the analysis—since we can move "quickly and cheaply" between any point in D for small μ. Henceforth, we simply assume the existence of the paths specified in (a) and (b) above.

We prove the theorem for Model I. The proof for Model II is entirely analogous. Let $0 < \delta_1 < \delta_2 < \frac{1}{2}$. By Theorem 4.1 there is $\rho_0 > 0$ such that $\rho < \rho_0$ implies, uniformly in $y \in D$ and in $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta_1}$,

$$P_{y,\xi(0)}\{\sup_{0 \leqq t \leqq T(y)} |x^\rho(t) - \phi^y(t)| < h\} \geqq \exp(-(S^* + d)/\varepsilon^2). \tag{4.5}$$

which implies that

$$P_{y,\xi(0)}\{\tau^\rho < T_2\} \geqq \exp(-(S^* + d)/\varepsilon^2).$$

In order to complete the proof, we need the following auxiliary lemma.

LEMMA 4.1. *There is $\rho_0 > 0$ such that for $\rho \leqq \rho_0$ and uniformly in $x \in G$ and in $|\xi(0)| \leqq \gamma^{-\delta_1}\varepsilon^{-1}$, we have*

$$P_{x,\xi(0)}\{\tau^\rho < T_1 + T_2\} \geqq \exp(-(S^* + d)/\varepsilon^2).$$

Proof of Lemma. Let τ_1 denote the time of first entrance into a μ-neighborhood of θ. For any $M < \infty$ and small ρ

$$P_{x,\xi(0)}\{\tau^\rho \leqq T_1 + T_2\} \geqq E_{x,\xi(0)}[P_{x^\rho(\tau_1)}\{\tau^\rho < T_2\} I_{\{\tau_1 \leqq T_1\}} \big| |\xi(\tau_1/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}](1 - e^{-M/\varepsilon^2})$$
$$- P_{x,\xi(0)}\{\sup_{0 \leqq t \leqq T_1/\gamma} |\xi(t)| \geqq \gamma^{-\delta_2}\varepsilon^{-1}\}.$$

By Lemma A2.1, uniformly in $|\xi(0)| \leqq \gamma^{-\delta_1}\varepsilon^{-1}$, the second term on the right is less than $\exp(-M/\varepsilon^2)$ for any given M if ρ is small enough. By (4.5), and the fact that the conditional probability that $\{\tau_1 \leqq T_1\}$ goes to unity as $\rho \to 0$, the first term is greater than (for small ρ)

$$\tfrac{1}{2}\exp(-(S^*+d/2)/\varepsilon^2), \tag{4.6}$$

and the lemma is proved.

Define $T = T_1 + T_2$ and the sets $B_\rho = \{\omega: \sup_{0\leqq t\leqq \exp(S^*+d)/\varepsilon^2} |\xi(t)| < \gamma^{-\delta_1}\varepsilon^{-1}\}$ and $B_\rho(n) = \{\omega: \sup_{0\leqq t\leqq nT} |\xi(t)| < \gamma^{-\delta_1}\varepsilon^{-1}\}$.

Select (by Lemma A2.1) $\rho_0 > 0$ such that for $\rho \leqq \rho_0$,

$$P\{\Omega - B_\rho\} \leqq \exp(-M/\varepsilon^2). \tag{4.7}$$

By the Markov property of $(x^\rho(\cdot), \xi^\gamma(\cdot))$, for $nT \leqq \exp(S^*+d)/\varepsilon^2$ we have

$$\begin{aligned} E_x P\{\tau^\rho \geqq nT\} I_{B_\rho} &\leqq E_x I_{\{\tau^\rho \geqq nT\}} I_{\{\tau^\rho \geqq nT-T\}} I_{B_\rho(n-1)} \\ &= E_x P_x\{\tau^\rho \geqq nT | \tau^\rho \geqq nT - T, \omega \in B_\rho(n-1)\} I_{\{\tau^\rho \geqq nT-T\}} I_{B_\rho(n-1)}. \end{aligned}$$

We have

$$\begin{aligned} P_x\{\tau^\rho \geqq nT | \tau^\rho \geqq nT - T, \omega \in B_\rho(n-1)\} &\leqq \sup_{\substack{y\in G \\ |\xi(0)|\leqq \varepsilon^{-1}\gamma^{-\delta_1}}} P_{y,\xi(0)}\{\tau^\rho \geqq nT\} \\ &= 1 - \inf_{\substack{y\in G \\ |\xi(0)|\leqq \varepsilon^{-1}\gamma^{-\delta_1}}} P_{y,\xi(0)}\{\tau^\rho < T\} \\ &\leqq 1 - \tfrac{1}{2}\exp(-(S^*+d/2)/\varepsilon^2). \end{aligned}$$

Then, iterating yields

$$E_x P\{\tau^\rho \geqq nT\} I_{B_\rho} \leqq (1 - \tfrac{1}{2}\exp(-(S^*+d/2)/\varepsilon^2)^n). \tag{4.8}$$

For $nT = \exp(S^*+d)/\varepsilon^2$, we find that for small ρ (so that $(\exp(d/2\varepsilon^2)/T \geqq 2M/\varepsilon^2)$)

$$\begin{aligned} E_x P\{\tau^\rho \geqq \exp(S^*+d)/\varepsilon^2\} I_B &\leqq [1 - \tfrac{1}{2}\exp(-(S^*+d/2)/\varepsilon^2)]^{[\exp(S^*+d)/\varepsilon^2]/T} \\ &\leqq \exp(-[\exp d/2\varepsilon^2]/2T) \leqq \exp - M/\varepsilon^2. \end{aligned}$$

Define $\tilde{B}_\rho = \{\omega: \tau^\rho \leqq \exp(S^*+d)/\varepsilon^2\}$ and $A_\rho = B_\rho \cap \tilde{B}_\rho$. Then

$$P\{A_\rho\} \geqq 1 - 2\exp(-M/\varepsilon^2)$$

and

$$\begin{aligned} E_x \tau^\rho I_{A_\rho} &\leqq T \sum_0^{\exp(S^*+d)/\varepsilon^2} P_x\{\tau^\rho \geqq nT\} \\ &\leqq T \sum_0^\infty [1 - \exp(-(S^*+d/2)/\varepsilon^2)]^n \qquad (4.9) \\ &\leqq \exp(S^*+d)/\varepsilon^2. \end{aligned}$$

Proof. Part II. We now prove the reverse inequality to (4.4), namely that *for each* $d > 0$, *there is a* $\rho_0 > 0$ *such that for* $\rho \leqq \rho_0$,

$$\lambda_\rho \log E_x \tau^\rho \geqq S^* - d, \qquad x \in G. \tag{4.10}$$

It is convenient to separate the proof into a few lemmas. We first prove

LEMMA 4.2. *Given $\delta > 0$, $M < \infty$ there is a $\rho_0 > 0$ such that for $\rho \leqq \rho_0$ and $x \in G$*

$$P_x\{\sup_{0 \leqq t \leqq \tau^\rho/\gamma} |\xi(t)| \geqq \gamma^{-\delta}\varepsilon^{-1}\} \leqq \exp(-M/\varepsilon^2). \tag{4.11}$$

If the probability in (4.11) *is conditioned on $\xi(0)$, then the result holds uniformly for $|\xi(0)| \leqq \gamma^{-\delta_1}\varepsilon^{-1}$ for any $\delta > \delta_1$.*

Proof of the lemma. By Part I of the proof, for any $M_1 < \infty$ and $h > 0$, there is a $\rho_0 > 0$ such that $\rho \leqq \rho_0$ implies that for $x \in G$, and $|\xi(0)| \leqq \gamma^{-\delta_1}\varepsilon^{-1}$,

$$P_{x,\xi(0)}\{\tau^\rho > \exp M_1/\varepsilon^2\} \leqq (\exp(-M_1/\varepsilon^2)) \exp(S^* + d)/\varepsilon^2.$$

It follows from Lemma A2.1 that for each $M_2 < \infty$ and small enough ρ (and uniformly in the desired $|\xi(0)|$ set),

$$P_{\xi(0)}\{\sup_{t \leqq (\exp M_1/\varepsilon^2)/\gamma} |\xi(t)| \leqq \gamma^{-\delta}\varepsilon^{-1}\} \leqq (\exp(-M_2/\varepsilon^2)) \exp M_1/\varepsilon^2.$$

Using the above two estimates and selecting M_1 and $M_2 - M_1$ large enough and ρ small enough yields the lemma

LEMMA 4.3. *Let $\delta \in (0, \frac{1}{2})$ and $\alpha > 0$ (and small). There are $c > 0$ and $T_0 < \infty$ such that for all $T < \infty$ and $x \in \bar{G} - N_\alpha(\theta)$ and $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ we have for small enough ε*

$$P_x\{\tau^\alpha > T\} \leqq \exp(-c(T - T_0)/\varepsilon^2), \tag{4.12}$$

where $\tau^\alpha = \inf\{t: x^\rho(t) \notin G - N_\alpha(\theta)\}$.

Remark on the proof. Using the bound on the noise $|\xi(t)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ on $[0, \tau^\rho/\gamma]$ (w.p. $\geqq 1 - \exp - M/\varepsilon^2$), the proof is a simple modification of that of [1, Chap. 4, Lemma 2.2].

We are now ready to start the proof of (4.10). Following the idea in [1], fix small $\mu > 0$ and define $\Gamma_i = \{x: d(x, \theta) = i\mu\}$, for $i = 1$ and 2. Define the Markov times $\{\tau_i, \sigma_i\}$ by $\tau_0 = 0$ and

$$\sigma_i = \inf\{t > \tau_i: x^\rho(t) \in \Gamma_2\},$$
$$\tau_i = \inf\{t > \sigma_{i-1}: x^\rho(t) \in \Gamma_1 \cup \partial G\}.$$

Let $0 < \delta_1 < \delta_2 < \frac{1}{2}$ and let B denote the set $\{\xi: |\xi| \leqq \gamma^{-\delta_1}\varepsilon^{-1}\}$. For simplicity, we always will assume that the various initial conditions $\xi(t) \in B$ for $t < \tau^\rho$. This is true w.p. $\geqq 1 - \exp(-M/\varepsilon^2)$ for small ρ by Lemma 4.2. If (4.10) holds under this assumption, then it holds as stated.

For $x \in \Gamma_1$,

$$\begin{aligned} P_{x,\xi(0)}\{x^\rho(\tau_1) \in \partial G\} \leqq \max_{\substack{y \in \Gamma_2 \\ \xi(0) \in B}} [&P_{y,\xi(0)}\{\tau^\rho = \tau_1 < T, |\xi(\sigma_0/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}\} \\ &+ P_{x,\xi(0)}\{\tau^\rho = \tau_1 \geqq T, |\xi(\sigma_0/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}\} \\ &+ P_{\xi(0)}\{|\xi(\sigma_0/\gamma)| \geqq \gamma^{-\delta_2}\varepsilon^{-1}\}]. \end{aligned} \tag{4.13}$$

Since $\sigma_0 \leqq \tau^\rho$, Lemma 4.2 implies that, for any $M < \infty$, the last term on the right side of (4.13) is $\leqq \exp(-M/\varepsilon^2)$ for small ρ. By Lemma 4.3, there is a $T_1 < \infty$ such that for all $y \in \Gamma_2$ and small ρ,

$$P_{y,\xi(0)}\{\tau^\rho = \tau_1 \geqq T_1 | |\xi(\sigma_0/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}\} \leqq \exp(-M/\varepsilon^2). \tag{4.14}$$

By Theorem 4.1 (with the appropriate choice for the set A) we have, for all $y \in \Gamma_2$ and

sufficiently small ρ, and large enough T,

$$
\begin{aligned}
&P_y\{\tau^\rho = \tau_1 < T_1 \,|\, |\xi(\sigma_0/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}\} \\
&\qquad \leqq P_y\{\tau^\rho < T_1 \,|\, |\xi(\sigma_0/\gamma)| \leqq \gamma^{-\delta_2}\varepsilon^{-1}\} \leqq \exp\,(-(S^* - d/2)/\varepsilon^2).
\end{aligned} \tag{4.15}
$$

Combining (4.13) to (4.15) yields, for small ρ,

$$
P_{x,\xi(0)}\{x^\rho(\tau_1) \in \partial G\} \leqq \exp\,(-(S^* - d)/\varepsilon^2). \tag{4.16}
$$

Let v denote the smallest n for which $x^\rho(\tau_n) \in \partial G$. Then by the strong Markov property of $(x^\rho(\cdot),\ \xi^\gamma(\cdot))$

$$
\begin{aligned}
P_{x,\xi(0)}\{v > n\} &= P_{x,\xi(0)}\{x^\rho(\tau_i) \in \Gamma_1,\ i < n\} \\
&= E_{x,\xi(0)} P_{x,\xi(0)}\{x^\rho(\tau_n) \in \Gamma_1 \,|\, \xi(\tau_{n-1}/\gamma),\ x^\rho(\tau_{n-1})\} I_{\{v > n-1\}} \\
&\geqq \inf_{\substack{y \in \Gamma_2 \\ \xi \in B}} P_{y,\xi}\{x^\rho(\tau_1) \in \Gamma_1\} \cdot P_{x,\xi(0)}\{v > n-1\}. \qquad (4.17) \\
&\geqq [1 - \exp -(S^* - d)/\varepsilon^2] P_{x,\xi(0)}\{v > n-1\}. \\
&\geqq [1 - \exp -(S^* - d)/\varepsilon^2]^n.
\end{aligned}
$$

By Lemma 4.3, there is a K_1 such that $E_{x,\xi(0)}(\tau_1 - \sigma_0) \geqq K_1$ for $x \in G - N_\mu(\theta)$. This and (4.17) yields

$$
\begin{aligned}
E_x\tau^\rho &= \sum_1^\infty E_x I_{\{v \geqq n\}}(\tau_n - \tau_{n-1}) \\
&\geqq \sum_1^\infty E_x I_{\{v \geqq n\}}(\tau_n - \sigma_{n-1}) \\
&\geqq \sum_1^\infty P_x\{v \geqq n\} \inf_{\substack{y \in \Gamma \\ \xi(0) \in B}} E_{y,\xi}(\tau_1 - \sigma_0) \qquad (4.18) \\
&\geqq K_1 \exp\,(S^* - d)/\varepsilon^2.
\end{aligned}
$$

Thus, (4.10) holds for $x \in \Gamma_1$; hence for all $x \in N_\mu(\theta)$. The result holds in general, for any $x \in G$, since $P_x\{\tau^\rho > \tau_1\} \to 1$ for any $x \in G$. Q.E.D.

COROLLARY 4.3. *Assume the conditions of Theorem* 4.2 *except we allow part of the boundary* ∂G *to be a trajectory of* $\dot{x} = b(x)$ *(i.e.,* $(b(x),\ n(x)) \leqq 0$ *on* ∂G*) and assume nondegeneracy (i.e., in* (4.2b) $\sigma(x)\Sigma\sigma'(x) \geqq \alpha I$ *in* $\bar{G}$*, where* $\alpha > 0$*). Then* (4.3) *continues to hold.*

Remark on the proof. The proof follows the same lines as that of Theorem 4.2. Although we cannot necessarily find the required T_1 for x near ∂G, to get (4.9), we simply use the fact that

$$
\inf_{\phi, T} S(\phi, T) = S_x \to 0 \quad \text{as } x \to \partial G,
$$

where the inf is over $\{\phi\colon \phi(0) = x,\ \phi(T) \in \partial G\}$, and the fact that for any $d > 0$, $P_{x,\xi(0)}\{\tau^\rho \leqq T\} \geqq \exp -(S_x + d)/\varepsilon^2$ for $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ (Model I, and analogously for Model II) and small ε. To get (4.10), we use a set G_a, $a < 0$, (to which Theorem 4.2 can be applied), and the fact that the S^* for this converges to the S^* for G, as $a \to 0$.

Many of the other results derived by Freidlin and Ventsel in [1] for the "white Gaussian noise" case carry over to our noise models. We have

THEOREM 4.4. *Assume all the conditions of Theorem* 4.2, *and let there be points*

$y_1, \cdots, y_q \in \partial G$ *such that*

$$\inf_{T>0} \inf_{\phi \in A_i} S(\phi, T) = \inf_{T>0} \inf_{\phi \in A_0} S(\phi, T), \tag{4.19}$$

where $A_i = \{\phi \in C_\theta[0, T]: \phi(T) = y_i\}$ *and* $A_0 = \{\phi \in C_\theta[0, T]: \phi(T) \in \partial G\}$. *Then for each* $x \in G$ *and* $\delta > 0$,

$$\lim_{\rho \to 0} P_x\{d(x^\rho(\tau^\rho), \bigcup_1^q \{y_i\}) < \delta\} \to 1 \tag{4.20}$$

(*i.e., the points of exit of* $x^\rho(\cdot)$ *from* G *converge to* $\bigcup_1^q \{y_i\}$ *as* $\rho \to 0$).

Remark. We omit the proof. The method of proof closely parallels that of [1, Thm. 4.2.1], with modifications of the type used in Theorem 4.2 in order to account for the unboundedness of $\xi(\cdot)$. We only note that, for any $M > 0$ there are $T_\rho \to \infty$ such that $P_{x,\xi(0)}\{\tau^\rho \leqq T_\rho\} \to 1$ and also $|\xi(t)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ (for $\delta \in (0, \frac{1}{2})$ and Model I, with an analogous estimate for Model II) for all $t \leqq T_\rho$, with the probability $\geqq 1 - \exp(-M/\varepsilon^2)$. When $\sigma(x)\Sigma\sigma'(x)$ is degenerate somewhere in $\bar{G}$, then we use the condition (A4.1) as an aid in constructing the "almost" optimal paths which the proof in [1] requires.

Although the details are many and tedious, it can be verified that Theorems 6.6.1 *and* 6.6.2 *of* [1] *hold for our noise models when the system is nondegenerate.* Since the statements of these theorems require the introduction of a great deal of new terminology, the reader is referred to [1]. These theorems give a fairly complete picture of the behavior of $x^\rho(\cdot)$ for large times, when $\dot{x} = b(x)$ has many invariant sets; in particular, they deal with the jump times from one collection of invariant sets to another.

5. The phase locked loop problem. From the point of view of asymptotic methods one of the most interesting systems in communication theory is the phase locked loop (PLL). In [3], the theory of large deviations was applied to estimate the mean time to "loss of track". The model was of the form (1.1)—a small white noise model, and the PLL system was reduced to "basehand", by dropping all terms with high frequency components.

The point of view here is a little more realistic. We use the wide bandwidth noise models I or II and show explicitly that the so-called high frequency terms can be neglected. For notational simplicity, we use the very simplest system, but the analysis and conclusions are applicable to general forms of the PLL and related systems.

Let ω^γ denote the carrier frequency, and suppose that the noise is wideband in an absolute sense but narrow band relative to ω^γ. In particular, we model the noise as follows: let $\xi_i(\cdot)$, $i = 1, 2$, be two mutually independent processes of the form of Model I or II. Let η_γ be such that $\eta_\gamma/\gamma \to^\gamma 0$. A standard way of describing wide bandwidth noise $n^\gamma(\cdot)$ of the desired type is via the formula (σ is a constant matrix here)

$$\begin{aligned} n^\gamma(t) &= \varepsilon u^\gamma(t), \\ u^\gamma(t) &= \sigma[\xi_1^\gamma(t) \sin(\omega_0 t/\eta_\gamma) + \xi_2^\gamma(t) \cos(\omega_0 t/\eta_\gamma)]. \end{aligned} \tag{5.1}$$

The bandwidth is $O(1/\gamma)$ and the "center" and "carrier" frequencies are $\omega_0/\eta_\gamma \equiv \omega^\gamma$. See Fig. 5.1 for a description of our system. The dotted box could contain a filter, but we omit it for simplicity until later. The VCO (voltage controlled oscillator) is an oscillator whose frequency deviation from a central (carrier) frequency is proportional to its input. The device is an essential component of many modern communications systems, and much effort has gone into its analysis [10], [11]. The purpose of the PLL is to provide an estimate $\hat{\theta}(t)$ of the unknown input phase θ. The statistics of escape

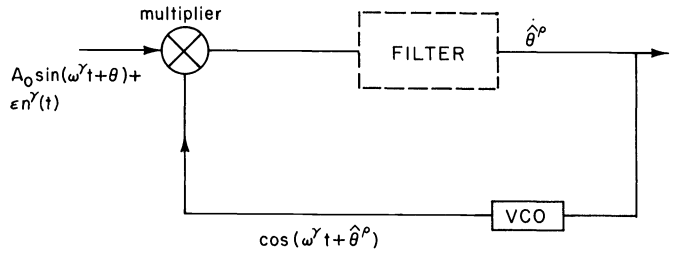

FIG. 5.1. *A phase locked loop.*

of the estimate from a neighborhood of θ are important in understanding the tracking ability of the system.

We first study the PLL system

$$\begin{aligned} &\dot{\hat{\theta}}^\rho = u^\rho, \\ &u^\rho = \cos(\omega^\gamma t+\hat{\theta}^\rho)[A_0 \sin(\omega^\gamma t+\theta)+\varepsilon n^\gamma(t)]. \end{aligned} \tag{5.2}$$

Thus

$$\begin{aligned} \dot{\hat{\theta}} = &\frac{A_0}{2}\sin(\theta-\hat{\theta}^\rho)+\frac{A_0}{2}\sin(\theta+\hat{\theta}^\rho+2\omega^\gamma t) \\ &+\frac{\varepsilon}{2}\sigma[\xi_1^\gamma(t)\cos\hat{\theta}^\rho-\xi_2^\gamma(t)\sin\hat{\theta}^\rho] \\ &+\frac{\varepsilon}{2}\sigma[\xi_1^\gamma(t)\cos(2\omega^\gamma t+\hat{\theta}^\rho)+\xi_2^\gamma(t)\sin(2\omega^\gamma t+\hat{\theta}^\rho)]. \end{aligned} \tag{5.3}$$

By a direct calculation using the definition of the H-functional, and the fact that $\cos(2\omega^\gamma t)$ and $\sin(2\omega^\gamma t)$ are scaled "faster" than θ_i^γ is, we can see that the H-functional for (5.3) is the same as for the system

$$\dot{x}^\rho = \frac{A_0}{2}\sin(\theta-x^\rho)+\frac{\varepsilon}{2}\sigma[\xi_1^\gamma(t)\cos x^\rho-\xi_2^\gamma(t)\sin x^\rho]. \tag{5.4}$$

The H-functional for (5.4) is of the "Gaussian white noise" form

$$H(x,\alpha) = \alpha\frac{A_0}{2}\sin(\theta-x)+\frac{\sigma\Sigma\sigma'\alpha^2}{8}, \tag{5.5}$$

where $\Sigma = \Sigma_1$ or Σ_2 depending on the noise model, and the normalizing sequence is $\lambda_\rho = \varepsilon^2$.

In fact, according to Appendix III, the large deviations formulas (4.1), (4.2) for (5.3) are the same as those for the model (5.4). The effects of these high frequency terms all disappear in the limit, from the point of view of the theory of large deviations, and these terms can be ignored in all the calculations.

If a filter is incorporated into the forward branch of the PLL, then the system (5.3) is replaced by

$$\dot{\nu}^\rho = A_1\nu^\rho + B_1 u^\rho, \qquad \dot{\hat{\theta}}^\rho = H_1\nu^\rho, \tag{5.6}$$

where A_1 is stable, and $H_1\nu^\rho$ is the filter output. The analysis is the same. Arguments such as that of Appendix III show that the "high frequency" terms can be dropped irrespective of the filtering action.

We next study the mean time required until $|\theta^\rho(t)|$ first reaches the critical level π, for a simple PLL with a first order filter.

Mean escape time for a PLL *with a simple filter.* As noted in Corollary 4.3, it is possible to generalize the conditions on the domain G in Theorem 4.2 if certain conditions hold near the boundary ∂G. The PLL treated below will be such a case. For specificity, let us use a first order filter in Fig. 5.1, although analogous results will hold if any order stable filter is used. Denote the filter by

$$\dot{v}_1 = -av_1 + b \cdot (\text{filter input})$$

$$\text{filter output} = cv_1, \quad a > 0, \quad b > 0, \quad c > 0.$$

Write $x = (x_1, x_2) = (v_1, \hat{\theta})$. For simplicity, let $\theta(t) \equiv 0$. This is not a restriction, since it is only the errors in the estimate which are important. Then

$$\begin{aligned} \dot{x}_1^\rho &= -ax_1^\rho + b \sin(-x_2^\rho) + \varepsilon n^\rho \\ \dot{x}_2^\rho &= cx_1^\rho \end{aligned} \qquad \equiv f(x^\rho) + \begin{pmatrix} \varepsilon n^\rho \\ 0 \end{pmatrix}. \tag{5.7}$$

The system is degenerate, but satisfies (A4.1), since the linearized system

$$\dot{x} = Ax - Bu, \quad A = \begin{bmatrix} -a & -b \\ c & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

is controllable.

In "PLL" parlance, a "cycle slip" refers to $\hat{\theta}(\cdot) = x_2(\cdot)$ reaching the level $\pm\pi$, or a movement away from the origin into the domain of attraction of another stable point. Refer to Fig. 5.2. The natural region of interest is G. A slip can occur if $|x_2(t)|$ exceeds π—or if $x(t)$ exists G through the curves C_1 or C_2, which are trajectories of the unperturbed system $\dot{x} = f(x)$. In the latter case, they will move quickly toward the stable points $(0, 2\pi)$ or $(0, -2\pi)$, at a "rapid" change in phase (often causing a noticeable effect on the behavior of the communications system with which the PLL is used). So, we are concerned with exit from G.

Near C_1 and C_2, the trajectories of $\dot{x} = f(x)$ are parallel to these curves, and the curve through x takes longer and longer to reach a neighborhood of the origin as $x \to C_1$ or C_2. Thus Theorem 4.2 cannot be used directly. But a slight modification of the proof yields (4.3). The method combines the ideas of Theorem 4.2 with the remarks after Corollary 4.3. We note the following facts. We restrict our attention to the point $(0, \pi)$ of C_1, although the identical remarks can be made about C_2 and $(0, -\pi)$.

(1) The system $\dot{x} = f(x) + Bu$ is controllable (in the sense of Assumption A4.1) in a neighborhood of $(0, \pi)$. To see this, we need only check controllability (in the usual sense for linear systems; see, e.g., [2]) for the linearized (about $(0, \pi)$) system

$$\dot{y} = Ay + Bu, \quad A = \begin{bmatrix} -a & b \\ c & 0 \end{bmatrix}, \quad B = \begin{bmatrix} b \\ 0 \end{bmatrix}.$$

(2) For any $\alpha > 0$ there is a neighborhood N^α of $(0, \pi)$ and positive δ such that if $x \in N^\alpha \cap G$, then there is a $u_x(\cdot)$ transferring x to $\partial N_\delta(G)$ at a time T_x with $\int_0^{T_x} |u_x(t)|^2 \, dt \leqq \alpha$.

(3) For α as in (2), there is a $\beta > 0$ and a neighborhood N^β of C_1 such that for $x \in N^\beta \cap G$,

$$\inf_T \inf_{\phi \in A_\beta} S(\phi, T) \leqq \alpha,$$

where $A_\beta = \{\phi(\cdot)\colon \phi(0) \in N^\beta, \ \phi(T) \in \partial N_\delta(G)\}$.

(4) For $x(0) \notin N^{\beta} \cap G$, and $u > 0$, there is a T_1^{β} such that the trajectory of $\dot{x} = f(x)$ reaches the u-neighborhood of the origin in time $\leqq T_1^{\beta}/2$.

By using these facts in the proof of Theorem 4.2 to treat points near to C_1 or C_3 (see also the remark after Corollary 4.3), we obtain (4.3).

Remark on "batches" of cycle slips. It is noted in applications that cycle slips (or what are taken to be cycle slips) often occur in "batches". Perhaps some insight into this *one possible cause* can be obtained from Fig. 5.2. If due to large noise, the path is pushed far out but between the upper and lower trajectories, it will quickly return to a neighborhood of a stable point, perhaps in an oscillatory manner, when the noise level drops, giving the impression that many cycle slips are occurring in a very short period of time. Similarly, if it returns to a stable point after reaching a neighborhood of the separatrices, the oscillations will give the appearance of a "batch" of cycle slips. An explanation of a possible alternative cause involving the crossing of several "π-levels" in a short time is given in [14, pp. 281–284].

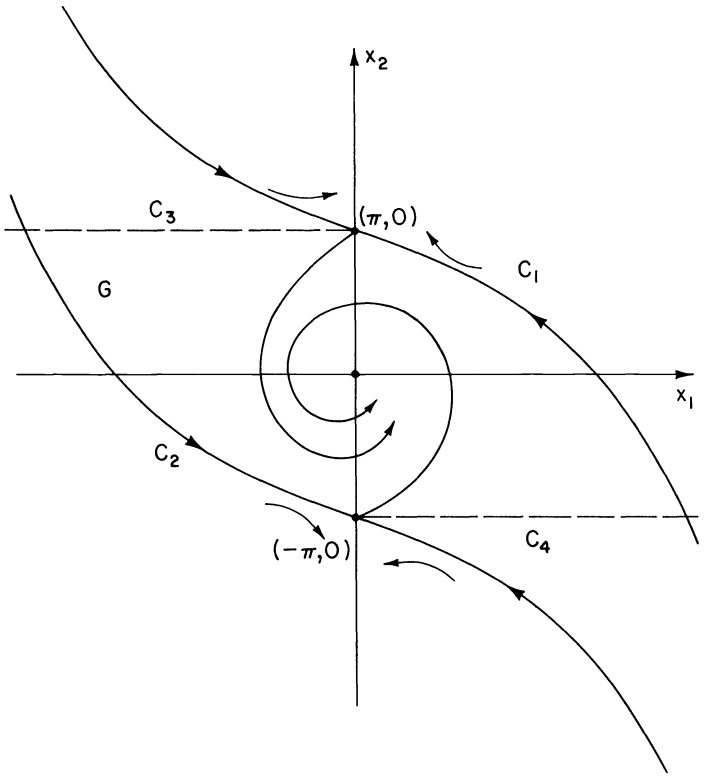

FIG. 5.2. *Trajectories for the noiseless phase locked loop.*

Appendix I. Proof of large deviations theorems. Here we state and prove the basic large deviations inequalities (A1.3), (A1.4) and indicate how these are used to prove (4.1). In order to satisfy the hypotheses of Theorem 4.2, it will be necessary to obtain our estimates uniformly in $x(0) \in G$, and $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ (Model I). The analogous uniformity that is required for Model II is for $|\bar{\xi}^{\gamma}(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$. Note that the uniformity for Model I is expressed in terms of $\xi(\cdot)$, while that of Model II is in terms of $\bar{\xi}^{\gamma}(\cdot)$. The reason for this difference is the different scaling required to get weak convergence to a Wiener process in the two cases. The main Theorem A1.1 is first stated. But before giving the proof, it is convenient to first obtain large deviations

results for the system,

$$y^\rho(t) = \varepsilon \int_0^t \xi^\gamma(s)\, ds + x, \tag{A1.1}$$

and this will be done in Lemmas A1.1 and A1.2. Following this, we modify the method which Varadhan [8] used to extend large deviations results for the process $\varepsilon w(\cdot)$ to system (1.1), in order to extend our results for (A1.1) to the system (1.6.).

THEOREM A1.1. *Consider system* (1.6), *the associated H, L, and S functionals, and the normalizing sequence* $\lambda_\rho = \varepsilon^2$. *Let A be a set in* $C_x[0, T]$. *Then for* $\frac{1}{2} > \delta > 0$, *the limits* (A1.2) *hold uniformly in* $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ (*noise Model* I) *and* $|\bar{\xi}^\gamma(0)| \leqq \gamma^{-\delta+1/2}\varepsilon^{-1}$ (*noise Model* II), *and for x in any compact set.*

$$\underline{\lim_\rho}\, \lambda_\rho \log P\{x^\rho(\cdot) \in A\} \geqq -\inf_{\phi \in A^0} S(\phi, T), \tag{A1.2a}$$

$$\overline{\lim_\rho}\, \lambda_\rho \log P\{x^\rho(\cdot) \in A\} \leqq -\inf_{\phi \in \bar{A}} S(\phi, T). \tag{A1.2b}$$

Definitions. By § 3, the *H*, *L* and *S* functionals for the process $y^\rho(\cdot)$ are defined by

$$H_y(\alpha) = \alpha'\Lambda\alpha/2, \tag{A1.3}$$

$$L_y(\beta) = \beta'\Lambda^{-1}\beta/2, \tag{A1.4}$$

$$S_y(\phi, T) = \int_0^T \dot{\phi}(s)'\Lambda^{-1}\dot{\phi}(s)\, ds/2. \tag{A1.5}$$

(Here, as elsewhere, $S_y(\phi, T) = \infty$ if ϕ is not absolutely continuous). For Model I, $\Lambda = \Sigma_1$, and for Model II, $\Lambda = \Sigma_2$ (see § 2 for the definition), and we can assume (w.l.o.g.) that Σ_i are nonsingular. Define $\Phi_s^y = \{\phi \in C_x[0, T]\colon S_y(\phi, T) \leqq s\}$. The set Φ_s is compact [7].

Before proving the main theorem, it is convenient to prove the following auxiliary lemmas.

LEMMA A1.1. *Let* $y^\rho(\cdot)$ *be given by* (A1.1). *Then given* $c > 0$, $h > 0$, $s > 0$, $\frac{1}{2} > \delta > 0$, *and* $\phi \in C_x[0, T]$, *there is* $\rho_0 > 0$ *such that for* $\rho < \rho_0$ *and* $x \in G$, $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ (*Model* I), *or* $|\bar{\xi}^\gamma(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$ (*Model* II),

$$P_{x,\xi(0)}\{d(y^\rho, \phi) < c\} \geqq \exp\left(-[S_y(\phi, T) + h]/\lambda_\rho\right), \tag{A1.6}$$

$$P_{x,\xi(0)}\{d(y^\rho, \Phi_s^y) > c\} \leqq \exp\left(-[s - h]/\lambda_\rho\right). \tag{A1.7}$$

Proof. First we prove the result for *Model* I. Via a change of variables $s \to s/\gamma$ and using $\xi(s)\, ds = A^{-1}A\xi(s)\, ds = A^{-1}\, d\xi(s) - A^{-1}B\, dw(s)$, we have

$$\begin{aligned} y^\rho(t) &= \varepsilon \int_0^t \xi(s/\gamma)\, ds/\sqrt{\gamma} + x \\ &= \sqrt{\gamma}\varepsilon A^{-1}(\xi(t/\gamma) - \xi(0)) - \sqrt{\gamma}\varepsilon A^{-1}B(w(t/\gamma) - w(0)) + x. \end{aligned}$$

By Lemma A2.1, for given $c > 0$, $M < \infty$, and uniformly in $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$, for small ρ we have

$$P\{\sup_{0 \leqq t \leqq T} |\sqrt{\gamma}\varepsilon A^{-1}(\xi(t/\gamma) - \xi(0))| \geqq c\} \leqq \exp\left(-M/\varepsilon^2\right).$$

Hence the large deviations properties of (A1.1) are the same as those of

$$-\varepsilon A^{-1}B\sqrt{\gamma}[w(t/\gamma) - w(0)] + x.$$

As $-\sqrt{\gamma}[w(t/\gamma)-w(0)]=\tilde{w}(t)$ is a *standard Brownian motion*, the inequalities (A1.6), (A1.7) follow from the fact that Theorem A1.1 holds if the $x^\rho(\cdot)$ there is replaced by (define $A^{-1}B=C$)

$$\tilde{y}^\rho(t)=\varepsilon C\tilde{w}(t)+x$$

and the action functional

$$S_y(\phi, T)=\int_0^T \dot{\phi}(s)'(CC')^{-1}\dot{\phi}(s)\,ds/2,$$

and normalizing sequence $\lambda_\rho=\varepsilon^2$ are used [1], [8].

We now consider Model II. We have

$$\begin{aligned} y^\rho(t) &= \varepsilon\int_0^t \xi^\gamma(s)\,ds+x \\ &= \varepsilon\int_0^{t/\gamma} \bar{\xi}^\gamma(s)\,ds+x \\ &= \varepsilon\int_0^{t/\gamma} A^{-1}[d\bar{\xi}^\gamma(s)-d\bar{J}^\gamma(s)]+x \\ &= \varepsilon A^{-1}(\bar{\xi}^\gamma(t/\gamma)-\bar{\xi}^\gamma(0))-\varepsilon A^{-1}(\bar{J}^\gamma(t/\gamma)-\bar{J}^\gamma(0))+x. \end{aligned} \tag{A1.8}$$

As for Model I, we may ignore the first term on the right (Lemma A4.1). Several standard "continuity" methods can be used to establish the statement of Lemma A1.1 for the system

$$\tilde{y}^\rho(t)=-\varepsilon A^{-1}(\bar{J}^\gamma(t/\gamma)-\bar{J}^\gamma(0))+x \tag{A1.9}$$

with action functional

$$S_y(\phi, T)=\int_0^T \dot{\phi}(s)'\Sigma_2^{-1}\dot{\phi}(s)\,ds/2$$

and normalizing sequence $\lambda_\rho=\varepsilon^2$. (For example, one can use the technique in [7, Thm. 2.1], based on Gartner's theorem for a sampled system.) Q.E.D.

From Lemma A1.1, by a standard argument in large deviations literature (see, e.g., [7], or [9, Prop. 7.6]) we obtain the following:

LEMMA A1.2. *Let* $A\subset C_x[0, T]$, $\frac{1}{2}>\delta>0$. *Then the limits in* (A1.10) *hold, uniformly for x in any compact set, and for* $|\xi(0)|\leqq\gamma^{-\delta}\varepsilon^{-1}$ (*Model* I) *or* $|\bar{\xi}^\gamma(0)|\leqq\gamma^{-\delta+1/2}\varepsilon^{-1}$ (*Model* II).

$$\begin{aligned} -\inf_{\phi\in A^0} S_y(\phi, T) &\leqq \underline{\lim}_\rho \lambda_\rho \log P_{x,\xi(0)}\{y^\rho(\cdot)\in A\} \\ &\leqq \overline{\lim}_\rho \lambda_\rho \log P_{x,\xi(0)}\{y^\rho(\cdot)\in A\} \leqq -\inf_{\phi\in\bar{A}} S_y(\phi, T). \end{aligned} \tag{A1.10}$$

The proof of Theorem A1.1 uses a device of Varadhan [8]. To facilitate this, it is convenient to next prove a form of Lemma A1.2 or, Theorem A1.1 for a special auxiliary system—driven by $\xi^\gamma(\cdot)$. Let $\alpha>0$, and define $\pi_\alpha(t)=\alpha[t/\alpha]$, where $[t]$ is the largest integer less than or equal to t. Define the system

$$\begin{aligned} \dot{x}_\alpha^\rho(t) &= b(x_\alpha^\rho(\pi_\alpha(t)))+\varepsilon\sigma(x_\alpha^\rho(\pi_\alpha(t)))\xi^\gamma(t), \\ x_\alpha^\rho(0) &= x. \end{aligned} \tag{A1.11}$$

Thus the arguments of $b(\cdot)$ or $\sigma(\cdot)$ are constant on intervals of length α. For each $\alpha > 0$, there exists a continuous map $F_{\alpha,x}$ from $C_x[0, T]$ to $C_x[0, T]$ such that

$$x_\alpha^\rho(\cdot) = F_{\alpha,x}\left(\varepsilon \int_0^\cdot \xi^\gamma(s)\, ds\right). \tag{A1.12}$$

The $F_{\alpha,x}$ is continuous uniformly in x in any compact set, and in $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ for noise Model I and $|\bar{\xi}^\gamma(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$ for noise Model II. Large deviations results may be transferred from one system to another if they are connected by a continuous map. Let $S_\alpha(\phi, T)$ denote the action functional for $x_\alpha^\rho(\cdot)$. Then ([8, Remark 1, on p. 5], [1, Thm. 3.3.1])

$$S_\alpha(\phi, T) = \inf_{F_{\alpha,x}(f)=\phi} S_y(f, T).$$

If $\sigma(x)\Lambda\sigma'(x)$ is uniformly positive definite (where $\Lambda = \Sigma_1$ or Σ_2 as appropriate), we can evaluate S_α explicitly, since $F_{\alpha,x}$ is 1:1 and we get

$$S_\alpha(\phi, T) = \frac{1}{2}\int_0^T [\dot{\phi}(s) - b(\phi(\pi_\alpha(s)))]'[\sigma(\phi(\pi_\alpha(s)))\Lambda\sigma'(\phi(\pi_\alpha(s)))]^{-1}$$
$$\cdot [\dot{\phi}(s) - b(\phi(\pi_\alpha(s)))]\, ds.$$

In general, the integrand is $L_\alpha(s)$, where

$$L_\alpha(s) = \inf_\alpha [\alpha'(\dot{\phi}(s) - b(\phi(\pi_\alpha(s)))) - \alpha'\sigma(\phi(\pi_\alpha(s)))\Lambda\sigma'(\phi(\pi_\alpha(s)))\alpha/2].$$

The normalizing sequence is still $\lambda_\rho = \varepsilon^2$.

Thus, the large deviations result, Theorem A1.1 holds for system (A1.11), uniformly in the desired initial conditions of $(x, \xi^\gamma(0))$, with the use of S_α. In order to extend the result to (1.6), we need to bound $|x_\alpha^\rho(t) - x^\rho(t)|$, and this is done in the next lemma.

Let $\phi_\alpha \to \phi$ in $C_x[0, T]$. Then the "lower semi-continuity"

$$\underline{\lim}_\alpha S_\alpha(\phi_\alpha, T) \geqq S(\phi, T)$$

can be proved, but we omit the details.

LEMMA A1.3. *For given $c > 0$, $M < \infty$, $T < \infty$, there is an $\alpha_0 > 0$ such that for each $\alpha < \alpha_0$ there is a $\rho_\alpha > 0$ such that for $\rho \leqq \rho_\alpha$ and all $x \in G$ and $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ (Model I) and $|\bar{\xi}^\gamma(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$ (Model II)*

$$P\{\sup_{0 \leqq t \leqq T} |x^\rho(t) - x_\alpha^\rho(t)| > c\} \leqq \exp(-M/\lambda_\rho). \tag{A1.13}$$

Proof. For simplicity, we only prove the lemma for noise Model I. The details in the other case are essentially the same. By writing,

$$x_\alpha^\rho(t) = x + \int_0^t b(x_\alpha^\rho(s))\, ds + \varepsilon \int_0^t \sigma(x_\alpha^\rho(s))\xi^\gamma(s)\, ds + \beta_1^\rho(t),$$

where

$$\beta_1^\rho(t) = \int_0^t [b(x_\alpha^\rho(\pi_\alpha(s))) - b(x_\alpha^\rho(s))]\, ds$$
$$+ \varepsilon \int_0^t [\sigma(x_\alpha^\rho(\pi_\alpha(s)) - \sigma(x_\alpha^\rho(s))]\xi^\gamma(s)\, ds,$$

we have

$$\begin{aligned}\Delta_\alpha^\rho(t) &\equiv x^\rho(t) - x_\alpha^\rho(t) \\ &= \int_0^t [b(x^\rho(s)) - b(x_\alpha^\rho(s))]\, ds \\ &\quad + \varepsilon \int_0^t [\sigma(x^\rho(s)) - \sigma(x_\alpha^\rho(s))]\xi^\gamma(s)\, ds - \beta_1^\rho(t).\end{aligned} \tag{A1.14}$$

We next prove the assertion: *For $c_1 > 0$, $M < \infty$, $T < \infty$, and small enough α, there is a $\rho_0 > 0$ such that for $\rho \leqq \rho_0$ and $x \in G$ and $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ (Model* I)

$$P\{\sup_{0 \leqq t \leqq T} |\beta_1^\rho(t)| > c_1\} \leqq \exp(-M/\lambda_\rho).$$

In order to prove the assertion, first note that for small enough α and for $s \in [i\alpha, i\alpha + \alpha)$, we may assume that $|x_\alpha^\rho(s) - x_\alpha^\rho(i\alpha)|$ is as small as desired (uniformly in the appropriate initial conditions), save on a set of measure $\leqq \exp(-2M/\varepsilon^2)$. This follows from the decomposition (see the proof of Lemma A1.1)

$$\varepsilon \int_{i\alpha}^{s} \sigma(x_\alpha^\rho(\pi_\alpha(t)))\xi^\gamma(t)\, dt = \sqrt{\gamma}\varepsilon\sigma(x_\alpha^\rho(\pi_\alpha(\gamma t)))A^{-1}[\xi(t) - Bw(t)]|_{i\alpha/\gamma}^{s/\gamma},$$

Lemma A2.5, and the boundedness of $b(\cdot)$ and $\sigma(\cdot)$. In fact, by Lemma A2.5 and the above decomposition ($v < 1/2$)

$$P\{\sup_{i \leqq T/\alpha} \sup_{t \leqq \alpha} |x_\alpha^\rho(s) - x_\alpha^\rho(i\alpha)| > \alpha^v\} \leqq \exp(-2M/\varepsilon^2)$$

for small Δ and ρ. We thus assume that $|x_\alpha^\rho(s) - x_\alpha^\rho(i\alpha)| \leqq \alpha^v$, for $s \in [i\alpha, i\alpha + \alpha)$.

Owing to the Lipschitz property of $b(\cdot)$ and $\sigma(\cdot)$, we may now assume that the terms $[b(x_\alpha^\rho(\pi_\alpha(s))) - b(x_\alpha^\rho(s))]$, $[\sigma(x_\alpha^\rho(\pi_\alpha(s))) - \sigma(x_\alpha^\rho(s))]$ entering into the definition of $\beta_1^\rho(\cdot)$ are as small as desired save on a set of measure $\leqq \exp(-M/\lambda_\rho)$ for arbitrary M. The first consequence of this fact is that in proving the *assertion*, we may *ignore* the first integral in the definition of $\beta_1^\rho(t)$. After a change of scale, the use of $A\xi(s)\, ds = d\xi(s) - B\, dW(s)$, and an integration by parts (for the term involving $d\xi$), the second term in $\beta_1^\rho(t)$ becomes a sum of the following terms:

$$\begin{aligned}&\sqrt{\gamma}\varepsilon \int_0^{t/\gamma} [\sigma(x_\alpha^\rho(\pi_\alpha(\gamma s))) - \sigma(x_\alpha^\rho(\gamma s))]A^{-1}B\, dW_s, \\ &\sqrt{\gamma}\varepsilon[\sigma(x_\alpha^\rho(\pi_\alpha(\gamma s))) - \sigma(x_\alpha^\rho(\gamma s))]A^{-1}\xi(s)|_0^{t/\gamma}, \\ &\gamma^{3/2}\varepsilon \int_0^{t/\gamma} b(x_\alpha^\rho(\gamma s))'\sigma_x(x_\alpha^\rho(\gamma s))A^{-1}\xi(s)\, ds, \\ &\gamma\varepsilon^2 \int_0^{t/\gamma} \xi(s)'\sigma'(x_\alpha^\rho(\gamma s))\sigma_x(x_\alpha^\rho(\gamma s))A^{-1}\xi(s)\, ds, \\ &\sqrt{\gamma}\varepsilon \sum_{i=0}^{t/\alpha} [\sigma(x_\alpha^\rho(i\alpha + \alpha)) - \sigma(x_\alpha^\rho(i\alpha))]A^{-1}\xi((i\alpha + \alpha)/\gamma).\end{aligned} \tag{A1.15}$$

The last term arises due to the discontinuity in $\sigma(x_\alpha^\rho(\pi_\alpha(\gamma s)))$ at $\gamma s = i\alpha$ for each i. These terms are taken care of, with the required uniformity, by Lemmas A2.2, A2.1, A2.4, A2.3, and A2.5 (owing to which we can assume that the coefficients in the last sum are less than $K\alpha^v$ for $v \in (0, \frac{1}{2})$, and obtain the appropriate estimate for the sum). This finishes the proof of the *assertion.*

Now, return to the proof of Lemma A1.3 and consider the second term in the definition of $\Delta_\alpha^\rho(\cdot)$ in (A1.14). By a decomposition analogous to the one above, we may write that term as

$$\varepsilon\int_0^t [\sigma(x^\rho(s))-\sigma(x_\alpha^\rho(s))]\xi^\gamma(\alpha)\,ds$$
$$=-\sqrt{\gamma}\varepsilon\int_0^{t/\gamma}[\sigma(x^\rho(\gamma s))-\sigma(x_\alpha^\rho(\gamma s))]A^{-1}B\,dw(s)+\beta_2^\rho(t)$$

where $\beta_2^\rho(t)$ satisfies the same conditions as $\beta_1^\rho(t)$ does. (It can be represented as a sum of the same types of terms (A1.15).) Thus we can assume that $|\beta_2^\rho(t)|\leqq$ any c_2 w.p.$\geqq 1-\exp(-2M/\varepsilon^2)$. There exists a standard Wiener process $\tilde{w}(t)$ such that $x^\rho(\cdot)$ and $x_\alpha^\rho(\cdot)$ are nonanticipative with respect to $\tilde{w}(\cdot)$ and

$$-\sqrt{\gamma}\varepsilon\int_0^{t/\gamma}[\sigma(x^\rho(\gamma s))-\sigma(x_\alpha^\rho(\gamma s))]A^{-1}B\,dw(s)$$
$$=\varepsilon\int_0^t[\sigma(x^\rho(s))-\sigma(x_\alpha^\rho(s))]A^{-1}B\,d\tilde{w}(s).$$

Define $\beta_3^\rho(t)=\beta_2^\rho(t)-\beta_1^\rho(t)$, $\tilde{\Delta}_\alpha^\rho(t)=\Delta_\alpha^\rho(t)-\beta_3^\rho(t)$, and the terms

$$b^*(s)=\int_0^1 b_x(x_\alpha^\rho(s)+\tau\Delta_\alpha^\rho(s))\,d\tau,$$
$$\sigma^*(s)=\int_0^1\sigma_x(x_\alpha^\rho(s)+\tau\Delta_\alpha^\rho(s)\,d\tau.$$

Then, by Taylor's formula with remainder

$$\Delta_\alpha^\rho(t)=\int_0^t b^*(s)\Delta_\alpha^\rho(s)\,ds+\varepsilon\int_0^t\sigma^*(s)\Delta_\alpha^\rho(s)A^{-1}B\,d\tilde{w}(s)+\beta_3^\rho(t),$$

so we can write

$$\tilde{\Delta}_\alpha^\rho(t)=\int_0^t b^*(s)\tilde{\Delta}_\alpha^\rho(s)\,ds+\varepsilon\int_0^t\sigma^*(s)\tilde{\Delta}_\alpha^\rho(s)A^{-1}B\,d\tilde{w}(s)$$
$$+\int_0^t b^*(s)\beta_3^\rho(s)\,ds+\varepsilon\int_0^t\sigma^*(s)\beta_3^\rho(s)A^{-1}B\,d\tilde{w}(s). \tag{A1.16}$$

By what we have shown above, given any $\eta>0$, for small enough α and ρ we may assume that $|\beta_3^\rho(t)|<\eta$ (w.p.$\geqq 1-\exp(-2M/\varepsilon^2)$).

In order to estimate the solution to (A1.16), we now introduce a technique of Varadhan [8, § 6] and develop an argument paralleling his. Define $\tau=\inf\{s: |\tilde{\Delta}_\sigma^\rho(s)|\geqq c\}\wedge T$. Consider the function

$$g(z)=(\theta+|z|^2)^l$$

where θ and l will be chosen later on. By Itô's formula, and the boundedness of $b^*(\cdot)$, $\sigma^*(\cdot)$, there are constants k_i such that

$$dg(\tilde{\Delta}_\alpha^\rho(t))=\alpha_1(t)\,dt+\alpha_2(t)\,d\tilde{w}(t) \tag{A1.17}$$

where

$$\begin{aligned}\alpha_1(t) &\leqq k_1 l(\theta+|\tilde{\Delta}^\rho_\alpha(t)|^2)^{l-1}(\eta+|\tilde{\Delta}^\rho_\alpha(t)|)|\tilde{\Delta}^\rho_\alpha(t)| \\ &\quad + k_2\varepsilon^2 l(l-1)(\theta+|\tilde{\Delta}^\rho_\alpha(t)|^2)^{l-2}(\eta^2+|\tilde{\Delta}^\rho_\alpha(t)|^2)|\tilde{\Delta}^\rho_\alpha(t)|^2 \\ &\quad + k_3\varepsilon^2 l(\theta+|\tilde{\Delta}^\rho_\alpha(t)|^2)^{l-1}(\eta^2+|\tilde{\Delta}^\rho_\alpha(t)|^2) \\ &\leqq k_4 l(\theta+|\tilde{\Delta}^\rho_\alpha(t)|^2)^{l-1}(\eta^2+|\tilde{\Delta}^\rho_\alpha(t)|^2) \\ &\quad + k_5\varepsilon^2 l^2(\theta+|\tilde{\Delta}^\rho_\alpha(t)|^2)^{l-2}(\eta^2+|\tilde{\Delta}^\rho_\alpha(t)|^2)^2.\end{aligned}$$

Let $\theta=\eta^2$. Then for some constant k,

$$\alpha_1(t)\leqq kl(1+\varepsilon^2 l)g(\tilde{\Delta}^\rho_\alpha(t)).$$

Let $\lambda=cl(1+\varepsilon^2 l)$. Then

$$e^{-\lambda(\tau\wedge t)}g(\tilde{\Delta}^\rho_\alpha(\tau\wedge t))$$

is a nonnegative supermartingale. Let l/ε^2 replace l. By the supermartingale property,

$$E[e^{-\lambda\tau}(\eta^2+|\tilde{\Delta}^\rho_\alpha(\tau)|^2)^{l/\varepsilon^2}]\leqq\eta^{2l/\varepsilon^2}.$$

Hence

$$P\{\tau<T\}\leqq(\exp cl(l+1)T/\varepsilon^2)(\eta^2/(\eta^2+c^2))^{l/\varepsilon^2}.$$

Choose $l=1$ and η small enough to obtain

$$P\{\tau<T\}\leqq\exp(-2M/\varepsilon^2).$$

From this and $|\beta^\rho_3(t)|\leqq\eta$, we get

$$P\{\sup_{0\leqq t\leqq T}|\Delta^\rho_\alpha(t)|\geqq c+\eta\}\leqq\exp(-M/\varepsilon^2)$$

for small α and ρ. This proves Lemma A1.3. Q.E.D.

We are now ready for the

Proof of Theorem A1.1. Recall that $A\subset C_x[0,T]$, and let A have a nonempty interior. Define $A^c=$ complement of A and define the sets

$$A^a=\begin{cases}\{\phi: d(\phi,A^c)>-a\}, & a<0,\\ A, & a=0,\\ \{\phi: d(\phi,A)<a\}, & a>0.\end{cases}$$

First we show (A1.2a). Recall the definition of $S_\alpha(\phi,T)$ given below (A1.12). Let $h>0$, and choose $a<0$ so that there is $\phi_a\in A^a$ such that

$$S(\phi_a,T)\leqq\inf_{\phi\in A^0}S(\phi,T)+h/4. \tag{A1.18}$$

Since $S_\alpha(\phi,T)\to S(\phi,T)$ for each ϕ as $\alpha\to0$, we may assume that α is small enough so that

$$S_\alpha(\phi_a,T)\leqq S(\phi_a,T)+h/4. \tag{A1.19}$$

From Lemma A1.2, by taking α smaller if necessary we may assume that for fixed $M<\infty$,

$$P_x\{\sup_{p\leqq t\leqq T}|x^\rho(t)-x^\rho_\alpha(t)|>a\}\leqq\exp-M/\lambda_\rho.$$

By picking M large enough, for small ρ, we have

$$P_x\{x^\rho(\cdot)\in A\}\geqq P_x\{x^\rho_\alpha(\cdot)\in A^a\}-\exp(-M/\lambda_\rho)$$
$$\geqq \exp(-[\inf_{\phi\in A^0} S(\phi, T)+3h/4])-\exp(-M/\lambda_\rho)$$
$$\geqq \exp(-[\inf_{\phi\in A^0} S(\phi, T)+h]).$$

The second inequality above is due to the fact that Theorem A1.1 holds for the $x^\rho_\alpha(\cdot)$ process (with action functional S_α), and (A1.18), (A1.19). Since $h>0$ is arbitrary, the string of inequalities proves (A1.2a).

Before proving (A1.2b), it is convenient to prove

LEMMA A1.4. *Let $F\subset C_x[0, T]$ be closed. Then*

(i) $$\varliminf_{\alpha\to 0}\inf_{\phi\in F} S_\alpha(\phi, T)\geqq \inf_{\phi\in F} S(\phi, T).$$

(ii) $$\varliminf_{a\to 0^+}\inf_{\phi\in \bar F^a} S(\phi, T)=\inf_{\phi\in F} S(\phi, T).$$

Proof. (ii) is a consequence of the lower semicontinuity of $S(\cdot, T)$ and the compactness of each set $\{\phi: S(\phi, T)\leqq s\}$. We only show (i) for the case

$$\inf_{\phi\in F} S(\phi, T)<\infty.$$

Assume (i) is not true. Then there are ϕ_n, α_n and $h>0$ so that for all $n=1, 2, \cdots$

$$S_{\alpha_n}(\phi_n, T)\leqq \inf_{\phi\in F} S(\phi, T)-h.$$

It is easily seen that $\{\phi_n\}$ has compact closure. Hence there is ϕ^* such that

$$\phi_n\to\phi^*\in F.$$

By the "lower semicontinuity" result cited above Lemma A1.3,

$$S(\phi^*, T)\leqq \varliminf_n S_{\alpha_n}(\phi_n, T)\leqq \inf_{\phi\in F} S(\phi, T)-h,$$

a contradiction. Q.E.D.

We can now complete the proof of (A1.2b). Let $h>0$ be given. By Lemmas A1.3 and A1.4 we may choose $a>0$, $\delta>0$ so that for small ρ and small fixed α

$$\inf_{\phi\in \bar A^a} S(\phi, T)\geqq \inf_{\phi\in \bar A} S(\phi, T)-h/4,$$

(A1.20)
$$\inf_{\phi\in \bar A^a} S_\alpha(\phi, T)\geqq \inf_{\phi\in \bar A^a} S(\phi, T)-h/4,$$
$$P_x\{\sup_{0\leqq t\leqq T}|x^\rho(t)-x^\rho_\alpha(t)|>a\}\leqq \exp(-M/\lambda_\rho).$$

By picking M large enough, the large deviations results for $x^\rho_\alpha(\cdot)$ (Theorem A1.1 for the $x^\rho_\alpha(\cdot)$ and action functional S_α) and (A1.20) yield (for small ρ and small fixed α)

$$P_x\{x^\rho(\cdot)\in A\}\leqq P_x\{x^\rho_\alpha(\cdot)\in \bar A^a\}+(\exp(-M/\lambda_\rho))$$
$$\leqq \exp(-[\inf_{\phi\in \bar A^a} S_\alpha(\phi, T)-h/4])+(\exp(-M/\lambda_\rho))$$
$$\leqq \exp(-[\inf_{\phi\in \bar A} S(\phi, T)-h]).$$

The proof of Theorem A1.1 is completed for Model I.

The proof for Model II is the same as that of Model I with the following three changes:

(a) When uniformity in $|\xi(0)| \leqq \gamma^{-\delta}\varepsilon^{-1}$ is required for Model I, we require $|\bar{\xi}^{\gamma}(0)| \leqq \gamma^{-\delta+1/2}\varepsilon^{-1}$ for Model II.

(b) When an estimate from Appendix II is used, we substitute the analogous estimate from Appendix IV.

(c) The upper bound on $\alpha_1(t)$ is even easier to get since we can use a standard differential. Q.E.D.

Appendix II. Estimates for noise Model I. The following estimates are used repeatedly in the large deviations proofs associated with the wide bandwidth Gaussian noise model I.

LEMMA A2.1. *Fix $a>0$, $T>0$, and $\delta>0$. For each $M<\infty$ there is a $\gamma_0>0$ such that for $\gamma \leqq \gamma_0$ and all T_0*

$$P\{\sup_{0\leqq t\leqq T/\gamma} [\xi((t+T_0)/\gamma)-\xi(T_0/\gamma)| \geqq a/\varepsilon\gamma^{\delta}\} \leqq \exp(-M/\varepsilon^2). \tag{A2.1}$$

If the probability in (A2.1) *is conditioned on $\xi(T_0/\gamma)$, then the estimates are uniform in $|\xi(T_0/\gamma)| \leqq \varepsilon^{-1}\gamma^{-\delta_1}$ for $\delta_1<\delta$.*

Proof. W.l.o.g., set $T_0=0$, then

$$\begin{aligned} &P\{\sup_{0\leqq t\leqq T/\gamma} |\xi(t)-\xi(0)| \geqq a/\varepsilon\gamma^{\delta}\} \\ &\quad \leqq \sum_{i=0}^{T/\gamma-1} P\{|\xi(i)| \geqq a/4\varepsilon\gamma^{\delta}\} + \sum_{i=0}^{T/\gamma-1} P\{\sup_{i\leqq s\leqq i+1} |\xi(s)-\xi(i)| \geqq a/4\varepsilon\gamma^{\delta}\}. \end{aligned} \tag{A2.2}$$

Via an integration by parts,

$$\begin{aligned} \xi(s)-\xi(i) &= [\exp As - I]\xi(i) + B[w(s)-w(i)] \\ &\quad + \int_i^s A\exp A(s-\tau)B[w(\tau)-w(i)]\,d\tau. \end{aligned} \tag{A2.3}$$

By the stability of A, there is $k<\infty$ such that

$$|\xi(s)-\xi(i)| \leqq k|\xi(i)| + k\sup_{i\leqq s\leqq i+1} |w(s)-w(i)|. \tag{A2.4}$$

Hence the estimate is reduced to sums of terms of the form (for appropriate values of a_1 and a_2)

$$P\{|\xi(i)| \geqq a_1/\varepsilon\gamma^{\delta}\}, \tag{A2.5}$$

$$P\{\sup_{i\leqq s\leqq i+1} |w(s)-w(i)| \geqq a_2/\varepsilon\gamma^{\delta}\}. \tag{A2.6}$$

As $\xi(i)$ is Gaussian, there are K_1 and K_2 such that

$$(\text{A2.5}) \leqq K_1\exp(-K_2/\varepsilon^2\gamma^{2\delta}).$$

To estimate (A2.6), we work with each component of $w(\cdot)$ separately. By the submartingale inequality, for $\lambda>0$,

$$P\{\sup_{i\leqq s\leqq i+1} \exp\lambda(w(s)-w(i)) \geqq \exp\lambda a_2/\varepsilon\gamma^{\delta}\} \leqq \exp(-\lambda a_2/\varepsilon\gamma^{\delta})\cdot\exp\lambda^2/2. \tag{A2.7}$$

By picking $\lambda = a_2/\varepsilon\gamma^{\delta}$, and repeating for $-w(\cdot)$, we see that there are K_3, K_4 such that

$$(\text{A2.6}) \leqq K_3\exp - K_4/\varepsilon^2\gamma^{2\delta}.$$

These estimates imply the first part of the Lemma, for small enough ρ_0.

In order to prove the uniformity assertion, note that the estimates on the Wiener process are unaffected by the values of $\xi(0)$, so all we need to do is get the appropriate bound on

$$P_{\xi(0)}\{|\xi(i)| \geqq \varepsilon^{-1}\gamma^{\delta}\}. \tag{A2.5'}$$

Since

$$\xi(i) = e^{Ai}\xi(0) + \int_0^i e^{A(i-t)}B\,dw(t), \tag{A2.8}$$

$$|\xi(i)| \leqq |\xi(0)| + \left|\int_0^i e^{A(i-t)}B\,dw(t)\right|. \tag{A2.9}$$

Thus there are a_3, a_4 such that

$$(\text{A2.5}') \leqq P_{\xi(0)}\{|\xi(0)| \geqq a_3/\varepsilon\gamma^{\delta}\} + P_{\xi(0)}\left\{\left|\int_0^i e^{A(i-t)}B\,dw(t)\right| \geqq a_4/\varepsilon\gamma^{\delta}\right\}.$$

The assumption $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta_1}$ and the first part of the proof yield the uniformity. Q.E.D.

LEMMA A2.2. *Let $f(\cdot)$ be bounded (by, say, k) in norm and nonanticipative with respect to $w(\cdot)$. Then,*

$$P\left\{\sup_{0\leqq t\leqq T/\gamma}\left|\int_0^t f(s)\,dw(s)\right| \geqq a/\varepsilon\sqrt{\gamma}\right\} \leqq 2\exp(-a^2/2Tk^2\varepsilon^2). \tag{A2.10}$$

Proof. We can suppose that $w(\cdot)$ and $f(\cdot)$ are scalar valued, and (by symmetry of $w(\cdot)$) drop the absolute value bars. The proof follows by bounding the expectation of the exponential martingale as

$$E\exp\lambda\int_0^{T/\gamma} f(s)\,dw(s) \leqq \exp\lambda^2k^2T/2\gamma,$$

and choosing λ properly, as in the proof of Lemma A2.1. Q.E.D.

LEMMA A2.3. *Fix $a>0$, $T>0$. For each $M<\infty$, there is a $\gamma_0>0$ such that for $\gamma \leqq \gamma_0$,*

$$P\left\{\gamma\int_0^{T/\gamma}|\xi(s)|^2\,ds \geqq a/\varepsilon^2\right\} \leqq \exp(-M/\varepsilon^2). \tag{A2.11}$$

If the probability is conditioned on $\xi(0)$, then the result holds uniformly for $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ for any $\frac{1}{2} > \delta > 0$.

Proof. For simplicity, we let $\xi(\cdot)$ and $w(\cdot)$ be scalar valued. With the appropriate notational changes, the proof for the vector valued case is the same. The K_i denote constants. Define $Q_n = \int_{n-1}^n \exp A(n-\tau)B\,dw(\tau)$. We have, for $s \in [i, i+1]$

$$\xi(s) = \exp A(s-i)\xi(i) + \int_i^s \exp A(s-\tau)B\,dw(\tau),$$

$$\xi(i) = \sum_{-\infty}^{i} \exp A(i-n)Q_n, \tag{A2.12}$$

$$\int_i^{i+1} ds\left|\int_i^s \exp A(s-\tau)B\,dw(\tau)\right|^2 \leqq K_1\int_i^{i+1}|w(s)-w(i)|^2\,ds.$$

By an integration by parts

$$|Q_n|^2 \leqq K_2\int_{n-1}^n |w(s)-w(i)|^2\,ds + K_2|w(n)-w(n-1)|^2.$$

Now write (for $T/\gamma = \text{integer}$)

$$\int_0^{T/\gamma} |\xi(s)|^2\, ds = \sum_0^{T/\gamma-1} \int_i^{i+1} |\xi(s)|^2\, ds$$

$$\text{(A2.13)} \qquad \leqq K_3 \sum_0^{T/\gamma-1} |\xi(i)|^2 + K_3 \sum_0^{T/\gamma-1} \int_i^{i+1} |w(s)-w(i)|^2\, ds$$

$$\equiv S_1^\gamma + S_2^\gamma.$$

For some $b \in [0,1)$,

$$\text{(A2.14)} \qquad |\xi(i)|^2 \leqq K_4 \sum_{n=-\infty}^{i} b^{i-n} |Q_n|^2,$$

$$\sum_0^{T/\gamma-1} |\xi(i)|^2 \leqq K_5 \sum_0^{T/\gamma-1} Q_n^2 + K_5 \sum_{n=0}^{\infty} b^n Q_{-n}^2.$$

Relations (A2.12) to (A2.14) imply that

$$\text{(A2.15)} \qquad \int_0^{T/\gamma} |\xi(s)|^2\, ds \leqq K_6 \left\{ \sum_{i=1}^{T/\gamma-1} \left[\int_i^{i+1} |w(s)-w(i)|^2\, ds + |w(i+1)-w(i)|^2 \right] \right\}$$

$$+ K_6 \left\{ \sum_{i=-\infty}^{0} b^{-i} \left[\int_i^{i+1} |w(s)-w(i)|^2\, ds + |w(i+1)-w(i)|^2 \right] \right\}.$$

For Gaussian x, $E \exp \alpha x^2 = (1-2\alpha E x^2)^{-1}$ if $Ex = 0$ and $2\alpha E x^2 < 1$. Let us first consider the term

$$\text{(A2.16)} \qquad M^\gamma \equiv \sum_{i=1}^{T/\gamma-1} \int_i^{i+1} |w(s)-w(i)|^2\, ds + \sum_{i=-\infty}^{0} b^{-i} \int_i^{i+1} |w(s)-w(i)|^2\, ds.$$

For any $\lambda > 0$, if $2\lambda\gamma < 1$, then

$$P\{\gamma M^\gamma \geqq a/\varepsilon^2\} \leqq (\exp(-\lambda a/\varepsilon^2)) E \exp \lambda\gamma M^\gamma$$

$$\text{(A2.17)} \qquad = \exp(-\lambda a/\varepsilon^2) \prod_{i=0}^{T/\gamma-1} E \exp \lambda\gamma \int_i^{i+1} |w(s)-w(i)|^2\, ds$$

$$\cdot \prod_{i=-\infty}^{0} E \exp \lambda\gamma b^{-i} \int_i^{i+1} |w(s)-w(i)|^2\, ds.$$

By Jensen's inequality, and the fact that $E \exp \alpha |w(s)-w(i)|^2$ is increasing for $\alpha > 0$, we get

$$\text{(A2.18)} \qquad E \exp \lambda\gamma \int_i^{i+1} |w(s)-w(i)|^2\, ds \leqq E \int_i^{i+1} \exp \lambda\gamma |w(s)-w(i)|^2\, ds$$

$$\leqq E \exp \lambda\gamma |w(i+1)-w(i)|^2.$$

Hence,

$$\text{(A2.19)} \qquad P\{\gamma M^\gamma \geqq a/\varepsilon^2\} \leqq [\exp -\lambda a/\varepsilon^2](1-2\lambda\gamma)^{-T/\gamma-1} \prod_{i=-\infty}^{0} (1-2\lambda\gamma b^{-i})^{-1}.$$

Picking $\lambda = 2M/a$, there is $K_7 < \infty$ such that for small γ,

$$\text{(A2.20)} \qquad P\{\gamma M^\gamma \geqq a/\varepsilon^2\} \leqq K_7 \exp(-2M/\varepsilon^2).$$

The other terms in (A2.15) are easier to estimate, although the same general argument

is used and we omit the details. Hence the first part of the lemma is proved. To see the asserted uniformity in $\xi(0)$ of the conditioned probability, note that for some $K_1 < \infty$,

$$\int_0^{T/\gamma} |\xi(s)|^2\, ds \leqq K_1 \left[\sum_{i=1}^{T/\gamma - 1} \left(\int_i^{i+1} |w(s) - w(i)|^2\, ds + |w(i+1) - w(i)|^2 \right) + |\xi(0)|^2 \right]. \tag{A2.21}$$

This estimate and the previous argument complete the proof. Q.E.D.

LEMMA A2.4. *Under the hypotheses of Lemma* A2.3, *for fixed* M *and small* γ

$$P\left\{ \int_0^{T/\gamma} |\xi(s)|\, ds \geqq a/\varepsilon\gamma^{3/2} \right\} \leqq \exp(-M/\varepsilon^2).$$

If the probability is conditioned on $\xi(0)$, *then the estimate is uniform in* $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ *for* $\frac{1}{2} > \delta > 0$.

Proof. For any $b > 0$ and $u \geqq 0$, $u \leqq b + u^2/b$. Let $b = a/2\varepsilon\sqrt{\gamma}T$. Then

$$|\xi(s)| \leqq \frac{a}{2\varepsilon\sqrt{\gamma}T} + 2|\xi(s)|^2 \frac{\varepsilon\sqrt{\gamma}T}{a}.$$

Thus, we need only show that

$$P\left\{ \int_0^{T/\gamma} |\xi(s)|^2\, ds \left(\frac{2\varepsilon\sqrt{\gamma}T}{a} \right) \geqq \frac{a}{\varepsilon\gamma^{3/2}} \right\} \leqq \exp(-M/\varepsilon^2)$$

for small ρ. But this follows from Lemma A2.3. The proof for the conditional probability is similar. Q.E.D.

LEMMA A2.5. *Let* $0 < v < 1/2$. *Then for fixed* $M < \infty$, $T < \infty$, *there are* $\gamma_0 > 0$, $\Delta_0 > 0$, *such that for* $\gamma \leqq \gamma_0$, *and* $\Delta \leqq \Delta_0$,

$$P\{\sqrt{\gamma}\varepsilon \sup_{i \leqq T/\Delta} \sup_{t \leqq \Delta} |w(i\Delta + t) - w(i\Delta)| \geqq \Delta^v\} \leqq \exp(-M/\varepsilon^2),$$

$$P\{\sqrt{\gamma}\varepsilon \sup_{i \leqq T/\Delta} \sup_{t \leqq \Delta} |\xi(i\Delta + t) - \xi(i\Delta)| \geqq \Delta^v\} \leqq \exp(-M/\varepsilon^2).$$

If the last probability is conditioned on $\xi(0)$, *and* $0 < \delta < \frac{1}{2}$, *then the estimate is uniform for* $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$.

The proof follows the lines of the previous lemmas and is omitted.

Appendix III. An estimate for the phase locked loop problem. We wish to show that the last (the high frequency) term in (5.3) can be dropped when calculating the large deviations estimates. Here, we do this for a simpler (and scalar) problem, to simplify the notation. We prove the result for noise Model I. An analogous result can be obtained for noise Model II.

Define $\tilde{x}^\rho(\cdot)$ by

$$\begin{aligned} \dot{\tilde{x}}^\rho(t) &= b(\tilde{x}^\rho(t)) + \varepsilon\sigma(\tilde{x}^\rho(t))\xi^\gamma(t) + \varepsilon(\sin \omega_0 t/\eta_\gamma)\sigma_1(\tilde{x}^\rho(t))\xi^\gamma(t), \\ \tilde{x}^\rho(0) &= x \end{aligned} \tag{A3.1}$$

where $\eta_\gamma/\gamma \to 0$, and $\sigma_1(\cdot)$ satisfies the same conditions as does $\sigma(\cdot)$. We first prove the following auxiliary lemma.

LEMMA A3.1. *For each* $M < \infty$, $T > 0$, *and* $a > 0$ *there is a* $\rho_0 > 0$ *such that for* $\rho < \rho_0$,

$$P\{ \sup_{0 \leqq t \leqq T} |I^\rho(t)| \geqq a\} \leqq \exp -M/\varepsilon^2, \tag{A3.2}$$

where

$$I^\rho(t) = \int_0^t \varepsilon(\sin \omega_0 s/\eta_\gamma)\sigma_1(\tilde{x}^\rho(s))\xi^\gamma(s)\, ds.$$

The same estimate holds uniformly in $|\xi(0)| \leqq \varepsilon^{-1}\gamma^{-\delta}$ *for* $\delta \in (0, \frac{1}{2})$, *and in* x *in any compact set, when the probability is replaced by the probability conditioned on* $\xi(0)$.

Proof. By repeating the proof for $-I^\rho$, we may drop the absolute value bars in (A3.2). By a change of variable $s/\gamma \to s$, we obtain

$$I^\rho(t) = \varepsilon\sqrt{\gamma}\int_0^{t/\gamma} (\sin \gamma\omega_0 s/\eta_\gamma)\sigma_1(\tilde{x}^\rho(\gamma s))\xi(s)\, ds.$$

By an integration by parts with

$$da = \sin \gamma\omega_0 s/\eta_\gamma, \qquad b = \sigma_1(\tilde{x}^\rho(\gamma s))\xi(s)\, ds$$

we obtain

$$I^\rho(t) = \frac{\varepsilon\sqrt{\gamma}\eta_\gamma}{\omega_0}\int_0^{t/\gamma} (\cos \gamma\omega_0 s/\eta_\gamma)\sigma_1(\tilde{x}^\rho(\gamma s))A\xi(s)\, ds + \text{terms of smaller order.} \tag{A3.3}$$

By repeating the integration by parts on the first term on the r.h.s. of (A3.3) and collecting like terms, we find $(N = [I + \eta_\gamma^2 A^2/\omega_0^2]^{-1} \cdot [\eta_\gamma I(\cos \gamma\omega_0 s/\eta_\gamma)\omega_0 - \eta_\gamma^2 A(\sin \gamma\omega_0 s/\eta_\gamma)/\omega_0^2])$

$$\begin{aligned} I^\rho(t) = {} & -\varepsilon\sqrt{\gamma}\sigma_1(\tilde{x}^\rho(\gamma s))N\xi(s)|_0^{t/\gamma} \\ & + \varepsilon\sqrt{\gamma}\int_0^{t/\gamma} \sigma_1(x^\rho(\gamma s))NB\, ds(s) \\ & + \varepsilon\gamma^{3/2}\int_0^{t/\gamma} b'(\tilde{x}^\rho(\gamma s))\sigma_{1x}(\tilde{x}^\rho(\gamma s))N\xi(s)\, ds \\ & + \varepsilon^2\gamma\int_0^{t/\gamma} \xi'(s)(\sigma(\tilde{x}^\rho(\gamma s)) \\ & \qquad + (\sin \gamma\omega_0 s/\eta_\gamma)\sigma_1(\tilde{x}^\rho(\gamma s)))'\sigma_{1x}(\tilde{x}^\rho(\gamma s))N\xi(s)\, ds. \end{aligned}$$

As $|N| \to 0$ when $\gamma \to 0$, Lemmas A2.1, A2.2, A2.3, and A2.4 imply the estimates and the required uniformity.

LEMMA A3.2. *Theorem A1.1 holds for the system defined by* (A3.1), *where the S-functional is that for* (A3.1) *with the high frequency term* (*the last one on the right of* (A3.1)) *dropped.*

Proof. The proof is essentially the same as that of Theorem A1.1. Simply add the "high frequency" term in (A3.1) to the β_1^0 in the proof of Theorem A1.1. This is justified by Lemma A3.2. There is also an additional term in the β_2^ρ in Theorem A1.1, due to the "high frequency term." The term appears due to the "high frequency" contribution to the terms which arise during the partial integration. But these terms are of the same type as (A3.1) and can also be collected in the β_1^β. The other details are the same. Q.E.D.

Remark. In (A3.1), we retain only one high frequency term, but the result for (5.3) is the same; i.e., Theorem 4.1 or Theorem A1.1 (equivalently) hold, where the S-functional is that for the system without the high frequency terms; namely for (5.4.).

Appendix IV. Estimates for noise Model II. Estimates analogous to those obtained in Appendix II can also be obtained for the noise Model II. Using the appropriate analogues of Lemmas A2.1 to A2.5, the proofs are the same as for the noise Model I case. In order to obtain the correct forms of the lemmas, simply replace $dw(s)$ by $d\bar{J}^\gamma(s)$ and $\xi(s)$ by $\bar{\xi}^\gamma(s)/\sqrt{\gamma}$ in the statements of the Lemmas A2.1 to A2.5. We only give details where they are significantly different from those used in Appendix II. We do the proofs in the scalar cases for notational convenience. In every lemma, the method of proving the required uniformity is the same as in Appendix II, and the details are omitted. For simplicity, all the details are for scalar case only.

LEMMA A4.1. *Fix $a>0$, $T>0$, and $\delta>0$. For each $M<\infty$ there is $\gamma_0>0$ such that for $\gamma\leqq\gamma_0$ and all T_0*

$$P\{\sup_{t\leqq T/\gamma}|\bar{\xi}^\gamma((t+T_0/\gamma))-\bar{\xi}^\gamma(T_0/\gamma)|\geqq a/\varepsilon\gamma^{\delta-1/2}\}\leqq\exp(-M/\varepsilon^2). \tag{A4.1}$$

If the probability in (A4.1) *is conditioned on $\xi^\gamma(T_0/\gamma)$, then the estimates are uniform in $|\bar{\xi}^\gamma(T_0/\gamma)|\leqq\varepsilon^{-1}\gamma^{-\delta_1+1/2}$ for $\delta_1<\delta$.*

Proof. Following the argument used in Lemma A2.1, all that is needed are estimates on (for arbitrary $a_i>0$)

$$P\{|\bar{\xi}^\gamma(i)|\geqq a_1/\varepsilon\gamma^{\delta-1/2}\}, \tag{A4.2}$$

$$P\{\sup_{i\leqq s\leqq i+1}|\bar{J}^\gamma(s)-\bar{J}^\gamma(i)|>a_2/\varepsilon\gamma^{\delta-1/2}\}. \tag{A4.3}$$

Write $\bar{\xi}^\gamma(i)=\int_{-\infty}^{i}(\exp(-A(s-i)))\,d\bar{J}^\gamma(s)$. Then for $\lambda>0$,

$$\log E\exp\lambda\bar{\xi}^\gamma(i)=\mu_\gamma\gamma\int_0^\infty E[\exp(\lambda\psi^\gamma\exp As)-1]\,ds.$$

Hence as $\gamma\to0$

$$\frac{1}{\gamma}\log E\exp\lambda\bar{\xi}^\gamma(i)\to C_0\frac{\lambda^2}{2}\int_0^\infty\exp 2As\,ds.$$

Via the exponential Chebyshev's inequality, for $\lambda=a_1/C_0[\int_0^\infty\exp 2As\,ds]\varepsilon\gamma^{\delta+1/2}$ we find (for small γ, and similarly for $-\bar{\xi}^\gamma(i)$)

$$\begin{aligned}P\{\bar{\xi}^\gamma(i)\geqq a_1/\varepsilon\gamma^{\delta-1/2}\}&\leqq(\exp-a_1\lambda/\varepsilon\gamma^{\delta-1/2})E\exp\lambda\bar{\xi}^\gamma(i)\\&\leqq\exp\left[-a_1^2\Big/\left[2C_0\left[\int_0^\infty\exp As\,ds\right]\varepsilon^2\gamma^{2\delta}\right]\right].\end{aligned}$$

In order to estimate (A4.3), we use the fact that $\exp\lambda(\bar{J}^\gamma(s)-\bar{J}^\gamma(i))$ is a submartingale to get

$$\begin{aligned}&P\{\sup_{i\leqq s\leqq i+1}(\bar{J}^\gamma(s)-\bar{J}^\gamma(i))\geqq a_2/\varepsilon\gamma^{\delta-1/2}\}\\&\qquad\leqq(\exp(-\lambda a_2/\varepsilon\gamma^{\delta-1/2}))[(E\exp\lambda(\bar{J}^\gamma(i+1)-\bar{J}^\gamma(i))].\end{aligned}$$

Picking $\lambda=a_2/C_0\varepsilon\gamma^{\delta+1/2}$, and using the fact that

$$\lim_\rho[E\exp\lambda(\bar{J}^\gamma(i+1)-\bar{J}^\gamma(i))]=\lim_\rho\gamma\mu_\gamma[E\exp\lambda\psi^\gamma-1]=C_0\lambda^2/2,$$

yields the desired estimate.

LEMMA A4.2. *Let $f(\cdot)$ be bounded (by, say, k) in norm and nonanticipative with respect to $\bar{J}^\gamma(\cdot)$. Then,*

$$P\left\{\sup_{0\leq t\leq T/\gamma}\left|\int_0^t f(s)\,d\bar{J}^\gamma(s)\right|\geq a/\varepsilon\right\}\leq 2\exp-(a^2/2TC_0k^2\varepsilon^2). \tag{A4.4}$$

LEMMA A4.3. *Fix $a>0$, $T>0$. For each $M<\infty$, there is a $\rho_0>0$ such that for $\rho\leq\rho_0$*

$$P\left\{\int_0^{T/\gamma}|\bar{\xi}^\gamma(s)|^2\,ds\geq a/\varepsilon^2\right\}\leq\exp(-M/\varepsilon^2). \tag{A4.5}$$

If the probability is conditioned on $\bar{\xi}^\gamma(0)$ then the result holds uniformly for $|\bar{\xi}^\gamma(0)|\leq\varepsilon^{-1}\gamma^{-\delta+1/2}$ for any $\frac{1}{2}>\delta>0$.

Proof. By an expansion analogous to that used in Lemma A2.3, there is a K such that

$$\begin{aligned}\int_0^{T/\gamma}|\bar{\xi}^\gamma(s)|^2\,ds &\leq K\sum_1^{T/\gamma-1}\int_i^{i+1}|\bar{J}^\gamma(s)-\bar{J}^\gamma(i)|^2\,ds\\ &\quad+K\sum_1^{T/\gamma-1}|\bar{J}^\gamma(i+1)-\bar{J}^\gamma(i)|^2\\ &\quad+K\sum_{-\infty}^{0}b^{-i}\int_i^{i+1}|\bar{J}^\gamma(s)-\bar{J}^\gamma(i)|^2\,ds+K\sum_{-\infty}^{0}b^{-i}|\bar{J}^\gamma(i+1)-\bar{J}^\gamma(i)|^2\\ &\equiv S_1^\gamma+S_2^\gamma+S_3^\gamma+S_4^\gamma.\end{aligned}$$

We evaluate only

$$P\{S_1^\gamma\geq a/\varepsilon^2\}, \tag{A4.6a}$$

as the others are handled in a similar manner. Recall the restriction (2.3):

$$\gamma^{1+\alpha/2}/\varepsilon\to 0\quad\text{as }\rho\to 0, \tag{A4.6b}$$

and that $\mu_\gamma=O(\gamma^{-2-\alpha})$ for some $\alpha>0$. For notational convenience (and w.l.o.g.), we let $\mu_\gamma=\gamma^{-2-\alpha}$. Let N_i denote the number of jumps of $\bar{J}^\gamma(\cdot)$ on the interval $[i,i+1)$. Then

$$P\{N_i=n\}=\exp(-\gamma\mu_\gamma)(\gamma\mu_\gamma)^n/n! \tag{A4.7}$$

Fix $m>1$. The terms in (A4.7) decrease geometrically for $n\geq\gamma\mu_\gamma m$, hence for $n\geq\mu_\gamma m$ if $\gamma<1$. Thus, using Stirling's formula (and always using $\gamma<1$) there are K_i (not depending on γ) such that

$$\begin{aligned}P\{N_i\geq m\mu_\gamma\}&\leq K_1(\exp-\gamma\mu_\gamma)(\gamma\mu_\gamma)^{m\mu_\gamma}/(m\mu_\gamma)!\\ &\leq K_2\exp-\left[1+\frac{m}{\gamma}\left(\log\left(\frac{m}{\gamma}\right)-1\right)\right]\gamma\mu_\gamma.\end{aligned} \tag{A4.8}$$

Hence

$$P\{\sup_{i\leq T/\gamma}N_i\geq m\mu_\gamma\}\leq\frac{T}{\gamma}\exp-\left[1+\frac{m}{\gamma}\left(\log\left(\frac{m}{\gamma}\right)-1\right)\right]\gamma^{-1-\alpha}.$$

By (A4.56b), we have

$$\varepsilon^2\left[1+\frac{m}{\gamma}\left(\log\left(\frac{m}{\gamma}\right)-1\right)\right]\gamma^{-1-\alpha}\geq(\varepsilon^2m/\gamma^{2+\alpha})\left(\log\left(\frac{m}{\gamma}\right)-1\right)=\delta_\rho\left(\log\left(\frac{m}{\gamma}\right)-1\right)$$

where $\delta_\rho \to \infty$ as $\rho \to 0$. Then

$$P\{\sup_{i \leqq T/\gamma} N_i \geqq m\mu_\gamma\} \leqq T/\gamma \exp\left(-\left[\delta_\rho\left(\log\left(\frac{m}{\gamma}\right)-1\right)\Big/\varepsilon^2\right]\right) \leqq \exp(-\delta_\rho/\varepsilon^2)$$

for small ρ. Henceforth, in evaluating (A4.6a), we can assume that $\delta_\rho > 2M$ and that $N_i \leqq m\mu_\gamma$. We have for $\lambda > 0$,

$$\begin{aligned} E\exp\lambda S_1^\gamma &= \left(E\exp\lambda\int_0^1 |\bar{J}^\gamma(s)-\bar{J}^\gamma(0)|^2\,ds\right)^{T/\gamma} \\ &\leqq (E\exp\lambda|\bar{J}^\gamma(1)-\bar{J}^\gamma(0)|^2)^{T/\gamma}. \end{aligned} \tag{A4.9}$$

The inequality in (A4.9) follows from Jensen's inequality and the fact that if $\{z_1, z_2\}$ is a zero mean martingale, then by the submartingale inequality,

$$E\exp\lambda|z_1|^2 \leqq E\exp\lambda|z_2|^2.$$

Neglecting jumps above $m\mu_\gamma$ on each interval $[i, i+1)$, we get

$$E\exp\lambda|\bar{J}^\gamma(1)-\bar{J}^\gamma(0)|^2 \sim \sum_{n=0}^{m\mu_\gamma} E\exp\lambda\left(\sum_1^n \psi_i^\gamma\right)^2 (\exp(-\gamma\mu_\gamma))(\gamma\mu_\gamma)^n/n!,$$

where the $\{\psi_i^\gamma\}$ are mutually independent and each has the distribution of ψ^γ. Assume for the moment that the ψ_i^γ are normally distributed. Then $\sum_1^n \psi_i^\gamma$ is normally distributed in the mean zero and variance $n\nu_\gamma$, and for small enough λ we would have the bounds

$$\begin{aligned} \sum_0^{m\mu_\gamma}(1-2\lambda n\nu_\gamma)^{-1}(\exp(-\gamma\mu_\gamma))(\gamma\mu_\gamma)^n/n! &\leqq \sum_0^{m\mu_\gamma}(1+4\lambda n\nu_\gamma)(\exp(-\gamma\mu_\gamma))(\gamma\mu_\gamma)^n/n! \\ &\leqq 1+4\lambda\nu_\gamma\mu_\gamma\gamma. \end{aligned}$$

Thus for purposes of evaluating (A4.6), we may bound (A4.9) by

$$(1+4\lambda C_0\gamma)^{T/\gamma} \leqq \exp 4\lambda C_0 T.$$

Next, use the exponential Chebyshev inequality to obtain (neglecting a set whose probability is $\leqq \exp(-2M/\varepsilon^2)$)

$$P\{S_1^\gamma \geqq a/\varepsilon^2\} \leqq (\exp(-\lambda a/\varepsilon^2))\exp 4\lambda C_0 T$$

choosing $\lambda = 2M/a$ yields the desired estimate for small γ.

If the ψ_i are not normally distributed, the estimate remains the same, owing to the assumptions made on the upper bounds to the moments of the ψ_i^γ in (2.3). The same procedure is used to estimate S_2^γ, S_3^γ, and S_4^γ. Q.E.D.

LEMMA A4.4 *Under the hypotheses of Lemma* A4.3, *for any fixed M and small* ρ

$$P\left\{\int_0^{T/\gamma} |\bar{\xi}^\gamma(s)|\,ds \geqq a/\varepsilon\gamma\right\} \leqq \exp(-M/\varepsilon^2).$$

If the probability is conditioned on $\bar{\xi}^\gamma(0)$, *then the estimate is uniform in* $|\bar{\xi}^\gamma(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$, *for* $\frac{1}{2} > \delta > 1$.

LEMMA A4.5. *Let* $0 < \nu < \frac{1}{2}$. *Then for fixed* $M < \infty$ *and* $T < \infty$, *there are* $\rho_0 > 0$ *and* $\Delta_0 > 0$ *such that for* $\rho \leqq \rho_0$ *and* $\Delta \leqq \Delta_0$,

$$P\{\varepsilon \sup_{i \leqq T/\Delta} \sup_{t \leqq \Delta} |\bar{J}^\gamma(i\Delta+t)-\bar{J}^\gamma(i\Delta)| \geqq \Delta^\nu\} \leqq \exp(-M/\varepsilon),$$

$$P\{\varepsilon \sup_{i \leqq T/\Delta} \sup_{t \leqq \Delta} |\bar{\xi}^\gamma(i\Delta+t)-\bar{\xi}^\gamma(i\Delta)| \geqq \Delta^\nu\} \leqq \exp(-M/\varepsilon^2).$$

If the last probability is conditioned on $\bar{\xi}^\gamma(0)$, *and* $0 < \delta < \frac{1}{2}$, *then the estimate is uniform for* $|\bar{\xi}^\gamma(0)| \leqq \varepsilon^{-1}\gamma^{-\delta+1/2}$.

INVARIANCE CONCEPTS IN INFINITE DIMENSIONS*

RUTH F. CURTAIN†

Abstract. The concepts of (A, B) and (C, A)-invariance are examined for infinite-dimensional linear systems. Examples such as reachability, A-reachability, inobservability and A-inobservability subspaces are given. These concepts are then used to solve various disturbance decoupling problems.

Key words. (A, B)-invariance, (C, A)-invariance, observability, reachability, disturbance decoupling, infinite-dimensional systems

1. Introduction. The concept of (A, B)-invariance has been used by Wonham in [11] to solve various decoupling and control problems. Use is made of the equivalence of (A, B)-invariance of a subspace V: $AV \subset V + \operatorname{Im} B$ and the holdability under the linear system $\dot{x} = Ax + Bu$. Unfortunately this does not hold in general in infinite-dimensions, as indicated by Schmidt and Stern in [6], where they investigated this concept in detail. Here we take a different approach and seek natural conditions under which (A, B)-invariance and holdability are equivalent: for example V is closed and in $D(A)$ and B has finite rank. A key concept in solving disturbance decoupling problems is the existence of a supremal (A, B)-invariant subspace contained in a closed subspace. Although this exists in infinite dimensions it is not in general invariant for trajectories of $\dot{x} = Ax + Bu$ and this is the property which is needed to solve disturbance decoupling problems. We are able to establish sufficient conditions for this property of trajectory invariance, but only by considering the dual concept of the trajectory invariance of the infimal (C, A)-invariant subspace. These dual concepts have also been exploited by researchers to solve various disturbance decoupling and regulator problems, for example by Schumacher in [7] and Willems and Commault in [10]. Surprisingly enough the duality in infinite dimensions is incomplete, but fortunately sufficient to allow us to solve several interesting disturbance decoupling problems.

The organization of this paper is as follows:

§ 2. A-invariance. § 3. (C, A)-invariance. § 4. (A, B)-invariance.
§ 5. Duality between (A, B)- and (C, A)-invariance.
§ 6. Supremal (A, B)-invariant subspaces and infimal (C, A)-invariant subspaces.
§ 7. Some disturbance decoupling problems.
§ 8. Examples.

Essentially the results on disturbance decoupling are that if the supremal (A, B)- (or infimal (C, A))-invariant subspace in question is trajectory invariant and we have finite-dimensional inputs and outputs and some operators are smooth, then we obtain the solvability conditions reminiscent of the finite-dimensional case in [10] and [11]. Some sufficient conditions for trajectory invariance of the supremal (A, B)- or infimal (C, A)-invariant subspaces are given in § 6 and they are applied to retarded systems using the M^2-formulation of [9] and also to the so-called spectral systems introduced by Curtain in [1] in § 8. These illustrate the fact that the existence of a trajectory invariant supremal (A, B)-invariant subspace is in general difficult to establish, especially for retarded systems. Various extensions have been completed recently, such as the disturbance decoupling problem by measurement feedback in [2] and disturbance

decoupling problems with boundary control or boundary disturbances in [3]. It is also possible to solve disturbance decoupling problems with stability for certain classes of systems using a similar approach to that in [10] (see [1a]).

2. *A*-invariance. Throughout X will denote a real, separable Hilbert space and A the infinitesimal generator of a strongly continuous semigroup $T(t)$ on X. This implies that A is closed, linear and densely defined on X. We summarize the useful factors about A-invariance from Taylor and Lay [8].

DEFINITION 2.1. *A-invariance.* The linear subspace V of X is A-invariant if $A(V \cap D(A)) \subset V$. If V is closed, then X has the direct sum decomposition

$$X = V \oplus V^{\perp}$$

and relative to this A has the following block decomposition

$$A = \begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix}.$$

The case of a diagonal decomposition with $A_{12} = 0$ corresponds to the following.

DEFINITION 2.2. *Reducing subspaces.* Let M_1, M_2 be 2 closed subspaces of X such that $X = M_1 \oplus M_2$. Then (M_1, M_2) are said to completely reduce A if M_i is A-invariant and $P_i D(A) \subset D(A)$, $i = 1, 2$, where P_1 is the continuous projection on M_1 along M_2 and similarly for P_2. Sufficient conditions for (M_1, M_2) to completely reduce A are that $P_i D(A) \subset D(A)$ and $P_i A x = A P_i x$ for all $x \in D(A)$ hold for *one* value of i.

We are interested in conditions under which the A-invariance of V implies that V is also $T(t)$-invariant. That this is not in general true was pointed out by Schmidt and Stern in [6], and sufficient conditions were established by Schumacher in [7, Chap. 4].

LEMMA 2.3. *Suppose that A is the infinitesimal generator of a semigroup $T(t)$ on X and that $X = S \oplus M$, where S and M are closed linear subspaces of X. If S is A-invariant and $S \subset D(A)$, then S is also $T(t)$ invariant for all $t \geqq 0$. Furthermore, the restriction of A to S is the infinitesimal generator of the semigroup $T(t)|S$. The factor space X/S is well defined and we can define the mappings $\bar{T}(t)$ and $\bar{A}$ by*

$$\bar{T}(t)(x \bmod S) = (T(t)x) \bmod S, \tag{2.1}$$

$$\bar{A}(x \bmod S) = (Ax) \bmod S \text{ for } x \in D(A). \tag{2.2}$$

Then $\bar{T}(t)$ is a semigroup on X/S whose generator is an extension of $\bar{A}$. We shall write $[T(t)]_S$ and $[A]_S$, for $\bar{T}(t)$ and its generator.

Another special case where A-invariance implies $T(t)$-invariance is when S and M are reducing subspaces for A.

LEMMA 2.4. *Suppose that (M_1, M_2) completely reduce A, then they also reduce $T(t)$ for $t \geqq 0$.*

Proof. Since (M_1, M_2) reduces A, we have that $P_1 D(A) \subset D(A)$ and $P_1 A x = A P_1 x$ for $x \in D(A)$. Then for $\lambda \notin \sigma(A)$, we have $P_1 R(\lambda, A)x = R(\lambda, A) P_1 x$. Now from [4] we have

$$R(\lambda, A)x = \int_0^{\infty} e^{-\lambda t} T(t)x \, dt$$

and so

$$0 = P_1 R(\lambda, A)x - R(\lambda, A) P_1 x = \int_0^{\infty} e^{-\lambda t} (P_1 T(t)x - T(t) P_1 x) \, dt;$$

and by the uniqueness of the Laplace transform, we obtain

$$P_1 T(t) = T(t) P_1$$

and M_1 reduces $T(t)$. Since $P_2 = I - P_1$, M_2 also reduces $T(t)$.

$T(t)$-invariance does however imply a type of A-invariance.

LEMMA 2.5. *If V is $T(t)$ invariant for $t \geqq 0$, then $A(V \cap D(A)) \subset \bar{V}$.*

Proof. $T(t)V \subset V$ for $t \geqq 0$, and for $v \in V \cap D(A)$. We may differentiate with respect to t

$$AT(t)V \subset \bar{V} \Rightarrow A(V \cap D(A)) \subset \bar{V}.$$

Lemmas 2.3 and 2.5 indicate that to obtain useful results we should only consider closed invariant subspaces, which we henceforth do.

3. (C, A)-invariance. We consider the following observed system on X

$$\begin{aligned} &\dot{x} = Ax, \qquad x(0) = x_0, \\ &y = Cx = CT(t)x_0 \end{aligned} \tag{3.1}$$

where $C \in \mathscr{L}(X, Y)$, $x_0 \in X$ and Y is a separable Hilbert space.

The finite-dimensional concept of (C, A)-invariance extends naturally to the following.

DEFINITION 3.1. *(C, A)-invariance.* A closed linear subspace S of X is (C, A)-invariant if

$$A(S \cap \operatorname{Ker} C \cap D(A)) \subset S \tag{3.2}$$

Anticipating that this will not be the same as the semigroup invariance we define $T(C, A)$-invariance.

DEFINITION 3.2. *$T(C, A)$-invariance.* A closed linear subspace S and X is $T(C, A)$-invariant if there exists a $G \in \mathscr{L}(Y, X)$ such that S is invariant under the semigroup $T_{A+GC}(t)$, which is generated by $A + GC$.

We shall also use a third related concept as follows.

DEFINITION 3.3. *Feedback (C, A)-invariance.* A closed linear subspace S of X is feedback (C, A)-invariant if there exists a $G \in \mathscr{L}(Y, X)$ such that

$$(A + GC)(S \cap D(A)) \subset S. \tag{3.3}$$

If S is $T(C, A)$-invariant, then we have the interpretation that the data processor on X/S defined by

$$\dot{w} = [A + GS]_S w - [G]_S y, \qquad w(0) \in S \tag{3.4}$$

with error dynamics

$$\dot{e} = [A + GC]_S e, \qquad e = w - [z]_S$$

is an estimator for $[z]_S$ in (3.1).

It is not enough that S be (C, A)-invariant, as then we could not guarantee that $[A + GC]_S$ is a generator of a semigroup on X/S. (See Lemma 2.3 and Willems and Commault [10]).

We are interested in conditions under which Definitions 3.1, 3.2, 3.3 coincide.

LEMMA 3.4. *$T(C, A)$-invariance $\Rightarrow$ feedback (C, A)-invariance $\Rightarrow$ (C, A)-invariance.*

Proof. Suppose that $s \in S \cap D(A)$. Then since S is closed,

$$\frac{d}{dt}(T_{A+GC}(t))S = (A+GC)T_{A+GC}(t)S \subset S$$

and setting $t=0$, we have $(A+GC)s \in S$ which yields (3.3) and this implies (3.2).

LEMMA 3.5. *Feedback (C, A)-invariance and $T(C, A)$-invariance are equivalent in either of the following cases*:

(a) *$S \subset D(A)$ and S is closed*;

(b) *S is reducing subspace for $A+GC$.*

Proof. Lemmas 2.3 and 2.4 since $D(A+GC) = D(A)$. Our main result is the following.

LEMMA 3.6. *Suppose that S and CS are closed subspaces, $S \subset D(A)$, then the following statements are equivalent*;

(i) *S is (C, A)-invariant.*

(ii) *There exists a bounded linear map $G: Y \to X$ such that $(A+GC)S \subset S$.*

Proof. (ii)$\Rightarrow$(i) is obvious.

(i)$\Rightarrow$(ii): Define $W = S \cap (S \cap \operatorname{Ker} C)^{\perp}$. Then W is closed and $W \cap \operatorname{Ker} C = \{0\}$, and

$$S = W \oplus (S \cap \operatorname{Ker} C). \tag{3.5}$$

Let $Y_0 = CW$ and note that since $W \cap \operatorname{Ker} C = \{0\}$, C is $1-1$ from W to Y_0. By our assumption, Y_0 is closed and thus C^{-1} is a bounded operator from Y_0 to W (Taylor and Lay [8]). We now decompose Y as follows

$$Y = Y_0 \oplus Y_0^{\perp} \tag{3.6}$$

and define

$$\begin{aligned} &G: Y \to X \text{ by} \\ &Gy = 0 \text{ if } y \in Y_0^{\perp}, \end{aligned} \tag{3.7}$$

$$\begin{aligned} Gy = -As \text{ if } y \in D(G) &= \{y \in Y_0 \colon S = C^{-1}y \in D(A)\} \\ &= Y_0 \text{ since } S \in D(A). \end{aligned} \tag{3.8}$$

We now show that that restriction of G to Y_0 is closed. Suppose that $\{y_i\} \subset Y_0$ and $y_i \to y$ in Y_0, $Gy_i \to x \in X$. Since $y_i \in Y_0$ there exists $s_i \in W$ such that $Gy_i = -As_i$ and $y_i = Cs_i$. Since C^{-1} is bounded from Y_0 to W, $s_i = C^{-1}y_i \to s = C^{-1}y$ as $i \to \infty$. Now A is closed and $s_i \to s$ together with $As_i \to x$ imply that $s \in D(A)$ and $As = -x$. Summarizing, we have shown that $Gy_i \to As$ and $y_i \to y = Cs$ as $i \to \infty$ and from (3.8) we have that $Gy_i \to Gy$ as $i \to \infty$, completing the proof that G is closed. Since $D(G) \supset Y_0$, G is bounded. Now if $s \in S \cap \operatorname{Ker} C$, we have $(A+GC)s = As \in S$ by (i) and if $s \in S$, $s \notin \operatorname{Ker} C$, then $s \in W$, $Cs \in D(G)$ and from (3.8) $(A+GC)s = As - As = 0$. Thus (ii) holds.

We remark that CS will be closed if C has finite rank and this is usually the case in applications, so we state a corollary for this special case:

COROLLARY 3.7. *If C has finite rank and S is closed and $\subset D(A)$, then the three concepts $T(C, A)$-invariance, feedback (C, A)-invariance and (C, A)-invariance are all equivalent.*

We now give examples of some infinite-dimensional $T(C, A)$-invariant subspace, which are useful in applications.

DEFINITION 3.8. *Inobservability subspace.* For the system (3.1) we define the inobservability subspace, $\langle \operatorname{Ker} C|T(t)\rangle$ by

$$\langle \operatorname{Ker} C|T(t)\rangle = \bigcap_{t\geqq 0} \operatorname{Ker} CT(t) = \operatorname{Ker}\left(\bigcap_{t\geqq 0} CT(t)\right). \tag{3.9}$$

$\langle \operatorname{Ker} C|T(t)\rangle$ is closed and if $\langle \operatorname{Ker} C|T(t)\rangle = \{0\}$, then the system is initially observable (cf. Curtain and Pritchard [4]). Useful properties of inobservability subspaces are the following.

LEMMA 3.9.

(a) $\langle \operatorname{Ker} C|T(t)\rangle$ *is the largest* $T(t)$*-invariant subspace which is contained in* $\operatorname{Ker} C$;

(b) $\langle \operatorname{Ker} C|T(t)\rangle$ *is output-injection-invariant*: $\langle \operatorname{Ker} C|T_{A+GC}(t)\rangle = \operatorname{Ker}\langle C|T(t)\rangle$;

(c) $\langle \operatorname{Ker} C|T(t)\rangle$ *is* $T(C, A)$*-invariant*;

(d) *If* $\operatorname{Ker} C$ *is* $T(t)$*-invariant, then* $\langle \operatorname{Ker} C|T(t)\rangle = \operatorname{Ker} C$;

(e) *If* $\operatorname{Ker} C \subset D(A)$, *then* $\langle \operatorname{Ker} C|T(t)\rangle = \bigcap_{n=0}^{\infty} CA^n$.

Proof.

(a) If $x \in \langle \operatorname{Ker} C|T(t)\rangle$ then $CT(0)x = Cx = 0$. So $x \in \operatorname{Ker} C$. Furthermore, $T(a)x \in \langle \operatorname{Ker} C|T(t)\rangle$ for all $a > 0$, since

$$CT(t)T(a)x = CT(t+a)x \quad \text{for } a+t \geqq 0.$$

Suppose that Q is another closed $T(t)$-invariant subspace with $Q \subset \operatorname{Ker} C$. If $q \in Q$, then $CT(t)q = 0$ for all $t \geqq 0$ and so $Q \subset \langle \operatorname{Ker} C|T(t)\rangle$.

(b) The semigroup $T_{A+GC}(t)$ generated by $A+GC$ is given by [4],

$$T_{A+GC}(t) = T(t) + \int_0^t T_{A+GC}(t-s)GCT(s)\, ds. \tag{3.10}$$

So if $x \in \langle \operatorname{Ker} C|T(t)\rangle$, $x \in \langle \operatorname{Ker} C|T(t)\rangle$ since C is bounded. The converse holds since $T(t)$ is generated by $(A+GC)-GC$.

(c) From (b) $\langle \operatorname{Ker} C|T_{A+GC}(t)\rangle = \langle \operatorname{Ker} C|T(t)\rangle$ and from (a), $\langle \operatorname{Ker} C|T(t)\rangle$ is $T(C, A)$-invariant and by Lemma 3.4, (C, A)-invariant.

(d), (e) obvious.

We find that the following related inobservability subspace is important for the applications.

DEFINITION 3.10. *A-inobservability subspace.* We define the A-inobservability subspace, $\langle \operatorname{Ker} C|A\rangle$, by

$$\langle \operatorname{Ker} C|A\rangle = \bigcap_{n=0}^{\infty} \operatorname{Ker} CA^n. \tag{3.11}$$

It is easy to show that $\langle \operatorname{Ker} C|A\rangle$ is the largest A-invariant subspace, which is contained in the $\operatorname{Ker} C \cap D(A)$.

Notice that $\langle \operatorname{Ker} C|A\rangle$ is not necessarily closed. If A is bounded, it is easy to show that $\langle \operatorname{Ker} C|A\rangle = \langle \operatorname{Ker} C|T(t)\rangle$, but in general they are different due to the lack of equivalence of A and $T(t)$-invariance. If $\operatorname{Ker} C \subset D(A)$, then

$$\langle \operatorname{Ker} C|A\rangle \supset \langle \operatorname{Ker} C|T(t)\rangle \cap \mathcal{D}(A). \tag{3.12}$$

4. (A, B)-invariance. We consider the following system on X

$$\dot{x} = Ax + Bu, \qquad x(0) = x_0 \tag{4.1}$$

and we define the solution to be mild solution

$$x(t) = T(t)x_0 + \int_0^t T(t-s)Bu(s)\,ds \tag{4.2}$$

which exists and is continuous for all $u \in L_2(0, t; U)$, and $B \in \mathscr{L}(U, X)$ where X is a real, separable Hilbert space.

We shall be concerned with the following concept for (4.1).

DEFINITION 4.1. *(A, B)-invariance.* A closed, linear subspace V of X is (A, B)-invariant if

$$A(V \cap D(A)) \subset \overline{V + \operatorname{Im} B} \tag{4.3}$$

where Im B denotes the range of B.

(A, B)-invariance in infinite dimensions was studied by Schmidt and Stern in [6], where they found that the concept is much more complicated than in finite dimensions. We use a modified version of their definition, because we need the closure of $V + \operatorname{Im} B$ to obtain the existence of a supremal (A, B)-invariant subspace and to obtain a duality with (C, A)-invariance in § 5. Even for our slightly stronger definition, however, (A, B)-invariance does not imply "holdability." This is the property that if the system (4.1) starts with $x(0) = x_0$ in V one can find a control u so that the mild solutions (4.2) always remain in V. In fact we need the following stronger property in our applications.

DEFINITION 4.2. *$T(A, B)$-invariance.* A closed, linear subspace V of X is $T(A, B)$-invariant if there exists an $F \in \mathscr{L}(X, U)$ such that V is invariant under the semigroup $T_{A+BF}(t)$, which is generated by $A + BF$. $T(A, B)$-invariance means that if $x_0 \in V$, then we can choose a feedback control $(u = Fx)$ so that the trajectory of (4.1) remains in V. As already mentioned, this is quite a strong property in infinite dimensions and it is convenient to introduce a weaker concept.

DEFINITION 4.3. *Feedback (A, B)-invariance.* A closed, linear subspace V of X is feedback (A, B)-invariant if there exists an $F \in \mathscr{L}(X, U)$ such that

$$(A + BF)(V \cap D(A)) \subset V. \tag{4.4}$$

In finite dimensions all three types of (A, B)-invariance are equivalent, but in infinite dimensions we have the following hierarchy.

LEMMA 4.4. *$T(A, B)$-invariance $\Rightarrow$ feedback (A, B)-invariance $\Rightarrow$ (A, B)-invariance.*

Proof. $T(A, B)$-invariance means that there exists an $F \in \mathscr{L}(X, U)$ such that

$$T_{A+BF}(t)V \subset V \quad \text{for all } t \geqq 0. \tag{4.5}$$

Differentiating (4.5) with respect to t yields

$$(A + BF)T_{A+BF}(t)V \cap D(A) = \bar{V} = V. \tag{4.6}$$

Letting $t = 0$ we obtain (4.4) and this implies (4.3).

An easy consequence of Lemma 2.3 is the following.

LEMMA 4.5. *If V is closed and $\subset D(A)$, then $T(A, B)$-invariance is equivalent to feedback (A, B)-invariance.*

As pointed out in Schmidt and Stern [6], (A, B)-invariance does not imply $T(A, B)$-invariance, in general, but we can prove equivalence under certain assumptions on V and B.

LEMMA 4.6. *If V is closed and $\subset D(A)$ and* Im B *and* $V+$ Im B *are closed subspaces, then (A, B), feedback (A, B) and $T(A, B)$-invariance are equivalent.*

Proof. In view of Lemmas 4.4 and 4.5 we only need prove that (A, B)-invariance implies feedback (A, B)-invariance. Under our assumptions on V and Im B we obtain the direct sum decomposition

$$V+\operatorname{Im} B = W\oplus \operatorname{Im} B \tag{4.7}$$

where

$$W = V\cap (V\cap \operatorname{Im} B)^{\perp}.$$

Let P be the projection of $W\oplus$ Im B onto Im B along W. We introduce further

$$U_0 = U/\operatorname{Ker} B \text{ and write } U = U_0\oplus \operatorname{Ker} B. \tag{4.8}$$

Now $AV\subset \bar{V}+$ Im $B = W\oplus$ Im B implies that for all $v\in V$ there exists a unique $u\in U_0$ so that

$$PAv = Bu. \tag{4.9}$$

We define $F: V\to U_0$ by

$$\begin{aligned} &Fv = -u \quad \text{if } v\in V,\\ &F = 0 \text{ on } V^{\perp}. \end{aligned} \tag{4.10}$$

Since $V\subset D(A)$ and A is closed we may conclude that A restricted to a closed subspace V is bounded (Taylor and Lay [8, p. 213]) and so PA is bounded. We now prove that F is closed by considering $v_i\to v$ in V and $u_i = -Fv_i\to y$ in U_0. Since PA is bounded, from (4.9) we have $PAv_i\to PAv$ and $Bu_i\to By$ as $i\to\infty$. So $PAv = By$ and $Fv = -y$ proving that F is closed. Since F is everywhere defined, F is bounded and V is invariant under $A+BF$.

We remark that Lemma 4.6 is not a strict dual of Lemma 3.6 and we have been unable to prove one. We do, however, have a dual to Corollary 3.7.

COROLLARY 4.7. *If B has finite rank and V is closed and $\subset D(A)$ then the three concepts $T(A, B)$-invariance, feedback (A, B)-invariance and (A, B)-invariance are equivalent.*

We remark in passing that if V is the span of finitely many eigenvectors of $A+BF$ for some bounded map F, then V satisfies Corollary 4.7 and these finite-dimensional (A, B)-invariant subspaces are used implicitly in the work of Schumacher in [7]. An infinite-dimensional example is the following.

DEFINITION 4.8. *Reachability subspace.* The reachability subspace $\langle T(t)|\operatorname{Im} B\rangle$ is defined by

$$\langle T(t)|\operatorname{Im} B\rangle = \overline{\bigcup_{t\geqq 0}\left\{\int_0^t T(t-s)Bu(s)\,ds\colon u\in L_2(0, t; U)\right\}}. \tag{4.11}$$

$\langle T(t)|\operatorname{Im} B\rangle$ is by definition closed and if $\langle T(t)|\operatorname{Im} B\rangle = X$, then (3.1) is approximately controllable. (See Curtain and Pritchard [4].) $\langle T(t)|\operatorname{Im} B\rangle$ is not in $D(A)$ in general, but we can prove the following.

LEMMA 4.9

(a) $\langle T(t)|\operatorname{Im} B\rangle$ *is the smallest closed, $T(t)$-invariant subspace which contains* Im B.

(b) $\langle T(t)|\operatorname{Im} B\rangle$ *is feedback invariant:* $\langle T_{A+BF}(t)|\operatorname{Im} B\rangle = \langle T(t)|\operatorname{Im} B\rangle$.

(c) $\langle T(t)|\operatorname{Im} B\rangle$ *is an (A, B)-invariant subspace.*

(d) *If* Im B *is $T(t)$-invariant, then* $\langle T(t)|\operatorname{Im} B\rangle = \overline{\operatorname{Im} B}$.

(e) $\overline{\langle T(t)|\operatorname{Im} B\rangle}\cap D(A) = \langle T(t)|\operatorname{Im} B\rangle$.

Proof.

(a) If $r \in \langle T(t)|\text{Im } B\rangle$ there exists a sequence $t_n \in R^+$, $u_n(\cdot) \in L_2([0, t]; U)$ so that

$$r = \lim_{n\to\infty} \int_0^{t_n} T(t_n - s)Bu_n(s)\, ds,$$

$$T(a)r = \lim_{n\to\infty} \int_0^{t_n} T(a + t_n - s)Bu_n(s)\, ds \quad \text{by the semigroup property} \tag{4.12}$$

$$= \lim_{n\to\infty} \int_0^{t_n} T(a + t_n - s)B\hat{u}_n(s)\, ds,$$

where

$$\hat{u}_n(s) = \begin{cases} u_n(s) & \text{on } [0, t_n], \\ 0 & \text{on } [t, t_n + a]. \end{cases}$$

Clearly,

$$T(a)r \in \langle T(t)|\text{Im } B\rangle.$$

Finally, for $u \in U$,

$$Bu = \lim_{t\to 0} 1/t \int_0^t T(t-s)Bu\, ds \in \rangle T(t)|\text{Im } B\rangle$$

since $\langle T(t)|\text{Im } B\rangle$ is closed. Suppose now that Q is another closed, $T(t)$-invariant subspace and $\text{Im } B \subset Q \subset \langle T(t)|\text{Im } B\rangle$. Consider r in $\langle T(t)|\text{Im } B\rangle$ given by (4.12). Then $Bu_n(s) \in Q$ since $Q \supset \text{Im } B$ and $T(t_n - s)Bu_n(s) \in Q$, since Q is $T(t)$-invariant, and since Q is closed $r \in Q$ and $Q = \langle T(t)|\text{Im } B\rangle$.

(b) The semigroup $T_{A+BF}(t)$ generated by $A + BF$ is given by [4]

$$T_{A+BF}(t) = T(t) + \int_0^t T(t-s)BFT_{A+BF}(s)\, ds \tag{4.13}$$

so

$$\int_0^t T_{A+BF}(t-s)Bu(s)\, ds$$

$$= \int_0^t T(t-s)Bu(s)\, ds + \int_0^t \int_s^t T(t-s)BFT_{A+BF}(\alpha - s)\, d\alpha\, Bu(s)\, ds$$

$$= \int_0^t T(t-s)Bu(s)\, ds + \int_0^t T(t-\alpha)B\left(\int_0^\alpha T_{A+BF}(\alpha - s)Bu(s)\, ds\right) d\alpha$$

$$\in \langle T(t)|\text{Im } B\rangle.$$

So $\langle T_{A+BF}(t)|\text{Im } B\rangle \subset \langle T(t)|\text{Im } B\rangle$ and a similar argument proves the reverse inclusion.

(c) $\langle T(t)|\text{Im } B\rangle$ is $T(t)$-invariant and $T_{A+BF}(t)$-invariant for $F = 0$ and so it is also (A, B)-invariant.

(d) Obvious.

(e) Since the simple functions are dense in $L_2(0, t; U)$, if $x \in \langle T(t)|\text{Im } B\rangle$ there exists a sequence $\{x_n\}$ converging to x, where

$$x_n = \int_0^{t_n} T(t_n - s)Bu_n\, ds = \int_0^{t_n} T(s)Bu_n\, ds$$

and from [4, p. 15], $x_n \in D(A) \cap \langle T(t)|\text{Im } B\rangle$.

In the applications it turns out that the following concept is more useful.

DEFINITION 4.10. *A-reachability subspace.* We define the A-reachability subspace of (4.1) to be

$$\langle A|\operatorname{Im} B\rangle = \operatorname{span}\{A^n B U^\infty;\ n = 0, 1, \cdots\} \tag{4.14}$$

where $U^\infty = \{u \in U: Bu \in D(A^\infty) = \bigcap_{n=1}^\infty D(A^n)\}$. $\langle A|\operatorname{Im} B\rangle$ is the smallest A-invariant subspace which contains $\operatorname{Im} B \cap D(A^\infty)$, but $\langle A|\operatorname{Im} B\rangle$ is not closed in general.

If A is bounded, then it is easy to see that $\langle A|\operatorname{Im} B\rangle = \langle T(t)|\operatorname{Im} B\rangle$ but that this does not hold in general is seen from the counterexample 3.17 of [4].

Often in the applications we assume that B has finite rank and in this case for $\langle A|\operatorname{Im} B\rangle$ to have meaning we shall require that $\operatorname{Im} B \subset D(A^\infty)$. If $\operatorname{Im} B \subset D(A^\infty)$, then we have the inclusion

$$\langle A|\operatorname{Im} B\rangle \subset \langle T(t)|\operatorname{Im} B\rangle. \tag{4.15}$$

5. Duality between (A, B)- and (C, A)-invariance. In finite dimensions there is a natural duality between (C, A)- and (A, B)-invariance concepts, which has been exploited by various researchers [7], [10]. In infinite dimensions the duality is not as sharp because of problems with the domain of the unbounded system operator. We need the following result, whose proof is straightforward and hence omitted.

LEMMA 5.1. *Suppose that X and Y are Hilbert spaces, $C \in \mathcal{L}(X, Y)$, V and S are closed linear subspaces of X, $T \in \mathcal{L}(X)$ and A is a closed, densely defined operator on X; then*

(a) $(S \cap V)^\perp = \overline{S^\perp + V^\perp}$,

(b) $(\operatorname{Ker} C)^\perp = \operatorname{Im} C^*$,

(c) $TS \subset V \Leftrightarrow T^* V^\perp \subset S^\perp$,

(d) $A(S \cap D(A)) \subset V \Rightarrow A^*(V^\perp \cap D(A^*)) \subset (S \cap D(A))^\perp$.

We have the following duality relationship between (A, B)- and (C, A)-invariance.

LEMMA 5.2.

(a) *V is $T(A, B)$-invariant $\Leftrightarrow$ $V^\perp$ is $T(B^*, A^*)$-invariant.*

(b) *If $V \subset D(A)$ is feedback (A, B)-invariant, then $V^\perp$ is feedback (B^*, A^*)-invariant.*

(c) *If $S \subset D(A)$ is feedback (C, A)-invariant, then $S^\perp$ is feedback-(A^*, C^*)-invariant.*

(d) *If $S \subset D(A)$ is (C, A)-invariant, then $S^\perp$ is (A^*, C^*)-invariant.*

(e) *If $V \subset D(A)$ is (A, B)-invariant and $\operatorname{Im} B$ and $V + \operatorname{Im} B$ are closed, then $V^\perp$ is (B^*, A^*)-invariant.*

Proof.

(a) This follows from (c) of Lemma 5.1 since $T_{A+BF}(t)$ is bounded and $A^* + F^* B^*$ is the generator of $(T_{A+BF}(t))^*$ in a Hilbert space.

(b) If V is feedback (A, B)-invariant, then by (e) Lemma 5.1 we have that

$$(A + BF)^*(V^\perp \cap D(A^*)) \subset (V \cap D(A))^\perp$$
$$\subset V^\perp \text{ under our assumption}$$

and $V^\perp$ is invariant under $A^* + F^* B^*$.

(c) Is proved similarly to (b).

(d) Applying (d) of Lemma 5.1, we see that if S is (C, A)-invariant, then

$$A^*(S^\perp \cap D(A^*)) \subset (S \cap D(A) \cap \operatorname{Ker} C)^\perp$$

and if $S \subset D(A)$, then by (a) of Lemma 5.1

$$A^*(S^\perp \cap D(A^*)) \subset \overline{S^\perp + \operatorname{Ker} C^\perp} = \overline{S^\perp + \overline{\operatorname{Im} C^*}} = \overline{S^\perp + \operatorname{Im} C^*}$$

by (b) of Lemma 5.1 and $S^\perp$ is (A^*, C^*)-invariant.

(e) Applying (d) of Lemma 5.1, we see that if V is (A, B)-invariant, then

$$A^*((V + Im\, B)^\perp \cap D(A^*)) \subset (V \cap D(A))^\perp = V^\perp \quad \text{if } V \subset D(A)$$

and

$$\begin{aligned} V + \operatorname{Im} B &= (V^\perp)^\perp + (\operatorname{Ker} B^*)^\perp \text{ since Im } B \text{ is closed} \\ &= (V^\perp \cap \operatorname{Ker} B^*)^\perp \text{ by Lemma 5.1(a),} \end{aligned}$$

since Im B and $V + \operatorname{Im} B$ are closed.

We see that there is a nice duality between $T(A, B)$- and $T(B^*, A^*)$-invariance, but not between (A, B) and (B^*, A^*)-invariance or between their feedback versions; one is forced to impose additional assumptions on the spaces and on B. This explains the lack of symmetry between Lemma 3.6 and Lemma 4.6. Of course for the special case that A is bounded one does have nice duality for all three invariance concepts. Finally we examine the duality between reachability and inobservability spaces.

LEMMA 5.3.

$$\langle \operatorname{Ker} C | T(t) \rangle = \langle T^*(t) | \operatorname{Im} C^* \rangle^\perp.$$

Proof. $x \in \langle T^*(t) | \operatorname{Im} C^* \rangle$ has the representation as the limit of terms like

$$x_n = \int_0^t T^*(t-s) C^* u_n(s)\, ds \quad \text{for some } u_n \in L_2(0, t; U).$$

So $y \in \langle T^*(t) | \operatorname{Im} C^* \rangle^\perp$ iff

$$\left\langle y, \int_0^t T^*(t \cdot s) C^* u(s)\, ds \right\rangle = 0 \quad \text{for all } u \in L_2(0, t; U)$$

iff

$$\int_0^t \langle CT(t-s)y, u(s) \rangle\, ds = 0 \quad \text{for all } u \in L_2(0, t; U)$$

and this holds iff $y \in \langle \operatorname{Ker} C | T(t) \rangle$.

6. Supremal (A, B)-invariant subspaces and infimal (C, A)-invariant subspaces. In finite-dimensions one can show that there always exists an infimal (C, A)-invariant subspace, which contains a given subspace. We address this question here for the infinite-dimensional case and introduce the following notation:

(6.1) $\underline{S}(C, A; \operatorname{Im} E)$ is the set of closed subspaces of X which are (C, A)-invariant and which contain Im E, where $E \in \mathscr{L}(Q, X)$ and Q is another Hilbert space.

We give conditions under which $\underline{S}(C, A; \operatorname{Im} E)$ possesses an infimal element, which we denote by $S^\infty(\operatorname{Im} E)$.

LEMMA 6.1. *Consider the following subspace algorithm*

$$S^n = \overline{\operatorname{Im} E + A(\operatorname{Ker} C \cap S^{n-1} \cap D(A))}, \qquad S_0 = \overline{\operatorname{Im} E}. \tag{6.2}$$

The algorithm (6.2) *is strictly increasing in n and converges in countably many steps to* S^∞. *If* S^∞ *is closed, then* S^∞ *is the smallest* (C, A)*-invariant subspace in* $\underline{S}(C, A; \operatorname{Im} E)$.

Proof.

(a) $S^n \supset S^{n-1}$ follows by a simple induction argument. So we have $X \supset S^n \supset S^{n-1} \supset \cdots \supset \operatorname{Im} E$ and since X is a separable Hilbert space, this must terminate in S^∞ after countably many steps. Since S^∞ is closed we have

$$\begin{aligned} S^\infty &= \overline{\operatorname{Im} E + A(\operatorname{Ker} C \cap S^\infty \cap D(A))} \\ &\supset \overline{\operatorname{Im} E} + \overline{A(\operatorname{Ker} C \cap S^\infty \cap D(A))} \\ &\supset A(\operatorname{Ker} C \cap S^\infty \cap D(A)). \end{aligned}$$

So S^∞ is (C, A)-invariant.

(b) Let V be any closed (C, A)-invariant subspace $\supset \operatorname{Im} E$. Then $V \supset S^n$ for all n by induction. For suppose that this holds for n, then

$$\begin{aligned} V &\supset \overline{\operatorname{Im} E + A(V \cap D(A) \cap \operatorname{Ker} C)} \\ &\supset \overline{\operatorname{Im} E + A(S^n \cap D(A) \cap \operatorname{Ker} C)} = S^{n+1}. \end{aligned}$$

In the limit $V \supset S^\infty$ and so S^∞ is the smallest element of $S(C, A; \operatorname{Im} E)$.

In general $S^\infty(\operatorname{Im} E)$ will not be $T(C, A)$-invariant and this property is essential in the applications. To understand this we consider the following special cases, where $\operatorname{Im} E = \operatorname{span}(e)$.

Case 1. $e \in D(A^{p+1})$; $CA^i e = 0$; $i = 0, \cdots, p-1$ and $CA^p e \neq 0$. Then we obtain $S^\infty = \operatorname{span}\{A^i e;\ i = 0, \cdots p\} \subset D(A)$ and from Corollary 3.7 we conclude that there exists a $G \in \mathscr{L}(Y, X)$ such that

$$(A + GC)S^\infty \subset S^\infty \quad \text{and} \quad S^\infty \text{ is } T_{A+GC}(t),$$

invariant, where $T_{A+GC}(t)$ is the semigroup generated by $A + GC$ given by (3.11).

Case 2. $e \in D(A^\infty) = \bigcap_{p=1}^\infty D(A^p)$ and $e \in \langle \operatorname{Ker} C | T(t) \rangle$. Then we obtain $S^\infty = \overline{\operatorname{span}}\{A^i e;\ i = 0, 1, \cdots, \infty\} = \overline{\langle A | e \rangle}$ and for all $G \in \mathscr{L}(Y, X)$, $(A + GC)(S^\infty \cap D(A)) = A(S^\infty \cap D(A)) \subset S^\infty$. The semigroup generated by $A + GC$ is given by (3.11) and so

$$T_{A+GC}(t)s = T(t)s \quad \text{for } s \in S^\infty.$$

Now S^∞ is not in general $T(t)$-invariant, but

$$S_1 = \langle T(t) | \operatorname{Im} e \rangle \text{ is} \quad \text{and} \quad T_{A+GC}|S_1 = T(t)|S_1$$

for all $G \in \mathscr{L}(Y, X)$. Thus S_1 is the infimal $T(C, A)$-invariant subspace containing e and it is invariant under $T_{A+GC}(t)$ for *all* $G \in \mathscr{L}(Y, X)$.

Case 3. $e \in \langle \operatorname{Ker} C | A \rangle$, but $e \notin \langle \operatorname{Ker} C | T(t) \rangle$. Again $S^\infty = \overline{\langle A | e \rangle}$ as in Case 2 and for all $G \in \mathscr{L}(Y, X)$, $(A + GC)(S^\infty \cap D(A)) \subset S^\infty$ but S^∞ need not be $T(C, A)$-invariant. Since $e \notin \langle \operatorname{Ker} C | T(t) \rangle$, we cannot proceed as in Case 2 to choose S_1 as S_1 will not be $T_{A+GC}(t)$-invariant in general. The only remaining alternative is to assume that $\langle A | e \rangle$ is $T(t)$-invariant, for then from (3.11) we may conclude that $T_{A+GC}(t)S^\infty = T(t)S^\infty$. Consequently, S^∞ is $T_{A+GC}(t)$-invariant for all $G \in \mathscr{L}(X, Y)$.

From these three special cases it is clear that the key to the general case is to consider the following partition of $\operatorname{Im} E \subset D(A^\infty)$. We shall use the following notation

$$\begin{aligned} &\mathscr{E}_1 = \overline{\operatorname{Im} E} \cap \langle \operatorname{Ker} C | T(t) \rangle;\ \mathscr{E}_2 = \mathscr{E}_1^\perp \cap \overline{\langle \operatorname{Ker} C | A \rangle \cap \operatorname{Im} E}, \\ &\mathscr{E}_3 = \overline{\operatorname{Im} E} \cap \overline{(\operatorname{Im} E \cap \langle \operatorname{Ker} C | A \rangle)}^\perp. \end{aligned} \tag{6.3}$$

We now state sufficient conditions for the existence of an infimal $T(C, A)$-invariant subspace containing $\operatorname{Im} E$.

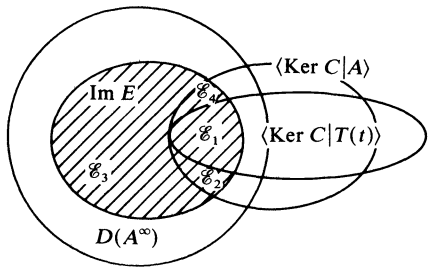

FIG. 6.1

LEMMA 6.2. *Suppose that E has finite rank,* Im $E \subset D(A^\infty)$,

$$\overline{\langle A|e\rangle} = \langle T(t)|e\rangle \quad \text{for } e \in \mathscr{E}_2 \tag{6.4}$$

and the algorithm (6.2) *with* $\mathscr{E}_3$ *in place of* Im E *terminates in finitely many steps, then there exists an infimal* $T(C, A)$*-invariant subspace containing* Im E, *which we denote by* $S^*(\text{Im } E)$, *and*

$$\overline{S^*(\text{Im } E) \cap D(A)} = S^*(\text{Im } E). \tag{6.5}$$

Proof.

(a) Since the algorithm (6.2) with $\mathscr{E}_3$ in place of Im E terminates in finite many steps, we obtain a finite-dimensional (C, A)-invariant subspace, S_f, which is therefore closed and is in the domain of A.

So by Corollary 3.7 there exists a $G \in \mathscr{L}(Y, X)$ such that S_f is $A+GC$ and $T_{A+GC}(t)$-invariant.

(b) For $e \in \mathscr{E}_2$ we are in Case 3 and writing $S_2 = \overline{\langle A|\mathscr{E}_2\rangle} = \langle T(t)|\mathscr{E}_2\rangle$, we see that $(A+GC)(S_2 \cap D(A)) = A(S_2 \cap D(A)) \subset S_2$ and $T_{A+GC}(t)S_2 = T(t)S_2 \subset S_2$. Thus S_2 is $T_{A+GC}(t)$-invariant.

(c) For $e \in \mathscr{E}_1$, $\overline{\langle A|e\rangle}$ may not necessarily equal $\langle T(t)|e\rangle$, but in any case, we choose $S_1 = \langle T(t)|\mathscr{E}_1\rangle$. As in Case 2, S_1 is $(A+GC)$-invariant and $T_{A+GC}(t)S_1 = T(t)S_1 \subset S_1$ and so S_1 is $T_{A+GC}(t)$-invariant. Choosing now

$$S^*(\text{Im } E) = S_f \oplus S_2 \oplus S_1 \tag{6.6}$$

we have a $T(C, A)$-invariant subspace containing Im E. An examination of the algorithm (6.2) and the special Cases 1-3 shows that the smallest (C, A)-invariant subspace containing Im E, $S^\infty(\text{Im } E)$ is given by

$$S^\infty(\text{Im } E) = S_f \oplus S_2 \oplus \overline{\langle A|\mathscr{E}_1\rangle}. \tag{6.7}$$

(d) *Now* $S^\infty(\text{Im } E) \subset S^*(\text{Im } E)$ and we wish to show that $S^*(\text{Im } E)$ is the smallest $T(C, A)$-invariant subspace. Suppose that S_0 is another $T(C, A)$-invariant subspace containing Im E. Since $S^\infty(\text{Im } E)$ is minimal, $S_0 \supset S^\infty(\text{Im } E)$ and

$$\begin{aligned} T_{A+G_0C}(t)S^\infty(\text{Im } E) &= T_{A+G_0C}(t)S_f \oplus T_{A+G_0C}(t)S_2 \oplus T_{A+G_0C}(t)\overline{\langle A|\mathscr{E}_1\rangle} \\ &= T_{A+G_0C}(t)S_f \oplus T(t)S_2 \oplus T(t)\overline{\langle A|\mathscr{E}_1\rangle}, \\ \bigcup_{t\geqq 0} T_{A+G_0C}(t)S^\infty(\text{Im } E) &= \bigcup_{t\geqq 0} T_{A+G_0C}(t)S_f \oplus S_2 \oplus S_1 \qquad \text{from (3.11)} \\ &\subset \bigcup_{t\geqq 0} T_{A+G_0C}(t)S_0 \subset S_0. \end{aligned}$$

But by (3.11) $\bigcup_{t\geqq 0} T_{A+G_0C}(t)S^*(\text{Im } E) = \bigcup_{t>0} T_{A+G_0C}(t)S^\infty(\text{Im } E) \subset S_0$ and in particular $S_0 \supset S^*(\text{Im } E)$ and $S^*(\text{Im } E)$ is indeed minimal.

(e) From (6.6) it follows that

$$S^*(\text{Im } E) = S_f \oplus \langle T(t) | \mathscr{E}_1 : \mathscr{E}_2 \rangle$$

and $S_f \subset D(A)$ and appealing to Lemma 4.9(e) proves (6.5).

In fact what we have shown in the proof is that $(S_f, S_1 \oplus S_2)$ reduces $A+GC$ in the sense of Definition 2.2.

We remark that Im $E \subset D(A^\infty)$ is stronger than is really needed; more precisely we need $\mathscr{E}_3 \subset D(A^{p+1})$, where $p = \dim S_f$ and $\mathscr{E}_1, \mathscr{E}_2 \subset D(A^\infty)$. This leads to the following useful corollary.

COROLLARY 6.3. *If E has finite rank, $\mathscr{E}_3 \subset D(A^{p+1})$, $\mathscr{E}_1 \subset D(A^\infty)$,*

$$\text{Im } E \cap \langle \text{Ker } C | T(t) \rangle = \text{Im } E \cap \langle \text{Ker } C | A \rangle \tag{6.8}$$

and the algorithm (6.2) *with $\mathscr{E}_3$ terminates in finitely many steps, then $S^*(\text{Im } E)$ exists and satisfies* (6.5).

In general $S^*(\text{Im } E)$ may not exist. This can be seen by examining Case 3 and (3.11): $\langle T_{A+GC}(t) | e \rangle$ depends on G. One could obtain a $T(C, A)$-invariant subspace containing $S^\infty(\text{Im } E)$ by choosing

$$S^\#(\text{Im } E) = S_f \oplus \langle T_{A+GC}(t) | \text{Im } E \cap \overline{\langle \text{Ker } C | A \rangle} \rangle$$

where S_f from the proof of Lemma 6.2 is $(A+GC)$-invariant. However, $S^\#(\text{Im } E)$ need not be infimal.

We now examine the dual problem of the existence of a supremal (A, B)-invariant subspace. We introduce the following notation.

(6.9) $\underline{V}(A, B; K)$ is the set of (A, B)-invariant subspaces contained in the closed subspace K.

Because of the lack of duality between (A, B) and (B^*, A^*)-invariance, we cannot dualize Lemma 6.1 to obtain the existence of a supremal element $V^\infty(K)$ of $\underline{V}(A, B; K)$. We consider the following algorithm

$$V^0 = K,\ V^n = K \cap (\lambda - A)^{-1}(V^{n-1} + \text{Im } B) \quad \text{for some } \lambda \in \rho(A). \tag{6.10}$$

LEMMA 6.4. *$\{V^n\}$ is strictly decreasing in n and has a limiting (A, B)-invariant subspace, $V^\infty(K)$, which is the largest (A, B)-invariant subspace contained in K, and is independent of λ; however, $V^\infty(K)$ need not be closed.*

Proof. Without loss of generality we can take $\lambda = 0$.

$V^n \supset V^{n+1}$ follows by induction. $V_1 \subset V_0 = K$ and suppose it holds for n. Then we have

$$V^n = K \cap A^{-1}(V^{n-1} + \text{Im } B) \supset K \cap A^{-1}(V^n + \text{Im } B) = V^{n+1}.$$

So $K \supset V_1 \supset V_2 \cdots \supset V^n \supset \{0\}$ and either the sequence terminates in finitely or countably many steps, since X is a separable Hilbert space. The limit V^∞ satisfies

$$V^\infty = K \cap A^{-1}(V^\infty + \text{Im } B). \tag{6.11}$$

So $V^\infty \subset K$ and $A(V^\infty \cap D(A)) \subset V^\infty + \text{Im } B$ and $V^\infty \subset D(A)$ and is (A, B)-invariant, but V^∞ need not be closed.

We show that V^∞ is the largest such subspace by supposing that W is another (A, B)-invariant subspace $\subset D(A)$

$$W \subset K \cap A^{-1}(W + \text{Im } B) \subset K = V_0.$$

If $W \subset V^n$, then from the above inclusion we obtain that $W \subset V^{n+1}$. So using induction

we have proved that $W \subset V^\infty$. So V^∞ is the largest (A, B)-invariant subspace $\supseteq D(A)$, but V^∞ need not be closed.

Unfortunately we cannot prove the existence of a closed supremal (A, B)-invariant subspace contained in K directly and the lack of duality between (B^*, A^*) and (A, B)-invariance means that we cannot appeal to Lemma 6.1. For the applications we also need $T(A, B)$-invariance and in this case we can appeal to the duality with $T(B^*, A^*)$-invariance implied by Lemma 5.2(a).

LEMMA 6.5. *Suppose that D has finite rank, $D \in L(X, R^k)$, say, and $\operatorname{Im} D^* \subset D(A^{*\infty}) = \bigcap_{n=1}^{\infty} D(A^{*n})$. Under the conditions that the algorithm* (6.2) *with* $\mathscr{E}_3 = \overline{(\langle \operatorname{Ker} B^* | A^* \rangle \cap \operatorname{Im} D^*)^\perp} \cap \operatorname{Im} D^*$ *terminates in finitely many steps and*

$$\overline{\langle A^* | d \rangle} = \langle T^*(t) | d \rangle \tag{6.12}$$

for all $d \in \operatorname{Im} D^* \cap \langle \operatorname{Ker} B^* | A^* \rangle$, but $d \perp \langle \operatorname{Ker} B^* | T^*(t) \rangle \cap \operatorname{Im} D^*$ there exists a supremal $T(A, B)$-invariant subspace contained in Ker D *which we denote by* $V^*(\operatorname{Ker} D)$.

Proof. We dualize Lemma 6.2, identifying

$$S^*(\operatorname{Im} D^*)^\perp = V^*(\operatorname{Ker} D). \tag{6.13}$$

An important special case in the applications is, in Lemma 6.2, when $\mathscr{E}_3$ has rank one, for then the algorithm (6.2) terminates in finitely many steps. This leads to a useful corollary for the existence of $V^*(\operatorname{Ker} D)$, where we make use of the fact that if $\operatorname{Im} D^* \subset D(A^{*\infty})$ and D has finite rank, then DA^i has a bounded extension for all i.

COROLLARY 6.6. *Suppose that D has finite rank, $D \in \mathscr{L}(X, R^k)$ and $DA^i \in \mathscr{L}(X; R^k)$ for all $i \geq 0$ and we partition D into three parts $D = (D_1 : D_2 : D_3)$, where*

$$\left.\begin{aligned} &D_1 T(t) B = 0 \quad \text{for all } t \geq 0; \\ &D_2 A^i B = 0,\ i \geq 0,\ D_2 T(t) B \neq 0,\ t \geq 0; \\ &D_3 = \langle \cdot, d_3 \rangle \quad \text{for some } d_3 \in X \text{ and} \\ &D_3 A^i B = 0,\ i = 0, \cdots p-1,\ D_3 A^p B \neq 0. \end{aligned}\right\} \tag{6.14}$$

Then there exists a supremal $T(A, B)$-invariant subspace contained in Ker D *if*

$$\langle T(t) | \operatorname{Im} D_2 \rangle = \overline{\langle A | \operatorname{Im} D_2 \rangle}. \tag{6.15}$$

Again we remark that we only need that $D_1 A^i$, $D_2 A^i \in \mathscr{L}(X, R^k)$ for all $i \geq 0$ and $D_3 A^i \in \mathscr{L}(X, R^k)$ for $i = 0, \cdots, p+1$.

7. Some disturbance decoupling problems. We consider the following disturbance decoupling problem (DDP)

$$\dot{x} = Ax + Bu + Eq, \tag{7.1}$$

$$z = Dx, \qquad u = Fx. \tag{7.2}$$

Where A, B are as before, q represents a disturbance, $q(\cdot) \in L_2(0, t; Q)$, $u(t) \in U$ represents the control and $z(t) \in Z$ represents the output to be decoupled. X, Q, Z and Y are real separable Hilbert spaces and $E \in \mathscr{L}(Q, X)$, $D \in \mathscr{L}(X, Z)$, $F \in \mathscr{L}(X, U)$. The DDP is to design a feedback control law $u = Fx$, such that

$$D \int_0^t T_{A+BF}(t-s) E q(s)\, ds = 0 \quad \text{for all } q \in L_2(0, t; Q). \tag{7.3}$$

From Definition 4.8 it is clear that (7.3) holds iff

$$\langle T_{A+BF}(t)|\operatorname{Im} E\rangle \subset \operatorname{Ker} D. \tag{7.4}$$

We now prove our first DDP theorem.

THEOREM 7.1. *If* $V^*(\ker D)$ *exists, then* DDP *is solvable iff*

$$V^*(\operatorname{Ker} D) \supset \operatorname{Im} E. \tag{7.5}$$

Proof.

(a) *Necessity.* Suppose that $F \in \mathscr{L}(X, U)$ is such that (7.4) holds. Now $\langle T_{A+BF}(t)|\operatorname{Im} E\rangle$ is $T(A, B)$-invariant and is contained in Ker D. Thus

$$V^*(\operatorname{Ker} D) \supset \langle T_{A+BF}(t)|\operatorname{Im} E\rangle \supset \operatorname{Im} E.$$

(b) *Sufficiency.* Suppose that (7.5) holds. Since $V^*(\operatorname{Ker} D)$ exists, there exists an $F \in \mathscr{L}(X, U)$ so that

$$(A+BF)(V^*(\operatorname{Ker} D) \cap D(A)) \subset V^*(\operatorname{Ker} D)$$

and by Lemma 4.9(d)

$$\langle T_{A+BF}(t)|V^*(\operatorname{Ker} D)\rangle = V^*(\operatorname{Ker} D).$$

Lemma 4.9 and (7.5) imply that

$$\langle T_{A+BF}(t)|\operatorname{Im} E\rangle \subset \rangle T_{A+BF}(t)|V^*(\operatorname{Ker} D)\rangle = V^*(\operatorname{Ker} D) \subset \operatorname{Ker} D$$

and (7.4) holds.

It is clear from the proof that the existence of $V^\infty(\operatorname{Ker} D)$ is not sufficient to solve DDP; one needs the $T(A, B)$-invariance. From Lemma 6.5 we see that for $V^*(\operatorname{Ker} D)$ to exist it is sufficient that B and D have finite rank (that is, finite-dimensional input and output) and D satisfy smoothness conditions. We do not need to impose any extra conditions on the disturbance other than (7.5).

One can also consider the disturbance decoupling problem when one allows a feedforward term in the control (DDPF) [10].

$$u = Fx + Rq, \qquad R \in \mathscr{L}(Q, U). \tag{7.6}$$

THEOREM 7.2. *If* $V^*(\operatorname{Ker} D)$ *exists, then* DDPF *has a solution iff*

$$V^*(\operatorname{Ker} D) + \operatorname{Im} B \supset \operatorname{Im} E. \tag{7.7}$$

Proof. From Theorem 7.1, DDPF has a solution iff there exists a $R \in \mathscr{L}(X, U)$, such that

$$\operatorname{Im}(BR+E) \subset V^*(\operatorname{Ker} D) \tag{7.8}$$

and clearly this implies (7.7).

Conversely, if (7.7) holds, then

$$V^*(\operatorname{Ker} D) \supset \operatorname{Im} B + \operatorname{Im} E \supset \operatorname{Im}(BR+E) \tag{7.9}$$

for any $R \in \mathscr{L}(Q, U)$ and in particular, we can always choose $R = 0$.

Now we consider the disturbance decoupled estimation problem DDEP (Willems and Commault [10]) for the system (7.1), (7.2), where we suppose that we cannot measure the state, but the following

$$y = Cx \tag{7.10}$$

where $C \in \mathscr{L}(X; Y)$ and the output space, Y, is a real, separable Hilbert space. The

DDEP is to construct a data processor for z on $W \cong Z$:

$$\begin{aligned} \dot{w} &= Fw + Hy + Ru, \\ \hat{z} &= Mw + Ny + Ju, \end{aligned} \tag{7.11}$$

where F is the infinitesimal generator of a strongly continuous semigroup on W and H, R, M, N and J are bounded linear operators and we require that the resulting estimation error $e = z - \hat{z}$ depends only on the initial conditions and not on q or u. For the DDEP we are unable to prove as sharp a result as for the DDP.

THEOREM 7.3. *If $S^*(\text{Im } E)$ exists and C has finite rank, then* DDEP *has a solution if*

$$S^*(\text{Im } E) \cap \text{Ker } C \subset \text{Ker } D \quad \textit{and} \quad J = 0 \tag{7.12}$$

and only if

$$S^{\infty}(\text{Im } E) \cap \text{Ker } C \subset \text{Ker } D \quad \textit{and} \quad J = 0. \tag{7.13}$$

Proof. (a) *Necessity.* Let $e = z - \hat{z}$ and $x^e = (x, w) \in X^e = X \oplus W$. Combining (7.1), (7.10, 11), we obtain the extended system

$$\begin{aligned} \Sigma^e: \dot{x}^e &= A^e x^e + E^e (u, q)^T, \\ y^e &= C^e x^e, \end{aligned} \tag{7.14}$$

where

$$A^e = \begin{pmatrix} A & 0 \\ HC & F \end{pmatrix}, \qquad E^e = \begin{pmatrix} B & E \\ R & O \end{pmatrix}$$

and the error is given by

$$e = D^e x^e + J^e (u, q) \tag{7.15}$$

where

$$D^e = (D - NC : -M); \qquad J^e = (-J, 0).$$

Solution of DDEP requires that $J^e = 0$ and

$$D^e \int_0^t T^e(t-s) E^e (u, q)(s)\, ds = 0 \quad \text{for } t \geqq 0 \tag{7.16}$$

where $T^e(t)$ is the strongly continuous semigroup generated by A^e.

Equivalently

$$\text{Im } E^e \subset \langle \text{Ker } D^e \mid T^e_{(t)} \rangle = S^e. \tag{7.17}$$

Defining

$$S_1 = \left\{ x \in X : \begin{pmatrix} x \\ 0 \end{pmatrix} \in S^e \right\}$$

it is easy to verify that S_1 is (C, A)-invariant. Taking intersections of (7.17) with X yields

$$\text{Im } E \subset S_1 \subset \text{Ker } (D - NC) \tag{7.18}$$

so $S_1 \in \underline{S}(C, A; \text{Im } E)$ and $S_1 \cap \text{Ker } C \subset \text{Ker } D$.

(b) *Sufficiency.* Suppose that $S \in \underline{S}(C, A; \operatorname{Im} E)$ and that S is $T(C, A)$-invariant with $S \cap \operatorname{Ker} C \subset \operatorname{Ker} D$. This holds for $S^*(\operatorname{Im} E)$, for example. So there exists an $L \in \mathscr{L}(Y, X)$ such that S is invariant under the semigroup, $T_L(t)$, generated by $A+LC$. We denote the generator of $T_L(t)$ by A_L.

We have the decomposition

$$X \cong X/S \oplus S \tag{7.19}$$

and since S is invariant with respect to A_L and $T_L(t)$ we have the block decompositions with respect to (7.19):

$$A_L = \begin{pmatrix} A_1 & 0 \\ A_2 & A_3 \end{pmatrix}, \qquad T_L(t) = \begin{pmatrix} T_1(t) & 0 \\ T_2(t) & T_3(t) \end{pmatrix}; \tag{7.20}$$

and the identities:

$$T_L(t)T_L(s) = T_L(t+s), \tag{7.21}$$

$$\frac{d}{dt}(T_L(t)x) = A_L T_L(t)x \quad \text{for } x \in D(A_L), \tag{7.22}$$

which yield

$$T_1(t)T_1(s)[x]_S = T_1(t+s)[x]_S \quad \text{for } [x]_S \in X/S, \tag{7.23}$$

$$\frac{d}{dt}(T_1(t)[x]_S) = A_1 T_1(t)[x]_S \quad \text{for } [x]_S \in D(A_1). \tag{7.24}$$

Thus, $T_1(t)$ defines a strongly continuous semigroup on X/S with generator A_1. We write these as $[T_L(t)]_S$ and $[A_L]_S$ and define the following observer on $W \cong X/S$

$$\begin{aligned} \dot{w} &= [A_L]_S w - [L]_S y + [B]_S u, \\ \hat{z} &= \bar{M} w + N y, \end{aligned} \tag{7.25}$$

where $[L]_S$ is defined by $[L]_S y = [Ly]_S$ and similarly for $[B]_S$ and we define $\bar{m}: W \to Z$ and $N: Y \to Z$ as follows. As in Lemma 3.6, we decompose $Y = Y_0 \oplus Y_0^{\perp}$, where $Y_0 = C(S \cap (S \cap \operatorname{Ker} C)^{\perp})$ is closed since C has finite rank. Then we define $N: Y \to Z$ by

$$\begin{aligned} Ny &= 0 \quad \text{if } y \in Y_0^{\perp}, \\ Ny &= D(C^{-1}y) \quad \text{if } y \in Y_0, \end{aligned} \tag{7.26}$$

and N is bounded, since D is bounded.

Note that $S \subset \operatorname{Ker}(D - NC)$ and so $\bar{M} \in \mathscr{L}(W, Z)$ is well defined by

$$\bar{M}[x]_S = (D - NC)[x]_S. \tag{7.27}$$

So (7.25) is a well defined observer and for $[x]_S \in D([A_L]_S)$, we have

$$\frac{d}{dt}[x]_S = [A_L]_S[x]_S - [L]_S y + [B]_S u \tag{7.28}$$

and

$$\dot{r} = [A_L]_S r \tag{7.29}$$

where $r=[x]_S-w$ and

$$\begin{aligned} e &= z-\hat{z} \\ &= Dx+\bar{M}w-NCx \\ &= [(D-NC)x]_S-\bar{M}w \qquad \text{by (7.26)} \\ &= \bar{M}([x]_S-w) \qquad \text{by (7.27)} \\ &= \bar{M}r \end{aligned}$$

and so (u, q) has no effect on the error e and the DDEP is solved.

We remark that the assumption that C have finite rank was only used to generate bounded operators $\bar{M}$ and N in the data processor in the sufficiency proof.

Sufficient conditions for $S^*(\text{Im } E)$ to exist are provided by Lemma 6.2, namely that C and E have finite rank and that E satisfy some smoothness assumptions. So for the DDEP we can only treat finite-dimensional disturbances, but infinite-dimensional outputs are allowed.

As remarked in [9], in some applications it may be desired that the observations be filtered before being used in $\hat{z}$, which means taking $N=J=0$. Then if $S^*(\text{Im } E)$ exists we can prove that the DDEP is solvable if

$$S^*(\text{Im } E)\subset \text{Ker } D. \tag{7.30}$$

8. Examples. From the results of § 7 we see that DDP (DDEP) can be solved if $V^*(\text{Ker } D)$ ($S^*(\text{Im } E)$) exists and Lemma 6.2 (Corollary 6.6) gives sufficient conditions for this. For distributed systems these conditions are easy to check and we illustrate this with a parabolic example.

Consider a heated rod which we suppose is heated around one point and due to some experimental setup is subject to disturbances in another region. We desire that the temperature at a certain measurement point be independent of the disturbances. The configuration can be schematized as below in Fig. 8.1. For the mathematical model we take

$$\frac{\partial x}{\partial t}=\frac{\partial^2 x}{\partial \xi^2}+b(\xi)u(t)+e(\xi)q(t), \tag{8.1}$$

$$x(0, t)=0=x(1, t), \tag{8.2}$$

$$z(t)=\int_0^1 d(\xi)x(t, \xi)\, d\xi \tag{8.3}$$

where we have chosen various shape-functions b, e and d to approximate our sensor and control actuators.

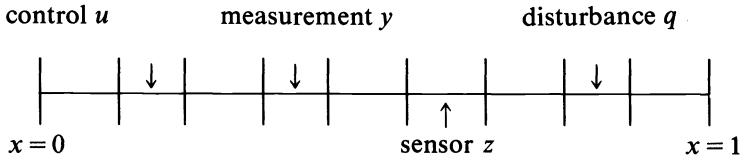

FIG. 8.1

This can be formulated as a system of the form (8.1), (8.2) on the Hilbert space $X = L_2(0, 1)$, where the system operator A is given by

$$A = \frac{d^2}{d\xi^2}; \qquad D(A) = \{h \in H^2 : h(0) = 0 = h(1)\}. \tag{8.4}$$

A is self adjoint and has eigenvalues $\{-n^2\pi^2; n = 1 \cdots \infty\}$ and eigenvectors $\{\phi_n(\xi) = \sqrt{2} \sin n\pi\xi; n = 1, 2, \cdots \infty\}$. The other operators are given by

$$B = b, \qquad E = e, \qquad D = \langle \cdot, d \rangle \tag{8.5}$$

where b, d and e are considered as elements of $L_2(0, 1)$. By Corollary 6.6, $V^*(\text{Ker } D)$ will exist if either of the following conditions hold

$$\langle T(t)b, d \rangle = 0, \qquad t \geqq 0, \tag{8.6}$$

$$\langle T(t) | \text{Im } D \rangle = \overline{\langle A | \text{Im } D \rangle}, \qquad \langle b, A^i d \rangle = 0, \; i \geqq 0, \tag{8.7}$$

$$\langle b, A^i d \rangle = 0, \quad i = 0, p-1, \quad \langle b, A^p d \rangle \neq 0. \tag{8.8}$$

Now if (A, b) is approximately controllable, (8.6) implies that $d = 0$, so (8.6) will not hold in general. Considering (8.7) we remark that $\langle T(t) | ImD \rangle = \overline{\langle A | \text{Im } D \rangle}$ will only hold if d is an eigenvector of A, so (8.7) will not hold in general. This leaves (8.8) as a possibility and the most likely situation is that $p = 0$. Then by Theorem 7.1, sufficient conditions for disturbance decoupling are

$$\langle b, d \rangle \neq 0, \quad \langle e, d \rangle = 0, \quad d \in D(A). \tag{8.9}$$

The feedback law is then given by

$$u = \langle \cdot ; f \rangle, \qquad f = \frac{\alpha d - Ad}{\langle b, d \rangle} \tag{8.10}$$

where α is an arbitrary constant.

Physically one can interpret the conditions (8.9) as requiring that the shape function d be smooth and confined to the interior of $(0, 1)$, that the shape functions e and d do not overlap, but that b and d do. One could give other sufficient conditions on b, d and e for the solvability of the disturbance decoupling problem, but they will not have such a natural physical interpretation.

If one is interested in disturbance decoupling and pole-assignment, then it is clear from (8.10) that at least two controls will be necessary.

Of course we cannot measure that full state $x(t, \cdot)$, but only a functional of it, for example

$$y(t) = \int_0^1 c(\xi) x(t, \xi) \, d\xi \tag{8.11}$$

and we can then consider the DDEP for (8.1)-(8.3), (8.11). From Theorem 7.3, we see that DDEP can be solved if $S^*(e)$ exists and

$$S^*(e) \cap \text{Ker } \langle \cdot, c \rangle \subset \text{Ker } \langle \cdot, d \rangle. \tag{8.12}$$

Generic conditions for the existence of $S^*(e)$ are

$$\langle c, e \rangle \neq 0; \; e \in D(A) \tag{8.13}$$

and then $S^*(e) = \text{span } \{e\}$ and (8.13) is sufficient for the solvability of DDEP; that is, we can construct an observer, as in the proof of Theorem 7.3, provided that the

measurements and disturbances are disjoint. We remark here that the observer is infinite-dimensional and that we have had to assume smooth and finite-dimensional disturbances to solve the DDEP. So the application of the DDEP is not quite as general as for the DDP.

We conclude with a simple example of a retarded system:

$$\dot{\xi}(t) = \alpha\xi(t) + \beta\xi(t-1) + \int_1^0 \gamma(\theta)\xi(t+\theta)\,d\theta + bu(t) + eq(t),$$
$$\xi(\theta) = \xi_0(\theta) \quad \text{on } [-1, 0], \tag{8.14}$$

$$z(t) = \delta\xi(t) + \int_{-1}^0 d(\theta)x(t+\theta)\,d\theta, \tag{8.15}$$

where α, β, b, e, δ are scalars and γ, ξ_0 and d are functions on $[-1, 0]$. Then (8.18) can be formulated as an abstract system on the product space $M^2 = R \times L^2(-1, 0)$, [9], where the system operator A on M^2 is defined by

$$A(h_0, h_1) = (\alpha h_1(0) + \beta h_1(-1) + \int_{-1}^0 \gamma(\theta)h_1(\theta)\,d\theta, Dh_1),$$
$$D(A) = W^{1,2}(-1, 0) = \{h \in L^2(-1, 0);\ Dh \in L^2(-1, 0)\}, \tag{8.16}$$

where Dh denotes the distributional derivative of h.

The remaining system operators in (7.1), (7.2) are

$$Bu = (bu, 0), \qquad Eq = (eq, 0),$$
$$Dh = \langle h, d^*\rangle_2 = \delta h_0 + \int_{-1}^0 d(\theta)h_1(\theta)\,d\theta, \tag{8.17}$$

where $\langle \cdot\,, \rangle_2$ denotes the inner product in M^2.

The conditions for DDP depend on the domain of A^*, which for retarded systems is very special.

$$D(A^*) = \{(h_0, h_1) \in M^2 | \exists w \in W^{1,2} \text{ with } w(-1) = 0 \text{ and } h_1(\theta) = w(\theta) + \beta h_0\}, \tag{8.18}$$

$$A^*(h_0, h_1) = ((\alpha + \beta)h_0 + \int_{-1}^0 Dw(\theta)\,d\theta,\ \gamma(\theta)h_0 - Dw(\theta)). \tag{8.19}$$

In our example, with one delay, $(h_0, h_1) \in D(A^*)$ implies that h_1 is in $W^{1,2}$, but in general it would be piecewise continuous [9]. The condition $d^* \in D(A^*)$ reduces to

$$d \in W^{1,2} \quad \text{and} \quad d(-1) = \beta\delta \tag{8.20}$$

and

$$A^*d^* = (\alpha\delta + d(0),\ \gamma(\theta)\delta - Dd(\theta)). \tag{8.21}$$

It is easy to see that $d^* \in D(A^{*p})$ implies that $D^p d \in W^{1,2}$ and that various conditions on $D^p d(-1)$ in terms of $D^{p-1}\gamma(-1)$ and $D^i d(0)$ be satisfied; $i = 0, \cdot, p-1$. Let us evaluate some terms DA^iV as in (6.13).

$$DB = \langle (b, 0)d^*\rangle_2 = b\delta, \tag{8.22}$$

$$DAB = \langle (b, 0), A^*d^*\rangle_2 = b\alpha\delta + bd(0), \tag{8.23}$$

$$DA^2B = \langle (b, 0), (A^*)^2d^*\rangle_2 = b(\alpha^2\delta + \delta d(0) + \gamma(0)\delta - Dd(0)). \tag{8.24}$$

If

$$DA^iB=0, \quad i=1\cdots p-1, \quad \text{and} \quad DA^pB\neq 0. \tag{8.25}$$

Then from Lemma 6.5 and Theorem 7.1 it follows that DDP is solvable iff

$$\langle (e,0), A^{*i}d^*\rangle_2=0, \qquad i=0,\cdot,p. \tag{8.26}$$

From (8.26) with $i=0$ it is clear that we must have $\delta=0$ and since $b, e\neq 0$ it is clear from (8.25) and (8.26) that DDP for system (8.14), (8.15) is *not* solvable. This was a very simple example, so now we suppose that the disturbances are of the form

$$eq(t)+\int_{-1}^{0}\delta(\theta)q(\theta)\,d\theta \tag{8.27}$$

where $\mu\in L_2(0,1)$. Then (8.26) is replaced by

$$\langle (e,\mu), A^{*i}d^*\rangle_2=0, \qquad i=0,\cdot,p \tag{8.28}$$

which yields for

$$i=0, \qquad e\delta+\int_{-1}^{0}\mu(\theta)\,d(\theta)\,d\theta=0, \tag{8.29}$$

$$i=1, \qquad e(\alpha\delta+d(0))+\int_{-1}^{0}\mu(\theta)(\delta\gamma(\theta)-Db(\theta))\,d\theta=0, \tag{8.30}$$

and so on. Examining the case $p=0$, $(b\delta\neq 0)$, we see that DDP for the disturbance (8.27) will be solvable iff (8.29) holds.

$$u(t)=\frac{\nu\delta-\alpha\delta-d(0)}{b\delta}x(t)+\frac{1}{b\delta}\int_{-1}^{0}x(t+\theta)[\nu d(\theta)-\delta\gamma(\theta)+Dd(\theta)]\,d\theta \tag{8.31}$$

is the decoupling control law, where ν is an arbitrary parameter.

For the case $p=1(\delta=0,\ d(0)\neq 0)$, DDP is solvable iff both (8.29) and (8.30) hold and these reduce to the following

$$\int_{-1}^{0}\mu(\theta)\,d(\theta)\,d\theta=0, \qquad ed(0)=\int_{-1}^{0}\mu(\theta)Dd(\theta)\,d\theta. \tag{8.32}$$

The decoupling feedback law in this case is

$$u(t)=\frac{1}{b}\left(\nu_2-\alpha+\frac{1}{d(0)}Dd(0)\right)x(t)+\frac{1}{bd(0)}\int_{-1}^{0}x(t+\theta)k(\theta)\,d\theta \tag{8.33}$$

where $k(\theta)=-d(\theta)\gamma(\theta)-D^2d(\theta)+\nu_1d(\theta)+\nu_2Dd(\theta)$ and ν_1, ν_2 are two arbitrary constants.

Acknowledgments. I would like to thank Hans Zwart for his careful reading of the original manuscript and for his valuable suggestions.

Note. After submitting this paper the author became aware of the related work by L. Pandolfi on DDP for retarded systems: L. Pandolfi, *Disturbance decoupling and invariant subspaces for delay systems*, Int. Report No. 7, 1984, Politechnico di Torino, Italy.

DIFFUSIONS FOR GLOBAL OPTIMIZATION*

STUART GEMAN† AND CHII-RUEY HWANG‡

Abstract. We seek a global minimum of $U:[0,1]^n \to R$. The solution to $(d/dt)x_t = -\nabla U(x_t)$ will find local minima. The solution to $dx_t = -\nabla U(x_t)\,dt + \sqrt{2T}\,dw_t$, where w is standard (n-dimensional) Brownian motion and the boundaries are reflecting, will concentrate near the global minima of U, at least when "temperature" T is small: the equilibrium distribution for x_t is Gibbs with density $\pi_T(x)\alpha \exp\{-U(x)/T\}$. This suggests setting $T = T(t)\downarrow 0$ to find the global minima of U. We give conditions on $U(x)$ and $T(t)$ such that the solution to $dx_t = -\nabla U(x_t)\,dt + \sqrt{2T}\,dw_t$ converges weakly to a distribution concentrated on the global minima of U.

Key words. global optimization, simulated annealing, diffusion, reflecting boundaries

AMS(MOS) subject classifications. 60J60, 60J70

1. Introduction.

We can find a local minimum of a function U on R^n by starting at an arbitrary $x_0 \in R^n$ and solving the equation

$$\frac{dx_t}{dt} = -\nabla U(x_t).$$

A continuous path, x, seeking a *global* minimum will in general be forced to "climb hills" as well as follow down-hill gradients. One way of introducing hill-climbing, while preserving the tendency to descend along gradients, is to introduce random fluctuations into the path of x:

$$dx_t = -\nabla U(x_t)\,dt + \sqrt{2T}\,dw_t \tag{1.1}$$

where w is a standard Brownian motion and T, the "temperature," controls the magnitude of the random fluctuations. Under suitable conditions on U, x_t approaches (weakly) an equilibrium, which is a *Gibbs distribution* with density

$$\pi_T(x) = \frac{1}{Z_T}\exp\{-U(x)/T\} \quad \text{where } Z_T = \int_{R^n} \exp\{-U(x)/T\}\,dx.$$

As $T \to 0$, π_T concentrates on the global minima of U. Hence, in low temperature equilibrium we can expect to find x_t near a global minimum.

Unfortunately, the time required to approach equilibrium increases exponentially with $1/T$; solutions to (1.1) with small T will be very slow to find the important minima of U. This suggests that (1.1) be integrated with a gradually decreasing temperature, $T = T(t)\downarrow 0$. The hope is that the early and large random fluctuations will allow x_t to quickly escape from local minima, whereas the later (large t) behavior will be essentially a gradient descent into a prominent minimum of U.

The theorem presented here gives sufficient conditions on U and $T(t)$ for the weak convergence of x_t to a measure concentrating on the global minimum of U. We have simplified the mathematics by confining x to a rectangle in R^n (the diffusion is "reflected at the boundaries"). The rectangle is taken for convenience to be the unit

cube. For illustration, let us assume that $U:[0,1]^n \to R$ has a unique global minimum at $x=\xi$. If U is sufficiently smooth, and properly-behaved at the boundaries (see § 2), and if $T(t)=c/\log(2+t)$ for c sufficiently large, then the solution to (1.1), with $T=T(t)$, converges to ξ:

$$P(|x_t-\xi|<\varepsilon)\to 1$$

for all $\varepsilon>0$ and all starting points.[1]

Our work was inspired by the "simulated annealing" recently proposed by Černý [2] and Kirkpatrick et al. [10]. Given a function U of n binary variables $x_1,\cdots,x_n$ they propose to find global minima of U by running the "Metropolis algorithm" [13] while gradually lowering the temperature. The Metropolis algorithm produces a Markov process with state space $\{0,1\}^n$. As in (1.1), there is a "temperature", T, and at fixed T the Metropolis algorithm also has the Gibbs distribution as equilibrium. The same heuristics, then, motivate gradually lowering $T=T(t)$. This is called simulated annealing since it copies the physical procedure, called annealing, of melting and then slowly cooling a physical substance (such as a crystal) in search of a low energy configuration. The latter typically corresponds to a high degree of spatial regularity, useful for some applications. Černý and Kirkpatrick apply their simulated annealing to certain combinatorial optimization problems, often with striking success.

Simulated annealing has also played a role in overcoming some of the computational problems that arise in image processing (Geman and Geman [4], Grenander [8], Marroquin [12]). In these applications, the procedure is modified to accommodate arbitrary discrete variables $x_1,\cdots,x_n$ with finite state spaces (rather than binary), and Geman and Geman have established weak convergence to the global minima of U, provided again that the temperature is lowered sufficiently slowly. Unfortunately, the extension of the Metropolis algorithm to *continuous* variables, $x_1,\cdots,x_n$, involves some awkward computational problems. Nevertheless, many of the variables that arise in image processing are most naturally modelled as continuous, such as pixel grey levels, line orientations, and the sizes and orientations of objects. This motivated both Grenander (in [8]) and us to look at a diffusion-process alternative. In future image processing experiments, we will be comparing the computational performance of the continuous-valued Metropolis scheme to the diffusion scheme presented here.

Some encouraging simulation results have been recently obtained by Aluffi-Pentini, Parisi, and Zirilli [1]. They study the performance of a modified version of (1.1), which includes repeated runs, and an interactive "annealing schedule" $T=T(t)$. The experiments involve 22 different test functions U. These are defined on R^n, with n ranging from one to fourteen, and have multiple local minima. Properly tuned, the algorithm finds a global minimum for each test function.

2. Statement of result. Given a real-valued function U on the unit cube

$$U:[0,1]^n \to R,$$

and an "annealing schedule" $T(t)\downarrow 0$, we define a diffusion x:

$$dx_t=-\nabla U(x_t)\,dt+\sqrt{2T(t)}\,dw_t$$

[1] B. Gidas [6] and H. Kushner [11] have recently improved on our result. Gidas gets a tight characterization of the minimum allowed c in the schedule $T(t)=c/\log(2+t)$, and removes the reflecting boundaries. Kushner generalizes to a richer class of diffusions, allowing state-dependent diffusion coefficients and a random drift. The latter makes the connection to "stochastic approximation" in which U, or its functionals, cannot be directly observed.

where $w_t \in R^n$ is standard Brownian motion. x is confined to $[0, 1]^n$ "by reflection," which will be made precise shortly. The theorem gives conditions on $T(t)$ and U which insure the convergence of x_t to the set of global minima of U, in a suitable (weak) sense. Conditions on $T(t)$ will be given later. As for U, the conditions include:

(A) There exists an extension of U to an open set $S \supseteq [0, 1]^n$, which is twice continuously differentiable, and whose gradient has zero normal component at all noncorner boundary elements of $[0, 1]^n$.[2]

There are many equivalent ways to make precise the notion of a reflected diffusion. We will proceed in a manner that best fits with the methods to be used later in the proof of the theorem. First, we extend U "periodically" to $\hat{U}$, defined on all of R^n. Let Z denote the integers, and for every $(i_1, \cdots, i_n) \in Z^n$ define

$$S_{i_1,\cdots,i_n} = \prod_{k=1}^{n} [i_k, i_k + 1]$$

and define $G_{i_1,\cdots,i_n}: [0, 1]^n \to S_{i_1,\cdots,i_n}$ by

$$(G_{i_1,\cdots,i_n}(x))_k = \begin{cases} i_k + x, & i_k \text{ even}, \\ i_k + 1 - x, & i_k \text{ odd}. \end{cases}$$

Finally, define $\hat{U}: R^n \to R$ by

$$x \in S_{i_1,\cdots,i_n} \Rightarrow \hat{U}(s) = U(G^{-1}_{i_1,\cdots,i_n}(x)).$$

If x is "on a boundary" (i.e. $x_k = l$ some $l \in Z$, $1 \leqq k \leqq n$), then x is an element of two or more cubes: for example $x \in S_{i_1,\cdots,i_n}$ and $x \in S_{j_1,\cdots,j_n}$ where $(i_1, \cdots, i_n) \neq (j_1, \cdots, j_n)$. But then

$$G^{-1}_{i_1,\cdots,i_n}(x) = G^{-1}_{j_1,\cdots,j_n}(x),$$

and hence $\hat{U}$ is well-defined.

The definition of the reflected process, x, is in terms of a "free" (ordinary diffusion) process $\hat{x}$:

$$d\hat{x}_t = -\nabla \hat{U}(\hat{x}_t)\, dt + \sqrt{2T(t)}\, dw_t.$$

Fix $t \geqq s \geqq 0$ and $x \in [0, 1]^n$. The conditional distribution on x_t given $x_s = x$ is the same as if we had set $\hat{x}_s = x$ and then defined $x_t = G^{-1}_{i_1,\cdots,i_n}(\hat{x}_t)$ whenever $\hat{x}_t \in S_{i_1,\cdots,i_n}$. In other words, we reflect $\hat{x}_t$ at the boundaries of the unit cube. More precisely, let $\hat{p}(s, x, t, y)$ be transition probability densities for the process $\hat{x}$ (density on x_t evaluated at y, given that $x_s = x$). Then x is the Markov process with the following transition probability densities:

$$p(s, x, t, y) = \sum_{i_1,\cdots,i_n} \hat{p}(s, x, t, G_{i_1,\cdots,i_n}(y))$$

$\forall x, y \in [0, 1]^n$, $t > s \geqq 0$. To check that these actually satisfy the Markov property, first observe that for any $(i_1, \cdots, i_n)$, $(j_1, \cdots, j_n) \in Z^n$, $x, y \in [0, 1]^n$, and $t > s \geqq 0$,

$$\hat{p}(s, G_{j_1,\cdots,j_n}(x), t, G_{i_1,\cdots,i_n}(y)) = \hat{p}(s, x, t, G_{k_1,\cdots,k_n}(y))$$

[2] We believe, but are not certain, that the theorem still holds when the normal component of ∇U does not vanish on the boundaries of $[0, 1]^n$.

where

$$k_p = \begin{cases} i_p - j_p & \text{if } j_p \text{ is even,} \\ j_p - i_p & \text{if } j_p \text{ is odd,} \end{cases}$$

for each $1 \leqq p \leqq n$. Thus, for any $x, y \in [0,1]^n$, $t > s \geqq 0$, and $t_0 \in (s, t)$,

$$\begin{aligned} p(s,x,t,y) &= \sum_{i_1,\cdots,i_n} \hat{p}(s,x,t,G_{i_1,\cdots,i_n}(y)) \\ &= \sum_{i_1,\cdots,i_n} \int_{R^n} \hat{p}(s,x,t_0,z)\hat{p}(t_0,z,t,G_{i_1,\cdots,i_n}(y))\,dz \\ &= \sum_{i_1,\cdots,i_n} \sum_{j_1,\cdots,j_n} \int_{[0,1]^n} \hat{p}(s,x,t_0,G_{j_1,\cdots,j_n}(z))\hat{p}(t_0,G_{j_1,\cdots,j_n}(z),t,G_{i_1,\cdots,i_n}(y))\,dz \\ &= \sum_{j_1,\cdots,j_n} \int_{[0,1]^n} \hat{p}(s,x,t_0,G_{j_1,\cdots,j_n}(z)) \sum_{i_1,\cdots,i_n} \hat{p}(t_0,G_{j_1,\cdots,j_n}(z),t,G_{i_1,\cdots,i_n}(y))\,dz \\ &= \sum_{j_1,\cdots,j_n} \int_{[0,1]^n} \hat{p}(s,x,t_0,G_{j_1,\cdots,j_n}(z)) \sum_{k_1,\cdots,k_n} \hat{p}(t_0,z,t,G_{k_1,\cdots,k_n}(y))\,dz \\ &= \sum_{j_1,\cdots,j_n} \int_{[0,1]^n} \hat{p}(s,x,t_0,G_{j_1,\cdots,j_n}(z))p(t_0,z,t,y)\,dz \\ &= \int_{[0,1]^n} p(s,x,t_0)p(t_0,z,t,y)\,dz. \end{aligned}$$

If the temperature were constant, then x would have a unique equilibrium distribution (as will be clear from the proof of the theorem):

$$\pi_T(B) = \int_{B \cap [0,1]^n} \frac{1}{Z_T} \exp\{-U(x)/T\}\,dx \tag{2.1}$$

where

$$Z_T = \int_{[0,1]^n} \exp\{-U(x)/T\}\,dx.$$

As $T \to 0$, π_T concentrates on the global minima of U. In fact, for well-behaved functions U, $\{\pi_T\}_{T>0}$ has a unique weak limit, call it π_0, and this satisfies

$$\pi_0(\{x\colon U(x) = \inf_y U(y)\}) = 1$$

(see Hwang [9]). If, for example, the global minimum of U is attained at a finite number of points, then $\pi_T \xrightarrow{w} \pi_0$, where π_0 concentrates on the global minima and has a simple characterization in terms of the Hessian of U. On the other hand, if the global minima of U form a set of positive Lebesgue measure, then again $\pi_T \xrightarrow{w} \pi_0$, but the latter is *uniform* on the set of global minima. In any case, we will assume the existence of a unique weak limit π_0:

(B) There exists π_0 such that $\pi_T \xrightarrow{w} \pi_0$ as $T \to 0$.

Most commonly, U will possess only one global minimum, in which case (B) is trivial. Of course, π_0 necessarily concentrates on the global minima.

The following theorem gives conditions for the weak convergence of x_t to π_0.

THEOREM. *Assume* (A) *and* (B) *and that* $T(t) = c/\log(2+t)$. *For all c sufficiently large,*

$$P(x_t \in \cdot \,|x_0 = x) \xrightarrow{w} \pi_0(\cdot) \quad \forall x \in [0,1]^n.$$

Remarks. (1) Actually, the result holds if $T(t) \geqq c/\log(2+t)$, c sufficiently large, and if (1) $T(t) \downarrow 0$; (2) $T(t)$ is continuously differentiable; and (3)

$$\frac{dT(t)/dt}{T(t)^3} e^{2\Delta/T(t)} \to 0$$

where $\Delta = \sup_{x,y\in[0,1]^n}(U(x) - U(y))$. The proof is the same.

(2) Almost sure convergence to the set minimizing U is, in general, impossible, as can be demonstrated already with $n = 1$ and a very simple function U. The reason can be put loosely as follows. If $T(t) \downarrow 0$ sufficiently slowly to guarantee escape from local minima, then repeated escapes from global minima are also guaranteed (albeit with increasing rareness).

(3) For most problems, the constant c necessary to guarantee convergence to global minima will most likely be too large to be practical. But if the discrete case is any guide, then our image processing experiments suggest that significant improvement is obtained over greedy algorithms (such as zero-temperature gradient descent) with a constant far too small to invoke the theorem. (See Geman and Geman [4] for further discussion. Hajek (personal communication) and Gidas [5] have actually identified the needed constant for the discrete case.)

3. Proof of the theorem. For any $x \in [0,1]^n$, $t > s \geqq 0$, $f \in C[0,1]^n$, and μ a probability measure on $[0,1]^n$, we give the following definitions:

(i) $\pi^s = \pi_{T(s)}$, π_T as in (2.1).

Notice that π^s has a density for all $0 \leqq s < \infty$. We will use the same symbol, π^s, to denote this density:

(ii) $$\pi^s(x) = \frac{\exp\{-U(x)/T(s)\}}{\int_{[0,1]^n} \exp\{-U(x)/T(s)\}\,dx},$$

(iii) $$\mu(f) = \int_{[0,1]^n} f(x)\,\mu(dx),$$

(iv) $$p(s, x, t, f) = \int_{[0,1]^n} f(y) p(s, x, t, y)\,dy,$$

(v) $$p(s, \mu, t, f) = \int_{[0,1]^n} \int_{[0,1]^n} f(y) p(s, x, t, y) \mu(dx)\,dy.$$

The proof of the theorem is based upon the following two lemmas.

LEMMA 1. $\forall f \in C[0,1]^n$, $s \geqq 0$,

$$\lim_{t\to\infty} \sup_{w\in[0,1]^n} |p(s, v, t, f) - p(s, w, t, f)| = 0.$$

LEMMA 2. $\forall f \in C[0,1]^n$,

$$\lim_{s\to\infty} \overline{\lim_{t\to\infty}} |p(s, \pi^s, t, f) - \pi^t(f)| = 0.$$

Assuming the validity of these, we establish the theorem as follows: fixing $x \in [0,1]^n$ and $f \in C[0,1]^n$,

$$\begin{aligned}
&\overline{\lim_{t\to\infty}} |p(0,x,t,f) - \pi_0(f)| \\
&\quad \leqq \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} |p(s, p(0,x,s,\cdot), t, f) - p(s, \pi^s, t, f)| \\
&\qquad + \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} |p(s, \pi^s, t, f) - \pi^t(f)| + \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} |\pi^t(f) - \pi_0(f)| \\
&\qquad\qquad \text{(by Lemma 2 and } \pi^t = \pi_{T(t)} \xrightarrow{w} \pi_0) \\
&\quad = \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} |p(s, p(0,x,s,\cdot), t, f) - p(s, \pi^s, t, f)| \\
&\quad = \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} \left| \int_w \int_z [p(0,x,s,z) - \pi^s(z)] p(s,z,t,w) f(w)\, dz\, dw \right| \\
&\quad = \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} \left| \int_z [p(0,x,s,z) - \pi^s(z)] p(s,z,t,f)\, dz \right| \\
&\quad \leqq \overline{\lim_{s\to\infty}}\, \overline{\lim_{t\to\infty}} \sup_{v,w} |p(s,v,t,f) - p(s,w,t,f)| = 0
\end{aligned}$$

by Lemma 1.

Proof of Lemma 1. $\forall t \geqq 0$ let

$$\delta_t = \inf_{x,y} p(t, x, t+1, y).$$

Then

$$\begin{aligned}
&\overline{\lim_{t\to\infty}} \sup_{v,w} |p(s,v,t,f) - p(s,w,t,f)| \\
&\quad = \overline{\lim_{t\to\infty}} \sup_{v,w} \left| \int p(s,v,s+1,z) p(s+1,z,t,f)\, dz \right. \\
&\qquad\qquad \left. - \int p(s,w,s+1,z) p(s+1,z,t,f)\, dz \right| \\
&\quad = \overline{\lim_{t\to\infty}} \sup_{v,w} \left| \int (p(s,v,s+1,z) - \delta_s) p(s+1,z,t,f)\, dz \right. \\
&\qquad\qquad \left. - \int (p(s,w,s+1,z) - \delta_s) p(s+1,z,t,f)\, dz \right| \\
&\quad \leqq \overline{\lim_{t\to\infty}} \sup_{v,w} |(1-\delta_s) \sup_z p(s+1,z,t,f) - (1-\delta_s) \inf_z p(s+1,z,t,f)| \\
&\quad = \overline{\lim_{t\to\infty}} (1-\delta_s) \sup_{v,w} |p(s+1,v,t,f) - p(s+1,w,t,f)| \\
&\quad \cdots \\
&\quad \leqq \overline{\lim_{t\to\infty}} \left\{ \prod_{k=0}^{[t-s]-1} (1-\delta_{s+k}) \right\} \\
&\qquad \cdot \sup_{v,w} |p(s+[t-s], v, t, f) - p(s+[t-s], w, t, f)| \\
&\quad \leqq 2\|f\|_\infty \overline{\lim_{t\to\infty}} \prod_{k=0}^{[t-s]-1} (1-\delta_{s+k}) = 2\|f\|_\infty \prod_{k=0}^{\infty} (1-\delta_{s+k})
\end{aligned}$$

(where $[x]$ is the greatest integer not exceeding x). Hence, for the proof of Lemma 1 it is sufficient to show that

$$\sum_{k=0}^{\infty} \delta_{s+k} = \infty \quad \forall s \geqq 0.$$

Let $\hat{\delta}_t = \inf_{x,y\in[0,1]^n} \hat{p}(t, x, t+1, y)$. Notice that $\hat{\delta}_t \leqq \delta_t$ for all $t \geqq 0$. We will show that

$$\sum_{k=0}^{\infty} \hat{\delta}_{s+k} = \infty \quad \forall s \geqq 0.$$

Define $\mathcal{H} = \{f : [t, t+1] \to R^n, f \text{ continuous}\}$, and let P_x and Q_x be the probability measures on $\mathcal{H}$ induced by

$$dZ_u = -\nabla \hat{U}(Z_u)\, du + \sqrt{2T(u)}\, dw_u, \quad Z_t = x, \quad u \in [t, t+1],$$

and

$$dZ_u = \sqrt{2T(u)}\, dw_u, \quad Z_t = x, \quad u \in [t, t+1],$$

respectively. Then $P_x \ll Q_x$ and

$$\frac{dP_x}{dQ_x}(Z(\circ)) = \exp\left\{\int_t^{t+1} \frac{1}{2T(u)} \langle -\nabla \hat{U}(Z(u)), dZ(u)\rangle - \frac{1}{2}\int_t^{t+1} \frac{1}{2T(u)} |\nabla \hat{U}(Z(u))|^2\, du\right\} \tag{3.1}$$

(see Stroock and Varadhan [14]). We will bound the exponent on the right-hand side. Apply Ito's formula, for the zero drift equations (i.e. under Q_x):

$$\frac{1}{2T(u)} \langle -\nabla \hat{U}(Z(u)), dZ(u)\rangle = \frac{1}{2}\sum_{i=1}^{n} \hat{U}_{x_i x_i}(Z(u))\, du - \frac{1}{2T(u)}\, d\hat{U}(Z(u))$$

$$\Rightarrow \int_t^{t+1} \frac{1}{2T(u)} \langle -\nabla \hat{U}(Z(u)), dZ(u)\rangle = \frac{1}{2}\sum_{i=1}^{n} \int_t^{t+1} \hat{U}_{x_i x_i}(Z(u))\, du - \int_t^{t+1} \frac{1}{2T(u)}\, d\hat{U}(Z(u)).$$

Under the assumptions on U, $\sup_{z\in R^n} |\hat{U}_{x_i x_i}(z)| \leqq C_1 < \infty$ for some C_1, and consequently

$$\left|\frac{1}{2}\sum_{i=1}^{n} \int_t^{t+1} \hat{U}_{x_i x_i}(Z(u))\, du\right| \leqq \frac{nC_1}{2}.$$

Using again the assumptions on U, together with the monotonicity and smoothness of $T(t)$,

$$\left|\int_t^{t+1} \frac{1}{2T(u)}\, d\hat{U}(Z(u))\right| = \left|\frac{\hat{U}(Z(t+1))}{2T(t+1)} - \frac{\hat{U}(Z(t))}{2T(t)} - \int_t^{t+1} \hat{U}(Z(u))\, d\left(\frac{1}{2T(u)}\right)\right| \leqq \frac{C_2}{T(t+1)}.$$

Hence

$$\left|\int_t^{t+1} \frac{1}{2T(u)}\langle -\nabla \hat{U}(Z(u)),\, dZ(u)\rangle\right| \leqq \frac{nC_1}{2} + \frac{C_2}{T(t+1)}.$$

As for the other term in the exponent of (3.1), we easily get a bound $C_3/T(t+1)$. Therefore, for some constant C_4,

$$\frac{dP_x}{dQ_x}(Z(\cdot)) \geqq \exp\{-C_4/T(t+1)\}.$$

Consequently, for any $\varepsilon > 0$, $x, y \in R^n$,

$$P_x(|Z(t+1)-y|<\varepsilon) \geqq e^{-C_4/T(t+1)} Q_x(|Z(t+1)-y|<\varepsilon).$$

Under Q_x, $\{Z_i(t+1)\}_{i=1}^n$ are independent normal with

$$Z_i(t+1) \sim N\left(x_i, \int_t^{t+1} 2T(u)\, du\right).$$

Taking $x, y \in [0,1]^n$,

$$\begin{aligned} P_x(|Z(t+1)-y|<\varepsilon) &\geqq e^{-C_4/T(t+1)} \int_{|z-y|<\varepsilon} \frac{1}{(2\pi \int_t^{t+1} 2T(u)\, du)^{n/2}} \\ &\quad \cdot \exp\left(-|z-x|^2 \Big/ \left\{4\int_t^{t+1} T(u)\, du\right\}\right) dz \\ &\geqq C_5\, e^{-C_4/T(t+1)} \int_{|z-y|<\varepsilon} \exp\left(-(\sqrt{n}+\varepsilon)^2 \Big/ \left\{4\int_t^{t+1} T(u)\, du\right\}\right) dz. \end{aligned}$$

Finally, then,

$$\begin{aligned} \hat{\delta}_t &= \inf_{x,y\in[0,1]^n} \hat{p}(t, x, t+1, y) \\ &= C_6 \inf_{x,y\in[0,1]^n} \lim_{\varepsilon\to 0} \frac{1}{\varepsilon^n} P_x(|z(t+1)-y|<\varepsilon) \\ &\geqq e^{-C_7/T(t+1)} \end{aligned}$$

for a sufficiently large constant C_7. It now follows that the condition

$$\sum_{k=0}^{\infty} \hat{\delta}_{s+k} = \infty \quad \forall s \geqq 0$$

is satisfied for $T(t) \geqq c/\log(2+t)$, provided c is sufficiently large.

Proof of Lemma 2. For $t > s \geqq 0$ define

$$N(s,t) = \int \pi^t(x)\left(\frac{p(s, \pi^2, t, x)}{\pi^t(x)} - 1\right)^2 dx.$$

We will show that

$$\lim_{s\to\infty} \overline{\lim_{t\to\infty}}\, N(s,t) = 0. \tag{3.2}$$

From this, Lemma 2 is obtained as follows: For any $f \in [0,1]^n$

$$\begin{aligned}
&\overline{\lim_{s\to\infty}}\,\overline{\lim_{t\to\infty}} \left| p(s, \pi^s, t, f) - \pi^t(f) \right| \\
&\quad = \overline{\lim_{s\to\infty}}\,\overline{\lim_{t\to\infty}} \left| \int (p(s, \pi^s, t, x) - \pi^t(x)) f(x)\, dx \right| \\
&\quad \leqq \|f\|_\infty \overline{\lim_{s\to\infty}}\,\overline{\lim_{t\to\infty}} \int \left| p(s, \pi^s, t, x) - \pi^t(x) \right| dx \\
&\quad = \|f\|_\infty \overline{\lim_{s\to\infty}}\,\overline{\lim_{t\to\infty}} \int \pi^t(x) \left| \frac{p(s, \pi^s, t, x)}{\pi^t(x)} - 1 \right| dx \\
&\quad \leqq \|f\|_\infty \overline{\lim_{s\to\infty}}\,\overline{\lim_{t\to\infty}} \sqrt{\int \pi^t(x) \left(\frac{p(s, \pi^s, t, x)}{\pi^t(x)} - 1 \right)^2 dx} \\
&\quad = 0.
\end{aligned}$$

The proof of (3.2) rests upon the following lemma.

LEMMA 3. *Let* $\Delta = \sup_{x,y\in[0,1]^n} (U(x) - U(y))$. *For all* $t > s \geqq 0$

$$\frac{\partial}{\partial t} N(s, t) \leqq \Delta \left(\frac{d}{dt} \left(\frac{1}{T(t)} \right) \right) (1 + N(s, t)) - 2T(t)\, e^{-2\Delta/T(t)} N(s, t).$$

Accept, for now, Lemma 3. We have with $T(t) = c/\log(2+t)$,

$$\frac{\partial}{\partial t} N(s, t) \leqq \frac{\Delta}{c} \left(\frac{1}{2+t} \right) - \left\{ \frac{2c}{\log(2+t)} \left(\frac{1}{2+t} \right)^{2\Delta/c} - \frac{\Delta}{c} \left(\frac{1}{2+t} \right) \right\} N(s, t). \tag{3.3}$$

From this, and the observation that $\lim_{t\downarrow s} N(s, t) = 0$, (3.2) is easily established, provided that c is sufficiently large. We will forgo these details; they only involve integrating (3.3), with the inequality replaced by equality.

All that remains is the proof of Lemma 3.

Proof of Lemma 3. First, observe that

$$N(s, t) = \int \frac{p(s, \pi^s, t, x)^2}{\pi^t(x)}\, dx - 1.$$

Hence

$$\begin{aligned}
N_t(s, t) &= \int \left(\frac{d}{dt} \frac{1}{\pi^t(x)} \right) p(s, \pi^s, t, x)^2\, dx \\
&\quad + 2 \int p_t(s, \pi^s, t, x) p(s, \pi^s, t, x) \left(\frac{1}{\pi^t(x)} \right) dx \\
&= A(s, t) + B(s, t)
\end{aligned}$$

where

$$A(s, t) = \int \left(\frac{d}{dt} \frac{1}{\pi^t(x)} \right) p(s, \pi^s, t, x)^2\, dx$$

and

$$B(s, t) = 2 \int p_t(s, \pi^s, t, x) p(s, \pi^s, t, x) \left(\frac{1}{\pi^t(x)} \right) dx.$$

Let $g(t) = 1/T(t)$. Then

$$\begin{aligned} A(s,t) &= -\int \left(\frac{1}{\pi^t(x)}\right)^2 \left(\frac{d}{dt}\pi^t(x)\right) p(s,\pi^s,t,x)^2\,dx \\ &= -\int \left(\frac{1}{\pi^t(x)}\right)^2 (-g_t(t)U(x)\pi^t(x) + g_t(t)\pi^t(x)\pi^t(U)) p(s,\pi^s,t,x)^2\,dx \\ &= g_t(t)\int \frac{1}{\pi^t(x)}(U(x)-\pi^t(U)) p(s,\pi^s,t,x)^2\,dx \qquad (3.4) \\ &\leqq \Delta g_t(t)\int \frac{p(s,\pi^s,t,x)^2}{\pi^t(x)}\,dx \\ &= \Delta g_t(t)(1+N(s,t)). \end{aligned}$$

The treatment of $B(s,t)$ is more involved. The first step will be to show that

$$B(s,t) = -2T(t)\int |\nabla[p(s,\pi^s,t,x)/\pi^t(x)]|^2 \pi^t(x)\,dx.$$

From this, we will then derive the bound

$$B(s,t) \leqq -2T(t)\, e^{-2\Delta/T(t)} N(s,t),$$

which, together with (3.4), completes the proof.

We rewrite $B(s,t)$ with the help of the forward equation for the original ($\hat{}$) process: for $t > s \geqq 0$,

$$\hat{p}_t(s,y,t,x) = \sum_{k=1}^{n} \{T(t)\hat{p}_{x_kx_k}(s,y,t,x) + \hat{U}_{x_k}(x)\hat{p}_{x_k}(s,y,t,x) + \hat{U}_{x_kx_k}(x)\hat{p}(s,y,t,x)\}.$$

Integration over y, with respect to π^s, gives

$$\begin{aligned} \hat{p}_t(s,\pi^s,t,x) = \sum_{k=1}^{n} \{&T(t)\hat{p}_{x_kx_k}(s,\pi^s,t,x) \\ &+ \hat{U}_{x_k}(x)\hat{p}_{x_k}(s,\pi^s,t,x) + \hat{U}_{x_kx_k}(x)\hat{p}(s,\pi^s,t,x)\}. \end{aligned} \qquad (3.5)$$

We wish to convert (3.5) into a similar equation for p. This conversion is based upon the following identities, which are justified by the assumed smoothness of U, and the resulting smoothness of $\hat{p}$ (see, for example, [3]). For each integer i define

$$P(i) = \begin{cases} 1 & \text{if } i \text{ is even,} \\ -1 & \text{if } i \text{ is odd.} \end{cases}$$

Recalling that

$$x, y \in [0,1]^n \Rightarrow p(s,y,t,x) = \sum_{i_1,\cdots,i_n} \hat{p}(s,y,t,G_{i_1,\cdots,i_n}(x)),$$

we have, for each $1 \leqq k \leqq n$ and each $x, y \in [0,1]^n$:

$$\begin{aligned} &\hat{U}_{x_k}(G_{i_1,\cdots,i_n}(x)) = P(i_k)U_{x_k}(x), \\ &\hat{U}_{x_kx_k}(G_{i_1,\cdots,i_n}(x)) = U_{x_kx_k}(x), \\ &p(s,\pi^s,t,x) = \sum_{i_1,\cdots,i_n} \hat{p}(s,\pi^s,t,G_{i_1,\cdots,i_n}(x)), \end{aligned}$$

$$p_t(s, \pi^s, t, x) = \sum_{i_1,\cdots,i_n} \hat{p}_t(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)),$$

$$p_{x_k}(s, \pi^s, t, x) = \sum_{i_1,\cdots,i_n} p(i_k)\hat{p}_{x_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)),$$

$$p_{x_kx_k}(s, \pi^s, t, x) = \sum_{i_1,\cdots,i_n} \hat{p}_{x_kx_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)).$$

Now take $x, y \in [0, 1]^n$ and replace x by $G_{i_1,\cdots,i_n}(s)$ in (3.5):

$$\begin{aligned}\hat{p}_t(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)) = \sum_{k=1}^{n} \{&T(t)\hat{p}_{x_kx_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)) \\ &+ U_{x_k}(x)P(i_k)\hat{p}_{x_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x)) \\ &+ U_{x_kx_k}(x)\hat{p}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x))\}.\end{aligned}$$

Summation over $i_1, \cdots, i_n$ yields:

$$\begin{aligned}p_t(s, \pi^s, t, x) &= \sum_{k=1}^{n} \{T(t)p_{x_kx_k}(s, \pi^s, t, x) + U_{x_k}(x)p_{x_k}(s, \pi^s, t, x) + U_{x_kx_k}(x)p(s, \pi^s, t, x)\} \\ &= T(t) \sum_{k=1}^{n} \frac{\partial}{\partial x_k}\left\{\pi^t(x)\frac{\partial}{\partial x_k}[p(s, \pi^s, t, x)/\pi^t(x)]\right\}. \qquad (3.6)\end{aligned}$$

The associated boundary conditions are

$$p_{x_k}(s, \pi^s, t, x) = 0 \quad \text{whenever } x_k = 0 \text{ or } 1.$$

To see how these arise, take, for example, $x_k = 0$: letting $x = (x_1, x_2, \cdots, x_{k-1}, 0, x_{k+1}, \cdots, x_n)$, and letting e_k be the unit vector along the kth coordinate,

$$\begin{aligned}&p_{x_k}(s, \pi^s, t, x) \\ &= \lim_{\varepsilon \downarrow 0} \sum_{i_1,\cdots,i_n} P(i_k)\hat{p}_{x_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x_1, \cdots, x_{k-1}, \varepsilon, x_{k+1}, \cdots, x_n)) \\ &= \lim_{\varepsilon \downarrow 0} \sum_{i_j : j \neq k} \sum_{p=-\infty}^{\infty} \\ &\quad \cdot \{\hat{p}_{x_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x_1, \cdots, x_{k-1}, 0, x_{k+1}, \cdots, x_n) + (2p + \varepsilon)e_k) \\ &\qquad - \hat{p}_{x_k}(s, \pi^s, t, G_{i_1,\cdots,i_n}(x_1, \cdots, x_{k-1}, 0, x_{k+1}, \cdots, x_n) + (2p - \varepsilon)e_k)\} \\ &= 0.\end{aligned}$$

Now combine the boundary conditions on p with our boundary assumptions on ∇U (set out in (A)):

$$\frac{\partial}{\partial x_k}[p(t, \pi^s, t, x)/\pi^t(x)] = 0$$

for all x such that $x_k = 0$ or 1. Multiplying the equation in (3.6) by $p(s, \pi^s, t, x)/\pi^t(x)$

and integrating x over $[0,1]^n$ gives:

$$\frac{1}{2}B(s,t) = \int p_t(s,\pi^s,t,x)p(s,\pi^s,t,x)\left(\frac{1}{\pi^t(x)}\right)dx$$

$$= T(t)\sum_{k=1}^{n}\int_{x_j:j\neq k}\left\{\int_{x_k}(p(s,\pi^s,t,x)/\pi^t(x))\right.$$

$$\left.\cdot\frac{\partial}{\partial x_k}\left\{\pi^t(x)\frac{\partial}{\partial x_k}[p(s,\pi^s,t,x)/\pi^t(x)]\right\}dx_k\right\}$$

$$\cdot\, dx_1\cdots dx_{k-1}\,dx_{k+1}\cdots dx_n$$

$$= (\text{integrating over } x_k \text{ by parts})$$

$$-T(t)\sum_{k=1}^{n}\int\left\{\frac{\partial}{\partial x_k}[p(s,\pi^s,t,x)/\pi^t(x)]\right\}^2\pi^t(x)\,dx$$

$$= -T(t)\int|\nabla[p(s,\pi^s,t,x)/\pi^t(x)]|^2\pi^t(x)\,dx.$$

It remains to show that

$$\int|\nabla[p(s,\pi^s,t,x)/\pi^t(x)]|^2\pi^t(x)\,dx \geqq e^{-2\Delta/T(t)}N(s,t). \tag{3.7}$$

This final step is a consequence of the following proposition.

PROPOSITION. *If $\theta:[0,1]^n\to R$ is continuously differentiable, and if*

$$\int\theta(x)\,dx = 0,$$

then

$$\int\theta(x)^2\,dx \leqq \int|\nabla\theta(x)|^2\,dx.$$

For a more general version of this, see Gilbarg and Trudinger [7, p. 157].

Finally, fix s and t, and let

$$\phi(x) = \frac{p(s,\pi^s,t,x)}{\pi^t(x)} - 1$$

and $\alpha = \int\phi(x)\,dx$. Since $\int\phi(x)\pi^t(x)\,dx = 0$,

$$N(s,t) = \int\phi(x)^2\pi^t(x)\,dx \leqq \int(\phi(x)-\alpha)^2\pi^t(x)\,dx.$$

Notice that $e^{-\Delta/T(t)} \leqq \pi^t(x) \leqq e^{\Delta/T(t)}$, and therefore

$$N(s,t) \leqq e^{\Delta/T(t)}\int(\phi(x)-\alpha)^2\,dx$$

$$\leqq e^{\Delta/T(t)}\int|\nabla\phi(x)|^2\,dx \quad (\text{by the proposition})$$

$$\leqq e^{2\Delta/T(t)}\int|\nabla\phi(x)|^2\pi^t(x)\,dx,$$

which is the same as (3.7).

NECESSARY AND SUFFICIENT CONDITIONS FOR ISOLATED LOCAL MINIMA OF NONSMOOTH FUNCTIONS*

MARCIN STUDNIARSKI†

Abstract. We consider the mathematical programming problem: find $\inf\{f(x)|x\in C\}$ where f is an arbitrary extended-real-valued function, and C a subset of a finite dimensional space. We give necessary and sufficient optimality conditions for this problem, generalizing previous results of A. Auslender (this Journal, 22 (1984), pp. 239-254).

Key words. nonsmooth optimization, higher order optimality conditions, isolated local minima, lower and upper Dini directional derivatives

1. Introduction. This research was inspired by the recent results of Auslender [2, § 2], who derived necessary and sufficient conditions for isolated local minima with order 1 and 2 for the mathematical programming problem

$$\text{(P)} \qquad \inf\{f(x)|x\in C\},$$

assuming that $f:\mathbb{R}^n\to\mathbb{R}$ is a locally Lipschitzian function, and C a closed subset of $\mathbb{R}^n$. Our aim is to demonstrate that those conditions can be reformulated and generalized so as to be valid for any extended-real-valued function $f:\mathbb{R}^n\to\bar{\mathbb{R}}$ and to encompass isolated local minima with order greater than two.

Throughout the paper we assume that C is a subset of $\mathbb{R}^n$ (not necessarily closed), $\bar{x}$ is a point of C and $f:\mathbb{R}^n\to\mathbb{R}$ is a function such that $|f(\bar{x})|<\infty$. We denote by $\mathcal{N}(x)$ the collection of all neighbourhoods of the point $x\in\mathbb{R}^n$.

Let k be any positive integer. Extending Definition 2.1 of [2], we shall say that $\bar{x}$ is an *isolated local minimum with order k of problem* (P) if there exist $\beta>0$ and $U\in\mathcal{N}(\bar{x})$ such that

$$f(x)>f(\bar{x})+\beta|x-\bar{x}|^k \quad \text{for all } x\in U\cap C,\quad x\neq\bar{x} \tag{1.1}$$

(here $|\cdot|$ stands for the Euclidean norm).

We shall state our optimality conditions for problem (P) by means of lower and upper Dini directional derivatives of f at $\bar{x}$, and of higher order counterparts of these notions. Before formulating the definitions, let us note the following.

Remark 1.1. For any function $\varphi:]0,+\infty[\times\mathbb{R}^n\to\bar{\mathbb{R}}$, the function

$$\psi(x)=\liminf_{\substack{t\downarrow 0\\ v\to x}}\varphi(t,v)=\sup_{V\in\mathcal{N}(x)}\inf_{\substack{\alpha>0\\ 0<t<\alpha\\ v\in V}}\varphi(t,v) \tag{1.2}$$

is lower semicontinuous on $\mathbb{R}^n$.

Let us now introduce the following notation (for each $h\in\mathbb{R}^n$ and $k=1,2,\cdots$):

$$\begin{aligned}\underline{d}^k f(\bar{x};h)&=\liminf_{\substack{t\downarrow 0\\ v\to h}} t^{-k}(f(\bar{x}+tv)-f(\bar{x})),\\ \bar{d}^k f(\bar{x};h)&=\limsup_{\substack{t\downarrow 0\\ v\to h}} t^{-k}(f(\bar{x}+tv)-f(\bar{x})).\end{aligned} \tag{1.3}$$

If $k=1$, we obtain the lower and the upper Dini directional derivatives [3], [4] (called also contingent derivatives [1], or semiderivatives [5]). One can refer to the above-

* Received by the editors December 12, 1984, and in revised form August 2, 1985.
† Institute of Mathematics, University of Łódź, 90-238 Łódź, Poland.

mentioned literature for more information on this subject as well as for further references. We shall write $\underline{d}f$ and $\bar{d}f$ instead of $\underline{d}^1 f$ and $\bar{d}^1 f$; this notation coincides with that used in [5].

Remark 1.2 [1, p. 286]. If f is locally Lipschitzian, then

$$\underline{d}f(\bar{x}; h) = \liminf_{t \downarrow 0} t^{-1}(f(\bar{x}+th) - f(\bar{x}));$$

of course, a similar formula is valid for $\bar{d}f$.

Let $\delta(\cdot|C)$ denote the indicator function of C:

$$\delta(x|C) = \begin{cases} 0 & \text{if } x \in C, \\ +\infty & \text{if } x \notin C, \end{cases}$$

and let $f_C = f + \delta(\cdot|C)$. Then

$$\underline{d}^k f_C(\bar{x}; h) = \liminf_{\substack{t \downarrow 0 \\ v \to h}} [t^{-k}(f(\bar{x}+tv) - f(\bar{x})) + \delta(\bar{x}+tv|C)]. \tag{1.4}$$

We now introduce lower kth order directional derivatives of f at $\bar{x}$ (in the direction $h \in \mathbb{R}^n$). Let us denote $h^k = (h, \cdots, h) \in (\mathbb{R}^n)^k$ and define

$$f'_-(\bar{x}; h) = \underline{d}f(\bar{x}; h),$$

$$f^{(k)}_-(\bar{x}; h^k) = k! \liminf_{\substack{t \downarrow 0 \\ v \to h}} t^{-k}[f(\bar{x}+tv) - f(\bar{x}) - \sum_{j=1}^{k-1} t^j f^{(j)}_-(\bar{x}; v^j)/j!], \tag{1.5}$$

$$k = 2, 3, \cdots.$$

It follows from Remark 1.1 that the functions $\underline{d}^k f(\bar{x}; \cdot)$, $\underline{d}^k f_C(\bar{x}; \cdot)$ and $h \mapsto f^{(k)}_-(\bar{x}; h^k)$ $(k = 1, 2, \cdots)$ are lower semicontinuous. Moreover, we have the following.

Remark 1.3. If $k > 1$ and

$$f^{(j)}_-(\bar{x}; h^j) \geqq 0 \quad \text{for all } h \in \mathbb{R}^n \quad \text{and } j = 1, \cdots, k-1, \tag{1.6}$$

then

$$f^{(k)}_-(\bar{x}; h^k) \leqq k! \underline{d}^k f(\bar{x}; h) \quad \text{for all } h \in \mathbb{R}^n. \tag{1.7}$$

If we assume (1.6) to be equalities, then also equality holds in (1.7).

Using Taylor's formula (in such a form as in [6, Thm. 21]), we easily obtain, by induction with respect to k, the following

PROPOSITION 1.1. *If f is $(k-1)$-times $(k > 1)$ Fréchet differentiable on $\mathbb{R}^n$ and if the kth derivative $f^{(k)}(\bar{x})$ of f at $\bar{x}$ exists, then*

$$f^{(k)}(\bar{x})h^k = f^{(k)}_-(\bar{x}; h^k) \quad \textit{for all } h \in \mathbb{R}^n.$$

2. Optimality conditions for problem (P). In this section we present different types of optimality conditions for (P). We first consider conditions which characterize isolated local minima with order k of (P) and are stated by means of limits (1.4). They are difficult to apply as they involve the indicator function of C. Therefore, we shall next give other conditions, stated in terms of limits (1.3), which are easier to verify. However, in this form, the necessary conditions are essentially weaker than the sufficient ones; this is demonstrated by simple examples. Finally, we shall give, for the case $C = \mathbb{R}^n$, sufficient optimality conditions using directional derivatives (1.5). A detailed comparison between our results and those of Auslender [2] will be made in § 3.

We denote by $T(C;\bar{x})$ the tangent cone to C at $\bar{x}$ [5] (called also contingent cone [1], [3]). It may be defined in some equivalent manners. We recall three of them:

(2.1) $T(C;\bar{x})=\{h\in\mathbb{R}^n|\forall\alpha>0,\forall V\in\mathcal{N}(h),\ C\cap(\bar{x}+]0,\alpha[V)\neq\emptyset\}$,

(2.2) $h\in T(C;\bar{x})$ if and only if there exist sequences $t_m\downarrow 0$ and $h_m\to h$ such that $\bar{x}+t_mh_m\in C$ for all m,

(2.3) $h\in T(C;\bar{x})$ if and only if there exists a sequence $\{x_m\}\subset C$ converging to $\bar{x}$ and a sequence $\{\lambda_m\}\subset]0,+\infty[$ such that $h=\lim_{m\to\infty}\lambda_m(x_m-\bar{x})$.

Since $T(C;\bar{x})$ is a closed cone and $\underline{d}f(\bar{x};\cdot)$ is positively homogeneous and lower semicontinuous, the set

$$K(\bar{x})=T(C;\bar{x})\cap\{h\in\mathbb{R}^n|\underline{d}f(\bar{x};h)\leqq 0\} \tag{2.4}$$

is also a closed cone (containing 0).

THEOREM 2.1. (i) *If $k>1$, then the following three conditions are equivalent*:

(a) *$\bar{x}$ is an isolated local minimum with order k of problem* (P);

(b) *for all $h\in\mathbb{R}^n\backslash\{0\}$, we have*

$$\underline{d}^kf_C(\bar{x};h)>0; \tag{2.5}$$

(c) *inequality* (2.5) *holds for all $h\in K(\bar{x})\backslash\{0\}$.*

(ii) *If $k=1$, then analogous equivalences are true with condition* (c) *replaced by the following one*:

(c′) *inequality* (2.5) *holds for all $h\in T(C;\bar{x})\backslash\{0\}$.*

Proof. (i); (a)$\Rightarrow$(b): Suppose that (1.1) holds and that the desired conclusion is false, that is, there exists $y\in\mathbb{R}^n\backslash\{0\}$ satisfying $\underline{d}^kf_C(\bar{x};y)\leqq 0$. Hence, by the definition of "lim inf" (see (1.2)), it follows that, for each $\alpha>0$ and $V\in\mathcal{N}(y)$,

$$\inf_{\substack{0<t<\alpha\\ v\in V}}[t^{-k}(f(\bar{x}+tv)-f(\bar{x}))+\delta(\bar{x}+tv|C)]\leqq 0. \tag{2.6}$$

In particular, we may choose α and V so as to satisfy the following conditions:

$$V\subset\{x\in\mathbb{R}^n||x-y|<|y|/2\}, \tag{2.7}$$

$$\bar{x}+]0,\alpha[V\subset U \tag{2.8}$$

(where U is the neighbourhood occurring in (1.1)). Take any $\varepsilon>0$. By (2.6), there exist $s\in]0,\alpha[$ and $w\in V$ such that

$$\bar{x}+sw\in C\quad\text{and}\quad s^{-k}(f(\bar{x}+sw)-f(\bar{x}))\leqq\varepsilon. \tag{2.9}$$

In view of (2.7), we have $|w-y|<|y|/2$, hence $|w|>|y|/2$. By (2.8), $\bar{x}+sw\in U\cap C$. Thus, making use of (2.9) and (1.1), we obtain

$$\varepsilon\geqq s^{-k}(f(\bar{x}+sw)-f(\bar{x}))>s^{-k}\beta|sw|^k>\beta(|y|/2)^k,$$

which leads to a contradiction since ε is arbitrary whereas $\beta(|y|/2)^k>0$ does not depend on ε.

(b)$\Rightarrow$(c) is trivial.

(c)$\Rightarrow$(a). Since the set $S(\bar{x})=\{h\in K(\bar{x})||h|=1\}$ is compact and $\underline{d}^kf_C(\bar{x};\cdot)$ is lower semicontinuous, we deduce from (c) that there exists $\gamma=\min\{\underline{d}^kf_C(\bar{x};h)|h\in S(\bar{x})\}>0$. (*If* $S(\bar{x})$ is empty, the proof is valid for any $\gamma>0$.) Suppose that (a) is false, then (1.1) is false with $\beta=\gamma/2$. Thus, we can choose a sequence $\{x_m\}\subset C$ such that $x_m\to\bar{x}$, $x_m\neq\bar{x}$

for all m, and

$$f(x_m) \leqq f(\bar{x}) + (\gamma/2)|x_m - \bar{x}|^k \quad \text{for all } m. \tag{2.10}$$

Let $t_m = |x_m - \bar{x}|$, $v_m = (x_m - \bar{x})/|x_m - \bar{x}|$. We have $t_m \downarrow 0$ and we may assume, by taking a subsequence, that $\{v_m\}$ converges to a vector y such that $|y| = 1$. By (2.3), we have also $y \in T(C; \bar{x})$. Moreover, in view of (2.10),

$$\begin{aligned} \underline{d}f(\bar{x}; y) &\leqq \liminf_{m\to\infty} t_m^{-1}(f(\bar{x} + t_m v_m) - f(\bar{x})) \\ &= \liminf_{m\to\infty} t_m^{-1}(f(x_m) - f(\bar{x})) \\ &\leqq \lim_{m\to\infty} (\gamma/2) t_m^{k-1} = 0, \end{aligned} \tag{2.11}$$

and so $y \in S(\bar{x})$ (see (2.4)), which implies $\underline{d}^k f_C(\bar{x}; y) \geqq \gamma$. Hence, by (1.4), we obtain that there exist $\alpha > 0$ and $V \in \mathcal{N}(y)$ such that

$$t^{-k}(f(\bar{x} + tv) - f(\bar{x})) > \gamma/2 \tag{2.12}$$

for all $t \in]0, \alpha[$ and $v \in V$ satisfying $\bar{x} + tv \in C$. For all sufficiently large m, we have $t_m \in]0, \alpha[$ and $v_m \in V$. Since $\bar{x} + t_m v_m = x_m \in C$, we obtain for those m, by (2.12), $t_m^{-k}(f(x_m) - f(\bar{x})) > \gamma/2$, which contradicts (2.10).

(ii) The only change with respect to the case (i) is now the following: when proving $(c') \Rightarrow (a)$, we cannot verify (2.11) (since it contradicts (2.5) for $k = 1$ and $C = \mathbb{R}^n$), and so $K(\bar{x})$ has to be replaced by $T(C; \bar{x})$. □

From Theorem 2.1 and from the obvious inequality $\underline{d}^k f_C(\bar{x}; \cdot) \geqq \underline{d}^k f(\bar{x}; \cdot)$, we deduce the following.

COROLLARY 2.1. (i) *If* $\underline{d}f(\bar{x}; h) > 0$ *for all* $h \in T(C; \bar{x})\backslash\{0\}$, *then* $\bar{x}$ *is an isolated local minimum with order* 1 *of problem* (P).

(ii) *If* $k > 1$ *and* $\underline{d}^k f(\bar{x}; h) > 0$ *for all* $h \in K(\bar{x})\backslash\{0\}$, *then* $\bar{x}$ *is an isolated local minimum with order* k *of problem* (P).

We now establish necessary optimality conditions in a similar form.

THEOREM 2.2. *If* $\bar{x}$ *is an isolated local minimum with order* $k \geqq 1$ *of problem* (P), *then* $\bar{d}^k f(\bar{x}; h) > 0$ *for all* $h \in T(C; \bar{x})\backslash\{0\}$.

Proof. Suppose that the conclusion is false, hence there exists $y \in T(C; \bar{x})\backslash\{0\}$ satisfying $\bar{d}^k f(\bar{x}; y) \leqq 0$. This means, in view of (1.3), that, for any $\varepsilon > 0$, there exist $\alpha > 0$ and $V \in \mathcal{N}(y)$ such that

$$t^{-k}(f(\bar{x} + tv) - f(\bar{x})) \leqq \varepsilon \quad \text{for all } t \in]0, \alpha[\quad \text{and } v \in V. \tag{2.13}$$

We may assume that α and V satisfy conditions (2.7) and (2.8) (if necessary, we can take them smaller and (2.13) remains true). Since $y \in T(C; \bar{x})$, we have $(\bar{x} +]0, \alpha[\, V) \cap C \neq \emptyset$ by (2.1). From this fact and from (2.13) we infer that there exist $s \in]0, \alpha[$ and $w \in V$ satisfying (2.9). The remaining part of the proof is the same as in Theorem 2.1, (a)$\Rightarrow$(b). □

In the following two examples we assume that $k \geqq 1$, $n = 2$, $C = \mathbb{R} \times \{0\}$, and $\bar{x} = (0, 0)$.

Example 2.1. Let f be given by

$$f(x_1, x_2) = \begin{cases} 0 & \text{if } x_2 = 0, \\ |x_1|^k & \text{if } x_2 \neq 0. \end{cases}$$

We have $\bar{d}^k f(\bar{x}; (h_1, 0)) = |h_1|^k > 0$ for all $h_1 \neq 0$, and so f satisfies the necessary optimality condition given in Theorem 2.2. Nevertheless, $\bar{x}$ is not an isolated local minimum with order k of problem (P).

Example 2.2. Let f be given by

$$f(x_1, x_2) = \begin{cases} |x_1|^k & \text{if } x_2 = 0, \\ 0 & \text{if } x_2 \neq 0. \end{cases}$$

Then $\bar{x}$ is an isolated local minimum with order k of problem (P), but sufficient conditions of Corollary 2.1 are not satisfied since $\underline{d}f(\bar{x}; \cdot)$ and $\underline{d}^k f(\bar{x}; \cdot)$ are identically zero.

Let us now consider the unconstrained case $C = \mathbb{R}^n$. The following corollary is a direct consequence of Corollary 2.1 (ii) and Remark 1.3.

COROLLARY 2.2. *Suppose that* $k > 1$, *that conditions* (1.6) *are fulfilled, and that* $f_-^{(k)}(\bar{x}; h^k) > 0$ *for all* $h \neq 0$ *satisfying* $\underline{d}f(\bar{x}; h) = 0$. *Then* $\bar{x}$ *is an isolated local minimum with order* k *of problem* (P) *where* $C = \mathbb{R}^n$.

It follows from Proposition 1.1 that Corollary 2.2 generalizes the classical higher order sufficient conditions for a local minimum of a smooth function (let us note that, in the smooth case, the condition $\underline{d}f(\bar{x}; h) = 0$ is a consequence of (1.6), and so may be omitted).

3. Comparison with Auslender's results. Auslender [2, Prop. 2.1] gives necessary and sufficient optimality conditions for (P) (with locally Lipschitzian f), using the following expression:

$$f^*(\bar{x}; h) = 2 \liminf_{\substack{h \\ u \to 0}} [|u|^{-2}(f(\bar{x}+u) - f(\bar{x})) + \delta(\bar{x}+u|C)] \tag{3.1}$$

where, for any $\varphi : \mathbb{R}^n \setminus \{0\} \to \bar{\mathbb{R}}$ and $h \neq 0$,

$$\liminf_{\substack{h \\ u \to 0}} \varphi(u) = \sup_{\varepsilon > 0} \left(\inf \left\{ \varphi(u) \middle| \left| \frac{u}{|u|} - \frac{h}{|h|} \right| \leqq \varepsilon, 0 < |u| \leqq \varepsilon \right\} \right). \tag{3.2}$$

Let us first compare the limits (1.2) and (3.2).

LEMMA 3.1.

$$\liminf_{\substack{h \\ u \to 0}} \varphi(u) = \liminf_{\substack{t \downarrow 0 \\ v \to h}} \varphi(tv).$$

Proof. Observe that

$$\liminf_{\substack{t \downarrow 0 \\ v \to h}} \varphi(tv) = \sup_{\eta > 0} (\inf \{ \varphi(tv) | 0 < t \leqq \eta, |v - h| \leqq \eta \}).$$

Thus, it suffices to verify the following two conditions:

(3.3) for any $\varepsilon > 0$, there exists $\eta > 0$ such that $|tv/|tv| - h/|h|| \leqq \varepsilon$ and $0 < |tv| \leqq \varepsilon$ for all t and v satisfying $0 < t \leqq \eta$, $|v - h| \leqq \eta$;

(3.4) for any $\eta > 0$, there exists $\varepsilon > 0$ such that each vector u satisfying $|u/|u| - h/|h|| \leqq \varepsilon$ and $0 < |u| \leqq \varepsilon$ can be represented in the form $u = tv$ where $0 < t \leqq \eta$ and $|v - h| \leqq \eta$.

In order to prove (3.3), take any $\varepsilon > 0$ (we may assume $\varepsilon \leqq 1$) and define $\eta = \min(\varepsilon|h|/2, 2\varepsilon/3|h|)$. If $0 < t \leqq \eta$ and $|v - h| \leqq \eta$, then $|v - h| \leqq |h|/2$, hence $0 < |h|/2 \leqq$

$|v| \leqq (3/2)|h|$. Consequently, $0 < |tv| \leqq \varepsilon$ and

$$\left|\frac{tv}{|tv|} - \frac{h}{|h|}\right| = \frac{1}{|v||h|}|(|h| - |v|)v + |v|(v-h)|$$

$$\leqq \frac{1}{|h|}(\|h| - |v\| + |v-h|) \leqq \frac{2}{|h|}|v-h| \leqq \varepsilon.$$

Let us now verify (3.4). For any $\eta > 0$, we define $\varepsilon = \min(\eta|h|, \eta/|h|)$. If u satisfies the assumptions of (3.4), we put $t = |u|/|h|$, $v = (|h|/|u|)u$, and obtain $0 < t \leqq \eta$, $|v-h| = |h||u/|u| - h/|h|| \leqq \eta$. □

We are now able to establish a relation between the limits (1.4) (for $k=2$) and (3.1). Note that we need not assume f to be locally Lipschitzian.

PROPOSITION 3.1. *For all $h \neq 0$, we have*

$$f^*(\bar{x}; h) = \frac{2}{|h|^2}\, \underline{d}^2 f_C(\bar{x}; h).$$

Proof. Making use of (1.4), (3.1) and Lemma 3.1, we find that

$$f^*(\bar{x}; h) = 2 \liminf_{\substack{t \downarrow 0 \\ v \to h}} [|tv|^{-2}(f(\bar{x}+tv) - f(\bar{x})) + \delta(\bar{x}+tv|C)]$$

$$= 2\,(\lim_{\substack{t \downarrow 0 \\ v \to h}} |v|^{-2})\, \underline{d}^2 f_C(\bar{x}; h) = \frac{2}{|h|^2}\, \underline{d}^2 f_C(\bar{x}; h). \qquad \square$$

Remark 3.1. In a similar way, using (1.5) (for $k=2$), Remark 1.2 and Lemma 3.1, we can show that the lower second-order directional derivative introduced in [2, (2.2)] is equal to $h \mapsto (1/|h|^2) f_-^{(2)}(\bar{x}; h^2)$ if f is locally Lipschitzian.

4. Conclusions. Let us now consider the case of locally Lipschitzian f. It follows from Remark 1.2 and Proposition 3.1 that all the statements of [2, Prop. 2.1] are particular cases of our results presented in § 2. More precisely, it is easy to see that:

(a) the necessary condition for an isolated local minimum with order 1 is a consequence of Theorem 2.2 (where $k=1$),

(b) the necessary condition [2, (2.6)] for an isolated local minimum with order 2 follows from Theorem 2.1, (a)⇒(b) (where $k=2$),

(c) the sufficient condition for an isolated local minimum with order 1 is another formulation of Corollary 2.1(i),

(d) the sufficient condition [2, (2.8)] for an isolated local minimum with order 2 follows from Theorem 2.1, (c)⇒(a) (where $k=2$).

Similarly, it follows from Remark 3.1 that Corollary 2.2 of [2] is a consequence of our Corollary 2.2 (where $k=2$).

SOLVING THE LINEAR COMPLEMENTARITY PROBLEM IN CIRCUIT SIMULATION*

J. T. J. VAN EIJNDHOVEN†

Abstract. In the simulation of electronic circuits piecewise linear modelling yields a global circuit description which in principle can be used to solve for a circuit response in a finite number of steps. During the solution process a sequence of linear complementarity problems (LCP) has to be solved within the piecewise linear system description. The purpose of this paper is to present and discuss some new methods to solve this LCP for certain matrix classes.

To start with, two types of LCP solution algorithms are briefly described: pivoting algorithms and the modulus algorithm. It is shown that these algorithms have certain disadvantages if applied to the problem as stated above. Those problems can be overcome by the new methods to be presented. The first one is a modified version of an iterative algorithm of O. L. Mangasarian. The second one is a so-called simplicial method, based on a new integer labelling and an efficient labelling algorithm. Convergence conditions are given, as is a bound for the error in the approximate solution.

In both new algorithms full advantage can be taken of sparse matrix techniques. The labelling algorithm turns out to converge for a large class of matrices, comparable with standard pivoting methods.

Key words. linear complementarity, piecewise linear, large scale, simulation, integer labelling

1. Introduction. In the electronic industry, the use of simulation programs is widely accepted. Especially in the design of large scale integrated circuits these programs have become indispensable. The testing of the correctness of a circuit prior to the actual integration by building a model with discrete components, will deliver increasingly poorer results with growing circuit complexity. The high frequencies and the short distances in the extremely small and complex structures, being recognized in recent devices, make a good electronic equivalent of an integrated circuit with discrete components impossible.

In a computer simulation all these effects can be incorporated. Hence a better approximation can be achieved. However, the design of such a program is enormously complex. The program must be able to perform logic simulation of digital circuits, timing simulation of these devices as well as the computation of transient responses of analog circuits. Furthermore, the communication between these different simulation levels through a common database is a very difficult problem. Finally, the resulting set of nonlinear equations is in general solved by applying the Newton-Raphson iteration scheme, which implies problems of numerical stability.

Recently, a new method was proposed for the simulation of electronic circuits. This method uses piecewise-linear approximations for all nonlinear functions [v. Bokhoven, '80]. It has the following advantages:

- The method is extremely well suited for macro modelling, which is an important feature in the simulation of LSI circuits.
- Mixed analog/digital simulation is automatically incorporated. The structure of the equations is identical for each device, no matter whether it is a macromodel of a logic gate or a detailed Gummel-Poon transistor model.

† Eindhoven University of Technology, Department of Electrical Engineering, P.O. Box 513, Eindhoven, the Netherlands. This work was sponsored by the Netherlands Organization for the Advancement of Pure Research (ZWO).

- A complete system description consists of a single matrix, with a standard block structure yielding a very compact datastructure.
- Analytic nonlinear functions (like exp, ln, sqrt) no longer need to be evaluated, so a speed-up of the simulation can be expected.
- A network can easily be built up from smaller blocks, which allows for a hierarchical structure. This is indispensable in the design of LSI circuits. It also renders the possibility to construct a library of standard functions and networks.
- Numerical problems with discontinuous signals are almost absent, while conventional programs, using some version of Newton–Raphson iteration, show very serious convergence problems and large computation times if signals contain fast transients.

Some new problems are introduced, however. The most serious of those problems is that during a transient simulation at each time step a linear complementarity problem (LCP) has to be solved. This LCP is given as follows: For given vector q and matrix M, find vectors v and i such that

$$v = M \cdot i + q, \quad v, i \in \mathbb{R}^n_+, \quad v^t \cdot i = 0$$

where:

- M is a large sparse matrix,
- M is generally not restricted to a certain class of matrices (see § 2),
- the LCP has one or more solutions.

The main purpose of this paper is to present new algorithms particularly suitable to solve the LCP as stated above. In the next section we shall give the piecewise linear system description and derive the associate LCP.

2. The linear complementarity problem. A piecewise linear system (see Fig. 1) will be described by the following equations:

$$\begin{pmatrix} y \\ v \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} x \\ i \end{pmatrix} + \begin{pmatrix} g \\ h \end{pmatrix} \tag{2.1}$$

$$v, i \in \mathbb{R}^n_+, \qquad v^t \cdot i = 0.$$

In general this set of equations describes different linear relations between x and y on maximally 2^n different polytopes. This can be shown as follows: Define 2^n different n-vectors S^k, $1 \leqq k \leqq 2^n$, such that

$$S^k_j \in \{0, 1\}, \qquad 1 \leqq j \leqq n.$$

Let the n-vectors i^k and v^k be such that:

$$i^k_j = i_j, \qquad v^k_j = v_j \quad \text{if } S^k_j = 0,$$
$$i^k_j = v_j, \qquad v^k_j = i_j \quad \text{if } S^k_j = 1.$$

Transform the equations (2.1) by partial inversion into

$$\begin{pmatrix} y \\ v^k \end{pmatrix} = \begin{pmatrix} A^k & B^k \\ C^k & D^k \end{pmatrix} \begin{pmatrix} x \\ i^k \end{pmatrix} + \begin{pmatrix} g^k \\ h^k \end{pmatrix} \tag{2.2}$$

and assume $V^k = \{x \mid C^k x + h^k \in \mathbb{R}^n_+\}$.

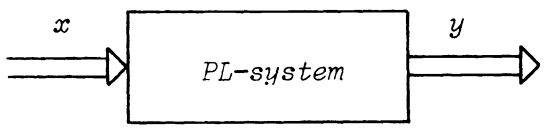

FIG. 1. *A piecewise linear system.*

Now $v^k = C^k \cdot x + h^k$, $i^k = 0$ is a solution of (2.1) for a given $x \in V^k$. Thus $y = A^k \cdot x + g^k$ is the linear mapping in the region V^k. Obviously, there are at most 2^n different regions V^k and any of these regions may have its own linear mapping. In general some V^k may be empty, may overlap, or some x may not belong to any V^k (no solution exists).

For given x, (2.1) can be solved by determining

$$q = Cx + h, \qquad M = D$$

and solving the LCP:

$$\begin{aligned} &v = M \cdot i + q, \\ &v, i \in \mathbb{R}^n_+, \qquad v^t \cdot i = 0. \end{aligned} \tag{2.3}$$

Then y can easily be computed when i is found. However, solving the LCP may be difficult. For example multiple solutions may exist (circuits with memory, for instance flip-flops and thyristors).

For the characterization of the LCP some classes of matrices have been defined by various authors (see for instance [Karamardian, '72]). Four of them are repeated here:

- *Positive definite matrices* (PD).
  M is of class PD if and only if
  $\forall x \in \mathbb{R}^n, \quad x \neq 0: x^t M x > 0.$
- *P-matrices* (P).
  M is of class P if and only if
  $\forall x \in \mathbb{R}^n, \quad x \neq 0, \quad \exists k: x_k \cdot (Mx)_k > 0.$
- *Strictly copositive matrices* (SCP).
  M is of class SCP if and only if
  $\forall x \in \mathbb{R}^n_+, \quad x \neq 0: x^t M x > 0$
- *Strictly semimonotone matrices* (SSM) (*completely $-Q$ matrices*).
  M is of class SSM if and only if
  $\forall x \in \mathbb{R}^n_+, \quad x \neq 0, \quad \exists k: x_k \cdot (Mx)_k > 0.$

These definitions imply that PD $\subset$ P $\subset$ SSM and PD $\subset$ SCP $\subset$ SSM.

In relation to the LCP it is known that $M \in$ SSM implies that there exists at least one solution for each q. There exists a unique solution for each q if and only if $M \in$ P.

An example of a PL-system with hysteresis (multiple solutions) and $M \in$ SCP is the following system:

$$\left(\begin{array}{c} y \\ \hline v_1 \\ v_2 \end{array}\right) = \left(\begin{array}{c|cc} 0 & 1 & 0 \\ \hline 0 & 1 & 2 \\ \frac{1}{2} & 1 & 1 \end{array}\right) \left(\begin{array}{c} x \\ \hline i_1 \\ i_2 \end{array}\right) + \left(\begin{array}{c} 0 \\ \hline -1 \\ -1 \end{array}\right).$$

This system has an input-output relation as shown in Fig. 2.

Solving the LCP, in the context of piecewise linear simulation, was investigated earlier by van Bokhoven (see [van Bokhoven, '81]). He mainly considered pivoting algorithms and the modulus algorithm.

At the moment there are many different versions of pivoting algorithms, (see for instance [Lemke, '70], [Eaves, '71], [Cottle, '68], [van der Heyden '80]. They are based on the original algorithm of Lemke [Lemke, '65], and differ mainly in the choice of the pivots and the class of matrices for which convergence is assured.

In a simulation process, the matrices do not necessarily belong to any of such classes. The algorithm may be unable to choose a nonzero pivot and terminates

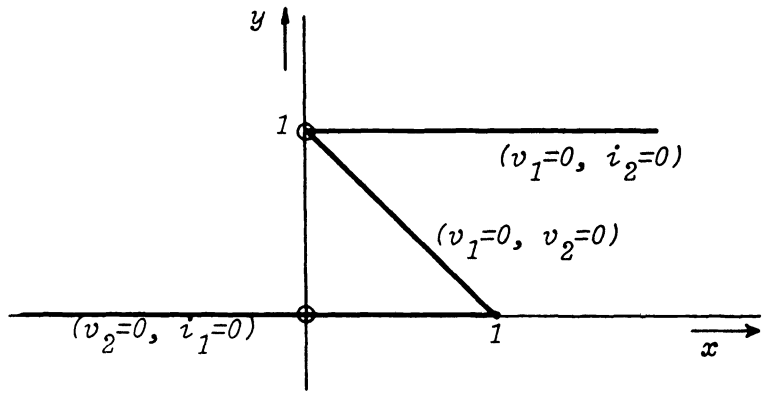

FIG. 2. *An example of a system with hysteresis.*

unsuccessfully. Furthermore, M will be a large sparse matrix, and a complex datastructure is required for the pivoting operations. In addition sparsity may be lost as a consequence of pivoting [van Eijndhoven, '82] [van Eijndhoven, '84] [Saigal, '81] [Fujisawa, '72].

The modulus algorithm [van Bokhoven, '81] has the advantage that for a given conditioning of the problem the time-complexity is a polynomial function of the dimension n. The method is based on contraction mapping and is more appropriate for sparse matrix processing. Unfortunately however, convergence can only be assured for positive-definite matrices.

Because both the pivoting method and the modulus algorithm did not have the desired properties, other methods have been searched for. The results are presented in the next two sections. In § 3 an iterative algorithm is presented to minimize a quadratic function, related to the LCP. Basically the algorithm is the same as [Mangasarian, '77], but by using a different quadratic function we can process non-symmetric matrices as well. The new method solves the LCP for all class P matrices.

In § 4 a simplex method is presented. The space $\mathbb{R}^n_+$ is triangulated and a new type of integer labelling is given. An algorithm of v.d. Laan and Talman [v.d. Laan, '80] is used to search for a completely labelled simplex, starting from an arbitrary chosen initial point. Convergence is proved for all matrices of class SSM, independent of the gridsize. A bound for the error of the approximate solution is derived.

3. A minimization algorithm. In this section we will solve the LCP by transforming it into a quadratic programming problem, which is subsequently solved by systematic overrelaxation. This approach was also followed in [Cryer, '71] and [Mangasarian, '77] but we apply this method to a different quadratic function. This will lead to a different class of matrices for which convergence can be guaranteed as we shall see later on.

Consider the LCP:

find vectors $v, i \in \mathbb{R}^n_+$ such that

$$v = Mi + q, \qquad v^t i = 0. \tag{3.1}$$

This problem is equivalent to:

find vectors $v, i \in \mathbb{R}^n_+$ such that

$$f(i, v) = \alpha v^t \cdot i + \tfrac{1}{2}(Mi + q - v)^t (Mi + q - v) = 0 \tag{3.2}$$

for some $\alpha > 0$.

The equivalence of (3.1) and (3.2) is obvious: $f(i^*, v^*) = 0$ for all pairs (i^*, v^*) that solve (3.1), and $f(i, v) > 0$ for all other pairs $(i, v) \in \mathbb{R}^n_+ \times \mathbb{R}^n_+$.

To find the point (i^*, v^*) (which minimizes f) one can use an algorithm as found in [Mangasarian, '77] and we shall show that $M \in P$ is a sufficient condition to solve (3.2) by this algorithm.

Let $u = \binom{i}{v} \in \mathbb{R}^{2n}_+$ and let $f(u) = f(i, v)$ according to (3.2). Denote the gradient $g(u)$ and the hessian H_α of $f(u)$ by:

$$g(u) = g(i, v) = \alpha \begin{pmatrix} v \\ i \end{pmatrix} + \begin{pmatrix} M^t(Mi + q - v) \\ -(Mi + q - v) \end{pmatrix}, \tag{3.3}$$

$$H_\alpha = (h_{ij}) = \alpha \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix} + \begin{pmatrix} M^tM & -M^t \\ -M & I \end{pmatrix}. \tag{3.4}$$

A possible algorithm to minimize $f(u)$ can be:

Define for $k = 1, 2, \cdots$ the vectors $u^k \in \mathbb{R}^{2n}_+$ and for each k, for $l = 0, 1, 2, \cdots, 2n$ the vectors $u^{k,l} \in \mathbb{R}^{2n}_+$ such that

$u^0 \in \mathbb{R}^{2n}_+$ is a given starting point of the algorithm

$$u_j^{k,l} = \begin{cases} u_j^k & \text{for } 1 \leqq j \leqq l, \\ u_j^{k-1} & \text{for } l+1 \leqq j \leqq 2n, \end{cases}$$

with

$$u_j^k = \max\,(0,\, u_j^{k-1} - \omega g_j(u^{k,j-1})/h_{jj}) \tag{3.5}$$

where ω is a relaxation parameter with $0 < \omega < 2$, and h_{jj} is positive due to the definition of f.

This algorithm can be found in [Cryer, '71] and is only a special case of a more general class of algorithms found in [Mangasarian, '77]. In the next three theorems it will be proved that the sequence will converge for $M \in$ SSM and that the limit points determine a solution of the LCP if $M \in$ P.

THEOREM 3.1. *H_α is symmetrical and $\forall \alpha > 0$: $M \in$ SSM $\rightarrow H_\alpha \in$ SCP.*

Proof.

(1) The symmetry of H_α is obvious.

(2) $$\begin{pmatrix} i \\ v \end{pmatrix}^t H_\alpha \begin{pmatrix} i \\ v \end{pmatrix} = 2\alpha i^t v + (Mi - v)^t(Mi - v)$$

$$M \in \text{SSM} \rightarrow \forall 0 \neq i \geqq 0 \exists_k\colon i_k(Mi)_k > 0$$

$$\rightarrow \forall 0 \neq \begin{pmatrix} i \\ v \end{pmatrix} \geqq 0\colon v = M \cdot i,\ i^t v = 0 \text{ has no solution}$$

$$\rightarrow \forall 0 \neq \begin{pmatrix} i \\ v \end{pmatrix} \geqq 0,\ \alpha > 0\colon \begin{pmatrix} i \\ v \end{pmatrix}^t H_\alpha \begin{pmatrix} i \\ v \end{pmatrix} > 0$$

$$\rightarrow \forall \alpha > 0\colon H_\alpha \in \text{SCP}. \qquad \square$$

THEOREM 3.2. *The sequence (u^k) has at least one limit point u^* if $M \in$ SSM. Each limit point u^* satisfies*

$$u^* \geqq 0, \qquad g_\alpha(u^*) \geqq 0, \qquad u^{*t} \cdot g_\alpha(u^*) = 0. \tag{3.6}$$

Proof. Because $M \in$ SSM implies $H_\alpha \in$ SCP, the more general algorithms with convergence proofs found in [Mangasarian, '77] apply here. Basically the existence

of limit points follows from the nonincreasing property of the sequence $(f(u^k))$ and $H_\alpha \in \mathrm{SCP}$, which implies that the sequence (u^k) is bounded an *a* compact set. The inequalities for u^* easily follow from the definition of the algorithm. □

THEOREM 3.3. *If* $M \in \mathrm{P}$ *then* $f(u^*)=0$, *with* u^* *a limit point of* (3.5), *and hence a solution of* (3.1) *is found.*

Proof. From (3.5) (see also [Cryer, '71]) it follows that:

$$\forall k, 1 \leqq k \leqq 2n \quad u_k^* \geqq 0, \quad g_k(u^*) \geqq 0, \quad u_k^* \cdot g_k(u^*) = 0.$$

Now returning to a notation in i and v, computing $g_k(u^*) \cdot g_{k+n}(u^*) \geqq 0$ $(1 \leqq k \leqq n)$ and substituting $u_k^* \cdot g_k(u^*) = 0 \wedge u_{k+n}^* \cdot g_{k+n}(u^*) = 0$ yields:

$$(3.7) \qquad \forall k, 1 \leqq k \leqq n \qquad \alpha^2 i_k^* \cdot v_k^* + (Mi^* + q - v^*)_k [M^t(Mi^* + q - v^*)]_k \leqq 0.$$

Now let M in class P (which implies M^t in class P) and assume $\|Mi^* + q - v^*\| \neq 0$.

Then, due to the definition of class P

$$\exists j, 1 \leqq j \leqq n \qquad (Mi^* + q - v^*)_j \cdot [M^t(Mi^* + q - v^*)]_j > 0$$

which contradicts (3.7) because $i_j^* \cdot v_j^* \geqq 0$. Therefore $\|Mi^* + q - v^*\| = 0$ and (from (3.7)) $v^{*t} \cdot i^* = 0$. So $f(i^*, v^*) = 0$ and (i^*, v^*) is a solution of (3.1). □

If $M \in \mathrm{P}$ it is known that there exists only one solution to the LCP [Karamardian, '72], therefore only one limit point u^* exists and thus (see Theorem 3.2)

$$\lim_{k \to \infty} u^k = u^* \text{ is the unique solution of (3.1).}$$

About the algorithm we would like to remark:

1. The new method solves (3.1) for all class P matrices, whereas the algorithms of Mangasarian apply to symmetrical matrices only. For our application though, the restriction to class P remains disappointing.

2. Like the problem, the algorithm is symmetrical in v and i.

3. The sequence (u^k) will converge for a much larger class of matrices. However, for $M \notin \mathrm{P}$ the algorithm may find a vector u^* for which $f(u^*) > 0$ and then u^* is not a solution of the LCP.

4. One must choose $\alpha > 0$ and $0 < \omega < 2$. Fast convergence is obtained in practice with $\omega = 1.5$ and α in the order of magnitude of the elements of M.

4. A simplex algorithm. In this section we shall use a simplex method to find a solution of the LCP. A choice was made for an algorithm developed by v.d. Laan and Talman because they presented a closed theory in combination with a set of related efficient algorithms, triangulations and labelling functions (see [v.d. Laan, '80] and [Talman, '80]).

However, these algorithms were mainly intended to solve equations of the form $x = f(x)$. Therefore another integer labelling is developed, especially suited for the LCP, which satisfies all conditions of a so-called "proper" labelling. It can be proved that the algorithm will find an approximate solution from each starting point in $\mathbb{R}_+^n$ and with each grid-size if the matrix of the LCP is of class SSM. We will restrict ourselves to integer labelling because vector labelling requires the repeated solving of large sets of linear equations, which is just the type of operations we would like to avoid as stated in § 2. It is noted that the infinite norm will be used, i.e.

$$\|x\| = \|x\|_\infty = \max_i |x_i|, \qquad \|M\| = \|M\|_\infty = \max_i \sum_{j=1}^{n} |m_{ij}|.$$

4.1. Triangulation. Let $I_n = \{1, 2, \cdots, n\}$ and for each $k \in I_n$ the vector $e(k)$ be defined such that

$$e_i(k) = \begin{cases} 1 & \text{if } i = k, \\ 0 & \text{if } i \neq k,\ i \in I_n. \end{cases}$$

Let $C_\lambda = \{x \in \mathbb{R}^n_+ \mid \|x\| \leqq \lambda\}$ and the boundaries C^j_λ of C_λ

$$C^j_\lambda = \begin{cases} \{x \in C_\lambda \mid \|x\| = \lambda\} & \text{if } j = 0, \\ \{x \in C_\lambda \mid x_j = 0\} & \text{if } j \in I_n. \end{cases}$$

C_λ is triangulated by the collection of simplices $\sigma(y^1, P)$ with vertices $y^1, y^2, \cdots, y^{n+1}$ in C_λ given by:

- each coordinate of y^1 is an integer multiple of δ(=gridsize) where $\lambda = k\delta$ for some positive integer k,
- $P = (p_1, p_2, \cdots, p_n)$ is a permutation of the elements of I_n,
- $y^{i+1} = y^i + \delta \cdot e(p_i)$, $i \in I_n$.

This collection of simplices yields the standard K-triangulation.

4.2. Labelling. Define a labelling function l on C_λ such that

$$l(x) \in \{0, 1, \cdots, n\} \quad \text{for all } x \in C_\lambda.$$

A simplex is called *completely labelled* if the $(n+1)$ vertices carry all the $(n+1)$ different labels.

A labelling function is called *proper* if

$$l(x) \neq j \text{ for all } x \in C^j_\lambda, \qquad j \in I_n \cup \{0\}.$$

Let $f(x) = Mx + q$; the LCP can then be rephrased as follows:

(4.1) find a vector $x \in \mathbb{R}^n_+$ such that $f(x) \in \mathbb{R}^n_+$ and $x^t \cdot f(x) = 0$.

For solving the LCP by using a simplicial algorithm the labelling function must be such that

- The labelling is proper. This guarantees that the algorithm, given in § 4.3, does not leave C_λ and will find a completely labelled simplex.
- A completely labelled simplex provides an approximation of the solution of the LCP (4.1).

We prove that the labelling defined below satisfies these conditions if $M \in \text{SSM}$.

$$l(x) = \begin{cases} 0 & \text{if } \forall i \in I_n\colon x_i \cdot f_i(x) \leqq 0, \\ j & \text{if } j = \min\{k \in I_n \mid x_k \cdot f_k(x) = \max_{i \in I_n} x_i \cdot f_i(x) > 0\}. \end{cases} \tag{4.2}$$

THEOREM 4.1. *A completely labelled simplex yields an approximation of the* LCP.

Proof. Let x^j the vertex of the completely labelled simplex with label j and

$$f^j = f(x^j), \qquad j \in I_n \cup \{0\}$$

then

$$\|x^j - x^0\| = \delta, \qquad j \in I_n$$

and

$$|f^j_j - f^0_j| \leqq \|f^j - f^0\| \leqq \delta \cdot \|M\| \to f^0_j > -\delta \cdot \|M\|.$$

Furthermore by definition (4.2)

$$x_j^0 = 0 \quad \text{for all } j \text{ with } f_j^0 > 0.$$

Thus x^0, f^0approximates the solution of the LCP, and the approximation becomes arbitrarily accurate with decreasing δ. □

Furthermore, if $M \in \mathrm{P}$ it is known that there exists a unique solution $\tilde{x}, \tilde{f}$ of the LCP and the distance between x^0 and $\tilde{x}$ can be bounded.

THEOREM 4.2. *If $M \in \mathrm{P}$ then $\|x^0 - \tilde{x}\| < \delta \cdot C$ with C a condition number of the matrix M and δ the gridsize.*

Proof. If $x^0 = \tilde{x}$ we are ready. Otherwise for some $\beta \in \mathbb{R}^n$, $\beta \neq 0$, $\tilde{x} = x^0 + \beta$ and:

$$\tilde{x} = x^0 + \beta \in \mathbb{R}^n_+,$$
$$\tilde{f} = f^0 + M \cdot \beta \in \mathbb{R}^n_+,$$
$$\tilde{x}^t \cdot \tilde{f} = 0.$$

Next we use

$$M \in \mathrm{P} \to \exists \varepsilon_M > 0 \forall \beta \in \mathbb{R}^n, \beta \neq 0 \exists k \in I_n : \frac{\beta_k \cdot (M\beta)_k}{\|\beta\|^2} \geqq \varepsilon_M. \tag{4.3}$$

The proof of this implication is analogous to the proof of Lemma 1, given in the Appendix.

Now let the pair β, k satisfy (4.3). Then

$$\left.\begin{aligned} &\beta_k \cdot (M\beta)_k > 0 \\ &\tilde{x}_k \geqq 0 \wedge \tilde{f}_k \geqq 0 \\ &x_k^0 \cdot f_k^0 \leqq 0 \text{ (due to the labelling)} \end{aligned}\right\} \to \beta_k > 0 \wedge (M\beta)_k > 0.$$

This implies that $\tilde{x}_k > 0$, thus $\tilde{f}_k = 0$ and $(M\beta)_k = -f_k^0 > 0$ where $-f_k^0 < \delta \cdot \|M\|$ due to labelling.

Thus finally

$$\|\beta\| \leqq \frac{1}{\varepsilon_M} \frac{\beta_k}{\|\beta\|} (M\beta)_k < \frac{1}{\varepsilon_M} \cdot \delta \cdot \|M\|$$

or

$$\|\beta\| < \delta \cdot C \text{ with condition number } C = \frac{\|M\|}{\varepsilon_M}. \qquad \square$$

Next we shall prove that the labelling (4.2) is proper for matrices $M \in \mathrm{SSM}$. To this purpose we shall apply again Lemma 1 which is proved in the Appendix.

LEMMA 1.

$$M \in \mathrm{SSM} \to \exists \varepsilon_M > 0 \forall x \in \mathbb{R}^n_+, x \neq 0 \exists k \in I_n : \frac{x_k \cdot (Mx)_k}{\|x\|^2} \geqq \varepsilon_M. \tag{4.4}$$

THEOREM 4.3. *$M \in \mathrm{SSM} \to \exists \lambda_M > 0 \forall \lambda \geqq \lambda_M [l(x)$ as defined in (4.2) is proper on $C_\lambda] \to$*

$$x_i = 0 \to l(x) \neq i, \qquad i \in I_n, \tag{4.5a}$$

$$\|x\| = \lambda \geqq \lambda_M \to l(x) \neq 0. \tag{4.5b}$$

Proof. (4.5a) follows immediately from (4.2) independent of the matrix. So only (4.5b) needs to be proved.

Let ε_M according to (4.4) and choose $\lambda_M > 0$ such that

$$\min_{i \in I_n} (\varepsilon_M \cdot \lambda_M + q_i) > 0.$$

Then

$$x \in \mathbb{R}^n_+ \wedge \|x\| = \lambda \geqq \lambda_M \to \exists_{i \in I_n} x_i \cdot f_i = x_i (Mx+q)_i$$
$$\geqq \varepsilon_M \|x\|^2 + x_i \cdot q_i \geqq x_i \cdot (\varepsilon_M \cdot \lambda_M + q_i) > 0 \to l(x) \neq 0.$$

We shall see that ε_M and λ_M need not be computed for the algorithm. Their existence is already sufficient for the convergence of the algorithm. □

4.3. The algorithm. Now we shall use the "variable dimension restart algorithm" of v. d. Laan and Talman in order to find a completely labelled simplex (see for instance [v.d. Laan, '80a] or [v.d. Laan, '80b]). The algorithm will be given in a slightly different notation and without proof. It has the following properties:

- No special points are to be defined outside C_λ to bound the domain or to start the algorithm.
- The algorithm generates a sequence of adjacent simplices of variable dimension.
- The algorithm is started with a zero-dimensional simplex: the starting point, an arbitrary chosen gridpoint in $\mathbb{R}^n_+$

Let

$$u(i) = \begin{cases} -e(i) & \text{if } i \in I_n, \\ (1, 1, \cdots, 1)^t & \text{if } i = 0. \end{cases}$$

Define a t-dimensional simplex $\sigma(y^1, P(T))$, $0 \leqq t \leqq n$ with its vertices $y^1, y^2, \cdots, y^{t+1}$ by:

- y^1 is a gridpoint of the triangulation,
- $P(T) = (p_1, p_2, \cdots, p_t)$ is a permutation of the elements of T with $|T| = t$, $T \subset \{0, 1, \cdots, n\}$,
- $y^{i+1} = y^i + \delta \cdot u(p_i)$, $1 \leqq i \leqq t$.

Now the algorithm generates for varying T a sequence of simplices such that:

1. Each t-dimensional simplex has at least t different labels.

2. Each t-simplex $\sigma(y^1, \cdots, y^{t+1})$ satisfies $y^1 = v + \delta \cdot \sum_{j=0}^n R_j u(j)$ where v is the starting point and R is an $(n+1)$ vector with $R_j = 0$ if $j \notin T$, $R_j \geqq 0$ if $j \in T$ $(0 \leqq j \leqq n)$.

The algorithm is given in a flow diagram in Fig. 3. In each cycle of the algorithm a t-dimensional simplex σ is "flipped" to its successor, which is determined by having a face in common containing all different labels present in σ. So if σ has t different labels, σ has exactly two such faces, one in common with its predecessor and one wth its successor. If σ has $t+1$ different labels $(t < n)$ its successor is a $(t+1)$-dimensional simplex with σ as one face. The dimension of σ can be decreased to prevent one component of R becoming negative. During these steps σ will never leave C_λ due to the (with the labels of σ related) positiveness of R together with the proper labelling. In this way each simplex has a unique predecessor and successor in C_λ except for the starting point (a zero dimensional simplex) which only has a successor and cannot be entered again. Because there is only a finite number of simplices in C_λ the algorithm must end, which only occurs by finding a completely labelled simplex, thus yielding an approximation of the solution of the LCP. For the various proofs see [v. d. Laan, '80a] or [v. d. Laan, '80b].

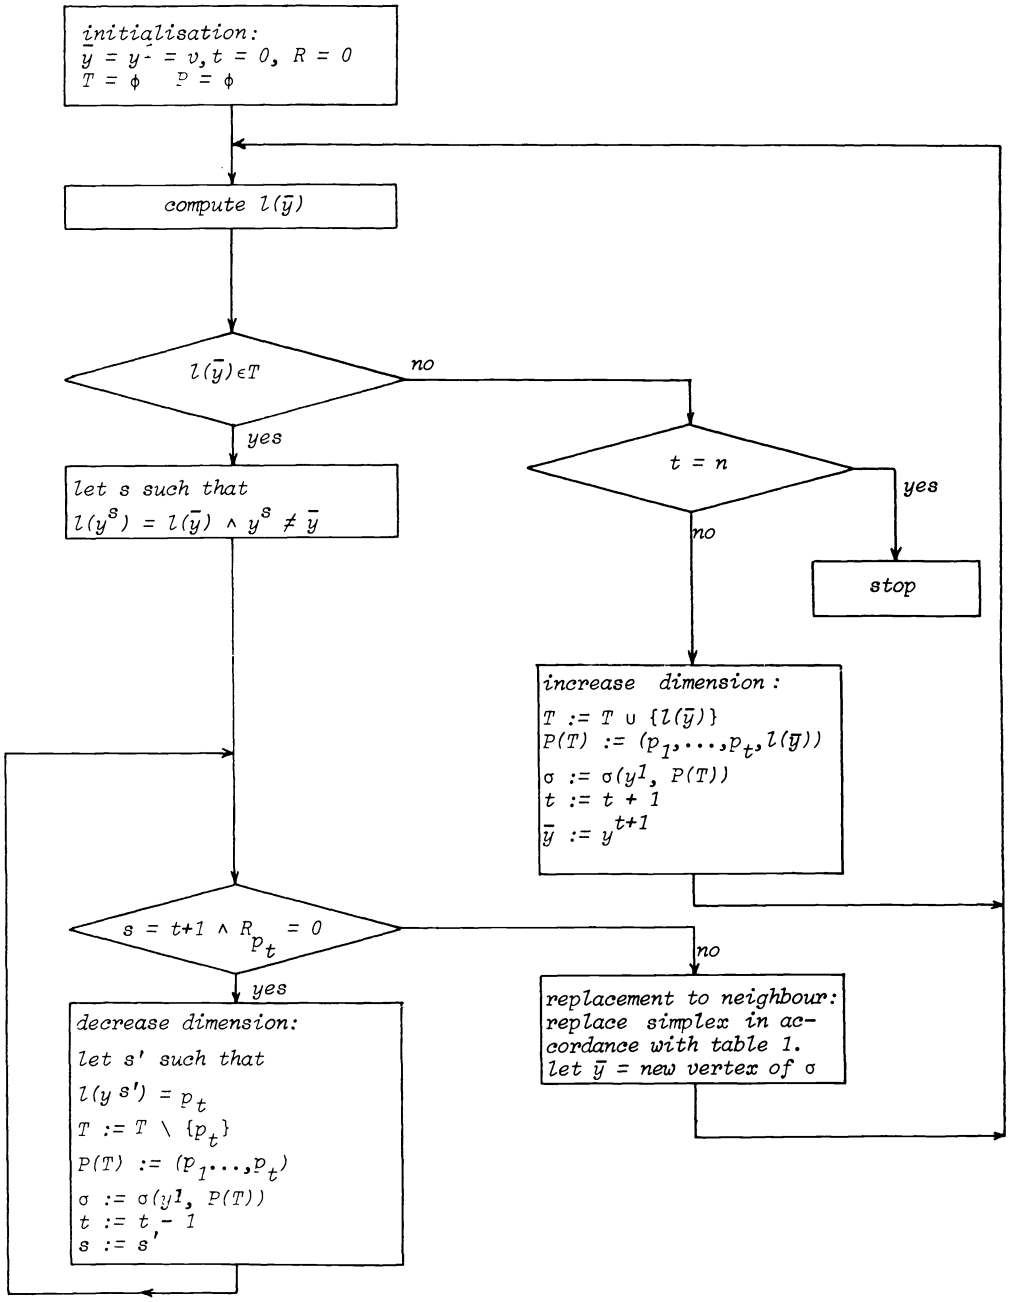

FIG. 3. *Flow diagram of simplex algorithm.*

The flow of the algorithm for $n = 2$ is demonstrated in Fig. 4. Note the proper labelling.

About this method to solve the LCP the following remarks must be applied.

- Full advantage can be taken of sparse matrix techniques, because only matrix-vector products have to be computed.
- Like the pivoting algorithms, the simplex algorithms are combinatorial algorithms and they converge for a relatively large class of matrices.

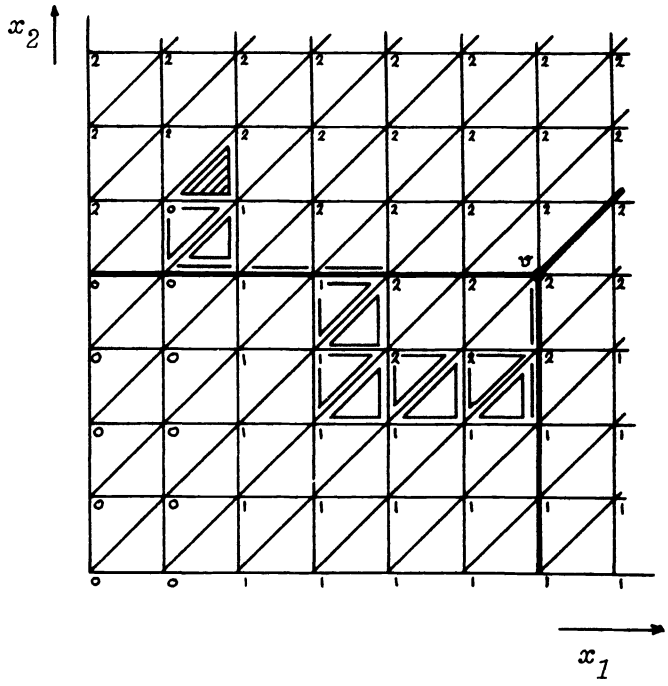

FIG. 4. *Flow of the algorithm for* $n = 2$.

- The algorithm can also be used for matrices that do not belong to SSM. The algorithm will either stop with a solution or generate a chain of simplices towards infinity and thus will not end.
- The algorithm will find a solution if $M \in$ SSM with each starting point and with each grid size. Therefore the approximate solution can be used as initial point in a next run with a smaller grid size.
- Where we want to solve a sequence of LCP's, we can choose the starting point to be the solution to the previous problem.

TABLE 1
Table for the replacement of the simplex. s is the number of the vertex to be replaced.

	y^1 becomes	$P(T)$ becomes	R
$s = 1$	$y^1 + \delta \cdot u(p_1)$	$(p_2, \cdots, p_t, p_1)$	$R_{p_1} := R_{p_1} + 1$
$2 \leqq s \leqq t$	no changes	$(p_1, \cdots, p_{s-2}, p_s, p_{s-1}, p_{s+1}, \cdots, p_t)$	no changes
$s = t+1$	$y^1 - \delta \cdot u(p_t)$	$(p_t, p_1, \cdots, p_{t-1})$	$R_{p_t} := R_{p_t} - 1$

5. Conclusions. A search is made of suitable algorithms to solve the LCP, characterized by a large sparse matrix, not necessarily restricted to some specific class. A minimization method is developed that can process matrices with a good sparse matrix behaviour. Convergence is proved for all class P matrices.

Pivoting algorithms are combinatorial methods which converge for a relatively large class of matrices. However, these algorithms lead to complex sparse matrix processing.

A good alternative is found in a simplex method. Good sparse matrix behaviour is obtained and convergence is proved for a large class of matrices (SSM), independent of starting point and grid size. Furthermore, any matrix can be processed but convergence is not assured. This method could be a good alternative for the pivoting algorithms when the dimension of the problem increases or pivoting does not find a solution of the LCP.

Appendix.

LEMMA 1.

$$M \in \mathrm{SSM} \to \exists \varepsilon > 0 \forall x \in \mathbb{R}^n_+, x \neq 0 \exists k, 1 \leqq k \leqq n \quad \frac{x_k \cdot (Mx)_k}{\|x\|^2} \geqq \varepsilon.$$

Proof. Let $U = \{x \in \mathbb{R}^n_+ \mid \|x\| = 1\}$ and for all $x \in U$: $h(x) = \max_i x_i \cdot (Mx)_i$, $1 \leqq i \leqq n$. U is a compact set and $h(x)$ is continuous and thus has a minimum ε and U [Griffiths, '70 pp. 427]. Then from the definition of SSM, ε will be positive. Thus:

$$\forall x \in \mathbb{R}^n_+, \|x\| = 1 \exists k, 1 \leqq k \leqq n \quad x_k \cdot (Mx)_k \geqq \varepsilon.$$

Now substitute $y \in \mathbb{R}^n_+$, $y \neq 0$, $y = ax$, $a = \|y\|$ which leads to:

$$\forall y \in \mathbb{R}^n_+, y \neq 0 \exists k, 1 \leqq k \leqq n \quad \frac{y_k \cdot (My)_k}{\|y\|^2} \geqq \varepsilon. \qquad \square$$

Acknowledgment. The author is indebted to the referees for clarifying the text and mentioning related work, thus improving the paper.

THE MATCHING OF NONLINEAR MODELS VIA DYNAMIC STATE FEEDBACK*

MARIA DOMENICA DI BENEDETTO† AND ALBERTO ISIDORI†

Abstract. It is well known that, for linear systems, the model matching problem is equivalent to a disturbance decoupling problem with disturbance measurement. The solution of both problems can be expressed in terms of properties of invariant subspaces of the system and of the model.

In this paper, it is shown that, for nonlinear systems, under appropriate hypotheses, analogous results can be obtained. The solvability of a model matching problem can be expressed in terms of properties of suitable invariant distributions. It is also shown that, as for linear systems, those properties are related to the so-called "structures at infinity" of the system and of the model.

Key words. nonlinear control systems, model matching, dynamic state feedback

AMS(MOS) subject classifications. 93, also 93B, 93C

1. Introduction. In this paper we investigate the problem of designing, for a nonlinear system, a compensating control such that the resulting input-output behavior exactly matches that of a prespecified nonlinear model.

The problem of compensating a linear multivariable system in order to match a prescribed linear model has been solved in different forms by several authors in the last decades. Moore and Silverman [1] gave a solution based on the use of Silverman's structure algorithm [2]. Morse [3] used geometric concepts and proposed a solution which involves the construction of a suitable controllability subspace. Later, Morse [4] and Emre and Hautus [5] pointed out the equivalence between model matching and disturbance decoupling. Recently, Malabre [6] showed that the conditions found by Morse in [3] may be expressed as the equality of suitable "structures at infinity."

More recently, the problem of compensating a nonlinear system in order to obtain a linear input-output behavior has been investigated in [7], [8]. In particular, a solution to the problem of matching a prescribed linear model has been found [8], which somehow extends the one proposed by Silverman.

In a recent paper [9], the problem of matching a nonlinear model is set, by definition, as a disturbance decoupling problem. The corresponding solution may thus be found in terms of earlier results on nonlinear decoupling (see e.g. [11]). A similar approach is followed in [10].

In this paper we investigate the nonlinear version of Morse's approach. For this purpose, we make extensive use of the differential geometric concepts introduced in [11]. We also discuss the nonlinear version of Malabre's results, using the recent Nijmeijer and Schumacher's definition for the "structure at infinity" of a nonlinear system [12].

2. Problem statement. Consider a fixed nonlinear *plant P*, described by equations of the form

$$\dot{x} = f(x) + g(x)u, \tag{2.1a}$$

$$y = h(x), \tag{2.1b}$$

* Received by the editors March 4, 1985, and in revised form July 26, 1985. Portions of this paper appear in The 23rd IEEE Conference on Decision and Control, December 12-14, 1984, Las Vegas, Nevada, pp. 416-420.

† Department of Systems and Computer Science, University of Rome "La Sapienza", Rome, Italy.

with state $x \in X \subset \mathbb{R}^n$, input $u \in \mathbb{R}^m$ and output $y \in \mathbb{R}^p$. f and the m columns $g_1, \cdots, g_m$ of the matrix g are real analytic vector fields on $\mathbb{R}^n$ and h is a real analytic function.

In addition, suppose a *model* M is given, described by equations of the form

$$\dot{x}_M = f_M(x_M) + g_M(x_M)u_M, \tag{2.2a}$$

$$y_M = h_M(x_M), \tag{2.2b}$$

with state $x_M \in X_M \subset \mathbb{R}^{n_M}$, input $u_M \in \mathbb{R}^{m_M}$ and output $y_M \in \mathbb{R}^p$, and real analytic f_M, g_M, h_M. The problem of interest is to find a compensator Q for the plant P so that the resulting closed loop system displays the same input-output behavior as the model M.

The compensator Q used to control P consists of a dynamical system with inputs x and u_M and output u, described by equations of the form:

$$\dot{z} = a(z, x) + b(z, x)u_M, \tag{2.3a}$$

$$u = c(z, x) + d(z, x)u_M, \tag{2.3b}$$

with state $z \in Z \subset \mathbb{R}^\nu$ and real analytic a, b, c, d. The composition $P \circ Q$ of (2.1) and (2.3) is clearly a new dynamical system with the same structure as (2.1).

In the case of linear systems, the objective of model matching synthesis is to design a compensator such as to impose the coincidence between the transfer function of the model and that of the compensated plant. In the case of nonlinear systems, where the input-output behavior is usually described in terms of Volterra series expansions, the object of the model matching is to impose the coincidence of the associated Volterra kernels.

To be precise, let us recall that the output $y(t)$ of any nonlinear system of the form (2.1) may be expanded as

$$y(t) = w_0(t, x) + \sum_{i=1}^{m} \int_0^t w_i(t, \tau_1, x)u_i(\tau_1)\, d\tau_1 + \sum_{i_1, i_2 = 1}^{m} \int_0^t \int_0^{\tau_1} w_{i_1 i_2}(t, \tau_1, \tau_2, x)u_{i_1}(\tau_1)u_{i_2}(\tau_2)\, d\tau_1\, d\tau_2 + \cdots$$

where x is the initial state at time $t = 0$. Let $w^M_{j_1 \cdots j_i}(t, \tau_1, \cdots, \tau_i, x_M)$ denote the $(j_1 \cdots j_i)$th kernel of model M and $w^{P \circ Q}_{j_1 \cdots j_i}(t, \tau_1, \cdots, \tau_i, (x, z))$ the $(j_1 \cdots j_i)$th kernel of the compensated plant $P \circ Q$. Since $w^M_{j_1 \cdots j_i}$ depends on the initial state x_M of M and $w^{P \circ Q}_{j_1 \cdots j_i}$ on the initial state (x, z) of $P \circ Q$, when imposing the coincidence between these kernels one must specify how x_M and (x, z) are chosen. Depending on this choice, one may formulate different matching problems.

In what follows, we ask the solution Q of the model matching problem to be such that for each initial state x of P and each initial state x_M of M, there exists an initial state z of Q with the property that the Volterra kernels $w^M_{j_1 \cdots j_i}$, evaluated at x_M, and $w^{P \circ Q}_{j_1 \cdots j_i}$, evaluated at (x, z), coincide, for all $i \geqq 1$ and $1 \leqq j_i \leqq m_M$. In other words, each input-output behavior of the model is reproduced from any initial state of the process, provided that the compensator is set in a suitable initial state. Note that we are not requiring the "zero-input" terms w_0^M and $w_0^{P \circ Q}$ to be the same, thus following a practice in use for the linear model matching problem.

In general a global solution (i.e. with a, b, c, d defined on the whole $Z \times X$) may be hard to find. So we restrict ourselves to local solutions, i.e. defined on an open subset of $Z \times X$. In this way we arrive at the following formal statement.

Nonlinear model matching problem (MMP). Given a plant $P = (f, g, h)$, a model $M = (f_M, g_M, h_M)$ and a point $(x^0, x^0_M) \in X \times X_M \subset \mathbb{R}^n \times \mathbb{R}^{n_M}$, find neighborhoods U of

x^0 and U_M of x_M^0, an integer ν, an open subset V of $Z \subset \mathbb{R}^\nu$, a compensator $Q = (a, b, c, d)$ with a, b, c, d real analytic functions defined on $V \times U$, a map $F: U \times U_M \to V$, with the property that

$$w_{j_1 \cdots j_i}^{P \circ Q}(t, \tau_1, \cdots, \tau_i, (x, F(x, x_M))) = w_{j_1 \cdots j_i}^{M}(t, \tau_1, \cdots, \tau_i, x_M)$$

for all $i \geqq 1$, for all $1 \leqq j_i \leqq m_M$ and for all (x, x_M) in $U \times U_M$.

3. An associated disturbance decoupling problem. In this section, we show that the existence of a solution of a given model matching problem is implied by that of a suitable associated disturbance decoupling problem. To this end, we recall that for a nonlinear system of the form

$$\dot{\hat{x}} = \hat{f}(\hat{x}) + \hat{g}(\hat{x})\hat{u} + \hat{p}(\hat{x})\hat{w}, \qquad \hat{y} = \hat{h}(\hat{x}), \tag{3.1}$$

with input $\hat{u}$, disturbance $\hat{w}$ and output $\hat{y}$, the *disturbance decoupling problem with disturbance measurement* is defined in the following way: given a plant $\hat{P} = (\hat{f}, \hat{g}, \hat{h})$, a point $\hat{x}^0$, find a neighborhood $\hat{U}$ of $\hat{x}^0$ and a pair of real analytic functions $\hat{\alpha}$ and $\hat{\gamma}$ defined on $\hat{U}$, with the property that the control law

$$\hat{u} = \hat{\alpha}(\hat{x}) + \hat{\gamma}(\hat{x})\hat{w} \tag{3.2}$$

decouples the output $\hat{y}$ from the disturbance $\hat{w}$. Note that this control mode includes feedback on the state $\hat{x}$ and feedforward on the disturbance $\hat{w}$.

It is known [11] that the disturbance $\hat{w}$ does not influence the output $\hat{y}$ of the composite system (3.1)-(3.2), for every initial state in $\hat{U}$, if and only if the functions $\hat{\alpha}$ and $\hat{\gamma}$ are such as to make the conditions

$$L_{(\hat{g}\hat{\gamma}+\hat{p})} L_{(\hat{f}+\hat{g}\hat{\alpha})}^k \hat{h}(\hat{x}) = 0 \tag{3.3}$$

satisfied for all $\hat{x} \in \hat{U}$ and for all $k \geqq 0$. As a matter of fact, if and only if these conditions are satisfied, the Volterra series expansion of $\hat{y}$ in the composite system (3.1)-(3.2) reduces to the "zero-input" term alone.

In what follows we associate with a given model matching problem a disturbance decoupling problem with disturbance measurement (abbreviated ADDPdm) in this way. We set in (3.1)

$$\hat{x} = (x, x_M), \quad \hat{u} = u, \quad \hat{w} = u_M,$$

and

$$\hat{f}(\hat{x}) = \begin{pmatrix} f(x) \\ f_M(x_M) \end{pmatrix}, \quad \hat{g}(\hat{x}) = \begin{pmatrix} g(x) \\ 0 \end{pmatrix}, \quad \hat{p}(\hat{x}) = \begin{pmatrix} 0 \\ g_M(x_M) \end{pmatrix}, \tag{3.4a}$$

$$\hat{h}(\hat{x}) = h(x) - h_M(x_M). \tag{3.4b}$$

The following result is straightforward.

LEMMA 3.1. *A model matching problem is solvable if the associated disturbance decoupling problem with disturbance measurement is.*

Proof. Suppose the ADDPdm is solved at $\hat{x}^0 = (x^0, x_M^0)$. Then there exist α and γ defined locally around $\hat{x}^0$ such that, in the system

$$\begin{aligned} \dot{x} &= f(x) + g(x)\alpha(x, x_M) + g(x)\gamma(x, x_M)u_M, \\ \dot{x}_M &= f_M(x_M) + g_M(x_M)u_M, \\ \hat{y} &= h(x) - h_M(x_M), \end{aligned}$$

the input u_M does not influence the output $\hat{y}$ for every possible initial state (x, x_M) in

a neighborhood of (x^0, x_M^0). This means that, in the system

$$\dot{x} = f(x) + g(x)\alpha(x, x_M) + g(x)\gamma(x, x_M)u_M,$$
$$\dot{x}_M = f_M(x_M) + g_M(x_M)u_M,$$
$$y = h(x),$$

initialized at (x, x_M), the output $h(x(t))$ equals the output $h_M(x_M(t))$ of the model initialized at x_M, modulo a "zero-input" term.

The last system can be viewed as the process P, initialized at x, composed with a controller Q defined by the equations

$$\dot{z} = f_M(z) + g_M(z)u_M,$$
$$u = \alpha(x, z) + \gamma(x, z)u_M,$$

initialized at $z = x_M$. □

4. Main results. In what follows the possibility of solving a MMP will be expressed in terms of properties of certain (f, g)-invariant distributions.

For convenience, we summarize hereafter some basic facts about nonlinear geometric control theory and we quote, without proof, a series of properties of interest (see [11] for details). We recall that, for the control system (2.1), a distribution Δ is said to be (f, g)-invariant (or controlled invariant) if there exists a nonlinear feedback $u = \alpha(x) + \beta(x)v$, where α and β are defined on X, such that the modified dynamics

$$\dot{x} = f(x) + g(x)\alpha(x) + g(x)\beta(x)v$$

leaves Δ invariant, i.e. such that

$$[f + g\alpha, \Delta](x) \subset \Delta(x), \tag{4.1a}$$

$$[(g\beta)_i, \Delta](x) \subset \Delta(x) \quad \text{for all } 1 \leqq i \leqq m, \tag{4.1b}$$

for all $x \in X$. Conditions (4.1) are sometimes abbreviated as

$$[f + g\alpha, \Delta] \subset \Delta,$$
$$[g\beta, \Delta] \subset \Delta.$$

It is known that, if β is nonsingular,

$$[f, \Delta] \subset \Delta + \mathcal{G}, \tag{4.2a}$$

$$[g, \Delta] \subset \Delta + \mathcal{G}, \tag{4.2b}$$

where $\mathcal{G}$ denotes the distribution

$$\mathcal{G} = \text{span}\{g_1, \cdots, g_m\}.$$

Conversely, if Δ is an involutive distribution of constant dimension and also $\mathcal{G}$ and $\Delta + \mathcal{G}$ have constant dimension, then (4.2) imply the existence of *local* feedback functions α and β such that (4.1) are satisfied.

Let dh denote the codistribution spanned by the differentials of the entries of h, i.e.

$$dh = \text{span}\{dh_1, \cdots, dh_p\}.$$

Moreover, let $\mathbb{I}(f, g, (dh)^\perp)$ denote the class of all distributions satisfying (4.2) and contained in $(dh)^\perp$ and Δ^* its unique maximal element.

The computation of Δ^* is usually performed by means of the so-called Controlled Invariant Distribution Algorithm. With the triplet (f, g, h) one associates a sequence of codistributions defined in the following way:

$$\Omega_0 = dh,$$
$$\Omega_k = \Omega_{k-1} + L_f(\Omega_{k-1} \cap \mathcal{G}^\perp) + \sum_{i=1}^{m} L_{g_i}(\Omega_{k-1} \cap \mathcal{G}^\perp). \tag{4.3}$$

This sequence is clearly increasing and, if $\Omega_{k^*} = \Omega_{k^*+1}$ for some k^*, then $\Omega_k = \Omega_{k^*}$ for all $k > k^*$.

For practical purposes, we shall henceforth assume that the codistributions involved in this algorithm have constant dimension around the point of interest x^0. More precisely, we say that the point x^0 is a *regular point* for the algorithm (2.1) if for all x in a neighborhood of x^0:

(i) the dimension of $\mathcal{G}$ is constant,

(ii) the dimension of Ω_k is constant, for all $k \geqq 0$,

(iii) the dimension of $(\Omega_k \cap \mathcal{G}^\perp)$ is constant, for all $k \geqq 0$.

Note that if x^0 is a regular point for the algorithm (4.3), then there exists an integer $k^* < n$ such that $\Omega_{k^*} = \Omega_{k^*+1}$ and this, as we have seen, implies the convergence of the algorithm (4.3), in a neighborhood of x^0, in a finite number of steps. Moreover, (see [11])

$$\Delta^* = \Omega_{k^*}^\perp.$$

If x^0 is a regular point for the algorithm (4.3), the codistributions Ω_k, for all $k \geqq 0$, are spanned by exact one-forms and, in particular, Δ^* is involutive. The one-forms spanning Ω_k can be recursively computed via an algorithm proposed by Krener [14] and described in the Appendix.

We may now return to the model matching problem. In the following statement, for $\hat{f}$, $\hat{g}$, $\hat{p}$ and $\hat{h}$ we mean the vector fields and the function defined on the right-hand side of (3.4a) and (3.4b), and we set

$$\hat{\mathcal{P}} = \text{span}\{\hat{p}_1, \cdots, \hat{p}_{m_M}\}.$$

THEOREM 4.1. *Let (x^0, x_M^0) be a regular point for the algorithm* (4.3) *for the triplet $(\hat{f}, \hat{g}, \hat{h})$. Let $\hat{\Delta}^*$ be the unique maximal element of $\mathbb{I}(\hat{f}, \hat{g}, (d\hat{h})^\perp)$. If*

$$\hat{\mathcal{P}} \subset \hat{\Delta}^* + \hat{\mathcal{G}} \tag{4.4}$$

in a neighborhood of (x^0, x_M^0), then the MMP *is solvable.*

Proof. As a consequence of the assumptions, the distribution $\hat{\Delta}^*$ is such that:

(i) $\hat{\Delta}^* \subset (d\hat{h})^\perp$;

and, locally around (x^0, x_M^0),

(ii) there exists a function $\hat{\alpha}$ such that:

$$[\hat{f} + \hat{g}\hat{\alpha}, \hat{\Delta}^*] \subset \hat{\Delta}^*;$$

(iii) there exists a function $\hat{\gamma}$ such that:

$$\hat{g}\hat{\gamma} + \hat{p} \in \hat{\Delta}^*$$

(because of (4.4)).

The existence of a distribution which satisfies (i), (ii) and (iii) proves that the conditions (3.3) are satisfied. Then, as a consequence of Lemma 3.1, the result follows. □

In the case of linear systems the condition expressed by this theorem is also necessary for the solvability of an MMP. In the present case of nonlinear systems the proof of the necessity requires some further assumption. As we shall see later on, this is essentially due to the fact that, for nonlinear systems, the invariance condition (4.1a) *alone* does not imply (4.2a) and (4.2b).

In order to proceed with the proof of necessity of (4.4), we introduce some other notations. With the plant P and the model M we associate, in addition to the system (3.4), the system

$$\dot{x}^E = f^E(x^E) + g^E(x^E)u^E, \qquad y^E = h^E(x^E),$$

where $x^E = \hat{x}$ and

$$f^E = \hat{f}, \quad g^E = (\hat{g} \quad \hat{p}), \quad h^E = \hat{h}.$$

Moreover, we consider also a *dynamic extension* of the latter, defined by

$$\dot{\bar{x}} = \bar{f}(\bar{x}) + \bar{g}(\bar{x})\bar{u}, \qquad \bar{y} = \bar{h}(\bar{x}), \tag{4.5}$$

where $\bar{x} = (x^E, z)$,

$$\bar{f}(\bar{x}) = \begin{pmatrix} f^E(x^E) \\ 0 \end{pmatrix}, \quad \bar{g}(\bar{x}) = \begin{pmatrix} g^E(x^E) & 0 \\ 0 & I \end{pmatrix}, \quad \bar{h}(\bar{x}) = h^E(x^E),$$

and $\dim(z) = \nu$. Note that this new system is completely specified by the triplet (f^E, g^E, h^E), which incorporates all the data of the MMP, and by the integer ν.

It is easy to see that the *difference* between the output of the composed system $P \circ Q$ and that of the model M may be interpreted as the output of the system (4.5) subject to a static state-feedback of the form

$$\bar{u} = \bar{\alpha}(\bar{x}) + \bar{\beta}(\bar{x})u_M$$

with

$$\bar{\alpha}(\bar{x}) = \begin{pmatrix} c(z, x) \\ 0 \\ a(z, x) \end{pmatrix}, \qquad \bar{\beta}(\bar{x}) = \begin{pmatrix} d(z, x) \\ I \\ b(z, x) \end{pmatrix}.$$

Thus, if the controller Q solves the MMP, the above feedback is such as to make the output $\bar{y}$ of the system

$$\begin{aligned} \dot{\bar{x}} &= \bar{f}(\bar{x}) + \bar{g}(\bar{x})\bar{\alpha}(\bar{x}) + \bar{g}(\bar{x})\bar{\beta}(\bar{x})u_M, \\ \bar{y} &= \bar{h}(\bar{x}), \end{aligned} \tag{4.6}$$

independent of u_M, whenever the initial state is chosen as

$$\bar{x} = (x, x_M, F(x, x_M)). \tag{4.7}$$

To prove a partial "converse" of Theorem 4.1, we need to consider one of the following assumptions:

(A1) The triplet (f^E, g^E, h^E) is such that, for all $\nu \geqq 1$ and for all α

$$\bigcap_{k \geqq 0} \ker dL^k_{\bar{f}+\bar{g}\alpha}\bar{h} \subset \bar{\Delta}^* \tag{4.8}$$

where $\bar{\Delta}^*$ is the maximal element of $\mathbb{I}(\bar{f}, \bar{g}, (d\bar{h})^\perp)$.

(A2) The triplet (f^E, g^E, h^E) is such that

$$\sum_{i=1}^{m+m_M} L_{g_i^E}(\Omega_k^E \cap \mathcal{G}^{E\perp}) \subset \Omega_k^E$$

for all $k \geqq 0$.

(A3) The model (f_M, g_M, h_M) is linear and the process (f, g, h) can be made linear, from an input-output point of view, via static state-feedback (see [7]).

A short comment on the relative importance of the above assumptions is in order.

LEMMA 4.2. (A3) *implies* (A2) *and* (A2) *implies* (A1).

Proof. (A3) clearly implies that (f^E, g^E, h^E) can be made linear, from an input-output point of view, via static state-feedback. This, in turn, implies (see [16])

$$\sum_{i=1}^{m+m_M} L_{g_i^E}(\Omega_k^E \cap \mathcal{G}^{E\perp}) \subset \Omega_k^E \cap \mathcal{G}^{E\perp}$$

i.e. (A2).

In order to prove that (A2) implies (A1), it is useful to note that, from the algorithm (4.3), one easily obtains

$$\bar{\Omega}_k = \Omega_k^E \times \{0\}$$

for all $k \geqq 0$. Thus, (A2) implies

$$\sum_{i=1}^{m+m_M+\nu} L_{\bar{g}_i}(\bar{\Omega}_k \cap \bar{\mathcal{G}}^{\perp}) \subset \bar{\Omega}_k.$$

This, in turn, implies (A1) (see [17]). □

The distribution Δ on the left-hand side of (4.8) is invariant under $(\bar{f} + \bar{g}\alpha)$ and contained in $(d\bar{h})^{\perp}$. As a matter of fact, it turns out to be the largest distribution invariant under $(\bar{f} + \bar{g}\alpha)$ and contained in $(d\bar{h})^{\perp}$. However, Δ does not necessarily belong to $\mathbb{I}(\bar{f}, \bar{g}, (d\bar{h})^{\perp})$ because, as we already noted, the inclusion (4.1a) alone does not imply both (4.2a) and (4.2b). For this to be true, we would need, e.g., the existence of a nonsingular matrix β such that (4.1b) holds also. In the present case, the solution of an MMP implies the existence of a distribution which is invariant under $\bar{f} + \bar{g}\bar{\alpha}$ and under $\bar{g}\bar{\beta}$, but where $\bar{\beta}$ is a singular matrix. Thus, this distribution does not necessarily belong to the class $\mathbb{I}(\bar{f}, \bar{g}, (d\bar{h})^{\perp})$. This motivates the introduction of the assumption (A1).

However, the assumption (A1) is not testable in practice because it involves a condition to be satisfied for all possible integers ν and functions α. One may wish to use the stronger assumption (A2) which is indeed testable because it involves only a property of the chain of codistributions Ω_k^E generated by means of the algorithm (4.3) for the triplet (f^E, g^E, h^E).

The assumption (A3) is even stronger but it is exactly the one considered in [8] for linear model matching. We mention it here in order to show that the result of [8] can be deduced as a special case of the more general results established in this paper.

THEOREM 4.3. *Suppose the* MMP *is solved by some controller Q. Let* (x^0, x_M^0) *be a regular point for the algorithm* (4.3) *for the triplet* (f^E, g^E, h^E). *Suppose* (A1) *holds. Then*

$$\hat{\mathcal{P}} \subset \Delta^{E*} + \hat{\mathcal{G}} \tag{4.9}$$

where Δ^{E*} *is the maximal element of* $\mathbb{I}(f^E, g^E, (dh^E)^{\perp})$.

Proof. Since, by assumption, the controller Q solves the MMP, the Volterra kernels of (4.6) vanish in the initial state (4.7). In particular, looking at the first-order kernel, this implies that

$$L_{(\bar{g}\bar{\beta})_i} L^k_{(\bar{f}+\bar{g}\bar{\alpha})} \bar{h}(x, x_M, F(x, x_M)) = 0 \tag{4.10}$$

for all $1 \leqq i \leqq m_M$, for all $k \geqq 0$ and for all $(x, x_M) \in U \times U_M$. It is immediate to see that (4.10) implies

$$(\bar{g}\bar{\beta})_i(\bar{x}) \in \bigcap_{k \geqq 0} \ker\,(dL^k_{(\bar{f}+\bar{g}\bar{\alpha})}\bar{h})(\bar{x}) \tag{4.11}$$

for all $1 \leqq i \leqq m_M$ and for all $\bar{x}$ in the subset M of $U \times U_M \times V$

$$M = \{(x, x_M, z) \in U \times U_M \times V \,|\, z = F(x, x_M)\}.$$

As a consequence of the assumption (4.8) it follows that

$$(\bar{g}\bar{\beta})_i(\bar{x}) \in \bar{\Delta}^*(\bar{x}) \tag{4.12}$$

for all $1 \leqq i \leqq m_M$ and for all $\bar{x} \in M$.

Let Q be the natural surjection of $X \times X_M \times Z$ on $X \times X_M$ and Q_* the corresponding differential. Since $\bar{\Delta}^* = \Delta^{E*} \times TZ$, we have

$$Q_* \bar{\Delta}^* = \Delta^{E*} \circ Q.$$

Moreover, from (4.12) we have also

$$Q_*(\bar{g}\bar{\beta})_i(\bar{x}) = \begin{pmatrix} g(x)d(z, x) \\ g_M(x_M) \end{pmatrix}_i \in Q_* \bar{\Delta}^*(\bar{x}) = \Delta^{E*} \circ Q(\bar{x})$$

for all $\bar{x} \in M$. Since $Q|_M$ is onto $U \times U_M$, from this condition one obtains

$$\operatorname{span}\left\{\begin{pmatrix} 0 \\ g_M \end{pmatrix}\right\} \subset \Delta^{E*} + \operatorname{span}\left\{\begin{pmatrix} g \\ 0 \end{pmatrix}\right\}$$

i.e. (see (3.4a))

$$\hat{\mathscr{P}} \subset \Delta^{E*} + \hat{\mathscr{G}}$$

and this completes the proof. □

At this point, the "necessity" of the condition (4.4) is a consequence of the following trivial result.

LEMMA 4.4. *The condition* (4.9) *implies the condition* (4.4).

Proof. Clearly

$$[\hat{f}, \Delta^{E*}] \subset \Delta^{E*} + \mathscr{G}^E = \Delta^{E*} + \hat{\mathscr{G}} + \hat{\mathscr{P}},$$
$$[\hat{g}, \Delta^{E*}] \subset \Delta^{E*} + \mathscr{G}^E = \Delta^{E*} + \hat{\mathscr{G}} + \hat{\mathscr{P}}.$$

If (4.9) holds, then

$$[\hat{f}, \Delta^{E*}] \subset \Delta^{E*} + \hat{\mathscr{G}},$$
$$[\hat{g}, \Delta^{E*}] \subset \Delta^{E*} + \hat{\mathscr{G}},$$

i.e. $\Delta^{E*} \in \mathbb{I}(\hat{f}, \hat{g}, (d\hat{h})^\perp)$. Thus $\Delta^{E*} \subset \hat{\Delta}^*$ and (4.4) follows. □

5. A link with the structure at infinity. In this section we show that the condition (4.9) may be reformulated in terms of properties of the structures at infinity of the triplet (f, g, h) and the triplet (f^E, g^E, h^E). Following Nijmeijer and Schumacher [12] the structure at infinity of a triplet (f, g, h) may be defined as the list of integers

$$r_k = \dim\,(\mathscr{G}^\perp + \Omega_k) - \dim\,(\mathscr{G}^\perp), \qquad k \geqq 0$$

where $\Omega_0, \Omega_1, \cdots, \Omega^*$ is the sequence of codistributions generated by means of the

algorithm (4.3):

$$\Omega_0 = dh,$$

$$\Omega_k = \Omega_{k-1} + \sum_{i=0}^{m} L_{g_i}(\mathscr{G}^{\perp} \cap \Omega_{k-1}),$$

where $g_0 := f$.

In the same way, one can define a list of integers r_k^E, $k \geqq 0$, as the structure at infinity of the triplet (f^E, g^E, h^E), by considering the sequence

$$\Omega_0^E = dh^E,$$

$$\Omega_k^E = \Omega_{k-1}^E + \sum_{i=0}^{m+m_M} L_{g_i^E}(\mathscr{G}^{E\perp} \cap \Omega_{k-1}^E),$$

where $g_0^E := f^E$, and setting

$$r_k^E = \dim(\mathscr{G}^{E\perp} + \Omega_k^E) - \dim(\mathscr{G}^{E\perp}), \qquad k \geqq 0.$$

Clearly, these definitions make sense under the assumption that all the codistributions involved have constant dimension. We shall thus always assume, in what follows, that the point x^0 and the point (x^0, x_M^0) are regular points.

The following statement extends a recent result by Malabre [6].

THEOREM 5.1. *Suppose the sequence r_k and r_k^E, $k \geqq 0$, are defined. The condition* (4.9) *is satisfied if and only if*

$$r_k = r_k^E \tag{5.1}$$

for all $k \geqq 0$.

Proof. Recall that $\Delta^{E*} = (\Omega^{E*})^{\perp}$, so the condition (4.9) may be rewritten as

$$\hat{\mathscr{P}}^{\perp} \supset \Omega^{E*} \cap \hat{\mathscr{G}}^{\perp}. \tag{5.2}$$

Since the sequence of the Ω_k's is nondecreasing, (5.2) is equivalent to

$$\hat{\mathscr{P}}^{\perp} \supset \Omega_k^E \cap \hat{\mathscr{G}}^{\perp} \quad \text{for all } k \geqq 0. \tag{5.3}$$

This, in turn, is equivalent to

$$\hat{\mathscr{G}}^{\perp} \cap \Omega_k^E = \mathscr{G}^{E\perp} \cap \Omega_k^E \quad \text{for all } k \geqq 0 \tag{5.4}$$

because $\hat{\mathscr{G}}^{\perp} \cap \hat{\mathscr{P}}^{\perp} = \mathscr{G}^{E\perp}$.

Therefore, what we need is to prove the necessity and sufficiency of (5.4). To this end, we need a preliminary result. In what follows, we identify the Ω_k with codistributions on $X \times X_M$ (by taking, at $(x, x_M) \in X \times X_M$, the subspace of $T_x^*X \times T_{x_M}^*X_M$ spanned by the pairs $(\omega, 0)$ with $\omega \in \Omega_k(x)$). It is easy to realize that the above codistributions satisfy the recursions:

$$\Omega_0' = dh \times \{0\},$$

$$\Omega_k' = \Omega_{k-1}' + \sum_{i=0}^{m} L_{\hat{g}_i}(\mathscr{G}^{\perp} \cap \Omega_{k-1}'),$$

where $\hat{g}_0 := \binom{f}{0}$.

Moreover, let Γ denote a codistribution on $X \times X_M$ defined by taking

$$\Gamma(x, x_M) = \{0\} \times T_{x_M}^* X_M.$$

These objects will be used in the sequel.

LEMMA 5.2. *If, for some* $k \geqq 0$,

$$\hat{\mathcal{G}}^{\perp} \cap \Omega_k^E = \mathcal{G}^{E\perp} \cap \Omega_k^E \tag{5.5}$$

and

$$\Omega'_k = \Omega_k^E \qquad (\text{mod } \Gamma) \tag{5.6}$$

then

$$\Omega'_{k+1} = \Omega_{k+1}^E \qquad (\text{mod } \Gamma). \tag{5.7}$$

Proof. By definition, the codistributions Ω'_k defined by the algorithm (4.3) are locally spanned by one-forms which do not depend on x_M. Clearly $\hat{\mathcal{G}}^{\perp}$ is spanned by one-forms which do not depend on x_M. Thus $\hat{\mathcal{G}}^{\perp} \cap \Omega'_k$, for $k \geqq 0$, has the same property.

Moreover, since $\Gamma \subset \hat{\mathcal{G}}^{\perp}$, from (5.6) we get

$$\hat{\mathcal{G}}^{\perp} \cap \Omega'_k + \Gamma = \hat{\mathcal{G}}^{\perp} \cap (\Omega'_k + \Gamma) = \hat{\mathcal{G}}^{\perp} \cap (\Omega_k^E + \Gamma) = \hat{\mathcal{G}}^{\perp} \cap \Omega_k^E + \Gamma. \tag{5.8}$$

Thus

$$\begin{aligned}
\Omega'_{k+1} + \Gamma &= \Omega'_k + \sum_{i=0}^{m} L_{\hat{g}_i}(\hat{\mathcal{G}}^{\perp} \cap \Omega'_k) + \Gamma \\
&= \Omega'_k + \sum_{i=0}^{m+m_M} L_{g_i^E}(\hat{\mathcal{G}}^{\perp} \cap \Omega'_k) + \Gamma \\
&= \Omega'_k + \sum_{i=0}^{m+m_M} L_{g_i^E}(\hat{\mathcal{G}}^{\perp} \cap \Omega'_k + \Gamma) + \Gamma \\
&= \Omega'_k + \sum_{i=0}^{m+m_M} L_{g_i^E}(\hat{\mathcal{G}}^{\perp} \cap \Omega_k^E + \Gamma) + \Gamma \quad \text{by (5.8)} \\
&= \Omega'_k + \sum_{i=0}^{m+m_M} L_{g_i^E}(\mathcal{G}^{E\perp} \cap \Omega_k^E + \Gamma) + \Gamma \quad \text{by (5.5)} \\
&= \Omega'_k + \sum_{i=0}^{m+m_M} L_{g_i^E}(\mathcal{G}^{E\perp} \cap \Omega_k^E) + \Gamma \\
&= \Omega_k^E + \sum_{i=0}^{m+m_M} L_{g_i^E}(\mathcal{G}^{E\perp} \cap \Omega_k^E) + \Gamma = \Omega_{k+1}^E + \Gamma \quad \text{by (5.6).}
\end{aligned}$$

This concludes the proof of the lemma. □

At this point it is possible to show that $r_k = r_k^E$, for all $k \geqq 0$, if and only if (5.4) is true, thus concluding the proof of the theorem.

(if). Note that (5.6) is true for $k = 0$. Then, since (5.5) is true for all $k \geqq 0$, (5.6) holds for all $k > 0$. As a consequence, since $\Gamma \subset \hat{\mathcal{G}}^{\perp}$,

$$\hat{\mathcal{G}}^{\perp} + \Omega'_k = \hat{\mathcal{G}}^{\perp} + \Omega'_k + \Gamma = \hat{\mathcal{G}}^{\perp} + \Omega_k^E + \Gamma = \hat{\mathcal{G}}^{\perp} + \Omega_k^E \tag{5.9}$$

for all $k \geqq 0$. It follows that

$$\begin{aligned}
r_k &= \dim (\Omega'_k + \hat{\mathcal{G}}^{\perp}) - \dim \hat{\mathcal{G}}^{\perp} \\
&= \dim (\Omega_k^E + \hat{\mathcal{G}}^{\perp}) - \dim \hat{\mathcal{G}}^{\perp} \qquad \text{(by (5.9))} \\
&= \dim \Omega_k^E - \dim (\Omega_k^E \cap \hat{\mathcal{G}}^{\perp}) \\
&= \dim \Omega_k^E - \dim (\Omega_k^E \cap \hat{\mathcal{G}}^{E\perp}) \\
&= r_k^E
\end{aligned}$$

(only if). Note that the equality $r_k = r_k^E$ may be rewritten

$$\dim (\Omega_k' + \hat{\mathcal{G}}^\perp) - \dim \hat{\mathcal{G}}^\perp = \dim (\Omega_k^E + \mathcal{G}^{E\perp}) - \dim \mathcal{G}^{E\perp}.$$

Suppose that (5.6) is true for some k. Then the following implications hold:

$$\begin{aligned}
\Omega_k' = \Omega_k^E (\text{mod } \Gamma) &\Rightarrow \Omega_k' + \hat{\mathcal{G}}^\perp = \Omega_k^E + \hat{\mathcal{G}}^\perp \quad (\text{since } \Gamma \subset \hat{\mathcal{G}}^\perp) \\
&\Rightarrow \dim (\Omega_k^E + \hat{\mathcal{G}}^\perp) - \dim \hat{\mathcal{G}}^\perp = \dim (\Omega_k^E + \mathcal{G}^{E\perp}) - \dim \mathcal{G}^{E\perp} \\
&\Rightarrow \dim (\Omega_k^E \cap \hat{\mathcal{G}}^\perp) = \dim (\Omega_k^E \cap \mathcal{G}^{E\perp}) \\
&\Rightarrow \Omega_k^E \cap \hat{\mathcal{G}}^\perp = \Omega_k^E \cap \mathcal{G}^{E\perp} \quad (\text{because } \mathcal{G}^{E\perp} \subset \hat{\mathcal{G}}^\perp)
\end{aligned}$$

i.e. (5.5) for k.

Since (5.6) is true for $k = 0$, (5.5) is also true for $k = 0$. Then, by Lemma 5.2, (5.6) is true for all k. As a consequence of the previous sequence of implications, we have that (5.5) is true for all k, i.e. (5.4) is true. □

Remark 5.3. The integers r_k which characterize the structure at infinity of a nonlinear system, may be computed as the ranks of appropriate matrices obtained via the algorithm proposed by Krener for the construction of the maximal element Δ^* of $\mathbb{I}(f, g, (dh)^\perp)$ and described in the Appendix.

This algorithm makes the computation of the r_k possible as follows. Using the notations introduced in the Appendix, it is immediately seen that:

$$\dim \Omega_k = s_k.$$

It is also clear that the intersection $\mathcal{G}^\perp \cap \Omega_k$ has a dimension equal to $s_k - \rho_k$. Thus

$$r_k = \dim \Omega_k - \dim (\Omega_k \cap \mathcal{G}^\perp) = s_k - (s_k - \rho_k) = \rho_k.$$

Using those properties, in a recent paper [19], the authors have proposed a procedure for the computation of the structure at infinity on the input-output data. □

Merging Theorem 5.1 with the results of the previous section, it is seen that if the regularity assumption holds and if (A1) is satisfied, then a necessary and sufficient condition for the MMP to be solvable is that $r_k = r_k^E$, for all k. It should be stressed that the latter condition is no longer necessary whenever (A1) is removed. This is illustrated by the following example.

Example 5.4. Let $X = \mathbb{R}^4$ and

$$f(x) = \begin{pmatrix} 0 \\ x_4 \\ 0 \\ 0 \end{pmatrix}, \quad g(x) = \begin{pmatrix} x_3 & 0 \\ 0 & 1 \\ 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad h(x) = \begin{pmatrix} x_2 - x_3 \\ x_1 \end{pmatrix}. \tag{5.10}$$

Let also $X_M = \mathbb{R}^4$ and

$$f_M(x_M) = \begin{pmatrix} x_{M2} \\ 0 \\ x_{M4} \\ 0 \end{pmatrix}, \quad g_M(x_M) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad h_M(x_M) = \begin{pmatrix} x_{M1} \\ x_{M3} \end{pmatrix}.$$

An easy computation shows that

$$r_0 = 1, \qquad r_k = 2 \quad \text{for } k \geqq 1$$

and

$$r_0^E = 1, \qquad r_k^E = 3 \quad \text{for } k \geqq 1,$$

so the equality (5.1) is not met. However, the MMP is solvable by the dynamic state-feedback

$$\begin{aligned} \dot{z} &= -\frac{z^2}{z+x_3} + \frac{1}{z+x_3}(-z \;\; 1)u_M, \\ u &= \begin{pmatrix} z \\ -\dfrac{z^2}{z+x_3} \end{pmatrix} + \frac{1}{z+x_3}\begin{pmatrix} 0 & 0 \\ x_3 & 1 \end{pmatrix} u_M. \end{aligned} \tag{5.11}$$

In fact it is rather simple to compute the Volterra kernels of (5.10) composed with (5.11), which have the following expression

$$w_1^{P\circ Q}(t, \tau, (x, z)) = \begin{pmatrix} t-\tau \\ 0 \end{pmatrix}, \qquad w_2^{P\circ Q}(t, \tau, (x, z)) = \begin{pmatrix} 0 \\ t-\tau \end{pmatrix}$$

and

$$w_{j_1 \cdots j_i}^{P\circ Q}(t, \tau_1, \cdots, \tau_i, (x, z)) = 0 \quad \text{if } i > 1.$$

Thus, this shows that the MMP is solved. □

6. Concluding remarks. The purpose of this paper was to investigate the problem of designing a dynamic compensator which makes it possible to match a prescribed input-output behavior in a given nonlinear plant. A simple geometric condition, which involves the computation of a suitable maximal controlled invariant distribution, was proved to be sufficient and, in some cases, necessary for the existence of a solution to the problem. Such a condition is the nonlinear version of a similar condition established by Morse in [3]. Moreover, it was shown that the condition in question may be reexpressed in terms of an equality between the structures at infinity of the plant and of a composed system in which the model appears as a "disturbance" on the output of the plant. This extends recent results by Malabre [6].

Appendix.

Krener's algorithm. Suppose the codistribution dh has constant dimension s_0. Let $\lambda_0(x)$ be an s_0-vector whose entries are entries of h such that $d\lambda_{0,1}, \cdots, d\lambda_{0,s_0}$ are linearly independent.

Iteration $(k+1)$. Consider the $s_k \times m$ matrix $A_k(x)$ defined at iteration k whose (i,j)th entry is $\langle d\lambda_{k,i}, g_j \rangle(x)$. Suppose the rank ρ_k of $A_k(x)$ is constant. Then, there exists an $s_k \times s_k$ permutation matrix

$$P_k = \begin{pmatrix} P_{k1} \\ P_{k2} \end{pmatrix}$$

such that the ρ_k rows of $P_{k1}A_k(x)$ are linearly independent. Let $B_k(x)$ denote an s_k vector whose ith element is $\langle d\lambda_{k,i}, f \rangle(x)$. Then, the equations

$$P_{k1}A_k(x)\alpha(x) = -P_{k1}B_k(x), \tag{A.1a}$$

$$P_{k1}A_k(x)\beta(x) = K, \tag{A.1b}$$

where K is a matrix of real numbers of rank ρ_k, are solved by an m-vector α and an $m \times m$ invertible matrix β. Construct the set of functions

$$\Lambda_k = \{\lambda = L_{\tilde{g}_i}\lambda_{k,j} \,|\, 1 \leqq j \leqq s_k, 0 \leqq i \leqq m\}$$

with $\tilde{g}_0 = f + g\alpha$ and $\tilde{g} = g\beta$. Moreover, consider the codistribution

$$\operatorname{span}\{d\lambda \mid \lambda \in \Lambda_k\} + \operatorname{span}\{d\lambda_{k,j} \mid 1 \leqq j \leqq s_k\}.$$

Suppose the dimension s_{k+1} of this codistribution is constant and let

$$\{d\lambda_{k+1,1}, \cdots, d\lambda_{k+1,s_{k+1}}\}$$

be a basis for it. Then, it is possible to prove [14] that at each iteration

$$\Omega_{k+1} = \operatorname{span}\{d\lambda_{k+1,i} \mid 1 \leqq i \leqq s_{k+1}\}.$$

Moreover, there exists an integer k^* such that the algorithm terminates at the k^*th iteration (i.e. $s_{k^*+1} = s_{k^*}$) and one has:

$$\Omega^* = \operatorname{span}\{d\lambda_{k^*,i} \mid 1 \leqq i \leqq s_{k^*}\}.$$

This ends the description of the algorithm. □

ON THE SENSITIVITY MINIMIZATION PROBLEM FOR LINEAR TIME-VARYING PERIODIC SYSTEMS*

AVRAHAM FEINTUCH†, PRAMOD KHARGONEKAR‡ AND ALLEN TANNENBAUM§

Abstract. An optimal control problem is formulated in the context of linear, discrete-time, periodic systems. The cost is the supremum over all exogenous inputs in a weighted ball of plant inputs. The controller is required to be causal, periodic of the fixed order of the system and to achieve internal stability. Existence of an optimal controller is proved and a formula for the minimum cost is derived.

Key words. optimal control, periodic systems, time-varying systems, uniform optimality

AMS(MOS) classifications. 93C25, 93C50, 93C55, 47B35

1. Introduction. Since the classic paper of Zames [18] (in which he formulated a linear-quadratic optimal control problem where the exogeneous signals are not fixed but belong to weighted balls in appropriate function spaces), there has been a great deal of work on various problems of weighted sensitivity minimization.

At first the work was restricted to time-invariant systems (see [4] and [6] for a complete bibliography). Most of the results are presented in a unified fashion in [6]. Feintuch and Francis then showed that these problems can be formulated and solved for time-varying systems in a Hilbert resolution space framework and that in fact one could recover the results of the time-invariant problems as special cases of the more general time-varying problem [4]. In particular, it was shown that for time-invariant systems there is no time-varying controller which is better than an optimal time-invariant one. A special case of this result was also obtained independently by Khargonekar, Poolla and Tannenbaum [11].

While the class of linear time-varying controllers is quite large and unruly, there are certain subclasses that are quite similar in their structure to time-invariant systems and yet different enough so that for problems of robustness, they are superior to time-invariant ones. One such class is that of periodic controllers.

The importance of such systems has been noted in the work of various authors such as Davis [2], Jury and Mullin [10], and Meyer and Burrus [13].

Here we were influenced mainly by the paper of Khargonekar, Poolla and Tannenbaum [11], with one major difference. While the authors have formulated their theory in terms of transfer functions in the frequency domain, we feel that it is often (though not always) more useful to look at operator-representations of systems in the time domain. This is consistent with the approach in [4].

In this paper we formulate and solve an optimal control problem of the Zames-type for N-periodic discrete-time, time-varying systems. The existence of an optimal controller is shown and a formula is obtained for the optimal cost. Finally, it is shown that no better result can be obtained by a time-varying nonperiodic controller. The formulae we obtain of course reduce to the classical formulae obtained by Francis and Zames [7], and Francis et al. in [8] when applied to time-invariant systems.

This paper is similar both in format and spirit to [4], and in fact shows that the methods used there seem to be especially appropriate for attacking problems of this sort.

Finally, it should be noted that the results of this paper again indicate the fundamental importance of the system sensitivity function. Indeed in Khargonekar and Tannenbaum [12], it was shown that in the linear finite-dimensional time-invariant case that certain robust stabilization problems (for example, the gain margin problem, see Tannenbaum [16]) are equivalent to the sensitivity minimization problem of Zames [18]. From the results of Feintuch and Francis [4] and Khargonekar, Poolla and Tannenbaum [11], it can already be seen that in time-varying cases the analogous problem of robust design and sensitivity minimization become dichotomous. However the results of the present paper together with [4] and [11] indicate that sensitivity is a true system *invariant* in the sense that apparently sensitivity can always be minimized within a given class of systems (for example, time-invariant, periodic), and hence sensitivity must be regarded as a fundamental measure of system performance. This is of course precisely the design philosophy of [18].

2. Preliminaries. The purpose of this section is to introduce notation and definitions, and to collect some basic facts regarding linear operators and complex functions.

For an integer $n \geqq 1$, $\mathbb{C}^n$ denotes complex n-dimensional Hilbert space, the inner product of two vectors x and y being x^*y where * denotes complex conjugate transpose. The norm on $\mathbb{C}^n$ is denoted by $\|\cdot\|_2$, that is,

$$\|x\|_2 = (x^*x)^{1/2}.$$

Let $\mathbb{C}^{m\times n}$ denote the set of all $m \times n$ complex matrices. Then the norm on $\mathbb{C}^{m\times n}$, $\|\cdot\|_\infty$, is taken to be that induced by the one on $\mathbb{C}^n$, that is,

$$\|A\|_\infty = \sup\{\|Ax\|_2 : \|x\|_2 \leqq 1\}.$$

The set of all sequences $\{x_k : k \geqq 0\}$ in $\mathbb{C}^n$ is denoted by $\mathcal{A}(\mathbb{C}^n)$. In discussions where the integer n is immaterial, $\mathcal{A}(\mathbb{C}^n)$ will be shortened to $\mathcal{A}$. The subset of $\mathcal{A}(\mathbb{C}^n)$ of all square-summable sequences is denoted by $h_2(\mathbb{C}^n)$, or simply by h_2; that is, $\{x_k\} \in h_2$ if and only if

$$\sum_{k=0}^{\infty} \|x_k\|_2^2 < \infty.$$

Then h_2 is a Hilbert space under the inner product

$$\langle\{x_k\}, \{y_k\}\rangle = \sum x_k^* y_k.$$

The induced norm on h_2 is also denoted by $\|\cdot\|_2$.

Let $F : \mathcal{A}(\mathbb{C}^n) \to \mathcal{A}(\mathbb{C}^n)$ be a linear mapping. Then F has a natural matrix representation $(F_{ij} : i \geqq 0, j \geqq 0)$; $F_{ij} \in \mathbb{C}^{n\times m}$, defined by the equation

$$F\{0, \cdots, 0, x_i 0, \cdots\} = \{F_{0i}x_i, F_{1i}x_i, \cdots\}.$$

The operator F is termed *causal*, *strictly causal* or *time-invariant* if its matrix is lower block triangular, strictly lower block triangular, or constant along block diagonals, respectively.

The Banach space of bounded linear operators from $h_2(\mathbb{C}^m)$ to $h_2(\mathbb{C}^n)$ is denoted by $\mathcal{B}[h_2(\mathbb{C}^m), h_2(\mathbb{C}^n)]$ or simple $\mathcal{B}$. The subspaces of $\mathcal{B}$ of causal operators and of time-invariant operators are denoted by $\mathcal{C}$ and $\mathcal{T}$, respectively, and if $m = n$ these are in fact weakly closed subalgebras of $\mathcal{B}$ [5].

For frequency domain theory, we need some notation and facts concerning complex functions. The space of square-integrable functions defined on the unit circle and taking values in $\mathbb{C}^n$ is denoted by $L_2(\mathbb{C}^n)$ or simply by L_2. The closed subspace of L_2 of functions having analytic continuations into the unit disc is the Hardy space H_2. Its orthogonal complement is denoted by $H_2^{\perp}$. The *inner product* of f and g in L_2 is defined to be

$$(2\pi)^{-1}\int_0^{2\pi} f(e^{i\theta})^* g(e^{i\theta})\, d\theta$$

and the corresponding norm is denoted (also) by $\|\cdot\|_2$. It is a standard fact in the theory of Fourier series that h_2 and H_2 are isomorphic Hilbert spaces.

The set of essentially bounded functions defined on the unit circle and taking values in $\mathbb{C}^{m\times n}$ is denoted by $L_\infty(\mathbb{C}^{m\times n})$ or L_∞. The norm on L_∞ is one induced by that on L_2: For F in $L_\infty(\mathbb{C}^{m\times n})$,

$$\|F\|_\infty := \sup\{\|Fg\|_2 : g\in L_2, \|g\|_2 \leqq 1\}.$$

It can be proved that

$$\|F\|_\infty = \operatorname{ess\,sup}\{\|F(e^{i\theta})\|_\infty : \theta\in[0,2\pi]\}$$

the right-hand norm being the one on $\mathbb{C}^{m\times n}$. We then set H_∞ to be the subset of L_∞ consisting of matrices having analytic continuations into the unit disc.

There is a clear connection between operators which act in the time domain and complex functions in the frequency domain. If F is a time-invariant bounded linear operator on h_2, the matrix of F has the Toeplitz form

$$\begin{bmatrix} F_0 & F_{-1} & F_{-2} & \cdots \\ F_1 & F_0 & F_{-1} & \cdots \\ F_2 & F_1 & F_0 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}.$$

Define the transfer function of F to be $\mathring{F}(e^{i\theta}) := \sum_{-\infty}^{\infty} F_k e^{ki\theta}$. It is a standard fact that $\mathring{F}\in L_\infty$ and $\|F\| = \|\mathring{F}\|_\infty$. If $F\in\mathscr{C}\cap\mathscr{T}$ then the above matrix of F is lower block triangular and $\mathring{F}\in H_\infty$. By slight abuse of notation, we will many times identify F and $\mathring{F}$.

3. Periodic operators. Let Λ denote the right shift operator on $\mathscr{A}(\mathbb{C}^n)$; if

$$x=\{x_k\}\in\mathscr{A}(\mathbb{C}^n),\ \Lambda x = y \quad \text{where } y_0=0,\ y_i = x_{i-1},\ i\geqq 1.$$

DEFINITION 3.1. $T\in\mathscr{C}$ is N-periodic if $T\Lambda^N = \Lambda^N T$.

The fundamental properties of these operators were presented in [11] following the approach in [15]. Here we rework these facts in the time domain. We will present these results for 2-periodic operators in order to simplify notation. *All the results go through immediately for N-periodic operators for* $N>2$. The space of N-periodic operators on h_2 will be denoted by $\mathscr{P}_N$, and in particular the space of 2-periodic operators by $\mathscr{P}_2$.

It is easily checked that the block matrix representation of $T\in\mathscr{P}_2\cap\mathscr{C}$ is of the form

$$\begin{bmatrix} x_0 & 0 & 0 & \cdots \\ x_1 & y_0 & 0 & \cdots \\ x_2 & y_1 & x_0 & \cdots \\ x_3 & y_2 & x_1 & \\ \vdots & \vdots & \vdots & \end{bmatrix},$$

that is, T is determined by two sequences of "Fourier coefficients." As was shown in [11], there is an isometric isomorphism W of h_2 onto $h_2 \oplus h_2 \cong h_2(\mathbb{C}^{2n})$ which has the property that if $\tilde{T} = WTM^{-1} = WTW^*$, then $\tilde{T}\tilde{\Lambda} = \tilde{\Lambda}\tilde{T}$ where $\tilde{\Lambda}$ is the right shift on $h_2(\mathbb{C}^{2n}) = h_2 \oplus h_2$. The matrix representation of $\tilde{T}$ on $h_2(\mathbb{C}^{2n})$ is simply the Toeplitz of the form

$$\begin{bmatrix} T_0 & 0 & \cdots \\ T_1 & T_0 & \cdots \\ T_2 & T_1 & \cdots \\ \vdots & \vdots & \end{bmatrix},$$

where T_i is the 2×2 block matrix given by

$$T_i := \begin{bmatrix} x_{2i} & y_{2i-1} \\ x_{2i+1} & y_{2i} \end{bmatrix}$$

where y_{-1} is understood to be zero. In particular, T_0 is lower triangular and it is easy to see that for $A \in \mathcal{T} \cap \mathcal{C}$ on $h_2(\mathbb{C}^{2n})$, $A = \tilde{T}$ for some $T \in \mathcal{P}_2 \cap \mathcal{C}$ on $h_2(\mathbb{C}^n)$ if and only if A_0 is lower triangular.

If we look at $\tilde{T}$ from the frequency domain point of view, then $\tilde{T} \in H_\infty$ and the matrix-valued functions in H_∞ which correspond to 2-periodic operators are those $A \in H_\infty$ for which $A(0)$ is lower triangular.

For the general N-periodic case, a similar computation to that given above (see [11, (2.6)] for details) shows that with any m-input p-output, N-periodic linear time-varying causal input/output map f, one can canonically associate a $pN \times mN$ transfer function matrix T_f such that $T_f(0)$ is lower triangular. Conversely, any $pN \times mN$ transfer function matrix T_f such that $T_f(0)$ is lower triangular, defines an m-input, p-output, N-periodic linear time-varying causal input/output map f. We should emphasize the fact that it is the lower triangularity of $T_f(0)$ that corresponds to the *causality* of f.

Finally we recall that since W is unitary, the correspondence between T and $\tilde{T}$ is norm preserving, and is an isometric isomorphism between the weakly closed subalgebra $\mathcal{P}_2 \cap \mathcal{C}$ of $\mathcal{C}$ and its image, the weakly closed subalgebra of H_∞ consisting of functions which are lower triangular matrices at the origin.

4. Factorizations. There are two kinds of factorizations that play a role in the theory of minimum sensitivity, one being technical and the other fundamental to the nature of the problem being solved. The first is the inner-outer factorization of functions in H_∞ and the second is the coprime factorization of systems used in the Youla stabilization theory.

Since periodic operators have representations as H_∞ functions, we can obtain both types of factorizations (under the appropriate assumptions [3], [6], [17]) in H_∞. However for such factorizations to be useful it must be shown that the factors correspond to periodic systems; that is, that they are lower triangular at the origin.

THEOREM 4.1. *Suppose $P \in H_\infty$, and that $P(0)$ is lower triangular. Then*

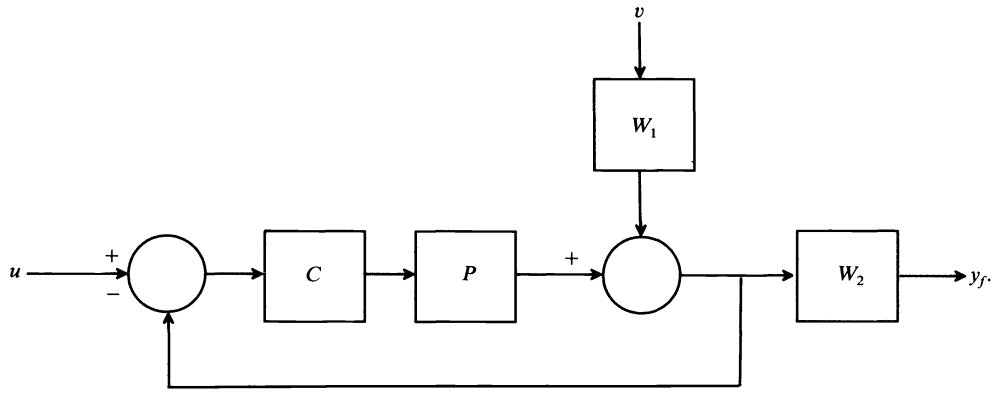
(1) *If P has a left (or right) coprime factorization in H_∞, the factors can be chosen so that they are lower triangular at the origin.*

(2) *P has an inner-outer factorization $P = P_i P_0$ such that $P_i(0)$ and $P_0(0)$ are lower triangular.*

Proof. For (1) suppose $P = AB^{-1}$ where $A, B \in H_\infty$. If $B(0)$ is not lower triangular there exists a constant invertible square matrix F (of appropriate dimension) such that $B(0)F$ is lower triangular. Then $P = (AF)(F^{-1}B^{-1})$, and $AF = PBF$ has the property that $(AF)(0)$ is lower triangular since $P(0)$ and $(BF)(0)$ are lower triangular.

For (2) note that if $P_i P_0$ is an inner-outer factorization for P, there exists a constant unitary matrix U such that $(UP_0)(0)$ is lower triangular. Thus $P=(P_0U^*)(UP_0)$ is an inner-outer factorization with the required properties. Q.E.D.

5. Formulation of the control problem. Consider the discrete-time linear feedback system below



Again for the sake of notational simplicity, we will assume P is a 2-periodic plant, the general N-periodic case being similar. W_1 and W_2 are stable 2-periodic operators with stable inverses (it is clear that W_i^{-1} are periodic when they are defined). We assume that P is such that in its time domain matrix representation $x_0=y_0=0$; that is, P is strictly causal. This assumption is standard and completely technical. Finally again by slight abuse of notation we will identify a time-invariant, time-domain operator F with its transfer function $\mathring{F}$ (as in § 2).

Our objective will be to design C to minimize the energy of y_f for the worst v of unit energy, C being constrained to be causal, 2-periodic and to achieve internal stability. Thus the cost is

$$\text{cost}=\sup\{\|y_f\|_2\colon v\in h_2,\ \|v\|_2\leqq 1\}.$$

In terms of the transfer matrix from v to y_f, we have

$$\text{cost}=\|W_2(I+PC)^{-1}W_1\|,$$

the induced operator norm in h_2.

Let μ denote the infimum of the cost taken over all causal 2-periodic C's achieving internal stability.

Since the family of 2-periodic operators on h_2 is a ring the parameterization of Youla et al. [6] is applicable whenever P has the appropriate right and left coprime factorizations. For example, if it is assumed that $\tilde{P}\in RH_\infty$ (:= the subspace of real-rational functions in H_∞) such factorizations exist and are computable [16], [17]. So assume $\tilde{P}$ has such factorization, and note that by Theorem 4.1 and the isometric isomorphism between $\mathscr{P}_2\cap\mathscr{C}$ and the above-mentioned subalgebra of H_∞, this gives rise to comprime factorizations in $\mathscr{P}_2\cap\mathscr{C}$. So assume $P=\hat{B}^{-1}\hat{A}=AB^{-1}$, such that

$$\hat{A}\hat{X}+\hat{B}\hat{Y}=I,\qquad XA+YB=I,$$

with A, B, $\hat{A}$, $\hat{B}$, X, Y, $\hat{X}$, $\hat{Y}\in\mathscr{P}_2\cap\mathscr{C}$. Then $C=(\hat{X}+BZ)(\hat{Y}-AZ)^{-1}$, $Z\in\mathscr{P}_2\cap\mathscr{C}$ parameterizes all controllers in $\mathscr{P}_2\cap\mathscr{C}$ achieving internal stability. With C so expressed the sensitivity matrix is affine in the parameter Z

$$(I+PC)^{-1}=(\hat{Y}-AZ)\hat{B}.$$

Thus the cost is

$$\text{cost} = \| W_2(\hat{Y} - AZ)\hat{B}W_1 \|.$$

Using the isometric isomorphism defined earlier, we rewrite this as

$$\text{cost} = \| \tilde{W}_2(\tilde{\hat{Y}} - \tilde{A}\tilde{Z})\hat{B}\tilde{W}_1 \|_\infty.$$

To simplify this further, bring in the appropriate inner-outer factorization of $\tilde{W}_2\tilde{A}$ (with periodic factors) and (under appropriate assumptions on P, [6]) an outer-inner factorization of $\tilde{\hat{B}}\tilde{W}_1$. Defining (under the assumption that $(\tilde{W}_2\tilde{A})_i$ is invertible)

$$\tilde{T} = (\tilde{W}_2\tilde{A})_i^* \tilde{W}_2 \tilde{Y}(\tilde{\hat{B}}\tilde{W}_1)_0, \qquad \tilde{V} = (\tilde{W}_2\tilde{A})_0 \tilde{Z}(\tilde{\hat{B}}\tilde{W}_1)_0$$

and using the properties of inner matrices and the assumptions on P, W_1, W_2, we obtain that

$$\text{cost} = \| \tilde{T} - \tilde{V} \|_\infty.$$

Note that $\tilde{V} \in H_\infty$ and corresponds to a periodic system $V \in \mathscr{P}_2 \cap \mathscr{C}$. $\tilde{T}$ is of course not in H_∞. However $\tilde{T} \in L^\infty$ and its periodicity property is preserved in the following way: If we apply the unitary mapping W to obtain $T = W^* \tilde{T} W$, then T has the block matrix representation

$$\begin{bmatrix} x_0 & y_{-1} & x_{-2} & \cdots \\ x_1 & y_0 & x_{-1} & \cdots \\ x_2 & y_1 & x_0 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}.$$

Thus we can write μ as

$$\mu = \inf\{\| T - V \| : V \in \mathscr{P}_2 \cap \mathscr{C}\}$$

which in topological terms is just the distance from the given noncausal 2-periodic operator T to the weakly closed subalgebra $\mathscr{P}_2 \cap \mathscr{C} \subset \mathscr{C}$. The existence of a $V \in \mathscr{P}_2 \cap \mathscr{C}$ for which μ is attained is now (as in [4] only easier) a consequence of the compactness of the unit-ball in the weak operator topology.

In the next section we obtain a formula for μ in terms of the entries of T.

6. The main results. In this section we derive a formula for μ in terms of the parameters given in T. The idea is the same as that in [4]. We make use of the following proposition due to Parrot [14] and, independently, Davis et al. [1]. Let X_i, Y_i, $(i = 1, 2)$ be Hilbert spaces and let

$$\begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} : X_1 \oplus X_2 \to Y_1 \oplus Y_2$$

be a bounded linear operator.

PROPOSITION 6.1.

$$\inf\left\{\left\|\begin{bmatrix} G_{11} & G_{12} \\ G_{21} - X & G_{22} \end{bmatrix}\right\|\right\} = \max\left\{\|[G_{11}, G_{12}]\|, \left\|\begin{bmatrix} G_{12} \\ G_{22} \end{bmatrix}\right\|\right\},$$

where the infimum is over all bounded operators X from X_1 to Y_2.

Our main result can be stated.

THEOREM 6.2. *Suppose T is an operator on h_2 of the form*

$$T = \begin{bmatrix} x_0 & y_{-1} & x_{-2} & y_{-3} & \cdots \\ x_1 & y_0 & x_{-1} & y_{-2} & \cdots \\ x_2 & y_1 & x_0 & y_{-1} & \cdots \\ x_3 & y_2 & x_1 & y_0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \end{bmatrix}.$$

Then $d(T, \mathscr{P}_2 \cap \mathscr{C})$, the distance from T to $\mathscr{P}_2 \cap \mathscr{C}$ in the norm topology on $\mathscr{B}(\mathscr{H})$, is

$$\max\left\{\left\|\begin{bmatrix} \vdots & \vdots & \vdots & \\ x_{-4} & y_{-5} & x_{-6} & \cdots \\ x_{-3} & y_{-4} & x_{-5} & \cdots \\ x_{-2} & y_{-3} & x_{-4} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & \cdots \end{bmatrix}\right\|, \left\|\begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ y_{-3} & x_{-4} & y_{-5} & x_{-6} & \cdots \\ y_{-2} & x_{-3} & y_{-4} & x_{-5} & \cdots \\ y_{-1} & x_{-2} & y_{-3} & x_{-4} & \cdots \end{bmatrix}\right\|\right\}.$$

We begin the proof of Theorem 6.2 with the following lemma.

LEMMA 6.3. *Set*

$$A_1 := \begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ x_{-4} & y_{-5} & x_{-6} & y_{-7} & \cdots \\ x_{-3} & y_{-4} & x_{-5} & y_{-6} & \cdots \\ x_{-2} & y_{-3} & x_{-4} & y_{-5} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & y_{-4} & \cdots \end{bmatrix},$$

$$A_2 := \begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ y_{-4} & x_{-5} & y_{-6} & x_{-7} & \cdots \\ y_{-3} & x_{-4} & y_{-5} & x_{-6} & \cdots \\ y_{-2} & x_{-3} & y_{-4} & x_{-5} & \cdots \\ y_{-1} & x_{-2} & y_{-3} & x_{-4} & \cdots \end{bmatrix}.$$

Then

$$\inf_{\{a_0, a_1, b_0\}} \left\|\begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ x_{-2} & y_{-3} & x_{-4} & y_{-5} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & y_{-4} & \cdots \\ x_0 - a_0 & y_{-1} & x_{-2} & y_{-3} & \cdots \\ x_1 - a_1 & y_0 - b_0 & x_{-1} & y_{-2} & \cdots \end{bmatrix}\right\| = \max\{\|A_1\|, \|A_2\|\}.$$

Proof. The idea is the same as that given in Parrot's proof of Nehari's theorem [14, p. 317]. By Parrot's theorem, Proposition 6.1

$$\inf_{a_0} \left\|\begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ x_{-3} & y_{-4} & x_{-5} & y_{-6} & \cdots \\ x_{-2} & y_{-3} & x_{-4} & y_{-5} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & y_{-4} & \cdots \\ x_0 - a_0 & y_{-1} & x_{-2} & y_{-3} & \cdots \end{bmatrix}\right\| = \max\{\|A_1\|, \|A_2\|\},$$

Choose a_0 to attain this infimum.

In the same way one can choose b_0 so that

$$\inf_{b_0}\left\|\begin{bmatrix} \vdots & \vdots & \vdots & \\ y_{-3} & x_{-4} & y_{-5} & \cdots \\ y_{-2} & x_{-3} & y_{-4} & \cdots \\ y_{-1} & x_{-2} & y_{-3} & \cdots \\ y_0-b_0 & x_{-1} & y_{-2} & \cdots \end{bmatrix}\right\| = \max\{\|A_1\|, \|A_2\|\}.$$

Choose a_1 so that

$$\inf_{a_1}\left\|\begin{bmatrix} \vdots & \vdots & \vdots & \\ x_{-4} & y_{-5} & x_{-6} & \cdots \\ x_{-3} & y_{-4} & x_{-5} & \cdots \\ x_{-2} & y_{-3} & x_{-4} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & \cdots \\ x_0-a_0 & y_{-1} & x_{-2} & \cdots \\ x_1-a_1 & y_0-b_0 & x_{-1} & \cdots \end{bmatrix}\right\|$$

$$= \max\left\{\left\|\begin{bmatrix} \vdots & \vdots & \vdots & \\ x_{-3} & y_{-4} & x_{-5} & \cdots \\ x_{-2} & y_{-3} & x_{-4} & \cdots \\ x_{-1} & y_{-2} & x_{-3} & \cdots \\ x_0-a_0 & y_{-1} & x_{-2} & \cdots \end{bmatrix}\right\|, \left\|\begin{bmatrix} \vdots & \vdots & \vdots & \\ y_{-3} & x_{-4} & y_{-5} & \cdots \\ y_{-2} & x_{-3} & y_{-4} & \cdots \\ y_{-1} & x_{-2} & y_{-3} & \cdots \\ y_0-b_0 & x_{-1} & y_{-2} & \cdots \end{bmatrix}\right\|\right\}$$

$$= \max\{\|A_1\|, \|A_2\|\}.$$

This completes the proof. Q.E.D.

Proof of Theorem 6.2.

$$d(T, \mathscr{P}_2 \cap \mathscr{C}) = \inf_{\substack{\{a_i : i\geqq 0\} \\ \{b_i : i\geqq 0\}}}\left\{\left\|\begin{bmatrix} x_0-a_0 & y_{-1} & x_{-2} & \cdots \\ x_1-a_1 & y_0-b_0 & x_{-1} & \cdots \\ x_2-a_2 & y_1-b_1 & x_0-a_0 & \cdots \\ x_3-a_3 & y_2-b_2 & x_1-a_1 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}\right\|\right\}$$

$$= \inf_{a_0,a_1,b_0}\left\{\inf_{\substack{\{a_i : i\geqq 2\} \\ \{b_i : i\geqq 1\}}}\left\{\left\|\begin{bmatrix} X_0 & X_{-1} & X_{-2} & \cdots \\ X_1 & X_0 & X_{-1} & \cdots \\ X_2 & X_1 & X_0 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}\right\|\right\}\right\}$$

$$= \inf_{a_0,a_1,b_0}\left\{\inf_{\{X_i : i\geqq 1\}}\left\{\left\|\begin{bmatrix} X_0 & X_{-1} & X_{-2} & \cdots \\ X_1 & X_0 & X_{-1} & \cdots \\ X_2 & X_1 & X_0 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}\right\|\right\}\right\}$$

where

$$X_1 := \begin{bmatrix} x_2-a_2 & y_1-b_1 \\ x_3-a_3 & y_2-b_2 \end{bmatrix}, \qquad X_0 := \begin{bmatrix} x_0-a_0 & y_{-1} \\ x_1-a_1 & y_0-b_0 \end{bmatrix},$$

etc. The infimum inside the bracket is over Toeplitz matrices and therefore by Nehari's

theorem [14] it is just the norm of the Hankel matrix defined by $\{X_i: i \leqq 0\}$:

$$\left\| \begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \\ X_{-2} & X_{-3} & X_{-4} & X_{-5} & \cdots \\ X_{-1} & X_{-2} & X_{-3} & X_{-4} & \cdots \\ X_0 & X_{-1} & X_{-2} & X_{-3} & \cdots \end{bmatrix} \right\|.$$

Thus

$$d(T, \mathscr{P}_2 \cap \mathscr{C}) = \inf_{a_0, a_1, b_0} \left\{ \left\| \begin{bmatrix} \vdots & \vdots & \\ X_{-2} & X_{-3} & \cdots \\ X_{-1} & X_{-2} & \cdots \\ X_0 & X_{-1} & \cdots \end{bmatrix} \right\| \right\}.$$

By the Lemma 6.3, this is simply $\max\{\|A_1\|, \|A_2\|\}$ and the proof is complete. Q.E.D.

We now ask the question: Can we obtain a lower sensitivity if we allow time-varying controllers? Clearly, since $\mathscr{P}_2 \cap \mathscr{C} \subset \mathscr{C}$, $d(T, \mathscr{P}_2 \cap \mathscr{C}) \geqq d(T, \mathscr{C})$.

However by [4]

$$d(T, \mathscr{C}) = \sup_n \|P_n T(I - P_n)\|.$$

This is again easily computed as in [4, Thm. 4] and we obtain the same number as in Theorem 6.2. Thus $d(T, \mathscr{C}) = d(T, \mathscr{P}_2 \cap \mathscr{C})$ and a nonperiodic controller will *not* improve the minimal sensitivity.

7. The *N*-periodic case. All the results given above relate to the N-periodic case for $N > 2$ (finite). In this case we simply state the result. Recall that N-periodic systems will be determined by N sequences $\{x_i^1\}, \cdots, \{x_i^N\}$. In this case T will be of the form

$$\begin{bmatrix} x_0^1 & x_{-1}^2 & x_{-2}^3 & \cdots & x_{-N+1}^N & x_{-N}^1 & \cdots \\ x_1^1 & x_0^2 & x_{-1}^3 & \cdots & x_{-N+2}^N & x_{-N+1}^1 & \cdots \\ \vdots & \vdots & \vdots & & \vdots & \vdots & \end{bmatrix}.$$

Then

$$d(T, \mathscr{P}_N \cap \mathscr{C}) = \max\{\|A_1\|, \cdots, \|A_N\|\}$$

where

$$A_i = \begin{bmatrix} \vdots & \vdots & \vdots & \\ x_{-2}^i & x_{-3}^{i+1} & x_{-4}^{i+2} & \cdots \\ x_{-1}^i & x_{-2}^{i+1} & x_{-3}^{i+2} & \cdots \end{bmatrix}.$$

We note that, of course, if $N = 1$ our formulas simply reduce to the norm of the Hankel operator determined by the single sequence $\{x_{-1}, x_{-2}, \cdots\}$ which is of course the classical result.

8. Conclusions. The utility of periodic systems in control design has been discussed by a number of authors [2], [11], [13]. In this note, we applied the design philosophy of sensitivity minimization (Zames [18]) to periodic plants. As in the time-invariant case, we showed that apparently one can always minimize sensitivity within a given class of systems, this time for periodic plants.

Moreover, the powerful time-domain input/output techniques of [4] were again shown to be appropriate for the successful solution of sensitivity minimization prob-

lems. We should note that the authors were not successful in pushing through their results using transfer-function techniques and in particular an appropriate version of the commutant lifting theorem (as for the time-invariant case). However given the importance of such techniques in robust system design [11], it seems that this should be a topic of future research.

The reader will notice that even though only the sensitivity minimization problem for a set-up of the kind discussed in § 5 was treated here, the results go through immediately for the more general situation considered in [4]. Moreover in the finite-dimensional case, one can explicitly compute the norms of the Hankel matrices involved in the solution of the sensitivity minimization problem for periodic plants. In the present work however, we have only considered the issue of existence.

Finally, the problem of sensitivity minimization for other interesting classes of time-varying systems should make an interesting subject for future investigation.

Acknowledgment. We would like to thank P. Fuhrmann for some interesting discussions on the problems considered in this paper.

DIFFERENTIAL GAMES AND DIRECTIONAL DERIVATIVES OF VISCOSITY SOLUTIONS OF ISAACS' EQUATIONS II*

P.-L. LIONS† AND P. E. SOUGANIDIS‡

Abstract. Recent work by the authors [this Journal, 23 (1985), pp. 566–583], has demonstrated the connections between the notion of viscosity sub- and super-solutions of first-order, dynamic programming PDE and the optimality principle of dynamic programming, as well as the directional derivatives of viscosity solutions of the above equations at an arbitrary point. The present note contains a remark and a counterexample which complement the results cited.

Key words. differential games, optimal control, Hamilton–Jacobi equations, directional derivatives, viscosity solutions

AMS (MOS) subject classifications. 35F30, 35L60, 90D25, 49C20

Introduction. We present here a remark and a counterexample which complement the results of P.-L. Lions and P. E. Souganidis [2]. In [2], we considered deterministic control and differential games problems and we studied the relations between two formulations of the associated Bellman and Isaacs' equations. In the case of Lipschitz continuous functions, we compared the notion of viscosity solutions of general Hamilton–Jacobi equations (introduced by M. G. Crandall and P.-L. Lions [1]) and a formulation due to A. I. Subbotin [3] concerning directional derivatives of the value functions. The equivalence of these notions was shown in [2] in the case of control or differential games problems under the Isaacs' condition: in fact, even in the general case of upper and lower value functions, we proved "one half" of the set of the inequalities to be checked. This combined with the Isaacs' condition was enough for the value functions. Here we present a simple example showing that the other half is in general false and we give a positive answer in a very particular situation.

To simplify the presentation, we restrict ourselves to the case of infinite horizon problems without state constraints

$$\inf_{y\in Y}\sup_{z\in Z}\{-f(x,y,z)\cdot DV - l(x,y,z)\} + V(x) = 0 \quad \text{in } R^N, \tag{1}$$

where Y, Z are fixed compact metric spaces and f, l are bounded, uniformly continuous on $R^N \times Y \times Z$ and Lipschitz continuous in $x \in R^N$ uniformly in $(y, z) \in Y \times Z$. As is well known, (1) corresponds to the equation satisfied by the lower value of a differential game (see [2] and below for more details).

In [2] we proved that a Lipschitz continuous function V is a viscosity supersolution (see below for the definition) of (1) if and only if

$$\inf_{y\in Y}\sup_{(f,l)\in K(x,y)}\left\{\overline{\lim_{t\to 0+}}\frac{V(x)-V(x+tf)}{t} - l\right\} + V(x) \geqq 0 \quad \text{in } R^N, \tag{2}$$

where for $x \in R^N$, $y \in Y$ $K(x, y) = \overline{\text{co}}\,\{(f(x, y, z), l(x, y, z))/z \in Z\}$. On the other hand, it is easy to check (see also [2]) that if V satisfies

$$\inf_{y\in Y}\sup_{(f,l)\in K(x,y)}\left\{\lim_{t\to 0+}\frac{V(x)-V(x+tf)}{t}-l\right\}+V(x)\leqq 0 \quad \text{in } R^N, \tag{3}$$

then V is a viscosity subsolution of (1). The converse statement was left open. In §1 we show that a Lipschitz continuous viscosity subsolution of (1) does not necessarily satisfy (3). Recalling that lower values are always viscosity solutions of (1), this counterexample shows the limitation of the formulation of (1) by the pair of inequalities (2) and (3). Finally, in §2 we describe a particular situation where the converse statement holds. (Some other situations where the equivalence holds are indicated in [2].)

We conclude the introduction by recalling the definition of the viscosity solution. Let $C(\mathcal{O})$ ($C^{0,1}(\mathcal{O})$) denote the set of continuous (Lipschitz continuous) functions defined on $\mathcal{O}$. We have:

DEFINITION. Let $F\in C(R^N\times R\times R^N)$. $u\in C(R^N)$ is a viscosity supersolution (subsolution) of

$$F(x, u, Du)=0 \quad \text{in } R^N$$

if

$$F(x, u(x), D\phi(x))\leqq 0 \qquad (F(x, u(x), D\phi(x))\geqq 0),$$

for every smooth function ϕ in R^N and every local maximum (minimum) x of $u-\phi$ in R^N.

1. A counterexample. Let $l(x)$ be a bounded Lipschitz continuous function on R^N such that

$$|l(x)-l(y)|\leqq |x-y| \quad \text{for all } x, y\in R^N$$

and

$$l(x)=-|x| \quad \text{in a neighborhood of 0.}$$

We take $Y=Z=\{\xi\in R^N, |\xi|\leqq 1\}$ and choose

$$f(x, y, z)=z, \qquad l(x, y, z)=l(x)-(y, z).$$

Thus,

$$\sup_{z\in Z}\{-f\cdot p-l\}=|p-y|-l(x) \quad \text{for all } x, p\in R^N$$

and

$$\inf_{y\in Y}\sup_{z\in Z}\{-f\cdot p-l\}=(|p|-1)^+-l(x).$$

Obviously, $V(x)=l(x)$ is a viscosity solution of (1). On the other hand, if we try to check (3) at $x=0$ we obtain

$$\sup_{(f,l)\in K(0,y)}\left\{\lim_{t\to 0+}\frac{V(0)-V(0+tf)}{t}-l\right\}+V(0)=\sup_{z\in Z}\{|z|+(y, z)\}=1+|y|.$$

The infimum over y yields 1. Hence, (3) does not hold at $x=0$.

2. A particular situation. In this section we prove that if $N=1$ and $l(x, y, z)=l(x)$, then any viscosity subsolution $V\in C^{0,1}(R)$ of (1) satisfies (3). We will prove this claim following a general scheme of proof and indicating where the above restrictive assumptions are needed.

Let $P(Z)$ be the set of probability measures on Z and identify Z with the subspace of $P(Z)$ consisting of Dirac measures. For $\mu\in P(Z)$, $y\in Y$, $x\in R^N$ we set

$$f(x, y, \mu)=\int_Z f(x, y, z)\,d\mu(z),$$

$$l(x, y, \mu)=\int_Z l(x, y, z)\,d\mu(z).$$

Let M and N be the set of measurable functions y_s and z_s from $[0, \infty)$ into Y and $P(Z)$, respectively. We consider the set Δ of strategies β which are maps from M into N such that for all $t \geqq 0$

$$\beta(y^1)_s = \beta(y^2)_s \text{ on } [0, t] \quad \text{if } y_s^1 = y_s^2 \text{ on } [0, t].$$

Observing that for all $x \in R^N$, $y \in Y$, $p \in R^N$

$$\sup_{z \in Z} \{-f(x, y, z) \cdot p - l(x, y, z)\} = \sup_{\mu \in P(z)} \{-f(x, y, \mu) \cdot p - l(x, y, \mu)\},$$

we deduce from [2] that if $V \in C(R^N)$ is a viscosity subsolution of (1), then for all $h > 0$ and $x \in R^N$ we have

$$V(x) \leqq \inf_{\beta \in \Delta} \sup_{y \in M} \left\{ \int_0^h e^{-s} l(x_s, y_s, \beta[y]_s)\, ds + V(x_h) e^{-h} \right\}, \tag{4}$$

where x_t is the solution of

$$\frac{dx_t}{dt} = f(x_t, y_t, \beta[y]_t) \quad \text{on } [0, \infty), \qquad x_0 = x.$$

To prove (3) we argue by contradiction. Indeed, we assume that there exist $x \in R^N$ and $\delta > 0$ such that

$$\inf_{y \in Y} \sup_{(f,l) \in K(x,y)} \left\{ \lim_{t \to 0+} \frac{V(x) - V(x + tf)}{t} - l \right\} + V(x) \geqq \delta > 0.$$

Hence, for every $y \in Y$, there exist $t_y > 0$, $m_y \in N^+$ (positive integers), $z(y) \in Z$ and $\theta_i(y) \in (0, 1)$ with $i = 1, \cdots, m_y$ such that

$$\sum_{i=1}^{m_y} \theta_i(y) = 1,$$

and

$$\frac{V(x) - V(x + tf_y)}{t} - l_y + V(x) \geqq \frac{\delta}{2} > 0 \quad \text{for } 0 < t < t_y,$$

where

$$f_y = \sum_i^{m_y} \theta_i(y) f(x, y, z_i(y)), \qquad l_y = \sum_i^{m_y} \theta_i(y) l(x, y, z_i(y)).$$

Here we used the fact that $V \in C^{0,1}(R^N)$ and that $(V(x) - V(x + tf))/t$ is continuous in f uniformly for $t > 0$. If we set

$$f_{\bar{y},y} = \sum_{i=1}^{m_y} \theta_i(y) f(x, \bar{y}, z_i(y)), \qquad l_{\bar{y},y} = \sum_{i=1}^{m_y} \theta_i(y) l(x, \bar{y}, z_i(y)),$$

the properties of f and l imply that for every $y \in Y$ there exists $r_y > 0$ such that

$$\frac{1}{t} \{V(x) - V(x + tf_{\bar{y},y})\} - l_{\bar{y},y} + V(x) \geqq \frac{\delta}{4} > 0$$

for $0 < t < t_y$ and $d(\bar{y}, y) < r_y$, where d denotes the metric of Y. Using the compactness of Y we obtain the existence of $M \geqq 1$, $\bar{t} > 0$, $y_1, \cdots, y_M \in Y$ and $r_1, \cdots, r_M > 0$ such that $Y \subset \cup_{k=1}^M B(y_k, r_k)$ and

$$\frac{1}{t} \{V(x) - V(x + t\bar{f}_y)\} - \bar{l}_y + V(x) \geqq \frac{\delta}{4} \quad \text{for } 0 < t < \bar{t}, \tag{5}$$

where for $y \in B(y_j, r_j) \setminus \cup_{k=1}^{j-1} B(y_k, r_k)$, $\bar{f}_y$, $\bar{l}_y$ are defined by

$$\bar{f}_y = \sum_{i=1}^{m_{y_j}} \theta_i(y_j) f(x, y, z_i(y_j)), \qquad \bar{l}_y = \sum_{i=1}^{m_{y_j}} \theta_i(y_j) l(x, y, z_i(y_j)).$$

Next, we introduce a map $\tilde{\beta}$ from Y into $P(z)$ defined by

$$\tilde{\beta}(y) = \sum_{i=1}^{m_{y_j}} \theta_i(y_j)\delta_{z_i(y_j)} \quad \text{if } y \in B(y_j, r_j) \setminus \bigcup_{k=1}^{j-1} B(y_k, r_k).$$

This map obviously defines a strategy of $\beta \in \Delta$ by

$$\beta[y]_s = \tilde{\beta}(y_s) \quad \text{for } s \geqq 0.$$

Moreover,

$$f(x, y_s, \beta[y]_s) = \bar{f}_{y_s}, \qquad l(x, y_s, \beta[y]_s) = \bar{l}_{y_s}.$$

Hence, for any $y \in M$, we have

$$\begin{aligned}
&\frac{1}{t}\{V(x) - V(x_t)e^{-t}\} - \frac{1}{t}\int_0^t e^{-s} l(x_s, y_s, \beta[y]_s)\, ds \\
&\quad \geqq -Ct + \frac{1}{t}\{V(x) - V(x_t)\} - \frac{1}{t}\int_0^t l(x_s, y_s, \beta[y]_s)\, ds + V(x) \\
&\quad \geqq -Ct + V(x) + \frac{1}{t}\left\{V(x) - V\left(x + \int_0^t f(x, y_s, \beta[y]_s)\, ds\right)\right\} - \frac{1}{t}\int_0^t l(x, y_s, \beta[y]_s)\, ds \\
&\quad \geqq -Ct + V(x) + \frac{1}{t}\left\{V(x) - V\left(x + \int_0^t \bar{f}_{y_s}\, ds\right)\right\} - \frac{1}{t}\int_0^t \bar{l}_{y_s}\, ds,
\end{aligned}$$

where C denotes various constants independent of t, $y \in M$.

Next observe that the suboptimality principle (4) yields that the left-hand side of the preceding inequality is nonpositive. We wish to reach a contradiction by showing that (5) implies that the right-hand side is nonnegative for t small. The counterexample of §1 shows that this is not possible in general. However, in the particular situation where $l(x, y, z) = l(x)$ (hence $l_y = l(x)$ for all y) and $N = 1$, there exists $s_0 \in (0, t)$ such that

$$\begin{aligned}
&V(x) + \frac{1}{t}\left\{V(x) - V\left(x + \int_0^t f_{y_s}\, ds\right)\right\} - \frac{1}{t}\int_0^t l_{y_s}\, ds \\
&\quad = \frac{1}{t}\{V(x) - V(x + t\bar{f}_{y_{s_0}})\} + V(x) - l(x) \geqq \frac{\delta}{4}
\end{aligned}$$

for $t < \bar{t}$. The contradiction proves our claim.

TRANSCENDENTAL AND INTERPOLATION METHODS IN SIMULTANEOUS STABILIZATION AND SIMULTANEOUS PARTIAL POLE PLACEMENT PROBLEMS*

B. K. GHOSH†

Abstract. In this paper, we investigate the existence of a compensator which simultaneously renders a given r-tuple of multiinput multioutput $p \times m$ linear dynamical systems internally stable. In particular we parametrize a set of simultaneously stabilizable r-tuples of plants and show that provided $r \leqq \max(m, p)$, the above set is semialgebraic and dense in the space Σ of r-tuples of plants. Furthermore, we also consider an extension of the classical pole placement and stabilization problems and investigate the simultaneous partial pole placement problem. Consequently, we consider a suitable topology in Σ and obtain a necessary condition and a sufficient condition for the generic partial pole placement problem. Surprisingly enough, the problem of simultaneously stabilizing a triplet of $m \times m$ plants, chosen generically, is shown equivalent to the problem of partially pole placing a single $m \times m$ plant by a stable minimum phase compensator. On the other hand the problem of simultaneously stabilizing $m+2$ tuple of $1 \times m$ plants, chosen generically, is shown equivalent to the problem of partially pole placing a $1 \times m$ plant by a stable minimum phase compensator. Investigating the $1 \times m$ plants in details, we parametrize the set of all compensators simultaneously stabilizing a m tuple of $1 \times m$ plants chosen generically. Consequently, we obtain a necessary and sufficient condition for simultaneously stabilizing a $m+1$ tuple of $1 \times m$ plants chosen generically. Lastly we construct two numerical examples. The first example is a triplet of simultaneously unstabilizable single input single output plants, each of McMillan degree 1 that are simultaneously stabilizable in pairs. The second example is a triplet of 1×3 plants that are not simultaneously stabilizable.

Key words. partial pole placement, simultaneous stabilization, generic, semialgebraic

1. Introduction.

In order to introduce and analyze the problems considered in this paper we need the following notation.

$\mathbb{C}$:	the complex plane
$\mathbb{R}$:	the real line
$\mathbb{C}_s$:	a self-conjugate subset of $\mathbb{C}$ which intersects $\mathbb{R}$
$\mathbb{C}_u$:	$[\mathbb{C}-\mathbb{C}_s] \cup \{\infty\}$
$\mathbb{R}_u$:	$\mathbb{R} \cap \mathbb{C}_u$
$\mathbb{C}^-$:	open left half of the complex plane
H:	ring of proper rational functions with real co-efficients with poles in $\mathbb{C}_s$
$H^{p \times m}$:	set of $p \times m$ matrices whose elements belong to H
J:	set of multiplicative units in H
F:	quotient field of H [21, pp. 88-90].

Let us consider a set $G_1(s), \cdots, G_r(s)$ of r real, linear time invariant, proper $p \times m$ dynamical systems, each of a given fixed McMillan degree n_i, $i = 1, \cdots, r$ with m inputs and p outputs and ask the following problem.

Problem 1.1 (simultaneous stabilization). "When does there exist a nonswitching p input m output real, linear, time-invariant, proper compensator of arbitrary large but finite McMillan degree q, which stabilizes each of the r given plants either in discrete time or in continuous time?"

* Received by the editors July 3, 1984, and in revised form September 16, 1985. This work was partially supported by National Aeronautics and Space Administration grant NSG-2265 while the author was at Harvard University, Cambridge, Massachusetts 02138.

† Department of Systems Science and Mathematics, Washington University, St. Louis, Missouri 63130.

The simultaneous stabilization problem 1.1 has been originally addressed by Birdwell, Castanon and Athans [2] for the case $m = p = 1$ and is followed up subsequently by Saeks and Murray [26] as a problem in reliability and in the design of a multi-mode control system. Subsequently, Vidyasagar and Viswanadham [34] addressed the above problem for the multiinput multioutput case and showed that if $\min(m, p) > 1$, a generic pair of $p \times m$ plants is simultaneously stabilizable in a suitably chosen topology. The case $m = p = 1$ is more difficult and it is shown [27], [34] that the problem of simultaneously stabilizing a pair of single input single output plants is equivalent to the well-known problem considered by Youla, Bongiorno and Lu [35]: When can a single plant be stabilized by a stable compensator? Moreover the problem of stabilizing a triplet of single input single output plant chosen generically has been shown by Ghosh [14] to be equivalent to the problem of partially pole placing a single input single output plant by a stable minimum phase compensator. The problem of simultaneous partial pole placement, introduced and analyzed for the single input single output plants in [14], consists in answering the following problem:

Problem 1.2 (simultaneous partial pole placement). "Given a r tuple $G_1(s), \cdots, G_r(s)$ of $p \times m$ proper transfer functions of degree n_i, $i = 1, \cdots, r$, respectively, together with a r tuple of proper rational functions $\psi_i(s)$ of degree d_i, $i = 1, \cdots, r$ respectively from H. Does there exist a proper $m \times p$ compensator $K(s)$ of degree $q \geqq \max_i [d_i - n_i]$ such that the closed loop systems $G_1(s)[I + K(s)G_1(s)]^{-1}, \cdots, G_r(s)[I + K(s)G_r(s)]^{-1}$ have, respectively, d_i poles precisely where $\psi_i(s)$ vanishes and all but the above d_i poles are in $\mathbb{C}_s$?"

As explained in [14], the partial pole placement problem 1.2 is an extension of the pole placement and stabilization problems. In fact, if we assume $d_1 = d_2 = \cdots = d_r = 0$ and $\mathbb{C}_s = \mathbb{C}^-$ then the problem 1.2 reduces to the simultaneous stabilization problem 1.1. On the other hand, if we choose $d_i = n_i + q$, one obtains the simultaneous pole placement problem described in [12] and [18]. Frequently however, it is necessary to choose d_i in between 0 and $n_i + q$ for all $i = 1, \cdots, r$. Such a choice, we remark, satisfies the need to shape the response of the closed loop system to the extent that the designer can place an arbitrary number of self conjugate poles in the closed loop while restricting the remaining poles in the region $\mathbb{C}_s$. The above problem 1.2 also includes the simultaneous version of the well-known dominant pole placement problem and the gain margin problem. It also appears in the analysis of a class of robust stabilization problems described in [15], [16], the reliable stabilization problem described in [11] and many other design problems described in [17].

The new ingredient in this paper is the application of interpolation and transcendental methods in analyzing the simultaneous partial pole placement problem. This is now described as follows.

Interpolation problem 1.3. "Given a self conjugate set of pairs of complex numbers (s_i, z_i), $i = 1, \cdots, t$, does there exist a $\Delta(s) \in J$ such that $\Delta(s_i) = z_i$, for all $i = 1, \cdots, t$?"

The problem of interpolation by a rational function is known to be very important in network theory and electrical engineering. For accounts of this see Youla-Saito [36], Zeheb-Lempel [39], Helton [20] and many other references therein. In control theory, similar interpolation methods have been successfully applied by Tannenbaum [30], Zames and Francis [37], Kimura [22] based on classical work of Nevanlinna [24] and Pick [25]. More recently, Vidyasagar and Davidson [32] have used interpolation methods to characterize the set of stable stabilizing compensators for a single input single output system.

Assuming $\mathbb{C}_s$ to be the open left half of the complex plane, the interpolation problem 1.3 has been posed and solved by Youla, Bongiorno and Lu [35] in order to

analyze the stabilizability problem of a single input single output system by a stable compensator, in the continuous time. Complete solution to the problem 1.3 when $\mathbb{C}_s$ is arbitrary is given in [14]. Moreover generalizing the results due to Saeks and Murray [26], the problem of simultaneously stabilizing (partially pole assigning) a pair of single input single output plants is completely solved in [14]. Surprisingly however, as shown in [12], [13] and [14], in order to analyze the simultaneous stabilizability problem 1.1 for a triplet of single input single output systems, it is not enough to analyze the interpolation problem 1.3 and one asks the following transcendental problem.

Transcendental problem 1.4. "Given a t-tuple of rational functions $\delta_1(s), \cdots, \delta_t(s)$ from H, when does there exist a t tuple of rational functions $\Delta_1(s), \cdots, \Delta_t(s)$ in J such that

$$\Delta_1(s)\delta_1(s)+\cdots+\Delta_t(s)\delta_t(s)\equiv 0." \tag{1.1}$$

As shown in [11], a triplet of single input single output plants $x_1(s)/y_1(s)$, $x_2(s)/y_2(s)$, $x_3(s)/y_3(s)$ chosen generically in the topology described in [3] is simultaneously stabilizable iff there exists a triplet of stable, minimum phase rational functions $\Delta_1(s)$, $\Delta_2(s)$, $\Delta_3(s)$ such that

$$\begin{aligned}\Delta_1(s)(x_1(s)y_3(s)-x_3(s)y_1(s))+\Delta_2(s)(x_2(s)y_3(s)-x_3(s)y_2(s))\\ +\Delta_3(s)(x_2(s)y_1(s)-x_1(s)y_2(s))\equiv 0.\end{aligned} \tag{1.2}$$

It may be remarked that (1.2) is satisfied just in case the plant $[x_1(s)y_3(s)-x_3(s)y_1(s)]/[x_2(s)y_3(s)-x_3(s)y_2(s)]$ is partially pole assignable at the zeros of $[x_1(s)y_2(s)-x_2(s)y_1(s)]$ in $\mathbb{C}_u$ by a stable, minimum phase compensator, Δ_1/Δ_2. Thus we remark that the partial pole assignability problem by a stable minimum phase compensator is an important problem in system theory which is addressed, among others, by the transcendental problem 1.4.

This paper is organized as follows. In § 2 we parametrize a set of simultaneously stabilizable r-tuples of plants and show that provided $r\leqq\max(m, p)$, the above set is semialgebraic and dense in the set of r-tuples of plants. In § 3 we analyze square systems, i.e. when $m=p$ and show that the problem of simultaneously stabilizing r tuples ($r\geqq 3$) of $m\times m$ systems chosen generically is equivalent to the problem of partially pole assigning a $r-2$ tuple of $m\times m$ systems by a stable, minimum phase compensator. Consequently, we obtain a necessary condition for the simultaneous partial pole placement of three or more square systems chosen generically. Finally in § 4 we discuss in considerable details the case when $\min(m, p)=1$, i.e. when the number of inputs or the number of outputs is one. In § 5 we construct two folklore examples which do not pre-exist in the literature. Section 6 concludes this paper with a discussion on the prospects of this rapidly growing simultaneous system design methodology.

2. A generic and/or semialgebraic parametrization of the partially pole assignable r-tuples of $p\times m$ systems.

2.1. We would first like to consider the basic mathematical setup, for the details of which we refer to Saeks et al. [26], [27], Vidyasagar et al. [33], [34] and Desoer et al. [9]. Every single input single output system, viewed as an element of F, can be written as $x(s)/y(s)$, where $x(s)$, $y(s)\in H$. Similarly, a $p\times m$ multiinput multioutput plant $G(s)$ has the left coprime representation $D(s)^{-1}N(s)$, where $N(s)\in H^{p\times m}$, $D(s)\in H^{p\times p}$. Moreover a r-tuple of m input p output plants can be written as

$$G_i(s)=D_i(s)^{-1}N_i(s), \qquad i=1,\cdots,r \tag{2.1}$$

where $N_i(s) \in H^{p\times m}$, $D_i(s) \in H^{p\times p}$, for all i. Of course if n_i is the McMillan degree of $G_i(s)$, $i=1,\cdots,r$ respectively, we consider the space Σ of r tuples of plants given by

$$\Sigma = \Sigma_{m,p}^{n_1} \times \cdots \times \Sigma_{m,p}^{n_r} \tag{2.2}$$

where

$$\Sigma_{m,p}^{n_i} = \{p \times m \quad G_i(s);\ \text{degree } G_i(s) = n_i\}. \tag{2.3}$$

As has been described in [12], Σ is a quasiaffine algebraic variety in the affine space $\mathbb{R}^{(2n_1+1)mp} \times \cdots \times \mathbb{R}^{(2n_r+1)mp}$ and inherits the subspace topology.

Our main results of this paper concern the following pair of questions.

Question 2.1 (generic partial pole placement problem). Fix m, p, r and n_i. Let $\psi_1(s),\cdots,\psi_r(s) \in H$ be given. Is the set Σ_p, of r-tuples $G_1(s),\cdots,G_r(s)$ which can be simultaneously partially pole assigned at the zeros of $\psi_1(s),\cdots,\psi_r(s)$ respectively by some compensator, open and dense in Σ?

Question 2.2 (semialgebraic parametrization). Does there exist a semialgebraic subset $\mathcal{S}$ in Σ which is open and dense in Σ_p?

A semialgebraic (see [4] for details) set is a finite union and intersection of sets defined by algebraic equations and inequations. It is a classical result by Tarski [31] and Seidenberg [28], that the property of being semialgebraic is preserved by a rational map. Anderson, Bose and Jury [1] have used this fact to show that the set of plants, of a given McMillan degree, which can be stabilized by some feedback gain is an open, semialgebraic subset in the space of all plants.

Before we state and prove the main results of this section, we refer to the following two well-known results, which also illustrate the significance of semialgebraicity. Routh and Hurwitz parametrized the set of monic polynomials of degree n in one variable, with real co-efficients that have roots in the open left half of the complex plane. They showed that the above set of polynomials is semialgebraic in $\mathbb{R}^n$. This result is surprising because their proof involves complex analytic methods. As a second application of semialgebraicity we note the following. Youla, Bongiorno and Lu [35] considered the problem of parametrizing the set of plants in $\Sigma_{m,p}^n$ which can be stabilized by a stable compensator. Their result shows that the above set may be described by an interlacing condition involving the poles and the blocking zeros of the plant on the nonnegative real axis. It is therefore a semialgebraic subset of $\Sigma_{m,p}^n$. This result is again surprising because the compensators under consideration is of a priori unbounded McMillan degree and therefore "decision-algebra" methods [1] are not applicable. In fact the parametrization problem involves solving a matrix analogue of the interpolation problem 1.3 which is once again a problem in "complex analysis."

At present a semialgebraic parametrization, of the space $\pi_{i=1}^t [\Sigma_{1,1}^{n_i} \cap H]$ of t tuples of rational functions $\delta_1(s),\cdots,\delta_t(s)$ which satisfy (1.1) for some $\Delta_1,\cdots,\Delta_t$ in J, does not exist. Thus it is unknown if Σ_p is semialgebraic. It is therefore of interest to answer Question 2.2. To clarify further, it is not enough to know that there exists a set of r-tuples of plants $\mathcal{S}$ that can be partially pole assignable by some compensator, where $\mathcal{S}$ is open and dense (generic) in Σ. It is also of interest to know if there exists a means to describe $\mathcal{S}$ as well—in particular, is $\mathcal{S}$ semialgebraic in Σ?

If $r=1$, every plant is pole assignable and is therefore partially pole assignable by some compensator. In this section we assume $r>1$ and prove the following:

THEOREM 2.4. *Assume* $\psi_1(s),\cdots,\psi_r(s) \in H^{p\times p}$ *such that* $\det \psi_i(s)$, $i=1,\cdots,r$ *have zeros only in* $\mathbb{C}_u$ *and do not have a zero in common in* $\mathbb{C}_u$. *Assume*

$$1 < r \leqq \lfloor (m+p)/\min(m,p) \rfloor. \tag{2.4}$$

There exists an open, semialgebraic subset $\mathcal{S}$ in Σ which is open and dense in Σ_p, the set of partially, pole assignable r-tuples of proper plants in Σ. ($\lfloor n \rfloor$ is defined to be the largest integer less than or equal to n.)

Remark. In principle, one might obtain the semialgebraic set $\mathcal{S}$ using the elimination methods of Tarski [31] and Seidenberg [28]. Indeed, Byrnes and Anderson [6] have successfully used the concept of elimination, for the generic output feedback stabilization problem. For the purpose of computation, however, it is of interest to know explicitly the semialgebraic set $\mathcal{S}$, without going through "elimination" since it is known [10] to be computationally inefficient. Theorem 2.4 is a result on such an explicit parametrization as its proof would show.

It is of theoretical interest, however, to use "elimination methods" and prove the following:

THEOREM 2.5. *Assume $r>1$, $\psi_i(s)$, $i=1,\cdots,r$ belong to $H^{p\times p}$ and satisfy the condition mentioned in Theorem 2.4. A sufficient condition that there exists an open, dense, semialgebraic subset $\mathcal{S}$ (in Σ) of r-tuples of $p\times m$ proper plants $G_1(s),\cdots,G_r(s)$ of McMillan degrees n_i, $i=1,\cdots,r$ respectively which can be partially pole assigned at the zeros of* $\det \psi_i(s)$, $i=1,\cdots,r$ *respectively by an arbitrary large but finite proper compensator q is given by*

$$r \leqq \max(m,p). \tag{2.5}$$

Remark. Except for the case $\min(m,p)=1$ we note that the hypothesis (2.4) is stronger than (2.5).

It is interesting to note that by choosing $\det \psi_i(s) \equiv 1$, $i=1,\cdots,r$, we have the following corollary from Theorem 2.5.

COROLLARY 2.6 (Vidyasagar and Viswanadham [34]). *Assume* $\max(m,p)>1$. *A generic pair of $p\times m$ proper plants is simultaneously stabilizable.*

Note that the Theorems 2.4 and 2.5 describe only the sufficiency conditions. We now obtain the following necessary condition for the partial pole placement problem.

THEOREM 2.7. *Assuming $r>1$, $\psi_i(s)$, $i=1,\cdots,r$ as in Theorem 2.4. A necessary condition for generic simultaneous partial pole placement of a r-tuple of proper plants at the zeros of a generic r tuple of stable rational functions* $\det \psi_1(s),\cdots,\det \psi_r(s)$ *in $\mathbb{C}_u$ by some proper compensator of arbitrary large but finite McMillan degree q is given by*

$$q(m+p)+mp \geqq \sum_{i=1}^{r} \alpha_i \tag{2.6}$$

where α_i is the number of zeros of $\det \psi_i(s)$, $i=1,\cdots,r$ *respectively.*

Remark. The inequality (2.6) is not surprising and is precisely what one would guess from a "dimension count."

From Theorem 2.7 we now deduce the following.

COROLLARY 2.8. *Assume $\alpha_i>q$, $r>1$, $\psi_i(s)$, $i=1,\cdots,r$ as in Theorem 2.4. A necessary condition for generic simultaneous partial pole placement of a r-tuple of proper plants is given by*

$$r \leqq \max[mp/(\min_i \beta_i), m+p-1] \tag{2.7}$$

where $\alpha_i = q+\beta_i$, $i=1,\cdots,r$.

We remark that Corollary 2.8 includes the simultaneous pole placement problem as a special case when $\alpha_i = n_i+q$, $i=1,\cdots,r$. It is interesting to observe that (2.7) is independent of q and in particular we have the following.

COROLLARY 2.9 (Saeks and Murray [26], Vidyasagar and Viswanadham [34]). *Assume $m = p = 1$, $r = 2$. A generic pair of single input single output proper plants is not simultaneously pole assignable.*

Finally we note from Theorem 2.5 and Corollary 2.8 that the condition (2.5) is sharp in the following sense.

COROLLARY 2.10. *If $\min(m, p) = 1$, $r > 1$ and $\alpha_i > q$ and $\psi_i(s)$, $i = 1, \cdots, r$ as in Theorem 2.4, the inequality (2.5) is a necessary and sufficient condition for generic simultaneous partial pole placement of a r tuple of proper plants.*

To summarize the theorems and corollaries of this section, we make the following remark: If r is sufficiently small (given by (2.5)) a generic r tuple of multiinput and multioutput plants is simultaneously partially pole assignable. On the other hand under the assumptions of Corollary 2.8, if r is sufficiently large and fails to satisfy (2.7), a generic r tuple of multiinput multioutput plants is not simultaneously partially pole assignable. It may also be noted that for the generic simultaneous stabilization problem, one assumes $\alpha_i = 0$, $i = 1, \cdots, r$, so that Corollary 2.8 is inapplicable. In fact, no other necessary condition to the problem is known to exist. This constitutes an outstanding open problem in system theory.

We now sketch the proof of the theorems.

2.2. Proof of Theorem 2.4. First of all, we need to prove the following lemmas.

LEMMA 2.1. *Given a set of t vectors $v_1, \cdots, v_t$ in $\mathbb{R}^{m+p}$ with nonzero components. Then there exists another set of t vectors $u_1, \cdots, u_t$ such that u_i is orthogonal to v_i, for all $i = 1, \cdots, t$ and such that each component of u_i has the same sign for all $i = 1, \cdots, t$ respectively iff the set of vectors $v_1, \cdots, v_t, -v_1, \cdots, -v_t$ misses an orthant in $\mathbb{R}^{m+p}$.*

Proof. (If part). Let θ be the orthant which does not contain the vectors $v_1, \cdots, v_t$, $-v_1, \cdots, -v_t$. For a given vector v_i belonging to the orthant θ_1 it is well known that there exists a vector orthogonal to v_i in the orthant θ, since θ is different from θ_1, for all $i = 1, \cdots, t$. Thus in particular it is possible to choose $u_1, \cdots, u_t \in \theta$ such that $u_i \cdot v_i = 0$, $i = 1, \cdots, t$.

(Only if part). Assume that the set of vectors $v_1, \cdots v_t, -v_1, \cdots, -v_t$ does not miss any orthant in $\mathbb{R}^{m+p}$. It is clear that there does not exist any orthant θ in $\mathbb{R}^{m+p}$ such that $u_i \in \theta$ and $u_i \cdot v_i = 0$, for otherwise there would exist two nonzero vectors in the same orthant θ of $\mathbb{R}^{m+p}$ that are orthogonal to each other, which is absurd. Thus there does not exist a set of t vectors $u_1, \cdots, u_t$ with the above mentioned property. Q.E.D.

LEMMA 2.2. *Given a self conjugate set of tuples (s_i, M_i), $i = 1, \cdots, t$ where $s_i \in \mathbb{C}$ and M_i is a $p \times p$ complex matrix, $i = 1, \cdots, t$ respectively. Moreover for all $i \in \{1, \cdots, t\}$ for which $s_i \in \mathbb{R}_u$, assume that* $\det M_i > 0$. *There exists $\Delta(s) \in H^{p \times p}$, $\det \Delta(s) \in J$ such that*

$$\Delta(s_i) = M_i \tag{2.8}$$

for all $i = 1, \cdots, t$.

Remark. The main idea of Lemma 2.2 is originally due to Vidyasagar and Viswanadham [34] and the proof that we now sketch is an adaptation of their procedure.

Proof. Assume first of all that $\mathbb{C}_s$ contains the open left half of the complex plane. Let us define $N_p(s) \in H^{p \times p}$ such that

$$N_p(s_j) = 0, \qquad j = 1, \cdots, t \tag{2.9}$$

and that $N_c(s)$ has no other blocking zero in $\mathbb{C}_u$. A blocking zero is a point where the matrix function $N_p(s)$ vanishes as a matrix. Let $D_p(s)$ be such that

$$D_p(s_j) = M_j, \qquad j = 1, \cdots, t \tag{2.10}$$

and that $N_p(s)$, $D_p(s)$ are co-prime. It has been shown by Youla, Bongiorno and Lu [35] that the plant $N_p(s)D_p(s)^{-1}$ is stabilizable by a stable compensator, since at the zeros s_j, $j=1,\cdots,t$ of $N_p(s)$ in $\mathbb{C}_u$, $\det D_p(s_j)=\det M_j$, $j=1,\cdots,t$ have the same sign. Thus there exists $N_c(s)$, $D_c(s)$, $\Delta_1(s)\in H^{p\times p}$, $\det D_c(s)\in J$, $\det \Delta_1(s)\in J$ such that

$$N_c(s)N_p(s)+D_c(s)D_p(s)=\Delta_1(s). \tag{2.11}$$

Clearly we have

$$D_c^{-1}(s_j)\Delta_1(s_j)=D_p(s_j)=M_j, \qquad j=1,\cdots,t. \tag{2.12}$$

Defining $\Delta(s)=D_c^{-1}(s)\Delta_1(s)$, we have the required matrix function $\Delta(s)$.

In general if $\mathbb{C}_s$ does not contain the open left half of the complex plane, assume that there exists ball B_ε of radius ε with center at $c_1\in\mathbb{R}$ contained in $\mathbb{C}_s$. Note that since $\mathbb{C}_s$ intersects $\mathbb{R}$, such a ball would always exist. Let us now conformally transform B_ε onto the open left half of the complex plane by the map

$$\psi: z\mapsto\frac{s-c_1+\varepsilon}{s-c_1-\varepsilon}. \tag{2.13}$$

Define $z_j=(s_j-c_1+\varepsilon)/(s_j-c_1-\varepsilon)$, $j=1,\cdots,t$ and construct $\Delta(z)\in H^{p\times p}$, $\det\Delta(z)\in J$ such that $\Delta(z_j)=M_j$, $j=1,\cdots,t$, $\det\Delta(1)\neq 0$. It follows that $\Delta[(s-c_1+\varepsilon)/(s-c_1-\varepsilon)]$ is the required matrix function. Q.E.D.

LEMMA 2.3. *Given a pair of nonzero vectors* $(\alpha_1,\cdots,\alpha_p)$, $(\beta_1,\cdots,\beta_p)\in\mathbb{R}^p$, $p>1$ *there exists a* $m\times m$ *matrix* M *such that*

$$(\alpha_1,\cdots,\alpha_p)M=(\beta_1,\cdots,\beta_p) \tag{2.14}$$

and

$$\det M>0. \tag{2.15}$$

Proof. Let the ijth entry of M be given by a_{ij}. We may expand $\det M$ as

$$\det M=\sum_{i=1}^{p} a_{1i}\Delta_{1i} \tag{2.16}$$

where Δ_{1i} is the adjoint of the $1i$th entry in M. Assume without any loss of generality that $\alpha_1\neq 0$. One can rewrite (2.14) as follows:

$$a_{1i}=-\sum_{j=2}^{p}\frac{\alpha_j}{\alpha_1}a_{ji}+\frac{1}{\alpha_1}\beta_i. \tag{2.17}$$

Substituting a_{1i} in (2.16), we may check by straightforward computation that

$$\det M=\frac{1}{\alpha_1}\sum_{i=1}^{p}\beta_i\Delta_{1i}. \tag{2.18}$$

Clearly for a given α_1 and $\beta_1,\cdots,\beta_p$ we can write (2.18) as

$$\det M=a_{21}a'+a'' \tag{2.19}$$

where a', a'' are nonzero multinomial expressions in a_{ij}, $i=2,\cdots,p$; $j=1,\cdots,p$; independent of a_{21}. For any choice of $a_{22},\cdots,a_{2p},a_{31},\cdots,a_{3p},\cdots,a_{pp}$, such that $a'\neq 0$, it is possible to choose a_{21} such that $\det M>0$. The entries $a_{11},\cdots,a_{1p}$ are to be computed using (2.17) completing the proof. Q.E.D.

We would now proceed to prove Theorem 2.4. Assume $p \leqq m$ without any loss of generality. Let the r tuple of plants be given by (2.1). Let us represent the compensator as

$$N_c(s)D_c(s)^{-1} \tag{2.20}$$

where $N_c(s) \in H^{m\times p}$, $D_c(s) \in H^{p\times p}$, $N_c(s)$, $D_c(s)$ are coprime. It is well known that the compensator (2.20) partially pole assigns the r-tuple of plants (2.1) at the zeros of $\det \psi_i(s)$, $i=1,\cdots,r$ iff

$$N_i(s)N_c(s)+D_i(s)D_c(s)=\psi_i(s)\Delta_i(s) \tag{2.21}$$

for some $\Delta_i(s)$, $\psi_i(s) \in H^{p\times p}$, $\det \Delta_i(s) \in J$, $i=1,\cdots,r$ respectively. We may write (2.21) in matrix form as

$$\begin{bmatrix} N_1(s) & D_1(s) \\ \vdots & \vdots \\ N_r(s) & D_r(s) \end{bmatrix}\begin{bmatrix} N_c \\ D_c \end{bmatrix}=\begin{bmatrix} \psi_1(s)\Delta_1(s) \\ \vdots \\ \psi_r(s)\Delta_r(s) \end{bmatrix}. \tag{2.22}$$

Let us denote the $(rp)\times(m+p)$ matrix in the left-hand side of (2.22) by $M(s)$. Let us also define a set of r-tuples of plants $(G_1,\cdots,G_r)$ as follows.

(2.23) $\Omega=\{(G_1,\cdots,G_r) | M(s)$ in (2.22) has full rank for all points in $\mathbb{C}\}$.

Note first of all that Ω can be defined as union and intersection of sets of the type

$$f_\alpha(g_1,\cdots,g_r) \neq 0 \tag{2.24}$$

where $f_\alpha(\cdot)$ are polynomials in the coefficients of $g_1(s),\cdots,g_r(s)$. Since $f_\alpha \not\equiv 0$, (2.24) describes a union and intersection of open and dense subsets of Σ. Thus Ω is open, semialgebraic and dense in Σ, the space of r-tuples of plants. We now show that when $r < \lfloor (m+p)/\min(m,p) \rfloor$, $\Omega \subset \Sigma_p$ so that it is enough to define the required set $\mathcal{S}=\Omega$. On the other hand we consider the case $\min(m,p)>1$, $r\min(m,p)=m+p$ and the case $\min(m,p)=1$, $r=m+p$ and show the existence of an open, semialgebraic and dense subset $\mathcal{S}$ of Σ_p.

Case 1 ($r<\lfloor (m+p)/\min(m,p)\rfloor$). Since H is a principal ideal domain [38], for every r tuple of plants in Ω, $M(s)$ has a right inverse $M'(s)$ in $H^{(m+p)\times rp}$ [33] provided $rp \leqq m+p$. Thus for a r-tuple of plants in Ω, (2.22) is indeed solvable for $N_c(s)$, $D_c(s)$. We need to check, however, that the solution would yield $N_c(s)$, $D_c(s)$ which are coprime and that the compensator $N_c(s)D_c(s)^{-1}$ is proper.

Assume that $N_c(s)$, $D_c(s)$ are not coprime. It follows that there exists $s^* \in \mathbb{C}_u$ such that $\operatorname{rank}[N_c^T D_c^T]^T(s^*) < p$. It follows from (2.22) that $\det[\psi_i(s^*)\Delta_i(s^*)]=0$ for $i=1,\cdots,r$. Since $\det \Delta_i(s) \in J$, it follows that $\det[\psi_i(s^*)]=0$ for $i=1,\cdots,r$ which contradicts the assumption on $\psi_i(s)$, $i=1,\cdots,r$. Hence $N_c(s)$, $D_c(s)$ are coprime.

To see that $N_c(s)D_c(s)^{-1}$ is proper, it is enough to show that $\det D_c(\infty)\neq 0$. We claim, first of all, that for every r-tuple of plants in Ω, the associated matrix $M(s)$ has a right inverse $M^1(s)$ with the property that if $[P_1(s)\cdots P_r(s)]$ is the last p row of $M^1(s)$, (where $P_i(s)$, $i=1,\cdots,r$ are $p\times p$ matrices), $\det P_i(\infty)\neq 0$ for all $i=1,\cdots,r$. First of all, let us assume the claim. Since $\det \psi_j(\infty)\neq 0$ for some $j=1,\cdots,r$, it follows that $\psi_j(\infty)\Delta_j(\infty)$ is an arbitrary $p\times p$ matrix for some $j=1,\cdots,r$ and for an arbitrary choice of $\Delta_j(s)$. Since $D_c(s)=\sum_{k=1}^r P_k(s)\psi_k(s)$, it follows from (2.22) that for a suitable choice of $\Delta_1(s),\cdots,\Delta_r(s)$, $\det D_c(\infty)\neq 0$.

Now we proceed to prove the claim. If $M^1(s)$ does not satisfy the above property, let P be a $(m+p)\times rp$ real matrix which satisfies the above property. Let us define $M_\varepsilon^1(s)=M(s)+\varepsilon P$ where ε is a nonzero real number. Clearly for all but finitely many

values of ε, $M_\varepsilon^1(s)$ satisfies the above property. Moreover for small ε we have $\det[M(s)M_\varepsilon^1(s)] \in J$ since by construction $\det[M(s)M^1(s)] \in J$. Thus there exists $\varepsilon = \varepsilon^*$ such that $M_{\varepsilon^*}^1(s)$ is the required right inverse.

Case 2 ($\min(m, p) > 1$, $r \min(m, p) = m + p$). Assume without any loss of generality the case $p \leqq m$ and consider the worst case when $rp = m + p$. The case $rp < m + p$ is analogous to Case 1 above. Note that the matrix $M(s)$ in (2.22) is square and we can write

$$[N_c(s)^T D_c(s)^T]^T = M(s)^{-1}[\Delta_1^T \psi_1^T \cdots \Delta_r^T \psi_r^T]. \tag{2.25}$$

We now define the required subset $\mathcal{S}$ of Ω as follows:

$$\begin{aligned}\mathcal{S} \triangleq \{(G_1, \cdots, G_r) &| \det M(s) \text{ has simple zeros at } s_1, \cdots, s_t \text{ in } \mathbb{C} \text{ and} \\ &\text{does not vanish at } \infty; \text{ Adj } M(s_i),\ i = 1, \cdots, t \text{ are of rank 1; if the} \\ &\text{rows of Adj } M(s_i) \text{ are spanned by the nonzero vector } [\mathbf{c}_{i1}, \cdots, \mathbf{c}_{ir}] \text{ then} \\ &\mathbf{c}_{ij}\psi_j(s_i) \neq \mathbf{0}, \qquad i = 1, \cdots, t; j = 1, \cdots, r.\}\end{aligned} \tag{2.26}$$

It is clear that $\mathcal{S}$ is open, dense and semialgebraic in Ω. Moreover, in order that $N_c(s) \in H^{m \times p}$, $D_c(s) \in H^{p \times p}$, it is necessary and sufficient that

$$\text{Adj } M(s_i)[\Delta_1^T \psi_1^T(s_1), \cdots, \Delta_r^T \psi_r^T(s_i)]^T = 0 \tag{2.27}$$

for all s_i where $\det M(s_i) = 0$, $i = 1, \cdots, t$. It follows from the definition of $\mathcal{S}$ in (2.26) that a necessary and sufficient condition for the solvability of (2.27) is that

$$\sum_{j=1}^{r} \mathbf{c}_{ij}\psi_j(s_i)\Delta_j(s_i) = 0 \tag{2.28}$$

for $i = 1, \cdots, t$. That indeed (2.28) is satisfied by a set of $\Delta_j(s)$, $j = 1, \cdots, r$ follows from Lemma 2.2 and Lemma 2.3.

Case 3 ($\min(m, p) = 1$, $r = m + p$). The computation of Case 2 can be repeated so that we obtain an equation of the type (2.28). Since $\mathbf{c}_{ij}\psi_j(s_i) \neq 0$, it follows from Lemmas 2.1 and 2.2 that indeed there exist $\Delta_1, \cdots, \Delta_r(s)$ which satisfy equation (2.28), provided for $s_i \in \{s_1, \cdots, s_t\} \cap \mathbb{R}$, $i = 1, \cdots, t_1$ the following condition is satisfied: Let us define $\{s_1, \cdots, s_{t_1}\} \triangleq \{s_1, \cdots, s_t\} \cap \mathbb{R}_u$. The real vectors

$$v_i = [\mathbf{c}_{i,1}\psi_1(s_i), \cdots, \mathbf{c}_{i,r}\psi_r(s_i)] \tag{2.29}$$

for $i = 1, \cdots, t_1$ and $-v_i$, $i = 1, \cdots, t_1$ miss an orthant in $\mathbb{R}^{m+p}$. Since "missing an orthant" in $\mathbb{R}^{m+p}$ may be described by open semialgebraic conditions, it follows that the partially pole assignable r tuples of plants in $\mathcal{S}$ is open, semialgebraic. Q.E.D.

Remark. The distinction between the results in Case 2 and Case 3 of Theorem 2.4 is to be noted. In Case 2, we claim that every r tuple of plants in the semialgebraic set $\mathcal{S}$ is simultaneously partially pole assignable. In Case 3, we only claim that the set of simultaneously partially pole assignable plants in $\mathcal{S}$ is semialgebraic and is given precisely by the above condition of "missing an orthant."

2.3. Proof of Theorem 2.5. The case $\min(m, p) = 1$ follows from Case 1 of Theorem 2.4. The case $\min(m, p) > 1$ proceeds by a reduction to the case $\min(m, p) = 1$ by a procedure called "vectoring down" adopted from Stevens' thesis [29] and from Brasch-Pearson [5]. The following two lemmas are now stated without proof (see [12], [18] for a proof).

LEMMA 2.4. *Given a r-tuple of $p \times m$ plants $G_i(s)$ of degrees n_i, each with n_i simple poles. There is an open dense set of $1 \times p$ vectors $v \in \mathbb{R}^p$ such that $vG_i(s)$ has degree n_i, for all i.*

LEMMA 2.5. *Given a r-tuple of $p \times m$ plants $G_i(s)$, $i = 1, \cdots, r$. There exists a constant gain output feedback K such that the closed-loop systems $G_i(s)[I + KG_i(s)]^{-1}$ have distinct simple poles.*

Thus by choosing any $(v, K) \in \mathbb{R}^p \times \mathbb{R}^{mp}$, we have a mapping

$$\phi: \Sigma \times \mathbb{R}^p \times \mathbb{R}^{mp} \to \Sigma_1, \tag{2.30}$$

$$\phi(G_1(s), \cdots, G_r(s), v, k) = (vG_i(s)[I + KG_i(s)]^{-1})_{i=1}^{r} \tag{2.31}$$

where Σ is the space of r-tuples of $p \times m$ plants and Σ_1 is the space of r-tuples of $1 \times m$ plants.

Since ϕ is rational in the coefficients of $G_1, \cdots, G_r, v, K$; the inequalities (2.24) together with the mapping ϕ would define semialgebraic, open, dense subset Ω_1 of $\Sigma \times \mathbb{R}^p \times \mathbb{R}^{mp}$ given by

$$f_\alpha(vG_1[I + KG_1]^{-1}, \cdots, vG_r[I + KG_r]^{-1}) \neq 0. \tag{2.32}$$

By considering the projection

$$\text{Proj}: \Sigma_{m,p}^{n_1} \times \cdots \times \Sigma_{m,p}^{n_r} \times \mathbb{R}^p \times \mathbb{R}^{mp} \to \Sigma_{m,p}^{n_1} \times \cdots \times \Sigma_{m,p}^{n_r} \tag{2.33}$$

we have the set

$$\mathcal{S} \triangleq \text{Proj}\, \Omega_1. \tag{2.34}$$

By the Tarski [31]-Seidenberg [28] theory of elimination over $\mathbb{R}$, $\mathcal{S}^1$ is semialgebraic. Moreover $\mathcal{S}^1$ is dense, since Ω_1 is dense. Thus $\mathcal{S}^1$ is semialgebraic, dense and is defined by union and/or intersection of sets given by polynomial equations or inequality

$$g_\alpha > 0 \quad \text{and} \quad [g_{\beta_1} > 0 \text{ or } g_{\beta_2} = 0] \quad \text{and} \quad g_\gamma = 0. \tag{2.35}$$

Since $g_\gamma(\mathcal{S}^1) = 0 \Rightarrow g_\gamma \equiv 0$, hence $\mathcal{S}$ defined by union and/or intersection of sets of the type $[g_\alpha > 0$ and $g_{\beta_1} > 0]$ is semialgebraic, open and dense in Σ. Note that $\mathcal{S}$ is dense in $\mathcal{S}^1$ since $\mathcal{S}$ is obtained by removing the set $[g_{\beta_2} \neq 0]$ from $\mathcal{S}^1$.

Thus a max (m, p) tuple of plants in $\mathcal{S}$ can be partially pole assigned by the vectoring down technique. Q.E.D.

2.4. Proof of Theorem 2.7. Let $G_1(s), \cdots, G_r(s)$ be the given r tuple of proper plants in Σ. Let $K(s)$ be a compensator in $\Sigma_{p,m}^{q}$. The associated return difference equation, $\det[I + K(s)G_i(s)] = 0$ is given by

$$\Pi_i(s) \overset{\Delta}{\equiv} \sum_{j=0}^{n_i+q} c_{ij} s^j \quad \text{for all } i = 1, 2, \cdots, r. \tag{2.36}$$

A generic r-tuple of plants defines a smooth mapping χ, between the compensator parameters and the coefficient of the return difference polynomials given by

$$\chi: \Sigma_{p,m}^{q} \to \mathbb{RP}^{n_1+q+1} \times \cdots \times \mathbb{RP}^{n_r+q+1}, \tag{2.37}$$

$$\chi(K) = ([c_{1,0}, \cdots, c_{1,n_1+q}], \cdots, [c_{r,0}, \cdots, c_{r,n_r+q}]) \tag{2.38}$$

where the right-hand side of (2.38) has been defined in homogeneous co-ordinates. It is well known [7], [8], [19] that $\Sigma_{p,m}^{q}$ is a manifold of dimension $q(m+p) + mp$. To say that there exists a compensator which partially pole assigns a generic r set of α_i self conjugated poles is to say that image χ contains a $\sum_{i=1}^{r} \alpha_i$ dimensional submanifold of $\mathbb{RP}^{n_1+q+1} \times \cdots \times \mathbb{RP}^{n_r+q+1}$. By Sard's theorem [23] a necessary condition is given by (2.6) concluding the proof. Q.E.D.

2.5. Proof of the corollaries. The Corollary 2.6 is immediate from Theorem 2.5 assuming $\psi_i(s) \equiv 1$, $i = 1, \cdots, r$. We now prove the Corollary 2.8. Substituting $\alpha_i = q + \beta_i$ in (2.6), we have

$$q(m+p-r)+mp \geqq \sum_{i=1}^{r} \beta_i \geqq r \min_i \beta_i. \tag{2.39}$$

A necessary condition that there exists some $q \in \mathbb{N}$ satisfying (2.39) is given by

$$r \leqq m+p-1 \quad \text{or} \quad r \min_i \beta_i \leqq mp. \tag{2.40}$$

Thus (2.7) is indeed a necessary condition concluding the proof of Corollary 2.8. Corollary 2.9 is a consequence of Corollary 2.8. Finally, the Corollary 2.10 follows from Theorems 2.5, 2.7 and Corollary 2.8.

3. Simultaneous partial pole placement of square systems.

3.1. The purpose of this section is to analyze the partial pole placement of a square system and obtain various equivalent characterization of the problem. Results of this type has been originally obtained by Saeks and Murray in [26] where they have shown that the problem of simultaneously stabilizing a pair of single input single output plants is equivalent to the problem of stabilizing a plant by a stable compensator. Likewise, it has been shown by Vidyasagar and Viswanadham [34] that the problem of simultaneously stabilizing r multiinput multioutput plants is equivalent to the problem of stabilizing $r-1$ plants by a stable compensator.

In this section we make contact with the "matrix version" of the transcendental problem described in the introduction. Adapting the proof of the "strong stabilization problem" in [35], we obtain a necessary condition for the solvability of the transcendental problem. We remark, however, that a necessary and sufficient condition for the transcendental problem is unknown, although for the scalar case, a separate necessary condition and a sufficient condition has been reported in [14]. The necessary condition also appears in the proof of Theorem 2.4 (Case 3). An interesting zero interlacing property of the necessary condition is described in § 5.

Let us now prove the following:

THEOREM 3.1. *A necessary and sufficient condition for the simultaneous partial pole placement of a r tuple* ($r \geqq 3$) *of* $m \times m$ *plants* $G_1(s), \cdots, G_r(s)$, *chosen generically, at the zeros of* $\det \psi_1(s), \cdots, \det \psi_r(s)$ *in* $\mathbb{C}_u$ *by a nonswitching* $m \times m$ *compensator is given by the existence of* $\Delta_1(s), \cdots, \Delta_r(s) \in H^{m\times m}$, $\det \Delta_i(s) \in J$, $i = 1, \cdots, r$ *satisfying*

$$[\Delta_1\psi_1(s) \quad \Delta_2\psi_2(s)]\begin{bmatrix} N_1(s) & N_2(s) \\ D_1(s) & D_2(s) \end{bmatrix}^{-1}\begin{bmatrix} N_i(s) \\ D_i(s) \end{bmatrix} = \Delta_i(s)\psi_i(s) \tag{3.1}$$

for $i = 3, \cdots, r$. *Here* $G_i(s) = N_i(s)D_i(s)^{-1}$ *is a coprime fraction representation of the ith plant and* $\psi_1(s), \cdots, \psi_r(s) \in H^{m\times m}$ *with the property that* $\det \psi_i(s)$, $i = 1, \cdots, r$ *do not have a common zero in* $\mathbb{C}_u$ *and have zeros only in* $\mathbb{C}_u$.

Remark. Let us define

$$[\mathcal{K}_{i1}^T(s) \quad \mathcal{K}_{i2}^T(s)]^T \triangleq \left\{\operatorname{Adj}\begin{bmatrix} N_1(s) & N_2(s) \\ D_1(s) & D_2(s) \end{bmatrix}\right\}\begin{bmatrix} N_i(s) \\ D_i(s) \end{bmatrix}, \tag{3.2}$$

$$\mathcal{K}_3(s) = \det\begin{bmatrix} N_1(s) & N_2(s) \\ D_1(s) & D_2(s) \end{bmatrix} \tag{3.3}$$

and rewrite (3.1) as

$$\Delta_1\psi_1\mathcal{K}_{i1} + \Delta_2\psi_2\mathcal{K}_{i2} = \Delta_i\psi_i\mathcal{K}_3, \tag{3.4}$$

$i=3,\cdots,r$. The matrix version of the transcendental Problem 1.4 is to solve (3.4) for a suitable $\Delta_i(s)$, where $\det \Delta_i(s) \in J$, $i=1,\cdots,r$. We now state the following necessary condition for the solvability of (3.4).

THEOREM 3.2. *Let $s_1,\cdots,s_t$ be a set of blocking zeros of $\psi_{i_0}(s)$, $i_0 \in \{3,\cdots,r\}$ in a connected component of $\mathbb{R}_u$. A necessary condition that the r-tuple of plants is simultaneously partially pole assignable at the zeros of* $\det \psi_i(s)$ *in $\mathbb{C}_u$, $i=1,\cdots,r$ respectively (where* $\det \psi_i(s)$, $i=1,\cdots,r$ *do not have a common zero in $\mathbb{C}_u$) is given by*

(3.5) "sign $[\det \psi_1 \mathcal{K}_{i_01}(s_j)] \times [\det \psi_2 \mathcal{K}_{i_02}(s_j)$ *is the same for $j=1,\cdots,t$.*"

3.2. Proof of Theorem 3.1. Let $K(s)=D_c(s)^{-1}N_c(s)$ be the coprime representation of the required compensator. (only if): Assume simultaneous partial pole assignability of the r-tuple of plants $G_1,\cdots,G_r$ by the compensator $K(s)$. Clearly there exists $\Delta_1(s),\cdots,\Delta_r(s) \in H^{m\times m}$, $\det \Delta_i(s) \in J$, $i=1,\cdots,r$ respectively such that

$$N_c(s)N_i(s)+D_c(s)D_i(s)=\Delta_i(s)\psi_i(s) \tag{3.6}$$

for all $i=1,\cdots,r$. Eliminating $D_c(s)$ and $N_c(s)$ from (3.6), we obtain (3.1).

(if): Assume that there exists $\Delta_1(s),\cdots,\Delta_r(s) \in H^{m\times m}$, $\det \Delta_i(s) \in J$ satisfying (3.1). Let us denote

$$P(s)=\begin{bmatrix} N_1(s) & N_2(s) \\ D_1(s) & D_2(s) \end{bmatrix}, \tag{3.7}$$

$$[N_c(s) \quad D_c(s)] \triangleq [\Delta_1\psi_1(s) \quad \Delta_2\psi_2(s)]P(s)^{-1}. \tag{3.8}$$

We need to show that $N_c(s)$, $D_c(s) \in H^{m\times m}$; $N_c(s)$, $D_c(s)$ are coprime, $N_c(s)$, $D_c(s)$ satisfy (3.6) and finally $D_c^{-1}N_c(s)$ is proper. Assume generically that

(3.9) a. $P(s)$ has simple zeros in $\mathbb{C}_u$ at $s_1,\cdots,s_t$,

(3.10) b. Adj $P(s_i)$, $i=1,\cdots,t$ are of rank 1,

(3.11) c. If the rows of Adj $P(s_i)$ are spanned by $[r_{i,1}\cdots r_{i,2m}]$, then
$$[r_{i1} \quad r_{i,2m}][N_j^T \quad D_j^T]^T(s_i) \neq 0 \quad \text{for } j=3,\cdots,r,$$

(3.12) d. $\det P(\infty) \neq 0$.

To see that $N_c(s)$, $D_c(s) \in H^{m\times m}$, we consider the following. From (3.1), (3.9) it follows that

$$[\Delta_1\psi_1(s_1) \quad \Delta_2\psi_2(s_i)] \text{ Adj } P(s_i)[N_j(s_i)^T \quad D_j(s_i)^T]^T = 0 \tag{3.13}$$

for $i=1,\cdots,t$; $j=3,\cdots,r$. From (3.10), (3.11) and (3.13) one infers that

$$[\Delta_1\psi_1(s_i) \quad \Delta_2\psi_2(s_i)] \text{ Adj } P(s_i) = 0. \tag{3.14}$$

From (3.8), (3.9) and (3.14) it follows that $N_c(s)$, $D_c(s) \in H^{m\times m}$. Moreover from (3.1), (3.8), it is clear that N_c, D_c satisfy (3.6). Also $N_c(s)$, $D_c(s)$ are coprime for otherwise there exists $s^* \in \mathbb{C}_u$ such that $[N_c(s^*), D_c(s^*)]$ has rank $< m$. This implies that for every $i=1,\cdots,r$,

$$\det [N_c(s)N_i(s)+D_c(s)D_i(s)] \tag{3.15}$$

vanishes at s^*. It follows that $\det \psi_i(s^*)=0$, which contradicts the hypothesis on $\psi_i(s)$, $i=1,\cdots,r$. Finally from (3.8) and (3.12) it follows that $D_c^{-1}N_c$ is proper. Q.E.D.

3.3. Proof of Theorem 3.2. From (3.4) one infers that

$$\Delta_1(s_j)\psi_1\mathcal{H}_{i_01}(s_j) = -\Delta_2(s_j)\psi_2\mathcal{H}_{i_02}(s_j) \tag{3.16}$$

for all $j = 1, \cdots, t$. Thus

$$\text{sign}\,[\det \Delta_1(s_j) \times \det \Delta_2(s_j)] = \text{sign}\,[\det (\psi_1\mathcal{H}_{i_01}(s_j))\ \det (\psi_2\mathcal{H}_{i_02}(s_j))]. \tag{3.17}$$

The proof now follows from the observation that the sign of the left-hand side of (3.17) does not change for $j = 1, \cdots, t$. Q.E.D.

4. Simultaneous partial pole placement of r min $(m, p) = 1$ plants.

4.1. In this section we consider the simultaneous stabilization problem of r single input or single output systems. The case $r \leqq \max(m, p)$ has been considered in Theorem 2.5. Here we restrict attention to $r > \max(m, p)$. First of all we parametrize the set of all compensators simultaneously stabilizing a generic m tuple of $1 \times m$ plants and prove the following.

THEOREM 4.1. *The problem of simultaneously stabilizing a $m+p$ tuple of* min $(m, p) = 1$ *systems is equivalent to the problem of stabilizing a* min $(m, p) = 1$ *system by a minimum phase compensator.*

In particular for $m = p = 1$ we obtain the following corollary.

COROLLARY 4.2. *The following three problems are equivalent.*

(i) *The problem of stabilizing a pair of single input single output systems.*

(ii) *The problem of stabilizing a single input single output system by a stable compensator.*

(iii) *The problem of stabilizing a single input single output system by a minimum phase compensator.*

Of course the equivalence between (i) and (ii) was originally obtained by Saeks and Murray [26], Vidyasagar and Viswanadham [34].

The importance of the partial pole placement problem is further emphasized by the following.

THEOREM 4.3. *Assume* min $(m, p) = 1$. *The problem of simultaneously stabilizing $m+p+k$, systems (assume $k \geqq 1$) chosen generically is equivalent to the problem of simultaneous partial pole placement of k systems by a stable minimum phase compensator.*

In particular for $m = p = k = 1$ we obtain

COROLLARY 4.4. (Ghosh [14]). *The problem of simultaneously stabilizing 3 single input single output plants chosen generically is equivalent to the problem of partially pole placing one single input single output plants by a stable minimum phase compensator.*

With reference to Theorem 4.3, we remark that the simultaneous partial pole placement problem of a single input single output plant by a stable, minimum phase compensator is precisely the transcendental Problem 1.4 and has been analyzed by Ghosh [14]. In particular conditions have been obtained which are separately necessary and sufficient. These conditions can be analogously stated for the min $(m, p) = 1$ case and we refer to [12] for details.

4.2. Parametrizing the set of all compensators simultaneously stabilizing a generic m-tuple of $1 \times m$ systems. Let us represent an m-tuple of $1 \times m$ plants as

$$g_i(s) = \left[\frac{x_{i,1}(s)}{x_{i,m+1}(s)}\ \frac{x_{i,2}(s)}{x_{i,m+1}(s)} \cdots \frac{x_{i,m}(s)}{x_{i,m+1}(s)}\right] \tag{4.1}$$

where $x_{i,j}(s) \in H$, $i = 1, \cdots, m$; $j = 1, \cdots, m+1$. Let us also represent a $m \times 1$ compensator as

$$k(s) = \left[\frac{y_1(s)}{y_{m+1}(s)}\ \frac{y_2(s)}{y_{m+1}(s)} \cdots \frac{y_m(s)}{y_{m+1}(s)}\right]^T \tag{4.2}$$

where $y_j(s) \in H$, $j = 1, \cdots, m+1$. To say that the above m-tuple of systems (4.1) is stabilizable by the compensator (4.2) is to say that there exists $\Delta_1(s), \cdots, \Delta_m(s) \in J$ such that

$$\sum_{j=1}^{m+1} x_{i,j}(s) y_j(s) = \Delta_i(s) \tag{4.3}$$

$i = 1, \cdots, m$. Let

$$\mathbf{y}^h(s) = [y_1^h(s) \cdots y_{m+1}^h(s)] \tag{4.4}$$

be the solution of the homogeneous equation

$$\sum_{j=1}^{m+1} x_{i,j}(s) y_j(s) = 0 \tag{4.5}$$

$i = 1, \cdots, m$ and

$$\mathbf{y}^{p_i} = [y_1^{p_i}(s), \cdots, y_{m+1}^{p_i}(s)] \tag{4.6}$$

be a particular solution of the equation.

$$\begin{bmatrix} x_{1,1}(s) & \cdots & x_{1,m+1}(s) \\ \vdots & & \vdots \\ x_{m,1}(s) & & x_{m,m+1}(s) \end{bmatrix} \cdot \begin{bmatrix} y_1(s) \\ \vdots \\ y_{m+1}(s) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} \leftarrow i\text{th spot.} \tag{4.7}$$

A complete solution of (4.3) is given by

$$\mathbf{y}(s) = \delta(s)\mathbf{y}^h(s) + \sum_{i=1}^{m} \Delta_i(s)\mathbf{y}^{p_i}(s) \tag{4.8}$$

where $\delta(s) \in H$, $\Delta_i(s) \in J$ for $i = 1, \cdots, m$. The set of all compensators simultaneously stabilizing the m tuple of $\min(m, p) = 1$ systems is given by

$$\left[\frac{\delta(s)y_1^h(s) + \sum_{i=1}^m \Delta_i(s) y_1^{p_i}(s)}{\delta(s)y_{m+1}^h(s) + \sum_{i=1}^m \Delta_i(s) y_{m+1}^{p_i}(s)}, \cdots, \frac{\delta(s)y_m^h(s) + \sum_{i=1}^m \Delta_i(s) y_m^{p_i}(s)}{\delta(s)y_{m+1}^h(s) + \sum_{i=1}^m \Delta_i(s) y_{m+1}^{p_i}(s)} \right] \tag{4.9}$$

for some $\delta(s) \in H$, $\Delta_i(s) \in J$, $i = 1, \cdots, m$.

4.3. Proof of Theorem 4.1. Consider a set of $m+1$ tuple of $1 \times m$ plants given by (4.1). The set of all compensators that would stabilize a m-tuple of $1 \times m$ plants is given by (4.9). In order that it also stabilizes the $(m+1)$th plant, we need to satisfy the equation

$$\sum_{j=1}^{m+1} x_{m+1,j}(s) \left[\delta(s) y_j^h(s) + \sum_{i=1}^{m} \Delta_i(s) y_j^{p_i}(s) \right] = \Delta_{m+1}(s) \tag{4.10}$$

for some $\Delta_1, \cdots, \Delta_{m+1} \in J$, $\delta(s) \in H$.

Equation (4.10) can be rewritten as

$$\delta(s) \left[\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^h(s) \right] + \sum_{i=1}^{m} \Delta_i(s) \left[\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^{p_i}(s) \right] = \Delta_{m+1}(s). \tag{4.11}$$

Thus if a $m+1$ tuple of plants is simultaneously stabilizable, the plant

$$\left[\frac{\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^{p_1}(s)}{\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^h(s)} \cdots \frac{\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^{p_m}(s)}{\sum_{j=1}^{m+1} x_{m+1,j}(s) y_j^h(s)} \right] \tag{4.12}$$

is stabilizable by the minimum phase compensator

$$\left[\frac{\Delta_1(s)}{\delta(s)}, \cdots, \frac{\Delta_m(s)}{\delta(s)}\right]. \tag{4.13}$$

Conversely the minimum phase compensator (4.13) also stabilizes the $1 \times m$ plants

$$[kl_1(s), 0, \cdots, 0], [0, kl_2(s), 0, \cdots, 0], \cdots, [0, 0, \cdots, 0, kl_m(s)] \tag{4.14}$$

for $l_i(s) \in J$ and where $k \in \mathbb{R}$ is to be chosen arbitrarily large. □

4.4. Proof of Theorem 4.3. First of all, we shall need the following lemma.

LEMMA 4.1. *The problem of simultaneously stabilizing a pair of* $\min(m, p) = 1$ *systems chosen generically by a minimum phase compensator is equivalent to the problem of partially pole placing a* $\min(m, p) = 1$ *system by a stable, minimum phase compensator.*

Proof. As before we consider a pair of $1 \times m$ systems given by (4.1). Assume that these two systems are stabilizable by a minimum phase compensator (4.2) where $y_i(s) \in J$, $i = 1, \cdots, m$ and $y_{m+1}(s) \in H$, and

$$\begin{aligned} x_{1,1}(s)y_1(s) + \cdots + x_{1,m+1}(s)y_{m+1}(s) &= \Delta_1, \\ x_{2,1}(s)y_1(s) + \cdots + x_{2,m+1}(s)y_{m+1}(s) &= \Delta_2. \end{aligned} \tag{4.15}$$

Assume $x_{1,m+1}(s) \not\equiv 0$, $x_{2,m+1}(s) \not\equiv 0$; we have

$$\begin{aligned} y_{m+1}(s) &= \frac{1}{x_{1,m+1}(s)}\Delta_1(s) - \sum_{j=1}^{m} \frac{x_{1,j}(s)}{x_{1,m+1}(s)} y_j(s) \\ &= \frac{1}{x_{2,m+1}(s)}\Delta_2(s) - \sum_{j=1}^{m} \frac{x_{2,j}(s)}{x_{2,m+1}(s)} y_j(s) \end{aligned} \tag{4.16}$$

or

$$\begin{aligned} x_{2,m+1}(s)\Delta_1(s) - \sum_{j=1}^{m} x_{2,m+1}(s)x_{1,j}(s)y_j(s) &= x_{1,m+1}(s)\Delta_2(s) \\ &\quad - \sum_{j=1}^{m} x_{1,m+1}(s)x_{2,j}(s)y_j(s) \end{aligned} \tag{4.17}$$

or equivalently

$$x_{2,m+1}(s)\Delta_1(s) + \sum_{j=1}^{m} [x_{1,m+1}(s)x_{2,j}(s) - x_{2,m+1}(s)x_{1,j}(s)]y_j(s) = x_{1,m+1}(s)\Delta_2(s). \tag{4.18}$$

We now claim the following. To say that (4.15) is solvable is to say that (4.18) is solvable for some $\Delta_1(s)$, $\Delta_2(s)$, $y_j(s) \in J$, $j = 1, \cdots, m$. Since (4.18) is the algebraic condition for the partial pole placement of a $\min(m, p) = 1$ plant, we have the lemma. Conversely note that if (4.18) is solvable then there exists a $y_{m+1}(s) \in H$ defined by (4.16) which satisfies (4.15), provided there does not exist $s^* \in \mathbb{C}_u$ where $x_{1,m+1}$, $x_{2,m+1}$, $(x_{1,m+1}x_{2,j} - x_{2,m+1}x_{1,j})$, $j = 1, \cdots, m$ vanish. Q.E.D.

The proof of Theorem 4.3 now follows by the following argument. Let $g_1, \cdots, g_{m+p+k}$ be a $m+p+k$ tuple of $\min(m, p) = 1$ systems. Consider the following k, $m+p+1$ tuples of systems

$$(g_1, \cdots, g_{m+p}, g_{m+p+1}), \cdots, (g_1, \cdots, g_{m+p}, g_{m+p+j}).$$

By Theorem 4.1 and Lemma 4.1, stabilizability of each of the above $m+p+1$ tuple of plants is equivalent to the partial pole assignment of a $\min(m, p) = 1$ plant by a stable

minimum phase compensator. Thus to say that all the k, $m+p+1$ tuples are stabilizable is to say that a k tuple of min $(m, p) = 1$ plants are partially pole assignable by a stable, minimum phase compensator. Q.E.D.

5. Examples. In this section we construct the following two examples:

5.1. *Example* 1. Assume $\mathbb{C}_u$ to be the closed right half of the complex plane. Consider the following triplet of single input single output plants of McMillan degrees 1.

$$\frac{s-7}{s-4.6}, \quad \frac{s-2}{2s-2.6}, \quad \frac{s-6}{4.8s-24.6}. \tag{5.1}$$

We claim that every pair of plants in the above triplet are simultaneously stabilizable. This may be trivially checked, using the necessary and sufficient condition due to Saeks and Murray [26]. On the other hand, the above triplet is simultaneously stabilizable iff there exists $\Delta_1(s)$, $\Delta_2(s)$, $\Delta_3(s) \in J$ such that

$$\begin{aligned}&\Delta_1(s)[2.8(s-4)(s-3)]/[(s-1)(s-9)]\\ &\quad+\Delta_2(s)[(-3.8s^2+47.6s-144.6)]/[(s-1)(s-9)]+\Delta_3(s)\equiv 0.\end{aligned} \tag{5.2}$$

A necessary condition that (6.2) is satisfied is that the vectors

$$\pm\left[\frac{2.8(s-4)(s-3)}{(s-1)(s-9)} \quad \frac{-3.8s^2+47.6s-144.6}{(s-1)(s-9)} \quad 1\right] \tag{5.3}$$

miss an orthant in $\mathbb{R}^3$ for all $s \in \mathbb{C}_u$. For $s = 0$, 2, 3.5, 6 the above vector (5.3) may be computed as

$$\begin{aligned}&\pm[3.73 \quad -16.066 \quad 1], \quad \pm[-.8 \quad 9.2286 \quad 1],\\ &\pm[.0501 \quad 1.7854 \quad 1], \quad \pm[-1.12 \quad -.28 \quad 1],\end{aligned}$$

respectively. Thus it follows that the triplet of plants in (5.1) is simultaneously unstabilizable.

Remark. The transcendental problem which arises in the simultaneous stabilization of a triplet of plants $x_i(s)/y_i(s)$, $i = 1, 2, 3$ is given by (1.2). A necessary condition that (1.2) is solvable is that every pair in the above triplet is simultaneously stabilizable. If the triplet is chosen generically, then it is easy to show that: "every pair in the above triplet is simultaneously stabilizable iff the total number of zeros of $\eta_{ij}(s)$, $\eta_{ik}(s)$ in between every two consecutive zeros of $\eta_{jk}(s)$ in any connected component of $\mathbb{R}_u$ is even, for $i, j, k \in \{1, 2, 3\}$, $i \neq j \neq k$, where $\eta_{ij} = x_i y_j - x_j y_i$." The three plants in (5.1) are an example of such a triplet. It is interesting however that even when the above interlacing condition is satisfied, if the zeros of η_{ij}, η_{ik}, η_{jk} are interlaced in a connected component of $\mathbb{R}_u$ as shown in Fig. 5.1, the equation (1.2) cannot be solved and the triplet under consideration is simultaneously unstabilizable.

FIG. 5.1. *The zeros of η_{ij}, η_{jk}, η_{ik} in a connected component of $\mathbb{R}_u$ are denoted by "×", "○" and "*". The zero distribution represents an example of a triplet of plants that are not simultaneously stabilizable but are simultaneously stabilizable in pairs.*

Example 2. Consider the following triplet of 1×3 plants

$$\left[\frac{-26}{18s-70}\quad\frac{54}{18s-70}\quad\frac{18s-42}{18s-70}\right], \tag{5.4}$$

$$\left[\frac{9s+10}{9s+2}\quad\frac{-9s}{9s+2}\quad\frac{9s+12}{9s+2}\right], \tag{5.5}$$

$$\left[\frac{-9s+9}{9s-9}\quad\frac{9s+9}{9s-9}\quad\frac{9s+9}{9s-9}\right]. \tag{5.6}$$

We now show that the above triplet is not simultaneously stabilizable.

Suppose not, and let (4.2) be the stabilizing compensator. Clearly we need to satisfy

$$\begin{bmatrix} \frac{-26}{s-a} & \frac{-54}{s-a} & \frac{-18s+42}{s-a} & \frac{-18s+42}{s-a} \\ \frac{9s+10}{s-a} & \frac{-9s}{s-a} & \frac{-9s}{s-a} & \frac{9s+2}{s-a} \\ \frac{-9s+9}{s-a} & \frac{9s+9}{s-a} & \frac{9s+9}{s-a} & \frac{9s-9}{s-a} \end{bmatrix} \begin{bmatrix} y_1(s) \\ y_2(s) \\ y_3(s) \\ y_4(s) \end{bmatrix} = \begin{bmatrix} \Delta_1(s) \\ \Delta_2(s) \\ \Delta_3(s) \end{bmatrix} \tag{5.7}$$

for some $y_i(s)\in H$, $i=1,2,3,4$ and $\Delta_i(s)\in J$, $i=1,2,3$. In (5.7) "a" is chosen in such a way that $s-a$ vanishes in $\mathbb{C}_s$. It may be checked that the rows of the matrix in (5.7) are linearly dependent so that Δ_1, Δ_2, Δ_3 must satisfy

$$\Delta_1(s)[(s^2-1)/(s^2-s-6)]+\Delta_2(s)[(s^2-6s+8)/(s^2-s-6)]+\Delta_3(s)=0. \tag{5.8}$$

By evaluating the vector

$$[(s^2-1)\quad(s^2-6s+8)\quad(s^2-s-6)] \tag{5.9}$$

at $s=1.5$, 2.5, 3.5, 4.5 and using Lemma 2.1, we may infer that the triplet (5.4), (5.5), (5.6) is not simultaneously stabilizable.

Remark. Considering the fact that a generic triplet of 1×3 systems is simultaneously stabilizable, the triplet of plants in Example 2 is an "exceptional triplet." This serves to illustrate that the transcendental technique introduced in this paper can analyze "nongeneric" problems as well.

6. Conclusion. In this paper, we discuss in great details the application of scalar and matrix interpolation and transcendental methods in system design. In particular the transcendental problem arises in the partial pole assignment of a multiinput multioutput plant by a stable, minimum phase compensator. The latter problem seems to arise in the simultaneous stabilization problems and also in the nonswitching compensator problem [15]. The interpolation problem on the other hand is well known in control theory and has already been introduced in [26], [27], [34] and [35].

Among the results that we have obtained in this paper, the most significant result is that if $r\min(m,p)\leqq m+p$, the simultaneous partial pole assignment problem may be analyzed via interpolation methods and one obtains a semialgebraic parametrization of the partially pole assignable r-tuples of plants. On the other hand if $r\min(m,p)>m+p$ (as would be the case if $m=p$, $r\geqq 3$), the simultaneous partial pole assignment problem is to be analyzed via transcendental methods of the type introduced in this paper. The proposed transcendental approach, we hope, would become a new simultaneous system design methodology and may be generalized to include sensitivity minimization and other system design criterion as well.

Acknowledgments. It is a pleasure to acknowledge the reviewers' comments on an earlier draft of this paper. Encouragement of Profs. C. I. Byrnes and M. Vidyasagar is gratefully acknowledged.

OPTIMAL CONTROL WITH STATE-SPACE CONSTRAINT II*

HALİL METE SONER†

Abstract. Optimal control of piecewise deterministic processes with state space constraint is studied. Under appropriate assumptions, it is shown that the optimal value function is the only viscosity solution on the open domain which is also a supersolution on the closed domain. Finally, the uniform continuity of the value function is obtained under a condition on the deterministic drift.

Key words. viscosity solutions, stochastic control, state-space constraint, piecewise deterministic processes

AMS(MOS) subject classifications. 93E20, 35J65, 35K60, 60J60

Introduction. We are interested in the optimal control of jump processes with a state-space constraint. By that we mean the trajectories of the controlled process have to stay within a given subset θ of $\mathbb{R}^n$. These kinds of processes arise naturally in some applications [5], [9], [10]. The deterministic counterpart of this problem is studied in [11] and the optimal value function is characterized as the viscosity solution of the corresponding Hamilton-Jacobi-Bellman (HJB) equation. Also the concept of viscosity solutions, introduced by M. G. Crandall and P.-L. Lions [2], was used to identify the boundary conditions satisfied by the optimal value function. For more information about viscosity solutions see [1], [3], [7], [8] and references therein.

In this paper we generalize the results mentioned above to a certain class of jump processes, namely piecewise deterministic processes. These kinds of processes are introduced by M. Davis [4] and used by D. Vermes in [12]. Let us summarize the construction of the piecewise deterministic processes.

Let u be a Borel measurable map of $\bar{\theta} = [0, \infty)$ into a compact, separable metric space U and $y_0(x, s; t, u)$ be the solution of

$$\frac{d}{dt} y_0(x, s, t, u) = b(y_0(x, s, t, u), u(x, t-s)) \quad \text{for } t \geqq s \tag{0.1}$$

with initial data $y(x, s, s, u) = x$. Pick the first jump time T_1 so that the jump rate is $\lambda(y_0(x, 0, t, u))$. Then construct the post-jump location Y_1 such that $Q(y_0(x, 0, \tau, u), u(x, \tau), \cdot)$ is its conditional distribution given $T_1 = \tau$. Starting from Y_1 at time T_1 select the inter-jump time $T_2 - T_1$ and the second post-jump location Y_2 similarly. Set $T_0 = 0$, $Y_0 = x$ and iterate the procedure above to obtain $\{(T_n, Y_n): n = 0, 1, \cdots\}$. Between the jumps T_n and T_{n+1} the process $y(x, t, u)$ follows the deterministic trajectory passing through (Y_n, T_n), i.e.

$$y(x, t, u) = y_0(Y_n, T_n, t, u) \quad \text{if } t \in [T_n, T_{n+1}). \tag{0.2}$$

Moreover, $\{(Y_n, T_n)\}$ satisfies

$$\begin{aligned} &P(T_{n+1} - T_n \geqq t \mid T_1, Y_1, \cdots, T_n, Y_n) \\ &\qquad = \exp\left\{-\int_{T_n}^{t+T_n} \lambda(y(x, s, u), u(Y_n, s - T_n))\, ds\right\}, \end{aligned} \tag{0.3}$$

* Received by the editors March 11, 1985, and in revised form August 6, 1985. This research was supported by the National Science Foundation under grant MCS 8121940.

† Lefschetz Center for Dynamical Systems, Division of Applied Mathematics, Brown University, Providence, Rhode Island 02912.

$$P(Y_{n+1} \in A | T_1, Y_1, \cdots, Y_n, T_{n+1}) = Q(y_0(Y_n, T_n, T_{n+1}, u), u(Y_n, T_{n+1} - T_n), A) \quad \text{for all } A \subset \bar{\theta}. \tag{0.4}$$

The process $y(x, \cdot, u)$ is a strong Markov process and the following version of Ito's lemma is proved in [4]. Set $y(t) = y(x, t, u)$ and $u_n(t) = u(Y_n, t - T_n)$. Then for any $\psi \in C^1(\bar{\theta} \times [0, T])$ we have

$$\begin{aligned} E\psi(y(T), T) &= \psi(x, 0) + E\left\{ \sum_{n=0}^{\infty} \int_{T_n \wedge T}^{T_{n+1} \wedge T} \left[b(y(t), u_n(t)) \nabla \psi(y(t), t) \right.\right. \\ &\qquad + \frac{\partial}{\partial t} \psi(y(t), t) + \lambda(y(t), u_n(t)) \\ &\qquad \left.\left. \cdot \int_{\bar{\theta}} [\psi(z, t) - \psi(y(t), t)] Q(y(t), u_n(t), dz) \right] dt \right\}. \end{aligned} \tag{0.5}$$

We assume that the post-jump locations are in $\bar{\theta}$. Then one can define the set of admissible strategies $\mathcal{A}_{ad}$ as:

$$\mathcal{A}_{ad} := \left\{ \begin{array}{l} u: \bar{\theta} \times [0, \infty) \to U, \text{ Borel measurable and} \\ P(y(x, t, u) \in \bar{\theta} \text{ for all } t \geqq 0) = 1, \text{ for all } x \in \bar{\theta} \end{array} \right\}. \tag{0.6}$$

The optimal value is given by

$$v(x) := \inf_{u \in \mathcal{A}_{ad}} E\left\{ \sum_{n=0}^{\infty} \int_{T_n}^{T_{n+1}} e^{-t} f(y(x, t, u), u(Y_n, t - T_n))\, dt \right\}. \tag{0.7}$$

It is shown, in § 2, that v is the only viscosity solution of the corresponding HJB equation, satisfying the same boundary condition as in the deterministic case [11]. This result holds if the optimal value is in $BUC(\bar{\theta})$ and the dynamic programming relation (0.8) is satisfied.

$$v(x) = \inf_{u \in \mathcal{A}_{ad}} E\left\{ \int_0^{T \wedge T_1} e^{-t} f(y(x, t, u), u(x, t))\, dt + e^{-T \wedge T_1} v(y(x, T \wedge T_1, u)) \right\} \quad \text{for all } T \geqq 0 \text{ and } x \in \bar{\theta}. \tag{0.8}$$

Finally, in § 3 we show that under assumptions (A2)-(A4) v is in $BUC(\bar{\theta})$ and satisfies the dynamic programming relation (0.8). Note that these assumptions yield that the optimal value of the corresponding deterministic problem is in $BUC(\bar{\theta})$. By an induction argument one can extend this result to piecewise deterministic processes with finitely many jumps. We eventually pass to the limit to conclude.

1. Main result. Let θ be an open subset of $\mathbb{R}^n$ with connected boundary satisfying:

(A.1) There are positive constants h, r and $\mathbb{R}^n$-valued bounded-uniformly continuous map η of $\bar{\theta}$ such that

$$B(x + t\eta(x), tr) \subset \bar{\theta} \quad \text{for all } x \in \bar{\theta} \text{ and } t \in (0, h].$$

Here $B(x, R)$ denotes the ball with center x and radius R.

Remark 1.1. If θ is bounded and $\partial\theta$ is C^1, then (A.1) is satisfied. Also boundaries with corners may satisfy (A.1), for example, $\theta = \{(x, y) \in R^2 : x > 0, y > 0\}$.

The strategies take values in U which is a compact, separable metric space. Also, we assume the following throughout the paper. Let x and y be in $\bar{\theta}$.

$$\sup_{\alpha\in U}|\gamma(x,\alpha)-\gamma(y,\alpha)|\leqq L(\gamma)|x-y|, \qquad \gamma=b,f \text{ or } \lambda, \tag{1.1}$$

$$\sup_{\substack{\alpha\in U\\ x\in\bar{\theta}}}|\gamma(x,\alpha)|\leqq K(\gamma), \qquad \gamma=b,f \text{ or } \lambda. \tag{1.2}$$

For each bounded, continuous function h on $\bar{\theta}$, there is a continuous function W_h with $W_h(0)=0$ such that

$$\sup_{\alpha\in U}\left|\int_{\bar{\theta}}h(z)Q(x,\alpha,dz)-\int_{\bar{\theta}}h(z)Q(y,\alpha,dz)\right|\leqq W_h(|x-y|). \tag{1.3}$$

$$Q(x,\alpha,\bar{\theta})=1 \quad \text{for all } x\in\bar{\theta} \text{ and } \alpha\in U. \tag{1.4}$$

$$\lambda(x,\alpha)\geqq 0 \quad \text{for all } x\in\bar{\theta} \text{ and } \alpha\in U. \tag{1.5}$$

The corresponding Hamiltonian H is a continuous map of $\bar{\theta}\times\mathbb{R}^n\times BUC(\bar{\theta})$ given as:

$$H(x,p,\psi)=\sup_{\alpha\in U}\left\{-b(x,\alpha)\cdot p-f(x,\alpha)-\lambda(x,\alpha)\int_{\bar{\theta}}[\psi(z)-\psi(x)]Q(x,\alpha,dy)\right\}. \tag{1.6}$$

This Hamiltonian is a nonlocal operator but still one can define a notion of viscosity solutions.

DEFINITION. Let K be a subset of $\mathbb{R}^n$ and $v\in BUC(\bar{K})$.

(i) We say v is a *viscosity subsolution* of $v(x)+H(x,Dv(x),v)=0$ on K if $v(x_0)+H(x_0,\nabla\psi(x_0),v)\leqq 0$ whenever $\psi\in C^1(N_{x_0})$ and $(v-\psi)$ has a global maximum, relative to K, at $x_0\in K$, where N_{x_0} is a neighborhood of x_0.

(ii) We say v is a *viscosity supersolution* of $v(x)+H(x,Dv(x),v)=0$ on K if $v(x_0)+H(x_0,\nabla\psi(x_0),v)\geqq 0$ whenever $\psi\in C^1(N_{x_0})$ and $(v-\psi)$ has a global minimum, relative to K, at $x_0\in K$, where N_{x_0} is a neighborhood of x_0.

Remark 1.2. This is an obvious generalization of the original notion introduced by M. G. Crandall and P.-L. Lions [2]. The definition we used above is analogous to one of the definitions introduced in [1].

We are interested in the following notion of viscosity solutions.

DEFINITION. $v\in BUC(\bar{\theta})$ is said to be a *constrained viscosity solution* of $v(x)+H(x,Dv(x),v)=0$ on $\bar{\theta}$ if it is a subsolution on θ and supersolution on $\bar{\theta}$.

Remark 1.3. The fact that v is a supersolution on the closed domain imposes a certain boundary condition. Suppose that v is smooth and a constrained viscosity solution. Then $H(x,\nabla v(x)+\alpha v(x),v)\geqq H(x,\nabla v(x),v)$ for all $x\in\partial\theta$ and $\alpha\geqq 0$ ($v(x)$ is the exterior normal vector). This effect is discussed in [11].

THEOREM 1.1. *Suppose* (A.1), (1.1)-(1.5) *hold. Then there is at most one constrained viscosity solution of* $v(x)+H(x,Dv(x),v)=0$ *on* θ. *Moreover if* $v\in BUC(\bar{\theta})$ *and dynamic programming relation* (0.8) *holds, then the optimal value function* v *is a constrained viscosity solution.*

2. Proof of the main theorem. We need the following lemma:

LEMMA 2.1. $v\in BUC(\bar{\theta})$ *is a viscosity subsolution of* $v(x)+H(x,Dv(x),v)=0$ *on* θ (*or supersolution on* $\bar{\theta}$) *if and only if*

$$v(x_0)+H(x_0,\nabla\psi(x_0),\psi)\leqq 0$$

(*or* $\geqq 0$) *whenever* $\psi\in C^1(N_{x_0})$ *and* $v-\psi$ *has a global maximum relative to* $\bar{\theta}$ *at* $x_0\in\theta$ (*or minimum at* $x_0\in\bar{\theta}$ *respectively*), *where* N_{x_0} *is a neighborhood of* x_0.

Proof. We will prove the statement for subsolutions only, the other statement is proved exactly the same way.

Necessity. Suppose $v \in BUC(\bar{\theta})$ is a viscosity subsolution and ψ, x_0 are as above, i.e.

$$v(x_0) - \psi(x_0) = \max_{x \in \theta} v(x) - \psi(x).$$

Then we have $v(x_0) - v(z) \leqq \psi(x_0) - \psi(z)$ for all $z \in \bar{\theta}$. Then (1.5) yields:

$$H(x_0, \nabla\psi(x_0), \psi) \leqq H(x_0, \nabla\psi(x_0, v).$$

Hence the viscosity property of v gives the result.

Sufficiency. Let $\psi \in C^1(N_{x_0})$ and $(v-\psi)(x_0) = \max_{x \in \theta}\{(v-\psi)(x)\} = 0$. For each $\varepsilon > 0$ we define Φ^ε as follows:

$$\Phi^\varepsilon(x) = \psi(x)\chi^\varepsilon(x) + v(x)(1-\chi^\varepsilon(x)) \quad \text{for } x \in \bar{\theta} \tag{2.1}$$

where χ^ε is a smooth function satisfying

$$\begin{aligned} &0 \leqq \chi^\varepsilon \leqq 1, \\ &\chi^\varepsilon(x) = 1 \quad \text{if } x \in B(x_0, \varepsilon), \\ &\chi^\varepsilon(x) = 0 \quad \text{if } x \in R^n \setminus B(x_0, 2\varepsilon). \end{aligned} \tag{2.2}$$

Observe $v(x_0) - \Phi^\varepsilon(x_0) = 0$ and $v(x) - \Phi^\varepsilon(x) = (v(x) - \psi(x))\chi^\varepsilon(x) \leqq 0$. Hence

$$v(x_0) - \Phi^\varepsilon(x_0) = \max_{x \in \bar{\theta}} \{v(x) - \Phi^\varepsilon(x)\}. \tag{2.3}$$

Thus the hypothesis of the lemma and $\nabla\Phi^\varepsilon(x_0) = \nabla\psi(x_0)$ yields

$$v(x_0) + H(x_0, \nabla\psi(x_0), \Phi^\varepsilon) \leqq 0. \tag{2.4}$$

The following estimate follows (1.5):

$$\begin{aligned} &|H(x_0, \nabla\psi(x_0), \Phi^\varepsilon) - H(x_0, \nabla\psi(x_0), v)| \\ &\leqq \sup_{\alpha \in U} \left\{ \lambda(x_0, \alpha) \int |\Phi^\varepsilon(x_0) - \Phi^\varepsilon(y) - v(x_0) + v(y)| Q(x_0, \alpha, dy) \right\}. \end{aligned} \tag{2.5}$$

Observe that $\Phi^\varepsilon(x_0) = v(x_0)$ and $\Phi^\varepsilon(x_0 + y) = v(x_0 + y)$ for $y \notin B(0, 2\varepsilon)$. Also for $y \in B(0, 2\varepsilon)$

$$\begin{aligned} |\Phi^\varepsilon(x_0+y) - v(x_0+y)| &= |\psi(x_0+y) - v(x_0+y)|\chi^\varepsilon(x_0+y) \\ &\leqq |\psi(x_0+y) - \psi(x_0)| + |v(x_0) - v(x_0+y)| \\ &\leqq \|\nabla\psi\|_\infty |y| + \omega_v(|y|) \\ &\leqq 2\|\nabla\psi\|_\infty \varepsilon + \omega_v(2\varepsilon). \end{aligned} \tag{2.6}$$

Here ω_v is the modulus of continuity of v and we used $\psi(x_0) = v(x_0)$ in the second inequality. Combine (2.4)–(2.6) to conclude that v is a viscosity subsolution. □

Remark 2.1. It is easy to prove that in Lemma 2.1 we may replace $\psi \in C^1(N_{x_0})$ by $\psi \in C^1(\bar{\theta})$ (see [1]).

Proof of Theorem 1.1. Suppose v_1 and v_2 are two solutions in $BUC(\bar{\theta})$. For $i = 1, 2$ define f_i and $\bar{H}_i$ as follows

$$f_i(x, \alpha) = f(x, \alpha) + \lambda(x, \alpha) \int_{\bar{\theta}} (v_i(y) - v_i(x)) Q(x, \alpha, dy) \quad \text{for } x \in \bar{\theta},\ \alpha \in U, \tag{2.7}$$

$$\bar{H}_i(x, p) = \sup_{\alpha \in U} \{-b(x, \alpha) \cdot p - f_i(x, \alpha)\} \quad \text{for } x \in \bar{\theta},\ p \in \mathbb{R}^n. \tag{2.8}$$

Notice that $\bar{H}_i$ is the Hamiltonian of the corresponding deterministic problem with running cost f_i. Using (1.1)-(1.4), one can show that the f_i's are uniformly continuous in x uniformly with respect to α. Pick $z_\delta \in \bar{\theta}$ such that

$$v_1(x) - v_2(x) \leqq v_1(z_\delta) - v_2(z_\delta) + \delta \quad \text{for all } x \in \bar{\theta}.$$

Then Corollary 2.3 in [11] yields

$$v_1(z_\delta) - v_2(z_\delta) \leqq c\delta + \omega_{f_1}(c\delta) + \omega_{f_2}(c\delta) + \sup_{\alpha \in U} \{f_1(z_\delta, \alpha) - f_2(z_\delta, \alpha)\}. \tag{2.9}$$

But $f_1(z_\delta, \alpha) - f_2(z_\delta, \alpha) \leqq \delta\lambda(z_\delta, \alpha) \leqq \delta K(\lambda)$ for every α. Substitute this into (2.9) and send δ to zero, to prove the uniqueness.

Let $\psi \in C^1(\bar{\theta})$ and $x_0 \in \theta$ such that $(v-\psi)(x_0) = \max\{(v-\psi)(x); x \in \bar{\theta}\} = 0$, where v is the optimal value. For any $u \in \mathcal{A}_{ad}$ the dynamic programming relation (0.8) yields

$$\psi(x_0) = v(x_0) \leqq E\left\{\int_0^{t \wedge T_1} e^{-s} f(y(x_0, s, u), u(x_0, s))\, ds + e^{-t \wedge T_1} v(y(x_0, t \wedge T_1, u))\right\}.$$

Set $y(s) = y(x_0, s, u)$ and $u(s) = u(x_0, s)$. Use $v \leqq \psi$ to obtain:

$$\psi(x_0) \leqq E\left\{\int_0^{t \wedge T_1} e^{-s} f(y(s), u(s))\, ds + e^{-t \wedge T_1} \psi(y(t \wedge T_1))\right\}. \tag{2.10}$$

Ito's formula (0.5) on $e^{-s\psi(y(s))}$ yields

$$E \int_0^{t \wedge T_1} e^{-s}[\psi(y(s)) - b(y(s), u(s)) \cdot \nabla\psi(y(s)) - \bar{f}(y(s), u(s))]\, ds \leqq 0 \tag{2.11}$$

where

$$\bar{f}(x, \alpha) = f(x, \alpha) + \lambda(x, \alpha) \int_{\bar{\theta}} (\psi(z) - \psi(x)) Q(x, \alpha, dz).$$

Observe that on $[0, t \wedge T_1)$ $y(\cdot)$ is a deterministic trajectory. Thus standard estimates on $y(\cdot)$ and (1.1)-(1.4) yield

$$\frac{1}{t} E \int_0^{t \wedge T_1} [\psi(x_0) - b(x_0, u(s)) \cdot \nabla\psi(x_0) - \bar{f}(x_0, u(s))]\, ds \leqq h(t) \tag{2.12}$$

where h is a continuous function with $h(0) = 0$. Since $x_0 \in \theta$, for any $\alpha \in U$ there is a strategy $u \in \mathcal{A}_{ad}$ such that $u(x_0, t) = \alpha$ for all $t \leqq \operatorname{dist}(x_0, \partial\theta)/K(b)$. Use this strategy in (2.12) to obtain

$$[\psi(x_0) - b(x_0, \alpha) \cdot \nabla\psi(x_0) - \bar{f}(x_0, \alpha)] E[(t \wedge T_1)/t] \leqq h(t).$$

Hence $\psi(x_0) + H(x_0, \nabla\psi(x_0), \psi) \leqq 0$. So Lemma 2.1 and Remark 2.1 imply that v is a subsolution on θ.

Now let $\psi \in C^1(\bar{\theta})$ and $(v-\psi)(x_0) = \min\{(v-\psi)(x): x \in \bar{\theta}\} = 0$ for some $x_0 \in \bar{\theta}$. The dynamic programming relation and $v \geqq \psi$ yield

$$v(x_0) = \psi(x_0) \geqq \inf_{u \in \mathcal{A}_{ad}} E\left[\int_0^{t \wedge T_1} e^{-s} f(y(s), u(s))\, ds + e^{-t \wedge T_1} \psi(y(t \wedge T_1))\right]. \tag{2.13}$$

For $t = 1/m$ one can pick $u_m \in \mathcal{A}_{ad}$ such that

$$\psi(x_0) + \left(\frac{1}{m}\right)^2 \geqq E\left[\int_0^{1/m \wedge T_1} e^{-s} f(y(s), u_m(s))\, ds + e^{-T_1 \wedge 1/m} \psi\left(y\left(T_1 \wedge \frac{1}{m}\right)\right)\right].$$

First, use Ito's lemma (0.5) on $e^{-s}\psi(y(s))$ then (1.1)-(1.4), as in (2.10)-(2.12) above to obtain

$$mE\int_0^{T_1\wedge 1/m}[\psi(x_0)-b(x_0,u_m(s))\cdot\nabla\psi(x_0)-\bar f(x_0,u_m(s))]\,ds\geqq K(m) \tag{2.14}$$

where $K(m)$ is converging to zero as m tends to infinity. Rewrite (2.14) as

$$[\psi(x_0)-B(m)\cdot\nabla\psi(x_0)-F(m)]E(mT_1\wedge 1)\geqq K(m) \tag{2.15}$$

where

$$B(m)=\left(E\left(T_1\wedge\frac{1}{m}\right)\right)^{-1}E\int_0^{T_1\wedge 1/m}b(x_0,u_m(s))\,ds,$$

$$F(m)=\left(E\left(T_1\wedge\frac{1}{m}\right)\right)^{-1}E\int_0^{T_1\wedge 1/m}\bar f(x_0,u_m(s))\,ds.$$

Observe that $(B(m),F(m))\in\overline{\text{co}}\{(b(x_0,\alpha),\bar f(x_0,\alpha)):\alpha\in U\}:=\overline{\text{co}}[BF(x_0)]$. Hence there is $(B,F)\in\overline{\text{co}}\,[BF(x_0)]$ such that $(B(m),F(m))$ converges to (B,F) on a subsequence, denoted by m again. Pass to the limit in (2.15) to obtain

$$\psi(x_0)+\sup\{-B\cdot\nabla\psi(x_0)-F:(B,F)\in\overline{\text{co}}\,[BF(x_0)]\}\geqq 0.$$

Also

$$\sup\{-B\cdot\nabla\psi(x_0)-F:(B,F)\in\overline{\text{co}}\,[BF(x_0)]\}=H(x_0,\nabla\psi(x_0),\psi).$$

Thus, Lemma 2.1 and Remark 2.1 imply that v is a viscosity supersolution on $\bar\theta$. □

3. Uniform continuity and dynamic programming. We assume the following.

(A.2) There is a Borel measurable map α of $\partial\theta$ into U and β positive satisfying $b(x,\alpha(x))\cdot\nu(x)\leqq-\beta<0$, where ν is the exterior normal vector.

(A.3) The boundary of θ is of class C^2.

(A.4) If $\partial\theta$ is not compact, there are constants ρ and l such that for any $x\in\partial\theta$ there is a $C^2(B(x,\rho))$ function T with $C^1(B(x,\rho))$ inverse T^{-1} satisfying

$$\begin{aligned}&\text{(i)}\quad T(B(x,\rho)\cap\theta)\subset\{y\in R^n:y_n>0\},\\ &\text{(ii)}\quad T(B(x,\rho)\cap\partial\theta)\subset\{y\in R^n:y_n=0\},\\ &\text{(iii)}\quad \|T\|_{C^2(B(x,\rho))}+\|T^{-1}\|_{C^1(B(x,\rho))}\leqq l.\end{aligned} \tag{3.1}$$

The subscript n denotes the nth component.

Remark 3.1. The assumption (A.2) holds with some $\beta>0$ if

$$\sup_{x\in\partial\theta}\min_{\alpha\in U}b(x,\alpha)\cdot\nu(x)<0.$$

Note that we do not assume that $b(x,\alpha)$ points inwards the domain θ for all α and $x\in\partial\theta$. Thus there may be controls that allow the deterministic process to reach the boundary.

Remark 3.2. The assumptions (A.2)-(A.4) are used to obtain the uniform continuity of the corresponding deterministic problem [11]. In particular see [11, Lemma 3.2].

Let v_0 be the optimal value of the deterministic problem and define v^N as follows

$$v^N(x)=\inf_{u\in\mathcal{A}_{ad}}J^N(x,u)$$

where

$$J^N(x,u)=E\left[\int_0^{T_1}e^{-t}f(y(x,t,u),u(x,t))\,dt+e^{-T_1}v^{N-1}(Y_1)\right]. \tag{3.2}$$

LEMMA 3.1. *Let $v^{N-1} \in BUC(\bar{\theta})$, then the dynamic programming relation holds for v^N, i.e., for all $T>0$*

$$
\begin{aligned}
v^N(x) = \inf_{u \in \mathcal{A}_{ad}} E\Bigg\{ & \int_0^{T \wedge T_1} e^{-T} f(y(x, t, u), u(x, t))\, dt \\
& + e^{-T_1} v^{N-1}(Y_1) \chi_{[0,T]}(T_1) + e^{-T} v^N(y(x, T, u)) \chi_{(T,\infty)}(T_1) \Bigg\}
\end{aligned} \tag{3.3}
$$

where χ_A is the indicator function of set A.

Proof. Fix $x \in \bar{\theta}$ and T positive. Let $I^N(x, u)$ be the right-hand side of (3.3) before taking the infimum. To simplify the notation, put $y(t) = y_0(x, 0; t, u)$, $u(t) = u(x, t)$, $\lambda(t) = \lambda(y(t), u(t))$ and $\Lambda(t) = \exp\{-\int_0^t \lambda(s)\, ds\}$. Recall that y_0 is the corresponding deterministic trajectory given by (0.1). In terms of these quantities $I^N(x, u)$ is given by

$$
\begin{aligned}
I^N(x, u) = & \int_0^\infty \lambda(t)\Lambda(t) \Bigg[\int_0^{T \wedge t} e^{-s} f(y(s), u(s))\, ds \\
& + e^{-t} \int_{\bar{\theta}} v^{N-1}(z) Q(y(t), u(t), dz) \chi_{[0,T]}(t) \\
& + e^{-T} v^N(y(T)) \chi_{(T,\infty)}(t) \Bigg] dt \\
& + \Lambda(\infty) \Bigg[\int_0^T e^{-t} f(y(t), u(t))\, dt + e^{-T} v^N(y(T)) \Bigg] \\
= & \int_0^T \lambda(t)\Lambda(t) \Bigg[\int_0^t e^{-s} f(y(s), u(s))\, ds + e^{-t} \int_{\bar{\theta}} v^{N-1}(z) Q(y(t), u(t), dz) \Bigg] dt \\
& + \Lambda(T) \int_0^T e^{-s} f(y(s), u(s))\, ds + \Lambda(T)\, e^{-T} v^N(y(T)).
\end{aligned} \tag{3.4}
$$

Since $y(T)$ is a deterministic quantity determined by x, T and u, one can pick $u^* \in \mathcal{A}_{ad}$ such that $v^N(y(T)) \geqq J^N(y(T), u^*) - \delta$. Now we define $\bar{u}$ as follows:

$$
\bar{u}(z, t) = u(z, t) \chi_{[0,T]}(t) + u^*(y_0(z, 0, T, u), t - T) \chi_{[T,\infty)}(t). \tag{3.5}
$$

Define $\bar{y}(t) = \bar{y}(x, 0; t, \bar{u})$ and $\bar{\lambda}$, $\bar{\Lambda}$ similarly. Then we have

$$
\begin{aligned}
J^N(y(T), u^*) = (\Lambda(T))^{-1} \Bigg\{ & \int_0^\infty \bar{\lambda}(t+T)\bar{\Lambda}(t+T) \\
& \cdot \Bigg[\int_0^t e^{-s} f(\bar{y}(s+T), \bar{u}(x, s+T))\, ds \\
& + e^{-t} \int_{\bar{\theta}} v^{N-1}(z) Q(\bar{y}(t+T), \bar{u}(x, t+T), dz) \Bigg] dt \\
& + \bar{\Lambda}(\infty) \int_0^\infty e^{-s} f(\bar{y}(s+T), \bar{u}(x, s+T))\, ds \Bigg\}.
\end{aligned} \tag{3.6}
$$

Change variables in (3.6) and use $v^N(y(T)) \geqq J^N(y(T), u^*) - \delta$ to obtain

$$e^{-T}\Lambda(T)v^N(y(T)) \geqq \int_T^\infty \bar{\lambda}(t)\bar{\Lambda}(t)\Big[\int_T^t e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,dx + e^{-t}\int_{\bar{\theta}} v^{N-1}(z)Q(\bar{y}(t), \bar{u}(x, t), dz)\Big]\,dt + \bar{\Lambda}(\infty)\int_T^\infty e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,ds - e^{-T}\Lambda(T)\delta.$$

The fact that $\int_T^\infty \bar{\lambda}(t)\bar{\Lambda}(t)\,dt = \Lambda(T) - \bar{\Lambda}(\infty)$ and the above inequality yield

$$\Lambda(T)\int_0^T e^{-s}f(y(s), u(s))\,ds + \Lambda(T)\,e^{-T}v^N(y(T)) \geqq \int_T^\infty \bar{\lambda}(t)\bar{\Lambda}(t)\Big[\int_0^t e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,ds + e^{-t}\int_{\bar{\theta}} v^{N-1}(z)Q(\bar{y}(t), \bar{u}(x, t), dz)\Big]\,dt + \bar{\Lambda}(\infty)\int_0^\infty e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,ds - \delta.$$

Substitute the above inequality into (3.4) and use the fact $\lambda(t) = \bar{\lambda}(t)$, $\Lambda(t) = \bar{\Lambda}(t)$ for $t \in [0, T]$ to obtain

$$\begin{aligned} I^N(x, u) &\geqq \int_0^\infty \bar{\lambda}(t)\bar{\Lambda}(t)\Big[\int_0^t e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,ds + e^{-t}\int_{\bar{\theta}} v^{N-1}(z)Q(\bar{y}(t), \bar{u}(x, t), dz)\Big]\,dt \\ &\quad + \bar{\Lambda}(\infty)\int_0^\infty e^{-s}f(\bar{y}(s), \bar{u}(x, s))\,ds - \delta \\ &= J^N(x, \bar{u}) - \delta \geqq v^N(x) - \delta. \end{aligned} \tag{3.7}$$

Thus, $v^N(x) \leqq \inf_{u \in \mathscr{A}_{ad}} I^N(x, u)$. One can prove the other inequality similarly. □

The following lemma is an analogue of Lemma 3.2 in [11].

LEMMA 3.2. *Let $v^{N-1} \in BUC(\bar{\theta})$ and* (1.1)-(1.4), (A.2)-(A.4) *hold. Then for any T positive, there is a positive function h_T and a projection $\mathscr{P}_T(u)$ of any Borel measurable map u of $\bar{\theta} \times [0, \infty)$ into U such that $\mathscr{P}_T(u) \in \mathscr{A}_{ad}$ and*

$$|J_T^N(x, u) - J_T^N(x, \mathscr{P}_T(u))| \leqq h_T(\sup\{\operatorname{dist}(y_0(x, 0, t, u), \bar{\theta}): t \in [0, T]\}) \tag{3.8}$$

where h_T is a continuous function with $h_T(0) = 0$ and

$$J_T^N(x, u) = E\Big\{\int_0^{T \wedge T_1} e^{-s}f(y(x, s, u), u(x, s))\,ds + e^{-T_1}v^{N-1}(Y_1)\chi_{[0,T]}(T_1)\Big\}. \tag{3.9}$$

Proof. Define $t_0(x, u) = \inf\{t \geqq 0: y_0(x, 0, t, u) \in \partial\theta\}$ or infinity. Let t^* and k be as in Lemma 3.2 of [11], i.e.

$$\begin{aligned} t^* &= \min\{\rho/K(\bar{b}), l\beta/L(\bar{b})K(\bar{b}), \ln(1 + \beta l/4K(\bar{b}))/L(\bar{b})\}, \\ k &= 2/l\rho \end{aligned} \tag{3.10}$$

where $K(\bar{b}) = lK(b)$ and $L(\bar{b}) = l^2K(b) + l^2L(b)$. We now construct u^1 as in Lemma 3.2 of [11]

$$u^1(x, t) = \begin{cases} u(x, t) & \text{if } t \leqq t_0(x, u) \quad \text{or } t \geqq t_0(x, u) + k\varepsilon_0(x, u), \\ \alpha(y_0(x, 0, t_0(x, u), u)) & \text{if } t_0(x, u) < t < t_0(x, u) + k\varepsilon_0(x, u) \end{cases} \tag{3.11}$$

where α as in (A.2) and $\varepsilon_0(x, u) = \sup\{\text{dist}(y_0(x, 0, t, u), \bar{\theta}): t \in [0, t^*]\}$. Since $x \to t_0(x, u)$ is a Borel measurable map u^1 is measurable. Also in Lemma 3.2 of [11] it is proved that

$$y_0(x, 0, t, u^1) \in \bar{\theta} \quad \text{for all } t \in [0, t^*]. \tag{3.12}$$

Now construct a sequence of strategies $\{u^n: n = 1, 2, \cdots\}$ by the following recursive formula

$$t_n(x, u^n) = \inf\{t \geqq nt^*: y_0(x, 0, t, u^n) \in \partial\theta\} \quad \text{or infinity},$$

$$\varepsilon_n(x, u^n) = \sup_{t \in [0,(n+1)t^*]} [\text{dist}(y_0(x, 0, t, u^n), \bar{\theta})],$$

then

$$u^{n+1}(x, t) = \begin{cases} u^n(x, t) & \text{if } t \leqq t_n(x, u^n) \quad \text{or } t \geqq t_n(x, u^n) + k\varepsilon_n(x, u^n), \\ \alpha(y_0(x, 0, t_n(x, u^n), u^n)) & \text{if } t_n(x, u^n) < t < t_n(x, u^n) + k\varepsilon_n(x, u^n). \end{cases}$$

Iterate (3.12) to get $y_0(x, 0, t, u^n) \in \bar{\theta}$ for $t \in [0, nt^*]$. We have to estimate the Lebesgue measure of the following set

$$M^n(x) = \{t \in [0, nt^*]: u^n(x, t) \neq u(x, t)\}. \tag{3.13}$$

For every t we have

$$|y_0(x, 0, t, u^n) - y_0(x, 0, t, u)|$$

$$\leqq \int_{[0,t] \cap M^n(x)} 2K(b) + \int_{[0,t] \setminus M^n(x)} L(b)|y_0(x, 0, s, u) - y_0(x, 0, s, u^n)|\, ds;$$

thus the Gronwall's inequality implies

$$\varepsilon_n(x, u^n) \leqq \varepsilon_n(x, u) + 2K(b)\, e^{(n+1)L(b)t^*} \text{ meas } M^n(x).$$

The construction of u^n yields

$$\begin{aligned} \text{meas } M^n(x) &\leqq k \sum_{i=0}^{n-1} \varepsilon_i(x, u^i) \\ &\leqq nk\varepsilon_{n-1}(x, u) + k2K(b)\, e^{nL(b)t^*} \sum_{i=0}^{n-1} \text{meas } M^i(x). \end{aligned} \tag{3.14}$$

Iterate this inequality to obtain $C(n)$, depending only on n, $K(b)$ and $L(b)$, such that

$$\text{meas } M^n(x) \leqq C(n)\varepsilon_{n-1}(x, u). \tag{3.15}$$

Now, for given T, choose $\bar{n}$ so that $T \leqq \bar{n}t^*$. Then define $\mathscr{P}_T u$ as

$$\mathscr{P}_T u(x, t) = \begin{cases} u^{\bar{n}}(x, t) & \text{for } t \leqq T, \\ \tilde{u}(y_0(x, 0, T, u^{\bar{n}}), t - T) & \text{for } t > T \end{cases}$$

where $\tilde{u}$ is any strategy in $\mathscr{A}_{ad}$.

Observe that for any u

$$J_T^N(x, u) = \int_0^T \lambda(t)\Lambda(t)\left[\int_0^t e^{-s} f(y(s), u(s))\, ds + e^{-t} \int_{\bar{\theta}} v^{N-1}(z) Q(y(t), u(t), dz)\right] dt$$

$$+ \Lambda(T) \int_0^T e^{-s} f(y(s), u(s))\, ds.$$

By using (1.1)-(1.4) one can show

$$|J_T^N(x,u)-J_T^N(x,\mathscr{P}_T(u))|\leqq CT[d_T(x)+W_{v^{N-1}}(d_T(x))+\text{meas } M^{\bar\theta}(x)] \tag{3.16}$$

where C is a positive constant and

$$\begin{aligned} d_T(x) &= \sup_{t\in[0,T]}\{|y_0(x,0,t,u)-y_0(x,0,t,\mathscr{P}_T(u))|\} \\ &\leqq 2K(b)\, e^{L(b)T}\,\text{meas } M^{\bar\theta}(x). \end{aligned}$$

Plug this into (3.16) together with (3.15) to conclude Lemma 3.2. □

LEMMA 3.3. *Let* (A.2)-(A.4) *and* (1.1)-(1.5) *hold*; *then* $v^N\in BUC(\bar\theta)$ *and there is a* δ*-optimal strategy* u^* *such that*

$$J^N(x,u^*)\leqq v^N(x)+\delta \quad \textit{for all } x\in\bar\theta.$$

Proof. It is proved that $v^0\in BUC(\bar\theta)$ [11, Thm. 3.3]. Now suppose $v^{N-1}\in BUC(\bar\theta)$ and define

$$\omega(r)=\sup\{|v^N(x)-v^N(y)|: x,y\in\bar\theta \text{ and } |x-y|<r\} \quad \text{for } r>0.$$

At the origin $\omega(0)=\lim_{r\downarrow 0}\omega(r)$. Using Lemmas 3.1 and 3.2, we can conclude, as in Theorem 3.3 of [11], that for some t positive,

$$\omega(r)\leqq h_t(Cr)+e^{-t}\omega(\tilde C r)+Ctr \tag{3.17}$$

where $\tilde C>1$, $C>0$ and h_t is as in Lemma 3.2. Iterate (3.17) to obtain

$$\omega(\tilde C^{-n})\leqq e^{-nt}\omega(1)+\sum_{m=0}^{n-1} e^{-mt}[h_t(C\tilde C^{(m-n)})+C\tilde C^{(m-n)}t].$$

Use dominated convergence theorem to get $\lim_{n\to\infty}\omega(\tilde C^{-n})=0$. Hence $v^N\in BUC(\bar\theta)$.

Pick $\{x_m: n=1,2,\cdots\}\subset\bar\theta$ such that $\bar\theta\subset\bigcup_m B(x_m,r)$ where r to be chosen. Then select $\{u_n: n=1,2,\cdots\}\subset\mathscr{A}_{ad}$

$$J^N(x_m,u_m)\leqq v^N(x_m)+\frac{\delta}{2}. \tag{3.18}$$

Now define u as follows

$$u(x,t)=u_m(x_m,t) \quad \text{if } x\in\theta_m=\bigcup_{n=1}^{m} B(x_n,r)\Big\backslash\bigcup_{n=1}^{m-1} B(x_n,r).$$

Let $u^*=\mathscr{P}_T(u)$ where T to be chosen. Note that u^* depends both on r and T but this dependence is suppressed in the notation. For every $x\in\theta_m$ we have

$$\begin{aligned} |J^N(x,u^*)-J^N(x_m,u)| &\leqq |J_T^N(x,u^*)-J_T^N(x,u)|+|J_T^N(x,u)-J_T^N(x_m,u)| \\ &\quad +2\sup_{\substack{x\in\theta\\ u\in\mathscr{A}_{ad}}}|J^N(x,u)-J_T^N(x,u)|:=I_1+I_2+I_3. \end{aligned} \tag{3.19}$$

The construction of u and standard ODE estimates yield

$$\sup_{\substack{x\in\theta_m\\ t\in[0,T]}}|y_0(x,0;t,u)-y_0(x_m,0;t,u)|\leqq C(T)r \tag{3.20}$$

where $C(T)$ is a positive constant. Since $y_0(x_m,0;t,u)\in\bar\theta$ for all $t\geqq 0$ above inequality implies that

$$\sup_{\substack{x\in\bar\theta\\ t\in[0,T]}} d(y_0(x,0;t,u),\bar\theta)\leqq C(T)r. \tag{3.21}$$

Now, in the case of I_1 use (3.8), (3.21) and in the case of I_2 use (3.20), (1.1)-(1.4) and the continuity of v^{N-1} to obtain

$$I_1 + I_2 \leqq h^N(T, r) \tag{3.22}$$

where $h^N \in C([0,\infty)\times[0,\infty))$ with $\lim_{r\downarrow 0} h^N(T, r) = 0$ for every T and N. Also (3.2) and (3.9) imply

$$|J^N(x,u) - J_T^N(x,u)| = \left| E\left[e^{-T_1} v^{N-1}(Y_1)\chi_{(T,\infty)}(T_1) + \int_{T\wedge T_1}^{T_1} e^{-s} f(y(x,s,u), u(x,s))\, ds \right] \right|$$
$$\leqq e^{-T}[\|v^{N-1}\|_{L^\infty(\bar\theta)} + K(f)].$$

Recall that $K(f)$ is the sup-norm of f and it is easy to show that v^N is bounded by $K(f)$ for every N. Hence we have

$$I_3 \leqq 4K(f)\, e^{-T}. \tag{3.23}$$

Substitute (3.22)-(3.23) into (3.19) to get for all $x_m \in \theta_m$

$$|J^N(x,u^*) - J^N(x_m,u)| \leqq h^N(T,r) + 4K(f)\, e^{-T}. \tag{3.24}$$

The continuity of v^N, (3.18) and the above inequality imply

$$J^N(x,u^*) \leqq v^N(x) + \frac{\delta}{2} + \omega_{v^N}(r) + h^N(T,r) + 4K(f)\, e^{-T}.$$

Recall that $\lim_{r\downarrow 0} h^N(T,r) = 0$; thus we can choose T and r so that $J^N(x,u^*) \leqq v^N(x) + \delta$. □

THEOREM 3.4. *If* (A.2)-(A.4), (1.1)-(1.5) *hold, then* $v \in BUC(\bar\theta)$ *and the dynamic programming relation* (0.8) *holds.*

Proof. Iterating the second assertion of the previous lemma, one gets

$$v^N(x) = \inf_{\{u_1,\cdots,u_N\}\subset \mathcal{A}_{ad}} E\left\{ \sum_{n=0}^{N-1} \int_{T_n}^{T_{n+1}} e^{-t} f(y_0(Y_n, T_n, t, u_n), u_n(Y_n, t-T_n))\, dt \right.$$
$$\left. + \int_{T_N}^{\infty} e^{-t} f(y_0(Y_N, T_N, t, u_N) u_N(Y_N, t-T_N)) \right\}. \tag{3.25}$$

Now define v^∞ by

$$v^\infty(x) = \inf_{\{u_n:\, n=1,2,\cdots\}\subset \mathcal{A}_{ad}} E\left\{ \sum_{n=0}^{\infty} \int_{T_n}^{T_{n+1}} e^{-t} f(y_0(Y_n, T_n, t, u_n), u_n(Y_n, t-T_n))\, dt \right\}. \tag{3.26}$$

Hence we have

$$\sup_{x\in\bar\theta} |v^N(x) - v^\infty(x)| \leqq 2K(f) \sup_{\{u_1,\cdots,u_N\}\subset \mathcal{A}_{ad}} E(e^{-T_N}).$$

To prove that v^N converges to v^∞ it suffices to show that $E(e^{-T_N})$ is decreasing to zero independent of control.

Let $\{u_n:\, n=1,\cdots\} \subset \mathcal{A}_{ad}$ and set $\lambda_n(t) = \lambda(y_0(Y_{n-1}, 0, t, u_n), u_n(Y_{n-1}, t))$.

$$E(e^{-T_n+T_{n-1}} | Y_1, \cdots, Y_{n-1}, T_{n-1}) = \int_0^\infty e^{-t}\lambda_n(t) \exp\left\{ -\int_0^t \lambda_n(s)\, ds \right\} dt$$
$$= 1 - \int_0^\infty e^{-t} \exp\left\{ -\int_0^t \lambda_n(s)\, ds \right\} dt$$
$$\leqq 1 - \int_0^\infty e^{(-(1+K(\lambda))t)}\, dt := \gamma < 1.$$

Observe that γ is independent of control and strictly less than one. Hence

$$\sup_{\{u_1,\cdots,u_N\}\subset \mathcal{A}_{ad}} E(e^{-T_N}) \leqq \gamma^N. \tag{3.27}$$

Therefore v^N converges to v^∞ uniformly on $\bar{\theta}$. So $v^\infty \in BUC(\bar{\theta})$ and v^∞ satisfies (0.8).

We now proceed to show that $v^\infty = v$. First observe that $v^\infty \leqq v$ because of the definitions of v^∞ and v. Also we can construct u^* as in the previous lemma such that for all $x \in \bar{\theta}$

$$E\left\{\int_0^{T_1} e^{-t} f(y_0(x, 0, t, u^*), u^*(x, t))\, dt + e^{-T_1} v^\infty(Y_1)\right\} \leqq v^\infty(x) + \delta. \tag{3.28}$$

Apply (3.28) at $x = Y_1$ to obtain

$$v^\infty(Y_1) \geqq -\delta + E\left\{\int_0^{T_2 - T_1} e^{-t} f(y_0(Y_1, 0, t, u^*), u^*(Y_1, t))\, dt + e^{-(T_2 - T_1)} v^\infty(Y_2) \,\middle|\, Y_1, T_1\right\}.$$

The above inequality and (3.28) yields

$$E\left\{\sum_{n=0}^{1} \int_{T_n}^{T_{n+1}} e^{-t} f(y_0(Y_n, T_n, t, u^*), u^*(Y_n, t - T_n))\, dt + e^{-T_2} v^\infty(Y_2)\right\} \leqq v^\infty(x) + \delta E \sum_{n=0}^{1} e^{-T_n}. \tag{3.29}$$

Iterate this procedure to obtain

$$J(x, u^*) \leqq v^\infty(x) + \delta E\left(\sum_{n=0}^{\infty} e^{-T_n}\right) \leqq v^\infty(x) + \delta(1 - \gamma)^{-1}$$

where γ is as in (3.27). □

Acknowledgments. This paper comprises a part of the author's thesis written under the direction of Professor W. H. Fleming at Brown University. The author would like to express thanks to Professor W. H. Fleming for suggesting the problem, helpful conversations, good advice and careful reading of an earlier manuscript, which led to substantial changes.

LIPSCHITZIAN SOLUTIONS OF PERTURBED NONLINEAR PROGRAMMING PROBLEMS*

B. CORNET† AND J.-PH. VIAL†

Abstract. We prove that if a second order sufficient condition and a constraint regularity assumption hold, then for sufficiently small perturbations of the constraints and the objective function, the set of local minimizers reduces to a singleton. Moreover, the minimizer and the associated multipliers are Lipschitzian functions of the parameter.

Key words. stability, nonlinear programming, weak convexity

AMS(MOS) subject classifications. 90C31, 90C30

1. Introduction. This paper deals with the stability of solutions and multipliers of nonlinear programming problems when the data are subjected to small perturbations. In order to formulate the problem, we introduce an open subset U of $\mathbb{R}^n$, a metric space P, functions f and g from $U \times P$ to $\mathbb{R}$ and $\mathbb{R}^m$ and a nonempty closed subset Q of $\mathbb{R}^m$. The problem of interest is then:

$$P(\alpha) \qquad \begin{array}{ll} \text{minimize} & f(x, \alpha), \\ \text{subject to} & g(x, \alpha) \in Q, \qquad x \in U, \end{array}$$

where x is the variable in which the minimization is done and α a perturbation parameter which belongs to P and which remains fixed in the minimization problem.

We are interested in the behavior of local minimizers of $P(\alpha)$ when the parameter α varies. Our main result can be informally stated as follows. Under a set of assumptions dealing with (i) the smoothness of the functions f and g, (ii) the regularity of the constraints at $(\bar{x}, \bar{\alpha})$, (iii) the weak convexity of the set Q and (iv) a strong sufficient second-order condition at $(\bar{x}, \bar{\alpha})$, it is shown that, for small perturbations of the parameter $\bar{\alpha}$, the solution $\bar{x}$ of $P(\bar{\alpha})$ persists and is in Lipschitzian dependence with respect to the parameter. The importance of this Lipschitz property should be appreciated in the light of recent developments of calculus for Lipschitzian mappings (Clarke (1975), Rockafellar (1981)).

The above formulation of problem $P(\alpha)$ allows us to take into account the classical nonlinear programming problem with equality and/or inequality constraints, i.e., $Q = \{0\}^{m_1} \times (-\mathbb{R}_+^{m_2})$ for nonnegative integers m_1 and m_2. The consideration of more general sets Q in $P(\alpha)$ is motivated by the following property of weakly convex sets, a class of sets introduced by Vial (1983) (see also Cornet (1981)), which includes as special cases, convex subsets of $\mathbb{R}^m$ and twice continuously differentiable submanifolds of $\mathbb{R}^m$ with or without a boundary. Let Q be a nonempty closed subset of $\mathbb{R}^m$ and let α be in $\mathbb{R}^m$; then the set of projections of α on Q, denoted $\pi(\alpha) = \{x \in Q \mid \|x - \alpha\| \leqq \|x' - \alpha\|$, for all x' in $Q\}$, clearly is the set of solutions of problem $P(\alpha)$ for well chosen mappings f and g. An important property of weakly convex sets is that the mapping π is single-valued and Lipschitzian on a neighborhood of Q. Our main theorem generalizes the known results for problems with equality and/or inequality constraints and also includes the above property of weakly convex sets.

We conclude this section by indicating the link between this paper and the rest of the literature. The standard problem with equality and/or inequality constraints has been studied by Fiacco and McCormick (1968), Robinson (1974), Fiacco (1976). The basic feature of these articles is that, under the strict complementarity slackness assumption, it is proved, using the standard implicit function theorem, that the stationary points (i.e., points that satisfy the first order necessary condition for optimality), and their associated multipliers are differentiable.

The strict complementarity slackness assumption has been removed, in the case of equality and/or inequality constraints by Robinson (1980), Kojima (1980), Jittorntrum (1984) and in the case where Q is a closed convex subset of $\mathbb{R}^m$ by Cornet-Laroque (1986) (see also Cornet-Laroque (1980), Cornet (1981)) and J.-P. Aubin (1981) when the constraints are linear. In these cases, under a somewhat stronger second order sufficient condition, a similar result is shown to hold, namely that the stationary points and associated multipliers are (locally) Lipschitzian mappings of the perturbation. The main tool for these analyses are generalizations of the standard implicit function theorem; for example Robinson (1980) proves a general implicit theorem for "generalized equations" (i.e. of variational inequalities), Cornet-Laroque (1986) use a generalization of the implicit function theorem in the case of Lipschitzian mappings due to Clarke (1976) (see also Auslender (1983)) and J.-P. Aubin (1981) a generalization of it in the case of convex processes.

Our approach in the present paper is different from the previous ones. It is direct in the sense that no implicit function theorem or generalization of it is used. We are able to show the local persistence of a local minimizer of our problem and next the Lipschitzian dependence with respect to the parameter α. The first step owes much to a result of Robinson (1982). Finally we shall mention the work of Levitin (1975) who made an analysis of the Lipschitz dependence of local minimizers, also by a direct approach. However, it contains an apparent error as is pointed out in the paper of Robinson (1982).

Our paper is organized as follows. In § 2, we recall some definitions and state the main result of the paper. We also discuss two noteworthy applications: the first deals with the projection of points on a weakly convex set, and the second deals with the standard nonlinear programming problem. The proof of the main theorem is given in § 3.

2. Statement of the main theorem and some consequences. Let us first introduce some notations and definitions. Let $x=(x_i)$, $y=(y_i)$ be in $\mathbb{R}^q$; we denote $\langle x, y\rangle = \sum_{i=1}^q x_i \cdot y_i$, the scalar product of $\mathbb{R}^q$, and $\|x\| = \langle x, x\rangle^{1/2}$ the Euclidean norm. Let A be a nonempty subset of $\mathbb{R}^q$ and let x be in $\mathbb{R}^q$; we denote $d_A(x) = \inf\{\|a-x\| \mid a \in A\}$, $B(A, \varepsilon) = \{x \in \mathbb{R}^q \mid d_A(x) < \varepsilon\}$ and $\bar{B}(A, \varepsilon) = \{x \in \mathbb{R}^q \mid d_A(x) \leqq \varepsilon\}$. Let Q be a subset of $\mathbb{R}^m$ and let x be in $\bar{Q}$; we recall the following definitions of Clarke (1975) of the tangent cone $T_Q(x)$ and the normal cone $N_Q(x)$ to Q at x,

$$T_Q(x) = \{v \in \mathbb{R}^m \mid \text{for all sequences } \{\theta_k\} \subset (0, \infty) \text{ and } \{x_k\} \subset \bar{Q} \text{ such that } \theta_k \to 0,$$
$$x_k \to x, \text{ there exists a sequence } \{v_k\} \to v \text{ such that, for all } k,\ x_k + \theta_k v_k \in \bar{Q}\},$$
$$N_Q(x) = \{\eta \in \mathbb{R}^m \mid \langle \eta, v\rangle \leqq 0, \text{ for all } v \in T_Q(x)\}.$$

DEFINITION 1. A subset Q of $\mathbb{R}^m$ is said to be weakly convex, with constant $\rho \geqq 0$, at an element y^0 in $\bar{Q}$, if there exists $\varepsilon > 0$ such that, for all y^1, y^2 in $\bar{Q} \cap B(y^0, \varepsilon)$ and for all $\lambda^2 \in N_Q(y^2) \cap \bar{B}(0, 1)$, one has

$$\langle \lambda^2, y^2 - y^1\rangle \geqq -\frac{\rho}{2}\|y^2 - y^1\|^2.$$

It is possible to give the following geometric interpretation of weakly convex sets, of constant $\rho > 0$. Let Q be such a set and let $X = \bar{Q} \cap B(y^0, \varepsilon)$ with $y_0 \in \bar{Q}$. Then for all $x \in X$ and $\eta \in N_Q(x) \cap \bar{B}(0, 1) (= N_X(x) \cap \bar{B}(0, 1))$,

$$X \cap B(x + \rho^{-1}\eta, \rho^{-1}\|\eta\|) = \varnothing.$$

For $\eta \neq 0$, one could view $B(x + \rho^{-1}\eta, \rho^{-1}\|\eta\|)$ as a "supporting ball," very much in a sense analogous to a supporting hyperplane for a convex set. In this terminology, if a set is weakly convex at y^0, one can exhibit a "supporting ball" at each point of the boundary of the set in a neighborhood of y^0. Note that the radius of the "supporting ball" is fixed in the given neighborhood. Clearly, a convex subset Q of $\mathbb{R}^m$ is weakly convex with respect to any constant $\rho \geqq 0$. We refer to Cornet (1981), Vial (1983) for other examples of weakly convex sets (such as C^2 submanifolds in $\mathbb{R}^m$ with or without a boundary) and/or for properties of weakly convex sets.

We posit the following assumptions, which describe the general framework of the paper.

Assumptions A.0

(i) U is an open subset of $\mathbb{R}^n$; P is a metric space endowed with a distance d;

(ii) the functions $f(\cdot, \cdot)$ and $g_i(\cdot, \cdot)$, $i = 1, \cdots, m$, are locally Lipschitzian from $U \times P$ to $\mathbb{R}$;

(iii) for all $\alpha \in P$, the functions $f(\cdot, \alpha)$ and $g_i(\cdot, \alpha)$, $i = 1, \cdots, m$, are twice continuously differentiable from U to $\mathbb{R}$;

(iv) the mappings $\nabla f(\cdot, \cdot)$ and $\nabla g_i(\cdot, \cdot)$, $i = 1, \cdots, m$, of first partial derivatives with respect to the first argument, are locally Lipschitzian from $U \times P$ to $\mathbb{R}^n$;

(v) the mapping $D^2 f(\cdot, \cdot)$ and $D^2 g_i(\cdot, \cdot)$ of second order derivatives with respect to the first argument, are continuous;

(vi) $m = m_1 + m_2$, where m_1 and m_2 are nonnegative integers; C is a nonempty closed subset of $\mathbb{R}^{m_2}$ and $Q = \{0\}^{m_1} \times C$ (with the convention that $Q = \{0\}^m$ if $m_2 = 0$ and $Q = C$ if $m_1 = 0$).

We consider the following perturbed nonlinear programming problem:

$$P(\alpha) \qquad \begin{array}{ll} \text{minimize} & g(x, \alpha), \\ \text{subject to} & g(x, \alpha) \in Q, \\ & x \in U, \end{array}$$

where $g(x, \alpha)$ is the vector in $\mathbb{R}^m$ with coordinates $g_i(x, \alpha)$, $i = 1, \ldots, m$, x is the variable in which the minimization is done, and $\alpha \in P$ is a perturbation term which remains fixed in the minimization problem. Note that it is possible to rewrite the constraints as follows. For all (x, α) in $U \times P$, let $g_E(x, \alpha)$ (resp. $g_I(x, \alpha)$) be the vector in $\mathbb{R}^{m_1}$ (resp. $\mathbb{R}^{m_2}$) with coordinates $g_i(x, \alpha)$, $i = 1, \cdots, m_1$ (resp. $i = m_1 + 1, \cdots, m$). Then x satisfies the constraints of $P(\alpha)$ if and only if:

$$g_E(x, \alpha) = 0 \quad \text{and} \quad g_I(x, \alpha) \in C, \qquad x \in U.$$

With $P(\alpha)$, we associate the following "generalized equation":

$$\begin{aligned} &\nabla f(x, \alpha) + \sum_{i=1}^{m} \lambda_i \nabla g_i(x, \alpha) = 0, \\ &g(x, \alpha) \in Q \quad \text{and} \quad \lambda = (\lambda_i) \in N_Q(g(x, \alpha)). \end{aligned} \tag{2.1}$$

We shall be concerned with pairs $(x^0, \alpha^0) \in U \times P$ such that x^0 is a local minimizer of $P(\alpha^0)$. If we further assume that:

Assumption A.1. The gradients $\nabla g_i(x^0, \alpha^0)$, $i = 1, \cdots, m$, are linearly independent, then we shall prove later (Lemma 3.1) that there exists $\lambda^0 \in \mathbb{R}^m$ such that $(x^0, \alpha^0, \lambda^0)$ solves (2.1). In other words, (2.1) is the first order necessary condition associated with $P(\alpha)$. For such a triplet we posit the following two assumptions:

Assumption A.2. Q is weakly convex with constant $\rho \geqq 0$ at $g(x^0, \alpha^0)$. (Note that it would be equivalent to replace the above statement by "C is weakly convex with constant $\rho \geqq 0$ at $g_I(x^0, \alpha^0)$.")

Assumption A.3. There exist real numbers $a \geqq 0$ and $c > 0$ such that, for all $h \in \mathbb{R}^n$, one has

$$\left\langle \left[D^2 f(x^0, \alpha^0) + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0) \right] h, h \right\rangle + a\langle \nabla f(x^0, \alpha^0), h\rangle^2 + a \sum_{i=1}^{m_1} \langle \nabla g_i(x^0, \alpha^0), h\rangle^2 \geqq c\|h\|^2.$$

Note that the index in the first sum runs from 1 to $m = m_1 + m_2$ and from 1 to m_1 in the second. (A.3) clearly implies the more familiar assumption:

Assumption A.3′. For all $h \in \mathbb{R}^n$, $h \neq 0$, such that $\langle \nabla f(x^0, \alpha^0), h\rangle = 0$ and $\langle \nabla g_i(x^0, \alpha^0), h\rangle = 0$, $i = 1, \cdots, m_1$, one has

$$\left\langle \left[D^2 f(x^0, \alpha^0) + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0) \right] h, h \right\rangle > 0.$$

It is an immediate consequence of a lemma of Debreu (1952) that (A.3′) implies (A.3). Thus the two assumptions are equivalent.

We can now state the main theorem.

THEOREM 2.1. *Assume* (A.0) *and let* $(x^0, \alpha^0, \lambda^0) \in U \times P \times \mathbb{R}^m$ *satisfy* (A.1), (A.2), (A.3). *Further, assume that the constants* $\rho \geqq 0$ *and* $c > 0$ *satisfy*

Assumption A.4. $c > \lambda_I^0 \|Dg_I(x^0, \alpha^0)\|^2$, *where* $\lambda_I^0 = (\lambda_{m_1}^0 + 1, \cdots, \lambda_m^0)$.

Then, if $(x^0, \alpha^0, \lambda^0)$ *satisfies condition* (2.1), *there exist neighborhoods* U' *of* x^0 *in* U, V' *of* α^0 *in* P *and mappings* $x(\cdot): V' \to U'$, $\lambda(\cdot): V' \to \mathbb{R}^m$ *such that*:

(i) $x(\cdot)$ *and* $\lambda(\cdot)$ *are Lipschitzian*;

(ii) $x(\alpha^0) = x^0$ *and* $\lambda(\alpha^0) = \lambda^0$;

(iii) *for all* α *in* V', $x(\alpha)$ *is the unique minimizer of* $P(\alpha)$ *in* U' *and* $\lambda(\alpha)$ *is the unique Kuhn-Tucker multiplier associated with* $x(\alpha)$ (*i.e.*, $(x(\alpha), \lambda(\alpha))$ *satisfies condition* (2.1)).

The proof of Theorem 2.1 is given in the next section.

Remark 1. Assumption (A.1) cannot be relaxed in the case of equality and/or inequality constraints (i.e., when $Q = \{0\}^{m_1} \times (-\mathbb{R}_+^{m_2})$) by only assuming the Mangasarian-Fromovitz's constraint qualification (see Robinson (1980)).

Remark 2. If C is convex, then (A.4) is trivially satisfied (since convex sets in $\mathbb{R}^{m_2}$ are weakly convex with constant $\rho = 0$). It is worth pointing out that in the case of equality and/or inequality constraints, (A.3) is stronger than the classical sufficient second-order condition of Fiacco and McCormick (1968). However, Theorem 2.1 does not hold if one replaces (A.3) by the classical second order condition as it has been shown by Robinson (1980).

We conclude this section by discussing two noteworthy applications of Theorem 2.1. The first one deals with the projection mapping on a weakly convex subset of $\mathbb{R}^n$.

Let Q be a nonempty closed subset of $\mathbb{R}^n$. For a fixed element α in $\mathbb{R}^n$, we consider the following minimization problem:

$$R(\alpha)\qquad \begin{aligned} &\text{minimize} && \tfrac{1}{2}\|x-\alpha\|^2,\\ &\text{subject to} && x\in Q, \end{aligned}$$

and we denote by $\pi(\alpha)$ the set of its solutions. Any element of $\pi(\alpha)$ is called a projection of α on Q. The next proposition gives some properties of the (multi-valued) mapping $\alpha\to\pi(\alpha)$ when Q is assumed to be weakly convex.

COROLLARY 2.2. *Let $(x^0,\alpha^0)\in\mathbb{R}^n\times\mathbb{R}^n$ be such that x^0 is a local minimizer of $R(\alpha^0)$. Assume that Q is weakly convex with constant $\rho\geqq 0$ at x^0 and that $1>\rho\|x^0-\alpha^0\|$. Then, there exist neighborhoods U' of x^0, V' of α^0 and a Lipschitzian mapping $x(\cdot):V'\to U'$ such that $x(\alpha^0)=x^0$ and, for all $\alpha\in V'$, $x(\alpha)$ is the unique minimizer of $R(\alpha)$ in U'.*

Proof. It is a trivial matter to check that (A.1) and (A.3) are satisfied with $c=1$ and that the Kuhn-Tucker multiplier λ^0 associated with x^0 satisfies $\lambda^0=-(x^0-\alpha^0)$. Thus (A.4) reduces to $1=c>\rho\|x^0-\alpha^0\|$. Hence the result.

Remark 3. When $m_1=0$, we give here an example showing that the inequality in (A.4) is the best possible. Let $Q=\{x\in\mathbb{R}^m\,|\,\|x\|\geqq 1\}$; clearly, Q is weakly convex at every element x in Q, with constant $\rho=1$. If $\alpha^0\neq 0$, let $\mu=\max\{1,\|\alpha^0\|^{-1}\}$, then $x^0=\mu\alpha^0$ is the unique minimizer of $R(\alpha^0)$. Since the hypotheses of Corollary 2.2 are satisfied at x^0, the conclusion of the corollary holds. However, if $\alpha^0=0$, any x^0 such that $\|x^0\|=1$ is a minimizer of $R(\alpha^0)$. Obviously, $1=\rho\|x^0-\alpha^0\|$; hence Assumption (A.4) is violated and one easily sees directly that the conclusion of Corollary 2.2 cannot hold.

The second application deals with standard nonlinear programming. Assume A.0 and assume furthermore that $Q=\{0\}^{m_1}\times(-\mathbb{R}_+^{m_2})$ (i.e., in (vi) of (A.0), $C=-\mathbb{R}_+^{m_2}$). We consider the standard perturbed nonlinear programming problem:

$$S(\alpha)\qquad \begin{aligned} &\text{minimize} && f(x,\alpha),\\ &\text{subject to} && g_i(x,\alpha)=0,\ i=1,\cdots,m_1,\\ &&& g_i(x,\alpha)\leqq 0,\ i=m_1+1,\cdots,m,\\ &&& x\in U. \end{aligned}$$

With $S(\alpha)$, we associate the first order necessary conditions:

$$\begin{aligned} &\nabla f(x,\alpha)+\sum_{i=1}^{m_1+m_2}\lambda_i\nabla g_i(x,\alpha)=0,\\ &g_i(x,\alpha)=0, \qquad i=1,\cdots,m_1,\\ &g_i(x,\alpha)\leqq 0,\quad \lambda_i\geqq 0,\quad \lambda_i g_i(x,\alpha)=0, \qquad i=m_1+1,\cdots,m_1+m_2. \end{aligned}\tag{2.2}$$

In the case of standard nonlinear programming, Assumptions (A.2) and (A.4) are satisfied, since $Q=\{0\}^{m_1}\times(-\mathbb{R}_+)^{m_2}$ is convex. We give now a consequence of Theorem 2.1, where the Assumptions (A.1) and (A.3) are weakened. First, let us introduce the following notation: for $(x,\alpha)\in U\times P$, satisfying the constraints of $S(\alpha)$, we let $I(x,\alpha)=\{i\in\{m_1+1,\cdots,m\}|g_i(x,\alpha)=0\}$ be the set of active inequality constraints.

COROLLARY 2.3. *Assume* (A.0) *and let $(x^0,\alpha^0,\lambda^0)\in U\times P\times\mathbb{R}^m$ be such that*:

(C.1) *the vectors $\nabla g_i(x^0,\alpha^0)$, $i\in\{1,\cdots,m_1\}\cup I(x^0,\alpha^0)$, are linearly independent*;

(C.2) *for all $h\in\mathbb{R}^n$, $h\neq 0$, satisfying $\langle\nabla f(x^0,\alpha^0),h\rangle=0$ and $\langle\nabla g_i(x^0,\alpha^0),h\rangle=0$, $i\in\{1,\cdots,m_1\}\cup\{i\in I(x^0,\alpha^0)|\lambda_i^0>0\}$, then*

$$\left\langle\left[D^2f(x^0,\alpha^0)+\sum_{i=1}^{m}\lambda_i^0D^2g_i(x^0,\alpha^0)\right]h,h\right\rangle>0.$$

Then, if $(x^0, \alpha^0, \lambda^0)$ *satisfies condition* (2.2), *there exist neighborhoods* U' *of* x^0 *in* U, V' *of* α^0 *in* P *and mappings* $x(\cdot): V' \to U'$, $\lambda(\cdot): V' \to \mathbb{R}^m$ *such that*:

(i) $x(\cdot)$ *and* $\lambda(\cdot)$ *are Lipschitzian*;

(ii) $x(\alpha^0) = x^0$ *and* $\lambda(\alpha^0) = \lambda^0$;

(iii) *for all* $\alpha \in V'$, $x(\alpha)$ *is the unique minimizer of* $S(\alpha)$ *in* U' *and* $\lambda(\alpha)$ *is the unique Kuhn–Tucker multiplier associated with it* (*i.e.*, $(x(\alpha), \lambda(\alpha))$ *satisfies condition* (2.2)).

The proof of Corollary 2.3 is given in the next section.

3. Proofs. We prepare the proofs of Theorem 2.1 by several lemmas. Some of them are more or less known. However the entire proofs are given for the sake of completeness. Our first lemma says that it is sufficient to prove Theorem 2.1 with Assumption (A.3) replaced by the stronger one

Assumption A.3. bis. There exist real numbers $a \geqq 0$, $c > 0$ such that for all $h \in \mathbb{R}^n$ one has

$$\left\langle D^2 f(x^0, \alpha^0)h + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0)h, h \right\rangle + a \sum_{i=1}^{m_1} \langle \nabla g_i(x^0, \alpha^0), h\rangle^2 \geqq c\|h\|^2,$$

(i.e. in (A.3.bis) the term $a\langle \nabla f(x^0, \alpha^0), h\rangle^2$ which appears in (A.3) has been removed.

LEMMA 3.0. *If Theorem* 2.1 *is true when* (A.3) *is replaced by the stronger Assumption* (A.3*bis*), *then it is also true under Assumption* (A.3).

Proof. Let us assume that the weak form of Theorem 2.1 holds (i.e. with Assumption (A.3) replaced by (A.3bis)). We show that Theorem 2.1 also holds. Let $(x^0, \alpha^0, \lambda^0) \in U \times P \times \mathbb{R}^m$ satisfy Assumptions (A.0), (A.1), (A.2), (A.3), (A.4) together with the necessary conditions (2.1) associated with the problem:

$$P(\alpha) \quad \begin{aligned} &\text{minimize } f(x, \alpha) \\ &\text{subject to } g(x, \alpha) \in Q, \\ &\qquad x \in U. \end{aligned}$$

We now associate to all $\alpha \in P$ the following modified problem:

$$\tilde{P}(\alpha) \quad \begin{aligned} &\text{minimize } v \\ &\text{subject to } f(x, \alpha) - v = 0, \\ &\qquad g(x, \alpha) \in Q, \\ &\qquad (v, x) \in \mathbb{R} \times U. \end{aligned}$$

Clearly (v, x) is a solution of $\tilde{\mathcal{P}}(\alpha)$ if and only if x is a solution of $\mathcal{P}(\alpha)$ and $v = f(x, \alpha)$. Moreover at this solution $[(v, x), (\mu, \lambda)]$ satisfies the necessary conditions (2.1) associated with $\tilde{\mathcal{P}}(\alpha)$ if and only if $\mu = 1$, (x, λ) satisfies the necessary conditions (2.1) associated with $P(\alpha)$ and $v = f(x, \alpha)$.

Hence $((v^0, x^0), (1, \lambda^0))$, with $v^0 = f(x^0, \alpha^0)$ satisfies the necessary conditions (2.1) associated with $\tilde{\mathcal{P}}(\alpha^0)$. From the fact that $(x^0, \alpha^0, \lambda^0)$ satisfies Assumptions (A.0), (A.1), (A.2), (A.3) and (A.4) for problem $\tilde{\mathcal{P}}(\alpha^0)$ one deduces that $((v^0, x^0), (1, \lambda^0))$ satisfies Assumptions (A.0), (A.1), (A.2), (A.3bis) and (A.4) for problem $\tilde{\mathcal{P}}(\alpha^0)$. Applying the weak form of Theorem 2.1 to $((v^0, x^0), (1, \lambda^0))$ and using the above equivalence property between $\mathcal{P}(\alpha)$ and $\tilde{\mathcal{P}}(\alpha)$ one deduces the end of the proof of Lemma 3.0.

In the sequel we shall assume that $(x^0, \alpha^0, \lambda^0)$ satisfies (A.0), (A.1), (A.2), (A.3bis) and (A.4).

LEMMA 3.1. *There exist neighborhoods U_1 of x^0, $U_1 \subset U$, V_1 of α^0 such that, for all $\alpha \in V_1$, if $x \in U_1$ is a local minimizer of $P(\alpha)$, then there exists $\lambda = (\lambda_i) \in \mathbb{R}^m$ such that (x, λ) satisfies the first order necessary conditions at α, i.e.,*

$$\nabla f(x, \alpha) + \sum_{i=1}^{m} \lambda_i \nabla g_i(x, \alpha) = 0,$$

$$g(x, \alpha) \in Q \quad \text{and} \quad \lambda \in N_Q(g(x, \alpha)).$$

Proof. Since by (A.1) the gradients $\nabla g_i(x^0, \alpha^0)$, $i \in \{1, \cdots, m\}$ are independent from (A.0), there exist neighborhoods U_1 of x^0, $U_1 \subset U$, V_1 of α^0 such that, for all $(x, \alpha) \in U_1 \times V_1$, the vectors $\nabla g_i(x, \alpha)$, $i \in \{1, \cdots, m\}$, are independent. In the sequel of this proof, since α is fixed, there is no ambiguity denoting $f(x, \alpha), \nabla f(x, \alpha), \cdots$, simply by $f(x), \nabla f(x), \cdots$.

Let $X = \{x \in U_1 | g(x) \in Q\}$. If x is a local minimizer of $P(\alpha)$, from Clarke (1975), for all $v \in T_x(x)$ one has $\langle -\nabla f(x), v \rangle \leqq 0$. Hence from Rockafellar (1970, Cor. 16.3.2), it is sufficient to prove that the following inclusion holds:

$$\{u \in \mathbb{R}^n | Dg(x)u \in T_Q(g(x))\} \subset T_X(x).$$

Indeed, let $u \in \mathbb{R}^n$ be such that $Dg(x)u \in T_Q(g(x))$ and let $\{\theta^q\} \subset (0, \infty)$, $\{x^q\} \subset X$ be sequences such that $\theta^q \to 0$ and $x^q \to x$. From the definition of the tangent cone it is sufficient to show that there exists a sequence $\{u^q\} \subset \mathbb{R}^n$, such that $u^q \to u$ and, for all q, $x^q + \theta^q u^q \in X$. Let $v = Dg(x)u$, then $v \in T_Q(g(x))$. Since, for all q, $g(x^q) \in Q$, and $g(x^q) \to g(x)$, there exists a sequence $\{v^q\} \subset \mathbb{R}^m$ such that, for all q, $g(x^q) + \theta^q v^q \in Q$ and $v^q \to v$. We can choose vectors $b_{m+1}, \cdots, b_n$ in $\mathbb{R}^n$ so that the vectors $\nabla g_1(x), \cdots, \nabla g_m(x)$, $b_{m+1}, \cdots, b_n$, form a basis in $\mathbb{R}^n$, and we define the mapping $G: U_1 \to \mathbb{R}^n$ by $G(y) = (g_1(y), \cdots, g_m(y), \langle b_{m+1}, y \rangle, \cdots, \langle b_n, y \rangle)$. Clearly, G is continuously differentiable, and the derivative $DG(x)$ is nonsingular. Hence, by the inverse mapping theorem, there exists q_0 such that, for $q \geqq q_0$, there exists $\hat{x}^q \in U_1$ satisfying:

$$g(\hat{x}^q) = g(x^q) + \theta^q v^q,$$

$$\langle b_i, \hat{x}^q \rangle = \langle b_i, x^q \rangle + \theta^q \langle b_i, u \rangle \qquad (i = m+1, \cdots, n),$$

and such that $\hat{x}^q \to x$. For $q \geqq q_0$, let $u^q = (\hat{x}^q - x^q)/\theta^q$. Recall that, for all q, $g(x^q) + \theta^q v^q \in Q$, hence, for $q \geqq q_0$, $g(\hat{x}^q) = g(x^q) + \theta^q v^q \in Q$; thus $\{\hat{x}^q\} \subset X$. Consequently, for $q \geqq q_0$, $x^q + \theta^q u^q = \hat{x}^q \in X$. To end the proof of the lemma, it suffices to show that $u^q \to u$. Indeed, from Taylor's theorem, for $q \geqq q_0$, one has $g(\hat{x}^q) - g(x^q) = [\int_Q^1 Dg(x^q + t(\hat{x}^q - x^q))\, dt](\hat{x}^q - x^q)$. Dividing by $\theta^q > 0$, one gets $v^q = [\int_0^1 Dg(x^q + t(\hat{x}^q - x^q))\, dt]u^q$ and one easily deduces that $\lim_{q\to\infty} Dg(x)u^q = \lim_{q\to\infty} v^q$. Recall that $\lim_{q\to\infty} v^q = v = Dg(x)u$; hence, for all $i \leqq m$, $\lim_{q\to\infty} \langle \nabla g_i(x), u^q \rangle = \langle \nabla g_i(x), u \rangle$. Furthermore, for all $i \geqq m+1$, $\langle b_i, u^q \rangle = \langle b_i, (\hat{x}^q - x^q)/\theta^q \rangle = \langle b_i, u \rangle$. Since the vectors $\{\nabla g_1(x), \cdots, \nabla g_m(x), b_{m+1}, \cdots, b_n\}$ are independent, one deduces that $u^q \to u$. This ends the proof of the lemma.

LEMMA 3.2. *For all $\varepsilon > 0$ and all $c' \in (0, c)$, there exist positive real numbers k_1, k_2, a positive real number δ (independent of ε) and neighborhoods U_2 of x^0, $U_2 \subset U$, V_2 of α^0, such that the two following properties are satisfied.*

(a) *For all (x, α), (y, β), (x^1, α^1), (x^2, α^2) in $U_2 \times V_2$ such that $g(x^1, \alpha^1) \in Q$, $g(x^2, \alpha^2) \in Q$, for all $\lambda \in B(\lambda^0, \delta)$ one has:*

$$\left\langle \left[D^2 f(x, \alpha) + \sum_{i=1}^{m} \lambda_i D^2 g_i(y, \beta) \right](x^2 - x^1), (x^2 - x^1) \right\rangle$$
$$\geqq c' \|x^2 - x^1\|^2 - k_1 \|x^2 - x^1\| d(\alpha^2, \alpha^1) - k_1 d(\alpha^2, \alpha^1)^2.$$

(b) *For all* (x^1, α^1), (x^2, α^2) *in* $U_2 \times V_2$, *such that* $g(x^2, \alpha^2) \in Q$, $g(x^1, \alpha^1) \in Q$, *for all* $\lambda^2 \in N_Q(g(x^2, \alpha^2))$ *one has*:

$$\langle \lambda^2, g(x^2, \alpha^2) - g(x^1, \alpha^1) \rangle$$

$$\geqq \|\lambda_I^2\| \cdot \left[-\frac{\rho}{2} [\|Dg_I(x^0, \alpha^0)\| + \varepsilon]^2 \cdot \|x^2 - x^1\|^2 - k_2 \|x^2 - x^1\| \, d(\alpha^2, \alpha^1) - k_2 d(\alpha^2, \alpha^1)^2 \right].$$

Proof. We first claim that, for all $\varepsilon > 0$, there exist a positive real number k' and neighborhoods U' of x^0, $U' \subset U$, V' of α^0 such that, for all (x^1, α^1), (x^2, α^2) in $U' \times V'$, for all $i \in \{1, \cdots, m\}$ one has:

$$|g_i(x^2, \alpha^2) - g_i(x^1, \alpha^1) - \langle \nabla g_i(x^0, \alpha^0), (x^2 - x^1) \rangle| \leqq \varepsilon \|x^2 - x^1\| + k' d(\alpha^2, \alpha^1). \tag{3.1}$$

Indeed, for all $i \in \{1, \cdots, m\}$, from (A.0), for all $\varepsilon > 0$, there exist open neighborhoods U' of x^0, $U' \subset U$, V' of α^0, such that U' is convex, and, for all $(x, \alpha) \in U' \times V'$, $\|\nabla g_i(x, \alpha) - \nabla g_i(x^0, \alpha^0)\| < \varepsilon$. Furthermore, without any loss of generality, we can assume that there exists a positive real number k' such that g_i is Lipschitzian of constant k' on $U' \times V'$. Hence, from Taylor's theorem,

$$\begin{aligned}
&|g_i(x^2, \alpha^2) - g_i(x^1, \alpha^1) - \nabla g_i(x^0, \alpha^0)(x^2 - x^1)| \\
&\quad \leqq \left| g_i(x^2, \alpha^2) - g_i(x^1, \alpha^2) - \left\langle \left[\int_0^1 \nabla g_i(x^1 + t(x^2 - x^1), \alpha^2) \, dt \right], x^2 - x^1 \right\rangle \right| \\
&\qquad + |g_i(x^1, \alpha^2) - g_i(x^1, \alpha^1)| \\
&\qquad + \int_0^1 \|\nabla g_i(x^1 + t(x^2 - x^1), \alpha^2) - \nabla g_i(x^0, \alpha^0)\| \, dt \cdot \|x^2 - x^1\| \\
&\quad \leqq 0 + k' d(\alpha^2, \alpha^1) + \varepsilon \|x^2 - x^1\|.
\end{aligned}$$

(a) For all $c' \in (0, c)$, let $c'' \in (c', c)$. From (A.3.bis) and the continuity of the mappings $D^2 f(\cdot, \cdot)$ and $D^2 g_i(\cdot, \cdot)$ $(i = 1, \cdots, m)$, there exist neighborhoods U'' of x^0, $U'' \subset U$, V'' of α^0 and a positive real number δ such that, for all (x, α), (y, β) in $U'' \times V''$, for all $\lambda \in B(\lambda^0, \delta)$ and all $h \in \mathbb{R}^n$, one has:

$$\left\langle \left[D^2 f(x, \alpha) + \sum_{i=1}^{m} \lambda_i D^2 g_i(y, \beta) \right] h, h \right\rangle \geqq c'' \|h\|^2 - a \sum_{i=1}^{m_1} \langle \nabla g_i(x^0, \alpha^0), h \rangle^2.$$

Let $\varepsilon > 0$ be such that $c'' - a \cdot m_1 \cdot \varepsilon^2 \geqq c'$, and let U', V' be the neighborhoods associated with ε in the above claim (3.1). Let $U_2 = U' \cap U''$ and $V_2 = V' \cap V''$. Recall that, for all $(x, \alpha) \in U \times V$ such that $g(x, \alpha) \in Q$, from (A.0.vi), for $i \in \{1, \cdots, m_1\}$, $g_i(x, \alpha) = 0$. Hence the end of the proof follows easily from (3.1) and the above inequality.

(b) From the weak convexity Assumption (A.2) and the continuity of the functions g_i $(i = 1, \cdots, m)$, there exist open neighborhoods U'' of x^0, $U'' \subset U$, and V'' of α^0 such that, for all (x^1, α^1), (x^2, α^2) in $U'' \times V''$ such that $g(x^k, \alpha^k) \in Q$ $(k = 1, 2)$, and for all $\mu^2 \in N_Q(g(x^2, \alpha^2)) \cap \bar{B}(0, 1)$, one has:

$$\langle \mu^2, g(x^2, \alpha^2) - g(x^1, \alpha^1) \rangle \geqq -\frac{\rho}{2} \|g(x^2, \alpha^2) - g(x^1, \alpha^1)\|^2.$$

Take any $\varepsilon > 0$ and let U', V' be the neighborhoods associated with ε in the above claim (3.1). Let $U_2 = U' \cap U''$ and $V = V' \cap V''$. From (3.1) and the above inequality, there exists k_2 such that

$$\langle \mu^2, g(x^2, \alpha^2) - g(x^1, \alpha^1) \rangle$$

$$\geqq -\frac{\rho}{2} [\|Dg_I(x^0, \alpha^0)\| + \varepsilon]^2 \cdot \|x^2 - x^1\|^2 - k_2 \|x^2 - x^1\| \cdot d(\alpha^2, \alpha^1) - k_2 d(\alpha^2, \alpha^1)^2.$$

Now letting $\lambda^2 \in N_Q(g(x^2, \alpha^2))$, we let $\mu^2 = (0, \lambda_I^2/\|\lambda_I^2\|)$ if $\lambda_I^2 \neq 0$ and $\mu^2 = 0$ if $\lambda_I^2 = 0$. Since $Q = \{0\} \times C$, $N_Q(g(x^2, \alpha^2)) = \mathbb{R}^{m_1} \times N_C(g_I(x^2, \alpha^2))$ and since $N_C(g_I(x^2, \alpha^2))$ is a cone, one deduces that $\mu^2 \in N_Q(g(x^2, \alpha^2)) \cap \bar{B}(0, 1)$. Applying the above inequality to μ^2 and noticing that

$$\langle \mu^2, g(x^2, \alpha^2) - g(x^1, \alpha^1)\rangle = (1/\|\lambda_I^2\|)\langle \lambda^2, g(x^2, \alpha^2) - g(x^1, \alpha^1)\rangle,$$

yields the inequality of Lemma 3.2(b).

LEMMA 3.3. *Let us suppose that* (x^0, λ^0) *satisfies the first order necessary condition at* α^0. *Then there exist positive real numbers* r *and* b *such that* $\bar{B}(x^0, r) \subset U$ *and, for all* $x \in \bar{B}(x^0, r)$ *satisfying* $g(x, \alpha^0) \in Q$, *one has* $f(x, \alpha^0) \geqq f(x^0, \alpha^0) + b\|x - x^0\|^2$.

Proof. For every $\lambda = (\lambda_i) \in \mathbb{R}^m$, let $L(\cdot, \lambda): U \to \mathbb{R}$ be the function defined by $L(x, \lambda) = f(x, \alpha^0) + \sum_{i=1}^m \lambda_i g_i(x, \alpha^0)$. From Taylor's theorem, one has:

$$L(x, \lambda^0) = L(x^0, \lambda^0) + \langle \nabla L(x^0, \lambda^0),\ x - x^0\rangle + \int_0^1 (1-t)\langle D^2 L(x^0 + t(x - x^0), \lambda^0)(x - x^0), (x - x^0)\rangle\, dt.$$

Let $\rho > 0$ be the constant of weak convexity defined by (A.2). From (A.4), $c > \rho\|\lambda_I^0\| \cdot \|Dg_I(x^0, \alpha^0)\|^2$. Hence, there exist $c' \in (0, c)$ and $\varepsilon > 0$ such that, if $b = c'/2 - \rho/2\|\lambda_I^0\|[\|Dg_I(x^0, \alpha^0)\| + \varepsilon]^2$, then $b > 0$. Let U_2, V_2 be the neighborhoods of x^0 and α^0 associated with c' and ε in Lemma 3.2, and let r be a positive real number such that $\bar{B}(x^0, r) \subset U_2$. Since (x^0, α^0) satisfies the first order necessary condition (2.1) at α^0, one deduces that $\nabla L(x^0, \lambda^0) = 0$. From Lemma 3.2(a) (taking $\alpha^1 = \alpha^2 = \alpha^0$), for all $x \in \bar{B}(x^0, r)$ one deduces that:

$$L(x, \lambda^0) - L(x^0, \lambda^0) \geqq \int_0^1 (1-t)c'\|x - x^0\|^2\, dt \geqq \frac{c'}{2}\|x - x^0\|^2,$$

and, from the definition of L, one gets:

$$f(x, \alpha^0) - f(x^0, \alpha^0) \geqq \langle \lambda^0, g(x^0, \alpha^0) - g(x, \alpha^0)\rangle + (c'/2)\|x - x^0\|^2.$$

By Lemma 3.2(b) (taking $\alpha^1 = \alpha^2 = \alpha^0$), for all $x \in \bar{B}(x^0, r) \subset U_2$, one gets:

$$\langle \lambda^0, g(x^0, \alpha^0) - g(x, \alpha^0)\rangle \geqq -(\rho/2)\|\lambda_I^0\|[\|Dg_I(x^0, \alpha^0)\| + \varepsilon]^2.$$

Hence, from the two above inequalities and the definition of b, for all $x \in \bar{B}(x^0, r)$, one has $f(x, \alpha^0) - f(x^0, \alpha^0) \geqq b\|x - x^0\|^2$. This completes the proof.

LEMMA 3.4. *Let* $(x^0, \lambda^0) \in U \times \mathbb{R}^m$ *satisfy the first order necessary condition* (2.1) *at* α^0. *Then, for every neighborhood* U' *of* x^0, $U' \subset U$, *there exist* $r' > 0$ *and a neighborhood* V' *of* α^0 *such that* $B(x^0, r') \subset U'$ *and, for all* $\alpha \in V'$, *there exists a minimizer* $x(\alpha)$ *of* $P(\alpha)$ *in* $B(x^0, r')$ *(i.e.,* $x(\alpha) \in B(x^0, r')$, $g(x(\alpha), \alpha) \in Q$ *and for all* $x \in B(r^0, r)$, $g(x, \alpha) \in Q$ *one has* $f(x(\alpha), \alpha) \leqq f(x, \alpha)$*).*

The above lemma is related to a previous result of Robinson (1982), proved when Q is a closed convex cone.

Proof. Let U' be a neighborhood of x^0, $U' \subset U$, and let b, r be the positive real numbers defined by Lemma 3.3. There exists a positive real number $r' < r$ and a neighborhood V_1' of α^0 such that $\bar{B}(x^0, r') \subset U'$ and f is k-Lipschitzian on $\bar{B}(x^0, r') \times V_1'$.

For all $\alpha \in P$, let $\Gamma(\alpha) = \{x \in \bar{B}(x^0, r') | g(x, \alpha) \in Q\}$. We claim that there exists a neighborhood V_2' of α^0 such that, for all α in V_2', there exists $x(\alpha) \in \Gamma(\alpha)$ satisfying:

$$f(x(\alpha), \alpha) \leqq f(x, \alpha) \quad \text{for all } x \in \Gamma(\alpha).$$

Since f is continuous and, for all α in P, $\Gamma(\alpha)$ is a compact subset of $\mathbb{R}^n$, it is sufficient to prove that, for α in a neighborhood of α^0, $\Gamma(\alpha)$ is nonempty. Indeed, by (A.1) the vectors $\nabla g_i(x^0, \alpha^0)$, $i \in \{1, \cdots, m\}$, are independent. Hence, by the implicit function theorem (Schwartz (1967)), there exists a neighborhood V_2' of α^0 and a continuous mapping $\varphi : V_2' \to \bar{B}(x^0, r')$ such that $\varphi(\alpha^0) = x^0$ and, for all $\alpha \in V_2'$, one has $g(\varphi(\alpha), \alpha) = g(x^0, \alpha^0) \in Q$. This ends the proof of the claim.

We now claim that there exists a neighborhood V' of α^0, $V' \subset V_2'$, such that, for all $\alpha \in V'$, the element $x(\alpha)$ defined before satisfies $\|x(\alpha) - x^0\| < r'$. Clearly, the proof of the claim will end the proof of the lemma. Recall that f is k-Lipschitzian on $\bar{B}(x^0, r') \times V_1'$. Let $V_3' = V_1' \cap B(\alpha^0, r'^2 b/16k)$ and let $\eta > 0$, $\eta < \min\{r'/2, r'^2 b/16k\}$. Then, for all $x^1, x^2 \in B(x^0, r')$ satisfying $\|x^2 - x^1\| < \eta$, for all $\alpha \in V_3'$, one has:

$$f(x^1, \alpha) - f(x^2, \alpha^0) \leqq k[\eta + d(\alpha, \alpha^0)] < r'^2 b/8.$$

Furthermore, the multivalued mapping $\alpha \to \Gamma(\alpha) = \{x \in \bar{B}(x^0, r') | g(x, \alpha) \in Q\}$, from V_2' to $\mathbb{R}^n$, is upper semicontinuous, with compact values. Hence, there exists a neighborhood V_4' of α^0, $V_4' \subset V_2'$, such that, for all $\alpha \in V_4'$, $\Gamma(\alpha) \subset B(\Gamma(\alpha^0), \eta)$ and (from the continuity of φ) $\varphi(\alpha) \in B(x^0, \eta)$.

Let $V' = V_1' \cap V_2' \cap V_3' \cap V_4'$. We now show that V' satisfies the conclusion of the lemma. Recall that, for all $\alpha \in V'$, $\varphi(\alpha) \in \Gamma(\alpha)$; thus, from the definition of $x(\alpha)$, one deduces that:

$$f(\varphi(\alpha), \alpha) \geqq f(x(\alpha), \alpha).$$

On the other hand, for all $\alpha \in V'$, $x(\alpha) \in \Gamma(\alpha) \subset B(\Gamma(\alpha^0), \eta)$. Hence, there exists $y^0 \in \Gamma(\alpha^0)$ such that $\|y^0 - x(\alpha)\| < \eta$. By Lemma 3.3, one has:

$$f(y^0, \alpha^0) \geqq f(x^0, \alpha^0) + b\|y^0 - x^0\|^2.$$

Summing up the two above inequalities, for all $\alpha \in V'$, one gets:

$$b\|y^0 - x^0\|^2 \leqq f(\varphi(\alpha), \alpha) - f(x^0, \alpha^0) + f(y^0, \alpha^0) - f(x(\alpha), \alpha).$$

Let us recall that, for $\alpha \in V'$, $\|\varphi(\alpha) - x^0\| < \eta$ and $\|y^0 - x(\alpha)\| < \eta$. Hence, from the above inequality and the inequality defining η, one gets $b\|y^0 - x^0\|^2 \leqq r'^2 b/8 + r'^2 b/8$. Thus, $\|y^0 - x^0\| < r'/2$, and $\|x(\alpha) - x^0\| \leqq \|x(\alpha) - y^0\| + \|y^0 - x^0\| \leqq \eta + r'/2 < r'$. This ends the proof of the claim and the proof of the lemma.

In the following, we denote by $Dg(x, \alpha)^*$ the $n \times m$ matrix whose columns are $\nabla g_i(x, \alpha)$ $(i = 1, \cdots, m)$, i.e., the transpose of the $m \times n$ matrix $Dg(x, \alpha)$.

LEMMA 3.5. *Let ε be a positive real number. There exist a positive real number k_3 and neighborhoods U_3 of x^0, $U_3 \subset U$, V_3 of α^0 such that, for all $(x, \alpha) \in U_3 \times V_3$, the matrix $Dg(x, \alpha) \circ Dg(x, \alpha)^*$ is nonsingular and the mapping $\varphi : U_3 \times V_3 \to \mathbb{R}^m$ defined by*

$$\varphi(x, \alpha) = [Dg(x, \alpha) \circ Dg(x, \alpha)^*]^{-1} \circ Dg(x, \alpha) \nabla f(x, \alpha),$$

satisfies the following properties:

$$\|\varphi(x^2, \alpha^2) - \varphi(x^1, \alpha^1)\| \leqq k_3[\|x^2 - x^1\| + d(\alpha^2, \alpha^1)] \quad \textit{for all } (x^1, \alpha^1), (x^2, \alpha^2) \textit{ in } U_3 \times V_3;$$

$$\|\varphi(x, \alpha) - \varphi(x^0, \alpha^0)\| \leqq \varepsilon, \quad \textit{for all } (x, \alpha) \in U_3 \times V_3.$$

Proof. The proof is a straightforward consequence of the independence Assumption (A.1), using the fact that the mappings $\nabla f(\cdot, \cdot)$, $\nabla g_i(\cdot, \cdot)$ $(i = 1, \cdots, m)$ are locally Lipschitzian and that the mappings $A \to (A \circ A^*)^{-1} \circ A$, defined on the set of $m \times n$ matrices of maximal rank, is infinitely differentiable, and hence locally Lipschitzian.

Proof of Theorem 2.1. Let $c>0$, $\rho>0$ be the constants defined by (A.2) and (A.3). From (A.4), $c>\rho\|\lambda_I^0\|\cdot\|Dg_I(x^0,\alpha^0)\|^2$. Hence, there exist $c'\in(0,c)$ and $\varepsilon>0$ such that

$$c'>\rho[\|\lambda_I^0\|+\varepsilon][\|Dg_I(x^0,\alpha^0)\|+\varepsilon]^2. \tag{3.2}$$

Let $\delta>0$ be the constant defined by Lemma 3.2; without any loss of generality, we can suppose that $\varepsilon<\delta$. From (A.0), there exist a positive real number k and neighborhoods U_0 of x^0, $U_0\subset U$, V_0 of α^0 such that all the mappings $g(\cdot,\cdot)$ $Dg(\cdot,\cdot)$ and $\nabla f(\cdot,\cdot)$ are k-Lipschitzian on $U_0\times V_0$. Furthermore, let U_1, V_1 (resp. U_2, V_2 and U_3, V_3) be the neighborhoods of x^0 and α^0 associated, in Lemma 3.1 (resp. Lemma 3.2 and Lemma 3.5) with the constants c' and ε as defined above.

Now, by Lemma 3.4, we associate with $U'=U_0\cap U_1\cap U_2\cap U_3$ a positive real number r' and an open neighborhood $\tilde{V}$ of α^0. We take $V'=\tilde{V}\cap V_0\cap V_1\cap V_2\cap V_3$. Let α^1, α^2 be two elements in V'. By Lemma 3.4, there exists a minimizer of $P(\alpha^1)$ (resp. $P(\alpha^2)$) in $B(x^0,r')$ not necessarily unique, that we denote by x^1 (resp. x^2). By Lemma 3.1, let $\lambda^1\in\mathbb{R}^m$ (resp. $\lambda^2\in\mathbb{R}^m$) be the Kuhn-Tucker multiplier associated with x^1 (resp. x^2), i.e., such that (x^h,λ^h) $(h=1,2)$ satisfies the first order necessary condition at α^h:

$$-\nabla f(x^h,\alpha^h)=Dg(x^h,\alpha^h)^*\lambda^h,$$

$$g(x^h,\alpha^h)\in Q \quad\text{and}\quad \lambda^h\in N_Q(g(x^h,\alpha^h)).$$

To end the proof of the theorem, it suffices to show that $\|x^2-x^1\|\leqq Kd(\alpha^2,\alpha^1)$ and $\|\lambda^2-\lambda^1\|\leqq Kd(\alpha^2,\alpha^1)$, where K is a positive real number independent of the choice of α^1, α^2 in V'.

From the first part of the first order necessary condition and Lemma 3.5, for $h=1,2$, the matrix $Dg(x^h,\alpha^h)\circ Dg(x^h,\alpha^h)^*$ is invertible and one deduces that:

$$\lambda^h=-[Dg(x^h,\alpha^h)\circ Dg(x^h,\alpha^h)^*]^{-1}Dg(x^h,\alpha^h)\nabla f(x^h,\alpha^h)(=\varphi(x^h,\alpha^h)),$$

$$\|\lambda^2-\lambda^1\|\leqq k_3[\|x^2-x^1\|+d(\alpha^2,\alpha^1)], \tag{3.3}$$

$$\|\lambda_I^h-\lambda_I^0\|\leqq\lambda^h-\lambda^0\|\leqq\varepsilon<\delta. \tag{3.4}$$

From (3.4) and from Lemma 3.2(b), one deduces that:

$$\begin{aligned}[\|\lambda_I^0\|+\varepsilon]^{-1}\cdot\langle\lambda^2-\lambda^1, g(x^2,\alpha^2)-g(x^1,\alpha^1)\rangle&\\ \geqq-\rho[\|Dg_I(x^0,\alpha^0)\|+\varepsilon]^2\|x^2-x^1\|^2&\\ -2k_2\|x^2-x^1\|d(\alpha^2,\alpha^1)-2k_2d(\alpha^2,\alpha^1)^2.&\end{aligned} \tag{3.5}$$

Furthermore,

$$\langle\lambda^2-\lambda^1, g(x^2,\alpha^2)-g(x^1,\alpha^1)\rangle=A+B+C, \tag{3.6}$$

where

$$A=\langle\lambda^2-\lambda^1, g(x^2,\alpha^2)-g(x^2,\alpha^1)\rangle,$$

$$B=\langle-\lambda^2, g(x^1,\alpha^1)-g(x^2,\alpha^1)-g(x^1,\alpha^2)+g(x^2,\alpha^2)\rangle,$$

$$C=\langle-\lambda^1, g(x^2,\alpha^1)-g(x^1,\alpha^1)\rangle+\langle-\lambda^2, g(x^1,\alpha^2)-g(x^2,\alpha^2)\rangle,$$

and we consider successively each one of the three terms. From (3.3), using the Cauchy-Schwarz inequality and the fact that g is k-Lipschitzian on $U'\times V'$, one gets:

$$A\leqq k\,k_3[\|x^2-x^1\|+d(\alpha^2,\alpha^1)]\cdot d(\alpha^2,\alpha^1). \tag{3.7}$$

By (3.4) the multiplier λ^2 is bounded by $\|\lambda^0\|+\varepsilon$; hence, from Taylor's theorem, using the Cauchy-Schwarz inequality, one gets:

$$B \leqq [\|\lambda^0\|+\varepsilon]\|x^2-x^1\| \left\| \int_0^1 Dg(x^2+t(x^1-x^2), \alpha^1)\, dt - \int_0^1 Dg(x^1+u(x^2-x^1), \alpha^2)\, du \right\|.$$

Upon performing the change of variable $t = 1-u$ in the second integral, and using the fact that the derivative $Dg(\cdot,\cdot)$ is k-Lipschitzian on $U' \times V'$, one gets:

$$\begin{aligned} &B \leqq [\|\lambda^0\|+\varepsilon]\|x^2-x^1\| \cdot \int_0^1 \|Dg(x^2+t(x^1-x^2), \alpha^1) - Dg(x^2+t(x^1-x^2), \alpha^2)\|\, dt, \\ &B \leqq k[\|\lambda^0\|+\varepsilon]\|x^2-x^1\| d(\alpha^2, \alpha^1). \end{aligned} \tag{3.8}$$

From Taylor's theorem, one has:

$$\begin{aligned} C = {} & \langle -\lambda^1, Dg(x^1, \alpha^1)(x^2-x^1)\rangle + \langle -\lambda^2, Dg(x^2, \alpha^2)(x^1-x^2)\rangle \\ & - \left\langle \left[\int_0^1 (1-t) \sum_{i=1}^m \lambda_i^1 D^2 g_i(x^1+t(x^2-x^1), \alpha^1)\, dt \right](x^2-x^1), (x^2-x^1) \right\rangle \\ & - \left\langle \left[\int_0^1 (1-t) \sum_{i=1}^m \lambda_i^2 D^2 g_i(x^2+t(x^1-x^2), \alpha^2)\, dt \right](x^2-x^1), (x^2-x^1) \right\rangle. \end{aligned}$$

From the first order necessary condition, Taylor's theorem, and using the fact that $\nabla f(\cdot,\cdot)$ is k-Lipschitzian on $U' \times V'$, one gets:

$$\begin{aligned} &\langle -\lambda^1, Dg(x^1, \alpha^1)(x^2-x^1)\rangle + \langle -\lambda^2, Dg(x^2, \alpha^2)(x^1-x^2)\rangle \\ &\quad = -\langle \nabla f(x^2, \alpha^2) - \nabla f(x^1, \alpha^1), x^2-x^1\rangle \\ &\quad = -\langle \nabla f(x^2, \alpha^2) - \nabla f(x^2, \alpha^1), x^2-x^1\rangle - \langle \nabla f(x^2, \alpha^1) - \nabla f(x^1, \alpha^1), x^2-x^1\rangle \\ &\quad \leqq kd(\alpha^2, \alpha^1)\|x^2-x^1\| \\ &\qquad - \left\langle \left[\int_0^1 D^2 f(x^1+t(x^2-x^1), \alpha^1)\, dt \right](x^2-x^1), (x^2-x^1) \right\rangle. \end{aligned}$$

One easily gets (by performing the change of variable $t = 1-u$) that:

$$\int_0^1 tD^2 f(x^1+t(x^2-x^1), \alpha^1)\, dt = \int_0^1 (1-u) D^2 f(x^2+u(x^1-x^2), \alpha^1)\, du.$$

Hence

$$\begin{aligned} \int_0^1 D^2 f(x^1+t(x^2-x^1), \alpha^1)\, dt = {} & \int_0^1 (1-t) D^2 f(x^1+t(x^2-x^1), \alpha^1)\, dt \\ & + \int_0^1 (1-u) D^2 f(x^2+u(x^1-x^2), \alpha^1)\, du. \end{aligned}$$

From (3.4), $\lambda^h \in \bar{B}(\lambda^0, \delta)$ $(h = 1, 2)$. Hence, from Lemma 3.2(a) and the above equalities and inequalities

$$\begin{aligned} &C \leqq kd(\alpha^2, \alpha^1)\|x^2-x^1\| \\ &\qquad -2 \int_0^1 (1-t)[c'\|x^2-x^1\|^2 - k_1\|x^2-x^1\| d(\alpha^2, \alpha^1) - k_1 d(\alpha^2, \alpha^1)^2]\, dt, \\ &C \leqq -c'\|x^2-x^1\|^2 + (k+k_1)\|x^2-x^1\| d(\alpha^2, \alpha^1) + k_1 d(\alpha^2, \alpha^1)^2. \end{aligned} \tag{3.9}$$

Let $b = c' - \rho[\|\lambda_I^0\| + \varepsilon][\|Dg_I(x^0, \alpha^0)\| + \varepsilon]^2$; then, from (3.2) one has $b > 0$. From (3.5), (3.6), (3.7), (3.8), (3.9), there exists a positive real number k' such that:

$$b\|x^2 - x^1\|^2 \leqq k' d(\alpha^2, \alpha^1)[\|x^2 - x^1\| + d(\alpha^2, \alpha^1)].$$

Let $K = \max\{2, (2k')/b\}$. Then, from the above inequality, one easily deduces that $\|x^2 - x^1\| \leqq K d(\alpha^2, \alpha^1)$, and, from (3.3), $\|\lambda^2 - \lambda^1\| \leqq (k_3 + Kk_3) d(\alpha^2, \alpha^1)$. This ends the proof of the theorem.

We now give the proof of Corollary 2.3.

Proof of Corollary 2.3. Let $(x^0, \alpha^0, \lambda^0)$ satisfy the assumptions of Corollary 2.3 and let:

$$I_+(x^0, \alpha^0) = \{i \in I(x^0, \alpha^0) | \lambda_i^0 > 0\}, \qquad I_0(x^0, \alpha^0) = \{i \in I(x^0, \alpha^0) | \lambda_i^0 = 0\},$$
$$J(x^0, \alpha^0) = \{i \in \{m_1 + 1, \cdots, m\} | g_i(x^0, \alpha^0) < 0\}.$$

For $\alpha \in P$, we consider the following problem:

$$\tilde{S}(\alpha) \quad \begin{aligned} &\text{minimize } f(x, \alpha) \\ &\text{subject to } g_i(x, \alpha) = 0,\ i \in \{1, \cdots, m_1\} \cup I_+(x^0, \alpha^0), \\ &\qquad g_i(x, \alpha) \leqq 0,\ i \in I_0(x^0, \alpha^0), \\ &\qquad x \in U. \end{aligned}$$

Clearly $\tilde{S}(\alpha)$ is a problem of type $P(\alpha)$ with $Q = \{0\}^p x (-\mathbb{R}_+)^q$, where $p = \text{card } I_+(x^0, \alpha^0) + m_1$ and $q = \text{card } I_0(x^0, \alpha^0)$. If we let $\tilde{\lambda}^0$ be the vector in $\mathbb{R}^{p+q}$ with coordinates $\tilde{\lambda}_i^0 = \lambda_i^0$, for $i \in \{1, \cdots, m_1\} \cup I(x^0, \alpha^0)$, then $(x^0, \alpha^0, \tilde{\lambda}^0)$ satisfies the assumptions of Theorem 2.1. Furthermore, $(x^0, \alpha^0, \tilde{\lambda}^0)$ satisfies the necessary condition (2.2) associated with $\tilde{S}(\alpha^0)$, since $(x^0, \alpha^0, \lambda^0)$ satisfies the necessary condition (2.2) associated with $S(\alpha^0)$. Consequently, from Theorem 2.1, there exist open neighborhoods U_1 of x^0 in U, V_1 of α^0 in P and Lipschitzian mappings $x(\cdot): V_1 \to U_1$ and $\tilde{\lambda}(\cdot): V_1 \to \mathbb{R}^{p+q}$ such that $x(\alpha^0) = x^0$, $\tilde{\lambda}(\alpha^0) = \tilde{\lambda}^0$ and, for all $\alpha \in V_1$, the pair $(x(\alpha), \tilde{\lambda}(\alpha))$ satisfies the necessary condition (2.2) associated with problem $\tilde{S}(\alpha)$. We let now $\lambda(\cdot): V_1 \to \mathbb{R}^m$ be the mapping defined by $\lambda_i(\alpha) = \tilde{\lambda}_i(\alpha)$ for $i \in \{1, \cdots, m_1\} \cup I(x^0, \alpha^0)$ and $\lambda_i(\alpha) = 0$ for $i \in J(x^0, \alpha^0)$. Since, for all $i \in I_+(x^0, \alpha^0)$, $\lambda_i(\alpha^0) = \lambda_i^0 > 0$ and, for all $i \in J(x^0, \alpha^0)$, $g_i(x^0, \alpha^0) = g_i(x(\alpha^0), \alpha^0) < 0$, from the continuity of the mappings $\lambda(\cdot)$, $x(\cdot)$ and $g_i(\cdot, \cdot)$, there exists an open neighborhood V_2 of α^0 in V_1 such that, for all α in V_2, for all $i \in I_+(x^0, \alpha^0)$, $\lambda_i(\alpha) > 0$ and, for all $i \in J(x^0, \alpha^0)$, $g_i(x(\alpha), \alpha) < 0$. Consequently, one easily checks that, for all $\alpha \in V_2$, $(x(\alpha), \lambda(\alpha))$ satisfies the necessary condition (2.2) associated with problem $S(\alpha)$.

It now remains to show that there exist neighborhoods V' of α^0 in V_2 and U' of x^0 in U_1 such that, for all $\alpha \in V'$ and all $x \in U'$, $x \neq x(\alpha)$, satisfying $g_i(x, \alpha) = 0$ for $i \in \{1, \cdots, m_1\}$ and, $g_i(x, \alpha) \leqq 0$, for $i \in \{m_1 + 1, \cdots, m\}$, then one has $f(x, \alpha) > f(x(\alpha), \alpha)$. We prove this assertion by contraposition. Assume that there exist sequences $\{x^k\} \subset U'$ and $\{\alpha^k\} \subset V'$ such that $\{x^k\} \to x^0$, $\{\alpha^k\} \to \alpha^0$ and, for all k, $x^k \neq x(\alpha^k)$, $g_i(x^k, \alpha^k) = 0$ for $i \in \{1, \cdots, m_1\}$, $g_i(x^k, \alpha^k) \leqq 0$ for $i \in \{m_1 + 1, \cdots, m\}$ and $f(x^k, \alpha^k) \leqq f(x(\alpha^k), \alpha^k)$. Without any loss of generality, one can assume that $(x^k - x(\alpha^k))/\|x^k - x(\alpha^k)\|$ converges to some element h in $\mathbb{R}^n$ such that $\|h\| = 1$.

From the mean value theorem and the continuity of $\nabla f(\cdot, \cdot)$ and $\nabla g_i(\cdot, \cdot)$ at (x^0, α^0) one has, for $i = 1, \cdots, m$,

$$\begin{aligned} \langle \nabla f(x^0, \alpha^0), h \rangle &= \lim_{k \to \infty} [f(x^k, \alpha^k) - f(x(\alpha^k), \alpha^k)]/\|x^k - x(\alpha^k)\|, \\ \langle \nabla g_i(x^0, \alpha^0), h \rangle &= \lim_{k \to \infty} [g_i(x^k, \alpha^k) - g_i(x(\alpha^k), \alpha^k)]/\|x^k - x(\alpha^k)\|. \end{aligned} \tag{3.10}$$

From the very definition of the sequences $\{x^k\}$ and $\{\alpha^k\}$ and recalling that from the first part of the proof, $g_i(x(\alpha^k), \alpha^k) = 0$, $i = \{1, \cdots, m_1\} \cup I_+(x^0, \alpha^0)$, one deduces from (3.10) that

$$
\begin{aligned}
&\langle \nabla f(x^0, \alpha^0), h\rangle \leqq 0,\\
&\langle \nabla g_i(x^0, \alpha^0), h\rangle = 0, \qquad i = 1, \cdots, m_1,\\
&\langle \nabla g_i(x^0, \alpha^0), h\rangle \leqq 0, \qquad i \in I_+(x^0, \alpha^0).
\end{aligned} \tag{3.11}
$$

Since (x^0, λ^0) satisfies the necessary condition (2.2) associated with $S(\alpha^0)$, one gets

$$
\langle \nabla f(x^0, \alpha^0), h\rangle + \sum_{i \in \{1, \cdots, m_1\} \cup I_+(x^0, \alpha^0)} \lambda_i^0 \langle \nabla g_i(x^0, \alpha^0), h\rangle = 0. \tag{3.12}
$$

From (3.11) and (3.12), since $\lambda_i^0 > 0$, for $i \in I_+(x^0, \alpha^0)$, it follows that the inequalities in (3.11) are in fact equalities. Hence, by (C.2) one gets

$$
\left\langle D^2 f(x^0, \alpha^0)h + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0)h, h \right\rangle > 0. \tag{3.13}
$$

We end the proof of the corollary by contradicting (3.13). Denote $L_k(x) = f(x, \alpha^k) + \sum_{i=1}^m \lambda_i(\alpha^k) g_i(x, \alpha^k)$. From Taylor's theorem and from the continuity of $D^2 f(\cdot, \cdot)$ and $D^2 g_i(\cdot, \cdot)$ at (x^0, α^0):

$$
\begin{aligned}
&\frac{1}{2}\left\langle D^2 f(x^0, \alpha^0)h + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0)h, h \right\rangle\\
&= \lim_{k \to \infty} \int_0^1 (1-t)\left\langle D^2 L_k[x(\alpha^k) + t(x^k - x(\alpha^k))] \frac{(x^k - x(\alpha^k))}{\|x^k - x(\alpha^k)\|}, \frac{x^k - x(\alpha^k)}{\|x^k - x(\alpha^k)\|} \right\rangle dt\\
&= \lim_{k \to \infty} [L_k(x^k) - L_k(x(\alpha^k)) - \langle \nabla L_k(x(\alpha^k)), x^k - x(\alpha^k)\rangle] / \|x^k - x(\alpha^k)\|^2,
\end{aligned}
$$

where

$$
h = \lim \frac{x^k - x(\alpha^k)}{\|x^k - x(\alpha^k)\|}.
$$

Since $(x(\alpha^k), \lambda(\alpha^k))$ satisfies the necessary conditions (2.2) associated with $S(\alpha^k)$, then $\nabla L_k(x(\alpha^k)) = 0$, $\lambda_i(\alpha^k) g_i(x(\alpha^k), \alpha^k) = 0$, for all $i \in \{1, \cdots, m\}$ and $\lambda_i(\alpha^k) \geqq 0$, for $i \in \{m_1 + 1, \cdots, m\}$. Consequently, $L_k(x(\alpha^k)) = f(x(\alpha^k))$ and $L_k(x^k) = f(x^k) + \sum_{i=1}^m \lambda_i(\alpha^k) g_i(x^k, \alpha^k) \leqq f(x^k)$. Hence, for all k,

$$
L_k(x^k) - L_k(x(\alpha^k)) - \langle \nabla L_k(x(\alpha^k)), x^k - x(\alpha^k)\rangle \leqq 0.
$$

Dividing the above inequality by $\|x^k - x(\alpha^k)\|^2$, passing to the limit, when $k \to \infty$, from the above equalities one deduces that:

$$
\left\langle D^2 f(x^0, \alpha^0)h + \sum_{i=1}^{m} \lambda_i^0 D^2 g_i(x^0, \alpha^0)h, h \right\rangle \leqq 0
$$

which contradicts (3.13). This ends the proof of the corollary.

ANALYSIS OF THE PERIODIC LYAPUNOV AND RICCATI EQUATIONS VIA CANONICAL DECOMPOSITION*

SERGIO BITTANTI†, PATRIZIO COLANERI‡ AND GUIDO GUARDABASSI†

Abstract. A new proof is given of the following result: a periodic Riccati equation admits a unique positive semidefinite periodic solution and the solution is stabilizing if and only if the underlying system is stabilizable and detectable. The proof hinges on the decomposition of the Riccati equation induced by the system canonical decomposition. The solution structure is therefore naturally pointed out.

Key words. periodic Riccati equation, periodic Lyapunov equation, periodic solutions, canonical decomposition

AMS(MOS) subject classifications. 93B10, 93G50, 93G60, 93G15, 43E30

1. Introduction. As is well known, the necessary and sufficient condition for the existence of a positive semidefinite solution of the time-invariant Riccati equation is stated in terms of stabilizability and detectability of the underlying (time-invariant) linear system. This fundamental fact was first proved by Wonham via quasi-linearization techniques [1]. An important alternative proof, based on the analysis of the associated Hamiltonian matrix, is due to Kucera [2]. The possibility of extending the above result to the periodically time-varying case, in order to solve many important periodic estimation and control problems, was considered by Hewer in [3] and by Kano and Nishimura in [4]. Precisely, Hewer adopted the quasi-linearization approach while Kucera's line of reasoning was followed by Kano and Nishimura. However, some preliminary yet basic results of [3] turned out not to be technically sound [5]. In particular, the very notions of stabilizability and detectability for linear periodic systems, introduced by Hewer in [3] and set then by Kano and Nishimura at the basis of their development, were not clearly related either to their original definitions or to the asymptotic stability of appropriate parts of the Kalman canonical decomposition (if any) of the periodic system at hand. These various issues have only recently found a satisfactory clarification [6]-[8], so that, in retrospective, Kano and Nishimura's paper can now be looked at as a valid extension to the periodic case of the basic Wonham-Kucera theorem recalled at the beginning of this introduction.

The main purpose of this paper is to provide, for the periodically time-varying case, a totally new and alternative proof of the Wonham-Kucera theorem. Our proof is based on the canonical decomposition of the periodic Riccati equation induced by the Kalman canonical decomposition of the underlying periodic dynamical system. Besides admitting an easy yet fairly deep system-theoretic interpretation, this proof does not require any simplifying assumption on the eigenvalues of the monodromy matrix of the associated Hamiltonian system. Last but not least, our approach, when specialized to the time-invariant case, does obviously provide a third and novel proof of the Wonham-Kucera theorem.

The paper is organized as follows. Preliminarily, in § 2 we study the action on the periodic Riccati equation of a state-space nonsingular transformation performed on

the underlying periodic dynamical system. In particular, the underlying dynamical system can, without any loss of generality, be assumed to be in the Kalman canonical form. A corresponding decomposition of the periodic Riccati equation is then obtained. The existence of a periodic solution for a periodic Lyapunov differential equation is discussed in § 3. The so-obtained results, together with the canonical decomposition of the periodic Riccati equation introduced in § 2, are used in § 4 to analyse the structure of periodic solutions to the periodic Riccati equation and to prove the main theorem.

2. Decomposition of the periodic matrix Riccati equation. Consider the linear system:

$$\dot{x}(t) = A(t)x(t) + B(t)u(t), \tag{1a}$$

$$y(t) = C(t)x(t) \tag{1b}$$

where $A: R \to R^{n\times n}$, $B: R \to R^{n\times m}$, $C: R \to R^{p\times n}$ are continuous functions. We assume that system (1) is T-periodic, namely:

$$A(t+T) = A(t), \quad B(t+T) = B(t), \quad C(t+T) = C(t) \quad \forall t.$$

We shall denote by $\Phi_A(t, \tau)$ the transition matrix (generated by A) of system (1).

According to most of the literature on linear periodic systems [9]-[11], $\Phi_A(T, 0)$ is referred to in the sequel as the *monodromy matrix* (of system (1)), while its eigenvalues are said to be the *characteristic multipliers* of A. System (1) is asymptotically stable if and only if the characteristic multipliers of A lie inside the open unit disk. In such a case, we also say, for short, that A (instead of system (1)) is asymptotically stable.

Associated with (1), let

$$-\dot{P}(t) = A(t)'P(t) + P(t)A(t) + C(t)'C(t) - P(t)B(t)B(t)'P(t) \tag{2}$$

be a T-periodic matrix Riccati differential equation the periodic solutions of which are the principal object of the present paper.

The first part of this section is devoted to showing the action on (2) of a nonsingular, continuously differentiable, T-periodic state-space transformation of (1). Specifically let

$$\hat{x}(t) = S(t)x(t) \tag{3}$$

where S is continuously differentiable, $S(t)$ is nonsingular and equal to $S(t+T)$, for all t. It is well known that (3) carries system (1) into

$$\dot{\hat{x}}(t) = \hat{A}(t)\hat{x}(t) + \hat{B}(t)u(t), \qquad y(t) = \hat{C}(t)\hat{x}(t) \tag{4}$$

with

$$\hat{A}(t) = S(t)A(t)S(t)^{-1} + \dot{S}(t)S(t)^{-1},$$
$$\hat{B}(t) = S(t)B(t),$$
$$\hat{C}(t) = C(t)S(t)^{-1}.$$

Being A, B, C continuous and S continuously differentiable, $\hat{A}$, $\hat{B}$, $\hat{C}$ are also continuous. Moreover, the periodicity of A, B, C and S entails the periodicity of $\hat{A}$, $\hat{B}$, $\hat{C}$. Therefore, the Riccati differential equation

$$-\dot{\hat{P}}(t) = \hat{A}(t)'\hat{P}(t) + \hat{P}(t)\hat{A}(t) + \hat{C}(t)'\hat{C}(t) - \hat{P}(t)\hat{B}(t)\hat{B}(t)'\hat{P}(t), \tag{5}$$

associated with system (4), is T-periodic as well. Now, the question is what are the relationships between the T-periodic solutions of (5) and the T-periodic solutions of (2). The answer is given by the following theorem, the proof of which is omitted, as the theorem is straightforward.

THEOREM 1. *$\hat{P}$ is a T-periodic solution to* (5) *if and only if $P = S'\hat{P}S$ is a T-periodic solution to* (2).

COROLLARY 1. *Since S is nonsingular, $P = S'\hat{P}S$ establishes a bijective correspondence between the positive semidefinite T-periodic solutions of* (2) *and the positive semidefinite T-periodic solution of* (5).

In view of Corollary 1, the existence of positive semi-definite T-periodic solutions of (2) can be investigated by looking at the equivalent S-transformed equation (5). In particular, reference can usefully be made to any state transformation S which brings system (1) into a canonical form. In [12] it is proven that, for any periodic system with continuous coefficients, a periodic state-space transformation does exist yielding a system in the Kalman canonical form.

In conclusion, there is no loss of generality in assuming that system (1) is in canonical form, i.e. that matrices A, B and C conform to the following zero-nonzero pattern:

$$A(t) = \begin{bmatrix} A_0(t) & 0 \\ \tilde{A}_0(t) & \bar{A}_0(t) \end{bmatrix} = \left[\begin{array}{cc:cc} A_{11}(t) & A_{12}(t) & 0 & 0 \\ 0 & A_{22}(t) & 0 & 0 \\ \hdashline A_{31}(t) & A_{32}(t) & A_{33}(t) & A_{34}(t) \\ 0 & A_{42}(t) & 0 & A_{44}(t) \end{array}\right], \tag{6a}$$

$$B(t) = \begin{bmatrix} B_0(t) \\ \bar{B}_0(t) \end{bmatrix} = \left[\begin{array}{c} B_{11}(t) \\ 0 \\ \hdashline B_{33}(t) \\ 0 \end{array}\right], \tag{6b}$$

$$C(t) = [C_0(t) \quad 0] = [C_{11}(t) \quad C_{22}(t) \quad 0 \quad 0]. \tag{6c}$$

Of course, the pair (A_0, C_0) is completely observable while the pair (A_r, B_r), where

$$A_r(t) = \begin{bmatrix} A_{11}(t) & 0 \\ A_{31}(t) & A_{33}(t) \end{bmatrix}, \qquad B_r(t) = \begin{bmatrix} B_{11}(t) \\ B_{33}(t) \end{bmatrix},$$

is completely reachable. For more information on the structural properties of periodic systems, the interested reader is referred to [7].

In the following we analyze the partition of the generic symmetric solution of (2) induced by the Kalman canonical structure of (1). With reference to the system decomposition into the observable and nonobservable parts, any symmetric solution of (2) can be given the form:

$$P(t) = \begin{bmatrix} P_0(t) & \tilde{P}_0(t) \\ \tilde{P}_0(t)' & \bar{P}_0(t) \end{bmatrix}, \tag{7}$$

where $P_0(t)$ and $A_0(t)$ ($\bar{P}_0(t)$ and $\bar{A}_0(t)$) are square matrices of the same dimensions. The matrix $P_0(t)$ will henceforth be referred to as the *observability submatrix* of $P(t)$. Furthermore, referring to (6), let

$$P(t) = [P_{ij}(t)]_{i,j=1,2,3,4}, \qquad P_{ij}(t) = P_{ji}(t)' \tag{8}$$

where, for any $i = 1, 2, 3, 4$, $P_{ii}(t)$ and $A_{ii}(t)$ are square matrices of the same dimensions. Then it should be apparent that

$$P_0(t) = \begin{bmatrix} P_{11}(t) & P_{12}(t) \\ P_{12}(t)' & P_{22}(t) \end{bmatrix}, \qquad \bar{P}_0(t) = \begin{bmatrix} P_{33}(t) & P_{34}(t) \\ P_{34}(t)' & P_{44}(t) \end{bmatrix}, \tag{9a}$$

$$\tilde{P}_0(t) = \begin{bmatrix} P_{13}(t) & P_{14}(t) \\ P_{23}(t) & P_{24}(t) \end{bmatrix}. \tag{9b}$$

In view of this *two-level canonical decomposition* of P, a corresponding two-level decomposition of (2) can be obtained.

The coarser decomposition is as follows:

$$\begin{aligned}
-\dot{P}_0(t) &= P_0(t)A_0(t) + \tilde{P}_0(t)\tilde{A}_0(t) + A_0(t)'P_0(t) + \tilde{A}_0(t)'\tilde{P}_0(t)' + C_0(t)'C_0(t) \\
&\quad - P_0(t)B_0(t)B_0(t)'P_0(t) - P_0(t)B_0(t)\bar{B}_0(t)'\tilde{P}_0(t)' \\
&\quad - \tilde{P}_0(t)\bar{B}_0(t)B_0(t)'P_0(t) - \tilde{P}_0(t)\bar{B}_0(t)\bar{B}_0(t)'\tilde{P}_0(t)', \qquad (10a)\\
-\dot{\tilde{P}}_0(t) &= \tilde{P}_0(t)\bar{A}_0(t) + A_0(t)'\tilde{P}_0(t) + \tilde{A}_0(t)'\bar{P}_0(t) \\
&\quad - P_0(t)B_0(t)B_0(t)'\tilde{P}_0(t) - P_0(t)B_0(t)\bar{B}_0(t)'\bar{P}_0(t)' \\
&\quad - P_0(t)\bar{B}_0(t)B_0(t)'\tilde{P}_0(t) - \tilde{P}_0(t)\bar{B}_0(t)\bar{B}_0(t)'\bar{P}_0(t), \qquad (10b)\\
-\dot{\bar{P}}_0(t) &= \bar{P}_0(t)\bar{A}_0(t) + \bar{A}_0(t)\bar{P}_0(t)' \\
&\quad - \tilde{P}_0(t)'B_0(t)B_0(t)'\tilde{P}_0(t) - \tilde{P}_0(t)'B_0(t)\bar{B}_0(t)'\bar{P}_0(t) \\
&\quad - P_0(t)\bar{B}_0(t)B_0(t)'\tilde{P}_0(t) - \bar{P}_0(t)\bar{B}_0(t)\bar{B}_0(t)'\bar{P}_0(t). \qquad (10c)
\end{aligned}$$

As for the finer decomposition, we shall consider only the subset of equations which corresponds to the elements of $P_0(t)$; namely:

$$\begin{aligned}
-\dot{P}_{11}(t) &= P_{11}(t)A_{11}(t) + A_{11}(t)'P_{11}(t) + P_{13}(t)A_{31}(t) \\
&\quad + A_{31}(t)'P_{13}(t)' + C_{11}(t)'C_{11}(t) \\
&\quad - P_{11}(t)B_{11}(t)B_{11}(t)'P_{11}(t) - P_{11}(t)B_{11}(t)B_{33}(t)'P_{13}(t)' \\
&\quad - P_{13}(t)B_{33}(t)B_{11}(t)'P_{11}(t) - P_{13}(t)B_{33}(t)B_{33}(t)'P_{13}(t)', \qquad (11a)\\
-\dot{P}_{12}(t) &= P_{11}(t)A_{12}(t) + P_{12}(t)A_{22}(t) + A_{11}(t)'P_{12}(t) + P_{13}(t)A_{32}(t) \\
&\quad + P_{14}(t)A_{42}(t) + A_{31}(t)'P_{23}(t)' + C_{11}(t)'C_{22}(t) \\
&\quad - P_{11}(t)B_{11}(t)B_{11}(t)'P_{12}(t) - P_{11}(t)B_{11}(t)B_{33}(t)'P_{23}(t)' \\
&\quad - P_{13}(t)B_{33}(t)B_{11}(t)'P_{12}(t) - P_{13}(t)B_{33}(t)B_{33}(t)'P_{23}(t)', \qquad (11b)\\
-\dot{P}_{22}(t) &= P_{12}(t)'A_{12}(t) + P_{22}(t)A_{22}(t) + A_{12}(t)'P_{12}(t) + A_{22}(t)'P_{22}(t) \\
&\quad + P_{23}(t)A_{32}(t) + P_{24}(t)A_{42}(t) + A_{32}(t)'P_{23}(t) \\
&\quad + A_{42}(t)'P_{24}(t) + C_{22}(t)'C_{22}(t) \\
&\quad - P_{12}(t)'B_{11}(t)B_{11}(t)'P_{12}(t) - P_{12}(t)'B_{11}(t)B_{33}(t)'P_{23}(t)' \\
&\quad - P_{23}(t)B_{33}(t)B_{11}(t)'P_{12}(t) - P_{23}(t)B_{33}(t)B_{33}(t)'P_{23}(t)'. \qquad (11c)
\end{aligned}$$

3. Periodic solutions of the periodic Sylvester matrix differential equation. This section deals with the T-periodic solutions of a T-periodic matrix differential equation of the form

$$-\dot{Q}(t) = M(t)Q(t) + Q(t)N(t)' + W(t) \qquad (12)$$

where $M: R \to R^{h\times h}$, $N: R \to R^{k\times k}$ and $W: R \to R^{h\times k}$ are given continuous and T-periodic functions. When $h = k$ and $M = N$, (12) is a Lyapunov differential equation. Besides its independent interest, the result stated below as Theorem 2 plays a crucial role in the next section, where the existence of periodic solutions to the periodic matrix Riccati differential equation are thoroughly investigated.

THEOREM 2. *If M and N are asymptotically stable, then*

i) *equation* (12) *admits a unique T-periodic solution*;

ii) *under the additional assumption $h = k$, $M = N$, $W(t) = W(t)' \leqq 0$ for all t and $W(t) \neq 0$ for some t,* (12) *does not admit any positive semidefinite T-periodic solution.*

Proof of (i). For any matrix H, define vec (H) as the vector obtained by composing in a single column all columns of H taken in their natural ordering; furthermore, let $q(t) = \text{vec}\,(Q(t))$, $w(t) = \text{vec}\,(W(t))$.

It is well known [13] that (12) can be rewritten as follows:

$$-\dot{q}(t) = (I_k \otimes M(t) + N(t) \otimes I_h) q(t) + W(t), \tag{13}$$

where $\otimes$ denotes the Kronecker product and I_j is the $j \times j$ identity matrix. First, we show that $\Phi_N(t, 0) \otimes \phi_M(t, 0)$ is the transition matrix of system (13). In fact, $\Phi_N(0, 0) \otimes \phi_M(0, 0) = I_k \otimes I_h = I_{hk}$ and, also in view of the "mixed product rule" [13, p. 24],

$$\begin{aligned}
\frac{d}{dt}(\Phi_N(t, 0) \otimes \Phi_M(t, 0)) &= \Phi_N(t, 0) \otimes \dot{\Phi}_M(t, 0) + \dot{\Phi}_N(t, 0) \otimes \Phi_M(t, 0) \\
&= \phi_N(t, 0) \otimes (M(t)\Phi_M(t, 0)) + (N(t)\Phi_N(t)) \otimes \Phi_M(t, 0) \\
&= (I_k \otimes M(t))(\Phi_N(t, 0) \otimes \Phi_M(t, 0)) \\
&\quad + (N(t) \otimes I_h)(\Phi_N(t, 0) \otimes \Phi_M(t, 0)) \\
&= (I_k \otimes M(t) + N(t) \otimes I_h)(\Phi_N(t, 0) \otimes \Phi_M(t, 0)).
\end{aligned}$$

As for the monodromy matrix of system (13), recall that the eigenvalues of $\Phi_M(T, 0)$ and $\phi_N(T, 0)$ lie, by assumption, in the open unit disk. Since the eigenvalues of the Kronecker product are given by the product of any pair of eigenvalues of the two factors, the conclusion can readily be drawn that system (13) is asymptotically stable. Hence, the T-periodic solution forced by W exists and is unique [10].

Proof of (ii). The line of reasoning adopted here is similar to the one developed in [14] to extend the so-called Lyapunov Lemma to the periodically time-varying case.

For any $V: R \to R^{h \times h}$ such that $W(t) = -V(t)V(t)'$, for all t, consider the Kalman canonical decomposition of the pair (N, V) into the reachable and unreachable parts:

$$N(t) = \begin{bmatrix} N_r(t) & \tilde{N}_r(t) \\ 0 & \bar{N}_r(t) \end{bmatrix}, \qquad V(t) = \begin{bmatrix} V_r(t) \\ 0 \end{bmatrix}.$$

Any possible solution of (12) can of course be partitioned accordingly, i.e.:

$$Q(t) = \begin{bmatrix} Q_r(t) & \tilde{Q}_r(t) \\ \tilde{Q}_r(t)' & \bar{Q}_r(t) \end{bmatrix}.$$

Thus (12) splits into:

$$\begin{aligned}
-\dot{Q}_r(t) &= N_r(t)Q_r(t) + Q_r(t)N_r(t)' - V_r(t)V_r(t)' + \tilde{N}_r(t)\tilde{Q}_r(t) + \tilde{Q}_r(t)\tilde{N}_r(t)', \\
-\dot{\tilde{Q}}_r(t) &= N_r(t)\tilde{Q}_r(t) + \tilde{Q}_r(t)\bar{N}_r(t)' + \tilde{N}_r(t)\bar{Q}_r(t), \\
-\dot{\bar{Q}}_r(t) &= \bar{N}_r(t)\bar{Q}_r(t) + \bar{Q}_r(t)\bar{N}_r(t)'.
\end{aligned}$$

By applying part (i) of this theorem to the last equation and recalling that N (whereby N_r and $\bar{N}_r$) is by assumption asymptotically stable, the conclusion can be drawn that the unique positive semidefinite T-periodic solution is $\bar{Q}_r = 0$. The same argument applied to the second equation leads to recognizing that the unique positive semidefinite T-periodic solution of (12), if any, must be of the form:

$$Q(t) = \begin{bmatrix} Q_r(t) & 0 \\ 0 & 0 \end{bmatrix},$$

where $Q_r(t)$ is a positive semidefinite T-periodic solution of

$$-\dot{Q}_r(t) = N_r(t)Q_r(t) + Q_r(t)N_r(t)' - V_r(t)V_r(t)'.$$

The remainder of the proof is meant to show that assuming the existence of such a solution leads to an unavoidable contradiction. In fact, let

$$G = \int_0^T \Phi_{N_r}(t,0)\,V(t)\,V(t)'\Phi_{N_r}(t,0)'\,dt.$$

By a well-known resolution formula for the Lyapunov equation [15], one gets

$$G = \Phi_{N_r}(T,0)\,Q_r(0)\Phi_{N_r}(T,0)' - Q_r(0).$$

Let now λ be an eigenvalue and z an associated nonzero eigenvector of $\Phi_{N_r}(T,0)$. Denoting by a star the conjugate transpose, elementary manipulations yield $z^*Gz = (|\lambda|^2-1)z^*Q_r(0)z$.

Since, by assumption, $|\lambda|<1$ (N_r is asymptotically stable) and a positive semidefinite Q_r exists, the corresponding value of the right-hand side must be nonpositive. As for the left-hand side, recall that the pair (N_r, V_r) is completely reachable (or, equivalently, controllable) only if $V_r(t)'\Phi_{N_r}(t,0)'z = 0$ a.e. in $[0, T]$ implies $z = 0$ [7].

Since $z^*Gz = \int_0^T \| V_r(t)'\Phi_{N_r}(t,0)'z\|^2\,dt$, by complete reachability the conclusion must be drawn that $z^*Gz > 0$. The contradiction completes the proof of (ii).

4. Periodic solutions of the periodic matrix Riccati equation. In this section, necessary and sufficient conditions for the existence of a unique positive semidefinite T-periodic solution of (2) are obtained in terms of stabilizability and detectability of system (1). It has recently been proved [12], that several different yet equivalent characterizations exist of stabilizability and detectability for linear periodic systems. Exactly as in the time-invariant case [1] one of the most interesting characterizations refers to the Kalman canonical decomposition.

Precisely [12], a T-periodic continuous matrix function $K: R \to R^{m\times n}$ such that $A+BK$ is asymptotically stable exists if and only if the uncontrollable part of system (1) is asymptotically stable (*stabilizability*).

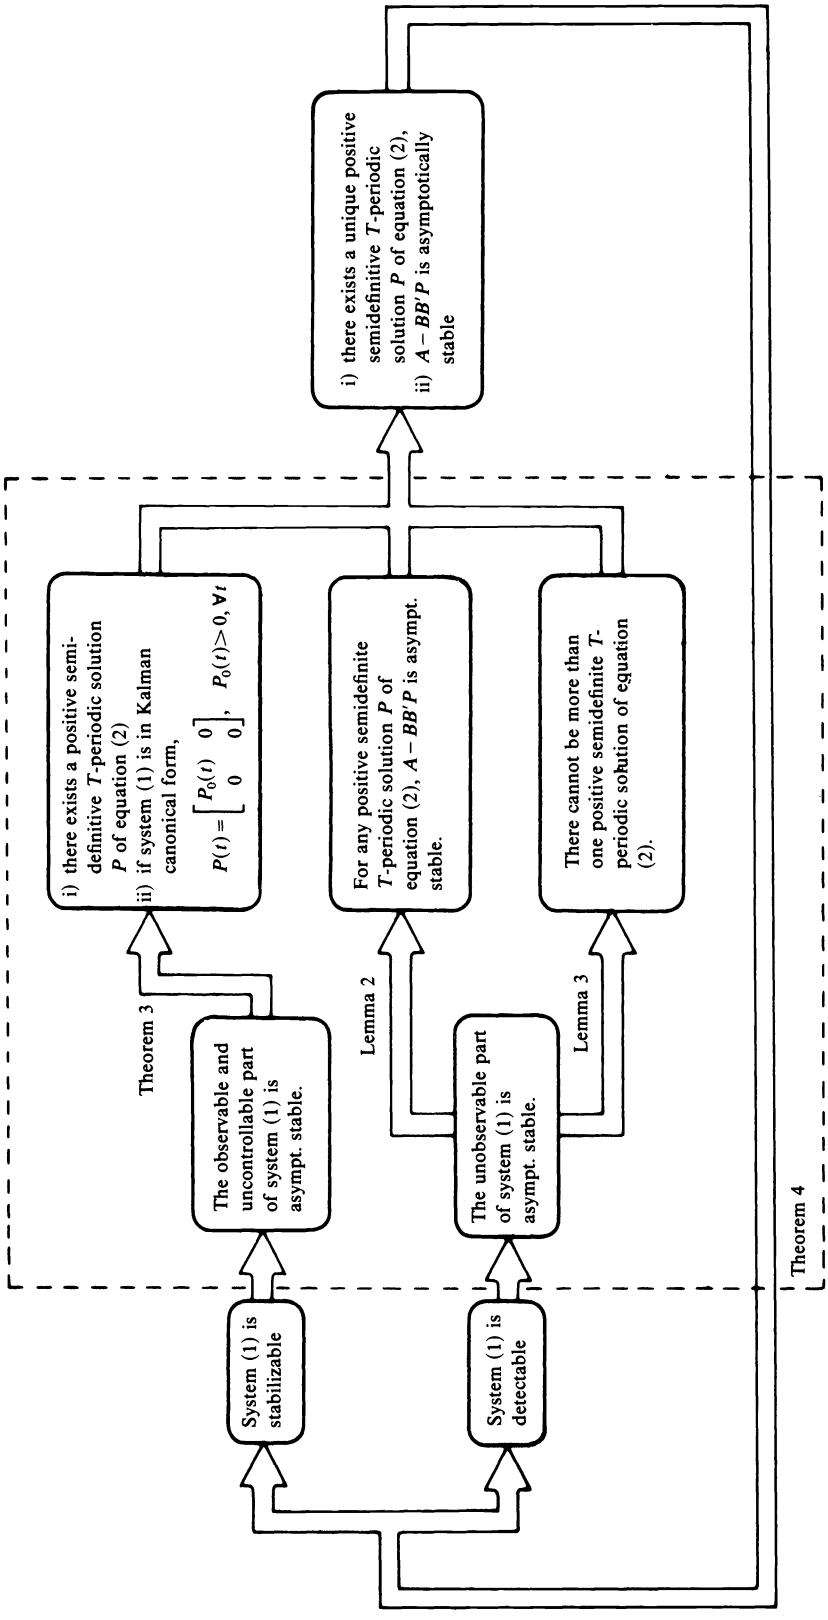
Dually, a T-periodic continuous matrix function $L: R \to R^{n\times p}$ such that $A-LC$ is asymptotically stable exists (whereby an asymptotic periodic state-reconstructor can actually be designed [12]) if and only if the unobservable part of system (1) is asymptotically stable (*detectability*). The main results of this section are visualized in Fig. 1. They can be stated as follows.

THEOREM 3. *If the unreachable and observable part of system* (1) *is asymptotically stable, then the Riccati differential equation* (2) *admits a positive semidefinite T-periodic solution* $P: R \to R^{n\times n}$. *If, in addition, system* (1) *is in Kalman canonical form, then, only the observability sub-matrix* P_0 *of this solution is different from zero and* $P_0(t)$ *is positive definite for all t.*

THEOREM 4. *The periodic Riccati differential equation* (2) *admits a unique positive semidefinite periodic solution* $P: R \to R^{n\times n}$ *and* $A-BB'P$ *is asymptotically stable if and only if system* (1) *is stabilizable and detectable.*

As is shown in Fig. 1, two preliminary lemmas (Lemmas 2 and 3) are needed, in addition to Theorem 3, to prove Theorem 4. On the other hand, to prove Lemma 2, one more lemma (Lemma 1) is needed which in turn stands on one of the Shayman "Inertia Theorems" [16]. The proof of Theorem 3 appeals to the same Inertia Theorem mentioned above, to Theorem 2 and to a third result, proved in [17]. The Shayman Inertia Theorem used in the sequel is reported below, without proof, for easy reference.

INERTIA THEOREM. *If system* (1) *is completely observable and the matrix Riccati differential equation* (2) *admits a symmetric T-periodic solution* $P: R \to R^{n\times n}$, *then, for each t,* $P(t)$ *is nonsingular and the number of positive eigenvalues of* $P(t)$ *is equal to the number of characteristic multipliers of* $A-BB'P$ *lying in the open unit disk.*



System (1) is stabilizable
System (1) is detectable
The observable and uncontrollable part of system (1) is asympt. stable.
The unobservable part of system (1) is asympt. stable.
Theorem 3
Lemma 2
Lemma 3
Theorem 4
i) there exists a positive semi-definitive T-periodic solution P of equation (2)
ii) if system (1) is in Kalman canonical form,
$P(t) = \begin{bmatrix} P_0(t) & 0 \\ 0 & 0 \end{bmatrix}$, $P_0(t) > 0, \forall t$
For any positive semidefinite T-periodic solution P of equation (2), $A - BB'P$ is asympt. stable.
There cannot be more than one positive semidefinite T-periodic solution of equation (2).
i) there exists a unique positive semidefinitive T-periodic solution P of equation (2),
ii) $A - BB'P$ is asymptotically stable

FIG. 1

BCG THEOREM. *If system* (1) *is completely reachable and completely observable, then*

i) *there exists a positive definite T-periodic solution P of equation* (2);

ii) *no other positive T-periodic semidefinite solution of equation* (2) *may exist different from P*;

iii) $A - BB'P$ *is asymptotically stable.*

A proof of the BCG theorem can be found in [17]. It consists of two distinct theorems, corresponding to points (i) and (ii), (iii), respectively, of the statement above. Since the proof of (i) [17, Thm. 1] is somewhat sketchy, a more complete proof is given in the Appendix.

LEMMA 1. *If system* (1) *is detectable and in Kalman canonical form, then the only nonzero element of the canonical decomposition* (7) *of any positive semidefinite T-periodic solution of equation* (2) *is* $P_0(t)$. *Furthermore* $P_0(t)$ *is positive definite, for all t.*

Proof. Referring to the canonical decomposition (7) of any possible T-periodic solution P of (2) and letting

$$\begin{aligned}
F(t) &= \tilde{P}_0(t)\tilde{A}_0(t) + \tilde{A}_0(t)'\tilde{P}_0(t)' - P_0(t)B_0(t)\bar{B}_0(t)\tilde{P}_0(t)' \\
&\quad - \tilde{P}_0(t)\bar{B}_0(t)B_0(t)'P_0(t) - \tilde{P}_0(t)\bar{B}_0(t)\bar{B}_0(t)'\tilde{P}_0(t)', \\
G(t) &= \tilde{P}_0(t)\bar{A}_0(t) + A_0(t)'\tilde{P}_0(t) + \tilde{A}_0(t)'\bar{P}_0(t) \\
&\quad - P_0(t)B_0(t)B_0(t)'\tilde{P}_0(t) - P_0(t)B_0(t)\bar{B}_0(t)'\bar{P}_0(t)' \\
&\quad - \tilde{P}_0(t)\bar{B}_0(t)B_0(t)'\tilde{P}_0(t) - \tilde{P}_0(t)\bar{B}_0(t)\bar{B}_0(t)'P_0(t), \\
H(t) &= B_0(t)'\tilde{P}_0(t) + \bar{B}_0(t)\bar{P}_0(t),
\end{aligned}$$

the corresponding decomposition (10) becomes

$$\begin{aligned}
-\dot{P}_0(t) &= P_0(t)A_0(t) + A_0(t)'P_0(t) + C_0(t)'C_0(t) \\
&\quad - P_0(t)B_0(t)B_0(t)'P_0(t) + F(t),
\end{aligned} \tag{14a}$$

$$-\dot{\tilde{P}}_0(t) = G(t), \tag{14b}$$

$$-\dot{\bar{P}}_0(t) = \bar{P}_0(t)\bar{A}_0(t) + \bar{A}_0(t)'\bar{P}_0(t) - H(t)'H(t). \tag{14c}$$

Thanks to the detectability assumption, $\bar{A}_0$ is asymptotically stable. Hence, by Theorem 2(ii), should H be not identically zero, (14c) would not admit any positive semidefinite T-periodic solution. Therefore, all positive semidefinite T-periodic solution of (2) must be such as to make $H = 0$.

In view of Theorem 2(i), the only positive T-periodic solution of (14c) is then $\bar{P}_0 = 0$, whereby $P(t) \geqq 0$ for all t implies $\tilde{P}_0 = 0$. Finally, $\bar{P}_0 = 0$ and $\tilde{P}_0 = 0$ imply $F = 0$ so that (14a) formally conforms to (2). In view of the Inertia Theorem, the complete observability of (A_0, C_0) implies that all positive semidefinite T-periodic solutions of (14a), being nonsingular, are in fact positive definite, for all t.

LEMMA 2. *Assume that system* (1) *is detectable and P is a positive semidefinite T-periodic solution of* (2); *then* $A - BB'P$ *is asymptotically stable.*

Proof. Assuming, without loss of generality, that system (1) is in Kalman canonical form; any positive semidefinite T-periodic solution P of equation (2) must, by Lemma 1, be such that

$$A(t) - B(t)B(t)'P(t) = \begin{bmatrix} A_0(t) - B_0(t)B_0(t)'P_0(t) & 0 \\ ? & \bar{A}_0(t) \end{bmatrix}$$

where ? denotes a block we do not consider specifically.

Detectability of (1) implies that $\bar{A}_0$ is asymptotically stable. On the other hand, the Inertia Theorem applied to (14a) ensures that $A_0 - B_0 B_0' P_0$ is asymptotically stable. Hence the lemma is proved.

LEMMA 3. *If system* (1) *is detectable, there cannot be more than one positive semidefinite T-periodic solution of* (2).

Proof. By contradiction, suppose that (2) admits two positive semidefinite T-periodic solutions $P^{(1)}$ and $P^{(2)}$. Let

$$P^{(12)}(t) = P^{(1)}(t) - P^{(2)}(t),$$
$$A^{(i)}(t) = A(t) - B(t)B(t)'P^{(i)}(t), \qquad i = 1, 2.$$

Obviously, $P^{(12)}$ is T-periodic and satisfies the equation:

$$-\dot{P}^{(12)}(t) = A^{(1)}(t)'P^{(12)}(t) + P^{(12)}(t)A^{(2)}(t). \tag{15}$$

By Lemma 2, $A^{(1)}$ and $A^{(2)}$ are asymptotically stable. Hence, Theorem 2(i), applied to (15), leads to concluding that the only T-periodic solution is $P^{(12)} = 0$, namely $P^{(1)} = P^{(2)}$.

Proof of Theorem 3. Without loss of generality, we can assume, since the very beginning, that system (1) is in Kalman canonical form. It is easy to check, then, that ($\bar{P}_0 = 0$, $\tilde{P}_0 = 0$) is a T-periodic solution of equations (10b) and (10c).

As for equation (10a), setting $\bar{P}_0 = 0$ and $\tilde{P}_0 = 0$ yields

$$-\dot{P}_0(t) = P_0(t)A_0(t) + A_0(t)'P_0(t) + C_0(t)'C_0(t) - P_0(t)B_0(t)B_0(t)'P_0(t). \tag{16}$$

Consider, then, the finer decomposition (11) of equation (16) induced by the Kalman canonical form of system (1):

$$\begin{aligned} -\dot{P}_{11}(t) &= P_{11}(t)A_{11}(t) + A_{11}(t)'P_{11}(t) + C_{11}(t)'C_{11}(t) \\ &\quad - P_{11}(t)B_{11}(t)B_{11}(t)'P_{11}(t), \end{aligned} \tag{17a}$$

$$\begin{aligned} -\dot{P}_{12}(t) &= P_{12}(t)A_{22}(t) + [A_{11}(t) - B_{11}(t)B_{11}(t)'P_{11}(t)]'P_{12}(t) \\ &\quad + P_{11}(t)A_{12}(t) + C_{11}(t)'C_{22}(t), \end{aligned} \tag{17b}$$

$$\begin{aligned} -\dot{P}_{22}(t) &= P_{22}(t)A_{22}(t) + A_{22}(t)'P_{22}(t) + P_{12}(t)'A_{12}(t) \\ &\quad + A_{12}(t)'P_{12}(t) + C_{22}(t)'C_{22}(t) - P_{12}(t)'B_{11}(t)B_{11}(t)'P_{12}(t). \end{aligned} \tag{17c}$$

Since (A_{11}, B_{11}) is completely controllable and (A_{11}, C_{11}) completely observable, the Riccati equation (17a)

(i) admits a unique positive semidefinite solution P_{11},

(ii) $P_{11}(t)$ is in fact positive definite, for all t, and $A_{11} - B_{11}B_{11}'P_{11}$ is asymptotically stable.

Substituting into (17b) and letting

$$M(t) = [A_{11}(t) - B_{11}(t)B_{11}(t)'P_{11}(t)]',$$
$$N(t) = A_{22}(t)',$$
$$W(t) = P_{11}(t)A_{12}(t) + C_{11}(t)'C_{22}(t),$$

(17b) takes on the form of (12).

Since M has already been recognized to be asymptotically stable and the asymptotic stability of the unreachable and observable part of system (1) implies the asymptotic stability of N, by Theorem 2(i), (17b) admits a (unique) T-periodic solution P_{12}.

Substituting back into (17c), and now letting

$$M(t) = N(t) = A_{22}(t)',$$

$$W(t) = P_{12}(t)'A_{12}(t) + A_{12}(t)'P_{12}(t) + C_{22}(t)'C_{22}(t) - P_{12}(t)'B_{11}(t)B_{11}(t)'P_{12}(t),$$

Theorem 2(i) enables us to conclude that (17c) as well admits a (unique) T-periodic solution.

To complete the proof, we have to show that

$$P_0(t) = \begin{bmatrix} P_{11}(t) & P_{12}(t) \\ P_{12}(t)' & P_{22}(t) \end{bmatrix}$$

is positive semidefinite, for all t. To this purpose consider

$$A_0(t) - B_0(t)B_0(t)'P_0(t) = \begin{bmatrix} A_{11}(t) - B_{11}(t)B_{11}(t)'P_{11}(t) & A_{12} - B_{11}(t)B_{11}(t)'P_{12}(t) \\ 0 & A_{22}(t) \end{bmatrix}.$$

Since both $A_{11} - B_{11}B_{11}'P_{11}$ and A_{22} are asymptotically stable, all the characteristic multipliers of $A_0 - B_0B_0'P_0$ lie in the open unit disk.

The Inertia Theorem applied to the Riccati equation (16) leads then to the conclusion that $P_0(t)$ is positive definite, for all t.

Proof of Theorem 4. Again we assume, without any loss of generality, that system (1) is in Kalman canonical form.

Sufficiency. Stabilizability and detectability of system (1) imply that all the assumptions of Lemma 2, Lemma 3 and Theorem 3 are verified (Fig. 1). Hence, it should be apparent that existence follows from Theorem 3, uniqueness from Lemma 3 and "feedback stabilization" from Lemma 2.

Necessity. Conversely, the existence of a stabilizing feed back control law based on a unique positive semidefinite T-periodic solution P of equation (2) obviously implies that system (1) is stabilizable.

To complete the proof, we only need to show that system (1) is detectable. To this end, observe first that stabilizability of system (1) implies, in particular, the asymptotic stability of its observable and unreachable part. Hence, by Theorem 3, only the observability submatrix P_0 of the unique positive semidefinite solution P of equation (2) can be different from zero. Furthermore, $P_0(t)$ is positive definite for all t. It is then easy to see that

$$A - BB'P = \begin{bmatrix} ? & 0 \\ ? & \bar{A}_0 \end{bmatrix}.$$

Therefore, the asymptotic stability of $A - BB'P$ implies the asymptotic stability of $\bar{A}_0$, namely the detectability of system (1).

5. Concluding remarks. In this paper, a new proof of the (periodic) Wonham-Kucera theorem has been presented. The proof is entirely based on the canonical

decomposition of the periodic Riccati equation induced by the Kalman canonical decomposition of the underlying periodic system. The novel approach enables gaining a deep insight into the structure of the T-periodic solutions of the periodic Riccati equation. The extent to which the knowledge of the solution structure can be exploited from a computational point of view in finding the unique positive semidefinite periodic solution of a given periodic Riccati equation is an interesting open issue worthy of further investigation.

Appendix. In this appendix we prove that if system (1) is completely reachable, then there exists a positive semidefinite periodic solution of (2). In fact, consider the following optimal periodic control problem.

Minimize

$$J=\frac{1}{2}\int_t^\tau \{\|y(\sigma)\|^2+\|u(\sigma)\|^2\}\,d\sigma \tag{A.1}$$

subject to

$$\dot{x}(\sigma)=A(\sigma)x(\sigma)+B(\sigma)u(\sigma), \tag{A.2}$$

$$y(\sigma)=C(\sigma)x(\sigma), \tag{A.3}$$

$$x(t)=x_t. \tag{A.4}$$

Let $\Delta(t, \tau, D)$ be the solution of (2) at time t such that $\Delta(\tau, \tau, D)=D$.

It is claimed that the limit

$$\bar{P}(t)=\lim_{\tau\to\infty}\Delta(t, \tau, 0) \tag{A.5}$$

exists and is a T-periodic positive semidefinite solution of (2). Indeed, it is well known that the optimal value J^0 of the performance index (A.1) is given by

$$J^0=\tfrac{1}{2}x_t'\Delta(t, \tau, 0)x_t. \tag{A.6}$$

From (A.6) it follows that $\Delta(t, \cdot, 0)$ is a monotonically nondecreasing matrix function. Furthermore, since $(A(\cdot), B(\cdot))$ is completely controllable, there exists a bounded control function $\tilde{u}(\cdot)$ and a time point $\tilde{\tau}>t$ such that

$$\tilde{u}(\sigma)=0 \quad \forall\sigma>\tilde{\tau},$$

$$\tilde{x}(\sigma)=0 \quad \forall\sigma\geqq\tilde{\tau},$$

where $\tilde{x}(\cdot)$ is the solution of (A.2)-(A.4) associated with control function $\tilde{u}(\cdot)$.

Hence,

$$\tilde{J}=\frac{1}{2}\int_t^\infty \{\|C(\sigma)\tilde{x}(\sigma)\|^2+\|\tilde{u}(\sigma)\|^2\}\,d\sigma<\infty.$$

Since $J^0\leqq\tilde{J}$, $\Delta(t, \cdot, 0)$ is bounded from above. Thus the conclusion is drawn that limit (A.5) does exists. Note that, as $\Delta(t, \tau, 0)$ is positive semidefinite for any t and τ, $\bar{P}(t)$ is also positive semidefinite. Furthermore, the time periodicity of (2) implies that

$$\Delta(t+T, \tau+T, 0)=\Delta(t, \tau, 0).$$

Consequently,

$$\bar{P}(t+T)=\lim_{\tau\to\infty}\Delta(t+T, \tau, 0)=\lim_{\tau\to\infty}\Delta(t, \tau, 0)=\bar{P}(t).$$

Finally, note that

$$\Delta(t, \tau, 0) = \Delta(t, \bar{\tau}, \Delta(\bar{\tau}, \tau, 0))$$

for any $\bar{\tau} \in [t, \tau]$. Since $\Delta(t, \tau, D)$ is differentiable with respect to D (see e.g. [9, p. 11]), then

$$\bar{P}(t) = \lim_{\tau \to \infty} \Delta(t, \tau, 0) = \Delta(t, \bar{\tau}, \lim_{\tau \to \infty} \Delta(\bar{\tau}, \tau, 0)) = \Delta(t, \bar{\tau}, \bar{P}(\bar{\tau}))$$

for all t and $\bar{\tau} \geqq t$. Hence, $\bar{P}(t)$ is a solution of (2).

ALMOST DISTURBANCE DECOUPLING WITH BOUNDED PEAKING*

HARRY L. TRENTELMAN†

Abstract. This paper is concerned with a generalization of the almost disturbance decoupling problem by state feedback. Apart from approximate decoupling from the external disturbances to a first to-be-controlled output, we require a second output to be uniformly bounded with respect to the accuracy of decoupling. The problem is studied using the geometric approach to linear systems. We introduce some new almost controlled invariant subspaces and study their geometric structure. Necessary and sufficient conditions for the solvability of the above problem are formulated in terms of these controlled invariant subspaces. A conceptual algorithm is introduced to calculate the feedback laws needed to achieve the design purpose.

Key words. almost disturbance decoupling, almost invariant subspaces, linear systems, geometric approach, high gain feedback, output stabilization

1. Introduction. In this paper we are concerned with the problem of almost disturbance decoupling by state feedback as introduced by Willems [20]. This problem deals with the situation in which we cannot achieve exact decoupling from the external disturbances to an exogenous output channel as, for example, in [22], but only *approximate* decoupling with any desired degree of accuracy. In general, the feedback gain necessary to achieve this will increase as the desired degree of accuracy increases. It may then happen however that some of the state variables tend to peak excessively. It is of considerable practical interest to know when it is possible to achieve disturbance decoupling within any desired degree of accuracy, while this peaking phenomenon will not occur.

The system that we will be considering in this paper is given by the equations

$$\begin{aligned} \dot{x} &= Ax + Bu + Gd, \\ z_1 &= H_1 x, \\ z_2 &= H_2 x, \end{aligned} \tag{1.1}$$

where the control $u(t)$, the state $x(t)$, the disturbance $d(t)$ and the outputs $z_1(t)$ and $z_2(t)$ are real vectors of finite dimensions. We will assume that the vector $z_2(t)$ is an *enlargement* of $z_1(t)$, i.e., there is a matrix M such that $H_1 = MH_2$. If for any positive real number ε a feedback matrix F_ε can be chosen such that in the closed loop system with zero initial condition, for all disturbances $d(\cdot)$ in the unit ball of $L_p[0, \infty)$ we have

$$\|z_1\|_{L_p} \leqq \varepsilon \tag{1.2}$$

then we say that for the system under consideration the L_p-almost disturbance decoupling problem from d to z_1 is solvable. After choosing F_ε to achieve this approximate decoupling, the output $z_2(t)$ of course depends on ε and, for certain disturbances $d(\cdot)$, it may then happen that $\|z_2\|_{L_p} \to \infty$ as $\varepsilon \to 0$, i.e., as the accuracy of decoupling increases.

† Department of Mathematics and Computing Science, Eindhoven University of Technology, 5600 MB Eindhoven, the Netherlands. This research was supported by the Netherlands Organization for the Advancement of Pure Science Research (Z.W.O.).

As an example, consider the system (1.1) with

$$A=\begin{pmatrix}0 & 1 & 0\\ 0 & 0 & 1\\ 0 & 0 & 0\end{pmatrix},\qquad B=\begin{pmatrix}0\\ 0\\ 1\end{pmatrix},\qquad G=\begin{pmatrix}1\\ 0\\ 0\end{pmatrix},$$

$$H_1=(1\quad 0\quad 0),\qquad H_2=\begin{pmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix}.$$

Define a feedback matrix F_ε by

$$F_\varepsilon := \left(-\frac{27}{\varepsilon^3},\quad -\frac{27}{\varepsilon^2},\quad -\frac{9}{\varepsilon}\right).$$

It can then be verified that the impulse response from the disturbance d to z_1 is given by

$$W_{1,\varepsilon}(t) := H_1 e^{(A+BF_\varepsilon)t}G = e^{-3t/\varepsilon}\left(1+\frac{3}{\varepsilon}t+\frac{9}{2\varepsilon^2}t^2\right)$$

and that $\| W_{1,\varepsilon}\|_{L_1} = \varepsilon$. Hence, for any $1 \leqq p \leqq \infty$, the above feedback matrix F_ε achieves L_p-amost disturbance decoupling from d to z_1. On the other hand, however, the impulse response from d to z_2 is calculated to be

$$W_{2,\varepsilon}(t) := H_2 e^{(A+BF_\varepsilon)t}G = e^{-3t/\varepsilon}\begin{pmatrix}1+\frac{3}{\varepsilon}t+\frac{9}{2\varepsilon^2}t^2\\ -\frac{27}{2\varepsilon^3}t^2\\ -\frac{27}{\varepsilon^3}t+\frac{81}{2\varepsilon^4}t^2\end{pmatrix}$$

and it can be verified that $\| W_{2,\varepsilon}\|_{L_1} = O(1/\varepsilon) \to \infty$ as $\varepsilon \to 0$, i.e., we have obtained almost disturbance decoupling from d to z_1 at the cost of highly undesired peaking behaviour of the output $z_2(t)$.

The question which we ask in this paper is this: *When is it possible to choose F_ε such that simultaneously* (1.2) *holds and there exists a constant C (independent of ε) such that for all disturbances $d(\cdot)$ in the unit ball of $L_p[0,\infty)$ we have*

$$\|z_2\|_{L_p} \leqq C \tag{1.3}$$

for all ε? That is, the output $z_2(t)$ is bounded uniformly as ε tends to zero. If this behaviour is achieved, we say that we have *L_p-bounded peaking* from d to z_2. Problems of this kind have been considered before. Francis and Glover [3] considered a bounded peaking problem in the context of cheap control. More recently, Kimura [9] found conditions that guarantee bounded peaking in the context of perfect regulation. We will study the above problem using the by now well known concepts of almost controlled invariant and almost controllability subspace [19], [20]. We will also use the approach of frequency domain description of geometric concepts as initiated in Hautus [5].

The outline of this paper is as follows. In § 2 we will introduce some notational conventions used in this paper and state some preliminary results and background.

Section 3 contains a description of the main problem we will be concerned with in this paper. In § 4 we will introduce the disturbance decoupling problem with output stability. This problem is an extension of the (exact) disturbance decoupling problem

as treated in [22]. Its solution will be needed to solve our main problem, but is also important in its own right. In § 5 we will derive a necessary condition for the solvability of $(\text{ADDPBP})_p$. This condition will be in the form of a subspace inclusion involving an almost controlled invariant subspace. Section 6 contains an investigation of the geometric structure of the almost controlled invariant subspace that was introduced in § 5. In § 7 these structural results will be used to prove that for certain classes of systems the subspace inclusion derived in § 5 in fact constitutes a necessary and sufficient condition for solvability of $(\text{ADDPBP})_p$. The sequences of state feedback maps that achieve the design purpose will be constructed explicitly. Section 8 contains some corollaries of our main result and some extensions. In § 9 a numerical example is worked out to illustrate the computational feasibility of our theory. Finally, the paper closes with some concluding remarks in § 10. Several technical details of proofs in this paper are deferred to Appendices A, B and C.

2. Preliminaries and background. In this section we will introduce some notation used in this paper and review some relevant facts on controlled invariant and almost controlled invariant subspaces. Also some basic facts on the convergence of subspaces will be given.

2.1. In this paper the following notation will be used: If $\mathscr{X}$ is a normed vector space, we will write $\|\cdot\|$ for the norm on $\mathscr{X}$. If $l:[0,\infty)\to\mathscr{X}$ is a measurable function, then we will denote

$$\|l\|_{L_p} := \begin{cases} \left(\int_0^\infty \|l(t)\|^p\,dt\right)^{1/p} & \text{if } 1 \leqq p < \infty, \\ \operatorname{ess\,sup}_{t\geqq 0} \|l(t)\| & \text{if } p = \infty. \end{cases}$$

If $\|l\|_{L_p} < \infty$, we will say that $l \in L_p[0,\infty)$. If M is a square matrix then $\sigma(M)$ will denote its spectrum. If Λ_1 and Λ_2 are sets of complex numbers then $\Lambda_1 \cup \Lambda_2$ will denote their disjoint union. For any positive integer n, we will denote $\underline{n} := \{1, 2, \cdots, n\}$.

Consider the system (1.1). Let $u(t) \in \mathscr{U} := \mathbb{R}^m$, $x(t) \in \mathscr{X} := \mathbb{R}^n$, $d(t) \in \mathscr{D} := \mathbb{R}^q$, $z_1(t) \in \mathscr{Z}_1 := \mathbb{R}^{p_1}$ and $z_2(t) \in \mathscr{Z}_2 := \mathbb{R}^{p_2}$. Let A, B, G, H_1 and H_2 be real matrices of appropriate dimensions. We will write $\mathscr{K}_i := \ker H_i$ $(i = 1, 2)$, $\mathscr{B} := \operatorname{im} B$ and $A_F := A + BF$. The reachable subspace will be denoted by $\langle A \mid \mathscr{B}\rangle := \mathscr{B} + A\mathscr{B} + \cdots + A^{n-1}\mathscr{B}$. A collection of subspaces $\mathscr{B}_1, \mathscr{B}_2, \cdots, \mathscr{B}_k$ will be called a chain in $\mathscr{B}$ if $\mathscr{B} \supset \mathscr{B}_1 \supset \mathscr{B}_2 \supset \cdots \supset \mathscr{B}_k$. If $0 \neq b \in \mathscr{B}$ we will denote $\mathscr{b} := \operatorname{span} b$.

If $\mathscr{V} \subset \mathscr{X}$ is A_F-invariant, the restriction of A_F to $\mathscr{V}$ will be denoted by $A_F \mid \mathscr{V}$. We will write $A_F \mid \mathscr{X}/\mathscr{V}$ or $\bar{A}_F$ for the quotient map induced by A_F on the factor space $\mathscr{X}/\mathscr{V}$ (see [22]). If $\mathscr{V}$ and $\mathscr{W}$ are both A_F-invariant and $\mathscr{W} \subset \mathscr{V}$, then $A_F \mid \mathscr{V}/\mathscr{W}$ will denote the map induced by $A_F \mid \mathscr{V}$ on the factor space $\mathscr{V}/\mathscr{W}$. We define the canonical projection $P: \mathscr{X} \to \mathscr{X}/\mathscr{V}$ by $Px := x + \mathscr{V}$. If $\bar{B} := PB$, then $(\bar{A}_F, \bar{B})$ will be called the system induced in $\mathscr{X}/\mathscr{V}$. If $H: \mathscr{X} \to \mathscr{Z}$ is a linear map and $\mathscr{V} \subset \ker H$, then $\bar{H}: \mathscr{X}/\mathscr{V} \to \mathscr{Z}$ is defined by $\bar{H}P = H$. A distribution $f \in \mathscr{D}'_+$ (i.e., the space of finite-dimensional valued distributions with support on $[0,\infty)$) will be called a Bohl distribution if there exist vectors f_i and matrices K, L, M such that $f = \sum_{i=0}^{N} f_i \delta^{(i)} + f_{-1}$. Here $f_{-1}(t) := Ke^{Lt}M$, $\delta^{(0)}$ denotes Dirac's delta and $\delta^{(i)}$ its ith distributional derivative. f will be called regular if $f_i = 0$ $(i = 0, \cdots, N)$ and impulsive if $f_{-1} \equiv 0$.

2.2. We will now review some basic facts from geometric control theory. If $\mathscr{K} \subset \mathscr{X}$ is a subspace, then $\mathscr{V}^*(\mathscr{K})$ will denote the largest (A, B)- or controlled invariant subspace in $\mathscr{K}$ and $\mathscr{R}^*(\mathscr{K})$ will denote the largest controllability subspace in $\mathscr{K}$ [22].

If $\mathbb{C}_g$ is a symmetric subset of the complex plane $\mathbb{C}$ (i.e., $\lambda \in \mathbb{C}_g \Leftrightarrow \bar{\lambda} \in \mathbb{C}_g$ and $\mathbb{C}_g$ contains at least one point of the real axis), then $\mathcal{V}_g^*(\mathcal{K})$ will denote the largest stabilizability subspace in $\mathcal{K}$ ([5] or [11]).

A subspace $\mathcal{V}_a \subset \mathcal{X}$ will be called almost controlled invariant if for all $x_0 \in \mathcal{V}_a$ and for all $\varepsilon > 0$ there is a state trajectory $x_\varepsilon(\cdot)$ such that $x_\varepsilon(0) = x_0$ and $d(\mathcal{V}_a, x_\varepsilon(t)) \leq \varepsilon$ for all t. A subspace $\mathcal{R}_a \subset \mathcal{X}$ will be called an almost controllability subspace if for all $x_0, x_1 \in \mathcal{R}_a$ there is a $T > 0$ such that for all $\varepsilon > 0$ there is a state trajectory $x_\varepsilon(\cdot)$ such that $x_\varepsilon(0) = x_0$, $x_\varepsilon(T) = x_1$ and $d(\mathcal{R}_a, x_\varepsilon(t)) \leqq \varepsilon$ for all t. Basic facts on these classes of subspaces can be found in [19] or [20] (see also [17]). A subspace $\mathcal{V}_a \subset \mathcal{X}$ is almost controlled invariant if and only if $\mathcal{V}_a = \mathcal{V} + \mathcal{R}_a$, where $\mathcal{V}$ is controlled invariant and $\mathcal{R}_a$ is an almost controllability subspace. A subspace $\mathcal{R}_a$ is an almost controllability subspace if and only if there is a map $F: \mathcal{X} \to \mathcal{U}$ and a chain $\{\mathcal{B}_i\}_{i=1}^k$ in $\mathcal{B}$ such that $\mathcal{R}_a = \mathcal{B}_1 + A_F\mathcal{B}_2 + \cdots + A_F^{k-1}\mathcal{B}_k$. We will say that $\mathcal{R}_a$ is a singly generated almost controllability subspace if there is a map $F: \mathcal{X} \to \mathcal{U}$, a vector $b \in \mathcal{B}$ and an integer $k > 0$ such that $\mathcal{R}_a = \mathcal{b} \oplus A_F\mathcal{b} \oplus \cdots \oplus A_F^{k-1}\mathcal{b}$.

Again, for $\mathcal{K} \subset \mathcal{X}$, $\mathcal{V}_a^*(\mathcal{K})$ will denote the largest almost controlled invariant subspace in $\mathcal{K}$ and $\mathcal{R}_a^*(\mathcal{K})$ the largest almost controllability subspace in $\mathcal{K}$. We will denote $R_b^*(\mathcal{K}) := \mathcal{B} + A\mathcal{R}_a^*(\mathcal{K})$ and $\mathcal{V}_b^*(\mathcal{K}) := \mathcal{V}^*(\mathcal{K}) + \mathcal{R}_b^*(\mathcal{K})$. The subspace $\mathcal{V}_b^*(\mathcal{K})$ plays an important role in the problem of almost disturbance decoupling. In fact, in [20] the following result was obtained:

PROPOSITION 2.1. *Consider the system $\dot{x} = Ax + Bu$, $z = Hx$. Then for all $\varepsilon > 0$ there exists a map $F_\varepsilon: \mathcal{X} \to \mathcal{U}$ such that $\|H \exp[t(A + BF_\varepsilon)]G\|_{L_1} \leqq \varepsilon$ if and only if* $\operatorname{im} G \subset \mathcal{V}_b^*(\ker H)$.

Let $\mathcal{K} := \ker H$. The space $\mathcal{V}_b^*(\mathcal{K})$ will be called the space of distributionally weakly unobservable states with respect to the output z. $\mathcal{R}_b^*(\mathcal{K})$ will be called the space of strongly controllable states with respect to the output z. For this terminology see [6].

A proof of the following result can be found in [1, Lemma 1].

LEMMA 2.2. *Let $\mathcal{K} \subset \mathcal{X}$. Then the following equalities hold:*

(i) $\mathcal{R}_b^*(\mathcal{K}) \cap \mathcal{K} = \mathcal{R}_a^*(\mathcal{K})$,

(ii) $\mathcal{R}_a^*(\mathcal{K}) \cap \mathcal{V}^*(\mathcal{K}) = \mathcal{R}^*(\mathcal{K})$,

(iii) $\mathcal{R}_b^*(\mathcal{K}) \cap \mathcal{V}^*(\mathcal{K}) = \mathcal{R}^*(\mathcal{K})$. □

This paper will sometimes deal with a new system (A, BW), obtained by deleting the part of the input matrix B lying in $\mathcal{V}^*(\mathcal{K})$. This system is obtained by taking $\tilde{\mathcal{B}} \subset \mathcal{B}$ such that $\tilde{\mathcal{B}} \oplus (\mathcal{B} \cap \mathcal{V}^*(\mathcal{K})) = \mathcal{B}$ and by letting W be a map such that $\tilde{\mathcal{B}} = \operatorname{im} BW$ (see also [1]). The supremal almost controllability subspace contained in $\mathcal{K}$ with respect to this new system (A, BW) will be denoted by $\tilde{\mathcal{R}}_a^*(\mathcal{K})$. We will correspondingly denote $\tilde{\mathcal{B}} + A\tilde{\mathcal{R}}_a^*(\mathcal{K})$ by $\tilde{\mathcal{R}}_b^*(\mathcal{K})$. The following result follows from [1, Lemma 2]:

LEMMA 2.3.

$$\mathcal{V}^*(\mathcal{K}) \cap \tilde{\mathcal{R}}_b^*(\mathcal{K}) = \{0\}. \qquad \square$$

Assume now that $\mathcal{V} \subset \mathcal{X}$ is (A, B)-invariant. Let F be such that $(A + BF)\mathcal{V} \subset \mathcal{V}$. Let $(\bar{A}_F, \bar{B})$ be the system induced in $\mathcal{X}/\mathcal{V}$ and $P: \mathcal{X} \to \mathcal{X}/\mathcal{V}$ the canonical projection. We then have the following result:

LEMMA 2.4. *If $\mathcal{R}_a$ is an almost controllability subspace with respect to (A, B), then $P\mathcal{R}_a$ is an almost controllability subspace with respect to $(\bar{A}_F, \bar{B})$.*

Proof. Let Px_0 and Px_1 be in $P\mathcal{R}_a$, with $x_0, x_1 \in \mathcal{R}_a$. There is a $T > 0$ and, for all $\varepsilon > 0$, a trajectory $x_\varepsilon(\cdot)$ such that $x_\varepsilon(0) = x_0$, $x_\varepsilon(T) = x_1$ and $d(\mathcal{R}_a, x_\varepsilon(t)) \leqq \varepsilon$ for all t. It can be seen immediately that $z_\varepsilon(t) := Px_\varepsilon(t)$ is a trajectory of the system $(\bar{A}_F, \bar{B})$. Moreover, $z_\varepsilon(0) = Px_0$, $z_\varepsilon(T) = Px_1$ and $d(P\mathcal{R}_a, z_\varepsilon(t)) = \inf_{r \in R_a} \|Pr - Px_\varepsilon(t)\| \leqq \|P\| d(\mathcal{R}_a, x_\varepsilon(t)) \leqq \varepsilon \|P\|$. □

We will also need the following proposition, which is proven in [17, Thm. 2.39] (see also [15] or [16]).

PROPOSITION 2.5. *Consider the system* $\dot{x} = Ax + Bu$. *Let* $\mathcal{R}_a$ *be an almost controllability subspace. Suppose* Λ *is a symmetric set of* $\dim \langle A \mid \mathcal{B} \rangle - \dim \mathcal{R}_a$ *complex numbers. Then there is an* (A, B)*-invariant subspace* $\mathcal{V}$ *and a map* $F: \mathcal{X} \to \mathcal{U}$ *such that* $\mathcal{V} \oplus \mathcal{R}_a = \langle A \mid \mathcal{B} \rangle$ *and* $\sigma(A_F \mid \mathcal{V}) = \Lambda$.

To conclude this section, we shall recall some facts on left-invertibility of linear systems. Again consider the system $\dot{x} = Ax + Bu$, $z = Hx$. Assume that the map B is injective. We will say that the system (A, B, H) is left-invertible if the transfer matrix $H(Is - A)^{-1}B$ is an injective rational matrix. The following result was proven in [22, Ex. 4.4] (see also [6, Thm. 3.26]).

LEMMA 2.6. (A, B, H) *is a left-invertible system if and only if* $\mathcal{R}^*(\ker H) = 0$. □

2.3. In the following, we will review some basic facts on the frequency domain approach to the geometric concepts of this paper. We will denote $\mathcal{X}[s]$ (respectively, $\mathcal{X}(s)$, $\mathcal{X}_+(s)$) for the set of all n-vectors whose components are polynomials (respectively, rational functions, strictly proper rational functions) with coefficients in $\mathbb{R}$. If $\mathcal{K} \subset \mathcal{X} = \mathbb{R}^n$, then $\mathcal{K}[s]$ (respectively, $\mathcal{K}(s)$, $\mathcal{K}_+(s)$) will denote the set of all $\xi(s) \in \mathcal{X}[s]$ (respectively, $\mathcal{X}(s)$, $\mathcal{X}_+(s)$) with the property that $\xi(s) \in \mathcal{K}$ for all s. Slightly generalizing a definition by Hautus [5], if for a given $x \in \mathcal{X}$ there are rational functions $\xi(s) \in \mathcal{X}(s)$ and $\omega(s) \in \mathcal{U}(s)$ such that $x = (Is - A)\xi(s) + B\omega(s)$ for all s, we will say that x has a (ξ, ω)*-representation.*

For a description of (almost) controlled invariant subspaces in terms of (ξ, ω)-representations, we refer to [5], [12], [13] and [17]. We shall need the following fact:

LEMMA 2.7. *Let* $\mathcal{K} \subset \mathcal{X}$. *Then we have:* $x \in \mathcal{R}_b^*(\mathcal{K})$ *if and only if* x *has a* (ξ, ω)*-representation with* $\xi(s) \in \mathcal{K}[s]$ *and* $\omega(s) \in \mathcal{U}[s]$. □

2.4. Finally, we will recall some facts on the convergence of subspaces. In this paper we will use the common notion of convergence of subspaces in the sense of Grassmanian topology. Let $\{\mathcal{V}_\varepsilon; \varepsilon > 0\}$ be a sequence of subspaces of $\mathcal{X}$ of fixed dimension. It can be proven that $\mathcal{V}_\varepsilon \to \mathcal{V} (\varepsilon \to 0)$ if and only if there is a basis $\{v_1, \cdots, v_q\}$ for $\mathcal{V}$ and there are bases $\{v_1(\varepsilon), \cdots, v_q(\varepsilon)\}$ of $\mathcal{V}_\varepsilon$ such that, for all i, $v_i(\varepsilon) \to v_i$ as $\varepsilon \to 0$ (convergence in $\mathcal{X}$). We will need the following lemma, which can be proven by standard means:

LEMMA 2.8. *Suppose* $v_1, \cdots, v_q$ *are independent vectors and* $v_i(\varepsilon) \to v_i$ *for all* i. *Then for* ε *sufficiently small,* $v_1(\varepsilon), \cdots, v_q(\varepsilon)$ *are linearly independent. Consequently, if* $\mathcal{V}_\varepsilon \to \mathcal{V}$ *and* $\mathcal{W}_\varepsilon \to \mathcal{W}$, *where* $\mathcal{V} \cap \mathcal{W} = \{0\}$, *then for* ε *sufficiently small* $\mathcal{V}_\varepsilon \cap \mathcal{W}_\varepsilon = \{0\}$ *and* $\mathcal{V}_\varepsilon \oplus \mathcal{W}_\varepsilon \to \mathcal{V} \oplus \mathcal{W}$. □

3. Mathematical problem formulation. Consider the system (1.1). We will assume that $z_2(t)$ is an *enlargement* of $z_1(t)$, that is, there is a matrix M such that $H_1 = MH_2$ or, equivalently,

$$\ker H_2 =: \mathcal{K}_2 \subset \mathcal{K}_1 := \ker H_1. \tag{3.1}$$

From now on, (3.1) will be a standing assumption. Throughout this paper we will also assume that B is injective.

Consider the following synthesis problem. Fix $1 \leqq p \leqq \infty$. We will say that *the* L_p*-almost disturbance decoupling problem with bounded peaking* $(\text{ADDPBP})_p$ is solvable if there is a constant C and for all $\varepsilon > 0$ there is a feedback map $F_\varepsilon: \mathcal{X} \to \mathcal{U}$ such that, with the feedback law $u = F_\varepsilon x$ in the closed loop system for $x(0) = 0$ for all $d \in L_p[0, \infty)$, the following inequalities hold:

$$\|z_1\|_{L_p} \leqq \varepsilon \|d\|_{L_p}, \tag{3.2}$$

$$\|z_2\|_{L_p} \leqq C\|d\|_{L_p}. \tag{3.3}$$

Note that if we take $H_1 = H_2$, we obtain the original L_p-almost disturbance decoupling problem, $(\text{ADDP})_p$, without the requirement of bounded peaking (see [20] or [17]). Another interesting special case is to take $H_2 = I$, which corresponds to the requirement of bounded peaking *of the entire state vector.*

In the present paper, necessary and sufficient geometric conditions for the solvability of the above problem will be derived for the cases $p = 1$, $p = 2$ and $p = \infty$. We will first show how the solvability of $(\text{ADDPBP})_p$ can be expressed in terms of the closed loop impulse response matrices from the disturbance d to the outputs z_1 and z_2, respectively. If $F_\varepsilon : \mathscr{X} \to \mathscr{U}$ is a state feedback map, then denote the closed loop transition matrix by

$$T_\varepsilon(t) := e^{(A+BF_\varepsilon)t} \tag{3.4}$$

and let

$$\hat{T}_\varepsilon(s) := (Is - A - BF_\varepsilon)^{-1} \tag{3.5}$$

denote its Laplace transform. We then have the following:

LEMMA 3.1. *Fix $p \in \{1, \infty\}$. Then $(\text{ADDPBP})_p$ is solvable if and only if there is a constant C and for all $\varepsilon > 0$ a feedback map $F_\varepsilon : \mathscr{X} \to \mathscr{U}$ such that $\|H_1 T_\varepsilon G\|_{L_1} \leqq \varepsilon$ and $\|H_2 T_\varepsilon G\|_{L_1} \leqq C$.*

$(\text{ADDPBP})_2$ is solvable if and only if there is a constant C and for all $\varepsilon > 0$ a feedback map F_ε such that $H_1\hat{T}_\varepsilon(s)G$ and $H_2\hat{T}_\varepsilon(s)G$ are asymptotically stable and such that $\sup_{\omega\in\mathbb{R}} \|H_1\hat{T}_\varepsilon(i\omega)G\| \leqq \varepsilon$ and $\sup_{\omega\in\mathbb{R}} \|H_2\hat{T}_\varepsilon(i\omega)G\| \leqq C$.

Proof. The proof follows immediately from the fact that for $p = 1$ and for $p = \infty$ the L_p-included norm of the closed loop convolution operator from d to z_i equals exactly the L_1-norm of its kernel, i.e., $\|H_i T_\varepsilon G\|_{L_1}$. The second statement follows from the fact that the L_2-induced norm of the convolution operator from d to z_i equals the H^∞-norm $\sup_{\omega\in\mathbb{R}} \|H_i\hat{T}_\varepsilon(i\omega)G\|$ (see, for example, [2]). □

4. Disturbance decoupling with stability constraints. Prior to considerations involving the peaking behaviour of the enlarged output z_2, we should make sure that the output z_2 is in $L_p[0, \infty)$ at all. Hence, an important part of the solution of the problem posed in § 3 is to construct the required feedback maps F_ε in such a way that, for any $d \in L_p[0, \infty)$, in the closed loop system with $x(0) = 0$ we have $z_2 \in L_p[0, \infty)$. Therefore, in this section the following variation on the well known (exact) disturbance decoupling problem [22] will be considered. Again, consider the system given by (1.1). The usual disturbance decoupling problem is concerned with the determination of a feedback map $F : \mathscr{X} \to \mathscr{U}$ such that in the closed loop system the external disturbance d does not influence a specified output z_1. We will consider the more general situation in which simultaneously we demand stability of the second, larger, output z_2.

In this section, $\mathbb{C}_g$, the stability set, will be a given subset of the complex plane $\mathbb{C}$ which is symmetric. Asymptotic stability is thus obtained by taking $\mathbb{C}_g = \{\lambda \in \mathbb{C} : \operatorname{Re}\lambda < 0\}$. A rational matrix or rational vector is called stable if all its poles are in $\mathbb{C}_g$. We will consider the following problem: (DDPOS) *the disturbance decoupling problem with output stabilization* is said to be solvable if there is a feedback map F such that $H_1(Is - A_F)^{-1}G = 0$ and $H_2(Is - A_F)^{-1}G$ is stable.

In order to be able to formulate conditions for the solvability of the above problem, introduce the following subspace:

DEFINITION 4.1. $\mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2)$ will denote the subspace of all points $x \in \mathscr{K}_1$ for which there is a (ξ, ω)-representation with $\xi(s) \in \mathscr{K}_{1,+}(s)$, $\omega(s) \in \mathscr{U}_+(s)$ and $H_2\xi(s)$ is *stable.*

Thus, interpreted in the time domain, $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ is the subspace consisting of all points in which a regular Bohl state trajectory starts that lies entirely in $\mathcal{K}_1$. The components of this trajectory modulo $\mathcal{K}_2$ are stable. It follows immediately from the definition that $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ is contained in $\mathcal{V}^*(\mathcal{K}_1)$. By the assumption (3.1), if a trajectory lies in $\mathcal{K}_2$, the same is true for $\mathcal{K}_1$. Consequently we also have the inclusion $\mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$.

We note that Definition 4.1 is a generalization of a definition by Hautus [5]. His space S_Σ^- (see [5, p. 706]) coincides with $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ if $\mathcal{K}_1$ is taken to be $\mathcal{X}$. The following theorem can be proven to be completely analogous to [5, Thm. 4.3]:

THEOREM 4.2.

$$\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g^*(\mathcal{K}_1) + \mathcal{V}^*(\mathcal{K}_2). \qquad \square$$

Note that it follows from the above theorem that $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ is controlled invariant. The next theorem provides the key step in the solution of DDPOS. The result states that what can be done in Definition 4.1 by open loop control can in fact be done by state feedback:

THEOREM 4.3. *There exists a map $F: \mathcal{X} \to \mathcal{U}$ such that*

$$A_F \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) \subset \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2), \tag{4.1}$$

$$A_F \mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}^*(\mathcal{K}_2), \tag{4.2}$$

$$\sigma(A_F | \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)/\mathcal{V}^*(\mathcal{K}_2)) \subset \mathbb{C}_g. \tag{4.3}$$

Proof. During this proof, denote $\mathcal{V}_g := \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$. Since $\mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}_g$ and since both spaces are controlled invariant, they are compatible (see [22, Ex. 9.1]). Hence, there is a map $F_0: \mathcal{X} \to \mathcal{U}$ such that $A_{F_0}\mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}^*(\mathcal{K}_2)$ and $A_{F_0}\mathcal{V}_g \subset \mathcal{V}_g$. Let $\bar{\mathcal{B}} := \mathcal{B} \cap \mathcal{V}_g$ and let V be any matrix such that $\bar{\mathcal{B}} = \operatorname{im} BV$.

Consider the controllability subspace $\langle A_{F_0} | \bar{\mathcal{B}} \rangle$. By the facts that $\bar{\mathcal{B}} \subset \mathcal{V}_g$ and $A_{F_0}\mathcal{V}_g \subset \mathcal{V}_g$, this controllability subspace is contained in $\mathcal{K}_1$. Since any controllability subspace is also a stabilizability subspace, it must be contained in the largest stabilizability subspace $\mathcal{V}_g^*(\mathcal{K}_1)$ in $\mathcal{K}_1$. It then follows that $\bar{\mathcal{B}} \subset \mathcal{V}_g^*(\mathcal{K}_1)$, so

$$\mathcal{B} \cap \mathcal{V}_g^*(\mathcal{K}_1) = \bar{\mathcal{B}}. \tag{4.4}$$

Next, we claim that $\mathcal{V}_g^*(\mathcal{K}_1)$ is A_{F_0}-invariant. First, since it is (A, B)-invariant, we have $A_{F_0}\mathcal{V}_g^*(\mathcal{K}_1) \subset \mathcal{V}_g^*(\mathcal{K}_1) + \mathcal{B}$. On the other hand, $A_{F_0}\mathcal{V}_g^*(\mathcal{K}_1) \subset A_{F_0}\mathcal{V}_g \subset \mathcal{V}_g$. Hence, again using $\mathcal{V}_g^*(K_1) \subset \mathcal{V}_g$, we obtain $A_{F_0}\mathcal{V}_g^*(\mathcal{K}_1) \subset (\mathcal{V}_g^*(\mathcal{K}_1) + \mathcal{B}) \cap \mathcal{V}_g \subset \mathcal{V}_g^*(\mathcal{K}_1) + (\mathcal{B} \cap \mathcal{V}_g) = \mathcal{V}_g^*(\mathcal{K}_1)$. The last equality follows from (4.4).

Using (4.4) and [5, Prop. 2.16], we deduce that the pair $(A_{F_0} | \mathcal{V}_g^*(\mathcal{K}_1), BV)$ is stabilizable.

Let $P_1: \mathcal{V}_g \to \mathcal{V}_g/\mathcal{V}^*(\mathcal{K}_2)$ be the canonical projection. Let $(\bar{A}_{F_0}, \overline{BV})$ be the system induced in $\mathcal{V}_g/\mathcal{V}^*(\mathcal{K}_2)$. It can easily be seen, for example, by using a rank test (see [4] or [5, Thm. 2.13]), that the latter system is stabilizable. Hence, there is a map $\bar{F}_1$ on the factor space such that $\sigma(\bar{A}_{F_0} + \overline{BV}\bar{F}_1) \subset \mathbb{C}_g$. Now, let F_1 be any map on $\mathcal{V}_g$ such that $F_1 = \bar{F}_1 P_1$ and define F_1 arbitrary on a complement of $\mathcal{V}_g$. Define $F := F_0 + VF_1$. Since $F | \mathcal{V}^*(\mathcal{K}_2) = F_0 | \mathcal{V}^*(\mathcal{K}_2)$ ("$|$" denotes "restriction to"), we then have $A_F\mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}^*(\mathcal{K}_2)$ and it can be verified that Fig. 1 commutes.

We are now in a position to prove the main result of this section.

THEOREM 4.4. DDPOS *is solvable iff* $\operatorname{im} G \subset \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$.

Proof. ($\Leftarrow$) Choose F as in Theorem 4.3. Then $\langle A_F | \operatorname{im} G \rangle \subset \mathcal{K}_1$, which yields the decoupling from d to z_1.

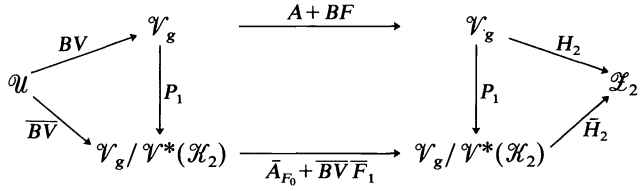

FIG. 1

Let $\bar{H}_2$ be as in the Fig. 1 and let $\bar{A}_F := A_F \mid \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)/\mathcal{V}^*(\mathcal{K}_2)$. Then $H_2(Is - A_F)^{-1}G = \bar{H}_2(Is - \bar{A}_F)^{-1}P_1G$, which is stable since $\sigma(\bar{A}_F) \subset \mathbb{C}_g$.

($\Rightarrow$) *If* F is such that $H_1(Is - A_F)^{-1}G = 0$ and $H_2(Is - A_F)^{-1}G$ is stable then for $d \in \mathcal{D}$ let $\xi(s) := (Is - A_F)^{-1}Gd$ and $\omega(s) := F\xi(s)$. Then clearly $Gd = (Is - A)\xi(s) + B\omega(s)$ and $H_2\xi(s)$ is stable. □

Remark 4.5. If in the above problem we take $H_1 = H_2 = H$, DDPOS reduces to the ordinary disturbance decoupling problem DDP (see [22]). In this case we have, denoting $\mathcal{K} := \ker H$, $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g^*(\mathcal{K}) + \mathcal{V}^*(\mathcal{K}) = \mathcal{V}^*(\mathcal{K})$. If we take $H_1 = 0$ and $H_2 = H$, we arrive at OSDP as studied in Hautus [5]. The solvability of this problem requires the existence of a state feedback F such that $H(Is - A_F)^{-1}G$ is stable. Necessary and sufficient conditions can be found by noting that $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g^*(\mathcal{X}) + \mathcal{V}^*(\mathcal{K})$. As also noted in [5], if we take $H_1 = 0$, $H_2 = H$ and im $G = \mathcal{X}$, the above theorem provides necessary and sufficient conditions for the solvability of the output stabilization problem, OSP.

5. A necessary geometric condition for the solvability of (ADDPBP)$_p$. In this section we shall establish a necessary condition for the solvability of (ADDPBP)$_p$. This condition will be in the form of a subspace inclusion. The proof is rather technical and some of the details are deferred to Appendix A. In the rest of this paper, the stability set will be taken to be $\mathbb{C}_g = \{\lambda \in \mathbb{C} \mid \text{Re } \lambda < 0\}$.

Consider the system $\dot{x} = Ax + Bu$, $z_1 = H_1x$, $z_2 = H_2x$ and assume that (3.1) is satisfied. The following subspace will play an important role in the sequel:

DEFINITION 5.1. $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ will denote the subspace of all $x \in X$ that have a (ξ, ω)-representation with $\xi(\omega) \in \mathcal{K}_1(s)$, $\omega(s) \in \mathcal{U}(s)$ and $H_2\xi(s)$ is proper and stable.

Interpreted in the time domain, $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ consists exactly of those points in $\mathcal{X}$ that can serve as an initial condition for some Bohl distributional trajectory that lies entirely in $\mathcal{K}_1$, while the vector of components of the trajectory modulo $\mathcal{K}_2$ is the sum of a stable regular Bohl function and a Dirac delta.

It follows immediately from the definition and [12, Thm. 4.1] that $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ is contained in $\mathcal{V}_b^*(\mathcal{K}_1)$, the subspace of distributionally weakly unobservable states with respect to the output z_1. It is also immediate that $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ is contained in $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. We are now in a position to state the main result of this section:

THEOREM 5.2. *Fix* $p \in \{1, 2, \infty\}$. *Then the following holds*:

$$\{(\text{ADDPBP})_p \textit{ is solvable}\} \Rightarrow \{\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)\}.$$

In the remainder of this section we will establish a proof of the above theorem. Again, consider the system $\dot{x} = Ax + Bu$, $z_1 = H_1x$, $z_2 = H_2x$. Assume that for $\varepsilon > 0$, $u_\varepsilon(t)$ is a regular Bohl input. Let $x_0 \in X$. Let $z_{1,\varepsilon}(t)$ and $z_{2,\varepsilon}(t)$ be the outputs corresponding to the above input and initial condition $x(0) = x_0$. Denote $\hat{z}_{i,\varepsilon}(s)$ for the corresponding Laplace transforms of $z_{i,\varepsilon}(t)$. We then have the following lemma:

LEMMA 5.3. *Suppose that either of the following conditions is satisfied*:

(i) $\|z_{1,\varepsilon}\|_{L_1} \to 0$ *as* $\varepsilon \to 0$ *and there exists a constant* C *such that* $\|z_{2,\varepsilon}\|_{L_1} \leqq C$ *for all* ε.

(ii) $\hat{z}_{1,\varepsilon}(s)$ *and* $\hat{z}_{2,\varepsilon}(s)$ *are stable for all* ε, $\sup_{\omega\in\mathbb{R}} \|\hat{z}_{1,\varepsilon}(i\omega)\| \to 0$ *as* $\varepsilon \to 0$ *and there exists a constant* C *such that* $\sup_{\omega\in\mathbb{R}} \|\hat{z}_{2,\varepsilon}(i\omega)\| \leqq C$ *for all* ε.
Then $x_0 \in \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. □

A detailed proof of Lemma 5.3 can be found in Appendix A. The idea of the proof is the following. First we note that the initial condition x_0 above has for each $\varepsilon > 0$ a (ξ, ω)-representation $x_0 = (Is - A)\xi_\varepsilon(s) + B\omega_\varepsilon(s)$. Here $\omega_\varepsilon(s)$ is the (rational) Laplace transform of $u_\varepsilon(t)$. Using the asymptotic behaviour as described by the condition (i) or (ii) above, we then analyse the limiting behaviour for $\varepsilon \to 0$ of the sequences of rational vectors $\xi_\varepsilon(s)$ and $\omega_\varepsilon(s)$. This will lead to a (ξ, ω)-representation for x_0 with the properties described in Definition 5.1. To conclude this section we apply Lemma 5.3 to obtain the following:

Proof of Theorem 5.2. Assume that $(\text{ADDPBP})_p$ is solvable. Let $x_0 \in \text{im } G$. Let F_ε be as in Lemma 3.1 and define $u_\varepsilon(t) := F_\varepsilon T_\varepsilon(t)x_0$. Then, depending on p, one of the conditions (i) or (ii) in Lemma 5.3 is satisfied. It follows that $x_0 \in \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. □

6. The geometric structure of $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. In the sequel, it will turn out that under certain assumptions on the system (1.1) the subspace inclusion in Theorem 5.2 is also a sufficient condition for the solvability of $(\text{ADDPBP})_p$. In order to prove this and to be able to construct the required feedback maps, we need more detailed information on the geometric structure of the subspace $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ as introduced in the previous section. In the present section, we will first show that the subspace $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ can always be written as the sum of the subspace $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ (see § 4) together with an almost controllability subspace depending on $\mathcal{K}_1$ and $\mathcal{K}_2$. Using this result, we will show that if either $\mathcal{R}^*(\mathcal{K}_1) = \{0\}$ or $\mathcal{K}_2 = \{0\}$, then $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ admits a decomposition into the direct sum of $\mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ together with a number of singly generated almost controllability subspaces, with a particular position with respect to the subspaces $\mathcal{K}_1$ and $\mathcal{K}_2$. The main result of this section will be the following theorem:

THEOREM 6.1. *Assume that* $\mathcal{R}^*(\mathcal{K}_1) = \{0\}$ *or that* $\mathcal{K}_2 = \{0\}$. *Then there is an integer* $m' \in \mathbb{N}$, *there are integers* $r_1, \cdots, r_{m'} \in \mathbb{N}$ *and vectors* $b_1, \cdots, b_{m'} \in \mathcal{B}$ *and there is a map* $F: \mathcal{X} \to \mathcal{U}$ *such that*

$$\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) \oplus \bigoplus_{i=1}^{m'} \mathcal{L}_i, \tag{6.1}$$

where

$$\mathcal{L}_i := \bigoplus_{j=1}^{r_i} A_F^{j-1} b_i,$$

with

$$\bigoplus_{j=1}^{r_i-1} A_F^{j-1} b_i \subset \mathcal{K}_1 \tag{6.2}$$

and

$$\bigoplus_{j=1}^{r_i-2} A_F^{j-1} b_i \subset \mathcal{K}_2. \tag{6.3}$$

If in the statement of the above theorem one of the integers r_i is such that $r_i - 1 < 1$ or $r_i - 2 < 1$, then the corresponding sums in (6.2) or (6.3) are understood to be equal to $\{0\}$. It will turn out in the proof of Theorem 6.1 that in the case that $\mathcal{R}^*(\mathcal{K}_1) = \{0\}$ the integer m' may be chosen to be equal to m $(= \dim \mathcal{B})$. In the case that $\mathcal{K}_2 = \{0\}$ it will appear that m' may be chosen to be equal to $m - \dim [\mathcal{V}^*(\mathcal{K}_1) \cap \mathcal{B}]$ and also that

in this case the integers r_i may be taken to be either 1 or 2. Since $\mathcal{V}_g(\mathcal{K}_1, \{0\}) = \mathcal{V}_g^*(\mathcal{K}_1)$ (see Theorem 4.2) the theorem thus states that $\mathcal{V}_b(\mathcal{K}_1, \{0\})$ is equal to the direct sum of $\mathcal{V}_g^*(\mathcal{K}_1)$ together with a number of singly generated almost controllability subspaces which are equal to either span $\{b_i\}$ (with $0 \neq b_i \in \mathcal{B}$) or span $\{b_i, A_F b_i\}$, with $\{b_i, A_F b_i\}$ linearly independent and $b_i \in \mathcal{K}_1 \cap \mathcal{B}$.

The result of Theorem 6.1 will be instrumental in the next section, where we will consider the sufficiency of the subspace inclusion im $G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ for solvability of $(\text{ADDPBP})_p$ and propose a "scheme" for calculation of the required feedback maps. In the remainder of the present section we will establish a proof of Theorem 6.1.

We introduce the following subspace:

DEFINITION 6.2. $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$ will denote the subspace of all $x \in \mathcal{X}$ that have a (ξ, ω)-representation with $\xi(s) \in \mathcal{K}_1[s]$, $\omega(s) \in \mathcal{U}[s]$ and $H_2\xi(s)$ is *constant* (i.e., if $\xi(s) = \sum_{i=0}^{N} x_i s^i$ then $H_2 x_i = 0$ for $i \geqq 1$).

Interpreted in the time domain, $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$ consists exactly of those points in $\mathcal{X}$ that can be driven to 0 along a purely distributional Bohl trajectory that lies entirely in $\mathcal{K}_1$, while the vector of components of this trajectory modulo $\mathcal{K}_2$ is a Dirac delta.

It follows immediately from the definition and Lemma 2.7 that every point in $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$ is strongly controllable with respect to the output z_1. Moreover, it is also immediate that every point x that is strongly controllable with respect to the output z_2, is an element of $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$. Hence, the inclusion $\mathcal{R}_b^*(\mathcal{K}_2) \subset \mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2) \subset \mathcal{R}_b^*(\mathcal{K}_1)$ holds. In fact, we have the following nice result:

THEOREM 6.3.

(i) $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{B} + A(\mathcal{R}_b^*(\mathcal{K}_2) \cap \mathcal{K}_1)$,

(ii) $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) + \mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$.

Proof. (i) Suppose that $x = (Is - A)\xi(s) + B\omega(s)$, with $\xi(s) \in \mathcal{K}_1[s]$, $\omega(s) \in \mathcal{U}[s]$ and $H_2\xi(s)$ is constant. Let $\xi(s) = \sum_{i=0}^{N} x_i s^i$ and $\omega(s) = \sum_{i=0}^{N+1} u_i s^i$. Obviously, $\xi(s) = x_0 + s\xi_1(s)$ and $\omega(s) = u_0 + s\omega_1(s)$, where $\xi_1(s) \in \mathcal{K}_2[s]$ and $\omega_1(s) \in \mathcal{U}[s]$. Hence, $x = Bu_0 - Ax_0 + sx_0 + s^2\xi_1(s) - As\xi_1(s) + Bs\omega_1(s)$ and by equating powers it follows that

$$x = -Ax_0 + Bu_0, \tag{6.4}$$

$$-x_0 = (Is - A)\xi_1(s) + B\omega_1(s). \tag{6.5}$$

Therefore, $x_0 \in \mathcal{R}_b^*(\mathcal{K}_2)$ (see Lemma 2.7). Since also $x_0 \in \mathcal{K}_1$, we obtain $x \in \mathcal{B} + A(\mathcal{R}_b^*(\mathcal{K}_2) \cap \mathcal{K}_1)$. Conversely, if $x = Bu_0 - Ax_0$ with $x_0 \in \mathcal{R}_b^*(\mathcal{K}_2) \cap \mathcal{K}_1$, there is $\xi_1(s) \in \mathcal{K}_2[s]$ and $\omega_1(s) \in \mathcal{U}[s]$ such that $-x_0 = (Is - A)\xi_1(s) + B\omega_1(s)$. Defining then $\xi(s) := x_0 + s\xi_1(s)$ and $\omega(s) := u_0 + s\omega_1(s)$, we obtain a (ξ, ω)-representation of x with $\xi(s) \in \mathcal{K}_1[s]$, $\omega(s) \in \mathcal{U}[s]$ and $H_2\xi(s) = H_2x_0$ is constant.

(ii) Assume that $x \in \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. There is a (ξ, ω)-representation for x with $\xi(s) \in \mathcal{K}_1(s)$, $\omega(s) \in \mathcal{U}(s)$ and $H_2\xi(s)$ proper and stable. Decompose $\xi(s) = \xi_1(s) + \xi_2(s)$ and $\omega(s) = \omega_1(s) + \omega_2(s)$, where $\xi_1(s)$ and $\omega_1(s)$ are polynomial vectors and $\xi_2(s)$ and $\omega_2(s)$ are strictly proper. Obviously, $\xi_1(s) \in \mathcal{K}_1[s]$, $\xi_2(s) \in \mathcal{K}_{1,+}(s)$, $\omega_1(s) \in \mathcal{U}[s]$ and $\omega_2(s) \in \mathcal{U}_+(s)$. Moreover, $H_2\xi_1(s)$ is constant and $H_2\xi_2(s)$ is strictly proper and stable. Now, since the left-hand side of this equation is proper and the right-hand side is a polynomial vector, both sides must, in fact, be constant. Thus, there is a vector $x_1 \in \mathcal{X}$ such that $x_1 = (Is - A)\xi_1(s) + B\omega_1(s) = x - (Is - A)\xi_2(s) - B\omega_2(s)$. It follows that $x_1 \in \mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$ and $x - x_1 \in \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$. Since $x = x_1 + (x - x_1)$, we obtain that $x \in \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2) + \mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$. The converse inclusion follows immediately from the definitions. □

The importance of the above theorem is that it shows, together with Theorem 4.2, that

$$\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{V}_g^*(\mathcal{K}_1) + \mathcal{V}^*(\mathcal{K}_2) + \mathcal{B} + A(\mathcal{R}_b^*(\mathcal{K}_2) \cap \mathcal{K}_1). \tag{6.6}$$

Thus, the space $\mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$ can, in principle, be calculated using existing algorithms. The stabilizability subspace and the controlled invariant subspace appearing in (6.6) can be calculated using the invariant subspace algorithm ISA [22, p. 91] and a construction as in [22, p. 114]. The almost controllability subspace $\mathscr{R}_b^*(\mathscr{K}_2)$ can be calculated using the almost controllability subspace algorithm (ACSA)' [20]. For any fixed subspace $\mathscr{K} \subset \mathscr{X}$, this algorithm is defined by

$$\mathscr{T}^{i+1}(\mathscr{K}) = \mathscr{B} + A(\mathscr{T}^i(\mathscr{K}) \cap \mathscr{K}); \ \mathscr{T}^0(\mathscr{K}) = \{0\}. \tag{6.7}$$

It is well known, see [20], that (6.7) defines a nondecreasing sequence of subspaces which reaches a limit after a finite number of iterations. Moreover, this limit equals $\mathscr{T}^n(\mathscr{K}) = \mathscr{R}_b^*(\mathscr{K})$. In the sequel, denote

$$\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2) := \mathscr{T}^i(\mathscr{K}_2) \cap \mathscr{K}_1. \tag{6.8}$$

Using the properties of the sequence $\mathscr{T}^i(\mathscr{K})$ stated above, together with Theorem 6.3, the following result is immediate:

LEMMA 6.4. *$\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)$ is a nondecreasing sequence which reaches a limit after a finite number of iterations. This limit equals $\mathscr{F}^n(\mathscr{K}_1, \mathscr{K}_2) = R_b^*(\mathscr{K}_2) \cap \mathscr{K}_1$. Consequently,*

$$\mathscr{R}_b(\mathscr{K}_1, \mathscr{K}_2) = \mathscr{B} + A\mathscr{F}^n(\mathscr{K}_1, \mathscr{K}_2). \tag{6.9}$$

□

Other properties of the sequence $\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)$ are proven in Lemma B.1, Appendix B. Using these properties, we obtain the following lemma:

LEMMA 6.5. *Assume that $\mathscr{R}^*(\mathscr{K}_1) = \{0\}$. Then there is a chain $\{\mathscr{B}_i\}_{i=1}^n$ in $\mathscr{B}$ and a map $F: \mathscr{X} \to \mathscr{U}$ such that*

$$\mathscr{R}_b(\mathscr{K}_1, \mathscr{K}_2) = \mathscr{B} \oplus A_F\mathscr{B}_1 \oplus \cdots \oplus A_F^n\mathscr{B}_n, \tag{6.10}$$

$$\bigoplus_{i=1}^{n} A_F^{i-1}\mathscr{B}_i \subset \mathscr{K}_1, \tag{6.11}$$

$$\bigoplus_{i=2}^{n} A_F^{i-2}\mathscr{B}_i \subset \mathscr{K}_2, \tag{6.12}$$

$$\dim \mathscr{B}_i = \dim A_F^i\mathscr{B}_i = \dim [\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)/\mathscr{F}^{i-1}(\mathscr{K}_1, \mathscr{K}_2)]. \tag{6.13}$$

Proof. See Appendix B. □

We are now in a position to establish a proof of Theorem 6.1 for the case $\mathscr{R}^*(\mathscr{K}_1) = \{0\}$:

Proof of Theorem 6.1 (*Case* 1: $\mathscr{R}^*(\mathscr{K}_1) = \{0\}$). During this proof we will denote $\mathscr{R}_b(\mathscr{K}_1, \mathscr{K}_2)$ by $\mathscr{R}_b$, $\mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$ by $\mathscr{V}_b$ and $\mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2)$ by $\mathscr{V}_g$. According to Theorem 6.5 we have that $\mathscr{V}_b = \mathscr{V}_g + \mathscr{R}_b$. We claim that the latter sum is a direct sum. Indeed, this follows immediately from the facts that $\mathscr{V}_g \subset \mathscr{V}^*(\mathscr{K}_1)$ and $\mathscr{R}_b \subset \mathscr{R}_b^*(\mathscr{K}_1)$, while $\mathscr{V}^*(\mathscr{K}_1) \cap \mathscr{R}_b^*(\mathscr{K}_1) = \mathscr{R}^*(\mathscr{K}_1) = \{0\}$ (see Lemma 2.2). By Lemma 6.5 there is a chain $\{\mathscr{B}_i\}_{i=1}^n$ in $\mathscr{B}$ and a map F such that (6.10) to (6.13) hold. Let $\mathscr{B}_l$ be the first subspace in the chain which is not zero, i.e., $\mathscr{B}_l \neq \{0\}$ and $\mathscr{B}_j = \{0\}$ for $j = l+1, \cdots, n$. Choose a basis for $\mathscr{B}$ as follows. First choose a basis $\{b_1, \cdots, b_{d_l}\}$ for $\mathscr{B}_l$. Extend this to a basis $\{b_1, \cdots, b_{d_l}, b_{d_l+1}, \cdots, b_{d_{l-1}}\}$ for $\mathscr{B}_{l-1}$ (here, $d_i := \dim \mathscr{B}_i$). Continue this procedure until we have a basis for $\mathscr{B}$.

By the fact that $\dim \mathscr{B}_i = \dim A_F^i\mathscr{B}_i$, $\forall_i$, the following vectors form a basis for $\mathscr{R}_b$:

$$\begin{array}{l}
A_F^l b_1, \cdots, A_F^l b_{d_l}, \\
A_F^{l-1} b_1, \cdots, A_F^{l-1} b_{d_l}, A_F^{l-1} b_{d_l+1}, \cdots, A_F^{l-1} b_{d_{l-1}}, \\
\quad \vdots \qquad\qquad \vdots \qquad\quad \vdots \\
A_F b_1, \cdots, \quad A_F b_{d_l}, \quad A_F b_{d_l+1}, \cdots, \quad A_F b_{d_{l-1}}, \cdots, \cdots, A_F b_{d_1}, \\
b_1, \cdots, b_{d_l}, b_{d_l+1}, \cdots, b_{d_{l-1}}, \cdots, \cdots, b_{d_1}, \cdots, b_m.
\end{array}$$

It may immediately be verified that the above list of vectors can be rearranged to obtain m subspaces $\mathscr{L}_i := \operatorname{span}\{b_i, A_F b_i, \cdots, A_F^{r_i-1} b_i\}$, with

$$\operatorname{span}\{b_i, A_F b_i, \cdots, A_F^{r_i-2} b_i\} \subset \mathscr{K}_1$$

and

$$\operatorname{span}\{b_i, A_F b_i, \cdots, A_F^{r_i-3} b_i\} \subset \mathscr{K}_2.$$

This completes the proof of Theorem 6.1 for the case that $\mathscr{R}^*(\mathscr{K}_1) = \{0\}$. □

In the remainder of this section, we will set up a proof of Theorem 6.1, the case that $\mathscr{K}_2 = \{0\}$. In the following, let $\tilde{\mathscr{B}}$ be a subspace of $\mathscr{B}$ such that $\tilde{\mathscr{B}} \oplus [\mathscr{B} \cap \mathscr{V}^*(\mathscr{K}_1)] = \mathscr{B}$. Let W be a map such that $\tilde{\mathscr{B}} = \operatorname{im} BW$ and let $\tilde{\mathscr{R}}_b^*(\mathscr{K}_1) := \tilde{\mathscr{B}} + A\tilde{\mathscr{R}}_a^*(\mathscr{K}_1)$, where $\tilde{\mathscr{R}}_a^*(\mathscr{K}_1)$ denotes the supremal almost controllability subspace contained in $\mathscr{K}_1$ with respect to the system (A, BW) (see also Lemma 2.3). Define

$$\tilde{\mathscr{W}}(\mathscr{K}_1) := \tilde{\mathscr{B}} + A(\tilde{\mathscr{B}} \cap \mathscr{K}_1). \tag{6.14}$$

We will show that if $\mathscr{K}_2 = \{0\}$, then $\mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$ has a decomposition into the direct sum of $\mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2)$ (which, in that case, is equal to $\mathscr{V}_g^*(\mathscr{K}_1)$) and the subspace $\tilde{\mathscr{W}}(\mathscr{K}_1)$:

LEMMA 6.6. *Let $\mathscr{K}_1$ be a subspace of $\mathscr{X}$. Then*

$$\mathscr{V}_b(\mathscr{K}_1, \{0\}) = \mathscr{V}_g(\mathscr{K}_1, \{0\}) \oplus \tilde{\mathscr{W}}(\mathscr{K}_1). \tag{6.15}$$

Proof. In this proof, denote $\mathscr{V}_g := \mathscr{V}_g(\mathscr{K}_1, \{0\})$. Also, let $\mathscr{B}_1 := \mathscr{B} \cap \mathscr{V}^*(\mathscr{K}_1)$. Since $\mathscr{R}_b^*(\{0\}) = \mathscr{B}$, it follows from Theorem 6.3 that

$$\begin{aligned}\mathscr{V}_b(\mathscr{K}_1, \{0\}) &= \mathscr{V}_g + \mathscr{B} + A[\mathscr{B} \cap \mathscr{K}_1] \\ &= \mathscr{V}_g + \mathscr{B} + A[(\mathscr{B}_1 \oplus \tilde{\mathscr{B}}) \cap \mathscr{K}_1] \\ &= \mathscr{V}_g + \mathscr{B} + A[\mathscr{B}_1 + (\tilde{\mathscr{B}} \cap \mathscr{K}_1)].\end{aligned}$$

Now, note that $\mathscr{B}_1 \subset \mathscr{R}^*(\mathscr{K}_1)$ (see [22, Thm. 5.5]). Consequently, $A\mathscr{B}_1 \subset \mathscr{R}^*(\mathscr{K}_1) + \mathscr{B} \subset \mathscr{V}_g + \mathscr{B}$. Hence we find

$$\begin{aligned}\mathscr{V}_b(\mathscr{K}_1, \{0\}) &= \mathscr{V}_g + \mathscr{B} + A(\tilde{\mathscr{B}} \cap \mathscr{K}_1) \\ &= \mathscr{V}_g + \mathscr{B}_1 + \tilde{\mathscr{B}} + A(\tilde{\mathscr{B}} \cap \mathscr{K}_1).\end{aligned}$$

Again, by the fact that $\mathscr{B}_1 \subset \mathscr{R}^*(\mathscr{K}_1) \subset \mathscr{V}_g$, we have

$$\mathscr{V}_b(\mathscr{K}_1, \{0\}) = \mathscr{V}_g + \tilde{\mathscr{B}} + A(\tilde{\mathscr{B}} \cap \mathscr{K}_1).$$

Finally, since $\mathscr{V}_g \subset \mathscr{V}^*(\mathscr{K}_1)$ and $\tilde{\mathscr{W}}(\mathscr{K}_1) \subset \tilde{\mathscr{R}}_b^*(\mathscr{K}_1)$, it follows from Lemma 2.3 that the sum in (6.15) is direct. □

Using the above lemma we may now obtain the following proof of Theorem 6.1, the case that $\mathscr{K}_2 = \{0\}$;

Proof of Theorem 6.1 (*Case* 2: $\mathscr{K}_2 = \{0\}$). We claim that $\tilde{\mathscr{W}}(\mathscr{K}_1) = \tilde{\mathscr{B}} \oplus A(\tilde{\mathscr{B}} \cap \mathscr{K}_1)$. To prove this, assume that there is a vector $0 \neq x \in \tilde{\mathscr{B}}$ such that $x = A\bar{x}$, with $\bar{x}$ a vector in $\tilde{\mathscr{B}} \cap \mathscr{K}_1$. Define $\mathscr{V} := \operatorname{span}\{\bar{x}\}$. Since $A\mathscr{V} \subset \mathscr{V} + \mathscr{B}$, $\mathscr{V}$ is controlled invariant. Since also $\mathscr{V} \subset \mathscr{K}_1$, we find that $\mathscr{V} \subset \mathscr{V}^*(\mathscr{K}_1)$. It follows that $\bar{x} \in \mathscr{V}^*(\mathscr{K}_1) \cap \tilde{\mathscr{B}} = \{0\}$ and hence that $x = 0$. This yields a contradiction. Next, we claim that $\dim \tilde{\mathscr{B}} \cap \mathscr{K}_1 = \dim A(\tilde{\mathscr{B}} \cap \mathscr{K}_1)$. Assume the contrary. Then we may find a vector $0 \neq x \in \tilde{\mathscr{B}} \cap \mathscr{K}_1$ such that $Ax = 0$. It follows that $\operatorname{span}\{x\}$ is a controlled invariant subspace contained in $\mathscr{K}_1$ and hence that $x \in \mathscr{V}^*(\mathscr{K}_1) \cap \tilde{\mathscr{B}} = \{0\}$. Again, this is a contradiction. Now, choose a basis for $\tilde{\mathscr{W}}(\mathscr{K}_1)$ as follows: first choose a basis $b_1, \cdots, b_r$ of $\tilde{\mathscr{B}} \cap \mathscr{K}_1$. Extend this to a basis $\{b_1, \cdots, b_r, b_{r+1}, \cdots, b_{m'}\}$ of $\tilde{\mathscr{B}}$. By the above, the vectors $\{b_1, \cdots, b_r, Ab_1, \cdots, Ab_r, b_{r+1}, \cdots, b_{m'}\}$ form a basis for $\tilde{\mathscr{W}}(\mathscr{K}_1)$. These vectors can be rearranged

into one- and two-dimensional singly generated almost controllability subspaces with the properties (6.2) and (6.3). This completes the proof of Theorem 6.1. □

7. The main result. In the present section we will combine our results of the previous sections to show that if the system (1.1) is such that it satisfies at least one of the following two properties:

(7.1) the system (A, B, H_1) is left-invertible,

(7.2) the mapping H_2 is injective,

then the subspace inclusion $\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ is both a necessary and sufficient condition for solvability of the L_p-almost disturbance decoupling problem with bounded peaking $(\text{ADDPBP})_p$ for the values $p=1$, $p=2$ and $p=\infty$.

Recall from § 5 that for these values of p the latter subspace inclusion was already shown to be a necessary condition without the extra assumptions (7.1), (7.2). Here we shall, in fact, prove that if either (7.1) or (7.2) holds then $\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ is a sufficient condition for solvability of $(\text{ADDPBP})_p$ *for all* $1 \leqq p \leqq \infty$.

The following result is the main result of this paper:

THEOREM 7.1. *Assume that at least one of the two conditions* (7.1), (7.2) *is satisfied. Let* $p \in \{1, 2, \infty\}$. *Then* $(\text{ADDPBP})_p$ *is solvable if and only if* $\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. □

In order to obtain a proof of the latter statement, we will prove the following:

LEMMA 7.2. *Assume that at least one of the two conditions* (7.1), (7.2) *is satisfied. Let* $T_\varepsilon(t)$ *and* $\hat{T}_\varepsilon(s)$ *be defined by* (3.4) *and* (3.5). *Then the following statements are equivalent*:

(i) *There exists a constant* C *and a sequence* $\{F_\varepsilon;\ \varepsilon > 0\}$ *such that* $\|H_1 T_\varepsilon G\|_{L_1} \to 0$ $(\varepsilon \to 0)$ *and* $\|H_2 T_\varepsilon G\|_{L_1} \leqq C\ \forall \varepsilon$.

(ii) *There exists a constant* C *and a sequence* $\{F_\varepsilon;\ \varepsilon > 0\}$ *such that, for all* ε, $H_1 \hat{T}_\varepsilon G$ *and* $H_2 \hat{T}_\varepsilon G$ *are stable and* $\sup_{\omega \in \mathbb{R}} \|H_1 \hat{T}_\varepsilon(i\omega) G\| \to 0$ $(\varepsilon \to 0)$ *and* $\sup_{\omega \in \mathbb{R}} \|H_2 \hat{T}_\varepsilon(i\omega) G\| \leqq C$, $\forall \varepsilon$.

(iii) $\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$.

Note that the implications (i)⇒(iii) and (ii)⇒(iii) follow immediately from Lemma 5.3. Also note that once we have proven the above lemma, a proof of our main result Theorem 7.1 may be obtained by combining Theorem 5.2 and Lemma 3.1. We stress that the implications (iii)⇒(i) in the above, in fact, yields sufficiency of the subspace inclusion $\text{im } G \subset \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ for solvability of $(\text{ADDPBP})_p$ *for all* $1 \leqq p \leqq \infty$.

The idea of the proof of the implication (iii)⇒(i) of Lemma 7.2 is as follows. First we note that left-invertibility of the system (A, B, H_1) is equivalent to the condition $\mathcal{R}^*(\mathcal{K}_1) = \{0\}$ (Lemma 2.6), while injectivity of the map H_2 is equivalent to $\mathcal{K}_2 = \{0\}$. Thus, under the assumptions of Lemma 7.2, $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$ may be decomposed according to (6.1), (6.2) and (6.3). Each of the singly generated almost controllability subspaces L_i appearing in this decomposition will then be approximated by sequences of controlled invariant subspaces $\{\mathcal{L}_{j\varepsilon};\ \varepsilon > 0\}$. If we then define $\mathcal{V}_\varepsilon := \mathcal{V}_g \oplus \bigoplus_{j=1}^{m'} \mathcal{L}_{j\varepsilon}$, the sequence $\{\mathcal{V}_\varepsilon;\ \varepsilon > 0\}$ will converge to $\mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$. In this sense, $\text{im } G$ is "almost contained" in the controlled invariant subspace $\mathcal{V}_\varepsilon$. The subspace $\mathcal{V}_\varepsilon$ in turn is "almost contained" in $\mathcal{K}_1$ (where the latter "almost" should be interpreted in the L_1-sense, see also [20]), while its distance from $\mathcal{K}_2$ is uniformly bounded with respect to ε. Using the structure of the $\mathcal{L}_{j\varepsilon}$ above, we will construct a particular sequence of feedback maps $\{F_\varepsilon;\ \varepsilon > 0\}$ such that $(A + BF_\varepsilon)\mathcal{V}_\varepsilon \subset \mathcal{V}_\varepsilon$. Finally it will be shown that this sequence has the properties required by (i) and (ii) in Lemma 7.2. To start with, we will show how a singly generated almost controllability subspace can be approximated by controlled invariant subspaces. Let $b \in \mathcal{B}$ and let $\mathcal{L} := \ell \oplus \cdots \oplus A_F^{k-1}\ell$. For $i \in \underline{k}$ and $\varepsilon > 0$,

define vectors in $\mathscr{X}$ by

$$x_1(\varepsilon) := (I + \varepsilon A_F)^{-1} b, \qquad x_i(\varepsilon) := (I + \varepsilon A_F)^{-1} A_F x_{i-1}(\varepsilon). \tag{7.3}$$

Note that the matrix inversions in the above expressions are defined for ε sufficiently small. Moreover, it can be seen immediately that $x_i(\varepsilon) \to A_F^{i-1} b (\varepsilon \to 0)$. Thus it follows from Lemma 2.8 that for ε sufficiently small, the vectors $\{x_i(\varepsilon), i \in \underline{k}\}$ are linearly independent. For each ε, define a subspace $\mathscr{L}_\varepsilon$ by

$$\mathscr{L}_\varepsilon := \operatorname{span}\{x_1(\varepsilon), \cdots, x_k(\varepsilon)\}. \tag{7.4}$$

Assume $u \in \mathscr{U}$ is such that $b = Bu$ and define a map $F_\varepsilon : \mathscr{L}_\varepsilon \to U$ by

$$F_\varepsilon x_i(\varepsilon) := -\varepsilon^{-i} u, \qquad (i \in \underline{k}). \tag{7.5}$$

The main properties of the sequences $\{\mathscr{L}_\varepsilon; \varepsilon > 0\}$ and $\{F_\varepsilon; \varepsilon > 0\}$ are summarized in the following lemma:

LEMMA 7.3. *For $i \in \underline{k}$ we have $x_i(\varepsilon) \to A_F^{i-1} b$ as $\varepsilon \to 0$. Consequently, $\mathscr{L}_\varepsilon \to \mathscr{L}$. Each $\mathscr{L}_\varepsilon$ is controlled invariant and, with F_ε defined by* (7.5), *$(A_F + BF_\varepsilon)\mathscr{L}_\varepsilon \subset \mathscr{L}_\varepsilon$. Moreover, a matrix of $(A_F + BF_\varepsilon)|\mathscr{L}_\varepsilon$ is given by*

$$M_\varepsilon := -\begin{pmatrix} \varepsilon^{-1} & \varepsilon^{-2} & \cdots & \varepsilon^{-k} \\ 0 & \varepsilon^{-1} & \ddots & \\ \vdots & \ddots & \ddots & \varepsilon^{-2} \\ 0 & \cdots & 0 & \varepsilon^{-1} \end{pmatrix}. \tag{7.6}$$

Finally, for each ε, $\mathscr{L}_\varepsilon \subset \langle A | \mathscr{B} \rangle$, the reachable subspace of (A, B).

Proof. The claim $x_i(\varepsilon) \to A_F^{i-1} b$ is immediate. Since the vectors $A_F^{i-1} b$ are a basis for $\mathscr{L}$, it follows from §§ 2 and 4 that $\mathscr{L}_\varepsilon \to \mathscr{L}$. Using (7.3) and (7.5), it may be verified by straightforward calculation that $(A_F + BF_\varepsilon)x_i(\varepsilon) = -\sum_{j=1}^{i} \varepsilon^{j-i-1} x_j(\varepsilon)$. It follows that $\mathscr{L}_\varepsilon$ is indeed $A_F + BF_\varepsilon$-invariant and that a matrix of the map restricted to $\mathscr{L}_\varepsilon$ is given by (7.6). Finally, to prove that $\mathscr{L}_\varepsilon$ is contained in the reachable subspace, make a Taylor expansion to find that $(I + \varepsilon A_F)^{-1} = \sum_{m=0}^{\infty} (-\varepsilon)^m A_F^m$. It then follows immediately that $x_1(\varepsilon) \in \langle A_F | \mathscr{B} \rangle$ for all ε. The same follows for $x_2(\varepsilon)$, $x_3(\varepsilon)$ etc.

We note that a slightly different construction leading to an approximating sequence for a singly generated controllability subspace was described in [13]. The construction described by us however exhibits an important property which will be formulated in the following lemma. The proof of this result is straightforward but rather technical and will be deferred to Appendix C.

LEMMA 7.4. *Let $\mathscr{L} := \bigoplus_{i=1}^{k} A_F^{i-1} \mathscr{b}$ be such that $\bigoplus_{i=2}^{k} A_F^{i-2} \mathscr{b} \subset \mathscr{K}_1$ and $\bigoplus_{i=3}^{k} A_F^{i-3} \mathscr{b} \subset \mathscr{K}_2$. Let $x_i(\varepsilon)$ and F_ε be as defined above. Then the following holds: there is constant C such that for all $i \in \underline{k}$:*

$$\| H_1 e^{(A_F + BF_\varepsilon)t} x_i(\varepsilon) \|_{L_1} \to 0 \quad \text{as } \varepsilon \to 0, \tag{7.7}$$

$$\| H_2 e^{(A_F + BF_\varepsilon)t} x_i(\varepsilon) \|_{L_1} \leqq C \quad \text{for all } \varepsilon. \tag{7.8}$$

□

Now, in order to complete a proof of Lemma 7.2, we need one more preliminary result. Up to now we have constructed a sequence of controlled invariant subspaces converging to a singly generated almost controllability subspace and defined a feedback map on each of these controlled invariant subspaces. By applying the decomposition theorem, Theorem 6.1, and applying the above construction to each $\mathscr{L}_j$ appearing in (6.1), we can find a sequence of controlled invariant subspaces $\mathscr{R}_\varepsilon$ converging to $\bigoplus_{i=1}^{m'} \mathscr{L}_i$. In the obvious way we can define a map F_ε on $\mathscr{R}_\varepsilon$. Now the question is, can we define F_ε appropriately on a subspace complementary to $\mathscr{R}_\varepsilon$? The next construction

theorem states that, indeed, we can. It is here that we will use the results on exact disturbance decoupling with stability constraints from § 4. In the following, $\mathcal{V}_b := \mathcal{V}_b(\mathcal{K}_1, \mathcal{K}_2)$, $\mathcal{V}_g := \mathcal{V}_g(\mathcal{K}_1, \mathcal{K}_2)$ and $\mathcal{R}_b := \mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2)$ are denoted:

THEOREM 7.5. *Consider the system* (1.1). *Let* Λ *be a symmetric set of* $\dim[(\langle A \mid \mathcal{B}\rangle + \mathcal{V}_g)/\mathcal{V}_b]$ *complex numbers. Then there is a map* $F_1 : \mathcal{X} \to \mathcal{U}$ *and a subspace* $\mathcal{Z} \subset \mathcal{X}$ *such that the following conditions are satisfied*:

$$(A + BF_1)\mathcal{V}_g \subset \mathcal{V}_g, \tag{7.9}$$

$$(A + BF_1)\mathcal{V}^*(\mathcal{K}_2) \subset \mathcal{V}^*(\mathcal{K}_2), \tag{7.10}$$

$$\sigma(A + BF_1 \mid \mathcal{V}_g/\mathcal{V}^*(\mathcal{K}_2)) \subset \mathbb{C}_g, \tag{7.11}$$

$$\mathcal{V}_b \oplus \mathcal{Z} = \mathcal{V}_g + \langle A \mid \mathcal{B}\rangle, \tag{7.12}$$

$$(A + BF_1)(\mathcal{V}_g \oplus \mathcal{Z}) \subset \mathcal{V}_g \oplus \mathcal{Z}, \tag{7.13}$$

$$\sigma(A + BF_1 \mid (\mathcal{V}_g \oplus \mathcal{Z})/\mathcal{V}_g) = \Lambda. \tag{7.14}$$

Proof. Let $F_0 : \mathcal{X} \to \mathcal{U}$ be a map that satisfies the conditions (4.1), (4.2) and (4.3) of Theorem 4.3. Let $P : \mathcal{X} \to \mathcal{X}/\mathcal{V}_g$ be the canonical projection. Let $(\bar{A}_{F_0}, \bar{B})$ be the system induced by (A_{F_0}, B) in the factor space $\mathcal{X}/\mathcal{V}_g$. Since $\mathcal{V}_b = \mathcal{V}_g + \mathcal{R}_b$ and $\ker P = \mathcal{V}_g$, we have $P\mathcal{V}_b = P\mathcal{R}_b$. By Lemma 2.4 and the fact that $\mathcal{R}_b$ is an almost controllability subspace, it follows that $P\mathcal{R}_b$ is an almost controllability subspace with respect to the system $(\bar{A}_{F_0}, \bar{B})$. By [22, Prop. 1.2], $P\langle A \mid \mathcal{B}\rangle = \langle \bar{A}_{F_0} \mid \operatorname{im} \bar{B}\rangle$. Let Λ be as above. It can easily be verified that $\#\Lambda = \dim[\langle \bar{A}_{F_0} \mid \operatorname{im} \bar{B}\rangle / P\mathcal{R}_b]$. Thus, we may apply Proposition 2.5 to find an $(\bar{A}_{F_0}, \bar{B})$-invariant subspace $\bar{\mathcal{Z}} \subset \mathcal{X}/\mathcal{V}_g$ and a map $\bar{F} : \mathcal{X}/\mathcal{V}_g \to \mathcal{U}$ such that

$$P\mathcal{R}_b \oplus \bar{\mathcal{Z}} = \langle \bar{A}_{F_0} \mid \operatorname{im} \bar{B}\rangle, \tag{7.15}$$

$$(\bar{A}_{F_0} + \bar{B}\bar{F})\bar{\mathcal{Z}} \subset \bar{\mathcal{Z}}, \tag{7.16}$$

$$\sigma(\bar{A}_{F_0} + \bar{B}\bar{F} \mid \bar{\mathcal{Z}}) = \Lambda. \tag{7.17}$$

Now let $\mathcal{Z} \subset \mathcal{X}$ be any subspace such that $P\mathcal{Z} = \bar{\mathcal{Z}}$ and $\mathcal{Z} \cap \mathcal{V}_g = \{0\}$. Define a map $F_1 : \mathcal{X} \to \mathcal{U}$ by $F_1 := F_0 + \bar{F}P$. We contend that the subspace $\mathcal{Z}$ and the map F_1 satisfy the claims of the theorem. To prove (7.9) to (7.11), note that $F_1 \mid \mathcal{V}_g = F_0 \mid \mathcal{V}_g$. The claim (7.12) can be proven as follows: From (7.15) we have $P(\mathcal{V}_b + \mathcal{Z}) = P\langle A \mid \mathcal{B}\rangle$. Hence, since $\mathcal{V}_g \subset \mathcal{V}_b$, $\mathcal{V}_b + \mathcal{Z} = \mathcal{V}_g + \langle A \mid \mathcal{B}\rangle$. Assume $x \in \mathcal{V}_b \cap \mathcal{Z}$. Then $Px \in P\mathcal{V}_b \cap \bar{\mathcal{Z}} = \{0\}$. Thus, $x \in \ker P \cap \mathcal{Z} = \mathcal{V}_g \cap \mathcal{Z} = \{0\}$. It follows that $\mathcal{V}_b + \mathcal{Z} = \mathcal{V}_b \oplus \mathcal{Z}$.

To prove (7.13), note by using (7.16) that $P(A + BF_1)(\mathcal{V}_g \oplus \mathcal{Z}) = P(A_{F_0} + B\bar{F}P)(\mathcal{V}_g \oplus \mathcal{Z}) = (\bar{A}_{F_0} + \bar{B}\bar{F}_1)\bar{\mathcal{Z}} \subset \bar{\mathcal{Z}} = P(\mathcal{V}_g \oplus \mathcal{Z})$. Finally, (7.14) follows immediately from (7.17). □

We are now in a position to complete the proof of Lemma 7.2:

Proof of Lemma 7.2. (i)⇒(ii). This follows immediately from the fact that the L_2-induced norm of a convolution operator is bounded from above by the L_1-norm of its kernel (see, for example, [2]).

(iii)⇒(i). In this part we will construct a sequence of feedback maps $\{F_\varepsilon;\ \varepsilon > 0\}$ such that, for each $x \in \mathcal{V}_b$, $\|H_1 T_\varepsilon x\|_{L_1} \to 0$ and $\|H_2 T_\varepsilon x\|_{L_1} \leqq C$ for all ε, for some constant C. The construction is divided into five steps:

1. *Decomposition.* Apply Theorem 6.1 to find a decomposition $\mathcal{V}_b = \mathcal{V}_g \oplus \bigoplus_{j=1}^{m'} \mathcal{L}_j$, with $\mathcal{L}_j = \bigoplus_{i=1}^{r_j} A_F^{i-1} b_j$, such that (6.2) and (6.3) hold.

2. *Approximation of singly generated controllability subspaces.* For each $\mathcal{L}_j$, apply the construction (7.3) to (7.6). Thus we find vectors $x_i^{(j)}(\varepsilon)$ $(i \in \underline{r}_j)$, subspaces $\mathcal{L}_{j\varepsilon} := \operatorname{span}\{x_i^{(j)}(\varepsilon);\ i \in \underline{r}_j\}$ and maps $F_{j\varepsilon} : \mathcal{L}_{j\varepsilon} \to \mathcal{U}$ such that

$$x_i^{(j)}(\varepsilon) \to A_F^{i-1} b_j; \qquad \mathcal{L}_{j\varepsilon} \to \mathcal{L}_j (\varepsilon \to 0). \tag{7.18}$$

Moreover, by applying Lemma 7.4, there are constants C_j such that

$$\|H_1 e^{(A_F+BF_{j\varepsilon})t}x_i^{(j)}(\varepsilon)\|_{L_1} \to 0 (\varepsilon \to 0), \tag{7.19}$$

$$\|H_2 e^{(A_F+BF_{j\varepsilon})t}x_i^{(j)}(\varepsilon)\|_{L_1} \leqq C \quad \text{for all } \varepsilon. \tag{7.20}$$

3. *Composition.* Since the $\mathscr{L}_j$ are independent, it follows from Lemma 2.8 that for ε sufficiently small the $\mathscr{L}_{j\varepsilon}$ ($j \in \underline{m}'$) are independent. Define $\mathscr{R}_\varepsilon := \mathscr{L}_{1\varepsilon} \oplus \cdots \oplus \mathscr{L}_{m'\varepsilon}$. It follows that $\mathscr{R}_\varepsilon \to \bigoplus_j \mathscr{L}_j$. Define now $F_\varepsilon^0 : \mathscr{R}_\varepsilon \to \mathscr{U}$ by defining $F_\varepsilon^0 | \mathscr{L}_{j\varepsilon} := (F + F_{j\varepsilon}) | \mathscr{L}_{j\varepsilon}$ ($j \in \underline{m}'$).

4. *Construction of feedback outside $\mathscr{R}_\varepsilon$.* To define a map on a complement of $\mathscr{R}_\varepsilon$, let $\Lambda \subset \mathbb{C}_g$ be a symmetric set of $\dim [(\langle A | \mathscr{B} \rangle + \mathscr{V}_g)/\mathscr{V}_b]$ complex numbers and apply the construction theorem Theorem 7.5 to find a subspace $\mathscr{Z} \subset \mathscr{X}$ and a map $F_1 : \mathscr{X} \to \mathscr{U}$ such that (7.9) to (7.14) are satisfied. In the remainder of this proof, denote $\bigoplus_{j=1}^{m'} \mathscr{L}_j$ by $\tilde{\mathscr{R}}_b$. We may then prove the following:

LEMMA 7.6. *For all ε sufficiently small the following holds*:

$$\mathscr{V}_g \oplus \tilde{\mathscr{R}}_b \oplus \mathscr{Z} = \mathscr{V}_g \oplus \mathscr{R}_\varepsilon \oplus \mathscr{Z}. \tag{7.21}$$

Proof. By Lemma 6.6, $\mathscr{V}_b \oplus \mathscr{Z} = \mathscr{V}_g \oplus \tilde{\mathscr{R}}_b \oplus \mathscr{Z}$. Since, for each ε, $\mathscr{R}_\varepsilon \subset \langle A | \mathscr{B} \rangle$ (Lemma 7.3), it follows from (7.12) that $\mathscr{R}_\varepsilon \subset \mathscr{V}_g \oplus \tilde{\mathscr{R}}_b \oplus \mathscr{Z}$. Since $\mathscr{R}_\varepsilon \to \tilde{\mathscr{R}}_b$, we obtain from Lemma 2.8 that $\mathscr{R}_\varepsilon \cap (\mathscr{V}_g \oplus \mathscr{Z}) = \{0\}$ for ε sufficiently small. The equality (7.21) now follows immediately by noting that for ε sufficiently small $\dim \mathscr{R}_\varepsilon = \dim \tilde{\mathscr{R}}_b$.

5. *Definition of the sequence* $\{F_\varepsilon; \varepsilon > 0\}$. Let $\mathscr{W}$ be an arbitrary subspace of $\mathscr{X}$ such that $\mathscr{X} = \mathscr{V}_g \oplus \mathscr{R}_\varepsilon \oplus \mathscr{Z} \oplus \mathscr{W}$. In this ($\varepsilon$-dependent) decomposition of $\mathscr{X}$ define $F_\varepsilon : \mathscr{X} \to \mathscr{U}$ by $F_\varepsilon | \mathscr{V}_g \oplus \mathscr{Z} := F_1 | \mathscr{V}_g \oplus \mathscr{Z}$, $F_\varepsilon | \mathscr{R}_\varepsilon = F_\varepsilon^0 | \mathscr{R}_\varepsilon$ and F_ε arbitrary on $\mathscr{W}$.

We contend that the sequence $\{F_\varepsilon; \varepsilon > 0\}$ defined in this way satisfies the condition (i) of Lemma 7.2. To prove this, first let $x \in \mathscr{V}_g$. Since $F_\varepsilon | \mathscr{V}_g = F_1 | \mathscr{V}_g$, we have by (7.9) and the fact that $\mathscr{V}_g \subset \mathscr{K}_1$ that $x \in \langle A_{F_\varepsilon} | \mathscr{V}_g \rangle \subset \mathscr{K}_1$ for all ε. Thus, for all ε, $H_1 T_\varepsilon(t)x = 0$ for all t. Let $\bar{A}_{F_1}$ and $\bar{H}_2$ be defined by the following commutative diagram (Fig. 2), in which P_1 is the canonical projection:

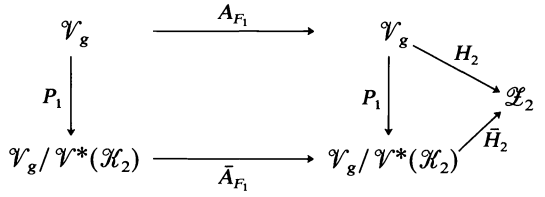

FIG. 2

We then have $H_2 T_\varepsilon(t)x = \bar{H}_2 e^{\bar{A}_{F_1}t}x$ for all ε. It follows from (7.11) that $H_2 T_\varepsilon x$ is in $L_1[0, \infty)$ with, obviously, L_1-norm independent of ε. To complete the proof it now suffices to show that for all $x \in \tilde{\mathscr{R}}_b$, $\|H_1 T_\varepsilon x\|_{L_1} \to 0$ and $\|H_2 T_\varepsilon x\|_{L_1}$ is uniformly bounded with respect to ε. Since $\tilde{\mathscr{R}}_b$ is spanned by the vectors $A_F^{s-1} b_l$, it suffices to take $x = A_F^{s-1} b_l$. By (7.21), we have $\tilde{\mathscr{R}}_b \subset \mathscr{V}_g \oplus \mathscr{R}_\varepsilon \oplus \mathscr{Z}$. Thus, there are vectors $v(\varepsilon) \in \mathscr{V}_g \oplus \mathscr{Z}$ and coefficients $\tau_{ij}(\varepsilon) \in \mathbb{R}$ such that

$$A_F^{s-1} b_l = v(\varepsilon) + \sum_{j=1}^{m'} \sum_{i=1}^{r_j} \tau_{ij}(\varepsilon) x_i^{(j)}(\varepsilon). \tag{7.22}$$

Since $x_i^{(j)}(\varepsilon) \to A_F^{i-1} b_j$, it can be proven by standard means that $v(\varepsilon) \to 0$, $\tau_{ij}(\varepsilon) \to 0$

$(i,j) \neq (s,l)$ and that $\tau_{sl}(\varepsilon) \to 1 (\varepsilon \to 0)$. Now, for $\alpha = 1, 2$ we have

$$\|H_\alpha T_\varepsilon A_F^{s-1} b_l\|_{L_1} \leqq \|H_\alpha e^{(A+BF_1)t} v(\varepsilon)\|_{L_1} + \sum_{j=1}^{m'} \sum_{i=1}^{r_j} |\tau_{ij}(\varepsilon)| \|H_\alpha e^{(A_F+BF_{j\varepsilon})t} x_i^{(j)}(\varepsilon)\|_{L_1}. \tag{7.23}$$

By (7.19), note that for $\alpha = 1$ the last term converges to 0 as $\varepsilon \to 0$. Using (7.20), it follows that for $\alpha = 2$ the last term is bounded from above, independent of ε.

Finally, we will show that for both $\alpha = 1, 2$ the first term on the right in (7.23) tends to 0 as $\varepsilon \to 0$. For this, let $\tilde{A}_{F_1}$ and $\tilde{H}_1$ be defined by the commutative diagram (Fig. 3) (P_2 is the canonical projection):

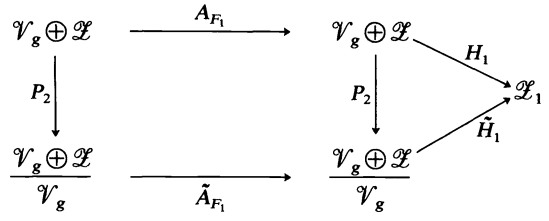

FIG. 3

By (7.14), note that $\sigma(\tilde{A}_{F_1}) = \Lambda \subset \mathbb{C}_g$. Moreover,

$$\|H_1 e^{A_{F_1} t} v(\varepsilon)\|_{L_1} = \|\tilde{H}_1 e^{\tilde{A}_{F_1} t} P_2 v(\varepsilon)\|_{L_1} \leqq \|\tilde{H}_1 e^{\tilde{A}_{F_1} t} P_2\|_{L_1} \|v(\varepsilon)\|.$$

Since $v(\varepsilon) \to 0$, this expression tends to 0 as $(\varepsilon \to 0)$.

Let $\hat{A}_{F_1}$ and $\hat{H}_2$ be defined by the commutative diagram (Fig. 4) (P_3 is the canonical projection):

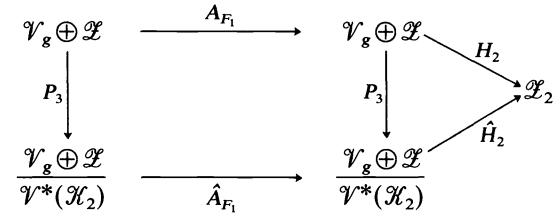

FIG. 4

It can be verified that $\sigma(\hat{A}_{F_1}) = \sigma(\tilde{A}_{F_1}) \cup \sigma(A_{F_1} | \mathscr{V}_g / \mathscr{V}^*(\mathscr{K}_2))$, which, by (7.11) and (7.14) is contained in $\mathbb{C}_g$. It follows that

$$\|H_2 e^{A_{F_1} t} v(\varepsilon)\|_{L_1} = \|\hat{H}_2 e^{\hat{A}_{F_1} t} P_3 v(\varepsilon)\|_{L_1} \leqq \|\hat{H}_2 e^{\hat{A}_{F_1} t} P_3\|_{L_1} \|v(\varepsilon)\|,$$

which again converges to 0 as $\varepsilon \to 0$. This completes the proof of Lemma 7.2. □

Remark 7.7. It is worthwhile to point out which freedom in the spectrum assignment we have in $A + BF_\varepsilon$ when we use the construction of the sequence $\{F_\varepsilon; \varepsilon > 0\}$ as in the proof of Lemma 7.2.

The lattice diagram (Fig. 5) shows the hierarchy of the relevant subspaces in combination with the freedom in the spectrum of $A + BF_\varepsilon$.

Denote $\mathscr{V}_\varepsilon := \mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2) \oplus R_\varepsilon$.

Note by Lemma 7.3 that the spectrum of the map $A + BF_\varepsilon | \mathscr{R}_\varepsilon$ consists of an eigenvalue in $-\varepsilon^{-1}$ with multiplicity equal to $\dim [\mathscr{V}_b / \mathscr{V}_g]$.

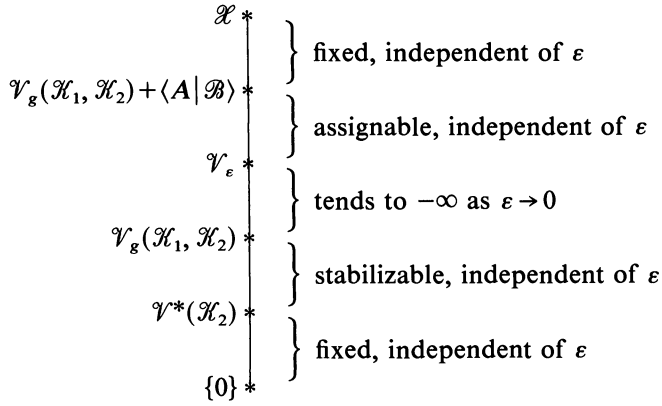

FIG. 5

8. Some special cases and extensions. In this section we will consider some special cases of the main theorem, Theorem 7.1, and spend a few words on some extensions of this result. One interesting special case of $(\text{ADDPBP})_p$ is the situation that we take $H_1 = H$ and $H_2 = I$. This corresponds to the almost disturbance decoupling problem with bounded peaking of the entire state vector. Denote $\mathscr{K} := \ker H$. Since, by Theorem 4.2, $\mathscr{V}_g(\mathscr{K}, \{0\}) = \mathscr{V}_g^*(\mathscr{K}) + \mathscr{V}^*(\{0\}) = \mathscr{V}_g^*(\mathscr{K})$ and since, by Theorem 6.3, $\mathscr{R}_b(\mathscr{K}, \{0\}) = \mathscr{B} + A(\mathscr{R}_b^*(\{0\}) \cap \mathscr{K}) = \mathscr{B} + A(\mathscr{B} \cap \mathscr{K})$, we have the following corollary of Theorem 7.1:

COROLLARY 8.1. *Fix $p \in \{1, 2, \infty\}$. Then the L_p-almost disturbance decoupling problem with bounded peaking of the entire state vector is solvable if and only if* $\operatorname{im} G \subset \mathscr{V}_g^*(\mathscr{K}) + \mathscr{B} + A(\mathscr{B} \cap \mathscr{K})$.

Next, we will spend some words on possible extensions of the results of this paper.

First we would like to point out that, while $(\text{ADDPBP})_p$ is a nontrivial extension of $(\text{ADDP})_p$, we might also consider an extension of the $L_P - L_q$ almost disturbance decoupling problem (ADDP)′, see [20] or [17]. This would lead to the following synthesis problem:

We will say that *the $L_p - L_q$ almost disturbance decoupling problem with bounded peaking* (ADDPBP)′ is solvable if there is a constant C and, for all $\varepsilon > 0$, a feedback map $F_\varepsilon : \mathscr{X} \to \mathscr{U}$ such that with the feedback law $u = F_\varepsilon x$, in the closed loop system for $x(0) = 0$ there holds, *for all* $1 \leqq p \leqq q \leqq \infty$, for all $d \in L_q[0, \infty)$

$$\|z_1\|_{L_p} \leqq \varepsilon \|d\|_{L_q}, \qquad \|z_2\|_{L_p} \leqq C \|d\|_{L_q}.$$

It may be shown that the solvability of the above problem is equivalent to the existence of a sequence of feedback maps $\{F_\varepsilon;\ \varepsilon > 0\}$ and a constant C such that for both $p = 1$ and $p = \infty$ $\|H_1 T_\varepsilon G\|_{L_p} \to 0 (\varepsilon \to 0)$ and $\|H_2 T_\varepsilon G\|_{L_p} \leqq C$ for all ε.

A theory analogous to the one above may be developed around this problem. It can be shown that, again under the assumption that either (A, B, H_1) is left-invertible or that H_2 is injective, a necessary and sufficient condition for the solvability of this problem is that

$$\operatorname{im} G \subset \mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2) + (\mathscr{R}_b^*(\mathscr{K}_2) \cap \mathscr{K}_1).$$

For more details, the reader is referred to [17].

A final extension of the results of the present paper is the situation in which we require internal stability of the closed loop system. This would lead to the following synthesis problem: We will say that *the L_p-almost disturbance decoupling problem with*

bounded peaking and strong stabilization $(\text{ADDPBPSS})_p$ is solvable if the following is true. There is a constant C and for all $\varepsilon > 0$ and all real numbers S a feedback map $F_{\varepsilon,S}: \mathscr{X} \to \mathscr{U}$ such that, with the feedback law $u = F_{\varepsilon,S}x$, in the closed loop system for $x(0) = 0$ for all $d \in L_p[0, \infty)$ the inequalities (3.2) and (3.3) hold and such that $\operatorname{Re} \sigma(A + BF_{\varepsilon,S}) \leqq S$.

Thus, we require that the spectrum of the closed loop matrix can be located to the left of any vertical line $\operatorname{Re} s = S$ in the complex plane. It may be proven that if at least one of the conditions (7.1), (7.2) hold, then for $p \in \{1, 2, \infty\}$ the latter problem is solvable if and only if (A, B) is controllable and

$$\operatorname{im} G \subset \mathscr{R}^*(\mathscr{K}_1) + \mathscr{R}_b(\mathscr{K}_1, \mathscr{K}_2). \tag{8.1}$$

We note that if (A, B, H_1) is a left-invertible system then the inclusion (8.1) becomes

$$\operatorname{im} G \subset \mathscr{B} + A[\mathscr{R}_b^*(\mathscr{K}_2) \cap \mathscr{K}_1],$$

(see Theorem 6.3). If H_2 is injective then (8.1) becomes

$$\operatorname{im} G \subset \mathscr{R}^*(\mathscr{K}_1) + \mathscr{B} + A[\mathscr{B} \cap \mathscr{K}_1].$$

Again, for details the reader is referred to [17].

9. A worked example. To illustrate the theory developed in this paper and to demonstrate its computational feasibility, in this section we will present a worked example. We will consider a linear system with two outputs and check whether $(\text{ADDPBP})_p$ is solvable for this system. Next, we will actually compute a sequence of feedback mappings that achieves our design purpose. The system that will be considered is given by $\dot{x}(t) = Ax(t) + Bu(t) + Gd(t)$, $z_1(t) = H_1x(t)$, $z_2(t) = H_2x(t)$, with

$$A = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad H_1 = (0\ 0\ 0\ 1\ 0), \quad H_2 = I_{5\times 5}$$

and

$$G = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}.$$

Thus, $\mathscr{X} = \mathbb{R}^5$ and $\mathscr{U} = \mathbb{R}^2$. Denote $\mathscr{K}_i = \ker H_i$. The route that we will take is as follows. First, we will check whether the subspace inclusion $\operatorname{im} G \subset \mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$ holds to see if $(\text{ADDPBP})_p$ is solvable. It turns out that this is indeed true. After this, we will follow closely the lines of the development in § 7 and construct a required sequence $\{F_n\}$. As before, $\mathbb{C}_g = \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda < 0\}$ and the subspaces $\mathscr{V}_g^*(\mathscr{K}_1)$ and $\mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2)$ are taken with respect to this stability set. Let the standard basis vectors in $\mathbb{R}^5$ be denoted by e_i.

Using the algorithm ISA (see [22, p. 91]) and a construction as in [22, p. 114], we calculate that $\mathscr{V}_g(\mathscr{K}_1, \mathscr{K}_2) = \mathscr{V}_g^*(\mathscr{K}_1) = \operatorname{span}\{e_1, e_2\}$ (since $\mathscr{V}^*(\mathscr{K}_2) = \{0\}$). Thus, by Theorem 4.4, DDPOS is not solvable for the above system. Since $\mathscr{K}_2 = \{0\}$, by Theorem 6.3 we should check if the subspace inclusion $\operatorname{im} G \subset \mathscr{V}_g^*(\mathscr{K}_1) + \mathscr{B} + A(\mathscr{B} \cap \mathscr{K}_1)$ holds. It may be calculated that $\mathscr{V}_g^*(\mathscr{K}_1) + \mathscr{B} + A(\mathscr{B} \cap \mathscr{K}_1) = \operatorname{span}\{e_1, e_2, e_4, e_5\}$. Since $\operatorname{im} G$ is

indeed contained in this subspace, $(\text{ADDPBP})_p$ is solvable for all $1 \leqq p \leqq \infty$. Unfortunately, $(\text{ADDPBPSS})_p$ is *not* solvable because (A, B) is an uncontrollable pair. We will now construct a required sequence of feedback mappings:

Step 1: *decomposition.* We decompose $\mathcal{V}_b = \mathcal{V}_g \oplus \tilde{\mathcal{W}}$, with $\tilde{\mathcal{W}} := \tilde{\mathcal{B}} + A(\tilde{\mathcal{B}} \cap \mathcal{K}_1)$ and $\tilde{\mathcal{B}}$ such that $\tilde{\mathcal{B}} \oplus (\mathcal{B} \cap \mathcal{V}^*(\mathcal{K}_1)) = \mathcal{B}$. Then $\tilde{\mathcal{W}} = \text{span}\{e_4, e_5\}$. Since $e_5 \in \mathcal{B}$ and $e_4 = Ae_5$, $\tilde{\mathcal{W}}$ is equal to the two-dimensional singly generated almost controllability subspace $\mathcal{b} \oplus A\mathcal{b}$, *where* $b = e_5$. Note that indeed (6.2) and (6.3) are satisfied.

Step 2: *approximation.* Approximate $\mathcal{b} \oplus A\mathcal{b}$ by (A, B)-invariant subspaces $\mathcal{R}_\varepsilon = \text{span}\{x_1(\varepsilon), x_2(\varepsilon)\}$ according to (7.3). In our case it can be calculated that $x_1(\varepsilon) = (0\,0\,-\varepsilon^2\,-\varepsilon\,1)^T$ and $x_2(\varepsilon) = Ab = (0\,0\,0\,1\,0)^T$. Note that $b = Bu$ with $u = \binom{0}{1}$. Following (7.5) for $\varepsilon > 0$ define $F_\varepsilon^0 : \mathcal{R}_\varepsilon \to \mathcal{U}$ by $F_\varepsilon^0 x_1(\varepsilon) = -\varepsilon^{-1}\binom{0}{1}$ and $F_\varepsilon^0 x_2(\varepsilon) = -\varepsilon^{-2}\binom{0}{1}$.

Step 3: *a feedback mapping outside* $\mathcal{R}_\varepsilon$. Note that for our system $\langle A \mid \mathcal{B} \rangle + \mathcal{V}_g = \mathcal{X}$. It can be verified that the conditions (7.9) to (7.14) are satisfied with $\Lambda = \{-3\}$; $\mathcal{Z} = \text{span}\{(0\,0\,1\,-3\,9)^T\}$ and $F_1 : \mathcal{Z} \to \mathcal{U}$ given by

$$F_1 = \begin{pmatrix} -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -3 \end{pmatrix}.$$

Step 4: *definition of the required sequence* $\{F_\varepsilon;\ \varepsilon > 0\}$. Note that $\mathcal{X} = \mathcal{V}_g \oplus \mathcal{R}_\varepsilon \oplus \mathcal{Z}$. In this decomposition define $F_\varepsilon | (\mathcal{V}_g \oplus \mathcal{Z}) := F_1 | (\mathcal{V}_g \oplus \mathcal{Z})$ and $F_\varepsilon | \mathcal{R}_\varepsilon := F_\varepsilon^0 | \mathcal{R}_\varepsilon$. It can be verified that the matrix of F_ε with respect to the standard bases in $\mathcal{X} = \mathcal{R}^5$ and $\mathcal{U} = \mathcal{R}^2$ is given by

$$F_\varepsilon := \begin{pmatrix} -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & f_{23}(\varepsilon) & -1/\varepsilon^2 & f_{25}(\varepsilon) \end{pmatrix},$$

where

$$f_{23}(\varepsilon) = \frac{-27\varepsilon^2 + 18\varepsilon - 3}{\varepsilon^2 + 9\varepsilon^4} \quad \text{and} \quad f_{25}(\varepsilon) = \frac{27\varepsilon^3 - 3\varepsilon - 2}{9\varepsilon^3 + \varepsilon}.$$

Finally, by valuating $A + BF_\varepsilon$ in the basis suggested by the decomposition $\mathcal{X} = \mathcal{V}_g \oplus \mathcal{R}_\varepsilon \oplus \mathcal{Z}$, we can calculate the closed loop impulse response matrices from d to z_1 and z_2, respectively:

$$W_{1\varepsilon}(t) := H_1 e^{(A+BF_\varepsilon)t} G = \left(\frac{t}{\varepsilon} + 1\right) e^{-t/\varepsilon},$$

$$W_{2\varepsilon}(t) := H_2 e^{(A+BF_\varepsilon)t} G = \begin{pmatrix} 0 \\ 0 \\ t \\ t/\varepsilon + 1 \\ -t/\varepsilon^2 \end{pmatrix} e^{-t/\varepsilon}.$$

A standard calculation shows that $\| W_{1\varepsilon} \|_{L_1} = 2\varepsilon \to 0$ and that

$$\| W_{2\varepsilon} \|_{L_1} = \int_0^\infty \| W_{2\varepsilon}(t) \|\, dt \leqq 1 + 2\varepsilon + \varepsilon^2.$$

Here, $\| \cdot \|$ denotes the Euclidean norm. From this it can be seen that indeed for every $1 \leqq p \leqq \infty$ the $L_p - L_p$ induced norm of the closed loop operator from d to z_1 tends to zero as $\varepsilon \to 0$ and that the induced norm of the operator from d to z_2 is bounded with respect to ε. Note that $\| F_\varepsilon \| \to \infty$ as $\varepsilon \to 0$.

10. Conclusions. In this paper we have developed a theory around the almost disturbance decoupling problem with bounded peaking. Necessary and sufficient conditions for the solvability of this synthesis problem were formulated in terms of a subspace inclusion involving a certain almost controlled invariant subspace. We showed that this almost controlled invariant subspace can be calculated using existing algorithms. We also provided a conceptual algorithm to calculate the sequence of feedback maps that achieve the design purpose. The calculations involved were illustrated in a numerical example.

Several questions remain to be answered. As a first direction for future research we mention the extension of the above results to the case that the system under consideration does not satisfy one of the conditions (7.1), (7.2), i.e., the system (A, B, H_1) is not left-invertible and the map H_2 is not injective. Another interesting issue would be to extend this theory to the more general situation that we allow only output feedback instead of state feedback. In this context we mention [21] and recent results in [18]. Finally, connections between this work and results on bounded peaking in the context of the nearly singular optimal control problem [3] remain to be worked out.

Appendix A. In this appendix we will establish a proof of Lemma 5.3. The proof will proceed through a series of lemmas. The first lemma is concerned with the convergence of sequence of rational functions and was proven in [7]. In the following, if $f(s)$ is a strictly proper rational function, then $\deg f$ will denote its McMillan degree. We have:

LEMMA A.1. *Let* $\{f_\varepsilon\}$ *be a sequence of strictly proper rational functions. Suppose that there exists* $r \in \mathbb{N}$ *such that* $\deg f_\varepsilon \leqq r$ *for all* ε. *Assume that* $\lim_{\varepsilon \to 0} f_\varepsilon(s)$ *exists for infinitely many* $s \in \mathbb{C}$. *Then there exists a rational function* f *such that* $f_\varepsilon(s) \to f(s)$ $(\varepsilon \to 0)$ *for all but finitely many* $s \in \mathbb{C}$. □

We can then prove the following:

LEMMA A.2. *Suppose that either the condition* (i) *or* (ii) *in Lemma* 5.3 *is satisfied. Then there are a rational vector* $\hat{z}(s)$, *proper and stable and, for* $i = 1, 2$, *subsequences* $\{\hat{z}_{i,\varepsilon'}(s)\}$ *such that* $\hat{z}_{1,\varepsilon'}(s) \to 0$ $(\varepsilon' \to 0)$ *and* $\hat{z}_{2,\varepsilon'}(s) \to \hat{z}(s)$ $(\varepsilon' \to 0)$ *for all but finitely many* s.

Proof. If the condition (i) of Lemma 5.3 holds, then for $\sigma := \operatorname{Re} s \geqq 0$:

$$\|\hat{z}_{i,\varepsilon}(s)\| \leqq \int_0^\infty e^{-\sigma t} \|z_{i,\varepsilon}(t)\| \, dt \leqq \|z_{i,\varepsilon}\|_{L_1}. \tag{A.1}$$

If the condition (ii) of Lemma 5.3 holds, then by the fact that $\hat{z}_{i,\varepsilon}(s)$ is strictly proper and has no poles in $\operatorname{Re} s \geqq 0$, applying the maximum modulus principle [8] gives, for all $\operatorname{Re} s \geqq 0$,

$$\|\hat{z}_{i,\varepsilon}(s)\| \leqq \sup_{\omega \in \mathbb{R}} \|\hat{z}_{i,\varepsilon}(i\omega)\|. \tag{A.2}$$

Hence, in both cases we have $\hat{z}_{1,\varepsilon}(s) \to 0$ $(\varepsilon \to 0)$ and $\|\hat{z}_{2,\varepsilon}(s)\| \leqq C \forall \varepsilon$. Since, for all ε, $\hat{z}_{2,\varepsilon}(s)$ is analytic in $\operatorname{Re} s > 0$ and since the sequence $\{\hat{z}_{2,\varepsilon}(s)\}$ is uniformly bounded there, by Vitali's theorem [8] there exists a function $\hat{z}(s)$, analytic in $\operatorname{Re} s > 0$, and a subsequence $\{\hat{z}_{2,\varepsilon'}(s)\}$ such that $\hat{z}_{2,\varepsilon'}(s) \to \hat{z}(s)$ $(\varepsilon' \to 0)$ *uniformly* on each compact set K in the open right half plane. Therefore, $\hat{z}_{2,\varepsilon'}(s) \to \hat{z}(s)$ $(\varepsilon' \to 0)$ pointwise in $\operatorname{Re} s > 0$. By Lemma A.1, we may assume that $\hat{z}_{2,\varepsilon'}(s) \to \hat{z}(s)$ $(\varepsilon' \to 0)$ *for all but finitely many* s and $\hat{z}(s)$ is *rational.* We contend that $\hat{z}(s)$ cannot have poles in $\operatorname{Re} s = 0$, for define $J := \{s \mid \operatorname{Re} s = 0, s \text{ is not a pole of } \hat{z}(s) \text{ and } \hat{z}_{2,\varepsilon'}(s) \to \hat{z}(s) \ (\varepsilon' \to 0)\}$. Then the complement of J in $\operatorname{Re} s = 0$ is a finite set. Suppose $s_0 \in J$. For ε' sufficiently small, $\|\hat{z}_{2,\varepsilon'}(s_0) - \hat{z}(s_0)\| \leqq 1$. Hence we have

$$\|\hat{z}(s_0)\| \leqq \|\hat{z}(s_0) - \hat{z}_{2,\varepsilon'}(s_0)\| + \|\hat{z}_{2,\varepsilon'}(s_0)\| \leqq 1 + C. \tag{A.3}$$

Therefore, $\hat{z}(s)$ is bounded on J and hence bounded on the entire imaginary axis. Also from (5.3) there follows that $\hat{z}(s)$ is *proper*. Finally, $\hat{z}_{1,\varepsilon'}(s) \to 0$ $(\varepsilon' \to 0)$ in Re $s \geqq 0$ and hence, again by Lemma A.1, for all but finitely many s. □

We will now complete the proof of Lemma 5.3. Recall that $u_\varepsilon(t)$ is a regular Bohl input and $z_{1,\varepsilon}(t) = H_1 x_\varepsilon(t)$, $z_{2,\varepsilon}(t) = H_2 x_\varepsilon(t)$, where $\dot{x}_\varepsilon = Ax_\varepsilon + Bu_\varepsilon$, $x_\varepsilon(0) = x_0$. We will prove that if either the condition (i) or (ii) in Lemma 5.3 is satisfied, then $x_0 \in \mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$:

Proof of Lemma 5.3. Let $F: \mathscr{X} \to \mathscr{U}$ be such that $A_F \mathscr{V}^*(\mathscr{K}_2) \subset \mathscr{V}^*(\mathscr{K}_2)$. Denote $v_\varepsilon(t) := u_\varepsilon(t) - Fx_\varepsilon(t)$. Then $\dot{x}_\varepsilon = A_F x_\varepsilon + Bv_\varepsilon$. Note that x_ε and v_ε have rational Laplace transforms. Let $P: \mathscr{X} \to \mathscr{X}/\mathscr{V}^*(\mathscr{K}_2)$ be the canonical projection and let $\overline{A_F}$ be the quotient map of A_F modulo $\mathscr{V}^*(\mathscr{K}_2)$. Let $\bar{B} := PB$ and let $\bar{H}_1$ and $\bar{H}_2$ be mappings such that $\bar{H}_1 P = H_1$ and $\bar{H}_2 P = H_2$. Decompose $\mathscr{U} = \mathscr{U}_1 \oplus \mathscr{U}_2$ with $\mathscr{U}_1 = \ker \bar{B}$ and $\mathscr{U}_2$ an arbitrary complement. Accordingly, partition $\bar{B} = (0, \bar{B}_2)$. Then $\bar{B}_2$ is injective. Let $\bar{G}(s) := \bar{H}_2(Is - \bar{A}_F)^{-1}\bar{B}_2$. Let $\bar{\mathscr{R}}^*(\bar{\mathscr{K}}_2)$ be the supremal controllability subspace in $\bar{\mathscr{K}}_2$ with respect to $(\bar{A}_F, \bar{B})$. By [22, Ex. 5.8], we have $\bar{\mathscr{R}}^*(\bar{\mathscr{K}}_2) = \{0\}$. Hence, by [22, Ex. 4.4], $\bar{G}(s)$ is a left-invertible rational matrix, with left-inverse $\bar{G}^+(s)$. Now, let $\xi_\varepsilon(s)$ and $\omega_\varepsilon(s)$ be the Laplace transforms of x_ε and v_ε respectively. Let $\bar{\xi}_\varepsilon(s) := P\xi_\varepsilon(s)$ and $\bar{x}_0 := Px_0$. Partition

$$\omega_\varepsilon(s) = \begin{pmatrix} \omega_{1,\varepsilon}(s) \\ \omega_{2,\varepsilon}(s) \end{pmatrix},$$

and conform the decomposition $\mathscr{U} = \mathscr{U}_1 \oplus \mathscr{U}_2$. The following relations then hold

$$x_0 = (Is - A_F)\xi_\varepsilon(s) - B\omega_\varepsilon(s), \tag{A.4}$$

$$\bar{x}_0 = (Is - \bar{A}_F)\bar{\xi}_\varepsilon(s) - \bar{B}_2\omega_{2,\varepsilon}(s), \tag{A.5}$$

and hence

$$\omega_{2,\varepsilon}(s) = \bar{G}^+(s)[\hat{z}_{2,\varepsilon}(s) - \bar{H}_2(Is - \bar{A}_F)^{-1}\bar{x}_0], \tag{A.6}$$

$$\bar{\xi}_\varepsilon(s) = (Is - \bar{A}_F)^{-1}(\bar{x}_0 + \bar{B}_2\omega_{2,\varepsilon}(s)). \tag{A.7}$$

Apply Lemma A.2 to obtain $\hat{z}(s)$ such that $\hat{z}_{2,\varepsilon}(s) \to \hat{z}(s)$ $(\varepsilon \to 0)$ for all but finitely many s (write ε in the subsequence for which this holds). It follows that there are rational vectors $\omega_2(s)$ and $\bar{\xi}(s)$ such that $\omega_{2,\varepsilon}(s) \to \omega_2(s)$ and $\bar{\xi}_\varepsilon(s) \to \bar{\xi}(s)$ for all but finitely many s. Define now

$$\omega(s) := \begin{pmatrix} 0 \\ \omega_2(s) \end{pmatrix}.$$

Then we have $\bar{x}_0 = (Is - \bar{A}_F)\bar{\xi}(s) - \bar{B}\omega(s)$. Moreover, since $\bar{H}_1\bar{\xi}_\varepsilon(s) = \hat{z}_{1,\varepsilon}(s) \to 0$ $(\varepsilon \to 0)$, we have $\bar{H}_1\bar{\xi}(s) = 0$. Also, since $\bar{H}_2\bar{\xi}_\varepsilon(s) = \hat{z}_{2,\varepsilon}(s) \to \hat{z}(s)$, $\bar{H}_2\bar{\xi}(s)$ is proper and stable.

Finally, let $\xi(s)$ be any rational vector such that $\bar{\xi}(s) = P\xi(s)$. Then $H_1\xi(s) = 0$, $H_2\xi(s)$ is proper and stable and, for some vector $x_1 \in \mathscr{V}^*(\mathscr{K}_2)$, $x_0 = (Is - A_F)\xi(s) - B\omega(s) + x_1$. It follows that $x_0 - x_1 \in \mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$. Since $\mathscr{V}^*(\mathscr{K}_2) \subset \mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$ we thus obtain $x_0 \in \mathscr{V}_b(\mathscr{K}_1, \mathscr{K}_2)$. This completes the proof of Lemma 5.3. □

Appendix B. In this appendix we will state and prove a result on the geometrical structure of the sequence of subspaces $\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)$, given by (6.8). Our result is a generalization of [19, Thm. 7.1] and deals with the representation of subspaces in terms of chains in the input space $\mathscr{B}$. Related results can be found in [14] and [10]. Further, in this appendix we will prove Lemma 6.5.

LEMMA B.1. *Given the system* $\dot{x} = Ax + Bu$ *and subspaces* $\mathscr{K}_2 \subset \mathscr{K}_1 \subset \mathscr{X}$, *let* $\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)$ *be defined by* (6.7) *and* (6.8). *Then the following holds: for all* $i \in \underline{n}$, *there are a chain* $\{\mathscr{B}_l\}_{l=1}^i$ *and a map* $F: \mathscr{X} \to \mathscr{U}$ *such that*

$$\mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2) = \bigoplus_{l=1}^{i} A_F^{l-1}\mathscr{B}_l, \tag{B.1}$$

$$\bigoplus_{l=2}^{i} A_F^{l-2}\mathscr{B}_l \subset \mathscr{K}_2, \tag{B.2}$$

$$\dim \mathscr{B}_l = \dim A_F^{l-1}\mathscr{B}_l = \dim [\mathscr{F}^l(\mathscr{K}_1, \mathscr{K}_2)/\mathscr{F}^{l-1}(\mathscr{K}_1, \mathscr{K}_2)] \qquad (l \in \underline{i}). \tag{B.3}$$

Remark. In the above, for consistence define $\bigoplus_{l=2}^{i} A_F^{l-2}\mathscr{B}_l = \{0\}$ if $i = 1$. In the following we will denote $\mathscr{F}^i := \mathscr{F}^i(\mathscr{K}_1, \mathscr{K}_2)$.

Proof. The proof is by induction. For $i = 1$, the lemma is trivially true: take $\mathscr{B}_1 := \mathscr{B} \cap \mathscr{K}_1$. Suppose now the lemma is true for i. Let $\{\mathscr{B}_l\}_{l=1}^i$ be a chain in $\mathscr{B}$ and F be a map such that the conditions (B.1), (B.2) and (B.3) are satisfied. We will show that $\mathscr{F}^{i+1}$ can also be represented as above. This will be done by constructing an *extra term* $\mathscr{B}_{i+1}$ for the chain $\{\mathscr{B}_l\}_{l=1}^i$ and by defining *a new feedback map* F_{new}. First, let $\mathscr{B}'_l$, $l \in \underline{i}$, be subspaces such that $\mathscr{B}'_l \oplus \mathscr{B}_l = \mathscr{B}_{l-1}$ (define $\mathscr{B}_0 := \mathscr{B}$). Using (B.1) we then have:

$$\begin{aligned}\mathscr{F}^i \cap \mathscr{K}_2 &= \left(\sum_{l=1}^{i} A_F^{l-1}(\mathscr{B}_{l+1} + \mathscr{B}'_{l+1}) + A_F^{i-1}\mathscr{B}_i\right) \cap \mathscr{K}_2 \\ &= \left(\sum_{l=1}^{i-1} A_F^{l-1}\mathscr{B}_{l+1} + \sum_{l=1}^{i-1} A_F^{l-1}\mathscr{B}'_{l+1} + A_F^{i-1}\mathscr{B}_i\right) \cap \mathscr{K}_2.\end{aligned}$$

Using the modular distributive rule [22, p. 4] and (B.2), it follows that

$$\mathscr{F}^i \cap \mathscr{K}_2 = \sum_{l=1}^{i} A_F^{l-1}\mathscr{B}_{l+1} + \left(\sum_{l=1}^{i-1} A_F^{l-1}\mathscr{B}'_{l+1} + A_F^{i-1}\mathscr{B}_i\right) \cap \mathscr{K}_2. \tag{B.4}$$

On the other hand, by (6.8),

$$\mathscr{F}^{i+1} = \mathscr{T}^{i+1}(\mathscr{K}_2) \cap \mathscr{K}_1 = (\mathscr{B} + A_F(\mathscr{T}^i(\mathscr{K}_2) \cap \mathscr{K}_2)) \cap \mathscr{K}_1. \tag{B.5}$$

Since, by the fact that $\mathscr{K}_2 \subset \mathscr{K}_1$, $\mathscr{T}^i(\mathscr{K}_2) \cap \mathscr{K}_2 = \mathscr{F}^i \cap \mathscr{K}_2$, it follows by combining (B.4) and (B.5)

$$\begin{aligned}\mathscr{F}^{i+1} &= \left(\mathscr{B} + \sum_{l=1}^{i} A_F^l\mathscr{B}_{l+1} + A_F\left[\left(\sum_{l=1}^{i-1} A_F^{l-1}\mathscr{B}'_{l+1} + A_F^{i-1}\mathscr{B}_i\right) \cap \mathscr{K}_2\right]\right) \cap \mathscr{K}_1 \\ &= (\mathscr{F}^i + \mathscr{G}) \cap \mathscr{K}_1.\end{aligned} \tag{B.6}$$

Here, we defined

$$\mathscr{G} := \mathscr{B}'_1 + A_F\left[\left(\sum_{l=1}^{i} A_F^{l-1}\mathscr{B}'_{l+1} + A_F^{i-1}\mathscr{B}_i\right) \cap \mathscr{K}_2\right].$$

Again using the modular distributive rule and $\mathscr{F}^i \subset \mathscr{K}_1$, we obtain

$$\mathscr{F}^{i+1} = \mathscr{F}^i + (\mathscr{G} \cap \mathscr{K}_1). \tag{B.7}$$

Let $\hat{\mathscr{G}} \subset \mathscr{G} \cap \mathscr{K}_1$ be a subspace such that $\mathscr{F}^{i+1} = \mathscr{F}^i \oplus \hat{\mathscr{G}}$ and let $\{v_1, \cdots, v_r\}$ be a basis for $\hat{\mathscr{G}}$. By definition of $\mathscr{G}$, each v_j can be represented as $v_j = \sum_{l=1}^{i} A_F^{l-1}b'_{l,j} + A_F^i b_j$, with

$$\sum_{l=2}^{i} A_F^{l-2}b'_{l,j} + A_F^{i-1}b_j \in \mathscr{K}_2. \tag{B.8}$$

Here, $b_j \in \mathcal{B}_i$ and $b'_{l,j} \in \mathcal{B}'_l$ ($j \in \underline{r}$, $l \in \underline{i}$). By the assumption that $\hat{\mathcal{G}} \cap \mathcal{F}^i = \{0\}$, it can be verified that for fixed $l \in \{0, \cdots, i\}$, the vectors $\{A_F^l b_1, \cdots, A_F^l b_r\}$ are linearly independent. Define now

$$\mathcal{B}_{i+1} := \text{span}\,\{b_1, \cdots, b_r\}. \tag{B.9}$$

Note that $\mathcal{B}_{i+1} \subset \mathcal{B}_i$. Also, for $l \in \underline{i}$, define vectors $x_{j,l}$ by

$$x_{j,i} := b_j,\ x_{j,l} := \sum_{k=1}^{l-1} A_F^{l-k-1} b'_{i-k+1,j} + A_F^{l-1} b_j. \tag{B.10}$$

From (B.10), for $l = 2, \cdots, i$ we have $x_{j,l} = A_F x_{j,l-1} + b'_{i-l+2,j}$ and $v_j = A_F x_{j,i} + b'_{i,j}$. Moreover, by the independency of the vectors $\{A_F^l b_j; j \in \underline{r}\}$ and by the fact that the spaces $A_F^{l-1}\mathcal{B}_l$ ($l \in \underline{i}$) are independent (the sum in (B.1) is direct), it can be shown that the vectors $\{x_{j,l}; j \in \underline{r}, l \in \underline{i}\}$ are linearly independent. Extend this system to a basis for $\mathcal{X}$. Let $u_{j,k} \in \mathcal{U}$ be such that $b'_{i-k+1,j} = Bu_{j,k}$ and define a map $F'' : \mathcal{X} \to \mathcal{U}$ by defining it in the above basis by $F'' x_{j,l} := u_{j,l}$ and F'' arbitrary on the extension. It can then be seen that for $l \in \underline{i}$

$$\begin{aligned} &\text{span}\,\{x_{1,l}, \cdots, x_{r,l}\} = (A_F + BF'')^{l-1}\mathcal{B}_{i+1}, \\ &\hat{\mathcal{G}} = \text{span}\,\{v_1, \cdots, v_r\} = (A_F + BF'')^i \mathcal{B}_{i+1} \end{aligned} \tag{B.11}$$

and, for $l = 1, \cdots, i-1$

$$BF''(A_F + BF'')^{l-1}\mathcal{B}_{i+1} \subset \mathcal{B}'_{i+1-l} \subset \mathcal{B}_1. \tag{B.12}$$

Let $\{\mathcal{B}''_l\}_{l=1}^i$ be a chain in $\mathcal{B}$ such that $\mathcal{B}_{i+1} \oplus \mathcal{B}''_l = \mathcal{B}_l$. Since $\mathcal{F}^{i+1} = \mathcal{F}^i \oplus \hat{\mathcal{G}}$, by (B.1) and (B.11) we obtain

$$\begin{aligned} \mathcal{F}^{i+1} &= \sum_{l=1}^{i} A_F^{l-1}\mathcal{B}_l + (A_F + BF'')^i \mathcal{B}_{i+1} \\ &= \sum_{l=1}^{i} A_F^{l-1}\mathcal{B}_{i+1} + (A_F + BF'')^i \mathcal{B}_{i+1} + \sum_{l=1}^{i} A_F^{l-1}\mathcal{B}''_l. \end{aligned}$$

Thus, by (B.1^):

$$\mathcal{F}^{i+1} = \sum_{l=1}^{i+1} (A_F + BF'')^{l-1}\mathcal{B}_{i+1} + \sum_{l=1}^{i} A_F^{l-1}\mathcal{B}''_l. \tag{B.13}$$

We contend that *all* sums in (B.13) are, in fact, direct sums. To prove this, assume the contrary. Then the following strict inequality must hold

$$\begin{aligned} \dim \mathcal{F}^{i+1} &< \sum_{l=1}^{i+1} \dim (A_F + BF'')^{l-1}\mathcal{B}_{i+1} + \sum_{l=1}^{i} \dim A_F^{l-1}\mathcal{B}''_l \\ &\leqq \sum_{l=1}^{i} \dim \mathcal{B}_{i+1} + \dim \hat{\mathcal{G}} + \sum_{l=1}^{i} \dim \mathcal{B}''_l = \sum_{l=1}^{i} \dim \mathcal{B}_l + \dim \hat{\mathcal{G}}, \end{aligned}$$

where the last equality follows from the fact that $\mathcal{B}_{i+1} \oplus \mathcal{B}''_l = \mathcal{B}_l$. On the other hand, however, $\dim \mathcal{F}^{i+1} = \dim \mathcal{F}^i + \dim \hat{\mathcal{G}}$, which by (B.3) and (B.1) equals $\sum_{l=1}^{i} \dim \mathcal{B}_l + \dim \hat{\mathcal{G}}$. Hence we obtain a contradiction. It follows that

$$\mathcal{F}^{i+1} = \bigoplus_{l=1}^{i+1} (A_F + BF'')^{l-1}\mathcal{B}_{i+1} \oplus \bigoplus_{l=1}^{i} A_F^{l-1}\mathcal{B}''_l. \tag{B.14}$$

Define $\mathcal{V} := \bigoplus_{l=1}^{i} (A_F + BF'')^{l-1}\mathcal{B}_{i+1}$ and $\mathcal{W} := \bigoplus_{l=1}^{i} A_F^{l-1}\mathcal{B}_l''$. By (B.14) we have that $\mathcal{V} \cap \mathcal{W} = \{0\}$. Decompose $\mathcal{X} = \mathcal{V} \oplus \mathcal{W} \oplus \mathcal{R}$, where $\mathcal{R}$ is arbitrary. In this decomposition, define $F_{\text{new}}: \mathcal{X} \to \mathcal{U}$ as follows

$$F_{\text{new}}|\mathcal{V} := (F + F'')|\mathcal{V}, \qquad F_{\text{new}}|\mathcal{W} := F|\mathcal{W} \tag{B.15}$$

and F_{new} arbitrary on $\mathcal{R}$. It can now be seen immediately from (B.14) that

$$\mathcal{F}^{i+1} = \bigoplus_{l=1}^{i+1} (A + BF_{\text{new}})^{l-1}\mathcal{B}_{i+1} \oplus \bigoplus_{l=1}^{i} (A + BF_{\text{new}})^{l-1}\mathcal{B}_l'' = \bigoplus_{l=1}^{i+1} (A + BF_{\text{new}})^{l-1}\mathcal{B}_l. \tag{B.16}$$

This already verifies (B.1). Next, we will verify (B.3).

It is claimed that for $l = 1, 2, \cdots, i+1$, $\dim (A + BF_{\text{new}})^{l-1}\mathcal{B}_l = \dim \mathcal{B}_l$. Suppose the contrary. Then we have

$$\begin{aligned} \sum_{l=1}^{i} \dim \mathcal{B}_l + \dim \hat{\mathcal{G}} = \dim \mathcal{F}^{i+1} &= \sum_{l=1}^{i+1} \dim (A + BF_{\text{new}})^{l-1}\mathcal{B}_l \\ &= \sum_{l=1}^{i} \dim (A + BF_{\text{new}})^{l-1}\mathcal{B}_l + \dim \hat{\mathcal{G}} \\ &< \sum_{l=1}^{i} \dim \mathcal{B}_l + \dim \hat{\mathcal{G}}, \end{aligned}$$

which is a contradiction. Equation (B.3) then follows immediately by noting that $\dim (A + BF_{\text{new}})^{i}\mathcal{B}_{i+1} = \dim \hat{\mathcal{G}} = \dim [\mathcal{F}^{i+1}/\mathcal{F}^{i}]$. Finally, it can be verified using (B.2), (B.8), (B.11) and (B.15) that $\bigoplus_{l=2}^{i+1} (A + BF_{\text{new}})^{l-2}\mathcal{B}_l \subset \mathcal{K}_2$. □

Remark B.2. Note that the proof of the above lemma is straightforward but notationally rather involved. An alternative proof could be given using the concept of train basis, see [14].

The above lemma is needed in the following:

Proof of Lemma 6.5. By Lemma B.1, there is a chain $\{\mathcal{B}_i\}_{i=1}^{n}$ in $\mathcal{B}$ and a map $F: \mathcal{X} \to \mathcal{U}$ such that $\mathcal{F}^n = \bigoplus_{i=1}^{n} A_F^{i-1}\mathcal{B}_i$ and such that (6.12) holds. Since $\mathcal{F}^n \subset \mathcal{K}_1$, also (6.11) holds. By (B.3), to prove (6.13) it is sufficient to show that, for $i \in \underline{n}$, $\dim A_F^{i-1}\mathcal{B}_i = \dim A_F^{i}\mathcal{B}_i$. Suppose the contrary, i.e., suppose that $\dim A_F^{i-1}\mathcal{B}_i > \dim A_F^{i}\mathcal{B}_i$ for some i. Then there is a vector $v \neq 0$ in $A_F^{i-1}\mathcal{B}_i$ such that $A_F v = 0$. Since a subspace $\mathcal{V} \subset \mathcal{X}$ is controlled invariant iff $A_F\mathcal{V} \subset \mathcal{V} + \mathcal{B}$ [22, Lemma 4.2] it follows that $\operatorname{span}\{v\}$ is controlled invariant. Since also $v \in \mathcal{K}_1$, v must be contained in $\mathcal{V}^*(\mathcal{K}_1)$, the largest controlled invariant subspace in $\mathcal{K}_1$. On the other hand, $v \in \mathcal{F}^n = \mathcal{R}_b^*(\mathcal{K}_2) \cap \mathcal{K}_1 \subset \mathcal{R}_b^*(\mathcal{K}_1) \cap \mathcal{K}_1$. By Lemma 2.2 it follows that $b \in \mathcal{R}_a^*(\mathcal{K}_1)$. Thus, $v \in \mathcal{R}_a^*(\mathcal{K}_1) \cap \mathcal{V}^*(\mathcal{K}_1)$, which by Lemma 2.2 contradicts the assumption that $\mathcal{R}^*(\mathcal{K}_1) = \{0\}$. Thus, we have proved formula (6.13).

Finally, to prove (6.10), note from (6.9) that $\mathcal{R}_b(\mathcal{K}_1, \mathcal{K}_2) = \mathcal{B} + A_F\mathcal{F}^n = \mathcal{B} + A_F\mathcal{B}_1 + \cdots + A_F^n\mathcal{B}_n$. It will be shown that this is, in fact, a direct sum. Suppose it is not. Then there are vectors $b_i \in \mathcal{B}_i$ and $b_0 \in \mathcal{B}$, not all zero, such that $\sum_{i=0}^{n} A_F^i b_i = 0$. Define $w := \sum_{i=1}^{n} A_F^{i-1} b_i$. Then we have $A_F w = -b_0 \in \mathcal{B}$. Since also $w \in \mathcal{K}_1$, w must be contained in $\mathcal{V}^*(\mathcal{K}_1)$. On the other hand, $w \in \mathcal{R}_a^*(\mathcal{K}_1)$, and it follows as above that $w = 0$. Hence, $b_0 = 0$. Repeating this argument with $w = \sum_{i=1}^{n} A_F^{i-1} b_i$ replaced by $w = \sum_{i=2}^{n} A_F^{i-2} b_i$ then yields $A_F w = -b_1$, and thus $b_1 = 0$, etc. In this way we find $b_i = 0$ $(i \in \underline{n})$, which is a contradiction. □

Appendix C. This appendix will be devoted to a proof of Lemma 7.4. The proof will be given through a series of smaller lemmas. For $\varepsilon > 0$, let $x_i(\varepsilon)$, $i \in \underline{k}$, a subspace $\mathcal{L}_\varepsilon$ and a map $F_\varepsilon: \mathcal{L}_\varepsilon \to \mathcal{U}$ be given by (7.3) to (7.5). Recall from Lemma 7.3 that a

matrix of the map $(A_F+BF_\varepsilon)|\mathscr{L}_\varepsilon$ with respect to the basis $X_\varepsilon := \{x_1(\varepsilon), \cdots, x_k(\varepsilon)\}$ is given by (7.6). Now, let $D_\varepsilon : \mathscr{L}_\varepsilon \to \mathscr{L}_\varepsilon$ be the linear map with matrix diag $(-1/\varepsilon, \cdots, -1/\varepsilon)$ with respect to X_ε. Define a nilpotent map $N_\varepsilon : \mathscr{L}_\varepsilon \to \mathscr{L}_\varepsilon$ by $N_\varepsilon := (A_F+BF_\varepsilon)|\mathscr{L}_\varepsilon - D_\varepsilon$. Obviously, the matrix of N_ε with respect to X_ε is given by

$$\text{(C.1)} \qquad \text{mat } N_\varepsilon = \begin{pmatrix} 0 & -\varepsilon^{-2} & \cdots & -\varepsilon^{-k} \\ 0 & 0 & \ddots & \vdots \\ \vdots & \vdots & \ddots & -\varepsilon^{-2} \\ 0 & 0 & \cdots & 0 \end{pmatrix}.$$

The following lemma is then immediate:

LEMMA C.1. *Let $i \in \underline{k}$. Then for $j = i, i+1, \cdots, k$ we have $N_\varepsilon^j x_i(\varepsilon) = 0$. On the other hand, for $j = 1, 2, \cdots, i-1$ the following holds*

$$\text{(C.2)} \qquad N_\varepsilon^j x_i(\varepsilon) = \sum_{l_1=1}^{i-1} \sum_{l_2=1}^{l_1-1} \cdots \sum_{l_j=1}^{l_{j-1}-1} (-1)^j \varepsilon^{l_j-i-j} x_{l_j}(\varepsilon).$$

(*For consistency, define $l_0 := i$.*)

Proof. Use (C.1) to obtain an expression for $N_\varepsilon x_i(\varepsilon)$. Apply N_ε to the result, etc. □

Another technical ingredient we will need in our proof is:

LEMMA C.2. *Let $i \in \underline{k}$. Then we have*

$$\text{(C.3)} \qquad x_i(\varepsilon) = A_F^{i-1} b - \varepsilon \sum_{l=1}^{i} A_F^{i-l+1} x_l(\varepsilon).$$

Proof. This follows immediately from (7.3), using induction. □

Finally, we will need the following result:

LEMMA C.3. *Under the assumptions of Lemma 7.4, the following holds for all $i \in \underline{k}$: $H_1 x_i(\varepsilon) = O(\varepsilon^{k-i})$ and $H_2 x_i(\varepsilon) = O(\varepsilon^{k-i-1})$.*

Proof. By iterating formula (C.3), we obtain

$$\begin{aligned} x_i(\varepsilon) = {} & A_F^{i-1} b - \varepsilon \sum_{l_1=1}^{i} A_F^i b + \varepsilon^2 \sum_{l_1=1}^{i} \sum_{l_2=1}^{l_1} A_F^{i+1} b + \cdots \\ & + (-\varepsilon)^{k-i-1} \left(\sum_{l_1=1}^{i} \sum_{l_2=1}^{l_1} \cdots \sum_{l_{k-i-1}=1}^{l_{k-i-2}} A_F^{k-2} b \right) \\ & + (-\varepsilon)^{k-i} \left(\sum_{l_1=1}^{i} \sum_{l_2=1}^{l_1} \cdots \sum_{l_{k-i}=1}^{l_{k-i-1}} A_F^{k-l_{k-i}} x_{l_{k-i}}(\varepsilon) \right) \end{aligned} \qquad \text{(C.4)}$$

(assume that $1 \leqq i \leqq k-2$). Under the assumptions of Lemma 7.4 we have $A_F^{i-1} b, \cdots, A_F^{k-3} b \in \mathscr{K}_2 \subset \mathscr{K}_1$ and $A_F^{k-2} b \in \mathscr{K}_1$. Thus, in (C.4) all terms but the last are in $\mathscr{K}_1$ and all terms but the last two are in $\mathscr{K}_2$. It follows then that $\lim_{\varepsilon \to 0} \varepsilon^{i-k} \cdot H_1 x_i(\varepsilon)$ exists and that $\lim_{\varepsilon \to 0} \varepsilon^{i+1-k} \cdot H_2 x_i(\varepsilon)$ exists.

For $i = k-1$, the existence of the former limit follows again from (C.4), while the existence of the latter is obvious. For $i = k$, the existence of both limits is obvious. □

Proof of Lemma 7.4. By the nilpotency of N_ε, note that for $i \in \underline{k}$

$$e^{(A_F+BF_\varepsilon)t} x_i(\varepsilon) = e^{N_\varepsilon t} e^{D_\varepsilon t} x_i(\varepsilon) = \left(\sum_{j=0}^{k-1} \frac{t^j N_\varepsilon^j}{j!} \right) e^{-(1/\varepsilon)t} x_i(\varepsilon).$$

By the triangle inequality it therefore suffices to prove the following: for $j = 0, 1, \cdots, k-1$, the sequence $\| t^j e^{-(1/\varepsilon)t} H_\alpha N_\varepsilon^j x_i(\varepsilon) \|_{L_1}$ tends to 0 as $\varepsilon \to 0$ for $\alpha = 1$ and is uniformly bounded with respect to ε if $\alpha = 2$. Since $\int_0^\infty t^j e^{-(1/\varepsilon)t} \, dt = j! \varepsilon^{j+1}$, it suffices to prove this asymptotic behaviour for $\| \varepsilon^{j+1} H_\alpha N_\varepsilon^j x_i(\varepsilon) \|$ (Euclidean norm!). Apply now Lemma

C.1 to obtain a representation of $N_\varepsilon^j x_i(\varepsilon)$. Again by the triangular inequality, it is then sufficient to prove that $\lim_{\varepsilon\to 0} \varepsilon^{j+1} H_\alpha \varepsilon^{l-i-j} x_l(\varepsilon)$ is 0 for $\alpha = 1$ and exists for $\alpha = 2$. (l is some index ranging between 1 and k.) Now, by Lemma C.3 $H_1 x_l(\varepsilon) = O(\varepsilon^{k-l})$ and $H_2 x_l(\varepsilon) = O(\varepsilon^{k-l-1})$. Thus, indeed $\lim_{\varepsilon\to 0} \varepsilon^{l-i-1} H_1 x_l(\varepsilon) = 0$ for *all* $l \in \underline{k}$ and $i \in \underline{k}$ and $\lim_{\varepsilon\to 0} \varepsilon^{l-i-1} H_2 x_l(\varepsilon)$ exists for *all* $l \in \underline{k}$ and $i \in \underline{k}$. This completes the proof of Lemma 7.4. □

Acknowledgments. The author would like to thank Professor Jan Willems for inspiring discussions and valuable comments and Dr. Kees Praagman for several helpful suggestions during the preparation of this paper.

DIAGONALLY MODIFIED CONDITIONAL GRADIENT METHODS FOR INPUT CONSTRAINED OPTIMAL CONTROL PROBLEMS*

J. C. DUNN†

Abstract. Many iterative methods for constrained minimization problems conform to the general scheme, $u_{i+1} \in A_i(\Omega, F, u_i)$, $u_1 \in \Omega$ where Ω is a set of feasible vectors in a Banach space X, F is a payoff function whose minimum is sought in Ω and A_i is a map with range in the set of subsets of Ω. If $\{(\Omega_i, F_i)\}$ is a sequence of related problems that approximate (Ω, F) in some sense, with $\Omega_i \subset \Omega_{i+1} \subset \Omega$, then the corresponding diagonal modification of the original algorithm generates iterates via the recursion, $u_{i+1} \in A_i(\Omega_i, F_i, u_i)$, $u_1 \in \Omega_1$. If (Ω_i, F_i) is properly selected, the diagonal modification can compute approximate solutions for (Ω, F) efficiently in circumstances where the original algorithm is difficult or impossible to implement for (Ω, F). In particular, this happens for certain gradient-related descent methods and increasingly refined finite-dimensional approximations to infinite-dimensional optimal control problems. Convergence rate estimates are obtained for a diagonally modified conditional gradient method, and this algorithm is applied to bounded input continuous-time optimal control problems.

Key words. conditional gradient method, diagonal modification, adaptive precision, optimal control, input constraints, convergence rates

AMS(MOS) subject classifications. 49D10, 49D37, 65B99

1. Introduction.

Conditional gradient algorithms belong to the general iterative scheme

$$u_{i+1} \in A_i(\Omega, F, u_i), \qquad u_1 \in \Omega \tag{1}$$

for $i = 1, 2, 3, \cdots$, where Ω is a set of "feasible" vectors in a real Banach space X, F is a real valued "payoff" function whose minimum is sought in Ω, and $A_i(\Omega, F, \cdot)$ is a map from X to the set of subsets of Ω, defined for each member of a certain class of problems (Ω, F). While it is often possible to clearly *imagine* the implementation of a given algorithm (1) and to determine its convergence properties *in theory*, an exact implementation may be computationally difficult (or even impossible) for certain (Ω, F)'s, and by design or otherwise one may end up generating iterates with

$$u_{i+1} \in A_i(\Omega_*, F_*, u_i), \qquad u_1 \in \Omega_*, \tag{2}$$

where (Ω_*, F_*) is in some sense close to the original problem. If (Ω_*, F_*) is held constant in (2), the iterates u_i will generally yield at best an approximate solution of (Ω, F) even in the limit as $i \to \infty$. On the other hand, if the quality of the approximation (Ω_*, F_*) is repeatedly upgraded during the iteration, the sequence $\{u_i\}$ may actually "solve" (Ω, F) as $i \to \infty$. In the simplest application of this basic principle, $\{u_i\}$ is recursively generated by

$$u_{i+1} \in A_i(\Omega_i, F_i, u_i), \qquad u_1 \in \Omega, \tag{3}$$

where $\{(\Omega_i, F_i)\}$ is a sequence of increasingly refined approximations to (Ω, F) satisfying

$$\Omega_i \subset \Omega_{i+1} \subset \Omega. \tag{4}$$

The iteration scheme (3) will be referred to here as a *diagonal modification* of (1) (see Fig. 1), following Tapia's terminology in [1].

$u_j^{(i)}$ = j^{th} iterate of (1.2) for $(\Omega_*, F_*) = (\Omega_i, F_i)$

u_i = i^{th} iterate of (1.3)

FIG. 1. *Diagonal modifications of* (1.1).

The so-called adaptive precision minimization algorithms formulated by Klessig and Polak [2] and Schittkowski [3] in the 1970's are essentially elaborations of (3) applied to Armijo rule descent methods for unconstrained minimization problems. These references deal extensively with "finite dimensional" approximations (Ω_i, F_i) to unconstrained Mayer final value problems (Ω, F), with

$$\Omega = \mathscr{L}^p([0,1], U), \tag{5a}$$

$$F(u(\cdot)) = P(x(1)), \tag{5b}$$

$$\frac{dx}{dt} = f(x, t, u(t)), \quad x \in \mathbb{R}^n, \quad t \in [0,1], \tag{5c}$$

$$x(0) = x_0, \tag{5d}$$

where $P: \mathbb{R}^n \to \mathbb{R}^1$ and $f: \mathbb{R}^n \times \mathbb{R}^1 \times \mathbb{R}^m \to \mathbb{R}^n$ are given functions, U is a given set in $\mathbb{R}^m$, $p \in [1, \infty)$ and x_0 is a given vector in $\mathbb{R}^n$. In reference [2], $U = \mathbb{R}^m$ and the corresponding approximations Ω_i consist of step functions in Ω that are *constant* on the intervals of a given net $\mathcal{N}_i$ for $[0,1]$, and the functions F_i are obtained by replacing the differential equation in (5) with an approximating *difference* equation on $\mathcal{N}_i$. Other possibilities for (Ω_i, F_i) are considered in [3]. Reference [2] describes two encouraging numerical experiments with an adaptive precision gradient method for (5), and shows that every subsequential limit of an iterate sequence produced by this method is a critical point of the limiting problem (Ω, F) under reasonable conditions on $\{(\Omega_i, F_i)\}$ and (Ω, F). Convergence theorems of a similar nature are established in [3]; however, convergence *rate* estimates are not developed in either study, and input constraints are not treated.

In the light of certain results developed in [4], [5] it seems likely that when $\{(\Omega_i, F_i)\}$ converges quickly enough to (Ω, F), the iterates generated by (1) and (3) will have the same *asymptotic* convergence properties, even though this may *not* be

true of (2) and (3) with (Ω_*, F_*) *fixed* at any particular (Ω_j, F_j) different from (Ω, F). This suggests that efficient computational procedures for a given (Ω, F) might be obtained by selecting an algorithm known to have good asymptotics for (Ω, F), and then implementing a diagonal modification of this algorithm with (Ω_i, F_i) chosen to simplify the computation of vectors in $A_i(\Omega_i, F_i, u)$, especially for small and moderate values of i. The guiding principle in the selection of (Ω_i, F_i) is to achieve reductions in computational cost mainly at the expense of degraded *asymptotics* for (2) with (Ω_*, F_*) fixed at any (Ω_j, F_j); so long as the latter algorithm substantially reduces F_j in the *first few* iterations, the diagonal modification (3) may well compute refined approximate solutions for (Ω, F) more efficiently than (2) for any fixed (Ω_*, F_*) near (Ω, F).

As outlined above, the diagonal modification principle amounts to a general strategy for deriving new and possibly more efficient iterative methods from existing algorithms. To realize the full potential of this idea in particular situations, it is necessary to know more about special structure in the problem at hand, and to exploit that structure in the selection of (1) and $\{(\Omega_i, F_i)\}$. Nevertheless, for large classes of minimization algorithms, problem structure influences the *asymptotic* behavior of (3) *only implicitly* through a few basic continuity, growth and convergence properties of (Ω, F) and $\{(\Omega_i, F_i)\}$, and for this reason it is possible to construct nontrivial general asymptotic convergence rate theories for (3) that can help in identifying likely candidate algorithms for diagonal modification in a variety of problem contexts. One such theory is formulated here for diagonal modifications of the conditional gradient method (DMCG). Together with certain results in [6]–[11], this theory indicates that DMCG methods should have acceptable asymptotic properties for bounded input versions of (5) with "bang-bang" solutions, notwithstanding the notoriously poor *generic* asymptotic behavior of the unmodified CG methods in finite-dimensional polytopes. Numerical results are also presented for a prototype bounded input control problem (5), and a DMCG method on nested nets $\mathcal{N}_i$ for $[0, 1]$. The net sequences employed in this example are generated by doubling the number of equally spaced net points at each iteration. Even for this crude scheme, i iterations of the DMCG appear to be $i/2$ times less costly than the same number of iterations of the unmodified CG method on the net $\mathcal{N}_i$. When $\mathcal{N}_i$ is highly refined, it should be noted that a single CG iterate is already much cheaper to implement than one iterate of a typical "higher order" method with better asymptotics.

The results presented here are part of a more extensive theory developed in [12] for diagonally modified recursive linear-quadratic programming methods.

2. A diagonally modified conditional gradient method. Let Ω be a nonempty convex set in a real Banach space X and suppose, without loss in generality, that X is the closed linear hull of Ω. Let F be a Frechet differentiable real valued function defined on some neighborhood of Ω in X, and assume that

$$\mathcal{T}(\Omega, F, u) \triangleq \arg\min_{v \in \Omega} F'(u)v \neq \varnothing, \qquad u \in \Omega \tag{1}$$

(this is certainly true if Ω is closed and bounded and X is reflexive). Fix δ in $(0, \frac{1}{2})$, and for $u \in \Omega$ and $\bar{u} \in \mathcal{T}(\Omega, F; u)$ let $W(\Omega, F; u, \bar{u})$ be a set of "step lengths" in $[0, 1]$ that satisfy Goldstein's rule [13], namely: for all $\omega \in W$,

$$\omega = 0 \quad \text{if } u \in \mathcal{T}(\Omega, F; u), \tag{2a}$$

$$\omega = 1 \quad \text{if } u \notin \mathcal{T}(\Omega, F; u) \quad \text{and} \quad \frac{F(u) - F(\bar{u})}{F'(u)(u - \bar{u})} \geqq \delta, \tag{2b}$$

$$\text{(2c)}\quad 1-\delta \geqq \frac{F(u)-F(u+\omega(\bar{u}-u))}{\omega F'(u)(u-\bar{u})} \geqq \delta \quad \text{if } u \notin \mathcal{T}(\Omega, F; u) \quad \text{and} \quad \frac{F(u)-F(\bar{u})}{F'(u)(u-\bar{u})} < \delta.$$

The associated recursion,

$$\text{(3a)}\qquad u_{i+1} = u_i + \omega_i(\bar{u}_i - u_i), \qquad u_1 \in \Omega,$$

$$\text{(3b)}\qquad \bar{u}_i \in \mathcal{T}(\Omega, F, u_i),$$

$$\text{(3c)}\qquad \omega_i \in W(\Omega, F; u_i, \bar{u}_i),$$

defines a *conditional gradient method* for the constrained minimization problem (Ω, F). For convex polyhedral sets in $\mathbb{R}^n$ and quadratic objective functions F, (3) reduces to the Frank-Wolf method with Goldstein step lengths.

Note 1. By definition ξ is an *extremal* of F in the set Ω iff

$$F'(\xi)(u-\xi) \geqq 0, \qquad u \in \Omega.$$

Equivalently,

$$u \text{ is an extremal of } F \text{ in } \Omega \Leftrightarrow \xi \in \mathcal{T}(\Omega, F; \xi).$$

Thus (3) "stops" at ξ iff ξ is an extremal. For convex Ω, every local minimizer of F in Ω is an extremal. For convex F, every extremal is a minimizer. □

For certain feasible sets Ω, the algorithm (3) costs little more to implement than simple unconstrained steepest descent. For example, if Ω is the unit cube,

$$\text{(4a)}\qquad \Omega = \{u \in \mathbb{R}^n : |u_j| \leqq 1; j = 1, 2, \cdots, n\},$$

then

$$\text{(4b)}\qquad \mathcal{T}(\Omega, F; u) = \left\{\bar{u} \in \Omega : \bar{u}_j \in -\operatorname{sgn}\frac{\partial F}{\partial u_j}(u); j = 1, 2, \cdots, n\right\}.$$

Similarly, if Ω is the unit simplex

$$\text{(5a)}\qquad \Omega = \left\{\bar{u} \in \mathbb{R}^n : \sum_{i=1}^{n} u_i = 1 \text{ and } u_i \geqq 0; i = 1, 2, \cdots, n\right\},$$

then

$$\text{(5b)}\qquad \mathcal{T}(\Omega, F; u) = \left\{\bar{u} \in \Omega : \sum_{j \in J} \bar{u}_j = 1 \text{ for } J = \arg\min_j \frac{\partial F}{\partial u_j}(u)\right\}.$$

More generally, if Ω is a convex polyhedral set in $\mathbb{R}^n$ then $\mathcal{T}(\Omega, F; u)$ consists of all solutions of a linear program with $F'(u)v$ as the objective function; if the linear constraints that define Ω are few in number, or are suitably structured, this program is easily solved and (3) is readily implemented. The sets $\mathcal{T}$ can also be written down at once for certain "round" convex sets Ω. Thus, if Ω is the unit ball,

$$\text{(6a)}\qquad \{u \in \mathbb{R}^n : \|u\| \leqq 1\},$$

then

$$\text{(6b)}\qquad \mathcal{T}(\Omega, F; u) = \begin{cases} \Omega & \text{if } \nabla F(u) = 0, \\ \left\{\dfrac{\nabla F(u)}{\|\nabla F(u)\|}\right\} & \text{if } \nabla F(u) \neq 0. \end{cases}$$

Still more generally, if Ω is a cartesian product

$$\text{(7a)}\qquad \Omega = \prod_{j=1}^{k} U^{(j)} = U^{(1)} \times U^{(2)} \times \cdots \times U^{(k)}$$

of convex sets $U^{(j)} \subset \mathbb{R}^{n_j}$, then

$$\mathcal{T}(\Omega, F; u) = \prod_{j=1}^{k} \arg \min_{v^{(j)} \in U^{(j)}} \nabla F^{(j)}(u) \cdot v^{(j)} \tag{7b}$$

where

$$\nabla F(u) = (\nabla F^{(1)}(u), \nabla F^{(2)}(u), \cdots, \nabla F^{(k)}(u)) \in \prod_{j=1}^{k} \mathbb{R}^{n_j}. \tag{7c}$$

Hence $\mathcal{T}(\Omega, F; u)$ will be easy to construct if the individual minimizer sets in (7b) are easy to compute.

Feasible sets with simple product structure arise naturally in discrete-time counterparts of the control problem (1.5). In fact, the set (1.5a) itself may be viewed as a kind of "infinite" product set with an associated decomposition formula analogous to (7b). Thus, for $p \in [1, \infty)$, let $q = p(p-1)^{-1} \in (1, \infty]$. If the real valued function F is Frechet differentiable at u in the set $\mathcal{L}^p([0, 1], \mathbb{R}^m)$, then by the Riesz representation theorem, there is a unique function g_u in $\mathcal{L}^q([0, 1], \mathbb{R}^m)$ such that,

$$F'(u)v = \int_0^1 g_u(t) \cdot v(t)\, dt, \qquad v \in \mathcal{L}^p([0, 1], \mathbb{R}^m) \tag{8}$$

where $\cdot$ signifies the standard inner product in $\mathbb{R}^m$. If U is a bounded closed convex set in $\mathbb{R}^m$ and if

$$\Omega = \mathcal{L}^p([0, 1], U) \tag{9a}$$

then it follows from (8) that

$$\mathcal{T}(\Omega, F; u) = \left\{ \bar{u} \in \mathcal{L}^p([0, 1], \mathbb{R}^m) \colon u(t) \overset{a.e.}{\in} \arg \min_{v \in U} g_u(t) \cdot v \right\}. \tag{9b}$$

This is the counterpart of formula (7b) for finite Cartesian products.

While the CG method (3) is easy to implement in specially structured finite-dimensional convex poyhedra, its generic convergence rate is known to be poor in *any* convex polyhedron [6]. On the other hand, when Ω is defined by nonlinear inequalities in $\mathbb{R}^n$, or when Ω is an *infinite* product of polyhedral sets U, the CG algorithm may converge well *in principle*, even though an exact computation of $\mathcal{T}(\Omega, F; u)$ is no longer possible [6], [7]. In such cases, one is led naturally to consider diagonally modified CG recursions

$$u_{i+1} = u_i + \omega_i(\bar{u}_i - u_i), \qquad u_1 \in \Omega, \tag{10a}$$

$$\bar{u}_i \in \mathcal{T}(\Omega_i, F_i; u_i), \tag{10b}$$

$$\omega_i \in W(\Omega_i, F_i; u_i, \bar{u}_i), \tag{10c}$$

$$\Omega_i \subset \Omega_{i+1} \subset \Omega, \tag{10d}$$

where F_i is Frechet differentiable on some neighborhood of Ω_i in the closed linear hull X_i of Ω_i, where $\{(\Omega_i, F_i)\}$ "converges" to (Ω, F) in some appropriate sense, and where $\mathcal{T}(\Omega_i, F_i; u)$ is relatively easy to compute, especially in the early iterations.

More specifically, $O(i^{-1})$ convergence is generic for (3) and convex F on convex polyhedral $\Omega \subset \mathbb{R}^n$ [6], [7]; however, *linear* convergence is generic for (3) and convex F on the set (9a), provided $p = 1$, F' is Lipschitz continuous, U is a convex polyhedron in $\mathbb{R}^m$, and the minimizer of F is a "bang-bang" (i.e., piecewise constant vertex-valued) function [4], [6]. Consider now that the set $\Omega = L^1([0, 1], U)$ is readily approximated

from below by sets Ω_i of *step functions* that have finite ranges in U and are constant on the subintervals of nets,

$$\mathcal{N}_i = \{t_0^{(i)}, t_1^{(i)}, \cdots, t_{n_i}^{(i)}\} \tag{11a}$$

with

$$0 = t_0^{(i)} < t_1^{(i)} < \cdots < t_{n_i}^{(i)} = 1, \tag{11b}$$

$$\mathcal{N}_i \subset \mathcal{N}_{i+1}, \qquad i = 1, 2, \cdots, \tag{11c}$$

$$\lim_{i \to \infty} \max_{1 \leqq j \leqq n_i} (t_j^{(i)} - t_{j-1}^{(i)}) = 0. \tag{11d}$$

In the case of (1.5), the objective function F is defined implicitly through a differential equation whose exact solutions are generally unknown, and hence F must also be approximated on the step function sets Ω_i; however, this is readily done by replacing (1.5c) with an approximating *difference* equation on the nets $\mathcal{N}_i$ (as in [2], [3]). Hence if U is a convex polyhedral set in $\mathbb{R}^m$, if (1.5) has a "bang-bang" solution, and if the nets $\mathcal{N}_i$ in (11) are refined quickly enough, it is plausible that the DMCG method will achieve the "theoretical" convergence rate for (3) and the limiting infinite-dimensional control problem (1.5). This conjecture is supported by the analysis in § 3, and by the numerical example in § 4. The results in § 3 can also be applied to continuous-time control problems in $\Omega = \mathcal{L}^p([0, 1], U)$, with U a "uniformly convex" set in $\mathbb{R}^m$.

3. Convergence rate estimates. When (Ω_*, F_*) is "close" to (Ω, F) it does *not* necessarily follow that the *asymptotic* convergence rate of (1.2) is like the corresponding rate for (1.1). For instance, it can happen that (Ω, F) has a "regular" minimizer for which (1.1) has good asymptotic properties, while (Ω_*, F_*) has a "singular" minimizer for which (1.2) behaves poorly. This point is illustrated in a control problem setting by the example in § 4 of [3], and § 4 of the present article. On the other hand, when (Ω_*, F_*) is near (Ω, F), these examples and the analysis in [5] show that (1.1) and (1.2) can behave similarly in the *exterior* of a small ball $B(\xi_*, \sigma_*)$ with radius σ_* and center $\xi_* \in \arg_{\Omega_*} \min F_*$, even though their asymptotic properties may be quite different *inside* the ball; in such cases the radius σ_* depends on the "distance" between (Ω_*, F_*) and (Ω, F) and typically *shrinks to zero* as $(\Omega_*, F_*) \to (\Omega, F)$ (roughly speaking, $B(\xi_*, \sigma_*)$ is like a "boundary-layer" in singular perturbation theory). These considerations suggest that the diagonal modifications (1.3) can have the *same* asymptotic behavior as (1.1) for (Ω, F) if the sequence $\{(\Omega_i, F_i)\}$ is chosen to make the balls $B(\xi_i, \sigma_i)$ shrink fast enough. This is the central idea in the convergence rate analysis presented below for conditional gradient method methods, and in the more extensive treatment of gradient-related methods in [12].

The convergence rate for the algorithm (2.3) is directly correlated with the growth properties of the local first order approximation $F'(\xi)\ (u - \xi)$ restricted to $u \in \Omega$ near a minimizer ξ for (Ω, F). To understand how this algorithm behaves for nearby problems (Ω_*, F_*), it is therefore important to know how the growth properties of $F'_*(\xi)(u - \xi_*)$ in Ω_* differ from those of $F'(\xi)(u - \xi)$ in Ω. A result of this kind is established in the following variant of Lemma 3.1 in [5].

LEMMA 1. *Let ξ and ξ_* be minimizers for (Ω, g) and (Ω_*, g_*) with $\Omega_* \subset \Omega$. Suppose that for some $a > 0$ and all $\sigma \geqq 0$*

$$\inf_{\substack{u \in \Omega \\ \|u - \xi\| \geqq \sigma}} g(u) - g(\xi) \geqq a\sigma^2. \tag{1}$$

Let a' be any fixed positive number less than a. Then for all $\varepsilon > 0$, the conditions

(2a) $$\sup_{u\in\Omega_*} |g(u) - g_*(u)| \leqq \frac{a\varepsilon^2}{3}$$

and

(2b) $$\inf_{u\in\Omega_*} g(u) - \inf_{u\in\Omega} g(u) \leqq \frac{a\varepsilon^2}{3}$$

imply that

(3) $$\|\xi - \xi_*\| \leqq \varepsilon$$

and

(4a) $$\inf_{\substack{u\in\Omega_* \\ \|u-\xi_*\|\geqq\sigma}} g_*(u) - g_*(\xi_*) \geqq a'\sigma^2$$

for

(4b) $$\sigma \geqq \sigma(\varepsilon) \triangleq 2a\varepsilon(a-a')^{-1}.$$

Proof. By hypothesis

$$\frac{a\varepsilon^2}{3} \geqq \inf_{u\in\Omega_*} g(u) - g(\xi) \geqq \inf_{u\in\Omega_*} g_*(u) - \frac{a\varepsilon^2}{3} - g(\xi)$$

$$= g_*(\xi_*) - \frac{a\varepsilon^2}{3} - g(\xi) \geqq g(\xi_*) - \frac{2a\varepsilon^2}{3} - g(\xi) \geqq a\|\xi_* - \xi\|^2 - \frac{2a\varepsilon^2}{3}.$$

Hence

$$\|\xi_* - \xi\| \leqq \varepsilon.$$

Furthermore, for all $u \in \Omega_*$,

$$g_*(u) - g_*(\xi_*) = g(u) - g(\xi) + g(\xi) - g_*(\xi_*) + g_*(u) - g(u)$$

$$\geqq g(u) - g(\xi) + g(\xi) - g_*(\xi_*) - \frac{a\varepsilon^2}{3}$$

and

$$g(\xi) - g_*(\xi_*) \geqq \inf_{u\in\Omega} g(u) - \inf_{u\in\Omega_*} g(u) - \frac{a\varepsilon^2}{3} \geqq \frac{-2a\varepsilon^2}{3}$$

and therefore,

$$g_*(\xi) - g_*(\xi_*) \geqq g(u) - g(\xi) - a\varepsilon^2.$$

Since $\Omega_* \subset \Omega$, and since $\|u - \xi_*\| \geqq \sigma$ implies that $\|u - \xi\| \geqq \sigma - \|\xi - \xi_*\| \geqq \sigma - \varepsilon$, it now follows that for all $\sigma \geqq \varepsilon$,

$$\inf_{\substack{u\in\Omega_* \\ \|u-\xi_*\|\geqq\sigma}} g_*(u) - g_*(\xi_*) \geqq \inf_{\substack{u\in\Omega \\ \|u-\xi\|\geqq\sigma-\varepsilon}} g(u) - g(\xi) - a\varepsilon^2$$

(5)

$$\geqq a[(\sigma-\varepsilon)^2 - \varepsilon^2] = a(\sigma^2 - 2\varepsilon\sigma).$$

Observe that

$$a(\sigma^2 - 2\varepsilon\sigma) \geqq a'\sigma^2$$

for all $\sigma \geqq \sigma(\varepsilon) = 2a\varepsilon(a-a')^{-1} > \varepsilon$ (Fig. 2). □

Note 1. *Inside* the ball with center ξ_* and radius $\sigma(\varepsilon)$, g_* may have an asymptotic growth rate completely different than g's growth rate near ξ.

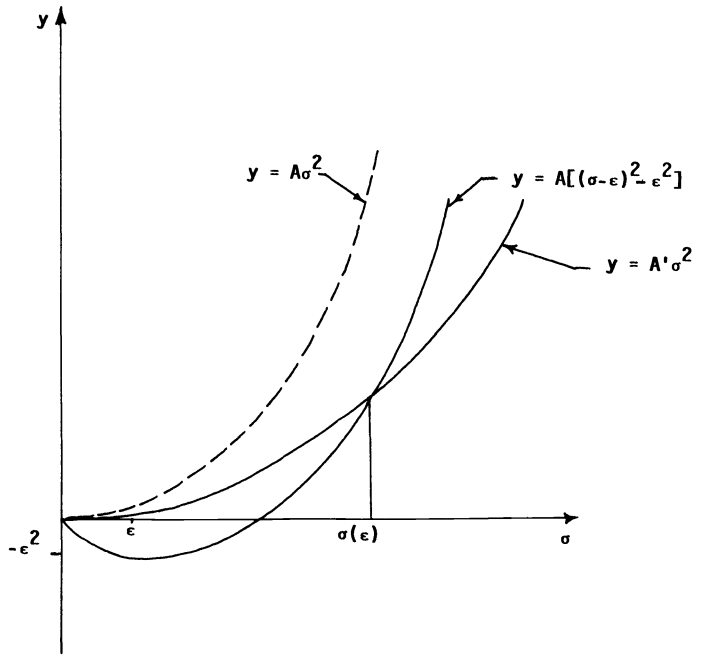

FIG. 2

Note 2. A result analogous to Lemma 1 is readily proved for *local* minimizers ξ, ξ_* satisfying

$$\inf_{\substack{u\in\Omega \\ \bar\sigma>\|u-\xi\|\geqq\sigma}} g(u)-g(\xi)\geqq a\sigma^2 \tag{6}$$

and

$$\|\xi-\xi_*\|<\bar\sigma \tag{7}$$

for some $a>0$, some $\bar\sigma>0$ and all $\sigma\in[0,\bar\sigma)$. In place of (4), one now obtains the growth condition

$$\inf_{\substack{u\in\Omega_* \\ \bar\sigma-\varepsilon>\|u-\xi_*\|\geqq\sigma}} g_*(u)-g_*(\xi_*)\geqq a'\sigma^2 \tag{8a}$$

for

$$\bar\sigma-\varepsilon\geqq\sigma\geqq\sigma(\varepsilon)=2a\varepsilon(a-a')^{-1}. \tag{8b}$$

In addition to Lemma 1, the convergence rate estimate in Theorem 1 below also depends on the following result.

LEMMA 2. *Let* $\{r_i\}$ *be a sequence of nonnegative real numbers such that for some* $\beta\in[0,1)$, $\lambda\in[0,1)$ *and* $c>0$,

$$r_{i+1}\leqq\beta r_i+c\lambda^i, \qquad i=1,2,3,\cdots. \tag{9}$$

If $\lambda\neq\beta$, *then*

$$r_i\leqq\beta^{i-1}r_1+\frac{c\lambda}{|\beta-\lambda|}\left|\beta^{i-1}-\lambda^{i-1}\right|, \qquad i=1,2,3,\cdots. \tag{10a}$$

On the other hand, if $\lambda = \beta$, *then*

$$r_i \leqq (r_1 + c(i-1))\beta^{i-1}, \qquad i = 1, 2, 3, \cdots. \tag{10b}$$

Proof. By induction,

$$r_i \leqq \beta^{i-1} r_1 + c \sum_{j=1}^{i-1} \beta^{i-j-1}\lambda^j \tag{11a}$$

and

$$(\beta - \lambda) \sum_{j=1}^{i-1} \beta^{i-j-1}\lambda^j = \lambda(\beta^{i-1} - \lambda^{i-1}) \tag{11b}$$

for $i = 2, 3, \cdots$. The inequalities (10) follow immediately from (11). □

With Lemmas 1 and 2, it is now possible to prove the following convergence rate theorem for the DMCG method (2.10). The growth condition (12) imposed in this theorem is known to hold for important classes of continuous-time optimal control problems (1.5) and for standard nonlinear programs in $\mathbb{R}^n$ with feasible sets Ω defined by finitely many uniformly convex inequalities (see Note 4 below).

THEOREM 1. *Let* Ω *be a nonempty convex set in a real Banach space* X, *let* F *be a convex Frechet differentiable real valued function defined on some neighborhood of* Ω *in* X, *and let* F *be Lipschitz continuous on bounded sets in* Ω. *Suppose that* ξ *minimizes* F *in* Ω *and that*

$$F'(\xi)(u - \xi) \geqq a\|u - \xi\|^2 \tag{12}$$

for some $a > 0$ *and all* $x \in \Omega$. *Let* $\{\Omega_i\}$ *be a nondecreasing sequence of nonempty convex subsets of* Ω, *and let* $\{F_i\}$ *be a sequence of convex Frechet differentiable real valued functions defined on neighborhoods of the corresponding sets* Ω_i *in their closed linear hulls* $X_i \subset X$. *Assume that* $\{F_i'\}$ *satisfies the uniform Lipschitz continuity condition*

$$\|F_i'(u) - F_i'(v)\| \triangleq \sup_{\substack{w \in X_i \\ \|w\| = 1}} |(F_i'(u) - F_i'(v))w| \leqq L\|u - v\| \tag{13}$$

for some $L > 0$, *all* $u, v \in \Omega_i$ *and* $i = 1, 2, 3, \cdots$. *In addition, let* $\{\xi_i\}$ *be a sequence of minimizers for the associated problems* (Ω_i, F_i), *and suppose that for some* $b > 0$, *some* $\lambda \in [0, 1)$ *and all* i,

$$\sup_{u \in \Omega_i} |F_i(u) - F(u)| \leqq b\lambda^i, \tag{14a}$$

$$\inf_{u \in \Omega_i} F(u) - \inf_{u \in \Omega} F(u) \leqq b\lambda^i, \tag{14b}$$

and

$$\sup_{u \in \Omega_i} |(F_i'(\xi_i) - F'(\xi))u| \leqq b\lambda^i. \tag{14c}$$

Finally, for $l > 0$, *let* S_l *denote the level set*

$$S_l = \{u \in \Omega: F(u) - F(\xi) \leqq l\}.$$

Then there is a number $\rho \in [0, 1)$, *independent of* l, *and positive numbers* C_1 *and* C_2 *depending on* l, *such that*

$$0 \leqq F(u_i) - F(\xi) \leqq C_1\rho^{i-1}, \qquad i = 1, 2, 3, \cdots \tag{15a}$$

and

$$0 \leqq F_i(u_i) - F_i(\xi_i) \leqq C_2\rho^{i-1}, \qquad i = 1, 2, 3, \cdots \tag{15b}$$

for every sequence $\{u_i\}$ that satisfies the diagonally modified conditional gradient recursion (2.10) *and originates at* $u_1 \in S_l$.

Proof. By Note 2.1, (14b) and the convexity of F,

$$\inf_{\Omega_i} F'(\xi)u - \inf_{\Omega} F'(\xi)u = \inf_{\Omega_i} F'(\xi)(u-\xi) \leqq \inf_{\Omega_i} F(u) - F(\xi) \leqq b\lambda^i. \tag{16}$$

Fix a' in $(0, a)$ and put

$$\alpha_1 = (12ab)^{1/2}(a-a')^{-1}, \tag{17a}$$

$$\alpha_2 = (3b/a)^{1/2}, \tag{17b}$$

$$\sigma_i = \alpha_1 \lambda^{i/2}. \tag{17c}$$

Let $g(u) = F'(\xi)u$ and $g_i(u) = F_i'(\xi_i)u$. Then by (12), (14), (16) and Lemma 1,

$$\|\xi_i - \xi\| \leqq \alpha_2 \lambda^{i/2} \tag{17d}$$

and

$$u \in \Omega_i \quad \text{and} \quad \|u - \xi_i\| \geqq \sigma_i \Rightarrow F_i'(\xi_i)(u-\xi_i) \geqq a'\|u-\xi_i\|^2. \tag{17e}$$

Let $\{u_i\}$ satisfy (2.10) with $\{\bar{u}_i\}$ and $\{\omega_i\}$, and put

$$r_i = F(u_i) - F(\xi) \geqq 0, \qquad i = 1, 2, 3, \cdots.$$

Suppose that

$$\|u_i - \xi_i\| < \sigma_i$$

for some particular value of i. Then by (17)

$$\|u_i - \xi\| \leqq \|u_i - \xi_i\| + \|\xi_i - \xi\| < (\alpha_1 + \alpha_2)\lambda^{i/2}. \tag{18}$$

Hence,

$$r_i \leqq K\|u_i - \xi\| \leqq \alpha_3 \lambda^{i/2} \tag{19a}$$

where K is a Lipschitz constant for F in the ball $\{u \in \Omega: \|u-\xi\| \leqq \alpha_1 + \alpha_2\}$, and

$$\alpha_3 = K(\alpha_1 + \alpha_2). \tag{19b}$$

It now follows from (2.10), (14) and (19) that

$$\begin{aligned} r_{i+1} &= F(u_{i+1}) - F(\xi) = F_i(u_{i+1}) + F(u_{i+1}) - F_i(u_{i+1}) - F(\xi) \\ &\leqq F_i(u_i) - F(\xi) + b\lambda^i \leqq r_i + 2b\lambda^i \leqq \alpha_4 \lambda^{i/2} \end{aligned} \tag{20a}$$

where

$$\alpha_4 = \alpha_3 + 2b\lambda^{1/2}. \tag{20b}$$

On the other hand, suppose that

$$\|u_i - \xi_i\| \geqq \sigma_i$$

for some particular i. Then (13), (14) and (17) can be used to estimate r_{i+1} as follows. First, observe that (2.10), (14) and the convexity of F_i imply that

$$\begin{aligned} r_i - r_{i+1} &= F(u_i) - F(u_{i+1}) \\ &= F_i(u_i) - F_i(u_{i+1}) + F(u_i) - F_i(u_i) + F_i(u_{i+1}) - F(u_{i+1}) \\ &\geqq \delta\omega_i F_1'(u_i)(u_i - \bar{u}_i) - 2b\lambda^i \\ &\geqq \delta\omega_i F_1'(u_i)(u_i - \xi_i) - 2b\lambda^i \\ &\geqq \delta\omega_i (F_i(u_i) - F_i(\xi_i)) - 2b\lambda^i \end{aligned} \tag{21}$$

and

$$|F_i(\xi_i) - F(\xi)| = \left|\inf_{\Omega_i} F_i = \inf_{\Omega} F\right| \leqq \left|\inf_{\Omega_i} F - \inf_{\Omega} F\right| + b\lambda^i \leqq 2b\lambda^i \tag{22}$$

and therefore

$$r_i - r_{i+1} \geqq \delta\omega_i r_i - 4b\lambda^i. \tag{23}$$

If $u_i \in \mathcal{T}(\Omega_i, F_i; u_i)$ then $r_i = 0$, by Note 2.1; in this case (23) gives

$$r_{i+1} \leqq 4b\lambda^i. \tag{24}$$

However, if $u_i \notin \mathcal{T}(\Omega_i, F_i; u_i)$ then $F_1'(u_i)(u_i - \bar{u}_i) > 0$, and (2.10), (13) and the Fundamental Theorem of Calculus imply that

$$\omega_i = 1 \tag{25a}$$

or

$$1 - \delta \geqq \frac{F_i(u_i) - F_i(u_{i+1})}{\omega_i F_i'(u_i)(u_i - \bar{u}_i)} \geqq 1 - \frac{\omega_i L\|u_i - \bar{u}_i\|^2}{2F_1'(u_i)(u_i - \bar{u}_i)}. \tag{25b}$$

Consequently, by (17) and the convexity of F_i,

$$\omega_i \geqq \min\left\{1, 2\delta\frac{F_1'(u_i)(u_i - \bar{u}_i)}{L\|u_i - \bar{u}_i\|^2}\right\} \geqq \min\left\{1, \frac{2\delta a'\|u_i - \xi_i\|^2}{L(\|u_i - \xi_i\| + \|\bar{u}_i - \xi_i\|)^2}\right\}. \tag{26}$$

Observe now that

$$\|\bar{u}_i - \xi_i\| < \sigma_i \Rightarrow \|\bar{u}_i - \xi_i\| < \|u_i - \xi_i\|$$

whereas

$$\begin{aligned}\|\bar{u}_i - \xi_i\| \geqq \sigma_i &\Rightarrow L\|u_i - \xi_i\| \cdot \|\bar{u}_i - \xi_i\| \\ &\geqq (F_i'(\xi_i) - F_i'(u_i))(\bar{u}_i - \xi_i) \geqq a'\|\bar{u}_i - \xi_i\|^2\end{aligned}$$

in view of (17). In all cases,

$$\|\bar{u}_i - \xi_i\| \leqq \gamma\|u_i - \xi_i\| \tag{27a}$$

with

$$\gamma = \max\left\{1, \frac{L}{a'}\right\}. \tag{27b}$$

With (23), (26) and (27) one obtains

$$\omega_i \geqq \omega \triangleq \min\left\{1, \frac{2\delta a'}{L(1+\gamma)^2}\right\} > 0 \tag{28a}$$

and

$$r_{i+1} \leqq \beta r_i + 4b\lambda^i \tag{28b}$$

with

$$\beta = \max\{0, 1 - \delta\omega\}. \tag{28c}$$

Together, the inequalities (20), (24) and (28) yield

$$r_{i+1} \leqq \beta r_i + c\lambda^{i/2} \tag{29a}$$

with

$$c = \max\{\alpha_4, 4b\lambda^{1/2}\}. \tag{29b}$$

If $\lambda \neq \beta$, then (10a) in Lemma 2 yields,

$$r_i \leqq C\rho^{i-1}, \qquad i = 1, 2, 3, \cdots \tag{30a}$$

with

$$\rho = \max\{\lambda, \beta\} \tag{30b}$$

and

$$C = r_1 + \frac{c\lambda}{|\beta - \lambda|}. \tag{30c}$$

On the other hand, if $\lambda = \beta$, let ρ be any fixed number in the interval

$$\beta < \rho < 1 \tag{31a}$$

and put

$$C = r_1 + c(e \ln(\rho/\beta))^{-1}. \tag{31b}$$

Since $x\mu^x \leqq -(e \ln \mu)^{-1}$ for $x \geqq 0$ and $\mu \in [0, 1)$, it now follows from (10b) that

$$r_i \leqq C\rho^{i-1}. \tag{31c}$$

Finally, (14), (22) and (30) or (31) imply that

$$F_i(u_i) - F_i(\xi_i) \leqq r_i + 3b\lambda^i \leqq (C + 3b\lambda)\rho^{i-1}, \qquad i = 1, 2, 3, \cdots. \tag{32}$$

Note 3. When $0 \leqq \lambda < \beta$, the factor ρ in (30)–(32) is equal to β, and β is essentially determined by parameters of the limiting problem (Ω, F). In fact, when $\lambda = 0$, (30) provides a convergence rate estimate for the unmodified CG method (2.3) applied to (Ω, F). This suggests that if λ is "sufficiently small" compared to β the DMCG method (2.10) ought to behave like (2.3) for (Ω, F), even though (2.3) may exhibit a much poorer asymptotic convergence rate when implemented for any one of the problems (Ω_i, F_i).

Note 4. If U is a polyhedral convex set in $\mathbb{R}^n$ and if $\Omega = \mathscr{L}^1([0, 1], U)$, then condition (12) typically holds in the $\mathscr{L}^1$ norm at "bang-bang" extremals, i.e., piecewise constant ξ with range in the vertex set for U [4], [6]. According to Lemma 1, (12) can therefore hold in the *exterior* of small neighborhoods of extremals ξ_* in polyhedral product approximations $\Omega_* = U^{n_*} \subset \mathbb{R}^{m \times n_*}$.

If Ω satisfies the uniform convexity condition,

$$x, y \in \Omega \quad \text{and} \quad \left\| z - \left(\frac{x+y}{2}\right)\right\| \leqq c\|x - y\|^2 \Rightarrow z \in \Omega \tag{33}$$

for some $c > 0$ and all x, y, z, and if $F'(\xi) \neq 0$ at an extremal in the boundary of Ω, then (12) holds with $a = 2c\|F'(\xi)\|$ [6]. The convexity condition (33) is satisfied by any ball in a Hilbert space, and more generally by sets defined by finitely many smooth convex nonlinear inequalities,

$$h_i(u) \leqq 0, \qquad i = 1, \cdots, l \tag{34a}$$

with

$$h_i''(u)vv \geqq \mu\|v\|^2 \tag{34b}$$

for some $\mu > 0$, all i, and all $u \in \Omega$ [6].

Finally, if $U \subset \mathbb{R}^m$ satisfies (33), and $\Omega = \mathscr{L}^1([0, 1], U)$, then (12) holds at extremals ξ with continuous nonvanishing Riesz representors g_ξ in (2.8) [10]; extremals of this type are continuous and have range in the boundary of U.

Note 5. The convexity conditions imposed on F and F_i in Theorem 1 may be replaced with the weaker "uniform pseudoconvexity" condition described in [8].

Note 6. A result analogous to Theorem 1 is established in [12] for projected gradient methods; in both cases, the proofs are readily modified for Armijo step lengths [14]. References [15] and [16] establish similar results for full-step Newton and quasi-Newton methods.

4. An optimal control problem. As explained earlier, the continuous-time optimal control problem (1.5) can be approximated by discrete-time problems (Ω_i, F_i), where the Ω_i's are sets of step functions that have range in the control input set U and are constant on intervals of the nets $\mathcal{N}_i$, and where the F_i's are computed by replacing the differential equation (1.5c) with a standard "numerical integrator" on $\mathcal{N}_i$ (for example, an Euler, modified Euler, or Runge-Kutta difference equation). Conditions (3.13) and (3.14) will hold for this type of approximation if the functions P and G are "sufficiently smooth" and the lengths of the largest intervals in $\mathcal{N}_i$ decrease geometrically with increasing i. Moreover, condition (3.12) typically holds in $\mathscr{L}^1$ if U is a convex polyhedron in $\mathbb{R}^m$ and (Ω, F) has a "bang-bang" solution ξ, or if U satisfies the uniform convexity condition (3.33) and $F'(\xi)$ has a continuous nonvanishing Riesz representor (Note 3.4). For control problems of this sort, Theorem 1 suggests that i iterations of the DMCG method (2.10) will yield values of F_i comparable to those produced by the same number of iterations of the CG method (2.3) for (Ω_i, F_i), provided the nets N_j are refined at a suitable rate for $1 \leqq j \leqq i$. If this is so, the DMCG method may have a decided advantage, since the cost of one CG iterate for (Ω_j, F_j) increases roughly in proportion to the number n_j of intervals in the net N_j. More precisely if $n_j \cong \nu^j$ for some $\nu > 1$, then

$$\frac{\text{CG cost } (i \text{ iterations for } (\Omega_i, F_i))}{\text{DMCG cost } (i \text{ iterations})} = in_i \left(\sum_{j=1}^{i} n_j \right)^{-1} \cong i\nu^i \cdot \left(\sum_{j=1}^{i} \nu^j \right)^{-1} = \frac{i(\nu-1)\nu^i}{\nu(\nu^i-1)} \geqq \frac{i(\nu-1)}{\nu}. \tag{1}$$

Example 1. Consider a particle of unit mass that moves along a straight line in response to a time-dependent force $u(t)$ whose magnitude cannot exceed 1. Suppose that at time $t = 0$ the particle's position coordinate x_1 and velocity x_2 are both zero. How should one choose $u(t)$ on the interval $0 \leqq t \leqq 1$ in order to make $x(1)$ large while keeping $|x_2(1)|$ small? There are several ways to formulate this problem in precise mathematical terms. For present purposes, the formulation (1.5) will serve with $p = 1$, $m = 1$, $n = 2$, $x_1(0) = x_2(0) = 0$, $U = [-1, 1]$, $f_1 = x_2$, $f_2 = u$, $P = -x_1 + \frac{1}{2}\Lambda x_2^2$, where Λ is a positive penalty constant (the larger the value assigned to Λ, the more stress is placed on bringing the particle to rest at $t = 1$). The corresponding optimal control problem (Ω, F) has a bang-bang solution,

$$\xi(t) = \begin{cases} 1, & 0 \leqq t < t_*, \\ -1, & t_* \leqq t \leqq 1, \end{cases} \tag{2a}$$

with

$$t_* = \frac{1+\Lambda}{1+2\Lambda}; \tag{2b}$$

and

$$F(\xi) = -\frac{1+\Lambda}{2(1+2\Lambda)}. \tag{3}$$

Moreover, this solution satisfies condition (3.12) in $\mathscr{L}^1$ [4].

Now let Ω_i consist of step function controls that have range in $[-1, 1]$ and are constant on intervals of the net $\mathcal{N}^{(i)} = \{t_0^{(i)}, t_1^{(i)}, \cdots t_{n_i}^{(i)}\}$ with

$$n_i = 2^i,$$
$$t_0^{(i)} = 0,$$
$$t_{l+1}^{(i)} = t_l^{(i)} + \Delta t_i, \qquad l = 0, 1, \cdots, n_i - 1,$$

and

$$\Delta t_i = \frac{1}{n_i}.$$

Construct F_i by replacing the differential equations $\dot{x}_1 = x_2$, $\dot{x}_2 = u(t)$ by a corresponding pair of modified Euler difference equations on the net $\mathcal{N}^{(i)}$. According to (1), i iterations of the CG method (2.3) applied to (Ω_i, F_i) will cost roughly $i/2$ times as much as i iterations of the DMCG method. Furthermore, numerical computations performed for this example indicate that i iterations of the two method produce comparable values of F_i. Some of these results are presented in Table 1 for $\Lambda = 6$ and $\delta = .1$.

(NOTE: Multiply entries by −1 to obtain payoff values $F_i(u_{i+1})$).

Table 1 contains four pairs of columns labelled A, B, C, D, corresponding to four different starting functions in Ω_1, namely $u_1^{\mathrm{A}}(\cdot) \equiv 1$, $u_1^{\mathrm{B}}(\cdot) \equiv 0$, $u_1^{\mathrm{C}}(\cdot) \equiv -.5$ and the step function $u^{\mathrm{D}}(\cdot)$ with $u^{\mathrm{D}}(t) = 1$ for $t \in [0, \frac{1}{2}]$ and $u^{\mathrm{D}}(t) = -1$ for $t \in (\frac{1}{2}, 1]$. The second column in each pair lists the values of $-F_i(u_{i+1})$ obtained after i iterations of the DMCG method, for $i = 1, 2, \cdots, 10$. The first column in each pair lists the corresponding values of $-F_i(u_{i+1})$ obtained by doing i iterations of the *unmodified* CG method for the *fixed* problem (Ω_i, F_i). It can be seen that for each i, the modified conditional gradient method typically produces a sub-optimal solution for (Ω_i, F_i) that is comparable to, or significantly better than, the approximate solution produced by the same number of iterations with the unmodified method. What is more, since DMCG uses crude nets in the early iterations, it is less costly to implement; in particular, for $i = 10$ DMCG has a better than 5 to 1 cost advantage over CG, as explained above.

Computations were halted in the present example after 10 iterations, since the simple grid refinement rule used here produces a net $\mathcal{N}_{10}$ with 1024 intervals; nevertheless for three out of four starting points, the DMCG values $F_{10}(u_{11})$ in Table 1 are already close to the optimal value $F(\xi) = -.2692\cdots$ for the *limiting continuous-time problem* (Ω, F) with $\Lambda = 6$ (see (3)). It seems likely that still better approximations to $F(\xi)$ could be obtained more efficiently with variable Δt nets $\mathcal{N}_i$ that increase in size more slowly than 2^i but concentrate their smallest intervals where the $(i-1)$st iterate function is changing most rapidly (for example, near "switching points"). It might also pay to increase the precision of the difference equation approximation as the iteration commences.

CONTROLLABILITY OF CONVEX PROCESSES*

JEAN-PIERRE AUBIN†, HALINA FRANKOWSKA† AND CZESŁAW OLECH‡

Abstract. The purpose of this paper is to provide several characterizations of controllability of differential inclusions whose right-hand sides are convex processes. Convex processes are the set-valued maps whose graphs are convex cones; they are the set-valued analogues of linear operators. Such differential inclusions include linear systems where the controls range over a convex cone (and not only a vector space). The characteristic properties are couched in terms of invariant cones by convex processes, or eigenvalues of convex processes, or a rank condition. We also show that controllability is equivalent to observability of the adjoint inclusion.

Key words. convex process, differential inclusion, tangent cone, duality, invariant cones, viability domain

AMS(MOS) subject classifications. 49A55, 93B05, 93C05, 93C10

Introduction. A *convex process* A from $\mathbb{R}^n$ to itself is a set-valued map satisfying

$$\forall x, y \in \operatorname{Dom} A, \quad \lambda, \mu \geqq 0, \qquad \lambda A(x) + \mu A(y) \subset A(\lambda x + \mu y), \tag{0.1}$$

or, equivalently, a set-valued map whose graph is a convex cone. Convex processes are the set-valued analogues of linear operators. We shall say that a convex process is *closed* if its graph is closed and that it is *strict* if its domain is the whole space.

We associate with a strict closed convex process A the Cauchy problem for the differential inclusion: find an absolutely continuous function $x(\cdot)$ satisfying

$$\text{for almost all } t \in [0, T], \quad x'(t) \in A(x(t)), \quad x(0) = 0. \tag{0.2}$$

We denote by R_T the *reachable set* at *time* T defined by

$$R_T := \{x(T) : x(\cdot) \text{ is a solution to (0.2)}\}. \tag{0.3}$$

We also say that

$$R := \bigcup_{T>0} R_T \text{ is the reachable set} \tag{0.4}$$

and that the differential inclusion (0.2) (or the convex process A) is *controllable* if the reachable set R is equal to the whole space $\mathbb{R}^n$.

Convex processes were introduced and thoroughly studied in Rockafellar [1967], [1970], [1974] and in Aubin and Ekeland [1984], for instance. Derivatives of set-valued maps (see Aubin and Ekeland [1984, Chap. 7]) provide examples of closed convex processes. These are used, for instance, in Frankowska [1984], [1985] for deriving local controllability of differential inclusions from the controllability of convex processes which "approximate" in some sense the original differential inclusion around the equilibrium:

THEOREM (Frankowska). *Let F be a set-valued map from $\mathbb{R}^n$ into the compact subsets of $\mathbb{R}^n$, Lipschitzian around zero and $0 \in F(0)$. Denote by $F'(0)$ the derivative of F at zero and by L the closed convex cone spanned by* co $F(0)$ *(convex hull of $F(0)$). Set*

$$A(x) = \operatorname{cl}(F'(0)x + L).$$

*Received by the editors November 16, 1984, and in revised form September 3, 1985.

‡ International Institute of Applied Systems Analysis, (IIASA) Laxenburg, Austria, and Institute of Mathematics, Polish Academy of Sciences, Warsaw, Poland.

Then the differential inclusion

$$x' \in F(x), \qquad x(0) = 0$$

is locally controllable around zero at time T if the "linearized" inclusion

$$x' \in A(x)$$

is controllable at time T.

We know that for linear problems the reachable sets are invariant. Hence we wish to extend the usual concept of invariant subspace by a linear operator. This can be done in two different ways: let A be a convex process and P be a closed convex cone contained in Dom A. We recall that the *tangent cone* $T_P(x)$ at a point $x \in P$ is defined by

$$T_P(x) := \operatorname{cl}\left(\bigcup_{h>0} \frac{1}{h}(P - x) \right) = \operatorname{cl}(P + \mathbb{R}x). \tag{0.5}$$

We shall say that P is *invariant by* A if

$$\forall x \in P, \qquad A(x) \subset T_P(x) \tag{0.6}$$

and that P is a *viability domain* for A if

$$\forall x \in P, \qquad A(x) \cap T_P(x) \neq \varnothing. \tag{0.7}$$

When P is a vector space, then $T_p(x) = P$, so that a subspace is invariant by A if $\forall x \in P$, $A(x) \subset P$ and is a viability domain for A if $\forall x \in P$, $A(x) \cap P \neq \varnothing$.

The first example of an invariant cone is provided by the closure of the reachable set.

THEOREM 0.1. *Let A be a strict closed convex process. Then the closure of the reachable set is the smallest closed convex cone invariant by A and the subspace $R - R$ spanned by R is the smallest subspace invariant by A.*

Furthermore, if $R - R = \mathbb{R}^n$ and $R \neq \mathbb{R}^n$, there exists $\lambda \in \mathbb{R}$ such that $\operatorname{Im}(A - \lambda I) \neq \mathbb{R}^n$.

We could say that a real number λ such that $\operatorname{Im}(A - \lambda I) \neq \mathbb{R}^n$ is an *eigenvalue of* A.

We shall prove this theorem by "duality." Indeed, convex processes can be transposed, as can linear operators. Let A be a convex process; we define its *transpose* A^* by

$$p \in A^*(q) \Leftrightarrow \forall (x, y) \in \operatorname{Graph} A, \langle p, x \rangle \leqq \langle q, y \rangle. \tag{0.8}$$

We also replace the orthogonality between subspaces by polarity between cones. If G is a subset of $\mathbb{R}^n$, we denote by G^+ its (positive) *polar cone* defined by

$$G^+ := \{ p \in \mathbb{R}^n \mid \forall x \in G, \langle p, x \rangle \geqq 0 \}. \tag{0.9}$$

We recall that the separation theorem implies that

$$G^{++} \text{ is the closed convex cone spanned by } G. \tag{0.10}$$

Therefore, it is convenient to bear in mind that

$$(q, p) \in \operatorname{Graph}(A^*) \Leftrightarrow (-p, q) \in \operatorname{Graph}(A)^+ \tag{0.11}$$

so that when A is a closed convex process, then $A = A^{**}$.

Example. Let F be a linear operator from $\mathbb{R}^n$ to itself, let L be a closed convex cone of controls and let A be the strict closed convex process defined by

$$A(x) := Fx + L. \tag{0.12}$$

Then its transpose is equal to

$$A^*(q) = \begin{cases} F^*q & \text{if } q \in L^+, \\ \varnothing & \text{if } q \notin L^+. \end{cases} \tag{0.13}$$

When $L = \{0\}$, i.e., when $A = F$, we deduce that $A^* = F^*$, so that transposition of convex processes is a legitimate extension of transposition of linear operators.

When A is a strict closed convex process, we shall prove that A^* is upper semi-continuous with convex compact values, that $A^*(0) = \{0\}$, $\operatorname{Dom} A^* = A(0)^+$ is closed and that the restriction of A^* to the vector space $\operatorname{Dom} A^* \cap -\operatorname{Dom} A^*$ is a linear (single-valued) operator.

As expected, we associate with the differential inclusion (0.2) the *adjoint inclusion*

$$\text{for almost all } t \in [0, T], \qquad -q'(t) \in A^*(q(t)). \tag{0.14}$$

We introduce the cones Q_T and Q defined by

$$\begin{aligned} &\text{i)} \quad Q_T := \{\eta \mid \exists q(\cdot), \text{ a solution to (0.14) satisfying } q(T) = \eta\}, \\ &\text{ii)} \quad Q := \bigcap_{T>0} Q_T. \end{aligned} \tag{0.15}$$

To say that $Q = \{0\}$ amounts to saying that the only solution to (0.14) defined on $[0, \infty[$ is $q \equiv 0$, or, in the language of systems theory, that the *adjoint system is observable.*

The "duality" method lies in the following statement.

THEOREM 0.2. *Let A be a strict closed convex process. Then*

$$R_T^+ = Q_T \quad \textit{and} \quad R^+ = Q. \tag{0.16}$$

Furthermore, a closed convex cone $P \supset A(0)$ is invariant by A if and only if its polar cone $P^+ \subset \operatorname{Dom} A^*$ is a viability domain for A^*.

Indeed, it allows one to derive Theorem 0.1 from

THEOREM 0.3. *Let A be a strict closed convex process. The cone Q is the largest closed convex cone which is a viability domain for A^* and $Q \cap -Q$ is the largest subspace invariant by (the linear operator) A^*.*

Furthermore, if Q is not reduced to $\{0\}$ and contains no line, there exists a solution $q \neq 0$ and $\lambda \in \mathbb{R}$ to the inclusion $\lambda q \in A^*(q)$.

We could say that such a q is an *eigenvector of A^**.

It will be convenient to introduce the following definition. We say that A satisfies the *rank condition* if

$$\begin{aligned} &\text{the subspace spanned by the cone } A^m(0) \text{ is the whole space} \\ &\mathbb{R}^n \text{ for some integer } m \geqq 1. \end{aligned} \tag{0.17}$$

This is motivated by the terminology used for linear systems. Indeed, when $A(x) := Fx + L$ where F is a linear operator and L is a convex cone of controls, we observe that $A^m(0) = L + FL + \cdots + F^{m-1}L$.

We shall derive from these results the following characterization of controllability of convex processes.

THEOREM 0.4. *Let A be a strict closed convex process. The following conditions are equivalent.*

(a) *differential inclusion* (0.2) *is controllable* (*i.e.*, $R = \mathbb{R}^n$),

(b) *differential inclusion* (0.2) *is controllable at some time* $T > 0$ (*i.e.*, $R_T = \mathbb{R}^n$),

(c) *the adjoint inclusion* (0.14) *is observable* (*i.e.*, $Q = \{0\}$),

(d) *the adjoint inclusion* (0.14) *is observable at some time* $T > 0$ (*i.e.*, $Q_T = \{0\}$),

(e) $\mathbb{R}^n$ *is the smallest closed convex cone invariant by A,*

(f) $\{0\}$ *is the largest closed convex cone which is a viability domain for* A^*,

(g) A *has neither proper invariant subspace nor eigenvalues,*

(h) A^* *has neither proper invariant subspace nor eigenvectors,*

(i) *the rank condition holds true and* A *has no eigenvalues,*

(j) *the rank condition is satisfied and* A^* *has no eigenvectors,*

(k) *for some* $m \geqq 1$, $A^m(0) = (-A)^m(0) = \mathbb{R}^n$.

Example. Let F be a linear operator from $\mathbb{R}^n$ to itself and let L be a closed convex cone of controls. We consider the differential inclusion

$$x'(t) \in Fx(t) + L, \qquad x(0) = 0, \tag{0.18}$$

and its adjoint inclusion

$$-q'(t) = F^*q(t), \qquad \forall t \geqq 0, \quad q(t) \in L^+. \tag{0.19}$$

COROLLARY 0.5. *The following conditions are equivalent:*

(a) *the system* (0.18) *is controllable,*

(b) *the adjoint equation* (0.19) *is observable* (*the only solution of* $-q' = F^*q$ *remaining in* L^+ *on* $[0, \infty[$ *is* $q \equiv 0$),

(c) $\{0\}$ *is the largest closed convex cone contained in* L^+ *which is invariant by* F^*,

(d) F^* *has neither proper invariant subspace contained in* L^+ *nor eigenvector in* L^+,

(e) *the subspace spanned by* $L, FL, \cdots, F^{n-1}L$ *is equal to* $\mathbb{R}^n$ *and* F^* *has no eigenvector in* L^+ (*see Brammer* [1972]),

(f) *for some* $m \geqq 1$, $L + FL + \cdots + F^mL = L - FL + \cdots + (-1)^mF^mL = \mathbb{R}^n$ (*see Korobov* [1980]).

This example also illustrates another advantage of duality, because some properties bearing on the adjoint system have a simpler formulation. This explains why some criteria mentioned in Theorem 0.4 disappear in Corollary 0.5.

When L is a vector space, statements (c), (d) and (f) are the same and the mention of eigenvector in statement (e) is redundant. This is not the case when L is a proper cone. It is sufficient to consider the example

$$x' \in -x + \mathbb{R}_+, \qquad x(0) = 0.$$

The rank condition is satisfied ($A^2(0) = \mathbb{R}$) and the reachable set is $\mathbb{R}_+$.

We summarize in § 1 the results on convex processes and their transpose that we will need later. Section 2 is devoted to the proof of the duality Theorem 0.2, characterizing the positive polar cones of the reachable set. We then derive the characterization of the closure of the reachable set as the smallest invariant cone by A and its dual version in § 3 and the existence of eigenvalues of A and eigenvectors of A^* in § 4. These results are used to prove Theorem 0.4 in § 5.

1. Convex processes and their transposes.

DEFINITION 1.1. A set-valued map from $\mathbb{R}^n$ to $\mathbb{R}^n$ is said to be a *convex process* if its graph is a convex cone. It is *closed* if its graph is closed. It is called *strict* if

$$\text{Dom } A := \{x \in \mathbb{R}^n \mid A(x) \neq \varnothing\} \text{ is the whole space.}$$

DEFINITION 1.2. Let X be a Hilbert space and let $G \subset X$ be a subset. We denote by G^+, the (positive) *polar cone* of G, the closed convex cone defined by

$$G^+ := \{p \in X^* \mid \forall x \in G, \langle p, x \rangle \geqq 0\}. \tag{1.1}$$

The separation theorem implies that the "bipolar" G^{++} is the closed convex cone spanned by G. We shall use the following consequence of this fact.

LEMMA 1.3 (closed image lemma). *Let X, Y be two Hilbert spaces, let ϕ be a continuous linear operator from X to Y and let L be a closed convex cone of Y. Assume that*

$$\text{Im } \phi - L = Y \quad (\textit{surjectivity condition}). \tag{1.2}$$

Then

$$\phi^{-1}(L)^+ = \phi^*(L^+). \tag{1.3}$$

Proof. (a) We prove first that $\phi^*(L^+)$ is closed. Let $q_n \in L^+$ be a sequence such that $\phi^*(q_n)$ converges to some p in X^* and let us prove that p belongs to $\phi^*(L^+)$.

We begin by showing that q_n is weakly bounded. Indeed, for any $v \in Y$, there exist $x \in X$ and $y \in L$ such that $v = \phi(x) - y$. Hence

$$\langle q_n, v\rangle = \langle \phi^*(q_n), x\rangle - \langle q_n, y\rangle \leqq \langle \phi^*(q_n), x\rangle \leqq \|\phi^*(q_n)\| \cdot \|x\|.$$

Therefore, since X is reflexive, the sequence q_n is in a weakly compact subset and a subsequence $q_{n'}$ converges weakly to some $q \in Y^*$. Since L^+ is closed and convex, and thus is weakly closed, q belongs to L^+. Since $\phi^*(q_{n'})$ converges weakly to $\phi^*(q)$ and strongly to p, we deduce that $p = \phi^*(q) \in \phi^*(L^+)$.

(b) We observe that $\phi^*(L^+)^+ = \phi^{-1}(L)$ because $x \in \phi^*(L^+)^+$ if and only if $\langle \phi^* q, x\rangle = \langle q, \phi(x)\rangle \geqq 0$ for all $q \in L^+$, i.e., if and only if $\phi(x)$ belongs to $L^{++} = L$. Hence, since $\phi^*(L^+)$ is closed, we deduce that

$$\phi^*(L^+) = \phi^*(L^+)^{++} = \phi^{-1}(L)^+. \qquad \square$$

We now recall some properties of convex processes, some of them already are known (see Rockafellar [1967], [1970, § 39], [1974], Aubin and Ekeland [1984, Chap. 3]).

DEFINITION 1.4. Let A be a convex process from $\mathbb{R}^n$ to itself. The transpose A^* of A is the set-valued map from $\mathbb{R}^n$ to itself given by

$$p \in A^*(q) \Leftrightarrow \forall (x, y) \in \text{Graph } (A), \qquad \langle p, x\rangle \leqq \langle q, y\rangle. \tag{1.4}$$

In other words,

$$(q, p) \in \text{Graph } (A^*) \Leftrightarrow (-p, q) \in (\text{Graph } A)^+. \tag{1.5}$$

The transpose of A^* is obviously a closed convex process and $A = A^{**}$ if and only if the convex process A is closed. When A is a linear operator its transpose as a linear operator coincides with its transpose as a convex process.

LEMMA 1.5. *If A is a closed convex process, then*

$$A(0) = (\text{Dom } A^*)^+. \tag{1.6}$$

Proof. We observe that y belongs to $A(0)$ if and only if $0 = \langle p, 0\rangle \leqq \langle q, y\rangle$ for all $q \in \text{Dom } A^*$ and $p \in A^*(q)$, i.e., if and only if $\langle q, y\rangle \geqq 0$ for all $q \in \text{Dom } A^*$. $\square$

DEFINITION 1.6. Let B denote the unit ball. When A is a closed convex process, we define

$$\|A\| := \sup_{x \in B \cap \text{Dom } A} \inf_{y \in A(x)} \|y\| \in [0, +\infty]. \tag{1.7}$$

PROPOSITION 1.7. *Let A be a strict closed convex process. Then*

(a) $\forall x, y \in \mathbb{R}^n$, $A(x) \subset A(y) + \|A\| \, \|x - y\| B$ *(i.e., A is Lipschitzian with finite Lipschitz constant equal to $\|A\|$).*

(b) $\text{Dom } A^* = A(0)^+$ *and A^* is upper semicontinuous with compact convex images, mapping the unit ball into the ball or radius $\|A\|$.*

(c) *The restriction of* A^* *to the vector space* $\operatorname{Dom} A^* \cap -\operatorname{Dom} A^*$ *is single-valued and linear* (*and thus,* $A^*(0)=0$).

Proof. (a) The first statement is a reformulation of the Robinson-Ursescu theorem (see Robinson [1972], Ursescu [1975], and Aubin and Ekeland [1984, Cor. 3.3.3, p. 132]).

(b) We observe that

$$\forall q \in \operatorname{Dom} A^*, \qquad \sup_{p \in A^*(q)} \|p\| \leqq \|A\| \|q\|, \tag{1.8}$$

because for all $x \in \operatorname{Dom} A = \mathbb{R}^n$ and for all $p \in A^*(q)$ we have

$$\|p\| = \sup_{x \in \mathbb{R}^n} \frac{\langle p, x\rangle}{\|x\|} \leqq \sup_{x \in \mathbb{R}^n} \inf_{y \in A(x)} \frac{\langle q, y\rangle}{\|x\|}$$

$$\leqq \sup_{x \in \mathbb{R}^n} \inf_{y \in A(x)} \frac{\|q\| \|y\|}{\|x\|} = \|A\| \|q\|.$$

Then A^* maps bounded sets to bounded sets. Since its graph is a closed convex cone we deduce that A^* is upper semicontinuous with compact convex images. By Lemma 1.5, $\operatorname{Dom} A^* = A(0)^+$. Therefore it remains to prove that $\operatorname{Dom} A^*$ is closed. Indeed let $q_n \in \operatorname{Dom} A^*$ be a sequence converging to some q and let $p_n \in A^*(q_n)$. The sequence $\{p_n\}$ being bounded contains a subsequence $\{p_{n'}\}$ converging to some p. Thus

$$(q, p) = \lim_{n' \to \infty} (q_{n'}, p_{n'}), \qquad (q_{n'}, p_{n'}) \in \operatorname{graph} A^*.$$

The graph of A^* being closed, we proved that $q \in \operatorname{Dom} A^*$.

Statement (c) follows from Rockafellar [1970, Thm. 39.1, p. 414]. □

We observe that we always have

$$\sup_{p \in A^*(q_0)} \langle p, x_0\rangle \leqq \inf_{y \in A(x)} \langle q_0, y\rangle.$$

LEMMA 1.8. *Let* A *be a closed convex process.*

For any $x_0 \in \operatorname{Int} \operatorname{Dom} A$, *and* $q_0 \in \operatorname{Dom} A^*$,

$$\sup_{p \in A^*(q_0)} \langle p, x_0\rangle = \inf_{y \in A(x_0)} \langle q_0, y\rangle. \tag{1.9}$$

(See Rockafellar [1970, Thm. 39.3, p. 419]).

We now extend to the case of closed convex cones the concepts of invariant subspace. When K is a subspace and F is a linear operator, we recall that K is invariant by F when $Fx \in K$ for all $x \in K$. When A is a convex process, there are two ways of extending this notion: we shall say that K is invariant by A if, for any $x \in K$, $A(x) \subset K$ and that K is a viability domain for A if, for any $x \in K$, $A(x) \cap K \neq \emptyset$. We also need to extend these notions to the case when K is a closed convex cone. For that purpose, we recall the

DEFINITION 1.9. If K is a closed convex set and x belongs to K, we say that

$$T_K(x) := \operatorname{cl}\left(\bigcup_{h>0} \frac{1}{h}(K - x) \right)$$

is the *tangent cone* to K at x.

LEMMA 1.10. *When* K *is a vector subspace, then for all* $x \in K$, $T_K(x) = K$ *and when* K *is a closed convex cone then,*

$$\forall x \in K, \qquad T_K(x) = \operatorname{cl}(K + \mathbb{R}x). \tag{1.10}$$

(See Aubin and Ekeland [1984, Prop. 4.1.9, p. 171]).

Now, we can introduce

DEFINITION 1.11. Let K be a closed convex cone and let A be a convex process. We say that K is *invariant* by A if

$$\forall x \in K, \quad A(x) \subset T_K(x) \tag{1.11}$$

and that K is a *viability domain* for A if

$$\forall x \in K, \quad A(x) \cap T_K(x) \neq \emptyset. \tag{1.12}$$

These are dual notions, as the following proposition shows.

PROPOSITION 1.12. *Let A be a strict closed convex process and let K be a closed convex cone containing $A(0)$. Then K is invariant by A if and only if K^+ is a viability domain for A^*.*

Proof. By Proposition 1.7 (b) the condition $A(0) \subset K$ implies that $K^+ \subset A(0)^+ = \text{Dom } A^*$. To say that K is invariant by A amounts to saying that

$$\forall x \in K, \quad \forall q \in T_K(x)^+, \quad \inf_{y \in A(x)} \langle q, y \rangle \geqq 0. \tag{1.13}$$

Lemma 1.10 states $T_K(x) = \text{cl}\,(\mathbb{R}x + K)$, $T_{K^+}(q) = \text{cl}\,(\mathbb{R}q + K^+)$. Therefore

$$q \in T_K(x)^+ \Leftrightarrow \{\langle q, x \rangle = 0, x \in K, q \in K^+\} \Leftrightarrow x \in T_{K^+}(q)^+. \tag{1.14}$$

On the other hand, Lemma 1.8 implies that

$$\inf_{y \in A(x)} \langle q, y \rangle = \sup_{p \in A^*(q)} \langle p, x \rangle.$$

Therefore condition (1.13) is equivalent to the condition

$$\forall q \in K^+, \quad \forall x \in T_{K^+}(q)^+, \quad \sup_{p \in A^*(q)} \langle p, x \rangle \geqq 0. \tag{1.15}$$

By Proposition 1.7 (b) for all $q \in K^+$ the set $A^*(q)$ is compact. The separation theorem implies that $A^*(q)$ has a nonempty intersection with $T_K{}^+(q)$ if and only if for all $x \in \mathbb{R}^n$,

$$\sup_{p \in A^*(q)} \langle p, x \rangle \geqq \inf_{z \in T_{K^+}(q)} \langle z, x \rangle.$$

Since $T_{K^+}(q)$ is a cone the latter inequality is equivalent to (1.15). This ends the proof. □

We now introduce the concepts of eigenvalues and eigenvectors of closed convex processes.

DEFINITION 1.13. We shall say that $\lambda \in \mathbb{R}$ is an *eigenvalue* of a convex process A if $\text{Im}\,(A - \lambda I) \neq \mathbb{R}^n$ and that $x \in \text{Dom } A$ is an *eigenvector* of A if $x \neq 0$ and if there exists $\lambda \in \mathbb{R}$ such that $\lambda x \in A(x)$.

We observe that half-lines spanned by eigenvectors of A^* are viability domains for A^*.

LEMMA 1.14. *Let A be a strict convex process. Then A^* has an eigenvector if and only if $\text{Im}\,(A - \lambda I) \neq \mathbb{R}^n$ for some $\lambda \in \mathbb{R}$.*

Proof. (a) Let η be an eigenvector of A^*, a solution to $\lambda\eta \in A^*(\eta)$, $\eta \neq 0$. Thus, for all $y \in A(x)$, $\langle \eta, y - \lambda x \rangle \geqq 0$ and thus, $\text{Im}\,(A - \lambda I) \subset \{\eta\}^+ \neq \mathbb{R}^n$.

(b) Conversely, assume that for some $\lambda \in \mathbb{R}$, $\text{Im}\,(A - \lambda I) \neq \mathbb{R}^n$. Since it is a convex cone of a finite-dimensional space, there exists a nonzero $\eta \in \mathbb{R}^n$ such that $\langle \eta, z \rangle \geqq 0$ for all $z \in \text{Im}\,(A - \lambda I)$. This implies that for all $x \in \mathbb{R}^n$ and $y \in A(x)$,

$$\lambda \langle \eta, x \rangle \leqq \langle \eta, y \rangle.$$

By the very definition of A^*, we deduce that $\lambda\eta$ belongs to $A^*(\eta)$. □

Example 1.15. Let F be a linear operator from $\mathbb{R}^n$ to itself, let L be a closed convex cone of controls and let A be the strict closed convex process defined by $A(x) := Fx + L$.

A cone K is invariant by A if

$$\forall x \in K, \qquad Fx + L \subset T_K(x),$$

and λ is an eigenvalue of A if

$$\operatorname{Im}(F - \lambda I) + L \neq \mathbb{R}^n.$$

The transpose A^* of A is defined by

$$A^*q = \begin{cases} F^*q & \text{if } q \in L^+, \\ \varnothing & \text{if } q \notin L^+. \end{cases}$$

A cone $P \subset L^+ = \operatorname{Dom} A^*$ is a viability domain for A^* if and only if

$$\forall q \in P, \qquad F^*q \in T_P(q).$$

An element $q \neq 0$ is an eigenvector of A^* if and only if q is an eigenvector of F^* which belongs to the cone L^+.

Example 1.16. Let $f : \mathbb{R}^n \to \mathbb{R}^n$ be a single-valued map and $L \subset R^n$ be a closed convex cone, to which we associate the set-valued map A defined by

$$\forall x \in \mathbb{R}^n, \qquad A(x) := f(x) + L. \tag{1.16}$$

We observe that A is a closed convex process if and only if

$$\forall q \in L^+, x \to \langle q, f(x) \rangle \text{ is convex, lower semicontinuous and positively homogeneous} \tag{1.17}$$

or, in other words, if and only if

$$\forall q \in L^+, x \to \langle q, f(x) \rangle \text{ is the support function of a compact convex subset which we denote by } F^*(q). \tag{1.18}$$

We then verify that the transpose A^* of A is equal to

$$A^*(q) := \begin{cases} F^*(q) & \text{if } q \in L^+, \\ \varnothing & \text{if not.} \end{cases} \tag{1.19}$$

We observe that

$$\forall q_1, q_2 \in L^+, \qquad A^*(q_1 + q_2) = F^*(q_1) + F^*(q_2) = A^*(q_1) + A^*(q_2). \tag{1.20}$$

Furthermore, $F^*(q) = A^*(q)$ is single-valued when q ranges over $L^+ \cap -L^+$.

To say that q is an eigenvector of A^* is to say that

$$q \neq 0, \quad q \in L^+, \quad \lambda q \in F^*(q), \tag{1.21}$$

and that $\lambda \in \mathbb{R}$ is an eigenvalue of A is to say that

$$\operatorname{Im}(f - \lambda I) + L \neq \mathbb{R}^n. \tag{1.22}$$

We check that

$$\sum_{k=1}^{m} f^k(L) \subset \sum_{k=1}^{m} A^k(0). \tag{1.23}$$

2. The duality theorem. We devote this section to the duality theorem, which characterizes the polar cones of the reachable sets.

We denote by $W^{1,p}(0, T)$, $p \in [1, \infty]$, the Sobolev space of functions $x \in L^p(0, T; \mathbb{R}^n)$ such that $x'(\cdot)$ belongs to $L^p(0, T; \mathbb{R}^n)$.

Let us consider the Cauchy problem for the differential inclusion

$$\text{(2.1)} \quad \begin{cases} \text{(i)} & x'(t) \in A(x(t)) \quad \text{for almost all } t \in [0, T], \\ \text{(ii)} & x(0) = 0. \end{cases}$$

We recall that the reachable set R_T is defined by

$$R_T := \{x(T) \mid x \in W^{1,1}(0, T) \text{ is a solution to (2.1)}\}. \tag{2.2}$$

We shall characterize its positive polar cone R_T^+. For that purpose, we associate with the differential inclusion (2.1) the adjoint inclusion

$$\text{(2.3)} \quad \begin{cases} \text{(i)} & -q'(t) \in A^*(q(t)) \quad \text{for almost all } t \in [0, T], \\ \text{(ii)} & q(T) = \eta, \end{cases}$$

and we denote by $Q_T \subset \operatorname{Dom} A^*$ the set of "final" values η such that the differential inclusion (2.3) has a solution.

$$Q_T := \{\eta \mid \exists q \in W^{1,1}(0, T) \text{ a solution to (2.3)}\}. \tag{2.4}$$

The statement of the duality theorem is the following.

THEOREM 2.1. *Let A be a strict closed convex process. Then*

$$R_T^+ = Q_T. \tag{2.5}$$

We need the following technical lemma.

LEMMA 2.2. *Let A be a strict closed convex process. Then the $W^{1,\infty}(0, T)$ solutions to* (2.1) *are dense in $W^{1,1}(0, T)$ solutions to* (2.1) *in the metric of uniform convergence on* $[0, T]$.

Proof. Indeed let $w \in W^{1,1}(0, T)$ be a solution of (2.1) and $\varepsilon > 0$ be a given number. Denote by $C \geqq 1$ a Lipschitz constant of A which exists thanks to Proposition 1.7 (a). Let $M \subset [0, T]$ be such that w' is bounded on $[0, T] \setminus M$ and

$$2C(T+1)e^{CT} \int_M (\|w(s)\| + \|w'(s)\|)\, ds < \varepsilon. \tag{2.6}$$

Set

$$y'(t) := \begin{cases} 0 & \text{if } t \in M, \\ w'(t) & \text{otherwise,} \end{cases}$$

and

$$y(t) := \int_0^t y'(s)\, ds.$$

Then

$$\|y(t) - w(t)\| \leqq \int_M \|w'(s)\|\, ds \leqq \varepsilon/2 \tag{2.7}$$

and

$$p(t) := \operatorname{dist}(y'(t), A(y(t))) \leqq \begin{cases} C\|y(t)\| & \text{if } t \in M, \\ C\|w(t) - y(t)\| & \text{otherwise.} \end{cases}$$

Thus

$$\int_0^T p(t)\,dt \leqq C\left(\int_M \|w(t)\|\,dt + \int_0^T \|w(t)-y(t)\|\,dt\right) \leqq C\int_M (\|w(s)\| + T\|w'(s)\|)\,ds. \tag{2.8}$$

By a Filippov theorem (see Aubin and Cellina [1984, p. 120]) there exists a solution $x(\cdot)$ to (2.1) satisfying, by (2.6) and (2.8),

$$\text{(i)}\quad \|x(t)-y(t)\| \leqq e^{CT}\int_0^T p(t)\,dt < \varepsilon/2,$$

$$\text{(ii)}\quad \|x'(t)-y'(t)\| \leqq C\,e^{CT}\int_0^T p(t)\,dt + p(t) \quad \text{a.e.} \tag{2.9}$$

Since $p(\cdot)$ is a bounded function and $y \in W^{1,\infty}(0, T)$, the solution $x(\cdot)$ belongs to $W^{1,\infty}(0, T)$. Moreover by (2.7), (2.9), for all $t \in [0, T]$,

$$\|x(t)-w(t)\| \leqq \|x(t)-y(t)\| + \|y(t)-w(t)\| < \varepsilon.$$

Since ε is an arbitrary positive number the proof ensues. □

Proof of Theorem 2.1. (a) We denote by S the closed convex cone of solutions to the differential inclusion (2.1) in the Hilbert space

$$X := \{x \in W^{1,2}(0, T) \,|\, x(0) = 0\}. \tag{2.10}$$

Consider the continuous linear operator

$$\gamma_T : x(\cdot) \in X \to x(T) \in \mathbb{R}^n.$$

The transpose γ_T^* maps $\mathbb{R}^n$ into the dual X^* of X and for all $\eta \in R_T^+$

$$\forall x \in S, \qquad \langle \gamma_T^* \eta, x\rangle = \langle \eta, \gamma_T x\rangle \geqq 0. \tag{2.11}$$

By Lemma 2.2, S is dense in the $W^{1,1}(0, T)$ solutions to (2.1) in the metric of uniform convergence on $[0, T]$. This and (2.11) yield

$$R_T^+ = \{\eta : \gamma_T^* \eta \in S^+\}. \tag{2.12}$$

Let us set

$$\text{(i)}\quad Y := L^2(0, T; \mathbb{R}^n) \times L^2(0, T; \mathbb{R}^n),$$

$$\text{(ii)}\quad L := \{(x, y) \in Y : y(t) \in A(x(t)) \text{ a.e.}\}, \tag{2.13}$$

$$\text{(iii)}\quad D, \text{ the differential operator defined on } X \text{ by } Dx = x'.$$

Then $S = (1 \times D)^{-1}(L)$. The closed image Lemma 1.3 applied to the continuous linear operator $\phi = (1 \times D)$ states that

$$S^+ = (1 \times D)(L^+) \tag{2.14}$$

provided that the "surjectivity assumption"

$$\operatorname{Im}(1 \times D) - L = Y \tag{2.15}$$

is satisfied.

(b) It can be written

$$\forall (u, v) \in Y \text{ there exists } x \in X \text{ such that } x'(t) \in A(x(t) - u(t)) + v(t) \text{ a.e.} \tag{2.16}$$

Since the domain of A is the whole space, then A is Lipschitzian. The set-valued map $F(t, x) := A(x-u(t))+v(t)$ is then measurable in t, Lipschitzian with respect to x, has closed images and satisfies the following estimate

$$d(0, F(t, 0)) \leqq \|A\| \|u(t)\| + \|v(t)\|.$$

The function $t \to \|A\| \|u(t)\| + \|v(t)\|$ being in $L^1(0, T)$ we can apply a Filippov theorem [1967] (see Clarke [1983]) which states the existence of a solution $x(\cdot)$ to the differential inclusion $x'(t) \in F(t, x(t))$, $x(0) = 0$, satisfying

$$\|x'(t)\| \leqq \|A\| e^{\|A\|T} \int_0^T d(0, F(t, 0))\, dt + d(0, F(t, 0)).$$

Thus $x \in X$ and the surjectivity assumption (2.15) holds true.

(c) Therefore, by (2.12) and (2.14), we obtain the formula

$$R_T^+ = \{\eta : \gamma_T^* \eta \in (1 \times D)^*(L^+)\}. \tag{2.17}$$

Let $\eta \in Q_T$ and q be a solution to the adjoint inclusion (2.3). By Proposition 1.7(b), $q(\cdot) \in W^{1,\infty}(0, T)$ and for all $x \in S$

$$\langle \eta, x(T)\rangle = \langle (q', q), (x, x')\rangle_Y.$$

This is nonnegative by the definition of A^*. Thus $Q_T \subset R_T^+$.. To prove the opposite, let η belong to R_T^+. By (2.17), there exists $(p, q) \in L^+$ such that

$$\langle \eta, \gamma_T x\rangle = \langle p, x\rangle_{L^2} + \langle q, Dx\rangle_{L^2} \quad \forall x \in X. \tag{2.18}$$

By taking x so that $x(T) = 0$ we deduce that $p = Dq$ in the sense of distributions. Since p and q belong to L^2, we infer that q belongs to the Sobolev space $W^{1,2}(0, T)$. Thus $Dq = q'$. Integrating by parts in equation (2.18) and taking into account that $x(0) = 0$, we obtain

$$\langle \eta, \gamma_T x\rangle = \langle p - q', x\rangle_{L^2} + \langle q(T), x(T)\rangle = \langle q(T), x(T)\rangle.$$

The surjectivity of γ_T implies that $\eta = q(T)$. Thus $q(\cdot)$ is a solution to (2.3) and then, η belongs to Q_T. This achieves the proof. □

3. Invariant cones and viability domains. We devote this section to a thorough study of the viability domains for A^*, the transpose of a strict closed convex process. We then derive, thanks to the duality theorem, corresponding properties of the invariant cones.

We consider the Cauchy problem for the differential inclusion

$$\text{for almost all } t \in [0, T], \quad x'(t) \in A(x(t)), \quad x(0) = 0, \tag{3.1}$$

the reachable sets R_T defined by (2.2), the adjoint differential inclusion

$$\text{for almost all } t \in [0, T], \qquad -q'(t) \in A^*(q(t)). \tag{3.2}$$

We associate with any $\eta \in \operatorname{Dom} A^*$ the "solution set" $S_T(\eta)$ of solutions to the differential inclusion (3.2) satisfying $q(T) = \eta$ and we denote by Q_T the domain of the "solution map" S_T

$$Q_T := \{\eta \in \operatorname{Dom} A \mid S_T(\eta) \neq \emptyset\}. \tag{3.3}$$

We shall use the following technical lemma.

LEMMA 3.1. *Let A be a strict closed convex process. The following properties hold true*:

(a) *the graph of the restriction of S_T to any compact subset of* Dom A^* *is compact in* $\mathbb{R}^n \times \mathscr{C}(0, T; \mathbb{R}^n)$.

(b) *Any viability domain P for A^* is contained in Q_T.*

Proof. (a) Let $\mathscr{C}$ be a compact subset of Dom A^* and let us consider a sequence (η_n, q_n) where $\eta_n \in C$ and $q_n \in S_T(\eta_n)$. Then a subsequence (again denoted η_n) of η_n converges to some $\eta \in C$ because C is compact.

For almost all $t \in [0, T]$

$$\left|\frac{d}{dt}\|p_n(t)\|^2\right| = 2|\langle p_n(t), p_n'(t)\rangle| \leqq 2\|p_n(t)\|\,\|p_n'(t)\| \leqq 2\|A\|\,\|p_n(t)\|^2$$

(by formula (1.8), because $-p_n'(t) \in A^*(p_n(t))$).

Gronwall's lemma implies that

$$\|p_n(t)\| \leqq \|\eta_n\| \exp(\|A\|(t-T)). \tag{3.4}$$

This and formula (1.8) imply that for almost all $t \in [0, T]$,

$$\|p_n'(t)\| \leqq \|A\|\,\|\eta_n\| \exp(\|A\|(t-T)). \tag{3.5}$$

Thus, by the Banach-Alaoglu theorem, p_n' lies in a weakly compact subset of $L^\infty(0, T; \mathbb{R}^n)$ and by the Ascoli-Arzela theorem, p_n lies in a compact subset of $\mathscr{C}(0, T; \mathbb{R}^n)$. Therefore there exists a subsequence (again denoted) $p_n(\cdot)$ and an absolutely continuous function $p: [0, T] \to \mathbb{R}^n$ such that

$$\begin{array}{ll} \text{(i)} & p_n \text{ converges uniformly to } p \text{ on } [0, T], \\ \text{(ii)} & p_n' \text{ converges weakly } p' \text{ in } L^1(0, T; \mathbb{R}^n). \end{array} \tag{3.6}$$

The weak convergence of the pair (p_n, p_n') in $L^1(0, T; \mathbb{R}^n) \times L^1(0, T; \mathbb{R}^n)$ implies the strong convergence of convex combinations of elements of this sequence (Mazur's lemma). Since $(p_n(t), p_n'(t))$ belongs to Graph A^* for almost all $t \in [0, T]$ and since it is closed and convex, we infer that for almost all $t \in [0, T]$, $(p(t), p'(t)) \in$ Graph (A^*). Hence $p(\cdot)$ belongs to $S_T(\eta)$.

(b) Let P be a viability domain for A and $\eta \in P$. We shall show that there exists a solution $p \in S_T(\eta)$.

The viability theorem (see Haddad [1981]) implies that for all $t_0 \leqq T$ a solution p of the differential inclusion

$$-p'(t) \in A^*(p(t)), \quad p(t) \in P, \quad p(T) = \eta, \tag{3.7}$$

defined on a time interval $[t_0, T]$, can be extended to a solution of (3.7) defined on a larger time interval $[t_1, T]$, $t_1 < t_0$. Setting $\eta_n = \eta$ in (3.4) and (3.5), we obtain that

$$\begin{array}{ll} \text{(i)} & \|p(t)\| \leqq \|\eta\| \quad \text{for all } t \in [t_1, T], \\ \text{(ii)} & \|p'(t)\| \leqq \|A\|\,\|\eta\| \quad \text{for a.e. } t \in [t_1, T]. \end{array} \tag{3.8}$$

As in the case of ordinary differential equations, one can show that $p(\cdot)$ can be extended to a solution (again denoted $p(\cdot)$) defined on the time interval $[0, T]$. Thus $p(\cdot)$ belongs to $S_T(\eta)$ and thus, η belongs to A_T. □

We observe now that the sequence of the closed domains Q_T decreases

$$\text{if } T_1 \geqq T_2, \quad \text{then } Q_{T_1} \subset Q_{T_2}. \tag{3.9}$$

We introduce the intersection Q of these cones

$$Q := \bigcap_{T>0} Q_T. \tag{3.10}$$

Since the compact subsets $S^{n-1} \cap Q_T$ form a decreasing sequence, we observe that $Q \neq \{0\}$ if and only if all the cones Q_T are different from 0. We shall see that Q is the *largest viability domain*, thanks to the following theorem.

THEOREM 3.2. *Let A be a strict closed convex process. Then the closed convex cone Q is the largest closed convex cone which is a viability domain for A^*.*

Proof. Lemma 3.1 (b) implies that Q is a closed convex cone which contains any viability domain P. It remains to prove that Q is a viability domain, i.e., that

$$\forall q \in Q, \qquad A^*(q) \cap T_Q(q) \neq \emptyset. \tag{3.11}$$

Assume that $Q \neq \{0\}$.

Thanks to the necessary condition of the viability theorem (see Haddad [1981]), it is sufficient to prove that for some $T > 0$,

$$\forall \eta \in Q, \quad \exists p(\cdot) \in S_T(\eta) \quad \text{which is viable on } Q. \tag{3.12}$$

Since η belongs to Q_{nT} for all $n \geqq 2$, there exists a solution $p_n(\cdot) \in S_{nT}(\eta)$. By the very definition of Q_t, we know that $p(t) \in Q_t$ for all $t \leqq nT$.

Therefore, the translated function $\hat{p}_n(\cdot)$ defined on $[0, T]$ by

$$\hat{p}_n(t) := p_n(t + (n-1)T) \tag{3.13}$$

belongs to $S_T(\eta)$ and satisfies for all $t \in [0, T]$, $k \leqq n-1$,

$$\hat{p}_n(t) = p_n(t + (n-1)T) \in Q_{t+(n-1)T} \subset Q_{(n-1)T} \subset Q_{kT}. \tag{3.14}$$

By Lemma 3.1 (a), $S_T(\eta)$ is compact in $\mathscr{C}(0, T; \mathbb{R}^n)$. Thus there exists a subsequence of $\hat{p}_n(\cdot)$ converging to some $\hat{p}(\cdot) \in S_T(\eta)$ uniformly on $[0, T]$. By (3.14) for all $t \in [0, T]$, $k \geqq 1$, $\hat{p}(t) \subset Q_{kT}$. Therefore

$$\hat{p}(t) \subset \bigcap_{k \geqq 1} Q_{kT} = Q. \qquad \square$$

We now translate this result in terms of reachable sets R_T.

Since $0 \in A(0)$ the reachable cones $R(T)$ do form an increasing sequence. We define the reachable set of the inclusion (3.1) to be

$$R := \bigcup_{T>0} R(T). \tag{3.15}$$

It is a convex cone, which is equal to the whole space if and only if for some $T > 0$, $R(T) = \mathbb{R}^n$.

THEOREM 3.3. *Let A be a strict closed convex process. Then the closed convex cone $\bar{R}$ is the smallest closed convex cone invariant by A.*

Proof. Indeed Theorem 2.1 and the definition of $\bar{R}$ and Q imply that $\bar{R}^+ = Q$. By Theorem 3.2 and Proposition 1.12, $\bar{R}$ is the smallest closed convex cone containing $A(0) = (\text{Dom } A^*)^+$ which is invariant by A. $\square$

We consider now the largest subspace

$$Q \cap -Q \subset \text{Dom } A^* \cap -\text{Dom } A^* \tag{3.16}$$

of Q.

PROPOSITION 3.4. *Let A be a strict closed convex process. The subspace $Q \cap -Q$ is the largest subspace invariant by A^* and its orthogonal space $R - R$ is invariant by A in the sense that*

$$\forall x \in R - R, \qquad A(x) \subset R - R. \tag{3.17}$$

Proof. By Proposition 1.7 (c) the restriction of A^* to $Q \cap -Q$ is a linear (single-valued) operator. We have to check that $A^*(Q \cap -Q) \subset Q \cap -Q$. Let q belong to $Q \cap -Q$. Then by Theorem 3.2, since $\mathbb{R}q \subset Q \cap -Q$

$$A^*q \in T_Q(q) = \overline{(\mathbb{R}q + Q)} \subset Q + Q \cap -Q \subset Q.$$

Since $-q \in Q \cap -Q$, we also have

$$A^*q = -A^*(-q) \subset -Q.$$

Thus

$$A^*q \in Q \cap -Q.$$

Since $Q = \bar{R}^+$, the orthogonal space to $Q \cap -Q$ is the (closed) vector space spanned by R. Since we are in finite-dimensional space, we infer that

$$(Q \cap -Q)^\perp = R - R. \tag{3.18}$$

Proposition 1.12 implies that the vector space $R - R$ is invariant by A, because we have proved that $Q \cap -Q$ is a viability domain for A^*. □

We consider now the cones $A(0)$, $A^2(0) := A(A(0)), \cdots, A^k(0) = A(A^{k-1}(0))$, etc. Since 0 belongs to $A(0)$, these convex cones form an increasing sequence. We introduce the cone

$$N := \operatorname{cl}\left(\bigcup_{k \geq 1} A^k(0)\right) \tag{3.19}$$

and the vector subspace

$$M \text{ spanned by } N. \tag{3.20}$$

THEOREM 3.5. *Let A be a strict closed convex process. Then*

(a) $A(N) \subset N$,

(b) $\bar{R} \subset N \subset M \subset R - R$,

(c) $Q \cap -Q \subset \bigcap_{k \geq 1} A^k(0)^\perp \subset \bigcap_{k \geq 1} A^k(0)^+ \subset Q$.

Proof. (a) It is clear that $A(\bigcup_{k \geq 1} A^k(0)) \subset N$.

Let $x \in N$, $y \in A(x)$ and $x_n \in \bigcup_{j \geq 1} A^j(0)$ be a sequence converging to x. Since A is Lipschitzian, there exists a sequence $y_n \in A(x_n) \subset N$ converging to y, which belongs to N because it is closed.

(b) Since N is a closed invariant cone containing $A(0)$, Theorem 3.3 implies that N contains the reachable set $\bar{R}$. On the other hand, 0 belongs to $R - R$ and this vector space is invariant by A, thanks to Proposition 3.4. Therefore the cones $A^k(0) = A(A^{k-1}(0))$ are contained in $R - R$ and so does M.

(c) We deduce the other inclusions by polarity, noticing that $N^+ = \bigcap_{k \geq 1} A^k(0)^+$ and

$$M^\perp = \bigcap_{k \geq 1} A^k(0)^\perp.$$

Remark. When the reachable set R is a vector space, the subsets R, N, M and $R - R$ coincide. This happens when, for instance, A is symmetric (in the sense that $A(-x) = -A(x)$), i.e., when the graph of A is a vector subspace.

4. Eigenvectors and eigenvalues of convex processes. When $Q \cap -Q = \{0\}$ (or $R - R = \mathbb{R}^n$), there is no proper subspace invariant by A^* (or there is no proper subspace invariant by A). Moreover, when $Q \neq \{0\}$ (or $R \neq \mathbb{R}^n$), we can still prove the existence of an eigenvalue of A (see Definition 1.13 and Lemma 1.14), or eigenvectors of A^*.

Actually, eigenvectors η of A^*, nonzero solutions of the inclusion $\lambda\eta \in A^*(\eta)$, do belong to the largest viability domain Q because for all $T>0$ the function $p(t) := \eta \exp(\lambda(T-t))$ belongs to $S_T(\eta)$.

THEOREM 4.1. *Let A be a strict closed convex process. If the largest viability domain Q for A^* is different from $\{0\}$ and contains no line, then A^* has at least one eigenvector.*

By Lemma 1.14 and duality Theorem 2.1, the following dual version of this theorem holds true.

THEOREM 4.2. *Let A be a strict closed convex process. Assume that the reachable set R is different from $\mathbb{R}^n$ and spans the whole space. Then A has at least one eigenvalue.*

First we recall the following property

LEMMA 4.3. *Let Q be a closed convex cone of $\mathbb{R}^n$. The following properties are equivalent:*

(i) $Q \cap -Q = \{0\}$,

(ii) *Q is spanned by a compact convex subset which does not contain zero,*

(iii) *The interior of Q^+ is nonempty.*

If one of these properties holds true, then for all $x_0 \in \operatorname{Int} Q^+$, the compact convex subset

$$M := \{q \in Q : \langle q, x_0\rangle = 1\} \tag{4.1}$$

spans Q.

Proof. We provide the proof for the convenience of the reader.

Condition (i) means that zero is the extremal point of Q, which is equivalent to the assertion $0 \notin \operatorname{co}(Q \cap S^{n-1})$. Since the compact convex set $\operatorname{co}(Q \cap S^{n-1})$ spans the cone Q we proved the equivalence of (i) and (ii). Condition (iii) means that $Q^{++} = Q$ contains no line, which is precisely the statement (i).

If $x_0 \in \operatorname{Int} Q^+$ and $q,\ q_i \in M,\ i = 1, 2, \cdots$ are such that

$$\langle q_i, x_0\rangle = 1, \qquad \lim_{i\to\infty} q_i/\|q_i\| = q \in Q \cap S^{n-1}.$$

Then

$$0 < \langle q, x_0\rangle = \lim_{i\to\infty} \langle q_i, x_0\rangle/\|q_i\| = \lim_{i\to\infty} \|q_i\|^{-1}.$$

It implies that the norms $\|q_i\|$ are bounded and, therefore, M is bounded. Obviously it is also convex and closed. □

Proof of Theorem 4.1. Let $x_0 \in \operatorname{Int} Q^+$ and let M be defined by (4.1). Then for all $p \in M$

$$T_M(p) := \{v \in T_Q(x_0) : \langle v, x_0\rangle = 0\}. \tag{4.2}$$

We introduce the following projectors

$$\forall p \in M, \qquad \pi(p)q = q - \langle q, x_0\rangle p. \tag{4.3}$$

For all $p \in M$ and $q \in Q$, $\langle \pi(p)p, x_0\rangle = 0 = \langle \pi(p)q, x_0\rangle$. Hence the projector $\pi(p)$ maps the set $\mathbb{R}p + Q$ into $T_M(p)$. Since $T_Q(p) = \overline{\mathbb{R}p + Q}$ and $\pi(p)$ is a continuous linear operator, we obtain

$$\forall p \in M, \qquad \pi(p) \text{ maps } T_Q(p) \text{ into } T_M(p). \tag{4.4}$$

Consider the set-valued map $p \in M \to \pi(p)A^*(p)$. It is upper semicontinuous with nonempty compact convex images. By assumptions of Theorem 4.1, for all $p \in M \subset Q$, $A^*(p) \cap T_Q(p) \neq \emptyset$. Thus by (4.4)

$$\forall p \in M, \qquad \pi(p)A^*(p) \cap T_M(p) \neq \emptyset. \tag{4.5}$$

The assumptions of Aubin and Ekeland [1984, Thm. 6.4.11, p. 341] are satisfied. Therefore, for some $\bar{p} \in M$, $0 \in \pi(\bar{p})A^*(\bar{p})$. Hence there exists $\bar{q} \in A^*(\bar{p})$ such that $\langle \bar{q}, x_0 \rangle \bar{p} = \bar{q} \in A^*(\bar{p})$. In other words $\bar{p}$ is an eigenvector of A^* associated to the eigenvalue $\langle \bar{q}, x_0 \rangle$. □

5. Characterization of controllable convex processes. We shall deduce from the preceding results several characterizations of the controllability of differential inclusions

$$\text{for almost all } t \in [0, T], \quad x'(t) \in A(x(t)), \quad x(0) = 0 \tag{5.1}$$

or, equivalently, of the observability of the adjoint inclusion

$$\text{for almost all } t \in [0, T], \quad -q'(t) \in A^*(q(t)). \tag{5.2}$$

DEFINITION 5.1. We shall say that (5.1) is *controllable at time T* (respectively, *controllable*) if $R_T = \mathbb{R}^n$ (respectively, $R = R^n$). We shall say that the adjoint inclusion (5.2) is *observable at time T* (respectively, *observable*) if $Q_T = \{0\}$ (respectively, $Q = \{0\}$).

We also observe the following property.

LEMMA 5.2. *Let A be a strict closed convex process. The three following properties are equivalent.*

$$\begin{aligned} &\text{(a)} \quad \exists m \geqq 1 \text{ such that } A^m(0) - A^m(0) = \mathbb{R}^n, \\ &\text{(b)} \quad \exists m \geqq 1 \text{ such that } A^m(0)^{\perp} = \{0\}, \\ &\text{(c)} \quad \exists m \geqq 1 \text{ such that } \operatorname{Int} A^m(0) \neq \varnothing. \end{aligned} \tag{5.3}$$

It is convenient to introduce the

Rank condition 5.3. We say that a convex process A satisfies the rank condition if one of the equivalent properties (5.3) holds true.

LEMMA 5.4. *Consider the strict closed convex process $A(x) = Fx + L$, where $F \in \mathbb{R}^{n \times n}$ is a matrix and L is a vector subspace of $\mathbb{R}^n$. Then A satisfies the rank condition if and only if $A^n(0) - A^n(0) = \mathbb{R}^n$.*

Proof. The rank condition is satisfied if and only if for some $m \geqq 1$ the cone $L + AL + \cdots + A^{m-1}L$ spans the whole space. The Cayley-Hamilton theorem ends the proof. □

We begin by stating characteristic properties of observability of the adjoint system (5.2) and then use the duality results to infer the equivalent characteristic properties of system (5.1).

THEOREM 5.5. *Let A be a strict closed convex process. The following properties are equivalent*:

(a*) *the adjoint inclusion* (5.2) *is observable,*

(b*) *the adjoint inclusion* (5.2) *is observable at time $T > 0$ for some T,*

(c*) $\{0\}$ *is the largest closed convex cone which is a viability domain for A^*,*

(d*) *A^* has neither proper invariant subspace nor eigenvectors,*

(e*) *the rank condition is satisfied and A^* has no eigenvectors.*

Proof. (α) Since the intersections $Q_T \cap S^{n-1}$ of the cones Q_T and the unit sphere S^{n-1} form a decreasing sequence of compact subsets, we deduce that $Q \cap S^{n-1}$ is empty if and only if $Q_T \cap S^{n-1}$ is empty for some T, i.e., that $Q = \{0\}$ if and only if $Q_T = \{0\}$ for some $T > 0$. Thus (a*)$\Leftrightarrow$(b*).

(β) Property (c*) is equivalent to $Q = \{0\}$ by Theorem 3.2, i.e. (a*)$\Leftrightarrow$(c*).

(γ) When $Q = \{0\}$, then $Q \cap -Q = \{0\}$ (there is no proper invariant subspace) and there is no eigenvector (because an eigenvector is contained in Q).

When $Q \neq \{0\}$, then either $Q \cap -Q \neq \{0\}$ and, by Proposition 3.4, there is a proper invariant subspace or $Q \cap -Q = \{0\}$ and, by Theorem 4.1, there exists at least an eigenvector of A^*. This proves the equivalence of (d*) with $Q = \{0\}$, i.e., (a*)$\Leftrightarrow$(d*).

(δ) Since the sequence of cones $A^k(0)$ is increasing, the sequence of vector spaces $A^k(0)^\perp$ is decreasing, so that

$$\bigcap_{k \geq 1} A^k(0)^\perp = \{0\} \Leftrightarrow \exists m \geq 1 \quad \text{such that } A^m(0)^\perp = \{0\}$$
$$\Leftrightarrow \text{the rank condition is satisfied.}$$

Assume that $Q = \{0\}$. Then, by Theorem 3.5(c), and the above remark, the rank condition is satisfied and there is no eigenvector. Assume now that the rank condition is satisfied. Then $Q \cap -Q = \{0\}$ by Theorem 3.5(c). Then Theorem 4.1 implies that if A^* does not have an eigenvector, the cone Q is equal to $\{0\}$. Equivalence between (e*) and $Q = \{0\}$ ensues. □

THEOREM 5.6. *Let A be a strict closed convex process. The equivalent properties* (a*), (b*), (c*), (d*) *and* (e*) *of Theorem* 5.5 *are equivalent to the following properties*:

(a) *the differential inclusion* (5.1) *is controllable,*

(b) *the differential inclusion* (5.1) *is controllable at some time $T > 0$,*

(c) $\mathbb{R}^n$ *is the smallest closed convex cone invariant by A,*

(d) *A has neither proper invariant subspace nor eigenvalues,*

(e) *the rank condition is satisfied and A has no eigenvalues,*

(f) *for some $m \geq 1$, $A^m(0) = (-A)^m(0) = \mathbb{R}^n$.*

Proof. Statements (a) through (e) follow from the duality results (Proposition 1.12, Lemma 1.14 and Theorem 2.1) and Theorem 5.5. We shall show that (a) is also equivalent to (f).

Step 1. Consider the closed convex process $A_1(x) = A(-x)$. Then $A_1^* = -A^*$. We claim that (5.1) is controllable if and only if the inclusion

$$(5.1)' \qquad x' \in A_1(x), \qquad x(0) = 0$$

is controllable.

Indeed invariant subspaces and eigenvectors of A_1^* and A^* coincide and our claim follows from Theorem 5.5(d*).

Step 2. If (5.1) is controllable, then by Step 1 and Theorem 3.5(b)

$$\bigcup_{k \geq 1} A^k(0) = \bigcup_{k \geq 1} A_1^k(0) = \mathbb{R}^n.$$

Since $\{A^k(0)\}$ and $\{A_1^k(0)\}$ are increasing sequences of convex cones it implies that for some $m \geq 1$, $A^m(0) = A_1^m(0) = \mathbb{R}^n$. Moreover $A_1^m(0) = -(-A)^m(0)$. This implies (f).

Step 3. Assume that (f) holds true. If (5.1) is not controllable then there exist $\lambda \in \mathbb{R}$, $q \in A(0)^+$, $q \neq 0$ such that $\lambda q \in A^*(q)$. Then $(-\lambda)q \in A_1^*(q)$. Therefore,

$$\lambda^m q \in (A^*)^m(q) \quad \text{if } \lambda \geq 0,$$

$$(-\lambda)^m q \in (A_1^*)^m(q) \quad \text{if } \lambda \leq 0.$$

If $\lambda \geq 0$, then for all $y \in A^m(0)$, $0 = \langle \lambda^m q, 0 \rangle \leq \langle q, y \rangle$. If $\lambda \leq 0$, then for all $y \in A_1^m(0)$, $0 = \langle (-\lambda)^m q, 0 \rangle \leq \langle q, y \rangle$. In both cases we obtain a contradiction with (f). The proof is complete. □

So, the conjunction of Theorems 5.5 and 5.6 imply Theorem 0.4 stated in the Introduction.

Example 1. In the case when the set-valued map A is defined by $A(x) := Fx + L$, we derive known results due to Kalman when L is a vector space of controls and to

Brammer, and Saperstone and Yorke when L is an arbitrary set of controls containing 0.

Consider the linear control system in $\mathbb{R}^n$

$$x' = Fx + Gu, \quad u \in U, \quad x(0) = 0, \tag{5.4}$$

where $F \subset \mathbb{R}^{n\times n}$, $G \subset \mathbb{R}^{n\times m}$ are constant matrices and $U \subset \mathbb{R}^m$ is the given control set.

By Lemma 5.4 the rank condition 5.3 for the closed convex process $Ax = Fx + \operatorname{cl} G\{\lambda u: \lambda \geqq 0, u \in \operatorname{co} U\}$ is equivalent to

$$\sum_{i=0}^{n-1} F^i G(\operatorname{span} U) = \mathbb{R}^n. \tag{5.5}$$

This and Theorem 5.6(f) imply

THEOREM (Kalman). *If $U = \mathbb{R}^m$ then the control system* (5.4) *is controllable if and only if* $\operatorname{rank}[G, FG, \cdots, F^{n-1}G] = n$.

We shall study next the question of local controllability.

The control system (5.4) is said to be *locally controllable* around zero if zero is an interior point of the reachable set of (5.4).

To provide necessary and sufficient conditions for local controllability of (5.4) let us consider convex hull co U of U, and

$$N := \operatorname{cl}\{\lambda u: \lambda \geqq 0, u \in \operatorname{co} U\}$$

and the associated control system

$$x' \in Fx + \overline{GN}, \qquad x(0) = 0. \tag{5.6}$$

LEMMA 5.7. *If $0 \in \overline{\operatorname{co}}\, GU$ then the control system* (5.4) *is locally controllable around zero if and only if the system* (5.6) *is controllable.*

Proof. The reachable set of system (5.6) is a convex cone equal to

$$\left\{\int_0^t e^{F(t-s)}v(s)\,ds: t \geqq 0, v(s) \in \operatorname{cl} GN\right\} \tag{5.7}$$

and containing the reachable set of (5.4). Hence the local controllability of (5.4) implies the controllability of (5.6).

Because $0 \in \overline{\operatorname{co}}\, GU = \overline{G \operatorname{co} U}$, by a density argument, it is possible to verify that the cone given by (5.7) is equal to $\mathbb{R}^n$ if and only if

$$0 \in \operatorname{Int}\left\{\int_0^t e^{F(t-s)}Gu(s)\,ds: t \geqq 0, u(s) \in \operatorname{co} U\right\}. \tag{5.8}$$

Because the sets

$$\left\{\int_0^t e^{F(t-s)}Gu(s)\,ds: u(s) \in U\right\}$$

are convex and dense in

$$\left\{\int_0^t e^{F(t-s)}Gu(s)\,ds: t \geqq 0, u(s) \in \operatorname{co} U\right\}$$

(Lee and Markus [1967]) the inclusion (5.8) is equivalent to

$$0 \in \operatorname{Int}\left\{\int_0^t e^{F(t-s)}Gu(s)\,ds: t \geqq 0, u(s) \in U\right\}. \tag{5.9}$$

□

THEOREM 5.8. *Assume that* $0 \in \overline{\text{co}}\, GU$. *Then the system* (5.4) *is locally controllable around zero if and only if the rank condition* (5.5) *is satisfied and there is no eigenvector of* F^* *in* $(GU)^+$.

Proof. Observe that $GU^+ = (GN)^+$. By Lemma 5.7 it is enough to prove that the system (5.6) is controllable if and only if the rank condition 5.3 is satisfied and F^* has no eigenvector in $(GN)^+$. But this follows from Theorem 5.5(e*) and (5.5). □

In particular when $m = 1$ we obtain the result from Saperstone and Yorke [1971]. The above theorem is a generalization of Brammer's theorem [1972] (see also Jacobson [1977]). Theorem 5.6(f) and Example 1.15 imply

THEOREM 5.9. *Let* F *be an* $n \times n$ *matrix and let* L *be a closed convex subcone of* $\mathbb{R}^n$. *The control system*

$$x' = Fx + L, \qquad x(0) = 0$$

is controllable if and only if for some $m \geqq 1$

$$L + FL + \cdots + F^m L = L - FL + \cdots + (-1)^m F^m L = \mathbb{R}^n.$$

The last theorem together with Lemma 5.7 imply a result of Korobov [1980].

Example 2. Let $f = (f_1, \cdots, f_n)\colon \mathbb{R}^n \to \mathbb{R}^n$ be a single-valued map. Assume that for all $i = 1, \cdots, n$

f_i is lower semicontinuous, positively homogeneous convex function.

Observe that the assumption (1.17) holds true with $L = \mathbb{R}^n_+$. Consider the control system

$$x' = f(x) + u, \qquad u \in \mathbb{R}^n_+, \quad x(0) = 0. \tag{5.10}$$

THEOREM 5.10. *System* (5.10) *is controllable if and only if* f *has no proper invariant subspace containing* $\mathbb{R}^n_+$ *and if*

$$\sup_{\substack{q \in \mathbb{R}^n_+ \\ \lambda \in \mathbb{R}}} \inf_{x \in S^{n-1}} (\langle q, f(x)\rangle - \lambda \langle q, x\rangle) < 0$$

where S^{n-1} *denotes the unit sphere of* $\mathbb{R}^n$.

Proof. Set $A(x) := f(x) + \mathbb{R}^n_+$. By Theorem 0.4(g) the local controllability of (5.10) is equivalent to the two following properties:

(5.11) There is no proper subspace S satisfying $f(S) + \mathbb{R}^n_+ \subset S$.

(5.12) There is no $\lambda \in \mathbb{R}$ so that $\text{Im}\,(A - \lambda I) \neq \mathbb{R}^n$.

Since $f(0) = 0$ and $0 \in \mathbb{R}^n_+$ (5.11) is equivalent to

(5.11)′ there is no subspace S containing $\mathbb{R}^n_+$ such that $f(S) \subset S$.

By the separation theorem, (5.12) is equivalent to: for all $q \in \mathbb{R}^n_+$ and all $\lambda \in \mathbb{R}$ there exists $x \in \mathbb{R}^n$ such that $\langle f(x), q\rangle - \lambda \langle x, q\rangle < 0$. This ends the proof. □

Remark. Criterion (0.4)(k) can be used as well to derive a necessary and sufficient condition for the controllability of (5.10).

Let us consider the control system in $\mathbb{R}^2$

$$\begin{aligned} x' &= |x| + y + u, \qquad u \in \mathbb{R}_+, \\ y' &= |y| - x + v, \qquad v \in \mathbb{R}_+, \\ x(0) &= y(0) = 0. \end{aligned} \tag{5.12}′$$

We wish to know whether it is controllable. For this we consider the closed convex process $A: \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ defined by

$$A(x, y) = (|x| + y, |y| - x) + \mathbb{R}_+ \times \mathbb{R}_+ .$$

Then

$$A(0) = \mathbb{R}_+ \times \mathbb{R}_+, \qquad -A(0) = \mathbb{R}_- \times \mathbb{R}_-,$$
$$A^2(0) = \mathbb{R}_+ \times \mathbb{R}, \qquad (-A)^2(0) = \mathbb{R} \times \mathbb{R}_-,$$
$$A^3(0) = \mathbb{R} \times \mathbb{R}, \qquad (-A)^3(0) = \mathbb{R} \times \mathbb{R}.$$

By Theorem 0.4(k) the system (5.12) is controllable.

SPECTRAL ASSIGNABILITY OF SYSTEMS WITH SCALAR CONTROL AND APPLICATION TO A DEGENERATE HYPERBOLIC SYSTEM*

LOP FAT HO†

Abstract. Some distributed parameter systems with scalar boundary control can be represented as systems in Hilbert spaces for which the input functional may not be continuous, but are admissible in some sense. We prove a spectral assignability result for such systems. The conditions we need are that the system be approximately controllable and that feedback relations of a certain type be continuous. We show that these conditions are satisfied by systems that are exactly controllable. We then apply the general results to a degenerate hyperbolic system. Having shown that it is exactly controllable, we obtain a spectral assignability result. Finally, we consider systems that may have multiple eigenvalues.

Key words. spectral assignability, controllability, linear feedback, Carleson measure

AMS(MOS) subject classification. 93B55

1. Introduction. It is a well-known fact that if a finite dimensional autonomous control system is completely controllable, then we can arbitrarily prescribe the eigenvalues of the closed loop system by means of a suitable linear feedback. The main purpose of this paper is to generalize this result, under some restriction, to infinite dimensional systems with scalar controls. Sun has obtained a similar result of this kind in [12]. The main difference between the work of this paper and that of Sun is that our work also includes systems with boundary controls. The problem of spectral assignability of stabilizability for various distributed parameter systems has been considered in [3], [11], [12], [13].

We will consider the system

$$\frac{d}{dt}x(t) = Ax(t) + u(t)b, \qquad x(t) \in X, \quad t \geqq 0 \tag{1.1}$$

where X is a Hilbert space, A is the generator of a strongly continuous semigroup, $u(\cdot)$ is a scalar value function and b is what we call an admissible input element, which will be defined in § 2. (See Definition 2.1 and also [9].) An admissible input element may not be in X. (In [12], b is required to be in X.) This less restrictive requirement on b allows us to include also systems with boundary controls in our consideration.

The problem of spectral assignability for the system (1.1) can be stated as follows.

For a given complex sequence $\{\mu_n\}_{n=-\infty}^{\infty}$ find a feedback relation $u(t) = \langle x(t), h\rangle$ such that the set of eigenvalues of the "closed loop system"

$$\frac{d}{dt}x(t) = Ax(t) + \langle x(t), h\rangle b$$

is exactly $\{\mu_n\}_{n=-\infty}^{\infty}$.

Most known results concerning this problem for the case of scalar controls say that the problem can be solved (i.e. we can find the desired h) if

$$\sum_{n=-\infty}^{\infty} \frac{|\lambda_n - \mu_n|^2}{|b_n|^2} < \infty$$

where $\{b_n\}$ is a sequence of complex numbers related to b (see [11], [12]).

* Received by the editors December 18, 1984, and in revised form June 10, 1985.

† Department of Mathematics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong.

Also, most of the systems that have been considered possess, or are assumed to possess, the properties

1. that it is approximately controllable in some time $T>0$, and

2. that the numbers $\beta_n=\sum_{m\neq n} 1/[\lambda_n-\lambda_m|^2$, $-\infty<n<\infty$, are finite and the set $\{\beta_n\}$ is uniformly bounded.

The second property implies that the points λ_n cannot be too closed to each other asymptotically.

To prove the main spectral assignability result in this paper, we do not need property 2 as an assumption. Thus $\{\beta_n\}$ may be unbounded, but we will find out that the magnitudes of β_n will affect the class of sequences $\{\mu_n\}$ that can be assigned as eigenvalues of the closed loop system. More precisely, condition 2 will be replaced by

$$\sum_{h=-\infty}^{\infty} \frac{(1+\beta_n)|\mu_n-\lambda_n|^2}{|b_n|^2}<\infty.$$

Another assumption we need is that feedback relations of a certain type are continuous (see (4.3)). We will see that this assumption is valid if the system is exactly controllable in some time T. So we have a result of the type "exact controllability implies spectral assignability."

We now give an outline of the rest of this paper.

In § 2, we define the notion of an admissible input element and give meaning to the solution of the closed loop system. The definition we give here for admissible input element is slightly more restrictive than that given in [9].

In § 3, we study the spectrum of the closed loop system and show that it consists of zeros of a function analytic outside the spectrum of A, with possible points from the spectrum of A also. Our work here is somewhat complicated by the fact that we do not have a good expression for the generator of the closed loop system. We expect the generator to be $A_h x=Ax+\langle x, h\rangle b$, but if $b\notin X$, then this does not make sense; for example, when $\langle x, h\rangle\neq 0$. However, we can avoid this difficulty by defining A_h to be the adjoint of $Lx=A^*x+\langle x, b\rangle h$.

In § 4, we give an exact description of the spectrum of the closed loop system under the assumption that the spectrum of A consists of only simple eigenvalues. We establish the spectral assignability result, using a method which is a generalization of that used in [12], assuming that a certain class of feedback relations is continuous. We show that the continuity of such relations is implied by exact controllability, using a result on Carleson measure.

In § 5, we prove a controllability result for a degenerate hyperbolic system and apply the general theory we have developed to yield a result on spectral assignability.

Finally, in § 6, we show how we can modify the results we have developed to include the cases where there is a finite number of eigenvalues of A with multiplicities greater than one.

We will use $\sigma(\cdot)$ to denote the spectrum of the operator $\cdot$. Also we will use $\langle\cdot,\cdot\rangle$ to denote both inner product and duality pairing. $\langle x, y\rangle$ is linear in x and conjugate linear in y. We always identify X' so that $D(A^*)\subseteq X\subseteq D(A^*)'$ and the duality pairing on $D(A^*)'\times D(A^*)$ is an extension of the inner product on X. Also if $b\in D(A^*)'$ and $x\in D(A^*)$ then $\langle b, x\rangle=\overline{\langle x, b\rangle}$.

2. A scalar control system. We study the control system

$$\begin{aligned}&\frac{d}{dt}x(t)=Ax(t)+u(t)b, \qquad x(t)\in X,\\ &x(0)=x_0\end{aligned} \tag{2.1}$$

where X is a Hilbert space, A is the infinitesimal generator of a strongly continuous semigroup $S(t)$ of bounded operators on X and b is an admissible input element in the sense defined below.

DEFINITION 2.1. We suppose that $D(A^*)$ is considered as a Hilbert space equipped with the graph norm $\|x\|_{D(A^*)} \triangleq (\|x\|^2 + \|A^*x\|^2)^{1/2}$. A continuous linear functional b on $D(A^*)$ is said to be an *admissible input element* for the system (2.1) if for every $T > 0$, there exists a positive constant K_T, uniformly bounded for T sufficiently small, such that

$$\int_0^T |\langle b, S^*(t)y\rangle|^2 \, dt \leqq K_T^2 \|y\|^2 \quad \text{for all } y \in D(A^*). \tag{2.2}$$

Sufficient conditions for b to be an admissible input element can be found in [8].

If b is an admissible input element, then (cf. reference just cited) there exists, for each $t > 0$, a bounded linear operator $B(t)$ from $L^2[0, t]$ into X such that

$$\langle B(t)u(\cdot), y\rangle = \int_0^t \langle b, S^*(t-s)y\rangle u(s) \, ds \quad \text{for all } y \in D(A^*). \tag{2.3}$$

The solution of (2.1) is, by definition, equal to

$$x(t) = S(t)x_0 + B(t)u(\cdot). \tag{2.4}$$

We also remark that from (2.2) and (2.3), we have

$$\|B(t)\| \leqq K_T. \tag{2.5}$$

LEMMA 2.1.

$$B(t+s)u(\cdot) = S(t)B(s)u(\cdot) + B(t)u(s+\cdot). \tag{2.6}$$

Proof. Let $y \in D(A^*)$, then

$$\begin{aligned}
\langle B(t+s)u(\cdot), y\rangle &= \int_0^{t+s} \langle b, S^*(t+s-\tau)y\rangle u(\tau) \, d\tau \\
&= \int_0^s \langle b, S^*(s-\tau)S^*(t)y\rangle u(\tau) \, d\tau \\
&\quad + \int_s^{t+s} \langle b, S^*(t+s-\tau)y\rangle u(\tau) \, d\tau \\
&= \langle B(s)u(\cdot), S^*(t)y\rangle + \int_0^t \langle b, S^*(t-\tau)y\rangle u(s+\tau) \, d\tau \\
&= \langle S(t)B(s)u(\cdot), y\rangle + \langle B(t)u(s+\cdot), y\rangle.
\end{aligned}$$

Since $D(A^*)$ is dense in X, it follows that (2.6) holds. This finishes the proof of Lemma 2.1.

Remark. It follows from Lemma 2.1 that if $x(\cdot)$ is the solution of (2.1) with initial condition $x(0) = x_0$, then $x_t(\cdot) = x(t+\cdot)$ is the solution of (2.1) with initial condition $x_t(0) = x(t)$ and control $u(t+\cdot)$.

LEMMA 2.2. *Let h be a continous linear functional on X; then there exists a continuous function $x(\cdot)$ from $[0, \infty)$ into X such that*

$$x(t) = S(t)x_0 + B(t)\langle x(\cdot), h\rangle \quad \textit{for all } t > 0. \tag{2.7}$$

Proof. Fix $t_1>0$. Let M be the space of continuous functions from $[0, t_1]$ into X equipped with the supremum norm

$$\|x(\cdot)\|_\infty = \sup_{t\in[0,t_1]} \|x(t)\|, \quad x(\cdot)\in M.$$

We define a mapping F from M into itself by the equation $(Fx(\cdot))(t) = S(t)x_0 + B(t)\langle x(\cdot), h\rangle$, $0\leqq t\leqq t_1$. We have

$$\begin{aligned}\|Fx_1(\cdot) - Fx_2(\cdot)\|_\infty &= \sup_{t\in[0,t_1]} \|B(t)\langle x_1(\cdot) - x_2(\cdot), h\rangle\| \\ &\leqq \sup_{t\in[0,t_1]} \|B(t)\|\,\|h\| t_1^{1/2} \|x_1 - x_2\|_\infty.\end{aligned}$$

Here $\sup_{t\in[0,t_1]} \|B(t)\|$ is finite because of (2.5) and the boundedness of K_T. Hence if t_1 is chosen such that

$$\sup_{t\in[0,t_1]} \|B(t)\|\,\|h\| t_1^{1/2} < 1, \tag{2.8}$$

then F is a contraction mapping. Hence F has a unique fixed point $x_1(\cdot)$ in M. Such an x_1 then satisfies (2.7) in $[0, t_1]$. The condition (2.8) is independent of x_0, so we can also find $x_2(\cdot)\in M$ such that $x_2(t) = S(t)x_1(t_1) + B(t)\langle x_2(\cdot), h\rangle$, $0\leqq t\leqq t_1$. By virtue of the remark after Lemma 2.1, the function

$$x(s) = \begin{cases} x_1(s), & 0\leqq s\leqq t_1, \\ x_2(s-t_1), & t_1 < s\leqq 2t_1 \end{cases}$$

satisfies (2.7) for $0\leqq t\leqq 2t_1$. In a similar way, we can extend the function x to $[0, 3t_1]$, $[0, 4t_1]$, etc., on which (2.7) is satisfied. This finishes the proof of the lemma.

The unique solution of (2.7) will be denoted by $S_h(t)x_0$. For each t, $S_h(t)$ is then defined, in this way, as a linear operator from X into itself. And from the remark after Lemma 2.1, we have the semigroup property $S_h(\tau+t) = S_h(\tau)S_h(t)$. Furthermore, Lemma 2.2 implies that for any $x_0\in X$, the function mapping t to $S_h(t)x_0$ is continuous on $[0, \infty)$. Hence we have proved

LEMMA 2.3. *Let the solution in* (2.7) *be denoted by* $S_h(t)x_0$, *then* $S_h(t)$ *is a strongly continuous semigroup on* X.

We will define the solution of the system (2.1) with feedback relation $U(t) = \langle x(t), h\rangle$ to be $S_h(t)x_0$. The infinitesimal generator of S_h will be denoted by A_h.

3. Spectrum of the closed loop system. In this section, we will study the spectrum of the generator A_h of the semigroup S_h (see Lemma 2.3) associated with the closed loop system. Thinking of A_h as a perturbation of A, we will see that such a perturbation produces some new eigenvalues which are zeros of a certain function outside $\sigma(A)$. Part of $\sigma(A_h)$ may still be in $\sigma(A)$. To have a more precise characterization of $\sigma(A)$, we must make some more assumptions on A. This we will do in the next section.

We recall that if b is an admissible input element, then $b\in D(A^*)'$. Now if λ is not in the spectrum of A, then $R(\bar\lambda, A^*)$ is a bounded linear operator from X onto $D(A^*)$. Hence the expression $\langle b, R(\bar\lambda, A^*)x\rangle$ makes sense.

LEMMA 3.1. *The function* $\Delta_h(\lambda) = \langle b, R(\bar\lambda, A^*)h\rangle - 1$ *is defined and analytic on the resolvent set of* A.

Proof. Let λ be in the resolvent set of A. We have $R(\bar\mu, A^*) = R(\bar\lambda, A^*)\sum_{n=0}^\infty (\bar\lambda - \bar\mu)^n R(\bar\lambda, A^*)^n$, the sum being convergent in $L(X, D(A^*))$ equipped with uniform norm, whenever $|\bar\lambda - \bar\mu|\,\|R(\bar\lambda, A^*)\|_{L(X,D(A^*))} < 1$. It follows that for such μ, $\Delta_h(\mu) = \sum_{n=0}^\infty (\lambda - \mu)^n \langle b, R(\bar\lambda, A^*)^{n+1}h\rangle - 1$. This shows that Δ_h is analytic at λ and hence finishes the proof of the lemma.

To find the spectrum of A_h, we will (in Theorem 3.3) show that A_h is the adjoint of the operator L defined by

$$Ly = A^*y + \langle y, b\rangle h, \qquad D(L) = D(A^*). \tag{3.1}$$

We remark that L is closed because the mapping $Ty = \langle y, b\rangle h$ is A^* bounded with A^*-bound equal to zero. (T has finite rank). (See [10, p. 190].)

We first find a set that contains $\sigma(L)$. Let

$$\Lambda = \text{set of zeros of } \Delta_h. \tag{3.2}$$

LEMMA 3.2. *Suppose $\lambda \notin \sigma(A) \cup \Lambda$. Then given any x in X, the equation $(\bar{\lambda} I - L)y = x$ has the unique solution*

$$y = -(\langle R(\bar{\lambda}, A^*)x, b\rangle) R(\bar{\lambda}, A^*)h/(\bar{\Delta}_h(\lambda)) + R(\bar{\lambda}, A)x$$

in $D(A^*)$. If $\lambda \in \Lambda$ then $(\bar{\lambda} I - L)R(\bar{\lambda}, A^*)h = 0$.

Proof. That the given y indeed satisfies $(\bar{\lambda} I - L)y = 0$ can be proved by direct computation. To prove uniqueness, we note that if $(\bar{\lambda} I - L)y = 0$, then $y = R(\bar{\lambda}, A^*)\langle y, b\rangle h$. Hence $\langle y, b\rangle = \langle y, b\rangle \langle R(\bar{\lambda}, A^*)h, b\rangle$. Because $\Delta_h(\lambda) = \langle R(\bar{\lambda}, A^*)h, b\rangle - 1$ is assumed to be nonzero, it follows that $\langle y, b\rangle = 0$. Hence $y = 0$. Finally, the equality $(\bar{\lambda} I - L)R(\bar{\lambda}, A^*)h = 0$ can be proved by direct computation. This finishes the proof of the lemma.

THEOREM 3.3. *Let L be as in* (3.1) *and A_h be the generator of the closed loop system* (*cf. end of* § 2). *Then $A_h = L^*$. Consequently, $\sigma(A_h) \subseteq \sigma(A) \cup \Lambda$.*

Proof. Let $x \in D(A_h)$. Then for $y \in D(A^*) = D(L)$, we have

$$\begin{aligned}
\langle A_h x, y\rangle &= \lim_{t\to 0} \frac{1}{t}\langle S_h(t)x - x, y\rangle \\
&= \lim_{t\to 0}\left(\frac{1}{t}\langle S(t)x - x, y\rangle + \frac{1}{t}\int_0^t \langle b, S^*(t-s)y\rangle\langle S_h(s)x, h\rangle\, ds\right) \\
&= \langle x, A^*y\rangle + \langle b, y\rangle\langle x, h\rangle \\
&= \langle x, Ly\rangle.
\end{aligned}$$

Hence we have made use of the fact that $\langle b, S^*(t-s)y\rangle\langle h, S_h(s)x\rangle$ is continuous in s.

Hence $x \in D(L^*)$ and $L^*x = A_h x$. So we have proved that L^* is an extension of A_h. It remains to show that $D(L^*) \subseteq D(A_h)$.

We know that L is closed. So Lemma 3.2 implies that $\sigma(L) \subseteq \{\lambda : \bar{\lambda} \in \sigma(A) \cup \Lambda\}$. It follows that $\sigma(L^*) \subseteq \sigma(A) \cup \Lambda$. Since both A and A_h are generators of strongly continuous semigroups, there exists a real number ω such that every number with real part greater than ω lies in the resolvent set of both A and A_h. Since Λ consists only of discrete points, we can certainly find a $\lambda \notin \Lambda$ with real part greater than ω. Such a λ does not belong to $\sigma(L^*) \cup \sigma(A_h)$. Now let $x \in D(A^*)$ and let $x_1 = R(\lambda, A_h)(\lambda I - L^*)x$. Then $x_1 \in D(A_h)$. Furthermore, $(\lambda I - L^*)x_1 = (\lambda I - A_h)x_1 = (\lambda I - L^*)x$. Since $\lambda \notin \sigma(L^*)$, it follows that $x = x_1$, showing that $x \in D(A_h)$. Hence indeed $L = A_h$. Finally, we have $\sigma(A_h) = \sigma(L^*) \subseteq \sigma(A) \cup \Lambda$. This completes the proof of the Theorem.

4. Spectral assignability. In this section, we make the following assumption on A.

Assumption A. The spectrum of A consists of simple eigenvalues $\{\lambda_n\}_{n=-\infty}^{\infty}$.

We will denote by $\{\varphi_n\}_{n=-\infty}^{\infty}$ the corresponding eigenvectors of A. We also let $\{\psi_n\}_{n=-\infty}^{\infty}$ be eigenvectors of A^* such that $\langle \psi_m, \varphi_n\rangle = \delta_{m,n}$.

PROPOSITION 4.1. *Let A satisfy assumption A. Then*

$$\sigma(A_h) = \Lambda \cup \{\lambda_n : \langle h, \varphi_n\rangle = 0 \text{ or } \langle \psi_n, b\rangle = 0\}.$$

Proof. It follows from Theorem 3.4 and the last statement of Lemma 3.2 that $\lambda \in \Lambda$ are eigenvalues of A_h.

Suppose $\langle h, \varphi_n \rangle = 0$. Let $y \in D(A^*)$. By Theorem 3.4 and (3.1), we have

$$\begin{aligned}\langle \lambda_n \varphi_n - A_h \varphi_n, y \rangle &= \langle \lambda_n \varphi_n, y \rangle - \langle \varphi_n, A^* y + \langle b, y \rangle h \rangle \\ &= \langle \lambda_n \varphi_n, y \rangle - \langle A \varphi_n, y \rangle \\ &= 0.\end{aligned}$$

Since $D(A^*)$ is dense in X, it follows that $\lambda_n \varphi_n - A_h \varphi_n = 0$. Hence $\lambda_n \in \sigma(A_h)$.

Now suppose $\langle \psi_n, b \rangle = 0$. Then $\bar{\lambda}_n \psi_n - L\psi_n = \bar{\lambda}_n \psi_n - A^* \psi_n = 0$. Hence $\bar{\lambda}_n$ is an eigenvalue of L and so λ_n is an eigenvalue of $L^* = A_h$.

Finally, suppose both $\langle h, \psi_n \rangle$ and $\langle \psi_n, b \rangle$ are nonzero. Since $\bar{\lambda}_h$ is an isolated eigenvalue of A^*, X can be decomposed into the direct sum of two subspaces $\langle \psi_n \rangle$ and M where $\langle \psi_n \rangle$ is the one-dimensional subspace generated by ψ_n and M is a closed subspace invariant under A^* such that the restriction of $\bar{\lambda}_n I - A^*$ to M has a bounded inverse [10, p.178]. We denote this inverse by $R_1(\bar{\lambda}_n, A^*)$.

We take any $y \in X$ and let $\alpha = \langle y, \varphi_n \rangle / \langle h, \varphi_n \rangle$ and $y_1 = y - \alpha h$. We claim that $y_1 \in M$. Indeed, because of the decomposition $X = \langle \varphi_n \rangle \oplus M$ and the boundedness of $R_1(\bar{\lambda}_n, A^*)$, we can write $y_1 = a\psi_n + (\bar{\lambda}_n I - A^*) y_2$, $y_2 \in M_2$. Since $\langle \varphi_n, y_1 \rangle = \langle \varphi_n, y \rangle - \bar{\alpha} \langle \varphi_n, h \rangle = 0$ and $\langle \varphi_n, (\bar{\lambda}_n I - A^*) y_2 \rangle = \langle (\lambda_n I - A) \varphi_n, y_2 \rangle = 0$, it follows that $\langle \varphi_n, a\psi_n \rangle = 0$. Hence $a = 0$ and so $y_1 \in M$.

Let $x_1 = R_1(\bar{\lambda}_n, A^*) y_1$ and let $t = -(\alpha + \langle x_1, b \rangle) / \langle \psi_n, b \rangle$. It is easy to verify that $x = t\psi_n + x_1$ satisfies $(\bar{\lambda}_n I - L)x = y$. Hence $\bar{\lambda}_n I - L$ is onto.

Now suppose $x = a\psi_n + x_1$, $x_1 \in M$ satisfies $(\bar{\lambda}_n I - L)x = 0$. Then this implies that

$$(\bar{\lambda}_n I - A^*) x_1 - \langle a\psi_n + x_1, b \rangle h = 0. \tag{4.1}$$

Since $\bar{\lambda}_n I - A^*$ is one-to-one on M, it follows that $\langle a\psi_n + x_1, b \rangle \neq 0$ unless $x_1 = 0$. On the other hand, taking the inner product of (4.1) with φ_n, we obtain $-\langle a\psi_n + x_1, b \rangle \langle \varphi_n, h \rangle = 0$. This is impossible. So we must have $x_1 = 0$. (4.1) then implies that $a = 0$. Hence $x = 0$. This proves that $\bar{\lambda}_n I - L$ is one-to-one. We have already shown that $\bar{\lambda}_n I - L$ is onto. Hence $\bar{\lambda}_n \notin \sigma(L)$ and thus $\lambda_n \notin \sigma(L^*) = \sigma(A_h)$. This finishes the proof of the proposition.

We now make another assumption.

Assumption B. $b_n \triangleq \langle b, \psi_n \rangle \neq 0$ for all n.

PROPOSITION 4.2. *If the system* (2.1) *is approximately controllable in some time* T (*i.e., range of* $B(T)$ *is dense in* X), *then assumption B is satisfied.*

Proof.

$$\begin{aligned}\langle B(T)u(\cdot), \psi_n \rangle &\int_0^T \langle b, S^*(T-s)\psi_n \rangle u(s)\, ds \\ &= \int_0^T \langle b, e^{\bar{\lambda}_n (T-s)} \psi_n \rangle u(s)\, ds \\ &= b_n \int_0^T e^{\lambda_n (T-s)} u(s)\, ds.\end{aligned} \tag{4.2}$$

It follows that if $b_n = 0$, then $\langle x, \psi_n \rangle = 0$ for all x in the range of $B(T)$. So the range of $B(T)$ cannot be dense.

We will now study the effect of a feedback of the form

$$u(t) = \langle x(t), h \rangle = \sum_{n=-\infty}^{\infty} \langle x(t), \psi_n \rangle h_n, \quad \text{where} \sum_{n=-\infty}^{\infty} |h_n|^2 < \infty. \tag{4.3}$$

We will find sufficient conditions on the operator A so that the above h indeed represents a continuous linear functional on X. One such sufficient condition is that $\{\psi_n\}_{n=-\infty}^{\infty}$ forms a Riesz basis of X (see, for example, [7, p. 309] for the definition of Riesz basis). However, this condition is sometimes rather difficult to verify. We are going to give another sufficient condition which is based on the exact controllability of the system (2.1) and a certain property about the distribution of the eigenvalues of A related to the Carleson measure.

Let μ be a nonnegative measure defined on the Borel subsets of $\{z: \operatorname{Re} z > \alpha\}$. Then μ is a *Carleson measure* if for every τ and every $\nu > 0$, $\mu(\{z: \tau - \nu \leqq \operatorname{Im} z \leqq \tau + \nu, \alpha < \operatorname{Re} z < \alpha + \nu\}) \leqq C\nu$ for some positive constant C depending only on μ (not on ν).

If $\{a_n\}$ is a sequence of complex numbers with $\operatorname{Re} a_n > \alpha$, we can define a measure on Borel subsets of $\{z: \operatorname{Re} z > \alpha\}$ by

$$\mu(E) = \text{number of elements of } E \cap \{a_n: -\infty < n < \infty\}. \tag{4.4}$$

We will simply refer to μ as *the measure induced by* $\{a_n\}$.

Remark. If the system (2.1) is exactly controllable in some time $T > 0$ (i.e. $B(T)$ is onto), then in particular each $b_n \neq 0$. For convenience, we normalize $\{\phi_n\}$ and $\{\psi_n\}$ so that $\langle \psi_n, b\rangle = 1$. (Note that we always have $\langle \phi_n, \psi_n\rangle = 1$ so this will automatically give a corresponding normalization for ϕ_n.)

PROPOSITION 4.3. *Suppose the system* (2.1) *is exactly controllable in some time* $T > 0$ (*i.e., $B(T)$ is onto*) *and* $\{-\lambda\}_{n=-\infty}^{\infty}$ *induces a Carleson measure on* $\{z: \operatorname{Re} z > \alpha\}$ *where* α *is a real number less than* $-\operatorname{Re} \lambda_n$ *for all* n. *Then there exists a constant* $K > 0$ *so that*

$$\sum_{n=-\infty}^{\infty} |\langle x, \psi_n\rangle|^2 \leqq K\|x\|^2.$$

(Note that the above relation in fact depends on b because we require $\langle b, \psi_n\rangle = 1$. This is to be expected because exact controllability depends on b.)

To prove Proposition 4.3, we need to use the Carleson Theorem as applied to the space

$$H_\alpha^2 \equiv H^2\{z: \operatorname{Re} z > \alpha\}, \quad \alpha \text{ real.}$$

One way to define H_α^2 is to define it as the space of complex functions which are Laplace transforms of functions f on $[0, \infty)$ such that $e^{-\alpha t} f(t)$ is square integrable on $[0, \infty)$ and we have

$$\|\mathscr{L}f\|_{H_\alpha^2} = \int_0^\infty |e^{-\alpha t} f(t)|^2 \, dt.$$

H_α^2 is a Hilbert space. We have the following Carleson's theorem ([2], [5] or [9]).

THEOREM (Carleson). *If* μ *is a Carleson measure on* $\{z: \operatorname{Re} z > \alpha\}$ *then for* $\phi \in H_\alpha^2$, *we have*

$$\int_{\{z: \operatorname{Re} z > \alpha\}} |\phi(z)|^2 \, d\mu(z) \leqq K^2 \|\phi\|_{H_\alpha^2}^2 \tag{4.5}$$

where K *is a constant independent of* ϕ.

Proof of Proposition 4.3. Since $B(T)$ is onto, it has a bounded right inverse $B(T^{-1})$, say. (4.2) implies that for $x \in X$ (with $b_n = 1$ now),

$$\langle x, \psi_n\rangle = \int_0^T e^{\lambda_n (T-s)} (B(T)^{-1} x)(s) \, ds.$$

Letting

$$\phi_x(z) = \int_0^T \bar{e}^{z(T-s)}(B(T)^{-1}(x))(s)\, ds,$$

then $\phi_x \in H_\alpha^2$ and

$$\|\phi_x\|_{H_\alpha^2} = \left(\int_0^T |e^{-\alpha(T-s)}(B(T)^{-1}x)(s)|^2\, ds\right)^{1/2}$$
$$\leqq \max\{1, e^{-\alpha T}\}\|(B(T)\|^{-1}\|x\|.$$

Combining this with inequality (4.5) as applied to the measure induced by $\{-\lambda_n\}$, we have $(\sum_{n-\infty}^{\infty}|\phi_x(-\lambda_n)|^2)^{1/2} \leqq K_1\|x\|$ where $K_1 = K \max\{1, e^{-\alpha T}\}\|B(T)^{-1}\|$. Since $\phi_x(-\lambda_n) = \langle x, \psi_n\rangle$, the proof of the proposition is completed.

Remark. The conclusion of Proposition 4.3 is equivalent to saying that for every $\{h_n\} \in l^2$ the mapping $\langle x, h\rangle = \sum_{n=-\infty}^{\infty} h_n\langle x, \psi_n\rangle$ is a continuous linear functional in X.

THEOREM 4.4. *Suppose the system* (2.1) *is approximately controllable in some time T and the operator A has only simple eigenvalues λ_n, $-\infty < n < \infty$. (So Assumptions* A *and* B *are satisfied.) Suppose also that the set $\{b_n\}$ is uniformly bounded, $\{{}^{1/\lambda}n\} \in l^2$ and every h of the form in* (4.3) *represents a continuous linear functional on X. Denoting $\beta_n = \sum_{m\neq n} 1/|\lambda_m - \lambda_n|^2$, if $\{\mu_n\}_{n=-\infty}^{\infty}$ is a sequence of complex numbers such that*

$$\sum_{n=-\infty}^{\infty} \frac{(1+\beta_n)|\mu_n - \lambda_n|^2}{|b_n|^2} < \infty, \tag{4.6}$$

then there exists $h \in X$ of the form in (4.3) *such that $\sigma(A_h) = \{\mu_n\}_{n=-\infty}^{\infty}$.*

Proof. Let $h \in X'$ be defined by

$$\langle x, h\rangle = \sum_n \langle x, \psi_n\rangle h_n, \qquad \{h_n\} \in l^2.$$

We first find a more explicit form for $\Delta_h(\lambda)$ (cf. Lemma 3.1). Let $R_\lambda b$ be the unique element in X such that

$$\langle b, R(\bar{\lambda}, A^*)x\rangle = \langle R_\lambda b, x\rangle$$

for all x in X. Clearly, $\langle R_\lambda b, \psi_n\rangle = \langle b, \psi_n\rangle/(\lambda - \lambda_n)$.

Hence

$$\begin{aligned}\Delta_h(\lambda) &= \langle R_\lambda b, h\rangle - 1\\ &= \sum_n \langle R_\lambda b, \psi_n\rangle h_n - 1\\ &= \sum_n \frac{\langle b, \psi_n\rangle h_n}{\lambda - \lambda_n} - 1\\ &= \sum_n \frac{b_n h_n}{\lambda - \lambda_n} - 1.\end{aligned}$$

So in order that $\sigma(A_n)$ be equal to a given sequence $\{\mu_n\}$, a necessary and sufficient condition is that

$$\sum_{n\in\mathcal{N}} \frac{b_n h_n}{\mu_n - \lambda_n} = 1 \quad \text{for all } m \in \mathcal{N} \tag{4.7}$$

where $\mathcal{N} = \{n: \mu_n \neq \lambda_n\}$.

For simplicity of notation, we assume $\mathcal{N}=\mathcal{Z}$. The proof for the case $\mathcal{N}\subset\mathcal{Z}$ is similar. Multiplying both side of (4.7) by $(\mu_m-\lambda_m)/b_m$, it becomes

$$\sum_n \frac{b_n(\mu_m-\lambda_m)}{b_m(\mu_m-\lambda_n)}h_n=\frac{\mu_m-\lambda_m}{b_m} \quad \text{for all } m. \tag{4.8}$$

We can rewrite this in the form of a matrix equation

$$M\mathbf{h}=\mathbf{c}. \tag{4.9}$$

where M is the infinite matrix with i, j entries $(b_j(\mu_i-\lambda_i))/(b_i(\mu_i-\lambda_j))$, $\mathbf{h}$ and $\mathbf{c}$ are infinite column vectors with ith entry equal to h_i and $(\mu_i-\lambda_i)/b_i$ respectively. Notice that the diagonal elements of M are 1 and the sum of the squares of the off diagonal elements is finite.

Indeed (4.6) implies that

$$\sum_{\substack{n,m\\ n\neq m}}\left|\frac{\mu_n-\lambda_n}{\mu_m-\lambda_n}\right|^2<\infty.$$

Hence there is an integer $N>0$ such that

$$\left|\frac{\mu_n-\lambda_n}{\lambda_m-\lambda_n}\right|<\frac{1}{2} \quad \text{wherever } |m|\geqq N \text{ or } |n|\geqq N.$$

So

$$\begin{aligned}\frac{1}{|\mu_m-\lambda_m|}&\leqq\frac{1}{(|\lambda_m-\lambda_n|-|\mu_n-\lambda_n)|}\\ &\leqq\frac{1}{(|\lambda_m-\lambda_n|-\frac{1}{2}|\lambda_m-\lambda_n|)}=\frac{2}{|\lambda_m-\lambda_n|}\end{aligned}$$

if $|m|\geqq N$ or $|n|\geqq N$.

It follows that the set

$$\left\{\frac{|\lambda_m-\lambda_n|}{|\mu_m-\lambda_n|}: m\neq n\right\}$$

is uniformly bounded. Let K be an upper bound for this set. Then

$$\begin{aligned}\sum_{\substack{m,n\\ m\neq n}}\left|\frac{b_n(\mu_m-\lambda_n)}{b_m(\mu_m-\lambda_n)}\right|^2&\leqq\sup_n|b_n|^2K^2\sum_{\substack{m,n\\ m\neq n}}\left|\frac{\mu_m-\lambda_m}{b_m(\lambda_m-\lambda_n)}\right|^2\\ &=\sup_n|b_n|^2K^2\sum_m\left|\frac{\mu_m-\lambda_m}{b_m}\right|^2\beta_m\\ &<\infty.\end{aligned}$$

Hence the sum of the squares of the off diagonal elements of M is indeed finite.

So by Fredholm Theory [15, Chap. 9, § 17], (4.9) has a solution if the determinant of M is convergent, i.e. if $\det M_n$ converges to a nonzero limit where M_n is the truncated $2n+1\times 2n+1$ matrix

$$(a_{ij})_{\substack{-n\leqq i\leqq n\\ -n\leqq j\leqq n}}.$$

By [12, Lemma 3.1] the limit of $\det M_n$ is given by the infinite product

$$\prod_{n=-\infty}^{\infty}\prod_{m=n+1}^{\infty}\frac{(\mu_m-\mu_n)(\lambda_n-\lambda_m)}{(\lambda_m-\mu_n)(\lambda_n-\mu_m)}=\prod_{n=-\infty}^{\infty}\prod_{m=n+1}^{\infty}\left(1+\frac{(\mu_m-\lambda_m)(\lambda_n-\mu_n)}{(\lambda_m-\mu_n)(\lambda_n-\mu_m)}\right). \tag{4.10}$$

Now by Schwartz' inequality,

$$\sum_{n=-\infty}^{\infty}\sum_{m=n+1}^{\infty}\left|\frac{(\mu_m-\lambda_m)(\lambda_n-\mu_n)}{(\lambda_m-\mu_n)(\lambda_n-\mu_m)}\right| \leqq \sum_{n=-\infty}^{\infty}\sum_{\substack{m=-\infty\\ m\neq n}}^{\infty}\left|\frac{\mu_n-\lambda_n}{\lambda_m-\mu_n}\right|^2. \tag{4.11}$$

Since $\sum_{n=-\infty}^{\infty}\beta_n|\mu_n-\lambda_n|^2$ is finite, we can choose N sufficiently large such that $|\mu_n-\lambda_n|^2\beta_n<\frac{1}{4}$ if $|n|>N$. This implies that if $|n|>N$, then $|\mu_n-\lambda_n|^2<\frac{1}{4}|\lambda_m-\lambda_n|^2$ for all $m\neq n$. Hence (4.11) implies that

$$\sum_{n=-\infty}^{\infty}\sum_{m=n+1}^{\infty}\left|\frac{(\mu_m-\lambda_m)(\lambda_n-\mu_n)}{(\lambda_m-\mu_n)(\lambda_n-\mu_m)}\right|$$

$$\leqq \sum_{n=-N}^{N}\sum_{\substack{m=-\infty\\ m\neq n}}^{\infty}\left|\frac{\mu_n-\lambda_n}{\mu_n+\lambda_m}\right|^2+\sum_{|n|>N}\sum_{\substack{m=-\infty\\ m\neq n}}^{\infty}\frac{|\mu_n-\lambda_n|^2}{\|\lambda_m-\lambda_n|-|\mu_n-\lambda_n\|^2}.$$

The first term of the last expression is finite and the second term is less than

$$4\sum_{|n|>N}\sum_{\substack{m=-\infty\\ m\neq n}}^{\infty}\frac{|\mu_n-\lambda_n|^2}{|\lambda_m-\lambda_n|^2}=4\sum_{|n|>N}|\mu_n-\lambda_n|^2\beta_n.$$

So by familiar results, [14, p. 15], for example, the infinite product in (4.10) converges. So (4.9) has a solution $\mathbf{h}=\{h_n\}$ in l^2. This completes the proof of the theorem.

5. A degenerate hyperbolic system. We consider the two-dimensional control system

$$\frac{\partial}{\partial t}\begin{pmatrix}v\\ w\end{pmatrix}(x,t)=\begin{pmatrix}-\gamma_1 & 0\\ 0 & \gamma_2\end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix}v\\ w\end{pmatrix}(x,t)+B\begin{pmatrix}v\\ w\end{pmatrix}(x,t),$$

$$v(0,t)=0, \qquad w(1,t)=u(t), \tag{5.1}$$

$$v(x,0)=v_0(x), \qquad w(x,0)=w_0(x).$$

Here both γ_1 and γ_2 are positive numbers,

$$B=\begin{pmatrix}b_{11} & b_{12}\\ b_{21} & b_{22}\end{pmatrix}$$

is a 2×2 matrix and $(x,t)\in\Omega\triangleq\{(\xi,s)\colon 0\leqq\xi\leqq 1, 0\leqq s\}$. This system is a degenerate case of the more general system with the boundary condition in (5.1) being replaced by

$$\alpha_1 v(0,t)+\alpha_2 w(0,t)=0, \qquad \beta_1 v(1,t)+\beta_2 w(1,t)=u(t). \tag{5.2}$$

The fact that $\alpha_2=\beta_1=0$ in our case says roughly that information is lost as it reaches the boundary and thus this system is not time reversible.

To put this system in the abstract form (2.1), we let

$$X=\left\{\begin{pmatrix}v(\cdot)\\ W(\cdot)\end{pmatrix}\colon v(\cdot)\in H^1[0,1],\ w(\cdot)\in L^2[0,1],\ v(0)=0\right\}$$

equipped with the $H^1[0,1]\times L^2[0,1]$ norm.

$$A\begin{pmatrix}v\\ w\end{pmatrix}=\begin{pmatrix}-\gamma_1 & 0\\ 0 & \gamma_2\end{pmatrix}\frac{d}{dX}\begin{pmatrix}v\\ w\end{pmatrix}+B\begin{pmatrix}v\\ w\end{pmatrix} \tag{5.3}$$

with

$$D(A)=\left\{\begin{pmatrix} v(\cdot) \\ w(\cdot) \end{pmatrix}: v(\cdot)\in H^2[0,1],\ w(\cdot)\in H^1[0,1],\right.$$
$$\left. v(0)=w(1)=0,\ -\gamma_1 v'(0)+b_{12}w(0)=0\right\}.$$

We shall identify X' as a space of distributions so that

$$X\subseteq (L^2[0,1])^2\subseteq X'$$

and the duality pairing of $X\times X'$ when restricted to $X\times(L^2[0,1])^2$ coincides with the inner product on $(L^2[0,1])^2$.

We denote by A' the operator from X' into X' so that

$$D(A')=\{y\in X': \text{there exists a constant } K \text{ such that } \langle Ax, y\rangle_{X\times X'}\leqq K\|x\|_X \text{ for all } x\in D(A)\}$$

and $\langle x, A'y\rangle_{X\times X'}=\langle Ax, y\rangle_{X\times X'}$ for all $x\in D(A)$, $y\in D(A')$.

Let C be the isometry from X onto X' defined in such a way so that $\langle x, Cy\rangle_{X\times X'}=\langle x, y\rangle_{X\times X}$ for all $x, y\in X$. The right-hand side is the inner product of x and y in X. The relation between A' and A^* is as follows.

(i) $x\in D(A^*)$ if and only if $Cx\in D(A')$.

(ii) $CA^*=A'C$.

(iii) If we equip $D(A')$ with the norm

$$\|y\|_{D(A')}=\|y\|_{X'}+\|A'y\|_{X'}$$

then C is an isometry from $D(A^*)$ onto $D(A')$.

We define

$$\hat{b}\begin{pmatrix} y \\ z \end{pmatrix}=\gamma_2 z(1) \quad \text{for} \begin{pmatrix} y \\ z \end{pmatrix}\in D(A'). \tag{5.4}$$

We now prove some results showing that the various assumptions we made in the preceding sections are satisfied by their system.

LEMMA 5.1. *The linear functions $\hat{b}$ defined in* (5.2) *is a continuous linear functional on $D(A')$.*

Proof. We define another operator A_1 on x:

$$A_1\begin{pmatrix} v \\ w \end{pmatrix}=\begin{pmatrix} -\gamma_1 & 0 \\ 0 & \gamma_2 \end{pmatrix}\frac{d}{dx}\begin{pmatrix} v \\ w \end{pmatrix}+B\begin{pmatrix} v \\ w \end{pmatrix} \tag{5.5}$$

with

$$D(A_1)=\left\{\begin{pmatrix} v(\cdot) \\ w(\cdot) \end{pmatrix}: v\in H^2[0,1],\ w\in H^1[0,1],\ v(0)=0,\ -\gamma_1 v'(0)+b_{12}w(0)=0\right\}.$$

We claim that

$$\left\langle A_1\begin{pmatrix} v \\ w \end{pmatrix}, \begin{pmatrix} y \\ Z \end{pmatrix}\right\rangle-\left\langle \begin{pmatrix} v \\ w \end{pmatrix}, A'\begin{pmatrix} y \\ z \end{pmatrix}\right\rangle=w(1)\hat{b}\begin{pmatrix} y \\ z \end{pmatrix} \tag{5.6}$$

for all

$$\begin{pmatrix} v \\ w \end{pmatrix}\in D(A_1) \quad \text{and} \quad \begin{pmatrix} y \\ z \end{pmatrix}\in D(A').$$

If (5.6) indeed holds, then obviously $\hat{b}$ is a continuous linear functional on $D(A')$ because we can certainly find some $\binom{v}{w}$ in $D(A_1)$ such that $w(1)\neq 0$. So it remains to prove (5.6).

We identify the dual space of X as consisting of ordered pairs of distributions so that

$$X \subseteq (L^2[0,1])^2 \subseteq X'$$

and the duality pairing when restricted to $X \times (L^2[0,1])^2$ coincides with the inner product on $(L^2[0,1])^2$.

Let $F \in X'$, then there are functions f_1 and f_2 in $L^2[0,1]$ such that

$$\left\langle \begin{pmatrix} v \\ w \end{pmatrix}, F \right\rangle = \int_0^1 v'(x) f_1(x) + w(x) f_2(x)\, dx \quad \text{for all } \begin{pmatrix} v \\ w \end{pmatrix} \in X. \tag{5.7}$$

Suppose $F \in D(A')$ and $A'F = G$; then since

$$\left\langle A\begin{pmatrix} v \\ w \end{pmatrix}, F \right\rangle = \int_0^1 (-\gamma_1 v'' + b_{11} v' + b_{12} w') f_1 + (\gamma_2 w' + b_{21} v + b_{22} w) f_2\, dx$$

and

$$\left\langle \begin{pmatrix} v \\ w \end{pmatrix}, G \right\rangle = \int_0^1 v' g_1 + w g_2\, dx$$

for some $g_1, g_2 \in L^2[0,1]$, it follows that

$$\begin{aligned} &f_1, f_2, \gamma_2 f_1' - g_1 \in H'[0,1], \\ &f_1(1) = f_2(0) = (\gamma_1 f_1' - g_1)(1) = 0, \\ &(\gamma_1 f_1' - g_1)' + b_{11} f_1' + b_{21} f_2' = 0 \\ &b_{12} f_1' + \gamma_2 f_2' = b_{22} f_2 - g_2. \end{aligned} \tag{5.8}$$

Hence integrating the right-hand side of (5.7) by parts, we get

$$\begin{aligned} \left\langle \begin{pmatrix} v \\ w \end{pmatrix}, F \right\rangle &= \int_0^1 -v(x) f_1'(x) + w(x) f_2(x)\, dx \\ &= \int_0^1 v(x)\overline{y(x)} + w(x)\overline{z(x)}\, dx \end{aligned}$$

where $y(x) = \overline{-f_1'(x)}$ and $z(x) = \overline{f_2(x)}$. So we see that

$$D(A') = \left\{ \begin{pmatrix} y \\ z \end{pmatrix} : y \in L^2[0,1],\ z \in H^1[0,1] \text{ and } z(0) = 0 \right\}.$$

From (5.6), we have

$$\begin{aligned} &-\gamma_1 \bar{y} - g_1 \in H^1[0,1], \\ &(-\gamma_1 \bar{y} - g_1)(0) = 0, \\ &(-\gamma_1 \bar{y} - g_1)' + b_{11} \bar{y} + b_{21} \bar{z} = 0, \\ &g_2 = -\gamma_2 \bar{z}' + b_{12} \bar{y} + b_{22} \bar{z}. \end{aligned}$$

Hence

$$\left\langle \begin{pmatrix} v \\ w \end{pmatrix}, A'\begin{pmatrix} y \\ z \end{pmatrix} \right\rangle = \int_0^1 v' g_1 + w(-\gamma_2 \bar{z}' + b_{12} \bar{y} + b_{22} \bar{z})\, dx. \tag{5.9}$$

Now if $\binom{v}{w} \in D(A_1)$, then $\binom{v}{w} - \binom{0}{xw(1)} \in D(A)$. Hence for $\binom{v}{w} \in D(A_1)$ and $\binom{y}{z} \in D(A')$, we have

$$\left\langle A_1\begin{pmatrix} v \\ w \end{pmatrix}, \begin{pmatrix} y \\ z \end{pmatrix}\right\rangle - \left\langle \begin{pmatrix} v \\ w \end{pmatrix}, A\begin{pmatrix} y \\ z \end{pmatrix}\right\rangle = \left\langle A_1\begin{pmatrix} 0 \\ xw(1) \end{pmatrix}, \begin{pmatrix} y \\ z \end{pmatrix}\right\rangle - \left\langle \begin{pmatrix} 0 \\ xw(1) \end{pmatrix}, A'\begin{pmatrix} y \\ z \end{pmatrix}\right\rangle$$

(by (5.9))
$$= \int_0^1 b_{12}xw(1)\bar{y} + \gamma_2 w(1) + b_{22}xw(1)\bar{z}\, dx$$
$$- \int_0^1 xw(1)(-\gamma_2\bar{z}' + b_{12}\bar{y} + b_{22}\bar{z})\, dx$$
$$= \int_0^1 \gamma_2 w(1)(\bar{z} + x\bar{z}')\, dx$$
$$= \int_0^1 \gamma_2 w(1)\frac{d}{dx}(x\bar{z})\, dx$$
$$= \gamma_2 w(1)\overline{z(1)}.$$

So (5.6) indeed holds. This completes the proof of the lemma.

We now consider the following system.

$$\frac{\partial}{\partial t}\begin{pmatrix} v \\ w \end{pmatrix}(x, t) = \begin{pmatrix} -\gamma_1 & 0 \\ 0 & \gamma_2 \end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix} v \\ w \end{pmatrix}(x, t) + B\begin{pmatrix} v \\ w \end{pmatrix}(x, t) + \begin{pmatrix} 0 \\ g(x, t) \end{pmatrix},$$

(5.10)
$$v(0, t) = 0, \qquad w(1, t) = u(t),$$
$$v(x, 0) = v_0(x), \qquad w(x, 0) = w_0(x).$$

For $T > 0$, we denote

$$\Omega_T \triangleq \{(\xi, s): 0 \leqq \xi \leqq 1, 0 \leqq s \leqq T\}.$$

PROPOSITION 5.2. *Suppose that* $v_0(x)$, $w_0(x) \in C^1[0, 1]$, $g \in C^1(\Omega_T)$ *and* $u(t)$ *is continuous and* $v_0(0) = 0$. *Then* (5.4) *admits a unique solution. Furthermore, there exists a constant* K *independent of* v_0, w_0, u *and* $0 \leqq t \leqq T$ *such that*

$$\left\|\begin{pmatrix} v \\ w \end{pmatrix}(t)\right\|_X \leqq K\left(\left\|\begin{pmatrix} v_0 \\ w_0 \end{pmatrix}\right\|_X + \|u\|_{L^2[0,T]} + \|g\|_{L^2(\Omega_T)}\right). \tag{5.11}$$

Proof. Existence and uniqueness of the solution with the given data is well known (see, e.g., [4, Chap. 5]).

For a point (x, t) in Ω_T, we will denote by $C_1(x, t)$ and $C_2(x, t)$ respectively the backward characteristics passing through (x, t) with slopes $1/\gamma_1$ and $-1/\gamma_2$ respectively and by $P_1(x, t)$ and $P_2(x, t)$ respectively the points at which these characteristics hit the boundary of Ω_T. We parametrize the characteristics by the t variable. Take a fixed point (x, t) in Ω_T. By integrating the first component equation of (5.4) along $C_1(x, t)$, we have

$$v(x, t) = \int_{C_1(x,t)} (b_{11}v + b_{12}w)(x(s), s)\, ds + v(P_1) \tag{5.12}$$

from which we can easily get the estimate

$$\int_0^1 |v(x, t)|^2\, dx \leqq K_1\left(\int_0^t \int_0^1 |v(x, s)|^2 + |w(x, s)|^2\, dx\, ds + \int_0^1 |v_0(x)|^2\, dx\right) \tag{5.13}$$

where K_1 is a constant which can be chosen to be independent of $t \in [0, T]$. Similarly, we have

$$w(x, t) = \int_{C_2(x,t)} (b_{21}v + b_{22}w + g)(x(s), s)\, ds + w(P_2) \tag{5.14}$$

from which we can obtain the inequality

$$\int_0^1 |w(x, t)|^2\, dx \leqq K_2\Big(\int_0^t \int_0^1 |v(x, s)|^2 + |w(x, s)|^2 + |g(x, s)|^2\, dx\, ds + \int_0^1 |v_0(x)|^2\, dx + \int_0^t |u(s)|^2\, ds\Big), \tag{5.15}$$

K_2 a constant independent of t.

Combining (5.13) and (5.15) and applying the Gronwall inequality, we have

$$\int_0^1 |v(x, t)|^2 + |w(x, t)|^2\, dx \leqq K_3\Big(\int_0^T \int_0^1 |g(x, s)|^2\, dx\, ds + \int_0^T |u(s)|^2\, ds + \int_0^1 |v_0(x)|^2 + |w_0(x)|^2\, dx\Big). \tag{5.16}$$

Next, we estimate $\partial v/\partial x$. First,

$$\begin{aligned} \frac{\partial}{\partial x}\int_{C_1(x,t)} v(x(s), s)\, ds &= \frac{\partial}{\partial x}\int_{t-x/\gamma_1}^t v(x + \gamma_1(s-t), s)\, ds \\ &= \frac{1}{\gamma_1} v(0, t - x/\gamma_1) + \int_{t-x/\gamma_1}^t \frac{\partial}{\partial x} v(x + \gamma_1(s-t), s)\, ds \\ &= \frac{1}{\gamma_1} v(P_1(x, t)) + \int_{C_1(x,t)} \frac{\partial}{\partial x} v(x(s), s)\, ds. \end{aligned} \tag{5.17}$$

Also,

$$\frac{\partial}{\partial x}\int_{C_1(x,t)} w(x(s), s)\, ds = \frac{1}{\gamma_1} w(0, t - x/\gamma_1) + \int_{t-x/\gamma_1}^t \frac{\partial}{\partial x} w(x + \gamma_1(s-t), s)\, ds.$$

We can rewrite the second term in the above expression. Since

$$\begin{aligned} &\int_{t-x/\gamma_1}^t \frac{\partial}{\partial x} w(x + \gamma_1(s-t), s) + \frac{\partial}{\partial s} w(x + \gamma_1(s-t), s)\, ds \\ &\quad = \int_{t-x/\gamma_1}^t \frac{d}{ds} w(x + \gamma_1(s-t), s)\, ds \\ &\quad = w(x, t) - w(P_1(x, t)) \end{aligned} \tag{5.18a}$$

and because of (5.10), we have

$$\gamma_2 \frac{\partial}{\partial x} w(x, s) - \frac{\partial w}{\partial s}(x, s) + b_{21}v(x, s) + b_{22}w(x, s) + g(x, s) = 0, \tag{5.18b}$$

it follows from (5.18a) and (5.18b) that

$$\int_{C_1(x,t)} (\gamma_1 + \gamma_2)\frac{\partial}{\partial x} w(x(s), s) + b_{21}v(x(s), s) + b_{22}w(x(s), s) + g(x(s), s)\, ds = w(x, t) - w(P_1(x, t)).$$

Hence,

$$\frac{\partial}{\partial x}\int_{C_1(x,t)} w(x(s), s)\,ds = \left(\frac{1}{\gamma_1}-\frac{1}{\gamma_1+\gamma_2}\right)w(P_1(x,t))+\frac{1}{\gamma_1+\gamma_2}w(x,t)$$

$$+\frac{1}{\gamma_1+\gamma_2}\int_{C_1(x,t)} -b_{21}v(x(s), s)-b_{22}w(x(s), s)-g(x(s), s)\,ds. \tag{5.19}$$

Combining (5.12), (5.17) and (5.19) we can easily obtain

$$\int_0^1 \frac{\partial}{\partial x}|v(x,t)|^2\,dx \leqq K_4\Bigg(\int_0^t\int_0^1 \left|\frac{\partial}{\partial x}v(x,s)\right|^2+|w(x,s)|^2\,dx\,ds$$

$$+\int_0^T\int_0^1 |g(x,s)|^2\,dx\,ds \tag{5.20}$$

$$+\int_0^1 |v_0(x)|^2+|w_0(x)|^2+\left|\frac{\partial}{\partial x}v_0(x)\right|^2 dx+\int_0^T |u(s)|^2\,ds\Bigg).$$

The desired result then follows by applying Gronwall's inequality to (5.20) and combining the result with (5.16). This finishes the proof of the proposition.

Letting u and g be zero in (5.10), we have the estimate

$$\left\|\begin{pmatrix} v \\ w\end{pmatrix}(t)\right\|_X \leqq K\left\|\begin{pmatrix} v_0 \\ w_0\end{pmatrix}\right\|_X,$$

where K is a constant independent of $t\in[0, T]$. Since T is arbitrary, we have in general

$$\left\|\begin{pmatrix} v \\ w\end{pmatrix}(t)\right\|_X \leqq K_t\left\|\begin{pmatrix} v_0 \\ w_0\end{pmatrix}\right\|$$

where K_t is some constant depending on t. This implies that when we apply no control on the system (5.1), the mapping carrying $\binom{v_0}{w_0}$ to $\binom{v(t)}{w(t)}$ can be extended to a continuous linear operator mapping X into itself. We denote this operator by $S(t)$. It is easy to see that the family $\{S(t): t\geqq 0\}$ forms a strongly continuous semigroup of continuous linear operators on X. It is easy to verify that the generator of this semigroup is exactly A. So we have proved.

PROPOSITION 5.3. *The operator as defined in* (5.3) *generates a strongly continuous semigroup in X.*

PROPOSITION 5.4. *Let $\hat{b}$ be the linear function on $D(A')$ as defined in* (5.4). *Then the linear functional $b=\hat{b}C$ defined on $D(A^*)$ is an admissible input element. Here C denotes the isometry from X into X' such that $\langle x, Cy\rangle_{X\times X'}=\langle x, y\rangle_{X\times X}$ for all $x, y\in X$.*

Proof. Let v and w be the solution of

$$\frac{\partial}{\partial t}\begin{pmatrix} v \\ w\end{pmatrix}=\begin{pmatrix} -\gamma_1 & 0 \\ 0 & \gamma_2\end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix} v \\ w\end{pmatrix}+B\begin{pmatrix} v \\ w\end{pmatrix},$$

$$v(0,t)=0,\quad w(1,t)=u(t),\quad v(x,0)=w(x,0)=0.$$

We assume that $u\in c^1(0,\tau)$, $\tau>0$. For each fixed t, $0\leqq t\leqq\tau$, we have

$$\begin{pmatrix} v(x,t) \\ w(x,t)\end{pmatrix}\in D(A_1)$$

and

$$\frac{d}{dt}\begin{pmatrix} v(x,t) \\ w(x,t)\end{pmatrix}=A_1\begin{pmatrix} v(x,t) \\ w(x,t)\end{pmatrix}.$$

Let

$$\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \in D(A').$$

Then (5.6) implies that

$$\begin{aligned} &\left\langle \frac{d}{dt}\begin{pmatrix} v(x,t) \\ w(x,t) \end{pmatrix}, S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\rangle - \left\langle \begin{pmatrix} v(x,t) \\ w(x,t) \end{pmatrix}, A'S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\rangle \\ &\quad = u(t)\overline{\hat{b}\left(S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right)}. \end{aligned} \tag{5.20)'}$$

Note that the left-hand side of the above equality equals

$$\frac{d}{dt}\left\langle \begin{pmatrix} v(x,t) \\ w(x,t) \end{pmatrix}, S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\rangle.$$

Hence integrating from 0 to τ, one has

$$\left\langle \begin{pmatrix} v(x,t) \\ w(x,t) \end{pmatrix}, \begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\rangle = \int_0^\tau u(t)\overline{\hat{b}\left(S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right)}\, dt.$$

But by Proposition 5.2, we have (on letting $v_0 = w_0 = 0$, $g = 0$)

$$\left\| \begin{pmatrix} v(\cdot,\tau) \\ w(\cdot,\tau) \end{pmatrix} \right\|_X \leqq K\left(\int_0^\tau |u(s)|^2\, ds \right)^{1/2}$$

the constant K being independent of τ for τ sufficiently small. Hence (5.20)' implies that

$$\int_0^\tau u(t)\overline{\hat{b}\left(S(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right)}\, dt \leqq K\left(\int_0^\tau |u(s)|^2\, ds \right)^{1/2} \left\| \begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\|_{X'}.$$

Since u is an arbitrary function in $C^1(0, \tau)$, it follows that

$$\int_0^\tau \left| \hat{b}\left(S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right) \right| dt \leqq K^2 \left\| \begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right\|_{X'}^2$$

for all $\binom{y_0}{z_0} \in D(A')$. Let $C\mathbf{y} = \binom{y_0}{z_0}$. Then

$$\hat{b}\left(S'(\tau-t)\begin{pmatrix} y_0 \\ z_0 \end{pmatrix} \right) = \hat{b}(S'(\tau-t)C\mathbf{y}) = \hat{b}(CS^*(\tau-t)\mathbf{y}) = b(S^*(\tau-t)\mathbf{y}).$$

So we have $\int_0^\tau |b(S^*(\tau-t)\mathbf{y})|^2 \leqq K^2\|\mathbf{y}\|_{X'}^2$. This proves that b is an admissible input element.

Next, we prove a controllability result. We will denote

$$T = \frac{1}{\gamma_1} + \frac{1}{\gamma_2}.$$

THEOREM 5.5. *For the system* (5.1), *if* $b_{12} \neq 0$ *and* $|b_{21}|$ *is sufficiently small, then given any* $\binom{v_T}{w_T}$ *in* X, *we can find a unique* $u \in L^2[0, T]$ *such that the solution of* (5.1) *with initial condition* $v_0 = w_0 = 0$ *satisfies*

$$\begin{pmatrix} v \\ w \end{pmatrix}(x, T) = \begin{pmatrix} v_T \\ w_T \end{pmatrix}(x), \qquad 0 \leqq x \leqq 1. \tag{5.21}$$

Proof. Case 1: $b_{21}=0$. In this case, by integrating along characteristic $C_2(x, t)$ we have the relation

$$w(x, T)=\exp[b_{22}(1-x)/\gamma_2]u(T-(1-x)/\gamma_2)$$

from which we can solve for u as a function in $L^2[1/\gamma_1, T]$.

Next,

$$\begin{aligned} v(x, T) &= \int_{-x/\gamma_2}^{0} b_{12}\exp[-b_{11}s+b_{22}(1-x-\gamma_1)s/\gamma_2] \\ &\quad \times u(T+s-(1-x-\gamma_1 s)/\gamma_2)\,ds \\ &= \int_{(1-x)/\gamma_1}^{t-(1-x)/\gamma_2} b_{12}\gamma_2/(\gamma_1+\gamma_2)\cdot\exp[\alpha_1(1-x)+\alpha_2(t-\xi)]u(\xi)\,d\xi \end{aligned}$$

where $\alpha_1=(b_{22}-b_{11})/(\gamma_1+\gamma_2)$ and $\alpha_2=(b_{11}\gamma_1+b_{22}\gamma_2)/(\gamma_1+\gamma_2)$.

Differentiating with respect to x, we obtain

$$\begin{aligned} \frac{d}{dx}v_T(x) &= -\alpha_1 v_T(x)+b_{12}\gamma_2\exp[b_{22}(1-x)/\gamma_2]u(T-(1-x)/\gamma_2)/(\gamma_1+\gamma_2) \\ &\quad - b_{12}\gamma_2\exp[(b_{22}/\gamma_2)-(b_{11}\gamma_1)]u\left(\frac{1}{\gamma_2}-\frac{x}{\gamma_1}\right)\Big/(\gamma_1+\gamma_2). \end{aligned}$$

Since $u(T-(1-x)/\gamma_2)$ is known for $0\leqq x\leqq 1$, we could solve for $u(T-x/\gamma_1-1/\gamma_2)$ as a function in L^2. Because $\tau=T-x/\gamma_1-1/\gamma_2$ ranges from 0 to $1/\gamma_1$ as x ranges from 0 to 1, this gives u as a function in $L^2[0, 1/\gamma_1]$. This finishes the proof for Case 1.

Case 2: $b_{21}\neq 0$ *but is sufficiently small.* We prove by a fixed point argument. We introduce the two systems

$$\frac{\partial}{\partial t}\begin{pmatrix}\hat{v}\\ \hat{w}\end{pmatrix}(x, t)=\begin{pmatrix}-\gamma_1 & 0\\ 0 & \gamma_2\end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix}\hat{v}\\ \hat{w}\end{pmatrix}(x, t)+B\begin{pmatrix}\hat{v}\\ \hat{w}\end{pmatrix}(x, t),$$

$(\tilde{\ })$ $\quad \hat{v}(0, t)=0, \qquad \hat{w}(1, t)=\hat{u}(t),$

$$\hat{v}(x, 0)=\hat{w}(x, 0)=0;$$

$$\frac{\partial}{\partial t}\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}(x, t)=\begin{pmatrix}-\gamma & 0\\ 0 & \gamma_2\end{pmatrix}\frac{\partial}{\partial x}\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}(x, t)+B\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}(x, t)+\begin{pmatrix}0 & 0\\ b_{21} & 0\end{pmatrix}\begin{pmatrix}\hat{v}\\ \hat{w}\end{pmatrix}(x, t),$$

$(\hat{\ })$ $\quad \tilde{v}(0, t)=\tilde{w}(1, t)=0,$

$$\tilde{v}(x, 0)=\tilde{w}(x, 0)=0.$$

We define an operator M from $L^2[0, T]$ into itself as follow.

For $u\in L^2[0, T]$, let $\begin{pmatrix}\hat{v}\\ \hat{w}\end{pmatrix}$ be the solution of $(\hat{\ })$ with $\hat{u}=u$ and $\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}$ be the corresponding solution of $(\tilde{\ })$. $M(u)$ is the control so that if $\hat{u}=M(u)$ in $(\hat{\ })$, then its solution $\begin{pmatrix}\hat{v}_1\\ \hat{w}_1\end{pmatrix}$ satisfies

$$\begin{pmatrix}\hat{v}_1\\ \hat{w}_1\end{pmatrix}(x, T)=\begin{pmatrix}v_T\\ w_T\end{pmatrix}(x)-\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}(x, T).$$

Applying Proposition 5.2, we see that $\begin{pmatrix}\tilde{v}\\ \tilde{w}\end{pmatrix}\in X$ and hence by Case 1, $M(u)$ exists and is unique. Now, we want to show that M is a contraction mapping. Indeed, if u_1 and u_2 are in $L^2[0, T]$, let

$$\begin{pmatrix}\hat{v}_1\\ \hat{w}_1\end{pmatrix}, \qquad \begin{pmatrix}\tilde{v}_1\\ \tilde{w}_1\end{pmatrix}, \qquad \begin{pmatrix}\hat{v}_2\\ \hat{w}_2\end{pmatrix}, \qquad \begin{pmatrix}\tilde{v}_2\\ \tilde{w}_2\end{pmatrix}$$

be respectively the corresponding solutions of ($\hat{}$) and ($\tilde{}$). Applying Proposition 5.1 to ($\tilde{}$) and then to ($\hat{}$), we have

$$\left\|\begin{pmatrix}\tilde{v}_1\\ \tilde{w}_1\end{pmatrix}(\cdot, T)-\begin{pmatrix}\tilde{v}_2\\ \tilde{w}_2\end{pmatrix}(\cdot, T)\right\| \leqq Kb_{21}\int_0^T\int_0^1 |\hat{v}_1(x, w)-\hat{v}_2(x, s)|^2\, dx\, ds$$

$$\leqq K^2 b_{21}\int_0^T |u_1(s)-u_2(s)|^2\, ds.$$

We remark that although K may depend on b_{21}, it remains bounded if b_{21} is bounded. So we may choose b_{21} small enough so that $b_{21}K^2<1$. M is then a contraction mapping and has a unique fixed point u, say. It is easy to see that u makes (5.21) true if and only if it is a fixed point of M. This finishes the proof of the theorem.

Next, we want to determine the location of the eigenvalues of A.

PROPOSITION 5.6. *The eigenvalues of A as defined in* (5.3) *are given by the asymptotic formula*

$$\lambda_n=\frac{1}{T}(-2\log|2n\pi|+i2n\pi+\varepsilon i\pi)+\omega+o(1) \tag{5.22}$$

where

$$\varepsilon=\begin{cases}-1 & \text{when } n>0,\\ 1 & \text{when } n<0.\end{cases}$$

Here, we assume that both b_{12} and b_{21} are nonzero.

Proof. If λ is an eigenvalue of A, then λ satisfies

$$\begin{pmatrix}-\gamma_1 & 0\\ 0 & \gamma_2\end{pmatrix}\frac{d}{dx}\begin{pmatrix}v\\ w\end{pmatrix}+B\begin{pmatrix}v\\ w\end{pmatrix}=\lambda\begin{pmatrix}v\\ w\end{pmatrix},\qquad v(0)=w(1)=0. \tag{5.23}$$

Once λ is fixed, (5.23) can be solved explicitly in terms of initial values $v(0)$ and $w(0)$. Indeed, we can rewrite (5.23) in the form

$$\frac{d}{dx}\begin{pmatrix}v\\ w\end{pmatrix}=M\begin{pmatrix}v\\ w\end{pmatrix} \tag{5.24}$$

where

$$M=\begin{bmatrix}(b_{11}-\lambda)/\gamma_1 & b_{12}/\gamma_1\\ -b_{21}/\gamma_2 & -(b_{22}-\lambda)/\gamma_2\end{bmatrix}.$$

Hence the solution of (5.23) is

$$\begin{pmatrix}v(x)\\ w(x)\end{pmatrix}=e^{xM}\begin{pmatrix}v(0)\\ w(0)\end{pmatrix}. \tag{5.25}$$

Because $v(0)=w(1)=0$, we have

$$\begin{pmatrix}v(1)\\ 0\end{pmatrix}=e^{M}\begin{pmatrix}0\\ w(0)\end{pmatrix}. \tag{5.26}$$

But $e^M=rI+sM$ where

$$r=(\lambda_2e^{\lambda_1}-\lambda_1e^{\lambda_2})/(\lambda_2-\lambda_1) \tag{5.27}$$

and

$$s=(e^{\lambda_2}-e^{\lambda_1})/(\lambda_2-\lambda_1) \tag{5.28}$$

[6, p. 101] and λ_1, λ_2 are the characteristic roots (which we may assume to be distinct when $|\lambda|$ is sufficiently large) of M. It follows from (5.26) that $E_{22}=0$ where E_{22} is the entry on the second row and second column of e^M.

Hence

$$E_{22}=r-s(b_{22}-\lambda)/\gamma_2=0. \tag{5.29}$$

Substituting (5.27) and (5.28) into (5.29), we have

$$(\lambda_2-\lambda_1)^{-1}\left(\left(\lambda_2+\frac{b_{22}-\lambda}{\gamma_1}\right)e^{\lambda_1}-\left(\lambda_1+\frac{b_{22}-\lambda}{\gamma_2}\right)e^{\lambda_2}\right)=0.$$

Now $\lambda_1=\frac{1}{2}((b_{11}-\lambda)/\gamma_1-(b_{22}-\lambda)/\gamma_2+\sqrt{D})$ and $\lambda_2=\frac{1}{2}((b_{11}-\lambda)/\gamma_1-(b_{22}-\lambda)/\gamma_2-\sqrt{D})$ where $D=((b_{11}-\lambda)/\gamma_1+(b_{22}-\lambda)/\gamma_2)^2-\alpha$ with $\alpha=b_{12}b_{21}/\gamma_1\gamma_2$. Letting $\xi=-(b_{11}-\lambda)/\gamma_1-(b_{22}-\lambda)/\gamma_2=-\alpha+\lambda T$, then (5.29) holds if and only if

$$((-\xi-\sqrt{D})\,e^{1/2\sqrt{D}}-(-\xi+\sqrt{D})\,e^{1/2\sqrt{D}})/\sqrt{D}=0 \tag{5.30}$$

where $D=\xi^2-b_{12}b_{21}/\gamma_1\gamma_2$.

An application of the Rouche's Theorem shows that the roots of (5.30) are asymptotically the same as that of the equation $\xi^2e^{\xi}-\alpha/4=0$. By [1, p. 410], we see that the roots of this equation are of the form.

$$\xi_n=-2\log|2n\pi|+i2n\pi+\varepsilon i\pi+\omega_1+o(1).$$

It follows that $\lambda_n=(1/T)(\xi_n+\alpha)$ is asymptotically of the form (5.22). This completes the proof of the theorem.

From the above proposition, it is easy to see that $\{-\lambda_n\}$ induces a Carleson measure on some half plane C_α. Furthermore, the numbers $\beta_n=\sum_{m\neq n}1/|\lambda_n-\lambda_m|^2$ are uniformly bounded if all the eigenvalues of A are simple. Proposition 4.3 implies that every feedback relation of the form (4.3) is continuous. (Again, we normalize ψ_n so that $b_n=\langle\psi_n, b\rangle=1$.) So we may apply Theorem 4.4 to yield immediately the following result.

THEOREM 5.7 (spectral assignability). *Suppose that in the system* (5.1) *the operator* A *as defined in* (5.3) *has only simple eigenvalues. Suppose also that both* b_{12} *and* b_{21} *are nonzero and* $|b_{21}|$ *is sufficiently small so that the conclusion of Theorem* 5.5 *holds. Then if* $\{\mu_j\}_{j=-\infty}^{\infty}$ *is any sequence of complex numbers such that*

$$\sum_{j=-\infty}^{\infty}|\mu_j-\lambda_j|^2<\infty$$

then there exists a feedback of the form $u(t)=\langle\binom{v}{w}(\cdot, T), h\rangle$ *where* h *is a continuous linear functional on* X *such that the set of eigenvalues of the closed loop system is exactly* $\{\mu_j\}_{j=-\infty}^{\infty}$.

6. Case of multiple eigenvalues. The system in § 5 may have multiple eigenvalues. So it seems that the assumption A in § 4 is rather arbitrary for this system. In this section, we will see how the theory we have developed can be modified to cover the case with multiple eigenvalues. We will only state the results and omit the proofs.

One can show that for the system in § 5, all except a finite number of eigenvalues are simple. We will take this last fact as a basic assumption. In other words, we now suppose that λ_n has multiplicity M_n, where $M_n>1$, for only finitely many n.

Let

$X_n=\{x=(\lambda_nI-A)^{M_n}x=0\}$,

$P_n=$ projection of X onto X_n such that $P_nA=AP_n$,

$P_n^*=$ adjoint of P_n (also a projection and $P_n^*A^*=A^*P_n^*$),

$X_n^*=$ image of P_n^*.

We denote by $\underset{\sim}{b}_n$ the unique element in X such that $\langle P_n^* y, b\rangle = \langle y, \underset{\sim}{b}_n\rangle$ for all $y \in X$. Then we see that $\underset{\sim}{b}_n \in \operatorname{Ker}(P_n^*)^\perp$ = closure of range of $P_n = X_n$.

We have the following generalization of Proposition 4.2.

PROPOSITION 6.1 (rank condition). *If the system* (2.1) *is approximately controllable in some time T, then for all n the set* $\{A^{M_n-1}\underset{\sim}{b}_n, A^{M_n-2}\underset{\sim}{b}_n, \ldots, \underset{\sim}{b}_n\}$ *spans* X_n.

Also, we have the following generalization of Theorem 4.4.

THEOREM 6.2. *Suppose the system* (2.1) *is approximately controllable in some time T and the eigenvalue* λ_n *has multiplicity* M_n, $-\infty < n < \infty$ *with* $M_n > 1$ *for only finitely many n. Suppose also that* $\{b_{j,n}\}_{j=1}^{M_n-1}{}_{n=-\infty}^{\infty}$ *is uniformly bounded,* $\{1/\lambda_n\} \in l^2$ *and every h of the form in* (6.4) *represents a continuous linear functional on X. Denoting* $\beta_n = \sum_{m\neq n} 1/|\lambda_m - \lambda_n|^2$, *if* $\{\mu_{j,n}\}_{j=0}^{M_n-1}{}_{n=-\infty}^{\infty}$ *is a sequence of complex numbers such that*

$$\sum_{n=-\infty}^{\infty} \sum_{j=0}^{M_n-1} \frac{(1+\beta_n)|\mu_{j,n} - \lambda_n|^2}{|b_{j,n}|^2} < \infty,$$

then there exists $h \in X$ *such that* $\sigma(A_h) = \{\mu_{j,n}\}_{j=0}^{M_n-1}{}_{n=-\infty}^{\infty}$.

THE REGULAR LOCAL NONINTERACTING CONTROL PROBLEM FOR NONLINEAR CONTROL SYSTEMS*

H. NIJMEIJER† AND J. M. SCHUMACHER‡

Abstract. We study the Noninteracting Control Problem for affine nonlinear control systems under the assumption that the number of scalar inputs equals the number of vector outputs. Our purpose is to find a static state feedback law for the system which achieves noninteraction. Using the recently developed differential geometric approach to nonlinear systems theory and working under a set of regularity assumptions, we give necessary and sufficient conditions for the local solvability of the problem. This work extends earlier results in the "geometric approach" for linear systems.

Key words. nonlinear control systems, noninteracting control, controlled invariance, controllability distributions

AMS(MOS) subject classifications. 93C10, 49E05

1. Introduction. This paper is intended as a contribution to the theory of noninteracting control of nonlinear systems. In general terms, the problem can be described as follows. Suppose that a dynamical system has been given, in which two sets of variables have been designated as instruments and as targets, respectively. The targets and instruments may be either scalar variables or vectors. One says that we have a situation of *noninteraction* (or *input-output decoupling*) if each instrument affects only one target and none of the others. If the given system does not have this property, one may ask whether it is possible to add control loops to the system in such a way, that noninteraction is obtained. This is the problem of noninteracting control.

To arrive at a precise problem statement, one has to specify: (i) the class of systems under study, (ii) the precise nature of the noninteraction one wants to obtain, and (iii) the control format. In this paper, we shall consider "affine" [13], [18], [22] systems, which constitute a class of nonlinear systems that has received considerable attention. We will assume that the input variables ("instruments") are scalars, but we allow the output variables ("targets") to be vectors. The condition of noninteraction will be defined using the concepts of "controllability distributions" [11], [14] and "output controllability" [16], [17]. The control schemes we shall consider consist of locally defined state feedback and (state-dependent) precompensation. This combination is often referred to in the literature simply as "static state feedback" [8], [18] or even just "feedback". Definitions of the concepts mentioned here will be given below.

The noninteracting control problem has been studied extensively and from various points of view. Most of the literature is concerned with linear systems. In this field, one has the option of dealing with the problem via the transfer function, and this approach has been taken in some of the earliest work in noninteraction [5], [10] as well as in recent contributions [6]. Within the state-space framework, a breakthrough was made around 1970 ([24]; see also [1]). The innovation centered around the introduction of the notion of "controllability subspace" as a means of expressing the intuitive notion of "subsystem", which is of obvious importance in the theory of noninteraction. Controllability subspaces came to play a key role in a successful line of research that has been termed the "geometric approach" to linear systems theory.

For more detailed accounts of the long history of noninteracting control of linear systems, we refer to [12] and [6]. In the nonlinear domain, progress has been slower. "Although efforts have been made to develop a decoupling theory for nonlinear systems, (...) considerable difficulties (...) have so far inhibited substantial progress", wrote the authors of [12] in 1971. A criterion for achievability of noninteraction by "static state feedback" was given by Sinha [20] for the case of scalar inputs and scalar outputs. Further work under the same restriction was reported in [3].

In the award winning paper [8] Isidori et al. were the first authors to give a geometric formulation for the general noninteracting control problem. They presented a solution to this problem [8, Thm. 5.1]; however, their necessary and sufficient conditions for solvability are, in the general case (allowing for vector outputs), not constructive (see [8, Thm. 5.1]). The purpose of this paper is to give constructive (verifiable) necessary and sufficient conditions also in the case of vector outputs, pertaining to the solvability of what we will call the *regular local noninteracting control problem.* In contrast to the results of [20], [3], [2] and also [8] we will use a nonlinear version of the concept of controllability subspaces. This extension was made in [11] and [14], leading to various definitions for the so-called "controllability distributions". The concept was applied to solve special versions of the decoupling problem in [16] and [17]. In this paper, we will show that controllability distributions can be used to rederive a major result from the linear theory [24] in a nonlinear context. This continues a line of research [7]–[9], [11], [13]–[18] that is directed towards a systematic generalization of the "geometric approach" [23] to nonlinear systems, using the methods of differential geometry.

The organization of the paper is as follows. In § 2, the precise formulation is given of the decoupling problem that we consider here. The main result follows in § 3, which is largely devoted to lemmas that are needed in the sufficiency part of the proof. Some remarks on the structure of a decoupled system are given in § 4.

2. Problem formulation. Consider the affine nonlinear control system

$$\dot{x}(t) = A(x(t)) + \sum_{i=1}^{m} B_i(x(t))u_i(t) \tag{2.1}$$

where x are local coordinates of a smooth n-dimensional manifold M, A, $B_1, \cdots, B_m$ are smooth vector fields on M and $u_i : \mathbb{R}_+ \to \mathbb{R}$ is a piecewise smooth input function, $i \in \underline{m}$. Together with the dynamics (2.1) we consider as output functions

$$z_i(t) = C_i(x(t)), \qquad i \in \underline{m} \tag{2.2}$$

where $C_i : M \to N_i$ is a smooth map from M to a smooth p_i-dimensional manifold N_i, $p_i \geqq 1$, $i \in \underline{m}$. We assume that each C_i, $i \in \underline{m}$, is a surjective submersion. We will observe later on that the output functions $C_i : M \to N_i$ play no role beyond specification of the distributions $\operatorname{Ker} C_{i*}$, $i \in \underline{m}$. To rule out obvious unsolvable problems, we will assume that the maps C_i are mutually independent, i.e. the rank of the map $C = (C_1, \cdots, C_m) : M \to N_1 \times \cdots \times N_m$ equals $p_1 + \cdots + p_m$. Also we will assume—as is usual in the differential geometric approach—that the distribution generated by the input vector fields has no singularities, so

$$\dim \Delta_0 := \dim \{B_1, \cdots, B_m\} = m.$$

Furthermore we will assume that for the system (2.1) the *accessibility* distribution, see [14], equals TM. That is, the system (2.1) is *strongly accessible*, cf. [21], [22], i.e. the set of reachable points at time $t > 0$ from $x_0 \in M$ has a nonempty interior in M. In this

paper we allow for static state feedback. Thus an admissible control law is of the form

$$u = \alpha(x) + \beta(x)v, \tag{2.3}$$

where $\alpha : M \to \mathbb{R}^m$, $\beta : M \to \mathbb{R}^{m \times m}$ are smooth maps, and $v = (v_1, \cdots, v_m)' \in \mathbb{R}^m$ represents a new input. To keep as much open-loop control as possible, we seek β such that $\beta(x) = (\beta_{ij}(x))$ is nonsingular for all $x \in M$. Applying the feedback law (2.3) to (2.1), we obtain as the new dynamics

$$\dot{x}(t) = \tilde{A}(x(t)) + \sum_{i=1}^{m} \tilde{B}_i(x(t))v_i(t), \tag{2.4}$$

where

$$\tilde{A}(x) = A(x) + \sum_{i=1}^{m} B_i(x)\alpha_i(x), \tag{2.5a}$$

$$\tilde{B}_i(x) = \sum_{j=1}^{m} B_j(x)\beta_{ji}(x), \qquad i \in \underline{m}. \tag{2.5b}$$

In the *static state feedback noninteracting control problem* we seek a control law (2.3) such that in the modified dynamics the control $v_i(\cdot)$ does not affect the outputs $z_j(\cdot)$ for $j \neq i$; moreover we want the scalar input $v_i(\cdot)$ to "control" the corresponding (vector-valued) output $z_i(\cdot)$, $i \in \underline{m}$. This problem can be nicely formulated in a differential geometric framework, see also [8]. For doing so we need some terminology. Consider the set $V(M)$ of all smooth vector fields on M as a Lie algebra with Lie product $[X_1, X_2]$ for $X_1, X_2 \in V(M)$. For any set of vector fields $S \subset V(M)$ we denote by $\{S\}_{LA}$ the Lie subalgebra generated by S. Furthermore for $X_1, X_2 \in V(M)$ define $ad^0_{X_1}X_2 = X_2$, $ad^1_{X_1}X_2 = [X_1, X_2]$ and recursively $ad^k_{X_1}X_2 = [X_1, ad^{k-1}_{X_1}]$, $k = 2, 3, \cdots$. Associated with the system (2.4) we define the following Lie algebras, see also [19]:

$$L_0 = \{ad^k_{\tilde{A}}\tilde{B}_j,\ k \in \mathbb{Z}_+, j \in \underline{m}\}_{LA}, \tag{2.6a}$$

$$L_{0i} = \{ad^k_{\tilde{A}}\tilde{B}_i,\ k \in \mathbb{Z}_+\}_{LA}, \qquad i \in \underline{m}, \tag{2.6b}$$

and the Lie ideal generated by L_{0i} in L_0 which will be denoted by $\hat{L}_{0i}$, $i \in \underline{m}$. Clearly $L_{0i} \subset \hat{L}_{0i}$, $i \in \underline{m}$. Also we introduce the corresponding distributions

$$R_0 = \text{Span}\,\{L_0\}, \qquad R_i = \text{Span}\,\{L_{0i}\}, \quad \hat{R}_i = \text{Span}\,\{\hat{L}_{0i}\}, \quad i \in \underline{m}. \tag{2.7}$$

To take care that in the new dynamics (2.4) the input $v_i(\cdot)$ has no interaction with $z_j(\cdot)$, $j \neq i$, we must have

$$\hat{R}_i \subset \bigcap_{j \neq i} \text{Ker}\, C_{j*}, \qquad i \in \underline{m}. \tag{2.8}$$

To achieve that $v_i(\cdot)$ "controls" the corresponding output $z_i(\cdot)$, $i \in \underline{m}$, we need the nonlinear version of *output controllability*, that is

$$C_{i*}R_i = TN_i, \qquad i \in \underline{m} \tag{2.9}$$

which is equivalent to the fact that the set of reachable output values has nonempty interior in N_i, $i \in \underline{m}$, see [16], [17]. Because $R_i \subset \hat{R}_i$, we see that (2.9) implies

$$C_{i*}\hat{R}_i = TN_i, \qquad i \in \underline{m}. \tag{2.10}$$

There is a nice and in our context useful interpretation of (2.8), (2.9) and (2.10) in geometric terms. Recall the following definitions, see [7], [9], [13], [18]. An involutive

distribution D on M is called *controlled invariant* if there exists a feedback (2.3) such that the modified dynamics (2.4)-(2.5) satisfies

$$\begin{aligned} &[\tilde{A}, D] \subset D, \\ &[\tilde{B}_i, D] \subset D, \qquad i \in \underline{m}. \end{aligned} \tag{2.11}$$

An involutive distribution D on M is called a (*degenerate*) *controllability distribution* if there exists a feedback (2.3) and a subset $I \subset \underline{m}$ such that

$$D = \text{Span}\,(\{ad_{\tilde{A}}^k \tilde{B}_i \mid i \in I, k \in \mathbb{Z}_+\}_{LA}). \tag{2.12}$$

Finally an involutive distribution D on M is called a *regular controllability distribution* if there exists a feedback (2.3) and a subset $I \subset \underline{m}$ such that

$$\begin{aligned} &[\tilde{A}, D] \subset D, \\ &[\tilde{B}_i, D] \subset D, \qquad i \in \underline{m} \end{aligned} \tag{2.13}$$

and

$$D = \text{Span}\,(\{ad_{\tilde{A}}^k \tilde{B}_i, ad_{\tilde{B}_j}^k \tilde{B}_i \mid i \in I, k \in \mathbb{Z}_+\}_{LA}). \tag{2.14}$$

Returning to the noninteracting control problem, we see, by definition of the distributions $\hat{R}_i$, $i \in \underline{m}$, that for all $i \in \underline{m}$

$$\begin{aligned} &[\tilde{A}, \hat{R}_i] \subset \hat{R}_i, \\ &[\tilde{B}_j, \hat{R}_i] \subset \hat{R}_i, \qquad j \in \underline{m}. \end{aligned} \tag{2.15}$$

That is, $\hat{R}_i$ is controlled invariant and moreover it is a regular controllability distribution, $i \in \underline{m}$, whereas R_i is a degenerate controllability distribution, $i \in m$.

In this way the static state feedback noninteracting control problem can be stated as follows:

> Given the system (2.1)-(2.2), find, if possible, a feedback law (2.3) such that the distributions $\hat{R}_i$ defined by (2.6)-(2.7) satisfy (2.8) and (2.10).

In this paper we will solve a *regular local version* of this problem, to be called the *regular local noninteracting control problem.* In this context "local" means, that given an arbitrary initial state $x_0 \in M$, we are interested in the existence of a local feedback (2.3), i.e. the maps α and β in (2.3) are only well defined on a neighborhood of x_0. Working locally, we are able to fully exploit the differential geometric approach set up in [7], [8] and worked out in a series of papers [9], [13]-[18], [22], [25], [26]. It is a logical first step, and a common practice in the literature just cited, to exclude singularities. In this paper, too, we shall work under a series of regularity assumptions. In particular, we look for a specific set of "regular" distributions R_i^*, $i \in \underline{m}$, that satisfy the conditions (2.8) and (2.10). The exact definition of the word "regular" will be given in § 3; among its implications is that we demand that the distributions $\cup_{i \in I} R_i^*$ and $(\cup_{i \in I} R_i^*) \cap \Delta_0$ have constant dimension for all $I \subset \underline{m}$. This surely is a restrictive assumption, but we feel that it is necessary to complete the "regular" analysis before one can hope to successfully attack the singular cases. Moreover, one should realize that for analytic systems (2.1)-(2.2) the regularity assumptions will hold on an open and dense submanifold M' of M. Therefore, a (global) solution to the general noninteracting control problem has to satisfy the necessary and sufficient conditions of the next section on this submanifold M'.

3. Necessary and sufficient conditions for the regular local noninteracting control problem. We now come to the necessary and sufficient conditions for the solvability of the regular local noninteracting control problem. For this we need some notation and assumptions.

A1. The distribution $\Delta_0 = \text{Span}\{B_1, \cdots, B_m\}$ has dimension m on M.

A2. The strong accessibility distribution of (2.1), $R_0 = \text{Span}\{ad_A^k B_i \mid k \in \mathbb{Z}_+\}_{LA}$ has dimension n.

A3. The output maps (2.2) are mutually independent, i.e. the rank of the map $C = (C_1, \cdots, C_m): M \to N_1 \times \cdots \times N_m$ equals $p_1 + \cdots + p_m$.

For each subset $I \subset \underline{m}$ let us define R_I^* as the maximal regular local controllability distribution contained in $\bigcap_{j \notin I} \text{Ker } C_{j*}$. The involutive distributions R_I^*, $I \subset \underline{m}$, are well defined (see [11], [14]) but their dimension may vary on M. (We set $R_{\underline{m}}^* = TM$, as a consequence of the rule from logic that the empty intersection of parts is the whole.)

A4. The distributions R_I^*, $\sum_{i \in I} R_i^*$, $(\sum_{i \in I} R_i^*) \cap \Delta_0$, $I \subset \underline{m}$, as well as $\overline{\sum_{i \in I} R_i^*}$ and $\overline{\sum_{i \in I} R_i^* \cap \Delta_0}$, $I \subset \underline{m}$, all have constant dimension on M (here the bar denotes involutive closure).

THEOREM 3.1. *Consider the system* (2.1)-(2.2) *and assume* A1-A4 *hold. Then the regular local static state feedback noninteracting control problem is solvable if and only if*

$$\Delta_0 = \Delta_0 \cap R_1^* + \cdots + \Delta_0 \cap R_m^*. \tag{3.1}$$

Furthermore, if these conditions hold, then $\{R_i^*\}_{i=1}^m$ *is the only solution of the noninteracting control problem.*

Before we are able to prove this theorem, we need some preliminary results on the distributions R_I^*, $I \subset \underline{m}$. The following lemmas are also of independent interest, and give, even in the linear case, additional information on the structure of the distributions R_I^*, $I \subset \underline{m}$. Everywhere below, we shall consider the system (2.1)-(2.2), assuming that A1-A4 hold.

LEMMA 3.2. *Suppose that* (3.1) *holds. Then, for all* $i \in \underline{m}$,

$$\Delta_0 \cap R_i^* \not\subset \sum_{j \neq i} R_j^*. \tag{3.2}$$

Proof. Suppose that (3.1) were true and that (3.2) would not hold. It would then follow that

$$\Delta_0 \subset \sum_{j \neq i} R_j^* \subset \overline{\sum_{j \neq i} R_j^*}. \tag{3.3}$$

Note that the last distribution in (3.3) is controlled invariant, since it is the sum of controlled invariant distributions. Under the condition of strong accessibility, any controlled invariant distribution containing Δ_0 must be equal to TM (see [22]). Since it is clear from the definition of the distributions R_i^* that

$$\sum_{j \neq i} R_j^* \subset \overline{\sum_{j \neq i} R_j^*} \subset \text{Ker } C_{i*}, \tag{3.4}$$

it would follow that $\text{Ker } C_{i*} = TM$, or the map C_i is trivial. This contradicts our assumptions. □

We can use the above lemma in some counting arguments. Set $\gamma_1 = \dim(\Delta_0 \cap R_1^*)$, and define

$$\gamma_k = \dim \sum_{i=1}^{k} (\Delta_0 \cap R_i^*) - \dim \sum_{i=1}^{k-1} (\Delta_0 \cap R_i^*) \tag{3.5}$$

for $k=2, \cdots, m$. Note that the γ_k's are constant by A4. It is obviously true that $\gamma_k \geqq 0$ for all k, but if (3.1) holds then it follows from the above lemma that even $\gamma_k \geqq 1$ for $k \in \underline{m}$. For, suppose that $\gamma_i = 0$ for some i; then we would have

$$\Delta_0 \cap R_i^* \subset \sum_{j=1}^{i-1} (\Delta_0 \cap R_j^*) \subset \sum_{j \neq i} (\Delta_0 \cap R_j^*), \tag{3.6}$$

a situation which has been excluded by Lemma 3.2. On the other hand, still under the assumption that (3.1) holds, it is clear that

$$\sum_{k=1}^{m} \gamma_k = \dim \sum_{i=1}^{m} (\Delta_0 \cap R_i^*) = \dim \Delta_0 = m. \tag{3.7}$$

So the γ_k's form a set of m integers $\geqq 1$ which add up to m. It follows, of course, that $\gamma_k = 1$ for all k. As a consequence,

$$\dim \sum_{i=1}^{j} (\Delta_0 \cap R_i^*) = \sum_{i=1}^{j} \gamma_j = j \tag{3.8}$$

for all $j \in \underline{m}$. Since the order in which we numbered the output functions is arbitrary, the conclusion can be formulated as follows.

LEMMA 3.3. *Suppose that* (3.1) *holds. Then, for all* $I \subset \underline{m}$,

$$\dim \sum_{i \in I} (\Delta_0 \cap R_i^*) = |I|. \tag{3.9}$$

An obvious consequence of this is that the distributions $\Delta_0 \cap R_i^*$ are independent. Now, set $\theta_1 = \dim (\Delta_0 \cap R_1^*)$ and define the constants (see A4)

$$\theta_k = \dim \left(\Delta_0 \cap \sum_{i=1}^{k} R_i^* \right) - \dim \left(\Delta_0 \cap \sum_{i=1}^{k-1} R_i^* \right) \tag{3.10}$$

for $k=2, \cdots, m$. If we reason in the same way as above, now using the fact that $\sum_{i=1}^{m} R_i^* = TM$, then the conclusion we obtain is the following.

LEMMA 3.4. *Suppose that* (3.1) *holds. Then, for all* $I \subset \underline{m}$,

$$\dim \left(\Delta_0 \cap \sum_{i \in I} R_i^* \right) = |I|. \tag{3.11}$$

Since it is clear that

$$\sum_{i \in I} (\Delta_0 \cap R_i^*) \subset \Delta_0 \cap \sum_{i \in I} R_i^* \tag{3.12}$$

for all $I \subset \underline{m}$, we obtain as a corollary:

LEMMA 3.5. *Suppose that* (3.1) *holds. Then, for all* $I \subset \underline{m}$,

$$\Delta_0 \cap \sum_{i \in I} R_i^* = \sum_{i \in I} (\Delta_0 \cap R_i^*). \tag{3.13}$$

Set $\rho_1 = \dim (R_1^* \cap \Delta_0)$, and define

$$\rho_k = \dim (R_{\underline{k}}^* \cap \Delta_0) - \dim (R_{\underline{k-1}}^* \cap \Delta_0) \tag{3.14}$$

for $k=2, \cdots, m$. These numbers are constants by Assumption A4. We can use them to prove:

LEMMA 3.6. *Suppose that* (3.1) *holds. Then, for all* $I \subset \underline{m}$,

$$\dim (\Delta_0 \cap R_I^*) = |I|. \tag{3.15}$$

Proof. It is sufficient to show that $\rho_k \neq 0$ for all $k \in \underline{m}$. So, suppose that $\rho_k = 0$ for some $k \in \underline{m}$. Then we have

$$R_{\underline{k}}^* \cap \Delta_0 = R_{\underline{k-1}}^* \cap \Delta_0. \tag{3.16}$$

The distributions $R_{\underline{k-1}}^*$ and $R_{\underline{k}}^*$ are both regular local controllability distributions, and, of course, $R_{\underline{k-1}}^* \subset R_{\underline{k}}^*$. It follows from [17] that there exists a feedback $u = \alpha(x) + \beta(x)v$ for the system (2.1) such that both $R_{\underline{k}}^*$ and $R_{\underline{k-1}}^*$ are invariant for the modified dynamics. It then follows from the characterization of regular local controllability distributions given in [11] (Lemma 4.1) that

$$R_{\underline{k}}^* = R_{\underline{k-1}}^*. \tag{3.17}$$

Since $R_k^* \subset R_{\underline{k}}^*$ and $R_{\underline{k-1}}^* \subset \ker C_{k*}$, we obtain

$$R_k^* \subset \operatorname{Ker} C_{k*}. \tag{3.18}$$

Since we also have, by definition,

$$\sum_{i \neq k} R_k^* \subset \operatorname{Ker} C_{k*} \tag{3.19}$$

it follows from the strong accessibility condition that the map C_k is trivial, and we have reached a contradiction. □

We can use this to establish the following lemma, which will be instrumental in proving that, under the assumption (3.1), the distribution $\sum_{i \in I} R_i^*$ is involutive.

LEMMA 3.7. *Suppose that* (3.1) *holds. Then, for any* $I \subset \underline{m}$,

$$R_I^* = \bar{R}_I := \text{inv. clos.} \left[\sum_{i \in I} R_i^* \right]. \tag{3.20}$$

Proof. Let $I \subset \underline{m}$. Since R_I^* is involutive, and $R_i^* \subset R_I^*$ for all $i \in I$, we have

$$\sum_{i \in I} R_i^* \subset \bar{R}_I \subset R_I^*. \tag{3.21}$$

By Lemmas 3.4 and 3.6, it follows that

$$\Delta_0 \cap \bar{R}_I = \Delta_0 \cap R_I^*. \tag{3.22}$$

From [14], we know that $\bar{R}_I$ is a regular local controllability distribution. By the same argument as was used in the proof of Lemma 3.6, it follows that (3.20) holds. □

For linear systems, the above result already implies that, under the given circumstances, the subspace corresponding to the distribution $\sum_{i \in I} R_i^*$ is equal to the maximal controllability subspace contained in the intersection of the kernels of the output mappings C_i ($i \in \underline{m} \backslash I$)—a result which doesn't seem to have been formulated explicitly before. In the nonlinear context, we have to worry about involutiveness. Somewhat surprisingly, it turns out that this is not a problem. The key lemma is the following.

LEMMA 3.8. *Let* R_1 *and* R_2 *be regular local controllability distributions such that* $\overline{R_1 + R_2}$ *and* $\Delta_0 \cap \overline{R_1 + R_2}$ *have fixed dimension, and*

$$\Delta_0 \cap \overline{R_1 + R_2} = \Delta_0 \cap R_1 + \Delta_0 \cap R_2. \tag{3.23}$$

Then $R_1 + R_2$ *is involutive* (*and hence—see* [14]—$R_1 + R_2$ *is itself a regular local controllability distribution*).

Proof. Locally, we can choose sets of independent vector fields $\{B_{11}, \cdots, B_{1k}\}$ and $\{B_{21}, \cdots, B_{2l}\}$ such that

$$\Delta_0 \cap R_1 = \text{Span}\{B_{11}, \cdots, B_{1k}\}, \tag{3.24}$$

$$\Delta_0 \cap R_2 = \text{Span}\{B_{21}, \cdots, B_{2l}\}. \tag{3.25}$$

Note that

$$[B_{1i}, R_2] \subset (R_2 + \Delta_0) \cap \overline{R_1 + R_2} = R_2 + (\Delta_0 \cap \overline{R_1 + R_2}) = R_2 + \text{Span}\{B_{11}, \cdots, B_{1k}\} \tag{3.26}$$

for all $i \in \underline{k}$. Using [13], we see that there exist vector fields $\tilde{B}_{11}, \cdots, \tilde{B}_{1k}$ such that

$$\text{Span}\{\tilde{B}_{11}, \cdots, \tilde{B}_{1k}\} = \text{Span}\{B_{11}, \cdots, B_{1k}\} = \Delta_0 \cap R_1, \tag{3.27}$$

$$[\tilde{B}_{1i}, R_2] \subset R_2, \qquad i \in \underline{k}. \tag{3.28}$$

Likewise, one can find vector fields $\tilde{B}_{21}, \cdots, \tilde{B}_{2l}$ such that

$$\text{Span}\{\tilde{B}_{21}, \cdots, \tilde{B}_{2l}\} = \text{Span}\{B_{21}, \cdots, B_{2l}\} = \Delta_0 \cap R_2, \tag{3.29}$$

$$[\tilde{B}_{2i}, R_1] \subset R_1, \qquad i \in \underline{l}. \tag{3.30}$$

Since $\overline{R_1 + R_2}$ is controlled invariant (see [14]) and $R_1 \subset \overline{R_1 + R_2}$, we can find, as in [17], a closed-loop mapping $\tilde{A}$ such that

$$[\tilde{A}, R_1] \subset R_1, \tag{3.31}$$

$$[\tilde{A}, \overline{R_1 + R_2}] \subset \overline{R_1 + R_2}. \tag{3.32}$$

Now, note that

$$[\tilde{A}, R_2] \subset (R_2 + \Delta_0) \cap (\overline{R_1 + R_2}) = R_2 + \text{Span}\{\tilde{B}_{11}, \cdots, \tilde{B}_{1k}\}. \tag{3.33}$$

It follows from (3.33) and (3.28) (see [7]) that there exist functions γ_i ($i \in \underline{k}$) such that $\bar{A} = \tilde{A} + \sum_{i=1}^{k} \tilde{B}_{1i}\gamma_i$ satisfies

$$[\bar{A}, R_2] \subset R_2. \tag{3.34}$$

Using the general formula

$$[X \cdot c, Y] = [X, Y] \cdot c - X \cdot Y(c), \tag{3.35}$$

we find that also

$$[\bar{A}, R_1] \subset R_1, \tag{3.36}$$

$$[\bar{A}, \overline{R_1 + R_2}] \subset \overline{R_1 + R_2}. \tag{3.37}$$

By the characterization of regular local controllability distributions in [14], we know that, if we define

$$\hat{R}_i = \text{Span}\{ad_{\bar{A}}^j \tilde{B}_{is} \mid s \in \underline{k}, j \in \mathbb{Z}_+\}, \qquad i = 1, 2, \tag{3.38}$$

then

$$R_i = \text{inv.clos. } \hat{R}_i. \tag{3.39}$$

Using the Jacobi identity, one can easily prove by induction that

$$[ad_{\bar{A}}^j \tilde{B}_{1i}, R_2] \subset R_2 \tag{3.40}$$

for all $j \in \mathbb{Z}_+$ and $i \in \underline{k}$. Using (3.35) again, we find that

$$[\hat{R}_1, R_2] \subset R_1 + R_2. \tag{3.41}$$

Another induction argument based on the Jacobi identity then shows that

$$[R_1, R_2] \subset R_1 + R_2. \tag{3.42}$$

Hence, $R_1 + R_2$ is involutive. □

The result that we were after is now an easy consequence.

LEMMA 3.9. *Suppose that* (3.1) *holds. Then, for any subset* $I \subset \underline{m}$, *the distribution* $\sum_{i \in I} R_i^*$ *is involutive.*

Proof. It is sufficient to show that $\sum_{i=1}^{k} R_i^*$ is involutive for every $k \in \underline{m}$, and we do this by induction. Of course, R_1^* is involutive by definition. Now assume that $\sum_{i=1}^{k-1} R_i^*$ is involutive. Then $\sum_{i=1}^{k-1} R_i^* = R_{k-1}^*$ according to Lemma 3.7, and so it follows that $\sum_{i=1}^{k-1} R_i^*$ is a regular local controllability distribution. Moreover, the results of Lemmas 3.7, 3.6 and 3.5 show that

$$\Delta_0 \cap \text{inv.clos.} \left(\sum_{i=1}^{k} R_i^* \right) = \Delta_0 \cap \left(\sum_{i=1}^{k-1} R_i^* \right) + \Delta_0 \cap R_k^*. \tag{3.43}$$

An application of the preceding lemma now completes the proof. □

One notes that it is now immediate that, under the assumption (3.1), we have

$$R_I^* = \sum_{i \in I} R_i^* \tag{3.44}$$

just as in the linear case.

Now, let us proceed to an argument that will be directly needed in the proof of the main theorem. The issue is the "compatibility" of the distributions R_i^*.

LEMMA 3.10. *Suppose that* (3.1) *holds. Then, locally, there exists a basis of vector fields* $\{\tilde{B}_1, \cdots, \tilde{B}_m\}$ *for* Δ_0 *such that*

$$\text{Span}\{\tilde{B}_i\} = \Delta_0 \cap R_i^*, \qquad i \in \underline{m}, \tag{3.45}$$

$$[\tilde{B}_i^*, R_j^*] \subset R_j^*, \qquad i, j \in \underline{m}. \tag{3.46}$$

Proof. Take $i \in \underline{m}$, and let $\hat{B}_i$ be a vector field such that

$$\text{Span}\{\hat{B}_i\} = \Delta_0 \cap R_i^*. \tag{3.47}$$

From the fact that the R_j^*'s are controlled invariant, it follows that

$$[\hat{B}_i, R_j^*] \subset R_j^* + \Delta_0, \qquad j \in \underline{m}. \tag{3.48}$$

Since $\hat{B}_i \in R_i^*$ and $R_i^* + R_j^*$ is involutive (Lemma 3.9), we also have

$$[\hat{B}_i, R_j^*] \subset R_i^* + R_j^*, \qquad j \in \underline{m}. \tag{3.49}$$

Consequently, we have (using Lemma 3.5)

$$[\hat{B}_i, R_j^*] \subset (R_j^* + \Delta_0) \cap (R_i^* + R_j^*) = R_j^* + \Delta_0 \cap (R_i^* + R_j^*) = R_j^* + \text{Span}\{\hat{B}_i\}. \tag{3.50}$$

It is also clear that

$$\left[\hat{B}_i, \sum_{j \neq i} R_j^* \right] \subset \sum_{j \neq i} R_j^* + \text{Span}\{\hat{B}_i\}. \tag{3.51}$$

From this, it follows (see [13]) that there exists a function β_i such that $\tilde{B}_i := \hat{B}_i \beta_i$ satisfies

$$\left[\tilde{B}_i, \sum_{j \neq i} R_j^* \right] \subset \sum_{j \neq i} R_j^*. \tag{3.52}$$

But then we also have (from (3.50) and (3.52); cf. also [18]), for $i \neq j$

$$[\tilde{B}_i, R_j^*] \subset \sum_{j \neq i} R_j^* \cap (R_j^* + \text{Span}\{\tilde{B}_i\}) = R_j^* + \left(\sum_{j \neq i} R_j^* \cap \Delta_0 \cap R_i^* \right) = R_j^*. \tag{3.53}$$

Of course, the equality (3.53) also holds for $i=j$ since R_j^* is involutive. Going through this construction for each $i \in \underline{m}$, we obtain a set of vector fields $\{\tilde{B}_1, \cdots, \tilde{B}_m\}$ which satisfies (3.46), and which is then automatically a basis for Δ_0. □

We now proceed to the proof of the main theorem.

Proof (of Theorem 3.1). For sufficiency, we assume that (3.1) holds. First of all, note that $\sum_{i=1}^m R_i^*$ contains Δ_0 and is controlled invariant for the system (2.1), so that, as noted in the proof of Lemma 3.2,

$$\sum_{i=1}^{m} R_i^* = TM. \tag{3.54}$$

Since we have, for each i,

$$\sum_{j \neq i} R_j^* \subset \operatorname{Ker} C_{i*}, \tag{3.55}$$

it follows that

$$R_i^* + \operatorname{Ker} C_{i*} = TM \qquad (i \in \underline{m}) \tag{3.56}$$

i.e., (2.14) is satisfied.

Next, we have to show that there exists a local feedback of the form $u = \alpha(x) + \beta(x)v$ that leaves each of the distributions R_i^* $(i \in \underline{m})$ invariant; i.e., the R_i^*'s are "compatible". An appropriate $\beta := \operatorname{diag}(\beta_1, \cdots, \beta_m)$ was already shown to exist in Lemma 3.10. Vector fields $\tilde{B}_1, \cdots, \tilde{B}_m$ can be constructed that satisfy $[\tilde{B}_i, R_j^*] \subset R_j^*$ $(i, j \in \underline{m})$, and there exists a unique nonsingular map $\beta : M \to \mathbb{R}^{m \times m}$ (locally defined) such that $\tilde{B}_i(x) = \hat{B}_i(x)\beta_i(x)$, where the vector fields $\hat{B}_i$ have been selected to satisfy (3.47); clearly, these vector fields are obtained from a nonsingular transformation of the original input vector fields appearing in (2.1).

We have shown in Lemma 3.9 that $\sum_{j \neq i} R_j^*$ is locally controlled invariant, so

$$\left[A, \sum_{j \neq i} R_j^*\right] \subset \sum_{j \neq i} R_j^* + \Delta_0 = \sum_{j \neq i} R_j^* + \operatorname{Span}\{\hat{B}_i\}. \tag{3.57}$$

Also, we have

$$\left[\tilde{B}_i, \sum_{j \neq i} R_j^*\right] \subset \sum_{j \neq i} R_j^*. \tag{3.58}$$

According to [7], it follows from this that we can, locally, define a function α_i such that the vector field $A + \tilde{B}_i\alpha_i$ leaves $\sum_{j \neq i} R_j^*$ invariant:

$$\left[A + \tilde{B}_i\alpha_i, \sum_{j \neq i} R_j^*\right] \subset \sum_{j \neq i} R_j^*. \tag{3.59}$$

Having done this for each $i \in \underline{m}$, we next consider the vector field $A + \sum_{j=1}^m \tilde{B}_j\alpha_j$. The following holds:

$$\begin{aligned} \left[A + \sum_{j=1}^{m} \tilde{B}_j\alpha_j, \sum_{j \neq i} R_j^*\right] &\subset \left[A + \tilde{B}_i\alpha_i, \sum_{j \neq i} R_j^*\right] + \left[\sum_{j \neq i} \tilde{B}_j\alpha_j, \sum_{j \neq i} R_j^*\right] \\ &\subset \sum_{j \neq i} R_j^* + \sum_{j \neq i} \left[\tilde{B}_j\alpha_j, \sum_{j \neq i} R_j^*\right] \subset \sum_{j \neq i} R_j^*. \end{aligned} \tag{3.60}$$

This shows that the distributions $\sum_{j \neq i} R_j^*$ are compatible. Now, define

$$\tilde{R}_i = \bigcap_{j \neq i} \sum_{k \neq j} R_k^*. \tag{3.61}$$

Clearly, we have $R_i^* \subset \tilde{R}_i$ for all $i \in \underline{m}$. It is immediate from (3.60) that

$$\left[A + \sum_{j=1}^{m} \tilde{B}_j \alpha_j, \tilde{R}_i\right] \subset \tilde{R}_i, \qquad i \in \underline{m}. \tag{3.62}$$

Furthermore, one has

$$\tilde{R}_i \cap \Delta_0 = \bigcap_{j \neq i} \sum_{k \neq j} (R_k^* \cap \Delta_0) = R_i^* \cap \Delta_0. \tag{3.63}$$

It now follows from Lemma 4.1 of [11] that R_i^* is the maximal regular local controllability distribution in $\tilde{R}_i$, and that R_i^* is also invariant under $A + \sum_{j=1}^{m} \tilde{B}_j \alpha_j$, i.e.,

$$\left[A + \sum_{j=1}^{m} \tilde{B}_j \alpha_j, R_i^*\right] \subset R_i^*, \qquad i \in \underline{m}. \tag{3.64}$$

With the properties (3.45), (3.46) and (3.64) all fulfilled, we see that the first part of the proof is complete. To show that (3.1) is necessary, let $\{R_i\}_{i \in \underline{m}}$ be a set of regular local controllability distributions that gives a solution of the decoupling problem (see § 2). Since

$$\begin{aligned} \Delta_0 = \operatorname{Span}\{B_1, \cdots, B_m\} = \operatorname{Span}\{\tilde{B}_1, \cdots, \tilde{B}_m\} &\subset \sum_{i=1}^{m} (\Delta_0 \cap R_i) \\ &\subset \sum_{i=1}^{m} (\Delta_0 \cap R_i^*) \subset \Delta_0, \end{aligned} \tag{3.65}$$

we see immediately that (3.1) must hold. Finally, it is also clear that, for any solution of the decoupling problem, we must have

$$\Delta_0 \cap R_i = \Delta_0 \cap R_i^*. \tag{3.66}$$

By the same argument as was used in the proof of Lemma 3.6, it follows from (3.66) that $R_i = R_i^*$. This completes the proof of the theorem. □

Remarks. (i) In connection with the solution of the noninteracting control problem given in [8] we note the following. The distributions $\Delta_i = \sum_{j \neq i} R_j^*$, $i \in \underline{m}$, are locally compatible, i.e. there locally exists a feedback which leaves each of the Δ_i's, $i \in \underline{m}$, invariant. Moreover we have that $\tilde{B}_j \subset \Delta_i \subset \operatorname{Ker} C_{i*}$, $j \neq i$, and for any two disjoint subsets $I, J \subset \underline{m}$ we have $(\bigcap_{i \in I} \Delta_i) + (\bigcap_{j \in J} \Delta_j) = TM$. In other words we have shown that the Δ_i's, $i \in \underline{m}$, are compatible and satisfy the conditions of Theorem 5.1 of [8]; so we have produced a *constructive* local solution of the input-output decoupling problem. For the case of scalar outputs, such a constructive solution has already been provided in [8, Thm. 5.2].

(ii) In general the feedback $u = \alpha(x) + \beta(x)v$ is only locally well defined. Without any further requirements on the state space M nothing can be said about the global solution of the noninteracting control problem. For instance, the question whether or not the manifold M is simply connected will probably be of importance (see [9]). From [18] comes the suggestion that the holonomy group of a certain integrable connection plays a crucial role. An approach to global problems via singularity theory is advocated by C.I. Byrnes in [27], [28]. Much further work will be needed to fully develop a theory of global nonlinear decoupling.

(iii) Combining (2.10) (or (3.56)) with the result on nonlinear systems invertibility from [15], we see that each subsystem

$$\begin{aligned} \dot{x}(t) &= \tilde{A}(x(t)) + \tilde{B}_i(x(t))v_i(t), \qquad x(0) = x_0, \\ z_i(t) &= C_i(x(t)) \end{aligned} \tag{3.67}$$

is strongly invertible at x_0. In the case that each output function is 1-dimensional, so $p_1 = \cdots = p_m = 1$, our results coincide with the results obtained in [20], which is the nonlinear version of a result of [4], see also [8], [2].

(iv) As we also assume that $p_1 + \cdots + p_m = n$ the total output map $C = (C_1, \cdots, C_m)$ is a (local) diffeomorphism, we have that $\bigcap_{i \in \underline{m}} \operatorname{Ker} C_{i*} = 0$ and our result follows by the fact that in this case the conditions $\Delta_0 = \Delta_0 \cap R_1^* + \cdots + \Delta_0 \cap R_m^*$ and $R_i^* + \operatorname{Ker} C_{i*} = TM$, $i \in \underline{m}$, are equivalent. By using some easy dimension arguments one can show that $R_i^* = \bigcap_{j \neq i} \operatorname{Ker} C_{j*}$ provided that the preceding condition holds, see also [16] and (3.44).

(v) The strong accessibility assumption for (2.1) is not needed. What is necessary in Theorem 3.1 is that the strongly accessible distribution (see [14], [22]) R_0 satisfies $C_*(R_0) = T(N_1 \times \cdots \times N_m)$, where $C = (C_1, \cdots, C_m)$.

(vi) If the number of input channels exceeds the number of outputs, we obtain by doing similar computations as in Lemma 3.2-Lemma 3.7 that a *sufficient* condition for the solvability of the regular local noninteracting control problem is $\Delta_0 = \bigoplus_{i \in \underline{m}} \Delta_0 \cap R_i^*$, provided that $A_1 - A_4$ hold. This serves as a starting point for a more general decoupling problem in [26].

4. The structure of a decoupled system. Next we want to discuss the (local) structure of an input-output decoupled system. We will show that as in the linear theory, see [12], our decoupled system possesses a natural local canonical form which can be built up from the distributions R_i^*. An alternative derivation is given in [8], and in [25] one can find a more algebraically oriented approach to the same problem. We consider a nonlinear system (2.1)-(2.2) satisfying the conditions and assumptions for the regular local noninteracting control problem, see § 3. For simplicity we will take $m = 2$; the general case follows by an easy induction argument. For $m = 2$ consider the nested sequence of involutive distributions

$$R_1^* \cap R_2^* \subset R_1^* \subset R_1^* + R_2^* = TM \tag{4.1}$$

(here the last equality follows from the strong accessibility assumption). By [19] we know that around $x_0 \in M$ there exists a coordinate system such that

$$R_1^* \cap R_2^* = \operatorname{Span}\left\{\frac{\partial}{\partial x_3}\right\}, \tag{4.2a}$$

$$R_1^* = \operatorname{Span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}\right\}, \tag{4.2b}$$

$$R_1^* + R_2^* = \operatorname{Span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}\right\} \tag{4.2c}$$

with each x_i, $i \in \underline{3}$, possibly being a vector.

Let us write the (locally) decoupled system as

$$\begin{aligned} \dot{x} &= \tilde{A}(x) + \tilde{B}_1(x)v_1 + \tilde{B}_2(x)v_2, \\ y_1 &= C_1(x), \\ y_2 &= C_2(x); \end{aligned} \tag{4.3}$$

then we have by definition of the regular local controllability distributions R_1^* and R_2^* that for $i = 1, 2$

$$R_i = \operatorname{Span}\{ad_{\tilde{A}}^k \tilde{B}_i,\ ad_{\tilde{B}_j}^k \tilde{B}_i \mid k \in \mathbb{Z}_+, j = 1, 2\}_{LA} \tag{4.4}$$

and so

$$
\begin{aligned}
&[\tilde{A}, R_i^*] \subset R_i^*, \\
&[\tilde{B}_j, R_i^*] \subset R_i^*, \qquad j = 1, 2.
\end{aligned} \tag{4.5}
$$

From (4.4) and (4.5) one can easily verify, by using the Jacobi identity extensively, that there exist sets of vector fields $\{X_\alpha\}_{\alpha \in I}$ and $\{Y_\beta\}_{\beta \in J}$ which span R_1^* and R_2^* respectively, such that

$$
[X_\alpha, Y_\beta] \in R_1^* \cap R_2^* = \operatorname{Span}\left\{\frac{\partial}{\partial x_3}\right\}, \qquad \alpha \in I, \quad \beta \in J. \tag{4.6}
$$

Here we recognize the ideal property of § 2. But (4.6) exactly implies, e.g. [19], [22], that the distribution R_2^* is locally given as

$$
R_2^* = \operatorname{Span}\left\{\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}\right\}. \tag{4.7}
$$

Let us now see what this implies for our system. Using (4.2)–(4.7) and the fact that $R_1^* \subset \operatorname{Ker} C_{2*}$ and $R_2^* \subset \operatorname{Ker} C_{1*}$ we obtain that (4.3) reads in our local coordinates as

$$
\begin{aligned}
\dot{x}_1 &= \tilde{A}_1(x_1) + \tilde{B}_1(x_1)v_1, \\
\dot{x}_2 &= \tilde{A}_2(x_2) + \tilde{B}_2(x_2)v_2, \\
\dot{x}_3 &= \tilde{A}_3(x_1, x_2, x_3) + \sum_{i=1}^{2} \tilde{B}_{3i}(x_1, x_2, x_3)v_i, \\
y_1 &= C(x_1), \\
y_2 &= C(x_2).
\end{aligned} \tag{4.8}
$$

This is what one might call a *local canonical form* for the input-output decoupled system. This is a direct generalization of the well-known linear result of [12]. In the same way one has for $m > 2$ the following *local canonical form*:

$$
\begin{aligned}
\dot{x}_1 &= \tilde{A}_1(x_1) + \tilde{B}_1(x_1)v_1, \\
&\vdots \\
\dot{x}_m &= \tilde{A}_m(x_m) + \tilde{B}_m(x_m)v_m, \\
\dot{x}_{m+1} &= \tilde{A}_{m+1}(x_1, \cdots, x_{m+1}) + \sum_{i=1}^{m} \tilde{B}_{(m+1)i}(x_1, \cdots, x_{m+1})v_i, \\
y_1 &= C(x_1), \\
&\vdots \\
y_m &= C(x_m).
\end{aligned} \tag{4.9}
$$

In this coordinate system one has $R_i^* = \operatorname{Span}\{\partial/\partial x_i, \partial/\partial x_{m+1}\}$, $i = 1, \cdots, m$. It is immediately seen from (4.9) that we have output controllability in each channel; this is an aspect that is not covered in [8].

Acknowledgment. The developments of § 4 benefited from suggestions by a reviewer.

INFINITE HORIZON STOCHASTIC PROGRAMS*

RICHARD C. GRINOLD†

Abstract. This paper considers a discrete time infinite horizon stochastic program with the objective of minimizing the expected present value of a sum of convex cost functions. In any finite time we assume that only a finite number of outcomes can occur. The paper presents a sequence of solvable finite horizon problems that converge in value and decision to the value and decision of the infinite problem.

Key words. mathematical programming, stochastic programming, infinite horizon, convergence, convexity

AMS(MOS) subject classifications. 60G, 65K

1. Introduction. This paper shows how an infinite horizon stochastic program that minimizes a convex objective, subject to linear constraints, with finite uncertainty at each stage can be approximated by a finite horizon stochastic program. The infinite horizon stochastic program can be considered as a decision tree starting from a single node at time 0. Each path through the tree corresponds to a realization of both the decision process and the stochastic process. At each time T we assume there is a finite collection of paths representing system evolution to that time. The state of the system at time t corresponds to a node in the decision tree; from any of the time t nodes there is a unique path back to the time 0 node. Since the problem has an infinite horizon, there can be an uncountable number of nodes.

The difficulty in solving such a problem is roughly proportional to the number of nodes. Our solution procedure looks at the time T nodes, and, by taking expectations, aggregates the paths emanating from each of the time T nodes into a single path. Then an end effects correction procedure is used to terminate that single path in a loop, at time T or at a later time. The paper shows that this procedure works. As $T \to \infty$, we get objective values that converge monotonically to the optimal value of the stochastic program, and the decisions of the T period problems converge to the optimal decisions of the infinite horizon problems.

This paper is organized as follows. Section 2 describes the stochastic process. Section 3 presents the decision problem along with our assumptions. The problem is a multistage stochastic program with linear constraints and a convex objective. The uncertainty is restricted to the right-hand side (constraining) vector. In § 4 we show how to aggregate the stochastic program into a deterministic program that will give a lower bound on the stochastic program. This idea is used to develop a T period approximation and in § 5 we prove that the values and solutions of the T period problems converge to their long-term counterparts. In § 6 we extend the model to include infinite time lags in the carry over of decisions; thus a time t decision can have an impact at all future times $t+s$ for $s \geqq 1$. In § 7 we consider the case in which the stochastic process is a finite homogeneous Markov chain. In that case we can allow the constraint matrix to depend on the state of the Markov chain. A final section describes how these ideas can be implemented.

The paper is based on two earlier treatments on infinite horizon problems. Grinold (1977) treats the deterministic linear case, and Grinold (1983) treats the deterministic convex case. Flam and Wets (1984) have recently extended these results. See the references in those papers for background on infinite horizon programs. This paper uses the result of the 1977 and 1983 papers to extend the treatment to the stochastic case in §§ 3, 4, and 5. This calls for two insights: first correctly building the model, so that results of the 1977 and 1983 papers apply and second, using the method of proof in the 1983 paper twice-aggregating over outcomes and over time. In § 6, we extend the basic results of 1977 and 1983 to allow for infinite time lags. Finally in § 7, we synthesize the new results of this paper with an earlier paper, Grinold (1976), on a Markovian multi-stage system.

In some ways our procedure is an example of the successive use of partitioning the sample space, see Pfanzangl (1974). Huang, Ziemba and Ben-Tal (1977), Hausch and Ziemba (1983), Marti (1977) and Birge (1985) have used this idea in relation to stochastic programs. More recently Birge (1984) has applied a technique similar to the one proposed here to a finite horizon stochastic production planning problem.

Some basic work on multi-stage stochastic programs can be found in Rockafellar and Wets (1974), (1976), Eisner and Olsen (1975) and Olsen (1976). In these papers the complicating element is the nonfinite range of the random variables. In our model stochastic process has finite range over any finite time span. The complicating factor is the infinite horizon and the compounding of uncertainty.

There is a large literature on infinite horizon problems in the Markov programming literature. However, those results do not carry over to our case. There are two main approaches to infinite horizon problems in the Markov programming literature. The first is called value iteration. In value iteration one ignores the effect of period T decisions on all rewards and constraints in later periods $t > T$. Grinold (1977) considered the analogous procedure for the class of infinite horizon multistage programming problems. The procedure will not work in the general case. An example is given in Grinold (1977). The basic reason is an ability to borrow against the future; if the model allows us to borrow (either money or backlogged orders) then we can build up a huge debt that is ignored in period $T+1$. The other solution procedure advanced in the Markov programming literature is called policy iteration. In that case we focus on a policy, and test for possible improvements. If there are none the policy is optimal; if improvements exist then a better policy is obtained. This procedure may be possible for the class of problems considered here, but it seems far more complicated than the solution procedure we suggest. A policy in our context is a function that depends on the stochastic process of right-hand side (constraint) vector. This is not a promising approach unless we can prove that the optimal policy has a very special form; e.g. if the matrices A in what follows are Leontief substitution matrices and K and the sequence $b(t)$ are nonnegative, and the objective $f[x]$ is linear.

In particular, Schal (1975) considers a very general class of decision problems. Despite its generality there are differences between our model and Schal's. First, our model is essentially nonstationary. A complete state description at time t calls for knowledge of the subset of the partition $\Omega(t)$ that was obtained as well as the decisions $x(0), x(1), \cdots, x(t-1)$ taken at earlier times. In addition, we do not impose any strong boundedness assumptions on our objective function or compactness assumption on our set of decisions. The boundedness assumption we use, see § 3, is the natural analogue of the boundedness assumptions in linear and nonlinear programming. The boundedness assumption is as weak as possible, if the problem is to have a finite optimal value and a proper optimal value function.

2. The stochastic process. Consider a set Ω of possible evolutions of the underlying stochastic process. Knowledge of $\omega \in \Omega$ gives us a complete history of all random events. As the stochastic process gradually unfolds, we learn more and more about the actual ω. This is made precise by considering a sequence of partitions $\Omega(t)$ of Ω where $\Omega(t+1)$ is a refinement of $\Omega(t)$. At time t we know that ω is in some particular member, say Q, of the partition $\Omega(t)$; at time $t+1$ we can be sure ω is in some subset of Q that is a member of the partition $\Omega(t+1)$. Since we are interested in practical solution methods, we will assume that $\Omega(t)$ is finite for all t.

Let $\mathcal{F}(t)$ be the smallest Borel field containing $\Omega(t)$. Since $\Omega(t+1)$ has finite cardinality $N(t)$, $\mathcal{F}(t)$ will consist of $2^{N(t)}$ possible unions of sets in $\Omega(t)$.

A measurable function $x(t):(\Omega, \mathcal{F}(t)) \to \mathbb{R}^n$ will be called t-measurable. Such an $x(t)$ will be constant on each of the sets in the partition $\Omega(t)$. A t-measurable function $x(t)$ will also be s measurable for $s \geqq t$ since $\Omega(s)$ refines $\Omega(t)$. A t-measurable function cannot anticipate events that occur after time t. It is constant on each element of $\Omega(t)$; it cannot exploit subsequent refinements of $\Omega(t)$. This property is called a *nonanticipation* condition.

Let $\mathcal{F}$ be the smallest Borel field including all of the $\mathcal{F}(t)$ and π be a probability measure defined on F.

The expectations operation E is defined by

$$E[z] = \int_{\Omega} z(\omega)\, d\pi(\omega). \tag{2.1}$$

Let E^T denote the conditional expectations operator with respect to $\mathcal{F}(t)$. For any $t > T$ and t-measurable function $x(t)$, $E^T[x(t)]$ is the expectation of $x(t)$ conditional on knowledge up to time T. As such $E^T[x(t)]$ will be T-measurable; i.e. it will be constant on each set in $\Omega(T)$.

3. The decision problem. For $t = 0, 1, 2, \cdots$, let $b(t):(\Omega, \mathcal{F}(t)) \to \mathbb{R}^n$ be a t-measurable function; $b(t)$ will depend only on the partition $\Omega(t)$; b satisfies the regularity condition

$$\sum_{t=0}^{\infty} \alpha^t E\{\|b(t)\|\} < \infty.$$

At time t the decision maker will know which set in $\Omega(t)$ has obtained and a history of past decision $x(s)$ for $s = 0, 1, \cdots, t-1$.

The decision maker's policy at time t is a t-measurable function $x(t)$ that must satisfy

$$Ax(t) = b(t) + Kx(t-1), \qquad x(t) \geqq 0. \tag{3.1}$$

This section considers only a one period decision carry over; the decision $x(t-1)$ effects the constraints at time t but earlier decisions $x(t-s)$ for $s \geqq 2$ have no effect. The one period lag is theoretically equivalent to any finite lag. In § 6 the model is extended to include infinite lags. The relation (3.1) holds almost surely; consider any set Q in the partition $\Omega(t)$ where the probability of Q obtaining is positive. The functions $x(t)$, $b(t)$, and $x(t-1)$ are all t-measurable and therefore all constant for $\omega \in Q$. Since $\Omega(t)$ has finite cardinality $N(t)$, then (3.1) is just a set of $N(t)$ linear equations, one for each possible history up to time t. This notation suppresses the dependence of the decision function $x(t)$ and right-hand side $b(t)$ on the stochastic process. If the partition $\Omega(t)$ has cardinality $N(t)$, then $x(t)$ is a vector with $n \cdot N(t)$ elements; i.e. an n element vector for each member of $\Omega(t)$. Similarly $b(t)$ is an $m \cdot N(t)$ element vector.

A policy x is the sequence $x(t)$ for $t=0,1,\cdots$, of random variables satisfying (3.1). The value of that policy is given by

$$F[x]=\limsup_{T\to\infty}\sum_{t=0}^{T}\alpha^t E\{f[x(t)]\} \tag{3.2}$$

where α is a discount factor lying between zero and one, and f is a closed (lower semi-continuous), proper, convex function.

Let $X(b)$ be the set of policies that satisfy (3.1). Our problem then is to find

Problem P

$$V(b)=\operatorname{Inf}\{F[x]\,|\,x\in X(b)\}. \tag{3.3}$$

If $X(b)$ is empty, then $V(b)$ is defined as $+\infty$.

We will make two assumptions about Problem P.

A1: *Feasibility.* A solution $x\in X(b)$ is said to be *α-convergent* if

$$\sum_{t=0}^{\infty}\alpha^t E\{ex(t)\}<\infty, \tag{3.4}$$

e is a summation vector. We assume there is an α-convergent solution.

A2: *Boundedness.* Let $f0^+[y]$ be the recession function of f. From Rockafellar (1970, pp. 66–71), we see that the recession function is closed, convex and homogeneous of degree one.

Let $0\leqq\lambda\leqq\alpha$ and y satisfy

$$[A-\lambda K]y=0,\quad y\geqq 0,\qquad ey=1. \tag{3.5}$$

Then A2 requires

$$f0^+[y]>0.$$

These assumptions are discussed in detail in Grinold (1977) and (1983). We shall prove below that if A2 is satisfied and A1 is not, then $V(b)=+\infty$. It is also true, and easy to show (see Grinold (1977)), that if A1 is satisfied, and if $f0^+[y]<0$ for some λ and y satisfying (3.5), then V is an improper convex function; i.e. $V(b)=-\infty$ on the relative interior of its domain. With the exception of a borderline case, A1 and A2 only rule out problems with infinite optimal values. Theorem 1 shows the importance of A1.

THEOREM 1. *Under* A2. *If $x\in X(b)$ is not α-convergent, then $F[x]=+\infty$.*

Proof. Let

$$z(t)=E[x(t)] \tag{3.6}$$

and

$$d(t)=E[b(t)]. \tag{3.7}$$

Then, by taking expectations on the constraints (3.1) we get

$$Az(t)=d(t)+Kz(t-1),\qquad z(t)\geqq 0. \tag{3.8}$$

By Jensen's inequality

$$E\{f[x(t)]\}\geqq f[z(t)]. \tag{3.9}$$

Thus

$$F[x]\geqq\limsup_{T\to\infty}\sum_{t=0}^{T}\alpha^t f[z(t)]=F[z]. \tag{3.10}$$

Consider the deterministic problem of minimizing the right-hand side of (3.10) subject to the constraints (3.8). If x is not α-convergent, then z will not be α-convergent since

$$\sum_{t=0}^{\infty} \alpha^t E\{ex(t)\} = \sum_{t=0}^{\infty} \alpha^t ez(t) = \infty. \tag{3.11}$$

By Theorem 4.1 of Grinold (1983), we have

$$\limsup_{T\to\infty} \sum_{t=0}^{T} \alpha^t f[z(t)] = +\infty;$$

thus from (3.10) $F[x] = +\infty$. Q.E.D.

4. The T-period problem. Theorem 1 focuses attention on α-convergent solutions. Solutions that are not α-convergent have infinite value and are not candidates for optimality when the objective value $V(b)$ is finite. The T period approximating problem, called $P(T)$, is motivated by showing how an α-convergent policy x maps into a feasible policy x^T for $P(T)$, and that the objective value of x^T in $P(T)$ is less than its value, $F[x]$, in P. Assumption A1 guarantees the existence of an α-convergent policy so $P(T)$ is feasible for all T, and the optimal values $V^T(b)$ of $P(T)$ converge monotonically upwards to $V(b)$.

Let $E^T[\ ]$ be the expectations operator conditional on $\mathcal{F}(T)$. For b and any policy x define

$$\begin{aligned} &\text{(i)} && b^T(t) = E^T[b(t)], \\ &\text{(ii)} && x^T(t) = E^T[x(t)]. \end{aligned} \tag{4.1}$$

The functions $b^T(t)$ and $x^T(t)$ are T-measurable for all $t \geqq T$. In particular, $b^T(t) = b(t)$ and $x^T(t) = x(t)$ for $t \leqq T$. Moreover, $b^T(t)$ and $x^T(t)$ satisfy the constraints

$$Ax^T(t) = b^T(t) + Kx^T(t-1), \qquad x^T(t) \geqq 0 \tag{4.2}$$

for all t.

We will aggregate the constraints (4.2) for $t \geqq T$ by multiplying the tth constraint by $(1-\alpha)\alpha^{t-T}$ and summing. This gives

$$(A - \alpha K)\tilde{x}(T) = \tilde{b}(T) + (1-\alpha)Kx^T(T-1), \qquad \tilde{x}(T) \geqq 0, \tag{4.3}$$

where

$$\begin{aligned} &\text{(i)} && \tilde{x}(T) = (1-\alpha) \sum_{t=T}^{\infty} \alpha^{t-T} x^T(t), \\ &\text{(ii)} && \tilde{b}(T) = (1-\alpha) \sum_{t=T}^{\infty} \alpha^{t-T} b^T(t). \end{aligned} \tag{4.4}$$

The constraints for $P(T)$ are equations (4.2) for $0 \leqq t < T$, and equation (4.3). Recall A is an m by n matrix; $P(T)$ will have $m * \sum_{t=0}^{T} N(T)$ constraints with $n * \sum_{t=0}^{T} N(t)$ variables where $N(t)$ is the cardinality of the partition $\Omega(t)$. A vector $x^T = (x^T(0), x^T(1), \cdots, x^T(T-1), \tilde{x}(T))$ is feasible for $P(T)$ if x^T satisfies (4.2) for $t < T$ and (4.3). Let $X^T(b)$ be the set of feasible solutions for $P(T)$; each α-convergent solution in $X(b)$ maps into a solution in $X^T(b)$.

The objective for $P(T)$ is

$$F^T[x^T] = \sum_{t=0}^{T-1} \alpha^t E[f\{x^T(t)\}] + \frac{\alpha^T}{(1-\alpha)} E[f\{\tilde{x}(T)\}]. \tag{4.5}$$

Problem $P(T)$ and its optimal value are thus defined by

Problem $P(T)$

$$V^T(b) = \text{Inf}[F^T[x^T] \mid x^T \in X^T(b)]. \tag{4.6}$$

For an α-convergent solution, one can show by Jensen's inequality, lower semi-continuity, and the definition of $\tilde{x}(T)$ that an α-convergent x must satisfy

$$\sum_{t=T}^{\infty} \alpha^t E[f[x(t)]] \geqq \frac{\alpha^T}{(1-\alpha)} E[f[\tilde{x}(T)]]. \tag{4.7}$$

Therefore $F^T[x^T] \leqq F[x]$, and $V^T(b) \leqq V(b)$.

The properties of $P(T)$ are summarized in Proposition 1.

PROPOSITION 1. *Under* A1 *and* A2.

(i) $$-\infty < V^0(b) \leqq \cdots \leqq V^T(b) \leqq V^{T+1}(b) \leqq V(b),$$

and

(ii) *An optimal solution to $P(T)$ exists.*

Proof. $V^T(b) \leqq V(b)$ has already been demonstrated. To show $V^T(b) \leqq V^{T+1}(b)$ let x^{T+1} be feasible for $P(T+1)$. Then x^T defined by

$$\begin{aligned} &\text{(i)} && x^T(t) = x^{T+1}(t) \quad \text{for } t < T, \\ &\text{(ii)} && \tilde{x}(T) = (1-\alpha)x^{T+1}(T) + \alpha\tilde{x}(T+1) \end{aligned} \tag{4.8}$$

will be feasible for $P(T)$ and by Jensen's inequality will have a lower objective value; i.e. $F^T[x^T] \leqq F^{T+1}[x^{T+1}]$.

Assume $V^0(b)$ is not bounded below. Then there will exist a sequence of feasible solutions z^k for $P(0)$ with

$$F^0[z^k] = \frac{1}{1-\alpha} f[z^k]. \tag{4.9}$$

The z^k are not bounded so $ez^k \to \infty$.

Let $y^k = z^k / ez^k$, and let y be a limit point of the y^k; y must satisfy

$$[A - \alpha K]y = 0, \quad y \geqq 0, \qquad ey = 1. \tag{4.10}$$

However, Lemma 3 of Grinold (1983), and the presumption that $F^0[z^k] \to -\infty$, imply $f0^+[y] \leqq 0$ in violation of A2. Thus $V^0(b)$ must be bounded below.

To prove (ii) use A2 and the results on existence in Rockafellar (1970, pp. 77, 267). Q.E.D.

5. Convergence. The optimal values and solutions of the T-period problems $P(T)$ converge, in a sense described exactly below, to the optimal value and solution of the infinite horizon problem P.

Before we state the convergence theorem, we need a definition; the sequence x^T *converges diagonally* to x if for every τ there exists a subsequence of integers $S(\tau)$ with $S(\tau)$ a subsequence of $S(\tau-1)$ such that for all $t \leqq \tau$

$$x^T(t) \to x(t)$$

as $T \in S(\tau)$ goes to infinity.

THEOREM 2. *Under* A1 *and* A2.

(i) $\lim_{T\to\infty} V^T(b) = V(b)$.

(ii) *Suppose $V(b)$ is finite. If x^T is optimal for $P(T)$, then there exists an x such that x is optimal for P and x^T converges diagonally to x.*

Proof. Let k be the limit of the $V^T(b)$. If k is infinite, then (i) is true and (ii) is not relevant.

Let x^T be optimal for $P(T)$. Define:

$$\text{(i)} \qquad z^T(t) = E\{x^T(t)\},$$

$$\text{(ii)} \qquad \tilde{z}(T) = E\{\tilde{x}(T)\},$$

$$\text{(iii)} \qquad d^T(t) = E\{b^T(t)\},$$

$$\text{(iv)} \qquad \tilde{d}(T) = E\{\tilde{b}(T)\},$$

$$\text{(5.1)} \quad \text{(v)} \qquad \tilde{z}(T,0) = (1-\alpha)\sum_{t=0}^{T-1} \alpha^t z^T(t) + \alpha^T \tilde{z}(T),$$

$$\text{(vi)} \qquad \tilde{d} = (1-\alpha)\sum_{t=0}^{T-1} \alpha^t d^T(t) + \alpha^T \tilde{d}(T),$$

$$\text{(vii)} \qquad M(T) = e\tilde{z}(T,0),$$

$$\text{(viii)} \qquad y(T) = \tilde{z}(T,0)/M(T).$$

Take the constraints of $P(T)$, take expectations, aggregate by multiplying constraints 0 through $T-1$ by $(1-\alpha)\alpha^T$ and constraint T by α^T and summing, divide the result by $M(T)$; this yields

$$\text{(5.2)} \qquad [A-\alpha K]y[T] = \tilde{d}/M(T) \quad \text{where } ey(T) = 1,\ y(T) \geqq 0.$$

We will show by contradiction that $M(T)$ is bounded above.

An application of Jensen's inequality to (4.5) gives

$$\text{(5.3)} \qquad (1-\alpha)V(b) \geqq (1-\alpha)V^T(b) = (1-\alpha)F^T[x^T] \geqq f[\tilde{z}(T,0)].$$

If $V(b)$ is finite and $M(T)$ is unbounded on some subsequence, then there exists a refinement of that subsequence and a vector y such that $y(T) \to y$, and $f[\tilde{z}(T,0)]/M(T) \to \mu \leqq 0$. Lemma 3 of Grinold (1983) tells us that $f0^+[y] \leqq 0$. However, from (5.2) we have

$$\text{(5.4)} \qquad [A-\alpha K]y = 0, \quad ey = 1, \quad y \geqq 0.$$

Thus, by assumption A2, $f0^+[y] > 0$. This contradiction shows $M(T)$ is bounded above; there exists a finite M such that $M(T) \leqq M$ for all T.

Since $\Omega(t)$ is finite for any t and we can assume, with no loss of generality, that each set in the partition $\Omega(t)$ has positive probability of occurrence, so $x^T(t)$ is a bounded sequence in $N(t)^*n$ space.

Therefore we can first find $x(0)$ and subsequence $S(0)$ of the integers such that $x^T(0) \to x(0)$ for $t \in S(0)$, then successively refine $S(\tau)$ and produce the limiting policy x such that x^T diagonally converges to x. It is easy to show x is feasible for P and that x is α-convergent, in fact

$$\text{(5.5)} \qquad \sum_{t=0}^{\infty} \alpha^T E[ex(t)] \leqq M.$$

It remains to show x is optimal.

For fixed τ and $T > \tau$ define

$$\text{(5.6)} \qquad \tilde{x}(T,\tau) = \sum_{t=\tau}^{T-1} (1-\alpha)\alpha^{t-\tau} x^T(t) + \alpha^{T-\tau}\tilde{x}(T).$$

The expected value of $\tilde{x}(T, \tau)$ conditional on events up to time T is

$$\tilde{z}(T, \tau) = \sum_{t=\tau}^{T-1} (1-\alpha)\alpha^{t-\tau} z^T(t) + \alpha^{T-\tau}\tilde{z}(T). \tag{5.7}$$

Several applications of Jensen's inequality yield

$$(1-\alpha)V^T(b) \geqq \sum_{t=0}^{\tau-1} (1-\alpha)\alpha^T E\{f[x^T(t)]\} + \alpha^\tau f[\tilde{z}(T, \tau)]. \tag{5.8}$$

For all $T > \tau$ we have

$$\alpha^\tau e\tilde{z}(T, \tau) \leqq M. \tag{5.9}$$

Thus there will be a subsequence $\hat{S}(\tau)$ of $S(\tau)$ and a vector $\tilde{y}(\tau)$ such that $x^T(t) \to x(t)$ for $t \leqq \tau$ and $z(T, \tau) \to \tilde{y}(\tau)$ as $T \in \hat{S}(\tau)$ goes to infinity.

Take the lim inf of (5.8) for $T \in S(\tau)$, and the result is

$$k(1-\alpha) \geqq (1-\alpha) \sum_{t=0}^{\tau-1} \alpha^T E\{f[x(t)]\} + \alpha^\tau f[\tilde{y}(\tau)]. \tag{5.10}$$

Now take the lim sup of (5.10) as $\tau \to \infty$; this yields

$$(1-\alpha)k \geqq (1-\alpha)F[x] + \limsup_{\tau\to\infty} \alpha^\tau f[\tilde{y}(\tau)]. \tag{5.11}$$

Note, by definition, $F[x] \geqq k$ so

$$\limsup_{\tau\to\infty} \alpha^\tau f[\tilde{y}(\tau)] \leqq 0. \tag{5.12}$$

From (5.9), $\alpha^\tau \tilde{y}(\tau)$ is bounded. In fact $\alpha^\tau \tilde{y}(\tau) \to 0$. If not, suppose $\alpha^\tau y(\tau) \to y \neq 0$.

By the usual aggregating of equations one can show that $z = y/ey$ satisfies (5.4) and therefore, by A2 and the homogeneity of $f0^+$, that

$$f0^+[z] = \frac{1}{ey} f0^+[y] > 0. \tag{5.13}$$

However, (5.12) and Lemma 3 of Grinold (1983) imply that

$$f0^+[y] \leqq \limsup_{\tau\to\infty} \alpha^\tau f[\tilde{y}(\tau)] \leqq 0. \tag{5.14}$$

The assumption that $y \neq 0$ has produced a contradiction. When $y = 0$, then $f0^+[y] = 0$, so (5.14) implies the lim sup is zero and, by (5.11), $F[x] = k$. Q.E.D.

6. Infinite time lags. The model presented in earlier sections had a one period lag; the time t constraints were only influenced by time $t-1$ decisions. For theoretical purposes that result covers lags of any finite length. In this section the one period lag model is extended to cover infinite time lags and thus allow for many realistic situations in which new capital stock decays exponentially or remains indefinitely.

Let $K(t-s)$ be the $t-s$ period lag. The constraints of P become

$$Ax(t) = b(t) + \sum_{s=0}^{t-1} K(t-s)x(s), \qquad x(t) \geqq 0. \tag{6.1}$$

Since $x(t)$ and $x(s)$ for $s < t$ are t-measurable, the constraint (6.1) holds for all sets in the partition $\Omega(t)$.

Now define

$$\tilde{K}(t, \theta) = \sum_{j=t}^{\infty} \theta^j K(j). \tag{6.2}$$

The constraints in approximating problem $P(T)$ coincide with (6.1) for $t < T$. The Tth constraint is

$$[A - \tilde{K}(1, \alpha)]\tilde{x}(T) = \tilde{b}(T) + (1-\alpha)\sum_{s=0}^{T-1} \tilde{K}(T-s, \alpha)\alpha^s x(s), \qquad \tilde{x}(T) \geqq 0. \tag{6.3}$$

The boundedness condition, A2, becomes: for $0 \leqq \theta \leqq \alpha$ and y satisfying

$$[A - \tilde{K}(1, \theta)]y = 0, \qquad ey = 1, \quad y \geqq 0, \tag{6.4}$$

we must have $f0^+[y] > 0$.

For any $z \in R^n$, let the norm of z be defined as

$$\|z\| = \sum_{i=1}^{n} |z_i|, \tag{6.5}$$

and for K an m by n matrix

$$\|K\| = \text{Max}\,\{\|Kz\| \mid \|z\| = 1\}; \tag{6.6}$$

therefore

$$\|Kz\| \leqq \|K\|\,\|z\| \quad \text{for all } z. \tag{6.7}$$

The assumption we make on the matrices $K(t)$ is

$$\|K(t)\| \leqq \psi^t k \tag{6.8}$$

where $\psi\alpha < 1$.

PROPOSITION 2. *Under* (6.8), *Theorems* 1 *and* 2 *are valid with infinite time lags.*

Proof. We need only extend Theorem 4.1 of Grinold (1983) to cover infinite lags. That requires a different method of proof: We wish to show that a non-α-convergent solution $z(t)$ of the deterministic constraints

$$Az(t) = d(t) + \sum_{s=0}^{t-1} K(t-s)z(s) \tag{6.9}$$

will have objective value $F(z)$ (see (3.10)) equal to plus infinity.

Let ρ be the radius of convergence of the series $\sum_{t=0}^{\infty} \theta^t ez(t)$. Suppose first that $0 < \rho \leqq \alpha$. Choose $\theta < \rho$, multiply constraint t of (6.9) by $(1-\theta)\theta^t$ and sum. We get

$$[A - \tilde{K}(1, \theta)]\tilde{z}(\theta) = \tilde{d}(\theta), \qquad \tilde{z}(\theta) \geqq 0, \tag{6.10}$$

where

$$\begin{aligned} &\text{(i)} && \tilde{z}(\theta) = (1-\theta)\sum_{t=0}^{\infty} \theta^t z(t), \\ &\text{(ii)} && \tilde{d}(\theta) = (1-\theta)\sum_{t=0}^{\infty} \theta^t d(t). \end{aligned} \tag{6.11}$$

Now define

$$M(\theta) = e\tilde{z}(\theta), \qquad \tilde{y}(\theta) = \tilde{z}(\theta)/M(\theta). \tag{6.12}$$

Recall that $\rho < 1$ is the radius of convergence of $\sum_{t=0}^{\infty} \theta^t ez(t)$. As θ increases to ρ, $M(\theta)$ increases to $+\infty$. Therefore $\tilde{d}(\theta)/M(\theta)$ converges to zero. Consider a sequence of θ increasing to ρ and a limit point y of the sequence $\tilde{y}(\theta)$.

The vector y will satisfy

$$[A-K(1,\rho)]y=0, \quad ey=1, \quad y\geqq 0. \tag{6.13}$$

By assumption A2, $f0^{+}[y]>0$.

If the

$$\limsup_{T\to\infty} \sum_{t=0}^{T} \rho^{t} f[z(t)] = +\infty, \tag{6.14}$$

then, by Lemma 2 of Grinold (1977),

$$F[z]=+\infty. \tag{6.15}$$

If (6.14) is false, then there exists a B such that

$$\sum_{t=0}^{T} \rho^{t} f[x(t)] \leqq B \quad \text{for all } T. \tag{6.16}$$

Now apply the logic of Lemma 2 of Grinold (1977) again with

$$a_t=\theta^{t} f[z(t)], \quad \mu=\frac{\theta}{\rho}<1, \quad r_T=\sum_{t=0}^{T} \rho^{t} f[z(t)]. \tag{6.17}$$

We have

$$\sum_{t=0}^{T} \theta^{t} f[z(t)] = (1-\mu) \sum_{t=0}^{T} \mu^{t} r_T + \mu^{T+1} r_T. \tag{6.18}$$

From (6.16), $r_T \leqq B$ for all T, so

$$\sum_{t=0}^{T} \theta^{t} f[z(t)] \leqq B \quad \text{for all } t. \tag{6.19}$$

By the convexity of f

$$\frac{(1-\theta)}{(1-\theta^{T+1})} \sum_{t=0}^{T} \theta^{t} f[z(t)] \geqq f[\tilde{z}(T,\theta)] \tag{6.20}$$

where

$$\tilde{z}(T,\theta)=\frac{1-\theta}{1-\theta^{T+1}} \sum_{t=0}^{T} \theta^{t} z(t). \tag{6.21}$$

As $T\to\infty$, $\tilde{z}(T,\theta)\to\tilde{z}(\theta)$.

Since f is lower semi-continuous

$$\limsup_{T\to\infty} f[\tilde{z}(T,\theta)] \geqq \liminf_{T\to\infty} f[\tilde{z}(T,\theta)] \geqq f[\tilde{z}(\theta)]. \tag{6.22}$$

When (6.22) is combined with (6.19), we have

$$B \geqq \frac{1}{1-\theta} f[\tilde{z}(\theta)] \quad \text{for } \theta<\rho. \tag{6.23}$$

Now $\tilde{z}(\theta)/M(\theta)\to y$, on some sequence of θ ascending to ρ. On a subsequence we must have

$$\frac{1}{M(\theta)} f[\tilde{z}(\theta)] \to \mu \leqq 0,$$

by (6.23) and $M(\theta)$ increasing to plus infinity. By Lemma 3 of Grinold (1983), $f0^+[y] \leqq \mu \leqq 0$. However, by A2, $f0^+[y]$ is positive. This contradiction arises when we accept (6.16) rather than (6.14). Thus (6.14) is valid and $F[z] = +\infty$.

Now consider the case $\rho = 0$. For T fixed and $0 < \theta \leqq \alpha$ use the weights $((1-\theta)/1-\theta^{T+1})\theta^t$ to multiply the tth constraint of (6.9), for $t \leqq T$, and to multiply the identity.

$$-\sum_{s=0}^{T-1} K(t-s)z(s) = -\sum_{s=1}^{T} K(s)z(T-s) \tag{6.24}$$

for $t > T$. Sum the terms; this yields

$$[A-\tilde{K}(1,\theta)]\tilde{z}(T,\theta) = \tilde{d}(T,\theta) - \frac{1-\theta}{1-\theta^{T+1}} \sum_{s=1}^{T} \tilde{K}(s,\theta)\theta^{T-s}z(T-s) \tag{6.25}$$

where $\tilde{K}(s,\theta)$ is defined by (6.2), $\tilde{z}(T,\theta)$ by (6.21) and $\tilde{d}(T,\theta)$ by

$$\tilde{d}(T,\theta) = \frac{1-\theta}{1-\theta^{T+1}} \sum_{t=0}^{T} \theta^t d(t). \tag{6.26}$$

Now let

$$\begin{aligned} &\text{(i)} && M(T,\theta) = e\tilde{z}(T,\theta), \quad \text{and} \\ &\text{(ii)} && L(T,\theta) = (1-\theta^{T+1})M(T,\theta)/(1-\theta). \end{aligned} \tag{6.27}$$

For θ fixed, as $T \to \infty$, we can find a convergent subsequence $S(0)$ of $\tilde{z}(T,\theta)/M(T,\theta)$ converging to $y(\theta)$. Let $S(1)$ be a subsequence of $S(0)$ such that

$$\frac{\theta^{T-1}\tilde{z}(T-1,\theta)}{L(T,\theta)} \to y(1,\theta) \tag{6.28}$$

for $T \in S(0)$.

In general let $S(\tau)$ be a subsequence of $S(z-1)$ such that

$$\frac{\theta^{T-s}\tilde{z}(T-s,\theta)}{L(T,\theta)} \to y(s,\theta) \tag{6.29}$$

for $T \in S(\tau)$ where $s \leqq \tau$.

We wish to show that $y(\theta)$, and $y(s,\theta)$ for $s \geqq 1$ satisfy

$$[A-\tilde{K}(1,\theta)]y(\theta) = -\sum_{s=1}^{\infty} \tilde{K}(s,\theta)y(s,\theta). \tag{6.30}$$

For τ fixed and $T \in S(\tau)$,

$$\begin{aligned} &\lim_{T\in S(\tau)} \left\{ -\sum_{s=\tau+1}^{T} \tilde{K}(s,\theta)\frac{\theta^{T-s}z(T-s)}{L(T,\theta)} \right\} \\ &\quad = \lim_{T\in S(\theta)} \left\{ [A-\tilde{K}(1,\theta)]\frac{z(T,\theta)}{M(T,\theta)} + \sum_{s=1}^{\tau} \tilde{K}(s,\theta)\frac{\theta^{T-s}z(T-s)}{L(T,\theta)} \right\}. \end{aligned} \tag{6.31}$$

Note that assumption (6.8) implies

$$\begin{aligned} &\text{(i)} && \|K(s,\theta)\| \leqq \frac{(\theta\psi)^s k}{1-\theta\psi}, \quad \text{also that} \\ &\text{(ii)} && \left\| \frac{\theta^{T-s}z(T-s)}{L(T,\theta)} \right\| \leqq 1. \end{aligned} \tag{6.32}$$

Therefore the limit on the left of (6.31) satisfies

$$\left\| \lim_{T \in S(\theta)} \sum_{s=\tau+1}^{T} \tilde{K}(s, \theta) \frac{\theta^{T-s} z(T-s)}{L(T, \theta)} \right\| \leqq \frac{(\theta\psi)^{\tau+2} k}{(1-\theta\psi)^2}. \tag{6.33}$$

The limit on the right of (6.31) is

$$[A - \tilde{K}(1, \theta)] y(\theta) + \sum_{s=1}^{\tau} \tilde{K}(s, \theta) y(s, \theta). \tag{6.34}$$

As $\tau \to \infty$, we see, since $\theta\psi < 1$, that (6.30) holds.

Now consider a sequence converging to zero. Each $y(\theta)$ satisfies $ey(\theta) = 1$, $y(\theta) \geqq 0$, so there will be a y and sequence $y(\theta) \to y$. The $y(s, \theta)$ are all bounded, and $K(s, \theta) \to 0$ as $0 \to 0$; thus y will satisfy

$$Ay = 0, \qquad ey = 1, \quad y \geqq 0. \tag{6.35}$$

By assumption A2, $f0^+[y] > 0$. The lower semi-continuity $f0^+$ ensures

$$f0^+[y(\theta)] > 0 \quad \text{for } \theta \text{ small and positive.} \tag{6.36}$$

However, for this same θ

$$\frac{(1-\theta)}{1-\theta^{T+1}} \sum_{t=0}^{T} \theta^t f[z(t)] \geqq f[z(t, \theta)]. \tag{6.37}$$

The remainder of the proof is like the $\rho > 0$ case. If lim sup of $\sum_{t=0}^{T} \theta^t f[z(t)]$ is infinite we are done; if not the sequence $\sum_{t=0}^{T} \theta^t f[z(t)]$ is bounded. From (6.37) this leads us to conclude $f0^+[y(\theta)] \leqq 0$ in contradiction to (6.36). Q.E.D.

7. The Markovian case. This section presents a refined treatment of the expectations problem when the underlying stochastic process is a finite Markov chain. The Markovian assumption allows us to introduce some randomness into the technology matrix, A, and the carry over matrices, $K(t-s)$, and to still obtain the same strong results of earlier sections.

Let the realization ω be a vector with coordinates $\omega(t)$ that are states of a finite Markov chain. For each t, $\omega(t) \in \{1, 2, \cdots, N\}$ and the distribution of $\omega(t)$ given $\omega(t-1)$ is independent of t and of $\omega(s)$ for $s < t-1$. Thus the probabilities of moving from $\omega(s) = j$ to $\omega(t) = i$ depends only on j and $t-s$; i.e.

$$\pi[\omega(t) = i \,|\, \omega(s) = j] = \pi(i \,|\, j, t-s). \tag{7.1}$$

In this more restricted stochastic process the problem data, A and K can depend on the stochastic evolution of the system, although in a special way. Let $A(\omega, t)$ and $K(\omega, t, s)$ be the data conditional on outcome ω.

The assumption is

$$\begin{aligned} &\text{(i)} && A(\omega, t) = A(i) \quad \text{if } \omega(t) = i, \\ &\text{(ii)} && K(\omega, t-s) = K(i, j, t-s) \quad \text{if } \omega(t) = i \quad \text{and } \omega(s) = j. \end{aligned} \tag{7.2}$$

Let $z(i, t)$ be 1 if $\omega(t) = i$ and 0 if not, and $\pi^T(i, t)$ expectation of $z(i, t)$ given the evolution of the stochastic process up to time T; i.e. given $\omega(0), \omega(1), \cdots, \omega(T)$. For $t \leqq T$, $\pi^T(i, t)$ is 1 if $\omega(t) = i$, and 0 if not. For $t > T$ and $\omega(T) = j$, $\pi^T(i, t)$ equals $\pi(i \,|\, j, t-T)$.

Let

$$
\begin{aligned}
&\text{(i)} && z(i,t)=1 \quad \text{if } \omega(t)=i, 0 \quad \text{if not,}\\
&\text{(ii)} && \pi^T(i,t)=E^T[z(i,t)],\\
&\text{(iii)} && x^T(i,t)=E^T[x(t)\,|\,\omega(t)=i],\\
(7.3)\quad &\text{(iv)} && y^T(i,t)=\pi^T(i,t)x^T(i,t),\\
&\text{(v)} && b^T(i,t)=E^T[b(t)\,|\,\omega(t)=i],\\
&\text{(vi)} && d^T(i,t)=\pi^T(i,t)b^T(i,t),\\
&\text{(vii)} && H(i,j,t-s)=\pi(i\,|\,j,t-s)K(i,j,t-s),
\end{aligned}
$$

where E^T is expectation conditional on the partition $\Omega(T)$. Note that

$$
E^T[x(t)]=\sum_{i=1}^{N} y^T(i,t). \tag{7.4}
$$

PROPOSITION 3. *For any T and $x\in X(b)$ the variables y^T defined in* (7.3) *satisfy*

$$
\text{(i)}\quad A(i)y^T(i,t)=g^T(i,t)+\sum_{s=T+1}^{t-1}\sum_{j=1}^{N} H(i,j,t-s)y^T(j,s) \text{ and}
$$

$$
y^T(i,t)\geqq 0, \quad \textit{for all } t>T, \textit{ where} \tag{7.5}
$$

$$
\text{(ii)}\quad g^T(i,t)=d^T(i,t)+\pi^T(i,t)\sum_{s=0}^{T} E^T\{K(t-s)x(s)\,|\,\omega(t)=i\}.
$$

In addition

$$
\text{(iii)}\quad f\left[\sum_{i=1}^{N} y^T(i,t)\right]\leqq E^T\{f[x(t)]\} \quad \textit{for all } t>T.
$$

Proof. The first result is trivial if $\pi^T(i,t)=0$. That implies $y^T(i,t)$ and $d^T(i,t)$ are zero. Also for each j and $s<t$, either $\pi^T(j,s)=0$ or $\pi(i\,|\,j,t-s)=0$ since

$$
\pi^T(i,t)=\sum_{j=1}^{N}\pi^T(j,s)\pi(i\,|\,j,t-s)=0. \tag{7.6}
$$

So either $y^T(j,s)=0$ or $H(i,j,t-s)=0$ for all j and $s<t$.

Now consider $\pi^T(i,t)$ positive. The constraints defining $X(b)$ are

$$
Ax(t)=b(t)+\sum_{s=0}^{t-1} K(t-s)x(s), \qquad x(t)\geqq 0. \tag{7.7}
$$

We will take expectations of each term conditional on the history up to time T and the state at time t.

$$
E^T\{Ax(t)\,|\,\omega(t)=i\}=A(i)x^T(i,t), \tag{7.8}
$$

$$
E^T\{b(t)\,|\,\omega(t)=i\}=b^T(i,t). \tag{7.9}
$$

For any $T<s<t$, condition on $\omega(s)=j$

$$
\begin{aligned}
&E^T\{K(t-s)x(s)\,|\,\omega(t)=i\}\\
&\quad=\sum_{j=1}^{N}\frac{\pi(i\,|\,j,t-s)\pi^T}{\pi^T(i,t)}(j,s)K(i,j,t-s)E^T\{x(s)\,|\,\omega(s)=j,\omega(t)=i\}.
\end{aligned} \tag{7.10}
$$

Since $x(s)$ is s-measurable and $t > s$, the nonanticipation condition implies

$$E^T\{x(s) \mid \omega(s) = j, \psi(t) = i\} = E^T\{x(s) \mid \omega(s) = j\} = x^T(j, s). \tag{7.11}$$

Thus (7.10) becomes

$$\frac{1}{\pi^T(i, t)} \sum_{j=1}^{N} H(i, j, t-s) y^T(j, s). \tag{7.12}$$

When all expectations are multiplied by $\pi^T(i, t)$, we get item (i) of (7.5).

Item (iii) of (7.5) just is an application of Jensen's inequality using (7.4). Q.E.D.

We have derived an infinite horizon deterministic problem from our stochastic problem. If we fix T, then the vector $y^T(t)$ will have $n \times N^T$ elements. For each $i = 1, 2, \cdots, N$, $y^T(i, t)$ is an n element random variable, with a different value for each of the N^T possible evolutions in the period 0 to T.

From item (iii) of Proposition 2 we see that the deterministic problems will give a lower bound on the value of the stochastic problem. The finite horizon lower bounds will get arbitrarily close to the actual value when we impose a variant, described below, of assumption A2 on the problem.

Let A be the N block by N block diagonal matrix with $A(i)$, an m by n matrix, in diagonal block i for $i = 1, 2, \cdots, N$. Similarly, let $H(t-s)$ be an N block by N block matrix with $H(i, j, t-s)$ the m by n matrix in block (i, j) for i and j running from 1 to N. Let J be a one block by N block matrix with an n by n identity matrix in each block, (i, j). Now let y be an $N * n$ element vector $y(1), y(2), \cdots, Y(N)$ where $y(i)$ is an n element vector for each i. Then Jy is just the sum of the $y(i)$. The variant of A2 is:

For any $\lambda, 0 \leqq \lambda \leqq \alpha$ and y satisfying

$$[A - H(\lambda)]y = 0, \qquad ey = 1, \quad y \geqq 0, \tag{7.13}$$

we have

$$f0^+[Jy] > 0. \tag{7.14}$$

8. Practical considerations. Except in the Markov case of § 7 we have assumed that the technology (as described by A and matrices $K(t-s)$) is independent of the stochastic process and thus of time. We show by example that this does not necessarily have to be true. Suppose there is a technology, say electricity generated by fusion, that may or may not be available in the future. We could include the fusion power technology in the matrices A, $K(1), \cdots$. If fusion is not available in certain events at time t, then we can place an upper bound of zero on the amount of fusion power used in those events. If fusion power is available at time t, then we place a positive bound on the amount used. This moves the uncertainty to an upper bound, and thus to the right-hand side vector $b(t)$.

Notice that this is silly if the upper bound is either zero or five times the amount of electricity demand anticipated in period t. If, on the other hand, we assume a realistic phase-in of the new technology, e.g. the bound is 2% of demand in the first period, 5% in the second up to 15% after several periods, then we could expect reasonable results.

A second item is how to put the theory of this paper into practice. The idea is to break an infinite horizon problem into a three phase problem. The first phase, periods $t = 0, 1, 2, \cdots, T-1$ is a transition phase. During this phase the objectives and constraints depend on the stochastic process. The second phase is called the expectations phase. For $T \leqq t < \tau$ there will be one set of constraints and variables for each outcome

in $\Omega(T)$. The data in this phase can depend on what happened in $[0, T]$. The final phase is called the termination phase. In this phase we aggregate the remainder of the expectations problem for $t = \tau, \tau+1, \cdots$, into one period problem in the manner described for problem $P(T)$.

Some limited experience in the linear deterministic case, Grinold (1983), shows that we can make T and τ relatively small and still get good results.

Acknowledgments. My thanks to the editor and referees for their thorough reports, patience and prodding. Thanks also to Linda Lane who did a superb job of typing.

CONSTRAINED CONTROLLABILITY IN BANACH SPACES*

G. PEICHL† AND W. SCHAPPACHER†‡

Abstract. The aim of this paper is to study null-controllability of the linear infinite dimensional control problem $\dot{x} = Ax + Bu$ where the control u is constrained to lie in a convex, weakly compact subset Ω of the control space with $0 \in \Omega$. A necessary and sufficient condition for a particular initial state to be Ω-null-controllable within a fixed, finite time T is given. The result is extended to the case Ω = convex cone with vertex at 0. Applications to the one-dimensional heat- and wave-equation are given.

Key words. constrained null-controllability, infinite dimensional control problem

AMS(MOS) subject classifications. 93B05, 93C25

1. Introduction. Whereas there is an extensive literature on unconstrained controllability problems, little is known if the control is constrained to take on values in a preassigned subset Ω of the control space U. Classical results in this direction in the finite dimensional case, differing in the assumptions on Ω, can be found in [13], [17], [4]. These assert that controllability is equivalent, in a certain sense, to the famous Kalman rank condition plus an additional one due to the constraint. Only a few years ago W. E. Schmitendorf and B. R. Barmish presented in a series of papers [2], [3], [18] another point of view, which may already be found in a similar form in [11]. They assumed $\Omega \subset R^n$ compact. Their basic argument is as follows: if the origin were not in the reachable set one could find a strictly separating hyperplane. By contraposition and the use of Ekeland's selection theorem [8] they derived a characterization of the domain of Ω-null-controllability which amounts to a finite dimensional optimization problem. This forms the base for various controllability results. Basically, their conditions are integral conditions in terms of the nontrivial solutions of the adjoint equation.

In infinite dimensions there are only a few attacks on the constrained controllability problem, cf. [9], for the boundary control of the heat equation and [10], [15], [16] for the wave equation with distributed controls. In [10] Fattorini applied the theory of sine and cosine operators to show that any state in a suitably defined state space of a system governed by a second order differential equation in a Hilbert space may be controlled to the origin in finite time by means of controls whose values range in the unit ball of the control space. In [15] K. Narukawa presented a theorem which, roughly speaking, asserts that if there is a fixed time $T_0 > 0$, such that an initial state in the controlled space may be steered to the origin within $[0, T_0]$ by means of an unconstrained control (and other hypotheses concerning the solution semigroup are met) it may also be transferred to the origin in finite time T by a control $u(\cdot)$ such that $\|u(\cdot)\|_{p,[0,T]}$ is arbitrarily small. Observe that Narukawa bounds the controls in $L^p_{\text{loc}}(0, \infty; U)$. However, using this theorem, he succeeded in showing global controllability for certain subspaces for the wave equation with respect to appropriate Sobolev spaces even if one applies controls subject to rather arbitrary pointwise constraints [16]. Basically both authors reduce the controllability problem to a moment problem. But, when Ω is different from the unit ball in U, this procedure may cause some difficulties inasmuch as it is by no means clear how certain properties of the control, such as positivity, affect its Fourier coefficients. Therefore we tried, instead, to generalize the ideas of Schmitendorf and Barmish.

Throughout this paper let X be a reflexive, U a separable reflexive Banach space, A be the infinitesimal generator of a C_0-semigroup $S(\cdot)$, $B \in L(U, X)$ and fix $T > 0$. Let X^*, U^* be the respective dual spaces and $\langle \cdot, \cdot \rangle$ be the duality pairing, the involved spaces being clear from the context. We consider the abstract Cauchy problem

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), \qquad t \geqq 0, \\ x(0) &= x_0 \end{aligned} \tag{1.1}$$

where $u(\cdot) \in L^p(0, T; U)$, $1 < p < \infty$. The mild solution of (1.1) is given by

$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\, ds, \qquad t \geqq 0.$$

Let Ω be a convex, weakly compact subset of U such that $0 \in \Omega$ and define the set of admissible controls

$$\mathcal{U}_{\text{ad}}(T) = \{u \in L^p(0, T; U) \mid u(t) \in \Omega \text{ a.e. on } [0, T]\}$$

and the corresponding reachable set

$$\mathcal{A}(T, x_0) = \{x(T) \mid x(\cdot) \text{ is a mild solution of (1.1), } x(0) = x_0,\ u \in \mathcal{U}_{\text{ad}}(T)\}.$$

DEFINITION 1.1. (a) $x_0 \in X$ is Ω-null-controllable (within T) iff $0 \in \mathcal{A}(T, x_0)$.

(b) $\{x \mid 0 \in \mathcal{A}(T, x)\}$ will be called the domain of Ω-null-controllability (with respect to T).

Since in infinite dimensions there is in general no analogue to the adjoint equation, we focus our attention on the characterization of the domain of Ω-null-controllability. This is accomplished in Theorem 2.3, which is the straightforward generalization of the corresponding result in finite dimensions [18, Thm. 2.3]. Though this characterization still involves—as should be expected—an infinite dimensional optimization problem, it is shown in the final section that in simple situations it yields results in a most elementary way. It should be pointed out that, in contrast to the aforementioned results, this paper deals with what can be achieved within a fixed (finite) time period. Also, rather than studying Ω-null-controllability of subspaces, our main result enables one to establish (at least theoretically) whether a given particular state may be controlled to the origin in fixed finite time (or not, which is much simpler to verify). For instance, we discuss the one-dimensional heat equation and show that, in case Ω = unitball in U every initial state ϕ with $\sup_{t \in [0,T]} |\phi(t)| < 1$ can be steered to the origin within time $T = 1$. In case $\Omega = [0, 1]$ an initial state ϕ cannot be controlled to the origin as long as the solution to the corresponding homogeneous system is positive on a set of positive measure. We also consider the one-dimensional wave equation and show that for every $T > 0$ the domain of Ω-null-controllability contains a ball with positive radius centered at the origin, and we thus sharpen an earlier result of Fattorini [10].

We would like to emphasize that the assumption $B \in L(U, X)$ rules out the application of our theory to boundary control problems, because in this situation B is typically unbounded. Since the connection between a boundary control problem and a Cauchy problem of the type (1.1) is by no means straightforward, see for example the recent article [6], Narukawa's remark that he also could handle boundary control problems in [15] is not evident (observe, that the proof of Theorem 1 in [15] heavily rests upon the boundedness of B).

Finally, we believe that the assumption $0 \in \Omega$ (but 0 need not be an interior point) is not a severe one from the practical point of view. Otherwise one could incorporate an additional inhomogeneity in the system (1.1).

2. Null controllability with constraints.

PROPOSITION 2.1. *$\mathcal{U}_{ad}(T)$ and $\mathcal{A}(T, x_0)$ are weakly compact.*

Proof. Since Ω is bounded, so is $\mathcal{U}_{ad}(T)$. Thus, by the Eberlein-Smulian theorem, it suffices to show that $\mathcal{U}_{ad}(T)$ is weakly closed. We have to show that the weak limit $u(\cdot)$ of any weakly convergent sequence in $\mathcal{U}_{ad}(T)$ satisfies $u(t) \in \Omega$ a.e. on $[0, T]$. This is followed immediately by a mimicry of the classical proof in [13, p. 157], once we observe that Ω is, by convexity, strongly closed and may therefore be represented as the intersection of a denumerable number of its supporting halfspaces by a theorem of Bishop and Phelps [14, p. 75]. Now, the weak compactness of $\mathcal{A}(T, x_0)$ is clear from

$$\begin{aligned} &\mathcal{T}: L^p(0, T; U) \to X, \\ &\mathcal{T}u = \int_0^T S(T-s)Bu(s)\, ds. \end{aligned} \tag{2.1}$$

Obviously $\mathcal{T} \in L(L^p(0, T; U), X)$ and hence also is continuous with respect to the corresponding weak topologies, which implies the weak compactness of $\mathcal{T}\mathcal{U}_{ad}(T)$. But $\mathcal{A}(T, x_0)$ is merely a translate of $\mathcal{T}\mathcal{U}_{ad}(T)$.

The next proposition gathers some technicalities.

PROPOSITION 2.2. (i) *For each $s \in [0, T]$, $x^* \to \max_{v \in \Omega} \langle x^*, S(s)Bv \rangle$ defines an equicontinuous family of mappings $X^* \to R_+$.*

(ii) *For each $x^* \in X^*$, $s \to \max_{v \in \Omega} \langle x^*, S(s)Bv \rangle$, as a mapping $[0, T] \to R_+$, is continuous.*

(iii) *For each $x^* \in X^*$ there is $u \in \mathcal{U}_{ad}(T)$, such that $\langle x^*, S(\cdot)Bu(\cdot) \rangle = \max_{v \in \Omega} \langle x^*, S(\cdot)Bv \rangle$, where equality is to hold a.e. on $[0, T]$.*

Proof. It should be noted that the maximum above really is obtained on Ω. Hence, for each $x^* \in X^*$, $u^* \in U^*$, $t \in [0, T]$ the following subsets of Ω are nontrivially defined:

$$\begin{aligned} &\Gamma(u^*) = \{\hat{v} \in \Omega \mid \max_{v \in \Omega} \langle u^*, v \rangle = \langle u^*, \hat{v} \rangle\}, \\ &\Gamma(x^*, t) = \{\hat{v} \in \Omega \mid \max_{v \in \Omega} \langle x^*, S(t)Bv \rangle = \langle x^*, S(t)B\hat{v} \rangle\}. \end{aligned} \tag{2.2}$$

First consider the time-independent version of (i), i.e.

$$u^* \to \max_{v \in \Omega} \langle u^*, v \rangle. \tag{2.3}$$

Choose u_0^* and any sequence $u_n^* \in U^*$, so that $\lim_{n \to \infty} u_n^* = u_0^*$ and correspondingly select $v_i \in \Gamma(u_i^*)$, $i = 0, 1, \cdots$. By weak compactness of Ω we may extract a weakly convergent subsequence $v_{i_k} \xrightarrow[k \to \infty]{} \tilde{v} \in \Omega$, which implies

$$\lim_{k \to \infty} \langle u_{n_k}^*, v_{n_k} \rangle = \langle u_0^*, \tilde{v} \rangle.$$

Now assume

$$\langle u_0^*, \tilde{v} \rangle < \langle u_0^*, v_0 \rangle.$$

Then by

$$\langle u_0^*, v_0 \rangle = \lim_{k \to \infty} \langle u_{n_k}^*, v_0 \rangle \leqq \lim_{k \to \infty} \langle u_{n_k}^*, v_{n_k} \rangle = \langle u_0^*, \tilde{v} \rangle$$

we arrive at a contradiction, which shows $\tilde{v} \in \Gamma(u_0^*)$, and hence (2.3) is continuous. From this it is easy to prove (i). Next fix $x^* \in X^*$, $t^* \in [0, T]$ and choose any sequence

t_n, $v_n \in \Gamma(x^*, t_n)$, such that $\lim_{k\to\infty} t_k = t^*$ and without loss of generality $w - \lim v_n = v_0 \in \Omega$.

$$\left|\max_{v\in\Omega} \langle x^*, S(t_n)Bv\rangle - \langle x^*, S(t^*)Bv_0\rangle\right| \leqq |\langle (S^*(t_n) - S^*(t^*))x^*, Bv_n\rangle| + |\langle x^*, S(t^*)B(v_n - v_0)\rangle|. \tag{2.4}$$

Since $S^*(\cdot)$ is a C_0-semigroup on X^* and Ω is bounded, the right-hand side of (2.4) tends to zero. As in part (i) we may show that $v_0 \in \Gamma(x^*, t^*)$, which completes the proof of (ii).

As to the last statement, we have to resort to a measurable selection theorem. For the reader's convenience we present here one which is perfectly suited for our purposes

MEASURABLE SELECTION THEOREM [1]. *Let U be a separable reflexive Banach space, $WC(U)$ be the class of nonempty weakly compact subsets of U, K a compact metric space with finite Lebesgue measure, and let $\Gamma: K \to WC(U)$ be such that*

(1) $\bigcup_{t\in K} \Gamma(t)$ *is bounded in U,*

(2) *for any sequence $\{t_i\}$, $t^* \in K$, $\lim_{i\to\infty} t_i = t^*$ one has*

$$\bigcap_{n=1}^{\infty} \overline{\bigcup_{i=n}^{\infty} \Gamma(t_i)}^{w} \subset \Gamma(t^*),$$

where $^{-w}$ denotes weak closure. Then there exists a strongly measurable selection $u: K \to U$ such that $u(t) \in \Gamma(t)$ a.e. on K.

Define for fixed $x^* \in X^*$ by (2.2) the set-valued mapping $\Gamma: [0, T] \to 2^U$, $\Gamma(t) = \Gamma(x^*, t)$. Clearly $\Gamma(t) \in WC(U)$ for $t \in [0, T]$ and $\bigcup_{t\in[0,T]} \Gamma(t) \subset \Omega$. Hence it remains to show (2). For this purpose assume that for some sequence $t_i \to t^*$

$$\hat{v} \in \bigcap_{n=1}^{\infty} \overline{\bigcup_{i=n}^{\infty} \Gamma(t_i)}^{w} \quad \text{and} \quad \hat{v} \notin \Gamma(t^*).$$

Consequently there is some $\rho > 0$, such that

$$\alpha = \max_{v\in\Omega} \langle x^*, S(t^*)Bv\rangle = \langle x^*, S(t^*)B\hat{v}\rangle + \rho.$$

Because of (ii) and the strong continuity of the dual semigroup we can find $N(\rho)$ so that for $n \geqq N(\rho)$ we have

$$\max_{v\in\Omega} \langle x^*, S(t_i)Bv\rangle \geqq \alpha - \rho/3$$

and

$$\|(S^*(t^*) - S^*(t_i))x^*\| \leqq \rho(3M\|B^*\|)^{-1},$$

M being a bound for Ω. Now consider the weak neighborhood of $\hat{v}$ given by

$$N = \{v \mid \langle B^*S^*(t^*)x^*, v - \hat{v}\rangle < \rho/3\}.$$

For any $v_i \in \Gamma(t_i)$, $i \geqq N(\rho)$ we find

$$\begin{aligned} |\langle B^*S^*(t^*)x^*, v_i - \hat{v}\rangle| &\geqq |\langle B^*S^*(t^*)x^*, v_i\rangle| - |\langle B^*S^*(t^*)x^*, \hat{v}\rangle| \\ &\geqq |\langle B^*S^*(t_i)x^*, v_i\rangle| \\ &\quad - |\langle B^*(S^*(t^*) - S^*(t_i))x^*, v_i\rangle| - \alpha + \rho \\ &\geqq \alpha - \rho/3 - \|B^*\| \cdot \|(S^*(t_i) - S^*(t^*))x^*\| \cdot \|v_i\| - \alpha + \rho \\ &\geqq \rho/3, \end{aligned}$$

which shows that $v_i \notin N$ in contradiction to

$$\hat{v} \in \overline{\bigcup_{i \geqq N} \Gamma(t_i)}^{w}.$$

Now we are prepared to present our main theorem, which gives a characterization of the domain of Ω-null-controllability:

THEOREM 2.3. *Let X, U be reflexive Banach spaces with U separable. Let $B \in L(U, X)$, A be the infinitesimal generator of a C_0-semigroup on X and $\Omega \subset U$ be weakly compact and convex with $0 \in \Omega$. Then for each $T > 0$ the following are equivalent:*

(2.5)
$$\text{(i)} \quad 0 \in \mathcal{A}(T, x_0),$$
$$\text{(ii)} \quad \langle x^*, S(T)x_0 \rangle + \int_0^T \max_{v \in \Omega} \langle x^*, S(t)Bv \rangle \, dt \geqq 0 \quad \textit{for all } x^* \in X^*.$$

Remark 2.4. Because of the positive homogeneity of the functional in (2.5), it suffices to check (2.5) for $x^* \in X^*$ with $\|x^*\| \leqq r$ $(= r)$ for some $r > 0$ and in view of Proposition 2.2(ii) we may further reduce to a dense subset of such a ball.

Proof of Theorem 2.3. Though the proof of Theorem 2.3 follows exactly the pattern given in [18], we sketch it here for the reader's convenience. Taking into account the strict separation theorem [14, p. 25], we find by contraposition

$$0 \in \mathcal{A}(T, x_0) \quad \text{iff } \sup \{x^*(x) \mid x \in \mathcal{A}(T, x_0)\} \geqq 0 \quad \text{for all } x^* \in X^*.$$

This amounts to

$$0 \leqq \langle x^*, S(T)x_0 \rangle + \sup \{\langle x^*, \mathcal{T}u \rangle \mid u \in \mathcal{U}_{ad}(T)\}$$

where $\mathcal{T}$ is the operator defined in (2.1). According to Proposition 2.1 we may find $u_n \in \mathcal{U}_{ad}(T)$, $n = 0, 1, \cdots$, so that

$$w - \lim_{n \to \infty} u_n = u_0,$$

$$\lim_{n \to \infty} \langle x^*, \mathcal{T}u_n \rangle = \sup \{\langle x^*, \mathcal{T}u \rangle \mid u \in \mathcal{U}_{ad}(T)\} \equiv \gamma.$$

Assuming

$$\gamma < \int_0^T \max_{v \in \Omega} \langle x^*, S(T-s)Bv \rangle \, ds,$$

we immediately arrive at a contradiction since by Proposition 2.2(iii) there is $u_0 \in \mathcal{U}_{ad}(T)$ with

$$\int_0^T \max_{v \in \Omega} \langle x^*, S(T-s)Bv \rangle \, ds = \langle x^*, \mathcal{T}u_0 \rangle.$$

We easily derive the following corollaries:

COROLLARY 2.5. *Choose $\Omega = \{u \mid \|u\| \leqq 1\} \equiv B_U$.*

Then the domain of Ω-null-controllability (at time T) contains a ball centered at the origin with radius γ iff for all $x^* \in X^*$

$$\|B^*S^*(\cdot)x^*\|_{L^1(0,T;U^*)} \geqq \gamma \|S^*(T)x^*\|. \tag{2.6}$$

Inequality (2.6) strongly resembles the well-known condition for exact controllability given in [5]. The difference in the norms is due to the fact that Curtain and Pritchard work with unconstrained controls in $L^p(0, T; U)$, whereas in our case the constraints imply that actually $u \in L^\infty(0, T; U)$; $u \in L^2(0, T; U)$ was assumed merely for technical reasons.

COROLLARY 2.6. *Let X be a Hilbert space, $S(\cdot)$ be a unitary group and $\Omega = B_U$. Then no initial datum with $\|x\| > T\|B\|$ can be steered to the origin within time T.*

COROLLARY 2.7. *Let $S(\cdot)$ be a group on X.*

Then necessary for global Ω-(null)-controllability is

$$V(x^*) = \int_{-\infty}^{0} \max_{v\in\Omega} \langle B^*S^*(t)x^*, v\rangle \, dt = \infty \quad \text{for all } x^* \in X^*\backslash\{0\} \tag{2.7}$$

and sufficient is

$$W = \sup_{t\geqq 0} \inf_{\|x^*\|=1} \int_{-t}^{0} \max_{v\in\Omega} \langle B^*S^*(s)x^*, v\rangle \, ds = \infty. \tag{2.8}$$

Equations (2.7) and (2.7) are the natural generalizations of the corresponding conditions in the finite dimensional case. We will give some comments on them in the final section. The proof of Corollary 2.7 is exactly the same as in finite dimensions [2].

Though the boundedness of Ω was crucial in the derivation of Theorem 2.3, we can get a similar result when Ω is a closed convex cone in U. This seems to be new even in finite dimensions. However, in this case $\mathcal{A}(T, x_0)$ need not be closed, which can be seen by the following simple example.

Example 2.8. Choose $X = R^2 = U$ and $\Omega = \{(u, v) \mid u \geqq 0,\ v \geqq 0\}$ and consider

$$\begin{aligned} \dot{x}_1 &= x_2 + u, & x_1(0) &= 0, \\ \dot{x}_2 &= -x_1 + v, & x_2(0) &= 0. \end{aligned} \tag{2.9}$$

We will show

$$\mathcal{A}(\pi/2, 0) = \{(x_1, x_2) \mid x_1 > 0,\ x_2 \in R\} \cup \{(0, 0)\}.$$

Obviously any $(0, x_2)$, $x_2 \in R\backslash\{0\}$, is not reachable in time $\pi/2$, any (x_1, x_2), $x_1 \geqq x_2 > 0$ may be reached by the constant control

$$\begin{pmatrix} u(\cdot) \\ v(\cdot) \end{pmatrix} = \frac{1}{2}\begin{pmatrix} x_1 - x_2 \\ x_1 + x_2 \end{pmatrix}$$

and for any (x_1, x_2), $0 < x_1 < x_2$, a successful control is given by

$$u(s) = \begin{cases} \alpha \sin s, & s \in [0, t^*), \\ \beta \cos s, & s \in [t^*, \pi/2], \end{cases} \qquad v(s) = \begin{cases} \alpha \cos s, & s \in [0, t^*), \\ \beta \sin s, & s \in [t^*, \pi/2] \end{cases}$$

with

$$\begin{aligned} \beta &= 2x_2 \cdot (\sin 2t^*)^{-1}, \\ \alpha &= t^{*-1} \cdot (x_1 - x_2(1 + \cos 2t^*)(\sin 2t^*)^{-1}) \end{aligned}$$

where $t^* \in (\pi/4, \pi/2)$ is chosen so that $\alpha > 0$. Similar controls with u and v interchanged work for $x_2 < 0$.

This suggests that in the following we replace $\mathcal{A}(T, x_0)$ by its closure. Next we recall the notion of the dual cone Ω^*

$$\Omega^* = \{x^* \in X^* \mid x^*(x) \geqq 0,\ x \in \Omega\}.$$

THEOREM 2.9. *Let Ω be a closed convex cone in U with apex at 0 and let the hypotheses of Theorem 2.3 hold. Then for $x_0 \in X$ and $T > 0$ the following are equivalent:*

(i) $0 \in \overline{\mathcal{A}(T, x_0)}$,

(ii) $\langle S^*(T)x^*, x_0\rangle \geqq 0$ *for all* $x^* \in \{x^* \in X^* \mid B^*S^*(t)x^* \in -\Omega^*$ *for all* $t \in [0, T]\}$. (2.10)

Proof. As in the proof of Theorem 2.3, we find

$$0 \in \overline{\mathcal{A}(T; x_0)}$$

iff for any $x^* \in X^*$

$$\langle x^*, S(T)x_0\rangle + \sup\left\{\int_0^T \langle x^*, S(t)Bu(t)\rangle\, dt \,\middle|\, u \in \mathcal{U}_{\mathrm{ad}}(T)\right\} \geqq 0. \tag{2.11}$$

Define

$$\gamma(x^*, T) = \sup\left\{\int_0^T \langle x^*, S(t)Bu(t)\rangle\, dt \,\middle|\, u \in \mathcal{U}_{\mathrm{ad}}(T)\right\}.$$

Since $\mathcal{U}_{\mathrm{ad}}(T)$ is a cone with vertex at 0, we readily see

$$\gamma(X^*, T) = \{0, \infty\}.$$

However, $\langle x^*, S(T)x_0\rangle$ does not matter for

$$x^* \in \gamma^{-1}(\infty),$$

so we may rewrite (2.11) as

$$x^* \in \gamma^{-1}(0) \Rightarrow \langle x^*, S(T)x_0\rangle \geqq 0.$$

Now we define, for $M > 0$,

$$\Omega_M = \Omega \cap \{u \,|\, \|u\| \leqq M\},$$

$$\mathcal{U}_{\mathrm{ad},M}(T) = \{u \in \mathcal{U}_{\mathrm{ad}}(T) \,|\, u(t) \in \Omega_M \text{ a.e. on } [0, T]\}.$$

It is easy to see that

$$x^* \in \gamma^{-1}(0) \quad \text{iff} \quad \sup_{M>0} \sup\left\{\int_0^T \langle x^*, S(t)Bu(t)\rangle\, dt \,\middle|\, u \in \mathcal{U}_{\mathrm{ad},M}(T)\right\} = 0. \tag{2.12}$$

But Ω_M is weakly compact and hence we infer, as for Theorem 2.3,

$$\sup\left\{\int_0^T \langle x^*, S(t)Bu(t)\rangle\, dt \,\middle|\, u \in \mathcal{U}_{\mathrm{ad},M}(T)\right\} = \int_0^T \max_{v \in \Omega_M} \langle x^*, S(t)Bv\rangle\, dt.$$

Therefore, by Proposition 2.2(ii), (2.12) is equivalent to

$$\max_{v \in \Omega_M} \langle x^*, S(t)Bv\rangle = 0 \quad \text{for all } M > 0 \text{ and for all } t \in [0, T]$$

or, equivalently, to

$$\sup_{v \in \Omega} \langle x^*, S(t)Bv\rangle = 0 \quad \text{for all } t \in [0, T].$$

This may be interpreted as

$$B^*S^*(t)x^* \in -\Omega^* \quad \text{for all } t \in [0, T].$$

Remark 2.10. In case $\Omega = U$ and consequently $\Omega^* = \{0\}$, we immediately read off the familiar result that, if $\overline{\mathrm{Im}\, B} = X$, any initial state may be transferred arbitrarily near zero in arbitrarily short time. If, furthermore, we assume that $S(\cdot)$ is a C_0-group, then from

$$\{x^* \in X^* \cap D(A^*) \,|\, B^*S^*(t)x^* = 0,\ t \in [0, T]\} = \bigcap_{n=0}^{\infty} \ker\,(B^*(A^*)^n)$$

we easily recover the well-known characterization of approximate controllability of R. Triggiani [19].

3. Examples. In this section we will show that, although (2.5) represents an infinite dimensional optimization problem, it may in simple cases yield a characterization of the domain of Ω-null-controllability in a most elementary way.

Example 3.1. We choose $X = U = l^2$ and consider

$$\dot{x} = x + u, \tag{3.1}$$

so

$$S(t)x_0 = e^t x_0.$$

First we take $\Omega_1 = B_U$. We easily see that x may be steered to the origin in finite time iff $\|x\| < 1$. Furthermore, in this case

$$V(x^*) = \|x^*\|, \qquad W = 1.$$

If we replace Ω_1 by

$$\Omega_2 = \{u \in l^2 \mid \|u\|_2 \leqq 1,\ u = (\omega_i),\ 0 \leqq \omega_i,\ i = 1, 2, \cdots\},$$

an easy calculation based on (2.5) yields x_0 controllable to the origin iff $\|x_0\| < 1$ and $-1 < \xi_i \leqq 0$ for $x = (\xi_i)$, which perfectly agrees with the scalar case [18]. It is easily seen that now

$$V(x^*) = \|x_+^*\|, \qquad W = 0,$$

x_+^* being the positive part of x^*. Finally let us consider $u_0 = (\eta_i) \in l^2$, $\eta_i \neq 0$, $i = 1, \cdots$,

$$\Omega_3 = \{u \in l^2 \mid u = (\omega_i),\ |\omega_i| \leqq |\eta_i|\}.$$

From (2.5) it is readily verified that $x_0 = 2u_0$ may not be controlled to zero in finite time and, accordingly, a simple calculation results in

$$V(x^*) = \sum_{i=1}^{\infty} |\xi_i^*||\eta_i| < \infty, \qquad W = 0$$

and again $V(x^*) \neq W$. If we modify (3.1) slightly to get an exponentially stable semigroup, i.e.

$$\dot{x} = -x + u, \tag{3.1'}$$

then in case $\Omega = \Omega_1$, (3.1') is globally Ω_1-null-controllable and

$$W = V(x^*) = \infty.$$

In case $\Omega = \Omega_2$, one has

$$V(x^*) = \begin{cases} 0, & x_+^* = 0, \\ \infty, & \text{else}, \end{cases} \qquad W = 0.$$

Hence the system is not globally Ω_2-null-controllable. Finally, if $\Omega = \Omega_3$ one has

$$V(x^*) = \infty, \qquad W = 0.$$

These simple examples show that (2.7) and (2.8) in general do not coincide and even that a controllability gap may arise, i.e. that the necessary but not the sufficient condition applies. Remember that in the finite dimensional case it can be shown that for linear

autonomous systems and $0 \in \Omega$ the controllability gap does not occur [3]. Its occurrence here is somewhat surprising since (3.1) is the simplest extension of the analogue scalar equation. Example (3.1) may seem somewhat artificial and therefore we present one closely linked to the one-dimensional wave equation which also shows this strange behavior.

Example 3.2. Choose $X = L^2(R)xL^2(R)$, $U = L^2(R)$, $\Omega = B_U$ and consider

$$\begin{aligned} &v_t = w_x + u(t, x), && t \geqq 0, \\ &w_t = v_x, \\ &v(x, 0) = \alpha(x), \\ &w(x, 0) = \beta(x), && x \in R. \end{aligned} \tag{3.2}$$

It is well known that the solution semigroup is given by

$$S(t)(\alpha, \beta) = \frac{1}{2}\begin{pmatrix} T(t)+T(-t) & T(t)-T(-t) \\ T(t)-T(-t) & T(t)+T(-t) \end{pmatrix}\begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

where $T(\cdot)$ denotes the translation semigroup in $L^2(R)$. For any $x^* = (x_1^*, x_2^*) \in X^* \sim X$, $\|x^*\| = 1$ we find, after some rearrangement,

$$\int_{-t}^{0} \max_{v \in \Omega} \langle x^*, S(\tau)(v, 0)\rangle \, d\tau = \frac{1}{2}\int_{-t}^{0} \| T(-\tau)(x_1^* + x_2^*) + T(\tau)(x_1^* - x_2^*)\| \, d\tau. \tag{3.3}$$

Squaring the integrand in (3.3) and applying the parallelogram law, we find

$$2(1 + \langle T(\tau)(x_1^* - x_2^*), T(-\tau)(x_1^* + x_2^*)\rangle).$$

Hence, in considering the sufficient condition (2.8) we are faced with

$$\begin{aligned} 0 &\leqq \inf_{\|x^*\|=1} \int_{-t}^{0} (1 + \langle T(\tau)(x_1^* - x_2^*), T(-\tau)(x_1^* + x_2^*)\rangle)^{1/2} \, d\tau \\ &\leqq \inf_{\|x^*\|=1} \sqrt{t}\left(\int_{-t}^{0} (1 + \langle T(\tau)(x_1^* - x_2^*), T(-\tau)(x_1^* + x_2^*)\rangle) \, d\tau\right)^{1/2}, \end{aligned} \tag{3.4}$$

the inequality at the utmost left of (3.4) being a consequence of the parallelogram law. This also shows that the integrals in (3.4) are well defined. Choosing

$$x_1^* = \begin{cases} -(2\sqrt{t})^{-1}, & x \in [-t, 0], \\ (2\sqrt{t})^{-1}, & x \in [0, t], \\ 0, & \text{else}, \end{cases} \qquad x_2^* = |x_1^*|,$$

we calculate

$$\int_{-t}^{0} \langle T(\tau)(x_1^* - x_2^*), T(-\tau)(x_1^* + x_2^*)\rangle \, d\tau = -t,$$

so that the right-hand side of (3.4) equals zero and consequently $W = 0$. Thus, the sufficient condition does not apply. As to the necessary condition (2.7), in view of (3.4) we consider for $x^* \in X^*$, $\|x^*\| = 1$,

$$\begin{aligned} &\int_{-\infty}^{0} \| T(-t)(x_1^* + x_2^*) + T(t)(x_1^* - x_2^*)\| \, dt \\ &\qquad \geqq \lim_{t \to \infty}\left(t - \int_{-t}^{0} |\langle T(\tau)(x_1^* + x_2^*), T(-\tau)(x_1^* + x_2^*)\rangle| \, d\tau\right). \end{aligned} \tag{3.5}$$

Let $u, v \in L^2(R)$, $\varepsilon > 0$, and choose $M > 0$ so that

$$\max\left(\int_{-\infty}^{-M} |u|^2\,dx, \int_M^{\infty} |v|^2\,dx\right) \leqq \varepsilon^2(2\|u\|)^{-2}.$$

We find that

$$\begin{aligned}\int_{-t}^{0} |\langle T(\tau)u, T(\tau)v\rangle|\,d\tau \leqq &\int_{-t}^{0}\int_{-\infty}^{-M} |u(x+2\tau)||v(x)|\,dx\,d\tau \\ &+ \int_{-t}^{0}\int_{-M}^{M} |u(x+2\tau)||v(x)|\,dx\,d\tau \\ &+ \int_{-t}^{0}\int_{M}^{\infty} |u(x+2\tau)||v(x)|\,dx\,d\tau.\end{aligned}$$

The first and the last term above are estimated by $\varepsilon/2t$, the middle one by $\sqrt{2Mt}\cdot\|u\|\,\|v\|$. Collecting things together and inserting into (3.5), we find a lower bound for $V(x^*)$:

$$V(x^*) \geqq \tfrac{1}{2}\lim_{t\to\infty}(t - \varepsilon t - \sqrt{t}\sqrt{2M}\,\|x_1^* + x_2^*\|\,\|x_1^* - x_2^*\|) = \infty$$

which shows the occurrence of the controllability gap in this example.

We believe these examples indicate that the corresponding generalizations of the necessary and sufficient conditions for global Ω-null-controllability in [3] are not the appropriate tool to handle this problem. In the next two examples, however, we will show that in case the solution semigroup of (1.1) is fairly well known, one can get a complete characterization of the domain of Ω-null-controllability in a very elementary way.

Example 3.3. Let us consider the one-dimensional heat equation. We take $X = U = L^2(0, 1)$.

$$\begin{aligned} &z_t = z_{xx} + u, && (t, x) \in (0, \infty)\times[0, 1], \\ &z(0, t) = z(1, t) = 0, && t \geqq 0, \\ &z(\cdot, 0) = \phi, && \phi \in X. \end{aligned} \tag{3.6}$$

The solution semigroup is given by

$$(S(t)\phi)(x) = \int_0^1 G(t, x, \xi)\phi(\xi)\,d\xi, \qquad t > 0,$$

where $G(\cdot, \cdot, \cdot)$ is the Green's function given by

$$G(t, x, \xi) = 2\sum_{k=1}^{\infty} e^{-(k\pi)^2 t}\sin k\pi x \cdot \sin k\pi\xi,$$

$$(t, x, \xi) \in (0, \infty)\times[0, 1]\times[0, 1].$$

At first we will discuss the case

$$\Omega_1 = \{v \in U \mid v(x) \in [0, 1] \text{ a.e. on } [0, 1]\}.$$

Choosing $x^* = -1$ it is obvious from (2.5) and the properties of G that no ϕ, with $\phi \geqq 0$ a.e., can be steered to the origin in finite time. This perfectly agrees with one's physical intuition. Assume $\phi \leqq 0$ a.e.; hence $S(t)\phi \leqq 0$ for $t > 0$. W.l.o.g. we may suppose

$-1<\phi\leqq 0$. In view of Proposition 2.2(ii) we may apply the classical mean value theorem to deduce existence of a $t^*\in(0, T)$ such that

$$\int_0^T \max_{v\in\Omega}\langle x^*, S(t)v\rangle\, dt = T\cdot \max_{v\in\Omega}\langle x^*, S(t^*)v\rangle$$
$$= T\cdot\langle S(t^*)x^*, v_0\rangle,$$

where v_0 is the characteristic function of the support of $(S(t^*)x^*)_+$, the positive part of $S(t^*)x^*$. Thus (2.5) is equivalent to

$$\langle S(T)x^*, \phi\rangle + T\cdot\langle S(t^*)x^*, v_0\rangle$$
$$= \langle S(t^*)x^*, S(T-t^*)\phi\rangle + T\cdot\langle S(t^*)x^*, v_0\rangle$$
$$= \langle (S(t^*)x^*)_+, S(T-t^*)\phi + T\cdot v_0\rangle + \langle (S(t^*)x^*)_-, S(T-t^*)\phi\rangle \geqq 0.$$

The last inequality is valid, because

$$S(T-t^*)\phi + Tv_0 \geqq 0$$

on the support of $(S(t^*)x^*)_+$ if $T\geqq 1$. This shows that any ϕ, $-1<\phi\leqq 0$, may be steered to rest in any time $T\geqq 1$. As to the general case, it is easy to deduce from the above that

$$0\notin \bigcup_{t>0}\mathscr{A}(t,\phi) \quad \text{if} \quad \text{meas}\,(E_+(t,\phi))>0, \quad t>0, \tag{3.7}$$

where we have defined

$$E_+(t,\phi)=\{x\in[0,1]\,|\,S(t)\phi(x)\geqq 0\}.$$

Note that meas $(E_+(T,\phi))>0$ implies meas $(E_+(t,\phi))>0$ for all $t\in[0,T]$. Unfortunately it is hard to characterize those ϕ satisfying (3.7), but we may give two readily available sufficient conditions:

$$\text{(a)} \quad \alpha \sin k\pi x \leqq \phi(x) \quad \text{for some } \alpha\in R, k\in N, \tag{3.8}$$

or

$$\text{(b)} \quad \phi_{2k+1}\geqq 0, \quad k=0,1,\cdots, \tag{3.9}$$

where $\phi_k=\int_0^1\phi(x)\sin k\pi x\,dx$. It is easily verified that the latter condition implies $\int_0^1 (S(t)\phi)(x)\,dx\geqq 0$ giving (3.7). Next we discuss the case $\Omega=\Omega_2=B_U$. Again without loss of generality we assume $\|\phi\|\leqq 1$ and, as above, we derive

$$\langle S(T)x^*, \phi\rangle + \int_0^T \|S(t)x^*\|\,dt \geqq -\|S(T)x^*\| + T\cdot\|S(t^*)x^*\|\geqq 0.$$

The last inequality is valid for $T\geqq 1$, which is seen from the representation of the semigroup. Therefore, in this case, (3.6) is globally Ω_2-null-controllable and if $\|\phi\|\leqq 1$, ϕ may be controlled to the origin in any time $T\geqq 1$.

Example 3.4. Consider the one-dimensional wave equation with distributed controls:

$$\begin{aligned} &u_{tt}=u_{xx}+f(t,x), && (x,t)\in[0,1]\times[0,\infty),\\ &u(0,\cdot)=\phi,\\ &u_t(0,\cdot)=\psi,\\ &u(t,0)=u(t,1)=0, && t\geqq 0. \end{aligned} \tag{3.10}$$

Let $W_0^{1,2}(0,1)$ be the usual Sobolev space endowed with the scalar product

$$((\phi,\psi))=\int_0^1 \frac{\partial\phi}{\partial x}\frac{\partial\psi}{\partial x}\,dx$$

and let X be the Hilbert space $W_0^{1,2}(0,1)\times L^2(0,1)$. It is well known [12] that the solution of (3.10) may be described in terms of the unitary group $S(\cdot)$ on X

$$S(t)(\phi,\psi)=(u(\cdot,t),u_t(\cdot,t)),\qquad t\geqq 0,$$

$$u(x,t)=\sum_{k=1}^{\infty}\{(k\pi)^{-1}\psi_k\sin k\pi t+\phi_k\cos k\pi t)\sin k\pi x\},\qquad x\in[0,1],$$

$$\phi_k=2\int_0^1\phi(s)\sin k\pi s\,ds,$$

$$\psi_k=2\int_0^1\psi(s)\sin k\pi s\,ds,\qquad k=1,\cdots.$$

In the following we will sharpen somewhat the result of [10]: we will show, that for fixed (but arbitrary time $T>0$) the domain of Ω-null-controllability contains a ball centered at the origin if controls are taken from B_U. In [10] it is shown that any state in such a ball may be controlled to the origin in finite time but no uniform bound on the consumed time may be given. According to Corollary 2.5 we have to show the existence of $\gamma>0$ such that for $x^*\in X^*$

$$\int_0^T\|B^*S(-t)x^*\|_2\,dt\geqq\gamma\|x^*\| \tag{3.11}$$

holds. In other words, the interior of the domain of Ω-null-controllability is nonempty iff

$$G: X^*\to L^1(0,T;L^2(0,1))$$

defined by

$$(Gx^*)(t)=B^*S(-t)x^*,\qquad t\in[0,T]$$

is continuously invertible or, equivalently (since G turns out to be 1-1), iff the range of G is closed in $L^1(0,T;L^2(0,1))$. Actually G maps into $C(0,T;L^2(0,1))$. If $z\in L^1(0,T;L^2(0,1))$ we may expand $z(t)$

$$z(t)=\sum_{k=1}^{\infty}z_k(t)\sin k\pi x$$

and

$$(z_k(\cdot))\in L^1(0,T;l^2).$$

Hence, for each $z=G(\sigma,\rho)$ the following identity holds:

$$z_k(t)=-\rho_k\cos k\pi t-\sigma_k k\pi\sin k\pi t. \tag{3.12}$$

Case 1. $T\geqq 1$. Now observe that there are k disjoint intervals A_{jk}, B_{jk}, $j=0,1,\cdots,k-1$, of length $(2k)^{-1}$ on $[0,1]$ on which $\sin k\pi t$, $\cos k\pi t$ do not change sign and such that

$$\left|\int_{A_{jk}}\cos k\pi x\,dx\right|=\sqrt{2}(k\pi)^{-1}=\left|\int_{B_{jk}}\sin k\pi x\,dx\right|,$$

$$\int_{A_{jk}}\sin k\pi x\,dx=0=\int_{B_{jk}}\cos k\pi x\,dx,\qquad j=0,\cdots,k-1.$$

Hence we may recover the Fourier coefficients of $x^* = (\sigma, \rho)$ from $z = Gx^*$ via

$$(3.13) \qquad \int_{A_{0k}} z_k(t)\,dt = \sqrt{2}(k\pi)^{-1}\rho_k, \qquad \int_{B_{0k}} z_k(t)\,dt = \sqrt{2}\sigma_k, \qquad k = 2, \cdots,$$

σ_1, ρ_1 may be calculated by integrating (3.12) over $[0, 1]$ and $[0, \frac{1}{2}]$, respectively. Adding the above integrals leads to

$$k|\sigma_k| \leqq \frac{\sqrt{2}}{2}\int_0^1 |z_k(t)|\,dt, \qquad |\rho_k| \leqq \frac{\sqrt{2}}{2}\int_0^1 |z_k(t)|\,dt, \quad k = 1, 2, \cdots,$$

and hence we infer that G is injective and that

$$\sum_{k=1}^{\infty} (|\rho_k|^2 + k^2|\sigma_k|^2) \leqq \tfrac{1}{2}(1+\pi^2)\int \sum_{k=1}^{\infty} |z_k(t)|^2\,dt,$$

which is finite since $z(\cdot) \in C(0, T; L^2(0, 1))$. Hence (σ, ρ), represented by (3.13), belongs to X. By Theorem VI.6.5 in [7], it suffices to show that G maps bounded closed sets into closed sets. Thus, let A be any bounded closed set in X, i.e.

$$(3.14) \qquad \sum_{k=1}^{\infty} (k^2|\sigma_k|^2 + |\rho_k|^2) \leqq M^2 \quad \text{for } (\sigma, \rho) \in A$$

for some $M > 0$, and let $z_n(\cdot)$ be a convergent sequence in GA. There exist (uniquely determined) $(\sigma_n, \rho_n) \in A$, such that

$$z_n(\cdot) = G(\sigma_n, \rho_n) \quad \text{and} \quad \lim_{n\to\infty} z_n(\cdot) = z(\cdot).$$

Let $z_k^n(t)$, σ_k^n, ρ_k^n denote the corresponding Fourier coefficients. By (3.14)

$$\sum_{k=1}^{\infty} |z_k(t)|^2 \leqq 2M^2 \quad \text{for } z \in GA$$

so that

$$(3.15) \qquad \left((2M)^{-2}\sum_{k=1}^{\infty} (z_k^n(t) - z_k^m(t))^2\right)^{1/2} \leqq 1$$

for every choice of n, m. Since $z_n(\cdot)$ is a Cauchy sequence in $L^1(0, T; L^2(0, 1))$, $(2M)^{-1}z_n(\cdot)$ also is. Consequently,

$$(2M)^{-1}\|z_n - z_m\| = \int_0^T \left((2M)^{-2}\sum_{k=1}^{\infty} (z_k^n(t) - z_k^m(t))^2\right)^{1/2} dt$$

$$\geqq (2M)^{-1}\sum_{k=1}^{\infty}\int_0^1 (z_k^n(t) - z_k^m(t))^2\,dt$$

(by (3.15)). However, by (3.12) we calculate

$$\int_0^1 (z_k^n(t) - z_k^m(t))^2\,dt = (\rho_k^n - \rho_k^m)^2 + k^2\pi^2(\sigma_k^n - \sigma_k^m)^2,$$

from which we deduce that (σ_n, ρ_n) is a Cauchy sequence in X. Therefore, there exists $(\sigma, \rho) \in X$ such that

$$\lim_{n\to\infty} (\sigma_n, \rho_n) = (\sigma, \rho)$$

and, by closedness of A, $(\sigma, \rho) \in A$. By continuity of G we conclude that

$$\lim_{n\to\infty} G(\sigma_n, \rho_n) = G(\sigma, \rho)$$

and by the uniqueness of the limit we infer

$$z(\cdot) = G(\sigma, \rho) \in GA.$$

Case 2. $0 < T < 1$. Choose n such that $n^{-1} < T$. In this case (σ_k, ρ_k), $k = 1, 2, \cdots, n$ may be determined by integrating (3.12) over $[0, 1/n]$ and $[0, 1/2n]$, respectively. (σ_k, ρ_k), $k > n$ are given by (3.13). Writing $k = n + m$ the interval $[0, 1/n]$ contains $[mn^{-1}]$ intervals A_{jk}, B_{jk}, where $[\cdot]$ denotes the largest integer function. Now the result follows from the preceding proof once we observe that

$$k[mn^{-1}]^{-1} \leqq 3n \quad \text{for all } k \geqq 2n.$$

Finally we want to present an example which illustrates the use of Theorem 2.9.

Example 3.5. Again consider the one-dimensional heat equation (3.6) but choose $X = U = L^2(R, R)$. In this case the solution semigroup is given by

$$(S(t)\phi)(x) = (4\pi t)^{-1/2} \int_R \exp(-(s-x)^2/4t)\phi(s)\, ds, \qquad t > 0.$$

Let

$$\Omega = \{u \in U \mid u(x) \geqq 0 \text{ a.e.}\}.$$

It is easily seen that

$$\Omega^* = \Omega.$$

Furthermore, we find that

$$S(t)^* x^* \in -\Omega^* \quad \text{for all } t \in [0, T] \quad \text{iff } x^* \in -\Omega^* = -\Omega.$$

This shows

$$\begin{aligned} x_0 \in \overline{\mathscr{A}(T, x_0)} \quad &\text{iff} \quad S(T)x_0 \in (-\Omega^*)^*, \\ &\text{iff} \quad S(T)x_0 \leqq 0, \end{aligned}$$

which is equivalent to (3.7).

FREQUENCY/PERIOD ESTIMATION AND ADAPTIVE REJECTION OF PERIODIC DISTURBANCES*

D. L. RUSSELL†

Abstract. We discuss a method for suppressing the oscillations of a linear system subject to an external periodic disturbance of fixed, but unknown, period. The method entails augmentation of the original plant with a compensator and parameter identifier. The near equilibrium dynamics of the resulting system are analyzed and shown to be related to a linear delay equation with infinite delay and periodic coefficients. A corresponding Floquet theory is indicated. A FORTRAN program approximately realizing the period identifier is included and numerical results obtained with this program are graphically displayed and analyzed.

Key words. adaptive control, decoupling, delay equations

0. Introduction. In a wide variety of applications one encounters a system of the form

$$\dot{x} = Ax + Cu + v, \qquad \left(\dot{x} = \frac{dx}{dt}\right) \tag{0.1}$$

wherein x is the n-dimensional state vector, u is the m-dimensional control vector and v is a periodic n-dimensional vector disturbance function with least positive period T

$$v(t) = v(t+T). \tag{0.2}$$

In many cases $\dot{x} = Ax$ by itself represents the dynamics of an elastic system, the disturbance v arises from the environment in which the elastic system is placed, and the control u is used to mitigate the effects of this disturbance. Examples include sighting devices (cameras, telescopes, etc.), weapons, and machine tool arms, operated under conditions which involve significant oscillatory disturbances, such as would be the case for a telescope operated from an aircraft. Another important application arises in connection with the measurement and active suppression of aerodynamic flutter in aircraft wings, tail structures, etc.

The approach taken in this paper is to suppose that $v(t)$ can be adequately modelled by

$$v(t) = Bz(t), \qquad Bn \times 2t, \tag{0.3}$$

where $z(t)$ satisfies a linear system

$$\dot{z} = Fz, \tag{0.4}$$

$$F=\begin{pmatrix} 0 & \alpha_1 & 0 & 0 & \cdots & 0 & 0 \\ -\alpha_1 & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 0 & \alpha_2 & \cdots & 0 & 0 \\ 0 & 0 & -\alpha_2 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 0 & \alpha_r \\ 0 & 0 & 0 & 0 & \cdots & -\alpha_r & 0 \end{pmatrix}, \tag{0.5}$$

$$\alpha_j=\frac{2k_j\pi}{T}\equiv k_j\alpha, \qquad j=1,2,\cdots,r, \tag{0.6}$$

the k_j being positive integers. These need not necessarily be $1, 2, \cdots, r$; in some cases it is known, for example, that only odd order harmonics occur so that we would use $k_1=1$, $k_2=3, \cdots, k_r=2r-1$.

Assuming F known (this will bring us to the subject of frequency estimation later on), we can construct a compensator

$$\dot{y}=Sx+Fy \tag{0.7}$$

where y is the $2r$-dimensional compensator state, and consider the combined system

$$\begin{aligned} \dot{x}&=Ax+Bz+Cu, \\ \dot{y}&=Sx+Fy, \\ \dot{z}&=Fz. \end{aligned} \tag{0.8}$$

We will suppose that the range of C includes the range of B. This means that, in principle, one could solve

$$Cu=-Bz \tag{0.9}$$

and cancel the effect of the disturbance altogether. For a telescope operated from a moving vehicle, neglecting translational motion and considering only the angular displacements, this would be the case if the controls, acting through the mounting, have both azimuth and elevation correction capability. In practice the direct cancellation (0.9) is rarely feasible due to noise, measurement delays, limited measurement instrumentation, etc.

Let Φ be any nonsingular $2r\times 2r$ matrix which commutes with F; in most cases we would use the identity matrix. We may then find an $m\times 2r$ matrix L such that

$$CL=-B\Phi^{-1}. \tag{0.10}$$

Assuming additionally that (A, C) is stabilizable, let K be an $m\times n$ matrix such that $A+CK$ is a stability matrix and let u be generated by the feedback control law

$$u=Kx+Ly. \tag{0.11}$$

Using this in (0.8) we have

$$\frac{d}{dt}\begin{pmatrix} x \\ y \\ z \end{pmatrix}=\begin{pmatrix} A+CK & -B\Phi^{-1} & B \\ S & F & 0 \\ 0 & 0 & F \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix}. \tag{0.12}$$

We will see in § 1 that it is possible to select S in such a way that the control law (0.11) dynamically decouples the plant state x from the periodic disturbance $v(t)=Bz(t)$.

The foregoing scheme, to be developed more fully in the next section, clearly amounts to the construction of a reduced order observer for the disturbance state $z(t)$ (see [10]) and assumes that the plant state $x(t)$ is completely accessible. If this is not the case, dynamic decoupling is probably best realized with the construction of a full $(n+2r)$-dimensional state observer. Assuming an observation

$$w = H_0 x + H_1 z \tag{0.13}$$

is available such that the pair

$$(H_0, H_1)\begin{pmatrix} A+CK & B \\ 0 & F \end{pmatrix} \tag{0.14}$$

is observable, compatible matrices L_0, L_1 are selected (see, for example, [8]) such that

$$\begin{pmatrix} A+CK-L_0H_0 & B-L_0H_1 \\ -L_1H_0 & F-L_1H_1 \end{pmatrix} \tag{0.15}$$

is a stability matrix. We then adjoin to the plant disturbance system

$$\dot{x} = (A+CK)x + Bz + Cu, \tag{0.16}$$

$$\dot{z} = Fz, \tag{0.17}$$

the estimator system

$$\begin{aligned} \dot{\xi} &= (A+CK)\xi + L_0(H_0x - H_0\xi) + L_0(H_1z - H_1\zeta), \\ \dot{\zeta} &= Fz + L_1(H_0x - H_0\xi) + L_1(H_1z - H_1\zeta). \end{aligned} \tag{0.18}$$

Then, choosing u such that

$$Cu = -B\xi \tag{0.19}$$

and letting $e = x - \xi$, $f = z - \zeta$ we find that

$$\begin{pmatrix} \dot{e} \\ \dot{f} \end{pmatrix} = \begin{pmatrix} A+CK-L_0H_0 & B-L_0H_1 \\ -L_1H_0 & F-L_1H_1 \end{pmatrix}\begin{pmatrix} e \\ f \end{pmatrix}$$

and we conclude, since (0.15) is a stability matrix, that

$$\lim_{t\to\infty} e(t) = \lim_{t\to\infty} f(t) = 0.$$

Since, with (0.19), (0.16), (0.17) become

$$\dot{x} = (A+CK)x + Bf, \tag{0.20}$$

$$\dot{z} = Fz, \tag{0.21}$$

we conclude that

$$\lim_{t\to\infty} x(t) = 0$$

and thus $x(t)$ is decoupled from z. This is a standard procedure, such as described in [10], for example.

The subject of dynamic decoupling, which includes our rather specialized topic, has an extensive literature. Major current references are [10] and [11]; a large number

of additional references are at the end of Chapter 9 in [10] and at the end of Chapter 8 in [11]. In general one considers a system x, A, B, C not necessarily the same as earlier in this section

$$\dot{x} = \begin{pmatrix} \dot{x}^1 \\ \dot{x}^2 \\ \vdots \\ \dot{x}^r \end{pmatrix} = \begin{pmatrix} A_1^1 & A_2^1 & \cdots & A_r^1 \\ A_1^2 & A_2^2 & \cdots & A_r^2 \\ \vdots & \vdots & & \vdots \\ A_1^r & A_2^r & \cdots & A_r^r \end{pmatrix} \begin{pmatrix} x^1 \\ x^2 \\ \vdots \\ x^r \end{pmatrix} + \begin{pmatrix} B_1^1 & B_2^1 & \cdots & B_\rho^1 \\ B_1^2 & B_2^2 & \cdots & B_\rho^2 \\ \vdots & \vdots & & \vdots \\ B_1^\rho & B_2^\rho & \cdots & B_\rho^\rho \end{pmatrix} \begin{pmatrix} v^1 \\ v^2 \\ \vdots \\ v^\rho \end{pmatrix} + Cu = Ax + Bv + Cu. \tag{0.22}$$

It is required to find a state feedback relation $u = Kx$ such that, assuming $r \leqq \rho, x^1, \cdots, x^{r-\rho}$ are decoupled from $v^1, v^2, \cdots, v^\rho$ and for $k = r-\rho+1, \cdots, r$, only the output x^k is dynamically coupled to v^k. This means that the closed loop transfer matrix for (0.22), i.e.,

$$T(\lambda) \equiv (\lambda I - (A + CK))^{-1} B$$

is block diagonal with $T_k^k(\lambda) = 0$, $k = 1, 2, \cdots, r-\rho$, $T_k^k(\lambda)$ possibly nonzero for $k = r-\rho+1, \cdots, r$, $T_k^j = 0, j \neq k$. Our problem can be cast in this form with x^1, x^2, x^3 replaced by x, y, z and A replaced by

$$\begin{pmatrix} A & 0 & B \\ S & F & 0 \\ 0 & 0 & F \end{pmatrix} \quad (A, B \text{ here referring to the matrices in (0.8))},$$

B replaced by

$$\begin{pmatrix} 0 \\ 0 \\ I_r \end{pmatrix},$$

and C replaced by

$$\begin{pmatrix} C \\ 0 \\ 0 \end{pmatrix} \quad (C \text{ here referring to the matrix in (0.8))}.$$

It is not our goal to provide any general discussion of dynamic decoupling; our primary focus is on the period identification problem required for *adaptive* dynamic decoupling in the special context of (0.8). Nevertheless, we do present a simplified dynamic decoupling procedure for (0.8) in § 1 which we have used in conjunction with our period estimation procedure.

Whether decoupling is carried out as in § 1 to follow, or as in one of the cited references, it is clear that the estimator system requires knowledge of the matrix (0.5) and hence the parameter $\alpha = 2\pi/T$ in (0.6). When the period T, and hence α, is unknown it is necessary to adjoin a parameter estimator to supply the system with an estimate for T. Such a parameter estimator is described in § 2. Stability considerations in connection with the period estimator lead to examination of a related functional equation of retarded type in § 3. A numerical realization of the estimator of § 2 is developed in § 4 and examples of its use are presented in § 5.

1. Compensator design for a known disturbance frequency. If the period T, or equivalently, the frequency $\nu = 1/T$ of the disturbance v is known, then we may assume that F is known and the only problem in constructing the compensator (0.7) is the selection of the $2r \times n$ matrix S. Let us note that the matrix equation

$$\begin{pmatrix} A+CK & -B\Phi^{-1} \\ S & F \end{pmatrix}\begin{pmatrix} 0 \\ \Phi \end{pmatrix} - \begin{pmatrix} 0 \\ \Phi \end{pmatrix} F + \begin{pmatrix} B \\ 0 \end{pmatrix} = 0 \tag{1.1}$$

is clearly valid whatever S may be. This means that if we define ξ, η by

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ \Phi \end{pmatrix} z + \begin{pmatrix} \xi \\ \eta \end{pmatrix} \qquad (\dot{z} = Fz) \tag{1.2}$$

we shall have

$$\begin{pmatrix} \dot{\xi} \\ \dot{\eta} \end{pmatrix} = \begin{pmatrix} A+CK & -B\Phi^{-1} \\ S & F \end{pmatrix}\begin{pmatrix} \xi \\ \eta \end{pmatrix}, \tag{1.3}$$

as is easily checked. If the matrix in (1.3) is a stability matrix, then $x(t) = \xi(t)$ will have the property

$$\lim_{t\to\infty} \|x(t)\| = 0$$

so that the periodic disturbance $v(t) = Bz(t)$ has only a transient effect on $x(t)$; the range of the transfer function matrix from z to $\binom{x}{y}$ includes only vectors of the form $\binom{0}{y}$. Thus the plant state vector x is dynamically decoupled from z. If the matrix in (1.3) is not a stability matrix no such inferences are valid. Our proof that S can be selected so as to satisfy this stability requirement begins with

THEOREM 1. *Let F be antihermitian (as in (0.5)), so that*

$$F^* = -F.$$

Then the $n \times m$ linear matrix equation

$$(A+CK)P_0 - P_0F - B\Phi^{-1} = 0 \tag{1.4}$$

has a unique $n \times 2r$ solution P_0. If the pair (P_0, F) is observable, then the $2r \times n$ matrix S can be chosen in such a way that

$$M = \begin{pmatrix} A+CK & -B\Phi^{-1} \\ S & F \end{pmatrix} \tag{1.5}$$

is a stability matrix.

Proof. Since $F^* = -F$ implies that F has only purely imaginary eigenvalues, the existence of a unique solution P_0 of (1.4) is assured by a familiar theorem in matrix theory (see, for example, [2]). An easy application of the implicit function theorem then shows that the cubic matrix equation

$$(A+CK)P - PF - B\Phi^{-1} + \varepsilon PP^*P \equiv Q(P, \varepsilon) = 0 \tag{1.6}$$

has a unique solution $P = P(\varepsilon)$ defined for small $\varepsilon \to 0$ with

$$\lim_{\varepsilon\to 0} P(\varepsilon) = P_0. \tag{1.7}$$

Setting

$$S = S(\varepsilon) = -\varepsilon P(\varepsilon)^* \tag{1.8}$$

we note that M in (1.5) is similar to

$$\tilde{M}(\varepsilon)=\begin{pmatrix} I_n & -P(\varepsilon) \\ 0 & I_{2r} \end{pmatrix}\begin{pmatrix} A+CK & -B\Phi^{-1} \\ -\varepsilon P(\varepsilon)^* & F \end{pmatrix}\begin{pmatrix} I_n & P(\varepsilon) \\ 0 & I_{2r} \end{pmatrix}$$
$$=\begin{pmatrix} A+CK+\varepsilon P(\varepsilon)P(\varepsilon)^* & Q(P(\varepsilon),\varepsilon) \\ -\varepsilon P(\varepsilon)^* & F-\varepsilon P(\varepsilon)^*P(\varepsilon) \end{pmatrix}$$
$$=\begin{pmatrix} A+CK+\varepsilon P(\varepsilon)P(\varepsilon)^* & 0 \\ -\varepsilon P(\varepsilon)^* & F-\varepsilon P(\varepsilon)P(\varepsilon)^* \end{pmatrix}.$$

Since K has been chosen so that $A+CK$ is a stability matrix,

$$M_n(\varepsilon)\equiv A+CK+\varepsilon P(\varepsilon)P(\varepsilon)^*$$

is an $n\times n$ stability matrix for sufficiently small $\varepsilon>0$. From the antihermitian property of F we can see that

$$(F-\varepsilon P(\varepsilon)^*P(\varepsilon))^*I_{2r}+I_{2r}(F-\varepsilon P(\varepsilon)^*P(\varepsilon))+2\varepsilon P(\varepsilon)^*P(\varepsilon)=0.$$

Applying a well-known modification of Lyapunov's theorem (see, for example, [8]) we conclude that

$$M_{2r}(\varepsilon)\equiv F-\varepsilon P(\varepsilon)^*P(\varepsilon)$$

is a stability matrix for $\varepsilon>0$ if $(P(\varepsilon), F)$ is observable. Since we have assumed (P_0, F) observable and (1.7) is true, $(P(\varepsilon), F)$ is observable for $\varepsilon>0$ sufficiently small and $M_{2r}(\varepsilon)$ is thus a stability matrix for these values of ε, at least. Since $\tilde{M}(\varepsilon)$ is lower block triangular with blocks $M_n(\varepsilon)$, $M_{2r}(\varepsilon)$, its stability, and hence that of $M=M(\varepsilon)$ in (1.5), is assured with the choice (1.8) for $S=S(\varepsilon)$ for sufficiently small $\varepsilon>0$.

It will be noted that the choice of the feedback matrix K is important in at least two ways. Improvement of the convergence of $\Phi^{-1}y$ to z, i.e., reduction of the transient effect of the disturbance $v=Bz$, dictates choosing ε larger to improve the stability properties of $F-\varepsilon P(\varepsilon)^*P(\varepsilon)$. But, since $A+CK+\varepsilon P(\varepsilon)P(\varepsilon)^*$ suffers stability-wise as ε is increased, K must be used to offset this effect. In § 3 we will find even further considerations to take into account in the selection of ε and K.

Since $P(\varepsilon)$ satisfies a cubic equation, which may entail some difficulty of solution, the following corollary is useful in applications.

COROLLARY 2. *If ε is sufficiently small, then*

$$\hat{M}(\varepsilon)=\begin{pmatrix} A+CK & -B\Phi^{-1} \\ -\varepsilon P_0^* & F \end{pmatrix}, \tag{1.9}$$

corresponding to

$$S=\hat{S}(\varepsilon)=-\varepsilon P_0^* \tag{1.10}$$

in (1.5) *is also a stability matrix.*

Proof. With the indicated choice of S, the matrix $\hat{M}(\varepsilon)$ is similar to

$$\begin{pmatrix} I & -P_0 \\ 0 & I \end{pmatrix}\begin{pmatrix} A+CK & -B\Phi^{-1} \\ -\varepsilon P_0^* & F \end{pmatrix}\begin{pmatrix} I & P_0 \\ 0 & I \end{pmatrix}$$
$$=\begin{pmatrix} A+CK+\varepsilon P_0P_0^* & (A+CK)P_0-P_0F-B\Phi^{-1}+\varepsilon P_0P_0^*P_0 \\ -\varepsilon P_0^* & F-\varepsilon P_0^*P_0 \end{pmatrix} \tag{1.11}$$
$$=\text{cf. (1.4)}=\begin{pmatrix} A+CK+\varepsilon P_0P_0^* & \varepsilon P_0P_0^*P_0 \\ -\varepsilon P_0^* & F-\varepsilon P_0^*P_0 \end{pmatrix}.$$

Let $\mu = \varepsilon^{1/2}$ for $\varepsilon \geqq 0$. With $P_0(\mu) = \mu P_0$, the matrix (1.11) becomes

$$\begin{pmatrix} A + CK + P_0(\mu)P_0(\mu)^* & (1/\mu)P_0(\mu)P_0(\mu)^*P_0(\mu) \\ -\mu P_0(\mu)^* & F - P_0(\mu)^*P_0(\mu) \end{pmatrix}$$

which is similar to

$$\text{(1.12)} \quad \begin{pmatrix} A + CK + P_0(\mu)P_0(\mu)^* & P_0(\mu)P_0(\mu)^*P_0(\mu) \\ -P_0(\mu)^* & F - P_0(\mu)^*P_0(\mu) \end{pmatrix} \equiv \begin{pmatrix} A_1(\mu) & P_3(\mu) \\ -P_0(\mu)^* & F_1(\mu) \end{pmatrix}.$$

The corresponding lower triangular matrix

$$\begin{pmatrix} A_1(\mu) & 0 \\ -P_0(\mu)^* & F_1(\mu) \end{pmatrix}$$

is a stability matrix, using essentially the same argument as in Theorem 1, provided $\mu > 0$ is sufficiently small. Consider the equation

$$\text{(1.13)} \quad \begin{pmatrix} A_1(\mu)^* & -P_0(\mu) \\ 0 & F_1(\mu)^* \end{pmatrix}\begin{pmatrix} Q & R \\ R^* & T \end{pmatrix} + \begin{pmatrix} Q & R \\ R^* & T \end{pmatrix}\begin{pmatrix} A_1(\mu) & 0 \\ -P_0(\mu)^* & F_1(\mu) \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & 2P_0(\mu)^*P_0(\mu) \end{pmatrix} = 0.$$

Solving this, we find that $T = I_{2r}$ and

$$\text{(1.14)} \quad A_1(\mu)^*Q - P_0(\mu)R^* + QA_1(\mu) - RP_0(\mu)^* + I = 0,$$

$$\text{(1.15)} \quad A_1(\mu)^*R - P_0(\mu) + RF_1(\mu) = 0.$$

For small μ (equivalently, small ε) the eigenvalues of $A_1(\mu)$ and $-F_1(\mu)$ are uniformly separated and the solution of (1.15) shows that

$$R = Q(\|P_0(\mu)\|) = (\mu)$$

and then a similar analysis of the first equation shows that

$$Q = Q_0(\mu) + (\mu^2)$$

where

$$A_1(\mu)^*Q_0(\mu) + Q_0(\mu)A_1(\mu) + I_n = 0.$$

Thus $Q_0(\mu)$, and hence Q, remains bounded for $\mu > 0$ small. Since (1.13) is satisfied, using the matrix of (1.12) instead, we have

$$\begin{pmatrix} A_1(\mu)^* & -P_0(\mu) \\ P_3(\mu)^* & F_1(\mu)^* \end{pmatrix}\begin{pmatrix} Q & R \\ R^* & T \end{pmatrix} + \begin{pmatrix} Q & R \\ R^* & T \end{pmatrix}\begin{pmatrix} A_1(\mu) & P_3(\mu) \\ -P_0(\mu)^* & F_1(\mu) \end{pmatrix}$$
$$= -\begin{pmatrix} I & (-\mu^2/\sqrt{2})QP_0P_0^* \\ 0 & \sqrt{2}\mu P_0^* \end{pmatrix}\begin{pmatrix} I & 0 \\ (-\mu^2/\sqrt{2})P_0P_0^*Q & \sqrt{2}\mu P_0 \end{pmatrix}$$
$$+ \begin{pmatrix} (\mu^4/2)QP_0P_0^*P_0P_0^*Q & 0 \\ 0 & 0 \end{pmatrix}.$$

From this it is easy to see that the matrix on the right-hand side is nonpositive for small $\mu > 0$ and the result follows by the familiar Lyapunov theorem, provided that whenever

$$\begin{pmatrix} \dot{\zeta} \\ \dot{\eta} \end{pmatrix} = \begin{pmatrix} A_1(\mu) & P_3(\mu) \\ -P_0(\mu)^* & F_1(\mu) \end{pmatrix}\begin{pmatrix} \hat{\zeta} \\ \hat{\eta} \end{pmatrix}$$

the quadratic form

$$(\hat{\zeta}(t)^*, \hat{\eta}(t)^*)\left[-\begin{pmatrix} I & (-\mu^2/\sqrt{2})QP_0P_0^* \\ O & \sqrt{2}\mu P_0^* \end{pmatrix}\begin{pmatrix} I & 0 \\ (-\mu^2/\sqrt{2})P_0P_0^*Q & \sqrt{2}\mu P_0 \end{pmatrix} + \begin{pmatrix} \mu^4 QP_0P_0^*P_0P_0^*Q & 0 \\ 0 & 0 \end{pmatrix}\right]\begin{pmatrix} \hat{\zeta}(t) \\ \hat{\eta}(t) \end{pmatrix}$$

cannot vanish on any interval of positive length. For small $\mu > 0$ this question reduces very quickly to the observability of the pair (P_0, F), which has already been assumed. This completes the proof.

2. Period estimation and a related stability problem. Whether the submatrix S in the definition (1.5) of M is selected as in Theorem 1, or as in Corollary 2, or by some other procedure, it is clear that the overall matrix M will depend on the period T, of the disturbance v so that, supposing now that the design parameter ε has been fixed, we have

$$M = M(\alpha) = \begin{pmatrix} A + CK & -B\Phi(\alpha)^{-1} \\ S(\alpha) & F(\alpha) \end{pmatrix} \tag{2.1}$$

where $\alpha = (2\pi/T)$ (cf. (0.6)).

It would be possible to estimate α directly using various well-known parameter estimation procedures [6], [9]. However, in these procedures one tends to encounter either instability or slow convergence, or other difficulties. For example, the model reference algorithm of [6] cannot be applied because in the complete system (0.12) the portion $\dot{z} = Fz$ of that system is not controllable with respect to u.

We have elected to use a very simple procedure to estimate the period T, directly. Assuming that an output, or observation,

$$\omega(t) = H_1x(t) + H_2y(t) = (H_1, H_2)\begin{pmatrix} x(t) \\ y(t) \end{pmatrix} \equiv Hw(t), \tag{2.2}$$

where (cf. (0.3), (0.12), (1.5))

$$\dot{w} = M(\alpha)w + \beta \qquad \left(\beta = \begin{pmatrix} v \\ 0 \end{pmatrix}\right), \tag{2.3}$$

is available, from the assumed stability property of the matrix $M(\alpha)$ it follows that a periodic disturbance input v will result in an output $\omega(t)$ which, except for transient behavior, is also periodic with the same period. It therefore makes sense, in the continuous framework which we use here for analysis, to consider the cost functional for $\gamma > 0$,

$$\begin{aligned} C_0(T, t) &= \int_0^t e^{\gamma(s-t)}(\omega(s) - \omega(s-T))^*(\omega(s) - \omega(s-T))\, ds \\ &= \int_0^t e^{\gamma(s-t)}(w(s) - w(s-T))^*H^*H(w(s) - w(s-T))\, ds \end{aligned} \tag{2.4}$$

and select as our estimate for the period T at time t, that value $T(t)$ which minimizes $C(T, t)$ within a given range $T_1 \leqq T \leqq T_2$. (The range must be restricted in order to avoid the trivial period $T = 0$ and multiples of the minimum period of the disturbance.) Then

$$\alpha(t) = \frac{2\pi}{T(t)} \tag{2.5}$$

is the estimate at time t for α in (0.6), (2.3). A numerical procedure approximating this optimization process is described in § 4 and is used to obtain the computational results of § 5. There it will be seen that certain steps do have to be taken in order to ensure the stability of the combined control/estimation system. Our purpose here is to provide a framework for the stability analysis by developing a linearized variational equation for that system about the nominal time trajectory in the case where the true period, which we will call T_0, lies in the interior of the interval $T_1 \leqq T \leqq T_2$.

For our analysis of the combined use of (2.3) and (2.4) we will consider, instead of $C_0(T, t)$, as given by (2.4), the cost

$$C(T, t) = \int_{-\infty}^{t} e^{\gamma(s-t)}(w(s) - w(s-T))^* H^* H(w(s) - w(s-T))\, ds, \tag{2.6}$$

wherein we assume that the trajectory $w(s)$ is defined in the indefinite past. The justification for this lies in the fact that if (2.3) and (2.6) together yield a stable process, the difference between the use of (2.6) and (2.4) will be transient.

To carry out this program we begin by supposing that when the correct value $\alpha_0 = (2\pi/T_0)$ is used in (2.3) the steady-state (T_0)-periodic solution resulting from the (T_0)-periodic input $\beta(t)$ is $w_0(t)$ and $\omega_0(t) = Hw_0(t)$. Since our estimate $\alpha(t)$ will vary from α_0, we suppose that the actual solution of (2.3) which we obtain is $w(t)$. Thus

$$\beta(t) = \beta(t - T_0), \tag{2.7}$$

$$w(t) = w_0(t) + \Delta w(t), \tag{2.8}$$

$$\alpha(t) = \alpha_0 + \Delta\alpha(t), \tag{2.9}$$

$$T(t) = T_0 + \Delta T(t). \tag{2.10}$$

A necessary condition in order that $T(t)$ should minimize $C(T, t)$ is obtained by differentiating $C(T, t)$ with respect to T and setting the result at $T = T(t)$ equal to zero. Thus (cf. (2.2), (2.3), (2.5))

$$\begin{aligned} 0 &= \frac{1}{2}\frac{\partial C(T, t)}{\partial T}\bigg|_{T=T(t)} \\ &= \int_{-\infty}^{t} e^{\gamma(s-t)}(w(s) - w(s - T(t)))^* H^* H\dot{w}(s - T(t))\, ds \\ &= \int_{-\infty}^{t} e^{\gamma(s-t)}(w(s) - w(s - T(t)))^* H^* H \\ &\quad \times [M(\alpha(s - T(t)))w(s - T(t)) + \beta(s - T(t))]\, ds. \end{aligned} \tag{2.11}$$

Noting (2.5), we see that (2.11) is implicitly an equation for $T(t)$ which is coupled with the system (2.3) satisfied by $w(t)$. The resulting coupled system is clearly a nonlinear functional equation of delay type. We are concerned with the (at least local with respect to α_0 and $w_0(t)$) existence, uniqueness and asymptotic stability of solutions.

LEMMA 3. *For fixed t and a trajectory $w(s) - \infty < s \leqq t$, for* (2.3), *corresponding to a continuous (T_0)-periodic $\beta(s)$, $-\infty < s \leqq t$, the equation* (2.11) *is solvable for $T(t)$ near T_0 if*

$$-(w(t) - w(t - T_0))^* H^* H\dot{w}(t - T_0) + \int_{-\infty}^{t} e^{\gamma(s-t)}\dot{w}(s)^* H^* H\dot{w}(s - T_0)\, ds$$

$$
\begin{aligned}
&+\gamma\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\dot{w}(s-T_0)\,ds\\
&=\int_{-\infty}^{t} e^{\gamma(s-t)}\dot{w}(s)^*H^*H\dot{w}(s-T_0)\,ds\\
&-\frac{\partial}{\partial t}\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\dot{w}(s-T_0)\,ds\neq 0.
\end{aligned}
\tag{2.12}
$$

Within the class of w which satisfy

$$\|w(s)\|\leqq M_0,\qquad -\infty<s\leqq t, \tag{2.13}$$

$$\|w(s)-w_0(s)\|\leqq\varepsilon,\qquad t-\tau\leqq s\leqq t, \tag{2.14}$$

this is true for sufficiently large τ and sufficiently small ε if

$$\int_{-\infty}^{t} e^{\gamma(s-t)}\dot{w}_0(s)H^*H\dot{w}_0(s)\,ds\neq 0 \tag{2.15}$$

and this, in turn, is true if the (T_0)-periodic function $Hw_0(s)=\omega_0(s)$ is not constant.

Proof. Assume for the moment that $\beta(t)$ is a function in C^1. Differentiating the second line of (2.11) with respect to T at $T=T_0$ and retaining only zero and first order terms in $\Delta T(t)$ we obtain the equation, linearized with respect to ΔT,

$$
\begin{aligned}
0=&\int_{-\infty}^{t} e^{\gamma(s-t)}\dot{w}(s-T_0)^*H^*H\dot{w}(s-T_0)\,ds\,\Delta T(t)\\
&-\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\ddot{w}(s-T_0)\,ds\,\Delta T(t)\\
&+\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\dot{w}(s-T_0)\,ds+\cdots.
\end{aligned}
\tag{2.16}
$$

Integrating the second term by parts we have

$$
\begin{aligned}
0=&\Big[-(w(t)-w(t-T_0))^*H^*H\dot{w}(t-T_0)+\int_{-\infty}^{t} e^{\gamma(s-t)}\dot{w}(s)^*H^*H\dot{w}(s-T_0)\,ds\\
&+\gamma\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\dot{w}(s-T_0)\,ds\Big]\Delta T(t)\\
&+\int_{-\infty}^{t} e^{\gamma(s-t)}(w(s)-w(s-T_0))^*H^*H\dot{w}(s-T_0)\,ds+\cdots.
\end{aligned}
\tag{2.17}
$$

This expression no longer depends on $\ddot{w}(s-T_0)$, hence we may relax the requirement $\beta\in C^1$ since $\beta\in C^0$ can be uniformly approximated in the C^0 norm by $\beta\in C^1$. Examination of the remainder term shows that the same argument applies there and we conclude that (2.16) is indeed valid to first order in $\Delta T(t)$. The first statement of our lemma then follows immediately from the implicit function theorem.

The last statement follows from the property

$$w_0(s)-w_0(s-T_0)\equiv 0,\qquad -\infty<s\leqq t, \tag{2.18}$$

and together with (2.3), (2.7), (2.17), this enables one to make the first term in (2.16) arbitrarily close to the left-hand side of (2.15) and the second term arbitrarily close to zero. This completes the proof of Lemma 3.

The linearization with respect to $\Delta T, \Delta w$ is obtained by using (2.18) in (2.16). Because $w_0(s) - w_0(s - T_0) \equiv 0$ and because only zero order terms are retained as coefficients of the first order term $\Delta T(t)$, the result is

$$\left[\int_{-\infty}^{t} e^{\gamma(s-t)} \dot{w}_0(s)^* H^* H \dot{w}_0(s - T_0)\, ds\right] \Delta T(t)$$

$$+ \int_{-\infty}^{t} e^{\gamma(s-t)} (\Delta w(s) - \Delta w(s - T_0))^* H^* \dot{w}_0(s - T_0)\, ds = 0,$$

and using (2.18), $\dot{w}_0(s - T_0) \equiv \dot{w}(s)$, and the assumption (2.15) we have

$$\Delta T(t) = \frac{-\int_{-\infty}^{t} e^{\gamma(s-t)} (\Delta w(s) - \Delta w(s - T_0))^* H^* H \dot{w}_0(s)\, ds}{\int_{-\infty}^{t} e^{\gamma(s-t)} \dot{w}_0(s)^* H^* H \dot{w}_0(s)\, ds}, \tag{2.19}$$

which is a delay type functional equation relating $\Delta T(t)$ and the time history of Δw. Then from (2.3) we have, to first order,

$$\Delta \dot{w} + \dot{w}_0 = M(\alpha_0) w_0 + \beta + M(\alpha_0) \Delta w + \left(\frac{\partial M}{\partial \alpha}(\alpha_0) \Delta \alpha\right) w_0 + \cdots$$

and, since $\dot{w}_0 = M(\alpha_0) w_0 + \beta$ and (2.5) applies, we have as our linearized system (2.19) and

$$\Delta \dot{w}(t) = M(\alpha_0) \Delta w(t) - \left(\frac{2\pi}{T_0^2} \frac{\partial M}{\partial \alpha}(\alpha_0) w_0(t)\right) \Delta T(t). \tag{2.20}$$

A single equation may be obtained by noting that for $\tau > T_0$

$$\Delta \dot{w}(s) - \Delta \dot{w}(s - T_0) = M(\alpha_0)(\Delta w(s) - \Delta w(s - T_0)) - \frac{2\pi}{T_0^2} \frac{\partial M}{\partial \alpha}(\alpha_0) w_0(s) \Delta T(s)$$

$$+ \frac{2\pi}{T_0^2} \frac{\partial M}{\partial \alpha}(\alpha_0) w_0(s - T_0) \Delta T(s - T_0)$$

$$= M(\alpha_0)(\Delta w(s) - \Delta w(s - T_0))$$

$$- \frac{2\pi}{T_0^2} \frac{\partial M}{\partial \alpha}(\alpha_0) w_0(s)(\Delta T(s) - \Delta T(s - T_0)),$$

where we have used $w_0(s) = w_0(s - T_0)$. Then

$$\Delta w(t) - \Delta w(t - T_0) = \frac{-2\pi}{T_0^2} \int_{-\infty}^{t} e^{M(\alpha_0)(t-\sigma)} \frac{\partial M}{\partial \alpha}(\alpha_0) w_0(\sigma)(\Delta T(\sigma) - \Delta T(\sigma - T_0))\, ds$$

and thus

$$\Delta T(t) = \frac{2\pi / T_0^2}{\int_{-\infty}^{t} e^{\gamma(s-t)} \dot{w}_0(s)^* H^* \dot{w}_0(s)\, ds}$$

$$\times \int_{-\infty}^{t} e^{\gamma(s-t)} \int_{-\infty}^{s} w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* e^{M(\alpha_0)^*(s-\sigma)}$$

$$\times (\Delta T(\sigma) - \Delta T(\sigma - T_0))\, d\sigma\, H^* H \dot{w}_0(s)\, ds.$$

Letting

$$W_0(\gamma, t) = \frac{2\pi / T_0^2}{\int_{-\infty}^{t} e^{\gamma(s-t)} \dot{w}_0(s)^* H^* H \dot{w}_0(s)\, ds} \tag{2.21}$$

we have

$$\Delta T(t) = W_0(\gamma, t) \int_{-\infty}^{t} w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \int_{\sigma}^{t} e^{\gamma(s-t)}\, e^{M(\alpha_0)^*(s-\sigma)} H^* H \dot{w}_0(s)\, ds \times (\Delta T(\sigma) - \Delta T(\sigma - T_0))\, d\sigma,$$

which has the form

$$\Delta T(t) = \int_{-\infty}^{t} W_1(\gamma, t, \sigma, M(\alpha_0))(\Delta T(\sigma - T_0))\, d\sigma \tag{2.22}$$

with

$$W_1(\gamma, t, \sigma, M(\alpha_0)) = W_0(\gamma, t) w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \times \int_{\sigma}^{t} e^{\gamma(s-t)}\, e^{M(\alpha_0)^*(s-\sigma)} H^* H \dot{w}_0(s)\, ds. \tag{2.23}$$

LEMMA 4. *$W_1(\gamma, t, \sigma, M(\alpha_0))$ is periodic in t and σ with period T_0, in the sense*

$$W_1(\gamma, t, \sigma, M(\alpha_0)) = W_1(\gamma, t + T_0, \sigma + T_0, M(\alpha_0)).$$

Proof. Using the formula (2.23) directly we see that

$$W_1(\gamma, t + T_0, \sigma + T_0, M(\alpha_0)) = W_0(\gamma, t + T_0) w_0(\sigma + T_0)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \times \int_{\sigma + T_0}^{t + T_0} e^{\gamma(s - t - T_0)}\, e^{M(\alpha_0)^*(s - \sigma - T_0)} H^* H \dot{w}_0(s)\, ds.$$

From the (T_0)-periodicity of $w_0(t)$ the same periodicity of $W_0(\gamma, t)$ follows easily. Then with $r = s - T_0$

$$W_1(\gamma, t + T_0, \sigma + T_0, M(\alpha_0)) = W_0(\gamma, t) w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \times \int_{\sigma}^{t} e^{\gamma(r-t)}\, e^{M(\alpha_0)^*(r-\sigma)} H^* H \dot{w}_0(r + T_0)\, dr$$

and, using the (T_0)-periodicity of $\dot{w}_0$ we have

$$W_1(\gamma, t + T_0, \sigma + T_0, M(\alpha_0)) = W_1(\gamma, t, \sigma, M(\alpha_0)),$$

as claimed.

The equation (2.22) can be rewritten as

$$\Delta T(t) = \int_{-\infty}^{t} W(\gamma, t, \sigma, M(\alpha_0)) \Delta T(\sigma)\, d\sigma \tag{2.24}$$

with

$$W(\gamma, t, \sigma, M(\alpha_0)) = W_1(\gamma, t, \sigma, M(\alpha_0)), \qquad t - T_0 < \sigma \leqq t,$$

$$W(\gamma, t, \sigma, M(\alpha_0)) = W_1(\gamma, t, \sigma, M(\alpha_0)) - W_1(\gamma, t, \sigma + T_0, M(\alpha_0)), \qquad -\infty < \sigma \leqq t - T_0.$$

Since, for $\sigma = t - T_0$, $W_1(\gamma, t, \sigma + T_0, M(\sigma_0)) = W_1(\gamma, t, t, M(\alpha_0)) = 0$ we see that $W(\gamma, t, \sigma, M(\alpha_0))$ is continuous as a function of σ and, clearly, $W(\gamma, t + T_0, \sigma + T_0, M(\alpha_0)) = W(\gamma, t, \sigma, M(\alpha_0))$.

We have shown $\gamma, M(\alpha_0)$ directly as arguments of W because γ, ε and K, the last two involved in the construction of $M(\alpha_0)$ (see (2.1)) are the parameters which we have to work with in order to influence W, and hence the solutions of (2.24). It is clear from (2.22) that W depends on T_0 as well.

The stability and rate of convergence of our estimation procedure depends on the behavior of solutions of the variational equation (2.24), for $T(t)$ in a neighborhood of the exact value T_0, i.e., for $\Delta T(t)$ small. In the next section we show that the asymptotic behavior of solutions of (2.24) is dominated by solutions of "Floquet type" which can be analyzed by standard procedures.

3. Analysis of Floquet type solutions. The fact that (2.24) involves an infinite time delay places it in a class of functional differential equations with periodic coefficients whose properties have not been fully explored. From the behavior of solutions of such equations with finite delays [3], [4] we expect that, with some restrictions on the kernel $W(\gamma, t, \sigma, M(\alpha_0))$, the dominant solutions should be solutions of "Floquet type," i.e., solutions of the form

$$\Delta T(t) = e^{\lambda t} P(t), \tag{3.1}$$

where $P(t)$ is a continuous (T_0)-periodic function

$$P(t+T_0) = P(t).$$

The main point of this section is to indicate that this is, indeed, the case for kernels satisfying a uniform decay condition

$$|W(\gamma, t, \sigma, M(\alpha_0))| \leqq C e^{-c(t-\sigma)}, \qquad \sigma \leqq t, \tag{3.2}$$

for positive C, c.

Before entering upon the proof of this, let us note some rather transparent results which, however superficial, give some indication of the factors which are likely to play a role in our analysis. Suppose an inequality (3.2) is satisfied for positive c, C. Supposing a solution of the form (3.1) to exist, we normalize $P(t)$ so that

$$\sup_{s \in [t, t-T_0]} |P(s)| = 1.$$

Then we let t be such that $|P(t)| = 1$. Multiplying by a constant, if need be, we may assume $P(t) = 1$. Then

$$e^{\lambda t} - \int_{-\infty}^{t} W(\gamma, t, \sigma, M(\alpha_0))\, e^{\lambda \sigma} P(\sigma)\, d\sigma = 0$$

or

$$\int_{-\infty}^{t} W(\gamma, t, \sigma, M(\alpha_0))\, e^{\lambda(\sigma - t)} P(\sigma)\, d\sigma = 1.$$

But

$$|W(\gamma, t, \sigma, M(\alpha_0))\, e^{\lambda(\sigma-t)} P(\sigma)| \leqq C e^{(c + \mathrm{Re}(\lambda))(\sigma - t)}$$

so that

$$C \int_{-\infty}^{t} e^{(c+\mathrm{Re}(\lambda))(\sigma-t)}\, d\sigma \geqq 1,$$

yielding an upper bound on $\mathrm{Re}(\lambda)$

$$\frac{C}{c + \mathrm{Re}(\lambda)} \geqq 1 \quad \Rightarrow \mathrm{Re}(\lambda) \leqq C - c.$$

Under what circumstances could a bound of the type (3.2) be expected? Recalling that

$$W_1(\gamma, t, \sigma, M(\alpha_0)) = W_0(\gamma, t) w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \, e^{\gamma(\sigma - t)} \times \int_\sigma^t e^{\gamma(s-\sigma)} \, e^{M(\alpha_0)^*(s-\sigma)} H^* H \dot{w}_0(s) \, ds,$$

we note that with $r = s - \sigma$,

$$\int_\sigma^t e^{\gamma(s-\sigma)} \, e^{(M(\alpha_0)^* + \gamma I)r} H^* H \dot{w}(r+\sigma) \, ds = \int_0^{t-\sigma} e^{(M(\alpha_0)^* + \gamma I)r} H^* H \dot{w}_0(r+\sigma) \, dr.$$

Since $\dot{w}_0$ is periodic, if the eigenvalues μ of $M(\alpha_0)$ satisfy

$$\operatorname{Re}(\mu) \leqq -\delta$$

for some $\delta > 0$, we will have, for some $M_0 > 0$

$$\| e^{(M(\alpha_0)^* + \gamma I)r} H^* H \dot{w}_0(r+\sigma) \| \leqq M_0 \, e^{(\gamma - \delta)r},$$

so that

$$\left\| \int_0^{t-\sigma} e^{(M(\alpha_0)^* + \gamma I)r} H^* H \dot{w}_0(r+\sigma) \, dr \right\| \leqq M_0 \int_0^{t-\sigma} e^{(\gamma-\delta)r} \, dr = \frac{M_0}{\gamma - \delta} [e^{(\gamma-\delta)(t-\sigma)} 1]. \tag{3.3}$$

We expect $W_0(t, \gamma)$ to be (γ) from (2.21); write

$$|W_0(t, \gamma)| \leqq M_1 \gamma$$

and then, since $w_0(\sigma)$ is periodic,

$$\left\| W_0(t, \gamma) w_0(\sigma)^* \frac{\partial M}{\partial \alpha}(\alpha_0)^* \, e^{\gamma(\sigma - t)} \right\| \leqq M_2 \gamma \, e^{\gamma(\sigma - t)}. \tag{3.4}$$

Combining this with (3.3), (2.23)

$$|W_1(\gamma, t, \sigma, M(\alpha_0))| \leqq M_0 M_2 \frac{\gamma}{\gamma - \delta} \, e^{\delta(\sigma - t)}$$

giving $C = M_0 M_2 (\gamma/(\gamma - \delta))$, $c = \delta$. A comparable estimate will then apply to $W(\gamma, t, \sigma, M(\alpha_0))$.

From this we see that if we are to control the identifier stability properties, this must be done through γ and through the system matrix $M(\gamma_0)$, by choice of γ, ε and K (or through choice of γ, K, L_0, L_1 if we use the full system estimator as described in § 7). Further, we see from (2.21) that $W_0(\gamma, t)$, and hence $W_1(\gamma, t, \sigma, M(\alpha_0))$, $W(\gamma, t, \sigma, M(\alpha_0))$ increase rapidly as the frequency parameter $\alpha = 2\pi / T_0$ increases, i.e., as T_0 decreases. Thus, to be able to reject higher frequencies while maintaining stability we must expect to find it necessary to increase the damping in the system (2.3) by use of higher gains ε and K (of (1.5), (1.8)). We will also see in § 5 that this expectation is realized.

We proceed now to state a theorem to the effect that if a bound of the form (3.2) applies, then all solutions of (2.24) which do not satisfy

$$\|\Delta T(t)\| \leqq B \, e^{-\beta t}, \qquad 0 \leqq t < \infty, \tag{3.5}$$

where B is positive and $\beta > 0$ is less than c by an arbitrarily small amount, must be linear combinations of Floquet type solutions.

THEOREM 5. *Consider the vector functional equation*

$$z(t) = \int_{-\infty}^{t} W(t, s)z(s)\, ds, \qquad z \in R^m, \tag{3.6}$$

where $W(t, s)$ is a (piecewise continuous, at least) $m \times m$ matrix function satisfying

$$\| W(t, s)\| \leqq C e^{-c(t-s)}, \qquad -\infty < s \leqq t, \tag{3.7}$$

$$W(t+T, s+t) = W(t, s), \tag{3.8}$$

for positive numbers C, c, T. Then, given any $\beta < c$, and any solution $z(t)$ with locally square integrable initial function satisfying

$$\int_{-\infty}^{0} e^{2cs} \| \tilde{z}(s)\|_{R^m}^2 \, ds < \infty, \tag{3.9}$$

we can write

$$z(t) = z_F(t) + z_\beta(t), \qquad t \geqq 0 \tag{3.10}$$

where, for some positive B,

$$\| z_\beta(t)\| \leqq B e^{-\beta t}, \qquad t \geqq 0 \tag{3.11}$$

and $z_F(t)$ is a linear combination of Floquet type solutions, i.e., solutions of the form

$$\zeta(t) = e^{\lambda t} P(t), \quad P(t+T) = P(t), \quad P \in C([0, \infty], R^m), \tag{3.12}$$

or, in some cases (multiple "eigenvalues")

$$\zeta(t) = e^{\lambda t} t^p P(t), \tag{3.13}$$

where p is a positive integer and $P(t)$ is as in (3.12).

A complete proof of Theorem 5 is beyond the scope of the present work but a sketch of the proof will be given in the Appendix.

From this result we see that whenever an inequality of the type (3.2) is valid with $c > 0$, then all solutions of (2.24) decay at a uniform exponential rate unless there are actually solutions (3.1) of Floquet type for which $\mathrm{Re}\,(\lambda) > 0$. The question arises, of course, as to how such Floquet exponents might actually be computed. It seems almost certain that the most efficient procedure involves actual solution of (2.24) or (2.19), (2.20), assuming an adequate approximation procedure is available. The procedure is essentially the same one as is used to compute the dominant (pairs of) root(s) of an ordinary polynomial.

Returning to $\Delta T(t)$ as the name for the solution, we select a more or less arbitrary initial state $\Delta T(t)$ on some interval $[-\tau, 0]$ (in terms of § 6 this should be a $\tilde{z}$ such that the residue of $(I - Q(\lambda))^{-1} q(\lambda, \tilde{z})$ at $\lambda = \lambda z$ is not zero, which is generically true). The resulting solution $\Delta T(t)$, $t \geqq 0$, is computed and we examine successive segments of length T_0

$$\Delta T_k(s) = \Delta T(kT_0 + s), \qquad 0 \leqq s \leqq T_0, \quad k = 0, 1, 2, 3, \cdots.$$

If the largest multiplier

$$\mu_\nu = e^{\lambda_\nu T_0}$$

is a unique real number, then generically with respect to the choice of initial function $\Delta T(t)$, $t \in [-\tau, 0]$, we shall have (using the least squares approach)

$$\mu_\nu = \lim_{k \to \infty} \frac{\int_0^T \Delta T_k(s) \Delta T_{k-1}(s)\, ds}{\int_0^T (\Delta T_{k-1}(s))^2\, ds}.$$

In the case of a dominant complex conjugate pair the procedure is only slightly more complicated. We solve

$$\Delta T_k(s)+\alpha\Delta T_{k-1}(s)+\beta\Delta T_{k-2}(s)=0$$

for α and β in the least squares (least L^2 norm) sense, which amounts to

$$\begin{pmatrix} \int_0^T \Delta T_{k-1}(s)^2\,ds & \int_0^T \Delta T_{k-1}(s)\Delta T_{k-2}(s)\,ds \\ \int_0^T \Delta T_{k-2}(s)\Delta T_{k-1}(s)\,ds & \int_0^T \Delta T_{k-2}(s)^2\,ds \end{pmatrix} \begin{pmatrix} \alpha_k \\ \beta_k \end{pmatrix} + \begin{pmatrix} \int_0^T \Delta T_k(s)\Delta T_{k-1}(s)\,ds \\ \int_0^T \Delta T_k(s)\Delta T_{k-2}(s)\,ds \end{pmatrix} = 0.$$

The pair $\mu_\nu, \bar{\mu}_\nu$ is then approximated at the kth stage by the roots $\mu_k, \bar{\mu}_k$ of

$$\mu^2+\alpha_k\mu+\beta_k=0.$$

It seems likely that while (2.24) is nicer from the viewpoint of mathematical simplicity, it is better to solve (2.19), (2.20) rather than (2.24) because the formula for the kernel $W(\gamma, t, \sigma, M(\alpha_0))$ in (2.24) is rather complicated.

If a simulation routine combining the period estimator, compensator and a mathematical model of the plant to be controlled is already in hand, as was the case for the writer, approximate solutions of the variation equation can be obtained by running the simulator with slightly different initial conditions and forming the appropriate difference quotient of the resulting solutions. This does not test the validity of our derivation of the variational equation but, as we will see in § 5, it does provide results consistent with the proposed functional equation model for error propagation.

4. Numerical realization of the period estimator. If $x(t)$ is a solution of

$$\dot{x}(t)=(A+CK)x(t)+v(t), \quad t\geqq 0,$$

and the disturbance $v(t)$ is periodic with period T

$$v(t)=v(t+T),$$

then an observation on $x(t)$,

$$\omega(t)=Hx(t)$$

will tend exponentially to a periodic observation, i.e.,

$$\lim_{t\to\infty}(\omega(t)-\omega(t+T))=0.$$

In this section we develop a numerical procedure for estimation of T which is a realization of the continuous procedure described in § 2. We will take ω to be scalar here but the extension to vector observations is quite immediate.

We will suppose that $\omega(t)$ is not available continuously. Rather, we have discrete samples

$$\omega_k=\omega(t_k), \quad t_{k+1}-t_k=h>0, \quad k=0, 1, 2, \cdots.$$

For computational purposes we define the interpolated observation on $t_k\leqq t\leqq t_{k+1}$ by

$$\tilde{\omega}(t_k+\sigma h)\equiv\eta_k(\sigma)=\sigma\omega_{k+1}+(1-\sigma)\omega_k, \qquad 0\leqq\sigma\leqq 1. \tag{4.1}$$

We note that $\tilde{\omega}(t_k) = \omega_k$, $\tilde{\omega}(t_{k+1}) = \omega_{k+1}$. We define $\eta_k = \omega_k$, $k = 0, 1, 2, \cdots$. Our method for estimating T is to form, at each instant t_k, and for a range $L_{\min} \leqq l \leqq L_{\max}$ (we use L_m, L_M below), the functions

$$\rho_{k,l}(\sigma) = \eta_k - \eta_{k-l}(\sigma) \tag{4.2}$$

and determine values l_k, σ_k of l, σ which minimize

$$C_{k,l}(\sigma) = \sum_{j=0}^{k} \gamma^j \rho_{k-j,l}(\sigma),$$

which should be compared with (2.6). The functions (4.2), of course, require only the values $\eta_k = \omega_k$, $\eta_{k+1} = \omega_{k+1}$ for this description and the $\rho_{k,l}$ admit a comparable finite characterization. Once l_k, σ_k have been determined, the estimate for T at the instant t_k is

$$T_k = (l_k - \sigma_k)h. \tag{4.3}$$

If γ is close to one this estimate may be expected to change only slowly, as k varies, in response to varying periodic behavior of $\omega(t)$ while values of γ closer to zero provide more rapid updating capability. The use of the parameter σ, allowing for interpolation between recorded discrete data, permits one to obtain accurate results without an excessively fast sampling rate.

Let us now examine the computational considerations applying to the method. For $0 < \sigma < 1$ we have

$$\rho_{k,l}(\sigma) = \eta_k - [\sigma\eta_{k-l+1} + (1-\sigma)\eta_{k-l}]$$

and thus

$$\rho_{k,l}(\sigma)^2 = \eta_k^2 + \sigma^2\eta_{k-l+1}^2 + (1-\sigma)^2\eta_{k-l}^2 - 2\sigma\eta_{kk-l+1} - 2(1-\sigma)\eta_k\eta_{k-l} + 2\sigma(1-\sigma)\eta_{k-l+1}\eta_{k-l}.$$

Defining

$$S_k = \sum_{j=0}^{\infty} \gamma^j \eta_{k-j}^2, \quad S_{k-l+1} = \sum_{j=0}^{\infty} \gamma^j \eta_{k-l+1-j}^2, \quad S_{k-l} = \sum_{j=0}^{\infty} \gamma^j \eta_{k-l-j}^2,$$

$$P_{k,k-l} = \sum_{j=0}^{\infty} \gamma^j \eta_{k-j}\eta_{k-l-j}, \qquad P_{k,k-l+1} = \sum_{j=0}^{\infty} \gamma^j \eta_{k-j}\eta_{k-l+1-j},$$

$$P_{k-l+1,k-l} = \sum_{j=0}^{\infty} \gamma^j \eta_{k-l+1-j}\eta_{k-l-j},$$

we see that

$$C_{k,l}(\sigma) = \sigma^2[S_{k-l+1} - S_{k-l} - 2P_{k-l+1,k-l}] + 2\sigma[S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l}] + [S_k + S_{k-l} - 2P_{k,k-l}].$$

The numbers S_k, S_{k-l}, S_{k-l+1} are included in $S_k, \cdots, S_{k-L_M}$, and these are stored in a "push-down" mode and updated via

$$S_{k+1} = \eta_{k+1}^2 + \gamma S_k, \qquad S_{(k+1)-1} = S_k, \cdots,$$

$$S_{(k+1)-L_M} = S_{k-(L_M-1)}.$$

Similarly $P_{k,k-l}$, $P_{k,k-l+1}$ are stored among $P_{k,k-1}, \cdots, P_{k,k-L_M}$ are are updated via

$$P_{k+1,k+1-l} = \eta_{k+1}\eta_{k+1-l} + \gamma P_{k,k-l}, \text{ etc.} \tag{4.4}$$

Finally, it is necessary to store

$$P_{k,k-1}, P_{k-1,k-2}, \cdots, P_{k-L_M+1,k-L_M}.$$

The numbers $P_{k,k-1}$ are also updated via (4.4) and

$$P_{(k+1)-l,(k+1)-(l+1)} = P_{k-(l-1),k-l}$$

defines the "push-down" operation.

With the above numbers available we clearly have

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma} = \sigma[S_{k-l+1} - S_{k-l} - 2P_{k-l+1,k-l}] + [S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l}]. \tag{4.5}$$

In particular,

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=0} = S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l},$$

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=1} = S_{k-l+1} - P_{k,k-l+1} + P_{k,k-l} - P_{k-l+1,k-l}.$$

Each pair l, σ corresponds to a delay $T(l, \sigma) = (l-\sigma)h$. Thus $C_{k,l}(\sigma)$ can be associated with a function $C_k(t)$ defined for $t_k - L_M h < t < t_k - L_m h$, the values of l corresponding, when $\sigma = 0$, to the points $t = t_k - lh$. As σ increases from zero to one we pass from $t = t_k - lh$ to $t = t_k - (l-1)h$. Thus we have

$$\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=0} = \frac{\partial C_k}{\partial t}\bigg|_{t=(t_k-lh)+},$$

$$\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=1} = \frac{\partial C_k}{\partial t}\bigg|_{t=(t_k-(l-1)h)-}.$$

It follows that $T(l, 0) = lh$ is a candidate for the minimizing value T_k just in case

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=0} \geqq 0, \qquad \frac{1}{2}\frac{\partial C_{k,l+1}}{\partial \sigma}\bigg|_{\sigma=1} \leqq 0,$$

i.e.,

$$S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l} \geqq 0,$$

$$S_{k-l} - P_{k,k-l} + P_{k,k-l+1} - P_{k-l,k-l-1} \leqq 0.$$

On the other hand, the interval $[(l-1)h, lh]$ is a candidate for containing the minimizing value of T_k just in case

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=1} > 0, \qquad \frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma}\bigg|_{\sigma=0} < 0,$$

i.e.,

$$S_{k-l+1} - P_{k,k-l+1} + P_{k,k-l} - P_{k-l+1,k-l} > 0, \tag{4.6}$$

$$S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l} < 0. \tag{4.7}$$

If (4.6), (4.7) are true for a given l, we compute the corresponding σ by setting (4.5) equal to zero, i.e.,

$$\sigma = -\frac{[S_{k-l} - P_{k,k-l+1} + P_{k,k-l} + P_{k-l+1,k-l}]}{[S_{k-l+1} - S_{k-l} - 2P_{k-l+1,k-l}]}. \tag{4.8}$$

Once the finitely many possible candidates for T_k have been selected by this process, T_k is chosen from these as the one yielding the smallest value of $C_{k,l}(\sigma)$.

It is possible to economize on memory space by using slightly modified quantities. With

$$\begin{aligned} &\rho_{k,l} = \eta_k - \eta_{k-l}, \qquad \hat{S}_{k,l} = \sum_{j=0}^{\infty} \gamma^j (\rho_{k-j,l})^2, \\ &\hat{P}_{k,l,l-1} = \sum_{j=0}^{\infty} \gamma^j \rho_{k-j,l}\rho_{k-j,l-1}, \qquad \hat{S}_{k,l-1} = \sum_{j=0}^{\infty} \gamma^j (\rho_{k-j,l-1})^2, \end{aligned} \tag{4.9}$$

updated via

$$\begin{aligned} &\rho_{k+1,l} = (\eta_{k+1} - \eta_k) + \rho_{k,l-1}, \qquad l = 1, 2, \cdots, L_M, \\ &\hat{S}_{k+1,l} = (\rho_{k+1,l})^2 + \gamma \hat{S}_{k,l}, \qquad l = 1, 2, \cdots, L_M, \\ &\hat{P}_{k+1,l,l-1} = \rho_{k+1,l}\rho_{k+1,l-1} + \gamma \hat{P}_{k,l,l-1}, \qquad l = 2, \cdots, L_M, \end{aligned}$$

it may be seen that we have

$$C_{k,l}(\sigma) = \sigma^2[\hat{S}_{k,l} - 2\hat{P}_{k,l,l-1} + \hat{S}_{k,l-1}] - 2\sigma[\hat{S}_{k,l} - \hat{P}_{k,l,l-1}] + \hat{S}_{k,l-1} \tag{4.10}$$

so

$$\frac{1}{2}\frac{\partial C_{k,l}}{\partial \sigma} = \sigma[\hat{S}_{k,l} - 2\hat{P}_{k,l,l-1} + \hat{S}_{k,l-1}] - [\hat{S}_{k,l} - \hat{P}_{k,l,l-1}]$$

and this vanishes when

$$\sigma = [\hat{S}_{k,l} - \hat{P}_{k,l,l-1}]/[\hat{S}_{k,l} - 2P_{k,l,l-1} + \hat{S}_{k,l-1}].$$

The other aspects of the analysis remain as above. This procedure is one actually used in FORTRAN SUBROUTINE PERIOD (LMAX, LMIN, GAMMA, H, PER, Y), whose listing is included here and which forms the basis for the numerical experiments carried out in § 5.

If there is some danger of confusing the minimal period T with one of its multiples $2T$, $3T$, etc., this can usually be overcome by specifying LMIN, LMAX correctly.

5. Some numerical experience with period. We have carried out extensive computer based simulations using SUBROUTINE PERIOD described in the preceding section. Here we will describe results obtained in connection with the plant

$$\begin{pmatrix} \dot{x}^1 \\ \dot{x}^2 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 0 & -.2 \end{pmatrix} \begin{pmatrix} x^1 \\ x^2 \end{pmatrix} + \begin{pmatrix} 0 \\ 28 \end{pmatrix} (u+v) \tag{5.1}$$

with

$$v(t) = z^1(t), \tag{5.2}$$

$$\begin{pmatrix} \dot{z}^1 \\ \dot{z}^2 \end{pmatrix} = \begin{pmatrix} 0 & \alpha \\ -\alpha & 0 \end{pmatrix} \begin{pmatrix} z^1 \\ z^2 \end{pmatrix}. \tag{5.3}$$

The rather nondescript parameters appearing in (5.1) result from the fact that this damped inertial system is a model for a certain physical plant of interest. A compensator was constructed in the form (0.7) using $S=-\varepsilon P_0^*$ with P_0 as in (1.10). To provide a more or less standard basis of comparison the feedback coefficients in all cases were chosen to achieve critical damping (i.e., multiple real eigenvalues) at various rates in the closed loop matrix

$$A+CK=\begin{pmatrix} 0 & 1 \\ 28k_1 & -.2+28k_2 \end{pmatrix}. \tag{5.4}$$

The feedback coefficients k_1 and k_2 are identified as FB1 and FB2, respectively, on the accompanying figures. In this very simple example

$$B=\begin{pmatrix} 0 & 0 \\ 28 & 0 \end{pmatrix}, \quad C=\begin{pmatrix} 0 \\ 28 \end{pmatrix}, \quad -L=(1,0)$$

and Φ is chosen to be the 2×2 identity matrix. For the values of k_1 and k_2 which were used P_0 turns out to be a very small matrix and we used $\varepsilon=1000$.

The output used for the period estimation was $w(t)=x^1(t)+y^1(t)$ and the output shown on the diagrams is $x^1(t)$. It will be seen that the initial estimates for the period $T(t)$ are wildly inaccurate but, in the cases when the complete plant/compensator/identifier system is asymptotically stable, the estimate $T(t)$ converges to the correct value T_0 (within the accuracy permitted by the approximations inherent in PERIOD, as described in the preceding section). In all cases we selected $z^1(0)=1$, $z^2(0)=0$, so that

$$z^1(t)=\cos(\alpha t), \qquad z^2(t)=-\alpha\sin(\alpha t).$$

In Figs. 1-16 the odd numbered figures show the output $x^1(t)$ while the next, even numbered figure in each case shows the period estimate $T(t)$ for the same run.

Figures 1 through 4 correspond to choices of k_1 and k_2 such that the matrix (5.4) has a double eigenvalue $\lambda=-5$. In Figs. 1 and 2 $\alpha_0=20\pi$ (10 Hertz) corresponding to $T_0=.1$, indicated by the dotted line. Figures 3 and 4 illustrate the corresponding experience for $\alpha_0=30\pi$ (15 Hertz), or $T_0=.0667$. Here the period identifier diverges from the correct value and, as seen in Fig. 3, no significant reduction of the oscillation of $x^1(t)$ is realized. We believe that this is accounted for by the fact that the term $2\pi/(T_0)^2$ in (2.21) changes from 200π in the 10 Hz case to 450π in the 15 Hz case.

Figures 5 through 8 show the 10 Hz case with k_1 and k_2 chosen so that (5.4) has a double eigenvalue $\lambda=-8$ (Figs. 5 and 6) and with k_1 and k_2 chosen so that $\lambda=-9$ (Figs. 7 and 8). These cases seem quite satisfactory with rapid attenuation of the oscillation in $x^1(t)$, better in the second case than in the first, and rapid convergence of the period estimate $T(t)$ to $T_0=.1$. The corresponding experience in the 15 Hz case is not nearly so satisfactory. Figures 9 and 10 show the performance for $\lambda=-8.5$ while Figs. 11 and 12 show $\lambda=-10$. We see from Figs. 10 and 12 that, although the value T_0 is unstable, the estimate $T(t)$ tends to undergo a self-excited oscillation about the equilibrium value indicated by the dotted lines. The evidence favors the conjecture that in these cases the nonlinear equation (2.11) may exhibit a Hopf type bifurcation as the parameter T_0 passes from .1 (10 Hz) to .0667 (15 Hz). Detailed analysis of this possibility must await later treatment.

Figures 13 through 16 show experience in the 15 Hz case with k_1 and k_2 selected so that $\lambda=-14$ (Figs. 13 and 14) and so that $\lambda=-20$ (Figs. 15 and 16). We see that the performance improves as (5.4) is made progressively more stable, in agreement with the conjectures of § 3. The small residual oscillation evident in Fig. 15 is probably

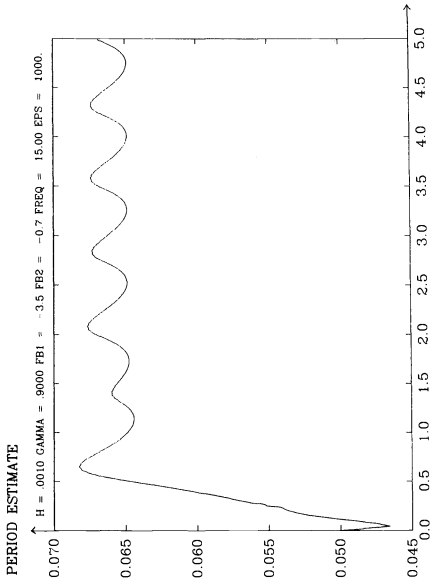

FIG. 12

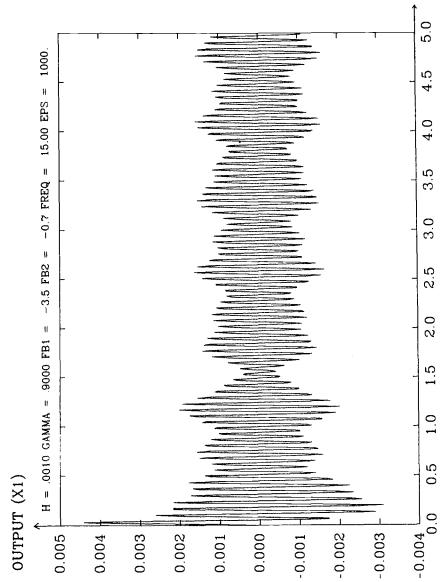

FIG. 11

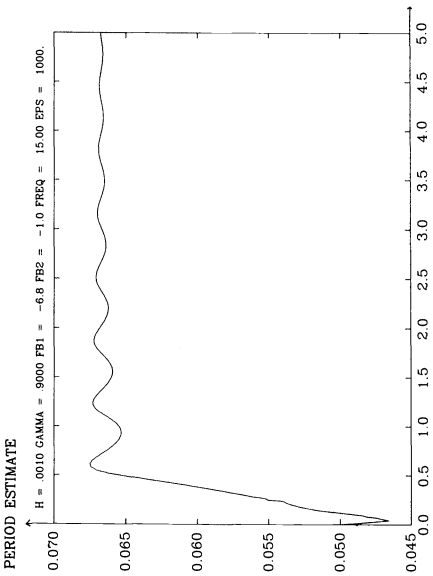

FIG. 14

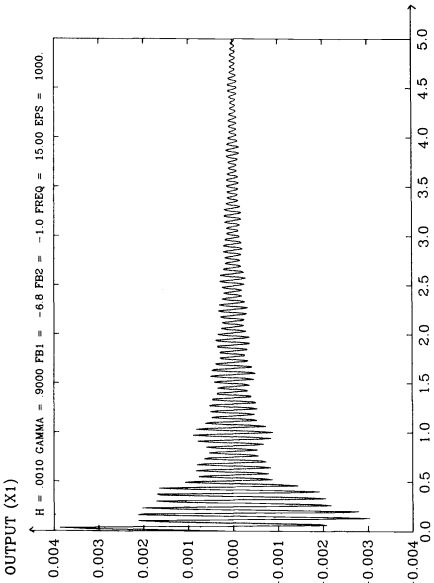

FIG. 13

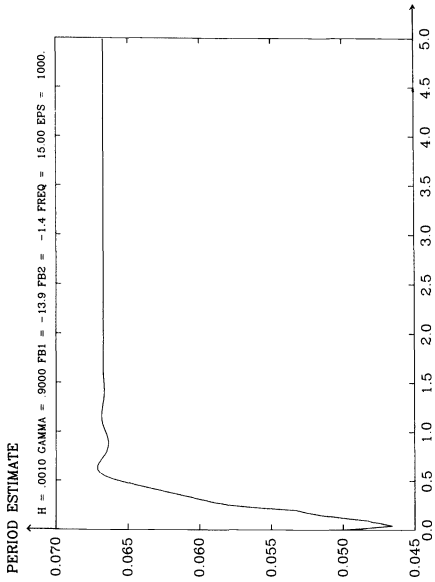

FIG. 16

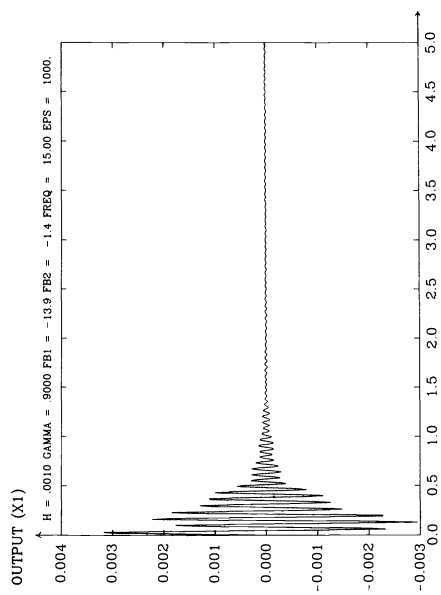

FIG. 15

due to the fact that PERIOD does not provide an exact estimate even when the corresponding continuous process associated with minimization of (2.4) or (2.6) is asymptotically stable.

Figures 17 and 18 show variational ΔT solutions, obtained in the manner described at the end of § 3, for the 15 Hz case with $\lambda = -9$ and $\lambda = -14$, respectively. Because $T(t)$ does not converge to T_0 in the first case (cf. Fig. 12), even the variational solutions are not sinusoidal.

In Fig. 18, corresponding to $\lambda = -14$, $T(t)$ converges to $T_0 = .0667$ (cf. Fig. 14) and the corresponding variational solution tends to zero in a convincing exponentially damped sinusoidal manner, this behavior becoming more convincing as t increases. It is of interest to estimate the frequencies and damping factors here and compare them with the eigenvalues of $M(\alpha_0)$, $F(\alpha_0)$. Analyzing the data plotted in Fig. 18 one obtains the estimate $T = .66$ and, comparing the successive amplitudes, we see that the oscillation there is approximated by

$$C_+ e^{(-.525+i9.52)t} + C_- e^{(-.525-i952)t}. \tag{5.5}$$

Here

$$M(\alpha_0) = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -190.12 & -27.188 & -28 & 0 \\ -2.966 & 82.417 & 0 & 1 \\ -.009 & -2.966 & -8873.8 & 0 \end{pmatrix}$$

and its eigenvalues may be computed to be

$$-2.77 \pm i105.32, \qquad -10.82 \pm i5.9.$$

None of these corresponds to (5.5) and we conclude that the dynamics exhibited in the identification process arise from a different source which, on the basis of our earlier investigations in this paper, we believe to be the functional equation (2.22) (equivalently (2.19), (2.20)).

In Figs. 19 through 26 we indicate the effect of varying the parameters γ and ε (cf. (1.9), (2.4)) while leaving the feedback parameters in K fixed at the values which produced Figs. 13 and 14 with $\gamma = .9$ and $\varepsilon = 1000$. This corresponds to the double eigenvalue $\lambda = -14$ for (5.4). Here it needs to be explained that the value "GAMMA" referred to on the figure heading corresponds to $e^{-\gamma h}$, where h is the length of the sampling interval used by PERIOD. For all cases studied here h is ten times the H value shown in the figure heading; thus $h = .01$ and

$$\text{GAMMA} = .8 = e^{-.01\gamma} \to \gamma = \frac{\log_e .8}{-.01} = -22.3,$$

$$\text{GAMMA} = .9 \to \gamma = -10.5,$$

$$\text{GAMMA} = .95 \to \gamma = -5.13.$$

As we see by comparison of Figs. 19 and 20 with 13 and 14, performance is substantially degraded by discounting past values too much; $\gamma = -5.13$ gives better performance than $\gamma = -10.5$.

For Figs. 23 and 24 we have set GAMMA = .9 again but have increased ε to 2000 rather than the earlier 1000. The improvement over the results in Figs. 13 and 24 is

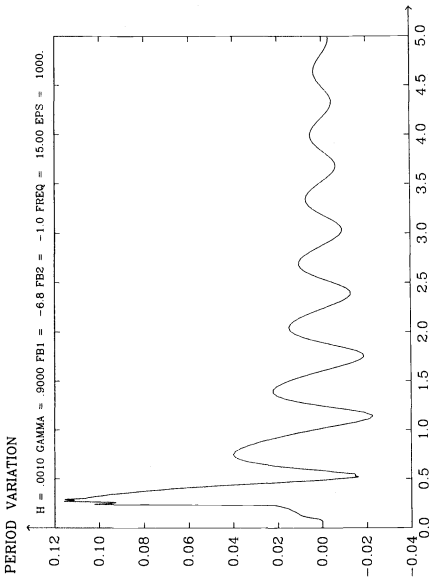

FIG. 18

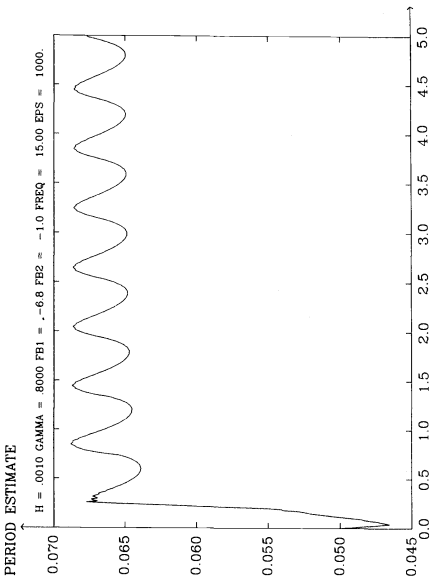

FIG. 20

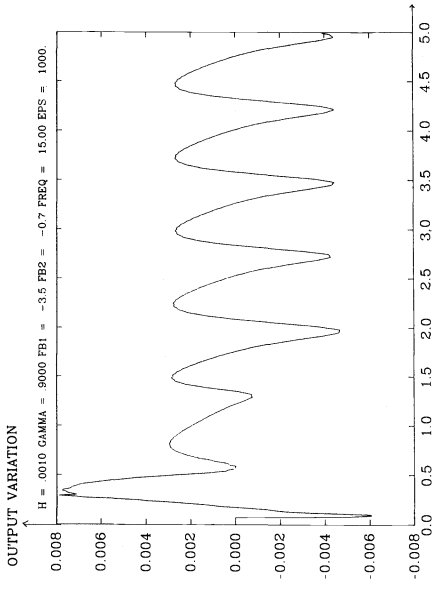

FIG. 17

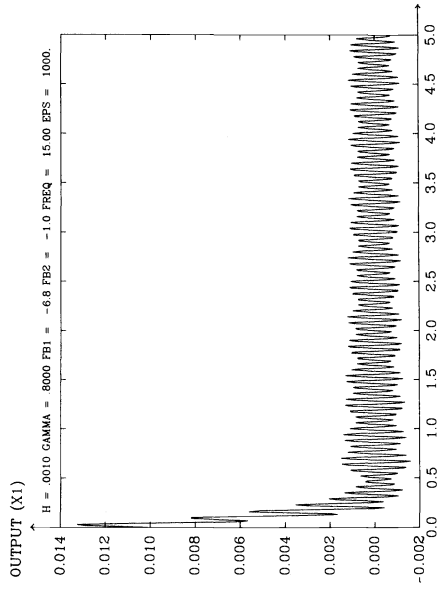

FIG. 19

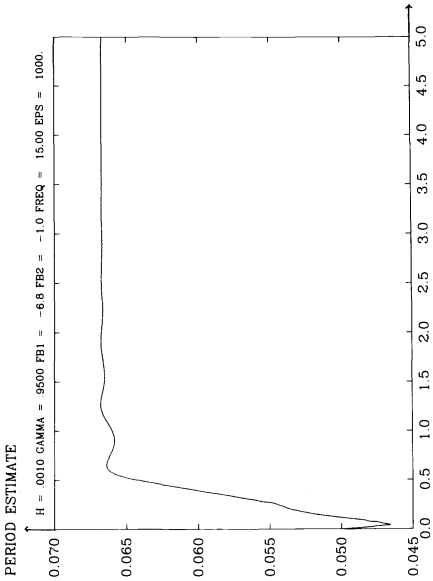

FIG. 22

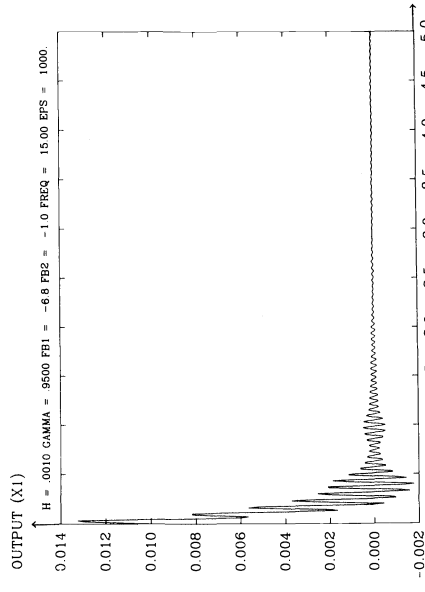

FIG. 21

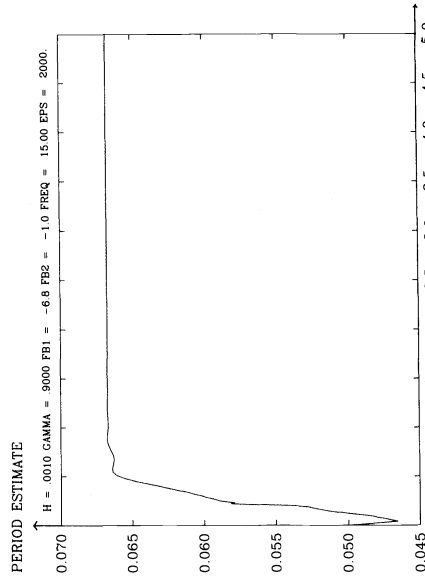

FIG. 24

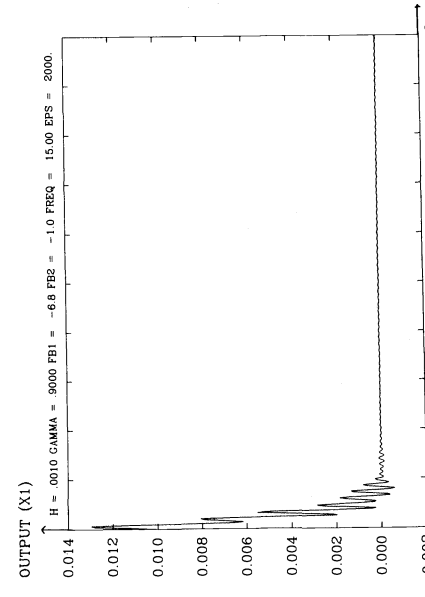

FIG. 23

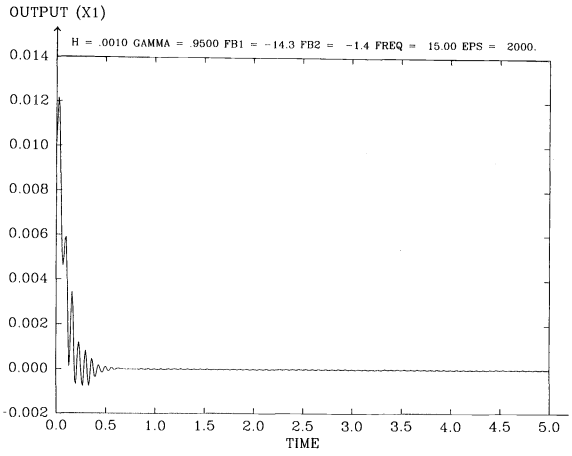

FIG. 25

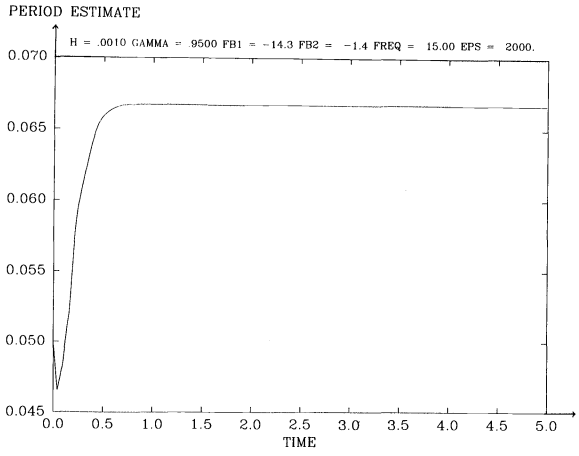

FIG. 26

again quite marked. To obtain the results of Figs. 25 and 26 we "pulled out all the stops" and set GAMMA = .95, $\varepsilon = 2000$ and chose feedback parameters corresponding to a double eigenvalue $\lambda = -20$ for (5.4). Here we finally obtain the sort of sinusoidal disturbance rejection one would hope for.

To summarize our work: we have presented a method, based on a certain optimality criterion, for identification of the period of a periodic disturbance affecting a finite-dimensional linear dynamic disturbance decoupling procedures. We have shown that the linearized dynamics of the plant/compensator/estimator in the neighborhood of the equilibrium trajectory are governed by a certain Volterra type functional equation with periodic coefficients. That functional equation has been analyzed, in brief, and its stability characteristics have been seen to be determined by the location of the characteristic exponents of certain solutions of "Floquet type." Numerical studies have been presented indicating how variation of the design parameters of the system affect the overall performance and indications for needed future research have been given.

6. Appendix: Sketch of the proof of Theorem 5. Let $z(t)$, $W(t, s)$, etc., be as in the statement of Theorem 5. For any $t \geqq 0$ we have

$$\begin{aligned} z(t) &= \int_{-\infty}^{t} W(t, s)z(s)\, ds \\ &= \int_{kT}^{t} W(t, s)z(s)\, ds + \int_{0}^{kT} W(t, s)z(s)\, ds + \int_{-\infty}^{0} W(t, s)\tilde{z}(s)\, ds, \end{aligned} \tag{6.1}$$

where k is the largest integer such that $kT \leqq t$. We define $z_l \in L_m^2[0, T]$ by

$$z_l(\tau) = z((l-1)T + \tau), \quad \tau \in [0, T], \quad l \geqq 1,$$

and we define $\tilde{z}_{-l} \in L_m^2[0, t]$ by

$$\tilde{z}_{-l}(\tau) = \tilde{z}(-(l+1)T + \tau), \quad \tau \in [0, T], \quad l \geqq 0.$$

Then, with

$$t = kT + \tau, \quad s = lT + \sigma, \quad s \in [lT, (l+1)T],$$

(6.1) yields

$$\begin{aligned} z_{k+1}(\tau) &- \int_{0}^{\tau} W(kT + \tau, kT + \sigma)z_{k+1}(\sigma)\, d\sigma \\ &- \sum_{j=1}^{k} \int_{0}^{T} W(kT + \tau, (j-1)T + \sigma)z_j(\sigma)\, d\sigma \\ &= \sum_{l=0}^{\infty} \int_{0}^{T} W(kT + \tau, -(l+1)T + \sigma)\tilde{z}_{-l}(\sigma)\, d\sigma. \end{aligned} \tag{6.2}$$

Using the periodicity relation (3.7) we have

$$W(kT + \tau, (j-1)T + \sigma) = W(\tau, -(k-j)T + \sigma) \equiv W_{k-j}(\tau, \sigma)$$

for any integer $j \leqq k$. Then (6.2) becomes

$$\begin{aligned} z_{k+1}(\tau) &= \int_{0}^{\tau} W_0(\tau, \sigma)z_{k+1}(\sigma)\, d\sigma - \sum_{j=1}^{k} \int_{0}^{T} W_{k+1-j}(\tau, \sigma)z_j(\sigma)\, d\sigma \\ &= \sum_{l=0}^{\infty} \int_{0}^{T} W_{k+1+l}(\tau, \sigma)\tilde{z}_{-l}(\sigma)\, d\sigma. \end{aligned} \tag{6.3}$$

The conditions (3.7), (3.8) show that the last sum converges in $L_m^2[0, T]$. We may write (6.3) as a vector linear recursion equation in $L_m^2[0, T]$

$$(I - P_0)z_{k+1} - \sum_{j=1}^{k} P_{k+1-j}z_j = \sum_{l=0}^{\infty} P_{k+1+l}\tilde{z}_{-l} \tag{6.4}$$

where

$$(P_0 z)(\tau) = \int_{0}^{\tau} W_0(\tau, \sigma)z(\sigma)\, d\sigma,$$

$$(P_k z)(\tau) = \int_{0}^{T} W_k(\tau, \sigma)z(\sigma)\, d\sigma, \qquad k = 1, 2, 3, \cdots.$$

As is well known [3], $I - P_0$ is boundedly invertible, and $P_0, P_1, P_2, \cdots$ are all compact. Then

$$Q_{-k} = -(I - P_0)^{-1}P_k, \qquad k = 1, 2, 3, \cdots \tag{6.5}$$

are all compact and, keeping (3.7) in mind, it may be seen that for some positive number D

$$\|Q_{-k}\| \leqq D e^{-kcT}, \qquad k = 1, 2, 3, \cdots. \tag{6.6}$$

Then (6.4) can be written, with an obvious re-indexing, as

$$z_k + \sum_{l=-k+1}^{-1} Q_l z_{l+k} + \sum_{l=-\infty}^{-k} Q_l \tilde{z}_{l+k}, \qquad k = 1, 2, 3, \cdots. \tag{6.7}$$

Given a sequence $\{y_k | -\infty < k < \infty\} CH$, where H is a Hilbert space, and supposing that

$$\|y_k\| \leqq M^+(\gamma+)^k, \qquad k = 1, 2, 3, \cdots, \tag{6.8}$$

$$\|y_k\| \leqq M^-(\gamma-)^k, \qquad k = 0, -1, -2, -3, \cdots, \tag{6.9}$$

where M^+, M^-, γ^+, γ^- are all positive numbers and $\gamma^+ \geqq \gamma^-$, we define the bilateral "Z-transform" (discrete Laplace transform) of $\{y_k\}$ by

$$\eta(\gamma) = \begin{cases} \sum_{k=1}^{\infty} y_k \lambda^{-k} \equiv \eta^+(\lambda), & |\lambda| > \gamma^+, \\ -\sum_{k=0}^{\infty} y_{-k} \lambda^k \equiv \eta^-(\lambda), & |\lambda| < \gamma^-. \end{cases} \tag{6.10}$$

Clearly, $\eta(\lambda)$ is analytic in neighborhoods of both 0 and ∞. In many cases $\eta^+(\lambda)$ and $\eta^-(\lambda)$ are analytic continuations of each other. For example, if for all integers k

$$y_k = \mu^k y_0, \quad y_0 \in H, \quad \mu \neq 0,$$

then with $\gamma^+ = \gamma^- = |\mu|$, $M^+ = M^- = 1$, all of the above are valid for

$$\eta^+(\lambda) = \eta(\lambda), \quad |\lambda| > |\mu|, \quad \eta^-(\lambda) = \eta(\lambda), \quad |\lambda| < |\mu|, \quad \eta(\lambda) = \frac{1}{\lambda - \mu}.$$

If, correspondingly, $\{Q_k | -\infty < k < \infty\}$, is a sequence of bounded operators on H such that

$$\|Q_k\| \leqq B^+(\rho^+)^{-k}, \qquad k = 1, 2, 3, \cdots, \tag{6.11}$$

$$\|Q_{-k}\| \leqq B^-(\rho^-)^{-k}, \qquad k = 0, -1, -2, \cdots, \tag{6.12}$$

where B^+, B^-, ρ^+, ρ^- are all positive (and $\rho^+ > \gamma^+$, $\rho - < \gamma^-$ in our application), we may define the discrete Fourier transform of $\{Q_k\}$ by

$$Q(\lambda) = \sum_{k=-\infty}^{\infty} Q_k \lambda^k. \tag{6.13}$$

Clearly the series converges and $Q(\lambda)$ is a holomorphic operator valued function for $\rho^- < |\lambda| < \rho^+$. If $Q_k = 0$ for all positive k, then ρ^+ may be taken to be ∞ and $Q(\lambda)$ will be homomorphic for $|\lambda| > \rho^-$, including $\lambda = \infty$.

The convolution of $\{Q_k\} \equiv Q$ and $\{y_k\} \equiv y$ is defined by

$$f_l \equiv (Q^* y)_l = \sum_{k=-\infty}^{\infty} Q_k y_{k+l}, \tag{6.14}$$

the sum being convergent when (6.8), (6.9), (6.11) and (6.12) apply and $\rho^+ > \gamma^+$, $\rho^- < \gamma^-$, as we suppose. To anyone familiar with transforms of this type the first question occurring concerns the relationship of the transform $\phi(\lambda)$ of $\{f_l\}$ to the

transforms $Q(\lambda)$, $\eta(\lambda)$. The answer is easy but not completely obvious. Let Γ^+ and Γ^- be positively oriented circles centered at $\lambda = 0$ with radii r^+, r^-, $\gamma^+ < r^+ < \rho^+$, $\rho^- < r^- < \gamma^-$. Then, as we show in the more complete discussion [7], if $\Gamma = \Gamma^+ - \Gamma^-$ and λ lies in the exterior of the annular regions between Γ^+ and Γ^-,

$$\phi(\lambda) = \frac{1}{2\pi i} \int_\Gamma \frac{Q(\zeta)\eta(\zeta)\, d\zeta}{\lambda - \zeta}. \tag{6.15}$$

This condition is necessary and sufficient for (6.14) to be true.

When $Q_k = 0$ for k positive and Q_0 has a bounded inverse, (6.14) becomes

$$\sum_{k=-\infty}^{0} Q_k y_{k+l} = f_l \tag{6.16}$$

and, given the initial values

$$y_{-l} = \tilde{y}_{-l}, \qquad l = 0, 1, 2, 3, \cdots, \tag{6.17}$$

and $f_1, f_2, f_3, \cdots$, we can compute $y_1, y_2, y_3, \cdots$. The case of interest to us is the homogeneous case $f_1 = f_2 = f_3 = \cdots = 0$. Here it may be seen that with

$$\tilde{\eta}(\lambda) = \sum_{l=0}^{\infty} \tilde{y}_{-l}\lambda^l, \qquad \eta(\lambda) = \sum_{k=1}^{\infty} y_k \lambda^{-k}, \tag{6.18}$$

and for $|\lambda| > r^-$, λ not a singularity of $Q(\lambda)$

$$\eta(\lambda) = \frac{1}{2\pi i} Q(\lambda)^{-1} \int_{\Gamma^-} \frac{Q(\zeta)\tilde{\eta}(\zeta)\, ds}{\lambda - \zeta}. \tag{6.19}$$

Since $Q(\lambda)$ is analytic at $\lambda = \infty$ and $Q(\infty) = Q_0$, which is nonsingular, if we take r^+, the radius of Γ^+, so large that all singularities of $Q(\lambda)$ are included in the interior of Γ^+, then the individual y_k, $k = 1, 2, 3, \cdots$ may be recovered via

$$y_k = \frac{1}{2\pi i} \int_{\Gamma^+} \eta(\lambda)\lambda^{k-1}\, d\lambda, \qquad k = 1, 2, 3, \cdots. \tag{6.20}$$

With the use of formula (6.16) the proof of Theorem 5 may be completed. In our application $H = L_m^2[0, T]$, $Q_k = 0$ for k positive, $Q_0 = I, Q_{-1}, Q_{-2}, Q_{-3}, \cdots$ are all compact and the series (6.13) converges uniformly for $|\lambda| \geqq r^- + \delta$ for any $\delta > 0$. It is known [1], [5] that the singularities of $Q(\lambda)$ must be isolated in any such region and, for each such singularity λ_k the null space of $Q(\lambda_k)$ must be finite-dimensional. Let Γ_δ^- be the circle centered at zero with radius $r^- + \delta$. We may assume that Γ_δ^- meets no singularities of $Q(\lambda)$. Then, applying (6.16) to the z_k of (6.7) we have

$$\begin{aligned} z_k &= \frac{1}{2\pi i} \int_{\Gamma_\delta} \eta(\lambda)\lambda^{k-1}\, d\lambda + \frac{1}{2\pi i} \int_{\Gamma_\delta^-} \eta(\lambda)\lambda^{k-1}\, d\lambda \\ &= z_{k,F} + z_{k,r^-+\delta}, \qquad k = 1, 2, 3, \cdots, \end{aligned} \tag{6.21}$$

where $\Gamma_\delta = \Gamma^+ - \Gamma_\delta^-$. From (6.19) and (6.21) it is clear that

$$\| z_{k,r^-+\delta} \| \leqq \tilde{M}(r^- + \delta)^k$$

where $\tilde{M}$ is a constant which may be bounded in terms of $\tilde{\eta}$, hence in terms of the $\tilde{z}_{-l}$, $l = 0, 1, 2, \cdots$. On the other hand,

$$z_{k,F} = \sum_{\lambda_2 \in \operatorname{Int} \Gamma_\delta} \lambda_j^k \operatorname{Res} \eta(\lambda_j).$$

In the case of a simple eigenvalue λ_j with one-dimensional null space, which is all we will study here, from the formula (6.19) for η it may be seen that

$$\text{Res } \eta(\lambda_j) = \frac{1}{(\psi_j, Q^*(\lambda_j)\phi_j)} \int_{\Gamma^-} \frac{(\psi_j, Q(\zeta)\tilde{\eta}(\zeta)\, ds}{\lambda_2 - \zeta} \phi_j \tag{6.22}$$

where ϕ_j is a nonzero vector in the one-dimensional null space of $Q(\lambda_j)$ and ψ_j is a corresponding vector in the null space of $Q(\lambda_j)^*$ such that $(\psi_j, \phi_j)_{L_m^2[0,T]} = 0$. We see in any case that $z_{k,F}$ is a sum of the form

$$z_{k,F} = \sum_{\lambda_j \in \text{Int } \Gamma_\delta} \lambda_j^k C_j \phi_j, \qquad k = 1, 2, 3, \cdots. \tag{6.23}$$

The corresponding solutions $z_F(t)$, $z_\beta(t)$ of (3.6) (or (6.1)) are obtained by inverting the transformations which follow (6.1). The term $e^{-\beta T}$ of (3.11) is identified with $r^- + \delta$. It is greater than e^{-CT} which is identified with r^-. Thus $z_\beta(t)$ satisfies (3.11).

Since $z_F(t)$ is a solution of (6.2), the form of that equation shows that $z_F(t)$ must be a continuous function. The form (6.23) then implies that z_F on any interval $[kT, (k+1)T]$ is λ_j times the corresponding value of z_F on $[(k-1)T, kT]$. From this it is clear that

$$\phi_j(t) = \lambda_j \phi_j(0).$$

We identify $e^{\lambda T}$ in (3.12) with λ_j and $P(T)$ with the T-periodic extension of $e^{-\lambda t}\phi_j(t)$ (which satisfies

$$P(T) = e^{-\lambda T}\phi_j(T) = \lambda_j^{-1}\phi_j(T) = \phi_j(0) = e^{-\lambda 0}\phi_j(0) = P(0)).$$

Thus, modulo the usual remarks which must apply to nonsimple poles of $Q(\lambda)^{-1}$, which lead to solutions of the form (3.13), we have completed the proof of Theorem 5. Further details may be found in [7]. The main point of the theorem is that the dominant solutions of (3.6) (or (6.1)) are those associated with the larger singularities of $Q(\lambda)$ and those solutions are of the type (3.12) or (3.13).

Acknowledgment. I would like to express my thanks to Dr. Norman Coleman, Jr. of ARRADCOM, Dover, New Jersey, for background information and helpful conversations which stimulated the development of this work.

CONTROL OF AN ELLIPTIC PROBLEM WITH POINTWISE STATE CONSTRAINTS*

EDUARDO CASAS†

Abstract. This paper deals with a quadratic control problem for elliptic equations with pointwise state constraints. Existence and uniqueness of the solution is proved. Optimality conditions are given and regularity of the optimal solution is investigated.

Key words. quadratic control problems, pointwise state constraints, elliptic equations, optimality conditions, Borel measures, Sobolev spaces, Lagrange multipliers

AMS(MOS) subject classification. 49B22

1. Introduction. This paper is concerned with distributed control problems with restrictions on the control u as well as on the state y. Our main interest is the derivation of optimality conditions and regularity results.

Let $\Omega \subset R^n$ $(1 \leqq n \leqq 3)$ be an open and bounded set whose boundary Γ is Lipschitz continuous (Nečas [17]) and Ω is locally on one side of Γ.

Let us consider the following differential operator

$$Ay = -\sum_{i,j=1}^{n} \partial_{x_j}(a_{ij}\partial_{x_i} y) + a_0 y \tag{1.1}$$

where

$$\begin{aligned} &a_0 \in L^\infty(\Omega), \quad a_0(x) \geqq 0 \quad \text{a.e. } x \in \Omega, \\ &a_{ij} \text{ is Lipschitz on } \bar{\Omega} \qquad (1 \leqq i, j \leqq n), \\ &\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq \alpha|\xi|^2, \quad \alpha > 0, \quad \forall x \in \Omega, \quad \forall \xi \in R^n. \end{aligned} \tag{1.2}$$

Our aim is to consider a control problem for the system governed for the following equation

$$\begin{aligned} &Ay = v \quad \text{on } \Omega, \\ &y = 0 \qquad \text{on } \Gamma. \end{aligned} \tag{1.3}$$

It is well known (Nečas [17]) that the problem (1.3) has a unique solution $y(v) \in H_0^1(\Omega)$ for each $v \in L^2(\Omega)$, where $H^m(\Omega)$ and $H_0^m(\Omega)$, m being an integer, are the usual Sobolev spaces on Ω.

We will assume that the problem (1.3) satisfies the following regularity condition: for each $v \in L^2(\Omega)$, $y(v) \in H^2(\Omega)$ and

$$\|y(v)\|_{H^2(\Omega)} \leqq c\|v\|_{L^2(\Omega)} \tag{1.4}$$

where $c \in R$.

The condition (1.4) is satisfied, for example, if either $\Omega \in R^{(1),1}$ (Nečas [17]) or Ω is a polygonally $(n=2)$ or polyhedrally $(n=3)$ convex set open (Grisvard [10]).

Let K be a nonempty, convex and closed subset of $L^2(\Omega)$ and let J be the functional

$$J(v)=\frac{1}{2}\int_\Omega (y(v)-y_0)^2\,dx+\frac{r}{2}\int_\Omega v^2(x)\,dx \tag{1.5}$$

where y_0 is a fixed element of $L^2(\Omega)$ and $r\geqq 0$.

We consider the following control problem:

$$\text{(P)}\qquad \begin{array}{ll}\text{Minimize} & J(v)\\ \text{Subject to} & v\in K \text{ and } |y(v;x)|\leqq 1 \quad \forall x\in\Omega.\end{array}$$

There are several papers dealing with control problems with state constraints. In these problems, there exists a fundamental difference between integral and pointwise state constraints. Lagrange multipliers in the optimality conditions are integrable functions in the first case and measures in the second case. The choice of the functional spaces is very important for proving the existence of a Lagrange multiplier associated with the constraint in the state, Bonnans and Casas [5], [6].

One of the first papers in distributed optimal control problems with state constraints was written by Mossino [15]. She studies a dual control problem, but she cannot prove the existence of a solution (which would be a Lagrange multiplier) because the choice of the functional spaces is not suited to the state constraint. See also [21].

The existence of this multiplier is interesting because it allows one to prove regularity results of the optimal control and state, which is useful in determining error estimates for approximating schemes. Barbu and Precupanu [3] and Lasiecka [11] derive the existence of a Lagrange multiplier for some control problems with integral state constraints.

Mackenroth in [14] considers a parabolic system controlled by Neumann conditions and subject to pointwise state constraints on the final state. He, like Mossino, studies a dual control problem, but now the functional spaces are well chosen, which allows one to prove the existence of a multiplier as a solution of this dual problem.

In this paper, the first objective is to prove the existence of a Lagrange multiplier which allows one to derive the optimality conditions. This is done by a direct and simple method that uses the well-known results of convex analysis. We do this without introducing any dual control problem. We prove that this multiplier is a Borel measure. This is done in § 2. In § 3, we study some properties of these measures.

In § 4, we give some regularity results for the optimal control and state, which is the second objective of this paper.

Smoothness properties of solutions to distributed control problems for systems governed by parabolic equations subject to control constraints have been proved by Lasiecka and Malanowski [12]. Lasiecka [11] derives some regularity properties of optimal solutions of distributed control problems with state constraints in integral form. The author is not aware of other regularity results for problems with pointwise state constraints governed by partial differential equations other than these proved in this paper and those proved in [5] for a different problem and using different techniques.

2. Existence of solution and optimality conditions. Let $C(\bar\Omega)$ be the space of real and continuous functions on $\bar\Omega$, endowed with the supremum-norm $\|\ \|_\infty$. It is known [1] that $H^2(\Omega)\subset C(\bar\Omega)$ $(1\leqq n\leqq 3)$, the inclusion being continuous.

We will denote by $C_0(\Omega)$ the subspace of $C(\bar\Omega)$ formed by the null functions on Γ. Then it is obvious that $H^2(\Omega)\cap H_0^1(\Omega)$ is included in $C_0(\Omega)$, the inclusion being continuous.

Let us denote the linear map $v\to y(v)$ by T, $T: L^2(\Omega)\to C_0(\Omega)$. An obvious consequence of (1.4) is that T is continuous.

Let B be the following subset:

$$B=\{z\in C_0(\Omega):\ \|z\|_\infty\leqq 1\}$$

and let I_B be the indicator of B

$$I_B(z)=\begin{cases}+\infty & \text{if } z\notin B,\\ 0 & \text{if } z\in B.\end{cases}$$

Then the problem (P) can be stated in the following way:

$$\inf_{v\in K}\{J(v)+(I_B\circ T)(v)\}. \tag{2.1}$$

Now we assume that the following hypothesis holds:

$$\text{Either } K \text{ is bounded in } L^2(\Omega) \text{ or } r>0. \tag{2.2}$$

THEOREM 1. *Suppose that there exists an element $v_0\in K$ such that $Tv_0\in B$. Then, under the hypothesis* (2.2), (P) *has a unique optimal solution.*

The proof is standard (Lions [13]), it is enough to note that $J+I_B\circ T$ is a lower semicontinuous convex functional and, from (2.2), the problem (P) is coercive. Note also that, even if $r=0$, the functional J is strictly convex and so we deduce the uniqueness of the solution.

To derive some optimality conditions, we will assume that the following Slater condition holds:

$$\exists v_0\in K \text{ such that } Tv_0\in \mathring{B}. \tag{2.3}$$

We will denote by $M(\Omega)$ the space of all real and regular Borel measures on Ω endowed with the norm

$$\|\mu\|_{M(\Omega)}=|\mu|(\Omega) \tag{2.4}$$

where $|\mu|$ is the total variation measure of μ.

According to the Riesz representation theorem (Rudin [19]), $M(\Omega)$ is the dual space of $C_0(\Omega)$ and the following equality holds:

$$|\mu|(\Omega)=\sup_{z\in B}\int_\Omega z\,d\mu. \tag{2.5}$$

Now we consider the space $H=H^2(\Omega)\cap H_0^1(\Omega)$ endowed with the norm $\|\ \|_{H^2(\Omega)}$. It is obvious that H is a Hilbert space. On the other hand, since the coefficients a_{ij} $(1\leqq i,j\leqq n)$ are Lipschitz functions, we see that $Az\in L^2(\Omega)$ for all $z\in H^2(\Omega)$ and so it follows from (1.4) that A is an isomorphism from H onto $L^2(\Omega)$.

As usual, we will denote by $\partial\psi$ the subdifferential of a convex function (Rockafellar [18], Ekeland and Temam [9]).

THEOREM 2. *Under the hypothesis* (2.3), *$u\in K$ is a solution of the problem* (P) *if and only if there exist $\mu\in M(\Omega)$, $p\in L^2(\Omega)$ and $y\in H$ such that*

$$Ay=u \quad \text{on } \Omega, \tag{2.6}$$

$$\int_\Omega pAz\,dx=\int_\Omega z(y-y_0)\,dx+\int_\Omega z\,d\mu \quad \forall z\in H, \tag{2.7}$$

$$\int_\Omega y\,d\mu=\sup_{z\in B}\int_\Omega z\,d\mu, \qquad y\in B, \tag{2.8}$$

$$\int_\Omega (p+ru)(v-u)\,dx\geqq 0 \quad \forall v\in K. \tag{2.9}$$

Proof. u is a solution of the problem (P) if and only if u minimizes in $L^2(\Omega)$ the functional

$$\psi(v) = J(v) + (I_B \circ T)(v) + I_K(v) \tag{2.10}$$

where I_K is the indicator of K.

But $\psi(u) = \mathrm{Inf}_{v \in L^2(\Omega)} \psi(v)$ if and only if $0 \in \partial\psi(u)$. By using the hypothesis (2.3) and the standard formulas for subdifferentials of convex functions (Rockafellar [18], Ekeland and Temam [9]) we obtain

$$0 \in J'(u) + T^* \circ \partial I_B(Tu) + \partial I_K(u) \tag{2.11}$$

which is equivalent to $u \in K$ and the existence of $\mu \in \partial I_B(Tu)$ such that

$$\begin{aligned} &\int_\Omega (y(u) - y_0)(y(v) - y(u))\, dx + r \int_\Omega u(v-u)\, dx \\ &\qquad + \int_\Omega T^*\mu(v-u)\, dx \geqq 0 \quad \forall v \in K, \end{aligned} \tag{2.12}$$

$$\mu \in \partial I_B(Tu). \tag{2.13}$$

Take $y = y(u)$, $p_1 = T^*\mu$ and let $p_2 \in H_0^1(\Omega)$ be the solution of the Dirichlet problem

$$\begin{aligned} &A^*p_2 = -\sum_{i,j=1}^{n} \partial_{x_j}(a_{ji}\partial_{x_i}p_2) + a_0 p_2 = y - y_0 \quad \text{on } \Omega, \\ &p_2 = 0 \quad \text{on } \Gamma. \end{aligned} \tag{2.14}$$

Finally, taking $p = p_1 + p_2$, we have

$$\begin{aligned} &\int_\Omega (y - y_0)(y(v) - y(u))\, dx + \int_\Omega T^*\mu(v-u)\, dx \\ &\quad = \int_\Omega A^*p_2(y(v) - y(u))\, dx + \int_\Omega p_1(v-u)\, dx \\ &\quad = \int_\Omega p_2(v-u)\, dx + \int_\Omega p_1(v-u)\, dx = \int_\Omega p(v-u)\, dx. \end{aligned} \tag{2.15}$$

From (2.12) and (2.15) we obtain (2.9), (2.8) follows from (2.13) and (2.6) is obvious. Now we prove (2.7). Let $z \in H$, then

$$\begin{aligned} \int_\Omega pAz\, dx &= \int_\Omega p_2 Az\, dx + \int_\Omega p_1 Az\, dx \\ &= \int_\Omega A^*p_2 z\, dx + \int_\Omega T^*\mu Az\, dx \\ &= \int_\Omega (y - y_0)z\, dx + \int_\Omega (T \circ A)z\, d\mu \\ &= \int_\Omega (y - y_0)z\, dx + \int_\Omega z\, d\mu. \end{aligned} \tag{2.16}$$

Q.E.D.

Remark. From (2.7) it follows that p satisfies the adjoint state equation

$$A^*p = y - y_0 + \mu \quad \text{on } \Omega. \tag{2.17}$$

We will prove in Theorem 4 that p has a null trace on Γ. The approximation by a finite element method of this equation has been studied by the author in [8].

3. Study of the multiplier μ. Next we prove some properties of the Lagrange multiplier μ. First recall that if the solution u of (P) satisfies $\|y(u)\|_\infty < 1$, then we deduce from (2.8) that $\mu = 0$. Now we examine the case $\|y(u)\|_\infty = 1$.

THEOREM 3. *Let u be the solution of* (P) and let $\mu \in M(\Omega)$ *satisfying* (2.8). *Take $y = Tu$ and consider the sets*

$$\Omega_+ = \{x \in \Omega: y(x) = +1\}, \qquad \Omega_- = \{x \in \Omega: y(x) = -1\}$$

and

$$\Omega_0 = \{x \in \Omega: |y(x)| < 1\}.$$

Let $\mu = \mu^+ - \mu^-$ be the Jordan decomposition of μ and $|\mu| = \mu^+ + \mu^-$ the total variation measure of μ. Then μ^+ and μ^- are concentrated in Ω_+ and Ω_-, respectively, that is to say

$$\mu^+(\Omega_- \cup \Omega_0) = \mu^-(\Omega_+ \cup \Omega_0) = |\mu|(\Omega_0) = 0. \tag{3.1}$$

Moreover

$$\int_\Omega (|y(x)| - 1)\, d|\mu|(x) = 0. \tag{3.2}$$

Proof. From (2.5), $\mu = \mu^+ - \mu^-$ and $|\mu| = \mu^+ + \mu^-$ we see that (2.8) is equivalent to

$$\int_\Omega y\, d\mu^+ - \int_\Omega y\, d\mu^- = |\mu|(\Omega) = \int_\Omega 1\, d\mu^+ + \int_\Omega 1\, d\mu^-. \tag{3.3}$$

This can be rewritten as

$$\int_\Omega (y-1)\, d\mu^+ - \int_\Omega (y+1)\, d\mu^- = 0. \tag{3.4}$$

From $-1 \leqq y \leqq +1$ we see that each of the integrals must vanish. The assertion (3.1) follows now from the definition of Ω_+, Ω_- and Ω_0.

Equation (3.2) is an obvious consequence of (3.1). Q.E.D.

Finally, we analyze a very frequent situation. As an immediate consequence of Theorem 3 we prove a fact that the numerical experimentation has clearly shown: the Lagrange multiplier is null at the points where the state constraint is not active and it is a Dirac measure when the constraint is active at a unique point, Casas [7] and Mossino [16].

COROLLARY 1. *Under the same hypothesis as in Theorem* 3 *and, furthermore, if the equality $|y(x)| = 1$ is satisfied at a finite set of points $\{x_j\}_{j=1}^m$, we have*

$$\mu = \sum_{j=1}^{m} \lambda_j \delta_{[x_j]} \tag{3.5}$$

where $\lambda_j \in R$ and $\delta_{[x_j]}$ is the Dirac measure concentrated at x_j. Moreover,

$$\lambda_j \geqq 0 \quad \text{if } y(x_j) = +1, \tag{3.6}$$

and

$$\lambda_j \leqq 0 \quad \text{if } y(x_j) = -1. \tag{3.7}$$

4. Regularity of the optimal solution. Next we investigate the regularity of the optimal solution u as well as the optimal state and Lagrange multiplier p.

If $s \in R$, $s \geqq 1$, and m is an integer, we will denote by $W^{m,s}(\Omega)$ and $W_0^{m,s}(\Omega)$ the usual Sobolev spaces (Adams [1]).

THEOREM 4. *Let $\mu \in M(\Omega)$ and $q \in L^2(\Omega)$ be such that*

$$\int_\Omega qAz\,dx = \int_\Omega z\,d\mu \quad \forall z \in H. \tag{4.1}$$

Then $q \in W_0^{1,s}(\Omega)$ for all $s \in [1, n/(n-1))$ and there exists $c_s > 0$ such that

$$\|q\|_{W_0^{1,s}(\Omega)} \leqq c_s \|\mu\|_{M(\Omega)}. \tag{4.2}$$

Proof. We first consider the one-dimensional case.

A) Case $n = 1$. In this case, it is well known that $W_0^{1,s}(\Omega) \subset C_0(\Omega)$ for all $s \in [1, \infty]$, the inclusion being continuous (Adams [1]); hence $M(\Omega) \subset W^{-1,s}(\Omega)$ for all $s \in (1, \infty)$. In particular, $\mu \in H^{-1}(\Omega)$ and so by density, it follows from (4.1) that

$$\langle q, Az\rangle_{H_0^1(\Omega)H^{-1}(\Omega)} = \int_\Omega z\,d\mu \quad \forall z \in H_0^1(\Omega). \tag{4.3}$$

Since A is an isomorphism from $H_0^1(\Omega)$ onto $H^{-1}(\Omega)$, we deduce the existence of $c_1 > 0$ such that

$$\begin{aligned} \langle q, Az\rangle_{H_0^1(\Omega)H^{-1}(\Omega)} &\leqq \|\mu\|_{M(\Omega)}\|z\|_\infty \\ &\leqq c_0\|\mu\|_{M(\Omega)}\|z\|_{H_0^1(\Omega)} \leqq c_1\|\mu\|_{M(\Omega)}\|Az\|_{H^{-1}(\Omega)} \end{aligned} \tag{4.4}$$

which proves that $q \in (H^{-1}(\Omega))' = H_0^1(\Omega)$ and

$$\|q\|_{H_0^1(\Omega)} \leqq c_1\|\mu\|_{M(\Omega)}. \tag{4.5}$$

On the other hand, since $n = 1$, the operator A can be written in the following way:

$$Az = -a_{11}\frac{d^2z}{dx^2} - \frac{da_{11}}{dx}\frac{dz}{dx} + a_0 z. \tag{4.6}$$

Finally, it is obvious that $A^*q = Aq = \mu$ on Ω, therefore

$$\frac{d^2q}{dx^2} = \frac{1}{a_{11}}\left(-\frac{da_{11}}{dx}\frac{dq}{dx} + a_0 q - \mu\right) \in W^{-1,s}(\Omega) \tag{4.7}$$

for all $s \in (1, +\infty)$.

So from (4.5) and (4.7) we obtain (4.2). Q.E.D.

Before proving the case $n > 1$, we will prove the following lemma.

LEMMA 1. *Let $f \in W^{-1,t}(\Omega)$ where $t > n$ is a real number, $n = 2$ or 3. Let $z \in H_0^1(\Omega)$ be the solution of the Dirichlet problem*

$$\begin{aligned} Az &= f \quad \text{on } \Omega, \\ z &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.8}$$

Then $z \in C_0(\Omega)$ and there exists $c > 0$ such that

$$\|z\|_\infty \leqq c\|f\|_{W^{-1,t}(\Omega)}. \tag{4.9}$$

Proof. Let $f \in W^{-1,t}(\Omega)$ and let $\{f_j\}_{j=0}^n \subset L^t(\Omega)$ be such that (Adams [1, pp. 47–51])

$$f = f_0 + \sum_{j=1}^n \partial_{x_j} f_j \tag{4.10}$$

and

$$\|f\|_{W^{-1,t}(\Omega)} = \sum_{j=0}^{n} \|f_j\|_{L^t(\Omega)}. \tag{4.11}$$

Let $z_0 \in H_0^1(\Omega)$ be the solution of

$$\begin{aligned} Az_0 &= f_0 \quad \text{on } \Omega, \\ z_0 &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.12}$$

Then, from (1.4), we deduce that $z_0 \in H^2(\Omega) \cap H_0^1(\Omega)$ and consequently

$$\|z_0\|_\infty \leqq c_1 \|z_0\|_{H^2(\Omega)} \leqq c_2 \|f_0\|_{L^2(\Omega)} \leqq c_3 \|f_0\|_{L^t(\Omega)}. \tag{4.13}$$

Let now $z_1 \in H_0^1(\Omega)$ be the solution of

$$\begin{aligned} Az_1 &= \sum_{j=1}^{n} \partial_{x_j} f_j \quad \text{on } \Omega, \\ z_1 &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.14}$$

Since $t > n$, we deduce from (4.14) and the Lax-Milgram theorem (Nečas [17]):

$$\begin{aligned} \|z_1\|_{H_0^1(\Omega)} &\leqq c_4 \left\| \sum_{j=1}^{n} \partial_{x_j} f_j \right\|_{H^{-1}(\Omega)} \\ &\leqq c_5 \sum_{j=1}^{n} \|f_j\|_{L^2(\Omega)} \leqq c_6 \sum_{j=1}^{n} \|f_j\|_{L^t(\Omega)}. \end{aligned} \tag{4.15}$$

Furthermore, by using the theorem (1.4) of Nečas [17, p. 319], we obtain

$$\|z_1\|_\infty \leqq c_7 \left(\sum_{j=1}^{n} \|f_j\|_{L^t(\Omega)} + \|z_1\|_{H_0^1(\Omega)} \right). \tag{4.16}$$

Now, (4.9) follows from (4.13), (4.15) and (4.16).

In order to prove that $z \in C_0(\Omega)$ it is enough to consider a sequence $\{f_n\} \subset L^t(\Omega)$ such that $f_n \to f$ in $W^{-1,t}(\Omega)$. Now from (1.4) it follows that the solution z_n of

$$\begin{aligned} Az_n &= f_n \quad \text{on } \Omega, \\ z_n &= 0 \quad \text{on } \Gamma \end{aligned} \tag{4.17}$$

belongs to $H^2(\Omega) \cap H_0^1(\Omega) \subset C_0(\Omega)$ and using (4.9) we derive

$$\|z - z_n\|_\infty \leqq c_8 \|f - f_n\|_{W^{-1,t}(\Omega)} \to 0 \tag{4.18}$$

which proves that $z \in C_0(\Omega)$. Q.E.D.

B) Case $n > 1$. Take $s \in (1, n/(n-1))$ and let $t > n$ be such that $(1/s) + (1/t) = 1$. Given $\psi \in L^t(\Omega)$, let $z \in H$ be the solution of the Dirichlet problem

$$\begin{aligned} Az &= \psi \quad \text{on } \Omega, \\ z &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.19}$$

From (1.4) and (4.9) we derive

$$\begin{aligned} \left| \int_\Omega q\psi \, dx \right| &= \left| \int_\Omega qAz \, dx \right| = \left| \int_\Omega z \, d\mu \right| \\ &\leqq \|\mu\|_{M(\Omega)} \|z\|_\infty \leqq c \|\mu\|_{M(\Omega)} \|\psi\|_{W^{-1,t}(\Omega)}. \end{aligned} \tag{4.20}$$

Since $L^t(\Omega)$ is dense in $W^{-1,t}(\Omega)$ and $W^{-1,t}(\Omega)$ is the dual space of $W_0^{1,s}(\Omega)$ it follows from (4.20) that $q \in W_0^{1,s}(\Omega)$ and q satisfies (4.2).

The case $s=1$ is a consequence of the continuity of the inclusion $W_0^{1,s'}(\Omega)\subset W_0^{1,1}(\Omega)$ for all $s'>1$. Q.E.D.

Stampacchia [20] proved Theorem 4 under the hypothesis: $a_0(x)\geqq\beta>0$ in Ω. Moreover, he supposed that Ω is a H_0^1-admissible subset which is not easy to verify.

THEOREM 5. *Let $\mu\in M(\Omega)$ and $q\in L^2(\Omega)$ be as described in the statement of Theorem 4 and let $E\subset\Omega$ be a closed set such that $|\mu|(\Omega\backslash E)=0$. Then $q\in H^2_{\text{loc}}(\Omega\backslash E)$ and hence is continuous on $\Omega\backslash E$.*

Proof. From (4.1) we derive

$$\int_{\Omega\backslash E} qA\psi\,dx=\int_{\Omega} qA\psi\,dx=\int_{\Omega}\psi\,d\mu=\int_{\Omega\backslash E}\psi\,d\mu=0 \tag{4.21}$$

for all $\psi\in D(\Omega\backslash E)$.

Thus we obtain that $q\in L^2(\Omega)$ is a local solution of $A^*q=0$ on $\Omega\backslash E$, then (Nečas [17]) it follows that $q\in H^2_{\text{loc}}(\Omega\backslash E)$. On the other hand $H^2_{\text{loc}}(\Omega\backslash E)\subset C(\Omega\backslash E)$ which completes the proof. Q.E.D.

As an immediate consequence of this theorem we obtain a regularity result for the Lagrange multiplier p.

COROLLARY 2. *Let $\mu\in M(\Omega)$ and $p\in L^2(\Omega)$ be the Lagrange multipliers obtained in Theorem 2. Then $p\in W_0^{1,s}(\Omega)$ for all $s\in[1, n/(n-1))$. If, furthermore, Ω_0 is the set defined in Theorem 3, we have $p\in H^2_{\text{loc}}(\Omega_0)$.*

Now in order to investigate the regularity of the optimal solution u of (P), we are going to suppose that r is strictly positive in (1.5).

COROLLARY 3. *Let K be one of the following sets:*

$$K_1=\{v\in L^2(\Omega): v(x)\geqq 0 \text{ a.e. in } \Omega\},$$
$$K_2=\{v\in L^2(\Omega): \|v\|_{L^2(\Omega)}\leqq 1\}.$$

Let u be the optimal solution of (P), then $u\in W_0^{1,s}(\Omega)$ for all $s\in[1, n/(n-1))$. Furthermore we have that $u\in H^1_{\text{loc}}(\Omega_0)\cap C(\Omega_0)$ if $K=K_1$ and u belongs to $H^2_{\text{loc}}(\Omega_0)$ if $K=K_2$.

Proof. If $K=K_1$, it follows easily from (2.9)

$$u(x)=-\frac{1}{r}\operatorname{Inf}\{0, p(x)\}\quad \text{a.e. in } \Omega. \tag{4.22}$$

If $K=K_2$, also from (2.9) we derive that

$$\begin{aligned} &u(x)=-\frac{p(x)}{\|p\|_{L^2(\Omega)}} && \text{if } \|p\|_{L^2(\Omega)}>r,\\ &u(x)=-\frac{1}{r}p(x) && \text{if } \|p\|_{L^2(\Omega)}\leqq r. \end{aligned} \tag{4.23}$$

The assertion follows now from (4.22), (4.23) and Corollary 2 (Lions [13]). Q.E.D.

COROLLARY 4. *Let ψ_1, $\psi_2\in H^1(\Omega)$ be such that*

$$K=\{v\in L^2(\Omega): \psi_1(x)\leqq v(x)\leqq\psi_2(x) \text{ a.e. in } \Omega\}$$

Then $u\in W^{1,s}(\Omega)\forall s\in[1, n/(n-1))$ and if, furthermore, the functions ψ_1, ψ_2 are continuous, we have that $u\in H^1_{\text{loc}}(\Omega_0)\cap C(\Omega_0)$.

Proof. From (2.9) it follows

$$u(x)=\max\left\{\psi_1(x), \min\left\{-\frac{1}{r}p(x), \psi_2(x)\right\}\right\}\quad \text{a.e.} \tag{4.24}$$

Now the corollary is a consequence of Corollary 2 (Lions [13]). Q.E.D.

Remark. The formulas (4.22), (4.23) and (4.24) prove that the regularity of u depends essentially on the regularity of p. In general, $p \notin H^1(\Omega)$ and consequently the result $u \in W^{1,s}(\Omega)$ for all $s \in [1, n/(n-1))$ is optimal. Consider, for example, a control problem where the state constraint is active at a unique point $x_0 \in \Omega$, then the Lagrange multiplier μ is a Dirac measure (Corollary 1) and consequently $p \notin H^1(\Omega)$.

When u is given by (4.23) and the coefficients a_{ij} and a_0 of A are C^∞ functions on Ω, then it is easy to prove that p and u are C^∞ functions on Ω_0.

Finally, in order to study the regularity of the optimal state, we assume that Γ is a manifold of class C^∞ and a_0, a_{ij} $(1 \leqq i, j \leqq n)$ are functions of class C^∞ (it is possible to weaken these regularity hypotheses, see [2], [17]).

COROLLARY 5. *Let K be defined as in one of the Corollaries* 3 *or* 4. *Then the optimal state y belongs to the Sobolev space $W^{3,s}(\Omega) \cap H_0^1(\Omega)$ for all $s \in [1, n/(n-1))$ and moreover $y \in H^3_{\text{loc}}(\Omega_0)$. If furthermore $n \leqq 2$, then $y \in C^1(\bar{\Omega})$.*

Proof. Since $u \in W^{1,s}(\Omega)$, it follows from [2] that y belongs to $W^{3,s}(\Omega) \cap H_0^1(\Omega)$. On the other hand, $u \in H^1_{\text{loc}}(\Omega_0)$ implies (see [17]) that $y \in H^3_{\text{loc}}(\Omega_0)$.

Finally, if $n \leqq 2$ and $(n/(n-1)) - s$ is small enough, we have $W^{3,s}(\Omega) \subset C^1(\bar{\Omega})$, from where $y \in C^1(\bar{\Omega})$. Q.E.D.

Acknowledgment. The author wishes to thank the referees for several important suggestions on this paper. In particular, the proof of Theorem 3 presented in this paper was suggested by one of them.

EVEN MORE STATES REACHABLE BY BOUNDARY CONTROL FOR THE HEAT EQUATION*

E. J. P. GEORG SCHMIDT†

Abstract. In this note we show how both known and new sufficient conditions for reachability in boundary control for the heat equation can easily be derived from null controllability. A characterisation of reachable states remains elusive.

Key words. distributed control, heat equation, reachability

Let Ω be a bounded domain in R^n whose boundary $\partial\Omega$ is a C^∞ manifold. Let Δ denote the Laplacian operator on R^n, $\partial/\partial\nu$ denote differentiation in the direction of the outward pointing normal ν to $\partial\Omega$, a be a nonnegative constant, and $\mathcal{B}$"=" $a(\partial/\partial\nu)+1$. We consider the following initial boundary value problem:

$$\begin{aligned} &\frac{\partial u}{\partial t}(x,t)=\Delta u(x,t) \quad \text{for } x\in\Omega, \qquad t\in(0,T], \\ &\mathcal{B}u(x,t)=f(x,t) \quad \text{for } x\in\partial\Omega, \qquad t\in(0,T], \\ &u(x,0)=u_0(x) \quad \text{for } x\in\Omega. \end{aligned} \tag{1}$$

It can be shown that, given u_0 in $\mathcal{H}=L_2(\Omega)$ and f in $\mathcal{U}=L_\infty(\partial\Omega\times(0,T))$ (1) has a unique weak solution $u(x,t)$ in $L_2(\Omega\times(0,T))\cap C^\infty(\Omega\times(0,T))$ in the following sense (see [4] or [8]):

$$\begin{aligned} \int_\Omega\int_0^T u(x,t)\left[\frac{\partial\phi}{\partial t}(x,t)+\Delta\phi(x,t)\right]dx\,dt+\int_\Omega u_0(x)\phi(x,0)\,dx \\ +\int_{\partial\Omega}\int_0^T f(x,t)\phi^\partial(x,t)\,dS_x\,dt=0, \end{aligned} \tag{2}$$

where dS_x denotes an element of surface area of $\partial\Omega$, ϕ belongs to the space of test functions

$$\mathcal{T}=\{\phi\in C^\infty(\bar{\Omega}\times[0,T]):\ \phi(\cdot,T)\equiv 0,\ \mathcal{B}\phi(\cdot,t)\equiv 0\}$$

and

$$\phi^\partial(x,t)=\begin{cases} a^{-1}\phi(x,t) & \text{for } x\in\partial\Omega,\ t>0 \quad \text{if } a>0, \\ -\dfrac{\partial\phi}{\partial\nu}(x,t) & \text{for } x\in\partial\Omega,\ t>0 \quad \text{if } a=0. \end{cases} \tag{3}$$

Moreover $u(\cdot,T)$ lies in $\mathcal{H}$, so that one can define the set of states reachable from u_0 in time T by

$$\mathcal{R}_T(u_0,\mathcal{U})=\{u(\cdot,T):\ \text{there exists } f\in\mathcal{U} \text{ with } u(x,t) \text{ the corresponding solution of (1)}\}.$$

† Department of Mathematics and Statistics, McGill University, Montreal, Quebec, Canada H3A 2K6.

It is well known that $\mathcal{R}_T(u_0, \mathcal{U})$ is dense in $\mathcal{H}$ (see, for example [5]), that $0 \in \mathcal{R}_T(u_0, \mathcal{U})$ (a fundamental and deep result known as "null controllability" and proved in [6] or [9]) and that $\mathcal{R}_T(u_0, \mathcal{U})$ is independent of u_0 and T (see [2] or [10]). From now on we denote $\mathcal{R}_T(u_0, \mathcal{U})$ by $\mathcal{R}$; it forms a nonclosed subspace of $\mathcal{H}$. We refer to the functions in that subspace as "reachable." No intrinsic characterisation of reachable functions has yet been given. However there exist various sufficient conditions for reachability, which allow one to identify some interesting classes of reachable functions (see, for example, [6], [8], [7], [11], [12]). In this note a new sufficient condition is given which subsumes most of the known conditions.

We remark that the space $\mathcal{U}$ of controls can be chosen in other ways without affecting the validity of all the previously stated facts. If, for example, $a \neq 0$ one can choose $\mathcal{U} = L_2(\partial\Omega \times (0, T))$ while, if $a = 0$ (the case of Dirichlet boundary conditions) $\mathcal{U}$ can be chosen as in [11].

Given w in $\mathcal{H}$ with Δw in $\mathcal{H}$ (in the distribution sense) we say that $\mathcal{B}w = f$ (with f in $L_\infty(\partial\Omega)$) if

$$\int_\Omega \Delta w(x)\phi(x)\,dx = \int_\Omega w(x)\Delta\phi(x)\,dx + \int_{\partial\Omega} f(x)\phi^\partial(x)\,dS_x, \tag{4}$$

for any ϕ in $C^\infty(\bar{\Omega})$ satisfying $\mathcal{B}\phi = 0$.

Let $\|\cdot\|_{\mathcal{H}}$ and $\|\cdot\|_{\mathcal{U}}$ denote the norms on $\mathcal{H}$ and $\mathcal{U}$, respectively. Since $L_\infty(\partial\Omega)$ can be regarded as a subspace of $\mathcal{U}$ (consisting of functions independent of t), $\|\cdot\|_{\mathcal{U}}$ can be used on $L_\infty(\partial\Omega)$, and in fact coincides with the usual norm.

We can now state our main theorem.

THEOREM. *Let v in $\mathcal{H}$ satisfy*

(i) $\Delta^n v \in \mathcal{H}$, *for all positive integers n and for some $p > 0$ the series*

$$\sum_{n=0}^{\infty} \frac{(-p)^n}{n!} \Delta^n v(\cdot)$$

converges in $\mathcal{H}$.

(ii) $\mathcal{B}(\Delta^n v) \in L_\infty(\partial\Omega)$, *for all positive integers n, and furthermore the series*

$$\sum_{n=0}^{\infty} \frac{(-p)^n}{n!} \mathcal{B}(\Delta^n v)$$

converges in $L_\infty(\partial\Omega)$. Then v is reachable.

Proof. Pick T in $(0, p)$ and note that the series

$$\sum_{n=0}^{\infty} \frac{(t-T)^n}{n!} \Delta^n v \quad \text{and} \quad \sum_{n=0}^{\infty} \frac{(t-T)^n}{n!} \mathcal{B}(\Delta^n v)$$

converge uniformly and "absolutely" (with the appropriate norm replacing absolute values) to yield functions $u(x, t)$ in $L_2(\Omega \times (0, T))$ and $f(x, t)$ in $\mathcal{U}$ respectively. Note that $u(x, T) = v(x)$. Let $u_N(x, t)$ and $f_N(x, t)$ denote the partial sums of the two series (with n running from 0 to N); then $(\partial/\partial t)u_N(x, t) = \Delta u_{N-1}(x, t)$. Now integration by parts and (4) readily yield, for test functions ϕ in $\mathcal{T}$,

$$\int_\Omega \int_0^T \left[u_N(x, t) \frac{\partial\phi}{\partial t}(x, t) + u_{N-1}(x, t)\Delta\phi(x, t) \right] dx\,dt + \int_\Omega u_N(x, 0)\phi(x, 0)\,dx$$
$$+ \int_{\partial\Omega} \int_0^T f_{N-1}(x, t)\phi^\partial(x, t)\,dS_x\,dt = 0.$$

Letting N tend to infinity one obtains (2), so that one can conclude that $v(x) = u(x, T)$ belongs to $\mathcal{R}(u(x, 0), \mathcal{U}) = \mathcal{R}$.

This theorem has a number of easy corollaries.

COROLLARY 1. *The following classes of functions are included in* $\mathcal{R}$:

(a) *Polynomials in the space variables* (*see also* [7] *and* [11]).

(b) *Functions* v *which satisfy* $\Delta v = \lambda v$ *with* $\mathcal{B}v$ *in* $L_\infty(\partial\Omega)$, *a class of functions which includes "holdable targets"* (*see* [8]), *the eigenfunctions of* Δ *corresponding to homogeneous boundary conditions, the restrictions to* Ω *of such eigenfunctions on bigger domains and functions of the form* $\prod_{i=1}^{n} \psi_i(x_i)$ *with* $\psi_i(x_i) = \cos(a_i x_i)$, $\sin(a_i x_i)$ *or* $\exp(a_i x_i)$ (*see* [7, Cor. 6]).

(c) *The restrictions to* Ω *of functions* v *in* $L_2(R^n)$ *whose Fourier transforms* $\hat{v}$ *satisfy* $\exp(p\xi^2)\hat{v}(\xi) \in L_2(R^n)$ *for some* $p > 0$.

The proofs of (a) and (b) are trivial; (c) requires Plancherel's theorem and the observation that, when p is replaced by a slightly smaller positive constant, the series occurring in hypotheses (i) and (ii) of the theorem, written in terms of Fourier transforms, converge uniformly in x.

The next corollary partially generalises a result to be found in [6]. To formulate this one needs to introduce the selfadjoint operator $\mathcal{L}$ defined as Δ acting on the appropriate domain of functions ϕ in $L_2(\Omega)$ satisfying $\mathcal{B}\phi = 0$. Then (see [1]) $\mathcal{L}$ has a complete orthonormal system of eigenfunctions $\{\phi_k\}_{k=1}^{\infty}$ corresponding to negative eigenvalues $\{-\lambda_k\}_{k=1}^{\infty}$. Given v in $L_2(\Omega)$ let v_k denote the coefficient of v with respect to ϕ_k.

COROLLARY 2. *Let* v *in* $L_2(\Omega)$ *satisfy* $\sum_{k=1}^{\infty} \exp(2p\lambda_k) v_k^2 < \infty$ *for some* $p > 0$; *then* v *is reachable.*

To prove this we note that $\Delta^n v = \sum_{k=1}^{\infty} (-\lambda_k)^n v_k \phi_k$ belongs to the domain of $\mathcal{L}$ for all n and hence $\mathcal{B}(\Delta^n v) = 0$, so that hypothesis (ii) of our theorem is satisfied for any choice of p. Moreover (i) is satisfied since one easily justifies

$$\sum_{n=1}^{\infty} \frac{(-p)^n}{n!} \Delta^n v = \sum_{k=1}^{\infty} \exp(p\lambda_k) v_k \phi_k,$$

which is convergent in $L_2(\Omega)$ by hypothesis.

Without describing the details we remark that Theorems 5 and 5^0 of [11] can also be obtained immediately from our theorem (adapted to handle the space of controls used in the cited paper).

It is also possible to give a generalisation of a result in [7] which is not contained in the previous theorem.

PROPOSITION. *Let* w *in* $L_2(\Omega)$ *be a solution of*

$$(\Delta - \lambda) w = v \quad \text{and} \quad \mathcal{B}w = g,$$

where v *is in* $\mathcal{R}$ *and* g *is in* $L_\infty(\partial\Omega)$. *Then* w *is reachable.*

When $v = 0$ this is just Corollary 1(b); by linearity it is then enough to prove the result for $g = 0$. This involves minor changes in the proof for the case $\lambda = 0$ (given in [7, Thm. 3]).

An easy induction proof on the degree of the polynomial then yields

COROLLARY 3. *The functions* $p(x)v(x)$, *where* p *is a polynomial and* v *is as described in Corollary* 1(b), *are reachable.*

ON HERMITIAN SOLUTIONS OF THE SYMMETRIC ALGEBRAIC RICCATI EQUATION*

I. GOHBERG†, P. LANCASTER‡ AND L. RODMAN§

Abstract. The structure of the set of hermitian solutions of the matrix quadratic equation $XDX - XA - A^*X - C = 0$ is studied under the conditions that $C = C^*$, D is positive semidefinite and (A, D) is stabilizable. New features (e.g., nonexistence of the minimal solution) appear in contrast with the known case when (A, D) is controllable.

Key words. algebraic Riccati equation, hermitian solutions, extremal solutions, stabilizability, invariant subspaces

AMS(MOS) subject classifications. 93B25, 49E30, 15A24

1. Introduction. Our primary concern is the analysis of hermitian solutions X of the Riccati equation of the form

$$XDX - XA - A^*X - C = 0. \tag{1}$$

This equation will be considered under the assumptions that A, C, D are $n \times n$ matrices with complex entries with C hermitian, D positive semidefinite, and the pair (A, D) stabilizable.

The now classical problem of quadratic optimization of a time-invariant finite-dimensional linear problem can be reduced to the solution of (1). Namely, the control $u(t)$ of the time invariant system

$$\dot{x} = Ax + Bu \tag{2}$$

which minimizes the cost functional

$$\int_0^\infty (x^*Cx + u^*Ru)\, dt \tag{3}$$

with constant positive definite matrix R and positive semidefinite C, is given by the formula

$$u(t) = -R^{-1}B^*X_+x(t),$$

where X_+ is the maximal hermitian solution (which is assumed to exist) of the matrix equation

$$XBR^{-1}B^*X - XA - A^*X - C = 0. \tag{4}$$

The maximality of X_+ means that $X_+ - X$ is positive semidefinite for any hermitian solution X of (4).

It is important to know when the solutions of (2) are stable, and it is well known that this happens if and only if all the eigenvalues of A are in the open left halfplane. More generally, we ask when the stability of (2) can be achieved by feedback. This

means that after a transformation $u = Fx + v$ with some matrix F (where v is the new control) the equation

$$\dot{x} = (A + BF)x + Bv$$

is stable. In other words, the eigenvalues of $A + BF$ are in the open left halfplane. If such an F exists, the pair (A, B) is called *stabilizable.*

It is possible to check that (A, B) is stabilizable if and only if $(A, BR^{-1}B^*)$ is stabilizable. So a natural additional restriction on the coefficients of (1) is that (A, D) be stabilizable. Indeed, this is a useful sufficient condition for the problem of minimizing the cost functional to be well posed.

In particular, (A, D) is stabilizable if this pair is *controllable*, which means that its controllability subspace $C_{A,D} = \sum_{j=1}^{n} \operatorname{Im}(A^{j-1}D)$ coincides with $\mathbb{C}^n$. For a theory of equation (1) under the controllability of (A, D) see [6], [15] and expositions in [2], [3], [12] (many references concerning the development of this theory are found in [12]). Our purpose in this paper is to extend this algebraic theory to the case when only stabilizability of (A, D) is required. In the course of this extension new features appear: First, in contrast with the controllability case, the minimal hermitian solution of (1) does not always exist. However, the reader's attention is drawn to the sufficient condition (called *regularity*) under which a minimal solution exists given in Corollary 4.4, and to two other characterizations of equations for which minimal solutions exist (Corollary 5.2).

Second, in the geometric description of the hermitian solutions there is a distinction between two cases. In one case (the *regular* case) this description goes in the same way as when (A, D) is controllable (see [6], [15]). In the nonregular case the situation is more complicated and only partial results are obtained.

The paper consists of 6 sections. In the second section we study the existence question and properties of the maximal hermitian solution and also give an example of nonexistence of the minimal hermitian solution. Existence of hermitian solutions of (1) is studied in § 3 in the geometric terms of invariant subspaces associated with

$$\begin{bmatrix} -A & D \\ C & A^* \end{bmatrix}.$$

The regular and nonregular cases are studied in §§ 4 and 5, respectively. In § 6 we discuss the Riccati equation with real coefficients and the properties of real symmetric solutions.

2. Existence and properties of extremal solutions. Consider the algebraic Riccati equation

$$XDX - XA - A^*X - C = 0, \tag{1}$$

where A, D and C are $n \times n$ (complex) matrices, D is positive semidefinite, C is hermitian and the pair (A, D) is stabilizable, and hermitian solutions X of (1) are required. These conditions on A, D, C will be maintained throughout the paper. Our first result asserts the existence of the maximal hermitian solution. We say that a hermitian solution X_+ of (1) is *maximal* if $X_+ \geqq X$ for any other hermitian solution of (1). Here and elsewhere $X \geqq Y$ for hermitian matrices X and Y means that $X - Y$ is positive semidefinite. Clearly, a maximal hermitian solution is unique if it exists.

THEOREM 2.1. *If* (1) *has a hermitian solution, then it has the maximal hermitian solution* X_+. *The matrix* X_+ *has the property that all eigenvalues of* $A - DX_+$ *are in the closed left halfplane.*

The case when $C \geqq 0$ arises naturally in quadratic optimal control problems (see the Introduction). For this case we have the following.

THEOREM 2.2. *If $C \geqq 0$, then* (1) *has a hermitian solution, and its maximal hermitian solution X_+* (*which exists by Theorem* 2.1) *is positive semidefinite.*

For completeness, we remark that hypotheses on the pair (A^*, C) arise naturally in the quadratic optimal control problem and give stronger conclusions. It is shown in [19], for example, that if, in addition to the hypotheses of Theorem 2.2, (A^*, C) is stabilizable then the matrix $A - DX_+$ is stable (i.e. has all its eigenvalues in the open left half-plane), and if (A^*, C) is controllable, then X_+ is positive definite.

We shall prove Theorem 2.1 together with the following result concerning existence of hermitian solutions if the hermitian matrix C is increased.

THEOREM 2.3. *Assume* (1) *has a hermitian solution. Then for every hermitian matrix C' satisfying $C' \geqq C$ the equation*

$$XDX - XA - A^*X - C' = 0 \tag{2}$$

has a hermitian solution as well. Moreover, the maximal hermitian solutions X_+ and X'_+ of (1) *and* (2), *respectively* (*which exist by Theorem* 2.1), *satisfy the inequality $X'_+ \geqq X_+$.*

Theorem 2.2 is a simple corollary of Theorem 2.3. Indeed, equation $XDX - XA - A^*X = 0$ obviously has the hermitian solution $X = 0$. Now use Theorem 2.3 to obtain Theorem 2.2.

In case (A, D) is controllable the result of Theorem 2.1 is known and goes back to [13] (see also [2]).

Theorem 2.2 seems to be new although closely related results with stronger hypotheses on the pair (A, D) have been known for some time (see [4], [5], [1], [9]). Similarly, Theorem 2.3 seems to be new, although a related result (without the existence statement) appears in the work of Willems [16]. Also, using other methods, and during the preparation of this paper, A.C.M. Ran has proved Theorem 2.3 in the case that (A, D) is controllable.

Theorems 2.3 and 2.1 will be proved together. In the proof we use an approach introduced (in a special case) in [5] and further developed in [18], [2].

It is well known that under the stronger condition of controllability of (A, D) equation (1) has the *minimal* hermitian solution X_- which is defined by the property that $X \geqq X_-$ for any hermitian solution X of (1), provided (1) has hermitian solutions at all (see e.g., [2]). This fact follows easily from Theorem 2.1. Indeed, if (A, D) is controllable, so is $(-A, D)$. In particular, $(-A, D)$ is stabilizable. Apply Theorem 2.1 to the equation

$$XDX + XA + A^*X - C = 0, \tag{3}$$

and observe that X satisfies (3) if and only if $-X$ satisfies (1). The following example shows that, in contrast with the controllable case, the minimal hermitian solution need not exist under the conditions of Theorem 2.1:

Example 2.1. Let

$$D = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

A calculation shows that the hermitian solutions of (1) are

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad \begin{bmatrix} -1 & b \\ \bar{b} & -|b|^2/2 \end{bmatrix}, \quad b \in \mathbb{C}.$$

Clearly,

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$$

is the maximal solution, but there is no minimal solution.

Proof of Theorems 2.1 *and* 2.3. Let

$$\mathrm{C} = \mathrm{Im}\,[D, AD, \cdots, A^{n-1}D]$$

be the controllable subspace of (A, D). Clearly, C is A-invariant and contains Im D. Hence with respect to the orthogonal decomposition $\mathbb{C}^n = C \oplus C^{\perp}$ we have

$$A = \begin{bmatrix} A_1 & A_{12} \\ 0 & A_2 \end{bmatrix}, \qquad D = \begin{bmatrix} D_1 & 0 \\ 0 & 0 \end{bmatrix}, \tag{4}$$

where D_1 is positive semidefinite and (A_1, D_1) controllable. Further, the stabilizability of (A, D) implies that A_2 is stable. As (A_1, D_1) is controllable, there is a hermitian matrix Y such that $A_1 - D_1 Y$ is stable. Indeed,

$$Y = \left(\int_0^1 e_0^{-A_1 t} D_1 e^{-A_1^* t} \, dt \right)^{-1}$$

will do (see [8] and also [14, Thm. III.2.1]).

Now for the hermitian matrix

$$X_0 = \begin{bmatrix} Y & 0 \\ 0 & 0 \end{bmatrix}$$

we have that $A - DX_0$ is stable.

Starting[1] with X_0, we shall define a sequence of hermitian matrices $\{X_\nu\}_{\nu=0}^{\infty}$ satisfying the equalities

$$X_{\nu+1}(A - DX_\nu) + (A - DX_\nu)^* X_{\nu+1} = -X_\nu D X_\nu - C', \qquad \nu = 0, 1, \cdots, \tag{5}$$

where $C' \geqq C$ is a fixed hermitian matrix. The sequence will also have the property that $A - DX_\nu$ is stable for all ν. Assuming inductively that we have defined $X_\nu = X_\nu^*$ already with $A - DX_\nu$ stable, (5) has a unique solution $X_{\nu+1}$. Taking adjoints in (5) and using the uniqueness of the solution, we obtain $X_{\nu+1} = X_{\nu+1}^*$. We are to show that $A - DX_{\nu+1}$ is stable. To this end note the following identity which holds for any hermitian matrices Y and $\hat{Y}$:

$$\begin{aligned} Y(A - DY) + (A - DY)^* Y + YDY \\ = Y(A - D\hat{Y}) + (A - D\hat{Y})^* Y + \hat{Y}D\hat{Y} - (Y - \hat{Y})D(Y - \hat{Y}). \end{aligned} \tag{6}$$

By assumption, there exists a hermitian solution X of (1). Letting $Y = X$ and $\hat{Y} = X_\nu$ in (6), we get

$$X(A - DX_\nu) + (A - DX_\nu)^* X + X_\nu D X_\nu - (X - X_\nu)D(X - X_\nu) = -C. \tag{7}$$

Subtract (7) from (5):

$$(X_{\nu+1} - X)(A - DX_\nu) + (A - DX_\nu)^*(X_{\nu+1} - X) = -(X - X_\nu)D(X - X_\nu) - (C' - C).$$

[1] In this part of the proof the line of argument follows that of the second proof of Theorem 2.1 in [2].

As $A-DX_\nu$ is stable it follows from Proposition 8.13.1 of [7], for example, that

$$X_{\nu+1}-X=\int_0^\infty e^{(A-DX_\nu)t}[(X-X_\nu)D(X-X_\nu)+C'-C]\,e^{(A-DX_\nu)^*t}\,dt.$$

In particular, $X_{\nu+1}\geqq X$.

Next, use (6) again with $Y=X_{\nu+1}$, $Y=X_\nu$ and apply (5) to get

$$\begin{aligned}(8)\qquad &X_{\nu+1}(A-DX_{\nu+1})+(A-DX_{\nu+1})^*X_{\nu+1}+X_{\nu+1}DX_{\nu+1}\\ &\quad=-C'-(X_{\nu+1}-X_\nu)D(X_{\nu+1}-X_\nu).\end{aligned}$$

Subtracting the equality (7) with X_ν replaced by $X_{\nu+1}$, we obtain

$$\begin{aligned}(9)\qquad &(X_{\nu+1}-X)(A-DX_{\nu+1})+(A-DX_{\nu+1})^*(X_{\nu+1}-X)\\ &\quad=-(X_{\nu+1}-X_\nu)D(X_{\nu+1}-X_\nu)-(X_{\nu+1}-X)D(X_{\nu+1}-X)-C'+C.\end{aligned}$$

Assume now $(A-DX_{\nu+1})x=\lambda x$ for some λ with $\operatorname{Re}\lambda\geqq 0$ and vector $x\neq 0$. Then

$$(10)\qquad (\bar\lambda+\lambda)x^*(X_{\nu+1}-X)x=x^*Wx,$$

where $W\leqq 0$ is the right-hand side of (9). As $X_{\nu+1}-X\geqq 0$, the equality (10) implies $x^*Wx=0$ which, using the definition of W, in turn implies

$$x^*(X_{\nu+1}-X_\nu)D(X_{\nu+1}-X_\nu)x=0.$$

But $D\geqq 0$, so $D(X_{\nu+1}-X_\nu)x=0$. Now

$$(A-DX_\nu)x=(A-DX_{\nu+1})x=\lambda x,$$

a contradiction with the stability of $A-DX_\nu$. Hence $A-DX_{\nu+1}$ is stable as well.

Next it will be shown that the sequence $\{X_\nu\}_{\nu=0}^\infty$ is nonincreasing. Consider the equality (8) with ν replaced by $\nu-1$, and subtract from it the equality (5) to get

$$(X_\nu-X_{\nu+1})(A-DX_\nu)+(A-DX_\nu)^*(X_\nu-X_{\nu+1})=-(X_\nu-X_{\nu-1})D(X_\nu-X_{\nu-1}).$$

As $A-DX_\nu$ is stable,

$$X_\nu-X_{\nu+1}=\int_0^\infty e^{(A-DX_\nu)t}(X_\nu-X_{\nu-1})D(X_\nu-X_{\nu-1})\,e^{(A-DX_\nu)^*t}\,dt\geqq 0.$$

So $\{X_\nu\}_{\nu=0}^\infty$ is a nonincreasing sequence of hermitian matrices bounded below by X. Hence the limit $X'_+=\lim_{\nu\to\infty}X_\nu$ exists. Passing to the limit in (5) when $\nu\to\infty$ shows that X'_+ is a hermitian solution of (2). Since $A-DX_\nu$ is stable for all $\nu=0,1,\cdots$, the matrix $A-DX'_+$ has all its eigenvalues in the closed left halfplane. Also, $X'_+\geqq X$ for every hermitian solution of (1). In particular, taking $C'=C$ we see that the hermitian solution X'_+ of (1) is maximal. It follows now that $X'_+\geqq X_+$, where X_+ is the maximal hermitian solution of (1). □

3. Existence of hermitian solutions in geometric terms. We continue our discussion of (2.1) with the hypothesis $D\geqq 0$, $C=C^*$ and (A, D) stabilizable. Write

$$(1)\qquad A=\begin{bmatrix}A_1 & A_{12}\\ 0 & A_2\end{bmatrix},\quad D=\begin{bmatrix}D_1 & 0\\ 0 & 0\end{bmatrix},\quad C=\begin{bmatrix}C_1 & C_{12}\\ C_{12}^* & C_2\end{bmatrix}$$

with respect to the decomposition $\mathbb{C}^n=\mathcal{C}\oplus\mathcal{C}^\perp$, where $\mathcal{C}$ is the controllable subspace of (A, D), as in (2.4). So (A_1, D_1) is controllable, and A_2 is stable. Letting

$$X=\begin{bmatrix}X_1 & X_{12}\\ X_{12}^* & X_2\end{bmatrix}$$

be partitioned conformally with (1), it is found that (2.1) is equivalent to the three equations:

$$X_1D_1X_1 - X_1A_1 - A_1^*X_1 - C_1 = 0, \tag{2}$$

$$(A_1^* - X_1D_1)X_{12} + X_{12}A_2 = -(C_{12} + X_1A_{12}), \tag{3}$$

$$A_2^*X_2 + X_2A_2 = X_{12}^*D_1X_{12} - X_{12}^*A_{12} - A_{12}^*X_{12} - C_2. \tag{4}$$

(Molinari [9] and Wimmer [17] have also taken advantage of this observation.)

The existence of a hermitian solution of (2) is equivalent to any one of the following properties:

(a) There exists an m-dimensional, H-neutral, M_1-invariant subspace of $C \times C$, where $m = \dim C$,

$$H = i\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} \quad \text{and} \quad M_1 = \begin{bmatrix} -A_1 & D_1 \\ C_1 & A_1^* \end{bmatrix}$$

and I is the identity map on C. (See [6]. This generalizes the description using eigenvectors of M_1 introduced in [10].) (Recall that a subspace $L \subset C \times C$ is called H-neutral if $(Hx, y) = 0$ for every $x, y \in L$, where $(\cdot, \cdot)$ stands for the standard scalar product in $C \times C$.)

(b) The partial multiplicities of M_1 (i.e. the sizes of Jordan blocks in the Jordan normal form of M_1) which correspond to the pure imaginary eigenvalues of M_1 (if any) are all even (see [6]).

(c) The rational matrix function

$$Z(\lambda) = I + D_0^*(\lambda I + iA_1^*)^{-1}C_1(\lambda I - A_1)^{-1}D_0,$$

where D_0 is any $m \times m$ matrix with $D_1 = D_0D_0^*$, is positive semidefinite for every real λ which is not a pole of $Z(\lambda)$ (see [16] or [3]).

It turns out that these properties determine also the existence of hermitian solutions of (2.1):

THEOREM 3.1. *Equation* (2.1) *has a hermitian solution if and only if there is an m-dimensional, H-neutral invariant subspace of M_1, or, equivalently, if one of the conditions* (b) *and* (c) *holds.*

Proof. Assume that (2) has a hermitian solution. Taking the maximal hermitian solution of (2) for X_1 (which exists by Theorem 2.1), we find that, because all eigenvalues of $A_1 - D_1X_1$ are in the closed left halfplane, equation (3) is uniquely solvable for X_{12}. Then (4) is uniquely solvable for X_2 and this solution is hermitian. Thus a hermitian solution X of (2.1) is obtained.

Conversely, if (2.1) has a hermitian solution X, then (2) holds with X_1 hermitian. □

We shall distinguish between two cases. If

$$\sigma(M_1) \cap \overline{\sigma(A_2)} = \varnothing, \tag{5}$$

where A_2 is defined by (1), the equation (2.1) will be called *regular.* Otherwise, it will be called *nonregular.* This distinction is dictated by the fact that in the regular case the hermitian solutions of (2.1) are completely described in terms of certain M_1-invariant subspaces, while in the nonregular case such a description is only partial. These two cases are discussed separately in the next two sections.

4. The regular case. In this section we shall assume that the equation (2.1) is regular, i.e. M_1 and A_2^* have no common eigenvalues. It turns out that there is a

one-to-one correspondence between the set of hermitian solutions of (1) and the set of M_1-invariant subspaces corresponding to the spectrum of M_1 in the open right halfplane, as follows. We denote by L_+ the maximal M-invariant subspace with $\sigma(M_1|_{L_+})$ lying in the open right halfplane.

THEOREM 4.1. *Assume* (2.1) *has hermitian solutions and is regular. For every* M_1*-invariant subspace* $L \subset L_+$ *there exists a unique hermitian solution* $X = \varphi(L)$ *of* (2.1) *satisfying*

$$\text{Im}\begin{bmatrix} I \\ PXP \end{bmatrix} \cap L_+ = L, \tag{1}$$

where P *is the orthogonal projector on* C. *Conversely, for every hermitian solution* X *of* (2.1) *there is a unique* M_1*-invariant subspace* $L \subset L_+$ *such that* (1) *holds, i.e.* $X = \varphi(L)$.

Proof. Write (3.1) in the equivalent form of (3.2), (3.3), (3.4). As shown in [6] (see also [3]) there is a one-to-one correspondence between the set of hermitian solutions X_1 of (2) and the set of all M_1-invariant subspaces L which are contained in L_+ given by the formula

$$\text{Im}\begin{bmatrix} I \\ X_1 \end{bmatrix} \cap L_+ = L. \tag{2}$$

Further note that the restriction of M_1 to $\text{Im}\,[{}^{I}_{X_1}]$ is similar to $-(A_1 - D_1X_1)$. Therefore the regularity condition (3.5) ensures that equation (3.3) can be uniquely solved for X_{12} for any hermitian solution X_1 of (3.2). Also (3.4) can be uniquely solved for X_2 in view of the stability of A_2. □

The one-to-one correspondence φ in Theorem 4.1 preserves topology, analyticity and a partial order as shown in the next theorem. In connection with topology note that the set of subspaces in $\mathbb{C}^{2m}$ (where $m = \dim C$) is considered as a metric space with the gap metric

$$\theta(L_1, L_2) = \|P_{L_1} - P_{L_2}\|, \qquad L_1, L_2 \subset \mathbb{C}^{2m},$$

where P_{L_i} is the orthogonal projector on L_i, $i = 1, 2$, and the norm is understood in the Hilbert space sense.

THEOREM 4.2. (i) *The correspondence* φ *introduced in Theorem* 4.1 *is a homeomorphism between the set of hermitian solutions of* (2.1) *and the set of all* M_1*-invariant subspaces which are contained in* L_+.

(ii) *Let* L_1 *and* L_2 *be* M_1*-invariant subspaces contained in* L_+, *and let* $X_1 = \varphi(L_1)$, $X_2 = \varphi(L_2)$ *be the corresponding hermitian solutions of* (1). *Then* $L_1 \supset L_2$ *if and only if* $X_1 \geqq X_2$.

(iii) *If* $P(t)$ *is a* $2m \times 2m$ *matrix function which is analytic on an open connected set* $\Omega \subset \mathbb{R}^k$ *and whose values are orthogonal projectors such that for every* $t \in \Omega$, $\text{Im}\,P(t)$ *is an* M_1*-invariant subspace contained in* L_+, *then* $X(t) \overset{\text{def}}{=} \varphi(\text{Im}\,P(t))$ *is an analytic* $n \times n$ *matrix function whose values are hermitian solutions of* (2.1). *Conversely, if* $X(t)$, $t \in \Omega$ *is an analytic matrix function whose values are hermitian solutions of* (2.1), *then the orthogonal projector* $P(t)$ *on* $\varphi^{-1}(X(t))$ *is an analytic* $2m \times 2m$ *matrix function on* Ω *as well.*

Proof. (i) As shown in [13] and Theorem 4.2 of [9], the one-to-one correspondence between the set of hermitian solutions X_1 of (3.2) and the set of all M_1-invariant subspaces $L \subset L_+$ given by (2) is actually a homeomorphism. Now (i) follows from the proof of Theorem 4.1, taking into account the fact that both X_{12} and X_2 depend continuously on the hermitian solution X_1 of (2).

(iii) This part follows from the corresponding analyticity property for hermitian solutions of (3.2) (see [11]) taking into account the fact that the solutions X_{12} and X_2 of equations (3.3) and (3.4), respectively, depend analytically on the data of these equations.

(ii) It is known (see [1], [11]) that the correspondence between hermitian solutions $X_1 = \psi(L)$ of (3.2) and the subspace

$$L = \operatorname{Im} \begin{bmatrix} I \\ X_1 \end{bmatrix} \cap L_+$$

is partial order preserving in the sense that $L_1 \supset L_2$ holds if and only if $\psi(L_1) - \psi(L_2)$ is positive semidefinite. In view of this property, the proof of statement (ii) will follow from the following result which concerns the possibility of extending (or dilating) solutions of (3.2) to solutions of (2.1) in such a way as to retain their partial ordering.

LEMMA 4.3. *Let $D_1, A_1, C_1, A_2, C_2, A_{12}, C_{12}$ be complex matrices of sizes $m \times m$, $m \times m$, $m \times m$, $p \times p$, $p \times p$, $m \times p$, $m \times p$, respectively, where D_1, C_1 and C_2 are hermitian. Assume that $\sigma(-A_2) \cap \overline{\sigma(A_2)} = \varnothing$, and that*

$$\sigma(-(A_1 - D_1 X_1)) \cap \overline{\sigma(A_2)} = \varnothing$$

for every hermitian solution X_1 of the equation

$$X_1 D_1 X_1 - X_1 A_1 - A_1^* X_1 - C_1 = 0. \tag{3}$$

Then for every hermitian solution X_1 of (3) there are unique matrices X_{12} and X_2 such that

$$X = \begin{bmatrix} X_1 & X_{12} \\ X_{12}^* & X_2 \end{bmatrix}$$

satisfies the equation

$$X \begin{bmatrix} D_1 & 0 \\ 0 & 0 \end{bmatrix} X - X \begin{bmatrix} A_1 & A_{12} \\ 0 & A_2 \end{bmatrix} - \begin{bmatrix} A_1^* & 0 \\ A_{12}^* & A_2^* \end{bmatrix} X - \begin{bmatrix} C_1 & C_{12} \\ C_{12}^* & C_2 \end{bmatrix} = 0, \tag{4}$$

and if $X_1 \geqq Y_1$ are hermitian solutions of (3) then the corresponding solutions X and Y of (4) satisfy $X \geqq Y$.

Proof. Equation (4) is equivalent to three equations: Equation (3) together with

$$(A_1 - D_1 X_1)^* X_{12} + X_{12} A_2 = -(C_{12} + X_1 A_{12}),$$

$$A_2^* X_2 + X_2 A_2^* = X_{12}^* D_1 X_{12} - X_{12}^* A_{12} - A_{12}^* X_{12} - C_2.$$

Hence the existence and uniqueness of X_{12} and X_2 follow from the assumptions on the spectra of A_2 and $A_1 - D_1 X_1$.

To prove the second statement of the lemma, we can (and will) assume without loss of generality that $C_1 = 0$, $C_2 = 0$, $C_{12} = 0$ and that A_2 is in upper triangular form. Indeed, for a fixed hermitian solution $\tilde{X}$ of (4), a hermitian matrix X is a solution of (4) if and only if

$$(X - \tilde{X}) D (X - \tilde{X}) - (X - \tilde{X})(A - D\tilde{X}) - (A^* - D\tilde{X})(X - \tilde{X}) = 0, \tag{5}$$

where

$$A = \begin{bmatrix} A_1 & A_{12} \\ 0 & A_2 \end{bmatrix}, \qquad D = \begin{bmatrix} D_1 & 0 \\ 0 & 0 \end{bmatrix},$$

i.e. $X - \tilde{X}$ satisfies an equation analogous to (4) with $C_1 = 0$, $C_2 = 0$, $C_{12} = 0$ and A replaced by $A - D\tilde{X}$. One checks easily that the assumptions on the spectra of A_2 and

of $A_1 - D_1X_1$ remain valid for the equation (5) as well. Further, for any nonsingular $p \times p$ matrix S, X satisfies (4) if and only if

$$\hat{X} = \begin{bmatrix} I & 0 \\ 0 & S^* \end{bmatrix} X \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix}$$

satisfy the equation

$$\hat{X}\begin{bmatrix} D_1 & 0 \\ 0 & 0 \end{bmatrix}\hat{X} - \hat{X}\begin{bmatrix} A_1 & A_{12}S \\ 0 & S^{-1}A_2S \end{bmatrix} - \begin{bmatrix} A_1^* & 0 \\ S^*A_{12}^* & S^*A_2^*S^{-1*} \end{bmatrix}\hat{X} - \begin{bmatrix} C_1 & C_{12}S \\ S^*C_{12}^* & S^*C_{12}S \end{bmatrix} = 0,$$

and for a suitable S the matrix $S^{-1}A_2S$ is upper triangular.

For a fixed j, $1 \leqq j \leqq p-1$, write

$$A_2 = \begin{bmatrix} A_{22} & A_{23} \\ 0 & A_{33} \end{bmatrix}, \qquad A_{12} = [A_{122}, \quad A_{123}],$$

where A_{22}, A_{23}, A_{33}, A_{122} and A_{123} are matrices of sizes $j \times j$, $j \times (p-j)$, $(p-j) \times (p-j)$, $m \times j$ and $m \times (p-j)$, respectively. It is easy to see that, since $\sigma(-A_2) \cap \overline{\sigma(A_2)} = \varnothing$, the assumptions of the lemma hold with D_1, A_1, A_2, A_{12} replaced by

$$\begin{bmatrix} D_1 & O_{m\times j} \\ O_{j\times m} & O_{j\times j} \end{bmatrix}, \quad \begin{bmatrix} A_1 & A_{122} \\ 0 & A_{22} \end{bmatrix}, \quad A_{33}, \quad \begin{bmatrix} A_{123} \\ A_{23} \end{bmatrix},$$

respectively (here $O_{r\times s}$ stands for the $r \times s$ zero matrix). Hence, using induction on the size p of the matrix A_2, we can restrict ourselves to the case $p = 1$, i.e. $A_2 = a_2$ is a scalar. In this case (4) is equivalent to the three equations

$$X_1D_1X_1 - X_1A_1 - A_1^*X_1 = 0, \tag{6}$$

$$(A_1 - D_1X_1)^*X_{12} + a_2X_{12} = -X_1A_{12}, \tag{7}$$

$$(a_2 + \bar{a}_2)X_2 = X_{12}^*D_1X_{12} - X_{12}^*A_{12} - A_{12}^*X_{12}. \tag{8}$$

Equation (7) gives (recall that, from the hypotheses of the lemma, $a_2I + (A_1 - D_1X_1)^*$ is nonsingular)

$$X_{12} = -[a_2I + (A_1 - D_1X_1)^*]^{-1}X_1A_{12}.$$

But in view of (6) the equality

$$[\lambda I + (A_1 - D_1X_1)^*]^{-1}X_1 = X_1(\lambda I - A_1)^{-1}$$

holds for every λ not belonging to $\overline{\sigma(-A_1 + D_1X_1)} \cup \sigma(A_1)$ and therefore

$$[a_2I + (A_1 - D_1X_1)^*]^{-1}X_1 = X_1(a_2I - A_1)^{-1},$$

where the right-hand side is meaningful in the sense that $X_1(a_2I - A_1)^{-1} = \lim_{\lambda \to a_2}[X_1(\lambda I - A_1)^{-1}]$ even when $a_2 \in \sigma(A_1)$. Hence

$$X_{12} = -X_1(a_2I - A_1)^{-1}A_{12}.$$

Now (8) becomes

$$\begin{aligned}(a_2 + \bar{a}_2)X_2 = {} & A_{12}^*(\bar{a}_2I - A^*)X_1D_1X_1(a_2I - A_1)^{-1}A_{12} + A_{12}^*(\bar{a}_2I - A_1^*)^{-1}X_1A_{12} \\ & + A_{12}^*X_1(a_2I - A_1)^{-1}A_{12},\end{aligned}$$

and assuming $a_2 \notin \sigma(A_1)$ and inserting $X_1A_1 + A_1^*X_1$ in place of $X_1D_1X_1$, we obtain eventually

$$(a_2 + \bar{a}_2)X_2 = A_{12}^*(a_2I - A_1^*)^{-1}(a_2 + \bar{a}_2)X_1(a_2I - A_1)^{-1}A_{12}.$$

As $a_2+\bar{a}_2\neq 0$, we have

$$X_2=A_{12}^*(\bar{a}_2I-A_1^*)^{-1}X_1(a_2I-A_1)^{-1}A_{12}$$

and

$$X=\begin{bmatrix} X_1 & -X_1(a_2I-A_1)^{-1}A_{12} \\ -A_{12}^*(\bar{a}_2I-A_1^*)^{-1}X_1 & A_{12}^*(\bar{a}_2I-A_1^*)^{-1}X_1(a_2I-A_1)^{-1}A_{12}\end{bmatrix}$$
$$=K^*\begin{bmatrix} X_1 & X_1 \\ X_1 & X_1\end{bmatrix}K,$$

where $K=\operatorname{diag}(I,-(a_2I-A_1)^{-1}A_{12})$.

Analogously, for a hermitian solution Y_1 of (6) and the corresponding solution

$$Y=\begin{bmatrix} Y_1 & Y_{12} \\ Y_{12}^* & Y_2\end{bmatrix}$$

of (6), (7) and (8) we have

$$Y=K^*\begin{bmatrix} Y_1 & Y_1 \\ Y_1 & Y_1\end{bmatrix}K.$$

So if $X_1\geqq Y_1$, then

$$\begin{bmatrix} X_1 & X_1 \\ X_1 & X_1\end{bmatrix}\geqq\begin{bmatrix} Y_1 & Y_1 \\ Y_1 & Y_1\end{bmatrix}$$

and consequently $X\geqq Y$. The assumption $a_2\notin\sigma(A_1)$ is immaterial, because one can take a complex sequence $\{b_m\}_{m=1}^{\infty}$ tending to a_2 with $b_m\notin\sigma(A_1)$, apply the already proved result for each b_m (in place of a_2), and pass to the limit when $m\to\infty$. □

As a corollary to Theorem 4.2 we obtain the existence of minimal solutions:

COROLLARY 4.4. *Under the regularity assumption* $\sigma(M_1)\cap\overline{\sigma(A_2)}=\varnothing$, *there exists a minimal hermitian solution of* (2.1).

Indeed, the hermitian solution $X=\varphi(\{0\})$ (in the notation of Theorem 4.1) is minimal in view of Theorem 4.2.

5. The nonregular case. We consider now the nonregular case:

$$\sigma(M_1)\cap\overline{\sigma(A_2)}\neq\varnothing.$$

Let $\tilde{L}_+$ be the maximal M_1-invariant subspace such that $\sigma(M_1|_{\tilde{L}_+})$ lies in the open right halfplane and $\sigma(M_1|_{\tilde{L}_+})\cap\sigma(-A_2)=\varnothing$. Such an $\tilde{L}_+$ always exists; if $\sigma(M_1|_L)\cap\sigma(-A_2)\neq\varnothing$ for every nonzero M-invariant subspace L with $\sigma(M_1|_L)$ lying in the open right halfplane, we put $\tilde{L}_+=\{0\}$. We have now a partial description of hermitian solutions of (2.1) in terms of M_1-invariant subspaces contained in $\tilde{L}_+$:

THEOREM 5.1. *Assume that* (2.1) *has a hermitian solution. For every* M_1*-invariant subspace* $L\subset\tilde{L}_+$ *there exists a unique hermitian solution* $X=\tilde{\varphi}(L)$ *of* (2.1) *satisfying*

$$\operatorname{Im}\begin{bmatrix} I \\ PMP\end{bmatrix}\cap\tilde{L}_+=L, \tag{1}$$

where P *is the orthogonal projector on the controllable subspace* C *of* (A, D). *The solution* X *satisfies*

$$\sigma(-A|_C+PDPXP)\cap\overline{\sigma(A_2)}=\varnothing. \tag{2}$$

Conversely, for every hermitian solution X of (2.1) *with* $\sigma(-A|_C + PCPXP) \cap \overline{\sigma(A_2)} = \varnothing$ *there exists a unique* M_1*-invariant subspace* $L \subset \tilde{L}_+$ *such that* (1) *holds. The correspondence* $\tilde{\varphi}$ *between* M_1*-invariant subspaces contained in* $\tilde{L}_+$ *and hermitian solutions satisfying* (2) *is analytic and a homeomorphism and preserves the partial order.*

The continuity, analyticity and the partial order preservation of $\tilde{\varphi}$ are understood as in Theorem 4.2.

Theorem 5.1 is proved in the same way as Theorem 4.2.

It can happen, in general, that there exist hermitian solutions X of (2.1) for which (2) does not hold (see Example 2.1). In this case, for at least one hermitian solution X_1 of (3.2) the linear equation (3.3) has many solutions X_{12}, and therefore the set of hermitian solutions of (2.1) is not compact. In particular, there is no minimal hermitian solution. Conversely, if the set of hermitian solutions of (2.1) is compact, then equation (3.3) has no solution X_{12} for any hermitian solution X_1 of (3.2) satisfying $\sigma(-A_1 + D_1X_1) \cap \overline{\sigma(A_2)} = \varnothing$. Hence all hermitian solutions X of (2.1) satisfy (2). In particular, Theorem 5.1 ensures the existence of a minimal hermitian solution (which is obtained from $L = (0)$). We have proved the following:

COROLLARY 5.2. *The following statements are equivalent for the equation* (2.1) *with* $D \geqq 0$, $C^* = C$ *and* (A, D) *stabilizable* (*in either the regular or nonregular case*):

(i) *the set of hermitian solutions of* (2.1) *is compact*;

(ii) *there exists a minimal hermitian solution of* (2.1);

(iii) *every hermitian solution X of* (2.1) *satisfies*

$$\sigma(-A|_C - PDPXP) \cap \overline{\sigma(A_2)} = \varnothing,$$

where P is the orthogonal projector on the controllable subspace C of (A, D), and $A_2 = (I - P)A(I - P)$.

6. The real case. Consider the equation

$$XDX - XA - A^*X - C = 0 \tag{1}$$

with $D \geqq 0$, $C = C^*$, (A, D) stabilizable, and assume in addition that A, C, D are real matrices. Naturally, in this case real symmetric solutions X of (1) are sought. The results of § 2, together with their proofs, remain valid if "hermitian" is replaced by "real symmetric" throughout § 2. Note that the maximal hermitian solution of (1) is necessarily real. Note also that if there is a hermitian solution of (1), then there is also a real symmetric solution.

To characterize real symmetric solutions of (1) in terms of invariant subspaces, introduce the M_1-invariant subspace $L_{++} \subset \mathbb{C}^{2m}$ which corresponds to the eigenvalues of M_1 lying in the quadrant $\{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda > 0, \operatorname{Im} \lambda \geqq 0\}$.

THEOREM 6.1. *Assume* (1) *has a real symmetric solutions and is regular. For every* M_1*-invariant subspace* $L \subset L_{++}$ *there exists a unique real symmetric solution* $X = \tau(L)$ *of* (1) *satisfying*

$$\operatorname{Im} \begin{bmatrix} I \\ PXP \end{bmatrix} \cap L_{++} = L, \tag{2}$$

where P is the orthogonal projector on the controllable subspace of (A, D). Conversely, for every real symmetric solution X of (1) *there exists a unique M-invariant subspace* $L \subset L_{++}$ *such that* (2) *holds, i.e.* $X = \tau(L)$. *The correspondence φ is homeomorphic, analytic, and preserves partial order.*

The proof of Theorem 6.1 is obtained in the same way as the proof of Theorems 4.1 and 4.2 using Theorem II.4.14 of [3].

In the nonregular case a result holds for real symmetric solutions of (1) which is analogous to Theorem 5.1. We leave its statement to the reader. Corollary 5.2 is valid in the real symmetric case as well. Finally, we remark that if a minimal hermitian solution of (1) exists, it is necessarily real.
