By Lemma 2.4, there exists a unique couple of controls $(u, v) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that, P a.s.,

$$\alpha(v) = u \text{ and } \beta_\epsilon(u) = v.$$

Since α is nonanticipative and β_ϵ is admissible, and since $\alpha(v^\epsilon) \equiv u^\epsilon$ and $\beta_\epsilon(u^\epsilon) \equiv v^\epsilon$ on $[t, \theta]$, it is easy to check that

$$u \equiv u^\epsilon \text{ and } v \equiv v^\epsilon \text{ on } [t, \theta].$$

Thus $X_\theta^{t,x,u,v} = X_\theta^{t,x,\alpha(v),v} = X_\theta^\epsilon$. It follows then from (5.2) and (5.3) that

$$\begin{aligned} J_2(t,x,u,\beta_\epsilon(u)) = J_2(t,x,\alpha(v),v) &= E[E(g_2(X_T^{t,x,\alpha(v),v})|\mathcal{F}_{t,\theta})] \\ &\le E[W_2(\theta, X_\theta^{t,x,\alpha(v),v})] + \epsilon/2 \\ &< W_2(t,x) - \epsilon/2, \end{aligned}$$

which is in contradiction with (5.1). □

LEMMA 5.3. *Let us fix $\epsilon > 0$ and $t_0 = t < t_1 < \cdots < t_m = T$. Then there is some $(u^\epsilon, v^\epsilon) \in \mathcal{U}(t) \times \mathcal{V}(t)$ such that, for any $i = 0, \ldots, (m-1)$, for $j = 1, 2$, P a.s.,*

$$E[W_j(t_{i+1}, X_{t_{i+1}}^\epsilon)|\mathcal{F}_{t,t_i}] \ge W_j(t_i, X_{t_i}^\epsilon) - \epsilon,$$

where $X_\cdot^\epsilon = X_\cdot^{t,x,u^\epsilon,v^\epsilon}$.

Proof. We construct (u^ϵ, v^ϵ) by induction on the interval $[t_i, t_{i+1})$. Let us first notice that the result for $i = 0$ is given by Lemma 5.2.

Let us now assume that (u^ϵ, v^ϵ) is constructed on $[t_0, t_i)$ and let us define it on $[t_i, t_{i+1})$. From Lemma 5.2, for any $y \in \mathbb{R}^n$, there is some $(u^y, v^y) \in \mathcal{U}(t_i) \times \mathcal{V}(t_i)$ such that for any $s \in [t_i, T]$ and for $j = 1, 2$,

$$E[W_j(s, X_s^{t_i,y,u^y,v^y})] \ge W_j(t_i, y) - \epsilon/2.$$

Using the continuity of $W_j(t_i, \cdot)$ and of $E[W_j(s, X_s^{t_i,\cdot,u^y,v^y})]$, we can find a Borel partition $(O_l \; i = 1, 2, \ldots)$ of $\mathbb{R}^n$ such that, for any l, there is some $y_l \in O_l$ with, for $j = 1, 2$,

$$\forall z \in O_l, \; E[W_j(s, X_s^{t_i,z,u^{y_l},v^{y_l}})] \ge W_j(t_i, z) - \epsilon.$$

Then we define, for any $z \in \mathbb{R}^n$, the control pair $(\tilde{u}(z), \tilde{v}(z))$ by

$$\forall s \ge t, \; \tilde{u}(z)_s = \sum_l 1_{O_l}(z) u_s^{y_l} \text{ and } \tilde{v}(z)_s = \sum_l 1_{O_l}(z) v_s^{y_l},$$

and we set

$$(u^\epsilon, v^\epsilon) = (\tilde{u}(X_{t_i}^{t,x,u^\epsilon,v^\epsilon}), \tilde{v}(X_{t_i}^{t,x,u^\epsilon,v^\epsilon})) \text{ on } [t_i, t_{i+1}).$$

We have, for all $s \ge t_i$, P a.s.,

$$E[W_j(s, X_s^\epsilon)|\mathcal{F}_{t,t_i}] \ge W_j(t_i, X_{t_i}^\epsilon) - \epsilon,$$

where, as usual, $X^{\epsilon}_{\cdot} = X^{t,x,u^{\epsilon},v^{\epsilon}}_{\cdot}$. Using the above inequality for $s = t_{i+1}$ completes the proof by induction. □

We are now ready to prove Proposition 5.1. Let us choose a partition $t_0 = t < t_1 < \cdots < t_m = T$ and let us set

$$\tau = \sup_i |t_{i+1} - t_i|.$$

Since $W_j(\cdot, y)$ are uniformly Hölder continuous and $W_j(s, \cdot)$ are uniformly Lipschitz continuous and since the dynamic is bounded, we can choose τ sufficiently small in such a way that, for all $k \in \{0, \dots, m-1\}$ and all $s \in [t_k, t_{k+1})$,

$$\|W_j(t_{k+1}, X^{t,x,u,v}_{t_{k+1}}) - W_j(s, X^{t,x,u,v}_{s})\|_2 \le \gamma, \tag{5.4}$$

where $\gamma = \epsilon^{\frac{3}{2}}/4$.

Let $(u, v) \in \mathcal{U}(t) \times \mathcal{V}(t)$ be defined by Lemma 5.3 for $\epsilon = \epsilon/(2m)$: for any $i = 0, \dots, (m-1)$, for $j = 1, 2$, P a.s.,

$$E[W_j(t_{i+1}, X_{t_{i+1}})|\mathcal{F}_{t,t_i}] \ge W_j(t_i, X_{t_i}) - \epsilon/(2m), \tag{5.5}$$

where $X_{\cdot} = X^{t,x,u,v}_{\cdot}$. Let us now fix $t \le s_1 < s_2 \le T$. Let also t_i and t_k be such that $t_{i-1} \le s_1 < t_i$ and $t_k < s_2 \le t_{k+1}$. Then we have, thanks to (5.5), for $j = 1, 2$, P a.s.,

$$E[W_j(t_{k+1}, X_{t_{k+1}})|\mathcal{F}_{t,t_i}] \ge W_j(t_i, X_{t_i}) - \epsilon/2.$$

Taking the conditional expectation with respect to $\mathcal{F}_{t,s_1}$ gives, since $t_i \ge s_1$, P a.s.,

$$E[W_j(t_{k+1}, X_{t_{k+1}})|\mathcal{F}_{t,s_1}] \ge E[W_j(t_i, X_{t_i})|\mathcal{F}_{t,s_1}] - \epsilon/2. \tag{5.6}$$

Let us set

$$Z_1 = E[W_j(t_{k+1}, X_{t_{k+1}})|\mathcal{F}_{t,s_1}] - E[W_j(t_i, X_{t_i})|\mathcal{F}_{t,s_1}] + \epsilon/2$$

and

$$Z_2 = E[W_j(s_2, X_{s_2})|\mathcal{F}_{t,s_1}] - W_j(s_1, X_{s_1}) + \epsilon/2.$$

From (5.4) and (5.6), we have $Z_1 \ge 0$, P a.s., and $\|Z_2 - Z_1\|_2 \le 2\gamma$. Therefore,

$$P[Z_2 < -\epsilon/2] \le P[|Z_2 - Z_1| > \epsilon/2] \le 4\gamma^2/(\epsilon/2)^2 = \epsilon,$$

i.e.,

$$P\left\{E[W_j(s_2, X_{s_2})|\mathcal{F}_{t,s_1}] \ge W_j(s_1, X_{s_1}) - \epsilon\right\} \ge 1 - \epsilon.$$

Therefore the proof of Proposition 5.1 is complete. □

6. Appendix: On strategies. In the appendix we bring together several technical facts on strongly nonanticipative strategies. Some of them (Lemma 6.1 and Corollary 6.4) are used in the proofs of Theorems 2.9 and 2.10, and some others have seemed to us of general interest for a better understanding of the different notions of strategies.

In the following lemma we prove that the strategy built in the proof of Lemma 3.1 is strongly nonanticipative. Let us first recall the construction of the strategy α.

Let $\theta \in (t,T)$ be a fixed time, $(O_i)_{i\in\mathbb{N}}$ be a Borel partition of $\mathbb{R}^n$, and, for any $i \in \mathbb{N}$, $\alpha_i \in \mathcal{A}(\theta)$ be an admissible strategy. We also fix some control $u \in \mathcal{U}(t)$. The strategy α is defined by setting

$$\forall v \in \mathcal{V}(t), \alpha(v)_s = \begin{cases} u_s & \text{for } s \in [t,\theta], \\ \alpha_i(v|_{[\theta,T]})_s & \text{for } s \in (\theta,T], \text{ on } \{X_\theta^{t,x,u,v} \in O_i\}. \end{cases}$$

LEMMA 6.1. *The strategy α is strongly nonanticipative.*

Proof. Let S be an $(\mathcal{F}_{t,s})_{s\in[t,T]}$-stopping time and let $v_1, v_2 \in \mathcal{V}(t)$ be such that $v_1 \equiv v_2$ on $[\![t,S]\!]$. We have to prove that $\alpha(v_1) \equiv \alpha(v_2)$ on $[\![t,S]\!]$.

Let us notice that the result is obvious on $\{S \le \theta\}$, because we have $\alpha(v_1) = \alpha(v_2) = u$ on $[t,\theta]$. Let us now set $B = \{S > \theta\}$ and $B_i = B \cap \{X_\theta^{t,x,u,v} \in O_i\}$. We can assume that B is not neglectable, since otherwise there is nothing to prove. Let us now prove that $\alpha(v_1) \equiv \alpha(v_2)$ on $[\![\theta,S]\!] \cap ([t,T] \times B)$.

For this, let us first recall the identifications $\Omega_{t,T} = \Omega_{t,\theta} \times \Omega_{\theta,T}$ and $P_{t,T} = P_{t,\theta} \otimes P_{\theta,T}$. We know that, for almost all $\omega_1 \in \Omega_{t,\theta}$, the controls $v_1(\omega_1)$ and $v_2(\omega_1)$ belong to $\mathcal{V}(\theta)$. Let us finally introduce, for any $0 \le r \le s \le T$, $\mathcal{F}^0_{r,s} = \sigma\{B_\tau - B_r,\ \tau \in [r,s]\}$ (let us underline that $\mathcal{F}_{r,s}$ is nothing but $\mathcal{F}^0_{r,s}$ augmented by all null-sets of P). Using the identification $\mathcal{F}^0_{t,T} = \mathcal{F}^0_{t,\theta} \otimes \mathcal{F}^0_{\theta,T}$ and the fact that the section $N(\omega_1) = \{\omega_2 \in \Omega_{\theta,T},\ (\omega_1,\omega_2) \in N\}$ of a $P_{t,T}$-neglectable set $N \in \mathcal{F}_{t,T}$ is $P_{\theta,T}$-neglectable for almost all $\omega_1 \in \Omega_{t,\theta}$, it can also be proved that, for almost all $\omega_1 \in \Omega_{t,\theta}$, $S(\omega_1)$ is an $(\mathcal{F}_{\theta,s})_{s\in[\theta,T]}$-stopping time. From the definition of the strategy α, we have, for any $i \in \mathbb{N}$ and for almost all $\omega_1 \in B_i$, $\alpha(v_1)(\omega_1,\cdot) = \alpha_i(v_1(\omega_1)_{[\theta,T]})$ and $\alpha(v_2)(\omega_1,\cdot) = \alpha_i(v_2(\omega_1)_{[\theta,T]})$ on $[\theta,T]$. Since α_i is strongly nonanticipative and since $v_1(\omega_1)_{[\theta,T]} \equiv v_2(\omega_1)_{[\theta,T]}$ on $[\![\theta,S(\omega_1)]\!]$ for almost all $\omega_1 \in B_i$, we have, for almost all $\omega_1 \in B_i$,

$$\alpha_i(v_1(\omega_1)_{[\theta,T]}) \equiv \alpha_i(v_2(\omega_1)_{[\theta,T]}) \qquad \text{on } [\![\theta,S(\omega_1)]\!].$$

Therefore, $\alpha(v_1)(\omega_1,\cdot) \equiv \alpha(v_2)(\omega_1,\cdot)$ on $[\![\theta,S(\omega_1)]\!]$ for almost all $\omega_1 \in B$. This completes the proof of the lemma. □

Let us now introduce the following notion, which appears naturally in the proof of Theorem 2.10.

DEFINITION 6.2 (condition (**C**)). *Let $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ be a nonanticipative strategy. We say that α satisfies condition* (**C**) *if for any (deterministic) $\theta \in [t,T)$, for any control $v, \bar{v} \in \mathcal{V}(t)$ with $v \equiv \bar{v}$ on $[t,\theta]$ and for any $A \in \mathcal{F}_{t,\theta}$, we have*

$$\alpha(v\mathbf{1}_A + \bar{v}\mathbf{1}_{A^c}) \equiv \alpha(v)\mathbf{1}_A + \alpha(\bar{v})\mathbf{1}_{A^c},$$

where $v\mathbf{1}_A + \bar{v}\mathbf{1}_{A^c}$ denotes for simplicity the control equal to $v \equiv \bar{v}$ on $[t,\theta] \times \Omega$, to v on $[\theta,T] \times A$, and to $\bar{v}$ on $[\theta,T] \times A^c$.

Remark. Although condition (**C**) is weaker than the assumption of being strongly nonanticipative for a strategy (cf. Corollary 6.4), the main results of this paper, Theorems 2.9 and 2.10, remain unchanged if condition (i) in the definition of admissible strategies is replaced by condition (**C**). However, as we shall see, condition (**C**) does not seem to be the right definition for modelizing the fact that a player can take into account only the observation of the control played by his opponent.

An equivalent formulation of condition (**C**) follows.

PROPOSITION 6.3. *Let $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ be a nonanticipative strategy. The following assertions are equivalent:*

1. *α satisfies condition* (**C**).

2. *For all stopping times S taking a finite number of values in $[t,T]$, if $v \equiv \tilde{v}$ on $[\![t,S]\!]$, then $\alpha(v) \equiv \alpha(\tilde{v})$ on $[\![t,S]\!]$.*

This result implies that condition (**C**) is weaker than the notion of strongly nonanticipative strategies.

COROLLARY 6.4. *A strongly nonanticipative strategy α satisfies condition* (**C**).

Indeed, a strongly nonanticipative strategy α obviously satisfies the second condition of the proposition.

Proof of Proposition 6.3. Let us first assume that α satisfies the second condition. For proving that α satisfies condition (**C**), let us fix $\theta \in [t,T)$, $A \in \mathcal{F}_{t,\theta}$, and $v, \bar{v}$ in $\mathcal{V}(t)$ such that $v \equiv \bar{v}$ on $[t,\theta]$. We set $v_1 = v1_A + \bar{v}1_{A^c}$. We want to prove that $\alpha(v_1) = \alpha(v)1_A + \alpha(\bar{v})1_{A^c}$ on $[\theta,T]$.

For this let us introduce the stopping time S defined by

$$S = \theta \text{ on } A^c \text{ and } S = T \text{ on } A.$$

Then $v_1 \equiv v$ on $[\![t,S]\!]$. Since α satisfies 2, $\alpha(v_1) \equiv \alpha(v)$ on $[\![t,S]\!]$. This implies that $\alpha(v_1) \equiv \alpha(v)$ on $[\theta,T] \times A$. We can prove in the same way (using the stopping time $S' = \theta$ on A and $S' = T$ on A^c) that $\alpha(v_1) \equiv \alpha(\bar{v})$ on $[\theta,T] \times A^c$. Therefore, α satisfies condition (**C**).

Let us now assume that α satisfies condition (**C**). Let S be a stopping time taking values in $t_0 = t < t_1 < \cdots < t_m = T$, and let $v, \bar{v}$ be such that $v \equiv \bar{v}$ on $[\![t,S]\!]$. We have to prove that $\alpha(v) \equiv \alpha(\bar{v})$ on $[\![t,S]\!]$. For this, let us set, for any $j \in \{0,\dots,m\}$,

$$A_j = \{S \le t_j\} \text{ and } v_j = \begin{cases} v & \text{in } ([t,t_j) \times \Omega) \cup ([t_j,T] \times A_j), \\ \bar{v} & \text{in } [t_j,T] \times A_j^c. \end{cases}$$

We are going to prove by induction that

$$\alpha(v_j) \equiv \alpha(\bar{v}) \quad \text{in } [t_j,T] \times A_j^c \quad \text{and } \alpha(v) \equiv \alpha(\bar{v}) \quad \text{in } [\![t, S \wedge t_j]\!]. \tag{6.1}$$

For $j = m$, this shows the desired result: $\alpha(v) = \alpha(\bar{v})$ on $[\![t,S]\!]$.

For $j = 0$, we have $A_0 = \{S = t\} \in \mathcal{F}_{t,t} = \{\emptyset, \Omega\}$ P a.s., and thus either $v_0 = v$ a.s. (if $A_0 = \Omega$) or $v_0 = \bar{v}$ a.s. (if $A_0 = \emptyset$). In both cases, equalities in (6.1) are clear.

Let us assume that (6.1) holds for some j. Let us first prove that $\alpha(\bar{v}) = \alpha(v)$ in $[\![t, S \wedge t_{j+1}]\!]$. For that purpose, let us notice that $v_j \equiv v$ on $[t,t_{j+1})$, because $v \equiv \bar{v}$ on $[t_j,t_{j+1}) \times A_j^c$, since $A_j^c = \{S \ge t_{j+1}\}$ and $v \equiv \bar{v}$ on $[\![t,S]\!]$. Since α is nonanticipative, we have therefore that $\alpha(v_j) \equiv \alpha(v)$ on $[t,t_{j+1})$. Using assumption (6.1), which states that $\alpha(v_j) \equiv \alpha(\bar{v})$ in $[t_j,T] \times A_j^c$, we deduce that $\alpha(\bar{v}) = \alpha(v)$ in $[t_j,t_{j+1}] \times A_j^c$. Let us now notice that

$$[\![t, S \wedge t_{j+1}]\!] = [\![t, S \wedge t_j]\!] \cup ([t_j,t_{j+1}] \times A_j^c).$$

From assumption (6.1) we know that $\alpha(\bar{v}) = \alpha(v)$ in $[\![t, S \wedge t_j]\!]$ and we have just proved that $\alpha(\bar{v}) = \alpha(v)$ in $[t_j,t_{j+1}] \times A_j^c$. Therefore, we have established that $\alpha(\bar{v}) = \alpha(v)$ in $[\![t, S \wedge t_{j+1}]\!]$.

It remains to show that $\alpha(v_{j+1}) \equiv \alpha(\bar{v})$ in $[t_{j+1},T] \times A_{j+1}^c$. Let us first notice that $v_{j+1} = v_j 1_{A_{j+1}^c} + v1_{A_{j+1}}$. Then, since $v_j \equiv v$ on $[t,t_{j+1}]$ and since $A_{j+1} \in \mathcal{F}_{t,t_{j+1}}$, we have, from assumption (**C**),

$$\alpha(v_{j+1}) = \alpha(v_j 1_{A_{j+1}^c} + v1_{A_{j+1}}) \equiv \alpha(v_j)1_{A_{j+1}^c} + \alpha(v)1_{A_{j+1}} \quad \text{on } [t,T]. \tag{6.2}$$

In particular, $\alpha(v_{j+1}) \equiv \alpha(v_j)$ on $[t,T] \times A^c_{j+1}$. Moreover, from (6.1), $\alpha(v_j) \equiv \alpha(\bar{v})$ on $[t_{j+1},T] \times A^c_{j+1}$, because $A^c_{j+1} \subset A^c_j$. Thus

$$\alpha(v_{j+1}) \equiv \alpha(v_j) \equiv \alpha(\bar{v}) \text{ on } [t_{j+1},T] \times A^c_{j+1}.$$

By induction the proof is now complete. □

We complete this appendix by showing that condition (**C**) is not equivalent to the notion of strongly nonanticipative strategies. More precisely, we build a strategy that is nonanticipative with delay, is an r-strategy, and satisfies condition (**C**) but is not strongly nonanticipative.

Let us suppose that each of the spaces in which the controls take their values has only two elements: $U = \{u_1, u_2\}$ and $V = \{v_1, v_2\}$. Let $t \in [0,T]$. We define the strategy $\alpha : \mathcal{V}(t) \to \mathcal{U}(t)$ in the following way.

Let $t = t_0 < t_1 < t_2 = T$ be a partition of $[t,T]$. For any $v \in \mathcal{V}(t)$, we set $\alpha(v)_s = u_1$ for $s \in [t,T]$ if v satisfies the following property:

$$\exists \epsilon > 0 \text{ such that } v \equiv v_1 \text{ on } [t, t+\epsilon]. \tag{6.3}$$

Otherwise we set $\alpha(v)_s = u_1$ for $s \in [t,t_1]$ and $\alpha(v)_s = u_2$ for $s \in (t_1,T]$.

It is easy to check that α is a nonanticipative strategy with delay. Let us now prove that α is an r-strategy. If $t > 0$, for $\bar{t} \in [0,t)$ and $v \in \mathcal{V}(\bar{t})$, define the process $(\tilde{u}_s = \alpha(v|_{[t,T]})_s, s \in [t,T])$ (using the notation of section 2). This process satisfies $\tilde{u} \equiv u_1$ on $[t,t_1]$ and then is constant on $(t_1,T]$ equal to u_1 or u_2, with

$$\{\tilde{u}_s = u_1, s \in (t_1,T]\} = \bigcap_{\epsilon > 0 \text{ rational}} \{v \equiv v_1 \text{ in } [t, t+\epsilon]\} \in \mathcal{F}_{\bar{t},t+} \subset \mathcal{F}_{\bar{t},t_1}.$$

Thus $\tilde{u}$ is adapted to the filtration $(\mathcal{F}_{\bar{t},s})_{s \geq t}$. Since, moreover, its paths are left continuous, it follows that $\tilde{u}$ is $(\mathcal{F}_{\bar{t},s})_{s \geq t}$-progressively measurable.

Let us now prove that α satisfies the condition (**C**). Let us point out that $\mathcal{F}_{t,t} = \{\emptyset, \Omega\}$ P a.s. Thus (**C**) is trivially satisfied for $\theta = t$. Further, by the construction of α, if for $v, \bar{v} \in \mathcal{V}(t)$, we have $v \equiv \bar{v}$ on some time interval $[t,\theta], \theta > t$, then $\alpha(v) = \alpha(\bar{v})$ on $[t,T]$. In particular, α satisfies (**C**).

We finally show that α is not strongly anticipative. Let S be an $(\mathcal{F}_{t,s})_{s \in [t,T]}$-stopping time such that $P[S > t_1] > 0$ and, for all $\epsilon > 0, P[S \leq t+\epsilon] > 0$, say, $S = \inf\{s \geq t, B_s - B_t = 1\} \wedge T$. We define v and $\bar{v} \in \mathcal{V}(t)$ by

$$v \equiv v_1 \text{ on } [t,T],$$
$$\bar{v} \equiv v_1 \text{ on } [\![t,S]\!] \text{ and } \bar{v} \equiv v_2 \text{ on }]\!]S,T]\!].$$

It holds that $v \equiv \bar{v}$ on $[\![t,S]\!]$. But the strategy α applied to the two controls gives

$$\alpha(v) \equiv u_1 \text{ and } \alpha(\bar{v}) \equiv u_2 \text{ on } (t_1,T].$$

Remark 6.5. Note also that in assertion 2 of Proposition 6.3, we have found an example of a property that holds for every stopping time taking a finite number of values but that cannot be generalized to all stopping times.

ASYMPTOTIC STABILITY OF THE WONHAM FILTER: ERGODIC AND NONERGODIC SIGNALS*

PETER BAXENDALE†, PAVEL CHIGANSKY‡, AND ROBERT LIPTSER‡

Abstract. The stability problem of the Wonham filter with respect to initial conditions is addressed. The case of ergodic signals is revisited in view of a gap in the classic work of H. Kunita (1971). We give new bounds for the exponential stability rates, which do not depend on the observations. In the nonergodic case, the stability is implied by identifiability conditions, formulated explicitly in terms of the transition intensities matrix and the observation structure.

1. Introduction.

The optimal filtering estimate of a signal from the record of noisy observations is usually generated by a nonlinear recursive equation subject to the signal a priori distribution. If the latter is unknown and the filtering equation is initialized by an arbitrary initial distribution, the obtained estimate is suboptimal in general. From an applications point of view, it is important to know whether such an estimate becomes close to the optimal one at least after enough time elapses. This property of filters to forget the initial conditions is far from being obvious and in fact generally remains an open and challenging problem.

In this paper, we consider the filtering setting for signals with a finite state space. Specifically, let $X = (X_t)_{t\geq 0}$ be a continuous time homogeneous Markov chain observed via

$$Y_t = \int_0^t h(X_s)ds + \sigma W_t \tag{1.1}$$

with the Wiener process $W = (W_t)_{t\geq 0}$, independent of X, some bounded function h, and $\sigma \neq 0$.

We assume that X_t takes values in the finite alphabet $\mathbb{S} = \{a_1, \dots, a_n\}$ and admits several ergodic classes. Namely,

$$\mathbb{S} = \Big\{ \underbrace{a_1^1, \dots, a_{n_1}^1}_{\mathbb{S}_1}, \dots, \underbrace{a_1^m, \dots, a_{n_m}^m}_{\mathbb{S}_m} \Big\},$$

where the subalphabets $\mathbb{S}_1, \dots, \mathbb{S}_m$ are noncommunicating in the sense that for any $i \neq j$ and $t \geq s$

$$P\big(X_t \in \mathbb{S}_j | X_s \in \mathbb{S}_i\big) = 0. \tag{1.2}$$

‡Department of Electrical Engineering Systems, Tel Aviv University, 69978 Tel Aviv, Israel (pavelm@eng.tau.ac.il, liptser@eng.tau.ac.il).

So, unless $m = 1$, X_t is a compound Markov chain with the transition intensities matrix

$$\Lambda = \begin{pmatrix} \Lambda_1 & 0 & 0 \\ 0 & \Lambda_2 & 0 \\ \dots & \dots & \dots \\ 0 & 0 & \Lambda_m \end{pmatrix} \tag{1.3}$$

of m ergodic classes and is not ergodic itself.

The filtering problem consists in computation of the conditional distribution,

$$\pi_t^\nu(1) = P(X_t^\nu = a_1 | \mathscr{Y}_{[0,t]}^\nu), \dots, \pi_t^\nu(n) = P(X_t^\nu = a_n | \mathscr{Y}_{[0,t]}^\nu),$$

where $\mathscr{Y}_{[0,t]}^\nu$ is the filtration, generated by $\{Y_s^\nu, 0 \le s \le t\}$ satisfying the usual conditions (henceforth, the superscript ν is used to emphasize that the distribution of X_0 is ν).

The vector-valued random process π_t^ν with entries $\pi_t^\nu(1), \dots, \pi_t^\nu(n)$ is generated by the Wonham filter [45] (see also [29, Chap. 9])

$$\begin{aligned} \pi_0^\nu &= \nu, \\ d\pi_t^\nu &= \Lambda^* \pi_t^\nu dt + \sigma^{-2}\big(\operatorname{diag}(\pi_t^\nu) - \pi_t^\nu (\pi_t^\nu)^*\big) h (dY_t^\nu - h^* \pi_t^\nu dt), \end{aligned} \tag{1.4}$$

where $\operatorname{diag}(x)$ is the scalar matrix with the diagonal $x \in \mathbb{R}^n$, h is the column vector with entries $h(a_1), \dots, h(a_n)$, and * is the transposition symbol. If ν is unknown and some other distribution β (on $\mathbb{S}$) is used to initialize the filter, the "wrong" conditional distribution $\pi_t^{\beta\nu}$ is obtained:

$$\begin{aligned} \pi_0^{\beta\nu} &= \beta, \\ d\pi_t^{\beta\nu} &= \Lambda^* \pi_t^{\beta\nu} dt + \sigma^{-2}\big(\operatorname{diag}(\pi_t^{\beta\nu}) - \pi_t^{\beta\nu} (\pi_t^{\beta\nu})^*\big) h (dY_t^\nu - h^* \pi_t^{\beta\nu} dt). \end{aligned} \tag{1.5}$$

According to the intuitive notion of stability, given at the beginning of this section, the filter defined in (1.5) is said to be asymptotically stable if

$$\lim_{t\to\infty} E\|\pi_t^\nu - \pi_t^{\beta\nu}\| = 0, \tag{1.6}$$

where $\|\cdot\|$ is the total variation norm.

If the state space of the Markov chain X consists of one ergodic class ($m = 1$), our setting is in the framework studied by Ocone and Pardoux [35]. In this case, there exists the unique invariant distribution μ, so that

$$\lim_{t\to\infty} \|S_t\gamma - \mu\| = 0, \tag{1.7}$$

where S_t is the semigroup corresponding to X and γ is an arbitrary probability distribution on $\mathbb{S}$. Moreover,

$$\lim_{t\to\infty} \int_{\mathbb{S}} |\mathcal{S}_t f(x) - \mu(f)| d\mu(x) = 0 \tag{1.8}$$

holds for any bounded $f : \mathbb{S} \mapsto \mathbb{R}$. So, it may seem that it remains only to assume

$$\nu \ll \beta \tag{1.9}$$

and allude to [35]. However, the proof of (1.6) given in [35] uses as its central argument the uniqueness theorem for the stationary measure of the filtering process π_t^ν which appeared in the work of H. Kunita [22]. Unfortunately, the proof of this theorem (Theorem 3.3 in [22]) contains a serious gap, as elaborated in the next section.

A different approach to the stability analysis of the filters for ergodic signals was initiated by Delyon and Zeitouni [19]. The authors studied the top Lyapunov exponent of the filtering equation

$$\gamma_\sigma(\beta',\beta'') = \overline{\lim}_{t\to\infty} \frac{1}{t} \log \bigl\|\pi_t^{\beta'\nu} - \pi_t^{\beta''\nu}\bigr\|, \quad \beta' \text{ and } \beta'' \text{ distributions on } \mathbb{S},$$

and showed that $\gamma_\sigma(\beta',\beta'') < 0$ too when Λ and h satisfy certain conditions. Moreover, the filter is found to be stable in the low signal-to-noise regime: $\overline{\lim}_{\sigma\to\infty} \gamma_\sigma(\beta',\beta'') \le \Re\bigl[\lambda^{\max}(\Lambda)\bigr]$ with $\lambda^{\max}(\Lambda)$ being the eigenvalue of Λ with the largest nonzero real part.

These results were further extended by Atar and Zeitouni [3], where it is shown that uniformly in $\sigma > 0$ and h

$$\gamma_\sigma(\beta',\beta'') \le -2 \min_{p\neq q} \sqrt{\lambda_{pq}\lambda_{qp}}, \text{ a.s.}, \tag{1.10}$$

and the high signal-to-noise asymptotics are obtained:

$$\overline{\lim}_{\sigma\to 0} \sigma^2 \gamma_\sigma \le -\frac{1}{2} \sum_{i=1}^d \mu_i \min_{j\neq i} \bigl[h(a_i) - h(a_j)\bigr]^2,$$

$$\underline{\lim}_{\sigma\to 0} \sigma^2 \gamma_\sigma \ge -\frac{1}{2} \sum_{i=1}^d \mu_i \sum_{j=1}^d \bigl[h(a_i) - h(a_j)\bigr]^2,$$

where μ is the ergodic measure of X.

The method in [3] (and its full development in [2]) does not rely on [22] and is based on the analysis of the Zakai equation, corresponding to (1.4) (see (5.2) below). The analysis is carried out by means of the Hilbert projective metric and the Birkhoff inequality, etc.; see section 5 for more details. This approach proved out its efficiency in several filtering scenarios (see [1], [9], [11]).

Other results and methods related to the filtering stability can be found in [4], [10], [12], [13], [14], [16], [17], [18], [15], [24], [25], [26], [27], [36], [37]. The linear Kalman–Bucy case, being the most understood, is extensively treated by several authors: [5], [32], [33], [19], [35], [28], [30] (sections 14.6 and 16.2).

In the present paper, we consider both ergodic and nonergodic signals. Applying the technique from Atar and Zeitouni [2], we show that in the ergodic case the asymptotic stability holds true without any additional assumptions. In other words, the conclusion of H. Kunita [22] is valid in the specific case under consideration.

In view of the counterexample given in section 3, it is clear that in general γ_σ may vanish at $\sigma = 0$. So, it is interesting to find out which ergodic properties of the signal are inherited by the filter regardless of the specific observation structure. In this connection we prove the inequality

$$\overline{\lim}_{t\to\infty} \frac{1}{t} \log \|\pi_t^{\beta\nu} - \pi_t^\nu\| \le -\sum_{r=1}^n \mu_r \min_{i\neq r} \lambda_{ri}.$$

Since μ is the positive measure on $\mathbb{S}$, unlike (1.10), this bound remains negative if at least one row of Λ has all nonzero entries.

Also we give the nonasymptotic bound (compare with (1.10))

$$\|\pi_t^\nu - \pi_t^{\beta\nu}\| \le C \exp\Big(- 2t \min_{p\neq q} \sqrt{\lambda_{pq}\lambda_{qp}}\Big)$$

with some positive constant C depending on ν and β only.

For the discrete time case, related results can be found in Del Moral and Guionnet [18] and Le Gland and Mevel [24]. For example, in [24] the positiveness assumption for all transition probabilities is relaxed under certain constraints on the observation process noise density.

In the case of nonergodic signal, $m > 1$, we show that the filtering stability holds true if the ergodic classes can be identified via observations and the filter matched to each class is stable. We formulate explicit sufficient identifiability conditions in terms of Λ and h.

The paper is organized as follows. In section 2, we introduce the necessary notations and clarify the role of condition $\nu \ll \beta$ in the filtering stability (Proposition 2.1). This section also gives a link to the gap in Kunita's proof [22], while in section 3 the filtering setting is described for which the stability fails and the gap becomes evident.

The main results are formulated in section 4 and proved in sections 5 and 6.

2. Preliminaries and connection to the gap in [22].

2.1. Notations. Throughout, $\nu \ll \beta$ is assumed.

In order to explain our approach, let us consider a general setting when (X, Y) is a Markov process with paths from the Skorokhod space $\mathbb{D} = \mathbb{D}_{[0,\infty)}(\mathbb{R}^2)$ of right continuous functions having limits to the left functions. Moreover, the signal component X is a Markov process itself.

We introduce a measurable space $(\mathbb{D}, \mathscr{D})$, where $\mathscr{D} = \sigma\{(x_s, y_s), s \ge 0\}$ is the Borel σ-algebra on $\mathbb{D}$. Let $D = (\mathscr{D}_t)_{t\ge 0}$ be the filtration of $\mathscr{D}_t = \sigma\{(x_s, y_s), s \le t\}$ and let $D^y = (\mathscr{D}_t^y)_{t\ge 0}$ be the filtration of $\mathscr{D}_t^y = \sigma\{y_s, s \le t\}$.

As before, we write (X_t^ν, Y_t^ν) and (X_t^β, Y_t^β), when the distribution of X_0 is ν or β, respectively, meaning that both pairs are defined on the same probability space, have the same transition semigroup, but different initial distributions.

For a bounded measurable function f, we introduce $\pi_t^\nu(f) := E(f(X_t^\nu)|\mathscr{Y}_{[0,t]}^\nu)$ and $\pi_t^\beta(f) := E(f(X_t^\beta)|\mathscr{Y}_{[0,t]}^\beta)$. Since $\pi_t^\nu(f)$ and $\pi_t^\beta(f)$ are $\mathscr{Y}_{[0,t]}^\nu$- and $\mathscr{Y}_{[0,t]}^\beta$-measurable random variables, respectively, it is convenient to identify $\pi_t^\nu(f)$ and $\pi_t^\beta(f)$ with some $\mathscr{D}_t^y$-measurable functionals of trajectories $Y_{[0,t]}^\nu = \{Y_s^\nu, s \le t\}$ and $Y_{[0,t]}^\beta = \{Y_s^\beta, s \le t\}$.

For this purpose, let Q^ν and Q^β denote the distributions of (X^ν, Y^ν) and (X^β, Y^β) on $(\mathbb{D}, \mathscr{D})$, respectively, and Q_t^ν and Q_t^β be their restrictions on $[0, t]$, so that Q_0^ν, Q_0^β are the distributions of $(X_0^\nu, Y_0^\nu), (X_0^\beta, Y_0^\beta)$. We also assume that

$$\frac{dQ_0^\nu}{dQ_0^\beta}(x, y) = \frac{d\nu}{d\beta}(x_0). \tag{2.1}$$

Since (X_t^ν, Y_t^ν) and (X_t^β, Y_t^β) have the same transition law, we have $Q^\nu \ll Q^\beta$ with

$$\frac{dQ^\nu}{dQ^\beta}(x, y) = \frac{d\nu}{d\beta}(x_0).$$

Without loss of generality, we assume that the filtrations D and D^y satisfy the general conditions with respect to $(Q^\nu + Q^\beta)/2$.

For fixed t, let $H_t^\beta(y)$ be a $\mathscr{D}_t^y$-measurable functional so that $H_t^\beta(Y^\beta) = \pi_t^\beta(f)$ a.s. Moreover, due to $Q^\nu \ll Q^\beta$, a version of $H_t^\beta(y)$ can be chosen such that the random variable $H_t^\beta(Y^\nu)$ is well defined. Then we identify $\pi_t^{\beta\nu}(f)$ with $H_t^\beta(Y^\nu)$.

We do not assume that $\beta \ll \nu$ (and thus $Q^\beta \not\ll Q^\nu$), so this construction fails for $\pi_t^{\nu\beta}(f)$. Nevertheless, a version of $H_t^\nu(y)$ can be chosen such that $H_t^\nu(Y^\nu) = \pi_t^\nu(f)$ a.s. and used for the definition of $\pi_t^{\nu\beta}(f)$. Indeed, let $\overline{Q}^\beta$ and $\overline{Q}^\nu$ be the distributions of Y^ν and Y^β, respectively, i.e., the marginal distributions of Q^β and Q^ν, obviously, $\overline{Q}^\nu \ll \overline{Q}^\beta$ as well as $\overline{Q}_t^\nu \ll \overline{Q}_t^\beta$; the restrictions of $\overline{Q}^\nu$ and $\overline{Q}^\beta$ on the interval $[0,t]$. Moreover, $\frac{d\overline{Q}_t^\nu}{d\overline{Q}_t^\beta}(Y^\beta) = E(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}_{[0,t]}^\beta)$. Now define

$$\pi_t^{\nu\beta}(f) := H_t^\nu(Y^\beta) I\left(\frac{d\overline{Q}_t^\nu}{d\overline{Q}_t^\beta}(Y^\beta) > 0\right).$$

We introduce the decreasing filtration $\mathscr{X}_{[t,\infty)}^\beta = \sigma\{X_s^\beta, s \ge t\}$, the tail σ-algebra

$$\mathscr{T}(X^\beta) = \bigcap_{t\ge 0} \mathscr{X}_{[t,\infty)}^\beta, \tag{2.2}$$

and σ-algebras $\mathscr{X}_t^\beta = \sigma\{X_t^\beta\}$, $\quad \mathscr{Y}_{[0,\infty)}^\beta = \bigvee_{t\ge 0} \mathscr{Y}_{[0,t]}^\beta$.

Set

$$\pi_t^{\beta_0}(f) = E\big(f(X_t^\beta)|\mathscr{Y}_{[0,t]}^\beta \vee \mathscr{X}_0^\beta\big). \tag{2.3}$$

2.2. Filter stability. For bounded and measurable f, the estimate $\pi_t^\nu(f)$ is asymptotically stable with respect to β if

$$\lim_{t\to\infty} E\big|\pi_t^\nu(f) - \pi_t^{\beta\nu}(f)\big| = 0. \tag{2.4}$$

Note that, when the signal process takes values in a finite alphabet and (2.4) holds for any bounded f, then (2.4) and (1.6) are equivalent.

We establish below that (2.4) holds if for large values of t the additional measurement X_0^β is useless for estimation of $f(X_t^\beta)$ via $Y_{[0,t]}^\beta$ or, analogously, if the additional measurement X_t^β is useless for estimation of $\frac{d\nu}{d\beta}(X_0^\beta)$ via $Y_{[0,\infty)}^\beta$.

PROPOSITION 2.1. *Assume $\nu \ll \beta$. Then, any of the conditions*

1.

$$\lim_{t\to\infty} E\big|\pi_t^\beta(f) - \pi_t^{\beta_0}(f)\big| = 0, \tag{2.5}$$

2.

$$E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}_{[0,\infty)}^\beta\Big) = \lim_{t\to\infty} E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}_{[0,\infty)}^\beta \vee \mathscr{X}_{[t,\infty)}^\beta\Big) \tag{2.6}$$

provides (2.4).

Proof. Let us first show that, under $\nu \ll \beta$, for any bounded f

$$\begin{aligned} &E\big|\pi_t^{\beta\nu}(f) - \pi_t^\nu(f)\big| \\ &= E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}_{[0,t]}^\beta\Big)E\Big(f(X_t^\beta)|\mathscr{Y}_{[0,t]}^\beta\Big) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)f(X_t^\beta)\big|\mathscr{Y}_{[0,t]}^\beta\Big)\Big|. \end{aligned} \tag{2.7}$$

Write

$$E\big|\pi_t^{\beta\nu}(f)-\pi_t^{\nu}(f)\big| = E\frac{d\nu}{d\beta}(X_0^\beta)\big|\pi_t^{\beta}(f)-\pi_t^{\nu\beta}(f)\big|$$
$$= EE\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\big|\pi_t^{\beta}(f)-\pi_t^{\nu\beta}(f)\big| = E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\big(\pi_t^{\beta}(f)-\pi_t^{\nu\beta}(f)\big)\Big|$$
$$= E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)E\Big(f(X_t^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\pi_t^{\nu\beta}(f)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\Big|.$$

So, it remains to show

$$E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\pi_t^{\nu\beta}(f)\big|\mathscr{Y}^\beta_{[0,t]}\Big) = E\Big(\frac{d\nu}{d\beta}(X_0^\beta)f(X_t^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big). \tag{2.8}$$

With $\mathscr{Y}_t^y$-measurable and bounded function $\Psi_t(y)$ we get

$$E\Big\{\Psi_t(Y^\beta)E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\pi_t^{\nu\beta}(f)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\Big\} = E\Big(\Psi_t(Y^\beta)\frac{d\nu}{d\beta}(X_0^\beta)\pi_t^{\nu\beta}(f)\Big)$$
$$= E\Big(\Psi_t(Y^\nu)\pi_t^{\nu}(f)\Big) = E\Big(\Psi_t(Y^\nu)f(X_t^\nu)\Big) = E\Big(\Psi_t(Y^\beta)\frac{d\nu}{d\beta}(X_0^\beta)f(X_t^\beta)\Big)$$

and notice that (2.8) is valid by the arbitrariness of Ψ_t.

The proof of (2.5)⇒(2.4). Using (2.7) and

$$E\Big(\frac{d\nu}{d\beta}(X_0^\beta)f(X_t^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) = E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\pi_t^{\beta_0}(f)\big|\mathscr{Y}^\beta_{[0,t]}\Big),$$

we derive

$$E\big|\pi_t^{\beta\nu}(f)-\pi_t^{\nu}(f)\big| = E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\pi_t^{\beta}(f) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\pi^{\beta_0}(f)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\Big|$$
$$= E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big(\pi_t^{\beta}(f)-\pi^{\beta_0}(f)\big)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\Big| \le E\frac{d\nu}{d\beta}(X_0^\beta)\big|\pi_t^{\beta}(f)-\pi_t^{\beta_0}(f)\big|,$$

where the Jensen inequality has been used. Let for definiteness $|f|\le K$ with some constant K. Then $\pi_t^\beta(f)$, $\pi_t^{\beta_0}(f)$ can also be chosen such that $|\pi_t^\beta(f)|$ and $|\pi_t^{\beta_0}(f)|$ are bounded by K. Hence, for any $C>0$, we have

$$E\big|\pi_t^{\beta\nu}(f)-\pi_t^{\nu}(f)\big| \le CE\big|\pi_t^{\beta}(f)-\pi_t^{\beta_0}(f)\big| + 2KP\Big(\frac{d\nu}{d\beta}(X_0^\beta)>C\Big).$$

Therefore, $\overline{\lim}_{t\to\infty}E\big|\pi_t^{\beta\nu}(f)-\pi_t^{\nu}(f)\big| \le 2KP\big(\frac{d\nu}{d\beta}(X_0^\beta)>C\big)$ and by the Chebyshev inequality $P\big(\frac{d\nu}{d\beta}(X_0^\beta)>C\big)\le C^{-1}\to 0,\ C\to\infty$.

The proof of (2.6)⇒(2.4). By (2.7)

$$E\big|\pi_t^{\beta\nu}(f)-\pi_t^{\nu}(f)\big|$$
$$= E\Big|E\Big(f(X_t^\beta)E\Big[\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big]\Big|\mathscr{Y}^\beta_{[0,t]}\Big) - E\Big(f(X_t^\beta)\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)\Big|.$$

Notice also

$$E\Big(f(X_t^\beta)\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) = E\Big(f(X_t^\beta)E\Big[\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)}\vee\mathscr{X}^\beta_{[t,\infty)}\Big]\big|\mathscr{Y}^\beta_{[0,t]}\Big).$$

Since $|f| \le K$, by the Jensen inequality we have

$$E\big|\pi_t^{\beta\nu}(f) - \pi_t^{\nu}(f)\big| \le KE\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big)\Big|. \tag{2.9}$$

Both random processes $E(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]})$ and $E(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)})$ are uniformly integrable forward and backward martingales with respect to the filtrations $(\mathscr{Y}^\beta_{[0,t]})_{t\ge0}$ and $(\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)})_{t\ge0}$. Therefore, they admit limits a.s. in $t \to \infty$: $E(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)})$ and $\lim_{t\to\infty} E(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)})$, respectively. By (2.6)

$$\lim_{t\to\infty}\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big)\Big| = 0.$$

We show also that

$$\lim_{t\to\infty} E\Big|E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big) - E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big)\Big| = 0. \tag{2.10}$$

Denote by α_t any of $E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,t]}\Big)$ and $E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big)$ and

$$\alpha_\infty = \lim_{t\to\infty} \alpha_t.$$

It is clear that (2.10) holds true if $\lim_{t\to\infty} E|\alpha_t - \alpha_\infty| = 0$. Since $\lim_{t\to\infty} \alpha_t = \alpha_\infty$, $\alpha_t \ge 0$, and $E\alpha_t \equiv E\alpha_\infty = 1$, by the Scheffe theorem we get the desired property.

Thus the right-hand side of (2.9) converges to zero and the result follows. □

2.3. Connection to the gap in [22]. In [22], H. Kunita studies[1] ergodic properties of the filtering process π_t^ν. He considers π_t^ν as a Markov process with values in the space of probability measures and claims (in Theorem 3.3) that there exists the unique invariant measure being "limit point" of marginal distributions of π_t^ν, $t \nearrow \infty$. As was later shown in [35], this result is the key to the stability analysis under (1.8).

Below we demonstrate that the main argument, used in the proof of Theorem 3.3 of [22], cannot be taken for granted. We discuss this issue in the context of Proposition 2.1. Suppose the Markov process X is ergodic in the sense of (1.7) and (1.8). It is well known that its tail σ-algebra $\mathscr{T}(X^\beta)$ (see (2.2) for definition) is empty a.s. It is very tempting in this case to change the order of intersection and supremum as follows:

$$\bigcap_{t\ge0} \mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)} = \mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{T}(X^\beta) \quad \text{a.s.} \tag{2.11}$$

Then, the right-hand side of (2.6) is transformed to

$$\lim_{t\to\infty} E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big) = E\left(\frac{d\nu}{d\beta}(X_0^\beta)\Big|\bigcap_{t\ge0}\Big\{\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{X}^\beta_{[t,\infty)}\Big\}\right)$$
$$= E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)} \vee \mathscr{T}(X^\beta)\Big) = E\Big(\frac{d\nu}{d\beta}(X_0^\beta)\big|\mathscr{Y}^\beta_{[0,\infty)}\Big)$$

[1] The notations of this paper are used here.

and (2.6) would be correct, regardless (!) of any other ingredients of the problem (e.g., with $\sigma = 0$ in (1.1)).

In [22], the relation of (2.11) type plays the key role in verification of the uniqueness for the invariant measure corresponding to $\pi^{\nu}_t, t \geq 0$. However, the validity of (2.11) is far from being obvious. According to Williams [44], it "...tripped up even Kolmogorov and Wiener" (see Sinai [39, p. 837] for some details). The reader can find a discussion concerning (2.11) in von Weizsäcker [43]; unfortunately, the counterexample there is incorrect. A proper counterexample to (2.11) is given in Exercise 4.12 in Williams [44], which, however, seems somewhat artificial in the filtering context. It turns out that the example, considered by Delyon and Zeitouni in [19] (see [21] by Kaijser for its earlier discrete time version), is nothing but another case when (2.11) fails.

For the reader's convenience, we give below a detailed analysis of this example.

It is important to note that the counterexamples mentioned above do not fit exactly into the setup considered by Kunita. They merely indicate that (2.11) is not evident and so the claim of Theorem 3.3 in [22] remains a conjecture.

Generally, the stability of nonlinear filters for ergodic Markov processes remains an open problem, and some results [23], [40], [41], [6], [8], [7], [35] based on [22] have to be revised.

3. Counterexample. Below we give a detailed discussion of one counterexample to (2.11). Consider Markov process X with values in $\mathbb{S} = \{1, 2, 3, 4\}$, with the initial distribution ν and the transition intensities matrix

$$\Lambda = \begin{pmatrix} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & -1 & 1 \\ 1 & 0 & 0 & -1 \end{pmatrix}. \tag{3.1}$$

All states of Λ communicate, and so X is an ergodic Markov process (see, e.g., [34]) with the unique invariant measure $\mu = \begin{pmatrix} 1/4 & 1/4 & 1/4 & 1/4 \end{pmatrix}$. Let $h(x) = I(x = 1) + I(x = 3)$, that is,

$$Y_t = \int_0^t \big[I(X_s = 2) + I(X_s = 3)\big]\, ds + \sigma W_t.$$

By Theorem 4.1 below, the filter is stable in this case for any $\sigma > 0$.

3.1. Noiseless observation. Consider the case $\sigma = 0$.

It will be convenient to redefine the observation process as follows:

$$Y_t = [I(X_t = 1) + I(X_t = 3)].$$

We assume $\nu \ll \beta$ and notice that (2.1) holds true. We omit the superscripts ν and β when the initial condition does not play a significant role. Since X is an ergodic Markov process, satisfying (1.8), $\mathscr{T}(X) = (\Omega, \varnothing)$ a.s.

Proposition 3.1.

$$\bigcap_{t\geq 0} \Big(\mathscr{Y}_{[0,\infty)} \vee \mathscr{X}_{[t,\infty)}\Big) \supsetneq \mathscr{Y}_{[0,\infty)} \ \ a.s. \tag{3.2}$$

Proof. It suffices to show that X_0 is a $\bigcap_{t\geq 0}(\mathscr{Y}_{[0,\infty)} \vee \mathscr{X}_{[t,\infty)})$-measurable random variable and at the same time $X_0 \notin \mathscr{Y}_{[0,\infty)}$.

TABLE 3.1
Typical trajectory of π_t for $Y_0 = 1$.

t	$[0,\tau_1)$	$[\tau_1,\tau_2)$	$[\tau_2,\tau_3)$	$[\tau_3,\tau_4)$	$[\tau_4,\tau_5)$	$\dots$
Y_t	1	0	1	0	1	$\dots$
$\pi_t(1)$	$\frac{\nu_1}{\nu_1+\nu_3}$	0	$\frac{\nu_3}{\nu_1+\nu_3}$	0	$\frac{\nu_1}{\nu_1+\nu_3}$	$\dots$
$\pi_t(2)$	0	$\frac{\nu_1}{\nu_1+\nu_3}$	0	$\frac{\nu_3}{\nu_1+\nu_3}$	0	$\dots$

The structure of matrix Λ admits only cyclic transitions in the following order:

$$\cdots \to \{3\} \to \{4\} \to \{1\} \to \{2\} \to \{3\} \to \cdots .$$

So, since Y and X jump simultaneously, X_0 can be recovered exactly from the trajectory $Y_s, s \le t$, and X_t for any $t > 0$, i.e., X_0 is $\mathscr{X}_t \vee \mathscr{Y}_{[0,t]}$-measurable. Owing to $\mathscr{X}_t \vee \mathscr{Y}_{[0,t]} \subset \mathscr{X}_{[t,\infty)} \vee \mathscr{Y}_{[0,\infty)}$, X_0 is measurable with respect to

$$\bigcap_{t\ge 0} \Big(\mathscr{Y}_{[0,\infty)} \vee \mathscr{X}_{[t,\infty)} \Big).$$

Denote by $(\tau_i)_{i\ge 1}$ the time moments where Y jumps. It is not hard to check that $(\tau_i)_{i\ge 0}$ is independent of (X_0, Y_0) and, moreover,

$$\mathscr{Y}_{[0,t]} = \bigvee_{i\ge 0} \sigma\{\tau_i \le t\} \vee \sigma\{Y_0\}.$$

Thus for any $t \ge 0$

$$\begin{aligned} P\big(X_0 = 1 | \mathscr{Y}_{[0,t]}\big) &= P\left(X_0 = 1 | \bigvee_{i\ge 0} \sigma\{\tau_i \le t\} \vee \sigma\{Y_0\} \right) \\ &= P\big(X_0 = 1 | Y_0\big) = \frac{\nu_1}{\nu_1+\nu_3} Y_0. \end{aligned} \tag{3.3}$$

Since (3.3) is valid for any $t \ge 0$, we conclude that

$$P\big(X_0 = 1 | \mathscr{Y}_{[0,\infty)}\big) = \frac{\nu_1}{\nu_1+\nu_3} Y_0.$$

Obviously $I(X_0 = 1) \ne \frac{\nu_1}{\nu_1+\nu_3} Y_0$ and thus X_0 is not $\mathscr{Y}_{[0,\infty)}$-measurable. □

3.2. Invariant measures of π_t and the filter instability. Since $I_t(2) + I_t(4) = 1 - Y_t$ and $I_t(1) + I_t(3) = Y_t$, only $I_t(1)$ and $I_t(2)$ have to be filtered while $\pi_t(3) = Y_t - \pi_t(1)$ and $\pi_t(4) = (1 - Y_t) - \pi_t(2)$. The derivation of the filtering equations is sketched in the appendix.

PROPOSITION 3.2. *The optimal filtering estimate satisfies*

$$\begin{aligned} d\pi_t(1) &= \big(1 - \pi_{t-}(2)\big)(1 - Y_{t-})dY_t + \pi_{t-}(1) Y_{t-} dY_t, \\ d\pi_t(2) &= -\pi_{t-}(2)(1 - Y_{t-})dY_t - \pi_{t-}(1) Y_{t-} dY_t \end{aligned}$$

subject to $\pi_0(1) = \frac{\nu_1}{\nu_1+\nu_3} Y_0$, $\pi_0(2) = \frac{\nu_2}{\nu_2+\nu_4}(1 - Y_0)$.

Let us examine the behavior of the filter from Proposition 3.2. A pair of typical trajectories are given in Table 3.1 (for $Y_0 = 1$) and Table 3.2 (for $Y_0 = 0$).

It is not hard to see that Y is itself a Markov chain with values in $\{0, 1\}$ and the transition intensities matrix $\left(\begin{smallmatrix} -1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, and thus its invariant measure is $\mu' =$

TABLE 3.2
Typical trajectory of π_t for $Y_0 = 0$.

t	$[0,\tau_1)$	$[\tau_1,\tau_2)$	$[\tau_2,\tau_3)$	$[\tau_3,\tau_4)$	$[\tau_4,\tau_5)$	$\dots$
Y_t	0	1	0	1	0	$\dots$
$\pi_t(1)$	0	$\frac{\nu_2}{\nu_2+\nu_4}$	0	$\frac{\nu_4}{\nu_2+\nu_4}$	0	$\dots$
$\pi_t(2)$	$\frac{\nu_2}{\nu_2+\nu_4}$	0	$\frac{\nu_4}{\nu_2+\nu_4}$	0	$\frac{\nu_2}{\nu_2+\nu_4}$	$\dots$

$\begin{pmatrix}1/2 & 1/2\end{pmatrix}$. Hence, the invariant measure Φ of the filtering process $(\pi_t(1),\pi_t(2))$ is concentrated on eight vectors

$$\phi_1=\begin{pmatrix}\frac{\nu_1}{\nu_1+\nu_3}\\0\end{pmatrix},\quad \phi_2=\begin{pmatrix}0\\\frac{\nu_1}{\nu_1+\nu_3}\end{pmatrix},\quad \phi_3=\begin{pmatrix}\frac{\nu_3}{\nu_1+\nu_3}\\0\end{pmatrix},\quad \phi_4=\begin{pmatrix}0\\\frac{\nu_3}{\nu_1+\nu_3}\end{pmatrix},$$
$$\phi_5=\begin{pmatrix}\frac{\nu_2}{\nu_2+\nu_4}\\0\end{pmatrix},\quad \phi_6=\begin{pmatrix}0\\\frac{\nu_2}{\nu_2+\nu_4}\end{pmatrix},\quad \phi_7=\begin{pmatrix}\frac{\nu_4}{\nu_2+\nu_4}\\0\end{pmatrix},\quad \phi_8=\begin{pmatrix}0\\\frac{\nu_4}{\nu_2+\nu_4}\end{pmatrix}$$

with

$$\Phi(\phi_i)=(\nu_1+\nu_3)/4,\quad i=1,2,3,4,$$
$$\Phi(\phi_i)=(\nu_2+\nu_4)/4,\quad i=5,6,7,8,$$

and, consequently, Φ is not unique. Moreover, the optimal filter is not stable in the sense of (1.6). In fact, for different initial conditions, the filtering distribution $\pi_t, t>0$, can "sit" on different vectors!

4. Main results.

4.1. Ergodic case. Markov chain X is ergodic if and only if all entries of its transition intensities matrix Λ *communicate*, i.e., for any pair of indices i and j, a string of indices $\{\ell_1,\dots,\ell_m\}$ can be found so that $\lambda_{i\ell_1}\lambda_{\ell_1\ell_2}\dots\lambda_{\ell_m j}\neq 0$ (see, e.g., [34]). In this case, the distribution of X_t converges to the positive invariant distribution μ being the unique solution of $\Lambda^*\mu=0$ in the class of vectors with positive entries the sum of which is equal to one.

THEOREM 4.1. *If all states of Λ communicate, then there exists a positive constant c such for any ν and β*

$$\overline{\lim}_{t\to\infty}\frac{1}{t}\log\|\pi_t^{\beta\nu}-\pi_t^{\nu}\|<-c\ \ a.s.$$

Remark 1. Clearly, Theorem 4.1 provides (1.6). Also it allows us to conclude that $\lim_{t\to\infty}\|\pi_t^{\beta\nu}-\pi_t^{\nu}\|=0$ a.s. for β concentrated in a single state of $\mathbb{S}$. Then, in particular, we have

$$\lim_{t\to\infty}\|\pi_t^{\mu_0}-\pi_t^{\mu}\|=0$$

which is the main argument in the proof of existence of the unique invariant measure for the process $(\pi_t)_{t\geq 0}$. This fact corroborates Kunita's result from [22] in the finite state space setup of Theorem 4.1.

Actually, Theorem 4.1 verifies the logarithmic rate in $t\to\infty$ which is in general a function of Λ, h and σ. However, stronger assumptions on Λ guarantee exponential or logarithmic rates, regardless of h and σ (σ is only required to be nonzero).

THEOREM 4.2. *Assume all states of* Λ *communicate. Then*

$$\overline{\lim}_{t\to\infty}\frac{1}{t}\log\|\pi_t^{\beta\nu}-\pi_t^{\nu}\| \le -\sum_{r=1}^{n}\mu_r\min_{i\neq r}\lambda_{ri}. \tag{4.1}$$

Remark 2. The bound (4.1) is negative if at least one row of Λ has all nonzero entries.

THEOREM 4.3. *Assume all entries of* Λ *are nonzero.*

1. *If* $\nu \ll \beta$, *then*

$$E\|\pi_t^{\beta\nu}-\pi_t^{\nu}\| \le n\sum_{j=1}^{n}\frac{d\nu}{d\beta}(a_j)\exp\Big(-2t\min_{p\neq q}\sqrt{\lambda_{pq}\lambda_{qp}}\Big),\ t>0. \tag{4.2}$$

2. *If* $\nu \sim \beta$, *then*

$$\|\pi_t^{\beta\nu}-\pi_t^{\nu}\| \le n^2\max_j\frac{d\nu}{d\beta}(a_j)\max_j\frac{d\beta}{d\nu}(a_j)\exp\Big(-2t\min_{p\neq q}\sqrt{\lambda_{pq}\lambda_{qp}}\Big),\ t>0. \tag{4.3}$$

4.2. Nonergodic case. Let $m \ge 2$ and Λ be given in (1.3). If $X_0 \in \mathbb{S}_j$, then X is a Markov process with values in $\mathbb{S}_j$ with transition intensities matrix Λ_j. We denote this process by X^j. In addition to h, introduce column vectors h_j, $j = 1, \dots, m$, with entries $h(a_1^j), \dots, h(a_{n_j}^j)$, respectively.

THEOREM 4.4. *Assume the following.*

A-1. For any j, all states of Λ_j communicate.

A-2. For each j, k with $j \neq k$, either

$$h_j^*\mu^j \neq h_k^*\mu^k$$

or

$$h_j^*\,\mathrm{diag}(\mu^j)\Lambda_j^q h_j \neq h_k^*\,\mathrm{diag}(\mu^k)\Lambda_k^q h_k,\ \textit{for some}\ \ 0 \le q \le n_j+n_k-1.$$

Then the asymptotic stability (1.6) *holds true.*

The condition A-1 is inherited from Theorem 4.1 to ensure the stability within each ergodic class, while under A-2, $\mathscr{Y}_{[0,\infty)}$ completely identifies the class in which X actually resides.

5. Proofs for the ergodic case. Recall that under $m = 1$, X is a homogeneous ergodic Markov chain with values in the finite alphabet $\mathbb{S} = \{a_1, \dots, a_n\}$ with the transition intensities matrix Λ. The unique invariant measure $\mu = (\mu_1, \dots, \mu_n)$ is the positive distribution on $\mathbb{S}$. Let ν be the distribution of X_0 and β a probability measure on $\mathbb{S}$. The observation process Y is defined in (1.1). Recall that the entries of π_t^{ν} and $\pi_t^{\beta\nu}$ are the true and "wrong" conditional probabilities, respectively, as defined in the introduction.

5.1. The proof of Theorem 4.1. We use the method proposed by Atar and Zeitouni in [2], which is elaborated for the considered filtering setup for the reader's convenience.

Recall the following facts from the theory of nonnegative matrices. For a pair (p, q) of nonnegative measures on $\mathbb{S}$ (i.e., vectors with nonnegative entries), the Hilbert projective metric $H(p, q)$ is defined as the following (see, e.g., [38]):

$$H(p,q) = \begin{cases} \log\dfrac{\max\limits_{j:q_j>0}(p_j/q_j)}{\min\limits_{i:q_i>0}(p_i/q_i)}, & p \sim q, \\ \infty, & p \not\sim q. \end{cases} \tag{5.1}$$

The Hilbert metric is known to satisfy the following properties:

1. $H(c_1p, c_2q) = H(p,q)$ for any positive constants c_1 and c_2.
2. For matrix A with nonnegative entries (A_{ij}),

$$H\big(Ap, Aq\big) \le \tau(A) H\big(p,q\big) \quad \text{(see, e.g., [38])},$$

where $\tau(A) = \frac{1-\sqrt{\psi(A)}}{1+\sqrt{\psi(A)}}$ is the Birkhoff contraction coefficient with

$$\psi(A) = \min_{i,j,k,\ell} \frac{A_{ik}A_{j\ell}}{A_{i\ell}A_{jk}}.$$

3. $\|p-q\| \le \frac{2}{\log 3} H(p,q)$ (Lemma 1 in [2]).

Returning to the filtering problem, let us first consider the special case when $\nu = \mu$, and thus the signal X^μ is the stationary Markov chain. It is well known that $\pi_t^\mu = \eta_t^\mu / \langle \mathbf{1}, \eta_t^\mu \rangle$, where $\mathbf{1}$ denotes the vector with unit entries, $\langle \cdot, \cdot \rangle$ is the usual inner product, and η_t^μ solves the Zakai equation

$$d\eta_t^\mu = \Lambda^* \eta_t^\mu dt + \sigma^{-2} \operatorname{diag}(h) \eta_t^\mu dY_t^\mu \tag{5.2}$$

subject to $\eta_0^\mu = \mu$. Similarly, $\pi_t^{\beta\mu} = \eta_t^{\beta\mu} / \langle \mathbf{1}, \eta_t^{\beta\mu} \rangle$, where $\eta_t^{\beta\mu}$ is the solution of (5.2) subject to $\eta_0^{\beta\mu} = \beta$.

The Zakai equation possesses the unique strong solution which is linear with respect to the initial condition. Hence, $\eta_t^\mu = J_{[0,t]}\mu$ and $\eta_t^{\beta\mu} = J_{[0,t]}\beta$, $t > 0$, where $J_{[0,t]}$ is the random Cauchy matrix corresponding to (5.2).

The matrix $J_{[0,t]}$ can be factored (here $\lfloor t \rfloor$ is the integer part of t):

$$J_{[0,t]} = J_{[\lfloor t \rfloor, t]} \left(\prod_{n=2}^{\lfloor t \rfloor} J_{[n-1,n]} \right) J_{[0,1]}.$$

The properties of the Hilbert metric, listed above, provide

$$\begin{aligned} \big\| \pi_t^\mu - \pi_t^{\beta\mu} \big\| &\le \frac{2}{\log 3} H\big(\pi_t^\mu, \pi_t^{\beta\mu}\big) = \frac{2}{\log 3} H\big(J_{[0,t]}\mu, J_{[0,t]}\beta\big) \\ &\le \frac{2}{\log 3} \tau\big(J_{[\lfloor t \rfloor, t]}\big) \prod_{n=2}^{\lfloor t \rfloor} \tau\big(J_{[n-1,n]}\big) H\big(J_{[0,1]}\mu, J_{[0,1]}\beta\big). \end{aligned}$$

Assume for a moment that $H\big(J_{[0,1]}\mu, J_{[0,1]}\beta\big) < \infty$ a.s. Then

$$\begin{aligned} \overline{\lim}_{t\to\infty} \frac{1}{t} \log \big\| \pi_t^\mu - \pi_t^{\beta\mu} \big\| &\le \overline{\lim}_{t\to\infty} \frac{1}{\lfloor t \rfloor} \sum_{n=2}^{\lfloor t \rfloor} \log \tau\big(J_{[n-1,n]}\big) \\ &\le \overline{\lim}_{t\to\infty} \frac{1}{\lfloor t \rfloor} \sum_{n=2}^{\lfloor t \rfloor} \big\{ -1 \vee \log \tau\big(J_{[n-1,n]}\big) \big\} = E\big[-1 \vee \log \tau\big(J_{[0,1]}\big) \big] \le 0. \end{aligned} \tag{5.3}$$

The equality is implied by the law of large numbers, which is valid since $-1 \le \big\{ -1 \vee \log \tau\big(J_{[n-1,n]}\big) \big\} \le 0$ and $\log \tau\big(J_{[n-1,n]}\big)$ is generated by

$$\{ X_s^\mu - X_{n-1}^\mu,\ W_s - W_{n-1} \},\ n-1 \le s < n,$$

where the processes X^μ and W are independent and X^μ is an ergodic Markov chain.

Let $J^{\nu}_{[n-1,n]}$ be the matrices defined similarly to $J_{[n-1,n]}$ with Y^{μ} replaced by Y^{ν}. Recall that μ is the positive measure on $\mathbb{S}$, so that $\nu \ll \mu$ and, in turn, $\overline{Q}^{\nu} \ll \overline{Q}^{\mu}$ (here $\overline{Q}^{\mu}$ is the distribution of Y^{μ}).

Since (5.3) holds $\overline{Q}^{\mu}$-a.s., it also holds $\overline{Q}^{\nu}$-a.s., i.e., with $J_{[n-1,n]}$ replaced by $J^{\nu}_{[n-1,n]}$ which gives the following theorem.

THEOREM 5.1. (version of Theorem 1(a) in Atar and Zeitouni [2]). *Assume that all states of* Λ *communicate, i.e.,* X *is an ergodic Markov chain. Assume* $J_{[0,1]}\beta$ *and* $J_{[0,1]}\nu$ *have positive entries a.s. Then,*

$$\overline{\lim}_{t\to\infty} \frac{1}{t} \log \left\| \pi^{\nu}_t - \pi^{\beta\nu}_t \right\| \le E\big[-1 \vee \log \tau\big(J_{[0,1]}\big)\big] \ \text{a.s.} \tag{5.4}$$

Now the statement of Theorem 4.1 follows from the lemma below.

LEMMA 5.2. *The right-hand side of* (5.4) *is strictly negative.*

Proof. It suffices to show that all entries of $J_{[0,1]}$ are positive a.s. For fixed i, j, we have

$$J_{[0,t]}(i,j) = \delta_{ij} + \int_0^t J_{[0,s]}(i,j)\big[\lambda_{ii}ds + \sigma^{-2}h(a_i)dY^{\mu}_s\big] + \int_0^t \sum_{r\ne i} \lambda_{ri} J_{[0,s]}(r,j)ds.$$

With the help of the Itô formula and with

$$\phi_t(i) = \exp\big\{\lambda_{ii}t + \sigma^{-2}h(a_i)Y^{\mu}_t - (1/2)\sigma^{-2}h^2(a_i)t\big\}$$

we derive

$$\begin{aligned} J_{[0,t]}(j,j) &= \phi_t(j)\Big(1 + \int_0^t \phi_s^{-1}(j) \sum_{r\ne j} \lambda_{rj} J_{[0,s]}(r,j)ds\Big), \\ J_{[0,t]}(i,j) &= \phi_t(i) \int_0^t \phi_s^{-1}(i) \sum_{r\ne i} \lambda_{ri} J_{[0,s]}(r,j)ds, \quad i \ne j. \end{aligned} \tag{5.5}$$

Also notice that the entries of $J_{[0,t]}$ are unnormalized conditional probabilities and so nonnegative a.s. Since all states of Λ communicate, for a pair of indices (i,j) there is a string of indexes $j = i_\ell, \dots, i_1 = i$ such that $\lambda_{i_\ell i_{\ell-1}}, \dots, \lambda_{i_2 i_1} > 0$. So from (5.5), it follows that a.s.

$$\begin{aligned} &J_{[0,t]}(i_\ell, i_\ell) \ge \phi_t(i_\ell) > 0, \\ &J_{[0,t]}(i_{\ell-1}, i_\ell) \ge \phi_t(i_{\ell-1}) \int_0^t \phi_s^{-1}(i_{\ell-1}) \lambda_{i_\ell i_{\ell-1}} J_{[0,s]}(i_\ell, i_\ell)ds > 0, \\ &J_{[0,t]}(i_{\ell-2}, i_\ell) \ge \phi_t(i_{\ell-2}) \int_0^t \phi_s^{-1}(i_{\ell-2}) \lambda_{i_{\ell-1} i_{\ell-2}} J_{[0,s]}(i_{\ell-1}, i_\ell)ds > 0 \end{aligned}$$

for any $t > 0$, and so on until we get $J_{[0,t]}(i_1, i_\ell) > 0$, $t > 0$. □

5.2. The proof of Theorem 4.2. Denote $\rho_{ji}(t) = P\big(X^{\beta}_0 = a_j | \mathscr{Y}^{\beta}_{[0,t]}, X^{\beta}_t = a_i\big)$. If β is a positive distribution, then by Lemma 9.5 in [29, Chap. 9] we have

$$\begin{aligned} \rho_{ji}(0) &= \begin{cases} 1, & j = i, \\ 0, & j \ne i, \end{cases} \\ \frac{d\rho_{ji}(t)}{dt} &= \sum_{r\ne i} \frac{\lambda_{ri}\pi^{\beta}_t(r)}{\pi^{\beta}_t(i)} \big(\rho_{jr}(t) - \rho_{ji}(t)\big), \quad i = 1, \dots, n. \end{aligned} \tag{5.6}$$

Remark 3. By the arguments used in the proof of Lemma 5.2, it can be readily shown that $\pi^\beta_t(i) > 0$ a.s., $i = 1, \dots, n$, for any $t > 0$. Then (5.6) remain valid for $t > t_0$ for any $t_0 > 0$ initialized by

$$\rho_{ji}(t_0) = P\big(X^\beta_0 = a_j | \mathscr{Y}^\beta_{[0,t_0]}, X^\beta_{t_0} = a_i\big).$$

Set $i^\diamond(t) = \operatorname{argmax}_{i\in\mathbb{S}} \rho_{ji}(t)$ and $i_\diamond(t) = \operatorname{argmin}_{i\in\mathbb{S}} \rho_{ji}(t)$ (if the maximum or the minimum is attained at several indices, the lowest one is taken by convention). Set

$$\rho^\diamond(t) := \rho_{ji^\diamond(t)}(t) \quad \text{and} \quad \rho_\diamond(t) := \rho_{ji_\diamond(t)}(t). \tag{5.7}$$

LEMMA 5.3. *The processes $\rho^\diamond(t)$ and $\rho_\diamond(t)$ have absolutely continuous paths with*

$$\begin{aligned} d\rho^\diamond(t) &= \sum_{i=1}^n I(i^\diamond(t) = i)\dot\rho_{ji}(t)dt, \\ d\rho_\diamond(t) &= \sum_{i=1}^n I(i_\diamond(t) = i)\dot\rho_{ji}(t)dt. \end{aligned} \tag{5.8}$$

The proof of this lemma uses two results formulated in Propositions 5.4 and 5.5 below.

PROPOSITION 5.4 (Theorem A.6.3 in Dupuis and Ellis [20]). *Let $g = g(t)$ be an absolutely continuous function mapping of $[0,1]$ into $\mathbb{R}$. Then for each real number a the set $\{t : g(t) = a, \dot g(t) \neq 0\}$ has Lebesgue measure 0.*

PROPOSITION 5.5. *Let $X(t,\omega)$ be a random process with absolutely continuous paths with respect to dt in the sense that there exists a measurable random process $x(t,\omega)$ such that $\int_0^t |x(s,\omega)|ds < \infty$ a.s., $t > 0$, and*

$$X(t,\omega) = X(0,\omega) + \int_0^t x(s,\omega)ds. \tag{5.9}$$

Then

$$|X(t,\omega)| = |X(0,\omega)| + \int_0^t \operatorname{sign}(X(s,\omega))x(s,\omega)ds,$$

where $\operatorname{sign}(0) = 0$.

Proof. Set $V_t(\omega) = \int_0^t |x(s,\omega)|ds$ and notice that for any $t' \le t''$ it holds that

$$\big||X(t'',\omega)| - |X(t',\omega)|\big| \le |X(t'',\omega) - X(t',\omega)| \le (V_{t''}(\omega) - V_{t'}(\omega)).$$

Hence, for fixed ω, the function $|X(t,\omega)|$ possesses bounded total variation for any finite time interval. Denote by $U_t(\omega)$ this total variation corresponding to $[0,t]$. Obviously, $dU_t(\omega) \ll dV_t(\omega) \ll dt$. Recall that $U_t(\omega) = U'_t(\omega) + U''_t(\omega)$, where $U'_t(\omega)$, $U''_t(\omega)$ are increasing continuous in t functions such that for any $t > 0$ and measurable set A from $\mathbb{R}_+$, $\int_{A\cap[0,t]} dU''_s(\omega) = 0$ and $\int_{(\mathbb{R}_+\setminus A)\cap[0,t]} dU'_s(\omega) = 0$, and at the same time $|X(t,\omega)| = U''_t(\omega) - U'_t(\omega)$. Since $dU'_t \ll dU_t(\omega)$, $dU''_t \ll dU_t(\omega)$, it follows that

$d|X(t,\omega)| \ll dU_t(\omega) \ll dV_t(\omega) \ll dt$ and so that

$$|X(t,\omega)| = |X(0,\omega)| + \int_0^t g(s,\omega)ds \tag{5.10}$$

though we may not claim that $g(t,\omega)$ is measurable in (t,ω).

Now, we show that $\operatorname{sign}(X(s,\omega))x(s,\omega)$ is a measurable version of $g(s,\omega)$. By (5.9), we have $X^2(t,\omega) = X^2(0,\omega)+2\int_0^t X(s,\omega)x(s,\omega)ds$. At the same time, by (5.10) it holds that $|X(t,\omega)|^2 = |X(0,\omega)|^2 + 2\int_0^t |X(s,\omega)|g(s,\omega)ds$. Hence, the following identity is valid: For any $t \geq 0$

$$\int_0^t |X(s,\omega)|g(s,\omega)ds \equiv \int_0^t X(s,\omega)x(s,\omega)ds.$$

Therefore, $|X(s,\omega)|g(s,\omega) = X(s,\omega)x(s,\omega)$ for almost all s with respect to Lebesgue measure. Consequently, we have $I(|X(s,\omega)| \neq 0)g(s,\omega) = \operatorname{sign}(X(s,\omega))x(s,\omega)$ for almost all s with respect to Lebesgue measure. It remains to show that

$$I(X(s,\omega) = 0)g(s,\omega) = 0$$

for almost all s with respect to Lebesgue measure. Taking into account (5.10), it suffices to prove that $\int_0^\infty I(X(s,\omega) = 0)d|X(s,\omega)| = 0$ a.s. On the other hand, whereas $d|X(t,\omega)| \ll dV_t(\omega)$, it suffices to show that $\int_0^\infty I(X(s,\omega) = 0)dV_s(\omega) = 0$ a.s. The latter holds by Proposition 5.4. □

Now we give the proof for Lemma 5.3.

Proof. Let us introduce $\rho^{\diamond,i}(t) = \rho_{j1} \vee \rho_{j2} \vee \cdots \vee \rho_{ji}$ and $\rho_{\diamond,i}(t) = \rho_{j1} \wedge \rho_{j2} \wedge \cdots \wedge \rho_{ji}$ and notice that $\rho^{\diamond,n}(t) = \rho^{\diamond}(t)$, $\rho_{\diamond,n}(t) = \rho_{\diamond}(t)$.

The use of obvious identities

$$\begin{aligned}
\rho^{\diamond,2}(t) + \rho_{\diamond,2}(t) &= \rho_{j1}(t) + \rho_{j2}(t),\\
\rho^{\diamond,2}(t) - \rho_{\diamond,2}(t) &= |\rho_{j1}(t) - \rho_{j2}(t)|
\end{aligned}$$

and the fact, provided by Proposition 5.5, that $d|\rho_{j1}(t) - \rho_{j2}(t)| = p(t,\omega)dt$ with measurable derivative $p(\omega,t)$, allow us to claim that $\rho^{\diamond,2}(t)$ and $\rho_{\diamond,2}(t)$ are absolutely continuous with respect to dt with measurable derivatives.

Further, taking into account $\rho^{\diamond,i}(t) = \rho^{\diamond,i-1}(t) \vee \rho_{ji}$ and $\rho_{\diamond,i}(t) = \rho_{\diamond,i-1}(t) \wedge \rho_{ji}(t)$ and consequent identities

$$\begin{aligned}
\rho^{\diamond,i}(t) + \rho^{\diamond,i-1}(t) \wedge \rho_{ji}(t) &= \rho^{\diamond,i-1}(t) + \rho_{ji}(t),\\
\rho^{\diamond,i}(t) - \rho^{\diamond,i-1}(t) \wedge \rho_{ji}(t) &= |\rho^{\diamond,i-1}(t) - \rho_{ji}(t)|,\\
\rho_{\diamond,i-1}(t) \vee \rho_{ji}(t) + \rho_{\diamond,i}(t) &= \rho_{\diamond,i-1}(t) + \rho_{ji}(t),\\
\rho_{\diamond,i-1}(t) \vee \rho_{ji}(t) - \rho_{\diamond,i}(t) &= |\rho_{\diamond,i-1}(t) - \rho_{ji}(t)|,
\end{aligned}$$

absolute continuity for $\rho^{\diamond}(t)$ and $\rho_{\diamond}(t)$ is verified by the induction method.

Thus, $d\rho^{\diamond}(t) = u(t)dt$ with some density $u(t)$ such that $\int_0^t |u(s)|ds < \infty$ a.s., $t > 0$. On the other hand, since $\sum_{i=1}^n I(i^{\diamond}(t) = i) = 1$, we have

$$\rho^{\diamond}(t) = \rho^{\diamond}(0) + \int_0^t \sum_{i=1}^n I(i^{\diamond}(s) = i)u(s)ds.$$

So, it suffices to show that for any $t > 0$ and any $i = 1, 2, \dots, n$

$$\int_0^t I(i^\diamond(s) = i)|u(s) - \dot\rho_{ji}(s)|ds = 0 \text{ a.s.}$$

The latter holds true by Proposition 5.4, since

$$\begin{aligned}
&\int_0^t I(i^\diamond(s) = i)|u(s) - \dot\rho_{ji}(s)|ds \\
&= \int_0^t I(\rho^\diamond(s) - \rho_{ji}(s) = 0)|u(s) - \dot\rho_{ji}(s)|ds \\
&= \int_0^t I\big(\rho^\diamond(s) - \rho_{ji}(s) = 0, u(s) - \dot\rho_{ji}(s) \neq 0\big)|u(s) - \dot\rho_{ji}(s)|ds = 0. \qquad \square
\end{aligned}$$

LEMMA 5.6. *Under the assumptions of Theorem* 4.2,

$$\overline{\lim}_{t\to\infty} \frac{1}{t} \log \max_{1\le j,k,\ell\le n} \big|\rho_{jk}(t) - \rho_{j\ell}(t)\big| \le -\sum_{r=1}^n \mu_r \min_{i\neq r} \lambda_{ri}. \tag{5.11}$$

Proof. By (5.6) and (5.8), we have[2]

$$\begin{aligned}
\frac{d\rho_\diamond(t)}{dt} &= \sum_{r\neq i_\diamond(t)} \frac{\lambda_{ri_\diamond(t)}\pi_t^\beta(r)}{\pi_t^\beta(i_\diamond(t))}\big(\rho_{jr}(t) - \rho_\diamond(t)\big), \\
\frac{d\rho^\diamond(t)}{dt} &= \sum_{r\neq i^\diamond(t)} \frac{\lambda_{ri^\diamond(t)}\pi_t^\beta(r)}{\pi_t^\beta(i^\diamond(t))}\big(\rho_{jr}(t) - \rho^\diamond(t)\big).
\end{aligned} \tag{5.12}$$

In what follows, we will omit the time variable in $i_\diamond(t)$ and $i^\diamond(t)$ for brevity. Set $\triangle_t = \rho^\diamond(t) - \rho_\diamond(t)$. By (5.12) we have

$$\begin{aligned}
\frac{d\triangle_t}{dt} &= -\sum_{r\neq i^\diamond} \frac{\lambda_{ri^\diamond}\pi_t^\beta(r)}{\pi_t^\beta(i^\diamond)}\big(\rho^\diamond(t) - \rho_{jr}(t)\big) - \sum_{r\neq i_\diamond} \frac{\lambda_{ri_\diamond}\pi_t^\beta(r)}{\pi_t^\beta(i_\diamond)}\big(\rho_{jr}(t) - \rho_\diamond(t)\big) \\
&= -\triangle_t\left(\frac{\lambda_{i_\diamond i^\diamond}\pi_t^\beta(i_\diamond)}{\pi_t^\beta(i^\diamond)} + \frac{\lambda_{i^\diamond i_\diamond}\pi_t^\beta(i^\diamond)}{\pi_t^\beta(i_\diamond)}\right) \\
&\quad -\triangle_t\left(\sum_{\substack{r\neq i^\diamond(t)\\ r\neq i_\diamond(t)}}\left[\frac{\lambda_{ri^\diamond}\pi_t^\beta(r)}{\pi_t^\beta(i^\diamond)}\left(\frac{\rho^\diamond(t) - \rho_{jr}(t)}{\triangle_t}\right) + \frac{\lambda_{ri_\diamond}\pi_t^\beta(r)}{\pi_t^\beta(i_\diamond)}\left(\frac{\rho_{jr}(t) - \rho_\diamond(t)}{\triangle_t}\right)\right]\right).
\end{aligned} \tag{5.13}$$

Letting $0/0 = 1/2$, set $\alpha_r(t) = \frac{\rho^\diamond(t) - \rho_{jr}(t)}{\triangle_t}$. Then, we get $1 - \alpha_r(t) = \frac{\rho_{jr}(t) - \rho_\diamond(t)}{\triangle_t}$

[2] In (5.12)–(5.14) we use for brevity a form of differential equalities (inequalities) which are valid for any ω and almost all t with respect to Lebesgue measure.

and $0 \le \alpha_r(t) \le 1$ and (5.13) implies

$$
\begin{aligned}
\frac{d\triangle_t}{dt} &= -\triangle_t \left(\frac{\lambda_{i_\diamond i^\diamond} \pi_t^\beta(i_\diamond)}{\pi_t^\beta(i^\diamond)} + \frac{\lambda_{i^\diamond i_\diamond} \pi_t^\beta(i^\diamond)}{\pi_t^\beta(i_\diamond)} \right) \\
&\quad - \triangle_t \left(\sum_{\substack{r \neq i^\diamond(t) \\ r \neq i_\diamond(t)}} \left[\alpha_r(t) \frac{\lambda_{ri^\diamond} \pi_t^\beta(r)}{\pi_t^\beta(i^\diamond)} + \big(1 - \alpha_r(t)\big) \frac{\lambda_{ri_\diamond} \pi_t^\beta(r)}{\pi_t^\beta(i_\diamond)} \right] \right) \\
&\le -\triangle_t \Big(\lambda_{i_\diamond i^\diamond} \pi_t^\beta(i_\diamond) + \lambda_{i^\diamond i_\diamond} \pi_t^\beta(i^\diamond) \Big) \\
&\quad - \triangle_t \left(\sum_{\substack{r \neq i^\diamond(t) \\ r \neq i_\diamond(t)}} \Big[\alpha_r(t) \lambda_{ri^\diamond} + \big(1 - \alpha_r(t)\big) \lambda_{ri_\diamond} \Big] \pi_t^\beta(r) \right) \\
&\le -\triangle_t \left(\lambda_{i_\diamond i^\diamond} \pi_t^\beta(i_\diamond) + \lambda_{i^\diamond i_\diamond} \pi_t^\beta(i^\diamond) + \sum_{\substack{r \neq i^\diamond(t) \\ r \neq i_\diamond(t)}} \Big[\lambda_{ri^\diamond} \wedge \lambda_{ri_\diamond} \Big] \pi_t^\beta(r) \right).
\end{aligned} \tag{5.14}
$$

Recall that all offdiagonal entries of Λ are nonnegative and $\sum_{r=1}^n \lambda_{ir} = 0$ for any i. Then, $\big|\lambda_{i_\diamond i^\diamond}\big| \wedge \big|\lambda_{i_\diamond i_\diamond}\big| \ge \lambda_{i_\diamond i^\diamond}$, $\big|\lambda_{i^\diamond i^\diamond}\big| \wedge \big|\lambda_{i^\diamond i_\diamond}\big| \ge \lambda_{i^\diamond i_\diamond}$, and (5.14) provides

$$
\begin{aligned}
\frac{d\triangle_t}{dt} &\le -\triangle_t \sum_{r=1}^n \Big(|\lambda_{ri^\diamond}| \wedge |\lambda_{ri_\diamond}| \Big) \pi_t^\beta(r) \le -\triangle_t \sum_{r=1}^n \min_{1 \le i \le n} |\lambda_{ri}| \pi_t^\beta(r) \\
&= -\triangle_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri}.
\end{aligned}
$$

Since the derivative $\frac{d\triangle_t}{dt}$ is defined for each ω and almost everywhere (a.e.) in t with respect to dt, the above inequality $\frac{d\triangle_t}{dt} \le -\triangle_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri}$ is also valid a.e. So, it allows us to define a.e. the function

$$
H(t) = -\triangle_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} - \frac{d\triangle_t}{dt}.
$$

Moreover, for definiteness, we may redefine $H(t)$ everywhere so as $H(t) \ge 0$. Then we have

$$
d\triangle_t = -\left[\triangle_t \sum_{r=1}^n \pi_t^\beta(r) \min_{i \neq r} \lambda_{ri} + H(t) \right] dt.
$$

Notice also that $\int_0^t |H(s)| ds < \infty$ a.s. for any $t > 0$ and recall that $\triangle_0 = 1$. Then, we get

$$
\triangle_t = \exp\left(-\int_0^t \sum_{r=1}^n \pi_s^\beta(r) \min_{i \neq r} \lambda_{ri} ds \right) - \int_0^t \exp\left(-\int_s^t \sum_{r=1}^n \pi_u^\beta(r) \min_{i \neq r} \lambda_{ri} du \right) H(s) ds
$$

and in turn

$$
\frac{1}{t} \log \triangle_t \le -\sum_{r=1}^n \Big(\min_{i \neq r} \lambda_{ri} \Big) \frac{1}{t} \int_0^t \pi_s^\beta(r) ds.
$$

So, it is left to verify that

$$\lim_{t\to\infty}\frac{1}{t}\int_0^t \pi_s^\beta(r)ds=\mu_r \quad \text{a.s.} \tag{5.15}$$

Similarly to (1.4), π_t^β satisfies

$$\begin{aligned}\pi_0^\beta =&\beta,\\ d\pi_t^\beta =&\Lambda^*\pi_t^\beta dt+\sigma^{-2}\big(\operatorname{diag}(\pi_t^\beta)-\pi_t^\beta(\pi_t^\beta)^*\big)h(dY_t^\beta-h^*\pi_t^\beta dt).\end{aligned}$$

Recall that $\sigma^{-1}\big(Y_t^\beta-\int_0^t h^*\pi_s^\beta ds\big)$ is the innovation Wiener process (see, e.g., Theorem 9.1 in Chapter 10 in [30]). Hence $M_t=\int_0^t\big(\operatorname{diag}(\pi_s^\beta)-\pi_s^\beta(\pi_s^\beta)^*\big)h(dY_s^\beta-h^*\pi_s^\beta ds)$ is a vector-valued continuous martingale. Its entries $M_t(i)$, $i=1,\dots,n$, have predictable quadratic variation processes $\langle M(i)\rangle_t$ with the following property: For some positive constant c, $d\langle M(i)\rangle_t\le cdt$. Then by Theorem 10, Chapter 3 in [31], $\lim_{t\to\infty}\frac{1}{t}M_t(i)=0$ a.s. This fact and the boundedness of π_t^β provide $\Lambda^*\lim_{t\to\infty}\frac{1}{t}\int_0^t\pi_s^\beta ds=0$. The vector $Z_t=\frac{1}{t}\int_0^t\pi_s^\beta ds$ has nonnegative entries, whose sum equals 1. Therefore the limit vector Z_∞, obeying the same property, is the unique solution of the linear algebraic equation $\Lambda^*Z_\infty=0$, i.e., $Z_\infty=\mu$. □

To prove Theorem 4.2, without loss generality, due to Remark 3, we may assume that $\nu\sim\beta$. Then, we show that for any $t\ge 0$ and $i=1,\dots,n$

$$\big|\pi_t^\nu(i)-\pi_t^{\beta\nu}(i)\big|\le n\max_j\frac{d\nu}{d\beta}(a_j)\max_j\frac{d\beta}{d\nu}(a_j)\max_{1\le i,j,k\le d}\big|\rho_{ji}(t)-\rho_{jk}(t)\big|. \tag{5.16}$$

Recall that Q^ν and Q^β are distributions of (X^ν,Y^ν) and (X^β,Y^β), respectively, which are equivalent, by virtue of $\nu\sim\beta$, with

$$\frac{dQ^\beta}{dQ^\nu}(X^\nu,Y^\nu)\equiv\frac{d\beta}{d\nu}(X_0^\nu)\quad\text{and}\quad\frac{dQ^\nu}{dQ^\beta}(X^\beta,Y^\beta)\equiv\frac{d\nu}{d\beta}(X_0^\beta).$$

Now, we show that for any $i=1,\dots,d$ and $t>0$, Q^ν- and Q^β-a.s.

$$\pi_t^{\beta\nu}(i)=\frac{\sum_{j=1}^n\Big(\frac{d\beta}{d\nu}(a_j)P\big(X_0^\nu=a_j),X_t^\nu=a_i|\mathscr{Y}_{[0,t]}^\nu\Big)}{E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}_{[0,t]}^\nu\Big)}. \tag{5.17}$$

To this end, with any bounded $\mathscr{D}_t^y$-measurable function $\psi_t(y)$, write

$$\begin{aligned}&E\psi_t(Y^\nu)\pi_t^{\beta\nu}(i)E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}_{[0,t]}^\nu\Big)=E\psi_t(Y^\nu)\pi_t^{\beta\nu}(i)\frac{d\beta}{d\nu}(X_0^\nu)\\ &=E\psi_t(Y^\nu)\pi_t^{\beta\nu}(i)\frac{dQ^\beta}{dQ^\nu}(X^\nu,Y^\nu)=E\psi_t(Y^\beta)\pi_t^\beta(i)\\ &=E\psi_t(Y^\beta)I(X_t^\beta=a_i)=E\psi_t(Y^\nu)I(X_t^\nu=a_i)\frac{dQ^\beta}{dQ^\nu}(X^\nu,Y^\nu)\\ &=E\psi_t(Y^\nu)I(X_t^\nu=a_i)\frac{d\beta}{d\nu}(X_0^\nu)=E\psi_t(Y^\nu)E\Big(I(X_t^\nu=a_i)\frac{d\beta}{d\nu}(X_0^\nu)\big|\mathscr{Y}_{[0,t]}^\nu\Big).\end{aligned}$$

Hence, by the arbitrariness of $\psi_t(y)$,

$$\pi_t^{\beta\nu}(i)E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}_{[0,t]}^\nu\Big)=E\left(I(X_t^\nu=a_i)\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}_{[0,t]}^\nu\right).$$

Further, $Q^\nu \sim Q^\beta$ provides $E\big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\big) > 0$, Q^ν- and Q^β-a.s., so that

$$\pi_t^{\beta\nu}(i) = \frac{E\big(I(X_t^\nu = a_i)\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\big)}{E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\Big)}$$

and it remains to notice that

$$E\left(I(X_t^\nu = a_i)\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\right) = \sum_{j=1}^n \frac{d\beta}{d\nu}(a_j)P\big(X_t^\nu = a_i, X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big).$$

Taking into consideration (5.17), we find

$$\begin{aligned}\big|\pi_t^\nu(i) - \pi_t^{\beta\nu}(i)\big| &= \left|\pi_t^\nu(i) - \frac{\sum_{j=1}^n \Big(\frac{d\beta}{d\nu}(a_j)P\big(X_0^\nu = a_j, X_t^\nu = a_i|\mathscr{Y}^\nu_{[0,t]}\big)\Big)}{E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\Big)}\right| \\ &= \frac{\Big|\sum_{j=1}^n \frac{d\beta}{d\nu}(a_j)\Big(\pi_t^\nu(i)P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) - P\big(X_0^\nu = a_j, X_t^\nu = a_i|\mathscr{Y}^\nu_{[0,t]}\big)\Big)\Big|}{E\Big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\Big)}.\end{aligned}$$

Then, since by the Jensen inequality $1/E\big(\frac{d\beta}{d\nu}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\big) \le E\big(\frac{d\nu}{d\beta}(X_0^\nu)|\mathscr{Y}^\nu_{[0,t]}\big)$, we get the chain of estimates

$$\begin{aligned}\big|\pi_t^\nu(i) - \pi_t^{\beta\nu}(i)\big| &\le \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{a_j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j) \\ &\quad\times\left|\sum_{j=1}^n \pi_t^\nu(i)\Big(P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) - P\big(X_0^\nu = a_j\big|X_t^\nu = a_i, \mathscr{Y}^\nu_{[0,t]}\big)\Big)\right| \\ &\le \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{a_j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j) \\ &\quad\times\sum_{j=1}^n \pi_t^\nu(i)\Big|P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) - P\big(X_0^\nu = a_j|X_t^\nu = a_i, \mathscr{Y}^\nu_{[0,t]}\big)\Big| \qquad (5.18) \\ &\le \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j) \\ &\quad\times\sum_{j=1}^n \Big|P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) - P\big(X_0^\nu = a_j|X_t^\nu = a_i, \mathscr{Y}^\nu_{[0,t]}\big)\Big| \\ &= \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{a_j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j)\sum_{j=1}^n \Big|P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) - \rho_{ji}(t)\Big|.\end{aligned}$$

The obvious formula $P\big(X_0^\nu = a_j|\mathscr{Y}^\nu_{[0,t]}\big) = \sum_{k=1}^n \pi_t^\nu(k)\rho_{jk}(t)$, and (5.18) provide

$$\begin{aligned}\big|\pi_t^\nu(i) - \pi_t^{\beta\nu}(i)\big| &\le \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{a_j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j)\sum_{j=1}^n \Big|\sum_{k=1}^n \pi_t^\nu(k)\rho_{jk}(t) - \rho_{ji}(t)\Big| \\ &\le \max_{a_j\in\mathbb{S}}\frac{d\beta}{d\nu}(a_j)\max_{a_j\in\mathbb{S}}\frac{d\nu}{d\beta}(a_j)\sum_{j=1}^n\sum_{k=1}^n \pi_t^\nu(k)\big|\rho_{jk}(t) - \rho_{ji}(t)\big| \qquad (5.19)\end{aligned}$$

and (5.16). Thus, by Lemma 5.6, the desired statement (4.1) holds true.

5.3. The proof of Theorem 4.3. We start with the following lemma.

LEMMA 5.7. *Under the assumptions of Theorem* 4.3*, for any* $t > 0$

$$\max_{1\le j,k,\ell\le n}\big|\rho_{jk}(t)-\rho_{j\ell}(t)\big| \le \exp\Big(-2t\min_{p\neq q}\sqrt{\lambda_{pq}\lambda_{qp}}\Big). \tag{5.20}$$

Proof. Here we follow the notations from Lemma 5.6. From (5.14), it follows that

$$\frac{d\triangle_t}{dt} \le -\triangle_t\left(\frac{\lambda_{i_\diamond i^\diamond}\pi^\beta_t(i_\diamond)}{\pi^\beta_t(i^\diamond)}+\frac{\lambda_{i^\diamond i_\diamond}\pi^\beta_t(i^\diamond)}{\pi^\beta_t(i_\diamond)}\right) \tag{5.21}$$

subject to $\triangle_0 = 1$. Set $\tau = \inf\{t : i^\diamond(t) = i_\diamond(t)\}$. Since $\triangle_t$ is a nonincreasing function, $\triangle_t \equiv 0$ for $t \ge \tau$, and (5.20) holds trivially. For $t < \tau$, as previously we find

$$\begin{aligned}\triangle_t &\le \exp\left\{-\int_0^t\left(\frac{\lambda_{i_\diamond i^\diamond}\pi^\beta_s(i_\diamond)}{\pi^\beta_s(i^\diamond)}+\frac{\lambda_{i^\diamond i_\diamond}\pi^\beta_s(i^\diamond)}{\pi^\beta_s(i_\diamond)}\right)ds\right\}\\ &\le \exp\left\{-\int_0^t\min_{x\ge0}\left(\lambda_{i_\diamond i^\diamond}x+\lambda_{i^\diamond i_\diamond}\frac{1}{x}\right)ds\right\}\\ &= \exp\left\{-\int_0^t 2\sqrt{\lambda_{i_\diamond i^\diamond}\lambda_{i^\diamond i_\diamond}}ds\right\} \le \exp\Big(-2t\min_{p\neq q}\sqrt{\lambda_{pq}\lambda_{qp}}\Big),\end{aligned}$$

and (5.20) follows. □

To prove the first statement of the theorem, taking into account $\nu \ll \beta$ we replicate a fragment from the proof of Proposition 2.1.

Using the notations introduced in section 2.1, write $\pi^\nu_t(i) := \pi^\nu_t(f)$ and $\pi^{\beta\nu}_t(i) := \pi^{\beta\nu}_t(f)$ for $f(x) = I(x = a_i)$. Then,

$$E\big|\pi^{\beta\nu}_t(i)-\pi^\nu_t(i)\big| \le E\Big|E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,t]}\Big)-E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,\infty)}\vee\mathscr{X}^\beta_{[t,\infty)}\Big)\Big| \tag{5.22}$$

and, since (X^β, Y^β) is a Markov process,

$$E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,\infty)}\vee\mathscr{X}^\beta_{[t,\infty)}\Big) = E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,t]}\vee\mathscr{X}^\beta_t\Big).$$

Then,

$$\begin{aligned}&E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,t]}\Big)-E\Big(\frac{d\nu}{d\beta}(X^\beta_0)\big|\mathscr{Y}^\beta_{[0,\infty)}\vee\mathscr{X}^\beta_{[t,\infty)}\Big)\\ &=\sum_{j=1}^n\frac{d\nu}{d\beta}(a_j)\Big(P\big(X^\beta_0=a_j|\mathscr{Y}^\beta_{[0,t]}\big)-P\big(X^\beta_0=a_j|\mathscr{Y}^\beta_{[0,t]}\vee\mathscr{X}^\beta_t\big)\Big)\\ &=\sum_{j=1}^n\sum_{\ell=1}^n I(X^\beta_t=a_\ell)\frac{d\nu}{d\beta}(a_j)\Big(P\big(X^\beta_0=a_j|\mathscr{Y}^\beta_{[0,t]}\big)-\rho_{j\ell}(t)\Big) \qquad (5.23)\\ &=\sum_{j=1}^n\sum_{\ell=1}^n\sum_{k=1}^n\pi^\beta_t(k)I(X^\beta_t=a_\ell)\frac{d\nu}{d\beta}(a_j)\big(\rho_{jk}(t)-\rho_{j\ell}(t)\big)\\ &\le\max_{1\le j,k,\ell\le n}\big|\rho_{jk}(t)-\rho_{j\ell}(t)\big|\sum_{j=1}^n\frac{d\nu}{d\beta}(a_j).\end{aligned}$$

The first statement of Theorem 4.3 follows from (5.22), (5.23), and Lemma 5.7. The second statement follows from (5.16) and Lemma 5.7.

6. Proofs for the nonergodic case. Recall that in the nonergodic setting under consideration

$$\mathbb{S} = \Big\{ \underbrace{a_1^1, \dots, a_{n_1}^1}_{\mathbb{S}_1}, \dots, \underbrace{a_1^m, \dots, a_{n_m}^m}_{\mathbb{S}_m} \Big\}, \quad m \geq 2,$$

with subalphabets $\mathbb{S}_1, \dots, \mathbb{S}_m$ noncommunicating in the sense of (1.2).

6.1. Auxiliary lemmas. In this subsection, $\widetilde{X}_t^j$ is an independent copy of X_t^j with the initial distribution μ^j, defined on some auxiliary probability space $(\widetilde{\Omega}, \widetilde{\mathscr{F}}, \widetilde{P})$, and $\widetilde{E}$ is the expectation with respect to $\widetilde{P}$. Recall that μ^j is the invariant measure, so that $\widetilde{X}_t^j$ is a stationary process.

LEMMA 6.1. *Fix $r > 0$ and define $Z_n = \sum_{i=1}^n \big(Y_{ir}^\beta - Y_{(i-1)r}^\beta\big)^2$. Then with $n \to \infty$*

$$\frac{1}{n} Z_n \to r + \sum_{j=1}^m I(X_0^\beta \in \mathbb{S}_j) \widetilde{E} \left(\int_0^r h(\widetilde{X}_s^j)\, ds \right)^2.$$

Proof. Define

$$F(i) = E \left[\left(\int_0^r h(X_s^\beta)\, ds \right)^2 \Big| X_0^\beta = a_i \right]$$

and $\mathscr{G}_n = \sigma\{Y_{[0,nr]}\} \vee \sigma\{X_{[0,nr]}\}$. Then $E[(Y_{(n+1)r}^\beta - Y_{nr}^\beta)^2 | \mathscr{G}_n] = r + F(X_{nr}^\beta)$ so that the sequence $M_n = Z_n - nr - \sum_{i=0}^{n-1} F(X_{ir}^\beta)$ is a martingale with respect to the filtration $(\mathscr{G}_n)_{n \geq 1}$. It is easy to verify that there exists $K < \infty$ such that for all n we have $E(M_{n+1} - M_n)^2 \leq K$. It follows that $(1/n)M_n \to 0$ a.s. as $n \to \infty$ (see, e.g., Chapter VII, Section 5, Theorem 4 in [42]).

Now consider $(1/n) \sum_{i=0}^{n-1} F(X_{ir}^\beta)$. If $X_0 \in \mathbb{S}_j$, then $X_t \in \mathbb{S}_j$ for all $t \geq 0$ and the process is ergodic in $\mathbb{S}_j$ with stationary distribution μ^j. Applying the ergodic theorem for each class $\mathbb{S}_j$ we obtain

$$\frac{1}{n} \sum_{i=0}^{n-1} F(X_{ir}^\beta) \to \sum_{j=1}^m \widetilde{E}(F(\widetilde{X}_0)) I(X_0 \in \mathbb{S}_j) = \sum_{j=1}^m \widetilde{E} \left(\int_0^r h(\widetilde{X}_s^j)\, ds \right)^2 I(X_0^\beta \in \mathbb{S}_j)$$

as $n \to \infty$ a.s. Finally

$$\begin{aligned} \lim_{n \to \infty} \frac{1}{n} Z_n &= \lim_{n \to \infty} \frac{1}{n} M_n + r + \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} F(X_{ir}^\beta) \\ &= r + \sum_{j=1}^m \widetilde{E} \left(\int_0^r h(\widetilde{X}_s^j)\, ds \right)^2 I(X_0^\beta \in \mathbb{S}_j) \end{aligned}$$

and we are done. □

With $\widetilde{X}_t^j$ defined as in Lemma 6.1 and $r \geq 0$ let $d_j(r) = \widetilde{E}(\int_0^r h(\widetilde{X}_s^j)\, ds)^2$.

LEMMA 6.2. *For any $k \neq j$ the following are equivalent:*

i. *$d_k(r) = d_j(r)$ for all $r \geq 0$;*

ii. *$h_k^* \operatorname{diag}(\mu_k) \Lambda_k^q h_k = h_j^* \operatorname{diag}(\mu_j) \Lambda_j^q h_j$ for all $0 \leq q \leq n_i + n_j - 1$.*

Proof. Notice first that

$$d_j(r) = 2\widetilde{E}\int_0^r\int_0^s h(\widetilde{X}^j_u)h(\widetilde{X}^j_s)\,du\,ds = 2\int_0^r\int_0^s \widetilde{E}h(\widetilde{X}^j_u)h(\widetilde{X}^j_s)\,du\,ds$$
$$= 2\int_0^r\int_0^s \widetilde{E}h(\widetilde{X}^j_0)h(\widetilde{X}^j_{s-u})\,du\,ds = 2\int_0^r\int_0^s \widetilde{E}h(\widetilde{X}^j_0)h(\widetilde{X}^j_v)\,dv\,ds.$$

Now, introduce the vector $\widetilde{I}^j_t$ with entries $I(\widetilde{X}^j_t = a^j_1), \dots, I(\widetilde{X}^j_t = a^j_{n_j})$ and notice also that

$$\widetilde{E}h(\widetilde{X}^j_0)h(\widetilde{X}^j_v) = \widetilde{E}h^*_j\widetilde{I}^j_0(\widetilde{I}^j_v)^*h_j = \widetilde{E}h^*_j\widetilde{I}^j_0(\widetilde{I}^j_0)^*e^{\Lambda_j v}h_j$$
$$= h^*_j\widetilde{E}\,\mathrm{diag}(\widetilde{I}^j_0)e^{\Lambda_j v}h_j = h^*_j\,\mathrm{diag}(\mu^j)e^{\Lambda_j v}h_j.$$

Therefore $d_j(r) = 2\int_0^r\int_0^s h^*_j\,\mathrm{diag}(\mu^j)e^{\Lambda_j v}h_j dv ds$, so $d_j(0) = d_j{}'(0) = 0$ and

$$d_j{}''(r) = 2h^*_j\,\mathrm{diag}(\mu^j)e^{\Lambda_j r}h_j.$$

Differentiating with respect to r a further q times and then putting $r = 0$ we get

$$d_j^{(2+q)}(0) = 2h^*_j\,\mathrm{diag}(\mu^j)\Lambda^q_j h_j.$$

It follows immediately that if $d_k(r) = d_j(r)$ for all $r \geq 0$, then

$$h^*_k\,\mathrm{diag}(\mu^k)\Lambda^q_k h_k = h^*_j\,\mathrm{diag}(\mu^j)\Lambda^q_j h_j$$

for all $q \geq 0$ and so in particular for all $0 \leq q \leq n_k + n_j - 1$.

Suppose conversely that $h^*_j\,\mathrm{diag}(\mu^j)\Lambda^q_j h_j = h^*_k\,\mathrm{diag}(\mu^k)\Lambda^q_k h_k$ for all $0 \leq q \leq n_k + n_j - 1$. The Cayley–Hamilton theorem applied to the $(n_k+n_j)\times(n_k+n_j)$ block diagonal matrix $\left(\begin{smallmatrix}\Lambda_k & 0\\ 0 & \Lambda_j\end{smallmatrix}\right)$ gives constants $c_0, c_1, \dots, c_{n_k+n_j-1}$ so that

$$\Lambda^{n_k+n_j}_k = \sum_{q=0}^{n_k+n_j-1} c_q\Lambda^q_k \quad\text{and}\quad \Lambda^{n_i+n_j}_j = \sum_{q=0}^{n_k+n_j-1} c_q\Lambda^q_j.$$

Therefore we have $h^*_k\,\mathrm{diag}(\mu^k)\Lambda^q_k h_k = h^*_j\,\mathrm{diag}(\mu^j)\Lambda^q_j h_j$ for all $q > n_j + n_k - 1$ as well. Using the fact that $e^{\Lambda_j r} = \sum_{q=0}^\infty \frac{r^q\Lambda^q_j}{q!}$, we see that $d_k{}''(r) = d_j{}''(r)$ for all $r \geq 0$, and hence $d_k(r) = d_j(r)$ for all $r \geq 0$. ∎

LEMMA 6.3. *Assume* A-2. *For any* β

$$\lim_{t\to\infty} E\Big|P\big(X^\beta_0 \in \mathbb{S}_j|\mathscr{Y}^\beta_{[0,t]}\big) - I(X^\beta_0 \in \mathbb{S}_j)\Big| = 0,\ j \geq 1.$$

Proof. We use the notation $Z^{(r)}_n$ to express the dependence on r of the function Z_n in Lemma 6.1. We have $\frac{1}{n}Y^\beta_n \to \sum_{j=1}^m h^*_j\mu^j I(X^\beta_0 \in \mathbb{S}_j)$ and

$$\frac{1}{n}Z^{(r)}_n \to r + \sum_{j=1}^m d_j(r)I(X^\beta_0 \in \mathbb{S}_j)$$

as $n \to \infty$ a.s. Using assumption A-2 and Lemma 6.2 we can find an integer ℓ and numbers $r_i > 0, i = 1, \dots, \ell$, and construct a random variable of the form $V_n = (Y^\beta_n, Z^{(r_1)}_n - nr_1, \dots, Z^{(r_\ell)}_n - nr_\ell)$ so that $\frac{1}{n}V_n \to \sum_{j=1}^m v_j I(X^\beta_0 \in \mathbb{S}_j)$ as $n \to \infty$, P-a.s., where the $v_1, \dots, v_m$ are distinct vectors in $\mathbb{R}^{\ell+1}$. Therefore $\{X^\beta_0 \in \mathbb{S}_j\}$ is $Y^\beta_{[0,\infty)}$-measurable a.s. and the result follows immediately. ∎

6.2. The proof of Theorem 4.4. By Proposition 2.1, it suffices to show that

$$\lim_{t\to\infty} E\big\|\pi_t^{\beta} - \pi_t^{\beta_0}\big\| = 0.$$

We introduce a new filter, intermediate between π_t^{β} and $\pi_t^{\beta_0}$. Define the random variable U by $U = j$ on the set $\{X_0^{\beta} \in \mathbb{S}_j\}$, and then define

$$\pi_t^{\beta,U}(i) = P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U).$$

Then

$$\begin{aligned}
\big\|\pi_t^{\beta} - \pi_t^{\beta,U}\big\| &= \sum_{i=1}^{n} \Big| P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}) - P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U) \Big| \\
&= \sum_{i=1}^{n} \left| \sum_{j=1}^{m} P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U = j) \Big(P(U = j | \mathscr{Y}_{[0,t]}^{\beta}) - I(U = j) \Big) \right| \\
&\le \sum_{j=1}^{m} \Big| P(U = j | \mathscr{Y}_{[0,t]}^{\beta}) - I(U = j) \Big|
\end{aligned}$$

and

$$\begin{aligned}
&\big\|\pi_t^{\beta,U} - \pi_t^{\beta_0}\big\| = \sum_{i=1}^{n} \Big| P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U) - P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, X_0^{\beta}) \Big| \\
&= \sum_{i=1}^{n} \sum_{j=1}^{m} I(U = j) \Big| P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U = j) - P(X_t^{\beta} = a_i | \mathscr{Y}_{[0,t]}^{\beta}, U = j, X_0^{\beta}) \Big| \\
&= \sum_{j=1}^{m} I(U = j) \big\|\pi_t^{\beta^j} - \pi_t^{\beta_0^j}\big\|,
\end{aligned}$$

where β^j denotes the conditional distribution of β restricted to the subalphabet $\mathbb{S}_j$. By Lemma 6.3,

$$\sum_{j=1}^{m} \Big| P(U = j | \mathscr{Y}_{[0,t]}^{\beta}) - I(U = j) \Big| \xrightarrow[t\to\infty]{P} 0$$

while $\sum_{j=1}^{m} I(U = j) \big\|\pi_t^{\beta^j} - \pi_t^{\beta_0^j}\big\| \xrightarrow[t\to\infty]{\mathbb{L}_1} 0$ by applying Theorem 4.1 to each $\mathbb{S}_j$.

Appendix. Proof of Proposition 3.2.

Proof (sketch). We use the following construction for X. Let X_0 be a random variable with values in $\mathbb{S} = \{1, 2, 3, 4\}$ and $P(X_0 = j) = \nu_j$, $j = 1, \dots, 4$. Introduce independent of X_0 the matrix-valued process

$$\mathcal{N}_t = \begin{pmatrix} -N_{12}(t) & N_{12}(t) & 0 & 0 \\ 0 & -N_{23}(t) & N_{23}(t) & 0 \\ 0 & 0 & -N_{34}(t) & N_{34}(t) \\ N_{41}(t) & 0 & 0 & -N_{41}(t) \end{pmatrix}, \tag{A.1}$$

where $N_{ij}(t)$ are independent copies of the Poisson process with the unit rate. Let us consider the Itô equation

$$I_t = I_0 + \int_0^t d\mathcal{N}_s^* I_{s-} \tag{A.2}$$

with I_0 the vector with entries $I_0(j) = I(X_0 = j)$, $j = 1, \dots, 4$. Since the jumps of Poisson processes $N_{ij}(t)$'s are disjoint, for any $t > 0$ the vector I_t has only one nonzero entry. Moreover, whereas the increments of $\mathcal{N}_t$ are independent for nonoverlapping intervals, I_t is a Markov process. It is readily checked that, with the row vector $g = \begin{pmatrix} 1 & 2 & 3 & 4 \end{pmatrix}$, $X_t = gI_t$ is a Markov process with values in $\mathbb{S}$ and the transition intensities matrix Λ and $I_t(j) = I(X_t = j)$, $j = 1, \dots, 4$.

We will follow Theorem 4.10.1 from [31]. The random process Y has piecewise constant paths with jumps of two magnitudes, $+1$ and -1. Due to (A.2), its saltus measure $p(dt, dy)$ is completely described by

$$\begin{aligned} p(dt, \{1\}) &= \big\{ I_{t-}(4) dN_{41}(t) + I_{t-}(2) dN_{23}(t) \big\}, \\ p(dt, \{-1\}) &= \big\{ I_{t-}(1) dN_{12}(t) + I_{t-}(3) dN_{34}(t) \big\}. \end{aligned}$$

So, the compensator $\overline{q}(dt, dy)$ of $p(dt, dy)$ with respect to the filtration $(\mathscr{Y}_{[0,t]})_{t \geq 0}$ is defined as

$$\begin{aligned} \overline{q}(dt, \{1\}) &= \big(\pi_{t-}(4) + \pi_{t-}(2) \big) dt = (1 - Y_{t-}) dt, \\ \overline{q}(dt, \{-1\}) &= \big(\pi_{t-}(1) + \pi_{t-}(3) \big) dt = Y_{t-} dt. \end{aligned} \tag{A.3}$$

Notice also that

$$p(dt, \{1\}) = (1 - Y_{t-}) dY_t \quad \text{and} \quad p(dt, \{-1\}) = -Y_{t-} dY_t. \tag{A.4}$$

Equation (A.2) also gives "drift+martingale" presentation for $I_1(t)$, $I_2(t)$:

$$\begin{aligned} dI_t(1) &= \big(- I_t(1) + I_t(4) \big) dt + dM_1(t), \\ dI_t(2) &= \big(I_t(1) - I_t(2) \big) dt + dM_2(t) \end{aligned} \tag{A.5}$$

with martingales

$$\begin{aligned} M_1(t) &= \int_0^t \Big(- I_{s-}(1) d(N_{12}(s) - s) + I_{s-}(4) d(N_{41}(s) - s) \Big), \\ M_2(t) &= \int_0^t \Big(I_{s-}(1) d(N_{12} - s) - I_{s-}(2) d(N_{23}(s) - s) \Big). \end{aligned}$$

Then, by Theorem 4.10.1 in [31], adapted to the case considered, we have

$$\begin{aligned} d\pi_1(t) &= \big(- \pi_t(1) + \pi_t(4) \big) dt + \int H_1(\omega, t, y) \big[p(dt, dy) - \overline{q}(dt, dy) \big], \\ d\pi_2(t) &= \big(\pi_t(1) - \pi_t(2) \big) dt + \int H_2(\omega, t, y) \big[p(dt, dy) - \overline{q}(dt, dy) \big], \end{aligned} \tag{A.6}$$

where $H_i(\omega, t, y)$, $i = 1, 2$, are $\mathscr{P}(Y) \otimes \mathscr{B}(\mathbb{R})$-measurable functions (here $\mathscr{B}(\mathbb{R})$ is the Borel σ-algebra on $\mathbb{R}$ and $\mathscr{P}(Y)$ is the predictable σ-algebra on $\Omega \times \mathbb{R}_+$ with respect to the filtration $(\mathscr{Y}_{[0,t]})_{t \geq 0}$). Moreover

$$H_i(\omega, t, y) = \mathsf{M}\big(\triangle M_i + I_-(i) | \mathscr{P}(\mathcal{Y}) \otimes \mathscr{B}(\mathbb{R}) \big)(\omega, t, y) - \pi_{t-}(i),$$

where $\triangle M_i$ and $I_-(i)$ are the processes $M_i(t) - M_i(t-)$ and $I_{t-}(i)$, respectively, and $\mathsf{M}\big(\,\cdot\,|\mathscr{P}(Y)\otimes\mathscr{B}(\mathbb{R})\big)$ is the conditional expectation with respect to the measure $\mathsf{M}(d\omega, dt, dy) = P(d\omega)p(dt, dy)$ given $\mathscr{P}(Y)\otimes\mathscr{B}(\mathbb{R})$.

By (A.5), $\triangle M_i(t) + I_{t-}(i) = I_t(i)$ and the structure of compensator $\overline{q}$ provides (here $\triangle I_t(i) = I_t(i) - I_{t-}(i)$)

$$\mathsf{M}\big(I(i)|\mathscr{P}(Y)\otimes\mathscr{B}(\mathbb{R})\big) - \pi_{t-}(i) = \mathsf{M}\big(\triangle I(i)|\mathscr{P}(Y)\otimes\mathscr{B}(\mathbb{R})\big).$$

The desired conditional expectation is determined uniquely from the following identity: For any bounded, compactly supported in t and $\mathscr{P}(\mathcal{Y})\otimes\mathscr{B}(\mathbb{R})$-measurable function $\phi(\omega, t, y)$

$$E\int_0^\infty\int \phi(\omega,t,y)\triangle I_t(i)p(dt,dy) = E\int_0^\infty\int \phi(\omega,t,y)\mathsf{M}\big(\triangle I(i)|\mathscr{P}(Y)\otimes\mathscr{B}(\mathbb{R})\big)(\omega,t,y)\overline{q}(dt,dy).$$

By (A.2)

$$\begin{aligned}\triangle I_t(1) &= -I_{t-}(1)\triangle N_{12}(t) + I_{t-}(4)\triangle N_{41}(t),\\ \triangle I_t(2) &= I_{t-}(1)\triangle N_{12}(t) - I_{t-}(2)\triangle N_{23}(t),\end{aligned}$$

and so

$$\begin{aligned}\triangle I_t(1)p(dt,\{1\}) &= I_{t-}(4)dN_{41}(t),\\ \triangle I_t(1)p(dt,\{-1\}) &= -I_{t-}(1)dN_{12}(t),\\ \triangle I_t(2)p(dt,\{1\}) &= -I_{t-}(2)dN_{23}(t),\\ \triangle I_t(2)p(dt,\{-1\}) &= I_{t-}(1)dN_{12}(t).\end{aligned}$$

Owing to the obvious relations

$$\begin{aligned}I_4(t) \equiv I_4(t)(1-Y_t),\quad I_2(t) \equiv I_2(t)(1-Y_t),\\ I_1(t) \equiv I_1(t)Y_t,\quad I_3(t) \equiv I_3(t)Y_t\end{aligned}$$

we have

$$\begin{aligned}\pi_{t-}(2)dt = \pi_{t-}(2)(1-Y_{t-})dt,\quad \pi_{t-}(2)dt = \pi_{t-}(2)(1-Y_{t-})dt,\\ \pi_{t-}(1)dt = \pi_{t-}(1)Y_{t-}dt,\quad \pi_{t-}(3)dt = \pi_{t-}(3)Y_{t-}dt.\end{aligned}\tag{A.7}$$

Taking into account (A.3), we find

$$H_1(\omega,t,y) = \begin{cases}\pi_{t-}(4), & y=1,\\ -\pi_{t-}(1), & y=-1,\end{cases}$$

$$H_2(\omega,t,y) = \begin{cases}-\pi_{t-}(2), & y=1,\\ \pi_{t-}(1), & y=-1.\end{cases}$$

In accordance with (A.3), (A.4), the formulae for H_1, H_2, and (A.7), we transform (A.6) to

$$\begin{aligned}d\pi_1(t) &= \big(-\pi_t(1)+\pi_t(4)\big)dt + \pi_{t-}(4)(1-Y_{t-})(dY_t - dt) + \pi_{t-}(1)Y_{t-}(dY_t + dt)\\ &= \pi_{t-}(4)(1-Y_{t-})dY_t + \pi_{t-}(1)Y_{t-}dY_t\\ &= \big(1-\pi_{t-}(2)\big)(1-Y_{t-})dY_t + \pi_{t-}(1)Y_{t-}dY_t,\\ d\pi_2(t) &= \big(\pi_t(1)-\pi_t(2)\big)dt - \pi_{t-}(2)(1-Y_{t-})(dY_t - dt) - \pi_{t-}(1)Y_{t-}(dY_t + dt)\\ &= -\pi_{t-}(2)(1-Y_{t-})dY_t - \pi_{t-}(1)Y_{t-}dY_t.\qquad\square\end{aligned}$$

Acknowledgments. The authors gratefully acknowledge Boris Tsirelson for bringing [43] and the example in [44] to their attention, Rami Atar for suggesting use of Theorem 1 in [2] for the proof of Theorem 4.1, and the anonymous referees whose comments and advice allowed us to improve the paper significantly.

SLIDING MODE DESIGN VIA QUADRATIC PERFORMANCE OPTIMIZATION WITH POLE-CLUSTERING CONSTRAINT*

KYUNG-SOO KIM† AND YOUNGJIN PARK‡

Abstract. We consider a novel method for designing the sliding mode that minimizes the quadratic performance while keeping a pole-clustering constraint. Our approach is based on the manipulations of linear matrix inequalities (LMIs) imposed by the design objectives. For this purpose, we newly propose LMI conditions for the quadratic performance optimization and the pole-clustering problem, respectively, in a full order state. Then they are combined in the LMI framework that is typically devised for the sliding mode design in the convex form. An effort is made to reduce the generic conservatism by allowing different Lyapunov matrices. In addition, a class of polytope uncertain systems is addressed to illustrate the advantages of the proposed method.

Key words. sliding mode, linear matrix inequalities (LMIs), Lyapunov matrix, quadratic performance optimization, pole-clustering problem, polytopic uncertain system

1. Introduction.

Sliding mode control has been one of the major concerns in control theory thanks to the robustness against matched uncertainties (or disturbances) through the sliding mode behavior. Once the system reaches the sliding manifold, the system dynamics becomes invariant to the matched disturbances. This typical characteristic has drawn much attention to many practical problems which are hard to solve by using only the linear control methods. For example, the robot manipulators with friction or stabilized head mirror systems can be effectively dealt with by the sliding mode control. Refer to DeCarlo, Zak, and Matthews [2] and the references therein for more details.

In the literature, much effort has been made to design sliding modes that satisfy the desired performance criteria. The well-known criteria include quadratic performance optimization [1], guaranteed H_2 cost minimization [14], the eigen-structure assignment including pole clustering [3, 4, 6], the robustness to parametric uncertainties [5, 7, 13], etc. It is noted that most of the design methods developed so far have considered only the single design objective. In fact, there have been few researches that address multiple design objectives in the sliding mode. Recently, in [15], the sliding mode design with multiple constraints has been introduced based on the linear matrix inequality (LMI) approach by employing the linear full state feedback design. On the other hand, remarkable progress has been made in linear control theory for solving optimal problems with multiple constraints based on LMIs (e.g., see [10] and [18]). The basic idea of the multiobjective approach based on LMIs is to seek a *common* Lyapunov matrix that satisfies different parametric constraints imposed by the design performances simultaneously. Assuming the common variables may cause the conservatism, however, it does provide the flexibility of the control design with multiple objectives, and the ease of synthesis in the parameter space based on LMIs

[8]. Also, there have been notable results in the literature in reducing the design conservatism (e.g., see [11] and [16]).

The paper is devoted to establishing an LMI framework for the sliding mode design which effectively solves the constrained optimization problems by adopting the common Lyapunov matrix idea of the linear control theory. To this end, attention is paid especially to quadratic performance optimization with the pole-clustering constraint in the sliding mode. First, we newly present the parametric constraints in LMIs for describing quadratic performance optimization and the pole-clustering condition, respectively. Then they are combined in an LMI-based optimization problem of special structure. It will be shown that the proposed approach for the sliding mode design should be different from the standard full state feedback problem by Chilali and Gahinet [10] in linear control theory. Furthermore, the proposed approach is further extended to reduce the generic conservatism by adopting the bounding technique in Shimomura and Fujii [16].

The basic idea of the paper starts from the derivation of LMI conditions in the full order state (not in the reduced order) by adopting and generalizing the parameterization technique in Kim, Park, and Oh [7] to allow all the feasible linear sliding modes to be represented explicitly. Any feasible sliding modes can be obtained immediately by combining the partitions of the Lyapunov matrix in an explicit manner. From this point of view, the proposed approach generalizes the previous results using the full order Lyapunov (or Riccati-type) approaches (see [5, 6]), which motivated the study. Note that the approach in the full order state has the advantage of simplicity in description and easy application of the linear full state feedback theories to the sliding mode design with least modification (which will be further discussed with a class of polytopic uncertain systems later on).

In section 2, the problem of interest is formulated with a brief explanation for the LMI scheme with multiple constraints. In section 3, we deal with quadratic performance optimization and the pole-clustering problem separately based on parametric constraints. Then in section 4, we formulate the LMI approach by accumulating parametric constraints in a single problem of convex form. Also, to reduce the design conservatism, a numerically tractable algorithm is presented. In section 5, we address the extension of the proposed scheme to a class of polytopic uncertain systems in order to show the potential advantage of the basic idea of the paper.

The notations used in the paper are fairly standard, among them, the inequality signs for matrices denote sign-definiteness for real symmetric matrices.

2. Problem formulation and preliminary. Consider the system

$$\dot{x} = Ax + B(u + Dw), \tag{2.1}$$

where $x \in \Re^n$ and $u \in \Re^m$ are the state vector and the control input, respectively, and $w \in \Re^l$ is the disturbance of which each element is bounded as $|w_j(t)| \le \overline{w}_j \ \forall j \in [0, l]$ for the known $\overline{w}_j$. The stabilizability of the pair (A, B) is assumed. And, for simplicity of description, suppose that the system is of the regular form [1, 2]

$$\begin{cases} \dot{x}_1 = A_{11}x_1 + A_{12}x_2, \\ \dot{x}_2 = A_{21}x_1 + A_{22}x_2 + B_2(u + Dw), \end{cases} \tag{2.2}$$

where $x_1 \in \Re^{n-m}$, $x_2 \in \Re^m$, and B_2 is nonsingular. Without loss of generality, consider the sliding function

$$s(t) = Sx_1 + x_2 \tag{2.3}$$

for some $S \in \Re^{m\times(n-m)}$. Suppose that a control law is employed to satisfy the reachability condition such that $\dot{s}(t)^T s(t) < 0\ \forall t > 0$, which would result in the sliding mode (i.e., $s(t) = 0\ \forall t \geq t_s$ for some $t_s > 0$). Then the system behavior would be governed by the reduced order system and the constrained state as follows:

$$\begin{cases} \dot{x}_1 = (A_{11} - A_{12}S)\, x_1, \\ x_2 = -Sx_1. \end{cases} \tag{2.4}$$

Note that in the sliding mode, the system dynamics will be determined by the choice of sliding function coefficient S. Among many criteria for selecting the matrix S, one may consider the quadratic performance optimization to make a tradeoff between the system states behaviors. In the paper, we are interested in solving the following problem.

Problem formulation. Given the real scalars c and $\rho > 0$ and a matrix $0 < Q \in \Re^{n\times n}$, find the sliding function coefficient S that minimizes the quadratic performance

$$J(S) \triangleq \int_{t_s}^{\infty} x^T Q x\ dt \tag{2.5}$$

subject to the dynamics (2.4) and the pole-clustering constraint

$$\lambda\,(A_{11} - A_{12}S) \subset \mathcal{Z}(c, \rho), \tag{2.6}$$

where $\lambda(\cdot)$ is the set of eigenvalues of the argument matrix, and $\mathcal{Z}(c, \rho)$ denotes the circular region, in the complex domain,

$$\mathcal{Z}(c, \rho) \triangleq \{z \in \mathcal{C} \mid\ |z + c| < \rho,\ \mathrm{Re}(z) < 0\}\,. \tag{2.7}$$

For the set $\mathcal{Z}(c, \rho)$ to be nonempty, it is necessary that $c > -\rho$.

Note that the problem above consists of two design objectives (i.e., the quadratic performance optimization and the pole-clustering problem). To tackle the above problem, suppose that the quadratic performance is bounded as $J < \gamma$ if there exist some Lyapunov matrices P_1 satisfying an affine matrix inequality $F_1(P_1, S) < 0$. Also, suppose that the pole-clustering constraint is satisfied if there exist some multipliers P_2 satisfying $F_2(P_2, S) < 0$. Often, each of the parametric constraints (i.e., $F_1 < 0$ and $F_2 < 0$) can be converted to be convex, but not jointly. In this case, let us consider this problem: *find a matrix S that satisfies the constraints $F_i(P_i, S) < 0$ $(i = 1, 2)$ simultaneously.* Since the constraints are not jointly convex, the problem is difficult to solve. One way to recover the convexity is to further assume that $P_1 = P_2$ regardless of the conservatism, which is one of the main approaches in the LMI-based constrained optimization (or multiobjective) theory. See [10] and [18] for more details.

In the next section, two objectives are dealt with distinctly based on the parameterization technique for the sliding mode in the LMI form. Then in section 4, they are combined in an LMI optimization approach specifically adapted to the sliding mode design and different from the standard full state feedback method [10].

3. LMI approaches to sliding mode design.

3.1. Quadratic performance optimization. In this subsection, we handle the quadratic performance optimization problem in the parameter space by manipulating the Lyapunov equation.

Given a matrix $Q > 0$, let us define the set

$$\Omega(Q) \triangleq \left\{P \mid (A - BK)^T P + P(A - BK) + Q = 0,\ P > 0,\ K \in \Re^{m\times n}\right\}, \tag{3.1}$$

which is the nonempty set of positive definite matrices as long as the pair (A, B) is stabilizable (e.g., see [17]). Then we present the following result.

THEOREM 3.1. *Suppose that a matrix $Q > 0$ is arbitrarily chosen. Then the following statements hold:*

(i) *Any stabilizing sliding function coefficient exists in the form*

$$S = P_{22}^{-1} P_{12}^T \tag{3.2}$$

for a $P \in \Omega(Q)$, where P_{ij}'s are defined as

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{12}^T & P_{22} \end{bmatrix} \in \begin{bmatrix} \Re^{(n-m)\times(n-m)} & \Re^{(n-m)\times m} \\ \Re^{m\times(n-m)} & \Re^{m\times m} \end{bmatrix}.$$

(ii) *For any $P \in \Omega(Q)$, the matrix S given by* (3.2) *is a stabilizing sliding function coefficient.*

Proof. Statement (i). Let S be the stabilizing sliding function coefficient which guarantees the stability of the matrix $A_s := A_{11} - A_{12}S$. Define a positive definite matrix as $Q_r = \left[I_{n-m},\ -S^T\right] Q \left[I_{n-m},\ -S^T\right]^T$. Then there should exist a $P_r > 0$ satisfying

$$\left(A_{11} - A_{12}S\right)^T P_r + P_r \left(A_{11} - A_{12}S\right) + Q_r = 0 \tag{3.3}$$

due to the stability of A_s. Now, for an arbitrary matrix $0 < P_{22} \in \Re^{m\times m}$, define the matrices

$$P_{12} \triangleq S^T P_{22}, \quad P_{11} \triangleq P_r + P_{12}^T P_{22}^{-1} P_{12}, \quad K \triangleq [K_1,\ K_2], \tag{3.4}$$

where

$$K_1 = B_2^{-1}\left\{A_{21} + P_{22}^{-1}P_{12}^T A_{11} + P_{22}^{-1}A_{12}^T P_r\right\}, \quad K_2 = B_2^{-1}\left\{A_{22} + P_{22}^{-1}P_{12}^T A_{12}\right\}.$$

Observe that $P := \left[\begin{smallmatrix} P_{11} & P_{12} \\ P_{12}^T & P_{22} \end{smallmatrix}\right]$ is positive definite since $P_{22} > 0$ and $P_{11} - P_{12}P_{22}^{-1}P_{12}^T$ $(= P_r) > 0$. With the matrices P and K above, it may be shown, through some manipulations, that

$$\begin{bmatrix} I_{n-m} & -S^T \\ 0 & I_m \end{bmatrix} \left\{(A - BK)^T P + P(A - BK) + Q\right\} \begin{bmatrix} I_{n-m} & -S^T \\ 0 & I_m \end{bmatrix}^T = 0, \tag{3.5}$$

which implies that $P \in \Omega(Q)$.

Statement (ii). For a $P \in \Omega(Q)$, define $T_r \triangleq \left[I_{n-m},\ -P_{12}P_{22}^{-1}\right]$. Then pre- and postmultiplying the Lyapunov equation in (3.1) by T_r and T_r^T, respectively, yields

$$\left(A_{11} - A_{12}P_{22}^{-1}P_{12}^T\right)^T P_r + P_r \left(A_{11} - A_{12}P_{22}^{-1}P_{12}^T\right) + T_r Q T_r^T = 0, \tag{3.6}$$

where $P_r = P_{11} - P_{12}^T P_{22}^{-1} P_{12}$, which is positive definite since $P > 0$. Then, by choosing $S = P_{22}^{-1}P_{12}^T$, the asymptotic stability of the matrix $A_{11} - A_{12}S$ is guaranteed. This completes the proof. □

Theorem 3.1 shows that all of the linear sliding modes can be represented by combining portions of the full order Lyapunov matrix (i.e., P_{12} and P_{22}). Using the result, the sliding mode can be obtained easily simply by solving the Lyapunov equation. Here, we point out that the specific choice of Q does not constrain the

range of the feasible sliding function coefficients. The matrix Q will be used to define the quadratic performance in the following.

Using Theorem 3.1, we can tackle the linear quadratic sliding (LQS) mode optimization problem in the following.

THEOREM 3.2. *Given the stabilizing sliding function coefficient S, the quadratic cost function* (2.5) *satisfies*

$$J(S) = x_1(t_s)^T P_r x_1(t_s) \tag{3.7}$$

for the $P \in \Omega(Q)$ satisfying (3.2)*, where $P_r = P_{11} - P_{12}P_{22}^{-1}P_{12}^T$.*

Proof. For the sliding function coefficient S, there exists a $P \in \Omega(Q)$ satisfying $S = P_{22}^{-1}P_{12}^T$ for some K (from result (i) of Theorem 3.1). Then it follows that

$$\begin{aligned} s(t) &= x_2 + Sx_1 \\ &= P_{22}^{-1}\left[\, P_{12}^T \quad P_{22}\,\right] x \\ &= \left(P_{22}^{-1}B_2^{-T}\right) B^T P x, \end{aligned} \tag{3.8}$$

which implies $B^T P x = 0$ on $s(t) = 0$ $(\forall t \geq t_s)$ since $B_2^T P_{22}$ is nonsingular. Note that $B^T = [0_{m\times(n-m)},\ B_2^T]$ from (2.1) and (2.2).

Let us consider the derivative of a quadratic function $V = x^T P x$ for $t \geq t_s$. Rewriting the system equation as

$$\dot{x} = (A - BK)x + B(u + Dw + Kx)$$

for the matrix K associated with the matrix P, it follows that

$$\begin{aligned} \dot{V} &= x^T\left\{(A-BK)^T P + P(A-BK)\right\} x + 2x^T PB\,(u + Dw + Kx) \\ &= -x^T Q x + 2x^T PB\,(u + Dw + Kx) \\ &= -x^T Q x, \end{aligned} \tag{3.9}$$

since $B^T P x = 0$ on $s(t) = 0$. Integrating both sides in (3.9), we have

$$\begin{aligned} \int_{t_s}^{\infty} x^T Q x\ dt &= x(t_s)^T P x(t_s) \\ &= x_1(t_s)^T\left(P_{11} - P_{12}P_{22}^{-1}P_{12}^T\right) x_1(t_s), \end{aligned} \tag{3.10}$$

since $x_2(t_s) = -P_{22}^{-1}P_{12}^T x_1(t_s)$. This completes the proof. ∎

Theorems 3.1 and 3.2 provide an important result—that the quadratic performance index is redefined in the parameter space so that the optimization can be equivalently expressed as

$$\min_S J(S) = \min_{P\in\Omega(Q)} x_1(t_s)^T P_r x_1(t_s). \tag{3.11}$$

One of the advantages of the above results is that a convex approach is allowed based on the LMI method [8] that utilizes the change of variables such as $Y := P^{-1}$ and $L := KP^{-1}$. For converting the LQS design problem into LMIs, the cost index (expressed by P_r) should be of concern when using the matrix inversion property

$$Y = P^{-1} = \begin{bmatrix} Y_{11} & Y_{12} \\ Y_{12}^T & Y_{22} \end{bmatrix}, \tag{3.12}$$

where Y_{ij}'s are as follows:

$$\begin{aligned} Y_{11} &= (P_{11} - P_{12}P_{22}^{-1}P_{12}^T)^{-1}, \\ Y_{12} &= -(P_{11} - P_{12}P_{22}^{-1}P_{12}^T)^{-1}P_{12}P_{22}^{-1}, \\ Y_{22} &= P_{22}^{-1} + P_{22}^{-1}P_{12}^T Y_{11} P_{12} P_{22}^{-1}. \end{aligned}$$

Observe that P_r is described by the inverse of Y_{11}. Now, we summarize the LQS design method in the following.

LQS PROBLEM. *Given $Q > 0$, minimize γ w.r.t. $Y > 0$ and L satisfying*

$$\begin{bmatrix} AY + YA^T - BL - L^T B^T & YC_Q \\ C_Q^T Y & -I_q \end{bmatrix} < 0, \tag{3.13}$$

$$\begin{bmatrix} \gamma I_{n-m} & I_{n-m} \\ I_{n-m} & Y_{11} \end{bmatrix} > 0, \tag{3.14}$$

where $Q = C_Q C_Q^T$ and $q = rank(Q)$. Then, for the optimal value of Y, the sliding function coefficient (3.2) *is determined by*

$$S = -Y_{12}^T Y_{11}^{-1}. \tag{3.15}$$

Remark 3.3. The inequality (3.14) removes the optimal solution's dependency on the initial state, which results in $\int_{t_s}^{\infty} x^T Q x dt < \gamma \|x_1(t_s)\|^2$. Since the initial state is hardly known in reality, we adopt (3.14) instead of the inequality

$$\begin{bmatrix} \gamma & x_1(t_s)^T \\ x_1(t_s) & Y_{11} \end{bmatrix} > 0 \ .$$

The quadratic performance optimization was first introduced and solved by Utkin and Yang [1] based on the manipulation of an algebraic Riccati equation of reduced order, which has been considered a standard approach in the literature (e.g., see [12]). On the other hand, the approach of the paper is derived in the full order state while preserving the generality of the sliding mode design (i.e., in terms of the optimality and the existence of stabilizing sliding surfaces). In this context, the above results can be seen as a generalization, in the full order state, of the conventional approach. Furthermore, emphasis is placed on the underlying features in the parameterization technique (introduced in Theorem 3.1) in the full order state. That is, the Lyapunov matrices that solve the full state feedback provide all the feasible sliding modes. As a matter of fact, the idea can be consistently applied not only to the quadratic performance problem but also to other issues such as the pole-clustering constraint and the polytope uncertain systems, which can be dealt with by the Lyapunov (or Riccati) approaches developed for the full state feedback design. This will be investigated later. As pointed out by Su, Drakunov, and Özgüner [5], the simplicity of the problem description (by manipulating the full order system) is one of the practical advantages.

3.2. Pole-clustering problem in the sliding mode. We consider a method to represent the pole-clustering constraint (2.6) in terms of a parametric approach. To this end, we rely on the result from Yedavalli [9] and Chilali and Gahinet [10] in the following.

LEMMA 3.4. *The pole clustering constraint* (2.6) *holds for the matrix* S *if and only if there exist some* $0 < P_r \in \Re^{(n-m)\times(n-m)}$ *satisfying*

$$\begin{bmatrix} \rho P_r & (A_{11} - A_{12}S)^T P_r + cP_r \\ P_r(A_{11} - A_{12}S) + cP_r & \rho P_r \end{bmatrix} > 0. \tag{3.16}$$

Note that the Lyapunov matrix (i.e., P_r) of reduced order may be used to parameterize the sliding function coefficient alone. However, it is not apparent how it is related to the Lyapunov matrix of full order. Regarding this issue, we present the following result.

THEOREM 3.5. *Given the region* (2.7)*, the following statements hold.*

(i) *Any sliding function coefficient satisfying* (2.6) *exists in the form* $S = P_{22}^{-1}P_{12}^T$ *for a* $0 < P \in \Re^{n\times n}$ *satisfying, for some* $K \in \Re^{m\times n}$*,*

$$\begin{bmatrix} \rho P & (A - BK)^T P + cP \\ P(A - BK) + cP & \rho P \end{bmatrix} > 0\ . \tag{3.17}$$

(ii) *For any* $P > 0$ *satisfying* (3.17)*, the matrix* $S = P_{22}^{-1}P_{12}^T$ *attains the pole-clustering property* (2.6)*.*

Proof. Statement (i). Let S be the sliding function coefficient matrix satisfying (2.6). Then we can prove that there exists $P_r > 0$ satisfying (3.16) based on the necessity condition of Lemma 3.4. Define the matrices, for an arbitrary $0 < P_{22} \in \Re^{m\times m}$, as

$$P_{12} \triangleq S^T P_{22}, \quad P_{11} \triangleq P_r + P_{12}^T P_{22}^{-1} P_{12}, \quad K \triangleq [K_1,\ K_2], \tag{3.18}$$

where

$$\begin{aligned} K_1 &= B_2^{-1}\left\{P_{22}^{-1}P_{12}^T(A_{11} + cI_{n-m}) + A_{21}\right\}, \\ K_2 &= B_2^{-1}\left\{P_{22}^{-1}P_{12}^T A_{12} + A_{22} + cI_m\right\}. \end{aligned}$$

Note that the matrix $P := \left[\begin{smallmatrix} P_{11} & P_{12} \\ P_{12}^T & P_{22} \end{smallmatrix}\right]$ is positive definite since $P_{22} > 0$ and $P_r > 0$. In the following, we want to show that P and K defined above satisfy (3.17). To this end, consider the matrices

$$H = \left[\begin{array}{cc|cc} 0_{m\times(n-m)} & I_m & 0_{m\times(n-m)} & 0_m \\ \hline 0_{m\times(n-m)} & 0_m & 0_{m\times(n-m)} & I_m \end{array}\right], \tag{3.19}$$

$$T = \left[\begin{array}{cc|cc} I_{n-m} & -P_{12}P_{22}^{-1} & 0_{n-m} & 0_{(n-m)\times m} \\ \hline 0_{n-m} & 0_{(n-m)\times m} & I_{n-m} & -P_{12}P_{22}^{-1} \end{array}\right], \tag{3.20}$$

which have the nonsingular matrix $\left[\begin{smallmatrix} H \\ T \end{smallmatrix}\right] \in \Re^{2n\times 2n}$. For brevity of notation, let $L_{(3.16)}$ and $L_{(3.17)}$ denote the left-hand sides of (3.16) and (3.17), respectively. Through some elaborate manipulations, it may be shown that

$$\begin{aligned} \begin{bmatrix} H \\ T \end{bmatrix} L_{(3.17)} \begin{bmatrix} H \\ T \end{bmatrix}^T &= \left[\begin{array}{c|c} HL_{(3.17)}H^T & HL_{(3.17)}T^T \\ \hline TL_{(3.17)}H^T & TL_{(3.17)}T^T \end{array}\right] \\ &= \left[\begin{array}{cc|c} \rho P_{22} & 0 & \\ 0 & \rho P_{22} & 0 \\ \hline & 0 & L_{(3.16)} \end{array}\right]. \end{aligned} \tag{3.21}$$

Therefore, the inequality (3.17) holds because $P_{22} > 0$ and $L_{(3.16)} > 0$.

Statement (ii). For T_r (as defined in (3.6)), define the augmented matrix

$$T = \begin{bmatrix} T_r & 0_{(n-m)\times n} \\ 0_{(n-m)\times n} & T_r \end{bmatrix}. \tag{3.22}$$

Pre- and postmultiplying (3.17) by T and T^T, respectively, one may have (3.16) for the choice of $S = P_{22}^{-1}P_{12}^T$ and $P_r = P_{11} - P_{12}^T P_{22}^{-1} P_{12}$. This completes the proof. □

Remark 3.6. Note that the inequality (3.17) is the necessary and sufficient condition for the existence of the full state feedback, which places the closed loop poles in the specified region such that $\lambda(A - BK) \subset \mathcal{Z}(c, \rho)$.

Using change of variables such as $Y := P^{-1}$ and $L := KP^{-1}$, one may have the LMI for (3.17) as follows:

$$\begin{bmatrix} \rho Y & YA^T - L^T B^T + cY \\ AY - BL + cY & \rho Y \end{bmatrix} > 0. \tag{3.23}$$

Also, the sliding function coefficient is given by $S = -Y_{12}^T Y_{11}^{-1}$ as in (3.15).

Here, we stress the common structure of the sliding function coefficient under Theorems 3.1 and 3.5. That is, once the full state feedback problem is feasible, the sliding mode can be obtained immediately by defining and combining the partitions of the Lyapunov matrix without loss of generality. Also, the sliding function coefficient is concerned only with some portions of the Lyapunov matrix.

4. The LMI-based constrained optimization. In this section, we present the (sub-)optimal solution to the problem of concern (defined in section 2) using the LMI constraints proposed in the previous sections. For the readability of the manuscript, the basic idea is illustrated first, and the typical approaches to the sliding mode design will be derived both in the convex form and in the nonconvex but numerically tractable form.

4.1. Combining the parametric constraints. To tackle the problem defined in section 2, let us consider solving the LQS problem with the matrix variables Y and L for a certain level of γ (see (3.13) and (3.14)). At the same time, assume that the matrix variables are also satisfying the inequality (3.23). Then, if the problem is feasible, it is easy to see that the pole-clustering constraint is met by the resulting sliding mode with the upper bound of the quadratic performance. Even though the assumption for the common variables may cause conservatism—the infeasibility or the overly conservative upper bound of the performance index—the approach has proven to be effective in providing flexibility in the control design requiring multiple performances with convexity (see Chilali and Gahinet [10] and the references therein).

For reducing conservatism, the assumption for the common variables can be relaxed by using scales either in scalar [11] or matrix [16] form. Particularly, we focus on the idea of the matrix scale which results in the iterative convex searches. Once an initial guess is found, each step of synthesis is convex and convergent through the iteration.

Relying on the above ideas (i.e., the convex approach and the relaxation idea), the remainder of the paper is devoted to devising novel methods for the constrained optimization problem. Then the methods will be verified by an example.

4.2. Convex formulation. To avoid confusion, let Y_{LQS} and Y_{POL} be the Lyapunov matrices in the LQS problem (i.e., (3.13) and (3.14)) and the pole-clustering constraint (i.e., (3.23)), respectively. According to the typical structure of the sliding function coefficient (i.e., $S = -Y_{12}^T Y_{11}^{-1}$), the optimal solution to the problem (defined in section 2) needs the condition

$$Y_{LQS,12}^T Y_{LQS,11}^{-1} = Y_{POL,12}^T Y_{POL,11}^{-1} \tag{4.1}$$

to produce the single optimal sliding mode. The conventional way to remove nonconvexity is to assume that $Y_{LQS} = Y_{POL}$, as in the aforementioned full state feedback design. However, we assume that the Lyapunov matrices are composed as

$$Y_{LQS} = \begin{bmatrix} M & N \\ N^T & Z_1 \end{bmatrix}, \quad Y_{POL} = \begin{bmatrix} M & N \\ N^T & Z_2 \end{bmatrix} \tag{4.2}$$

for some M, N, Z_1, and Z_2 with dimensions as partitioned in (3.2). Note that (4.1) is simply satisfied with the above structure (4.2). Also, the matrix variables L in inequalities (3.13) and (3.23) can be allowed to be independent while keeping convexity. Based on these properties, we have the following result.

THEOREM 4.1. *Given $Q > 0$ and $\mathcal{Z}(c, \rho)$, there exist some S such that* (i) $\lambda(A_{11} - A_{12}S) \subset \mathcal{Z}(c, \rho)$ *and* (ii) $\int_{t_s}^{\infty} x^T Q x dt < \gamma \|x_1(t_s)\|^2$ *if there exist some M, N, Z_i, L_i ($\forall i = 1, 2$), and γ satisfying*

$$Y_{LQS} > 0, \tag{4.3}$$

$$Y_{POL} > 0, \tag{4.4}$$

$$\begin{bmatrix} \rho Y_{POL} & Y_{POL}A^T - L_1^T B^T + cY_{POL} \\ AY_{POL} - BL_1 + cY_{POL} & \rho Y_{POL} \end{bmatrix} > 0, \tag{4.5}$$

$$\begin{bmatrix} AY_{LQS} + Y_{LQS}A^T - BL_2 - L_2^T B^T & Y_{LQS}C_Q \\ C_Q^T Y_{LQS} & -I_q \end{bmatrix} < 0, \tag{4.6}$$

$$\begin{bmatrix} \gamma I_{n-m} & I_{n-m} \\ I_{n-m} & M \end{bmatrix} > 0, \tag{4.7}$$

where Y_{LQS} and Y_{POL} have the structure in (4.2). *Then the admissible sliding mode is given by $S = -N^T M^{-1}$ for the feasible parameters.*

Since the problem is convex, the minimal γ can be computed within polynomial time using the LMI method. Note that the proposed scheme is different from the standard feedback design [10] in that matrix L and the $(2, 2)$ blocks of the Lyapunov matrices are not necessarily common.

4.3. Reducing conservatism. So far, an effort has been made to keep convexity in the analysis. Now we present a general method in order to eliminate the conservatism while losing the convexity. However, the proposed method is suited for numerical efficiency based on the iteratively convex search.

Without loss of generality, instead of starting with (4.2), we start with the Lyapunov matrices

$$Y_{LQS} = \begin{bmatrix} M_1 & M_1 M_2^{-1} N_2 \\ N_2^T M_2^{-1} M_1 & Z_1 \end{bmatrix}, \quad Y_{POL} = \begin{bmatrix} M_2 & N_2 \\ N_2^T & Z_2 \end{bmatrix} \tag{4.8}$$

for some $M_i,\ Z_i$ $(\forall i = 1, 2)$, and N_2, which guarantee the essential requirement (4.1). Note that the structure in (4.2) is a special case of (4.8) when $M_1 = M_2$.

Hereafter, we consider the case in which (4.8) is employed in Theorem 4.1 instead of (4.2). Then the convexity of inequalities (4.3) and (4.6) related to Y_{LQS} would be destroyed. Hence, attention is paid to handling them by the convex approach in this section. For this purpose, we introduce the following properties.

PROPOSITION 4.2. *Given matrices G and H and symmetric W with appropriate dimensions, it holds that*

$$G^T W^{-1} H + H^T W^{-1} G \geq \begin{pmatrix} \Pi(H+G) + (H+G)^T \Pi^T + \Pi W \Pi^T \\ - G^T W^{-1} G - H^T W^{-1} H \end{pmatrix} \tag{4.9}$$

for any Π. Moreover, the equality holds when $\Pi = (H+G)^T W^{-1}$.

Proof. Consider the inequality

$$(G^T + H^T - \Pi W) W^{-1} (G^T + H^T - \Pi W)^T \geq 0, \tag{4.10}$$

which is always true for any Π. Note that the equality holds when $\Pi = (G^T + H^T) W^{-1}$. Then the completion of the square proves Proposition 4.2. This completes the proof. □

PROPOSITION 4.3. *Given matrices G and H and symmetric W with appropriate dimensions, it holds that*

$$G^T W^{-1} H + H^T W^{-1} G \leq \begin{pmatrix} \Pi(H-G) + (H-G)^T \Pi^T + \Pi W \Pi^T \\ + G^T W^{-1} G + H^T W^{-1} H \end{pmatrix} \tag{4.11}$$

for any Π. Moreover, the equality holds when $\Pi = (G-H)^T W^{-1}$.

Proof. Similar to the proof of Proposition 4.2, it is easy to show Proposition 4.3 using the relationship

$$(G^T - H^T - \Pi W) W^{-1} (G^T - H^T - \Pi W)^T \geq 0 \tag{4.12}$$

for any Π. This completes the proof. □

The bounding idea with scale is adapted from the result in Shimomura and Fujii [16], which was applied to the dynamic output feedback synthesis. We point out that scales have an important role in converting nonconvex inequalities into convex ones through an iterative procedure. This will be further illustrated in what follows.

First, the inequality (4.3) with the structure (4.8) is investigated. For description, rewrite Y_{LQS} as

$$Y_{LQS} = Y_{BD} + G^T M_2^{-1} H + H^T M_2^{-1} G, \tag{4.13}$$

where $Y_{BD} \triangleq \mathit{blockdiag}[M_1, Z_1],\ G \triangleq [0_{n-m},\ N_2]$, and $H \triangleq [M_1,\ 0_{(n-m)\times m}]$ are linear in terms of the variables. Then, using Proposition 4.2 and the Schur complement [8], the inequality (4.3) (i.e., $Y_{LQS} > 0$) is assured if and only if the following inequality is satisfied:

$$\begin{bmatrix} Y_{BD} + \Pi_1(H+G) + (H+G)^T \Pi_1^T + \Pi_1 M_2 \Pi_1^T & \star & \star \\ G & M_2 & \star \\ H & 0_{n-m} & M_2 \end{bmatrix} > 0 \tag{4.14}$$

TABLE 4.1
Illustration for the sequentially feasible iteration procedure.

Iteration no.	Scales		Feasible variables
k	$\Pi_{1,k}$	$\rightarrow$	$(M_{1,k},\ M_{2,k},\ N_{2,k})$
		$\swarrow$	*scale update*
$k+1$	$\Pi_{1,k+1}$	$\rightarrow$	$(M_{1,k+1},\ M_{2,k+1},\ N_{2,k+1})$
		$\swarrow$	*scale update*
$k+2$	$\Pi_{1,k+2}$	$\rightarrow$	$(M_{1,k+2},\ M_{2,k+2},\ N_{2,k+2})$
$\vdots$	$\vdots$		$\vdots$

for some Π_1, where $\star$ denotes the transpose of the corresponding off-diagonal block. Note that the necessity holds when

$$\Pi_1 = (H+G)^T M_2^{-1}. \tag{4.15}$$

In order to illustrate the property of (4.14), assume that the scale is fixed with $\Pi_1 := \Pi_{1,k}$ to make (4.14) a feasible LMI. Also, given $\Pi_{1,k}$, let $(M_{1,k},\ M_{2,k},\ N_{2,k})$ be the set of feasible variables for (4.14). Then the set should guarantee that $Y_{LQS,k} > 0$ due to sufficiency. In turn, according to necessity, the updated scale

$$\Pi_{1,k+1} = (H_k + G_k)^T M_{2,k}^{-1} \tag{4.16}$$

makes the inequality (4.14) feasible again (with the fixed scale $\Pi_1 := \Pi_{1,k+1}$). The procedure is depicted in Table 4.1. Consequently, these properties—the convex form by an LMI and the successive feasibility—allow us to handle the nonconvex inequality (i.e., $Y_{LQS} > 0$) by the convex one in the iterative procedure.

In a similar manner, one may eliminate nonconvexity in the inequality (4.6) by applying Proposition 4.3. That is, inequality (4.6) (with the nonconvex Y_{LQS}) holds if and only if the following inequality is satisfied:

$$\begin{bmatrix} \Psi(\Pi_2,\Pi_3) & \star & \star & \star & \star \\ GA_e^T & -M_2 & \star & \star & \star \\ HU_e^T & 0_{n-m} & -M_2 & \star & \star \\ HA_e^T & 0_{n-m} & 0_{n-m} & -M_2 & \star \\ GU_e^T & 0_{n-m} & 0_{n-m} & 0_{n-m} & -M_2 \end{bmatrix} < 0 \tag{4.17}$$

for some Π_2 and Π_3, where $A_e^T = [A^T,\ C_Q]$, $U_e^T = [I_n,\ 0_{n\times q}]$, and

$$\begin{aligned} \Psi(\Pi_2,\Pi_3) = &\begin{bmatrix} AY_{BD} + Y_{BD}A^T - BL_2 - L_2^T B^T & Y_{BD}C_Q \\ C_Q^T Y_{BD} & -I_q \end{bmatrix} \\ &+ \Pi_2(HU_e^T - GA_e^T) + (HU_e^T - GA_e^T)^T\Pi_2^T + \Pi_2 M_2 \Pi_2^T \\ &+ \Pi_3(GU_e^T - HA_e^T) + (GU_e^T - HA_e^T)^T\Pi_3^T + \Pi_3 M_2 \Pi_3^T. \end{aligned}$$

Moreover, the necessity holds when

$$\Pi_2 = \left(A_e G^T - U_e H^T\right) M_2^{-1}, \tag{4.18}$$

$$\Pi_3 = \left(A_e H^T - U_e G^T\right) M_2^{-1}. \tag{4.19}$$

Note that (4.17) becomes an LMI as long as the scales are fixed. Based on the discussion above, we now present an iterative algorithm that is successively feasible and convergent.

ALGORITHM I.

1. Assume $\Pi_{i,0}$ ($\forall i = 1, 2, 3$) that admit the feasibility of (4.14) and (4.17). And, set as $k := 1$.
2. Given $\Pi_i := \Pi_{i,k-1}$ ($\forall i = 1, 2, 3$), minimize γ w.r.t. $M_1,\ M_2,\ N_2,\ L_1$, and L_2 subject to (4.14), (4.4), (4.5), (4.17), and

$$\begin{bmatrix} \gamma I_{n-m} & I_{n-m} \\ I_{n-m} & M_1 \end{bmatrix} > 0, \tag{4.20}$$

   where Y_{POL} has the structure in (4.8).
3. Set $\gamma_k := \gamma_*$ and update the scales as

$$\Pi_{1,k} := (H_* + G_*)^T M_{2*}^{-1}, \tag{4.21}$$

$$\Pi_{2,k} := \left(A_e G_*^T - U_e H_*^T\right) M_{2*}^{-1}, \tag{4.22}$$

$$\Pi_{3,k} := \left(A_e H_*^T - U_e G_*^T\right) M_{2*}^{-1}, \tag{4.23}$$

   where $(_*)$ denotes the optimal values from step 2.
4. If $\gamma_{k-1} - \gamma_k < \epsilon$, stop the iteration. Otherwise, increase $k := k + 1$ and go to step 2.

Observe that the typical features of the algorithm are (a) the iteration is successively feasible once the initial guesses $\Pi_{i,0}$ ($i = 1, 2, 3$) are given, and (b) the performance upper-bound γ_k is successively decreasing such that $\gamma_{LQS} \le \gamma_{k+1} \le \gamma_k$, where γ_{LQS} alone is the optimum for the LQS problem.

Remark 4.4. For initiating Algorithm I, a set of matrix scales is needed in step 1. Observe that the solution from Theorem 4.1 is a special case when $M_1 = M_2$. Hence, the initial scales can be easily computed, according to (4.21)–(4.23), by utilizing the solution of Theorem 4.1. However, in case Theorem 4.1 is infeasible, we suggest the following steps. First, solve the pole-clustering problem alone to have matrices S and Y_{POL}. Then, given the sliding function coefficient S, construct $P_{LQS}(:= Y_{LQS}^{-1})$ following the construction method in the proof for statement (i) of Theorem 3.1 (i.e., use (3.4)). Now, using matrices Y_{LQS} and Y_{POL}, compute the scales following (4.21)–(4.23). In this way, Algorithm I can always be started as long as the pole-clustering constraint is feasible.

4.4. A numerical example. Consider the system borrowed from [5]:

$$A = \begin{bmatrix} 0.2325 & -0.9285 & 0.0154 & 0.1222 \\ -0.7274 & 1.0116 & -0.0224 & 0.1576 \\ -1.6883 & 0.2214 & 0.6534 & 1.6278 \\ -0.5310 & -0.2603 & -0.0052 & 1.1025 \end{bmatrix}, \quad B = \begin{bmatrix} 3.00 & 2.00 \\ 0 & 1.00 \\ 0.50 & -2.00 \\ 1.30 & 0 \end{bmatrix}.$$

The design objectives are defined by

$$Q = I_{4\times 4}, \quad c = 2, \quad \rho = 0.5.$$

To obtain the regular form (2.2), we choose a state transformation matrix $X = [U_2,\ U_1]^T$ from the singular value decomposition of B such that $B = [U_1,\ U_2]\left[\begin{smallmatrix} \sigma \\ 0_{2\times 2} \end{smallmatrix}\right] V^T$. Then we can start the design procedure using the transformed system

$$A := XAX^{-1}, \quad B := XB, \quad Q := X^{-T} Q X^{-1}.$$

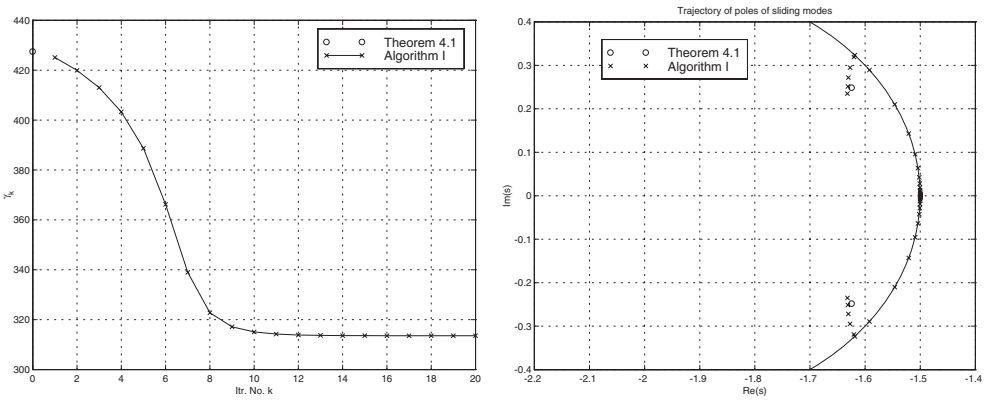

FIG. 4.1. *Convergence of γ_k (left). Trajectory of poles during iteration (right).*

First, we apply Theorem 4.1 to the above system, and the results are as follows:

$$\gamma_{cnvx} = 427.44, \quad S_{cnvx} = \begin{bmatrix} -2.8104 & -1.274 \\ -3.8506 & 36.686 \end{bmatrix}.$$

The poles of the sliding mode are placed at $\{-1.6244 \pm 0.24845i\}$, inside the constraint circle.

Now, as illustrated in Remark 4.4, we solve the algorithm using the results above (i.e., Y_{POL} and Y_{LQS} in solving Theorem 4.1) and calculate (4.21)–(4.23) in order to obtain the initial guesses for scales (i.e., $\Pi_{i,0}$). Then Algorithm I was started with them. As shown in Figure 4.1, the performance index ever decreases as the iteration proceeds. Interestingly, the poles in each iteration step move toward $s = -1.5$ following the circle boundary for the pole-clustering constraint. The algorithm shows the fast convergence and produces the results (at the 20th iteration)

$$\gamma_{20} = 313.56, \quad S_{20} = \begin{bmatrix} -1.6732 & -15.951 \\ -2.3586 & 21.139 \end{bmatrix},$$

which locates the sliding mode poles at $s = -1.5$. Observe that γ_{20} is reduced by 27% compared with γ_{cnvx}. The numerical results are summarized in Table 4.2.

TABLE 4.2
Comparison of numerical results.

Applied methods	Theorem 4.1	Algorithm I
Minimal γ	427.44	313.56

5. Further study. One of the interesting features of the proposed approach is that the sliding mode is derived from the usage of LMI conditions known for full state feedback design. In fact, this idea enables us to solve a few important issues in the sliding mode control context. Among them, let us consider polytopic uncertain systems [8] as follows:

$$(A, B) \in \mathbf{Co}\{(A^1, B^1), \ldots, (A^L, B^L)\}, \tag{5.1}$$

where $\mathbf{Co}\{\cdot\}$ denotes the convex hull and the matrices (A^i, B^i), $i = 1, \ldots, L$, are given and of the regular form. Then we have the result.

THEOREM 5.1. *There exist some stabilizing sliding function coefficients if there exist some matrices* $P > 0$ *and* $K \in \Re^{m\times n}$, *given any* $0 \le Q \in \Re^{n\times n}$, *satisfying*

$$(A^i - B^iK)^T P + P(A^i - B^iK) + Q < 0 \tag{5.2}$$

$\forall i \in [1, \ldots, L]$. *Furthermore, for the feasible matrix* P, *the matrix* $S = P_{22}^{-1}P_{12}^T$ *is a stabilizing sliding function coefficient.*

The proof is very similar to that of Theorem 3.1 (i.e., as in (3.6)). By pre- and postmultiplying the equation (5.2) by T_r and T_r^T, respectively, we have

$$\left(A_{11}^i - A_{12}^i P_{22}^{-1} P_{12}^T\right)^T P_r + P_r \left(A_{11}^i - A_{12}^i P_{22}^{-1} P_{12}^T\right) + T_r Q T_r^T < 0, \tag{5.3}$$

where $P_r = P_{11} - P_{12}^T P_{22}^{-1} P_{12}$. Since $P_r > 0$, the above implies that the matrix $P_{22}^{-1}P_{12}^T$ stabilizes the polytopic uncertain system defined in $\mathbf{Co}\{(A_{11}^1, A_{12}^1), \ldots, (A_{11}^L, A_{12}^L)\}$ in the reduced order space. Hence, with the matrix $S = P_{22}^{-1}P_{12}^T$, the sliding mode dynamics is stable in the invariant subspace $\{x \in \Re^n | x_2 + Sx_1 = 0\}$.

From the discussion above, the basic technique is expected, in a similar fashion, to be easily extended to a number of issues that have been treated by LMI-based full state feedback methods. For example, for the time-delayed systems or the parametric uncertain systems, the sliding mode can be obtained simply by solving the full state feedback problem and then combining the partitions of the corresponding Lyapunov matrix.

6. Concluding remarks. We proposed a new method for optimizing quadratic performance with the pole-clustering constraint in the sliding mode. It was explicitly shown that quadratic performance optimization and the pole-clustering problem can be solved by LMI approaches of full order without loss of generality. Using the proposed parametric constraints, the design objectives were combined under the LMI framework typically suited for sliding mode design in both convex and nonconvex forms. In the case of nonconvex formulation, a numerically tractable and efficient algorithm was presented. The effectiveness of the proposed approaches was illustrated by an example.

Finally, we illustrated the possible extension of the proposed approach to a class of polytopic uncertain systems. The sliding mode can be obtained easily by simply solving a full state feedback problem known in the literature. Note that the idea significantly simplifies sliding mode design procedures both conceptually and technically.

Acknowledgments. The authors sincerely thank the anonymous reviewers for their valuable comments and keen insights that substantially improved the study. In particular, the issue on the polytopic uncertain systems (motivated by the reviewers' suggestion) considerably extended the scope of the paper.

NULL CONTROLLABILITY OF THE FREE SURFACE OF A LIQUID IN A CONTAINER*

VILMOS KOMORNIK†, PAOLA LORETI‡, AND LEONARDO MAZZINI§

Abstract. This paper deals with the well-posedness, boundary observability, and boundary controllability of a model of lateral sloshing in moving containers. It begins with a short review of the lateral sloshing theory, then the problem is solved by combining the Fourier method and the Hilbert uniqueness method of J.-L. Lions. At the end an application is discussed.

Key words. controllability, Fourier series, fluid model, free surface

AMS subject classifications. 93B05, 93C20, 42C15, 76B10

DOI. 10.1137/S0363012902405285

1. The control of sloshing in moving containers. The sloshing equations in moving containers are used in many applications to study the motion of propellant fluids inside ships, aircraft, or space platforms; see, e.g., Silverman and Abramson [6]. The motion is often analyzed in order to demonstrate the stability of attitude control systems of the propellant carriers.

The behavior of the solutions depend very much on the proportion between the gravity forces and the surface tension terms, i.e., on the so-called Bond number defined by

$$\text{Bond number} = \frac{g\rho r^2}{\sigma}.$$

The equations we use are widely applied when the Bond number is much higher than one, as in the sloshing of water in a 1-g environment or in the sloshing of standard monomethile hydrazine propellant in accelerated rockets (with acceleration between $0,1$ g and 1 g) when the dimension (r) is larger than a half meter (as is often the case).

The model of lateral sloshing proposed in the paper has been used for many years in the sloshing of propellant inside satellite tanks in propulsed phases. The same model is used world-wide for the same purposes because the Bond number in such cases is typically higher than 10.

Today the sloshing in moving containers is best controlled by passive techniques like baffles and separators inside the tank. The control of the actual profile of the liquid phase has gotten less attention thus far, although it may become interesting in industrial applications to control the low frequency disturbances in spacecraft or ships that try to maintain a very quiet attitude. The generation of a pressure slope over a liquid phase is very far from being an impossible technical problem.

A simple implementation locates a number of valves connected to a high pressure air reservoir and a number of low pressure valves connected to a low pressure reservoir.

The valves are distributed on the top of the tank and are controlled by a computer. A set of pressure sensors located in the tank in the gas phase provides the computer with information for commanding the valves in order to obtain the desired slope of pressure.

The aim of this paper is to provide exact controllability results via the Hilbert uniqueness method (HUM) technique for the problem of controlling the liquid motion in a container via the distribution of the pressures in the container itself. This result deviates from any classic approach because it applies directly to the partial differential equations that describe the motion of the liquid without using any preliminary discretization of the problem, while most of the research on this subject uses preliminary discretization.

Active control of the liquid itself inside its container may be achieved by controlling the pressure distribution above the fluid free surface.

At the beginning of the paper, we introduce the equations for studying the linearized motion of an incompressible fluid inside a moving container, then we establish a proper mathematical setting for this problem, and finally we provide necessary and sufficient conditions for the control of this motion.

This control problem may find proper applications where the frequency of motion of the fluid strongly interferes with the controller of the attitude of the carrier, making it necessary to actively control the dynamics of the fluids. This approach is new in engineering and in control theory for this particular subject.

1.1. The sloshing equations. Our treatment shall start with the basic Navier–Stokes equations written for an accelerating frame introducing the hypothesis of fluid incompressibility and fluid irrotational motion. Following the reference [1], we introduce the following quantities:

Ω	liquid free boundary,
h	tank height,
$Q = \Omega \times (-h, 0)$	tank interior,
$\Gamma = \partial\Omega \times [-h, 0]$	tank wet boundary,
$\overrightarrow{x} = (x, y, z) \in \Omega \times [-h, 0]$	position coordinate inside the tank.

The following fields are relevant to the physics of the problem:

$\delta(x, y, t)$	liquid free surface height,
$\overrightarrow{v}(x, y, z, t) \in \mathbb{R}^3$	liquid velocity in the accelerating frame,
$\overrightarrow{u} = \int \overrightarrow{v}\, dt$	liquid displacement,
$\phi(x, y, z, t)$	scalar potential of liquid velocity $\nabla\phi = v$,
$\psi(x, y, z, t)$	scalar potential of liquid displacement $\nabla\psi = u$,
$p(x, y, z, t)$	pressure of the liquid,
$p_0(x, y, t)$	ullage pressure above the liquid surface,
$\overrightarrow{n} \in \mathbb{R}^3$	normal to the container,
$\overrightarrow{V} \in \mathbb{R}^3$	velocity of the container walls in the accelerating frame,
$\overrightarrow{w}(t)$	container rigid motion translation vector,
$\overrightarrow{\theta}(t)$	container rigid motion rotation vector;

furthermore, g denotes the acceleration $+z$ of the reference frame or equivalent gravitational acceleration in the $-z$ direction.

From the classical Navier–Stokes equations written in a gravitational field (taken, for example, from reference [7]), introducing the hypotheses of incompressibility and irrotational motion with respect to that frame, we derive that the liquid velocity can be derived as gradient of a potential that satisfies the so-called Bernoulli equation:

$$\nabla\left(\partial_t\phi + \frac{1}{2}\nabla\phi^T\nabla\phi + \frac{p}{\rho} + gz\right) = 0.$$

The velocity is derived by the following statements:

$$\Delta\phi = 0, \qquad \nabla\phi = \overrightarrow{v}.$$

The potential is not unique, for a generic time function can be added to it leaving the same physical solution, and we can add as a gauge condition that the Bernoulli equation is written as

$$\partial_t\phi + \frac{1}{2}\nabla\phi^T\nabla\phi + \frac{p}{\rho} + gz = 0.$$

The boundary conditions for such equations are

$$\partial_n\phi = \overrightarrow{V}\cdot\overrightarrow{n} \quad \text{in} \quad \Gamma$$

and

$$p(x,y,0,t) = p_0(x,y,t) \quad \text{in} \quad \Omega.$$

When the container is stationary in the accelerating frame and the ullage pressure is constant, we can derive the static equilibrium solution:

$$p = p_0 - \rho g z, \quad \phi = 0, \quad v = 0, \quad \delta = 0.$$

Now, let us consider a small rigid motion of the container and a small pressure variation in the ullage produced either by a control action or by external environmental conditions. We then have

$$\overrightarrow{V}(x,y,z,t) = \frac{d\overrightarrow{w}}{dt}(t) + \frac{d\overrightarrow{\theta}}{dt}(t)\times\overrightarrow{x}.$$

Since we consider rigid motion of the container, we have

$$\overrightarrow{u} = \nabla\psi = \nabla\int\phi dt,$$

$$\delta(x,y,t) = u_z(x,y,0,t) = \partial_z\psi|_{z=0}.$$

We can finally write for the linearized problem in the displacement potential

$$\Delta\psi = 0 \quad \text{in} \quad Q\times[0,T] \tag{1.1}$$

with boundary conditions at the container wet wall

$$\partial_n\psi = \overrightarrow{n}\cdot(\overrightarrow{w} + \overrightarrow{\theta}\times\overrightarrow{x}) \quad \text{on} \quad \Gamma\times[0,T] \tag{1.2}$$

and boundary conditions at the free surface derived by the Bernoulli equation:

$$\partial_{tt}^2\psi + g\partial_z\psi + \frac{p_0}{\rho} = 0 \quad \text{on} \quad \Omega \times [0,T]. \tag{1.3}$$

The pressure inside the liquid and at the container boundary can be derived by the Bernoulli equation

$$\partial_{tt}^2\psi + g(\partial_z\psi + z) + \frac{p}{\rho} = 0. \tag{1.4}$$

Equations (1.1) and (1.2), (1.3) in a suitable functional setting provide a well-defined set of equations, as will be shown in the following.

It is quite common in practice to divide the potential into components:

$$\psi = \overrightarrow{\psi}_w \cdot \overrightarrow{w} + \overrightarrow{\psi}_\theta \cdot \overrightarrow{\theta} + \psi_K.$$

Here $\overrightarrow{\psi}_w$ satisfies

$$\begin{aligned}
&\Delta \overrightarrow{\psi}_w = 0 \quad \text{in} \quad Q \times [0,T],\\
&\partial_n \overrightarrow{\psi}_w = \overrightarrow{n} \quad \text{in} \quad \Gamma \times [0,T],\\
&\partial_{tt}^2 \overrightarrow{\psi}_w + g\partial_z \overrightarrow{\psi}_w = 0 \quad \text{in} \quad \Omega \times [0,T],
\end{aligned}$$

while $\overrightarrow{\psi}_\theta$ satisfies

$$\begin{aligned}
&\Delta \overrightarrow{\psi}_\theta = 0 \quad \text{in} \quad Q \times [0,T],\\
&\partial_n \overrightarrow{\psi}_\theta = \overrightarrow{n} \quad \text{in} \quad \Gamma \times [0,T],\\
&\partial_{tt}^2 \overrightarrow{\psi}_\theta + g\partial_z \overrightarrow{\psi}_\theta = 0 \quad \text{in} \quad \Omega \times [0,T].
\end{aligned}$$

The last potential ψ_K has homogeneous boundary conditions at the wet container walls. So, ψ_K satisfies

$$\begin{aligned}
&\Delta\psi_K = 0 \quad \text{in} \quad Q \times [0,T],\\
&\partial_n\psi_K = 0 \quad \text{in} \quad \Gamma \times [0,T],
\end{aligned}$$

and

$$\partial_{tt}^2\psi_K + g\partial_z\psi_K + \frac{p_0}{\rho} = -\left(\overrightarrow{\psi}_w \cdot \frac{d^2\overrightarrow{w}}{dt^2} + g\partial_z \overrightarrow{\psi}_w \overrightarrow{w}\right) - \left(\overrightarrow{\psi}_\theta \cdot \frac{d^2\overrightarrow{\theta}}{dt^2} + g\partial_z \overrightarrow{\psi}_\theta \cdot \overrightarrow{\theta}\right)$$

in $\Omega \times [0,T]$.

While the first two vectorial potentials depend only on the shape of the container and can be solved a priori, the third scalar potential has homogeneous conditions at the wet boundary of the container and boundary conditions at the free surface containing all the external inputs, which are the ullage pressure distribution and the container motion variables with their second derivatives. These external inputs can be considered as control variables or external perturbations. It is to be remarked that controlling $\psi_K(x,y,z,t)$ to zero means that the motion of the fluid is rigid with the container. In the following we will focus our study on the production of a suitable controlling ullage pressure $p_0(x,y,t)$, so to produce $\psi_K(x,y,z,t) = 0$ for $t \geq T$ when the potential has been previously excited by a container motion occurring before $t = 0$, as per the classic paradigm of continuous controllability.

2. Well-posedness and boundary observability of the homogeneous problem. Let Ω be a bounded open domain in $\mathbb{R}^2$, having a sufficiently smooth boundary Γ. Given two positive numbers h and g, consider the following problem for an unknown function $\varphi(x,y,z,t)$:

$$\begin{cases} \Delta\varphi = 0 \quad \text{in} \quad \Omega\times(-h,0)\times\mathbb{R}, \\ \partial_\nu\varphi = 0 \quad \text{on} \quad \Gamma\times(-h,0)\times\mathbb{R}, \\ \partial_\nu\varphi = 0 \quad \text{on} \quad \Omega\times\{-h\}\times\mathbb{R}, \\ \frac{\partial^2\varphi}{\partial t^2} + g\frac{\partial\varphi}{\partial z} = 0 \quad \text{on} \quad \Omega\times\{0\}\times\mathbb{R}, \\ \varphi(x,y,0,0) = \varphi_0(x,y) \quad (x,y)\in\Omega, \\ \frac{\partial\varphi}{\partial t}(x,y,0,0) = \varphi_1(x,y), \quad (x,y)\in\Omega. \end{cases} \tag{2.1}$$

Let us introduce an orthonormal basis (e_n) of $L^2(\Omega)$, consisting of eigenfunctions of $-\Delta$ with homogeneous Neumann boundary conditions, corresponding to nonnegative eigenvalues λ_n, tending to ∞. Set

$$\omega_n = \sqrt{g\lambda_n \tanh(\lambda_n h)}.$$

PROPOSITION 2.1. *Given $\varphi_0 \in L^2(\Omega)$ and $\varphi_1 \in (H^1(\Omega))'$, problem (2.1) has a unique solution of the form*

$$\varphi(x,y,z,t) = \sum_{n=1}^{\infty} e_n(x,y)\cosh[\lambda_n(z+h)]\big(a_n e^{i\omega_n t} + b_n e^{-i\omega_n t}\big), \tag{2.2}$$

with suitable complex coefficients a_n and b_n. The series converges in $L^2(\Omega)$ uniformly in z and t, and its termwise derivative with respect to t,

$$\sum_{n=1}^{\infty} e_n(x,y)\cosh[\lambda_n(z+h)]i\omega_n\big(a_n e^{i\omega_n t} - b_n e^{-i\omega_n t}\big), \tag{2.3}$$

converges in $(H^1(\Omega))'$ uniformly in z and t.

Furthermore,

$$\varphi(\cdot,\cdot,0,\cdot) \in C(\mathbb{R};L^2(\Omega)) \cap C^1(\mathbb{R};(H^1(\Omega))')$$

and

$$\|\varphi(\cdot,\cdot,0,t)\|^2_{L^2(\Omega)} + \left\|\frac{\partial\varphi}{\partial t}(\cdot,\cdot,0,t)\right\|^2_{(H^1(\Omega))'} \le \alpha\big(\|\varphi_0\|^2_{L^2(\Omega)} + \|\varphi_1\|^2_{(H^1(\Omega))'}\big)$$

with some constant α, independent of $t\in\mathbb{R}$ and of the particular choice of the initial data φ_0 and φ_1.

Proof. Thanks to the choice of the eigenfunctions $e_n(x,y)$ and of the numbers ω_n, the functions of the form (2.2) satisfy the boundary conditions (2.3), regardless of the particular choice of the coefficients a_n and b_n. Setting $h=0$ and $t=0$ in (2.2) and (2.3) and using the initial conditions, we obtain the equations

$$\varphi_0(x,y) = \sum_{n=1}^{\infty} e_n(x,y)\cosh(\lambda_n h)(a_n+b_n)$$

and

$$\varphi_1(x,y)=\sum_{n=1}^{\infty} e_n(x,y)i\omega_n\cosh(\lambda_n h)(a_n-b_n).$$

Since (e_n) is an orthogonal basis in both $L^2(\Omega)$ and $(H^1(\Omega))'$, these equations determine the coefficients a_n and b_n uniquely.

On the other hand, choosing the coefficients according to these equations, a straightforward computation shows the convergence of the series as stated in the proposition.

For the proof of the inequality we first obtain by a direct computation the following estimates:

$$\|\varphi(\cdot,\cdot,0,t)\|^2_{L^2(\Omega)}\le\sum_{n=1}^{\infty}\cosh(\lambda_n h)^2\left|a_n e^{i\omega_n t}+b_n e^{-i\omega_n t}\right|^2$$

and

$$\left\|\frac{\partial\varphi}{\partial t}(\cdot,\cdot,0,t)\right\|^2_{(H^1(\Omega))'}\le\sum_{n=1}^{\infty}\cosh(\lambda_n h)^2\frac{|\omega_n|^2}{\lambda_n}\left|a_n e^{i\omega_n t}+b_n e^{-i\omega_n t}\right|^2.$$

Since ${\omega_n}^2/\lambda_n$ converges to one, it follows that

$$\begin{aligned}c_1\sum_{n=1}^{\infty}\cosh(\lambda_n h)^2\big(|a_n|^2+|b_n|^2\big)&\\ \le\|\varphi(\cdot,\cdot,0,t)\|^2_{L^2(\Omega)}+\left\|\frac{\partial\varphi}{\partial t}(\cdot,\cdot,0,t)\right\|^2_{(H^1(\Omega))'}&\\ \le c_2\sum_{n=1}^{\infty}\cosh(\lambda_n h)^2\big(|a_n|^2+|b_n|^2\big),&\end{aligned}$$

with two positive constants c_1 and c_2 which do not depend on the particular choice of t. Hence the desired inequality follows with $\alpha=c_2/c_1$. □

Fix an arbitrary positive number T and set

$$\delta:=\max_n\left|\frac{\sin(\omega_n T)}{\omega_n T}\right|.$$

Observe that $0\le\delta<1$.

We are going to establish the following inequalities.

PROPOSITION 2.2. *All solutions of* (2.1) *satisfy the inequalities*

$$\begin{aligned}(1-\delta)\sum_{n=1}^{\infty}\cosh^2(\lambda_n h)\big(|a_n|^2+|b_n|^2\big)\le\frac{1}{T}\int_0^T\int_\Omega|\varphi(x,y,0,t)|^2\,dx\,dy\,dt&\\ \le(1+\delta)\sum_{n=1}^{\infty}\cosh^2(\lambda_n h)\big(|a_n|^2+|b_n|^2\big).&\end{aligned}$$

Proof. We obtain by a straightforward computation, using the orthonormality of the sequence (e_n), the equality

$$\int_\Omega|\varphi(x,y,0,t)|^2\,dx\,dy=\sum_{n=1}^{\infty}\cosh^2(\lambda_n h)\left|a_n e^{i\omega_n t}+b_n e^{-i\omega_n t}\right|^2,$$

and then the equality

$$\int_0^T \int_\Omega |\varphi(x,y,0,t)|^2 \, dx \, dy \, dt = \sum_{n=1}^{\infty} \cosh^2(\lambda_n h) \int_0^T |a_n|^2 + |b_n|^2 + 2\Re(a_n \overline{b_n} e^{2i\omega_n t}) \, dt.$$

The proof will be completed if we show for every n the estimate

$$\left| \int_0^T 2\Re(a_n \overline{b_n} e^{2i\omega_n t}) \, dt \right| \le \delta T \big(|a_n|^2 + |b_n|^2 \big).$$

This can be shown as follows:

$$\begin{aligned} \left| \int_0^T 2\Re(a_n \overline{b_n} e^{2i\omega_n t}) \, dt \right| &= \left| 2\Re \left(a_n \overline{b_n} \int_0^T e^{2i\omega_n t} \, dt \right) \right| \\ &= \left| 2\Re \left(a_n \overline{b_n} \frac{e^{2i\omega_n T} - 1}{2i\omega_n} \right) \right| \\ &= \left| 2\Re \left(a_n \overline{b_n} e^{i\omega_n T} \frac{\sin \omega_n T}{\omega_n} \right) \right| \\ &\le 2|a_n| \cdot |b_n| \cdot \left| \frac{\sin(\omega_n T)}{\omega_n} \right| \\ &\le \delta T \big(|a_n|^2 + |b_n|^2 \big). \qquad \square \end{aligned}$$

Let us consider two examples.

Example 1. If Ω is a rectangle, say

$$\Omega = (0,a) \times (0,b),$$

then it is more convenient to arrange the eigenfunctions and eigenvalues in a double sequence

$$\begin{aligned} e_{m,n}(x,y) &= \frac{2}{\sqrt{ab}} \cos \frac{m\pi x}{a} \cdot \cos \frac{n\pi y}{b}, \\ \lambda_{m,n} &= \pi^2 \left(\frac{m^2}{a^2} + \frac{n^2}{b^2} \right), \end{aligned}$$

where m, n are integers ranging from 0 to ∞, and to set

$$\omega_{m,n} = \sqrt{g \lambda_{m,n} \tanh(\lambda_{m,n} h)}.$$

Then the formula (2.2) is replaced by

$$\begin{aligned} &\varphi(x,y,z,t) \\ &= \frac{2}{\sqrt{ab}} \sum_{m,n=0}^{\infty} \cos \frac{m\pi x}{a} \cdot \cos \frac{n\pi y}{b} \cdot \cosh[\lambda_{m,n}(z+h)] \big(a_{m,n} e^{i\omega_{m,n} t} + b_{m,n} e^{-i\omega_{m,n} t} \big), \end{aligned}$$

and the sums in the estimate of Proposition 2.1 are replaced by

$$\sum_{m,n=0}^{\infty} \cosh^2(\lambda_{m,n}h)\big(|a_{m,n}|^2+|b_{m,n}|^2\big).$$

Example 2. If Ω is a disc of radius R, then it is more convenient to use polar coordinates (r,θ) and to arrange the eigenfunctions and eigenvalues in a double sequence by using the Bessel functions, as, e.g., in [2] or [3, pp. 138–141]. Then the solutions of (2.1) are given by the series

$$\varphi(r,\theta,z,t)=\sum_{n=0}^{\infty}\sum_{k=1}^{\infty} J_n(\lambda_{nk}r)\cosh[\lambda_{nk}(z+h)]\cdot\Big(A_{nk}(\theta)e^{i\omega_{nk}t}+B_{nk}(\theta)e^{-i\omega_{nk}t}\Big),$$

where for each fixed n,

- J_n denotes the Bessel function of order n,
- $R\lambda_{n1}<R\lambda_{n2}<\cdots$ are the (strictly) positive roots of its derivative J_n',
- $\omega_{nk}=\sqrt{g\lambda_{nk}\tanh(\lambda_{nk}h)}$,
- $A_{nk}(\theta)$ and $B_{nk}(\theta)$ are suitable linear combinations of the functions $\cos(k\theta)$ and $\sin(k\theta)$, depending on the initial data.

The sums in the estimate of Proposition 2.1 are replaced by

$$\sum_{n=0}^{\infty}\sum_{k=1}^{\infty}\left(\int_0^R rJ_n(r)^2\,dr\right)\cdot\cosh^2(\lambda_{nk}h)\cdot\left(\int_0^{2\pi}|A_{nk}(\theta)|^2+|B_{nk}(\theta)|^2\,d\theta\right).$$

3. Well posedness of the nonhomogeneous problem. Now let us consider the following nonhomogeneous version of problem (2.1) for an unknown function $\psi(x,y,z,t)$:

$$\begin{cases}\Delta\psi=0 \quad \text{in} \quad \Omega\times(-h,0)\times\mathbb{R},\\ \partial_\nu\psi=0 \quad \text{on} \quad \Gamma\times(-h,0)\times\mathbb{R},\\ \partial_\nu\psi=0 \quad \text{on} \quad \Omega\times\{-h\}\times\mathbb{R},\\ \frac{\partial^2\psi}{\partial t^2}+g\frac{\partial\psi}{\partial z}=v \quad \text{on} \quad \Omega\times\{0\}\times\mathbb{R},\\ \psi(x,y,0,0)=\psi_0(x,y), \quad (x,y)\in\Omega,\\ \frac{\partial\psi}{\partial t}(x,y,0,0)=\psi_1(x,y), \quad (x,y)\in\Omega.\end{cases} \tag{3.1}$$

We are going to define the solutions of this problem by the method of transposition. Consider an arbitrary solution of (2.1). By a formal computation, we have for every real number T the following equalities:

$$\begin{aligned}0&=\int_0^T\int_{-h}^0\int_\Omega(\Delta\varphi)\psi-\varphi(\Delta\psi)\,dx\,dy\,dz\,dt\\ &=\int_0^T\int_{-h}^0\int_\Gamma(\partial_\nu\varphi)\psi-\varphi(\partial_\nu\psi)\,\Gamma\,dz\,dt\\ &\qquad+\int_0^T\int_\Omega\big((\partial_\nu\varphi)\psi-\varphi(\partial_\nu\psi)\big)(x,y,-h,t)\,dx\,dy\,dt\\ &\qquad+\int_0^T\int_\Omega\big((\partial_\nu\varphi)\psi-\varphi(\partial_\nu\psi)\big)(x,y,0,t)\,dx\,dy\,dt\\ &=\int_0^T\int_\Omega\left(\frac{\partial\varphi}{\partial z}\psi-\varphi\frac{\partial\psi}{\partial z}\right)(x,y,0,t)\,dx\,dy\,dt\end{aligned}$$

$$= \frac{1}{g}\int_0^T \int_\Omega \left(-\frac{\partial^2\varphi}{\partial t^2}\psi + \varphi\frac{\partial^2\psi}{\partial t^2} - \varphi v\right)(x,y,0,t)\ dx\ dy\ dt$$
$$= -\frac{1}{g}\int_0^T \int_\Omega (\varphi v)(x,y,0,t)\ dx\ dy\ dt + \frac{1}{g}\left[\int_\Omega \left(-\frac{\partial\varphi}{\partial t}\psi + \varphi\frac{\partial\psi}{\partial t}\right)(x,y,0,t)\ dx\ dy\right]_0^T.$$

Taking the initial conditions into account, it follows that

$$\int_\Omega \left(-\frac{\partial\varphi}{\partial t}\psi + \varphi\frac{\partial\psi}{\partial t}\right)(x,y,0,T)\ dx\ dy = \int_\Omega (-\varphi_1\psi_0 + \varphi_0\psi_1)\ dx\ dy + \int_0^T\int_\Omega (\varphi v)(x,y,0,t)\ dx\ dy\ dt.$$

Identifying $L^2(\Omega)$ with its dual $(L^2(\Omega))'$ as usual, we have the dense and continuous inclusions

$$(H^1(\Omega))' \subset (L^2(\Omega))' = L^2(\Omega) \subset H^1(\Omega).$$

Then we may rewrite the last identity in the following form:

$$\left\langle \left(\frac{\partial\psi}{\partial t}, -\psi\right)(\cdot,\cdot,0,T), \left(\varphi, \frac{\partial\varphi}{\partial t}\right)(\cdot,\cdot,0,T)\right\rangle_{L^2(\Omega)\times H^1(\Omega), L^2(\Omega)\times(H^1(\Omega))'} = \langle(\psi_1,-\psi_0),(\varphi_0,\varphi_1)\rangle_{L^2(\Omega)\times H^1(\Omega), L^2(\Omega)\times(H^1(\Omega))'} + (\varphi(\cdot,\cdot,0,\cdot), v)_{L^2(\Omega\times(0,T)}. \tag{3.2}$$

This leads to the following definition.

DEFINITION 3.1. *A solution of* (3.1) *is a function*

$$\psi(\cdot,\cdot,0,\cdot) \in C(\mathbb{R}; H^1(\Omega)) \cap C^1(\mathbb{R}; L^2(\Omega)),$$

satisfying (3.2) *for all* $\varphi_0 \in L^2(\Omega)$ *and* $\varphi_1 \in (H^1(\Omega))'$.

The definition is justified by the following claim.

PROPOSITION 3.2. *Given* $\psi_0 \in H^1(\Omega)$, $\psi_1 \in L^2(\Omega)$, *and* $v \in L^2_{loc}(\mathbb{R}; L^2\Omega))$ *arbitrarily, problem* (3.1) *has a unique solution.*

Proof. For any fixed T, the right-hand side of (3.2) defines a bounded linear form of

$$(\varphi_0,\varphi_1) \in L^2(\Omega)\times(H^1(\Omega))'.$$

Since the linear map

$$(\varphi_0,\varphi_1) \mapsto \left(\varphi, \frac{\partial\varphi}{\partial t}\right)(\cdot,\cdot,0,T)$$

is an automorphism of $L^2(\Omega)\times(H^1(\Omega))'$ onto itself, the existence of a unique couple

$$\left(\psi, \frac{\partial\psi}{\partial t}\right)(\cdot,\cdot,0,T) \in L^2(\Omega)\times(H^1(\Omega))'$$

satisfying (3.2) follows.

Since both sides of (3.2) change continuously with T, the solution also depends continuously of T, thereby completing the proof of Proposition 3.2. ∎

4. Boundary controllability of liquid containers. A crucial idea in the HUM of Lions (see [4] and [5]) was the construction of suitable controls by solving a corresponding homogeneous dual problem. Using this duality approach, we establish in this section the following controllability result for problem (3.1).

THEOREM 4.1. *Given a positive number T and initial data $\psi_0 \in H^1(\Omega)$, $\psi_1 \in L^2(\Omega)$, there exists a function $v \in L^2(0,T;L^2(\Omega))$ such that the solution of* (3.1) *satisfies*

$$\left(\psi, \frac{\partial \psi}{\partial t}\right)(\cdot,\cdot,0,T) = 0.$$

Proof. Given $\varphi_0 \in L^2(\Omega)$ and $\varphi_1 \in (H^1(\Omega))'$ arbitrarily, solve the homogeneous problem (2.1) and then solve the following nonhomogeneous problem:

$$\begin{cases} \Delta\psi = 0 \quad \text{in} \quad \Omega \times (-h,0) \times \mathbb{R}, \\ \partial_\nu \psi = 0 \quad \text{on} \quad \Gamma \times (-h,0) \times \mathbb{R}, \\ \partial_\nu \psi = 0 \quad \text{on} \quad \Omega \times \{-h\} \times \mathbb{R}, \\ \frac{\partial^2 \psi}{\partial t^2} + g\frac{\partial \psi}{\partial z} = \varphi \quad \text{on} \quad \Omega \times \{0\} \times \mathbb{R}, \\ \psi(x,y,0,T) = 0, \quad (x,y) \in \Omega, \\ \frac{\partial \psi}{\partial t}(x,y,0,T) = 0, \quad (x,y) \in \Omega. \end{cases} \tag{4.1}$$

(The well-posedness of this problem follows from Proposition 3.2 because the time 0 does not play any special role in this problem.) It is sufficient to prove that for a suitable choice of the initial data φ_0 and φ_1 we have

$$\psi(x,y,0,0) = \psi_0(x,y) \quad \text{and} \quad \frac{\partial \psi}{\partial t}(x,y,0,0) = \psi_1(x,y), \quad (x,y) \in \Omega.$$

Using the identity (3.2) of the preceding section, now we have

$$\langle (-\psi_1, \psi_0), (\varphi_0, \varphi_1) \rangle_{L^2(\Omega)\times H^1(\Omega), L^2(\Omega)\times (H^1(\Omega))'} = \int_0^T \int_\Omega |\varphi(x,y,0,t)|^2 \, dx \, dy \, dt. \tag{4.2}$$

Thanks to Proposition 2.2, the right-hand side of this identity is a positive definite quadratic form of $(\varphi_0, \varphi_1) \in L^2(\Omega) \times (H^1(\Omega))'$. Applying the Lax–Milgram theorem (or simply the Riesz–Fréchet theorem), we conclude that the linear map

$$(\varphi_0, \varphi_1) \mapsto (-\psi_1, \psi_0)$$

maps $L^2(\Omega) \times (H^1(\Omega))'$ onto $L^2(\Omega) \times H^1(\Omega)$, and the theorem follows. □

5. Spectral boundary controllability of liquid containers. The controls applied in the preceding section are difficult to realize in practice. Here we present a more realistic variant: we apply simpler controls but we only look for partial controllability by eliminating a finite number of modes from the solution.

Choose a positive integer N and N functions $f_1(x,y), \dots, f_N(x,y)$ on Ω. Using controls of the form

$$v(x,y,t) := \sum_{j=1}^{N} (a_j t + b_j) f_j(x,y),$$

where we can act by choosing suitable constants a_j and b_j for $j = 1, \dots, N$, we try to drive the system to a final state satisfying the orthogonality conditions

$$\int_\Omega \psi(x,y,0,T)e_n(x,y)\,dx\,dy = \int_\Omega \frac{\partial\psi}{\partial t}(x,y,0,T)e_n(x,y)\,dx\,dy = 0$$

for $n = 1, \dots, N$.

Expanding the given functions $f_j(x,y)$ into Fourier series

$$f_j(x,y) = \sum_{n=1}^{\infty} f_{jn}e_n(x,y), \quad j = 1, \dots, N,$$

the control takes the form

$$v(x,y,t) := \sum_{n=1}^{\infty} \left(\sum_{j=1}^{N} f_{jn}(a_j t + b_j) \right) e_n(x,y).$$

Therefore the solution of (3.1) is given by the series

$$\psi(x,y,z,t) = \sum_{n=1}^{\infty} e_n(x,y)\cosh[\lambda_n(z+h)]g_n(t),$$

where the functions $g_n(t)$ are solutions to the initial-value problems

$$\begin{aligned} &g_n''(t)\cosh(\lambda_n h) + g_n(t)g\lambda_n \sinh(\lambda_n h) = \sum_{j=1}^{N} f_{jn}(a_j t + b_j), \\ &g_n(0)\cosh(\lambda_n h) = c_n, \\ &g_n'(0)\cosh(\lambda_n h) = d_n, \end{aligned}$$

where the constants c_n and d_n depend on the initial data.

We have to prove that for any given c_n and d_n there exist constants a_n and b_n such that

$$g_n(T) = g_n'(T) = 0, \quad n = 1, \dots, N. \tag{5.1}$$

Equivalently, we have to prove that if $c_n = d_n = 0$ for $n = 1, \dots, N$, then we only have the trivial solution $a_n = b_n = 0$ for $n = 1, \dots, N$.

In this homogeneous case we explicitly compute the solution: setting

$$\omega_n = \sqrt{g\lambda_n \tanh(\lambda_n h)}$$

as before, we have

$$g_n(t) = \sum_{j=1}^{N} f_{jn} \left(\frac{\omega_n t - \sin(\omega_n t)}{\omega_n^3} a_j + \frac{1 - \cos(\omega_n t)}{\omega_n^2} b_j \right)$$

for $n = 1, \dots, N$. It follows that the conditions (5.1) are equivalent to the following system of linear equations:

$$\begin{aligned} &\sum_{j=1}^{N} f_{jn}\big(\omega_n T - \sin(\omega_n T)\big)a_j + \sum_{j=1}^{N} f_{jn}\omega_n\big(1 - \cos(\omega_n T)\big)b_j = 0, \qquad n = 1, \dots, N, \\ &\sum_{j=1}^{N} f_{jn}\big(1 - \cos(\omega_n T)\big)a_j + \sum_{j=1}^{N} f_{jn}\omega_n \sin(\omega_n T)b_j = 0, \qquad n = 1, \dots, N. \end{aligned}$$

We arrive in this way at the following result.

THEOREM 5.1. *Assume that the determinant of the above system is different from zero for some $T > 0$. Then for any given initial data $\psi_0 \in H^1(\Omega)$, $\psi_1 \in L^2(\Omega)$, there exist constants $a_1, \dots, a_N$ and $b_1, \dots, b_N$ such that, applying the control*

$$v(x, y, t) := \sum_{j=1}^{N} (a_j t + b_j) f_j(x, y),$$

the solution of (3.1) *satisfies*

$$\int_\Omega \psi(x, y, 0, T) e_n(x, y)\ dx\ dy = \int_\Omega \frac{\partial \psi}{\partial t}(x, y, 0, T) e_n(x, y)\ dx\ dy = 0$$

for $n = 1, \dots, N$.

Example 3. Let us consider the simplest case where $N = 1$ and $f_1(x, y) = e_1(x, y)$. Then, setting $\alpha := T\omega_1$ for brevity, the determinant is equal to

$$\begin{vmatrix} \alpha - \sin\alpha & \omega_1(1 - \cos\alpha) \\ 1 - \cos\alpha & \omega_1 \sin\alpha \end{vmatrix} = 2\omega_1 \sin\alpha \left(\frac{\alpha}{2} - \tan\frac{\alpha}{2} \right).$$

It follows that the determinant vanishes if and only if $\alpha = T\omega_1$ is an integer multiple of π, i.e., if and only if

$$T = \frac{k\pi}{\sqrt{g\lambda_1 \tanh(\lambda_1 h)}}$$

for some positive integer k. For all other values of $T > 0$ the problem is controllable in the above sense.

Remark. From the point of view of applications, it is interesting to find control constants a_j and b_j of a moderate size: in some sense the size of these constants may be viewed as a measure of the cost of the control. (Furthermore, for large values of the controls our model may not be any more realistic.) This is equivalent to choosing functions $f_1, \dots f_N$ such that the inverse of the matrix of the above linear system has a sufficiently large norm. On the other hand, it is also useful to find relatively simple functions f_j, concentrated on some points of the domain Ω. These two, in a sense contradictory, requirements lead to an interesting optimization problem of a geometric nature, which can be studied in special cases if, for example, Ω is a rectangle or a disk.

CHARACTERIZATION OF THE STATE CONSTRAINED MINIMAL TIME FUNCTION*

R. J. STERN†

Abstract. A standard class of finite dimensional control systems is considered, along with a state constraint set S and a target set $\Sigma \subset S$. Under certain geometric assumptions on S and a required S-constrained small time controllability property, a proximal Hamilton–Jacobi characterization of the S-constrained minimal time function to target Σ is obtained.

Key words. state constrained minimal time function, proximal Hamilton–Jacobi inequalities, small time controllability

DOI. 10.1137/S0363012903426033

1. Introduction. We shall consider a standard finite dimenisonal control system $\dot{x}(t) = f(x(t), u(t))$, $u(\cdot) \in U$, along with a state constraint $x(t) \in S$ and a closed target set $\Sigma \subset S$. Our goal is to provide, apparently for the first time, Hamilton–Jacobi (HJ) characterizations of the S-constrained minimal time function with target Σ. The unconstrained (that is, $S = \mathbb{R}^n$) form of this problem was considered by several researchers. In Bardi [1] such a characterization was obtained under a continuity hypothesis encapsulated as a small time controllability condition. In Bardi and Staicu [2] the discontinuous case was settled for targets which are the closure of their interior, while the general case was resolved in Soravia [23]. The nonsmooth characterizations obtained in the aforementioned references are provided in viscosity terms. A proximal characterization equivalent to that of Soravia is among the results obtained by Wolenski and Zhuang [25]. There it was shown that under mild hypotheses, the unconstrained minimal time function is the unique function satisfying, among other properties, a proximal HJ equation on the complement of Σ, along with a boundary condition which takes the form of a certain proximal HJ inequality holding on Σ itself. Useful references on the minimal time function and viscosity approaches are Bardi and Capuzzo-Dolcetta [3] and Cannarsa and Sinestrari [5]. Of related interest to this discussion are recent results of Clarke and Nour [11], where the proximal HJ equation was reconsidered, but in the absence of the aforementioned boundary condition. The solutions obtained to the proximal HJ equation in this new framework were studied, and shown to be associated with geodesic trajectories.

As in [25] and [11], our methods here are based upon nonsmooth proximal monotonicity-invariance considerations as developed in Clarke, Ledyaev, Stern, and Wolenski [8], [10]. But as will be seen, the imposition of a state constraint necessitates additional techniques. Of particular interest is the role played by a required S-constrained small time controllability hypothesis. Geometric sufficient conditions for the latter property will be provided as well, in the concluding comments.

State constrained control problems have received attention in recent years. Differ-

ential games with state constraints were studied in Bardi, Koike, and Soravia [4] and Cardaliaguet, Quincampoix, and Saint-Pierre [6]. In Clarke, Rifford, and Stern [12], a state constrained Mayer problem was studied, and in Clarke and Stern [13], the problem of state constrained stabilization was considered. In the two latter references, the emphasis was on the construction of feedback controls. In Clarke and Stern [14], the value function of the state constrained problem studied in [12] was characterized in proximal HJ terms; in this regard, see also Frankowska and Vinter [18] and Vinter [24]. As is the case in [14], the method here will rely upon state constrained trajectory tracking properties developed in [12], and the proximal characterizations can be reframed, as they were in [14], in the "constrained viscosity solution" framework introduced by Soner [22]. This too will be remarked upon in the concluding comments.

We shall consider a control system of the form

$$\dot{x}(t) = f(x(t), u(t)) \quad \text{a.e.} \tag{1.1}$$

The state trajectory $x(\cdot)$ evolves in $\mathbb{R}^n$ and control functions $u(\cdot)$ are Lebesgue measurable functions $u : \mathbb{R} \to U$, where $U \subset \mathbb{R}^m$ is a compact control restraint set.

Hypotheses on the dynamics $f : \mathbb{R}^n \times U \to \mathbb{R}^n$ are as follows, and will be assumed to hold throughout. (The Euclidean norm is denoted by $\|\cdot\|$.)

(F1) The function f is continuous and locally Lipschitz in the state variable x, uniformly for $u \in U$; that is, for each bounded set $\Gamma \subset \mathbb{R}^n$, there exists $K_\Gamma > 0$ such that

$$\|f(x,u) - f(y,u)\| \le K_\Gamma \|x - y\|$$

whenever (x,u) and (y,u) are in $\Gamma \times U$.

(F2) The function f satisfies a linear growth condition; that is, there exist positive numbers c_1, c_2 such that

$$\|f(x,u)\| \le c_1\|x\| + c_2 \quad \forall\, (x,u) \in \mathbb{R}^n \times U.$$

(F3) The velocity set $f(x,U)$ is convex for every $x \in \mathbb{R}^n$.

Under (F1)–(F2), for every initial state α and every control function $u(\cdot)$, there exists a unique trajectory $x(t) = x(t;\alpha,u(\cdot))$ defined for all $t \ge 0$ and satisfying $x(0) = \alpha$. Actually, as is explained in the concluding comments, condition (F2) can be dropped in the results to follow, but we include it now for ease of exposition. The imposition of (F3) is needed in order to have available the familiar property of sequential compactness of trajectories on compact time intervals, as is explained in [10].

The next section provides a required result on S-constrained trajectory tracking. The main result is presented in section 3, while section 4 consists of the concluding comments. Prior to proceeding, we refer the reader to [10] for all the basic definitions and facts from nonsmooth analysis that will be required.

2. *S*-constrained trajectory tracking. Geometric hypotheses on S are now posited and will be assumed to hold throughout.

(S1) S is compact and *wedged* at each $x \in \mathrm{bdry}(S)$, meaning that at each boundary point x one has pointedness of $N_S^C(x)$; that is, $N_S^C(x) \cap \{-N_S^C(x)\} = \{0\}$. Here $N_S^C(x)$ denotes the Clarke normal cone to S at x. (This is equivalent to $T_S^C(x)$ having nonempty interior for each $x \in \mathrm{bdry}(S)$, where $T_S^C(x)$ denotes the Clarke tangent cone to S at x.)

(S2) The following "strict inwardness" condition holds:

$$\min_{u\in U}\langle \zeta, f(x,u)\rangle < 0 \quad \forall\, 0 \neq \zeta \in N_S^C(x), \quad \forall\, x \in \mathrm{bdry}(S). \tag{2.1}$$

The set S being wedged at $x \in \mathrm{bdry}(S)$ is also referred to in the literature as *epi-Lipschitzness* of S at x, since it is equivalent to S being locally linearly homeomorphic to the epigraph of a Lipschitz function; see Rockafellar [20] and Clarke [7].

Remark 2.1.

(a) We will require the fact that when S is wedged at each of its boundary points, then S is the closure of its interior.

(b) (S1)–(S2) are sufficient but not necessary for S to be *weakly invariant*; that is, for any initial state $\alpha \in S$, there exists a control $u(\cdot)$ producing a trajectory $x(t) = x(t;\alpha,u(\cdot))$ with $x(0) = \alpha$ and $x(t) \in S$ for all $t \geq 0$.

Given $r \geq 0$, an *inner approximation* of S is given by

$$S_r := \{x \in S : d_{\hat{S}}(x) \geq r\}.$$

Here $\hat{S}$ denotes the closure of the complement of S, and $d_\Gamma(\cdot)$ denotes the Euclidean distance function to a set Γ. (Note that $S_0 = S$.) The geometry of inner approximations was studied in Clarke, Ledyaev, and Stern [9], as well as in [12].

We will require the following S-constrained tracking result from the proofs of Proposition 3.13 and Theorem 3.10 in [12]. This result generalizes one due to Soner [22]; see also Forcellini and Rampazzo [16] and Frankowska and Rampazzo [17].

LEMMA 2.2.

(a) *Given $T > 0$, there exists a constant $M = M(T) > 0$ such that the following holds: Let $\alpha_0 \in S$, $\alpha_1 \in S$, and let $u_0(\cdot)$ be a control function on $[0,T]$ producing a trajectory which satisfies*

$$x(t;\alpha_0,u_0(\cdot)) \in S \quad \forall\, t \in [0,T]. \tag{2.2}$$

Then there exists a control function $u_1(\cdot)$ on $[0,T]$ which produces a trajectory that satisfies

$$\|x(t;\alpha_1,u_1(\cdot)) - x(t;\alpha_0,u_0(\cdot))\| \leq M\|\alpha_1 - \alpha_0\| \quad \forall\, t \in [0,T] \tag{2.3}$$

and

$$x(t;\alpha_1,u_1(\cdot)) \in S \quad \forall\, t \in [0,T]. \tag{2.4}$$

(b) *There exists a constant $r_0 > 0$ so that the following holds: Given $T > 0$, there exists $W = W(T) > 0$ such that for any initial state $\alpha \in \mathrm{int}(S)$, if $r \in [0,r_0]$ is such that $r \leq d_{\hat{S}}(\alpha)$ and $u(\cdot)$ is a control function on $[0,T]$ such that*

$$x(t;\alpha,u(\cdot)) \in S \quad \forall\, t \in [0,T], \tag{2.5}$$

then there exists a control function $\bar{u}(\cdot)$ on $[0,T]$ such that

$$\|x(t;\alpha,\bar{u}(\cdot)) - x(t;\alpha,u(\cdot))\| \leq rW \quad \forall\, t \in [0,T] \tag{2.6}$$

and

$$x(t;\alpha,\bar{u}(\cdot)) \in S_r \quad \forall\, t \in [0,T]. \tag{2.7}$$

3. The *S*-constrained minimal time function. Let Σ be a closed subset of S, and denote by Γ_S the set of $\alpha \in S$ such that for some control $u(\cdot)$ and some $\hat{t} \geq 0$ one has

$$x(\hat{t}; \alpha, u(\cdot)) \in \Sigma$$

and

$$x(t; \alpha, u(\cdot)) \in S \quad \forall\, t \in [0, \hat{t}].$$

In other words, Γ_S consists of those initial states in S which can be controlled in finite time to the target Σ along an S-constrained trajectory. (Trivially, we have $\Sigma \subset \Gamma_S$.) Denote by $\tau(\alpha)$ the infimal time from an initial state $\alpha \in \Gamma_S$ to the target Σ along such a trajectory. By a standard sequential compactness of trajectories argument, the infimum is attained as a minimum. We go on to define an extended real-valued function $T : \mathbb{R}^n \to [0, +\infty]$ as follows:

$$T(\alpha) := \begin{cases} \tau(\alpha) & \text{if } \alpha \in \Gamma_S, \\ +\infty & \text{otherwise.} \end{cases}$$

$T(\cdot)$ is called the *S-constrained minimal time function* with respect to the target Σ. One can show that $T(x) \geq 0$ for all $x \in \mathbb{R}^n$ and $T(\alpha) = 0$ if and only if $\alpha \in \Sigma$. Observe that there are *two* ways for $T(\alpha)$ to be nonfinite:

(i) $\alpha \in S$, but Σ is not reachable from α via an S-constrained trajectory; that is, $\alpha \in S \backslash \Gamma_S$.
(ii) $\alpha \notin S$.

Let us collect some basic properties of the functions $T(\cdot)$ and $g(\cdot, \cdot)$, where

$$g(t, x) := t + T(x).$$

We denote the set of strictly positive real numbers by $\mathbb{R}_+$, and the complement of Σ by Σ^c.

(LSC) $T(\cdot)$ is lower semicontinuous at every $\alpha \in \mathbb{R}^n$; that is,

$$T(\alpha) \leq \liminf_{\alpha' \to \alpha} T(\alpha').$$

(SI) $g(\cdot, \cdot)$ is *strongly increasing* on $\mathbb{R}_+ \times \operatorname{int}(S)$. This means that for every $\alpha \in \operatorname{int}(S)$, for every trajectory of (1.1) with $x(0) = \alpha$, one has $g(t, x(t)) \geq T(\alpha)$ on $[0, s]$ for every $s > 0$ such that $x(t) \in \operatorname{int}(S)$ on $[0, s]$.

(WD) $g(\cdot, \cdot)$ is *weakly decreasing* on $\mathbb{R}_+ \times \Sigma^c$. This means that for every $\alpha \in \Sigma^c$, there exists a trajectory of (1.1) with $x(0) = \alpha$, for which $g(t, x(t)) \leq T(\alpha)$ on $[0, s]$ for every $s > 0$ such that $x(t) \in \Sigma^c$ on $[0, s]$.

Note that in (SI) and (WD), infinite values of $T(\cdot)$ and $g(\cdot, \cdot)$ are possible. In particular, in (SI), note that if a trajectory in $\operatorname{int}(S)$ exits Γ_S, it cannot re-enter Γ_S while remaining in S. Property (LSC) readily follows from a sequential compactness of trajectories argument. The strong increase property (SI) is a straightforward consequence of the principle of optimality, while the weak decrease property (WD) is due to the existence of S-constrained time-optimal trajectories from any startpoint α where $T(\alpha)$ is finite; that is, $\alpha \in \Gamma_S$. (Startpoints for which $T(\alpha) = +\infty$ trivially satisfy the weak decrease condition.)

We now introduce the *lower Hamiltonian* $h : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ by

$$h(x, p) := \min_{u \in U} \langle p, f(x, u) \rangle, \tag{3.1}$$

where $\langle \cdot, \cdot \rangle$ denotes the standard inner product.

The next lemma provides proximal characterizations of (SI) and (WD) in terms of proximal HJ inequalities. It follows in a straightforward manner from Exercise 4.6.4(a) and Proposition 4.6.5 in [10].

LEMMA 3.1.

(i) *Property* (SI) *is equivalent to*

$$h(x, \partial_P T(x)) + 1 \geq 0 \quad \forall\, x \in \text{int}(S). \tag{3.2}$$

(ii) *Property* (WD) *is equivalent to*

$$h(x, \partial_P T(x)) + 1 \leq 0 \quad \forall\, x \in \Sigma^c. \tag{3.3}$$

Here ∂_P denotes the *proximal subdifferential*; recall that for an extended real-valued lower semicontinuous function $w : \mathbb{R}^n \to (-\infty, +\infty]$ and a point x, where $w(x) < +\infty$, $\zeta \in \partial_P w(x)$ if and only if there exists $\sigma = \sigma(x, \zeta)$ such that

$$w(y) - w(x) + \sigma \|y - x\|^2 \geq \langle \zeta, y - x \rangle$$

for all y near x. Thus (3.2) says that

$$h(x, \zeta) + 1 \geq 0 \quad \forall\, \zeta \in \partial_P T(x), \quad \forall\, x \in \text{int}(S),$$

and (3.3) says that

$$h(x, \zeta) + 1 \leq 0 \quad \forall\, \zeta \in \partial_P T(x), \quad \forall\, x \in \Sigma^c.$$

These inequalities hold vacuously when the proximal subdifferentials involved are empty, as is the case when $T(x) = +\infty$, but emptiness is not precluded even when $T(x)$ is finite.

Note also that (3.2) and (3.3) together are equivalent to $T(\cdot)$ satisfying

$$h(x, \partial_P T(x)) + 1 = 0 \quad \forall\, x \in \{\text{int}(S)\} \backslash \Sigma, \tag{3.4}$$

$$h(x, \partial_P T(x)) + 1 \geq 0 \quad \forall\, x \in \{\text{int}(S)\} \cap \Sigma, \tag{3.5}$$

and

$$h(x, \partial_P T(x)) + 1 \leq 0 \quad \forall\, x \in \{\text{bdry}(S)\} \backslash \Sigma. \tag{3.6}$$

We require the following definition, where the open unit ball is denoted $B := \{z \in \mathbb{R}^n : \|z\| < 1\}$.

DEFINITION 3.2. *A function $\varphi : \mathbb{R}^n \to (-\infty, +\infty]$ is said to be* (Σ, S)-continuous *provided that there exist $\gamma_\varphi > 0$ and a function $\omega_\varphi : [0, \gamma_\varphi] \to [0, +\infty)$ such that $\lim_{s \downarrow 0} \omega_\varphi(s) = 0$ and $\varphi(x) \leq \omega_\varphi(d_\Sigma(x))$ for all $x \in S \cap \{\Sigma + \gamma_\varphi B\}$.*

In the absence of a state constraint (i.e., $S = \mathbb{R}^n$), the minimal time function being $(\Sigma, \mathbb{R}^n)$-continuous is often referred to as *small time controllability*. Accordingly, when the S-constrained minimal time function $T(\cdot)$ is (Σ, S)-continuous, then we say that *S-constrained small time controllability* holds.

Remark 3.3. Results concerning the small time controllability property in the absence of a state constraint may be found in [3] and [5], as well as [25]. "Classical" trajectory tracking based on Gronwall's lemma features in these discusssions. Specifically, one has the following facts:

(a) Small time controllability is equivalent to $T(\cdot)$ being continuous on an open neighborhood of Σ.

(b) When small time controllability holds, then Γ, the set of startpoints controllable to Σ, is open, and small time controllability implies that the minimal time function $T(\cdot)$ is continuous on Γ.

In the state constrained case being considered, one can employ the tracking result of Lemma 2.2(a) in order to obtain the following analogues of (a) and (b):

(a′) S-constrained small time controllability is equivalent to $T(\cdot)$ being continuous on $S \cap \{\Sigma + \gamma B\}$ for some $\gamma > 0$.

(b′) When S-constrained small time controllability holds, the set Γ_S is open relative to S, and small time controllability implies that the minimal time function $T(\cdot)$ is continuous on Γ_S.

The preceding remarks are not required in the following main result.

THEOREM 3.4. *Let* (F1)–(F3), (S1)–(S2) *hold, and assume that S-constrained small time controllability holds. Then there is a unique lower semicontinuous extended real-valued function $\varphi : \mathbb{R}^n \to (-\infty, +\infty]$ which is (Σ, S)-continuous, bounded below on $\mathbb{R}^n$, identically 0 on Σ, identically $+\infty$ on S^c, and satisfies*

$$h(x, \partial_P \varphi(x)) + 1 = 0 \quad \forall\, x \in \{\mathrm{int}(S)\} \backslash \Sigma, \tag{3.7}$$

$$h(x, \partial_P \varphi(x)) + 1 \geq 0 \quad \forall\, x \in \{\mathrm{int}(S)\} \cap \Sigma, \tag{3.8}$$

and

$$h(x, \partial_P \varphi(x)) + 1 \leq 0 \quad \forall\, x \in \mathrm{bdry}(S) \backslash \Sigma. \tag{3.9}$$

That function is the S-constrained minimal time function $T(\cdot)$. Furthermore, Γ_S is open relative to S and $T(\cdot)$ is continuous on Γ_S.

In order to understand the role played by S-constrained small time controllability and (Σ, S)-continuity in this result, consider the case where $\Sigma \subset \mathrm{bdry}(S)$, and note that then the indicator function of Σ, namely,

$$\varphi(x) = \begin{cases} +\infty & \text{if } x \notin \Sigma, \\ 0 & \text{if } x \in \Sigma, \end{cases}$$

will *always* satisfy the conditions set out in the theorem; in particular (3.7)–(3.9) hold vacuously. Therefore there is no hope of uniqueness holding, in general, without further conditions. In fact, the proof will require these conditions even if $\Sigma \subset \mathrm{int}(S)$.

Proof of the theorem. That $T(\cdot)$ satisfies the stated conditions has already been explained. Hence the uniqueness assertion remains to be verified. To this end, let $\varphi(\cdot)$ be as in the statement of the theorem. The proof will follow from the verification of two claims.

Claim 1. $T(\alpha) \leq \varphi(\alpha)$ for all $\alpha \in S$.

To see this, note that (3.7) and (3.9) imply that the function $\tilde{g}(t, \alpha) := t + \varphi(\alpha)$ is weakly decreasing on $\mathbb{R}_+ \times \Sigma^c$. We need only consider $\alpha \in S \backslash \Sigma$, since if $\alpha \in \Sigma$ we have $T(\alpha) = \varphi(\alpha) = 0$. Furthermore, we can assume that $\varphi(\alpha) < +\infty$, for otherwise the claim is trivially true.

Now, for $\alpha \in S \backslash \Sigma$ with $\varphi(\alpha) < +\infty$, weak decrease implies that for some trajectory of (1.1) with $x(0) = \alpha$, one has

$$t + \varphi(x(t)) \leq \varphi(\alpha) \tag{3.10}$$

as long as $x(t) \notin \Sigma$. Since $\varphi(\cdot)$ is globally bounded below and $\varphi(\alpha)$ is finite, we conclude that the trajectory eventually enters Σ. Then $T(\alpha) < +\infty$ and

$$t + \varphi(x(t)) \leq \varphi(\alpha) \quad \forall\, t \in [0, T(\alpha)). \tag{3.11}$$

Upon invoking the lower semicontinuity of $\varphi(\cdot)$, we then have

$$\begin{aligned} T(\alpha) &= T(\alpha) + \varphi(x(T(\alpha))) \\ &\leq \liminf_{t \uparrow T(\alpha)} [t + \varphi((x(t)))] \\ &\leq \varphi(\alpha), \end{aligned}$$

proving the claim.

Claim 2. $T(\alpha) \geq \varphi(\alpha)$ for all $\alpha \in S$.

Let us first consider the case where $\alpha \in \text{int}(S)$. Without loss of generality, we can assume that $\alpha \in \Gamma_S$, for otherwise $T(\alpha) = +\infty$ and the claim will be trivial. Let $x(\cdot)$ be an S-constrained time-optimal trajectory of (1.1) to target Σ, with $x(0) = \alpha$. By the tracking result of Lemma 2.2(b), there exists $W = W(T(\alpha)) > 0$ such that for each sufficiently small $r > 0$ there exists an S_r-constrained trajectory $x_r(\cdot)$ of (1.1) on the interval $[0, T(\alpha)]$ with $x_r(0) = \alpha$ and

$$\|x_r(T(\alpha)) - x(T(\alpha))\| \leq rW. \tag{3.12}$$

Then

$$x_r(T(\alpha)) \in \Sigma + rW\overline{B}, \tag{3.13}$$

where $\overline{B}$ denotes the closure of the unit ball B.

In view of (3.7)–(3.8), the function $\varphi(\cdot)$ is strongly increasing on $\text{int}(S)$. Consequently

$$T(\alpha) + \varphi(x_r(T(\alpha))) \geq \varphi(\alpha). \tag{3.14}$$

Since $\varphi(\cdot)$ is (Σ, S)-continuous, (3.13) implies that the term $\varphi(x_r(T(\alpha)))$ can be made arbitrarily small by decreasing r, and we deduce that

$$T(\alpha) \geq \varphi(\alpha). \tag{3.15}$$

It remains to consider the case where $\alpha \in \text{bdry}(S)$. Again, we can assume that $T(\alpha)$ is finite, and we consider an S-constrained time-optimal trajectory $x(\cdot)$ of (1.1) to target Σ, with $x(0) = \alpha$. In view of Remark 2.1(a), there exists a sequence $\{\alpha_i\}$ in the interior of S, such that $\alpha_i \to \alpha$. From the preceding argument, we have that

$$T(\alpha_i) \geq \varphi(\alpha_i) \tag{3.16}$$

for each $i = 1, 2, \ldots$.

By the tracking result of Lemma 2.2(a), there exists $M = M(T(\alpha)) > 0$ such that for each i there is a trajectory $x_i(\cdot)$ of (1.1) for which $x_i(0) = \alpha_i$,

$$\|x(t) - x_i(t)\| \leq M\|\alpha_i - \alpha\| \quad \forall\, t \in [0, T(\alpha)], \tag{3.17}$$

and

$$x_i(t) \in S \quad \forall\, t \in [0, T(\alpha)]. \tag{3.18}$$

Since $x(T(\alpha)) \in \Sigma$, we have $x_i(T(\alpha)) \in \Sigma + M\|\alpha_i - \alpha\|\overline{B}$, and therefore the S-constrained small time controllability assumption, inequality (3.16), and the preceding case yield

$$T(\alpha) + \omega_T(M\|\alpha_i - \alpha\|) \geq T(\alpha_i) \geq \varphi(\alpha_i) \tag{3.19}$$

for each i. Since $\omega_T(M\|\alpha_i - \alpha\|) \to 0$ as $i \to +\infty$ and $\varphi(\cdot)$ is lower semicontinuous, we obtain $T(\alpha) \geq \varphi(\alpha)$, as required. Finally, the "furthermore" part of the statement is simply Remark 3.3(b′). □

4. Concluding comments.

4.1. Sufficient conditions for *S*-constrained small time controllability. It is possible to replace the S-constrained small time controllability hypothesis in Theorem 3.4 by stronger geometric hypotheses. Specifically, we introduce the following condition, in which $\mathrm{proj}_\Sigma(x)$ denotes the set of closest points in Σ to x, and $N_S^P(x)$ denotes the proximal normal cone to S at x; see [10].

(S3) There exist $\delta_1 > 0$, $\delta_2 > 0$ such that the following holds: For each $x \in S \cap \Sigma^c \cap \{\Sigma + \delta_1 B\}$, there exists $u(x) \in U$ for which

$$\langle \eta, f(x, u(x))\rangle \leq 0 \quad \forall\, \eta \in N_S^P(x) \tag{4.1}$$

and

$$\langle x - y, f(x, u(x))\rangle \leq -\delta_2\|x - y\| \tag{4.2}$$

for some $y \in \mathrm{proj}_\Sigma(x)$.

Intuitively, condition (S3) says that at each point x in S which is near but exterior to Σ, there exists a velocity $f(x, u(x))$ which "points into S" (this is (4.1)) while *simultaneously* "pointing towards Σ" (this is (4.2)). The "proximal aiming" technique of [8], [10] and Clarke and Wolenski [15] can now be brought to bear, whereby one can show that for some $\gamma_1 > 0$, $\gamma_2 > 0$, all limiting Euler solutions $x(\cdot)$ of the initial value problem

$$\dot{x}(t) = f(x(t), u(x(t))), \quad x(0) = \alpha \in S \cap \{\Sigma + \gamma_1 B\},$$

are bona fide trajectories of the control system (1.1) which remain in S and enter Σ prior to time $t = \gamma_2 d_\Sigma(\alpha)$. Hence one has

$$T(\alpha) \leq \gamma_2 d_\Sigma(\alpha) \quad \forall\, \alpha \in S \cap \{\Sigma + \gamma_1 B\}.$$

The foregoing comments show that we can take $\omega_T(z) = \gamma_2 z$, in the notation of Definition 3.2. One can then invoke Lemma 2.2(b) in order to show that $T(\cdot)$ is Lipschitz on $S \cap \{\Sigma + \gamma_3 B\}$ for some $\gamma_3 > 0$, and similarly to Remark 3.3(b′), one can show that $T(\cdot)$ is Lipschitz on Γ_S, where, as noted earlier, this set is open relative to S. We omit these details, as they are very similar to familiar arguments used in the case of no state constraints, as in [3] and [25].

A variant of Theorem 3.4 ensues.

COROLLARY 4.1. *Let* (F1)–(F3) *and* (S1)–(S3) *hold. Then there is a unique lower semicontinuous extended real-valued function $\varphi(\cdot)$ which is (Σ, S)-continuous, bounded below on $\mathbb{R}^n$, identically 0 on Σ, identically $+\infty$ on S^c, and satisfies*

$$h(x, \partial_P\varphi(x)) + 1 = 0 \quad \forall\, x \in \{\mathrm{int}(S)\}\backslash\Sigma, \tag{4.3}$$

$$h(x, \partial_P\varphi(x)) + 1 \geq 0 \quad \forall\, x \in \{\mathrm{int}(S)\} \cap \Sigma, \tag{4.4}$$

and

$$h(x, \partial_P \varphi(x)) + 1 \leq 0 \quad \forall\, x \in \mathrm{bdry}(S) \backslash \Sigma. \tag{4.5}$$

That function is the S-constrained minimal time function $T(\cdot)$. Furthermore, Γ_S is open relative to S and $T(\cdot)$ is Lipschitz on Γ_S.

4.2. Constrained viscosity formulation. Given a lower semicontinuous extended real-valued function $w : \mathbb{R}^n \to (-\infty, +\infty]$, we denote the *Dini subderivate* at x in the direction v by

$$Dw(x; v) := \liminf_{\substack{t \downarrow 0 \\ u \to v}} \frac{w(x + tu) - w(x)}{t}.$$

The D-subdifferential (or *viscosity subdifferential*) of $w(\cdot)$ at x is the set

$$\partial_D w(x) := \{\zeta \in \mathbb{R}^n : \langle \zeta, v \rangle \leq Dw(x; v) \ \forall\, v \in \mathbb{R}^n\}.$$

Similarly to remarks made in [14], Theorem 3.4 and Corollary 4.1 hold true if ∂_P is replaced by ∂_D in the statement, because the P- and D-subdifferentials approximate one another in a suitable sense. This in turn rests upon a theorem of Subbotin; see Proposition 3.4.5 in [10]. By Proposition 3.4.12 in [10], the ∂_D-form of the theorem can in turn be put into "constrained viscosity" terms, in Soner's terminology [22]; see also [3]. Specifically, (3.7) can be replaced by the condition

$$h(x, g'(x)) + 1 = 0 \quad \forall\, x \in \{\mathrm{int}(S)\} \backslash \Sigma \tag{4.6}$$

for any $g \in C^1(\mathbb{R}^n)$ such that $\varphi - g$ has a local minimum at x. Furthermore, conditions (3.8) and (3.9) have analogous constrained viscosity reformulations.

4.3. *S*-restricted dynamics. Suppose that the dynamics are specified only for $x \in S$; that is, $f : S \times U \to \mathbb{R}^n$. Such a restricted domain can be expected in control problems where the state is S-constrained. Again, similarly to [14], it can be shown that Theorem 3.4 remains true if (F1)–(F3) are replaced by the following *two* conditions, where (F2) is not present explicitly:

(G1) The function f is continuous on $S \times U$ and is Lipschitz in the state variable x, uniformly for $u \in U$; that is, there exists K such that

$$\|f(x, u) - f(y, u)\| \leq K \|x - y\|$$

whenever (x, u) and (y, u) are in $S \times U$.

(G2) The velocity set $f(x, U)$ is convex for every $x \in S$.

We can extend f from $S \times U$ to $\mathbb{R}^n \times U$ as follows: Let f_i denote the ith component function of f, $i = 1, 2, \ldots, n$. For each fixed $u \in U$, define a function $x \to \hat{f}_i(x, u)$ on $\mathbb{R}^n$ via

$$\hat{f}_i(x, u) = \min_{y \in S} \{f_i(y, u) + K \|y - x\|\}.$$

Then $x \to \hat{f}_i(x, u)$ agrees with $f_i(x, u)$ on S, and is globally Lipschitz of rank K, facts first noted by Hiriart-Urruty [19]; see also [10] and Rockafellar and Wets [21]. We then extend f componentwise by setting $f_i(x, u) = \hat{f}_i(x, u)$ for every $(x, u) \in \mathbb{R}^n \times U$.

The resulting function $f : \mathbb{R}^n \times U \to \mathbb{R}^n$ is continuous on $\mathbb{R}^n \times U$ and is globally Lipschitz of rank nK in the state variable x, uniformly for $u \in U$; that is,

$$\|f(x,u) - f(y,u)\| \leq nK\|x - y\|,$$

whenever (x,u) and (y,u) are in $\mathbb{R}^n \times U$. The *global* Lipschitz condition on the extended dynamics implies the linear growth condition needed for the global extendability of solutions, and possible nonconvexity of the velocity sets $f(x,U)$ for $x \notin S$ does not cause a problem in the required state constrained tracking considerations as their proofs in [12] show.

4.4. The case of unbounded S. The main results in this article (as well as [12] and [13]) have been stated for the case of compact S, but can be generalized to the case where S is merely assumed to be closed. Then the growth condition (F2) is indispensible. The generalizations follow from appropriately localized versions of the state constrained tracking properties employed in the compact case. We omit these details here.

SINGULAR STOCHASTIC CONTROL PROBLEMS*

F. DUFOUR† AND B. MILLER‡

Abstract. In this paper, we study an optimal singular stochastic control problem. By using a time transformation, this problem is shown to be equivalent to an auxiliary control problem defined as a combination of an optimal stopping problem and a classical control problem. For this auxiliary control problem, the controller must choose a stopping time (optimal stopping), and the new control variables belong to a compact set. This equivalence is obtained by showing that the (discontinuous) state process governed by a singular control is given by a time transformation of an auxiliary state process governed by a classical bounded control. It is proved that the value functions for these two problems are equal. For a general form of the cost, the existence of an optimal singular control is established under certain technical hypotheses. Moreover, the problem of approximating singular optimal control by absolutely continuous controls is discussed in the same class of admissible controls.

Key words. nonlinear stochastic systems, optimal control, singular control, time change

1. Introduction.

In this paper, the existence of optimal singular controls is studied for the nonlinear stochastic system defined by the following equation:

$$x_t \doteq \zeta + \int_0^t A(s, x_s)ds + \int_0^t B(s)du_s + \int_0^t D(s, x_s)dW_s, \tag{1}$$

where the functions A, B, D are deterministic, $\{W_t\}$ is a Brownian motion, and $\{u_t\}$ is the control. All the processes are assumed to be defined on a probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$. Let $K \subset \mathbb{R}^p$ be a closed convex cone and T be the finite horizon. The class of admissible controls, labeled $\mathfrak{C}^a$, is defined by the class of K-valued, continuous on the right with left-hand limits, $\{\mathcal{F}_t\}$-progressively measurable processes for which almost every sample path is of finite variation on the interval $[0, T]$:

$$v_T^u < \infty, \qquad Q\text{-a.s.}, \tag{2}$$

where $v_t^u = |u_0| + \lim_{n\to\infty} \sum_{k=1}^n |u_{tk/n} - u_{t(k-1)/n}|$ ($|z|$ is the norm of the vector z). For an admissible control u, the cost is given by

$$J[u] = E\left[\int_0^T k(t, x_t)du_t^c + \sum_{0\le t\le T} \int_0^{\Delta v_t^u} k\left(t, x_{t-} + B(t)\frac{\Delta u_t}{\Delta v_t^u}s\right)\frac{\Delta u_t}{\Delta v_t^u}ds + g(x_T, v_T^u)\right], \tag{3}$$

where g, k are deterministic functions and u^c is the continuous part of u (Δz_t denotes $z_t - z_{t-}$ for a process $\{z_t\}$ which is continuous on the right with left-hand limits). The interested reader may consult [42] for a nice interpretation of the cost defined by (3).

Singular stochastic control problems have received considerable attention in the literature. The authors do not pretend to present here an exhaustive panorama of singular control problems. However, the interested reader may consult the work of Boetius [9], especially the sections at the end of the chapters for an interesting and complete survey on stochastic singular control problems including theoretical results and applications.

This problem was first introduced by Bather and Chernoff [6] in 1967 by considering a simplified model for the control of a spaceship. It was noted for this special model that there was a connection between the singular control problem and optimal stopping problem. This link was established through the derivative of the value function of this initial singular control problem and the value function of the corresponding optimal stopping problem.

After this seminal work, this connection and its properties were extensively studied in different contexts but mainly in the one-dimensional case or in the multidimensional linear case. Two approaches were used: one is based on the theory of partial differential equations and on variational arguments, and can be found in the works of Alvarez [1, 2], Chow, Menaldi, and Robin [13], Karatzas [27], Karatzas and Shreve [31], and Menaldi and Taksar [36]. The other approach is related to probabilistic methods; see, for example, Baldursson [4], Boetius [8, 9], Boetius and Kohlmann [10], El Karoui and Karatzas [17, 18], Karatzas [28], and Karatzas and Shreve [29, 30].

Other problems, such as the dynamic programming principle, have been studied in a general context, for example, by Boetius [9], Haussmann and Suo [24], Fleming and Soner [21], and Zhu [43], as well as the stochastic maximum principle in [11].

Singular control problems correspond to many applications in diverse areas such as mathematical finance (see, for example, Baldursson and Karatzas [5], Chiarolla and Haussmann [12], Kobila [34], and Karatzas and Wang [33]), manufacturing systems (see, for example, Shreve, Lehoczky, and Gaver [41]), and queuing systems (see, for example, Martins and Kushner [35]).

In this paper, we focus our attention on the existence problem and the connection between the singular control and optimal stopping problems.

As we have already mentioned, the connection between singular stochastic control problems and optimal stopping problems has only been studied in the one-dimensional case or in the multidimensional linear case. A generalization of this connection to the multidimensional nonlinear case has been proposed by Benth and Reikvam [7] but under a very strong hypothesis, namely, the model of the state process must have a special structure in order to ensure that the ith component of $x(t)$ depends only on the ith component of the initial state process ζ. In the work of Boetius and Kohlmann [10], the result of Karatzas and Shreve [29] was generalized to a nonlinear one-dimensional state process. A multidimensional problem (see section 5.2 in [10]) was also considered but again under a strong hypothesis, since the control process could influence the state through only one variable.

In the present paper, this link is revisited by using a completely different approach. It will be shown that a multidimensional and nonlinear singular control problem can be converted into an auxiliary control problem where the control variables are of the classical type and where the controller must choose a stopping time (optimal stopping as described by Haussmann and Lepeltier, p. 851 in [22]). Consequently this auxiliary problem combines classical control and optimal stopping. Moreover, it will

be shown that these two optimization problems have the same value function. It must be pointed out that our result differs from existing results in the literature on two points. First, our auxiliary equivalent control problem is defined as a combination of optimal stopping and classical control, but in the literature, the equivalent control problem is formulated by a *pure* optimal stopping problem (the controller cannot influence the trajectory of the state process). Second, our connection is obtained directly through the value function, but in the literature, this link was established through the gradient of the value function of the singular control problem and the value of the related optimal stopping problem.

In this auxiliary control problem, the state processes are defined on a probability space $(\Omega, \mathcal{F}, P, \{\mathcal{G}_t\})$ by the following equations:

$$\xi_t \doteq \zeta + \int_0^t A(\eta_s, \xi_s)(1-\theta_s)ds + \int_0^t \theta_s B(\eta_s)\alpha_s ds + \int_0^t D(\eta_s, \xi_s)\sqrt{(1-\theta_s)}dV_s, \tag{4}$$

$$\eta_t \doteq \int_0^t (1-\theta_s)ds, \tag{5}$$

where $\{V_t\}$ is a Brownian motion. The new control variables are $\{(\alpha_t, \theta_t)\}$ and ρ, which is a $\{\mathcal{G}_t\}$-stopping time to be chosen by the controller. A key feature of this formulation is that the processes $\{(\alpha_t, \theta_t)\}$ belong to a compact set (labeled $\mathfrak{B}$; for the definition of this set, see the notation section at the end of the introduction). The cost is defined by

$$J[\alpha, \theta, \rho] = E\left[g(\xi_\rho, \rho - \eta_\rho) + \int_0^\rho \theta_s k(\eta_s, \xi_s)\alpha_s ds + G(\eta_\rho)\right] \tag{6}$$

(the function G is equal to $+\infty$ everywhere excepted at T, where it takes the value zero).

The idea used to show this equivalence result is based on a time transformation. This method, originally developed in deterministic control theory (for a complete exposition on the subject see the recent book [37] and the references therein), has been introduced recently in the stochastic context in [15, 38] and in [3]. In the latter reference, Alavarez, Gyllenberg, and Shepp used a time change technique to show that a one-dimensional singular control problem subject to a state-dependent killing rate is equivalent to an associated one-dimensional singular control problem with constant discount rate. Note that in this work, the time change does not depend explicitly on the control but is related to the integral of the discount factor, which is dependent on the state process.

Our result provides a set of weak hypotheses (Assumptions A1–A5, defined below) to ensure the existence of an optimal singular control for a general model, but it has the drawback that it provides no information about the nature and the properties of the optimal control. The existence of singular stochastic controls has been investigated by Haussmann and Suo for a general nonlinear model [23]. Using a compactification method, the authors show an existence result under certain technical conditions. Our result can be viewed as extending the work of Haussmann and Suo [23] in several directions.

We assume that the functions A and C must satisfy a Lipschitz condition but are not necessarily bounded as in [23], where these functions are required to be bounded continuous (for example, linear control problems cannot be considered).

Moreover, an important difference is that the form of the cost presented in our paper is more general. The part of the cost depending on the singular control in [23] has the following form:

$$E\left[\int_{[0,T)} c(s)du_s\right], \tag{7}$$

where $c(.)$ is lower semicontinuous and each of its components is strictly positive.

In our work, we propose a more general form given by

$$E\left[\int_0^T k(t,x_t)du_t^c + \sum_{0\le t\le T}\int_0^{\Delta v_t^u} k\left(t, x_{t-} + B(t)\frac{\Delta u_t}{\Delta v_t^u}s\right)\frac{\Delta u_t}{\Delta v_t^u}ds\right]. \tag{8}$$

It must be pointed out that the cost defined by (8) depends explicitly on the state process $\{x_t\}$, which is not the case in (7). Singular control problems defined with such general cost functions (see (3)) have been studied by many authors (for example, Zhu [43] studied a finite horizon problem and Taksar [42] and Davis and Zervos [14] analyzed infinite horizon problems). To the best knowledge of the authors, the work presented in this paper is the first attempt to derive an existence result for a multidimensional nonlinear model with such a general form for the cost. Zhu [43] derived a dynamic programming principle for a nonlinear model where D (with our notation) is assumed to be time independent (see the remark in [43, p. 229]) and nondegenerate. Taksar [42] considered a singular control problem where the state process satisfies an equation where A and D are time independent, A is bounded, and D is nondegenerate. The author showed the equivalence between the original singular problem and a linear programming problem. In [14], Davis and Zervos proved a verification theorem for a nonlinear time independent model. Two special one-dimensional cases were explicitly solved by the authors. The hypotheses used here are weaker than the assumptions previously cited.

Another important difference is that in [23], the variation of an admissible control needs to be integrable: $E[v_t^u] < \infty$ (see the proof of Proposition 3.4, p. 34, in Suo's thesis). Here a weaker hypothesis is introduced in the sense that the variation of an admissible control needs to satisfy the following assumption: $E[g(x_T, v_T^u)] < +\infty$, where g must satisfy $\lim_{t\to+\infty}\inf_{x\in\mathbb{R}^n} g(x,t) = +\infty$.

An interesting point is that a large number of results presented in the literature concern singular control problems where the control process is left continuous, rejecting the possibility of a jump at the terminal time (see, for example, Karatzas and Shreve [29]). In contrast, we consider singular controls which are continuous on the right and have limits on the left, allowing a jump at the terminal time. Our approach is more direct than in [23], where the left continuous control process is considered for which a modification is proposed, allowing jumps at the terminal time (see Remark 2.2 and section 4 in [23]). The advantage of our approach is that one can find an optimal solution to those singular control problems which do not admit optimal solutions when the control is assumed to be left continuous. In order to illustrate this point, the well-known example of nonexistence of Karatzas and Shreve in [29] is revisited in section 6.

In section 6, we also discuss some extensions and generalizations of the model initially presented in section 2. In particular, it is shown how our results can be modified in order to study other singular control problems, such as monotone follower problems (where the process $\{u_t\}$ is assumed to be a nondecreasing function).

The problem of approximating singular optimal control by absolutely continuous controls is studied in the final section. The main difficulty is that the control may have a jump at the terminal time and, consequently, the associated state process. Therefore, it is difficult to find a sequence of absolutely continuous control process $\{v_n(t)\}$ defined on $[0,T]$ and a sequence of filtration $\{\mathcal{F}_t^n\}$ defined on the probability space $(\Omega,\mathcal{F},P)$ satisfying both of the following conditions: $\{v_n(t)\}$ is $\{\mathcal{F}_t^n\}$-progressively measurable and $\lim_{n\to+\infty} x_n(T) = x(T)$, where $\{x_n(t)\}$ is the state process controlled by $\{v_n(t)\}$. Our equivalence result provides a way of overcoming this difficulty. However, it must be pointed out that although this problem is simpler, it remains difficult to solve mainly because one needs to approximate the combination of an optimal stopping problem (where the stopping is not necessarily bounded) and a classical control problem under the strong admissibility condition of the control and the stopping time given by $E[G(\eta_\rho)] = 0$.

In [15], the authors considered a general stochastic control problem where the controls have to satisfy an integral constraint. It was shown that there exists an optimal control within the class of generalized controls leading to impulse actions. The problem studied in [15] is related to singular control problems in the sense that the optimal generalized state process is given in terms of stochastic differential equations governed by a measure. However, the main difference is that the jump of the optimal state process cannot be explicitly expressed in terms of the jump of the optimal control process contrary to the case of the singular control problem ($\Delta x_t = B(t)\Delta u_t$). Although the general idea of time change is used here and in [15], the results presented in [15] cannot be applied to solve the problem studied in this paper. Indeed, in this work, it is required that the control process be only of finite variation contrary to [15], where the control is assumed to satisfy the integral constraint $P(\{\int_0^T |u_s|ds < M\}) = 1$ for a constant M (this point is a crucial hypothesis in [15]). Finally, it must be pointed out that in the present paper, the stopping time is not necessarily bounded, which represents a difficulty which makes the technique proposed in [15] inapplicable.

The paper is organized as follows. In section 2, we formulate the singular control problem. The description of the time transformation is presented in section 3. In section 4, an auxiliary control problem is introduced that will be shown to be equivalent to the original one. On the basis of known results, the existence theorem is proved for the auxiliary problem and consequently for the original problem in section 5. In section 6, we show how our existence result can be modified and applied to other problems, and we revisit a well-known example found in the literature. In the last part of the paper, it is shown that the optimal singular control can be approximated by continuous controls in a sense that will be defined below (see Theorem 7.5).

Now, we present some notation and terminology.

Notation. $\mathbb{N}_N$ is the set of the first N integers; that is, $\mathbb{N}_N = \{1,\dots,i,\dots,N\}$.

$\mathbb{N}^* \doteq \{k \in \mathbb{N} : k > 0\}$ and $\mathbb{R}_+ \doteq \{x \in \mathbb{R} : x \geq 0\}$.

For a vector x in $\mathbb{R}^p$, the ith component of x is denoted by x^i, $|x| \doteq \sum_{i=1}^p |x^i|$ is the norm of x, and 0_p is the zero vector in $\mathbb{R}^p$.

If A is an $m \times n$ matrix, the norm of A is defined by $|A| = \max_{|x|\leq 1} |Ax|$ and $(')$ denotes the transpose operation.

The indicator function of a set A is defined as $I_A(x)$.

The function δ defined on $\mathbb{N}\times\mathbb{N}$ is such that $\delta_{ij} = 1$ if $i = j$ and $\delta_{ij} = 0$ otherwise.

For $x \in \mathbb{R}$, x^+ is defined by $x^+ = \frac{1}{x}$ if $x \neq 0$ and by $x^+ = 0$ if $x = 0$.

If X is a metric space, then $\mathcal{B}(X)$ denotes its associated Borel σ-field.

A process is said to be *corlol* if it is continuous on the right and have limits on the left.

On the probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$, the mathematical expectation is denoted by $E_P[.]$, and for an $\mathbb{R}^p$-valued corlol process $\{u_t\}$, the total variation of $\{u_t\}$ on the interval $[0,t]$ is defined by

$$v_t^u \doteq |u_0| + \lim_{n\to\infty} \sum_{k=1}^{n} |u_{tk/n} - u_{t(k-1)/n}|, \tag{9}$$

and $\{u_t\}$ is said to be of finite variation on $[0,t]$ if $v_t^u < +\infty$, P-a.s.

Let $\{w_t\}$ be a real-valued corlol process of finite variation on $[0,T]$. $\{w_t\}$ is the distribution function of a signed measure defined on $[0,T]$; this measure is denoted by dw.

In order to define the state processes, let us introduce the following data:

- T is a fixed real number.
- K is a subset of $\mathbb{R}^p$.
- $\mathfrak{B} \doteq \{(x,y) \in K \times [0,1] : |x| \leq 1\}$.
- $A : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n$.
- $B : [0,T] \to \mathbb{R}^{n\times p}$.
- $D : [0,T] \times \mathbb{R}^n \to \mathbb{R}^{n\times m}$.
- $g : \mathbb{R}^n \times \mathbb{R}_+ \to \mathbb{R}_+$.
- $k : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}_+^p$.
- ζ is a fixed vector in $\mathbb{R}^n$.
- $G : \mathbb{R}_+ \to \overline{\mathbb{R}}_+$ such that $G(T) = 0$ and $G(t) = \infty$ for $t \neq T$.

The following assumptions will be used in the paper.

Assumption A1. The functions $A(.,.)$, $B(.)$, and $D(.,.)$ are continuous, and $\forall\, t \in \mathbb{R}_+$, there is a constant L_1 such that, $\forall\, (x,y) \in \mathbb{R}^n \times \mathbb{R}^n$,

$$|A(t,x) - A(t,y)| + |D(t,x) - D(t,y)| \leq L_1|x-y|.$$

Assumption A2. The function g is lower semicontinuous and satisfies $\lim_{t\to+\infty} \inf_{x\in\mathbb{R}^n} g(x,t) = +\infty$ and $(\forall x \in \mathbb{R}^n)$, $(\forall (y_1,y_2) \in \mathbb{R}_+ \times \mathbb{R}_+)$, if $y_1 \leq y_2$, then $g(x,y_1) \leq g(x,y_2)$.

Assumption A3. Each component of k is lower semicontinuous. There exists a continuously differentiable function $L : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ such that

$$\nabla_x L(t,x) B(t) = k(t,x). \tag{10}$$

Assumption A4. K is a closed cone which is convex.

Assumption A5. For all $(t,x) \in [0,T] \times \mathbb{R}^n$, the set $K(t,x)$, defined by

$$K(t,x) \doteq \{(A(t,x)(1-\theta) + \theta B(t)\alpha, (1-\theta)D(t,x)D(t,x)', 1-\theta) : (\alpha,\theta) \in \mathfrak{B}\},$$

is convex.

Unless clearly mentioned, we shall always follow the convention that $X_{0-} = 0$, P-a.s., for any *corlol* process $\{X_t\}$ defined on a probability space $(\Omega, \mathcal{F}, P)$.

2. Preliminaries and statement of the problem. In this section, we formulate the stochastic control problem presented in the introduction using the formulation described in [20] and in [22].

DEFINITION 2.1. *A singular control is defined by the following term:*

$$C \doteq (\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{u_t\}, \{W_t\}, \{x_t\}),$$

where

(i) $(\Omega, \mathcal{F}, P)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{F}_t\}$*;*

(ii) $\{u_t\}$ *is an* $\mathbb{R}^p$*-valued, corlol* $\{\mathcal{F}_t\}$*-progressively measurable process such that*

$$(\forall A \in \mathcal{B}([0,T]) \otimes \mathcal{F}), \quad \int_0^T I_A du_t \in K, \tag{11}$$

$$v_T^u < +\infty; \tag{12}$$

(iii) $\{W_t\}$ *is a standard* m*-dimensional* $\{\mathcal{F}_t\}$*-Brownian motion;*

(iv) $\{x_t\}$ *is an* $\mathbb{R}^n$*-valued, corlol* $\{\mathcal{F}_t\}$*-progressively measurable process such that* $(\forall t \in [0,T])$

$$x_t \doteq \zeta + \int_0^t A(s, x_s) ds + \int_{[0,t]} B(s) du_s + \int_0^t D(s, x_s) dW_s \tag{13}$$

and $x_{0-} = \zeta$*.*

We write $\mathfrak{C}$ *for the set of controls satisfying the previous conditions.*

The cost is given by

$$J[C] \doteq E_P \left[\int_0^T k(t, x_t) du_t^c + \sum_{0 \le t \le T} \int_0^{\Delta v_t^u} k\left(t, x_{t-} + B(t) \frac{\Delta u_t}{\Delta v_t^u} s\right) \frac{\Delta u_t}{\Delta v_t^u} ds \right.$$

$$\left. + g(x_T, v_T^u) \right]. \tag{14}$$

The set $\mathfrak{C}^a$ *of admissible controls is defined by*

$$\mathfrak{C}^a \doteq \{C \in \mathfrak{C} : J[C] < \infty\}. \tag{15}$$

The singular control problem is defined by the minimization of $J[C]$ on $\mathfrak{C}^a$.

3. Time transformation. In this section, it is assumed that on a probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ satisfying the usual hypotheses (completion and right continuity), there exists a process $\{u_t\}$ satisfying item (ii) of Definition 2.1.

Let us define the process $\{\Gamma_t\}$ by

$$\Gamma_t \doteq t + v_t^u. \tag{16}$$

$\{\Gamma_t\}$ is a corlol strictly increasing, $\{\mathcal{F}_t\}$-progressively measurable process. Denote by $\{\eta_t\}$ the right inverse of $\{\Gamma_t\}$:

$$\eta_t \doteq \inf\{s \ge 0 : \Gamma_s > t\}. \tag{17}$$

Therefore, applying Proposition 1.1 of Chapter V in [40], $\{\eta_t\}$ is a time change satisfying

$$\eta_{\Gamma_t} = t. \tag{18}$$

PROPOSITION 3.1. *There exists a process* $\{(\overline{\alpha}_t, \overline{\theta}_t)\}$, $\{\mathcal{F}_t\}$*-progressively measurable process taking value in* $\mathfrak{B}$ *such that* $(\forall j \in \mathbb{N}_p)$

$$v_t^u = \int_0^t \overline{\theta}_s d\Gamma_s \tag{19}$$

$$= \int_0^{\Gamma_t} \overline{\theta}_{\eta_s} ds, \tag{20}$$

$$u_t = \int_0^t \overline{\alpha}_s dv_s^u \tag{21}$$

$$= \int_0^{\Gamma_t} \overline{\theta}_{\eta_s} \overline{\alpha}_{\eta_s} ds. \tag{22}$$

Proof. By definition, the measure dv^u is absolutely continuous with respect to the measure $d\Gamma$ for almost all $\omega \in \Omega$. Consequently, using Proposition 3.13 of Chapter I in [26], it follows that there exists an $\{\mathcal{F}_t\}$-optional process $\{\widetilde{\theta}_t\}$ such that

$$v_t^u = \int_0^t \widetilde{\theta}_s d\Gamma_s. \tag{23}$$

Using the fact that $(\forall A \in \mathcal{B}([0,T]))\ dv^u(A) \leq d\Gamma(A)$, we obtain from (23) that

$$v_t^u = \int_0^t \overline{\theta}_s d\Gamma_s, \tag{24}$$

where $\overline{\theta}_s \doteq (0 \vee \widetilde{\theta}_s) \wedge 1$. Moreover, using Proposition 4.9 in [40, p. 8] and (24), we obtain (20).

Using the same arguments, it can be shown that there exists a process $\{\overline{\alpha}_t\}$ such that $|\overline{\alpha}_t| \leq 1$ and which satisfies (21). By combining (19), (21), and [40, Proposition 4.9, p. 8], we have (22), giving the result.

Now using (11), it can be shown easily that $\{\overline{\alpha}_t\}$ is a K-valued process giving the result. □

PROPOSITION 3.2. *The process* $\{\overline{\theta}_t\}$ *satisfies the following equality:*

$$\eta_t = \int_0^{\Gamma_t} (1 - \overline{\theta}_{\eta_s}) ds. \tag{25}$$

Proof. Combining (16) and (20), we obtain that

$$\int_0^{\Gamma_t} (1 - \overline{\theta}_{\eta_s}) ds = \Gamma_t - v_t^u = t.$$

Consequently, using (18), we have

$$\int_0^{\Gamma_t} (1 - \overline{\theta}_{\eta_s}) ds = \eta_{\Gamma_t}.$$

Since $\{\int_0^t (1 - \overline{\theta}_{\eta_s}) ds\}$ and $\{\eta_t\}$ are increasing continuous processes and $\{\Gamma_t\}$ is a strictly increasing corlol process, the result follows. □

4. Auxiliary control and equivalence result. We introduce an auxiliary control problem given in terms of a classical control problem and an optimal stopping problem. It is shown that this problem is equivalent to the initial one. The new control variables are defined by $\{(\alpha_t, \theta_t)\}$ and by ρ, which is a $\{\mathcal{G}_t\}$-stopping time to be chosen by the controller (see Definition 4.1 below). A key property of the auxiliary control problem is that the new control variables $\{(\alpha_t, \theta_t)\}$ take their values in a compact set.

DEFINITION 4.1. *An auxiliary control is defined by the following term:*

$$\Psi \doteq (\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\alpha_t, \theta_t)\}, \{V_t\}, \{\Lambda_t\}, \rho),$$

where

(i) $(\Omega, \mathcal{G}, Q)$ *is a complete probability space with a right continuous complete filtration* $\{\mathcal{G}_t\}$*;*

(ii) $\{(\alpha_t, \theta_t)\}$ *is a* $\mathfrak{B}$*-valued,* $\{\mathcal{G}_t\}$*-progressively measurable process;*

(iii) $\{V_t\}$ *is a standard* m*-dimensional* $\{\mathcal{G}_t\}$*-Brownian motion;*

(iv) ρ *is a* $\{\mathcal{G}_t\}$*-stopping time such that*

$$\rho < +\infty, \quad Q\text{-a.s.}; \tag{26}$$

(v) $\{\Lambda_t \doteq (\xi_t', \eta_t)'\}$ *is an* $\mathbb{R}^{n+1}$*-valued,* $\{\mathcal{G}_t\}$*-progressively measurable process such that*

$$\begin{aligned} \xi_t &\doteq \zeta + \int_0^t A(\eta_s, \xi_s)(1-\theta_s)ds + \int_0^t \theta_s B(\eta_s)\alpha_s ds \\ &\quad + \int_0^t D(\eta_s, \xi_s)\sqrt{(1-\theta_s)}dV_s, \end{aligned} \tag{27}$$

$$\eta_t \doteq \int_0^t (1-\theta_s)ds \tag{28}$$

for $t \in [0, \rho]$.

We write Υ *for the set of controls satisfying the previous conditions. The cost is given by*

$$\mathcal{M}[\Psi] \doteq E_Q\left[g(\xi_\rho, \rho - \eta_\rho) + \int_0^\rho \theta_s k(\eta_s, \xi_s)\alpha_s ds + G(\eta_\rho)\right]. \tag{29}$$

The set Υ^a *of admissible auxiliary controls is defined by*

$$\Upsilon^a \doteq \{\Psi \in \Upsilon : \mathcal{M}[\Psi] < \infty\}. \tag{30}$$

The auxiliary control problem is defined by the minimization of $\mathcal{M}[\Psi]$ on Υ^a.

In this section, the equivalence between the auxiliary and the initial control problems is shown.

THEOREM 4.2. *Assume Assumption* A1. *Let* C *be an element of* $\mathfrak{C}^a$*. Then there exists an auxiliary control* Ψ *in* Υ^a *such that*

$$\mathcal{M}[\Psi] = J[C]. \tag{31}$$

Proof. Let us define C as $\big(\overline{\Omega}, \overline{\mathcal{F}}, \overline{P}, \{\overline{\mathcal{F}}_t\}, \{u_t\}, \{W_t\}, \{x_t\}\big)$. Define the process $\{\Gamma_t\}$ by (16) and its right inverse $\{\eta_t\}$ by (17). Clearly, the probability space

$(\overline{\Omega}, \overline{\mathcal{F}}, \overline{P}, \{\overline{\mathcal{F}}_{\eta_t}\})$ satisfies the usual hypotheses. Since $\{u_t\}$ satisfies item (i) of Definition 2.1, we can apply the results of the previous section to obtain the existence of an $\{\mathcal{F}_t\}$-progressively measurable process $\{(\overline{\alpha}_t, \overline{\theta}_t)\}$ satisfying (19) and (21) (see Proposition 3.1). Therefore, we have the process $\{(\alpha_t, \theta_t)\}$, where $\alpha_t \doteq \overline{\alpha}_{\eta_t}$ and $\theta_t \doteq \overline{\theta}_{\eta_t}$ is $\{\overline{\mathcal{F}}_{\eta_t}\}$-progressively measurable.

Using Proposition 1.1 in [40, Chapter V], Γ_T is an $\{\overline{\mathcal{F}}_{\eta_t}\}$-stopping time and $\Gamma_T < +\infty$ by definition since $v_T^u < +\infty$.

Let us introduce the following stochastic differential equation:

$$\begin{aligned}\overline{\xi}_t = \zeta &+ \int_0^t A(\eta_s, \overline{\xi}_s)(1-\theta_s)ds + \int_0^t \theta_s B(\eta_s)\alpha_s ds \\ &+ \int_0^t D(\eta_s, \overline{\xi}_s)\sqrt{(1-\theta_s)(1-\theta_s)^+}dW_{\eta_s}.\end{aligned} \tag{32}$$

Using Assumption A1 and [39, Theorem 6, p. 194], it follows that the solution to the previous equation exists and is unique and continuous on the probability space $\big(\overline{\Omega}, \overline{\mathcal{F}}, \overline{P}, \{\overline{\mathcal{F}}_{\eta_t}\}\big)$.

Using [40, Proposition 4.9, p. 8], Propositions 3.1 and 3.2, and (18), it follows that $\forall\, t \in [0, \Gamma_T]$

$$\int_0^{\Gamma_t} A(\eta_s, \overline{\xi}_s)(1-\theta_s)ds = \int_0^t A(s, \overline{\xi}_{\Gamma_s})ds \quad \text{and} \quad \int_0^{\Gamma_t} \theta_s B(\eta_s)\alpha_s ds = \int_{[0,t]} B(s)du_s. \tag{33}$$

Define the process $\{\overline{W}_t\}$ by $\overline{W}_t = \int_0^t \sqrt{(1-\theta_s)(1-\theta_s)^+}dW_{\eta_s}$. It is a continuous $\{\overline{\mathcal{F}}_{\eta_t}\}$-local martingale such that

$$\langle \overline{W}^i, \overline{W}^j \rangle_t = \int_0^t (1-\theta_s)(1-\theta_s)^+ d\langle W_\eta^i, W_\eta^j \rangle_s = \delta_{ij}\int_0^t (1-\theta_s)(1-\theta_s)^+ d\eta_s = \delta_{ij}\eta_t,$$

where the last equality has been obtained using Proposition 3.2. Moreover, it is easy to show that $\overline{W}_{\Gamma_t} = W_t$. Now using [32, Proposition 4.8, p. 176] and (18), it follows that

$$\begin{aligned}\int_0^{\Gamma_t} D(\eta_s, \overline{\xi}_s)\sqrt{(1-\theta_s)(1-\theta_s)^+}dW_{\eta_s} &= \int_0^{\Gamma_t} D(\eta_s, \overline{\xi}_s)d\overline{W}_s \\ &= \int_0^t D(s, \overline{\xi}_{\Gamma_s})dW_s.\end{aligned} \tag{34}$$

Finally, combining (33) and (34), we obtain that $\{\overline{\xi}_{\Gamma_t}\}$ is a *corlol* process which satisfies (13). From Theorem 6 in [39, p. 194], it follows that (13) has a unique solution and, consequently, $\overline{\xi}_{\Gamma_t} = x_t$

Let $(\widetilde{\Omega}, \widetilde{\mathcal{F}}, \widetilde{P}, \{\widetilde{\mathcal{F}}_t\})$ be a filtered probability space supporting a standard m-dimensional Brownian motion $\{\widetilde{W}_t\}$, and set

$$\Omega = \overline{\Omega} \times \widetilde{\Omega}, \qquad \mathcal{F} = \overline{\mathcal{F}} \otimes \widetilde{\mathcal{F}}, \qquad P = \overline{P} \otimes \widetilde{P}, \qquad \mathcal{F}_t = \overline{\mathcal{F}}_{\eta_t} \otimes \widetilde{\mathcal{F}}_t.$$

A process $\overline{X}$ defined on $\overline{\Omega}$ may be viewed as being defined on Ω by setting $X(\overline{\omega}, \widetilde{\omega}) = \overline{X}(\overline{\omega})$. For simplicity of exposition, the same notation will be used in the rest of the paper to identify the process $\overline{X}$ and X. This approach will also be applied to the processes defined on $\widetilde{\Omega}$.

Let us introduce the process $\{V_t\}$ defined on $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ by

$$V_t = \int_0^t \sqrt{(1-\theta_s)^+} dW_{\eta_s} + \int_0^t \sqrt{1-(1-\theta_s)(1-\theta_s)^+} d\widetilde{W}_s. \tag{35}$$

Clearly, $\{W_{\eta_t}\}$ and $\{\widetilde{W}_t\}$ are two independent continuous $\{\mathcal{F}_t\}$-martingales. Therefore, $\{V_t\}$ is a continuous $\{\mathcal{F}_t\}$-local martingale such that

$$\langle V^i, V^j \rangle_t = \delta_{ij} \left[\int_0^t (1-\theta_s)^+ d\eta_s + \int_0^t (1-(1-\theta_s)(1-\theta_s)^+) ds \right].$$

However, using Proposition 3.2, it follows that $\langle V^i, V^j \rangle_t = \delta_{ij}\, t$, which, by Levy's characterization theorem, gives that $\{V_t\}$ is a standard m-dimensional $\{\mathcal{F}_t\}$-Brownian motion.

On $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$, let us consider the equation

$$\xi_t = \zeta + \int_0^t A(\eta_s, \xi_s)(1-\theta_s) ds + \int_0^t \theta_s B(\eta_s)\alpha_s ds + \int_0^t D(\eta_s, \xi_s)\sqrt{1-\theta_s} dV_s. \tag{36}$$

Since

$$\int_0^t D(\eta_s, \xi_s)\sqrt{(1-\theta_s)} dV_s = \int_0^t D(\eta_s, \xi_s)\sqrt{(1-\theta_s)(1-\theta_s)^+} dW_{\eta_s},$$

it can be shown that $\{\bar{\xi}_t\}$, defined by (32), is a solution to (36).

Let $(\Omega, \mathcal{G}, Q)$ be the completion of the probability space $(\Omega, \mathcal{F}, P)$. Denote by $\mathcal{N}$ the σ-field, generated by all Q-null sets. Introduce $\mathcal{G}_t = \bigcap_{s>t} (\mathcal{F}_s \vee \mathcal{N})$. Then the probability space $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$ satisfies the usual hypotheses (item (i) in Definition 4.1). Clearly, Γ_T is a $\{\mathcal{G}_t\}$-stopping time and $\{(\alpha_t, \theta_t)\}$ is a $\{\mathcal{G}_t\}$-progressively measurable process. Moreover, using Lemmas A.1 and A.2 in [15], it follows that $\{V_t\}$ is a $\{\mathcal{G}_t\}$-Brownian motion.

Let us define the auxiliary control Ψ by

$$\left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\alpha_t, \theta_t)\}, \{V_t\}, \{(\bar{\xi}'_t, \eta_t)'\}, \Gamma_T\right).$$

To complete the proof, it remains to be shown that the costs are equal: $\mathcal{M}[\Psi] = J[C]$. Since $\eta_{\Gamma_T} = T$, we have by definition of $\{\Gamma_t\}$ that $\Gamma_T - \eta_{\Gamma_T} = v_T^u$. Therefore,

$$E_P[g(x_T, v_T^u)] = E_Q[g(\xi_{\Gamma_T}, \Gamma_T - \eta_{\Gamma_T})]. \tag{37}$$

Denote by $\{\tau_n\}_{n\in\mathbb{N}^*}$ the sequence of $\{\overline{\mathcal{F}}_t\}$-stopping times which exhausts the jumps of $\{\Gamma_t\}$. Since $\{\eta_t\}$ is a time change on $\left(\overline{\Omega}, \overline{\mathcal{F}}, \overline{P}, \{\overline{\mathcal{F}}_t\}\right)$, and using [25, Lemma 10.5(a)], it follows that $\{\Gamma_{\tau_n}\}_{n\in\mathbb{N}^*}$ is a sequence of $\{\overline{\mathcal{F}}_{\eta_t}\}$-stopping times. We have that $\{\Gamma_{\tau_n -} > t\} = \{\eta_t < \tau_n\} \in \overline{\mathcal{F}}_{\eta_t}$; therefore, $\{\Gamma_{\tau_n -}\}_{n\in\mathbb{N}^*}$ is a sequence of $\{\overline{\mathcal{F}}_{\eta_t}\}$-stopping times. Remark that

$$\bigcup_{n=1}^{\infty} [\![\Gamma_{\tau_n -}, \Gamma_{\tau_n}]\!] \subset \{(t,\omega) \in \mathbb{R}_+ \times \Omega : \theta_t = 1\}.$$

Define

$$\mathcal{D} \doteq \{(t,\omega) \in \mathbb{R}_+ \times \Omega : \theta_t = 1\} - \bigcup_{n=1}^{\infty} [\![\Gamma_{\tau_n -}, \Gamma_{\tau_n}]\!].$$

Consequently,

$$(\forall t \in [0,T]), \quad u_t = \int_0^{\Gamma_t} I_{\{\theta_s<1\}}\theta_s\alpha_s ds + \int_0^{\Gamma_t} I_{\{\theta_s=1\}}\theta_s\alpha_s ds$$
$$= \int_0^{\Gamma_t} [I_{\{\theta_s<1\}} + I_{\mathcal{D}}]\theta_s\alpha_s ds + \sum_{n\in\mathbb{N}^*} \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} \alpha_s ds\, I_{[\![\tau_n,T]\!]}.$$

For $(s,\omega) \in \bigcup_{n=1}^{\infty} [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!]$, we have $I_{\{\theta_s<1\}}(\omega) + I_{\mathcal{D}}(t,\omega) = 0$. So the process $\{\int_0^t [I_{\{\theta_s<1\}} + I_{\mathcal{D}}]\theta_s\alpha_s ds\}$ is $\{\Gamma_t\}$-continuous. Consequently, the decomposition of the process $\{u_t\}$ is given by

$$u_t^c = \int_0^{\Gamma_t} [I_{\{\theta_s<1\}} + I_{\mathcal{D}}]\theta_s\alpha_s ds,$$
$$u_t^d = \sum_{n\in\mathbb{N}^*} \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} \alpha_s ds\, I_{[\![\tau_n,T]\!]}.$$

Clearly, we have

$$\int_0^{\Gamma_T} \theta_s k(\eta_s, \overline{\xi}_s)\alpha_s ds = \int_0^{\Gamma_t} k(\eta_s, \overline{\xi}_s)[I_{\{\theta_s<1\}} + I_{\mathcal{D}}]\theta_s\alpha_s ds$$
$$+ \sum_{n\in\mathbb{N}^*} \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} k(\eta_s, \overline{\xi}_s)\alpha_s ds\, I_{[\![\tau_n,T]\!]}. \tag{38}$$

Moreover, from Proposition 1.4, Chapter V in [40], we obtain that

$$\int_0^{\Gamma_t} k(\eta_s, \overline{\xi}_s)[I_{\{\theta_s<1\}} + I_{\mathcal{D}}]\theta_s\alpha_s ds = \int_0^t k(s, \overline{\xi}_{\Gamma_s}) du_s^c. \tag{39}$$

Since $\{\eta_t\}$ is the right inverse of $\{\Gamma_t\}$, we have that $(\forall (s,\omega) \in [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!])$, $\eta_s = \tau_n$, and with (25), it gives $(\forall (s,\omega) \in [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!])$, $\theta_s = \overline{\theta}_{\tau_n} = 1$. By definition of the processes $\{\alpha_t\}$, we have

$$(\forall (s,\omega) \in [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!]), \quad \alpha_s = \overline{\alpha}_{\tau_n}. \tag{40}$$

Note that $\{\tau_n\}_{n\in\mathbb{N}^*}$ exhausts the jumps of $\{u_t\}$. Using (25), we have that

$$\Delta u_{\tau_n} = \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} \overline{\theta}_{\tau_n}\overline{\alpha}_{\tau_n} ds = \Delta\Gamma_{\tau_n}\overline{\alpha}_{\tau_n}. \tag{41}$$

Using the fact that $\Delta\Gamma_{\tau_n} = \Delta v^u_{\tau_n}$ and combining (40) and (41), we obtain that

$$(\forall (s,\omega) \in [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!]), \quad \alpha_s = \frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}}. \tag{42}$$

Consequently, we have that

$$(\forall (s,\omega) \in [\![\Gamma_{\tau_n-}, \Gamma_{\tau_n}]\!]), \quad \overline{\xi}_s = \overline{\xi}_{\Gamma_{\tau_n-}} + \int_{\Gamma_{\tau_n-}}^{s} \theta_t B(\eta_t)\alpha_t dt$$
$$= \overline{\xi}_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}}(s - \Gamma_{\tau_n-}). \tag{43}$$

Therefore,

$$\int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} k(\eta_s,\overline{\xi}_s)\alpha_s ds = \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} k\left(\tau_n, \overline{\xi}_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}}(s-\Gamma_{\tau_n-})\right)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} ds$$

$$= \int_0^{\Delta v^u_{\tau_n}} k\left(\tau_n, \overline{\xi}_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}}s\right)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} ds. \tag{44}$$

Combining (38), (39), and (44), we obtain that

$$\int_0^{\Gamma_T} \theta_s k(\eta_s,\overline{\xi}_s)\alpha_s ds = \int_0^t k(s,\overline{\xi}_{\Gamma_s}) du^c_s$$

$$+ \sum_{0\le t\le T} \int_0^{\Delta v^u_t} k\left(t, x_{t-} + B(t)\frac{\Delta u_t}{\Delta v^u_t}s\right)\frac{\Delta u_t}{\Delta v^u_t} ds. \tag{45}$$

Using (37) and (45), we can conclude that Ψ is in Υ^a and satisfies $\mathcal{M}[\Psi] = J[C]$, thus giving the result. □

PROPOSITION 4.3. *Suppose* $(\Omega,\mathcal{G},Q,\{\widetilde{\mathcal{G}}_t\},\{(\alpha_t,\theta_t)\},\{V_t\},\{(\xi'_t,\eta_t)'\},\rho)$ *is an element in* Υ^a. *Let* $\{\Gamma_t\}$ *be the right inverse of* $\{\eta_t\}$. *Then* $\{\Gamma_{\eta_t}\}$ *is a time change on* $(\Omega,\mathcal{G},Q,\{\widetilde{\mathcal{G}}_t\})$. *Moreover, the process* $\{\int_0^t \sqrt{1-\theta_s}dV_s\}$ *is a* $\{\widetilde{\mathcal{G}}_{\Gamma_{\eta_t}}\}$ *martingale.*

Proof. The first item is a straightforward consequence from Lemma 1 in [19]. Now let us denote $\int_0^t \sqrt{1-\theta_s}dV_s$ by $\widetilde{V}_t$. Using the fact that $\Gamma_{\eta_t} \ge t$, we obtain that $\{\widetilde{V}_t\}$ is adapted to $\{\widetilde{\mathcal{G}}_{\Gamma_{\eta_t}}\}$ and $\forall\, j \in \mathbb{N}_m$

$$E_Q[(\widetilde{V}^j_{\Gamma_{\eta_t}} - \widetilde{V}^j_t)^2] = E_Q[(\widetilde{V}^j_{\Gamma_{\eta_t}})^2 - (\widetilde{V}^j_t)^2]$$
$$= E_Q[\eta_{\Gamma_{\eta_t}} - \eta_t].$$

However, $\eta_{\Gamma_{\eta_t}} = \eta_t$, implying that $\{\widetilde{V}_t\}$ and $\{\widetilde{V}_{\Gamma_{\eta_t}}\}$ are indistinguishable, thus giving the result. □

THEOREM 4.4. *Assume Assumptions* A1, A2, A3, *and* A4. *Let* Ψ *be an element in* Υ^a. *Then there exists an admissible control* C *in* $\mathfrak{C}^a$ *such that*

$$J[C] \le \mathcal{M}[\Psi]. \tag{46}$$

Proof. Denote Ψ by $(\Omega,\mathcal{G},Q,\{\widetilde{\mathcal{G}}_t\},\{(\alpha_t,\theta_t)\},\{V_t\},\{(\xi'_t,\eta_t)'\},\rho)$. Let $\{\Gamma_t\}$ be the right inverse of $\{\eta_t\}$. Using Proposition 1.1, Chapter V in [40], $\{\Gamma_t\}$ is a time change on $(\Omega,\mathcal{G},Q,\{\widetilde{\mathcal{G}}_t\})$. Consequently, let us define by $\{\tau_n\}_{n\in\mathbb{N}_*}$ the sequence of $\{\widetilde{\mathcal{G}}_{\Gamma_t}\}$-stopping times which exhaust the jumps of $\{\Gamma_t\}$. Using [19, Lemma 11(a)], it follows that $\{\Gamma_{\tau_n}\}$ is a sequence of $\{\widetilde{\mathcal{G}}_t\}$-stopping times. Using Proposition 4.3, we can define the filtration $\{\mathcal{G}_t\}$ by $\mathcal{G}_t \doteq \widetilde{\mathcal{G}}_{\Gamma_{\eta_t}}$, which is right continuous and complete. Moreover, using [19, Remark (b), p. 73], it follows that $\{\Gamma_{\tau_n-}\}$ is a sequence of $\{\mathcal{G}_t\}$-stopping times. Note that the introduction of the filtration $\{\mathcal{G}_t\}$ is necessary since $\{\Gamma_{\tau_n-}\}$ may not be a stopping time with respect to $\{\widetilde{\mathcal{G}}_t\}$.

Let us denote $\int_0^t \sqrt{1-\theta_s}dV_s$ by $\widetilde{V}_t$. Clearly, the processes $\{(\alpha_t,\theta_t)\}$, $\{(\xi'_t,\eta_t)'\}$ are $\{\mathcal{G}_t\}$-progressively measurable and ρ is a $\{\mathcal{G}_t\}$ stopping time. Applying Proposition 4.3, the process $\{\xi_t\}$ satisfies the following equation:

$$\xi_t \doteq \zeta + \int_0^t A(\eta_s,\xi_s)(1-\theta_s)ds + \int_0^t \theta_s B(\eta_s)\alpha_s ds + \int_0^t D(\eta_s,\xi_s)d\widetilde{V}_s.$$

Clearly, $\{\mathcal{G}_{\Gamma_t}\}$ is a right continuous complete filtration. Since $\Psi \in \Upsilon^a$, we have that $\Gamma_T = \rho$.

Define

$$u_t \doteq \int_0^{\Gamma_t} \theta_s \alpha_s ds. \tag{47}$$

Since $\{(\alpha_t, \theta_t)\}$ is a $\mathfrak{B}$-valued process, it follows easily that the process $\{u_t\}$ satisfies (11). Moreover, it is easy to check that $\int_0^{\Gamma_t} I_{\{\eta_s \in (a,b]\}} \theta_s \alpha_s ds = \int_{(a,b]} du_s$ for any real $a < b$. By using the fact that $B(.)$ is continuous and a monotone class theorem, we obtain that

$$\int_0^{\Gamma_t} B(\eta_s)\theta_s \alpha_s ds = \int_0^t B(s) du_s. \tag{48}$$

From Proposition 3.2 and [32, Theorem 4.13, p. 178], it follows that $\{\widetilde{V}_{\Gamma_t}\}$ is a standard m-dimensional $\{\mathcal{G}_{\Gamma_t}\}$-Brownian motion. From the definition of $\{\eta_t\}$, [40, Proposition 4.9, p. 8], [32, Theorem 4.8, p. 176], and (48), it follows that on the filtered probability space $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_{\Gamma_t}\})$, the process $\{\xi_{\Gamma_t}\}$ satisfies the following equation on $[0, T]$:

$$\xi_{\Gamma_t} = \zeta + \int_0^t A(s, \xi_{\Gamma_s}) ds + \int_{[0,t]} B(s) du_s + \int_0^t D(s, \xi_{\Gamma_s}) d\widetilde{V}_{\Gamma_s}. \tag{49}$$

From the definition of $\{u_t\}$ (see (47)), we have that

$$v_T^u \leq \int_0^\rho \theta_s \sum_{i=1}^p |\alpha_s| ds,$$

and since the process $\{(\alpha_t, \theta_t)\}$ takes its value in $\mathfrak{B}$ and using equation (28), we obtain that

$$v_T^u \leq \rho - \eta_\rho. \tag{50}$$

Since $\Psi \in \Upsilon^a$ and $\lim_{t \to +\infty} \inf_{x \in \mathbb{R}^n} g(x,t) = +\infty$ (see Assumption A2), we have that $\rho - \eta_\rho < \infty$ Q-a.s., and therefore $\{u_t\}$ is of finite variation on $[0, T]$: $v_T^u < \infty$ Q-a.s.

Using (50) and Assumption A2, it follows that

$$E_Q\left[g(\xi_\rho, \rho - \eta_\rho)\right] \geq E_Q\left[g(x_T, v_T^u)\right]. \tag{51}$$

As in the proof of Theorem 4.2, we have $(\forall (s,\omega) \in [\![\Gamma_{\tau_n -}, \Gamma_{\tau_n}]\!]), \eta_s = \tau_n$, and with (25), it gives $\theta_s = 1$. However, it must be pointed out that (42) may not be valid here. Therefore, we obtain

$$(\forall (s,\omega) \in [\![\Gamma_{\tau_n -}, \Gamma_{\tau_n}]\!]), \quad \overline{\xi}_s = \overline{\xi}_{\Gamma_{\tau_n -}} + \int_{\Gamma_{\tau_n -}}^s B(\tau_n)\alpha_t dt. \tag{52}$$

Using Assumption A3 and the previous equation, we have that

$$\begin{aligned} L(\tau_n, \xi_{\Gamma_{\tau_n}}) - L(\tau_n, \xi_{\Gamma_{\tau_n -}}) &= \int_{\Gamma_{\tau_n -}}^{\Gamma_{\tau_n}} \frac{d}{ds} L\left(\tau_n, \xi_{\Gamma_{\tau_n -}} + \int_{\Gamma_{\tau_n -}}^s B(\tau_n)\alpha_t dt\right) ds \\ &= \int_{\Gamma_{\tau_n -}}^{\Gamma_{\tau_n}} k\left(\tau_n, \xi_{\Gamma_{\tau_n -}} + \int_{\Gamma_{\tau_n -}}^s B(\tau_n)\alpha_t dt\right) \alpha_s ds. \end{aligned} \tag{53}$$

However, note that $\Delta u_{\tau_n} = \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} \alpha_t dt$, and so it follows from using Assumption A3 again that

$$\begin{aligned} L(\tau_n, \xi_{\Gamma_{\tau_n}}) - L(\tau_n, \xi_{\Gamma_{\tau_n-}}) &= L(\tau_n, \xi_{\Gamma_{\tau_n-}} + B(\tau_n)\Delta u_{\tau_n}) - L(\tau_n, \xi_{\Gamma_{\tau_n-}}) \\ &= \int_0^{\Delta v^u_{\tau_n}} \frac{d}{ds} L\left(\tau_n, \xi_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} s\right) ds \\ &= \int_0^{\Delta v^u_{\tau_n}} k\left(\tau_n, \xi_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} s\right) \frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} ds. \end{aligned} \tag{54}$$

Combining (53) and (54), we have that

$$\begin{aligned} &\int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} k\left(\tau_n, \xi_{\Gamma_{\tau_n-}} + \int_{\Gamma_{\tau_n-}}^{s} B(\tau_n)\alpha_t dt\right) \alpha_s ds \\ &\qquad = \int_0^{\Delta v^u_{\tau_n}} k\left(\tau_n, \xi_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} s\right) \frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} ds. \end{aligned} \tag{55}$$

Similarly to the proof of Theorem 4.2, we obtain that

$$\int_0^{\rho} \theta_s k(\eta_s, \xi_s)\alpha_s ds = \int_0^T k(s, \xi_{\Gamma_s}) du^c_s + \sum_{n\in\mathbb{N}^*} \int_{\Gamma_{\tau_n-}}^{\Gamma_{\tau_n}} k(\eta_s, \xi_s)\alpha_s ds \, I_{[\![\tau_n, T]\!]}. \tag{56}$$

Using (55) and (56), we obtain that

$$\begin{aligned} \int_0^{\rho} \theta_s k(\eta_s, \xi_s)\alpha_s ds &= \int_0^T k(s, \xi_{\Gamma_s}) du^c_s \\ &\quad + \sum_{n\in\mathbb{N}^*} \int_0^{\Delta v^u_{\tau_n}} k\left(\tau_n, \xi_{\Gamma_{\tau_n-}} + B(\tau_n)\frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} s\right) \frac{\Delta u_{\tau_n}}{\Delta v^u_{\tau_n}} ds \, I_{[\![\tau_n, T]\!]} \\ &= \int_0^T k(s, \xi_{\Gamma_s}) du^c_s + \sum_{0\le t\le T} \int_0^{\Delta v^u_t} k\left(t, \xi_{\Gamma_{t-}} + B(t)\frac{\Delta u_t}{\Delta v^u_t} s\right) \frac{\Delta u_t}{\Delta v^u_t} ds. \end{aligned} \tag{57}$$

Consequently, combining (51) and (57), the control

$$C \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_{\Gamma_t}\}, \left\{\int_0^{\Gamma_t} \theta_s \alpha_s ds\right\}, \{\widetilde{V}_{\Gamma_t}\}, \{\xi_{\Gamma_t}\}\right)$$

is such that $J[C] \le \mathcal{M}[\Psi]$, and therefore C is in $\mathfrak{C}^a$, thus giving the result. □

An immediate consequence of Theorems 4.2 and 4.4 is the following result.

THEOREM 4.5. *Assume Assumptions* A1, A2, A3*, and* A4*. The singular and the auxiliary control problems are equivalent:*

$$\inf_{C\in\mathfrak{C}^a} J[C] = \inf_{\Psi\in\Upsilon^a} \mathcal{M}[\Psi]. \tag{58}$$

5. Existence of optimal singular control. The existence of an optimal control for the singular control problem is guaranteed by the following result.

THEOREM 5.1. *Assume Assumptions* A1, A2, A3, A4*, and* A5*. For the singular control problem there exists an optimal control $C^* \in \mathfrak{C}^a$:*

$$J[C^*] = \inf_{C\in\mathfrak{C}^a} J[C]. \tag{59}$$

Proof. The existence of C^* is obtained through the equivalence result obtained in Theorem 4.5. Let us introduce the set $\mathcal{H}$ of controls $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\alpha_t, \theta_t)\}, \{V_t\}, \{\Lambda_t\}, \rho)$, for which $(\Omega, \mathcal{G}, Q)$ is a probability space with filtration $\{\mathcal{G}_t\}$, the processes $\{(\alpha_t, \theta_t)\}$, $\{V_t\}, \{\Lambda_t\}, \rho$ satisfy items (i)–(v) in Definition 4.1, and such that

$$\mathcal{N}[\Psi] \doteq E_Q \left[g(\xi_\rho, \rho - \eta_\rho) + \int_0^\rho \theta_s k(\eta_s, \xi_s) \alpha_s ds + G(\eta_\rho) \right].$$

Define the corresponding admissible class of controls $\mathcal{H}^a \doteq \{\Psi \in \mathcal{H} : \mathcal{N}[\Psi] < \infty\}$. Using the fact that $\mathfrak{B}$ is a compact set and Remark 4.3 in [22], and applying Corollary 4.8 in [22], it follows that there exists an optimal control $\widetilde{\Psi}$ in the class of control $\mathcal{H}^a$ such that

$$\inf_{\Psi \in \mathcal{H}^a} \mathcal{N}[\Psi] = \mathcal{N}[\widetilde{\Psi}].$$

Note that Corollary 4.8 in [22] provides a way of showing the existence of an optimal control in the class $\mathcal{H}^a$, but in order to use our equivalence result given by Theorem 4.5, we need to find an optimal control in the class of controls Υ^a. It must be pointed out that $\Upsilon^a \subset \mathcal{H}^a$ (for the definition of Υ^a, see Definition 4.1), since a control in $\mathcal{H}^a$ is defined on a filtered probability space, which is not necessarily right continuous, and is completely contrary to a control in Υ^a, which must be defined on a filtered probability space satisfying the usual hypotheses (right continuity and completeness). However, by using Lemmas A.1 and A.2 in [15], it can be shown that there exists a modification Ψ^* in Υ^a of $\widetilde{\Psi}$ such that $\mathcal{M}[\Psi^*] = \mathcal{N}[\widetilde{\Psi}]$. Since $\Upsilon^a \subset \mathcal{H}$, it follows that $\inf_{\Psi \in \Upsilon^a} \mathcal{M}[\Psi] = \mathcal{M}[\Psi^*]$. Finally, Theorem 4.5 gives the result. □

6. Extensions and example. We want to point out that our work can be extended in several directions. Hard and soft constraints can be added, such as a finite fuel constraint. The model defined by (1)–(3) is used in order to simplify and clarify the exposition and the derivation of our results. Other related problems, such as the maximum principle for singular control problems, can be studied using our approach. In [16], it is shown how this method can be applied to reexamine the maximum principle studied in [11]. In the deterministic context, such extensions have been studied in detail in the recent book [37].

For example, the results we obtained in the previous sections (the equivalence results and the existence results) remain unchanged if we assume that the control is nondecreasing. We write $\overline{\mathfrak{C}}$ for the set of controls satisfying the conditions of Definition 2.1, except that item (ii) is replaced by the following:

(ii′) $\{u_t\}$ is an $\mathbb{R}^p$-valued, nondecreasing *corlol* $\{\mathcal{F}_t\}$-progressively measurable process such that

$$(\forall A \in \mathcal{B}([0,T]) \otimes \mathcal{F}), \quad \int_0^T I_A du_t \in K,$$
$$v_T^u < +\infty.$$

Let $\overline{\mathfrak{C}}^a$ be the corresponding class of admissible control:

$$\overline{\mathfrak{C}}^a \doteq \{C \in \overline{\mathfrak{C}} : J[C] < \infty\}.$$

In the same way, we write $\overline{\Upsilon}$ for the set of controls satisfying the conditions of Definition 4.1, except that item (ii) is replaced by the following item:

(ii′) $\{(\alpha_t, \theta_t)\}$ is a $\overline{\mathfrak{B}}$-valued, $\{\mathcal{G}_t\}$-progressively measurable process, where $\overline{\mathfrak{B}} \doteq \{(x, y) \in K \times [0, 1] : (\forall j \in \mathbb{N}_p),\ 0 \leq x^j, \sum_{i=1}^{p} x^j \leq 1\}$.

It is necessary to replace $\mathfrak{B}$ by $\overline{\mathfrak{B}}$, since now we need to consider nondecreasing control processes. Moreover, denote

$$\overline{\Upsilon}^a \doteq \{\Psi \in \overline{\Upsilon} : \mathcal{M}[\Psi] < \infty\}.$$

Now let us introduce the following new assumption.

Assumption A6. For all $(t, x) \in [0, T] \times \mathbb{R}^n$, the set $\overline{K}(t, x)$ defined by

$$\overline{K}(t, x) \doteq \{(A(t, x)(1 - \theta) + \theta B(t)\alpha, (1 - \theta)D(t, x)D(t, x)', 1 - \theta) : (\alpha, \theta) \in \overline{\mathfrak{B}}\}$$

is convex.

Proceeding as before, the following can be easily shown.

COROLLARY 6.1. *Assume Assumptions* A1, A2, A3, *and* A4. *The singular and the auxiliary control problems are equivalent:*

$$\inf_{C \in \overline{\mathfrak{C}}^a} J[C] = \inf_{\Psi \in \overline{\Upsilon}^a} \mathcal{M}[\Psi].$$

COROLLARY 6.2. *Assume Assumptions* A1, A2, A3, A4, *and* A6. *For the singular control problem there exists an optimal control* $C^* \in \overline{\mathfrak{C}}^a$*:*

$$J[C^*] = \inf_{C \in \overline{\mathfrak{C}}^a} J[C].$$

Classically, optimal singular controls are studied by assuming that the class of admissible controls is characterized by left continuous processes and that the cost function has a terminal cost. Sometimes it leads to nonexistence of optimal control within the class of left continuous controls (see the well-known example in [29, section 4, p. 863] by Karatzas and Shreve). Indeed, in such examples, one may interpret this nonexistence in the following manner. The control minimizing the cost function can be left continuous on the time interval $[0, T)$ and has a jump at the terminal time. This control does not belong to the class of left continuous admissible controls but can be obtained as a limit of a sequence of left continuous control processes, implying, therefore, the nonexistence of an admissible optimal control. In order to reject such a possibility, a special assumption must be made on the terminal cost, rendering the possibility of a terminal jump unfavorable to any state (x_{T-}, v^u_{T-}) that precedes the terminal state, namely,

$$g(x_{T-} + B(T)\Delta u_T, v^u_{T-} + |\Delta u_T|) \geq g(x_{T-}, v_{T-})$$

for any admissible impulse Δu_T of the singular control applied at the terminal time, and for any (x_{T-}, v^u_{T-}). Other related conditions guaranteeing the existence of the optimal control in the class of left continuous control processes can be found, for example, in [29, Condition 4.2] or in [7, Condition 3.6] and in many other papers. Note that with our approach, we can study in a straightforward manner problems where the control is assumed to be right continuous (allowing a jump at the terminal time) and where the cost function admits a terminal cost. The advantage of our approach is that one can find an optimal solution to singular control problems which do not admit optimal solutions when the control is supposed to be left continuous.

In [29, section 4, p. 863], Karatzas and Shreve present an example of nonexistence of optimal control when the control is left continuous. With our notation, the state

$\{x_t\}$ is a real-valued process satisfying (13) with $A = 0$, $B = -1$, and $D = 1$, where the control process $\{u_t\}$ is a nondecreasing function, and where the cost is defined by $g(x, y) = x^2 + y$. However, using Corollary 6.2, we obtained that there exists an optimal control in the class of right continuous controls which shows the importance of choosing such a class of admissible controls.

7. Continuous approximation of the singular optimal control. This section addresses the problem of approximating singular optimal control C^* using absolutely continuous controls. In Theorem 7.5, it is shown that there exists a sequence of admissible continuous controls $\{C^k\}$ such that $\lim_{k\to\infty} J[C^k] = J[C^*]$. We assume in this section that $k = 0$.

The following assumption will be used in this section.

Assumption A7. There exist a bounded, continuous function $g_1 : \mathbb{R}^n \to \mathbb{R}_+$ and a Lipschitz function $g_2 : \mathbb{R}^p \to \mathbb{R}_+$ such that

$$(\forall (x, y) \in \mathbb{R}^n \times \mathbb{R}^p), \quad g(x, y) \doteq g_1(x) + g_2(y).$$

Let us denote by $\Psi^* \doteq (\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\alpha_t, \theta_t)\}, \{V_t\}, \{(\xi_t', \eta_t, \mu_t')'\}, \rho)$ an optimal control for the auxiliary control problem, and let $\{\Gamma_t\}$ be the right inverse of $\{\eta_t\}$.

Let us introduce the following processes on the probability space $(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\})$:

$$\gamma^m \doteq \rho \wedge m, \tag{60}$$

$$(\forall t \in \mathbb{R}_+), \qquad \theta_t^m \doteq \theta_t I_{[\![0,\gamma^m]\!]}(t), \tag{61}$$

$$(\forall t \in \mathbb{R}_+), \qquad \eta_t^m \doteq \int_0^t (1 - \theta_s^m) ds, \tag{62}$$

$$(\forall t \in [0, T]), \qquad \Gamma_t^m \doteq \inf\{s \in \mathbb{R}_+ : \eta_s^m > t\}, \tag{63}$$

$$\rho^m \doteq \Gamma_T^m, \tag{64}$$

and define

$$\begin{aligned} \xi_t^m \doteq \zeta &+ \int_0^t A(\eta_s^m, \xi_s^m)(1 - \theta_s^m) ds + \int_0^t \theta_s^m B(\eta_s^m) \alpha_s ds \\ &+ \int_0^t D(\eta_s^m, \xi_s^m) \sqrt{1 - \theta_s^m} dV_s \end{aligned} \tag{65}$$

for $m \in \mathbb{N}$.

Remark 7.1. *Since the processes* $\{\Gamma_t\}$ *are continuous on the right with left-hand limits, the process* $\{\widetilde{\Gamma}_t\}$ *can be defined by*

$$(\forall t \in [0, T)), \qquad \widetilde{\Gamma}_t \doteq \lim_{\substack{s \to t \\ s < t}} \Gamma_s, \tag{66}$$

and by $\widetilde{\Gamma}_T \doteq \rho$.

LEMMA 7.2. *For each* $m \in \mathbb{N}$, *write*

$$\Psi^m \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\theta_t^m, \alpha_t)\}, \{V_t\}, \{(\xi_t^{m\prime}, \eta_t^m)'\}, \rho^m\right). \tag{67}$$

Then for each $m \in \mathbb{N}$, *the control* Ψ^m *belongs to* Υ^a *and satisfies*

$$\xi_{\rho^m}^m \xrightarrow[m\to\infty]{Q} \xi_\rho, \qquad \rho^m \xrightarrow[m\to\infty]{Q} \rho, \tag{68}$$

$$\sup_{t \in \mathbb{R}_+} |\xi_{t\wedge\rho^m}^m - \xi_{t\wedge\rho}| \xrightarrow[m\to\infty]{Q} 0. \tag{69}$$

Proof. Clearly, $\{(\theta_t^m, \alpha_t)\}$ is a $\mathfrak{B}$-valued, $\{\mathcal{G}_t\}$-progressively measurable process. From Theorem 6 in [39, p. 194], it follows that a solution to (65) exists. By definition, ρ^m is a $\{\mathcal{G}_t\}$-stopping time such that $\eta^m_{\rho^m} = T$, implying that $G(\eta^m_{\rho^m}) = 0$.

Using Assumption A7, we have

$$E_Q[g(\xi^m_{\rho^m}, \rho^m - \eta^m_{\rho^m}) + G(\eta^m_{\rho^m})] \leq L_3(1 + E_Q[g_2(\rho^m - \eta^m_{\rho^m})]).$$

However, using the definitions of ρ^m and $\{\eta^m_t\}$ (see (60) and (62)), we obtain that

$$\rho^m \leq \gamma^m + T. \tag{70}$$

Consequently, using (64), we have that $\rho^m \leq T + m$, implying $\mathcal{M}[\Psi^m] < \infty$ and $\Psi^m \in \Upsilon^a$. Moreover, we have $\{\gamma^m = \rho\} \subset \{\xi^m_{\rho^m} = \xi_\rho\}$, $\{\gamma^m = \rho\} \subset \{\rho^m = \rho\}$, and $\{\gamma^m = \rho\} \subset \{\sup_{t\in\mathbb{R}_+} |\xi^m_{t\wedge\rho^m} - \xi_{t\wedge\rho}| = 0\}$. It is easy to show that $(\forall \delta \in \mathbb{R}^*_+)$, $(\exists M \in \mathbb{N})$ such that $(\forall m \geq M)$, $Q(\{\gamma^m = \rho\}) \geq 1 - \delta$, giving (68) and (69). ∎

LEMMA 7.3. *For each $m \in \mathbb{N}$, there exists a control*

$$\Psi^{m,n} \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\theta^{m,n}_t, \alpha_t)\}, \{V_t\}, \{(\xi^{m,n\prime}_t, \eta^{m,n}_t)'\}, \rho^{m,n}\right) \in \Upsilon^a$$

such that $\{\eta^{m,n}_t\}$ is a strictly increasing process, and

$$\xi^{m,n}_{\rho^{m,n}} \xrightarrow[n\to\infty]{Q} \xi^m_{\rho^m}, \qquad \rho^{m,n} \xrightarrow[n\to\infty]{Q} \rho^m, \tag{71}$$

and

$$\rho^{m,n} \leq T + \rho^m. \tag{72}$$

Moreover, we have

$$(\forall m \in \mathbb{N}), \quad \sup_{t\in\mathbb{R}_+} |\xi^{m,n}_{t\wedge\rho^{m,n}} - \xi^m_{t\wedge\rho^m}| \xrightarrow[n\to\infty]{Q} 0. \tag{73}$$

Proof. The arguments used to show these results are similar to those presented in [15, Lemma 4.7, Proposition 4.8] and are therefore omitted. ∎

PROPOSITION 7.4. *There exists a sequence of controls $\{\Phi^k\}$ in Υ^a where*

$$\Phi^k \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\overline{\theta}^k_t, \alpha_t)\}, \{V_t\}, \{(\overline{\xi}^{k\prime}_t, \overline{\eta}^k_t)'\}, \overline{\rho}^k\right) \tag{74}$$

such that $\{\overline{\eta}^k_t\}$ is a strictly increasing process and

$$\lim_{k\to\infty} \mathcal{M}[\Phi^k] = \mathcal{M}[\Psi^*], \tag{75}$$

$$\lim_{k\to\infty} \overline{\xi}^k_{\overline{\rho}^k} = \xi_\rho, \tag{76}$$

$$\lim_{k\to\infty} \sup_{t\in\mathbb{R}_+} |\overline{\xi}^k_{t\wedge\overline{\rho}^k} - \xi_{t\wedge\rho}| = 0, \tag{77}$$

$$(\forall t \in [0, T]), \quad \lim_{k\to\infty} \overline{\Gamma}^k_t = \widetilde{\Gamma}_t, \tag{78}$$

where $\{\overline{\Gamma}^k_t\}$ denotes the right inverse of the process $\{\overline{\eta}^k_t\}$.

Proof. Using (68)–(73), a subsequence denoted by $\{\Psi^{m_k,n_k}\}$ can be extracted from $\{\Psi^{m,n}\}$ to give

$$\xi^{m_k,n_k}_{\rho^{m_k,n_k}} \xrightarrow[k\to\infty]{Q} \xi_\rho, \qquad \rho^{m_k,n_k} \xrightarrow[k\to\infty]{Q} \rho, \tag{79}$$

and

$$\sup_{t\in\mathbb{R}_+} |\xi^{m_k,n_k}_{t\wedge\rho^{m_k,n_k}} - \xi_{t\wedge\rho}| \xrightarrow[k\to\infty]{Q} 0. \tag{80}$$

Again, a subsequence denoted by

$$\left\{\Phi^k \doteq \left(\Omega, \mathcal{G}, Q, \{\mathcal{G}_t\}, \{(\overline{\alpha}^k_t, \theta_t)\}, \{V_t\}, \{(\overline{\xi}^{k\prime}_t, \overline{\eta}^k_t, \overline{\mu}^{k\prime}_t)'\}, \overline{\rho}^k\right)\right\}$$

can be extracted from $\{\Psi^{m_k,n_k}\}$ to ensure that the previous limits hold almost surely. Moreover, using arguments similar to those presented in the proof of Theorem 5.1 in [15], it can be shown that $(\forall t \in [0,T])$, $\lim_{k\to\infty} \overline{\Gamma}^k_t = \widetilde{\Gamma}_t$, where $\{\overline{\Gamma}^k_t\}$ denotes the right inverse of the process $\{\overline{\eta}^k_t\}$, giving equations (76) and (77).

By definition, we have that $\forall\, k \in \mathbb{N}$, $\{\overline{\eta}^k_t\}$ is a strictly increasing process and $G(\overline{\eta}^k_{\overline{\rho}^k}) = 0$. Now, using the fact that g_1 is bounded and continuous, we have that

$$\lim_{k\to\infty} E_Q[g_1(\overline{\xi}^k_{\overline{\rho}^k})] = E_Q[g_1(\xi_\rho)].$$

Note that we have $\eta_\rho = T$ and $\overline{\eta}^k_{\overline{\rho}^k} = T$. From (60), (70), and (72), it follows easily that $\overline{\rho}^k \le \rho + 2T$. Since g_2 is monotone increasing, we have that $g_2(\overline{\rho}^k - T) \le g_2(\rho + T)$. Using the fact that $\Psi^* \in \Upsilon^a$, we obtain that $E_Q[g_2(\rho - T)] < \infty$, and by hypothesis g_2 is Lipschitz, it follows that $E_Q[g_2(\rho + T)] < \infty$. Therefore the sequence $\{g_2(\overline{\rho}^k - T)\}$ is uniformly integrable and converges to $\{g_2(\rho - T)\}$ in L_1. Finally, we obtain that

$$\lim_{k\to\infty} E_Q[g_2(\overline{\rho}^k - \overline{\eta}^k_{\overline{\rho}^k})] = E_Q[g_2(\rho - \eta_\rho)],$$

showing the last part of the result. □

THEOREM 7.5. *There exists a sequence of control $\{C^k\}$ in $\mathfrak{C}^a$,*

$$C^k \doteq \left(\Omega, \mathcal{F}, P, \{\mathcal{F}^k_t\}, \{u^k_t\}, \{W^k_t\}, \{x^k_t\}\right),$$

such that $\{u^k_t\}$ is an absolutely continuous process and

$$\lim_{k\to\infty} J[C^k] = J[C^*], \tag{81}$$

where C^* is an optimal control for the singular control problem. Moreover, the sequence of control $\{C^k\}$ satisfies

$$(\forall t \in [0,T)), \quad \lim_{k\to\infty} x^k_t = \lim_{\substack{s\to t\\ s<t}} x_s, \tag{82}$$

$$\lim_{k\to\infty} x^k_T = x_T. \tag{83}$$

Proof. From Theorems 4.4, 4.5, and 5.1, it follows that there exists a filtered probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ satisfying the usual hypotheses such that the control defined by

$$C^* \doteq \left(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \left\{\int_0^{\Gamma_t} \theta_s \alpha_s ds\right\}, \left\{\int_0^{\Gamma_t} \sqrt{(1-\alpha_s)} dV_s\right\}, \{\xi_{\Gamma_t}\}\right)$$

is an optimal control for the singular control problem. Moreover, we have that

$$J[C^*] = \mathcal{M}[\Phi^*]. \tag{84}$$

From the sequence of control $\{\Phi^k\}$ in Υ^a defined by (74) and using Theorem 4.4, we obtain that there exists a sequence of control $\{C^k\}$ in $\mathfrak{C}^a$ where

$$C^k \doteq \left(\Omega, \mathcal{F}, P, \{\mathcal{F}_t^k\}, \{u_t^k\}, \{W_t^k\}, \{x_t^k\}\right),$$

satisfying

$$J[C^k] \leq \mathcal{M}[\Phi^k], \tag{85}$$

$$x_t^k \doteq \overline{\xi}^k_{\overline{\Gamma}^k_t}, \tag{86}$$

$$u_t^k \doteq \int_0^{\overline{\Gamma}^k_t} \overline{\theta}^k_s \alpha_s ds, \tag{87}$$

with $\{\overline{\Gamma}^k_t\}$ the right inverse of $\{\overline{\eta}^k_t\}$.

Combining (75), (84), and (85), we obtain (81). Moreover, with (77) and (78), we have

$$\lim_{k\to\infty} \overline{\xi}^k_{\overline{\Gamma}^k_t \wedge \overline{\rho}^k} = \xi_{\widetilde{\Gamma}_t \wedge \rho}.$$

Then because $\overline{\Gamma}^k_t \wedge \overline{\rho}^k = \overline{\Gamma}^k_{t\wedge T}$ and $\widetilde{\Gamma}_t \wedge \rho = \widetilde{\Gamma}_{t\wedge T}$, we obtain (82) and (83).

Since $\{\overline{\eta}^k_t\}$ is a strictly increasing continuous process, we have that $\forall\, k \in \mathbb{N}$, $\overline{\Gamma}^k_{\overline{\eta}^k_t} = t$, and $\{\overline{\Gamma}^k_t\}$ is a strictly increasing process. Differentiating the previous equality and using the fact that $\overline{\eta}^k_t = \int_0^t (1-\overline{\theta}^k_s) ds$, we obtain that $\overline{\Gamma}^k_t = \int_0^t \frac{1}{1-\overline{\theta}^k_{\overline{\Gamma}^k_s}} ds$. Consequently, we have that

$$u_t^k = \int_0^t \alpha^k_{\overline{\Gamma}^k_s} \frac{\overline{\theta}_{\overline{\Gamma}^k_s}}{1-\overline{\theta}^k_{\overline{\Gamma}^k_s}} ds,$$

showing the result. ∎

PROXIMAL METHODS FOR COHYPOMONOTONE OPERATORS*

PATRICK L. COMBETTES† AND TEEMU PENNANEN‡

Abstract. Conditions are given for the viability and the weak convergence of an inexact, relaxed proximal point algorithm for finding a common zero of countably many cohypomonotone operators in a Hilbert space. In turn, new convergence results are obtained for an extended version of the proximal method of multipliers in nonlinear programming.

Key words. cohypomonotone operator, common zero problem, hypomonotone operator, method of multipliers, nonlinear programming, proximal point method, weak convergence

1. Introduction. Let $\mathcal{H}$ be a real Hilbert space with scalar product $\langle \cdot\,,\cdot \rangle$, norm $\|\cdot\|$, and distance d. A basic problem in applied mathematics and optimization is to find a zero of a maximal monotone operator $A\colon \mathcal{H} \rightrightarrows \mathcal{H}$, that is, a point $x \in \mathcal{H}$ such that $0 \in Ax$ [22, 23, 29]. Assuming $0 \in \operatorname{ran} A$, since the resolvent $(\mathrm{Id}+A)^{-1}$ of A is a firmly nonexpansive operator with fixed point set $A^{-1}(0)$, a zero of A can be constructed iteratively through the recursion

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = (\mathrm{Id}+A)^{-1}x_n. \tag{1.1}$$

Indeed, since an operator T is nonexpansive if and only if its average $(T+\mathrm{Id})/2$ is firmly nonexpansive [28, Lemma 1.1], it follows from [19, Theorem 3] that, for any $x_0 \in \mathcal{H}$, the sequence $(x_n)_{n\in\mathbb{N}}$ generated by the successive approximations (1.1) converges weakly to a zero of A (see also [17] for a special case). More generally, let $(\gamma_n)_{n\in\mathbb{N}}$ be a sequence in $]0,+\infty[$ such that $\inf_{n\in\mathbb{N}}\gamma_n > 0$ and let $(e_n)_{n\in\mathbb{N}}$ be an absolutely summable sequence in $\mathcal{H}$. Then, for every $x_0 \in \mathcal{H}$, the so-called proximal point iterations $x_{n+1} = (\mathrm{Id}+\gamma_n A)^{-1}x_n + e_n$ converge weakly to a zero of A [22, Theorem 1] (see also [4] for further analysis). This result was shown in [11, Theorem 3] to remain true for the relaxed proximal iterations

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n\big((\mathrm{Id}+\gamma_n A)^{-1}x_n + e_n - x_n\big), \tag{1.2}$$

where $(\lambda_n)_{n\in\mathbb{N}}$ lies in $[\varepsilon, 2-\varepsilon]$ for some arbitrary $\varepsilon \in]0,1[$. A further extension was proposed in [2, Corollary 6.1(i)] (for $e_n \equiv 0$) and then in [7, Theorem 6.9(i)], where weak convergence to a common zero of a countable family of maximal monotone operators $(A_i)_{i\in I}$ was established for the iterations

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n\big((\mathrm{Id}+\gamma_n A_{\mathrm{i}(n)})^{-1}x_n + e_n - x_n\big), \tag{1.3}$$

where $\mathrm{i}\colon \mathbb{N} \to I$ sweeps through the indices with some regularity. It will be convenient to cast this algorithm in the following more general framework.

ALGORITHM 1.1. *Let $(A_i)_{i\in I}$ be a countable family of set-valued operators from $\mathcal{H}$ to $\mathcal{H}$, let $(\gamma_n)_{n\in\mathbb{N}}$ and $(\lambda_n)_{n\in\mathbb{N}}$ be sequences in $]0,+\infty[$, let $(u_n)_{n\in\mathbb{N}}$ and $(v_n)_{n\in\mathbb{N}}$ be sequences in $\mathcal{H}$, let* i *be a mapping from $\mathbb{N}$ to I, and let x_0 be a point in $\mathcal{H}$. A sequence $(x_n)_{n\in\mathbb{N}}$ is constructed according to the updating rule*

$$(\forall n\in\mathbb{N})\quad x_{n+1}=x_n+\lambda_n(x_{n+\frac{1}{2}}+u_n-x_n), \tag{1.4}$$

where $x_{n+\frac{1}{2}}$ is a solution to the inclusion

$$v_n\in x_{n+\frac{1}{2}}-x_n+\gamma_n A_{\mathrm{i}(n)}x_{n+\frac{1}{2}}. \tag{1.5}$$

In the case of maximal monotone operators, the weak convergence properties of Algorithm 1.1 are summarized in the next theorem, which is derived from a result of [7]. This theorem captures the weak convergence results of [2, 11, 17, 22] for the proximal point algorithm, as well as standard results on the weak convergence of sequential projection methods for convex feasibility problems, such as those of [5, 6, 13], when the operators are taken to be normal cones to closed convex sets.

THEOREM 1.2. *Suppose that in Algorithm* 1.1 *the following conditions are satisfied:*

(i) (a) *For every $i\in I$, A_i is maximal monotone;*
(b) $S=\bigcap_{i\in I}A_i^{-1}(0)\neq\varnothing$.
(ii) $(\forall i\in I)(\exists\, M_i\in\mathbb{N}\smallsetminus\{0\})(\forall n\in\mathbb{N})\ \ i\in\{\mathrm{i}(n),\dots,\mathrm{i}(n+M_i-1)\}$.
(iii) $\inf_{n\in\mathbb{N}}\gamma_n>0$.
(iv) $(\exists\,\varepsilon\in\,]0,1[)(\forall n\in\mathbb{N})\ \ \varepsilon\leq\lambda_n\leq 2-\varepsilon$.
(v) $\sum_{n\in\mathbb{N}}\|u_n\|<+\infty$ *and* $\sum_{n\in\mathbb{N}}\|v_n\|<+\infty$.

Then every orbit generated by Algorithm 1.1 *converges weakly to a point in S.*

Proof. For every $n\in\mathbb{N}$, set

$$e_n=u_n+(\mathrm{Id}+\gamma_n A_{\mathrm{i}(n)})^{-1}(x_n+v_n)-(\mathrm{Id}+\gamma_n A_{\mathrm{i}(n)})^{-1}x_n. \tag{1.6}$$

Then (1.4)–(1.5) coincides with (1.3), which is itself a special case of [7, Algorithm 6.7] (obtained by taking $I^{(1)}=I^{(2)}=\varnothing$ and $(I_n)_{n\in\mathbb{N}}=(\{\mathrm{i}(n)\})_{n\in\mathbb{N}}$ there). On the other hand, since the resolvents $\big((\mathrm{Id}+\gamma_n A_{\mathrm{i}(n)})^{-1}\big)_{n\in\mathbb{N}}$ are nonexpansive [1, Proposition 3.5.3], we obtain

$$(\forall n\in\mathbb{N})\quad \|e_n\|\leq\|u_n\|+\|v_n\|. \tag{1.7}$$

Hence, (v) implies that $\sum_{n\in\mathbb{N}}\|e_n\|<+\infty$ and the claim therefore follows at once from [7, Theorem 6.9(i)]. □

Remark 1.3. The sequences $(v_n)_{n\in\mathbb{N}}$ and $(u_n)_{n\in\mathbb{N}}$ model errors at various steps of the execution of the iterations, thereby allowing for some tolerance in the numerical implementation of the algorithm. It is clear from the above proof that, in the presence of monotone operators, the errors $(v_n)_{n\in\mathbb{N}}$ can easily be absorbed in the errors $(u_n)_{n\in\mathbb{N}}$ and are, in this sense, redundant. However, since our ultimate goal is to investigate the behavior of Algorithm 1.1 with nonmonotone operators, the use of two error sequences is required to obtain a more flexible algorithmic model. An illustration of how condition (v) can be checked in practice is provided in section 4 (see Remark 4.2).

Extensions of the basic proximal iterations (1.1) have also been investigated in another direction, namely, by relaxing the monotonicity requirements on A. The motivation for this line of work stems from the fact that proximal iterations have been observed to converge to zeros of nonmonotone operators in certain numerical

experiments, e.g., [12]. Attempts to explain this behavior in the case of general variational inclusions can be traced back to [26], where a convergence proof is given which does not assume monotonicity. However, the assumptions made in that early work are rather stringent as they impose, essentially, that the inverse of the operator be differentiable at the origin with a monotone derivative.

Relaxing the monotonicity property of an operator is equivalent to relaxing the monotonicity property of its inverse. In some applications, however, it is more natural to work directly with the inverse. For instance, since multiplier methods are based on applying the proximal algorithm to a dual formulation of the original problem, it is more pertinent to impose relaxed monotonicity conditions on the inverse of the operator. This observation was the starting point of the investigation proposed in [20], where local convergence is analyzed under the condition that the mapping be cohypomonotone, i.e., that its inverse be hypomonotone (see Definition 2.2). The analysis of [20] is incomplete, however, at least in the sense that it assumes that the proximal steps can be computed exactly. This is an unrealistic assumption in most practical applications. In [14], an effort was made to remove this assumption by investigating the convergence in the case of inexact computations under a so-called relative error criterion. The analysis of [14] requires that the values of the operator outside a certain neighborhood be discarded. However, since this neighborhood is usually unknown in concrete applications, the applicability of this conceptual analysis is limited.

The goal of this paper is to unify and extend various convergence results on proximal iterations, by investigating the asymptotic behavior of Algorithm 1.1 when applied to a family of cohypomonotone operators. Such operators are discussed in section 2. Our main result is presented in section 3, where local viability and weak convergence conditions are established for Algorithm 1.1. An application to nonlinear programming is presented in section 4, where local convergence of a relaxed inexact proximal method of multipliers is proven for a nonconvex problem.

Throughout, $B(x;\eta)$ denotes the closed ball of center $x \in \mathcal{H}$ and extended radius $\eta \in\ ]0,+\infty]$; d_C the distance function to a nonempty set $C \subset \mathcal{H}$; P_C the projection operator onto a nonempty closed convex set $C \subset \mathcal{H}$; and N_C its normal cone map. $\operatorname{Fix} T$ the set of fixed points of an operator T, $\operatorname{dom} T$ its domain, $\operatorname{ran} T$ its range, and $\operatorname{gph} T$ its graph. The complement of a set C is denoted by $\complement C$.

2. Cohypomonotone operators. Our goal is to prove the local convergence of Algorithm 1.1 under a relaxed monotonicity assumption on the operators $(A_i)_{i\in I}$ that we now define.

DEFINITION 2.1. *Let U be a subset of $\mathcal{H}^2$. The U-localization of an operator $A\colon \mathcal{H} \rightrightarrows \mathcal{H}$ is the operator denoted by $A|^U\colon \mathcal{H} \rightrightarrows \mathcal{H}$ whose graph is* $\operatorname{gph}(A|^U) = U \cap \operatorname{gph} A$.

DEFINITION 2.2. *Let $A\colon \mathcal{H} \rightrightarrows \mathcal{H}$, $\rho \in [0,+\infty[$, and $U \subset \mathcal{H}^2$. Then A is* [maximal] ρ-hypomonotone *on U if there exists an operator $\bar{A}\colon \mathcal{H} \rightrightarrows \mathcal{H}$ such that $\bar{A} + \rho\,\mathrm{Id}$ is [maximal] monotone and $\bar{A}|^U = A|^U$. The operator A is* [maximal] ρ-cohypomonotone *on U if A^{-1} is [maximal] ρ-hypomonotone on U.*

The above definition of ρ-hypomonotonicity on a set is related to the pointwise notion of hypomonotonicity of [25, Example 12.28] and [8] as follows: If W is a neighborhood of $x \in \mathcal{H}$ and there exists $\rho \in [0,+\infty[$ such that A is ρ-hypomonotone on $W \times \mathcal{H}$, then A is hypomonotone at x in the sense of [8, 25].

Maximal hypomonotonicity has been studied extensively in the variational analysis literature. Thus, classes of functions with hypomonotone subdifferentials have

been investigated in various settings [8, 24, 25, 27]. Interesting connections between hypomonotonicity and Aubin continuity, Lipschitz continuity, and strict graphical derivatives have also been found [15, 16]. On the other hand, maximal hypomonotonicity is a less stringent requirement than imposing the existence of Lipschitz localizations. The latter has been studied in the context of variational inequality and nonlinear programming problems, e.g., [9, 10, 15, 16]. For completeness, we provide a simple proof of this important fact.

LEMMA 2.3. *Suppose that $A\colon \mathcal{H} \rightrightarrows \mathcal{H}$ has a Lipschitz localization at a point $(x, y) \in \operatorname{gph} A$; that is, there exist open sets $X \ni x$ and $Y \ni y$ such that the mapping $z \mapsto A(z) \cap Y$ is single-valued and ρ-Lipschitz continuous on X. Then A is maximal ρ-hypomonotone on $X \times Y$.*

Proof. Set $\widetilde{A} = A|^{X\times Y} + \rho\,\mathrm{Id}$ and take $(u, v) \in X^2$. Then, by Cauchy–Schwarz,

$$\Big\langle u - v\,,\, \widetilde{A}u - \widetilde{A}v \Big\rangle \geq \|u - v\| \big(\rho\|u - v\| - \big\|A|^{X\times Y}(u) - A|^{X\times Y}(v)\big\|\big) \geq 0. \tag{2.1}$$

Hence, $\widetilde{A}$ is monotone. Let A' be a maximal monotone extension of $\widetilde{A}$ and set $\bar{A} = A' - \rho\,\mathrm{Id}$. Then $\bar{A} + \rho\,\mathrm{Id}$ is maximal monotone and, to complete the proof, it suffices to show that $\bar{A}|^{X\times Y} = A|^{X\times Y}$. By construction, $\operatorname{gph}(A|^{X\times Y}) \subset \operatorname{gph}(\bar{A}|^{X\times Y})$. Conversely, take $(\bar{x}, \bar{y}) \in \operatorname{gph} \bar{A}|^{X\times Y}$ and let $z = \bar{y} - A|^{X\times Y}(\bar{x})$. Then $(\bar{x}, \bar{y} + \rho\bar{x}) \in \operatorname{gph} A'$ and, since X is open, we have $\bar{x} + \varepsilon z \in X$ for $\varepsilon > 0$ sufficiently small. Since $\operatorname{gph}(A|^{X\times Y} + \rho\,\mathrm{Id}) \subset \operatorname{gph} A'$ and A' is monotone, we have

$$\begin{aligned} 0 &\leq \big\langle \bar{x} + \varepsilon z - \bar{x}\,,\, A|^{X\times Y}(\bar{x} + \varepsilon z) + \rho(\bar{x} + \varepsilon z) - (\bar{y} + \rho\bar{x}) \big\rangle \\ &= \big\langle \varepsilon z\,,\, A|^{X\times Y}(\bar{x} + \varepsilon z) + \rho\varepsilon z - \bar{y} \big\rangle. \end{aligned} \tag{2.2}$$

Dividing by ε and letting $\varepsilon \downarrow 0^+$, the continuity of $A|^{X\times Y}$ gives $0 \leq -\big\|A|^{X\times Y}(\bar{x}) - \bar{y}\big\|^2$, whence $(\bar{x}, \bar{y}) \in \operatorname{gph} A|^{X\times Y}$. ∎

The relevance of cohypomonotonicity in proximal methods hinges on the following identity.

LEMMA 2.4. *Let $A\colon \mathcal{H} \rightrightarrows \mathcal{H}$ and let $(\gamma, \rho) \in \mathbb{R}^2$, where $\gamma \neq 0$. Then*

$$\mathrm{Id} + \left(1 - \frac{\rho}{\gamma}\right)\Big(\big(\mathrm{Id} + \gamma A\big)^{-1} - \mathrm{Id}\Big) = \Big(\mathrm{Id} + (\gamma - \rho)\big(A^{-1} + \rho\,\mathrm{Id}\,\big)^{-1}\Big)^{-1}. \tag{2.3}$$

Proof. If $\gamma = \rho$, the identity is clear. Otherwise, take $(x, u) \in \mathcal{H}^2$. Then

$$\begin{aligned} u \in \Big(\mathrm{Id} + (\gamma - \rho)\big(A^{-1} + \rho\,\mathrm{Id}\,\big)^{-1}\Big)^{-1} x \\ \Leftrightarrow \frac{x - u}{\gamma - \rho} \in \big(A^{-1} + \rho\,\mathrm{Id}\,\big)^{-1} u \\ \Leftrightarrow u \in A^{-1}\left(\frac{x - u}{\gamma - \rho}\right) + \frac{\rho}{\gamma - \rho}(x - u) \\ \Leftrightarrow \frac{x - u}{\gamma - \rho} \in A\left(\frac{\gamma u - \rho x}{\gamma - \rho}\right) \\ \Leftrightarrow x \in \big(\mathrm{Id} + \gamma A\big)\left(\frac{\gamma u - \rho x}{\gamma - \rho}\right) \\ \Leftrightarrow u \in \left(\mathrm{Id} + \left(1 - \frac{\rho}{\gamma}\right)\Big(\big(\mathrm{Id} + \gamma A\big)^{-1} - \mathrm{Id}\Big)\right) x. \end{aligned} \tag{2.4}$$

∎

The above lemma states that relaxing a proximal step for the original operator A amounts to computing a proximal step for the operator $(A^{-1}+\rho\,\mathrm{Id})^{-1}$. Clearly, when A is cohypomonotone, the latter behaves locally like a monotone operator. This observation will play a central role in our convergence analysis.

3. Proximal iterations with cohypomonotone operators. In this section, we establish our main convergence result for the inexact relaxed proximal point Algorithm 1.1 with cohypomonotone operators.

THEOREM 3.1. *Suppose that in Algorithm* 1.1 *the following conditions are satisfied:*

(i) *There exist a number* $\delta\in\,]0,+\infty[$, *a sequence* $(\rho_i)_{i\in I}$ *in* $[0,+\infty[$, *and open sets* V *and* $(X_i)_{i\in I}$ *in* $\mathcal{H}$ *for which the following hold:*
  (a) $0\in V$;
  (b) *for every* $i\in I$, $S_i=X_i\cap A_i^{-1}(0)$ *is closed and* $S_i+B(0;\delta)\subset X_i$;
  (c) *for every* $i\in I$, A_i *is maximal* ρ_i*-cohypomonotone on* $V\times X_i$;
  (d) $S=\bigcap_{i\in I}S_i\neq\varnothing$.

(ii) $(\forall i\in I)(\exists\, M_i\in\mathbb{N}\smallsetminus\{0\})(\forall n\in\mathbb{N})\ \ i\in\{\mathrm{i}(n),\dots,\mathrm{i}(n+M_i-1)\}$.

(iii) $\inf_{n\in\mathbb{N}}(\gamma_n-\rho_{\mathrm{i}(n)})>0$.

(iv) $(\exists\,\varepsilon\in\,]0,1[)(\forall n\in\mathbb{N})\ \ \varepsilon\leq\frac{\lambda_n}{1-\rho_{\mathrm{i}(n)}/\gamma_n}\leq 2-\varepsilon$.

Then there exists a closed ball B *of radius* $\eta\in\,]0,+\infty]$ *centered at a point in* S *such that if the following conditions hold:*

(v) x_0 *is sufficiently close to* S, *say,*

$$d_S(x_0)<\nu=\frac{4-2\varepsilon}{5-2\varepsilon}\eta; \tag{3.1}$$

(vi) $\sum_{n\in\mathbb{N}}(\|u_n\|+2\|v_n\|)<\frac{\nu-d_S(x_0)}{2-\varepsilon}$;

(vii) *for every* $n\in\mathbb{N}$, *one selects* $x_{n+\frac{1}{2}}\in B$ *in* (1.5),

then there is one and only one orbit $(x_n)_{n\in\mathbb{N}}$ *of Algorithm* 1.1 *contained in* B *and, furthermore,* $(x_n)_{n\in\mathbb{N}}$ *converges weakly to a point in* $B\cap S$.

Proof. Take $i\in I$. By (i)(c), there exists an operator $\bar{A}_i\colon\mathcal{H}\rightrightarrows\mathcal{H}$ such that

$$(X_i\times V)\cap\operatorname{gph}\bar{A}_i=(X_i\times V)\cap\operatorname{gph}A_i \tag{3.2}$$

and $\bar{A}_i^{-1}+\rho_i\,\mathrm{Id}$ is maximal monotone. Consequently, it follows from (i)(a), (i)(b), and (i)(d) that

$$X_i\cap\bar{A}_i^{-1}(0)=X_i\cap A_i^{-1}(0)\neq\varnothing \tag{3.3}$$

is closed. Therefore, by maximal monotonicity, $\bar{A}_i^{-1}(0)=(\bar{A}_i^{-1}+\rho_i\,\mathrm{Id})(0)$ is closed and convex [1, Proposition 3.5.6]. Thus, the convex set $\bar{A}_i^{-1}(0)$ is the union of the two disjoint closed sets $X_i\cap\bar{A}_i^{-1}(0)\neq\varnothing$ and $(\complement X_i)\cap\bar{A}_i^{-1}(0)$, which forces the latter to be empty. Indeed, otherwise, by convexity of $\bar{A}_i^{-1}(0)$, we could find $a\in X_i\cap\bar{A}_i^{-1}(0)$ and $b\in(\complement X_i)\cap\bar{A}_i^{-1}(0)$ such that the closed segment $[a,b]$ is the union of the two disjoint closed sets $[a,b]\cap X_i\cap\bar{A}_i^{-1}(0)$ and $[a,b]\cap(\complement X_i)\cap\bar{A}_i^{-1}(0)$, which is impossible since $[a,b]$ is connected by [3, Théorème IV.2.5.4]. To sum up,

$$S_i=X_i\cap A_i^{-1}(0)=X_i\cap\bar{A}_i^{-1}(0)=\bar{A}_i^{-1}(0) \tag{3.4}$$

is closed and convex. It therefore follows from (i)(d) that the projection P_Sx_0 of x_0 onto S is well defined. On the other hand, (i)(a) and (i)(b) yield $0\in\operatorname{int}V$ and

$P_S x_0 \in \operatorname{int} \bigcap_{i\in I} X_i$, respectively. As a result, we can find $\eta \in \left]0, +\infty\right]$ such that

$$B(P_S x_0; \eta) \subset \bigcap_{i\in I} X_i \quad \text{and} \quad B\bigg(0; 2\eta/\inf_{n\in\mathbb{N}} \gamma_n\bigg) \subset V. \tag{3.5}$$

We now set

$$B = B(P_S x_0; \eta) \quad \text{and} \quad D = B(P_S x_0; \nu) \tag{3.6}$$

and observe that (3.1) forces

$$x_0 \in \operatorname{int} D. \tag{3.7}$$

Next, take $(x, u) \in B^2$ and $n \in \mathbb{N}$. Then it follows from (3.5) that $\big(u, (x-u)/\gamma_n\big) \in X_{\mathrm{i}(n)} \times V$. Consequently, by (3.2),

$$\begin{aligned} u \in \big(\operatorname{Id} + \gamma_n A_{\mathrm{i}(n)}\big)^{-1} x &\Leftrightarrow \bigg(u, \frac{x-u}{\gamma_n}\bigg) \in \operatorname{gph} A_{\mathrm{i}(n)} \\ &\Leftrightarrow \bigg(u, \frac{x-u}{\gamma_n}\bigg) \in \operatorname{gph} \bar{A}_{\mathrm{i}(n)} \\ &\Leftrightarrow u \in \big(\operatorname{Id} + \gamma_n \bar{A}_{\mathrm{i}(n)}\big)^{-1} x. \end{aligned} \tag{3.8}$$

Thus,

$$\big(\operatorname{Id} + \gamma_n A_{\mathrm{i}(n)}\big)^{-1}\big|^{B\times B} = \big(\operatorname{Id} + \gamma_n \bar{A}_{\mathrm{i}(n)}\big)^{-1}\big|^{B\times B}. \tag{3.9}$$

On the other hand, let

$$T_n = \operatorname{Id} + \bigg(1 - \frac{\rho_{\mathrm{i}(n)}}{\gamma_n}\bigg)\Big(\big(\operatorname{Id} + \gamma_n \bar{A}_{\mathrm{i}(n)}\big)^{-1} - \operatorname{Id}\Big). \tag{3.10}$$

Alternatively, using Lemma 2.4, we can write

$$T_n = \Big(\operatorname{Id} + \tau_n\big(\bar{A}^{-1}_{\mathrm{i}(n)} + \rho_{\mathrm{i}(n)} \operatorname{Id}\big)^{-1}\Big)^{-1}, \quad \text{where} \quad \tau_n = \gamma_n - \rho_{\mathrm{i}(n)}. \tag{3.11}$$

Since $\tau_n > 0$ by (iii), T_n is therefore the resolvent of the operator $\tau_n C_{\mathrm{i}(n)}$, where

$$C_{\mathrm{i}(n)} = \big(\bar{A}^{-1}_{\mathrm{i}(n)} + \rho_{\mathrm{i}(n)} \operatorname{Id}\big)^{-1}, \tag{3.12}$$

which is maximal monotone as the inverse of such an operator. Hence, it follows from [2, Proposition 2.3] that

$$T_n\colon \operatorname{dom} T_n = \mathcal{H} \to \mathcal{H} \quad \text{and} \quad (\forall (x, z) \in \mathcal{H} \times \operatorname{Fix} T_n) \;\; \langle z - T_n x \,, x - T_n x\rangle \leq 0, \tag{3.13}$$

which, by [7, Proposition 2.3(ii)], implies

$$\begin{aligned} &(\forall \mu \in [0, 2])(\forall (x, z) \in \mathcal{H} \times \operatorname{Fix} T_n) \\ &\qquad \|x + \mu(T_n x - x) - z\|^2 \leq \|x - z\|^2 - \mu(2-\mu)\|T_n x - x\|^2. \end{aligned} \tag{3.14}$$

Now, let

$$\mu_n = \frac{\lambda_n}{1 - \rho_{\mathrm{i}(n)}/\gamma_n}. \tag{3.15}$$

Then we get from (iv) that

$$\mu_n \in [\varepsilon, 2 - \varepsilon]. \tag{3.16}$$

We also obtain from (3.5), (3.3), (3.12), and (3.11) that

$$B \cap S_{\mathrm{i}(n)} = B \cap A_{\mathrm{i}(n)}^{-1}(0) = B \cap \bar{A}_{\mathrm{i}(n)}^{-1}(0) = B \cap C_{\mathrm{i}(n)}^{-1}(0) = B \cap \operatorname{Fix} T_n. \tag{3.17}$$

Hence, $P_S x_0 \in B \cap S \subset B \cap \operatorname{Fix} T_n$, and it results from (3.14) with $\mu = 1$ and $z = P_S x_0$ that

$$T_n(B) \subset B. \tag{3.18}$$

Let us now show that Algorithm 1.1 is viable, i.e., that the recursion (1.4)–(1.5) does generate an infinite sequence. To this end, we shall show that the sequence $(x_n)_{n\in\mathbb{N}}$ is well defined and that it lies in $\operatorname{int} D$, whereas the sequence $(x_n + v_n)_{n\in\mathbb{N}}$ lies in $\operatorname{int} B$. Since (vi) yields $\|v_0\| < \eta - d_S(x_0)$, it follows from (3.7) that $\|x_0 + v_0 - P_S x_0\| \leq \|v_0\| + d_S(x_0) < \eta$, whence $x_0 + v_0 \in \operatorname{int} B$. Now assume that, for some $n \in \mathbb{N}$, the points $(x_k)_{0\leq k\leq n}$ and $(x_k + v_k)_{0\leq k\leq n}$ lie in $\operatorname{int} D$ and $\operatorname{int} B$, respectively. Then it results from (vii) and (3.9) that (1.5) can be written as

$$x_{n+\frac{1}{2}} \in (\mathrm{Id} + \gamma_n A_{\mathrm{i}(n)})^{-1}\big|^{B\times B}(x_n + v_n) = (\mathrm{Id} + \gamma_n \bar{A}_{\mathrm{i}(n)})^{-1}\big|^{B\times B}(x_n + v_n). \tag{3.19}$$

In view of (3.15), (1.4) can now be written as

$$x_{n+1} \in x_n + \mu_n \left(1 - \frac{\rho_{\mathrm{i}(n)}}{\gamma_n}\right) \left((\mathrm{Id} + \gamma_n \bar{A}_{\mathrm{i}(n)})^{-1}\big|^{B\times B}(x_n + v_n) + u_n - x_n\right), \tag{3.20}$$

which, by virtue of (3.10), yields

$$x_{n+1} \in x_n + \mu_n \left(T_n\big|^{B\times B}(x_n + v_n) + w_n - x_n\right), \tag{3.21}$$

where

$$w_n = \left(1 - \frac{\rho_{\mathrm{i}(n)}}{\gamma_n}\right) u_n - \frac{\rho_{\mathrm{i}(n)}}{\gamma_n} v_n. \tag{3.22}$$

However, since $x_n + v_n \in B$, (3.18) yields $T_n\big|^{B\times B}(x_n + v_n) = T_n(x_n + v_n)$. Hence, since T_n is single-valued and defined everywhere on $\mathcal{H}$ (see (3.13)), we deduce from (3.21) that x_{n+1} is uniquely defined by

$$x_{n+1} = x_n + \mu_n\big(T_n(x_n + v_n) + w_n - x_n\big). \tag{3.23}$$

Now put

$$e_n = w_n + T_n(x_n + v_n) - T_n x_n. \tag{3.24}$$

Then we derive from (3.23) that

$$x_{n+1} = x_n + \mu_n(T_n x_n - x_n) + \mu_n e_n, \tag{3.25}$$

and it follows from (3.16) and (3.14) that

$$\begin{aligned} \|x_{n+1} - P_S x_0\| &\leq \|x_n - P_S x_0 + \mu_n(T_n x_n - x_n)\| + \mu_n\|e_n\| \\ &\leq \|x_n - P_S x_0\| + \mu_n\|e_n\|. \end{aligned} \tag{3.26}$$

Consequently, since $(x_k + v_k)_{0\leq k\leq n}$ lies in B, we have

$$\begin{aligned} \|x_{n+1} - P_S x_0\| &\leq \|x_0 - P_S x_0\| + \sum_{k=0}^{n} \mu_k\|e_k\| \\ &\leq d_S(x_0) + (2-\varepsilon)\sum_{k\in\mathbb{N}} \|e_k\|. \end{aligned} \tag{3.27}$$

On the other hand, it follows from (3.24), the nonexpansivity of T_n [1, Proposition 3.5.3], (3.22), and (iii) that

$$\|e_n\| \leq \|w_n\| + \|T_n(x_n + v_n) - T_n x_n\| \leq \|w_n\| + \|v_n\| \leq \|u_n\| + 2\|v_n\|. \tag{3.28}$$

Therefore, we derive from (vi) that

$$d_S(x_0) + (2-\varepsilon)\sum_{k\in\mathbb{N}} \|e_k\| < \nu, \tag{3.29}$$

and deduce from (3.27) that $\|x_{n+1} - P_S x_0\| < \nu$, i.e., $x_{n+1} \in \operatorname{int} D$. In turn, (vi) and (3.1) yield

$$\|x_{n+1} + v_{n+1} - P_S x_0\| < \nu + \|v_{n+1}\| < \nu + \frac{\nu}{2(2-\varepsilon)} = \eta, \tag{3.30}$$

i.e., $x_{n+1} + v_{n+1} \in \operatorname{int} B$. We have thus shown by induction that the entire sequence $(x_n + v_n)_{n\in\mathbb{N}}$ lies in B and that $(x_n)_{n\in\mathbb{N}}$ is a well-defined sequence which lies entirely in $\operatorname{int} D \subset \operatorname{int} B$. In view of (3.23), (3.11), and (3.12), the recursion governing the sequence $(x_n)_{n\in\mathbb{N}}$ can now be rewritten as

$$(\forall n \in \mathbb{N})\ \ x_{n+1} = x_n + \mu_n(x_{n+\frac{1}{2}} + w_n - x_n), \tag{3.31}$$

where $x_{n+\frac{1}{2}}$ is the unique solution to the inclusion

$$v_n \in x_{n+\frac{1}{2}} - x_n + \tau_n C_{\mathrm{i}(n)} x_{n+\frac{1}{2}}, \tag{3.32}$$

namely, $x_{n+\frac{1}{2}} = \big(\operatorname{Id} + \tau_n C_{\mathrm{i}(n)}\big)^{-1}(x_n + v_n) = T_n(x_n + v_n) \in B$, where the last inclusion follows from $x_n + v_n \in B$ and (3.18). In summary, since the operators $(C_i)_{i\in I}$ are maximal monotone, $\inf_{n\in\mathbb{N}} \tau_n > 0$, $(\mu_n)_{n\in\mathbb{N}}$ lies in $[\varepsilon, 2-\varepsilon]$, $\sum_{n\in\mathbb{N}} \|w_n\| \leq \sum_{n\in\mathbb{N}} \|u_n\| + \sum_{n\in\mathbb{N}} \|v_n\| < +\infty$, and $\sum_{n\in\mathbb{N}} \|v_n\| < +\infty$, it follows from Theorem 1.2 that $(x_n)_{n\in\mathbb{N}}$ converges weakly to a point x in $\bigcap_{i\in I} C_i^{-1}(0)$. On the other hand, since $(x_n)_{n\in\mathbb{N}}$ lies in the weakly closed set B, $x \in B$. As a result, (3.17) yields $x \in B \cap \bigcap_{i\in I} C_i^{-1}(0) = B \cap S$. □

Remark 3.2. The above result unifies and extends several results found in the literature.

- If $I = \{1\}$ (a single operator is considered), $\lambda_n \equiv 1$, and $u_n \equiv 0 \equiv v_n$, then Theorem 3.1 is found in [20, Theorem 9].
- If $I = \{1\}$, $\rho_1 = 0$, and $V = \mathcal{H} = X_1$, Theorem 3.1 reduces to [11, Theorem 3], and to [22, Theorem 1] if we further assume $\lambda_n \equiv 1$.
- If $\rho_i \equiv 0$ and $V = \mathcal{H} \equiv X_i$, Theorem 3.1 reduces to Theorem 1.2.
- If $\rho_i \equiv 0$, $V = \mathcal{H} \equiv X_i$, and $u_n \equiv 0 \equiv v_n$, Theorem 3.1 corresponds to [2, Corollary 6.1(i)].
- If $I = \{1, \ldots, m\}$, $(S_i)_{i\in I}$ is a family of closed convex sets in $\mathcal{H}$ with associated projection operators $(P_i)_{i\in I}$, $\mathrm{i}\colon n \mapsto n$ modulo $m+1$, for every $i \in I$, $A_i = N_{S_i}$ (hence $\rho_i \equiv 0$ and $V = \mathcal{H} \equiv X_i$), and $u_n \equiv 0 \equiv v_n$, then Algorithm 1.1 produces the method of cyclic projections

(3.33)
$$(\forall n \in \mathbb{N})\ \ x_{n+1} = x_n + \lambda_n(P_{n \text{ modulo } m+1}x_n - x_n), \quad \text{where} \quad \varepsilon \leq \lambda_n \leq 2 - \varepsilon,$$

and Theorem 3.1 reduces to [13, Theorem 1].

4. Nonlinear programming application. Using the same arguments as in [20, section 5], one can derive multiplier methods for quite general variational inclusions by combining Theorem 3.1 with an abstract duality framework for set-valued mappings. Instead of going through all the steps and applications discussed in [20], we analyze the proximal method of multipliers for nonlinear (nonconvex) programming as an example. The proximal method of multipliers was introduced and analyzed in the convex case by Rockafellar [23] and in the nonconvex case in [20, section 7] with exact, unrelaxed iterates.

Consider the nonlinear programming problem

$$\text{minimize} \quad f_0(x) \quad \text{subject to} \quad \begin{cases} f_i(x) = 0 & \text{for } 1 \leq i \leq r, \\ f_i(x) \leq 0 & \text{for } r+1 \leq i \leq m, \end{cases} \tag{4.1}$$

where $(f_i)_{0\leq i\leq m}$ are real-valued C^2-functions defined on the standard Euclidean space $\mathbb{R}^N$. Our aim is to find Karush–Kuhn–Tucker (KKT) points for (4.1). To this end, we introduce the closed convex cone $K = \{0\}^r \times \mathbb{R}_-^{m-r}$, let $F\colon x \mapsto \big(f_1(x), \ldots, f_m(x)\big)$, and set $\mathcal{H} = \mathbb{R}^N \times \mathbb{R}^m$. We shall derive from Theorem 3.1 a local convergence result for the following proximal method of multipliers.

ALGORITHM 4.1. *Let $(x_0, y_0) \in \mathcal{H}$, let $(\gamma_n)_{n\in\mathbb{N}}$ be a sequence in $]0, +\infty[$, and let $(w_n)_{n\in\mathbb{N}}$ be a sequence in $\mathbb{R}^N$. A sequence $\big((x_n, y_n)\big)_{n\in\mathbb{N}}$ is constructed according to the updating rule*

$$(\forall n \in \mathbb{N})\ \ (x_{n+1}, y_{n+1}) = (x_n, y_n) + \lambda_n\big((x_{n+\frac{1}{2}}, y_{n+\frac{1}{2}}) - (x_n, y_n)\big), \tag{4.2}$$

where $x_{n+\frac{1}{2}}$ minimizes approximately the function

$$\varphi_n\colon x \mapsto f_0(x) + \frac{1}{2\gamma_n}\|x - x_n\|^2 + \frac{1}{2\gamma_n}d_K\big(y_n + \gamma_n F(x)\big)^2 \tag{4.3}$$

in the sense that $\nabla\varphi_n(x_{n+\frac{1}{2}}) = w_n$, and

$$\begin{cases} y^i_{n+\frac{1}{2}} = y^i_n + \gamma_n f_i(x_{n+\frac{1}{2}}) & \text{for } 1 \leq i \leq r, \\ y^i_{n+\frac{1}{2}} = \max\big\{y^i_n + \gamma_n f_i(x_{n+\frac{1}{2}}), 0\big\} & \text{for } r+1 \leq i \leq m. \end{cases} \tag{4.4}$$

Remark 4.2. It was shown in the proof of [20, Theorem 19] that, under condition (i) of Theorem 4.3 and for x near $\bar{x}$, the condition $\nabla\varphi_n(x) = 0$ implies that x is a local minimizer of φ_n. For this reason, the condition $\nabla\varphi_n(x_{n+\frac{1}{2}}) = w_n$ is interpreted in Algorithm 4.1 as an approximate minimization. In practice, the parameter γ_n is often chosen adaptively while the size of the vector $\|w_n\|$ can be made arbitrarily small by choosing the stopping criterion appropriately in the minimization of φ_n in (4.3).

Define a mapping $L\colon \mathcal{H} \rightrightarrows \mathcal{H}$ by

$$L\colon (x,y) \mapsto \big(\nabla f_0(x) + \langle y\,,\nabla F(x)\rangle\,, -F(x) + N_{K^*}(y)\big), \tag{4.5}$$

where $K^* = \mathbb{R}^r \times \mathbb{R}^{m-r}_+$ is the polar cone of K. Then the KKT system for (4.1) can be written as [25, Example 11.46]

$$(0,0) \in L(x,y). \tag{4.6}$$

Let $(\bar{x},\bar{y}) \in \mathcal{H}$ be a point satisfying the KKT conditions for (4.1) and define

$$I^+ = \{1,\ldots,r\} \cup \{r+1 \leq i \leq m \mid f_i(\bar{x}) = 0 \ \text{ and } \ \bar{y}_i > 0\}. \tag{4.7}$$

Now let $l\colon (x,y) \mapsto f_0(x) + \langle y\,,F(x)\rangle$. Recall that $(\bar{x},\bar{y})$ is said to satisfy the *strong second order sufficient condition* for (4.1) if [21]

$$(\forall y \in \mathbb{R}^m)\ \begin{cases} y \neq 0 \\ (\forall i \in I^+)\ \ \langle y\,,\nabla f_i(\bar{x})\rangle = 0 \end{cases} \quad\Rightarrow\quad \big\langle y\,,\nabla^2_{xx} l(\bar{x},\bar{y})y\big\rangle > 0. \tag{4.8}$$

THEOREM 4.3. *Suppose that in Algorithm* 4.1 *the following conditions are satisfied:*

(i) $(\bar{x},\bar{y}) \in \mathcal{H}$ *is a KKT point for* (4.1) *satisfying* (4.8) *and such that the gradients* $\big(\nabla f_i(\bar{x})\big)_{i\in I^+}$ *are linearly independent;*
(ii) $\inf_{n\in\mathbb{N}}\gamma_n$ *is large enough;*
(iii) $(\exists\,\varepsilon \in\,]0,1[)(\forall n \in \mathbb{N})\ \ \varepsilon \leq \lambda_n \leq 2-\varepsilon$.

Then there exists a closed ball B *centered at* $(\bar{x},\bar{y})$ *such that if the following conditions hold:*

(iv) (x_0,y_0) *is sufficiently close to* $(\bar{x},\bar{y})$;
(v) $\sum_{n\in\mathbb{N}}\gamma_n\|w_n\|$ *is small enough;*
(vi) *for every* $n \in \mathbb{N}$, $(x_{n+\frac{1}{2}},y_{n+\frac{1}{2}}) \in B$,

then there is one and only one orbit $\big((x_n,y_n)\big)_{n\in\mathbb{N}}$ *of Algorithm* 4.1 *contained in* B *and, furthermore,* $\big((x_n,y_n)\big)_{n\in\mathbb{N}}$ *converges to* $(\bar{x},\bar{y})$.

Proof. By [18, Exemple 4.b and Proposition 7.d],

$$\nabla d^2_K = 2(\mathrm{Id} - P_K) = 2P_{K^*}. \tag{4.9}$$

Thus, it follows from (4.3) that

$$\nabla\varphi_n(x) = \nabla f_0(x) + \gamma_n^{-1}(x-x_n) + \big\langle P_{K^*}\big(y_n + \gamma_n F(x)\big)\,,\nabla F(x)\big\rangle\,. \tag{4.10}$$

Note also that $y_{n+\frac{1}{2}}$ in (4.4) can be expressed as

$$y_{n+\frac{1}{2}} = P_{K^*}\big(y_n + \gamma_n F(x_{n+\frac{1}{2}})\big) = (I + N_{K^*})^{-1}\big(y_n + \gamma_n F(x_{n+\frac{1}{2}})\big). \tag{4.11}$$

The update rules for $(x_{n+\frac{1}{2}}, y_{n+\frac{1}{2}})$ are thus equivalent to the system

$$\begin{cases} w_n = \nabla f_0(x_{n+\frac{1}{2}}) + \gamma_n^{-1}(x_{n+\frac{1}{2}} - x_n) + \left\langle y_{n+\frac{1}{2}}\,, \nabla F(x_{n+\frac{1}{2}}) \right\rangle, \\ y_n + \gamma_n F(x_{n+\frac{1}{2}}) \in y_{n+\frac{1}{2}} + N_{K^*}(y_{n+\frac{1}{2}}). \end{cases} \tag{4.12}$$

Alternatively, $(x_{n+\frac{1}{2}}, y_{n+\frac{1}{2}})$ is a solution to

$$(\gamma_n w_n, 0) \in (x_{n+\frac{1}{2}}, y_{n+\frac{1}{2}}) - (x_n, y_n) + \gamma_n L(x_{n+\frac{1}{2}}, y_{n+\frac{1}{2}}). \tag{4.13}$$

Now, set $A_1 = L$, $I = \{1\}$, and $\mathrm{i}(n) = 1$ for all $n \in \mathbb{N}$. Then, in view of (4.13), the iterations described by (4.2)–(4.4) are seen to conform to the format (1.4)–(1.5), and Algorithm 4.1 therefore fits the general framework of Algorithm 1.1. Accordingly, it suffices to verify the conditions of Theorem 3.1 to establish the claims. By [21, Theorem 4.1], condition (i) implies that L^{-1} has a Lipschitz localization at $\big((0,0),(\bar{x},\bar{y})\big)$. Therefore, by Lemma 2.3, condition (i) of Theorem 3.1 holds with $S = S_1 = \{(\bar{x},\bar{y})\}$ for some $\rho \in [0, +\infty[$. Now let $\gamma = \inf_{n\in\mathbb{N}} \gamma_n$. Then condition (iii) of Theorem 3.1 reads $\gamma > \rho$, and is trivially implied by condition (ii) above. Next, let us show that condition (iii) above implies condition (iv) of Theorem 3.1, i.e.,

$$(\exists\, \zeta \in]0,1[)(\forall n \in \mathbb{N})\ \ \zeta \leq \frac{\lambda_n}{1-\rho/\gamma_n} \leq 2 - \zeta. \tag{4.14}$$

It is readily checked that for $\gamma > 2\rho/\varepsilon$ (as is allowed by (ii) above), we have

$$\zeta = \frac{\varepsilon\gamma - 2\rho}{\gamma - \rho} \in]0, \varepsilon[\,. \tag{4.15}$$

Hence, it follows from (iii) above that

$$(\forall n \in \mathbb{N})\ \ \zeta < \varepsilon \leq \lambda_n < \frac{\lambda_n}{1-\rho/\gamma_n} \leq \frac{2-\varepsilon}{1-\rho/\gamma} = 2 - \zeta, \tag{4.16}$$

which establishes (4.14). Finally, it is clear that conditions (v)–(vii) of Theorem 3.1 are implied by conditions (iv)–(vi) above. □

Remark 4.4.

(i) In most concrete problems, it is not possible to obtain the value of ρ in the above proof [21]. As a result, condition (ii) and (v) in Theorem 4.3 are stated in qualitative terms rather than with hard bounds involving ρ.

(ii) The above result extends [20, Theorem 19] by allowing for relaxations and inexact computation of the iterates, thus making the algorithm more practical and flexible.

MODELING AND CONTROL OF THE TIMOSHENKO BEAM. THE DISTRIBUTED PORT HAMILTONIAN APPROACH*

ALESSANDRO MACCHELLI† AND CLAUDIO MELCHIORRI†

Abstract. The purpose of this paper is to show how the Timoshenko beam can be fruitfully described within the framework of distributed port Hamiltonian (dpH) systems so that rather simple and elegant considerations can be drawn regarding both the modeling and control of this mechanical system. After the dpH model of the beam is introduced, the control problem is discussed. In particular, it is shown how control approaches already presented in the literature can be unified, and a new control methodology is presented and discussed. This control methodology relies on the generalization to infinite dimensions of the concept of structural invariant (Casimir function) and on the extension to distributed systems of the so-called control by interconnection methodology. In this way, finite dimensional passive controllers can stabilize distributed parameter systems by shaping their total energy, i.e., by assigning a new minimum in the desired equilibrium configuration that can be reached if a dissipative effect is introduced.

Key words. modeling and control of flexible structures, Stokes–Dirac structures, infinite dimensional port Hamiltonian systems, control by damping injection, Casimir functions, control by interconnection

1. Introduction.

The port Hamiltonian approach has been introduced as a systematic framework for geometric modeling and control of lumped-parameter physical systems [15, 26]. The port Hamiltonian model of a finite dimensional system takes its inspiration from circuit analysis: the behavior of a physical system is the result of a network of atomic multiport elements, each of them characterized by a particular energy property. The key point is the identification of the interconnection structure, mathematically described by a Dirac structure [2, 26], a generalization of the well-known Kirchhoff laws [16]. In this way, the variation of a system's total energy is related to the power exchanged with the environment, and the dynamics is the result of internal power flows among different parts of the whole system. It has been shown that this approach can be fruitfully applied for modeling a wide class of physical (mechanical, electrical, hydraulic, and chemical) systems, and several control techniques, based on energy considerations, have been developed in order to solve the regulation problem [20, 21, 26].

In some sense, it seems natural to extend the finite dimensional Hamiltonian formulation in order to deal with distributed parameter systems. Many results on integrability, existence of solutions or stability, and several applications have been proposed in the last decades; see, for example, [24] for an application to fluid dynamics and [19] for a nice introduction and historical remarks. On the other hand, it is interesting to note that some problems regarding the treatment of *boundary conditions* are still open. In fact, most of the research activity has been focused on the study of

infinite dimensional systems characterized by an infinite spatial domain, for which the state variables tend to zero when the spatial variable tends to infinity (with respect to some norm), or on the analysis of infinite dimensional systems with zero boundary conditions (on the finite spatial domain).

These are autonomous systems: no interaction, i.e., power exchange, with the environment is taken into account. This is a strong limitation since it is not possible to study the effect of nonzero boundary conditions (e.g., voltages and currents at both ends of a transmission line) on the dynamics of the system. In this way, it is difficult to deal with control application for infinite dimensional systems in Hamiltonian form. The controller, in fact, can act on the system only by properly modifying the boundary variables or, equivalently, by exchanging power with the (infinite dimensional) system.

From a mathematical point of view, it is not evident how a nonzero energy flow through the boundary can be incorporated into the *classical* distributed Hamiltonian framework. The key point is the notion of Dirac structure in infinite dimensions that will be defined, in this case, on a space of differential forms on the spatial domain of the system and its boundary. Since the relation between variation of internal energy and power flow through the boundary relies on the Stokes theorem [17, 18], these structures are called Stokes–Dirac structures.

Once the Stokes–Dirac structure of a particular infinite dimensional system is deduced, the distributed port Hamiltonian (dpH) model follows *automatically* [17, 18] and the control problem can be approached. When dealing with the control of distributed parameter systems, the main problem concerns the intrinsic difficulties related to the proof of stability of an equilibrium configuration. It is important to emphasize that this *limitation* does not depend on the particular approach adopted. Even if a distributed parameter system is described within the port Hamiltonian framework, the stability proof of a certain control scheme will always be a difficult task. On the other hand, the main advantages in adopting the dpH framework can be the following:

- The development of control schemes for infinite dimensional systems is usually based on energy considerations or, equivalently, the stability proof often relies on the properties of an energy-like functional, a generalization of the Lyapunov function to the distributed parameters case. The Hamiltonian description of a distributed parameter system is given in terms of time evolution of energy variables depending on the variation of the total energy of the system. In this way, the energy of the system, which is generally a *good* Lyapunov function, appears explicitly in the mathematical model of the system itself and, consequently, both the design of the control law and the proof of its stability can be deduced and presented in a more intuitive (in some sense *physical*) and elegant way.
- The port Hamiltonian formulation of distributed parameter systems deeply relies on the notion of Dirac structure, as in finite dimensions. This fact is important and allows us to go further; in particular, it is of great interest to understand whether the control schemes developed for finite dimensional port Hamiltonian systems could also be generalized in order to deal with the distributed parameter case. For example, suppose that the total energy (Hamiltonian) of the system is characterized by a minimum at the desired equilibrium configuration. This happens, for example, in the case of flexible beams, for which the zero-energy configuration corresponds to the undeformed beam. In this situation, the controller can be developed in order to

behave as a dissipative element to be connected to the system at the boundary or along the distributed port. The amount of dissipated power can be increased in order to quickly reach the configuration with minimum energy. As in the finite dimensional case, it can happen that the minimum of the energy does not correspond to a desired configuration. Then it is necessary to shape the energy function so that a new minimum is introduced. This can be achieved by generalizing the control by interconnection and energy-shaping methodology to deal with distributed parameter systems, as presented in [22], where the infinite dimensional system is a lossless transmission line.

In this paper, it is shown how the modeling and control problems of an infinite dimensional system, the Timoshenko beam, can be solved within the framework of dpH systems. Flexible beams are generally modeled according to the classical Euler–Bernoulli theory: this formulation provides a good description of the dynamical behavior of the system if the beam's cross sectional dimension is small in comparison to its length. In this case, the effects of the rotary inertia of the beam are not considered. A more accurate beam model is provided by the Timoshenko theory, according to which the rotary inertia and also the deformation due to shear are considered. The resulting Timoshenko model of the beam is generally more accurate in predicting the beam's response than the Euler–Bernoulli one but, on the other hand, it is more difficult to utilize for control purposes because of its complexity.

As already pointed out, the dpH formulation of the Timoshenko model of the beam [6] (but refer also to [7, 11, 12]) does not reduce the complexity of the model itself, but it is useful both for modeling considerations and control purposes. From the modeling point of view, the internal and external interconnections of the system are revealed: it is clear how the kinetic and potential elastic energy domains interact and how the system can exchange power with the environment through its border and/or a distributed port. Furthermore, the dpH representation of the system makes it possible to extend well-established passive control strategies that were originally developed for finite dimensional port Hamiltonian systems and to elegantly unify control approaches already presented in the literature [8, 25].

The paper is organized as follows. In section 2, a brief background on Dirac structures and on the classical formulation of the Timoshenko model of the beam is provided, and then the Stokes–Dirac structure of the Timoshenko beam is presented and the dpH model introduced. The control problem is approached in sections 3 and 4. In section 3, the *control by damping injection* methodology is extended to infinite dimensions in order to stabilize the beam in its undeformed configuration, as already presented in [8, 25]. In section 4, the *control by interconnection and energy shaping* methodology [20, 26, 21] is extended to distributed parameter systems in order to control a mechanical system made of a flexible (Timoshenko) beam with a rigid body connected at one of its extremities. The finite dimensional controller, acting on the system through the other extremity, is developed by properly extending the concept of Casimir functions to the infinite dimensional case and by generalizing the results presented in [22] (see also [12, 11]). Finally, conclusions and suggestions for future work are illustrated in section 5.

2. Timoshenko beam in dpH form.

2.1. Timoshenko beam—the *classical* formulation. According to the Timoshenko theory, the motion of a beam can be described by the following system of

PDEs:

$$\begin{aligned} \rho\frac{\partial^2 w}{\partial t^2} - K\frac{\partial^2 w}{\partial x^2} + K\frac{\partial \phi}{\partial x} &= 0, \\ I_\rho\frac{\partial^2 \phi}{\partial t^2} - EI\frac{\partial^2 \phi}{\partial x^2} + K\left(\phi - \frac{\partial w}{\partial x}\right) &= 0, \end{aligned} \tag{2.1}$$

where t is the time and $x \in [0, L]$ is the spatial coordinate along the beam in its equilibrium position, and $w(x,t)$ is the deflection of the beam from the equilibrium configuration and $\phi(x,t)$ is the rotation of the beam's cross section due to bending; the motion takes place in the wx-plane. Denote by $\mathcal{D} := [0, L]$ the spatial domain and by $\partial\mathcal{D} = \{0, L\}$ its boundary.

The coefficients ρ, I_ρ, E, and I, assumed to be constant, are the mass per unit length, the mass moment of inertia of the cross section, Young's modulus, and the moment of inertia of the cross section, respectively. The coefficient K is equal to kGA, where G is the modulus of elasticity in shear, A is the cross sectional area, and k is a constant depending on the shape of the cross section.

The mechanical energy is given by the following relation [8]:

$$\begin{aligned} \mathcal{H}(t) := \overbrace{\frac{1}{2}\int_0^L \rho\left(\frac{\partial w}{\partial t}\right)^2 + I_\rho\left(\frac{\partial \phi}{\partial t}\right)^2 dx}^{\textit{kinetic energy}} \\ \underbrace{+\frac{1}{2}\int_0^L K\left(\phi - \frac{\partial w}{\partial x}\right)^2 + EI\left(\frac{\partial \phi}{\partial x}\right)^2 dx}_{\textit{potential elastic energy}}. \end{aligned} \tag{2.2}$$

Note the presence of two interactive energy domains, the *kinetic* and the *potential elastic*.

2.2. Dirac structures. The starting point in the definition of a port Hamiltonian system (both finite and infinite dimensional) is the identification of a suitable space of power variables, strictly related to the geometry of the system, and the definition of a Dirac structure on this space of power variables, in order to describe the internal and external interconnection of the system. The Dirac structures were introduced in [2], while in [4, 26] it is pointed out that they are the geometric *tool* that allows us to formalize and generalize the notion of power-conserving interconnection.

Before stating the general definition of Dirac structure, it is necessary to introduce the space of *power variables*. Consider a linear space $\mathcal{F}$, possibly infinite dimensional (space of generalized velocities or *flows*), and denote by $\mathcal{E} = \mathcal{F}^*$ its dual (space of generalized forces or *efforts*). The space of power variables is $\mathcal{F} \times \mathcal{E}$. Then, from [18], we take the following fundamental definition.

DEFINITION 2.1 (Dirac structure). *Denote by $\mathcal{F} \times \mathcal{E}$ a space of power variables (possibly infinite dimensional). There exists on $\mathcal{F} \times \mathcal{E}$ the canonically defined symmetric bilinear form (+pairing operator)*

$$\ll (f_1, e_1), (f_2, e_2) \gg := \langle e_1, f_2\rangle + \langle e_2, f_1\rangle, \tag{2.3}$$

where $f_i \in \mathcal{F}$, $e_i \in \mathcal{E}$, $i = 1, 2$, and $\langle\cdot,\cdot\rangle$ denotes the duality product between $\mathcal{F}$ and its dual space $\mathcal{E}$. A constant Dirac structure on $\mathcal{F}$ is a linear subspace $\mathbb{D} \subset \mathcal{F} \times \mathcal{E}$ such that

$$\mathbb{D} = \mathbb{D}^\perp, \tag{2.4}$$

where $\perp$ denotes the orthogonal complement with respect to the bilinear form $\ll \cdot, \cdot \gg$.

An immediate consequence of the previous definition is that, if $(f, e) \in \mathbb{D}$, then

$$0 = \ll (f, e), (f, e) \gg = 2 \langle e, f \rangle . \tag{2.5}$$

Consequently, $\langle e, f \rangle = 0$ for every $(f, e) \in \mathbb{D}$. In other words, if $(f, e) \in \mathcal{F} \times \mathcal{E}$ is a couple of power conjugated variables, the fact that they belong to the Dirac structure $\mathbb{D}$ implies power conservation, i.e., the dual product is equal to 0. The Dirac structure is the geometrical tool by means of which it is possible to deal with power-conserving interconnection in physical systems. As will be pointed out in section 2.4 for the Timoshenko beam, once a proper interconnection structure is defined, the port Hamiltonian model of a physical system follows automatically.

2.3. Timoshenko beam—The Stokes–Dirac structure. Consider the mechanical energy (2.2). The potential elastic energy is a function of the *shear* and of the *bending*, given by the following 1-forms:

$$\epsilon_t(t, x) = \left[\frac{\partial w}{\partial x}(t, x) - \phi(t, x) \right] dx, \qquad \epsilon_r(t, x) = \frac{\partial \phi}{\partial x}(t, x) dx. \tag{2.6}$$

The associated coenergy variables are the 0-forms (functions) *shear force* and the *bending momentum*, given by $\sigma_t(t, x) = K * \epsilon_t(t, x)$ and $\sigma_r(t, x) = EI * \epsilon_r(t, x)$, where $*$ is the Hodge star operator defined, for example, in [14]. Besides, the kinetic energy is a function of the *translational* and *rotational momenta*, i.e., of the following 1-form:

$$p_t(t, x) = \rho \frac{\partial w}{\partial t}(t, x) dx, \qquad p_r(t, x) = I_\rho \frac{\partial \phi}{\partial t}(t, x) dx, \tag{2.7}$$

and the associated coenergy variables are the 0-forms *translational* and *rotational momenta*, given by $v_t(t, x) = \frac{1}{\rho} * p_t(t, x)$ and $v_r(t, x) = \frac{1}{I_\rho} * p_r(t, x)$.

Consider an n-dimensional (Riemannian) manifold $\mathcal{N}$ and denote by $\Omega^k(\mathcal{N})$ the space of k-forms on $\mathcal{N}$, i.e., the space of k-linear alternating functions. So, we have that $p_t, p_r, \epsilon_t, \epsilon_r \in \Omega^1(\mathcal{D})$ and that $w, \phi \in \Omega^0(\mathcal{D})$. If $\mathrm{d} : \Omega^k(\mathcal{N}) \to \Omega^{k+1}(\mathcal{N})$ is the exterior derivative on the space of forms, it is possible to rewrite (2.6) and (2.7) as

$$p_t = \rho * \frac{\partial w}{\partial t}, \qquad \epsilon_t = \mathrm{d}w - * \phi, \qquad p_r = I_\rho * \frac{\partial \phi}{\partial t}, \qquad \epsilon_r = \mathrm{d}\phi,$$

and the total energy (2.2) becomes the following (quadratic) functional:

$$\begin{aligned} \mathcal{H}(p_t, p_r, \epsilon_t, \epsilon_r) &= \int_{\mathcal{D}} H(p_t, p_r, \epsilon_t, \epsilon_r) \\ &= \frac{1}{2} \int_{\mathcal{D}} \left(\frac{1}{\rho} * p_t \wedge p_t + \frac{1}{I_\rho} * p_r \wedge p_r + K * \epsilon_t \wedge \epsilon_t + EI * \epsilon_r \wedge \epsilon_r \right) \end{aligned} \tag{2.8}$$

with $H : \Omega^1(\mathcal{D}) \times \cdots \times \Omega^1(\mathcal{D}) \times \mathcal{D} \to \Omega^1(\mathcal{D})$ the energy density. Consider a time function

$$(p_t(t), p_r(t), \epsilon_t(t), \epsilon_r(t)) \in \Omega^1(\mathcal{D}) \times \cdots \times \Omega^1(\mathcal{D})$$

with $t \in \mathbb{R}$, and evaluate the energy $\mathcal{H}$ along this trajectory. At any time t, the variation of internal energy, that is, the power exchanged with the environment, is

given by

$$\begin{aligned}\frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t} &= \int_{\mathcal{D}} \left(\delta_{p_t}\mathcal{H} \wedge \frac{\partial p_t}{\partial t} + \delta_{p_r}\mathcal{H} \wedge \frac{\partial p_r}{\partial t} + \delta_{\epsilon_t}\mathcal{H} \wedge \frac{\partial \epsilon_t}{\partial t} + \delta_{\epsilon_r}\mathcal{H} \wedge \frac{\partial \epsilon_r}{\partial t} \right) \\ &= \int_{\mathcal{D}} \left[\left(\frac{1}{\rho} * p_t \right) \wedge \frac{\partial p_t}{\partial t} + \left(\frac{1}{I_\rho} * p_r \right) \wedge \frac{\partial p_r}{\partial t} + (K * \epsilon_t) \wedge \frac{\partial \epsilon_t}{\partial t} + (EI * \epsilon_r) \wedge \frac{\partial \epsilon_r}{\partial t} \right].\end{aligned} \tag{2.9}$$

The differential forms $\frac{\partial p_t}{\partial t}$, $\frac{\partial p_r}{\partial t}$, $\frac{\partial \epsilon_t}{\partial t}$, and $\frac{\partial \epsilon_r}{\partial t}$ are the time derivatives of the energy variables p_t, p_r, ϵ_t, and ϵ_r and represent the *generalized velocities* (flows), while $\delta_{p_t}\mathcal{H}$, $\delta_{p_r}\mathcal{H}$, $\delta_{\epsilon_t}\mathcal{H}$, and $\delta_{\epsilon_r}\mathcal{H}$ are the variational derivatives of the total energy (2.8). They are related to the rate of change of the stored energy and represent the *generalized forces* (efforts).

The dpH formulation of the Timoshenko beam can be obtained either by expressing (2.1) in terms of p_t, p_r, ϵ_r, and ϵ_t as introduced in (2.6) and (2.7), or, in a more rigorous way, by revealing the underlying Dirac structure of the model. For this purpose, it is necessary to define the space of power variables. The space of flows is given by

$$\mathcal{F} := \underbrace{\Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D})}_{\textit{generalized velocities}} \times \underbrace{\Omega^0(\partial\mathcal{D}) \times \Omega^0(\partial\mathcal{D})}_{\text{border } \textit{flow}}, \tag{2.10}$$

and it is well known that the space of effort $\mathcal{E}$ is the *dual* of $\mathcal{F}$. The concept of duality over the space of forms can be given by the following proposition [17].

PROPOSITION 2.2. *Consider an n-dimensional Riemannian manifold $\mathcal{N}$. Then the dual space $(\Omega^k(\mathcal{N}))^*$ of $\Omega^k(\mathcal{N})$ can be identified with $\Omega^{n-k}(\mathcal{N})$ and the duality product between $\Omega^k(\mathcal{N})$ and $(\Omega^k(\mathcal{N}))^*$ by*

$$\langle \beta, \alpha \rangle := \int_{\mathcal{N}} \alpha \wedge \beta \tag{2.11}$$

with $\alpha \in \Omega^k(\mathcal{N})$ and $\beta \in \Omega^{n-k}(\mathcal{N})$. The same result holds for $\Omega^k(\partial\mathcal{N})$.

An immediate consequence of Proposition 2.2 is that the dual space $\mathcal{E}$ of $\mathcal{F}$, the space of efforts, can be easily identified with

$$\mathcal{E} := \underbrace{\Omega^0(\mathcal{D}) \times \Omega^0(\mathcal{D}) \times \Omega^0(\mathcal{D}) \times \Omega^0(\mathcal{D})}_{\textit{generalized forces}} \times \underbrace{\Omega^0(\partial\mathcal{D}) \times \Omega^0(\partial\mathcal{D})}_{\text{border } \textit{effort}}. \tag{2.12}$$

Thus, the duality product (2.11) and the +pairing operator (2.3) can be easily specialized in order to deal with the space of power variables $\mathcal{F} \times \mathcal{E}$ defined by (2.10) and (2.12). Suppose that

$$\left(f_{p_t}, f_{p_r}, f_{\epsilon_t}, f_{\epsilon_r}, f_b^t, f_b^r, e_{p_t}, e_{p_r}, e_{\epsilon_t}, e_{\epsilon_r}, e_b^t, e_b^r\right), \left(f_{p_t}^i, \ldots, f_b^{r,i}, e_{p_t}^i, \ldots, e_b^{r,i}\right) \in \mathcal{F} \times \mathcal{E}$$

with $i = 1, 2$. Then

$$\begin{aligned}
&\langle (e_{p_t}, e_{p_r}, e_{\epsilon_t}, e_{\epsilon_r}, e_b^t, e_b^r), (f_{p_t}, f_{p_r}, f_{\epsilon_t}, f_{\epsilon_r}, f_b^t, f_b^r) \rangle \\
&\quad := \int_{\mathcal{D}} (f_{p_t} \wedge e_{p_t} + f_{p_r} \wedge e_{p_r} + f_{\epsilon_t} \wedge e_{\epsilon_t} + f_{\epsilon_r} \wedge e_{\epsilon_r}) + \int_{\partial\mathcal{D}} \left(f_b^t \wedge e_b^t + f_b^r \wedge e_b^r \right), \\
&\ll \left(f_{p_t}^1, \ldots, f_b^{r,1}, e_{p_t}^1, \ldots, e_b^{r,1}, \right) \left(f_{p_t}^2, \ldots, f_b^{r,2}, e_{p_t}^2, \ldots, e_b^{r,2} \right) \gg \\
&\qquad := \int_{\mathcal{D}} \left(f_{p_t}^1 \wedge e_{p_t}^2 + f_{p_t}^2 \wedge e_{p_t}^1 + f_{p_r}^1 \wedge e_{p_r}^2 + f_{p_r}^2 \wedge e_{p_r}^1 \right) \\
&\qquad\quad + \int_{\mathcal{D}} \left(f_{\epsilon_t}^1 \wedge e_{\epsilon_t}^2 + f_{\epsilon_t}^2 \wedge e_{\epsilon_t}^1 + f_{\epsilon_r}^1 \wedge e_{\epsilon_r}^2 + f_{\epsilon_r}^2 \wedge e_{\epsilon_r}^1 \right) \\
&\qquad\quad + \int_{\partial\mathcal{D}} \left(f_b^{t,1} \wedge e_b^{t,2} + f_b^{t,2} \wedge e_b^{t,1} + f_b^{r,1} \wedge e_b^{r,2} + f_b^{r,2} \wedge e_b^{r,1} \right).
\end{aligned} \tag{2.13}$$

With the following proposition, the main result of this section is presented.

PROPOSITION 2.3 (the Timoshenko beam Dirac structure). *Consider the space of power variables $\mathcal{F} \times \mathcal{E}$ with $\mathcal{F}$ and $\mathcal{E}$ defined in* (2.10) *and* (2.12) *and the bilinear form (+pairing operator) $\ll \cdot, \cdot \gg$ given by* (2.13). *Define the following linear subspace $\mathbb{D}$ of $\mathcal{F} \times \mathcal{E}$:*

$$\begin{aligned}
\mathbb{D} \;=\; \Bigg\{ & (f_{p_t}, f_{p_r}, f_{\epsilon_t}, f_{\epsilon_r}, f_b^t, f_b^r, e_{p_t}, e_{p_r}, e_{\epsilon_t}, e_{\epsilon_r}, e_b^t, e_b^r) \in \mathcal{F} \times \mathcal{E} \mid \\
& \begin{bmatrix} f_{p_t} \\ f_{p_r} \\ f_{\epsilon_t} \\ f_{\epsilon_r} \end{bmatrix} = - \begin{bmatrix} 0 & 0 & \mathrm{d} & 0 \\ 0 & 0 & * & \mathrm{d} \\ \mathrm{d} & -* & 0 & 0 \\ 0 & \mathrm{d} & 0 & 0 \end{bmatrix} \begin{bmatrix} e_{p_t} \\ e_{p_r} \\ e_{\epsilon_t} \\ e_{\epsilon_r} \end{bmatrix}, \quad \begin{bmatrix} f_b^t \\ f_b^r \\ e_b^t \\ e_b^r \end{bmatrix} = \begin{bmatrix} e_{p_t} \mid_{\partial\mathcal{D}} \\ e_{p_r} \mid_{\partial\mathcal{D}} \\ e_{\epsilon_t} \mid_{\partial\mathcal{D}} \\ e_{\epsilon_r} \mid_{\partial\mathcal{D}} \end{bmatrix} \Bigg\},
\end{aligned} \tag{2.14}$$

where $\mid_{\partial\mathcal{D}}$ denotes the restriction on the border of the (spatial) domain $\mathcal{D}$. Then $\mathbb{D} = \mathbb{D}^\perp$; that is, $\mathbb{D}$ is a Dirac structure.

Proof. The proof can be divided into two steps. In the first one, it is verified that $\mathbb{D} \subseteq \mathbb{D}^\perp$ while in the second one, that $\mathbb{D}^\perp \subseteq \mathbb{D}$. Suppose that

$$\omega^i = \left(f_{p_t}^i, f_{p_r}^i, f_{\epsilon_t}^i, f_{\epsilon_r}^i, f_b^{t,i}, f_b^{r,i}, e_{p_t}^i, e_{p_r}^i, e_{\epsilon_t}^i, e_{\epsilon_r}^i, e_b^{t,i}, e_b^{r,i} \right) \in \mathcal{F} \times \mathcal{E}$$

with $i = 1, 2$; clearly, $\mathbb{D} \subseteq \mathbb{D}^\perp$ if $\forall\, \omega^1, \omega^2 \in \mathbb{D}$, it happens that $\ll \omega_1, \omega_2 \gg = 0$. From (2.13) and from the definition (2.14) of the Dirac structure $\mathbb{D}$, we have

$$\begin{aligned}
\ll \omega^1, \omega^2 \gg = & \int_{\mathcal{D}} \left[-\mathrm{d}e_{\epsilon_t}^1 \wedge e_{p_t}^2 - \mathrm{d}e_{\epsilon_t}^2 \wedge e_{p_t}^1 + (-*e_{\epsilon_t}^1 - \mathrm{d}e_{\epsilon_r}^1) \wedge e_{p_r}^2 \right] \\
& + \int_{\mathcal{D}} \left[(-*e_{\epsilon_t}^2 - \mathrm{d}e_{\epsilon_r}^2) \wedge e_{p_r}^1 + (-\mathrm{d}e_{p_t}^1 + *e_{p_r}^1) \wedge e_{\epsilon_t}^2 \right] \\
& + \int_{\mathcal{D}} \left[(-\mathrm{d}e_{p_t}^2 + *e_{p_r}^2) \wedge e_{\epsilon_t}^1 - \mathrm{d}e_{p_r}^1 \wedge e_{\epsilon_r}^2 - \mathrm{d}e_{p_r}^2 \wedge e_{\epsilon_r}^1 \right] \\
& + \int_{\partial\mathcal{D}} \left[f_b^{t,1} \wedge e_b^{t,2} + f_b^{t,2} \wedge e_b^{t,1} + f_b^{r,1} \wedge e_b^{r,2} + f_b^{r,2} \wedge e_b^{r,1} \right]
\end{aligned}$$

$$
\begin{aligned}
&= -\int_{\mathcal{D}} \left[(\mathrm{d}e^2_{p_t} \wedge e^1_{\epsilon_t} + e^2_{p_t} \wedge \mathrm{d}e^1_{\epsilon_t}) + (\mathrm{d}e^1_{p_t} \wedge e^2_{\epsilon_t} + e^1_{p_t} \wedge \mathrm{d}e^2_{\epsilon_t}) \right] \\
&\quad - \int_{\mathcal{D}} \left[(\mathrm{d}e^2_{p_r} \wedge e^1_{\epsilon_r} + e^2_{p_r} \wedge \mathrm{d}e^1_{\epsilon_r}) + (\mathrm{d}e^1_{p_r} \wedge e^2_{\epsilon_r} + e^1_{p_r} \wedge \mathrm{d}e^2_{\epsilon_r}) \right] \\
&\quad + \int_{\partial\mathcal{D}} \left[f^{t,1}_b \wedge e^{t,2}_b + f^{t,2}_b \wedge e^{t,1}_b + f^{r,1}_b \wedge e^{r,2}_b + f^{r,2}_b \wedge e^{r,1}_b \right].
\end{aligned}
$$

Since $\mathrm{d}(e^1 \wedge e^2) = \mathrm{d}e^1 \wedge e^2 + e^1 \wedge \mathrm{d}e^2$ and, for the Stokes theorem, if $\alpha \in \Omega^0(\mathcal{D})$, then $\int_{\mathcal{D}} \mathrm{d}\alpha = \int_{\partial\mathcal{D}} \alpha$, we deduce that $\ll \omega^1, \omega^2 \gg = 0$ and $\mathbb{D} \subseteq \mathbb{D}^\perp$.

In order to prove that $\mathbb{D}^\perp \subseteq \mathbb{D}$, consider $\omega^2 \in \mathbb{D}^\perp$. From the definition of Dirac structure we have that $\forall\, \omega^1 \in \mathbb{D}$, $\ll \omega^1, \omega^2 \gg = 0$. Since $\omega^1 \in \mathbb{D}$, from (2.14) we have

$$
\begin{aligned}
0 &= \ll \omega^1, \omega^2 \gg \\
&= \int_{\mathcal{D}} \left[-\mathrm{d}e^1_{\epsilon_t} \wedge e^2_{p_t} + f^2_{p_t} \wedge e^1_{p_t} + (-{*}e^1_{\epsilon_t} - \mathrm{d}e^1_{\epsilon_r}) \wedge e^2_{p_r} + f^2_{p_r} \wedge e^1_{p_r} \right] \\
&\quad + \int_{\mathcal{D}} \left[(-\mathrm{d}e^1_{p_t} + {*}e^1_{p_r}) \wedge e^2_{\epsilon_t} + f^2_{\epsilon_t} \wedge e^1_{\epsilon_t} - \mathrm{d}e^1_{p_r} \wedge e^2_{\epsilon_r} + f^2_{\epsilon_r} \wedge e^1_{\epsilon_r} \right] \\
&\quad + \int_{\partial\mathcal{D}} \left[e^1_{p_t}\,|_{\partial\mathcal{D}} \wedge e^{t,2}_b + f^{t,2}_b \wedge e^1_{\epsilon_t}\,|_{\partial\mathcal{D}} + e^1_{p_r}\,|_{\partial\mathcal{D}} \wedge e^{r,2}_b + f^{r,2}_b \wedge e^1_{\epsilon_r}\,|_{\partial\mathcal{D}} \right].
\end{aligned}
$$

From the Stokes theorem and the properties of the exterior derivative, it is possible to obtain that

$$
\begin{aligned}
0 &= \int_{\mathcal{D}} \left[e^1_{\epsilon_t} \wedge (\mathrm{d}e^2_{p_t} - {*}e^2_{p_r} + f^2_{\epsilon_t}) + e^1_{p_t} \wedge (f^2_{p_t} + \mathrm{d}e^2_{\epsilon_t}) \right] \\
&\quad + \int_{\mathcal{D}} \left[e^1_{\epsilon_r} \wedge (\mathrm{d}e^2_{p_r} + f^2_{\epsilon_r}) + e^1_{p_r} \wedge (f^2_{p_r} + {*}e^2_{\epsilon_t} + \mathrm{d}e^2_{\epsilon_r}) \right] \\
&\quad + \int_{\partial\mathcal{D}} \left[e^1_{\epsilon_t}\,|_{\partial\mathcal{D}} \wedge (-e^2_{p_t}\,|_{\partial\mathcal{D}} + f^{t,2}_b) + e^1_{\epsilon_r}\,|_{\partial\mathcal{D}} \wedge (-e^2_{p_r}\,|_{\partial\mathcal{D}} + f^{r,2}_b) \right] \\
&\quad + \int_{\partial\mathcal{D}} \left[e^1_{p_t}\,|_{\partial\mathcal{D}} \wedge (-e^2_{\epsilon_t}\,|_{\partial\mathcal{D}} + e^{t,2}_b) + e^1_{p_r}\,|_{\partial\mathcal{D}} \wedge (-e^2_{\epsilon_r}\,|_{\partial\mathcal{D}} + e^{r,2}_b) \right]
\end{aligned}
$$

for every $\omega^1 \in \mathbb{D}$. We deduce that the previous relation holds if and only if $\omega^2 \in \mathbb{D}$. So, $\mathbb{D}^\perp \subseteq \mathbb{D}$, and this completes the proof. ∎

2.4. dpH formulation of the Timoshenko beam. Consider the total energy (2.8) as the Hamiltonian of the system, i.e., a (quadratic) functional of the energy variables p_t, p_r, ϵ_t, and ϵ_r bounded from below. The rate of change of these energy variables (generalized velocities) can be connected to the Dirac structure (2.14) by setting

$$
f_{p_t} = -\frac{\partial p_t}{\partial t}, \quad f_{\epsilon_t} = -\frac{\partial \epsilon_t}{\partial t}, \quad f_{p_r} = -\frac{\partial p_r}{\partial t}, \quad f_{\epsilon_r} = -\frac{\partial \epsilon_r}{\partial t}, \tag{2.15}
$$

where the minus sign is necessary in order to have a consistent energy flow description. Moreover, the rate of change of the Hamiltonian with respect to the energy variables,

that is, its variational derivatives, can be related to the Dirac structure by setting

$$e_{p_t} = \delta_{p_t}\mathcal{H}, \quad e_{\epsilon_t} = \delta_{\epsilon_t}\mathcal{H}, \quad e_{p_r} = \delta_{p_r}\mathcal{H}, \quad e_{\epsilon_r} = \delta_{\epsilon_r}\mathcal{H}. \tag{2.16}$$

From (2.15) and (2.16), it is possible to obtain the distributed Hamiltonian formulation with boundary energy flow of the Timoshenko beam. We give the following.

DEFINITION 2.4 (dpH model of Timoshenko beam). *The dpH model of the Timoshenko beam with Dirac structure* $\mathbb{D}$ (2.14) *and Hamiltonian* $\mathcal{H}$ (2.8) *is given by*

$$\begin{bmatrix} \partial_t p_t \\ \partial_t p_r \\ \partial_t \epsilon_t \\ \partial_t \epsilon_r \end{bmatrix} = \begin{bmatrix} 0 & 0 & \mathrm{d} & 0 \\ 0 & 0 & * & \mathrm{d} \\ \mathrm{d} & -* & 0 & 0 \\ 0 & \mathrm{d} & 0 & 0 \end{bmatrix} \begin{bmatrix} \delta_{p_t}\mathcal{H} \\ \delta_{p_r}\mathcal{H} \\ \delta_{\epsilon_t}\mathcal{H} \\ \delta_{\epsilon_r}\mathcal{H} \end{bmatrix}, \quad \begin{bmatrix} f_b^t \\ f_b^r \\ e_b^t \\ e_b^r \end{bmatrix} = \begin{bmatrix} \delta_{p_t}\mathcal{H}\,|_{\partial\mathcal{D}} \\ \delta_{p_r}\mathcal{H}\,|_{\partial\mathcal{D}} \\ \delta_{\epsilon_t}\mathcal{H}\,|_{\partial\mathcal{D}} \\ \delta_{\epsilon_r}\mathcal{H}\,|_{\partial\mathcal{D}} \end{bmatrix}. \tag{2.17}$$

Since the elements of every Dirac structure satisfy the power conserving property, we have, given

$$(f_{p_t}, \ldots, f_{\epsilon_r}, e_{p_t}, \ldots, e_{\epsilon_r}, f_b^t, \ldots, e_b^r) \in \mathbb{D},$$

that

$$\int_{\mathcal{D}} (f_{p_t} \wedge e_{p_t} + f_{p_r} \wedge e_{p_r} + f_{\epsilon_t} \wedge e_{\epsilon_t} + f_{\epsilon_r} \wedge e_{\epsilon_r}) + \int_{\partial\mathcal{D}} \left(f_b^t \wedge e_b^t + f_b^r \wedge e_b^r\right) = 0$$

and, consequently, from (2.9), (2.15), and (2.16), the following proposition can be proved.

PROPOSITION 2.5 (energy balance). *Consider the dpH model of the Timoshenko beam* (2.17). *Then*

$$\begin{aligned} \frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t}(t) &= \int_{\partial\mathcal{D}} \left(e_b^t \wedge f_b^t + e_b^r \wedge f_b^r\right) \\ &= \left[e_b^t(t,L) f_b^t(t,L) + e_b^r(t,L) f_b^r(t,L)\right] - \left[e_b^t(t,0) f_b^t(t,0) + e_b^r(t,0) f_b^r(t,0)\right] \end{aligned} \tag{2.18}$$

or, in other words, the increase of total energy of the beam is equal to the power supplied through the border.

2.5. Introducing the distributed port. Power exchange through the boundaries is not the only means by which the system can interact with the environment. The "distributed control" is a well-known control technique that can be fruitfully applied to flexible structures. The actuators are connected along the flexible structure and can act on the system by applying forces/couples that are functions of the configuration of the beam. The final result is that vibrations can be damped in a more efficient way than by acting only on the border of the beam.

In order to introduce a distributed port, the space of power variables $\mathcal{F} \times \mathcal{E}$ defined in (2.10) and (2.12) and the Dirac structure $\mathbb{D}$ defined in (2.14) have to be modified. The space of power variables becomes $\mathcal{F}_d \times \mathcal{E}_d$, where

$$\mathcal{F}_d := \mathcal{F} \times \underbrace{\Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D})}_{\textit{distrib. flow}}, \qquad \mathcal{E}_d := \mathcal{E} \times \underbrace{\Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D})}_{\textit{distrib. effort}}. \tag{2.19}$$

The modified Dirac structure that incorporates the distributed port is given by the following.

PROPOSITION 2.6. *Consider the space of power variables* $\mathcal{F}_d \times \mathcal{E}_d$ *defined in* (2.19) *and the bilinear form (+pairing operator)* $\ll \cdot, \cdot \gg$ *given by* (2.13). *Define the following linear subspace* $\mathbb{D}_d$ *of* $\mathcal{F}_d \times \mathcal{E}_d$*:*

$$
\begin{aligned}
\mathbb{D}_d \;=\; \Bigg\{ & (f_{p_t}, f_{p_r}, f_{\epsilon_t}, f_{\epsilon_r}, f_b^t, f_b^r, f_d^t, f_d^r, e_{p_t}, e_{p_r}, e_{\epsilon_t}, e_{\epsilon_r}, e_b^t, e_b^r, e_d^t, e_d^r) \in \mathcal{F}_d \times \mathcal{E}_d \mid \\
& \begin{bmatrix} f_{p_t} \\ f_{p_r} \\ f_{\epsilon_t} \\ f_{\epsilon_r} \end{bmatrix} = - \begin{bmatrix} 0 & 0 & \mathrm{d} & 0 \\ 0 & 0 & * & \mathrm{d} \\ \mathrm{d} & -* & 0 & 0 \\ 0 & \mathrm{d} & 0 & 0 \end{bmatrix} \begin{bmatrix} e_{p_t} \\ e_{p_r} \\ e_{\epsilon_t} \\ e_{\epsilon_r} \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} f_d^t \\ f_d^r \end{bmatrix}, \\
& \begin{bmatrix} e_d^t \\ e_d^r \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} e_{p_t} \\ e_{p_r} \\ e_{\epsilon_t} \\ e_{\epsilon_r} \end{bmatrix}, \quad \begin{bmatrix} f_b^t \\ f_b^r \\ e_b^t \\ e_b^r \end{bmatrix} = \begin{bmatrix} e_{p_t} \mid_{\partial \mathcal{D}} \\ e_{p_r} \mid_{\partial \mathcal{D}} \\ e_{\epsilon_t} \mid_{\partial \mathcal{D}} \\ e_{\epsilon_r} \mid_{\partial \mathcal{D}} \end{bmatrix} \Bigg\},
\end{aligned}
\tag{2.20}
$$

where $|_{\partial \mathcal{D}}$ *denotes the restriction on the border of the (spatial) domain* $\mathcal{D}$. *Then* $\mathbb{D}_d = \mathbb{D}_d{}^{\perp}$*; that is,* $\mathbb{D}_d$ *is a Dirac structure.*

Proof. The proof is very similar to the one given for Proposition 2.3. □

The dpH formulation of the Timoshenko beam with boundary and distributed energy flow can be obtained simply by combining the Dirac structure $\mathbb{D}_d$ (2.20) with (2.15) and (2.16). The resulting model is given in the following.

DEFINITION 2.7. *The dpH model of the Timoshenko beam with Dirac structure* $\mathbb{D}_d$ (2.20) *and Hamiltonian* $\mathcal{H}$ (2.8) *is given by*

$$
\begin{aligned}
& \begin{bmatrix} \partial_t p_t \\ \partial_t p_r \\ \partial_t \epsilon_t \\ \partial_t \epsilon_r \end{bmatrix} = \begin{bmatrix} 0 & 0 & \mathrm{d} & 0 \\ 0 & 0 & * & \mathrm{d} \\ \mathrm{d} & -* & 0 & 0 \\ 0 & \mathrm{d} & 0 & 0 \end{bmatrix} \begin{bmatrix} \delta_{p_t} \mathcal{H} \\ \delta_{p_r} \mathcal{H} \\ \delta_{\epsilon_t} \mathcal{H} \\ \delta_{\epsilon_r} \mathcal{H} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} f_d^t \\ f_d^r \end{bmatrix}, \\
& \begin{bmatrix} e_d^t \\ e_d^r \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \delta_{p_t} \mathcal{H} \\ \delta_{p_r} \mathcal{H} \\ \delta_{\epsilon_t} \mathcal{H} \\ \delta_{\epsilon_r} \mathcal{H} \end{bmatrix}, \quad \begin{bmatrix} f_b^t \\ f_b^r \\ e_b^t \\ e_b^r \end{bmatrix} = \begin{bmatrix} \delta_{p_t} \mathcal{H} \mid_{\partial \mathcal{D}} \\ \delta_{p_r} \mathcal{H} \mid_{\partial \mathcal{D}} \\ \delta_{\epsilon_t} \mathcal{H} \mid_{\partial \mathcal{D}} \\ \delta_{\epsilon_r} \mathcal{H} \mid_{\partial \mathcal{D}} \end{bmatrix}.
\end{aligned}
\tag{2.21}
$$

The energy balance equation (2.18) becomes

$$
\frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t} = \int_{\partial \mathcal{D}} \left(f_b^t \wedge e_b^t + f_b^r \wedge e_b^r \right) + \int_{\mathcal{D}} \left(f_d^t \wedge e_d^t + f_d^r \wedge e_d^r \right),
\tag{2.22}
$$

which expresses the fact that the variation of internal stored energy equals the power supplied to the system through the border and the distributed port. From a *bond graph* point of view, the Timoshenko beam can be described as in Figure 2.1, where the power flows through the border ($f_b^{t,r} \mid_{x=\cdot}, e_b^{t,r} \mid_{x=\cdot}$) and the distributed port (f_d, e_d) are shown.

3. Control by damping injection.

3.1. Introduction. In this section, some considerations about control by damping injection applied to the Timoshenko beam are presented. In order to be as general as possible, consider the dpH formulation of the Timoshenko beam with distributed

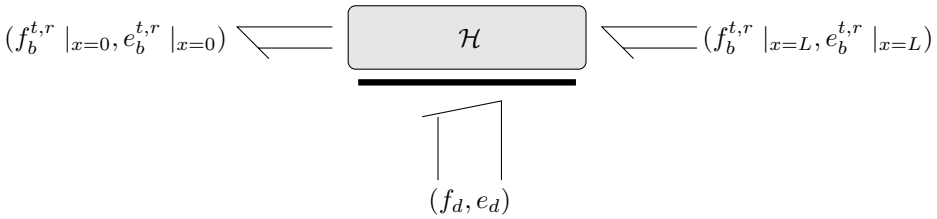

FIG. 2.1. *Bond graph representation of the Timoshenko beam.*

port (2.21). The energy functional (2.8) assumes its minimum in the *zero* configuration, i.e., when

$$p_t = 0, \qquad p_r = 0, \qquad \epsilon_t = 0, \quad \text{and} \quad \epsilon_r = 0 \tag{3.1}$$

or, equivalently, when

$$w(t,x) = \alpha^* x + d^*, \qquad \phi(t,x) = \alpha^*, \tag{3.2}$$

where the constants α^* and d^* are determined by the boundary conditions on w and ϕ. In (3.2), α^* represents the rotation angle of the beam around the point $x = 0$, while d^* is the vertical displacement in $x = 0$.

If some dissipation effect is introduced by means of a controller, it is possible to drive the state of the beam to the configuration where the (open loop) energy functional (2.8) assumes its minimum. If the controller is interconnected on the boundary of the spatial domain, we can speak about *boundary control* of the distributed parameter system (more precisely, about damping injection through the boundary). If the controller is interconnected along the distributed port, we can speak about *distributed control* of the infinite dimensional system (distributed damping injection). Energy dissipation can be introduced by *terminating* these ports with a *dissipative element*, i.e., by a generalized *impedance*, simulated by the control algorithm.

In order to simplify some stability proofs that are presented in the remaining part of this section, it is important to characterize the behavior of the Timoshenko beam equation when the energy function becomes constant and when the boundary conditions are equal to zero. We give this important remark (see [9, Assumption 5.12]).

Remark 3.1. Consider the dpH model of the Timoshenko beam (2.21). The only invariant solution compatible with $\dot{\mathcal{H}} = 0$ and with the boundary conditions

$$\begin{cases} f_b^t(0) = f_b^r(0) = 0, \\ e_b^t(L) = e_b^r(L) = 0 \end{cases} \quad \text{or} \quad \begin{cases} f_b^t(L) = f_b^r(L) = 0, \\ e_b^t(0) = e_b^r(0) = 0 \end{cases}$$

is the zero solution (3.1).

Note 3.1. More precisely, Remark 3.1 should be extended in order to also contain information about the *observability* of the infinite dimensional system (the Timoshenko beam, in this case), as discussed in [3, from page 154 onward]. These conditions can be interpreted as the generalization of the definition of detectability and observability (see [1]) to the infinite dimensional case (see also [3, pp. 227ff.]).

3.2. Boundary control. Suppose that a finite dimensional controller can be interconnected to the beam in $x = L$ and that the beam can interact with the environment in $x = 0$. Moreover, suppose that no interaction can take place through the

distributed port. The last hypothesis means that, in (2.21), it can be assumed that

$$f_d^t(t,x) = 0, \qquad f_d^r(t,x) = 0.$$

The controller is designed in order to act as if a dissipative element is connected to the power port of the beam in $x = L$, whose causality is represented in Figure 2.1. Dissipation can be introduced if it is possible to impose the following relation between flow and effort in $x = L$:

$$\left\{ \begin{array}{l} f_b^t(t,L) = -b^t(t) * e_b^t(t,L), \\ \\ f_b^r(t,L) = -b^r(t) * e_b^r(t,L) \end{array} \right. \Leftrightarrow \left\{ \begin{array}{l} \dfrac{1}{\rho} * p_t(L) = -b^t(\cdot) * K * \epsilon_t(L), \\ \\ \dfrac{1}{I_\rho} * p_r(L) = -b^r(\cdot) * EI * \epsilon_r(L) \end{array} \right. \tag{3.3}$$

with $b^t, b^r > 0$ functions of time t.

In this way, the energy balance equation (2.22) becomes

$$\begin{aligned} \frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t}(t) &= -\int_{x=L} \left[b^t(t)\, e_b^t \wedge *e_b^t + b^r(t)\, e_b^r \wedge *e_b^r \right] + \int_{x=0} \left(e_b^t \wedge f_b^t + e_b^r \wedge f_b^r \right) \\ &= -b^t(t) \left[K * \epsilon_t \mid_{x=L} \right]^2 - b^r(t) \left[EI * \epsilon_r \mid_{x=L} \right]^2 \\ &\quad + \left[e_b^t(t,0) f_b^t(t,0) + e_b^r(t,0) f_b^r(t,0) \right]. \end{aligned} \tag{3.4}$$

If, for example, the boundary conditions in $x = 0$ are

$$w(t,0) = 0, \qquad \phi(t,0) = 0, \tag{3.5a}$$

and, consequently,

$$f_b^t(t,0) = f_b^r(t,0) = 0, \tag{3.5b}$$

then (3.4) becomes

$$\frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t}(t) = -b^t(t) \left[K * \epsilon_t \mid_{x=L} \right]^2 - b^r(t) \left[EI * \epsilon_r \mid_{x=L} \right]^2 \leq 0.$$

So it is possible to state the following proposition [8].

PROPOSITION 3.1. *Consider the dpH model of the Timoshenko beam* (2.21)*, and suppose that the boundary conditions in* $x = 0$ *are given by* (3.5) *and that the controller* (3.3) *is interconnected to the beam in* $x = L$*. Then the final configuration is* (3.2)*, with* $\alpha^* = 0$ *and* $d^* = 0$*; that is,*

$$w(t,x) = 0, \qquad \phi(t,x) = 0.$$

Proof. The proof follows from Remark 3.1 and the LaSalle theorem generalized to infinite dimensions (see [9, section 3.7]). Furthermore, it is necessary that $\alpha^* = 0$ and $d^* = 0$ in (3.2), in order to be compatible with the boundary conditions (3.5a). ∎

Note 3.2. These results were already presented in [8] using a different approach. The proposed control law was written in the following form:

$$\begin{aligned} \frac{\partial w}{\partial t}(t,L) &= -b^t(t) \cdot K \left[\frac{\partial w}{\partial x}(t,L) - \phi(t,L) \right], \\ \frac{\partial \phi}{\partial t}(t,L) &= -b^r(t) \cdot EI \frac{\partial \phi}{\partial x}(t,L), \end{aligned}$$

which is clearly equivalent to (3.3). The main advantage in approaching the problem within the framework of dpH systems is that both the way the control law is deduced and the proof of its stability can be presented in a more intuitive (in some sense *physical*) and elegant way. The same considerations hold for the distributed control of the beam by damping injection presented in the next subsection: in this case, the same results were already presented in [5], but with a different approach.

3.3. Distributed control. Following the same ideas presented in the previous section, it is possible to extend the control by damping injection to the case in which the interaction between system and controller takes place through a distributed port. In this case, the (distributed) power port has to be terminated by a desired impedance implemented by a *distributed* controller. In other words, in this section it is shown how to stabilize the Timoshenko beam with a locally distributed control based on an extension to the infinite dimensional case of the damping injection control technique.

Assume that $b_d^t(t,x)$ and $b_d^r(t,x)$ are smooth functions on $\mathcal{D}$, and suppose that it is possible to find $\bar{\mathcal{D}} \subset \mathcal{D}$ and $b_0 > 0$ such that $b_d^t(\cdot,x), b_d^r(\cdot,x) \geq b_0 > 0$ if $x \in \bar{\mathcal{D}} \subset \mathcal{D}$. By taking into account the causality of the distributed port illustrated in Figure 2.1, the dissipation effects can be introduced through the distributed port if the *controller* can impose the following relation between flows and efforts on $\mathcal{D}$:

$$\text{(3.6a)} \qquad \begin{cases} f_d^t = -b_d^t * e_d^t, \\ f_d^r = -b_d^r * e_d^r. \end{cases}$$

This relation can be equivalently written as

$$\text{(3.6b)} \qquad \begin{cases} f_d^t = -\dfrac{b_d^t}{\rho}\, p_t, \\ f_d^r = -\dfrac{b_d^r}{I_\rho}\, p_r, \end{cases}$$

and, clearly, the closed-loop system is described by the following set of PDEs:

$$\begin{aligned} \rho \frac{\partial^2 w}{\partial t^2} - K\left(\frac{\partial^2 w}{\partial x^2} - \frac{\partial \phi}{\partial x}\right) + b_d^t \frac{\partial w}{\partial t} &= 0, \\ I_\rho \frac{\partial^2 \phi}{\partial t^2} - EI \frac{\partial^2 \phi}{\partial x^2} + K\left(\frac{\partial w}{\partial x} - \phi\right) + b_d^r \frac{\partial \phi}{\partial t} &= 0, \end{aligned}$$

in which the boundary conditions still have to be specified. Moreover, the energy balance (2.22) becomes

$$\text{(3.7)} \qquad \begin{aligned} \frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t} &= \int_{\partial\mathcal{D}} \left(e_b^t \wedge f_b^t + e_b^r \wedge f_b^r\right) + \int_{\bar{\mathcal{D}}} \left(e_d^t \wedge f_d^t + e_d^r \wedge f_d^r\right) \\ &= \int_{\partial\mathcal{D}} \left(e_b^t \wedge f_b^t + e_b^r \wedge f_b^r\right) - \int_{\bar{\mathcal{D}}} \left(b_d^t\, e_d^t \wedge *e_d^t + b_d^r\, e_d^r \wedge *e_d^r\right). \end{aligned}$$

Assume, for simplicity, that the beam is clamped in $x = 0$, that is,

$$\text{(3.8a)} \qquad w(t,0) = 0 \qquad \text{and} \qquad \phi(t,0) = 0,$$

and that there is no force/torque acting on $x = L$. Moreover, the boundary conditions, i.e., the values assumed by the power variables on the (power) ports on $\partial\mathcal{D}$, are given

by

$$\text{(3.8b)} \qquad \begin{cases} f_b^t(t,0) = 0, \\ f_b^r(t,0) = 0, \end{cases} \qquad \begin{cases} e_b^t(t,L) = 0, \\ e_b^r(t,L) = 0. \end{cases}$$

From (3.7), the energy balance relation (2.22) becomes

$$\text{(3.9)} \qquad \begin{aligned} \frac{\mathrm{d}\mathcal{H}}{\mathrm{d}t} &= -\int_{\bar{\mathcal{D}}} \left(b_d^t \, e_d^t \wedge *e_d^t + b_d^r \, e_d^r \wedge *e_d^r \right) \\ &= -\int_{\bar{\mathcal{D}}} \left[\frac{1}{b_d^t} \left(\frac{\partial w}{\partial t} \right)^2 + \frac{1}{b_d^r} \left(\frac{\partial \phi}{\partial t} \right)^2 \right] \mathrm{d}x \leq 0. \end{aligned}$$

So it is possible to state the following proposition.

PROPOSITION 3.2. *Consider the dpH system of the Timoshenko beam with distributed port* (2.21) *and suppose that the boundary conditions are given by* (3.5). *Then the distributed control action* (3.3) *asymptotically stabilizes the system in*

$$w(t,x) = 0 \qquad \textit{and} \qquad \phi(t,x) = 0.$$

Proof. From (3.9), we have that $\dot{\mathcal{H}} = 0$ if $\epsilon_t = \epsilon_r = 0$ and $p_t = p_r = 0$ on $\bar{\mathcal{D}}$. Consequently, from Proposition 3.1 and from the boundary conditions (3.8), we deduce that also on $\mathcal{D} \setminus \bar{\mathcal{D}}$ we have $\epsilon_t = \epsilon_r = 0$ and $p_t = p_r = 0$. The only configuration compatible with this *energy* configuration and the boundary conditions (3.8a) is clearly $w(t,x) = 0$ and $\phi(t,x) = 0$. ∎

Note 3.3. It is important to underscore that the most difficult points in the analysis of the stability of the proposed control schemes are the proof of Remark 3.1, which characterizes the invariant solutions of the Timoshenko beam equations for zero boundary conditions, and the verification of the applicability of LaSalle theorem. More details on these problems and the rigorous way to solve them can be found in [3, Chapter 5] and [9, Chapters 3 and 5].

4. Control by interconnection and energy shaping.

4.1. Model of the plant. Consider the mechanical system of Figure 4.1, in which a flexible beam, modeled according to the Timoshenko theory and whose dpH model is given by (2.17), is connected to a rigid body with mass m and inertia momentum J in $x = L$ and to a controller in $x = 0$. The controller acts on the system with a force f_c and a torque τ_c. Since the Timoshenko model of the beam is valid only for small deformations, it is possible to assume that the motion of the rigid body is the combination of a rotational and a translational motion along $x = L$. The port Hamiltonian model of the rigid body is given by

$$\text{(4.1)} \qquad \begin{aligned} \begin{bmatrix} \dot{q} \\ \dot{p} \end{bmatrix} &= \left(\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} - \begin{bmatrix} 0 & 0 \\ 0 & D \end{bmatrix} \right) \begin{bmatrix} \partial_q H \\ \partial_p H \end{bmatrix} + \begin{bmatrix} 0 \\ I \end{bmatrix} \mathbf{f}, \\ \mathbf{e} &= \partial_p H, \end{aligned}$$

where $q = [q_1,\ q_2]^T \in Q \subset \mathbb{R}^2$ are the generalized coordinates, with q_1 the distance from the equilibrium configuration and q_2 the rotation angle, p are the generalized momenta, $\mathbf{f}, \mathbf{e} \in \mathbb{R}^2$ are the port variables,

$$\text{(4.2)} \qquad H(q,p) := \frac{1}{2} \left(\frac{p_1^2}{m} + \frac{p_2^2}{J} \right) + V(q)$$

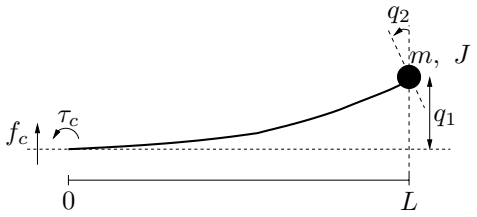

FIG. 4.1. *Flexible link with mass in $x = L$.*

FIG. 4.2. *Bond graph representation of the closed-loop system.*

is the total energy (Hamiltonian) function, with V the potential, and $D = D^{\mathrm{T}} \geq 0$ is a matrix taking into account energy dissipation.

As regards the controller, we assume that it can be modeled by means of the following finite dimensional port Hamiltonian systems:

$$\begin{aligned} \begin{bmatrix} \dot{q}_c \\ \dot{p}_c \end{bmatrix} &= \left(\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} - \begin{bmatrix} 0 & 0 \\ 0 & D_c \end{bmatrix} \right) \begin{bmatrix} \partial_{q_c} H_c \\ \partial_{p_c} H_c \end{bmatrix} + \begin{bmatrix} 0 \\ G_c \end{bmatrix} \mathbf{f}_c, \\ \mathbf{e}_c &= G_c^T \partial_{p_c} H_c, \end{aligned} \tag{4.3}$$

where $q_c \in Q_c \subset \mathbb{R}^2$ are the generalized coordinates, with $\dim(Q_c) = 2$, p_c are the generalized momenta, $\mathbf{f}_c, \mathbf{e}_c \in \mathbb{R}^2$ are the power conjugated port variables, and $D_c = D_c^{\mathrm{T}} \geq 0$ is a matrix taking into account energy dissipation. Moreover, $H_c(q_c, p_c)$ is the Hamiltonian, and it will be specified in the remaining part of this section in order to drive the whole system in a desired equilibrium configuration. Note that $\mathbf{f}_c = [f_c,\ \tau_c]^{\mathrm{T}}$.

The port causality of both the mass and the controller is assumed to be with flows as inputs and efforts as outputs. As pointed out in [23], it is possible to interconnect two port Hamiltonian systems only if a port dualization is applied on one of them. In this way, a system can have an effort as input and a flow as output. Since the port causality and orientation of the beam are given in Figure 2.1, the bond graph representation of the closed-loop system made of the Timoshenko beam, the mass in $x = L$, and the finite dimensional port Hamiltonian controller acting in $x = 0$ are given in Figure 4.2. Then, the interconnection constraints between the port variables of the subsystems are given by the following power-preserving relations:

$$\begin{cases} \begin{bmatrix} f_b^t(L) & f_f^r(L) \end{bmatrix}^{\mathrm{T}} = -\mathbf{e}, \\ \begin{bmatrix} e_b^t(L) & e_b^r(L) \end{bmatrix}^{\mathrm{T}} = \mathbf{f}, \end{cases} \qquad \begin{cases} \begin{bmatrix} f_b^t(0) & f_f^r(0) \end{bmatrix}^{T} = \mathbf{e}_c, \\ \begin{bmatrix} e_b^t(0) & e_b^r(0) \end{bmatrix}^{T} = \mathbf{f}_c. \end{cases} \tag{4.4}$$

From (2.17), (4.1), (4.3), and (4.4), it is possible to obtain the mixed finite and infinite dimensional port Hamiltonian (m-pH) representation of the closed-loop system. The total energy $\mathcal{H}_{cl}$ is defined in the extended space

$$\mathcal{X}_{cl} := \underbrace{Q \times T^*Q \times Q_c \times T^*Q_c}_{\mathcal{X}} \times \underbrace{\Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D}) \times \Omega^1(\mathcal{D})}_{\mathcal{X}_\infty} \tag{4.5}$$

and is given by the sum of the energy functions of the subsystems, that is,

$$\mathcal{H}_{cl} := H + H_c + \mathcal{H}. \tag{4.6}$$

Moreover, it is easy to verify that the energy rate is equal to

$$\frac{\mathrm{d}\mathcal{H}_{cl}}{\mathrm{d}t} = -\left(\frac{\partial^{\mathrm{T}}\mathcal{H}_{cl}}{\partial p} D \frac{\partial \mathcal{H}_{cl}}{\partial p} + \frac{\partial^{\mathrm{T}}\mathcal{H}_{cl}}{\partial p_c} D_c \frac{\partial \mathcal{H}_{cl}}{\partial p_c}\right),$$

where D_c and H_c have to be designed in order to drive the system in the desired equilibrium position, which is still to be specified. Following the same procedure presented in [20, 26] for finite dimensional port Hamiltonian systems, the idea is to *shape* the total energy $\mathcal{H}_{cl}$ by properly choosing the controller Hamiltonian H_c in order to have a new minimum of energy in the desired configuration that can be reached if some dissipative effect is introduced. The first step is to find the Casimir functionals of the closed-loop system.

4.2. Casimir functionals for the closed-loop system. The applicability of the control by interconnection and energy shaping relies on the possibility of relating the controller state variables to the state variables of the plant by means of Casimir functions [13]. Equivalently, we can say that the controller structure is chosen in order to constrain the closed-loop trajectory to evolve on a particular submanifold of the whole state space. The key point is, then, to find necessary and sufficient conditions on the existence of Casimir functions for a given dynamical system. Since a Casimir function is a structural invariant, that is, a scalar function defined on the state space of a dynamical system which is constant along its trajectories independently from the Hamiltonian function (see [20] and [26, p. 87]), a possible generalization can be given by means of the following definition [10].

DEFINITION 4.1 (Casimir functionals). *Consider a scalar function* $\mathcal{C} : \mathcal{X}_{cl} \to \mathbb{R}$ *defined on the extended state space* (4.5). *Then,* $\mathcal{C}$ *is a Casimir functional for the m-pH of Figure* 2.1 *if and only if*

$$\frac{\mathrm{d}\mathcal{C}}{\mathrm{d}t} = 0 \qquad \forall \mathcal{H}_{cl} : \mathcal{X}_{cl} \to \mathbb{R},$$

where $\mathcal{H}_{cl}$ *has the structure given in* (4.6).

The definition is quite general. In the case under study, we have that

$$\begin{aligned}\frac{\mathrm{d}\mathcal{C}}{\mathrm{d}t} &= \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q}\dot{q} + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p}\dot{p} + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q_c}\dot{q}_c + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p_c}\dot{p}_c \\ &\quad + \int_{\mathcal{D}} \left(\frac{\partial p_t}{\partial t} \wedge \delta_{p_t}\mathcal{C} + \frac{\partial p_r}{\partial t} \wedge \delta_{p_r}\mathcal{C} + \frac{\partial \epsilon_t}{\partial t} \wedge \delta_{\epsilon_t}\mathcal{C} + \frac{\partial \epsilon_r}{\partial t} \wedge \delta_{\epsilon_r}\mathcal{C}\right)\end{aligned}$$

and, from (2.17), (4.1), (4.3), and the interconnection constraints (4.4), we obtain

$$\begin{aligned}\frac{\mathrm{d}\mathcal{C}}{\mathrm{d}t} &= \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q}\frac{\partial H}{\partial p} + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p}\left\{-\frac{\partial H}{\partial q} - D\frac{\partial H}{\partial p} + [\delta_{\epsilon_t}\mathcal{H}\mid_{x=L} \quad \delta_{\epsilon_r}\mathcal{H}\mid_{x=L}]^{\mathrm{T}}\right\} \\ &\quad + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q_c}\frac{\partial H_c}{\partial p_c} + \frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p_c}\left\{-\frac{\partial H_c}{\partial q_c} - D_c\frac{\partial H_c}{\partial p_c} + G_c[\delta_{\epsilon_t}\mathcal{H}\mid_{x=0} \quad \delta_{\epsilon_r}\mathcal{H}\mid_{x=0}]^{\mathrm{T}}\right\} \\ &\quad + \int_{\mathcal{D}} [\mathrm{d}\delta_{\epsilon_t}\mathcal{H} \wedge \delta_{p_t}\mathcal{C} + (\mathrm{d}\delta_{\epsilon_r}\mathcal{H} + *\delta_{\epsilon_t}\mathcal{H}) \wedge \delta_{p_r}\mathcal{C}] \\ &\quad + \int_{\mathcal{D}} [(\mathrm{d}\delta_{p_t}\mathcal{H} - *\delta_{p_r}\mathcal{H}) \wedge \delta_{\epsilon_r}\mathcal{C} + \mathrm{d}\delta_{p_r}\mathcal{H} \wedge \delta_{\epsilon_t}\mathcal{C}].\end{aligned} \tag{4.7}$$

The integral term in (4.7) is equal to

$$\begin{aligned}
&\int_{\mathcal{D}} \left[\mathrm{d}\left(\delta_{\epsilon_t}\mathcal{H}\wedge\delta_{p_t}\mathcal{C}\right)+\mathrm{d}\left(\delta_{\epsilon_r}\mathcal{H}\wedge\delta_{p_r}\mathcal{C}\right)+\mathrm{d}\left(\delta_{p_t}\mathcal{H}\wedge\delta_{\epsilon_t}\mathcal{C}\right)+\mathrm{d}\left(\delta_{p_r}\mathcal{H}\wedge\delta_{\epsilon_r}\mathcal{C}\right)\right]\\
&\qquad -\int_{\mathcal{D}}\left[\delta_{p_t}\mathcal{H}\wedge\mathrm{d}\delta_{\epsilon_t}\mathcal{C}+\delta_{p_r}\mathcal{H}\wedge\left(\mathrm{d}\delta_{\epsilon_r}\mathcal{C}+*\delta_{\epsilon_t}\mathcal{C}\right)\right]\\
&\qquad\qquad -\int_{\mathcal{D}}\left[\delta_{\epsilon_t}\mathcal{H}\wedge\left(\mathrm{d}\delta_{p_t}\mathcal{C}-*\delta_{p_r}\mathcal{C}\right)+\delta_{\epsilon_r}\mathcal{H}\wedge\mathrm{d}\delta_{p_r}\mathcal{C}\right],
\end{aligned}\tag{4.8}$$

where, from the Stokes theorem, the first term can be written as

$$\begin{aligned}
&\int_{\partial\mathcal{D}}\left[\delta_{\epsilon_t}\mathcal{H}\mid_{\partial\mathcal{D}}\wedge\delta_{p_t}\mathcal{C}\mid_{\partial\mathcal{D}}+\cdots+\delta_{p_r}\mathcal{H}\mid_{\partial\mathcal{D}}\wedge\delta_{\epsilon_r}\mathcal{C}\mid_{\partial\mathcal{D}}\right]\\
&\qquad=\int_{\partial\mathcal{D}}\begin{bmatrix}\delta_{p_t}\mathcal{C}\mid_{\partial\mathcal{D}} & \delta_{p_r}\mathcal{C}\mid_{\partial\mathcal{D}}\end{bmatrix}\begin{bmatrix}\delta_{\epsilon_t}\mathcal{H}\mid_{\partial\mathcal{D}} & \delta_{\epsilon_r}\mathcal{H}\mid_{\partial\mathcal{D}}\end{bmatrix}^{\mathrm{T}}\\
&\qquad\quad+\int_{\partial\mathcal{D}}\begin{bmatrix}\delta_{\epsilon_t}\mathcal{C}\mid_{\partial\mathcal{D}} & \delta_{\epsilon_r}\mathcal{C}\mid_{\partial\mathcal{D}}\end{bmatrix}\begin{bmatrix}\delta_{p_t}\mathcal{H}\mid_{\partial\mathcal{D}} & \delta_{p_r}\mathcal{H}\mid_{\partial\mathcal{D}}\end{bmatrix}^{\mathrm{T}}.
\end{aligned}\tag{4.9}$$

From (4.1) and (4.3) and the interconnection constraints (4.4), we have that

$$\begin{bmatrix}\delta_{p_t}\mathcal{H}\mid_{x=L}\\ \delta_{p_r}\mathcal{H}\mid_{x=L}\end{bmatrix}=-e=-\frac{\partial H}{\partial p}\quad\text{and}\quad\begin{bmatrix}\delta_{p_t}\mathcal{H}\mid_{x=0}\\ \delta_{p_r}\mathcal{H}\mid_{x=0}\end{bmatrix}=e_c=G_c^{\mathrm{T}}\frac{\partial H_c}{\partial p_c}.$$

Then, combining (4.7) with (4.8) and (4.9), we obtain that

$$\begin{aligned}
\frac{\mathrm{d}\mathcal{C}}{\mathrm{d}t} \;=\; & -\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p}\frac{\partial H}{\partial q}-\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p_c}\frac{\partial H_c}{\partial q_c}\\
&-\left\{-\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q}+\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p}D+\begin{bmatrix}\delta_{\epsilon_t}\mathcal{C}\mid_{x=L} & \delta_{\epsilon_r}\mathcal{C}\mid_{x=L}\end{bmatrix}\right\}\frac{\partial H}{\partial p}\\
&-\left\{-\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial q_c}+\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p_c}D_c+\begin{bmatrix}\delta_{\epsilon_t}\mathcal{C}\mid_{x=0} & \delta_{\epsilon_r}\mathcal{C}\mid_{x=0}\end{bmatrix}G_c^{\mathrm{T}}\right\}\frac{\partial H_c}{\partial p_c}\\
&+\left\{\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p}+\begin{bmatrix}\delta_{p_t}\mathcal{C}\mid_{x=L} & \delta_{p_r}\mathcal{C}\mid_{x=L}\end{bmatrix}\right\}\begin{bmatrix}\delta_{\epsilon_t}\mathcal{H}\mid_{x=L} & \delta_{\epsilon_r}\mathcal{H}\mid_{x=L}\end{bmatrix}^{\mathrm{T}}\\
&+\left\{\frac{\partial^{\mathrm{T}}\mathcal{C}}{\partial p_c}-\begin{bmatrix}\delta_{p_t}\mathcal{C}\mid_{x=0} & \delta_{p_r}\mathcal{C}\mid_{x=0}\end{bmatrix}\right\}\begin{bmatrix}\delta_{\epsilon_t}\mathcal{H}\mid_{x=0} & \delta_{\epsilon_r}\mathcal{H}\mid_{x=0}\end{bmatrix}^{\mathrm{T}}\\
&-\int_{\mathcal{D}}\left[\delta_{p_t}\mathcal{H}\wedge\mathrm{d}\delta_{\epsilon_t}\mathcal{C}+\delta_{p_r}\mathcal{H}\wedge\left(\mathrm{d}\delta_{\epsilon_r}\mathcal{C}+*\delta_{\epsilon_t}\mathcal{C}\right)\right]\\
&-\int_{\mathcal{D}}\left[\delta_{\epsilon_t}\mathcal{H}\wedge\left(\mathrm{d}\delta_{p_t}\mathcal{C}-*\delta_{p_r}\mathcal{C}\right)+\delta_{\epsilon_r}\mathcal{H}\wedge\mathrm{d}\delta_{p_r}\mathcal{C}\right]
\end{aligned}$$

has to be equal to zero for every Hamiltonian H, H_c, and $\mathcal{H}$ (see Definition 4.1). This is true if and only if

$$\begin{aligned}
&\mathrm{d}\delta_{\epsilon_t}\mathcal{C}=0, && \mathrm{d}\delta_{p_t}\mathcal{C}-*\delta_{p_r}\mathcal{C}=0,\\
&\mathrm{d}\delta_{\epsilon_r}\mathcal{C}+*\delta_{\epsilon_t}\mathcal{C}=0, && \mathrm{d}\delta_{p_r}\mathcal{C}=0,\\
&\frac{\partial\mathcal{C}}{\partial p}=0,\quad \frac{\partial\mathcal{C}}{\partial p_c}=0,\quad \begin{bmatrix}\delta_{p_t}\mathcal{C}\mid_{x=L}\\ \delta_{p_r}\mathcal{C}\mid_{x=L}\end{bmatrix}=0,\quad \begin{bmatrix}\delta_{p_t}\mathcal{C}\mid_{x=0}\\ \delta_{p_r}\mathcal{C}\mid_{x=0}\end{bmatrix}=0,\\
&\frac{\partial\mathcal{C}}{\partial q}=\begin{bmatrix}\delta_{\epsilon_t}\mathcal{C}\mid_{x=L}\\ \delta_{\epsilon_r}\mathcal{C}\mid_{x=L}\end{bmatrix}, && \frac{\partial\mathcal{C}}{\partial q_c}=G_c\begin{bmatrix}\delta_{\epsilon_t}\mathcal{C}\mid_{x=0}\\ \delta_{\epsilon_r}\mathcal{C}\mid_{x=0}\end{bmatrix}.
\end{aligned}\tag{4.10}$$

In other words, the following proposition has been proved [11, 12].

PROPOSITION 4.2. *Consider the m-pH system of Figure* 4.2*, that is, the result of the power conserving interconnection* (4.4) *of the subsystems* (2.17), (4.1)*, and* (4.3)*. If* $\mathcal{X} \times \mathcal{X}_\infty$ *is the extended state space of the system, introduced in* (4.5)*, then a functional* $\mathcal{C} : \mathcal{X} \times \mathcal{X}_\infty \to \mathbb{R}$ *is a Casimir for the closed-loop system if and only if conditions* (4.10) *hold.*

Since the necessary and sufficient conditions for the existence of Casimir functions have been deduced, the control problem can be approached.

4.3. Control by energy shaping of the Timoshenko beam. In order to control the flexible beam with the finite dimensional controller (4.3), the first step is to find Casimir functionals for the closed-loop system that can relate the state variables of the controller q to the state *variables* that describe the configuration of the flexible beam and the mass connected to its extremity. In particular, we are looking for some functionals $\tilde{\mathcal{C}}_i$, $i = 1, 2$, such that

$$\mathcal{C}_i(q, p, q_c, p_c, p_t, p_r, \epsilon_t, \epsilon_r) := q_{c,i} - \tilde{\mathcal{C}}_i(q, p, p_c, p_t, p_r, \epsilon_t, \epsilon_r) \quad \text{with} \quad i = 1, 2$$

are Casimir functionals for the closed-loop system, i.e., satisfying the conditions of Proposition 4.2.

First of all, from (4.10), we note immediately that every Casimir functional cannot depend on p and p_c. Moreover, since it is necessary that $\mathrm{d}\delta_{\epsilon_t}\mathcal{C}_i = 0$ and $\mathrm{d}\delta_{p_r}\mathcal{C}_i = 0$, we deduce that $\delta_{\epsilon_t}\mathcal{C}_i$ and $\delta_{p_r}\mathcal{C}_i$ have to be constant as a function on x on $\mathcal{D}$ and their value will be determined by the boundary conditions on $\mathcal{C}_i$. Since, from (4.3), $\delta_{p_r}\mathcal{C}_i \,|_{\partial\mathcal{D}} = 0$, we deduce that $\delta_{p_r}\mathcal{C}_i = 0$ on $\mathcal{D}$. Since $\mathrm{d}\delta_{p_t}\mathcal{C}_i = *\delta_{p_r}\mathcal{C}_i = 0$, then, from the boundary conditions, we deduce that also $\delta_{p_t}\mathcal{C}_i = 0$ on $\mathcal{D}$. As a consequence, all the admissible Casimir functionals are also independent from p_t and p_r. In other words, we are interested in finding Casimir functionals in the following form:

$$\mathcal{C}_i(q, q_c, \epsilon_t, \epsilon_r) := q_{c,i} - \tilde{\mathcal{C}}_i(q, \epsilon_t, \epsilon_r), \qquad i = 1, 2.$$

Assuming $G_c = I$, we have that

$$\frac{\partial \mathcal{C}_1}{\partial q_c} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} \delta_{\epsilon_t}\mathcal{C}_1 \,|_{x=0} \\ \delta_{\epsilon_r}\mathcal{C}_1 \,|_{x=0} \end{bmatrix} \tag{4.11}$$

and, consequently, $\delta_{\epsilon_t}\mathcal{C}_1 = 1$ on $\mathcal{D}$. From (4.10), we have that $\mathrm{d}\delta_{\epsilon_r}\mathcal{C}_1 = -*\delta_{\epsilon_t}\mathcal{C}_1 = -*1 = -\mathrm{d}x$; then, $\delta_{\epsilon_r}\mathcal{C}_1 = -x + c_1$, where c_1 is determined by the boundary conditions. Since, from (4.11), $\delta_{\epsilon_r}\mathcal{C}_1 \,|_{x=0} = 0$, then $c_1 = 0$; moreover, we deduce that $\delta_{\epsilon_r}\mathcal{C} \,|_{x=L} = -L$, i.e., a new boundary condition in $x = L$. A consequence is that

$$\frac{\partial \mathcal{C}_1}{\partial q} = \begin{bmatrix} \delta_{\epsilon_t}\mathcal{C}_1 \,|_{x=L} \\ \delta_{\epsilon_r}\mathcal{C}_1 \,|_{x=L} \end{bmatrix} = \begin{bmatrix} 1 \\ -L \end{bmatrix}.$$

The first conclusion is that

$$\mathcal{C}_1(q, q_c, \epsilon_t, \epsilon_r) = q_{c,1} - (Lq_2 - q_1) - \int_{\mathcal{D}} (x\epsilon_r - \epsilon_t) \tag{4.12}$$

is a Casimir for the closed-loop system. Following the same procedure, it is possible to calculate $\mathcal{C}_2$. From (4.10), we have that

$$\frac{\partial \mathcal{C}_2}{\partial q_c} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} \delta_{\epsilon_t}\mathcal{C}_2 \,|_{x=0} \\ \delta_{\epsilon_r}\mathcal{C}_2 \,|_{x=0} \end{bmatrix},$$

and then $\delta_{\epsilon_t}\mathcal{C}_2 = 0$ on $\mathcal{D}$; moreover, $\mathrm{d}\delta_{\epsilon_r}\mathcal{C}_2 = 0$ and, consequently, $\delta_{\epsilon_r}\mathcal{C}_2 = 1$ on $\mathcal{D}$ since (4.6) holds. Again from (4.10), we deduce that

$$\frac{\partial \mathcal{C}_2}{\partial q} = \begin{bmatrix} \delta_{\epsilon_t}\mathcal{C}_2 \mid_{x=L} \\ \delta_{\epsilon_r}\mathcal{C}_2 \mid_{x=L} \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

So we can state that

$$\mathcal{C}_2(q, q_c, \epsilon_t, \epsilon_r) = q_{c,2} + q_2 + \int_{\mathcal{D}} \epsilon_r \tag{4.13}$$

is another Casimir functional for the closed-loop system. In conclusion, the following proposition has been proved [11, 12].

PROPOSITION 4.3. *Consider the m-pH system of Figure* 4.2*, that is, the result of the power conserving interconnection* (4.4) *of the subsystems* (2.17), (4.1)*, and* (4.3)*. Then* (4.12) *and* (4.13) *are Casimir functionals for this system.*

Note 4.1. Since $\mathcal{C}_i$, $i = 1, 2$, are Casimir functionals, they are invariant for the system of Figure 4.2. Then, for every energy function H_c of the controller, we have that

$$q_{c,1} = (Lq_2 - q_1) + \int_{\mathcal{D}} (x\epsilon_r - \epsilon_t) + C_1, \qquad q_{c,2} = -q_2 - \int_{\mathcal{D}} \epsilon_r + C_2, \tag{4.14}$$

where C_1 and C_2 depend on the initial conditions. If the initial configuration of the system is known, then it is possible to assume these constants are equal to zero. Since H_c is an arbitrary function of q_c, it is possible to *shape* the total energy function of the closed-loop system in order to have a minimum of energy in a desired configuration: if some dissipation effect is present, the new equilibrium configuration will be reached.

Suppose that the potential energy V in (4.2) is equal to

$$V(q_1, q_2) := \frac{1}{2}\left(k_1 q_1^2 + k_2 q_2^2\right) \tag{4.15}$$

with $k_1, k_2 > 0$. In other words, suppose that a translational and rotational spring is acting on the rigid body in $x = L$. Furthermore, suppose that $(q^*, 0)$, with $q^* = [q_1^* \; q_2^*]^{\mathrm{T}}$, is the desired equilibrium configuration of the mass (4.1). Then, the corresponding equilibrium configuration of the beam can be calculated as the solution of (2.17) with

$$\frac{\partial p_t}{\partial t} = \frac{\partial p_r}{\partial t} = \frac{\partial \epsilon_t}{\partial t} = \frac{\partial \epsilon_r}{\partial t} = 0 \quad \text{on} \quad \mathcal{D}$$

and with boundary conditions (in $x = L$) given by

$$\begin{bmatrix} f_b^t(L) \\ f_b^r(L) \end{bmatrix} = \frac{\partial H}{\partial p}(q^*, 0) = 0, \qquad \begin{bmatrix} e_b^t(L) \\ e_b^r(L) \end{bmatrix} = \frac{\partial H}{\partial q}(q^*, 0) = \begin{bmatrix} k_1 q_1^* \\ k_2 q_2^* \end{bmatrix}. \tag{4.16}$$

From (2.17), we have that the equilibrium configuration has to satisfy the following system of PDEs:

$$\begin{cases} \mathrm{d}\delta_{\epsilon_t}\mathcal{H} = 0, \\ *\delta_{\epsilon_t}\mathcal{H} + \mathrm{d}\delta_{\epsilon_r}\mathcal{H} = 0, \end{cases}$$

whose solution, compatible with the boundary conditions (4.16), is equal to

$$\begin{cases} {\epsilon_t}^*(x,t) = \dfrac{k_1}{K} q_1^*, \\ {\epsilon_r}^*(x,t) = \dfrac{k_1 q_1^*}{EI}(L-x) + \dfrac{k_2 q_2^*}{EI}. \end{cases} \tag{4.17}$$

Furthermore, at the equilibrium, it is easy to compute that $p_t = {p_t}^* = 0$ and that $p_r = {p_r}^* = 0$. From (4.14) and (4.17), define

$$\begin{aligned} q_{c,1}^* &= q_{c,1}(q_1^*, q_2^*, {\epsilon_t}^*, {\epsilon_r}^*) = L q_2^* - q_1^* + \int_0^L (x {\epsilon_r}^* - {\epsilon_t}^*)\,\mathrm{d}x \\ &= L q_2^* - q_1^* + \int_0^L \left[\frac{k_1 q_1^*}{EI}(L-x)x + \frac{k_2 q_2^*}{EI} x - \frac{k_1}{K} q_1^* \right] \mathrm{d}x \\ &= \left(\frac{k_1}{EI}\frac{L^3}{6} - \frac{k_1}{K} L - 1 \right) q_1^* + \left(\frac{k_2}{EI}\frac{L^2}{2} + L \right) q_2^*, \\ q_{c,2}^* &= q_{c,2}(q_2^*, {\epsilon_r}^*) = -q_2^* - \int_0^L \epsilon_r \mathrm{d}x \\ &= -q_2^* - \int_0^L \left[\frac{k_1 q_1^*}{EI}(L-x) + \frac{k_2 q_2^*}{EI} \right] \mathrm{d}x = -\frac{k_1}{EI}\frac{L^2}{2} q_1^* - \left(\frac{k_2}{EI} L + 1 \right) q_2^*. \end{aligned}$$

Note that, at the equilibrium, $p_c = p_c^* = 0$. The energy function H_c of the controller (4.3) will be developed in order to regulate the closed-loop system in the configuration

$$\chi^* = (q^*, p^*, p_c^*, {p_t}^*, {p_r}^*, {\epsilon_t}^*, {\epsilon_r}^*).$$

In the remaining part of this section it will be proved that, by choosing the controller energy as

$$\begin{aligned} H_c(p_c, q_c) = {} & \frac{1}{2} p_c^{\mathrm{T}} M_c^{-1} p_c + \frac{1}{2} K_{c,1}(q_{c,1} - q_{c,1}^*)^2 + \frac{1}{2} K_{c,2}(q_{c,2} - q_{c,2}^*)^2 \\ & + \Psi_1(q_{c,1}) + \Psi(q_{c,2}) \end{aligned} \tag{4.18}$$

with $M_c = M_c^{\mathrm{T}} > 0$, $K_{c,1}, K_{c,1} > 0$, and Ψ_1, Ψ_2 functions still to be specified, the configuration χ^* is stable.

Remark 4.1. It is important to point out that the proposed control methodology is *solution free*; that is, a stabilizing controller is provided by (4.3) and (4.18) but the problem of the existence of a solution of the PDE modeling the Timoshenko beam is not approached. As discussed in [9, Example 5.6], the Timoshenko beam equation generates a contraction semigroup; thus the equation has a unique classical solution. Furthermore, when closing the loop, what we obtain is a *hybrid system*, that is, a system consisting of a coupled PDE with an ODE, and also in this case it should be necessary to check under which conditions a classical solution exists. The problem can be solved by extending the approach proposed in [9, section 4.6.1], for the boundary control of an Euler–Bernoulli beam by means of a PI + strain feedback controller, to the case discussed in this paper.

As in the case of a finite dimensional Hamiltonian system, the stability of an m-pH system can be proved if it can be shown that the equilibrium is a strict extremum of the total energy of the closed-loop system. The only difference is that, in order

to prove the stability for the infinite dimensional part, it is necessary to fix a norm: it is important to note that the stability with respect to this norm, in general, will not assure the stability with respect to a different one (see, e.g., [24, p. 114]). The stability definition in the sense of Lyapunov for mixed finite and infinite dimensional systems can be given as follows [24, Definition 4.18].

DEFINITION 4.4 (Lyapunov stability for *mixed* systems). *The equilibrium configuration χ^* for a mixed finite and infinite dimensional system is said to be stable in the sense of Lyapunov with respect to the norm $\|\cdot\|$ if, for every $\epsilon > 0$, there exists $\delta_\epsilon > 0$ such that*

$$\|\chi(0) - \chi^*\| < \delta_\epsilon \quad \Rightarrow \quad \|\chi(t) - \chi*\| < \epsilon$$

$\forall t > 0$, where $\chi(0)$ is the initial configuration of the system.

As proposed in [24, pp. 116–117] and in [22], in order to verify the stability of χ^*, it is necessary to show that it is an extremum of the closed-loop energy function $\mathcal{H}_{cl}$ introduced in (4.6), with H_c given by (4.18); that is, the condition

$$\nabla \mathcal{H}_{cl}(\chi^*) = 0 \tag{4.19}$$

must hold. Moreover, if $\Delta\chi$ is the displacement from the equilibrium configuration χ^*, introduce the nonlinear functional

$$\mathcal{N}(\Delta\chi) := \mathcal{H}_{cl}(\chi^* + \Delta\chi) - \mathcal{H}_{cl}(\chi^*) \tag{4.20}$$

that is proportional to the second variation of $\mathcal{H}_{cl}$. Then the configuration χ^* is stable if it is possible to find $\gamma_1, \gamma_2, \alpha > 0$ such that [24, Theorem 4.20]

$$\gamma_1 \|\Delta\chi\|^2 \leq \mathcal{N}(\Delta\chi) \leq \gamma_2 \|\Delta\chi\|^\alpha . \tag{4.21}$$

Denote by χ the state variable of the closed-loop system. From (2.8), (4.2), (4.15), and (4.18), the total energy function is given by

$$\begin{aligned}
\mathcal{H}_{cl}(\chi) = {} & \frac{1}{2}\left(\frac{p_1^2}{m} + \frac{p_2^2}{J}\right) + \frac{1}{2}\left(k_1 q_1^2 + k_2 q_2^2\right) \\
& + \frac{1}{2}\int_{\mathcal{D}} \left(\frac{1}{\rho} p_t \wedge *p_t + \frac{1}{I_\rho} p_r \wedge *p_r + K\epsilon_t \wedge *\epsilon_t + EI\epsilon_r \wedge *\epsilon_r\right) \\
& + \frac{1}{2} p_c^{\mathrm{T}} M_c^{-1} p_c + \frac{1}{2} K_{c,1}(q_{c,1} - q_{c,1}^*)^2 + \frac{1}{2} K_{c,2}(q_{c,2} - q_{c,2}^*)^2 \\
& + \Psi_1(q_{c,1}) + \Psi(q_{c,2}).
\end{aligned}$$

The first step in the stability proof is to find under which conditions, that is, for what particular choice of the functions Ψ_1 and Ψ_2, relation (4.19) is satisfied. We have that

$$\nabla \mathcal{H}_{cl}(\chi) = \begin{bmatrix} \partial_p \mathcal{H}_{cl} \\ \partial_q \mathcal{H}_{cl} \\ \delta_{p_t} \mathcal{H}_{cl} \\ \delta_{p_r} \mathcal{H}_{cl} \\ \delta_{\epsilon_t} \mathcal{H}_{cl} \\ \delta_{\epsilon_r} \mathcal{H}_{cl} \end{bmatrix} = \begin{bmatrix} \partial_p H \\ \partial_q (H + H_c) \\ \delta_{p_t} \mathcal{H} \\ \delta_{p_r} \mathcal{H} \\ \delta_{\epsilon_t} (\mathcal{H} + H_c) \\ \delta_{\epsilon_r} (\mathcal{H} + H_c) \end{bmatrix}.$$

Clearly,

$$\frac{\partial H}{\partial p}(\chi^*) = 0, \quad \frac{\partial H_c}{\partial p_c}(\chi^*) = 0, \quad \delta_{p_t}\mathcal{H}(\chi*) = 0, \quad \text{and} \quad \delta_{p_r}\mathcal{H}(\chi^*) = 0.$$

Furthermore,

$$\begin{aligned}
\frac{\partial \mathcal{H}_{cl}}{\partial q_1} &= k_1 q_1 - K_{c,1}\left(q_{c,1} - q^*_{c,1}\right) - \frac{\partial \Psi_1}{\partial q_{c,1}}, \\
\frac{\partial \mathcal{H}_{cl}}{\partial q_2} &= k_2 q_2 + K_{c,1}\left(q_{c,1} - q^*_{c,1}\right) L - K_{c,2}\left(q_{c,2} - q^*_{c,2}\right) + \frac{\partial \Psi_1}{\partial q_{c,1}} L - \frac{\partial \Psi_2}{\partial q_{c,2}},
\end{aligned}$$

and

$$\begin{aligned}
\delta_{\epsilon_t}\mathcal{H}_{cl} &= K*\epsilon_t - K_{c,1}\left(q_{c,1} - q^*_{c,1}\right) - \frac{\partial \Psi_1}{\partial q_{c,1}}, \\
\delta_{\epsilon_r}\mathcal{H}_{cl} &= EI*\epsilon_r + K_{c,1}\left(q_{c,1} - q^*_{c,1}\right) x - K_{c,2}\left(q_{c,2} - q^*_{c,2}\right) + \frac{\partial \Psi_1}{\partial q_{c,1}} x - \frac{\partial \Psi_2}{\partial q_{c,2}}.
\end{aligned}$$

Then $\nabla \mathcal{H}_{cl}(\chi^*) = 0$ if

$$\begin{cases}
\Psi_1(q_{c,1}) = k_1 q_1^* q_{c,1} + \psi_{c,1}, \\
\Psi_2(q_{c,2}) = \left(k_2 q_2^* + k_1 q_1^* L\right) q_{c,2} + \psi_{c,2},
\end{cases}$$

with $\psi_{c,1}$ and $\psi_{c,2}$ arbitrary constants. Once the equilibrium is assigned in χ^*, it is necessary to verify the convexity condition (4.21) in χ^* on the nonlinear functional $\mathcal{N}$. After simple calculations, it can be obtained (see [10]) that

$$\begin{aligned}
\|\Delta\chi\| = {} & \frac{1}{2}\Delta p^{\mathrm{T}} M^{-1} \Delta p + \frac{1}{2}\Delta p_c^{\mathrm{T}} M_c^{-1} \Delta p_c + \frac{1}{2} k_1 \Delta q_1^2 + \frac{1}{2} k_2 \Delta q_2^2 \\
& + \frac{1}{2}\int_0^L \left(\frac{1}{\rho}\Delta p_t \wedge *p_t + \frac{1}{I_\rho}\Delta p_r \wedge *p_r + K \Delta\epsilon_t \wedge *\Delta\epsilon_t + EI \Delta\epsilon_r \wedge *\Delta\epsilon_r \right) \\
& + \frac{1}{2} K_{c,1} \left[L\Delta q_2 - \Delta q_1 + \int_0^L \left(x\Delta\epsilon_r - \Delta\epsilon_t\right) \right]^2 + \frac{1}{2} K_{c,2} \left[\Delta q_2 + \int_0^L \Delta\epsilon_r \right]^2 .
\end{aligned}$$

The convexity condition (4.21) requires a norm in order to be verified: a possible choice can be

$$\begin{aligned}
\|\chi\|^2 = {} & \frac{1}{2}\Delta p^{\mathrm{T}} \Delta p + \frac{1}{2}\Delta p_c^{\mathrm{T}} \Delta p_c + \frac{1}{2}\Delta q_1^2 + \frac{1}{2}\Delta q_2^2 \\
& + \frac{1}{2}\int_0^L \left(\Delta p_t \wedge *p_t + \Delta p_r \wedge *p_r + \Delta\epsilon_t \wedge *\Delta\epsilon_t + \Delta\epsilon_r \wedge *\Delta\epsilon_r \right).
\end{aligned}$$

Then, in (4.21), assume that

$$\gamma_1 = \frac{1}{2}\min\left\{ |M^{-1}|,\ |M_c^{-1}|,\ k_1,\ k_2,\ \frac{1}{\rho},\ \frac{1}{I_\rho},\ K,\ EI \right\}.$$

Moreover, if

$$\tilde{\gamma}_2 = \frac{1}{2}\max\left\{ |M^{-1}|,\ |M_c^{-1}|,\ k_1,\ k_2,\ \frac{1}{\rho},\ \frac{1}{I_\rho},\ K,\ EI,\ K_{c,1},\ K_{c,2} \right\},$$

we have that

$$\mathcal{N}(\Delta\chi) \leq \tilde{\gamma}_2 \|\Delta\chi\| + \tilde{\gamma}_2 \left[L\Delta q_2 - \Delta q_1 + \int_0^L (x\Delta\epsilon_r - \Delta\epsilon_t) \right]^2 + \tilde{\gamma}_2 \left[\Delta q_2 + \int_0^L \Delta\epsilon_r \right]^2.$$

Since

$$\begin{aligned}
\left[L\Delta q_2 - \Delta q_1 + \int_0^L (x\Delta\epsilon_r - \Delta\epsilon_t) \right]^2 &\leq 2\left(L\Delta q_2 - \Delta q_1\right)^2 + 2\left[\int_0^L (x\Delta\epsilon_r - \Delta\epsilon_t) \right]^2 \\
&\leq 4\left(|\Delta q_1|^2 + L^2|\Delta q_2|^2\right) + 4\left(\int_0^L x\Delta\epsilon_r \right)^2 + 4\left(\int_0^L \Delta\epsilon_t \right)^2 \\
&\leq 4\left(|\Delta q_1|^2 + L^2|\Delta q_2|^2\right) + 4L\left(\int_0^L \Delta\epsilon_t \wedge *\Delta\epsilon_t + L\int_0^L \Delta\epsilon_r \wedge *\Delta\epsilon_r \right), \\
\left[\Delta q_2 + \int_0^L \Delta\epsilon_r \right]^2 &\leq 2|\Delta q_2|^2 + 2\left(\int_0^L \Delta\epsilon_r \right)^2 \leq 2|\Delta q_2|^2 + 2L\int_0^L \Delta\epsilon_r \wedge *\Delta\epsilon_r,
\end{aligned}$$

it is possible to satisfy (4.21) by choosing $\alpha = 2$ and

$$\gamma_2 = \tilde{\gamma}_2 \cdot \max\left\{4,\ 4L^2 + 2,\ 4L,\ 4L^2 + 2L\right\},$$

which completes the stability proof. In other words, the following proposition has been proved.

PROPOSITION 4.5. *Consider the m-pH system of Figure* 4.2*, that is, the result of the power conserving interconnection* (4.4) *of the subsystems* (2.17), (4.1)*, and* (4.3)*. If in* (4.3) *it is assumed that* $G_c = I$ *and* H_c *is chosen according to* (4.18)*, then the configuration* χ^* *is stable in the sense of Lyapunov, i.e., in the sense of Definition* 4.4*.*

5. Conclusions. Once the Timoshenko model of the beam has been reformulated within the framework of dpH systems, some considerations about control strategies of the flexible beam have been presented. In particular, the well-known control by damping injection is extended to distributed parameter systems in order to stabilize the beam acting through its boundary and/or its distributed port. Some well-known results already presented in the literature are obtained in this new framework.

Moreover, it has been shown that it is possible to extend the energy shaping by interconnection control technique to treat mixed finite and infinite dimensional systems following the same ideas presented in [22], of which this work is a continuation. In particular, the control of a mechanical system made of a flexible beam with a rigid body connected at one of its extremities has been presented. The finite dimensional controller, acting on the system through the other extremity, is developed by properly extending the concept of Casimir functions to infinite dimensions. The main advantage is that the controller is suitable for a clear physical interpretation, with the drawback that the whole approach is *solution free*, in the sense of Remark 4.1.

Future work will deal with the extension of these concepts to the modeling and control of simple kinematic chains with flexible links.

LINEAR HAMILTONIAN BEHAVIORS AND BILINEAR DIFFERENTIAL FORMS*

P. RAPISARDA† AND H. L. TRENTELMAN‡

Abstract. We study linear Hamiltonian systems using bilinear and quadratic differential forms. Such a representation-free approach allows us to use the same concepts and techniques to deal with systems isolated from their environment and with systems subject to external influences and allows us to study systems described by higher-order differential equations, thus dispensing with the usual point of view in classical mechanics of considering first- and second-order differential equations only.

Key words. linear Hamiltonian systems, two-variable polynomial matrices, bilinear and quadratic differential forms, behavioral system theory

1. Introduction.

This paper aims to give a unified treatment of linear Hamiltonian systems using the formalism of bilinear and quadratic differential forms introduced in [24]. We consider systems with and without external influences, and we deal with both cases using the same techniques and the same concepts. Moreover, we formulate concepts and study the properties of Hamiltonian systems in a representation-free way, thus dispensing with the usual point of view in mechanics and in physics (see, for example, [1]) of concentrating on first-order representations in the (generalized) coordinates and the (generalized) momenta. Instead of *postulating* the existence of a function (the Lagrangian, or the Hamiltonian) on the basis of physical considerations (conservation of energy, etc.) and deducing from such a function the equations of motion, we proceed by assuming that a set of linear differential equations with constant coefficients describing the system is given, and we *deduce* the Hamiltonian nature of the system from such equations, by proving the existence of certain bilinear functionals of the variables of the system and of their derivatives satisfying some additional property. Our approach is of a system-theoretic nature rather than derived from the study of mechanics: as happens in optimal control theory for linear systems, we consider the interplay of (quadratic and bilinear) functionals of the system variables and of the equations of motion as the central object of study when dealing with Hamiltonian systems.

In this paper we also reconcile our point of view with that of classical mechanics by showing how to construct a "generalized Lagrangian" on the basis of the equations of the system, in the sense that the trajectories of the system are stationary with respect to such a quadratic functional of the variables of the system and their derivatives. In this context, the concept of internal force also arises naturally from the equations describing the system: in this paper we show that generalized internal forces can be defined which depend on higher-order derivatives of the external variables and not only first-order ones at most, as happens in classical mechanics.

The works more closely connected with the approach proposed in this paper are [8] and [7, 19]. The approach of [8] is devoted to examining the consequences of the Hamiltonian symmetry of the transfer function on the possibility of realizing a linear system in some special form; the treatment is carried out in the framework of polynomial models. In the present paper we obtain some of the results of [8] when treating Hamiltonian systems with external influences. The work of [7, 19] (see also [6, 12, 18, 20]) deals with nonlinear systems and consequently has a larger application area than the one illustrated in the present paper. In some cases, most notably in the study of external characterizations of (nonlinear) Hamiltonian systems, such an approach provides results which indeed have a more general nature than some of those presented in this article. However, we believe that the approach presented in this paper, although applicable in its present form only to finite-dimensional linear systems, is relevant for the following reasons. First, the simpler structure of linear systems and the array of algebraic techniques available in the behavioral framework to deal with them allow us to devise constructive methods based on polynomial algebra in order to solve many of the problems arising when considering linear Hamiltonian systems, for example, the computation of "conserved quantities," of special representations, etc. (an example of the technical difficulties involved in solving similar problems in the nonlinear case is given in section III of [6]). Second, the representation-free approach that we pursue allows us to describe systems of a different nature using the same formalism, independent of the domain of application. Such a feature of our approach is especially relevant in view of the potential application of our techniques in the description of possibly infinite-dimensional nonmechanical systems, for example, those arising in the theory of fields. Moreover, proceeding directly from the equations of motion allows us to study Hamiltonianity also for complex systems (for example, those resulting from the interconnection of many simple subsystems), for which the identification of functionals representing the "conserved quantities" is not immediate; this is of particular interest when considering the application of the results presented in this paper to computer-assisted modeling and simulation.

The paper is organized as follows: in section 2 we review some notions regarding linear differential systems and bilinear differential forms, which form the setting in which we study linear Hamiltonian systems. In section 3 we define Hamiltonianity for autonomous systems. In classical mechanics, a Hamiltonian system consists of the trajectories which are stationary with respect to a Lagrangian function; in section 4 we show how such a point of view fits with our definition of Hamiltonianity, and we define the notion of generalized Lagrangian. In section 5 we consider the notion of internal forces, which we propose to see as latent variables arising naturally from the equations describing an autonomous Hamiltonian system. The relationship between internal forces and external variables in an autonomous Hamiltonian system forms the basis for our definition of a controllable Hamiltonian system. In section 6 we discuss our results and outline some directions for future research.

We give a few words on notation. The space of $\mathtt{n}$-dimensional real, respectively, complex, vectors is denoted by $\mathbb{R}^{\mathtt{n}}$, respectively, $\mathbb{C}^{\mathtt{n}}$, and the space of $\mathtt{m} \times \mathtt{n}$ real, respectively, complex, matrices, by $\mathbb{R}^{\mathtt{m}\times\mathtt{n}}$, respectively, $\mathbb{C}^{\mathtt{m}\times\mathtt{n}}$. Whenever one of the two dimensions is not specified, a bullet $\bullet$ is used so that, for example, $\mathbb{C}^{\bullet\times\mathtt{n}}$ denotes the set of complex matrices with $\mathtt{n}$ columns and an unspecified number of rows. In order to enhance readability, when dealing with a vector space $\mathbb{R}^{\bullet}$ whose elements are commonly denoted with w, we use the notation $\mathbb{R}^{\mathtt{w}}$ (note the typewriter font type); similar considerations hold for matrices representing linear operators on such spaces.

Given two column vectors x and y, we denote with $\mathrm{col}(x, y)$ the vector obtained by stacking x over y; a similar convention holds for the stacking of matrices with the same number of columns. If $A \in \mathbb{R}^{\mathtt{m}\times\mathtt{n}}$, then $A^T \in \mathbb{R}^{\mathtt{n}\times\mathtt{m}}$ denotes its transpose. If $A_i \in \mathbb{R}^{\mathtt{k}_i\times\mathtt{k}_i}$, $i = 1, \ldots, \mathtt{m}$, then block $\mathrm{diag}(A_i)_{i=1,\ldots,\mathtt{m}}$ denotes the $(\sum_{i=1}^{\mathtt{m}} \mathtt{k}_i) \times (\sum_{i=1}^{\mathtt{m}} \mathtt{k}_i)$ matrix having the A_i's on the main diagonal.

The ring of polynomials with real coefficients in the indeterminate ξ is denoted by $\mathbb{R}[\xi]$; the ring of two-variable polynomials with real coefficients in the indeterminates ζ and η is denoted by $\mathbb{R}[\zeta, \eta]$. A polynomial p in the indeterminate ξ is called *even* if $p(\xi) = p(-\xi)$ and *odd* if $p(-\xi) = -p(\xi)$. The space of all $\mathtt{n} \times \mathtt{m}$ polynomial matrices in the indeterminate ξ is denoted by $\mathbb{R}^{\mathtt{n}\times\mathtt{m}}[\xi]$, and that consisting of all $\mathtt{n} \times \mathtt{m}$ polynomial matrices in the indeterminates ζ and η is denoted by $\mathbb{R}^{\mathtt{n}\times\mathtt{m}}[\zeta, \eta]$. Given a matrix $R \in \mathbb{R}^{\mathtt{n}\times\mathtt{m}}[\xi]$, we define $R^\sim(\xi) := R^T(-\xi) \in \mathbb{R}^{\mathtt{m}\times\mathtt{n}}[\xi]$. If $R(\xi)$ has complex coefficients, then $R^\sim(\xi)$ denotes the matrix obtained from R by substituting $-\xi$ in place of ξ, transposing, and conjugating.

We denote with $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{q}})$ the set of infinitely often differentiable functions from $\mathbb{R}$ to $\mathbb{R}^{\mathtt{q}}$, and we denote with $\mathfrak{D}(\mathbb{R}, \mathbb{R}^{\mathtt{q}})$ the subset of $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{q}})$ consisting of compact support functions.

Finally, if K is an $\mathtt{n} \times \mathtt{n}$ matrix, the bilinear form on $\mathbb{R}^{\mathtt{n}}$ defined by $(x_1, x_2) \mapsto x_1^T K x_2$ is denoted by $\langle x_1, x_2\rangle_K$. If $K = K^T$, then it also induces a quadratic form $x \to x^T K x$, which we denote with $|x|_K^2$.

2. Basics. In order to make the paper as self-contained as possible, we now illustrate some basic notions regarding linear differential behaviors and bilinear and quadratic differential forms; detailed expositions of such concepts can be found, respectively, in [15] and in [24]. We conclude the section with a brief introduction to Hamiltonian constant matrices, which are relevant in the discussion of state-space representations of Hamiltonian behaviors.

2.1. Linear differential behaviors. A *linear differential behavior* is a linear subspace $\mathfrak{B}$ of $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{w}})$ consisting of all solutions w of a given system of linear constant-coefficient differential equations. Such a set is represented as

$$R\left(\frac{d}{dt}\right) w = 0, \tag{2.1}$$

where $R \in \mathbb{R}^{\bullet\times\mathtt{w}}[\xi]$; (2.1) is called a *kernel representation* of the behavior $\mathfrak{B} := \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{w}}) \mid w \text{ satisfies (2.1) }\}$, and w is called the *manifest* or *external variable* of $\mathfrak{B}$. The class of all such behaviors is denoted with $\mathfrak{L}^{\mathtt{w}}$.

When modeling physical systems from first principles, we often introduce a number of *latent* (or *auxiliary*) variables ℓ besides the manifest ones: thus *latent variable representations*

$$R\left(\frac{d}{dt}\right) w = M\left(\frac{d}{dt}\right) \ell \tag{2.2}$$

are obtained. Equation (2.2) describes the *full behavior*

$$\mathfrak{B}_{\mathrm{f}} := \{(w, \ell) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{w}+\mathtt{l}}) \mid (2.2) \text{ holds}\},$$

and we call the projection of $\mathfrak{B}_{\mathrm{f}}$ on the w variable, i.e.,

$$\mathfrak{B} := \{w \mid \exists \ell \text{ such that (2.2) holds}\},$$

the *manifest behavior* associated with (2.2). It can be shown that $\mathfrak{B}$ can also be described in kernel form, i.e., $\mathfrak{B} = \ker R'(\frac{d}{dt})$ for a suitable $R' \in \mathbb{R}^{\bullet \times \mathtt{w}}[\xi]$. The computation of such an R' from R and M is called the *elimination of the latent variable* ℓ.

When the matrix R in (2.2) is the $\mathtt{w}$-dimensional identity, we call

$$w = M\left(\frac{d}{dt}\right)\ell \tag{2.3}$$

an *image representation* of $\mathfrak{B}$. A behavior can be represented by (2.3) if and only if each of its kernel representations is associated with a polynomial matrix $R \in \mathbb{R}^{\bullet \times \mathtt{w}}[\xi]$ such that $\operatorname{rank}(R(\lambda))$ is constant for all $\lambda \in \mathbb{C}$, or equivalently, $\mathfrak{B}$ is controllable in the behavioral sense (see Chapter 5 of [15]). The latent variable ℓ in (2.3) is called *observable* from w if $[w = M(\frac{d}{dt})\ell = 0] \Longrightarrow [\ell = 0]$. It can be shown that this is the case if and only if the matrix $M(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}$.

An important class of behaviors is that of *autonomous behaviors*, which admit kernel representations (2.1) in which the matrix R is $\mathtt{w} \times \mathtt{w}$ and nonsingular. Given an autonomous behavior $\mathfrak{B} \in \mathcal{L}^{\mathtt{w}}$, the $\mathtt{w} \times \mathtt{w}$ matrices associated with any two kernel representations of $\mathfrak{B}$ have the same Smith form (see, for example, section 6.3.3 of [10]). The diagonal elements in such a Smith form are nonzero polynomials called the *invariant polynomials of* $\mathfrak{B}$; the product of such polynomials of $\mathfrak{B}$ is denoted by $\chi_{\mathfrak{B}}$ and is called the *characteristic polynomial of* $\mathfrak{B}$.

By permuting the components of w with a permutation matrix $\Pi \in \mathbb{R}^{\mathtt{w} \times \mathtt{w}}$ if necessary, we can write $\Pi w = \operatorname{col}(u, y)$ with y having $\operatorname{rank}(R)$ components and u having $\mathtt{w} - \operatorname{rank}(R)$ components, so that $\mathfrak{B}$ admits the representation $P(\frac{d}{dt})y = Q(\frac{d}{dt})u$, with P square and nonsingular. We call such a partition of the external variables of $\mathfrak{B}$ an *input/output* (*i/o*) partition, u the *input variable*, y the *output variable*, and the rational matrix $P^{-1}Q$ the *transfer function* associated with the given i/o partition. Observe that in general many choices are possible for the permutation matrix Π above: the i/o partition is not unique. Observe also that $P^{-1}Q$ is not necessarily a matrix of proper rational functions; however, among all i/o partitions for $\mathfrak{B}$, there exists at least one whose corresponding transfer function is proper.

The number of input variables is an invariant denoted with $\mathtt{m}(\mathfrak{B})$; evidently, the number $\mathtt{p}(\mathfrak{B}) := \mathtt{w} - \mathtt{m}(\mathfrak{B})$ of output variables is also an invariant. If $\mathfrak{B}$ is autonomous, it has no input variables; in other words, $\mathtt{m}(\mathfrak{B}) = 0$, or equivalently $\mathtt{p}(\mathfrak{B}) = \mathtt{w}$. If $\mathfrak{B}$ is controllable, then it admits an observable image representation (2.3) with $M \in \mathbb{R}^{\mathtt{w} \times \mathtt{1}}[\xi]$; an i/o partition then corresponds to a partition of M as $M = \operatorname{col}(U, Y)$ with $U \in \mathbb{R}^{\mathtt{1} \times \mathtt{1}}[\xi]$ nonsingular; note that $\mathtt{m}(\mathfrak{B}) = \mathtt{1}$, the dimension of ℓ. In such a case the transfer function from u to y is the matrix of rational functions $G = YU^{-1}$.

In this paper we also use the concept of state and of state representation (see [16] for a thorough discussion). A latent variable ℓ is a *state variable* for $\mathfrak{B}$ if and only if $\mathfrak{B}$ admits a representation (2.2) of first order in ℓ and zeroth order in w: $E\frac{d\ell}{dt} + F\ell + Gw = 0$. Such a representation is called a *state representation* of $\mathfrak{B}$. The minimal number of state variables that can be used in order to represent $\mathfrak{B}$ in state-space form is an invariant called the *McMillan degree* of $\mathfrak{B}$ and is denoted $\mathtt{n}(\mathfrak{B})$. By combining the notion of state with that of inputs and outputs we arrive at the *input/state/output representation* (*i/s/o*) $\frac{d}{dt}x = Ax + Bu$, $y = Cx + Du$, $w = \operatorname{col}(u, y)$.

2.2. Bilinear and quadratic differential forms. In modeling and control problems it is often necessary to study certain functionals of the system variables and their derivatives; when considering linear systems, such functionals are quadratic.

In [24] the parametrization of such functionals using two-variable polynomial matrices has been studied in detail, resulting in the definition of bilinear and quadratic differential form and in the development of a calculus with applications in stability theory, optimal and H_∞-control, and dissipativity theory. Two-variable polynomials and their algebraic properties have been used before in systems theory, for example, by Kalman [11] and Willems and Fuhrmann [22] in the context of stability analysis. We also refer to the pioneering work of Brockett [2] on path independence of integrals of quadratic functionals in the system variables and their derivatives, which prefigures some of the results obtained in [24]. In this section we review those definitions and results of the framework developed in [24] which are used in the rest of this paper.

First, some words about bilinear forms on abstract vector spaces. A *bilinear form* $\mathcal{L}$ on a vector space $\mathbb{V}$ over $\mathbb{R}$ is a mapping $\mathcal{L} : \mathbb{V} \times \mathbb{V} \to \mathbb{R}$ that is linear in each of its arguments separately. We sometimes denote a bilinear form as $\mathcal{L}|_{\mathbb{V}}$ in order to emphasize its domain. The *rank* of a bilinear form $\mathcal{L}|_{\mathbb{V}}$ equals the number of independent linear functionals $\mathcal{L}(\cdot, v)$, where v ranges over $\mathbb{V}$. A bilinear form $\mathcal{L}|_{\mathbb{V}}$ is called *nondegenerate* if for all $v \in \mathbb{V}$ we have that $\mathcal{L}(\cdot, v) = 0$ is equivalent with $v = 0$, i.e., $[\mathcal{L}(\mathbb{V}, v) = 0] \Leftrightarrow [v = 0]$. The bilinear form $\mathcal{L}$ on $\mathbb{V}$ is called *skew-symmetric* if for all $v_1, v_2 \in \mathbb{V}$ we have $\mathcal{L}(v_1, v_2) = -\mathcal{L}(v_2, v_1)$. A *symplectic space* is a pair $(\mathbb{V}, \mathcal{L})$, where $\mathbb{V}$ is a vector space over $\mathbb{R}$ and $\mathcal{L}$ is a nondegenerate, skew-symmetric, bilinear form on $\mathbb{V}$; in such a case $\mathcal{L}$ is called a *symplectic form* on $\mathbb{V}$. If $\mathbb{V}$ is a finite-dimensional space on $\mathbb{R}$, then nondegenerate symplectic forms are in one-one correspondence with nonsingular skew-symmetric matrices in the sense that for every symplectic form $\mathcal{L}$ there exists a nonsingular $K \in \mathbb{R}^{\mathtt{n}\times\mathtt{n}}$ with $K^T = -K$ such that $\mathcal{L}(x, y) = \langle x, y\rangle_K$, and conversely, every such K defines a symplectic form on $\mathbb{V}$. Obviously, such K exists only if $\mathtt{n}$ is even.

Next, we examine bilinear differential forms. Let $\Phi \in \mathbb{R}^{\mathtt{w}_1\times\mathtt{w}_2}[\zeta, \eta]$; then $\Phi(\zeta, \eta) = \sum_{h,k=0}^{N} \Phi_{h,k}\zeta^h\eta^k$, where $\Phi_{h,k} \in \mathbb{R}^{\mathtt{w}_1\times\mathtt{w}_2}$ and N is a nonnegative integer. The two-variable polynomial matrix Φ induces the bilinear functional acting on $\mathtt{w}_1$-, respectively, $\mathtt{w}_2$-dimensional infinitely differentiable trajectories, defined as $L_\Phi(w_1, w_2) = \sum_{h,k=0}^{N} (\frac{d^h w_1}{dt^h})^T \Phi_{h,k} \frac{d^k w_2}{dt^k}$. Such a functional is called a *bilinear differential form* (BDF). L_Φ is *skew-symmetric*, meaning $L_\Phi(w_1, w_2) = -L_\Phi(w_2, w_1)$ for all w_1, w_2, if and only if Φ is a *skew-symmetric* two-variable polynomial matrix, i.e., if $\mathtt{w}_1 = \mathtt{w}_2$ and $\Phi(\zeta, \eta) = -\Phi^T(\eta, \zeta)$.

A two-variable polynomial matrix $\Phi(\zeta, \eta)$ is called *symmetric* if $\mathtt{w}_1 = \mathtt{w}_2 = \mathtt{w}$ and $\Phi(\zeta, \eta) = \Phi^T(\eta, \zeta)$. In such a case, Φ induces also a quadratic functional acting on $\mathtt{w}$-dimensional infinitely smooth trajectories as $Q_\Phi(w) := L_\Phi(w, w)$. We will call Q_Φ the *quadratic differential form* (QDF) associated with Φ.

With every $\Phi \in \mathbb{R}^{\mathtt{w}_1\times\mathtt{w}_2}[\zeta, \eta]$ we associate its *coefficient matrix* $\tilde{\Phi}$, which is defined as the infinite matrix $\tilde{\Phi} := (\Phi_{i,j})_{i,j=0,\ldots}$. Observe that although $\tilde{\Phi}$ is infinite, only a finite number of its entries are nonzero. Note that Φ is skew-symmetric if and only if $\tilde{\Phi}^T = -\tilde{\Phi}$; also, Φ is symmetric if and only if $\tilde{\Phi}^T = \tilde{\Phi}$.

The association of two-variable polynomial matrices with BDFs and QDFs allows us to develop a calculus that has applications in stability theory, optimal control, and H_∞-control. We restrict our attention only to those concepts that are used in this paper. One of them is the map $\partial : \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta] \longrightarrow \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ defined by $\partial\Phi(\xi) := \Phi(-\xi, \xi)$. Observe that if $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta, \eta]$ is symmetric, then $\partial\Phi$ is *para-Hermitian*, i.e., $\partial\Phi = (\partial\Phi)^\sim$, and if Φ is skew-symmetric, then $\partial\Phi$ is *skew para-Hermitian*, i.e., $(\partial\Phi)^\sim = -\partial\Phi$. Given a BDF L_Ψ we define its *derivative* as the BDF L_Φ defined by $L_\Phi(w_1, w_2) := \frac{d}{dt}(L_\Psi(w_1, w_2))$ for all w_1, w_2. In terms of the two-variable polynomial

matrices associated with the BDFs, the relationship between a BDF and its derivative is expressed as $\Phi(\zeta,\eta) = (\zeta+\eta)\Psi(\zeta,\eta)$. The notion of a derivative of a QDF is analogous and algebraically characterized in the same way; we will not repeat its definition here.

We now discuss the notions of *rank* and of *nondegeneracy of BDFs*. Let $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$ and $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$. Then the BDF L_Φ induces a bilinear form on the real vector space $\mathfrak{B}$ by assigning to $(v,w) \in \mathfrak{B}\times\mathfrak{B}$ the real number $L_\Phi(v,w)(0)$. We denote this bilinear form by $L_\Phi|_{\mathfrak{B}}$. We can hence speak about the rank and the nondegeneracy of this induced bilinear form. In particular, $L_\Phi|_{\mathfrak{B}}$ is nondegenerate if for all $w \in \mathfrak{B}$ we have $[L_\Phi(\mathfrak{B},w)(0)=0] \Leftrightarrow [w=0]$. If $\mathfrak{B}$ is autonomous, then the following result, whose proof is easy and is left to the reader, holds.

PROPOSITION 2.1. *Let $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$, and let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$ be autonomous. Let $\frac{d}{dt}x = Ax$, $w = Cx$ be a state representation of $\mathfrak{B}$, with full behavior $\mathfrak{B}_{\mathrm{f}} = \{(x,w)|\frac{d}{dt}x = Ax, w = Cx\}$. Define $N_\infty := \mathrm{col}(CA^i)_{i=0,\dots}$; note that it has an infinite number of rows. Then $L_\Phi(w_1,w_2) = x_1^T N_\infty^T \tilde{\Phi} N_\infty x_2$ $\forall (x_1,w_1)$, $(x_2,w_2) \in \mathfrak{B}_{\mathrm{f}}$. Consequently,* rank $(L_\Phi|_{\mathfrak{B}}) =$ rank $(N_\infty^T\tilde{\Phi}N_\infty)$.

We can now characterize nondegeneracy in terms of rank.

PROPOSITION 2.2. *Let $\Phi \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\zeta,\eta]$, and let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$ be autonomous, with McMillan degree $\mathtt{n}(\mathfrak{B})$. Then $L_\Phi|_{\mathfrak{B}}$ is nondegenerate if and only if* $\mathrm{rank}(L_\Phi|_{\mathfrak{B}}) \geq \mathtt{n}(\mathfrak{B})$.

Proof. Let $\frac{d}{dt}x = Ax$, $w = Cx$ be a minimal state representation of $\mathfrak{B}$. Then $N_\infty^T\tilde{\Phi}N_\infty$ has size $\mathtt{n}(\mathfrak{B}) \times \mathtt{n}(\mathfrak{B})$. We now prove that $L_\Phi|_{\mathfrak{B}}$ is nondegenerate if and only if $N_\infty^T\tilde{\Phi}N_\infty$ is nonsingular. This will prove the claim.

(Only if) Assume $N_\infty^T\tilde{\Phi}N_\infty x_0 = 0$. Define w by $w(t) = Ce^{At}x_0$. For an arbitrary $w' = Ce^{At}x_0'$, it holds that $L_\Phi(w',w)(0) = x_0'^T N_\infty^T\tilde{\Phi}N_\infty x_0 = 0$; by the nondegeneracy of L_Φ, we conclude that $w=0$. Minimality of $\frac{d}{dt}x = Ax$, $w = Cx$ implies $x_0 = 0$.

(If) Let $w = Ce^{At}x_0 \in \mathfrak{B}$, and assume $L_\Phi(w',w)(0) = 0$ for all $w' = Ce^{At}x_0' \in \mathfrak{B}$. Then clearly $x_0'^T N_\infty^T\tilde{\Phi}N_\infty x_0 = 0$ for all x_0', so $N_\infty^T\tilde{\Phi}N_\infty x_0 = 0$. Since $N_\infty^T\tilde{\Phi}N_\infty$ is nonsingular, this implies $x_0 = 0$ and consequently $w = 0$. □

2.3. Hamiltonian matrices. Given a symplectic form $\langle x,y\rangle_K$ on $\mathbb{R}^{\mathtt{n}}$, a linear map $A : \mathbb{R}^{\mathtt{n}} \to \mathbb{R}^{\mathtt{n}}$ (or matrix $A \in \mathbb{R}^{\mathtt{n}\times\mathtt{n}}$) is called *Hamiltonian* if $\langle Ax,y\rangle_K + \langle x,Ay\rangle_K = 0$ for all $x,y \in \mathbb{R}^{\mathtt{n}}$; equivalently $A^TK + KA = 0$. For the purposes of this paper, we are especially interested in the invariant polynomials of $\xi I - A$, where A is Hamiltonian; we call them the *invariant polynomials of* A. The relevant result is the following.

PROPOSITION 2.3. *Let $A \in \mathbb{R}^{\mathtt{n}\times\mathtt{n}}$ be Hamiltonian. Then its invariant polynomials are either even or odd, and the odd ones can be divided into pairs, so that the multiplicity of zero as a root is the same for the polynomials of each pair.*

Proof. In order to prove our statement we use the results of [4]. Such results make use of the concept of *elementary divisors* of A, i.e., the irreducible factors of the invariant polynomials of $\xi I - A$, which are in one-one correspondence with the diagonal blocks appearing in the Jordan form of A (see, for example, section VII.7 of [9]).

In Theorem 2.2 of [4] it is proved that if A is Hamiltonian, then its elementary divisors $q_i \in \mathbb{C}[\xi]$ are either even polynomials: $q_i(\xi) = (\xi^2 + a^2)^{\mathtt{k}}$, with $a \in \mathbb{R}$; or, if they are not even, then they occur in pairs: as well as $q_i(\xi) = (\xi-\lambda)^{\mathtt{k}}$, $\lambda \in \mathbb{C}$, also $q_i^{\sim}(\xi) = (-\xi-\lambda)^{\mathtt{k}}$ appears. Observe that if $\lambda = 0$, then such paired elementary divisors are necessarily $\pm\xi^{2\mathtt{k}+1}$, and if $\lambda \neq 0$, then they are coprime with each other.

Conclude from these remarks that $\xi I - A$ is Smith equivalent to a diagonal form, where on the diagonal appear either even polynomials, or pairs of polynomials of the

form $\xi^{2\mathtt{k}+1}$. We now use the argument of Theorem 2 of [5] in order to prove the claim. Let $1 \leq \mathtt{k} \leq \mathtt{n}$, and consider the set $M_{\mathtt{k}}$ consisting of all $\mathtt{k} \times \mathtt{k}$ minors of $\xi I - A$; observe that $M_{\mathtt{k}}$ contains only even or odd polynomials. Now consider the greatest common divisor $\Delta_{\mathtt{k}}$ of the polynomials in $M_{\mathtt{k}}$, and observe that for every $m \in M_{\mathtt{k}}$ there exists $m' \in \mathbb{R}[\xi]$ such that $m = \Delta_{\mathtt{k}} m'$; moreover, since m is either even or odd, it holds that $m^{\sim} = \pm m = \Delta_{\mathtt{k}}^{\sim} m'^{\sim}$. It follows that $\Delta_{\mathtt{k}}^{\sim}$ divides every polynomial in $M_{\mathtt{k}}$. Consequently $\Delta_{\mathtt{k}}^{\sim}$ divides $\Delta_{\mathtt{k}}$, and by symmetry also the converse holds. It follows that $\Delta_{\mathtt{k}} = \pm \Delta_{\mathtt{k}}^{\sim}$. Since the invariant polynomials are obtained dividing $\Delta_{\mathtt{k}}$ by $\Delta_{\mathtt{k}-1}$ (with $\Delta_0 := 1$), it follows that the invariant polynomials of $\xi I - A$ are either even or odd.

In order to prove the claim regarding the paired odd polynomials, assume by contradiction that there exists a pair of odd invariant polynomials of A for which zero is a root with multiplicity $2\mathtt{k}_1 + 1$ and $2\mathtt{k}_2 + 1$, respectively, $\mathtt{k}_1 \neq \mathtt{k}_2$, and which cannot be paired otherwise. Observe that $\xi^{2\mathtt{k}_1+1}$ and $\xi^{2\mathtt{k}_2+1}$ are elementary divisors of A. Conclude that in the Jordan form of A there are two blocks associated with zero, of dimension $2\mathtt{k}_1 + 1$ and $2\mathtt{k}_2 + 1$, respectively, which cannot be paired otherwise. This, however, is in contradiction with the results of [4] on the elementary divisors. This concludes the proof. □

3. Autonomous Hamiltonian systems. The definition of an autonomous Hamiltonian system is as follows.

DEFINITION 3.1. *Let $\mathfrak{B} \in \mathcal{L}^{\mathtt{w}}$ be autonomous. $\mathfrak{B}$ is called Hamiltonian if there exists a bilinear differential form L_Ψ, such that*

(i) $\frac{d}{dt} L_\Psi(w_1, w_2) = 0$ *for all* w_1, $w_2 \in \mathfrak{B}$;
(ii) L_Ψ *is skew-symmetric;*
(iii) $L_\Psi|_{\mathfrak{B}}$ *is nondegenerate.*

In Definition 3.1 no assumption on the number $\mathtt{w}$ of external variables of $\mathfrak{B}$ is made. This point of view is in contrast with the usual definition of an autonomous Hamiltonian system, in which a symplectic structure on the space of the external variables (and consequently, an even number of such variables) is assumed. We believe that in order to investigate linear, finite-dimensional Hamiltonian systems, Definition 3.1 is a natural starting point, more so than the classical one in mechanics, as argued in the following examples.

Example 3.2. Consider a spring-mass system without friction, with behavior $\mathfrak{B}$ represented by the equation $m \frac{d^2}{dt^2} w$ where w is the displacement from the equilibrium position. The BDF L_Ψ induced by $\Psi(\zeta, \eta) = m(\zeta - \eta)$ is skew-symmetric. In fact, $L_\Psi(w_1, w_2) = m(\frac{d}{dt} w_1) w_2 - m(\frac{d}{dt} w_2) w_1$. It is easily seen that $\frac{d}{dt} L_\Psi(w_1, w_2) = 0$ for all $w_1, w_2 \in \mathfrak{B}$. Also

$$L_\Psi(w_1, w_2)(0) = \begin{pmatrix} w_1(0) \\ \frac{d}{dt} w_1(0) \end{pmatrix}^T \begin{pmatrix} 0 & -m \\ m & 0 \end{pmatrix} \begin{pmatrix} w_2(0) \\ \frac{d}{dt} w_2(0) \end{pmatrix},$$

which clearly defines a nondegenerate bilinear form on $\mathfrak{B}$. It follows that this spring-mass system with only one external variable is Hamiltonian according to Definition 3.1. It is difficult to understand why, in order to study the Hamiltonianity of such a system from the point of view of classical mechanics, one should first transform the natural second-order differential equation description into a first-order representation in which the position *and* the momentum of the mass are the external variables and then study the symplectic structure of the resulting state-space system.

The previous example illustrates but one situation in which a representation-free definition of Hamiltonianity appears to be more natural than the classical one. The

argument for a definition of Hamiltonianity independent of the particular representation at hand becomes even stronger if one realizes that very often a dynamical system is described by a set of higher-order differential equations, obtained, for example, after elimination of auxiliary variables. The following example illustrates this point.

Example 3.3. Consider two masses m_1 and m_2 attached to springs with constants k_1 and k_2. The first mass is connected to the second one via the first spring, and the second mass is connected to a "wall" with the second spring. Denote by w_1 and w_2 the positions of the masses. Then we can write down the equation of the system as $m_1\frac{d^2w_1}{dt^2} + k_1w_1 - k_1w_2 = 0$, $-k_1w_1 + m_2\frac{d^2w_2}{dt^2} + (k_1+k_2)w_2 = 0$. Eliminate w_2 from the equations and take the position w_1 of the first mass as our external variable w. The behavior $\mathfrak{B}$ of w is represented by

$$m_1m_2\frac{d^4}{dt^4}w + (k_1m_1 + k_2m_1 + k_1m_2)\frac{d^2}{dt^2}w + k_1k_2w = 0.$$

In order to simplify the notation, define $r_0 := k_1k_2$, $r_2 := k_1m_1 + k_2m_1 + k_1m_2$, and $r_4 := m_1m_2$, so that the equation describing w can be rewritten as $r(\frac{d}{dt})w = 0$, where $r(\xi) := r_0 + r_2\xi^2 + r_4\xi^4$. Define the skew-symmetric polynomial $\Psi(\zeta,\eta)$ by $\Psi(\zeta,\eta) = r_2(\zeta-\eta) + r_4(\zeta^3-\eta^3) + r_4(\zeta\eta^2-\zeta^2\eta)$. Observe that $(\zeta+\eta)\Psi(\zeta,\eta) = r(\zeta) - r(\eta)$, and consequently $\frac{d}{dt}L_\Psi(v,w) = (r(\frac{d}{dt})v)^Tw - v^T(r(\frac{d}{dt})w) = 0$ for all $v, w \in \mathfrak{B}$. Moreover, $\Psi(\eta,\zeta) = -\Psi(\zeta,\eta)$, implying that the BDF $L_\Psi(v,w)$ is skew-symmetric. Finally, since the coefficient matrix $\tilde{\Psi}$ of $\Psi(\zeta,\eta)$ is nonsingular, $L_\Psi(v,w)(0)$ clearly defines a nondegenerate bilinear form on $\mathfrak{B}$. Hence the behavior $\mathfrak{B}$ is a Hamiltonian system in the sense of Definition 3.1.

The following theorem gives conditions under which a given autonomous linear differential behavior is Hamiltonian.

THEOREM 3.4. *Let $\mathfrak{B} \in \mathcal{L}^{\mathbb{w}}$ be autonomous. The following conditions are equivalent:*

(1) *$\mathfrak{B}$ is Hamiltonian;*
(2) *every invariant polynomial of $\mathfrak{B}$ is either even or odd, and the odd invariant polynomials can be divided into pairs so that the multiplicity of zero as a root is the same for the polynomials of each pair;*
(3) *there exists a minimal state representation $\frac{d}{dt}x = Ax$, $w = Cx$ of $\mathfrak{B}$, and a symplectic form $\langle\cdot,\cdot\rangle_K$ on the state space $\mathbb{R}^{\mathbb{n}(\mathfrak{B})}$ such that A is a Hamiltonian matrix;*
(4) *for any minimal state representation $\frac{d}{dt}x = Ax$, $w = Cx$ of $\mathfrak{B}$ there exists a symplectic form $\langle\cdot,\cdot\rangle_K$ on the state space $\mathbb{R}^{\mathbb{n}(\mathfrak{B})}$ such that A is a Hamiltonian matrix.*

Proof. We prove (1) $\Rightarrow$ (4) $\Rightarrow$ (3) $\Rightarrow$ (2) $\Rightarrow$ (1).

((1) $\Rightarrow$ (4)) Let L_Ψ satisfy Definition 3.1. Let $\frac{d}{dt}x = Ax$, $w = Cx$ be a minimal state representation of $\mathfrak{B}$. From Proposition 2.1 we have that for $K_\Psi := N_\infty^T\tilde{\Psi}N_\infty \in \mathbb{R}^{\mathbb{n}(\mathfrak{B})\times\mathbb{n}(\mathfrak{B})}$ we have $L_\Psi(w_1,w_2) = x_1^TK_\Psi x_2$ for all (w_i,x_i) $(i=1,2)$ satisfying the system equations and, moreover, $\operatorname{rank}(L_\Psi|_{\mathfrak{B}}) = \operatorname{rank}(K_\Psi)$. Since $L_\Psi|_{\mathfrak{B}}$ is nondegenerate, it follows from Proposition 2.2 that $\operatorname{rank}(K_\Psi) = \mathbb{n}(\mathfrak{B})$. Consequently K_Ψ is nonsingular. Conclude from $\frac{d}{dt}L_\Psi(w_1,w_2) = 0$ for all $w_1, w_2 \in \mathfrak{B}$ that $x_1^T(A^TK_\Psi + K_\Psi A)x_2 = 0$ for all x_i such that $\frac{d}{dt}x_i = Ax_i$, $i = 1,2$. This implies $A^TK_\Psi + K_\Psi A = 0$.

((4) $\Rightarrow$ (3)) is trivial.

((3) $\Rightarrow$ (2)) Conclude from Proposition 2.3 that the invariant polynomials of A are either even or odd and that the odd ones come in pairs and have zero as a root with the same multiplicity. Now let $R \in \mathbb{R}^{\bullet\times\mathbb{w}}[\xi]$ be such that $\mathfrak{B} = \ker R(\frac{d}{dt})$. Since $\mathfrak{B}$ is

autonomous, R has full column rank. Let λ_i, $i = 1, \dots, \mathtt{w}$, be the invariant polynomials of R. Let U and V be the unimodular matrices such that $R = U\mathrm{col}(\Lambda, 0)V$, with $\Lambda := \mathrm{diag}(\lambda_i)_{i=1,\dots,\mathtt{w}}$, the Smith form of R. Then $\mathfrak{B}$ is alternatively represented by $w = V(\frac{d}{dt})^{-1}w'$, $0 = \Lambda(\frac{d}{dt})w'$. We now construct a minimal state representation of $\mathfrak{B}$. For $i = 1, \dots, \mathtt{w}$, define $A_{c,i}$ to be the companion matrix associated with the ith invariant polynomial; also, let C_i be the first vector of the canonical basis of $\mathbb{R}^{\deg(\lambda_i)}$. Define $\hat{A} :=$ block $\mathrm{diag}(A_{c,i})_{i=1,\dots,\mathtt{w}}$, $\hat{C} :=$ block $\mathrm{diag}(C_i)_{i=1,\dots,\mathtt{w}}$. Then $\frac{d}{dt}x = \hat{A}x$, $w' = \hat{C}x$ is a minimal state representation of $\ker \Lambda(\frac{d}{dt})$. In order to come up with a minimal state representation of $\mathfrak{B}$, let $V^{-1}(\xi) = V_0 + V_1\xi + \cdots + V_N\xi^N$; then it is easy to verify that $\frac{d}{dt}x = \hat{A}x$, $w = (V_0\hat{C} + V_1\hat{C}\hat{A} + \cdots + V_N\hat{C}\hat{A}^{N-1})x$ is such a representation. Observe also that $\xi I - \hat{A}$ has the same invariant polynomials of $\xi I - A$, since $\frac{d}{dt}x = Ax$, $w = Cx$ is another minimal state-space representation of $\mathfrak{B}$ (see Lemma 6.3-19 of [10]). This concludes the proof of ((3) $\Rightarrow$ (2)).

((2) $\Rightarrow$ (1)) We first derive a special representation of $\mathfrak{B}$. Let $\mathfrak{B} = \ker R(\frac{d}{dt})$ be a minimal kernel representation of $\mathfrak{B}$, and let $R = U\Delta V$ be a Smith decomposition of R, with Δ the diagonal matrix of the invariant polynomials. Denote the even invariant polynomials of $\mathfrak{B}$ with λ_i, where $i = 1, \dots, \mathtt{e}$. We denote the odd, paired, invariant polynomials with μ_i, $i = 1, \dots, \mathtt{w} - \mathtt{e}$ (observe that $\mathtt{w} - \mathtt{e}$ is even). Now reorder if necessary the invariant polynomials so that the first $\mathtt{e}$ diagonal entries of Δ are the λ_i and the last $\mathtt{w}-\mathtt{e}$ the μ_i. From the division property of the invariant polynomials and from the pairing property of the odd invariant polynomials, it follows that we can write $\mu_{2i+1}(\xi) = \xi\pi_i(\xi)$, $\mu_{2i+2}(\xi) = \xi\pi_i(\xi)g_i(\xi)g_i(-\xi)$ with π_i even and g_i and $g_i^\sim$ coprime; in other words, $g(0) \neq 0$. (Observe that g_i in general has complex coefficients, and consequently in the following it may be necessary to work with polynomial matrices with complex coefficients.)

From these considerations it follows that each 2×2 submatrix $\mathrm{diag}(\mu_{2i+1}, \mu_{2i+2})$, $i = 0, \dots, \frac{\mathtt{w}-\mathtt{e}}{2} - 1$, is Smith-equivalent to

$$\Delta_i'(\xi) = \begin{pmatrix} 0 & -\xi\pi_i(\xi)g_i(-\xi) \\ \xi\pi_i(\xi)g_i(\xi) & 0 \end{pmatrix};$$

in other words, there exist unimodular matrices T_i and $S_i \in \mathbb{C}^{2\times 2}[\xi]$ such that $\Delta_i' = T_i\mathrm{diag}(\mu_{2i+1}, \mu_{2i+2})S_i$. Now define

$$T = \mathrm{diag}(I_r, T_1, \dots, T_{\frac{\mathtt{w}-\mathtt{e}}{2}})$$

and

$$S = \mathrm{diag}(I_r, S_1, \dots, S_{\frac{\mathtt{w}-\mathtt{e}}{2}}),$$

and observe that $T\Delta S = \mathrm{diag}(\Lambda, \Delta_1', \dots, \Delta_{\frac{\mathtt{w}-\mathtt{e}}{2}}') =: \hat{\Delta}$, where $\Lambda := \mathrm{diag}(\lambda_1, \dots, \lambda_{\mathtt{e}})$. Conclude that $(S^{-1}V)^\sim TU^{-1}R = (S^{-1}V)^\sim \hat{\Delta}S^{-1}V =: R' \in \mathbb{R}^{\mathtt{w}\times\mathtt{w}}[\xi]$ is another kernel representation of $\mathfrak{B}$ satisfying $R' = R'^\sim$. It is such a representation that we use in order to come up with a BDF as in Definition 3.1.

Consider the unimodular transformation of the external variables represented by $w' := (S^{-1}V)(\frac{d}{dt})w$, and observe that the ith component of w', $i = 1, \dots, \mathtt{e}$, satisfies $\lambda_i(\frac{d}{dt})w_i' = 0$, while the remaining components satisfy $\Delta_i'(\frac{d}{dt})\mathrm{col}(w_i', w_{i+1}') = 0$, $i = 0, \dots, \frac{\mathtt{w}-\mathtt{e}}{2} - 1$. We proceed to construct a skew-symmetric BDF L_{Ψ_i} acting on the ith component w_i' and satisfying Definition 3.1. From such BDFs we will construct a BDF for $\mathfrak{B}$ with the right properties.

We begin by computing such a BDF for the case of even invariant polynomials. Since $\lambda_i - \lambda_i^\sim = 0$, it follows from Theorem 3.1 of [24] that there exists $\Psi_i \in \mathbb{R}[\zeta, \eta]$ such that $(\zeta + \eta)\Psi_i(\zeta, \eta) = \lambda_i(\zeta) - \lambda_i(\eta)$. Observe that $\Psi_i(\zeta, \eta)$ is skew-symmetric and moreover, $\frac{d}{dt} L_{\Psi_i}(w_1, w_2) = 0$ for all $w_1,\ w_2 \in \ \ker \lambda_i(\frac{d}{dt})$. We now prove that L_{Ψ_i} is nondegenerate. Write $\lambda_i(\xi) = \lambda_{i0} + \lambda_{i2}\xi^2 + \cdots + \lambda_{i,2n_i}\xi^{2n_i}$. It is easy to verify that the coefficient matrix $\tilde{\Psi}_i$ of $\Psi(\zeta, \eta)$ is a $2n_i \times 2n_i$ left-upper-triangular matrix with $\pm\lambda_{i,2n_i}$ on the main antidiagonal; as a consequence, the bilinear differential form $L_{\Psi_i}|_{\ker(\lambda_i(\frac{d}{dt}))}$ is nondegenerate. This settles the case of even invariant polynomials.

We now examine the case of paired odd invariant polynomials. Observe first that since π_i is even, the two-variable polynomial $\zeta\pi_i(\zeta)g_i(\zeta) + \eta\pi_i(\eta)g_i(-\eta)$ is divisible by $\zeta + \eta$. Now define the skew-symmetric two-variable polynomial matrix $\Psi_i(\zeta, \eta) \in \mathbb{C}^{2\times 2}[\zeta, \eta]$ as

$$\Psi_i(\zeta, \eta) := \begin{pmatrix} 0 & \frac{\zeta\pi_i(\zeta)g_i(\zeta)+\eta\pi_i(\eta)g_i(-\eta)}{\zeta+\eta} \\ -\frac{\zeta\pi_i(\zeta)g_i(-\zeta)+\eta\pi_i(\eta)g_i(\eta)}{\zeta+\eta} & 0 \end{pmatrix}.$$

We observe that $\frac{d}{dt} L_{\Psi_i}(\mathrm{col}(w_i', w_{i+1}'), \mathrm{col}(\bar{w}_i', \bar{w}_{i+1}')) = 0$ for each pair $\mathrm{col}(w_i', w_{i+1}')$, $\mathrm{col}(\bar{w}_i', \bar{w}_{i+1}')$ of trajectories in $\ker \Delta_i'(\frac{d}{dt})$. We now prove that $L_{\Psi_i}|_{\ker\Delta_i'(\frac{d}{dt})}$ is nondegenerate.

Let $\deg(\pi_i) = 2K_i$, $\deg(g_i) = L_i$. It is a matter of straightforward verification to prove that the coefficients of the terms $\zeta^k\eta^{L_i+2K_i-k}$, $k = 0, \ldots, L_i + 2K_i$, in $\frac{\zeta\pi_i(\zeta)g_i(\zeta)+\eta\pi_i(\eta)g_i(-\eta)}{\zeta+\eta}$ are equal to $g_{i,L_i}\pi_{i,2K_i} \neq 0$. It follows that the coefficient matrix $\tilde{\Psi}_i$ is a block-left-upper-triangular matrix with on the diagonal 2×2 blocks of the form

$$(-1)^k \begin{pmatrix} 0 & g_{i,L_i}\pi_{i,2K_i} \\ -g_{i,L_i}\pi_{i,2K_i} & \end{pmatrix}.$$

We conclude from this that $\tilde{\Psi}_i$ is nonsingular, and consequently the bilinear form $L_{\Psi_i}|_{\ker\Delta_i'(\frac{d}{dt})}$ is nondegenerate. This settles the case of paired odd invariant polynomials.

In order to complete the proof of the claim (2) $\Rightarrow$ (1), assume $\Psi_i(\zeta, \eta)$ has been constructed as described above; now define

$$\Psi(\zeta, \eta) := (S^{-1}V)(\zeta)^T \mathrm{diag}(\Psi_i(\zeta, \eta))(S^{-1}V)(\eta) \in \mathbb{R}^{\mathbf{q}\times\mathbf{q}}[\zeta, \eta],$$

where S, V are the unimodular matrix involved in obtaining the special decomposition of R'. (Observe that if some $\Psi_i(\zeta, \eta)$ has complex coefficients, then transposition *and* complex conjugation are required.) $\Psi(\zeta, \eta)$ induces a skew-symmetric BDF L_Ψ whose derivative is zero along $\mathfrak{B}$. The nondegeneracy of $L_\Psi|_{\mathfrak{B}}$ follows immediately from the nondegeneracy of the forms $L_{\Psi_i}|_{\ker\lambda_i(\frac{d}{dt})}$ and $L_{\Psi_i}|_{\ker\Delta_i'(\frac{d}{dt})}$. This concludes the proof. □

4. Hamiltonian systems and the Euler–Lagrange equations. In section 3 we introduced the notion of Hamiltonianity on the basis of the interplay of a skew-symmetric BDF with the dynamics of the system, without reference to the notion of Lagrangian as occurs in classical mechanics. In this section we reconcile the classical point of view with our standpoint.

We begin by introducing the notion of stationarity of a trajectory with respect to a QDF. Let $\Phi \in \mathbb{R}^{\mathbf{w}\times\mathbf{w}}[\zeta, \eta]$ be symmetric and consider the corresponding QDF

$Q_\Phi(w)$ on $\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{\mathbb{w}})$. For a given w we define the *cost degradation* of adding the compact-support function $\delta \in \mathfrak{D}(\mathbb{R},\mathbb{R}^{\mathbb{w}})$ to w as

$$J_w(\delta) := \int_{-\infty}^{+\infty} (Q_\Phi(w+\delta) - Q_\Phi(w))dt.$$

The cost degradation equals $J_w(\delta) = \int_{-\infty}^{+\infty} Q_\Phi(\delta)dt + 2\int_{-\infty}^{+\infty} L_\Phi(w,\delta)dt$, and we call the second integral on the right of the equality sign the *variation associated with* w. It defines a linear functional which associates with every $\delta \in \mathfrak{D}(\mathbb{R},\mathbb{R}^{\mathbb{w}})$ a real number $2\int_{-\infty}^{+\infty} L_\Phi(w,\delta)dt$. We call w a *stationary trajectory* of Q_Φ if the variation associated with w is the zero functional. The following proposition establishes a representation of all stationary trajectories of given QDF Q_Φ. Recall that, for a given two-variable polynomial matrix $\Phi(\zeta,\eta)$, $\partial\Phi(\xi)$ is defined as the one-variable polynomial matrix $\Phi(-\xi,\xi)$.

PROPOSITION 4.1. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{\mathbb{w}\times\mathbb{w}}[\zeta,\eta]$ be symmetric. Then $w \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{\mathbb{w}})$ is a stationary trajectory of the QDF Q_Φ if and only if w satisfies the differential equation*

$$\partial\Phi\left(\frac{d}{dt}\right) w = 0. \tag{4.1}$$

Proof. Factor $\Phi(\zeta,\eta) = M^T(\zeta)\Sigma M(\eta)$, with Σ a nonsingular signature matrix, and $M(\xi) = M_0 + M_1\xi + M_2\xi^2 + \cdots + M_L\xi^L$ (see section 3 of [24]). Integrating by parts on $\delta \in \mathfrak{D}(\mathbb{R},\mathbb{R}^{\mathbb{w}})$, the variation $\int_{-\infty}^{+\infty}(M(\frac{d}{dt})w)^T\Sigma M(\frac{d}{dt})\delta dt$ is seen to be equal to

$$\sum_{k=1}^{L}\sum_{j=k}^{L}(-1)^{k-1}\delta^{(j-k)}M_j^T\Sigma\left(M\left(\frac{d}{dt}\right)w\right)^{(k-1)}\Bigg|_{-\infty}^{+\infty} + \int_{-\infty}^{+\infty}\delta^T\left(M\left(-\frac{d}{dt}\right)^T\Sigma M\left(\frac{d}{dt}\right)w\right)dt.$$

Such a quantity is zero if and only if $M(-\frac{d}{dt})^T\Sigma M(\frac{d}{dt})w = 0$; equivalently, $\partial\Phi(\frac{d}{dt})w = 0$. ∎

From the classical theory of calculus of variations it is well known that the stationary trajectories for a given functional can be characterized in terms of the so-called higher-order Euler equations, often called the Euler–Poisson equations. If the functional is given by a QDF Q_Φ, then (4.1) can indeed be interpreted as a classical Euler–Poisson equation. In order to verify this, let $\tilde{\Phi}_{\text{eff}} := (\Phi_{k,\ell})_{k,\ell=0,\ldots,L}$. Now observe that $Q_\Phi(w)$ can be written as $F(w,w^{(1)},w^{(2)},\ldots,w^{(L)})$, with the functional $F : \mathbb{R}^{\mathbb{w}}\times\mathbb{R}^{\mathbb{w}}\times\cdots\times\mathbb{R}^{\mathbb{w}} \to \mathbb{R}$ defined by

$$F(w_0,w_1,w_2,\ldots,w_L) := \operatorname{col}(w_0,w_1,w_2,\ldots,w_L)^T\ \tilde{\Phi}_{\text{eff}}\ \operatorname{col}(w_0,w_1,w_2,\ldots,w_L).$$

In terms of this functional F, the stationary trajectories w are the solutions of the Euler–Poisson equation

$$\left(\frac{\partial F}{\partial w_0} - \frac{d}{dt}\frac{\partial F}{\partial w_1} + \frac{d^2}{dt^2}\frac{\partial F}{\partial w_2} - \cdots + (-1)^L\frac{d^L}{dt^L}\frac{\partial F}{\partial w_L}\right)(w^{(0)},\ldots,w^{(L)}) = 0. \tag{4.2}$$

It is a matter of straightforward computation to see that the equations given by (4.1) and (4.2) indeed coincide. Henceforth we will, for a given QDF Q_Φ, refer to the differential equation (4.1) as the *Euler–Poisson equation associated with* Q_Φ.

According to the *principle of least action*, the motions that are possible in a mechanical system can be obtained as the stationary trajectories of the Lagrangian, the difference between the kinetic and potential energy of the system, which is in general represented as a function of displacement and velocity. Accordingly, the corresponding Euler–Poisson equation is a system of second-order differential equations, called the *Euler–Lagrange equations* associated with the mechanical system. Thus, the possible motions in a mechanical system form a behavior represented by the Euler–Lagrange equations. We now study the converse problem (called the "inverse problem of the calculus of variations"; see [17]): *under which conditions does a linear differential behavior* $\mathfrak{B}$ *(typically described by a system of higher-order linear differential equations) consist of the stationary trajectories with respect to some functional interpretable as a Lagrangian (i.e., a functional that represents the difference between kinetic and potential energy in a suitable sense), and how does one construct such a functional on the basis of the equations describing* $\mathfrak{B}$*?* It turns out that under mild assumptions, this is the case if and only if $\mathfrak{B}$ is a Hamiltonian system. This leads us to define the notion of generalized position and generalized Lagrangian and to address the issue of the existence of second-order latent variable representations of Hamiltonian behaviors. See also [7] and [6], where the inverse problem is considered for nonlinear i/o systems, and a characterization of Hamiltonian systems is given in terms of the properties of the i/o differential equations describing them.

THEOREM 4.2. *Let* $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$ *be autonomous, and assume that* $\chi_{\mathfrak{B}}$*, the characteristic polynomial of* $\mathfrak{B}$*, has no root in zero,* $\chi_{\mathfrak{B}}(0) \neq 0$*. Then the following statements are equivalent:*

(1) $\mathfrak{B}$ *is Hamiltonian.*

(2) $\mathtt{n}(\mathfrak{B})$ *is even, and there exists a full column rank matrix* $P(\xi) \in \mathbb{R}^{\mathtt{q}\times\mathtt{w}}[\xi]$*, and nonsingular matrices* $M = M^T, K = K^T \in \mathbb{R}^{\mathtt{q}\times\mathtt{q}}$*, with* $\mathtt{q} := \mathtt{n}(\mathfrak{B})/2$*, such that* $\mathfrak{B}$ *is equal to the space of all stationary trajectories with respect to the QDF*

$$Q_L(w) = \left|\frac{d}{dt}P\left(\frac{d}{dt}\right)w\right|^2_M - \left|P\left(\frac{d}{dt}\right)w\right|^2_K;$$

equivalently, $\mathfrak{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{w}}) \mid \partial L(\frac{d}{dt})w = 0\}$*, with* $L(\zeta, \eta)$ *defined by*

$$L(\zeta, \eta) := P(\zeta)^T(\zeta\eta M - K)P(\eta). \tag{4.3}$$

Furthermore, if any of these conditions holds, then P*,* M*, and* K *satisfying the conditions in* (2)*. can be chosen in such a way that in addition*

$$\frac{d}{dt}Q_H(w) = 0 \text{ for all } w \in \mathfrak{B}, \tag{4.4}$$

where $Q_H(w) := |\frac{d}{dt}P(\frac{d}{dt})w|^2_M + |P(\frac{d}{dt})w|^2_K$.

Proof. ((1) $\Rightarrow$ (2)) Since $\mathfrak{B}$ is Hamiltonian and $\chi_{\mathfrak{B}}(0) \neq 0$, $\mathfrak{B}$ has only even invariant polynomials. We reduce to the scalar case by use of the Smith form. Consider a minimal representation of the behavior $\mathfrak{B}$ as $\mathfrak{B} = \ker R(\frac{d}{dt})$, and let $R = U\Delta V$ be the Smith decomposition of R, with Δ being a diagonal matrix. Define the behavior $\mathfrak{B}' := V(\frac{d}{dt})\mathfrak{B}$ with manifest variable w', and observe that $\mathfrak{B}' = \ker \Delta(\frac{d}{dt})$. We now examine each of the behaviors $\mathfrak{B}'_i := \ker \lambda_i(\frac{d}{dt})$, $i = 1, \ldots, \mathtt{w}$, one at a time.

Let $\lambda_i(\xi) := \lambda_{i0} + \lambda_{i2}\xi^2 + \cdots + \lambda_{i,2L_i}\xi^{2L_i}$, $\lambda_{i,2L_i} \neq 0$. Consider the following two matrices:

$$M_i := \begin{pmatrix} \lambda_{i,2} & \lambda_{i,4} & \lambda_{i,6} & \cdots & \lambda_{i,2L_i} \\ \lambda_{i,4} & \lambda_{i,6} & \lambda_{i,8} & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ \lambda_{i,2L_i-2} & \lambda_{i,2L_i} & 0 & \cdots & 0 \\ \lambda_{i,2L_i} & 0 & 0 & \cdots & 0 \end{pmatrix} \tag{4.5}$$

and

$$K_i := \begin{pmatrix} \lambda_{i,0} & 0 & 0 & \cdots & 0 \\ 0 & -\lambda_{i,4} & -\lambda_{i,6} & \dots & -\lambda_{i,2L_i} \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & -\lambda_{i,2L_i-2} & -\lambda_{i,2L_i} & \cdots & 0 \\ 0 & -\lambda_{i,2L_i} & 0 & \cdots & 0 \end{pmatrix}. \tag{4.6}$$

It is immediate to see that M_i is nonsingular; the nonsingularity of K_i follows from $\lambda_{i,2L_i} \neq 0$ and the fact that $\lambda_{i,0} \neq 0$, since $\chi_{\mathfrak{B}}(0) \neq 0$. Let $E_i(\xi) := \mathrm{col}(1, \xi^2, \dots, \xi^{2L_i-2})$ and $e_i := \mathrm{col}(1, 0, \dots, 0) \in \mathbb{R}^{L_i \times 1}$. Then the following equation holds:

$$(M_i\xi^2 + K_i)E_i(\xi) = \lambda_i(\xi)e_i. \tag{4.7}$$

This implies $E_i^T(-\xi)(M_i\xi^2 + K_i)E_i(\xi) = \lambda_i(\xi)$. Define $E(\xi) :=$ block diag$(E_i(\xi))$, $M =$ block diag(M_i), and $K =$ block diag(K_i); then $\Delta(\xi) = E^T(-\xi)((M\xi^2+K)E(\xi)$. Finally, let $P(\xi) := E(\xi)V(\xi)$. Since $\mathfrak{B}' = \ker \Delta(\frac{d}{dt})$, also $\mathfrak{B} = \ker P^T(-\frac{d}{dt})(M\frac{d^2}{dt^2} + K)P(\frac{d}{dt})$. By defining $L(\zeta, \eta) := P^T(\zeta)M\zeta\eta - K)P(\eta)$ we then obtain $\mathfrak{B} = \ker \partial L(\frac{d}{dt})$; equivalently, $\mathfrak{B}$ is the space of stationary trajectories of the QDF $Q_L(w)$.

((2) $\Rightarrow$ (1)) Since $\mathfrak{B} = \ker \partial\Phi(\frac{d}{dt})$, the claim is proved if we show that the invariant polynomials of ∂L are all even. Observe first that ∂L is para-Hermitian. Now let $1 \leq \mathtt{k} \leq \mathtt{w}$, and consider the set $M_{\mathtt{k}}$ consisting of all $\mathtt{k} \times \mathtt{k}$ minors of $\partial L(\xi)$. Observe that since $\partial L = (\partial L)^{\sim}$, if $m \in M_{\mathtt{k}}$, then also $m^{\sim} \in M_{\mathtt{k}}$. Now use an argument analogous to that used in the proof of Proposition 2.3 in order to conclude that the invariant polynomials of ∂L are either even or odd. Conclude from $\chi_{\mathfrak{B}}(0) \neq 0$ that there are no odd invariant polynomials; then it follows from statement (2) of Theorem 3.4 that $\mathfrak{B}$ is Hamiltonian.

The rest of the claim of the theorem follows easily from the definition of L. This concludes the proof. ∎

If, in statement (2) of Theorem 4.2, we interpret $q = P(\frac{d}{dt})w$ as generalized position, then $\frac{d}{dt}q = \frac{d}{dt}P(\frac{d}{dt})w$ is generalized velocity, and consequently $|\frac{d}{dt}P(\frac{d}{dt})w|^2_M = |\frac{d}{dt}q|^2_M$ and $|P(\frac{d}{dt})w|^2_K = |q|^2_K$ can be interpreted, respectively, as kinetic and potential energy. From this point of view, the QDF $Q_L(w)$ can be interpreted as a Lagrangian, and the QDF $Q_H(w)$ can be interpreted as a Hamiltonian of the system.

The equation $\partial L(\frac{d}{dt})w = 0$ is the Euler–Poisson equation associated with the QDF Q_L. Motivated by the fact that $Q_L(w)$ can be interpreted as a Lagrangian of the system $\mathfrak{B}$, we also call it an *Euler–Lagrange equation* associated with the system $\mathfrak{B}$.

The next theorem relates Hamiltonianity with the existence of a latent variable representation of second order in the latent variable $q = P(\frac{d}{dt})w$, with P as in Theorem 4.2.

THEOREM 4.3. *Let $\mathfrak{B} \in \mathcal{L}^{\mathtt{w}}$ be autonomous. Assume that $\chi_{\mathfrak{B}}(0) \neq 0$, i.e., its characteristic polynomial has no root in 0. Then the following statements are equivalent:*

(1) *$\mathfrak{B}$ is Hamiltonian.*

(2) *$\mathtt{n}(\mathfrak{B})$ is even, and there exist $M = M^T, K = K^T \in \mathbb{R}^{\mathtt{q}\times\mathtt{q}}$ nonsingular, $C_1 \in \mathbb{R}^{\mathtt{w}\times\mathtt{q}}$ and $C_2 \in \mathbb{R}^{\mathtt{w}\times\mathtt{q}}$, with $\mathtt{q} := \mathtt{n}(\mathfrak{B})/2$, such that*

$$M\frac{d^2}{dt^2}q + Kq = 0, \qquad C_1 q + C_2\frac{d}{dt}q = w \tag{4.8}$$

is an observable latent variable representation of $\mathfrak{B}$ with latent variable q. Furthermore, if $M\frac{d^2}{dt^2}q + Kq = 0$, $w = C_1q + C_2\frac{d}{dt}q$ is an observable latent variable representation of $\mathfrak{B}$ with latent variable q, then the equations $\bar{M}\frac{d^2}{dt^2}\bar{q} + \bar{K}\bar{q} = 0$, $w = \bar{C}_1\bar{q} + \bar{C}_2\frac{d}{dt}\bar{q}$ form an observable latent variable representation of $\mathfrak{B}$ with latent variable $\bar{q}$ if and only if there exist $S, T \in \mathbb{R}^{\mathtt{q}\times\mathtt{q}}$ such that the matrix

$$\begin{pmatrix} S & T \\ -TM^{-1}K & S \end{pmatrix} \tag{4.9}$$

is nonsingular, and the relations $SM^{-1}K = \bar{M}^{-1}\bar{K}S$, $TM^{-1}K = \bar{M}^{-1}\bar{K}T$, $C_1 = \bar{C}_1S - \bar{C}_2TM^{-1}K$, and $C_2 = \bar{C}_1T + \bar{C}_2S$ hold.

Proof. ((1) $\Rightarrow$ (2)) Define M_i and K_i by (4.5) and (4.6), respectively. From (4.7) it follows that $w_i' \in \mathfrak{B}_i' = \ker \lambda_i(\frac{d}{dt})$ if and only if $(M_i\frac{d^2}{dt^2} + K_i)E_i(\frac{d}{dt})w_i' = 0$. Using this, it is easily seen that the equations $M_i\frac{d^2q}{dt^2} + K_iq = 0$, $q_i = E_i(\frac{d}{dt})w_i'$ form an observable latent variable representation of $\mathfrak{B}_i'$ with latent variable q_i. Next consider the equations $M_i\frac{d^2q_i}{dt^2} + K_iq_i = 0$, $e_i^Tq_i = w_i'$, where as before $e_i := \mathrm{col}(1, 0, \ldots, 0) \in \mathbb{R}^{L_i\times 1}$. Using the special structure of M_i and K_i, it can be verified that also these equations form an observable latent variable representation of $\mathfrak{B}_i'$. Now define $C :=$ block diag(e_i^T). Then clearly $M\frac{d^2q}{dt^2} + Kq = 0$, $Cq = w'$ is an observable latent variable representation of $\mathfrak{B}'$. An observable latent variable representation of the original system $\mathfrak{B}$ is then obtained by replacing the equation $w' = Cq$ by $w = V^{-1}(\frac{d}{dt})Cq$. Note that $V^{-1}(\xi)C$ is a polynomial matrix and that any derivative $q^{(i)}$ with $i \geq 2$ can be expressed in terms of q or $q^{(1)}$ using the first equation in (4.8). From this we conclude that matrices C_1 and C_2 exist such that $M\frac{d^2q}{dt^2} + Kq = 0$, $w = C_1q + C_2\frac{d}{dt}q$ is an observable latent variable representation of $\mathfrak{B}$.

((2) $\Rightarrow$ (1)) By defining $x_1 = q$, $x_2 = \frac{dq}{dt}$, and $C = (C_1 \quad C_2)$, the state-space representation of $\mathfrak{B}$ given by $\frac{d}{dt}x_1 = x_2$, $\frac{d}{dt}x_2 = M^{-1}Kx_1$, $w = Cx$ is obtained. Clearly, (x_1, x_2) is observable from w, so this state-space representation is minimal. Observe also that

$$\begin{pmatrix} 0 & I \\ -M^{-1}K & 0 \end{pmatrix}^T \begin{pmatrix} 0 & M \\ -M & 0 \end{pmatrix} + \begin{pmatrix} 0 & M \\ -M & 0 \end{pmatrix}\begin{pmatrix} 0 & I \\ -M^{-1}K & 0 \end{pmatrix} = 0.$$

Since M is nonsingular, we conclude from statement (3) of Theorem 3.4 that $\mathfrak{B}$ is Hamiltonian.

Assume now that $M\frac{d^2}{dt^2}q + Kq = 0$, $w = C_1q + C_2\frac{d}{dt}q$ is an observable latent variable representation of $\mathfrak{B}$ with latent variable q. Suppose the equations $\bar{M}\frac{d^2}{dt^2}\bar{q} +$

$\bar{K}\bar{q} = 0$, $w = \bar{C}_1\bar{q} + \bar{C}_2\frac{d}{dt}\bar{q}$ form an observable latent variable representation of $\mathfrak{B}$ with latent variable $\bar{q}$. Then clearly $\frac{d}{dt}x = Ax$, $w = Cx$ and $\frac{d}{dt}\bar{x} = \bar{A}\bar{x}$, $w = \bar{C}\bar{x}$ with

$$A := \begin{pmatrix} 0 & I \\ -M^{-1}K & 0 \end{pmatrix}, \qquad \bar{A} := \begin{pmatrix} 0 & I \\ \bar{M}^{-1}\bar{K} & 0 \end{pmatrix},$$

$$C := \begin{pmatrix} C_1 & C_2 \end{pmatrix}, \ \bar{C} := \begin{pmatrix} \bar{C}_1 & \bar{C}_2 \end{pmatrix}$$

are two minimal state representations of $\mathfrak{B}$. Consequently there exists a nonsingular $F \in \mathbb{R}^{2\mathtt{q}\times 2\mathtt{q}}$ such that $\bar{A}F = FA$ and $\bar{C}F = C$. Using the special structure of the state-space representations it is easily seen that F must be of the form (4.9) and that the relations in the claim must hold. Conversely, by defining F by (4.9), we see that $\bar{A}F = FA$ and $\bar{C}F = C$, so that the corresponding state realizations have the same manifest behavior $\mathfrak{B}$. □

Remark 4.4. Note that in the proof of implication (2) ⇒ (1) the assumption that $\chi_{\mathfrak{B}}(\xi)$ has no root in $\xi = 0$ is not used. Our proof of implication (1) ⇒ (2) does use this assumption. At present we do not have a proof of or a counterexample to this implication without the assumption $\chi_{\mathfrak{B}}(0) \neq 0$.

In classical mechanics, the variable q consists of the position of the masses, and (4.8) is obtained by writing down Newton's second law. Theorem 4.3 shows that a Hamiltonian behavior can *always* be interpreted in some sense as a *"mechanical* system," with q "generalized position," $\frac{d}{dt}q$ "generalized velocity," M a "mass matrix," and K a matrix of "elastic constants." Further, the theorem characterizes all such representations. Of course $\frac{d}{dt}q^T M \frac{d}{dt}q$ can be interpreted as kinetic energy, $q^T Kq$ as potential energy, $(\frac{d}{dt}q)^T M(\frac{d}{dt}q) - q^T Kq$ as a Lagrangian, and $(\frac{d}{dt}q)^T M(\frac{d}{dt}q) + q^T Kq$ (which is constant along solutions q of the first equation in (4.8)) as total energy.

The similarity between (4.8) and the second-order representation typical of conservative mechanical systems should not, however, be pushed too far. Indeed, the reader can verify that the matrix M defined in the proof of Theorem 4.3 is in general not positive-definite, as a bona fide mass matrix should be. Nor would the "kinetic" and "potential" terms $\mid P(\frac{d}{dt})w \mid^2_M$ and $\mid P(\frac{d}{dt})w \mid^2_K$ have in general the physical dimensions of energies. For further discussion on these issues see the following example.

Example 4.5. Consider the configuration of Example 3.3. As shown in that example, the behavior $\mathfrak{B}$ of the position w of the first mass is represented by

$$r\left(\frac{d}{dt}\right)w = m_1m_2\frac{d^4}{dt^4}w + (k_1m_1 + k_2m_1 + k_1m_2)\frac{d^2}{dt^2}w + k_1k_2w = 0.$$

In order to obtain an observable second-order latent variable representation (4.8) of $\mathfrak{B}$ we proceed as in the proof of Theorem 4.3 and define the latent variable $q = \mathrm{col}(w, \frac{d^2}{dt^2}w)$. Then

$$M := \begin{pmatrix} r_2 & r_4 \\ r_4 & 0 \end{pmatrix}, \quad K := \begin{pmatrix} r_0 & 0 \\ 0 & -r_4 \end{pmatrix}, \quad C_1 = 1, \quad C_2 = 0.$$

The matrix M is not positive-definite, as can be verified choosing $k_1 = k_2 = 1\ \frac{\mathrm{N}}{\mathrm{m}}$ and $m_1 = m_2 = 1$ kg. Observe also that with such a choice of M, a physical interpretation of $\frac{d}{dt}q^T M \frac{d}{dt}q$ is impossible, since the physical dimensions of such a quantity are not those of an energy. However, by choosing

$$\bar{K} := \begin{pmatrix} k_2 & \frac{k_2m_1}{k_1} \\ \frac{k_2m_1}{k_1} & \frac{m_1^2(k_1+k_2)}{k_1^2} \end{pmatrix}, \quad \bar{M} := \begin{pmatrix} m_1+m_2 & \frac{m_1m_2}{k_1} \\ \frac{m_1m_2}{k_1} & \frac{m_1^2m_2}{k_1^2} \end{pmatrix}, \quad \bar{C}_1 := 1, \quad \bar{C}_2 := 0,$$

we obtain an alternative second-order latent variable representation of $\mathfrak{B}$, with the same latent variable as before. Note that $\bar{M}^{-1}\bar{K} = M^{-1}K$ so that this alternative representation is obtained from the original one by taking in Theorem 4.3 $S = I$, $T = 0$. For this second choice of representation, the generalized kinetic energy $(\frac{d}{dt}q)^T M(\frac{d}{dt}q)$ and generalized potential energy $q^T Kq$ coincide with the *physical* kinetic energy and potential energy of the system with the two masses, that is, $E_{\text{kin}}(w_1, w_2) = \frac{1}{2}(m_1(\frac{d}{dt}w_1)^2 + m_2(\frac{d}{dt}w_2)^2)$ and $E_{\text{pot}}(w_1, w_2) = \frac{1}{2}(k_1 w_1^2 - 2k_1 w_1 w_2 + (k_1 + k_2)w_2^2)$. This can be verified observing that the generalized position $q = (w, \frac{d^2}{dt^2}w)$ is related to the actual position (w_1, w_2) as $w_1 = w$, $w_2 = w + \frac{m_1}{k_1}\frac{d^2}{dt^2}w$.

It is a matter for further investigation to see whether and how a physically consistent choice of the matrices M and K can always be performed. Such an issue is particularly pressing when considering the use of the procedures presented in this paper for computer-assisted modeling and simulation.

5. Internal forces and controllable Hamiltonian systems. In this section we define internal forces as auxiliary variables and we show how they can be obtained from a higher-order Lagrangian such as that introduced in Theorem 4.2. The notion of internal force obtained in this way brings us in a natural way to the definition of a controllable Hamiltonian system; in this section we also give various characterizations of such systems in terms of their kernel, image, or state-space representations.

According to Theorem 4.2, an autonomous system $\mathfrak{B} \in \mathcal{L}^{\mathtt{w}}$ with $\chi_{\mathfrak{B}}(0) \neq 0$ is Hamiltonian if and only if there exists a polynomial matrix $P \in \mathbb{R}^{\mathtt{q}\times\mathtt{w}}[\xi]$ with full column rank, $M = M^T, K = K^T \in \mathbb{R}^{\mathtt{q}\times\mathtt{q}}$ nonsingular, with $\mathtt{q} := \mathfrak{n}(\mathfrak{B})/2$, such that $\mathfrak{B}$ has a kernel representation $P^T(-\frac{d}{dt})(M\frac{d^2}{dt^2} + K)P(\frac{d}{dt})w = 0$. Obviously, a latent variable representation with latent variable f of $\mathfrak{B}$ is then given by the equations

$$\begin{aligned} P^T\left(-\frac{d}{dt}\right) M\frac{d^2}{dt^2}P\left(\frac{d}{dt}\right) w &= f, \\ f &= -P^T\left(-\frac{d}{dt}\right) KP\left(\frac{d}{dt}\right) w. \end{aligned} \tag{5.1}$$

For a given $w \in \mathfrak{B}$, the associated $f = -P^T(-\frac{d}{dt})KP(\frac{d}{dt})w$ is called the *internal force* associated with w. Observe that there are as many internal forces as there are external variables, and that in the case of systems described by differential equations of order higher than two, the internal force depends on higher-order derivatives of the external variable (see Chapter 2, section 31 of [21], where, in the context of the dynamics of a moving charge in an electromagnetic field, an internal force is considered which depends on a potential function which depends on position *and* velocity). Such a definition harmonizes with the classical mechanics point of view of seeing the internal force as an auxiliary variable of the same dimension as the external variables and coming from some potential function depending on the configuration (external) variables. Indeed, when applied to the prototypical mechanical system $M\frac{d^2}{dt^2}q + Kq = 0$, $w = q$, equations (5.1) result in the internal force being defined as $f = -Kq$ and coming from the potential $V(q) = q^T Kq$.

The notion of internal force sheds light on the structure of autonomous Hamiltonian systems. Define $\mathfrak{B}_1, \mathfrak{B}_2 \in \mathcal{L}^{\mathtt{w}+\mathtt{f}}$ by

$$\mathfrak{B}_1 := \left\{ \begin{pmatrix} w \\ f \end{pmatrix} \mid \begin{pmatrix} P^T(-\frac{d}{dt})M\frac{d^2}{dt^2}P(\frac{d}{dt}) & -I \end{pmatrix} \begin{pmatrix} w \\ f \end{pmatrix} = 0 \right\}, \tag{5.2}$$

$$\mathfrak{B}_2 := \left\{ \begin{pmatrix} w \\ f \end{pmatrix} \mid \begin{pmatrix} P^T(-\frac{d}{dt})KP(\frac{d}{dt}) & I \end{pmatrix} \begin{pmatrix} w \\ f \end{pmatrix} = 0 \right\}. \tag{5.3}$$

Note that both $\mathfrak{B}_1$ and $\mathfrak{B}_2$ are controllable linear differential systems. The set of trajectories (w, f) compatible with the laws of both $\mathfrak{B}_1$ and $\mathfrak{B}_2$ is the behavior $\mathfrak{B}_1 \cap \mathfrak{B}_2$; we call it the *full interconnection* of $\mathfrak{B}_1$ and $\mathfrak{B}_2$. Now assume that P, M, and K in (5.1) have been computed as in the proof of ((1) $\Rightarrow$ (2)) of Theorem 4.2. It is a matter of straightforward verification to see that in such a case $P^T(-\xi)MP(\xi)$ is nonsingular; this implies that in $\mathfrak{B}_1$, f is input and w is output; it can also be verified that in $\mathfrak{B}_2$, w is input and f is output. In such a case the interconnection of $\mathfrak{B}_1$ and $\mathfrak{B}_2$ is called a *feedback interconnection* (see [23]).

We conclude that *any autonomous Hamiltonian behavior* $\mathfrak{B}$ *is the feedback interconnection of two systems, the first one* ($\mathfrak{B}_1$) *having a free* f *variable and the second one* ($\mathfrak{B}_2$) *imposing on such a variable the additional constraint represented by the second equation in* (5.1). From this standpoint, in $\mathfrak{B}_1$, f is an *external force* which can be chosen freely, while $\mathfrak{B}_2$ constrains it to be a function of the external variables w. This point of view has much in common with the notion of "Hamiltonian interconnection" introduced in [18], where the concept of an open Hamiltonian system is introduced from a system-theoretic point of view.

Example 5.1. We consider again the system described in Examples 3.3 and 4.5. Following the procedure illustrated above, $\mathfrak{B}_1$ and $\mathfrak{B}_2$ defined in (5.2) and (5.3) are described, respectively, by

$$\begin{aligned} &(m_1 + m_2)w + 2\frac{m_1 m_2}{k_1}\frac{d^2}{dt^2}w + \frac{m_1^2 m_2}{k_1^2}\frac{d^4}{dt^4}w = f, \\ &f = k_2 w + \frac{2k_2 m_1}{k_1}\frac{d^2}{dt^2}w + \left(\frac{m_1^2}{k_1} + \frac{k_2 m_1^2}{k_1^2}\right)\frac{d^4}{dt^4}w. \end{aligned} \tag{5.4}$$

Using the fact that w satisfies the fourth-order differential equation

$$m_1 m_2 \frac{d^4}{dt^4}w + (k_1 m_1 + k_2 m_1 + k_1 m_2)\frac{d^2}{dt^2}w + k_1 k_2 w = 0,$$

the expression for f obtained from the second equation in (5.4) can be rewritten in terms of the generalized position $q = \mathrm{col}(w, \frac{d^2}{dt^2}w)$ as

$$f = \left(k_2 - \frac{k_2 m_1}{m_2} - \frac{k_2^2 m_1}{k_1 m_2}\right)w + \left(-m_1 + \frac{k_2 m_1}{k_1} - \frac{m_1^2}{m_2} - 2\frac{k_2 m_1^2}{k_1 m_2} - \frac{k_2^2 m_1^2}{k_1^2 m_2}\right)\frac{d^2}{dt^2}w.$$

Such an expression can also be given in terms of the positions of the two masses described in Example 3.3 as

$$f = \left(k_2 + \frac{k_1 m_1}{m_2} + \frac{k_2 m_1}{m_2}\right)w_1 + \left(k_2 - k_1 - \frac{k_1 m_1}{m_2} - \frac{2k_2 m_1}{m_2} - \frac{k_2^2 m_1}{k_1 m_2}\right)w_2.$$

The physical interpretation of such a quantity is not easy, though it should be remarked that the *physical dimensions* of such a latent variable are indeed those of a force.

When modeling physical phenomena, closed (i.e., autonomous) systems are the exception rather than the rule: the environment in which the system is embedded almost always interacts with it, exerting some influence. Sometimes it is reasonable to assume that the way in which the environment interacts with the system—in other

words, the generating mechanism of the external influences—depends only on the attributes of the system itself, the paramount example of such a situation being the motion of a point mass or charge in a force field depending on its position. By modeling the external influence as a function of the system "configuration" we obtain an autonomous system, whose evolution depends only on its laws of motion and the "initial state."

If we take such a point of view when considering the description of $\mathfrak{B}$ as the interconnection of $\mathfrak{B}_1$ and $\mathfrak{B}_2$ defined in (5.2) and (5.3), it is natural to consider $\mathfrak{B}_1$ as a model of an open system with external influences modeled by f and $\mathfrak{B}_2$ as a description of the way in which f depends on the variables w. In principle different constraints could be imposed by $\mathfrak{B}_2$ on f, and therefore it is natural to consider the open system $\mathfrak{B}_1$ as the starting point for a study of controllable Hamiltonian systems and to investigate the consequences of the Hamiltonianity of $\mathfrak{B}$ on $\mathfrak{B}_1$. This leads us to the definition of *controllable Hamiltonian behavior*, which we presently give.

Observe first that $\mathfrak{B}_1$ defined by (5.2) has as many outputs (external variables w) as inputs (the auxiliary variables f), in accordance with the point of view adopted in classical mechanics of considering the configuration variables as manifest ones and the external forces as inputs, each acting on a configuration variable (as in the case of collocated sensors and actuators; see section 12.1 of [12]). Now consider two compact-support trajectories $(w_i, f_i) \in \mathfrak{B}_1$, $i = 1, 2$, and compute the integral $\int_{-\infty}^{+\infty} w_1 f_2 - w_2 f_1 \, \mathrm{d}t$. Integrating by parts using (5.2) and the fact that the trajectories (w_i, f_i) are compact support, it is not difficult to verify that such an integral is zero. Such an observation brings us to the notion of a *controllable Hamiltonian system.*

DEFINITION 5.2. *Let $\mathfrak{B} \in \mathcal{L}^{\mathtt{w}}$ be controllable, with $\mathtt{w}$ even. Denote*

$$J_{\mathtt{w}} := \begin{pmatrix} 0 & I_{\frac{\mathtt{w}}{2}} \\ -I_{\frac{\mathtt{w}}{2}} & 0 \end{pmatrix}. \tag{5.5}$$

$\mathfrak{B}$ is called Hamiltonian if for all trajectories w_1, $w_2 \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^{\mathtt{w}})$ we have

$$\int_{-\infty}^{+\infty} L_{J_{\mathtt{w}}}(w_1, w_2) dt = 0.$$

We discuss the relationship of Definition 5.2 with other notions of Hamiltonianity in Remarks 5.5 and 5.6 below. We proceed by illustrating Definition 5.2 with an example and then give a number of characterizations of Hamiltonianity for controllable systems in Theorem 5.4, the main result of this section.

Example 5.3. Take the same system considered in Example 4.5, but with an external force applied to the first mass. Choose as external variables the position q of the first mass and the external force f; then it is easy to see that the behavior of the system is represented by the equation

$$m_1 m_2 \frac{d^4 q}{dt^4} + (m_1 k_1 + m_1 k_2 + m_2 k_1) \frac{d^2 q}{dt^2} + k_1 k_2 q = m_2 \frac{d^2 f}{dt^2} + (k_1 + k_2) f.$$

In order for this system to be controllable, the polynomials $d(\xi) := m_1 m_2 \xi^4 + (m_1 k_1 + m_1 k_2 + m_2 k_1)\xi^2 + k_1 k_2$ and $n(\xi) := m_2 \xi^2 + k_1 + k_2$ must be coprime. In that case the system also admits an observable image representation induced by the polynomial matrix $M(\xi) := \mathrm{col}(n(\xi), d(\xi))$. We now show that this system is Hamiltonian. Observe that for any pair of compact-support trajectories $w_i = M(\frac{d}{dt})\ell_i$, $i = 1, 2$, it holds that $L J_2(w_1, w_2) = L_\Phi(\ell_1, \ell_2)$, where $\Phi(\zeta, \eta) := M(\zeta)^T J_2 M(\eta)$. In order

to prove that $\int_{-\infty}^{+\infty} LJ_2(w_1, w_2)dt = 0$, observe that $\Phi(-\xi, \xi) = 0$. Conclude from Theorem 3.1 of [24] that there exists $\Psi \in \mathbb{R}[\zeta, \eta]$ such that $\Phi(\zeta, \eta) = (\zeta + \eta)\Psi(\zeta, \eta)$, equivalently, $\frac{d}{dt}L_\Psi = L_\Phi$. Now using the fact that the latent variable trajectories ℓ_i also have compact support, we can infer that $\int_{-\infty}^{+\infty} L_\Phi(\ell_1, \ell_2)dt = L_\Psi(\ell_1, \ell_2)\big|_{-\infty}^{+\infty} = 0$.

In order to state the main result of this section, consisting of several alternative characterizations of Hamiltonianity for controllable behaviors, we need to introduce the notion of an orthogonal of a controllable behavior. Given a controllable linear differential behavior $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$, we define its *orthogonal complement* $\mathfrak{B}^\perp$ as

$$\mathfrak{B}^\perp := \left\{ w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathtt{w}}) \,\middle|\, \int_{-\infty}^{+\infty} w^T w' \, \mathrm{d}t = 0 \text{ for all } w' \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^{\mathtt{w}}) \right\}.$$

The orthogonal $\mathfrak{B}^\perp$ is again an element of $\mathfrak{L}^{\mathtt{w}}$, and it is controllable (see section 10 of [24]).

THEOREM 5.4. *Let $\mathfrak{B} \in \mathfrak{L}^{\mathtt{w}}$ be controllable, with $\mathtt{w}$ even. Let $J_{\mathtt{w}}$ be given by* (5.5)*. Then the following statements are equivalent:*

(1) $\mathfrak{B}$ *is Hamiltonian.*
(2) $\mathfrak{B} = (J_{\mathtt{w}}\mathfrak{B})^\perp$.
(3) $M^\sim J_{\mathtt{w}} M = 0$ *for each* M *such that* $w = M(\frac{d}{dt})\ell$ *is an image representation of* $\mathfrak{B}$.
(4) $RJ_{\mathtt{w}}R^\sim = 0$ *for each* R *such that* $R(\frac{d}{dt})w = 0$ *is a kernel representation of* $\mathfrak{B}$.
(5) *For every i/o partition* $\mathrm{col}(u, y) = \Pi w$ *of* $\mathfrak{B}$ *the transfer function* G *from* u *to* y *satisfies* $G^\sim\Sigma = \Sigma G$, *with* Σ *the* $\frac{\mathtt{w}}{2} \times \frac{\mathtt{w}}{2}$ *signature matrix determined by*

$$\Pi J_{\mathtt{w}} \Pi^T = \begin{pmatrix} 0 & \Sigma \\ -\Sigma & 0 \end{pmatrix}. \tag{5.6}$$

(6) $\mathtt{n} := \mathtt{n}(\mathfrak{B})$ *is even, and there exists a minimal i/s/o representation*

$$\frac{d}{dt}x = Ax + Bu, \quad y = Cx + Du, \quad \mathrm{col}(u, y) = \Pi w$$

of $\mathfrak{B}$, *such that* $J_{\mathtt{n}}A + A^T J_{\mathtt{n}} = 0$, $\Sigma D = D^T\Sigma$, *and* $B^T J_{\mathtt{n}} = -\Sigma C$, *with* Σ *the* $\frac{\mathtt{w}}{2} \times \frac{\mathtt{w}}{2}$ *signature matrix determined by* (5.6).
(7) $\mathtt{n} := \mathtt{n}(\mathfrak{B})$ *is even, and for every minimal i/s/o representation*

$$\frac{d}{dt}x = Ax + Bu, \quad y = Cx + Du, \quad \mathrm{col}(u, y) = \Pi w$$

of $\mathfrak{B}$, *there exists a nonsingular skew-symmetric matrix* $K \in \mathbb{R}^{\mathtt{n}\times\mathtt{n}}$ *such that* $KA + A^T K = 0$, $\Sigma D = D^T\Sigma$, *and* $B^T K = -\Sigma C$, *with* Σ *the* $\frac{\mathtt{w}}{2} \times \frac{\mathtt{w}}{2}$ *signature matrix determined by* (5.6).

Proof. ((1) $\Leftrightarrow$ (3)) Let $w = M(\frac{d}{dt})\ell$ be an image representation of $\mathfrak{B}$. Observe that $\int_{-\infty}^{\infty} L_{J_{\mathtt{w}}}(w_1, w_2)dt = 0$ for all $w_1, w_2 \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^{\mathtt{w}})$ if and only if $\int_{-\infty}^{\infty} L_\Psi(\ell_1, \ell_2)dt = 0$ for all ℓ_1, ℓ_2 of compact support, where $\Psi(\zeta, \eta) := M(\zeta)^T J_{\mathtt{w}} M(\eta)$. By Theorem 3.1 of [24] this holds if and only if $M^\sim J_{\mathtt{w}} M = 0$.

((3) $\Leftrightarrow$ (5)) Let Π be a $\mathtt{w} \times \mathtt{w}$ permutation matrix such that for $\mathrm{col}(u, y) \in \Pi\mathfrak{B}$, u is input and y is output. Let $w = M(\frac{d}{dt})\ell$ be any image representation of $\mathfrak{B}$ with M full column rank. Then correspondingly $\Pi M = \mathrm{col}(U, Y)$, with $\det(U) \neq 0$. The transfer matrix from u to y is equal to the matrix of rational functions $G = YU^{-1}$. We have

$$M^\sim J_{\mathtt{w}} M = M^\sim \Pi^T \Pi J_{\mathtt{w}} \Pi^T \Pi M = M^\sim \Pi^T \begin{pmatrix} 0 & \Sigma \\ -\Sigma & 0 \end{pmatrix} \Pi M = U^\sim \Sigma Y - Y^\sim \Sigma U,$$

with Σ a nonsingular $\frac{\mathtt{w}}{2} \times \frac{\mathtt{w}}{2}$ signature matrix. Since $M^\sim J_{\mathtt{w}} M = 0$ we obtain $U^\sim \Sigma Y - Y^\sim \Sigma U = 0$, equivalently, $G^\sim \Sigma = \Sigma G$. Conversely, if $G^\sim \Sigma = \Sigma G$ then take a coprime factorization $G = YU^{-1}$. Then $M := \Pi^T \mathrm{col}(U, Y)$ yields an observable image representation $w = M(\frac{d}{dt})\ell$ of $\mathfrak{B}$ which clearly satisfies $M^\sim J_{\mathtt{w}} M = 0$. It then follows easily that $M^\sim J_{\mathtt{w}} M = 0$ for any M such that $w = M(\frac{d}{dt})\ell$ is an image representation of $\mathfrak{B}$.

((3) $\Rightarrow$ (2)) Observe that $M^T(-\frac{d}{dt})w' = 0$ is a kernel representation of $\mathfrak{B}^\perp$ and $M^T(-\frac{d}{dt})J_{\mathtt{w}} w'' = 0$ is a kernel representation of $(J_{\mathtt{w}}\mathfrak{B})^\perp$. From $M^\sim J_{\mathtt{w}} M = 0$ it thus follows that $\mathfrak{B} \subseteq (J_{\mathtt{w}}\mathfrak{B})^\perp$. The equivalence ((3) $\Leftrightarrow$ (5)) shows that every transfer matrix of $\mathfrak{B}$ is square, and consequently $\mathtt{m}(\mathfrak{B}) = \mathtt{p}(\mathfrak{B})$. Hence we have $\mathtt{m}((\mathtt{J_w}\mathfrak{B})^\perp) = \mathtt{p}(\mathtt{J_w}\mathfrak{B}) = \mathtt{p}(\mathfrak{B}) = \mathtt{m}(\mathfrak{B})$. Using the calculus of behavioral equations (see [15]) it is not difficult to prove that two controllable behaviors $\mathfrak{B}_1$ and $\mathfrak{B}_2$, with the same number of inputs such that $\mathfrak{B}_1 \subseteq \mathfrak{B}_2$, must be equal. This implies that, in fact, the equality $\mathfrak{B} = (J_{\mathtt{w}}\mathfrak{B})^\perp$ holds.

((2) $\Rightarrow$ (1)) $\mathfrak{B} \subseteq (J_{\mathtt{w}}\mathfrak{B})^\perp$ by definition implies that $\int_{-\infty}^{\infty} L_{J_{\mathtt{w}}}(w_1, w_2)dt = 0$ for all $w_1, w_2 \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^{\mathtt{w}})$.

((2) $\Leftrightarrow$ (4)) Let $R(\frac{d}{dt})w = 0$ be a kernel representation of $\mathfrak{B}$. Then $w' = R^T(-\frac{d}{dt})\ell$ is an image representation of $\mathfrak{B}^\perp$ and $w'' = J_{\mathtt{w}} R^T(-\frac{d}{dt})\ell$ is an image representation of $(J_{\mathtt{w}}\mathfrak{B})^\perp$ (see section 10 of [24]). Clearly $(J_{\mathtt{w}}\mathfrak{B})^\perp \subseteq \mathfrak{B}$ implies $RJ_{\mathtt{w}}R^\sim = 0$. Conversely, if $RJ_{\mathtt{w}}R^\sim = 0$ then $(J_{\mathtt{w}}\mathfrak{B})^\perp \subseteq \mathfrak{B}$. Also, it is easily seen that $RJ_{\mathtt{w}}R^\sim = 0$ implies condition (5), so that $\mathtt{p}(\mathfrak{B}) = \mathtt{m}(\mathfrak{B})$. By the same argument used in the proof of the implication (3) $\Rightarrow$ (2) this yields that $\mathfrak{B} = (J_{\mathtt{w}}\mathfrak{B})^\perp$.

((5) $\Rightarrow$ (7)) Let (A, B, C, D) be the quadruple of matrices associated with a minimal i/s/o representation of $\mathfrak{B}$. This yields an i/o partition with transfer matrix $G(\xi) = D + C(\xi I - A)^{-1}B$. By minimality of the i/s/o representation it follows that the pair (C, A) is observable; moreover, by controllability of $\mathfrak{B}$, it follows that the pair (A, B) is controllable. Recall that there exists a nonsingular signature matrix Σ such that $\Sigma G = G^\sim \Sigma$. This implies that $(A, B, \Sigma C, \Sigma D)$ and $(-A^T, C^T\Sigma, -B^T, D^T\Sigma)$ are minimal realizations of the same transfer matrix. Consequently there exists a unique nonsingular matrix K such that $-A^T = KAK^{-1}$, $C^T\Sigma = KB$, $-B^T = \Sigma C K^{-1}$, $\Sigma D = D^T\Sigma$. It is easily verified that also $-A^T = (-K^T)A(-K^{-T})$, $C^T\Sigma = (-K^T)B$, $-B^T = \Sigma C(-K^{-T})$. Due to the uniqueness of K, it follows that $K^T = -K$, i.e., K is skew-symmetric.

((7) $\Rightarrow$ (6)) Let (A, B, C, D) be the quadruple of matrices associated with a minimal i/s/o representation of $\mathfrak{B}$. Let K be nonsingular and skew-symmetric and let Σ be a nonsingular signature matrix such that $KA + A^TK = 0$, $\Sigma D = D^T\Sigma$, and $B^TK = -\Sigma C$. There exists a nonsingular matrix S such that $S^T J_{\mathtt{n}} S = K$. Define $\hat{A} := SAS^{-1}$, $\hat{B} = SB$, $\hat{C} = CS^{-1}$, and $\hat{D} = D$. This quadruple also defines a minimal i/s/o representation of $\mathfrak{B}$. Moreover, it is easily verified that $J_{\mathtt{n}}\hat{A} + \hat{A}^T J_{\mathtt{n}} = 0$, $\Sigma\hat{D} = \hat{D}^T\Sigma$, and $\hat{B}^T J_{\mathtt{n}} = -\Sigma\hat{C}$.

((6) $\Rightarrow$ (3)) If an i/s/o representation of $\mathfrak{B}$ exists satisfying the conditions in (6), then it follows that the transfer matrix from u to y satisfies $G^\sim\Sigma = \Sigma G$. Take a coprime factorization $G = YU^{-1}$. Then $M := \Pi^T \mathrm{col}(U, Y)$ yields an observable image representation $w = M(\frac{d}{dt})\ell$ of $\mathfrak{B}$ which clearly satisfies $M^\sim J_{\mathtt{w}} M = 0$. It then follows easily that $M^\sim J_{\mathtt{w}} M = 0$ for any M such that $w = M(\frac{d}{dt})\ell$ is an image representation of $\mathfrak{B}$. □

Remark 5.5. The definition of a nonlinear Hamiltonian i/o system put forward in [7, 6] is based on the self-adjointness of the i/o map of the system. We now discuss how such a point of view relates with that given in Definition 5.2 and elaborated on

in Theorem 5.4. Assume that the variables w of the controllable system described in kernel form by $R(\frac{d}{dt})w = 0$, R of full row rank, are partitioned as $w = \mathrm{col}(u, y)$, with u consisting of $\frac{\mathtt{w}}{2}$ input variables, and y consisting of $\frac{\mathtt{w}}{2}$ output variables. Then the matrix R can be partitioned as $R = \begin{pmatrix} P & -Q \end{pmatrix}$, with P square and invertible.

Under these assumptions, the condition $RJ_{\mathtt{w}}R^{\sim} = 0$ appearing in statement (4) of Theorem 5.4 reads $QP^{\sim} - PQ^{\sim} = 0$, which is equivalent with formula (51) of [6], once it is recalled that an image representation of the adjoint system (equivalently, of the orthogonal behavior) to $\ker R(\frac{d}{dt})$ is given by $\mathrm{Im}\ R^T(-\frac{d}{dt})$.

Remark 5.6. The characterization of Hamiltonian transfer functions given in statement (5) of Theorem 5.4 is the same given in [3] in the context of i/s/o systems and in [8] in the polynomial model context. See also [20], where an external characterization of the adjoint of a linear system is given, and several of the techniques used (see, in particular, section III loc. cit.) foreshadow those based on the calculus of Q/BDFs used in the present paper.

Remark 5.7. It follows from Theorem 5.4 (for example, by applying condition (4)) that the systems $\mathfrak{B}_1$ and $\mathfrak{B}_2$ represented by, respectively, (5.2) and (5.3) are controllable Hamiltonian systems. In other words, if $\mathfrak{B}$ is an autonomous Hamiltonian system with $\chi_{\mathfrak{B}}(0) \neq 0$, then there exist two controllable Hamiltonian behaviors $\mathfrak{B}_i$, $i = 1, 2$, such that $\mathfrak{B}$ is the feedback interconnection of $\mathfrak{B}_1$ and $\mathfrak{B}_2$.

We conclude this section with two examples of controllable Hamiltonian systems.

Example 5.8. Newton's second law defines a controllable Hamiltonian system $\mathfrak{B} = \{(F, q) \mid F = m\frac{d^2}{dt^2}q\}$, as it is easy to verify using, for example, statement (4) of Theorem 5.4.

Example 5.9. Consider a parallel interconnection of a capacitor C with an inductance L subject to an external current I_e. Assume that we choose as external variables for such a system the external current and the magnetic flux ϕ_L in the inductance; it is easy to verify that in such a case the system equation is $(\frac{d^2}{dt^2} + \frac{1}{CL})\phi_L - \frac{1}{C}I_e = 0$. We show that this system is Hamiltonian. An observable image representation of the system is induced by the matrix $M(\xi) = \mathrm{col}(1, C\xi^2 + \frac{1}{L})$. Consider that $M(\zeta)^T J_2 M(\eta) = (\zeta+\eta)\Psi(\zeta, \eta)$ with $\Psi(\zeta, \eta) := C(\zeta-\eta)$. Consequently such a BDF satisfies $\frac{d}{dt}L_\Psi = L_{J_2}$ on $\mathfrak{B}$, and therefore $\int_{-\infty}^{+\infty} L_{J_2}(w_1, w_2) = 0$ for all w_1, $w_2 \in \mathfrak{B}$.

6. Conclusions. In this paper we have used the formalism of bilinear and quadratic differential forms in order to study Hamiltonian systems. The approach followed in this paper is representation-free, i.e., independent of the existence of a special representation of the system, such as a transfer function or a state-space representation. However, we have also given a characterization of Hamiltonianity for various system representations such as kernel, state-space, and transfer function, in the case of autonomous systems (Theorem 3.4) and of controllable ones (Theorem 5.4). We have also proposed a definition of generalized total energy and generalized Lagrangian (see section 4), and we introduced the notion of generalized internal forces for systems described by higher-order differential equations (see section 5).

The major limitation of the present work is its treatment of Hamiltonianity for the controllable and autonomous case only, leaving out the general case of a system comprising a nonzero controllable part and a nonzero "autonomous part" (for the difficulty in defining uniquely such a subbehavior, see [15, p. 192]). The development of a general theory of linear Hamiltonian behaviors that includes completely controllable and completely autonomous behaviors as special cases is a pressing issue in our research.

In view of the encouraging results of the application of quadratic differential forms in the context of infinite-dimensional systems (see [13, 14]), it can be hoped that some of the results presented in this paper can be generalized also to systems described by linear constant-coefficient partial differential equations; such an area of research is presently under investigation. Another direction in which the research presented in this paper is being extended is that of the connections between Hamiltonian systems and optimal control.

Acknowledgments. The authors thank Prof. Dr. Ir. Jan C. Willems and Prof. Dr. A. J. van der Schaft, on whom several preliminary versions of this paper were inflicted; they stimulated several discussions conducive to the elaboration of very valuable ideas and pointed out important references in the literature. Many thanks also to Dr. H. K. Pillai for his help in understanding the more technical points of [5].

COMPUTING THE EFFECTIVE HAMILTONIAN USING A VARIATIONAL APPROACH*

DIOGO A. GOMES† AND ADAM M. OBERMAN‡

Abstract. A numerical method for homogenization of Hamilton–Jacobi equations is presented and implemented as an L^∞ calculus of variations problem. Solutions are found by solving a nonlinear convex optimization problem. The numerical method is shown to be convergent, and error estimates are provided. One and two dimensional examples are worked in detail, comparing known results with the numerical ones and computing new examples. The cases of nonstrictly convex Hamiltonians and Hamiltonians for which the cell problem has no solution are treated.

Key words. Hamilton–Jacobi, homogenization, numerics, calculus of variations

1. Introduction.

Given the Hamiltonian $H(p, x)$, which is smooth, convex in p, and periodic in the second variable x, we are interested in finding for a given $P \in \mathbb{R}^n$ a periodic solution of the Hamilton–Jacobi equation

$$H(P + D_x u, x) = \bar{H}(P). \tag{HB}$$

For each fixed P the problem (HB) can be regarded as a nonlinear eigenvalue problem for the function $u(x)$ and the number $\bar{H}(P)$. We regard $\bar{H}(P)$, the *effective Hamiltonian*, as a function of the parameter P. It encodes information about $H(x, p)$, as we shall describe below.

Problem (HB) requires that we determine for a given $P \in \mathbb{R}^n$ the pair $(u, \bar{H}(P))$. Classical solutions do not exist for all P, so viscosity solutions [CIL92, BCD97, FS93] are used.

Solving (HB) directly involves finding the viscosity solution to a degenerate elliptic partial differential equation coupled to an unknown constant, $\bar{H}(P)$. While this may be done, it is not an easy task. We choose instead to reduce the problem of finding the (approximate) effective Hamiltonian to a finite dimensional convex optimization problem, which may be solved numerically using optimization routines.

Numerical computations of effective Hamiltonians have been done by [EMS95, KBM01], with applications to front propagation and combustion. At the time of preparation of this manuscript, the authors also discovered work by [Qia01]. The numerical approach taken by these authors was to find the effective Hamiltonian by partial differential equations methods.

In this work we circumvent the difficulties of solving (HB) by computing $\bar{H}(P)$ without finding the solution u. Our methods are based on the representation formula

$$\bar{H}(P) = \inf_{\phi \in C^1_{per}} \sup_x H(P + D_x \phi, x) \tag{1}$$

due, for strictly convex Hamiltonians, to [CIPP98], in which the infimum is taken over all periodic C^1 functions, $C^1(\mathbb{T}^n)$. This formula is a problem in the calculus of variations problem in L^∞. Such problems were studied by Aronsson in the 1960s [Aro66, Aro65]. Recently there has been a renewed interest in calculus of variations in L^∞ [BJW01a, BJW01b, Bar94]. Related methods in the calculus of variations in L^∞ were applied to the effective Hamiltonian problem in [Eva03].

In this paper we always assume that H is convex but not necessarily strictly convex. This assumption has implications for the existence and smoothness of solutions of (HB). For instance, if H is strictly convex, then there are viscosity solutions of (HB) which are Lipschitz continuous. However, if strict convexity fails, solutions may (see section 5.2) or may not (see section 5.3) exist, and the degree of smoothness will depend on the Hamiltonian in question.

1.1. Applications. Computing the effective Hamiltonian is relevant to several classes of applications: homogenization problems, the long time behavior of Hamilton–Jacobi equations, classical mechanics, Aubry–Mather theory, ergodic control, and front propagation.

In *homogenization problems* [LPV88, Con95], if w^ϵ solves

$$-w_t^\epsilon + H\left(D_x w^\epsilon, \frac{x}{\epsilon}\right) = 0,$$

then, as ϵ goes to 0, the solution w^ϵ converges to w^0, which is a solution of the limiting problem

$$-w_t^0 + \bar{H}(D_x w^0) = 0.$$

The effective Hamiltonian also appears in the study of *long time limits of viscosity solutions of Hamilton–Jacobi equations*:

$$-w_t + H(P + D_x w, x) = 0.$$

It turns out that $w(x,t) - \bar{H}(P)\,t$ converges as $t \to -\infty$ to a stationary solution of (HB) [Fat98b, BS00]; see also [AI01, CDI01].

In *classical mechanics* [AKN97], smooth solutions u of (HB) yield a canonical change of coordinates $X(p,x)$ and $P(p,x)$ defined by the equations

$$p = P + D_x u, \qquad X = x + D_P u. \tag{2}$$

This would simplify the Hamiltonian dynamics

$$\dot{x} = -D_p H(p,x), \qquad \dot{p} = D_x H(p,x) \tag{3}$$

into the trivial dynamics

$$\dot{P} = 0, \qquad \dot{X} = -D_P \bar{H}(P).$$

In other words, for each P there is an invariant torus in which the dynamics is simply a rotation. However, (HB) does not admit smooth solutions in general (see section 4), and one must deal with viscosity solutions [CIL92, BCD97, FS93, Eva98].

In *Aubry–Mather theory* [Mat89a, Mat89b, Mat91, Mn92, Mn96], instead of looking for invariant tori, one looks for probability measures μ on $\mathbb{T}^n \times \mathbb{R}^n$ that minimize the average action

$$\int L(x,v) + P \cdot v \, d\mu \tag{4}$$

and satisfy a holonomy condition

$$\int v D_x \phi \, d\mu = 0$$

for all $\phi(x) \in C^1(\mathbb{T}^n)$.

Here $L(x, v)$ is the Legendre transform of $H(p, x)$, defined by

$$L(x, v) = \sup_p -v \cdot p - H(p, x).$$

The supports of these measures are called the Aubry–Mather sets and are the natural generalizations of invariant tori. Recent results [E99, Fat97a, Fat97b, Fat98a, Fat98b, CIPP98], some by one of the authors [EG01, EG02, Gom01b], show that viscosity solutions encode the Aubry–Mather sets. In particular, we have

$$\int L(x, v) + P \cdot v d\mu = -\bar{H}(P),$$

and the support of the Mather measure is a subset of the graph

$$(x, -D_p H(P + D_x u, x))$$

for any viscosity solution of (HB).

In the Mather set the asymptotics of the Hamiltonian dynamics are controlled by viscosity solutions. Indeed let (x, p) be any point in $\mathbb{T}^n \times \mathbb{R}^n$. Consider its flow by the Hamilton equations (3). If (x, p) belongs to any Mather set, then

$$\frac{x(T)}{T} \to Q$$

as $T \to \infty$ for some vector $Q \in \mathbb{R}^n$, with $Q = D_P \bar{H}(P)$ for some P if $\bar{H}$ is differentiable.

Equation (HB) and related stationary first and second order Hamilton–Jacobi equations are also important to the *ergodic control problem* [Ari98, Ari97]. While this article was being reviewed, the authors became aware of [FSar]. Aubry–Mather theory can also be generalized to second order equations [Gom02], and many of the techniques that we develop can be generalized appropriately.

The computation of effective Hamiltonians has applications to the *propagation of flame fronts in combustion*: Hamilton–Jacobi equations which are homogeneous of order one, for example $u_t = c|Du|$, can represent the evolution of a propagating front moving in the normal direction with speed c. If the front is propagating in a periodic media, an equation of the form $u_t = c(x)|Du|$ holds, where $c(x)$ is positive and periodic in x. In this case, solving a homogenization problem gives the effective or averaged front speed. As mentioned earlier, numerical computations for this problem have been performed by [EMS95, KBM01].

2. Solvability and approximation of the homogenization problem.

2.1. Solvability of the homogenization problem. We start this section by reviewing some results concerning the function $\bar{H}(P)$. In particular, we recall the uniqueness result of $\bar{H}$ from [LPV88], and we generalize a representation formula for $\bar{H}$ due to [CIPP98].

PROPOSITION 2.1 (from Lions, Papanicolao, Varadhan [LPV88]). *There is at most one value $\bar{H}$ for which* (HB) *has a periodic viscosity solution.*

Proof. Suppose, for contradiction, that (HB) admits viscosity solutions u_1 and u_2 for $\bar{H} = \bar{H}_1, \bar{H}_2$, respectively, with $\bar{H}_1 > \bar{H}_2$. We may assume $v_1 \equiv u_1 + C > u_2$ for a sufficiently large positive constant C. For ϵ sufficiently small

$$\epsilon v_1 + H(D_x v_1, x) \geq \epsilon u_2 + H(D_x u_2, x)$$

in the viscosity sense. The comparison principle [BCD97] then implies $v_1 \leq u_2$, which is a contradiction. □

Next we prove a representation formula for $\bar{H}$. Our result extends [CIPP98] to nonstrictly convex Hamiltonians H, for which the solution may fail to be Lipschitz.

PROPOSITION 2.2 (from Contreras, Iturriaga, Paternain, Paternain [CIPP98]). *Suppose that H is periodic in x and convex in p (strict convexity is not required). Suppose further that there exists a viscosity solution u of* (HB). *Then*

$$\bar{H} = \inf_{\psi \in C^1(\mathbb{T}^n)} \sup_{x \in \mathbb{T}^n} H(D_x \psi, x), \tag{5}$$

in which the infimum is taken over the space $C^1(\mathbb{T}^n)$ of periodic functions.

First we recall some facts concerning the sup convolution. The proof may be found in [FS93].

LEMMA 2.3. *Suppose u is a viscosity of* (HB). *Define*

$$u_\epsilon(x) = \sup_y \left[u(y) - \frac{|x-y|^2}{\epsilon} \right]. \tag{6}$$

Then

1. *$u_\epsilon \to u$ uniformly as $\epsilon \to 0$,*
2. *u_ϵ is semiconvex,*
3. *u_ϵ satisfies*

$$H(D_x u_\epsilon, x) \leq \bar{H} + o(1),$$

in the viscosity sense and almost everywhere.

Proof of Proposition 2.2. Let

$$\bar{H}^* = \inf_{\psi \in C^1(\mathbb{T}^n)} \sup_{x \in \mathbb{T}^n} H(D_x \phi, x).$$

At some point x_0, $u - \psi$ has a local minimum. By the viscosity property

$$H(D_x \psi(x_0), x_0) \geq \bar{H},$$

which implies $\bar{H}^* \geq \bar{H}$.

Let η_ϵ be a smoothing kernel. Set $v_\epsilon = u_\epsilon * \eta_\epsilon$. Then, using convexity,

$$H(D_x v_\epsilon(x), x) \leq \int H(D_x u_\epsilon(y), y) \eta_\epsilon(x-y) dy + o(1) \leq \bar{H} + o(1),$$

and thus $\bar{H}^* \leq \bar{H}$. □

Before proceeding with the discretization of this problem we will prove an elementary bound.

PROPOSITION 2.4. *We have*

$$\inf_{\psi \in C^1(\mathbb{T}^n)} \sup_{x \in \mathbb{T}^n} H(D_x \psi, x) \geq \inf_{x \in \mathbb{T}^n} H(0, x).$$

Proof. For any function $\psi \in C^1(\mathbb{T}^n)$ there is a point x_0 for which $D_x \phi(x_0) = 0$. Therefore $\sup_{x \in \mathbb{T}^n} H(D_x \psi, x) \geq H(0, x_0) \geq \inf_{x \in \mathbb{T}^n} H(0, x)$. □

2.2. Approximation. The next issue we study is the approximation of the problem (1).

To this effect, consider a triangulation of $\mathbb{T}^n$ with cells of diameter smaller than h. Let $C(T_h)$ be the collection of continuous piecewise linear grid functions which interpolate given nodal values. We avoid the use of the term finite elements to emphasize the pointwise nature of the approximation.

The following proposition is an approximation result: we do not assume the existence of a viscosity solution of (HB).

PROPOSITION 2.5. *Suppose $H(p,x)$ is convex in p. Then*

$$\inf_{\psi\in C^1(\mathbb{T}^n)} \sup_x H(D_x\psi, x) = \lim_{h\to 0} \inf_{\phi\in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x).$$

Proof. Fix $\epsilon > 0$. Let ψ be a C^1 function for which

$$\sup_{x\in\mathbb{T}^n} H(D_x\psi, x) \le \inf_{\psi\in C^1(\mathbb{T}^n)} \sup_{x\in\mathbb{T}^n} H(D_x\psi, x) + \epsilon.$$

Because ψ is C^1, $D_x\psi$ is uniformly continuous. Thus, for h sufficiently small, there is $\phi \in C(T_h)$ such that

$$\operatorname*{esssup}_{x\in\mathbb{T}^n} |D_x\phi - D_x\psi| \le \epsilon. \tag{7}$$

In fact, in each triangle along an edge e_i with length $|e_i|$ pointing in the direction ν_i we have

$$D_x\psi\cdot\nu_i = \frac{1}{|e_i|}\int_{e_i} D_x\phi\cdot dz = D_x\phi(\bar{x})\cdot\nu_i + o(1),$$

in which $\bar{x}$ is, for instance, the center of the triangle. Since the shape factor is bounded, there are at least n edges ν_i linearly independent such that

$$|\det[\nu]| \ge \theta \tag{8}$$

for some θ for all triangles. Therefore

$$D_x\psi = D_x\phi(\bar{x}) + o(1),$$

as required.

This therefore implies

$$\operatorname*{esssup}_{x\in\mathbb{T}^n} H(D_x\phi, x) \le \sup_{x\in\mathbb{T}^n} H(D_x\psi, x) + O(\epsilon),$$

by the Lipschitz continuity of H in p. Thus, taking first $\lim_{h\to 0}\inf_{\phi\in C(T_h)}$ and then $\inf_{\psi\in C^1(\mathbb{T}^n)}$, we obtain

$$\lim_{h\to 0}\inf_{\phi\in C(T_h)} \operatorname*{esssup}_{x\in\mathbb{T}^n} H(D_x\phi, x) \le \inf_{\psi\in C^1(\mathbb{T}^n)} \sup_{x\in\mathbb{T}^n} H(D_x\psi, x) + O(\epsilon).$$

Send $\epsilon\to 0$.

To prove the converse inequality observe that if $\phi\in C(T_h)$, η_ϵ is a smooth mollifier, and $\psi = \eta_\epsilon * \phi$, then convexity yields

$$H(D_x\psi(x), x) \le \int H(D_x\phi(y), y)\eta_\epsilon(x-y)dy + O(\epsilon),$$

for every x, and so

$$H(D_x\psi(x),x) \le \operatorname*{esssup}_{x\in\mathbb{T}^n} H(D_x\phi(x),x) + O(\epsilon).$$

Thus, taking first $\inf_{\psi\in C^1}$ and then $\lim_{h\to 0}\inf_{\phi\in C(T_h)}$,

$$\inf_{\psi\in C^1}\sup_x H(D_x\psi,x) \le \lim_{h\to 0}\inf_{\phi\in C(T_h)}\operatorname*{esssup}_{x\in\mathbb{T}^n} H(D_x\phi,x) + O(\epsilon).$$

Since ϵ is arbitrary, we have the claim. □

Before stating and proving an improved version of the previous proposition for the case in which (HB) has a viscosity solution, we record some important properties of the L^∞ calculus of variations problem. First observe that

$$\mathcal{H}(\phi) = \sup_{x\in\mathbb{T}^n} H(D_x\phi,x)$$

is a convex, but not strictly convex, functional. Therefore for any ϕ_1 and ϕ_2 we have

$$\mathcal{H}(\lambda\phi_1 + (1-\lambda)\phi_2) \le \lambda\mathcal{H}(\phi_1) + (1-\lambda)\mathcal{H}(\phi_2).$$

This in particular implies that any local minimum is a global minimum.

However, in general the minimizers are not unique, and it is not true that a minimizing sequence will converge to a viscosity solution of

$$H(D_xu,x) = \bar{H}.$$

For example, $H = p^2/2 + \cos x$ has $\bar{H} = 1$, and $u \equiv 0$ is a minimizer. However, $H(D_xu,x) \ne \bar{H}$.

A similar argument applied to the discretized problem yields that

$$\mathcal{H}_h(\phi) = \operatorname*{esssup}_{x\in\mathbb{T}^n} H(D_x\phi,x)$$

is convex for $\phi \in C(T_h)$, and so a local minimum is a global minimum.

PROPOSITION 2.6. *The approximate Hamiltonian*

$$\bar{H}_h(P) = \inf_{\phi\in C(T_h)}\operatorname*{esssup}_{x\in\mathbb{T}^n} H(P + D_x\phi,x)$$

is convex in P.

Proof. Let $P_1, P_2 \in \mathbb{R}^n$, and let $\phi_1, \phi_2 \in C(T_h)$ be the corresponding minimizers. Let $0 \le \lambda \le 1$, and set $P = \lambda P_1 + (1-\lambda)P_2$ and $\phi = \lambda\phi_1 + (1-\lambda)\phi_2$. Then, for any x we have

$$H(P + D_x\phi,x) \le \lambda H(P_1 + D_x\phi_1,x) + (1-\lambda)H(P_2 + D_x\phi_2,x).$$

Thus

$$\operatorname*{esssup}_{x\in\mathbb{T}^n} H(P + D_x\phi,x) \le \lambda\bar{H}_h(P_1) + (1-\lambda)\bar{H}_h(P_2),$$

and so

$$\bar{H}_h(P) = \inf_{\phi\in C(T_h)}\operatorname*{esssup}_{x\in\mathbb{T}^n} H(P + D_x\phi,x) \le \lambda\bar{H}_h(P_1) + (1-\lambda)\bar{H}_h(P_2)$$

if $P = \lambda P_1 + (1-\lambda)P_2$. □

THEOREM 2.7. *For any convex Hamiltonian $H(p,x)$ for which* (HB) *has a viscosity solution*

$$\bar{H} \leq \inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x).$$

If there exists a globally C^2 solution of (HB)*, then*

$$\inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x) = \bar{H} + O(h).$$

If (HB) *has a Lipschitz solution (for instance, if $H(p,x)$ is strictly convex in p), then*

$$\inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x) = \bar{H} + O(h^{1/2}).$$

If H is convex but not strictly convex and (HB) *has a viscosity solution, then*

$$\inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x) = \bar{H} + o(1).$$

Proof. Observe that

$$\bar{H} = \inf_{\psi \in C^1(\mathbb{T}^n)} \sup_x H(D_x\psi, x) \leq \inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x),$$

because by convexity we can associate to each $\phi \in C(T_h)$ a function

$$\psi = \phi * \eta_\epsilon \in C^1(\mathbb{T}^n)$$

such that

$$\sup_x H(D_x\psi, x) \leq \operatorname*{esssup}_x H(D_x\phi, x) + O(\epsilon),$$

for arbitrary $\epsilon > 0$, as seen in the previous proposition.

To prove the second assertion suppose that u is a C^2 viscosity solution of (HB). Fix h and construct a function $\phi_u \in C(T_h)$ by interpolating linearly the values of u at the nodal points. In each triangle T^i, the oscillation of the derivative of u is $O(h)$, since u is C^2. Thus, proceeding as in the proof of (7), we obtain

$$D_x\phi_u(x) = D_x u(x) + O(h)$$

for any x. Since $H(D_x u, x) = \bar{H}$, at every point $x \in T^i$ we have

$$H(D_x\phi_u, x) \leq \bar{H} + O(h).$$

This implies

$$\inf_{\phi \in C(T_h)} \operatorname*{esssup}_{x \in \mathbb{T}^n} H(D_x\phi, x) \leq \bar{H} + O(h).$$

If u is a Lipschitz viscosity solution, let $\tilde{u} = \eta_{h^{1/2}} * u$. Observe that

$$|D^2_{xx}\tilde{u}| \leq \frac{C}{h^{1/2}}$$

and

$$H(D_x\tilde{u}, x) \leq \bar{H} + O(h^{1/2}).$$

Construct a function $\phi_u \in C(T_h)$ by interpolating linearly the values of $\tilde{u}$ at the nodal points. In each triangle T^i, the oscillation of the derivative of $\tilde{u}$ is $O(h^{1/2})$. Thus

$$D_x\phi_u(x) = D_x\tilde{u}(x) + O(h^{1/2})$$

for any x. Since $H(D_x\tilde{u}, x) \leq \bar{H} + O(h^{1/2})$, for every point $x \in T^i$,

$$H(D_x\phi_u, x) \leq \bar{H} + O(h^{1/2}).$$

This implies

$$\inf_{\phi \in C(T_h)} \operatorname{esssup}_{x \in \mathbb{T}^n} H(D_x\phi, x) \leq \bar{H} + O(h^{1/2}).$$

In the final case of nonstrictly convex Hamiltonians, the sup convolution (6) with $\epsilon = h^{1/3}$ yields a function $u_{h^{1/3}}$ that satisfies

$$H(D_x u_{h^{1/3}}, x) \leq \bar{H} + o(1)$$

almost everywhere and has Lipschitz constant bounded by $Ch^{-1/3}$. Define $\tilde{u} = \eta_{h^{1/3}} * u_{h^{1/3}}$, which satisfies

$$H(D_x\tilde{u}, x) \leq \bar{H} + o(1)$$

and

$$|D^2_{xx}\tilde{u}| \leq \frac{C}{h^{2/3}}.$$

Since in each triangle the oscillation of the derivative is $O(h^{1/3})$, we obtain

$$H(D_x\phi_u, x) \leq \bar{H} + o(1),$$

thereby proving the last statement of the theorem. □

A corollary to the previous theorem is the following.

COROLLARY 2.8. *Suppose $\xi_h \in \mathbb{R}^n$ is a supporting plane for $\bar{H}_h(P)$ that converges as $h \to 0$ to ξ. Then ξ is a supporting hyperplane for $\bar{H}(P)$. As a consequence, if $\bar{H}(P)$ is differentiable at P, then ξ_h converges to the unique supporting hyperplane of $\bar{H}(P)$ at P.*

Proof. The previous theorem asserts that $\bar{H}(P)$ converges uniformly to $\bar{H}(P)$. In Proposition 2.6 we proved that $\bar{H}_h(P)$ is convex. Therefore the corollary follows from a standard convex analysis argument. □

3. Numerical implementation. In this section we discuss the numerical implementation of the fully discretized minimax problem (4). There are two parts to the discussion: (i) implementing the discrete version of the problem and (ii) solving the resulting optimization problem. If the discretization is performed properly, the resulting minimax problem is convex, and standard routines can be used to find the solution.

3.1. Discretization. In the last section we discussed the approximation of the infinite dimensional problem

$$\bar{H}(P) = \inf_{\phi \in C^1_{per}} \sup_x H(P + D_x\phi, x)$$

by the finite dimensional problem

$$\inf_{\phi \in C(T_h)} \operatorname*{esssup}_x H(D_x\phi, x),$$

for ϕ in the space of continuous piecewise linear grid functions.

To fully discretize the problem, we make a further approximation: we discretize the spatial variable by computing the supremum only at the nodes x_i, which gives the minimax problem

$$\min_{\phi \in C(T_h)} \max_{x_i} H(D_x\phi, x_i) \tag{9}$$

for x_i at the nodal points of the grid function space. The spatial approximation introduces a small additional error of $O(h)$, which is proportional to the Lipschitz constant (in the x variable) of H.

The minimax problem (9) is a finite dimensional nonlinear optimization problem which can by solved using standard optimization routines.

Discretization in one dimension. We first present the discretization scheme in one dimension. Choosing n to be the number of nodes, we get a partition of $\mathbb{T}$, the unit interval with periodic boundary conditions, into n intervals of length $h = 1/n$. For any ϕ in the grid function space $C(T_h)$, we identify ϕ with the vector of values on the nodes

$$\phi \text{ is identified with } u = (u_1, \dots, u_n) = (\phi(0), \dots \phi(ih), \dots \phi((n-1)h)).$$

Then, choosing $x_i = (i + 1/2)h$ to be the midpoint of the interval gives the discretization

$$H(\phi_x, x) = H\left(\frac{u_{i+1} - u_i}{h}, x_i\right) \text{ on } T_i = [ih, (i+1)h]. \tag{10}$$

As long as $H(p, x)$ is convex in p, for each x, the right-hand side of (10) is convex in u_{i+1} and u_i. Taking the maximum over the nodes gives a convex function of n variables to be minimized.

Discretization in two dimensions. Next, in two dimensions, take an $n \times n$ grid for $\mathbb{T}^2$, the unit square with periodic boundary conditions. Create a regular tiling by triangles as follows. To each node i, j, let

$$T^{\pm}_{i,j} = \text{ the triangle with vertices } (i, j), (i \pm 1, j), (i, j \pm 1).$$

For ϕ in the grid function space $C(T_h)$, we identify ϕ with the matrix of values on the nodes:

$$\phi \text{ is identified with } u = (u_{i,j}) = (\phi(ih, jh)), \quad i, j = 1, \dots, n.$$

As a result we have $2n^2$ triangles on which ϕ is linear.

On each triangle, choosing $x^{\pm}_{i,j}, y^{\pm}_{i,j}$ to be a point in the middle of $T^{\pm}_{i,j}$, we get the discretization

$$H(\phi_x, \phi_y) = H^{\pm}\left(\frac{u_{i\pm1,j} - u_{i,j}}{h}, \frac{u_{i,j\pm1} - u_{i,j}}{h}, x^{\pm}_i, y^{\pm}_i\right) \text{ on } T^{\pm}_{i,j}. \tag{11}$$

As long as $H(p, x)$ is convex in p, for each x, the right-hand side of (11) is convex in the variables $u_{i,j}$ and $u_{i\pm1,j\pm1}$.

Taking the maximum over the triangles gives a convex function of $2n^2$ variables to be minimized. Alternately, we can take $x^{\pm}_{i,j} = x_{i,j}, y^{\pm}_{i,j} = y^{i,j}$ and take the maximum $H^{\pm}$ with these values to reduce the number of variables by a factor of two.

3.2. Numerical solution of the minimax problem. The implementation required only that a suitable discretization of the Hamiltonian be given. This discretization takes the form of a map from $\mathbb{R}^n$ to $\mathbb{R}^n$, or a map from $\mathbb{R}^{2n}$ to $\mathbb{R}^{2n}$, in the case of one and two dimensional Hamiltonians, respectively. Each component of the map is convex in each of the variables, and the map is sparse, in the sense that it depends on only a small number of other variables.

Taking the maximum of the components of the map gives a convex function which is to be minimized. In general, there are many minimizers, but the minimum is unique.

At this point, publicly available routines for convex optimization may be used to solve the problem. We carried out the implementation in MATLAB, using the Optimization Toolbox. The Optimization Toolbox contains an assortments of routines for solving multidimensional nonlinear optimization problems, some of which take advantage of sparse linear algebra. We used `fminimax`, which is specially designed for minimax problems but does not use sparse linear algebra. A possible alternative would have been to use the a more general solver with sparse linear algebra, which might have performed better on larger problems. For the problems we implemented, which were of modest size (128 variables in two dimensions), the minimization problem was solved in a few seconds on a laptop computer. Solving for a range of a few hundred values of P took between twenty minutes and a few hours to compute for each problem.

For background on convex optimization we refer to [Fle80]. Briefly, the minimax is solved by searching for the worst of the objective functions, then improving that function by solving a sequence of quadratic programs, which are in turn computed by solving a sequence of linear equations. The error in the solution of the optimization problem is insignificant compared to the discretization error.

3.3. Error estimates. There are three main issues which may lead to errors in the numerical computation of $\bar{H}(P)$: the error which arises from the discretization (which was discussed in the previous section), the error involved in computing the esssup approximately, and the error in solving the discrete problem numerically.

To compute the essential supremum we chose to evaluate the function at a single point in each node. This gives an additional contribution to the error of $O(h)$, depending on the Lipschitz constant of the Hamiltonian. This discretization error was nonnegligible, but it could be eliminated by computing the maximum at the endpoints of the nodes, instead of the middle of each node. Since a linear function on a segment of a triangle achieves its maximum at the nodes, this supremum would have been computed accurately up to $O(h^2)$, decreasing the discretization error at the expense of increasing the number of functions to be evaluated in the minimax.

Improved convergence estimates. Because of the improved convergence when smooth solutions exist, for most values of P we expected to get, and indeed we saw,

linear convergence. Nevertheless, there should be examples where the convergence is sublinear.

Global convergence of $\bar{H}_h(P)$ to $\bar{H}(P)$ may be better than expected. Since $\bar{H}_h(P)$ is convex, and is an upper bound for $\bar{H}(P)$, if for some values of P we get $\bar{H}_h(P)$ accurately (for instance, because there is a smooth solution of (HB)), that immediately implies improved bounds for other values of P. If, for instance, $\bar{H}_h(P) = \bar{H} + O(h)$ in a set of full measure, then immediately one gets $\bar{H}_h(P) = \bar{H}(P) + O(h)$ in the remaining points.

Secondly, in Theorem 2.7 we constructed the approximate minimizer from a viscosity solution. However, there may be other minimizers which may be smoother than the viscosity solution.

Finally, in the proof we used convolutions with a smoothing kernel, to get estimates of the form $H(D_x\tilde{u}, x) \leq \bar{H} + O(h^\alpha)$ for some exponent α. In practice the inequality may be strict at points in which the original viscosity solution is not smooth, which could help to improve the estimates since we are taking suprema.

4. Validation. We begin by studying a one dimensional case for which explicit analytical information is available. This analytical information is used to validate the numerical method.

Theorem 2.7 gives convergence of order $O(h)$ when there exists a smooth solution of (HB). Despite the lack of smoothness in the solution, we obtained convergence rates of $O(h)$.

4.1. Analytical results. Consider the Hamiltonian corresponding to a one dimensional pendulum with mass and length normalized to unity,

$$H(p, x) = \frac{p^2}{2} - \cos 2\pi x.$$

For this Hamiltonian one can find explicitly the solution of (HB).

PROPOSITION 4.1. *The solution* $(u, \bar{H}(P))$ *of* (HB)*, when* H *corresponds to the one dimensional pendulum, is given by*

$$u(x) = \int_0^x -P + s(y)\sqrt{2(\bar{H}(P) + \cos 2\pi y)}\, dy, \tag{12}$$

where $|s(y)| = 1$*, with* $\bar{H}(P) = 1$ *for* $|P| \leq 4\pi^{-1}$ *and*

$$P = \pm \int_0^1 \sqrt{2(\bar{H}(P) + \cos 2\pi y)}\, dy \tag{13}$$

otherwise.

Proof. For each $P \in \mathbb{R}$ and a.e. (almost every) $x \in \mathbb{R}$, the solution $u(P, x)$ satisfies

$$\frac{(P + D_x u)^2}{2} = \bar{H}(P) + \cos 2\pi x.$$

This implies $\bar{H}(P) \geq 1$ and so

$$D_x u = -P \pm \sqrt{2(\bar{H}(P) + \cos 2\pi x)}, \quad \text{a.e. } x \in \mathbb{R}.$$

Thus (12) holds for $|s(y)| = 1$.

TABLE 1
Computed values for $\bar{H}$ as a function of the number of points, comparing the sine and cosine potential, with $P = 0.5$ and $\bar{H}(0.5) = 1$.

Number of points n =	9	17	33	65
Values (using sine)	0.98480	0.99573	0.99887	0.99971
Max of sin on the grid	0.98480	0.99573	0.99887	0.99971
Values (using cosine)	1.00000	1.00000	1.00000	1.00000
Max of cosine on the grid	1.00000	1.00000	1.00000	1.00000

Because H is convex in p and u is a viscosity solution, u is semiconcave, and so the only possible discontinuities in the derivative of u are the ones that satisfy $D_x u(x^-) - D_x u(x^+) > 0$ (see [Eva98]). Therefore s can change sign from 1 to -1 at any point, but jumps from -1 to 1 can happen only when $\sqrt{2(\bar{H}(P) + \cos 2\pi x)} = 0$.

If we require 1-periodicity, then there are two cases. (i) If $\bar{H}(P) > 1$, the solution is C^1 since $\sqrt{2(\bar{H}(P) + \cos 2\pi y)}$ is never zero. These solutions correspond to invariant tori. In this case P and $\bar{H}(P)$ satisfy (13). It is easy to check that this equation has a solution $\bar{H}(P)$ whenever

$$|P| \geq \int_0^1 \sqrt{2(1 + \cos 2\pi y)}dy,$$

that is, whenever $|P| > 4\pi^{-1}$. (ii) Otherwise, when $|P| \leq 4\pi^{-1}$, $\bar{H}(P) = 1$ and $s(x)$ can have a discontinuity. Indeed, $s(x)$ jumps from -1 to 1 when $x = \frac{1}{2} + k$, with $k \in \mathbb{Z}$, and there is a point x_0, defined by the equation

$$-\int_0^1 s(y)\sqrt{2(1 + \cos 2\pi y)}dy = P,$$

in which $s(x)$ jumps from 1 to -1. In this last case the graph $(x, P + D_x u)$ is a backwards invariant set contained in the unstable manifold of the hyperbolic equilibria of the pendulum. The graph of $\bar{H}(P)$ has a flat spot near $P = 0$. □

This example also shows that (HB) does not have a unique solution. Indeed, $\cos 2\pi x$ is also 2-periodic. So if we look for 2-periodic solutions, we find out that for $|P|$ small we can have two points where the derivative is discontinuous, and we can choose one of them freely because our only constraint is periodicity. Note, however, that the value of $\bar{H}$ is uniquely determined and is the same whether we look for 1- or 2-periodic solutions.

4.2. Validation in one dimension. To test our numerical method we varied the number of nodes n, computing $\bar{H}$ for $n = 8, 16, 32, 64$ and with $P = 0.5$. Here the exact value is $\bar{H} = 1$.

For each of the above values of n, the exact answer was achieved with an error bounded by 10^{-10}. However, this is an artifact of the special nature of the example, related to the fact that we resolved the maximum of $\sin(x)$ well. To illustrate this, we use a poorer choice of n values and get a larger error, as seen from Table 1. With these choices of n we see that the discrete problem is solved to within the tolerance of 10^{-6}, but the exact problem is solved only up to the resolution error of the Hamiltonian.

We repeated the same test for $P = 2$, which puts us in the strictly convex part of $\bar{H}(P)$. The value $\bar{H}(2) = 2.0637954$ can be obtained by solving the equation

$$2 = \int_0^1 \sqrt{2(\bar{H}(2) - \cos(2\pi x))}dx$$

TABLE 2

Computed error for $\bar{H}$ as a function of the number of points, comparing the sine and cosine potential, with $P = 2$.

Number of points n =	8	16	32	64	96
Error (using sine) $\times 10^{-5}$	0.1912	0.0013	0.0009	0.0005	0.0183
Error (using cosine) $\times 10^{-5}$	0.1912	-0.0013	-0.0014	0.0074	0.0017

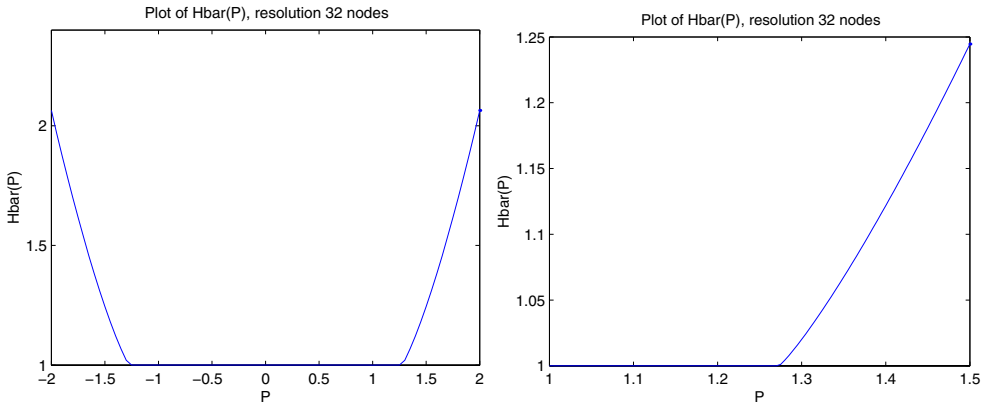

FIG. 1. *$\bar{H}(P)$ for the pendulum, over the range $[-2, 2]$ (left), and an enlargement near the lower-right corner.*

with respect to $\bar{H}(2)$. The error is plotted in Table 2; in this case except for the smallest (n = 8) discretization, the computed values fall within the tolerance of the scheme. The conclusion is that the dominant error comes from the discretization, not the optimization routines.

The values of $\bar{H}(P)$, computed with a resolution of 32 points, are shown in Figure 1. The largest error occurs near the corner. The location of the corner is close to the analytical value $P = 4\pi^{-1} \simeq 1.27324$.

4.3. Validation in two dimensions. In this section we study two uncoupled pendulums. This problem is a direct sum of the one dimensional case, so it is used to validate the method in two dimensions.

The Hamiltonian corresponding to two pendulums is

$$H(p_x, p_y, x, y) = \frac{p_x^2}{2} + \frac{p_y^2}{2} + \cos 2\pi x + \cos 2\pi y.$$

The effective Hamiltonian is thus

$$\bar{H}(P_x, P_y) = \bar{H}_0(P_x) + \bar{H}_0(P_y),$$

in which $\bar{H}_0$ is the effective Hamiltonian for a one dimensional pendulum. For instance, $\bar{H}(1.5) = 1.244638$, $\bar{H}(2.5) = 3.165327$, and thus the analytical value is $\bar{H}(1.5, 2, 5) = 4.4099660$.

As an accuracy test in the two dimensional case, we computed for $P = (1.5, 2.5)$ and $n = 8, 12, 16, 32$ the value of $\bar{H}(P)$ and the corresponding error; see Table 3.

TABLE 3
Computed values for $\bar{H}(1.5, 2.5)$ as a function of the number of points.

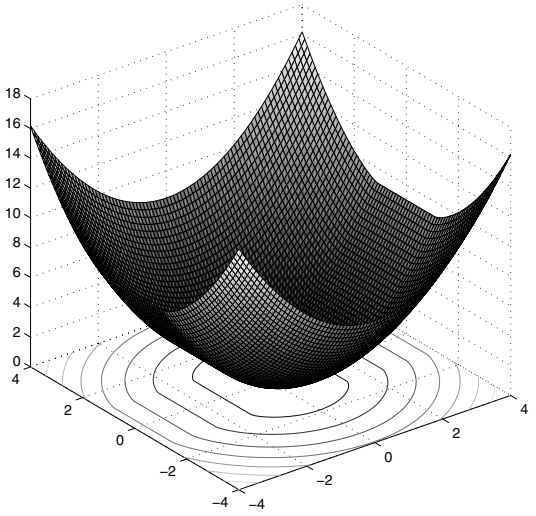

FIG. 2. *Visualization of $\bar{H}(P)$ for the potential $V(x, y) = \cos(2\pi x)$.*

5. Computational results.

5.1. Strictly convex Hamiltonians. In this section we study several strictly convex Hamiltonians. Unless stated otherwise, all the numerical examples use $n = 8$, that is, 64 nodes and 128 triangular elements.

Example 1 (pendulum and a free particle). Potential: $V(x, y) = \cos(2\pi x)$. This potential is y-independent, and therefore $\bar{H}(P_1, P_2)$ for P_2 fixed should be the same as the effective Hamiltonian for the one dimensional pendulum. With P_1 fixed, $\bar{H}$ should be a parabola in P_2. We solved for $\bar{H}(P)$ with a resolution of .1 for $P \in [-4, 4] \times [-4, 4]$. The result is presented in Figure 2.

Example 2 (potential $V(x, y) = \cos(2\pi x)\cos(2\pi y)$). We computed $\bar{H}(P)$ with a resolution in P of .1 for $P \in [-4, 4] \times [-4, 4]$. The result is presented in Figure 3.

Example 3 (potential $V(x, y) = \cos(2\pi x) + \cos(2\pi y) + \cos(2\pi(x - y))$). We computed $\bar{H}(P)$ with a resolution of .25 in P for $P \in [-3, 3] \times [-3, 3]$. The result is presented in Figure 4.

Example 4 (double pendulum). The double pendulum is a well known non-integrable example for which the effective Hamiltonian is not known. The Hamiltonian for the double pendulum is

$$H(p_x, p_y, x, y) = \frac{p_x^2 - 2p_x p_y \cos(2\pi(x - y)) + 2p_y^2}{2 - \cos^2(2\pi(x - y))} + 2\cos 2\pi x + \cos 2\pi y.$$

We computed the values of $\bar{H}(P)$ with a resolution in P of .2 for P in $[-5, 5] \times [-5, 5]$. The result is presented in Figure 5.

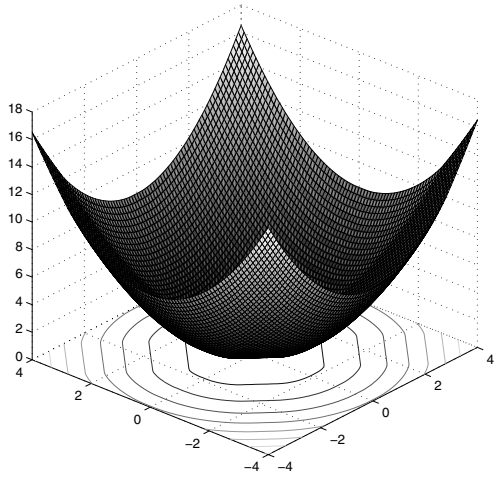

FIG. 3. *Visualization of* $\bar{H}(P)$ *for the potential* $V(x,y) = \cos(2\pi x)\cos(2\pi y)$.

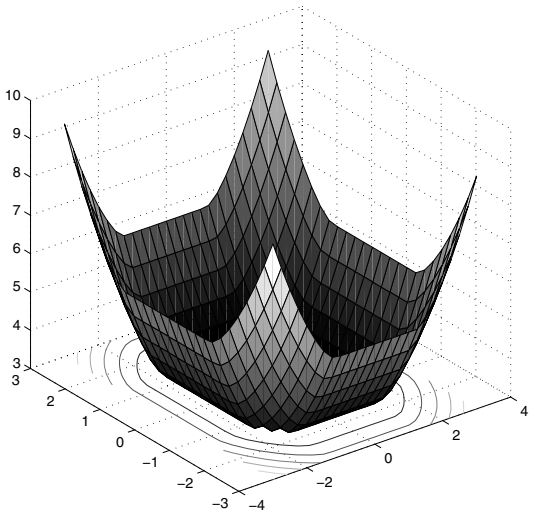

FIG. 4. *Visualization of* $\bar{H}(P)$ *for the potential* $V(x,y) = \cos(2\pi x) + \cos(2\pi y) + \cos(2\pi(x-y))$.

5.2. Nonstrictly convex problems. In this section we study several examples, in which H is convex but not strictly convex, for which there is a viscosity solution of (HB).

Example 5 (linear nonresonant). Consider the linear (nonresonant) Hamiltonian

$$H(p,x) = \omega \cdot p + V(x,y). \tag{14}$$

Suppose u is a smooth viscosity solution of (HB) for this Hamiltonian. The divergence theorem yields

$$\int_{\mathbb{T}^n} \omega \cdot D_x u = 0.$$

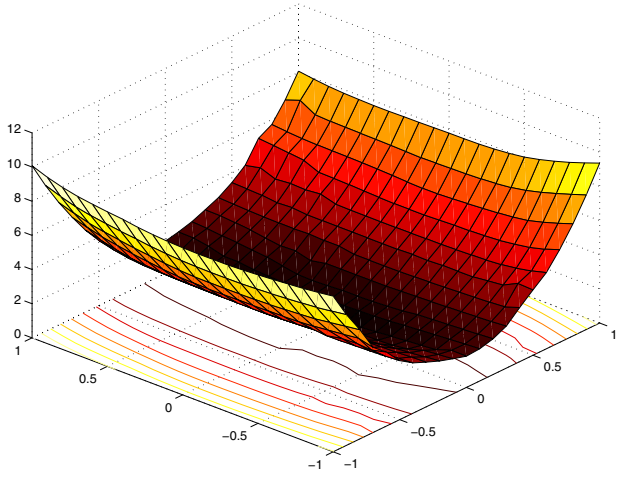

FIG. 5. *Visualization of $\bar{H}(P)$ for the double pendulum.*

Therefore

$$\bar{H}(0) = \int_{\mathbb{T}^n} V \tag{15}$$

and $\bar{H}(P) = \bar{H}(0) + \omega \cdot P$. For the example $u_x + \sqrt{2}u_y + \cos(2\pi x)$ we obtained $D_P\bar{H} = (1, \sqrt{2})$ and $\bar{H}(0,0) = 0$. Despite the fact that the vector $(1,1)$ is rationally dependent, the Hamilton–Jacobi equation $u_x + u_y + \cos(2\pi x)$ is nonresonant because of the nature of the potential. Numerically we obtained $D_P\bar{H} = (1,1)$ and $\bar{H}(0,0) = 0$. In this (linear) case the optimization routine converged very quickly.

Example 6 (time-periodic). Another example is a periodic time-dependent one-space-dimension Hamilton–Jacobi equation

$$-u_t + H(D_x u, x, t) = \bar{H}.$$

There exists a unique value $\bar{H}$ for which this problem admits space-time-periodic solutions [EG02]. Moreover, this solution is Lipschitz, and thus we have a $O(h)$ convergence.

Note also that $P = (P_t, P_x)$ but $\bar{H}(P)$ is linear in P_t, and so we may as well consider the problem

$$\inf_{\phi} \sup_{(x,t)} -\phi_t + H(P_x + D_x\phi, x, t) = \bar{H}(P_x).$$

For the forced pendulum

$$H(p, x) = \frac{p^2}{2} + \cos 2\pi x + \sin 2\pi x \sin 2\pi t.$$

We set $P_t = 0$ and plot $\bar{H}(P_x)$; see Figure 6.

Observe that the maximum of the potential $\cos 2\pi x + \sin 2\pi x \sin 2\pi t$ is $\sqrt{2}$, which coincides with the minimum of $\bar{H}(P)$.

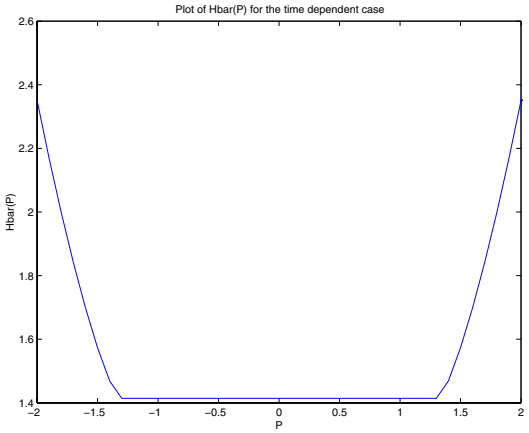

FIG. 6. *Values of $\bar{H}(P)$ for the time-periodic Hamiltonian.*

Example 7 (vakonomic). Finally, we study an example of a nonstrictly convex Hamiltonian which satisfies commutation relations related to vakonomic mechanics [AKN97],

$$H(p,x) = \frac{|f_1 \cdot Du|^2}{2} + \frac{|f_2 \cdot Du|^2}{2} + V(x,y).$$

Here the vector fields f_1, f_2 do not span $\mathbb{R}^2$ in every point, but when we consider the commutator $[f_1, f_2]$, we have that $f_1, f_2, [f_1, f_2]$ span $\mathbb{R}^2$ in every point. In this situation (HB) has Hölder continuous viscosity solutions [EJ89, Gom01a].

We choose $V = 0$, $f_1 = (0,1)$, and $f_2 = (\cos 2\pi y, \sin 2\pi y)$. If $\sin 2\pi y = 0$, $f_2 = (0, \pm 1)$, and so f_1 and f_2 are linearly dependent. However,

$$[f_1, f_2] = 2\pi(-\sin 2\pi y, \cos 2\pi y),$$

and so the vectors $f_1, f_2, [f_1, f_2]$ always span $\mathbb{R}^2$. Therefore there is a Hölder continuous viscosity solution.

In fact, this example can be reduced to a one dimensional problem. The Hamilton–Jacobi equation is

$$\frac{\cos^2 2\pi y}{2}(P_x + u_x)^2 + \frac{(1 + \sin^2 2\pi y)}{2}(P_y + u_y)^2 + \sin 2\pi y \cos 2\pi u (P_x + u_x)(P_y + u_y) = \bar{H}(P_x, P_y).$$

Since there is no explicit dependence in x, there are solutions independent of x, given by the equation

$$\frac{\cos^2 2\pi y}{2} P_x^2 + \frac{(1 + \sin^2 2\pi y)}{2}(P_y + u_y)^2 + \sin 2\pi y \cos 2\pi y P_x (P_y + u_y) = \bar{H}(P_x, P_y).$$

Since this equation is strictly convex in u_y, there is a Lipschitz solution.

To remove this degeneracy we considered the potential $V(x,y) = \cos 2\pi x + \sin 2\pi(x - y)$, for which the previous reduction procedure does not work. The result is presented in Figure 7.

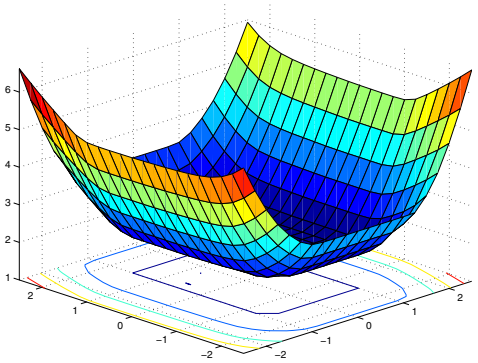

FIG. 7. *Values of $\bar{H}(P)$ for the time-periodic Hamiltonian.*

5.3. Nonexistence of viscosity solutions. There are situations where there do not exist viscosity solutions to (HB), but where $\bar{H}$ can still be defined by solving a more general problem; see [BS00, BS01] and [LS03]. In some of these situations, the solution of the minimax problem (1) may exist and give a consistent result.

We work out two interesting examples and try to explain the results obtained numerically.

The problem

$$\alpha u^\alpha + H(P + D_x u^\alpha, x) = 0, \tag{16}$$

which (when $\alpha \neq 0$) has a unique solution, is considered in [LS03]. Sending $\alpha \to 0$ gives the effective Hamiltonian

$$\bar{H}(P) \equiv \lim_{\alpha \to 0} \alpha u^\alpha. \tag{17}$$

These results are consistent with (HB) but determine a value $\bar{H}(P)$ even under weaker conditions, for example, as long as αu^α converges uniformly to a constant, which happens when

$$u^\alpha - \min_x u^\alpha \to \text{ bounded function of } x$$

uniformly.

For example, in the simpler case when H is strictly convex in p, we get that $u^\alpha - \min_x u^\alpha$ is bounded uniformly in α, since in this case the solutions u^α are Lipschitz independently of α.

The result (1) may also give a correct value for $\bar{H}$ in these more general situations.

PROPOSITION 5.1. *Let u^α be a solution of* (16)*, and suppose that αu^α converges uniformly to a constant number $\bar{H}(P)$. Then*

$$\bar{H}(P) = \lim_{\alpha \to 0} \alpha u^\alpha = \inf_{\phi} \sup_{x \in \mathbb{T}^n} H(P + D_x \phi, x).$$

Proof. 1. Define $\bar{H}_\alpha \equiv -\alpha \min_x u^\alpha$ and

$$v^\alpha \equiv u^\alpha + \frac{\bar{H}_\alpha}{\alpha},$$

so that $\min_x v^\alpha = 0$. We will demonstrate $\bar{H}_\alpha \to \bar{H}$. We have

$$\bar{H} = \lim_{\alpha\to 0} H(P + D_x u^\alpha, x) = \lim_{\alpha\to 0} -\alpha u^\alpha = \lim_{\alpha\to 0} \alpha(u^\alpha - \min_x u^\alpha) + \alpha \min_x u^\alpha = \bar{H}_\alpha.$$

2. Let v_α^ϵ denote the sup convolution of v_α, and let $\phi = \eta_\epsilon * v_\alpha^\epsilon$. Then

$$H(D_x\phi, x) \le \bar{H}_\alpha + O(\epsilon).$$

Therefore

$$\inf_\phi \sup_{x\in\mathbb{T}^n} H(D_x\phi, x) \le \bar{H}_\alpha \to \bar{H}.$$

3. Now let

$$e_\alpha = \sup_x \alpha v_\alpha,$$

which converges to 0.

Let ϕ be any function. Then $v_\alpha - \phi$ has a local minimum at a point x_0. At this point

$$\alpha v_\alpha(x_0) + H(D_x\phi(x_0), x_0) \ge \bar{H}_\alpha.$$

Thus

$$e_\alpha + H(D_x\phi(x_0), x_0) \ge \bar{H}_\alpha,$$

and so

$$\sup_{x\in\mathbb{T}^n} H(D_x\phi, x) \ge \bar{H}_\alpha - e_\alpha \to \bar{H}.$$

Therefore $\inf_\phi \sup_{x\in\mathbb{T}^n} H(D_x\phi, x) \ge \bar{H}$. □

Example 8 (quasiperiodic Hamiltonians). We consider an example from [LS03] for which there is no viscosity solution to (HB), yet where $\bar{H}(P)$ can be determined from (17). Let

$$H(p_x, p_y, x, y) = |p_x + \alpha p_y| + \sin(x) + \sin(y)$$

with α irrational. We computed $\bar{H}(P)$ numerically from (1). The results are presented in Figure 8.

Example 9 (linear resonant). Resonant linear Hamiltonians (14) may fail to have a viscosity solution. An example is

$$(0,1)\cdot Du + \sin(2\pi x) = \bar{H}.$$

The formula (15) yields $\bar{H}(0) = 0$ if there is a solution of (HB). However, we have

$$\inf_\phi \sup_x H(D_x\phi, x) = 1.$$

Let ϕ be an arbitrary periodic function. Set $x_0 = 1/4$, so that $\sin 2\pi x_0 = 1$. Then $\phi(x_0, y)$ is a periodic function of y, and so $D_y\phi(x_0, y) = 0$ at some $y = y_0$. Thus

$$\sup_x H(D_x\phi, x) \ge H(D_x\phi(x_0, y_0), x_0, y_0) = 1.$$

Numerically we obtained $D_P\bar{H} = (0,1)$ and $\bar{H}(0,0) = 1$. This is interesting, because $\bar{H}(0,0)$ should be 0, not 1, and this shows the nonexistence of solutions.

EXISTENCE OF OPTIMAL STOCHASTIC CONTROLS AND GLOBAL SOLUTIONS OF FORWARD-BACKWARD STOCHASTIC DIFFERENTIAL EQUATIONS *

MARCO FUHRMAN† AND GIANMARIO TESSITORE‡

Abstract. We consider an optimal stochastic control problem, assuming Lipschitz conditions and allowing degeneracy of the diffusion coefficient, under some structural constraint on the state equation. We formulate the problem in the strong form; i.e., we fix the probability space. We relate the value function and the feedback law to a forward-backward stochastic differential system. We prove existence and uniqueness of a global solution to the latter and deduce existence and, in some cases, uniqueness of an optimal control. To solve the (coupled) forward-backward system we use a priori estimates which follow from its control-theoretic interpretation.

Key words. stochastic optimal control, forward-backward stochastic differential equations

AMS subject classifications. 93E20, 60H10

DOI. 10.1137/S0363012903428664

1. Introduction.

We consider a controlled Markov process X^u in $\mathbb{R}^n$, on a time interval $[t,T] \subset [0,T]$, described by an Ito stochastic differential equation of the form

$$\text{(1.1)} \quad \begin{cases} dX^u_\tau = f(\tau, X^u_\tau)\, d\tau + g(\tau, X^u_\tau) r(\tau, X^u_\tau, u_\tau)\, d\tau + g(\tau, X^u_\tau)\, dW_\tau, \quad \tau \in [t,T], \\ X^u_t = x \in \mathbb{R}^n, \end{cases}$$

where $u_\cdot$ is the control process, W is a standard Wiener process in $\mathbb{R}^d$, and f, r, g are functions with values in $\mathbb{R}^n$, $\mathbb{R}^d$, $\mathbb{R}^{n\times d}$, respectively. We introduce the cost functional

$$J(t,x,u_\cdot) = \mathbb{E}\int_t^T l(\tau, X^u_\tau, u_\tau)\, d\tau + \mathbb{E}\,\phi(X^u_T),$$

where l, ϕ are real functions. We wish to minimize the cost over all admissible controls, i.e., processes $\{u_s, s \in [0,T]\}$ taking values in a prescribed set $\mathcal{U} \subset \mathbb{R}^m$ and predictable with respect to the (augmented) filtration generated by W. We introduce the value function

$$V(t,x) = \inf_{u_\cdot} J(t,x,u_\cdot), \qquad t \in [0,T],\ x \in \mathbb{R}^n,$$

where the infimum is taken over all admissible controls $u_\cdot$.

The particular form of the control system is essential for our results, but it covers a number of interesting cases. For instance, if $d = n$ and g takes values in the set of invertible matrices, then starting from a system of the form

$$\begin{cases} dX^u_\tau = h(\tau, X^u_\tau, u_\tau)\, d\tau + g(\tau, X^u_\tau)\, dW_\tau, \qquad s \in [t,T], \\ X^u_t = x, \end{cases}$$

where h takes values in $\mathbb{R}^n$, we can arrive at the form (1.1) setting $r = g^{-1}h$. We also note that in the special case $r(\tau, x, u) = u$, the term $u_\tau\, d\tau + dW_\tau$ admits a natural interpretation as a *control affected by noise*.

On the functions f, g, r we impose some Lipschitz and linear growth (or boundedness) conditions, but no further regularity is assumed (see Hypothesis 2.1 below for precise statements). Moreover, we do not assume any kind of nondegeneracy on the diffusion coefficient g. We solve the optimal control problem completely; i.e., we prove existence and we characterize the value function and the optimal control law. We also show solvability of the closed-loop equation. Under some mild additional assumptions we prove uniqueness of the optimal control and of the solution of the closed-loop equation.

We stress that these results are proved for the *strong formulation* of the control problem, that is, when the probability space in which (1.1) is considered is prescribed. This is a distinctive feature of this paper.

We note that under the present assumptions, due to lack of regularity of the coefficients and possible degeneracy of g, the Hamilton–Jacobi–Bellman equation has only (nondifferentiable) viscosity solutions; see [7] and the references within. In general this is not sufficient either to prove existence of the optimal control or to find an optimal feedback law since this usually involves the gradient of a solution of the Hamilton–Jacobi–Bellman equation. Consequently, an appropriate formulation and well-posedness of the closed-loop equation seem to be a difficult task here. We also notice that even when the Hamilton–Jacobi–Bellman equation has differentiable solutions, well-posedness, in strong sense, of the closed-loop equation is not obvious (see [3]).

Our starting point is the well-known idea of replacing the approach based on the Hamilton–Jacobi–Bellman equation with the analysis of a forward-backward stochastic differential system: we recall that if we define the hamiltonian function

$$\psi(t,x,z) = \inf_{u\in\mathcal{U}}\{l(t,x,u) + zr(t,x,u)\}, \qquad t\in[0,T],\ x\in\mathbb{R}^n,\ z\in\mathbb{R}^d, \tag{1.2}$$

and we consider the uncoupled forward-backward system

$$\begin{cases} dX_\tau = f(\tau, X_\tau)\, d\tau + g(\tau, X_\tau)\, dW_\tau, & \tau\in[t,T],\\ X_t = x,\\ dY_\tau = Z_\tau\, dW_\tau - \psi(\tau, X_\tau, Z_\tau)\, d\tau, & \tau\in[t,T],\\ Y_T = \phi(X_T), \end{cases} \tag{1.3}$$

then it is not difficult to prove that $J^*(t,x) := Y_t$ is a lower bound for the value function; see [6] or Proposition 2.7 and Corollary 2.6 below. At this point, if the control problem is considered in its *weak formulation*, that is, the probability space in which (1.1) is solved is not fixed (see, e.g., [7]), then it is easily proved that the lower bound $J^*(t,x)$ is attained and the process Z in (1.3) allows us to construct an optimal control. In this case the closed-loop equation can be solved but only in the sense of weak solutions of stochastic differential equations. See [5], [12], and [8] for other results stating, in wider generality, existence of optimal control for the weak formulation of the problem. Finally, we notice that backward stochastic differential equations have also been successfully applied to the search for equilibrium points in stochastic differential games (see [9], [10], [11]). In particular, the basic idea in [9] is, in a certain sense, comparable to the one inspiring the present paper; namely, the proof of existence of open-loop Nash equilibrium points relies on an existence and uniqueness result for coupled forward-backward stochastic systems under monotonicity assumptions.

Coming back to our optimal control problem in its original strong formulation, the main idea for circumventing the difficulties outlined above is to relate the existence of an optimal control to the solvability of a different, coupled forward-backward stochastic differential system. Namely, we assume that the infimum in (1.2) is attained at some $u = \gamma(t, x, z)$ and we consider

$$\begin{cases} dX_\tau = f(\tau, X_\tau)\, d\tau + g(\tau, X_\tau) r(\tau, X_\tau, \gamma(\tau, X_\tau, Z_\tau))\, d\tau + g(\tau, X_\tau)\, dW_\tau, \quad \tau \in [t, T], \\ X_t = x, \\ dY_\tau = Z_\tau\, dW_\tau - l(\tau, X_\tau, \gamma(\tau, X_\tau, Z_\tau))\, d\tau, \quad \tau \in [t, T], \\ Y_T = \phi(X_T). \end{cases} \tag{1.4}$$

We prove that if this forward-backward system has a solution (an appropriate predictable process (X, Y, Z) in $\mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d$), then the control $u_\tau = \gamma(\tau, X_\tau, Z_\tau)$ is optimal, the corresponding trajectory X^u coincides with X, and the optimal cost $V(t, x)$ is equal to Y_t. We then prove, imposing only some Lipschitz and boundedness conditions on γ (see Hypothesis 2.4 and Examples 1 and 2 below), that the system (1.4) is uniquely solvable. Moreover, we show, still relying only on properties of the forward-backward system, that the optimal control u found above is in feedback form, i.e., $u_\tau = \underline{u}(\tau, X_\tau)$ for some deterministic function $\underline{u}$. Finally, if the minimum in (2.3) is unique, we obtain uniqueness of the optimal control and of the solution to the closed-loop equation corresponding to the feedback $\underline{u}$. In particular, we give results for well-posedness of the closed-loop equations under conditions that do not guarantee the classical Lipzchitz conditions on its coefficients.

It is well known that solvability of forward-backward systems of general form is particularly delicate, even if the classical conditions of Lipschitz continuity and linear growth are imposed on the coefficients. Global solutions, i.e., for arbitrary T, for the system (1.4) have been found under various assumptions. In the so-called four step scheme introduced in [16] (see also [17]), as well as in the extensions proved in [4], analytic results on partial differential equations are used (see [15]) which require either regularity of the coefficients [17] or nondegeneracy of the diffusion coefficient g [4]. Several other results give sufficient conditions for the solvability of forward-backward systems: in [20] existence and uniqueness are obtained, by purely probabilistic techniques, under lipschitzianity and monotonicity requirements, in [13] and [21] dissipativity conditions are assumed, and finally in [23] the regularity requirements in [14] are relaxed but only existence is proved.

None of these results is directly applicable to (1.4). To our knowledge, for the system (1.4) only a local solvability result is available in the literature (see [4], [1], or [17]). To obtain a global solution we argue as follows. By the above mentioned local result we know that a unique solution exists in $[T - \delta, T]$ when δ is small enough. Then we prove that if (X, Y, Z) solves the system (1.4) in an arbitrary interval $[t, T]$ with initial condition $X_t = x \in \mathbb{R}^n$ and final condition $Y_T = \phi(X_T)$, then Y_t is equal to the value function $V(t, x)$. At this point we can rely on an estimate of the form

$$|V(t, x_1) - V(t, x_2)| \le c|x_1 - x_2|, \qquad t \in [0, T],\ x_1, x_2 \in \mathbb{R}^n,$$

which is easily obtained from the definition of the value function (and is basically known); thus denoting (X^i, Y^i, Z^i), $i = 1, 2$, the solutions in $[t, T]$ corresponding to initial points x_i $(i = 1, 2)$, we obtain

$$|Y_t^1 - Y_t^2| \le c|x_1 - x_2|,$$

with c independent of t. The above can be considered as a sort of a priori estimate for the Lipschitz dependence of Y_t on x obtained by means of the control-theoretic interpretation of the forward-backward system. This allows us to conclude global existence and uniqueness of the solution to system (1.4) by an argument introduced in [4] consisting in solving the system recursively starting from T in small intervals with fixed length and suitable final conditions.

Finally, in view of the great attention that forward-backward systems have received recently, we stress the fact that our original problem has led us to focus on a special class of such systems for which existence of a unique global solution is not a direct consequence of the results already existing in the literature but rather follows from its control-theoretic interpretation.

2. Formulation of the problem and preliminary results. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space, and let $\mathcal{N}$ be the family of elements of $\mathcal{F}$ with probability zero. Let $\{W_t,\ t \in [0,T]\}$ be a standard Wiener process defined in $(\Omega, \mathcal{F}, \mathbb{P})$ with values in $\mathbb{R}^d$. By $(\mathcal{F}_t)_{t\in[0,T]}$ we denote the filtration generated by W augmented by the null sets of $\mathcal{F}$; namely, $\mathcal{F}_t$ denotes the σ-algebra generated by $\mathcal{N}$ and by the random variables W_s, $s \in [0,t]$. We are given a set $\mathcal{U} \subset \mathbb{R}^m$ and functions

$$
\begin{aligned}
&f : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n,\\
&g : [0,T] \times \mathbb{R}^n \to \mathbb{R}^{n\times d},\\
&r : [0,T] \times \mathbb{R}^n \times \mathcal{U} \to \mathbb{R}^d,\\
&\phi : \mathbb{R}^n \to \mathbb{R},\\
&l : [0,T] \times \mathbb{R}^n \times \mathcal{U} \to \mathbb{R}
\end{aligned}
$$

satisfying the following assumptions.

Hypothesis 2.1. $\mathcal{U}$ is a Borel subset of $\mathbb{R}^m$, the functions f, g, r, ϕ, l are Borel measurable, the function $x \to f(t,x)$ is continuous on $\mathbb{R}^n$ for every $t \in [0,T]$, and there exists a constant C such that

$$
\begin{aligned}
&|\phi(x) - \phi(x')| \le C|x - x'|,\\
&\langle f(t,x) - f(t,x'), x - x'\rangle \le C|x - x'|^2,\\
&|g(t,x) - g(t,x')| \le C|x - x'|,\\
&|r(t,x,u) - r(t,x',u')| + |l(t,x,u) - l(t,x',u')| \le C(|x - x'| + |u - u'|),\\
&|f(t,x)| \le C(1 + |x|),\\
&|g(t,x)| + |r(t,x,u)| + |l(t,0,0)| \le C,\\
&l(t,0,u) \ge -C
\end{aligned}
$$

for every $t \in [0,T]$, $x, x' \in \mathbb{R}^n$, $u, u' \in \mathcal{U}$.

This implies in particular

$$
-C(1 + |x|) \le l(t,x,u) \le C(1 + |x| + |u|), \qquad t \in [0,T],\ x \in \mathbb{R}^n,\ u \in \mathcal{U}. \tag{2.1}
$$

We also note that if $r(t,x,u) = u$, then $\mathcal{U}$ is required to be bounded.

A stochastic process $\{u_s,\ s \in [0,T]\}$ in $\mathbb{R}^m$ will be called an *admissible control* if it is predictable with respect to $(\mathcal{F}_t)$ and it takes values in $\mathcal{U}$.

For any admissible control $u_\cdot$ and any $(t,x) \in [0,T] \times \mathbb{R}^n$ we consider the process $\{X^u_\tau,\ \tau \in [t,T]\}$, solution of the Ito stochastic equation: $\mathbb{P}$-a.s.,

$$
X^u_\tau = x + \int_t^\tau f(\sigma, X^u_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma) r(\sigma, X^u_\sigma, u_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma)\, dW_\sigma, \quad \tau \in [t,T].
$$

Taking into account that, in particular, the function $g(t,\cdot)r(t,\cdot,u)$ is Lipschitz, uniformly with respect to t and u, it is easy to check that a classical solvability result applies to this equation: namely, under Hypothesis 2.1, there exists a continuous, $(\mathcal{F}_\tau)$-adapted solution, unique up to indistinguishability. It also satisfies $\mathbb{E}\sup_{\tau\in[t,T]}|X^u_\tau|^2<\infty$.

We introduce the cost functional

$$J(t,x,u_\cdot)=\mathbb{E}\int_t^T l(\sigma,X^u_\sigma,u_\sigma)\,d\sigma+\mathbb{E}\phi(X^u_T).$$

As a consequence of our assumptions, in particular the first inequality in (2.1), it is easy to check that for some constant c independent of $u_\cdot$ we have

$$\mathbb{E}\int_t^T l^-(\sigma,X^u_\sigma,u_\sigma)\,d\sigma+\mathbb{E}|\phi(X^u_T)|\le c,$$

where l^- denotes the negative part of l. It follows that for all admissible controls $u_\cdot$ the cost $J(t,x,u_\cdot)$ is a well-defined element in $(-\infty,+\infty]$, and its values are bounded below by $-c$ (which may depend on t and x). We also note that the cost is not identically $+\infty$.

For given $x\in\mathbb{R}^n$ and $t\in[0,T]$, we consider the problem of minimizing $J(t,x,u_\cdot)$ over all admissible controls $u_\cdot$. Any admissible control which minimizes $J(t,x,\cdot)$, if it exists, is called optimal for the control problem starting from x at time t. The minimal value of the cost is then called the optimal cost.

We introduce the value function $V:[0,T]\times\mathbb{R}^n\to\mathbb{R}$ defined by

$$V(t,x)=\inf_{u_\cdot}J(t,x,u_\cdot),\qquad t\in[0,T],\ x\in\mathbb{R}^n,$$

where the infimum is taken over all admissible controls $u_\cdot$. By the previous discussion V is clearly well defined. The following lemma gives an a priori estimate on the Lipschitz constant of $V(t,\cdot)$, which is of basic importance for what follows.

LEMMA 2.2. *Assume Hypothesis* 2.1. *Then there exists a constant c such that*

$$|V(t,x)-V(t,x')|\le c|x-x'|$$

for every $t\in[0,T]$, $x,x'\in\mathbb{R}^n$.

Proof. We fix an arbitrary $u_\cdot$ and we denote by X (respectively, X') the corresponding solution starting from x (respectively, x') at time t. By c we denote a positive constant which may vary from line to line but does not depend on t, x, x', and $u_\cdot$. Applying the Ito formula to $\{|X_\tau-X'_\tau|^2,\tau\in[t,T]\}$ and taking expectation, we obtain

$$\begin{aligned}\mathbb{E}|X_\tau-X'_\tau|^2&=|x-x'|^2+\mathbb{E}\int_t^\tau\langle X_\sigma-X'_\sigma,f(\sigma,X_\sigma)-f(\sigma,X'_\sigma)\rangle\,d\sigma\\&\quad+\mathbb{E}\int_t^\tau\langle X_\sigma-X'_\sigma,g(\sigma,X_\sigma)r(\sigma,X_\sigma,u_\sigma)-g(\sigma,X'_\sigma)r(\sigma,X'_\sigma,u_\sigma)\rangle\,d\sigma\\&\quad+\mathbb{E}\int_t^\tau|g(\sigma,X_\sigma)-g(\sigma,X'_\sigma)|^2\,d\sigma,\qquad\tau\in[t,T].\end{aligned}$$

Recalling that the function $g(t,\cdot)r(t,\cdot,u)$ is Lipschitz, uniformly with respect to $t\in[0,T]$ and $u\in\mathcal{U}$, we easily obtain

$$\mathbb{E}|X_\tau-X'_\tau|^2\le|x-x'|^2+c\mathbb{E}\int_t^\tau|X_\sigma-X'_\sigma|^2\,d\sigma,\qquad\tau\in[t,T],$$

and therefore, by the Gronwall lemma, $\mathbb{E}|X_\tau - X'_\tau|^2 \le c|x-x'|^2$.

Moreover, our assumptions on l and ϕ imply that for all x and x' in $\mathbb{R}^n$,

$$J(t,x,u_\cdot) < +\infty \quad \Rightarrow \quad J(t,x',u_\cdot) < +\infty,$$
$$|J(t,x,u_\cdot) - J(t,x',u_\cdot)| \le c\mathbb{E}\int_t^T |X_\sigma - X'_\sigma|\, d\sigma + c\mathbb{E}|X_T - X'_T| \le |x-x'|.$$

To conclude, for fixed $\epsilon > 0$, we choose $u^\epsilon_\cdot$ such that $J(t,x,u^\epsilon_\cdot) \le V(t,x) + \epsilon$. Then

$$V(t,x') \le J(t,x',u^\epsilon_\cdot) \le J(t,x,u^\epsilon_\cdot) + c|x-x'| \le V(t,x) + c|x-x'| + \epsilon,$$

and the claim follows inverting the role of x and x'. □

We introduce the hamiltonian function $\psi : [0,T] \times \mathbb{R}^n \times \mathbb{R}^d \to \mathbb{R}$ setting

$$\psi(t,x,z) = \inf_{u\in\mathcal{U}}\{l(t,x,u) + zr(t,x,u)\}, \qquad t \in [0,T],\ x \in \mathbb{R}^n,\ z \in \mathbb{R}^d. \tag{2.2}$$

By the boundedness of r and by (2.1), ψ is well defined as a real-valued function. For further use we prove some additional properties of ψ.

LEMMA 2.3. *Assume Hypothesis* 2.1. *Then there exists a constant c such that*

$$|\psi(t,0,0)| \le c, \qquad |\psi(t,x,z) - \psi(t,x',z')| \le c|z-z'| + c|x-x'|(1+|z|+|z'|)$$

for every $t \in [0,T]$, $x, x' \in \mathbb{R}^n$, $z, z' \in \mathbb{R}^d$.

Proof. Since $l(t,0,u) \ge -C$, therefore $\psi(t,0,0) = \inf_{u\in\mathcal{U}} l(t,0,u) \ge -C$. From (2.1) we obtain, for an arbitrary fixed element $u_0 \in \mathcal{U}$,

$$\psi(t,0,0) = \inf_{u\in\mathcal{U}} l(t,0,u) \le l(t,0,u_0) \le C(1+|u_0|),$$

and the first inequality of the lemma is proved.

For $u \in \mathcal{U}$ we have

$$\begin{aligned} l(t,x,u) + zr(t,x,u) &\le l(t,x',u) + z'r(t,x',u) + |l(t,x,u) - l(t,x',u)| \\ &\quad + |zr(t,x,u) - z'r(t,x',u)| \\ &\le l(t,x',u) + z'r(t,x',u) + |l(t,x,u) - l(t,x',u)| \\ &\quad + |(z-z')r(t,x,u)| + |z'(r(t,x,u) - r(t,x',u))| \\ &\le l(t,x',u) + z'r(t,x',u) + C|x-x'| \\ &\quad + C|z-z'| + C|z'||x-x'|. \end{aligned}$$

Taking the infimum over all $u \in \mathcal{U}$, we obtain

$$\psi(t,x,z) - \psi(t,x',z') \le C|x-x'| + C|z-z'| + C|z'||x-x'| \le c|z-z'| + c|x-x'|(1+|z|+|z'|)$$

for some c. Exchanging x, z with x', z', we get the conclusion. □

We will assume that the infimum in (2.2) is attained at some u which can be chosen to depend measurably on t, x, z, and the resulting function satisfies additional conditions. More precisely we assume the following.

Hypothesis 2.4. There exists a Borel measurable function $\gamma : [0,T] \times \mathbb{R}^n \times \mathbb{R}^d \to \mathcal{U}$ such that

$$\psi(t,x,z) = l(t,x,\gamma(t,x,z)) + zr(t,x,\gamma(t,x,z)), \qquad t \in [0,T],\ x \in \mathbb{R}^n,\ z \in \mathbb{R}^d, \tag{2.3}$$

and such that, for some constant C, we have

$$|\gamma(t,x,z) - \gamma(t,x',z')| \le C(|x-x'| + |z-z'|),$$
$$|\gamma(t,0,0)| \le C$$

for every $t \in [0,T]$, $x, x' \in \mathbb{R}^n$, $z, z' \in \mathbb{R}^d$.

In general we do not assume that, for any given $t \in [0,T]$, $x \in \mathbb{R}^n$, $z \in \mathbb{R}^d$, the infimum in (2.2) is attained at a unique point. However, this will be required for some of our results below; in this case the equality $\psi(t,x,z) = l(t,x,u) + zr(t,x,u)$ implies $u = \gamma(t,x,z)$.

Next we present two examples where our assumptions on ℓ, r, and $\mathcal{U}$, including Hypothesis 2.4, are satisfied.

Example 1. Let $d = m = 1$, $r(t,x,u) = u$, $\mathcal{U} = [-\delta, \delta]$.

Suppose that ℓ satisfies the assumptions in Hypothesis 2.1 and moreover that it can be extended to a function on $[0,T] \times \mathbb{R}^n \times \mathbb{R}$, still denoted by $\ell(t,x,z)$, such that $\ell(t,\cdot,\cdot) \in C^{1,2}(\mathbb{R}^n \times \mathbb{R}; \mathbb{R})$ and, for a suitable $c > 0$,

$$\frac{1}{c} \le \frac{\partial^2 \ell}{\partial u^2}(t,x,u) \le c, \qquad \left| \frac{\partial \ell}{\partial x}(t,x,u) \right| \le c$$

for all $t \in [0,T]$, $x \in \mathbb{R}^n$, $u \in \mathbb{R}$.

Under the previous assumptions we have

$$\lim_{u \to +\infty} \frac{\partial \ell}{\partial u}(t,x,u) = +\infty, \qquad \lim_{u \to -\infty} \frac{\partial \ell}{\partial u}(t,x,u) = -\infty.$$

Moreover, the infimum in (2.2) is attained at a unique point,

$$\gamma(t,x,z) = (-\delta) \vee (\widehat{u}(t,x,z) \wedge \delta),$$

where $\widehat{u}(t,x,z)$ is the unique solution of the equation

$$\frac{\partial \ell}{\partial u}(t,x,\widehat{u}(t,x,z)) = -z.$$

Thus the partial derivatives

$$\frac{\partial \widehat{u}}{\partial x}(t,x,z) = -\left[\frac{\partial^2 \ell}{\partial u^2}(t,x,\widehat{u}(t,x,z)) \right]^{-1} \frac{\partial \ell}{\partial x}(t,x,\widehat{u}(t,x,z)),$$
$$\frac{\partial \widehat{u}}{\partial z}(t,x,z) = -\left[\frac{\partial^2 \ell}{\partial u^2}(t,x,\widehat{u}(t,x,z)) \right]^{-1}$$

are bounded, and consequently $\gamma(t,\cdot,\cdot)$ is Lipschitz continuous uniformly in t.

Example 2. Let $\ell(t,x,u) = \ell^0(t,x) + |u|^2$, $r(t,x,u) = Bu$ with $\ell^0 : [0,T] \times \mathbb{R}^n \to \mathbb{R}$ such that $\ell^0(\cdot,0)$ is bounded, $\ell^0(t,\cdot)$ is Lipschitz uniformly with respect to t, and $B \in L(\mathbb{R}^m, \mathbb{R}^d)$. Moreover, let $\mathcal{U} = \{u \in \mathbb{R}^m : |u| \le \delta\}$, where $\delta > 0$. Then the infimum in (2.2) is attained at a unique point:

$$\gamma(z) = \begin{cases} -(1/2)B^*z & \text{if } |B^*z| \le 2\delta, \\ -\delta |B^*z|^{-1} B^*z & \text{if } |B^*z| > 2\delta, \end{cases}$$

and clearly γ is a Lipschitz function.

In Proposition 2.5 and Corollary 2.6 we collect some results relating the optimal control problem introduced above to suitable backward stochastic differential equations. Such results are mainly known. From now on we assume that Hypotheses 2.1 and 2.4 hold.

Let $\widetilde{W}$ be a standard Wiener process in $\mathbb{R}^d$, defined in some complete probability space $(\widetilde{\Omega}, \widetilde{\mathcal{F}}, \widetilde{\mathbb{P}})$. For $0 \le t \le \tau \le T$, we denote by $\widetilde{\mathcal{F}}_t$ (respectively, $\widetilde{\mathcal{F}}_{[t,\tau]}$) the σ-algebra generated by $\widetilde{W}_s$, $s \in [0,t]$ (respectively, $s \in [t,\tau]$), and augmented by the null sets of $\widetilde{\mathcal{F}}$.

For fixed $t \in [0,T]$ and $x \in \mathbb{R}^n$ we consider the equation

$$\widetilde{X}_\tau = x + \int_t^\tau f(\sigma, \widetilde{X}_\sigma)\, d\sigma + \int_t^\tau g(\sigma, \widetilde{X}_\sigma)\, d\widetilde{W}_\sigma, \qquad \tau \in [t,T]. \tag{2.4}$$

The solution $\{\widetilde{X}_\tau,\ \tau \in [t,T]\}$ is a continuous process in $\mathbb{R}^n$, adapted to the filtration $(\widetilde{\mathcal{F}}_{[t,\tau]})_{\tau\in[t,T]}$. Moreover, the law of $(\widetilde{W}, \widetilde{X})$ is uniquely determined by x, f, and g. Next we consider the backward stochastic differential equation

$$\widetilde{Y}_\tau + \int_\tau^T \widetilde{Z}_\sigma\, d\widetilde{W}_\sigma = \phi(\widetilde{X}_T) + \int_\tau^T \psi(\sigma, \widetilde{X}_\sigma, \widetilde{Z}_\sigma)\, d\sigma, \qquad \tau \in [t,T]. \tag{2.5}$$

By a solution of (2.5) we mean a process $\{(\widetilde{Y}_\tau, \widetilde{Z}_\tau),\ \tau \in [t,T]\}$ with values in $\mathbb{R}\times\mathbb{R}^d$, predictable with respect to $(\widetilde{\mathcal{F}}_{[t,\tau]})_{\tau\in[t,T]}$, such that, denoting by $\widetilde{\mathbb{E}}$ the expectation with respect to $\widetilde{\mathbb{P}}$, we have

$$\widetilde{\mathbb{E}} \sup_{\tau\in[t,T]} |\widetilde{Y}_\tau|^2 + \widetilde{\mathbb{E}} \int_t^T |\widetilde{Z}_\tau|^2\, d\tau < \infty,$$

and $\widetilde{\mathbb{P}}$-a.s., $\{\widetilde{Y}_\tau,\ \tau \in [t,T]\}$ has continuous trajectories and the equality (2.5) holds.

From Lemma 2.3 it follows that

$$\widetilde{\mathbb{E}} \int_t^T |\psi(\sigma, \widetilde{X}_\sigma, 0)|^2\, d\sigma < \infty.$$

Moreover, for a suitable constant c, $\mathbb{P}$-a.s.,

$$|\psi(\sigma, \widetilde{X}_\sigma, z) - \psi(\sigma, \widetilde{X}_\sigma, z')| \le c|z - z'|, \qquad z, z' \in \mathbb{R}^d, \sigma \in [t,T].$$

Therefore, we conclude that there exists a solution $(\widetilde{Y}, \widetilde{Z})$ of (2.5) on the interval $[t,T]$, $\widetilde{Y}$ is unique up to indistinguishability, and $\widetilde{Z}$ is unique up to modification; a proof of this result can be found, for instance, in [18, Theorem 1.3] or [19, Theorem 2.2]. From this proof it also follows that the law of $(\widetilde{Y}, \widetilde{Z})$ is uniquely determined by the law of $(\widetilde{W}, \widetilde{X})$ and by ϕ and ψ. We note that $\widetilde{Y}_t$, being measurable with respect to the degenerate σ-algebra $\widetilde{\mathcal{F}}_{[t,t]}$, is deterministic; in particular, $\widetilde{Y}_t = \widetilde{\mathbb{E}}\widetilde{Y}_t$ depends only on the law of $\widetilde{Y}$, and thus it is a functional of t, x, f, g, ϕ, ψ.

To stress dependence on the parameters t and x, we will denote the solution of (2.4)–(2.5) by $\{(\widetilde{X}_\tau(t,x), \widetilde{Y}_\tau(t,x), \widetilde{Z}_\tau(t,x)),\ \tau \in [t,T]\}$. We set

$$J^*(t,x) = \widetilde{Y}_t(t,x).$$

The previous discussion shows that $J^*(t,x)$ is a number whose value is uniquely determined by t, x, f, g, ψ, and ϕ. The relevance of $J^*(t,x)$ to our control problem is explained in the following proposition.

PROPOSITION 2.5. *For every $t \in [0,T]$ and $x \in \mathbb{R}^n$ and for every admissible control $u_\cdot$, we have $J^*(t,x) \le J(t,x,u_\cdot)$.*

Proof. Let $\{X_\tau^u,\ \tau \in [t,T]\}$ be the solution to (1.1) corresponding to $u_\cdot$. We define the process

$$W_\tau^u = W_\tau + \int_{\tau\wedge t}^{\tau} r(\sigma, X_\sigma^u, u_\sigma)\, d\sigma, \qquad \tau \in [0,T], \tag{2.6}$$

and we note that X^u solves the equation

$$X_\tau^u = x + \int_t^\tau f(\sigma, X_\sigma^u)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma^u)\, dW_\sigma^u, \qquad \tau \in [t,T]. \tag{2.7}$$

Since r is bounded, by the Girsanov theorem there exists a probability measure $\mathbb{P}^u$ on $(\Omega, \mathcal{F})$ such that W^u is a Wiener process under $\mathbb{P}^u$. Moreover, the density $\rho = d\mathbb{P}/d\mathbb{P}^u$ satisfies $\mathbb{E}^u\rho^p < \infty$ for every $p \in [1,\infty)$ (where $\mathbb{E}^u$ denotes expectation with respect to $\mathbb{P}^u$). Let us consider the backward equation for the unknown process $\{(Y_\tau^u, Z_\tau^u),\ \tau \in [t,T]\}$:

$$Y_\tau^u + \int_\tau^T Z_\sigma^u\, dW_\sigma^u = \phi(X_T^u) + \int_\tau^T \psi(\sigma, X_\sigma^u, Z_\sigma^u)\, d\sigma, \qquad \tau \in [t,T]. \tag{2.8}$$

By the result recalled earlier, there exists a unique solution (Y^u, Z^u) of this equation. Comparing (2.7)–(2.8) with (2.4)–(2.5), we conclude that $J^*(t,x) = Y_t^u$.

Next we write (2.8) with respect to W:

$$\begin{aligned} Y_\tau^u + \int_\tau^T Z_\sigma^u\, dW_\sigma + \int_\tau^T Z_\sigma^u r(\sigma, X_\sigma^u, u_\sigma)\, d\sigma \\ = \phi(X_T^u) + \int_\tau^T \psi(\sigma, X_\sigma^u, Z_\sigma^u)\, d\sigma, \qquad \tau \in [t,T]. \end{aligned} \tag{2.9}$$

Now we notice that

$$\begin{aligned} \mathbb{E}\left(\int_0^T |Z_\sigma^u|^2 d\sigma\right)^{1/2} &= \mathbb{E}^u\left[\rho\left(\int_0^T |Z_\sigma^u|^2 d\sigma\right)^{1/2}\right] \\ &\le (\mathbb{E}^u\,\rho^2)^{1/2}\left(\mathbb{E}^u \int_0^T |Z_\sigma^u|^2 d\sigma\right)^{1/2} < +\infty. \end{aligned}$$

Thus the stochastic integral in (2.9) has zero expectation with respect to the original probability $\mathbb{P}$. So, if we set $\tau = t$ in (2.9) and we take the expectation with respect to $\mathbb{P}$, we obtain

$$J^*(t,x) = Y_t^u = \mathbb{E}\phi(X_T^u) + \mathbb{E}\int_t^T [\psi(\sigma, X_\sigma^u, Z_\sigma^u) - Z_\sigma^u r(\sigma, X_\sigma^u, u_\sigma)]\, d\sigma.$$

Adding and subtracting $\mathbb{E}\int_t^T l(\sigma, X_\sigma^u, u_\sigma)\, d\sigma$, we arrive at 1:

$$J^*(t,x) = J(t,x,u_\cdot) + \int_t^T [\psi(\sigma, X_\sigma^u, Z_\sigma^u) - Z_\sigma^u r(\sigma, X_\sigma^u, u_\sigma) - l(\sigma, X_\sigma^u, u_\sigma)]\, d\sigma. \tag{2.10}$$

By the definition of ψ (formula (2.2)) the term in the square brackets is nonpositive, and consequently $J(t,x,u_\cdot) \ge J^*(t,x)$. ∎

We notice that relation (2.10) is a version of the *fundamental relation* in terms of backward stochastic differential equations. It immediately yields important consequences.

COROLLARY 2.6. *We fix $t \in [0,T]$, $x \in \mathbb{R}^n$.*

If, for an admissible control $u_\cdot$, we have $J(t,x,u_\cdot) = J^*(t,x)$, then $u_\cdot$ is optimal for the control problem starting from x at time t.

If an admissible control $u_\cdot$ verifies

$$u_\tau = \gamma(\tau, X^u_\tau, Z^u_\tau), \qquad \mathbb{P}\text{-a.s. for a.e. } \tau \in [t,T], \tag{2.11}$$

then $J(t,x,u_\cdot) = J^*(t,x)$ and $u_\cdot$ is optimal.

Conversely, suppose that the infimum in (2.2) is attained at a unique point and that an admissible control $u_\cdot$ satisfies $J(t,x,u_\cdot) = J^*(t,x)$. Then (2.11) holds and moreover we have, $\mathbb{P}$-a.s.,

$$\begin{cases} X^u_\tau = x + \displaystyle\int_t^\tau f(\sigma, X^u_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma) r(\sigma, X^u_\sigma, \gamma(\sigma, X^u_\sigma, Z^u_\sigma))\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma)\, dW_\sigma, \\ Y^u_\tau + \displaystyle\int_\tau^T Z^u_\sigma\, dW_\sigma = \phi(X^u_T) + \int_\tau^T l(\sigma, X^u_\sigma, \gamma(\sigma, X^u_\sigma, Z^u_\sigma))\, d\sigma, \qquad \tau \in [t,T]. \end{cases} \tag{2.12}$$

Proof. The optimality of $u_\cdot$ when $J(t,x,u_\cdot) = J^*(t,x)$ follows immediately from Proposition 2.5. Moreover, if (2.11) holds, then $J(t,x,u_\cdot) = J^*(t,x)$ by (2.10).

For the converse, the equalities $J(t,x,u_\cdot) = J^*(t,x) = Y^u_t$ and (2.10) imply that

$$\int_t^T [\psi(\sigma, X^u_\sigma, Z^u_\sigma) - Z^u_\sigma r(\sigma, X^u_\sigma, u_\sigma) - l(\sigma, X^u_\sigma, u_\sigma)]\, d\sigma = 0, \qquad \mathbb{P}\text{-a.s.}$$

By our assumption on ψ (compare formula (2.2)) this is possible only if (2.11) holds.

Finally, writing (2.7)–(2.8) in terms of W and replacing u_τ by $\gamma(\tau, X^u_\tau, Z^u_\tau)$, we obtain

$$\begin{cases} X^u_\tau = x + \displaystyle\int_t^\tau f(\sigma, X^u_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma) r(\sigma, X^u_\sigma, \gamma(\sigma, X^u_\sigma, Z^u_\sigma))\, d\sigma + \int_t^\tau g(\sigma, X^u_\sigma)\, dW_\sigma, \\ Y^u_\tau + \displaystyle\int_\tau^T Z^u_\sigma\, dW_\sigma + \int_\tau^T Z^u_\sigma r(\sigma, X^u_\sigma, \gamma(\sigma, X^u_\sigma, Z^u_\sigma))\, d\sigma = \phi(X^u_T) + \int_\tau^T \psi(\sigma, X^u_\sigma, Z^u_\sigma)\, d\sigma, \end{cases}$$

and recalling the identity (2.3), we get the final assertion of the corollary. □

In order to prove the existence of an optimal control, Corollary 2.6 suggests that it might be useful to investigate general properties of the following fully coupled forward-backward stochastic differential system:

$$\begin{cases} X_\tau = \xi + \displaystyle\int_t^\tau f(\sigma, X_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma) r(\sigma, X_\sigma, \gamma(\sigma, X_\sigma, Z_\sigma))\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW_\sigma, \\ Y_\tau + \displaystyle\int_\tau^T Z_\sigma\, dW_\sigma = \phi(X_T) + \int_\tau^T l(\sigma, X_\sigma, \gamma(\sigma, X_\sigma, Z_\sigma))\, d\sigma, \qquad \tau \in [t,T], \end{cases} \tag{2.13}$$

where t is fixed in $[0,T]$ and ξ is a given $\mathcal{F}_t$-measurable random variable in $\mathbb{R}^n$, satisfying $\mathbb{E}|\xi|^2 < \infty$. We denote by $\mathcal{F}^\xi_{[t,\tau]}$ the σ-algebra generated by ξ and $\{W_s - W_t : s \in [t,\tau]\}$ augmented by the class $\mathcal{N}$ of zero probability sets in $\mathcal{F}$. Notice that $\mathcal{F}_{[t,\tau]} \subset \mathcal{F}^\xi_{[t,\tau]} \subset \mathcal{F}_\tau$, $\tau \in [t,T]$. By a solution of (2.13) we mean an $(\mathcal{F}^\xi_{[t,\tau]})_{\tau\in[t,T]}$-predictable process $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in [t,T]\}$, with values in $\mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d$, such that

$$\mathbb{E} \sup_{\tau\in[t,T]} |X_\tau|^2 + \mathbb{E} \sup_{\tau\in[t,T]} |Y_\tau|^2 + \mathbb{E} \int_t^T |Z_\tau|^2\, d\tau < \infty$$

and, $\mathbb{P}$-a.s., X and Y have continuous trajectories and equalities (2.13) hold. With slight abuse of terminology to shorten some of the statements, we will say that (X, Y, Z) *is a solution on* $[t, T]$ *with boundary conditions* ξ *and* ϕ. In the following we say that such a solution is unique if the following holds: if (X', Y', Z') is another solution, then (X, Y) is indistinguishable from (X', Y') and Z is a modification of Z'.

When $\xi = x \in \mathbb{R}^n$ is deterministic, $\mathcal{F}^{\xi}_{[t,\tau]} = \mathcal{F}_{[t,\tau]}$. In this case Y_t is deterministic, since it is measurable with respect to the degenerate σ-algebra $\mathcal{F}_{[t,t]}$.

PROPOSITION 2.7. *Suppose that, for some* $(t, x) \in [0, T] \times \mathbb{R}^n$, *the forward-backward system* (2.13) *has a solution* (X, Y, Z) *on* $[t, T]$ *with boundary conditions* $\xi = x$ *and* ϕ. *Then setting* $u^*_\tau = \gamma(\tau, X_\tau, Z_\tau)$, $\tau \in [t, T]$, *the process* $u^*_\cdot$ *is optimal for the control problem starting from* x *at time* t *with optimal cost* $J(t, x, u^*_\cdot) = J^*(t, x) = Y_t$.

Proof. It is clear that $u^*_\cdot$ is admissible and that X is the corresponding solution (i.e., $X = X^{u^*}$). Moreover, by definition of γ the system (2.13) can be rewritten

$$\begin{cases} X_\tau = x + \displaystyle\int_t^\tau f(\sigma, X_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma) r(\sigma, X_\sigma, u^*_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW_\sigma, \\ Y_\tau + \displaystyle\int_\tau^T Z_\sigma\, dW_\sigma = \phi(X_T) + \int_\tau^T [\psi(\sigma, X_\sigma, u^*_\sigma) - Z_\sigma r(\sigma, X_\sigma, u^*_\sigma)]\, d\sigma, \quad \tau \in [t, T]. \end{cases}$$

And letting W^{u^*} be defined as in (2.6), we obtain

$$\begin{cases} X_\tau = x + \displaystyle\int_t^\tau f(\sigma, X_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW^{u^*}_\sigma, \\ Y_\tau + \displaystyle\int_\tau^T Z_\sigma\, dW^{u^*}_\sigma = \phi(X_T) + \int_\tau^T \psi(\sigma, X_\sigma, u^*_\sigma) d\sigma, \qquad \tau \in [t, T]. \end{cases}$$

Comparing this with (2.7) and (2.8), we get $Y_\tau = Y^{u^*}_\tau$, $Z_\tau = Z^{u^*}_\tau$. Thus $Y_t = Y^{u^*}_t = J^*(t, x)$. Since by definition $u^*_\tau = \gamma(\tau, X^{u^*}_\tau, Z^{u^*}_\tau)$, the claim follows by Proposition 2.6. □

In the following section we will show that a solution of the forward-backward system actually exists, and this will lead to the desired existence of an optimal control in the strong formulation.

3. Main results. In this section we will assume that Hypotheses 2.1 and 2.4 hold.

For $t \in [0, T]$, $x \in \mathbb{R}^n$, $z \in \mathbb{R}^d$, we set for brevity

$$f_0(t, x, z) = f(t, x) + g(t, x) r(t, x, \gamma(t, x, z)), \qquad l_0(t, x, z) = l(t, x, \gamma(t, x, z)),$$

so that the forward-backward system (2.13) can be written

$$\begin{cases} X_\tau = \xi + \displaystyle\int_t^\tau f_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW_\sigma, \\ Y_\tau + \displaystyle\int_\tau^T Z_\sigma\, dW_\sigma = \phi(X_T) + \int_\tau^T l_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma, \qquad \tau \in [t, T], \end{cases}$$

and we note that there exists a constant c such that

$$\begin{aligned} &\langle f_0(t, x, z) - f_0(t, x', z), x - x' \rangle \le c|x - x'|^2, \\ &|f_0(t, x, z) - f_0(t, x, z')| \le c|z - z'|, \\ &|l_0(t, x, z) - l_0(t, x', z')| \le c(|x - x'| + |z - z'|), \\ &|f_0(t, x, z)| + |l_0(t, x, z)| \le c(1 + |x| + |z|). \end{aligned}$$

Further, let us denote by L a Lipschitz constant for ϕ:

$$|\phi(x) - \phi(x')| \le L|x - x'|, \qquad x, x' \in \mathbb{R}^n.$$

Concerning the solvability of the forward-backward system (2.13), we will use the following proposition; this is Theorem 1.1 in [4], which generalizes an earlier result by [1] (see also [17] and the references therein).

PROPOSITION 3.1. *There exists $\delta > 0$, depending only on f_0, l_0, g, and L, with the following property: for any $t \in [0,T]$ satisfying $t \ge T - \delta$ and any $\mathcal{F}_t$-measurable ξ satisfying $\mathbb{E}|\xi|^2 < \infty$ there exists a unique solution of* (2.13).

When $\xi = x$ we denote the solution by $\{(X_\tau(t,x), Y_\tau(t,x), Z_\tau(t,x)),\ \tau \in [t,T]\}$, to stress dependence on the parameters (t,x), and we recall that $Y_t(t,x)$ is deterministic. It can be shown that the solution can be chosen in such a way that, for fixed t, the mapping $(\omega,\tau,x) \to (X_\tau(t,x,\omega), Y_\tau(t,x,\omega), Z_\tau(t,x,\omega))$ is measurable with respect to $\mathcal{P}_{[t,T]} \times \mathcal{B}(\mathbb{R}^n)$, where $\mathcal{B}(\mathbb{R}^n)$ denotes the Borel sets of $\mathbb{R}^n$ and $\mathcal{P}_{[t,T]}$ denotes the predictable σ-algebra on $\Omega \times [t,T]$ with respect to the filtration $(\mathcal{F}_{[t,\tau]})_{\tau \in [t,T]}$. In the following we always assume that this measurability property holds.

The general solution of the system (2.13) can be represented in terms of this family of solutions; more precisely, given t and ξ as in Proposition 3.1, it is easy to verify that the solution on $[t,T]$ with boundary conditions ξ and ϕ is

$$X_\tau = X_\tau(t,\xi), \quad Y_\tau = Y_\tau(t,\xi), \quad Z_\tau = Z_\tau(t,\xi), \qquad \tau \in [t,T].$$

Remark 3.2. With the present notation, Proposition 2.7 states that if $t \ge T - \delta$, then there exists an optimal control for the control system starting from x at time t, with optimal cost $V(t,x) = Y_t(t,x)$.

Proposition 3.1 is a local existence and uniqueness result for solutions of (2.13). In order to obtain a global result we need to study extensions of solutions. This is the subject of the following lemma.

LEMMA 3.3. *Let $0 \le t < s < T$, and assume that for every $x \in \mathbb{R}^n$ there exists a solution $(X^1(x), Y^1(x), Z^1(x))$ on $[s,T]$ with boundary conditions x and ϕ such that the mapping $(\omega,\tau,x) \to (X^1_\tau(x,\omega), Y^1_\tau(x,\omega), Z^1_\tau(x,\omega))$ is measurable with respect to $\mathcal{P}_{[s,T]} \times \mathcal{B}(\mathbb{R}^n)$.*

Setting $V(x) = Y^1_s(x)$, $x \in \mathbb{R}^n$, assume that there exists a solution (X,Y,Z) on $[t,s]$ with boundary conditions ξ and V. Then defining, for $\tau \in (s,T]$,

$$X_\tau = X^1_\tau(X_s), \quad Y_\tau = Y^1_\tau(X_s), \quad Z_\tau = Z^1_\tau(X_s),$$

the process $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in [t,T]\}$ is a solution on $[t,T]$ with boundary conditions ξ and ϕ.

Proof. For $x \in \mathbb{R}^n$ and $\tau \in [s,T]$,

$$\begin{cases} X^1_\tau(x) = x + \displaystyle\int_t^\tau f_0(\sigma, X^1_\sigma(x), Z^1_\sigma(x))\, d\sigma + \int_t^\tau g(\sigma, X^1_\sigma(x))\, dW_\sigma, \\ Y^1_\tau(x) + \displaystyle\int_\tau^T Z^1_\sigma(x)\, dW_\sigma = \phi(X^1_T(x)) + \int_\tau^T l_0(\sigma, X^1_\sigma(x), Z^1_\sigma(x))\, d\sigma. \end{cases}$$

Since X_s is $\mathcal{F}_s$-measurable, we can replace x by X_s obtaining, for $\tau \in [s,T]$,

$$\begin{cases} X_\tau = X_s + \displaystyle\int_t^\tau f_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW_\sigma, \\ Y_\tau + \displaystyle\int_\tau^T Z_\sigma\, dW_\sigma = \phi(X_T) + \int_\tau^T l_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma. \end{cases} \tag{3.1}$$

By definition, for $\tau \in [t,s]$,

$$\begin{cases} X_\tau = \xi + \displaystyle\int_t^\tau f_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma + \int_t^\tau g(\sigma, X_\sigma)\, dW_\sigma, \\ Y_\tau + \displaystyle\int_\tau^s Z_\sigma\, dW_\sigma = V(X_s) + \int_\tau^s l_0(\sigma, X_\sigma, Z_\sigma)\, d\sigma, \end{cases} \tag{3.2}$$

so that, in particular, $Y_s = V(X_s)$. Now the required result follows easily from (3.1) and (3.2). □

We are now ready to state one of our main results.

THEOREM 3.4. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold. For every* $t \in [0,T]$ *and every* $\mathcal{F}_t$*-measurable* ξ *with* $\mathbb{E}|\xi|^2 < \infty$ *there exists a unique solution of the forward-backward system* (2.13) *on* $[t,T]$ *with boundary conditions* ξ *and* ϕ.

Proof. By Lemma 2.2 and our assumptions, there exists a constant L such that

$$|V(t,x) - V(t,x')| \le L|x - x'|, \tag{3.3}$$

and in particular $|\phi(x) - \phi(x')| \le L|x - x'|$ for every $t \in [0,T]$, $x, x' \in \mathbb{R}^n$. We choose δ as in Proposition 3.1.

Proof of existence. Step 1. If $t \ge T - \delta$, then by Proposition 3.1 the required solution exists.

In particular, for every $x \in \mathbb{R}^n$, the process $\{(X_\tau(T-\delta,x), Y_\tau(T-\delta,x), Z_\tau(T-\delta,x)),\ \tau \in [T-\delta,T]\}$, introduced above, is well defined. By Proposition 2.7, or by Remark 3.2, we have $Y_{T-\delta}(T-\delta,x) = V(T-\delta,x)$.

Step 2. Assume now that $T - 2\delta \le t < T - \delta$. We note that (3.3) holds for $t = T - \delta$ and consequently, by Proposition 3.1, there exists a solution (X,Y,Z) on $[t, T-\delta]$ with boundary conditions ξ and $V(T-\delta,\cdot)$. By Lemma 3.3, if we define, for $\tau \in (T-\delta, T]$,

$$X_\tau = X_\tau(T-\delta, X_{T-\delta}), \quad Y_\tau = Y_\tau(T-\delta, X_{T-\delta}), \quad Z_\tau = Z_\tau(T-\delta, X_{T-\delta}),$$

then the process $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in [t,T]\}$ is a solution on $[t,T]$ with boundary conditions ξ and ϕ.

In particular, choosing $t = T - 2\delta$ and $\xi = x \in \mathbb{R}^n$, the constructed solution is denoted $\{(X_\tau(T-2\delta,x), Y_\tau(T-2\delta,x), Z_\tau(T-2\delta,x)),\ \tau \in [T-2\delta,T]\}$, in agreement with the previous notation. By Proposition 2.7 or by Remark 3.2, we have $Y_{T-2\delta}(T-2\delta,x) = V(T-2\delta,x)$. □

Conclusion. If $T - 3\delta \le t < T - 2\delta$, we can repeat the above construction and, after a finite number of steps, we obtain the required solution for arbitrary $t \in [0,T]$.

Proof of uniqueness. If $t \ge T - \delta$, then the solution is unique by Proposition 3.1.

Assume now $T - 2\delta \le t < T - \delta$ and let (X,Y,Z) and (X',Y',Z') be solutions on $[t,T]$ with boundary conditions ξ and ϕ.

For every $x \in \mathbb{R}^n$, we consider again the process $\{(X_\tau(T-\delta,x), Y_\tau(T-\delta,x), Z_\tau(T-\delta,x)),\ \tau \in [T-\delta,T]\}$, introduced above, and we define, for $\tau \in [T-\delta,T]$,

$$\widetilde{X}_\tau = X_\tau(T-\delta, X_{T-\delta}), \quad \widetilde{Y}_\tau = Y_\tau(T-\delta, X_{T-\delta}), \quad \widetilde{Z}_\tau = Z_\tau(T-\delta, X_{T-\delta}).$$

It is easy to see that $(\widetilde{X}, \widetilde{Y}, \widetilde{Z})$ is a solution on $[T-\delta,T]$ with boundary conditions $X_{T-\delta}$ and ϕ. Since we have already proved uniqueness on the interval $[T-\delta,T]$, it follows that it is a modification of $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in [T-\delta,T]\}$, and, in particular, $Y_{T-\delta} = \widetilde{Y}_{T-\delta}$. Since by Proposition 2.7 we have $Y_{T-\delta}(T-\delta,x) = V(T-\delta,x)$, we conclude that $Y_{T-\delta} = V(T-\delta, X_{T-\delta})$. It follows easily that the process $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in$

$[t, T-\delta]\}$ is a solution on $[t, T-\delta]$ with boundary conditions ξ and $V(T-\delta, \cdot)$. Repeating this argument, we also conclude that the process $\{(X'_\tau, Y'_\tau, Z'_\tau),\ \tau \in [t, T-\delta]\}$ is also solution on $[t, T-\delta]$ with the same boundary conditions ξ and $V(T-\delta, \cdot)$. We note that (3.3) holds for $t = T-\delta$ and, consequently, by Proposition 3.1, the two solutions coincide on $[t, T-\delta]$. Since $\{(X_\tau, Y_\tau, Z_\tau),\ \tau \in [T-\delta, T]\}$ and $\{(X'_\tau, Y'_\tau, Z'_\tau),\ \tau \in [T-\delta, T]\}$ are clearly solutions on $[T-\delta, T]$ with the same boundary conditions $X_{T-\delta} = X'_{T-\delta}$ and ϕ, and since uniqueness holds on $[T-\delta, T]$, it follows that the two solutions also coincide on this interval and that uniqueness holds on $[t, T]$.

If $T - 3\delta \le t < T - 2\delta$, we can repeat the above argument and, after a finite number of steps, we obtain the required uniqueness property for arbitrary $t \in [0, T]$.

In the following, for every $(t, x) \in [0, T] \times \mathbb{R}^n$, we denote by $\{(X_\tau(t, x), Y_\tau(t, x), Z_\tau(t, x)),\ \tau \in [t, T]\}$ the (global) solution on $[t, T]$ with boundary conditions x and ϕ, constructed in Theorem 3.4. It follows from the construction that for fixed t, the mapping $(\omega, \tau, x) \to (X_\tau(t, x, \omega),\ Y_\tau(t, x, \omega),\ Z_\tau(t, x, \omega))$ is measurable with respect to $\mathcal{P}_{[t,T]} \times \mathcal{B}(\mathbb{R}^n)$.

Now we consider the implications of Theorem 3.4 on the existence of optimal controls. The following theorem is an immediate consequence of Theorem 3.4 and Proposition 2.7.

THEOREM 3.5. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold and, for every* $t \in [0, T]$ *and* $x \in \mathbb{R}^n$, *let us denote by* $\{(X_\tau(t, x), Y_\tau(t, x), Z_\tau(t, x)),\ \tau \in [t, T]\}$ *the solution of the forward-backward system* (2.13) *on* $[t, T]$ *with boundary conditions* x *and* ϕ. *Setting*

$$u^*_\tau = \gamma(\tau, X_\tau(t, x), Z_\tau(t, x)), \qquad \tau \in [t, T], \tag{3.4}$$

the process $u^*_\cdot$ *is then an optimal control for the control problem starting from* x *at time* t. *Denoting by* X^{u^*} *the corresponding solution, then,* $\mathbb{P}$*-a.s.,* $X^{u^*}_\tau = X_\tau(t, x)$ *for* $\tau \in [t, T]$. *Finally, the optimal cost* $V(t, x) = J(t, x, u^*_\cdot)$ *is equal to* $J^*(t, x)$ *and to* $Y_t(t, x)$.

We can now state a uniqueness result.

THEOREM 3.6. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold and suppose that, for any given* $t \in [0, T]$, $x \in \mathbb{R}^n$, $z \in \mathbb{R}^d$, *the infimum in* (2.2) *is attained at a unique point.*

Then, for any $x \in \mathbb{R}^n$ *and* $t \in [0, T]$, *there exists a unique optimal control, up to modification.*

Proof. Let $u_\cdot$ be an optimal control for the control system starting from x at time t. By Theorem 3.5 the optimal cost is $J^*(t, x) = J(t, x, u_\cdot)$ and therefore, by Corollary 2.6, we have, $\mathbb{P}$-a.s.,

$$u_\tau = \gamma(\tau, X^u_\tau, Z^u_\tau) \qquad \text{for a.e. } \tau \in [t, T],$$

where X^u is the solution of (1.1) corresponding to $u_\cdot$, and (Y^u, Z^u) denotes the solution of (2.8). Corollary 2.6 also states that (X^u, Y^u, Z^u) satisfies the systems (2.12), and consequently (X^u, Y^u, Z^u) is a solution of the forward-backward system (2.13) on $[t, T]$ with boundary conditions x and ϕ. By uniqueness it must coincide with $\{(X_\tau(t, x), Y_\tau(t, x),\ Z_\tau(t, x)),\ \tau \in [t, T]\}$. Thus

$$u_\tau = \gamma(\tau, X_\tau(t, x), Z_\tau(t, x)), \qquad \mathbb{P}\text{-a.s., for a.e. } \tau \in [t, T],$$

and therefore $u_\cdot$ is a modification of the optimal control $u^*_\cdot$ introduced in Theorem 3.5. ∎

Remark 3.7. It follows from Lemma 3.3 and from uniqueness of the forward-backward system (2.13) that for $x \in \mathbb{R}^n$ and $0 \le t \le s \le \tau \le T$ we have, $\mathbb{P}$-a.s.,

$$Y_\tau(t,x) = Y_\tau(s, X_s(t,x)). \tag{3.5}$$

Letting u^* be defined as in (3.4) and recalling that $X_\tau^{u^*} = X_\tau(t,x)$ the second equation in (2.13) gives

$$\mathbb{E}Y_\tau(t,x) = Y_t(t,x) - \mathbb{E}\int_t^\tau l(\sigma, X_\sigma^{u^*}, u_\sigma^*)d\sigma.$$

By Proposition 2.7 we have $Y_\tau(\tau,x) = V(\tau,x)$ and setting $s=\tau$ in (3.5) we obtain

$$V(t,x) = \mathbb{E}\left[V(\tau, X_\tau^{u^*}) + \int_t^\tau l(\sigma, X_\sigma^{u^*}, u_\sigma^*)d\sigma\right].$$

By standard techniques (see [7] or [23]) we have that for an arbitrary admissible control u

$$V(t,x) \le \mathbb{E}\left[V(\tau, X_\tau^u) + \int_t^\tau l(\sigma, X_\sigma^u, u_\sigma)d\sigma\right].$$

So we immediately obtain the usual dynamic programming principle:

$$\begin{aligned} V(t,x) &= \min_u \mathbb{E}\left[V(\tau, X_\tau^u) + \int_t^\tau l(\sigma, X_\sigma^u, u_\sigma)d\sigma\right] \\ &= \mathbb{E}\left[V(\tau, X_\tau^{u^*}) + \int_t^\tau l(\sigma, X_\sigma^{u^*}, u_\sigma)d\sigma\right], \end{aligned}$$

where the minimum is over all admissible controls.

4. The feedback law and the closed-loop equation. Throughout this section, Hypotheses 2.1 and 2.4 are still in force.

The following lemma introduces a function ζ which will enter the definition of the optimal feedback law. In its formulation we refer to the process $\{(\widetilde{X}_\tau(t,x), \widetilde{Y}_\tau(t,x), \widetilde{Z}_\tau(t,x)),\ \tau \in [t,T]\}$, solution of (2.4)–(2.5) for given $t \in [0,T]$ and $x \in \mathbb{R}^n$.

LEMMA 4.1. *There exists a Borel measurable function $\zeta : [0,T] \times \mathbb{R}^n \to \mathbb{R}^d$ such that, for every $t \in [0,T]$, $x \in \mathbb{R}^n$, $\mathbb{P}$-a.s.,*

$$\zeta(\tau, \widetilde{X}_\tau(t,x)) = \widetilde{Z}_\tau(t,x) \qquad \text{for a.e. } \tau \in [t,T].$$

ζ depends only on the functions f, g, ϕ, ψ (not on the particular probability space $(\widetilde{\Omega}, \widetilde{\mathcal{F}}, \widetilde{\mathbb{P}})$ nor on the Wiener process $\widetilde{W}$).

Proof. This is a kind of result which is familiar in the theory of backward stochastic differential equations (see, e.g., [2, Theorem 28]) so we will only sketch the proof. We first note that, as a consequence of uniqueness for the system (2.4)–(2.5), for $x \in \mathbb{R}^n$ and $0 \le t \le s \le \tau \le T$ we have, $\mathbb{P}$-a.s.,

$$\widetilde{X}_\tau(t,x) = \widetilde{X}_\tau(s, \widetilde{X}_s(t,x)), \qquad \widetilde{Y}_\tau(t,x) = \widetilde{Y}_\tau(s, \widetilde{X}_s(t,x)). \tag{4.1}$$

In particular, the family $\widetilde{X} = \{\widetilde{X}_\tau(t,x),\ 0 \le t \le \tau \le T,\ x \in \mathbb{R}^n\}$ is a Markov process. Let us denote by $\widetilde{W}^i$ and $\widetilde{Z}^i$ the ith components of $\widetilde{W}$ and $\widetilde{Z}$. For $0 \le t \le T$ and $x \in \mathbb{R}^n$ we denote by $\{A^i(\tau,t,x), \tau \in [t,T]\}$ the joint quadratic variation process

between $\{\widetilde{Y}_\tau(t,x), \tau \in [t,T]\}$ and $\{\widetilde{W}^i_\tau, \tau \in [t,T]\}$. It follows from the backward equation in the system (2.13) that

$$A^i(\tau,t,x) = \int_t^\tau \widetilde{Z}^i_s(t,x)\, ds,$$

which implies in particular that $A^i(\cdot,t,x)$ is absolutely continuous with respect to the Lebesgue measure. Next we note the following equality, which is a consequence of the definition of A^i and (4.1): for $x \in \mathbb{R}^n$ and $0 \le t \le s \le \tau \le T$ we have, $\mathbb{P}$-a.s.,

$$A^i(\tau,t,x) = A^i(s,t,x) + A^i(\tau,s,X_s(t,x)).$$

If $\widetilde{X}$ is a Markov process homogeneous in time, then the above relation means that A^i is an additive functional of $\widetilde{X}$, absolutely continuous with respect to the Lebesgue measure, and the existence of ζ is classical (see, e.g., Theorem 66.2 in [22]). In the general case the proof is similar. □

COROLLARY 4.2. *Let $\{(X_\tau(t,x), Y_\tau(t,x), Z_\tau(t,x)), \tau \in [t,T]\}$ denote the solution of the forward-backward system* (2.13) *on $[t,T]$ with boundary conditions x and ϕ. Then, $\mathbb{P}$-a.s.,*

$$\zeta(\tau, X_\tau(t,x)) = Z_\tau(t,x) \qquad \text{for a.e. } \tau \in [t,T].$$

Proof. During the proof of Proposition 2.7 we showed that (X,Y,Z) solves (2.7)–(2.8), which coincides with (2.4)–(2.5) (with different, suitable probability measure and Wiener process). The claim then follows from Lemma 4.1. □

We define a Borel measurable function $\underline{u} : [0,T] \times \mathbb{R}^n \to \mathcal{U}$ setting

$$\underline{u}(t,x) = \gamma(t,x,\zeta(t,x)), \qquad t \in [0,T],\ x \in \mathbb{R}^n,$$

and, for $t \in [0,T]$ and $x \in \mathbb{R}^n$, we introduce the so-called *closed-loop* equation:

$$\begin{aligned} \overline{X}_\tau = \ & x + \int_t^\tau f(\sigma, \overline{X}_\sigma)\, d\sigma + \int_t^\tau g(\sigma, \overline{X}_\sigma) r(\sigma, \overline{X}_\sigma, \underline{u}(\sigma, \overline{X}_\sigma))\, d\sigma \\ & + \int_t^\tau g(\sigma, \overline{X}_\sigma)\, dW_\sigma, \qquad \tau \in [t,T]. \end{aligned} \tag{4.2}$$

Since r is bounded, it is meaningful to look for a continuous $(\mathcal{F}_t)$-adapted solution of this equation. However, it is difficult to prove directly any existence or uniqueness result for (4.2) in its strong form, since regularity properties of ζ, and hence of $\underline{u}$, are not immediate. Nevertheless, we have the following result.

THEOREM 4.3. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold. For every $t \in [0,T]$ and $x \in \mathbb{R}^n$, let $u^*_\cdot$ be the optimal control introduced in* (3.4). *Then $u^*_\cdot$ is related to the corresponding solution X^{u^*} by the* feedback relation

$$u^*_\tau = \underline{u}(\tau, X^{u^*}_\tau), \qquad \mathbb{P}\text{-a.s. for a.e. } \tau \in [t,T].$$

In particular, X^{u^*} solves the closed-loop equation.

Proof. We have, $\mathbb{P}$-a.s., for almost every $\tau \in [t,T]$,

$$u^*_\tau = \gamma(\tau, X_\tau(t,x), Z_\tau(t,x)) = \gamma(\tau, X_\tau(t,x), \zeta(\tau, X_\tau(t,x))) = \underline{u}(\tau, X_\tau(t,x)).$$

Indeed, the first and third equalities follow from the definition of $u^*_\cdot$ and $\underline{u}$, and the second equality follows from Corollary 4.2. Since Theorem 3.5 states that $\{X_\tau(t,x),\ \tau \in [t,T]\}$ coincides with X^{u^*}, the result follows immediately. □

THEOREM 4.4. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold. For given* $t \in [0,T]$ *and* $x \in \mathbb{R}^n$*, assume that there exists a continuous,* $(\mathcal{F}_t)$*-adapted solution* $\overline{X}$ *of the closed-loop equation. Then the process defined by*

$$\overline{u}_\tau = \underline{u}(\tau, \overline{X}_\tau), \qquad \tau \in [t,T], \tag{4.3}$$

is an optimal control, and $\overline{X}$ *is the solution corresponding to* $\overline{u}_\cdot$*.*

Proof. Let $\overline{u}$ be given by (4.3) and let $X^{\overline{u}}$, $W^{\overline{u}}$, $Y^{\overline{u}}$, $Z^{\overline{u}}$ be defined as in (1.1), (2.6), (2.7)–(2.8), respectively. Then by definition $X^{\overline{u}}_\tau = \overline{X}_\tau$. Moreover, by Lemma 4.1, $Z^{\overline{u}}_\tau = \zeta(\tau, \overline{X}_\tau)$ for almost every $\tau \in [t,T]$. Joining the above relations with the definition of the map $\underline{u}$, we get $\overline{u}_\tau = \gamma(\tau, X^{\overline{u}}_\tau, Z^{\overline{u}}_\tau)$ and the claim follows by Corollary 2.6. □

THEOREM 4.5. *Assume that the Hypotheses* 2.1 *and* 2.4 *hold and suppose that, for any given* $t \in [0,T]$*,* $x \in \mathbb{R}^n$*,* $z \in \mathbb{R}^d$*, the infimum in* (2.2) *is attained at a unique point.*

Then, for every $t \in [0,T]$ *and* $x \in \mathbb{R}^n$*, there exists a unique continuous* $(\mathcal{F}_t)$*-adapted solution* $\overline{X}$ *of the closed-loop equation* (4.2)*. The process defined by*

$$\overline{u}_\tau = \underline{u}(\tau, \overline{X}_\tau), \qquad \tau \in [t,T],$$

is the unique optimal control and $\overline{X}$ *is the solution corresponding to* $\overline{u}_\cdot$*.*

Proof. Assume that $\overline{X}$ is a solution of the closed-loop equation. Then, by Theorem 4.4, the control $\overline{u}_\cdot$ is optimal, and $\overline{X} = X^{\overline{u}}$ is the solution of (1.1) corresponding to $\overline{u}_\cdot$. Since, by Theorem 3.6, under our assumptions the optimal control is unique, $\overline{u}_\cdot$ must coincide with the (optimal) control $u^*_\cdot$ introduced in (3.4), and consequently $\overline{X}$ must coincide with X^{u^*}.

The existence of a solution of the closed-loop equation follows from Theorem 4.3. □

NONSQUARE SPECTRAL FACTORS OF NONLINEAR CONTROL SYSTEMS IN TERMS OF INNER-INNER FACTORIZATIONS*

MARK A. PETERSEN†

Abstract. This paper considers nonsquare spectral factors of nonlinear input affine state space control systems in continuous time. More specifically, we obtain a parametrization of nonsquare spectral factors in terms of a special class of inner-inner factorizations. Explicit formulas for different classes of spectral factors and related inner systems in terms of solutions of Hamilton–Jacobi equations are provided. Furthermore, the important notion of a minimal inner embedding for nonlinear control systems is introduced and used to derive several relationships between inner systems.

Key words. spectral factorization, nonlinear control systems, inner systems

AMS subject classifications. Primary, 47A68, 93C10; Secondary, 34A34

DOI. 10.1137/S0363012902409568

1. Introduction and preliminaries. The problem of finding spectral factors for nonlinear control systems has attracted some recent attention (see [1, 2, 3, 4, 5, 6, 14, 20, 27, 32]). Our main aim in this paper is to treat the (nonsquare) spectral factorization problem for nonlinear control systems that are one-sided invertible. In particular, we establish a parametrization of nonsquare minimal spectral factors that are stable in terms of a special class of inner-inner factorizations of inner systems (see [3, 20, 27, 32] for the nonlinear case, see [11, 12, 13, 21, 22] for the linear case).

Our motivation for understanding the spectral factorization problem referred to above is that it has important applications in systems and control theory. For instance, several important connections with the control of mechanical systems that may not be invertible have been identified (see [17] and [32]). In this regard, it is important to note that our paper discusses classes of nonlinear control systems that are one-sided invertible. Furthermore, spectral factorization of nonlinear control systems plays an important part in H_∞-control (see [5]) and chemical process control (see [10] and [35]). Also, in economics, the understanding of realizations of financial models with multidimensional state spaces can be simplified by considering the dynamics of financial systems of reduced state space dimension and certain disturbance errors (see [24] and [28]). In the above, we recall that spectral factorization is related to inner-outer factorization (as will be demonstrated below) with the inner factor often sharing asymptotic behavior with the system that is being factored. In many cases, the inner factor may have more favorable properties and its control may form a basis for the control of the system being factored. Another reason for considering the spectral factorization problem for nonlinear control systems is its relation with stochastic control via stochastic realization theory, although this connection may currently not be as apparent as for the linear case. In the problem of linear stochastic realization, any minimal factor W of the spectral density Δ determines a minimal realization for the output process y. If Δ is of size $m \times m$ and W is of size $m \times p$, then the number p actually determines the space in which the driving white noise process is taken. Usually, if one chooses W to be square, this space is also taken to be as small as possible.

However, the stochastic realization problem does not actually require this, and hence nonsquare minimal spectral factors of Δ are of interest. A further practical reason for understanding the nonsquare spectral factorization problem is multichannel signal transmission. For instance, a situation that arises in the mobile phone industry is that a mobile phone has to decode signals that reach it from surrounding transmitters that themselves have to retain the capacity to emit signals destined for other phones.

Next, we make clear the additional value of the current paper when compared with recent research on the subject of spectral factorization of nonlinear control systems. In the first instance, this paper extends results obtained for nonlinear, minimal, square, stable spectral factors by Ball and Petersen in [3] and Ball and van der Schaft in [6] to the nonsquare case. In [3] we obtained a natural extension of the idea of an equivalence between minimal square spectral factors of a given spectral density, invariant subspaces of an associated Hamiltonian matrix, solutions of an appropriate algebraic Riccati equation, and minimal unitary left divisors of a certain unitary function on the imaginary line to a nonlinear setting. More specifically, we established a bijective correspondence between nonlinear, minimal, square, stable spectral factors, invariant Lagrangian submanifolds, solutions of Hamilton–Jacobi equations, and minimal right inner divisors. The scheme in the current paper is more complicated since it treats the situation where the nonlinear, minimal, stable spectral factors may be nonsquare. In contrast to [3], the work in this paper entails studying a slightly different type of Hamilton–Jacobi equation and a parametrization of the spectral factors in terms of a finer inner-inner factorization that, in addition, involves coprime factors. [6] is different from our paper in that the other work establishes a relationship between the inner-outer and spectral factorization problems and makes no attempt to discuss their connection with inner-inner factorizations. In the aforementioned contribution by Ball and van der Schaft, a nonlinear state space system is expressed as the cascade connection of an inner (lossless) system and a stable minimum phase (outer) system that is found to be a solution of an associated nonlinear spectral factorization problem. To the best of our knowledge, the first attempt to understand nonlinear, nonsquare, stable, spectral factors was made in [25] and the related conference paper [26]. In these contributions we obtain a parametrization of nonsquare spectral factors in terms of an invariant Lagrangian submanifold and associated solutions of a Hamilton–Jacobi inequality that is a nonlinear analogue of the bounded real lemma and the control algebraic Riccati inequality. By way of an application, we discussed an alternative characterization of minimum and maximum phase spectral factors and introduced the notion of a rigid nonlinear system. Our current paper makes use of some of this information to establish an equivalence between nonsquare spectral factors and coprime inner-inner factorizations. It is important to note that in the present paper we make use of a more general nonsquare spectral factor and associated Hamilton–Jacobi equation than in [25]. This is done in order to derive explicit formulas for the spectral factors comparable to those that are determined in the linear case. Moreover, the results established in this paper may be regarded as natural nonlinear analogues of those obtained in [11, 12, 13, 16, 21, 22, 23]. In particular, the explicit formulas for the spectral factors derived here bear a resemblance to those in [13] and [22], where the formulas are written in terms of solutions of algebraic Riccati equations.

We provide a brief description of the class of nonlinear control systems that we study. We consider a smooth nonlinear input-affine system

$$\Sigma\colon \begin{cases} \dot{x} = a(x) + b(x)u, & u \in \mathbf{R}^{\mathbf{m}}, \\ y = c(x) + d(x)u, & y \in \mathbf{R}^{\mathbf{p}}, \end{cases} \tag{1}$$

where $a : \mathbf{R^n} \to \mathbf{R^n}, b : \mathbf{R^n} \to \mathbf{R^{n\times m}}, c : \mathbf{R^n} \to \mathbf{R^p}$, and $d : \mathbf{R^n} \to \mathbf{R^{p\times m}}$ are smooth functions. The fact that Σ is assumed to be input affine will result in explicit formulas that resemble those obtained in the linear case. We suppose that $p \geq m$ and that $d(x)$ and $d(x)^T$ are injective for all $x = (x_1, \ldots, x_n) \in \mathbf{R^n}$ that are local coordinates for the n-dimensional state space manifold $\mathcal{X}$, with globally asymptotically stable equilibrium $x_0 = 0$ for $u = 0$ (so $a(x_0) = 0$ and $c(x_0) = 0$). In this case, we have that

$$F(x) := d(x)d(x)^T \tag{2}$$

is invertible for each x. We suppose that $x \to a(x) + b(x)u$ is *complete* for each $u \in \mathbf{R^m}$. This means that there exists a unique solution of $\dot{x} = a(x) + b(x)u$ for all $t > 0$ for any initial condition $x(0) = x_1 \in \mathcal{X}$. Hence, given any initial condition $x_1 \in \mathcal{X}$, the system of equations (1) induces a well-defined causal input-output map $T_\Sigma^{x_1}$, from piecewise constant input signals $u(t)$ defined on the nonnegative real line $\mathbf{R}^+$ to smooth output functions $y(t)$ defined for all $t \geq 0$. Operators $T_\Sigma^{x_1}$ arising in this way from a system of equations (1) are automatically *causal*, i.e., $T_\Sigma^{x_1}[u](t) = T_\Sigma^{x_1}[u'](t)$ for $t \leq T$ whenever $u(t) = u'(t)$ for $t \leq T$. We assume that $T_\Sigma^{x_1}$ extends by continuity to define a well-defined map on $L^m_{2,e}[0,\infty)$ (the space of measurable $\mathbf{R^m}$-valued functions $u(\cdot)$ on $[0,\infty)$ such that $\int_0^T \|u(t)\|^2 dt < \infty$ for all $T < \infty$). We consider only systems Σ that are *stable*. In other words, at the systems level, the vector field $x \to a(x)$ is globally asymptotically stable while $T_\Sigma^{x_1}$ is a diffeomorphism of $L_2^m[0,\infty)$ for each $x_1 \in \mathcal{X}$ at the input-output level. We call the system of equations (1) a (state space) *realization* of the input-output operator $T_\Sigma\colon L^m_{2,e}[0,\infty) \to L^p_{2,e}[0,\infty)$. If the dimension n of the state manifold $\mathcal{X}$ is as small as possible among all possible state space realizations of the given input-output operator $T_\Sigma^{x_1}$, we say that the realization Σ is *minimal*. Minimality with regard to realization and factorization plays a indispensable part at various levels in the ensuing discussion. Although the existence of realizations of input-output maps is important, the uniqueness of such realizations may also be required. We know that the uniqueness of any realization of a given input-output map is not always guaranteed. However, if we consider the minimal case, uniqueness of the realizations may become a definite possibility (see, for instance, Propositions 1 and 4). In addition, the major objective of our paper is to characterize *minimal*, stable, spectral factors and provide explicit formulas for them. Here, the assumption that the realizations for most of the nonlinear systems are *minimal* makes computations much easier. Furthermore, our handling of *minimal* inner-inner factorization throughout this paper is informed by the contributions made in [7, 8] and [14], where *minimal*, cascade factorization of nonlinear systems is discussed.

Next, we consider two types of extensions of Σ given by (1) that play a part in the analysis in what follows. We recall for Σ, where $a : \mathbf{R^n} \to \mathbf{R^n}$, $b : \mathbf{R^n} \to \mathbf{R^{n\times m}}$, $c : \mathbf{R^n} \to \mathbf{R^p}$, and $d : \mathbf{R^n} \to \mathbf{R^{p\times m}}$, that if $m < p$, then Σ is a nonsquare nonlinear system, and if $m = p$, then Σ is square. Thus, a requirement for Σ to be square is that m should be increased in order to equal p. This can be accomplished by introducing the concept of a *zero extension*. We say that Σ^e is a zero extension of Σ if it is the square system that is obtained from a (possibly) nonsquare Σ by augmenting b and d with an appropriate null function so that $m = p$. Of course, this notion can also be extended to the input-output map $T_\Sigma\colon L^m_{2,e}[0,\infty) \longmapsto L^p_{2,e}[0,\infty)$ introduced earlier, where for the zero extension we require that $m = p$. The *Hamiltonian extension* of Σ (where Σ is given as in (1)) has the form

$$
(3)\qquad \begin{cases} \dot{x} = a(x) + b(x)u, \\ \dot{p} = -\left[\dfrac{\partial a}{\partial x}(x) + \dfrac{\partial b}{\partial x}(x)u\right]^T p \\ \qquad\quad -\left[\dfrac{\partial c}{\partial x}(x) + \dfrac{\partial d}{\partial x}(x)u\right]^T u_a, \\ y = c(x) + d(x)u, \\ y_a = b^T(x)p + d^T(x)u_a \end{cases}
$$

(see [9]), where $u, y_a \in \mathbf{R^m}$ and $u_a \in \mathbf{R^p}$. This system has state space equal to the *cotangent bundle* of the state space manifold $\mathcal{X}$, denoted by $T^*\mathcal{X}$, with *natural* local coordinates $(x,p) = (x_1,\dots,x_n,\ p_1,\dots,p_n)$, inputs equal to (u,u_a), and outputs equal to (y,y_a). If we impose the interconnection law $u_a = y$ in (3), we get the Hamiltonian system of the form

$$
(4)\qquad \Phi = [D\Sigma]^T \circ \Sigma : \begin{cases} \dot{x} = \dfrac{\partial H}{\partial p}(x,p,u), \\ \dot{p} = -\dfrac{\partial H}{\partial x}(x,p,u), \\ y_a = \dfrac{\partial H}{\partial u}(x,p,u), \end{cases}
$$

with the Hamiltonian function $H(x,p,u)$ given by

$$
H(x,p,u) = p^T[a(x) + b(x)u] + \frac{1}{2}[c(x) + d(x)u]^T[c(x) + d(x)u].
$$

Here the state space is $T^*\mathcal{X}$, the inputs $u \in \mathbf{R^m}$, and the outputs $y_a \in \mathbf{R^m}$. We introduce the notion of the Hamiltonian extension of a nonlinear system in (3) to transform the (all-pass) inner-outer factorization problem into a nonlinear spectral factorization problem (see [32] for more details). In this regard, the Σ appearing in (4) is known as a *spectral factor* of Φ. In this paper we discuss a large variety of spectral factors that, for instance, may be minimal, stable, antistable, minimum phase, or maximum phase. Furthermore, Φ in (4) is *weakly coercive* if the spectral factor Σ is at least one-sided invertible. More specifically, in what follows, we consider right-sided inverses of various nonlinear spectral factors.

The main achievements of the analysis in this paper are listed below.

1. In Theorem 3 of section 3 we suggest a method of extending column- and row-rigid systems to inner systems.
2. We derive essentially unique factorizations that involve zero-extended stable and antistable, minimum and maximum phase spectral factors (Proposition 4, section 4). We recall that the term *essentially unique factorization* refers to the situation where uniqueness pertains to the underlying factorization structure only, with any variation in the form not affecting the mathematical meaning.
3. A necessary and sufficient condition for the existence of a minimal stable spectral factor is established in Theorem 6 of section 4.

4. We deduce certain factorization and coprimeness properties for inner systems (Theorem 7, section 4) that play a pivotal role in the rest of the paper. This result is dependent on the internal-external and external-internal factorizations introduced in Definition 5 of section 4.
5. We find necessary and sufficient conditions for the existence of an internal spectral factor in terms of an inner extension whose formula is given explicitly (Proposition 9, section 4). In order to accomplish this we introduce internal and external spectral factors in Definition 8 of section 4.
6. In Definition 12 we introduce the notion of a coprime inner-inner factorization. In addition, we prove the existence of such a factorization in Proposition 13.
7. We verify that a bijective correspondence exists between minimal, external, decomposable, nonsquare spectral factors and coprime inner-inner factorizations (Theorem 14, section 4).
8. Finally, in Theorem 15 of section 4, we make use of the preceding analysis to parametrize minimal, decomposable, nonsquare spectral factors in terms of coprime inner-inner factorizations.

Although many of the concepts mentioned in this list have not yet been defined, a comment on notation is in order. Throughout the paper, Σ denotes a general (square or nonsquare) nonlinear system that may be a spectral factor. On the other hand, R is a nonsquare spectral factor that is the starting point for our analysis in the sense that subsequent explicit formulas for various types of spectral factors and inner systems are written in terms of its components and associated Hamilton–Jacobi equation. We denote the minimal, stable, minimum and maximum phase spectral factors by Σ_- and Σ_+, respectively, while Σ_-^e (resp., Σ_+^e) is the notation used to denote a zero extension of Σ_- (resp., Σ_+). Minimal, antistable, minimum and maximum phase spectral factors are denoted by $\overline{\Sigma}_-$ and $\overline{\Sigma}_+$, respectively. Θ_c and Θ_r is the notation used for column-rigid and row-rigid systems, respectively. S denotes a minimal, stable spectral factor that may be decomposable. Φ is the symbol used to denote the nonlinear system that undergoes spectral factorization of the type given in (4). Various types of inner systems are introduced in what follows and are denoted by a Θ in combination with tildes, overlines, and sub- and superscripts.

The rest of the paper is arranged in the following manner. Section 2 provides a cursory exposition on minimum and maximum phase spectral factors. The third section considers various issues related to nonlinear inner systems. Section 4 contains the main results of the paper on the parametrization of minimal stable nonsquare spectral factors in terms of coprime inner-inner factorizations. An illustrative example is given in the fifth section, while we make conclusive remarks and comments on possible future research in section 6.

2. Minimum and maximum phase spectral factors. In this section, we consider a special class of spectral factors, namely, those that are maximum and minimum phase. In particular, we consider their connection with column- and row-rigid systems. Our starting point is the nonsquare, stable nonlinear system R of the form

$$R\colon \begin{cases} \dot{x} = a(x) + b(x)u, \\ y = \begin{pmatrix} c_1(x) \\ c_2(x) \end{pmatrix} + \begin{pmatrix} d(x) \\ 0 \end{pmatrix} u, \end{cases} \tag{5}$$

which provides a spectral factorization $\Phi = [D\Sigma]^T \circ \Sigma = [DR]^T \circ R$ for Φ. From [25] we know that there is a bijective correspondence between R in (5) and the set of triples

$(\mathcal{X}, P, c_2)$. Here, $\mathcal{X}$ is an invariant Lagrangian submanifold, P is a smooth solution of the Hamilton–Jacobi inequality

$$-P_x(x)[a(x) - b(x)d^T(x)F^{-1}(x)c(x)] + P_x(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TP_x(x)^T$$
$$-P_x(x)a(x) + c(x)^TF^{-1}(x)d(x)b(x)^TP_x(x)^T \leq 0,$$

$c_1(x) = c(x) + F^{-1}(x)d(x)b(x)^TP_x(x)^T$, and c_2 satisfies the equation

(6)
$$-P_x(x)[a(x) - b(x)d^T(x)F^{-1}(x)c(x)] + P_x(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TP_x(x)^T$$
$$-P_x(x)a(x) + c(x)^TF^{-1}(x)d(x)b(x)^TP_x(x)^T + c_2(x)^Tc_2(x) = 0.$$

Moreover, if P is any solution of (6), then there exists a map X such that

$$c_2(x) = -X_x(x)^TP_x(x)^T. \tag{7}$$

Next, we discuss *minimum* and *maximum phase* nonlinear systems that may be given explicitly in terms of R in (5) and its associated Hamilton–Jacobi equation (6). We recall that the *output nulling (or zero) dynamics* of a nonlinear system is the set of all system trajectories $x(\cdot)$ generated by some input trajectory $u(\cdot)$ such that $y(\cdot)$ is identically zero. Under some regularity conditions and the assumption that an appropriate function f exists, the zero dynamics can be computed as

$$\dot{x} = f(x, u), \quad x \in \mathcal{N}^* \subset \mathcal{X}. \tag{8}$$

Under additional conditions, it will actually be a system without inputs:

$$\dot{x} = f(x), \quad x \in \mathcal{N}^* \subset \mathcal{X}.$$

In this case the system is minimum phase if $f(x)$ is asymptotically stable and maximum phase if $f(x)$ is antistable. For (8) we define the system to be minimum phase if there exists $u = \alpha(x)$ such that the system is stable and maximum phase if there exists $u = \alpha(x)$ such that the system is antistable.

Column- and row-rigidness was introduced in [25] (see also [20] and [27]) and forms an integral part of the analysis in what follows. In what follows, we shall denote by Θ_c a column-rigid system and by Θ_r a row-rigid system. Moreover, we consider the Hamiltonian system $[D\Theta_c]^T \circ \Theta_c$ (Hamiltonian extension with $u_a = y$) with Hamiltonian

$$H(x, p, u) = p^T[a(x) + b(x)u] + \frac{1}{2}[c(x) + u]^T[c(x) + u].$$

We investigate the observability function P^o (see [29] for more details) defined as the solution of

$$P_x^o(x)a(x) + \frac{1}{2}c(x)^Tc(x) = 0$$

and define new coordinates $\overline{p} = p - P_x^o(x)$. It follows that

$$H(x, \overline{p}, u) = \overline{p}^T[a(x) + b(x)u] + u^T[b(x)^TP_x^o(x)^T + c(x)] + \frac{1}{2}u^Tu.$$

In addition, if P^o satisfies $P_x^o(x)b(x) + c(x)^T = 0$, then the submanifold $\overline{p}$ is an invariant manifold, with $[D\Theta_c]^T \circ \Theta_c$ restricted to this manifold being given by the static

input-output identity map $u \longmapsto y_a = u$. Here, the system Θ_c is said to be *column-rigid*. For the related concept of *row-rigidness*, we investigate the Hamiltonian system $[D\Theta_r] \circ \Theta_r^T$ (Hamiltonian extension with $u = y_a$) with Hamiltonian

$$H(x, p, u_a) = p^T a(x) + \frac{1}{2} p^T b(x) b(x)^T p + p^T b(x) u_a + c(x)^T u_a + \frac{1}{2} u_a^T u_a.$$

Consider the controllability function P^c (see [29] for more details) defined as the solution of

$$P_x^c(x) a(x) + \frac{1}{2} P_x^c(x) b(x) b(x)^T P_x^c(x)^T = 0,$$

where P^c is the solution such that $a(x) + b(x) b(x)^T P_x^c(x)^T$ is antistable. Furthermore, define canonical coordinates $\overline{p} = p - P_x^c(x)$. Here we have

$$\begin{aligned} H(x, \overline{p}, u_a) = {} & \overline{p}^T a(x) + \frac{1}{2} \overline{p}^T b(x) b(x)^T \overline{p} + P_x^c(x)^T [b(x) b(x)^T \overline{p} - b(x) u_a] \\ & + c(x)^T u_a + \frac{1}{2} u_a^T u_a. \end{aligned}$$

For the situation where P^c satisfies $P_x^c(x) b(x) + c(x)^T = 0$, the submanifold $\overline{p}$ is invariant, and the system $[D\Theta_r] \circ \Theta_r^T$ restricted to this manifold is given by the static input-output identity map $u_a \longmapsto y = u_a$. In this case, the system Θ_r is *row-rigid*.

In the following proposition, we collect facts that are pertinent to our investigation from the series of papers [20, 25] and [27] involving minimum and maximum phase spectral factors and their connection with row- and column-rigid systems.

PROPOSITION 1. *Suppose that weakly coercive* $\Phi = [D\Sigma]^T \circ \Sigma = [DR]^T \circ R$ *as in* (4), *with* Σ *and* R *given by* (1) *and* (5), *respectively. A minimal realization of the stable, minimum phase (outer) spectral factor* Σ_- *is given by*

$$\Sigma_- : \begin{cases} \dot{x} = a(x) + b(x) u, \\ y = c_1(x) + F^{-1}(x) d(x) b(x)^T P_x^-(x)^T + d(x) u, \end{cases} \tag{9}$$

where F *is given by* (2) *and* P^- *is the smooth solution of the Hamilton–Jacobi equation*

$$\begin{aligned} & P_x^-(x)[a(x) - b(x) d(x)^T F^{-1}(x) c_1(x)] \\ & \quad - \frac{1}{2} P_x^-(x) b(x) d(x)^T (F^{-1}(x))^2 d(x) b(x)^T P_x^-(x)^T + \frac{1}{2} c_2(x)^T c_2(x) = 0, \end{aligned} \tag{10}$$

with $P^-(0) = 0$ *and where the stability side condition*

$$a(x) - b(x) d^T(x) F^{-1}(x) c_1(x) \tag{11}$$

is Lyapunov stable. A minimal realization of the stable, maximum phase spectral factor Σ_+ *is given by*

$$\Sigma_+ : \begin{cases} \dot{x} = a(x) + b(x) u, \\ y = c_1(x) + F^{-1}(x) d(x) b(x)^T P_x^+(x)^T + d(x) u, \end{cases} \tag{12}$$

where F *is given by* (2) *and* P^+ *is the smooth solution of the Hamilton–Jacobi equation*

$$\begin{aligned} & P_x^+(x)[a(x) - b(x) d(x)^T F^{-1}(x) c_1(x)] \\ & \quad - \frac{1}{2} P_x^+(x) b(x) d(x)^T (F^{-1}(x))^2 d(x) b(x)^T P_x^+(x)^T + \frac{1}{2} c_2(x)^T c_2(x) = 0, \end{aligned} \tag{13}$$

with $P^+(0) = 0$ *and where the antistability side condition*

$$a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \tag{14}$$

is antistable. Minimal realizations for the right inverses of Σ_- *and* Σ_+ *are*

$$\Sigma_-^{-R}\colon \begin{cases} \dot{x} = a(x) - b(x)d(x)^T F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + b(x)d(x)^T F^{-1}(x)y, \\ u = -d(x)^T F^{-1}(x)c_1(x) \\ \qquad - d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + d(x)^T F^{-1}(x)y \end{cases} \tag{15}$$

and

$$\Sigma_+^{-R}\colon \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^+(x)^T \\ \qquad + b(x)d^T(x)F^{-1}(x)y, \\ u = -d^T(x)F^{-1}(x)c_1(x) \\ \qquad - d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^+(x)^T \\ \qquad + d(x)^T F^{-1}(x)y, \end{cases}$$

respectively. If Σ_- *is the stable, minimum phase* (*outer*) *spectral factor of* Φ *given by* (9)*, then there exists an essentially unique minimal column-rigid system* Θ_c *for which*

$$R = \Theta_c \circ \Sigma_-, \tag{16}$$

with

$$\Theta_c\colon \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + b(x)d^T(x)F^{-1}(x)y, \\ y_a = \begin{pmatrix} -F^{-1}(x)d(x)b(x)^T P_x^-(x)^T \\ c_2(x) \end{pmatrix} + \begin{pmatrix} I \\ 0 \end{pmatrix} u. \end{cases} \tag{17}$$

If Σ_+ *is the stable, maximum phase spectral factor of* Φ *given by* (12)*, then there exists an essentially unique minimal row rigid system* Θ_r *for which*

$$\Sigma_+ = \Theta_r \circ R, \tag{18}$$

with

$$\Theta_r\colon \begin{cases} \dot{x} = -a(x)^T + c_1(x)^T F^{-1}(x)d(x)b(x)^T \\ \qquad + P_x^+(x)b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T \\ \qquad + (P_x^+(x)b(x)d(x)^T F^{-1}(x) - c_2(x)^T)u, \\ y = F^{-1}(x)d(x)b(x)^T + (I \quad 0)u. \end{cases} \tag{19}$$

Proof. The proof of the various components of the result can be found in [20, 25] or [27]. □

3. Nonlinear inner systems. In this section we lay down the structure of nonlinear inner systems that will be useful in proving the main results in this paper. In particular, we prove in subsection 3.2 that the column- and row-rigid systems introduced earlier may be extended to inner systems in a minimal way. Moreover, explicit formulas for these extended inner systems in terms of solutions of Hamilton–Jacobi equations are given. Subsection 3.3 outlines an approach to inner-inner factorization developed by Ball and Petersen in the recent contribution [3].

3.1. Basic properties. First, we provide a brief description of a *nonlinear inner system*. We assume that j is any $m \times m$ signature matrix ($j = j^* = j^{-1}$) and J is any $p \times p$ signature matrix ($J = J^* = J^{-1}$).

DEFINITION 2. *Nonlinear* Θ *is* (j, J)-inner (*or* (j, J)-stable conservative) *if*

- $x \to a(x)$ *is stable* (*with respect to assumed equilibrium point* $x = 0$) *and*
- *there is a nonnegative-valued storage function* $P(x)$ *with* $P(0) = 0$ *such that*

$$P(x(t_2)) - P((x(t_1)) = \frac{1}{2}\int_{t_1}^{t_2} [u(t)^T j u(t) - y(t)^T J y(t)]dt \tag{20}$$

over all trajectories $(u(t), x(t), y(t))$ *of the system. This is true for all* $t_1 \le t_2$ *and* $u(\cdot)$, *with* $x(t_2)$ *denoting the state at time* t_2 *that originates from the initial state* $x(t_1)$ *at time* t_1 *and input* $u(\cdot)$ *on the time interval* $[t_1, t_2]$.

Alternatively, Θ *is said to be* (j, J)-inner *if it is lossless with respect to the* L_2*-gain supply rate*

$$s(u, y) = \frac{1}{2}u^T j u - \frac{1}{2}y^T J y.$$

The above characterization of nonlinear (j, J)-inner systems was achieved within the dissipative systems framework of Hill and Moylan [15] and Willems [34]. Here, the dissipation equality in (20) may be derived from a state space implementation of the L_2-gain condition in the formulation of the nonlinear H_∞-problem (see [31, 32]). Note that the function defined in (20) may also be thought of as a Lyapunov function (see [15]). If P is assumed to be smooth, the energy balance relation (20) can be expressed as

$$P_x(x)[a(x) - b(x)c(x)] = \frac{1}{2}u^T j u - \frac{1}{2}[c(x) + d(x)u]^T J[c(x) + d(x)u], \quad P(0) = 0,$$

for all x and u, or equivalently, in infinitesimal form as

$$\begin{aligned} P_x(x)b(x) + c(x)^T J d(x) &= 0, \\ P_x(x)a(x) + \frac{1}{2}c(x)^T J c(x) &= 0, \\ d(x)^T J d(x) &= j. \end{aligned} \tag{21}$$

In fact, realizations for nonlinear invertible (j, J)-inner systems may be expressed in terms of smooth solutions of Hamilton–Jacobi equations as follows:

$$\Theta : \begin{cases} \dot{x} = a(x) + b(x)u, & u \in \mathbf{R^m}, \\ y_a = -b(x)^T P_x(x)^T + u, & y_a \in \mathbf{R^p}, \end{cases} \tag{22}$$

where P is a solution of the Hamilton–Jacobi equation

$$P_x(x)[a(x) - b(x)c(x)] - \frac{1}{2}P_x(x)b(x)b(x)^T P_x(x)^T = 0, \quad P(0) = 0,$$

with $P_x(x) = (\frac{\partial P}{\partial x_1}(x), \ldots, \frac{\partial P}{\partial x_n}(x))$. In the linear case, the function Θ_{linear} is said to be (j, J)-*inner* if it has the property that

$$\Theta^*_{\text{linear}} J \Theta_{\text{linear}} = \Theta_{\text{linear}} J \Theta^*_{\text{linear}} = j.$$

In subsequent discussions, we assume that $j = J = I$. We say that the inner system Θ_1 *divides* Θ_2 *on the right (left)* if the interconnection of Θ_1^T and Θ_2 (Θ_2 and Θ_1^T) is stable. Given two inner systems Θ_1 and Θ_2, we denote the *greatest common right (left) divisor* by $\Theta_1 \wedge_R \Theta_2$ ($\Theta_1 \wedge_L \Theta_2$). Also, we denote the *least common right (left) multiple* by $\Theta_1 \vee_R \Theta_2$ ($\Theta_1 \vee_L \Theta_2$). Two inner systems are *right (left) coprime* if their greatest common right (left) divisor is the identity (see [18] and [19] for more details).

3.2. Minimal inner embeddings. In this subsection, we study the embedding of inner and rigid systems in minimal inner systems. In particular, in the next result, we extend a column-rigid system Θ_c given by (17) in a minimal way in order to obtain a system that is inner. Similarly, we extend a row-rigid system Θ_r given by (19) minimally to an inner system.

THEOREM 3. *The column-rigid system* Θ_c *from* (17) *can be extended minimally to the inner system*

$$\begin{cases} \dot{x} = a(x) - b(x)d(x)^T F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T (F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + (b(x)d(x)^T F^{-1}(x) X_x^-(x))u, \\ y_a = \begin{pmatrix} -F^{-1}(x)d(x)b(x)^T P_x^-(x)^T \\ c_2(x) \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u, \end{cases} \tag{23}$$

where F *is given by* (2) *and* P^- *is a smooth solution of* (10) *with stability side condition* (11) *and where* X^- *satisfies* (7). *Moreover,* Θ_r *given as in* (19) *may be extended to the inner system*

$$\begin{cases} \dot{x} = -a(x)^T + c_1(x)^T F^{-1}(x)d(x)b(x)^T \\ \qquad + P_x^+(x)b(x)d(x)^T (F^{-1}(x))^2 d(x)b(x)^T \\ \qquad + (P_x^+(x)b(x)d(x)^T F^{-1}(x) - c_2(x)^T)u, \\ y = \begin{pmatrix} F^{-1}(x)d(x)b(x)^T \\ X_x^+(x)^T \end{pmatrix} + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u, \end{cases} \tag{24}$$

where F *is given by* (2) *and* P^+ *is a smooth solution of* (13) *with stability side condition* (14) *and where* X^+ *satisfies* (7).

Proof. It is clear that any minimal inner extension of column-rigid Θ_c given by (17) will be of the form (23). Next, we have to establish that (23) is, in fact, inner. In order to accomplish this, we rewrite (23) as

$$\begin{cases} \dot{x} = f(x) + g(x)u, \\ y_a = -g(x)^T Q_x(x)^T + u, \end{cases}$$

where Q is a solution of the Hamilton–Jacobi equation

$$Q_x(x)[f(x)-g(x)h(x)]-\frac{1}{2}Q_x(x)g(x)g(x)^TQ_x(x)^T=0,\quad Q(0)=0.$$

It remains to show that $Q=P^-$ is a solution of this equation. Indeed, it is clear that

$$\begin{aligned}&P_x^-(x)[a(x)-b(x)d(x)^TF^{-1}(x)c_1(x)]+c_2(x)^Tc_2(x)\\&\quad-\frac{1}{2}[P_x^-(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TP_x^-(x)^T+c_2(x)^Tc_2(x)]\\&\quad=P_x^-(x)[a(x)-b(x)d(x)^TF^{-1}(x)c_1(x)]\\&\quad-\frac{1}{2}P_x^-(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TP_x^-(x)^T+\frac{1}{2}c_2(x)^Tc_2(x)=0.\end{aligned}$$

As was the case in the above, any minimal, inner extension of row-rigid Θ_r given by (19) will be of the form (24). The remainder of the proof of the second part can be obtained from the observation that

$$\begin{aligned}&\frac{1}{2}P_x^+(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TP_x^+(x)^T-\frac{1}{2}c_2(x)^Tc_2(x)\\&\quad=[-a(x)^T+c_1(x)^TF^{-1}(x)d(x)b(x)^T]P_x^+(x)^T\\&\quad=P_x^+(x)[a(x)-b(x)d(x)^TF^{-1}(x)c_1(x)].\end{aligned}$$

This computation is made possible by the symmetry in the Hamilton–Jacobi equation. □

The extensions from rigid to minimal inner systems referred to in Theorem 3 are known as *minimal inner embeddings*. A special subclass of these embeddings are the extensions from inner to minimal inner systems. The extension from the inner system

$$\begin{cases}\dot{x}=a(x)-b(x)d^T(x)F^{-1}(x)c_1(x)\\\qquad-b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TQ_x^-(x)^T\\\qquad+b(x)d^T(x)F^{-1}(x)u,\\y=-F^{-1}(x)d(x)b(x)^TQ_x^-(x)^T+u,\end{cases}$$

with corresponding Hamilton–Jacobi equation

$$\begin{aligned}&Q_x^-(x)[a(x)-b(x)d(x)^TF^{-1}(x)c_1(x)]\\&\quad-\frac{1}{2}Q_x^-(x)b(x)d(x)^T(F^{-1}(x))^2d(x)b(x)^TQ_x^-(x)^T=0,\end{aligned}$$

to the minimal inner system (23) is an example of such an embedding. The latter type of inner embedding will play a prominent role in the discussion in what follows.

3.3. Minimal inner factorizations of nonlinear inner systems. Our approach to the factorization of nonlinear inner systems is dependent on the adaptation of the cascade factorization of general nonlinear systems to nonlinear inner systems. This approach was developed in the recent paper by Ball and Petersen [3] (see also [30] for an earlier work) and was central to the solution of the problem of parametrizing square solutions of the nonlinear spectral factorization problem in terms of minimal

inner-inner factorizations of nonlinear systems. As this approach will underpin our analysis, the highlights of this scheme are outlined below.

Suppose that the state manifold has a foliation $x = (x_1, x_2)$ (a diffeomorphism of the state space $\mathcal{X}$ with the Cartesian product $\mathcal{X}_1 \times \mathcal{X}_2$ of two manifolds $\mathcal{X}_1$ and $\mathcal{X}_2$), so that (x_1, x_2) becomes a new system of coordinates for Θ. Then, in terms of these coordinates, we write the state space equations (22) in the form

$$\Theta\colon \begin{cases} \dot{x}_1 = \mathbf{a}_1(x_1, x_2) + \mathbf{b}_1(x_1, x_2)u, \\ \dot{x}_2 = \mathbf{a}_2(x_1, x_2) + \mathbf{b}_2(x_1, x_2)u, \\ \ \ y = \mathbf{c}(x_1, x_2) + u. \end{cases}$$

In this case the inverse system has the form

$$\Theta^{-1}\colon \begin{cases} \dot{x}_1 = \mathbf{a}_1^{\times}(x_1, x_2) + \mathbf{b}_1(x_1, x_2)y, \\ \dot{x}_2 = \mathbf{a}_2^{\times}(x_1, x_2) + \mathbf{b}_2(x_1, x_2)y, \\ \ \ u = -\mathbf{c}(x_1, x_2), \end{cases}$$

where $\mathbf{a}^{\times}(x_1, x_2) = \mathbf{a}(x_1, x_2) - \mathbf{b}(x_1, x_2)\mathbf{c}(x_1, x_2)$, or

$$\begin{pmatrix} \mathbf{a}_1^{\times}(x_1, x_2) \\ \mathbf{a}_2^{\times}(x_1, x_2) \end{pmatrix} = \begin{pmatrix} \mathbf{a}_1(x_1, x_2) - \mathbf{b}_1(x_1, x_2)\mathbf{c}(x_1, x_2) \\ \mathbf{a}_2(x_1, x_2) - \mathbf{b}_2(x_1, x_2)\mathbf{c}(x_1, x_2) \end{pmatrix}. \tag{25}$$

The foliation $x = (x_1, x_2)$ is known as an *inner product-coordinate pair* for the inner system Θ with storage function P (see (21) and (26)) if the functions $P(x_1, x_2)$, $\mathbf{b}_j(x_1, x_2)$, and $\mathbf{a}_1(x_1, x_2)$ and $\mathbf{a}_2^{\times}(x_1, x_2)$ have the form

$$\begin{aligned} P(x_1, x_2) &= P_1(x_1) + P_2(x_2), \\ \mathbf{b}_1(x_1, x_2) &= b_1(x_1), \\ \mathbf{b}_2(x_1, x_2) &= b_2(x_2), \\ \mathbf{a}_1(x_1, x_2) &= a_1(x_1), \\ \mathbf{a}_2^{\times}(x_1, x_2) &= a_2^{\times}(x_2) \end{aligned} \tag{26}$$

for some single-variable functions $P_1(x_1), P_2(x_2), b_1(x_1), b_2(x_2), a_1(x_1)$, and $a_2^{\times}(x_2)$. From (25) and the first three equations in (26), we see that

$$\begin{aligned} \mathbf{a}_2^{\times}(x_1, x_2) &= \mathbf{a}_2(x_1, x_2) + b_2(x_2)(b_1(x_1)^T P_{1,x_1}(x_1)^T + b_2(x_2)^T P_{2,x_2}(x_2)^T) \\ &= [\mathbf{a}_2(x_1, x_2) + b_2(x_2)b_1(x_1)^T P_{1,x_1}(x_1)^T] + b_2(x_2)b_2(x_2)^T P_{2,x_2}(x_2)^T. \end{aligned}$$

Thus, we see that the last two equations in (26), in the definition of inner product-coordinate pairs, can be replaced with

$$\begin{aligned} \mathbf{a}_2(x_1, x_2) = a_2(x_2) - b_2(x_2)b_1(x_1)^T P_{1,x_1}(x_1)^T \\ \text{for a single-variable function } a_2(x_2), \end{aligned}$$

with $a_2(x_2) = a_2^{\times}(x_2) - b_2(x_2)b_2(x_2)^T P_{2,x_2}(x_2)^T$. These conventions are used to show that if we suppose that Θ is a nonlinear inner system with storage function P as in (21) and (26), then factorizations $\Theta = \Theta_2 \circ \Theta_1$, with Θ_2 and Θ_1 inner, are in bijective

correspondence with inner product-coordinate pairs $x = (x_1, x_2)$. Indeed, given an inner product-coordinate pair as in (26), define systems Θ_1 and Θ_2 by

$$\Theta_1 : \begin{cases} \dot{x}_1 = a_1(x_1) + b_1(x_1)u_1, \\ y_1 = -b_1(x_1)^T P_{1,x_1}(x_1)^T + u_1, \end{cases}$$

$$\Theta_2 : \begin{cases} \dot{x}_2 = a_2(x_2) + b_2(x_2)u_2, \\ y_2 = -b_2(x_2)^T P_{2,x_2}(x_2)^T + u_2, \end{cases}$$

with $a_2(x_2) = a_2^{\times}(x_2) - b_2(x_2)b_2(x_2)^T P_{2,x_2}(x_2)^T$. Then Θ_1 and Θ_2 are inner systems with storage functions $P_1(x_1)$ and $P_2(x_2)$, respectively, and we recover Θ as $\Theta = \Theta_2 \circ \Theta_1$. The same analysis as in the above can, of course, be done for the minimal inner extensions of Θ_1 and Θ_2.

4. Parametrizations of minimal stable nonsquare spectral factors. The main results of the paper are contained in this section. In the subsequent analysis, subsection 4.1 addresses some of the issues related to extremal spectral factors, while internal and external spectral factors are described in subsection 4.2. In subsection 4.3 the important notion of a coprime inner-inner factorization is introduced. Finally, the set of all minimal stable nonsquare spectral factors is parametrized in terms of the aforementioned inner-inner factorization in subsection 4.4.

Next, we state the problem that will be solved in the ensuing discussion.

Problem. Given a stable, nonlinear, input-affine control system, parametrize all nonsquare, stable, nonlinear, input-affine spectral factors in terms of a special class of inner-inner factorizations.

4.1. Extremal spectral factors. The next proposition discusses minimal stable and minimal antistable spectral factors of Φ and their zero extensions.

PROPOSITION 4. *Let Σ_- and Σ_+ be the stable minimum and maximum phase spectral factors of Φ given by* (9) *and* (12)*, respectively. Also, assume that $\overline{\Sigma}_-$ and $\overline{\Sigma}_+$ are the corresponding antistable minimum and maximum phase spectral factors of Φ, respectively.*

1. *Assume that Σ_-^e and Σ_+^e are the zero-extended, stable, minimum and maximum phase spectral factors of Φ, respectively. Given any minimal stable spectral factor S of Φ, there exist, essentially unique, inner systems Θ' and Θ'' for which*

$$\begin{cases} \Sigma_+^e = \Theta' \circ S, \\ S = \Theta'' \circ \Sigma_-^e. \end{cases} \tag{27}$$

2. *Suppose that $\overline{\Sigma}_-^e$ and $\overline{\Sigma}_+^e$ are the zero-extended, antistable, minimum and maximum phase spectral factors of Φ, respectively. Given any minimal antistable spectral factor $\overline{S}$ of Φ, there exist, essentially unique, inner systems $\overline{\Theta}'$ and $\overline{\Theta}''$ for which*

$$\begin{cases} \overline{\Sigma}_+^e = \overline{\Theta}' \circ \overline{S}, \\ \overline{S} = \overline{\Theta}'' \circ \overline{\Sigma}_-^e. \end{cases}$$

Proof.

1. First we verify the properties of the inner system Θ'' in the second equation of (27). We know from Proposition 1 that there exists an essentially unique column-rigid system Θ_c for which $S = \Theta_c \circ \Sigma_-$. Furthermore, the existence of Θ'' as a minimal inner extension of Θ_c is evident from Theorem 3. Since Σ_- and Σ_-^e are spectral factors of Φ, we have that

$$\begin{aligned}\Phi(u) &= [DS(u)]^T \circ S(u)\\ &= [D(\Theta_c \circ \Sigma_-)(u)]^T \circ (\Theta_c \circ \Sigma_-)(u)\\ &= [D(\Theta'' \circ \Sigma_-^e)(u)]^T \circ (\Theta'' \circ \Sigma_-^e)(u),\end{aligned}$$

with Σ_-^e extended outer. Conversely, let $S = \Theta_*'' \circ \Sigma_-^e$, with Θ_*'' being a minimal inner extension of the column-rigid system Θ_{c*}. Then $S = \Theta_c \circ \Sigma_- = \Theta_{c*} \circ \Sigma_-$ which, by the right invertibility of Σ_-, implies that

$$[D\Theta_{c*}(u)]^T \circ \Theta_{c*}(u) = [D\Theta_c(u)]^T \circ \Theta_c(u) = u.$$

It follows by minimality that $\Theta_{c*}(u) = \Theta_c(u)K$ for some inner system K. If Θ_{c*} and Θ_c have the same state space dimension, then K is a constant system. From this we may deduce that Θ'' is an essentially unique inner system with the property that $S = \Theta'' \circ \Sigma_-^e$. The properties of the inner system Θ' in the first equation of (27) can be verified in a similar manner.

2. The proof of the second part will be analogous to the first.

The result follows from the discussion above. ∎

Note that the factorization in the second equation of (27) is, in fact, an *inner-outer* factorization. The rigid and inner systems described in Proposition 4 can be factorized further. In this regard, we consider for row-rigid Θ_r and column-rigid Θ_c the finer factorizations

$$\begin{cases}\Theta_r = \Theta_r^1 \circ \Theta_r^2,\\ \Theta_c = \Theta_c^2 \circ \Theta_c^1,\end{cases} \tag{28}$$

where Θ_r^1 and Θ_c^1 are inner and Θ_r^2 and Θ_c^2 are right and left outer. Next, we introduce an important type of factorization.

Definition 5. *We call the equations occurring in* (28) *the* internal-external *and* external-internal factorizations *of Θ_r and Θ_c, respectively.*

Similarly, for Θ' and Θ'' we consider finer factorizations

$$\begin{cases}\Theta' = \Theta_1' \circ \Theta_2',\\ \Theta'' = \Theta_2'' \circ \Theta_1'',\end{cases} \tag{29}$$

where Θ_1' and Θ_1' are inner and Θ_2' and Θ_2'' are right and left outer. Likewise, we call (29) the *internal-external* and *external-internal factorizations* of Θ' and Θ'', respectively.

Theorem 6. *Suppose that Σ_+^e is an extended, maximum phase, stable spectral factor of the nonlinear system Φ. Then S is a minimal, stable, spectral factor of Φ if and only if there exists an inner system Θ' such that*

$$[DS(u)]^T \circ S(u) = [D(\Theta'^T \circ \Sigma_+^e)(u)]^T \circ (\Theta'^T \circ \Sigma_+^e)(u), \tag{30}$$

where we restrict the state manifold to the diagonal (x, x).

Proof. We prove the forward assertion by considering Proposition 4 and the properties of Σ_+^e. Indeed, from the first part of Proposition 4, if S is a minimal, stable spectral factor and Σ_+^e is the extended, maximum phase, stable spectral factor, then

$$\begin{aligned}[DS(u)]^T \circ S(u) &= [D\Sigma_+^e(u)]^T \circ \Sigma_+^e(u) \\ &= [D\Sigma_+^e(u)]^T \circ [D\Theta'^T(u)]^T \circ \Theta'^T(u) \circ \Sigma_+^e(u) \\ &= [D(\Theta'^T \circ \Sigma_+^e)(u)]^T \circ (\Theta'^T \circ \Sigma_+^e)(u)\end{aligned}$$

for some inner system Θ'. Conversely, assume that (30) holds for some inner system Θ'. Then clearly S is a stable spectral factor. The minimality of the realization S follows from the fact that in general

$$\begin{aligned}&\text{dimension of state manifold associated with } S \\ &\leq \text{dimension of state manifold associated with } \Sigma_+^e,\end{aligned}$$

which implies that

$$\begin{aligned}&2 \times \text{dimension of state manifold associated with } \Sigma_+^e \\ &= \text{dimension of state manifold associated with } \Phi \\ &\leq 2 \times \text{dimension of state manifold associated with } S \\ &\leq 2 \times \text{dimension of state manifold associated with } \Sigma_+^e.\end{aligned}$$

As a result of this, we have that

$$\begin{aligned}&\text{dimension of state manifold associated with } \Phi \\ &= 2 \times \text{dimension of state manifold associated with } S \\ &= 2 \times \text{dimension of state manifold associated with } \Sigma_+^e\end{aligned}$$

and S is a stable, spectral factor that is minimal. □

The next result provides an important first step for a parametrization of the set of all nonsquare minimal stable spectral factors. This result will be used extensively in the proofs of the main theorems in subsection 4.4, where the parametrization will be described explicitly.

THEOREM 7. *Suppose that Φ is a weakly coercive nonlinear control system with minimal nonsquare stable spectral factor S. Let Θ_+ and Θ_- be the inner systems with the properties*

$$\begin{cases} \Sigma_+ = \Theta_+ \circ \Sigma_-, \\ \overline{\Sigma}_+ = \Theta_- \circ \overline{\Sigma}_-. \end{cases} \tag{31}$$

Assume that $\Theta', \Theta'', \overline{\Theta}'$, and $\overline{\Theta}''$ are determined by Proposition 4, with internal-external factorizations

$$\Theta' = \Theta'_1 \circ \Theta'_2, \ \overline{\Theta}' = \overline{\Theta}'_1 \circ \overline{\Theta}'_2 \tag{32}$$

and the external-internal factorization

$$\Theta'' = \Theta''_2 \circ \Theta''_1, \ \overline{\Theta}'' = \overline{\Theta}''_2 \circ \overline{\Theta}''_1. \tag{33}$$

In this case we have that

1. (a) *Θ'_1 is the greatest common left inner factor of Θ' and Θ^e_+ and Θ''_1 is the greatest common right inner factor of Θ'' and Θ^e_+. $\overline{\Theta}'_1$ is the greatest common left inner factor of $\overline{\Theta}'$ and $\overline{\Theta}^e_+$ and $\overline{\Theta}''_1$ is the greatest common right inner factor of $\overline{\Theta}''$ and $\overline{\Theta}^e_+$.*
   (b) *$\overline{\Theta}''_1$ is the greatest common right inner factor of $\overline{\Theta}''$ and $\overline{\Theta}^e_-$ and Θ''_1 is the greatest common right inner factor of $\overline{\Theta}''$ and $\overline{\Theta}^e_+$.*
2. *$\Theta' \circ \Theta''$ is an inner extension of Θ_+ and $\overline{\Theta}' \circ \overline{\Theta}''$ is an inner extension of Θ_-.*
3. *There exists a unique inner system Θ such that*

$$\Theta^e_+ = \Theta'_1 \circ \Theta \circ \Theta''_1.$$

Likewise for $\overline{\Theta}^e_+$, we have for the factorization

$$\overline{\Theta}^e_+ = \overline{\Theta}'_1 \circ \overline{\Theta} \circ \overline{\Theta}''_1 \tag{34}$$

that $\overline{\Theta}$ exists and is unique.
4. (a) *Θ and Θ'_2 are left coprime while Θ and Θ''_2 are right coprime.*
   (b) *$\overline{\Theta}$ and $\overline{\Theta}'_2$ are left coprime while $\overline{\Theta}$ and $\overline{\Theta}''_2$ are right coprime.*

Proof.

1. (a) We recall from $\Theta_r = \Theta^1_r \circ \Theta^2_r$ in (28) that Θ^2_r is outer. Also, from (16) and (18) we know that $\Sigma_+ = \Theta_r \circ \Theta_c \circ \Sigma_-$. Hence it follows from the first equation in (31) that $\Theta_+ = \Theta_r \circ \Theta_c$. Furthermore, Θ^1_r is a left inner factor of Θ_+ and the inner extension of Θ^1_r is a common left inner factor of Θ' and Θ^e_+. Any left inner factor of Θ^e_+ is, up to a constant right unitary factor, an inner extension of Θ_r. Since Θ^2_r is outer, it is clear that Θ'_1 is the greatest common left inner factor of Θ' and Θ^e_+. The proof of the second assertion is similar to the one for the above.
   (b) The proof of part (b) is similar to that for part (a).
2. First, recall from the proof of part 1 that $\Theta_+ = \Theta_r \circ \Theta_c$. From this equality and the fact that Θ' is an inner extension of Θ_r and Θ'' is an inner extension of Θ_c, we must have that $\Theta' \circ \Theta''$ is an inner extension of Θ_+. That $\overline{\Theta}'\overline{\Theta}''$ is an inner extension of Θ_- can be proven in a similar manner.
3. Using the extended version of (31) and the factorizations (32) and (33), we compute that

$$\begin{aligned}\Sigma^e_+ &= \Theta' \circ \Theta'' \circ \Sigma^e_- \\ &= \Theta'_1 \circ \Theta'_2 \circ \Theta''_2 \circ \Theta''_1 \circ \Sigma^e_- \\ &= \Theta'_1 \circ \Theta \circ \Theta''_1 \circ \Sigma^e_-.\end{aligned}$$

   In addition, we have that

$$\Sigma^e_+ = \Theta^e_+ \circ \Sigma^e_-$$

   so that $\Theta_+ = \Theta^1_r \circ \widehat{\Theta} \circ \Theta^1_c$, where $\widehat{\Theta} = \Theta^2_r \circ \Theta^2_c$. Clearly, from Propositions 1 and 4, it follows that $\Theta = \Theta'_2 \circ \Theta''_2$ is unique.
4. (a) From part 1 of the statement of this theorem, we know that Θ'_1 is the greatest common left inner factor of Θ' and Θ^e_+. Hence we have that Θ'_2 and $\Theta \circ \Theta''_1$ are left coprime. Also, from the above, it is clear that Θ'_2 and Θ are left coprime. The fact that Θ''_2 and Θ are right coprime may be proved in a similar manner.

(b) The proof of this part may be achieved by using techniques similar to those in (a) above. □

4.2. Internal and external spectral factors. In order to parametrize spectral factors in terms of inner-inner factorizations, we study two particular types of spectral factors, namely, those that are internal and those that are external. The definitions of these classes of spectral factors are provided below.

DEFINITION 8. *Let S be a minimal, stable spectral factor and let Θ' and Θ'' be the inner systems characterized in Proposition* 4. *Then we say the following:*

1. *S is an* internal spectral factor *if we have*

$$\Theta_+^e = \Theta' \circ \Theta''. \tag{35}$$

2. *S is an* external spectral factor *if we have that*
   (a) *Θ' and Θ_+^e are left coprime and*
   (b) *Θ'' and Θ_+^e are right coprime.*

The analysis of general spectral factors in subsection 4.4 will depend on the properties of both the external and internal spectral factors. In the next result, we determine necessary and sufficient conditions for the existence of an internal spectral factor and provide explicit formulas for Θ_+ and its minimal inner extension Θ_+^e as referred to in Theorem 7 and (35) of Definition 8.

PROPOSITION 9. *Let S be a minimal, stable spectral factor and let Θ' and Θ'' be the inner systems characterized in Proposition* 4. *Then S is an internal spectral factor if and only if we have that*

$$\Theta_+^e = \Theta' \circ \Theta'' \colon \begin{cases} \dot{x} = a(x) - b(x)d(x)^T F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T (F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + (b(x)d(x)^T F^{-1}(x) X_x^-(x))u, \\ y_a = \begin{pmatrix} -F^{-1}(x)d(x)b(x)^T (P_x^-(x) - P_x^+(x))^T \\ c_2(x) \end{pmatrix} \\ \qquad + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u \end{cases} \tag{36}$$

is an inner extension of the minimal inner system

$$\Theta_+ =: \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T (F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + b(x)d^T(x)F^{-1}(x)u, \\ y = -F^{-1}(x)d(x)b(x)^T (P_x^-(x) - P_x^+(x))^T + u, \end{cases} \tag{37}$$

where Θ_+ is the inner factor of Σ_+ in $\Sigma_+ = \Theta_+ \circ \Sigma_-$ after restriction of the state space to the diagonal (x, x). Furthermore, $(P^- - P^+)$ is the solution of the Hamilton–Jacobi equation

$$Z_x(x)[a(x) - b(x)c(x)] - \frac{1}{2} Z_x(x)b(x)b(x)^T Z_x(x)^T = 0, \quad Z(0) = 0.$$

Moreover, up to a right unitary factor for Θ' and a left factor for Θ'', the factoriza-

tions of the inner extension (36) *are in a bijective correspondence with inner-inner factorizations of* Θ_+*—that is, factorizations* $\Theta_+ = \Theta_1 \circ \Theta_2$.

Proof. By the discussion in subsection 3.2, the equation $\Sigma_+^e = \Theta' \circ S$ from Proposition 4, and the fact that Σ_+^e is a zero extension of Σ_+, we know that Θ' is a minimal inner extension of some inner system Θ_1. Similarly, for $S = \Theta'' \circ \Sigma_-^e$, we know that an inner system Θ_2 exists that may be minimally extended to Θ''. In this case, the discussion on inner-inner factorizations in subsection 3.3 may be used to obtain the equality $\Theta_+ = \Theta_1 \circ \Theta_2$ (compare Theorem 3.4 in [3]).

The explicit formula $\Theta_+ = \Sigma_+ \circ \Sigma_-^{-R}$ arises from computing the product of the stable maximum phase spectral factor Σ_+ in (12) and the right inverse of the stable minimum phase spectral factor Σ_-^{-R} from (15) (compare with Proposition 3.3 in [3]). ∎

Remark 10. It is always possible to obtain explicit formulas for the inner factors Θ' and Θ'' of the inner-inner factorization $\Theta' \circ \Theta''$ in (36) by utilizing the scheme suggested in subsection 3.3.

The following corollary to Proposition 9 states that any minimal, stable spectral factor is, in fact, internal.

COROLLARY 11. *If* S *is a minimal, stable spectral factor, then it is internal.*

Proof. From the proof of Proposition 9, we have that Θ_1 must be a left factor of Θ_+ and hence S must be internal. ∎

4.3. Coprime inner-inner factorization. In this subsection we discuss a special type of factorization associated with inner systems, namely, *coprime inner-inner factorizations*. In order to define this concept, we introduce the inner systems

$$V : \begin{cases} \dot{x}_V = a_V(x_V) + b_V(x_V)u_V, & u_V \in \mathbf{R^{m_0}}, \\ y_V = c_V(x_V) + u_V, & y_V \in \mathbf{R^{m_0}}, \end{cases} \tag{38}$$

with $a_V : \mathbf{R^n} \to \mathbf{R^n}, b_V : \mathbf{R^n} \to \mathbf{R^{n \times m_0}}$, and $c_V : \mathbf{R^n} \to \mathbf{R^{m_0}}$, and

$$W : \begin{cases} \dot{x}_W = a_W(x_W) + b_W(x_W)u_W, & u_W \in \mathbf{R^{m-m_0}}, \\ y_W = c_W(x_W) + u_W, & y_W \in \mathbf{R^{m-m_0}}, \end{cases} \tag{39}$$

where $a_W : \mathbf{R^n} \to \mathbf{R^n}, b_W : \mathbf{R^n} \to \mathbf{R^{n \times (m-m_0)}}$, and $c_W : \mathbf{R^n} \to \mathbf{R^{m-m_0}}$.

DEFINITION 12. *Let* V *and* W *be inner systems given by the general formulas* (38) *and* (39)*, respectively. We say that a factorization*

$$\widetilde{\Theta} = \Theta' \circ \Theta''$$

into the product of two inner systems is a coprime inner-inner factorization *if* Θ' *is left coprime and* Θ'' *is right coprime with both the inner extensions* V^e *and* W^e *of* V *and* W*, respectively.*

The result below postulates the existence of a coprime inner-inner factorization of an appropriate extension of the inner system Θ_+ given by (37).

PROPOSITION 13. *Let* P^- *be a smooth solution of* (10) *with stability side condition* (11) *and* X^- *satisfying* (7)*. Furthermore, assume that* P^+ *is a smooth solution of* (13) *with stability side condition* (14) *and* X^+ *satisfying* (7)*. Let* Θ_+ *be an inner system*

given as in (37). *Then there exists a coprime inner-inner factorization*

$$\Theta' \circ \Theta'' : \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + (b(x)d(x)^T F^{-1}(x)X_x^-(x))u, \\ y = \begin{pmatrix} -F^{-1}(x)d(x)b(x)^T(P_x^-(x) - P_x^+(x))^T \\ \qquad -(X_x^-(x) - X_x^+(x))^T P_x^-(x)^T \end{pmatrix} \\ \qquad + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u. \end{cases} \tag{40}$$

Proof. We start by choosing inner systems V and W that appear in Definition 12 as

$$V : \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T Q_x^-(x)^T \\ \qquad + b(x)d^T(x)F^{-1}(x)u, \\ y = -F^{-1}(x)d(x)b(x)^T Q_x^-(x)^T + u, \end{cases}$$

with corresponding Hamilton–Jacobi equation

$$Q_x^-(x)[a(x) - b(x)d(x)^T F^{-1}(x)c_1(x)] \\ -\frac{1}{2}Q_x^-(x)b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T Q_x^-(x)^T = 0,$$

and as

$$W : \begin{cases} \dot{x} = -a(x)^T + c_1(x)^T F^{-1}(x)d(x)b(x)^T \\ \qquad + Q_x^+(x)b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T \\ \qquad + Q_x^+(x)b(x)d(x)^T F^{-1}(x)u, \\ y = F^{-1}(x)d(x)b(x)^T + u, \end{cases}$$

with corresponding Hamilton–Jacobi equation

$$Q_x^+(x)[a(x) - b(x)d(x)^T F^{-1}(x)c_1(x)] \\ -\frac{1}{2}Q_x^+(x)b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T Q_x^+(x)^T = 0,$$

respectively. The rest of the proof may be outlined as follows. We obtain explicit formulas for the inner factors Θ' and Θ'' of the inner-inner factorization $\Theta' \circ \Theta''$ in (40) by utilizing the scheme suggested in subsection 3.3. Next, from subsection 3.2, we extend V and W to minimal inner systems V^e and W^e, respectively. Then by Theorem 7 we have that Θ' is left coprime and Θ'' is right coprime with both V^e and W^e. ∎

We note that the explicit formulas for $\Theta' \circ \Theta''$ in (36) of Proposition 9 and (40) of Proposition 13 have the same form since it was established in (7) that there exists a map X such that $c_2(x) = -X_x(x)^T P_x(x)^T$ (see Theorem 3 of [25]).

4.4. Parametrizing nonsquare spectral factors in terms of coprime inner-inner factorizations. In this section, we establish a bijective correspondence between coprime inner-inner factorizations of inner systems and a certain subclass of minimal, stable spectral factors S for Φ. This special class arises as follows.

Our description of the class of *decomposable* spectral factors will follow [3] rather closely. Let $P(x)$ be a solution of the Hamilton–Jacobi equation (6) and let $P^-(x)$ be the solution also satisfying the stabilizing side condition (11). As in subsection 3.3, we suppose that the state space manifold $\mathcal{X}$ has a decomposition $x = (x_1, x_2)$. We start with the extended outer factor Σ_-^e, where $S = \Theta'' \circ \Sigma_-^e$ from Proposition 4. In the language of [3], the outer factor Σ_-^e will assume the form

$$\Sigma_-^e : \begin{cases} \dot{x}_1 = \mathbf{a}_1(x_1, x_2) + \mathbf{b}_1(x_1, x_2)u, \\ \dot{x}_2 = \mathbf{a}_2(x_1, x_2) + \mathbf{b}_2(x_1, x_2)u, \\ \quad y = \mathbf{c}(x_1, x_2) + u, \end{cases}$$

and we write $P(x) = P(x_1, x_2), P^-(x) = P^-(x_1, x_2)$. We assume that $P^-(x_1, x_2)$, $P(x_1, x_2), \mathbf{a}_1, \mathbf{a}_2, \mathbf{b}_1$, and $\mathbf{b}_2$ have the special form

$$\begin{aligned} P^-(x_1, x_2) &= P_1(x_1) + P_2(x_2), \\ P(x_1, x_2) &= P_2(x_2), \\ \mathbf{b}_1(x_1, x_2) &= b_1(x_1), \mathbf{b}_2(x_1, x_2) = b_2(x_2), \\ a^{U_1}(x_1) &:= \mathbf{a}_1(x_1, x_2) \\ &\quad - b_1(x_1)\mathbf{c}(x_1, x_2) - b_1(x_1)b_1(x_1)^T P_{1,x_1}(x_1)^T \\ &\quad - b_1(x_1)b_2(x_2)^T P_{2,x_2}(x_2)^T \\ &\quad \text{(a function only of } x_1\text{)}, \\ a^{U_2}(x_2) &:= \mathbf{a}_2(x_1, x_2) \\ &\quad - b_2(x_2)\mathbf{c}(x_1, x_2) - b_2(x_2)b_2(x_2)^T P_{2,x_2}(x_2)^T \\ &\quad \text{(a function only of } x_2\text{)} \end{aligned} \tag{41}$$

for some single-variable functions $P_1(x_1), P_2(x_2), b_1(x_1), b_2(x_2), a^{U_1}(x_1)$, and $a^{U_2}(x_2)$. Whenever $P(x)$ is a solution of the Hamilton–Jacobi equation for which there is a decomposition $x = (x_1, x_2)$ for which all the relations (41) are satisfied, we shall say that P is a *decomposable solution* of the Hamilton–Jacobi equation (6), and that the associated minimal, stable factor S of Φ given earlier is a *decomposable minimal, stable, spectral factor*.

The following result gives an explicit correspondence between decomposable, minimal, stable, spectral factors S of Φ and coprime inner-inner factorizations $\Theta' \circ \Theta''$.

THEOREM 14. *Let P^- be a smooth solution of* (10) *with stability side condition* (11) *and X^- satisfying* (7). *Furthermore, assume that P^+ is a smooth solution of* (13) *with stability side condition* (14) *and X^+ satisfying* (7). *A bijective correspondence exists between minimal, external, decomposable, nonsquare spectral factors of Φ and coprime inner-inner factorizations $\Theta' \circ \Theta''$ of the form given by* (40).

Proof. Let S be a minimal stable, nonsquare external spectral factor of Φ. By Theorem 7 and Proposition 13, we know that the factorization $\Theta' \circ \Theta''$ exists. From Definition 12, this factorization is also coprime inner-inner.

In order to prove the converse statement, let $\Theta' \circ \Theta''$ be any coprime inner-inner factorization. The existence of such factorizations is guaranteed by Proposition 13. Next, define $S = \Theta'' \circ \Sigma_-^e$. It is clear that S is a stable spectral factor of Φ—since $\Sigma_+^e = \Theta' \circ S$, it has to be minimal. Also, it is immediately apparent that the correspondence between S and coprime inner-inner factorizations $\Theta' \circ \Theta''$ is bijective. □

A complete parametrization of the set of all nonsquare minimal stable decomposable spectral factors is given in the following theorem.

THEOREM 15. *There is a bijective correspondence between the set of all minimal, stable, decomposable, nonsquare spectral factors S of Φ and factorizations of the form*

$$\Theta_1'\Theta_2'\Theta_2''\Theta_1'' : \begin{cases} \dot{x} = a(x) - b(x)d^T(x)F^{-1}(x)c_1(x) \\ \qquad - b(x)d(x)^T(F^{-1}(x))^2 d(x)b(x)^T P_x^-(x)^T \\ \qquad + (b(x)d(x)^T F^{-1}(x)X_x^-(x))u, \\ y = \begin{pmatrix} -F^{-1}(x)d(x)b(x)^T(P_x^-(x) - P_x^+(x))^T \\ \qquad -(X_x^-(x) - X_x^+(x))^T P_x^-(x)^T \end{pmatrix} \\ \qquad + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u, \end{cases}$$

with $\Theta_+ = \Theta_r \circ \Theta_c$ given by (37), *P^- and P^+ satisfying* (10) *and* (13), *respectively, and X^- and X^+ satisfying* (7). *Furthermore, we have that $\Theta_2' \circ \Theta_2''$ is a coprime inner-inner factorization.*

Proof. The proof of this result follows directly from Theorems 7 and 14 above. □

5. An illustrative example. By way of illustration we discuss how the robust stabilization problem that was treated in [33] (see also [6]) by using the certainty equivalence principle can be solved in terms of concepts related to the spectral factorization problem discussed in this paper. Before we present the example, we provide some background from nonlinear H_∞-control that will prove useful. Consider the nonlinear plant $P : \binom{w}{u} \to \binom{z}{y}$ with state space realization

$$P : \begin{cases} \dot{x} = A(x) + B_1(x)w + B_2(x)u, & w \in \mathbf{R^{n_w}}, \quad u \in \mathbf{R^{n_u}}, \\ z = C_1(x) + D_{12}(x)u, & z \in \mathbf{R^{n_z}}, \\ y = C_2(x) + D_{21}(x)w, & y \in \mathbf{R^{n_y}}, \end{cases} \tag{42}$$

where w is a reference and/or disturbance, u is the control, z is the error, and y is a measurement. The nonlinear H_∞-problem is to design a dynamic compensator $K : y \to u$ of the form

$$K : \begin{cases} \dot{x}_K = A_K(x_K) + B_K(x_K)y, \\ u = C_K(x_K) + D_K(x_K)y, \end{cases} \tag{43}$$

with the properties that (42) and (43) are internally stable and the closed-loop input-output map with $x(0) = 0$ and $x_K(0) = 0$ has L_2-gain at most γ, i.e.,

$$\|z\|_2 \leq \gamma \|w\|_2$$

for all $w \in L_2^{n_w}(\mathbf{R}^+)$. In the above, the assumption is that

$$A(0) = 0,\ C_1(0) = 0,\ C_2(0) = 0,\ A_K(0) = 0,\ C_K(0) = 0,$$

and all functions $A, B_1, B_2, C_1, C_2, D_{12}$, and D_{21} are smooth. Internal stability may be taken in either the input-output sense or the internal state space sense.

From [6] (see also [5]), we have that, under the additional assumptions that $D_{21}(x)$ is square and invertible for all x and $A(x) - B_1(x)D_{21}(x)^{-1}C_2(x)$ is asymptotically stable, the disturbance feedforward case of the nonlinear H_∞-control problem mentioned earlier can be reduced to a spectral factorization problem via an inner-outer factorization problem. This problem can, in turn, be reduced to solving a Hamilton–Jacobi equation with stabilizing side condition. More specifically, solutions of the type given by K in (43) of the disturbance feedforward case of the nonlinear H_∞-control problem for the plant P in (42) can be related to an inner-outer factorization of the form

$$G = \Omega \circ \Sigma_-.$$

Here G has the same trajectories as P and leads to a Hamilton–Jacobi equation with stabilizing side condition, Ω is an inner system, and Σ_- is a stable minimum phase (outer) spectral factor that is at least right-sided invertible (see Proposition 1). As is well known, it may be difficult to find an explicit solution for the aforementioned Hamilton–Jacobi equation. However, in the example below, we demonstrate that with additional assumptions on the plant P, the associated Hamilton–Jacobi equation may be solved explicitly.

For the ensuing example, we consider the zero-state detectable system

$$\Omega : \begin{cases} \dot{x} = q(x) + r(x)u, & q(0) = 0, \quad u \in \mathbf{R^m}, \\ y = s(x), & s(0) = 0, \quad y \in \mathbf{R^m}, \end{cases} \tag{44}$$

where q and s are smooth functions and x is contained in the state manifold $\mathcal{X}$. We assume that Ω is an inner system with the property that there exists a storage function $H : \mathcal{X} \to \mathbf{R}$ with $H(0) = 0$ and $H(x) > 0$ for $x > 0$ such that

$$\frac{d}{dt}\{H(x(t))\} = u(t)^T y(t) \tag{45}$$

over all trajectories $(u(t), x(t), y(t))$ of Ω or, equivalently,

$$H_x(x)q(x) = 0,\ H_x(x)r(x) = s(x)^T.$$

The perturbation Ω_p of Ω that comes from the normalized kernel representation of Ω (see [33]) has the form

$$P\colon \begin{cases} \dot{x} = q(x) + r(x)u + r(x)w, w \in \mathbf{R^m}, \\ z = \begin{pmatrix} u \\ y \end{pmatrix}, \\ y = s(x)^T H_x(x)^T + w. \end{cases} \tag{46}$$

We are now in a position to state the robust stabilization problem (see [33]) that we will solve by using a spectral factorization approach.

Problem. Construct a measurement feedback law $K : y \to u$ to minimize the L_2-gain from w to z for the resulting closed-loop system.

First, we introduce a related system G that has the same trajectories as P in (46) but with inputs equal to (u, y) and outputs equal to (z, w). In this case, G may be given by

$$G: \begin{cases} \dot{x} = [q(x) - r(x)r(x)^T H_x(x)^T] + r(x)u + r(x)w, \\ z = \begin{pmatrix} u \\ y \end{pmatrix}, \\ \widetilde{w} = -\gamma s(x)^T H_x(x)^T + \gamma y. \end{cases} \tag{47}$$

With G in (47), we can associate the Hamilton–Jacobi equation

$$P_x(x)[q(x) - (1-\gamma^2)^{-1} r(x)r(x)^T H_x(x)^T] - \frac{1}{2}[(1-\gamma^2)^{-1} + 1] \times P_x(x)r(x)r(x)^T P_x(x)^T - \frac{1}{2}\gamma^2(1-\gamma^2)^{-1} H_x(x)r(x)r(x)^T H_x(x)^T = 0$$

with stability side condition

$$q(x) - (1-\gamma^2)^{-1} r(x)r(x)^T H_x(x)^T - (2-\gamma^2)(1-\gamma^2)^{-1} r(x)r(x)^T P_x(x)^T$$

as being asymptotically stable. Next, we note that (48) has the solution

$$P(x) = \gamma^2(\gamma^2 - 2)^{-1} H(x)$$

for $\gamma > \sqrt{2}$. From this, it is possible to find an explicit formula for a stable minimum phase (outer) spectral factor Σ_- (compare Σ_- in (9); see details in [6]) in the inner-outer factorization $G = \Omega \circ \Sigma_-$ given by

$$\Sigma_-: \begin{cases} \dot{x} = [q(x) - r(x)r(x)^T H_x(x)^T] + r(x)u + r(x)w, \\ \begin{pmatrix} u' \\ y' \end{pmatrix} = \overline{d}(x) \left[\begin{pmatrix} \gamma^2(\gamma^2-2)^{-1} r(x)^T H_x(x)^T \\ \gamma^2(\gamma^2-2)^{-1}(\gamma^2-1)^{-1} r(x)^T H_x(x)^T \end{pmatrix} + \begin{pmatrix} u \\ y \end{pmatrix} \right], \end{cases}$$

where $\overline{d}(x) = \begin{pmatrix} 1 & 0 \\ 0 & \sqrt{\gamma^2 - 1} \end{pmatrix}$. In [6] it was found that the solution K_c (also known as the central compensator) of the robust stabilization problem may be deduced from this outer spectral factor Σ_- by putting $u' = 0$. In fact, an explicit formula for this controller, which corresponds exactly to the one in [33], is given by

$$K_c: \begin{cases} \dot{x} = q(\widehat{x}) - r(\widehat{x})r(\widehat{x})^T H_x(\widehat{x})^T \\ \qquad - \gamma^2(\gamma^2-2)^{-1} r(\widehat{x})r(\widehat{x})^T H_x(\widehat{x})^T + r(\widehat{x})y \\ \quad = [q(\widehat{x}) - \gamma^2(\gamma^2-2)^{-1} r(\widehat{x})r(\widehat{x})^T H_x(\widehat{x})^T] \\ \qquad + r(\widehat{x})[y - r(\widehat{x})^T H_x(\widehat{x})^T]y, \\ u = -\gamma^2(\gamma^2-2)^{-1} r(\widehat{x})r(\widehat{x})^T H_x(\widehat{x})^T. \end{cases}$$

6. Conclusions and future directions. This paper enables us to obtain nonlinear analogues of results in [11, 12, 13, 21] and [22], where state space formulas for nonsquare spectral factors of given size and related unitary or inner functions were derived. We use the Ball–Helton–van der Schaft nonlinear factorization theory [1, 2, 6, 14] and several recent contributions [3, 20, 25, 26, 27] to establish the equivalence between stable nonsquare spectral factors and coprime inner-inner factorizations of inner systems. In addition, we demonstrate the utility of the spectral factorization problem discussed in the above by applying it to issues that arise in the context of the nonlinear H_∞-control problem. More specifically, we investigate how the robust stabilization problem discussed in [33] (see also [6]) can be solved in terms of concepts related to the spectral factorization problem.

Several interesting open problems involving nonlinear spectral factorization (and the related inner-outer factorization) remain. For instance, a characterization of the relationship between the spectral factorization problem for nonlinear control systems and the control of mechanical systems requires further investigation (see [17] and [32]). Another issue that requires attention in the future is the solvability of the Hamilton–Jacobi equations. Here we assume throughout that the solutions of said equations are smooth. If this assumption is removed, we will probably have to work with viscosity-type solutions. Furthermore, we would like to obtain analogues of the results presented in this paper in a nonminimal setting. We suspect that in such a situation, it may still be true that inner systems may be expressed in terms of the solutions of Hamilton–Jacobi equations. A consideration of spectral factors that are nonstable, where a functional Hamilton–Jacobi equation may be used instead of the one used in earlier discussions appears to be another interesting topic to be researched. The establishment of further connections between nonlinear systems and control theory and financial mathematics (see [24] and [28]) seems to be a fertile area of endeavor related to our discussions in this paper. For instance, it has recently been discovered that it is possible to attach an economic interpretation to the state space associated with (minimal) realizations of certain input-affine interest rate models. As a result, standard factorization theory has a significant part to play in advancing that field of research.

BACKSTEPPING WITH BOUNDED FEEDBACKS FOR TIME-VARYING SYSTEMS*

FREDERIC MAZENC† AND SAMUEL BOWONG‡

Abstract. A family of time-varying nonlinear systems is globally uniformly asymptotically stabilized by bounded feedbacks constructed through a new extension of the backstepping approach. Explicit expressions of control laws and Lyapunov functions are given.

Key words. backstepping, bounded feedback, time-varying system

1. Introduction. One of the most popular nonlinear techniques of design of control laws is the backstepping approach. The multiple advantages offered by it are well known. Observe in particular that this technique yields a wide family of globally asymptotically stabilizing control laws, and it allows one to address robustness issues and to solve adaptive problems. However, for a long time, it was a widely held belief that this technique could not be used to solve the problem of designing feedbacks bounded in norm, which in many practical situations should be addressed: For instance, the possibility of actuator saturation or constraints on actuators imposes bounded input. But it turns out that, as a matter of fact, the backstepping approach can be adapted to the problem of designing bounded feedbacks. In three recent works [22, 2, 10], it is shown that for some time-invariant systems (an n-dimensional chain of integrators, for instance), bounded stabilizing feedbacks can be constructed by applying new versions of this technique: The approach of [22, 2] mainly relies on the nested saturation control laws proposed in [18, 20], and the approach of [10] mainly relies on the determination of a particular family of control Lyapunov functions. However, for families of time-varying systems, no bounded backstepping method has ever been developed, and the main results of [22, 2] and [10] cannot be straightforwardly extended.

In the present work, we address the problem of constructing globally uniformly asymptotically stabilizing differentiable bounded feedbacks and accompanying strict Lyapunov functions, using the backstepping approach for time-varying systems of the following form:

$$\begin{cases} \dot{x} = f(t,x) + g(t,x)z, \\ \dot{z} = p(t)(u + b(t,x,z)) \end{cases} \tag{1}$$

with $x \in R^{n_x}$, $z \in R$, where $u \in R$ is the input, $p(t)$ is a bounded function of t, and $f(t,x)$ and $b(t,x,z)$ satisfy $f(t,0) = 0$, $b(t,0,0) = 0$ for all t.

In the particular case where $p(t)$ is a continuous function larger (resp., smaller) than a strictly positive real number (resp., a strictly negative real number), then a

Lyapunov design of bounded feedbacks can be carried out, for instance, by combining the results of [23, 24] and [22]. But when $p(t)$ is a time-varying function which is neither strictly positive nor strictly negative, then the construction of globally uniformly stabilizing feedbacks and accompanying strict Lyapunov functions for systems (1) is a challenging open problem: To the best of our knowledge, no technique of construction of this type of Lyapunov functions is available in the literature, even in the case where the systems (1) are stabilized by unbounded control laws. We want to emphasize that in the present paper, we *will not impose* on $p(t)$ to be a function which is never equal to zero: We will only assume that $p(t)$ satisfies a persistency of excitation property and is of class C^1. Observe that the study of nonlinear time-varying systems is motivated in particular by the fact that a tracking problem for a nonlinear system can be reformulated as a stabilization problem for the time-varying error system. Through the family of chained form nonholonomic systems, we will show in section 4 how tracking problems for nonlinear systems may lead to the study of systems of the form (1), where $p(t)$ is a function which takes positive and negative values, and how, by applying the main result of the present work repeatedly, one can solve the open problem of determining explicit expressions of globally uniformly asymptotically and locally exponentially stabilizing bounded feedbacks and of accompanying strict Lyapunov functions for time-varying chains of integrators, which in turn implies that one can solve the problem of constructing globally uniformly asymptotically and locally exponentially stabilizing bounded feedbacks and accompanying strict Lyapunov functions for error equations of systems in chained form.

The approach we propose relies extensively on two results. On the one hand, we exploit the family of changes of coordinates used in [10] to obtain explicit expressions of globally uniformly asymptotically stabilizing bounded feedbacks. On the other hand, we construct explicitly strict Lyapunov functions using the main result of [9].

Observe that the strict Lyapunov functions (which at the same time are control Lyapunov functions) we will construct are not just tools enabling us to establish the asymptotic stability of the closed-loop system: The knowledge of continuously differentiable strict Lyapunov functions can be of great help. The potential benefits they offer are so numerous that they cannot be exhaustively enumerated. However, observe in particular the following:

- Recent advances in stabilization of nonlinear delay systems are based on the knowledge of continuously differentiable Lyapunov functions (see in particular [21, 3, 11]).
- Lyapunov functions are known to be very efficient tools for robustness analysis: For example, many proofs of nonlinear disturbance-to-state L^p stability properties rely on Lyapunov functions (see [19, 8]). Moreover, the control Lyapunov function–based theory has provided control designs with guaranteed robustness to different types of disturbances, including deterministic [1] and stochastic [6], as well as the robustness to unmodeled dynamics [13, 15].
- When a control Lyapunov function satisfying the small control property is available, one can apply universal formulas, in particular the one proposed in [16], and obtain that way the expression of an asymptotically stabilizing feedback which is optimal with respect to the control Lyapunov function as optimal value function.

The expressions of the bounded control law and of the Lyapunov function we propose are far from being the only possible expressions that can be obtained; many different formulas can be determined. Moreover, many extensions of the result can

be proved; we have briefly mentioned some of them in the discussion of the main result given in section 3 and in the concluding remarks of section 5. For the sake of clarity, we have chosen to restrict ourselves to the systems (1); the control design can be easily carried out for them. However, it is worth noting that the key ideas of our approach can be used in several contexts beyond the scope of the present work. In particular, they can be utilized to solve the problem of constructing bounded feedbacks for systems of the form

$$\begin{cases} \dot{x} = f(t,x,z) + h(t,x,z,u)u, \\ \dot{z} = p(t)u + b(t,x,z), \end{cases} \tag{2}$$

which, due to the term $h(t,x,z,u)u$, are not in feedback form.

The paper is organized as follows. In section 2, a technical lemma is given. In section 3 the main result is stated and proved. The technique is applied to an illustrative example in section 4. Concluding remarks in section 5 end the work.

Preliminaries.

1. The argument of the functions will be omitted whenever no confusion can arise from the context.

2. We assume throughout the paper that the functions encountered are sufficiently smooth.

3. For a real-valued C^1 function $k(\cdot)$, we denote by $k'(\cdot)$ its first derivative.

4. $|x| = \sqrt{x^\top x}$ stands for the Euclidean norm of vector $x \in R^{n_x}$.

5. A function $k(\cdot) : R_{\geq 0} \to R_{\geq 0}$ is of class $\mathcal{K}_\infty$ if it is continuous, zero at zero, strictly increasing, and unbounded.

6. By S, we denote the set of the functions $\sigma : R \to R$ such that

(a) $\sigma(s)$ is a bounded function,

(b) $s\sigma(s)$ is positive definite,

(c) $s\sigma(s) \leq s^2$,

(d) $\sigma'(s)$ is nonnegative and bounded and $\sigma'(0) = 1$.

7. A function $V(\cdot)$ is a strict Lyapunov function for the time-varying system

$$\dot{\chi} = \varphi(t,\chi)$$

if there exists a positive definite function $W(\chi)$ such that, for all t and χ,

$$\frac{\partial V}{\partial \chi}(t,\chi)\varphi(t,\chi) + \frac{\partial V}{\partial t}(t,\chi) \leq -W(\chi)$$

and there exist two functions $\Gamma_1(\cdot), \Gamma_2(\cdot)$ of class $\mathcal{K}_\infty$ such that, for all t and χ,

$$\Gamma_1(|\chi|) \leq V(t,\chi) \leq \Gamma_2(|\chi|).$$

2. Technical result. In this section, we give a technical result which will be used in the next section to prove the main result of the work. We construct a strict Lyapunov function for the one-dimensional time-varying system

$$\dot{\xi} = -q(t)\sigma(\xi), \tag{3}$$

where $q(t)$ is a nonnegative function of class C^1 such that

$$0 \leq q(t) \leq \delta_1 \qquad \forall t, \tag{4}$$

$$\int_t^{t+T} q(s)ds \geq \delta_2 > 0 \qquad \forall t, \tag{5}$$

where δ_1, δ_2, and T are positive real numbers and where $\sigma(\cdot)$ belongs to the set S defined in the preliminaries. We carry out the construction by adapting the approach of [9] to the case where $q(t)$ is not necessarily a periodic function of t but satisfies the persistency of excitation condition (5). First, observe that the property $0 \leq s\sigma(s) \leq s^2$ implies that the function $\frac{|\sigma(s)|}{|s|}$ is bounded. Moreover, $\sigma'(\cdot)$ is bounded and (4) is satisfied. It follows that

$$M := \sup_{t\in R}\left[T + \left|\int_t^{t+T}(s-t-T)q(s)ds\right| \sup_{s\in R, s\neq 0}\left(\frac{|\sigma(s)| + |s\sigma'(s)|}{|s|}\right)\right] \tag{6}$$

is finite and positive. We are now in position to give a technical lemma.

LEMMA 2.1. *The function*

$$\nu(t,\xi) := (M+1)\xi^2 + \left(\int_t^{t+T}(s-t-T)q(s)ds\right)\xi\sigma(\xi) \tag{7}$$

is a strict Lyapunov function for the system (3).

REMARK 1. *When $q(t)$ is a periodic function, then $\nu(t,\xi)$ is a periodic function of t as well, and these functions have the same period.*

Proof. The derivatives of the functions

$$R_1(t,\xi) := \left(\int_t^{t+T}(s-t-T)q(s)ds\right)\xi\sigma(\xi), \qquad R_2(\xi) := \frac{1}{2}\xi^2 \tag{8}$$

along the trajectories of (3) satisfy

$$\begin{aligned}\dot{R}_1 &= \left[-\int_t^{t+T} q(s)ds + Tq(t)\right]\xi\sigma(\xi)\\ &\quad - \left[\int_t^{t+T}(s-t-T)q(s)ds\right][\sigma(\xi) + \xi\sigma'(\xi)]\,q(t)\sigma(\xi),\\ \dot{R}_2 &= -q(t)\xi\sigma(\xi).\end{aligned} \tag{9}$$

Further, since

$$\nu(t,\xi) = 2(M+1)R_2(\xi) + R_1(t,\xi), \tag{10}$$

it follows from (9), (6), and (5) that

$$\begin{aligned}\dot{\nu}(t,\xi) &\leq -\left(\int_t^{t+T} q(s)ds\right)\xi\sigma(\xi) + Mq(t)\xi\sigma(\xi) - 2(M+1)q(t)\xi\sigma(\xi)\\ &\leq -\delta_2\xi\sigma(\xi) < 0 \qquad \forall \xi \neq 0.\end{aligned} \tag{11}$$

Moreover, (7) and (6) imply that

$$(M+1)\xi^2 - M\xi^2 \leq \nu(t,\xi) \leq (M+1)\xi^2 + M\xi^2, \tag{12}$$

which results in

$$\xi^2 \leq \nu(t,\xi) \leq (2M+1)\xi^2. \tag{13}$$

According to (11) and (13), the function $\nu(t,\xi)$ is a strict Lyapunov function for the system (3). This concludes the proof. ∎

3. Main result. In this section, we state and prove the main result of the paper. Consider the nonlinear time-varying system (1). We introduce a set of assumptions.

ASSUMPTION A1. *The functions $p(t)$ and $\dot{p}(t)$ are bounded in norm by a positive real number P and two positive numbers T and γ such that, for all t,*

$$\int_t^{t+T} p(s)^2 ds \geq \gamma > 0 \tag{14}$$

are known.

ASSUMPTION A2. *Let ε be a positive real number and n a nonnegative integer. A Lyapunov function $V(t,x)$ such that*

$$\alpha_1(|x|) \leq V(t,x) \leq \alpha_2(|x|), \qquad \left|\frac{\partial V}{\partial x}(t,x)\right| \leq \alpha_3(|x|), \tag{15}$$

where the $\alpha_i(\cdot)$'s are functions of class $\mathcal{K}_\infty$, a positive definite function $W(x)$, and a feedback $z_s(t,x) := p(t)^{n+2}\mu_s(t,x)$, bounded in norm by ε such that $\mu_s(t,0) = 0$ and

$$\frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)[f(t,x) + g(t,x)z_s(t,x)] \leq -W(x), \tag{16}$$

are known. Moreover, the functions

$$|\mu_s(t,x)|, \quad \left|\frac{\partial \mu_s}{\partial t}(t,x)\right|, \quad \left|\frac{\partial \mu_s}{\partial x}(t,x)f(t,x)\right|, \quad \left|\frac{\partial \mu_s}{\partial x}(t,x)g(t,x)\right|, \quad |b(t,x,z)| \tag{17}$$

are bounded.

ASSUMPTION A3. *A real-valued function $\zeta(\cdot)$ such that $\zeta(s) > 0$ for all $s \neq 0$ and $\int_0^r \zeta(s)ds$ is of class $\mathcal{K}_\infty$, a function $\alpha_4(\cdot)$ of class $\mathcal{K}_\infty$, and a nonnegative function $\beta(\cdot)$ such that the inequalities*

$$\zeta(V(t,x))\left|\frac{\partial V}{\partial x}(t,x)g(t,x)\right|^2 \leq \frac{1}{2}W(x), \tag{18}$$

$$|f(t,x)| \leq \alpha_4(|x|)\ ,\ |g(t,x)| \leq \beta(|x|) \tag{19}$$

are satisfied for all t, x are known.

ASSUMPTION A3′. *The function $W(x)$ is such that, for a real number $c_1 > 0$,*

$$W(x) \geq c_1|x|^2 \qquad \forall x : |x| \leq 1. \tag{20}$$

THEOREM 3.1. *Assume that the system* (1) *satisfies Assumptions* A1, A2, *and* A3. *Then the system* (1) *is globally uniformly asymptotically stabilizable by a bounded feedback $u_s(t,x,z)$ such that, for all t, $u_s(t,0,0) = 0$. For the corresponding closed-loop system, a strict Lyapunov function can be constructed. This Lyapunov function belongs to the family of functions of the form*

$$U(t,x,z) = l(V(t,x)) + k(\nu(t,\Omega(z) - z_s(t,x))) \tag{21}$$

with

$$\nu(t,Z) = (M+1)Z^2 + \left(\int_t^{t+T}(s-t-T)p(s)^{2m}ds\right)Z\sigma(Z), \tag{22}$$

where m is a positive integer, $l(\cdot), k(\cdot)$ are functions of class $\mathcal{K}_\infty$, and $\Omega(\cdot)$ is a real-valued function zero at zero such that $\Omega'(z) \geq 1$ for all z. If in addition Assumption A3′ *is satisfied, the system* (1) *is globally uniformly asymptotically and locally exponentially stabilizable by a bounded feedback $u_s(t,x,z)$ such that, for all t, $u_s(t,0,0) = 0$, and a strict Lyapunov function for the corresponding closed-loop system with a derivative along the trajectories upper bounded on a neighborhood of the origin by a negative definite quadratic function of (x,z) can be constructed. This Lyapunov function belongs to the family of functions* (21).

Discussion of Theorem 3.1.

- All the real-valued periodic functions of class C^1 which are not identically equal to zero satisfy Assumption A1. In the particular case where, for all t, $p(t) > 0$ or $p(t) < 0$, a simpler proof than the one we shall give can be carried out by taking advantage of the change of feedback $v = p(t)(u + b(t,x,z))$. But assuming that, for all t, $p(t) > 0$ or $p(t) < 0$ is very restrictive.
- The boundedness property of the functions in (17) in Assumption A2 and the growth property in Assumption A3 are not surprising assumptions: In the time-invariant case, similar assumptions have been imposed (see [2, 10]). Due to the finite escape time phenomenon, they cannot be removed without being replaced by other assumptions.
- Assumption A3′ ensures that the feedback $z_s(t,x)$ not only globally uniformly asymptotically stabilizes the origin of x-subsystem of (1) but also locally exponentially stabilizes it.
- In the formula of the stabilizing feedback we shall construct (see (27)), the function $V(t,x)$ is not involved: So it turns out that the control design strategy we propose can be applied even when the function $V(t,x)$ is not accurately known.
- An important issue is whether or not Theorem 3.1 can be applied recursively. In general, it appears that the assumptions will not be satisfied repeatedly because the presence of $b(t,x,z)$ in the expression of the control law we will construct (see (27)) typically prevents $u_s(t,x,z)$ and its derivatives along the trajectories from vanishing with $p(t)$. However, in particular cases, Theorem 3.1 can be applied recursively. Basically, this can be done for systems of the form

$$\begin{cases} \dot{x} = f(t,x,z_1), \\ \dot{z}_1 = p_1(t)z_2 + b_1(t,x,z), \\ \quad \vdots \\ \dot{z}_n = p_n(t)u + b_n(t,x,z), \end{cases} \tag{23}$$

  when the $b_i(t,x,z)$'s are identically equal to zero or when, roughly speaking, they are sufficiently "small": Indeed, since one can construct explicitly a globally uniformly asymptotically stabilizing feedback with an accompanying strict Lyapunov function for a system (23) in absence of the $b_i(t,x,z)$'s, one can take advantage of these tools to determine in a second step how "small" the terms $b_i(t,x,z)$, regarded as disturbances, should be for not destroying the stability properties of the system stabilized by the control law constructed in their absence. It is quite clear that the choice of the feedback at each step plays an important role in this approach. In particular at each step the control law must anticipate the $p_i(t)$'s that follow: One understands from the mechanism of the control design used to prove Theorem 3.1 that a possible strategy

of design for the system (23) consists in repeatedly constructing feedbacks, which for convenience we denote $z_{i,f}(t,x,z_1,\dots,z_{i-1})$ for $i=2$ to $n+1$, such that $z_{i,f}(t,x,z_1,\dots,z_{i-1}) = p_i(t)^2\dots p_n(t)^{n-i+2}\psi_i(t,x,z_1,\dots,z_{i-1})$, where $\psi_i(t,x,z_1,\dots,z_{i-1})$'s are sufficiently smooth functions. We will not present a rigorous and complete study of this problem; it would require pages of simple but lengthy calculations which can be inferred from the ideas of the proof of Theorem 3.1. For the sake of simplicity, we restrict ourselves to illustrating the possibility of applying the approach repeatedly by solving in section 4 the problem of stabilizing a three-dimensional chain of integrators with time-varying coefficients.

Proof of Theorem 3.1.

Step 1: *New variable.* We introduce the variable

$$Z := \Omega(z) - z_s(t,x), \tag{24}$$

where $\Omega(\cdot)$ is the function present in (21). In addition to the properties $\Omega(0)=0$ and $\Omega'(z)\geq 1$ for all z, we require that this function be such that

(a) $\Omega'(z)=1$ when $|z|\leq 2\varepsilon$,

(b) $\Omega'(z)\geq |z|$ when $|z|\geq 2\varepsilon+1$.

Its time derivative satisfies

$$\begin{aligned}\dot{Z} &= \Omega'(z)p(t)(u+b(t,x,z)) - \frac{\partial z_s}{\partial t}(t,x) - \frac{\partial z_s}{\partial x}(t,x)[f(t,x)+g(t,x)z]\\ &= \Omega'(z)p(t)(u+b(t,x,z)) + p(t)\lambda(t,x,z)\end{aligned} \tag{25}$$

with

$$\begin{aligned}\lambda(t,x,z) &= -(n+2)\dot{p}(t)p(t)^n\mu_s(t,x) - p(t)^{n+1}\frac{\partial \mu_s}{\partial t}(t,x)\\ &\quad - p(t)^{n+1}\frac{\partial \mu_s}{\partial x}(t,x)[f(t,x)+g(t,x)z].\end{aligned} \tag{26}$$

We choose for u

$$u = u_s(t,x,z) := -b(t,x,z) - \frac{p(t)^{2m-1}\sigma(Z)+\lambda(t,x,z)}{\Omega'(z)}, \tag{27}$$

where m is a positive integer and where $\sigma(\cdot)$ is a function belonging to the set S defined in the preliminaries. Such a choice of feedback yields

$$\dot{Z} = -p(t)^{2m}\sigma(Z). \tag{28}$$

One can check readily that Assumption A1 and the properties of $\sigma(\cdot)$ imply that this system is globally uniformly asymptotically and locally exponentially stable. Our objective is now to construct a strict Lyapunov function for the system (1) in closed-loop with (27) by exploiting the stability properties of (28).

Step 2: *Strict Lyapunov function for the system* (28). Using Young's inequality, one can check readily that Assumption A1 implies that for all positive integer m one can find a positive real number γ_m such that, for all t,

$$\int_t^{t+T} p(s)^{2m}ds \geq \gamma_m > 0. \tag{29}$$

Moreover, $p(t)$ is bounded in norm. It follows that Lemma 2.1 applies to the system (28): The function defined in (22), where

$$M = \sup_{t\in R}\left[T + \left|\int_t^{t+T}(s-t-T)p(s)^{2m}ds\right| \sup_{s\in R, s\neq 0}\left(\frac{|\sigma(s)| + |s\sigma'(s)|}{|s|}\right)\right], \tag{30}$$

is a strict Lyapunov function for the system (28). Its time derivative along the trajectories of (28) satisfies

$$\dot\nu(t,Z) \leq -\left(\int_t^{t+T} p(s)^{2m}ds\right) Z\sigma(Z) \leq -\gamma_m Z\sigma(Z) < 0 \qquad \forall Z \neq 0. \tag{31}$$

Step 3: *Strict Lyapunov function for the system* (1). We construct a strict Lyapunov function for the system (1) in closed-loop with the feedback (27) by using a combination of the Lyapunov functions $V(t,x)$ and $\nu(t,Z)$. This construction is reminiscent of the constructions of Lyapunov functions presented in [17, 12]. Consider a function $U(t,x,z)$, belonging to the family of functions (21), and require that the function $k(\cdot)$ be such that $k'(s) \geq 1$ for all $s \geq 0$. Thanks to Assumption A2, the properties satisfied by the functions $\Omega(\cdot), k(\cdot), l(\cdot)$, and Lemma 2.1, one can prove that there exist two functions $\gamma_1(\cdot)$, $\gamma_2(\cdot)$ of class $\mathcal{K}_\infty$ such that

$$\gamma_1(|(x,z)|) \leq U(t,x,z) \leq \gamma_2(|(x,z)|). \tag{32}$$

The derivative of $U(t,x,z)$ along the trajectories of the closed-loop system satisfies

$$\begin{aligned}\dot U &= l'(V(t,x))\dot V + k'(\nu(t,Z))\dot\nu \\ &\leq -l'(V(t,x))W(x) + l'(V(t,x))\frac{\partial V}{\partial x}(t,x)g(t,x)(z - z_s(t,x)) \\ &\quad - k'(\nu(t,Z))\gamma_m Z\sigma(Z).\end{aligned} \tag{33}$$

From the triangular inequality, the inequality

$$\begin{aligned}\dot U \leq\ & -l'(V(t,x))W(x) + l'(V(t,x))^2\left|\frac{\partial V}{\partial x}(t,x)g(t,x)\right|^2 \\ &+ \frac{1}{4}(z - z_s(t,x))^2 - k'(\nu(t,Z))\gamma_m Z\sigma(Z)\end{aligned} \tag{34}$$

can be deduced. According to Assumption A3, a possible choice for $l(\cdot)$ is $l(r) := \int_0^r \zeta(s)ds$, since this function is of class $\mathcal{K}_\infty$. Moreover, for such a choice, the inequality

$$\dot U \leq -\frac{1}{2}\zeta(V(t,x))W(x) + \frac{1}{4}(z - z_s(t,x))^2 - \gamma_m k'(\nu(t,Z))Z\sigma(Z) \tag{35}$$

is satisfied. Next, observe that

$$Z^2 = (\Omega(z) - z_s(t,x))^2 = (\Omega(z) - \Omega(z_s(t,x)))^2 \tag{36}$$

because $|z_s(t,x)| \leq \varepsilon$ and $\Omega(s) = s$ when $|s| \leq 2\varepsilon$. It follows that

$$Z^2 = \left(\int_{z_s(t,x)}^{z} \Omega'(s)ds\right)^2. \tag{37}$$

Since $\Omega'(s) \geq 1$ for all s, the inequality

$$Z^2 \geq (z - z_s(t,x))^2 \tag{38}$$

holds. Combining (38) and (35) yields

$$\dot{U} \leq -\frac{1}{2}\zeta(V(t,x))W(x) + \frac{1}{4}Z^2 - \gamma_m k'(\nu(t,Z))Z\sigma(Z). \tag{39}$$

Thanks to the inequalities (13) and the properties of $\sigma(\cdot)$, one can easily determine a function $k(\cdot)$ such that

$$\gamma_m k'(\nu(t,Z))Z\sigma(Z) \geq \frac{1}{2}Z^2. \tag{40}$$

This inequality leads to

$$\dot{U} \leq -\frac{1}{2}\zeta(V(t,x))W(x) - \frac{\gamma_m}{2}k'(\nu(t,Z))Z\sigma(Z) \leq -N(x,z), \tag{41}$$

where $N(x,z)$ is the positive definite function

$$N(x,z) := \inf_{t\in R}\left(\frac{1}{2}\zeta(V(t,x))W(x) + \frac{\gamma_m}{2}k'(\nu(t,Z))Z\sigma(Z)\right). \tag{42}$$

It follows that $U(t,x,z)$ is a strict Lyapunov function for the system (1) in closed-loop with the feedback (27). This implies that the system (1) in closed-loop with the feedback (27) is globally uniformly asymptotically stable.

Step 4: *Boundedness of the feedback* (27). Since $\Omega'(z) \geq 1$, $|p(t)| \leq P$, and $|\dot{p}(t)| \leq P$, the inequality

$$\begin{aligned} |u| \leq\ & |b(t,x,z)| + P^{2m-1}|\sigma(Z)| + (n+2)P^{n+1}|\mu_s(t,x)| + P^{n+1}\left|\frac{\partial \mu_s}{\partial t}(t,x)\right| \\ & + P^{n+1}\left|\frac{\partial \mu_s}{\partial x}(t,x)f(t,x)\right| + P^{n+1}\left|\frac{\partial \mu_s}{\partial x}(t,x)g(t,x)\right|\left|\frac{z}{\Omega'(z)}\right| \end{aligned} \tag{43}$$

is satisfied. On the one hand, Assumption A2 ensures that the functions $|b(t,x,z)|$, $|\mu_s(t,x)|$, $|\frac{\partial \mu_s}{\partial t}(t,x)|$, $|\frac{\partial \mu_s}{\partial x}(t,x)f(t,x)|$, and $|\frac{\partial \mu_s}{\partial x}(t,x)g(t,x)|$ are bounded. On the other hand, the functions $\sigma(\cdot)$ and $\Omega(\cdot)$ have been chosen such that $|\sigma(Z)|$ and $|\frac{z}{\Omega'(z)}|$ are bounded. It follows that the feedback (27) is bounded in norm.

Step 5: *The particular case where Assumption* A3′ *is satisfied.* When (20) holds, then, according to (40), the function $N(x,z)$ defined in (42) satisfies

$$N(x,z) \geq \inf_{t\in R}\left(\frac{c_1}{2}\zeta(V(t,x))|x|^2 + \frac{1}{4}Z^2\right) \qquad \forall (x,z) : |x| \leq 1. \tag{44}$$

Assumptions A2, A3, and A3′ ensure that there exists a positive real number c_2 such that

$$c_2\left|\frac{\partial V}{\partial x}(t,x)g(t,x)\right|^2 \leq \frac{c_1}{2}|x|^2 \leq \frac{1}{2}W(x) \qquad \forall (x,z) : |x| \leq 1. \tag{45}$$

It follows that, if necessary, $\zeta(\cdot)$ can be modified in such a way that $\zeta(0) > 0$ and (18) is satisfied. In that case, $c_3 = \inf_{t\in R,|x|\leq 1}(\frac{1}{2}\zeta(V(t,x)))$ is a positive real number and the property

$$N(x,z) \geq c_1c_3|x|^2 + \frac{1}{4}\inf_{t\in R}\left(Z^2\right) \qquad \forall (x,z) : |x| \leq 1 \tag{46}$$

is satisfied. Through lengthy but simple calculations, one can deduce from (46) that there exists a positive real number c_4 such that

$$N(x,z) \geq c_4(|x|^2 + |z|^2) \qquad \forall (x,z) : |(x,z)| \leq 1. \tag{47}$$

This implies that the system (1) in closed-loop with the feedback (27) is globally uniformly asymptotically stable and locally exponentially stable. This concludes the proof. □

4. Illustration: Time-varying chain of integrators. We will illustrate Theorem 3.1 by using it to construct for the particular three-dimensional chain of integrators with time-varying coefficients

$$\begin{cases} \dot{x}_1 = \cos(t)x_2, \\ \dot{x}_2 = \cos(t)x_3, \\ \dot{x}_3 = \cos(t)u \end{cases} \tag{48}$$

a globally uniformly asymptotically and locally exponentially stabilizing bounded state feedback and a strict Lyapunov function for the corresponding closed-loop system. Before doing that, we give a motivation for it.

4.1. Motivation: Systems in chained form. For the sake of simplicity, we will restrict our attention to the system (48). But it is worth noting that Theorem 3.1 can be successfully applied repeatedly to any time-varying chain of integrators

$$\begin{cases} \dot{x}_n = p_n(t)x_{n-1}, \\ \dot{x}_{n-1} = p_{n-1}(t)x_{n-2}, \\ \qquad \vdots \\ \dot{x}_1 = p_1(t)u, \end{cases} \tag{49}$$

where the $p_i(t)$'s are bounded functions with bounded first derivatives such that the product $p_1(t)\cdots p_n(t)$ satisfies Assumption A1.

One of the motivations for solving the problem of globally uniformly asymptotically stabilizing time-varying chains of integrators by bounded feedback arises from the tracking problem for systems in chained form under input saturation. The importance of this family of systems is well known: The kinematic model of several nonholonomic systems can be transformed into a system in chained form, and a lot of interest has been devoted to the stabilization and the tracking of these systems. In particular, in [4, 5, 7] the backstepping approach has been used to achieve for these systems the global tracking of trajectories. Let us briefly recall how. Systems in chained form of order n with two inputs (see, for instance, [14]) are described by the equations

$$\begin{cases} \dot{z}_n = z_{n-1}v_1, \\ \qquad \vdots \\ \dot{z}_3 = z_2 v_1, \\ \dot{z}_2 = v_2, \\ \dot{z}_1 = v_1. \end{cases} \tag{50}$$

Assume that the trajectory to be tracked satisfies

$$\begin{cases} \dot{z}_{n,r}(t) = z_{n-1,r}(t)v_{1,r}(t), \\ \qquad\vdots \\ \dot{z}_{3,r}(t) = z_{2,r}(t)v_{1,r}(t), \\ \dot{z}_{2,r}(t) = v_{2,r}(t), \\ \dot{z}_{1,r}(t) = v_{1,r}(t) \end{cases} \tag{51}$$

and is bounded. Then, after the change of feedbacks $v_1 = v_{1,r}(t)+u_1, v_2 = v_{2,r}(t)+u_2$, and denoting $v_{1,r}(t)$ simply by $p(t)$, the error equation is

$$\begin{cases} \dot{z}_{n,e} = p(t)z_{n-1,e} + z_{n-1}u_1, \\ \qquad\vdots \\ \dot{z}_{3,e} = p(t)z_{2,e} + z_2u_1, \\ \dot{z}_{2,e} = u_2, \\ \dot{z}_{1,e} = u_1, \end{cases} \tag{52}$$

where $z_{i,e} = (z_i - z_{i,r}(t))$ for all $i = 1$ to n. Assume that for the chain of integrators

$$\begin{cases} \dot{z}_{n,e} = p(t)z_{n-1,e}, \\ \qquad\vdots \\ \dot{z}_{3,e} = p(t)z_{2,e}, \\ \dot{z}_{2,e} = u_2 \end{cases} \tag{53}$$

there are a bounded control law $u_2(t, z_e)$ with $z_e = (z_{2,e}, \ldots, z_{n,e})$, a strict Lyapunov function $V_e(t, z_e)$, and a positive definite function $W_e(z_e)$ such that the derivative of $V_e(\cdot)$ along the trajectories of (53) in closed-loop with $u_2(t, z_e)$ satisfies

$$\dot{V}_e \leq -W_e(z_e). \tag{54}$$

Then the derivative of the function

$$U_e(t, z_e, z_{1,e}) = V_e(t, z_e) + \frac{1}{2}z_{1,e}^2 \tag{55}$$

along the trajectories of (52) in closed-loop with $u_2(t, z_e)$ and the bounded feedback

$$u_1(t, z_{1,e}, z_e) = -\frac{\frac{\partial V_e}{\partial z_{n,e}}(t, z_e)z_{n-1} + \cdots + \frac{\partial V_e}{\partial z_{3,e}}(t, z_e)z_2 + z_{1,e}}{1 + \left(\frac{\partial V_e}{\partial z_{n,e}}(t, z_e)z_{n-1}\right)^2 + \cdots + \left(\frac{\partial V_e}{\partial z_{3,e}}(t, z_e)z_2\right)^2 + z_{1,e}^2} \tag{56}$$

satisfies

$$\dot{U}_e \leq -W_e(z_e) - \frac{\left(\frac{\partial V_e}{\partial z_{n,e}}(t, z_e)z_{n-1} + \cdots + \frac{\partial V_e}{\partial z_{3,e}}(t, z_e)z_2 + z_{1,e}\right)^2}{1 + \left(\frac{\partial V_e}{\partial z_{n,e}}(t, z_e)z_{n-1}\right)^2 + \cdots + \left(\frac{\partial V_e}{\partial z_{3,e}}(t, z_e)z_2\right)^2 + z_{1,e}^2}. \tag{57}$$

One can check readily that this implies that $U_e(\cdot)$ is a strict Lyapunov function for the system (52) in closed-loop with the bounded feedbacks $u_1(t, z_{1,e}, z_e)$, $u_2(t, z_e)$.

Consequently, we have shown that the problem of determining globally uniformly asymptotically stabilizing bounded feedbacks and strict Lyapunov functions for error equations resulting from the problem of tracking a bounded trajectory of a system in chained form can be reduced to the problem of determining globally uniformly asymptotically stabilizing bounded feedbacks for time-varying chains of integrators (49) and accompanying strict Lyapunov functions.

4.2. Control design for the system (48). We begin the construction with a preliminary result which will be used throughout the remainder of the section.

Preliminary result. By applying Lemma 2.1, one can prove that the derivative of the function

$$V(t,x) = 80x^2 + \left(\int_t^{t+2\pi} (s-t-2\pi)\cos^6(s)ds\right)\frac{x^2}{\sqrt{1+x^2}} \tag{58}$$

along the trajectories of

$$\dot{x} = -\cos^6(t)\frac{x}{\sqrt{1+x^2}} \tag{59}$$

satisfies

$$\dot{V}(t,x) \le -\frac{5\pi}{8}\frac{x^2}{\sqrt{1+x^2}}. \tag{60}$$

Moreover, $V(t,x)$ is periodic of period 2π and

$$70x^2 \le V(t,x) \le 90x^2. \tag{61}$$

We are ready now to carry out the backstepping construction of a bounded feedback for (48) by applying repeatedly the main result of section 3.

The x_1-subsystem. According to the preliminary result, the time derivative of the function $V(t,x_1)$ along the trajectories of (48) satisfies

$$\begin{aligned}\dot{V} &\le -\frac{5\pi}{8}\frac{x_1^2}{\sqrt{1+x_1^2}} + \frac{\partial V}{\partial x_1}(t,x_1)\cos(t)\left[x_2 + \cos^5(t)\frac{x_1}{\sqrt{1+x_1^2}}\right] \\ &\le -\frac{5\pi}{8}\frac{x_1^2}{\sqrt{1+x_1^2}} + 180|x_1|\left|x_2 + \cos^5(t)\frac{x_1}{\sqrt{1+x_1^2}}\right|.\end{aligned} \tag{62}$$

The x_2-subsystem. Consider the variable

$$X_2 = \Omega_a(x_2) + \cos^5(t)\frac{x_1}{\sqrt{1+x_1^2}}, \tag{63}$$

where $\Omega_a(\cdot)$ is the odd function

$$\Omega_a(r) = \int_0^r \left(1 + \max\{0, 9(|s|-2)^3\}\right) ds. \tag{64}$$

An immediate calculation yields

$$\begin{aligned}\dot{X}_2 &= \Omega_a'(x_2)\cos(t)x_3 - 5\sin(t)\cos^4(t)\frac{x_1}{\sqrt{1+x_1^2}} + \cos^6(t)\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}} \\ &= -\cos^6(t)\frac{X_2}{\sqrt{1+X_2^2}} + \Omega_a'(x_2)\cos(t)x_3 + \cos^6(t)\frac{X_2}{\sqrt{1+X_2^2}} \\ &\quad - 5\sin(t)\cos^4(t)\frac{x_1}{\sqrt{1+x_1^2}} + \cos^6(t)\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}}.\end{aligned} \tag{65}$$

Considering x_3 as a fictitious input v and choosing for it

$$v(t,x_1,x_2) = \frac{-\cos^5(t)\frac{X_2}{\sqrt{1+X_2^2}} + 5\sin(t)\cos^3(t)\frac{x_1}{\sqrt{1+x_1^2}} - \cos^5(t)\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}}}{\Omega_a'(x_2)}, \tag{66}$$

the dynamics (65) become

$$\dot{X}_2 = -\cos^6(t)\frac{X_2}{\sqrt{1+X_2^2}}. \tag{67}$$

The derivative of

$$U(t,x_1,X_2) = l(V(t,x_1)) + k(V(t,X_2)) \tag{68}$$

satisfies

$$\begin{aligned}
\dot{U} \leq & -\frac{5\pi}{8}l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} + 180l'(V(t,x_1))|x_1|\left|x_2 + \cos^5(t)\frac{x_1}{\sqrt{1+x_1^2}}\right| \\
& - \frac{5\pi}{8}k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}} \\
\leq & -\frac{5\pi}{8}l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} + 180l'(V(t,x_1))|x_1||X_2| \\
& - \frac{5\pi}{8}k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}} \\
\leq & -\frac{\pi}{2}l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} + \frac{2}{\pi}180^2\sqrt{1+x_1^2}l'(V(t,x_1))X_2^2 \\
& - \frac{5\pi}{8}k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}}.
\end{aligned} \tag{69}$$

Choosing for $l(\cdot)$

$$l(r) = \sqrt{(80-4\pi^2)+r} - \sqrt{80-4\pi^2} \tag{70}$$

leads to

$$\begin{aligned}
\dot{U} \leq & -\frac{\pi}{2}l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} + \frac{180^2\sqrt{1+x_1^2}}{\pi\sqrt{(80-4\pi^2)+(80-4\pi^2)x_1^2}}X_2^2 \\
& - \frac{5\pi}{8}k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}}.
\end{aligned} \tag{71}$$

Choosing for $k(\cdot)$

$$k(r) \;=\; 480\left[\left((80-4\pi^2)+r\right)^{\frac{3}{2}} - \left(80-4\pi^2\right)^{\frac{3}{2}}\right] \tag{72}$$

leads to

$$\dot{U} \leq -\frac{\pi}{2}l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} - \frac{\pi}{2}k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}}. \tag{73}$$

The overall system. From the above analysis, it results that the system (48) is equivalent to the system

$$\begin{cases}
\dot{x}_1 \;=\; \cos(t)x_2, \\
\dot{X}_2 \;=\; -\cos^6(t)\dfrac{X_2}{\sqrt{1+X_2^2}} + \Omega_a'(x_2)\cos(t)(x_3 - v(t,x_1,x_2)), \\
\dot{x}_3 \;=\; \cos(t)u
\end{cases} \tag{74}$$

with $x_2 = \Omega_a^{-1}(X_2 - \cos^5(t)\frac{x_1}{\sqrt{1+x_1^2}})$. Using the inequality

$$\begin{aligned}(75)\qquad &\frac{(k^{-1})'(U(t,x_1,X_2))}{\sqrt{1+k^{-1}(U(t,x_1,X_2))}}\left[\left|\frac{\partial U}{\partial X_2}((t,x_1,X_2))\right| + \left|\frac{\partial U}{\partial x_1}((t,x_1,X_2))\right|\right]\\ &\qquad \le\ c\left(l'(V(t,x_1))\frac{x_1^2}{\sqrt{1+x_1^2}} + k'(V(t,X_2))\frac{X_2^2}{\sqrt{1+X_2^2}}\right),\end{aligned}$$

where c is a positive constant,[1] and observing that the function $\int_0^r \frac{(k^{-1})'(s)}{\sqrt{1+k^{-1}(s)}}ds$ is of class $\mathcal{K}_\infty$, one can prove that Assumptions A1, A2, A3, and A3′ of Theorem 3.1 are satisfied by the system (74) with $(x_1, X_2)^\top$ playing the role of x, x_3 playing the role of z, and $U(\cdot)$ playing the role of $V(\cdot)$. It follows that the construction of a globally uniformly asymptotically and locally exponentially stabilizing bounded feedback for the system (74) can be achieved. The last part of the section is devoted to this construction.

The function $v(t, x_1, x_2)$ defined in (66) satisfies

$$(76)\qquad |v(t,x_1,x_2)| \le \frac{6+|x_2|}{1+\max\{0,(|x_2|-2)^3\}} \le 10.$$

These inequalities lead one to consider the change of variable

$$(77)\qquad X_3 = \Omega_b(x_3) - v(t,x_1,x_2),$$

where $\Omega_b(\cdot)$ is the odd function defined as

$$(78)\qquad \Omega_b(r) = \int_0^r \left(1+\max\{0,21(|s|-20)^3\}\right)ds.$$

Its time derivative satisfies

$$(79)\qquad \dot{X}_3 = \Omega_b'(x_3)\cos(t)u - \dot{v}(t,x_1,x_2)$$

with

$$\begin{aligned}\dot{v} &= \cos^2(t)\zeta(t,x_1,x_2,x_3),\\ \zeta &= \frac{5\left[\sin(t)\cos^2(t)\left(\frac{X_2}{\sqrt{1+X_2^2}}+\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}}\right)+(\cos^4(t)+3\sin^2(t))\frac{x_1}{\sqrt{1+x_1^2}}\right]}{1+\max\{0,9(|x_2|-2)^3\}}\\ &\quad + \frac{\cos^2(t)}{1+\max\{0,9(|x_2|-2)^3\}}\left[\frac{5\sin(t)}{(1+x_1^2)^{\frac{3}{2}}}x_2 - \frac{3\cos^2(t)x_2^2}{(1+x_1^2)^{\frac{5}{2}}} - \cos^3(t)\frac{x_3}{(1+x_1^2)^{\frac{3}{2}}}\right]\\ &\quad - \frac{\cos^4(t)\left[(1+\max\{0,9(|x_2|-2)^3\})x_3 - 5\sin(t)\cos^3(t)\frac{x_1}{\sqrt{1+x_1^2}}+\cos^5(t)\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}}\right]}{(1+\max\{0,9(|x_2|-2)^3\})(1+X_2^2)^{\frac{3}{2}}}\\ &\quad + \cos(t)\frac{\cos^2(t)\frac{X_2}{\sqrt{1+X_2^2}} - 5\sin(t)\frac{x_1}{\sqrt{1+x_1^2}}+\cos^2(t)\frac{x_2}{(1+x_1^2)^{\frac{3}{2}}}}{(1+\max\{0,9(|x_2|-2)^3\})^2}\max\{0,27(|x_2|-2)^2\}.\end{aligned}\qquad(80)$$

[1] The explicit value of c can be determined through lengthy calculations. But an explicit value is useless; to carry out the proof, it is only required that we know that c exists.

One can check readily that the feedback

$$
\begin{aligned}
u &= \frac{-\cos^5(t)\frac{X_3}{\sqrt{1+X_3^2}} + \cos(t)\zeta(t,x_1,x_2,x_3)}{\Omega_b'(x_3)} \\
&= \frac{-\cos^5(t)\frac{X_3}{\sqrt{1+X_3^2}} + \cos(t)\zeta(t,x_1,x_2,x_3)}{1+\max\{0,21(|x_3|-20)^3\}}
\end{aligned} \tag{81}
$$

yields

$$
\dot{X}_3 = -\cos^6(t)\frac{X_3}{\sqrt{1+X_3^2}}. \tag{82}
$$

Moreover, the feedback u is bounded:

$$
\begin{aligned}
|u| &\le \frac{1+|\zeta(t,x_1,x_2,x_3)|}{1+\max\{0,21(|x_3|-20)^3\}} \\
&\le 25 + \frac{6|x_2|+x_2^2}{1+\max\{0,9(|x_2|-2)^3\}} + \frac{2|x_3|}{1+\max\{0,21(|x_3|-20)^3\}} \le 94.
\end{aligned} \tag{83}
$$

REMARK 2. *The feedback we have constructed is bounded in norm by* 94. *But for all* $\varepsilon > 0$, *one can modify the design in such a way that the resulting control law is bounded by* ε *instead of* 94.

5. Conclusion. We have proposed a new extension of the backstepping technique which applies to time-varying nonlinear systems and thereby can be utilized in particular for solving problems of global tracking. We have proposed families of bounded control laws. We have not explored all the possible extensions of the approach: We want to emphasize that the key ideas of the technique are even more important than the results themselves. Much remains to be done; robustness and disturbance attenuation issues and applications to the control design for systems with delay are some issues that may be pursued.

Acknowledgments. The authors are grateful to the referees and L. Praly for their insightful remarks and suggestions.

LEARNING COMPLEXITY DIMENSIONS FOR A CONTINUOUS-TIME CONTROL SYSTEM*

PIRKKO KUUSELA†, DANIEL OCONE†, AND EDUARDO D. SONTAG†

Abstract. This paper takes a computational learning theory approach to a problem of linear systems identification. It is assumed that inputs are generated randomly from a known class consisting of linear combinations of k sinusoidals. The output of the system is classified at some single instant of time. The main result establishes that the number of samples needed for identification with small error and high probability, independently from the distribution of inputs, scales polynomially with n, the system dimension, and logarithmically with k.

Key words. linear systems identification, learning theory, VC dimension

DOI. 10.1137/S0363012901384302

1. Introduction.

Systems identification may be regarded as an instance of the general problem of "learning" an unknown function. Computational learning theory (CLT), which provides a theory for understanding the complexity of a learning problem, can then be used to obtain new insight into identification; conversely, the input/output maps associated to systems theory supply interesting new families of classifiers to consider in CLT. The early paper by Ljung [16] already explored the connection between CLT and identification. Independently, the papers [6, 7] had already developed learning theory complexity results for discrete-time linear systems acting on finite-window data. However, continuous-time linear systems have not been much explored from the CLT viewpoint. The immediate problem is that even for finite-length inputs, the family of maps associated to a continuous-time linear system is not "learnable" in the precise mathematical sense defined in probably approximately correct (PAC) learning theory; for continuous-time systems, the Vapnik–Chervonenkis (VC) dimension, which measures the learning rate, is infinite. This was proved in [23] and, alternatively, can be derived by applying the discrete-time results from [6, 7] at higher and higher sampling rates. However, if we have prior information on the system we wish to learn, or if we are interested in less than the full input/output map, we can ask if the identification problem becomes learnable in the CLT setting, and if so, how many samples are needed. This is the issue motivating the work of this paper.

In practice, it is not necessary or feasible to learn how a linear system classifies every continuous-time input; it usually suffices to know how it acts on a sufficiently rich class. In this paper we consider continuous-time systems acting on linear combinations of k sinusoidals, which constitute a class of inputs used in assessing frequency responses. The parameter k will then measure the richness of the class. To keep things

as simple as possible, we focus our attention on two cases: (a) the map that gives the sign of the output, observed at a single instant of time, namely, zero-one classifiers; and (b) the full output observed at a single instant of time. For the learning theory framework, we have opted for the cleanest setting. In the training stage, inputs are generated randomly from our class of sinusoidals, and our object is to classify further randomly drawn inputs correctly with high probability.

Variations on the above set-up, such as allowing selection of inputs (called active learning) or modeling noise in the observations, can also be formulated. It is important to emphasize that, in this work, we ignore observations at time instants other than the last. This simplifies the problem and makes it easier to formulate our question in the framework of learning theory. However, a full treatment of the identification question in that framework will require further substantial research. One possibility is to see the additional information afforded by data at intermediate instants as "side information" available to the learner. In general, one expects side information to speed learning, so our results here will bound any learning rates that incorporate it. However, quantifying the advantage of side information in a general learning theory framework is a very challenging problem. A preliminary study of how side information can affect learning rates is carried out in [14, 15], in a simple model of learning intervals. One insight of this study is that the side information advantage very much depends on the probability distributions assumed on the training data and the structure of the problem. Because of this, the possibility of distribution free, model-independent side information improvement in learning rates, based on general complexity measures such as VC dimension, is not even clear; in any case, it is an open and difficult problem.

In summary, the system identification problem is posed as a noise-free parametric function identification problem with observations $\{(G_1, S_1), \ldots, (G_n, S_n)\}$, where $G_1, \ldots, G_n$ are independent random variables defining the input as a linear combination of basis input functions $\omega = (\omega_1, \ldots, \omega_k)^T$ and $S_i = \text{sign}(\Phi_\Sigma(G_i\omega; 1))$, where sign $z = 0$ if $z \leq 0$ and sign $z = 1$ if $z > 0$. Here $\Sigma(u; t)$ is the output of the linear system $\Sigma = (A, B, C, x^0)$ at time t when the input is u.

Our results show that the upper bound of samples needed to learn (i.e., identify) Σ in the above setting with a small error and high probability, independently of the distribution of G_i, scales logarithmically with the "bandwidth" k. The sample bound is analogous to the discrete-time case, in which k appeared as the length of the window employed. Also, we provide lower bounds on the number of samples needed. Hence the results can also be seen as unlearnability results where the difficulty arises from the richness of the input signals. Our second class of results concerns systems, with additional assumptions, in which the full output is observed at some time τ.

Our problem setting is selected so that it corresponds to the most standard learning scenario, which serves as the basic problem. In particular, our focus will be on calculating certain complexity dimensions that determine the number of samples needed to learn, given required accuracy and confidence. The CLT framework can accommodate various learning paradigms, and they share a number of common features. In particular, sample complexities are derived from complexity dimensions. Hence, the complexity dimension estimates from the basic problem can be utilized easily also in modified learning settings. We give more pointers to modified problems in the next section.

For papers combining learning theoretic ideas to control theory, see [11, 9] and references there as well as [12] for several results for nonlinear systems in discrete time. The reader is referred to [19] for results that apply to a class of nonlinear continuous-

time systems but which are formulated in terms of learning derivatives evaluated at a particular instant (as opposed to time data).

This paper is organized in a top-down fashion. We give definitions and main results in section 2, and in section 3 we state main upper and lower bounds for the complexity dimensions. After that we concentrate on proving the results; central techniques are discussed in section 4, and proofs are in sections 5 and 6. An example of a class with VC dimension k is given in section 7.

2. Definitions and statement of main results. The simplest learning setting is concept learning, in which there is some known concept class (e.g., "cars") and some target concept (e.g., "a sports car") we wish to learn from a sequence of N randomly chosen observations. Each observation is classified by some "oracle" that knows the target concept. After N classified observations we are required to form an estimate for the unknown target concept so that with high confidence, specified by parameter δ, the misclassification probability for a future unseen sample is smaller than a given level ϵ. The concept class is *learnable* if we can form an estimate that achieves any given confidence level, δ, and misclassification accuracy, ϵ, by taking enough observations. In this case, the number $s(\epsilon, \delta)$ of observations needed to achieve the confidence and misclassification levels is called the *sample complexity*. With this definition, learnability is equivalent to the finiteness of the VC dimension, which describes the "richness" of the concept class; VC dimension together with confidence parameter δ and accuracy parameter ϵ determine the sample complexity $s(\epsilon, \delta)$.

In the following subsections, we provide formal definitions, frame a linear system learning problem, and state some main results.

2.1. VC dimension and fat-shattering dimension. We begin by defining the key complexity dimension for this work.

Definition 2.1 (Vapnik–Chervonenkis dimension). *The richness of the collection $\mathcal{C}$ can be measured by its Vapnik–Chervonenkis (VC) dimension introduced in* [20]. *A set $S = \{x_1, \ldots, x_n\} \subseteq X$ is said to be* shattered *by $\mathcal{C}$ if, for every subset $B \subseteq S$, there exists a set $A \in \mathcal{C}$ such that $S \cap A = B$. The* VC dimension of $\mathcal{C}$, *denoted $VC(\mathcal{C})$, equals the largest integer n such that there exists a set of cardinality n that is shattered by $\mathcal{C}$.*

For example, in $\mathbb{R}^k$ the VC dimension of closed half-spaces through the origin is k [22]. Thus, if $\mathrm{VC}(\mathcal{C}) = d$, $\mathcal{C}$ is not rich enough to distinguish all subsets of any $d+1$ element set, but there is some d element set where subsets can be distinguished. Proving exact values of the VC dimension is hard, and typically one looks for upper and lower bounds for the VC dimension, as is also done in this paper.

For our purposes, it is more convenient to work with shattering in terms of dichotomies, i.e., Boolean-valued maps. We identify subsets of D with Boolean functions $\phi : D \to \{0, 1\}$. Similarly, each set $C \in \mathcal{C}$ gives rise to a Boolean function on X, and intersections $C \cap D$ are restrictions of functions to D. In this language, a subset $D \subset X$ is shattered by $\mathcal{F} := \{\phi;\ \phi : X \to \{0, 1\}\}$ if every dichotomy on D is a restriction to D of some $\phi \in \mathcal{F}$.

The VC dimension characterizes learnability of $\{0, 1\}$-valued functions, as formulated in section 2.2. For learning real-valued functions we look for a generalization of the VC dimension with similar properties. One such generalization is the pseudo-dimension. Unfortunately, pseudodimension does not share the property the VC dimension has; there are learnable function classes with infinite pseudodimension; see [21, p. 206] and [3].

DEFINITION 2.2 (pseudodimension with respect to a loss function). *Given a class of functions $\mathcal{F} : X \to Y$ and a loss function $L : Y \times Y \to [0, r]$, we introduce for each $f \in \mathcal{F}$ the function*

$$A_{f,L} : X \times Y \times \mathbb{R} \to \{0,1\}; \quad (x, y, \rho) \mapsto \operatorname{sign}(L(f(x), y) - \rho), \tag{1}$$

and let $A_{\mathcal{F},L}$ denote all such $A_{f,L}$ with $f \in \mathcal{F}$. The pseudodimension of $\mathcal{F}$ with respect to the loss function L, *$PD[\mathcal{F}, L]$, is defined as*

$$PD[\mathcal{F}, L] := VC(A_{\mathcal{F},L}).$$

Next we define the fat-shattering dimension that corresponds to shattering with fixed "margin" γ. Both the pseudodimension and the fat-shattering dimension can be used to bound certain covering numbers, and in this sense they act like the VC dimension. Moreover, the fat-shattering dimension gives upper and lower bounds for covering numbers of function classes, and the finiteness of the fat-shattering dimension can characterize learnability (see [1] and [2]).

DEFINITION 2.3 (fat-shattering dimension). *Let $\mathcal{F}$ be a set of real-valued functions. We say that a set of points X is* γ-shattered by $\mathcal{F}$ *if there are real numbers r_x indexed by $x \in X$ such that for all binary vectors b_x indexed by X, there is a function $f_b \in \mathcal{F}$ satisfying*

$$\begin{aligned} f_b(x) &\geq r_x + \gamma \quad \text{if } b_x = 1 \text{ and} \\ f_b(x) &\leq r_x - \gamma \quad \text{otherwise.} \end{aligned}$$

The fat-shattering dimension $\operatorname{fat}_\gamma(\mathcal{F})$ *is a function from positive real numbers to integers which maps a value γ to the size of the largest fat-shattered set if it is finite or infinity otherwise.*

The shattering dimension when the margin γ equals 0 *is called the* pseudodimension, *and it is denoted by $PD(\mathcal{F})$. Clearly, for all $\gamma > 0$, $\operatorname{fat}_\gamma(\mathcal{F}) \leq PD(\mathcal{F})$.*

2.2. Learning. In this section we discuss the learning setting more formally, beginning with a general introduction to classification problems. In section 2.3.1 we also indicate briefly modified learning settings that can be relevant in control problems.

Assume that a set X, to be called the *input space*, is given together with a collection $\mathcal{C}$ of mappings $X \to \{0,1\}$.[1] Let W be the set of all sequences

$$w = (u_1, \phi(u_1)), \ldots, (u_s, \phi(u_s))$$

over all $s \geq 1$, $(u_1, \ldots, u_s) \in X^s$, and let $\phi \in \mathcal{C}$. An *identifier* is a map $\psi : W \to \mathcal{C}$. The value of ψ on a sequence w above is denoted as ψ_w instead of $\psi(w)$. The "error" of ψ is the probability that ψ will misclassify a future sample. More formally, the *error of ψ with respect to a probability measure P on X, a $\phi \in \mathcal{C}$, and a sequence* $(u_1, \ldots, u_s) \in X^s$, is

$$\operatorname{Err}(P, \phi, u_1, \ldots, u_s) := P\{u \in X;\ \psi_w(u) \neq \phi(u)\}.$$

[1] The set X is assumed to be either countable or a Euclidean space, and the maps in $\mathcal{C}$ are assumed to be measurable. In addition, a mild regularity assumption called "permissibility" is needed so that all sets appearing below are measurable; for further discussion on the topic, see an appendix in [17]. In our context the measurability assumptions are satisfied.

The class $\mathcal{C}$ is said to be PAC *learnable* if there is some identifier ψ with the following property: For each *accuracy parameter* $\epsilon > 0$ and *confidence parameter* $\delta > 0$ there is some s so that, for every probability P and every $\phi \in \mathcal{C}$,

$$P^s\{(u_1, \ldots, u_s) \in X^s;\ \mathrm{Err}(P, \phi, u_1, \ldots, u_s) > \epsilon\} < \delta,$$

where P^s is the s-fold product of P. In the learnable case, the function $s(\epsilon, \delta)$ which provides the smallest s achieving for any positive ϵ and δ is called the *sample complexity*. It can be proved that learnability is equivalent to the finiteness of the *VC dimension* $\mathrm{VC}(\mathcal{C})$ of the class $\mathcal{C}$. Moreover, for learning algorithms that classify the observed samples correctly, the sample complexity is bounded by [18]

$$s(\epsilon, \delta) \leq \max\left\{ \frac{1}{\epsilon(1-\sqrt{\epsilon})} \left(2\mathrm{VC}(\mathcal{C}) \ln\left(\frac{6}{\epsilon}\right) + \ln\left(\frac{2}{\delta}\right)\right), \frac{4}{\epsilon}\log_2\left(\frac{2}{\delta}\right)\right\}.$$

In addition, there is a similar lower bound for the sample complexity.

Classification may be viewed as a problem of identifying systems with binary outputs. More generally, we introduce a problem of identification for systems having bounded outputs ($[0,1]$-valued, for technical reasons) via an L^1-error, following [4, 5] (for similar statements with L^2-error see [2]). Denote by $\mathcal{F}$ a class of mappings from X to $[0,1]$.

By definition, an *identifier* is a mapping from $\cup_{s\in\mathbb{N}} (X \times [0,1])^s$ to $[0,1]^X$. Such a map takes as data a sequence of labeled samples and produces a hypothesis. If h is a $[0,1]$-valued function defined on X and P is a probability measure over $X \times [0,1]$, we define the *error of h with respect to P* as

$$\mathrm{Er}_P(h) := \int_{X\times[0,1]} |h(u) - y|\, dP(u,y).$$

For $\epsilon > 0$ and $\delta > 0$ we say that an identifier ψ (ϵ, δ)*-learns in the agnostic sense with respect to $\mathcal{F}$ from s examples* if, for all distributions P on $X \times [0,1]$,

$$P^s\{w;\ \mathrm{Er}_P(\psi_w) \geq \inf_{f\in\mathcal{F}} \mathrm{Er}_P(f) + \epsilon\} < \delta.$$

Similarly, for $\epsilon > 0$ the function class $\mathcal{F}$ is said to be ϵ*-agnostically learnable* if there is a function $s_0 : (0,1) \to \mathbb{N}$ such that, for all $0 < \delta < 1$, there is an identifier ψ which (ϵ, δ)-learns in the above sense with s_0 samples. In addition, if the identifier always chooses a hypothesis from $\mathcal{F}$, we say that $\mathcal{F}$ is *properly ϵ-agnostically learnable*.

For learning $[0,1]$-valued functions, a sample complexity result may be stated in terms of the fat-shattering dimension. For $\epsilon > 0$ and $\delta > 0$ there is an identifier ψ that properly (ϵ, δ)-learns in the agnostic sense with respect to $\mathcal{F}$ from [4, 5]

$$\frac{4}{\alpha^2}\left(\frac{6d}{\ln 2}\ln\frac{7}{\alpha}\left(\frac{336e}{\alpha^3\ln 2}\ln\frac{7}{\alpha}\right) + \ln\frac{8}{\delta}\right) = O\left(\frac{1}{\alpha^2}\left(d\log^2\frac{1}{\alpha} + \log\frac{1}{\delta}\right)\right)$$

samples, where $0 < \alpha < \epsilon/4$ is chosen so that $d = \mathrm{fat}_{\epsilon/4-\alpha}(\mathcal{F})$ is finite. The quantity $\mathrm{fat}_\gamma(\mathcal{F})$ is called the *fat-shattering dimension* of the class $\mathcal{F}$, and it measures the richness of the class $\mathcal{F}$ with scale γ.

The sample complexity results show us that the difficulty of system identification in the learning theoretic setting can be analyzed by studying various complexity dimensions, and deriving bounds on the complexity dimension is the main focus of this paper.

2.3. Linear systems. In the context of learning we discuss continuous-time linear control systems

$$\dot{x} = Ax + Bu, \qquad x(0) = x^0, \qquad y = Cx, \tag{2}$$

where A, B, and C are $n \times n$, $n \times m$, and $p \times n$ real matrices, and the time interval is [0,1]. We study sign-observations (see [13] for related work in control theory)

$$\text{sign } y(1) = (\text{sign } y_1(1), \ldots, \text{sign } y_p(1))^T,$$

where sign $z = 0$ if $z \leq 0$, sign $z = 1$ if $z > 0$, and ^{T} stands for the transpose. For scalar observations this is a classification problem; each output is classified as either 0 or 1. The value of the final time plays no role in the results and is taken to be 1 for notational convenience.

Unlike the VC dimension associated to discrete-time linear systems [6, 12], the VC dimension of the classification problem for continuous-time control systems is unbounded [23], even when $n = 1$, and the identification problem is not learnable in the sense discussed earlier. Therefore, we restrict the class of admissible controls in order to achieve a bound for the VC dimension. We consider controls $u = (u_1, \ldots, u_m)$ such that $u = G\omega$, where G is an $m \times k$ matrix that parameterizes the control. The set of basis input functions $\Omega = \{\omega_1, \ldots, \omega_k\}$ is fixed. The bounds for the VC dimension or other complexity dimensions will depend on the properties of the set Ω.

For scalar inputs (i.e., $m = 1$) the VC dimension associated to the mapping from inputs G to scalar sign-observations is bounded by k, which in fact can be very large in applications.[2] However, by considering band-limited controls a better bound can be achieved. In this work we consider the set of basis input functions

$$\begin{aligned} \Omega = \Big\{ & \omega_1, \ldots, \omega_k; \ \omega_1, \ldots, \omega_k \text{ linearly independent and} \\ & \omega_j = t^{\ell_j} e^{\alpha_j t} \sin(\beta_j t) \text{ or } \omega_j = t^{\ell_j} e^{\alpha_j t} \cos(\beta_j t) \\ & \text{with } \ell_j \in \mathbb{N}, \alpha_j, \beta_j \in \mathbb{R}, j = 1, \ldots, k \Big\}, \end{aligned} \tag{3}$$

and let

$$\ell_{\max} = \max\{\ell_1, \ldots, \ell_k\}. \tag{4}$$

The results in this paper hold with straightforward modifications if the basis input functions $\omega_j, j = 1, \ldots, k$, are, for example, linear combinations of functions of the above form.

DEFINITION 2.4 (sign system concept class, $\mathcal{C}_{m,p}$). *Order the set of basis input functions Ω and denote $\omega = (\omega_1, \ldots, \omega_k)^T$. Let*

$$X_\Omega = \{G\omega : [0,1] \to \mathbb{R}^m; \ G \in \mathbb{R}^{mk}\},$$

and for each linear system $\Sigma = (A, B, C, x^0)$ of dimension n define the mapping $\Phi_\Sigma : X_\Omega \to \mathbb{R}^p$ by $\Phi_\Sigma(G\omega) = y(1)$, where $y(1)$ is the solution of Σ with control $u = G\omega$. Similarly, we define the mapping for sign-observations as

$$S_\Sigma : X_\Omega \to \{0,1\}^p, \quad G\omega \mapsto \text{sign}(\Phi_\Sigma(G\omega)).$$

[2] This bound is tight; we give an example of a function class Ω for which the associated VC dimension is indeed k (see section 7).

We call the class of above mappings the sign system concept class, $\mathcal{C}_{m,p} = \{S_\Sigma;\ \Sigma$ *linear system of dimension* $n\}$.

We formulate two theorems about bounding sample complexities as main results. They are immediate corollaries of learning complexity bounds proved in this paper.

THEOREM 2.5 (sample complexity for concept learning). *For sign systems concept class* $\mathcal{C}_{m,1}$ *with scalar observations, i.e.,* $p = 1$*, the sample complexity* $s(\epsilon, \delta)$ *for identifiers which agree with the observed sample can be bounded as*

$$s(\epsilon,\delta) \le \max\left\{ \frac{1}{\epsilon(1-\sqrt{\epsilon})}\left(2\,VC(\mathcal{C}_{m,1})\ln\left(\frac{6}{\epsilon}\right)+\ln\left(\frac{2}{\delta}\right)\right), \frac{4}{\epsilon}\log_2\left(\frac{2}{\delta}\right)\right\},$$

where

$$VC(\mathcal{C}_{m,1}) \le 2(2mn^2+4n+1)\log_2[8e(8mn^2k(n+\ell_{\max})+1)(2nk+2(1+2k)^n)]$$

and $\ell_{\max}$ *is given by* (4).

Sketch of proof. The VC dimension bound is based on the observation that, due to the structure of the input, Ω_Σ can be written as a function of the parameters of Σ which is piecewise rational. (The parameterization is derived from the eigenstructure of matrix A.) The complexity upper bound utilizes the Goldberg–Jerrum bound. (Matching lower bounds are based on the notion of dual VC dimension and axis shattering.) ∎

In terms of n (the dimension of the state space) and k (the bandwidth), the upper bound for the VC dimension is of the form $O(n^3\log_2(nk))$. The next section states also a corresponding VC dimension lower bound, in terms of the bandwidth, of the form $O(\log(k))$, and, together with a lower bound for the sample complexity, this provides an estimate for the number of samples needed in learning. In particular, in a typical setting of fairly small system dimension n and large bandwidth k, the $\log k$ bound is a clear improvement over the linear bound given by elementary analysis.

For learning $[0,1]$-valued functions the role of the VC dimension is replaced by other complexity dimensions such as the pseudodimension or the fat-shattering dimension that give upper bounds on sample complexities in the corresponding learning paradigms. In the setting of learning $[0,1]$-valued functions we consider the time interval $[0,\tau]$, with $\tau > 1$ in order to show the impact of the final time on the sample complexity.

For the system

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ y &= Cx, \end{aligned} \tag{5}$$

we can write $Ce^{At}B = [\gamma_1, \ldots, \gamma_m]$, where each γ_i is a linear combination of n functions $\xi_1, \ldots, \xi_n$. Each ξ_i is of the form $t^\ell e^{at}\sin(bt)$ or $t^\ell e^{at}\cos(bt)$ with $\ell \in \{0, \ldots, n-1\}$ and $a+ib$ an eigenvalue of A. Assume that A has a fixed Jordan block structure, and let a_k+ib_k be an eigenvalue of A. We take $\alpha_{11}, \ldots, \alpha_{nm}, a_1, b_1, \ldots, a_r, b_r$ to be the system parameters, where $\gamma_i(t) = \sum_{j=1}^n \alpha_{ij}\xi_j(t)$ for $i = 1, \ldots, m$ and $a_1, b_1, \ldots, a_r, b_r$ are n eigenvalue parameters. For example, the eigenvalue parameters for a real 4×4 matrix A with eigenvalues $a_1 \pm b_1 i$, a_2, and a_3 would be a_1, b_1, a_2, and a_3. Similarly, the eigenvalue parameters with purely complex eigenvalues $a_1 \pm b_1 i$ and $a_2 \pm b_2 i$ would be a_1, b_1, a_2, and b_2, whereas real eigenvalue parameters would be listed as a_1, a_2, a_3, and a_4.

Let $U \subset \mathbb{R}^{mk}$ be a bounded set. Define a mapping $F : \lambda \times U \to \mathbb{R}$ such that $F(\lambda, u) = y(\tau)$, where $\tau \geq 1$ and $y(\tau)$ is a solution of (5) with system parameters λ and initial condition $x(0) = 0$.

DEFINITION 2.6. *Assume that the system $\dot{x} = Ax + Bu$, $y = Cx$, $x(0) = 0$ can be parameterized by $\lambda \in \mathbb{R}^{n(m+1)}$ as above and $\|\lambda\|_\infty = \max_{1 \leq i \leq n(m+1)} \lambda_i < 1$. Let $F(\lambda, u) = y(\tau)$ be the solution of (5) with system parameters λ and control $u = (u_1, \ldots, u_m) \in U = \{u = (u_1, \ldots, u_m);\ \int_0^\tau |u_i(t)|dt \leq M, i = 1, \ldots, m\}$. Denote $B_\infty^k(c) := \{x \in \mathbb{R}^k;\ \|x\|_\infty < c\}$ and define*

$$\mathcal{F}_B = \{F(\lambda, \cdot) \colon U \to \mathbb{R};\ \lambda \in B_\infty^{n(m+1)}(1)\}.$$

A suitable learning notion for the above function class $\mathcal{F}_B$ is the proper agnostic learning, defined formally in section 2.2. The related sample complexity result is as follows.

THEOREM 2.7 (sample complexity for proper agnostic learning). *Let $1/4 > \kappa > 0$ be an arbitrary real number; then the class $\mathcal{F}_B$, given in Definition 2.6, is properly agnostically learnable from*

$$O\left(\frac{1}{\epsilon^2}\left(\mathrm{fat}_{(1/4-\kappa)\epsilon}(\mathcal{F}_B)\log^2\frac{1}{\epsilon} + \log\frac{1}{\delta}\right)\right)$$

samples, where

$$\mathrm{fat}_{(1/4-\kappa)\epsilon}(\mathcal{F}_B) \leq (m+1)n\log_2\left\lfloor \frac{n^2 m \tau^n e^\tau k M}{(1/4-\kappa)\epsilon} \right\rfloor,$$

and M is a constant satisfying

$$\int_0^\tau |u_i(\tau - t)|dt \leq kM$$

for all $i = 1, \ldots, m$. In the above, $\lfloor x \rfloor$ stands for the integer part of x. If the inputs are of the form $u = G\omega$, then also

$$\mathrm{fat}_{(1/4-\kappa)\epsilon}(\mathcal{F}_B) \leq 2(m+4)n\log_2(8e(nmk4(n+\ell_{\max})+1)(2nk+2(2k+1)^n)),$$

where $\ell_{\max}$ is as given by (3) and (4).

Sketch of proof. The proof is developed around a Lipschitz bound on Ω_Σ as a function of unknown parameters, which gives the upper term in the fat-shattering bound. The lower term in the bound is in turn a pseudodimension bound that can be derived from an associated VC dimension bound. □

2.3.1. Modified learning settings. In this paper we have opted for the standard setting in CLT in which inputs are random and observations are noiseless. However, CLT can accommodate various modified learning settings that typically share common features with the standard setting.

A paradigm in which a learner can select the samples to be classified is called active learning. The set of PAC learnable concept classes is not enlarged by active learning but, in general, fewer training samples are needed (concept classes that are "dense in themselves" make an exception) [8].

For dealing with the case of noisy observations the reader is referred to [21]. For example, it is shown that learning a concept class with a "noisy oracle" (that makes

a mistake with probability $\beta < 1/2$) to accuracy ϵ is the same as learning the same concept class to an accuracy $\epsilon/(1-2\beta)$ with a perfect oracle.

Finally, we have considered the case in which only the final state output is observed; i.e., observation is done only on a single instant of time. However, typically in control applications observations are made at multiple time instances. If one wishes to learn the mapping from inputs to final state outputs, but one can also see intermediate observations, can one learn faster by utilizing this additional information? This has motivated further research by the authors on "learning with side information" [14, 15]. The main problem is that in the control problem considered the samples become dependent, which poses a challenge in the theory of learning.

3. Complexity dimensions; main upper and lower bounds.

3.1. Bounds. We begin by stating bounds in the easiest learning setting, i.e., classifying the final state observations as either 0 or 1.

THEOREM 3.1 (VC dimension upper bound, $p = 1$). *The VC dimension of the sign system concept class $\mathcal{C}_{m,1}$ with scalar observations can be bounded as*

$$VC(\mathcal{C}_{m,1}) \leq 2(2mn^2 + 4n + 1)\log_2[8e(8mn^2k(n + \ell_{\max}) + 1)(2nk + 2(1 + 2k)^n)],$$

where $\ell_{\max}$ is given by (4).

In terms of n (the dimension of the state space) and k (the bandwidth) the upper bound is of the form $O(n^3 \log_2(nk))$.

All VC dimension upper bounds are based on the fact that input basis functions satisfy a certain rationality condition. Remark 5.3 indicates how the bound is formed when the input functions satisfy the more abstract rationality condition. In that case the degrees of the polynomials and the number of polynomial evaluations are different. However, in terms of n and k, the bound is of the same form. VC dimension or pseudodimension bounds stated in this paper can be modified for the rationality condition in the same way.

The lower bound for the VC dimension is in terms of n and k. It holds for linearly independent, continuous basis input functions, and, compared to upper bounds, no particular form of the functions is needed. The bound is obtained by imposing a specific structure on control systems, and a lower bound for a restricted class of control systems provides a lower bound for more general classes.

THEOREM 3.2 (VC dimension lower bound, $m = 1$, $p = 1$).

$$VC(\mathcal{C}_{1,1}) \geq \max\left\{m' \left\lfloor \log_2 \left\lfloor \frac{k}{m'} \right\rfloor \right\rfloor, m'\right\},$$

where $m' = \min\{n, k\}$.

In terms of k the upper and the lower bound match up to a constant. For n and k the lower bound is typically of the form $O(n \log_2(k/n))$. Note that if the system dimension n is small compared to the bandwidth k, the VC dimension upper and lower bounds in Theorems 3.1 and 3.2 become tighter, both being of the form $c \log_2 k$ (with different values of the constant c).

Extending the upper bounds to the case of vector-valued observations can be done in various ways based on the result obtained for scalar observations. For example, we may consider the p-dimensional output as bits representing a number in $\{0, \ldots, 2^p - 1\}$ and introduce a loss function for each $f \in \mathcal{C}_{m,p}$ as $L_{0\text{-}1,f}(z, a) = L_{0\text{-}1}(f(z), a) = 1$, when $f(z) \neq a$, and 0 otherwise. We define the VC dimension of the p-dimensional

observation as the VC dimension of the above class of loss functions. Modifying the argument used with scalar observations leads to a bound of the following form.

THEOREM 3.3 (VC dimension upper bound).

$$VC(\mathcal{C}_{m,p}) \le 2(2pmn^2 + 4n + p) \times \log_2\Big[8e\big(8mn^2k(n+\ell_{\max})+1\big)\big(2^p - 1 + 2p(2k+1)^n + 2nk\big)\Big],$$

where $\ell_{\max}$ *is given by* (4).

Next we state the main result concerning learnability of the actual input/output mapping, i.e., learning without taking the sign of the final state observation.

DEFINITION 3.4 (control system concept class, $\mathcal{G}_{p,L}$). *Let* $\widetilde{\mathcal{F}} = \{\Phi_\Sigma : X_\Omega \to \mathbb{R}^p;\ \Sigma$ *linear system of dimension* $n\}$, *and define the* control system concept class *as* $\mathcal{G}_{p,L} = A_{\widetilde{\mathcal{F}},L}$, *where* $A_{\widetilde{\mathcal{F}},L}$ *is given by* (1).

Methods for calculating upper bounds for the VC dimension readily extend to the case of pseudodimension with respect to loss that preserves the rationality structure of the output. A typical example is illustrated by the loss function,

$$L(z_1, z_2) = (z_1 - z_2)^2/(1 + (z_1 - z_2)^2), \tag{6}$$

and the following result.

THEOREM 3.5 (pseudodimension upper bound, $p = 1$).

$$PD(\mathcal{G}_{1,L}) \le 2\left(2mn^2 + 4n + 1\right)\log_2[16e(8mn^2k(n+\ell_{\max})+1)(2nk + 2(2k+1)^n)],$$

where the loss function L *is given by* (6) *and* $\ell_{\max}$ *is given by* (4).

This differs from the corresponding VC dimension bound only by the maximum degree of the polynomials, which is doubled. Extending this pseudodimension bound for p-dimensional observations can be done naturally by modifying the loss function. Lower bounds for the VC dimension are lower bounds for the pseudodimension as such.

The next results summarize upper bounds for the fat-shattering dimension. We begin by illustrating how the fat-shattering dimension can be bounded for Lipschitz functions in certain cases.

THEOREM 3.6 (fat-shattering bound). *Let* $F(\lambda, u) : \mathbb{R}^k \times U \to \mathbb{R}$ *be such that* $F(\cdot, u)$ *is Lipschitz with constant* L, *i.e.,* $|F(\lambda_1, u) - F(\lambda_2, u)| \le L\|\lambda_1 - \lambda_2\|$ *for all* $u \in U$. *For any subset* $B \subseteq \mathbb{R}^k$, *consider the following class of functions:*

$$\mathcal{F}_B = \{F(\lambda, \cdot) : U \to \mathbb{R};\ \lambda \in B\}.$$

Then

$$\mathrm{fat}_\gamma(\mathcal{F}_{B^k_\infty(C)}) \le k \log_2 \left\lfloor \frac{CL}{\gamma} \right\rfloor,$$

$$\mathrm{fat}_\gamma(\mathcal{F}_{\bar{B}^k_\infty(C)}) \le k \log_2 \left(1 + \left\lfloor \frac{CL}{\gamma} \right\rfloor\right),$$

$$\mathrm{fat}_\gamma(\mathcal{F}_{\bar{B}_{2,1}}) \le k \log_2 \left(C + \frac{L}{\gamma}\right),$$

where

$$B_\infty^k(C) = \{x \in \mathbb{R}^k;\ \|x\|_\infty = \max_{1\le i\le k} |x_i| < C\},$$
$$\bar{B}_\infty^k(C) = \{x \in \mathbb{R}^k;\ \|x\|_\infty = \max_{1\le i\le k} |x_i| \le C\},$$
$$\bar{B}_2^k(C) = \left\{x \in \mathbb{R}^k;\ \|x\|_2 = \sqrt{\sum\nolimits_{i=1}^k x_i^2} \le C\right\}.$$

THEOREM 3.7 (fat-shattering bound for a control system). *Assume that the system* $\dot{x} = Ax + Bu$, $y = Cx$, $x(0) = 0$, *can be parameterized by* $\lambda \in \mathbb{R}^{n(m+1)}$ *as in Definition* 2.6 *and* $\|\lambda\|_\infty < 1$. *Let* $F(\lambda, u) = y(\tau)$ *be the solution with system parameters* λ *and control* $u = (u_1, \dots, u_m) \in U = \{u = (u_1, \dots, u_m);\ \int_0^\tau |u_i(t)|dt \le M,\ i = 1, \dots, m\}$. *Define*

$$\mathcal{F}_B = \{F(\lambda, \cdot)\colon U \to \mathbb{R};\ \lambda \in B_\infty^k(1)\}.$$

Then

$$\mathrm{fat}_\gamma(\mathcal{F}_B) \le n(m+1)\log_2\left\lfloor \frac{n^2 m \tau^n e^\tau M}{\gamma}\right\rfloor.$$

4. Techniques for proving VC dimension results. Our main results are based on the fact that the basis input functions satisfy a certain rationality condition. In this section we first formulate this rationality condition, and then we summarize existing results that are used in proving upper and lower bounds for the complexity dimensions.

We recall briefly the control system setting. We study systems

$$\dot{x} = Ax + Bu, \quad x(0) = x^0, \quad y = Cx,$$
$$u = G\omega, \quad \text{and} \quad \omega_j \in \Omega \text{ for } j = 1, \dots, k,$$

with basis input functions

$$\Omega = \Big\{\omega_1, \dots, \omega_k; \omega_1, \dots, \omega_k \text{ linearly independent and}$$
$$\omega_j = t^{\ell_j} e^{\alpha_j t}\sin(\beta_j t) \text{ or } \omega_j = t^{\ell_j} e^{\alpha_j t}\cos(\beta_j t)$$
$$\text{with } \ell_j \in \mathbb{N}, \alpha_j, \beta_j \in \mathbb{R}, j = 1, \dots, k\Big\},$$

such that $\ell_{\max} = \max\{\ell_1, \dots, \ell_k\}$.

DEFINITION 4.1 (rationality condition (RAT)). *Let* n *be a positive integer. We say that a bounded function* $\omega : [0, 1] \to \mathbb{R}$ *satisfies the rationality condition relative to the class of* n*-dimensional systems if there exist* h *polynomial functions* $f_1, \dots, f_h : \mathbb{R}^4 \to \mathbb{R}$ *and* $2\gamma n$ *rational functions* $r_{ij\tilde{\ell}}$, $i \in \{1, 2\}$, $j \in \{1, \dots, \gamma\}$, *and* $\tilde{\ell} \in \{1, \dots, n\}$, *with no poles on subsets* $S_{ij\tilde{\ell}}$ *of* $\mathbb{R}^4$, *such that the following properties hold:*

1. *For each* $i \in \{1, 2\}$, $\tilde{\ell} \in \{1, \dots, n\}$, $\mathbb{R}^4$ *is a disjoint union of* $S_{i1\tilde{\ell}}, \dots, S_{i\gamma\tilde{\ell}}$.
2. *Each* $S_{ij\tilde{\ell}}$ *can be defined in terms of a Boolean expression involving* $[f_1 = 0]$, $\dots$, $[f_h = 0]$, *where we say that for functions* $f_1, \dots, f_h : \mathbb{R}^4 \to \mathbb{R}$, $[f_i = 0]$ *has value* 1 *if* $f_i(x_1, x_2, x_3, x_4) = 0$ *and* 0 *otherwise.*

3. *Let* $r_{i\tilde{\ell}} : \mathbb{R}^4 \to \mathbb{R}$, $i \in \{1,2\}$, $\tilde{\ell} \in \{1,\dots,n\}$, *be defined as*

$$r_{i\tilde{\ell}}(v) = \begin{cases} r_{i1\tilde{\ell}}(v) & \text{if } v \in S_{i1\tilde{\ell}}, \\ \vdots & \vdots \\ r_{i\gamma\tilde{\ell}}(v) & \text{if } v \in S_{i\gamma\tilde{\ell}}; \end{cases}$$

then for each $a, b \in \mathbb{R}$, *and for all* $\tilde{\ell} \in \{1,\dots,n\}$,

$$\int_0^1 t^{\tilde{\ell}-1} e^{at} \cos(bt)\omega(t)dt = r_{1\tilde{\ell}}(a, b, e^a \cos b, e^a \sin b),$$
$$\int_0^1 t^{\tilde{\ell}-1} e^{at} \sin(bt)\omega(t)dt = r_{2\tilde{\ell}}(a, b, e^a \cos b, e^a \sin b).$$

We denote by $d_{\max}$ the maximum degree of any polynomial (i.e., $f_1, \dots, f_h$, numerators and denominators of $r_{ij\tilde{\ell}}$'s) appearing in the rationality condition.

Remark 4.2. First, entries of e^{At} are functions of the form $t^s e^{at}\cos(bt)$ and $t^s e^{at}\sin(bt)$. Solving (2) involves convolutions of e^{At} and the basis input functions ω_j, and we require those to be rational functions.

Example 4.3. Let $\omega(t) = \sin(ct)$, with nonzero c. Then

$$\int_0^1 e^{at}\sin(bt)\omega(t)dt = \frac{1}{2}\int_0^1 e^{at}\cos((b-c)t)dt - \frac{1}{2}\int_0^1 e^{at}\cos((b+c)t)dt.$$

After integration this can be split into cases with no poles yielding

$$\int_0^1 e^{at}\sin(bt)\omega(t)dt = \begin{cases} \frac{p(a,b,e^a\cos b, e^a\sin b)}{(a^2+(b+c)^2)(a^2+(b-c)^2)} & \text{if } f_1 \neq 0, f_2 \neq 0, \\ \frac{b-\sin b\cos b}{2b} & \text{if } f_1 = 0, f_2 \neq 0, \\ \frac{\sin b\cos b - b}{2b} & \text{if } f_1 \neq 0, f_2 = 0, \end{cases}$$

where $f_1(a, b, e^a \sin b, e^a \cos b) = a^2 + (b+c)^2$, $f_2(a, b, e^a \sin b, e^a \cos b) = a^2 + (b-c)^2$, and $p(a, b, e^a \cos b, e^a \sin b)$ stands for the polynomial

$$\begin{aligned} &-4abc + 4abce^a \cos b \cos c - 2a^2 ce^a \cos c \sin b + 2b^2 ce^a \cos c \sin b \\ &\quad -2c^3 e^a \cos c \sin b - 2a^2 be^a \cos b \sin c - 2b^3 e^a \cos b \sin c + 2bc^2 e^a \cos b \sin c \\ &\quad +2a^3 e^a \sin b \sin c + 2ab^2 e^a \sin b \sin c + 2ac^2 e^a \sin b \sin c. \end{aligned}$$

LEMMA 4.4. *Each* $\omega_j \in \Omega$ *given by* (3) *satisfies the rationality condition. Further, the maximum degree of polynomials in (RAT) is at most* $4(n + \ell_{\max})$, *where* $\ell_{\max}$ *is given by* (4).

Review of VC dimension techniques. In the context of control theory it is sometimes easier to work with the dual VC dimension. Assume that a function $F : \Lambda \times X \to \{0,1\}$ is given. This induces two function classes

$$\mathcal{F} := \{F(\lambda, \cdot) : X \to \{0,1\};\ \lambda \in \Lambda\}$$

and

$$\mathcal{F}^* := \{F(\cdot, x) : \Lambda \to \{0,1\};\ x \in X\}.$$

The complexity dimension $\mathrm{VC}(\mathcal{F}^*)$ is called the *dual VC dimension* of $\mathcal{F}$, and it is related to $\mathrm{VC}(\mathcal{F})$ as follows [21]:

$$\mathrm{VC}(\mathcal{F}) \geq \lfloor \log_2 \mathrm{VC}(\mathcal{F}^*) \rfloor, \tag{7}$$

where $\lfloor x \rfloor$ is the integer part of x.

A sharper estimate can be obtained if Λ can be written as a product $\Lambda_1 \times \cdots \times \Lambda_n$. The following construction and result are due to DasGupta and Sontag [6]. We study in particular those dichotomies that are defined on "rectangular" subsets of Λ. Let $L = L_1 \times \cdots \times L_n$ be a subset of Λ such that for each i, $L_i \subset \Lambda_i$ is nonempty. Given any index $1 \leq \kappa \leq n$, a *κ-axis dichotomy* on L is any function $\delta : L \to \{0,1\}$ which depends only on the κth coordinate; i.e., there is some function $\phi : L_\kappa \to \{0,1\}$ so that $\delta(\lambda_1, \ldots, \lambda_n) = \phi(\lambda_\kappa)$ for all $(\lambda_1, \ldots, \lambda_n) \in L$. We say that a mapping is an axis dichotomy if it is a κ-axis dichotomy for some κ. A rectangular set L is said to be *axis-shattered* by $\mathcal{F}^*$ if every axis dichotomy is a restriction to L of some function of the form $F(\cdot, x) : \Lambda \to \{0,1\}$ for some $x \in X$.

THEOREM 4.5 (axis-shattering bound [6]). *If $L = L_1 \times \cdots \times L_n \subset \Lambda$ can be axis-shattered and each L_i has cardinality $r_i > 0$, then $VC(\mathcal{F}) \geq \lfloor \log_2(r_1) \rfloor + \cdots + \lfloor \log_2(r_n) \rfloor$.*

Upper bounds for VC dimensions of concept classes that are obtained by evaluating polynomial equalities and inequalities can be obtained in terms of the number and degrees of the polynomials.

THEOREM 4.6 (Goldberg–Jerrum bound [10]). *Given a function $F : \Lambda \times X \to \{0,1\}$ and the associated concept class $\mathcal{F} := \{F(\lambda, \cdot) : X \to \{0,1\};\ \lambda \in \Lambda\}$, suppose that $\Lambda = \mathbb{R}^\ell$ and $X = \mathbb{R}^k$. Let F be defined in terms of a Boolean formula involving at most s polynomial equalities and inequalities in $\ell + k$ variables, each polynomial being of degree at most d in λ for all $x \in \mathbb{R}^k$. Then, $VC(\mathcal{F}) \leq 2\ell \log_2(8eds)$.*

The Goldberg–Jerrum bound is based on a result showing that the number of sign assignments $\{-1, 0, 1\}$ to polynomials cannot grow too quickly.

THEOREM 4.7 (see [10]). *Suppose that $f_1, \ldots, f_m$ are polynomials of degree at most d in $n \leq m$ variables. Then the number of distinct vectors*

$$[\operatorname{sign} f_1(x), \ldots, \operatorname{sign} f_m(x)] \in \{-1, 0, 1\}^m$$

that can be generated by varying x over $\mathbb{R}^n$ is at most $\left((8edm)/n\right)^n$.

5. Proofs of VC dimension bounds.

5.1. An upper bound for the VC dimension with scalar observations. We begin this section by proving Lemma 4.4 stating that the input basis functions satisfy the rationality condition (RAT) and bounding the degrees of polynomials appearing in (RAT). As a proposition we formalize how control systems can be parameterized. After that, as a lemma, we develop an upper bound for the VC dimension induced by the control system (2) with its initial state fixed to be zero. Theorem 3.1 with an arbitrary initial condition is then a simple modification of the argument.

Proof of Lemma 4.4. If $\omega(t) = t^\ell e^{\alpha t} \sin(\beta t)$ or $\omega(t) = t^\ell e^{\alpha t} \cos(\beta t)$ with $\ell \leq \ell_{\max}$, then in place of

$$\int_0^1 t^{\tilde{\ell}} e^{at} \sin(bt)\omega(t)dt \quad \text{or} \quad \int_0^1 t^{\tilde{\ell}} e^{at} \cos(bt)\omega(t)dt, \tag{8}$$

by combining exponents and using sum formulae for sin and cos (see Example 4.3), it is enough to study terms of the form $\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \sin(\tilde{b}t)dt$ or $\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \cos(\tilde{b}t)dt$, where $\tilde{k} \in \{0, \dots, n + \ell_{\max} - 1\}$. In fact, each expression in (8) is one of the following types:

$$\frac{1}{2}\left(\int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \cos\left((b-\beta)t\right) dt - \int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \cos\left((b+\beta)t\right) dt\right),$$
$$\frac{1}{2}\left(\int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \cos\left((b+\beta)t\right) dt + \int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \cos\left((b-\beta)t\right) dt\right),$$
$$\frac{1}{2}\left(\int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \sin\left((b-\beta)t\right) dt - \int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \sin\left((b+\beta)t\right) dt\right),$$
$$\frac{1}{2}\left(\int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \sin\left((b+\beta)t\right) dt + \int_0^1 t^{\tilde{\ell}} e^{\tilde{a}t} \sin\left((b-\beta)t\right) dt\right),$$

where $\tilde{a} = a + \alpha$. Because for $\tilde{k} > 0$

$$\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \sin(\tilde{b}t)dt = \frac{e^{\tilde{a}}}{\tilde{a}^2 + \tilde{b}^2}(\tilde{a}\sin\tilde{b} - \tilde{b}\cos\tilde{b}) - \frac{\tilde{k}}{\tilde{a}^2 + \tilde{b}^2}\int_0^1 t^{\tilde{k}-1} e^{\tilde{a}t}(\tilde{a}\sin(\tilde{b}t) - \tilde{b}\cos(\tilde{b}t))dt \tag{9}$$

and

$$\int_0^1 e^{\tilde{a}t} \sin(\tilde{b}t)dt = \frac{e^{\tilde{a}}(\tilde{a}\sin\tilde{b} - \tilde{b}\cos\tilde{b}) + \tilde{b}}{\tilde{a}^2 + \tilde{b}^2} \tag{10}$$

and similar formulae for $\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \cos(\tilde{b}t)dt$ hold, we see by induction that the numerator of $\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \sin(\tilde{b}t)dt$ is a polynomial of $\tilde{a}, \tilde{b}, e^{\tilde{a}}\cos\tilde{b}$, and $e^{\tilde{a}}\sin\tilde{b}$. By using sum formulae for sin and cos, the previous expression is in turn a polynomial of $a, b, e^a \cos b$, and $e^a \sin b$ because $\tilde{a} = a + \alpha$ and $\tilde{b} = b \pm \beta$ for some fixed α and β. By similar arguments, the denominator is a polynomial of a and b. Note that, for example, e^{α} equals a constant times e^a, so this process does not change the degrees of the polynomials.

Further, observe that the denominator of $\int_0^1 t^{\tilde{\ell}} e^{at} \sin(bt)\omega(t)dt$ consists of at most two products of variables a and b of the form $((a+\alpha)^2 + (b \pm \beta)^2)^{\tilde{\ell}+\ell+1}$, and similarly with the $\cos(bt)$ term. Let us index the basis input functions $\omega_1, \dots, \omega_k$ so that ω_κ has parameters α_κ and β_κ. Hence the functions f_i in (RAT), defining the subsets without poles, can be taken as

$$\{(a+\alpha_\kappa)^2 + (b-\beta_\kappa)^2, (a+\alpha_\kappa)^2 + (b+\beta_\kappa)^2 \,;\, \kappa = 1, \dots, k\}.$$

Furthermore, the sets $S_{ij\tilde{\ell}}$ are as simple as

$$\cup_{\kappa=1}^k \{\{(x_1,x_2,x_3,x_4);\ x_1 = -\alpha_\kappa, x_2 = -\beta_\kappa\} \cup \{(x_1,x_2,x_3,x_4);\ x_1 = -\alpha_\kappa, x_2 = \beta_\kappa\}\}$$

and

$$\mathbb{R}^4 \setminus \cup_{\kappa=1}^k \{\{(x_1,x_2,x_3,x_4);\ x_1 = -\alpha_\kappa, x_2 = -\beta_\kappa\} \cup \{(x_1,x_2,x_3,x_4);\ x_1 = -\alpha_\kappa, x_2 = \beta_\kappa\}\}.$$

We turn to estimating the maximum degree of polynomials appearing in (RAT). We already saw that functions f_i are polynomials of degree 2. Equations (9) and (10) show that the degree of numerator is not higher than the one of denominator. We claim that

$$\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \begin{cases} \sin(\tilde{b}t) \\ \cos(\tilde{b}t) \end{cases} dt = \frac{P(2(\tilde{k}+1))}{(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}+1}} \quad \text{for } \tilde{k} = 0, 1, \ldots,$$

where $P(2(\tilde{k}+1))$ stands for some polynomial in $\tilde{a}$, $\tilde{b}$, $e^{\tilde{a}}\sin(\tilde{b})$, and $e^{\tilde{a}}\cos(\tilde{b})$ of degree $2(\tilde{k}+1)$. Clearly, the claim is true for $\tilde{k} = 0$ by (10), and the inductive argument follows from (9). Assuming the claim is true for $\tilde{k}-1$, we get

$$\begin{aligned}
&\int_0^1 t^{\tilde{k}} e^{\tilde{a}t} \sin(\tilde{b}t) dt \\
&\quad = \frac{P(2)}{\tilde{a}^2+\tilde{b}^2} - \frac{\tilde{k}\tilde{a}}{\tilde{a}^2+\tilde{b}^2} \int_0^1 t^{\tilde{k}-1} e^{\tilde{a}t} \sin(\tilde{b}t) dt + \frac{\tilde{k}\tilde{b}}{\tilde{a}^2+\tilde{b}^2} \int_0^1 t^{\tilde{k}-1} e^{\tilde{a}t} \cos(\tilde{b}t) dt \\
&\quad = \frac{P(2)}{\tilde{a}^2+\tilde{b}^2} - \frac{P(1)}{(\tilde{a}^2+\tilde{b}^2)} \frac{P(2\tilde{k})}{(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}}} + \frac{P(1)}{(\tilde{a}^2+\tilde{b}^2)} \frac{P(2\tilde{k})}{(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}}} \\
&\quad = \frac{P(2)(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}} - 2P(2\tilde{k}+1)}{(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}+1}} = \frac{P(2(\tilde{k}+1))}{(\tilde{a}^2+\tilde{b}^2)^{\tilde{k}+1}},
\end{aligned}$$

and similarly for the $\cos(\tilde{b}t)$ term, concluding the proof of the claim. As a corollary of the claim,

$$\int_0^1 t^{\tilde{\ell}} e^{at} \sin(bt)\omega(t) dt = \frac{P(2(\tilde{k}+1))}{(\tilde{a}^2+(b+\beta)^2)^{\tilde{k}+1}} + \frac{P(2(\tilde{k}+1))}{(\tilde{a}^2+(b-\beta)^2)^{\tilde{k}+1}},$$

where $\tilde{k} = \ell + \tilde{\ell}$ and $\tilde{a} = a + \alpha$.

Hence the maximum degree of denominators of expressions in (8) is $2(\tilde{k}+1) + 2(\tilde{k}+1) = 4(\tilde{k}+1)$ with $\tilde{k} \in \{0, \ldots, \ell_{\max} + n - 1\}$. Thus the maximum degree of polynomials appearing in the (RAT) is $4(n + \ell_{\max})$. □

The next proposition indicates how control systems are parameterized and later the concept or function classes associated to control systems are obtained by varying the parameter vector.

PROPOSITION 5.1. *Denote the basis input functions by* $\omega = (\omega_1, \ldots, \omega_k)^T$, *assume that each* ω_i, $i = 1, \ldots, k$, *satisfies the rationality condition (RAT), and let* $\Lambda = \mathbb{R}^{2pn^2m} \times \mathbb{R}^{4n} \times \mathbb{R}^p$. *Then there exists a mapping* $H : \Lambda \times \mathbb{R}^{mk} \to \mathbb{R}^p$ *(depending on* ω*) such that for each* $\Sigma = (A, B, C, x^0)$ *there exists a* $\lambda \in \Lambda$ *satisfying*

$$\Phi_\Sigma(G\omega) = H(\lambda, G) \quad \forall\ G \in \mathbb{R}^{mk}.$$

Proof. Given a system $\Sigma = (A, B, C, x^0)$,

$$\Phi_\Sigma(u) = y(1) = Ce^A x^0 + C \int_0^1 e^{A(1-t)} Bu(t) dt.$$

By an argument based on the real Jordan form of e^{At}, the entries of $e^{A(1-t)}$ are linear combinations of functions of the form $t^{\tilde{\ell}} e^{at}\cos(bt)$ and $t^{\tilde{\ell}} e^{at}\sin(bt)$, where $\tilde{\ell} \in \{0, \ldots, n-1\}$ and $a + ib$ is an eigenvalue of A. Hence we define the $2n$ functions $\xi_j(a, b, t) = t^{j-1} e^{at}\cos(bt)$, $\xi_{n+j}(a, b, t) = t^{j-1} e^{at}\sin(bt)$ for $j = 1, \ldots, n$.

By the rationality condition (RAT), for all $\ell = 1, \dots, 2n$,

$$\int_0^1 \xi_\ell(a,b,t)\omega_j(t)dt = \frac{\hat{P}_{\ell j}(a,b,e^a\cos b, e^a \sin b)}{\hat{Q}_{\ell j}(a,b,e^a\cos b, e^a \sin b)}$$

for all $a, b \in \mathbb{R}$ and where $\hat{P}_{\ell j}$ and $\hat{Q}_{\ell j}$ are piecewise polynomial expressions.

Let $H(\mathbf{A}, \mathbf{X}, h, G) = (H_1, \dots, H_p)^T$, where for $1 \le \kappa \le p$

$$H_\kappa(\mathbf{A}, \mathbf{X}, h, G) = \sum_{i=1}^{m}\sum_{r=1}^{n}\sum_{\ell=1}^{2n} \alpha_{ir\ell\kappa} \sum_{j=1}^{k} g_{ij} \frac{\hat{P}_{\ell j}(x_{r1}, x_{r2}, x_{r3}, x_{r4})}{\hat{Q}_{\ell j}(x_{r1}, x_{r2}, x_{r3}, x_{r4})} + h_\kappa$$

and

$$\mathbf{A} = (\alpha_{ir\ell\kappa})_{\substack{i=1,\dots,m\\ r=1,\dots,n\\ \ell=1,\dots,2n\\ \kappa=1,\dots,p}}, \qquad \mathbf{X} = (x_{r\eta})_{\substack{r=1,\dots,n\\ \eta=1,\dots,4}},$$
$$h = (h_1, \dots, h_p)^T, \qquad G = (g_{ij})_{\substack{i=1,\dots,m\\ j=1,\dots,k}}.$$

Next, we relate Φ_Σ and H and we write

$$Ce^{A(1-t)}B = \begin{bmatrix} \gamma_{11} & \cdots & \gamma_{1m} \\ \vdots & & \vdots \\ \gamma_{p1} & \cdots & \gamma_{pm} \end{bmatrix}.$$

We list the eigenvalues of A as $a_r + ib_r$ for $r = 1, \dots, n$ and let $\xi_{r\ell}(t) = \xi_\ell(a_r, b_r, t)$ for $r = 1, \dots, n$ and $\ell = 1, \dots, 2n$. Then there exists some $(\alpha_{ir\ell\kappa})$ such that

$$\gamma_{\kappa i}(t) = \sum_{r=1}^{n}\sum_{\ell=1}^{2n} \alpha_{ir\ell\kappa}\xi_{r\kappa}(t). \tag{11}$$

Let $\lambda = (\mathbf{A}, \mathbf{X}, h)$, where $\mathbf{A}$ satisfies (11), $\mathbf{X} = (x_{r\eta})$, where $x_{r1} = a_r, x_{r2} = b_r, x_{r3} = e^{a_r}\cos b_r$ and $x_{r4} = e^{a_r}\sin b_r$, and $h = Ce^A x^0$. We claim that

$$H(\lambda, G) = y(1) = \Phi_\Sigma(G\omega) \quad \forall\, G \in \mathbb{R}^{mk}.$$

Note that the κth component of $\Phi_\Sigma(G\omega)$ is given by

$$\begin{aligned}
&\int_0^1 \sum_{i=1}^{m} \gamma_{\kappa i}(t)u_i(t)dt + h_\kappa \\
&= \sum_{i=1}^{m}\sum_{r=1}^{n}\sum_{\ell=1}^{2n} \alpha_{ir\ell\kappa} \int_0^1 \xi_{r\ell}(t) \sum_{j=1}^{k} g_{ij}\omega_j(t)dt + h_\kappa \\
&= \sum_{i=1}^{m}\sum_{r=1}^{n}\sum_{\ell=1}^{2n} \alpha_{ir\ell\kappa} \sum_{j=1}^{k} g_{ij} \int_0^1 \xi_\ell(a_r, b_r, t)\omega_j(t)dt + h_\kappa \\
&= \sum_{i=1}^{m}\sum_{r=1}^{n}\sum_{\ell=1}^{2n} \alpha_{ir\ell\kappa} \sum_{j=1}^{k} g_{ij} \frac{\hat{P}_{\ell j}(x_{r1}, x_{r2}, x_{r3}, x_{r4})}{\hat{Q}_{\ell j}(x_{r1}, x_{r2}, x_{r3}, x_{r4})} + h_\kappa \\
&= H_\kappa(\mathbf{A}, \mathbf{X}, h, G). \qquad \square
\end{aligned}$$

Next we take $p = 1$ and study the VC dimension of the sign system concept class, $\mathcal{C}_{m,1}$, where each control parameterized by G gives rise to $\operatorname{sign} y(1)$.

LEMMA 5.2. *The sign system concept class $\mathcal{C}_{m,1}$ with initial condition $x(0) = 0$ satisfies*

$$VC(\mathcal{C}_{m,1}) \leq 2\left(2mn^2 + 4n\right) \log_2[8e(8mn^2k(n + \ell_{\max}) + 1)(2nk + 2(1 + 2k)^n)],$$

where $\ell_{\max}$ is given by (4).

Proof. By Proposition 5.1, $y(1) = H(\lambda, G)$, where $\lambda \in \mathbb{R}^{2mn^2} \times \mathbb{R}^{4n}$ are considered as parameters. In fact, $y(1) = \frac{P}{Q}$, where P and Q denote piecewise polynomial functions. As in the statement of Goldberg–Jerrum bounds, we have a function $F : \Lambda \times \mathbb{R}^{mk} \to \{0, 1\}$ defined by $F(\lambda, G) = \operatorname{sign} H(\lambda, G)$. The concept class associated to the system identification problem is $\mathcal{F} := \{F(\lambda, \cdot) : \mathbb{R}^{mk} \to \{0, 1\};\ \lambda \in \Lambda\}$, where $\Lambda = \mathbb{R}^{2mn^2+4n}$. Before applying the Goldberg–Jerrum bound, we need to determine the possible degrees of P and Q with respect to the parameters.

The rationality condition implies that

$$\max_{\substack{i \leq \ell \leq n \\ 1 \leq j \leq k}} \left\{ \deg(\hat{P}_{\ell j}), \deg(\hat{Q}_{\ell j}) \right\} \leq d_{\max}.$$

Then

$$\frac{\widetilde{P}_{i\ell}}{\widetilde{Q}_{i\ell}} = \sum_{j=1}^{k} g_{ij} \frac{\hat{P}_{\ell j}}{\hat{Q}_{\ell j}},$$

so $\deg(\widetilde{Q}_{i\ell}) \leq kd_{\max}$ and $\deg(\widetilde{P}_{i\ell}) \leq kd_{\max}$. Note here that we are calculating the degree with respect to the system parameters, and the inputs g_{ij} do not contribute. By continuing in a similar fashion and combining r-summation to the ℓ-summation in Proposition 5.1, we write $P_i/Q_i = \sum_{\ell=1}^{2n^2} \alpha_{i\ell} \widetilde{P}_{i\ell} / \widetilde{Q}_{i\ell}$ to conclude that $\deg(Q_i) \leq 2n^2 \deg(\widetilde{Q}_{i\ell}) = 2n^2 kd_{\max}$ and $\deg(P_i) \leq 2n^2 kd_{\max} + 1$. Finally, $P/Q = \sum_{i=1}^{m} P_i/Q_i$ with $\deg(Q) \leq m2n^2 kd_{\max}$ and $\deg(P) \leq m2n^2 kd_{\max} + 1$.

Recall that with $p = 1$ and initial condition $x(0) = 0$, using the notation of Proposition 5.1,

$$y(1) = \sum_{i=1}^{m} \sum_{r=1}^{n} \sum_{\ell=1}^{2n} \alpha_{ir\ell} \sum_{j=1}^{k} g_{ij} \int_0^1 \xi_\ell(x_{r1}, x_{r2}, t) \omega_j(t) dt.$$

The proof of Lemma 4.4 indicates that the denominator of $\int_0^1 \xi_\ell(x_{r1}, x_{r2}, t) \omega_j(t) dt$ equals

$$((x_{r1} + \alpha_j)^2 + (x_{r2} + \beta_j)^2)^{z_{\ell j}} ((x_{r1} + \alpha_j)^2 + (x_{r2} - \beta_j)^2)^{z_{\ell j}},$$

where α_j, β_j are fixed parameters of the basis input function ω_j and $z_{\ell j} \in \mathbb{N}$.

By carrying out the summations we get $y(1) = P/Q$, where Q consists of powers of polynomials f_{ij1}, f_{ij2} with

$$f_{ij1}(\mathbf{A}, \mathbf{X}, G) = (x_{i1} + \alpha_j)^2 + (x_{i2} + \beta_j)^2,$$
$$f_{ij2}(\mathbf{A}, \mathbf{X}, G) = (x_{i1} + \alpha_j)^2 + (x_{i2} - \beta_j)^2,$$

and $i = 1, \ldots, n$, $j = 1, \ldots, k$.

Our final step before applying the Goldberg–Jerrum bound is finding out the number of polynomial inequalities s needed in the Boolean formula and evaluating the sign of the final state output. This is done by studying the number of different P/Q expressions without poles.

An upper bound for different P/Q expressions without poles can be obtained by applying Theorem 4.7 to $2nk$ polynomials f_{ij1}, f_{ij2}, $i = 1, \dots, n$ and $j = 1, \dots, k$, and viewing those as polynomials of $2n$ variables and each polynomial having degree 2. This gives the upper bound $(16ek)^{2n}$.

However, a more specific bound can be obtained in this problem. Note that varying x_{i1} and x_{i2} we can make at most one of the $2k$ polynomials f_{ij1}, f_{ij2}, $j = 1, \dots, k$, to be zero. For example, γ zeros among f_{ij1}, f_{ij2}, $i = 1, \dots, n$ and $j = 1, \dots, k$, can be obtained in $(2k)^\gamma \binom{n}{\gamma}$ ways, and the number of possible sign assignments is obtained by summing over γ yielding

$$\sum_{\gamma=0}^{n} (2k)^\gamma \binom{n}{\gamma} = (1+2k)^n.$$

Thus the number of P/Q expressions without poles is $(1+2k)^n$, which gives rise to $2(1+2k)^n$ polynomials.

Note that in order to write $\operatorname{sign} y(1)$ as a Boolean formula evaluating polynomial inequalities and equalities one also has to include the $2nk$ polynomials f_{ij1}, f_{ij2}, $i = 1, \dots, n$, $j = 1, \dots, k$. Values of these polynomials determine which P/Q expression is the valid one to determine $\operatorname{sign} y(1)$. The Boolean formula for $\operatorname{sign} y(1)$ can be given as a truth table involving polynomial inequalities of $2nk$ f_{ij1}, f_{ij2} expressions and $2(1+2k)^n$ different P and Q expressions.

Using Lemma 4.4 for bound on $d_{\max}$, we apply the Goldberg–Jerrum bound with $s = 2nk + 2(2k+1)^n$, $d = m2n^2k4(n+\ell_{\max})+1$, and $\ell = 2mn^2+4n$. □

A simple example of a piecewise polynomial function P/Q together with the decision table for the final output is provided in the appendix.

Remark 5.3. The VC dimension bound is modified for the more abstract rationality conditions as follows. Evaluating the sign of the output involves the evaluation of $2(8ed_{\max}2n^2kh/4n)^{4n} + 2n^2kh$ polynomials; $2n^2kh$ evaluations are needed to find an appropriate piece, and by Theorem 4.7 the maximum number of possible expressions of the type P/Q is bounded by $(8ed_{\max}2n^2kh/4n)^{4n}$. Applying the Goldberg–Jerrum bound with $s = 2(8ed_{\max}2n^2kh/4n)^{4n}+2n^2kh$, $d = m2n^2kd_{\max}+1$, and $\ell = 2mn^2+4n$ gives the result.

Proof of Theorem 3.1*, the VC dimension upper bound,* $p = 1$. By using the previous notation, $y = Ce^Ax^0 + C\int_0^1 e^{A(1-t)}Bu(t)dt$. Let $\widetilde{x} = Ce^Ax^0$. Then $y = \widetilde{x} + P/Q = (\widetilde{x}Q+P)/Q = \widetilde{P}/Q$. This has $2mn^2+4n+1$ parameters and $\deg(\widetilde{P}) \le m2n^2kd_{\max}+1$. □

5.2. Lower bounds for the VC dimension. The lower bounds for the VC dimension are developed for a single-input single-output system with initial state zero. The control is

$$u = \sum_{j=1}^{k} g_j\omega_j : [0,1] \to \mathbb{R}.$$

We derive lower bounds by fixing the structure of A, B, and C and using the dual VC dimension and axis shattering following the ideas of DasGupta and Sontag [6].

Lemmas 5.5, 5.6, and 5.7 given in this section together prove Theorem 3.2. These lower bounds are very general; we just assume that the input functions are continuous and linearly independent; thus no particular structure of input functions is required as in the upper bounds.

To make the next proof cleaner we formulate a part of it as a separate proposition. (The proposition is a standard fact and we omit the proof.)

PROPOSITION 5.4. *Let $\omega_j : [0,1] \to \mathbb{R}$, $j = 1, \dots, k$, be continuous and linearly independent. Then the functions*

$$h_j(\lambda) = \int_0^1 e^{\lambda t} \omega_j(t) dt, \quad j = 1, \dots, k,$$

are linearly independent.

LEMMA 5.5 (lower bound 1). *The sign system concept class $\mathcal{C}_{1,1}$ with scalar inputs and scalar outputs satisfies*

$$VC(\mathcal{C}_{1,1}) \geq m' \left\lfloor \log_2 \left\lfloor \frac{k}{m'} \right\rfloor \right\rfloor,$$

where $m' = \min\{n, k\}$.

Proof. Let $\omega_j(t)$, $j = 1, \dots, k$, be continuous and linearly independent. Let A have n distinct real eigenvalues $-\lambda_1, \dots, -\lambda_n$, and take B and C so that

$$Ce^{A(1-t)}B = \sum_{i=1}^{m'} e^{\lambda_i t},$$

where $m' = \min\{n, k\}$. Then the final output of the system is

$$y(1) = \int_0^1 Ce^{A(1-t)}B \sum_{j=1}^{k} g_j \omega_j(t) dt = \sum_{i=1}^{m'} \sum_{j=1}^{k} g_j \int_0^1 e^{\lambda_i t} \omega_j(t) dt.$$

Define $h_j(\lambda) = \int_0^1 e^{\lambda t} \omega_j(t) dt$. By Proposition 5.4 the h_j's are linearly independent and we can find $\lambda_1, \dots, \lambda_k$ such that the matrix

$$\begin{bmatrix} h_1(\lambda_1) & \cdots & h_k(\lambda_1) \\ \vdots & & \vdots \\ h_1(\lambda_k) & \cdots & h_k(\lambda_k) \end{bmatrix}$$

has rank k.

The control system with sign-observations gives the mapping $F : \mathbb{R}^{m'} \times \mathbb{R}^k \to \{0, 1\}$ by

$$(\lambda_1, \dots, \lambda_{m'}, g_1, \dots, g_k) \mapsto \operatorname{sign} \left[\sum_{i=1}^{m'} \sum_{j=1}^{k} g_j h_j(\lambda_i) \right].$$

We show that the mapping from parameters $\lambda_1, \dots, \lambda_{m'}$ to $\{0, 1\}$ can be axis-shattered. Let $L = \{\lambda_1, \dots, \lambda_k\}$ be so that $[h_j(\lambda_i)]_{i,j}$ has rank k. Denote by $L_1, \dots, L_{m'}$ disjoint subsets of L such that $|L_i| = \lfloor k/m' \rfloor$, and let $M = L \setminus \{\bigcup_{i=1}^{m'} L_i\}$. Next we want to interpolate in the points of L.

Fix s, $1 \le s \le m'$, and let $\phi : L_s \to \{0,1\}$ be any dichotomy. Next find $g_1, \dots, g_k$ such that

$$\begin{aligned} &\sum_{j=1}^{k} g_j h_j(\lambda_s) = \phi(\lambda_s) \qquad \forall\, \lambda_s \in L_s, \\ &\sum_{j=1}^{k} g_j h_j(\lambda) = 0 \qquad\quad \forall\, \lambda \in (L \cup M) \setminus L_s. \end{aligned} \tag{12}$$

Let $g_1^*, \dots g_k^*$ satisfy (12). (A unique solution exists because $[h_j(\lambda_i)]$ has rank k.) Then

$$F[\lambda_1, \dots, \lambda_{m'}, g_1^*, \dots, g_k^*] = \operatorname{sign}\left[\sum_{i=1}^{m'} \sum_{j=1}^{k} g_j^* h_j(\lambda_i)\right] = \phi(\lambda),$$

when $\lambda \in L_s$ and for all $(\lambda_1, \dots, \lambda_{m'}) \in L_1 \times \cdots \times L_{m'}$.

Let $\widetilde{\mathcal{F}} = \{F(\lambda_1, \dots, \lambda_{m'}, \cdot) : \mathbb{R}^k \to \{0,1\};\ (\lambda_1, \dots, \lambda_{m'}) \in \mathbb{R}^{m'}\}$. By the axis-shattering bound given in Theorem 4.5,

$$\mathrm{VC}(\widetilde{\mathcal{F}}) \ge m' \left\lfloor \log_2 \left\lfloor \frac{k}{m'} \right\rfloor \right\rfloor,$$

and thus $\mathrm{VC}(\mathcal{C}_{1,1}) \ge \mathrm{VC}(\widetilde{\mathcal{F}})$, where $\mathcal{C}_{1,1}$ is the control system concept class with $p = m = 1$. □

LEMMA 5.6 (lower bound 2). *If $k \le n$, then*

$$VC(\mathcal{C}_{1,1}) \ge k.$$

Proof. We make a small modification of the above argument. Assume that $k \le n$, and let A have n real eigenvalues $\lambda_1, \dots, \lambda_n$. Next we take B and C so that $Ce^{A(1-t)}B = \sum_{i=1}^{n} e^{\lambda_i t}\beta_i$, where $(\beta_1, \dots, \beta_n, \lambda_1, \dots, \lambda_n)$ are considered as system parameters.

We study the mapping

$$\begin{aligned} (\beta_1, \dots, \beta_n, \lambda_1, \dots, \lambda_n, g_1, \dots, g_k) &\mapsto \operatorname{sign}\left[\sum_{i=1}^{n} \sum_{j=1}^{k} g_j h_j(\lambda_i)\beta_i\right] \\ = \operatorname{sign}\left[\sum_{j=1}^{k} g_j \underbrace{\sum_{i=1}^{n} h_j(\lambda_i)\beta_i}_{\gamma_j}\right] &= \operatorname{sign}\left[\sum_{j=1}^{k} g_j \gamma_j\right]. \end{aligned}$$

Given $(\gamma_1, \dots, \gamma_k)$, by linear independence of $h_1, \dots, h_k$, we can find $\lambda_1, \dots, \lambda_n, \beta_1, \dots, \beta_n$ such that $\sum_{i=1}^{n} h_j(\lambda_i)\beta_i = \gamma_j$, $j = 1, \dots, k$. But $(\gamma_1, \dots, \gamma_k)$ can be viewed as a normal vector for a hyperplane through the origin in $\mathbb{R}^k$, and the concept class associated to the mapping $(g_1, \dots, g_k) \mapsto \operatorname{sign}[\sum_{j=1}^{k} g_j \gamma_j]$ as $(\gamma_1, \dots, \gamma_k)$ varies has VC dimension k. Hence $\mathrm{VC}(\mathcal{C}_{1,1}) \ge k$. □

LEMMA 5.7 (lower bound 3). *If $n \le k$, then*

$$VC(\mathcal{C}_{1,1}) \ge n.$$

Proof. Our construction for the control system is as in the previous proof, but now we assume that $n \leq k$, and we study

$$(\beta_1, \ldots, \beta_n, \lambda_1, \ldots, \lambda_n, g_1, \ldots, g_k) \mapsto \operatorname{sign}\left[\sum_{i=1}^{n}\sum_{j=1}^{k} g_j h_j(\lambda_i)\beta_i\right]$$
$$= \operatorname{sign}\left[\sum_{i=1}^{n} \underbrace{\sum_{j=1}^{k} g_j h_j(\lambda_i)}_{\tilde{g}_i} \beta_i\right] = \operatorname{sign}\left[\sum_{i=1}^{n} \tilde{g}_i \beta_i\right],$$

and again by linear independence and the above hyperplane argument (now via first transforming $(g_1, \ldots, g_k)$) we can conclude that the above mapping has VC dimension n. Thus $\mathrm{VC}(\mathcal{C}_{1,1}) \geq n$. ∎

5.3. VC dimension upper bounds for p-dimensional outputs. We begin by proving Theorem 3.3.

Proof of the VC dimension upper bound. We develop an upper bound based on the bound for a scalar sign-observation. We have seen that under the rationality assumption (RAT) the scalar output is a piecewise rational expression P/Q. In general, the control system maps G to $(\operatorname{sign}(P_1/Q_1), \ldots, \operatorname{sign}(P_p/Q_p))^T$, which is understood as a binary representation of a number in $\{0, 1, \ldots, 2^p - 1\}$. Let $f : \mathbb{R}^{mk} \to \{0, \ldots, 2^p - 1\}$ be the mapping given by the control system, and denote the class of all such mappings by $\mathcal{F}$. For each $f \in \mathcal{F}$ introduce a loss function $L_{0\text{-}1,f}(z, a) = L_{0\text{-}1}(f(z), a) = 1$, when $f(z) \neq a$, and 0 otherwise. Define the class $L_{0\text{-}1,\mathcal{F}} = \{L_{0\text{-}1,f};\ f \in \mathcal{F}\}$.

In order to calculate the value of the output, after determining an appropriate piece, one needs to know the truth values of the expressions $P_1 > 0, Q_1 > 0, \ldots, P_p > 0$, and $Q_p > 0$, where P's and Q's are polynomials on inputs and parameters of the control system. To evaluate the value of the loss function $L_{0\text{-}1,f}(z, a)$, one needs the truth values of $y = 0, y = 1, \ldots, y = 2^p - 2$.

In the general case one needs $2nk + 2p(2k + 1)^n + 2^p - 1$ truth values. As this procedure evaluates only polynomials, we can use the Goldberg–Jerrum bound again. The maximum degree of the polynomials is $m2n^2k4(n + \ell_{\max}) + 1$, and the total number of parameters is $2pn^2m + 4n + p$, where the last term comes from the initial condition. ∎

6. A fat-shattering bound. We begin this section by proving Theorems 3.6 and 3.7. As a corollary of Theorem 3.7 we prove the fat-shattering bound appearing in Theorem 2.7 bounding the sample complexity for proper agnostic learning.

Proof of Theorem 3.6. For the first part of the proof we use a generic set B for the parameters. Assume that we can γ-shatter a set of inputs $\{u_1, \ldots, u_d\}$ and there exists $\{r_1, \ldots, r_d\}$ such that, for each assignment $b \in \{0, 1\}^d$, there exists a $\lambda \in B$ such that

$$\begin{aligned} F(\lambda, u_i) &\geq r_i + \gamma \quad \text{if } b_i = 1, \text{ and} \\ F(\lambda, u_i) &\leq r_i - \gamma \quad \text{otherwise.} \end{aligned}$$

We write $\lambda \sim \mu$ if and only if the parameters λ and μ give the same assignment for all $\{u_1, \ldots, u_d\}$. Further, let $\Lambda = \{\lambda_1, \ldots, \lambda_{2^d}\}$ be a collection of parameters that shatter $\{u_1, \ldots, u_d\}$, and let $\lambda_i, \lambda_j \in \Lambda$. Now $\lambda_i \not\sim \lambda_j$ implies that there exist $u^* \in \{u_1, \ldots, u_d\}$ and $r^* \in \{r_1, \ldots, r_d\}$ such that $F(\lambda_i, u^*) \geq \gamma + r^*$ and $F(\lambda_j, u^*) \leq$

$\gamma - r^*$, or vice versa. Hence $2\gamma \le |F(\lambda_i, u^*) - F(\lambda_j, u^*)| \le L\|\lambda_i - \lambda_j\|$ and so $\|\lambda_i - \lambda_j\| \ge 2\gamma/L$. That is, the set Λ of cardinality 2^d is a $2\gamma/L$-separated set in B. Now the fat-shattering bounds follow by calculating $2\gamma/L$-packing numbers for different sets B.

If $B = B^k_\infty(C)$, the maximum possible cardinality for an ϵ-separated set is $\lfloor 2C/\epsilon \rfloor^k$, and thus

$$2^d \le \left\lfloor \frac{2C}{2\gamma/L} \right\rfloor^k = \left\lfloor \frac{CL}{\gamma} \right\rfloor^k,$$

and solving for d yields $d \le k \log_2 \lfloor CL/\gamma \rfloor$.

Similarly, if $B = \bar{B}^k_\infty(C)$, the maximum possible cardinality for an ϵ-separated set is $(1 + \lfloor 2C/\epsilon \rfloor)^k$ and by a similar argument we arrive at the bound $d \le k \log_2(1 + \lfloor LC/\gamma \rfloor)$.

For $B = \bar{B}^k_2(C)$, let $P(\epsilon)$ be a collection of ϵ-separated sets in $\bar{B}^k_2(C)$, and let $|P(\epsilon)|$ denote its cardinality. As all open balls with radius $\epsilon/2$ with centers at ϵ-separated points have to be disjoint and their union has to be inside a ball of radius $C+\epsilon/2$, we get that $|P(\epsilon)|\alpha(k)(\epsilon/2)^k \le \alpha(k)(C+\epsilon/2)^k$, where $\alpha(k) = \pi^{k/2}/\Gamma(k/2+1)$ is the volume of a unit ball in $\mathbb{R}^k$. Hence $|P(\epsilon)| \le (C + 2/\epsilon)^k$ and $2^d \le (C + L/\gamma)^k$; i.e., $d \le k \log_2(C + L/\gamma)$. □

Next we prove Theorem 3.7 by applying the Lipschitz bound to a control system.

Proof of Theorem 3.7. Our aim is to compute the Lipschitz constant associated to the control system in Definition 2.6, and then we apply Theorem 3.6.

Denote the system parameters $(\alpha_{11}, \dots, \alpha_{nm}, a_1, b_1, \dots, a_r, b_r)$ by λ and assume $\|\lambda\|_\infty < 1$. Let

$$F(\lambda, u) = y(\tau) = \int_0^\tau \sum_{i=1}^m \sum_{\ell=1}^n \alpha_{i\ell} \xi_\ell(t) u_i(\tau - t) dt.$$

Functions $\xi_1(t), \dots, \xi_n(t)$ are of the form $\xi(t) = t^c e^{at} \sin(bt)$ or $\xi(t) = t^c e^{at} \cos(bt)$, where $a + ib$ is an eigenvalue of A and $c \in \{0, \dots, n-1\}$. Thus taking a partial derivative with respect to a or b will increase the power of t by one and change the trigonometric functions. Therefore,

$$\left| \frac{\partial F(\lambda, u)}{\partial \alpha_{\kappa\rho}} \right| = \left| \frac{\partial y(\tau)}{\partial \alpha_{\kappa\rho}} \right| = \left| \sum_{i=1}^m \sum_{\ell=1}^n d(i, \ell) \int_0^\tau \xi_\ell(t) u_i(\tau - t) dt \right|$$
$$\le nm \int_0^\tau |\xi_\ell(t) u_i(\tau - t)|\, dt \le nm\tau^{n-1} e^\tau M,$$

because $\sup_{t\in[0,\tau]} |\xi_\ell(t)| \le e^\tau \tau^n$ and $d(i, \ell) = \partial\alpha_{ij}/\partial\alpha_{\kappa\rho} = 1$ if $(i, \ell) = (\kappa, \rho)$ and zero otherwise. Similarly we calculate

$$\left| \frac{\partial F(\lambda, u)}{\partial a_\kappa} \right| = \left| \frac{\partial y(\tau)}{\partial a_\kappa} \right| \le nm\tau^n e^\tau M \text{ and}$$
$$\left| \frac{\partial F(\lambda, u)}{\partial b_\kappa} \right| = \left| \frac{\partial y(\tau)}{\partial b_\kappa} \right| \le nm\tau^n e^\tau M$$

as $\sup_{t\in[0,\tau]} |\frac{\partial \xi_\ell(t)}{\partial_\kappa}| \le e^\tau \tau^n$ and $\sup_{t\in[0,\tau]} |\frac{\partial \xi_\ell(t)}{\partial b_\kappa}| \le e^\tau \tau^n$.

Now the Lipschitz constant can be taken to be $L = n^2 m e^\tau \tau^n M$ as

$$|F(\lambda, u) - F(\lambda^*, u)| = |\nabla F \cdot (\lambda - \lambda^*)| \le L\|\lambda - \lambda^*\|_\infty.$$

The number of system parameters is at most $nm+n=(m+1)n$ and we get the level fat-shattering bound by applying Theorem 3.6 with space dimension $n(m+1)$ and $L=n^2me^\tau\tau^nM$. ∎

As a corollary, we combine the above result together with a pseudodimension bound to prove the fat-shattering bound given in Theorem 2.7.

COROLLARY 6.1 (fat-shattering bound in Theorem 2.7). *Assume that the system* $\dot{x}=Ax+Bu$, $y=Cx$, $x(0)=0$, *can be parameterized by* $\lambda\in\mathbb{R}^{n(m+1)}$ *as in Definition* 2.6 *with* $\|\lambda\|_\infty<1$, *and assume in addition that the control is given by* $u=G\omega$, *where the input basis functions* ω_j *are in* Ω *given by* (3). *We denote the corresponding control system class by*

$$\mathcal{F}_B=\{F(\lambda,\cdot):U\to\mathbb{R};\ \lambda\in B\}.$$

Then

$$\operatorname{fat}_\gamma(\mathcal{F}_B)\le\min\begin{cases}(m+1)n\log_2\left\lfloor\frac{n^2m\tau^ne^\tau kM}{\gamma}\right\rfloor,\\ 2(m+4)n\log_2\big(8e\big(nmk4(n+\ell_{\max})+1\big)\big(2nk+2(2k+1)^n\big)\big),\end{cases}$$

where $\ell_{\max}$ *is given by* (3) *and* (4) *and* M *is a constant satisfying*

$$\int_0^\tau|u_i(\tau-t)|dt\le kM$$

for all $i=1,\dots,m$.

Proof. The first part of the bound follows from Theorem 3.7 with kM in place of M.

The remaining part of the bound comes from the pseudodimension bound. First we derive the associated VC dimension bound. As we assumed that A has a fixed Jordan block structure, every entry of $e^{A(1-t)}$ is a linear combination of n functions $\xi_1(t),\dots,\xi_n(t)$. (That is, we do not need to consider all possible functions over different Jordan block structures.) This implies that in the Goldberg–Jerrum argument of section 5.1 we can take $\ell=mn+4n$, $d=nmk4(n+\ell_{\max})+1$, and $s=2nk+2(2k+1)^n$. Moreover, in that section the VC dimension bounds were derived for the time interval $[0,1]$. However, the upper bound depends on the number of system parameters and the degrees of polynomials to be evaluated. Changing the time interval to $[0,\tau]$ means just that we replace the eigenvalue parameters (referring to the proof of Proposition 5.1) $a,b,e^a\cos b,e^a\sin b$ by $a\tau,b\tau,e^{a\tau}\cos b\tau,e^{a\tau}\sin b\tau$.

The above bound is also a bound for the pseudodimension. Observe that for $\mathcal{G}=\{g:X\to\mathbb{R}\}$, the pseudodimension can be defined as $\operatorname{PD}(\mathcal{G})=\operatorname{VC}\{\operatorname{Ind}(x,y)=\operatorname{sign}(g(x)-y);\ g\in\mathcal{G}\}$. Hence we want to study the VC dimension associated to $\operatorname{sign}(y(\tau)-z)=\operatorname{sign}(P/Q-z)=\operatorname{sign}(\hat{P}/Q)$, where $\hat{P}=P-zQ$ has the same degree as P with respect to the parameters. Here z is a new input, but the bound utilizing Goldberg–Jerrum technique does not depend on the dimension of the inputs, and hence the above VC dimension bound is also a bound for the pseudodimension. (Note that here in the scale sensitive setting we do not apply the pseudodimension results of section 5.3 using loss functions, as those rescaled the outputs.) ∎

7. A class of systems with VC dimension *k*. For the control system (2) with scalar control $u(t)=\sum_{i=1}^k g_i\omega_i(t)$ and unrestricted $\omega_1,\dots,\omega_k$, the standard half-space argument gives an upper bound k. This bound is tight. We will give an example of a single-input, single-output one-parameter family of control systems in dimension two

that has VC dimension k, when the controls are of the form $u(t) = \sum_{i=1}^{k} g_i \omega_i(t)$ and $\omega_i(1-t) = 1_{[2^{-i}, 2^{-i}+2^{\alpha}]}$, where $\alpha = -2(k+1)$.

Consider a control system

$$\begin{aligned} \dot{x_1} &= x_2, \\ \dot{x_2} &= -\lambda^2 x_1 + u, \\ y &= -x_1. \end{aligned} \tag{13}$$

For time interval [0,1] and initial condition $(x_1, x_2) = (0,0)$, the output is given by $y(1) = \int_0^1 \sin(\lambda t) u(1-t)dt$.

LEMMA 7.1. *Controls* $\{\omega_1, \ldots, \omega_k\}$ *such that* $\omega_i(1-t) = 1_{[2^{-i}, 2^{-i}+2^{\alpha}]}$, *where* $\alpha = -2(k+1)$, *are shattered by the control system* (13) *with sign-observations.*

Proof. Let $T = \{2^{-i},\ i = 1, \ldots, k\}$ and $J \subseteq T$. Define $\lambda_J = \pi \sum_{i=1}^{k} a_i 2^i$, where $a_i = 1$ if $2^{-i} \notin J$ and $a_i = 0$ otherwise. Now if $t = 2^{-\ell}$, then

$$\lambda_J t = \pi \sum_{i=1}^{k} a_i 2^{i-\ell} = \pi \left(\underbrace{\sum_{i=1}^{\ell-1} a_i 2^{i-\ell}}_{1/2\, c_2} + a_\ell + \underbrace{\sum_{i=\ell+1}^{k} a_i 2^{i-\ell}}_{2c_1} \right),$$

where $c_1 \in \mathbb{N}$ and $0 \le c_2 < 2$.

Hence $\sin(\lambda_J t) = \sin(\pi(1/2\, c_2 + a_\ell))$. Note that if $a_\ell = 0$, then $1/2\, c_2 + a_\ell \in [0, 1 - 2^{-\ell}]$, and if $a_\ell = 1$, then $1/2\, c_2 + a_\ell \in [1, 2 - 2^{-\ell}]$. Thus $\sin(\pi(1/2\, c_2 + a_\ell)) \ge 0$ if $a_\ell = 0$, and $\sin(\pi(1/2\, c_2 + a_\ell)) \le 0$ if $a_\ell = 1$. Therefore, $\sin(\lambda_J t) \ge 0 \Leftrightarrow a_\ell = 0$ $\sin(\lambda_J t) \ge 0 \Leftrightarrow t \in J$. Further,

$$\int_{2^{-\ell}}^{2^{-\ell}+2^{\alpha}} \sin(\lambda_J t)dt \ge 0 \Leftrightarrow a_\ell = 0,$$

where α is taken so that

$$\sum_{j=1}^{k} 2^j 2^{\alpha} \le 2^{-(k+1)}. \tag{14}$$

This ensures that when $\ell \le k$ and $t \in [2^{-\ell}, 2^{-\ell} + 2^{\alpha}]$, $\lambda_J t \in [0, \pi(1 - 2^{-\ell} + \sum_{j=1}^{k} 2^j 2^{\alpha})] \subset [0, \pi)$ if $a_\ell = 0$ or similarly $\lambda_J t \in [\pi, 2\pi)$ if $a_\ell = 1$. In (14) we can take $\alpha = -2(k+1)$ as $\sum_{j=1}^{k} 2^j = 2^{k+1} - 2$.

In this way the integrand in $\int_{2^{-\ell}}^{2^{-\ell}+2^{\alpha}} \sin(\lambda_J t)dt$ is either positive or negative.

For $S \subseteq \{1, \ldots, k\}$, let $J = \{2^{-i}, i \in S\}$. For each ω_i,

$$\int_0^1 \sin(\lambda_J t)\omega_i(1-t)dt = \int_{2^{-i}}^{2^{-i}+2^{\alpha}} \sin(\lambda_J t)dt > 0 \Leftrightarrow i \in S;$$

i.e., the set of controls $\{\omega_1, \ldots, \omega_k\}$ is shattered by the mapping

$$\omega_i \mapsto \operatorname{sign}\left[\int_0^1 \sin(\lambda_J t)\omega_i(1-t)dt \right]. \qquad \square$$

Appendix. An example of the Goldberg–Jerrum bound.

We begin this appendix with an informal discussion on the Goldberg–Jerrum technique used to prove the VC dimension upper bounds in this paper.

We want to write $y(1) = P/Q$, where P and Q are polynomials. Unfortunately, the value of $\operatorname{sign} y(1)$ cannot be obtained by just evaluating P and Q since Q may have zeros. Therefore, we need to write

$$y(1) = \begin{cases} P_1/Q_1 & \text{if } f_1 \neq 0, \dots, f_\mu \neq 0, \\ \quad \vdots & \\ P_\gamma/Q_\gamma & \text{if } f_1 = 0, \dots, f_\mu \neq 0 \end{cases}$$

so that after evaluating μ polynomials $f_1, \dots, f_\mu$ we can pick a definition P_i/Q_i without poles in a region defined by the μ polynomials. When $y(1)$ is defined in this way, $\operatorname{sign} y(1)$ can be easily expressed by a Boolean formula evaluating $2\gamma + \mu$ polynomial inequalities and equalities.

For simplicity we assume that $p = 1$ and the initial condition $x(0) = 0$. Then using the notation of Proposition 5.1 we write

$$y(1) = \sum_{i=1}^{m} \sum_{r=1}^{n} \sum_{\ell=1}^{2n} \alpha_{ir\ell} \sum_{j=1}^{k} g_{ij} \int_0^1 \xi_\ell(x_{r1}, x_{r2}, t) \omega_j(t) dt,$$

and by the proof of Lemma 4.4

$$\int_0^1 \xi_\ell(x_{r1}, x_{r2}, t) \omega_j(t) dt = \frac{P_{\ell j}}{\left((x_{r1} + \alpha_j)^2 + (x_{r2} + \beta_j)^2\right)^{z_{\ell j}} \left((x_{r1} + \alpha_j)^2 + (x_{r2} - \beta_j)^2\right)^{z_{\ell j}}},$$

where $P_{\ell j}$ is some polynomial, $z_{\ell j} \in \mathbb{N}$, and $\omega_j(t) = t^{\ell_j} e^{\alpha_j t} \sin(\beta_j t)$ or $\omega_j(t) = t^{\ell_j} e^{\alpha_j t} \cos(\beta_j t)$. Hence the denominator of $\sum_{j=1}^{k} g_{ij} \int_0^1 \xi_\ell(x_{r1}, x_{r2}, t) \omega_j(t) dt$ is

$$\begin{aligned} &\left((x_{r1} + \alpha_1)^2 + (x_{r2} + \beta_1)^2\right)^{z_{\ell 1}} \left((x_{r1} + \alpha_1)^2 + (x_{r2} - \beta_1)^2\right)^{z_{\ell 1}} \\ &\quad \times \cdots \times \left((x_{r1} + \alpha_k)^2 + (x_{r2} + \beta_k)^2\right)^{z_{\ell k}} \left((x_{r1} + \alpha_k)^2 + (x_{r2} - \beta_k)^2\right)^{z_{\ell k}}. \end{aligned}$$

By carrying out all summations $y(1) = P/Q$. The denominator Q consists of the product

$$\begin{aligned} \prod_{r=1}^{n} \Big(&\left((x_{r1} + \alpha_1)^2 + (x_{r2} + \beta_1)^2\right)^* \left((x_{r1} + \alpha_1)^2 + (x_{r2} - \beta_1)^2\right)^* \\ &\times \cdots \times \left((x_{r1} + \alpha_k)^2 + (x_{r2} + \beta_k)^2\right)^* \left((x_{r1} + \alpha_k)^2 + (x_{r2} - \beta_k)^2\right)^* \Big), \end{aligned}$$

where $*$'s stand for some unspecified powers. Hence the zeros of Q are determined by $2nk$ polynomials $f_{ij1} = (x_{i1} + \alpha_j)^2 + (x_{i2} + \beta_j)^2$, $f_{ij2} = (x_{i1} + \alpha_j)^2 + (x_{i2} - \beta_j)^2$, and $i = 1, \dots, n$, $j = 1, \dots, k$. The number of different sign assignments determining γ is calculated as in the proof of Lemma 5.2.

Example. The purpose of the following example is to illustrate the function $y = P/Q$ used in the Goldberg–Jerrum technique together with the sequence of polynomial evaluations involved and a table for the final output depending on the outcomes of the polynomial evaluations.

Take $m = 1$, $n = 2$, $k = 2$, and assume that A has complex eigenvalues $a \pm ib$. Take basis input functions to be $\omega_1(t) = e^t$ and $\omega_2(t) = e^{2t}$. Then $y(1) = \sum_{l=1}^{2} \alpha_l \sum_{j=1}^{2} g_j \int_0^1 \xi_l(t) \omega_j(t)\, dt$, where $\xi_1(t) = e^{at} \sin(bt)$, $\xi_2(t) = e^{at} \cos(bt)$, α_1, α_2, a, b, $e^a \sin b$, and $e^a \cos b$ are system parameters and g_1, g_2 are input parameters.

By using formulae

$$\int_0^1 e^{\tilde{a}t}\sin(\tilde{b}t)\,dt = \frac{e^{\tilde{a}}(\tilde{a}\sin\tilde{b} - \tilde{b}\cos\tilde{b}) + \tilde{b}}{\tilde{a}^2+\tilde{b}^2} \quad \text{and}$$
$$\int_0^1 e^{\tilde{a}t}\cos(\tilde{b}t)\,dt = \frac{e^{\tilde{a}}(\tilde{a}\cos\tilde{b} + \tilde{b}\sin\tilde{b}) - \tilde{a}}{\tilde{a}^2+\tilde{b}^2},$$

we calculate the integrals appearing in the rationality condition, and we call them r_{11}, r_{12}, r_{21}, and r_{22}:

$$\int_0^1 \xi_1(t)\omega_1(t)\,dt = \int_0^1 e^{(a+1)t}\sin(bt)\,dt = \begin{cases} r_{11} & \text{if } (a+1)^2+b^2 \neq 0, \\ 0 & \text{if } (a+1)^2+b^2 = 0, \end{cases}$$
$$\int_0^1 \xi_1(t)\omega_2(t)\,dt = \begin{cases} r_{12} & \text{if } (a+2)^2+b^2 \neq 0, \\ 0 & \text{if } (a+2)^2+b^2 = 0, \end{cases}$$
$$\int_0^1 \xi_2(t)\omega_1(t)\,dt = \begin{cases} r_{21} & \text{if } (a+1)^2+b^2 \neq 0, \\ 1 & \text{if } (a+1)^2+b^2 = 0, \end{cases}$$
$$\int_0^1 \xi_2(t)\omega_2(t)\,dt = \begin{cases} r_{22} & \text{if } (a+2)^2+b^2 \neq 0, \\ 1 & \text{if } (a+2)^2+b^2 = 0. \end{cases}$$

The computation of $\operatorname{sign} y(1) = \operatorname{sign}(\sum_{l=1}^2 \alpha_l \sum_{j=1}^2 g_j \int_0^1 \xi_l(t)\omega_j(t)\,dt)$ is divided into three cases:

- Case $(a+1)^2+b^2 \neq 0$, $(a+2)^2+b^2 \neq 0$:

$$\operatorname{sign} y(1) = \operatorname{sign}(\alpha_1 g_1 r_{11} + \alpha_1 g_2 r_{12} + \alpha_2 g_1 r_{21} + \alpha_2 g_2 r_{22}) = \operatorname{sign}\left(\frac{P_1}{Q_1}\right).$$

- Case $(a+1)^2+b^2 = 0$, $(a+2)^2+b^2 \neq 0$:

$$\operatorname{sign} y(1) = \operatorname{sign}(\alpha_1 g_2 r_{12} + \alpha_2 g_1 + \alpha_2 g_2 r_{22}) = \operatorname{sign}\left(\frac{P_2}{Q_2}\right).$$

- Case $(a+1)^2+b^2 \neq 0$, $(a+2)^2+b^2 = 0$:

$$\operatorname{sign} y(1) = \operatorname{sign}(\alpha_1 g_1 r_{11} + \alpha_2 g_2 r_{21} + \alpha_2 g_2) = \operatorname{sign}\left(\frac{P_3}{Q_3}\right).$$

Thus we have three different expressions of the form $\frac{P}{Q}$.

Next we form the Boolean formula, $F = \operatorname{sign} y(1)$, evaluating polynomials $f_1 = (a+1)^2+b^2 = 0$, $f_2 = (a+2)^2+b^2 = 0$, $P_i > 0$, $Q_i > 0$ for $i \in \{1,2,3\}$. In the following table 1 means true and 0 means false for the above polynomial evaluation ($** = 1$ or 0, i.e., extend the table).

$f_1=0$	$f_2=0$	$P_1>0$	$Q_1>0$	$P_2>0$	$Q_2>0$	$P_3>0$	$Q_3>0$	F
0	0	1	1	**	**	**	**	1
0	0	1	0	**	**	**	**	0
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
1	0	**	**	1	1	**	**	1
1	0	**	**	1	0	**	**	0
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
0	1	**	**	**	**	0	0	1

In this case (see the statement of Goldberg–Jerrum bounds), $\Lambda = \{\alpha_1, \alpha_2, a, b, e^a \cos b, e^a \sin b\}$, $X = \{g_1, g_2\}$, $s = 8$, $d = 12$, and $l = 6$.

THE TOPOLOGICAL ASYMPTOTIC FOR THE HELMHOLTZ EQUATION WITH DIRICHLET CONDITION ON THE BOUNDARY OF AN ARBITRARILY SHAPED HOLE*

JULIEN POMMIER† AND BESSEM SAMET‡

Abstract. The aim of the topological sensitivity analysis is to obtain an asymptotic expansion of a design functional with respect to the creation of a small hole in the domain. In this paper, such an expansion is obtained for the Helmholtz equation, in two and three space dimensions, with a Dirichlet condition on the boundary of an arbitrarily shaped hole. In this case, the main difficulty is related to the nonhomogeneous symbol of the Helmholtz operator. In the numerical part of this work, we will show that the topological sensitivity method is very promising for solving shape inverse problems in electromagnetic applications.

Key words. topological optimization, topological asymptotic, topological gradient, nonhomogeneous problem, Helmholtz equation, shape inversion, electromagnetic applications, inverse scattering

1. Introduction.

The same numerical methods are generally used in shape inversion and optimal shape design. There are mainly two categories of shape inversion or shape optimization methods. In the first category we deform continuously the boundary of the object to be optimized in order to decrease a given cost function [5, 20, 25, 28, 31]. The final shape has the same topology as the initial shape given by the designer. Therefore, to reach the optimal geometry, we need a priori knowledge of its topology. However, the topology of the optimal shape is often the main unknown in object detection problems. For example, the knowledge of the number and the locations of buried mines is more important than their accurate shapes. The second category of algorithms allows topology modifications. Many important contributions in this field are concerned with structural mechanics and, in particular, the optimization of the compliance (external work) subject to a volume constraint [4, 16]. In view of the fact that the optimal structure has generally a large number of small holes, most authors [1, 3, 14] have considered composite material optimization. Using the homogenization theory, Allaire and Kohn [1] exhibit a class of laminated materials with an explicit expression for the optimal material at any point of the structure. In this case, the optimal solution is not a classical design—it is a distribution of composite materials. Then penalization methods must be applied in order to retrieve a realistic shape. For all these reasons, global optimization methods are used to solve more general problems [15, 26]. Unfortunately these methods are quite slow.

More recently, Eschenauer and Olhoff [7], Schumacher [27], Céa et al. [6], Garreau, Guillaume, and Masmoudi [8], Sokolowski and Zochowski [29, 30], and Nazarov and Sokolowski [21] presented a method to obtain the optimal topology by calculating the so-called topological gradient (or topological derivative). This gradient is a function

defined in the domain of interest where, at each point, it gives the sensitivity of the cost function when a small hole is created at that point. This approach seems to be general and efficient. To present the basic idea, we consider Ω a domain of $\mathbb{R}^n$, where n equals 2 or 3, and $j(\Omega) = J(u_\Omega)$ a cost function to be minimized, where u_Ω is the solution to a given PDE problem defined in Ω. For $\varepsilon > 0$, let $\Omega_\varepsilon = \Omega \backslash \overline{x_0 + \varepsilon\omega}$ be the subset obtained by removing a small part $\overline{x_0 + \varepsilon\omega}$ from Ω, where $x_0 \in \Omega$ and $\omega \subset \mathbb{R}^n$ is a fixed open and bounded subset containing the origin. We can generally prove that the variation of the criterion is given by the asymptotic expansion

$$j(\Omega_\varepsilon) = j(\Omega) + f(\varepsilon)g(x_0) + o(f(\varepsilon)), \tag{1.1}$$

$$\lim_{\varepsilon \to 0} f(\varepsilon) = 0, \quad f(\varepsilon) > 0. \tag{1.2}$$

This expansion is called the topological asymptotic. To minimize the criterion, we have to create holes where g (called the topological gradient) is negative.

In this paper, using the adjoint method and the domain truncation technique introduced in [17], we compute the topological asymptotic expansion for the Helmholtz equation in two and three space dimensions with a Dirichlet condition on the boundary of an arbitrarily shaped hole. The originality of this work is that the symbol of the Helmholtz operator is nonhomogeneous. The basic idea is to say that the leading term of the topological asymptotic expansion is given by the principal part of the operator in the case of a Dirichlet condition on the boundary of the hole. Our work generalizes the contribution of Guillaume and Sid Idris [9] for the Poisson equation and is easily applicable to other problems for which the symbol of the operator is nonhomogeneous, as, for example, the quasi-Stokes problem and the elastic waves problem. In the numerical part, we present some applications that illustrate the ability of the topological sensitivity approach to solve inverse scattering problems.

As a background to our work, we cite the contributions of Il'in [11, 12, 13] for the construction of asymptotic expansions of solutions to boundary value problems in domains with small holes, as in the case of second order scalar equations, by the use of the method of matched asymptotic expansions. Various spectral problems in domains with small holes are investigated by Maz'ya et al. [23, 24, 18, 22]. In [32], Vogelius and Volkov provided a rigorous derivation for solutions to the time-harmonic Maxwell's equations of a transverse electric (TE) nature, in the presence of a finite number of diametrically small inhomogeneities. Based on layer potential techniques, Ammari and Kang [2] provided a rigorous derivation of complete asymptotic expansions for solutions to the Helmholtz equation in two and three dimensions, in the presence of small inhomogeneities in the domain. In our work, we derive asymptotic expansions not for solutions, but for a given cost function.

The generalized adjoint method is recalled in section 2. Next, the formulation of the Helmholtz problem is presented in section 3 and its truncated version is described in section 4. Section 5 presents the main results whose proofs are given in section 6. Finally, numerical examples illustrate in section 7 the abilities of the topological sensitivity to solve inverse scattering problems.

2. A generalized adjoint method. In this section, the generalized adjoint method introduced in [17, 8] is slightly modified. The first modification is due to the fact that the cost function is defined in a $\mathbb{C}$-Hilbert space and takes values in $\mathbb{R}$; then it is not differentiable. For this reason, the differentiability property is replaced by the formulation (2.5). The second modification is due to the fact that the sesquilinear form associated with our problem is not coercive. For this reason, the coercivity property is replaced by the inf-sup condition (see Hypothesis 2).

Let $\mathcal{V}$ be a fixed complex Hilbert space. For $\varepsilon \geq 0$, let $a_\varepsilon(.,.)$ be a sesquilinear and continuous form on $\mathcal{V}$ and let l_ε be a semilinear and continuous form on $\mathcal{V}$. We consider the following assumptions.

Hypothesis 1. There exists a sesquilinear and continuous form δa, a semilinear and continuous form δ_l, and a real function $f(\varepsilon) > 0$ defined on $\mathbb{R}^*{}_+$ such that

$$\lim_{\varepsilon \to 0} f(\varepsilon) = 0, \tag{2.1}$$

$$\|a_\varepsilon - a_0 - f(\varepsilon)\delta a\|_{\mathcal{L}_2(\mathcal{V})} = o(f(\varepsilon)), \tag{2.2}$$

$$\|l_\varepsilon - l_0 - f(\varepsilon)\delta_l\|_{\mathcal{L}(\mathcal{V})} = o(f(\varepsilon)), \tag{2.3}$$

where $\mathcal{L}(\mathcal{V})$ (respectively, $\mathcal{L}_2(\mathcal{V})$) denotes the space of continuous and semilinear (respectively, sesquilinear) forms on $\mathcal{V}$.

Hypothesis 2. There exists a constant $\alpha > 0$ such that

$$\inf_{u \neq 0} \sup_{v \neq 0} \frac{|a_0(u,v)|}{\|u\|_{\mathcal{V}} \|v\|_{\mathcal{V}}} \geq \alpha.$$

We say that a_0 satisfies the inf-sup condition.

According to (2.2), there exists a constant $\beta > 0$ independent of ε such that

$$\inf_{u \neq 0} \sup_{v \neq 0} \frac{|a_\varepsilon(u,v)|}{\|u\|_{\mathcal{V}} \|v\|_{\mathcal{V}}} \geq \beta.$$

For $\varepsilon \geq 0$, let u_ε be the solution to the following problem: Find $u_\varepsilon \in \mathcal{V}$ such that

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \qquad \forall v \in \mathcal{V}. \tag{2.4}$$

We have the following lemma.

LEMMA 2.1. *If Hypotheses* 1 *and* 2 *are satisfied, then*

$$\|u_\varepsilon - u_0\|_{\mathcal{V}} = O(f(\varepsilon)).$$

Proof. It follows from Hypothesis 2 that there exists $v_\varepsilon \in \mathcal{V}, v_\varepsilon \neq 0$, such that

$$\beta \|u_\varepsilon - u_0\|_{\mathcal{V}} \|v_\varepsilon\|_{\mathcal{V}} \leq |a_\varepsilon(u_\varepsilon - u_0, v_\varepsilon)|,$$

which implies

$$\begin{aligned}
\beta \|u_\varepsilon - u_0\|_{\mathcal{V}} \|v_\varepsilon\|_{\mathcal{V}} &\leq |a_\varepsilon(u_0, v_\varepsilon) - l_\varepsilon(v_\varepsilon)| \\
&= |a_\varepsilon(u_0, v_\varepsilon) - (l_\varepsilon - l_0 - f(\varepsilon)\delta_l)(v_\varepsilon) - l_0(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)| \\
&= |(a_\varepsilon(u_0, v_\varepsilon) - a_0(u_0, v_\varepsilon)) - (l_\varepsilon - l_0 - f(\varepsilon)\delta_l)(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)| \\
&\leq |a_\varepsilon(u_0, v_\varepsilon) - a_0(u_0, v_\varepsilon) - f(\varepsilon)\delta a(u_0, v_\varepsilon)| \\
&\quad + |l_\varepsilon(v_\varepsilon) - l_0(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)| + f(\varepsilon)(|\delta a(u_0, v_\varepsilon)| + |\delta_l(v_\varepsilon)|).
\end{aligned}$$

Using Hypothesis 1 we obtain

$$\beta \parallel u_\varepsilon - u_0 \parallel_{\mathcal{V}} \|v_\varepsilon\|_{\mathcal{V}} \leq \big(o(f(\varepsilon)) + f(\varepsilon)(\|\delta a\|_{\mathcal{L}_2(\mathcal{V})} \|u_0\|_{\mathcal{V}} + \|\delta_l\|_{\mathcal{L}(\mathcal{V})})\big) \|v_\varepsilon\|_{\mathcal{V}}. \qquad \square$$

Consider now a cost function $j(\varepsilon) = J(u_\varepsilon)$, where the functional J satisfies

$$J(u+h) = J(u) + \Re(L_u(h)) + o(\|h\|) \qquad \forall u, h \in \mathcal{V}, \tag{2.5}$$

where L_u is a linear and continuous form on $\mathcal{V}$.

For $\varepsilon \geq 0$, we define the Lagrangian operator $\mathcal{L}_\varepsilon$ by

$$\mathcal{L}_\varepsilon(u,v) = J(u) + a_\varepsilon(u,v) - l_\varepsilon(v) \qquad \forall u,v \in \mathcal{V}.$$

The next theorem gives the asymptotic expansion of $j(\varepsilon)$.

THEOREM 2.2. *If Hypotheses* 1 *and* 2 *are satisfied, then*

$$j(\varepsilon) - j(0) = f(\varepsilon)\Re(\delta_{\mathcal{L}}(u_0,p_0)) + o(f(\varepsilon)), \tag{2.6}$$

where u_0 is the solution to (2.4) *with $\varepsilon = 0$, and p_0 is the solution to the following adjoint problem: Find $p_0 \in \mathcal{V}$ such that*

$$a_0(v,p_0) = -L_{u_0}(v) \qquad \forall v \in \mathcal{V} \tag{2.7}$$

and

$$\delta_{\mathcal{L}}(u,v) = \delta a(u,v) - \delta_l(v) \qquad \forall u,v \in \mathcal{V}.$$

Proof. We have that

$$j(\varepsilon) = \mathcal{L}_\varepsilon(u_\varepsilon, v) \qquad \forall \varepsilon \geq 0 \qquad \forall v \in \mathcal{V}.$$

Next, choosing $v = p_0$, we obtain

$$\begin{aligned} j(\varepsilon) - j(0) &= \mathcal{L}_\varepsilon(u_\varepsilon,p_0) - \mathcal{L}_0(u_0,p_0) \\ &= J(u_\varepsilon) - J(u_0) + a_\varepsilon(u_\varepsilon,p_0) - a_0(u_0,p_0) + l_0(p_0) - l_\varepsilon(p_0) \\ &= J(u_\varepsilon) - J(u_0) + \Re(a_\varepsilon(u_\varepsilon,p_0) - a_0(u_0,p_0)) - \Re(l_\varepsilon(p_0) - l_0(p_0)) \\ &= J(u_\varepsilon) - J(u_0) + \Re(a_\varepsilon(u_\varepsilon,p_0) - a_0(u_\varepsilon,p_0) + a_0(u_\varepsilon - u_0,p_0)) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

Using (2.5), we have that

$$J(u_\varepsilon) - J(u_0) = \Re(L_{u_0}(u_\varepsilon - u_0)) + o(\|u_\varepsilon - u_0\|).$$

Hence,

$$\begin{aligned} j(\varepsilon) - j(0) = \Re(a_\varepsilon(u_\varepsilon,p_0) - a_0(u_\varepsilon,p_0)) + \Re(a_0(u_\varepsilon - u_0,p_0) + L_{u_0}(u_\varepsilon - u_0)) \\ +o(\|u_\varepsilon - u_0\|) - \Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

Using that p_0 is the adjoint solution, we obtain

$$\begin{aligned} j(\varepsilon) - j(0) &= \Re(a_\varepsilon(u_\varepsilon,p_0) - a_0(u_\varepsilon,p_0)) + o(\|u_\varepsilon - u_0\|) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)) \\ &= \Re((a_\varepsilon - a_0)(u_0,p_0)) + \Re((a_\varepsilon - a_0)(u_\varepsilon - u_0,p_0)) + o(\|u_\varepsilon - u_0\|) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

It follows from Hypothesis 1 that

$$\begin{aligned} j(\varepsilon) - j(0) = f(\varepsilon)\Re(\delta a(u_0,p_0)) + o(f(\varepsilon)) + f(\varepsilon)\Re(\delta a(u_\varepsilon - u_0,p_0)) + o(f(\varepsilon))\|u_\varepsilon - u_0\| \\ +o(\|u_\varepsilon - u_0\|) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

Finally, from Lemma 2.1 and the hypothesis $\lim_{\varepsilon\to 0} f(\varepsilon) = 0$, we have

$$j(\varepsilon) = j(0) + f(\varepsilon)\Re(\delta a(u_0,p_0) - \delta_l(p_0)) + o(f(\varepsilon)),$$

since δ_a is continuous by assumption. ∎

3. The Helmholtz problem in a domain with a small hole. Let Ω be an open and bounded subset of $\mathbb{R}^n$ with boundary $\Gamma = \Gamma_0 \cup \Gamma_1$, $n = 2$ or 3. The Helmholtz problem is

$$\left\{\begin{array}{lll} \Delta u_\Omega + k^2 u_\Omega &= 0 & \text{in } \Omega, \\ u_\Omega &= 0 & \text{on } \Gamma_0, \\ \dfrac{\partial u_\Omega}{\partial n} &= \Lambda u_\Omega + \Theta & \text{on } \Gamma_1, \end{array}\right. \tag{3.1}$$

where $k \in \mathbb{R}^*$, $\Theta \in H_{00}^{\frac{1}{2}}(\Gamma_1)'$, and $\Lambda \in \mathcal{L}(H_{00}^{\frac{1}{2}}(\Gamma_1), H_{00}^{\frac{1}{2}}(\Gamma_1)')$.

We define

$$\left\{\begin{array}{lll} \mathcal{V}(\Omega) &=& \{v \in H^1(\Omega), v = 0 \text{ on } \Gamma_0\}, \\ a(\Omega, u, v) &=& \displaystyle\int_\Omega \nabla u.\nabla \overline{v}\, dx - k^2 \int_\Omega u\overline{v}\, dx - \langle \Lambda u, \overline{v}\rangle, \\ \ell(v) &=& \langle \Theta, \overline{v}\rangle, \end{array}\right. \tag{3.2}$$

where $\langle , \rangle$ is the duality product between $H_{00}^{\frac{1}{2}}(\Gamma_1)'$ and $H_{00}^{\frac{1}{2}}(\Gamma_1)$. The variational formulation associated with (3.1) is the following: Find $u_\Omega \in \mathcal{V}(\Omega)$ such that

$$a(\Omega, u_\Omega, v) = \ell(v) \qquad \forall v \in \mathcal{V}(\Omega). \tag{3.3}$$

We consider the following assumption.

Hypothesis 3. The operator Λ is split into $\Lambda_0 + \Lambda_1$, with $\Lambda_1 \in \mathcal{L}(H_{00}^{\frac{1}{2}}(\Gamma_1), H_{00}^{\frac{1}{2}}(\Gamma_1)')$, and satisfies

$$\Re\langle \Lambda_1 \psi, \overline{\psi}\rangle \le 0 \qquad \forall \psi \in H_{00}^{\frac{1}{2}}(\Gamma_1), \tag{3.4}$$

and $\Lambda_2 \in \mathcal{L}(H_{00}^{\frac{1}{2}}(\Gamma_1), H_{00}^{\frac{1}{2}}(\Gamma_1))$. We assume the following property of uniqueness.

Hypothesis 4. We have

$$a(\Omega, u, v) = 0 \qquad \forall v \in \mathcal{V}(\Omega) \Rightarrow u = 0, \tag{3.5}$$

$$a(\Omega, u, v) = 0 \qquad \forall u \in \mathcal{V}(\Omega) \Rightarrow v = 0. \tag{3.6}$$

From the Lax–Milgram theorem and the fact that the imbeddings $\mathcal{V}_\Omega \to L^2(\Omega)$ and $H_{00}^{\frac{1}{2}}(\Gamma_1) \to L^2(\Gamma_1)$ are compact, and due to the Fredholm alternative, we obtain the following result (see, e.g., [10] for a detailed argument).

PROPOSITION 3.1. *If Hypotheses* 3 *and* 4 *are satisfied, we have the following:*

1. *Problem* (3.3) *has one and only one solution.*
2. *The sesquilinear form* $a(\Omega, ., .)$ *satisfies the inf-sup condition: There exists a constant* $a > 0$ *such that*

$$\inf_{u\neq 0} \sup_{v\neq 0} \frac{|a_\Omega(u, v)|}{\|u\|_{\mathcal{V}(\Omega)} \|v\|_{\mathcal{V}(\Omega)}} \ge a. \tag{3.7}$$

For a given $x_0 \in \Omega$, consider the modified open subset $\Omega_\varepsilon = \Omega \backslash \overline{\omega_\varepsilon}$, $\omega_\varepsilon = x_0 + \varepsilon\omega$, where ω is a fixed open and bounded subset of $\mathbb{R}^n$ containing the origin ($\omega_\varepsilon = \emptyset$ if $\varepsilon = 0$), whose boundary $\partial\omega$ is connected and piecewise of class $\mathcal{C}^1$. The modified solution u_{Ω_ε} satisfies

$$\left\{\begin{array}{lll} \Delta u_{\Omega_\varepsilon} + k^2 u_{\Omega_\varepsilon} &= 0 & \text{in } \Omega_\varepsilon, \\ u_{\Omega_\varepsilon} &= 0 & \text{on } \Gamma_0, \\ u_{\Omega_\varepsilon} &= 0 & \text{on } \partial\omega_\varepsilon, \\ \dfrac{\partial u_{\Omega_\varepsilon}}{\partial n} &= \Lambda u_{\Omega_\varepsilon} + \Theta & \text{on } \Gamma_1. \end{array}\right. \tag{3.8}$$

The function u_{Ω_ε} is defined on the variable open set Ω_ε, and thus belongs to a functional space which depends on ε. Hence, if we want to derive the asymptotic expansion of a function of the form

$$j(\varepsilon) = J(u_{\Omega_\varepsilon}), \tag{3.9}$$

we cannot apply directly the tools of section 2, which require a fixed functional space. For this reason, we use the domain truncation method introduced in [17] to avoid this complication.

4. The truncation method. Let $R > 0$ be such that the closed ball $\overline{B(x_0, R)}$ is included in Ω. It is supposed throughout this paper that ε remains small enough so that $\overline{\omega_\varepsilon} \subset B(x_0, R)$. The truncated open subset is defined by

$$\Omega_R = \Omega \backslash \overline{B(x_0, R)}. \tag{4.1}$$

The open subset $B(x_0, R)\backslash\overline{\omega_\varepsilon}$ is denoted by D_ε (see Figure 4.1). For $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$ and $\varepsilon > 0$, let u_ε^φ be the solution to the following problem: Find u_ε^φ such that

$$\left\{ \begin{array}{lll} \Delta u_\varepsilon^\varphi + k^2 u_\varepsilon^\varphi & = 0 & \text{in } D_\varepsilon, \\ u_\varepsilon^\varphi & = 0 & \text{on } \partial\omega_\varepsilon, \\ u_\varepsilon^\varphi & = \varphi & \text{on } \Gamma_R, \end{array} \right. \tag{4.2}$$

where Γ_R is the boundary of the ball $B(x_0, R)$. For $\varepsilon = 0$, u_0^φ is the solution to

$$\left\{ \begin{array}{lll} \Delta u_0^\varphi + k^2 u_0^\varphi & = 0 & \text{in } B(x_0, R), \\ u_0^\varphi & = \varphi & \text{on } \Gamma_R. \end{array} \right. \tag{4.3}$$

Using the Poincaré inequality, it can easily be seen that for $R < \frac{1}{\sqrt{2}|k|}$, (4.2) has one and only one solution.

For $\varepsilon \geq 0$, the Dirichlet-to-Neumann operator T_ε is defined by

$$\begin{array}{rccc} T_\varepsilon : & H^{1/2}(\Gamma_R) & \longrightarrow & H^{-1/2}(\Gamma_R), \\ & \varphi & \longmapsto & T_\varepsilon\varphi = \nabla u_\varepsilon^\varphi . n_{|\Gamma_R}, \end{array}$$

where the normal $n_{|\Gamma_R}$ is chosen outward to D_ε on Γ_R and $\partial\omega_\varepsilon$.

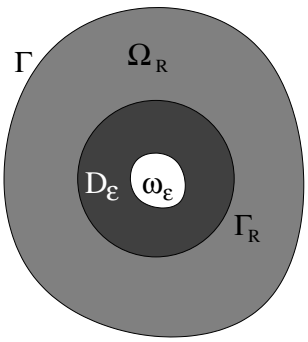

FIG. 4.1. *The truncated domain.*

Finally, we define for $\varepsilon \geq 0$ the solution u_ε to the truncated problem

$$\left\{\begin{array}{lll} \Delta u_\varepsilon + k^2 u_\varepsilon & = 0 & \text{in } \Omega_R, \\ u_\varepsilon & = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial u_\varepsilon}{\partial n} & = \Lambda u_\varepsilon + \Theta & \text{on } \Gamma_1, \\ \dfrac{\partial u_\varepsilon}{\partial n} - T_\varepsilon u_{\varepsilon|\Gamma_R} & = 0 & \text{on } \Gamma_R. \end{array}\right. \tag{4.4}$$

The variational formulation associated with (4.4) is as follows: Find $u_\varepsilon \in \mathcal{V}_R$ such that

$$a_\varepsilon(u_\varepsilon, v) = \ell(v) \qquad \forall v \in \mathcal{V}_R, \tag{4.5}$$

where the functional space $\mathcal{V}_R$ and the sesquilinear form a_ε are defined by

$$\mathcal{V}_R = \{v \in H^1(\Omega_R);\ v_{|\Gamma_0} = 0\}, \tag{4.6}$$

$$a_\varepsilon(u, v) = \int_{\Omega_R} \nabla u . \nabla \overline{v}\ dx - k^2 \int_{\Omega_R} u . \overline{v}\ dx - \langle \Lambda u, \overline{v} \rangle + \int_{\Gamma_R} T_\varepsilon u_{|\Gamma_R} \overline{v}\ d\gamma(x). \tag{4.7}$$

Here, $\int_{\Gamma_R}$ denotes the duality product between $H^{1/2}(\Gamma_R)$ and $H^{-1/2}(\Gamma_R)$. The following result is standard in PDE theory.

PROPOSITION 4.1. *Problems* (3.8) *and* (4.4) *have a unique solution. Moreover, the restriction to* Ω_R *of the solution* u_{Ω_ε} *to* (3.8) *is the solution* u_ε *to* (4.4).

We now have at our disposal the fixed Hilbert space $\mathcal{V}_R$ required by section 2. We assume that the following hypothesis holds.

Hypothesis 5. The function J introduced in (3.9) is defined in a neighboring part of Γ and satisfies

$$J(u + h) = J(u) + \Re\left(L_u(h)\right) + o\left(\|h\|\right) \qquad \forall u, h \in \mathcal{V}_R,$$

where L_u is a linear and continuous form on $\mathcal{V}_R$.

Then we obtain that

$$j(\varepsilon) = J(u_{\Omega_\varepsilon}) = J(u_\varepsilon) \qquad \forall \varepsilon \geq 0. \tag{4.8}$$

Remark 1. We can also consider a more general cost function (see, e.g., [9]); the truncation method does not restrict the choice of the function. In the numerical part of this work, only measurements on the boundary of the domain are used. For this reason and to simplify the presentation, we considered the previous assumption about the cost function.

Let v_Ω be the solution to the adjoint problem

$$a(\Omega, w, v_\Omega) = -L_{u_\Omega}(w) \qquad \forall w \in \mathcal{V}(\Omega), \tag{4.9}$$

where the functional space $\mathcal{V}(\Omega)$ and the sesquilinear form $a(\Omega, ., .)$ are defined in (3.2). It has been shown in Proposition 4.1 that u_0 is the restriction to Ω_R of u_Ω. Similarly, v_0, the solution to

$$a_0(w, v_0) = -L_{u_0}(w) \qquad \forall w \in \mathcal{V}_R, \tag{4.10}$$

is the restriction to Ω_R of v_Ω.

5. The main results. This section contains the main results of this paper. All the proofs are reported in section 6. Henceforth, we have to distinguish between the cases $n = 2$ and $n = 3$. This is due to the fact that the fundamental solutions to the Laplace equation in $\mathbb{R}^2$ and $\mathbb{R}^3$ have an essentially different asymptotic expansion at infinity, and (5.1) has generally no solution if $n = 2$.

5.1. The three-dimensional case. Possibly changing the coordinate system, we can suppose for convenience that $x_0 = 0$. In order to derive the topological sensitivity of the function j, we introduce two auxiliary problems.

The first problem, called the *exterior problem*, is formulated in $\mathbb{R}^3\backslash\overline{\omega}$ and consists of finding v_ω, solution to

$$\left\{\begin{array}{lll} -\Delta v_\omega & = 0 & \text{in } \mathbb{R}^3\backslash\overline{\omega}, \\ v_\omega & = 0 & \text{at } \infty, \\ v_\omega & = u_\Omega(x_0) & \text{on } \partial\omega, \end{array}\right. \tag{5.1}$$

where u_Ω is the solution to the direct problem (3.1). Here, one can remark that just the principal part of the Helmholtz operator is used, which was described by the Laplace equation. The function v_ω can be expressed by a single layer potential on $\partial\omega$. Let

$$E(y) = \frac{1}{4\pi r} \tag{5.2}$$

with $r = ||y||$. It is a fundamental solution for the Laplace equation in $\mathbb{R}^3$. Then the function v_ω reads

$$v_\omega(y) = \int_{\partial\omega} E(y-x) p_\omega(x)\ d\gamma(x), \quad y \in \mathbb{R}^3\backslash\overline{\omega}, \tag{5.3}$$

where $p_\omega \in H^{-\frac{1}{2}}(\partial\omega)$ is the solution to boundary integral equation

$$\int_{\partial\omega} E(y-x) p_\omega(x)\ d\gamma(x) = u_\Omega(x_0) \qquad \forall y \in \partial\omega. \tag{5.4}$$

For x bounded and large $r = ||y||$, we have

$$E(y-x) = E(y) + O\left(\frac{1}{r^2}\right), \tag{5.5}$$

and the asymptotic expansion at infinity of the function v_ω is given by

$$v_\omega(y) = P_\omega(y) + W_\omega(y), \tag{5.6}$$

$$P_\omega(y) = A_\omega\left(u_\Omega(x_0)\right) E(y), \tag{5.7}$$

$$A_\omega\left(u_\Omega(x_0)\right) = \int_{\partial\omega} p_\omega(x)\ d\gamma(x), \tag{5.8}$$

$$W_\omega(y) = O\left(\frac{1}{r^2}\right). \tag{5.9}$$

Notice that $P_\omega \in L^m_{loc}$ for all $m < 3$. Clearly, the function $\alpha \longmapsto A_\omega(\alpha)$ is linear on $\mathbb{R}$, and the number $A_\omega(\alpha)$ depends on the shape of ω.

The second problem, which we call *interior problem*, is formulated in $D_0 = B(x_0, R)$ and consists to find Q^1_ω solution to

$$\left\{ \begin{array}{ll} \Delta Q^1_\omega + k^2 Q^1_\omega & = 0 \qquad \text{in } D_0, \\ Q^1_\omega & = P_{\omega|\Gamma_R} \quad \text{on } \Gamma_R. \end{array} \right. \tag{5.10}$$

Here, the idea is to consider an interior and exterior problem that gives a good "first order approximation" of $(u^\varphi_\varepsilon - u^\varphi_0)_{|D_\varepsilon}$, $\varphi = u_{\Omega|\Gamma_R}$, in the form $f(\varepsilon)(Q^1_\omega - P_\omega)$, in a way which will be stated precisely in section 6. But the given formulation (5.10) of the interior problem, which is the "natural" choice, is not sufficient to get the behavior needed by the adjoint technique described in section 2. More precisely, in this case one can construct the sesquilinear form δa but there is no positive function $f(\varepsilon)$ such that $||a_\varepsilon - a_0 - f(\varepsilon)\delta_a||_{\mathcal{L}_2(\mathcal{V}_R)} = o(f(\varepsilon))$. Indeed, one can observe through the proof of Proposition 6.7 that the behavior of $||a_\varepsilon - a_0 - f(\varepsilon)\delta_a||_{\mathcal{L}_2(\mathcal{V}_R)}$ is not of order $o(\varepsilon)$, but only of order $O(\varepsilon)$. This is due to the approximation used on the exterior problem (5.1), where just the principal part of the operator is considered. For this reason, a new term Q^2_ω is used in order to correct the error caused by this approximation. We construct Q^2_ω as the solution to

$$\left\{ \begin{array}{ll} \Delta Q^2_\omega + k^2 Q^2_\omega & = k^2 P_\omega \quad \text{in } D_0, \\ Q^2_\omega & = 0 \qquad \text{on } \Gamma_R. \end{array} \right. \tag{5.11}$$

Setting $Q_\omega = Q^1_\omega + Q^2_\omega$, then Q_ω is the solution to

$$\left\{ \begin{array}{ll} \Delta Q_\omega + k^2 Q_\omega & = k^2 P_\omega \quad \text{in } D_0, \\ Q_\omega & = P_{\omega|\Gamma_R} \quad \text{on } \Gamma_R. \end{array} \right. \tag{5.12}$$

Using the corrected interior problem (5.12), one can derive the good approximation of $(u^\varphi_\varepsilon - u^\varphi_0)_{|D_\varepsilon}$. The main result is the following, which will be proved in section 6.

THEOREM 5.1. *Let $j(\varepsilon) = J(u_{\Omega_\varepsilon})$ be a cost function satisfying Hypothesis* 5. *Then the topological asymptotic expansion is given by*

$$j(\varepsilon) - j(0) = \varepsilon \Re \left(A_\omega \left(u_\Omega(x_0) \right) \overline{v_\Omega(x_0)} \right) + o(\varepsilon), \tag{5.13}$$

where u_Ω is the direct state solution to (3.1) *and v_Ω is the adjoint state solution to* (4.9).

Then the topological gradient is given by

$$g(x) = \Re \left(A_\omega \left(u_\Omega(x) \right) \overline{v_\Omega(x)} \right) \qquad \forall x \in \Omega,$$

and only two systems must be solved in order to compute $g(x)$ for all $x \in \Omega$.

When ω is the unit ball $B(0,1)$, then $v_\omega(y)$, $P_\omega(y)$, and $W_\omega(y)$ can be computed explicitly:

$$v_\omega(y) = \frac{u_\Omega(x_0)}{r} = P_\omega(y), \quad W_\omega(y) = 0, \quad 0 \neq y \in \mathbb{R}^3. \tag{5.14}$$

Then it follows from (5.2) and (5.7) that

$$A_\omega \left(u_\Omega(x_0) \right) = 4\pi u_\Omega(x_0). \tag{5.15}$$

We have the following result.

COROLLARY 5.2. *Under the assumptions of Theorem* 5.1 *and when ω is the unit ball $B(0,1)$, the topological asymptotic expansion is given by*

$$j(\varepsilon) - j(0) = 4\pi\varepsilon \Re \left(u_\Omega(x_0) \overline{v_\Omega(x_0)} \right) + o(\varepsilon). \tag{5.16}$$

5.2. The two-dimensional case. In this section, we intend to derive the asymptotic expansion of the function j in the two-dimensional case. The technique used is similar to that of the three-dimensional case. We use the principal part of the Helmholtz operator to derive the topological sensitivity expression. Next, we briefly describe the transposition of the previous results to the two-dimensional case. As before, u_Ω and the adjoint state v_Ω are, respectively, the solutions to (3.1) and (4.9).

The exterior problem must now be defined differently than in (5.1). It consists of finding v_ω, the solution to

$$\left\{\begin{array}{lll} -\Delta v_\omega & = 0 & \text{in } \mathbb{R}^2\backslash\overline{\omega}, \\ v_\omega(y)/\log r & = u_\Omega(x_0) & \text{at } \infty, \\ v_\omega & = 0 & \text{on } \partial\omega. \end{array}\right. \tag{5.17}$$

A fundamental solution for the Laplace equation in $\mathbb{R}^2$ is given by

$$E(y) = -\frac{1}{2\pi}\log r. \tag{5.18}$$

The function v_ω has the form

$$v_\omega(y) = u_\Omega(x_0)\log\|y\| + P_\omega + W_\omega(y), \tag{5.19}$$

where P_ω is constant and $W_\omega(y) = o(1)$ at infinity [9]. In the next proposition (where ω is not supposed to be a ball), one can observe that in the two-dimensional case the topological sensitivity does not depend on the shape of the hole ω, in contrast to the three-dimensional case.

THEOREM 5.3. *The assumptions are the same as in Theorem* 5.1. *The function j has the asymptotic expansion*

$$j(\varepsilon) = j(0) - \frac{2\pi}{\log\varepsilon}\Re\left(u_\Omega(x_0)\overline{v_\Omega(x_0)}\right) + o\left(\frac{1}{\log\varepsilon}\right). \tag{5.20}$$

The proof for the two-dimensional case uses the same tools as the three-dimensional case (see section 6) and will not be repeated.

6. Proofs. This section consists of the proof of Theorem 5.1. The variation of the sesquilinear form a_ε reads

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Gamma_R}(T_\varepsilon - T_0)u\overline{v}\; d\gamma(x). \tag{6.1}$$

Hence, the problem reduces to the analysis of $(T_\varepsilon - T_0)\varphi$ for $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$. More precisely, it will be shown that there exists an operator $\delta T \in \mathcal{L}(H^{\frac{1}{2}}(\Gamma_R), H^{-\frac{1}{2}}(\Gamma_R))$ such that

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H^{\frac{1}{2}}(\Gamma_R),H^{-\frac{1}{2}}(\Gamma_R))} = O(\varepsilon^{3/2}). \tag{6.2}$$

Consequently, defining δa by

$$\delta a(u,v) = \int_{\Gamma_R}\delta T u\overline{v}\; d\gamma(x) \qquad \forall u,v \in \mathcal{V}_R \tag{6.3}$$

will yield straightforwardly

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}(H^{\frac{1}{2}}(\Gamma_R),H^{-\frac{1}{2}}(\Gamma_R))} = O(\varepsilon^{3/2}). \tag{6.4}$$

First we need some definitions and preliminary lemmas.

6.1. Definitions. For convenience, the following norms and seminorms are chosen for the functional spaces which will be used.

- For a bounded and open subset $\mathcal{O} \subset \mathbb{R}^3$ and $m \geq 0$, the Sobolev space $H^m(\mathcal{O})$ is equipped with the norm defined by

$$\|u\|^2_{m,\mathcal{O}} = \sum_{j=0}^{m} |u|^2_{j,\mathcal{O}},$$

where the seminorms $|u|_{j,\mathcal{O}}$ are given by

$$|u|^2_{j,\mathcal{O}} = \sum_{|\alpha|=j} \int_{\mathcal{O}} |\partial_\alpha u|^2 \, dx. \tag{6.5}$$

- For a given $\varepsilon > 0$, the space $H^{\frac{1}{2}}(\Gamma_{R/\varepsilon})$ is equipped with the norm

$$\|u\|_{\frac{1}{2},\Gamma_{R/\varepsilon}} = \inf\{\|v\|_{1,C(R/2\varepsilon,R/\varepsilon)};\ v_{|\Gamma_{R/\varepsilon}} = u\},$$

where $C(r,r') = \{x \in \mathbb{R}^3; r < ||x|| < r'\}$.

- The dual space $H^{-\frac{1}{2}}(\Gamma_{R/\varepsilon})$ is equipped with the natural norm

$$\|w\|_{-\frac{1}{2},\Gamma_{R/\varepsilon}} = \sup\{|\langle w, v\rangle_{-\frac{1}{2},\frac{1}{2}};\ v \in H^{\frac{1}{2}}(\Gamma_{R/\varepsilon}); \|v\|_{\frac{1}{2},\Gamma_{R/\varepsilon}} = 1\},$$

where $\langle , \rangle_{-\frac{1}{2},\frac{1}{2}}$ is the duality product between $H^{\frac{1}{2}}(\Gamma_{R/\varepsilon})$ and $H^{-\frac{1}{2}}(\Gamma_{R/\varepsilon})$.

6.2. Preliminary lemmas. Recall that $x_0 = 0$. We will use extensively the following change of variable: For a given function u defined on a subset $\mathcal{O}$, the function $\tilde{u}$ is defined on $\widetilde{\mathcal{O}} = \mathcal{O}/\varepsilon$ by

$$\tilde{u}(y) = u(x), \quad y = \frac{x}{\varepsilon}.$$

LEMMA 6.1. *We have that*

$$|u|_{1,\mathcal{O}} = \varepsilon^{1/2} |\tilde{u}|_{1,\widetilde{\mathcal{O}}}, \tag{6.6}$$

$$\|u\|_{0,\mathcal{O}} = \varepsilon^{3/2} \|\tilde{u}\|_{0,\widetilde{\mathcal{O}}}. \tag{6.7}$$

Proof. Due to $\nabla u(x) = \nabla \tilde{u}(y)/\varepsilon$ and to definition (6.5), we have

$$|u|^2_{1,\mathcal{O}} = \int_{\mathcal{O}} |\nabla u|^2 \, dx = \frac{1}{\varepsilon^2} \int_{\widetilde{\mathcal{O}}} |\nabla \tilde{u}|^2 \varepsilon^3 \, dy.$$

Similarly, we have

$$\|u\|_{0,\mathcal{O}} = \varepsilon^{3/2} \|\tilde{u}\|_{0,\widetilde{\mathcal{O}}}. \qquad \square$$

LEMMA 6.2 (see [9]). *For $\varphi \in H^{\frac{1}{2}}(\partial\omega)$, let v be the solution to the problem*

$$\begin{cases} -\Delta v &= 0 \quad \text{in } \mathbb{R}^3 \backslash \overline{\omega}, \\ v &= 0 \quad \text{at } \infty, \\ v &= \varphi \quad \text{on } \partial\omega. \end{cases} \tag{6.8}$$

The function v is split into

$$\begin{aligned} v(y) &= V(y) + W(y), \\ V(y) &= E(y) \int_{\partial\omega} p(x)\ d\gamma(x), \end{aligned}$$

where $E(y) = \frac{1}{4\pi\|y\|}$ *and* $p \in H^{-\frac{1}{2}}(\partial\omega)$ *is the unique solution to*

$$\int_{\partial\omega} E(y-x)p(x)\ d\gamma(x) = \varphi(y) \qquad \forall y \in \partial\omega. \tag{6.9}$$

There exists a constant $c > 0$ *(independent of* φ *and* ε*) such that*

$$\begin{aligned} \|V\|_{0,C(R/2\varepsilon,R/\varepsilon)} &\leq c\varepsilon^{-1/2}\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ |V|_{1,C(R/2\varepsilon,R/\varepsilon)} &\leq c\varepsilon^{1/2}\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ \|V\|_{0,D_\varepsilon/\varepsilon} &\leq c\varepsilon^{-1/2}\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ |V|_{1,D_\varepsilon/\varepsilon} &\leq c\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ \|W\|_{0,C(R/2\varepsilon,R/\varepsilon)} &\leq c\varepsilon^{1/2}\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ |W|_{1,C(R/2\varepsilon,R/\varepsilon)} &\leq c\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\partial\omega}, \\ \|W\|_{0,D_\varepsilon/\varepsilon} &\leq c\|\varphi\|_{\frac{1}{2},\partial\omega}. \end{aligned}$$

LEMMA 6.3. *We assume that* $R < \frac{1}{\sqrt{2}|k|}$*. For a given* $\varepsilon > 0$*,* $f_\varepsilon \in L^2(D_\varepsilon)$*, and* $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$*, let* v_ε *be the solution to*

$$\begin{cases} \Delta v_\varepsilon + k^2 v_\varepsilon &= f_\varepsilon \quad \text{in } D_\varepsilon, \\ v_\varepsilon &= 0 \quad \text{on } \partial\omega_\varepsilon, \\ v_\varepsilon &= \varphi \quad \text{on } \Gamma_R. \end{cases} \tag{6.10}$$

There exists a constant $C(R,k) > 0$ *(independent of* φ *and* ε*) such that*

$$\|v_\varepsilon\|_{1,D_\varepsilon} \leq C(R,k)\left(\|\varphi\|_{\frac{1}{2},\Gamma_R} + \|f_\varepsilon\|_{0,D_\varepsilon}\right). \tag{6.11}$$

Proof. Let $\mathcal{R}\varphi$ be the lifting of φ in the space $H^1(C(R/2,R))$ such that $\mathcal{R}\varphi_{|\Gamma_{R/2}} = 0$. We extend $\mathcal{R}\varphi$ by zero to the domain D_ε. We denote this extension by $\widetilde{\mathcal{R}\varphi}$. It belongs to $H^1(D_\varepsilon)$. We introduce

$$u_\varepsilon = \widetilde{\mathcal{R}\varphi} - v_\varepsilon, \tag{6.12}$$

$$g_\varepsilon = -f_\varepsilon + \Delta\widetilde{\mathcal{R}\varphi} + k^2\widetilde{\mathcal{R}\varphi}. \tag{6.13}$$

The function g_ε belongs to the space $H^{-1}(D_\varepsilon)$ and the new unknown u_ε is the solution to

$$\begin{cases} \Delta u_\varepsilon + k^2 u_\varepsilon &= g_\varepsilon \quad \text{in } D_\varepsilon, \\ u_\varepsilon &= 0 \quad \text{on } \partial\omega_\varepsilon, \\ u_\varepsilon &= 0 \quad \text{on } \Gamma_R. \end{cases} \tag{6.14}$$

Using the Poincaré inequality and the elliptic regularity, we obtain

$$\|u_\varepsilon\|_{1,D_\varepsilon} \leq \left(\frac{1+2R^2}{1-2k^2R^2}\right)\|g_\varepsilon\|_{-1,D_\varepsilon}. \tag{6.15}$$

Finally, the result follows from (6.12), (6.13), (6.15), and the continuity of the lifting $\mathcal{R}$. ∎

Here and in what follows, we assume that $R < \frac{1}{\sqrt{2}|k|}$.

LEMMA 6.4. *For $\varepsilon > 0$ and $\psi \in H^1(D_0)$, let X_ε be the solution to the problem*

$$\left\{ \begin{array}{lll} \Delta X_\varepsilon + k^2 X_\varepsilon & = 0 & \text{in } D_\varepsilon, \\ X_\varepsilon & = \psi & \text{on } \partial\omega_\varepsilon, \\ X_\varepsilon & = 0 & \text{on } \Gamma_R. \end{array} \right. \tag{6.16}$$

There exists a constant $c > 0$ (independent of φ and ε) such that for all $\varepsilon > 0$,

$$|X_\varepsilon|_{1,C(R/2,R)} \leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}, \tag{6.17}$$

$$\|X_\varepsilon\|_{0,D_\varepsilon} \leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}, \tag{6.18}$$

$$|X_\varepsilon|_{1,D_\varepsilon} \leq c\varepsilon^{1/2} \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}. \tag{6.19}$$

Proof. Let $\tilde{v_\varepsilon}$ be the solution to the exterior problem

$$\left\{ \begin{array}{lll} -\Delta \tilde{v_\varepsilon} & = 0 & \text{in } \mathbb{R}^3 \backslash \overline{\omega}, \\ \tilde{v_\varepsilon} & = 0 & \text{at } \infty, \\ \tilde{v_\varepsilon} & = \psi(\varepsilon y) & \text{on } \partial\omega. \end{array} \right. \tag{6.20}$$

The function X_ε can be written

$$X_\varepsilon = v_\varepsilon - w_\varepsilon,$$

where $v_\varepsilon(x) = \tilde{v_\varepsilon}\left(\frac{x}{\varepsilon}\right)$. The function w_ε itself is the solution to

$$\left\{ \begin{array}{lll} \Delta w_\varepsilon + k^2 w_\varepsilon & = k^2 v_\varepsilon & \text{in } D_\varepsilon, \\ w_\varepsilon & = 0 & \text{on } \partial\omega_\varepsilon, \\ w_\varepsilon & = v_\varepsilon & \text{on } \Gamma_R. \end{array} \right. \tag{6.21}$$

It follows from Lemma 6.3 that there exists a constant $c > 0$ such that

$$\|w_\varepsilon\|_{1,D_\varepsilon} \leq c \left(\|v_{\varepsilon|\Gamma_R}\|_{\frac{1}{2},\Gamma_R} + k^2 \|v_\varepsilon\|_{0,D_\varepsilon} \right). \tag{6.22}$$

It follows from Lemmas 6.1 and 6.2 that

$$\|v_{\varepsilon|\Gamma_R}\|_{\frac{1}{2},\Gamma_R} \leq c\|v_\varepsilon\|_{1,C(R/2,R)} \tag{6.23}$$

$$\leq c \left(\|v_\varepsilon\|_{0,C(R/2,R)} + |v_\varepsilon|_{1,C(R/2,R)} \right) \tag{6.24}$$

$$= c \left(\varepsilon^{3/2} \|\tilde{v_\varepsilon}\|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2} |\tilde{v_\varepsilon}|_{1,C(R/2\varepsilon,R/\varepsilon)} \right) \tag{6.25}$$

$$\leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}. \tag{6.26}$$

We have that

$$\|v_\varepsilon\|_{0,D_\varepsilon} = \varepsilon^{3/2} \|\tilde{v_\varepsilon}\|_{0,D_\varepsilon/\varepsilon} \tag{6.27}$$

$$\leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}. \tag{6.28}$$

From (6.22), (6.26), and (6.28), we obtain that

$$\|w_\varepsilon\|_{1,D_\varepsilon} \leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}. \tag{6.29}$$

Then we have

$$|X_\varepsilon|_{1,C(R/2,R)} = |v_\varepsilon - w_\varepsilon|_{1,C(R/2,R)} \tag{6.30}$$
$$\leq |v_\varepsilon|_{1,C(R/2,R)} + |w_\varepsilon|_{1,C(R/2,R)} \tag{6.31}$$
$$\leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} + \|w_\varepsilon\|_{1,D_\varepsilon} \tag{6.32}$$
$$\leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}, \tag{6.33}$$
$$\|X_\varepsilon\|_{0,D_\varepsilon} \leq \|v_\varepsilon\|_{0,D_\varepsilon} + \|w_\varepsilon\|_{1,D_\varepsilon} \tag{6.34}$$
$$\leq c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}, \tag{6.35}$$
$$|X_\varepsilon|_{1,D_\varepsilon} \leq |v_\varepsilon|_{1,D_\varepsilon} + |w_\varepsilon|_{1,D_\varepsilon} \tag{6.36}$$
$$\leq \varepsilon^{1/2} |\tilde{v_\varepsilon}|_{1,D_\varepsilon/\varepsilon} + \|w_\varepsilon\|_{1,D_\varepsilon} \tag{6.37}$$
$$\leq c\varepsilon^{1/2} \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} + c\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} \tag{6.38}$$
$$\leq c\varepsilon^{1/2} \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega}. \tag{6.39}$$

This completes the proof. ∎

Lemmas 6.3 and 6.4 are summarized in the following lemma.

LEMMA 6.5. *For $\varepsilon > 0$, $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$, $\psi \in H^1(D_0)$, and $f_\varepsilon \in L^2(D_\varepsilon)$, let v_ε be the solution to the problem*

$$\begin{cases} \Delta v_\varepsilon + k^2 v_\varepsilon &= f_\varepsilon \quad \text{in } D_\varepsilon, \\ v_\varepsilon &= \psi \quad \text{on } \partial\omega_\varepsilon, \\ v_\varepsilon &= \varphi \quad \text{on } \Gamma_R. \end{cases} \tag{6.40}$$

There exists a constant $c > 0$ (independent of φ, ψ, f_ε, and ε) such that for all $\varepsilon > 0$,

$$|v_\varepsilon|_{1,C(R/2,R)} \leq c\left(\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} + \|\varphi\|_{\frac{1}{2},\Gamma_R} + \|f_\varepsilon\|_{0,D_\varepsilon}\right), \tag{6.41}$$
$$\|v_\varepsilon\|_{0,D_\varepsilon} \leq c\left(\varepsilon \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} + \|\varphi\|_{\frac{1}{2},\Gamma_R} + \|f_\varepsilon\|_{0,D_\varepsilon}\right), \tag{6.42}$$
$$|v_\varepsilon|_{1,D_\varepsilon} \leq c\left(\varepsilon^{1/2} \|\psi(\varepsilon y)\|_{\frac{1}{2},\partial\omega} + \|\varphi\|_{\frac{1}{2},\Gamma_R} + \|f_\varepsilon\|_{0,D_\varepsilon}\right). \tag{6.43}$$

LEMMA 6.6. *Let u belong to the space $H^1(C(R/2,R))$ and satisfy $\Delta u + k^2 u = 0$ in $C(R/2,R)$, $u_{|\Gamma_R} = 0$. Then there exists a constant $c > 0$ (independent of u) such that*

$$\|\nabla u.n_{|\Gamma_R}\|_{-\frac{1}{2},\Gamma_R} \leq c|u|_{1,C(R/2,R)}. \tag{6.44}$$

Proof. Let $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$. We define v as the solution to the problem

$$\begin{cases} \Delta v &= 0 \quad \text{in } C(R/2,R), \\ v &= 0 \quad \text{on } \Gamma_{R/2}, \\ v &= \varphi \quad \text{on } \Gamma_R. \end{cases}$$

Using the Green formula, we obtain

$$\int_{\Gamma_R} \nabla u.n_{|\Gamma_R} \overline{\varphi}\, d\gamma(x) = \int_{C(R/2,R)} \nabla u.\nabla \overline{v}\, dx - k^2 \int_{C(R/2,R)} u\overline{v}\, dx.$$

Then we have

$$\begin{aligned} \left| \int_{\Gamma_R} \nabla u.n_{|\Gamma_R} \overline{\varphi}\, d\gamma(x) \right| &\leq |u|_{1,C(R/2,R)} \|v\|_{1,C(R/2,R)} + k^2 \|u\|_{0,C(R/2,R)} ||v||_{1,C(R/2,R)} \\ &\leq |u|_{1,C(R/2,R)} \|\varphi\|_{\frac{1}{2},\Gamma_R} + ck^2 |u|_{1,C(R/2,R)} \|\varphi\|_{\frac{1}{2},\Gamma_R} \\ &\leq c|u|_{1,C(R/2,R)} \|\varphi\|_{\frac{1}{2},\Gamma_R}. \end{aligned}$$

This completes the proof. ∎

6.3. Variation of the sesquilinear form. The variation of the sesquilinear form a_ε reads

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Gamma_R} (T_\varepsilon - T_0) u\overline{v}\; d\gamma(x).$$

For $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$, recall that u_ε^φ is the solution to (4.2), or to (4.3) if $\varepsilon = 0$. Let v_ω^φ be the solution to the problem

$$\left\{ \begin{array}{lll} \Delta v_\omega^\varphi &= 0 & \text{in } \mathbb{R}^3 \backslash \overline{\omega}, \\ v_\omega^\varphi &= 0 & \text{at } \infty, \\ v_\omega^\varphi &= u_0^\varphi(x_0) & \text{on } \partial\omega. \end{array} \right. \tag{6.45}$$

As in (5.6) and (5.7), let $P_\omega^\varphi(y) = A_\omega\left(u_0^\varphi(x_0)\right) E(y)$ be the dominant part of v_ω^φ, and let Q_ω^φ be the solution to the associated interior problem

$$\left\{ \begin{array}{lll} \Delta Q_\omega^\varphi + k^2 Q_\omega^\varphi &= k^2 P_\omega^\varphi & \text{in } D_0, \\ Q_\omega^\varphi &= P_{\omega\,|\Gamma_R}^\varphi & \text{on } \Gamma_R. \end{array} \right. \tag{6.46}$$

The linear operator δT (independent of ε) is defined as follows:

$$\begin{array}{rccc} \delta T: & H^{1/2}(\Gamma_R) & \longrightarrow & H^{-1/2}(\Gamma_R), \\ & \varphi & \longmapsto & \delta T\varphi = \nabla(Q_\omega^\varphi - P_\omega^\varphi).n_{|\Gamma_R}. \end{array} \tag{6.47}$$

PROPOSITION 6.7. *The operator T_ε admits the following asymptotic expansion:*

$$\left\| T_\varepsilon - T_0 - \varepsilon\delta T \right\|_{\mathcal{L}(H^{\frac{1}{2}}(\Gamma_R), H^{-\frac{1}{2}}(\Gamma_R))} = O(\varepsilon^{3/2}).$$

Proof. Let $\varphi \in H^{\frac{1}{2}}(\Gamma_R)$. For simplicity we drop the superscript $(.)^\varphi$. For $y = x/\varepsilon$, we have

$$v_\omega(y) = P_\omega(y) + W_\omega(y),$$

with $P_\omega(\frac{x}{\varepsilon}) = \varepsilon P_\omega(x)$ and $W_\omega(y) = O(\frac{1}{||y||^2})$. Let

$$\psi_\varepsilon(x) = \left(T_\varepsilon - T_0 - \varepsilon\delta T\right)\varphi(x).$$

We have

$$\begin{aligned} \psi_\varepsilon(x) &= \left(\nabla u_\varepsilon - \nabla u_0 - \varepsilon(\nabla Q_\omega - \nabla P_\omega)\right).n_{|\Gamma_R} \\ &= \nabla\left(w_\varepsilon(x) - W_\omega\left(\frac{x}{\varepsilon}\right)\right).n_{|\Gamma_R}, \end{aligned}$$

where w_ε is defined by

$$w_\varepsilon(x) = u_\varepsilon(x) - u_0(x) - \varepsilon Q_\omega(x) + v_\omega\left(\frac{x}{\varepsilon}\right).$$

The function w_ε is the solution to

$$\left\{ \begin{array}{lll} \Delta w_\varepsilon + k^2 w_\varepsilon &= k^2 W_\omega(x/\varepsilon) & \text{in } D_\varepsilon, \\ w_\varepsilon &= W_\omega(x/\varepsilon) & \text{on } \Gamma_R, \\ w_\varepsilon &= -u_0(x) + u_0(0) - \varepsilon Q_\omega(x) & \text{on } \partial\omega_\varepsilon. \end{array} \right. \tag{6.48}$$

In order to apply Lemma 6.5, we have to estimate the right-hand side terms, as follows.

- In D_ε, we have

$$\|W_\omega(x/\varepsilon)\|_{0,D_\varepsilon} = \varepsilon^{3/2}\|W_\omega(y)\|_{0,D_\varepsilon/\varepsilon}.$$

Using Lemma 6.2, we obtain

$$\begin{aligned}\|W_\omega(y)\|_{0,D_\varepsilon/\varepsilon} &\leq c\|u_0(x_0)\|_{\frac{1}{2},\partial\omega}\\ &\leq c|u_0(x_0)|\\ &\leq c\|\varphi\|_{\frac{1}{2},\Gamma_R}.\end{aligned}$$

Then we have

$$\|W_\omega(x/\varepsilon)\|_{0,D_\varepsilon} \leq c\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\Gamma_R}.$$

- On Γ_R, using Lemmas 6.1 and 6.2 and the elliptic regularity, we obtain

$$\begin{aligned}\|W_\omega(x/\varepsilon)\|_{\frac{1}{2},\Gamma_R} &\leq c\|W_\omega(x/\varepsilon)\|_{1,C(R/2,R)}\\ &\leq c\left(\|W_\omega(x/\varepsilon)\|_{0,C(R/2,R)} + |W_\omega(x/\varepsilon)|_{1,C(R/2,R)}\right)\\ &= c\left(\varepsilon^{3/2}\|W_\omega(y)\|_{0,C(R/2\varepsilon,R/\varepsilon)} + \varepsilon^{1/2}|W_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)}\right)\\ &\leq c\varepsilon^2\|u_0(x_0)\|_{\frac{1}{2},\partial\omega}\\ &\leq c\varepsilon^2|u_0(x_0)|\\ &\leq c\varepsilon^2\|\varphi\|_{\frac{1}{2},\Gamma_R}.\end{aligned}$$

- On $\partial\omega_\varepsilon$, putting

$$\theta_\varepsilon(x) = \frac{-u_0(x) + u_0(x_0) - \varepsilon Q_\omega(x)}{\varepsilon},$$

we have for small ε

$$\begin{aligned}\|\theta_\varepsilon(\varepsilon y)\|_{\frac{1}{2},\partial\omega} &\leq c\|\theta_\varepsilon(\varepsilon y)\|_{1,\omega}\\ &= c\left\|\frac{u_0(\varepsilon y) - u_0(x_0)}{\varepsilon} + Q_\omega(\varepsilon y)\right\|_{1,\omega}\\ &\leq c\left(\|u_0\|_{\mathcal{C}^2(B(0,R/2))} + \|Q_\omega\|_{\mathcal{C}^1(B(0,R/2))}\right)\\ &\leq c\|\varphi\|_{\frac{1}{2},\Gamma_R}.\end{aligned}$$

We can now apply Lemma 6.5, which gives

$$\begin{aligned}|w_\varepsilon|_{1,C(R/2,R)} &\leq c\left(\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\Gamma_R} + \varepsilon^2\|\varphi\|_{\frac{1}{2},\Gamma_R} + \varepsilon\|\varepsilon\theta_\varepsilon(\varepsilon y)\|_{\frac{1}{2},\partial\omega}\right)\\ &\leq c\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\Gamma_R}.\end{aligned}$$

Finally, it follows from Lemmas 6.1 and 6.6 that

$$\begin{aligned}\|\psi\|_{-\frac{1}{2},\Gamma_R} &= \|\nabla(w_\varepsilon - W_\omega(x/\varepsilon)).n_{|\Gamma_R}\|_{-\frac{1}{2},\Gamma_R}\\ &\leq c\left(|w_\varepsilon|_{1,C(R/2,R)} + |W_\omega(x/\varepsilon)|_{1,C(R/2,R)}\right)\\ &= c\left(|w_\varepsilon|_{1,C(R/2,R)} + \varepsilon^{1/2}|W_\omega(y)|_{1,C(R/2\varepsilon,R/\varepsilon)}\right)\\ &\leq c\left(\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\Gamma_R} + \varepsilon^2\|\varphi\|_{\frac{1}{2},\Gamma_R}\right)\\ &\leq c\varepsilon^{3/2}\|\varphi\|_{\frac{1}{2},\Gamma_R}.\end{aligned}$$

Hence,

$$\|T_\varepsilon - T_0 - \varepsilon\delta T\|_{\mathcal{L}(H^{\frac{1}{2}}(\Gamma_R),H^{-\frac{1}{2}}(\Gamma_R))} = O(\varepsilon^{3/2}). \qquad \square$$

The asymptotic expansion of the sesquilinear form a_ε follows now straightforwardly.

PROPOSITION 6.8. *Let*

$$\delta a(u,v) = \int_{\Gamma_R} \delta T u\overline{v}\; d\gamma(x), \quad u,v \in \mathcal{V}_R.$$

Then the asymptotic expansion of the sesquilinear form a_ε is given by

$$\|a_\varepsilon - a_0 - \varepsilon\delta a\|_{\mathcal{L}(H^{\frac{1}{2}}(\Gamma_R),H^{-\frac{1}{2}}(\Gamma_R))} = O(\varepsilon^{3/2}).$$

6.4. Proof of Theorem 5.1. The proof of this theorem is done in two steps. First, we prove that Hypothesis 2 is satisfied. More precisely, we prove that the sesquilinear form a_0 satisfies the inf-sup condition. Second, we apply Theorem 2.2 to compute the topological asymptotic expansion.

6.4.1. The first step: The inf-sup condition. For all $u \in \mathcal{V}_R$, we set

$$\tilde{u} = \begin{cases} u & \text{in } \Omega_R, \\ u_0^\varphi & \text{in } B(x_0,R), \end{cases}$$

where $\varphi = u_{|\Gamma_R}$ and u_0^φ is the solution to

$$\begin{cases} \Delta u_0^\varphi + k^2 u_0^\varphi = 0 & \text{in } B(x_0,R), \\ u_0^\varphi = \varphi & \text{on } \Gamma_R. \end{cases}$$

It can easily be proved that

$$a_0(u, v_{|\Omega_R}) = a(\Omega, \tilde{u}, v) \qquad \forall u \in \mathcal{V}_R \qquad \forall v \in \mathcal{V}(\Omega),$$

where the functional space $\mathcal{V}(\Omega)$ and the sesquilinear form $a(\Omega,.,.)$ are defined by (3.2). From Proposition 3.1, the sesquilinear form $a(\Omega,.,.)$ satisfies the inf-sup condition. As a consequence, there exists $v \in \mathcal{V}(\Omega), v \neq 0$, such that

$$\begin{aligned} a_0(u, v_{|\Omega_R}) = a(\Omega, \tilde{u}, v) &\geq a\|\tilde{u}\|_{\mathcal{V}(\Omega)}\|v\|_{\mathcal{V}(\Omega)} \\ &\geq a\|u\|_{\mathcal{V}_R}\|v_{|\Omega_R}\|_{\mathcal{V}_R}. \end{aligned}$$

Then a_0 satisfies the inf-sup condition and Hypothesis 2 is satisfied.

6.4.2. Applying Theorem 2.2. All the hypotheses of section 2 are satisfied and we can apply Theorem 2.2. We obtain the following asymptotic formula:

$$\begin{aligned} j(\varepsilon) - j(0) &= \varepsilon\Re(\delta a(u_\Omega, v_\Omega)) + o(\varepsilon) \\ &= \varepsilon\Re\left(\int_{\Gamma_R} \nabla(Q_\omega^\varphi - P_\omega^\varphi).n_{|\Gamma_R}\overline{v_\Omega}\; d\gamma(x)\right) + o(\varepsilon), \end{aligned}$$

where $\varphi = u_{\Omega|\Gamma_R} = u_{0|\Gamma_R}$. Thanks to Green's formula and (6.46), we obtain that

$$\begin{aligned} \int_{\Gamma_R} \nabla(Q_\omega^\varphi - P_\omega^\varphi).n_{|\Gamma_R}\overline{v_\Omega}\; d\gamma(x) = k^2 \int_{D_0} P_\omega\overline{v_\Omega}\; dx + \int_{\Gamma_R} \nabla\overline{v_\Omega}.n_{|\Gamma_R}P_\omega\; d\gamma(x) \\ - \int_{\Gamma_R} \nabla P_\omega.n_{|\Gamma_R}\overline{v_\Omega}\; d\gamma(x). \end{aligned} \tag{6.49}$$

It can be shown that

$$\begin{aligned}\int_{\Gamma_R} \nabla\overline{v_\Omega}.n_{|\Gamma_R} P_\omega \; d\gamma(x) - \int_{\Gamma_R} \nabla P_\omega.n_{|\Gamma_R}\overline{v_\Omega} \; d\gamma(x) &= A_\omega\left(u_\Omega(x_0)\right)\langle -\Delta E, \overline{v_\Omega}\psi\rangle_{\mathcal{D}'(D_0),\mathcal{D}(D_0)} \\ &\quad -k^2\int_{D_0} P_\omega\overline{v_\Omega}\; dx \\ &= A_\omega\left(u_\Omega(x_0)\right)\langle \delta, \overline{v_\Omega}\psi\rangle_{\mathcal{D}'(D_0),\mathcal{D}(D_0)} \\ &\quad -k^2\int_{D_0} P_\omega\overline{v_\Omega}\; dx \\ &= A_\omega\left(u_\Omega(x_0)\right)\overline{v_\Omega(x_0)} - k^2\int_{D_0} P_\omega\overline{v_\Omega}\; dx,\end{aligned}$$

where $\psi \in \mathcal{D}(D_0)$ satisfies $\psi(x_0) = 1$. We insert this expression into (6.49) and obtain the desired result.

7. Numerical results: Buried objects detection. We consider a simple problem of detection of metallic objects buried in soil. The aim is to find the number and the positions of metallic objects (supposedly infinite in the $\vec{e}_z$ direction) using scattered field measurements from a monostatic antenna horizontally translated above the soil. This is a rough model of the facilities described in [19]. The two-dimensional Helmholtz equation is solved with time-domain finite differences (FDTD), the frequency-domain solution obtained with a Fourier transform. The antenna is roughly approximated by a single source point, which will be translated at various locations above the soil. At each point of the mesh, the topological sensitivity will be computed.

Let $\mathcal{X} = \{x_i\}_{i=1,\dots,n_x}$ be the set of the successive locations of the source (and sensors, since the antenna is supposed to be monostatic), and let $\mathcal{F} = \{f_i\}_{i=1,\dots,n_f}$ be the set of measurement frequencies. Let ε_s be the soil permittivity. The set of metallic objects buried in the soil is denoted by Ω.

We associate with Ω a set of "measurements" $\mathcal{M}(\Omega)$. At each couple $(x_i, f_j) \in \mathcal{X} \times \mathcal{F}$, we first define the field $u^\Omega_{x_i,f_j}$, the solution of

$$\left\{\begin{array}{lll} \Delta u + k_j^2 u & = s_{x_i} & \text{in } \mathbb{R}^2 \setminus \overline{\Omega}, \\ u & = 0 & \text{on } \partial\Omega, \\ \lim\limits_{r\to\infty} \sqrt{r}(\partial_r u - iku) & = 0, & \end{array}\right. \tag{7.1}$$

where s_{x_i} represents a source point centered at x_i, and where

$$\begin{aligned} k_j^2(x) &= \varepsilon(x)\mu\omega_j^2, \\ w_j &= 2\pi f_j, \\ \varepsilon(x) &= \left\{\begin{array}{ll} \varepsilon_0 & \text{if } x \geq 0, \\ \varepsilon_s & \text{if } x < 0. \end{array}\right. \end{aligned}$$

Then the "measurements" are $\mathcal{M}(\Omega) = \{m_{x_i,f_j}(\Omega)\}$. In our numerical tests, $m_{x_i,f_j}(\Omega)$ is the value of the scattered field at point x_i.

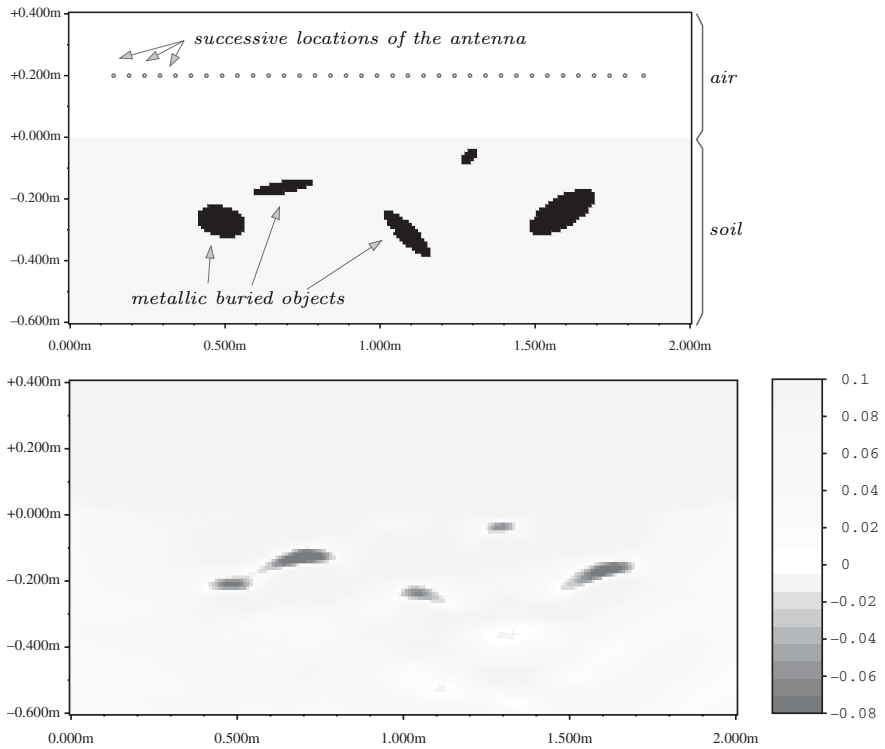

FIG. 7.1. *Repartition of metallic objects in the soil and the corresponding topological sensitivity computed on empty flat soil (dry soil, flat surface* $\varepsilon_r = 2.3$*, 20 frequencies ranging from* $400MHz$ *to* $2GHz$*).*

Reference measurements $\widetilde{\mathcal{M}} = \{\widetilde{m}_{x_i,f_j}\}$ are those values obtained from the real objects in the soil. Ideally, these would have been real measurements, but in the following numerical results, we consider only synthetical data obtained via FDTD.

The cost function, which expresses the adequacy between the measurements obtained for a distribution of metallic objects Ω and the reference data, is

$$j(\Omega) = \|\mathcal{M} - \widetilde{\mathcal{M}}\|^2 = \sum_{i,j} j_{x_i,f_j}(\Omega), \tag{7.2}$$

where

$$j_{x_i,f_j}(\Omega) = |m_{x_i,f_j}(\Omega) - \widetilde{m}_{x_i,f_j}|^2. \tag{7.3}$$

Applying the expression of the topological asymptotic (see Proposition 5.3), one has

$$j(\Omega \setminus \overline{B(x,\varepsilon)}) - j(\Omega) = \sum_{i,j} -\frac{2\pi}{\log \varepsilon} \Re\left(u^{\Omega}_{x_i,f_j}(x)\overline{v^{\Omega}_{x_i,f_j}}(x)\right) + o\left(\frac{1}{\log \varepsilon}\right), \tag{7.4}$$

where $v^{\Omega}_{x_i,f_j}$ is the adjoint state associated with the couple (x_i, f_j).

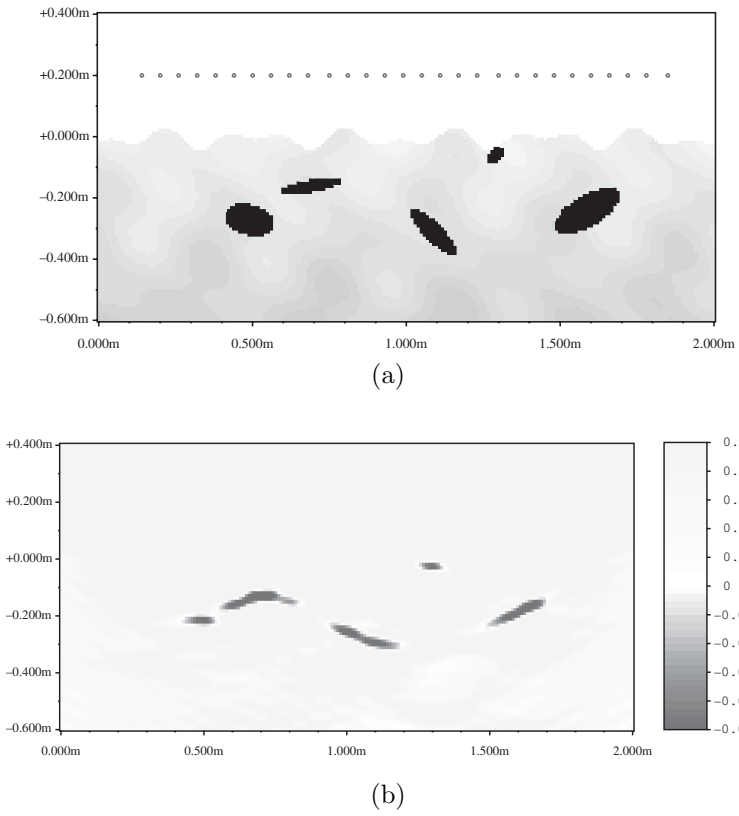

FIG. 7.2. (a) *Reference distribution of objects. The measures are computed on a dry inhomogeneous soil (ε_s ranging from* 1.6 *to* 4.15*) with a rough surface, using* 29 *measurement points and* 20 *frequencies ranging from* $260MHz$ *to* $1.86GHz$. (b) *Topological sensitivity computed on a flat empty homogeneous soil ($\varepsilon_s = 2.3$).*

The first example (see Figure 7.1) shows the topological sensitivity computed on an "ideal" case: There is no noise on the data, and the reference soil is a flat and homogeneous dry sand soil. One can see that the top of the five objects is clearly identified by the negative values of the topological sensitivity. This topological sensitivity can be obtained very quickly since it is evaluated on an empty flat soil, which is invariant by translation: All direct states and adjoint states are just horizontal translations of a "canonical" solution. The computational cost is only 10 seconds on a 300MHz personal computer.

The second example (see Figure 7.2) is a little more realistic: The data is artificially noised since the reference data $\widetilde{\mathcal{M}}$ was obtained on a nonflat inhomogeneous soil, while the topological sensitivity was still computed on a flat homogeneous soil. One can observe that, although the objects are still located correctly, the image (see Figure 7.2(b)) is a bit distorted.

The third example shows that using an iterative process might give good results at the expense of some computational cost. In this example, the basic iterative algorithm just inserts a metal point at the point where the topological sensitivity is the most negative. Then the topological sensitivity is reevaluated, taking into account the metal points inserted at previous iterations, etc. Figure 7.3 shows the objects and the metal points that were inserted at iterations 10 and 55.

MEASURING DISTANCE BETWEEN SYSTEMS UNDER BOUNDED POWER EXCITATION*

P. DATE† AND G. VINNICOMBE‡

Abstract. This work suggests a way of measuring distance between two linear systems under a given bounded power excitation. The measure introduced can be used to bound from above and below the difference in closed-loop behavior of two plants with the same controller for a specified reference or disturbance spectrum. Given an unknown, single input "real" plant and its identified model, an upper bound on the distance between the plant and its model as expressed by this measure can be obtained from time domain data.

Key words. ν-gap metric, uncertainty in linear models, persistent excitation

AMS subject classifications. 93A05, 93A30

DOI. 10.1137/S0363012902410113

1. Introduction. Robust control theory is often motivated based on square summable or square integrable (bounded energy) signals. In many practical applications, the signals are better modeled as persistent disturbances. Motivating robust control design or analysis from a persistent signals viewpoint is complicated by the fact that the set of "quasi-stationary" bounded power signals which induces the infinity norm is *not* a linear vector space [5]. Nevertheless, interpreting and extending standard robust control results in a persistent signals set-up has been an active area of research for the last few years; see [13], [5] and references therein.

Given a controller which robustly stabilizes two plants (or a plant and its model), it is known that the difference in closed-loop frequency response of the two plants with the same controller can be bounded from below and above using pointwise chordal distance between the frequency responses of the two plants. A natural question to ask is whether the difference in closed-loop response of two systems for a given reference and disturbance spectrum can be bounded from above and below using an appropriate, *signal dependent* notion of distance. This work provides an affirmative answer to this question.

Specifically, the problem considered is as follows. Consider two closed-loops (P_1, C_1, C_2) and (P_2, C_1, C_2), each with the same controller $C = C_1C_2$, the same controller configuration (C_1 in the forward path, C_2 in the feedback path), and (possibly) different plants P_1, P_2. These two loops may represent the "achieved" closed-loop (i.e., with the real plant) and the "designed" closed-loop (i.e., with the model). For a given bounded power excitation (which could be a reference or a disturbance signal), the difference in the closed-loop behavior will be small if the two plants P_1 and P_2 are close in an appropriate sense. It is known that the difference in closed-loop behavior would be small (at least, for any square summable excitation) if the distance between the two systems as measured by the ν-gap metric (discussed in more details in section 3) or by the gap metric were small. However, *even if* the ν-gap is large, it is possible that the difference in the closed-loop response is small for a specific range

of spectra of interest, provided we find a controller which stabilizes both systems with adequate stability margins. Here, a measure of distance over a subset of linear shift invariant systems is introduced which characterizes the difference in closed-loop response for a given range of signal spectra. Upper and lower bounds on this difference are established in terms of this new measure. For a plant and its candidate model, bounds on this measure are given in terms of time domain data.

The rest of the paper is organized as follows. Section 2 outlines the notation and defines the sets of signals and systems used in this paper. Section 3 introduces the ν-gap metric. A new function δ_x for measuring distance between two systems is introduced in section 4. In section 5, this function δ_x is used to bound from above and below the difference in closed-loop performance for a given range of signal spectrum. Bounds on δ_x from time domain data are introduced in section 6. Section 7 illustrates the use of this function with examples, and finally section 8 briefly summarizes the contribution of this paper.

2. Preliminaries. Let $\mathbb{R}$ and $\mathbb{C}$ denote the sets of real and complex numbers, respectively. $\mathbb{C}^{m\times n}$ denotes the space of $m \times n$ complex matrices. $\mathbb{Z}$ denotes set of integers. $l_\infty(\mathbb{Z})$ denotes the space of bounded sequences indexed by integers. For $A \in \mathbb{C}^{m\times n}$, $\sigma_i(A)$ denotes the ith largest singular value of A. Maximum and minimum singular values of a matrix A are denoted by $\overline{\sigma}(A)$ and $\underline{\sigma}(A)$, respectively.

(i) *Signals.* Let $R_u(\tau) = \lim_{N\to\infty} \frac{1}{N}\sum_{t=0}^{N-1} u(t-\tau)u^T(t)$. Define

$$\mathcal{S}^n = \left\{ u \,|\, u \in l_\infty(\mathbb{Z}), u(t) = 0 \quad \forall\, t < 0,\ R_u(\tau) \text{ exists } \forall\, \tau, \right.$$

$$\left. \phi_u(\omega) := \sum_{\tau=-\infty}^{\infty} R_u(\tau)e^{-j\tau\omega} \text{ exists } \forall\, \omega \right\}. \tag{2.1}$$

Here, *power spectrum* $\phi_u(\omega)$ need not be bounded and may contain impulses in general. This set is called as a set of *quasi-stationary* signals in [4]. Define seminorm $\|f\|_s := \sqrt{\operatorname{trace} R_f(0)}$. For signals with continuous spectra, the equality

$$\|f\|_s = \sqrt{\frac{1}{2\pi}\int_{-\pi}^{\pi} \operatorname{trace}\, \phi_f(\omega)\, d\omega}$$

also holds.

For two signals $v, w \in \mathcal{S}^n$, define

$$R_{wv}(\tau) := \lim_{N\to\infty} \frac{1}{N}\sum_{t=0}^{N-1} v(t-\tau)w^T(t)$$

$$\text{and} \quad \phi_{wv}(\omega) := \sum_{\tau=-\infty}^{\infty} R_{wv}(\tau)e^{-j\tau\omega},$$

provided the limits exist for each τ and each ω. For $v, w \in \mathcal{S}^n$, note that $v+w \in \mathcal{S}^n$ *provided* the cross-correlation function $R_{wv}(\tau)$ exists for all τ and the cross power spectrum $\phi_{wv}(\omega)$ exists for all ω. This set is obviously not a linear space and may be embedded in a linear space which includes nonstationary signals [5]. However, the use of $\mathcal{S}^n$ here to model persistent signals is motivated by two reasons. First, the correlation or spectrum based description is deemed as natural to describe persistent

disturbances, even in a nonprobabilistic setting. Second, the spectral content of a signal in $\mathcal{S}^n$ proves useful in assessing the performance of feedback systems in terms of their graph symbols restricted to the imaginary axis. This point will become apparent in sections 4 and 5.

(ii) *Systems.* Let $\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}$. Let $\partial\mathbb{D}$ denote the boundary of $\mathbb{D}$. $\mathcal{L}_\infty$ denotes the normed space of all functions essentially bounded on $\mathbb{D}$ and having norm $\|f\|_{\mathcal{L}_\infty} := \text{ess sup}_\omega \overline{\sigma}(f(e^{j\omega}))$, where $\overline{\sigma}(\cdot)$ represents the maximum singular value. $\mathcal{H}_\infty$ denotes the normed space of functions analytic in $\mathbb{D}$ and having norm $\|f\|_\infty := \sup_{z\in\mathbb{D}} \overline{\sigma}(f(z)) < \infty$.

Consider a linear, shift invariant discrete time system P, which can be expressed as $P = NM^{-1} = \tilde{M}^{-1}\tilde{N}$ with

1. N and M are right coprime and $G = \left[\begin{smallmatrix} N \\ M \end{smallmatrix}\right]$ inner; and
2. $\tilde{N}$ and $\tilde{M}$ are left coprime and $\tilde{G} = [-\tilde{M} \quad \tilde{N}]$ coinner.

G (resp., $\tilde{G}$) is called the normalized right (resp., normalized left) graph symbol of plant P. The set of systems of interest here are those with continuous normalized graph symbols:

$$\mathcal{P}^{m\times n} = \left\{P : G, \tilde{G} \text{ exist and are continuous on } \partial\mathbb{D}\right\}.$$

The superscript $m \times n$ is dropped when it is clear from context. The normalized graph symbols of a plant P_i will be denoted as $\tilde{G}_i$ and G_i. The set $\mathcal{P}^{m\times n}$ includes all systems whose normalized graph symbols may be uniformly approximated by real rational transfer functions; this follows from [8, Theorem 7.12]. However, it is worth mentioning that there are systems which have a continuous frequency response on the unit circle but whose normalized graph symbols are *not* continuous on the unit circle; see [9] for an example.

The set of all real rational transfer functions with n inputs and m outputs, denoted by $\mathcal{R}^{m\times n}$, is a subset of $\mathcal{P}^{m\times n}$.

The controller is denoted by C and its normalized right (left) inverse graph symbol is denoted by $K = \left[\begin{smallmatrix} V \\ U \end{smallmatrix}\right]$ ($\tilde{K} = [-\tilde{U} \quad \tilde{V}]$).

3. The ν-gap metric. The notion of measuring distance between linear systems in terms of distance between their graph spaces was introduced by Vidyasagar in [10]. In this paper, a metric called the graph metric was introduced which is characterized by the smallest distance, in a certain sense, between the coprime factors of two systems. This work was followed by a number of advances in characterization and computation of similar metrics under which feedback stability is a robust property. The pointwise gap metric [7], the gap metric [1], and the chordal metric [6] induce the same topology as the graph metric. The authors of [3] discuss the properties of gap metrics related to robustness for normalized coprime factor perturbations.

In [11], a metric called the ν-gap metric was defined. It is closely related to the gap metric but has a nicer frequency response interpretation and leads to less conservative robustness results in general. Specifically, the *ν-gap* between two plants P_1 and P_2 is defined as [11]

$$\begin{aligned} \delta_\nu(P_1, P_2) &= \inf_{Q, Q^{-1}\in\mathcal{L}_\infty} \| G_1 - G_2 Q \|_\infty \quad \text{if } I(P_1, P_2) = 0 \\ &= \quad 1 \quad \text{otherwise,} \end{aligned} \tag{3.1}$$

where $I(P_1, P_2) := \text{wno}\, \det(G_2^* G_1) = \text{wno}\, \det(\tilde{G}_1 \tilde{G}_2^*)$ and wno (g) denotes the winding number of $g(z)$ evaluated on the standard Nyquist contour indented around

any poles and zeros on $\partial\mathbb{D}$. For a real rational transfer matrix X such that $X, X^{-1} \in \mathcal{L}_\infty$, the winding number wno det $(X) = \eta(X^{-1}) - \eta(X)$, where $\eta(f)$ denotes the number of unstable poles of f. Thus, the ν-gap is seen to be the infinity norm of the smallest perturbation of the normalized coprime factorization G_1 of P_1 which yields a—not necessarily coprime—factorization G_2Q of P_2. The choice of factorization of P_2, i.e., the choice of Q, is constrained by the winding number condition. If G_2Q is constrained to be coprime instead, one gets the gap (instead of the ν-gap) between P_1 and P_2. See, e.g., section 9.3 in [12] for details.

When the winding number condition is satisfied, $\delta_\nu(P_1, P_2)$ equals the $\mathcal{L}_2$-gap,

$$\delta_{\mathcal{L}_2}(P_1, P_2) := \|\tilde{G_2}G_1\|_\infty = \sup_\omega \kappa(P_1, P_2)(e^{j\omega}). \tag{3.2}$$

$\kappa(P_1, P_2)(e^{j\omega})$ is the pointwise *chordal* distance defined by

$$\kappa(P_1, P_2)(e^{j\omega}) := \overline{\sigma}\left((I + P_2P_2^*)^{-\frac{1}{2}}(P_1 - P_2)(I + P_1^*P_1)^{-\frac{1}{2}}\right)(e^{j\omega}). \tag{3.3}$$

$\delta_\nu(P_1, P_2)$ is a measure of difference in the closed-loop performance of P_1 in feedback with a controller C and P_2 in feedback with the same controller C. Given a nominal controller C that stabilizes a (possibly frequency weighted) plant P_i, a useful closed-loop performance measure is

$$\begin{aligned} b(P_i, C) &= \|H(P_i, C)\|_\infty^{-1} = \inf_\omega \underline{\sigma}(\tilde{K}G_i)(e^{j\omega}) \\ &= \inf_\omega \underline{\sigma}(\tilde{G}_iK)(e^{j\omega}), \end{aligned} \tag{3.4}$$

where the closed-loop transfer function $H(P_i, C)$ is defined by

$$H(P_i, C) = \begin{bmatrix} P_i \\ I \end{bmatrix}(I - CP_i)^{-1}\begin{bmatrix} -C & I \end{bmatrix}.$$

It is known that any controller stabilizing a plant P_1 and achieving $b(P_1, C) > \alpha$ stabilizes the plant set $\{P_2 : \delta_\nu(P_1, P_2) \le \alpha\}$ [11]. More important, the *pointwise* difference in the closed-loop performance of nominal plant P_1 and a perturbed plant P_2 for the same controller C can be quantified in terms of $\kappa(P_1, P_2)$ as [11]:

$$\begin{aligned} \kappa(P_1, P_2)(e^{j\omega}) &\le \overline{\sigma}(H(P_1, C) - H(P_2, C))(e^{j\omega}) \\ &\le \kappa(P_1, P_2)(e^{j\omega})\,\overline{\sigma}(H(P_1, C))(e^{j\omega})\,\overline{\sigma}(H(P_2, C))(e^{j\omega}). \end{aligned} \tag{3.5}$$

The upper bound in (3.5) is useful only if C stabilizes both P_1 and P_2.

The aim here is to characterize the difference in closed-loop behavior, in a fashion similar to (3.5), for signals belonging to the set $\mathcal{S}^n$ as defined in (2.1). The next section defines a way of measuring distance between systems under a specific bounded power excitation.

4. A new measure of distance. Let Φ be a set of functions defined by

$$\begin{aligned} \Phi := \big\{ X \,|\, X : [-\pi, \pi] \to \mathbb{R},\ X(\omega) \ge 0, \\ X(\omega) \text{ is monotonic nondecreasing and bounded} \big\}. \end{aligned} \tag{4.1}$$

For $X \in \Phi$, define a seminorm

$$\|X\|_\Phi = \frac{1}{2\pi}\int_{-\pi}^{\pi} dX(\omega). \tag{4.2}$$

The definition (4.2) may be related to the set $\mathcal{S}^n$ as follows. Let $r \in \mathcal{S}^n$ be such that $\phi_r = xI^{n\times n}$, where $x(\omega) \geq 0$ is a continuous, scalar, and bounded real function over $[-\pi, \pi]$. Let

$$X(\omega) = \int_{-\pi}^{\omega} x(\tau)d\tau.$$

Then $X \in \Phi$ and $\frac{dX}{d\omega} = x$ [8, Theorem 6.20]. Also, the equality

$$\|r\|_{\mathcal{S}}^2 = n\|X\|_{\Phi} \tag{4.3}$$

follows from the definitions of seminorms $\|\cdot\|_{\mathcal{S}}$ and $\|\cdot\|_{\Phi}$. Functions belonging to the set Φ will later be used in section 5 to express bounds on the range of the spectra of interest.

Now define a function $\delta_x : \mathcal{P}^{m\times n} \times \mathcal{P}^{m\times n} \times \Phi \to \mathbb{R}_+$,

$$\delta_x(P_1, P_2, X) := \left\{ \frac{1}{2\pi} \int_{-\pi}^{\pi} \text{trace}\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)(e^{j\omega})\right) dX(\omega) \right\}^{\frac{1}{2}}. \tag{4.4}$$

Thus $\delta_x^2(P_1, P_2, X)$ is seen to be a Stieltjes integral of trace $\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)\right)$ with respect to a "weight" $X(\omega)$.[1] The choice of this weight will be determined by the shape of the spectrum of interest. For a given pair $P_1, P_2 \in \mathcal{P}^{m\times n}$, trace $\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)\right)$ may be easily shown to be a continuous function mapping $[-\pi, \pi]$ to $\mathbb{R}$. Also, X is monotonic from the definition of Φ. From these two facts, it follows that $\delta_x(P_1, P_2, X)$ is well defined for any $P_1, P_2 \in \mathcal{P}^{m\times n}$ [8, Theorem 6.8].

The following lemma sums up properties of δ_x as a measure of distance between systems in $\mathcal{P}^{m\times n}$.

LEMMA 1.

(i) *For a given $X_0 \in \Phi$ and $P_1, P_2 \in \mathcal{P}^{m\times n}$,*

$$0 \leq \delta_x^2(P_1, P_2, X_0) \leq n\|X_0\|_{\Phi} \quad \textit{and} \tag{4.5}$$

$$\delta_x(P_1, P_2, X_0) = \delta_x(P_2, P_1, X_0). \tag{4.6}$$

(ii) *For given $X_0 \in \Phi$ and $P_1, P_2, P_3 \in \mathcal{P}^{m\times n}$,*

$$\delta_x(P_1, P_2, X_0) \leq \delta_x(P_1, P_3, X_0) + \delta_x(P_3, P_2, X_0). \tag{4.7}$$

(iii) *Suppose $X_0 \in \Phi$ is continuously differentiable, with $\frac{dX_0}{d\omega} > 0$ over an interval $[\omega_0, \omega_p] \subseteq [-\pi, \pi]$. Then*

$$\delta_x(P_1, P_2, X_0) = 0 \Leftrightarrow \kappa(P_1, P_2)(e^{j\omega}) = 0 \quad \forall\, \omega \in [\omega_0, \omega_p], \tag{4.8}$$

where $\kappa(\cdot,\cdot)$ is chordal distance as defined in (3.3).

(iv) *Suppose $X_0(\omega) = \sum_{i=1}^{\infty} a_i h(\omega - \omega_i)$, where $\{\omega_i\}$, $i = 1, 2, 3, \ldots$, is a sequence of distinct points in $[-\pi, \pi]$ and $\{a_i\}$ is such that $a_i > 0$ for all i and the sequence of partial sums $\sum a_i$ is convergent. Here $h(\cdot)$ represents the unit step function. Then*

$$\delta_x(P_1, P_2, X_0) = 0 \Leftrightarrow \kappa(P_1, P_2)(e^{j\omega_i}) = 0 \quad \forall\, \omega_i. \tag{4.9}$$

[1] Wherever square roots of positive numbers are used, it will be assumed that the positive square root is considered.

Proof. See the appendix. □

For any continuously differentiable $X \in \Phi$ such that $\frac{dX}{d\omega} > 0$ for all $\omega \in [-\pi, \pi]$, the above result shows that $\delta_x(P_1, P_2, X)$ is a metric over $\mathcal{P}^{m\times n}$. Further, for $P_1, P_2 \in \mathcal{P}^{m\times n}$ and a scalar transfer function x, $x^{-1} \in \mathcal{H}_\infty \cap \mathcal{P}^{1\times 1}$, it may be easily shown that

$$\begin{aligned} &\text{if} \quad X(\omega) = \int_{-\pi}^{\omega} |x(e^{j\tau})|^2 \, d\tau, \\ &\text{then} \quad \delta_x(P_1, P_2, X) \;=\; \|\tilde{G}_2 G_1 x\|_2. \end{aligned}$$

In general, however, X need not even be continuous for $\delta_x(P_1, P_2, X)$ to be well defined.

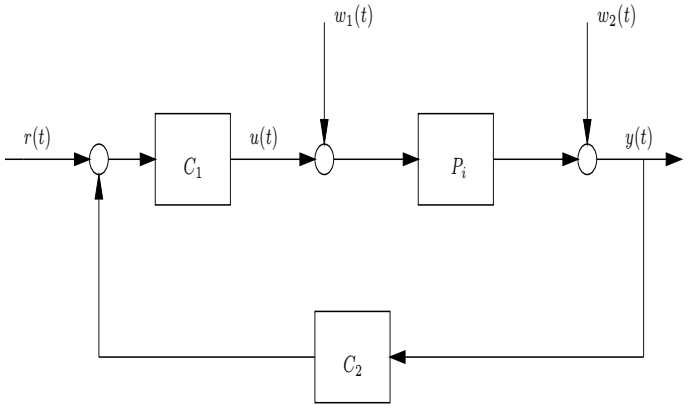

FIG. 5.1. *Closed-loop system.*

5. Closed-loop error bounds. Consider the closed-loop in Figure 5.1. Let $[-\tilde{U} \quad \tilde{V}]$ be the normalized left inverse graph symbol of controller $C = C_1 C_2$ (i.e., $C = \tilde{V}^{-1}\tilde{U}$ and $\tilde{U}$ and $\tilde{V}$ are left coprime). C_1 is a square transfer function matrix and is chosen such that $\tilde{V}C_1 \in \mathcal{H}_\infty$, $\inf_\omega \underline{\sigma}(\tilde{V}C_1)(e^{j\omega}) > 0$. The transfer function from r to $\left[\begin{smallmatrix} y \\ u \end{smallmatrix}\right]$ in Figure 5.1 with $P = P_i$ can easily be shown to be

$$T(P_i, C_1, C_2) \;:=\; G_i(\tilde{K}G_i)^{-1}\tilde{V}C_1. \tag{5.1}$$

Define two constants dependent on controller configuration:

$$\begin{aligned} \alpha_c \;&=\; \inf_\omega \, \underline{\sigma}\,(\tilde{V}C_1)(e^{j\omega}) \\ &=\; 1 \quad \text{if } C_1 = \tilde{V}^{-1},\ C_2 = \tilde{U} \qquad (5.2) \\ &=\; \frac{1}{\sqrt{1 + \|C\|_\infty^2}} \quad \text{if } C_1 = I,\ C_2 = \tilde{V}^{-1}\tilde{U}, \qquad (5.3) \\ \text{and} \quad \beta_c \;&=\; \sup_\omega \, \overline{\sigma}\,(\tilde{V}C_1)(e^{j\omega}) \\ &=\; 1 \quad \text{if } C_1 = \tilde{V}^{-1},\ C_2 = \tilde{U} \\ &\leq\; 1 \quad \text{if } C_1 = I,\ C_2 = \tilde{V}^{-1}\tilde{U} \quad \text{or if } C_1 = \tilde{V}^{-1}\tilde{U},\ C_2 = I. \qquad (5.4) \end{aligned}$$

Note that these definitions do not exclude the "open-loop" case: $C_1 = I$, $C_2 = 0$.

Suppose that upper and lower bounds on the spectrum of disturbance or excitation r of interest are known. This information can be used to bound the difference in closed-loop response of two plants to r, as the next theorem shows.

THEOREM 1. *Suppose $T(P_i, C_1, C_2)$ as defined in (5.1) are exponentially stable, with P_1, $P_2 \in \mathcal{P}^{m\times n}$. Let $r \in \mathcal{S}^n$ be such that $\phi_r(\omega)$ is continuous, where $\mathcal{S}^n$ is the set defined in (2.1). Let x_1, x_2 be Riemann integrable functions on $[-\pi, \pi]$ such that $\exists\ \gamma > 0$ for which*

$$\gamma\, x_1 \ \le\ \sigma_i(\phi_r)(\omega)\ \le \gamma\, x_2 \quad \forall\, \omega, \quad i = 1, 2, \ldots, n. \tag{5.5}$$

Let

$$X_k(\omega)\ =\ \int_{-\pi}^{\omega} x_k(\tau) d\tau,\ k = 1, 2. \tag{5.6}$$

Then, for $b(P_i, C)$ as defined in (3.4), α_c and β_c as defined in (5.2)–(5.4), and the seminorm $\|\cdot\|_\Phi$ as defined in (4.2), the following inequalities hold:

$$\begin{aligned} \frac{\alpha_c\, \delta_x(P_1, P_2, X_1)}{\sqrt{n\, \|X_2\|_\Phi}} &\le \frac{\|(T(P_1, C_1, C_2) - T(P_2, C_1, C_2))\, r\|_{\mathcal{S}}}{\|r\|_{\mathcal{S}}} \\ &\le\ \frac{\beta_c\, \delta_x(P_1, P_2, X_2)}{\sqrt{n\, \|X_1\|_\Phi}\, b(P_1, C)\, b(P_2, C)}. \end{aligned} \tag{5.7}$$

Further, if $C_1 = \tilde{V}^{-1}(\tilde{K} G_1)$ and $C_2 = C_1^{-1} C$, then

$$\begin{aligned} \frac{\delta_x(P_1, P_2, X_1)}{\sqrt{n\, \|X_2\|_\Phi}} &\le \frac{\|(T(P_1, C_1, C_2) - T(P_2, C_1, C_2))\, r\|_{\mathcal{S}}}{\|r\|_{\mathcal{S}}} \\ &\le\ \frac{\delta_x(P_1, P_2, X_2)}{\sqrt{n\, \|X_1\|_\Phi}\, b(P_2, C)}. \end{aligned} \tag{5.8}$$

Proof. See the appendix. □

Several remarks on this result are in order.

(i) To guarantee that the filtered signal $T(P_i, C_1, C_2)\, r$ to be in $\mathcal{S}^n$, the impulse response of $T(P_i, C_1, C_2)$ should be in l_1 (i.e., should be absolutely summable) [5]. One simple way to ensure this is to impose the exponential stability condition. From a practical point of view, of course, this is a perfectly sensible requirement.

(ii) The equality (4.3) explains the presence of $\sqrt{n\|X_k\|_\Phi}$ in (5.7). To explore this further, let $\hat{r} \in \mathcal{S}^1$ be such that $\phi_{\hat{r}}$ is continuous. Let X_1, $X_2 \in \Phi$ be such that $\frac{dX_1}{d\omega} = \phi_{\hat{r}} = \frac{dX_2}{d\omega}$. Then $\|\hat{r}\|_{\mathcal{S}}^2 = \|X_1\|_\Phi = \|X_2\|_\Phi$. Define *spectral distribution function* [5]

$$F_{\hat{r}}(\omega) = \int_{-\pi}^{\omega} \phi_{\hat{r}}(\tau) d\tau.$$

Then $F_{\hat{r}}$ is continuous over $[-\pi, \pi]$ and $\frac{dF_{\hat{r}}}{d\omega} = \phi_{\hat{r}}$. Using this definition in (5.7) yields a simpler expression,

$$\alpha_c\, \delta_x(P_1, P_2, F_{\hat{r}}) \le \|(T(P_1, C_1, C_2) - T(P_2, C_1, C_2))\, \hat{r}\|_{\mathcal{S}}\ \le\ \frac{\beta_c\, \delta_x(P_1, P_2, F_{\hat{r}})}{b(P_1, C)\, b(P_2, C)}.$$

To reemphasize the main motivation of this work, note that $\delta_x(P_1, P_2, F_{\hat{r}})$ may be small for $F_{\hat{r}}$ of interest even if $\delta_\nu(P_1, P_2)$ is large.

(iii) In proving Theorem 1, we will use the equality

$$\operatorname{trace} R_r(0) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \operatorname{trace}\, \phi_r(\omega)\, d\omega.$$

This is certainly true when ϕ_r is continuous but may not be true in general. For single input systems, ϕ_r may be allowed to have the form

$$\phi_r(\omega) = \phi_{\hat{r}}(\omega) + \sum_{i=1}^{l} \delta(\omega - \omega_i),$$

where $\phi_{\hat{r}}(\omega)$ is continuous, $\omega_i \in [-\pi, \pi]$, and $\delta(\cdot)$ is a Dirac delta function. Impulses in the spectral density of r represent periodic excitation. It is reasonable to expect that the frequencies of periodic reference (or disturbance) are known. The bounds in (5.7)–(5.8) will still make sense if we allow jump discontinuities in X_1, X_2 at the frequencies of periodic excitation. For multi-input systems, it is more difficult to account for delta functions due to the necessity of bounding singular values of the spectrum.

(iv) Note that the parameter γ in (5.5) doesn't appear in (5.7) or (5.8). This is important, since it implies that the bounds in (5.7)–(5.8) are *scale invariant* in the sense that one needs only to know the bounds on the *shape* of singular values of spectral density ϕ_r. The actual magnitude of spectral density is irrelevant.

(v) For a multi-input system, these bounds make sense for comparing performance under simultaneous excitation of all inputs. To compare behavior when $\sigma_n(\phi_r)(\omega) = 0$ for all ω (i.e., to compare the response when some but not all inputs are excited), x_1 should be zero; but that makes the lower bound in (5.7) zero, and the upper bound becomes unbounded. Even in that case, the following bound still holds:

$$\|(T(P_1, C_1, C_2) - T(P_2, C_1, C_2))\, r\|_{\mathcal{S}} \;\le\; \frac{\beta_c\, \gamma\, \delta_x(P_1, P_2, X_2)}{b(P_1, C)\, b(P_2, C)}.$$

This may be easily shown following the steps of the proof of Theorem 1.

Suppose P_2 is a model for a "true" plant P_1. For a "reasonable" controller C (i.e., which stabilizes both the true plant and the model with adequate stability margins), Theorem 1 shows that the difference in the designed and the achieved closed-loop response to a persistent excitation $r \in \mathcal{S}^n$ is small if $\delta_x(P_1, P_2, \phi_r)$ is small. The results are relevant in comparing the designed and the achieved tracking performance (when r is a reference) and in comparing noise rejection of two closed-loops (when r is a disturbance). These error bounds may also prove useful in assessing the suitability of a reduced order model to design a controller for a high order plant.

If $r_0 \in \mathcal{S}^n$ is such that the $\phi_{r_0}(\omega) = I^{n\times n}$, then

$$\|T(P_1, C_1, C_2) - T(P_2, C_1, C_2) r_0\|_{\mathcal{S}} \;=\; \|T(P_1, C_1, C_2) - T(P_2, C_1, C_2)\|_2.$$

This observation leads to the following 2-norm inequality.

COROLLARY 1. *Suppose P_1, $P_2 \in \mathcal{P}^{m\times n}$ and a controller C stabilizes both P_1 and P_2. Let $C = \tilde{V}^{-1}\tilde{U} = C_1C_2$, where $[-\tilde{U} \quad \tilde{V}]$ is a normalized left graph symbol of C and C_1 is a square matrix function such that $\tilde{V}C_1 \in \mathcal{H}_\infty$, $\inf_\omega \underline{\sigma}(\tilde{V}C_1) > 0$. Further, suppose $T(P_1, C_1, C_2)$ as defined in* (5.1) *are exponentially stable. Then*

$$\alpha_c \,\|\, \tilde{G}_2 G_1 \,\|_2 \le \|T(P_1, C_1, C_2) - T(P_2, C_1, C_2)\|_2 \le \frac{\beta_c \,\|\, \tilde{G}_2 G_1 \,\|_2}{b(P_1, C)\, b(P_2, C)}, \tag{5.9}$$

where α_c, β_c are as defined in (5.2)–(5.4).

Proof. The proof follows from (5.7), with $\phi_r = I^{n\times n}$, $\frac{dX_1}{d\omega} = \frac{dX_2}{d\omega} = 1$. ∎

Given an unknown true plant P_0, a model P_θ, and a spectral distribution F_r, it is not possible to measure $\delta_x(P_0, P_\theta, F_r)$ directly. The next section introduces bounds on $\delta_x(P_0, P_\theta, F_r)$ for a given single input "true" plant P_0 and a model P_θ in terms of data from a time domain identification experiment.

6. Bounds on $\delta_x(P_0, P_\theta, X)$. The main result in this section is restricted to single input systems. A partial generalization to the multiple input case is possible and is discussed at the end of the section.

Consider a plant $P_0 \in \mathcal{P}^{m\times 1}$. For a closed-loop system as shown in Figure 5.1 (with $P_i = P_0$), the a posteriori data is given by

$$z := \begin{bmatrix} y \\ u \end{bmatrix} = G_0(\tilde{K}G_0)^{-1}\,\tilde{V}C_1\,r + H(C, P_0)w, \tag{6.1}$$

where $H(C, P_0)$ is a closed-loop transfer function as defined in section 3, $H(C, P_0) = K(\tilde{G}_0 K)^{-1}\tilde{G}_0$. y, u (and, possibly, r) are measured signals, and $w = \left[\begin{smallmatrix} -w_1 \\ w_2 \end{smallmatrix}\right]$ is unmeasured noise or disturbance. Suppose $r, w_1, \in \mathcal{S}^1$, $w_2 \in \mathcal{S}^m$ are such that

$$\lim_{N\to\infty} \frac{1}{N} \sum_{t=0}^{N-1} (r(t)w_i^T(t-\tau)) = 0 \quad \forall\, \tau, \quad i = 1, 2. \tag{6.2}$$

This deterministic assumption corresponds to the idea that the reference r and the noise signals w_i are uncorrelated. Also, suppose that the transfer function from

$$\begin{bmatrix} r & w_1 & w_2 \end{bmatrix}^T$$

to $\left[\begin{smallmatrix} y \\ u \end{smallmatrix}\right]$ is exponentially stable. Assume that ϕ_r is continuous and define the spectral distribution function of r as before,

$$F_r(\omega) = \int_{-\pi}^{\omega} \phi_r(\tau) d\tau.$$

The data z from (6.1) can be used for identifying a model for P_0. One common method for parametric time domain identification is the prediction error method [4]. This method solves

$$\min_\theta \|\tilde{X}_\theta z\|_{\mathcal{S}} \quad \text{subject to} \quad \tilde{X}_\theta(\infty) = \begin{bmatrix} I & 0 \end{bmatrix}. \tag{6.3}$$

Here, $\tilde{X}_\theta$ is a left graph symbol of model parameterized by a (real) parameter vector θ, and z is output-input data as in (6.1). This is sometimes referred to as the "direct" prediction error in the literature [2], as opposed to methods that use a measurable reference.

The prediction error identification approach has elegant statistical properties and is widely studied in the literature; [4] offers a very comprehensive treatment. For a model P_θ obtained by the prediction error method, it is desired to obtain an estimate of $\delta_x(P_0, P_\theta, F_r)$. Let $\tilde{G}_\theta$ be the normalized left graph symbol of P_θ. The following result gives bounds on $\delta_x(P_0, P_\theta, F_r)$ in terms of time domain data.

THEOREM 2. *Let P_θ be a candidate model for P_0 with both $P_0, P_\theta \in \mathcal{P}^{m\times 1}$. Suppose $r, w_1 \in \mathcal{S}^1$, $w_2 \in \mathcal{S}^m$ are such that* (6.2) *holds. Let $C = C_1C_2$ be such that the transfer function from*

$$\begin{bmatrix} r & w_1 & w_2 \end{bmatrix}^T$$

to $\left[\begin{smallmatrix} y \\ u \end{smallmatrix}\right]$ *in Figure* 5.1 *is exponentially stable. Let* z *be as defined in* (6.1)*, and let* α_c *and* β_c *be as defined in* (5.2)–(5.4)*. Then*

(6.4)
$$\frac{b^2(P_0,C)\,\|\tilde{G}_\theta\, z\|_{\mathcal{S}}^2 - \|\tilde{G}_0\, w\|_{\mathcal{S}}^2}{\beta_c^2} \;\le\; \delta_x^2(P_0,P_\theta,F_r) \;\le\; \frac{\|\tilde{G}_\theta\, z\|_{\mathcal{S}}^2 - b^2(P_\theta,C)\,\|\tilde{G}_0\, w\|_{\mathcal{S}}^2}{\alpha_c^2}.$$

Proof. See the appendix. ∎

From (6.4), it follows that

$$\delta_x(P_0,P_\theta,F_r) \le \frac{\|\tilde{G}_\theta\, z\|_{\mathcal{S}}}{\alpha_c}. \tag{6.5}$$

For a given model P_θ, measured data z, and a given α_c the right-hand side can be explicitly evaluated. Combining (5.7) and (6.5) gives

$$\frac{\|(T(P_0,C_1,C_2) - T(P_\theta,C_1,C_2))\, r\|_{\mathcal{S}}}{\|r\|_{\mathcal{S}}} \;\le \frac{\|\tilde{G}_\theta\, z\|_{\mathcal{S}}}{\|r\|_{\mathcal{S}}}\, \frac{\beta_c}{\alpha_c\, b(P_0,C)\, b(P_\theta,C)}.$$

If $\frac{\|\tilde{G}_\theta\, z\|_{\mathcal{S}}}{\|r\|_{\mathcal{S}}}$ is small, any "good" controller C (i.e., with sufficiently large robust stability margins $b(P_0,C)$ and $b(P_\theta,C)$) should yield a small difference in closed-loop behavior for excitation r. However, the upper bound above cannot be evaluated from data due to the presence of an unknown term $b(P_0,C)$.

If $\|\tilde{G}_0 w\|_{\mathcal{S}} \approx 0$ and if $C_1 = \tilde{V}^{-1}$, $C_2 = \tilde{U}$, then (6.4) yields an aesthetically pleasing expression,

$$b(P_0,C)\,\|\tilde{G}_\theta\, z\|_{\mathcal{S}} \;\le\; \delta_x(P_0,P_\theta,F_r) \;\le\; \|\tilde{G}_\theta\, z\|_{\mathcal{S}}.$$

Note that the model P_θ need not be obtained from the same experimental data z used in the bounds; the results hold for *any* candidate model P_θ so far as the data z is generated according to (6.1) and (6.2) holds. In particular, note that (6.5) does not use any a priori assumptions about the order or the relative stability of the plant P_0. The exponential stability of the *closed-loop* is the only assumption used here.

The result above is valid for single input systems. A generalization to multivariable plants is possible in the case when the spectrum of r is a scalar function times identity.

COROLLARY 2. *Let* P_θ *be a candidate model for* P_0 *with both* $P_0, P_\theta \in \mathcal{P}^{m\times n}$*. Suppose* $r, w_1 \in \mathcal{S}^n$, $w_2 \in \mathcal{S}^m$ *are such that* (6.2) *holds. Further, suppose* $r \in \mathcal{S}^n$ *is such that* $\phi_r = x\, I^{n\times n}$*, where* x *is a scalar, continuous spectrum. Let* $X(\omega) = \int_{-\pi}^{\omega} x(\tau)d\tau$*. Let* $C = C_1C_2$ *be such that the transfer function from*

$$\begin{bmatrix} r & w_1 & w_2 \end{bmatrix}^T$$

to $\left[\begin{smallmatrix} y \\ u \end{smallmatrix}\right]$ *in Figure* 5.1 *is exponentially stable. Let* z *be as defined in* (6.1)*, and let* α_c *and* β_c *be as defined in* (5.2)–(5.4)*. Then*

$$\begin{aligned} \frac{b^2(P_0,C)\,\|\tilde{G}_\theta\, z\|_{\mathcal{S}}^2 - \|\tilde{G}_0\, w\|_{\mathcal{S}}^2}{\beta_c^2} &\le \delta_x^2(P_0,P_\theta,X) \\ &\le \frac{\|\tilde{G}_\theta\, z\|_{\mathcal{S}}^2 - b^2(P_\theta,C)\,\|\tilde{G}_0\, w\|_{\mathcal{S}}^2}{\alpha_c^2}. \end{aligned} \tag{6.6}$$

Proof. This may be shown following the steps of the proof of Theorem 2. Details are omitted. □

Remark 1. Under the assumption (6.2), an upper bound similar to (6.5) also holds in the case of prediction error cost in (6.3). If $\theta_\star$ is an argument which minimizes the cost in (6.3), it can be shown that

$$\|\tilde{X}_{\theta_\star}\, X_0\, r\|_S \;\le\; \|\tilde{X}_{\theta_\star}\, z\|_S,$$

where $X_0 = G_0(\tilde{K}G_0)^{-1}\,\tilde{V}C_1$. This may be easily proved from the proof of Theorem 2. The quantity $\|\tilde{X}_{\theta_\star}\, X_0\, r\|_S$, unlike $\delta_x(P_0, P_{\theta_\star}, F_r)$, depends on the choice and the configuration of controller C.

Remark 2. The bounds presented above are "distribution-free" and use only a nonprobabilistic assumption (6.2) about noise. Developing results equivalent to Theorem 2 in a probabilistic setting is an interesting and challenging area of future research.

7. Examples. Here we consider some examples to see how this new measure can be useful in comparing the closed-loop response of systems to persistent excitation. Consider a pair of plants

$$P_1(z) = \frac{2(z+1)}{z-0.6}, \qquad P_2(z) = \frac{(z+1)^2}{(z^2-0.6z+1.2)}.$$

The ν-gap error between P_1 and P_2 is significantly large ($= 0.64$). Suppose the spectrum of interest is a low frequency spectrum which satisfies

$$\gamma\, x_1(\omega) \le\; \phi_{r_0} \;\le \gamma\, x_2(\omega)$$

$$\text{for some } \gamma > 0, \text{ where} \quad x_1(\omega) = f_1(e^{j\omega})f_1(e^{-j\omega}), \quad f_1(z) = \frac{0.01z}{z-0.99},$$

$$\text{and} \quad x_2(\omega) = f_2(e^{j\omega})f_2(e^{-j\omega}), \quad f_2(z) = \frac{0.02z}{z-0.98}.$$

Note that the exact value of γ (and hence the power in the signal) is immaterial. Let $F_i(\omega) = \int_{-\pi}^{\omega} x_i(\tau)d\tau$, $i = 1, 2$. Then

$$\frac{\delta_x(P_1, P_2, F_1)}{\|F_2\|_\Phi} = 0.0294 \qquad \text{and} \qquad \frac{\delta_x(P_1, P_2, F_2)}{\|F_1\|_\Phi} = 0.0724.$$

(These may be computed as 2-norm of $\tilde{G}_2 G_1 f_i$, $i = 1, 2$.) Thus, given a controller C which stabilizes both P_1 and P_2 with "good" stability margin, the difference in closed-loop gains $T(P_1, C_1, C_2) - T(P_2, C_1, C_2)$ over this spectrum is guaranteed to be small. In this particular case, a simple integral controller $C_1 = \frac{0.025(z+1)}{(z-1)}$, $C_2 = -1$ yields stability margins $b(P_1, C) = 0.408$, $b(P_2, C) = 0.401$.

For the same plants P_1, P_2 as above, if we consider $f_1(z) = f_2(z) = 1 - 0.9z^{-1}$, then

$$\frac{\delta_x(P_1, P_2, F_1)}{\|F_2\|_\Phi} = \frac{\delta_x(P_1, P_2, F_2)}{\|F_1\|_\Phi} = 0.4469$$

so that no controller can make the difference in closed-loop gains $T(P_1, C_1, C_2) - T(P_2, C_1, C_2)$ smaller than $0.4469\,\alpha_c$ over this spectrum, with α_c as defined in (5.2).

Next, consider another pair of plants

$$P_3(z) = \frac{z-1}{z-0.99}, \qquad P_4(z) = \frac{z-1}{z-1.01}.$$

The ν-gap between P_3 and P_4 is 1. Suppose P_3 and P_4 are to be compared from the perspective of white noise rejection. Then $\|\tilde{G}_4 G_3\|_2 = 0.055$, which means any "reasonable" controller will yield a similar closed-loop white noise rejection for both P_3 and P_4 (provided such a controller exists). The controller $C_1 = 1$, $C_2 = -1$ in this case yields $b(P_3, C) = b(P_4, C) = 0.7071$.

8. Conclusion. A new measure $\delta_x(\cdot,\cdot,X)$ is introduced for measuring distance between linear shift invariant systems. It is shown that this measure can be used to characterize the difference in closed-loop behavior of two feedback systems under a given persistent excitation. For a plant P_0 and a model P_θ, bounds on this measure with respect to a given reference spectrum are obtained in terms of data from a time domain identification experiment.

Appendix. First, some technical results necessary for the proofs of Lemma 1 and Theorems 1 and 2 are given.

FACT 1. *For any complex matrix $Q \in \mathbb{C}^{m\times n}$, let the Frobenius norm be defined as usual, $\|Q\|_F^2 = \text{trace}\,(Q^*Q) = \text{trace}\,(QQ^*) = \sum_{i=1}^{m} \sigma_i^2(Q)$, where $m = \min(m,n)$. For a pair of complex matrices Q, R of compatible dimensions, with R square and invertible, the following inequalities hold:*

$$\underline{\sigma}(R)\|Q\|_F \le \|QR\|_F \le \overline{\sigma}(R)\,\|Q\|_F. \tag{A.1}$$

Proof. The upper bound is well known [13]. The lower bound follows from

$$\|Q\|_F = \|QRR^{-1}\|_F \le \overline{\sigma}(R^{-1})\|QR\|_F. \qquad \square \tag{A.2}$$

The next result proves the formula for $\inf_\omega \underline{\sigma}(\tilde{V}C_1)(e^{j\omega})$ stated in (5.3).

LEMMA 2. *Let $[-\tilde{U} \quad \tilde{V}]$ be the normalized left inverse graph symbol for $C = \tilde{V}^{-1}\tilde{U}$. Then*

$$\inf_\omega \underline{\sigma}(\tilde{V})(e^{j\omega}) = \frac{1}{\sqrt{1+\|C\|_\infty^2}}. \tag{A.3}$$

Proof. From [12, section 2.3],

$$\overline{\sigma}^2(C) = \frac{\overline{\sigma}^2(\tilde{U})}{1-\overline{\sigma}^2(\tilde{U})} \quad \text{and} \quad \underline{\sigma}^2(\tilde{V}) = 1 - \overline{\sigma}^2(\tilde{U}). \tag{A.4}$$

A rearrangement of (A.4) and taking the infimum of both sides leads to (A.3). $\square$

The proofs that follow also use some identities from [12, section 3.2] for manipulation of normalized graph symbols:

$$(\tilde{G}_1G_2)^*(\tilde{G}_1G_2) + (G_2^*G_1)(G_2^*G_1)^* = I, \tag{A.5}$$

$$(\tilde{G}_2G_1)^*(\tilde{G}_2G_1) + (G_2^*G_1)^*(G_2^*G_1) = I, \tag{A.6}$$

$$\tilde{G}_2^*\tilde{G}_2 + G_2G_2^* = I, \tag{A.7}$$

$$K(\tilde{G}_2K)^{-1}\tilde{G}_2 + G_2(\tilde{K}G_2)^{-1}\tilde{K} = I. \tag{A.8}$$

In the rest of the proofs, the argument $e^{j\omega}$ will be omitted for brevity wherever it is obvious from the context.

Proof of Lemma 1. Property (4.5) is obvious. To prove (4.6), note that

$$\begin{aligned}\sigma_i^2(\tilde{G}_2G_1)(e^{j\omega}) &= 1-\sigma_{n-i+1}^2(G_2^*G_1)(e^{j\omega}) && \text{(from (A.5))}\\ &= \sigma_i^2(\tilde{G}_1G_2)(e^{j\omega}) && \text{(from (A.6)).}\end{aligned}$$

Next, using (A.7),

$$\begin{aligned}\delta_x^2(P_1,P_2,x) &= \frac{1}{2\pi}\int_{-\pi}^{\pi}\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_2G_1\right)dX_0(\omega)\\ &= \frac{1}{2\pi}\int_{-\pi}^{\pi}\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_2\left(G_3G_3^*+\tilde{G}_3^*\tilde{G}_3\right)G_1\right)dX_0(\omega)\\ &\le \frac{1}{2\pi}\int_{-\pi}^{\pi}\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_2\,G_3\right)dX_0(\omega)+\frac{1}{2\pi}\int_{-\pi}^{\pi}\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_3\,G_1\right)dX_0(\omega) \qquad \text{(A.9)}\\ &\le \left(\delta_x^2(P_2,P_3,X_0)+\delta_x^2(P_3,P_1,X_0)\right) \qquad \text{(A.10)}\end{aligned}$$

from which (4.7) follows.

To prove (4.8), let $x(\omega)=\frac{dX_0}{d\omega}$ and note that

$$\int_{-\pi}^{\pi}\left(\sum_{i=1}^{n}\sigma_i^2(\tilde{G}_2G_1)\right)dX(\omega)\ge\min_{\omega\in[\omega_0,\omega_p]}x(\omega)\int_{\omega_0}^{\omega_p}\text{trace}\,\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)\right)d\omega.$$

On the other hand, if $X_0(\omega)=\sum_{i=1}^{\infty}a_ih(\omega-\omega_i)$, then from [8, Theorem 6.16],

$$\delta_x^2(P_1,P_2,X_0)=\frac{1}{2\pi}\sum_{i=1}^{\infty}a_i\,\text{trace}\,\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)\right)(e^{j\omega_i})$$

from which (4.9) follows. □

Proof of Theorem 1. Note that

$$\delta_x^2(P_1,P_2,X_i)=\frac{1}{2\pi}\int_{-\pi}^{\pi}\text{trace}\,\left((\tilde{G}_2G_1)^*(\tilde{G}_2G_1)\right)x_i\,d\omega,\quad i=1,2.$$

This follows from the definition (5.6) of $X_i(\omega)$ and from [8, Theorem 6.20].

Upper bound. We have

$$\begin{aligned}\|(T(P_1,C_1,C_2)-T(P_2,C_1,C_2))\,r\|_{\mathcal{S}}^2 &= \left\|\left(G_1(\tilde{K}G_1)^{-1}-G_2(\tilde{K}G_2)^{-1}\right)(\tilde{V}C_1)\,r\right\|_{\mathcal{S}}^2\\ &= \left\|\left(K(\tilde{G}_2K)^{-1}\tilde{G}_2G_1(\tilde{K}G_1)^{-1}\right)(\tilde{V}C_1)\,r\right\|_{\mathcal{S}}^2 \qquad \text{(A.11)}\end{aligned}$$

(premultiplying by the left-hand side of the equality in (A.7) and using the fact $\tilde{G}_2G_2=0$)

$$\le\gamma\left(\sup_{\omega}\overline{\sigma}^2\,(\tilde{G}_2K)^{-1}\right)\left(\sup_{\omega}\overline{\sigma}^2\,(\tilde{K}G_1)^{-1}\right)\left(\sup_{\omega}\overline{\sigma}^2\,(\tilde{V}C_1)\right)\delta_x^2(P_1,P_2,X_2), \qquad \text{(A.12)}$$

where the last step uses

$$\overline{\sigma}\,(\phi_r)\,\sum_{i=1}^{n}\sigma_i^2\,(\tilde{G}_2G_1)\;\leq\;\gamma\,x_2\,\sum_{i=1}^{n}\sigma_i^2\,(\tilde{G}_2G_1).$$

Also, note that

$$\frac{1}{n\,\gamma\,\|X_2\|_\Phi}\;\leq\;\frac{1}{\|r\|_{\mathcal{S}}^2}\;\leq\;\frac{1}{n\,\gamma\,\|X_1\|_\Phi}. \tag{A.13}$$

The result then follows using (A.11)–(A.13) and using the definitions of β_c and of $b(P_i,C)$ in (5.4) and (3.4), respectively.

Lower bound. Put $L=(\tilde{K}G_1)^{-1}$, $Q=(\tilde{K}G_2)^{-1}(\tilde{K}G_1)$. Then

$$\begin{aligned}
&\left\|\left(G_1(\tilde{K}G_1)^{-1}-G_2(\tilde{K}G_2)^{-1}\right)(\tilde{V}C_1)\,r\right\|_{\mathcal{S}}^2=\left\|(G_1-G_2Q)\,L(\tilde{V}C_1)\,r\right\|_{\mathcal{S}}^2\\
&\geq\alpha_c^2\,\frac{1}{2\pi}\int_{-\pi}^{\pi}\sum_{i=1}^{n}\sigma_i^2\left((G_1-G_2Q)\phi_r^{\frac{1}{2}}\right)d\omega\quad(\text{using }\underline{\sigma}(L)\;\geq\;1)\\
&\geq\;\frac{\gamma\,\alpha_c^2}{2\pi}\int_{-\pi}^{\pi}x_1\sum_{i=1}^{n}\sigma_i^2(G_1-G_2Q)\,d\omega\\
\text{and}\quad&x_1\sum_{i=1}^{n}\sigma_i^2\,((G_1-G_2Q))\;=x_1\sum_{i=1}^{n}\sigma_i^2\,\left(\begin{bmatrix}\tilde{G}_2\\G_2^*\end{bmatrix}(G_1-G_2Q)\right)\quad(\text{using (A.6)})\\
&\geq\;x_1\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_2G_1\right).
\end{aligned}\tag{A.14}$$

Hence

$$\left\|\left(G_1(\tilde{K}G_1)^{-1}-G_2(\tilde{K}G_2)^{-1}\right)(\tilde{V}C_1)\,r\right\|_{\mathcal{S}}^2\;\geq\;\frac{\gamma\,\alpha_c^2}{2\pi}\int_{-\pi}^{\pi}x_1\sum_{i=1}^{n}\sigma_i^2\left(\tilde{G}_2G_1\right)d\omega. \tag{A.15}$$

The result follows from (A.15) and (A.13).

The upper and lower bounds in the second part may be proved similarly by substituting $C_1=\tilde{V}^{-1}(\tilde{K}G_1)$ in (A.11) and (A.14). □

Proof of Theorem 2. From (6.1),

$$z=\begin{bmatrix}y\\u\end{bmatrix}=G_0(\tilde{K}G_0)^{-1}\tilde{V}C_1r+K(\tilde{G}_0K)^{-1}\tilde{G}_0w \tag{A.16}$$

so that

$$\|\tilde{G}_\theta z\|_{\mathcal{S}}^2=\|(\tilde{G}_\theta G_0)(\tilde{K}G_0)^{-1}(\tilde{V}C_1)\,r\|_{\mathcal{S}}^2+\|(\tilde{G}_\theta K)(\tilde{G}_0K)^{-1}\,\tilde{G}_0\,w\|_{\mathcal{S}}^2 \tag{A.17}$$

(since $\phi_{r\omega}=0$)

$$\leq\left(\sup_\omega\overline{\sigma}^2(\tilde{K}G_0)^{-1}\right)\left(\sup_\omega\overline{\sigma}^2(\tilde{V}C_1)\right)\delta_x^2(P_0,P_\theta,F_r)+\left(\sup_\omega\overline{\sigma}^2(\tilde{G}_0K)^{-1}\right)\|\,\tilde{G}_0\,w\|_{\mathcal{S}}^2. \tag{A.18}$$

The lower bound follows from (A.1) using the definitions of β_c and $b(P_0, C)$. To derive the upper bound, note that

$$\begin{aligned}\|\tilde{G}_\theta z\|_S^2 \;\geq\; & \left(\inf_\omega \underline{\sigma}^2\,(\tilde{K}G_0)^{-1}\right)\left(\inf_\omega \underline{\sigma}^2\,(\tilde{V}C_1)\right)\delta_x^2(P_0, P_\theta, F_r) \\ & +\; \left(\inf_\omega \underline{\sigma}^2\,(\tilde{G}_\theta K)\right)\left(\inf_\omega \underline{\sigma}^2\,(\tilde{G_0}K)^{-1}\right)\|\,\tilde{G}_0\,w\|_S^2.\end{aligned}$$

The result then follows using

$$\begin{aligned}&\inf_\omega \underline{\sigma}\,(\tilde{K}G_0)^{-1}(e^{j\omega}) \;\geq\; 1, \qquad \inf_\omega \underline{\sigma}\,(\tilde{G}_0K)^{-1}(e^{j\omega}) \;\geq\; 1 \\ &\text{and} \quad \inf_\omega \underline{\sigma}\,(\tilde{G}_\theta K)(e^{j\omega}) \;=\; b(P_\theta, C). \qquad \square\end{aligned}$$

CONTROLLABILITY OF POISSON SYSTEMS*

PETRE BIRTEA†, MIRCEA PUTA‡, AND TUDOR S. RATIU†

Abstract. Sufficient conditions for the controllability of affine nonlinear control systems on Poisson manifolds are given. The important special case when the Poisson manifold is the reduced space of a symplectic manifold by a free Lie group action is studied. The controllability of the reduced system is linked to that of the given affine nonlinear system. Several examples illustrating the theory are also presented.

Key words. controllability, symplectic manifold, Poisson manifold, reduction, weak positive Poisson stability

1. Introduction.

The phase space of classical conservative mechanical systems is usually described by a Poisson manifold $(P, \{\cdot,\cdot\})$. The dynamics on P, subject to external forces, can often be written in the form of an affine nonlinear control system as

$$\dot{x} = X(x) + \sum_{i=1}^{m} Y_i(x) u_i \,,$$

where the drift vector field X is a complete vector field tangent to the symplectic leaves of P and also preserves the symplectic volume on each one of them, $Y_1, \ldots, Y_m \in \mathfrak{X}(P)$ are smooth complete vector fields on P, the control $u := (u_1, \ldots, u_m) : (0, \infty) \longrightarrow B \subset \mathbb{R}^m$ is a measurable function, and B is a bounded subset of $\mathbb{R}^m$.

Deciding the controllability of nonlinear control systems is usually a difficult problem that has generated a large body of literature. As opposed to linear control systems, the Lie algebra rank condition is not sufficient for proving controllability of a nonlinear control system. Nevertheless, there is a link between nonlinear controllability and linear controllability given by the following well-known result: If the linearization of a nonlinear system at an equilibrium is controllable, then the nonlinear system is locally controllable. For nonlinear systems without drift, various characterizations of controllability based on Chow's theorem were obtained. These were generalized to nonlinear systems with drift in terms of the Lie algebra generated by the control vector fields. Significant results were obtained by Hermann [14], Haynes and Hermes [13], Brockett [8], Lobry [28], Sussmann and Jurdjevic [45], Krener [23], and others. Sufficient conditions for controllability of nonlinear systems satisfying the Lie algebra rank condition were obtained by Lobry [29] in the case of Poisson stable systems. This work was generalized by Jurdjevic and Quinn [18] and Bonnard [6] to the case when

only the drift vector field is required to be Poisson stable. This method was applied by Crouch [11] to the study of spacecraft attitude control problems. In order to analyze the controllability of spacecraft systems, which include attitude-orbit coupling terms and are controlled only by attitude controllers using either reaction wheels or gas jets, Lian, Wang, and Fu [26] replaced the condition on the drift vector field to be Poisson stable with the less stringent condition of weak positive Poisson stability. More precisely, they showed that if an affine nonlinear control system verifies the Lie algebra rank condition and the drift vector field is weakly positively Poisson stable, then the system is controllable.

The problem of controllability for nonlinear systems that are invariant under the action of a Lie group was studied by San Martin and Crouch [42], Jurdjevic and Kupka [17] and, in a more general setting of fiber bundles, by Nijmeijer and van der Schaft [38] (see also Grizzle and Marcus [12] and Sánchez de Alvarez [43]). Other results concerning different aspects of the relation between the given and the reduced control system can be found in Jalnapurkar and Marsden [15], [16] and Bloch, Leonard, and Marsden [5].

The aim of this paper is to give sufficient conditions for the controllability of an affine control system on a Poisson manifold. For the case when the manifold is the cotangent bundle of a Lie group, this problem was studied by Manikonda and Krishnaprasad [30]; it was this paper that has inspired the present generalization. The strategy of the proof of the main results is to give topological conditions that guarantee that the drift vector field is weakly positively Poisson stable (WPPS). In order to do this, we will use the Poincaré recursion theorem for the dynamics of the drift vector field restricted to each symplectic leaf. We will prove that if one can find a continuous function $f : P \to \mathbb{R}$ that is constant on the flow of X and is such that either f restricted to each symplectic leaf is a proper function or f is a proper function from P to $\mathbb{R}$ and all symplectic leaves are closed and embedded submanifolds of P, then X is WPPS. There is a relatively subtle technical point in the proof of this theorem: The topology of a symplectic leaf is stronger than the relative topology induced by the ambient space P; that is, every open set in the induced topology on the leaf is also open in the immersed topology of the leaf, but there exist open sets in the immersed topology of the leaf that are not open in the induced topology. This immediately implies that there are subsets in the leaf which are compact in the induced topology but are not compact in the immersed topology on the leaf.

As an important case of this first result, we will study the situation when the Poisson manifold is the reduced space of a symplectic manifold by a free proper Lie group action which also admits a momentum map. We will show that if the momentum map is proper and the reduced affine nonlinear system verifies the Lie algebra rank condition, then it is controllable. Similarly, if the momentum map is not proper but the Lie group is compact and there is a proper map $f : M/G \to \mathbb{R}$ which is constant along the trajectories of the reduced drift vector field and in addition the reduced affine nonlinear system verifies the Lie algebra rank condition, then the system is controllable. We will also give the relation between the controllability of the reduced and initial affine nonlinear systems.

The paper ends with some examples of underactuated affine nonlinear control systems; for this, some useful technical lemmas implying the properness of functions are also given.

After this paper was submitted the authors were made aware of the work of Manikonda and Krishnaprasad [31] (a preliminary version of these results can be

found in Krishnaprasad and Manikonda [24]) with which the present work has a certain amount of overlap. We shall mention in the text explicitly where this is the case and compare their results to ours.

2. Controllability and Poisson stability. In this section we shall present a controllability result for affine nonlinear control systems on a general Poisson manifold. We begin by reviewing the classical definitions and results that will be used later on by adopting the terminology in the standard textbook of Nijmeijer and van der Schaft [39].

Let M be a smooth n-dimensional connected manifold and

$$\dot{x} = X(x) + \sum_{i=1}^{m} Y_i(x)u_i \tag{2.1}$$

an affine nonlinear control system on M, where $X, Y_1, \ldots, Y_m \in \mathfrak{X}(M)$ are smooth complete vector fields on M, the control $u := (u_1, \ldots, u_m) : (0, \infty) \longrightarrow B \subset \mathbb{R}^m$ is a measurable function, and B is a bounded subset of $\mathbb{R}^m$. We will denote by $\mathcal{L}$ the Lie subalgebra of $\mathfrak{X}(M)$ generated by the vector fields $X, Y_1, \ldots, Y_m$.

DEFINITION 2.1. *The system* (2.1) *satisfies the* Lie algebra rank condition (LARC) *if* $\operatorname{span} \mathcal{L}(x) = T_x M$ *for every* $x \in M$, *where* $\mathcal{L}(x) := \{Z(x) \mid Z \in \mathcal{L}\}$.

DEFINITION 2.2. *The system* (2.1) *is* controllable *if for any two points* $x_I, x_F \in M$ *there is a control* u *which takes the system from point* $x = x_I$ *at time* $t = t_I \in \mathbb{R}$ *to the point* $x = x_F$ *at time* $t = t_F \in \mathbb{R}$, *that is, if for a certain choice of the function* u *there is an integral curve* $x(t)$ *of* (2.1) *that begins at* x_I *and ends at* x_F *in finite time.*

It is well known that for a nonlinear control system without drift (i.e., $X = 0$), the LARC implies controllability. This is Chow's theorem [9]. For the general case $X \neq 0$, the situation is more complicated and, in general, the LARC is not sufficient to guarantee controllability. A lot of work was done in this direction and we will review below only the results relevant for our purposes.

In what follows we shall need a condition, called weak positive Poisson stability, on the drift vector field X. In order to understand how this concept appeared in the literature we shall quickly relate it to standard notions in the theory of dynamical systems. The next three definitions were introduced originally in Nijmeijer and van der Schaft [39], Lobry [28], [29], and Lian, Wang, and Fu [26]. Let $X \in \mathfrak{X}(M)$ be a smooth complete vector field on M and $\{\Phi_t\}_{t\in\mathbb{R}}$ its flow.

DEFINITION 2.3. *A point* $x \in M$ *is called* positively Poisson stable *for* $X \in \mathfrak{X}(M)$ *if for any* $T > 0$ *and any neighborhood* V_x *of* x *there exists a time* $t > T$ *such that* $\Phi_t(x) \in V_x$. *The vector field* $X \in \mathfrak{X}(M)$ *is called* positively Poisson stable *if the set of positively Poisson stable points of* X *is dense in* M.

DEFINITION 2.4. *A point* $x \in M$ *is called a* nonwandering point *of* $X \in \mathfrak{X}(M)$ *if for any* $T > 0$ *and for any neighborhood* V_x *of* x *there exists a time* $t > T$ *such that* $\Phi_t(V_x) \cap V_x \neq \emptyset$.

Let Γ_X be the set of all nonwandering points of X, usually called the *nonwandering set* of X. The following result and its proof can be found in Lian, Wang, and Fu [26].

THEOREM 2.5. *The nonwandering set of a positively Poisson stable vector field* X *is the entire manifold* M, *that is,* $\Gamma_X = M$.

Proof. For a given $x \in M$ one needs to prove that for any neighborhood V_x of x and for any $T > 0$ there exists a time $t > T$ such that $\Phi_t(V_x) \cap V_x \neq \emptyset$. Let

$\underline{S_X}$ denote the set of positively Poisson stable points of $X \in \mathfrak{X}(M)$. By definition, $\overline{S_X} = M$. Thus there is a positively Poisson stable point y in V_x. This implies that for all $T > 0$ there is a time $t > T$ such that $\Phi_t(y) \in V_x$. Hence $\Phi_t(V_x) \cap V_x \neq \emptyset$. So x is nonwandering for X. Since x was arbitrary, we get $\Gamma_X = M$. □

Positive Poisson stability of a vector field is hence a sufficient condition for the nonwandering set to be the entire manifold. Since the converse is not true, one introduces a weaker definition.

DEFINITION 2.6. *A vector field is called WPPS if its nonwandering set equals M (i.e., $\Gamma_X = M$).*

A natural question that arises now is the following: When is a vector field X on a manifold WPPS? In order to answer this question, we will recall the Poincaré recursion theorem (for a proof see, e.g., Abraham and Marsden [1], Abraham, Marsden, and Ratiu [2]).

Let (M, Ω) be a manifold with a volume form Ω. Let $\mathcal{B}$ denote the collection of Borel sets on M, that is, the σ-algebra generated by the open (or closed, or compact) subsets of M. Then there exists a unique Borel measure m_Ω on $\mathcal{B}$ such that for every continuous function f with compact support

$$\int_M f dm_\Omega = \int_M f\Omega. \tag{2.2}$$

For K a compact and U an open subset of M, we have $m_\Omega(K) < \infty$ and $m_\Omega(U) > 0$. If we consider on M a vector field whose flow preserves the volume form (i.e., $\Phi_t^*\Omega = \Omega$), then $m_\Omega(\Phi_t(A)) = m_\Omega(A)$ for any measurable subset A of M.

THEOREM 2.7 (Poincaré recursion theorem). *Let (M, Ω) be a manifold with a volume form Ω and m_Ω the associated Borel measure. Let X be a time-independent, complete vector field such that its flow $\{\Phi_t\}_{t\in\mathbb{R}}$ preserves the volume. Suppose A is a measurable subset of M with $0 < m_\Omega(A) < \infty$ which is also invariant under the flow of X. Then for each measurable subset B of A with $m_\Omega(B) > 0$ and for any $T > 0$, there exists $t > T$ such that $\Phi_t(B) \cap B \neq \emptyset$.*

An immediate consequence is the following proposition.

PROPOSITION 2.8. *Let (M, Ω) be a compact manifold with a volume form Ω and X a time-independent vector field such that its flow preserves the volume form. Then X is a WPPS vector field.*

The link between the WPPS condition and controllability is given by the following theorem which is due to Lian, Wang, and Fu [26]. Earlier versions of this theorem, where the hypothesis required X to be Poisson stable, are due to Lobry [29], Bonnard [6], and Crouch [11].

THEOREM 2.9. *Suppose that X is a WPPS vector field. Then the system* (2.1) *is controllable if and only if the LARC holds.*

We now state our first result on controllability of an affine nonlinear control system on a Poisson manifold. Recall that a finite dimensional Poisson manifold is a smooth manifold P whose ring of smooth real-valued functions $C^\infty(P)$ is endowed with a Lie algebra structure $\{\cdot,\cdot\}$ satisfying the Leibniz identity in every factor. Thus, if $h \in C^\infty(P)$, the derivation $\{\cdot, h\}$ defines a vector field X_h on P, called the *Hamiltonian vector field* induced by the *Hamiltonian function* h, that is, $\langle df, X_h\rangle = \{f, h\}$ for any $f \in C^\infty(P)$. The vector fields $\{X_h \mid h \in C^\infty(P)\}$ define a singular integrable distribution whose integral manifolds are symplectic immersed submanifolds whose Poisson bracket coincides with the given one on P; these integral manifolds are called the *symplectic leaves* of P. For further information on Poisson manifolds see, for

example, Libermann and Marle [27], Marsden [34], Marsden and Ratiu [35], and Puta [41].

Note that the topology of a symplectic leaf is stronger than the topology induced by the ambient manifold P, that is, every open set in the induced topology on the leaf is also open in the immersed topology but there exist open sets in the immersed topology of the leaf that are not open in the induced topology. Therefore, there are compact subsets in the induced topology of the leaf that are not compact in the immersed topology of the leaf. In the next proof one needs to come to grips with this problem.

THEOREM 2.10. *Let $(P, \{\cdot,\cdot\})$ be a connected Poisson manifold and*

$$\dot{x} = X(x) + \sum_{i=1}^{m} Y_i(x)u_i$$

an affine nonlinear control system such that the drift vector field X is tangent to the symplectic leaves of P and also preserves the symplectic volume on each one of them. Let $f : P \to \mathbb{R}$ be a continuous function that is constant on the flow of X. Assume that one of the following hypotheses holds:

(i) *f restricted to each symplectic leaf is a proper function.*

(ii) *f is a proper function and all symplectic leaves are closed and embedded submanifolds of P.*

Then X is WPPS. If the system also verifies the LARC, then it is controllable.

Proof. Let x_0 be an arbitrary point of P and U_{x_0} an arbitrary open neighborhood of x_0 in P. Denote by L_{x_0} the symplectic leaf containing x_0 and let $c_0 = f(x_0)$. There are two possibilities: $f(L_{x_0}) = c_0$, or $f(L_{x_0}) = I$, where I is a nondegenerate connected interval in $\mathbb{R}$.

Assume first that $f(L_{x_0}) = c_0$. Under hypothesis (i), $f_{|L_{x_0}} : L_{x_0} \to \mathbb{R}$ is a proper function, so $L_{x_0} = f^{-1}_{|L_{x_0}}(c_0)$ is compact. By Proposition 2.8 it follows that X restricted to the leaf L_{x_0} is a WPPS vector field, which implies that x_0 is a nonwandering point for the flow ϕ_t of X on L_{x_0}. Thus for any $T > 0$ there exists $t > T$ such that $(L_{x_0} \cap U_{x_0}) \cap \phi_t(L_{x_0} \cap U_{x_0}) \neq \emptyset$ which, in particular, implies that $U_{x_0} \cap \phi_t(U_{x_0}) \neq \emptyset$. Since x_0 and U_{x_0} were arbitrary, it follows that X is WPPS on P. Under hypothesis (ii), $f : P \to \mathbb{R}$ is a proper function, so $f^{-1}(c_0)$ is compact in P. Since $L_{x_0} \subset f^{-1}(c_0)$ and L_{x_0} is closed and embedded in P by hypothesis, it follows that L_{x_0} is compact in P. As before, applying Proposition 2.8, we obtain that X is WPPS.

Now assume that $f(L_{x_0}) = I$, where I is a nondegenerate connected interval. Then, without loss of generality (replacing x_0 with another point in the leaf, if necessary), we can assume that c_0 lies in the interior of I and hence there is an $\varepsilon > 0$ such that $[-\varepsilon + c_0, c_0 + \varepsilon] \subset I$. The set $K := L_{x_0} \cap f^{-1}([-\varepsilon + c_0, c_0 + \varepsilon])$ is compact in L_{x_0} in hypothesis (i) because $f_{|L_{x_0}}$ is proper and in hypothesis (ii) because L_{x_0} is closed and embedded in P and $f^{-1}([-\varepsilon + c_0, c_0 + \varepsilon])$ is compact in P. This implies that $m_{L_{x_0}}(K) < \infty$, where $m_{L_{x_0}}$ is the Borel measure associated to the symplectic volume form on L_{x_0}. Also, K contains an open set of L_{x_0}, for example, $f^{-1}_{|L_{x_0}}((-\varepsilon + c_0, c_0 + \varepsilon))$, and thus $m_{L_{x_0}}(K) > 0$. By the Poincaré recursion theorem (see Theorem 2.7), for any $T > 0$ there exists a $t > T$ such that $(K \cap U_{x_0}) \cap \phi_t(K \cap U_{x_0}) \neq \emptyset$ which, in particular, implies that $U_{x_0} \cap \phi_t(U_{x_0}) \neq \emptyset$. Consequently, x_0 is a nonwandering point of the flow of X. Since x_0 was arbitrary, it follows that X is WPPS on P.

If the control system also satisfies the LARC, Theorem 2.9 implies that it is controllable. □

It should be noted that in hypothesis (ii) there are two hypotheses on the symplectic leaves of P: They need to be embedded and closed. It can happen, even in the Lie–Poisson case, that the leaves are embedded but not closed. For example, the Poisson manifold $\mathbb{R}^2$ with the bracket given by $\{f,g\}(x,y) = y(f_x g_y - f_y g_x)$ has the upper and the lower half plane as open two-dimensional symplectic leaves and the points on the x-axis as the zero-dimensional leaves.

An important case in which the drift vector field X satisfies the hypotheses of the theorem is when $X = X_h$ for some Hamiltonian function $h \in C^\infty(P)$. Indeed, X_h is always tangential to the leaves and it preserves the symplectic volume on each leaf by the Liouville theorem.

Note that if P is a Poisson manifold, in order for the above affine nonlinear control system to verify the LARC it is necessary that at least one of the vector fields $Y_1, \ldots, Y_m \in \mathfrak{X}(P)$ be non-Hamiltonian.

Theorem 2.10 immediately implies both Theorems 4.3 and 4.11 in Manikonda and Krishnaprasad [31]. Finally, it should be noted that this theorem applies in the particular, but important, case of Lie–Poisson systems. In addition, Theorem 2.10(i) can handle Poisson manifolds with nonembedded and nonclosed symplectic leaves, such as the Kirillov example of the dual of a five-dimensional semidirect product Lie group with coadjoint orbits that accumulate on themselves (see Kirillov [22] or Marsden and Ratiu [35] for a discussion of this Lie group and its coadjoint orbits).

3. Controllability of reduced systems. In this section we shall study the important case of the previous theorem when the Poisson manifold is the reduction of a symplectic manifold by a compact Lie group action. In this particular case we can give sufficient topological conditions that imply the hypotheses of Theorem 2.10. To do this, we begin with a quick review of some standard results on symplectic reduction necessary in the subsequent proofs; detailed expositions of this subject can be found in standard textbooks such as Abraham and Marsden [1], Libermann and Marle [27], Marsden [34], Marsden and Ratiu [35], Ortega and Ratiu [40], and Puta [41].

Consider a $2n$-dimensional connected symplectic manifold (M,ω) on which there is a free proper symplectic action of a Lie group G. Denote by $\{\cdot,\cdot\}_\omega$ the Poisson bracket on M defined by the symplectic form ω. Then the orbit space M/G is a smooth Poisson manifold and the projection

$$\pi : (M, \{\cdot,\cdot\}_\omega) \longrightarrow \left(M/G, \{\cdot,\cdot\}_{M/G}\right)$$

is a Poisson surjective submersion. If, in addition, the Lie group G is compact, then π is a closed proper map. (Proofs of these statements can be found in, e.g., Abraham and Marsden [1], Abraham, Marsden, and Ratiu [2], Bredon [7], Kawakubo [19], Libermann and Marle [27], and Ortega and Ratiu [40].)

Suppose that the free and proper G-action on M admits an associated momentum map $J : M \longrightarrow \mathfrak{g}^*$. If the momentum map is not equivariant with respect to the coadjoint action of G on $\mathfrak{g}^*$, then there is a $\mathfrak{g}^*$-valued group one-cocycle σ on G such that $\sigma(g) = J(g \cdot m) - \mathrm{Ad}^*_{g^{-1}} J(m)$ for every $m \in M$ and $g \in G$, where Ad^* denotes the coadjoint representation of G on $\mathfrak{g}^*$. (The connectedness of M is needed to show that the right-hand side is independent of m.) Defining the affine action of G on $\mathfrak{g}^*$ by $g \cdot \mu := \mathrm{Ad}^*_{g^{-1}} \mu + \sigma(g)$, the momentum map $J : M \to \mathfrak{g}^*$ becomes now equivariant relative to the given action on M and the just defined affine action on $\mathfrak{g}^*$. The *Marsden–Weinstein reduction theorem* states that if $\mu \in \mathfrak{g}^*$ is a value of J, then the smooth quotient manifold $M_\mu := J^{-1}(\mu)/G_\mu$ is symplectic with symplectic form

ω_μ characterized by

$$\pi_\mu^* \omega_\mu = i_\mu^* \omega,$$

where G_μ denotes the isotropy subgroup of μ under the affine action, $i_\mu : J^{-1}(\mu) \longrightarrow M$ is the inclusion, and $\pi_\mu : J^{-1}(\mu) \longrightarrow M_\mu$ is the projection. (For a proof, see the original paper Marsden and Weinstein [36], or Abraham and Marsden [1], Libermann and Marle [27], Marsden [34], and Puta [41].) The symplectic manifolds (M_μ, ω_μ) will be called *point reduced spaces*.

These point reduced spaces M_μ can be understood in a natural way as symplectic leaves of the Poisson manifold $(M/G, \{\cdot,\cdot\}_{M/G})$. Indeed, the smooth map $j_\mu : M_\mu \longrightarrow M/G$ naturally defined by the commutative diagram

$$\begin{array}{ccc} J^{-1}(\mu) & \xrightarrow{\quad i_\mu \quad} & M \\ \Big\downarrow{\scriptstyle \pi_\mu} & & \Big\downarrow{\scriptstyle \pi} \\ M_\mu & \xrightarrow{\quad j_\mu \quad} & M/G \end{array}$$

is a Poisson injective immersion. Moreover, the j_μ-images in M/G of the connected components of the symplectic manifolds (M_μ, ω_μ) are its symplectic leaves (see Manikonda and Krishnaprasad [30] or Ortega and Ratiu [40]).

Observe that, in general, j_μ is only an injective immersion. So the topology of the image of j_μ, homeomorphic to the topology of M_μ, is stronger than the subspace topology induced by the ambient space M/G. This image topology on $j_\mu(M_\mu)$ is called the *immersed topology.* As in the previous section, we draw attention to the fact that we can have a subset of $j_\mu(M_\mu)$ which is compact in the induced topology from M/G and not compact in the immersed topology. A key point in the proof of Theorem 3.4 on controllability stated in what follows is to give sufficient and easily verifiable conditions under which these two topologies coincide.

The proof of the next proposition requires compactness of G.

PROPOSITION 3.1. *Suppose that the free symplectic compact G-action on (M, ω) admits a momentum map $J : M \longrightarrow \mathfrak{g}^*$. Then the symplectic leaves of $(M/G, \{\cdot,\cdot\}_{M/G})$ are closed sets.*

Proof. Since $J^{-1}(\mu)$ is closed in M and $\pi : M \longrightarrow M/G$ is a closed map (because G is compact), the set $j_\mu(M_\mu) = \pi(J^{-1}(\mu))$ is closed in the topology of M/G. Therefore, the connected components of $j_\mu(M_\mu)$, which are the symplectic leaves of M/G, are also closed in the topology of M/G. □

We return now to the general case with G noncompact. Up to now we have regarded the symplectic leaves of $(M/G, \{\cdot,\cdot\}_{M/G})$ as the j_μ-images of the connected components of M_μ. However, as sets,

$$j_\mu(M_\mu) = J^{-1}(\mathcal{O}_\mu)/G,$$

where $\mathcal{O}_\mu \subset \mathfrak{g}^*$ is the orbit through μ relative to the affine action of G on $\mathfrak{g}^*$. The set $M_{\mathcal{O}_\mu} := J^{-1}(\mathcal{O}_\mu)/G$ is called *the orbit reduced space* associated to the orbit $\mathcal{O}_\mu$. The smooth manifold structure (and hence the topology) on $M_{\mathcal{O}_\mu}$ is the one that makes $j_\mu : M_\mu \longrightarrow M_{\mathcal{O}_\mu}$ into a diffeomorphism.

The group one-cocycle σ induces by derivation a real-valued Lie algebra two-cocycle $\Sigma : \mathfrak{g} \times \mathfrak{g} \to \mathbb{R}$ which can be shown to equal $\Sigma(\xi, \eta) = J^{[\xi,\eta]}(m) - \{J^\xi, J^\eta\}(m)$

for every $m \in M$ and $\xi, \eta \in \mathfrak{g}$; $J^\xi : M \to \mathbb{R}$ denotes the ξ-component of J, that is, $J^\xi(m) := \langle J(m), \xi \rangle$. Denote by $\xi_{\mathfrak{g}^*}(\nu) := -\mathrm{ad}^*_\xi \nu + \Sigma(\xi, \cdot)$ the infinitesimal generator of the affine action of G on $\mathfrak{g}^*$, for $\nu \in \mathfrak{g}^*$, where ad^* denotes the dual of the adjoint representation ad of $\mathfrak{g}$ on $\mathfrak{g}$ defined by $\mathrm{ad}_\xi \eta := [\xi, \eta]$, for $\xi, \eta \in \mathfrak{g}$. The affine action orbit $\mathcal{O}_\mu$ carries two symplectic forms given by

$$\omega^{\pm}_{\mathcal{O}_\mu}(\nu)(\xi_{\mathfrak{g}^*}(\nu), \eta_{\mathfrak{g}^*}(\nu)) = \pm\langle \nu, [\xi, \eta]\rangle \mp \Sigma(\xi, \eta), \tag{3.1}$$

for any $\xi, \eta \in \mathfrak{g}$. They are the natural modifications of the usual Kirillov–Kostant–Souriau symplectic forms on coadjoint orbits. For the proofs of the statements above see Abraham and Marsden [1], Libermann and Marle [27], Ortega and Ratiu [40], and Puta [41]; the formulation used above is that of Ortega and Ratiu [40].

The next theorem characterizes the symplectic form and the Hamiltonian dynamics on $M_{\mathcal{O}_\mu}$.

THEOREM 3.2 (symplectic orbit reduction). *Assume that the free proper symplectic action of the Lie group G on the symplectic manifold (M, ω) admits an associated momentum map $J : M \longrightarrow \mathfrak{g}^*$.*

(i) *On $J^{-1}(\mathcal{O}_\mu)$ there is a unique immersed smooth manifold structure such that $\pi_{\mathcal{O}_\mu} : J^{-1}(\mathcal{O}_\mu) \longrightarrow M_{\mathcal{O}_\mu}$ is a surjective submersion, where $M_{\mathcal{O}_\mu}$ is endowed with the manifold structure making j_μ into a diffeomorphism. This smooth manifold structure does not depend on the choice of μ in the orbit $\mathcal{O}_\mu$. If $J^{-1}(\mathcal{O}_\mu)$ is a submanifold of M in its own right, then the immersed topology and the induced topology on $M_{\mathcal{O}_\mu}$ coincide.*

(ii) *$M_{\mathcal{O}_\mu}$ is a symplectic manifold with the symplectic form $\omega^{\maltese}_{\mathcal{O}_\mu}$ uniquely characterized by the relation*

$$i^*_{\mathcal{O}_\mu}\omega = \pi^*_{\mathcal{O}_\mu}\omega^{\maltese}_{\mathcal{O}_\mu} + J^*_{\mathcal{O}_\mu}\omega^{+}_{\mathcal{O}_\mu},$$

where $J_{\mathcal{O}_\mu}$ is the restriction of J to $J^{-1}(\mathcal{O}_\mu)$, $i_{\mathcal{O}_\mu} : J^{-1}(\mathcal{O}_\mu) \hookrightarrow M$ is the inclusion, and $\omega^+_{\mathcal{O}_\mu}$ is the $+$orbit symplectic form on $\mathcal{O}_\mu$ given by (3.1).

(iii) *Let H be a G-invariant function on M, and define $\widetilde{H} : M/G \longrightarrow \mathbb{R}$ by $H = \widetilde{H} \circ \pi$. Then the Hamiltonian vector field X_H is also G-invariant and hence induces a vector field on M/G which coincides with the Hamiltonian vector field $X_{\widetilde{H}}$. Moreover, the flow of $X_{\widetilde{H}}$ leaves the symplectic leaves $M_{\mathcal{O}_\mu}$ of M/G invariant. This flow restricted to the symplectic leaves is again Hamiltonian relative to the symplectic form $\omega^{\maltese}_{\mathcal{O}_\mu}$ and the Hamiltonian function $\widetilde{H}_{\mathcal{O}_\mu}$ given by*

$$\widetilde{H}_{\mathcal{O}_\mu} \circ \pi_{\mathcal{O}_\mu} = H \circ i_{\mathcal{O}_\mu}.$$

The proof of this theorem in the regular case and when $\mathcal{O}_\mu$ is an embedded submanifold of $\mathfrak{g}^*$ can be found in Marle [32], Kazhdan, Kostant, and Sternberg [20], and Marsden [33]. For the general case, when $\mathcal{O}_\mu$ is not a submanifold of $\mathfrak{g}^*$, see Ortega and Ratiu [40]. Here is the main idea of the proof. Consider for each value $\mu \in \mathfrak{g}^*$ of J the G-equivariant bijection

$$s : G \times_{G_\mu} J^{-1}(\mu) \to J^{-1}(\mathcal{O}_\mu),$$

$$[g, m] \mapsto g \cdot m,$$

where $G \times_{G_\mu} J^{-1}(\mu) := (G \times J^{-1}(\mu))/G_\mu$, the G_μ-action being the diagonal action. Endow $J^{-1}(\mathcal{O}_\mu)$ with the smooth manifold structure that makes the bijection s into a diffeomorphism. Then $J^{-1}(\mathcal{O}_\mu)$ with this smooth structure is an immersed submanifold of M. This is the manifold structure on $J^{-1}(\mathcal{O}_\mu)$ used in the statement of Theorem 3.2.

In the particular case in which $J^{-1}(\mathcal{O}_\mu)$ is a smooth submanifold of M in its own right, this manifold structure coincides with the one induced by the mapping s described previously since in this situation the bijection s becomes a diffeomorphism relative to the a priori given smooth manifold structure on $J^{-1}(\mathcal{O}_\mu)$.

If μ is a regular value of J and $\mathcal{O}_\mu$ is an embedded submanifold of $\mathfrak{g}^*$, then J is transverse to $\mathcal{O}_\mu$ and hence $J^{-1}(\mathcal{O}_\mu)$ is automatically an embedded submanifold of M.

The following result is important for our work through its consequences.

PROPOSITION 3.3 (bifurcation lemma). *Let (M, ω) be a symplectic manifold and G a Lie group acting symplectically on M (not necessarily freely). Suppose also that the action has an associated momentum map $J : M \longrightarrow \mathfrak{g}^*$. For any $m \in M$,*

$$(\mathfrak{g}_m)^\circ = \text{range}(T_m J),$$

where $\mathfrak{g}_m = \{\xi \in \mathfrak{g} \mid \xi_M(m) = 0\}$ is the Lie algebra of the isotropy subgroup $G_m = \{g \in G \mid g \cdot m = m\}$ and $(\mathfrak{g}_m)^\circ = \{\mu \in \mathfrak{g}^* \mid \mu_{|\mathfrak{g}_m} = 0\}$ denotes the annihilator of $\mathfrak{g}_m$ in $\mathfrak{g}^*$.

An immediate consequence of this is the fact that when the action of G is free, then every value $\mu \in \mathfrak{g}^*$ of the momentum map J is a regular value of J.

Now we give the setting for the controllability result on M/G. Let G be a Lie group acting freely properly and symplectically on a $2n$-dimensional connected symplectic manifold (M, ω). Suppose that the action admits an associated momentum map $J : M \longrightarrow \mathfrak{g}^*$. Consider on M the affine nonlinear control system

$$\dot{x} = X_H(x) + \sum_{i=1}^{m} Y_i(x)\, u_i\,, \tag{3.2}$$

where X_H is a complete Hamiltonian vector field with G-invariant Hamiltonian H, the smooth vector fields $Y_1, \ldots, Y_m \in \mathfrak{X}(M)$ are assumed to be G-invariant and complete, and the control $u := (u_1, \ldots, u_m) : (0, \infty) \longrightarrow B \subset \mathbb{R}^m$ is a measurable function with values in a bounded subset B of $\mathbb{R}^m$. Then the system (3.2) will naturally induce the affine nonlinear control system on $(M/G, \{\cdot, \cdot\}_{M/G})$,

$$\dot{\widetilde{x}} = X_{\widetilde{H}}(\widetilde{x}) + \sum_{i=1}^{m} \widetilde{Y}_i(\widetilde{x})\, u_i\,, \tag{3.3}$$

where $X_{\widetilde{H}}$ is the Hamiltonian vector field with respect to the Poisson bracket $\{\cdot, \cdot\}_{M/G}$ and Hamiltonian function $\widetilde{H}$ given by $H = \widetilde{H} \circ \pi$, for $\pi : M \longrightarrow M/G$ the canonical projection. The following theorem generalizes Theorem 4.11 in Manikonda and Krishnaprasad [31] in the sense that it can deal with noncompact Lie group actions and nonequivariant momentum maps.

THEOREM 3.4. *Suppose that the system* (3.3) *verifies the LARC.*

(i) *If the momentum map $J : M \longrightarrow \mathfrak{g}^*$ is proper, then the system* (3.3) *is controllable.*

(ii) *If the Lie group G is compact and if there exists a continuous proper map $f : M/G \longrightarrow \mathbb{R}$ which is constant along the trajectories of $X_{\widetilde{H}}$, then the system* (3.3) *is controllable.*

Proof. The strategy to prove the controllability of (3.3) is to show that $X_{\widetilde{H}}$ is WPPS and then the conclusion follows from Theorem 2.9.

(i) As subsets of M/G, the symplectic leaves are $M_{\mathcal{O}_\mu}$ or, equivalently, $j_\mu(M_\mu)$ and the symplectic form is given by $\omega^{\maltese}_{\mathcal{O}_\mu}$. Because J is a proper map, the set $J^{-1}(\mu)$ is a compact submanifold of M. Thus M_μ is a compact manifold, which implies that the injective immersion j_μ is in fact an embedding. So the immersed topology and the induced topology on $M_{\mathcal{O}_\mu}$ coincide and, therefore, the symplectic leaves are compact embedded submanifolds of M/G.

The vector field $X_{\widetilde{H}}$ is tangent to the leaves $M_{\mathcal{O}_\mu}$ of M/G and is Hamiltonian on each of them relative to the symplectic form $\omega^{\maltese}_{\mathcal{O}_\mu}$. In particular, its flow preserves the Liouville volume on each leaf. Since the leaves are compact, the restriction of the vector field $X_{\widetilde{H}}$ to every leaf is WPPS by Proposition 2.8. Thus each point of every leaf is a nonwandering point of the flow of $X_{\widetilde{H}}$; that is, the nonwandering set of $X_{\widetilde{H}}$ equals P. Thus $X_{\widetilde{H}}$ is WPPS.

(ii) For compact G, the coadjoint orbits are submanifolds of $\mathfrak{g}^*$ and J is transverse to the coadjoint orbits that lie in its image (since by hypothesis, the action is free). So $J^{-1}(\mathcal{O}_\mu)$ is a submanifold of M in its own right and by Theorem 3.2(i) the immersed topology and the induced topology on the symplectic leaves $M_{\mathcal{O}_\mu}$ of M/G coincide. By Proposition 3.1, these leaves are also closed. So we are in the hypotheses of Theorem 2.10(ii) and the result follows. □

The relationship between the controllability of the reduced system (3.3) and the initial system (3.2) is given by the following corollary, also contained in Theorem 4.11 of Manikonda and Krishnaprasad [31].

COROLLARY 3.5. *Suppose that the initial system* (3.2) *verifies the LARC and the hypotheses in Theorem* 3.4(ii). *Then the system* (3.2) *is also controllable.*

Proof. Since the vector fields X_H and $X_{\widetilde{H}}$ are π-related, the function $f \circ \pi$ is a constant of the motion for X_H. This function is proper as a composition of two proper maps; π is proper because G is compact. We are in the hypotheses of Theorem 2.10(ii) since M is a symplectic manifold and hence its symplectic leaves, when thinking of M as a Poisson manifold, are its connected components. □

Remark 3.6. Note that for the controllability of (3.3) it is not necessary for the vector fields $\widetilde{Y}_i \in \mathfrak{X}(M/G)$ to be induced by some G-invariant vector fields on M.

4. Examples. We will illustrate the theory with several examples. In all of them we will use the following well-known lemmas to prove the properness of the integrals of motion.

LEMMA 4.1. *Let $f : \mathbb{R}^n \to \mathbb{R}^k$ be a continuous function. Then f is proper if and only if*

$$\lim_{\|x\| \to \infty} \|f(x)\| = +\infty.$$

Proof. Suppose that f is proper. If $\lim_{\|x\|\to\infty} \|f(x)\| \neq +\infty$, there exists a sequence $\{x_n\}_{n\in\mathbb{N}}$ and a constant $M > 0$ such that $\|x_n\| \to \infty$ and $\|f(x_n)\| \leq M$. Thus $\{x_n\}_{n\in\mathbb{N}}$ lies in the inverse image by f of the closed ball of radius M, which is a compact set in $\mathbb{R}^n$ because f is assumed to be proper. Hence $\{x_n\}_{n\in\mathbb{N}}$ contains a convergent subsequence. However, $\|x_n\| \to \infty$, which is a contradiction.

Conversely, assume that $\lim_{\|x\|\to\infty} \|f(x)\| = +\infty$, and let $K \subset \mathbb{R}^k$ be a compact subset. The set $f^{-1}(K)$ is closed since f is continuous. To conclude that $f^{-1}(K)$ is compact we shall show that it is also bounded. If not, there would exist a sequence $\{x_n\}_{n\in\mathbb{N}} \subset f^{-1}(K)$ such that $\|x_n\| \to \infty$. By hypothesis, $\|f(x_n)\| \to \infty$, which contradicts the fact that $f(x_n) \in K$, which is bounded. □

LEMMA 4.2. *Let M, N, and P be Hausdorff topological spaces. Let $f : M \to N$ and $g : N \to P$ be two continuous functions. If $g \circ f : M \to P$ is proper, then f is also proper.*

Proof. Let $K \subset M$ be a compact subset. Then $g(K)$ is compact in P and hence $(g\circ f)^{-1}(g(K))$ is compact in M. Since $f^{-1}(K) \subset (g\circ f)^{-1}(g(K))$ is closed, it follows that it is also compact. □

Example 1. We will study the controllability of the Hamiltonian system describing the motion of a hollow rigid body and a particle oscillating in it; the body moves about a fixed point which is also the equilibrium position of the particle that oscillates along one of the principal axes of inertia. The description of this system and the proof of its nonintegrability by the method of Ziglin can be found in Christov [10].

The equations of motion are

$$\begin{aligned}
\dot{x}_1 &= \frac{x_2x_3}{C} - \frac{x_2x_3}{B+mx_4^2},\\
\dot{x}_2 &= \frac{x_1x_3}{A+mx_4^2} - \frac{x_1x_3}{C},\\
\dot{x}_3 &= \frac{x_1x_2}{B+mx_4^2} - \frac{x_1x_2}{A+mx_4^2},\\
\dot{x}_4 &= x_5,\\
\dot{x}_5 &= \frac{x_1^2x_4}{(A+mx_4^2)^2} + \frac{x_2^2x_4}{(B+mx_4^2)^2} - \frac{\sigma x_4}{m},
\end{aligned}$$

where $A > B > C$ are the principal moments of inertia, σ is the stiffness of the spring, and m is the mass of the particle.

This is a Hamiltonian system with phase space $so(3)^* \times \mathbb{R}^2$. The Poisson bracket is the product of the Lie–Poisson bracket on $so(3)^*$ with the Poisson bracket induced by the symplectic form $m dx_4 \wedge dx_5$ on $\mathbb{R}^2$. The Hamiltonian is given by

$$H = \frac{1}{2}\left(\frac{x_1^2}{A+mx_4^2} + \frac{x_2^2}{B+mx_4^2} + \frac{x_3^2}{C} + \sigma x_4^2 + mx_5^2\right).$$

It is easy to see that the symplectic leaves are embedded closed manifolds: Every four-dimensional leaf is the product of a sphere with $\mathbb{R}^2$, and the two-dimensional leaf is $\mathbb{R}^2$. One can easily check that the Hamiltonian H is a proper function.

Consider the underactuated control system with torques

$$\begin{aligned}
\dot{x}_1 &= \frac{x_2x_3}{C} - \frac{x_2x_3}{B+mx_4^2} + u_1,\\
\dot{x}_2 &= \frac{x_1x_3}{A+mx_4^2} - \frac{x_1x_3}{C} + u_2,\\
\dot{x}_3 &= \frac{x_1x_2}{B+mx_4^2} - \frac{x_1x_2}{A+mx_4^2} + u_3,\\
\dot{x}_4 &= x_5,\\
\dot{x}_5 &= \frac{x_1^2x_4}{(A+mx_4^2)^2} + \frac{x_2^2x_4}{(B+mx_4^2)^2} - \frac{\sigma x_4}{m} + u_4,
\end{aligned}$$

where the control $u := (u_1, u_2, u_3, u_4) : (0, \infty) \to B \subset \mathbb{R}^4$ is a measurable function with values in a bounded subset $B \subset \mathbb{R}^4$. The vector fields $\frac{\partial}{\partial x_1}$, $\frac{\partial}{\partial x_2}$, $\frac{\partial}{\partial x_3}$, $\frac{\partial}{\partial x_5}$, $[X_H, \frac{\partial}{\partial x_5}]$ verify the LARC and, as a result of Theorem 2.10(ii), we obtain that the above system is controllable.

Example 2. In this example we follow the presentation of the geometric structure in Adams and Ratiu [3]. The motion of three point vortices for an ideal inviscid incompressible fluid in the plane is given by the equations

$$\begin{cases} \dot{x}_j = -\frac{1}{2\pi} \sum\limits_{\substack{i=1 \\ i \neq j}}^{3} \Gamma_i (y_j - y_i)/r_{ij}^2, \\ \dot{y}_j = -\frac{1}{2\pi} \sum\limits_{\substack{i=1 \\ i \neq j}}^{3} \Gamma_i (x_j - x_i)/r_{ij}^2, \end{cases} \tag{4.1}$$

$j = 1, 2, 3$, where $r_{ij}^2 = (x_i - x_j)^2 + (y_i - y_j)^2$ and Γ_1, Γ_2, and Γ_3 are nonzero constants, the circulations given by the corresponding point vortices. These equations are defined on $\mathbb{R}^6$ after eliminating all the diagonals $\{(x_i, y_i) = (x_j, y_j)\}$ for $i \neq j$. Kirchhoff [21] noted that (4.1) can be written in the form

$$\begin{aligned} \Gamma_j \frac{dx_j}{dt} &= \frac{\partial H}{\partial y_j}, \\ \Gamma_j \frac{dy_j}{dt} &= -\frac{\partial H}{\partial x_j}, \end{aligned}$$

where

$$H(x_1, x_2, x_3, y_1, y_2, y_3) = -\frac{1}{4\pi} \sum_{\substack{i=1 \\ i \neq j}}^{3} \Gamma_i \Gamma_j \log r_{ij}$$

is the Hamiltonian and the symplectic form is given by

$$\Omega = \sum_{i=1}^{3} \Gamma_i dx_i \wedge dy_i. \tag{4.2}$$

In what follows it is convenient to identify $\mathbb{R}^2$ with $\mathbb{C}$ by the map $(x, y) \mapsto x + \sqrt{-1}y$. The special Euclidean group $SE(2) := \{(e^{\sqrt{-1}\theta}, w) \mid \theta \in \mathbb{R}, w \in \mathbb{C}\}$ acts on $\mathbb{C}$ by $(e^{\sqrt{-1}\theta}, w) \cdot z := e^{\sqrt{-1}\theta} z + w$. This action is not free. The diagonal action of $SE(2)$ on $\mathbb{C}^3$ is free on the open invariant subset $\mathbb{C}^3 \setminus \{(z, z, z) \mid z \in \mathbb{C}\}$ that contains the open invariant subset $S := \mathbb{C}^3 \setminus \{(z_1, z_2, z_3) \mid z_i \neq z_j \text{ for } i \neq j\}$ on which the three point vortex problem is defined. It can be easily verified that this action is proper on S. This action has an associated nonequivariant momentum map $J : \mathbb{R}^6 \equiv \mathbb{C}^3 \to \mathbb{R}^3$ relative to the symplectic form (4.2) given by

$$J(\mathbf{x}, \mathbf{y}) = \left(-\frac{1}{2} \sum_{i=1}^{3} \Gamma_i (x_i^2 + y_i^2), \sum_{i=1}^{3} \Gamma_i y_i, -\sum_{i=1}^{3} \Gamma_i x_i \right).$$

If the vortex strengths Γ_1, Γ_2, and Γ_3 have the same signs, then, by applying Lemmas 4.2 and 4.1, it follows that J is a proper map and we are in the hypotheses of Theorem 3.4(i).

In Adams and Ratiu [3] it is shown that the quotient $S/SE(2)$ is diffeomorphic to $T := \mathbb{R}^3\backslash(\{(0,0,c) \mid c \in \mathbb{R}\} \cup \{(a,0,0) \mid a \geq 0\})$, that the push forward of the quotient Poisson bracket on $S/SE(2)$ to T has the matrix

$$4\begin{bmatrix} 0 & 2a_3 & -2a_2 \\ -2a_3 & 0 & 2a_1 - \|\mathbf{a}\| \\ 2a_2 & -2a_1 + \|\mathbf{a}\| & 0 \end{bmatrix},$$

and that the reduced Hamiltonian is

$$\widetilde{H}(a_1,a_2,a_3) = -\frac{1}{4\pi}(\Gamma_1\Gamma_2 \log((a_3 + \|\mathbf{a}\|)/2) + \Gamma_1\Gamma_3 \log((-a_3 + \|\mathbf{a}\|)/2) + \Gamma_2\Gamma_3 \log(-a_1 + \|\mathbf{a}\|)).$$

Therefore, the reduced equations are

$$\begin{aligned}
\dot{a}_1 &= \frac{2}{\pi}\left(\Gamma_1\Gamma_2\frac{a_2}{(a_3+\|\mathbf{a}\|)} - \Gamma_1\Gamma_3\frac{a_2}{(-a_3+\|\mathbf{a}\|)}\right),\\
\dot{a}_2 &= \frac{1}{\pi}\left(\Gamma_1\Gamma_2\frac{(-2a_1+a_3+\|\mathbf{a}\|)}{(a_3+\|\mathbf{a}\|)} + \Gamma_1\Gamma_3\frac{(2a_1+a_3-\|\mathbf{a}\|)}{(-a_3+\|\mathbf{a}\|)} + \Gamma_2\Gamma_3\frac{a_3}{(-a_1+\|\mathbf{a}\|)}\right),\\
\dot{a}_3 &= \frac{1}{\pi}\left(\Gamma_2\Gamma_3\frac{a_2}{(-a_1+\|\mathbf{a}\|)} - \Gamma_1\Gamma_2\frac{a_2}{(a_3+\|\mathbf{a}\|)} - \Gamma_1\Gamma_3\frac{a_2}{(-a_3+\|\mathbf{a}\|)}\right).
\end{aligned}$$

Consider the reduced control system

$$\begin{aligned}
\dot{a}_1 &= \frac{2}{\pi}\left(\Gamma_1\Gamma_2\frac{a_2}{(a_3+\|\mathbf{a}\|)} - \Gamma_1\Gamma_3\frac{a_2}{(-a_3+\|\mathbf{a}\|)}\right) + u_1,\\
\dot{a}_2 &= \frac{1}{\pi}\left(\Gamma_1\Gamma_2\frac{(-2a_1+a_3+\|\mathbf{a}\|)}{(a_3+\|\mathbf{a}\|)} + \Gamma_1\Gamma_3\frac{(2a_1+a_3-\|\mathbf{a}\|)}{(-a_3+\|\mathbf{a}\|)} + \Gamma_2\Gamma_3\frac{a_3}{(-a_1+\|\mathbf{a}\|)}\right) + u_2,\\
\dot{a}_3 &= \frac{1}{\pi}\left(\Gamma_2\Gamma_3\frac{a_2}{(-a_1+\|\mathbf{a}\|)} - \Gamma_1\Gamma_2\frac{a_2}{(a_3+\|\mathbf{a}\|)} - \Gamma_1\Gamma_3\frac{a_2}{(-a_3+\|\mathbf{a}\|)}\right) + u_3,
\end{aligned}$$

where the control $u := (u_1,u_2,u_3) : (0,\infty) \to B \subset \mathbb{R}^3$ is a measurable function with values in a bounded subset $B \subset \mathbb{R}^3$. It is easy to check that the vector fields $X_{\widetilde{H}}, \frac{\partial}{\partial a_1}, \frac{\partial}{\partial a_2}, \frac{\partial}{\partial a_3}$ verify the LARC and, by Theorem 3.4(i), we conclude that this reduced system is controllable.

Example 3. The next example, whose geometric study can be found in Blaom [4], is the resonant three-wave interaction. This is a Hamiltonian system whose phase space is $\mathbb{R}^6 = \mathbb{C}^3$, equipped with the symplectic structure

$$\omega = \sum_{j=1}^{3} \frac{1}{s_j\gamma_j} dq_j \wedge dp_j,$$

where $s_1, s_2, s_3 \in \{-1,1\}$ and $\gamma_1, \gamma_2, \gamma_3 \in \mathbb{R}$ are parameters subject to the constraint $\gamma_1+\gamma_2+\gamma_3 = 0$. We will restrict our attention to the particular case when $(s_1,s_2,s_3) = (1,1,1)$ and $(\gamma_1,\gamma_2,\gamma_3) = (1,1,-2)$.

In standard coordinates on $\mathbb{C}^3$, $z_j := q_j + \sqrt{-1}p_j$, $j = 1,2,3$, the Hamiltonian is given by

$$H(z_1,z_2,z_3) = -\frac{1}{2}(\bar{z}_1 z_2 \bar{z}_3 + z_1 \bar{z}_2 z_3).$$

This Hamiltonian is invariant under the action of the compact Lie group $G \equiv S^1 \times S^1$ on P given by

$$(e^{i\theta_1}, e^{i\theta_2}) \cdot (z_1, z_2, z_3) = (e^{-i\theta_1} z_1, e^{-i(\theta_1+\theta_2)} z_2, e^{-i\theta_2} z_3), \qquad 0 \leq \theta_j < 2\pi.$$

The momentum map for this action is $J : P \to \mathfrak{g}^* \cong \mathbb{R}^2$,

$$J(z_1, z_2, z_3) = \left(\frac{1}{2} \left(|z_1|^2 + |z_2|^2 \right), \frac{1}{2} \left(|z_1|^2 - \frac{1}{2} |z_3|^2 \right) \right).$$

This action is free on the open invariant subset $\left[(\mathbb{C}\backslash\{0\}) \times \mathbb{C} \times (\mathbb{C}\backslash\{0\}) \right] \cup \left[\{0\} \times (\mathbb{C}\backslash\{0\}) \times (\mathbb{C}\backslash\{0\}) \right] \cup \left[(\mathbb{C}\backslash\{0\}) \times (\mathbb{C}\backslash\{0\}) \times \{0\} \right]$. As in Blaom [4], we shall restrict the study of the resonant three-wave interaction to $S := (\mathbb{C}\backslash\{0\}) \times \mathbb{C} \times (\mathbb{C}\backslash\{0\})$, where the action is free. The smooth map $(z_1, z_2, z_3) \in S \mapsto (z_2 \bar{z}_1 \bar{z}_3 / |z_1 z_3|, |z_1|, |z_3|) \in \mathbb{R}^2 \times (0, \infty)^2$ induces a diffeomorphism $S/G \approx \mathbb{R}^2 \times (0, \infty)^2$. The push forward by this diffeomorphism of the quotient Poisson bracket on S/G to $\{(q, p, a, b) \in \mathbb{R}^4 \mid q, p \in \mathbb{R}, a > 0, b > 0\} = \mathbb{R}^2 \times (0, \infty)^2$ has the expression

$$\begin{bmatrix} 0 & 1 & -\frac{p}{a} & 2\frac{p}{b} \\ -1 & 0 & \frac{q}{a} & -2\frac{q}{b} \\ \frac{p}{a} & -\frac{q}{a} & 0 & 0 \\ -2\frac{p}{b} & 2\frac{q}{b} & 0 & 0 \end{bmatrix}$$

and the reduced Hamiltonian is

$$\widetilde{H}(q, p, a, b) = -abq.$$

The reduced equations of motion are

$$\begin{cases} \dot{q} = \dfrac{qpb}{a} - 2\dfrac{qpa}{b}, \\ \dot{p} = ab - \dfrac{q^2 b}{a} + 2\dfrac{q^2 a}{b}, \\ \dot{a} = -pb, \\ \dot{b} = 2pa. \end{cases} \tag{4.3}$$

A constant of motion for the system (4.3) is given by the function $f : Q \to \mathbb{R}$, $f(q, p, a, b) = q^2 + p^2 + a^2 + b^2$, which is proper by Lemma 4.1.

Consider now the underactuated reduced control system

$$\begin{cases} \dot{q} = \dfrac{qpb}{a} - 2\dfrac{qpa}{b} + u_1, \\ \dot{p} = ab - \dfrac{q^2 b}{a} + 2\dfrac{q^2 a}{b} + u_2, \\ \dot{a} = -pb, \\ \dot{b} = 2pa + u_3, \end{cases} \tag{4.4}$$

where the control $u := (u_1, u_2, u_3) : (0, \infty) \to B \subset \mathbb{R}^3$ is a measurable function with values in a bounded subset B. A short computation shows that the vector

fields $\{\frac{\partial}{\partial q}, \frac{\partial}{\partial p}, \frac{\partial}{\partial b}, [\frac{\partial}{\partial b}, [\frac{\partial}{\partial p}, X_{\widetilde{H}}]]\}$ generate at every point $(q,p,a,b) \in \mathbb{R}^2 \times (0,\infty)^2$ the tangent space $T_{(q,p,a,b)}(\mathbb{R}^2 \times (0,\infty)^2)$, which proves that the system (4.4) verifies the LARC. By Theorem 3.4(ii), the system (4.4) is controllable.

Example 4. We will study the controllability of the reduced system of two coupled planar rigid bodies. We take the description of the system given in Sreenath, Oh, Krishnaprasad, and Marsden [44]. After the reduction to the center of mass frame we have the configuration space $S^1 \times S^1$ with the diagonal action of S^1. The phase space is $T^*(S^1 \times S^1)$ with the canonical symplectic form of a cotangent bundle. The momentum map for the lifted action of S^1 is given by

$$J((\theta_1, \mu_1), (\theta_2, \mu_2)) = \mu_1 + \mu_2.$$

Krishnaprasad and Marsden [25] have shown that the reduced Poisson space is

$$P := T^*(S^1 \times S^1)/S^1 \cong S^1 \times \mathbb{R}^2$$

and, if we chose coordinates (θ, μ_1, μ_2) on P, the matrix of the Poisson bracket is given by

$$\begin{bmatrix} 0 & -1 & 1 \\ 1 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}.$$

The reduced Hamiltonian is given by the formula

$$H = \frac{1}{2\triangle}(\widetilde{I}_2\mu_1^2 - 2\varepsilon\lambda(\theta)\mu_1\mu_2 + \widetilde{I}_1\mu_2^2),$$

where $\triangle = \widetilde{I}_1\widetilde{I}_2 - \varepsilon^2(\lambda(\theta))^2 > 0$ and

d_i	is the distance from the hinge to the center of mass of body $i = 1, 2$,
θ	is the joint angle from body 1 to body 2,
$\lambda(\theta)$	equals $d_1 d_2 \cos\theta$,
m_i	is the mass of body $i = 1, 2$,
ε	equals $m_1 m_2/(m_1 + m_2)$ (the reduced mass),
I_i	is the moment of inertia of body i about its center of mass, and
$\widetilde{I}_i$	equals $I_i + \varepsilon d_i^2$, $i = 1, 2$ (the augmented moments of inertia).

To apply Theorem 3.4 we need to show that H is a proper function. To do this, we need the following lemma.

LEMMA 4.3. *Let $f : K \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}$ be two continuous functions, where K is compact and g is a proper function. Then the function $h : K \times \mathbb{R}^n \to \mathbb{R}$ given by $h(x,y) := f(x)g(y)$ is a proper function.*

Proof. We shall prove that $h^{-1}([a,b])$ is compact in $K \times \mathbb{R}^n$. Let $z_n := (x_n, y_n)$ be an arbitrary sequence in $h^{-1}([a,b])$. Since K is compact, we can assume that $\{x_n\}_{n\in\mathbb{N}}$ is convergent. Because $\{f(x_n)g(y_n)\}_{n\in\mathbb{N}} \subset [a,b]$ and $\{f(x_n)\}_{n\in\mathbb{N}}$ is bounded, the sequence $\{g(y_n)\}_{n\in\mathbb{N}}$ is also bounded and hence there are $a', b' \in \mathbb{R}$ such that $\{g(y_n)\}_{n\in\mathbb{N}} \subset [a', b']$. Therefore, $\{y_n\}_{n\in\mathbb{N}} \subset g^{-1}([a', b'])$, which is a compact set in $\mathbb{R}^n$ because g is a proper function. Consequently, there is a convergent subsequence of $\{y_n\}_{n\in\mathbb{N}}$. The corresponding subsequence of $\{z_n\}_{n\in\mathbb{N}}$ is convergent, which proves that $h^{-1}([a,b])$ is compact. ∎

To apply this lemma we write H in the form

$$H = \frac{1}{2\triangle}\left(\left(\sqrt{\widetilde{I}_2}\,\mu_1 - \frac{\varepsilon\lambda(\theta)}{\sqrt{\widetilde{I}_2}}\mu_2\right)^2 + \left(\widetilde{I}_1 - \frac{\varepsilon^2\lambda^2(\theta)}{\widetilde{I}_2}\right)\mu_2^2\right).$$

Since

$$\widetilde{I}_1 - \frac{\varepsilon^2\lambda^2(\theta)}{\widetilde{I}_2} > 0,$$

the smooth change of variables $(\theta, \mu_1, \mu_2) \mapsto (\theta, X, Y)$, where

$$X := \sqrt{\widetilde{I}_2}\,\mu_1 - \frac{\varepsilon\lambda(\theta)}{\sqrt{\widetilde{I}_2}}\mu_2,$$

$$Y := \left(\widetilde{I}_1 - \frac{\varepsilon^2\lambda^2(\theta)}{\widetilde{I}_2}\right)^{1/2}\mu_2$$

transforms H to the function $\frac{1}{2\triangle}\left(X^2 + Y^2\right)$ with $\frac{1}{2\triangle}$ defined on S^1. This function is proper by Lemmas 4.1 and 4.3. Thus H is a proper integral of motion for the reduced system.

Now we consider the following underactuated reduced control system with torques u_1, u_2

$$\dot{\theta} = -\frac{\partial H}{\partial \mu_1} + \frac{\partial H}{\partial \mu_2},$$

$$\dot{\mu}_1 = \frac{\partial H}{\partial \theta} + u_1,$$

$$\dot{\mu}_2 = -\frac{\partial H}{\partial \theta} + u_2,$$

where the control $u := (u_1, u_2) : (0, \infty) \to B \subset \mathbb{R}^2$ is a measurable function with values in a bounded subset B. It is easy to see that the vector fields $[X_H, \frac{\partial}{\partial \mu_1}]$, $[X_H, \frac{\partial}{\partial \mu_2}]$, $\frac{\partial}{\partial \mu_1}$, $\frac{\partial}{\partial \mu_2}$ verify the LARC and, as a consequence of Theorem 3.4(ii), we obtain that the reduced control system above is controllable.

Using Corollary 3.5 one can study the controllability of the unreduced system of the two coupled planar rigid bodies by considering any system of controls that satisfies the LARC and reduces to a system of controls that also satisfies the LARC, for example, the one above.

Acknowledgments. We would like to thank V. Timofte and I. Casu for carefully reading the manuscript and for offering valuable comments which helped us to improve the exposition. We are also grateful to the referees both for their comments that have inspired the extension of our original results to arbitrary Poisson manifolds and for their editorial suggestions.

A LOCAL RESULT ON INSENSITIZING CONTROLS FOR A SEMILINEAR HEAT EQUATION WITH NONLINEAR BOUNDARY FOURIER CONDITIONS*

OLIVIER BODART†, MANUEL GONZÁLEZ-BURGOS‡, AND ROSARIO PÉREZ-GARCÍA‡

Abstract. In this paper we present a local result on the existence of insensitizing controls for a semilinear heat equation when nonlinear boundary conditions of the form $\partial_n y + f(y) = 0$ are considered. The problem leads to an analysis of a special type of nonlinear null controllability problem. A sharp study of the linear case and a later application of an appropriate fixed point argument constitute the scheme of the proof of the main result. The boundary conditions we are dealing with lead us to seek a fixed point, and thus also control functions, in certain Hölder spaces. The main strategy in this paper is the construction of controls with Hölderian regularity starting from L^2-controls in the linear case. Sufficient regularity in the data and appropriate assumptions on the right-hand side term ξ of the equation are required.

Key words. controllability, nonlinear PDE of parabolic type

1. Statement of the problem and main result. Let $\Omega \subset \mathbb{R}^N$ be, with $N \geq 1$, a bounded domain with boundary $\partial\Omega$ of at least class C^2. Let ω and $\mathcal{O}$ be nonempty open subsets of Ω. For $T > 0$, we denote by Q the cylinder $\Omega \times (0,T)$ and by Σ its lateral boundary $\partial\Omega \times (0,T)$. We consider a semilinear heat equation with nonlinear boundary conditions of Fourier type and partially known initial data:

$$\begin{cases} \partial_t y - \Delta y + F(y) = \xi + v\mathbf{1}_\omega & \text{in } Q, \\ \partial_n y + f(y) = 0 & \text{on } \Sigma, \\ y(x,0) = y_0(x) + \tau\, \hat{y}_0(x) & \text{in } \Omega, \end{cases} \tag{1.1}$$

where F and f are given C^1 functions defined on $\mathbb{R}$; ξ and y_0 are, respectively, a known heat source and a given initial datum, both regular enough; τ is an unknown small real number; and $\hat{y}_0$ is unknown in an appropriate Banach space $X \hookrightarrow L^2(\Omega)$ (the embedding being continuous and dense), with $\|\hat{y}_0\|_X = 1$. Here, $v = v(x,t)$ is a control function to be determined, $\mathbf{1}_\omega$ is the characteristic function of the set ω, ∂_t denotes the time derivative, and ∂_n represents the derivation with respect to the outward unit normal to $\partial\Omega$.

Let us define

$$\Phi(y) = \frac{1}{2} \iint_{\mathcal{O}\times(0,T)} |y(x,t;\tau,v)|^2 \, dx\, dt, \tag{1.2}$$

$y = y(\cdot,\cdot;\tau,v)$ being a solution of (1.1) (associated to τ and v) defined in $(0,T)$, if one exists. In this paper we analyze the existence of control functions that make

the functional Φ locally insensitive to small perturbations in the initial condition. A possible physical interpretation of this problem would be the following. The function $y = y(x,t)$ can be viewed as the relative temperature of a body (with respect to the exterior surrounding air). The semilinear parabolic equation in (1.1) means that there is a fixed heat source ξ acting on the body and that we can also act on a small part ω of the body by means of a heat source $v\mathbf{1}_\omega$. On the boundary, $-\frac{\partial y}{\partial n}$ can be viewed as the *normal heat flux*, directed inward, up to a positive coefficient. Thus, the equality

$$-\frac{\partial y}{\partial n} = f(y)$$

means that this flux is a (nonlinear) function of the temperature. The problem with insensitizing Φ means that we are seeking a control function acting on ω such that the energy in $\mathcal{O}$ is invariant for small perturbations in the initial data. A natural physical hypothesis would be to suppose that f is nondecreasing with $f(0) = 0$. Throughout this paper, we will assume no special behavior on the increasing of f.

By reasons that will be seen later, in this work we will slightly change the usual notion of insensitizing controls (see [1], [4], [10], [11]), which is equivalent to the usual one in the linear case.

DEFINITION 1.1. *A control function v is said to insensitize Φ if there exists $\tau_0 > 0$ such that system* (1.1) *admits a weak solution $y(\cdot,\cdot;\tau,v) \in L^2(0,T;H^1(\Omega)) \cap C^0(\overline{Q})$ for $|\tau| \le \tau_0$ and if the following insensitivity condition holds:*

$$\left.\frac{\partial \Phi(y(\cdot,\cdot;\tau,v))}{\partial \tau}\right|_{\tau=0} = 0 \quad \forall \hat{y}_0 \in X \text{ with } \|\hat{y}_0\|_X = 1, \tag{1.3}$$

where $X = C^{2+\beta}(\overline{\Omega}) \cap H_0^2(\Omega)$.

By a weak solution of (1.1) (associated to τ and v) we will define a function (if one exists) $y = y(\cdot,\cdot;\tau,v) \in L^2(0,T;H^1(\Omega)) \cap C^0(\overline{Q})$, with $\partial_t y \in L^2(0,T;H^{-1}(\Omega))$, such that

$$\begin{cases} \langle \partial_t y(t), u\rangle_{(H^1(\Omega))',H^1(\Omega)} + \displaystyle\int_\Omega \nabla y(t)\cdot\nabla u\,dx + \int_\Omega F(y(t))u\,dx + \int_{\partial\Omega} f(y(t))u\,d\sigma \\ \qquad = \displaystyle\int_\Omega (\xi(t) + v(t)\mathbf{1}_\omega)u\,dx \quad \text{in } L^2(0,T) \quad \forall u \in H^1(\Omega), \\ y(0) = y_0 + \tau\,\hat{y}_0. \end{cases}$$

Insensitivity problems were originally introduced by J.-L. Lions in [10] and were first studied for semilinear heat equations with globally Lipschitz-continuous nonlinearities $F = F(y)$ and Dirichlet boundary conditions. In [1], the existence of the so-called ε-insensitizing controls for partially known data in both the initial and boundary conditions is proved. In [11] it is shown that one cannot expect the existence of insensitizing controls for every $y_0 \in L^2(\Omega)$ when $\Omega \setminus \overline{\omega} \neq \emptyset$, even if $F \equiv 0$. In addition, for $y_0 = 0$ and suitable assumptions on the source term ξ, de Teresa proves the existence of insensitizing controls (see Theorem 1 in [11]). This last result is extended in [2] and [3] to nonlinearities with certain superlinear growth at infinity. It is also generalized in [4] to the case of a heat equation with a nonlinear term involving the state y and its gradient. In [4], the authors also present an insensitivity result for a semilinear heat equation with a nonlinear term $F(y)$ and linear boundary conditions of Fourier type. In the present paper, we prove a local result on the existence of insensitizing controls for system (1.1), which is, to our knowledge, the first insensitivity

result in the literature for a semilinear heat equation with nonlinear Fourier boundary conditions. In the framework of the controllability, both approximate and null controllability of the classical heat equation with nonlinear Fourier boundary conditions are analyzed in [5].

Before stating the main result in this paper, let us introduce the following notation. For $p \in [1,\infty]$ and any Banach space Y, $\|\cdot\|_{L^p(Y)}$ will denote the norm in the space $L^p(0,T;Y)$. For simplicity, the norm in $L^p(Q)$ will be represented by $\|\cdot\|_{L^p}$ for $p \in [1,\infty)$, $\|\cdot\|_\infty$ will stand for the norm in $L^\infty(Q)$, and $\|\cdot\|_{\infty;\Sigma}$ will denote the norm in $L^\infty(\Sigma)$. For $r \in (2,\infty)$ and any open set $\mathcal{V} \subset \mathbb{R}^N$, we introduce the Banach space

$$X^r(0,T;\mathcal{V}) = \left\{u \in L^r(0,T;W^{2,r}(\mathcal{V})) : \partial_t u \in L^r(0,T;L^r(\mathcal{V}))\right\},$$

with its natural norm

$$\|u\|_{X^r(0,T;\mathcal{V})} = \|u\|_{L^r(W^{2,r}(\mathcal{V}))} + \|\partial_t u\|_{L^r(L^r(\mathcal{V}))}.$$

On the other hand, for $\beta \in (0,1)$ and $u \in C^0(\overline{Q})$, we define the quantity

$$[u]_{\beta,\frac{\beta}{2}} = \sup_{\overline{Q}} \frac{|u(x,t)-u(x',t)|}{|x-x'|^\beta} + \sup_{\overline{Q}} \frac{|u(x,t)-u(x,t')|}{|t-t'|^{\frac{\beta}{2}}}.$$

We will consider the space $C^{\beta,\frac{\beta}{2}}(\overline{Q}) = \{u \in C^0(\overline{Q}) : [u]_{\beta,\frac{\beta}{2}} < \infty\}$, which is a Banach space with its natural norm $|u|_{\beta,\frac{\beta}{2};\overline{Q}} = \|u\|_\infty + [u]_{\beta,\frac{\beta}{2}}$. We will also consider the Banach spaces defined by

$$C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q}) = \left\{u \in C^0(\overline{Q}) : \frac{\partial u}{\partial x_i} \in C^{\beta,\frac{\beta}{2}}(\overline{Q}) \quad \forall i,\ \sup_{\overline{Q}} \frac{|u(x,t)-u(x,t')|}{|t-t'|^{\frac{1+\beta}{2}}} < \infty\right\},$$

$$C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q}) = \left\{u \in C^0(\overline{Q}) : \frac{\partial u}{\partial x_i} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q}) \quad \forall i,\ \partial_t u \in C^{\beta,\frac{\beta}{2}}(\overline{Q})\right\},$$

and

$$C^{3+\beta,\frac{3+\beta}{2}}(\overline{Q}) = \left\{u \in C^0(\overline{Q}) : \frac{\partial u}{\partial x_i} \in C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q}) \quad \forall i,\ \partial_t u \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q})\right\},$$

with norms denoted by $|\cdot|_{n+\beta,\frac{n+\beta}{2};\overline{Q}}$, $n = 1,2,3$. The Banach space formed by the restrictions to $\overline{\Sigma}$ of the functions in $C^{n+\beta,\frac{n+\beta}{2}}(\overline{Q})$ will be represented by $C^{n+\beta,\frac{n+\beta}{2}}(\overline{\Sigma})$ and its norm by $|\cdot|_{n+\beta,\frac{n+\beta}{2};\overline{\Sigma}}$. Finally, we shall write $|\cdot|_{2+\beta;\overline{\Omega}}$ to denote the norm in $C^{2+\beta}(\overline{\Omega})$, and the norm in the space $L^2(0,T;H^1(\Omega))\cap C([0,T];L^2(\Omega))$ will be denoted by $\|\cdot\|_{L^2(H^1)\cap C(L^2)}$.

The main goal in this paper is to prove the following local insensitivity result for system (1.1).

THEOREM 1.2. *Assume that $\partial\Omega \in C^{3+\beta}$ for some $\beta \in (0,1)$, $\omega \cap \mathcal{O} \neq \emptyset$, and $y_0 = 0$. Let $F, f \in C^3(\mathbb{R})$ verify $F(0) = f(0) = 0$. Then, there exist two positive constants $\mathcal{M}$ and η (depending on Ω, ω, $\mathcal{O}$, T, F, and f) such that, for any $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfying*

$$|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\|\exp\left(\frac{\mathcal{M}}{2t}\right)\xi\right\|_{L^2} \leq \eta, \tag{1.4}$$

one can find a control function $v \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ *that insensitizes the functional* Φ *defined by* (1.2).

It is of interest to notice that the explicit way the constant $\mathcal{M}$ depends on T and F can be known (see Remark 1).

As usual in insensitivity problems, the insensitivity condition (1.3) leads us to analyze a nonstandard nonlinear null controllability problem. In the case under consideration, the following holds.

PROPOSITION 1.3. *If there exists a control function* v *insensitizing the functional* Φ *given by* (1.2)*, then this control* v *solves the null controllability problem*

$$\begin{cases} \partial_t \overline{y} - \Delta \overline{y} + F(\overline{y}) = \xi + v\mathbf{1}_\omega & \text{in } Q, \\ \partial_n \overline{y} + f(\overline{y}) = 0 & \text{on } \Sigma, \\ \overline{y}(x,0) = y_0(x) & \text{in } \Omega, \end{cases} \tag{1.5}$$

$$\begin{cases} -\partial_t q - \Delta q + F'(\overline{y})q = \overline{y}\mathbf{1}_{\mathcal{O}} & \text{in } Q, \\ \partial_n q + f'(\overline{y})q = 0 & \text{on } \Sigma, \\ q(x,T) = 0 & \text{in } \Omega, \end{cases} \tag{1.6}$$

$$q(x,0) = 0 \quad \text{in } \Omega. \tag{1.7}$$

Furthermore, if a control function v *solves* (1.5)–(1.7) *and there exists* $\tau_0 > 0$ *such that* (1.1) *admits a weak solution* $y(\cdot,\cdot;\tau,v) \in L^2(0,T;H^1(\Omega)) \cap C^0(\overline{Q})$ *for* $|\tau| \le \tau_0$*, then* v *is insensitizing the functional* Φ*.*

Proof. We reason as in [10] and [1]. Assume the existence of a control v insensitizing the functional Φ given by (1.2) in the sense of Definition 1.1. Then, system (1.5) admits a weak solution $y(\cdot,\cdot;\tau,v) \in L^2(0,T;H^1(\Omega)) \cap C^0(\overline{Q})$ for all $|\tau| \le \tau_0$, for some $\tau_0 > 0$. The derivative of $\Phi(y(\cdot,\cdot;\tau,v))$ with respect to τ at $\tau = 0$ is given by

$$\left.\frac{\partial \Phi(y(\cdot,\cdot;\tau,v))}{\partial \tau}\right|_{\tau=0} = \iint_Q \overline{y}(x,t)\mathbf{1}_{\mathcal{O}}\, y_\tau(x,t)\,dx\,dt,$$

where $\overline{y} = y(\cdot,\cdot;0,v) \in C^0(\overline{Q})$ and $y_\tau = \left.\frac{\partial y(\cdot,\cdot;\tau,v)}{\partial \tau}\right|_{\tau=0}$ is the solution of the linear system

$$\begin{cases} \partial_t y_\tau - \Delta y_\tau + F'(\overline{y})y_\tau = 0 & \text{in } Q, \\ \partial_n y_\tau + f'(\overline{y})y_\tau = 0 & \text{on } \Sigma, \\ y_\tau(x,0) = \hat{y}_0(x) & \text{in } \Omega. \end{cases}$$

Let q be the solution of (1.6). Replacing $\overline{y}\mathbf{1}_{\mathcal{O}}$ with the left-hand side of the PDE satisfied by q and integrating by parts, one obtains

$$\iint_Q \overline{y}(x,t)\mathbf{1}_{\mathcal{O}}\, y_\tau(x,t)\,dx\,dt = \int_\Omega q(x,0)\hat{y}_0(x)\,dx,$$

regardless of what $\hat{y}_0 \in L^2(\Omega)$ is. Finally, from (1.3) one deduces that

$$q(0) = 0 \quad \text{in } X',$$

whence (1.7) follows, in view of the Hahn–Banach theorem. The rest of the proof follows immediately from Definition 1.1. □

Notice that a control function v solving (1.5)–(1.7), if one exists, does not necessarily insensitize the functional Φ (think, for instance, of an initial datum $y_0+\tau\,\hat{y}_0$ not lying in $C^0(\overline{\Omega})$, for which system (1.1) admits no weak solution in $C^0(\overline{Q})$). In other words, in this case the problem of seeking insensitizing controls cannot be reformulated in an equivalent way as a null controllability problem, as is usual in insensitivity problems. In order to prove Theorem 1.2, we will thus argue as follows (see section 3). Under the assumptions in the theorem, we will first prove the existence of a control v solving (1.5)–(1.7). In a second step, we will see that, for $\tau\hat{y}_0$ regular and small enough, such a control v can be chosen so that it also insensitizes the functional Φ defined by (1.2).

The existence of a control function solving (1.5)–(1.7) will be proved by linearization and a later application of an appropriate fixed point argument. This technique, introduced in [12] in the context of the controllability of the semilinear wave equation, has been used to prove several controllability results (cf., for example, [6], [7]). Analyzing a linear null controllability problem similar to (1.5)–(1.7) (see (2.1), (2.2), and (1.7)), we realize that the potentials $a, b \in L^\infty(\Sigma)$ need to have time derivatives in $L^\infty(\Sigma)$. This requirement comes from applying Lemma 1.2 of [8] to obtain an adequate observability inequality (see Proposition 2.1) for the solutions of the corresponding adjoint systems (2.5) and (2.6). To solve the nonlinear problem, we would have to search for a fixed point in a space containing the functions $z \in L^\infty(Q)$ such that the trace of $\partial_t z$ lies in $L^\infty(\Sigma)$. As was observed in Remark 15 of [5], we are not too far from imposing $\partial_t z \in L^\infty(0,T;W^{1,N+\gamma}(\Omega))$, with $\gamma > 0$. But these spaces are too small to achieve compactness and good estimates for the fixed point mapping. We will then seek a fixed point, and thus also control functions, in the Hölder spaces introduced above. In fact, one of the main points in this paper relies on the construction, in the linear case, of control functions with Hölderian regularity starting from L^2-controls.

In order to ensure the existence of a solution to system (1.1) in the above-mentioned Hölder spaces, appropriate regularity assumptions on the data and a compatibility condition on the initial datum are required (see Lemma 3.2). This is the reason why we have introduced the space $X = C^{2+\beta}(\overline{\Omega}) \cap H_0^2(\Omega)$, with $\beta \in (0,1)$, in Definition 1.1.

In the next section, we will analyze the corresponding linear null controllability problem, while section 3 will be devoted to proving our main result.

2. The linear null controllability problem. From now on, we will assume that $\omega \cap \mathcal{O} \neq \emptyset$ and $y_0 = 0$. This section is devoted to solving a linearized version of the null controllability problem (1.5)–(1.7). We consider the linear systems

$$\begin{cases} \partial_t y - \Delta y + cy = \xi + v\mathbf{1}_\omega & \text{in } Q, \\ \partial_n y + ay = 0 & \text{on } \Sigma, \\ y(x,0) = 0 & \text{in } \Omega, \end{cases} \tag{2.1}$$

$$\begin{cases} -\partial_t q - \Delta q + dq = y\mathbf{1}_{\mathcal{O}} & \text{in } Q, \\ \partial_n q + bq = 0 & \text{on } \Sigma, \\ q(x,T) = 0 & \text{in } \Omega, \end{cases} \tag{2.2}$$

where $a, b \in L^\infty(\Sigma)$, $c, d \in L^\infty(Q)$, and $\xi \in L^2(Q)$ (at least). For each $v \in L^2(Q)$, the cascade of linear systems (2.1), (2.2) admits exactly one solution (y, q) satisfying

$$y, q \in L^2(0,T; H^1(\Omega)) \cap C([0,T]; L^2(\Omega)), \quad \partial_t y, \partial_t q \in L^2(0,T; H^{-1}(\Omega)),$$

with

$$\|y\|_{L^2(H^1)\cap C(L^2)} + \|\partial_t y\|_{L^2(H^{-1})} \le C\left(\Omega, T, \|a\|_{\infty;\Sigma}, \|c\|_\infty\right)\left(\|\xi\|_{L^2} + \|v\|_{L^2}\right), \tag{2.3}$$

$$\begin{aligned} &\|q\|_{L^2(H^1)\cap C(L^2)} + \|\partial_t q\|_{L^2(H^{-1})} \\ &\quad \le C\left(\Omega, T, \|a\|_{\infty;\Sigma}, \|b\|_{\infty;\Sigma}, \|c\|_\infty, \|d\|_\infty\right)\left(\|\xi\|_{L^2} + \|v\|_{L^2}\right). \end{aligned} \tag{2.4}$$

Under additional assumptions on the potentials and on the source term ξ, we will build a regular control v, acting on a nonempty open subset of $\omega \cap \mathcal{O}$, such that the corresponding solution (y, q) of (2.1), (2.2) satisfies (1.7).

We proceed as follows. Let us fix a nonempty open set B_0 such that $B_0 \subset\subset \omega \cap \mathcal{O}$. In a first step, using an appropriate observability inequality, we obtain an L^2-control supported on $\overline{B}_0 \times [0,T]$. Then, by means of a construction similar to that made in [2] and [3] and due to the regularizing properties of the heat equation, we will be able to furnish a regular control with a slightly larger support.

Let us consider the adjoint systems

$$\begin{cases} \partial_t \varphi - \Delta \varphi + d\varphi = 0 & \text{in } Q, \\ \partial_n \varphi + b\varphi = 0 & \text{on } \Sigma, \\ \varphi(x,0) = \varphi^0(x) & \text{in } \Omega, \end{cases} \tag{2.5}$$

$$\begin{cases} -\partial_t \psi - \Delta \psi + c\psi = \varphi \mathbf{1}_{\mathcal{O}} & \text{in } Q, \\ \partial_n \psi + a\psi = 0 & \text{on } \Sigma, \\ \psi(x,T) = 0 & \text{in } \Omega, \end{cases} \tag{2.6}$$

where $\varphi^0 \in L^2(\Omega)$. For simplicity, we will denote by a_t (resp., b_t) the time derivative of a (resp., of b). Let $B_0 \subset\subset \omega \cap \mathcal{O}$ be the open set considered above. In [4], the following observability inequality for the solutions of (2.5), (2.6) is proved.

PROPOSITION 2.1. *Assume that $a, b, a_t, b_t \in L^\infty(\Sigma)$ and $c, d \in L^\infty(Q)$. Then, there exist positive constants M and C, depending on Ω, ω, $\mathcal{O}$, T, $\|a\|_{\infty;\Sigma}$, $\|b\|_{\infty;\Sigma}$, $\|a_t\|_{\infty;\Sigma}$, $\|b_t\|_{\infty;\Sigma}$, $\|c\|_\infty$, and $\|d\|_\infty$, such that*

$$\iint_Q \exp\left(-\frac{M}{t}\right)|\psi|^2 \, dx\, dt \le C \iint_{B_0\times(0,T)} |\psi|^2 \, dx\, dt,$$

for every $\varphi^0 \in L^2(\Omega)$, where ψ solves (2.6), φ being the solution of (2.5).

The proof of this result follows the scheme of demonstration of Proposition 2 in [11] and uses a global Carleman inequality for the classical heat equation with linear boundary Fourier conditions (see Lemma 1.2 of [8]).

Remark 1. In the previous proposition, and throughout this section, the dependence of the constants with respect to T and the potentials c and d could be stated precisely. This would allow one to know the precise way the constant $\mathcal{M}$ in Theorem 1.2 depends on T and F. Nevertheless, the dependence on the boundary data a and b is not explicit. This comes from the proof of Lemma 1.2 of [8].

Due to a unique continuation property for the solutions of (2.5) and (2.6) inferred from Proposition 2.1, under suitable assumptions on ξ, one obtains L^2-controls as follows.

PROPOSITION 2.2. *Assume that $a, b, a_t, b_t \in L^\infty(\Sigma)$ and $c, d \in L^\infty(Q)$. Let M and C be the positive constants (depending on Ω, ω, $\mathcal{O}$, T, $\|a\|_{\infty;\Sigma}$, $\|b\|_{\infty;\Sigma}$, $\|a_t\|_{\infty;\Sigma}$, $\|b_t\|_{\infty;\Sigma}$, $\|c\|_\infty$, and $\|d\|_\infty$) provided by Proposition* 2.1. *Then, for any $\xi \in L^2(Q)$ verifying*

$$\iint_Q \exp\left(\frac{M}{t}\right)|\xi|^2\,dx\,dt < \infty, \tag{2.7}$$

there exists a control function $\hat{v} \in L^2(Q)$, with $\operatorname{supp}\hat{v} \subset \overline{B}_0 \times [0,T]$, such that the solution $(\hat{y}, \hat{q})$ of (2.1), (2.2) *associated to $\hat{v}$ satisfies* (1.7). *Moreover, $\hat{v}$ can be chosen so that*

$$\|\hat{v}\|_{L^2} \le \sqrt{C}\left(\iint_Q \exp\left(\frac{M}{t}\right)|\xi|^2\,dx\,dt\right)^{1/2}. \tag{2.8}$$

The proof of this proposition is given in [4] and will be omitted here. The main result in this section is the following.

PROPOSITION 2.3. *Assume that $\partial\Omega \in C^{3+\beta}$ for some $\beta \in (0,1)$, $a, b, a_t, b_t \in L^\infty(\Sigma)$, $c \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$, and $d \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q})$. Let $M > 0$ be the constant (depending on Ω, ω, $\mathcal{O}$, T, $\|a\|_{\infty;\Sigma}$, $\|b\|_{\infty;\Sigma}$, $\|a_t\|_{\infty;\Sigma}$, $\|b_t\|_{\infty;\Sigma}$, $\|c\|_\infty$, and $\|d\|_\infty$) provided by Proposition* 2.1. *Then, for any $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfying* (2.7), *one can find a control $v \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ such that the associated solution (y,q) of* (2.1), (2.2) *satisfies* (1.7). *Moreover, the $C^{\beta,\frac{\beta}{2}}$-norm of v can be estimated as follows:*

$$|v|_{\beta,\frac{\beta}{2};\overline{Q}} \le C\left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\|\exp\left(\frac{M}{2t}\right)\xi\right\|_{L^2}\right), \tag{2.9}$$

where C is a new positive constant depending on Ω, ω, $\mathcal{O}$, T, $\|a\|_{\infty;\Sigma}$, $\|b\|_{\infty;\Sigma}$, $\|a_t\|_{\infty;\Sigma}$, $\|b_t\|_{\infty;\Sigma}$, $|c|_{\beta,\frac{\beta}{2};\overline{Q}}$, and $|d|_{1+\beta,\frac{1+\beta}{2};\overline{Q}}$.

The regularity of v and, accordingly, that of (y,q), will enable us to deal with the nonlinear null controllability problem (1.5)–(1.7).

Before proving Proposition 2.3, for the convenience of the reader we repeat some relevant material from [3] and [9] without proofs, thus making our exposition self-contained. We first recall a technical result on local regularity given in [3, Proposition 2.1 and Remark 4].

LEMMA 2.4. *Let $\widetilde{a} \in L^\infty(Q)$ and $h \in L^2(Q)$ be given. Let us consider a solution $u \in L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$ of*

$$\begin{cases} \partial_t u - \Delta u + \widetilde{a}u = h & \text{in } Q, \\ u(x,0) = 0 & \text{in } \Omega, \end{cases} \tag{2.10}$$

and let $\mathcal{V} \subset \Omega$ be an arbitrary open set.

(a) *If $h \in L^r(0,T;L^r(\mathcal{V}))$, with $r \in (2,\infty)$, then $u \in X^r(0,T;\mathcal{V}')$ for any open set $\mathcal{V}' \subset\subset \mathcal{V}$. Moreover, there exist two positive constants $C = C(\Omega, \mathcal{V}, \mathcal{V}', T, N, r)$ and $\mathcal{K} = \mathcal{K}(N)$ such that*

$$\|u\|_{X^r(0,T;\mathcal{V}')} \le C\left(1 + \|\widetilde{a}\|_\infty\right)^{\mathcal{K}}\left[\|h\|_{L^r(L^r(\mathcal{V}))} + \|u\|_{L^2(H^1)\cap C(L^2)}\right]. \tag{2.11}$$

(b) *Assume, in addition, that* $h \in L^r(0,T;W^{1,r}(\mathcal{V}))$, $r > 2$, *and* $\nabla \widetilde{a} \in L^\gamma(Q)^N$, *with*

$$\gamma = \begin{cases} \max\left\{r, \dfrac{N}{2}+1\right\} & \text{if} \quad r \neq \dfrac{N}{2}+1, \\ \dfrac{N}{2}+1+\varepsilon & \text{if} \quad r = \dfrac{N}{2}+1, \end{cases}$$

and ε *being an arbitrarily small positive number. Then, for any open set* $\mathcal{V}' \subset\subset \mathcal{V}$, *one has* $u \in L^r(0,T;W^{3,r}(\mathcal{V}'))$, $\partial_t u \in L^r(0,T;W^{1,r}(\mathcal{V}'))$, *and for a new positive constant* $C = C(\Omega, \mathcal{V}, \mathcal{V}', T, N, r)$, *the following estimate holds:*

$$\|u\|_{L^r(W^{3,r}(\mathcal{V}'))} + \|\partial_t u\|_{L^r(W^{1,r}(\mathcal{V}'))} \leq C\,\mathcal{H}\left[\|h\|_{L^r(W^{1,r}(\mathcal{V}))} + \|u\|_{L^2(H^1)\cap C(L^2)}\right],$$

where

$$\mathcal{H} = \mathcal{H}(N, \|\widetilde{a}\|_\infty, \|\nabla \widetilde{a}\|_{L^\gamma}) = (1+\|\widetilde{a}\|_\infty)^{\mathcal{K}+1}(1+\|\nabla \widetilde{a}\|_{L^\gamma}),$$

$\mathcal{K} = \mathcal{K}(N)$ *being as in* (2.11).

We also recall the following result, which is readily obtained by rewriting Lemma 3.3 of [9, p. 80] with the notation introduced at the beginning of this paper (also see Lemma 2.3 of [3]).

LEMMA 2.5. *Let* $\mathcal{V} \subset \mathbb{R}^N$, $N \geq 1$, *be a regular open set. The following continuous embeddings hold:*

1. *If* $r < \frac{N}{2}+1$, *then* $X^r(0,T;\mathcal{V}) \hookrightarrow L^p(\mathcal{V}\times(0,T))$, *where* $\frac{1}{p} = \frac{1}{r} - \frac{2}{N+2}$.
2. *If* $r = \frac{N}{2}+1$, *then* $X^r(0,T;\mathcal{V}) \hookrightarrow L^q(\mathcal{V}\times(0,T))$ *for all* $q < \infty$.
3. *If* $\frac{N}{2}+1 < r < N+2$, *then* $X^r(0,T;\mathcal{V}) \hookrightarrow C^{\alpha,\frac{\alpha}{2}}(\overline{\mathcal{V}}\times[0,T])$, $\alpha = 2 - \frac{N+2}{r}$.
4. *If* $r = N+2$, *then* $X^r(0,T;\mathcal{V}) \hookrightarrow C^{l,\frac{l}{2}}(\overline{\mathcal{V}}\times[0,T])$ *for all* $l \in (0,1)$.
5. *If* $r > N+2$, *then* $X^r(0,T;\mathcal{V}) \hookrightarrow C^{1+\beta,\frac{1+\beta}{2}}(\overline{\mathcal{V}}\times[0,T])$, *where* $\beta = 1 - \frac{N+2}{r}$.

We are now ready to prove Proposition 2.3. From now on, we will specify only the dependence of the constants on the arguments that will be relevant in our analysis. Thus, for instance, the dependence on the dimension N, on B_0, or on the other open sets appearing later will be omitted.

Proof of Proposition 2.3. Assume that $\partial\Omega \in C^{3+\beta}$ for some $\beta \in (0,1)$. Let a, b, c, and d be as in the statement, and let $M > 0$ be provided by Proposition 2.1. Given $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ verifying (2.7), Proposition 2.2 provides a control $\hat{v} \in L^2(Q)$ such that the associated solution $(\hat{y},\hat{q})$ of (2.1), (2.2) satisfies (1.7). Moreover, $\hat{v}$ verifies estimate (2.8) and $\operatorname{supp}\hat{v} \subset \overline{B}_0 \times [0,T]$, with B_0 being the open set considered at the beginning of this section. One has $\hat{y},\hat{q} \in L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$, $\partial_t\hat{y}, \partial_t\hat{q} \in L^2(0,T;H^{-1}(\Omega))$, and estimates such as (2.3) and (2.4) hold.

Let B, B_1, and B_2 be regular open sets such that $B_0 \subset\subset B_1 \subset\subset B_2 \subset\subset B \subset\subset \omega \cap \mathcal{O}$. As was anticipated above, a construction similar to the one made in [2] and [3] will allow one to construct a regular control supported on $\overline{B}\times[0,T]$. Indeed, we set

$$q = (1-\theta)\,\hat{q}, \tag{2.12}$$

$$y = (1-\theta)\,\hat{y} + 2\nabla\theta\cdot\nabla\hat{q} + (\Delta\theta)\hat{q}, \tag{2.13}$$

with $\theta \in \mathcal{D}(B)$ satisfying $\theta \equiv 1$ in B_2. We will analyze the interior regularity of $\hat{y}$ and $\hat{q}$, inferring that (y,q) solves (2.1), (2.2), and (1.7) with control term $v \in C^{\beta,\frac{\beta}{2}}(Q)$ given by

$$v = -\theta\xi + 2\nabla\theta\cdot\nabla\hat{y} + (\Delta\theta)\hat{y} + (\partial_t - \Delta + c)\left[2\nabla\theta\cdot\nabla\hat{q} + (\Delta\theta)\hat{q}\right], \tag{2.14}$$

which is, in fact, supported on $B \times [0,T]$.

First, as $c \in L^\infty(Q)$ and $\xi + \hat{v}\mathbf{1}_{B_0} \in L^2(Q) \cap L^\infty(0,T;L^\infty(\Omega \setminus \overline{B}_0))$, one can apply Lemma 2.4 with $r = (N+2)/(1-\beta)$, $\beta \in (0,1)$ given in the statement, to deduce that $\hat{y}$ lies in $X^r(0,T;(\omega \cap \mathcal{O}) \setminus \overline{B}_1)$ (notice that, without loss of generality, we can assume that $\omega \cap \mathcal{O} \subset\subset \Omega$ and that $\omega \cap \mathcal{O}$ is regular enough). Since $r > N+2$, this space is continuously embedded in $C^{1+\beta,\frac{1+\beta}{2}}(\overline{(\omega \cap \mathcal{O}) \setminus B_1} \times [0,T])$, by Lemma 2.5. Thus,

$$\hat{y} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{(\omega \cap \mathcal{O}) \setminus B_1} \times [0,T]), \tag{2.15}$$

and estimates (2.11) and (2.3) give

$$|\hat{y}|_{1+\beta,\frac{1+\beta}{2};\overline{(\omega\cap\mathcal{O})\setminus B_1}\times[0,T]} \leq C\left(\Omega,\omega,\mathcal{O},T,\|a\|_{\infty;\Sigma},\|c\|_\infty\right)\left(\|\xi\|_\infty + \|\hat{v}\|_{L^2}\right). \tag{2.16}$$

By the choice of θ, the term $v_1 = 2\nabla\theta\cdot\nabla\hat{y} + (\Delta\theta)\hat{y}$ in (2.14) then lies in $C^{\beta,\frac{\beta}{2}}(\overline{Q})$ and one can estimate

$$|v_1|_{\beta,\frac{\beta}{2};\overline{Q}} \leq C\left(\Omega,\omega,\mathcal{O},T,\|a\|_{\infty;\Sigma},\|c\|_\infty\right)\left(\|\xi\|_\infty + \|\hat{v}\|_{L^2}\right).$$

According to the interior regularity of $\hat{y}$, an argument such as the one above implies that $\hat{q} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{B \setminus B_2} \times [0,T])$, and estimates (2.11), (2.16), and (2.4) give

$$|\hat{q}|_{1+\beta,\frac{1+\beta}{2};\overline{B\setminus B_2}\times[0,T]} \leq C\left(\|\xi\|_\infty + \|\hat{v}\|_{L^2}\right), \tag{2.17}$$

with $C = C\left(\Omega,\omega,\mathcal{O},T,\|a\|_{\infty;\Sigma},\|b\|_{\infty;\Sigma},\|c\|_\infty,\|d\|_\infty\right)$. By the $C^{\beta,\frac{\beta}{2}}$-regularity of ξ and c, it is then clear that $v_2 = -\theta\xi + c[2\nabla\theta\cdot\nabla\hat{q} + (\Delta\theta)\hat{q}] \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ and

$$|v_2|_{\beta,\frac{\beta}{2};\overline{Q}} \leq C(\Omega,\omega,\mathcal{O})\left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + |c|_{\beta,\frac{\beta}{2};\overline{Q}}|\hat{q}|_{1+\beta,\frac{1+\beta}{2};\overline{B\setminus B_2}\times[0,T]}\right),$$

which combined with (2.17), yields

$$|v_2|_{\beta,\frac{\beta}{2};\overline{Q}} \leq C(\Omega,\omega,\mathcal{O},T,\|a\|_{\infty;\Sigma},\|b\|_{\infty;\Sigma},|c|_{\beta,\frac{\beta}{2};\overline{Q}},\|d\|_\infty)\left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \|\hat{v}\|_{L^2}\right).$$

We now analyze the term $v_3 = (\partial_t - \Delta)[2\nabla\theta\cdot\nabla\hat{q} + (\Delta\theta)\hat{q}]$. To this end, we use the following result on interior Hölderian regularity, whose proof is given at the end of this section.

LEMMA 2.6. *Assume that $\partial\Omega \in C^{3+\beta}$ for some $\beta \in (0,1)$. Let us consider a solution $u \in L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$ of (2.10), with $\widetilde{a} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q})$ and $h \in L^2(Q) \cap C^{1+\beta,\frac{1+\beta}{2}}(\overline{\mathcal{V}} \times [0,T])$, $\mathcal{V}$ being a nonempty open subset of Ω. Then, for any open set $\mathcal{V}' \subset\subset \mathcal{V}$, one has $u \in C^{3+\beta,\frac{3+\beta}{2}}(\overline{\mathcal{V}}' \times [0,T])$ and*

$$|u|_{3+\beta,\frac{3+\beta}{2};\overline{\mathcal{V}}'\times[0,T]} \leq C\left(|h|_{1+\beta,\frac{1+\beta}{2};\overline{\mathcal{V}}\times[0,T]} + \|u\|_{L^2(H^1)\cap C(L^2)}\right), \tag{2.18}$$

where C is a positive constant depending on Ω, $\mathcal{V}$, $\mathcal{V}'$, T, and $|\widetilde{a}|_{1+\beta,\frac{1+\beta}{2};\overline{Q}}$.

On account of (2.15) and the regularity of the potential d, Lemma 2.6 can be applied to $u = \hat{q}$, with $\mathcal{V} = (\omega \cap \mathcal{O}) \setminus \overline{B}_1$, $\mathcal{V}' = B \setminus \overline{B}_2$, $h = \hat{y}\mathbf{1}_{\mathcal{O}}$, and $\widetilde{a} = d$, to deduce that $\hat{q}$ lies in $C^{3+\beta,\frac{3+\beta}{2}}(\overline{B \setminus B_2} \times [0,T])$. Moreover, estimates (2.18), (2.16), and (2.4) give

$$|\hat{q}|_{3+\beta,\frac{3+\beta}{2};\overline{B\setminus B_2}\times[0,T]} \leq C\left(\|\xi\|_\infty + \|\hat{v}\|_{L^2}\right),$$

with $C = C(\Omega, \omega, \mathcal{O}, T, \|a\|_{\infty;\Sigma}, \|b\|_{\infty;\Sigma}, \|c\|_\infty, |d|_{1+\beta,\frac{1+\beta}{2};\overline{Q}})$. We infer from the choice of θ that $2\nabla\theta \cdot \nabla\hat{q} + (\Delta\theta)\hat{q} \in C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$, and hence that v_3 lies in $C^{\beta,\frac{\beta}{2}}(\overline{Q})$, and one can estimate

$$|v_3|_{\beta,\frac{\beta}{2};\overline{Q}} \leq C(\Omega, \omega, \mathcal{O}, T, \|a\|_{\infty;\Sigma}, \|b\|_{\infty;\Sigma}, \|c\|_\infty, |d|_{1+\beta,\frac{1+\beta}{2};\overline{Q}})\left(\|\xi\|_\infty + \|\hat{v}\|_{L^2}\right).$$

In view of the previous considerations on each term v_i, $1 \leq i \leq 3$, and using estimate (2.8), one concludes that v given by (2.14) lies in $C^{\beta,\frac{\beta}{2}}(\overline{Q})$ and that (2.9) holds. Finally, it is an easy exercise to see that (y, q) defined by (2.13) and (2.12), together with this control function v, solves (2.1), (2.2), and (1.7). The only delicate point could be to check that $y(x, 0) = 0$ in Ω. But this follows immediately from the interior regularity of $\hat{q}$ (which, in particular, gives $\hat{q} \in C([0,T]; H^1(B \setminus \overline{B}_2))$), the choice of θ, and the fact that $\hat{q}(x, 0) = 0$ in Ω. This ends the proof of Proposition 2.3. □

We end this section by giving the proof of Lemma 2.6, which relies on a localization argument.

Proof of Lemma 2.6. Assume the hypothesis in the statement, with $\beta \in (0, 1)$ and $\mathcal{V}$ being fixed. Given an open set $\mathcal{V}' \subset\subset \mathcal{V}$, we consider a regular open set $\mathcal{V}_1$, with $\mathcal{V}' \subset\subset \mathcal{V}_1 \subset\subset \mathcal{V}$. According to the regularity of h and the potential $\widetilde{a}$, we can apply the second point of Lemma 2.4, with $r = (N + 2)/(1 - \beta)$ (thus $\gamma = r$, since $r > N + 2$), and deduce that u, $\frac{\partial u}{\partial x_i} \in X^r(0, T; \mathcal{V}_1)$, $i = 1, \ldots, N$, together with the estimate

$$\|u\|_{X^r(0,T;\mathcal{V}_1)} + \|\nabla u\|_{X^r(0,T;\mathcal{V}_1)^N} \leq C\left[\|h\|_{L^r(W^{1,r}(\mathcal{V}))} + \|u\|_{L^2(H^1)\cap C(L^2)}\right],$$

with $C > 0$ depending on Ω, $\mathcal{V}$, $\mathcal{V}'$, T, $\|\widetilde{a}\|_\infty$ and $\|\nabla\widetilde{a}\|_{L^r}$. Since $r > N + 2$, by Lemma 2.5 we get

$$u,\ \frac{\partial u}{\partial x_i} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{\mathcal{V}}_1 \times [0,T]), \quad i = 1, \ldots, N, \tag{2.19}$$

with

$$\begin{aligned} &|u|_{1+\beta,\frac{1+\beta}{2};\overline{\mathcal{V}}_1\times[0,T]} + |\nabla u|_{1+\beta,\frac{1+\beta}{2};\overline{\mathcal{V}}_1\times[0,T]} \\ &\leq C\left(\Omega, \mathcal{V}, \mathcal{V}', T, \|\widetilde{a}\|_\infty, \|\nabla\widetilde{a}\|_{L^r}\right)\left(\|h\|_{L^r(W^{1,r}(\mathcal{V}))} + \|u\|_{L^2(H^1)\cap C(L^2)}\right). \end{aligned} \tag{2.20}$$

We claim that, indeed, u lies in $C^{3+\beta,\frac{3+\beta}{2}}(\overline{\mathcal{V}}' \times [0,T])$ and satisfies (2.18). To this end, let $\zeta \in \mathcal{D}(\mathcal{V}_1)$ be such that $\zeta \equiv 1$ in $\mathcal{V}'$ and set $w = \zeta u$. Then w solves

$$\begin{cases} \partial_t w - \Delta w = \widetilde{h} & \text{in } Q, \\ w = 0 \quad \text{on } \Sigma, \quad w(x, 0) = 0 & \text{in } \Omega, \end{cases} \tag{2.21}$$

with $\widetilde{h} = \zeta h - [\widetilde{a}\zeta u + 2\nabla\zeta \cdot \nabla u + (\Delta\zeta)u]$. The regularity of h and $\widetilde{a}$, together with (2.19), gives $\widetilde{h} \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q})$, and using (2.20), one has

$$|\widetilde{h}|_{1+\beta,\frac{1+\beta}{2};\overline{Q}} \leq C\left(|h|_{1+\beta,\frac{1+\beta}{2};\overline{\mathcal{V}}\times[0,T]} + \|u\|_{L^2(H^1)\cap C(L^2)}\right), \tag{2.22}$$

with $C = C(\Omega, \mathcal{V}, \mathcal{V}', T, |\widetilde{a}|_{1+\beta,\frac{1+\beta}{2};\overline{Q}})$. Since $\partial\Omega \in C^{3+\beta}$ and the compatibility condition of order 1 for system (2.21) is trivially fulfilled, one can apply Theorem 5.2 of [9] to obtain $w \in C^{3+\beta,\frac{3+\beta}{2}}(\overline{Q})$, with

$$|w|_{3+\beta,\frac{3+\beta}{2};\overline{Q}} \leq C(\Omega, T)|\widetilde{h}|_{1+\beta,\frac{1+\beta}{2};\overline{Q}}. \tag{2.23}$$

Finally, recalling that $u \equiv w$ in $\mathcal{V}'$, one infers the desired interior regularity of u, and estimate (2.18) holds, using (2.23) and (2.22). □

3. Proof of Theorem 1.2. We begin this section by recalling the following result for linear systems of the form

$$\begin{cases} \partial_t u - \Delta u + cu = h & \text{in } Q, \\ \partial_n u + au = 0 & \text{on } \Sigma, \\ u(x,0) = u_0(x) & \text{in } \Omega, \end{cases} \tag{3.1}$$

whose proof is given in [9, Theorem 5.3, p. 320].

LEMMA 3.1. *Assume that $\partial\Omega \in C^{2+\beta}$ for some $\beta \in (0,1)$. Let $a \in C^{1+\beta,\frac{1+\beta}{2}}(\overline{\Sigma})$ and $c \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ be given. Then, for any $h \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ and $u_0 \in C^{2+\beta}(\overline{\Omega})$ satisfying the compatibility condition*

$$\partial_n u_0(x) + a(x,0)u_0(x) = 0 \quad \text{on } \partial\Omega,$$

system (3.1) *admits exactly one solution $u \in C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$ verifying the estimate*

$$|u|_{2+\beta,1+\frac{\beta}{2};\overline{Q}} \leq C\left(\Omega, T, |a|_{1+\beta,\frac{1+\beta}{2};\overline{\Sigma}}, |c|_{\beta,\frac{\beta}{2};\overline{Q}}\right)\left(|h|_{\beta,\frac{\beta}{2};\overline{Q}} + |u_0|_{2+\beta;\overline{\Omega}}\right). \tag{3.2}$$

Let us now prove Theorem 1.2. Assume the hypothesis in the statement. From the considerations in the first section, the proof falls naturally into two steps.

Step 1. *Existence of a regular control solving the nonlinear null controllability problem* (1.5)–(1.7): *The fixed point argument.* Let G and g be the C^2 functions defined by

$$G(s) = \begin{cases} \dfrac{F(s)}{s} & \text{if } s \neq 0, \\ F'(0) & \text{if } s = 0, \end{cases} \qquad g(s) = \begin{cases} \dfrac{f(s)}{s} & \text{if } s \neq 0, \\ f'(0) & \text{if } s = 0. \end{cases}$$

Let us set

$$Z = C^1(\overline{Q}) \cap C^{1+\beta,\frac{1+\beta}{2}}(\overline{Q}).$$

For fixed $z \in \overline{B}(0;1) \subset Z$, we consider the linear systems

$$\begin{cases} \partial_t y - \Delta y + G(z)y = \xi + v\mathbf{1}_\omega & \text{in } Q, \\ \partial_n y + g(z)y = 0 & \text{on } \Sigma, \\ y(x,0) = 0 & \text{in } \Omega, \end{cases} \tag{3.3}$$

$$\begin{cases} -\partial_t q - \Delta q + F'(z)q = y\mathbf{1}_{\mathcal{O}} & \text{in } Q, \\ \partial_n q + f'(z)q = 0 & \text{on } \Sigma, \\ q(x,T) = 0 & \text{in } \Omega, \end{cases} \tag{3.4}$$

with potentials $G(z), F'(z) \in Z$ and $g(z), f'(z) \in \widetilde{Z} = C^1(\overline{\Sigma}) \cap C^{1+\beta,\frac{1+\beta}{2}}(\overline{\Sigma})$. By abuse of notation, from now on we will let $g(z)$ (resp., $f'(z)$) stand for both the function $g(z)$ in Z and its restriction to $\overline{\Sigma}$ (resp., for both $f'(z) \in Z$ and its restriction to $\overline{\Sigma}$). Let us set

$$\mathcal{M}(\Omega, \omega, \mathcal{O}, T, F, f) = \sup_{z \in \overline{B}(0;1)} M_z, \tag{3.5}$$

where M_z is, for fixed $z \in \overline{B}(0;1)$, the positive constant (depending on Ω, ω, $\mathcal{O}$, T, $\|g(z)\|_Z$, $\|f'(z)\|_Z$, $\|G(z)\|_Z$, and $\|F'(z)\|_Z$) provided by Proposition 2.1. Let ξ in $C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfy (1.4), with $\eta > 0$ to be chosen later (hence also verifying (2.7) with $M = M_z$ for all $z \in \overline{B}(0;1)$). From Proposition 2.3, there exists $v_z \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ such that the associated solution (y_z, q_z) of (3.3), (3.4) lies in $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q}) \times C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$ (by Lemma 3.1) and satisfies (1.7). Moreover, one has

$$|v_z|_{\beta,\frac{\beta}{2};\overline{Q}} \leq C(\Omega, \omega, \mathcal{O}, T, z) \left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\| \exp\left(\frac{M_z}{2t}\right) \xi \right\|_{L^2} \right),$$

with $C(\Omega, \omega, \mathcal{O}, T, z) = C(\Omega, \omega, \mathcal{O}, T, \|g(z)\|_Z, \|f'(z)\|_Z, \|G(z)\|_Z, \|F'(z)\|_Z)$, and y_z satisfies an estimate such as (3.2); hence

$$|y_z|_{2+\beta,1+\frac{\beta}{2};\overline{Q}} \leq C_1(\Omega, \omega, \mathcal{O}, T, z) \left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\| \exp\left(\frac{M_z}{2t}\right) \xi \right\|_{L^2} \right),$$

with $C_1(\Omega, \omega, \mathcal{O}, T, z) = C_1(\Omega, \omega, \mathcal{O}, T, \|g(z)\|_Z, \|f'(z)|_Z, \|G(z)\|_Z, \|F'(z)\|_Z)$ (and a similar estimate for q_z holds). Then, for any $z \in \overline{B}(0;1)$ one has

$$|v_z|_{\beta,\frac{\beta}{2};\overline{Q}} \leq \widetilde{C}(\Omega, \omega, \mathcal{O}, T, F, f) \left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\| \exp\left(\frac{\mathcal{M}}{2t}\right) \xi \right\|_{L^2} \right), \tag{3.6}$$

$$|y_z|_{2+\beta,1+\frac{\beta}{2};\overline{Q}} \leq C_2(\Omega, \omega, \mathcal{O}, T, F, f) \left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\| \exp\left(\frac{\mathcal{M}}{2t}\right) \xi \right\|_{L^2} \right), \tag{3.7}$$

together with a similar estimate for q_z, with

$$\widetilde{C}(\Omega, \omega, \mathcal{O}, T, F, f) = \sup_{z \in \overline{B}(0;1)} C(\Omega, \omega, \mathcal{O}, T, z),$$
$$C_2(\Omega, \omega, \mathcal{O}, T, F, f) = \sup_{z \in \overline{B}(0;1)} C_1(\Omega, \omega, \mathcal{O}, T, z).$$

For each $z \in \overline{B}(0;1) \subset Z$, we consider the families

$$\mathcal{A}(z) = \left\{ v \in C^{\beta,\frac{\beta}{2}}(\overline{Q}) : (y, q) \text{ satisfies (3.3), (3.4), and (1.7), } v \text{ verifying (3.6)} \right\},$$
$$\Lambda(z) = \left\{ y : (y, q) \text{ solves (3.3), (3.4) with } v \in \mathcal{A}(z) \right\}.$$

One can then define the set-valued mapping $\Lambda : z \in \overline{B}(0;1) \subset Z \mapsto \Lambda(z) \subset Z$. For fixed $z \in \overline{B}(0;1)$, each $y \in \Lambda(z)$ lies in $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$ and satisfies (3.7), and thus

$$\|y\|_Z \leq C_2(\Omega, \omega, \mathcal{O}, T, F, f) \left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\| \exp\left(\frac{\mathcal{M}}{2t}\right) \xi \right\|_{L^2} \right). \tag{3.8}$$

We claim that there exists $\eta(\Omega,\omega,\mathcal{O},T,F,f) > 0$ such that if a source term $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfies (1.4), with $\mathcal{M}$ given by (3.5), then the Kakutani fixed point theorem can be applied to Λ. First, for fixed $z \in \overline{B}(0;1) \subset Z$, it is easy to check that $\Lambda(z)$ is a nonempty closed convex subset of Z (here we use the linear character of systems (3.3) and (3.4)). By estimate (3.7), $\Lambda(z)$ is a bounded set in $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$. Since this space is compactly embedded into Z, one infers that each $\Lambda(z)$ is a compact subset of Z. Furthermore, there exists a fixed compact set $K \subset Z$ such that $\Lambda(z) \subset K$ for all $z \in \overline{B}(0;1)$.

In the second place, Λ is proved to be an upper hemicontinuous multivalued mapping, or, equivalently, it is proved that for any bounded linear form $\mu \in Z'$, the function

$$z \in \overline{B}(0;1) \subset Z \mapsto \sup_{y\in\Lambda(z)} \langle \mu, y\rangle \in \mathbb{R}$$

is upper semicontinuous. To this end, it suffices to show that the set

$$B_{\lambda,\mu} = \left\{ z \in \overline{B}(0;1) : \sup_{y\in\Lambda(z)} \langle \mu, y\rangle \geq \lambda \right\}$$

is closed in Z for any $\lambda \in \mathbb{R}$ and any $\mu \in Z'$. Let us fix $\lambda \in \mathbb{R}$ and $\mu \in Z'$, and consider a sequence $\{z_n\}_{n\geq 1} \subset B_{\lambda,\mu}$ such that

$$z_n \to z \text{ in } Z. \tag{3.9}$$

Our aim is to see that $z \in B_{\lambda,\mu}$. As stated above, each $\Lambda(z_n)$ is a compact set in Z. Then for fixed $n \geq 1$ one has

$$\sup_{y\in\Lambda(z_n)} \langle \mu, y\rangle = \langle \mu, y_n\rangle \geq \lambda \tag{3.10}$$

for some $y_n \in \Lambda(z_n)$. By the definition of $\Lambda(z_n)$ and $\mathcal{A}(z_n)$, there exist $v_n \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfying

$$|v_n|_{\beta,\frac{\beta}{2};\overline{Q}} \leq \widetilde{C}(\Omega,\omega,\mathcal{O},T,F,f)\left(|\xi|_{\beta,\frac{\beta}{2};\overline{Q}} + \left\|\exp\left(\frac{\mathcal{M}}{2t}\right)\xi\right\|_{L^2}\right) \tag{3.11}$$

($\widetilde{C}(\Omega,\omega,\mathcal{O},T,F,f)$ as in (3.6)) and $q_n \in C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$ such that (y_n,q_n) together with v_n solve

$$\begin{cases} \partial_t y_n - \Delta y_n + G(z_n)y_n = \xi + v_n\mathbf{1}_\omega & \text{in } Q,\\ \partial_n y_n + g(z_n)y_n = 0 & \text{on } \Sigma,\\ y_n(x,0) = 0 & \text{in } \Omega, \end{cases} \tag{3.12}$$

$$\begin{cases} -\partial_t q_n - \Delta q_n + F'(z_n)q_n = y_n\mathbf{1}_{\mathcal{O}} & \text{in } Q,\\ \partial_n q_n + f'(z_n)q_n = 0 & \text{on } \Sigma,\\ q_n(x,T) = 0, \quad q_n(x,0) = 0 & \text{in } \Omega. \end{cases} \tag{3.13}$$

From (3.11) and (3.7), $\{v_n\}$ and $\{(y_n,q_n)\}$ are uniformly bounded in $C^{\beta,\frac{\beta}{2}}(\overline{Q})$ and $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q}) \times C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$, respectively. Taking into account the compact embedding of $C^{\beta,\frac{\beta}{2}}(\overline{Q})$ (resp., $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$) into $C^0(\overline{Q})$ (resp., Z), there exist subsequences (still denoted by $\{v_n\}$ and $\{(y_n,q_n)\}$) such that

$$v_n \to \widetilde{v} \quad \text{in } C^0(\overline{Q}), \qquad (y_n,q_n) \to (\widetilde{y},\widetilde{q}) \quad \text{in } Z \times Z$$

for some $\widetilde{v} \in C^0(\overline{Q})$, $(\widetilde{y}, \widetilde{q}) \in Z \times Z$. It is easily seen that, in fact, $\widetilde{v} \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$. On account of the regularity of F and f, from (3.9) one also has

$$\begin{aligned} G(z_n) \to G(z) \quad \text{and} \quad F'(z_n) \to F'(z) \quad \text{in } Z, \\ g(z_n) \to g(z) \quad \text{and} \quad f'(z_n) \to f'(z) \quad \text{in } \widetilde{Z}. \end{aligned}$$

We can then pass to the limit in (3.11)–(3.13) and deduce that $(\widetilde{y}, \widetilde{q})$ solves (3.3), (3.4), and (1.7) with control term $\widetilde{v} \in \mathcal{A}(z)$. Thus, $\widetilde{y} \in \Lambda(z)$, and taking limits in (3.10), one infers that

$$\sup_{y \in \Lambda(z)} \langle \mu, y \rangle \geq \langle \mu, \widetilde{y} \rangle \geq \lambda.$$

We conclude that $z \in B_{\lambda,\mu}$; hence, Λ is an upper hemicontinuous mapping.

Now let $\eta = \eta(\Omega, \omega, \mathcal{O}, T, F, f) > 0$ be such that $\eta \leq C_2(\Omega, \omega, \mathcal{O}, T, F, f)^{-1}$. Then, for a given source term $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfying (1.4), with $\mathcal{M}$ given by (3.5), we infer from (3.8) that any $y \in \Lambda\left(\overline{B}(0;1)\right)$ verifies $\|y\|_Z \leq 1$; that is, Λ maps the nonempty closed convex set $\overline{B}(0;1)$ into itself. We can then apply the Kakutani fixed point theorem and conclude that there exists $\overline{y} \in Z$ such that $\overline{y} \in \Lambda(\overline{y})$. Hence, there exists $v \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$, solving the nonlinear null controllability problem (1.5)–(1.7) (for $y_0 = 0$). Moreover, by (3.6) one can estimate

$$|v|_{\beta,\frac{\beta}{2};\overline{Q}} \leq \widetilde{C}(\Omega, \omega, \mathcal{O}, T, F, f)\eta. \tag{3.14}$$

Step 2. *Existence of a control insensitizing the functional* Φ. Let us see that there exists $\eta(\Omega, \omega, \mathcal{O}, T, F, f) > 0$ such that for any $\xi \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ satisfying (1.4), with $\mathcal{M}$ given by (3.5), the control v in the previous step can be chosen so that, for τ small enough, the existence of a solution of (1.1) (with $y_0 = 0$) in $C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$ is ensured. This will conclude the proof of the theorem, since such a control v will then insensitize the functional Φ given by (1.2), in view of Proposition 1.3.

We use the following result, which can be proved by linearizing and applying an appropriate fixed point argument.

LEMMA 3.2. *Assume that* $\partial\Omega \in C^{2+\beta}$ *for some* $\beta \in (0,1)$. *Let* $F \in C^2(\mathbb{R})$ *and* $f \in C^3(\mathbb{R})$ *be given. Then, there exists* $\delta > 0$ *(depending on* Ω, T, F, *and* f*) with the property that for any* $h \in C^{\beta,\frac{\beta}{2}}(\overline{Q})$ *and* $u_0 \in C^{2+\beta}(\overline{\Omega})$ *satisfying*

$$|h - F(0)|_{\beta,\frac{\beta}{2};\overline{Q}} + |f(0)| + |u_0|_{2+\beta;\overline{\Omega}} \leq \delta$$

and the compatibility condition

$$\partial_n u_0 + f(u_0) = 0 \quad \text{on } \partial\Omega, \tag{3.15}$$

the nonlinear system

$$\begin{cases} \partial_t u - \Delta u + F(u) = h & \text{in } Q, \\ \partial_n u + f(u) = 0 & \text{on } \Sigma, \\ u(x,0) = u_0(x) & \text{in } \Omega, \end{cases}$$

admits a unique solution $u \in C^{2+\beta,1+\frac{\beta}{2}}(\overline{Q})$.

Let us consider $X = C^{2+\beta}(\overline{\Omega}) \cap H_0^2(\Omega)$, with $\beta \in (0,1)$ as in the statement. Let $\delta > 0$ be provided by Lemma 3.2 and let $\mathcal{M}(\Omega, \omega, \mathcal{O}, T, F, f)$ be given by (3.5).

Recalling (3.14), one can choose $\eta = \eta(\Omega, \omega, \mathcal{O}, T, F, f) > 0$ small enough so that for any $\xi \in C^{\beta, \frac{\beta}{2}}(\overline{Q})$ verifying (1.4), $\hat{y}_0 \in X$ with $\|\hat{y}_0\|_X = 1$, and $\tau \in \mathbb{R}$ small enough, one has

$$|\xi + v\mathbf{1}_\omega|_{\beta, \frac{\beta}{2}; \overline{Q}} + |\tau \hat{y}_0|_{2+\beta; \overline{\Omega}} \leq \delta.$$

Since the initial datum $\tau \hat{y}_0$ satisfies (3.15) (by choice of X), one infers from Lemma 3.2 that system (1.1) possesses a solution $y(\cdot, \cdot; \tau, v) \in C^{2+\beta, 1+\frac{\beta}{2}}(\overline{Q})$, which ends the proof of Theorem 1.2. □

SUPERCONVERGENCE PROPERTIES OF OPTIMAL CONTROL PROBLEMS*

C. MEYER† AND A. RÖSCH‡

Abstract. An optimal control problem for a two-dimensional (2-d) elliptic equation is investigated with pointwise control constraints. This paper is concerned with discretization of the control by piecewise constant functions. The state and the adjoint state are discretized by linear finite elements. Approximations of the optimal solution of the continuous optimal control problem will be constructed by a projection of the discrete adjoint state. It is proved that these approximations have convergence order h^2.

Key words. linear-quadratic optimal control problems, error estimates, elliptic equations, numerical approximation, control constraints, superconvergence

1. Introduction.

The paper is concerned with the discretization of the two-dimensional (2-d) elliptic optimal control problem

$$J(u) = F(y,u) = \frac{1}{2}\|y - y_d\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|u\|^2_{L^2(\Omega)} \tag{1.1}$$

subject to the state equations

$$\begin{aligned} Ay + a_0 y &= u \qquad \text{in } \Omega, \\ y &= 0 \qquad \text{on } \Gamma \end{aligned} \tag{1.2}$$

and subject to the control constraints

$$a \le u(t,x) \le b \qquad \text{for a.a. } x \in \Omega, \tag{1.3}$$

where Ω is a bounded domain and Γ is the boundary of Ω; A denotes a second order elliptic operator of the form

$$Ay(x) = -\sum_{i,j=1}^{2} D_i(a_{ij}(x)D_j y(x)),$$

where D_i denotes the partial derivative with respect to x_i and a and b are real numbers. Moreover, $\nu > 0$ is a fixed positive number. We denote the set of admissible controls by U_{ad}:

$$U_{ad} = \{u \in L^2(\Omega) : \ a \le u \le b \ \text{ a.e. in } \Omega\}.$$

We discuss here the full discretization of the control and the state equations by a finite element method. The asymptotic behavior of the discretized problem is studied, and superconvergence results are established.

The approximation of the discretization for semilinear elliptic optimal control problems is discussed in Arada, Casas, and Tröltzsch [1]. The optimal control problem (1.1)–(1.3) is a linear-quadratic counterpart of such a semilinear problem. Our aim is to construct controls $\tilde{u}$ which have an approximation order of h^2. This higher convergence order is the difference between our work and [1].

The discretization of optimal control problems by piecewise constant functions is well investigated; we refer to Falk [7] and Geveci [8]. Piecewise constant and piecewise linear discretization in space are discussed for a parabolic problem in Malanowski [12]. Theory and numerical results for elliptic boundary control problems are contained in Casas and Tröltzsch [5] and Casas, Mateos, and Tröltzsch [4].

Piecewise linear control discretizations for elliptic optimal control problems are studied by Casas and Tröltzsch; see [5]. In an abstract optimization problem, piecewise linear approximations are investigated in Rösch [14]. In all papers, the convergence order is h or $h^{3/2}$.

A quadratic convergence result is proved by Hinze [10]. In that approach only the state equation is discretized. The control is obtained by a projection of the adjoint state to the set of admissible controls.

In this paper, we combine the advantages of the different approaches. After solving a fully discretized optimal control problem, a control $\tilde{u}$ is calculated by the projection of the adjoint state p_h in a postprocessing step. Although the approximation of the discretized solution is only of order h, we will show that this postprocessing step improves the convergence order to h^2.

The paper is organized as follows: In section 2 the discretizations are introduced and the main results are stated. Section 3 contains auxiliary results. The proofs of the superconvergence results are placed in section 4. The paper ends with numerical experiments shown in section 5.

2. Discretization and superconvergence results. Throughout this paper, Ω denotes a convex bounded open subset in $\mathbb{R}^2$ of class $C^{1,1}$. The coefficients a_{ij} of the operator A belong to $C^{0,1}(\bar{\Omega})$ and satisfy the ellipticity condition

$$m_0|\xi|^2 \le \sum_{i,j=1}^{2} a_{ij}(x)\xi_i\xi_j \qquad \forall (\xi, x) \in \mathbb{R}^2 \times \bar{\Omega}, \quad m_0 > 0.$$

Moreover, we require $a_{ij}(x) = a_{ji}(x)$ and $y_d \in L^p(\Omega)$ for some $p > 2$. For the function $a_0 \in L^\infty(\Omega)$, we assume $a_0 \ge 0$. Next, we recall some results from Bonnans and Casas [2].

LEMMA 2.1 (see [2]). *For every $p > 2$ and every function $g \in L^p(\Omega)$, the solution y of*

$$Ay + a_0 y = g \qquad \text{in } \Omega, \quad y|_\Gamma = 0,$$

belongs to $H_0^1(\Omega) \cap W^{2,p}(\Omega)$. Moreover, there exists a positive constant c independent of a_0 such that

$$\|y\|_{W^{2,p}(\Omega)} \le c\|g\|_{L^p(\Omega)}.$$

Next, we introduce the adjoint equation

$$\begin{aligned} Ap + a_0 p &= y - y_d && \text{in } \Omega, \\ p &= 0 && \text{on } \Gamma. \end{aligned} \tag{2.1}$$

Due to Lemma 2.1, the state equation and the adjoint equation admit unique solutions in $H_0^1(\Omega) \cap W^{2,p}(\Omega)$ if $y_d \in L^p(\Omega)$ for $p > 2$. This space is embedded in $C^{0,1}(\bar{\Omega})$.

We call the solution y of (1.2) for a control u an associated state to u and write $y(u)$. In the same way, we call the solution p of (2.1) corresponding to $y(u)$ an associated adjoint state to u and write $p(u)$.

Introducing the projection

$$\Pi_{[a,b]}(f(x)) = \max(a, \min(b, f(x))),$$

we can formulate the necessary and sufficient first order optimality condition for (1.1)–(1.3).

LEMMA 2.2. *A necessary and sufficient condition for the optimality of a control $\bar{u}$ with corresponding state $\bar{y} = y(\bar{u})$ and adjoint state $\bar{p} = p(\bar{u})$, respectively, is that the equation*

$$\bar{u}(x) = \Pi_{[a,b]}\left(-\frac{1}{\nu}\bar{p}\right) \tag{2.2}$$

holds.

Since the optimal control problem is strictly convex, we obtain the existence of a unique optimal solution. The optimality condition can be formulated as a variational inequality (3.11). A standard pointwise a.e. discussion of this variational inequality leads to the above formulated projection formula; see [12].

We are now able to introduce the discretized problem. We define a finite element based approximation of the optimal control (1.1)–(1.3). To this aim, we consider a family of triangulations $(T_h)_{h>0}$ of $\bar{\Omega}$. With each element $T \in T_h$, we associate two parameters $\rho(T)$ and $\sigma(T)$, where $\rho(T)$ denotes the diameter of the set T and $\sigma(T)$ is the diameter of the largest ball contained in T. The mesh size of the grid is defined by $h = \max_{T \in T_h} \rho(T)$. We suppose that the following regularity assumptions are satisfied.

(A1) There exist two positive constants ρ and σ such that

$$\frac{\rho(T)}{\sigma(T)} \le \sigma, \qquad \frac{h}{\rho(T)} \le \rho$$

hold for all $T \in T_h$ and all $h > 0$.

(A2) Let us define $\bar{\Omega}_h = \cup_{T \in T_h} T$, and let Ω_h and Γ_h denote its interior and its boundary, respectively. We assume that $\bar{\Omega}_h$ is convex and that the vertices of T_h placed on the boundary of Γ_h are points of Γ. From [13, estimate (5.2.19)], it is known that

$$|\Omega \setminus \Omega_h| \le Ch^2,$$

where $|.|$ denotes the measure of the set. Next, to every boundary triangle T of T_h we associate another triangle $\hat{T}$ with curved boundary as follows: The edge between the two boundary nodes of T is substituted by the corresponding curved part of Γ. We

denote by $\hat{T}_h$ the union of these curved boundary triangles with the interior triangles to Ω of T_h, such that $\bar{\Omega} = \cup_{\hat{T}\in\hat{T}_h}\hat{T}$. Moreover, we set

$$U_h = \{u \in L^\infty(\Omega) :\ u|_{\hat{T}} \text{ is constant on all } \hat{T} \in \hat{T}_h\}, \quad U_h^{ad} = U_h \cap U_{ad},$$
$$V_h = \{y_h \in C(\bar{\Omega}) :\ y_h \in \mathcal{P}_1\, \forall\, T \in T_h, \text{ and } y_h = 0 \text{ on } \bar{\Omega} \setminus \Omega_h\},$$

where $\mathcal{P}_1$ is the space of polynomials of degree less than or equal to 1. For each $u_h \in U_h$, we denote by $y_h(u_h)$ the unique element of V_h that satisfies

$$a(y_h(u_h), v_h) = \int_\Omega u_h v_h\, dx \qquad \forall v_h \in V_h, \tag{2.3}$$

where $a :\ V_h \times V_h \to \mathbb{R}$ is the bilinear form defined by

$$a(y_h, v_h) = \int_\Omega \left(a_0(x) y_h(x) v_h(x) + \sum_{i,j=1}^{2} a_{ij}(x) D_i y_h(x) D_j v_h(x) \right) dx.$$

In other words, $y_h(u_h)$ is the approximated state associated with u_h. Because of $y_h = v_h = 0$ on $\bar{\Omega}\setminus\Omega_h$, the integrals over Ω can be replaced by integrals over Ω_h. The finite dimensional approximation of the optimal control problem is defined by

$$\inf J(u_h) = \frac{1}{2}\|y_h(u_h) - y_d\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|u_h\|^2_{L^2(\Omega)}, \qquad u_h \in U_h^{ad}. \tag{2.4}$$

The adjoint equation is discretized in the same way:

$$a(p_h(u_h), v_h) = \int_\Omega (y_h(u_h) - y_d) v_h\, dx \qquad \forall v_h \in V_h. \tag{2.5}$$

The approximation order of the solutions of (2.4) in the L^2-sense is investigated in [1].

We will go a different way. For our superconvergence result we need an additional assumption for $\bar{u}$. We know already that the associated adjoint state $\bar{p}$ belongs to a space $W^{2,p}(\Omega)$ for a certain $p > 2$. The optimal control $\bar{u}$ is obtained by the projection formula (2.2). Therefore, we can classify the triangles T_i in two sets K_1 and K_2:

$$K_1 = \{T_i :\ \bar{u} \text{ is only Lipschitz continuous on } T_i\}, \qquad K_2 = \{T_i :\ \bar{u} \in W^{2,p}(T_i)\}.$$

This classification is correct: $W^{2,p}(\Omega)$ is embedded in $C^{0,1}(\bar{\Omega})$. Moreover, the projection operator is continuous from $C^{0,1}(\bar{\Omega})$ to $C^{0,1}(\bar{\Omega})$. Clearly, the number of triangles in K_1 grows for decreasing h. Nevertheless, the following additional assumption is fulfilled in many practical cases.

(A3) $|K_1| \le c \cdot h$.

Let $\bar{u}$ be the optimal solution of (1.1)–(1.3). Next, we denote by S_i the centroid of the triangle T_i. We define a piecewise constant function by the values of $\bar{u}(S_i)$:

$$w_h(x) = \bar{u}(S_i) \quad \text{ if } x \in T_i. \tag{2.6}$$

It is easy to verify that $w_h \in U_h^{ad}$.

Now we are able to formulate our first superconvergence result.

THEOREM 2.3. *Assume that the assumptions* (A1)–(A3) *hold. Let* u_h *be the solutions of* (2.4). *Then the estimate*

$$\|u_h - w_h\|_{L^2(\Omega)} \le ch^2 \tag{2.7}$$

holds true.

The proof of Theorem 2.3 is contained in section 4.

Moreover, we can construct controls in a postprocessing step. We start with the solution u_h of (2.4). The control $\tilde{u}$ is calculated by a projection of the discrete adjoint state $p_h(u_h)$ to the admissible set

$$\tilde{u}(x) = \Pi_{[a,b]}\left(-\frac{1}{\nu}(p_h(u_h))(x)\right).$$

THEOREM 2.4. *Assume that the assumptions* (A1)–(A3) *hold. Let* $\tilde{u}$ *be the control constructed above. Then the estimate*

$$\|\bar{u} - \tilde{u}\|_{L^2(\Omega)} \le ch^2 \tag{2.8}$$

holds true.

The proof of Theorem 2.4 is also derived in section 4.

3. Auxiliary results. First, we recall some well-known results for finite element method approximations [6]. We start with the so-called Aubin–Nitsche lemma.

LEMMA 3.1. *Let* (A1) *and* (A2) *be fulfilled and* $u \in L^2(\Omega)$. *Then we have*

$$\|y(u) - y_h(u)\|_{L^2(\Omega)} \le ch^2\|u\|_{L^2(\Omega)}, \tag{3.1}$$

$$\|p(u) - p_h(u)\|_{L^2(\Omega)} \le ch^2(\|u\|_{L^2(\Omega)} + \|y_d\|_{L^2(\Omega)}). \tag{3.2}$$

Next, we prove an estimate for the numerical integration.

LEMMA 3.2. *Let* f *be a function belonging to* $H^2(T_i)$ *for all* i *in a certain index set* I. *Then the estimates*

$$\left|\int_{T_i} (f(x) - f(S_i))\ dx\right| \le ch^2\sqrt{|T_i|}|f|_{H^2(T_i)}$$

and

$$\sum_{i\in I}\left|\int_{T_i} (f(x) - f(S_i))\ dx\right| \le ch^2\left(\sum_{i\in I}|f|^2_{H^2(T_i)}\right)^{1/2}$$

are valid.

Proof. The proof is almost standard. First, we remark that $|.|_{H^2(T_i)}$ denotes the H^2-seminorm. Next, we transform the integral to an integral over the reference element by $E\hat{x} = x$ and apply the Bramble–Hilbert lemma:

$$\begin{aligned}
\left|\int_{T_i} (f(x) - f(S_i))\ dx\right| &= \frac{|T_i|}{|\hat{T}|}\left|\int_{\hat{T}} (f(E\hat{x}) - f(S_i))\ d\hat{x}\right| \\
&\le c|T_i|\left(\int_{\hat{T}}\sum_{|\alpha|=2}|D^\alpha_{\hat{x}} f(E\hat{x})|^2\ d\hat{x}\right)^{1/2} \\
&\le ch^2|T_i|\left(\frac{|\hat{T}|}{|T_i|}\int_{T_i}\sum_{|\alpha|=2}|D^\alpha_x f(x)|^2\ dx\right)^{1/2} \\
&\le ch^2\sqrt{|T_i|}|f|_{H^2(T_i)}.
\end{aligned}$$

This implies

$$\sum_{i\in I}\left|\int_{T_i}(f(x)-f(S_i))\;dx\right|\le ch^2\left(\sum_{i\in I}|f|^2_{H^2(T_i)}\right)^{1/2}$$

by the Cauchy–Schwarz inequality. ∎

LEMMA 3.3. *Let w_h be the functions defined by* (2.6). *In addition, we assume that the assumptions* (A1)–(A3) *are fulfilled. Then the estimate*

$$\|y_h(\bar u)-y_h(w_h)\|_{L^2(\Omega)}\le ch^2\|\bar p\|_{W^{2,p}(\Omega)} \tag{3.3}$$

holds true.

Proof. We start with the transformation

$$\begin{aligned}\|y_h(\bar u)-y_h(w_h)\|^2_{L^2(\Omega)}&=(y_h(\bar u)-y_h(w_h),y_h(\bar u)-y_h(w_h))_{L^2(\Omega)}\\&=(p_h(\bar u)-p_h(w_h),\bar u-w_h)_{L^2(\Omega)}\\&=\int_{K_1}(p_h(\bar u)-p_h(w_h))(\bar u-w_h)\;dx\\&\quad+\int_{K_2}(p_h(\bar u)-p_h(w_h))(\bar u-w_h)\;dx.\end{aligned}\tag{3.4}$$

It remains to estimate these two integrals. The K_1-part can be estimated by the following arguments: The function $\bar p$ belongs to $W^{2,p}(\Omega)$ with $p>2$. Hence, we have

$$\|\bar u\|_{C^{0,1}(\bar\Omega)}\le\frac{1}{\nu}\|\bar p\|_{C^{0,1}(\bar\Omega)}\le c\|\bar p\|_{W^{2,p}(\Omega)}.$$

Because of $\bar u(S_i)=w_h(S_i)$ and the fact that w_h is constant on T_i, this implies $|\bar u(x)-w_h(x)|\le c\|\bar p\|_{W^{2,p}(\Omega)}\cdot|x-S_i|\le ch\|\bar p\|_{W^{2,p}(\Omega)}$. Consequently, we obtain

$$\begin{aligned}\left|\int_{K_1}(p_h(\bar u)-p_h(w_h))(\bar u-w_h)\;dx\right|&\le\sum_{T_i\in K_1}\int_{T_i}|(p_h(\bar u)-p_h(w_h))(\bar u-w_h)|\;dx\\&\le\sum_{T_i\in K_1}ch\|\bar p\|_{W^{2,p}(\Omega)}\|p_h(\bar u)-p_h(w_h)\|_{C(\bar\Omega)}\int_{T_i}dx\\&\le ch\|\bar p\|_{W^{2,p}(\Omega)}\|p_h(\bar u)-p_h(w_h)\|_{C(\bar\Omega)}\int_{K_1}dx\\&\le ch^2\|\bar p\|_{W^{2,p}(\Omega)}\|p_h(\bar u)-p_h(w_h)\|_{C(\bar\Omega)}\end{aligned}\tag{3.5}$$

by means of assumption (A3). For a triangle T_i of the K_2-part we have for an arbitrary function $v_h\in V_h$

$$\int_{T_i}w_hv_h\;dx=\int_{T_i}\bar u(S_i)v_h\;dx=\int_{T_i}\bar u(S_i)v_h(S_i)\;dx.$$

This is a formula for the numerical integration of $\bar uv_h$. Consequently, we obtain by Lemma 3.2

$$\begin{aligned}\left|\int_{K_2}(\bar u-w_h)v_h\;dx\right|&\le\sum_{T_i\in K_2}\left|\int_{T_i}(\bar u-\bar u(S_i))v_h\;dx\right|\\&\le ch^2\left(\sum_{T_i\in K_2}|\bar uv_h|^2_{H^2(T_i)}\right)^{1/2}.\end{aligned}\tag{3.6}$$

Next, we divide each triangle T_i of K_2 in an "active" part (A_i) and an "inactive" part (I_i) with $A_i \cup I_i = T_i$. The optimal control $\bar{u}$ is constant on the active component A_i ($\bar{u} = a$ or $\bar{u} = b$). Therefore, the seminorm is 0 on these parts. On the inactive parts I_i, we have

$$\bar{u} = -\frac{1}{\nu}\bar{p}.$$

Therefore, we can estimate

$$|\bar{u}v_h|_{H^2(T_i)} = |\bar{u}v_h|_{H^2(I_i)} = \frac{1}{\nu}|\bar{p}v_h|_{H^2(I_i)} \le c|\bar{p}v_h|_{H^2(T_i)}.$$

Hence, we can continue by

$$\begin{aligned}
\left|\int_{K_2} (\bar{u} - w_h)v_h \, dx\right| &\le ch^2 \left(\sum_{T_i \in K_2} |\bar{u}v_h|^2_{H^2(T_i)}\right)^{1/2} \\
&\le ch^2 \left(\sum_{T_i \in K_2} |\bar{p}v_h|^2_{H^2(T_i)}\right)^{1/2} \\
&\le ch^2 \left(\sum_{T_i \in K_2} \sum_{|\alpha|,|\beta|=1} \|D^{\alpha+\beta}\bar{p}v_h\|^2_{L^2(T_i)} + \|D^{\alpha}\bar{p}D^{\beta}v_h\|^2_{L^2(T_i)}\right)^{1/2} \\
&\le ch^2 \|\bar{p}\|_{W^{2,p}(\Omega)} \|v_h\|_{H^1_0(\Omega)} \qquad (3.7)
\end{aligned}$$

by means of Hölder's inequality in the last step. Next, we set $v_h = p_h(\bar{u}) - p_h(w_h)$ and obtain

$$\left|\int_{K_2} (\bar{u} - w_h)(p_h(\bar{u}) - p_h(w_h)) \, dx\right| \le ch^2 \|\bar{p}\|_{W^{2,p}(\Omega)} \|p_h(\bar{u}) - p_h(w_h)\|_{H^1_0(\Omega)}. \qquad (3.8)$$

Inserting (3.5) and (3.8) in (3.4), we get

$$\|y_h(\bar{u}) - y_h(w_h)\|^2_{L^2(\Omega)} \le ch^2 \|\bar{p}\|_{W^{2,p}(\Omega)} (\|p_h(\bar{u}) - p_h(w_h)\|_{C(\bar{\Omega})} + \|p_h(\bar{u}) - p_h(w_h)\|_{H^1_0(\Omega)}).$$

We benefit now from the fact that $p_h(\bar{u})$ and $p_h(w_h)$ are the solutions of the discretized adjoint equation (2.5). Hence, we have

$$\|p_h(\bar{u}) - p_h(w_h)\|_{C(\bar{\Omega})} + \|p_h(\bar{u}) - p_h(w_h)\|_{H^1_0(\Omega)} \le c\|y_h(\bar{u}) - y_h(w_h)\|_{L^2(\Omega)}$$

with a positive constant c independent of h. The C-estimate can be obtained as follows: Take the adjoint equation (2.1) and the discretized adjoint equation (2.5), but with a right-hand side $f_h \in V_h$ instead of $y - y_d$. Then we find for the corresponding solutions z and z_h of the continuous and discretized adjoint equation

$$\begin{aligned}
\|z_h\|_{C(\bar{\Omega})} &\le \|z_h - z\|_{C(\bar{\Omega})} + \|z\|_{C(\bar{\Omega})} \\
&\le ch\|f_h\|_{L^2(\Omega)} + c\|z\|_{H^2(\Omega)} \\
&\le ch\|f_h\|_{L^2(\Omega)} + c\|f_h\|_{L^2(\Omega)}.
\end{aligned}$$

Substituting $f_h = y_h(\bar{u}) - y_h(w_h)$ and $z_h = p_h(\bar{u}) - p_h(w_h)$ delivers the desired estimate. For the estimate of the first expression, we refer to Braess [3].

Finally, we get

$$\|y_h(\bar{u}) - y_h(w_h)\|_{L^2(\Omega)} \le ch^2 \|\bar{p}\|_{W^{2,p}(\Omega)},$$

which is exactly inequality (3.3). □

COROLLARY 3.4. *Assume that the assumptions of Lemma* 3.3 *are fulfilled. Then, we have*

$$\|p_h(\bar{u}) - p_h(w_h)\|_{L^2(\Omega)} \le ch^2 \|\bar{p}\|_{W^{2,p}(\Omega)}. \tag{3.9}$$

By means of Lemma 3.1*, we obtain*

$$\|\bar{p} - p_h(w_h)\|_{L^2(\Omega)} \le ch^2 (\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}). \tag{3.10}$$

LEMMA 3.5. *The following variational inequalities are necessary and sufficient for the optimality of the unique solutions of* (1.1)–(1.3) *and* (2.4)*, respectively.*

$$(\bar{p} + \nu\bar{u}, u - \bar{u})_{L^2(\Omega)} \ge 0 \qquad \forall u \in U_{ad}, \tag{3.11}$$

$$(p_h(u_h) + \nu u_h, \zeta_h - u_h)_{L^2(\Omega)} \ge 0 \qquad \forall \zeta_h \in U_h^{ad}. \tag{3.12}$$

The variational inequality (3.11) is an equivalent formulation for the projection formula (2.2).

Next, we derive a variational inequality for the function w_h. First, formula (3.11) is true for all $u \in U_{ad}$. Therefore, we have pointwise a.e.

$$(\bar{p}(x) + \nu\bar{u}(x)) \cdot (u - \bar{u}(x)) \ge 0 \qquad \forall u \in [a, b].$$

We apply this formula for $x = S_i$ and $u = u_h(S_i)$. This is correct because of the continuity of $\bar{u}$, $\bar{p}$, and u_h in these points. We arrive at

$$(\bar{p}(S_i) + \nu\bar{u}(S_i)) \cdot (u_h(S_i) - \bar{u}(S_i)) \ge 0 \qquad \forall S_i.$$

Due to (2.6), this is equivalent to

$$(\bar{p}(S_i) + \nu w_h(S_i)) \cdot (u_h(S_i) - w_h(S_i)) \ge 0 \qquad \forall S_i.$$

We integrate this formula over T_i and add up over all i

$$(\hat{p} + \nu w_h, u_h - w_h)_{L^2(\Omega)} \ge 0 \tag{3.13}$$

with

$$\hat{p}(x) = \bar{p}(S_i) \qquad \text{if } x \in T_i.$$

Moreover, we can test inequality (3.12) with the function w_h and get

$$(p_h(u_h) + \nu u_h, w_h - u_h)_{L^2(\Omega)} \ge 0. \tag{3.14}$$

We add these two inequalities and obtain

$$(\hat{p} - p_h(u_h) + \nu(w_h - u_h), u_h - w_h)_{L^2(\Omega)} \ge 0.$$

This is equivalent to

$$\nu \|w_h - u_h\|^2_{L^2(\Omega)} \le (\hat{p} - p_h(u_h), u_h - w_h)_{L^2(\Omega)}. \tag{3.15}$$

4. Superconvergence properties. Inequality (3.15) is the starting point for the proofs of the superconvergence results. Now, we are ready to prove Theorem 2.3.

Proof. For the right-hand side of (3.15), we find

$$\begin{aligned}(\hat{p} - p_h(u_h), u_h - w_h)_{L^2(\Omega)} &= (p_h(w_h) - p_h(u_h), u_h - w_h)_{L^2(\Omega)} \\ &\quad + (\bar{p} - p_h(w_h), u_h - w_h)_{L^2(\Omega)} \\ &\quad + (\hat{p} - \bar{p}, u_h - w_h)_{L^2(\Omega)}. \end{aligned} \tag{4.1}$$

Next we estimate these three terms. We start with

$$(p_h(w_h) - p_h(u_h), u_h - w_h)_{L^2(\Omega)} = (y_h(w_h) - y_h(u_h), y_h(u_h) - y_h(w_h))_{L^2(\Omega)} \le 0. \tag{4.2}$$

The second term can be estimated by formula (3.10):

$$(\bar{p} - p_h(w_h), u_h - w_h)_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}) \cdot \|w_h - u_h\|_{L^2(\Omega)}. \tag{4.3}$$

The third term represents again a formula for the numerical integration. Using that u_h and w_h are constant on each triangle T_i, we obtain by Lemma 3.2

$$\begin{aligned}(\hat{p} - \bar{p}, u_h - w_h)_{L^2(\Omega)} &= \sum_i \int_{T_i} (\hat{p}(x) - \bar{p}(x))(u_h(x) - w_h(x))\, dx \\ &= \sum_i (u_h(S_i) - w_h(S_i)) \int_{T_i} (\bar{p}(S_i) - \bar{p}(x))\, dx \\ &\le \sum_i ch^2 |u_h(S_i) - w_h(S_i)| \sqrt{|T_i|} \cdot |\bar{p}|_{H^2(T_i)} \\ &\le ch^2 \cdot \|w_h - u_h\|_{L^2(\Omega)} \cdot \|\bar{p}\|_{W^{2,p}(\Omega)}. \end{aligned} \tag{4.4}$$

Inserting (4.2)–(4.4) in (4.1), we get

$$(\hat{p} - p_h(u_h), u_h - w_h)_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}) \cdot \|w_h - u_h\|_{L^2(\Omega)}.$$

Next, we combine this inequality with (3.15)

$$\nu \|w_h - u_h\|^2_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}) \cdot \|w_h - u_h\|_{L^2(\Omega)}.$$

This formula is equivalent to

$$\|w_h - u_h\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}),$$

which was the assertion of Theorem 2.3. ∎

Theorem 2.3 means that the values of the numerical solution u_h in the centroids already have a quadratic convergence rate. By the projection of the associated adjoint state $p_h(u_h)$, we obtain an admissible control $\tilde{u}$ that has a quadratic convergence order with respect to the L^2-norm. This was the assertion of Theorem 2.4.

Proof. We start with the result of Theorem 2.3

$$\|w_h - u_h\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

This inequality implies

$$\|p_h(w_h) - p_h(u_h)\|_{L^2(\Omega)} \le c\|w_h - u_h\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

From Corollary 3.4, we know formula (3.10):

$$\|\bar{p} - p_h(w_h)\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

Therefore, we obtain by the triangle inequality

$$\|\bar{p} - p_h(u_h)\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

The projection operator $\Pi_{[a,b]}$ is Lipschitz continuous with constant 1 from $L^2(\Omega)$ to $L^2(\Omega)$. Finally, we get

$$\|\bar{u} - \tilde{u}\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

The superconvergence result is proved. □

COROLLARY 4.1. *By the arguments of the proof of Theorem* 2.4*, we get another result. We find for the* L^∞*-error*

$$\|\bar{u} - \tilde{u}\|_{L^\infty(\Omega)} \le ch(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

Proof. From formula (3.3)

$$\|y_h(w_h) - y_h(\bar{u})\|_{L^2(\Omega)} \le ch^2\|\bar{p}\|_{W^{2,p}(\Omega)}$$

and the inequality

$$\|y_h(w_h) - y_h(u_h)\|_{L^2(\Omega)} \le c\|w_h - u_h\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}),$$

we get by the triangle inequality

$$\|y_h(\bar{u}) - y_h(u_h)\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

This inequality implies

$$\|p_h(\bar{u}) - p_h(u_h)\|_{L^\infty(\Omega)} \le c\|y_h(\bar{u}) - y_h(u_h)\|_{L^2(\Omega)} \le ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

Denoting the solution of (2.5) with $\bar{y}$ instead of $y_h(u_h)$, by $\bar{p}_h$, we continue with

$$\begin{aligned}\|\bar{p} - p_h(u_h)\|_{L^\infty(\Omega)} \le{}& \|\bar{p} - \bar{p}_h\|_{L^\infty(\Omega)} + \|\bar{p}_h - p_h(\bar{u})\|_{L^\infty(\Omega)} \\ &+ \|p_h(\bar{u}) - p_h(u_h)\|_{L^\infty(\Omega)}.\end{aligned} \tag{4.5}$$

The first term can be estimated by $ch\|\bar{p}\|_{H^2(\Omega)}$ (see [3]). For the second term, we use the argumentation of Lemma 3.1 with $z_h = p_h(\bar{u}) - p_h(u_h)$ and $f_h = y_h(\bar{u}) - \bar{y}$:

$$\begin{aligned}\|\bar{p} - p_h(u_h)\|_{L^\infty(\Omega)} &\le ch\|\bar{p}\|_{H^2(\Omega)} + c\|y_h(\bar{u}) - \bar{y}\|_{L^2(\Omega)} + ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}) \\ &\le ch\|\bar{p}\|_{H^2(\Omega)} + ch^2(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}) \\ &\le ch(\|\bar{p}\|_{W^{2,p}(\Omega)} + \|y_d\|_{L^2(\Omega)}).\end{aligned}$$

The properties of the projection operator imply the assertion. □

COROLLARY 4.2. *The first estimate can be improved if all data are sufficiently smooth:*

$$\|\bar{p} - \bar{p}_h\|_{L^\infty(\Omega)} \le ch^2|\ln h|^{3/2}\|\bar{p}\|_{W^{2,\infty}(\Omega)}$$

(see Braess [3]*). In this case, formula* (4.5) *implies*

$$\|\bar{u} - \tilde{u}\|_{L^\infty(\Omega)} \le ch^2|\ln h|^{3/2}(\|\bar{p}\|_{W^{2,\infty}(\Omega)} + \|y_d\|_{L^2(\Omega)}).$$

5. Numerical tests. We have tested the convergence theory by two examples. In both cases, the Laplace operator $-\Delta$ was chosen for the elliptic operator A. The first example exactly fits the presented theory.

Both optimization problems were solved numerically by a primal-dual active set strategy; see, for instance, [11]. The discretization was already described in section 2: The control function u is discretized by piecewise constant functions, whereas the state y and the adjoint state p were approximated by piecewise linear functions. We used uniform meshes. The additional numerical effort for the calculation of $\tilde{u}$ is very small. We have only to evaluate the pointwise projection of the function $-\frac{1}{\nu}p_h$ to the interval $[a, b]$.

In contrast to this, the numerical evaluation of the L^2-norm $\|\bar{u}-\tilde{u}\|_{L^2(\Omega)}$ and the graphical representation are not so simple. Therefore, we briefly sketch these aspects. We want to point out that this additional effort is only needed to confirm the theoretical results. This effort is not necessary for the computation of the approximated optimal control.

For the computation of the L^2-norms $\|\bar{u}-u_h\|_{L^2(\Omega)}$ and $\|\bar{u}-\tilde{u}\|_{L^2(\Omega)}$, respectively, we introduce sets $\tilde{K}_1$, $\tilde{K}_2$, analogous to the sets K_1 and K_2:

$$\tilde{K}_1 = \{T_i : \tilde{u} \text{ is only Lipschitz continuous on } T_i\}, \quad \tilde{K}_2 = \{T_i : \tilde{u} \in C^\infty(T_i)\}.$$

Moreover, we set $M_1 = K_1 \cup \tilde{K}_1$, $M_2 = K_2 \cap \tilde{K}_2$. The numerical evaluation of $\|\bar{u}-\tilde{u}\|_{L^2(\Omega)}$ differs on the sets M_1 and M_2. Therefore, we split the L^2-norm up into

$$\|\bar{u}-\tilde{u}\|^2_{L^2(\Omega)} = \|\bar{u}-\tilde{u}\|^2_{L^2(M_1)} + \|\bar{u}-\tilde{u}\|^2_{L^2(M_2)}.$$

In our examples, the part $\bar{u}|_{K_2} \in C^\infty(K_2)$ is smooth. Thus, $\|\bar{u}-\tilde{u}\|_{L^2(M_2)}$ can be evaluated with sufficient accuracy applying an appropriate quadrature formula. In contrast to this, the difference $\bar{u}-\tilde{u}$ belongs only to $C^{0,1}(T_i)$ for all triangles $T_i \in M_1$. Hence, an arbitrary accurate quadrature formula would only admit an error of order h. Therefore, we introduce a subgrid of a significantly smaller mesh size in each triangle $T_i \in M_1$ and evaluate the norm $\|\bar{u}-\tilde{u}\|_{L^2(M_1)}$ on this subgrid to ensure sufficient accuracy. We want to point out that this subgrid is only used for the evaluation of the norm $\|\bar{u}-\tilde{u}\|_{L^2(M_1)}$ with a sufficient high accuracy.

Example 1. In this example, we investigate the Laplace equation with homogeneous Dirichlet boundary conditions. Therefore, we choose $a_0 \equiv 0$ in (1.2). Thus, the state equation is given by

$$\begin{aligned} -\Delta y &= u \text{ in } \Omega, \\ y &= 0 \text{ on } \Gamma. \end{aligned} \tag{5.1}$$

Now, we define the optimal state by

$$\bar{y} = y_a - y_g$$

with an analytical part $y_a = \sin(\pi\, x_1)\, \sin(\pi\, x_2)$ and a less smooth function y_g. The function y_g is defined as the solution of

$$\begin{aligned} -\Delta y_g &= g \text{ in } \Omega, \\ y_g &= 0 \text{ on } \Gamma. \end{aligned}$$

The function g is given by

$$g(x_1,x_2)=\begin{cases} u_f(x_1,x_2)-a & \text{if } u_f(x_1,x_2)<a,\\ 0 & \text{if } u_f(x_1,x_2)\in[a,b],\\ u_f(x_1,x_2)-b & \text{if } u_f(x_1,x_2)>b \end{cases}$$

with $u_f(x_1,x_2)=2\,\pi^2\,\sin(\pi\,x_1)\,\sin(\pi\,x_2)$. Due to the state equation (5.1), we obtain for the exact optimal control $\bar{u}$

$$\bar{u}(x_1,x_2)=\begin{cases} a & \text{if } u_f(x_1,x_2)<a,\\ u_f(x_1,x_2) & \text{if } u_f(x_1,x_2)\in[a,b],\\ b & \text{if } u_f(x_1,x_2)>b. \end{cases}$$

For the optimal adjoint state $\bar{p}$, we find

$$\bar{p}(x_1,x_2)=-2\,\pi^2\,\nu\,\sin(\pi\,x_1)\,\sin(\pi\,x_2).$$

The desired state is given by

$$y_d(x_1,x_2)=\bar{y}+\Delta\bar{p}=y_a-y_g+4\,\pi^4\,\nu\,\sin(\pi\,x_1)\,\sin(\pi\,x_2).$$

It is easy to see that these functions fulfill the necessary and sufficient first order optimality conditions. Moreover, the sets with

$$-\frac{1}{\nu}\bar{p}=a \quad \text{or} \quad -\frac{1}{\nu}\bar{p}=b$$

are a finite number (here two) of curves γ_i. Hence, the measure of the set K_1 is bounded by the total length of these curves

$$|K_1|\le 2h\sum|\gamma_i|,$$

and assumption (A3) is fulfilled. We chose $\nu=1$ for the numerical calculations.

Figures 5.1 and 5.2 show the numerical solutions $\tilde{u}$ for $h=0.04$ and $h=0.02$. As described above, the function $\tilde{u}$ is obtained by the pointwise projection $\Pi_{[a,b]}(-\frac{1}{\nu}p_h)$ in a postprocessing step. Therefore, $\tilde{u}$ contains sharp breaks on the subset $\tilde{K}_1$. To visualize these breaks, we introduce new mesh points in all triangles $T_i\in\tilde{K}_1$. Notice that these new grid points are only used for the graphical presentation of the projection.

Figures 5.3 and 5.4 show the convergence behavior of $\|\bar{u}-u_h\|_{L^2(\Omega)}$ and $\|\bar{u}-\tilde{u}\|_{L^2(\Omega)}$, respectively, for $h=0.04$, 0.02, 0.01, and 0.005. In the figures, $\bar{u}$ is denoted by u_{opt}.

As one can see, the theoretical predictions are fulfilled and one obtains quadratic convergence for $\|\bar{u}-\tilde{u}\|_{L^2(\Omega)}$. Furthermore, the absolute value of the error is significantly reduced by the projection, as Table 5.1 shows.

Theoretical results with respect to the $L^\infty(\Omega)$-norm were addressed in Corollaries 4.1 and 4.2. Again, we used finer subgrids for the numerical evaluation of the norms (see Figures 5.5 and 5.6).

Example 2. A Neumann boundary problem is studied in this example. In this case, the theoretical results do not exactly fit the problem. The Lax–Milgram theorem implies the existence of weak solutions ($\bar{y},\bar{p}\in H^1(\Omega)$) for the state equation and the adjoint equation. The $W^{2,p}$-regularity of the solution of the adjoint equation

is obtained by a result of Grisvard [9, Theorem 4.4.1.2]. For this special structure (Laplace operator, homogeneous Neumann data, $\Omega = \Omega_h$), the proofs of our main results can be adapted. A general discussion of Neumann boundary conditions requires more detailed investigations. We discuss here the problem

$$\begin{aligned} -\Delta y + c\, y &= u \text{ in } \Omega, \\ \partial_n y &= 0 \text{ on } \Gamma, \end{aligned} \tag{5.2}$$

where ∂_n denotes the normal derivative with respect to the outward normal vector. Again, we construct the optimal state $\bar{y}$ by $\bar{y} = y_a - y_g$, with an analytical part $y_a(x_1, x_2) = \cos(\pi\, x_1)\, \cos(\pi\, x_2)$. The function y_g is now determined by the equation

$$\begin{aligned} -\Delta y_g + c\, y_g &= g \text{ in } \Omega, \\ \partial_n y_g &= 0 \text{ on } \Gamma, \end{aligned}$$

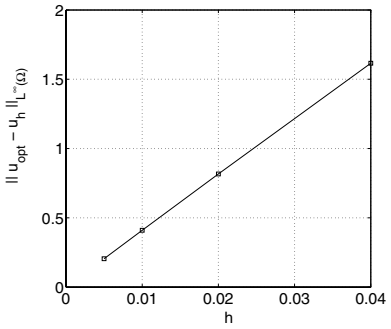

FIG. 5.5. $\|\bar{u} - u_h\|_{L^\infty(\Omega)}$.

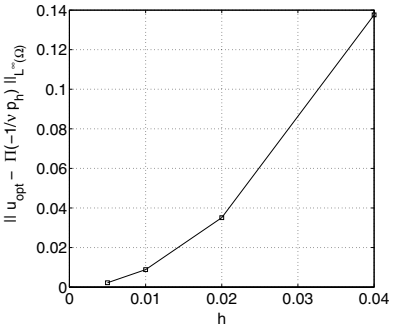

FIG. 5.6. $\|\bar{u} - \tilde{u}\|_{L^\infty(\Omega)}$.

with the inhomogenity

$$g(x_1, x_2) = \begin{cases} u_f(x_1, x_2) - a & \text{if } u_f(x_1, x_2) < a, \\ 0 & \text{if } u_f(x_1, x_2) \in [a, b], \\ u_f(x_1, x_2) - b & \text{if } u_f(x_1, x_2) > b \end{cases}$$

and $u_f(x_1, x_2) = (2\,\pi^2 + c)\,\cos(\pi\,x_1)\,\cos(\pi\,x_2)$. The optimal control $\bar{u}$ is given by (5.2):

$$\bar{u}(x_1, x_2) = \begin{cases} a & \text{if } u_f(x_1, x_2) < a, \\ u_f(x_1, x_2) & \text{if } u_f(x_1, x_2) \in [a, b], \\ b & \text{if } u_f(x_1, x_2) > b. \end{cases}$$

The optimal adjoint state is defined by

$$\bar{p}(x_1, x_2) = -(2\,\pi^2 + c)\,\nu\,\sin(\pi\,x_1)\,\sin(\pi\,x_2).$$

Moreover, the desired state y_d is chosen as

$$\begin{aligned} y_d(x_1, x_2) &= \bar{y} + \Delta\bar{p} - c\,\bar{p} \\ &= y_a - y_g + (4\,\pi^4\,\nu + 4\,\pi^2\,\nu\,c + \nu\,c^2)\,\sin(\pi\,x_1)\,\sin(\pi\,x_2). \end{aligned}$$

Again, it is easy to see that these functions fulfill the necessary and sufficient first order optimality conditions. Assumption (A3) can be verified with the same arguments as in Example 1. In the numerical test, we chose $\nu = c = 1$. The projected function $\tilde{u}$ for $h = 0.04$ and $h = 0.02$ is shown in Figures 5.7 and 5.8. For the visualization of this projection we introduced again new grid points.

Figures 5.9 and 5.10 illustrate that we obtain the same convergence results for this Neumann boundary example.

Comparable with the first example, the absolute error is considerable reduced by the projection, as Table 5.2 shows.

The convergence behavior of the $L^\infty(\Omega)$-errors is illustrated in Figures 5.11 and 5.12.

Figures 5.13 and 5.14 show the convergence behavior of $\|u_h - w_h\|_{L^2(\Omega)}$ (analyzed in Theorem 2.3) for the two examples.

A CLASS OF NONLINEAR DEGENERATE INTEGRODIFFERENTIAL CONTROL SYSTEMS*

HANG GAO†, PEIDONG LEI†, AND BO ZHANG‡

Abstract. In this paper, we study the approximate controllability and noncontrollability for a class of nonlinear degenerate integrodifferential control systems. Based on the property of finite propagation for the disturbances, we prove noncontrollability. We also establish sufficient conditions for approximate controllability of the system in $L^2(\Omega)$. Moreover, we prove the global existence and uniqueness of generalized solutions.

Key words. nonlinear degenerate integrodifferential equation, global existence, uniqueness, finite propagation, noncontrollability, approximate controllability

1. Introduction.

In this paper, we study the control system

$$\begin{cases} \dfrac{\partial}{\partial t}y(x,t) + Ly + \displaystyle\int_0^t f(y(x,s))ds = m(x)u(x,t) \quad \text{in } Q_T, \\ y(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad y(x,0) = y_0(x) \ \text{ in } \Omega, \end{cases} \tag{1.1}$$

where

$$Ly =: -\mathrm{div}(|\nabla y(x,t)|^{p-2}\nabla y(x,t)), \quad p > 2,$$

$Q_T = \Omega \times (0,T)$, $\Omega \subset R^3$, is a bounded domain with smooth boundary $\partial\Omega$, u is a control input, m is the characteristic function of an open set $\omega \subset \Omega$, while $f : R \to R$ is a given function.

Integrodifferential control systems of the type considered here arise in a variety of applications ranging from heat flow in material with memory to wave propagation. For $p = 2$, (1.1) becomes a standard integrodifferential equation which has a vast literature (see Fitzgibbon [4], Heard [6], Hussain [7], Webb [13]). In this case ($p = 2$), solutions have the property of infinite propagation of disturbances; i.e., a solution with nontrivial nonnegative initial data becomes positive after the initial time. For $p > 2$, (1.1) degenerates if $\nabla y = 0$. This degenerate equation appears in some nonlinear models with concentration dependent mobility. Just as the porous medium equation, solutions of (1.1) have the property of finite propagation. Such a property and the degenerative nature of (1.1) present a significant challenge to many investigators and have been the subject of intensive study in the last two decades. So far, a series of fine theories has been established for this p-Laplacian equation, namely, $f \equiv 0$ in (1.1); see Dibenedetto [3], Gao and Yin [5], Kalashnikov [8], Wu et al. [14], and Yin [15, 16]

for reference. However, to our knowledge, little is known for the nonlinear degenerate integrodifferential equation (1.1).

The goal of this paper is to study the noncontrollability and approximate controllability of the system (1.1). The problem of controllability in systems of partial differential equations, including integrodifferential equations for the case $p = 2$, has been studied by many researchers; we refer to the work of Balachandran, Balasubramaniam, and Dauer [1], Balachandran and Dauer [2], Teresa [10], Teresa and Zuazua [11], Wang and Wang [12], and Zuazua [17] for reference, fundamental theory, and recent development. In this paper, we are concerned with the degenerate case, i.e., $p > 2$.

To give readers an overview of results in the subsequent sections, we outline our main theorems below, beginning with the following definition.

DEFINITION 1.1. *A function y is called a generalized solution of* (1.1) *in Q_T if the following conditions are fulfilled:*

(1) $y \in L^\infty(0,T;W_0^{1,p}(\Omega))$ *and* $\frac{\partial y}{\partial t} \in L^2(Q_T)$.

(2) *For any $\varphi \in C^1(\bar{Q}_T)$ with $\varphi(x,t) = 0$ on $\partial\Omega \times (0,T)$, the following equality holds:*

$$\int_{Q_T} \frac{\partial y}{\partial t}\varphi dxdt + \int_{Q_T} |\nabla y|^{p-2}\nabla y \cdot \nabla\varphi dxdt + \int_{Q_T}\int_0^t f(y(x,s))ds\varphi dxdt = \int_{Q_T} mu\varphi dxdt.$$

(3) $\operatorname{ess\,lim}_{t\to 0^+} \int_\Omega |\nabla(y(x,t) - y_0(x))|^p dx = 0$.

If for any $T > 0$ the control system (1.1) *admits a generalized solution in Q_T, we say that* (1.1) *has a global solution.*

In order to obtain the global existence of a generalized solution, the following assumption is needed.

(H_1) *$f(\cdot)$ is Lipschitz continuous in R with a Lipschitz constant K.*

THEOREM 1.1. *Suppose condition* (H_1) *holds. Then for $y_0 \in W_0^{1,p}(\Omega)$ and $u \in L^q(Q_T)$ with $q > 3$, there exists a unique global solution $y(x,t) = y(x,t;u)$ of problem* (1.1).

Now we define the controllability and noncontrollability of the system (1.1).

We say that system (1.1) is approximately controllable in $L^2(\Omega)$ at time $T > 0$ if the following holds: "For any $y_0 \in W^{1,p}(\Omega)$, the set of reachable states at time T

$$E(T) = \{y(x,T); y \text{ is the solution of (1.1) with } u \in L^2(Q_T)\}$$

is dense in $L^2(\Omega)$." In other words, we say that system (1.1) is approximately controllable in $L^2(\Omega)$ at time $T > 0$ if and only if for any $y_1 \in L^2(\Omega)$ and for all $\varepsilon > 0$, there exists a control function $u \in L^2(Q_T)$ such that

$$\|y(\cdot,T;u) - y_1\|_{L^2(\Omega)} < \varepsilon. \tag{1.2}$$

We say that system (1.1) is noncontrollable at time $T > 0$ if for every $y_0 \in W^{1,p}(\Omega)$ there exists a function $y_1(x) \in L^\infty(\Omega)$ and $\varepsilon_0 > 0$ such that

$$\|y(x,T) - y_1(x)\|_{L^\delta(\Omega)} > \varepsilon_0$$

for any $\delta \geq 1$, where $y(x,t)$ is a generalized solution of (1.1) with $y(x,0) = y_0(x)$.

The following two theorems give the noncontrollability and controllability results.

(H_2) supp $m(x) \subset$ supp $y_0 \subset \Omega$, $f(0) \leq 0$.

THEOREM 1.2. *Suppose conditions* (H_1) *and* (H_2) *hold. If* $y_0 \geq 0$, *then the system* (1.1) *is noncontrollable.*

Remark 1.1. The condition $f(0) \leq 0$ is necessary; that is, if $f(0) > 0$, then Theorem 1.2 fails.

THEOREM 1.3. *Suppose condition* (H_1) *is fulfilled. If* $m(x) \equiv 1$ *in* Ω, *then for any* $T > 0$, (1.1) *is approximately controllable in* $L^2(\Omega)$ *at time* T.

Remark 1.2. It is easy to see that $m(x) \equiv 1$ means $\omega = \Omega$.

We shall prove these theorems in sections 2, 3, and 4, respectively.

2. Global existence and uniqueness. In this section, we discuss the global existence and uniqueness of solutions of (1.1). First, for any $T > 1$, consider the perturbed system

$$\begin{cases} \dfrac{\partial y}{\partial t} + L_n y + \displaystyle\int_0^t f(y(x,s))ds = m(x)u(x,t) \quad \text{in } Q_T, \\ y(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad y(x,0) = y_0(x) \ \text{ in } \Omega, \end{cases} \tag{2.1}$$

where

$$L_n y = -\operatorname{div}\left(\left(|\nabla y|^2 + \frac{1}{n}\right)^{(p-2)/2} \nabla y\right). \tag{2.2}$$

For f, u, m, y_0 given above and $z \in L^2(0,T;W^{1,p}(\Omega))$, we can find $f_k \in C^2(R)$, $u_k \in C^2(Q_T)$, $m_k \in C^2(\Omega)$, and $y_{0k} \in C_0^2(\Omega)$ such that

$$\int_{Q_T} \left[\int_0^t f_k(z(x,s))ds - \int_0^t f(z(x,s))ds\right]^2 dxdt \to 0,$$
$$\|y_{0k} - y_0\|_{W^{1,p}(\Omega)} \to 0, \quad \|m_k u_k - mu\|_{q,Q_T} \to 0,$$

where q is defined in Theorem 1.1. By the classical theory of parabolic equations (see [9, p. 452]), we know that for any $z \in L^2(0,T;W^{1,p}(\Omega))$, the problem

$$\begin{cases} \dfrac{\partial y}{\partial t} + L_n y + \displaystyle\int_0^t f_k(z(x,s))ds = m_k(x)u_k(x,t) \quad \text{in } Q_T, \\ y(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad y(x,0) = y_{0k}(x) \ \text{ in } \Omega \end{cases} \tag{2.3}$$

has one and only one classical solution y_k.

LEMMA 2.1. *Let* $z \in L^2(0,T;W^{1,p}(\Omega))$ *and* $y_k(x,t)$ *be a solution of* (2.3). *Then*

$$\|y_k\|_{L^p(0,T;W^{1,p}(\Omega))} \leq C, \tag{2.4}$$

$$\left\|\frac{\partial y_k}{\partial t}\right\|_{L^2(Q_T)} \leq C, \tag{2.5}$$

$$\|L_n y_k\|_{L^\infty(0,T;W^{-1,p'}(\Omega))} \leq C, \tag{2.6}$$

where $\frac{1}{p} + \frac{1}{p'}$, *and* C *is a constant depending on* $T, p, |\Omega|$, $\|u\|_{2,Q_T}$, $\|z\|_{L^2(0,T;W^{1,p}(\Omega))}$, *and* $\|y_0\|_{W^{1,p}(\Omega)}$.

Moreover, if $\|z\|_{L^2(0,T;W^{1,p}(\Omega))} \le C^*$ *(C^* is to be determined later), then there are positive constants* $t_1 \le T$ *such that*

$$\|y_k\|_{L^\infty(0,t_1;W^{1,p}(\Omega))} \le C^*, \tag{2.7}$$

$$\left\| \frac{\partial y_k}{\partial t} \right\|_{L^2(Q_{t_1})} \le C^*, \tag{2.8}$$

$$\|L_n y_k\|_{L^\infty(0,t_1;W^{-1,p'}(\Omega))} \le C^*. \tag{2.9}$$

Proof. Multiplying (2.3) by $\frac{\partial y_k}{\partial t}$ and integrating the resulting relation over $Q_t = \Omega \times (0,t)$, we have

$$\begin{aligned} &\int_{Q_t} \left(\frac{\partial y_k}{\partial t} \right)^2 dx d\tau + \int_{Q_t} \left(|\nabla y_k|^2 + \frac{1}{n} \right)^{(p-2)/2} \nabla y_k \cdot \nabla \frac{\partial y_k}{\partial t} dx d\tau \\ &\le \left\{ \int_{Q_t} \left[\int_0^\tau f_k(z(x,s)) ds \right]^2 dx d\tau + \int_{Q_t} u_k^2 dx d\tau \right\} + \frac{1}{2} \int_{Q_t} \left(\frac{\partial y_k}{\partial t} \right)^2 dx d\tau. \end{aligned} \tag{2.10}$$

Letting $\varepsilon > 0$ $(0 < \varepsilon < 1/2)$, we choose $\|u_k\|^2_{2,Q_t} \le \|u\|^2_{2,Q_t} + \varepsilon$ and

$$\int_{Q_t} \left[\int_0^\tau f_k(z(x,s)) ds \right]^2 dx d\tau \le \int_{Q_t} \left[\int_0^\tau f(z(x,s)) ds \right]^2 dx d\tau + \varepsilon.$$

Use condition (H_1) and apply Hölder's and Poincaré's inequalities to get

$$\begin{aligned} \int_{Q_t} \left[\int_0^\tau f(z(x,s)) ds \right]^2 dx d\tau &\le 2t^2 \int_{Q_t} [K^2 z^2(x,\tau) + f^2(0)] dx d\tau \\ &\le 2t^{\frac{3p-2}{p}} |\Omega|^{\frac{p-2}{p}} K^2 \|z\|^2_{L^2(0,t;W^{1,p}(\Omega))} + 2t^3 |\Omega| f^2(0). \end{aligned}$$

It follows from (2.10) that

$$\begin{aligned} &\frac{1}{2} \int_{Q_{t_1}} \left(\frac{\partial y_k}{\partial t} \right)^2 dx d\tau + \int_{Q_{t_1}} \left(|\nabla y_k|^2 + \frac{1}{n} \right)^{(p-2)/2} \nabla y_k \cdot \nabla \frac{\partial y_k}{\partial t} dx d\tau \\ &\le \|u\|^2_{2,Q_t} + 2t^{\frac{3p-2}{p}} |\Omega|^{\frac{p-2}{p}} K^2 \|z\|^2_{L^2(0,t;W^{1,p}(\Omega))} + 2t^3 |\Omega| f^2(0) + 1. \end{aligned} \tag{2.11}$$

Since

$$\int_{Q_t} \left(|\nabla y_k|^2 + \frac{1}{n} \right)^{(p-2)/2} \nabla y_k \cdot \nabla \frac{\partial y_k}{\partial t} dx d\tau = \frac{1}{p} \int_{Q_t} \frac{d}{d\tau} \left[\left(|\nabla y_k|^2 + \frac{1}{n} \right)^{p/2} \right] dx d\tau,$$

we get from (2.11) that

$$\begin{aligned} &\int_{Q_t} \left(\frac{\partial y_k}{\partial t} \right)^2 dx d\tau + \int_\Omega \left(|\nabla y_k(x,t)|^2 + \frac{1}{n} \right)^{p/2} dx \\ &\le p[\|u\|^2_{2,Q_t} + 2|\Omega|(K^2 t^{\frac{3p-2}{p}} \|z\|^2_{L^2(0,T;W^{1,p}(\Omega))} + f^2(0)t^3) + \|\nabla y_0\|^p_{p,\Omega} + 1]. \end{aligned} \tag{2.12}$$

This yields (2.4) and (2.5). To prove (2.6), we need only to use (2.4) and notice that

$$\left|\left(|\nabla y_k|^2+\frac{1}{n}\right)^{(p-2)/2}\nabla y_k\right|^{p/(p-1)} \le \left(|\nabla y_k|^2+\frac{1}{n}\right)^{p/2}.$$

From (2.12), we can select $t_1>0$ so small that

$$\begin{aligned}\int_{Q_t}\left(\frac{\partial y_k}{\partial t}\right)^2 dxd\tau+\int_\Omega\left(|\nabla y_k(x,t)|^2+\frac{1}{n}\right)^{p/2}dx\\ \le p(\|u\|^2_{2,Q_T}+\|\nabla y_0\|^p_{p,\Omega}+2)=:C^*\end{aligned}\tag{2.13}$$

for all $t\in[0,t_1]$. This completes the proof. □

LEMMA 2.2. *Assume that all conditions of Theorem* 1.1 *hold. Then there exists a unique generalized solution* $y(x,t)$ *of* (2.1).

Proof. For convenience, set $Y=L^2(0,T;W^{1,p}(\Omega))$. First, for any $z\in Y$, we prove the existence of a solution for the following problem:

$$\begin{cases}\dfrac{\partial}{\partial t}y(x,t)+L_ny+\displaystyle\int_0^t f(z(x,s))ds=m(x)u(x,t) & \text{in } Q_T,\\ y(x,t)=0 \text{ on } \partial\Omega\times(0,T), \quad y(x,0)=y_0(x) & \text{in } \Omega.\end{cases}\tag{2.14}$$

In fact, there exist sufficient smooth functions f_k, m_k, u_k, and y_{0k}, which satisfy

$$\int_{Q_T}\left[\int_0^t f_k(z(x,s))ds-\int_0^t f(z(x,s))ds\right]^2 dxdt\to 0,$$
$$\|y_{0k}-y_0\|_{W^{1,p}(\Omega)}\to 0, \quad \|m_ku_k-mu\|_{q,Q_T}\to 0.$$

Let y_k be the solution of (2.3). According to Lemma 2.1 we see that there exist a function $y\in L^\infty(0,T;W^{1,p}(\Omega))$ and a subsequence $\{y_{k_i}\}$ of $\{y_k\}$ such that as $k_i\to\infty$,

$$y_{k_i}(x,t)\to y(x,t) \quad \text{a.e. for } (x,t)\in Q_T;$$

$$y_{k_i}\to y, \quad \text{weakly-* in } \quad L^\infty(0,t_1;W^{1,p}(\Omega));$$

$$\frac{\partial y_{k_i}}{\partial t}\to\frac{\partial y}{\partial t}, \quad \text{weakly in } \quad L^2(Q_{t_1});$$

$$L_ny_{k_i}\to\eta, \quad \text{weakly-* in } \quad L^\infty(0,t_1;W^{-1,p'}(\Omega)).$$

It remains to show that $\eta=L_ny$. For this purpose, we define a functional

$$F_n(y)=\frac{1}{p}\int_\Omega\left(|\nabla y|^2+\frac{1}{n}\right)^{p/2}dx.$$

Then, $F_n(\cdot)$ is a convex functional on $W^{1,p}(\Omega)$, and $F_n'(y)=L_ny$ is a monotone operator. For any $g\in C_0^\infty(Q_T)$, we have

$$\int_0^{t_1}[F_n(g)-F_n(y_{k_i})]dt\ge\int_0^{t_1}\langle L_ny_{k_i},g-y_{k_i}\rangle dt,$$

where $\langle \cdot, \cdot \rangle$ denotes the dual product of $W^{1,p}(\Omega)$ and $W^{-1,p'}(\Omega)$. After a limiting process in the inequality above, we obtain

$$\int_0^{t_1} [F_n(g) - F_n(y)]dt \geq \int_0^{t_1} \langle \eta, g - y \rangle dt,$$

which implies $\eta = F_n'(y)$ immediately. Thus, $y = y(x,t)$ is a generalized solution of (2.14) in Q_{t_1}.

We can use a similar argument to obtain a solution of (2.14) on $(0,T)$. In fact, for the initial function $y(\cdot, t_1) \in W^{1,p}(\Omega)$, we can get a solution $y \in L^\infty(t_1, t_2; W^{1,p}(\Omega))$; that is, we have a solution $y \in L^\infty(0, t_2; W^{1,p}(\Omega))$. Continue this procedure to obtain a function $y \in L^\infty(0,T; W^{1,p}(\Omega))$, which is the solution of (2.14).

For $t_1 (0 < t_1 < 1)$, since $\|y\|_{L^\infty(0,t_1;W^{1,p}(\Omega))} \leq C^*$, we have $\|y\|_{L^2(0,t_1;W^{1,p}(\Omega))} \leq C^*$. We now introduce a set

$$Y_0(0,t_1) = \{y \in Y \ \mid \ \|y\|_{L^2(0,t_1;W^{1,p}(\Omega))} \leq C^*\},$$

where C^* is as given in Lemma 2.1. It is easy to see that $Y_0(0,t_1)$ is a bounded convex closed set in the Banach space $L^2(0,t_1;W^{1,p}(\Omega))$.

From the discussion above, we know that for any $z \in Y_0(0,t_1)$, there is a $y \in Y_0(0,t_1)$, which is the solution of problem (2.14). Now define a map $F : Y_0(0,t_1) \to L^2(0,t_1;W^{1,p}(\Omega))$ by $y = F(z)$. Obviously, $F(Y_0(0,t_1)) \subset Y_0(0,t_1)$. We will show that F has a fixed point y, which is a solution of (2.1).

We need only to prove that F is a continuous compact map. To this end, let $z_{k_1}, z_{k_2} \in Y_0(0,t_1)$, y_{k_1}, y_{k_2} be solutions of (2.14) corresponding to z_{k_1} and z_{k_2}, respectively. Then

$$(2.15)\quad \begin{cases} \dfrac{\partial}{\partial t}(y_{k_1} - y_{k_2}) + (L_n y_{k_1} - L_n y_{k_2}) \\ \qquad = \displaystyle\int_0^t [f(z_{k_2}(x,s)) - f(z_{k_1}(x,s))]ds \quad \text{in } Q_{t_1}, \\ (y_{k_1} - y_{k_2})(x,t) = 0 \quad \text{on } \partial\Omega \times (0,t_1), \quad (y_{k_1} - y_{k_2})(x,0) = 0 \quad \text{in } \Omega. \end{cases}$$

Observe that

$$\int_{Q_{t_1}} \left[\left(|\nabla y_{k_1}|^2 + \frac{1}{n} \right)^{\frac{p-2}{2}} \nabla y_{k_1} - \left(|\nabla y_{k_2}|^2 + \frac{1}{n} \right)^{\frac{p-2}{2}} \nabla y_{k_2} \right] \cdot \nabla (y_{k_1} - y_{k_2}) dxdt$$
$$\geq \left(\frac{1}{n} \right)^{\frac{p-2}{2}} \int_{Q_{t_1}} |(\nabla y_{k_1} - \nabla y_{k_2})|^2 dxdt.$$

Multiply (2.15) by $y_{k_1} - y_{k_2}$ and integrate in Q_{t_1} to derive

$$\int_\Omega (y_{k_1}(x,t_1) - y_{k_2}(x,t_1))^2 dx + \left(\frac{1}{n} \right)^{\frac{p-2}{2}} \int_{Q_{t_1}} |\nabla (y_{k_1} - y_{k_2})|^2 dxdt$$
$$\leq KC(\varepsilon) \int_{Q_{t_1}} |z_{k_1} - z_{k_2}|^2 dxdt + \varepsilon \int_{Q_{t_1}} (y_{k_1} - y_{k_2})^2 dxdt.$$

Here we have used condition (H_1). By Poincaré's inequality, we obtain

$$\int_\Omega (y_{k_1}(x,t_1)-y_{k_2}(x,t_1))^2dx+\frac{1}{2}\left(\frac{1}{n}\right)^{\frac{p-2}{2}}\int_{Q_{t_1}}|\nabla(y_{k_1}-y_{k_2})|^2dxdt$$
$$\le KC(\varepsilon)\int_{Q_{t_1}}|z_{k_1}(x,t)-z_{k_2}(x,t)|^2dxdt.$$

When $\|z_{k_1}-z_{k_2}\|_{L^2(0,t_1;W^{1,p}(\Omega))}\to 0$, we have

$$\|y_{k_1}-y_{k_2}\|_{2,Q_{t_1}}+\|\nabla(y_{k_1}-y_{k_2})\|_{2,Q_{t_1}}\to 0.$$

Since $\|y_{k_i}\|_{L^\infty(0,t_1;W^{1,p}(\Omega))}\le C^*$, we have

$$\|y_{k_1}-y_{k_2}\|_{L^2(0,t_1;W^{1,p}(\Omega))}\to 0.$$

This implies that F is a continuous map.

To prove that F is a compact map, we need to introduce a new space $W(q)=W_q^{2,1}(Q_{t_1})$ (see [9, p. 5]), endowed with the norm

$$\|y\|_W=\|D_{xx}y\|_{q,Q_{t_1}}+\|D_xy\|_{q,Q_{t_1}}+\|D_ty\|_{q,Q_{t_1}}+\|y\|_{q,Q_{t_1}}.$$

Suppose $\{y_k\}\subset F(Y_0(0,t_1))$. Then, there exists $\{z_k\}\subset Y_0(0,t_1)$ such that $y_k=F(z_k)$. At the same time, for any natural number k, there exists $a_k\in C^1(\bar{Q}_T)$ such that $\|(|\nabla y_k|^2+\frac{1}{n})^{(p-2)/2}-a_k\|_{p/(p-2),Q_{t_1}}<\frac{1}{k}$. We consider the following problem:

$$\begin{cases}\dfrac{\partial}{\partial t}y(x,t)-\operatorname{div}\big[a_k(x,t)\nabla y(x,t))\big]vspace.5pc\\ \quad =m(x)u(x,t)-\displaystyle\int_0^t f(z_k(x,s))ds=:\tilde{u}_k(x,t)\quad\text{in } Q_{t_1},\\ y=0\quad\text{on }\partial\Omega\times(0,t_1),\quad y(x,0)=y_0(x)\quad\text{in }\Omega.\end{cases}$$

Since $u\in L^q(Q_T)$ and $z_k\in L^2(0,T;W^{1,p}(\Omega))$, we have $\tilde{u}_k\in L^{q^*}(Q_T)$, where $q^*<3$. From [9, Chapter 4], we know that there exists a solution $\tilde{y}_k\in W(q^*)$ for the problem above, and $\|\tilde{y}_k\|_{W(q^*)}\le C\|\tilde{u}_k\|_{q^*,Q_T}\le C$. According to Sobolev's embedding theorem, we have $|D_x\tilde{y}_k|\le C$, and there exists a subsequence $\{\tilde{y}_{k_i}\}\subset\{\tilde{y}_k\}$ such that $\{\tilde{y}_{k_i}\}$ is a convergent sequence in $L^2(0,t_1;W^{1,p}(\Omega))$. Since

$$\begin{cases}\dfrac{\partial}{\partial t}(y_k-\tilde{y}_k)-\operatorname{div}\left[\left(|\nabla y_k|^2+\dfrac{1}{n}\right)^{\frac{p-2}{2}}\nabla(y_k-\tilde{y}_k)\right]\\ \qquad=\operatorname{div}\left[\left(\left(|\nabla y_k|^2+\dfrac{1}{n}\right)^{\frac{p-2}{2}}-a_k\right)\nabla\tilde{y}_k\right],\\ (y_k-\tilde{y}_k)|_{\partial\Omega\times(0,t_1)}=0,\quad (y_k-\tilde{y}_k)(x,0)=0,\end{cases}$$

we can obtain

$$\|\tilde{y}_k-y_k\|_{L^2(0,t_1;W^{1,p}(\Omega))}\le\frac{C}{k}.$$

Thus, $\{y_{k_i}\}$ is a convergent sequence in $Y_0(0,t_1)$, and F is a compact map.

Applying Schauder's fixed point theorem, we know that F has a fixed point y, which is a solution of (2.1) in Q_{t_1}. Similarly, for the initial function $y(\cdot, t_1) \in W^{1,p}(\Omega)$, we get a solution $y \in Y_0(t_1, t_2)$, that is, a solution $y \in Y_0(0, t_2)$. By repeating the discussion above, we obtain a function $y \in Y_0(0, T)$, which is a solution of (2.1). □

Now, we begin to prove Theorem 1.1.

Proof of Theorem 1.1. Suppose that $y_n \in L^2(0, T; W^{1,p}(\Omega))$ is the solution of problem (2.1). From Lemma 2.1, we see that there exist a function $y \in Y$ and a subsequence $\{y_{n_k}\}$ of $\{y_n\}$ such that as $n_k \to \infty$,

$$y_{n_k}(x,t) \to y(x,t) \quad \text{a.e. } (x,t) \in Q_T;$$

$$y_{n_k} \to y, \quad \text{weakly-* in} \quad L^\infty(0, T; W^{1,p}(\Omega));$$

$$\frac{\partial y_{n_k}}{\partial t} \to \frac{\partial y}{\partial t}, \quad \text{weakly in} \quad L^2(Q_T);$$

$$L_{n_k} y_{n_k} \to \eta, \quad \text{weakly-* in} \quad L^\infty(0, T; W^{-1,p'}(\Omega)).$$

Next, we show that $\eta = Ly$. To this end, we introduce two functionals

$$F_n(y) = 1/p \int_\Omega \left(|\nabla y|^2 + \frac{1}{n} \right)^{p/2} dx, \quad F(y) = 1/p \int_\Omega (|\nabla y|^2)^{p/2} dx.$$

It is clear that $F_n(\cdot)$ is a convex functional on $W^{1,p}(\Omega)$, and $F_n'(y) = L_n y$ is a monotone operator. For any $g \in C_0^\infty(Q_T)$, we have

$$\int_0^T [F_{n_k}(g) - F_{n_k}(y_{n_k})] dt \geq \int_0^T \langle L_{n_k} y_{n_k}, g - y_{n_k} \rangle dt,$$

where $\langle \cdot, \cdot \rangle$ denotes the dual product of $W^{1,p}(\Omega)$ and $W^{-1,p'}(\Omega)$. After a limiting process in the inequality above, we obtain

$$\int_0^T [F(g) - F(y)] dt \geq \int_0^T \langle \eta, g - y \rangle dt,$$

which implies $\eta = F'(y)$ immediately. Thus, $y \in L^2(0, T; W_0^{1,p}(\Omega))$ is a solution of (1.1). Furthermore, similar to Lemma 2.1, $y \in L^\infty(0, T; W_0^{1,p}(\Omega))$ is a solution of (1.1).

Finally, we prove the uniqueness of the generalized solution of (1.1). Set $z(x,t) = e^{-\beta t} y(x,t)$, where $y(x,t)$ is the solution of problem (1.1) and $\beta > \frac{K^2 T^2 + 1}{2}$ is a constant. Then,

$$\begin{cases} \dfrac{\partial}{\partial t} z(x,t) - \operatorname{div}(|\nabla y(x,t)|^{p-2} \nabla z(x,t)) + \beta z(x,t) \\ \qquad + \ e^{-\beta t} \displaystyle\int_0^t f(y(x,s)) ds = e^{-\beta t} m(x) u(x,t) \quad \text{in } Q_T, \\ z = 0 \quad \text{on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \quad \text{in } \Omega. \end{cases}$$

Let $y_1(x,t)$ and $y_2(x,t)$ be two generalized solutions of (1.1). Then

$$\begin{cases} \dfrac{\partial}{\partial t}(z_1-z_2) - \operatorname{div}\{|\nabla y_1|^{p-2}\nabla z_1 - |\nabla y_2|^{p-2}\nabla z_2\} + \beta(z_1-z_2) \\ \qquad + \ e^{-\beta t}\displaystyle\int_0^t [f(y_1(x,s)) - f(y_2(x,s))]ds = 0 \quad \text{in } \ Q_T, \\ (z_1-z_2) = 0 \quad \text{on } \partial\Omega\times(0,T), \quad (z_1-z_2)(x,0) = 0 \quad \text{in } \Omega. \end{cases} \tag{2.16}$$

We proceed to multiply (2.16) by $z_1 - z_2$ and integrate in Q_T. Taking into account the inequality

$$\int_Q \{|\nabla y_1|^{p-2}\nabla z_1 - |\nabla y_2|^{p-2}\nabla z_2\}\cdot\nabla(z_1-z_2)dxdt \geq 0, \tag{2.17}$$

we obtain

$$\begin{aligned} &\int_\Omega [z_1\ (x,T) - z_2(x,T)]^2dx + \beta\int_{Q_T}[z_1(x,t)-z_2(x,t)]^2dxdt \\ &\qquad \leq \int_{Q_T} e^{-\beta t}\left(\int_0^t Ke^{\beta s}|z_1(x,s)-z_2(x,s)|ds\right)|z_1(x,t)-z_2(x,t)|dxdt \\ &\qquad \leq \frac{1}{2}\int_{Q_T} e^{-2\beta t}\left(\int_0^t e^{\beta s}K|z_1(x,s)-z_2(x,s)|ds\right)^2 dxdt \\ &\qquad + \ \frac{1}{2}\int_{Q_T}|z_1(x,t)-z_2(x,t)|^2dxdt \\ &\qquad \leq \frac{K^2T^2+1}{2}\int_{Q_T}|z_1(x,t)-z_2(x,t)|^2dxdt. \end{aligned}$$

Since $\beta > \frac{K^2T^2+1}{2}$, we have $\int_{Q_T}|z_1(x,t)-z_2(x,t)|^2dxdt \leq 0$. Therefore, $y_1(x,t) = y_2(x,t)$, and the proof is complete. □

3. Noncontrollability. In this section, we discuss the noncontrollability of system (1.1). In order to obtain the noncontrollability, we need to prove that the speed of propagation for disturbances is finite. First, we prove the following lemma.

LEMMA 3.1. *Suppose* $f(0) \leq 0$ *and* (H$_1$) *holds. Let* $y(x,t)$ *be the solution of* (1.1) *with* $y_0(x) \geq 0$ *and* $u(x,t) \geq 0$. *Then* $y(x,t) \geq 0$ *in* Q.

Proof. Denote $y_- = \max\{-y, 0\}$. Multiplying (1.1) by y_- and integrating over Q_t, we obtain

$$\begin{aligned} &\frac{1}{2}\int_\Omega y_-^2(x,t)dx - \frac{1}{2}\int_\Omega y_-^2(x,0)dx + \int_{Q_t}|\nabla y_-(x,s)|^p dxds \\ &= \int_{Q_t}\int_0^t f(y(x,\tau))d\tau y_-(x,s)dxds - \int_{Q_t} m(x)u(x,s)y_-(x,s)dxds. \end{aligned}$$

Since $y_0(x) \geq 0$, $u(x,t) \geq 0$, we have $y_-^2(x,0) = 0$ a.e. in Ω and $u(x,s)y_-(x,s) \geq 0$ a.e. in Q_t. Thus

$$\frac{1}{2}\int_\Omega y_-^2(x,t)dx + \int_{Q_t}|\nabla y_-(x,s)|^p dxds \leq \int_{Q_t}\int_0^t f(y(x,\tau))d\tau y_-(x,s)dxds. \tag{3.1}$$

Using $f(0) \le 0$, condition (H_1), and Hölder's inequality, we obtain

$$\begin{aligned}
&\int_{Q_t} \int_0^t f(y(x,\tau))d\tau y_-(x,s)dxds \\
&\le K \int_{Q_t} \int_0^t |y(x,\tau)|d\tau y_-(x,s)dxds + tf(0) \int_{Q_t} y_-(x,s)dxds \\
&\le K \left(\int_{Q_t} \left(\int_0^t |y_-(x,\tau)|d\tau \right)^2 dxds \right)^{1/2} \left(\int_{Q_t} y_-^2(x,s)dxds \right)^{1/2} \\
&\le KT \int_{Q_t} y_-^2(x,s)dxds.
\end{aligned} \tag{3.2}$$

Substituting (3.2) into (3.1), we have

$$\int_\Omega y_-^2(x,t)dx \le KT \int_{Q_t} y_-^2(x,s)dxds.$$

By Gronwall's inequality, we get $\int_\Omega y_-^2(x,t)dx = 0$ immediately, which implies that $y(x,t) \ge 0$.

Now, we turn to prove the property of finite propagation of disturbances. Denote

$$\begin{aligned}
&G = \{(x,t) : y(x,t) > 0, t > 0\}, \quad G(t) = \{x : y(x,t) > 0\}, \\
&P = \partial G \cap \{(x,t) : t > 0\}, \quad P(t) = \partial G(t).
\end{aligned}$$

If $y(x,t)$ is continuous, then G and $G(t)$ are open sets of Q_T and Ω, respectively. We will call P the interface of the generalized solution $y(x,t)$.

PROPOSITION 3.1. *Suppose conditions* (H_1) *and* (H_2) *hold. If* $y_0 \ge 0$ *and* $u \ge 0$, *then there exists a time* $t^* > 0$ *such that* supp $y(\cdot,t) \subset \Omega$ *for* $0 < t < t^*$.

Proof. First, we consider a simple case, namely, supp $y_0 \subset \Pi_{i=1}^3 [\alpha_i, \beta_i] \subset \Omega$, where $[\alpha_i, \beta_i]$ for $i = 1,2,3$ is a closed bounded interval in R.

Set $z(x,t) = e^{-\beta t} y(x,t)$, $\beta > KT + KT^2$, where K is the Lipschitz constant given in (H_1). Then, supp$y(\cdot,t) =$ supp$z(\cdot,t)$. For each $r_1 \ge 0$, define

$$\Omega(r_1) = \{x | x = (x_1, x') \in \Omega, x_1 \le r_1\}.$$

We now prove supp$y(\cdot,t) \subset \Omega(\alpha_1(t), \beta_1(t))$, where

$$\Omega(\alpha_1(t), \beta_1(t)) = (\Omega \setminus \Omega(\alpha_1(t))) \cap \Omega(\beta_1(t))$$

for some functions $\alpha_1(t)$ and $\beta_1(t)$ to be determined later. From (1.1), we have

$$\begin{cases}
\dfrac{\partial}{\partial t} z(x,t) - \operatorname{div}(|\nabla y(x,t)|^{p-2} \nabla z(x,t)) + \beta z(x,t) \\
\qquad = e^{-\beta t} m(x) u(x,t) - e^{-\beta t} \displaystyle\int_0^t f(y(x,s))ds \quad \text{in } Q_T, \\
z(x,t) = 0 \text{ on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x).
\end{cases} \tag{3.3}$$

Let $\varphi(x, r_1) = (x_1 - r_1)^+$, $r_1 \ge \beta_1$ (given in (H_2)), where $(\cdot)^+ = \max\{\cdot, 0\}$, and

$x = (x_1, x_2, x_3)$. Taking $z\varphi^k$ as a test function, we get from Definition 1.1 that

$$\begin{aligned}
&\frac{1}{2}\int_\Omega z^2(x,t)\varphi^k dx + \int_{Q_t}(e^{\beta\tau}|\nabla z|)^{p-2}\nabla z\cdot\nabla(z\varphi^k)dxd\tau + \beta\int_{Q_t} z^2\varphi^k dxd\tau \\
&\quad = \int_{Q_t}\left[m(x)u(x,\tau) - \int_0^\tau f(e^{\beta s}z(x,s))ds\right]e^{-\beta\tau}z\varphi^k dxd\tau + \frac{1}{2}\int_\Omega y_0^2(x)\varphi^k dx \\
&\quad \le \int_{Q_t}\int_0^\tau [e^{-\beta(\tau-s)}Kz(x,s) + e^{-\beta\tau}f(0)]ds(z\varphi^k)dxd\tau \qquad (3.4)\\
&\quad \le K\int_{Q_t}\int_0^\tau z(x,s)ds(z\varphi^k)dxd\tau = \frac{1}{2}K\int_{Q_t}\frac{d}{d\tau}\left[\int_0^\tau z(x,s)ds\right]^2\varphi^k dxd\tau \\
&\quad = \frac{1}{2}K\int_\Omega\left[\int_0^t z(x,s)ds\right]^2\varphi^k dx \le \frac{1}{2}KT\int_{Q_t} z^2\varphi^k dxds.
\end{aligned}$$

Since $\beta > KT$, we obtain

$$\frac{1}{2}\int_\Omega z^2(x,t)\varphi^k dx + \int_{Q_t}(e^{\beta\tau}|\nabla z|)^{p-2}\nabla z\cdot\nabla(z\varphi^k)dxd\tau \le 0. \tag{3.5}$$

Next, observe

$$\begin{aligned}
&\int_{Q_t}(e^{\beta\tau}|\nabla z|)^{p-2}\nabla z\cdot\nabla(z\varphi^k)dxd\tau \\
&= \int_{Q_t}|e^{\beta\tau}\nabla z|^{p-2}|\nabla z|^2\varphi^k dxd\tau + k\int_{Q_t}|e^{\beta\tau}\nabla z|^{p-2}\nabla z\cdot\nabla\varphi\cdot z\varphi^{k-1}dxd\tau \\
&\ge \int_{Q_t} e^{\beta(p-2)\tau}|\nabla z|^p\varphi^k dxd\tau - k\int_{Q_t} e^{\beta(p-2)\tau}|\nabla z|^{p-1}\cdot z\varphi^{k-1}dxd\tau.
\end{aligned}$$

From this inequality and (3.5), we have

$$\int_{Q_t}|\nabla z(x,\tau)|^p\varphi^k dxd\tau \le C_1\int_{Q_t}|\nabla z(x,\tau)|^{p-1}\cdot z\varphi^{k-1}dxd\tau. \tag{3.6}$$

Choose a sufficiently large k such that $k - p - p^2 > 0$. Using Young's inequality on the right-hand side of (3.6) with $\mu = \frac{p}{p-1}$ and $\mu' = p$, we obtain

$$\int_{Q_t}|\nabla z|^p\varphi^k dxd\tau \le \frac{1}{2}\int_{Q_t}|\nabla z|^p\varphi^k dxd\tau + C_2\int_{Q_t} z^p\varphi^{k-p}dxd\tau.$$

This yields

$$\int_{Q_t}|\nabla z(x,\tau)|^p\varphi^k dxd\tau \le 2C_2\int_{Q_t} z^p(x,\tau)\varphi^{k-p}dxd\tau. \tag{3.7}$$

In order to estimate the right-hand side of (3.7), we take $z^{p-1}\varphi^{k-p}$ as a test function

and use an argument similar to that of (3.4) to obtain

$$\begin{aligned}
&\frac{1}{p}\int_\Omega z^p(x,t)\varphi^{k-p}dx + \int_{Q_t} |e^{\beta t}\nabla z|^{p-2}\nabla z\cdot\nabla(z^{p-1}\varphi^{k-p})dxd\tau \\
&\quad + \ \beta\int_{Q_t} z^p\varphi^{k-p}dxd\tau \le K\int_{Q_t}\left[\int_0^\tau z(x,s)ds\right] z^{p-1}(x,\tau)\varphi^{k-p}dxd\tau \\
&\quad \le K\int_{Q_t}\left\{\int_0^t z^p(x,s)ds\right\}^{\frac{1}{p}} t^{(p-1)/p} z^{p-1}(x,\tau)\varphi^{k-p}dxd\tau \\
&\quad \le Kt^{(2p-1)/p}\int_\Omega\left\{\int_0^t z^p(x,s)ds\right\}^{\frac{1}{p}}\left\{\int_0^t z^p(x,\tau)d\tau\right\}^{(p-1)/p} t^{1/p}\varphi^{k-p}dx \\
&\quad \le KT^2\int_{Q_t} z^p(x,\tau)\varphi^{k-p}dxd\tau.
\end{aligned}$$

Taking into account $\beta > KT^2$, we have

$$\frac{1}{p}\int_\Omega z^p(x,t)\varphi^{k-p}dx + \int_{Q_t} |e^{\beta t}\nabla z)|^{p-2}\nabla z\cdot\nabla(z^{p-1}\varphi^{k-p})dxd\tau \le 0. \tag{3.8}$$

Since

$$\begin{aligned}
&\int_{Q_t} |e^{\beta\tau}\nabla z|^{p-2}\nabla z\cdot\nabla(z^{p-1}\varphi^{k-p})dxd\tau \\
&\ge (p-1)\int_{Q_t} e^{(p-2)\beta\tau}|\nabla z|^p z^{p-2}\varphi^{k-p}dxd\tau \\
&\quad - \ (k-p)\int_{Q_t} e^{(p-2)\beta\tau}|\nabla z|^{p-1}z^{p-1}\varphi^{k-p-1}dxd\tau,
\end{aligned}$$

we obtain

$$\frac{1}{p}\int_\Omega z^p(x,t)\varphi^{k-p}dx \le C_3\int_{Q_t}|\nabla z|^{p-1}z^{p-1}\varphi^{k-p-1}dxd\tau$$

and thus

$$\sup_{\tau\in[0,t]}\int_\Omega z^p(x,\tau)\varphi^{k-p}dx \le C_3 p\int_{Q_t}|\nabla z|^{p-1}z^{p-1}\varphi^{k-p-1}dxd\tau.$$

Substituting this inequality into (3.7), we find

$$\int_{Q_t}|\nabla z|^p\varphi^k dxd\tau \le C_4 t\int_{Q_t}|\nabla z|^{p-1}z^{p-1}\varphi^{k-p-1}dxd\tau. \tag{3.9}$$

Apply Young's inequality to obtain

$$\begin{aligned}
&C_4 t\int_{Q_t}|\nabla z|^{p-1}z^{p-1}\varphi^{k-p-1}dxd\tau \\
&\le \frac{1}{2}\int_{Q_t}|\nabla z|^p\varphi^k dxd\tau + C_5 t^p\int_{Q_t} z^{(p-1)p}\varphi^{k-p-p^2}dxd\tau.
\end{aligned}$$

Combine this inequality and (3.9) to get

$$\int_{Q_t} |\nabla z|^p \varphi^k dx d\tau \le 2C_5 t^p \int_{Q_t} z^{(p-1)p} \varphi^{k-p-p^2} dx d\tau. \tag{3.10}$$

Again, using Sobolev's embedding theorem, we obtain

$$\int_{Q_t} z^{(p-1)p} \varphi^{k-p-p^2} dx d\tau \le C_6 \|z\|^{(p-1)p}_{1,p,Q(r_1)_t}, \tag{3.11}$$

where $Q(r_1)_t = \{(x,\tau)|\ \ x \in \Omega \setminus \Omega(r_1), \tau \in (0,t)\}$. Finally, we get from Poincaré's inequality that

$$\int_{Q_t} |\nabla z(x,\tau)|^p \varphi^k dx d\tau \le C_7 t^p \left(\int_{Q(r_1)_t} |\nabla z(x,\tau)|^p dx d\tau \right)^{p-1}. \tag{3.12}$$

Next, define

$$g_k(r_1) = \int_{Q_t} |\nabla z(x,\tau)|^p \varphi^k dx d\tau, \quad g_0(r_1) = \int_{Q(r_1)_t} |\nabla z(x,\tau)|^p dx d\tau.$$

Then

$$g_k(r_1) \le C t^p (g_0(r_1))^{p-1}.$$

Using Hölder's inequality, we obtain

$$\begin{aligned} g_1(r_1) &\le \left(\int_{Q_t} |\nabla z|^p \varphi^k dx d\tau \right)^{\frac{1}{k}} \left(\int_{Q(r_1)_t} |\nabla z|^p dx d\tau \right)^{\frac{k-1}{k}} \\ &\le C t^{\frac{p}{k}} (g_0(r_1))^{\frac{p-2+k}{k}}. \end{aligned}$$

Note that $\frac{p-2+k}{k} > 1$. Letting $\frac{p-2+k}{k} = 1+\theta$ ($\theta = \frac{p-2}{k} > 0$) and taking into account $g_1'(r_1) = -g_0(r_1)$, we have

$$g_1(r_1) \le C t^{\frac{p}{k}} (-g_1'(r_1))^{1+\theta}.$$

This implies

$$g_1'(r_1) \le -C t^{-\frac{p}{k(1+\theta)}} (g_1(r_1))^{\frac{1}{1+\theta}}. \tag{3.13}$$

If $g_1(\beta_1) = 0$, then $\nabla z(x,t) = 0$ for $(x,t) \in Q \setminus \Omega(\beta_1)_T$. Since $z(x,t) = 0$ on $\partial\Omega \times (0,T)$, we see that $z(x,t) = 0$ for $(x,t) \in Q \setminus \Omega(\beta_1)_T$. Thus we have supp $y(\cdot,t) \subset \Omega(\beta_1)$. If $g_1(\beta_1) > 0$, then there exists a maximal interval (β_1, β_1^*) on which $g_1(r_1) > 0$ and

$$(g_1(r_1)^{\frac{\theta}{1+\theta}})' = \frac{\theta}{1+\theta} \left(\frac{g_1'(r_1)}{[g_1(r_1)]^{\frac{1}{1+\theta}}} \right) \le -C t^{\frac{-p}{k(1+\theta)}}.$$

Integrating the above inequality over (β_1, β_1^*), we obtain

$$-(g_1(\beta_1)^{\frac{\theta}{1+\theta}}) \le -C(\beta_1^* - \beta_1) t^{-\frac{p}{k(1+\theta)}},$$

which implies that

$$\beta_1^* \le \beta_1 + C(p)t^{\frac{p}{k(1+\theta)}}[g_1(\beta_1)]^{\frac{\theta}{1+\theta}} \le \beta_1 + C(p)t^{\frac{p}{p-2+k}} =: \beta_1(t), \tag{3.14}$$

where $C(p)$ is a constant depending only upon p. This shows supp $y(\cdot,t) \subset \Omega(\beta_1(t))$.

Similarly, supp $y(\cdot,t) \subset \Omega \setminus \Omega(\alpha_1(t))$. Hence, supp $y(\cdot,t) \subset \Omega(\alpha_1(t),\beta_1(t))$. The discussion in the direction of x_i is similar to that for x_1. We finally obtain supp $y(\cdot,t) \subset \Omega(\alpha_i(t),\beta_i(t))$, $i = 1,2,3$.

Now we treat the general case, that is, supp$y_0 \subset \Omega$. Obviously, we can select a finite closed covering D of suppy_0 with $D = \cup_{j=1}^n D^{(j)} \subset \Omega$ and $D^{(j)} = \Pi_{i=1}^3[\alpha_i^{(j)},\beta_i^{(j)}]$, where $[\alpha_i^{(j)},\beta_i^{(j)}]$ for $i = 1,2,3,\ j = 1,2,\dots,n$, is a closed bounded interval in R. Moreover, we can require that the profile of $D^{(j)}$ is contained in suppy_0 (we call it the inner profile) or the cap set of the profile and the inner of suppy_0 is empty (we call it the outer profile). We are interested in the cuboids which are not contained in suppy_0 only. As a matter of convenience, we denote these cuboids by $D^{(1)},\dots,D^{(n_0)}$, where $n_0 \le n$.

For the cuboid $D^{(j)} = \Pi_{i=1}^3[\alpha_i^{(j)},\beta_i^{(j)}]$ $(j = 1,2,\dots,n_0)$, we can also obtain the finite propagation of the outer profile of $D^{(1)}$. Using the same technique for deriving (3.14), we can establish the estimate of the speed of finite propagation, and hence the proof is complete. □

Proof of Theorem 1.2. For simplicity, we assume that supp$y_0 \subset \Pi_{i=1}^3[\alpha_i,\beta_i] \subset \Omega$. We say that the interface P of the generalized solution y reaches $\partial\Omega$ "fully" at the time t if $P(t) = \partial\Omega$. Set

$$t^* = \inf\{t > 0 : P \text{ reaches } \partial\Omega \text{ fully}\}.$$

Now we estimate the time t^*. For any $z = (z_1,z_2,z_3) \in \partial\Pi_{i=1}^3[\alpha_i,\beta_i]$, if $z_i = \alpha_i$ or $z_i = \beta_i$, denote the line

$$l_i = \{x = z + te_i : \quad e_i \text{ is the unit normal of the hyperplane } x_i = 0\}$$

and the opposite point of z

$$w(z) = \begin{cases} w_\alpha(z) = \partial\Omega \cap \{x \in \Omega : x_i \le \alpha_i\} \cap l_i & \text{if } z_i = \alpha_i, \\ w_\beta(z) = \partial\Omega \cap \{x \in \Omega : x_i \ge \beta_i\} \cap l_i & \text{if } z_i = \beta_i. \end{cases}$$

Set

$$d_z = dist(z,\partial\Omega) = |z - w(z)|, \quad d = \sup_{z \in \partial\Pi_{i=1}^3[\alpha_i,\beta_i]} d_z.$$

In order to ensure that the interface of y reaches $\partial\Omega$, we get from the estimate of the speed of propagation (3.14) that

$$C(p)t^{\frac{p}{p-2+k}} \ge d$$

must be fulfilled. This implies that

$$t^* \ge C(p)d^{\frac{p-2+k}{p}}. \tag{3.15}$$

Using an argument similar to that in the proof of Proposition 3.1, we can obtain inequality (3.15) for the general case.

Thus, for any $0 < t < C(p)d^{\frac{p-2+k}{p}}$ and any input control u,

$$\sup\{|x-y| : \quad x \in \text{supp } y(\cdot,t;u), y \in \partial\Omega\} > 0.$$

This means that we can select a measurable subset $D \subset \Omega \backslash \text{supp} y(\cdot,t;u)$ with positive measure, such that $y = 0$ in D, and hence the system (1.1) is noncontrollable. The proof is complete. □

4. Approximate controllability. Under the condition $m(x) \equiv 1$ in Ω, the speed of propagation of the disturbances is infinite provided that $u(x,t) > 0$. In this section, we will discuss the approximate controllability of (1.1); that is, for all $t_1 > 0$, for all $\varepsilon > 0$, for all $y_1 \in L^2(\Omega)$, there exists a control function u such that $\|y(\cdot,t_1;u) - y_1\| \le \varepsilon$. For this purpose, we set $z(x,t) = e^{-\beta t}y(x,t)$ (β is to be determined later). Consider the control system

$$\begin{cases} \dfrac{\partial}{\partial t}z(x,t) - \text{div}(|\nabla e^{\beta t}z(x,s)|^{p-2}\nabla z(x,t)) + \beta z(x,t) \\ \quad + e^{-\beta t}\displaystyle\int_0^t f(e^{\beta t}z(x,s))ds = e^{-\beta t}u(x,t) \quad \text{in } \ Q_T, \\ z(x,t) = 0 \ \text{ on } \ \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \ \Omega. \end{cases} \tag{4.1}$$

Obviously, system (1.1) is approximately controllable if and only if system (4.1) is approximately controllable at time t_1. So, we need only to discuss the approximate controllability of (4.1) at t_1.

Remark 4.1. The choice of β depends not only on K but also on t_1.

We now introduce a Hilbert space $V_2(Q_T)$, endowed with the norm

$$\|y\|_V = \max_{t\in(0,T)} \|y(\cdot,t)\|_{2,\Omega} + \|D_x y\|_{2,Q_T}.$$

Define $V_2^{1,0}(Q_T) = V_2(Q_T) \cap C(0,T;L^2(\Omega))$, and set

$$V =: V_2^{1,1/2}(Q_T) = \left\{ z \in V_2^{1,0}(Q_T) \ \middle| \ \lim_{h\to 0}\int_0^{T-h}\int_\Omega h^{-1}[z(x,t+h) - z(x,t)]^2 = 0 \right\}.$$

First, we discuss the approximate controllability of the system

$$\begin{cases} \dfrac{\partial}{\partial t}z(x,t) + \tilde{L}_n z + \beta z(x,t) \\ \quad + e^{-\beta t}\displaystyle\int_0^t f(e^{\beta t}z(x,s))ds = e^{-\beta t}u(x,t) \quad \text{in } \ Q_T, \\ z(x,t) = 0 \ \text{ on } \ \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \ \Omega, \end{cases} \tag{4.2}$$

where

$$\tilde{L}_n z = -\text{div}\left(\left(|e^{\beta t}\nabla z(x,t)|^2 + \frac{1}{n}\right)^{(p-2)/2}\nabla z(x,t)\right);$$

that is, for any $z_1 \in L^2(\Omega)$ and $\varepsilon > 0$, we can find a $u \in L^p(Q_T)$ such that $\|z(\cdot,t_1) - z_1\|_{2,\Omega} \le \varepsilon$.

We endow a new norm to $z \in V$:

$$|z|_V^2 = \left(\frac{1}{n}\right)^{(p-2)/2} \|D_x z\|_{2,Q_T}^2 + \beta \|z\|_{2,Q_T}^2$$

for fixed n. Then $(V, |\cdot|_V)$ is a Banach space. Let

$$Z = \{z \ \mid \ |z|_V \le C^*\},$$

where C^* is a constant to be determined later. It is obvious that Z is a bounded closed convex set in V. For any $w \in Z$, we discuss the approximate controllability of the system

$$\text{(4.3)} \quad \begin{cases} \dfrac{\partial}{\partial t} z(x,t) + \tilde{L}_n(w) z + \beta z + e^{-\beta t} \displaystyle\int_0^t f(e^{\beta s} w(x,s)) ds = u(x,t) \quad \text{in } \ Q_T, \\ z(x,t) = 0 \ \text{ on } \ \partial\Omega \times (0,T), \quad z(x,0) = 0 \ \text{ in } \ \Omega, \end{cases}$$

where

$$\tilde{L}_n(w) z =: -\text{div}\left(\left(|e^{\beta t} \nabla w(x,t)|^2 + \frac{1}{n} \right)^{\frac{p-2}{2}} \nabla z(x,t) \right).$$

From [9, pp. 153–157], we know that for any $u \in L^p(Q_T)$, there exists a unique solution $z \in V$ with

$$\text{(4.4)} \qquad |z|_V \le \|u\|_{2,Q_T} + \left\| e^{-\beta t} \int_0^t f(e^{\beta s} w(x,s)) ds \right\|_{2,Q_T}.$$

Remark 4.2. If $\int_0^t f(e^{\beta s} w(x,s)) ds = 0$ and $z_1 = 0$, then we can choose $u = 0$ such that $z(x,t_1) = 0 = z_1$ for system (4.3).

For any $\varphi^0 \in L^2(\Omega)$, we discuss the following problem:

$$\text{(4.5)} \quad \begin{cases} -\dfrac{\partial}{\partial t} \varphi(x,t) + \tilde{L}_n(w) \varphi(x,t) + \beta \varphi(x,t) = 0 \quad \text{in } \ Q_T, \\ \varphi(x,t) = 0 \ \text{ on } \ \partial\Omega \times (0,T), \quad \varphi(x,t_1) = \varphi^0(x) \ \text{ in } \ \Omega. \end{cases}$$

We also know from [9, p. 153] that there exists a unique solution $\varphi \in V \cap L^\infty(\bar{Q})$ with

$$\text{(4.6)} \qquad |\ \varphi\ |_V \le \|\ \varphi^0\|_{2,\Omega}.$$

Remark 4.3. For any $\theta^0 \in L^2(\Omega)$, if θ is the solution of problem (4.5) with $\theta(x,t_1) = \theta^0(x)$, then

$$\int_\Omega z(x,t_1)\theta^0(x) dx = -\int_{Q_{t_1}} e^{-\beta t} \int_0^t f(e^{\beta s} w(x,s)) ds \theta(x,t) dx dt$$

if and only if $u = 0$ in (4.3), where $z(x,t)$ and $w(x,t)$ are given in (4.3).

For any given $z_1 \in L^2(\Omega)$ and $\varepsilon > 0$, we define a functional on $L^2(\Omega)$ as follows:

$$\text{(4.7)} \quad \begin{aligned} J(\varphi^0) = {} & \frac{1}{2} \int_{Q_{t_1}} \varphi^2(x,t) dx dt - \int_\Omega z_1(x) \varphi^0(x) dx + \varepsilon \|\varphi^0\|_{2,\Omega} \\ & - \int_{Q_{t_1}} e^{-\beta t} \int_0^t f(e^{\beta s} w(x,s)) ds \varphi(x,t) dx dt, \end{aligned}$$

where $\varphi(x,t)$ is the solution of (4.5) with $\varphi(x,t_1)=\varphi^0(x)$.

LEMMA 4.1. *There exists a unique* $\bar{\varphi}^0 \in L^2(\Omega)$ *such that*

$$J(\bar{\varphi}^0) \le J(\varphi^0) \quad \forall \varphi^0 \in L^2(\Omega).$$

Proof. First, we show that there exists a constant $M>0$ such that

$$J(\varphi^0) \ge -M \quad \forall \varphi^0 \in L^2(\Omega). \tag{4.8}$$

In fact, we need only to consider the case of $\|\varphi_k^0\|_{2,\Omega} \to +\infty$. Set $\tilde{\varphi}_k^0 = \varphi_k^0/\|\varphi_k^0\|_{2,\Omega}$ so that $\|\tilde{\varphi}_k^0\|_{2,\Omega}=1$. Let φ_k and $\tilde{\varphi}_k$ be solutions of (4.5) with $\varphi_k(x,t_1)=\varphi_k^0(x)$ and $\tilde{\varphi}_k(x,t_1)=\tilde{\varphi}_k^0(x)$, respectively. Then, we have $\varphi_k = \|\varphi_k^0\|_{2,\Omega}\tilde{\varphi}_k$. So, this implies

$$\begin{aligned}\frac{J(\varphi_k^0)}{\|\varphi_k^0\|_{2,\Omega}} &= \frac{1}{2}\int_{Q_{t_1}} (\tilde{\varphi}_k(x,t))^2 dxdt \|\varphi_k^0\|_{2,\Omega} - \int_\Omega z_1(x)\tilde{\varphi}_k^0(x)dx + \varepsilon\|\tilde{\varphi}_k^0\|_{2,\Omega} \\ &\quad - \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\tilde{\varphi}_k(x,t)dxdt.\end{aligned} \tag{4.9}$$

From this equality, we see that $\frac{J(\varphi_k^0)}{\|\varphi_k^0\|_{2,\Omega}} \to +\infty$ as $\|\varphi_k^0\|_{2,\Omega} \to +\infty$. Thus (4.8) holds.

According to (4.8), we can choose a minimizing sequence $\{\varphi_k^0\}$. From the discussion above, we know $\|\varphi_k^0\|_{2,\Omega} \le C$. So, there exist $\bar{\varphi}^0 \in L^2(\Omega)$ and a subsequence $\varphi_{k_i}^0$ such that $\varphi_{k_i}^0 \to \bar{\varphi}^0$ weakly in $L^2(\Omega)$. Suppose that φ_k and $\bar{\varphi}$ are solutions of (4.5) with $\varphi_k(x,t_1)=\varphi_k^0(x)$ and $\bar{\varphi}(x,t_1)=\bar{\varphi}^0(x)$, respectively. Since $\varphi_{k_i}^0 \to \bar{\varphi}^0$ weakly in $L^2(\Omega)$, then $\varphi_{k_i} \to \bar{\varphi}$ weakly in V. It follows from Sobolev's embedding theorem that $\varphi_{k_i} \to \bar{\varphi}$ in $L^2(Q_{t_1})$. Thus, we have

$$J(\bar{\varphi}^0) \le \lim_{k_i\to\infty} J(\varphi_{k_i}^0) = \inf\left\{J(\varphi^0) \mid \ \varphi^0 \in L^2(\Omega)\right\}.$$

Since the functional $J(\cdot)$ is strictly convex, the minimum function is unique. Lemma 4.1 is proved. ∎

LEMMA 4.2. *Suppose* $\bar{\varphi}^0$ *is the minimum function of functional* (4.7), $\bar{\varphi}$ *is the solution of* (4.5) *with* $\bar{\varphi}(x,t_1)=\bar{\varphi}^0(x)$, *and there exists* $\varphi_1^0 \in L^2(\Omega)$ *such that*

$$\int_\Omega z_1(x)\varphi_1^0(x)dx \ne -\int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\varphi_1(x,t)dxdt,$$

where φ_1 *is the solution of* (4.5) *with* $\varphi_1(x,t_1)=\varphi_1^0(x)$. *Then,* $\bar{\varphi}^0 \ne 0$ *and for any* $\theta^0 \in L^2(\Omega)$ *and* θ, *which is the solution of* (4.5) *with* $\theta(x,t_1)=\theta^0(x)$, *we have*

$$\begin{aligned}\int_{Q_{t_1}} \bar{\varphi}(x,t)\,\theta(x,t)dxdt &= \int_\Omega z_1(x)\theta^0(x)dx - \int_\Omega \varepsilon\frac{\bar{\varphi}^0(x)}{\|\bar{\varphi}^0\|_{2,\Omega}}\theta^0(x)dx \\ &\quad + \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\theta(x,t)dxdt.\end{aligned} \tag{4.10}$$

Proof. First, we define $\varphi_m^0 = \frac{1}{m}\varphi_1^0$ so that

$$\begin{aligned}J(\varphi_m^0) &= \frac{1}{2m^2}\int_{Q_{t_1}} \varphi_1^2(x,t)dxdt - \frac{1}{m}\int_\Omega z_1(x)\varphi_1^0(x)dx + \varepsilon\frac{1}{m}\|\varphi_1^0\|_{2,\Omega} \\ &\quad - \frac{1}{m}\int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\varphi_1(x,t)dxdt.\end{aligned}$$

We may assume

$$\int_\Omega z_1(x)\varphi_1^0(x)dx + \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\varphi_1(x,t)dxdt > 0.$$

If it is not, we choose $\hat{\varphi}_1^0(x) = -\varphi_1^0(x)$ so that

$$\int_\Omega z_1(x)\hat{\varphi}_1^0(x)dx + \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\hat{\varphi}_1(x,t)dxdt > 0.$$

We can also choose sufficiently large m and sufficiently small ε such that $J(\varphi_m^0) < 0$. So, $J(\bar{\varphi}^0) < 0$. Since $J(0) = 0$, we have $\bar{\varphi}^0 \neq 0$.

For any $\theta^0 \in L^2(\Omega)$, set $\varphi_\rho^0 = \bar{\varphi}^0 + \rho\theta^0$, $\rho \in (-1,1)$. Let φ_ρ satisfy (4.5) with $\varphi_\rho(x,t_1) = \varphi_\rho^0(x)$. Then $\varphi_\rho(x,t) = \bar{\varphi}(x,t) + \rho\theta(x,t)$. We carry out the following calculation:

$$\begin{aligned}
J(\varphi_\rho^0) - J(\bar{\varphi}^0) &= \frac{1}{2}\int_{Q_{t_1}} [\varphi_\rho^2(x,t) - \bar{\varphi}^2(x,t)]dxdt \\
&+ \varepsilon\frac{1}{\|\varphi_\rho^0\| + \|\bar{\varphi}^0\|}\int_\Omega \Big[(\varphi_\rho^0(x))^2 - (\bar{\varphi}^0(x))^2\Big]dx \\
&- \int_\Omega z_1(x)\rho\theta^0(x)dx - \rho\int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\theta(x,t)dxdt \\
&= \rho\int_{Q_{t_1}} \bar{\varphi}(x,t)\theta(x,t)dxdt + \frac{1}{2}\rho^2\int_{Q_{t_1}} \theta^2(x,t)dxdt \\
&+ \varepsilon\frac{1}{\|\varphi_\rho^0\| + \|\bar{\varphi}^0\|}\int_\Omega \Big[2\rho\bar{\varphi}^0(x)\theta^0(x) + \rho^2(\theta^0(x))^2\Big]dx \\
&- \rho\int_\Omega z_1(x)\theta^0(x)dx - \rho\int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\theta(x,t)dxdt.
\end{aligned}$$

Dividing the above equality by ρ and letting $\rho \to 0$, since $0 = \delta J(\bar{\varphi}^0)$, we obtain (4.10). □

LEMMA 4.3. *System* (4.3) *is approximately controllable.*

Proof. For any $t_1 > 0$, $\varepsilon > 0$, there exists a unique $\bar{\varphi}^0$, which is the minimum function of functional (4.7). So there exists a unique solution $\bar{\varphi}(x,t)$ of (4.5) with $\bar{\varphi}(x,t_1) = \bar{\varphi}^0(x)$. Now, let $u(x,t) = \bar{\varphi}(x,t)$; that is,

$$\text{(4.11)} \quad \begin{cases} \dfrac{\partial}{\partial t}z(x,t) + \tilde{L}_n(w)z + \beta z + e^{-\beta t}\displaystyle\int_0^t f(e^{\beta s}w(x,s))ds = \bar{\varphi}(x,t) \quad \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \ \partial\Omega\times(0,T), \quad z(x,0) = 0 \ \text{ in } \ \Omega. \end{cases}$$

Multiplying (4.11) by $\theta(x,t)$, where $\theta(x,t)$ is the solution of problem (4.5) with $\theta(x,t_1) = \theta^0(x)$, and integrating by parts the resulting relation over Q_{t_1}, we obtain

$$\begin{aligned}
&\int_\Omega z(x,t_1)\theta^0(x)\,dx + \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\theta(x,t)dxdt \\
&\qquad = \int_{Q_{t_1}} \bar{\varphi}(x,t)\theta(x,t)dxdt.
\end{aligned}$$

Using (4.10), we have

$$\int_\Omega \left[z(x,t_1) - z_1(x) + \varepsilon \frac{\bar{\varphi}^0(x)}{\|\bar{\varphi}^0\|_{2,\Omega}} \right] \theta^0(x)dx = 0 \quad \forall\ \theta^0 \in L^2(\Omega).$$

From this equality, we see that $\|z(\cdot,t_1) - z_1\|_{2,\Omega} \le \varepsilon$. □

COROLLARY 4.1. *For $y_0 \in W^{1,p}(\Omega)$ and $w \in Z$, the system*

$$\text{(4.12)} \quad \begin{cases} \dfrac{\partial}{\partial t} z(x,t) + \tilde{L}_n(w)z + \beta z + e^{-\beta t} \displaystyle\int_0^t f(e^{\beta s} w(x,s))ds = u(x,t) & \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \Omega \end{cases}$$

is approximately controllable.

Proof. Let z^1 and z^2 be solutions of the following problems, respectively:

$$\begin{cases} \dfrac{\partial}{\partial t} z^1(x,t) + \tilde{L}_n(w)z^1 + \beta z^1 + e^{-\beta t} \displaystyle\int_0^t f(e^{\beta s} w(x,s))ds = u(x,t) & \text{in } Q_T, \\ z^1(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z^1(x,0) = 0 \ \text{ in } \Omega, \end{cases}$$

$$\begin{cases} \dfrac{\partial}{\partial t} z^2(x,t) + \tilde{L}_n(w)z^2(x,t) + \beta z^2 = 0 & \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z^2(x,0) = y_0(x) \ \text{ in } \Omega. \end{cases}$$

It is easy to see that $z(x,t) = z^1(x,t) + z^2(x,t)$ is a solution of (4.12). Let

$$\text{(4.13)} \quad \begin{aligned} J(\varphi^0) = {} & \frac{1}{2} \int_{Q_{t_1}} \varphi^2(x,t)dxdt - \int_\Omega [z_1(x) - z^2(x,t_1)]\varphi^0(x)dx + \varepsilon \|\varphi^0\|_{2,\Omega} \\ & - \int_{Q_{t_1}} e^{-\beta t} \int_0^t f(e^{\beta s} w(x,s))ds \varphi(x,t)dxdt. \end{aligned}$$

From Lemma 4.3, we know that there exists $\bar{\varphi} \in W_2^{1,1}(Q_T)$ (see [9, p. 6]); when $u = \bar{\varphi}$, we have

$$\|z(\cdot,t_1) - z_1\|_{2,\Omega} = \|z^1(\cdot,t_1) - (z_1 - z^2(\cdot,t_1))\|_{2,\Omega} \le \varepsilon. \qquad \square$$

THEOREM 4.1. *Suppose condition* (H_1) *is fulfilled. Then system* (4.2) *is approximately controllable at t_1.*

Proof. From Corollary 4.1, we know that system (4.12) is approximately controllable. We define a map $F : Z = \{z \in V \ \mid \ |z|_V \le C^*\} \to Z$ by $F(w) = z$ for any $w \in Z$, with $z = z(x,t)$ being the solution of the equation

$$\text{(4.14)} \quad \begin{cases} \frac{\partial}{\partial t} z(x,t) + \tilde{L}_n(w)z(x,t) + \beta z + e^{-\beta t} \int_0^t f(e^{\beta s} w(x,s))ds = \bar{\varphi}(x,t) & \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \Omega, \end{cases}$$

where $\bar{\varphi}$ is the solution of problem (4.5) with $\bar{\varphi}(x,t_1) = \bar{\varphi}^0(x)$, and $\bar{\varphi}^0$ is the minimum function of the functional (4.13).

First, we should show that for sufficient large C^*, we have $F(Z) \subset Z$. In fact, multiplying (4.14) by z and integrating over Q_{t_1}, we have

$$
\begin{aligned}
|z|_V^2 &\le \left[\|\bar\varphi\|_{2,Q_T}^2 + \|y_0\|_{2,\Omega}^2 + \frac{1}{2}\int_{Q_{t_1}} \left(e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\right)^2 dxdt\right] \\
&\le \left[\frac{1}{\beta}\|\bar\varphi^0\|_{2,\Omega}^2 + \|y_0\|_{2,\Omega}^2 + t_1^2\int_{Q_{t_1}} (K^2w^2(x,t) + f^2(0))dxdt\right] \\
&\le \left[\frac{1}{\beta}\|\bar\varphi^0\|_{2,\Omega}^2 + \|y_0\|_{2,\Omega}^2 + T^2\|f(0)\|_{2,Q_T}^2 + \frac{T^2K^2}{\beta}|w|_V^2\right] \\
&\le \left[\frac{1}{\beta}\|\bar\varphi^0\|_{2,\Omega}^2 + \|y_0\|_{2,\Omega}^2 + T^2\|f(0)\|_{2,Q_T}^2 + \frac{T^2K^2}{\beta}(C^*)^2\right].
\end{aligned} \tag{4.15}
$$

From (4.13), we have

$$
\begin{aligned}
0 > J(\bar\varphi^0) > \frac{1}{2}\int_{Q_{t_1}} (\tilde\varphi(x,t))^2 dxdt\|\bar\varphi^0\|_{2,\Omega}^2 - \int_\Omega [z_1(x) - z^2(x,t_1)]\bar\varphi^0(x)dx \\
- \int_{Q_{t_1}} e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\bar\varphi(x,t)dxdt,
\end{aligned} \tag{4.16}
$$

where $\tilde\varphi(x,t)$ is the solution of (4.5) with $\tilde\varphi(x,t_1) = \frac{\bar\varphi^0(x)}{\|\bar\varphi^0\|_{2,\Omega}}$. Since $\tilde\varphi \in V$ and $\int_\Omega \tilde\varphi^2(x,t_1)dx = 1$, there exists a positive constant c_0, which is independent of $\tilde\varphi$, such that

$$
c_0 \le \frac{1}{2}\int_{Q_{t_1}} \tilde\varphi^2(x,t)dxdt.
$$

From (4.16), we obtain

$$
\begin{aligned}
c_0\|\bar\varphi^0\|_{2,\Omega}^2 &< C(\eta)\|z_1 - z^2(\cdot,t_1)\|_{2,\Omega}^2 + \eta\|\bar\varphi^0\|_{2,\Omega}^2 \\
&+ \frac{1}{2}\int_{Q_{t_1}} \left[e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\right]^2 dxdt + \frac{1}{2}\|\bar\varphi\|_{2,Q_{t_1}}^2 \\
&\le C(\eta)\|z_1 - z^2(\cdot,t_1)\|_{2,\Omega}^2 + \eta\|\bar\varphi^0\|_{2,\Omega}^2 \\
&+ \frac{T^2}{2}\int_{Q_{t_1}} [2K^2w^2(x,t) + 2f^2(x,t,0)]dxdt + \frac{1}{2\beta}\|\bar\varphi^0\|_{2,\Omega}^2,
\end{aligned} \tag{4.17}
$$

where we have used the inequality $\|\bar\varphi\|_{2,Q_{t_1}}^2 \le \frac{1}{\beta}\|\bar\varphi^0\|_{2,\Omega}^2$. Furthermore, we choose $\eta = \frac{c_0}{4}$ and $\frac{1}{2\beta} \le \frac{c_0}{4}$ so that

$$
\begin{aligned}
\|\bar\varphi^0\|_{2,\Omega}^2 &\le \frac{2}{c_0}\left[C(\eta)\|z_1 - z^2(\cdot,t_1)\|_{2,\Omega}^2 + \frac{T^2K^2}{\beta}|w|_V^2 + T^2\|f(0)\|_{2,Q_T}^2\right] \\
&\le \frac{2C(\eta)}{c_0}\|z_1 - z^2(\cdot,t_1)\|_{2,\Omega}^2 + \frac{2T^2}{c_0}\|f(0)\|_{2,Q_T}^2 + \frac{2T^2K^2}{c_0\beta}(C^*)^2.
\end{aligned}
$$

Substituting this inequality into (4.15), we have

$$
\begin{aligned}
|z|_V^2 &\le \frac{2C(\eta)}{c_0\beta}\|z_1 - z^2(\cdot,t_1)\|_{2,\Omega}^2 + \|y_0\|_{2,\Omega}^2 \\
&+ \left(T^2 + \frac{2T^2}{c_0\beta}\right)\|f(0)\|_{2,Q_T}^2 + \frac{T^2K^2}{\beta}\left(1 + \frac{2}{c_0\beta}\right)(C^*)^2.
\end{aligned} \tag{4.18}
$$

We can choose sufficiently large β such that $\frac{TK^2}{\beta}(1+\frac{2}{c_0\beta})=\frac{1}{2}$. Set

$$(C^*)^2=2\left[\frac{2C(\eta)}{c_0\beta}\|z_1-z^2(\cdot,t_1)\|^2_{2,\Omega}+\|y_0\|^2_{2,\Omega}+\left(T^2+\frac{2T^2}{c_0\beta}\right)\|f(0)\|^2_{2,Q_T}\right].$$

Then, from (4.18), we have $|z|^2_V\le(C^*)^2$. This implies that $F(Z)\subset Z$.

Next, we shall prove that F is a continuous map. Set $F=F_3\circ F_2\circ F_1$, where $F_1:Z\to L^2(\Omega)$, $F_2:L^2(\Omega)\to V\cap L^\infty(\bar{Q}_T)$, $F_3:V\to Z$; that is,

$$F_1(w)=\bar{\varphi}^0,\quad F_2(\bar{\varphi}^0)=\bar{\varphi},\quad F_3(\bar{\varphi})=z.$$

From (4.4) and (4.6), it is easy to see that F_2 and F_3 are continuous maps. So, we need only to prove that F_1 is a continuous map.

Suppose $w_k\in Z$, $w\in Z$, and $w_k\to w$ in Z; we prove that $F_1(w_k)\to F_1(w)$ in $L^2(\Omega)$. Set $\bar{\varphi}^0_k=F_1(w_k)$, $\bar{\varphi}^0=F_1(w)$; $\bar{\varphi}_k$ and $\bar{\varphi}$ are solutions of (4.5) with $\bar{\varphi}_k(x,t_1)=\bar{\varphi}^0_k(x)$, $\bar{\varphi}(x,t_1)=\bar{\varphi}^0(x)$, respectively. We have $\|\bar{\varphi}^0_k\|_{2,\Omega}\le C$ and $\|\bar{\varphi}_k\|_V\le C$. So there exist subsequences $\bar{\varphi}^0_{k_i}$ of $\bar{\varphi}^0_k$ and $\tilde{\varphi}^0\in L^2(\Omega)$ such that $\bar{\varphi}^0_{k_i}\to\tilde{\varphi}^0$ weakly in $L^2(\Omega)$, and $\bar{\varphi}_{k_i}\to\bar{\varphi}$ weakly in V.

For any $\varphi^0\in L^2(\Omega)$, we have $J(\bar{\varphi}^0_k,w_k)\le J(\varphi^0,w_k)$ and

$$J(\tilde{\varphi}^0,w)\le\lim_{k_i\to\infty}J(\bar{\varphi}^0_{k_i},w_{k_i}).$$

This implies

$$J(\tilde{\varphi}^0,w)\le\lim_{k_i\to\infty}J(\bar{\varphi}^0_{k_i},w_{k_i})\le\lim_{k_i\to\infty}J(\varphi^0,w_{k_i})=J(\varphi^0,w).$$

Thus, $\tilde{\varphi}^0$ is the minimal function of $J(\cdot,w)$. According to the uniqueness of the minimal function for $J(\cdot,w)$, we have $\tilde{\varphi}^0=\bar{\varphi}^0$.

Since $\bar{\varphi}_{k_i}\to\bar{\varphi}$ weakly in V, so $\bar{\varphi}_{k_i}\to\bar{\varphi}$ strongly in $L^2(\Omega)$. Thus,

$$\begin{aligned}\lim_{k_i\to\infty}&\left[\int_{Q_{t_1}}\bar{\varphi}^2_{k_i}(x,t)dxdt-\int_\Omega[z_1(x)-z^2(x,t_1)]\bar{\varphi}^0_{k_i}(x)dx\right.\\&\left.-\int_{Q_{t_1}}e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\bar{\varphi}_{k_i}(x,t)dxdt\right]\\&=\int_{Q_{t_1}}\bar{\varphi}^2(x,t)dxdt-\int_\Omega[z_1(x)-z^2(x,t_1)]\bar{\varphi}^0(x)dx\\&\quad-\int_{Q_{t_1}}e^{-\beta t}\int_0^t f(e^{\beta s}w(x,s))ds\bar{\varphi}(x,t)dxdt.\end{aligned}$$

Thus, from (4.7), we have $\lim_{k_i\to\infty}\|\bar{\varphi}^0_{k_i}\|_{2,\Omega}=\|\bar{\varphi}^0\|_{2,\Omega}$. Furthermore, we have $\lim_{k_i\to\infty}\|\bar{\varphi}^0_{k_i}-\bar{\varphi}^0\|_{2,\Omega}=0$.

We need to show that $\lim_{k\to\infty}\|\bar{\varphi}^0_k-\bar{\varphi}^0\|_{2,\Omega}=0$. If it is not true, then there exists a subsequence $\{\bar{\varphi}^0_{k_i}\}$ such that $\bar{\varphi}^0_{k_i}$ does not converge to $\bar{\varphi}^0$; that is, there exists a number $\delta>0$ such that $\|\bar{\varphi}^0_{k_i}-\bar{\varphi}^0\|_{2,\Omega}\ge\delta$ for all k_i. On the other hand, $\|\bar{\varphi}^0_{k_i}\|_{2,\Omega}\le C$. Using a similar argument as above, we obtain a subsequence $\{\bar{\varphi}^0_{k_i'}\}$ of $\{\bar{\varphi}^0_{k_i}\}$ with $\lim_{k_i'\to\infty}\|\bar{\varphi}^0_{k_i'}-\bar{\varphi}^0\|_{2,\Omega}=0$. This contradicts $\|\bar{\varphi}^0_{k_i}-\bar{\varphi}^0\|_{2,\Omega}\ge\delta>0$. So, $\lim_{k\to\infty}\|\bar{\varphi}^0_k-\bar{\varphi}^0\|_{2,\Omega}=0$. Thus, we have proved the continuity of F_1. Therefore, F is continuous.

Finally, we prove that F is a compact map. In fact, if $\{z_k\} \subset F(Z)$, then there exists $\{w_k\} \subset Z$ such that $z_k = F(w_k)$. Again, we choose $a_k \in C^\infty(Q_T)$ such that $\|(|e^{\beta t}\nabla w_k|^2 + \frac{1}{n})^{(p-2)/2} - a_k\|_{p,Q_T} < \frac{1}{k}$. Now consider the following problem:

$$\begin{cases} \dfrac{\partial}{\partial t}z(x,t) - \operatorname{div}\big[a_k(x,t)\nabla z(x,t))\big] + \beta z(x,t) \\ \qquad\qquad = u(x,t) - e^{-\beta t}\displaystyle\int_0^t f(e^{\beta s}w_k(x,s))ds =: \tilde{u}_k(x,t) \quad \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \Omega. \end{cases}$$

From [9, Chapter 4], we know that there exists a solution $\tilde{z}_k \in W$ to the above problem and $\|\tilde{z}_k\|_W \le C\|\tilde{u}_k\|_{p,Q_T} \le C$. According to Sobolev's embedding theorem, there exists a subsequence $\{\tilde{z}_{k_i}\} \subset \{\tilde{z}_k\}$ such that $\{\tilde{z}_{k_i}\}$ is a convergent sequence in $(V, |\cdot|_V)$. Since $\|\tilde{z}_k - z_k\|_V \le \frac{C}{k}$, we conclude that $\{z_{k_i}\}$ is a convergent sequence in V. Thus $F : Z \to Z$ is a continuous compact map. By Schauder's fixed point theorem, F has a fixed point z, and thus, system (4.14) becomes

$$\begin{cases} \dfrac{\partial}{\partial t}z(x,t) + \tilde{L}_n z(x,t) + \beta z + e^{-\beta t}\displaystyle\int_0^t f(e^{\beta s}z(x,s))ds = \bar{\varphi}(x,t) \quad \text{in } Q_T, \\ z(x,t) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad z(x,0) = y_0(x) \ \text{ in } \Omega, \end{cases}$$

and

$$\|z(\cdot,t_1) - z_1\|_{2,\Omega} \le \varepsilon.$$

This proves that (2.1) is approximately controllable.

Now, we give the proof of Theorem 1.3.

Proof. To complete the proof of Theorem 1.3, we need only to prove the following conclusion: For any $\varepsilon > 0$, there is a N such that $n > N$ implies

$$\| \ y_n(\cdot,t_1) - y(\cdot,t_1) \ \|_{2,\Omega} < \varepsilon,$$

where y and y_n are solutions of problems (1.1) and (2.1), respectively.

In fact, we repeat the argument in section 2 by setting $z_n = e^{-\beta s}y_n$ and $z = e^{-\beta s}y$, $\beta > K$. From (1.1) and (2.1), we find

$$(4.19)\quad \begin{cases} \dfrac{\partial}{\partial t}(z_n - z) - \operatorname{div}\Bigg[\left(|e^{\beta t}\nabla z_n(x,t)|^2 + \dfrac{1}{n}\right)^{(p-2)/2}\nabla z_n(x,t) \\ \qquad - \left(|e^{\beta t}\nabla z(x,t)|^2 + \dfrac{1}{n}\right)^{(p-2)/2}\nabla z(x,t)\Bigg] + \beta(z_n - z) \\ \qquad = \operatorname{div}\left\{\left[\left(|e^{\beta t}\nabla z(x,t)|^2 + \dfrac{1}{n}\right)^{(p-2)/2} - |e^{\beta t}\nabla z(x,t)|^{p-2}\right]\nabla z(x,t)\right\} \\ \qquad + \ e^{-\beta t}\displaystyle\int_0^t [f(e^{\beta s}z(x,s)) - f(e^{\beta s}z_n(x,s))]ds \quad \text{in } Q_T, \\ (z_n - z) = 0 \ \text{ on } \partial\Omega \times (0,T), \quad (z_n - z)(x,0) = 0 \ \text{ in } \Omega. \end{cases}$$

Multiplying (4.19) by $z_n - z$ and integrating in Q_{t_1}, we obtain

$$\begin{aligned}
&\frac{1}{2} \parallel z_n(\cdot,t_1) - z(\cdot,t_1) \parallel^2_{2,\Omega} \\
&\quad \le \int_{Q_{t_1}} \Bigg[\left(|e^{\beta t}\nabla z(x,t)|^2 + \frac{1}{n} \right)^{(p-2)/2} \\
&\qquad - \ |e^{\beta t}\nabla z(x,t)|^{p-2} \Bigg] \nabla z(x,t) \nabla (z(x,t) - z_n(x,t)) dxdt = I.
\end{aligned} \tag{4.20}$$

If $2 < p \le 4$, we set

$$Q_\eta = \{(x,t) \in Q_{t_1} \,|\, |e^{\beta t}\nabla z(x,t)| \ge \eta\}.$$

For any $\varepsilon > 0$, we can find an $\eta > 0$ such that

$$\begin{aligned}
I_1 = \int_{Q_{t_1} \setminus Q_\eta} &\Bigg[\left(|e^{\beta t}\nabla z(x,t)|^2 + \frac{1}{n} \right)^{(p-2)/2} \\
&- \ |e^{\beta t}\nabla z(x,t)|^{p-2} \Bigg] \nabla z(x,t) \nabla (z(x,t) - z_n(x,t)) dxdt < \frac{\varepsilon^2}{4},
\end{aligned}$$

$$\begin{aligned}
I_2 = \int_{Q_\eta} &\Bigg[\left(|e^{\beta t}\nabla z(x,t)|^2 + \frac{1}{n} \right)^{(p-2)/2} \\
&- \ |e^{\beta t}\nabla z(x,t)|^{p-2} \Bigg] \nabla z(x,t) \nabla (z(x,t) - z_n(x,t)) dxdt \\
&= \frac{p-2}{2} \frac{1}{n} \int_{Q_\eta} \left(|e^{\beta t}\nabla z(x,t)|^2 + \theta(x,t)\frac{1}{n} \right)^{(p-4)/2} \nabla z(x,t) \nabla (z(x,t) - z_n(x,t)) dxdt \\
&\le \frac{p-2}{2} \frac{1}{n} \left(\frac{1}{\eta^2} \right)^{(4-p)/2} \int_{Q_\eta} \nabla z(x,t) \nabla (z(x,t) - z_n(x,t)) dxdt \\
&< \frac{C}{n} \|\nabla z\|_{2,Q_\eta} \|\nabla (z - z_n)\|_{2,Q_\eta} = \frac{C_1}{n}.
\end{aligned}$$

Thus, there exists a number N, such that $n > N$ implies $I_2 < \frac{\varepsilon^2}{4}$. So we have

$$\frac{1}{2} \parallel z_n(\cdot,t_1) - z(\cdot,t_1) \parallel^2_{2,\Omega} \le I = I_1 + I_2 < \frac{\varepsilon^2}{2},$$

that is, $\|z_n(\cdot,t_1) - z(\cdot,t_1)\|_{2,\Omega} \le \varepsilon$.

If $p > 4$, from (4.20), we have

$$
\begin{aligned}
I &= \frac{p-2}{2}\frac{1}{n}\int_{Q_{t_1}} \left(|e^{\beta t}\nabla z(x,t)|^2 + \theta(x,t)\frac{1}{n}\right)^{(p-4)/2} \nabla z(x,t)\nabla(z(x,t) - z_n(x,t))dxdt \\
&\le \frac{p-2}{2}\frac{1}{n}2^{(p-4)/2}\int_{Q_{t_1}\setminus Q_1} |\nabla z(x,t)||\nabla(z(x,t) - z_n(x,t))|dxdt \\
&+ \frac{p-2}{2}\frac{1}{n}(2e^{\beta T})^{(p-4)/2}\int_{Q_1} |\nabla z(x,t)|^{p-3}|\nabla(z(x,t) - z_n(x,t))|dxdt \\
&\le \frac{C_{21}}{n}\|\nabla z\|_{2,Q_{t_1}}\|\nabla(z - z_n)\|_{2,Q_{t_1}} \\
&+ \frac{C_{22}}{n}\int_0^{t_1}\left(\int_\Omega |\nabla z(x,t)|^p dx\right)^{(p-3)/p}\left(\int_\Omega |\nabla(z(x,t) - z_n(x,t))|^{p/3}dx\right)^{3/p} dt \\
&\le \frac{C_{21}}{n}\|\nabla z\|_{2,Q_{t_1}}\|\nabla(z - z_n)\|_{2,Q_{t_1}} \\
&+ \frac{C_{22}^*}{n}\|z\|^{p-3}_{L^\infty(0,T;W^{1,p}(\Omega))}\|z - z_n\|_{L^\infty(0,T;W^{1,p}(\Omega))} \\
&= \frac{C_2}{n}.
\end{aligned}
$$

Thus, there exists a number N such that $n > N$ implies

$$\| z_n(\cdot,t_1) - z(\cdot,t_1) \|^2_{2,\Omega} \le C\frac{1}{n} \le \varepsilon^2.$$

The proof of Theorem 1.3 is complete. □

A CONVEX OPTIMIZATION APPROACH TO ARMA(n,m) MODEL DESIGN FROM COVARIANCE AND CEPSTRAL DATA*

P. ENQVIST†

Abstract. Methods for determining ARMA(n,m) filters from covariance and cepstral estimates are proposed. In [C. I. Byrnes, P. Enqvist, and A. Lindquist, *SIAM J. Control Optim.*, 41 (2002), pp. 23–59], we have shown that an ARMA(n,n) model determines and is uniquely determined by a window $r_0, r_1, \dots, r_n$ of covariance lags and $c_1, c_2, \dots, c_n$ of cepstral lags. This unique model can be determined from a convex optimization problem which was shown to be the dual of a maximum entropy problem. In this paper, generalizations of this problem are analyzed. Problems with covariance lags $r_0, r_1, \dots, r_n$ and cepstral lags $c_1, c_2, \dots, c_m$ of different lengths are considered, and by considering different combinations of covariances, cepstral parameters, poles, and zeros, it is shown that only zeros and covariances give a parameterization that is consistent with generic data.

However, the main contribution of this paper is a regularization of the optimization problems that is proposed in order to handle generic data. For the covariance and cepstral problem, if the data does not correspond to a system of desired order, solutions with zeros on the boundary occur and the cepstral coefficients are not interpolated exactly. In order to achieve strictly minimum phase filters for estimated covariance and cepstral data, a barrier-like term is introduced to the optimization problem. This term is chosen so that convexity is maintained and so that the unique solution will still interpolate the covariances but only approximate the cepstral lags. Furthermore, the solution will depend analytically on the covariance and cepstral data, which provides robustness, and the barrier term increases the entropy of the solution.

Key words. cepstrum, covariance, ARMA, entropy, convex optimization

1. Introduction.

In this paper some new methods for determining autoregressive (AR), moving average (MA), and ARMA filters from a finite sample of data are analyzed. These methods are based on an optimization approach to interpolation first introduced in [6] and then extended in various directions in [5, 8, 3, 4]. In particular, the data is matched using two different sets of characterizing parameters, that is, covariance lags and cepstral lags. Before going into details, the basic system identification problem considered here is described.

Let

$$w(z) = \frac{\sigma(z)}{a(z)}$$

be a real rational function, where z denotes a forward shift operator and

$$a(z) = a_0 z^n + a_1 z^{n-1} + \cdots + a_n \qquad (a_0 > 0), \tag{1.1}$$

$$\sigma(z) = z^m + \sigma_1 z^{m-1} + \cdots + \sigma_m \tag{1.2}$$

are stable polynomials, i.e., real polynomials having all their roots in the open unit disc. Consider the zero-mean stationary process $\{Y_t\}_{t=-\infty}^{\infty}$ obtained by passing a

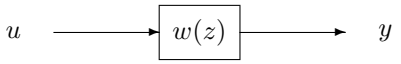

FIG. 1.1. *Shaping filter.*

white noise $\{U_t\}_{t=-\infty}^{\infty}$ through a filter with transfer function $w(z)$, as depicted in Figure 1.1, and let the system come to steady state. Such a process is called an *ARMA*(n, m) *process*, and the corresponding model

$$a_0 y_t + a_1 y_{t-1} + \cdots + a_n y_{t-n} = u_t + \sigma_1 u_{t-1} + \cdots + \sigma_m u_{t-m} \tag{1.3}$$

is called an ARMA(n, m) model. The stable polynomial $\sigma(z)$ defines the MA part, or the zeros of the filter, while the stable polynomial $a(z)$ defines the AR part, or the poles of the filter. Assume that the stochastic process $\{Y_t\}_{t=-\infty}^{\infty}$ is observed for $t = 1, \ldots, N$ to generate a string $\{y_t\}_{t=1}^{N}$ of data. In system identification the filter $w(z)$ that "best" matches the data $\{y_t\}_{t=1}^{N}$ is chosen in some prescribed class of models. The class of models that will be considered in this paper is the ARMA(n,m) filters. It will be assumed that the ARMA filters in the model class will be of fixed order, but how to choose the model class parameters m and n is not considered in this paper.

Design of AR, MA, and ARMA filters have a long history, and a number of different approaches have been used. Most methods minimize some error criterion over a set of parameterized models determining a model class. These approaches include, e.g., the maximum likelihood (ML) method [1], prediction error (PE) methods [18, 23], and others [14, 21, 16]. Even subspace methods [25] are based on optimization, but there the solution is given analytically by projections. This is appreciated in applications, but the subspace methods may yield a solution that is outside of the model class (e.g., nonstable models [10]), which is the main drawback of this approach. A common problem for the other methods mentioned above is that they may fail to deliver the global optima in the model class. For the ML and PE methods the error criterion function is not convex in the model parameters. This may lead to the minimization procedure getting stuck in a local optima which may be very different from the optimal solution. Consequently, although these methods are used with great success, they are not guaranteed to converge to a global optima.

The methods proposed in this paper can be used for system identification performed in two steps. The first step is the estimation of covariances and cepstral parameters from real data, and the second step determines the model that (approximatively) interpolates the estimated parameters. This is sometimes called estimation by the method of moments. In this paper we analyze only the second step. The proposed interpolation-based identification methods can be seen as generalizations of the widely used linear predictive coding (LPC) method [22], also called the maximum entropy method [2], which interpolates a set of covariances with an AR filter. The LPC method applies exact interpolation of estimated covariances, but as Burg describes it [2, p. xi], "Maximum entropy spectral analysis is based on choosing the spectrum which corresponds to the most random or the most unpredictable time series whose autocorrelation function agrees with the known values." The LPC filter parameters can be determined from a linear equation system. In the methods proposed in this paper the solution is derived from a well-behaved optimization problem. In fact, the information about the process is used in such a way that full ARMA models can be

designed using a convex error criterion. Since the optimization problems are convex there are no problems with local optima and there are optimization procedures that can be guaranteed to converge to the global optima for all initial points.

Next, the interpolation parameters are considered and standard methods for estimating them from data are presented.

The *covariances* of the stochastic process $\{Y_t\}_{t=-\infty}^{\infty}$ are defined by the second order moments

$$r_k \stackrel{\triangle}{=} \mathrm{E}(Y_t Y_{t+k}), \quad k = 0, 1, \ldots.$$

Taking the Fourier transform of the covariances, the *spectral density*

$$\Phi(e^{i\theta}) \stackrel{\triangle}{=} \sum_{k=-\infty}^{\infty} r_k e^{-ik\theta}$$

of the process is obtained. We will assume the estimated spectral densities are *coercive*, i.e., positive and bounded away from zero on the unit circle. For the sake of reference, we note that

$$r_k = \langle z^k, \Phi \rangle = \langle z^{-k}, \Phi \rangle, \quad k = 0, 1, 2, \ldots, \tag{1.4}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in the real $L_2[-\pi, \pi]$ space, i.e.,

$$\langle f, g \rangle \stackrel{\triangle}{=} \frac{1}{2\pi i} \int_{|z|=1} f(z)\overline{g(z)}\, \frac{dz}{z} = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{i\theta}) g(e^{-i\theta})\, d\theta. \tag{1.5}$$

If the process is generated by a shaping filter $w(z)$, the spectral density can be extended to a Laurent series, valid in an annulus around the unit circle, given by

$$\Phi(z) \stackrel{\triangle}{=} \sum_{k=-\infty}^{\infty} r_k z^{-k} = w(z) w(z^{-1}). \tag{1.6}$$

The last equality in (1.6) gives an important relation between the spectral density and the shaping filter. If all covariances were known, the shaping filter $w(z)$ could be determined from Φ by spectral factorization [23, 9]. However, only a finite number of covariances can be estimated, and then the spectral density is not completely determined. The covariances $r_0, r_1, \ldots, r_n$ can be estimated from data using ergodic estimates. For example, the estimate

$$\hat{r}_k = \frac{1}{N} \sum_{j=1}^{N-k} y_j y_{j+k}, \quad k \ll N, \tag{1.7}$$

can be used. This particular estimate has the nice property that the matrix of estimated covariances

$$\mathbf{R}_n \stackrel{\triangle}{=} \begin{bmatrix} \hat{r}_0 & \hat{r}_1 & \ldots & \hat{r}_n \\ \hat{r}_1 & \hat{r}_0 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \hat{r}_1 \\ \hat{r}_n & \ldots & \hat{r}_1 & \hat{r}_0 \end{bmatrix} \tag{1.8}$$

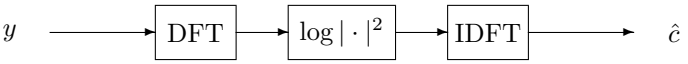

FIG. 1.2. *Cepstral estimation.*

is positive definite. The set of covariances $\hat{r}_0, \hat{r}_1, \ldots, \hat{r}_n$ such that $\mathbf{R}_n$ is positive definite is denoted by $\mathcal{R}_n$. For more about the statistical properties of the estimation of covariances, the reader is referred to [23, 17].

Since the spectral density is a positive function on the unit circle, its logarithm is well defined, and it has a Laurent series expansion in a neighborhood of the unit circle given by

$$\log \Phi(z) = \sum_{k=-\infty}^{\infty} c_k z^{-k}. \tag{1.9}$$

This defines the *cepstral coefficients*

$$c_k = \langle z^k, \log \Phi \rangle, \quad k = 0, 1, 2, \ldots. \tag{1.10}$$

A finite window of the cepstrum coefficients can also be estimated directly from data using ergodic estimates. In particular, taking the DFT of the data $\{y_j\}_{j=1}^N$, the absolute value square, the logarithm and the IDFT determines an estimate of the cepstrum [22, 13] as depicted in Figure 1.2. However, the problem of estimating cepstral coefficients directly from data is not by far as well analyzed as the problem of estimating covariances.

Two new design methods are presented in this paper. The first method is a regularization of the *cepstral-covariance matching* (CCM) method introduced in [3]. The CCM method determines an ARMA filter that simultaneously interpolates a finite window of covariances and cepstral lags, if that is possible, using a convex optimization formulation. In this paper an approximation in the interpolation of the cepstral parameters is introduced to make the global optima correspond to a stable minimum phase filter for generic covariance and cepstral estimates.

The second method is based on covariance matching. It is well known that design of MA models using covariance interpolation constraints lacks solutions for generic covariances. In this case some approximation in the covariance interpolation constraints is necessary, and an approximation similar to the one used for the CCM method is proposed.

The outline of this paper is as follows. In section 2, the optimization problem from [3] for determining the covariance and cepstrum interpolating filter is restated and analyzed. Actually, it is stated in a slightly more general form, allowing for ARMA(n,m) models, and the relation of poles and zeros to covariances and cepstral lags is discussed. In section 3, duality theory from mathematical programming is used for deriving some new optimization problems for solving interpolation problems. In section 4, a regularization of the CCM filter optimization problem is determined. By adding a barrier-like term to the objective function, stable minimum phase models are obtained at the price of approximate cepstral interpolation. It is also shown that the barrier term increases the entropy of the resulting model. In section 5, a regularization of an optimization problem derived in section 3 for designing zeros based on covariance interpolation is determined. By adding the same barrier-like term to this objective

function, stable minimum phase models are obtained at the price of approximate covariance interpolation. The barrier term is shown to increase the entropy of the resulting model. In section 6, a number of experiments are carried out in order to compare the method to other methods that are also well posed [24, 20].

2. Local coordinates for ARMA models in terms of cepstral and covariance windows. As a preliminary and to fix notation, pertinent facts on a method introduced in [3, 4] are now reviewed. As described in the introduction, the aim of this problem is to interpolate the covariances $r_0, r_1, \ldots, r_n \in \mathcal{R}_n$ and the cepstral coefficients $c_1, \ldots, c_m$. Therefore, the resulting filter is called a CCM filter [3].

The spectral density corresponding to a stable ARMA(n,m) filter can be parameterized as

$$\Phi = \frac{P}{Q},$$

where P and Q are pseudopolynomials

$$P(z) = p_0 + \frac{1}{2}p_1(z + z^{-1}) + \cdots + \frac{1}{2}p_m(z^m + z^{-m}), \tag{2.1}$$

$$Q(z) = q_0 + \frac{1}{2}q_1(z + z^{-1}) + \cdots + \frac{1}{2}q_n(z^n + z^{-n}) \tag{2.2}$$

such that $P(z) \in \hat{\mathcal{D}}_m^+$ and $Q(z) \in \mathcal{D}_n^+$, where $\hat{\mathcal{D}}_m^+$ and $\mathcal{D}_n^+$ are defined next.

Let $\mathcal{D}_n$ denote the class of real symmetric pseudopolynomials of degree at most n which are nonnegative on the unit circle, and let $\mathcal{D}_n^+$ be the subclass of all $D \in \mathcal{D}_n$ which are positive on the unit circle. Moreover, let $\boldsymbol{\mathcal{D}}_n$ and $\boldsymbol{\mathcal{D}}_n^+$ be the corresponding $(n+1)$-vectors of coefficients. In this notation, $P \in \mathcal{D}_m^+$, $Q \in \mathcal{D}_n^+$, $\mathbf{p} := (p_0, p_1, \ldots, p_m) \in \boldsymbol{\mathcal{D}}_m^+$, and $\mathbf{q} := (q_0, q_1, \ldots, q_n) \in \boldsymbol{\mathcal{D}}_n^+$. Finally, let $\hat{\mathcal{D}}_m^+$ and $\hat{\boldsymbol{\mathcal{D}}}_m^+$ be the subsets of $P \in \mathcal{D}_m^+$ and $\mathbf{p} \in \boldsymbol{\mathcal{D}}_m^+$, respectively, which have been normalized so that $p_0 = 1$. Clearly, these are all convex sets.

The following theorem is a generalization of Theorem 3.1 in [3] (see also Theorem 3.1 in [4]) in that it allows for $m \neq n$.

THEOREM 2.1. *Each* ARMA(n, m) *model* (1.3) *such that the polynomials* σ *and* a *are coprime determines and is uniquely determined by its window* $r_0, r_1, \ldots, r_n$ *of covariance lags and its window* $c_1, c_2, \ldots, c_m$ *of cepstral coefficients.*

Consequently, there is a one-to-one correspondence between the $n + m + 1$ coefficients $r_0, r_1, \ldots, r_n, c_1, c_2, \ldots, c_m$ and the $n + m + 1$ coefficients $a_0, a_1, \ldots, a_n$, $\sigma_1, \sigma_2, \ldots, \sigma_m$, provided σ and a are coprime. The proof is mutatis mutandis the same as in [3, 4]. The statement that $r_0, r_1, \ldots, r_n$, $c_1, c_2, \ldots, c_m$ are uniquely determined by $a_0, a_1, \ldots, a_n$, $\sigma_1, \sigma_2, \ldots, \sigma_m$ is trivial. The converse statement follows from the fact that the optimization problem

$$(\mathcal{P}) \quad \left[\begin{array}{ll} \min & \varphi(\mathbf{p}, \mathbf{q}), \\ \text{subject to (s.t.)} & (\mathbf{p}, \mathbf{q}) \in \hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n, \end{array} \right] \tag{2.3}$$

has a unique solution, which is an interior point whenever the coefficients $r_0, r_1, \ldots, r_n$, $c_1, c_2, \ldots, c_m$ are the exact theoretical ones. Here $\varphi : \hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n \to \mathbb{R}$ is the convex function

$$\varphi(\mathbf{p}, \mathbf{q}) \stackrel{\triangle}{=} -\sum_{k=1}^{m} c_k p_k + \sum_{k=0}^{n} r_k q_k + \left\langle P, \log \frac{P}{Q} \right\rangle. \tag{2.4}$$

In fact problem $(\mathcal{P})$ is the dual of maximizing the entropy

$$\mathcal{E}(\Phi) \triangleq \langle 1, \log \Phi \rangle \tag{2.5}$$

with covariance and cepstral interpolation constraints, and it has a solution in an interior point $(\tilde{\mathbf{p}}, \tilde{\mathbf{q}}) \in \hat{\boldsymbol{\mathcal{D}}}_m^+ \times \boldsymbol{\mathcal{D}}_n^+$ if and only if the gradient

$$\frac{\partial \varphi}{\partial p_k} = -c_k + \left\langle z^k, \log \frac{P}{Q} \right\rangle, \quad k = 1, \dots, m, \tag{2.6}$$

$$\frac{\partial \varphi}{\partial q_k} = r_k - \left\langle z^k, \frac{P}{Q} \right\rangle, \qquad k = 0, 1, \dots, n, \tag{2.7}$$

equals zero there. This happens precisely when

$$\left\langle z^k, \log \frac{P}{Q} \right\rangle = c_k, \quad k = 1, \dots, m, \tag{2.8}$$

$$\left\langle z^k, \frac{P}{Q} \right\rangle = r_k, \quad k = 0, 1, \dots, n, \tag{2.9}$$

which are the cepstral matching conditions (1.10) and the covariance matching conditions (1.4), respectively, when $\Phi = P/Q$.

However, for observed parameters $r_0, r_1, \dots, r_n, c_1, c_2, \dots, c_m$, which may be corrupted by measurement errors, or are otherwise generic, φ may fail to have an interior minimum. In this case, as shown in [4] using the methods of [6], the condition $\tilde{\mathbf{q}} \in \boldsymbol{\mathcal{D}}_n^+$ will nevertheless be satisfied so that the covariance matching condition (2.9) is fulfilled, whereas $\tilde{\mathbf{p}}$ will be on the boundary of $\hat{\boldsymbol{\mathcal{D}}}_m$. In section 4, problem $(\mathcal{P})$ will be regularized so that approximate cepstral matching is achieved for a $\tilde{\mathbf{p}} \in \hat{\boldsymbol{\mathcal{D}}}_m^+$.

It is clear that the number of covariance lags $r_0, r_1, \dots, r_n$ and cepstral parameters $c_1, \dots, c_m$, respectively, determines the number of poles and zeros of the ARMA(n,m) filter. This suggests that there is a deeper connection between the poles and the initial covariance lags, and between the zeros and the initial cepstral coefficients. The covariances are thus connected to the long-term effects of the filter and the cepstral parameters to the short-term effects. For example, a MA(m) filter can be determined as a special case when $n = 0$, where the zeros are determined using the cepstral parameters $c_1, \dots, c_m$ and the gain of the filter is determined by the variance r_0. The MA(m) filter has a finite impulse response—actually the impulse response is zero for lags larger than m—and thus only shapes the short-term response. In fact, for minimum phase systems the initial cepstral coefficients are equivalent to the initial impulse response parameters [4]. In case the long-term effects (i.e., the poles) of an ARMA(n,m) filter are known, the zeros can be designed by fixing the corresponding pseudopolynomial $Q \in \mathcal{D}_n^+$ in problem $(\mathcal{P})$. The amplification of the resulting filter has to be determined a posteriori, using, for example, the variance r_0. There is, however, no guarantee that there exists an ARMA(n,m) filter matching a generic cepstral sequence.

Using symmetrical arguments, an AR(n) filter can be determined as a special case when $m = 0$, where the poles are determined using the covariances $r_0, r_1, \dots, r_n \in \mathcal{R}_n$. This special case corresponds to the well-known LPC method. In case the short-term effects (i.e., the zeros) of an ARMA(n,m) filter are known, the poles can be designed by fixing the corresponding pseudopolynomial $P \in \mathcal{D}_n^+$ in problem $(\mathcal{P})$. The resulting optimization problem is thoroughly analyzed in [6, 11] and provides a solution to a

problem studied in [15, 7]. The filter designed with this method is called a *lattice-ladder notch* (LLN) filter [3], and it will always meet the covariance interpolation constraints. This problem is the starting point of the next section.

For curiosity it can be noted that the tails of the covariance and autocorrelation sequences hold similar complementary information. In [15] it was shown that the tail of the autocorrelation sequence asymptotically satisfies a recursion determined by the zeros. Similarly, it is well known that the tail of the covariances, and also the impulse response parameters, satisfies a recursion determined by the poles.

3. Optimization problems for cepstral and covariance interpolation. Next we consider four ARMA interpolation problems involving different combinations of covariances, cepstral parameters, poles and zeros as summarized in Table 3.1. By consistent we mean that there exists a matching ARMA model for each combination of valid parameters and by local coordinates we mean that the ARMA model locally depends analytically on the parameters.

TABLE 3.1
Summary of the interpolation problems.

Interpolation method	Consistent	Local coord.
Covariance matching with fixed numerator	Yes	Yes
Covariance matching with fixed denominator	No	Yes
Cepstral matching with fixed numerator	No	Yes
Cepstral matching with fixed denominator	No	Yes

Covariance matching with fixed numerator. Fixing P to be a given constant pseudopolynomial, the optimization problem $(\mathcal{P})$ is reduced to the problem $(\mathcal{P}_0)$ to minimize the strictly convex functional

$$\mathbb{J}_P(\mathbf{q}) \stackrel{\triangle}{=} \sum_{k=0}^{n} r_k q_k - \langle P, \log Q \rangle \tag{3.1}$$

over all $\mathbf{q} \in \boldsymbol{\mathcal{D}}_n^+$, i.e., the optimization problem introduced in [6]. As shown there, it has a unique solution $\hat{\mathbf{q}}$ which is an interior point, i.e., $\hat{\mathbf{q}} \in \boldsymbol{\mathcal{D}}_n^+$. This can be seen from the fact that

$$\frac{\partial \mathbb{J}_P}{\partial q_k} = r_k - \left\langle z^k, \frac{P}{Q} \right\rangle, \quad k = 0, 1, \ldots, n, \tag{3.2}$$

become infinite on the boundary of $\boldsymbol{\mathcal{D}}_n$. Setting the gradient (3.2) equal to zero, it is seen that $\hat{\Phi} = P/\hat{Q}$ satisfies the covariance matching condition

$$\langle z^k, \hat{\Phi} \rangle = r_k, \quad k = 0, 1, \ldots, n, \tag{3.3}$$

and that it is the unique such interpolant. This is the main result in [6].

In [3, 4] it was shown that this problem is the dual (in the sense of mathematical programming) of the problem of finding the unique spectral density Φ which minimizes the linear combination

$$p_0 c_0 + p_1 c_1 + \cdots + p_m c_m$$

of the cepstral coefficients

$$c_k \stackrel{\triangle}{=} \langle z^k, \log \Phi \rangle, \quad k = 0, 1, \ldots, m, \tag{3.4}$$

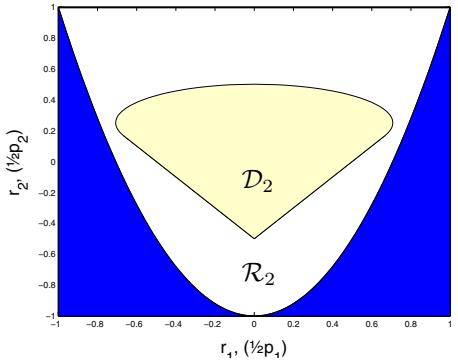

FIG. 3.1. *Comparison of the region of positive covariance sequences $\mathcal{R}_2$ and the region of positive pseudopolynomials $\mathcal{D}_2$.*

i.e., the functional

$$\langle P, \log \Phi \rangle$$

subject to the covariance matching condition (3.3). As a special case, we have the problem to maximize the entropy gain $\mathcal{E}(\Phi)$ subject to (3.3) which yields the well-known maximum entropy solution to the covariance extension problem. This duality is considered in [6].

Covariance matching with fixed denominator. Whereas, for each $P \in \mathcal{D}_m^+$, there is one and only one $Q \in \mathcal{D}_n^+$ such that

$$\Phi = \frac{P}{Q}$$

matches a prescribed window $r_0, r_1, \dots, r_n$ of covariance lags, in general there does not exist a Φ with a prescribed denominator Q matching $r_0, r_1, \dots, r_m$. This is illustrated by the following example, where $Q = 1$.

Example 3.1. Consider a MA(2) process defined by $\sigma(z) = z^2 + \sigma_1 z + \sigma_2$, and the corresponding pseudopolynomial $P = \sigma(z)\sigma(z^{-1})$ normalized so that $P \in \hat{\mathcal{D}}_2^+$. Then, in view of (1.6) and (2.1), $p_1/2$ and $p_2/2$ are the normalized covariances of the MA(2) process and they take values in the convex region $\mathcal{D}_2$ in Figure 3.1, defined by the curve $p_1 = 2\sqrt{2p_2(1-p_2)}$ and the lines $p_1 = 1 + p_2$ and $p_1 = -1 - p_2$. The covariances $r_0, r_1, r_2 \in \mathcal{R}_2$, normalized so that $r_0 = 1$, correspond to the convex region $\mathcal{R}_2$ restricted by the parabola $r_2 = 2r_1^2 - 1$ and the line $r_2 = 1$. It is clear that there does not exist a MA(2) process with covariances taken arbitrarily in $\mathcal{R}_2$. This is a special case of the fact that sample covariances do not form sufficient statistics for the MA parameter estimation problem.

Nonetheless, we may consider the optimization problem

$$(\mathcal{R}) \quad \left[\begin{array}{ll} \min\limits_{\mathbf{f} \in \boldsymbol{\mathcal{F}}^+} & \frac{1}{2}\langle \Phi^2, Q \rangle, \\ \text{s.t.} & \langle \Phi, z^k \rangle = r_k, \quad k = 0, 1, \dots, m, \end{array} \right]$$

where $\mathbf{f} = (f_0, f_1, \dots) \in \boldsymbol{\mathcal{F}}^+$ are the Fourier coefficients,

$$\Phi(z) = \sum_{k=-\infty}^{\infty} f_k z^{-k}, \quad f_{-k} = f_k,$$

to be chosen so that $\Phi(e^{i\theta}) > 0$.

Here the objective function

$$\mathbb{F}_Q(\mathbf{f}) \stackrel{\triangle}{=} \frac{1}{2}\langle \Phi^2, Q\rangle \tag{3.5}$$

puts a large cost on the peaks of Φ, at least where Q is not small, and this will thus provide a spectral density without unnecessary poles.

Taking $p_0, p_1, \ldots, p_m$ to be the Lagrange multipliers, the Lagrangian becomes

$$\begin{aligned} L_Q^{\mathcal{R}}(\mathbf{f}, \mathbf{p}) &= \frac{1}{2}\langle \Phi^2, Q\rangle - \sum_{k=0}^{m} p_k(\langle \Phi, z^k\rangle - r_k) \\ &= \sum_{k=0}^{m} p_k r_k + \frac{1}{2}\langle \Phi^2, Q\rangle - \langle \Phi, P\rangle. \end{aligned} \tag{3.6}$$

Clearly $\inf\{L_Q^{\mathcal{R}}(\mathbf{f}, \mathbf{p}) | \mathbf{f} \in \boldsymbol{\mathcal{F}}^+\} > -\infty$ if and only if $Q \in \mathcal{D}_n^+$. Then $\mathbf{f} \mapsto L_Q^{\mathcal{R}}(\mathbf{f}, \mathbf{p})$ has a unique minimum in $\hat{\mathbf{f}} \in \boldsymbol{\mathcal{F}}^+$ if and only if

$$\frac{\partial L_Q^{\mathcal{R}}}{\partial f_k} = \langle z^k, \Phi Q - P\rangle = 0, \quad k = 0, 1, 2, \ldots, \tag{3.7}$$

in this point, which in turn holds if and only if

$$\Phi = \frac{P}{Q},$$

requiring that $P \in \mathcal{D}_m^+$. Then, the dual functional $\psi : \boldsymbol{\mathcal{D}}_m^+ \to \mathbb{R}$ becomes

$$\begin{aligned} \psi(\mathbf{p}) &\stackrel{\triangle}{=} \inf_{\mathbf{f} \in \boldsymbol{\mathcal{F}}^+} L_Q^{\mathcal{R}}(\mathbf{f}, \mathbf{p}) \\ &= \sum_{k=0}^{n} r_k p_k - \frac{1}{2}\left\langle 1, \frac{P^2}{Q}\right\rangle. \end{aligned} \tag{3.8}$$

This is a strictly concave function. Consequently, we have the dual problem

$$(\mathcal{M}) \quad \left[\max_{\mathbf{p} \in \boldsymbol{\mathcal{D}}_m^+} \psi(\mathbf{p}) \right].$$

If there is a maximizing solution to problem $(\mathcal{M})$, then the gradient

$$\frac{\partial \psi}{\partial p_k} = r_k - \left\langle z^k, \frac{P}{Q}\right\rangle, \quad k = 0, 1, \ldots, m, \tag{3.9}$$

must be zero in this point, enforcing the covariance matching condition

$$\langle z^k, \Phi\rangle = r_k, \quad k = 0, 1, \ldots, m. \tag{3.10}$$

However, unlike (3.2), this gradient is finite on the boundary, and there is no reason why the optimum might not be there.

THEOREM 3.1. *If $Q \in \mathcal{D}_n^+$, then problem $(\mathcal{R})$ has a unique solution. Furthermore, if the dual function ψ has a maximum $\hat{\mathbf{p}} \in \boldsymbol{\mathcal{D}}_m^+$, which then must be unique, then*

$$\Phi = \frac{\hat{P}}{Q}$$

is the unique solution of problem $(\mathcal{R})$.

Proof. If $Q \in \mathcal{D}_n^+$, then $\mathbb{F}_Q(\mathbf{f})$ is strictly convex, and since the feasible region is the intersection of the convex cone $\boldsymbol{\mathcal{F}}^+$ and the linear constraints, problem $(\mathcal{R})$ has a unique optimum. Let $\hat{\mathbf{p}} \in \boldsymbol{\mathcal{D}}_m^+$ be the unique solution to the dual problem $(\mathcal{M})$, let $\hat{P} \in \mathcal{D}_n^+$ be the corresponding pseudopolynomial, and let

$$\hat{f}_k = \left\langle z^k, \frac{\hat{P}}{Q} \right\rangle.$$

Clearly $\hat{\mathbf{f}} \in \boldsymbol{\mathcal{F}}^+$. Since the gradient (3.9) is zero for $\mathbf{p} = \hat{\mathbf{p}}$, the covariance matching condition (3.10) is fulfilled for $\mathbf{f} = \hat{\mathbf{f}}$, and, therefore, $\mathbb{F}_Q(\hat{\mathbf{f}}) = L_Q^{\mathcal{R}}(\hat{\mathbf{f}}, \hat{\mathbf{p}})$. But by the construction above,

$$L_Q^{\mathcal{R}}(\hat{\mathbf{f}}, \hat{\mathbf{p}}) = \inf_{\mathbf{f} \in \boldsymbol{\mathcal{F}}^+} L_Q^{\mathcal{R}}(\mathbf{f}, \hat{\mathbf{p}}) \le L_Q^{\mathcal{R}}(\mathbf{f}, \hat{\mathbf{p}}) \quad \forall \mathbf{f} \in \boldsymbol{\mathcal{F}}^+.$$

Then for any $\mathbf{f} \in \boldsymbol{\mathcal{F}}^+$ which satisfies the covariance matching condition (3.10),

$$\mathbb{F}_Q(\mathbf{f}) = L_Q^{\mathcal{R}}(\mathbf{f}, \hat{\mathbf{p}}) \ge \mathbb{F}_Q(\hat{\mathbf{f}}),$$

which establishes the optimality of $\hat{\mathbf{f}}$. ∎

Cepstral matching with fixed denominator. An interesting question is whether a symmetric cepstral matching optimization problem can be formulated. That is, given a cepstral window

$$c_0, c_1, \dots, c_m,$$

consider the optimization problem to find a spectral density Φ which minimizes the linear combination

$$q_0 r_0 + q_1 r_1 + \cdots + q_n r_n$$

of theoretical covariances $r_k = \langle z^k, \Phi \rangle$ subject to the cepstral matching constraint

$$\langle z^k, \log \Phi \rangle = c_k, \quad k = 0, 1, \dots, m, \tag{3.11}$$

i.e., the optimization problem

$$(\mathcal{S}) \quad \left[\begin{array}{ll} \min\limits_{\mathbf{g} \in \boldsymbol{\mathcal{G}}} & \mathbb{I}_Q(\mathbf{g}), \\ \text{s.t.} & \langle \log \Phi, z^k \rangle = c_k, \quad k = 0, 1, \dots, m, \end{array} \right],$$

where

$$\mathbb{I}_Q(\mathbf{g}) \triangleq \langle \Phi, Q \rangle \tag{3.12}$$

and $\mathbf{g} = (g_0, g_1, \dots) \in \boldsymbol{\mathcal{G}}$ are the Fourier coefficients of the logarithm of the spectral density

$$\log \Phi(z) = \sum_{k=-\infty}^{\infty} g_k z^{-k}, \quad g_{-k} = g_k.$$

There is a dual optimization problem to problem $(\mathcal{S})$ (see [12]), namely, to find the supremum of

$$\mathbb{J}_Q(\mathbf{p}) = p_0 + \sum_{k=0}^{n} c_k p_k - \left\langle P, \log \frac{P}{Q} \right\rangle \tag{3.13}$$

over all $\mathbf{p} \in \boldsymbol{\mathcal{D}}_m$. Although this function is strictly concave, as is $-\mathbb{J}_P$, unlike $\mathbb{J}_P$ it may not have an optimum in the open region $\boldsymbol{\mathcal{D}}_m^+$. In fact, the gradient

$$\frac{\partial \mathbb{J}_Q}{\partial p_k} = c_k - \left\langle z^k, \log \frac{P}{Q} \right\rangle, \quad k = 0, 1, \ldots, n, \tag{3.14}$$

is finite on the boundary, by Szegö's theorem [9], so there is no guarantee that the stationary point is an interior point.

However, if there is a stationary point $\hat{\mathbf{p}} \in \boldsymbol{\mathcal{D}}_m^+$ at which the gradient (3.14) is zero, it is unique and

$$\hat{\Phi} = \frac{\hat{P}}{Q}$$

satisfies the cepstral matching condition (3.11).

THEOREM 3.2. *If $Q \in \mathcal{D}_n^+$, then problem $(\mathcal{S})$ has a unique solution. Furthermore, if the function $\mathbb{J}_Q$ has a maximum $\hat{\mathbf{p}} \in \boldsymbol{\mathcal{D}}_m^+$, which then must be unique, then*

$$\Phi = \frac{\hat{P}}{Q}$$

is the unique solution of problem $(\mathcal{S})$.

The proof follows the lines of Theorem 3.1 and is omitted.

Cepstral matching with fixed numerator. It is easy to see that we can instead prescribe the numerator polynomial P in cepstrum interpolation. In fact, if

$$\Phi = \frac{P}{Q}$$

is a coercive spectral density, then so is

$$\Phi^{-1} = \frac{Q}{P}.$$

Moreover, the cepstral matching condition (3.11) may be written as

$$\langle z^k, \log \Phi^{-1} \rangle = -c_k, \quad k = 0, 1, \ldots, n. \tag{3.15}$$

Consequently, there is an analogous optimization problem to find a coercive spectral density Φ minimizing

$$\langle \Phi^{-1}, P \rangle$$

subject to (3.15), which has a dual problem to maximize

$$\hat{\mathbb{J}}_P(\mathbf{q}) = q_0 - \sum_{k=0}^{n} c_k q_k - \left\langle Q, \log \frac{Q}{P} \right\rangle.$$

As before, an interpolant Φ with prescribed numerator P and prescribed cepstral window $(c_0, c_1, \dots, c_n)$ exists and is then unique if and only if $\hat{\mathbb{J}}_P$ has a maximum in $\boldsymbol{\mathcal{D}}_n^+$.

In this section some new optimization problems for cepstral and covariance matching have been proposed. However, like the simultaneous covariance and cepstral matching problem revisited in section 2, these problems do not have the consistency of problem $(\mathcal{P}_0)$ in that solutions may not exist (see Table 3.1). It is, therefore, natural to ask for good approximate solutions, based on the same principles. This will be done via regularization, a topic to be addressed in the next section.

4. Regularization of problem $(\boldsymbol{\mathcal{P}})$. Since the optimization problem $(\mathcal{P})$ defined in section 2 may have solutions on the boundary of the feasible region for $\mathbf{p}$, a regularization of that problem is proposed in this section. In order to force the solution to the interior of the feasible region, the optimization problem $(\mathcal{P})$ is modified by adding a barrier-like term to the objective function φ. In problem $(\mathcal{P}_0)$, the term $-\langle P, \log Q\rangle$ of the objective function $\mathbb{J}_P(\mathbf{q})$ pushes Q from the boundary. By adding the term $\beta = -\langle 1, \log P\rangle$ to the objective function φ of the problem $(\mathcal{P})$ the optimal P is forced into the interior of $\hat{\mathcal{D}}_m$.

It follows from [6] that $\beta = -\langle 1, \log P\rangle$ has bounded level sets, is finite for all $P \in \hat{\mathcal{D}}_m$, and has a derivative that tends to infinity as P tends to the boundary of $\hat{\mathcal{D}}_m$. It is further strictly convex in P. Since the function values of β are finite at the boundary, it is not a barrier function from a mathematical programming viewpoint [19], but since the derivatives of β with respect to P are infinite, it will constrain the optimum away from the boundary as a barrier function would. It is shown later that this term will also increase the entropy of the solution.

The regularized optimization problem is formulated as

$$(\mathcal{P}_\lambda) \quad \left[\begin{array}{ll} \min & \varphi_\lambda(\mathbf{p}, \mathbf{q}), \\ \text{s.t.} & (\mathbf{p}, \mathbf{q}) \in \hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n \end{array} \right],$$

where the modified objective function is given by

$$\varphi_\lambda(\mathbf{p}, \mathbf{q}) \triangleq -\sum_{k=1}^{m} c_k p_k + \sum_{k=0}^{n} r_k q_k + \left\langle P, \log \frac{P}{Q} \right\rangle - \langle \lambda, \log P\rangle. \tag{4.1}$$

LEMMA 4.1. *For each $\lambda > 0$, the function φ_λ has compact sublevel sets; i.e., for all $\mu \in \mathbb{R}$, $\varphi_\lambda^{-1}(-\infty, \mu]$ is compact.*

Proof. First note that the set $\hat{\boldsymbol{\mathcal{D}}}_m$ of all $\mathbf{p}$ such that $P \in \mathcal{D}_m$ and $p_0 = 1$ is compact. In fact, let

$$\sigma(z) = \sigma_0 z^m + \sigma_1 z^{m-1} + \cdots + \sigma_m$$

be the stable spectral factor of P, i.e., the Schur polynomial σ such that $\sigma\sigma^* = P$. Then

$$\sigma_0^2 + \sigma_1^2 + \cdots + \sigma_m^2 = p_0 = 1,$$

and hence $|\sigma_k| \le 1$ for $k = 0, 1, \dots, m$. Then it is easy to check that $|p_k| \le 2m$ for each $k = 0, 1, \dots, m$ proving compactness, since $\hat{\boldsymbol{\mathcal{D}}}_m$ is closed.

Now suppose that $(\mathbf{p}^{(k)}, \mathbf{q}^{(k)})$ is a sequence in $\varphi_\lambda^{-1}(-\infty, \mu]$. To show that $\varphi_\lambda^{-1}(-\infty, \mu]$ is compact, it suffices to show that $(\mathbf{p}^{(k)}, \mathbf{q}^{(k)})$ has a subsequence which

converges to a point in $\varphi_\lambda^{-1}(-\infty, \mu]$. Clearly $\mathbf{p}^{(k)} \in \hat{\boldsymbol{\mathcal{D}}}_m$, which is compact, so it has a convergent subsequence. As for $\mathbf{q}^{(k)}$, we can write

$$Q^{(k)}(z) = \rho_k \hat{Q}^{(k)}(z),$$

where $\hat{q}_0 = 1$ so that $\hat{\mathbf{q}}^{(k)}$ belongs to the compact set $\hat{\boldsymbol{\mathcal{D}}}_n$. Therefore, the sequence $\mathbf{q}^{(k)}$ has a convergent subsequence if and only if ρ_k has. However,

$$\varphi_\lambda(\mathbf{p}^{(k)}, \mathbf{q}^{(k)}) = \alpha_k + \beta_k \rho_k - \gamma_k \log \rho_k,$$

where

$$\alpha_k \stackrel{\triangle}{=} -\sum_{j=1}^{m} c_j p_j^{(k)} + \langle P^{(k)} - \lambda, \log P^{(k)} \rangle - \langle P^{(k)}, \log \hat{Q}^{(k)} \rangle$$

is bounded from above and below,

$$\beta_k \stackrel{\triangle}{=} \sum_{j=0}^{n} r_j \hat{q}_j^{(k)} = \langle \Phi_{\mathrm{ME}}, \hat{Q}^{(k)} \rangle > 0$$

and bounded, where Φ_{ME} denotes the maximum entropy spectral density with covariances $r_0, r_1, \ldots, r_n$, and

$$\gamma_k \stackrel{\triangle}{=} \langle P^{(k)}, 1 \rangle > 0$$

and bounded. From this we see that $\varphi_\lambda(\mathbf{p}^{(k)}, \mathbf{q}^{(k)})$ would exceed μ if either ρ_k were to tend to infinity or to zero. Hence $\{\rho_k\}$ is bounded with a convergent subsequence as claimed. □

It is easy to see that φ_λ is strictly convex on its closed convex domain. Therefore, Lemma 4.1 implies that φ_λ achieves a unique minimum in $\hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n$. If this minimum is located in the interior of $\hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n$, the gradient

$$\frac{\partial \varphi_\lambda}{\partial p_k} = -c_k + \left\langle z^k, \log \frac{P}{Q} \right\rangle - \left\langle z^k, \frac{\lambda}{P} \right\rangle, \quad k = 1, \ldots, m, \tag{4.2}$$

$$\frac{\partial \varphi_\lambda}{\partial q_k} = r_k - \left\langle z^k, \frac{P}{Q} \right\rangle, \quad k = 0, 1, \ldots, n, \tag{4.3}$$

is zero at this point. The barrier term will make sure that the optimum will occur at an interior point. This is guaranteed by the following lemma, which is proved along the lines of Lemma 5.4 in [6].

LEMMA 4.2. *If $\lambda > 0$, the function φ_λ never attains a minimum on the boundary $\partial(\hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}_n)$.*

Hence we have the following theorem.

THEOREM 4.3. *For each $\lambda > 0$, problem $(\mathcal{P}_\lambda)$ has a unique solution in $\hat{\boldsymbol{\mathcal{D}}}_m^+ \times \boldsymbol{\mathcal{D}}_n^+$. At this point*

$$\left\langle z^k, \frac{P}{Q} \right\rangle = r_k, \qquad k = 0, 1, \ldots, n, \tag{4.4}$$

$$\left\langle z^k, \log \frac{P}{Q} \right\rangle = c_k + \lambda \epsilon_k, \quad k = 1, \ldots, m, \tag{4.5}$$

where $\epsilon_k = \langle z^k, \frac{1}{P} \rangle$.

Proof. At the stationary point $(\hat{\mathbf{p}}, \hat{\mathbf{q}})$ the gradient is zero,

$$\frac{\partial \varphi_\lambda}{\partial p_k} = -c_k + \left\langle z^k, \log \frac{\hat{P}}{\hat{Q}} \right\rangle - \left\langle z^k, \frac{\lambda}{\hat{P}} \right\rangle = 0, \quad k = 1, \dots, m, \tag{4.6}$$

$$\frac{\partial \varphi_\lambda}{\partial q_k} = r_k - \left\langle z^k, \frac{\hat{P}}{\hat{Q}} \right\rangle = 0, \quad k = 0, 1, \dots, n, \tag{4.7}$$

and at that point

$$\frac{\hat{P}(z)}{\hat{Q}(z)} = \sum_{k=-\infty}^{\infty} R_k z^{-k},$$

where $R_k = r_k$ for $k = 0, 1, \dots, n$, and

$$\log \frac{\hat{P}(z)}{\hat{Q}(z)} = \sum_{k=-\infty}^{\infty} C_k z^{-k},$$

where $C_k = c_k + \lambda \epsilon_k$ for $k = 1, \dots, m$, with ϵ_k defined by the Laurent series

$$\frac{1}{\hat{P}(z)} = \sum_{k=-\infty}^{\infty} \epsilon_k z^{-k}. \tag{4.8}$$

□

If we would like to choose λ so that the error $\lambda \epsilon_k$ in the interpolation of the cepstral parameter c_k is as small as possible, there might seem to exist two ways to achieve a zero error. The first way is to choose $\lambda = 0$, in which case problem $(\mathcal{P}_\lambda)$ reduces to problem $(\mathcal{P})$. If problem $(\mathcal{P})$ has a solution in the interior of $\hat{\boldsymbol{\mathcal{D}}}_m \times \boldsymbol{\mathcal{D}}$, the coefficients ϵ_k are finite and the error will be zero. But if the solution is at the boundary, the expansion of $1/P$ will diverge, and the product $\lambda \epsilon_k$ will not tend to zero as λ tends to zero. The other way is to have $\epsilon_k = 0$ for $k = 1, \dots, m$. This is accomplished if P is constant, i.e., $P = p_0$. But since the solution then corresponds to the maximum entropy solution, and this solution does not interpolate generic cepstral parameters, λ must tend to infinity in order for P to tend to p_0. The connection to entropy is studied after the following example.

Example 4.1. An identification experiment is carried out to study the effect of the parameter λ on the filters determined by problem $(\mathcal{P}_\lambda)$. A MA(8) filter was driven by white noise to generate a data sequence of length 512, and from this data the variance $\hat{r}_0$ was estimated using (1.7) and cepstral parameters were estimated as described in Figure 1.2. Using problem $(\mathcal{P}_\lambda)$ with $m = 8$, $n = 0$, and six different values of λ, MA(8) filters were determined and the L_2 norm of the error, relative to the generating filter, was calculated. This was repeated for 100 MA(8) filters, and the mean of the L_2 norm of the errors for each value of λ was determined. As depicted in Figure 4.1, the mean L_2 norm of the error decreases as λ decreases, and it is almost constant for $\lambda < 10^{-3}$. This indicates that λ should be chosen small enough but not necessarily very close to zero. In Table 4.1 the means of the relative cepstral estimation errors and the means of the relative correction terms $\lambda \epsilon_k$, relative to the sums $\sum_{\ell=1}^{8} |c_\ell|$, are displayed in percents. It is clear that the estimated cepstral values are approximated better the smaller the value of λ is and that the correction term is about the same size as the estimation error for λ around $0.01 - 0.1$ and less than 10% of the estimation error for $\lambda \leq 0.0001$.

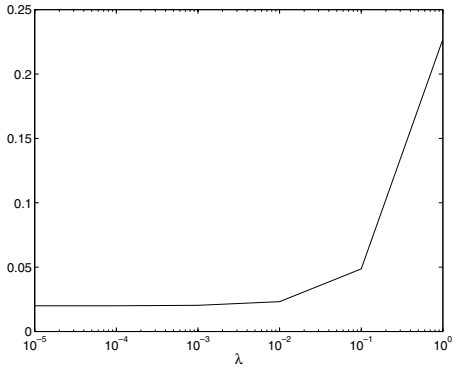

FIG. 4.1. *The L_2 norm for the errors of the method for different values of λ.*

TABLE 4.1

$\lambda = 0.00001$	0.21	0.19	0.20	0.21	0.20	0.20	0.19	0.21

If it is known that the estimated model is in the model class, to get consistent estimates the parameter λ should tend to zero as the number of data points tends to infinity and the estimation error tends to zero. In practice, such knowledge about the estimated model is uncommon, consistency cannot be guaranteed, and it is suggested that λ tends to some small positive value.

The entropy of a process is defined as in (2.5) (see, for example, [2]). For problem $(\mathcal{P})$ with fixed Q, the barrier term is equal to $-\mathcal{E}(\Phi)$ up to a constant. The barrier term is thus a measure of the entropy of the process. Then λ is a weight that determines how much the entropy should be maximized relative to the importance of the interpolation.

Next we will show that the entropy of the solution to problem $(\mathcal{P}_\lambda)$ is monotonically nondecreasing in λ. From this we can see that the price of a decrease in λ is a decreased entropy.

PROPOSITION 4.1. *The entropy of the filter Φ_λ, which solves problem $(\mathcal{P}_\lambda)$, is a monotonic nondecreasing function of λ.*

Proof. Denote the entropy of the filter $\Phi_\lambda = P_\lambda/Q_\lambda$ by $\mathcal{E}(\Phi_\lambda) = \langle \log(P_\lambda/Q_\lambda), 1\rangle$. This is a differentiable function of λ. Then

$$\frac{\mathrm{d}\mathcal{E}(\Phi_\lambda)}{\mathrm{d}\lambda} = \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle - \left\langle \frac{1}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle, \tag{4.9}$$

and taking the derivative of (4.2) and (4.3) with respect to λ gives

$$\left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda} - \frac{1}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, z^k \right\rangle - \left\langle \frac{1}{P_\lambda} - \frac{\lambda}{P_\lambda^2}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, z^k \right\rangle = 0, \quad k = 1, \dots, m, \tag{4.10}$$

$$-\left\langle \frac{1}{Q_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, z^k \right\rangle + \left\langle \frac{P_\lambda}{Q_\lambda^2}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, z^k \right\rangle = 0, \quad k = 0, 1, \dots, n. \tag{4.11}$$

Taking the linear combination of (4.11) corresponding to Q_λ gives

$$-\left\langle \frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle + \left\langle \frac{P_\lambda}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle = 0, \tag{4.12}$$

and that of (4.10) corresponding to P_λ yields

$$\left\langle \frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle - \left\langle \frac{P_\lambda}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle - 1 + \left\langle \frac{\lambda}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle = p_0 \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda} + \frac{\lambda}{P_\lambda^2}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda} - \frac{1}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda} - \frac{1}{P_\lambda}, 1 \right\rangle. \tag{4.13}$$

Setting $p_0 = 1$, (4.12) and (4.13) yield

$$-\left\langle \frac{1}{Q_\lambda}\frac{\mathrm{d}Q_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle = -1 + \lambda \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle - \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda} + \frac{\lambda}{P_\lambda^2}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda} - \frac{1}{P_\lambda}, 1 \right\rangle, \tag{4.14}$$

which inserted into (4.9) gives

$$\frac{\mathrm{d}\mathcal{E}(\Phi_\lambda)}{\mathrm{d}\lambda} = \left\langle \left(\frac{1}{P_\lambda} - 1\right)\left(1 - \lambda \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}\right), 1 \right\rangle.$$

For $\lambda = 0$ this reduces to

$$\frac{\mathrm{d}\mathcal{E}(\Phi_0)}{\mathrm{d}\lambda} = \left\langle \frac{1}{P_\lambda} - 1, 1 \right\rangle,$$

which is nonnegative by Lemma A.1 (see the appendix). We have thus proven that $\mathcal{E}(\Phi_\lambda)$ is a nondecreasing function in λ for $\lambda = 0$. For an arbitrary $\breve{\lambda} > 0$, let $\lambda = \breve{\lambda} + \tilde{\lambda}$ and $\breve{c}_k = c_k - \breve{\lambda}\breve{\epsilon}_k$, where

$$\frac{1}{P_{\breve{\lambda}}(z)} = \sum_{k=-\infty}^{\infty} \breve{\epsilon}_k z^{-k}.$$

Also, let $\breve{\varphi}_{\tilde{\lambda}}$ be given by (4.1) but with the parameters c_k replaced by $\breve{c}_k$. Then the equality

$$\frac{\partial \varphi_\lambda}{\partial p_k}(P_{\breve{\lambda}}, Q_{\breve{\lambda}}) = \frac{\partial \breve{\varphi}_{\tilde{\lambda}}}{\partial p_k}(P_{\breve{\lambda}}, Q_{\breve{\lambda}}) = 0$$

holds and the argument above applied on $\breve{\varphi}_{\tilde{\lambda}}$ instead of φ_λ holds for $\tilde{\lambda} = 0$; i.e., the derivative $\frac{\mathrm{d}\mathcal{E}(\Phi_\lambda)}{\mathrm{d}\lambda} \geq 0$ for $\lambda = \breve{\lambda}$. □

What happens to the solution if λ tends to infinity? If λ tends to infinity, the minimization over $\mathbf{p} \in \hat{\boldsymbol{\mathcal{D}}}$ will tend to minimize the barrier term $-\langle 1, \log P\rangle$. Taking $R = 1$ in the following lemma, which is proven in the appendix, the optimal P is seen to be $\hat{P}(z) = 1$.

LEMMA 4.4. *Let $P, R \in \hat{\mathcal{D}}_m^+$; then*

$$-\langle R, \log R\rangle \leq -\langle R, \log P\rangle.$$

Inserting $\hat{P} = 1$ into the objective function φ_λ results in a function equivalent to the maximum entropy objective function $\mathbb{J}_{\hat{P}}(\mathbf{q})$. Consequently, as λ tends to infinity, the resulting filter tends towards the maximum entropy filter.

Remark 4.1. It is clear from Lemma 4.4 that if a barrier of the form $\langle R, \log P\rangle$ is used, where R is in $\mathcal{D}_m^+$, the solution will tend to the LLN filter corresponding to $P = R$ as λ tends to infinity. Such a barrier will also guarantee a unique interior point solution, but the analogue of Proposition 4.1 does not hold. If an initial estimate R of P exists, this barrier will improve the solution by merging the information given in the interpolation parameters and in the initial estimate R.

Standard optimization algorithms can be used to solve problem $(\mathcal{P}_\lambda)$. For example, a damped Newton method, similar to the one proposed in [3] for problem $(\mathcal{P}_0)$, can be used. The best performance is probably achieved by using a homotopy method similar to the one presented in [11]. Since the function φ_λ is strictly convex, the global optimum can always be found. The strict convexity follows by considering the second derivatives of φ_λ in direction $(\delta\mathbf{p}, \delta\mathbf{q})$ at $(\mathbf{p}, \mathbf{q})$,

$$\left\langle (Q\delta P - P\delta Q)^2, \frac{1}{PQ^2} \right\rangle + \lambda \left\langle (\delta P)^2, \frac{1}{P^2} \right\rangle > 0 \quad \text{for } \delta\mathbf{p}, \delta\mathbf{q} \text{ not both zero.}$$

Since the Hessian is positive definite for $\lambda > 0$, φ_λ is strictly convex for all $\lambda > 0$.

5. Regularization of problem $(\mathcal{M})$. Next we return to problem $(\mathcal{M})$ introduced in section 3. There is no intrinsic reason why ψ should have a minimum in $\boldsymbol{\mathcal{D}}_m^+$ for generic values of the covariance lags, merely satisfying the usual positivity (Toeplitz) condition. In fact, it was demonstrated in [7, 3, 4] that covariance matching cannot be achieved with arbitrary poles, only with arbitrary zeros, and illustrated again in Example 3.1.

There is thus a need for a regularization of problem $(\mathcal{M})$. Reformulating problem $(\mathcal{M})$ as a minimization problem, the same barrier term β that was used for problem $(\mathcal{P})$ can be used here. To this end, given the window $r_0, r_1, \ldots, r_m \in \mathcal{R}_m$ of covariance lags and the pseudopolynomial $Q \in \mathcal{D}_n^+$, for each $\lambda > 0$, introduce the regularized problem

$$(\mathcal{M}_\lambda) \quad \left[\min_{\mathbf{p} \in \boldsymbol{\mathcal{D}}_m} \quad \psi_\lambda(\mathbf{p}) \right],$$

where $\psi_\lambda : \boldsymbol{\mathcal{D}}_m \to \mathbb{R}$ is given by

$$\psi_\lambda(\mathbf{p}) \triangleq \frac{1}{2} \left\langle 1, \frac{P^2}{Q} \right\rangle - \sum_{k=0}^{m} r_k p_k - \lambda \langle 1, \log P \rangle.$$

It is easy to see that ψ_λ is strictly convex for each $\lambda > 0$, and we know from before that $\boldsymbol{\mathcal{D}}_m$ is convex. Consequently, it follows from the following lemma that problem $(\mathcal{M}_\lambda)$ has a unique minimum.

LEMMA 5.1. *For each $\lambda > 0$, the function ψ_λ has compact sublevel sets; i.e., for all $\mu \in \mathbb{R}$, $\psi_\lambda^{-1}(-\infty, \mu]$ is compact.*

Proof. First note as before that the set $\hat{\boldsymbol{\mathcal{D}}}_m$ is compact. Next suppose that $\mathbf{p}^{(k)}$ is a sequence in $\psi_\lambda^{-1}(-\infty, \mu]$. To show that $\psi_\lambda^{-1}(-\infty, \mu]$ is compact, it suffices to show that $\mathbf{p}^{(k)}$ has a subsequence which converges to a point in $\psi_\lambda^{-1}(-\infty, \mu]$. We can write

$$P^{(k)}(z) = \rho_k \hat{P}^{(k)}(z),$$

where $\hat{p}_0 = 1$ so that $\hat{\mathbf{p}}^{(k)}$ belongs to the compact set $\hat{\boldsymbol{\mathcal{D}}}_m$. Therefore, the sequence $\mathbf{p}^{(k)}$ has a convergent subsequence if and only if ρ_k has. However,

$$\psi_\lambda(\mathbf{p}^{(k)}) = \alpha_k + \beta_k\rho_k + \gamma_k\rho_k^2 - \lambda\log\rho_k,$$

where

$$\begin{aligned}\alpha_k &\triangleq -\lambda\langle 1, \log\hat{P}^{(k)}\rangle,\\ \beta_k &\triangleq -\sum_{j=0}^{n} r_j\hat{p}_j^{(k)},\\ \gamma_k &\triangleq \frac{1}{2}\left\langle 1, \frac{(\hat{P}^{(k)})^2}{Q}\right\rangle > 0\end{aligned}$$

are all bounded from above and below.

From this we see that $\psi_\lambda(\mathbf{p}^{(k)})$ would exceed μ if either ρ_k were to tend to infinity or to zero. Hence $\{\rho_k\}$ is bounded with a convergent subsequence as claimed. ∎

The barrier term in ψ_λ ensures that the minimum does not occur on the boundary $\partial\mathcal{D}_m$ of $\mathcal{D}_m$ but in the interior $\mathcal{D}_m^+$. In fact, the following lemma can be proven along the same lines as Lemma 5.4 in [6].

LEMMA 5.2. *If $\lambda > 0$, the function ψ_λ never attains a minimum on the boundary $\partial\mathcal{D}_m$.*

Since thus the unique minimum of ψ_λ lies in the interior of $\mathcal{D}_m$, the gradient

$$\frac{\partial\psi_\lambda}{\partial p_k} = \left\langle z^k, \frac{P}{Q}\right\rangle - r_k - \left\langle z^k, \frac{\lambda}{P}\right\rangle, \quad k = 0, 1, \ldots, m, \tag{5.1}$$

is zero at this point. Consequently, we have the following theorem.

THEOREM 5.3. *For each $\lambda > 0$, problem $(\mathcal{M}_\lambda)$ has a unique solution in $\boldsymbol{\mathcal{D}}_m^+$. At this point*

$$\left\langle z^k, \frac{P}{Q}\right\rangle = r_k + \lambda\epsilon_k, \quad k = 0, 1, \ldots, m, \tag{5.2}$$

where $\epsilon_k = \langle z^k, \frac{1}{P}\rangle$.

Proof. This follows immediately from Lemma 5.2 and (5.1). ∎

Example 5.1. Example 4.1 is now revisited and repeated for the MA design method based on problem $(\mathcal{M}_\lambda)$. The influence of the parameter λ on the filters is studied by varying the parameter λ and plotting the error of the estimated filter. Using the same data, covariances were estimated using (1.7), the $(\mathcal{M}_\lambda)$ method was applied, and the L_2 norm for the error of the estimated filters compared to the generating filters was determined as a function of λ. As depicted in Figure 5.1, the L_2 norm of the error varies in a way very similar to Example 4.1; that is, the L_2 norm of the error decreases as λ decreases, and it is almost constant for $\lambda < 10^{-3}$. This indicates that λ should be chosen small enough but not necessarily very close to zero. It also indicates that the method corresponding to problem $(\mathcal{P}_\lambda)$ gives better results than that of problem $(\mathcal{M}_\lambda)$. This suggests that it is better to use cepstra than covariances for estimating zeros. In Table 5.1, the mean of the relative estimation errors of the covariances and the mean of the relative values of the correction terms $\lambda\epsilon_k$, relative to the sums $\sum_{\ell=0}^{8}|r_\ell|$, are displayed in percents. It is clear that the estimated covariance values are approximated better the smaller the value of λ is and that the correction term is

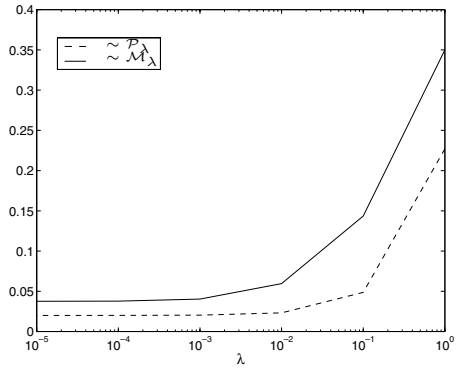

FIG. 5.1. *Comparison of the L_2 norm for the errors of the two methods for different values of λ.*

TABLE 5.1
The means of the relative covariance estimation errors and correction terms in percents.

Covariance	r_0	r_1	r_2	r_3	r_4	r_5	r_6	r_7	r_8

$\lambda = 1$	24.88	3.16	2.24	2.10	1.67	1.47	1.59	1.18	1.18
$\lambda = 0.1$	5.76	1.17	0.84	0.67	0.64	0.52	0.66	0.43	0.54
$\lambda = 0.01$	1.29	0.37	0.30	0.23	0.25	0.19	0.27	0.20	0.28
$\lambda = 0.001$	0.45	0.17	0.16	0.15	0.16	0.13	0.18	0.16	0.22
$\lambda = 0.0001$	0.33	0.14	0.14	0.14	0.14	0.12	0.17	0.16	0.22
$\lambda = 0.00001$	0.32	0.14	0.14	0.14	0.14	0.12	0.17	0.16	0.22

about the same size as the estimation error for λ around $0.1 - 1$ and about 10% of the estimation error for $\lambda \leq 0.001$.

A similar result as in Proposition 4.1 holds here.

PROPOSITION 5.1. *The entropy of the filter Φ_λ, which solves problem $(\mathcal{M}_\lambda)$, is a monotonic nondecreasing function of λ.*

Proof. First note that $\lambda \mapsto \mathcal{E}(\Phi_\lambda)$ is a differentiable function. Then

$$\frac{\mathrm{d}\mathcal{E}(\Phi_\lambda)}{\mathrm{d}\lambda} = \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle.$$

Moreover, taking the derivative of (5.1) with respect to λ gives

$$\left\langle \frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}\frac{1}{Q}, z^k \right\rangle - \left\langle \frac{1}{P_\lambda}, z^k \right\rangle + \left\langle \lambda \frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}\frac{1}{P_\lambda^2}, z^k \right\rangle = 0, \quad k = 0, 1, \ldots, m. \tag{5.3}$$

Now, forming the appropriate linear combination of (5.3) (corresponding to $\mathrm{d}P_\lambda/\mathrm{d}\lambda$) shows that

$$\frac{\mathrm{d}\mathcal{E}(\Phi_\lambda)}{\mathrm{d}\lambda} = \left\langle \frac{1}{P_\lambda}\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}, 1 \right\rangle = \left\langle \frac{1}{Q} + \frac{\lambda}{P_\lambda^2}, \left(\frac{\mathrm{d}P_\lambda}{\mathrm{d}\lambda}\right)^2 \right\rangle,$$

which is positive for nonnegative λ. This proves the lemma. □

The optimization methods that were suggested for problem $(\mathcal{P}_\lambda)$ should work for problem $(\mathcal{M}_\lambda)$ as well. Since problem $(\mathcal{M}_\lambda)$ is strictly convex the global optimum

can always be obtained. The strict convexity can be shown by considering the second order Fréchet derivative in the direction $\delta\mathbf{p}$ at $\mathbf{p}$

$$(\delta\mathbf{p})^\top \nabla^2_{\mathbf{pp}} \psi_\lambda(\delta\mathbf{p}) = \left\langle (\delta P)^2, \frac{1}{Q} \right\rangle + \lambda \left\langle (\delta P)^2, \frac{1}{P^2} \right\rangle > 0$$

for $\lambda > 0$ and nonzero $\delta\mathbf{p}$. Therefore, the Hessian is positive definite and the objective function ψ_λ is strictly convex.

6. Simulations. To illustrate our methods, we conclude with a few simulations where we fix $\lambda = 0.0005$ throughout.

6.1. MA filter design.

Experiment 1. For comparison, Example 2 in [24] is considered. The two methods were applied to 20 sets of data samples, each of length 400, which were generated from a MA(6) filter with its zeros located at $0.99e^{\pm i(\pi/4)}$, $0.99e^{\pm i(3\pi/4)}$, and $0.999e^{\pm i(\pi/2)}$. The power spectral densities of the estimated filters using problem $(\mathcal{P}_\lambda)$ and problem $(\mathcal{M}_\lambda)$ to estimate MA(6) filters are depicted in Figures 6.1 and 6.2, respectively. For comparison, the power spectral density of the generating filter is included in the graphs as a solid line. It is clear from the figures that the error is smaller for problem $(\mathcal{P}_\lambda)$ than for problem $(\mathcal{M}_\lambda)$. This suggests again that the cepstral lags are better than covariance lags for estimating zeros.

To allow comparison to the examples in [24], the experiments are repeated using enhanced estimates of the interpolation parameters. The covariance estimates are enhanced using the algorithm in [24] with $m = 40$. These estimates are determined by taking the least-squares error prediction of the covariances $r_0, r_1, \ldots, r_n$ using the estimates $\hat{r}_0, \hat{r}_1, \ldots, \hat{r}_m$, given that the true covariances $r_{n+1}, r_{n+2}, \ldots, r_m$ are zero. Due to the lack of an analogous enhanced cepstral estimate, the so-called LPC cepstrum is used. The cepstrum is estimated by first determining a 40th order maximum entropy AR filter (also called LPC an filter) and using the cepstra that this filter generates. The results are depicted in Figures 6.3 and 6.4, and they are of a similar quality to the results obtained in [24].

The results depicted in Figure 6.4 using the enhanced covariance estimates are of considerably better quality than the results depicted in Figure 6.2. In Table 6.1 it

can be seen that indeed the error of the estimated parameters $r_0, r_1, \ldots, r_n$ is much smaller for the enhanced estimate, and the correction terms are also smaller when using this estimate and quite negligible compared to the estimation errors.

However, the results depicted in Figure 6.3 with the cepstra obtained using the LPC cepstrum are of a similar quality to that in Figure 6.1. From this it appears that the LPC cepstrum fails to provide an enhanced estimate of the cepstrum, which is confirmed by Table 6.2, which is natural since it is not the same cepstrum. The AR approximation seems to generate a certain amount of regularization to the estimates, which can be seen from a bit less deep valleys in the spectrum of Figure 6.3 compared to Figure 6.1, and from smaller correction terms in Table 6.2.

6.2. ARMA filter design.

Experiment 2. In order to test the regularized CCM method, Experiment 1 is amended to provide an ARMA example. As before, 20 sets of data samples of length 400 are generated, this time using an ARMA filter. The zeros of the ARMA filter were located at $0.99e^{\pm i(\pi/4)}$, $0.99e^{\pm i(3\pi/4)}$, and $0.999e^{\pm i(\pi/2)}$ and the poles at $0.99e^{\pm i(\pi/6)}$, $0.99e^{\pm i(5\pi/6)}$, and $0.999e^{\pm i(2\pi/5)}$. As depicted in Figure 6.5, the peaks in the spectrum have a nice fit, but the notches are not reproduced as well. This is probably due to bad estimates of the cepstral lags. Using a higher order AR model for generating cepstrum estimates further degraded the results in this sense. If the experiment is repeated using the true cepstrum instead of the estimated cepstrum, the result in Figure 6.6 is obtained, and the very nice fit gives a strong indication that the weak point of the method is the estimation of the cepstrum. Hence the estimation of the cepstral lags needs to be improved.

Experiment 3. The scalar example in [20] is used here for comparison. Data of length 500 is generated by passing white noise through the filter $w(z) = \sigma(z)/a(z)$, where

$$\sigma(z) = z^5 - 1.051z^4 + 0.0718z^3 + 0.05164z^2 + 0.5322z - 0.5735$$

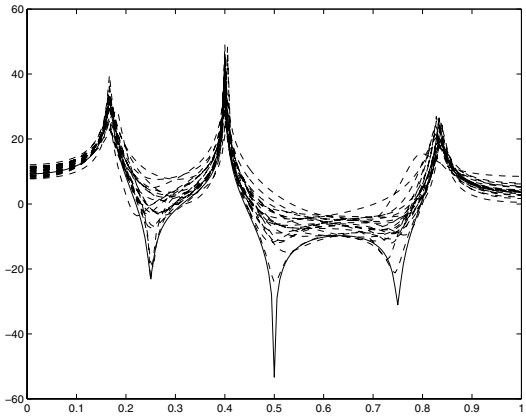

FIG. 6.5. *Comparison of ARMA(6,6) filters estimated using the regularized CCM method (dashed) relative to the true system (solid),* $\lambda = 5e-4$.

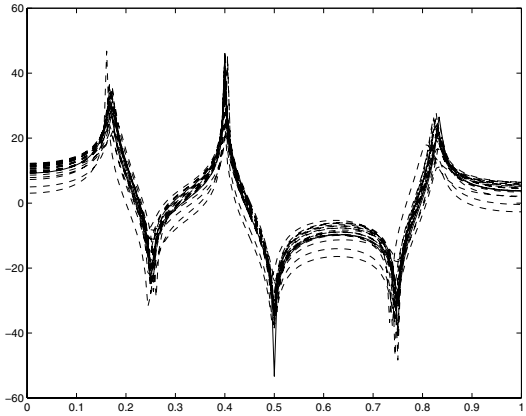

FIG. 6.6. *Comparison of ARMA(6,6) filters estimated using the regularized CCM method with true cepstral lags (dashed) relative to the true system (solid),* $\lambda = 5e{-}4$.

and

$$a(z) = z^5 - 0.8713z^4 - 1.539z^3 + 1.371z^2 + 0.6451z - 0.5827.$$

This was repeated 100 times, and the regularized CCM method was used to design an ARMA(5,5) filter for each output sequence. As in [20] the average power spectral density (in decibels) is plotted as a dashed line in Figure 6.7. The true spectral density is plotted as a solid line, and the dashed-dotted line represents the average estimated spectral density plus and minus the statistical standard deviations. The quality of the estimates is similar to the results obtained in [20].

Experiment 4: Speech. In order to show that the regularized CCM method provides good estimates for practical processes, a speech signal is considered. A sample of the phoneme "e" of length 200, corresponding to 25 milliseconds for a sampling rate of 8 kilohertz, is used for the analysis. Since there is no generic value for the orders m

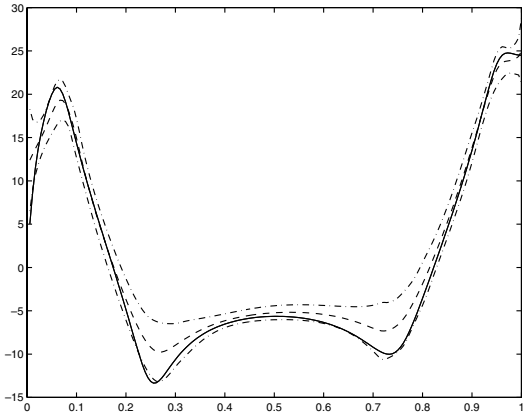

FIG. 6.7. *Comparison of ARMA*(5,5) *filters estimated using the regularized CCM method (dashed,* $\lambda = 5e{-}4$*) with standard deviations (dashed-dotted), relative to the true system (solid).*

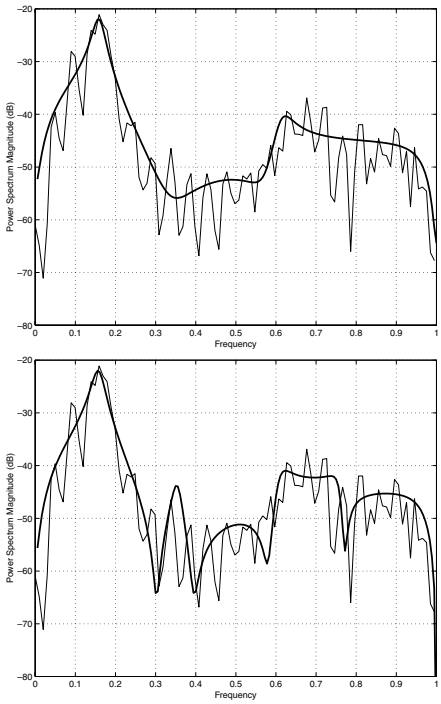

FIG. 6.8. *Comparison of ARMA*(6,6) *and ARMA*(10,10) *filters estimated using the regularized CCM method* ($\lambda = 5e-4$) *and the corresponding periodogram for the phoneme "e."*

and n, the regularized CCM method is applied for $m = n = 6$ and 10, and the results are depicted in Figure 6.8 plotted against the periodogram of the sample for reference. It is clear that the ARMA(6,6) filter describes the envelope of the periodogram well, whereas perhaps the ARMA(10,10) filter is overmodeling in that it models the fine structure of the signal.

Appendix.

LEMMA A.1. *Let* $P \in \hat{\mathcal{D}}_m^+$. *Then*

$$\left\langle \frac{1}{P} - 1, 1 \right\rangle \geq 0.$$

Proof. Consider the optimization problem

$$\min \left\{ \langle 1/P, 1\rangle \mid P \in \hat{\mathcal{D}}_m^+ \right\}.$$

Since the function $1/x$ is convex for positive x, any stationary point is minimal. Differentiating with respect to p_k, we get

$$\frac{\partial}{\partial p_k}\langle 1/P, 1\rangle = -\langle 1/P^2, z^k\rangle, \quad k = 1, \dots, m,$$

and it is clear that the gradient is zero if $P = 1$. The inequality

$$\langle 1/P, 1\rangle \geq \langle 1/1, 1\rangle$$

now follows from the minimality of $P = 1$, and this proves the lemma. □

Proof of Lemma 4.4. Consider the optimization problem

$$\max \left\{ \langle R, \log P\rangle \mid P \in \hat{\mathcal{D}}_m^+ \right\}.$$

Since the logarithm is concave for positive arguments, any stationary point is maximal. Differentiating with respect to p_k, we get

$$\frac{\partial}{\partial p_k}\langle R, \log P\rangle = \left\langle R, \frac{\cos k\theta}{P} \right\rangle, \quad k = 1, \dots, m,$$

and it is clear that the gradient is zero for $P = R$. The inequality

$$\langle R, \log R\rangle \geq \langle R, \log P\rangle$$

now follows from the optimality of $P = R$, and this proves the lemma. □

THE APPROXIMATE MAXIMUM PRINCIPLE IN CONSTRAINED OPTIMAL CONTROL*

BORIS S. MORDUKHOVICH† AND ILYA SHVARTSMAN‡

Abstract. This paper concerns optimal control problems for dynamical systems described by a parametric family of discrete/finite-difference approximations of continuous-time control systems. Control theory for parametric systems governed by discrete approximations plays an important role in both qualitative and numerical aspects of optimal control and occupies an intermediate position in dynamic optimization: between optimal control of discrete-time (with fixed steps) and continuous-time control systems. The central result in optimal control of discrete approximation systems is the approximate maximum principle (AMP), which gives the necessary optimality condition in a perturbed maximum principle form with no a priori convexity assumptions and thus ensures the stability of the Pontryagin maximum principle (PMP) under discrete approximation procedures. The AMP has been justified for optimal control problems of smooth dynamical systems with endpoint constraints under some properness assumption imposed on the sequence of optimal controls. In this paper we show, by a series of counterexamples, that the properness assumption is essential for the validity of the AMP, and that the AMP does not hold, in its expected (lower) subdifferential form, for nonsmooth problems. Moreover, a new upper subdifferential form of the AMP is established for ordinary and time-delay control systems. The results obtained surprisingly solve (in both negative and positive directions) a long-standing and well-recognized question about the possibility of extending the AMP to nonsmooth control problems, for which the affirmative answer has been expected in the conventional lower subdifferential form.

Key words. optimal control, discrete approximations, approximate maximum principle, stability under perturbations, nonsmooth and variational analysis, lower and upper subgradients, time delays

1. Introduction and preliminaries.

This paper is devoted to the study of optimal control problems for *discrete approximations* of continuous-time control systems that, viewed as a *parametric process* with a decreasing discretization step, occupy an *intermediate* position between control problems involving discrete-time and continuous-time systems. As the basic model for our study, we consider discrete approximations of the following Mayer-type optimal control problem governed by ordinary differential equations with endpoint constraints:

$$(P)\qquad \begin{cases} \text{minimize } J(x,u) := \varphi_0(x(t_1)) \\ \text{subject to} \\ \dot{x}(t) = f(t,x(t),u(t)) \ \text{ a.e. } \ t \in [t_0,t_1], \quad x(t_0) = x_0 \in \mathbb{R}^n, \\ u(t) \in U \ \text{ a.e. } \ t \in [t_0,t_1], \\ \varphi_i(x(t_1)) \le 0, \quad i = 1,\dots,m, \\ \varphi_i(x(t_1)) = 0, \quad i = m+1,\dots,m+r, \end{cases}$$

over measurable controls $u(\cdot)$ and absolutely continuous trajectories $x(\cdot)$ on the fixed time interval $T := [t_0, t_1]$. It is well known that many other control problems (of Lagrange and Bolza types, with integral constraints, on variable time intervals, etc.) reduce to the form of (P). Observe also that the results of this paper can be easily extended to control problems with a nonfixed initial vector (i.e., when φ_i in (P) depend on both endpoints $x(t_0)$ and $x(t_1)$ for all $i = 0, \dots, m + r$) as well as to problems with continuously time-dependent control sets $U = U(t)$.

Problem (P) may be treated as an infinite-dimensional optimization problem with special equality-type dynamic constraints governed by differential operators as well as with geometric constraints given by arbitrary control sets; this makes it *nonsmooth* even under all smooth functional data f and φ_i. On the other hand, it is natural to explore a different way to study continuous-time problems (P), which goes back to Leibnitz and Euler and which consists of approximating (P) by a family of discrete-time systems arising when the time-derivative $\dot{x}(t)$ is replaced with the *finite differences*

$$\dot{x}(t) \approx \frac{x(t+h) - x(t)}{h} \quad \text{as} \quad h \to 0.$$

Allowing also *perturbations* of the *endpoint constraints* (which is very essential for variational stability), problem (P) is replaced in this way by the following family of discrete-time problems (P_N) depending on the natural parameter $N = 1, 2, \dots$:

$$(P_N) \qquad \begin{cases} \text{minimize } J(x_N, u_N) := \varphi_0(x_N(t_1)) \\ \text{subject to} \\ x_N(t + h_N) = x_N(t) + h_N f(t, x_N(t), u_N(t)), \quad x_N(t_0) = x_0 \in \mathbb{R}^n, \\ u_N(t) \in U, \quad t \in T_N := \{t_0, t_0 + h_N, \dots, t_1 - h_N\}, \\ \varphi_i(x_N(t_1)) \le \gamma_{iN}, \quad i = 1, \dots, m, \\ |\varphi_i(x_N(t_1))| \le \delta_{iN}, \quad i = m+1, \dots, m+r, \\ h_N := \dfrac{t_1 - t_0}{N}, \quad N \in \mathbb{N} := \{1, 2, \dots\}, \end{cases}$$

where $\gamma_{iN} \to 0$ and $\delta_{iN} \downarrow 0$ as $N \to \infty$ for all i. For each fixed $N \in \mathbb{N}$ problem (P_N) is *finite-dimensional* and seems to be simpler than the continuous-time problem (P). Indeed, applying well-developed methods of finite-dimensional variational analysis, it is possible to derive necessary optimality conditions in problems (P_N) even with nonsmooth data and general dynamic constraints governed by discrete inclusions and then obtain the corresponding results for optimal control of differential inclusions by passing to the limit from those for discrete approximations; see [4, 6, 13] for detailed proofs and discussions. However, this approach has some limitation regarding necessary optimality conditions of the *maximum principle* type.

As is well known, the central result of the optimal control theory for continuous-time problems (P), the Pontryagin maximum principle (PMP) [11], holds with *no convexity* assumptions on the admissible velocity sets $f(t, x, U)$. This specific result, from the general viewpoint of optimization theory, is strongly due to continuous-time dynamic constraints in (P) governed by differential operators. It happens that continuous-type control systems enjoy a certain *hidden convexity*, which is deeply related to the classical Lyapunov theorem on the range convexity of nonatomic vector measures and eventually leads to the maximum principle form. It is not surprising, therefore, that an analogue of the maximum principle for optimal control problems

governed by discrete-time systems *does not generally hold* without a priori convexity assumptions. This may create troubles for applications of the PMP in numerical calculations of nonconvex continuous-time control systems, which inevitably involve finite-difference approximations via time discretization. To avoid such troubles, it is sufficient to justify not a full analogue of the PMP, with the exact maximum condition, but its *approximate* counterpart, where an error in the maximum condition depends on the discretization stepsize *tending to zero* when the latter is decreasing.

The first result of this type in the absence of convexity assumptions was given by Gabasov and Kirillova [2, 3], under the name of "quasi-maximum principle," for parametric discrete systems with smooth cost and dynamics and with no endpoint constraints. The proof of this result, purely analytic, essentially exploited the unconstrained nature of the problem.

The following *approximate maximum principle* (AMP) for the nonconvex constrained problems (P_N) was established by Mordukhovich [4, 5]. The proof in [4, 5] is geometric based on the discovered finite-difference counterpart of the hidden convexity property and the separation theorem. Denote

$$H(t,x,p,u) := \langle p, f(t,x,u)\rangle, \quad p \in \mathbb{R}^n, \tag{1.1}$$

the *Hamilton–Pontryagin function* for the dynamic constraints under consideration.

APPROXIMATE MAXIMUM PRINCIPLE. *Let the pairs $(\bar{x}_N, \bar{u}_N)$ be optimal to (P_N) for all $N \in \mathbb{N}$, where U is a compact subset of a metric space with the metric $d(\cdot,\cdot)$, where f is continuous with respect to its variables and continuously differentiable with respect to x in a tube containing the optimal trajectories $\bar{x}_N(t)$ for large N, and where each φ_i is continuously differentiable around the limiting point(s) of $\{\bar{x}_N(t_1)\}$. Impose the following assumptions.*

Assumption A. The *consistency condition* on the perturbation of the equality constraints, meaning that

$$\lim_{N\to\infty} \frac{h_N}{\delta_{iN}} = 0 \quad \text{for all} \quad i = m+1, \ldots, m+r. \tag{1.2}$$

Assumption B. The *properness* of the sequences of optimal controls $\{\bar{u}_N\}$, which means that for every increasing subsequence $\{N\}$ of natural numbers and every sequence of mesh points $\tau_{\theta(N)} \in T_N$ satisfying $\tau_{\theta(N)} = t_0 + \theta(N)h_N$, $\theta(N) = 0, 1, \ldots, N-1$, and $\tau_{\theta(N)} \to t \in [t_0, t_1]$ one has either

$$d\big(u_N(\tau_{\theta(N)}), u_N(\tau_{\theta(N)+q})\big) \to 0$$

or

$$d\big(u_N(\tau_{\theta(N)}), u_N(\tau_{\theta(N)-q})\big) \to 0$$

as $N \to \infty$ with any natural constant q.

Then there are numbers $\{\lambda_{iN} |\ i = 0, \ldots, m+r\}$ and a function $\varepsilon(t, h_N) \to 0$ as $N \to \infty$ uniformly in $t \in T_N$ such that

$$H(t, \bar{x}_N(t), p_N(t+h_N), \bar{u}_N(t)) = \max_{u\in U} H(t, \bar{x}_N(t), p_N(t+h_N), u) + \varepsilon(t, h_N) \tag{1.3}$$

for all $t \in T_N$ and

$$\lambda_{iN}(\varphi_i(\bar{x}_N(t_1)) - \gamma_{iN}) = O(h_N), \quad i = 1, \ldots, m, \tag{1.4}$$

$$\lambda_{iN} \geq 0, \quad i = 0, \ldots, m, \quad \text{and} \quad \sum_{i=0}^{m+r} \lambda_{iN}^2 = 1 \tag{1.5}$$

for all $N \in \mathbb{N}$, where $p_N(t)$, $t \in T_N \cup \{t_1\}$, is the corresponding trajectory of the adjoint system

$$p_N(t) = p_N(t + h_N) + h_N \frac{\partial H}{\partial x}(t, \bar{x}_N(t), p_N(t + h_N), \bar{u}_N(t)), \quad t \in T_N, \tag{1.6}$$

with the transversality condition

$$p_N(t_1) = -\sum_{i=0}^{m+r} \lambda_{iN} \nabla \varphi_i(\bar{x}_N(t_1)). \tag{1.7}$$

Observe that the closer h_N is to zero, the more precise the approximate maximum condition (1.3) and the approximate complementary slackness condition (1.4) are. This means that the AMP in (P_N) tends to the PMP in (P) as $N \to \infty$, which actually justifies the *stability* of the PMP with respect to discrete approximations under the assumptions made.

It has been shown in [4, 5] that the *consistency* condition in (a) is *essential* for the validity of the AMP in problems with equality constraints. The first goal of this paper is to examine the other two significant assumptions made in the above theorem: the *properness* condition in Assumption B and the *smoothness* of the initial data. We show in section 2 that *both of these assumptions are essential for the validity of the AMP*.

Note that the properness of the sequence of optimal controls in Assumption B is a *finite-difference counterpart* of the piecewise continuity (or, more generally, of *Lebesgue regular points* having full measure) for optimal controls in continuous-time systems. It turns out that the situation when sequences of optimal controls are not proper in discrete approximations is not unusual for systems with nonconvex velocities, and it leads to the violation of the AMP already in the case of smooth problems with inequality constraints.

The impact of nonsmoothness to the validity of the AMP happens to be even more striking: The AMP *does not hold* in the expected conventional subdifferential form already for minimizing *convex* cost functions in discrete approximations of linear systems with no endpoint constraints, as well as for problems with nonsmooth dynamics. It seems that the *AMP is one of very few results on necessary optimality conditions that do not have expected counterparts in nonsmooth settings*.

On the other hand, we derive the AMP in problems (P_N) with nonsmooth functions describing the objective and inequality constraints in a new *upper subdifferential* (or superdifferential) form, which is also new for necessary optimality conditions in continuous-time control systems. The main difference between the conventional subdifferential form, which does not hold for the AMP but holds for the PMP, and the new one is that the latter involves upper (not lower) subgradients of nonsmooth functions in transversality conditions. This form applies to a class of *uniformly upper subdifferentiable* functions described in this paper, which particularly contains smooth and concave continuous functions being closed with respect to taking the minimum over compact sets. The results obtained solve (in a surprising, unexpected way) a long-standing and widely discussed question about the possibility of establishing the AMP for nonsmooth control problems. We also derive the upper subdifferential form

of the AMP in discrete approximations of control systems with *time delays*, for which no results of this type have been known before. The main results of this paper have been announced in [9].

The rest of the paper is organized as follows. Section 2 contains examples on the *violation of the AMP* in smooth problems (P_N) without the properness condition as well as in problems with nonsmooth cost functions, nonsmooth dynamics, or both. In section 3 we discuss appropriate tools of nonsmooth analysis, paying attention mainly to the concepts of *upper regularity* and uniform *upper subdifferentiability*, which are new in the study of *minimization* problems. Section 4 is devoted to the derivation of the AMP for the discrete approximation problems (P_N) in the *upper subdifferential form*; it contains three slightly different modifications of this result in somewhat distinct settings. In section 5 we extend the AMP to discrete approximations of constrained *time-delay* systems, where the results obtained are new in both smooth and nonsmooth frameworks. We also present an example on the *violation* of the AMP in discrete approximations of functional-differential control systems of *neutral type*, even under smoothness assumptions in the absence of endpoint constraints.

Throughout the paper we use standard notation with some special symbols defined in the text where they are introduced.

2. Counterexamples. Let us start with an example on the violation of the AMP in discrete approximations of linear control systems with linear cost functions and linear endpoint inequality constraints but with *no properness condition*.

EXAMPLE 2.1 (AMP may not hold in smooth control problems with no properness condition). *There is a two-dimensional linear control problem with an inequality constraint such that optimal controls in the sequence of its discrete approximations are not proper and do not satisfy the AMP.*

Proof. Let us consider a linear continuous-time optimal control problem (P) with a two-dimensional state $x = (x_1, x_2) \in \mathbb{R}^2$ in the following form:

$$\begin{cases} \text{minimize } \varphi(x(1)) := -x_1(1) \\ \text{subject to} \\ \dot{x}_1 = u, \quad \dot{x}_2 = x_1 - at, \quad x_1(0) = x_2(0) = 0, \\ u(t) \in U := \{0,1\}, \quad 0 \le t \le 1, \\ x_2(1) \le -\dfrac{a-1}{2}, \end{cases} \tag{2.1}$$

where $a > 1$ is a given constant. Observe that the only "unpleasant" feature of this problem is that the control set $U = \{0,1\}$ is *nonconvex*, and hence the feasible velocity sets $f(t,x,U)$ are nonconvex as well. It is clear that $\bar{u}(t) \equiv 1$ is the unique optimal solution to problem (2.1) and that the corresponding optimal trajectory is $\bar{x}_1(t) = t$, $\bar{x}_2(t) = -\frac{a-1}{2}t^2$. Moreover, the inequality constraint is active, since $\bar{x}_2(1) = -\frac{a-1}{2}$.

Let us now discretize this problem with the stepsize $h_N := \frac{1}{2N}$, $N \in \mathbb{N}$. For notational convenience we omit the index N in what follows. Thus the discrete approximation problems (P_N) corresponding to (2.1) are written as

$$\begin{cases} \text{minimize } \varphi(x(1)) = -x_1(1) \\ \text{subject to} \\ x_1(t+h) = x_1(t) + hu(t), \quad x_1(0) = 0, \\ x_2(t+h) = x_2(t) + h\big(x_1(t) - at\big), \quad x_2(0) = 0, \\ u(t) \in \big\{0,1\big\}, \quad t \in \big\{0, h, \dots, 1-h\big\}, \\ x_2(1) \le -\dfrac{a-1}{2} + h^2; \end{cases} \tag{2.2}$$

i.e., we put $\gamma_N := h_N^2$ in the constraint perturbation for (P_N).

To proceed, we compute the trajectories of (2.2) corresponding to $u(t) \equiv 1$. It is easy to see that $x_1(t) = t$ for this u. To compute $x_2(t)$, observe that

$$\big[y(t+h) = y(t) + ht,\ y(0) = 0\big] \Longrightarrow y(t) = \frac{t^2}{2} - \frac{th}{2}.$$

Indeed, one has by the direct calculation that

$$y(t) = h\sum_{\tau=0}^{t-h} \tau = \big[\text{put } \tau = kh\big] = h^2 \sum_{k=0}^{\frac{t}{h}-1} k = h^2 \frac{\frac{t}{h}\big(\frac{t}{h}-1\big)}{2} = \frac{t^2}{2} - \frac{th}{2}.$$

Therefore, for $x_2(t)$ corresponding to $u(t) \equiv 1$ in (2.2) we have

$$x_2(t) = h\sum_{\tau=0}^{t-h} \big(\tau - a\tau\big) = -\frac{a-1}{2}t^2 + \frac{a-1}{2}ht.$$

By this calculation we see that, for h sufficiently small, $x_2(t_1)$ no longer satisfies the endpoint constraint, and thus $u(t) \equiv 1$ is not a feasible control to problem (2.2) for all h close to zero. This implies that an optimal control to (2.2) for small h, which obviously exists, must have at least one *switching point* s such that $u(s) = 0$, and hence the maximum value of the corresponding endpoint $x_1(1)$ will be less than or equal to $1 - h$. Put

$$u(t) := \begin{cases} 1, & t \neq s, \\ 0, & t = s, \end{cases}$$

and show that

$$x_2(t) = \begin{cases} -\dfrac{a-1}{2}t^2 + \dfrac{a-1}{2}ht, & t \leq s, \\ -\dfrac{a-1}{2}t^2 + \dfrac{a-1}{2}ht - h(t-s) + h^2, & t \geq s+h, \end{cases} \tag{2.3}$$

for the corresponding trajectories in (2.2) depending on h and s. We need only justify the second part of this formula. To compute $x_2(t)$ for $t \geq s+h$, substitute $x_1(t) = t-h$ into (2.2). It is easy to see that the increment $\Delta x_2(t)$ compared to the case when $u(t) \equiv 1$ is

$$h\sum_{\tau=s+h}^{t-h} (-h) = -h(t-h-s) = -h(t-s) + h^2,$$

which justifies (2.3). Now let us specify the parameters of the above control putting $a = 2$ and $s = 0.5$ for all N, i.e., considering the discrete-time function

$$\bar{u}(t) := \begin{cases} 1, & t \neq 0.5, \\ 0, & t = 0.5. \end{cases}$$

Note that the point $t = 0.5$ belongs to the grid T_N for all N due to $h_N := \frac{1}{2N}$. Observe that the sequence of these controls *does not satisfy the properness property* in Assumption B of the AMP formulated in section 1. It follows from (2.3) that the

corresponding trajectories satisfy the endpoint constraint in (2.2) for all $N \in \mathbb{N}$, since $\bar{x}_2(1) = -\frac{1}{2}t^2 + h^2$. Moreover, it is clear from the above calculations that the control $\bar{u}(t)$ is optimal to problem (P_N) in (2.2) for any N. Let us show that the sequence of optimal controls $\bar{u}(t)$ does not satisfy the approximate maximum condition (1.3) at the point of switch.

The adjoint system (1.6) for problem (2.2) with any h is

$$p(t) = p(t+h) + h\frac{\partial f}{\partial x}^*(t, \bar{x}_1, \bar{x}_2, \bar{u})p(t+h),$$

where the Jacobian matrix $\partial f/\partial x$ and its adjoint/transposed one equal

$$\frac{\partial f}{\partial x} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \qquad \frac{\partial f}{\partial x}^* = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Thus we have the adjoint trajectories

$$p_1(t) = p_1(t+h) + hp_2(t+h) \quad \text{and} \quad p_2(t) \equiv \text{const},$$

where (p_1, p_2) satisfy the transversality condition (1.7) with the corresponding sign/nontriviality conditions (1.5) written as

$$p_1(1) = \lambda_0,\ p_2(1) = -\lambda_1; \quad \lambda_0 \geq 0,\ \lambda_1 \geq 0,\ \lambda_0^2 + \lambda_1^2 = 1.$$

This implies that $p_1(t)$ is a linear nondecreasing function. The corresponding Hamilton–Pontryagin function (1.1) equals

$$H(t, x(t), p(t+h), u(t)) = p_1(t+h)u(t) + \text{terms not depending on } u.$$

Examining the latter expression and taking into account that the optimal controls are equal to one for all t but $t = 0.5$, we conclude that the approximate maximum condition (1.3) holds only if $p_1(t)$ is either nonnegative or tends to zero everywhere except $t = 0.5$. Observe that $p_1(t) \equiv 0$ yields $\lambda_1 = \lambda_2 = 0$, which contradicts the nontriviality condition. Hence $p_1(t)$ must be positive away from $t = 0$. Therefore, a sequence of controls having a point of switch not tending to zero as $h \downarrow 0$ *cannot* satisfy the approximate maximum condition at this point. This shows that the AMP does not hold for the sequence of optimal controls to (2.2) built above. □

Many examples of this type can be constructed based on the above idea, which essentially means the following. Take a continuous-time problem with active inequality constraints and *nonconvex* admissible velocity sets $f(t, x, U)$. It often happens that after the discretization the "former" optimal control becomes not feasible in discrete approximations, and the "new" optimal control in the sequence of discrete-time problems has a singular point of switch (thus making the sequence of optimal controls not proper), where the approximate maximum condition does not hold.

The next example demonstrates that the AMP may be violated in problems of minimizing *nonsmooth cost* functions in linear systems with no endpoint constraint.

EXAMPLE 2.2 (AMP may not hold for linear systems with nonsmooth and convex cost functions). *There is a one-dimensional control problem of minimizing a nonsmooth and convex cost function over a linear system with no endpoint constraints such that a proper sequence of optimal controls to discrete approximations does not satisfy the AMP.*

Proof. Consider the following sequence of one-dimensional optimal control problem (P_N), $N \in \mathbb{N}$, for discrete-time systems:

$$\text{(2.4)} \qquad \begin{cases} \text{minimize } \ \varphi(x_N(1)) := |x_N(1) - r| \\ \text{subject to} \\ x_N(t+h_N) = x_N(t) + h_N u_N(t), \quad x_N(0) = 0, \\ u_N(t) \in U := \{0,1\}, \quad t \in T_N := \{0, h_N, \ldots, 1 - h_N\}, \end{cases}$$

where r is a positive *irrational* number less than 1 whose choice will be specified below. The dynamics in (2.4) is a discretization of the simplest ODE control system $\dot{x} = u$. Observe that, since r is irrational and h_N is rational, we have $\bar{x}_N(1) \neq r$ for the endpoint of an optimal trajectory to (2.4) as $N \in \mathbb{N}$, while obviously $\bar{x}(1) = r$ for optimal solutions to the continuous-time counterpart. It is also clear that for sufficiently small h_N an optimal control to (2.4) will be neither $u_N(t) \equiv 0$ nor $u_N(t) \equiv 1$, but it will have at least one point of switch.

Suppose that for some subsequence $N_k \to \infty$ one has $\bar{x}_{N_k}(1) > r$; put $\{N_k\} = \mathbb{N}$ without loss of generality. Let us show that in this case the approximate maximum condition does *not* hold at points $t \in T_N$ for which $\bar{u}_N(t) = 1$. Indeed, we have

$$H(\bar{x}_N(t), p_N(t+h_N), u) = p_N(t+h_N)u \quad \text{and} \quad p_N(t) \equiv -1$$

for the Hamilton–Pontryagin function and the adjoint trajectory in (1.6) and (1.7), since $\bar{x}_N(1) > r$ along the optimal solution to (2.4). Thus

$$\begin{aligned} &\max_{u \in U} H(\bar{x}_N(t), p_N(t+h_N), u) = 0 \ \text{ for all } \ t \in T_N, \\ &\text{while } H(\bar{x}_N(s), p_N(s+h_N), \bar{u}_N(s)) = -1 \end{aligned}$$

at the points $s \in T_N$ of control switch, where $\bar{u}_N(s) = 1$ regardless of h_N.

Let us specify the choice of r in (2.4) ensuring that $\bar{x}_N(1) > r$ along some subsequence of natural numbers. We claim that $\bar{x}_N(1) > r$ if $r \in (0,1)$ is an irrational number whose decimal representation contains infinitely many digits from the set $\{5,6,7,8,9\}$; e.g., $r = 0.676676667\ldots$. Indeed, put $h_N := 10^{-N}$, which is a subsequence of $h_N = N^{-1}$ as required in (2.4). It is easy to see that in this case the set of all reachable points at $t = 1$ is the set of rational numbers between 0 and 1 with exactly N digits in the fractional part of their decimal representations. In particular, for $N = 3$ this set is $\{0, 0.001, 0.002, \ldots, 0.999, 1\}$. Therefore, by the construction of r, the closest point to r from the reachable set is greater than r, and such a point must be the endpoint of the optimal trajectory $\bar{x}_N(1)$.

It remains to show that one always can choose a sequence of optimal control to (2.4) satisfying the properness condition. Taking r as above, we denote by $s(N) \in T_N$ the point of the grid closest to r. It is easy to see that the control

$$\bar{u}_N(t) := \begin{cases} 1, & t \le s(N), \\ 0, & t \ge s(N) + h_N \end{cases}$$

is optimal to (2.4) for each $N \in \mathbb{N}$, and the sequence $\{\bar{u}_N\}$ satisfies the properness condition. □

Example 2.2 contradicts the AMP with the transversality condition in the *conventional subdifferential form*, which is

$$-p_N(t_1) \in \partial\varphi(\bar{x}_N(t_1))$$

for problems with no endpoint constraints. In our example the function $\varphi(x) = |x-r|$ is *convex*, and hence the subdifferential ∂ is understood in the sense of convex analysis. Note that we actually showed that the subdifferential agrees with the gradient

$$\partial\varphi(\bar{x}_N(1)) = \big\{\nabla\varphi(\bar{x}_N(1))\big\} = \big\{1\big\} \ \text{ for all } \ N \in \mathbb{N}$$

along the optimal trajectories in (2.4) due to the choice of r. Since any reasonable (lower) subdifferential for nonsmooth functions must reduce to the convex subdifferential for convex ones, Example 2.2 proves that there is *no hope for an extension of the AMP in the conventional subdifferential form to problems with nonsmooth costs.*

The next example, complemented to Example 2.2, shows that the AMP fails even for problems with *differentiable* but *not continuously differentiable* cost functions.

EXAMPLE 2.3 (AMP may not hold for linear systems with differentiable, but not C^1, cost functions). *There is a one-dimensional control problem of minimizing a Fréchet differentiable but not continuously differentiable cost function over a linear system with no endpoint constraints such that a proper sequence of optimal controls to discrete approximations does not satisfy the AMP.*

Proof. Consider the same control system as in (2.4) and construct a minimizing function $\varphi(x)$ satisfying the above requirements. Let $\psi(x)$ be a C^1 function with the properties

$$\begin{aligned}&\psi(x) \ge 0, \quad \psi(x) = \psi(-x), \quad \psi(x) \equiv 0 \ \text{ if } \ |x| > 2,\\ &|\nabla\psi(x)| \le 1 \ \text{ for all } \ x, \quad \text{and } \ \nabla\psi(-1) = a > 0.\end{aligned}$$

Define the cost function $\varphi(x)$ by

$$\varphi(x) := \Big(x - \frac{1}{9}\Big)^2 + \sum_{n=1}^{\infty} 10^{-2n-3}\psi\left(10^{2n+3}\left(x - \sum_{k=1}^{n} 10^{-k}\right) - 1\right),$$

which is continuously differentiable around every point but $x = \frac{1}{9}$, where it is differentiable and attains its absolute minimum at $x = \frac{1}{9}$. As in Example 2.2, we put $h_N := 10^{-N}$, and then the point $x = \frac{1}{9}$ *cannot be reached* by discretization. It is not hard to check that the endpoint of the optimal trajectory $\bar{x}_N$ for each N is

$$\bar{x}_N(1) = \sum_{k=1}^{N} 10^{-k} \quad \text{with} \quad \nabla\varphi(\bar{x}_N(1)) = a + \varepsilon_N,$$

where $\varepsilon_N \downarrow 0$ as $N \to \infty$. Proceeding as in Example 2.2, with the same sequence of optimal controls, we have $H(\bar{x}_N(t), p_N(t+h_N), u) \equiv -au$, and the approximate maximum condition (1.3) does not hold at those points where $\bar{u}_N(t) = 1$. □

The last example in this section concerns systems with *nonsmooth dynamics*. We actually consider a finite-difference analogue of minimizing an integral functional over a one-dimensional control system, which is equivalent to a two-dimensional optimal control problem of the Mayer type. The discrete "integrand" in this problem is nonsmooth with respect to the state variable x; it happens to be continuously differentiable with respect to x *along* the optimal process $\{\bar{x}_N(\cdot), \bar{u}_N(\cdot)\}$ under consideration but *not uniformly* in N. Thus the example below demonstrates that the *uniform smoothness* assumption on f in a tube containing optimal trajectories is essential for the validity of the AMP formulated in section 1.

EXAMPLE 2.4 (violation of AMP for control problems with nonsmooth dynamics). *The AMP does not hold in discrete approximations of a minimization problem*

for an integral functional over a one-dimensional linear control system with no endpoint constraints such that the integrand is linear with respect to the control variable while convex and nonsmooth with respect to the state one. Moreover, the integrand in this problem happens to be C^1 with respect to the state variable along the sequence of optimal solutions to the discrete approximations (P_N) for all $N \in \mathbb{N}$ but not uniformly in N.

Proof. First we consider the following continuous-time optimal control problem:

$$\begin{cases} \text{minimize} \;\; J(x,u) := \displaystyle\int_0^{t_1} \big(u(t) + |x(t) - t^2/2|\big)dt \\ \text{subject to} \\ \dot{x} = tu, \quad x(0) = 0, \\ u(t) \in U := \big\{1, c\big\}, \quad 0 \le t \le t_1, \end{cases} \tag{2.5}$$

where the terminal time t_1 and the number $c > 1$ will be specified below. It is obvious that the optimal control to (2.5) is $\bar{u}(t) \equiv 1$ and the corresponding optimal trajectory is $\bar{x}(t) = t^2/2$.

Discretizing (2.5), we get the sequence of finite-difference control problems

$$\begin{cases} \text{minimize} \;\; J(x_N, u_N) := h_N \displaystyle\sum_{t \in T_N} \big(u_N(t) + |x_N(t) - t^2/2|\big) \\ \text{subject to} \\ x_N(t + h_N) = x_N(t) + h_N t u_N(t), \quad x_N(0) = 0, \\ u_N(t) \in U = \big\{1, c\big\}, \quad t \in T_N := \big\{k h_N\big\}_{k=0}^{N-1}. \end{cases} \tag{2.6}$$

Let us first show that $\bar{u}_N(t) \equiv 1$ remains the (unique) optimal control to (2.6) if the stepsize h_N is sufficiently small and (t_1, c) are chosen appropriately. Indeed, similarly to Example 2.1 we compute the trajectory to (2.6) corresponding to the control $u_N(t) \equiv 1$ as

$$x_N(t) = \frac{t^2}{2} - \frac{t h_N}{2} \;\; \text{for all} \;\; N \in \mathbb{N}.$$

The value $J_N(1)$ of the cost functional at $u_N(t) \equiv 1$ equals

$$J_N(1) = t_1 + h_N^2 \sum_{t \in T_N} \frac{t}{2} = t_1 + \frac{t_1^2 h_N}{4} + o(h_N). \tag{2.7}$$

If we replace $u_N(t) = 1$ by $u_N(t) = c$ at some point $t \in T_N$, then the increment of the summation $h_N \sum_{t \in T_N} u_N(t)$ equals $(c-1)h_N$. Hence

$$J(x_N, u_N) = h_N \sum_{t \in T_N} u_N(t) + h_N \sum_{t \in T_N} |x_N(t) - t^2/2| > h_N \sum_{t \in T_N} u_N(t) \ge t_1 + (c-1)h_N$$

for any feasible control $u_N(t)$ to (2.6), which is not $u_N(t) \equiv 1$. Comparing the latter with (2.7), we conclude that the control $u_N(t) \equiv 1$ is *optimal* to (2.6) if $(t_1)^2/4 < c - 1$ and N is sufficiently large.

Let us finally show that for $t_1 > 2$ and $c > t^2/4 + 1$ (e.g., for $t_1 = 3$ and $c = 4$) the sequence of optimal controls $\bar{u}_N \equiv 1$ does *not* satisfy the approximate maximum condition (1.3) at points $t \in T_N$ sufficiently close to $t = t_1/2$. Compute the

Hamilton–Pontryagin function (1.1) as a function of $t \in T_N$ and $u \in U$ at the optimal trajectory $\bar{x}_N(t)$ corresponding to the optimal control under consideration with the adjoint trajectory $p_N(t)$ to (1.6). Reducing (2.6) to the standard Mayer form and taking into account that $\bar{x}_N(t) < t^2/2$ for all $t \in T_N$ due to the above formula for the trajectory of (2.6) corresponding to $u_N(t) \equiv 1$, we get

$$\begin{aligned} H(t, \bar{x}_N(t), p_N(t+h_N), u) &= tp_N(t+h_N)u - u - |\bar{x}_N(t) - t^2/2| \\ &= (tp_N(t+h_N) - 1)u + (\bar{x}_N(t) - t^2/2), \end{aligned}$$

where $p_N(t)$ satisfies the equation

$$p_N(t) = p_N(t+h_N) + h_N, \quad p_N(t_1) = 0,$$

whose solution is $p_N(t) = t_1 - t$. Therefore,

$$\begin{aligned} H(t, \bar{x}_N(t), p_N(t+h_N), u) &= \big(t(t_1 - t + h_N) - 1\big)u + O(h_N) \\ &= (-t^2 + t_1 t - 1)u + O(h_N). \end{aligned}$$

The multiplier $-t^2 + t_1 t - 1$ is positive in the neighborhood of $t = t_1/2$ if its discriminant $t_1^2 - 4$ is positive. Thus $u = c$, but not $u = 1$, provides the maximum to the Hamilton–Pontryagin function around $t = t_1/2$ if h_N is sufficiently small. □

Observe that the constructions in Examples 2.2 and 2.4 are actually based on the same idea. The crucial point in Example 2.2 (and similarly in Example 2.3) is that, due to the *incommensurability* of the reachable set and the ideal point of minimum $x_N(1) = r$, the endpoint of the optimal trajectory $\bar{x}_N(1)$ turns out to be in the zone, where the discontinuous derivative of the cost function has the "wrong sign." A similar situation is in Example 2.4, but in this case the function $\frac{\partial H}{\partial x}$ is discontinuous with respect to x, and the optimal trajectory in the discrete problem deviates to the "wrong side" of the ideal (continuous-time) optimal trajectory.

3. Uniformly upper subdifferentiable functions. In this section we present some tools of nonsmooth analysis needed for the formulation and proofs of the main *positive* results of the paper: the AMP for ordinary and time-delay systems in the new *upper subdifferential* form. Results in this form are definitely nontraditional in optimization, since they concern *minimization* problems for which *lower* subdifferential constructions are usually employed. However, we saw in the preceding section that results of the conventional lower type simply do not hold for the AMP. In sections 4 and 5 we are going to employ *upper* subdifferential constructions for nonsmooth minimization problems of optimal control, which happen to work for a special class of *uniformly upper subdifferentiable* functions we describe and discuss in this section.

Given an extended-real-valued function $\varphi\colon \mathbb{R}^n \to \overline{\mathbb{R}} := [-\infty, \infty]$ finite at $\bar{x}$, we first define its *Fréchet upper subdifferential* by

$$\widehat{\partial}^+ \varphi(\bar{x}) := \left\{ x^* \in \mathbb{R}^n \,\middle|\, \limsup_{x \to \bar{x}} \frac{\varphi(x) - \varphi(\bar{x}) - \langle x^*, x - \bar{x} \rangle}{\|x - \bar{x}\|} \le 0 \right\}. \tag{3.1}$$

This construction is known also as the "Fréchet superdifferential" or the "viscosity superdifferential"; it is extensively used in the theory of viscosity solutions. The set (3.1) is symmetric to the (lower) Fréchet subdifferential

$$\widehat{\partial}^+ \varphi(\bar{x}) = -\widehat{\partial}(-\varphi)(\bar{x}),$$

which is widely used in variational analysis under the name of "regular" or "strict" subdifferential; see, e.g., [12, 14]. The upper subdifferential (3.1) is our *primary* generalized differential construction in this paper. This set is closed and convex but may be empty for many functions useful in minimization. In fact, both $\widehat{\partial}^+\varphi(\bar{x})$ and $\widehat{\partial}\varphi(\bar{x})$ are nonempty simultaneously if and only if φ is Fréchet differentiable at $\bar{x}$ in which case

$$\widehat{\partial}^+\varphi(\bar{x}) = \widehat{\partial}\varphi(\bar{x}) = \big\{\nabla\varphi(\bar{x})\big\}.$$

Following [5], we define the *basic upper subdifferential* of φ at $\bar{x}$ by

$$\partial^+\varphi(\bar{x}) := \Big\{x^* \in \mathbb{R}^n \big| \ \exists\, x_k \to \bar{x} \ \text{ with } \ \varphi(x_k) \to \varphi(\bar{x}) \\ \text{and } \exists\, x_k^* \in \widehat{\partial}^+\varphi(x_k) \ \text{ with } \ x_k^* \to x^*\Big\}$$

and call φ *upper regular* at $\bar{x}$ if $\partial^+\varphi(\bar{x}) = \widehat{\partial}^+\varphi(\bar{x})$. This class includes, in particular, all strictly differentiable functions as well as proper concave functions. In the concave case $\widehat{\partial}^+\varphi(\bar{x})$ reduces to the upper subdifferential of convex analysis, which is nonempty whenever $\bar{x} \in \operatorname{ri}(\operatorname{dom}\varphi)$. Moreover, $\widehat{\partial}^+\varphi(\bar{x}) \neq \emptyset$ if φ is upper regular at $\bar{x}$ and Lipschitz continuous around this point. In the latter case the upper regularity of φ agrees with the subdifferential regularity of $-\varphi$ at the same point in the sense of [12]. It is interesting to observe that, for Lipschitzian upper regular functions, the Fréchet upper subdifferential (3.1) agrees with Clarke's generalized gradient $\overline{\partial}\varphi(\bar{x})$ of [1]. Indeed, one has

$$\overline{\partial}\varphi(\bar{x}) = \operatorname{co}\partial^+\varphi(\bar{x})$$

if φ is Lipschitz continuous around $\bar{x}$; see, e.g., [5, Theorem 2.1]. Since $\partial^+\varphi(\bar{x}) = \widehat{\partial}^+\varphi(\bar{x})$ for upper regular functions and since $\widehat{\partial}^+\varphi(\bar{x})$ is always convex, we arrive at $\overline{\partial}\varphi(\bar{x}) = \widehat{\partial}^+\varphi(\bar{x})$.

Let us now define a class of functions for which we obtain an extension of the AMP to nonsmooth control problems in the next section.

DEFINITION 3.1 (uniform upper subdifferentiability). *A function $\varphi\colon \mathbb{R}^n \to \overline{\mathbb{R}}$ is* uniformly upper subdifferentiable *around a point $\bar{x}$, where it is finite, if there is a neighborhood V of $\bar{x}$ such that for every $x \in V$ there exists $x^* \in \mathbb{R}^n$ with the following property: Given any $\varepsilon > 0$, there is $\eta > 0$ for which*

$$\varphi(v) - \varphi(x) - \langle x^*, v - x\rangle \le \varepsilon\|v - x\| \tag{3.2}$$

whenever $v \in V$ with $\|v - x\| \le \eta$.

It is easy to check that the class of uniformly upper subdifferentiable functions includes all continuously differentiable functions and concave continuous functions, and also is closed with respect to taking the minimum over compact sets. The uniform upper subdifferentiability property of φ around $\bar{x}$ is actually a localization of the so-called weak convexity property for $-\varphi$ in the sense of [10], which has been broadly used in numerical optimization. Note that if φ is Lipschitz continuous and differentiable at some point, it may not be uniformly upper subdifferentiable around it, for example, $\varphi(x) = x^2\sin(1/x)$ for $x \neq 0$ with $\varphi(0) = 0$. The following result shows, in particular, that uniformly upper subdifferential functions enjoy upper regularity and fully describe the set of x^* satisfying (3.2).

PROPOSITION 3.2 (upper regularity of uniformly upper subdifferentiable functions). *Let φ be uniformly upper subdifferentiable around $\bar{x}$. Then it is upper regular at $\bar{x}$ and Lipschitz continuous around this point, and property* (3.2) *holds for all $x^* \in \widehat{\partial}^+\varphi(x)$ with x around $\bar{x}$.*

Proof. Denote by $G(x)$ the set of x^* for which (3.2) holds. This set is nonempty and, as directly follows from (3.2), it is closed, convex, and bounded for all $x \in V$. One can immediately observe from the comparison of (3.1) and (3.2) that $G(x) \subset \widehat{\partial}^+\varphi(x)$. Let us show that in fact $G(x) = \widehat{\partial}^+\varphi(x)$ whenever $x \in V$.

It follows from the results of [10, section 1.1] that φ is locally Lipschitzian around $\bar{x}$ and directionally differentiable on V in any direction, and its directional derivative admits the representation

$$\varphi'(x;w) = \min\big\{\langle x^*, w\rangle \big|\ x^* \in G(x)\big\} \quad \text{for all} \quad x \in V,\ w \in \mathbb{R}^n. \tag{3.3}$$

As is well known, the Fréchet upper subdifferential (3.1) of a locally Lipschitzian function φ at x is representable as

$$\widehat{\partial}^+\varphi(x) = \left\{ x^* \in \mathbb{R}^n \,\middle|\, \langle x^*, w\rangle \ge \limsup_{\tau\downarrow 0} \frac{\varphi(x+\tau w) - \varphi(x)}{\tau} \ \text{ for all } \ w \in \mathbb{R}^n \right\}.$$

Comparing the latter with (3.3), we get $G(x) = \widehat{\partial}^+\varphi(x)$ for all $x \in V$. Furthermore, it is not hard to show directly from the definition that the mapping $G\colon V \rightrightarrows \mathbb{R}^n$ is closed-graph on any compact subset of V. Finally taking into account the construction of the basic subdifferential, we conclude that $\partial^+\varphi(x) = \widehat{\partial}^+\varphi(x)$ for all $x \in V$. ∎

Note that Proposition 3.2 is in accordance with [12, Theorem 9.16], which gives a characterization of the simultaneous Lipschitz continuity and subdifferential regularity of a function on an open set via the existence of the classical directional derivative and its upper semicontinuity with respect to directions. Note also that we need an extra requirement on the *uniform* upper subdifferentiability in Definition 3.1, which essentially restricts the class of functions suitable for applications to the AMP in the upper subdifferential form, due to the *parametric* nature of finite-difference systems viewed as a process as $N \to \infty$. In particular, the Lipschitz continuity and upper regularity are *not* needed for upper subdifferential results related to the necessary optimality condition for *fixed* solutions in various problems of constrained optimization and optimal control; cf. [7, 8].

4. AMP in upper subdifferential form. This is a central section of the paper, which collects the main positive results on the fulfillment of the AMP in the upper subdifferential form for the discrete approximation problems (P_N). We derive three closely related versions of the AMP in somewhat different settings of (P_N). The first version applies to problems with *no endpoint constraints* and establishes the upper subdifferential form of the AMP with *no properness* requirement on the sequence of optimal controls and with an *error estimate* as $\varepsilon(t, h_N) = O(h_N)$ in the approximate maximum condition. The second result, with a different proof, is the major version of the AMP for the *constrained nonsmooth* problems (P_N), which extends the one formulated in section 1. The last version of the AMP concerns discrete approximation problems in the case of *incommensurability* of the time interval $t_1 - t_0$ and the discretization step h_N. This version is basic for the extension of the AMP to time-delay systems obtained in the next section.

Let us start with the upper subdifferential form of the AMP for problems with

no endpoint constraints. Throughout this section impose the following *standing assumptions* on the mapping f and the control set U:

(H1) $f = f(t,x,u)$ is continuous with respect to all its variables and continuously differentiable with respect to the state variable x in some tube containing optimal trajectories for all u from the compact set U in a metric space and for all $t \in T_N$ uniformly in $N \in \mathbb{N}$.

THEOREM 4.1 (AMP for problems with no endpoint constraints). *Let the pairs $(\bar{x}_N, \bar{u}_N)$ be optimal to problems (P_N) with $\varphi_i = 0$ for all $i = 1, \dots, m+r$. Assume in addition to* (H1) *that φ_0 is uniformly upper subdifferentiable around the limiting point(s) of the sequence $\{\bar{x}_N(t_1)\}$, $N \in \mathbb{N}$. Then for every sequence of upper subgradients $x_N^* \in \widehat{\partial}^+\varphi_0(\bar{x}_N(t_1))$ there is $\varepsilon(t,h_N) \to 0$ as $N \to \infty$ uniformly in $t \in T_N$ such that the approximate maximum condition* (1.3) *holds for all $t \in T_N$, where each $p_N(t)$ satisfies the adjoint system* (1.6) *with the transversality condition*

$$p_N(t_1) = -x_N^* \quad \text{for all} \quad N \in \mathbb{N}. \tag{4.1}$$

Moreover, $\varepsilon(t,h_N) = O(h_N)$ in (1.3) *if φ_0 is locally concave around $\bar{x}_N(t_1)$ uniformly in N while $\partial f(\cdot,u,t)/\partial x$ is locally Lipschitz around $\bar{x}_N(t)$ with a constant uniform in $u \in U$, $t \in T_N$, $N \in N$.*

Proof. Considering a sequence of optimal solutions $(\bar{x}_N, \bar{u}_N)$ to (P_N), we suppose that $\bar{x}_N(t)$ belong to the uniform neighborhoods in the assumptions made for all $N \in \mathbb{N}$. It follows from the uniform upper subdifferentiability of φ_0 by Proposition 3.2 that $\widehat{\partial}^+\varphi_0(\bar{x}_N(t_1)) \neq \emptyset$ and that inequality (3.2) holds for any $x^* \in \widehat{\partial}^+\varphi_0(\bar{x}_N(t_1))$ as $N \to \infty$. Now taking an arbitrary sequence of $x_N^* \in \widehat{\partial}^+\varphi_0(\bar{x}_N(t_1))$, we get

$$\varphi_0(x) - \varphi_0(\bar{x}_N(t_1)) \le \langle x_N^*, x - \bar{x}_N(t_1)\rangle + o(\|x - \bar{x}_N(t_1)\|), \tag{4.2}$$

where

$$\frac{o(\|x - \bar{x}_N(t_1)\|)}{\|x - \bar{x}_N(t_1)\|} \to 0$$

as $x \to x_N(t_1)$ *uniformly* in N. Moreover, one can clearly eliminate o, i.e., put $o(\|x - \bar{x}_N(t_1)\|) \equiv 0$ if φ_0 is assumed to be uniformly locally concave. Letting $p_N(t_1) := -x_N^*$ as in (4.1), we derive from (4.2) that

$$J(x_N, u_N) - J(\bar{x}_N, \bar{u}_N) \le -\big\langle p_N(t_1), \Delta x_N(t_1)\big\rangle + o(\|\Delta x_N(t_1)\|) \tag{4.3}$$

with $\Delta x_N(t) := x_N(t) - \bar{x}_N(t)$ for all feasible processes (x_N, u_N) to (P_N) whenever $x_N(t_1)$ is sufficiently close to $\bar{x}_N(t_1)$. From the identity

$$\begin{aligned}\big\langle p_N(t_1), \Delta x_N(t_1)\big\rangle &= \sum_{t \in T_N} \langle p_N(t+h_N) - p_N(t), \Delta x_N(t)\rangle \\ &\quad + \sum_{t \in T_N} \langle p_N(t+h_N), \Delta x_N(t+h_N) - \Delta x_N(t)\rangle\end{aligned}$$

and (4.3) we get

(4.4)
$$\begin{aligned}0 &\le J(x_N,u_N)-J(\bar{x}_N,\bar{u}_N)\le -\big\langle p_N(t_1),\Delta x_N(t_1)\big\rangle+o(\|\Delta x_N(t_1)\|)\\ &=-\sum_{t\in T_N}\langle p_N(t+h_N)-p_N(t),\Delta x_N(t)\rangle\\ &\quad -h_N\sum_{t\in T_N}\left\langle p_N(t+h_N),\frac{\partial f}{\partial x}(t,\bar{x}_N,\bar{u}_N)\Delta x_N(t)\right\rangle\\ &\quad -h_N\sum_{t\in T_N}\Delta_u H(t,\bar{x}_N(t),p_N(t+h_N),\bar{u}_N(t))+h_N\sum_{t\in T_N}\eta_N(t)+o(\|\Delta x_N(t_1)\|),\end{aligned}$$

where the remainder $\eta_N(t)$ is computed by

(4.5)
$$\begin{aligned}\eta_N(t)=&\left\langle\frac{\partial H}{\partial x}(t,\bar{x}_N(t),p_N(t+h_N),u_N(t))-\frac{\partial H}{\partial x}(t,\bar{x}_N(t),p_N(t+h_N),\bar{u}_N(t)),\Delta x_N(t)\right\rangle\\ &+o(\|\Delta x_N(t)\|)\end{aligned}$$

with $o(\|\Delta x_N(t)\|)$ uniform in N due to (H1), and where

$$\begin{aligned}\Delta_u H(t,\bar{x}_N(t),p_N(t+h_N),\bar{u}_N(t)) :=\ & H(t,\bar{x}_N(t),p_N(t+h_N),u_N(t))\\ & -H(t,\bar{x}_N(t),p_N(t+h_N),\bar{u}_N(t)).\end{aligned}$$

One can easily see that $o(\|\Delta x_N(t)\|)=O\big(\|\Delta x_N(t)\|^2\big)$ in (4.5), uniformly in N, under the additional Lipschitzian assumption on $\partial f(\cdot,u,t)/\partial x$ in the theorem.

Now let us consider *needle variations* of the optimal controls $\bar{u}_N$ in the form

$$u_N(t)=\begin{cases}v & \text{if } t=\tau,\\ \bar{u}_N(t) & \text{if } t\in T_N\setminus\{\tau\},\end{cases}\tag{4.6}$$

where $v\in U$ and $\tau=\tau(N)\in T_N$ as $N\in\mathbb{N}$. All the controls (4.6) are feasible to the discrete problems with no endpoint constraints. The trajectory increments corresponding to the needle variations (4.6) satisfy

$$\Delta x_N(t)=0 \ \text{ for } \ t=t_0,\dots,\tau \quad \text{ and } \quad |\Delta x_N(t)|=O(h_N) \ \text{ for } \ t=\tau+h_N,\dots,t_1.$$

Taking this into account and substituting (4.6) into (4.4), we get

$$\begin{aligned}0 &\le J(x_N,u_N)-J(\bar{x}_N,\bar{u}_N)\\ &\le -h_N\Delta_u H(\tau,\bar{x}_N(\tau),p_N(\tau+h_N),\bar{u}_N(\tau))+o(h_N),\end{aligned}\tag{4.7}$$

where one obviously has $o(h_N)=O(h_N^2)$ under the additional concavity and Lipschitzian assumptions made in the theorem. Arguing by contradiction, we derive from (4.7) the approximate maximum condition (1.3), with the specification of $\varepsilon(t,h_N)$ under the additional assumptions, and complete the proof of the theorem. □

Remark 4.1 (upper versus lower subdifferential forms of transversality conditions). The main difference between the conventional (lower) subdifferential form, which is *not* actually fulfilled in the case of the AMP, and the upper subdifferential form of Theorem 4.1 is that the transversality condition (4.1) holds for *every* upper subgradient $x_N^*\in\widehat{\partial}^+\varphi_0(\bar{x}_N(t_1))$ instead of just for *some* lower subgradient in the

conventional transversality conditions for continuous-time and discrete-time (with a fixed step) systems. In particular, for discrete-time systems with convex velocity sets both lower and upper subdifferential forms of the (exact) discrete maximum principle hold; see [8], where the upper subdifferential/superdifferential form of the discrete maximum principle has been established under milder assumptions on φ_0 in comparison with Theorem 4.1. If φ_0 is Lipschitz continuous and upper regular and hence $\widehat{\partial}^+\varphi_0(\bar{x}) = \overline{\partial}\varphi_0(\bar{x})$, which is the case for uniformly upper subdifferential functions by Proposition 3.2, there is indeed a *dramatic* difference between the upper subdifferential form of transversality conditions and a well-recognized form in terms of the Clarke subdifferential: Instead of establishing the fulfillment transversality for just some element of $\overline{\partial}\varphi_0(\bar{x}(t_1))$ we establish it for the *whole set*. A similar situation takes place for continuous-time systems, where the upper subdifferential form of transversality in the maximum principle can be proved, in problems with no endpoint constraints, in the line of arguments of Theorem 4.1. Observe, however, that there is a more subtle lower subdifferential form of transversality conditions for continuous-time and discrete-time (of a fixed step) systems that involves basic/limiting subgradients but not Clarke ones; see [5, 14]. This form is generally independent of the upper subdifferential form of transversality conditions. Note that the major drawback of the upper subdifferential form is that it applies to a restrictive class of functions. But, as seen in section 2, there is *no alternative* to this form for the AMP.

Next let us consider a sequence of the discrete approximation problems (P_N) with *endpoint constraints* of the inequality and equality types. We are going to derive an extension of the AMP formulated in section 1 to these problems involving *nonsmooth* functions that describe the cost and inequality constraints. The following upper subdifferential version of the AMP for constrained problems imposes the *uniform upper subdifferentiability* property on the cost and inequality constraint functions, the *properness* assumption on the sequence of optimal controls, and the *consistency* condition on perturbations of the equality constraints. As seen in section 2, all three requirements are essential.

The proof of the AMP for constrained problems is substantially different from the one in Theorem 4.1 and much more involved, although it employs the same approach to handle nonsmoothness. The major part of the proof goes back to the smooth setting and is based on a finite-difference counterpart of the *hidden convexity* properties for sequences of discrete approximations.

Before formulating and proving the theorem, we need an auxiliary result that actually reflects the hidden convexity property in the nonsmooth setting under consideration. Let us first recall some definitions from [4, 5]. Given a sequence of feasible solutions (x_N, u_N) to (P_N), we say that the inequality constraint

$$\varphi_i(x_N(t_1)) \le \gamma_{iN} \ \text{ with } \ i \in \{1, \dots, m\}$$

is *essential* for x_N along a subsequence $\mathcal{M}$ of natural numbers if $\varphi_i(x_N(t_1)) - \gamma_{iN} = O(h_N)$ as $h_N \to 0$; i.e., there is $K_i \ge 0$ such that

$$-K_i h_N \le \varphi_i(x_N(t_1)) - \gamma_{iN} \le 0 \ \text{ as } \ N \to \infty, \ \ N \in \mathcal{M}.$$

This constraint is *inessential* for x_N along $\mathcal{M}$ if for any $K > 0$ there is $N_0 \in \mathbb{N}$ such that

$$\varphi_i(x_N(t_1)) - \gamma_{iN} \le -K h_N \ \text{ for all } \ N \ge N_0, \ \ N \in \mathcal{M}.$$

Note that the notion of essential constraints in sequences of discrete approximations corresponds to the notion of *active* constraints in nonparametric optimization problems. Without loss of generality we suppose that for the sequence of optimal trajectories $\bar{x}_N$ to (P_N) under consideration the first $l \in \{1,\dots,m\}$ inequality constraints are essential while the other $m-l$ constraints are inessential along all natural numbers, i.e., with $\mathcal{M} = \mathcal{N}$.

Assume now that $\widehat{\partial}^+\varphi_i(\bar{x}_N(t_1)) \neq \emptyset$ for all $i = 0,\dots,l$ and $N \in \mathbb{N}$ sufficiently large and fix some sequence of upper subgradients $x^*_{iN} \in \widehat{\partial}^+\varphi_i(\bar{x}_N(t_1))$ for such i and N. Denote by $\Delta_{\tau,v}\bar{x}_N(t_1)$ the *endpoint increment* generated by the *needle variation* (4.6) of the optimal control $\bar{u}_N$ with some $\tau \in T_N$ and $v \in U$. Form the set

$$S_N := \big\{(s_0,\dots,s_l) \in \mathbb{R}^n \big|\ s_i = \big\langle x^*_{iN}, \Delta_{\tau,v}\bar{x}_N(t_1)\big\rangle,\ \tau \in T_N,\ \ v \in U\big\} \tag{4.8}$$

along the fixed sequences of the above upper subgradients x^*_{iN} and consider the *negative orthant* in R^{l+1} given by

$$\mathbb{R}^{l+1}_< := \big\{(x_0,\dots,x_l) \in \mathbb{R}^{l+1} \big|\ x_i < 0 \ \text{ for all } \ i = 0,\dots,l\big\}.$$

The following result is due to the hidden convexity property of finite-difference systems established in [4, 5] with the adjustment to nonsmoothness via uniform upper subdifferentiability.

LEMMA 4.2 (hidden convexity). *Let $(\bar{x}_N, \bar{u}_N)$ be a sequence of optimal solutions to problems (P_N) with no equality constraints and with the inequality constraints such that the first $l \in \{1,\dots,m\}$ of them are essential for the sequence of $\bar{x}_N$ while the other are inessential for this sequence. In addition to* (H1) *assume that each φ_i, $i = 0,\dots,l$, is uniformly upper subdifferentiable around the limiting point(s) of $\{\bar{x}_N(t_1)\}$, $N \in \mathbb{N}$, and that*

(H2) *the sequence of optimal controls $\{\bar{u}_N\}$ is proper.*

Then there is a sequence of $(l+1)$-dimensional quantities of order $o(h_N)$ as $h_N \downarrow 0$ such that

$$\big(\operatorname{co} S_N + o(h_N)\big) \cap \mathbb{R}^{l+1}_< = \emptyset \ \text{ for large } \ N \in \mathbb{N}, \tag{4.9}$$

where $\operatorname{co} S_N$ stands for the convex hull of the set S_N in (4.8) *built upon the given sequences of upper subgradients $x^*_{iN} \in \widehat{\partial}^+\varphi_i(\bar{x}_N(t_1))$, $i = 0,\dots,l$.*

Proof. It follows the proof of Lemma 3 in [4] based on the hidden convexity property of Theorem 1 therein (respectively, [5, Lemma 16.2 and Theorem 15.1]). The only essential difference is that the equalities

$$\begin{aligned}\varphi_i(\bar{x}_N(t_1)) \ - \ \varphi_i(\bar{x}_N(t_1)) - \big\langle \nabla\varphi_i(\bar{x}_N(t_1)), \Delta x_N(t_1)\big\rangle \\ + \ o(\|\Delta x_N(t_1)\|) = 0, \quad i = 0,\dots,l,\end{aligned}$$

in the smooth case of [4, 5] are replaced with the inequalities

$$\varphi_i(\bar{x}_N(t_1)) - \varphi_i(\bar{x}_N(t_1)) - \big\langle x^*_{iN}, \Delta x_N(t_1)\big\rangle + o(\|\Delta x_N(t_1)\|) \le 0, \quad i = 0,\dots,l,$$

due to the uniform upper subdifferentiability of φ_i. Compare this proof to the proof of Theorem 4.1. □

Based on Lemma 4.2, we get the following extension of the AMP to finite-difference problems with nonsmooth inequality and smooth equality constraints.

THEOREM 4.3 (AMP for problems with endpoint constraints). *Let the pairs $(\bar{x}_N, \bar{u}_N)$ be optimal to problems (P_N), where the first $l \in \{1,\dots,m\}$ inequality constraints are essential for $\bar{x}_N$, $N \in \mathbb{N}$. In addition to* (H1) *and* (H2) *assume that*

φ_i are uniformly upper subdifferentiable around the limiting point(s) of $\{\bar{x}_N(t_1)\}$ for $i=0,\dots,l$ and continuously differentiable around them for $i=m+1,\dots,m+r$, and that

(H3) *the consistency condition* (1.2) *holds for the perturbations δ_{iN} of the equality constraints.*

Then for any sequences of upper subgradients $x_{iN}^*\in\widehat{\partial}^+\varphi_i(\bar{x}_N(t_1))$, $i=0,\dots,l$, there are numbers $\{\lambda_{iN}|\ i=0,\dots,l,m+1,\dots,m+r\}$ and a function $\varepsilon(t,h_N)\to 0$ as $N\to\infty$ uniformly in $t\in T_N$ such that the approximate maximum condition (1.3) *is fulfilled with the adjoint trajectory $p_N(t)$ to* (1.6) *satisfying the transversality condition*

$$p_N(t_1)=-\sum_{i=0}^{l}\lambda_{iN}x_{iN}^*-\sum_{i=m+1}^{m+r}\lambda_{iN}\nabla\varphi_i(\bar{x}_N(t_1)) \tag{4.10}$$

along with

$$\varphi_i(\bar{x}_N(t_1))-\gamma_{iN}=O(h_N)\quad\text{for}\quad i=1,\dots,l, \tag{4.11}$$

$$\lambda_{iN}\ge 0\ \text{ for }\ i=0,\dots,l,\quad\text{and}\quad\sum_{i=0}^{l}\lambda_{iN}^2+\sum_{i=m+1}^{m+r}\lambda_{iN}^2=1. \tag{4.12}$$

Proof. Let us first consider the case of inequality constraints, i.e., when $\varphi_i=0$ for the indices $i=m+1,\dots,m+r$ in (P_N). Take arbitrary sequences of $x_{iN}^*\in\widehat{\partial}^+\varphi_i(\bar{x}_N(t_1))$ as $i=0,\dots,l$. By Lemma 4.2 we apply the separation theorem to the convex sets in (4.9). It follows from the structures of these sets that there are $\lambda_{iN}\ge 0$ for $i=0,\dots,l$ and all N sufficiently large satisfying $\lambda_{0N}^2+\dots+\lambda_{lN}^2=1$ and

$$\sum_{i=0}^{l}\big\langle x_{iN}^*,\Delta_{\tau,v}\bar{x}_N(t_1)\big\rangle+o(h_N)\ge 0$$

for any $\tau\in T_N$ and $v\in U$. Then considering the trajectory $p_N(t)$ of the adjoint system (1.6) with the transversality condition

$$p(t_1)=-\sum_{i=0}^{l}\lambda_{iN}x_{iN}^*$$

and arguing as in the proof of Theorem 4.1, we get the inequality

$$h_N\big[H(\tau,\bar{x}_N(\tau),p_N(\tau+h_N),v)-H(\tau,\bar{x}_N(\tau),p_N(\tau+h_N),\bar{u}_N(\tau))\big]+o(h_N)\le 0$$

held for all $\tau\in T_N$ and $v\in U$. This easily implies the approximate maximum condition (1.3). Since (4.11) just means that the inequality constraints are essential for $\bar{x}_N$ as $i=1,\dots,l$, we arrive at all the conclusions of the theorem for the case of inequality constraints. Observe that the result obtained ensures the fulfillment of the AMP with *zero multipliers* corresponding to inessential inequality constraints.

Next let us consider the general case of (P_N) when the equality constraints are present as well. Each equality constraint $\varphi_{iN}(x)\le\delta_N$ can be obviously represented as the two inequality constraints

$$\varphi_{iN}^+(x):=\varphi_i(x)-\delta_{iN}\le 0,\quad\varphi_{iN}^-(x):=-\varphi_i(x)-\delta_{iN}\le 0 \tag{4.13}$$

for $i = m+1, \ldots, m+r$. Let us show that if one of the constraints (4.13) is essential for $\bar{x}_N$ along some subsequence $\mathcal{M} \subset \mathbb{N}$, then the other is inessential along the same subsequence under the consistency condition (1.2). Indeed, suppose for definiteness that the constraint $\varphi_{iN}^+(\bar{x}_N(t_1)) \le 0$ is essential for some $i \in \{m+1, \ldots, m+r\}$ along $\mathcal{M}$. Then by (1.2) we have

$$\varphi_{iN}^-(\bar{x}_N(t_1)) = -\varphi_i(\bar{x}_N(t_1)) + \delta_{iN} - 2\delta_{iN} = -\varphi_{iN}^+(\bar{x}_N(t_1)) - 2\delta_{iN} \le Kh_N, \quad N \in \mathcal{M},$$

for any $K > 0$ as $N \to \infty$, which means that the constraint $\varphi_{iN}^-(\bar{x}_N(t_1)) \le 0$ is inessential. Since φ_i is assumed to be C^1 for $i = m+1, \ldots, m+r$, both φ_{iN}^+ and φ_{iN}^- are uniformly upper subdifferentiable around the reference points. Applying now the inequality case of the theorem that has been already proved, we find either λ_{iN}^+ or λ_{iN}^- corresponding to one of the essential constraints $\varphi_{iN}^+(\bar{x}_N(t_1)) \le 0$ and $\varphi_{iN}^-(\bar{x}_N(t_1)) \le 0$, respectively. Finally putting

$$\lambda_{iN} := \lambda_{iN}^+ \quad \text{or} \quad \lambda_{iN} := -\lambda_{iN}^-, \quad i = m+1, \ldots, m+r,$$

depending on which of these constraints is essential, we complete the proof of the theorem. □

Note that both Theorems 4.1 and 4.3 concern the discrete approximation problems (P_N) with $t_1 - t_0 = Nh_N$, i.e., when the time interval and the discretization step are commensurable. Of course, it is not always the case in applications. Moreover, to extend the AMP to time-delay systems in the next section, we reduce them to systems with no delays but with *incommensurable* $t_1 - t_0$ and h_N. To proceed in this way, one needs to use modifications of the above results in the case of incommensurability. Let us present the corresponding modification of Theorem 4.1 for problems with no endpoint constraints. For simplicity we use the notation $f(t, x_N, u_N) := f(t, x_N(t), u_N(t))$ and consider the following sequences of discrete approximations with the grid

$$T_N := \{t_0, t_0 + h_N, \ldots, t_1 - \widetilde{h}_N - h_N\}, \quad h_N := \frac{t_1 - t_0}{N},$$

$$\widetilde{h}_N := t_1 - t_0 - h_N \left[\frac{t_1 - t_0}{h_N}\right],$$

where $[a]$ stands as usual for the greatest integer less than or equal to the real number a. The modified problems are written as

$$(\widetilde{P}_N) \qquad \begin{cases} \text{minimize } J(x_N, u_N) := \varphi(x_N(t_1)) \\ \text{subject to} \\ x_N(t + h_N) = x_N(t) + h_N f(t, x_N, u_N), \quad t \in T_N, \quad x_N(t_0) = x_0 \in \mathbb{R}^n, \\ x_N(t_1) = x_N(t_1 - \widetilde{h}_N) + \widetilde{h}_N f(t_1 - \widetilde{h}_N, x_N, u_N), \\ u_N(t) \in U, \quad t \in T_N. \end{cases}$$

THEOREM 4.4 (AMP for problems with incommensurability). *Let the pairs $(\bar{x}_N, \bar{u}_N)$ be optimal to problems $(\widetilde{P}_N)$. Assume in addition to* (H1) *that φ is uniformly upper subdifferentiable around the limiting point(s) of the sequence $\{\bar{x}_N(t_1)\}$, $N \in \mathbb{N}$. Then for every sequence of upper subgradients $x_N^* \in \widehat{\partial}^+\varphi(\bar{x}_N(t_1))$ there is $\varepsilon(t, h_N) \to 0$ as $N \to \infty$ uniformly in $t \in T_N$ such that the approximate maximum condition*

$$H(t, \bar{x}_N, p_N, u_N) = \max_{u \in U} H(t, \bar{x}_N, p_N, u) + \varepsilon(t, h_N)$$

holds for all $t \in \widetilde{T}_N := T_N \cup \{t_1 - \widetilde{h}_N\}$, *where the Hamilton–Pontryagin function is defined by*

$$H(t, x_N, p_N, u) := \begin{cases} \langle p_N(t + h_N), f(t, x_N, u)\rangle & \text{if } t \in T_N, \\ \langle p_N(t), f(t - \widetilde{h}_N, x_N, u)\rangle & \text{if } t = t_1 - \widetilde{h}_N, \end{cases}$$

and where each $p_N(t)$ *satisfies the adjoint system*

$$\begin{cases} p_N(t) = p_N(t + h_N) + h_N \dfrac{\partial f}{\partial x}^*(t, \bar{x}_N, \bar{u}_N) p_N(t + h_N), \quad t \in T_N, \\ p_N(t_1 - \widetilde{h}_N) = p_N(t_1) + \widetilde{h}_N \dfrac{\partial f}{\partial x}^*(t_1 - \widetilde{h}_N, \bar{x}_N, \bar{u}_N) p_N(t_1) \end{cases}$$

with the transversality condition $p_N(t_1) = -x_N^*$.

Proof. It is similar to the proof of Theorem 4.1 with the modification of the increment formula for the minimizing functional,

$$\begin{aligned} 0 \le\ & J(x_N, u_N) - J(\bar{x}_N, \bar{u}_N) \le -\langle p_N(t_1), \Delta x_N(t_1)\rangle + o(\|\Delta x_N(t_1)\|) \\ =\ & -\sum_{t \in T_N} \langle p_N(t + h_N) - p_N(t), \Delta x_N(t)\rangle \\ & -\langle p_N(t_1) - p_N(t_1 - \widetilde{h}_N), \Delta x_N(t_1 - \widetilde{h}_N)\rangle \\ & - h_N \sum_{t \in T_N} \left\langle p_N(t + h_N), \frac{\partial f}{\partial x}(t, \bar{x}_N, \bar{u}_N) \Delta x_N(t) \right\rangle \\ & - \widetilde{h}_N \left\langle p_N(t_1), \frac{\partial f}{\partial x}(t_1 - \widetilde{h}_N, \bar{x}_N, \bar{u}_N) \Delta x_N(t_1 - \widetilde{h}_N) \right\rangle \\ & - h_N \sum_{t \in \widetilde{T}_N} \Delta_u H(t, \bar{x}_N, p_N, \bar{u}_N) + h_N \sum_{t \in \widetilde{T}_N} \eta_N(t) + o(\|\Delta x_N(t_1)\|), \end{aligned}$$

where $\Delta_u H$ and $\eta_N(t)$ are defined as above. Substituting now the adjoint trajectory into this formula and using the needle variation (4.6), we arrive at the conclusions of the theorem. □

Similar to the proof of Theorem 4.3 we can get its modification to the case of incommensurability with the transversality and related conditions (4.10)–(4.12).

5. AMP for discrete approximations of delay systems. This section is devoted to the extension of the AMP in the upper subdifferential form to finite-difference approximations of *time-delay* control systems. Actually we are not familiar with any previous results on the AMP for optimal control problems with delays, so the results obtained below seem to be new even for smooth-delay problems.

We mainly pay attention to discrete approximations of the following time-delay problem with no endpoint constraints:

$$(D) \qquad \begin{cases} \text{minimize } J(x, u) := \varphi(x(t_1)) \\ \text{subject to} \\ \dot{x}(t) = f(t, x(t), x(t - \theta), u(t)) \ \text{ a.e. } \ t \in [t_0, t_1], \\ x(t) = c(t), \quad t \in [t_0 - \theta, t_0], \\ u(t) \in U \ \text{ a.e. } \ t \in [t_0, t_1] \end{cases}$$

over measurable controls and absolute continuous trajectories, where $\theta > 0$ is the constant time delay, and where $c\colon [t_0 - \theta, t_0] \to \mathbb{R}^n$ is a given function defining the

initial "tail" condition that is necessary to start the delay system. Based on the above constructions for nondelayed systems, one can derive similar results for delay systems with endpoint constraints. We may also extend the results obtained to more complicated delay systems involving variable delays, set-valued tail conditions, etc. On the other hand, we show in the end of this section that the AMP *does not hold* for discrete approximations of functional-differential systems of *neutral type* that contain time delays not only in state variables but in velocity variables as well.

Let us build discrete approximations of the time-delay problem (D) based on the Euler finite-difference replacement of the derivative. In the case of time-delay systems we need to ensure that the point $t-\theta$ belongs to the discrete grid when t does. It can be achieved by defining the discretization step as $h_N := \frac{\theta}{N}$ in contrast to $h_N = \frac{t_1-t_0}{N}$ for the nondelayed problems (P_N). In such a scheme the length of the time interval $t_1 - t_0$ is generally *no longer commensurable* with the discretization step h_N.

To this end we consider the following sequences of discrete approximations of the delay problem (D) with the grid on the main interval $[t_0, t_1]$ given by

$$T_N := \big\{t_0, t_0 + h_N, \ldots, t_1 - \widetilde{h}_N - h_N\big\}, \quad h_N := \frac{\theta}{N}, \quad \widetilde{h}_N := t_1 - t_0 - h_N \left[\frac{t_1 - t_0}{h_N}\right]$$

but also involving the grid T_{0N} on the initial interval $[t_0 - \theta, t_0]$ as follows:

$$(D_N) \qquad \begin{cases} \text{minimize } J(x_N, u_N) := \varphi(x_N(t_1)) \\ \text{subject to} \\ x_N(t + h_N) = x_N(t) + h_N f(t, x_N(t), x_N(t - Nh_N), u_N(t)), \ t \in T_N, \\ x_N(t_1) = x_N(t_1 - \widetilde{h}_N) + \widetilde{h}_N f(t_1 - \widetilde{h}_N, x_N(t_1 - \widetilde{h}_N), u_N(t_1 - \widetilde{h}_N)), \\ x_N(t) = c(t), \quad t \in T_{0N} := \big\{t_0 - \theta, t_0 - \theta + h_N, \ldots, t_0\big\}, \\ u_N(t) \in U, \quad t \in T_N. \end{cases}$$

To derive the AMP for the sequence of problems (D_N), we reduce these problems to the ones *without delays* and employ the results of section 4. This follows the "method of steps" developed by Warga [15] in the case of delay problems for continuous-time systems. Our assumptions on the initial data of (P) are similar to those in section 4 for nondelay systems. A counterpart of (H1) is formulated as follows:

(H) $f = f(t, x, y, u)$ is continuous with respect to all its variables and continuously differentiable with respect to (x, y) in some tube containing optimal trajectories for all u from the compact set U in a metric space and for all $t \in \widetilde{T}_N := T_N \cup \{t_1 - \widetilde{h}_N\}$ uniformly in $N \in \mathbb{N}$.

For convenience we introduce the notation

$$\begin{aligned} &\xi_N(t) := (x_N(t), x_N(t-\theta)), \quad \bar{\xi}_N(t) := (\bar{x}_N(t), \bar{x}_N(t-\theta)), \\ &f(t, \xi_N, u_N) := f(t, x_N(t), x_N(t-\theta), u_N(t)), \\ &f(t, \bar{\xi}_N, u_N) := f(t, \bar{x}_N(t), \bar{x}_N(t-\theta), u_N(t)) \end{aligned}$$

in which terms the *adjoint system* to (D_N) is written as

$$\begin{aligned} p_N(t) = p_N(t + h_N) &+ h_N \frac{\partial f}{\partial x}^*(t, \bar{\xi}_N, \bar{u}_N) p_N(t + h_N) \\ &+ h_N \frac{\partial f}{\partial y}^*(t + \theta, \bar{\xi}_N, \bar{u}_N) p_N(t + \theta + h_N) \quad \text{for } \ t \in T_N, \end{aligned}$$

$$p_N(t_1 - \widetilde{h}_N) = p_N(t_1) + \widetilde{h}_N \frac{\partial f}{\partial x}^*(t_1 - \widetilde{h}_N, \bar{\xi}_N, \bar{u}_N) p_N(t_1)$$

along the optimal processes $(\bar{x}_N, \bar{u}_N)$ to the delay problems for each $N \in \mathbb{N}$. Introducing the corresponding *Hamilton–Pontryagin function*

$$H(t, x_N, y_N, p_N, u) := \begin{cases} \langle p_N(t+h_N), f(t, x_N, y_N, u)\rangle & \text{if } t \in T_N, \\ \langle p_N(t), f(t-\widetilde{h}_N, x_N, y_N, u)\rangle & \text{if } t = t_1 - \widetilde{h}_N \end{cases} \tag{5.1}$$

with $y_N(t) = x_N(t-\theta)$, we rewrite the adjoint system as

$$\begin{cases} p_N(t) = p_N(t+h_N) + h_N\left[\dfrac{\partial H}{\partial x}(t, \bar{\xi}_N, p_N, \bar{u}_N) + \dfrac{\partial H}{\partial y}(t+\theta, \bar{\xi}_N, p_N, \bar{u}_N)\right], \ t \in T_N, \\ p_N(t_1 - \widetilde{h}_N) = p_N(t_1) + \widetilde{h}_N \dfrac{\partial H}{\partial x}(t_1 - \widetilde{h}_N, \bar{\xi}_N, p_N, \bar{u}_N). \end{cases} \tag{5.2}$$

THEOREM 5.1 (AMP for delay systems). *Let the pairs $(\bar{x}_N, \bar{u}_N)$ be optimal to problems (D_N). Assume in addition to* (H) *that φ is uniformly upper subdifferentiable around the limiting point(s) of the sequence $\{\bar{x}_N(t_1)\}$, $N \in \mathbb{N}$. Then for every sequence of upper subgradients $x_N^* \in \widehat{\partial}^+\varphi(\bar{x}_N(t_1))$, the approximate maximum condition*

$$H(t, \bar{\xi}_N, p_N, \bar{u}_N) = \max_{u \in U} H(t, \bar{\xi}_N, p_N, u) + \varepsilon(t, h_N), \quad t \in \widetilde{T}_N, \tag{5.3}$$

holds with the Hamilton–Pontryagin function (5.1) *and with some $\varepsilon(t, h_N) \to 0$ as $h_N \to 0$ uniformly in $t \in \widetilde{T}_N$, where the adjoint trajectory p_N satisfies* (5.2) *and the transversality relations*

$$p_N(t_1) = -x_N^*, \qquad p_N(t) = 0 \ \ \textit{as} \ \ t > t_1. \tag{5.4}$$

Proof. Let us reduce the delay discrete approximation problems to the ones with no delay by the following multistep procedure. Denote

$$\begin{aligned} &y_{1N}(t) := x_N(t-h_N), \quad t \in \{t_0 + 2h_N, \dots, t_1 - \widetilde{h}_N\}, \\ &y_{1N}(t) := c_N(t-h_N), \quad t \in \{t_0 - \theta + h_N, \dots, t_0 + h_N\}, \\ &y_{2N}(t) := y_{1N}(t-h_N), \quad t \in \{t_0 - \theta + 2h_N, \dots, t_1 - \widetilde{h}_N\}, \\ &\quad \vdots \\ &y_{NN}(t) := y_{N-1,N}(t-h_N), \quad t \in \{t_0, \dots, t_1 - \widetilde{h}_N\}, \end{aligned}$$

and observe that the values of $y_{1N}(t_1), \dots, y_{NN}(t_1)$ can be defined arbitrarily, since they do not enter either the adjoint system or the cost function. To match the setup of Theorem 4.1, define

$$y_{1N}(t_1) := x_N(t_1 - \widetilde{h}_N), \ \ y_{2N}(t_1) := y_{1N}(t_1 - \widetilde{h}_N), \dots, y_{NN}(t_1) := y_{N-1,N}(t_1 - \widetilde{h}_N).$$

After the change of variables one has

$$y_{NN}(t) = \begin{cases} x_N(t-\theta), & t \in \{t_0 + \theta + h_N, \dots, t_1 - \widetilde{h}_N\}, \\ c(t-\theta), & t \in \{t_0, \dots, t_0 + \theta\}. \end{cases}$$

The original system in (D_N) is thereby reduced, for each $N \in \mathbb{N}$, to the following *nondelayed* system of dimension $\mathbb{R}^{(N+1)n}$:

$$\begin{cases} z_N(t+h_N) = z_N(t) + h_N g(t, z_N, u_N), \ \ t \in T_N, \\ z_N(t_1) = z_N(t_1 - \widetilde{h}_N) + \widetilde{h}_N g(t_1 - \widetilde{h}_N, z_N, u_N), \end{cases} \tag{5.5}$$

with the state vector $z_N(t) := (x_N(t), y_{1N}(t), \dots, y_{NN}(t))^*$ (the star stands for transposing) and with the mapping $g(t, z_N, u_N)$ given by

$$g(t, z_N(t), u_N(t)) := \begin{pmatrix} f(t, x_N(t), y_{NN}(t), u_N(t)) \\ \dfrac{x_N(t) - y_{1N}(t)}{h_N} \\ \cdots\cdots \\ \dfrac{y_{N-1,N}(t) - y_{NN}(t)}{h_N} \end{pmatrix},$$

where h_N should be replaced by $\widetilde{h}_N$ for $t = t_1 - \widetilde{h}_N$ in the last formula.

Let us apply Theorem 4.1 to minimizing the same functional as in (D_N) on the feasible pairs (z_N, u_N) of the nondelayed system (5.5). The adjoint system in this problem, with respect to the new adjoint variable $q \in \mathbb{R}^{(N+1)n}$, has the form

$$\text{(5.6)} \qquad \begin{cases} q_N(t) = q_N(t + h_N) + h_N \dfrac{\partial g}{\partial z}^* (t, \bar{z}_N, \bar{u}_N) q(t + h_N), \quad t \in T_N, \\ q_N(t_1 - \widetilde{h}_N) = q_N(t_1) + \widetilde{h}_N \dfrac{\partial g}{\partial z}^* (t_1 - \widetilde{h}_N, \bar{z}_N, \bar{u}_N) q_N(t_1) \end{cases}$$

with the transversality condition

$$\text{(5.7)} \qquad q_N(t_1) = -(x_N^*, 0, \dots, 0)^* \ \text{ for } \ x_N^* \in \widehat{\partial}^+ \varphi(\bar{x}_N(t_1)).$$

Computing the matrix $\frac{\partial g}{\partial z}$, we get

$$\frac{\partial g^*}{\partial z} = \frac{1}{h_N} \begin{pmatrix} h_N \dfrac{\partial f^*}{\partial x} & 1 & \dots & 0 & 0 \\ 0 & -1 & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots \\ h_N \dfrac{\partial f^*}{\partial y_{NN}} & 0 & \dots & 0 & -1 \end{pmatrix}.$$

Taking this into account and performing elementary calculations, we arrive at the adjoint system (5.2) and the transversality relations (5.4) for the first component $p_N(t)$ of the adjoint trajectory $q_N(t)$ satisfying (5.6) and (5.7). Denoting by $\widetilde{H}(t, z_N, q_N, u)$ the Hamilton–Pontryagin function (5.1) to the nondelayed system (5.5), one has

$$\begin{aligned} \widetilde{H}(t, \bar{z}_N, q_N, u) &= \big\langle q_N(t + h_N), g(t, \bar{z}_N, u) \big\rangle \\ &= \big\langle p_N(t + h_N), f(t, \bar{\xi}_N, u) \big\rangle + r(t, \bar{z}_N, q_N, h_N) \\ &= H(t, \bar{\xi}_N, p_N, u) + r(t, \bar{z}_N, q_N, h_N), \quad t \in T_N, \end{aligned}$$

and similarly for $t = t_1 - \widetilde{h}_N$, where H is given in (5.1), and where the remainder $r(t, \bar{z}_N, q_N, h_N)$ does not depend on u. Finally applying the approximate maximum condition (1.3) from Theorem 4.1 to system (5.5), we arrive at (5.3) and complete the proof of the theorem. □

Note that in the case of continuously differentiable cost functions φ around $\bar{x}_N(t_1)$ uniformly in N, the transversality relations (5.4) reduce to

$$p_N(t_1) = -\nabla \varphi(\bar{x}_N(t_1)), \qquad p_N(t) = 0 \ \text{ as } \ t > t_1.$$

Similarly to the proof of Theorem 5.1 we can deduce from Theorem 4.3 its delay counterpart for discrete approximation problems with *endpoint constraints*. In this result we add assumptions (H2) and (H3) to those in (H) and replace the transversality relations (5.4) in Theorem 5.1 with the conditions (4.10)–(4.12) with $p_N(t) = 0$ as $t > t_1$.

Finally in this section, we consider optimal control problems for finite-difference approximations of the so-called *functional-differential systems of neutral type*

$$\dot{x}(t) = f(t, x(t), x(t-\theta), \dot{x}(t-\theta), u(t)) \ \text{ a.e. } \ t \in [t_0, t_1], \tag{5.8}$$

which contain time delays not only in state but also in *velocity* variables. A finite-difference counterpart of (5.8) with the stepsize h and with the grid $T := \{t_0, t_0 + h, \dots, t_1 - h\}$ is

$$x(t+h) = x(t) + hf\left(t, x(t), x(t-\theta), \frac{x(t-\theta+h) - x(t-\theta)}{h}, u(t)\right), \quad t \in T, \tag{5.9}$$

and the adjoint system is given by

$$\begin{aligned} p(t) = p(t+h) &+ h\frac{\partial f}{\partial x}^*(t, \bar{\xi}, \bar{u})p(t+h) + h\frac{\partial f}{\partial y}^*(t+\theta, \bar{\xi}, \bar{u})p(t+\theta+h) \\ &+ h\frac{\partial f}{\partial z}^*(t+\theta-h, \bar{\xi}, \bar{u})p(t+\theta) - h\frac{\partial f}{\partial z}^*(t+\theta, \bar{\xi}, \bar{u})p(t+\theta+h), \quad t \in T, \end{aligned} \tag{5.10}$$

where $(\bar{x}, \bar{u})$ is an optimal solution to the neutral analogue of problems (D_N) and where

$$\bar{\xi}(t) := \left(\bar{x}(t), \bar{x}(t-\theta), \frac{\bar{x}(t-\theta+h) - \bar{x}(t-\theta)}{h}\right), \quad t \in T.$$

It has been proved in [8] that optimal solutions to problems like (D_N) for discrete systems of the neutral type (5.9) satisfy the *exact discrete maximum principle* with transversality conditions in the *upper subdifferential form* provided that the velocity sets $f(t, x, y, z, U)$ are *convex* around $\bar{\xi}(t)$. What about an analogue of the AMP with no convexity assumptions on the velocity sets? The following example shows that the AMP is *not fulfilled* for finite-difference neutral systems, in contrast to ordinary and delay ones, even in the case of *smooth* cost functions.

Example 5.1 (AMP does not hold for neutral systems). *There is a two-dimensional control problem of minimizing a linear function over a smooth neutral system with no endpoint constraints such that some sequence of optimal controls to discrete approximations does not satisfy the AMP regardless of the stepsize and a mesh point.*

Proof. Consider the following parametric family of discrete optimal control problems with the parameter $h > 0$:

$$\begin{cases} \text{minimize } J(x_1, x_2, u) := x_2(2) \\ \text{subject to} \\ x_1(t+h) = x_1(t) + hu(t), \ \ t \in T := \{0, h, \dots, 2-h\}, \\ x_2(t+h) = x_2(t) + h\left(\dfrac{x_1(t-1+h) - x_1(t-1)}{h}\right)^2 - hu^2(t), \ \ t \in T, \\ x_1(t) \equiv x_2(t) \equiv 0, \ \ t \in T_0 := \{-1, \dots, 0\}, \\ |u(t)| \le 1, \ \ t \in T. \end{cases} \tag{5.11}$$

It is easy to see that

$$x_2(1) = -h\sum_{t=0}^{1-h} u^2(t)$$

and

$$\begin{aligned} J(x_1,x_2,u) := x_2(2) &= x_2(1) + h\sum_{t=1}^{2-h}\left(\frac{x_1(t-1+h)-x_1(t-1)}{h}\right)^2 - h\sum_{t=1}^{2-h} u^2(t) \\ &= -h\sum_{t=0}^{1-h} u^2(t) + h\sum_{t=0}^{1-h} u^2(t) - h\sum_{t=1}^{2-h} u^2(t) = -h\sum_{t=1}^{2-h} u^2(t). \end{aligned}$$

Thus the control

$$\bar{u}(t) = \begin{cases} 0, & t \in \{0,\dots,1-h\}, \\ 1, & t \in \{1,\dots,2-h\}, \end{cases}$$

is the only optimal control to (5.11) for any h. The corresponding trajectory is

$$\bar{x}_1(t) = \begin{cases} 0, & t \in \{0,\dots,1-h\}, \\ t-1, & t \in \{1,\dots,2-h\}; \end{cases} \quad \bar{x}_2(t) = \begin{cases} 0, & t \in \{0,\dots,1-h\}, \\ -t+1, & t \in \{1,\dots,2-h\}. \end{cases}$$

Computing the partial derivatives of f in (5.11), we get

$$\frac{\partial f}{\partial x} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad \frac{\partial f}{\partial y} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},$$

and

$$\frac{\partial f}{\partial z}(t+1) = \frac{1}{h}\begin{pmatrix} 0 & 0 \\ 2(x_1(t+h)-x_1(t)) & 0 \end{pmatrix}.$$

Hence the adjoint system (5.10) reduces to

$$\begin{aligned} &p_1(t) = p_1(t+h) + 2(\bar{x}_1(t)-\bar{x}_1(t-h))p_2(t+1) - 2(\bar{x}_1(t+h)-\bar{x}_1(t))p_2(t+1+h), \\ &p_2(t) \equiv \text{const}, \quad t \in \{0,\dots,2-h\}, \end{aligned}$$

with the transversality conditions

$$p_1(2) = 0, \;\; p_2(2) = -1; \quad p_1(t) = p_2(t) = 0 \;\text{ for }\; t > 2.$$

The solution of this system is

$$p_1(t) \equiv 0, \;\; p_2(t) \equiv -1 \;\text{ for all }\; t \in \{0,\dots,2-h\}.$$

Thus the Hamilton–Pontryagin function along the optimal solution is

$$\begin{aligned} H(t,\bar{x}_1,\bar{x}_2,p_1,p_2,u) &= p_1(t+h)u + p_2(t+h)\left\{\left(\frac{x_1(t-1+h)-x_1(t-1)}{h}\right)^2 - u^2\right\} \\ &= u^2 \;\text{ for all }\; t \in \{0,\dots,1-h\}. \end{aligned}$$

This shows that the optimal control $\bar{u}(t) = 0$ does not provide the approximate maximum to the Hamilton–Pontryagin function regardless of h and the mesh point $t \in \{0,\dots,1-h\}$. Note at the same time that another sequence of optimal controls with $\bar{u}(t) = 1$ for all $t \in \{0,\dots,2-h\}$ satisfies the exact discrete maximum principle regardless of h. □

ELIMINATION OF STRICT CONVERGENCE IN OPTIMIZATION*

DUŠAN BEDNAŘÍK† AND KAREL PASTOR‡

Abstract. We present second-order optimality conditions (sufficient and necessary) and the characterization of convexity in terms of generalized second-order derivatives. Some conclusions obtained by R. Cominetti and R. Correa are proved under weakened assumptions.

Key words. generalized second-order directional derivative, second-order optimality conditions, convex function

AMS subject classifications. 49K35, 26B02, 26B25

DOI. 10.1137/S0363012903424174

1. Introduction and preliminaries. Second-order optimality conditions in terms of the generalized second-order derivatives are very useful in various problems connected with optimization. See, for instance, [BZ], [CC], [CHN], [GZ], [HSN], [K], [Ma], [Q], [R1], [R2], [RW], [Y1], and references therein.

Much attention has been focused on $C^{1,1}$ functions (i.e., continuously differentiable functions with a locally Lipschitz gradient) which appear in, e.g., the augmented Lagrange method, the penalty function method, and the proximal point method.

Second-order optimality conditions (both sufficient and necessary) can be classified into two groups. One type assumes the existence of some second-order derivatives (which are defined, for example, as lim); see, e.g., the classical result in smooth analysis or the generalized results given in [BZ], [JY]. The other type uses the second-order derivatives which exist always (they are defined, for example, as lim inf or lim sup) [CC], [YJ], [Pa2]. On the contrary, the conditions of the first type are often tighter than those of the second. These advantages and disadvantages are compared, for example, in [Y1, section 5].

At this point we should say that we restrict our considerations to the second type of second-order optimality conditions.

By the process of elimination of strict convergence given in the title of this paper, we mean that some results (see [CC] and notice that it has been cited 37 times so far by Web of Science) presented in terms of Cominetti–Correa generalized second-order directional derivatives can be given in tighter form in such a way that, from the formal point of view, we wipe out the strict convergence $y \to x$ in second-order conditions expressed by means of Cominetti–Correa derivatives (compare Theorems 3.1 and 3.2, Theorems 5.1 and 5.3, Theorems 6.1 and 6.4, and Theorems 7.1 and 7.5).

This process was started in [Pa2] for second-order sufficient optimality conditions. In section 3, we present a new, more precise proof of this improved result.

Connections among generalized second-order directional derivatives introduced by Cominetti–Correa and those introduced in [Pa1] are established in section 4.

Section 5 is devoted to the characterization of convexity via generalized second-order derivatives (we note that convexity plays an important role not only in optimization theory).

A new (to the best of our knowledge) necessary second-order optimality condition introduced in section 6 is tighter than the ones in [YJ]. We finish our elimination process by studying certain minimax problems in section 7.

2. Survey of derivatives. Let X be a real Banach space with the norm $\|\cdot\|$, with X^* the topological dual space of X, and let $\langle x^*, x\rangle$ be a canonical pair, where $x^* \in X^*$, $x \in X$. S_X denotes the set $\{x \in X : \|x\| = 1\}$.

In fact, our results use only $f'^{l}_{+}(x;u,v)$ and $f'^{u}_{+}(x;u,v)$ (see below for definitions). Since we want to compare our results with those obtained before in terms of other generalized second-order directional derivatives, we give a survey of their definitions for the sake of completeness. On the other hand, there is maybe a pitfall that one might be caught in the mire of definitions. Therefore it might be helpful to skim section 2 during the first reading, then study it more carefully during the next.

Let us note, also on account of applications, that the calculus with $f'^{l}_{+}(x;u,v)$ and $f'^{u}_{+}(x;u,v)$ feels more comfortable than the calculus with some other generalized second-order directional derivatives.

For a function $f : X \to \mathbb{R}$, we denote the first-order directional derivative of f at $x \in X$ in the direction $v \in X$ by

$$f'(x;v) = \lim_{t\downarrow 0} \frac{f(x+tv) - f(x)}{t},$$

and the upper and lower Clarke directional derivatives of f at $x \in X$ in the direction $v \in X$, respectively, by

$$f^{\circ}(x;v) = \limsup_{y\to x, t\downarrow 0} \frac{f(y+tv) - f(y)}{t},$$

$$f_{\circ}(x;v) = \liminf_{y\to x, t\downarrow 0} \frac{f(y+tv) - f(y)}{t}.$$

As in [CC], we define the Cominetti–Correa upper and lower generalized second-order directional derivatives at $x \in X$ in the direction $(u,v) \in X \times X$ by, respectively,

$$f^{\infty}(x;u,v) = \limsup_{y\to x,\ s,t\downarrow 0} \frac{f(y+tu+sv) - f(y+tu) - f(y+sv) + f(y)}{st},$$

$$f_{\infty}(x;u,v) = \liminf_{y\to x,\ s,t\downarrow 0} \frac{f(y+tu+sv) - f(y+tu) - f(y+sv) + f(y)}{st}.$$

Considering a $C^{1,1}$ function $f : X \to \mathbb{R}$, the generalized upper and lower second-order directional derivatives of f at $x \in X$ in direction $(u,v) \in X \times X$ in the sense of Michel–Penot [MP] are given, respectively, as follows:

$$f^{\diamond u}(x;u,v) = \sup_{z\in X} \limsup_{t\downarrow 0} \frac{\langle \bigtriangledown f(x+tz+tu) - \bigtriangledown f(x+tz), v\rangle}{t},$$

$$f^{\diamond l}(x;u,v) = \inf_{z\in X} \liminf_{t\downarrow 0} \frac{\langle \bigtriangledown f(x+tz+tu) - \bigtriangledown f(x+tz), v\rangle}{t},$$

where the symbol $\bigtriangledown f(x)$ denotes the Gâteaux derivative of f at x.

We note that for a set-valued mapping $F : \mathbb{R} \rightsquigarrow \mathbb{R}$, it is natural to denote

$$\liminf_{t\downarrow 0} F(t) = \liminf_{t\downarrow 0} \inf\{a : a \in F(t)\}.$$

Similarly for lim sup. In [Pa1], there were introduced the following lower generalized second-order directional derivatives:

$$f'^{L}(x;u,v) = \liminf_{t\downarrow 0} \frac{\langle \partial_c f(x+tu) - \partial_c f(x), v\rangle}{t},$$

$$f^{*L}(x;u,v) = \liminf_{y\to x, t\downarrow 0} \frac{\langle \partial_c f(y+tu) - \partial_c f(y), v\rangle}{t},$$

where f is Lipschitz near $x \in X$, $(u,v) \in X \times X$, and the symbol $\partial_c f(x)$ stands for the Clarke subdifferential [Cl1] at x defined by

$$\partial_c f(x) = \{x^* \in X^* : \langle x^*, v\rangle \le f^\circ(x;v) \quad \forall v \in X\}.$$

One has that it holds

$$f^\circ(x;v) = \max\{\langle x^*, v\rangle : x^* \in \partial_c f(x)\},$$

$$f_\circ(x;v) = \min\{\langle x^*, v\rangle : x^* \in \partial_c f(x)\}.$$

Dually to $f'^{L}(x;u,v)$, we can define

$$f'^{U}(x;u,v) = \limsup_{t\downarrow 0} \frac{\langle \partial_c f(x+tu) - \partial_c f(x), v\rangle}{t}.$$

Let us recall that a locally Lipschitz function $f : X \to \mathbb{R}$ is said to be regular at $x \in X$ provided that $f'(x;v) = f^\circ(x;v)$ for every $v \in X$. It is natural to define the following upper and lower generalized derivatives at $x \in X$ in the direction $(u,v) \in X \times X$ for a function $f : X \to \mathbb{R}$ which is regularly locally Lipschitz near x by means of

$$f'^{u}(x;u,v) = \limsup_{t\downarrow 0} \frac{f'(x+tu;v) - f'(x;v)}{t}$$

and

$$f'^{l}(x;u,v) = \liminf_{t\downarrow 0} \frac{f'(x+tu;v) - f'(x;v)}{t}.$$

Finishing the survey of generalized derivatives used in the paper, we recall some of their properties and the relationships among them.

If f is regularly locally Lipschitz near $x \in X$, and $u, v \in X$, then it holds that [CC]

$$f^\infty(x;u,v) = \limsup_{y\to x, t\downarrow 0} \frac{f'(y+tu;v) - f'(y;v)}{t}, \tag{1}$$

$$f_\infty(x;u,v)=\liminf_{y\to x,t\downarrow 0}\frac{f'(y+tu;v)-f'(y;v)}{t}. \tag{2}$$

Thus, if f is continuously differentiable near x, then

$$f^\infty(x;u,v)=\limsup_{y\to x,t\downarrow 0}\frac{\langle\bigtriangledown f(y+tu)-\bigtriangledown f(y),v\rangle}{t},$$

$$f_\infty(x;u,v)=\liminf_{y\to x,t\downarrow 0}\frac{\langle\bigtriangledown f(y+tu)-\bigtriangledown f(y),v\rangle}{t}. \tag{3}$$

Further, for each continuously differentiable function f near $x\in X$, one has

$$f'^u(x;u,v)=\limsup_{t\downarrow 0}\frac{\langle\bigtriangledown f(x+tu)-\bigtriangledown f(x),v\rangle}{t}$$

and

$$f'^l(x;u,v)=\liminf_{t\downarrow 0}\frac{\langle\bigtriangledown f(x+tu)-\bigtriangledown f(x),v\rangle}{t}. \tag{4}$$

LEMMA 2.1 (see [Pa1, Proposition 2.1]). *Let $f:X\to\mathbb{R}$ be a $C^{1,1}$ function, $x\in X$, and let $(u,v)\in X\times X$. Then*

$$f'^L(x;u,v)\geq f^{\diamond l}(x;u,v)\geq f^{*L}(x;u,v).$$

LEMMA 2.2 (see [Pa1, Proposition 3.1]). *Let $f:X\to\mathbb{R}$ be a continuously differentiable function, $x,u,v\in X$. Then*

$$f_\infty(x;u,v)\leq f'^L(x;u,v).$$

3. Sufficient optimality conditions. Cominetti and Correa published the following result in 1990.

THEOREM 3.1 (see [CC, Proposition 5.2]). *Let $f:\mathbb{R}^n\to\mathbb{R}$ be a $C^{1,1}$ function near $\hat{x}\in\mathbb{R}^n$. If $\bigtriangledown f(\hat{x})=0$ and it holds that*

$$f_\infty(\hat{x};h,h)>0\quad\forall h\in S_{\mathbb{R}^n}, \tag{5}$$

then f attains a strict local minimum at $\hat{x}$.

As was shown in [Pa2, Theorem 3], the conclusion of Theorem 3.1 does not change when we wipe out the strict convergence in (5), as shown in the following. (Compare also with (3) and (4).)

THEOREM 3.2. *Let $f:\mathbb{R}^n\to\mathbb{R}$ be a $C^{1,1}$ function near $\hat{x}\in\mathbb{R}^n$. If $\bigtriangledown f(\hat{x})=0$ and it holds that*

$$f'^l(\hat{x};h,h)>0\quad\forall h\in S_{\mathbb{R}^n}, \tag{6}$$

then f attains a strict local minimum at $\hat{x}$.

The following example illustrates the advantage of Theorem 3.2.

Example 3.3. Consider a function $f:\mathbb{R}\to\mathbb{R}$ such that

$$f(x)=\begin{cases}\int_0^{\|x\|}t(\frac{5}{4}+\sin\ln t)dt & \text{if } x\neq 0,\\ 0 & \text{if } x=0.\end{cases}$$

It easy to show that f is a $C^{1,1}$ function, $\bigtriangledown f(0) = 0$, and $f'^l(0;1,1) = f'^l(0;-1,-1) = \frac{1}{4}$. On the other hand, $f_\infty(0;1,1) = \frac{5}{4} - \sqrt{2} < 0$. For the calculus, see [BP, Example]. So, Theorem 3.2 can be used to test strict local minimum at 0 in contrast to Theorem 3.1.

Now, we provide a new proof of Theorem 3.2 which appears to be more precise than those given in [Pa2]. Analogously, as in [DR, p. 229], we can prove Lemma 3.4.

LEMMA 3.4. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be Lipschitz near $\hat{x} \in \mathbb{R}^n$, and let*

$$\liminf_{t \downarrow 0} \frac{f(\hat{x}+th) - f(\hat{x})}{t} > 0 \quad \forall h \in S_{\mathbb{R}^n}.$$

Then f attains a strict local minimum at $\hat{x}$.

LEMMA 3.5. *Let $T : X \to X^*$ be Lipschitz near 0 and $T(0) = 0$. Then a function $g : X \to \mathbb{R}$,*

$$g(x) = \begin{cases} \left\langle Tx, \dfrac{x}{\|x\|} \right\rangle & \text{for } x \neq 0, \\ 0 & \text{for } x = 0, \end{cases}$$

is also Lipschitz near 0.

Proof. There exist $\delta > 0$ and $L > 0$ satisfying

$$\|Tx - Ty\| \leq L\|x - y\| \quad \forall x, y \in B(0,\delta),$$

where $B(x,r) = \{y \in X : \|y - x\| \leq r\}$ for an $x \in X$ and $r > 0$. We fix $x, y \in B(0,\delta)$. If $x \neq 0$ and $y \neq 0$, then let us calculate

$$\begin{aligned}
\|g(x) - g(y)\| &= \left\| \left\langle Tx, \frac{x}{\|x\|} \right\rangle - \left\langle Ty, \frac{y}{\|y\|} \right\rangle \right\| \\
&= \left\| \left\langle Tx, \frac{x}{\|x\|} \right\rangle - \left\langle Ty, \frac{x}{\|x\|} \right\rangle + \left\langle Ty, \frac{x}{\|x\|} \right\rangle - \left\langle Ty, \frac{y}{\|y\|} \right\rangle \right\| \\
&\leq \|Tx - Ty\| + \|Ty\| \left\| \frac{x}{\|x\|} - \frac{y}{\|y\|} \right\| \\
&\leq L\|x - y\| + L\|y\| \left\| \frac{x\|y\| - x\|x\| + x\|x\| - y\|x\|}{\|x\|\|y\|} \right\| \\
&= L\|x - y\| + L \left\| \frac{(\|y\| - \|x\|)x + \|x\|(x - y)}{\|x\|} \right\| \\
&\leq L\|x - y\| + L \left\| \frac{(\|y\| - \|x\|)}{\|x\|} x \right\| + L\|x - y\| \\
&\leq 3L\|x - y\|.
\end{aligned}$$

In the other cases (i.e., $x = 0, y \neq 0$ or $x = 0, y = 0$), the above formula $\|g(x) - g(y)\| \leq 3L\|x - y\|$ follows immediately. ∎

Proof of Theorem 3.2. Without any loss of generality, we can assume that $\hat{x} = 0$ and $f(0) = 0$.

Since $\bigtriangledown f(0) = 0$, one can rewrite condition (6) as

$$\liminf_{t \downarrow 0} \frac{\langle \bigtriangledown f(th), h \rangle}{t} > 0 \quad \forall h \in S_{\mathbb{R}^n}. \tag{7}$$

Let us consider a function $g : X \to \mathbb{R}$ such that

$$g(x) = \begin{cases} \left\langle \bigtriangledown f(x), \dfrac{x}{\|x\|} \right\rangle & \text{for } x \neq 0, \\ 0 & \text{for } x = 0. \end{cases}$$

The function $x \to \bigtriangledown f(x)$ is Lipschitz near 0. Subsequently, g is also Lipschitz near 0 by Lemma 3.5. Using condition (7), we have

$$\liminf_{t \downarrow 0} \frac{g(0+th) - g(0)}{t} = \liminf_{t \downarrow 0} \frac{\langle \bigtriangledown f(th), h \rangle}{t} > 0 \quad \forall h \in S_{\mathbb{R}^n}.$$

Due to Lemma 3.4, g attains a strict local minimum at 0, i.e., there exists $\delta > 0$ such that

$$\left\langle \bigtriangledown f(x), \frac{x}{\|x\|} \right\rangle > 0 \tag{8}$$

for every $x \in B(0, \delta)$. We fix $x \in B(0, \delta)$, $x \neq 0$. Applying the Lagrange mean value theorem, we get $\eta \in (0, 1)$ satisfying

$$f(x) - f(0) = \langle \bigtriangledown f(\eta x), x \rangle = \left\langle \bigtriangledown f(\eta x), \frac{\eta x}{\|\eta x\|} \right\rangle \|x\| > 0,$$

where the previous inequality follows from (8). Therefore, f attains a strict local minimum at 0. □

Unfortunately, as shown by the following counterexample, Theorem 3.2 is not true for an arbitrary continuously differentiable function.

Example 3.6. Define $f : \mathbb{R}^2 \to \mathbb{R}$, partially in polar coordinates, as shown by the following:

1. $f(x, y) = (y - x^{\frac{3}{2}})^2$ if $(x, y) \in \left\{(x, y) \in \mathbb{R}^2, x \geq 0, x^{\frac{3}{2}} \leq y \leq x^{\frac{3}{2}} + 1\right\}$;
2. $f(x, y) = 1$ if $(x, y) \in \left\{(x, y) \in \mathbb{R}^2, x \geq 0, x^{\frac{3}{2}} + 1 \leq y\right\}$;
3. $f(r \sin\varphi, r \cos\varphi) = \hat{f}(r, \varphi) = \left(r - \frac{\sin^2\varphi}{\cos^3\varphi}\right)^2$ if $\varphi \in \left(0, \frac{\pi}{2}\right)$ and $r > \frac{\sin^2\varphi}{\cos^3\varphi}$;
4. $f(r \sin\varphi, r \cos\varphi) = \hat{f}(r, \varphi) = r^2$ if $\varphi \in \left[\frac{3}{2}\pi, 2\pi\right]$;
5. $f(-x, y) = f(x, y)$.

For the main parts of the domain of f, see Figure 3.1.

First, we show that f is continuously differentiable near 0. Due to the symmetry of f, it suffices to calculate for the following subsets of the domain of f:

1. $M_1 = \left\{(x, y) \in \mathbb{R}^2, x \geq 0, x^{\frac{3}{2}} < y < x^{\frac{3}{2}} + 1\right\}$. Then

$$\bigtriangledown f(x, y) = \left[-3x^{\frac{1}{2}}\left(y - x^{\frac{3}{2}}\right), 2\left(y - x^{\frac{3}{2}}\right)\right]. \tag{9}$$

2. $M_2 = \left\{(r \cos\varphi, r \sin\varphi) \in \mathbb{R}^2, \varphi \in (0, \frac{\pi}{2}), r > \frac{\sin^2\varphi}{\cos^3\varphi}\right\}$. Then

$$\bigtriangledown \hat{f}(r, \varphi) = \left[2\left(r - \frac{\sin^2\varphi}{\cos^3\varphi}\right), -2\left(r - \frac{\sin^2\varphi}{\cos^3\varphi}\right)\frac{2\sin\varphi\cos^2\varphi + 3\sin^3\varphi}{\cos^4\varphi}\right].$$

3. $M_3 = \left\{(r \cos\varphi, r \sin\varphi) \in \mathbb{R}^2, \varphi \in \left[\frac{3}{2}\pi, 2\pi\right], r > 0\right\}$. Then

$$\bigtriangledown \hat{f}(r, \varphi) = [2r, 0].$$

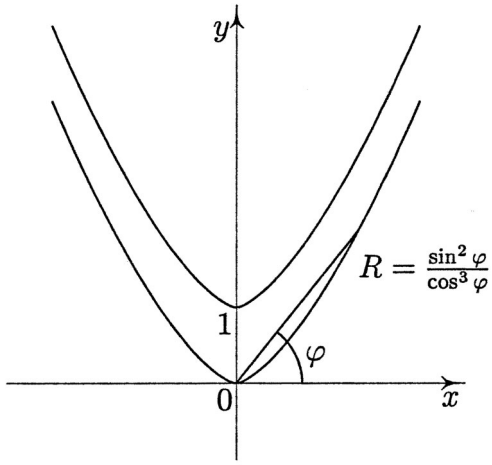

FIG. 3.1. *The division of the domain in Example* 3.6.

4. $M_4 = \{(x, y) \in \mathbb{R}^2, x \geq 0, y = x^{\frac{3}{2}}\}$. Then

$$\bigtriangledown f(x, y) = (0, 0).$$

Analyzing the previous calculation, one has that f is continuously differentiable near 0 (but is not a $C^{1,1}$ function near 0).

Now let us verify that $f'^{l}_{+}(0)(h, h) > 0$ whenever $h = (\cos\varphi, \sin\varphi)$ for $\varphi \in (0, 2\pi]$. Setting $x = r\cos\varphi, y = r\sin\varphi$ in (9) and using symmetry again, we obtain

$$f'^{l}_{+}(0)(h, h) = 2\sin^2\varphi > 0$$

whenever $h = (\cos\varphi, \sin\varphi)$ for $\varphi \in (0, \pi)$.

Finally, for $h = (\cos\varphi, \sin\varphi), \varphi \in [\pi, 2\pi]$,

$$f'^{l}_{+}(0)(h, h) = 2.$$

On the other hand, for every $(x, y) \in \left\{(x, y) \in \mathbb{R}^2, x \geq 0, y = x^{\frac{3}{2}}\right\}$, it holds that $f(x, y) = 0$. It implies that the function f does not attain a strict local minimum at 0.

4. Relations among derivatives. In order to generalize Lemma 2.2, we will employ the notion of minimal cusco mapping.

A set-valued mapping F from a topological space A into nonempty subsets of a Hausdorff locally convex space Y is called *cusco* if $F(t)$ is compact and convex for each $t \in A$ and F is upper-semicontinuous (i.e., $\{t \in A : F(t) \subset U\}$ is an open subset for each open subset U of Y).

Furthermore, F is said to be *minimal cusco* on A if its graph does not contain the graph of any other cusco on A. The Clarke subdifferential of a regularly locally Lipschitz function [Mo] or maximal monotone operator (see, e.g., [Ph]) are the well-known examples of minimal cusco mappings. We recall several basic facts concerning this notion.

As a particular case of a more general result given in [J, Corollary 4.1], the following lemma holds.

LEMMA 4.1. *Let $D \subset \mathbb{R}$ be an open set, and let $F : D \rightsquigarrow \mathbb{R}$ be minimal cusco. Then the set $\{x \in D : F$ is single-valued at $x\}$ is dense in D.*

We note that $f : A \to \mathbb{R} \cup \{+\infty\}$ (A is a topological space) is a lower-semicontinuous function provided that $\{x \in A : f(x) \leq r\}$ is closed in A for every $r \in \mathbb{R}$. By a lower hull of a densely defined function f from A into $\mathbb{R} \cup \{+\infty\}$, we mean

$$l(f) = \max\{h : A \to \mathbb{R} \cup \{+\infty\} : (h \leq \bar{f}) \text{ and } h \text{ is lower-semicontinuous}\},$$

where $\bar{f} : A \to \mathbb{R} \cup \{+\infty\}$ coincides with f on the domain of f and $\bar{f}(x) = +\infty$ otherwise.

LEMMA 4.2 (see [PB, section 2]). *Let A be a topological space and let $F : A \rightsquigarrow \mathbb{R}$ be minimal cusco. Then for arbitrary densely defined selections s and s', it holds that*

$$l(s) = l(s').$$

For more details about subdifferential mapping $x \rightsquigarrow \partial_c f(x)$ in terms of minimal cusco, see, e.g., [BM].

Now, we state the relationships among some generalized second-order directional derivatives mentioned in section 2.

By the analogous way as in [Cl2, the lemma near Theorem 2.3.7], we can obtain the following.

LEMMA 4.3. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function on an open subset containing the line segment $[x, y]$. Then the function $g : [0, 1] \to \mathbb{R}$ defined by $g(t) := f(x + t(y - x))$ is regularly locally Lipschitz on $(0, 1)$, and we have*

$$\partial_c g(t) = \langle \partial_c f(x + t(y - x)), y - x \rangle.$$

PROPOSITION 4.4. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function, $x, h \in X$. Then*

$$f'^L(x; h, h) = f'^l(x; h, h). \tag{10}$$

Proof. In order to prove (10), we want to show that

$$\liminf_{t \downarrow 0} \frac{f_\circ(x + th; h) - f^\circ(x; h)}{t} \geq \liminf_{t \downarrow 0} \frac{f^\circ(x + th; h) - f^\circ(x; h)}{t}. \tag{11}$$

Recall that by Lemma 4.3 the set-valued mapping $F : t \rightsquigarrow \langle \partial_c f(x + th), h \rangle$, $t \in \mathbb{R}$, is minimal cusco. Further on, we will use the notation

$$F_\circ(t) := \min\langle \partial_c f(x + th), h \rangle = f_\circ(x + th; h),$$

$$F^\circ(t) := \max\langle \partial_c f(x + th), h \rangle = f^\circ(x + th; h), \quad t \in \mathbb{R}.$$

Assuming that $f^\circ(x; h) = 0$, we can rewrite (11) as the following:

$$\liminf_{t \downarrow 0} \frac{F_\circ(t)}{t} \geq \liminf_{t \downarrow 0} \frac{F^\circ(t)}{t}. \tag{12}$$

Let us suppose for now that we have proved the following claim.

CLAIM. *If $0 < \varepsilon < t < 1$, then there exists a sequence $\{t_n\}_{n=1}^\infty$ such that $t_n \to t$ and*

$$\frac{F^\circ(t_n)}{t_n} \leq \frac{F_\circ(t)}{t} + \frac{\varepsilon}{t} \quad \text{for every } n \in \mathbb{N}.$$

Now, let $\{t_n\}_{n=1}^{\infty}$ be a sequence such that $t_n \downarrow 0$, $0 < t_n^2 < t_n < 1$ and which realizes the lim inf on the left-hand side of (12), i.e.,

$$\lim_{n\to\infty} \frac{F_\circ(t_n)}{t_n} = \liminf_{t\downarrow 0} \frac{F_\circ(t)}{t}.$$

Due to the claim above, for each $n \in \mathbb{N}$, there exists a sequence $\{t_k^n\}_{k=1}^{\infty}$ such that $\lim_{k\to\infty} t_k^n = t_n$ and such that, for each $k \in \mathbb{N}$,

$$\frac{F^\circ(t_k^n)}{t_k^n} \le \frac{F_\circ(t_n)}{t_n} + \frac{t_n^2}{t_n} = \frac{F_\circ(t_n)}{t_n} + t_n.$$

Now, for each $n \in \mathbb{N}$, we can find $k_n \in \mathbb{N}$ such that $t_{k_n}^n \downarrow 0$ as $n \to \infty$, and

$$\frac{F^\circ(t_{k_n}^n)}{t_{k_n}^n} \le \frac{F_\circ(t_n)}{t_n} + t_n \quad \forall n \in \mathbb{N}. \tag{13}$$

Letting $n \to \infty$ in (13), we obtain

$$\liminf_{t\downarrow 0} \frac{F^\circ(t)}{t} \le \liminf_{n\to\infty} \frac{F^\circ(t_{k_n}^n)}{t_{k_n}^n} \le \lim_{n\to\infty} \left(\frac{F_\circ(t_n)}{t_n} + t_n \right) = \liminf_{t\downarrow 0} \frac{F_\circ(t)}{t}.$$

Proof of the claim. Suppose, on the contrary, that there are $0 < \varepsilon < t < 1$ and $\delta > 0$ such that

$$\frac{F^\circ(t')}{t'} > \frac{F_\circ(t)}{t} + \frac{\varepsilon}{t} \quad \text{for every } t' > 0 \quad \text{such that } \|t' - t\| < \delta. \tag{14}$$

Obviously there is $\delta' > 0$ such that $0 < \delta' \le \delta$, and for any $t' > 0$, $\|t' - t\| < \delta'$ we have by (14)

$$F^\circ(t') > (F_\circ(t) + \varepsilon)\frac{t'}{t} \ge (F_\circ(t) + \varepsilon) - \frac{\varepsilon}{2} = F_\circ(t) + \frac{\varepsilon}{2}. \tag{15}$$

Let $A \subset \mathbb{R}$ denote a set of single valuedness of F which is dense according to Lemma 4.1. Now consider a densely defined selection s, s' of the mapping F, where $s(y) := F(y)$ for every $y \in A$ and

$$s'(y) = \begin{cases} s(y) & \text{if } y \in A, \\ F_\circ(t) & \text{if } y = t \end{cases}$$

(notice that by (15) $t \notin A$). Then it follows from (15) that

$$l(s')(t) = F_\circ(t) < F_\circ(t) + \frac{\varepsilon}{2} \le l(s)(t),$$

which contradicts Lemma 4.2. □

From (2) and Proposition 4.4, one can derive the extension of Lemma 2.2.

COROLLARY 4.5. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function, $x, h \in X$. Then*

$$f_\infty(x; h, h) \le f'^L(x; h, h).$$

Using lim inf and lim sup calculus, Proposition 4.4 and Corollary 4.5 imply the following.

COROLLARY 4.6. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function, $x, h \in X$. Then*

$$f'^U(x; h, h) = f'^u(x; h, h),$$

$$f^\infty(x; h, h) \ge f'^U(x; h, h).$$

5. Characterization of convexity. A former characterization of convexity via the Cominetti–Correa lower generalized second-order directional derivative given in [CC] for continuously differentiable and twice C-differentiable functions was proved under a more relaxed condition (when f is regularly locally Lipschitz) in [Y2, Theorem 4.1].

THEOREM 5.1. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function. Then the following conditions are equivalent:*

(i) *f is convex;*
(ii) $f_\infty(x; h, h) \geq 0 \quad \forall x, h \in X$.

A characterization of convexity for arbitrary locally Lipschitz functions was obtained in [Pa1, Theorem 1.3].

THEOREM 5.2. *Let $f : X \to \mathbb{R}$ be a locally Lipschitz function. Then the following conditions are equivalent:*

(i) *f is convex;*
(ii) $f^{*L}(x; h, h) \geq 0 \quad \forall x, h \in X$;
(iii) $f'^{L}(x; h, h) \geq 0 \quad \forall x, h \in X$.

Now, Theorem 5.2 and Proposition 4.4 imply the following.

THEOREM 5.3. *Let $f : X \to \mathbb{R}$ be a regularly locally Lipschitz function. Then the following conditions are equivalent:*

(i) *f is convex;*
(ii) $f'^{l}(x; h, h) \geq 0 \quad \forall x, h \in X$.

With respect to formula (2), we eliminate the strict convergence $y \to x$ in condition (ii) of Theorem 5.1 to obtain Theorem 5.3.

We note that the calculus with $f'^{l}(x; h, h)$ is more simple than the calculus with $f_\infty(x; h, h)$.

Example 5.4. Let the convex function f be defined by

$$f(x) = \begin{cases} x^2 & \text{if } x \geq 0, \\ -x & \text{if } x < 0. \end{cases}$$

Conditions given in Theorems 5.1 and 5.3 are satisfied. Indeed,

$$f_\infty(x; h, h) = \begin{cases} 2 & \text{if } x > 0,\ h \in \mathbb{R}, h \neq 0, \\ 0 & \text{otherwise,} \end{cases}$$

and

$$f'^{l}(x; h, h) = \begin{cases} 2 & \text{if } x = 0,\ h > 0 \quad \text{or} \quad x > 0,\ h \in \mathbb{R}, h \neq 0, \\ 0 & \text{otherwise.} \end{cases}$$

Another characterization of convexity for regularly locally Lipschitz functions in terms of generalized parabolic second-order directional derivatives is given in [HN, Theorem 3.3] (see also [Ch, Theorem 2.4] and [Y2, Theorem 4.1]).

6. Necessary optimality conditions. We begin this section by recalling two second-order necessary conditions.

THEOREM 6.1 (see [CC]). *Let $f : X \to \mathbb{R}$ attain a local minimum at $\hat{x} \in X$. Then*

$$f^\infty(\hat{x}; h, h) \geq 0 \quad \forall h \in X. \tag{16}$$

THEOREM 6.2 (see [YJ]). *Let $f : X \to \mathbb{R}$ be a $C^{1,1}$ function and let f attain a local minimum at $\hat{x} \in X$. Then*

$$f^{\diamond u}(\hat{x}; h, h) \geq 0 \quad \forall h \in X. \tag{17}$$

It was shown in [YJ] that condition (17) is tighter than condition (16) for $C^{1,1}$ functions.

For the proof of the following new second-order necessary condition, we use the Lebourg mean value theorem.

THEOREM 6.3 (see [L]). *Let $f : X \to \mathbb{R}$ be Lipschitz on an open convex set $U \subset X$, $x, y \in U$. Then there exists a point $u \in (x, y)$ with the property*

$$f(y) - f(x) \in \langle \partial_c f(u), y - x \rangle.$$

THEOREM 6.4. *Let $f : X \to \mathbb{R}$ be a locally Lipschitz function and let f attain a local minimum at $\hat{x}$. Then*

$$f'^{U}(\hat{x}; h, h) \geq 0 \quad \forall h \in X. \tag{18}$$

Proof. Inequality (18) is true for $h = 0$ because $f'^{U}(\hat{x}, 0, 0) = 0$. Now, we fix arbitrary $h \in X$, $h \neq 0$. By Theorem 6.3, for every $t > 0$, there exist $0 < \lambda(t) < t$ and $p \in \partial_c f(\hat{x} + \lambda(t)h)$ satisfying

$$f(\hat{x} + th) - f(\hat{x}) = \langle p, th \rangle.$$

Since $\hat{x}$ is a local minimum of f, one has $0 \in \partial_c f(\hat{x})$ and, moreover, it holds that $f(\hat{x} + th) - f(\hat{x}) \geq 0$ for every sufficiently small $t > 0$. Thus

$$f'^{U}(\hat{x}; h, h) \geq 0. \qquad \square$$

Lemma 2.1 and the calculus for lim sup and lim inf yield that (18) is tighter than (17) for $C^{1,1}$ functions. Moreover, using Corollary 4.6, we have that (18) is also tighter than (16) for regularly locally Lipschitz functions. (Compare formula (1) and Corollary 4.6 to see our process of elimination of strict convergence.)

We illustrate the results by giving examples.

Example 6.5. Consider a function $f : \mathbb{R} \to \mathbb{R}$,

$$f(x) = [\max\{x, 0\}]^2 \quad \forall x \in \mathbb{R}.$$

We can verify (see also [Y1, Example 5.2]) that f is $C^{1,1}$, 0 is a (local) minimum of f, $\bigtriangledown f(0) = 0$, and that for every $h \in \mathbb{R}$,

$$f^{\infty}(0; h, h) = f^{\diamond u}(0; h, h) = 2h^2 \geq 0.$$

Further, one has that it holds that

$$f'^{U}(0; h, h) = f'^{u}(0; h, h) = \begin{cases} 2h^2 & \text{if } h \geq 0, \\ 0 & \text{if } h < 0. \end{cases}$$

Thus, (16), (17), and (18) hold, but (18) is tighter than (16) and (17) because

$$f'^{U}(0; h, h) < f^{\infty}(0; h, h) = f^{\diamond u}(0; h, h)$$

for each $h < 0$.

Example 6.6. Let $f : \mathbb{R} \to \mathbb{R}$ be defined as

$$f(x) = \begin{cases} \displaystyle\int_0^{\|x\|} t\left(-\frac{4}{3} + \sin(\ln t)\right) dt & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

It can be shown (see also Example 3.3) that f is $C^{1,1}$, $\bigtriangledown f(0) = 0$,

$$f^\infty(0; h, h) = -\frac{4}{3}h^2 + \sqrt{2}h^2 \geq 0 \quad \forall h \in \mathbb{R},$$

and

$$f'^U(0; h, h) = f'^u(0; h, h) = -\frac{1}{3}h^2 < 0 \quad \text{for } h \neq 0.$$

Condition (18) excludes the possibility so that 0 may be a local minimum of f in contrast to condition (16).

It remains an open problem whether Corollary 4.6 is true also for arbitrary locally Lipschitz functions (a positive answer would mean that (18) is tighter than (16) not only for regularly locally Lipschitz functions).

7. Max-functions. In [CC, pp. 800–802], there was considered a finite family of C^2 functions $f_i : X \to \mathbb{R}$ for $i \in I = \{1, \ldots, n\}$ and the mapping $f : X \to \mathbb{R}$ given by

$$f(x) = \max\{f_i(x) : i \in I\}. \tag{19}$$

Before we recall the result stated in [CC], we denote $I(x) = \{i \in I : f_i(x) = f(x)\}$, $D^2g(x; u, v)$ as the usual second-order directional derivative at x with respect to the directions u, v. Finally, say that index $i \in I$ is essential at x if there exists a net $x_\alpha \to x$ with $I(x_\alpha) = \{i\}$, and denote by $I^*(x)$ the set of essential indexes at x.

THEOREM 7.1 (see [CC, Proposition 3.8]). *With the above notation we have*

$$f^\infty(x; u, v) \geq \max_{i \in I^*(x)} D^2 f_i(x; u, v) \quad \forall u, v \in X.$$

Now, we weaken assumptions setting on the regularity of functions f_i. Let $f_i : X \to \mathbb{R}$, $i \in I = \{1, \ldots, n\}$ be a collection of regular, locally Lipschitz functions. Let us consider a max-function $f : X \to \mathbb{R}$ defined as in (19). We recall some known results.

LEMMA 7.2. *The max-function f is locally Lipschitz provided that each of the functions f_i, $i \in I$, is locally Lipschitz.*

Proof. We can express the max-function f as the composition $f(x) = g(f_1(x), \ldots, f_n(x))$, where $g : \mathbb{R}^n \to \mathbb{R}$ and $g(\lambda_1, \ldots, \lambda_n) = \max\{\lambda_i : i \in I\}$. Clearly g is locally Lipschitz. Thus the composition of g and the maps $x \to (f_1(x), \ldots, f_n(x))$, which are locally Lipschitz from X into $\mathbb{R}^n$, must in turn also be locally Lipschitz. □

LEMMA 7.3. *The max-function f is regular provided that each of the functions f_i, $i \in I$, is regular.*

Proof. We can use an idea from the previous proof and [CLSW, Theorem 4.5]. □

Now, again put $I(x) := \{i \in \mathbb{N} : f_i(x) = f(x)\}$ for $x \in X$. We say that a locally Lipschitz function $g : X \to \mathbb{R}$ has a *directional second-order derivative at $x \in X$ along a vector $h \in S_X$* if there exists a finite limit

$$\lim_{t \downarrow 0} \frac{g^\circ(x + th; h) - g_\circ(x; h)}{t}.$$

Remark 7.4. Note that if $g : X \to \mathbb{R}$ is a C^2 function at $x \in X$, then it has a directional second-order derivative along $h \in S_X$ for every $h \in S_X$.

THEOREM 7.5. *Suppose that functions $f_i : X \to \mathbb{R}$, $i \in I$, are regularly locally Lipschitz and that each has a directional second-order derivative at $x \in X$ along $h \in S_X$. If f is defined as in* (19)*, then the following inequality holds:*

$$f'^u(x; h, h) \geq \max_{i \in I(x)} f_i'^u(x; h, h).$$

For the proof of this main result of section 7, we use Lemma 7.6.

LEMMA 7.6. *In the situation of Theorem* 7.5*, for every $i \in I(x)$, there exists a sequence $\{t_n\}_{n=1}^{+\infty}$ such that $t_n \downarrow 0$ and for any $n \in \mathbb{N}$ we have*

$$f'(x + t_n h; h) \geq f_i'(x + t_n h; h). \tag{20}$$

Proof. Due to Lemma 7.3 the max-function has a directional derivative because of regularity. Also notice that $f_i(x) = f(x)$ since $i \in I(x)$. Now suppose on the contrary that there is a $\delta > 0$ such that

$$f'(x + th; h) < f_i'(x + th; h) \tag{21}$$

for every $t \in (0, \delta)$.

The condition (21) implies that for every $t \in (0, \delta)$, we have

$$(f_i - f)'(x + th; h) > 0.$$

Hence, a function $t \to (f_i - f)(x + th)$ is increasing on $(0, \delta)$, which is contrary to the definition of f. □

Proof of Theorem 7.5. Fix an arbitrary $i \in I(x)$. By Lemma 7.6, there is a sequence $\{t_n\}_{n=1}^{+\infty}$ such that $t_n \downarrow 0$ and which holds condition (20). Notice also that

$$f^\circ(x; -h) = f'(x; -h) \geq f_i'(x; -h) = f_i^\circ(x; -h).$$

As a consequence we obtain

$$(f_i)_\circ(x; h) \geq f_\circ(x; h). \tag{22}$$

Now, with respect to (20) and (22), we have for any $n \in \mathbb{N}$

$$\frac{f^\circ(x + t_n h; h) - f_\circ(x; h)}{t_n} \geq \frac{f_i^\circ(x + t_n h; h) - (f_i)_\circ(x; h)}{t_n}. \tag{23}$$

By our assumption, the limit on the right side exists for $n \to +\infty$. Thus, by passing to the limit, we come to an inequality,

$$f'^U(x; h, h) \geq f_i'^u(x; h, h).$$

Using Lemma 7.3 and Corollary 4.6 on the left side of (23) and the fact that $i \in I(x)$ was arbitrary on the right side, one has

$$f'^u(x; h, h) \geq \max_{i \in I(x)} f_i'^u(x; h, h). \qquad \square$$

With respect to Remark 7.4, Theorem 7.5 generalizes Theorem 7.1 (according to formula (1), also in an elimination sense).

Acknowledgments. The authors are grateful to the referees for their detailed comments and valuable suggestions, which have contributed to the final preparation of the paper.

ROBUST ROOT-CLUSTERING OF A MATRIX IN INTERSECTIONS OR UNIONS OF REGIONS*

OLIVIER BACHELIER†, DIDIER HENRION‡, BERNARD PRADIN§, AND DRISS MEHDI†

Abstract. This paper considers robust stability analysis for a matrix affected by unstructured complex uncertainty. A method is proposed to compute a bound on the amount of uncertainty ensuring robust root-clustering in a combination (intersection and/or union) of several possibly nonsymmetric half planes, discs, and outsides of discs. In some cases to be detailed, this bound is not conservative. The conditions are expressed in terms of linear matrix inequalities (LMIs) and derived through Lyapunov's second method. As a distinctive feature of the approach, the Lyapunov matrices proving robust root-clustering (one per subregion) are not necessarily positive definite but have prescribed inertias depending on the number of roots in the corresponding subregions. As a special case, when root-clustering in a single half plane, disc, or outside of a disc is concerned, the whole clustering region reduces to only one convex subregion, and the corresponding unique Lyapunov matrix has to be positive definite as usual.

Key words. robust stability analysis, unstructured uncertainty, matrix root-clustering, $\mathcal{D}$-stability radius, inertia of a matrix, LMIs

DOI. 10.1137/S0363012903432365

1. Introduction.

Robust stability has been raising much interest in the last three decades. Indeed, in a linear state-space context, it matters to attest whether an uncertain state matrix has its eigenvalues in the open left half plane (OLHP) for continuous-time analysis or in the open unit disc (OUD) for discrete-time analysis. More precisely, assuming nominal stability, it can be useful to estimate the maximal size of the uncertainty domain for which stability is preserved.

The way to estimate this size obviously depends on the structure of the uncertainty. The structured (parametric) case should be distinguished from the unstructured (nonparametric) one as pointed out in one of the first contributions due to Patel and Toda [20]. The present contribution is restricted to an unstructured uncertainty, namely, the so-called norm-bounded uncertainty [22]. In this context, the maximal acceptable size of uncertainty was clearly defined, in continuous time, as the stability radius [13]. Such a stability radius was shown to equal the reciprocal of the $\mathcal{H}_\infty$-norm of a strictly proper transfer in [16] and thus also appears to be the reciprocal of the maximal structured singular value μ [9] along frequency. The discrete-time counterpart is described in [19]. In these references, the computation of the stability radius could be carried out with iterative resolutions of Riccati equations [6, 7]. Another technique consists in computing μ while sweeping frequencies. With the emergence of convex optimization over linear matrix inequalities (LMIs), the stability radius can be computed owing to the LMI version of the bounded real lemma [1].

§LAAS-CNRS, 7, Avenue du Colonel Roche, 31077 Toulouse CEDEX, France (pradin@laas.fr).

It is also important to distinguish between the complex stability radius and the real one. The former concerns a complex uncertainty and can be computed with LMI software as just mentioned. The latter takes the realness of the uncertainty into account (what is more discerning to analyze practical plants in automatic control) and is a bit more difficult to obtain, involving a one-dimensional sweeping over the second largest singular value of a parametrized matrix [23, 12]. The present contribution is restricted to the complex case.

When further performances are required, such as transient ones, it might be shrewd to consider a more sophisticated region for the state matrix root-clustering, different from the OLHP or the OUD. Based on the notions of Ω-regions and generalized Lyapunov equations (GLEs) due to Gutman and Jury [10], Yedavalli has proposed significant robustness bounds [31] (later improved by other authors), but the results are still conservative. The reader is also invited to see [29]. Moreover, the considered regions are usually connected, which might not be suitable for plants with separate dynamics or with specified robust damping ratios. One of the first attempts to consider unions of regions is provided in [2]. The concept of $\mathcal{D}_U$-stability (root-clustering in some region $\mathcal{D}_U$ whose form encompasses many unions of possible disjoint and nonsymmetric subregions) enables more general results [3]. However, these results remain quite conservative.

This paper is an attempt to consider sophisticated clustering regions by extending the notion of a complex stability radius to some combinations (unions and/or intersections) of half planes, discs, and exteriors of discs. Besides, the conservatism of the previously proposed methods is reduced. In some typical cases to be further detailed, the exact value of the complex radius is reached.

The paper is organized as follows: section 2 states the problem, presenting the clustering regions and extending the concept of a complex $\mathcal{D}$-stability radius to the case where $\mathcal{D}$ is some combination of regions. Section 3 introduces the notion of $\partial\mathcal{D}$-regularity of a nominal matrix, which is the nonmembership of the matrix eigenvalues to a geometric curve $\partial\mathcal{D}$. Such a property can often be checked through the derivation of a Lyapunov matrix which is not necessarily positive definite but is just nonsingular with constant inertia. When $\mathcal{D}$-stability is concerned, the Lyapunov matrix is required to be strictly positive or negative definite. In section 4, the considered matrix is affected by an additive norm-bounded uncertainty. Based upon the notion of $\partial\mathcal{D}$-regularity, a method to reach the complex $\mathcal{D}$-stability radius is proposed. In some cases to be detailed, the exact value is obtained. Numerical examples are provided in section 5 before the conclusion.

Notation. M' denotes the transpose conjugate of matrix M. Hence, s' is the conjugate of complex number s. M^H is the Hermitian matrix $M + M'$. The 2-norm of M induced by the Euclidean vector norm (maximal singular value) is denoted by $||M||_2$. $\mathbb{I}_n$ is the identity matrix of order n, and $\mathbb{O}$ is a null matrix of appropriate dimensions. Matrix inequalities are considered in the sense of Löwner, i.e., > 0 (resp., < 0) means positive (resp., negative) definite. The symbol $\mathbf{i}$ denotes the imaginary unit and $\lambda(A)$ denotes the spectrum of square matrix A. $\mathfrak{I}$ and $\mathfrak{C}$ are the imaginary axis and the unit circle, respectively. At last, the vector $\mathrm{In}(M) = [n_+ \; n_- \; n_0]$ is the inertia of a square matrix M if n_+, n_-, n_0 are the numbers of eigenvalues of M with positive, negative, and zero real part, respectively.

2. Problem statement. First, the form of the uncertain matrix to be analyzed is given. Then, the clustering region is introduced. At last, the problem to be solved is stated.

2.1. The uncertain matrix. The considered matrix reads

$$A_c = A + B\Delta C \in \mathbb{C}^{n\times n}. \tag{1}$$

In the above expression, Δ is constant, unknown, and assumed to belong to $\mathcal{B}(\rho)$, the ball of all matrices $\Delta \in \mathbb{C}^{q\times r}$ satisfying $||\Delta||_2 \leq \rho$. Matrices $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times q}$, and $C \in \mathbb{C}^{r\times n}$ are perfectly known. Such a description is referred to as norm-bounded uncertainty [22].

Remark 1. In this work, all the matrices are assumed to be complex. However, in practice, when transient performances of a linear state-space model are to be analyzed, state matrix A_c is real. In that case, Δ is then real and $\mathcal{B}(\rho)$ must be restricted to real matrices. Actually, this restriction is more difficult to take into account and this case is not investigated in the paper although some interesting results exist [23, 12].

2.2. Clustering region $\mathcal{D}$. Consider the following geometric curves:

$$\begin{cases} \partial\mathcal{D}_k = \left\{ s \in \mathbb{C} | f_k(s) = r_{k_{00}} + (r_{k_{10}} s)^H + r_{k_{11}} s' s = 0 \right\} \\ \\ \{ r_{k_{00}}, r_{k_{10}}, r_{k_{11}} \} \in \mathbb{R} \times \mathbb{C} \times \mathbb{R} \end{cases} \quad \forall k \in \{1, \ldots, m\}. \tag{2}$$

Relevant curves are lines or circles. Each curve $\partial\mathcal{D}_k$ enables us to define an associated region:

$$\mathcal{D}_k = \{ s \in \mathbb{C} \,|\, f_k(s) < 0 \} \quad \forall k \in \{1, \ldots, m\}. \tag{3}$$

Clearly, $\mathcal{D}_k$ denotes either one side or the other side of the boundary $\partial\mathcal{D}_k$. It can then be a half plane, a disc, or the outside of a disc. It is an open region (i.e., not including $\partial\mathcal{D}_k$) in order to encompass the concept of asymptotic stability for linear time invariant (LTI) systems. $\mathcal{D}_k$ can actually correspond to the scalar case of regions defined in [21] or to a special case of second order Ω-regions [10].

Also define the region $\mathcal{D}$ as a combination, i.e., any union and/or intersection of the various subregions $\mathcal{D}_k$. Such a formulation of $\mathcal{D}$ clearly enables a very large choice of clustering regions.

2.3. Problem statement. This contribution aims at computing the complex $\mathcal{D}$-stability radius.

More precisely, assume that A is $\mathcal{D}$-stable, i.e., that the whole of its spectrum lies in $\mathcal{D}$. Define $r_{\mathcal{D}}$ as the largest value of ρ, the radius of $\mathcal{B}(\rho)$, such that A_c defined in (1) remains $\mathcal{D}$-stable for any $\Delta \in \mathcal{B}(\rho)$. Such a value is the so-called complex $\mathcal{D}$-stability radius. A lower bound $\rho^\star$ of $r_{\mathcal{D}}$, as tight as possible, is to be computed. For this purpose, the concept of $\partial\mathcal{D}$-regularity is introduced in the next section.

3. $\partial\mathcal{D}$-regularity. In this section, only nominal matrices are considered. The concepts of matrix $\partial\mathcal{D}$-regularity and matrix $\partial\mathcal{D}$-singularity are introduced. A necessary and sufficient condition for matrix $\partial\mathcal{D}$-regularity to be satisfied when $\partial\mathcal{D}$ is defined as in (2) is expressed in terms of an LMI. After preliminary notions and assumptions in subsection 3.1, subsection 3.2 presents this condition through a first theorem. In subsection 3.3, the distribution of the matrix eigenvalues with respect to the boundary $\partial\mathcal{D}$ is connected to the inertia of the solution to the LMI, owing to a second theorem. Subsection 3.4 is devoted to a discussion of these theorems.

3.1. Preliminaries.

DEFINITION 1. *Let $\partial\mathcal{D}$ be any curve in the complex plane; then matrix $A \in \mathbb{C}^{n\times n}$ is called*

- *$\partial\mathcal{D}$-singular when* $\lambda(A) \cap \partial\mathcal{D} \neq \emptyset$;
- *$\partial\mathcal{D}$-regular when* $\lambda(A) \cap \partial\mathcal{D} = \emptyset$.

Remark 2. Assume that $\partial\mathcal{D}$ is a boundary separating two open regions $\mathcal{D}$ and $\bar{\mathcal{D}}^C$ (then $\mathbb{C} = \mathcal{D} \cup \partial\mathcal{D} \cup \bar{\mathcal{D}}^C$). Matrix A is $\mathcal{D}$-stable if and only if it is $\partial\mathcal{D}$-regular and the whole of its spectrum lies in $\mathcal{D}$. Otherwise, it is $\mathcal{D}$-unstable.

Now assume that $\partial\mathcal{D}$ here reduces to only one curve as defined in (2), i.e.,

$$\partial\mathcal{D} = \{s \in \mathbb{C} \,|\, f(s) = r_{00} + (r_{10}s)^H + r_{11}s's = 0\}. \tag{4}$$

In parallel with the work of Hill [11], we state two theorems in the next two parts. The result provided in [11] is based on Ostrowski and Schneider's theorem [18] and on Frobenius's theorem. Our contribution is more part of the framework relevant to Lyapunov's second method [17] and its extensions to root-clustering [10].

3.2. LMI condition for $\partial\mathcal{D}$-regularity.

THEOREM 1. *Let A and $\partial\mathcal{D}$ be, respectively, a complex square matrix of dimension n and a curve of the complex plane as defined in* (4). *Matrix A is $\partial\mathcal{D}$-regular if and only if there exists a Hermitian matrix $P \in \mathbb{C}^{n\times n}$ such that*

$$F(A,P) = r_{00}P + (r_{10}PA)^H + r_{11}A'PA < 0. \tag{5}$$

Proof. Some arguments are inspired from [14, 8].

Sufficiency. First assume that there exists a suitable P such that (5) holds. Also assume that A has $\bar{n} \leq n$ distinct eigenvalues. It suffices to prove the nonmembership of these $\bar{n}$ eigenvalues to $\partial\mathcal{D}$. Let λ_j denote the jth eigenvalue of A. There exists a nonzero vector v_j such that $Av_j = \lambda_j v_j$, so it follows that

$$v_j'F(A,P)v_j \;<\; 0 \quad \forall j \in \{1,\ldots,\bar{n}\}$$

$$\Leftrightarrow\; r_{00}v_j'Pv_j + (r_{10}v_j'PAv_j)^H + r_{11}v_j'A'PAv_j < 0 \quad \forall j \in \{1,\ldots,\bar{n}\}$$

$$\Leftrightarrow\; (r_{00} + (r_{10}\lambda_j)^H + r_{11}\lambda_j'\lambda_j)(v_j'Pv_j) < 0 \quad \forall j \in \{1,\ldots,\bar{n}\},$$

which implies

$$f(\lambda_j) = r_{00} + (r_{10}\lambda_j)^H + r_{11}\lambda_j'\lambda_j \neq 0 \quad \forall j \in \{1,\ldots,\bar{n}\},$$

and hence

$$\lambda_j \notin \partial\mathcal{D} \quad \forall j \in \{1,\ldots,\bar{n}\} \Leftrightarrow \lambda_i \notin \partial\mathcal{D} \quad \forall i \in \{1,\ldots,n\}.$$

Matrix A is then $\partial\mathcal{D}$-regular.

Necessity. Now assume that A is $\partial\mathcal{D}$-regular. Then

$$f(\lambda_i) \neq 0 \quad \forall i \in \{1,\ldots,n\}. \tag{6}$$

It means that $f(\lambda_i)$ is either strictly positive or strictly negative. Define matrix Λ as

$$\Lambda \;=\; \underset{i=1,\ldots,n}{\operatorname{diag}}\{\lambda_i\} \;=\; \begin{bmatrix} \Lambda_1 & \mathbb{O} \\ \mathbb{O} & \Lambda_2 \end{bmatrix},$$

where $\Lambda_1 \in \mathbb{C}^{n_-}$ contains the various λ_i for which $f(\lambda_i) > 0$ and $\Lambda_2 \in \mathbb{C}^{n_+}$ contains those for which $f(\lambda_i) < 0$. With

$$\mathcal{I} = \begin{bmatrix} -\mathbb{I}_{n_-} & \mathbb{O} \\ \mathbb{O} & \mathbb{I}_{n_+} \end{bmatrix}, \tag{7}$$

it holds that

$$F(\Lambda, \mathcal{I}) = r_{00} \begin{bmatrix} -\mathbb{I}_{n_-} & \mathbb{O} \\ \mathbb{O} & \mathbb{I}_{n_+} \end{bmatrix} + \left(r_{10} \begin{bmatrix} -\Lambda_1 & \mathbb{O} \\ \mathbb{O} & \Lambda_2 \end{bmatrix} \right)^H + r_{11} \begin{bmatrix} -\Lambda_1'\Lambda_1 & \mathbb{O} \\ \mathbb{O} & \Lambda_2'\Lambda_2 \end{bmatrix} < 0. \tag{8}$$

Let $\mathcal{J}$ be the Jordan canonical form of A. There exists a sequence of full rank matrices T_l such that [8]

$$\lim_{l \to \infty} (T_l \mathcal{J} T_l^{-1}) = \Lambda \tag{9}$$

(for example, if $\mathcal{J}$ is a single Jordan block $\left[\begin{smallmatrix} \lambda & 1 \\ 0 & \lambda \end{smallmatrix}\right]$, T_l equals $\left[\begin{smallmatrix} \frac{1}{l} & 0 \\ 0 & 1 \end{smallmatrix}\right]$). Since F is continuous with respect to its first argument, from (8) it follows that

$$\lim_{l \to \infty} F(T_l \mathcal{J} T_l^{-1}, \mathcal{I}) < 0. \tag{10}$$

Let $\mathcal{T}$ denote T_l for a sufficiently large $l < \infty$ (i.e., such that $\mathcal{T}^{-1}$ exists) so that

$$F(\mathcal{T}\mathcal{J}\mathcal{T}^{-1}, \mathcal{I}) < 0.$$

Applying congruence on the previous inequality leads to

$$\mathcal{T}' F(\mathcal{T}\mathcal{J}\mathcal{T}^{-1}, \mathcal{I})\mathcal{T} = F(\mathcal{J}, \mathcal{T}'\mathcal{I}\mathcal{T}) < 0.$$

Now assume that V denotes a matrix such that $\mathcal{J} = VAV^{-1}$. Left and right multiplying the previous inequality, respectively, by V' and V leads to (5) with

$$P = V'\mathcal{T}'\mathcal{I}\mathcal{T}V. \tag{11}$$

Note that if there exists a matrix V such that $\Lambda = VAV^{-1}$ (or, equivalently, $\Lambda = \mathcal{J}$), then the above reasoning stands with $T_l = \mathbb{I}_n \, \forall l$. This completes the proof. ∎

3.3. Root-distribution and the inertia of P.

THEOREM 2. *Let A and $\partial\mathcal{D}$ be, respectively, a complex square matrix of dimension n and a curve of the complex plane as defined in* (4). *Matrix A is $\partial\mathcal{D}$-regular with n_+ eigenvalues in $\mathcal{D}$ and n_- eigenvalues outside $\mathcal{D}$ if and only if any Hermitian solution P to LMI* (5) *has inertia* $\mathrm{In}(P) = [n_+,\ n_-,\ 0]$.

Proof. Some possible expression of P is given by (11). Since inertia is invariant under congruence, $\mathrm{In}(P) = \mathrm{In}(\mathcal{I}) = [n_+,\ n_-,\ 0]$, where $\mathcal{I}$ is as defined in (7). The question is to know if it is possible that there exists some other solution to LMI (5) with a different inertia. If it is possible, by continuity of the convex set of solutions, there exists a singular X such that

$$F(A, X) < 0.$$

Let $\mathcal{J}$ be a Jordan canonical form similar to A and V be the associated similarity matrix. By congruence, it follows that

$$F(\mathcal{J}, Z) < 0,$$

where $Z = (V')^{-1}XV^{-1}$ is also a singular matrix. Taking the sequence of full rank matrices T_l introduced in (9) into account enables us to deduce

$$F\left(\lim_{l\to\infty}(T_l^{-1}\Lambda T_l), Z\right) < 0,$$

which by continuity of F with respect to its first argument leads to

$$\lim_{l\to\infty} F(T_l^{-1}\Lambda T_l, Z) < 0.$$

Once again, let $\mathcal{T}$ denote T_l for a sufficiently large value of $l < \infty$ so that

$$F(\mathcal{T}^{-1}\Lambda\mathcal{T}, Z) < 0.$$

Applying congruence on the previous inequality leads to

$$F(\Lambda, Y) < 0, \tag{12}$$

where

$$Y = \begin{bmatrix} Y_1 & Y_3 \\ Y_3' & Y_2 \end{bmatrix} = (\mathcal{T}')^{-1}Z\mathcal{T}^{-1}$$

is singular. At this stage a distinction is made between two cases:

• $r_{11} = 0$. In this case, $\mathcal{D}$ and $\bar{\mathcal{D}}^C$ are half planes. By Schur factorization, there exists a unitary matrix U such that $Y = U'SU$, where S is a diagonal matrix whose diagonal entries are the eigenvalues of Y. With no loss of generality, Y being singular, the first diagonal entry is assumed to be zero. By congruence, one gets

$$F(U\Lambda U', S) < 0.$$

The previous inequality never holds since the first diagonal entry of the left member is zero. Hence, in this case, Y or X cannot be singular, and the inertia of the solution is invariant.

• $r_{11} \neq 0$. In this case, first note that $\partial\mathcal{D}$ can be defined another way:

$$\partial\mathcal{D} = \left\{ s \in \mathbb{C} \,|\, f(s) = \tilde{r}_{00} + r_{11}\left(s' + \frac{r_{10}}{r_{11}}\right)\left(s + \frac{r_{10}'}{r_{11}}\right) = 0 \right\} \tag{13}$$

with

$$\tilde{r}_{00} = r_{00} - \frac{r_{10}r_{10}'}{r_{11}}.$$

Note that $\frac{\tilde{r}_{00}}{r_{11}}$ is strictly negative; otherwise, $\partial\mathcal{D}$ reduces to $\emptyset$. In terms of matrix inequality, it leads to rewriting (12) as follows:

$$\tilde{F}(\tilde{\Lambda}, Y) = \tilde{r}_{00}Y + r_{11}\tilde{\Lambda}'Y\tilde{\Lambda} < 0,$$

where $\tilde{\Lambda} = \Lambda + \frac{r_{10}'}{r_{11}}\mathbb{I}_n$ is $\partial\tilde{\mathcal{D}}$-regular, $\partial\tilde{\mathcal{D}}$ being the circle centered around the new origin and of radius $\sqrt{-\tilde{r}_{00}/r_{11}}$. Two diagonal blocks can be extracted from the previous inequality:

$$\begin{cases} \tilde{F}(\tilde{\Lambda}_1, Y_1) < 0, \\ \tilde{F}(\tilde{\Lambda}_2, Y_2) < 0. \end{cases}$$

Clearly, $\tilde{\Lambda}_1 = \Lambda_1 + \frac{r'_{10}}{r_{11}}\mathbb{I}_{n_-}$ and $\tilde{\Lambda}_2 = \Lambda_2 + \frac{r'_{10}}{r_{11}}\mathbb{I}_{n_+}$ are such that $\tilde{\Lambda}_2$ is $\tilde{\mathcal{D}}$-stable and $\tilde{\Lambda}_1$ has its whole spectrum outside $\tilde{\mathcal{D}}$. It is clear, from the beginning of the proof, that there exists a Hermitian matrix $\tilde{Y}_1 < 0$ such that $\tilde{F}(\tilde{\Lambda}_1, \tilde{Y}_1) < 0$. It will now be shown that any other solution Y_1 remains negative definite by continuity, i.e., never becomes singular. First note that since $\tilde{\Lambda}_1$ has its spectrum outside of the disc $\tilde{\mathcal{D}}$, it can be inverted and it follows that

$$r_{11}Y_1 + \tilde{r}_{00}(\tilde{\Lambda}_1^{-1})'Y_1\tilde{\Lambda}_1^{-1} < 0.$$

Assume that Y_1 is negative semidefinite. Achieve Schur factorization of Y_1 such that $Y_1 = U_1'S_1U_1$. The diagonal entries of S_1 are negative, excepting the first one which is zero. By congruence, it follows that

$$S_1 + \frac{\tilde{r}_{00}}{r_{11}}U_1(\tilde{\Lambda}_1^{-1})'U_1'S_1U_1\tilde{\Lambda}_1^{-1}U_1' < 0.$$

Since $\frac{\tilde{r}_{00}}{r_{11}} < 0$, the first diagonal entry of the left-hand side member is positive or zero, and thus inequality never holds. Y_1 is then necessarily strictly negative definite.

In the same way, there also exists some Hermitian matrix $\tilde{Y}_2 > 0$ such that $\tilde{F}(\tilde{\Lambda}_2, \tilde{Y}_2) < 0$. Is it possible that, by continuity, some other solution Y_2 becomes singular, i.e., positive semidefinite? Assume that such a Y_2 exists and by Schur factorization $Y_2 = U_2'S_2U_2$ (S_2 is diagonal with the first diagonal entry zero and the other ones positive) and by congruence we have

$$\tilde{F}(U_2\tilde{\Lambda}_2U_2', S_2) < 0.$$

Since $\tilde{\Lambda}_2$ and S_2 are diagonal matrices and since the first diagonal entry of S_2 is zero, then the first diagonal entry of the left-hand side member is positive or zero, which leads to a contradiction. Thus, Y_2 is necessarily strictly positive definite.
Now, coming back to Y, using Schur complement, one gets

$$\mathrm{In}(Y) = \mathrm{In}\left(\left[\begin{array}{c|c} Y_1 & \mathbb{O} \\ \hline \mathbb{O} & Y_2 - Y_3'Y_1^{-1}Y_3 \end{array}\right]\right).$$

Clearly, since $Y_2 > 0$ and $Y_1 < 0$, none of the diagonal blocks of the above matrix can be singular. Hence, $\mathrm{In}(Y) = \mathrm{In}(X) = \mathrm{In}(P)$ and the proof is complete. ∎

As mentioned in subsection 3.1, our result is an alternative to results by Hill [11]. However, our result is summarized under the form of one single theorem valid both for any line and any circle. It does not require any preliminary mathematical lemma except Sylvester's well-known theorem ($\mathrm{In}(H) = \mathrm{In}(MHM')$ for any nonsingular matrix M). Although it is formulated as in Lyapunov's framework, the proofs basically require simple algebraic manipulations which, the authors hope, will help extension to other curves. In that sense, it is closer to the result of [14]. Nevertheless, some differences are pointed out in the discussion provided in the next subsection.

COROLLARY 1. *Let A and $\partial\mathcal{D}$ be, respectively, a complex square matrix of dimension n and a curve of the complex plane as defined in* (4). *Also let $\mathcal{D}$ and $\bar{\mathcal{D}}^C$ be the regions defined by $f(s) < 0$ and $f(s) > 0$, respectively. Matrix A is $\mathcal{D}$-stable (resp., $\bar{\mathcal{D}}^C$-stable) if and only if there exists a Hermitian positive (resp., negative) definite matrix $P \in \mathbb{C}^{n\times n}$ such that* (5) *holds.*

Proof. The proof follows directly from Theorem 2 considering inertia $\mathrm{In}(P) = [n\ 0\ 0]$ (resp., $\mathrm{In}(P) = [0\ n\ 0]$). ∎

As special cases, $\mathcal{D}$ can be the OLHP or the OUD. In those cases, Lyapunov's theorem [17] and Stein's theorem [26] are, respectively, recovered.

Remark 3. Since any solution to (5) is necessarily nonsingular, there is no need to specify it as a constraint, and (5) is a simple LMI in P easy to test with various existing LMI software. Note that the nonstrict LMI cannot be considered here because it would allow $\partial\mathcal{D}$-singularity.

3.4. Discussion. With appropriate changes, the above proof could be adapted to any second order Ω-transformable region. In that sense, this could be seen as a special case of [14]. However, although [14, Theorem 1] seems suitable to prove the first statement in Theorem 1, we do not agree with the proof of [14, Theorem 2] related to the inertia of P. Indeed after having proven that some solution P to an LMI exists and has expression [14, equation (6)], it is claimed that for any choice of the negative definite right member of the associated equality, the solution to this equality keeps the same expression. We do not agree with that point. Perhaps the same doubt led Jury to achieve a special proof for the nonsingularity of the solution of a GLE [15, Theorem 3.16]. The notion of Ω-transformability was required to prove this nonsingularity (see also [10, Theorem 12]). It could at first sight directly be derived from [14, Theorem 2], but we also think that this special proof was necessary.

Going on with Ω-transformability, it is interesting to see that although transformability seemed to be required to prove the *nonsingularity* of the solution to a GLE [10], we show here that, owing to the notion of $\partial\mathcal{D}$-regularity (rather than just $\mathcal{D}$-stability), $\mathcal{D}$ and $\bar{\mathcal{D}}^C$ are considered altogether (the reader is here reminded of the fact that $\mathcal{D}$-stability and $\bar{\mathcal{D}}^C$-stability are only special cases of $\partial\mathcal{D}$-regularity as stated in Corollary 1). As a consequence, the outside of a disc is a non-Ω-transformable region for which it is impossible to find a singular solution to a corresponding GLE. Otherwise, it would be in contradiction with Remark 3. In other words, any solution to a GLE attesting matrix root-clustering is necessarily nonsingular (existence and uniqueness of the solution to a GLE is another problem; see [10]). The outside of the disc is then a region for which Ω-transformability is not required to guarantee the nonsingularity of the solution to a corresponding GLE. It is what was illustrated by an example proposed in [28].

Apart from our doubt of the proof of [14, Theorem 2], we would like to add that this contribution seems to have been overlooked. Actually, [14, Theorem 1] is nothing but an LMI test for matrix root-clustering in an Ω-region. In 1971, such a test was not tractable from a computational point of view (at about the same time, Willems was just beginning to warn the control community about the great interest in handling LMIs [30]). For this reason, it mattered to "convert" this LMI test into a GLE [10]. Now that LMIs have become classical tools, although some significant contributions enabled us to test matrix root-clustering via LMI conditions [8], many authors should remember the pioneer work [14].

Furthermore, if solving an LMI is not an obstacle, results in [14] can be used to consider problem 85 formulated by Wang in the electronic book proposed by Blondel and Megretski [5]. In problem 85, the analysis of root-clustering in Ω-transformable regions of order greater than 2 is concerned and expressed in terms of GLEs. Of course, it is an interesting challenge from a mathematical point of view. At first sight, as far as root-clustering analysis is concerned, the LMI approach, as used in this paper or in [14], could be exploited to solve the problem and the GLE approach could seem useless. However, it is not really true because the problem is not purely theoretical. When problems involving very high dimensions are to be solved, the LMI

approach generates heavy computations and can lead to numerical failure while some P actually exists. This is why the GLE approach preserves all its interest. Solving a GLE requires choosing a right-hand side member in order to get a simple linear system. Thus it is important to be sure that this member can be arbitrarily chosen and will always lead to a unique nonsingular solution P. Such a possible arbitrary choice is probably strongly related to Ω-transformability and that is exactly the point presented in problem 85. To sum up this part of the discussion, for low-dimensional problems, the LMI approach might enable us to be free of the transformability assumption and of GLEs, but for high-dimensional problems, those notions are still fundamental.

Chapter 17 of [4] describes the guardian map as an alternative tool for checking $\mathcal{D}$-stability or $\partial\mathcal{D}$-regularity. The guardian map is a mapping ν such that $\nu(A) \neq 0$ if $A \in \mathcal{A}$ and $\nu(A) = 0$ if $A \notin \mathcal{A}$. For example, the mapping $\nu(A) = \det A$ guards the sets of nonsingular matrices, and $\nu(A) = \det H(p)$ guards the sets of Hurwitz stable matrices, where $H(p)$ is the Hurwitz matrix of characteristic polynomial $p(s) = \det(sI - A)$. As shown in [4], checking properties like robust regularity or stability then amounts to computing eigenvalues of matrices related to guardian maps. Our approach can be viewed as an alternative to guardian map techniques, in the sense that the robustness certificate for regularity or stability is the existence of a Lyapunov matrix with given inertia solving a given LMI.

4. Complex $\mathcal{D}$-stability radius. In this section, the uncertain case is studied. First, a necessary and sufficient condition for the uncertain A_c defined in (1) to be $\partial\mathcal{D}$-regular when $\partial\mathcal{D}$ complies with (4) is given. This condition is then used to compute the $\mathcal{D}$-stability radius when $\mathcal{D}$ is some combination of regions as defined in subsection 2.2.

THEOREM 3. *Let A_c and $\partial\mathcal{D}$ be, respectively, an uncertain matrix as defined in* (1) *and a geometric curve as defined in* (4). *Assume that nominal matrix A is $\partial\mathcal{D}$-regular. Matrix A_c is robustly $\partial\mathcal{D}$-regular against the ball $\mathcal{B}(\rho)$ if and only if there exists some Hermitian matrix P with inertia* $\mathrm{In}(P) = [n_+,\ n_-,\ 0]$ *such that*

$$\mathcal{Q}(P,\gamma) = \begin{bmatrix} r_{00P} + (r_{10}PA)^H + r_{11}A'PA + C'C & r_{10}PB + r_{11}A'PB \\ r'_{10}B'P + r_{11}B'PA & r_{11}B'PB - \gamma\mathbb{I}_q \end{bmatrix} < 0 \tag{14}$$

with $\gamma = \rho^{-2}$. In this event, A_c keeps n_+ eigenvalues inside $\mathcal{D}$ and n_- outside $\mathcal{D}$.

Proof. First assume that $r_{11} = 0$. Then $\partial\mathcal{D}$ is a line. By appropriate rotation and shifting, it can be transformed into the imaginary axis $\partial\hat{\mathcal{D}} = \mathfrak{I}$. Apply the same mapping on matrices A, and then the necessary and sufficient condition for the new matrix $\hat{A}_c = \hat{A} + B\Delta C$ to be $\partial\hat{\mathcal{D}}$-regular can be deduced from Lemma 1 recalled in the appendix. Indeed, consider Lemma 1. Condition (14) corresponds to (28) with A substituted by $\hat{A}$ and

$$M = \begin{bmatrix} C'C & \mathbb{O} \\ \mathbb{O} & -\gamma\mathbb{I}_q \end{bmatrix}, \tag{15}$$

which is equivalent to (27). It follows that

$$(C(\mathbf{i}\omega\mathbb{I} - \hat{A})^{-1}B)'(C(\mathbf{i}\omega\mathbb{I} - \hat{A})^{-1}B) < \gamma\mathbb{I}_q \quad \forall\omega \in \mathbb{R}. \tag{16}$$

In the same way, if $r_{11} \neq 0$, then $\partial\mathcal{D}$ is a circle. With appropriate scaling and shifting, $\partial\mathcal{D}$ can be transformed into the unit circle $\partial\hat{\mathcal{D}} = \mathfrak{C}$. Apply the same mapping on matrix A in order to get the new matrix $\hat{A}$. Uncertain matrix $\hat{A}_c = \hat{A} + B\Delta C$ has to be $\mathfrak{C}$-regular, which can be tested owing to Lemma 2 given in the appendix. Condition

(14) is equivalent to (30) with $A = \hat{A}$ and M given by (15), which is equivalent to (29). It follows that

$$(C(e^{\mathbf{i}\omega}\mathbb{I} - \hat{A})^{-1}B)'(C(e^{\mathbf{i}\omega}\mathbb{I} - \hat{A})^{-1}B) < \gamma\mathbb{I}_q \quad \forall\omega \in \mathbb{R}. \tag{17}$$

Both cases then lead to the equivalent condition

$$\Leftrightarrow ||C(s\mathbb{I}_n - \hat{A})^{-1}B||_2 < \sqrt{\gamma} = \rho^{-1} \quad \forall s \in \partial\hat{\mathcal{D}}.$$

Using classical arguments on singular values yields

$$[\inf\{||\Delta||_2 | \Delta \in \mathbb{C}^{q\times r} \text{ and } \det(\mathbb{I}_q - \Delta C(s\mathbb{I}_n - \hat{A})^{-1}B) = 0\}]^{-1} < \rho^{-1} \quad \forall s \in \partial\hat{\mathcal{D}},$$

which is the definition of the structured singular value. Using properties of det(.), the rewriting of the above expression leads to

$$[\inf\{||\Delta||_2 | \Delta \in \mathbb{C}^{q\times r} \text{ and } \det(s\mathbb{I}_n - (\hat{A} + B\Delta C)) = 0\}]^{-1} < \rho^{-1} \quad \forall s \in \partial\hat{\mathcal{D}} \Leftrightarrow$$

$$\eta^{-1}(s) = [\inf\{||\Delta||_2 | \Delta \in \mathbb{C}^{q\times r} \text{ and } s \in \lambda(\hat{A} + B\Delta C)\}]^{-1} < \rho^{-1} \ \forall s \in \partial\hat{\mathcal{D}} \tag{18}$$

$$\Leftrightarrow \eta(s) > \rho \quad \forall s \in \partial\hat{\mathcal{D}}.$$

The above inequality shows that any uncertain matrix Δ inducing the $\partial\hat{\mathcal{D}}$-singularity of matrix $\hat{A}_c$ is such that $||\Delta||_2 > \rho$. As a consequence, $\hat{A}_c$ is $\partial\hat{\mathcal{D}}$-regular over $\mathcal{B}(\rho)$. Because each eigenvalue of A is implicitly subject to the same mapping as A, the root-distribution of A with respect to $\partial\mathcal{D}$ is the same as the root-distribution of $\hat{A}$ with respect to $\partial\hat{\mathcal{D}}$. From the block $(1,1)$ in (14), it can be seen that P guarantees the $\partial\mathcal{D}$-regularity of A. By virtue of Theorem 2, the root-distribution of A with respect to $\partial\mathcal{D}$ is given by the inertia of P. Since A_c never becomes $\partial\mathcal{D}$-singular over $\mathcal{B}(\rho)$, the inertia of P gives the root-distribution of A_c over $\mathcal{B}(\rho)$. □

The value of ρ obtained when minimizing γ under LMI constraints (14) is the largest acceptable value of ρ. Thus, it is what can be called the complex $\partial\mathcal{D}$-regularity radius. It will be denoted by $\varrho_{\partial\mathcal{D}}$ in what follows.

Now come back to region $\mathcal{D}$ defined as a combination of several regions $\mathcal{D}_k$ (see subsection 2.2). Referring to previous works on stability radii [13, 23], the complex $\mathcal{D}$-stability radius can also be defined as follows:

$$r_{\mathcal{D}} = \inf\{||\Delta||_2 \,|\, \Delta \in \mathbb{C}^{q\times r} : \ A + B\Delta C \text{ is } \mathcal{D}\text{-unstable}\}. \tag{19}$$

The complex $\partial\mathcal{D}$-regularity of a complex matrix A (not necessarily $\mathcal{D}$-stable) is here defined by

$$\varrho_{\partial\mathcal{D}} = \inf\{||\Delta||_2 \,|\, \Delta \in \mathbb{C}^{q\times r} : \ \lambda(A + B\Delta C) \cap \partial\mathcal{D} \neq \emptyset\}, \tag{20}$$

where $\partial\mathcal{D}$ is the boundary of $\mathcal{D}$. The formulation of $r_{\mathcal{D}}$ implicitly assumes that A is $\mathcal{D}$-stable. That is the basic difference from the formulation of $\varrho_{\partial\mathcal{D}}$ for which no assumption of nominal $\mathcal{D}$-stability is made. For this reason, it follows that

$$A \text{ is } \mathcal{D}\text{-stable } \Rightarrow \ \varrho_{\partial\mathcal{D}} = r_{\mathcal{D}}. \tag{21}$$

Also define the set $\partial\mathcal{U}$ by

$$\partial\mathcal{U} = \bigcup_{k=1}^{m} \partial\mathcal{D}_k. \tag{22}$$

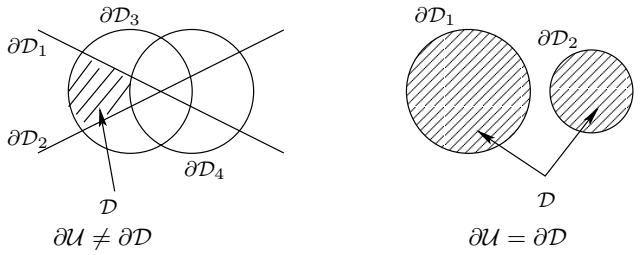

FIG. 1. $\varrho_{\partial\mathcal{D}} = \varrho_{\partial\mathcal{U}}$?

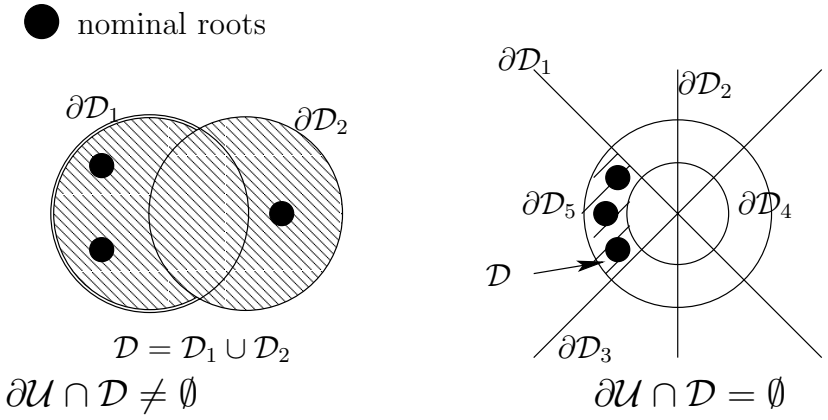

FIG. 2. $\varrho_{\partial\mathcal{U}} = r_{\mathcal{D}}$?

It is clear that $\partial\mathcal{D} \subset \partial\mathcal{U}$. Hence, A_c has no eigenvalue on $\partial\mathcal{D}$ if it has no eigenvalue on $\partial\mathcal{U}$, so we have

$$\varrho_{\partial\mathcal{U}} = \min_{k\in\{1,\ldots,m\}} \varrho_{\partial\mathcal{D}_k} \leq \varrho_{\partial\mathcal{D}}. \tag{23}$$

Moreover, if $\partial\mathcal{U} = \partial\mathcal{D}$, the above inequality becomes an equality. Besides, if A is assumed to be $\mathcal{D}$-stable and if $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$, it can be assessed that

$$\varrho_{\partial\mathcal{U}} = r_{\mathcal{D}}. \tag{24}$$

To make the previous reasoning clear, it is illustrated by Figures 1 and 2 where region $\mathcal{D}$ is hatched.

Figure 1 shows the two cases where $\partial\mathcal{D}$ is either different from $\partial\mathcal{U}$ (then $\varrho_{\partial\mathcal{D}} \neq \varrho_{\partial\mathcal{U}}$) or equal to $\partial\mathcal{U}$ (then $\varrho_{\partial\mathcal{D}} = \varrho_{\partial\mathcal{U}}$). Figure 2 highlights the fact that if A is $\mathcal{D}$-stable, and if $\partial\mathcal{U} \cap \mathcal{D}$ is empty, then $\varrho_{\partial\mathcal{U}}$ equals $r_{\mathcal{D}}$.

From the previous reasoning, the next theorem is deduced.

THEOREM 4. *Let A_c, $\mathcal{D}$, $\partial\mathcal{D}$ be, respectively, an uncertain matrix as defined in* (1)*, a clustering region as defined in subsection* 2.2*, and its boundary. Then A_c is robustly $\partial\mathcal{D}$-regular against $\mathcal{B}(\rho)$ if there exist m Hermitian matrices P_k, $k = 1, \ldots, m$, such that*

$$\mathcal{Q}_k(P_k, \gamma) < 0 \quad \forall k \in \{1, \ldots, m\}, \tag{25}$$

where

$$\mathcal{Q}_k(P_k,\gamma)=\begin{bmatrix} r_{k_{00}}P_k+(r_{k_{10}}P_kA)^H+r_{k_{11}}A'PA+C'C & r_{k_{10}}PB+r_{k_{11}}A'PB \\ r'_{k_{10}}B'P+r_{k_{11}}B'PA & r_{k_{11}}B'PB-\gamma\mathbb{I}_q \end{bmatrix}$$

and $\gamma=\rho^{-2}$.

In this event, A_c keeps the same number of eigenvalues inside $\mathcal{D}$ for any $\Delta\in\mathcal{B}(\rho)$.

Moreover, if the boundary of $\mathcal{D}$ can be identified with the union of the boundaries of all subregions (i.e., $\partial\mathcal{D}=\partial\mathcal{U}$), then condition (25) *is also necessary.*

Proof. LMI system (25) is found feasible if and only if A_c is $\partial\mathcal{D}_k$-regular for any k in $\{1,\dots,m\}$, by virtue of Theorem 3. Hence, it is equivalent to $\partial\mathcal{U}$-regularity. Another consequence of Theorem 3 is that A_c has the same root-distribution as A with respect to $\partial\mathcal{D}_k$ (and a fortiori with respect to $\partial\mathcal{D}$). This proves the first and second statements in Theorem 4. Besides, if $\partial\mathcal{U}=\partial\mathcal{D}$ as in the right part of Figure 1, then $\partial\mathcal{U}$-regularity is equivalent to $\partial\mathcal{D}$-regularity, which proves the third statement. ∎

In light of this theorem, the following statements, which can be seen as corollaries, can be formulated:

- γ can be minimized under LMI constraints (25) down to $\gamma^\star$, and then $\rho^\star=(\gamma^\star)^{-1/2}$ actually equals $\varrho_{\partial\mathcal{U}}$. It is the largest robust $\partial\mathcal{D}$-regularity bound provided by this approach. If A is $\mathcal{D}$-stable, then $\rho^\star$ is a robust $\mathcal{D}$-stability bound.
- If $\partial\mathcal{U}=\partial\mathcal{D}$, then $\rho^\star$ equals $\varrho_{\partial\mathcal{D}}$, the complex $\partial\mathcal{D}$-regularity radius.
- If A is $\mathcal{D}$-stable and if $\partial\mathcal{U}\cap\mathcal{D}=\emptyset$, then $\rho^\star$ equals both $\varrho_{\partial\mathcal{D}}$ and $r_{\mathcal{D}}$, the complex $\mathcal{D}$-stability radius.

5. Numerical illustration. In this section, we propose a simple illustration of the presented technique in order to highlight its relevance. Computations are performed on a PC Pentium 1.7 MHz with MATLAB LMI CONTROL TOOLBOX.

5.1. First example. This model is borrowed from [25]. The lateral dynamic of an aircraft is modeled by state and input matrices:

$$A_0=\begin{bmatrix} -0.3400 & 0.0517 & 0.0010 & -0.9970 & 0.0000 \\ 0.0000 & 0.0000 & 1.0000 & 0.0000 & 0.0000 \\ -2.6900 & 0.0000 & -1.1500 & 0.7380 & 0.0000 \\ 5.9100 & 0.0000 & 0.1380 & -0.5060 & 0.0000 \\ -0.3400 & 0.0517 & 0.0010 & 0.0031 & 0.0000 \end{bmatrix};$$

$$B_0=\begin{bmatrix} 0.0755 & 0.0000 & 0.0246 \\ 0.0000 & 0.0000 & 0.0000 \\ 4.4800 & 5.2200 & -0.7420 \\ -5.0300 & 0.0998 & 0.9848 \\ 0.0755 & 0.0000 & 0.0246 \end{bmatrix}.$$

A static state feedback control law associated with matrix

$$K=\begin{bmatrix} -3.9063 & -0.2869 & 0.0006 & -1.5109 & -1.8135 \\ 0.8077 & -2.4178 & -0.9356 & -0.2877 & -0.0296 \\ -21.5282 & -1.2212 & -0.0424 & -10.1518 & -11.1581 \end{bmatrix}$$

is applied to the previous model so that

$$\lambda(A=A_0+B_0K)=\{-0.5;-2\pm 2\mathbf{i};-3\pm 2\mathbf{i}\}. \tag{26}$$

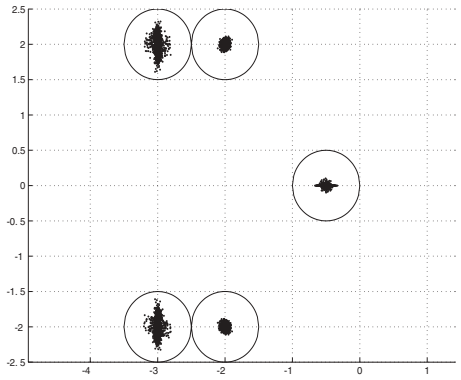

FIG. 3. *Pole migration of closed-loop aircraft model with norm-bounded complex uncertainty.*

Matrix A is assumed to be subject to an additive uncertainty, but no particular structure of this uncertainty is considered, so B and C are both assumed to equal $\mathbb{I}_5$ in (1) or, equivalently, $A_c = A + \Delta$. To analyze the robustness of the pole location in the presence of the uncertainty, $\mathcal{D}$ is chosen as the union of 5 discs $\mathcal{D}_k$, $k = 1, \ldots, 5$, centered around the nominal eigenvalues given by (26) and all of radius 0.5. In [2], a robust $\mathcal{D}$-stability bound is computed: $\rho^\star = 0.0729$. This value is improved owing to our approach. Indeed, since $\mathcal{D}_2$ and $\mathcal{D}_3$ (resp., $\mathcal{D}_4$ and $\mathcal{D}_5$) are symmetric to each other with respect to the real axis, it is only required to compute three values, namely, $\varrho_{\partial\mathcal{D}_1}$, $\varrho_{\partial\mathcal{D}_2} = \varrho_{\partial\mathcal{D}_3}$, $\varrho_{\partial\mathcal{D}_4} = \varrho_{\partial\mathcal{D}_5}$. After `2.58s` of computation time, we have

$$\rho^\star = \min_{k\in\{1,2,4\}} \varrho_{\partial\mathcal{D}_k} = \min\{0.3012; 0.1433; 0.1262\} = 0.1262 = r_{\partial\mathcal{D}}.$$

The bound of [2] is then increased by 73%. If many spectra are plotted for various values of complex Δ as in the first example, Figure 3 is obtained (to proceed, it suffices to generate many random complex matrices using standard MATLAB functions such as `rand` and to scale its entries so that its 2-norm is a random value in the range $[0; \rho^\star]$). It might seem that the bound is a bit conservative, but this example is not trivial, and since Δ is of dimension (5×5), it is hard to generate a random instance of Δ that corresponds to the worst case. However, the pole migration is not very far from $\partial\mathcal{D}$, especially from $\partial\mathcal{D}_4$ and $\partial\mathcal{D}_5$, and since A is $\mathcal{D}$-stable and since the five open subregions are disjoint (which implies that $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$), $\rho^\star$ actually equals $r_{\mathcal{D}}$. Hence, in this case, the exact value of the complex $\mathcal{D}$-stability radius is obtained, without conservatism.

Computing $\rho^\star$ leads to deriving five Lyapunov matrices P_k, $i = 1, \ldots, 5$. Each matrix P_k is such that $\mathrm{In}(P_k) = [1,\ 4,\ 0]$ since, for any $\Delta \in \mathcal{B}(\rho^\star)$, A_c has one root inside $\mathcal{D}_k$ and four roots outside $\mathcal{D}_k$.

5.2. Second example. This example is simpler but involves a clustering region that is of interest for the analysis of some plant models. It is inspired by [27] and is relevant to the short-period approximation of the F-16 dynamics (see [27] for further details). The open-loop model is

$$A_0 = \begin{bmatrix} -1.0188 & 0.0905 \\ 4.0639 & -0.7701 \end{bmatrix}; \quad B_0 = \begin{bmatrix} -0.0021 \\ -0.1692 \end{bmatrix}.$$

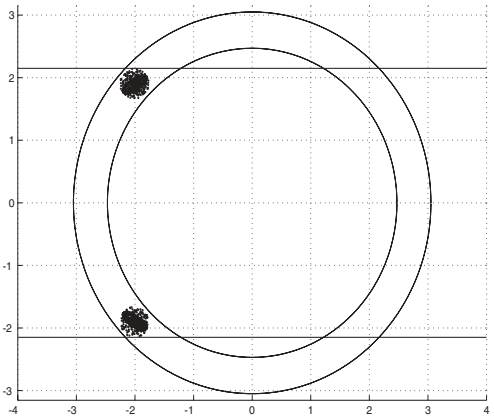

FIG. 4. *Pole migration of closed-loop model with norm-bounded complex uncertainty.*

A static state feedback control law associated with a matrix K is applied such that the spectrum of the closed-loop state matrix

$$A = A_0 + B_0 K = \begin{bmatrix} -1.1319 & 0.8790 \\ -4.9643 & -2.8683 \end{bmatrix}$$

is $\sigma(A) = \{-2 \pm 1.9\mathbf{i}\}$. We aim at analyzing the nonfragility induced by K. More precisely, assuming that K can be affected by an additive uncertainty Δ, the uncertain closed-loop state matrix A_c is given by expression (1) with $B = B_0$ and $C = \mathbb{I}_2$. The transient performances are supposed to be preserved when the spectrum of A_c remains in the clustering region $\mathcal{D}$ defined by the intersection of the OLHP, the ring centered around the origin and of interior and exterior radii 2.47 and 3.05, and the symmetric horizontal strip with a half width equaling 2.15. Such a region is the so-called good ride quality region of an aircraft [27]. The present approach can be used to compute the $\mathcal{D}$-stability radius in `1.52s`:

$$\rho^\star = \varrho_{\partial\mathcal{D}} = r_{\mathcal{D}} = 2.39.$$

Plotting the spectrum of A_c for many random instances of Δ highlights the relevance of our approach to computing this nonfragility criterion (see Figure 4).

6. Conclusion. In this paper, the concept of matrix $\partial\mathcal{D}$-regularity, i.e., absence of eigenvalues along a curve $\partial\mathcal{D}$ of the complex plane, was used to compute, through a Lyapunov approach, a robust $\mathcal{D}$-stability bound, i.e., a bound on an uncertainty affecting a matrix ensuring that the eigenvalues of the uncertain matrix remain inside a subregion $\mathcal{D}$ of the complex plane.

An original point in the paper is the wide class of allowed clustering regions since $\mathcal{D}$ can be a combination (i.e., the union and/or intersection) of several possibly nonsymmetric half planes, discs, and outsides of discs. Such an originality in the choice of the region is made possible by using Lyapunov matrices which are not necessarily positive definite but preserve their inertia over the uncertainty domain. When root-clustering in a single disc, a half plane, or the outside of a disc is to be analyzed, the Lyapunov matrix has to be strictly positive or negative definite. The computed bound proves to be not very conservative. When the boundaries of various subregions do not intersect $\mathcal{D}$, this bound turns out to be the exact complex $\mathcal{D}$-stability radius, that

is, the largest bound on a complex uncertainty preserving $\mathcal{D}$-stability, thus enabling efficient robust matrix root-location analysis. The bound is deduced from the solution of a very simple LMI problem.

As an extension of our work, a parametric structured uncertainty could therefore be very easily taken into account, especially through a polytopic description. Another challenge is the use of such an approach in a design context. More precisely, the question is to know if the inertia of various Lyapunov matrices P_k can be discerningly exploited to distribute the poles in various subregions while determining a control law.

Appendix. Two lemmas are here provided to the reader. They are exploited in the proof of Theorem 3.

LEMMA 1 (see [24]). *Given $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times m}$, and $M = M' \in \mathbb{C}^{(n+m)\times(n+m)}$, with $\det(\mathbf{i}\omega\mathbb{I} - A) \neq 0\ \forall\omega \in \mathbb{R}$ (i.e., A is $\mathfrak{I}$-regular), the following two statements are equivalent:*

(i)

$$\begin{bmatrix} (\mathbf{i}\omega\mathbb{I} - A)^{-1}B \\ \mathbb{I} \end{bmatrix}' M \begin{bmatrix} (\mathbf{i}\omega\mathbb{I} - A)^{-1}B \\ \mathbb{I} \end{bmatrix} < 0 \quad \omega \in \mathbb{R}. \tag{27}$$

(ii) *There exists a matrix $P = P' \in \mathbb{C}^{n\times n}$ such that*

$$M + \begin{bmatrix} A'P + PA & PB \\ B'P & \mathbb{O} \end{bmatrix} < 0. \tag{28}$$

The above lemma is known as the Kalman–Yakubovich–Popov lemma [30]. It is expressed here with complex matrices.

LEMMA 2 (see [24]). *Given $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times m}$, and $M = M' \in \mathbb{C}^{(n+m)\times(n+m)}$, with $\det(e^{\mathbf{i}\omega}\mathbb{I} - A) \neq 0\ \forall\omega \in \mathbb{R}$ (i.e., A is $\mathfrak{C}$-regular), the following two statements are equivalent:*

(i)

$$\begin{bmatrix} (e^{\mathbf{i}\omega}\mathbb{I} - A)^{-1}B \\ \mathbb{I} \end{bmatrix}' M \begin{bmatrix} (e^{\mathbf{i}\omega}\mathbb{I} - A)^{-1}B \\ \mathbb{I} \end{bmatrix} < 0 \quad \omega \in \mathbb{R} \cup \infty. \tag{29}$$

(ii) *There exists a matrix $P = P' \in \mathbb{C}^{n\times n}$ such that*

$$M + \begin{bmatrix} A'PA - P & PB \\ B'P & B'PB \end{bmatrix} < 0. \tag{30}$$

The above lemma is the discrete-time counterpart of the Kalman–Yakubovich–Popov lemma.

THE PONTRYAGIN MAXIMUM PRINCIPLE AND TRANSVERSALITY CONDITIONS FOR A CLASS OF OPTIMAL CONTROL PROBLEMS WITH INFINITE TIME HORIZONS*

SERGEI M. ASEEV† AND ARKADY V. KRYAZHIMSKIY†

Abstract. This paper suggests some further developments in the theory of first-order necessary optimality conditions for problems of optimal control with infinite time horizons. We describe an approximation technique involving auxiliary finite-horizon optimal control problems and use it to prove new versions of the Pontryagin maximum principle. Special attention is paid to the behavior of the adjoint variables and the Hamiltonian. Typical cases, in which standard transversality conditions hold at infinity, are described. Several significant earlier results are generalized.

Key words. optimal control, infinite horizon, Pontryagin maximum principle, transversality conditions, optimal economic growth

AMS subject classifications. 49K15, 91B62

DOI. 10.1137/S0363012903427518

1. Introduction. We deal with the following infinite-horizon optimal control problem (P):

$$\dot{x}(t) = f(x(t), u(t)), \qquad u(t) \in U; \tag{1.1}$$

$$x(0) = x_0; \tag{1.2}$$

$$\text{maximize } J(x,u) = \int_0^\infty e^{-\rho t} g(x(t), u(t))dt. \tag{1.3}$$

Here $x(t) = (x^1(t), \dots, x^n(t)) \in \mathbb{R}^n$ and $u(t) = (u^1(t), \dots, u^m(t)) \in \mathbb{R}^m$ are the current values of the system's states and controls; U is a nonempty convex compactum in $\mathbb{R}^m$; x_0 is a given initial state; and $\rho \geq 0$ is a discount parameter. The functions $f : G \times U \mapsto \mathbb{R}^n$, $g : G \times U \mapsto \mathbb{R}^1$, the matrix $\partial f/\partial x = (\partial f^i/\partial x^j)_{i,j=1,\dots,n}$, and the gradient $\partial g/\partial x = (\partial g/\partial x^1, \dots, \partial g/\partial x^n)$ are assumed to be continuous on $G \times U$. Here G is an open set in $\mathbb{R}^n$ such that $x_0 \in G$. As usual an admissible control in system (1.1) is identified with an arbitrary measurable function $u : [0, \infty) \mapsto U$. A trajectory corresponding to a control u is a Carathéodory solution x to (1.1), which satisfies the initial condition (1.2). We assume that, for any control u, a trajectory x corresponding to u exists on $[0, \infty)$ and takes values in G (due to the continuous differentiability of f, the trajectory x is unique). Any pair (u, x), where u is a control and x the trajectory corresponding to u, will be called an admissible pair.

Problems of this type naturally arise in the studies on optimization of economic growth (see [1], [2], [14], [23], [27], [33], [39]). Progress in this field of economics was initiated by Ramsey in the 1920s [35].

The first author was partially supported by the Russian Foundation for Basic Research (project 99-01-01051). The second author was partially supported by the Russian Foundation for Basic Research (project 03-01-00737).

Our basic assumptions are the following.

(A1) There exists a $C \geq 0$ such that

$$\langle x, f(x,u)\rangle \leq C(1+\|x\|^2) \quad \text{for all} \quad x \in G \quad \text{and all} \quad u \in U.$$

(A2) For each $x \in G$, the function $u \mapsto f(x,u)$ is affine, i.e.,

$$f(x,u) = f_0(x) + \sum_{i=1}^{m} f_i(x)u^i \quad \text{for all} \quad x \in G \quad \text{and all} \quad u \in U,$$

where $f_i : G \mapsto \mathbb{R}^n$, $i = 0, 1, \ldots, m$, are continuously differentiable.

(A3) For each $x \in G$, the function $u \mapsto g(x,u)$ is concave.

(A4) There exist positive-valued functions μ and ω on $[0,\infty)$ such that $\mu(t) \to 0$, $\omega(t) \to 0$ as $t \to \infty$, and for any admissible pair (u,x),

$$e^{-\rho t} \max_{u \in U} |g(x(t),u)| \leq \mu(t) \quad \text{for all} \quad t > 0;$$

$$\int_T^\infty e^{-\rho t} |g(x(t),u(t))| dt \leq \omega(T) \quad \text{for all} \quad T > 0.$$

Assumption (A1) is conventionally used in existence theorems in the theory of optimal control (see [19], [22]). Assumptions (A2) and (A3) imply that problem (P) is "linear-convex" in control; the "linear-convex" structure is important for the implementation of approximation techniques. The second condition in (A4) implies that the integral (1.3) converges absolutely for any admissible pair (u,x), which excludes any ambiguity in interpreting problem (P). As shown in [13, Theorem 3.6], assumptions (A1)–(A4) guarantee the existence of an admissible optimal pair in problem (P).

In this paper, we develop first-order necessary optimality conditions for problem (P). Note that, for infinite-horizon optimal control problems without a discounting factor ($\rho = 0$), the Pontryagin maximum principle was stated in [34]. For problems involving a positive discounting factor ($\rho > 0$), a general statement on the Pontryagin maximum principle was given in [24]. However, both statements establish the "core" relations of the Pontryagin maximum principle only and do not suggest any analogue of the transversality conditions, which constitute an immanent component of the Pontryagin maximum principle for classical finite-horizon optimal control problems with nonconstrained terminal states. The issue of transversality conditions for problem (P) is the focus of our study.

Introduce the Hamilton–Pontryagin function $\mathcal{H} : G \times [0,\infty) \times U \times \mathbb{R}^n \times \mathbb{R}^1 \mapsto \mathbb{R}^1$ and the Hamiltonian $H : G \times [0,\infty) \times \mathbb{R}^n \times \mathbb{R}^1 \mapsto \mathbb{R}^1$ for problem (P):

$$\mathcal{H}(x,t,u,\psi,\psi^0) = \langle f(x,u), \psi\rangle + \psi^0 e^{-\rho t} g(x,u);$$

$$H(x,t,\psi,\psi^0) = \sup_{u \in U} \mathcal{H}(x,t,u,\psi,\psi^0).$$

The Pontryagin maximum principle involves an admissible pair (u_*, x_*) and a pair (ψ, ψ^0) of adjoint variables associated with (u_*, x_*); here ψ is a solution to the adjoint equation

$$\dot{\psi}(t) = -\left[\frac{\partial f(x_*(t), u_*(t))}{\partial x}\right]^* \psi(t) - \psi^0 e^{-\rho t} \frac{\partial g(x_*(t), u_*(t))}{\partial x} \tag{1.4}$$

on $[0,\infty)$, and ψ^0 is a nonnegative real; (ψ,ψ^0) is said to be nontrivial if

$$\|\psi(0)\|+\psi^0>0. \tag{1.5}$$

We shall use the following definition. We shall say that an admissible pair (u_*,x_*) satisfies the core Pontryagin maximum principle (in problem (P)), together with a pair (ψ,ψ^0) of adjoint variables associated with (u_*,x_*), if (ψ,ψ^0) is nontrivial and the following maximum condition holds:

$$\mathcal{H}(x_*(t),t,u_*(t),\psi(t),\psi^0)=H(x_*(t),t,\psi(t),\psi^0)\quad\text{for a.a.}\quad t\geq 0. \tag{1.6}$$

Of special interest is the case where problem (P) is not abnormal, i.e., when the Lagrange multiplier ψ^0 in the core Pontryagin maximum principle does not vanish. In this case we do not lose generality if we set $\psi^0=1$. Accordingly, we define the normal-form Hamilton–Pontryagin function $\tilde{\mathcal{H}}:G\times[0,\infty)\times U\times\mathbb{R}^n\mapsto\mathbb{R}^1$ and the normal-form Hamiltonian $\tilde{H}:G\times[0,\infty)\times\mathbb{R}^n\mapsto\mathbb{R}^1$ as follows:

$$\tilde{\mathcal{H}}(x,t,u,\psi)=\mathcal{H}(x,t,u,\psi,1)=\langle f(x,u),\psi\rangle+e^{-\rho t}g(x,u);$$

$$\tilde{H}(x,t,\psi)=H(x,t,\psi,1)=\sup_{u\in U}\tilde{\mathcal{H}}(x,t,u,\psi).$$

Given an admissible pair (u_*,x_*), introduce the normal-form adjoint equation

$$\dot{\psi}(t)=-\left[\frac{\partial f(x_*(t),u_*(t))}{\partial x}\right]^*\psi(t)-e^{-\rho t}\frac{\partial g(x_*(t),u_*(t))}{\partial x}. \tag{1.7}$$

Any solution ψ to (1.7) on $[0,\infty)$ will be called an adjoint variable associated with (u_*,x_*). We shall say that an admissible pair (u_*,x_*) satisfies the normal-form core Pontryagin maximum principle together with an adjoint variable ψ associated with (u_*,x_*) if the following normal-form maximum condition holds:

$$\tilde{\mathcal{H}}(x_*(t),t,u_*(t),\psi(t))=\tilde{H}(x_*(t),t,\psi(t))\quad\text{for a.a.}\quad t\geq 0. \tag{1.8}$$

In the context of problem (P), [24] states the following (see also [17]).

THEOREM 1. *If an admissible pair (u_*,x_*) is optimal in problem* (P)*, then (u_*,x_*) satisfies relations* (1.4)–(1.6) *of the core Pontryagin maximum principle together with some pair (ψ,ψ^0) of adjoint variables associated with (u_*,x_*).*

Qualitatively, this formulation is weaker than the corresponding statement known for finite-horizon optimal control problems with nonconstrained terminal states. Indeed, consider the following finite-horizon counterpart of problem (P).

Problem (P_T):

$$\dot{x}(t)=f(x(t),u(t)),\qquad u(t)\in U;$$

$$x(0)=x_0;$$

$$\text{maximize } J_T(x,u)=\int_0^T e^{-\rho t}g(x(t),u(t))dt;$$

here $T>0$ is a fixed positive real. The classical theory [34] says that if an admissible pair (u_*,x_*) is optimal in problem (P_T), then (u_*,x_*) satisfies the core Pontryagin

maximum principle together with some pair (ψ, ψ^0) of adjoint variables associated with (u_*, x_*), and, moreover, (ψ, ψ^0) satisfies the transversality conditions

$$\psi^0 = 1, \qquad \psi(T) = 0. \tag{1.9}$$

In Theorem 1 any analogue of the transversality conditions (1.9) is missing.

There were numerous attempts to find specific situations in which the infinite-horizon Pontryagin maximum principle holds together with additional boundary conditions at infinity (see [12], [15], [16], [21], [26], [31], [36], [38]). However, the major results were established under rather severe assumptions of linearity or full convexity, which made it difficult to apply them to particular meaningful problems (see, e.g., [28] discussing the application of the Pontryagin maximum principle to a particular infinite-horizon optimal control problem).

In this paper we follow the approximation approach suggested in [9], [10], and [11]. We approximate problem (P) by a sequence of finite-horizon optimal control problems $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$ whose horizons go to infinity. Problems (P_k) $(k = 1, 2, \ldots)$ impose no constraints on the terminal states; in this sense, they inherit the structure of problem (P); on the other hand, problems (P_k) are not plain "restrictions" of problem (P) to finite intervals like problem (P_T): the goal functionals in problems (P_k) include special penalty terms associated with a certain control optimal in problem (P). This approach allows us to find limit forms of the classical transversality conditions for problems (P_k) as $k \to \infty$ and formulate conditions that complement the core Pontryagin maximum principle and hold with a necessity for every admissible pair optimal in problem (P). The results presented here generalize [9], [10], [11], and [12].

Earlier, a similar approximation approach was used to derive necessary optimality conditions for various nonclassical optimal control problems (see, e.g., [3], [4], [5], [7], [32], and also survey [6]). Based on relevant approximation techniques and the methodology presented here, one can extend the results of this paper to more complex infinite-horizon problems of optimal control (e.g., problems with nonsmooth data). In this paper, our primary goal is to show how the approximation approach allows us to resolve the major singularity emerging due to the unboundedness of the time horizon. Therefore, we restrict our consideration to the relatively simple nonlinear infinite-horizon problem (P), which is smooth, "linear-convex" in control, and free from any constraints on the system's states.

Finally, we note that the suggested approximation methodology, appropriately modified, can be used directly in analysis of particular nonstandard optimal control problems with infinite time horizons (see, e.g., [8]).

2. Transversality conditions: Counterexamples. Considering problem (P) as the "limit" of finite-horizon problems (P_T) whose horizons T tend to infinity, one can expect the following "natural" transversality conditions for problem (P):

$$\psi^0 = 1, \qquad \lim_{t\to\infty} \psi(t) = 0; \tag{2.1}$$

here (ψ, ψ^0) is a pair of adjoint variables satisfying the core Pontryagin maximum principle together with an admissible pair (u_*, x_*) optimal in problem (P). The relations

$$\psi^0 = 1, \qquad \lim_{t\to\infty} \langle \psi(t), x_*(t) \rangle = 0 \tag{2.2}$$

represent alternative transversality conditions for problem (P), which are frequently used in economic applications (see, e.g., [14]).

The interpretation of (2.2) as transversality conditions for problem (P) is also motivated by Arrow's statement on sufficient conditions of optimality (see [1], [2], and [36]), which (under some additional assumptions) asserts that if (2.2) holds for an admissible pair (u_*, x_*) and a pair (ψ, ψ^0) of adjoint variables, jointly satisfying the core Pontryagin maximum principle, then (u_*, x_*) is optimal in problem (P), provided the superposition $H(x, t, \psi(t), \psi^0)$ is concave in x. Another type of transversality condition formulated in terms of stability theory was proposed in [38]. In [12], global behavior of the adjoint variable associated with an optimal admissible pair was characterized in terms of appropriate integral functionals. In this paper, we concentrate on the derivation of pointwise transversality conditions of types (2.1) and (2.2).

Note that, generally, for infinite-horizon optimal control problems neither transversality condition (2.1) nor (2.2) is valid. For the case of no discounting ($\rho = 0$), illustrating counterexamples were given in [24] and [37], and for problems with discounting ($\rho > 0$), some examples were given in [12] and [31]. In particular, [31] presents an example showing that an infinite-horizon optimal control problem with a positive discount can be abnormal; i.e., in the core Pontryagin maximum principle, the Lagrange multiplier ψ^0 may necessarily vanish (which contradicts both (2.1) and (2.2)).

Here, we provide further counterexamples for problem (P) in the case where discount parameter ρ is positive.

Example 1 shows that for problem (P), the limit relation in (2.1) may be violated, whereas the alternative transversality conditions (2.2) may hold.

Example 1. Consider the optimal control problem

$$\dot{x}(t) = u(t) - x(t), \qquad u(t) \in U = [0, 1];$$

$$x(0) = \frac{1}{2};$$

$$\text{maximize } J(x, u) = \int_0^\infty e^{-t} \ln \frac{1}{x(t)} dt.$$

We set $G = (0, \infty)$ and treat the above problem as problem (P). Assumptions (A1)–(A4) are, obviously, satisfied. For an arbitrary trajectory x, we have $e^{-t}/2 \le x(t) < 1$ for all $t \ge 0$. Hence, (u_*, x_*), where $u_*(t) \overset{a.e.}{=} 0$ and $x_*(t) = e^{-t}/2$ for all $t \ge 0$, is the unique optimal admissible pair. The Hamilton–Pontryagin function is given by

$$\mathcal{H}(x, t, u, \psi, \psi^0) = (u - x)\psi - \psi^0 e^{-t} \ln x.$$

Let (ψ, ψ^0) be an arbitrary pair of adjoint variables such that (u_*, x_*) satisfies the core Pontryagin maximum principle together with (ψ, ψ^0). The adjoint equation (1.4) has the form

$$\dot{\psi}(t) = \psi(t) + \psi^0 e^{-t} \frac{1}{x_*(t)} = \psi + 2\psi^0,$$

and the maximum condition (1.6) implies

$$\psi(t) \le 0 \quad \text{for all} \quad t \ge 0. \tag{2.3}$$

Assume $\psi^0 = 0$. Then $\psi(0) < 0$ and $\psi(t) = e^t \psi(0) \to -\infty$ as $t \to \infty$; i.e., the limit relation in (2.1) does not hold. Let $\psi^0 > 0$. Without loss of generality (or multiplying

both ψ and ψ^0 by $1/\psi^0$), we assume $\psi^0 = 1$. Then $\psi(t) = (\psi(0) + 2)e^t - 2$. By (2.3), only two cases are admissible: (a) $\psi(0) = -2$ and (b) $\psi(0) < -2$. In case (a) $\psi(t) \equiv -2$, and in case (b) $\psi(t) \to -\infty$ as $t \to \infty$. In both situations the limit relation in (2.1) is violated. Note that $\psi(t) \equiv -2$ ($t \geq 0$) and $\psi^0 = 1$ satisfy (2.2).

The next example is complementary to Example 1; it shows that for problem (P), the limit relation in (2.2) may be violated, whereas (2.1) may hold.

Example 2. Consider the following optimal control problem:

$$\dot{x}(t) = u(t), \qquad u(t) \in U = \left[\frac{1}{2}, 1\right]; \tag{2.4}$$

$$x(0) = 0;$$

$$\text{maximize } J(x,u) = \int_0^\infty e^{-t}(1 + \gamma(x(t)))u(t)dt. \tag{2.5}$$

Here γ is a nonnegative continuously differentiable real function such that

$$I = \int_0^\infty e^{-t}\gamma(t)dt < \infty. \tag{2.6}$$

We set $G = \mathbb{R}^1$. Clearly, assumptions (A1)–(A3) are satisfied. Below, we specify the form of γ and show that assumption (A4) is satisfied too.

The admissible pair (u_*, x_*), where $u_*(t) \overset{a.e.}{=} 1$ and $x_*(t) = t$ for all $t \geq 0$, is optimal. Indeed, let (u, x) be an arbitrary admissible pair. Observing (2.4), we find that $\dot{x}(t) > 0$ for a.a. $t \geq 0$. Taking $\tau(t) = x(t)$ for a new integration variable in (2.5), we get $d\tau = u(t)dt$ and

$$t(\tau) = \int_0^\tau \frac{1}{u(t(s))}ds \quad \text{for all} \quad \tau \geq 0.$$

As far as

$$\int_0^\tau \frac{1}{u(t(s))}ds \geq \tau,$$

we get

$$J(x,u) = \int_0^\infty e^{-t}(1 + \gamma(x(t)))u(t)dt = \int_0^\infty e^{-\int_0^\tau \frac{1}{u(t(s))}ds}(1 + \gamma(\tau))d\tau$$

$$\leq \int_0^\infty e^{-\tau}(1 + \gamma(\tau))d\tau = J(u_*, x_*).$$

Hence, (u_*, x_*) is an optimal admissible pair. It is easy to see that there are no other optimal admissible pairs. The Hamilton–Pontryagin function has the form

$$\mathcal{H}(x,t,u,\psi,\psi^0) = u\psi + \psi^0 e^{-t}(1 + \gamma(x))u.$$

Let (ψ, ψ^0) be an arbitrary pair of adjoint variables such that (u_*, x_*) satisfies the core Pontryagin maximum principle together with (ψ, ψ^0). The adjoint equation (1.4) has the form

$$\dot{\psi}(t) = -\psi^0 \dot{\gamma}(t)e^{-t}.$$

If $\psi^0 = 0$, then the maximum condition (1.6) implies $\psi(t) \equiv \psi(0) > 0$; hence, $\psi(t)x_*(t) = \psi(0)t \to \infty$ as $t \to \infty$, and the limit relation in (2.2) is violated.

Suppose $\psi^0 > 0$, or, equivalently, $\psi^0 = 1$. Then, due to (1.4), we have

$$\psi(t) = \psi(0) - \int_0^t \dot{\gamma}(s)e^{-s}ds.$$

The limit relation in (2.2) has the form $\lim_{t\to\infty} t\psi(t) = 0$. Let us show that one can define γ so that the latter relation is violated; i.e., for any $\psi(0) \in \mathbb{R}^1$,

$$p(t) \not\to 0 \quad \text{as} \quad t \to \infty, \tag{2.7}$$

where $p(t) = t\psi(t)$. We represent $p(t)$ as follows:

$$\begin{aligned} p(t) &= t\psi(0) - t\int_0^t \dot{\gamma}(s)e^{-s}ds = t\psi(0) - t\left[\gamma(s)e^{-s}|_0^t + \int_0^t \gamma(s)e^{-s}ds\right] \\ &= t\psi(0) - t\gamma(t)e^{-t} + t\gamma(0) - tI(t), \end{aligned}$$

where

$$I(t) = \int_0^t \gamma(s)e^{-s}ds.$$

Introducing $\nu(t) = \gamma(t)e^{-t}$, rewrite

$$I(t) = \int_0^t \nu(s)ds; \tag{2.8}$$

$$p(t) = t\psi(0) - t\nu(t) + t\nu(0) - tI(t). \tag{2.9}$$

Due to (2.6),

$$\lim_{t\to\infty} I(t) = I. \tag{2.10}$$

Now let us specify the form of ν. For each natural k, we fix a positive $\varepsilon_k < 1/2$ and denote by Δ_k the ε_k-neighborhood of k. Clearly, $\Delta_k \cup \Delta_j = \emptyset$ for $k \neq j$. We set

$$\nu(k) = \frac{1}{k} \quad \text{for} \quad k = 1, 2, \ldots;$$

$$\nu(t) = 0 \quad \text{for} \quad t \notin \cup_{k=1}^{\infty} \Delta_k;$$

$$\nu(t) \in \left[0, \frac{1}{k}\right] \quad \text{for} \quad t \in \Delta_k \quad (k = 1, 2, \ldots).$$

Moreover, we require that

$$\sum_{k=j}^{\infty} \int_{\Delta_k} \nu(t)dt \le \frac{1}{j^2}. \tag{2.11}$$

This can be achieved, for example, by letting $\frac{2\varepsilon_k}{k} \le \frac{a_k}{k^2}$, where $\sum_{k=1}^{\infty} a_k = 1$, $a_k > 0$. Indeed, in this case

$$\sum_{k=j}^{\infty} \int_{\Delta_k} \nu(t)dt \le \sum_{k=j}^{\infty} \frac{2\varepsilon_k}{k} \le \sum_{k=j}^{\infty} \frac{a_k}{k^2} \le \frac{1}{j^2} \sum_{k=j}^{\infty} a_k \le \frac{1}{j^2};$$

i.e., (2.11) holds. Note that, for $j = 1$, the left-hand side in (2.11) equals I (see (2.6)); thus, (2.11) implies that assumption (2.6) holds.

Another fact following from (2.11) is that

$$\lim_{t\to\infty} t(I - I(t)) = 0. \tag{2.12}$$

Indeed, by (2.8), $I(j+\varepsilon_j) = \sum_{k=1}^{j} \int_{\Delta_k} \nu(t)dt$; hence, due to (2.11),

$$I - I(j+\varepsilon_j) = \sum_{k=j+1}^{\infty} \int_{\Delta_k} \nu(t)dt \le \frac{1}{(j+1)^2}.$$

For $t \in [j+\varepsilon_j,\, j+1+\varepsilon_{j+1}]$, we have $I(j+\varepsilon_j) \le I(t) \le I$; therefore, for $t \ge 1$,

$$0 \le I - I(t) \le \frac{1}{(j+1)^2} \le \frac{1}{(t-\varepsilon_{j+1})^2} \le \frac{1}{(t-1/2)^2},$$

which yields (2.12). The given definition of ν is equivalent to defining γ by

$$\begin{gathered} \gamma(k) = \frac{e^k}{k} \quad \text{for} \quad k = 1, 2, \ldots; \\ \gamma(t) = 0 \quad \text{for} \quad t \notin \cup_{k=1}^{\infty} \Delta_k; \\ \gamma(t) \in \left[0, \frac{e^k}{k}\right] \quad \text{for} \quad t \in \Delta_k \quad (k = 1, 2, \ldots) \end{gathered} \tag{2.13}$$

and requiring (2.11). Let us show that assumption (A4) is satisfied. Let (u, x) be an arbitrary admissible pair. By (2.4), $t/2 \le x(t) \le t$ for all $t \ge 0$. Hence, by the definition of ν, we have $\nu(x(t)) \le \left(\frac{t}{2} - 1\right)^{-1} = \frac{2}{(t-2)}$ for all $t > 2$. Hence,

$$0 \le e^{-\rho t} \max_{u\in U}[(1 + \gamma(x(t))u] \le \mu(t) = e^{-\rho t} + \frac{2}{(t-2)} \to 0 \quad \text{as} \quad t \to \infty.$$

Thus, the first condition in (A4) holds. Furthermore, introducing the integration variable $\tau(t) = x(t)$, we get

$$\begin{aligned} \int_T^{\infty} e^{-t}(1 + \gamma(x(t)))u(t)dt &= \int_{x(T)}^{\infty} e^{-\int_0^{\tau} \frac{1}{u(t(s))}ds}(1 + \gamma(\tau))d\tau \\ &\le \int_{x(T)}^{\infty} e^{-\tau}(1 + \gamma(\tau))d\tau \le \omega(T) \\ &= \int_{\frac{T}{2}}^{\infty} e^{-t}(1 + \gamma(t))dt \to 0 \quad \text{as} \quad T \to \infty. \end{aligned}$$

Hence, the second condition in (A4) holds. We stated the validity of assumption (A4).

By the definition of γ, for $t \in \Delta_k$, $k = 1, 2, \ldots$, we have

$$0 \le t\nu(t) \le \frac{k + \varepsilon_k}{k} \le 1 + \frac{1}{k}.$$

Hence,

$$0 \le t\nu(t) \le 2 \quad \text{for all} \quad t \ge 0; \tag{2.14}$$

i.e., the function $t\nu(t)$ is bounded. Furthermore, $k\nu(k) = 1$, and due to (2.13) for any sequence $t_k \to \infty$ such that $t_k \in [k, k+1] \setminus (\Delta_k \cup \Delta_{k+1})$, we have $t_k\nu(t_k) = 0$. Therefore, $\lim_{t\to\infty} t\nu(t)$ does not exist.

Using $\nu(0) = 0$, we specify (2.9) as

$$p(t) = t\psi(0) - t\nu(t) - tI(t). \tag{2.15}$$

If $\psi(0) > I$, then, in view of (2.10), $\lim_{t\to\infty} t(\psi(0) + I(t)) = \infty$, which implies $\lim_{t\to\infty} p(t) = \infty$, since $t\nu(t)$ is bounded. Similarly, we find that if $\psi(0) < I$, then $\lim_{t\to\infty} p(t) = -\infty$. Let, finally, $\psi(0) = I$. Then,

$$\lim_{t\to\infty} t(\psi(0) - I(t)) = \lim_{t\to\infty} t(I - I(t)) = 0,$$

as follows from (2.12). Thus, in the right-hand side of (2.15) the sum of the first and third terms has the zero limit at infinity, whereas the second term, $t\nu(t)$, has no limit at infinity, as we noted earlier. Consequently, $p(t)$, the left-hand side in (2.15), has no limit at infinity. We showed that (2.7) holds for every $\psi(0) \in \mathbb{R}^1$.

Thus, the limit relation in the transversality conditions (2.2) is violated. Note that setting $\psi^0 = 1$ and $\psi(0) = I$, we make the adjoint variable ψ satisfy the transversality conditions (2.1). Indeed, in this case $\psi(t) = p(t)/t = \psi(0) - I - \nu(t)$ for all $t > 0$, and the conditions $\psi(0) = I$ and (2.14) imply that $\psi(t) \to 0$ as $t \to \infty$.

Examples 1 and 2 show that assumptions (A1)–(A4) are insufficient for the validity of the core Pontryagin maximum principle together with the transversality conditions (2.1) or (2.2) as necessary conditions of optimality in problem (P). Below, we find mild additional assumptions that guarantee that necessary conditions of optimality in problem (P) include the core Pontryagin maximum principle and transversality conditions of type (2.1) or of type (2.2).

3. Basic constructions. In this section, we define a sequence of finite-horizon optimal control problems $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$ with horizons $T_k \to \infty$; we treat problems (P_k) as approximations to the infinite-horizon problem (P).

Let us describe the data defining problems (P_k) $(k = 1, 2, \ldots)$. Given a control u_* optimal in problem (P), we fix a sequence of continuously differentiable functions $z_k : [0, \infty) \to \mathbb{R}^m$ $(k = 1, 2, \ldots)$ and a sequence of positive σ_k $(k = 1, 2, \ldots)$ such that

$$\sup_{t\in[0,\infty)} \|z_k(t)\| \le \max_{u\in U} \|u\| + 1; \tag{3.1}$$

$$\int_0^\infty e^{-(\rho+1)t} \|z_k(t) - u_*(t)\|^2 dt \le \frac{1}{k}; \tag{3.2}$$

$$\sup_{t\in[0,\infty)} \|\dot z_k(t)\| \le \sigma_k < \infty; \tag{3.3}$$

$$\sigma_k \to \infty \quad \text{as} \quad k \to \infty$$

(obviously, such sequences exist). Next, we take a monotonically increasing sequence of positive T_k such that $T_k \to \infty$ as $k \to \infty$ and

$$\omega(T_k) \le \frac{1}{k(1 + \sigma_k)} \quad \text{for all} \quad k = 1, 2, \ldots; \tag{3.4}$$

recall that ω is defined in (A4). For every $k = 1, 2, \ldots$, we define problem (P_k) as follows.

Problem (P_k):

$$\dot{x}(t) = f(x(t), u(t)), \qquad u(t) \in U;$$

$$x(0) = x_0;$$

$$\text{maximize } J_k(x,u) = \int_0^{T_k} e^{-\rho t} g(x(t),u(t))dt - \frac{1}{1+\sigma_k}\int_0^{T_k} e^{-(\rho+1)t}\|u(t)-z_k(t)\|^2 dt.$$

By Theorem 9.3.i of [19], for every $k = 1, 2, \ldots$ there exists an admissible pair (u_k, x_k) optimal in problem (P_k).

The above-defined sequence of problems, $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$, will be said to be associated with the control u_*.

We are ready to formulate our basic approximation lemma.

LEMMA 1. *Let assumptions* (A1)–(A4) *be satisfied; let u_* be a control optimal in problem* (P)*; let $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$ be the sequence of problems associated with u_*; and for every $k = 1, 2, \ldots$, let u_k be a control optimal in problem (P_k). Then, for every $T > 0$, it holds that $u_k \to u_*$ in $L^2([0,T], \mathbb{R}^m)$ as $k \to \infty$.*

Proof. Take a $T > 0$. Let k_1 be such that $T_{k_1} \geq T$. For every $k \geq k_1$, we have

$$J_k(x_k,u_k) = \int_0^{T_k} e^{-\rho t}\left[g(x_k(t),u_k(t)) - e^{-t}\frac{\|u_k(t)-z_k(t)\|^2}{1+\sigma_k}\right]dt$$

$$\leq \int_0^{T_k} e^{-\rho t} g(x_k(t),u_k(t))dt - \frac{e^{-(\rho+1)T}}{1+\sigma_k}\int_0^{T}\|u_k(t)-z_k(t)\|^2 dt,$$

where x_k is the trajectory corresponding to u_k. Hence, introducing the trajectory x_* corresponding to u_* and taking into account the optimality of u_k in problem (P_k), optimality of u_* in problem (P), assumption (A4), and conditions (3.2) and (3.4), we find that, for all sufficiently large k,

$$\frac{e^{-(\rho+1)T}}{1+\sigma_k}\int_0^{T}\|u_k(t)-z_k(t)\|^2 dt \leq \int_0^{T_k} e^{-\rho t} g(x_k(t),u_k(t))dt - J_k(x_*,u_*)$$

$$\leq \int_0^{T_k} e^{-\rho t} g(x_k(t),u_k(t))dt - J(x_*,u_*)$$

$$+ \omega(T_k) + \int_0^{\infty}\frac{e^{-(\rho+1)t}}{1+\sigma_k}\|u_*(t)-z_k(t)\|^2 dt$$

$$\leq \int_0^{T_k} e^{-\rho t} g(x_k(t),u_k(t))dt - J(x_*,u_*) + \frac{2}{k(1+\sigma_k)}$$

$$\leq J(x_k,u_k) - J(x_*,u_*) + \frac{3}{k(1+\sigma_k)} \leq \frac{3}{k(1+\sigma_k)}.$$

Hence,

$$\|u_k - z_k\|_{L^2}^2 \leq \frac{3e^{(\rho+1)T}}{k}.$$

Then, in view of (3.2),

$$\|u_k - u_*\|_{L^2} \le \left(\int_0^T \|u_*(t) - z_k(t)\|^2 dt\right)^{1/2} + \left(\int_0^T \|u_k(t) - z_k(t)\|^2 dt\right)^{1/2}$$

$$\le \left(\frac{e^{(\rho+1)T}}{k}\right)^{1/2} + \left(\frac{3e^{(\rho+1)T}}{k}\right)^{1/2} = (1+\sqrt{3})\left(\frac{e^{(\rho+1)T}}{k}\right)^{1/2}.$$

Therefore, for any $\epsilon > 0$, there exists a $k_2 \ge k_1$ such that $\|u_k - u_*\|_{L^2} \le \epsilon$ for all $k \ge k_2$. □

Now, based on Lemma 1, we derive a limit form of the classical Pontryagin maximum principle for problems $(\mathrm{P}_k)\,(k = 1, 2, \ldots)$, which leads us to the core Pontryagin maximum principle for problem (P).

We use the following formulation of the Pontryagin maximum principle [34] for problems $(\mathrm{P}_k)\,(k = 1, 2, \ldots)$. Let an admissible pair (u_k, x_k) be optimal in problem (P_k) for some k. Then there exists a pair (ψ_k, ψ_k^0) of adjoint variables associated with (u_k, x_k) such that (u_k, x_k) satisfies relations (1.4)–(1.6) of the core Pontryagin maximum principle (in problem (P_k)) together with (ψ_k, ψ_k^0) and, moreover, $\psi_k^0 > 0$ and the transversality condition

$$\psi_k(T_k) = 0 \tag{3.5}$$

holds; recall that ψ_k is a solution on $[0, T_k]$ to the adjoint equation associated with (u_k, x_k) in problem (P_k), i.e.,

$$\dot{\psi}_k(t) \overset{a.e.}{=} -\left[\frac{\partial f(x_k(t), u_k(t))}{\partial x}\right]^* \psi_k(t) - \psi^0 e^{-\rho t} \frac{\partial g(x_k(t), u_k(t))}{\partial x}, \tag{3.6}$$

and the core Pontryagin maximum principle satisfied by (u_k, x_k), together with (ψ_k, ψ_k^0), implies that the following maximum condition holds:

$$\mathcal{H}_k(x_k(t), t, u_k(t), \psi_k(t), \psi_k^0) \overset{a.e.}{=} H_k(x_k(t), t, \psi_k(t), \psi_k^0); \tag{3.7}$$

here $\mathcal{H}_k$ and H_k, given by

$$\mathcal{H}_k(x, t, u, \psi, \psi^0) = \langle f(x, u), \psi\rangle + \psi^0 e^{-\rho t} g(x, u) - \psi^0 e^{-(\rho+1)t} \frac{\|u - z_k(t)\|^2}{1 + \sigma_k}; \tag{3.8}$$

$$H_k(x, t, \psi, \psi^0) = \sup_{u \in U} \mathcal{H}_k(x, t, u, \psi, \psi^0),$$

are, respectively, the Hamilton–Pontryagin function and the Hamiltonian in problem (P_k); note that in [34] it is shown that (3.6) and (3.7) imply

$$\frac{d}{dt} H_k(x_k(t), t, \psi_k(t), \psi_k^0) \overset{a.e.}{=} \frac{\partial \mathcal{H}_k}{\partial t}(x_k(t), t, u_k(t), \psi_k(t), \psi_k^0). \tag{3.9}$$

Lemma 2. *Let assumptions* (A1)–(A4) *be satisfied; let* (u_*, x_*) *be an admissible pair optimal in problem* (P)*; let* $\{(\mathrm{P}_k)\}\,(k = 1, 2, \ldots)$ *be the sequence of problems associated with* u_**; for every* $k = 1, 2, \ldots$, *let* (u_k, x_k) *be an admissible pair optimal in problem* (P_k)*; for every* $k = 1, 2, \ldots$, *let* (ψ_k, ψ_k^0) *be a pair of adjoint variables associated with* (u_k, x_k) *in problem* (P_k) *such that* (u_k, x_k) *satisfies relations* (3.6)

and (3.7) *of the core Pontryagin maximum principle in problem* (P_k) *together with* (ψ_k, ψ_k^0)*; and for every* $k = 1, 2, \ldots$*, one has* $\psi_k^0 > 0$*, and the transversality condition* (3.5) *holds. Finally, let the sequences* $\{\psi_k(0)\}$ *and* $\{\psi_k^0\}$ *be bounded and*

$$\|\psi_k(0)\| + \psi_k^0 \geq a \quad (k = 1, 2, \ldots) \tag{3.10}$$

for some $a > 0$*. Then there exists a subsequence of* $\{(u_k, x_k, \psi_k, \psi_k^0)\}$*, denoted again as* $\{(u_k, x_k, \psi_k, \psi_k^0)\}$*, such that*

(ii)

$$\psi_k^0 \to \psi^0 \quad \textit{as} \quad k \to \infty \tag{3.13}$$

and for every $T > 0$*,*

$$\psi_k \to \psi \quad \textit{uniformly on} \quad [0, T] \quad \textit{as} \quad k \to \infty, \tag{3.14}$$

where (ψ, ψ^0) *is a nontrivial pair of adjoint variables associated with* (u_*, x_*)*;*

(iii) (u_*, x_*) *satisfies relations* (1.4)–(1.6) *of the core Pontryagin maximum principle in problem* (P) *together with* (ψ, ψ^0)*;*

(iv) *the stationarity condition holds:*

$$H(x_*(t), t, \psi(t), \psi^0) = \psi^0 \rho \int_t^\infty e^{-\rho s} g(x_*(s), u_*(s)) ds \quad \textit{for all} \quad t \geq 0. \tag{3.15}$$

Proof. Lemma 1 and the Ascoli theorem (see, e.g., [19]) imply that, selecting a subsequence if needed, we get (3.11) and (3.12) for every $T > 0$. By assumption, the sequence $\{\psi_k^0\}$ is bounded; therefore, selecting a subsequence if needed, we obtain (3.13) for some $\psi^0 \geq 0$.

Now, our goal is to select a subsequence of $\{(u_k, x_k, \psi_k)\}$ such that for every $T > 0$, (3.14) holds and (ψ, ψ^0) is a nontrivial pair of adjoint variables associated with (u_*, x_*) (we do not change notation after the selection of a subsequence).

Consider the sequence $\{\psi_k\}$ restricted to $[0, T_1]$. Observing (3.6), taking into account the boundedness of the sequence $\{\psi_k(0)\}$ (see the assumptions of this lemma), using the Gronwall lemma (see, e.g., [25]), and selecting if needed a subsequence denoted further as $\{\psi_k^1\}$, we get that $\psi_k^1 \to \psi^1$ uniformly on $[0, T_1]$ and $\dot{\psi}_k^1 \to \dot{\psi}^1$ weakly in $L^1[0, T_1]$ as $k \to \infty$ for some absolutely continuous $\psi^1 : [0, T_1] \to \mathbb{R}^n$; here and in what follows $L^1[0, T] = L^1([0, T], \mathbb{R}^n)$ $(T > 0)$.

Now consider the sequence $\{\psi_k^1\}$ restricted to $[0, T_2]$. Taking if necessary a subsequence $\{\psi_k^2\}$ of $\{\psi_k^1\}$, we get that $\psi_k^2 \to \psi^2$ uniformly on $[0, T_2]$ and $\dot{\psi}_k^2 \to \dot{\psi}^2$ weakly in $L^1[0, T_2]$ as $k \to \infty$ for some absolutely continuous $\psi^2 : [0, T_2] \to \mathbb{R}^n$ whose restriction to $[0, T_1]$ coincides with ψ^1.

Repeating this procedure sequentially for $[0, T_i]$ with $i = 3, 4, \ldots$, we find that there exist absolutely continuous $\psi^i : [0, T_i] \to \mathbb{R}^n$ $(i = 1, 2, \ldots)$ and $\psi_k^i : [0, T_i] \to \mathbb{R}^n$ $(i, k = 1, 2, \ldots)$ such that for every $i = 1, 2, \ldots$, the restriction of ψ^{i+1} to $[0, T_i]$ is ψ^i, the restriction of the sequence $\{\psi_k^{i+1}\}$ to $[0, T_i]$ is a subsequence of $\{\psi_k^i\}$, and, moreover, $\psi_k^i \to \psi$ uniformly on $[0, T_i]$ and $\dot{\psi}_k^i \to \dot{\psi}^i$ weakly in $L^1[0, T_i]$ as $k \to \infty$.

Define $\psi : [0,\infty) \mapsto \mathbb{R}^n$ so that the restriction of ψ to $[0,T_i]$ is ψ^i for every $i = 1,2,\ldots$. Clearly, ψ is absolutely continuous. Furthermore, without changing notation, for every $i = 1,2,\ldots$ and every $k = 1,2,\ldots$, we extend ψ_k^i to $[0,\infty)$ so that the extended function is absolutely continuous and, moreover, the family $\dot{\psi}_k^i$ $(i,k = 1,2,\ldots)$ is bounded in $L^1[0,T]$ for every $T > 0$. Since $T_i \to \infty$ as $i \to \infty$, for every $T > 0$, we get that ψ_k^k converges to ψ uniformly on $[0,T]$ and $\dot{\psi}_k^k \to \dot{\psi}$ weakly in $L^1[0,T]$ as $k \to \infty$. Simplifying notation, we again write ψ_k instead of ψ_k^k and note that for ψ_k, (3.6) holds $(k = 1,2,\ldots)$. Thus, for every $T > 0$, we have (3.14) and also get that $\dot{\psi}_k \to \dot{\psi}$ weakly in $L^1[0,T]$ as $k \to \infty$. These convergences together with equalities (3.6) and convergences (3.11) and (3.12) (holding for every $T > 0$) yield that ψ solves the adjoint equation (1.4). Thus, (ψ,ψ^0) is a pair of adjoint variables associated with (u_*,x_*) in problem (P). The nontriviality of (ψ,ψ^0) (see (1.5)) is ensured by (3.10).

For every $k = 1,2,\ldots$, consider the maximum condition (3.7) and specify it as

$$\langle f(x_k(t),u_k(t)),\psi_k(t)\rangle + \psi_k^0 e^{-\rho t} g(x_k(t),u_k(t)) - \psi_k^0 e^{-(\rho+1)t}\frac{\|u_k(t)-z_k(t)\|^2}{1+\sigma_k}$$

$$\overset{a.e.}{=} \max_{u\in U}\left[\langle f(x_k(t),u),\psi_k(t)\rangle + \psi_k^0 e^{-\rho t} g(x_k(t),u) - \psi_k^0 e^{-(\rho+1)t}\frac{\|u-z_k(t)\|^2}{1+\sigma_k}\right].$$

Taking into account that $T_k \to \infty$ and $\sigma_k \to \infty$ as $k \to \infty$ and using convergences (3.13), (3.14), (3.11), and (3.12) (holding for every $T > 0$), we obtain the maximum condition (1.6) as the limit of (3.7). Thus, (u_*,x_*) satisfies the core Pontryagin maximum principle together with the pair (ψ,ψ^0) of adjoint variables associated with (u_*,x_*).

Now we specify (3.9) using the form of $\mathcal{H}_k$ (see (3.9)). We get

$$\frac{d}{dt}H_k(x_k(t),t,\psi_k(t),\psi_k^0) \overset{a.e.}{=} \frac{\partial \mathcal{H}_k}{\partial t}(x_k(t),t,u_k(t),\psi_k(t),\psi_k^0)$$

$$\overset{a.e.}{=} -\psi_k^0\rho e^{-\rho t}\left[g(x_k(t),u_k(t)) + (\rho+1)e^{-(\rho+1)t}\frac{\|u_k(t)-z_k(t)\|^2}{1+\sigma_k}\right]$$

$$+ 2\psi_k^0 e^{-(\rho+1)t}\frac{\langle u_k(t)-z_k(t),\dot{z}_k(t)\rangle}{1+\sigma_k}.$$

Take an arbitrary $t > 0$ and an arbitrary k such that $T_k > t$ and integrate the last equality over $[t,T_k]$ taking into account the boundary condition (3.5). We arrive at

$$H_k(x_k(t),t,\psi_k(t),\psi_k^0) = \psi_k^0 e^{-\rho T_k}\max_{u\in U}\left[g(x_k(T_k),u) - e^{-\rho T_k}\frac{\|u-z_k(T_k)\|^2}{1+\sigma_k}\right]$$

$$- \psi_k^0\rho\int_t^{T_k} e^{-\rho s} g(x_k(s),u_k(s))ds$$

$$+ \psi_k^0(\rho+1)\int_t^{T_k} e^{-(\rho+1)s}\frac{\|u_k(s)-z_k(s)\|^2}{1+\sigma_k}ds$$

$$+ 2\psi_k^0\int_t^{T_k} e^{-(\rho+1)s}\frac{\langle u_k(s)-z_k(s),\dot{z}_k(s)\rangle}{1+\sigma_k}ds.$$

Now, we take the limit using convergences (3.13), (3.14), (3.11), and (3.12) (holding for every $T > 0$) and also estimates (3.1)–(3.3). We end up with (3.15). □

Corollary 1 below specifies Lemma 2 for the case where the Pontryagin maximum principle for problems $(\mathrm{P}_k)\,(k = 1, 2, \ldots)$ is taken in the normal form. We use the following formulation of the normal-form Pontryagin maximum principle for problems $(\mathrm{P}_k)\,(k = 1, 2, \ldots)$. Let an admissible pair (u_k, x_k) be optimal in problem (P_k) for some k. Then there exists an adjoint variable ψ_k associated with (u_k, x_k) such that (u_k, x_k) satisfies the normal-form core Pontryagin maximum principle (in problem (P_k)) together with ψ_k, and the transversality condition (3.5) holds; here ψ_k is a solution on $[0, T_k]$ of the normal-form adjoint equation associated with (u_k, x_k) in problem (P_k), i.e.,

$$\dot{\psi}_k(t) \overset{a.e.}{=} -\left[\frac{\partial f(x_k(t), u_k(t))}{\partial x}\right]^* \psi_k(t) - e^{-\rho t}\frac{\partial g(x_k(t), u_k(t))}{\partial x}, \tag{3.16}$$

and the fact that (u_k, x_k) satisfies the normal-form core Pontryagin maximum principle, together with ψ_k, implies that the following maximum condition holds:

$$\tilde{\mathcal{H}}_k(x_k(t), t, u_k(t), \psi(t)) = \tilde{H}_k(x_k(t), t, \psi_k(t)) \quad \text{for a.a.} \quad t \in [0, T_k]; \tag{3.17}$$

here $\tilde{\mathcal{H}}_k$ and $\tilde{H}_k$, given by

$$\tilde{\mathcal{H}}_k(x, t, u, \psi) = \langle f(x, u), \psi\rangle + e^{-\rho t} g(x, u) - e^{-(\rho+1)t}\frac{\|u - z_k(t)\|^2}{1 + \sigma_k};$$

$$\tilde{H}_k(x, t, \psi) = \sup_{u \in \tilde{U}} \tilde{\mathcal{H}}_k(x, t, \tilde{u}, \psi),$$

are, respectively, the normal-form Hamilton–Pontryagin function and normal-form Hamiltonian in problem (P_k).

Corollary 1. *Let assumptions* (A1)–(A4) *be satisfied; let* (u_*, x_*) *be an admissible pair optimal in problem* (P)*; let* $\{(P_k)\}\,(k = 1, 2, \ldots)$ *be the sequence of problems associated with* u_**; for every* $k = 1, 2, \ldots$*, let* (u_k, x_k) *be an admissible pair optimal in problem* (P_k)*; and for every* $k = 1, 2, \ldots$*, let* ψ_k *be an adjoint variable associated with* (u_k, x_k) *in problem* (P_k) *such that* (u_k, x_k) *satisfies relations* (3.16) *and* (3.17) *of the normal-form core Pontryagin maximum principle in problem* (P_k) *together with* ψ_k*, and the transversality condition* (3.5) *holds. (ii) (u_*, x_*) *and* (ψ, ψ^0) *satisfy the stationarity condition* (3.15)*.*

Proof. Let $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$ be the sequence of problems associated with u_*, and for every $k = 1, 2, \ldots$, let (u_k, x_k) be an admissible pair optimal in problem (P_k). In accordance with the classical formulation of the Pontryagin maximum principle, for every $k = 1, 2, \ldots$, there exists a pair (ψ_k, ψ_k^0) of adjoint variables associated with (u_k, x_k) in problem (P_k) such that (u_k, x_k) satisfies the core Pontryagin maximum principle together with (ψ_k, ψ_k^0) and for every $k = 1, 2, \ldots$, $\psi_k^0 > 0$, and the transversality condition (3.5) holds.

Since $\psi_k^0 > 0$, the value $c_k = \|\psi_k(0)\| + \psi_k^0$ is positive. We keep the notation ψ_k and ψ_k^0 for the normalized elements ψ_k/c_k and ψ_k^0/c_k, thus achieving $\|\psi_k(0)\| + \psi_k^0 = 1$ and, clearly, preserving the transversality condition (3.5) and the fact that (u_k, x_k) satisfies the core Pontryagin maximum principle (in problem (P_k)) together with (ψ_k, ψ_k^0) $(k = 1, 2, \ldots)$. Now, the sequences $\{\psi_k(0)\}$ and $\{\psi_k^0\}$ are bounded and (3.10) holds with $a = 1$. Thus, the sequence $\{(u_k, x_k, \psi_k, \psi_k^0)\}$ satisfies all the assumptions of Lemma 2. By Lemma 2 there exists a subsequence of $\{(u_k, x_k, \psi_k, \psi_k^0)\}$, denoted again as $\{(u_k, x_k, \psi_k, \psi_k^0)\}$, such that for the pairs (ψ_k, ψ_k^0) of adjoint variables, convergences (3.13) and (3.14) hold with an arbitrary $T > 0$; the limit element (ψ, ψ^0) is a nontrivial pair of adjoint variables associated with (u_*, x_*) in problem (P); (u_*, x_*) satisfies the core Pontryagin maximum principle in problem (P) together with (ψ, ψ^0); and, finally, (u_*, x_*) and (ψ, ψ^0) satisfy the stationarity condition (3.15). □

It is easy to see that in the framework of problem (P) the necessary optimality conditions given by Corollary 2 are equivalent to those stated in [31]. Indeed, relation (3.15) implies the asymptotic stationarity condition introduced in [31]:

$$\lim_{t \to \infty} H(x_*(t), t, \psi(t), \psi^0) = 0; \tag{3.19}$$

on the other hand, if in problem (P), (u_*, x_*) satisfies the core Pontryagin maximum principle together with (ψ, ψ^0), then (3.19) implies (3.15). One can, however, anticipate that beyond setting (P) (for example, for problems with nonsmooth data), condition (3.15) complementing the core Pontryagin maximum principle can be substantially stronger than (3.19).

Note that in the problem considered in Example 1 the usage of the core Pontryagin maximum principle (Theorem 1) does not lead to the specification of an optimal control, whereas it can be shown that the latter control is determined uniquely if one applies the core Pontryagin maximum principle together with (3.15) (Corollary 2).

As an example given in [31] shows, under the assumptions of Corollary 2, the nontriviality condition (1.5) can hold with $\psi^0 = 0$; i.e., problem (P) can be abnormal. Below we find additional assumptions excluding abnormality of problem (P).

4. Normal-form maximum principle with positive adjoint variables. In this section, we suggest an assumption that excludes abnormality of problem (P), i.e., ensures that for problem (P), the normal-form Pontryagin maximum principle (see section 1) provides a necessary condition of optimality. Moreover, the basic result of this section formulated in Theorem 2 states that all the coordinates of the adjoint variable ψ in the Pontryagin maximum principle are necessarily positive-valued. Based on Theorem 2, we formulate conditions ensuring that the core Pontryagin maximum principle is complemented by the transversality conditions discussed in section 2. The proof of Theorem 2 is based on Corollary 1.

In what follows, the notation $a > 0$ (respectively, $a \geq 0$) for a vector $a \in \mathbb{R}^n$ designates that all coordinates of a are positive (respectively, nonnegative). Similarly, the notation $A > 0$ (respectively, $A \geq 0$) for a matrix A designates that all elements of A are positive (respectively, nonnegative).

The assumption complementing (A1)–(A4) is the following.

(A5) For every admissible pair (u, x) and for a.a. $t \geq 0$, one has

$$\frac{\partial g(x(t), u(t))}{\partial x} > 0 \quad \text{and} \quad \frac{\partial f^i(x(t), u(t))}{\partial x^j} \geq 0 \quad \text{for all} \quad i, j : i \neq j.$$

In typical models of regulated economic growth the coordinates of the state vector x represent positive-valued production factors. Normally it is assumed that the utility flow and the rate of growth of every production factor increase as all the production factors grow. In terms of problem (P), this implies that the integrand $g(x, u)$ in the goal functional (1.3), together with every coordinate of the right-hand side $f(x, u)$ of the system equation (1.1), is monotonically increasing in every coordinate of x. These monotonicity properties (specified so that $g(x, u)$ is strictly increasing in every coordinate of x) imply that assumption (A5) is satisfied. Note that the utility flow and the rates of growth of the production factors are normally positive, implying $g(x, u) > 0$ and $f(x, u) > 0$. The latter assumptions as well as the assumption $x > 0$ mentioned earlier appear in different combinations in the formulations of the results of this section.

The next theorem strengthens Theorem 1 under assumption (A5) and some positivity assumptions for f.

THEOREM 2. *Let assumptions* (A1)–(A5) *be satisfied. There exists a* $u_0 \in U$ *such that* $f(x_0, u_0) > 0$, *and for every admissible pair* (u, x), *it holds that* $f(x(t), u(t)) \geq 0$ *for a.a.* $t \geq 0$. *Let* (u_*, x_*) *be an admissible pair optimal in problem* (P). *Then there exists an adjoint variable* ψ *associated with* (u_*, x_*) *such that*

(i) (u_*, x_*) *satisfies relations* (1.7) *and* (1.8) *of the normal-form core Pontryagin maximum principle together with* ψ;

(ii) (u_*, x_*) *and* ψ *satisfy the normal-form stationarity condition* (3.18);

(iii)

$$\psi(t) > 0 \quad \textit{for all} \quad t \geq 0. \tag{4.1}$$

Proof. Let $\{(\mathrm{P}_k)\}\,(k = 1, 2, \ldots)$ be the sequence of problems associated with u_* and for every $k = 1, 2, \ldots$, let (u_k, x_k) be an admissible pair optimal in problem (P_k). In accordance with the classical formulation of the normal-form Pontryagin maximum principle, for every $k = 1, 2, \ldots$, there exists an adjoint variable ψ_k associated with (u_k, x_k) in problem (P_k) such that (u_k, x_k) satisfies the normal-form core Pontryagin maximum principle (in problem (P_k)) together with ψ_k and for every $k = 1, 2, \ldots$, the transversality condition (3.5) holds.

Observing assumption (A5), the adjoint equation resolved by ψ_k (see (3.16)), and transversality condition (3.5) for ψ_k, we easily find that $\psi_k(t) > 0$ for all t sufficiently close to T_k. Let us show that

$$\psi_k(t) > 0 \quad \text{for all} \quad t \in [0, T_k). \tag{4.2}$$

Suppose the contrary. Then, for some k, there exists a $\tau \in [0, T_k)$ such that at least one coordinate of the vector $\psi_k(\tau)$ vanishes. Let ξ be the maximum of all such $\tau \in [0, T_k)$, and let $i \in \{1, 2, \ldots, n\}$ be such that $\psi_k^i(\xi) = 0$. Then,

$$\psi_k(t) > 0 \quad \text{for all} \quad t \in (\xi, T_k) \tag{4.3}$$

and for all $t \in [\xi, T_k]$, we have

$$\psi_k^i(t) = -\int_\xi^t \left\langle \frac{\partial f^i(x_k(s), u_k(s))}{\partial x}, \psi_k(s) \right\rangle ds - \int_\xi^t e^{-\rho s} \frac{\partial g^i(x_k(s), u_k(s))}{\partial x} ds. \tag{4.4}$$

The latter equation and assumption (A5) imply that there is an $\epsilon > 0$ such that $\psi_k^i(t) < 0$ for all $t \in (\xi, \xi+\epsilon)$, which contradicts (4.3). The contradiction proves (4.2).

Let us show that the sequence $\{\psi_k(0)\}$ is bounded. The equation for ψ_k (see (3.16)) and maximum condition (3.17) yield

$$\begin{aligned}\frac{d}{dt}\tilde{H}_k(x_k(t),t,\psi_k(t)) &\overset{a.e.}{=} \frac{\partial\tilde{\mathcal{H}}_k}{\partial t}(x_k(t),t,\tilde{u}_k(t),\psi_k(t))\\ &\overset{a.e.}{=} -\rho e^{-\rho t}g(x_k(t),u_k(t)) + (\rho+1)e^{-(\rho+1)t}\frac{\|u_k(t)-z_k(t)\|^2}{1+\sigma_k}\\ &\quad + 2e^{-(\rho+1)t}\frac{\langle u_k(t)-z_k(t),\dot{z}_k(t)\rangle}{1+\sigma_k}.\end{aligned}$$

Integrating over $[0,T_k]$ and using the transversality condition (3.5), we arrive at

$$\begin{aligned}\tilde{H}_k(x_0,0,\psi_k(0)) &= e^{-\rho T_k}\max_{u\in U}\left[g(x_k(T_k),u) - e^{-T_k}\frac{\|u-z_k(T_k)\|^2}{1+\sigma_k}\right]\\ &\quad + \rho\int_0^{T_k} e^{-\rho t}g(x_k(t),u_k(t))dt\\ &\quad - (\rho+1)\int_0^{T_k} e^{-(\rho+1)t}\frac{\|u_k(t)-z_k(t)\|^2}{1+\sigma_k}dt\\ &\quad - 2\int_0^{T_k} e^{-(\rho+1)t}\frac{\langle u_k(t)-z_k(t),\dot{z}_k(t)\rangle}{1+\sigma_k}dt.\end{aligned}$$

This, together with (3.1)–(3.3), implies that $\tilde{H}_k(x_0,0,\psi_k(0)) \le M$ for some $M > 0$ and all $k = 1,2,\dots$. Hence, by virtue of

$$\langle f(x_0,u_0),\psi_k(0)\rangle + g(x_0,u_0) - \frac{\|u_0-z_k(0)\|^2}{1+\sigma_k} \le \tilde{H}_k(x_0,0,\psi_k(0)),$$

we have

$$\langle f(x_0,u_0),\psi_k(0)\rangle \le M + |g(x_0,u_0)| + (2|U|+1)^2,$$

where $|U| = \max_{u\in U}\|u\|$. The latter estimate, assumption $f(x_0,u_0) > 0$, and (4.2) yield that the sequence $\{\psi_k(0)\}$ is bounded.

Therefore, the sequence $\{(u_k,x_k,\psi_k)\}$ satisfies all the assumptions of Corollary 1. By Corollary 1, there exists a subsequence of $\{(u_k,x_k,\psi_k)\}$, denoted again as $\{(u_k,x_k,\psi_k)\}$, such that for every $T > 0$, one has convergence (3.14) for the adjoint variables ψ_k, where the limit element ψ is an adjoint variable associated with (u_*,x_*) in problem (P); (u_*,x_*) satisfies the normal-form core Pontryagin maximum principle in problem (P) together with ψ; and, finally, (u_*,x_*) and ψ satisfy the normal-form asymptotic stationarity condition (3.18). Thus, for (u_*,x_*) and ψ, statements (i) and (ii) are proved.

From (3.14) and (4.2) it follows that $\psi(t) \ge 0$ for all $t \ge 0$. Assumption (A5) and the fact that ψ solves the adjoint equation (1.7) imply (4.1), thus proving (iii). ∎

Now, we formulate conditions coupling the normal-form core Pontryagin maximum principle and the transversality conditions discussed in section 2.

COROLLARY 3. *Let the assumptions of Theorem 2 be satisfied and*

$$f(x_*(t), u_*(t)) \geq a_1 \quad \text{for a.a.} \quad t \geq 0, \tag{4.5}$$

where $a_1 > 0$. Then there exists an adjoint variable ψ associated with (u_*, x_*) such that statements (i), (ii), *and* (iii) *of Theorem 2 hold true and, moreover, ψ satisfies the transversality condition*

$$\lim_{t\to\infty} \psi(t) = 0. \tag{4.6}$$

Proof. By Theorem 2, there exists an adjoint variable ψ associated with (u_*, x_*) such that statements (i), (ii), and (iii) of Theorem 2 hold true. Let us prove (4.6). From (3.15) and (4.5) we get

$$\lim_{t\to\infty} \langle a_1, \psi(t)\rangle \leq \lim_{t\to\infty} \max_{u\in U} \langle f(x_*(t), u), \psi(t)\rangle = 0;$$

the latter, together with (4.1), implies (4.6). □

COROLLARY 4. *Let the assumptions of Theorem 2 be satisfied, and let*

$$x_0 \geq 0; \tag{4.7}$$

$$g(x_*(t), u_*(t)) \geq 0 \quad \text{for a.a.} \quad t \geq 0; \tag{4.8}$$

and

$$\frac{\partial f(x_*(t), u_*(t))}{\partial x} \geq A \quad \text{for a.a.} \quad t \geq 0, \tag{4.9}$$

where A is a matrix of order n such that $A > 0$. Then there exists an adjoint variable ψ associated with (u_*, x_*) such that statements (i), (ii), *and* (iii) *of Theorem 2 hold true and, moreover, ψ satisfies the transversality condition*

$$\lim_{t\to\infty} \langle x_*(t), \psi(t)\rangle = 0. \tag{4.10}$$

Proof. By Theorem 2, there exists an adjoint variable ψ associated with (u_*, x_*) such that statements (i), (ii), and (iii) of Theorem 2 hold true. Let us prove (4.10). The system equation (1.1) and normal-form adjoint equation (1.7) yield

$$\begin{aligned} \frac{d}{dt}\langle x_*(t), \psi(t)\rangle &= \langle f(x_*(t), u_*(t)), \psi(t)\rangle \\ &\quad - \left\langle x_*(t), \left[\frac{\partial f(x_*(t), u_*(t))}{\partial x}\right]^* \psi(t)\right\rangle \\ &\quad - e^{-\rho t}\left\langle x_*(t), \frac{\partial g(x_*(t), u_*(t))}{\partial x}\right\rangle \quad \text{for a.a.} \quad t \geq 0. \end{aligned} \tag{4.11}$$

From (4.7), assumption (A5), and (4.8), it follows that

$$-e^{-\rho t}\left\langle x_*(t), \frac{\partial g(x_*(t), u_*(t))}{\partial x}\right\rangle \leq 0 \leq e^{-\rho t} g(x_*(t), u_*(t)).$$

Taking this into account and using assumption (A5), the normal-form maximum condition (1.8), and assumption (4.9), we continue (4.11) as follows:

$$\begin{aligned}\frac{d}{dt}\langle x_*(t),\psi(t)\rangle &\le \langle f(x_*(t),u_*(t)),\psi(t)\rangle\\ &\quad - \left\langle x_*(t), \left[\frac{\partial f(x_*(t),u_*(t))}{\partial x}\right]^*\psi(t)\right\rangle + e^{-\rho t}g(x_*(t),u_*(t))\\ &\le -\langle Ax_*(t),\psi(t)\rangle + \tilde{H}(x_*(t),t,\psi(t)) \quad \text{for a.a.} \quad t\ge 0.\end{aligned}$$

Therefore, by (4.9), for some $\theta > 0$, we have

$$\frac{d}{dt}\langle x_*(t),\psi(t)\rangle \le -\theta\langle x_*(t),\psi(t)\rangle + \alpha(t),$$

where

$$\alpha(t) = \tilde{H}(x_*(t),t,\psi(t)) \to 0 \quad \text{as} \quad t\to\infty$$

(see (3.18)). Then, taking into account (4.7) and (4.1), we get

$$0 \le \langle x_*(t),\psi(t)\rangle \le e^{-\theta t}\langle x_0,\psi(0)\rangle + e^{-\theta t}\int_0^t e^{\theta s}\alpha(s)ds. \tag{4.12}$$

Furthermore,

$$\begin{aligned}\dot{\alpha}(t) &= \frac{d}{dt}\tilde{H}(x_*(t),t,\psi(t)) = \frac{\partial}{\partial t}\tilde{\mathcal{H}}(x_*(t),t,u_*(t),\psi(t))\\ &= -\rho e^{-\rho t}g(x_*(t),u_*(t)) \le 0 \quad \text{for a.a.} \quad t\ge 0\end{aligned}$$

(here we used (4.8)). Therefore,

$$\int_0^t e^{\theta s}\alpha(s)ds = \frac{1}{\theta}[e^{\theta t}\alpha(t) - \alpha(0)] + \frac{1}{\theta}\int_0^t e^{\theta s}\dot{\alpha}(s)ds \le \frac{1}{\theta}(e^{\theta t}\alpha(t) - \alpha(0)).$$

Substituting this estimate into (4.12), we get

$$0 \le \langle x_*(t),\psi(t)\rangle \le e^{-\theta t}\langle x_0,\psi(0)\rangle + e^{-\theta t}\frac{1}{\theta}[e^{\theta t}\alpha(t) - \alpha(0)] \to 0 \quad \text{as} \quad t\to\infty. \qquad \square$$

The next theorem is, to a certain extent, an inversion of Theorem 2. It adjoins works treating the Pontryagin maximum principle as a key component in sufficient conditions of optimality. Within the finite-horizon setting, this line of analysis was initiated in [30]. In [1] the approach was extended to infinite-horizon optimal control problems.

THEOREM 3. *Let assumptions* (A1)–(A5) *be satisfied,* $x_0 \ge 0$*, and for every admissible pair* (u,x)*, it holds that* $f(x(t),u(t)) \ge 0$ *and* $g(x(t),u(t)) \ge 0$ *for a.a.* $t\ge 0$*. Let* (u_*,x_*) *be an admissible pair satisfying* (4.9) *with some* $A > 0$*, and there exists an adjoint variable* ψ *associated with* (u_*,x_*) *such that statements* (i), (ii), *and* (iii) *of Theorem* 2 *hold true. Finally, let the set* G *be convex and the function* $x \mapsto \tilde{H}(x,t,\psi(t)) : G \mapsto \mathbb{R}^1$ *be concave for every* $t \ge 0$*. Then, the admissible pair* (u_*,x_*) *is optimal in problem* (P).

We omit the proof, which is similar to the proofs given in [2] and [36].

Combining Corollary 4 and Theorem 3, we arrive at the following optimality criterion for problem (P).

COROLLARY 5. *Let assumptions* (A1)–(A5) *be satisfied,* $x_0 \geq 0$*, and there exists a* $u_0 \in U$ *such that* $f(x_0, u_0) > 0$*. For every admissible pair* (u, x) *it holds that* $f(x(t), u(t)) \geq 0$*,* $g(x(t), u(t)) \geq 0$*, and* $\partial f(x(t), u(t))/\partial x \geq A$ *for a.a.* $t \geq 0$ *with some* $A > 0$*. Let, finally, the set* G *be convex and the function* $x \mapsto \tilde{H}(x, t, \psi) : G \mapsto \mathbb{R}^1$ *be concave for every* $t \geq 0$ *and for every* $\psi > 0$*. Then, an admissible pair* (u_*, x_*) *is optimal in problem* (P) *if and only if there exists an adjoint variable* ψ *associated with* (u_*, x_*) *such that statements* (i)*,* (ii)*, and* (iii) *of Theorem* 2 *hold true and the transversality condition* (4.10) *is satisfied.*

5. Case of dominating discount. In [12], infinite-horizon necessary optimality conditions involving the normal-form core Pontryagin maximum principle and an integral characterization of global behavior of the adjoint variable were stated for problems with sufficiently large (dominating) discount factors; in this work the control system was assumed to be linear. In this section, we consider problem (P) for the nonlinear control system (1.1) and apply the approximation scheme developed in section 3 in the case of the dominating discount. If system (1.1) is linear, the basic statement of this section (Theorem 4) leads to a formulation of the Pontryagin maximum principle (Corollary 7), which is stronger than that given in [12].

Following [12], we posit the next growth constraint on g.

(A6) There exist a $\kappa \geq 0$ and an $r \geq 0$ such that

$$\left\| \frac{\partial g(x, u)}{\partial x} \right\| \leq \kappa(1 + \|x\|^r) \quad \text{for all} \quad x \in G \quad \text{and for all} \quad u \in U.$$

Given an admissible pair (u, x), we denote by $Y_{(u,x)}$ the normalized fundamental matrix for the linear differential equation

$$\dot{y}(t) = \frac{\partial f(x(t), u(t))}{\partial x} y(t); \tag{5.1}$$

more specifically, $Y_{(x,u)}$ is the $n \times n$ matrix-valued function on $[0, \infty)$ whose columns y_i $(i = 1, \ldots, n)$ are the solutions to (5.1) such that $y_i^j(0) = \delta_{i,j}$ $(i, j = 1, \ldots, n)$, where $\delta_{i,i} = 1$ and $\delta_{i,j} = 0$ for $i \neq j$; for every $t \geq 0$, $\|Y_{(u,x)}(t)\|$ stands for the standard norm of $Y_{(u,x)}(t)$ as a linear operator in $\mathbb{R}^n$. Similarly, given an admissible pair (u, x), we denote by $Z_{(u,x)}$ the normalized fundamental matrix for the linear differential equation

$$\dot{z}(t) = -\left[\frac{\partial f(x(t), u(t))}{\partial x} \right]^* z(t).$$

Note that

$$[Z_{(u,x)}(t)]^{-1} = [Y_{(u,x)}(t)]^*. \tag{5.2}$$

We introduce the following growth assumption.

(A7) There exist a $\lambda \in \mathbb{R}^1$, a $C_1 \geq 0$, a $C_2 \geq 0$, and a $C_3 \geq 0$ such that for every admissible pair (u, x), one has

$$\|x(t)\| \leq C_1 + C_2 e^{\lambda t} \quad \text{for all} \quad t \geq 0$$

and

$$\|Y_{(u,x)}(t)\| \leq C_3 e^{\lambda t} \quad \text{for all} \quad t \geq 0.$$

It is easily seen that assumption (A6) implies that there exist a $C_4 \geq 0$ and a $C_5 \geq 0$ such that for every admissible pair (u, x), one has

$$|g(x(t), u(t))| \leq C_4 + C_5 \|x(t)\|^{r+1} \quad \text{for all} \quad t \geq 0. \tag{5.3}$$

Furthermore, (A7) and (5.3) imply that

$$e^{-\rho t}|g(x(t), u(t))| \leq C_6 e^{-\rho t} + C_7 e^{-(\rho-(r+1)\lambda)t}$$

holds for every admissible pair (u, x) with $C_6 \geq 0$ and $C_7 \geq 0$ not depending on (u, x). Therefore, if $\rho > 0$, then assumptions (A6) and (A7) imply (A4), provided $\rho > (r+1)\lambda$. The latter inequality implies that the discount parameter ρ in the goal functional (1.3) dominates the growth parameters r and λ (see (A6) and (A7)), which is a counterpart of a condition assumed in [12].

The proof of the next result is based on Corollary 1.

THEOREM 4. *Let assumptions* (A1)–(A4), (A6), *and* (A7) *be satisfied and let* $\rho > (r+1)\lambda$. *Let* (u_*, x_*) *be an admissible pair optimal in problem* (P). *Then there exists an adjoint variable* ψ *associated with* (u_*, x_*) *such that*

(i) (u_*, x_*) *satisfies relations* (1.7) *and* (1.8) *of the normal-form core Pontryagin maximum principle together with* ψ;

(ii) (u_*, x_*) *and* ψ *satisfy the normal-form stationarity condition* (3.18);

(iii) *for every* $t \geq 0$, *the integral*

$$I_*(t) = \int_t^\infty e^{-\rho s}[Z_*(s)]^{-1} \frac{\partial g(x_*(s), u_*(s))}{\partial x} ds, \tag{5.4}$$

where $Z_* = Z_{(u_*, x_*)}$, *converges absolutely and*

$$\psi(t) = Z_*(t) I_*(t). \tag{5.5}$$

Proof. Let $\{(\mathrm{P}_k)\}$ $(k = 1, 2, \ldots)$ be the sequence of problems associated with u_* and for every $k = 1, 2, \ldots$, let (u_k, x_k) be an admissible pair optimal in problem (P_k). In accordance with the classical formulation of the normal-form Pontryagin maximum principle, for every $k = 1, 2, \ldots$, there exists an adjoint variable ψ_k associated with (u_k, x_k) in problem (P_k) such that (u_k, x_k) satisfies the normal-form core Pontryagin maximum principle (in problem (P_k)) together with ψ_k and for every $k = 1, 2, \ldots$, the transversality condition (3.5) holds.

Let us show that the sequence $\{\psi_k(0)\}$ is bounded. Using the standard representation of the solution ψ_k to the linear normal-form adjoint equation (3.16) with the zero-boundary condition (3.5) through the fundamental matrix $Z_k = Z_{(u_k, x_k)}$ of the corresponding linear homogeneous equation (see, e.g., [25]), we get

$$\psi_k(0) = \int_0^{T_k} e^{-\rho s}[Z_k(s)]^{-1} \frac{\partial g(x_k(s), u_k(s))}{\partial x} ds.$$

Therefore, due to (5.2),

$$\|\psi_k(0)\| \leq \int_0^{T_k} e^{-\rho s} \|Y_{(x_k, u_k)}(s)\| \left\| \frac{\partial g(x_k(s), u_k(s))}{\partial x} \right\| ds,$$

and due to assumptions (A6) and (A7),

$$\|\psi_k(0)\| \leq \int_0^{T_k} (C_8 e^{-(\rho-\lambda)s} + C_9 e^{-(\rho-(r+1)\lambda)s}) ds,$$

where $C_8 \geq 0$ and $C_9 \geq 0$ do not depend on k. Now the assumption $\rho > (r+1)\lambda$ implies that the sequence $\{\psi_k(0)\}$ is bounded.

Therefore, the sequence $\{(u_k, x_k, \psi_k)\}$ satisfies all the assumptions of Corollary 1. By Corollary 1, there exists a subsequence of $\{(u_k, x_k, \psi_k)\}$, denoted again as $\{(u_k, x_k, \psi_k)\}$, such that for every $T > 0$, one has convergences (3.11) and (3.12) for the admissible pairs (u_k, x_k) and convergence (3.14) for the adjoint variables ψ_k, where the limit element ψ is an adjoint variable associated with (u_*, x_*) in problem (P); (u_*, x_*) satisfies the normal-form core Pontryagin maximum principle in problem (P) together with ψ; and, finally, (u_*, x_*) and ψ satisfy the normal-form stationarity condition (3.18). Thus, for (u_*, x_*) and ψ, statements (i) and (ii) are proved.

Consider the integral $I_*(t)$ in (5.4) for an arbitrary $t \geq 0$. Convergences (3.11) and (3.12) imply

$$Z_k(s) \to Z_*(s) \quad \text{for all} \quad s \geq 0. \tag{5.6}$$

Hence,

$$I_*(t) = \lim_{T\to\infty} \int_t^T e^{-\rho s}[Z_*(s)]^{-1} \frac{\partial g(x_*(s), u_*(s))}{\partial x} ds$$

$$= \lim_{T\to\infty} \lim_{k\to\infty} \int_t^T e^{-\rho s}[Z_k(s)]^{-1} \frac{\partial g(x_k(s), u_k(s))}{\partial x} ds.$$

Furthermore, from (5.2) and (A7) it follows that for all $s \geq 0$,

$$e^{-\rho t}\|[Z_k(s)]^{-1}\| \left\| \frac{\partial g(x_k(s), u_k(s))}{\partial x} \right\| \leq C_{10} e^{-(\rho-\lambda)s} + C_{11} e^{-(\rho-(r+1)\lambda)s}$$

with some positive C_{10} and C_{11}. Therefore, $I_*(t)$ converges absolutely. Let us prove (5.5). Integrate the adjoint equation for ψ_k (see (3.16)) over $[t, T_k]$ assuming that k is large enough (i.e., $T_k \geq t$) and taking into account the transversality condition (3.5). We get

$$\psi_k(t) = Z_k(t) \int_t^{T_k} e^{-\rho s} Z_k^{-1}(s) \frac{\partial g(x_k(s), u_k(s))}{\partial x} ds. \tag{5.7}$$

Convergences (3.11) and (3.12) (holding for every $T > 0$) imply that $x_k(s) \to x_*(s)$ for all $s \geq 0$ and $u_k(s) \to u_*(s)$ for a.a. $s \geq 0$. The latter convergences, convergences (5.6) and (3.14), and the absolute convergence of the integral $I_*(t)$ yield that the desired equality (5.5) is the limit of (5.7) with $k \to \infty$. Statement (iii) is proved. □

Now we recall some facts from the stability theory (see [18], [20]).

Consider a linear differential equation

$$\dot{x}(t) = A(t)x(t). \tag{5.8}$$

Here $t \in [0, \infty)$, $x \in \mathbb{R}^n$, and the components of the real $n \times n$ matrix function A are measurable and bounded.

Let x be a nonzero solution to (5.8). Then, a number

$$\lambda = \limsup_{t\to\infty} \frac{1}{t} \ln \|x(t)\|$$

is said to be the Lyapunov characteristic number of x. Note that the characteristic number λ was defined by A. M. Lyapunov with the opposite sign [29].

The Lyapunov characteristic number of any nonzero solution to (5.8) is finite. The set of the characteristic numbers for all nonzero solutions to (5.8) is called the Lyapunov spectrum of (5.8). The Lyapunov spectrum of (5.8) has no more than n elements. A fundamental system $x_1, \dots, x_n$ of solutions to (5.8) is said to be normal if the sum of their characteristic numbers is minimal in the set of all fundamental systems of solutions to (5.8). A normal fundamental system always exists. If $x_1, \dots, x_n$ is a normal fundamental system of solutions to (5.8), then the characteristic numbers for $x_1, \dots, x_n$ cover the Lyapunov spectrum of (5.8) (for different x_j and x_k the Lyapunov characteristic numbers may coincide). Any normal fundamental system contains the same number n_s of solutions to (5.8) with characteristic number λ_s, $1 \le s \le l$, $l \le n$, from the Lyapunov spectrum of (5.8).

Let $\sigma = \sum_{s=1}^{l} n_s \lambda_s$ be the sum of all numbers $\lambda_1, \dots, \lambda_l$ from the Lyapunov spectrum of (5.8) taken according to their multiplicity. Equation (5.8) is called regular if

$$\sigma = \liminf_{t \to \infty} \frac{1}{t} \int_0^t \mathrm{tr} A(s) ds,$$

where $\mathrm{tr}A(s)$ is the trace of matrix $A(s)$. If (5.8) is regular, then for every $\epsilon > 0$, the Cauchy matrix $(s,t) \mapsto K(s,t)$ for (5.8) satisfies

$$\|K(s,t)\| \le \kappa_1 e^{\bar{\lambda}(s-t)+\epsilon s} \quad \text{for all} \quad t \ge 0 \quad \text{and all} \quad s \ge t, \tag{5.9}$$

where $\bar{\lambda}$ is the maximum element in the Lyapunov spectrum of (5.8) and $\kappa_1 \ge 0$ is a constant depending only on ϵ (see [20]).

Corollary 6. *Let the assumptions of Theorem 4 be satisfied, let the linear differential equation*

$$\dot{y}(t) = \frac{\partial f(x_*(t), u_*(t))}{\partial x} y(t) \tag{5.10}$$

be regular, and let $\lambda \ge \bar{\lambda}$, where $\bar{\lambda}$ is the maximum element in the Lyapunov spectrum of (5.10). *Then for every $\epsilon > 0$, it holds that*

$$\|\psi(t)\| \le \kappa_2 (e^{-\rho t + \epsilon t} + e^{-(\rho - r\lambda)t + \epsilon t}) \quad \textit{for all} \quad t \ge 0, \tag{5.11}$$

where $\kappa_2 \ge 0$ is a constant depending only on ϵ.

Proof. By (5.5) and (5.2),

$$\begin{aligned}
\psi(t) &= \int_t^\infty e^{-\rho s} [[Y_*(t)]^*]^{-1} [Y_*(s)]^* \frac{\partial g(x_*(s), u_*(s))}{\partial x} ds \\
&= \int_t^\infty e^{-\rho s} [Y_*(s)[Y_*(t)]^{-1}]^* \frac{\partial g(x_*(s), u_*(s))}{\partial x} ds \\
&= \int_t^\infty e^{-\rho s} [K(s,t)]^* \frac{\partial g(x_*(s), u_*(s))}{\partial x} ds,
\end{aligned}$$

where $Y_* = Y_{(u_*, x_*)}$ is a normalized fundamental solution matrix of (5.10) and $K(s,t) = Y_*(s)[Y_*(t)]^{-1}$ is the Cauchy matrix of (5.10). Hence, by (A6), (A7), and

(5.9), for any $0 < \epsilon < \min\{\rho - \lambda,\ \rho - (r+1)\lambda\}$, we have

$$\begin{aligned}\|\psi(t)\| &\le \int_t^\infty e^{-\rho s}\|[K(s,t)]^*\| \left\| \frac{\partial g(x_*(s), u_*(s))}{\partial x} \right\| ds \\ &\le C_{12} \int_t^\infty e^{-\rho s} e^{\bar\lambda(s-t)} e^{\epsilon s}(1 + e^{r\lambda s}) ds \\ &\le \kappa_2 (e^{-\rho t + \epsilon t} + e^{-(\rho - r\lambda)t + \epsilon t}),\end{aligned}$$

where $C_{12} \ge 0$ and $\kappa_2 \ge 0$ depend only on ϵ. Hence, estimate (5.11) holds for any $\epsilon > 0$. □

Note that if $\rho > 0$, then Corollary 6 implies the validity of both (2.1) and (2.2).

Now, let us consider the situation where the control system (1.1) is linear and stationary. Problem (P) is specified as follows.

Problem (P1):

$$\dot x(t) = Fx(t) + u(t), \qquad u(t) \in U; \tag{5.12}$$

$$x(0) = x_0;$$

$$\text{maximize } J(x,u) = \int_0^\infty e^{-\rho t} g(x(t), u(t)) dt;$$

here F is a real $n \times n$ matrix.

Let λ_F be the maximum of the real parts of the eigenvalues of F. Then λ_F is the maximal number from the Lyapunov spectrum of the linear homogenous differential equation corresponding to (5.12), and for any $\epsilon > 0$, we have

$$\|e^{Ft}\| \le C_{13} e^{(\lambda_F + \epsilon)t} \quad \text{for all} \quad t \ge 0.$$

Here, e^{Ft} is the exponential of matrix F and $C_{13} \ge 0$ is a constant depending only on ϵ (see [20]). A standard representation of a solution to (5.12) through the matrix exponential e^{Ft} (see [25]) implies that for any $\epsilon > 0$ and for any admissible trajectory x of system (5.12), it holds that

$$\|x(t)\| \le C_{14} + C_{15} e^{(\lambda_F + \epsilon)t} \quad \text{for all} \quad t \ge 0,$$

where $C_{14} \ge 0$ and $C_{15} \ge 0$ depend only on ϵ. Thus, for an arbitrary $\lambda > \lambda_F$, assumption (A7) is satisfied. The latter observation and the fact that every linear stationary equation is regular [20] imply the following specification of Corollary 6 for problem (P1).

COROLLARY 7. *Let assumptions* (A3), (A4), *and* (A6) *be satisfied and let* $\rho > (r+1)\lambda_F$. *Let* (u_*, x_*) *be an admissible pair optimal in problem* (P1). *Then there exists an adjoint variable* ψ *associated with* (u_*, x_*) *such that*

(i) (u_*, x_*) *satisfies relations* (1.7) *and* (1.8) *of the normal-form core Pontryagin maximum principle together with* ψ;

(ii) (u_*, x_*) *and* ψ *satisfy the normal-form stationarity condition* (3.18);

(iii) *for every* $\epsilon > 0$, *it holds that*

$$\|\psi(t)\| \le \kappa_3 (e^{-\rho t + \epsilon t} + e^{-(\rho - r\lambda_F)t + \epsilon t}) \quad \textit{for all} \quad t \ge 0,$$

where $\kappa_3 \ge 0$ *is a constant depending only on* ϵ.

Note that if $\rho > 0$, then Corollary 7 implies the validity of both (2.1) and (2.2).

STOCHASTIC LINEAR-QUADRATIC CONTROL WITH CONIC CONTROL CONSTRAINTS ON AN INFINITE TIME HORIZON*

XI CHEN† AND XUN YU ZHOU‡

Abstract. This paper is concerned with a stochastic linear-quadratic (LQ) control problem in the infinite time horizon where the control is constrained in a given, arbitrary closed cone, the cost weighting matrices are allowed to be indefinite, and the state is scalar-valued. First, the (mean-square, conic) stabilizability of the system is defined, which is then characterized by a set of simple conditions involving linear matrix inequalities (LMIs). Next, the issue of well-posedness of the underlying optimal LQ control, which is necessitated by the indefiniteness of the problem, is addressed in great detail, and necessary and sufficient conditions of the well-posedness are presented. On the other hand, to address the LQ optimality two new algebraic equations à la Riccati, called extended algebraic Riccati equations (EAREs), along with the notion of their stabilizing solutions, are introduced for the first time. Optimal feedback control as well as the optimal value are explicitly derived in terms of the stabilizing solutions to the EAREs. Moreover, several cases when the stabilizing solutions do exist are discussed and algorithms of computing the solutions are presented. Finally, numerical examples are provided to illustrate the theoretical results established.

Key words. stochastic linear-quadratic control, infinite time horizon, constrained control, cone, (conic) stabilizability, well-posedness, extended algebraic Riccati equations

1. Introduction.

Linear-quadratic (LQ) control, pioneered by Kalman [17] for deterministic systems and extended to stochastic systems by Wonham [31, 32] and Bismut [5], constitutes, in both theory and applications, an extremely important class of control problems. In recent years, there has been considerable renewed interest in stochastic LQ control. In particular, the notion of mean-square stabilizability and detectability was introduced in [12]. On the other hand, initiated by Chen, Li, and Zhou [10], extensive research has been carried out in the so-called *indefinite* stochastic LQ control, where, quite contrary to the conventional belief, the cost weighting matrices are allowed to be indefinite; see [11, 2, 1, 33]. Moreover, this new theory has found applications in financial portfolio selection; see [35, 19, 18]. For systematic accounts of the deterministic and stochastic LQ theory, refer to [4] and [34], respectively.

A key assumption in the LQ theory at large, deterministic and stochastic alike, is that the control variable is unconstrained. This assumption renders the feedback control constructed via the Riccati equation *automatically* admissible, and in turn (along with the underlying LQ structure) makes possible the elegant explicit solution to the optimal LQ control problem. Because of this, the whole conventional LQ approach would collapse in the presence of any control constraint.

On the other hand, from a practical point of view, LQ control with control constraints is a well-defined and sensible problem. For example, in many real applications the control variable is required to take only nonnegative values. The mean-variance portfolio selection problem with short-selling prohibition exemplifies such problems. Other applications include models in medicine, chemistry, and economics where system inputs are inherently constrained.

There have been some attempts in dealing with *deterministic* LQ problems with positive controls or, more general, with controls contained in a given cone. For example, controllability for linear system $\dot{x} = Ax + Bu$ with positive/conic controls was studied in [26, 7, 25, 14, 8, 22]. These papers investigated the necessary and sufficient conditions of different types of controllability (null-controllability, global controllability, differential controllability, etc.). Later, conic stabilization was addressed in [23]. In a recent work on positive feedback stabilization [30], a stabilizing positive feedback controller was derived based on the pole placement technique.

Deterministic continuous-time LQ optimal control problems with positive controllers were studied in [21, 9, 13]. Discrete-time versions can be found in [27, 28]. In these works, however, only some necessary and sufficient conditions for optimality were derived based on Pontryagin's maximum principle and/or Bellman's dynamic programming, and some numerical schemes were suggested. The special LQ structure was not fully taken advantage of, and no explicit result comparable to those of unconstrained control was obtained.

As for the constrained *stochastic* LQ control, to the best of our knowledge it has never been studied by anyone else in the literature. A related, albeit specific, problem is the mean-portfolio selection model with no-shorting constraint solved in Li, Zhou, and Lim [18], which was formulated as a stochastic LQ control problem with positive controls in a finite time horizon. The approach developed in [18] is nevertheless rather ad hoc (via the Hamilton–Jacobi–Bellman equation and viscosity solution theory) and by no means suggests a remedy for a more general problem. More recently, a stochastic LQ control problem with conic control constraint, random coefficients, as well as possibly singular cost weighting matrices in a finite time horizon was solved by Hu and Zhou [15], with explicit solutions based on Tanaka's formula and the backward stochastic differential equation theory.

In this paper, we study stochastic LQ control in the infinite time horizon, where the control variable is constrained in a cone (which includes the problem with positive controls as a special case). Moreover, the problem is allowed to be indefinite in the sense that the cost weighting matrices are possibly indefinite. A main assumption of the paper is that the state variable is scalar-valued. Note that this assumption is valid in many meaningful practical applications, in particular in the area of finance where the one-dimensional wealth process is typically taken as the state. The investigation in this paper centers around several key issues associated with the problem, namely, conic stabilizability, well-posedness, and optimality. Conic stabilizability refers to the question of whether the system can be stabilized by a control satisfying the given conic constraint. It arises from the infinity of the time horizon under consideration, and is quite different from the normal stabilizability for unconstrained control. In this paper we will derive simple necessary and sufficient conditions for the conic stabilizability. The second issue, well-posedness of the LQ problem, becomes an *issue* because the problem is indefinite. To ensure well-posedness the problem data must coordinate well, which will be characterized in this paper by the nonemptiness of certain sets in the real space. Finally, for optimality, we aim to obtain *explicit* solutions comparable

to those classical unconstrained-control counterparts. To this end, we will introduce, for the first time in this paper, two algebraic equations termed the extended algebraic Riccati equations (EAREs) along with the notion of their stabilizing solutions. Then it will be shown that the existence of the stabilizing solutions is *sufficient* for the existence of optimal feedback control of the constrained LQ problem, and explicit forms of the optimal feedback control as well as the optimal cost value will be derived in terms of the stabilizing solutions. Furthermore, several important cases, including that of the definite LQ control, will be discussed where stabilizing solutions to the EAREs do exist, and algorithms for computing these solutions will be presented. To demonstrate the theoretical results obtained, numerical examples will be given.

The rest of the paper is organized as follows. In section 2, the constrained stochastic LQ control problem is formulated and conic stabilizability of the system defined. As a prelude to the main analysis, two technical lemmas are presented in section 3. The subsequent three sections, sections 4, 5, and 6, are devoted to the three major issues, namely, stabilizability, well-posedness, and optimality, respectively. Numerical examples are reported in section 7. Finally, section 8 concludes the paper.

2. Problem formulation.

Notation. We make use of the following basic notation in this paper:

$\mathbf{R}^n$	:	the set of n-dimensional column vectors.
$\mathbf{R}$	:	$= \mathbf{R}^1$.
$\mathbf{R}^n_+$	:	the subset of $\mathbf{R}^n$ consisting of elements with nonnegative components.
$\mathbf{R}^{m\times n}$	:	the set of all $m \times n$ matrices.
$\mathbf{S}^{n\times n}$	:	the set of all $n \times n$ symmetric matrices.
$\lvert v\rvert$	:	$= \sqrt{v'v}$, $v \in \mathbf{R}^n$.
x^+	:	$= \max\{x, 0\}$, $x \in \mathbf{R}$.
x^-	:	$= \max\{-x, 0\}$, $x \in \mathbf{R}$.
M'	:	the transpose of a matrix M.
$M > 0$	:	the square matrix M is positive definite.
$M \geq 0$	:	the square matrix M is positive semidefinite.
$\mathbf{E}[x]$	:	the expectation of a random variable x.

Let $(\Omega, \mathcal{F}, \mathbf{P}; \mathcal{F}_t)$ be a given filtered probability space with a standard $\mathcal{F}_t$-adapted, k-dimensional Brownian motion $w(t) \equiv (w_1(t), w_2(t), \ldots, w_k(t))'$ on $[0, +\infty)$. Let $\Gamma \subseteq \mathbf{R}^m$ be a given closed cone; i.e., Γ is closed, and if $u \in \Gamma$, then $\alpha u \in \Gamma$ $\forall \alpha \geq 0$. Typical examples of such a cone are $\Gamma = \mathbf{R}^m_+$, $\Gamma = \{u \in \mathbf{R}^m | Mu \leq 0\}$, and $\Gamma = \{u \in \mathbf{R}^m | Mu = 0\}$, where $M \in \mathbf{R}^{n\times m}$, or the so-called second-order cone (cf., e.g., [20, p. 221]) $\Gamma = \{(t, u) \in \mathbf{R} \times \mathbf{R}^{m-1} | t \geq |u|\}$. Next, for $M \in \mathbf{S}^{m\times m}$ if there is $\delta > 0$ so that $K'MK \geq \delta |K|^2$ $\forall 0 \neq K \in \Gamma$, then we denote $M|_\Gamma > 0$. Similarly we write $M|_\Gamma \geq 0$ if $K'MK \geq 0$ $\forall K \in \Gamma$. Clearly $M > 0$ (respectively, $M \geq 0$) implies $M|_\Gamma > 0$ (respectively, $M|_\Gamma \geq 0$). Finally, define the following Hilbert space:

$$L^2_{\mathcal{F}}(\Gamma) = \Big\{ \phi(\cdot,\cdot) : [0,+\infty) \times \Omega \to \Gamma \Big| \phi(\cdot,\cdot) \text{ is } \mathcal{F}_t\text{-adapted, measurable, and } \mathbf{E}\int_0^{+\infty} |\phi(t,\omega)|^2 dt < +\infty \Big\}$$

with the norm $\|\phi(\cdot,\cdot)\| := (\mathbf{E}\int_0^{+\infty} |\phi(t,\omega)|^2 dt)^{\frac{1}{2}}$.

Consider the Itô stochastic differential equation (SDE)

$$\begin{cases} dx(t) = [Ax(t) + Bu(t)]dt + \sum_{j=1}^{k} [C_j x(t) + D_j u(t)]dw_j(t), \quad t \in [0, \infty), \\ x(0) = x_0 \in \mathbf{R}, \end{cases} \tag{1}$$

where $A, C_j \in \mathbf{R}$ and $B, D_j \in \mathbf{R}^{1\times m}$. A process $u(\cdot)$ is called a control (with conic constraint) if $u(\cdot) \in L^2_{\mathcal{F}}(\Gamma)$.

DEFINITION 2.1. *A control $u(\cdot) \in L^2_{\mathcal{F}}(\Gamma)$ is called (mean-square, conic) stabilizing with respect to x_0 if the corresponding state $x(\cdot)$ of* (1) *with the initial state x_0 satisfies* $\lim_{t\to+\infty} \mathbf{E}|x(t)|^2 = 0$.

DEFINITION 2.2. *System* (1) *is said to be (mean-square, conic) stabilizable if there is a feedback control of the form $u(t) = K_+x^+(t) + K_-x^-(t)$, where K_+ and K_- are constant vectors with $K_+ \in \Gamma$ and $K_- \in \Gamma$, which is (mean-square, conic) stabilizing with respect to* every *initial state x_0.*

Now, for any $x_0 \in \mathbf{R}$, we define the set of admissible controls

$$\mathcal{U}_{x_0} := \{u(\cdot) \in L^2_{\mathcal{F}}(\Gamma) | u(\cdot) \text{ is stabilizing with respect to } x_0\}. \tag{2}$$

If $u(\cdot) \in \mathcal{U}_{x_0}$ and $x(\cdot)$ is the corresponding solution of (1), then $(x(\cdot), u(\cdot))$ is called an admissible pair (with respect to x_0). For each $(x_0, u(\cdot)) \in \mathbf{R} \times \mathcal{U}_{x_0}$ the associated cost to system (1) is

$$J(x_0; u(\cdot)) := \mathbf{E}\int_0^{+\infty} [Qx(t)^2 + u(t)'Ru(t)]dt, \tag{3}$$

where $Q \in \mathbf{R}$ and $R \in \mathbf{S}^{m\times m}$. Note that here Q and R are *not* assumed to be nonnegative/positive semidefinite. As a result, $J(x_0; u(\cdot))$ is not necessarily bounded below.

The indefinite LQ control problem with conic constraint entails minimizing the cost functional (3), for a given x_0, subject to (1) and $u(\cdot) \in \mathcal{U}_{x_0}$. Such a problem is denoted as problem (LQ). An admissible control $u(\cdot) \in \mathcal{U}_{x_0}$ is called optimal (with respect to x_0) if $u(\cdot)$ achieves the infimum of (3), and in this case problem (LQ) is also referred to as attainable (with respect to x_0).

The value function V is defined as

$$V(x_0) := \inf_{u(\cdot)\in\mathcal{U}_{x_0}} J(x_0; u(\cdot)), \quad x_0 \in \mathbf{R}, \tag{4}$$

where $V(x_0)$ is set to be $+\infty$ in the case when $\mathcal{U}_{x_0}$ is empty.

DEFINITION 2.3. *Problem* (LQ) *is called well-posed if*

$$V(x_0) > -\infty \quad \forall x_0 \in \mathbf{R}. \tag{5}$$

It is well known that V is a continuous, though not necessarily differentiable, function when problem (LQ) is well-posed. Also note that a well-posed problem is not necessarily attainable with respect to any x_0 (see Example 6.2).

3. Two lemmas. In this section we present two lemmas that are useful in what follows.

LEMMA 3.1 (Tanaka's formula). *Let $X(t)$ be a continuous semimartingale. Then*

$$\begin{aligned} dX^+(t) &= 1_{(X(t)>0)}dX(t) + \frac{1}{2}dL(t), \\ dX^-(t) &= -1_{(X(t)\le 0)}dX(t) + \frac{1}{2}dL(t), \end{aligned} \tag{6}$$

where $L(\cdot)$ is an increasing continuous process, called the local time of $X(\cdot)$ at 0, satisfying

$$\int_0^t |X(s)|dL(s) = 0, \quad \mathbf{P}\text{-a.s.} \tag{7}$$

In particular, $X^+(t)$ and $X^-(t)$ are semimartingales.

Proof. See, for example, [24, Chapter VI, Theorem 1.2 and Proposition 1.3]. □

LEMMA 3.2. *Let constants $N_+, N_- \in \mathbf{R}$ be given. Then for any admissible pair $(x(\cdot), u(\cdot))$ with respect to x_0, we have, for every $t \ge 0$,*

$$\begin{aligned} &\mathbf{E}\int_0^t [Qx(s)^2 + u(s)'Ru(s)]ds \\ &= N_+(x_0^+)^2 + N_-(x_0^-)^2 - \mathbf{E}[N_+x^+(t)^2] - \mathbf{E}[N_-x^-(t)^2] \\ &\quad + \mathbf{E}\int_0^t \left\{ Qx(s)^2 + \left(2A + \sum_{j=1}^k C_j^2\right) N_+x^+(s)^2 + \left(2A + \sum_{j=1}^k C_j^2\right) N_-x^-(s)^2 \right. \\ &\quad + u(s)' \left[R + 1_{(x(s)>0)}N_+ \sum_{j=1}^k D_j'D_j + 1_{(x(s)\le 0)}N_- \sum_{j=1}^k D_j'D_j \right] u(s) \\ &\quad \left. + 2\left(B + \sum_{j=1}^k C_jD_j\right) u(s)N_+x^+(s) - 2\left(B + \sum_{j=1}^k C_jD_j\right) u(s)N_-x^-(s) \right\} ds. \end{aligned} \tag{8}$$

Proof. Let $x(\cdot)$ be the solution of (1) under an arbitrary $u(\cdot) \in \mathcal{U}_{x_0}$. By Lemma 3.1, we have

$$\begin{aligned} dx^+(t) &= 1_{(x(t)>0)}[Ax(t) + Bu(t)]dt + 1_{(x(t)>0)} \sum_{j=1}^k [C_jx(t) + D_ju(t)]dw_j(t) \\ &\quad + \frac{1}{2}dL(t), \\ dx^-(t) &= -1_{(x(t)\le 0)}[Ax(t) + Bu(t)]dt - 1_{(x(t)\le 0)} \sum_{j=1}^k [C_jx(t) + D_ju(t)]dw_j(t) \\ &\quad + \frac{1}{2}dL(t). \end{aligned}$$

In the above equations, $L(\cdot)$ is the local time as specified in Lemma 3.1. Applying Itô's formula, we get

$$\begin{aligned}
&d[N_+x^+(t)^2]\\
&= 2N_+x^+(t)\left\{1_{(x(t)>0)}[Ax(t)+Bu(t)]dt+1_{(x(t)>0)}\sum_{j=1}^{k}[C_jx(t)+D_ju(t)]dw_j(t)+\frac{1}{2}dL(t)\right\}\\
&\quad+1_{(x(t)>0)}N_+\sum_{j=1}^{k}[C_jx(t)+u(t)'D_j'][C_jx(t)+D_ju(t)]dt\\
&=\left\{N_+[2Ax^+(t)^2+2Bu(t)x^+(t)+1_{(x(t)>0)}\sum_{j=1}^{k}(C_jx(t)+u(t)'D_j')(C_jx(t)+D_ju(t))]\right\}dt\\
&\quad+N_+\sum_{j=1}^{k}[2C_jx^+(t)^2+2D_ju(t)x^+(t)]dw_j(t)\\
&=\left[\left(2A+\sum_{j=1}^{k}C_j^2\right)N_+x^+(t)^2+2Bu(t)N_+x^+(t)+2\sum_{j=1}^{k}C_jD_ju(t)N_+x^+(t)\right.\\
&\quad\left.+1_{(x(t)>0)}N_+u(t)'\sum_{j=1}^{k}D_j'D_ju(t)\right]dt+\left[N_+(t)\sum_{j=1}^{k}(2C_jx^+(t)^2+2D_ju(t)x^+(t))\right]dw_j(t),
\end{aligned}\tag{9}$$

where we have used the fact that $x^+(t)dL(t)=0$ by virtue of (7). Similarly, for the constant $N_-\in\mathbf{R}$,

$$\begin{aligned}
&d[N_-x^-(t)^2]\\
&=\left\{N_-\left[2Ax^-(t)^2-2Bu(t)x^-(t)+1_{(x(t)\le0)}\sum_{j=1}^{k}(C_jx(t)+u(t)'D_j')(C_jx(t)+D_ju(t))\right]\right\}dt\\
&\quad+N_-\sum_{j=1}^{k}[2C_jx^-(t)^2-2D_ju(t)x^-(t)]dw_j(t)\\
&=\left[\left(2A+\sum_{j=1}^{k}C_j^2\right)N_-x^-(t)^2-2Bu(t)P_-x^-(t)-2\sum_{j=1}^{k}C_jD_ju(t)N_-x^-(t)\right.\\
&\quad\left.+1_{(x(t)\le0)}N_-u(t)'\sum_{j=1}^{k}D_j'D_ju(t)\right]dt+\left[N_-(t)\sum_{j=1}^{k}(2C_jx^-(t)^2-2D_ju(t)x^-(t))\right]dw_j(t).
\end{aligned}\tag{10}$$

Fix $t\ge0$ and define a sequence of stopping times

$$\begin{aligned}
\tau_n:=\inf\left\{r\in[0,t]:\int_0^r\left|N_+(s)\sum_{j=1}^{k}(2C_jx^+(s)^2+2D_ju(s)x^+(s))\right|^2ds\right.\\
\left.+\int_0^r\left|N_-(s)\sum_{j=1}^{k}(2C_jx^-(s)^2-2D_ju(s)x^-(s))\right|^2ds\ge n\right\},\quad n=1,2,\ldots,
\end{aligned}$$

where $\inf \emptyset := t$. It is clear that $\tau_n \uparrow t$ as $n \to +\infty$, due to $E\int_0^t (|x(s)|^2 + |u(s)|^2)ds < +\infty$. Now, summing up (9) and (10), taking integration from 0 to τ_n and then, taking expectation, we obtain (8) with t replaced by τ_n. Thus, (8) follows by sending $n \to +\infty$ together with Fatou's lemma. □

4. Conic stabilizability. In this section we address the issue of the conic stabilizability of system (1). Notice that conic stabilizability is different from the usual stabilizability with unconstrained controls, for clearly the former requires more stringent conditions. Here we will give a *complete* characterization of conic stabilizability in terms of simple conditions involving linear matrix inequalities (LMIs).

Introduce a pair of functions F_+, F_- from Γ to $\mathbf{R}$:

$$F_+(K) := 2A + \sum_{j=1}^k C_j^2 + 2\left(B + \sum_{j=1}^k C_j D_j\right) K + K' \sum_{j=1}^k D_j' D_j K, \tag{11}$$

and

$$F_-(K) := 2A + \sum_{j=1}^k C_j^2 - 2\left(B + \sum_{j=1}^k C_j D_j\right) K + K' \sum_{j=1}^k D_j' D_j K. \tag{12}$$

THEOREM 4.1. *The following assertions are equivalent.*

(i) *System* (1) *is mean-square conic stabilizable.*

(ii) *There exist* $K_+ \in \Gamma$ *and* $K_- \in \Gamma$ *such that* $F_+(K_+) < 0$ *and* $F_-(K_-) < 0$. *In this case the feedback control* $u(t) = K_+ x^+(t) + K_- x^-(t)$ *is stabilizing.*

(iii) *There exist* $K_+ \in \Gamma$ *and* $K_- \in \Gamma$ *such that*

$$\begin{pmatrix} 2A + \sum_{j=1}^k C_j^2 + 2\left(B + \sum_{j=1}^k C_j D_j\right) K_+ & K_+' D' \\ DK_+ & -I \end{pmatrix} < 0, \tag{13}$$

$$\begin{pmatrix} 2A + \sum_{j=1}^k C_j^2 - 2\left(B + \sum_{j=1}^k C_j D_j\right) K_- & K_-' D' \\ DK_- & -I \end{pmatrix} < 0, \tag{14}$$

where $D \in \mathbf{R}^{m\times m}$ *satisfies* $D'D = \sum_{j=1}^k D_j' D_j$. *In this case the feedback control* $u(t) = K_+ x^+(t) + K_- x^-(t)$ *is stabilizing.*

Proof. Take a feedback control $u(t) = K_+ x^+(t) + K_- x^-(t)$ and consider the corresponding state $x(\cdot)$ with an initial state x_0. Note that by standard SDE theory (cf., e.g., [16]) such $x(\cdot)$ uniquely exists. Moreover,

$$\mathbf{E} \sup_{0\le t\le T} |x(t)|^p dt < +\infty \ \ \forall T > 0 \ \ \forall p \ge 0. \tag{15}$$

Making use of (9) with $N_+ = 1$ and $u(t) = K_+x^+(t) + K_-x^-(t)$, we obtain

$$dx^+(t)^2 = \left[2A + \sum_{j=1}^k C_j^2 + 2\left(B + \sum_{j=1}^k C_jD_j\right)K_+ + K_+' \sum_{j=1}^k D_j'D_jK_+\right] x^+(t)^2dt$$
$$+ \sum_{j=1}^k (2C_j + 2D_jK_+)x^+(t)^2dw_j(t)$$
$$= F_+(K_+)x^+(t)^2dt + \sum_{j=1}^k (2C_j + 2D_jK_+)x^+(t)^2dw_j(t).$$

Taking integration and then expectation yields (after a localization argument as in the proof of Lemma 3.2)

$$\frac{d\mathbf{E}[x^+(t)^2]}{dt} = F_+(K_+)\mathbf{E}[x^+(t)^2], \tag{16}$$

where the expectation of the Itô integral vanishes due to (15). Similarly, we have

$$\frac{d\mathbf{E}[x^-(t)^2]}{dt} = F_-(K_-)\mathbf{E}[x^-(t)^2]. \tag{17}$$

Hence, the equivalence between the assertions (i) and (ii) is evident noting that $\lim_{t\to+\infty} \mathbf{E}|x(t)|^2 = 0$ if and only if $\lim_{t\to+\infty} \mathbf{E}|x^+(t)|^2 = 0$ and $\lim_{t\to+\infty} \mathbf{E}|x^-(t)|^2 = 0$.

Finally, the equivalence between the assertions (ii) and (iii) follows from Schur's lemma [6]. □

Conditions (13) and (14) are in terms of LMIs. On the other hand, some of the conic constraint can also be expressed as LMIs, e.g., when $\Gamma = \mathbf{R}_+^m$ or when Γ is a second-order cone. Hence, Theorem 4.1(iii) provides an easy way of numerically checking the stabilizability of system (1) due to the availability of many LMI solvers. Note that in general there may exist many feasible solutions to LMIs.

Denote the two sets of feedback gains as

$$\mathcal{K}_+ := \{K \in \Gamma | F_+(K) < 0\}, \quad \mathcal{K}_- := \{K \in \Gamma | F_-(K) < 0\}.$$

Then Theorem 4.1 implies the following

THEOREM 4.2. *System* (1) *is conic stabilizable if and only if* $\mathcal{K}_+ \neq \emptyset$ *and* $\mathcal{K}_- \neq \emptyset$.

COROLLARY 4.1. *If* $2A + \sum_{j=1}^k C_j^2 < 0$, *then system* (1) *is conic stabilizable.*

Proof. In this case $0 \in \mathcal{K}_+ \cap \mathcal{K}_-$. □

PROPOSITION 4.1. *We have the following results.*

(i) $\mathcal{K}_+$ *and* $\mathcal{K}_-$ *are convex sets if* Γ *is a convex set.*

(ii) $\mathcal{K}_+$ *and* $\mathcal{K}_-$ *are bounded if* $\sum_{j=1}^k D_j'D_j|_\Gamma > 0$.

Proof. (i) Define the following operator M_+ from Γ to $\mathbf{S}^{(m+1)\times(m+1)}$:

$$M_+(K) = \begin{pmatrix} 2A + \sum_{j=1}^k C_j^2 + 2\left(B + \sum_{j=1}^k C_jD_j\right)K & K'D' \\ DK & -I \end{pmatrix},$$

where $D'D = \sum_{j=1}^k D_j'D_j$. By Theorem 4.1, $\mathcal{K}_+$ can be equivalently represented as $\mathcal{K}_+ = \{K \in \Gamma | M_+(K) < 0\}$. Thus the convexity of $\mathcal{K}_+$ follows from that of Γ together

with the fact that the operator M_+ is affine. Similarly we can show the convexity of $\mathcal{K}_-$.

(ii) If $\mathcal{K}_+$ is unbounded, then there is a sequence $\{K_n\} \subset \mathcal{K}_+$ so that $|K_n| \to +\infty$. Since $\sum_{j=1}^k D_j' D_j|_\Gamma > 0$, we have $K_n' \sum_{j=1}^k D_j' D_j K_n \geq \delta |K_n|^2 \to +\infty$ as $n \to +\infty$, where $\delta > 0$ is some constant. Therefore $F_+(K_n) \to +\infty$ as $n \to +\infty$. This contradicts $F_+(K_n) < 0 \ \forall n$. Hence $\mathcal{K}_+$ is bounded. Similarly, $\mathcal{K}_-$ is bounded. □

5. Well-posedness. Since the cost weighting matrices Q and R are allowed to be indefinite, the well-posedness of the problem is no longer automatic or trivial (as opposed to the classical definite case when $Q \geq 0$ and $R > 0$). In fact, the well-posedness for an indefinite LQ control problem is a prerequisite for the optimality and is an interesting problem in its own right. In this section we will carry out an extensive investigation on the well-posedness and some related issues, including necessary and sufficient conditions for the well-posedness in terms of the nonemptiness of certain sets.

5.1. Representation of value function. In this subsection we present the following representation result, which is a key to many results of this paper.

PROPOSITION 5.1. *Problem* (LQ) *is well-posed if and only if the value function can be represented as*

$$V(x_0) = P_+(x_0^+)^2 + P_-(x_0^-)^2 \quad \forall x_0 \in \mathbf{R} \tag{18}$$

for some $P_+, P_- \in \mathbf{R}$.

Proof. We prove only the "only if" part, as the "if" part is evident.

Assume that problem (LQ) is well-posed. Fix any $x > 0, y > 0$. Since $V(y) > -\infty$, for any $\varepsilon > 0$ there is $u^\varepsilon(\cdot) \in \mathcal{U}_y$ along with the corresponding state $x^\varepsilon(\cdot)$ (with the initial state y) satisfying

$$V(y) \geq J(y; u^\varepsilon(\cdot)) - \varepsilon = \mathbf{E} \int_0^{+\infty} [Q x^\varepsilon(t)^2 + u^\varepsilon(t)' R u^\varepsilon(t)] dt - \varepsilon. \tag{19}$$

Now, as $x > 0$, the linearity of the dynamics (1) and the conic control constraint ensure that $x u^\varepsilon(\cdot) \in \mathcal{U}_{xy}$ with the corresponding state $x x^\varepsilon(\cdot)$. Hence it follows from (19) that

$$V(y) \geq \frac{1}{x^2} \mathbf{E} \int_0^{+\infty} [Q|x x^\varepsilon(t)|^2 + (x u^\varepsilon(t))' R(x u^\varepsilon(t))] dt - \varepsilon \geq \frac{1}{x^2} V(xy) - \varepsilon. \tag{20}$$

Sending $\varepsilon \to 0$ we obtain

$$V(xy) \leq V(y) x^2 \quad \forall x > 0, y > 0. \tag{21}$$

Similarly, one can show that

$$V(xy) \leq V(-y) x^2 \quad \forall x < 0, y > 0. \tag{22}$$

Now for any $x > 0$, by (21) we have $V(x) \leq V(1)x^2$. On the other hand, (21) also implies $V(1) = V(x\frac{1}{x}) \leq \frac{1}{x^2} V(x)$. So we have shown that

$$V(x) = V(1) x^2 \quad \forall x > 0. \tag{23}$$

Similarly, in view of (22) we can prove that

$$V(x) = V(-1) x^2 \quad \forall x < 0. \tag{24}$$

Finally, the continuity of the value function along with (23) yields

$$V(0) = 0. \tag{25}$$

The desired result (18) thus follows from (23)–(25) with $P_+ := V(1)$ and $P_- := V(-1)$. □

Remark 5.1. The preceding proposition, which suggests the form of the value function when the underlying LQ problem is well-posed, is crucial for all the main results in this paper. In fact, the proofs for the stabilizability in the previous section, the characterization of the well-posedness in this section, and the optimality in the next section are *all* inspired by this result. This also explains why one needs to apply Tanaka's formula to evaluate $dx^+(t)$ and $dx^-(t)$, as we have seen in the previous section and will continue to see in the subsequent sections.

Remark 5.2. We saw that the value function for the constrained LQ problem is *not* smooth.

5.2. Characterization of well-posedness. Define the following functions from $\mathbf{R}$ to $\mathbf{R} \cup \{-\infty\}$:

$$\Phi_+(P) := \inf_{K\in\Gamma} \left[K' \left(R + P\sum_{j=1}^k D_j'D_j \right) K + 2 \left(B + \sum_{j=1}^k C_jD_j \right) PK \right],$$

$$\Phi_-(P) := \inf_{K\in\Gamma} \left[K' \left(R + P\sum_{j=1}^k D_j'D_j \right) K - 2 \left(B + \sum_{j=1}^k C_jD_j \right) PK \right].$$

Remark 5.3. Since $0 \in \Gamma$, we must have

$$\Phi_+(P) \le 0 \quad \Phi_-(P) \le 0 \ \ \forall P \in \mathbf{R}. \tag{26}$$

On the other hand, $\Phi_+(P)$ and $\Phi_-(P)$ have finite values if $(R+P\sum_{j=1}^k D_j'D_j)|_\Gamma > 0$. Indeed, in this case there exist constants $\alpha_1 = \alpha_1(P) > 0$ and $\alpha_2 = \alpha_2(P) > 0$ such that

$$\begin{aligned} K' \left(R + P\sum_{j=1}^k D_j'D_j \right) K + 2 \left(B + \sum_{j=1}^k C_jD_j \right) PK &\ge \alpha_1|K|^2 - \alpha_2|K| \\ &= \alpha_1|K| \left(|K| - \frac{\alpha_2}{\alpha_1} \right) \qquad \forall K \in \Gamma. \end{aligned}$$

If $|K| > \frac{\alpha_2}{\alpha_1}$, then the above expression is positive. Taking (26) into consideration we conclude

$$\Phi_+(P) = \inf_{K\in\Gamma, |K| \le \frac{\alpha_2}{\alpha_1}} \left[K' \left(R + P\sum_{j=1}^k D_j'D_j \right) K + 2 \left(B + \sum_{j=1}^k C_jD_j \right) PK \right] > -\infty.$$

Hence, $\Phi_+(P)$ is finite. The same is true for $\Phi_-(P)$.

Next, we define the following two sets:

$$\mathcal{P}_+ := \left\{ P \in \mathbf{R} \,\middle|\, \left(2A + \sum_{j=1}^k C_j^2 \right) P + Q + \Phi_+(P) \ge 0, \ \left(R + P\sum_{j=1}^k D_j'D_j \right)\Big|_\Gamma \ge 0 \right\},$$

$$\mathcal{P}_- := \left\{ P \in \mathbf{R} \,\middle|\, \left(2A + \sum_{j=1}^k C_j^2 \right) P + Q + \Phi_-(P) \ge 0, \ \left(R + P\sum_{j=1}^k D_j'D_j \right)\Big|_\Gamma \ge 0 \right\}.$$

The following is the main result of the section, which characterizes the well-posedness of problem (LQ) by the nonemptiness of the sets $\mathcal{P}_+$ and $\mathcal{P}_-$.

THEOREM 5.1. *Assume that system* (1) *is conic stabilizable. Then problem* (LQ) *is well-posed if and only if* $\mathcal{P}_+ \neq \emptyset$ *and* $\mathcal{P}_- \neq \emptyset$. *Moreover, in this case*

$$V(x_0) \geq P_+(x_0^+)^2 + P_-(x_0^-)^2 \quad \forall x_0 \in \mathbf{R}, \quad \forall P_+ \in \mathcal{P}_+, \quad P_- \in \mathcal{P}_-. \tag{27}$$

Proof. First we prove the "if" part. For any $x_0 \in \mathbf{R}$ let $x(\cdot)$ be the solution of (1) under an arbitrary $u(\cdot) \in \mathcal{U}_{x_0}$. Pick any $P_+ \in \mathcal{P}_+$ and $P_- \in \mathcal{P}_-$. By Lemma 3.2, we have

$$\begin{aligned}
&\mathbf{E}\int_0^t [Qx(s)^2 + u(s)'Ru(s)]ds \\
&= P_+(x_0^+)^2 + P_-(x_0^-)^2 - \mathbf{E}[P_+x^+(t)^2] - \mathbf{E}[P_-x^-(t)^2] \\
&\quad + \mathbf{E}\int_0^t \left\{ Qx(s)^2 + \left(2A + \sum_{j=1}^k C_j^2\right) P_+x^+(s)^2 + \left(2A + \sum_{j=1}^k C_j^2\right) P_-x^-(s)^2 \right. \\
&\quad + u(s)' \left[R + 1_{(x(s)>0)} P_+ \sum_{j=1}^k D_j'D_j + 1_{(x(s)\leq 0)} P_- \sum_{j=1}^k D_j'D_j \right] u(s) \\
&\quad \left. + 2\left(B + \sum_{j=1}^k C_jD_j\right) u(s)P_+x^+(s) - 2\left(B + \sum_{j=1}^k C_jD_j\right) u(s)P_-x^-(s) \right\} ds.
\end{aligned} \tag{28}$$

Denote by $\psi(x(s), u(s))$ the integrand on the right-hand side of (28) and fix $s \in [0,t]$. If $x(s) > 0$, then write $u(s) = Kx(s)$ (note that K may depend on s). Since $u(s) \in \Gamma$ and Γ is a cone, we have $K \in \Gamma$. Hence at s, bearing in mind that $1_{(x(s)\leq 0)} = 0$, we have

$$\begin{aligned}
&\psi(x(s), u(s)) \\
&= Qx(s)^2 + \left(2A + \sum_{j=1}^k C_j^2\right) P_+x(s)^2 + K' \left[R + P_+ \sum_{j=1}^k D_j'D_j \right] Kx(s)^2 \\
&\quad + 2\left(B + \sum_{j=1}^k C_jD_j\right) KP_+x(s)^2 \\
&= \left[\left(2A + \sum_{j=1}^k C_j^2\right) P_+ + Q + K'\left(R + P_+ \sum_{j=1}^k D_j'D_j\right) K + 2\left(B + \sum_{j=1}^k C_jD_j\right) KP_+ \right] x(s)^2 \\
&\geq \left[\left(2A + \sum_{j=1}^k C_j^2\right) P_+ + Q + \Phi_+(P_+) \right] x(s)^2 \\
&\geq 0.
\end{aligned} \tag{29}$$

If $x(s) < 0$, then write $u(s) = -Kx(s)$. Again $K \in \Gamma$. An argument similar to that above yields

$$\psi(x(s), u(s)) \geq \left[\left(2A + \sum_{j=1}^k C_j^2\right) P_- + Q + \Phi_-(P_-) \right] x(s)^2 \geq 0$$

at s. Finally, if $x(s) = 0$ at s, then

$$\psi(x(s), u(s)) = u(s)' \left[R + P_- \sum_{j=1}^{k} D_j' D_j \right] u(s) \geq 0.$$

The preceding analysis shows that it always holds that $\psi(x(s), u(s)) \geq 0 \ \forall s \in [0, t]$. Consequently, it follows from (28) that

$$\begin{aligned} \mathbf{E} \int_0^t [Qx(s)^2 + u(s)' R u(s)] ds \geq P_+ (x_0^+)^2 + P_- (x_0^-)^2 - \mathbf{E}[P_+ x^+(t)^2] \\ - \mathbf{E}[P_- x^-(t)^2]. \end{aligned}$$

Letting $t \to +\infty$ and noting that $u(\cdot)$ is conic stabilizing, we obtain

$$\begin{aligned} J(x_0; u(\cdot)) &= \lim_{t \to +\infty} \mathbf{E} \int_0^t [Qx(s)^2 + u(s)' R u(s)] ds \\ &\geq P_+ (x_0^+)^2 + P_- (x_0^-)^2. \end{aligned}$$

Since $u(\cdot) \in \mathcal{U}_{x_0}$ is arbitrary, we conclude $V(x_0) \geq P_+ (x_0^+)^2 + P_- (x_0^-)^2 > -\infty$. Hence problem (LQ) is well-posed.

To prove the "only if" part, suppose that the LQ problem is well-posed. Then by Proposition 5.1 the value function has the following representation:

$$V(x) = P_+ (x^+)^2 + P_- (x^-)^2 \ \ \forall x \in \mathbf{R}.$$

We want to show that $P_+ \in \mathcal{P}_+, \ \ P_- \in \mathcal{P}_-$. To this end, applying the optimality principle of dynamic programming and noting the time-invariance of the underlying system, we obtain

$$\begin{aligned} & P_+ (x_0^+)^2 + P_- (x_0^-)^2 \\ & \leq \mathbf{E} \left\{ \int_0^h [Qx(t)^2 + u(t)' R u(t)] dt + P_+ [x^+(h)]^2 + P_- [x^-(h)]^2 \right\} \\ & \forall h > 0, \ \ \forall u(\cdot) \in \mathcal{U}_{x_0}, \ \ \forall x_0 \in \mathbf{R}. \end{aligned} \tag{30}$$

Using the above and applying Lemma 3.2, we obtain

$$\mathbf{E} \int_0^h \psi(x(s), u(s)) ds \geq 0 \quad \forall h > 0, \ \ \forall u(\cdot) \in \mathcal{U}_{x_0}, \ \ \forall x_0 \in \mathbf{R}, \tag{31}$$

where, as before, the mapping ψ is defined via the integrand on the right-hand side of (28). Set $x_0 > 0$ and take the following control

$$u_1(t) := \begin{cases} K, & 0 \leq t < 1, \\ K_+ x^+(t) + K_- x^-(t), & t \geq 1, \end{cases}$$

where $K \in \Gamma$ is arbitrarily fixed and $K_+ x^+(t) + K_- x^-(t)$ is a conic stabilizing feedback control which exists due to the stabilizability assumption. Clearly $u_1(\cdot) \in \mathcal{U}_{x_0}$, and

let $x_1(\cdot)$ be the corresponding state. Since $x_1(s) \to x_0$ and $u_1(s) \to K$ as $s \to 0$, **P**-a.s., we have

$$\begin{aligned}&\psi(x_1(s), u_1(s))\\ &\to \left[\left(2A + \sum_{j=1}^{k} C_j^2\right) P_+ + Q\right] x_0^2 + 2\left(B + \textstyle\sum_{j=1}^{k} C_j D_j\right) K P_+ x_0\\ &\quad + K'\left(R + P_+ \sum_{j=1}^{k} D_j' D_j\right) K \quad \text{as } s \to 0, \quad \mathbf{P}\text{-a.s.}\end{aligned}$$

Thus appealing to (31), the dominated convergence theorem yields

$$\begin{aligned}0 &\le \frac{1}{h}\mathbf{E}\int_0^h \psi(x_1(s), u_1(s))ds\\ &\to \left[\left(2A + \sum_{j=1}^{k} C_j^2\right) P_+ + Q\right] x_0^2 + 2\left(B + \textstyle\sum_{j=1}^{k} C_j D_j\right) K P_+ x_0\\ &\quad + K'\left(R + P_+ \sum_{j=1}^{k} D_j' D_j\right) K \quad \text{as } h \to 0.\end{aligned}$$

Letting $x_0 \to 0$ we obtain $K'(R + P_+ \sum_{j=1}^{k} D_j' D_j)K \ge 0$. The arbitrariness of $K \in \Gamma$ then implies $(R + P_+ \sum_{j=1}^{k} D_j' D_j)|_\Gamma \ge 0$. On the other hand, take $x_0 > 0$ and consider the following feedback control

$$u_2(t) := \begin{cases} Kx^+(t) + \tilde{K}x^-(t), & 0 \le t < 1,\\ K_+x^+(t) + K_-x^-(t), & t \ge 1,\end{cases}$$

where $K \in \Gamma$ and $\tilde{K} \in \Gamma$ are arbitrarily fixed. Let $x_2(\cdot)$ be the state under $u_2(\cdot)$. Noting $x_2(s) \to x_0$ and $u_2(s) = Kx_2^+(s) + \tilde{K}x_2^-(s) \to Kx_0$ as $s \to 0$, **P**-a.s., we obtain

$$\begin{aligned}&\psi(x_2(s), u_2(s))\\ &\to \left[\left(2A + \sum_{j=1}^{k} C_j^2\right) P_+ + Q + K'\left(R + P_+ \sum_{j=1}^{k} D_j' D_j\right) K + 2\left(B + \sum_{j=1}^{k} C_j D_j\right) K P_+\right] x_0^2\\ &\quad \text{as } s \to 0, \quad \mathbf{P}\text{-a.s.}\end{aligned}$$

An analysis similar to the preceding one leads to

$$\left(2A + \sum_{j=1}^{k} C_j^2\right) P_+ + Q + K'\left(R + P_+ \sum_{j=1}^{k} D_j' D_j\right) K + 2\left(B + \sum_{j=1}^{k} C_j D_j\right) K P_+ \ge 0.$$

Since $K \in \Gamma$ is arbitrary, we arrive at $(2A + \sum_{j=1}^{k} C_j^2)P_+ + Q + \Phi_+(P_+) \ge 0$. So far we have shown $P_+ \in \mathcal{P}_+$. Similarly, we can prove $P_- \in \mathcal{P}_-$.

Finally, the inequality (27) has been proved in the proof of the "if" part. □

Remark 5.4. From the above proof we see that the stabilizability assumption is in fact *not* necessary for the "if" part of the theorem.

Remark 5.5. The above theorem tells that the positive definiteness or positive semidefiniteness of Q and R are *not* necessary for problem (LQ) to be well-posed.

COROLLARY 5.1. *If* $R|_\Gamma \geq 0$ *and* $Q \geq 0$, *then problem* (LQ) *is well-posed.*

Proof. In this case $0 \in \mathcal{P}_+ \cap \mathcal{P}_-$. □

PROPOSITION 5.2. $\mathcal{P}_+$ *and* $\mathcal{P}_-$ *are both convex sets (hence they are both intervals). Moreover, if system* (1) *is stabilizable and problem* (LQ) *is well-posed, then* $\mathcal{P}_+$ *and* $\mathcal{P}_-$ *each has a finite maximum element.*

Proof. The convexity of $\mathcal{P}_+$ and $\mathcal{P}_-$ are clear noticing that the functions $\Phi_+(P)$ and $\Phi_-(P)$ are concave in P. To prove the existence of the finite maximum elements, we note that Proposition 5.1 provides

$$V(x_0) = P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2 \quad \forall x_0 \in \mathbf{R} \tag{32}$$

for some $P_+^*, P_-^* \in \mathbf{R}$. Moreover, the proof of Theorem 5.1 implies $P_+^* \in \mathcal{P}_+$ and $P_-^* \in \mathcal{P}_-$. Hence it follows from (27) that P_+^* and P_-^* are the maximum elements of $\mathcal{P}_+$ and $\mathcal{P}_-$, respectively. □

Remark 5.6. Proposition 5.2 indicates that if system (1) is stabilizable and problem (LQ) is well-posed, then the infimum value of problem (LQ) or, equivalently, the P_+ and P_- in the representation of the value function as stipulated in Proposition 5.1 can be obtained by solving the following two mathematical programming problems, respectively:

$$\begin{array}{ll} \text{maximize} & P \\ \text{subject to} & \left\{ \begin{array}{l} \left(2A + \displaystyle\sum_{j=1}^{k} C_j^2 \right) P + Q + \Phi_+(P) \geq 0, \\ \left(R + P \displaystyle\sum_{j=1}^{k} D_j' D_j \right) \Big|_\Gamma \geq 0, \end{array} \right. \end{array} \tag{33}$$

and

$$\begin{array}{ll} \text{maximize} & P \\ \text{subject to} & \left\{ \begin{array}{l} \left(2A + \displaystyle\sum_{j=1}^{k} C_j^2 \right) P + Q + \Phi_-(P) \geq 0, \\ \left(R + P \displaystyle\sum_{j=1}^{k} D_j' D_j \right) \Big|_\Gamma \geq 0. \end{array} \right. \end{array} \tag{34}$$

5.3. An algorithm. Theorem 5.1 stipulates that it suffices to check the nonemptiness of $\mathcal{P}_+$ and $\mathcal{P}_-$ or the feasibility of the problems (33) and (34) in order to verify the well-posedness of a given LQ problem. However, it is sometimes hard to check numerically the aforementioned feasibility because, on one hand, the functions $\Phi_+(\cdot)$ and $\Phi_-(\cdot)$ in general do not have analytical forms, and on the other hand, the constraint $(R + P\sum_{j=1}^{k} D_j' D_j)|_\Gamma \geq 0$ is usually very hard to verify for a general cone Γ (except second-order cones for which the constraint can be reformulated as an LMI; see [29, Theorem 1]).

In this subsection we give an algorithm that can check the well-posedness more directly. First we need a lemma.

LEMMA 5.1. *Assume that problem* (LQ) *is well-posed. Given* $K_+ \in \mathcal{K}_+$ *and* $K_- \in \mathcal{K}_-$, *set* $\tilde{P}_+ := -\frac{Q+K_+'RK_+}{F_+(K_+)}$ *and* $\tilde{P}_- := -\frac{Q+K_-'RK_-}{F_-(K_-)}$. *Then*

$$P_+ \le \tilde{P}_+ \ \forall P_+ \in \mathcal{P}_+ \ \text{ and } \ P_- \le \tilde{P}_- \ \forall P_- \in \mathcal{P}_-. \tag{35}$$

Proof. By their definitions $\tilde{P}_+$ and $\tilde{P}_-$ satisfy, respectively,

$$\left(2A+\sum_{j=1}^k C_j^2\right)\tilde{P}_+ + Q + K_+'\left(R+\tilde{P}_+\sum_{j=1}^k D_j'D_j\right)K_+ + 2\left(B+\sum_{j=1}^k C_jD_j\right)K_+\tilde{P}_+ = 0 \tag{36}$$

and

$$\left(2A+\sum_{j=1}^k C_j^2\right)\tilde{P}_- + Q + K_-'\left(R+\tilde{P}_-\sum_{j=1}^k D_j'D_j\right)K_- - 2\left(B+\sum_{j=1}^k C_jD_j\right)K_-\tilde{P}_- = 0. \tag{37}$$

Take a feedback control $u(t) = K_+x^+(t) + K_-x^-(t)$, which is stabilizing by Theorem 4.1 (bearing in mind the definitions of $\mathcal{K}_+$ and $\mathcal{K}_-$), and let $x(\cdot)$ be the corresponding state with $x(0) = x_0$. Then a similar calculation as in (28) yields

$$\begin{aligned}&\mathbf{E}\int_0^t [Qx(s)^2 + u(s)'Ru(s)]ds \\ &= \tilde{P}_+(x_0^+)^2 + \tilde{P}_-(x_0^-)^2 - \mathbf{E}[\tilde{P}_+x^+(t)^2] - \mathbf{E}[\tilde{P}_-x^-(t)^2] + \mathbf{E}\int_0^t \psi(x(s),u(s))ds,\end{aligned} \tag{38}$$

where $\psi(x(s),u(s))$ is as the integrand on the right-hand side of (28), with P_+ and P_- replaced by $\tilde{P}_+$ and $\tilde{P}_-$, respectively. However, $u(s) = K_+x(s)$ whenever $x(s) > 0$; hence

$$\begin{aligned}&\psi(x(s),u(s)) \\ &= \left[\left(2A+\sum_{j=1}^k C_j^2\right)\tilde{P}_+ + Q + K_+'\left(R+\tilde{P}_+\sum_{j=1}^k D_j'D_j\right)K_+ + 2\left(B+\sum_{j=1}^k C_jD_j\right)K\tilde{P}_+\right]x(s)^2 \\ &= 0\end{aligned}$$

in view of (36). Similarly, based on (37) one can show that $\psi(x(s),u(s)) = 0$ whenever $x(s) \le 0$. It then follows from (38) that

$$\mathbf{E}\int_0^t [Qx(s)^2 + u(s)'Ru(s)]ds = \tilde{P}_+(x_0^+)^2 + \tilde{P}_-(x_0^-)^2 - \mathbf{E}[\tilde{P}_+x^+(t)^2] - \mathbf{E}[\tilde{P}_-x^-(t)^2].$$

Since $u(\cdot)$ is stabilizing, we have

$$J(x_0;u(\cdot)) = \lim_{t\to+\infty}\mathbf{E}\int_0^t [Qx(s)^2 + u(s)'Ru(s)]ds = \tilde{P}_+(x_0^+)^2 + \tilde{P}_-(x_0^-)^2.$$

By virtue of Theorem 5.1, we conclude

$$\begin{aligned}\tilde{P}_+(x_0^+)^2 + \tilde{P}_-(x_0^-)^2 &= J(x_0; u(\cdot)) \\ &\geq V(x_0) \geq P_+(x_0^+)^2 + P_-(x_0^-)^2 \quad \forall P_+ \in \mathcal{P}_+,\ \forall P_- \in \mathcal{P}_-.\end{aligned}$$

This proves (35). □

We now assume that (1) is conic stabilizable. According to Theorem 4.1 there exist $K_+ \in \Gamma$ and $K_- \in \Gamma$ such that $F_+(K_+) < 0$ and $F_-(K_-) < 0$. Take $\delta > 0$ sufficiently small with $\delta < \min\{-F_+(K_+), -F_-(K_-)\}$. Calculate

$$P_+^{(1)} := \min_{F_+(K) \leq -\delta} \Big\{ -\frac{Q + K'RK}{F_+(K)} \Big\},\ \ P_-^{(1)} := \min_{F_-(K) \leq -\delta} \Big\{ -\frac{Q + K'RK}{F_-(K)} \Big\}. \tag{39}$$

In view of Lemma 5.1, $P_+^{(1)}$ (respectively, $P_-^{(1)}$) is a (very tight) upper bound of $\mathcal{P}_+$ (respectively, $\mathcal{P}_-$) under the well-posedness assumption. As a consequence, if problem (LQ) is well-posed, then it is necessary that $(R + P_+^{(1)} \sum_{j=1}^k D_j' D_j)|_\Gamma \geq 0$ and $(R + P_-^{(1)} \sum_{j=1}^k D_j' D_j)|_\Gamma \geq 0$. Now, calculate

$$P^{(0)} := \min_{(R + P \sum_{j=1}^k D_j' D_j)|_\Gamma \geq 0} P. \tag{40}$$

Then we know that points of $\mathcal{P}_+$ (respectively, $\mathcal{P}_-$), if any, must lie between $P^{(0)}$ and $P_+^{(1)}$ (respectively, $P_-^{(1)}$). Inspired by the above discussion, we have the following algorithm.

Step 1. Apply Theorem 4.1(iii) to obtain $K_+,\ K_- \in \Gamma$ with $F_+(K_+) < 0$ and $F_-(K_-) < 0$. Set $\delta := \min\{\varepsilon, -F_+(K_+), -F_-(K_-)\}$, where ε is a very small number allowed by the computer.

Step 2. Calculate $P_+^{(1)}$ and $P_-^{(1)}$ via (39). If either $(R + P_+^{(1)} \sum_{j=1}^k D_j' D_j)|_\Gamma < 0$ or $(R + P_-^{(1)} \sum_{j=1}^k D_j' D_j)|_\Gamma < 0$ holds, stop, and problem (LQ) is not well-posed.

Step 3. Calculate $P^{(0)}$ via (40).

Step 4. If there exists a $P \in [P^{(0)}, P_+^{(1)})$ satisfying $L_+(P) \geq 0$, then go to Step 5; otherwise, stop, and problem (LQ) is not well-posed.

Step 5. If there exists a $P \in [P^{(0)}, P_-^{(1)})$ satisfying $L_-(P) \geq 0$, then stop, and problem (LQ) is well-posed; otherwise, stop, and problem (LQ) is not well-posed.

5.4. Well-posedness margin. In view of Remark 5.5, problem (LQ) may still be well-posed when R is indefinite or even negative definite. That said, it is clear that R cannot be *too* negative for the well-posedness. Therefore, it is interesting to study the *range* of R over which problem (LQ) is well-posed, given that all the other data is fixed. Specifically, define

$$r^* := \inf\{r \in \mathbf{R} \,\big|\, \text{problem (LQ) is well-posed for any } R \in \mathbf{S}^{m\times m} \text{ with } R > rI\}, \tag{41}$$

where $\inf \emptyset := +\infty$. The value r^* is called the well-posedness margin. By its very definition, r^* has the following interpretation: Problem (LQ) is well-posed if the smallest eigenvalue of R, $\lambda_{min}(R)$, is such that $\lambda_{min}(R) > r^*$, and is not well-posed if the largest eigenvalue of R, $\lambda_{max}(R)$, is such that $\lambda_{max}(R) < r^*$.

It follows from Theorem 5.1 that, provided that system (1) is stabilizable, the well-posedness margin r^* can be obtained by solving the following nonlinear program

(with P and r being the decision variables):

$$\begin{array}{ll} \text{minimize} & r \\ \text{subject to} & \begin{cases} \left(2A+\sum_{j=1}^{k} C_j^2\right) P + Q + \Phi_+(P,r) \geq 0, \\ \left(2A+\sum_{j=1}^{k} C_j^2\right) P + Q + \Phi_-(P,r) \geq 0, \\ \left(rI + P\sum_{j=1}^{k} D_j' D_j\right)\Big|_{\Gamma} \geq 0, \end{cases} \end{array} \tag{42}$$

where

$$\Phi_+(P,r) := \inf_{K\in\Gamma}\left[K'\left(rI+P\sum_{j=1}^{k} D_j'D_j\right)K + 2\left(B+\sum_{j=1}^{k} C_jD_j\right)PK\right],$$

$$\Phi_-(P,r) := \inf_{K\in\Gamma}\left[K'\left(rI+P\sum_{j=1}^{k} D_j'D_j\right)K - 2\left(B+\sum_{j=1}^{k} C_jD_j\right)PK\right].$$

Notice, again, that it is hard to solve the preceding mathematical program as, in addition to the difficulty associated with the last constraint, $\Phi_+(P,r)$ and $\Phi_+(P,r)$ in general do not have analytical forms. In the following, we provide an explicit lower bound of r^*.

THEOREM 5.2. *Assume that system* (1) *is stabilizable. Then* $\bar{r} := \max\{\bar{r}_+, \bar{r}_-\}$ *is a lower bound of the well-posedness margin, where*

$$\bar{r}_+ := \begin{cases} \dfrac{\lambda Q}{\inf_{K\in\mathcal{K}_+}\{F_+(K)-\lambda K'K\}} & \text{if } Q \geq 0, \\ \dfrac{\lambda Q}{\sup_{K\in\mathcal{K}_+}\{F_+(K)-\lambda K'K\}} & \text{if } Q < 0 \end{cases} \tag{43}$$

and

$$\bar{r}_- := \begin{cases} \dfrac{\lambda Q}{\inf_{K\in\mathcal{K}_-}\{F_-(K)-\lambda K'K\}} & \text{if } Q \geq 0, \\ \dfrac{\lambda Q}{\sup_{K\in\mathcal{K}_-}\{F_-(K)-\lambda K'K\}} & \text{if } Q < 0, \end{cases} \tag{44}$$

with $\lambda := \inf_{K\in\Gamma,|K|=1} K'\sum_{j=1}^{k} D_j'D_jK \geq 0$.

Proof. Suppose problem (LQ) is well-posed with $R = -rI$, $r \in \mathbf{R}$. Then $\mathcal{P}_+ \neq \emptyset$. Since system (1) is stabilizable, we can take a $K \in \mathcal{K}_+$. It follows from Lemma 5.1 that $P := -\frac{Q+rK'K}{F_+(K)}$ is an upper bound of the nonempty set $\mathcal{P}_+$. Because $(rI + P_+\sum_{j=1}^{k} D_j'D_j)|_\Gamma \geq 0$ $\forall P_+ \in \mathcal{P}_+$, we conclude $(rI + P\sum_{j=1}^{k} D_j'D_j)|_\Gamma \geq 0$, which is equivalent to $r + PK'\sum_{j=1}^{k} D_j'D_jK \geq 0$ for any $K \in \Gamma, |K| = 1$. Hence $r + P\lambda \geq 0$. Substituting $P = -\frac{Q+rK'K}{F_+(K)}$ we obtain $r \geq \frac{\lambda Q}{F_+(K)-\lambda K'K}$. Since $K \in \mathcal{K}_+$ is arbitrary, we easily obtain that $r \geq \bar{r}_+$. Similarly, we have $r \geq \bar{r}_-$. Our analysis implies that problem (LQ) is *not* well-posed whenever the largest eigenvalue of R, $\lambda_{max}(R)$, is such that $\lambda_{max}(R) < \bar{r}$. Hence $\bar{r}$ is a lower bound of the well-posedness margin r^*. ∎

6. Optimality. This section is devoted to solving the optimal LQ control problem under consideration. We will first introduce two algebraic equations, in the spirit of the classical Riccati equation (for the unconstrained LQ problem), along with the notion of the so-called stabilizing solution. Then the optimality of problem (LQ) is addressed via the stabilizing solutions of the two algebraic equations.

We impose the following assumptions on the rest of the paper.

ASSUMPTION 6.1. *System* (1) *is conic stabilizable.*

ASSUMPTION 6.2. *Problem* (LQ) *is well-posed.*

6.1. Extended algebraic Riccati equations. In this subsection we define the two algebraic equations that play a key role in solving problem (LQ). Denote $\mathcal{R} := \{P \in \mathbf{R} | (R + P\sum_{j=1}^{k} D_j' D_j)|_\Gamma > 0\}$ and consider the following two functions from $\mathcal{R}$ to $\mathbf{R}$:

$$\xi_+(P) := \arg\min_{K\in\Gamma} \left[K' \left(R + P\sum_{j=1}^{k} D_j' D_j \right) K + 2 \left(B + \sum_{j=1}^{k} C_j D_j \right) PK \right],$$

$$\xi_-(P) := \arg\min_{K\in\Gamma} \left[K' \left(R + P\sum_{j=1}^{k} D_j' D_j \right) K - 2 \left(B + \sum_{j=1}^{k} C_j D_j \right) PK \right].$$

Note that the minimizers above are *uniquely* achievable due to a similar argument in Remark 5.3 and the fact that Γ is closed. Moreover, it is evident that both $\xi_+(\cdot)$ and $\xi_-(\cdot)$ are continuous on $\mathcal{R}$.

Define a pair of functions L_+ and L_- from $\mathcal{R}$ to $\mathbf{R}$:

$$L_+(P) := \left(2A + \sum_{j=1}^{k} C_j^2 \right) P + Q + \Phi_+(P),$$

$$L_-(P) := \left(2A + \sum_{j=1}^{k} C_j^2 \right) P + Q + \Phi_-(P).$$

The two equations

$$L_+(P) = 0, \quad \left(R + P\sum_{j=1}^{k} D_j' D_j \right)\Big|_\Gamma > 0, \tag{45}$$

$$L_-(P) = 0, \quad \left(R + P\sum_{j=1}^{k} D_j' D_j \right)\Big|_\Gamma > 0 \tag{46}$$

are called extended algebraic Riccati equations (EAREs). Note that the constraint $(R + P\sum_{j=1}^{k} D_j' D_j)|_\Gamma > 0$ is *part* of each of the two equations; so the EAREs are not exactly equations in a strict sense. Also, being an algebraic equation, each of them may admit more than one solution, or may admit no solution at all. Note that the EAREs introduced here both reduce to the *same* stochastic algebraic Riccati equation extensively studied in [2].

DEFINITION 6.1. *A solution P of the EARE* (45) *(respectively,* (46)*) is called a stabilizing solution if $\xi_+(P) \in \mathcal{K}_+$ (respectively, $\xi_-(P) \in \mathcal{K}_-$).*

It should be noted that the EAREs may not admit any stabilizing solution (see Proposition 6.1).

Before we conclude this subsection, we will present several lemmas.

LEMMA 6.1. *We have the inequalities*

$$(P_2 - P_1)[F_+(\xi_+(P_2)) - F_+(\xi_+(P_1))] \le 0, \tag{47}$$

$$(P_2 - P_1)[F_-(\xi_-(P_2)) - F_-(\xi_-(P_1))] \le 0, \tag{48}$$

$$L_+(P_2) - L_+(P_1) \le (P_2 - P_1)F_+(\xi_+(P_1)), \tag{49}$$

$$L_-(P_2) - L_-(P_1) \le (P_2 - P_1)F_-(\xi_-(P_1)) \tag{50}$$

for any $P_1, P_2 \in \mathcal{R}$.

Proof. Denoting $v_1 := \xi_+(P_1)$ and $v_2 := \xi_+(P_2)$, we have

$$\begin{aligned} v_2' \left(R + P_1 \sum_{j=1}^k D_j' D_j \right) v_2 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) P_1 v_2 - \Phi_+(P_1) \ge 0, \\ v_1' \left(R + P_2 \sum_{j=1}^k D_j' D_j \right) v_1 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) P_2 v_1 - \Phi_+(P_2) \ge 0. \end{aligned}$$

Then, adding the two inequalities, we get

$$\begin{aligned} &\left[v_2' \left(R + P_1 \sum_{j=1}^k D_j' D_j \right) v_2 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) P_1 v_2 \right] - \Phi_+(P_2) \\ &\ge \Phi_+(P_1) - \left[v_1' \left(R + P_2 \sum_{j=1}^k D_j' D_j \right) v_1 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) P_2 v_1 \right]. \end{aligned}$$

Recall that the infimum in $\Phi_+(P_i)$ is achieved by v_i, $i = 1, 2$; hence the above yields

$$\begin{aligned} &(P_2 - P_1) \left[v_2' \sum_{j=1}^k D_j' D_j v_2 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) v_2 \right] \\ &\le (P_2 - P_1) \left[v_1' \sum_{j=1}^k D_j' D_j v_1 + 2 \left(B + \sum_{j=1}^k C_j D_j \right) v_1 \right]. \end{aligned}$$

This is equivalent to (47). Similarly we can prove (48).

Next, we calculate

$$\begin{aligned}
&L_+(P_2) - L_+(P_1)\\
&= \left(2A + \sum_{j=1}^{k} C_j^2\right)(P_2 - P_1) + \Phi_+(P_2) - \Phi_+(P_1)\\
&\le \left(2A + \sum_{j=1}^{k} C_j^2\right)(P_2 - P_1) + v_1' \left(R + P_2 \sum_{j=1}^{k} D_j' D_j\right) v_1\\
&\quad + 2\left(B + \sum_{j=1}^{k} C_j D_j\right) P_2 v_1 - \Phi_+(P_1)\\
&= (P_2 - P_1)\left[\left(2A + \sum_{j=1}^{k} C_j^2\right) + v_1' \sum_{j=1}^{k} D_j' D_j v_1 + 2\left(B + \sum_{j=1}^{k} C_j D_j\right) v_1\right]\\
&= (P_2 - P_1) F_+(\xi_+(P_1)).
\end{aligned}$$

This proves (49). Similarly we can show (50). □

LEMMA 6.2. *Assume that $P_1 \in \mathcal{R}$ and $P_2 \ge P_1$. If $\xi_+(P_1) \in \mathcal{K}_+$ (respectively, $\xi_-(P_1) \in \mathcal{K}_-$), then $\xi_+(P_2) \in \mathcal{K}_+$ (respectively, $\xi_-(P_2) \in \mathcal{K}_-$).*

Proof. Since $P_2 \ge P_1$ it follows from (47) of Lemma 6.1 that

$$F_+(\xi_+(P_2)) - F_+(\xi_+(P_1)) \le 0.$$

As $F_+(\xi_+(P_1)) < 0$ we have $F_+(\xi_+(P_2)) < 0$, implying $\xi_+(P_2) \in \mathcal{K}_+$. Similarly we can prove the assertion for $\mathcal{K}_-$. □

LEMMA 6.3. *If there exists $P_+^{(0)} \in \mathcal{R}$ (respectively, $P_-^0 \in \mathcal{R}$) with $\xi_+(P_+^{(0)}) \in \mathcal{K}_+$ (respectively, $\xi_-(P_-^0) \in \mathcal{K}_-$), then $L_+(\cdot)$ (respectively, $L_-(\cdot)$) is strictly decreasing on $[P_+^{(0)}, +\infty)$ (respectively, $[P_-^0, +\infty)$).*

Proof. Take $P_2 > P_1 \ge P_+^{(0)}$. It follows from Lemma 6.2 that $F_+(\xi_+(P_1)) < 0$. On the other hand, it is clear that $P_1, P_2 \in \mathcal{R}$. Hence Lemma 6.1 yields

$$L_+(P_2) - L_+(P_1) \le (P_2 - P_1) F_+(\xi_+(P_1)) < 0.$$

This proves that $L_+(P_2) < L_+(P_1)$. We can prove the assertion for $L_-(P)$ in a similar manner. □

6.2. Optimality of the LQ problem via EAREs. In this subsection we prove that stabilizing solutions of (45) and (46), if any, lead to a complete and explicit solution to problem (LQ).

THEOREM 6.2. *If the EAREs* (45) *and* (46) *admit stabilizing solutions P_+^* and P_-^* respectively, then the feedback control*

$$u^*(t) = \xi_+(P_+^*) x^+(t) + \xi_-(P_-^*) x^-(t) \tag{51}$$

is optimal for problem (LQ) *with respect to any initial state x_0. Moreover, the value function is*

$$V(x_0) = P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2 \quad \forall x_0 \in \mathbf{R}. \tag{52}$$

Proof. Since P_+^* solves (45), we have

$$P_+^* = -\frac{Q + \xi_+(P_+^*)' R \xi_+(P_+^*)}{F_+(\xi_+(P_+^*))}.$$

Similarly,

$$P_-^* = -\frac{Q + \xi_-(P_-^*)' R \xi_-(P_-^*)}{F_-(\xi_-(P_-^*))}.$$

Moreover, $\xi_+(P_+^*) \in \mathcal{K}_+, \xi_-(P_-^*) \in \mathcal{K}_-$ as both P_+^* and P_-^* are stabilizing solutions. Thus the proof of Lemma 5.1 yields $V(x_0) \le J(x_0; u^*(\cdot)) = P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2$. On the other hand, $P_+^* \in \mathcal{P}_+$ and $P_-^* \in \mathcal{P}_-$. Hence it follows from Theorem 5.1 that $V(x_0) \ge P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2$. Therefore, $V(x_0) = J(x_0; u^*(\cdot)) = P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2$. □

The above proof has also shown the following result.

COROLLARY 6.1. *If the EAREs* (45) *and* (46) *admit stabilizing solutions P_+^* and P_-^*, respectively, then $P_+^* = \max\{P | P \in \mathcal{P}_+\}$ and $P_-^* = \max\{P | P \in \mathcal{P}_-\}$. As a result,* (45) *and* (46) *each has at most one stabilizing solution.*

Corollary 6.1 guarantees that any stabilizing solution is the maximal solution of the respective EAREs. This result is in parallel with the unconstrained case (see, e.g., [3, Theorem 2.3]).

Note that the converse of Theorem 6.2 is not necessarily true. The following example shows that the existence of a solution to the EAREs is not *necessary* for the LQ problem to be attainable with respect to any initial state.

Example 6.1. Consider the LQ problem

$$(53)\qquad \begin{aligned} &\text{minimize} && J(x_0; u(\cdot)) = \mathbf{E}\int_0^{+\infty} [|x(t)|^2 - |u(t)|^2]dt \\ &\text{subject to} && \begin{cases} dx(t) = [-x(t) + u(t)]dt + [-x(t) + u(t)]dw(t), \\ x(0) = x_0, \end{cases} \end{aligned}$$

where all the variables are scalar-valued and $\Gamma = \mathbf{R}$. This example was originally discussed in [33, Example 6.1, p. 817]. It was verified in [33] that the system is stabilizable, and the LQ problem is attainable with respect to any x_0 (in fact there are infinitely many optimal feedback controls). But both EAREs (45) and (46) in this case reduce to $-p + 1 = 0,\ -1 + p > 0$, which clearly admits no solution at all.

In spite of the preceding remarks and example, the following result shows that under an additional assumption, the EAREs indeed admit stabilizing solutions if problem (LQ) is attainable.

THEOREM 6.3. *Assume that there exist $P_+ \in \mathcal{P}_+$ and $P_- \in \mathcal{P}_-$ such that $(R + P\sum_{j=1}^k D_j' D_j)|_\Gamma > 0$ for $P = P_+, P_-$. If problem* (LQ) *is attainable with respect to any $x_0 \in \mathbf{R}$, then the EAREs* (45) *and* (46) *admit stabilizing solutions P_+^* and P_-^*, respectively. Moreover, any optimal control with respect to a given x_0 must be unique and represented by the feedback control* (51).

Proof. The proof of Proposition 5.2 yields that, under Assumptions 6.1 and 6.2, the value function can be represented as (32), where P_+^* and P_-^* are the maximum elements of $\mathcal{P}_+$ and $\mathcal{P}_-$, respectively. Moreover, by the assumption we have

$$(54)\qquad \left(R + P_+^* \sum_{j=1}^k D_j' D_j\right)\Bigg|_\Gamma > 0, \quad \left(R + P_-^* \sum_{j=1}^k D_j' D_j\right)\Bigg|_\Gamma > 0.$$

Now, for any $x_0 \in \mathbf{R}$ let $x^*(\cdot)$ be the solution of (1) under an optimal control $u^*(\cdot) \in \mathcal{U}_{x_0}$ which exists by the attainability assumption. Then a similar calculation to that of (28) leads to

$$\begin{aligned}&\mathbf{E}\int_0^t [Qx^*(s)^2 + u^*(s)'Ru^*(s)]ds \\ &= P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2 - \mathbf{E}[P_+^* x^{*+}(t)^2] - \mathbf{E}[P_-^* x^{*-}(t)^2] + \mathbf{E}\int_0^t \psi(x^*(s), u^*(s))ds,\end{aligned} \tag{55}$$

where $\psi(x^*(s), u^*(s))$ is the same as the integrand on the right-hand side of (28), with P_+ and P_- replaced by P_+^* and P_-^*, respectively. Letting $t \to +\infty$ and noting that $u^*(\cdot)$ is stabilizing, we obtain

$$\begin{aligned}V(x_0) \equiv J(x_0; u^*(\cdot)) &= \lim_{t\to+\infty} \mathbf{E}\int_0^t [Qx^*(s)^2 + u^*(s)'Ru^*(s)]ds \\ &= P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2 + \mathbf{E}\int_0^{+\infty} \psi(x^*(s), u^*(s))ds.\end{aligned}$$

Recalling that $V(x_0) = P_+^*(x_0^+)^2 + P_-^*(x_0^-)^2$ and that $\psi(x^*(s), u^*(s)) \geq 0$ (via the same proof of Theorem 5.1), we conclude

$$\psi(x^*(s), u^*(s)) = 0, \ \text{ a.e. } s \in [0, +\infty), \ \mathbf{P}\text{-a.s.}$$

Fix $s \in [0, +\infty)$, satisfying the above equality. If $x^*(s) > 0$, then we can write $u^*(s) = K(s)x^*(s)$, where $K(s) \in \Gamma$. Going through the same analysis as in (29), we obtain

$$\begin{aligned}0 &= \psi(x^*(s), u^*(s)) \\ &= \left[\left(2A + \sum_{j=1}^k C_j^2\right) P_+^* + Q + K(s)'\left(R + P_+^* \sum_{j=1}^k D_j' D_j\right) K(s)\right. \\ &\quad \left. + 2\left(B + \sum_{j=1}^k C_j D_j\right) K(s) P_+^*\right] x^*(s)^2 \\ &\geq \left[\left(2A + \sum_{j=1}^k C_j^2\right) P_+^* + Q + \Phi_+(P_+^*)\right] x^*(s)^2 \\ &\geq 0.\end{aligned}$$

Thus, all the inequalities above become equalities and, noting that $x^*(s) \neq 0$, one has $K(s) = \xi_+(P_+^*)$ and $L_+(P_+^*) = 0$. As a result, $u^*(s) \equiv K(s)x^*(s) = \xi_+(P_+^*)x^*(s)$ at s when $x^*(s) > 0$. Similarly, we can prove that $u^*(s) = -\xi_-(P_-^*)x^*(s)$ at s when $x^*(s) \leq 0$, and $L_-(P_-^*) = 0$. To summarize, we have shown that any optimal control $u^*(\cdot)$ can be represented by (51), and hence the uniqueness of optimal control follows. On the other hand, we have also proved that P_+^* and P_-^* are solutions to the EAREs (45) and (46), respectively. Moreover, they must be stabilizing solutions because $u^*(\cdot)$, which is now represented by (51), is a stabilizing control. □

Remark 6.1. Theorem 6.3 shows that the existence of stabilizing solutions to the EAREs (45) and (46) is *almost* necessary for the attainability of problem (LQ). The only exception, as also demonstrated by Example 6.1, is the "singular" case when $(R + P\sum_{j=1}^k D_j' D_j)|_\Gamma = 0$ for *all* elements P in at least one of the sets $\mathcal{P}_+$ and $\mathcal{P}_-$.

6.3. Existence of stabilizing solutions to EAREs. Theorem 6.2 asserts that if one can find stabilizing solutions to the EAREs, then the original optimal LQ control can be solved completely and explicitly in terms of obtaining the optimal feedback control as well as the value function. The next natural questions are, then, *when* do the EAREs admit stabilizing solutions, and *how* do we find them? These are the issues that we are going to address in this subsection. Indeed, we will identify and discuss three cases when the EAREs do have the stabilizing solutions.

THEOREM 6.4. *If there exist* $P_+^{(0)}$, $P_-^{(0)}$ *satisfying*

$$L_+(P_+^{(0)}) \geq 0, \quad \left(R + P_+^{(0)} \sum_{j=1}^{k} D_j' D_j\right)\Big|_\Gamma > 0, \tag{56}$$

$$L_-(P_-^{(0)}) \geq 0, \quad \left(R + P_-^{(0)} \sum_{j=1}^{k} D_j' D_j\right)\Big|_\Gamma > 0, \tag{57}$$

and

$$F_+(\xi_+(P_+^{(0)})) < 0, \quad F_-(\xi_-(P_-^{(0)})) < 0, \tag{58}$$

then the EAREs (45) *and* (46) *admit unique stabilizing solutions* P_+^* *and* P_-^**, respectively.*

Proof. If $L_+(P_+^{(0)}) = 0$, then $P_+^{(0)}$ is the stabilizing solution to (45) and we are done. So let us assume that $L_+(P_+^{(0)}) \equiv (2A + \sum_{j=1}^k C_j^2)P_+^{(0)} + Q + \Phi_+(P_+^{(0)}) > 0$, namely,

$$F_+(\xi_+(P_+^{(0)}))P_+^{(0)} + Q + \xi_+(P_+^{(0)})' R \xi_+(P_+^{(0)}) > 0.$$

Since $F_+(\xi_+(P_+^{(0)})) < 0$, we have

$$P_+^{(0)} < -\frac{Q + \xi_+(P_+^{(0)})' R \xi_+(P_+^{(0)})}{F_+(\xi_+(P_+^{(0)}))} := P_+^{(1)}. \tag{59}$$

By Lemma 6.2, we have $\xi_+(P_+^{(1)}) \in \mathcal{K}_+$ because $P_+^{(1)} > P_+^{(0)}$. Moreover,

$$\begin{aligned} L_+(P_+^{(1)}) &\equiv \left(2A + \sum_{j=1}^{k} C_j^2\right) P_+^{(1)} + Q + \Phi_+(P_+^{(1)}) \\ &\leq \left(2A + \sum_{j=1}^{k} C_j^2\right) P_+^{(1)} + Q + \xi_+(P_+^{(0)})' \left(R + P_+^{(1)} \sum_{j=1}^{k} D_j' D_j\right) \xi_+(P_+^{(0)}) \\ &\quad + 2\left(B + \sum_{j=1}^{k} C_j D_j\right) P_+^{(1)} \xi_+(P_+^{(0)}) \\ &= 0, \end{aligned} \tag{60}$$

where the last inequality was due to the very definition of $P_+^{(1)}$. Now, if $L_+(P_+^{(1)}) = 0$, then $P_+^{(1)}$ is the stabilizing solution of (45). If $L_+(P_+^{(1)}) < 0$, then, noting that $L_+(\cdot)$ is a strictly decreasing (by Lemma 6.3) continuous function on the interval $[P_+^{(0)}, P_+^{(1)}]$ along with $L_+(P_+^{(0)}) > 0$, we conclude that there exists a unique $P_+^* \in (P_+^{(0)}, P_+^{(1)})$ such that $L_+(P_+^*) = 0$. Clearly $(R + P_+^* \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$, and $\xi_+(P_+^*) \in \mathcal{K}_+$ thanks to Lemma 6.2. Hence P_+^* is the stabilizing solution of (45).

The proof for the existence of the stabilizing solution to the EARE (46) is completely analogous. Finally, the uniqueness of the stabilizing solutions follows from Corollary 6.1. □

THEOREM 6.5. *If there exist* $P_+^{(0)}$, $P_-^{(0)}$ *satisfying*

$$L_+(P_+^{(0)}) > 0, \quad \left(R + P_+^{(0)} \sum_{j=1}^k D_j' D_j \right) \Big|_\Gamma > 0, \tag{61}$$

and

$$L_-(P_-^{(0)}) > 0, \quad \left(R + P_-^{(0)} \sum_{j=1}^k D_j' D_j \right) \Big|_\Gamma > 0, \tag{62}$$

then the EAREs (45) *and* (46) *admit unique stabilizing solutions* P_+^* *and* P_-^**, respectively.*

Proof. Take $K_+ \in \mathcal{K}_+$, which exists by the stabilizability assumption. Set

$$P_+^{(1)} := -\frac{Q + K_+' R K_+}{F_+(K_+)}. \tag{63}$$

It follows from Lemma 5.1 that $P_+^{(1)} \geq P_+^{(0)}$ since $P_+^{(0)} \in \mathcal{P}_+$. Hence

$$\left(R + P_+^{(1)} \sum_{j=1}^k D_j' D_j \right) \Big|_\Gamma > 0.$$

Moreover,

$$\begin{aligned} L_+(P_+^{(1)}) &\equiv \left(2A + \sum_{j=1}^k C_j^2 \right) P_+^{(1)} + Q + \Phi_+(P_+^{(1)}) \\ &\leq \left(2A + \sum_{j=1}^k C_j^2 \right) P_+^{(1)} + Q + K_+' \left(R + P_+^{(1)} \sum_{j=1}^k D_j' D_j \right) K_+ \\ &\quad + 2 \left(B + \sum_{j=1}^k C_j D_j \right) P_+^{(1)} K_+ \\ &= 0. \end{aligned} \tag{64}$$

Applying Lemma 6.1 and noting that $L_+(P_+^{(0)}) > 0$ we get

$$0 < L_+(P_+^{(0)}) - L_+(P_+^{(1)}) \leq (P_+^{(0)} - P_+^{(1)}) F_+(\xi_+(P_+^{(1)})). \tag{65}$$

Hence $F_+(\xi_+(P_+^{(1)})) < 0$ or $\xi_+(P_+^{(1)}) \in \mathcal{K}_+$. Now set

$$P_+^{(2)} := -\frac{Q + \xi_+(P_+^{(1)})' R \xi_+(P_+^{(1)})}{F_+(\xi_+(P_+^{(1)}))}. \tag{66}$$

Again by Lemma 5.1 we obtain $P_+^{(2)} \geq P_+^{(0)}$ and, therefore, $(R+P_+^{(2)} \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$. On the other hand, the fact that $L_+(P_+^{(1)}) \leq 0$ can be rewritten as $P_+^{(2)} \leq P_+^{(1)}$ in view of the relation (66). Moreover, analysis similar to that for $P_+^{(1)}$ above leads to $L_+(P_+^{(2)}) \leq 0$, and $\xi_+(P_+^{(2)}) \in \mathcal{K}_+$ or $F_+(\xi_+(P_+^{(2)})) < 0$.

In general, we construct iteratively the following sequence:

$$P_+^{(i+1)} := -\frac{Q + \xi_+(P_+^{(i)})' R \xi_+(P_+^{(i)})}{F_+(\xi_+(P_+^{(i)}))}, \quad i = 1, 2, \ldots. \tag{67}$$

An induction argument shows that $P_+^{(0)} \leq \cdots \leq P_+^{(i+1)} \leq P_+^{(i)} \cdots \leq P_+^{(1)}$, $(R + P_+^{(i)} \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$, $L_+(P_+^{(i)}) \leq 0$, and $\xi_+(P_+^{(i)}) \in \mathcal{K}_+$, $i = 1, 2, \ldots$. Since the sequence $\{P_+^{(i)}\}$ is decreasing with a lower bound $P_+^{(0)}$, there exists $P_+^* \in \mathbf{R}$ so that $P_+^* = \lim_{i\to\infty} P_+^{(i)}$. Moreover it is clear that $(R + P_+^* \sum_{j=1}^k D_j' D_j)|_\Gamma \geq (R + P_+^{(0)} \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$. On the other hand, $L_+(P_+^*) \leq 0$ since each $L_+(P_+^{(i)}) \leq 0$. Thus an argument similar to (65) yields $\xi_+(P_+^*) \in \mathcal{K}_+$ or $F_+(\xi_+(P_+^*)) < 0$. As a result, we can pass the limit in (67) to obtain $P_+^* = -\frac{Q+\xi_+(P_+^*)' R \xi_+(P_+^*)}{F_+(\xi_+(P_+^*))}$, which is equivalent to $L_+(P_+^*) = 0$. This shows that P_+^* is the stabilizing solution to (45). Similarly we can prove that (46) admits the stabilizing solution. □

Remark 6.2. Recall that Theorem 5.1 characterizes the well-posedness of problem (LQ) by the nonemptiness of the sets $\mathcal{P}_+$ and $\mathcal{P}_-$. Theorems 6.4 and 6.5 spell out two important cases when the EAREs (45) and (46) have stabilizing solutions and, therefore, problem (LQ) can be completely solved with explicit solutions. These two cases are specified in terms of the existence of certain "special elements" of the sets $\mathcal{P}_+$ and $\mathcal{P}_-$. Specifically, the case with Theorem 6.4 is one when each of $\mathcal{P}_+$ and $\mathcal{P}_-$ has a "stabilizing element" in the sense that (58) holds. On the other hand, Theorem 6.5 asserts that the nonemptiness of the *interiors* of $\mathcal{P}_+$ and $\mathcal{P}_-$ is sufficient for the existence of stabilizing solutions to the EAREs. In view of the fact that the nonemptiness of $\mathcal{P}_+$ and $\mathcal{P}_-$ is the minimum requirement for the underlying LQ problem to be meaningful, the sufficient conditions respectively given in Theorems 6.4 and 6.5 are very mild indeed.

Remark 6.3. The proof of Theorem 6.5 constitutes an algorithm for finding the stabilizing solutions to the EAREs. In fact it is given by the iterative scheme (67) with an initial point (63). On the other hand, although the proof of Theorem 6.4 has not given an explicit algorithm for computing the stabilizing solutions, one can use a middle-point algorithm to find them based on the proof. Alternatively, one may use the same iterative scheme (67) with the initial point, $P_+^{(1)}$, given by (59). It can be proved, using almost the same analysis as that in the proof of Theorem 6.5, that the constructed sequence converges to the desired point, P_+^*. The only argument that needs to be modified is that for proving $\xi_+(P_+^*) \in \mathcal{K}_+$. In this case, $\xi_+(P_+^*) \in \mathcal{K}_+$ is seen from the fact that $P_+^* \geq P_+^{(0)}$ and $\xi_+(P_+^{(0)}) \in \mathcal{K}_+$ as well as from Lemma 6.2.

Finally we present the results on the definite case $Q \geq 0$ and $R|_\Gamma \geq 0$ (including the so-called singular case when R is allowed to be *singular*).

THEOREM 6.6. *Assume $Q \geq 0$ and $R|_\Gamma \geq 0$. Then the EAREs* (45) *and* (46) *admit unique stabilizing solutions P_+^* and P_-^*, respectively, under one of the following additional conditions:*

(i) *$Q > 0$ and $R|_\Gamma > 0$.*

(ii) *$Q = 0$, $R|_\Gamma > 0$, and $2A + \sum_{j=1}^k C_j^2 \neq 0$.*

(iii) *$Q > 0$, $R|_\Gamma \geq 0$, and $\sum_{j=1}^k D_j' D_j|_\Gamma > 0$.*

Proof. (i) In this case $P_+^{(0)} = P_-^{(0)} = 0$ satisfy the assumption of Theorem 6.5.

(ii) If $2A + \sum_{j=1}^k C_j^2 < 0$, then take $P_+^{(0)} = P_-^{(0)} = 0$. We see that $L_+(P_+^{(0)}) = L_-(P_-^{(0)}) = Q = 0$ and $F_+(\xi_+(P_+^{(0)})) = F_-(\xi_-(P_-^{(0)})) = 2A + \sum_{j=1}^k C_j^2 < 0$. Thus the assumption of Theorem 6.4 is satisfied.

If $2A + \sum_{j=1}^k C_j^2 > 0$, due to the stabilizability assumption there is $0 \neq K_+ \in \mathcal{K}_+$. Set $P_+^{(1)} := -\frac{K_+' R K_+}{F_+(K_+)}$. As $F_+(K_+) < 0$, $R|_\Gamma > 0$, and $K_+ \neq 0$, we have $P_+^{(1)} > 0$. Define

$$P_+^{(i+1)} := -\frac{\xi_+(P_+^{(i)})' R \xi_+(P_+^{(i)})}{F_+(\xi_+(P_+^{(i)}))}, \quad i = 1, 2, \ldots. \tag{68}$$

Then an analysis similar to that in the proof of Theorem 6.5 leads to $0 \leq \cdots \leq P_+^{(i+1)} \leq P_+^{(i)} \cdots \leq P_+^{(1)}$, $(R + P_+^{(i)} \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$, $L_+(P_+^{(i)}) \leq 0$, and $\xi_+(P_+^{(i)}) \in \mathcal{K}_+$, $i = 1, 2, \ldots$. Hence there exists $P_+^* \geq 0$ so that $P_+^* = \lim_{i\to\infty} P_+^{(i)}$. Moreover $(R + P_+^* \sum_{j=1}^k D_j' D_j)|_\Gamma \geq R|_\Gamma > 0$. Note that at this point we can no longer apply the same argument as that used in the proof of Theorem 6.5 to conclude $F_+(\xi_+(P_+^*)) < 0$, because the element 0, which substitutes the point $P_+^{(0)}$ of Theorem 6.5, does not satisfy $L_+(0) > 0$. To get around this, let us suppose $F_+(\xi_+(P_+^*)) = 0$ (recall that it always holds that $F_+(\xi_+(P_+^*)) \leq 0$ since $F_+(\xi_+(P_+^{(i)})) < 0$). Multiplying (68) by $F_+(\xi_+(P_+^{(i)}))$ and then passing to the limit, we obtain $\xi_+(P_+^*)' R \xi_+(P_+^*) = 0$, resulting in $\xi_+(P_+^*) = 0$. Thus $F_+(\xi_+(P_+^*)) = 2A + \sum_{j=1}^k C_j^2 > 0$, which is a contradiction. This proves that $F_+(\xi_+(P_+^*)) < 0$. The rest of the proof is the same as that of Theorem 6.5.

(iii) First note that for any $P > 0$,

$$\begin{aligned} 0 &\geq \Phi_+(P) \\ &\geq \inf_{K\in\Gamma} K' R K + P \inf_{K\in\Gamma} \left[K' \sum_{j=1}^k D_j' D_j K + 2 \left(B + \sum_{j=1}^k C_j D_j \right) K \right] \\ &= P \inf_{K\in\Gamma} \left[K' \sum_{j=1}^k D_j' D_j K + 2 \left(B + \sum_{j=1}^k C_j D_j \right) K \right]. \end{aligned}$$

Hence $\lim_{P\to 0+} \Phi_+(P) = 0$. Since $Q > 0$, we have, by the definition of $L_+(\cdot)$, that there exists $P_+^{(0)} > 0$ so that $L_+(P_+^{(0)}) > 0$. On the other hand, it is clear that $(R + P_+^{(0)} \sum_{j=1}^k D_j' D_j)|_\Gamma \geq P_+^{(0)} \sum_{j=1}^k D_j' D_j \Big|_\Gamma > 0$. Consequently Theorem 6.5 applies. □

One may be curious about what happens if $Q = 0$, $R|_\Gamma > 0$, and $2A + \sum_{j=1}^k C_j^2 = 0$ (refer to Theorem 6.6(ii)). It turns out that in this case the EAREs *never* admit stabilizing solutions.

PROPOSITION 6.1. *Neither* (45) *nor* (46) *admits any stabilizing solution when* $Q = 0$, $R|_\Gamma > 0$, *and* $2A + \sum_{j=1}^k C_j^2 = 0$.

Proof. By Assumption 6.1, there exists $0 \neq K_+ \in \mathcal{K}_+$ and $0 \neq K_- \in \mathcal{K}_-$ since $F_+(0) = F_-(0) = 0$. Denote $K_+^\varepsilon := \varepsilon K_+$ and $K_-^\varepsilon := \varepsilon K_-$ for $\varepsilon \in (0, 1]$. Then $K_+^\varepsilon \in \Gamma$ and $K_-^\varepsilon \in \Gamma$.

For any fixed $P_+ > 0$, set $\varepsilon := \min\left\{\frac{-P_+F_+(K_+)}{2K_+'RK_+}, 1\right\} \in (0, 1]$. Then

$$\begin{aligned}
L_+(P_+) &= \Phi_+(P_+) \\
&\leq (K_+^\varepsilon)' \left(R + P_+ \sum_{j=1}^k D_j' D_j\right) K_+^\varepsilon + 2P_+ \left(B + \sum_{j=1}^k C_j D_j\right) K_+^\varepsilon \\
&\leq \varepsilon \left\{\varepsilon K_+' R K_+ + P_+ \left[K_+' \sum_{j=1}^k D_j' D_j K_+ + 2\left(B + \sum_{j=1}^k C_j D_j\right) K_+\right]\right\} \\
&\leq \varepsilon \left[\frac{-P_+F_+(K_+)}{2K_+'RK_+}(K_+'RK_+) + P_+F_+(K_+)\right] \\
&= \frac{\varepsilon}{2} P_+ F_+(K_+) \\
&< 0.
\end{aligned}$$

This implies that there exists no *positive* solution to the EARE (45).

Next, for any fixed $P_+ < 0$ with $(R + P_+ \sum_{j=1}^k D_j' D_j)|_\Gamma > 0$, set

$$\varepsilon := \min\left\{\frac{-|P_+|F_-(K_-)}{2K_-'RK_-}, 1\right\} \in (0, 1].$$

Then

$$\begin{aligned}
L_+(P_+) &= \Phi_+(P_+) \\
&\leq (K_-^\varepsilon)' \left(R + P_+ \sum_{j=1}^k D_j' D_j\right) K_-^\varepsilon + 2P_+ \left(B + \sum_{j=1}^k C_j D_j\right) K_-^\varepsilon \\
&\leq \varepsilon \left\{\varepsilon K_-' R K_- + |P_+| \left[K_-' \sum_{j=1}^k D_j' D_j K_- - 2\left(B + \sum_{j=1}^k C_j D_j\right) K_-\right]\right\} \\
&\leq \varepsilon \left[\frac{-|P_+|F_-(K_-)}{2K_-'RK_-}(K_-'RK_-) + |P_+|F_-(K_-)\right] \\
&= \frac{\varepsilon}{2}|P_+|F_-(K_-) \\
&< 0.
\end{aligned}$$

Hence there is no *negative* solution to the EARE (45).

Finally, when $P_+ = 0$, we do have $L_+(P_+) = 0$ but $F_+(\xi_+(P_+)) = F_+(0) = 0$. So $P_+ = 0$ is not a stabilizing solution either.

Similarly, we can prove the nonexistence of a stabilizing solution to (46). □

Although the conclusion of Proposition 6.1 does not necessarily lead to the nonexistence of optimal feedback control for the corresponding LQ problem (refer to section 6.2), the following example shows that the latter could indeed occur.

Example 6.2. Consider the LQ problem

$$\begin{aligned} &\text{minimize} && J(x_0;u(\cdot)) = \mathbf{E}\int_0^{+\infty} r|u(t)|^2 dt \\ &\text{subject to} && \begin{cases} dx(t) = [ax(t)+bu(t)]dt + cx(t)dw(t), \\ x(0) = x_0, \end{cases} \end{aligned} \tag{69}$$

where all the variables are scalar-valued, $\Gamma = \mathbf{R}$, $2a + c^2 = 0$, $b > 0$, and $r > 0$. It is easy to verify that the problem is stabilizable and well-posed. Take a feedback control $u^\varepsilon(t) = -\varepsilon x^\varepsilon(t)$ for $\varepsilon > 0$. Under this control the state satisfies

$$\mathbf{E}|x^\varepsilon(t)|^2 = e^{(2a+c^2-2b\varepsilon)t}x_0^2 = e^{-2b\varepsilon t}x_0^2.$$

Hence u^ε is stabilizing. Moreover, the cost under this control is

$$J(x_0;u^\varepsilon(\cdot)) = \varepsilon^2 r^2 \mathbf{E}\int_0^{+\infty} |x^\varepsilon(t)|^2 dt = \frac{r^2 x_0^2}{2b}\varepsilon.$$

Letting $\varepsilon \to 0$ we see that $V(x_0) = 0$ $\forall x_0 \in \mathbf{R}$. Note that this value cannot be attained if $x_0 \neq 0$, for whenever $\mathbf{E}\int_0^{+\infty} r|u^*(t)|^2 dt = 0$ it is necessary that $u^*(t) = 0$, a.e. $t \geq 0$. However, this control, $u^*(t)$, is *not* stabilizable when $x_0 \neq 0$. In other words, the LQ problem is not attainable with respect to $x_0 \neq 0$.

Remark 6.4. Theorem 6.6(i),(ii) and Proposition 6.1 together with Example 6.2 give a complete answer to the question of optimality for problem (LQ) in the classical definite case $Q \geq 0$ and $R|_\Gamma > 0$. Moreover, Theorem 6.6(iii) addresses the case when R is possibly singular. Note that this case occurs often in financial applications (where typically $R = 0$).

Remark 6.5. In view of Theorem 6.2, under the respective assumptions of Theorems 6.4, 6.5, and 6.6, problem (LQ) has the optimal feedback control (51) and the value function (52). Moreover, as per Remark 5.6, in these cases the stabilizing solutions P_+^* and P_-^* can also be obtained, in addition to the preceding algorithms, by solving the mathematical programs (33) and (34) if the corresponding constraints are tractable.

7. Numerical examples. To numerically calculate the optimal solution to problem (LQ) one needs to carry out two steps: the first is to check the conic stabilizability and the well-posedness, and the second is to find the stabilizing solutions to the EAREs. The procedures for the first step are depicted in sections 4 and 5.3, whereas that for the second part is described in section 6. Here we give an example to illustrate the whole process (where we used the computing tool *Scilab* to carry out all the calculations).

Example 7.1. Consider problem (LQ) with $m = k = 3$, $\Gamma = \mathbf{R}^3_+$, and the dynamics coefficients as follows:

$$\begin{aligned} &A = 2.00, && B = (-50 \quad -100 \quad 200), \\ &C_1 = -0.84, && D_1 = (6.85 \quad -8.78 \quad 0.68), \\ &C_2 = -3.78, && D_2 = (11.22 \quad 13.24 \quad 14.53), \\ &C_3 = 0.849, && D_3 = (-1.98 \quad -5.44 \quad -2.32). \end{aligned}$$

The eigenvalues of $\sum_{j=1}^3 D_j' D_j$ are 1.5880509, 126.23912, and 547.84943. So $\sum_{j=1}^3 D_j' D_j$ is positive definite in this case. The cost parameters are

$$Q = 10, \quad R = \begin{pmatrix} 0 & 0 & 0 \\ 0 & -5.0 & 0 \\ 0 & 0 & 4.0 \end{pmatrix}.$$

Hence this is an indefinite LQ problem.

To solve this problem, we first apply Theorem 4.1(iii) (note that in this example the constraint $K \in \mathbf{R}^3_+$ is also an LMI) to obtain stabilizing feedback gains

$$K_+ = \begin{pmatrix} 0.5435353 \\ 0.5307289 \\ 0.0701460 \end{pmatrix}, \quad K_- = \begin{pmatrix} 0.0816967 \\ 0.0562570 \\ 0.7185273 \end{pmatrix}.$$

Next we use the algorithm in section 5.3 to find out that problem (LQ) is well-posed. Furthermore, when $P_+^{(0)} = P_-^{(0)} = 0.1$, the eigenvalues of $R + 0.1 * \sum_{j=1}^{3} D_j' D_j$ are 1.641309, 10.293806, and 54.632545; hence $R + 0.1 * \sum_{j=1}^{3} D_j' D_j > 0$. On the other hand, $L_+(0.1) = 1.6073676 > 0$ and $L_-(0.1) = 4.0651986 > 0$. According to Theorem 6.5, problem (LQ) has an optimal feedback control. Now we use the algorithm given in the proof of Theorem 6.5 to obtain the optimal control and optimal value. First, set the initial values $P_+^{(1)}$ and $P_-^{(1)}$ by using K_+, K_- and formulas similar to (63), respectively. They are

$$P_+^{(1)} = 1.1814412, \quad P_-^{(1)} = 13.167238.$$

By the iterative formula (67), we obtain

$$P_+^* = 0.1225762, \quad \xi_+(P_+^*) = \begin{pmatrix} 0.2889240 \\ 0.4918755 \\ 0 \end{pmatrix},$$

$$P_-^* = 0.1561608, \quad \xi_-(P_-^*) = \begin{pmatrix} 0 \\ 0 \\ 0.5875815 \end{pmatrix}.$$

Therefore, the optimal feedback control is

$$u^*(t) = \begin{pmatrix} 0.2889240 \\ 0.4918755 \\ 0 \end{pmatrix} x^+(t) + \begin{pmatrix} 0 \\ 0 \\ 0.5875815 \end{pmatrix} x^-(t),$$

with the optimal cost

$$J^*(x_0) = 0.1225762 * (x_0^+)^2 + 0.1561608 * (x_0^-)^2.$$

In the next example we demonstrate the calculation of a lower bound of the well-posedness margin (refer to section 5.4).

Example 7.2. Using the same values of the coefficients A, B, C_j, D_j, $j = 1, 2, 3$, and Q as in Example 7.1, we want to compute a lower bound of the well-posedness margin r^*.

According to Theorem 5.2, we first calculate $\lambda = 176.7313$. Next we have $\bar{r}_+ = -9.434553$ and $\bar{r}_- = -6.4967141$. Hence, the lower bound of the well-posedness margin is $\bar{r} = -6.4967141$. Note that, as seen in Example 7.1, the problem is still well-posed when one of the eigenvalues of R is -5.

8. Conclusion. In this paper, we studied an indefinite stochastic LQ control problem in the infinite time horizon with conic control constraint. Several key issues, including conic stabilizability, well-posedness, and optimality were addressed

with complete solutions. In particular, two algebraic equations, the EAREs, were newly introduced, in lieu of the classical algebraic Riccati equation, whose stabilizing solutions give rise to the explicit forms of the optimal feedback control and the value function. It was also seen that the representation of the value function given by Proposition 5.1 served as the technical key to all the main results of this paper, which motivated the utilization of the cerebrated Tanaka formula.

It should be stressed again that the approach of this paper crucially depended on the special structure of the problem. One main assumption is that the state of the system is one-dimensional. While the conclusion of Proposition 5.1 appears to hold, mutatis mutandis, for the problem with multidimensional state variable, it seems that an analogy of Lemma 3.2, if any, would be far more complicated. This makes the multidimensional problem very challenging. Another structural property of the model is that the dynamics of the system is homogeneous (in state and control) and the cost contains no first-order term of the state variable as well as no control-state cross term. As a result, our approach will fail, say, for the case when there is no state and control dependent noise, and with fixed variance. Solving these kinds of problems calls for different techniques. Finally, an even more difficult problem is the stochastic LQ control with state constraint.

Acknowledgment. We thank the three anonymous reviewers for their careful reading of an earlier version of the paper and for their constructive comments that led to an improved version.

OPTIMAL MOMENTUM HEDGING VIA HYPOELLIPTIC REDUCED MONGE–AMPÈRE PDEs*

SRDJAN STOJANOVIC†

Abstract. The celebrated optimal portfolio theory of Merton was successfully extended by the author to assets that do not obey Log-Normal price dynamics in [S. Stojanovic, *Computational Financial Mathematics Using Mathematica®: Optimal Trading in Stocks and Options*, Birkhäuser Boston, Boston, 2003]. Namely, a general one-factor model was solved and applied in the case of appreciation-rate reversing market dynamics. Here, we extend a general methodology to solve the stochastic control problem of optimal portfolio hedging under momentum market dynamics: the corresponding HJB PDE is transformed into the associated Monge–Ampère PDE, which is, utilizing the special structure of the problem, further reduced to a lower-dimensional Monge–Ampère PDE, which is then finally solved numerically. The present problem, in addition to being a two-factor model, has a substantive difficulty due to the degeneracy of the underlying Markov process, yielding the hypoellipticity of its infinitesimal generator, and the corresponding degeneracy of all the fully nonlinear PDEs derived. Furthermore, we solve the problem of optimal hedging and pricing of European and American options in momentum markets, derive a hypoelliptic Black–Scholes PDE/obstacle problem, and introduce a notion of options trading opportunity.

Key words. stochastic control, dynamic programming, optional hedging, Merton's problem, hypoellipticity

1. Introduction.

Optimal portfolio hedging under Log-Normal price dynamics is introduced and solved in the seminal work in the early 1970s by Merton (see, e.g., [6, 7]). More precisely, suppose that the asset market prices are governed by the SDE

$$\boldsymbol{d}S(t) = S(t)a\boldsymbol{d}t + S(t)\sigma.\boldsymbol{d}B(t), \tag{1.1}$$

where, for any t, vector (valued random variable) $S(t) = \{S_1(t), \dots, S_m(t)\}$ is a vector, i.e., a one-dimensional array of asset prices, where vector $a = \{a_1, \dots, a_m\} \in \mathbb{R}^m$ is the vector of appreciation rates of the corresponding assets, $\sigma = \{\{\sigma_{1,1}, \dots, \sigma_{1,n}\}, \dots, \{\sigma_{m,1}, \dots, \sigma_{m,n}\}\} \in \mathbb{R}^m \times \mathbb{R}^n$ is the (volatility) matrix, i.e., a two-dimensional array, and $B(t) = \{B_1(t), \dots, B_n(t)\}$ is a vector of n independent Brownian motions. So, m is the number of tradable assets, while n is the number of independent sources of randomness. In (1.1) the multiplication of two vectors of the same length, such as $S(t)a$, is done componentwise, the multiplication of a vector by a matrix of the same length (a length of a matrix is the number of rows), such as $S(t)\sigma$, is done by multiplying a component of vector $S(t)$ by a row of matrix σ, while the "dot" product between a matrix and a vector, such as $\sigma.\boldsymbol{d}B(t)$, is the usual linear-algebra-matrix–vector multiplication; also one can check easily that in such a framework $(S(t)\sigma).\boldsymbol{d}B(t) = S(t)(\sigma.\boldsymbol{d}B(t))$.

What exactly a and σ are, whether they are constants or only t-dependent functions, or whether they depend possibly in a complicated way on other quantities or on other random events, will make a great deal of difference below. For example, if

†Department of Mathematical Sciences, University of Cincinnati, Cincinnati, OH 45221-0025 (srdjan@math.uc.edu, http://math.uc.edu/~srdjan/).

some of the assets are stock-options, then the evolution of their prices depends on the evolution of underlying stock-prices (in addition to time). Later in this work we shall be very precise about such dependencies.

An investor has a cash account, whose balance at time t, denoted by $C(t)$, is obeying the equation

$$\boldsymbol{d}C(t) = rC(t)\boldsymbol{d}t + \boldsymbol{d}c(t), \tag{1.2}$$

where r is the interest rate and where, much more importantly, the $\boldsymbol{d}c(t)$ are the cumulative cash transactions in ($\boldsymbol{d}c(t) > 0$), or outside ($\boldsymbol{d}c(t) < 0$) of the cash account as a consequence of selling and buying assets during the time interval $\boldsymbol{d}t$ (see [8]).

The total wealth, or designated wealth for this investment exercise, shall be denoted by $X(t)$. It represents the cash value of the whole assets-portfolio, plus the balance in the cash account. The problem is to design a trading, or more precisely, a portfolio hedging strategy. A trading or hedging strategy is going to be any vector-valued function $\Pi(t) = \{\Pi_1(t), \Pi_2(t), \dots, \Pi_m(t)\}$, where $\Pi_j(t) = \Pi_j(t, X, .)$ is the cash value, positive or negative, depending on whether it is a long or short position, of the investment in the jth asset considered for trading.

So, the total portfolio value, i.e., the total wealth, is equal to

$$X(t) = C(t) + \sum_{i=1}^{m} \Pi_i(t). \tag{1.3}$$

It can be derived (see section 7.3.1 of [8]) that

$$\boldsymbol{d}X^{\Pi}(t) = \boldsymbol{d}X(t) = (\Pi(t).(a - r) + rX(t))\boldsymbol{d}t + \Pi(t).\sigma.\boldsymbol{d}B(t), \tag{1.4}$$

where, by definition, $a - r = \{a_1, \dots, a_m\} - r = \{a_1 - r, \dots, a_m - r\}$. This equation is referred to as the wealth evolution SDE. Notice that unless a and σ (or even r) are either constants or functions of t only, the first-order SDE (1.4) is not closed, and its solution will depend on some other equations as well.

The objective of the investor/trader is to maximize the expected value of the utility ψ of the final total wealth:

$$v(t, X, .) = \sup_{\Pi = \Pi(t,X,.)} E_{t,X,.}\psi(X^{\Pi}(T)) = \max_{\Pi} E_{t,X,.}\psi(X^{\Pi}(T)) = E_{t,X,.}\psi(X^{\Pi^*}(T)), \tag{1.5}$$

where $E_{t,X,.}$ is the conditional expectation under the condition that at time t the total portfolio value was equal to X, and under some other conditions generically denoted as ".". Also, most often, the class of utility functions considered is HARA class: $\mathcal{U} = \{\psi_\gamma, 0 < \gamma < \infty\}$, where

$$\psi_\gamma(X) = \frac{X^{1-\gamma}}{1-\gamma} \tag{1.6}$$

for $0 < \gamma \neq 1$, while for $\gamma = 1$

$$\psi_1(X) = \log(X). \tag{1.7}$$

The value function v, corresponding to a HARA utility ψ_γ, will be denoted v_γ. Although we shall not do that in this work, one can solve problems when the class of

admissible portfolio rules Π in (1.5) is constrained in some of the convenient ways (see [8, Chapters 7 and 8]).

It is the celebrated result of Merton that, if a and σ (and r) are functions of t only (or constants), then for any $\gamma \in (0,\infty)$, the *value function* $v_\gamma(t,X,.) = v_\gamma(t,X)$ can be computed explicitly as the unique solution of the Monge–Ampère-type PDE

$$-\frac{1}{2}(a(t)-r(t)).(\sigma(t).\sigma(t)^T)^{-1}.(a(t)-r(t))\left(\frac{\partial v_\gamma(t,X)}{\partial X}\right)^2 + X\frac{\partial^2 v_\gamma(t,X)}{\partial X^2}r(t)\frac{v_\gamma(t,X)}{\partial X} + \frac{\partial v_\gamma(t,X)}{\partial t}\frac{\partial^2 v_\gamma(t,X)}{\partial X^2} = 0 \tag{1.8}$$

together with the terminal condition

$$v_\gamma(T,X) = \psi_\gamma(X) \tag{1.9}$$

and such that $\frac{\partial^2 v_\gamma(t,X)}{\partial X^2} < 0$. The solution is equal to

$$v_\gamma(t,X) = \frac{f(t)X^{1-\gamma}}{1-\gamma} = \frac{\boldsymbol{e}^{\frac{(\gamma-1)\int_t^T (a(\tau)-r(\tau)).(\sigma(\tau).\sigma(\tau)^T)^{-1}.(a(\tau)-r(\tau))+2\gamma r(\tau)\boldsymbol{d}\tau}{-2\gamma}}X^{1-\gamma}}{1-\gamma} \tag{1.10}$$

for $\gamma \neq 1$. (If $\gamma = 1$, another formula holds; see, e.g., [8] and also below.) Equation (1.8) is already quite interesting: notice that if $\gamma \geq 1$, the solution $v_\gamma(t,X) \to -\infty$, when $X \to 0$, while $v_\gamma(t,0) = 0$ for $0 < \gamma < 1$—either way, a boundary value cannot be imposed at $X = 0$ due to the degeneracy of the equation. Furthermore, the Merton optimal portfolio hedging strategy $\Pi^\star_\gamma$ is equal to

$$\begin{aligned}\Pi^\star_\gamma(t,X) &= -\frac{\frac{\partial v_\gamma(t,X)}{\partial X}(\sigma(t).\sigma(t)^T)^{-1}.(a(t)-r(t))}{\frac{\partial^2 v_\gamma(t,X)}{\partial X^2}} \\ &= \frac{X(\sigma(t).\sigma(t)^T)^{-1}.(a(t)-r(t))}{\gamma} = XP^\star_\gamma(t)\end{aligned} \tag{1.11}$$

for any $\gamma \in (0,\infty)$, where

$$P^\star_\gamma(t) = \frac{(\sigma(t).\sigma(t)^T)^{-1}.(a(t)-r(t))}{\gamma} \tag{1.12}$$

is the optimal investment per unit wealth. Of course, above it is assumed that the matrix $\sigma(t).\sigma(t)^T$ is invertible. There will be similar assumptions below which we shall consider self-evident without specifying them explicitly. In [8] the author extends Merton's theory to the case when the underlying asset price dynamics is much more general, yielding complicated Monge–Ampère-type PDEs. The general methodology introduced there will be applied here on a new asset price dynamics, i.e., to the case of *momentum* asset price dynamics. The Monge–Ampère-type PDEs considered here will have an additional *degeneracy* feature; as a matter of fact, we shall consider equations that can be called *hypoelliptic Monge–Ampère-type PDEs*. No theory for such equations exists today.

A model for momentum asset price dynamics was introduced in [8] as

$$\begin{aligned}\boldsymbol{d}Y(t) &= Z(t)\boldsymbol{d}t + \sigma_0\boldsymbol{d}b(t), \\ \boldsymbol{d}Z(t) &= \left(\frac{2\pi}{p}\right)^2(e - Y(t))\boldsymbol{d}t,\end{aligned} \tag{1.13}$$

where $Y(t)$ is the price of the considered security at time t, where $Z(t)$ is the *trend* (or "price velocity"), and where $b(t)$ is a scalar Brownian motion. A Markov process $\{Y(t), Z(t)\}$ is called the Price/Trend process. The parameters of the model are σ_0 (the price-*diffusion*), e (the price-*equilibrium*), and p (the price-dynamics *period*). Notice that in that model $Z(t)$ is not the appreciation rate—$Z(t)/Y(t)$ is—and that σ_0 is not the volatility—$\sigma_0/Y(t)$ is. Notice that if $\sigma_0 = 0$, then (1.13) is equivalent to the second-order ODE

$$Y''(t) + \left(\frac{2\pi}{p}\right)^2 Y(t) = \left(\frac{2\pi}{p}\right)^2 e, \tag{1.14}$$

which is the classical model for (undamped) oscillations around an equilibrium e, with a period of oscillations being equal to p.

Since in the optimal portfolio hedging it is much more convenient to work with appreciation rates (growth rates or maybe, more concisely, *momentum*) and volatilities, we shall introduce below a simple modification of the model (1.13); i.e., we shall introduce the Price/Momentum process.

2. SDE model: Price/Momentum process. We modify here the Price/Trend system (1.13) into a Price/Momentum system; i.e., we *postulate* that the value of a market-index, or an underlying stock-price if options hedging is attempted (see below), is governed (in the short-run) by

$$\begin{aligned} \boldsymbol{d}Y(t) &= Y(t)A(t)\boldsymbol{d}t + Y(t)\sigma\boldsymbol{d}b(t), \\ \boldsymbol{d}A(t) &= \frac{1}{Y(t)}\left(\frac{2\pi}{p}\right)^2 (e - Y(t))\boldsymbol{d}t \end{aligned} \tag{2.1}$$

for $0 < t < T$, with an initial condition

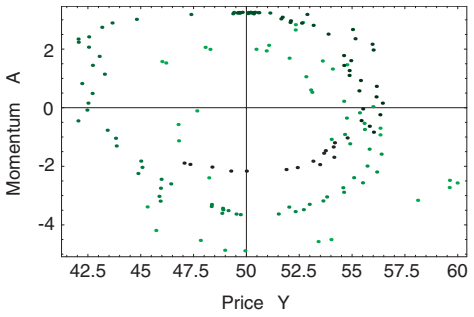
$$\begin{aligned} Y(0) &= Y_0, \\ A(0) &= A_0, \end{aligned} \tag{2.2}$$

where $Y(t)$ is the price or value of the asset at time t, while $A(t)$ is the growth rate or, more concisely, *momentum*. Notice that, unfortunately, in real trading the momentum $A(t)$ is not going to be observable—only the current price $Y(t)$ is. So, $A(t)$ would have to be estimated; i.e., one would have to compute $E[A(t)|Y(s), s \le t]$. Actually, it is not difficult, using the Liptser and Shiryaev theory of optimal filtering of conditionally Gaussian processes (see, e.g., [8] and references given there) that if $A(0) \sim N[m_0, g_0]$, then $m(t) = E[A(t)|Y(s), s \le t]$ can be computed from the equation

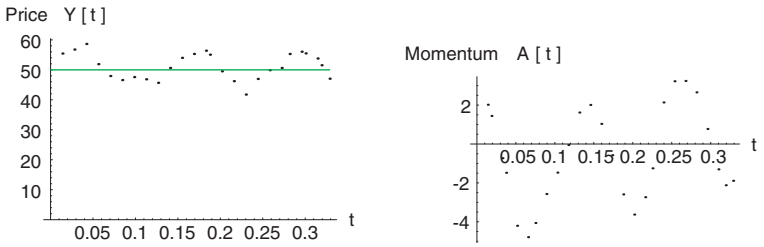
$$\begin{aligned} \boldsymbol{d}m(t) &= \left(\frac{2\pi}{p}\right)^2 \frac{(e - Y(t))}{Y(t)}\boldsymbol{d}t + \frac{g_0^2}{\sigma^2 + tg_0^2}\left(\frac{\boldsymbol{d}Y(t)}{Y(t)} - m(t)\boldsymbol{d}t\right), \\ m(0) &= m_0. \end{aligned} \tag{2.3}$$

Knowing $m(t)$ as opposed to knowing $A(t)$ would ideally have to be taken into account when computing an optimal hedging strategy. We shall not do that and we shall simply assume that $A(t)$, along with $Y(t)$, are observable or, equivalently, that $g_0 = 0$.

The model (2.1) is somewhat different from (1.13) and indeed may seem a bit arbitrary. Possibly the best defense are the Monte-Carlo experiments. For example, a single trajectory in the *phase plane*, for $e = 50$, $p = 60/365$, $Y_0 = 50, A_0 = 3$, and $0 < t < T = 2p$, looks like



The phase-plane plot does not refer to time. So, in order to see time dependence, we need two plots—one for the Price-trajectory and one for the Momentum-trajectory:



Notice that the momentum $A(t)$ is smooth, while the price $Y(t)$ is not.

It is not difficult to see that the infinitesimal generator of the Markov process $\{Y(t), A(t)\}_t$ is equal to

$$\mathcal{A} = \frac{1}{2}\sigma^2 Y^2 \frac{\partial^2}{\partial Y^2} + AY\frac{\partial}{\partial Y} + \frac{e-Y}{Y}\left(\frac{2\pi}{p}\right)^2 \frac{\partial}{\partial A}. \tag{2.4}$$

Operator $\mathcal{A}$ is quite interesting in $\{\{Y, A\}, Y > 0\}$. Indeed, $\frac{e-Y}{Y}$ changes sign at $Y = e$, and therefore $\mathcal{A}$ is backward parabolic in $Y < e$, and forward parabolic in $Y > e$. As a matter of fact, operator $\mathcal{A}$ is hypoelliptic in $\{\{Y, A\}, Y > 0\}$ (see [3]). Indeed, let a first-order differential operator X_1 be defined as

$$X_1 = \frac{1}{\sqrt{2}}\sigma Y \frac{\partial}{\partial Y}. \tag{2.5}$$

Then

$$X_1{}^2 = \left(\frac{1}{\sqrt{2}}\sigma Y\frac{\partial}{\partial Y}\right)\left(\frac{1}{\sqrt{2}}\sigma Y\frac{\partial}{\partial Y}\right) = \frac{1}{2}\sigma^2 Y\frac{\partial}{\partial Y} + \frac{1}{2}\sigma^2 Y^2\frac{\partial^2}{\partial Y^2}. \tag{2.6}$$

Therefore, if X_0 is a differential operator defined as

$$X_0 = \mathcal{A} - X_1{}^2 = \left(A - \frac{1}{2}\sigma^2\right) Y\frac{\partial}{\partial Y} + \frac{e-Y}{Y}\left(\frac{2\pi}{p}\right)^2\frac{\partial}{\partial A}, \tag{2.7}$$

then $\mathcal{A} = X_1{}^2 + X_0$. Notice that at $Y = e$, $\mathrm{Span}[X_0, X_1] \neq T_{(Y,A)}\mathbb{R}^2$. Nevertheless

the commutator can be computed to be

(2.8)
$$[X_0, X_1] = X_0X_1 - X_1X_0 = \left(\left(A - \frac{1}{2}\sigma^2\right) Y\frac{\partial}{\partial Y} + \frac{e-Y}{Y}\left(\frac{2\pi}{p}\right)^2 \frac{\partial}{\partial A}\right)\left(\frac{1}{\sqrt{2}}\sigma Y\frac{\partial}{\partial Y}\right)$$
$$- \left(\frac{1}{\sqrt{2}}\sigma Y\frac{\partial}{\partial Y}\right)\left(\left(A - \frac{1}{2}\sigma^2\right) Y\frac{\partial}{\partial Y} + \frac{e-Y}{Y}\left(\frac{2\pi}{p}\right)^2 \frac{\partial}{\partial A}\right) = \frac{1}{\sqrt{2}}\sigma\frac{e}{Y}\left(\frac{2\pi}{p}\right)^2 \frac{\partial}{\partial A},$$

and therefore, for any $Y \neq 0$ (see [3]),

(2.9)
$$\begin{aligned}\mathrm{Span}[\mathrm{Lie}[X_0, X_1]][Y, A] &= \mathrm{Span}[X_0, X_1, [X_0, X_1]][Y, A]\\ &= \mathrm{Span}\left[\frac{\partial}{\partial Y}, \frac{\partial}{\partial A}\right][Y, A] = T_{(Y,A)}\mathbb{R}^2,\end{aligned}$$

and consequently the Hörmander condition holds in $\{Y > 0\}$, and operator $\mathcal{A}$ is hypoelliptic there. From the applied point of view, the importance of hypoellipticity lies in the (numerical) solvability of the boundary value problems that will follow, as well as for the computational strategy. We notice, however, that in regard to the theoretical solvability of some of the problems below hypoelliptic Monge–Ampère-type PDEs are too difficult and still beyond the current theoretical reach. We hope that these applied considerations may provide some guidance to the theoretical investigations as well.

3. Optimal momentum portfolio hedging problem. Now consider an index (or underlying stock) with value (price) $Y(t)$ obeying the dynamics (2.1) or, a bit more generally, the dynamics

(3.1)
$$\begin{aligned}\boldsymbol{d}Y(t) &= Y(t)A(t)\boldsymbol{d}t + Y(t)\sigma_y(t, Y(t), A(t)).\boldsymbol{d}B(t),\\ \boldsymbol{d}A(t) &= \frac{1}{Y(t)}\left(\frac{2\pi}{p}\right)^2 (e - Y(t))\boldsymbol{d}t,\end{aligned}$$

where the vector-valued function $\sigma_y(t, Y, A) = \{\sigma_{y,1}(t, Y, A), \dots, \sigma_{y,n}(t, Y, A)\} \in \mathbb{R}^n$ is the vector-volatility of the considered index, and $B(t) = \{B_1(t), \dots, B_n(t)\}$ is the vector of n independent Brownian motions. Now in addition to the index, consider a set of *tradable assets* with prices $S(t) = \{S_1(t), \dots, S_m(t)\}$ obeying the dynamics

(3.2)
$$\boldsymbol{d}S(t) = S(t)a_s(t, Y(t), A(t))\boldsymbol{d}t + S(t)\sigma_s(t, Y(t), A(t)).\boldsymbol{d}B(t),$$

where the vector-valued function $a_s(t, Y, A) = \{a_{s,1}(t, Y, A), \dots, a_{s,m}(t, Y, A)\} \in \mathbb{R}^m$ is the vector of appreciation rates of the corresponding assets, and $\sigma_s(t, Y, A) \in \mathbb{R}^m \times \mathbb{R}^n$ is the (volatility) matrix. If the index is tradable (indeed there are securities that represent indices; for example, *qqq*), then it can be represented also as one of the equations in system (3.2). So, the above model attempts to describe a situation when a dominant security or an index, exhibiting a momentum price dynamics described by SDE system (3.1), is driving a number of additional securities considered for trading, whose price dynamics obeys the SDE system (3.2).

Also, we consider the cash account evolving according to (1.2). In such a framework the wealth evolution equation (1.4) still holds, now written more explicitly as

(3.3)
$$\begin{aligned}&\boldsymbol{d}X(t) = (\Pi(t, X(t), Y(t), A(t)).(a_s(t, Y(t), A(t)) - r) + rX(t))\boldsymbol{d}t\\ &+ \Pi(t, X(t), Y(t), A(t)).\sigma_s(t, Y(t), A(t)).\boldsymbol{d}B(t).\end{aligned}$$

In particular, the trading strategies are going to be vector-valued functions of time t, wealth X, index-value Y, and index-momentum A: $\Pi(t,X,Y,A)$. System (3.1), (3.3) is then a closed stochastic system to be controlled ((3.2) is hidden in (3.3)).

For any fixed trading strategy Π, the stochastic process $\mathcal{M}^{\Pi}=\{t,X(t),Y(t),A(t)\}_t$ is a Markov process. We compute its infinitesimal generator $\partial\mathcal{M}^{\Pi}$. To this end, using Itô's chain rule, we get after some calculus (we shall use an alternative notation for partial derivatives: for example, $\varphi^{(0,1,1,0)}=\varphi^{(0,1,1,0)}(t,X,Y,A)=\frac{\partial^2\varphi(t,X,Y,A)}{\partial X\,\partial Y}$)

(3.4)
$$\begin{aligned}
&\boldsymbol{d}\varphi=\varphi^{(1,0,0,0)}\boldsymbol{d}t+\varphi^{(0,1,0,0)}\boldsymbol{d}X(t)+\varphi^{(0,0,1,0)}\boldsymbol{d}Y(t)+\varphi^{(0,0,0,1)}\boldsymbol{d}A(t)+\frac{1}{2}\varphi^{(0,2,0,0)}(\boldsymbol{d}X(t))^2\\
&+\frac{1}{2}\varphi^{(0,0,2,0)}(\boldsymbol{d}Y(t))^2+\varphi^{(0,1,1,0)}\boldsymbol{d}X(t)\boldsymbol{d}Y(t)=\Bigg(\varphi^{(1,0,0,0)}+\varphi^{(0,1,0,0)}(\Pi.(a_s-r)\\
&+rX(t))+\varphi^{(0,0,1,0)}Y(t)A(t)+\varphi^{(0,0,0,1)}\frac{1}{Y(t)}\left(\frac{2\pi}{p}\right)^2(e-Y(t))+\frac{1}{2}\varphi^{(0,2,0,0)}\\
&\Pi.\sigma_s.\sigma_s{}^T.\Pi+\frac{1}{2}\varphi^{(0,0,2,0)}Y(t)^2\sigma_y.\sigma_y+\varphi^{(0,1,1,0)}Y(t)\Pi.\sigma_s.\sigma_y\Bigg)\boldsymbol{d}t+\varphi^{(0,1,0,0)}\Pi.\sigma_s.\boldsymbol{d}B(t)\\
&+\varphi^{(0,0,1,0)}Y(t)\sigma_y.\boldsymbol{d}B(t)=(\varphi^{(1,0,0,0)}+\mathcal{B}^{\Pi}(t)\varphi)\boldsymbol{d}t+\varphi^{(0,1,0,0)}\Pi.\sigma_s.\boldsymbol{d}B(t)\\
&+\varphi^{(0,0,1,0)}Y(t)\sigma_y.\boldsymbol{d}B(t),
\end{aligned}$$

and therefore, for any fixed hedging strategy Π, operator $\partial\mathcal{M}^{\Pi}$ is identified to be

(3.5)
$$\begin{aligned}
\partial\mathcal{M}^{\Pi}&=\frac{\partial}{\partial t}+\mathcal{B}^{\Pi}(t)=\frac{\partial}{\partial t}+(\Pi(t,X,Y,A).(a_s(t,Y,A)-r)+rX)\frac{\partial}{\partial X}+YA\frac{\partial}{\partial Y}\\
&+\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e-Y)\frac{\partial}{\partial A}+\frac{1}{2}\Pi(t,X,Y,A).\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T.\Pi(t,X,Y,A)\frac{\partial^2}{\partial X^2}\\
&+\frac{1}{2}Y^2\sigma_y(t,Y,A).\sigma_y(t,Y,A)\frac{\partial^2}{\partial Y^2}+Y\Pi(t,X,Y,A).\sigma_s(t,Y,A).\sigma_y(t,Y,A)\frac{\partial^2}{\partial X\partial Y}.
\end{aligned}$$

Under *appropriate conditions* on Π, similarly as in the case of operator $\mathcal{A}$ above, operators $\mathcal{B}^{\Pi}(t)$ are hypoelliptic in the semi-infinite domain $\{\{X,Y,A\},X>0,Y>0\}$, and so is $\partial\mathcal{M}^{\Pi}$ in

$$Q_T=\{\{t,X,Y,A\},t<T,X>0,Y>0\}. \tag{3.6}$$

This means, in particular, that for such a fixed hedging strategy Π, if φ is the solution of the *linear* hypoelliptic PDE

$$\partial\mathcal{M}^{\Pi}\varphi=0 \tag{3.7}$$

in Q_T, together with the terminal condition

$$\varphi(T,X,Y,A)=\psi(X,Y,A) \tag{3.8}$$

for some given function ψ, then, due to the hypoellipticity of $\partial\mathcal{M}^{\Pi}$, we have that $\varphi\in C^{\infty}(Q_T)$, and moreover

$$\varphi(t,X,Y,A)=E_{t,X,Y,A}\psi(X(T),Y(T),A(T)). \tag{3.9}$$

The objective of the investor/trader is to, for a given utility function ψ, maximize the expected value of the utility of the final total wealth, i.e., to find an optimal hedging strategy $\Pi^\star(t,X,Y,A)$ such that

(3.10)
$$v(t,X,Y,A)=\sup_{\Pi} E_{t,X,Y,A}\psi(X^{\Pi}(T))=\max_{\Pi} E_{t,X,Y,A}\psi(X^{\Pi}(T))=E_{t,X,Y,A}\psi(X^{\Pi^\star}(T)).$$

Above $E_{t,X,Y,A}$ is the conditional expectation under the condition that at time t the total portfolio value was equal to X, the index had a value Y, and the index-momentum was equal to A. Function $v(t,X,Y,A)$ is the value function.

4. From the HJB to the first Monge–Ampère PDE. The standard formalism for solving the stochastic control problem (3.10) is to attempt to solve the associated Hamilton–Jacobi–Bellman (HJB) PDE characterizing the value function $v=\varphi=\varphi(t,X,Y,A)$:

(4.1)
$$\begin{aligned}\mathrm{Max}[\partial\mathcal{M}^{\Pi}\varphi]=\mathrm{Max}\Big[&\varphi^{(1,0,0,0)}+\varphi^{(0,1,0,0)}(\Pi.(a_s-r)+rX)+\varphi^{(0,0,1,0)}YA\\&+\varphi^{(0,0,0,1)}\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e-Y)+\frac{1}{2}\varphi^{(0,2,0,0)}\Pi.\sigma_s.{\sigma_s}^T.\Pi+\frac{1}{2}\varphi^{(0,0,2,0)}Y^2\sigma_y.\sigma_y\\&+\varphi^{(0,1,1,0)}Y\Pi.\sigma_s.\sigma_y\Big]=0\end{aligned}$$

in the domain Q_T (see (3.6)), with the terminal condition

$$\varphi(T,X,Y,A)=\psi(X). \tag{4.2}$$

We notice that (4.1) is very much degenerate, if considered in the usual way, as a backward "parabolic" equation. Indeed, the linear operator under the max above is only hypoelliptic (due to the term $\varphi^{(0,0,0,1)}\frac{1}{Y}(\frac{2\pi}{p})^2(e-Y)$, whose coefficient changes sign at $Y=e$, and due to the absence of the second-order term $\varphi^{(0,0,0,2)}$). There are additional, less consequential, sources of degeneracies in (4.1), such as the fact that max is taken over all the strategies—think of $\Pi=0$ or, less dramatically, think of any Π proportional to X (as a matter of fact the optimal Π, the one for which the max in (4.1) is realized, and therefore the consequential one, is going to be such). Yet another already explicit degeneracy is at $Y=0$, due to the term $\frac{1}{2}\varphi^{(0,0,2,0)}(t,X,Y,A)Y^2\sigma_y(t,Y,A).\sigma_y(t,Y,A)$. These degeneracies account for lack of the boundary condition there. All of those degeneracies, and especially the first one, yield that (4.1) is beyond what is understood in the *theory* of HJB PDEs today. Our understanding of such equations is based on their equivalence to some simpler equations to be derived below, on their numerical solutions, and on stochastic representations. We rewrite (4.1) by extracting from the max all the terms independent of Π:

$$\begin{aligned}0&=\mathrm{Max}[\partial\mathcal{M}^{\Pi}\varphi]\\&=\varphi^{(1,0,0,0)}+rX\varphi^{(0,1,0,0)}+\varphi^{(0,0,1,0)}YA+\varphi^{(0,0,0,1)}\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e-Y)\\&\quad+\frac{1}{2}\varphi^{(0,0,2,0)}Y^2\sigma_y.\sigma_y+\mathrm{Max}F(\Pi),\end{aligned} \tag{4.3}$$

where

$$F(\Pi) = \varphi^{(0,1,0,0)}\Pi.(a_s - r) + \frac{1}{2}\varphi^{(0,2,0,0)}\Pi.\sigma_s.{\sigma_s}^T.\Pi + \varphi^{(0,1,1,0)}Y\Pi.\sigma_s.\sigma_y. \tag{4.4}$$

Since F is quadratic in Π, to find $\Pi^\star$ such that $\mathrm{Max}_\Pi F(\Pi) = F(\Pi^\star)$, we just need to solve the equation $\nabla F(\Pi) = 0$, yielding

(4.5)

$$\begin{aligned}\Pi^\star(t,X,Y,A) &= -\frac{\varphi^{(0,1,0,0)}}{\varphi^{(0,2,0,0)}}(\sigma_s.{\sigma_s}^T)^{-1}.(a_s - r) - \frac{\varphi^{(0,1,1,0)}}{\varphi^{(0,2,0,0)}}Y(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y \\ &= -\frac{\varphi^{(0,1,0,0)}}{\varphi^{(0,2,0,0)}}(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1} - \frac{\varphi^{(0,1,1,0)}}{\varphi^{(0,2,0,0)}}Y\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}.\end{aligned}$$

We are going to use both expressions in (4.5). Going back to the HJB PDE (4.3), we get (after multiplying by $\varphi^{(0,2,0,0)}$)

$$\begin{aligned}&\varphi^{(0,2,0,0)}\varphi^{(1,0,0,0)} + rX\varphi^{(0,2,0,0)}\varphi^{(0,1,0,0)} + \varphi^{(0,2,0,0)}\varphi^{(0,0,1,0)}YA \\ &+ \varphi^{(0,2,0,0)}\varphi^{(0,0,0,1)}\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e - Y) + \frac{1}{2}\varphi^{(0,2,0,0)}\varphi^{(0,0,2,0)}Y^2\sigma_y.\sigma_y \\ &+ \varphi^{(0,2,0,0)}\varphi^{(0,1,0,0)}\Pi^\star.(a_s - r) + \frac{1}{2}{\varphi^{(0,2,0,0)}}^2\Pi^\star.\sigma_s.{\sigma_s}^T.\Pi^\star \\ &+ \varphi^{(0,2,0,0)}\varphi^{(0,1,1,0)}Y\Pi^\star.\sigma_s.\sigma_y = 0.\end{aligned} \tag{4.6}$$

We also want to plug (4.5) back into (4.6). To this end, we prepare the formulas

$$\begin{aligned}&\varphi^{(0,2,0,0)}\varphi^{(0,1,0,0)}\Pi^\star.(a_s - r) \\ &= \varphi^{(0,1,0,0)}\big(-\varphi^{(0,1,0,0)}(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1} \\ &\quad - \varphi^{(0,1,1,0)}Y\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}\big).(a_s - r) \\ &= -{\varphi^{(0,1,0,0)}}^2(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1}.(a_s - r) \\ &\quad - \varphi^{(0,1,0,0)}\varphi^{(0,1,1,0)}Y\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}.(a_s - r)\end{aligned} \tag{4.7}$$

as well as

(4.8)

$$\begin{aligned}&\frac{1}{2}{\varphi^{(0,2,0,0)}}^2\Pi^\star.\sigma_s.{\sigma_s}^T.\Pi^\star \\ &= \frac{1}{2}{\varphi^{(0,2,0,0)}}^2\left(-\frac{\varphi^{(0,1,0,0)}}{\varphi^{(0,2,0,0)}}(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1} - \frac{\varphi^{(0,1,1,0)}}{\varphi^{(0,2,0,0)}}Y\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}\right).\sigma_s.{\sigma_s}^T \\ &.\left(-\frac{\varphi^{(0,1,0,0)}}{\varphi^{(0,2,0,0)}}(\sigma_s.{\sigma_s}^T)^{-1}.(a_s - r) - \frac{\varphi^{(0,1,1,0)}}{\varphi^{(0,2,0,0)}}Y(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y\right) \\ &= \frac{1}{2}{\varphi^{(0,1,0,0)}}^2(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1}.(a_s - r) + \varphi^{(0,1,0,0)}\varphi^{(0,1,1,0)}Y(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y \\ &+ \frac{1}{2}{\varphi^{(0,1,1,0)}}^2Y^2\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y\end{aligned}$$

and

(4.9)

$$\begin{aligned}&\varphi^{(0,2,0,0)}\varphi^{(0,1,1,0)}Y\Pi^\star.\sigma_s.\sigma_y \\ &= \varphi^{(0,1,1,0)}Y\big(-\varphi^{(0,1,0,0)}(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1} - \varphi^{(0,1,1,0)}Y\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}\big).\sigma_s.\sigma_y \\ &= -Y\varphi^{(0,1,1,0)}\varphi^{(0,1,0,0)}(a_s - r).(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y - {\varphi^{(0,1,1,0)}}^2Y^2\sigma_y.{\sigma_s}^T.(\sigma_s.{\sigma_s}^T)^{-1}.\sigma_s.\sigma_y.\end{aligned}$$

Using (4.7)–(4.9), (4.6) becomes

$$\begin{aligned}
&\varphi^{(0,2,0,0)}\varphi^{(1,0,0,0)}+rX\varphi^{(0,2,0,0)}\varphi^{(0,1,0,0)}+\varphi^{(0,2,0,0)}\varphi^{(0,0,1,0)}YA\\
&+\varphi^{(0,2,0,0)}\varphi^{(0,0,0,1)}\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e-Y)\\
&+\frac{1}{2}\varphi^{(0,2,0,0)}\varphi^{(0,0,2,0)}Y^2\sigma_y.\sigma_y-\varphi^{(0,1,0,0)^2}(a_s-r).(\sigma_s.\sigma_s{}^T)^{-1}.(a_s-r)\\
&-\varphi^{(0,1,0,0)}\varphi^{(0,1,1,0)}Y\sigma_y.\sigma_s{}^T.(\sigma_s.\sigma_s{}^T)^{-1}.(a_s-r)+\frac{1}{2}\varphi^{(0,1,0,0)^2}(a_s-r).(\sigma_s.\sigma_s{}^T)^{-1}.(a_s-r)\\
&+\varphi^{(0,1,0,0)}\varphi^{(0,1,1,0)}Y(a_s-r).(\sigma_s.\sigma_s{}^T)^{-1}.\sigma_s.\sigma_y+\frac{1}{2}\varphi^{(0,1,1,0)^2}Y^2\sigma_y.\sigma_s{}^T.(\sigma_s.\sigma_s{}^T)^{-1}.\sigma_s.\sigma_y\\
&-Y\varphi^{(0,1,1,0)}\varphi^{(0,1,0,0)}(a_s-r).(\sigma_s.\sigma_s{}^T)^{-1}.\sigma_s.\sigma_y\\
&-\varphi^{(0,1,1,0)^2}Y^2\sigma_y.\sigma_s{}^T.(\sigma_s.\sigma_s{}^T)^{-1}.\sigma_s.\sigma_y=0,
\end{aligned}$$

and consequently

$$\begin{aligned}
&\varphi^{(0,2,0,0)}\varphi^{(1,0,0,0)}+rX\varphi^{(0,2,0,0)}\varphi^{(0,1,0,0)}+\varphi^{(0,2,0,0)}\varphi^{(0,0,1,0)}YA\\
&+\varphi^{(0,2,0,0)}\varphi^{(0,0,0,1)}\frac{1}{Y}\left(\frac{2\pi}{p}\right)^2(e-Y)\\
&+\frac{1}{2}\varphi^{(0,2,0,0)}\varphi^{(0,0,2,0)}Y^2\sigma_y.\sigma_y-\frac{1}{2}\varphi^{(0,1,0,0)^2}(a_s-r).(\sigma_s.\sigma_s{}^T)^{-1}.(a_s-r)\\
&-\varphi^{(0,1,0,0)}\varphi^{(0,1,1,0)}Y\sigma_y.\sigma_s{}^T.(\sigma_s.\sigma_s{}^T)^{-1}.(a_s-r)\\
&-\frac{1}{2}\varphi^{(0,1,1,0)^2}Y^2\sigma_y.\sigma_s{}^T.(\sigma_s.\sigma_s{}^T)^{-1}.\sigma_s.\sigma_y=0
\end{aligned}\tag{4.10}$$

in the domain Q_T (see (3.6)), together with the terminal condition (4.2), and such that

$$\varphi^{(0,2,0,0)}(t,X,Y,A)<0.\tag{4.11}$$

So, the solution of the HJB PDE (4.1) solves the Monge–Ampère-type PDE (4.10). Equation (4.10) is simpler than (4.1), but it is still fully nonlinear, and strongly degenerate, if considered as backward parabolic. In much the same way as in (4.1), the most interesting term in (4.10) is $\varphi^{(0,2,0,0)}\varphi^{(0,0,0,1)}\frac{1}{Y}(\frac{2\pi}{p})^2(e-Y)$—the coefficient changes sign at $Y=e$, and (4.10) has no second-order term $\varphi^{(0,0,0,2)}$. Indeed, it yields a sort of a "hypoellipticity" of the Monge–Ampère equation (4.10). Also, other degeneracies are explicit now; at $X=0$ the degeneracy is due to the term $rX\varphi^{(0,1,0,0)}(t,X,Y,A)\varphi^{(0,2,0,0)}(t,X,Y,A)$, and similarly at $Y=0$. Consequently, the boundary condition is not imposed at $X=0$ and $Y=0$. Only the terminal condition (4.2) is imposed. One can compare (4.10) and (1.8)—they are analogous, (4.10) being so much more complicated.

5. From the first Monge–Ampère PDE to the reduced Monge–Ampère PDE. So far, we could have worked with pretty much any wealth-utility function $\psi(X)$. For example, the nonconcave or even the discontinuous utility function $\psi(X)$ (such a problem arises, for example, if one attempts to maximize a probability of reaching a certain wealth by the given deadline) would contradict (4.11), which would cause the terminal condition (4.2) to not be taken in a continuous way. Nevertheless, everything would work just fine, at least from the point of view of numerical solutions

and stochastic control, i.e., financial implications. On the other hand, from now on, the most fruitful study will be very much dependent on restricting our attention to the HARA class $\mathcal{U} = \{\psi_\gamma(X), \gamma > 0\}$ (see (1.6) and (1.7)). Furthermore, we shall have to restrict ourselves to the subclass $\mathcal{U}_1 = \{\psi_\gamma(X), \gamma \geq 1\}$. This is not a serious disadvantage considering the importance of $\mathcal{U}_1$—for the most reasonable investing one indeed has to use utilities ψ_γ for large γ's, since otherwise the investment decisions would be too aggressive and consequently too risky.

How do we solve (4.10), (4.2)? Similarly as was already introduced in [8] and inspired by (1.10), in the case of HARA utility, we seek the solution of (4.10), (4.2) in the form

$$\varphi(t, X, Y, A) = \frac{X^{1-\gamma} f(t, Y, A)}{1-\gamma} \tag{5.1}$$

if $\gamma \neq 1$, or

$$\varphi(t, X, Y, A) = f(t, Y, A) + \log(X) \tag{5.2}$$

in the case $\gamma = 1$. φ being the value function, we call f the *reduced value function.* Plugging (5.1) into (4.10), after symbolic simplifications (see [8] for a similar computation), we arrive at the Monge–Ampère-type PDE for $f(t, Y, A)$:

(5.3)

$$\begin{aligned}
\mathfrak{MA}[f] = {} & -p^2(\gamma-1)\sigma_y(t,Y,A).\sigma_s(t,Y,A)^T.\big(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T\big)^{-1}.\sigma_s(t,Y,A).\sigma_y(t,Y,A) \\
& f^{(0,1,0)}(t,Y,A)^2 Y^3 - p^2(\gamma-1)\big(2r\gamma + (a_s(t,Y,A)-r).\big(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T\big)^{-1}.(a_s(t,Y,A)-r)\big) \\
& f(t,Y,A)^2 Y + f(t,Y,A)\big(Y\big(2Y\big(A\gamma - (\gamma-1)\sigma_y(t,Y,A).\sigma_s(t,Y,A)^T \\
& .\big(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T\big)^{-1}.(a_s(t,Y,A)-r)\big) f^{(0,1,0)}(t,Y,A) \\
& + \gamma(\sigma_y(t,Y,A).\sigma_y(t,Y,A) f^{(0,2,0)}(t,Y,A) Y^2 + 2f^{(1,0,0)}(t,Y,A))\big)p^2 \\
& + 8\pi^2(e-Y)\gamma f^{(0,0,1)}(t,Y,A)\big) = 0
\end{aligned}$$

in the semi-infinite domain $\Omega_{T,\infty} = \{\{t, Y, A\}, t < T, Y > 0\}$, together with the terminal condition

$$f(T, Y, A) = 1 \tag{5.4}$$

in the case $0 < \gamma \neq 1$, or in the case $\gamma = 1$

$$\begin{aligned}
& Y(a_s(t,Y,A)-r).\big(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T\big)^{-1}.(a_s(t,Y,A)-r)p^2 \\
& + Y(\sigma_y(t,Y,A).\sigma_y(t,Y,A) f^{(0,2,0)}(t,Y,A) Y^2 + 2A f^{(0,1,0)}(t,Y,A) Y \\
& + 2(r + f^{(1,0,0)}(t,Y,A)))p^2 + 8\pi^2(e-Y) f^{(0,0,1)}(t,Y,A) = 0
\end{aligned} \tag{5.5}$$

in the same domain $\Omega_{T,\infty}$, together with the terminal condition

$$f(T, Y, A) = 0. \tag{5.6}$$

So, as in Merton's case, the variable X is eliminated. We refer to (5.3)–(5.4) as the *reduced Monge–Ampère PDE of optimal portfolio hedging.* Equations (5.5)–(5.6), on the other hand, are linear.

Due to the term $8\pi^2(e-Y)\gamma f^{(0,0,1)}(t,Y,A) f(t,Y,A)$, which changes sign, as before, at $Y = e$, we can describe (5.3) as the "hypoelliptic Monge–Ampère PDE." Equation (5.3) is also degenerate at $Y = 0$, but this is much less interesting, if not for

other reasons then because this degeneracy can and will be eliminated by truncation of the considered domain.

Also, plugging (5.1) as well as (5.2) into (4.5), we get the optimal portfolio hedging rule

(5.7)
$$\Pi^{\star}_{\gamma}(t,X,Y,A)=\frac{X}{\gamma}\Bigg((\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}.(a_s(t,Y,A)-r) + \frac{f_{\gamma}{}^{(0,1,0)}(t,Y,A)}{f_{\gamma}(t,Y,A)}Y\sigma_y(t,Y,A).\sigma_s(t,Y,A)^T.(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}\Bigg)$$

in the case $\gamma\neq 1$, and

$$\Pi^{\star}_{1}(t,X,Y,A)=X(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}.(a_s(t,Y,A)-r) \tag{5.8}$$

in the case $\gamma=1$. So, the case $\gamma=1$ (as always) is trivial: not only is the "reduced Monge–Ampère PDE" (5.5) linear but it actually does not need to be solved—(5.8) does not depend on f_1. On the other hand, if $\gamma\neq 1$, the optimal hedging strategy (5.7) is given in terms of the solution $f_\gamma=f$ of the reduced Monge–Ampère PDE (5.3). Nevertheless, we see that not only was one of the variables (X) eliminated, but also the optimal portfolio rule $\Pi^\star$ was computed in terms of f and its *first derivative* $f^{(0,1,0)}$, while before, if (4.10) was used, the optimal portfolio rule $\Pi^\star$ (see (4.5)) was computed using first derivative $\varphi^{(0,1,0,0)}$, and second derivatives $\varphi^{(0,2,0,0)}$ and $\varphi^{(0,1,1,0)}$, of the value function φ. Also, since $\varphi\sim X^{1-\gamma}$, the value function φ is extremely flat for large values of X when $\gamma\gg 1$. In practice, those are the values of interest for γ, since otherwise very aggressive trading strategies are inferred (see [8]). By studying the reduced value function f instead of the value function φ, one of the practical consequences is that we can compute the solution of the optimal portfolio hedging problem for large values of γ.

We further emphasize that the optimal portfolio rule $\Pi^\star(t,X,Y,A)$ is again proportional to the wealth:

$$\Pi^{\star}_{\gamma}(t,X,Y,A)=XP^{\star}_{\gamma}(t,Y,A), \tag{5.9}$$

where

(5.10)
$$P^{\star}_{\gamma}(t,Y,A)=\frac{1}{\gamma}\Bigg((\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}.(a_s(t,Y,A)-r) + \frac{f_{\gamma}{}^{(0,1,0)}(t,Y,A)}{f_{\gamma}(t,Y,A)}Y\sigma_y(t,Y,A).\sigma_s(t,Y,A)^T.(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}\Bigg)$$

is the optimal investment per unit of wealth. It is interesting to compare the computed strategy $P^\star_\gamma(t,Y,A)$ with the Merton strategy (1.12). To that end write $P^\star_\gamma(t,Y,A)=M^\star_\gamma(t,Y,A)+S_\gamma(t,Y,A)$, where

$$M^{\star}_{\gamma}(t,Y,A)=\frac{(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}.(a_s(t,Y,A)-r)}{\gamma} \tag{5.11}$$

is Merton's strategy (1.12) as applied directly in the present problem, while

(5.12)
$$S_{\gamma}(t,Y,A)=\frac{1}{\gamma}\frac{f_{\gamma}{}^{(0,1,0)}(t,Y,A)}{f_{\gamma}(t,Y,A)}Y\sigma_y(t,Y,A).\sigma_s(t,Y,A)^T.(\sigma_s(t,Y,A).\sigma_s(t,Y,A)^T)^{-1}$$

for $\gamma \neq 1$ and $S_1(t, Y, A) = 0$ is the correction provided by this methodology, assuming we can compute f_γ.

It turns out that (5.3)–(5.4) is (numerically) solvable in the case $\gamma > 1$. Of course, if numerical solution is attempted, then the semi-infinite domain $\Omega_{T,\infty}$ has to be truncated. So define

$$\Omega_T = \{\{t, Y, A\}, t_{\min} < t < T, y_{\min} < Y < y_{\max}, a_{\min} < A < a_{\max}\} \tag{5.13}$$

for some $0 < y_{\min} < e < y_{\max} < \infty$ and $-\infty < a_{\min} < 0 < a_{\max} < \infty$. The good understanding of the hypoelliptic operator $\mathcal{A}$ above is now quite important, since its properties are propagated into (5.3). We need to identify the $\left(\mathcal{A} + \frac{\partial}{\partial t}\right)$-hypoelliptic boundary of Ω_T—the set of all points on the boundary $\partial\Omega_T$ that *can* possibly be reached by the process (recall (3.1)) $\{t, Y(t), A(t)\}$ starting inside Ω_T. This is where the terminal/boundary condition is imposed. Since the time is running forward, the process obviously *cannot* exit at $t = t_{\min}$, but furthermore, more interestingly, due to the degeneracy, the process also *cannot* exit Ω_T at $\{\{t, Y, a_{\min}\}, t_{\min} < t < T, y_{\min} < Y < e\}$, just as well as it cannot exit at $\{\{t, Y, a_{\max}\}, t_{\min} < t < T, e < Y < y_{\max}\}$. Therefore, the $\left(\mathcal{A} + \frac{\partial}{\partial t}\right)$-hypoelliptic boundary of Ω_T, or $\partial_{\mathcal{A}+\frac{\partial}{\partial t}}\Omega_T$, which is the same $\partial_{\mathfrak{MA}}\Omega_T$, has two components: $\{t < T\} \cap \partial_{\mathfrak{MA}}\Omega_T$ (the complement of which was described above), where the lateral boundary condition is imposed, and $\{t = T\} \cap \partial_{\mathfrak{MA}}\Omega_T$, where the terminal condition $f = 1$ is imposed.

What would be a good (artificial) lateral boundary condition for f on $\{t < T\} \cap \partial_{\mathfrak{MA}}\Omega_T$? The simple choice is the Dirichlet condition $f = 1$. Nevertheless such a choice is shown to be a poor choice (see [8]). It turns out that a very useful property of the solution f is that it satisfies the inequality $0 < f < 1$ in $\Omega_{T,\infty}$. Consequently a nonlinear ("noninterfering") boundary condition

$$\frac{\partial f}{\partial \nu} = -\alpha f(1 - f) \tag{5.14}$$

on $\{t < T\} \cap \partial_{\mathfrak{MA}}\Omega_T$, where ν is the exterior unit normal, and where $\alpha > 0$ is a constant chosen experimentally in such a way to minimize the interference of the boundary condition with a solution (see [8]), is introduced. The condition (5.14) makes sense since, for example, the condition $0 < f < 1$ in $\Omega_{T,\infty}$ (not just Ω_T) implies that f is flat whenever taking values close to 0 or 1. The nonlinear boundary condition (5.14) was not studied in the context of Monge–Ampère PDEs as of yet (see, e.g., [2], [5]). Nevertheless the numerical calculations, some of which are showcased below, suggest very convincingly that the problem (5.3), (5.4), (5.14) is well posed.

Of course, by solving problem (5.3), (5.4), (5.14) in the truncated domain Ω_T, as opposed to solving problem (5.3), (5.4) in $\Omega_{T,\infty}$, we introduce a small error—it is an approximate solution to the original problem. In the rest of the paper we shall ignore the difference.

Thereby the extension of Merton's theory to momentum trading is complete: the optimal trading strategy is given by (5.7), where $f = f_\gamma$, the reduced value function, is computed as an appropriate solution of (5.3), (5.4), (5.14).

6. The simplest example: A single-stock portfolio. Consider the simplest case: a single stock whose price obeys (3.1) is considered for trading. More precisely, let it be in (3.1)–(3.2), $m = n = 1$,

$$\sigma_y(t, Y, A) = \{s\}, \sigma_s(t, Y, A) = \{\{s\}\}, a_s(t, Y, A) = \{A\}. \tag{6.1}$$

In other words, the stock-price dynamics is described by the system

$$\boldsymbol{d}Y(t) = Y(t)A(t)\boldsymbol{d}t + Y(t)\{s\}.\boldsymbol{d}B(t), \tag{6.2}$$

$$\boldsymbol{d}A(t) = \frac{1}{Y(t)}\left(\frac{2\pi}{p}\right)^2 (e - Y(t))\boldsymbol{d}t \tag{6.3}$$

and then again, as a tradable asset,

$$\boldsymbol{d}S(t) = S(t)\{A(t)\}\boldsymbol{d}t + S(t)\{\{s\}\}.\boldsymbol{d}B(t), \tag{6.4}$$

where $s > 0$ is constant volatility, $e > 0$ is constant price-equilibrium, and $p > 0$ is constant price-period. Also, $Y(t)$ and $A(t)$ are scalar-valued, while $S(t)$ and $B(t)$ are 1-vector-valued. $B(t) = \{B_1(t)\}$ is the one-dimensional "vector" Brownian motion. Of course, (6.2) and (6.4) are redundant; the purpose of having them both is to use the general framework above.

Then, from (5.7), the optimal portfolio rule is given by (we shall allow a bit of abuse of notation here: $P^\star_\gamma = \{P^\star_\gamma\}$, $M^\star_\gamma = \{M^\star_\gamma\}$, $S_\gamma = \{S_\gamma\}$)

$$\Pi^\star_\gamma(t, X, Y, A) = X\{P^\star_\gamma(t, Y, A)\} = \frac{X}{\gamma}\left\{\frac{A - r}{s^2} + \frac{Y f_\gamma{}^{(0,1,0)}(t, Y, A)}{f_\gamma(t, Y, A)}\right\} \tag{6.5}$$

for $\gamma \neq 1$, and $\Pi^\star_1(t, X, Y, A) = X\{P^\star_1(t, Y, A)\} = X\{\frac{A-r}{s^2}\}$, where the reduced value function $f = f_\gamma$ is the solution of the reduced Monge–Ampère PDE (5.3), which now simplifies to

$$\begin{aligned} &-p^2(\gamma - 1)s^2 f^{(0,1,0)}(t, Y, A)^2 Y^3 - p^2(\gamma - 1)\left(\frac{(A - r)^2}{s^2} + 2r\gamma\right) f(t, Y, A)^2 Y \\ &+ f(t, Y, A)(p^2 s^2 \gamma f^{(0,2,0)}(t, Y, A)Y^3 + 2p^2(A + r(\gamma - 1))f^{(0,1,0)}(t, Y, A)Y^2 + 2p^2\gamma \\ &\qquad f^{(1,0,0)}(t, Y, A)Y + 8\pi^2(e - Y)\gamma f^{(0,0,1)}(t, Y, A)) = 0 \end{aligned} \tag{6.6}$$

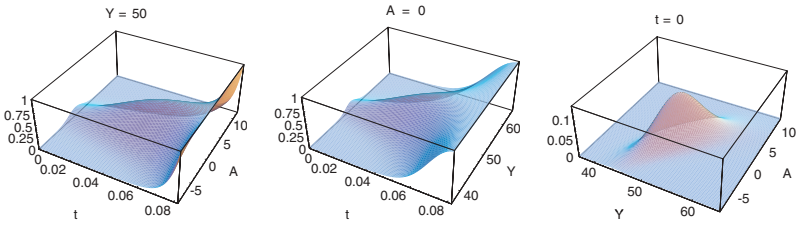
in Ω_T, together with boundary conditions (5.4) and (5.14). As before, we can write $P^\star_\gamma = M^\star_\gamma + S_\gamma$, where

$$M^\star_\gamma(t, Y, A) = \frac{A - r}{\gamma s^2} \tag{6.7}$$

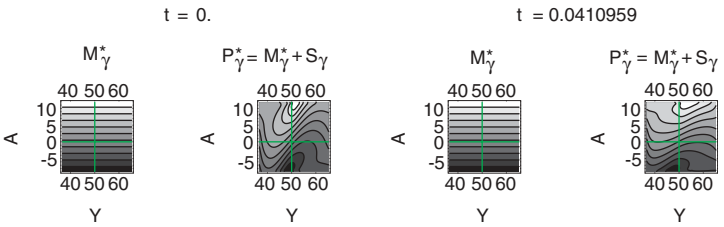
is the classical Merton's strategy, while

$$S_\gamma(t, Y, A) = \frac{Y f_\gamma{}^{(0,1,0)}(t, Y, A)}{\gamma f_\gamma(t, Y, A)} \tag{6.8}$$

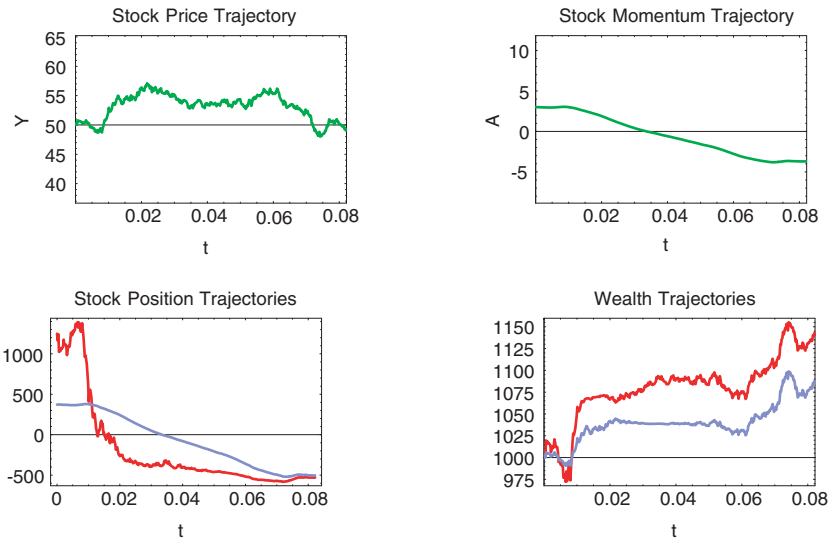
is the momentum correction provided by this methodology. Many numerical experiments were performed. Here are some results. For example, if $s = 0.4$, $e = 50$, $p = 2/12$, $r = 0.025$, $\gamma = 50$, $T = 30/365$, $y_{\min} = 36.6709$, $y_{\max} = 65.2239$, $a_{\min} = -8.85934$, $a_{\max} = 11.8334$, $\alpha = 0.05$, then the reduced value function $f = f_\gamma(t, Y, A)$, for fixed stock-price Y, for fixed momentum A, and for fixed time t, looks like



In particular, one can use the previous three figures to examine the validity of the artificial boundary condition (5.14); one can also try to examine the expected (hypoelliptic) C^∞-regularity of the solution. No PDE theory exists today to support such an expectation for equations such as (6.6). Next, we compare the strategy $M^\star_\gamma(t, Y, A)$ with the new optimal momentum strategy $P^\star_\gamma(t, Y, A)$ for a couple of fixed times (these are contour plots; dark means low relative value, and in this case short-selling, while light means a long position; see (6.7)):



We can conclude that the two strategies are quite a bit different long before the time of investment-success evaluation (T), and then, as time goes by, those two strategies converge. Finally, how much better is the new momentum strategy? We attempted to answer this question by means of Monte-Carlo experiments. For example, with initial condition $\{Y(0), A(0)\} = \{50, 3\}$, a very typical outcome looked like this:



where plotted are the wealth and investment-positions evolutions corresponding to strategy $M^\star_\gamma$ (blue-light), and corresponding to the strategy $P^\star_\gamma$ (red-dark); price and

momentum trajectories. One can notice that the investment position corresponding to $P^\star_\gamma$ is more aggressive in the beginning of the investment period and as time goes by converges to the one corresponding to the strategy $M^\star_\gamma$.

We postpone the more precise comparison based on extensive Monte-Carlo experiments until the end of the final section, when we compare these two strategies with three additional ones, involving also options.

7. Optimal hedging and pricing of European and American options in momentum markets. Now we consider a portfolio of an option, European or American, and the corresponding underlying stock. Let T_0 be the expiration time for the option, while $T \leq T_0$ is the time when, as before, we stop the trading and measure a level of success or failure. Let k be the option strike price, and let r be the interest rate. For simplicity, we assume no dividends are paid, although everything that precedes and follows can be modified for either continuous or instantaneous dividend-paying underlying. One tracks the stock-price $Y(t)$ and the price-momentum $A(t)$ while trading stocks and options. We assume that the underlying stock-price has volatility $s(t, Y, A)$, equilibrium e, and period p. More precisely, in (3.1), let $m = n = 2$, and let

$$\boldsymbol{d}Y(t) = Y(t)A(t)\boldsymbol{d}t + Y(t)\{s(t, Y(t), A(t)), 0\}.\boldsymbol{d}B(t), \tag{7.1}$$

$$\boldsymbol{d}A(t) = \frac{1}{Y(t)}\left(\frac{2\pi}{p}\right)^2 (e - Y(t))\boldsymbol{d}t, \tag{7.2}$$

identifying

$$\sigma_y(t, Y, A) = \{s(t, Y, A), 0\}. \tag{7.3}$$

Now, since we allow volatility $s = s(t, Y, A)$ to depend also on the momentum A, there is no reason to expect that the option price V does not depend on A. So, denote the option price as $V = V(t, Y, A)$. Under such a scenario, the tradable assets—the stock and the option—have a vector-price $S(t) = \{S_1(t), S_2(t)\} = \{Y(t), V(t, Y(t), A(t))\}$ with the dynamics

(7.4)

$$\begin{aligned}
\boldsymbol{d}S(t) = \boldsymbol{d}\{Y(t), V(t, Y(t), A(t))\} = \{Y(t), V(t, Y(t), A(t))\}\Bigg\{A(t), \frac{1}{V(t, Y(t), A(t))} \\
\left(\frac{1}{2}Y(t)^2 V^{(0,2,0)}(t, Y(t), A(t))s(t, Y(t), A(t))^2 + \frac{4\pi^2(e - Y(t))V^{(0,0,1)}(t, Y(t), A(t))}{p^2 Y(t)}\right. \\
\left. + A(t)Y(t)V^{(0,1,0)}(t, Y(t), A(t)) + V^{(1,0,0)}(t, Y(t), A(t))\right)\Bigg\}\boldsymbol{d}t + \{Y(t), V(t, Y(t), A(t))\} \\
\begin{pmatrix} s(t, Y(t), A(t)) & 0 \\ \dfrac{Y(t)s(t, Y(t), A(t))V^{(0,1,0)}(t, Y(t), A(t))}{V(t, Y(t), A(t))} & \epsilon \end{pmatrix}.\boldsymbol{d}B(t) = S(t)a_s(t, Y(t), A(t))\boldsymbol{d}t \\
+ S(t)\sigma_s(t, Y(t), A(t)).\boldsymbol{d}B(t)
\end{aligned}$$

for $\epsilon = 0$. This follows directly from Itô's chain rule. On the other hand, we shall assume that $\epsilon > 0$; i.e., we shall augment the option-price dynamics with an additional layer of randomness. This is motivated/justified by the well-known fact that, due to the reduced liquidity of options compared to the underlying stock, the relative difference between bid and ask prices for options is much more significant than for

the stocks. The assumption $\epsilon > 0$ is also of technical significance, and it will be further justified below by the beauty and by the consistency with the usual theory of the results obtained.

So, we identify the coefficients in (3.2) as

$$
\begin{aligned}
a_s(t,Y,A) = \Bigg\{ A, \frac{1}{V(t,Y,A)} \Bigg(& \frac{1}{2} Y^2 V^{(0,2,0)}(t,Y,A) s(t,Y,A)^2 \\
& + \frac{4\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A)}{p^2 Y} + AY V^{(0,1,0)}(t,Y,A) + V^{(1,0,0)}(t,Y,A) \Bigg) \Bigg\}
\end{aligned} \tag{7.5}
$$

and

$$
\sigma_s(t,Y,A) = \begin{pmatrix} s(t,Y,A) & 0 \\ \dfrac{Y s(t,Y,A) V^{(0,1,0)}(t,Y,A)}{V(t,Y,A)} & \epsilon(t,Y,A) \end{pmatrix}. \tag{7.6}
$$

We are in a position now to apply the general theory, and in particular formulas (5.7) and (5.8), which now read as

(7.7)

$$
\begin{aligned}
\Pi^\star_\gamma(t,X,Y,A) = \{ & (X(2p^2 Y s(t,Y,A)^2 V(t,Y,A)^2 f^{(0,1,0)}(t,Y,A) \epsilon(t,Y,A)^2 \\
& + f(t,Y,A)(2p^2 r Y V(t,Y,A) V^{(0,1,0)}(t,Y,A) s(t,Y,A)^2 - V^{(0,1,0)}(t,Y,A) \\
& \quad (Y(Y^2 V^{(0,2,0)}(t,Y,A) s(t,Y,A)^2 + 2rY V^{(0,1,0)}(t,Y,A) \\
& + 2V^{(1,0,0)}(t,Y,A)) p^2 + 8\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A)) s(t,Y,A)^2 \\
& + 2p^2 (A-r) V(t,Y,A)^2 \epsilon(t,Y,A)^2))) \\
& \quad / (2p^2 \gamma f(t,Y,A) s(t,Y,A)^2 V(t,Y,A)^2 \epsilon(t,Y,A)^2), \\
& \quad (X(-2rYV(t,Y,A)p^2 + Y(Y^2 V^{(0,2,0)}(t,Y,A) s(t,Y,A)^2 \\
& + 2rY V^{(0,1,0)}(t,Y,A) + 2V^{(1,0,0)}(t,Y,A)) p^2 \\
& + 8\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A))) / (2p^2 Y \gamma V(t,Y,A) \epsilon(t,Y,A)^2) \}
\end{aligned}
$$

for $\gamma \neq 1$, where $f = f_\gamma$, the reduced value function, is the solution of the reduced Monge–Ampère PDE (5.3), which now becomes

(7.8)

$$
\begin{aligned}
f(t,Y,A) (& Y(2Y(A + r(\gamma-1)) f^{(0,1,0)}(t,Y,A) + \gamma(Y^2 f^{(0,2,0)}(t,Y,A) s(t,Y,A)^2 \\
& + 2f^{(1,0,0)}(t,Y,A))) p^2 + 8\pi^2 (e-Y) \gamma f^{(0,0,1)}(t,Y,A)) - \big((\gamma-1) \\
& \big(4p^4 Y^4 f^{(0,1,0)}(t,Y,A)^2 s(t,Y,A)^4 + \big(f(t,Y,A)^2 \big(p^4 Y^6 V^{(0,2,0)}(t,Y,A)^2 s(t,Y,A)^6 \\
& + 4p^2 Y^3 V^{(0,2,0)}(t,Y,A) (Y(rYV^{(0,1,0)}(t,Y,A) + V^{(1,0,0)}(t,Y,A)) p^2 \\
& - p^2 rYV(t,Y,A) + 4\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A)) s(t,Y,A)^4 \\
& + 4\big(rY^2 V(t,Y,A)^2 (2\gamma \epsilon(t,Y,A)^2 + r) p^4 - 2rYV(t,Y,A) (Y(rY \\
& V^{(0,1,0)}(t,Y,A) + V^{(1,0,0)}(t,Y,A)) p^2 + 4\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A)) p^2 \\
& + (Y(rYV^{(0,1,0)}(t,Y,A) + V^{(1,0,0)}(t,Y,A)) p^2 + 4\pi^2 (e-Y) V^{(0,0,1)}(t,Y,A))^2 \big) \\
& s(t,Y,A)^2 + 4p^4 (A-r)^2 Y^2 V(t,Y,A)^2 \epsilon(t,Y,A)^2 \big) \big) / (V(t,Y,A)^2 \epsilon(t,Y,A)^2) \big) \big) \\
& / (4p^2 Y s(t,Y,A)^2) = 0
\end{aligned}
$$

in Ω_T, together with boundary conditions (5.4) and (5.14), while in the case $\gamma = 1$,

the formula is complete—nothing is left to compute:

(7.9)
$$\begin{aligned}\Pi_1^\star(t,X,Y,A)=\{&(X(2p^2rYV(t,Y,A)V^{(0,1,0)}(t,Y,A)s(t,Y,A)^2-V^{(0,1,0)}(t,Y,A)\\&(Y(Y^2V^{(0,2,0)}(t,Y,A)s(t,Y,A)^2+2rYV^{(0,1,0)}(t,Y,A)\\&+2V^{(1,0,0)}(t,Y,A))p^2+8\pi^2(e-Y)V^{(0,0,1)}(t,Y,A))s(t,Y,A)^2\\&+2p^2(A-r)V(t,Y,A)^2\epsilon(t,Y,A)^2))/(2p^2s(t,Y,A)^2V(t,Y,A)^2\epsilon(t,Y,A)^2),\\&(X(-2rYV(t,Y,A)p^2+Y(Y^2V^{(0,2,0)}(t,Y,A)\\&s(t,Y,A)^2+2rYV^{(0,1,0)}(t,Y,A)+2V^{(1,0,0)}(t,Y,A))p^2\\&+8\pi^2(e-Y)V^{(0,0,1)}(t,Y,A)))/(2p^2YV(t,Y,A)\epsilon(t,Y,A)^2)\}.\end{aligned}$$

In various places in (7.7)–(7.9) a linear (hypoelliptic) differential operator of fundamental importance appears. Indeed, let operator $\mathcal{H}$ be defined as

(7.10)
$$\begin{aligned}\mathcal{H}[V](t,Y,A)&=V^{(1,0,0)}(t,Y,A)+\frac{1}{2}Y^2V^{(0,2,0)}(t,Y,A)s(t,Y,A)^2+rYV^{(0,1,0)}(t,Y,A)\\&-rV(t,Y,A)+\frac{4\pi^2(e-Y)V^{(0,0,1)}(t,Y,A)}{Yp^2}.\end{aligned}$$

The importance of $\mathcal{H}$ can be deduced immediately by its comparison with the classical Black–Scholes operator $\mathcal{L}$:

(7.11)
$$\mathcal{L}[V](t,Y)=V^{(1,0)}(t,Y)+\frac{1}{2}Y^2V^{(0,2)}(t,Y)s(t,Y)^2+rYV^{(0,1)}(t,Y)-rV(t,Y).$$

$\mathcal{H}$ is a momentum version of $\mathcal{L}$—if there is no momentum-dependence, $\mathcal{L}=\mathcal{H}$, since $V^{(0,0,1)}=0$. $\mathcal{H}$ is not backward-parabolic like $\mathcal{L}$ but only hypoelliptic, due to the term $4\pi^2(e-Y)V^{(0,0,1)}(t,Y,A)/(Yp^2)$ and due to the absence of $V^{(0,0,2)}$ in (7.10). Now using (7.10), after some work (7.7)–(7.9) simplify quite significantly: the optimal portfolio rule is equal to

(7.12)
$$\begin{aligned}\Pi_\gamma^\star(t,X,Y,A)&=X\left\{Q_\gamma^\star(t,Y,A),\frac{\mathcal{H}[V](t,Y,A)}{\gamma\epsilon(t,Y,A)^2V(t,Y,A)}\right\}=\frac{X}{\gamma}\left\{\frac{A-r}{s(t,Y,A)^2}\right.\\&\left.+\frac{Yf^{(0,1,0)}(t,Y,A)}{f(t,Y,A)}-\frac{\mathcal{H}[V](t,Y,A)}{\epsilon(t,Y,A)^2V(t,Y,A)}\frac{YV^{(0,1,0)}(t,Y,A)}{V(t,Y,A)},\frac{\mathcal{H}[V](t,Y,A)}{\epsilon(t,Y,A)^2V(t,Y,A)}\right\}\end{aligned}$$

for $\gamma\neq1$, where $f=f_\gamma$, the reduced value function, is the solution of the reduced Monge–Ampère PDE

(7.13)
$$\begin{aligned}&-p^2(\gamma-1)s(t,Y,A)^2f^{(0,1,0)}(t,Y,A)^2Y^3\\&-p^2(\gamma-1)\left(\frac{(A-r)^2}{s(t,Y,A)^2}+2r\gamma+\frac{(\mathcal{H}[V](t,Y,A))^2}{\epsilon(t,Y,A)^2V(t,Y,A)^2}\right)\\&\quad f(t,Y,A)^2Y+f(t,Y,A)(p^2s(t,Y,A)^2\gamma f^{(0,2,0)}(t,Y,A)Y^3+2p^2(A+r(\gamma-1))\\&\quad f^{(0,1,0)}(t,Y,A)Y^2+2p^2\gamma f^{(1,0,0)}(t,Y,A)Y+8\pi^2(e-Y)\gamma f^{(0,0,1)}(t,Y,A))=0\end{aligned}$$

in Ω_T, together with boundary conditions (5.4) and (5.14), while in the case $\gamma = 1$

(7.14)
$$\Pi_1^\star(t,X,Y,A) = X\left\{Q_1^\star(t,Y,A), \frac{\mathcal{H}[V](t,Y,A)}{\epsilon(t,Y,A)^2 V(t,Y,A)}\right\}$$
$$= X\left\{\frac{A-r}{s(t,Y,A)^2} - \frac{\mathcal{H}[V](t,Y,A)}{\epsilon(t,Y,A)^2 V(t,Y,A)}\frac{YV^{(0,1,0)}(t,Y,A)}{V(t,Y,A)}, \frac{\mathcal{H}[V](t,Y,A)}{\epsilon(t,Y,A)^2 V(t,Y,A)}\right\}.$$

Notice that in the above, for comparison purposes below, we have introduced the notation $Q_\gamma^\star(t,Y,A)$, as opposed to $P_\gamma^\star(t,Y,A)$ from the previous section.

In (7.12) and (7.14) the quantity $\mathcal{H}[V]/(\epsilon^2 V)$ has a very prominent role: it is, modulo X/γ, the optimal investment in the option. Therefore, one can think of it as an *option trading opportunity* or, more precisely, *option-underpricing* (if positive, it implies a long position in the option, as a consequence of the option being cheap, and vice versa). So, let us define the *option trading opportunity* ω as

$$\omega = \frac{\mathcal{L}[V]}{\epsilon^2 V} \tag{7.15}$$

if there is no momentum-dependence, or $\omega = \mathcal{H}[V]/(\epsilon^2 V)$ in momentum markets.

This definition now makes it very natural to define a *fair price of a European option* (cf. [4] and references given there) as a function V for which option-underpricing ω is equal to zero, i.e., for which the Black–Scholes PDE

$$\mathcal{L}[V] = 0 \tag{7.16}$$

(or $\mathcal{H}[V] = 0$, a hypoelliptic Black–Scholes PDE) holds.

Furthermore (let $\eta = \eta_k(Y)$ denote the option-payoff), a *fair price of an American option* in a way does not always exist; it is a function $V \geq \eta$, for which option-underpricing ω is either equal to zero (the fair price does exist; implying $L[V] = 0$), or it is less than zero (option-underpricing ω is negative, i.e., the option is overpriced and therefore it is not rational to trade in such an option—it is rational to exercise it; implying $L[V] \leq 0$), or put all together, for which

$$\operatorname{Max}[\mathcal{L}[V], \eta - V] = 0 \tag{7.17}$$

or $\operatorname{Max}[\mathcal{H}[V], \eta - V] = 0$ in momentum markets. Equation (7.17) is the Black–Scholes obstacle problem (see [8] for many other equivalent formulations of obstacle problems). In the rest of the paper, for simplicity, we shall consider European options only.

Consider the simplest possible example. Let all the data be the same as in the previous section. In particular, that means that the assumed underlying volatility is constant, and therefore $\mathcal{H} = \mathcal{L}$. Additionally, let the considered option have a strike price $k = 50$, and the expiration date $T_0 = 60/365$. Let also the above-discussed bid/ask indeterminacy be modeled by $\epsilon = 1/2$. We shall also need an option-pricing formula $V(t,Y,A) = V(t,Y)$. We choose

(7.18)
$$V(t,Y) = V_{\gamma,\kappa,\epsilon}(t,Y) = \frac{1}{2}\boldsymbol{e}^{\left(\gamma\kappa\epsilon^2+r\right)(t-T_0)}\left(\left(\operatorname{erfc}\left(\frac{2\log\left(\frac{Y}{k}\right)-(2r-s^2)(t-T_0)}{2\sqrt{2}\sqrt{s^2(T_0-t)}}\right)-2\right)k\right.$$
$$\left.+\left(\operatorname{erf}\left(\frac{2\log\left(\frac{Y}{k}\right)-(s^2+2r)(t-T_0)}{2\sqrt{2}\sqrt{s^2(T_0-t)}}\right)+1\right)\boldsymbol{e}^{r(T_0-t)}Y\right).$$

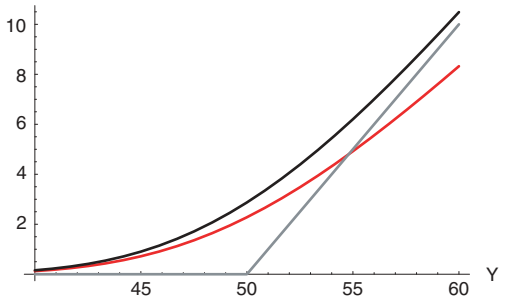
The pricing formula $V_{\gamma,\kappa,\epsilon}(t,Y)$ was computed as a solution of

$$\frac{\mathcal{L}[V](t,Y)}{\gamma\epsilon^2 V(t,Y)} = \kappa \tag{7.19}$$

with the usual Black–Scholes terminal condition

$$V(T_0,Y) = \eta_k(Y) = \mathrm{Max}[0, Y-k]. \tag{7.20}$$

Notice the difference between k, the strike price, and κ (Kappa) appearing in (7.19) and throughout below. Of course, for $\kappa = 0$ the solution $V_{\gamma,0,\epsilon}(t,Y)$ of (7.19)–(7.20) is the Black–Scholes fair option price, and according to the above, it would yield an optimal option investment of $\kappa = 0$. We choose $\kappa = 0.15$, which means we do a case study when an optimal option investment is *constant* and equal to 15% of the available wealth, and we are interested in seeing how such an optimal option investment, in such a badly priced option market, is hedged. It might be interesting to compare $V_{\gamma,0,\epsilon}$ and $V_{\gamma,\kappa,\epsilon}$, i.e., to see how badly the option is priced. For example, for $t = T/2 = 15/365$,



So, in order that under the risk-avoidance parameter $\gamma = 50$ it is optimal to invest 15% of the available wealth in the considered option, and under all of the other above conditions, the option needs to be quite a bit underpriced.

We present the results of numerical computations. The optimal trading strategy (7.12) is now equal to

$$\Pi^\star_\gamma(t,X,Y,A) = X\left\{Q^\star_\gamma(t,Y,A), \frac{\kappa}{\gamma}\right\} = \frac{X}{\gamma}\left\{\frac{A-r}{s^2} + \frac{Yf^{(0,1,0)}(t,Y,A)}{f(t,Y,A)} - \kappa\frac{YV^{(0,1)}(t,Y)}{V(t,Y)}, \kappa\right\}, \tag{7.21}$$

where the reduced value function f is the solution of (7.13), which now reduces to

$$\begin{aligned} &-p^2(\gamma-1)s^2 f^{(0,1,0)}(t,Y,A)^2 Y^3 - p^2(\gamma-1)\left(\frac{(A-r)^2}{s^2} + 2r\gamma + (\gamma\epsilon\kappa)^2\right) f(t,Y,A)^2 Y \\ &+ f(t,Y,A)(p^2s^2\gamma f^{(0,2,0)}(t,Y,A)Y^3 + 2p^2(A + r(\gamma-1))f^{(0,1,0)}(t,Y,A)Y^2 \\ &\qquad + 2p^2\gamma f^{(1,0,0)}(t,Y,A)Y + 8\pi^2(e-Y)\gamma f^{(0,0,1)}(t,Y,A)) = 0. \end{aligned} \tag{7.22}$$

For the purpose of comparison of various strategies later, let us introduce also the notation

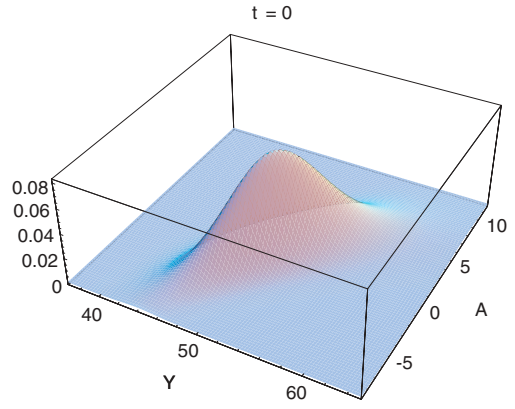
$$J^\star_\gamma(t,Y,A) = \frac{1}{\gamma}\left(\frac{A-r}{s^2} - \kappa\frac{YV^{(0,1)}(t,Y)}{V(t,Y)}\right) \tag{7.23}$$

and

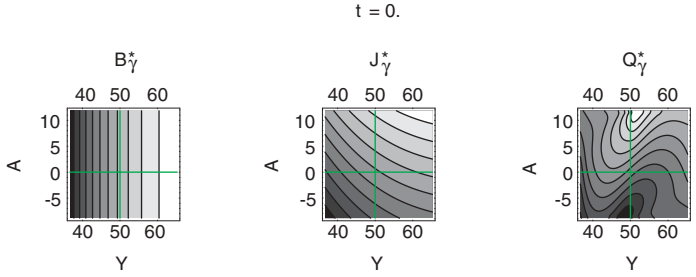
$$B^\star_\gamma(t,Y,A) = -\frac{\kappa}{\gamma}\frac{YV^{(0,1)}(t,Y)}{V(t,Y)}. \tag{7.24}$$

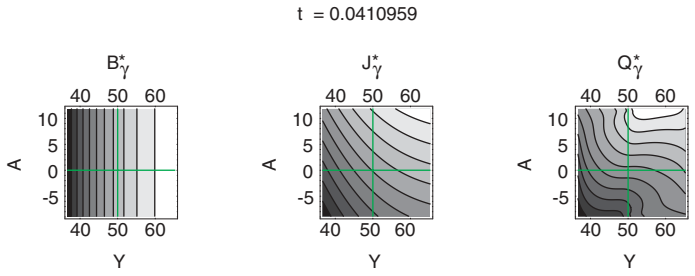
Notice that $B^\star_\gamma$ is the "Black–Scholes hedging strategy." Also notice, as it is going to be transparent on a sample trajectory below, that $B^\star_\gamma$ is not a riskless strategy, since the options pricing formula $V(t,Y)$ is not correct; i.e., it does not satisfy the Black–Scholes PDE (7.16). Therefore, strictly speaking, $B^\star_\gamma$ is *not* the Black–Scholes hedging strategy—it is just given by the same formula as the right one, when the correct options pricing formula is used. So, eventually we shall compare strategies $\{Q^\star_\gamma, \frac{\kappa}{\gamma}\}$, $\{P^\star_\gamma, 0\}$, $\{J^\star_\gamma, \frac{\kappa}{\gamma}\}$, $\{M^\star_\gamma, 0\}$, and $\{B^\star_\gamma, \frac{\kappa}{\gamma}\}$. Notice also that (7.22) and (6.6) are somewhat different when $\kappa\epsilon \neq 0$.

The solution of (7.22) looks like (for fixed time)

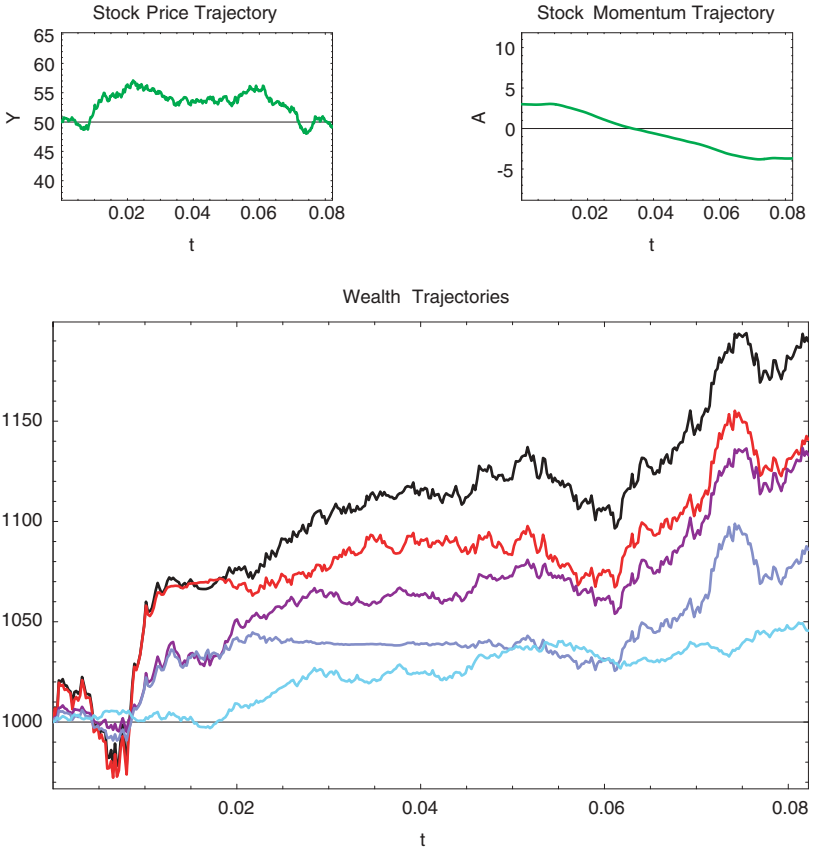


Compare this with the similar figure in the previous section: the present reduced value function is smaller than the one there, which implies that the current *value function* is bigger. Of course, the expected payoff is bigger now, since we have an additional opportunity—we have the opportunity to trade in options, as well. Next, we compare strategies $B^\star_\gamma(t,Y,A)$ and $J^\star_\gamma(t,Y,A)$, which do not depend on any numerical computations, and $Q^\star_\gamma(t,Y,A)$, which depends on the reduced value function above, for several fixed times (compare also with the similar plots in the previous section):





Finally, those three strategies $\{Q^\star_\gamma, \frac{\kappa}{\gamma}\}$, $\{J^\star_\gamma, \frac{\kappa}{\gamma}\}$, and $\{B^\star_\gamma, \frac{\kappa}{\gamma}\}$ were applied (in addition to two strategies already applied: $\{P^\star_\gamma, 0\}$ and $\{M^\star_\gamma, 0\}$) on some 10000 market trajectories (actually, 10452 trajectories were needed to select 10000 of them which stay inside Ω_T). A very typical one looks like (the same one is in the previous section)



where, looking on the right from the top, the wealth trajectories correspond to $\{Q^\star_\gamma, \frac{\kappa}{\gamma}\}$, $\{P^\star_\gamma, 0\}$, $\{J^\star_\gamma, \frac{\kappa}{\gamma}\}$, $\{M^\star_\gamma, 0\}$, and $\{B^\star_\gamma, \frac{\kappa}{\gamma}\}$. The average profit returns by these strategies were 15.767%, 13.176%, 11.138%, 8.605%, and 2.545%, respectively (a profit of 15.767% over 30 days yields a profit of 493.765% over a year).

Finally, as the most precise strategy-comparison gauge, the empirical cumulative distribution functions $F^{\{Q^\star_\gamma, \frac{\kappa}{\gamma}\}}(X)$, $F^{\{P^\star_\gamma, 0\}}(X)$, $F^{\{J^\star_\gamma, \frac{\kappa}{\gamma}\}}(X)$, $F^{\{M^\star_\gamma, 0\}}(X)$, $F^{\{B^\star_\gamma, \frac{\kappa}{\gamma}\}}(X)$, where $F(X) = \frac{1}{N}\sum_{i=1}^{N} \chi_{\{X \geq X_i(T)\}}$, and where χ_A is the characteristic function of an

event A, look like (recall that $N = 10000$, out of 10452; from the right to the left)

EFFICIENT HEDGING WHEN ASSET PRICES FOLLOW A GEOMETRIC POISSON PROCESS WITH UNKNOWN INTENSITIES*

MICHAEL KIRCH† AND WOLFGANG J. RUNGGALDIER‡

Abstract. We consider the problem of determining a strategy that is efficient in the sense that it minimizes the expectation of a convex loss function of the hedging error for the case when prices change at discrete random points in time according to a geometric Poisson process. The intensities of the jump process need not be fully known by the investor. The solution algorithm is based on dynamic programming for piecewise deterministic control problems, and its implementation is discussed as well.

Key words. geometric Poisson process, piecewise deterministic control problems, incomplete information, incomplete markets, efficient hedging, Bayesian approach

1. Introduction.

This paper concerns the problem of hedging a future liability. Depending on the hedging criterion, various approaches have been considered in the literature. A mathematically attractive criterion, related to mean-variance hedging, is the quadratic criterion. This criterion leads to the mathematical problem of approximating an L^2-random variable by stochastic integrals. Starting from the work by Föllmer and Sondermann [9] and Schweizer [22], much research has been dedicated to this criterion so that this topic can by now be considered as a well-studied one (for a survey with extensive literature see [24]). For more general criteria the approaches are in a sense in common with utility maximization. They are mainly the so-called *martingale approach* (see, e.g., [3], [16], [13], [21]) and approaches based on *optimal stochastic control*.

One of the main goals in the present paper is to study the hedging problem in the context of incomplete/partial information on the underlying price evolution model. The various approaches mentioned above have, to some extent, also been applied to the case of incomplete information. For the quadratic/mean variance approach and under a martingale measure see, e.g., [23] and [10]. The martingale approach for the case of incomplete information was first considered in [18]. For more recent studies see, e.g., [4], [14], [26]; they concern mainly diffusion-type models where the uncertainty is in the stock appreciation rates that are supposed to be unknown constants and treated, from the Bayesian point of view, as random variables with a given prior distribution. For a more typically stochastic control approach see [20]. In the present paper we concentrate on the stochastic control approach that can indeed be viewed as a rather general approach for problems with partial information.

Stochastic control methods, in particular the method of dynamic programming (DP), have been applied mainly to diffusion-type models, and here DP leads to HJB-

type equations; much current research is going on concerning analytical solutions to these equations. Diffusion-type models lead to continuous trajectories for the prices. In reality, prices change at discrete random points in time, and, in addition, they move at fixed increments (multiples of tick size). In this paper we consider a price evolution model that possesses these features, namely a geometric Poisson process (see also [15]). In order to concentrate better on the main issues, we consider a rather simple such model with a single risky asset and assume that the liability to be hedged is adapted to the filtration generated by the underlying price evolution. The approach can, however, be extended to markets with many assets, not all of them available for hedging, and with a liability that may be adapted to the filtration generated by all these assets. Furthermore, the simple geometric Poisson process can be extended to include compound Poisson processes. This simple model is also a natural generalization of the successful binomial (or Cox–Ross–Rubinstein) model, in which prices change at fixed proportions either up or down. While in the binomial model the changes occur at fixed points in time; here they occur more realistically at random points in time. In any case, an important test for a model is to check whether it is able to reproduce option prices observed in the market. The simple model (1) passes this test surprisingly well: it is able to reproduce both the smile observed in a foreign exchange market and the skew observed in equity markets.

A geometric Poisson process is driven by random jump processes that are characterized by their intensities. We assume the intensities to be constant in time, but, since one of our purposes is to highlight the problem of model uncertainty, we allow for the possibility that these intensities are not fully known to the investor. Taking the Bayesian point of view, they are considered as random variables with a distribution that is continuously updated on the basis of the information coming from observing the actual price evolution. This allows us to capture some of the most important features while keeping complexity low.

In the setting as described above, the market is incomplete, and so it is not possible to obtain for any given claim a self-financing and perfect hedging strategy. As a hedging criterion we consider here the expected value of a convex loss function applied to the hedging error and call a hedging strategy that minimizes this criterion *efficient (or optimal)*. Notice that this includes the quadratic criterion and also the well-known *shortfall risk criterion* (see, e.g., [2], [8]).

For our geometric Poisson models, the DP approach of stochastic control leads to Bellman equations for piecewise deterministic processes (see, e.g., [5], [25], [6], [1]) that are studied here both under full as well as partial information on the underlying price evolution model.

In summary, we consider the following optimization problem where, letting all the prices be discounted with respect to the nonrisky asset, X_t denotes the (for simplicity scalar) price process, V_t is the value process corresponding to a self-financing and predictable investment strategy ξ_t, and $F(X_S)$ is the claim for a fixed maturity S. The processes N_t^+ and N_t^- are jump processes where the intensity need not be fully known, a, b are given positive constants, and $l(\cdot)$ is an increasing and convex loss function:

$$\begin{cases} dX_t = X_{t-}\left[(e^a-1)dN_t^+ + (e^{-b}-1)dN_t^-\right], \\ dV_t = \xi_t X_{t-}\left[(e^a-1)dN_t^+ + (e^{-b}-1)dN_t^-\right], \\ E\left\{l\left(F(X_S)-V_S\right)\right\} \quad \longrightarrow \quad \min. \end{cases}$$

The outline of the paper is as follows. In section 2 we describe more precisely the problem setup and obtain some preliminary results. The DP approach for piecewise deterministic processes is studied, in the context of our problem, in section 3 and is extended to the case of incomplete information in section 4, more precisely in subsection 4.2. Since, in the context of our model, the incomplete information concerns uncertainty about the intensities of the driving Poisson processes, in subsection 4.1 we recall some facts about the Bayesian approach to uncertain intensities. The computation of real-size problems needs some approximations to be introduced. These are discussed in section 5, where also an example is given to better illustrate the approximation procedure itself.

2. Problem setup. We examine efficient strategies in the situation where, considering for simplicity only a single risky asset, its price follows a *geometric Poisson process*, i.e.,

$$X_t = x_0 e^{aN_t^+ - bN_t^-} \tag{1}$$

for two independent Poisson processes N^+, N^- with intensities λ^+, λ^- defined on a filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ and constants $a, b > 0$. To keep the presentation as simple as possible, we shall assume that all processes/values are already discounted; i.e. we implicitly assume the short rate r_t to be equal to zero. The more realistic case of $r_t > 0$ would not change the essence of the results but would considerably complicate the presentation.

For a hedging strategy ξ, where ξ_t denotes the number of units of the risky asset held in the portfolio at time t, and an initial capital V_0, we define the associated wealth process by

$$V_t = V_0 + \int_0^t \xi_s dX_s, \tag{2}$$

thereby enforcing ξ to be self-financing. Although we shall not pursue this here, transaction costs may be easily incorporated by subtracting from the right-hand side in (2) the total amount of transaction costs incurred up to time t. In order to keep the results below as general as possible, we shall consider ξ_t to be real valued. We say that a strategy ξ is admissible for initial capital V_0 if it is predictable and the associated wealth process satisfies

$$V_t \geq -c, \quad t \in [0, S], \quad P\text{-a.s.} \tag{3}$$

for some fixed $c \geq 0$ and a given time horizon S. Let $\mathcal{A}_{V_0}$ denote the class of all admissible strategies for initial capital $V_0 \geq -c$.

We denote by τ_n the time of the nth jump

$$\begin{aligned} \tau_n &= \inf\{t \geq 0 \mid N_t^+ + N_t^- = n\}, \\ \hat{\tau}_n &:= \tau_n \wedge S. \end{aligned}$$

PROPOSITION 2.1. *We have $\xi \in \mathcal{A}_{V_0}$ if and only if ξ is predictable and satisfies*

$$\xi_t \in \left[-\frac{c + V_{\hat{\tau}_n}}{X_{\hat{\tau}_n}(e^a - 1)}, \frac{c + V_{\hat{\tau}_n}}{X_{\hat{\tau}_n}(1 - e^{-b})} \right], \quad t \in (\hat{\tau}_n, \hat{\tau}_{n+1}], \quad n = 0, 1, \ldots, \quad P\text{-a.s.} \tag{4}$$

Proof. First, observe that

$$(0, S] = \bigcup_{n=0,1,\ldots} (\hat{\tau}_n, \hat{\tau}_{n+1}], \quad P\text{-a.s.}$$

holds; i.e., condition (3) is satisfied if and only if it is satisfied on every interval $(\hat{\tau}_n, \hat{\tau}_{n+1}]$.

Since X is a pure jump process, we obtain from (2)

$$\begin{aligned} V_t &= V_{\hat{\tau}_n} + \xi_t(X_{\hat{\tau}_{n+1}\wedge t} - X_{\hat{\tau}_n}), \quad t \in (\hat{\tau}_n, \hat{\tau}_{n+1}] \\ &= \begin{cases} V_{\hat{\tau}_n} & \text{for } t \in (\hat{\tau}_n, \hat{\tau}_{n+1}), \\ V_{\hat{\tau}_n} + \xi_t X_{\hat{\tau}_n}(e^a - 1) & \text{for } t = \hat{\tau}_{n+1},\ N_t^+ - N_{t-}^+ = 1, \\ V_{\hat{\tau}_n} + \xi_t X_{\hat{\tau}_n}(e^{-b} - 1) & \text{for } t = \hat{\tau}_{n+1},\ N_t^- - N_{t-}^- = 1. \end{cases} \end{aligned}$$

Hence condition (3) is satisfied if and only if (4) holds. □

Next, we examine *efficient hedging strategies* for a given European claim with maturity S and payoff $F(X_S) \geq -c$, assuming $F(\cdot)$ is a continuous function.

Let $\mathcal{M}$ denote the family of all equivalent martingale measures for X. The superhedge price for the option F at time $t < S$ admits the representation

$$F_{u,d} := \sup_{Q \in \mathcal{M}} E_Q[F(X_S) | N_t^+ = u, N_t^- = d]; \tag{5}$$

see [7] and [17]. It does not depend on t since, given t, we can find a measure P' equivalent to P such that N^i has constant intensity $\lambda^i \frac{S}{S-t}$, $i = +, -$. The name *superhedge price* is derived from the fact that, if the capital/wealth available to an investor at time t is $V_t \geq F_{u,d}$, then there exists a self-financing strategy (see (2)) such that the capital/wealth at maturity satisfies $V_S \geq F(X_S)$ a.s. Clearly, the model specified by (1) is incomplete. Especially, it can be shown that the superhedge price for a European call option with payoff $F(X_S) = (X_S - K)^+$ is given by x_0 for any maturity S and strike K (see, e.g., [11]). This price allows for arbitrage for the seller of the option. This example illustrates that superhedging may not be appropriate in model (1).

A feasible efficient strategy depends on the investors attitude towards risk. For our purposes, this attitude is incorporated in the choice of a loss function l such that l is increasing, convex, and $l(z) = 0$ for $z \leq 0$. A typical choice is $l(z) = z^p$ for $z \geq 0$. Here the parameter $p \geq 1$ corresponds directly to the investor's degree of risk aversion. We shall assume that

$$E[l(F(X_S) + c)] < \infty \tag{6}$$

holds.

As introduced in [8], an efficient hedging strategy ξ^* is a solution to the optimization problem

$$J_0^* := \min_{\xi \in \mathcal{A}_{V_0}} E\left[l\left(F(X_S) - V_0 - \int_0^S \xi_s dX_s \right) \right]. \tag{7}$$

The main reason for this criterion is that, since the market is incomplete, no perfect replication is possible. On the other hand, superreplication is neither appropriate nor economical, and so one tolerates some risk that one wants to minimize while taking into account the investor's attitude towards risk. The minimal risk J^* is called the value function (or optimal cost-to-go function). More generally, the value function at time t is given by

$$J^*(v,u,d,t) = \min_{\xi \in \mathcal{A}_{v,u,d,t}} E\left[l\left(F(X_S) - v - \int_t^S \xi_s dX_s \right) | \, N_t^+ = u,\ N_t^- = d \right], \tag{8}$$

where $\mathcal{A}_{v,u,d,t}$ denotes the class of admissible strategies on the interval $[t, S]$ given $V_t = v$, $N_t^+ = u$, and $N_t^- = d$. The value $J^*(v, u, d, t)$ represents the optimal minimal value at time t over the remaining period when the current information corresponds to $V_t = v$, $N_t^+ = u$, and $N_t^- = d$. In line with the comment after (5) notice also that, if at any time t one has $v \geq F_{u,d}$ with $F_{u,d}$ as in (5), then $J^* \equiv 0$. The optimization problem as such is therefore meaningful only if $v < F_{u,d}$. In what follows we shall consider for v the entire closed interval $[-c, F_{u,d}]$ since we want to obtain the hedging strategy also for $v = F_{u,d}$. In this situation, and up to the first jump after t, the interval in (4) is given by

$$I_{v,u,d} := \left[-\frac{c+v}{x_0 e^{au-bd}(e^a - 1)}, \frac{c+v}{x_0 e^{au-bd}(1 - e^{-b})} \right]. \tag{9}$$

We gather two facts about the structure of the model in the next lemma.

LEMMA 2.2.

(i) *The number $N_t := N_t^+ + N_t^-$ of jumps up to time t is a Poisson process with intensity $\lambda = \lambda^+ + \lambda^-$.*

(ii) *For any nonnegative function f we have*

$$\begin{aligned} &E[f(N^+_{\hat{\tau}_{u+d+1}}, N^-_{\hat{\tau}_{u+d+1}}, \hat{\tau}_{u+d+1}) |\ N_t^+ = u,\ N_t^- = d] \\ &\quad = \int_0^{S-t} \Big\{ \lambda^+ f(u+1, d, t+s) + \lambda^- f(u, d+1, t+s) \Big\} e^{-\lambda s} ds \\ &\qquad + e^{-\lambda(S-t)} f(u, d, S). \end{aligned} \tag{10}$$

Remark 1. The expression in (10) represents the expected value of f, taking into account that there may be a next jump either upwards or downwards or no further jump at all and given that at the current time t one has observed u jumps upwards and d downwards.

Proof. Only item (ii) requires a proof. To simplify notation, we assume, without loss of generality, $u = d = t = 0$. Let τ_1^+ (respectively, τ_1^-) denote the time of the first jump up (respectively, down). We then have

$$\begin{aligned} E[f(N^+_{\hat{\tau}_1}, N^-_{\hat{\tau}_1}, \hat{\tau}_1), \tau_1 \leq S] &= E[f(1,0,\tau_1^+),\ \tau_1^+ < \tau_1^-,\ \tau_1^+ \leq S] \\ &\quad + E[f(0,1,\tau_1^-),\ \tau_1^- < \tau_1^+,\ \tau_1^- \leq S] \\ &= E[f(1,0,\tau_1^+)\ P[\tau_1^+ < \tau_1^-,\ \tau_1^+ \leq S |\, \tau_1^+]\,] \\ &\quad + E[f(0,1,\tau_1^-)\ P[\tau_1^- < \tau_1^+,\ \tau_1^- \leq S |\, \tau_1^-]\,] \\ &= \int_0^S f(1,0,t)\ P[t < \tau_1^-] P[\tau_1^+ \in dt] \\ &\quad + \int_0^S f(0,1,t)\ P[t < \tau_1^+] P[\tau_1^- \in dt] \\ &= \int_0^S f(1,0,t)\ e^{-\lambda^- t} \lambda^+ e^{-\lambda^+ t} dt \\ &\quad + \int_0^S f(0,1,t)\ e^{-\lambda^+ t} \lambda^- e^{-\lambda^- t} dt. \end{aligned}$$

Adding to this expression the term

$$E[f(N^+_{\hat{\tau}_1}, N^-_{\hat{\tau}_1}, \hat{\tau}_1), \tau_1 > S] = e^{-\lambda S} f(0,0,S),$$

we arrive at (10). ∎

3. Known intensities. We first examine the structure of the efficient strategy in the case where the investor has no doubt regarding the true values of the jump intensities λ^+, λ^-.

3.1. The PD-DP equation. In our situation, the state space is given by

$$E = \{(v,u,d,t) \mid v \geq -c,\ u,d \in \mathbb{N},\ t \in [0,S]\}.$$

Let $\mathcal{C}(E)$ denote the class of all functionals J on E such that $(v,t) \mapsto J(v,u,d,t)$ is continuous for all $u,d \in \mathbb{N}$. We endow $\mathcal{C}(E)$ with the supremum norm

$$||J|| = \sup_{(v,u,d,t)\in E} |J(v,u,d,t)|.$$

The process X is piecewise deterministic. Hence problem (8) is a piecewise deterministic control problem. We only remark that, although the price process X is piecewise constant, the optimal control will, in general, not be piecewise constant. This is due to the fact that if X remains constant from time t to time $t+s$, the time horizon changes, and thus the optimal strategy needs to be adapted.

For $J : E \to \mathbb{R}^+$, we define the operator T mapping J to $TJ :\ E \to \mathbb{R}^+$ by

$$\begin{aligned}(11)\quad (TJ)(v,u,d,t) &= \int_0^{S-t} e^{-\lambda s} \cdot \min_{\zeta \in I_{v,u,d}} \left\{ \begin{matrix} \lambda^+ J(v+\zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ +\lambda^- J(v+\zeta x_0 e^{au-bd}(e^{-b}-1), u, d+1, t+s) \end{matrix} \right\} ds \\ &\quad + e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v),\end{aligned}$$

where $I_{v,u,d}$ is as in (9). In (11) one takes the min over the present control actions of the expectation of the optimal cost-to-go function at the next jump time, where one of the two possibilities may occur: a jump upwards for which the value process changes to $v+\zeta x_0 e^{au-bd}(e^a - 1)$ or a jump downwards (see also the proof of Lemma 3.2 and the explicit expressions (20) and (21) of J^1 and J^2 after its proof). From the proof of the next lemma it follows that the integral in (11) is well defined: indeed, the integrand is given by the continuous function $\hat{g}$ defined in (12).

LEMMA 3.1. *The operator $T : \mathcal{C}(E) \to \mathcal{C}(E)$ is a contraction with contraction constant $1 - e^{-\lambda S}$.*

Proof. 1. We first demonstrate that, for $J \in \mathcal{C}(E)$, the integral in (11) is well defined and $TJ \in \mathcal{C}(E)$. Let

$$\begin{aligned} g(\zeta,v,s) = \lambda^+ J(v+\zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ +\lambda^- J(v+\zeta x_0 e^{au-bd}(e^{-b}-1), u, d+1, t+s)\end{aligned}$$

denote the function inside the curly brackets in (11). This function is continuous on

$$\left[-\frac{c+F_{u,d}}{x_0 e^{au-bd}(e^a-1)}, \frac{c+F_{u,d}}{x_0 e^{au-bd}(1-e^{-b})}\right] \times [-c, F_{u,d}] \times [0,T];$$

hence it is also bounded on this domain. The multifunction $v \mapsto I_{v,u,d}$ is continuous. Applying Proposition D.3 (c) of [12], we obtain that the function

$$(12)\qquad \hat{g}(v,s) = \min_{z \in I_{v,u,d}} g(z,v,s)$$

is continuous.

2. The proof that T is a contraction is inspired by Theorem 3.2 of [1]. For $\xi : [0, S-t] \to I_{v,u,d}$, let

$$\begin{aligned}(T_\xi J)(v,u,d,t) = e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v) \\ + \int_0^{S-t} e^{-\lambda s} \Big\{ \lambda^+ J(v + \xi(s) x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ + \lambda^- J(v + \xi(s) x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t+s) \Big\} ds.\end{aligned}$$

We then have

$$||T_\xi J - T_\xi J'|| \leq (1 - e^{-\lambda S}) ||J - J'||.$$

Due to the continuity of J, there exists $\xi : [0, S-t] \to I_{v,u,d}$ such that

$$T_\xi J = TJ.$$

Hence we obtain

$$\begin{aligned}TJ' - TJ &\leq T_\xi J' - T_\xi J \\ &\leq (1 - e^{-\lambda S}) ||J' - J||.\end{aligned}$$

By symmetry we can conclude that

$$|TJ' - TJ| \leq (1 - e^{-\lambda S}) ||J' - J||. \qquad \square$$

Given $n \in \mathbb{N}$, let

$$J^0 = 0, \quad \text{and, for } h \leq n, \quad J^h = TJ^{h-1}, \tag{13}$$

and let $(\xi^n_s)_{s \in [0,S]}$ be the strategy induced by computing $J^n(V_0, 0, 0, 0)$ via (13) and (11). More precisely, this strategy is defined as follows. By induction over $h \leq n-2$ we define ξ^n on each interval $(\hat\tau_h, \hat\tau_{h+1}]$: For $s \in [0, \hat\tau_1]$ let $v = V_0$ and

$$\xi^n_s := \arg \min_{\zeta \in I_{v,0,0}} \Big\{ \lambda^+ J^{n-1}(v + \zeta x_0 (e^a - 1), 1, 0, s) + \lambda^- J^{n-1}(v + \zeta x_0 (e^{-b} - 1), 0, 1, s) \Big\}. \tag{14}$$

It was shown in [8] that the mapping $v \mapsto J^n(v, u, d, t)$ is decreasing and strictly convex on $(-c, F_{u,d})$. Hence the minimum in (14) and (15) below is assumed at a unique point ζ.

Suppose we defined the strategy ξ^n_s for all $s \leq \hat\tau_h$. At time $t = \hat\tau_h$, we observed $u = N^+_t$ jumps up and $d = N^-_t$ jumps down with $u + d = h$, and we have some capital $v = V_{\hat\tau_h}$ available. For $s \in (\hat\tau_h, \hat\tau_{h+1}]$, we define

$$\begin{aligned}\xi^n_s := \arg \min_{\zeta \in I_{v,u,d}} \Big\{ \lambda^+ J^{n-u-d-1}(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, s) \\ + \lambda^- J^{n-u-d-1}(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, s) \Big\}.\end{aligned} \tag{15}$$

We have thus defined the strategy ξ^n_t for $t \in [0, \hat\tau_{n-1}]$. On the event $\{\tau_{n-1} > S\}$, this is sufficient. For the general case, we set $\xi^n_t = 0$ for $t \in (\hat\tau_{n-1}, S]$; i.e., we transfer all funds to the cash account after the $(n-1)$st jump happened prior to S.

Clearly, the strategy ξ^n thus defined satisfies $\xi^n \in \mathcal{A}_{V_0}$. The associated wealth process

$$V_t^n := V_0 + \int_0^t \xi_s^n dX_s \tag{16}$$

is constant from time $\hat{\tau}_{n-1}$ on.

By analogy to (8), we define a new value function

$$J^{*,n}(v,u,d,t) = \min_{\xi \in \mathcal{A}_{v,u,d,t}} E[l(F(X_S) - V_S^\xi),\ \tau_{u+d+n} > S |\, N_t^+ = u,\ N_t^- = d], \tag{17}$$

where

$$V_S^\xi = v + \int_t^S \xi_s dX_s.$$

The difference is that for $J^{*,n}(v,u,d,t)$ we take the expectation on the event that less than n jumps occur on the interval $(t,S]$.

We have now defined three functions J^*, J^n, and $J^{*,n}$ via (8), (13), and (17). Of these, J^* is the value function associated with problem (7). The function J^n is defined as the nth iteration of the dynamic programming operator associated with problem (7). Hence, a priori, J^n is not a value function. However, $J^{*,n}$ is the value function for the problem obtained from (7) by replacing Ω by $\Omega \cap \{\tau_n > S\}$. In the next lemma, we demonstrate that J^n and $J^{*,n}$ coincide. Consequently, we obtain for $t = 0$ the equality

$$J_0^n := J^n(V_0,0,0,0) = E[l(F(X_S) - V_S^n),\ \tau_n > S] = \min_{\xi \in \mathcal{A}_{V_0}} E[l(F(X_S) - V_S^\xi),\ \tau_n > S] \tag{18}$$

with V^n defined as in (16). This is remarkable in that it gives a new interpretation for J^n as a value function to problem (17) which is related to the original problem in a simple intuitive way.

LEMMA 3.2. *We have* $J^n = J^{*,n}$.

Proof. Essentially, the assertion is an application of the DP principle, Proposition 2.1, and (10).

For $n = 0, 1$, the assertion is immediate, see also (20).

Assume $J^{*,n-1} = J^{n-1}$ holds for $n - 1 \in \mathbb{N}$. We now demonstrate the assertion for n. Conditioning the right-hand side of (17) on $\hat{\tau}_{u+d+1}$, we obtain from the DP principle that

$$\begin{aligned} &J^{*,n}(v,u,d,t) \\ &\quad = \min_{\xi \in \mathcal{A}_{v,u,d,t}} E[J^{*,n-1}(V_{\hat{\tau}_{u+d+1}}, N^+_{\hat{\tau}_{u+d+1}}, N^-_{\hat{\tau}_{u+d+1}}, \hat{\tau}_{u+d+1}) |\, N_t^+ = u,\ N_t^- = d] \\ &\quad = \min_{\xi \in \mathcal{A}_{v,u,d,t}} E[J^{n-1}(V_{\hat{\tau}_{u+d+1}}, N^+_{\hat{\tau}_{u+d+1}}, N^-_{\hat{\tau}_{u+d+1}}, \hat{\tau}_{u+d+1}) |\, N_t^+ = u,\ N_t^- = d]. \end{aligned}$$

Due to (10) and Proposition 2.1, the right-hand side of the previous equation evaluates to

$$\begin{aligned} \min_{\xi \in \mathcal{A}_{v,u,d,t}} \int_0^{S-t} e^{-\lambda s} &\left\{ \begin{array}{c} \lambda^+ J^{n-1}(v + \xi_s x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ + \lambda^- J^{n-1}(v + \xi_s x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t+s) \end{array} \right\} ds \\ &+ e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v) \end{aligned}$$

$$= \int_0^{S-t} e^{-\lambda s} \min_{\zeta \in I_{v,u,d}} \left\{ \begin{array}{c} \lambda^+ J^{n-1}(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ +\lambda^- J^{n-1}(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t+s) \end{array} \right\} ds$$

$$+ e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v),$$

$$= (TJ^{n-1})(v,u,d,t) = J^n(v,u,d,t) \tag{19}$$

which proves the assertion for n. □

We have explicit expressions for the first two iterations of T:

$$J^1(v,u,d,t) = e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v), \tag{20}$$

$$J^2(v,u,d,t) = J^1(v,u,d,t) \tag{21}$$

$$+ (S-t) \min_{\zeta \in I_{v,u,d}} \left\{ \begin{array}{c} \lambda^+ J^1(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t) \\ +\lambda^- J^1(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t) \end{array} \right\},$$

where we have used the fact that J^1 depends on t only through the factor given by the exponential function. Obtaining an explicit expression of $J^n(v,u,d,t)$ becomes difficult, if not impossible, for $n > 2$, unless one makes some simplifying assumptions that would, however, lead to a suboptimal solution. In section 5 we shall therefore describe a computable approximation approach and show its convergence.

THEOREM 3.3.

(i) *The value function J^* is the unique fixed point of T, i.e.,*

$$J^* = TJ^*, \tag{22}$$

and we have

$$||J^n - J^*|| \le e^{\lambda S}(1 - e^{-\lambda S})^n ||J^1||. \tag{23}$$

(ii) *The following strategy ξ^* is efficient: For $s \in (\hat\tau_{u+d}, \hat\tau_{u+d+1}]$ and $v = V_{\tau_{u+d}}$, let ξ_s^* be given by the unique solution to the deterministic optimization problem embedded in the computation of $(TJ^*)(u,d,v,t)$ according to (11), i.e.,*

$$\xi_s^* := \arg \min_{\zeta \in I_{v,u,d}} \Big\{ \lambda^+ J^*(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, s)$$

$$+\lambda^- J^*(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, s) \Big\}.$$

Proof. From (18) we obtain

$$J_0^n \le J_0^* \le J_0^n + E[l(F(X_S) + c),\ \tau_n \le S]. \tag{24}$$

Due to estimates (24) and (6), we have

$$\lim_{n \uparrow \infty} J^n(v,0,0,t) = J^*(v,0,0,t) \tag{25}$$

uniformly in v and t. Since N^+, N^- are stationary Markov processes, we obtain $J^n(v,u,d,t) \to J^*(v,u,d,t)$ uniformly in v and t for all u,d. This implies $J^* \in \mathcal{C}(E)$; i.e., J^* is in the domain of T. Application of the DP principle implies that J^* is a fixed point of T (alternatively, this follows from (25) and Lemma 3.1).

For item (ii), we obtain from the DP principle

$$J^*(v,u,d,t) = \min_{\xi \in \mathcal{A}_{v,u,d,t}} E\Bigg[J^* \left(v + \int_t^{\tau_{u+d+1}} \xi_s dX_s, N^+_{\tau_{u+d+1}}, N^-_{\tau_{u+d+1}}, \tau_{u+d+1} \right) \Bigg|$$

$$N_t^+ = u,\ N_t^- = d \Bigg].$$

Due to (10), the right-hand side of the previous equation evaluates to

$$\min_{\xi\in\mathcal{A}_{v,u,d,t}} \int_0^{S-t} e^{-\lambda s} \begin{Bmatrix} \lambda^+ J^*(v+\xi_s x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ +\lambda^- J^*(v+\xi_s x_0 e^{au-bd}(e^{-b}-1), u, d+1, t+s) \end{Bmatrix} ds$$
$$+ e^{-\lambda(S-t)} l(F(x_0 e^{au-bd}) - v).$$

The minimum is achieved by the strategy ξ^* prescribed in item (ii) (see also (19)). This proves optimality of the strategy ξ^*, and we obtain again the fixed-point equation

$$J^*(v,u,d,t) = (TJ^*)(v,u,d,t). \qquad \square$$

Remark 2. In computing the approximating strategy ξ^n, (23) gives a handle on the distance between the value of the nth iteration J_0^n and the optimal value J_0^*. However, from an economic point of view, one is equally interested in the expected loss incurred from implementing the strategy ξ^n associated with this iteration, i.e., in the term $E[l(F(X_S) - V_S^n)]$, where, we recall from (16), V_t^n is the wealth process associated with the strategy ξ^n. This can be estimated via

$$J_0^n \le E[l(F(X_S) - V_S^n)] \le J_0^n + E[l(F(X_S)+c),\ \tau_n \le S] \tag{26}$$

which follows from (18). In section 5, we examine the numerical implementation of the problem in more detail.

4. Uncertain intensities.

4.1. Bayesian updating. In this section, we assume λ^+ and λ^- are constant but unknown to the investor; i.e., the true probability distribution $P = P_{\lambda^+,\lambda^-}$ is unknown to the investor. In modeling this situation we take the Bayesian point of view, thereby assuming that λ^+ and λ^- are random variables to which the investor assigns some (prior) distributions $\pi_0^+(d\lambda^+)$ and $\pi_0^-(d\lambda^-)$. Let $(\Omega, \mathcal{F}, P)$ denote the given probability space where $P = P_{\lambda^+,\lambda^-}$. On $\overline{\Omega} := \mathbb{R}_+^2 \times \Omega$, the subjective probability measure of the investor is thus given by

$$P(d\overline{\omega}) = \pi_0^+(d\lambda^+)\pi_0^-(d\lambda^-)P_{\lambda^+,\lambda^-}(d\omega).$$

We consider two filtrations on $\overline{\Omega}$:

(i) The filtration $(\mathcal{F}_t)$ generated by the processes N^+ and N^-. This is the information available to the investor.

(ii) Let $\mathcal{G}_0$ denote the σ-algebra generated by λ^+ and λ^-. We then define the filtration $\mathcal{G}_t = \mathcal{F}_t \vee \mathcal{G}_0$ as the filtration corresponding to "full information."

We have that, with respect to the filtration $(\mathcal{F}_t)$, N is a Cox process, whereas, with respect to the filtration $(\mathcal{G}_t)$, N is a Poisson process with intensity $\lambda^+ + \lambda^-$.

We define P_0 via

$$\left.\frac{dP}{dP_0}\right|_{\mathcal{G}_t} = e^{-(\lambda^+ + \lambda^- - 2)t}(\lambda^+)^{N_t^+}(\lambda^-)^{N_t^-} =: L_t.$$

Under P_0, the random quantities λ^+, λ^-, N^+, and N^- are independent: N^+ and N^- are standard Poisson processes; i.e., both have known intensity one. The random variables λ^i have distribution π_0^i under P_0 for $i = +, -$. Let

$$\mathcal{L}_t(f) := E_0[L_t\, f(\lambda^+,\lambda^-)|\,\mathcal{F}_t]$$
$$= \int_0^\infty \int_0^\infty f(\lambda^+,\lambda^-) e^{-(\lambda^+ + \lambda^- - 2)t}(\lambda^+)^{N_t^+}(\lambda^-)^{N_t^-}\pi_0^+(d\lambda^+)\pi_0^-(d\lambda^-)$$

and put

$$\pi_t^i(d\lambda) := \frac{e^{-\lambda t}\lambda^{N_t^i}\pi^i(d\lambda)}{\int_0^\infty e^{-\lambda t}\lambda^{N_t^i}\pi^i(d\lambda)}, \quad i = +, -. \tag{27}$$

We then have the relation (filter equation)

$$E[f(\lambda^+, \lambda^-)|\,\mathcal{F}_t] = \frac{\mathcal{L}_t(f)}{\mathcal{L}_t(1)} = \int\int f(\lambda^+, \lambda^-)\pi_t^+(d\lambda^+)\pi_t^-(d\lambda^-), \tag{28}$$

and $\pi_t^i(d\lambda^i)$ is the posterior distribution of λ^i, $i = +, -$.

Recall that the density of the gamma distribution with shape parameter α and scale parameter β can be given in the form

$$\gamma(\lambda\,|\,\alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)}\lambda^{\alpha-1}e^{-\beta\lambda}.$$

We conclude from (27) that, if the prior distribution π_0^i for λ^i is a gamma distribution with parameters α_0^i and β_0, then the posterior distribution π_t at time t is again a gamma distribution with parameters

$$\alpha_t^i = \alpha_0^i + N_t^i, \quad \beta_t = \beta_0 + t \tag{29}$$

for $i = +, -$. Furthermore, the distribution of $\lambda = \lambda^+ + \lambda^-$ at time 0 is gamma with parameters $\alpha_0 = \alpha_0^+ + \alpha_0^-$ and β_0. At time t, the posterior distribution of λ is again gamma with β_t as in (29) and

$$\alpha_t = \alpha_t^+ + \alpha_t^- = \alpha_0 + N_t. \tag{30}$$

We can calculate by means of (28)

$$\overline{\lambda_t^i} := E[\lambda^i|\,\mathcal{F}_t] = \frac{\alpha_t^i}{\beta_t}, \quad i = +, -. \tag{31}$$

4.2. The PD-DP equation. The observed process X is still piecewise deterministic. Hence problem (8) is still a piecewise deterministic control problem. In the case of uncertain intensities, if X remains constant from time t to time $t+s$, this not only changes the time to maturity, but it also reveals additional information regarding the true intensities.

Let

$$p^+(u,d,t,s) := \left(\frac{\beta_0+t}{\beta_0+t+s}\right)^{\alpha_0+u+d}\frac{\alpha_0^+ + u}{\beta_0+t+s},$$
$$p^-(u,d,t,s) := \left(\frac{\beta_0+t}{\beta_0+t+s}\right)^{\alpha_0+u+d}\frac{\alpha_0^- + d}{\beta_0+t+s},$$
$$p^0(n,t) := \left(\frac{\beta_0+t}{\beta_0+S}\right)^{\alpha_0+n}.$$

LEMMA 4.1. *For any nonnegative function f, we have*

$$\begin{aligned} &E[f(N^+_{\hat\tau_{u+d+1}}, N^-_{\hat\tau_{u+d+1}}, \hat\tau_{u+d+1})|\ N_t^+ = u,\ N_t^- = d] \\ &= \int_0^{S-t}\Big\{p^+(u,d,t,s)f(u+1,d,t+s) + p^-(u,d,t,s)f(u,d+1,t+s)\Big\}ds \\ &\quad + p^0(u+d,t)f(u,d,S). \end{aligned} \tag{32}$$

Proof. Since N is a Poisson process with intensity $\lambda^+ + \lambda^-$ with respect to the filtration $(\mathcal{G}_t)$, we obtain from (10)

$$\begin{aligned}
&E[f(N^+_{\hat\tau_{u+d+1}}, N^-_{\hat\tau_{u+d+1}}, \hat\tau_{u+d+1})|\ N_t^+ = u,\ N_t^- = d] \\
&\quad = E[E[f(N^+_{\hat\tau_{u+d+1}}, N^-_{\hat\tau_{u+d+1}}, \hat\tau_{u+d+1})|\ \mathcal{G}_t]|\ N_t^+ = u,\ N_t^- = d] \\
&\quad = E\bigg[\int_0^{S-t} \Big\{\lambda^+ f(u+1,d,t+s) + \lambda^- f(u,d+1,t+s)\Big\} e^{-\lambda s} ds \\
&\qquad\quad + e^{-\lambda(S-t)} f(u,d,S)|\ N_t^+ = u,\ N_t^- = d\bigg].
\end{aligned}$$

Due to (28) and (29), the last expression is given by

$$\begin{aligned}
&\int\int \gamma(\lambda^+ \,|\, \alpha_0^+ + u, \beta_0 + t)\gamma(\lambda^- \,|\, \alpha_0^- + d, \beta_0 + t) d\lambda^+ d\lambda^- \\
&\cdot\Big[\int_0^{S-t} \Big\{\lambda^+ f(u+1,d,t+s) + \lambda^- f(u,d+1,t+s)\Big\} e^{-\lambda s} ds + e^{-\lambda(S-t)} f(u,d,S)\Big].
\end{aligned}$$

Applying Fubini's theorem to integrate first over λ^+, λ^- and then over s, we arrive at the right-hand side of (32). ∎

In the case of uncertain intensities, the DP operator T maps $J : E \to \mathbb{R}^+$ to $TJ :\ E \to \mathbb{R}^+$ defined by

$$\begin{aligned}
(TJ)(v,u,d,t) &= \int_0^{S-t} \min_{\zeta \in I_{v,u,d}} \left\{ \begin{matrix} p^+(u,d,t,s) J(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\ + p^-(u,d,t,s) J(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t+s) \end{matrix} \right\} ds \\
&\quad + p^0(u+d,t) l(F(x_0 e^{au-bd}) - v).
\end{aligned} \tag{33}$$

Let

$$E^k = \{(v,u,d,t) \,|\, v \geq -c,\ u,d \in \mathbb{N},\ u+d \leq k,\ t \in [0,S]\} \tag{34}$$

and

$$(T^k J)(v,u,d,t) := \begin{cases} (TJ)(v,u,d,t), & u+d \leq k-1, \\ 0, & u+d = k. \end{cases} \tag{35}$$

LEMMA 4.2. *For every $k \in \mathbb{N}$, the operator $T^k : \mathcal{C}(E^k) \to \mathcal{C}(E^k)$ is a contraction with contraction constant*

$$1 - p^0(k,0) = 1 - \left(\frac{\beta_0}{\beta_0 + S}\right)^{\alpha_0 + k},$$

and T^k has a unique fixed point in $\mathcal{C}(E^k)$.

Proof. 1. It follows as in Lemma 3.1 that $T^k J \in \mathcal{C}(E^k)$ for $J \in \mathcal{C}(E^k)$.

2. For $\xi : [0, S-t] \to I_{v,u,d}$ with values denoted, as previously, by ζ, let

$$\begin{aligned}
(T_\xi J)(v,u,d,t) &= p^0(u+d,t) l(F(x_0 e^{au-bd}) - v) \\
&\quad + \int_0^{S-t} \Big\{p^+(u,d,t,s) J(v + \zeta(s) x_0 e^{au-bd}(e^a - 1), u+1, d, t+s) \\
&\quad + p^-(u,d,t,s) J(v + \zeta(s) x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t+s)\Big\} ds.
\end{aligned}$$

We then have

$$\begin{aligned}||T_\xi J - T_\xi J'||_{E^k} &\leq \left|\left|\int_0^{S-t} \{p^+(u,d,t,s) + p^-(u,d,t,s)\} ds\right|\right|_{E^k} ||J - J'||_{E^k} \\ &= ||1 - p^0(u+d,t)||_{E^k}\ ||J - J'||_{E^k} \\ &= \left|\left|1 - \left(\frac{\beta_0 + t}{\beta_0 + S}\right)^{\alpha_0+u+d}\right|\right|_{E^k} ||J - J'||_{E^k} \\ &\leq \left(1 - \left(\frac{\beta_0}{\beta_0 + S}\right)^{\alpha_0+k}\right) ||J - J'||_{E^k}.\end{aligned}$$

Due to the continuity of J, there exists $\xi : [0, S-t] \to I_{v,u,d}$ such that, for $u+d \leq k-1$,

$$T_\xi J = T^k J.$$

Hence we obtain

$$T^k J' - T^k J \leq T_\xi J' - T_\xi J \leq \left(1 - \left(\frac{\beta_0}{\beta_0 + S}\right)^{\alpha_0+k}\right) ||J' - J||_{E^k}.$$

By symmetry we can conclude that

$$||T^k J' - T^k J||_{E^k} \leq \left(1 - \left(\frac{\beta_0}{\beta_0 + S}\right)^{\alpha_0+k}\right) ||J' - J||_{E^k}. \qquad \square$$

COROLLARY 4.3. *For $k \in \mathbb{N}$, a fixed point J_k^* of T^k coincides with a fixed point J^* of T on the set E^k.*

Proof. Let $G = J^*$ on E^{k-1} and $G = 0$ on $E^k \setminus E^{k-1}$. It follows from (35) that G is a fixed point of T^k. Due to Lemma 4.2, this implies $G = J_k^*$. $\square$

Remark 3. While the case of uncertain intensities follows in large part along the lines of known intensities, Lemma 4.2 highlights a major difference: The operator T is no longer a contraction on $\mathcal{C}(E)$. This is due to the fact that, as the number of observed jumps increases, the estimated probability that no more jumps occur prior to S tends to zero. But it is exactly this probability that makes T a contraction; see also [1] for the case without model uncertainty.

For practical purposes, however, this poses no difficulties since (see Corollary 4.3) we can instead work with the contraction T^k, and for this see section 5, especially Lemma 5.1.

We conclude this section by showing Theorem 4.5 below by which it follows that, despite the fact that in the present setting the operator T is no longer a contraction, this operator has a unique fixed point. Furthermore, an efficient strategy exists in complete analogy to the case of known intensities.

As in (13), we define

$$J^0 = 0, \quad \text{and, for } h \leq n, \quad J^h = TJ^{h-1}. \tag{36}$$

Again, we obtain explicit expressions for the first two iterations of T (compare with (20) and (21)):

$$J^1(v,u,d,t) = p^0(u+d,t)\, l(F(x_0 e^{au-bd}) - v), \tag{37}$$

$$\begin{aligned}J^2(v,u,d,t) = J^1(v,u,d,t) + \frac{S-t}{\beta_0 + S} \\ \cdot \min_{\zeta \in I_{v,u,d}} \left\{ \begin{array}{c} (\alpha_0^+ + u)\, J^1(v + \zeta x_0 e^{au-bd}(e^a - 1), u+1, d, t) \\ + (\alpha_0^- + d)\, J^1(v + \zeta x_0 e^{au-bd}(e^{-b} - 1), u, d+1, t) \end{array} \right\}.\end{aligned} \tag{38}$$

In (38), we see directly how the observed jumps affect the optimal strategy: The larger the number u of upward jumps in comparison to the number of downward jumps d, the higher the a posteriori probability that the next jump will be upwards. Concerning the explicit computation of the exact values of $J^n(v,u,d,t)$ for $n>2$ the same comments apply as after (21).

We define the strategy ξ^n analogous to (14) and (15) in which λ^i is replaced by p^i $(i=+,-)$.

LEMMA 4.4. *We have*

$$J^n(v,u,d,t)=\min_{\xi\in\mathcal{A}_{v,u,d,t}} E[l(F(X_S)-V_S^{\xi}),\ \tau_{u+d+n}>S|\,N_t^+=u,\ N_t^-=d].$$

Proof. The proof proceeds exactly as in Lemma 3.2, with the exception that (10) is replaced by (32). □

THEOREM 4.5.

(i) *The value function J^* is the unique fixed point of T, i.e.,*

$$J^*(v,u,d,t)=(TJ^*)(v,u,d,t),\quad (v,u,d,t)\in E. \tag{39}$$

(ii) *The following strategy ξ^* is efficient: For $s\in(\hat\tau_{u+d},\hat\tau_{u+d+1}]$ and $v=V_{\tau_{u+d}}$, let $\xi_s^*=\zeta^{u,d,v,t,*}(s)$, where the latter is given by the deterministic optimization problem embedded in the computation of $(TJ^*)(u,d,v,t)$, i.e.,*

$$\zeta_s^*:=\arg\min_{\zeta\in I_{v,u,d}}\Big\{p^+(u,d,t,s-t)J^*(v+\zeta x_0e^{au-bd}(e^a-1),u+1,d,s)$$
$$+p^-(u,d,t,s-t)J^*(v+\zeta x_0e^{au-bd}(e^{-b}-1),u,d+1,s)\Big\}.$$

Proof. We first prove (i), i.e., the uniqueness of the fixed point. Consider two fixed points J^a and J^b of T. Due to Corollary 4.3 and Lemma 4.2, we obtain

$$J^a(v,u,d,t)=J^b(v,u,d,t),\quad (v,u,d,t)\in E^{k-1}.$$

Since k is arbitrary, this implies $J^a=J^b$ on E.

As in (24), we obtain

$$J_0^n\le J_0^*\le J_0^n+E[l(F(X_S)+c),\ \tau_n\le S]. \tag{40}$$

From (40) and the uniqueness of the fixed point we obtain item (i) as in the proof of Theorem 3.3.

Similarly, (ii) follows from the DP principle and (32). Especially, this implies that J^* is a fixed point of T. □

For a version of the estimate (23) in the case of uncertain intensities, we refer to Lemma 5.1.

We also have the following analogue to the estimate (26):

$$J_0^n\le E[l(F(X_S)-V_S^n)]\le J_0^n+E[l(F(X_S)+c),\ \tau_n\le S]. \tag{41}$$

5. Algorithmic implementation: Interpolation of the value function. Due to Theorem 3.3 (respectively, 4.5), the value J_0^n converges to the optimal value and the strategy ξ^n to the efficient strategy in the sense of the estimate (26), respectively (41). In order to compute J_0^n and ξ^n for reasonably large values of n, we need to discretize the problem in the dimensions wealth and time (v,t) and then to interpolate it in the same variables. In this section, we provide Lemma 5.1 to

control the error incurred from both this interpolation and stopping after the nth iteration. To this effect, in order to include also the case of uncertain intensities, we shall consider the operator T^k in (35) for some fixed $k \leq n$ instead of T. This will lead to a fixed contraction constant $1 - p^0(k,0)$ (see Lemma 4.2) also for the case of uncertain intensities and thus also for this case to the same upper bound in Lemma 5.1 below that goes to zero for $n \to \infty$.

For the case of unknown intensities we shall examine an approximation J_k^n of J^n defined recursively via

$$J_k^0 = 0, \quad \text{and, for } \ h \leq n, \quad J_k^h = T^k J_k^{h-1}, \tag{42}$$

and restrict the arguments v and t to $(v,t) \in \mathcal{S} := [-c, F_k] \times [0, S]$ with

$$F_k := \max\{F_{u,d} |\ u + d \leq k - 1\}; \tag{43}$$

see (5). Notice in fact that, if at any time $v \geq F_k$, then superhedging is possible, and this leads to an optimal value $J^* = 0$. Since for $v = F_k$ we are interested also in the optimal strategy, in what follows we shall thus require that $v \leq F_k$, i.e., $v \in [-c, F_k]$.

For the case of known intensities we shall use the same approximations as in (42), and all that follows holds in the same way also for this case by simply putting $k = n$.

Consider then some finite grid $G \subset \mathcal{S}$ containing the extremal points of $\mathcal{S}$ and denote by $\mathcal{D}(E^k)$ the Banach space of cadlag functions on E^k endowed with the Skorokhod norm $||\cdot||_{E^k}$. Define the operator $T_G^k :\ \mathcal{D}(E^k) \to \mathcal{D}(E^k)$ via

$$(T_G^k H)(v,u,d,t) := \begin{cases} (TH)(v,d,u,t) & \text{if } (v,t) \in G,\ u + d \leq k - 1, \\ 0 & \text{if } u + d = k \ \text{ or } \ v > F_k, \\ \text{cadlag interpolation} & \text{else.} \end{cases}$$

Notice that, although for $v = F_k$ we have the possibility of superhedging, in our calculations we need to consider also this value in order to obtain the corresponding (superhedging) strategy. Due to our interpolation approximations, this strategy will, however, turn out to be only approximately superhedging.

Due to Corollary 4.3, we have

$$T_G^k J^* = \begin{cases} J^*(v,d,u,t) & \text{if } (v,t) \in G,\ u + d \leq k - 1, \\ 0 & \text{if } u + d = k \ \text{ or } \ v > F_k, \\ \text{cadlag interpolation} & \text{else.} \end{cases}$$

Due to the continuity of J^*, we have

$$\epsilon(G) := ||J^* - T_G^k J^*||_{E^{k-1}} \to 0 \tag{44}$$

for

$$\sup_{(v,t) \in \mathcal{S}} \min_{(v',t') \in G} (|v - v'| + |t - t'|) \to 0.$$

We approximate the optimal value J^* by the value H_k^n defined recursively via

$$H_k^1 = J_k^1, \quad H_k^n = T_G^k H_k^{n-1} \quad \text{for} \quad n \geq k. \tag{45}$$

This value can be achieved by some strategy $\tilde{\xi}^n$ defined in analogy to (14)–(16) and, similarly, for the case of uncertain intensities.

With relation (44), the next lemma provides a handle on the error.

LEMMA 5.1. *We have*

$$||J^* - H_k^n||_{E^{k-1}} \leq \frac{1}{1-\kappa}\Big(\kappa^n ||J_k^1||_{E^{k-1}} + \epsilon(G)\Big), \tag{46}$$

where κ *is given by*

(i) $\kappa = 1 - e^{-\lambda S}$ *in the case of known intensities,*

(ii) $\kappa = 1 - p^0(k,0)$ *in the case of uncertain intensities.*

Proof. 1. It follows by an immediate extension to the case of cadlag interpolations of the proof of Lemma 3.1 (respectively, Lemma 4.2) that the operator $T_G^k : \mathcal{D}(E^k) \to \mathcal{D}(E^k)$ is a contraction with contraction constant κ. Especially, T_G^k has a fixed point $H_k^* \in \mathcal{D}(E^k)$. Noticing that $H_k^1(v,u,d,t) = p^0(u+d,t)l(F(x_0e^{au-bd}) - v)$ and that, consequently,

$$\begin{aligned} ||H_k^2(v,u,d,t) - H_k^1(v,u,d,t)||_{E^{k-1}} &= ||T_G^k H_k^1(v,u,d,t) - H_k^1(v,u,d,t)||_{E^{k-1}} \\ &\leq \left| \int_0^{S-t} \{p^+(u,d,t,s) + p^-(u,d,t,s)\} ds \right| ||H_k^1||_{E^{k-1}}, \end{aligned}$$

one obtains

$$||H_k^n - H_k^*||_{E^{k-1}} \leq \frac{\kappa^n}{1-\kappa} ||J_k^1||_{E^{k-1}}.$$

2. We have

$$\begin{aligned} ||J^* - H_k^*||_{E^{k-1}} &\leq ||J^* - T_G^k J^*||_{E^{k-1}} + ||T_G^k J^* - T_G^k H_k^*||_{E^{k-1}} \\ &\leq \epsilon(G) + \kappa ||J^* - H_k^*||_{E^{k-1}}, \end{aligned}$$

namely,

$$||J^* - H_k^*||_{E^{k-1}} \leq \frac{1}{1-\kappa}\epsilon(G).$$

3. Due to

$$||J^* - H_k^n||_{E^{k-1}} \leq ||J^* - H_k^*||_{E^{k-1}} + ||H_k^n - H_k^*||_{E^{k-1}},$$

the estimate (46) follows from 1 and 2. ∎

By analogy to (26) and (41) we now have

$$H_k^n \leq E[l(F(X_S) - \tilde{V}_S^n)] \leq H_k^n + E[l(F(X_S) + c),\ \tau_k \leq S],$$

where $\tilde{V}_t^n$ is the wealth process associated with the strategy $\tilde{\xi}^n$.

Remark 4. The just-described algorithm hinges upon the specific form given to the operator T^k in (35) for the case $u + d = k$. Variants are possible, and they imply slight variants also for the algorithm with advantages and disadvantages.

5.1. Example. Here we consider a simple example to illustrate the interpolation algorithm described above in this section. The example is as follows.

Consider the geometric Poisson price model (1) with $x_0 = 1$ and suppose that a, b are such that $e^a = 2$, $e^{-b} = \frac{1}{2}$. For the case of known intensities of the driving Poisson processes we let them be given by $\lambda^+ = \lambda^- = 1$, so that $\lambda = 2$. For the case of unknown intensities we choose $\alpha_0^+ = \alpha_0^- = \beta_0 = 1$ so that $\overline{\lambda}_0^+ = \overline{\lambda}_0^- = 1$.

Take a claim of the form $F(X_S) = (X_S - 1)^+$, a time horizon of $S = 2$, and put $c = 0.5$. The superhedge price for F is (see the comment after (5)) $F_{u,d} \equiv x_0 = 1$. Let the loss function be of the form $l(z) = [\max(z, 0)]^p$ for $p = 2$. The optimization criterion is then

$$J_0^* := \inf_{\xi \in \mathcal{A}_{V_0}} E\left\{ \left[\max\left(\left(x_0 e^{au - bd} - 1 \right)^+ - V_S, 0 \right) \right]^2 \right\}, \tag{47}$$

and it is of the type of *shortfall risk minimization*. The interval of admissible values for ξ on $[0, \hat{\tau}_1]$ is given by (see (9))

$$I_{v,u,d} = \left[-\frac{c+v}{2^{u-d}},\ 2\,\frac{c+v}{2^{u-d}} \right]. \tag{48}$$

Since we have $F_{u,d} \equiv x_0 = 1$, also for F_k in (43) one has $F_k \equiv 1$. This implies that, for the given data, $(v, t) \in \mathcal{S} := [-\frac{1}{2}, 1] \times [0, 2]$. Consider then the following grid that, for the purpose of illustrating the procedure in the simplest possible way, is chosen to be very coarse. More precisely, $G \subset \mathcal{S}$ is obtained as follows: partition the time interval $[0, 2]$ into $L = 2$ subintervals $T_0 := [t_0 = 0, t_1 = 1]$, $T_1 := [t_1 = 1, t_2 = 2]$ and the wealth-value interval $[-\frac{1}{2}, 1]$ into $M = 3$ subintervals $V_0 := [v_0 = -\frac{1}{2}, v_1 = 0]$, $V_1 := [v_1 = 0, v_2 = \frac{1}{4}]$, $V_2 := [v_2 = \frac{1}{4}, v_3 = 1]$. The reason why we consider $v_2 = \frac{1}{4}$ and not, say, $v_2 = \frac{1}{2}$ is that at $v = \frac{1}{2}$ the optimal values are already equal to zero. Even though we are still far from the superhedge value of $v = 1$, this happens because we restrict ourselves to the event that no more than k jumps can occur.

5.1.1. Known intensities. We shall compute the values for H_k^n according to (45) (as well as (42)) for tuples (v_j, u, d, t_i) with $i \in \{0, 1\}$, $j \in \{0, 1, 2\}$, and $u + d \leq k - 1$. In fact, this last restriction for u and d and the sufficiency of considering only values of $v \leq 1$ come from the definition of the operator T_G^k. On the other hand, since we perform a cadlag interpolation, we do not need to consider the upper end point $t_i = 2$ of the time interval; i.e., it suffices to have $i \in \{0, 1\}$.

First we recall from (42) that, for our example,

$$J_k^1(v_j, u, d, t_i) = e^{-2(2-t_i)} \left[\max\left\{ \left(2^{u-d} - 1 \right)^+ - v_j, 0 \right\} \right]^2, \quad i \in \{0, 1\},\ j \in \{0, 1, 2\}, \tag{49}$$

and notice that (see by analogy the motivation for (21))

$$J_k^1(v_j, u, d, t_i + s) = e^{2s} J_k^1(v_j, u, d, t_i). \tag{50}$$

The recursions (45) now become, always for the case of our example and recalling

that we consider cadlag interpolations,

$$
\begin{aligned}
(51)\qquad & H_k^n(v_j,u,d,t_i) = \left(T_G^k H_k^{n-1}\right)(v_j,u,d,t_i) \\
& = J_k^1(v_j,u,d,t_i) + \int_0^{S-t_i} e^{-2s} \\
& \min_{\zeta\in I_{v_j,u,d}} \left\{ \begin{array}{l} \displaystyle\sum_{l=0}^{L-1}\sum_{m=0}^{M-1} 1_{\{T_l\}}(t_i+s)\, 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^a-1)) \\ \quad H_k^{n-1}(v_m,u+1,d,t_l) \\ \displaystyle +\sum_{l=0}^{L-1}\sum_{m=0}^{M-1} 1_{\{T_l\}}(t_i+s)\, 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^{-b}-1)) \\ \quad H_k^{n-1}(v_m,u,d+1,t_l) \end{array} \right\} ds \\
& = J_k^1(v_j,u,d,t_i) + \sum_{l=0}^{L-1} 1_{\{t_i\le t_l\}}\gamma_{i,l} \\
& \min_{\zeta\in I_{v_j,u,d}} \left\{ \begin{array}{l} \displaystyle\sum_{m=0}^{M-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^a-1))\, H_k^{n-1}(v_m,u+1,d,t_l) \\ \displaystyle +\sum_{m=0}^{M-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^{-b}-1))\, H_k^{n-1}(v_m,u,d+1,t_l) \end{array} \right\},
\end{aligned}
$$

where we have used the fact that

$$
\int_0^{S-t_i} e^{-2s} 1_{[t_l,t_{l+1})}(t_i+s)\, ds = \sum_{l=0}^{L-1} 1_{\{t_i\le t_l\}} \frac{e^{2t_i}}{2}\left[e^{-2t_l}-e^{-2t_{l+1}}\right]
$$

so that $\gamma_{i,l} := \frac{e^{2t_i}}{2}\left[e^{-2t_l}-e^{-2t_{l+1}}\right]$, in particular $\gamma_{0,0} = \frac{1-e^{-2}}{2}$ $\gamma_{0,1} = e^{-2}\gamma_{0,0}$. Since J_k^1 satisfies property (50), we have that for $n=2$ the above recursions (51) simplify to become

(52)

$$
\begin{aligned}
& H_k^2(v_j,u,d,t_i) = J_k^1(v_j,u,d,t_i) \\
& \quad +(S-t_i)\cdot \min_{\zeta\in I_{v_j,u,d}} \left\{ \begin{array}{l} \displaystyle\sum_{m=0}^{M-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^a-1))\, J_k^1(v_m,u+1,d,t_i) \\ \displaystyle +\sum_{m=0}^{M-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^{-b}-1))\, J_k^1(v_m,u,d+1,t_i) \end{array} \right\}.
\end{aligned}
$$

Always in order to illustrate the procedure in the simplest possible way, we shall now consider the case of $k=n=3$ with the objective of computing the values for $H_3^3(0,0,0,0)$ and $H_3^3(\frac{1}{4},0,0,0)$ as well as the corresponding minimizing strategy ξ_s^3 for $s\in[0,2]$.

For this purpose we first compute $J_3^1(v_j,u,d,t_i)$ for $v_j\in\{-\frac{1}{2},0,\frac{1}{4},1\}, t_i\in\{0,1\}$, and $u+d\le 2$. This can be easily done on the basis of (49) noticing that these values are zero for all tuples (v_j,u,d,t_i) with $u\le d$ and $v_j\ge 0$ and this is, thanks to (50), independently of t_i.

One then proceeds to compute $H_3^2(v_j, u, d, t_i)$ for $v_j \in \{-\frac{1}{2}, 0, \frac{1}{4}, 1\}, t_i \in \{0, 1\}$, and $u + d = 1$. Notice that the computation of these values leads then also to the minimizing strategy for $s \in (\hat{\tau}_1, \hat{\tau}_2]$. Since by (48) we have $I_{-\frac{1}{2},u,d} = \{0\}$, no minimization is required for the computation of $H_3^2(-\frac{1}{2}, u, d, t_i)$, and so, for this case of $v_j = -\frac{1}{2}$, the minimizing strategy is $\xi_s \equiv 0$ when $s \in (\hat{\tau}_1, \hat{\tau}_2]$. From (52) we now have

$$\begin{aligned} H_3^2\left(-\frac{1}{2}, 1, 0, 0\right) &= J_3^1\left(-\frac{1}{2}, 1, 0, 0\right) + 2\left\{J_3^1\left(-\frac{1}{2}, 2, 0, 0\right) + J_3^1\left(-\frac{1}{2}, 1, 1, 0\right)\right\} \\ &= \frac{109}{4}e^{-4}. \end{aligned}$$

With similar calculations one obtains $H_3^2(-\frac{1}{2}, 0, 1, 0) = \frac{5}{4}e^{-4}$, and, from here, by (50) $H_3^2(-\frac{1}{2}, 1, 0, 1) = \frac{59}{4}e^{-2}$ and $H_3^2(-\frac{1}{2}, 0, 1, 1) = \frac{3}{4}e^{-2}$.

Moving on to $v_j = 0$, we have that $I_{0,u,d} = \left[-\frac{c}{2^{u-d}}, 2\frac{c}{2^{u-d}}\right] \neq \{0\}$ so that this time one has to perform also the minimization according to (52). For this purpose notice that the partition $\{V_m\}_{m=1}^M$ of the wealth-value interval induces a partition of $I_{0,u,d}$ characterized by the fact that the right-hand side in (52) remains constant for all values of ζ in a same subinterval of the partition. We thus have

$$\begin{aligned} H_3^2(0,1,0,0) &= J_3^1(0,1,0,0) \\ &\quad + 2\min\Big\{1_{\{\zeta=-\frac{1}{4}\}}\left[J_3^1(-\tfrac{1}{2},2,0,0) + J_3^1(\tfrac{1}{4},1,1,0)\right], \\ &\qquad 1_{\{\zeta\in(-\frac{1}{4},0)\}}\left[J_3^1(-\tfrac{1}{2},2,0,0) + J_3^1(0,1,1,0)\right], \\ &\qquad 1_{\{\zeta=0\}}\left[J_3^1(0,2,0,0) + J_3^1(0,1,1,0)\right], \\ &\qquad 1_{\{\zeta\in(0,\frac{1}{8})\}}\left[J_3^1(0,2,0,0) + J_3^1(-\tfrac{1}{2},1,1,0)\right], \\ &\qquad 1_{\{\zeta\in(\frac{1}{8},\frac{1}{8})\}}\left[J_3^1(\tfrac{1}{4},2,0,0) + J_3^1(-\tfrac{1}{2},1,1,0)\right], \\ &\qquad 1_{\{\zeta=\frac{1}{2}\}}\left[J_3^1(1,2,0,0) + J_3^1(-\tfrac{1}{2},1,1,0)\right]\Big\} \\ &= e^{-4} + 2\min\left\{\tfrac{49}{4}e^{-4}, \tfrac{49}{4}e^{-4}, 9e^{-4}, \tfrac{37}{4}e^{-4}, \tfrac{125}{16}e^{-4}, \tfrac{17}{4}e^{-4}\right\} = \tfrac{19}{2}e^{-4}, \end{aligned}$$

where the min is achieved for $\zeta = \frac{1}{2}$ so that, for this case of $v_j = 0$, the minimizing strategy is $\xi_s^3 = \frac{1}{2}$ when $s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 1]$. Analogously, one obtains $H_3^2(0,1,0,1) = \frac{21}{4}e^{-2}$ where, thanks to (50), the minimizing value of ζ is the same as before so that we have again $\xi_s^3 = \frac{1}{2}$ for $v_j = 0$ also when $s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [(1, 2]$. By similar calculations one then obtains

$$\begin{aligned} &H_3^2(0,0,1,0) = H_3^2(0,0,1,1) = 0 && \text{with minimizing } \zeta = 0, \\ &H_3^2(\tfrac{1}{4},1,0,0) = \tfrac{145}{16}e^{-4} && \text{with minimizing } \zeta = \tfrac{3}{8}, \\ &H_3^2(\tfrac{1}{4},1,0,1) = \tfrac{77}{16}e^{-2} && \text{with minimizing } \zeta = \tfrac{3}{8}, \\ &H_3^2(\tfrac{1}{4},0,1,0) = H_3^2(\tfrac{1}{4},0,1,1) = 0 && \text{with minimizing } \zeta \text{ any } \zeta \in \left[-\tfrac{1}{2}, 1\right], \\ &H_3^2(1,1,0,0) = 8e^{-4} && \text{with minimizing } \zeta = 0, \\ &H_3^2(1,1,0,1) = 4e^{-2} && \text{with minimizing } \zeta = 0. \end{aligned}$$

At this point one can finally compute

$$
\begin{aligned}
H_3^3(0,0,0,0) &= J_3^1(0,0,0,0) \\
&\quad + \textstyle\sum_{l=0}^{1} \gamma_{0,l} \min \Big\{ 1_{\{\zeta=-\frac{1}{2}\}} \left[H_3^2(-\tfrac{1}{2},1,0,t_l) + H_3^2(\tfrac{1}{4},0,1,t_l) \right], \\
&\qquad\qquad 1_{\{\zeta\in(-\frac{1}{2},0)\}} \left[H_3^2(-\tfrac{1}{2},1,0,t_l) + H_3^2(0,0,1,t_l) \right], \\
&\qquad\qquad 1_{\{\zeta=0\}} \left[H_3^2(0,1,0,t_l) + H_3^2(0,0,1,t_l) \right], \\
&\qquad\qquad 1_{\{\zeta\in(0,\frac{1}{4})\}} \left[H_3^2(0,1,0,t_l) + H_3^2(-\tfrac{1}{2},0,1,t_l) \right], \\
&\qquad\qquad 1_{\{\zeta\in[\frac{1}{4},1)\}} \left[H_3^2(\tfrac{1}{4},1,0,t_l) + H_3^2(-\tfrac{1}{2},0,1,t_l) \right], \\
&\qquad\qquad 1_{\{\zeta=1\}} \left[H_3^2(1,1,0,t_l) + H_3^2(-\tfrac{1}{2},0,1,t_l) \right] \Big\} \\
&= 7e^{-4}(1-e^{-2}),
\end{aligned}
$$

where the min is achieved for $\zeta = 1$ both when $t_l = 0$ and when $t_l = 1$ so that, for $v_j = 0$, the minimizing strategy is $\xi_s^3 = 1$ when $s \in [0, \hat{\tau}_1] \cap [0, 2]$. Peforming analogous calculations one obtains that $H_3^3(\frac{1}{4}, 0, 0, 0) = \frac{221}{32} e^{-4}(1 - e^{-2})$, which is slightly less than the value for $H_3^3(0, 0, 0, 0)$, and the min here is achieved for any $\zeta \in [0, \frac{1}{2}]$ when $t_l = 0$ and for $\zeta = \frac{3}{4}$ when $t_l = 1$. This implies that, for $v_j = \frac{1}{4}$, the minimizing strategy is $\xi_s^3 \in [0, \frac{1}{2}]$ when $s \in (0, \hat{\tau}_1] \cap [0, 1]$ and $\xi_s^3 = \frac{3}{4}$ when $s \in (0, \hat{\tau}_1] \cap (1, 2]$.

Summarizing, we have obtained for the (approximating) minimizing strategy the following expression where, due to the right continuous interpolation, the strategy is the same for all values v of the wealth belonging to a same subinterval of the partition $\{V_m\}$ and given by the value computed in its lower end point. We have in fact

$$
\xi_s^3 = \begin{cases}
1 & \text{if } s \in [0, \hat{\tau}_1] \cap [0, 2] \text{ and } V_0 = 0, \\
\text{any } \zeta \in [0, \frac{1}{2}] & \text{if } s \in [0, \hat{\tau}_1] \cap [0, 1] \text{ and } V_0 = \frac{1}{4}, \\
\zeta = \frac{3}{4} & \text{if } s \in [0, \hat{\tau}_1] \cap (1, 2] \text{ and } V_0 = \frac{1}{4}, \\
\zeta = \frac{3}{8} & \text{if } s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 2],\ u = 1, d = 0,\ V_{\hat{\tau}_1} \in [\frac{1}{4}, 1), \\
\zeta = 0 & \text{if } s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 2],\ u = 1, d = 0,\ V_{\hat{\tau}_1} \geq 1, \\
0 & \text{if } s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 2],\ u = 0, d = 1,\ V_{\hat{\tau}_1} < 0, \\
0 & \text{if } s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 2],\ u = 0, d = 1,\ V_{\hat{\tau}_1} \in [0, \frac{1}{4}), \\
\text{any } \zeta \in [-\frac{1}{2}, 1] & \text{if } s \in (\hat{\tau}_1, \hat{\tau}_2] \cap [0, 2],\ u = 0, d = 1,\ V_{\hat{\tau}_1} = \frac{1}{4}, \\
0 & \text{if } s > \hat{\tau}_2.
\end{cases}
$$

5.1.2. Uncertain intensities. We choose $\alpha_0^+ = \alpha_0^- = \beta_0 = 1$ so that $\overline{\lambda}_0^+ = \overline{\lambda}_0^- = 1$. We start from the expression for J_k^1 that is given here by (see (42))

(53)
$$J_k^1(v_j, u, d, t_i)$$

$$= \left(\frac{t_i+1}{3}\right)^{u+d+2} \left[\max\left\{\left(2^{u-d}-1\right)^+ - v_j, 0\right\}\right]^2,\ i \in \{0,1\},\ j \in \{0,1,2\},$$

for which, analogously to (50), we have

$$J_k^1(v_j,u,d,t+s) = \left(\frac{t+s+1}{t+1}\right)^{u+d+2} J_k^1(v_j,u,d,t). \tag{54}$$

On the other hand, the recursions (45) become

(55)

$$\begin{aligned}
H_k^n(v_j,u,d,t_i) &= J_k^1(v_j,u,d,t_i) \\
&\quad + \int_0^{S-t_i} \min_{\zeta\in I_{v_j,u,d}} \left\{ \sum_{l,m=0}^{L-1} 1_{\{T_l\}}(t_i+s) \left(\frac{1+t_i}{1+t_l}\right)^{1+u+d} \frac{1+u}{1+t_l} \right. \\
&\qquad \cdot 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^a-1)) H_k^{n-1}(v_m,u+1,d,t_l) \\
&\quad + \sum_{l,m=0}^{L-1} 1_{\{T_l\}}(t_i+s) \left(\frac{1+t_i}{1+t_l}\right)^{1+u+d} \frac{1+d}{1+t_l} \\
&\qquad \left. \cdot 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^{-b}-1)) H_k^{n-1}(v_m,u,d+1,t_l) \right\} \\
&= J_k^1(v_j,u,d,t_i) + \sum_{l=0}^{L-1} 1_{\{t_i\le t_l\}} \\
&\quad \cdot \min_{\zeta\in I_{v_j,u,d}} \left\{ \gamma_{i,l}^u \sum_{m=0}^{L-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^a-1)) H_k^{n-1}(v_m,u+1,d,t_l) \right. \\
&\quad \left. + \gamma_{i,l}^d \sum_{m=0}^{L-1} 1_{\{V_m\}}(v_j+\zeta x_0 e^{au-bd}(e^{-b}-1)) H_k^{n-1}(v_m,u,d+1,t_l) \right\}
\end{aligned}$$

having put

$$\begin{cases} \gamma_{i,l}^u &= (t_{l+1}-t_l)\left(\frac{1+t_i}{1+t_l}\right)^{1+u+d} \frac{1+u}{1+t_l}, \\ \gamma_{i,l}^d &= (t_{l+1}-t_l)\left(\frac{1+t_i}{1+t_l}\right)^{1+u+d} \frac{1+d}{1+t_l}. \end{cases}$$

Due to (54) the relations (55) simplify slightly for $n=2$ but not anymore as much as in (52).

At this point the procedure parallels mostly the one described in the previous subsection for known values of the intensities and the calculations are similar.

Note added in proof. Improvements and extensions to the contents of section 5 can be found in [19].

LINEAR QUADRATIC GAUSSIAN BALANCING FOR DISCRETE-TIME INFINITE-DIMENSIONAL LINEAR SYSTEMS*

MARK R. OPMEER† AND RUTH F. CURTAIN†

Abstract. In this paper, we study the existence of linear quadratic Gaussian (LQG)–balanced realizations for discrete-time infinite-dimensional systems. LQG-balanced realizations are those for which the smallest nonnegative self-adjoint solutions of the control and filter Riccati equations are equal. We show that the control (filter) Riccati equation has a nonnegative self-adjoint solution if and only if the system is output (input) stabilizable. Our main result is that the transfer function of a discrete-time linear system has an approximately controllable and observable LQG-balanced realization iff it has an input and output stabilizable realization. The corresponding control and filter Riccati equations have unique nonnegative self-adjoint solutions. Moreover, approximately controllable and observable LQG-balanced realizations are unique up to a unitary state-space transformation. Finally, we show that the spectrum of the product of the smallest nonnegative self-adjoint solutions of the control and filter Riccati equations is independent of the particular realization.

Key words. balanced realization, discrete-time system, infinite-dimensional system, LQG-balanced realization, normalized factorization, Riccati equations

1. Introduction.

Simple models are normally preferred over complex ones in control systems design. Sometimes it is obvious how to construct a simple model for a physical system, but sometimes the characteristics essential to the controller design of a physical system are not obvious. One way to obtain a simple model in this last case is to first obtain a sophisticated model that takes into account every aspect that could be of interest and then perform model reduction on this sophisticated model. A simple model reduction procedure was introduced by Moore [7] and is now a textbook subject (see, e.g., Zhou and Doyle [17, Chapter 7]). The method proposed by Moore consists of truncating a balanced realization. A balanced realization (also called Lyapunov-balanced or internally balanced) is a realization for which the controllability and observability gramians are equal and diagonal. This procedure is applicable only to stable systems. Alternatively for unstable systems one can use truncations of a linear quadratic Gaussian (LQG)–balanced realization, which for rational transfer functions always exists. A LQG-balanced realization is a realization for which the smallest nonnegative self-adjoint solutions of the standard LQG control and filter Riccati equations are equal and diagonal. This method was proposed by Verriest [13], [14] and further developed by Jonckheere and Silverman [5]. For an alternative treatment see Mustafa and Glover [8]. The discrete-time case was considered by Hoffmann, Prätzel-Wolters, and Zerz [4].

In the case that the system is infinite-dimensional, the model/controller approximation becomes essential. One would like to use the methods of balanced truncation and LQG-balanced truncation in this case, too. The existence of Lyapunov-balanced and LQG-balanced realizations for irrational transfer functions, however, is nontrivial. Sufficient conditions for the existence of Lyapunov-balanced realizations were proved

by Young [15], [16]. The purpose of this article is to give necessary and sufficient conditions for the existence of LQG-balanced realizations for discrete-time infinite-dimensional systems.

The proof is based on the correspondence between the Riccati equations of the plant and the Lyapunov equations of a certain closed-loop system and the result of Young on the existence of Lyapunov-balanced realizations. Although discrete-time systems have bounded operators, a number of features make the infinite-dimensional case more complicated than the finite-dimensional case. One is that input and output stabilizability, the natural infinite-dimensional generalizations of stabilizability and detectability, are not sufficient to obtain unique solutions of the control Riccati equation. Another is that it is not a priori clear that the natural factorization generated by the closed-loop system is coprime. These uniqueness and coprime properties were key features in the finite-dimensional proofs. Consequently, we have been forced to develop different proofs, predominantly algebraic, to get around these complications. We exploit the factorization idea previously used by Meyer and Franklin [6] (see also Ober and McFarlane [9]) for the finite-dimensional continuous-time case.

This article is organized as follows. We begin by reviewing the known finite-dimensional theory on discrete-time LQG-balancing in section 2. In section 3 we review the relevant theory of discrete-time infinite-dimensional systems and, in particular, the linear quadratic regulator problem for this class of systems. Some of our results appear to be new. The previous standard results (e.g., Halanay and Ionescu [3]) assume a type of "exponential" stabilizability that is too strong for our purposes. In section 4 we review the relevant theory on Lyapunov-balanced realizations for discrete-time infinite-dimensional systems. The key result on the connection between normalized factorizations and the linear quadratic regulator theory is developed in section 5. In section 6 we define the LQG-characteristic values and show that they are system invariants. In section 7 we derive many algebraic relations between the solutions of the control and filter Riccati equations and the Lyapunov equations of the closed-loop system. The often tedious algebraic proofs are relegated to the appendix. Finally, all the results from the previous sections are linked up in section 8 to prove our main result: an input and output stabilizable discrete-time system possesses an approximately controllable and observable LQG-balanced realization. These realizations are unique up to a unitary state-space transformation. This represents an elegant generalization of the finite-dimensional theory under minimal assumptions.

2. LQG-balanced realizations: The finite-dimensional case. In this section we review some of the results on finite-dimensional LQG-balanced realizations. We consider systems of the form

$$x_{n+1} = Ax_n + Bu_n, \quad x(0) = x_0, \quad y_n = Cx_n + Du_n, \tag{2.1}$$

where A, B, C, D are matrices of compatible dimensions. For simplicity we consider the linear quadratic regulator (LQR) problem for the cost functional

$$J(x_0, u) := \sum_{n=0}^{\infty} \|u_n\|^2 + \|y_n\|^2,$$

where y is given in terms of x_0 and u by (2.1). The LQR problem consists of finding for a given x_0 that u for which $J(x_0, u)$ is minimal. As is well known, this problem has a unique solution when (A, B, C, D) is minimal: the optimal input $u^{\min}$ is given

by the state feedback $u_n^{\min} = -(I + D^*D + B^*QB)^{-1}(D^*C + B^*QA)x_n$, where Q is the unique nonnegative solution of the Riccati equation

$$A^*QA - Q + C^*C = (C^*D + A^*QB)(I + D^*D + B^*QB)^{-1}(D^*C + B^*QA),$$

and the optimal cost is given by $J(x_0, u^{\min}) = \langle x_0, Qx_0\rangle$. By duality the optimal filter cost is given by $\langle x_0, Px_0\rangle$, where P is the unique nonnegative solution of the Riccati equation

$$APA^* - P + BB^* = (BD^* + APC^*)(I + DD^* + CPC^*)^{-1}(DB^* + CPA^*).$$

The quantity $\langle x_0, Px_0\rangle$ can be interpreted as a measure of the difficulty of reconstructing the initial state x_0 from noisy measurements. The eigenvalues of the product PQ are similarity invariants. It was shown by Fuhrmann and Ober [2] that the square roots of the eigenvalues of PQ (called the LQG-characteristic values) are the singular values of a certain Hankel operator associated with the system. These invariants can be interpreted as a measure of how important the subspace generated by the eigenvector is for the compensator design. This can be seen from the LQG-balanced realization. An LQG-balanced realization is a realization of the plant such that $P = Q = \Lambda$, where Λ is the diagonal matrix containing the LQG-characteristic values. Let λ_i be the square root of an eigenvalue of PQ with eigenvector x_i of length one. Then, in the LQG-balanced realization, the optimal cost with initial condition x_i is λ_i and the difficulty of reconstructing this initial state from noisy measurements is also λ_i. The idea behind LQG-balanced truncation is to restrict the system to the subspace generated by the eigenvectors corresponding to the largest eigenvalues. Since this subspace is most important for compensator design, the system obtained by LQG-balanced truncation seems to be a reasonable approximation. There is a bound on the distance between a plant and an LQG-balanced truncation of the plant in terms of the discarded LQG-characteristic values; see Mustafa and Glover [8, section 8.4.5].

The existence of LQG-balanced realizations in the finite-dimensional case is easily proved as follows:

1. Start with a minimal realization (A, B, C, D) and compute the solutions Q and P of the Riccati equations.
2. Write $P^{1/2}QP^{1/2} = U\Lambda^2U^*$ with Λ diagonal.
3. Let $T := Q^{1/2}U\Lambda^{-1/2}$.

Then it is easily seen that $(TAT^{-1}, TB, CT^{-1}, D)$ is an LQG-balanced realization.

In the infinite-dimensional case this proof no longer works. The main problem is that the singular value decomposition performed at Step 2 cannot always be made in the infinite-dimensional case. (One has to assume a compactness condition.) Even if it can, then usually the singular values form a sequence with zero as limit point and the operator $\Lambda^{-1/2}$ mentioned at the third step is unbounded. Because of this unboundedness, it is unclear whether the expressions TAT^{-1} and TB make sense. To avoid these problems we take a different approach, mentioned in the introduction: we use the known result for the existence of Lyapunov-balanced realizations. In this article we consider only the existence of LQG-balanced realizations. The study of the properties of truncated LQG-balanced realizations will be done elsewhere. In slight contrast with the definition above we will call a realization LQG-balanced if $P = Q$. We do not require that they are diagonal, since this is not always possible in infinite dimensions.

3. Discrete-time infinite-dimensional systems. In this section we review that part of the theory of discrete-time infinite-dimensional systems that we need in

this article. Discrete-time infinite-dimensional systems have been treated in a number of texts (e.g., [1], [3], [12]). However, the standard treatments of the linear quadratic theory assume the strong concept of power stabilizability, i.e., the existence of an F such that $\|(A+BF)^n\| \leq M\lambda^n$ for some constants $M > 0, 0 < \lambda < 1$ and all positive integers n. Unfortunately, this concept is not suitable for a nice theory of LQG-balanced realizations. Thus in this section we reexamine the basic concepts under weaker stabilizability assumptions.

A discrete-time infinite-dimensional system or simply a system is a quadruple of bounded operators $(A, B, C, D) \in \mathcal{L}(X) \times \mathcal{L}(U, X) \times \mathcal{L}(X, Y) \times \mathcal{L}(U, Y)$, where X, U, Y are separable Hilbert spaces. For an input u and initial condition x_0, the state x and output y of the system are defined by

$$x_{n+1} = Ax_n + Bu_n \quad x(0) = x_0 \quad y_n = Cx_n + Du_n. \tag{3.1}$$

The observability map $\mathcal{C}$ of a discrete-time system (A, B, C, D) is defined by

$$(\mathcal{C}x)_i := CA^i x, \quad i \in \mathbb{N}. \tag{3.2}$$

The discrete-time system (A, B, C, D) is said to be approximately observable if $\ker \mathcal{C} = \{0\}$ (see Curtain and Zwart [1]). There are many generalizations of the finite-dimensional concept of observability to an infinite-dimensional setting, and the concept of approximate observability is one. Our main use of approximate observability is that realizations may, without loss of generality, be assumed to be approximately controllable and observable. This may not always be the case for other generalizations of observability. Here, approximately controllable and observable plays the role that minimal plays in finite dimensions.

The discrete-time system (A, B, C, D) is said to be output stable if the image of $\mathcal{C}$ is contained in $l^2(\mathbb{N}; Y)$. The observability gramian L_C of an output stable system is defined as $L_C := \mathcal{C}^*\mathcal{C}$. We now give an alternative characterization of output stability in terms of solutions of a certain Lyapunov equation.

LEMMA 3.1. *Let (A, B, C, D) be a discrete-time system. The following are equivalent statements:*

1. *The system is output stable.*
2. *The* observation Lyapunov equation

$$A^*LA - L + C^*C = 0 \tag{3.3}$$

has a nonnegative self-adjoint solution.

If one (and hence both) of these hold, then the observability gramian is the smallest nonnegative self-adjoint solution of the observation Lyapunov equation.

Proof. We first show that 1 implies 2. It is easily seen that the observability gramian is given by the formula $L_C = \sum_{i=0}^{\infty} A^{*i}C^*CA^i$, and substituting this into the observation Lyapunov equation shows that it is a solution.

That 2 implies 1 is proved as follows. Suppose that the observation Lyapunov equation has a nonnegative self-adjoint solution L. Then multiplying (3.3) from the left with A^{*n} and from the right with A^n and summing from $n = 0$ to N gives

$$\begin{aligned}\sum_{n=0}^{N} A^{*n}C^*CA^n &= \sum_{n=0}^{N} A^{*n}LA^n - \sum_{n=0}^{N} A^{*n+1}LA^{n+1} \\ &= L - A^{*N+1}LA^{N+1} \leq L.\end{aligned}$$

Letting $N \to \infty$ shows that L_C is a bounded map and so $\mathcal{C}$ is bounded. That L_C is smaller than any other nonnegative self-adjoint solution of the observation Lyapunov equation is obvious from the above inequality. ∎

The following result shows that strong stability implies the uniqueness of solutions of Lyapunov equations. We remind the reader that an operator A is called strongly (or asymptotically) stable if for all $x \in X$ we have $A^n x \to 0$ as $n \to \infty$.

LEMMA 3.2. *Let (A, B, C, D) be output stable and let A be strongly stable. Then the observability gramian is the unique nonnegative self-adjoint solution of the observation Lyapunov equation* (3.3).

Proof. According to Lemma 3.1 the observability gramian is a nonnegative self-adjoint solution of the observation Lyapunov equation, so we only have to show that it is the unique nonnegative self-adjoint solution. Let L be a nonnegative self-adjoint solution of the observation Lyapunov equation. Then, as in the proof of Lemma 3.1, we have for all $N \in \mathbb{N}$

$$\sum_{n=0}^{N} A^{*n} C^* C A^n = \sum_{n=0}^{N} A^{*n} L A^n - \sum_{n=0}^{N} A^{*n+1} L A^{n+1} = L - A^{*N+1} L A^{N+1}.$$

We then have for all $x, y \in X$

$$\left\langle \sum_{n=0}^{N} A^{*n} C^* C A^n x, y \right\rangle = \langle Lx, y\rangle - \langle LA^{N+1}x, A^{N+1}y\rangle.$$

Letting $N \to \infty$ and using that A is strongly stable, we have for all $x, y \in X$

$$\langle L_C x, y\rangle = \langle Lx, y\rangle.$$

This implies that $L = L_C$. Since L was an arbitrary nonnegative self-adjoint solution, this implies that L_C is the unique nonnegative self-adjoint solution of the observation Lyapunov equation. ∎

A discrete-time system (A, B, C, D) is called output stabilizable if there exists an $F \in \mathcal{L}(X, U)$ such that $(A + BF, 0, [F; C + DF], 0)$ is output stable. (Note that we use the notation $[-; -]$ for a block column vector and $[-, -]$ for a block row vector.) Output stabilizability is a necessary and sufficient condition for the solvability of the LQR problem. To show this we first review some well-known results on the LQR problem in infinite dimensions. For a system (A, B, C, D) with input, state, and output related by (3.1), we consider the cost functional

$$J(x_0, u) := \sum_{n=0}^{\infty} \|u_n\|^2 + \|y_n\|^2.$$

The well-known linear quadratic regulator problem is as follows. Find a sequence $u^{\min}$ such that $J(x_0, u^{\min}) \le J(x_0, u)$ for all sequences u. A system is said to satisfy the finite cost condition if for every initial state x_0 there exists a u such that $J(x_0, u) < \infty$. Just as in the finite-dimensional case one can prove that if the finite cost condition is satisfied, then there exists a unique optimal control $u^{\min}$; we actually have $J(x_0, u^{\min}) < J(x_0, u)$ for all other sequences u and $J(x_0, u^{\min}) = \langle x_0, Qx_0\rangle$, where Q is the smallest nonnegative self-adjoint solution of the control algebraic Riccati equation (CARE) associated with the system (A, B, C, D),

$$A^*QA - Q + C^*C = (C^*D + A^*QB)(S + B^*QB)^{-1}(D^*C + B^*QA), \tag{3.4}$$

where $S := I + D^*D$. Moreover, $u^{\min}$ can be given by a state feedback. All of this can be found, for example, in Curtain and Zwart [1, Exercise 6.34]. The operator Q is called the optimal cost operator. The following lemma gives conditions that are equivalent to the finite cost condition.

LEMMA 3.3. *The following statements about a discrete-time system* (A, B, C, D) *are equivalent:*

1. *The discrete-time system is output stabilizable.*
2. *The discrete-time system satisfies the finite cost condition.*
3. *The CARE* (3.4) *of the discrete-time system has a nonnegative self-adjoint solution.*

Proof. Suppose the discrete-time system is output stabilizable. Then there exists an F such that $(A + BF, 0, [F; C + DF], 0)$ is output stable; denote the observability map of this system by $\mathcal{C}_F$. Add the equation $u := Fx$ to (3.1). Call the solution (u, x, y) of this set of equations $\bar{u}, \bar{x}, \bar{y}$. Then $[\bar{u}, \bar{y}] = \mathcal{C}_F x_0$ and since $\mathcal{C}_F$ is bounded we see that $[\bar{u}, \bar{y}]$ has finite l^2 norm. That is, $J(x_0, \bar{u}) < \infty$ and the system satisfies the finite cost condition.

An outline of the proof that 2 implies 3 can be found in Curtain and Zwart [1, Exercise 6.34].

For 3 implies 1, we will show that the feedback $F := -(B^*QB+I+D^*D)^{-1}(D^*C+B^*QA)$, where Q is a solution of the CARE (3.4), is output stabilizing. We will do this by showing that Q is a solution of the observation Lyapunov equation of the system $(A + BF, 0, [F; C + DF], 0)$. We want to show that Q satisfies

$$(A + BF)^*Q(A + BF) - Q + [F^*, C^* + F^*D^*] \begin{bmatrix} F \\ C + DF \end{bmatrix} = 0.$$

This is equivalent to

$$\begin{aligned} A^*QA - Q + C^*C + F^*(B^*QB + I + D^*D)F \\ + F^*(B^*QA + D^*C) + (A^*QB + C^*D)F = 0. \end{aligned} \tag{3.5}$$

Substituting for F in (3.5) we obtain

$$A^*QA - Q + C^*C = (C^*D + A^*QB)(S + B^*QB)^{-1}(D^*C + B^*QA),$$

which is precisely CARE (3.4). ∎

The controllability map $\mathcal{B}$ of a discrete-time system (A, B, C, D) is defined for finitely nonzero U-valued sequences u by

$$\mathcal{B}u := \sum_{i=0}^{\infty} A^i B u_{-i-1}. \tag{3.6}$$

The discrete-time system (A, B, C, D) is said to be approximately controllable if $\ker \mathcal{B}^* = \{0\}$. The discrete-time system (A, B, C, D) is said to be input stable if $\mathcal{B}$ extends to a bounded map from $l^2(\mathbb{Z}^-; U)$ to X. The controllability gramian L_B of an input stable system is defined as $L_B := \mathcal{B}\mathcal{B}^*$. A discrete-time system (A, B, C, D) is called input stabilizable if there exists an $L \in \mathcal{L}(Y, X)$ such that $(A + LC, [L, B + LD], 0, 0)$ is input stable. The following dual results of the results proven earlier hold.

LEMMA 3.4. *Let* (A, B, C, D) *be a discrete-time system. The following are equivalent statements:*

1. *The system is input stable.*
2. *The* control Lyapunov equation

$$ALA^* - L + BB^* = 0 \tag{3.7}$$

has a nonnegative self-adjoint solution.

If one (and hence both) of the above holds, then the controllability gramian is the smallest nonnegative self-adjoint solution of the control Lyapunov equation.

LEMMA 3.5. *Let (A, B, C, D) be input stable and let A^* be strongly stable. Then the controllability gramian is the unique nonnegative self-adjoint solution of the control Lyapunov equation* (3.7).

LEMMA 3.6. *The following statements about a discrete-time system (A, B, C, D) are equivalent:*

1. *The discrete-time system is input stabilizable.*
2. *The dual system (A^*, C^*, B^*, D^*) satisfies the finite cost condition.*
3. *The filter algebraic Riccati equation (FARE)*

$$APA^* - P + BB^* = (BD^* + APC^*)(R + CPC^*)^{-1}(DB^* + CPA^*), \tag{3.8}$$

where $R := I + DD^*$, of the discrete-time system has a nonnegative self-adjoint solution.

We now give a condition under which CARE (3.4) has a unique nonnegative self-adjoint solution.

LEMMA 3.7. *Let (A, B, C, D) be an input and output stabilizable discrete-time system. Let Q be a nonnegative self-adjoint solution of the CARE* (3.4)*, and assume that $A_Q := A - B(S + B^*QB)^{-1}(D^*C + B^*QA)$ is strongly stable. Then Q is the unique nonnegative self-adjoint solution of CARE* (3.4).

Proof. For the proof we need the following algebraic relations, which are proved in the appendix (Lemmas 10.3 and 10.4). Suppose Q_1 and P_1 are nonnegative self-adjoint solutions of the CARE and FARE, respectively, and define A_{Q_1} similar to A_Q above and $A_{P_1} := A - (BD^* + AP_1C^*)(R + CP_1C^*)^{-1}C$. Then the following relation holds:

$$(I + P_1Q_1)A_{Q_1} = A_{P_1}(I + P_1Q_1). \tag{3.9}$$

The following algebraic relation is also proven in the appendix (Lemma 10.4). If Q_1 and Q_2 are nonnegative self-adjoint solutions of the CARE, and if A_{Q_1} and A_{Q_2} are defined similarly as A_Q above, then

$$Q_1 - Q_2 = A_{Q_2}^*(Q_1 - Q_2)A_{Q_1}. \tag{3.10}$$

With induction it follows that for all $n \in \mathbb{N}$ we have

$$Q_1 - Q_2 = A_{Q_2}^{*n}(Q_1 - Q_2)A_{Q_1}^n. \tag{3.11}$$

Using these facts we now prove the statement. Since (A, B, C, D) is input stabilizable, there exists a nonnegative self-adjoint solution P of the FARE (3.8). Since A_Q is assumed to be strongly stable and (3.9) shows that A_P is similar to A_Q, we have that A_P is strongly stable. Now let $\tilde{Q}$ be an arbitrary nonnegative self-adjoint solution of the CARE. According to (3.9), $A_{\tilde{Q}}$ is similar to the strongly stable operator A_P and hence is strongly stable. Since $A_{\tilde{Q}}$ is strongly stable there exists for every $x \in X$ a real number c_x such that for every $n \in \mathbb{N}$ we have $\|A_{\tilde{Q}}^n x\| \leq c_x$. By the uniform

boundedness theorem this implies that there exists a real number c such that for every $n \in \mathbb{N}$ we have $\|A_{\tilde{Q}}^n\| \leq c$. Using (3.11) with $Q_1 = Q$ and $Q_2 = \tilde{Q}$ we have for all $x \in X$ and $n \in \mathbb{N}$

$$\|(Q - \tilde{Q})x\| = \|A_{\tilde{Q}}^{*n}(Q - \tilde{Q})A_Q^n x\| \leq \|A_{\tilde{Q}}^{*n}\| \, \|Q - \tilde{Q}\| \, \|A_Q^n x\| \leq c \, \|Q - \tilde{Q}\| \, \|A_Q^n x\|.$$

Since A_Q is strongly stable, the right-hand side converges to zero as $n \to \infty$. This implies that the left-hand side is zero and so $\tilde{Q} = Q$. □

The input-output map $\mathcal{D}$ of a discrete-time system (A, B, C, D) is defined for finitely nonzero U-valued sequences u by

$$(\mathcal{D}u)_k := \sum_{i=0}^{\infty} CA^i Bu_{k-i-1} + Du_k. \tag{3.12}$$

The discrete-time system (A, B, C, D) is said to be input-output stable if $\mathcal{D}$ extends to a bounded map from $l^2(\mathbb{Z}; U)$ to $l^2(\mathbb{Z}; Y)$.

We define the transfer function G of a system (A, B, C, D) by

$$G(z) = D + \sum_{i=0}^{\infty} CA^i Bz^{i+1} \tag{3.13}$$

for those z for which the sum converges absolutely. Note that it converges absolutely for $|z| < 1/r(A)$ ($r(A)$ denotes the spectral radius of A) and it is equal to $D + Cz(I - zA)^{-1}B$ for those z. It is obvious that the transfer function of a system can be constructed from the input-output map and vice versa; in this sense transfer functions and input-output maps are equivalent notions. Given a transfer function G we call any system (A, B, C, D) such that (3.13) holds a realization of the transfer function. We note that the functions that appear as transfer functions of discrete-time infinite-dimensional systems are exactly the operator-valued functions that are analytic on some disc centered at the origin.

The (time-domain) Hankel operator Γ of a system is defined as $\Gamma := \mathcal{CB}$, where $\mathcal{C}$ and $\mathcal{B}$ are the observability and controllability maps of the system, respectively. It is easily seen that the Hankel operator does not depend on the particular realization but only on the input-output map.

4. Lyapunov-balanced realizations. In this section we review some results from Young [15], [16] and Ober and Wu [10] and translate them in terms more suitable for our purposes. The following result on the existence of Lyapunov-balanced realizations was proved by Young [15], [16]. We recall that an input and output stable system is called Lyapunov balanced if its controllability and observability gramians are equal (again, we do not require them to be diagonal).

LEMMA 4.1. *Every transfer function that has a bounded Hankel operator has an approximately controllable and observable Lyapunov-balanced realization. Moreover, approximately controllable and observable Lyapunov-balanced realizations are unique up to a unitary transformation.*

The next corollary gives an alternative condition for the existence of Lyapunov-balanced realizations.

COROLLARY 4.2. *A transfer function has a Lyapunov-balanced realization if and only if it has a realization that is both input and output stable.*

Proof. Since a Lyapunov-balanced realization is input and output stable, one implication is immediate. If the transfer function has a realization such that both

its controllability map $\mathcal{B}$ and observability map $\mathcal{C}$ are bounded, then its Hankel operator $\Gamma = \mathcal{C}\mathcal{B}$ is bounded and Lemma 4.1 shows that it has a Lyapunov-balanced realization. ∎

The following result was proved by Ober and Wu [10].

LEMMA 4.3. *Let (A, B, C, D) be Lyapunov-balanced and approximately controllable and approximately observable. Then A and A^* are strongly stable.*

Combining Lemmas 4.3, 3.2, and 3.5 we have the following corollary.

COROLLARY 4.4. *The gramian of an approximately controllable and approximately observable Lyapunov-balanced realization is the unique nonnegative self-adjoint solution of both the control and the observation Lyapunov equation.*

5. Normalized factorizations. In this section we generalize a result of Meyer and Franklin [6] on the connection between normalized factorizations and linear quadratic regulator theory to the infinite-dimensional case. This result will allow us to relate LQG-balanced realizations to Lyapunov-balanced realizations of a normalized factorization of the given transfer function.

Given an output stabilizable discrete-time system (A, B, C, D) with optimal cost operator Q we form the optimal closed-loop system

$$\check{A} := A + BF, \quad \check{B} := BW^{-1/2}, \quad \check{C} := [F; C + DF], \quad \check{D} := [I; D]W^{-1/2}, \tag{5.1}$$

where

$$W := S + B^*QB, \quad S := I + D^*D, \quad F := -W^{-1}(D^*C + B^*QA).$$

We first remark that the F above is the optimal state feedback operator for the LQR problem. We obtain the optimal closed-loop system from the system (A, B, C, D) by choosing $u = Fx + W^{-1/2}\check{u}$ and considering $\check{u}$ as the input of this new system and $[u; y]$ as the output. This amounts to closing the loop by the optimal state feedback operator, considering the input and output of the plant as the new output and prefiltering the new input.

Our first result in this section states that the optimal cost operator of the plant equals the observability gramian of the optimal closed-loop system.

LEMMA 5.1. *Let (A, B, C, D) be an output stabilizable discrete-time system. Denote its optimal cost operator by Q and define its optimal closed-loop system by* (5.1). *Denote the observability gramian of the optimal closed-loop system by L_C. Then $Q = L_C$.*

Proof. From the discussion above it is obvious that if $\check{u} = 0$, then the output of the optimal closed-loop system is $[u^{\min}; y^{\min}]$, the optimal input and output of the plant. From this it follows that

$$\langle L_C x_0, x_0\rangle = \langle \mathcal{C}x_0, \mathcal{C}x_0\rangle = \| \begin{bmatrix} u^{\min} \\ y^{\min} \end{bmatrix} \|^2 = J(x_0, u^{\min}) = \langle Qx_0, x_0\rangle.$$

Since this holds for all x_0 in the state space we have $Q = L_C$. ∎

The next lemma shows that the observability gramian of the optimal closed-loop system satisfies two additional equations.

LEMMA 5.2. *Let (A, B, C, D) be an output stabilizable discrete-time system. Denote its optimal cost operator by Q and define its optimal closed-loop system $(\check{A}, \check{B}, \check{C}, \check{D})$ by* (5.1). *Denote the observability gramian of the optimal closed-loop system by L_C. Then*

$$\check{B}^* L_C \check{B} + \check{D}^* \check{D} = I, \tag{5.2}$$

$$\check{B}^* L_C \check{A} + \check{D}^* \check{C} = 0. \tag{5.3}$$

Proof. The equations (5.2) and (5.3) are readily verified using (5.1) and the fact that $Q = L_C$ from Lemma 5.1. □

An input-output map $\mathcal{D}$ is called inner if it maps $l^2(\mathbb{Z}; U)$ into $l^2(\mathbb{Z}; Y)$ and satisfies $\mathcal{D}^*\mathcal{D} = I$. In the next lemma we give necessary and sufficient conditions on a realization for the input-output map to be inner.

LEMMA 5.3. *Let (A, B, C, D) be an output stable realization of the input-output map $\mathcal{D}$. Denote the observability gramian of this system by L_C. If*

$$B^* L_C B + D^* D = I$$

and

$$B^* L_C A + D^* C = 0,$$

then $\mathcal{D}$ is inner. If the system (A, B, C, D) is approximately controllable, then these conditions are also necessary.

Proof. We take u_k equal to u at the kth position and zero elsewhere and compute

$$(\mathcal{D}u_k)_m = \begin{cases} 0, & m < k, \\ Du, & m = k, \\ CA^{m-k-1}Bu, & m > k. \end{cases}$$

We define v_i similar to u_k above and compute for $k > i$

$$\langle (\mathcal{D}u_k)_n, (\mathcal{D}v_i)_n \rangle = \begin{cases} 0, & n < k, \\ \langle Du, CA^{k-i-1}Bv \rangle, & n = k, \\ \langle CA^{n-k-1}Bu, CA^{n-i-1}Bv \rangle, & n > k. \end{cases}$$

We then compute

$$\begin{aligned} \langle \mathcal{D}u_k, \mathcal{D}v_i \rangle &= \sum_{n=-\infty}^{\infty} \langle (\mathcal{D}u_k)_n, (\mathcal{D}v_i)_n \rangle \\ &= \langle Du, CA^{k-i-1}Bv \rangle + \sum_{n=k+1}^{\infty} \langle CA^{n-k-1}Bu, CA^{n-i-1}Bv \rangle \\ &= \langle u, D^*CA^{k-i-1}Bv \rangle + \sum_{n=k+1}^{\infty} \langle u, B^*A^{*n-k-1}C^*CA^{n-k-1}AA^{k-i-1}Bv \rangle \\ &= \langle u, (D^*C + B^*L_CA)A^{k-i-1}Bv \rangle. \end{aligned}$$

By the assumptions we thus have $\langle \mathcal{D}u_k, \mathcal{D}v_i \rangle = 0$ for $k > i$. Then obviously $\langle \mathcal{D}u_k, \mathcal{D}v_i \rangle = 0$ for $k \neq i$.

For $k = i$ we have

$$\begin{aligned} \langle \mathcal{D}u_k, \mathcal{D}v_i \rangle &= \sum_{n=-\infty}^{\infty} \langle (\mathcal{D}u_k)_n, (\mathcal{D}v_i)_n \rangle \\ &= \langle Du, Dv \rangle + \sum_{n=k+1}^{\infty} \langle CA^{n-k-1}Bu, CA^{n-k-1}Bv \rangle \\ &= \langle D^*Du, v \rangle + \sum_{j=0}^{\infty} \langle B^*A^{*j}C^*CA^jBu, v \rangle = \langle (D^*D + B^*L_CB)u, v \rangle. \end{aligned}$$

By the assumptions we thus have $\langle \mathcal{D}u_k, \mathcal{D}v_i\rangle = \langle u, v\rangle$ for $k = i$.

Let u and v be finitely nonzero sequences. Then

$$u = \sum_{k=-n}^{n} u^k e_k, \quad v = \sum_{i=-n}^{n} v^i e_i,$$

where $u^k, v^i \in U$ and e_j is the element of $l^2(\mathbb{Z}; U)$ with a 1 at the jth position and zeros elsewhere. Then

$$\begin{aligned}\langle \mathcal{D}u, \mathcal{D}v\rangle &= \sum_{k=-n}^{n}\sum_{i=-n}^{n} \langle \mathcal{D}(u^k e_k), \mathcal{D}(v^i e_i)\rangle = \sum_{j=-n}^{n} \langle \mathcal{D}(u^j e_j), \mathcal{D}(v^j e_j)\rangle \\ &= \sum_{j=-n}^{n} \langle u^j, v^j\rangle = \langle u, v\rangle.\end{aligned}$$

From the above we have for every finitely nonzero sequence u that $\|\mathcal{D}u\| = \|u\|$. Since the set of finitely nonzero sequences is dense in $l^2(\mathbb{Z}; U)$ this implies that $\mathcal{D}$ has a continuous extension to a map from $l^2(\mathbb{Z}; U)$ to $l^2(\mathbb{Z}; Y)$, and so $\mathcal{D}$ is stable. Further, since this extension satisfies $\langle \mathcal{D}u, \mathcal{D}v\rangle = \langle u, v\rangle$, we must have $\mathcal{D}^*\mathcal{D} = I$, and so $\mathcal{D}$ is inner.

Suppose that $\mathcal{D}$ is inner and the realization is approximately controllable. Since $\mathcal{D}$ is inner we have for all $i < 0$ that $\langle \mathcal{D}u_0, \mathcal{D}v_i\rangle = \langle u_0, v_i\rangle = 0$, where u_0 and v_i are defined as above. From the above we see that this implies that $\langle u, (D^*C + B^*L_CA)A^{-i-1}Bv\rangle = 0$. Since this holds for all $u \in U$ we must have $(D^*C + B^*L_CA)A^{-i-1}Bv = 0$ for all $v \in U$ and $i < 0$. This implies that for finitely nonzero U-valued sequences z we have $(D^*C + B^*L_CA)\mathcal{B}z = 0$. Since the system is approximately controllable, the set of elements of the form $\mathcal{B}z$ is dense in the state space, and so $D^*C + B^*L_CA = 0$ on a dense set and by continuity on the whole state space.

Since $\mathcal{D}$ is inner we have $\langle \mathcal{D}u_0, \mathcal{D}v_0\rangle = \langle u_0, v_0\rangle$, where u_0 and v_0 are as above. This implies that $\langle (D^*D + B^*L_CB)u, v\rangle = \langle u, v\rangle$ for all $u, v \in U$ and hence $D^*D + B^*L_CB = I$. ∎

Combining Lemmas 5.2 and 5.3 we have the following.

COROLLARY 5.4. *Let (A, B, C, D) be an output stabilizable discrete-time system. Then the input-output map of its optimal closed-loop system is inner.*

We can recover the system (A, B, C, D) from its optimal closed-loop system as follows.

LEMMA 5.5. *Let (A, B, C, D) be an output stabilizable discrete-time system. Let $(\check{A}, \check{B}, \check{C}, \check{D})$ be its optimal closed-loop system defined by* (5.1). *Partition $\check{C}$ and $\check{D}$ in the obvious way as $\check{C} = [\check{C}_1; \check{C}_2]$ and $\check{D} = [\check{D}_1; \check{D}_2]$. Then $\check{D}_1$ is boundedly invertible and*

$$(5.4)\quad A := \check{A} - \check{B}\check{D}_1^{-1}\check{C}_1, \quad B := \check{B}\check{D}_1^{-1}, \quad C := \check{C}_2 - \check{D}_2\check{D}_1^{-1}\check{C}_1, \quad D := \check{D}_2\check{D}_1^{-1}.$$

Proof. That $\check{D}_1$ is boundedly invertible is obvious from its definition. The identities (5.4) follow from simple algebraic manipulations. ∎

To relate the input-output maps of the plant and its optimal closed-loop system we first study the series interconnection of two systems.

Consider two systems (A_1, B_1, C_1, D_1) and (A_2, B_2, C_2, D_2) such that the output space of the first system and the input space of the second system are equal. Define the series interconnection of these two systems as the system we obtain by choosing

the input of the second system equal to the output of the first system. Obviously, the input-output map of the series interconnection is $\mathcal{D}_2\mathcal{D}_1$, the composition of the input-output maps of the first and second systems. A realization of this series interconnection is the following:

$$A = \begin{bmatrix} A_1 & 0 \\ B_2C_1 & A_2 \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ B_2D_1 \end{bmatrix}, \quad C = \begin{bmatrix} D_2C_1, & C_2 \end{bmatrix}, \quad D = D_2D_1.$$

If we apply the invertible state space transformation

$$\begin{bmatrix} I & 0 \\ I & I \end{bmatrix}$$

to this realization we obtain another realization of the series interconnection, namely,

$$A_s = \begin{bmatrix} A_1 & 0 \\ A_2 + B_2C_1 - A_1 & A_2 \end{bmatrix}, \quad B_s = \begin{bmatrix} B_1 \\ B_2D_1 - B_1 \end{bmatrix}, \tag{5.5}$$

$$C_s = \begin{bmatrix} D_2C_1 + C_2, & C_2 \end{bmatrix}, \quad D_s = D_2D_1.$$

We first use the series interconnection to obtain a result about the invertibility of input-output maps.

LEMMA 5.6. *Let (A, B, C, D) be a system with input-output map $\mathcal{D}$. If D is boundedly invertible, then the input-output map $\tilde{\mathcal{D}}$ of the system*

$$(A - BD^{-1}C, BD^{-1}, -D^{-1}C, D^{-1})$$

satisfies $\tilde{\mathcal{D}}\mathcal{D} = I = \mathcal{D}\tilde{\mathcal{D}}$. Thus in this case the input-output map $\mathcal{D}$ has an inverse.

Proof. Using (5.5) we see that the series interconnection of the two given systems has a realization

$$A_s = \begin{bmatrix} A & 0 \\ 0 & A - BD^{-1}C \end{bmatrix}, \quad B_s = \begin{bmatrix} B \\ 0 \end{bmatrix}, \quad C_s = \begin{bmatrix} 0, & -D^{-1}C \end{bmatrix}, \quad D_s = I.$$

From this we see that $C_sA_s^kB_s = 0$ for all $k \geq 0$ and so the input-output map of the series interconnection is the identity. This implies that $\tilde{\mathcal{D}}\mathcal{D} = I$. The other equality mentioned follows from interconnecting the systems in the opposite order. ∎

We now state the relation between the input-output map of a plant and its optimal closed-loop system.

LEMMA 5.7. *Let $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2])$ be a system such that $\check{D}_1$ is boundedly invertible. Denote its input-output map by $[\mathcal{M}; \mathcal{N}]$. Define the system (A, B, C, D) by* (5.4) *and denote its input-output map by $\mathcal{D}$. Then $\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}$.*

Proof. The realization $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2])$ of $[\mathcal{M}; \mathcal{N}]$ gives us (by Lemma 5.6) the following realization (A_1, B_1, C_1, D_1) of $\mathcal{M}^{-1}$:

$$A_1 = \check{A} - \check{B}\check{D}_1^{-1}\check{C}_1, \quad B_1 = \check{B}\check{D}_1^{-1}, \quad C_1 = -\check{D}_1^{-1}\check{C}_1, \quad D_1 = \check{D}_1^{-1}.$$

It also gives us the realization (A_2, B_2, C_2, D_2) of $\mathcal{N}$:

$$A_2 = \check{A}, \quad B_2 = \check{B}, \quad C_2 = \check{C}_2, \quad D_2 = \check{D}_2.$$

Using (5.5) we obtain the following realization of the series interconnection which has input-output map $\mathcal{N}\mathcal{M}^{-1}$:

$$A_s = \begin{bmatrix} \check{A} - \check{B}\check{D}_1^{-1}\check{C}_1 & 0 \\ 0 & \check{A} \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & \check{A} \end{bmatrix}, \quad B_s = \begin{bmatrix} \check{B}\check{D}_1^{-1} \\ 0 \end{bmatrix} = \begin{bmatrix} B \\ 0 \end{bmatrix},$$

$$C_s = \begin{bmatrix} \check{C}_2 - \check{D}_2\check{D}_1^{-1}\check{C}_1, & \check{C}_2 \end{bmatrix} = \begin{bmatrix} C, & \check{C}_2 \end{bmatrix}, \quad D_s = \check{D}_2\check{D}_1^{-1} = D,$$

where we have used (5.4). It follows that $D_s = D$ and $C_s A_s^k B_s = CA^k B$ for all $k \geq 0$. This implies that $\mathcal{N}\mathcal{M}^{-1} = \mathcal{D}$. ∎

We call an input-output map $[\mathcal{M};\mathcal{N}]$ a right factor of the input-output map $\mathcal{D}$ if $\mathcal{M}^{-1}$ is the input-output map of a system, $\mathcal{D} = \mathcal{N}\mathcal{M}^{-1}$ and $\mathcal{M}$ and $\mathcal{N}$ are stable. We call the factor normalized if $[\mathcal{M};\mathcal{N}]$ is inner. From Lemmas 5.5 and 5.7 and Corollary 5.4 we have the following.

COROLLARY 5.8. *Let (A, B, C, D) be an output stabilizable discrete-time system. Then the input-output map of its optimal closed-loop system is a normalized right factor of the input-output map of the plant.*

We next state a result about the uniqueness of a normalized right factor. We remark that we can interpret an operator V in $\mathcal{L}(U)$ as a map $\mathcal{V}$ from $l^2(\mathbb{Z};U)$ into itself by $(\mathcal{V}u)_k = Vu_k$.

LEMMA 5.9. *If the input-output map of a system has a normalized right factor $[\mathcal{M};\mathcal{N}]$, then all normalized right factors of this input-output map are $\{[\mathcal{M}V;\mathcal{N}V] : V \in \mathcal{L}(U)$ unitary$\}$.*

Proof. Let $[\mathcal{M};\mathcal{N}]$ be an arbitrary normalized right factor of $\mathcal{D}$. Since $[\mathcal{M};\mathcal{N}]$ is normalized we have

$$\mathcal{M}^*\mathcal{M} + \mathcal{N}^*\mathcal{N} = I.$$

Multiplying this equality with $\mathcal{M}^{-*}$ from the left and $\mathcal{M}^{-1}$ from the right we obtain

$$I + \mathcal{D}^*\mathcal{D} = \mathcal{M}^{-*}\mathcal{M}^{-1}.$$

Since the left-hand side of this equation does not depend on the particular factor, we have for two normalized factors $[\mathcal{M}_1;\mathcal{N}_1]$ and $[\mathcal{M}_2;\mathcal{N}_2]$ of $\mathcal{D}$ that $\mathcal{M}_1^{-*}\mathcal{M}_1^{-1} = \mathcal{M}_2^{-*}\mathcal{M}_2^{-1}$, which implies

$$\mathcal{M}_2^*\mathcal{M}_1^{-*} = \mathcal{M}_2^{-1}\mathcal{M}_1. \tag{5.6}$$

The operator on the right-hand side of (5.6) is the input-output map of some system (namely, the series interconnection of the systems corresponding to $\mathcal{M}_1$ and $\mathcal{M}_2^{-1}$). Define u_k to be the sequence equal to u at the kth position and zero elsewhere. Then $\mathcal{M}_2^{-1}\mathcal{M}_1 u_k$ is equal to zero at the positions i with $i < k$. The operator on the left-hand side of (5.6) is the adjoint of the input-output map of some system (namely, the series interconnection of the systems corresponding to $\mathcal{M}_2$ and $\mathcal{M}_1^{-1}$). This implies that $\mathcal{M}_2^*\mathcal{M}_1^{-*}u_k$ is zero at the positions i with $i > k$.

Since $\mathcal{M}_2^*\mathcal{M}_1^{-*} = \mathcal{M}_2^{-1}\mathcal{M}_1$ we must have that $\mathcal{M}_2^{-1}\mathcal{M}_1 u_k$ is equal to zero at all positions except possibly the kth one. Thus $\mathcal{M}_2^{-1}\mathcal{M}_1$ is a constant operator V, and so $\mathcal{M}_1 = \mathcal{M}_2 V$.

We have $\mathcal{N}_1 = \mathcal{D}\mathcal{M}_1 = \mathcal{D}\mathcal{M}_2 V = \mathcal{N}_2 V$.

It remains to be proved that V is unitary. We have that $V = \mathcal{M}_2^{-1}\mathcal{M}_1$ and so $V^* = \mathcal{M}_1^*\mathcal{M}_2^{-*} = \mathcal{M}_1^{-1}\mathcal{M}_2 = V^{-1}$ by (5.6). This proves that V is unitary. ∎

In the finite-dimensional case the transfer function of the optimal closed-loop system is known to be a normalized coprime factorization. In the infinite-dimensional case this is an open problem.

6. Some algebraic relations. In section 5 we proved that the optimal cost operator equals the observability gramian of the optimal closed-loop system. This can also be interpreted as follows. The smallest nonnegative self-adjoint solution of

the control algebraic Riccati equation equals the smallest nonnegative self-adjoint solution of the observation Lyapunov equation of a certain closed-loop system. In this section we show that a similar result holds for all nonnegative self-adjoint solutions of the control algebraic Riccati equation. We also study the relation between nonnegative self-adjoint solutions of the filter algebraic Riccati equation of the plant and nonnegative self-adjoint solutions of the control Lyapunov equation of the closed-loop system.

The CARE closed-loop system $(\check{A}, \check{B}, \check{C}, \check{D})$ associated with an output stabilizable discrete-time system (A, B, C, D) and a nonnegative self-adjoint solution Q of the CARE (3.4) is defined by (5.1). For the special case that Q is the smallest nonnegative self-adjoint solution of the CARE (3.4) the CARE closed-loop system is equal to the optimal closed-loop system defined earlier.

Lemma 5.5 holds in this more general case, which is obvious from its proof.

LEMMA 6.1. *Let (A, B, C, D) be a discrete-time system such that its CARE* (3.4) *has a nonnegative self-adjoint solution Q. Let $(\check{A}, \check{B}, \check{C}, \check{D})$ be its CARE closed-loop system defined by* (5.1). *Partition $\check{C}$ and $\check{D}$ in the obvious way as $\check{C} = [\check{C}_1; \check{C}_2]$ and $\check{D} = [\check{D}_1; \check{D}_2]$. Then $\check{D}_1$ is boundedly invertible and* (5.4) *holds.*

This lemma implies that the input-output map of the CARE closed-loop system is a factor of the input-output map of the plant by Lemma 5.7. If Q is not the smallest nonnegative self-adjoint solution of the CARE, the factorization need not be normalized (see, e.g., [11, Example 3.1.2]).

We now show that if a system is approximately controllable or observable, then its CARE closed-loop system is too.

LEMMA 6.2. *Let (A, B, C, D) be an output stabilizable discrete-time system and let Q be a nonnegative self-adjoint solution of its CARE* (3.4). *If (A, B, C, D) is approximately controllable, then its CARE closed-loop system is too. If (A, B, C, D) is approximately observable, then its CARE closed-loop system is too.*

Proof. As is well known, a system $(\check{A}, \check{B}, \check{C}, \check{D})$ is approximately controllable (observable) iff $(\check{A} + \check{B}K\check{C}, \check{B}, \check{C}, \check{D})$ is approximately controllable (observable). With $K = -W^{1/2}[I, 0]$ we see that the CARE closed-loop system is approximately controllable (observable) iff $(A, \check{B}, \check{C}, \check{D})$ is approximately controllable (observable). Obviously $(A, \check{B}) = (A, BW^{-1/2})$ is approximately controllable iff (A, B) is approximately controllable and $(A, \check{C}) = (A, [F; C + DF])$ is approximately observable if (A, C) is (but not only if). □

In the next four lemmas we prove a correspondence between the Riccati equations of a system and the Lyapunov equations of its CARE closed-loop system. Because this requires some extensive algebraic manipulations we have relegated some of the proofs to the appendix.

LEMMA 6.3. *Let (A, B, C, D) be an output stabilizable discrete-time system and let Q be a nonnegative self-adjoint solution of its CARE* (3.4). *Let $(\check{A}, \check{B}, \check{C}, \check{D})$ be its CARE closed-loop system defined by* (5.1). *Then*

$$\check{B}^*Q\check{B} + \check{D}^*\check{D} = I, \tag{6.1}$$

$$\check{B}^*Q\check{A} + \check{D}^*\check{C} = 0, \tag{6.2}$$

and Q is a solution of the observation Lyapunov equation of $(\check{A}, \check{B}, \check{C}, \check{D})$:

$$\check{A}^*Q\check{A} - Q + \check{C}^*\check{C} = 0. \tag{6.3}$$

Proof. The equations (6.1) and (6.2) are readily verified using (5.1). Equation (6.3) is more complicated and the proof is given in the appendix. ∎

LEMMA 6.4. *Let* $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1, \check{D}_2])$ *be a discrete-time system such that* $\check{D}_1$ *is boundedly invertible and define the discrete-time system* (A, B, C, D) *by* (5.4). *If the nonnegative self-adjoint operator* Q *satisfies* (6.2) *and* (6.3), *then* Q *is a solution of the CARE* (3.4) *of* (A, B, C, D).

Proof. See the appendix. ∎

LEMMA 6.5. *Let* (A, B, C, D) *be an input and output stabilizable discrete-time system and let* Q *be a nonnegative self-adjoint solution of its CARE* (3.4) *and* P *be a nonnegative self-adjoint solution of its FARE* (3.8). *Let* $(\check{A}, \check{B}, \check{C}, \check{D})$ *be its CARE closed-loop system defined by* (5.1). *Define* $L := (I + PQ)^{-1}P$. *Then* L *is a solution of the control Lyapunov equation of* $(\check{A}, \check{B}, \check{C}, \check{D})$:

$$\check{A}L\check{A}^* - L + \check{B}\check{B}^* = 0. \tag{6.4}$$

Proof. See the appendix for the proof. ∎

LEMMA 6.6. *Let* $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1, \check{D}_2])$ *be a discrete-time system such that* $\check{D}_1$ *is boundedly invertible and define the discrete-time system* (A, B, C, D) *by* (5.4). *If the nonnegative self-adjoint operators* Q *and* L *satisfy* (6.1), (6.2), (6.3), *and* (6.4) *and* $I - QL$ *is boundedly invertible, then* $L(I - QL)^{-1}$ *is a solution of the FARE* (3.8) *of* (A, B, C, D).

Proof. See the appendix for the proof. ∎

If Q and P are the smallest nonnegative self-adjoint solutions of their respective Riccati equations, then the operator $L := (I + PQ)^{-1}P$ defined in Lemma 6.5 is actually the smallest nonnegative self-adjoint solution of the Lyapunov equation (6.4). To prove this we first prove the following lemma. We note that the Hankel norm of an input-output map is the norm of the associated Hankel operator.

LEMMA 6.7. *Let* (A, B, C, D) *be an input and output stabilizable discrete-time system. Then the Hankel norm of the input-output map of the optimal closed-loop system* (5.1) *is strictly smaller than one.*

Proof. Denote the optimal cost operators by P and Q, the gramians of the optimal closed-loop system by L_B and L_C, and the Hankel operator of the optimal closed-loop system by Γ. From Lemma 5.1 it follows that $Q = L_C$. From Lemma 6.5 we know that $(I + PQ)^{-1}P$ is a solution of the control Lyapunov equation and hence by Lemma 3.4 we have $L_B \leq (I + PQ)^{-1}P$. This implies that $L_C^{1/2} L_B L_C^{1/2} \leq Q^{1/2}(I + PQ)^{-1}PQ^{1/2} = (I + Q^{1/2}PQ^{1/2})^{-1}Q^{1/2}PQ^{1/2}$. Now $\|\Gamma\| = \|\Gamma\Gamma^*\| = r(\Gamma\Gamma^*) = r(\mathcal{C}\mathcal{B}\mathcal{B}^*\mathcal{C}^*) = r(\mathcal{C}^*\mathcal{C}\mathcal{B}\mathcal{B}^*) = r(L_C L_B) = r(L_C^{1/2} L_B L_C^{1/2}) \leq r((I + Q^{1/2}PQ^{1/2})^{-1}Q^{1/2}PQ^{1/2})$. Next we show that if X is a nonnegative self-adjoint operator, then $(I + X)^{-1}X < I$. Since $X < I + X$ we have $(I + X)^{-1}X = (I + X)^{-1/2}X(I + X)^{-1/2} < (I + X)^{-1/2}(I + X)(I + X)^{-1/2} = I$. Finally, we apply this last result with $X := Q^{1/2}PQ^{1/2}$ to obtain $\|\Gamma\| \leq r((I + X)^{-1}X) < 1$. ∎

Lemma 6.7 has the following corollary.

COROLLARY 6.8. *Let* (A, B, C, D) *be an input and output stabilizable discrete-time system. Let* L_B *and* L_C *denote the gramians of an input and output stable realization of the input-output map of the optimal closed-loop system* (5.1). *Then* $r(L_B L_C) < 1$.

We now show for an approximately observable system that if Q and P are the smallest nonnegative self-adjoint solutions of their respective Riccati equations then the operator $L := (I + PQ)^{-1}P$ defined in Lemma 6.5 is actually the smallest nonnegative self-adjoint solution of the Lyapunov equation (6.4).

LEMMA 6.9. *Let (A, B, C, D) be an approximately observable input and output stabilizable discrete-time system. Let Q and P denote the optimal cost operators of the system and its dual, respectively. Define $L := (I + PQ)^{-1}P$. Then L is the controllability gramian of the optimal closed-loop system* (5.1).

Proof. We have by Lemma 5.1 that $Q = L_C$, the observability gramian of the optimal closed-loop system, and by Lemma 6.5 that $L = (I + PQ)^{-1}P$ is a solution of the control Lyapunov equation of the optimal closed-loop system. Since the control Lyapunov equation of the optimal closed-loop system has a nonnegative self-adjoint solution, the optimal closed-loop system is input stable and has a controllability gramian L_B which satisfies $L_B \leq L$. From Lemma 6.8 we know that $I - L_C L_B$ is boundedly invertible and hence by Lemma 6.6 we have that $\tilde{P} := L_B(I - L_C L_B)^{-1}$ is a solution of the FARE (3.8) of the system (A, B, C, D). We thus have $P \leq \tilde{P}$. Note that approximate observability ensures that $Q = L_C > 0$. Since Q is positive and thus has dense range we have $\tilde{P} \geq P$ iff $Q^{1/2}\tilde{P}Q^{1/2} \geq Q^{1/2}PQ^{1/2}$. This is true iff

$$\begin{aligned} I - Q^{1/2}(I + \tilde{P}Q)^{-1}\tilde{P}Q^{1/2} &= (I + Q^{1/2}\tilde{P}Q^{1/2})^{-1} \\ &\leq (I + Q^{1/2}PQ^{1/2})^{-1} = I - Q^{1/2}(I + PQ)^{-1}PQ^{1/2}. \end{aligned}$$

This is true iff $Q^{1/2}(I + \tilde{P}Q)^{-1}\tilde{P}Q^{1/2} \geq Q^{1/2}(I + PQ)^{-1}PQ^{1/2}$ and again using that Q has dense range this is true iff $(I + \tilde{P}Q)^{-1}\tilde{P} \geq (I + PQ)^{-1}P$. We conclude that $L = (I + PQ)^{-1}P \leq (I + \tilde{P}Q)^{-1}\tilde{P} = L_B$. Since we already had $L_B \leq L$, we must have $L = L_B$. ∎

7. LQG-characteristic values. In this section we show that the spectrum of the product of the optimal cost operators of a system and its dual does not depend on the realization but only on the input-output map. This generalizes the result from finite-dimensional theory that the eigenvalues of PQ are similarity invariants. We define the LQG-characteristic values of an input and output stabilizable discrete-time system to be the square roots of the spectral values of the product of the optimal cost operators P and Q. We first prove the following lemma on the spectrum of PQ.

LEMMA 7.1. *Let (A, B, C, D) be an approximately observable input and output stabilizable discrete-time system. Let Q and P denote the optimal cost operators of the system and its dual, respectively, and let L_B and L_C denote the gramians of the optimal closed-loop system* (5.1). *Then $\lambda \in \sigma(PQ)$ iff $\lambda/(1 + \lambda) \in \sigma(L_B L_C)$.*

Proof. From Lemmas 5.1 and 6.9 we have that $L_B L_C = (I + PQ)^{-1}PQ$, from which it follows that $PQ = (I - L_B L_C)^{-1}L_B L_C$. Let $\lambda \in \mathbb{C} - \{-1\}$ and define $\mu := \lambda/(1 + \lambda)$, then $\lambda = \mu/(1 - \mu)$. We have

$$\begin{aligned} \lambda I - PQ &= \frac{\mu}{1-\mu} I - L_B L_C (I - L_B L_C)^{-1} \\ &= \frac{1}{1-\mu}\left[\mu I - (1-\mu) L_B L_C (I - L_B L_C)^{-1}\right] \\ &= \frac{1}{1-\mu}\left[\mu(I - L_B L_C) - (1-\mu) L_B L_C\right](I - L_B L_C)^{-1} \\ &= \frac{1}{1-\mu}(\mu I - L_B L_C)(I - L_B L_C)^{-1}. \end{aligned}$$

This shows that $\lambda \in \sigma(PQ)$ iff $\mu = \lambda/(1 + \lambda) \in \sigma(L_B L_C)$. ∎

The following lemma gives the desired result.

LEMMA 7.2. *Let (A_i, B_i, C_i, D) with $i = 1, 2$ be two approximately observable input and output stabilizable discrete-time systems. Let Q_i and P_i denote the optimal cost operators of the system and its dual, respectively. If the two systems have the same input-output map, then the spectra of P_1Q_1 and P_2Q_2 are equal, with the possible exception of zero.*

Proof. Denote the gramians of the optimal closed-loop system of (A_i, B_i, C_i, D) by L_{B_i} and L_{C_i}. Then according to Lemma 7.1, the lemma would be proved if the nonzero elements in the spectrum of $L_{B_1}L_{C_1}$ equal the nonzero elements in the spectrum of $L_{B_2}L_{C_2}$. Since the input-output map of both optimal closed-loop systems is a normalized factor of the input-output map of the plant by Lemma 5.8, there exists a unitary V such that $[\mathcal{M}_2; \mathcal{N}_2] = [\mathcal{M}_1; \mathcal{N}_1]V$ by Lemma 5.9. For the Hankel operators of the optimal closed-loop systems this implies $\Gamma_2 = \Gamma_1 V$, which implies that $\Gamma_2\Gamma_2^* = \Gamma_1\Gamma_1^*$. Since for arbitrary bounded operators S and T we have that the nonzero elements in the spectrum of ST equal the nonzero elements in the spectrum of TS, we have that the nonzero elements in the spectrum of $L_BL_C = \mathcal{B}\mathcal{B}^*\mathcal{C}^*\mathcal{C}$ equal the nonzero elements in the spectrum of $\Gamma\Gamma^* = \mathcal{C}\mathcal{B}\mathcal{B}^*\mathcal{C}^*$. This shows that the nonzero elements in the spectrum of $L_{B_1}L_{C_1}$ equal the nonzero elements in the spectrum of $L_{B_2}L_{C_2}$. ∎

8. LQG-balanced realizations. In this section we prove the existence and some properties of LQG-balanced realizations. We first show that the input-output map of the optimal closed-loop system has a Lyapunov-balanced realization.

LEMMA 8.1. *Let (A, B, C, D) be an output stabilizable discrete-time system. Then the input-output map of the optimal closed-loop system has an approximately controllable and approximately observable Lyapunov-balanced realization.*

Proof. Lemma 5.8 shows that the optimal closed-loop system is input-output stable. This implies that the Hankel operator of the optimal closed-loop system is bounded and Lemma 4.1 then shows that the input-output map of the optimal closed-loop system has a Lyapunov-balanced realization. ∎

From this Lyapunov-balanced realization we can construct a LQG-balanced realization of the plant.

THEOREM 8.2. *Let (A, B, C, D) be an input and output stabilizable discrete-time system. Then the input-output map of the system (A, B, C, D) has a LQG-balanced realization.*

Proof. Denote the approximately controllable and approximately observable Lyapunov-balanced realization of the input-output map of the optimal closed-loop system by $(\check{A}, \check{B}, \check{C}, \check{D})$. Denote the equal controllability and observability gramians of this realization by L. Define

$$A_s := \check{A} - \check{B}\check{D}_1^{-1}\check{C}_1, \quad B_s := \check{B}\check{D}_1^{-1}, \quad C_s := \check{C}_2 - \check{D}_2\check{D}_1^{-1}\check{C}_1, \quad D_s := \check{D}_2\check{D}_1^{-1}.$$

Then (A_s, B_s, C_s, D_s) is a realization of the input-output map of (A, B, C, D) according to Lemma 5.7. Since the input-output map of the optimal closed-loop system is inner (Corollary 5.8) and $(\check{A}, \check{B}, \check{C}, \check{D})$ is approximately controllable we know from Lemma 5.3 that $\check{B}^*L\check{B} + \check{D}^*\check{D} = I$ and $\check{B}^*L\check{A} + \check{D}^*\check{C} = 0$. From Lemma 6.4 we see that L is a solution of the CARE of the system (A_s, B_s, C_s, D_s). From Corollary 6.8 we know that $I - L^2$ is boundedly invertible, and Lemma 6.6 now tells us that $L(I-L^2)^{-1}$ is a solution of the FARE of the system (A_s, B_s, C_s, D_s). From Lemma 4.3 we know that $\check{A}$ is strongly stable. Using Lemma 3.7 we see that this implies that L is the unique nonnegative self-adjoint solution of the CARE of the system (A_s, B_s, C_s, D_s). Assume that the FARE of the system (A_s, B_s, C_s, D_s) has two nonnegative self-adjoint

solutions, P_1 and P_2. From Lemma 6.5 we see that $(I+P_1L)^{-1}P_1$ and $(I+P_2L)^{-1}P_2$ are solutions of the control Lyapunov equation of the optimal closed-loop system of (A_s, B_s, C_s, D_s), which is the balanced realization $(\check{A}, \check{B}, \check{C}, \check{D})$. From Corollary 4.4 we see that $(I + P_1L)^{-1}P_1 = (I + P_2L)^{-1}P_2$, which implies that $P_1 = P_2$. We recall that if a system (A_1, B_1, C_1, D_1) has a solution Q to its CARE and P to its FARE and S is a boundedly invertible operator, then the system $(SAS^{-1}, SB, CS^{-1}, D)$ has a solution $S^{-*}QS^{-1}$ to its CARE and SPS^* to its FARE. It is easily seen that $I - L^2$ is a nonnegative operator (for example, using that the Hankel operator has norm smaller than one), from which it follows that $S := (I - L^2)^{-1/4}$ is well defined. Define $(A_l, B_l, C_l, D_l) = (SA_sS^{-1}, SB_s, C_sS^{-1}, D_s)$. Then the system (A_l, B_l, C_l, D_l) has $L(I - L^2)^{-1/2}$ as the unique solution to both its CARE and its FARE. □

We now prove that LQG-balanced realizations are essentially unique.

LEMMA 8.3. *Let (A, B, C, D) be an approximately controllable and approximately observable LQG-balanced realization. Then all approximately controllable and approximately observable LQG-balanced realizations of the same input-output map are given by $\{(TAT^{-1}, TB, CT^{-1}, D) : T \in \mathcal{L}(X)$ unitary$\}$.*

Proof. It is obvious that the given realizations are indeed LQG balanced; it remains to be proved that these are all approximately controllable and approximately observable LQG-balanced realizations. Let (A_1, B_1, C_1, D_1) and (A_2, B_2, C_2, D_2) be two approximately controllable and approximately observable LQG-balanced realizations of the same input-output map. Let Q_1 and Q_2 be the optimal cost operators of the respective systems. Define $S_i := (I + Q_i^2)^{1/4}$ and $(A_i^b, B_i^b, C_i^b, D_i^b) = (S_iA_iS_i^{-1}, S_iB_i, C_iS_i^{-1}, D_i)$ for $i = 1, 2$. Then $(A_i^b, B_i^b, C_i^b, D_i^b)$ has $Q_i^b := Q_i(I + Q_i^2)^{-1/2}$ as its optimal cost operator and $P_i^b := Q_i(I + Q_i^2)^{1/2}$ as the optimal cost operator of its dual system. Let $(\check{A}_i^b, \check{B}_i^b, \check{C}_i^b, \check{D}_i^b)$ be the optimal closed-loop system of $(A_i^b, B_i^b, C_i^b, D_i^b)$. Using Lemmas 5.1 and 6.9 we see that they are Lyapunov-balanced realizations with gramians $L_i := Q_i(I + Q_i^2)^{-1/2}$. According to Corollary 5.8 the input-output maps of $(\check{A}_1^b, \check{B}_1^b, \check{C}_1^b, \check{D}_1^b)$ and $(\check{A}_2^b, \check{B}_2^b, \check{C}_2^b, \check{D}_2^b)$ are normalized factors of the input-output map of (A_1, B_1, C_1, D_1) (which equals the input-output map of (A_2, B_2, C_2, D_2)). By Lemma 5.9 there exists an operator V such that $[\mathcal{M}_2; \mathcal{N}_2] = [\mathcal{M}_1; \mathcal{N}_1]V$. It is easily seen that $(\check{A}_1^b, \check{B}_1^bV, \check{C}_1^b, \check{D}_1^bV)$ is a Lyapunov-balanced realization of $[\mathcal{M}_1; \mathcal{N}_1]V = [\mathcal{M}_2; \mathcal{N}_2]$. From Lemma 6.2 it follows that both $(\check{A}_1^b, \check{B}_1^bV, \check{C}_1^b, \check{D}_1^bV)$ and $(\check{A}_2^b, \check{B}_2^b, \check{C}_2^b, \check{D}_2^b)$ are approximately controllable and approximately observable Lyapunov-balanced realizations of the input-output map $[\mathcal{M}_2; \mathcal{N}_2]$. From Lemma 4.1 it follows that there exists a unitary T such that

$$(T\check{A}_1^bT^{-1}, T\check{B}_1^bV, \check{C}_1^bT^{-1}, \check{D}_1^bV) = (\check{A}_2^b, \check{B}_2^b, \check{C}_2^b, \check{D}_2^b).$$

Using (5.4) for $i = 1, 2$ we see that

$$(TA_1^bT^{-1}, TB_1^b, C_1^bT^{-1}, D_1^b) = (A_2^b, B_2^b, C_2^b, D_2^b).$$

It now follows that

$$(S_2^{-1}TS_1A_1S_1^{-1}T^{-1}S_2, S_2^{-1}TS_1B_1, C_1S_1^{-1}T^{-1}S_2, D_1) = (A_2, B_2, C_2, D_2).$$

To complete the proof that (A_1, B_1, C_1, D_1) and (A_2, B_2, C_2, D_2) are unitarily equivalent we prove that $S_2^{-1}TS_1 = T$ or equivalently $TS_1T^{-1} = S_2$. Since $(I + Q_i^2)^{-1} = I - [Q_i(I + Q_i^2)^{-1/2}]^2 = I - L_i^2$ we have $S_i = (I + Q_i^2)^{-1/4} = (I - L_i^2)^{1/4}$ and since $L_2 = TL_1T^{-1}$ we then have

$$S_2 = (I - L_2^2)^{1/4} = T(I - L_1^2)^{1/4}T^{-1} = TS_1T^{-1}.$$

This proves that all approximately controllable and approximately observable LQG-balanced realizations of the same input-output map are unitarily equivalent. ∎

The following lemma states what the proof of Theorem 8.2 already indicated, namely, that the filter and control Riccati equations of an approximately controllable and approximately observable LQG-balanced realization have unique nonnegative self-adjoint solutions.

LEMMA 8.4. *Let (A, B, C, D) be an approximately controllable and approximately observable LQG-balanced realization. Then both the CARE* (3.4) *and the FARE* (3.8) *of (A, B, C, D) have a unique nonnegative self-adjoint solution.*

Proof. As in the proof of Lemma 8.3 we construct the approximately controllable and approximately observable realization (A^b, B^b, C^b, D^b) and the approximately controllable and approximately observable Lyapunov-balanced realization $(\check{A}^b, \check{B}^b, \check{C}^b, \check{D}^b)$. From Lemma 4.3 we know that $\check{A}^b$ is strongly stable. Lemma 3.7 shows that the CARE of (A^b, B^b, C^b, D^b) has a unique nonnegative self-adjoint solution. Obviously this implies that the CARE of (A, B, C, D) has a unique nonnegative self-adjoint solution. From Lemma 4.4 we know that the control Lyapunov equation of $(\check{A}^b, \check{B}^b, \check{C}^b, \check{D}^b)$ has a unique nonnegative self-adjoint solution. As in the proof of Theorem 8.2, it follows that the FARE of (A^b, B^b, C^b, D^b) and hence the FARE of (A, B, C, D) has a unique nonnegative self-adjoint solution. ∎

9. Conclusions. We have proved the existence of LQG-balanced realizations for the class of transfer functions that are analytic on some disc centered at the origin and have a (infinite-dimensional) realization that is both input and output stabilizable. We have also proved that approximately controllable and approximately observable LQG-balanced realizations are essentially unique and that the Riccati equations of approximately controllable and approximately observable LQG-balanced realizations have unique nonnegative self-adjoint solutions. Analogous continuous-time results and error bounds for truncations of LQG-balanced realizations will be given elsewhere.

10. Appendix.

10.1. Miscellaneous results on Riccati operators.

LEMMA 10.1. *Let P and Q be nonnegative self-adjoint operators. Define*

$$A_P := A - (BD^* + APC^*)(R + CPC^*)^{-1}C, \tag{10.1}$$

$$A_Q := A - B(S + B^*QB)^{-1}(D^*C + B^*QA), \tag{10.2}$$

$$\underline{A} := A - BS^{-1}D^*C. \tag{10.3}$$

where $S := I + D^*D$ and $R := I + DD^*$. Then

$$A_P(I + PC^*R^{-1}C) = \underline{A} = (I + BS^{-1}B^*Q)A_Q, \tag{10.4}$$

$$A_Q = (I + BS^{-1}B^*Q)^{-1}A_P(I + PC^*R^{-1}C), \tag{10.5}$$

$$A_P = (I + BS^{-1}B^*Q)A_Q(I + PC^*R^{-1}C)^{-1}. \tag{10.6}$$

Proof. We prove that $A_P(I+PC^*R^{-1}C) = \underline{A}$. The equality $\underline{A} = (I+BS^{-1}B^*Q)A_Q$ is proved similarly. By writing out A_P in full we have

$$\begin{aligned}
&A_P(I + PC^*R^{-1}C)\\
&\quad = A(I + PC^*R^{-1}C) - (BD^* + APC^*)(R + CPC^*)^{-1}C(I + PC^*R^{-1}C)\\
&\quad = A(I + PC^*R^{-1}C) - (BD^* + APC^*)(R + CPC^*)^{-1}(R + CPC^*)R^{-1}C\\
&\quad = A + APC^*R^{-1}C - (BD^* + APC^*)R^{-1}C = A - BD^*R^{-1}C\\
&\quad = A - BS^{-1}D^*C,
\end{aligned}$$

since $D^*R^{-1} = S^{-1}D^*$. This completes the proof of (10.4). Equations (10.5) and (10.6) easily follow from (10.4). □

Note that in the above lemma we have not assumed that P and Q are solutions of the Riccati equations.

We now prove that the Riccati equations can be written in several different but equivalent versions.

LEMMA 10.2.

1. *P is a nonnegative self-adjoint solution of*

$$A_P P(I + C^*R^{-1}CP)A_P^* - P + BS^{-1}B^* = 0, \tag{10.7}$$

where A_P is defined by (10.1)*, iff it is a nonnegative self-adjoint solution of*

$$\underline{A}P(I + C^*R^{-1}CP)^{-1}\underline{A}^* - P + BS^{-1}B^* = 0, \tag{10.8}$$

where $\underline{A}$ is defined by (10.3)*.*

2. *P is a nonnegative self-adjoint solution of* (10.7) *iff it is a nonnegative self-adjoint solution of the FARE* (3.8)*.*
3. *Q is a nonnegative self-adjoint solution of*

$$A_Q^*(I + QBS^{-1}B^*)QA_Q - Q + C^*R^{-1}C = 0, \tag{10.9}$$

where A_Q is defined by (10.2)*, iff it is a nonnegative self-adjoint solution of*

$$\underline{A}^*Q(I + BS^{-1}B^*Q)^{-1}\underline{A} - Q + C^*R^{-1}C = 0, \tag{10.10}$$

where $\underline{A}$ is defined by (10.3)*.*

4. *Q is a nonnegative self-adjoint solution of* (10.9) *iff it is a nonnegative self-adjoint solution of the CARE* (3.4)*.*

Proof. We shall prove the equivalence of the filter equations; the equivalence of the control equations is similar.

1. The equations (10.7) and (10.8) are equivalent iff the following holds:

$$\underline{A}P(I + C^*R^{-1}CP)^{-1}\underline{A}^* = A_P P(I + C^*R^{-1}CP)A_P^*. \tag{10.11}$$

We use Lemma 10.1 (which tells us that $\underline{A} = A_P(I + PC^*R^{-1}C)$) to write the left-hand side of (10.11) as

$$A_P(I + PC^*R^{-1}C)P(I + C^*R^{-1}CP)^{-1}(I + C^*R^{-1}CP)A_P^*,$$

which is indeed equal to the right-hand side of (10.11).

2. To prove the equivalence of (10.7) and (3.8) we substitute in (10.7) for A_P from (10.1) and for $(I + C^*R^{-1}CP)A_P^*$, we substitute $\underline{A}^*$ (using (10.4)) and then substitute (10.3) for $\underline{A}$. We then get

$$(A - (BD^* + APC^*)(R + CPC^*)^{-1}C)P(A^* - C^*DS^{-1}B^*) - P + BS^{-1}B^* = 0.$$

Rewriting this gives

$$\begin{aligned} APA^* - P + BB^* = {} & (BD^* + APC^*)(R + CPC^*)^{-1}CPA^* \\ & - (BD^* + APC^*)(R + CPC^*)^{-1}CPC^*DS^{-1}B^* + APC^*DS^{-1}B^* \\ & - BS^{-1}B^* + BB^*. \end{aligned}$$

We now focus on the last two lines of this last equation. We note that $I - S^{-1} = D^*DS^{-1}$ and we can thus rewrite these last two lines as

$$-(BD^* + APC^*)(R + CPC^*)^{-1}CPC^*DS^{-1}B^* + APC^*DS^{-1}B^* + BD^*DS^{-1}B^*,$$

and this can be rewritten as

$$(BD^* + APC^*)(R + CPC^*)^{-1}[-CPC^* + R + CPC^*]DS^{-1}B^*.$$

Noting that $RDS^{-1} = D$, we see that this is equal to

$$(BD^* + APC^*)(R + CPC^*)^{-1}DB^*.$$

This completes the proof of the equivalence of (10.7) and (3.8). ∎

We now show that the known relationship between A_Q and A_P extends to the infinite-dimensional case.

LEMMA 10.3. *Let (A, B, C, D) be an input and output stabilizable discrete-time system, let Q be a nonnegative self-adjoint solution of its CARE* (3.4)*, and let P be a nonnegative self-adjoint solution of its FARE* (3.8)*. Define A_P and A_Q by* (10.1) *and* (10.2)*, respectively. Then*

$$(I + PQ)A_Q = A_P(I + PQ).$$

Proof. We use FARE (10.7) to write

$$P = A_PP(I + C^*R^{-1}CP)A_P^* + BS^{-1}B^*,$$

which leads to

$$I + PQ = I + A_PP(I + C^*R^{-1}CP)A_P^*Q + BS^{-1}B^*Q$$

and so

$$(I + PQ)A_Q = (I + BS^{-1}B^*Q)A_Q + A_PP(I + C^*R^{-1}CP)A_P^*QA_Q.$$

We use (10.5) to write the right-hand side as

$$A_P(I + PC^*R^{-1}C) + A_PP(I + C^*R^{-1}CP)A_P^*QA_Q.$$

Rearranging gives

$$A_P + A_PP[C^*R^{-1}C + (I + C^*R^{-1}CP)A_P^*QA_Q],$$

and using (10.5) again we obtain

$$A_P + A_P P[C^* R^{-1} C + A_Q^*(I + QBS^{-1}B^*)QA_Q].$$

According to CARE (10.9), the term in square brackets equals Q. So the above is equal to $A_P(I + PQ)$. □

We now prove a relation concerning the difference of two solutions of a Riccati equation.

LEMMA 10.4. *Let (A, B, C, D) be an output stabilizable discrete-time system and let Q_1 and Q_2 be nonnegative self-adjoint solutions of its CARE* (3.4). *Define A_{Q_1} and A_{Q_2} similarly to* (10.2). *Then*

$$Q_1 - Q_2 = A_{Q_2}^*(Q_1 - Q_2)A_{Q_1}.$$

Proof. Subtract the form (10.9) of the CARE for Q_1 and Q_2 to obtain

$$Q_1 - Q_2 = A_{Q_1}^*(I + Q_1 BS^{-1}B^*)Q_1 A_{Q_1} - A_{Q_2}^*(I + Q_2 BS^{-1}B^*)Q_2 A_{Q_2}. \tag{10.12}$$

According to Lemma 10.1 (say with $P = I$) we have

$$\begin{aligned} A_{Q_2} &= (I + BS^{-1}B^*Q_2)^{-1} A_P (I + PC^* R^{-1} C) \\ &= (I + BS^{-1}B^*Q_2)^{-1}(I + BS^{-1}B^*Q_1)A_{Q_1}. \end{aligned} \tag{10.13}$$

Combining (10.12) and (10.13) we obtain

$$\begin{aligned} Q_1 - Q_2 &= A_{Q_2}^*(I + Q_2 BS^{-1}B^*)Q_1 A_{Q_1} - A_{Q_2}^* Q_2 (I + BS^{-1}B^*Q_1)A_{Q_1} \\ &= A_{Q_2}^*(Q_1 - Q_2)A_{Q_1}. \end{aligned}$$ □

10.2. Proofs for section 6. In this section we prove the relationships between the CARE and the FARE of a system and the control and observation Lyapunov equations of its CARE closed-loop system (Lemmas 6.3, 6.4, 6.5, and 6.6).

LEMMA 10.5. *Suppose that the system $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2])$ is such that $\check{D}_1$ is boundedly invertible and that there exists a nonnegative self-adjoint operator V such that*

$$\check{B}^* V \check{A} + \check{D}^* \check{C} = 0. \tag{10.14}$$

Define the system (A, B, C, D) by (5.4) *and $S := I + D^*D$ and $R := I + DD^*$. Then*

1. $\check{A} = A - B(S + B^*VB)^{-1}(D^*C + B^*VA)$ *and*
2. $\check{A}^* V \check{A} - V + \check{C}^* \check{C} = \check{A}^*(I + VBS^{-1}B^*)V\check{A} - V + C^* R^{-1} C$.

Proof. We first prove the equality

$$S\check{C}_1 = -(B^* V \check{A} + D^* C). \tag{10.15}$$

From (10.14) and (5.4) we obtain

$$\check{D}_1^* B^* V \check{A} + \check{D}_1^* \check{C}_1 + \check{D}_2^* \check{C}_2 = 0.$$

Thus

$$\check{C}_1 = -B^* V \check{A} - D^* \check{C}_2 = -B^* V \check{A} - D^*(C + D\check{C}_1)$$

and this yields (10.15):

$$S\check{C}_1 = (I + D^*D)\check{C}_1 = -B^* V \check{A} - D^* C.$$

We now prove the first equality stated in the lemma. We take the equality just proved (10.15) and substitute $\check{A} = A + B\check{C}_1$ to obtain

$$S\check{C}_1 = -(B^*V(A + B\check{C}_1) + D^*C).$$

Thus

$$(S + B^*VB)\check{C}_1 = -(B^*VA + D^*C).$$

We now solve for $\check{C}_1$ and substitute to obtain

$$\check{A} = A + B\check{C}_1 = A - B(S + B^*VB)^{-1}(B^*VA + D^*C).$$

We now prove the equality

$$\check{C}^*\check{C} = \check{A}^*VBS^{-1}B^*V\check{A} + C^*R^{-1}C. \tag{10.16}$$

We have

$$\check{C}^*\check{C} = \check{C}_1^*\check{C}_1 + \check{C}_2^*\check{C}_2$$

and substituting for $\check{C}_2$ from (5.4) gives

$$\check{C}^*\check{C} = \check{C}_1^*\check{C}_1 + (C + D\check{C}_1)^*(C + D\check{C}_1).$$

Finally, substituting for $\check{C}_1$ from (10.15) and simplifying gives the result.
The second equality stated in the lemma follows easily from (10.16). □

Proof of Lemma 6.3. We only have to prove (6.3). Noting (6.2), we apply Lemma 10.5 with $V := Q$ to the CARE closed-loop system. Since $\check{A}$ defined by (5.1) equals A_Q defined by (10.2), we have

$$\check{A}^*Q\check{A} - Q + \check{C}^*\check{C} = A_Q^*(I + QBS^{-1}B^*)QA_Q - Q + C^*R^{-1}C.$$

Since Q is a solution of the CARE (3.4) of (A, B, C, D) the right-hand side of this equation is zero by Lemma 10.2 and we have shown (6.3). □

Proof of Lemma 6.4. By assumption, there exists a nonnegative self-adjoint Q such that $\check{B}^*Q\check{A} + \check{D}^*\check{C} = 0$. We apply Lemma 10.5 with $V := Q$ to obtain $\check{A} = A_Q$ given by (10.2) and

$$\check{A}^*Q\check{A} - Q + \check{C}^*\check{C} = A_Q^*(I + QBS^{-1}B^*)QA_Q - Q + C^*R^{-1}C.$$

The left-hand side of this equation is zero since by assumption Q satisfies (6.3). This proves that the right-hand side is zero, and Lemma 10.2 now shows that Q is a solution of the CARE of the system (A, B, C, D). □

LEMMA 10.6. *Let a system* $(\check{A}, \check{B}, [\check{C}_1; \check{C}_2], [\check{D}_1; \check{D}_2])$ *with* $\check{D}_1$ *boundedly invertible be given and assume that a nonnegative self-adjoint operator* V *exists such that*

$$\check{B}^*V\check{B} + \check{D}^*\check{D} = I.$$

Define the system (A, B, C, D) *by* (5.4). *Then we have*

1. $B^*VB + S = \check{D}_1^{-*}\check{D}_1^{-1}$ *and*
2. $\check{B}\check{B}^*(I + VBS^{-1}B^*) = BS^{-1}B^*$.

Proof. 1. The given equation for V translates to

$$\check{D}_1^* B^* V B \check{D}_1 + \check{D}_1^* \check{D}_1 + \check{D}_1^* D^* D \check{D}_1 = I,$$

and multiplying from the left with $\check{D}_1^{-*}$ and from the right with $\check{D}_1^{-1}$ gives the result.

2. The first equality implies that $(S+B^*VB)^{-1} = \check{D}_1\check{D}_1^*$ and so $B(S+B^*VB)^{-1}B^* = \check{B}\check{B}^*$. Hence

$$\begin{aligned}\check{B}\check{B}^*(I + VBS^{-1}B^*) &= B(S + B^*VB)^{-1}B^*(I + VBS^{-1}B^*) \\ &= B(S + B^*VB)^{-1}(S + B^*VB)S^{-1}B^* = BS^{-1}B^*,\end{aligned}$$

which proves the second equality. □

We now prove Lemma 6.5.

Proof of Lemma 6.5. We remark that $L = (I + PQ)^{-1}P = P(I + QP)^{-1}$ and so we have to show that

$$\check{A}P(I + QP)^{-1}\check{A}^* - P(I + QP)^{-1} + \check{B}\check{B}^* = 0. \tag{10.17}$$

Recalling that $\check{A} = A_Q$ from (5.1) and (10.2) and using Lemmas 10.1 (10.5) and 10.3 we can substitute $\check{A} = (I + BS^{-1}B^*Q)^{-1}A_P(I + PC^*R^{-1}C)$ and $(I + QP)^{-1}\check{A}^* = A_P^*(I + QP)^{-1}$ to obtain for the left-hand side of (10.17)

$$\begin{aligned}&(I + BS^{-1}B^*Q)^{-1}A_P(I + PC^*R^{-1}C)PA_P^*(I + QP)^{-1} - P(I + QP)^{-1} + \check{B}\check{B}^* \\ &\quad = (I + BS^{-1}B^*Q)^{-1}[A_P(I + PC^*R^{-1}C)PA_P^* - (I + BS^{-1}B^*Q)P \\ &\quad + (I + BS^{-1}B^*Q)^{-1}\check{B}\check{B}^*(I + QP)](I + QP)^{-1}.\end{aligned}$$

We now apply Lemma 10.6 with $V := Q$ to obtain $(I+BS^{-1}B^*Q)^{-1}\check{B}\check{B}^* = BS^{-1}B^*$, and so we obtain for the left-hand side of (10.17)

$$\begin{aligned}(I + BS^{-1}B^*Q)^{-1}[&A_P(I + PC^*R^{-1}C)PA_P^* - (I + BS^{-1}B^*Q)P \\ &+ BS^{-1}B^*(I + QP)](I + QP)^{-1}.\end{aligned}$$

The term in square brackets is zero according to the FARE (10.7) and we have proved (10.17). □

Proof of Lemma 6.6. We first recall from the proof of Lemma 6.4 that $\check{A} = A_Q$, where A_Q is defined by (10.2), and that (10.6) holds with $A_Q = \check{A}$. Define $P := L(I - QL)^{-1}$ and define A_P by (10.1). The second step in the proof is establishing the identity

$$(I - LQ)A_P = \check{A}(I - LQ) \tag{10.18}$$

or by (10.6) the equivalent identity

$$(I - LQ)(I + BS^{-1}B^*Q)\check{A} = \check{A}(I - LQ)(I + PC^*R^{-1}C). \tag{10.19}$$

Since $P = L(I - QL)^{-1} = (I - LQ)^{-1}L$ the right-hand side of (10.19) is equal to

$$\check{A} - \check{A}LQ + \check{A}LC^*R^{-1}C.$$

We substitute $Q - C^*R^{-1}C = \check{A}^*(I + QBS^{-1}B^*)Q\check{A}$ (this identity holds because Q is a solution of the CARE; see (10.9)) to obtain for the right-hand side of (10.19)

$$\check{A} - \check{A}L\check{A}^*(I + QBS^{-1}B^*)Q\check{A}.$$

The control Lyapunov equation tells us that $\check{A}L\check{A}^* = L - \check{B}\check{B}^*$ and so the right-hand side of (10.19) is equal to

$$\check{A} - L(I + QBS^{-1}B^*)Q\check{A} + \check{B}\check{B}^*(I + QBS^{-1}B^*)Q\check{A}.$$

Substituting $\check{B}\check{B}^*(I + QBS^{-1}B^*) = BS^{-1}B^*$ from Lemma 10.6 with $V = Q$ we obtain for the right-hand side of (10.19)

$$\check{A} - L(I + QBS^{-1}B^*)Q\check{A} + BS^{-1}B^*Q\check{A},$$

which is equal to the left-hand side of (10.19). This proves (10.18). We now make the third and last step of the proof that P is a solution of the FARE. We start with the control Lyapunov equation

$$\check{A}L\check{A}^* - L + \check{B}\check{B}^* = 0$$

and substitute $\check{A} = (I-LQ)A_P(I-LQ)^{-1}$ from (10.18) and $\check{A}^* = (I+C^*R^{-1}CP)A_P^*(I+QBS^{-1}B^*)^{-1}$ from (10.6) to obtain

$$(I - LQ)A_P(I - LQ)^{-1}L(I + C^*R^{-1}CP)A_P^*(I + QBS^{-1}B^*)^{-1} - L + \check{B}\check{B}^* = 0.$$

We multiply by $(I - LQ)^{-1}$ from the left and by $(I + QBS^{-1}B^*)$ from the right to obtain

$$A_PP(I + C^*R^{-1}CP)A_P^* - P(I + QBS^{-1}B^*) + (I - LQ)^{-1}\check{B}\check{B}^*(I + QBS^{-1}B^*) = 0.$$

We again use the fact that $\check{B}\check{B}^*(I + QBS^{-1}B^*) = BS^{-1}B^*$ to obtain

$$A_PP(I + C^*R^{-1}CP)A_P^* - P - PQBS^{-1}B^* + (I - LQ)^{-1}BS^{-1}B^* = 0. \tag{10.20}$$

Using that $P = (I - LQ)^{-1}L$ we see that the sum of the two last terms of the left-hand side of (10.20) equals $BS^{-1}B^*$. This proves that P is a solution of the equivalent version (10.7) of the FARE. ∎

NONZERO-SUM STOCHASTIC DIFFERENTIAL GAMES WITH DISCONTINUOUS FEEDBACK*

PAOLA MANNUCCI†

Abstract. The existence of a Nash equilibrium feedback is established for a two-player nonzero-sum stochastic differential game with discontinuous feedback. This is obtained by studying a parabolic system strongly coupled by discontinuous terms.

Key words. nonzero-sum stochastic games, Nash point, strongly coupled parabolic systems, discontinuous feedbacks

AMS subject classifications. 35K50, 49K30, 49N35, 91A10, 91A15

DOI. 10.1137/S0363012903423715

1. Introduction. The aim of this paper is to study the existence of Nash equilibrium points for a two-player nonzero-sum stochastic differential game. The game is governed by a stochastic differential equation with two controls and two payoffs.

This problem can be found, for instance, in Friedman [7] and in a series of papers by Bensoussan and Frehse [2], [3], [4]. All these papers make the assumption that feedback is continuous.

We are interested in studying the problem assuming that the controls take values in compact sets. In this case one cannot expect a Nash equilibrium among continuous feedback, and the Hamiltonian functions associated with the game are nonsmooth.

We consider a simple multidimensional model problem taking two players, affine dynamics, affine payoff functions, and compact control sets.

The loss of continuity of the feedback, due to the hard constraints, leads us to consider a parabolic system strongly coupled by discontinuous terms. In fact, from the usual necessary condition satisfied by the value of the Nash equilibrium feedback in terms of the Hamilton–Jacobi theory, we reduce ourselves to studying the existence of a sufficiently regular solution to a system of nonlinear parabolic equations which contains the Heaviside graph. By this regularity result, we are able to construct Nash equilibrium feedback whose optimality is proved by using the verification approach in the sense of [2], [3], [4].

The motivation for studying games in compact control sets comes from standard nonlinear control theory; this seems a natural assumption in many applications. In particular, Nash equilibria for nonzero-sum deterministic differential games were recently studied by Olsder [12] and Cardaliaguet and Plaskacz [5].

2. Statement of the problem. Let Ω be a bounded smooth domain in $\mathbf{R}^N$. Let X be a process which satisfies the following stochastic differential equation

$$dX(s) = f(s, X(s), u_1(s, X(s)), u_2(s, X(s)))ds + \sigma(s, X(s))dw, \tag{2.1}$$

$$X(t) = x, \tag{2.2}$$

$$s \in [t, T],\ x \in \Omega \subset \mathbf{R}^N.$$

For each s, $X(s)$ represents the state evolution of a system controlled by two players. The ith player acts by means of a feedback control function $u_i : (t,T) \times \mathbf{R}^N \to U_i \subset \mathbf{R}^{k_i}$, where $i = 1, 2$.

Let $\mathcal{U}_i :\equiv \{u_i$ Borel-measurable applications $(t,T)\times\mathbf{R}^N \to U_i \subset \mathbf{R}^{k_i}\}$, $i = 1, 2$, be the set of the control functions u_i with values $u_i(s, X)$ in U_i. The term $\sigma(s, X(s))dw$ represents the "noise," where w is an N-dimensional standard Brownian motion and σ is an $N \times N$ matrix. We assume that σ does not depend on the control variables u_1, u_2 and that σ and σ^{-1} are bounded and Lipschitz on X. The function $f(s, X, u_1, u_2)$ is called the dynamic of the game (2.1).

We refer to [7] for the definitions about stochastic processes, stochastic differential equations and functional spaces.

A control function $u_i \in \mathcal{U}_i$ will be called *admissible* if it is adapted to the filtration defined on the probability space.

It is possible to prove, using Girsanov's theorem, that, under convenient assumptions on f, for all $(u_1, u_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ admissible controls, there exists a unique weak solution to the problem (2.1), (2.2) (see, for example, [4], [9], [6, Chapter 4]).

For any choice of admissible controls u_1, u_2 we have the following *payoff* functions:

$$J_i(t,x,u_1,u_2) = E_{tx}\left\{ \int_t^\tau l_i(s, X(s), u_1(s, X(s)), u_2(s, X(s)))ds + g_i(T, X(T)) \right\}, \quad i = 1, 2, \tag{2.3}$$

where $\tau \equiv T \wedge \inf\{s \geq t, X(s) \notin \Omega\}$, E_{tx} is the expectation under the probability P_{tx}, l_i and g_i are prescribed functions (the assumptions will be specified later), and $X = X(s)$ is the unique weak solution of (2.1)–(2.2) corresponding to $(u_1, u_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ admissible controls.

Each player wants to maximize his own payoff.

DEFINITION 2.1. *A pair of admissible controls $(\overline{u}_1, \overline{u}_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ is called the* Nash equilibrium point *of the differential game* (2.1)–(2.2)*, with payoff* (2.3)*, if*

$$J_1(t,x,\overline{u}_1,\overline{u}_2) \geq J_1(t,x,u_1,\overline{u}_2), \tag{2.4}$$

$$J_2(t,x,\overline{u}_1,\overline{u}_2) \geq J_2(t,x,\overline{u}_1,u_2), \tag{2.5}$$

for all $(t,x) \in (0,T) \times \Omega$ and for all $(u_1, u_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ admissible controls.

The functions

$$V_1(t,x) :\equiv J_1(t,x,\overline{u}_1,\overline{u}_2), \quad V_2(t,x) :\equiv J_2(t,x,\overline{u}_1,\overline{u}_2) \tag{2.6}$$

are a *value* of the Nash equilibrium point $(\overline{u}_1, \overline{u}_2)$.

We define the pre-Hamiltonians $H_i(t,x,p,u_1,u_2) : (0,T)\times\mathbf{R}^N\times\mathbf{R}^N\times U_1\times U_2 \to \mathbf{R}$, $i = 1, 2$:

$$\begin{aligned} H_1(t,x,p,u_1(t,x),u_2(t,x)) :\equiv\ & p \cdot f(t,x,u_1(t,x),u_2(t,x)) \\ & + l_1(t,x,u_1(t,x),u_2(t,x)), \\ H_2(t,x,p,u_1(t,x),u_2(t,x)) :\equiv\ & p \cdot f(t,x,u_1(t,x),u_2(t,x)) \\ & + l_2(t,x,u_1(t,x),u_2(t,x)). \end{aligned} \tag{2.7}$$

We set

$$a = \frac{1}{2}\sigma\sigma^*$$

(σ^* is the transpose of σ) to be the matrix with elements $a_{h,k}$, $h, k = 1, \ldots, N$.

If the value functions $V_1,\ V_2 \in C^{1,2}$, we can apply Itô's formula; changing the time variable $(T-t \to t)$, we get that $V_1,\ V_2$ solve, in $\Omega_T :\equiv (0,T)\times\Omega$, the following nonlinear parabolic system coupled by the Nash equilibrium problem:

$$\begin{aligned}(2.8)\qquad &\frac{\partial V_1(t,x)}{\partial t} - \sum_{h,k=1}^{N} a_{hk}(t,x)\frac{\partial^2 V_1(t,x)}{\partial x_h \partial x_k}\\ &= \max_{\{u_1\in U_1\}} H_1(t,x,\nabla_x V_1(t,x), u_1(t,x), \overline{u}_2(t,x))\\ &= H_1(t,x,\nabla_x V_1(t,x), \overline{u}_1(t,x), \overline{u}_2(t,x)),\end{aligned}$$

$$\begin{aligned}(2.9)\qquad &\frac{\partial V_2(t,x)}{\partial t} - \sum_{h,k=1}^{N} a_{hk}(t,x)\frac{\partial^2 V_2(t,x)}{\partial x_h \partial x_k}\\ &= \max_{\{u_2\in U_2\}} H_2(t,x,\nabla_x V_2(t,x), \overline{u}_1(t,x), u_2(t,x))\\ &= H_2(t,x,\nabla_x V_2(t,x), \overline{u}_1(t,x), \overline{u}_2(t,x)),\end{aligned}$$

$$(2.10)\qquad \overline{u}_1(t,x) \in \operatorname{argmax}_{\{u_1\in U_1\}} H_1(t,x,\nabla_x V_1(t,x), u_1(t,x), \overline{u}_2(t,x)),$$

$$(2.11)\qquad \overline{u}_2(t,x) \in \operatorname{argmax}_{\{u_2\in U_2\}} H_2(t,x,\nabla_x V_2(t,x), \overline{u}_1(t,x), u_2(t,x)),$$

$$(2.12)\qquad V_1 = g_1(t,x),\ V_2 = g_2(t,x) \quad \text{on } \partial_p\Omega_T,$$

where $\partial_p\Omega_T :\equiv \big((0,T)\times\partial\Omega\big) \cup \big(\{t=0\}\times\Omega\big)$. (Here and in the following we write, for the sake of brevity, $\operatorname{argmax}_{u_i\in U_i} H_i$, which means $\operatorname{argmax}_{u_i(t,x)\in U_i} H_i$).

The functions

$$\begin{aligned}&H_1(t,x,\nabla_x V_1(t,x), \overline{u}_1(t,x), \overline{u}_2(t,x))\\ &\quad = \max_{\{u_1\in U_1\}} H_1(t,x,\nabla_x V_1(t,x), u_1(t,x), \overline{u}_2(t,x)),\\ &H_2(t,x,\nabla_x V_1(t,x), \overline{u}_1(t,x), \overline{u}_2(t,x))\\ &\quad = \max_{\{u_2\in U_2\}} H_2(t,x,\nabla_x V_2(t,x), \overline{u}_1(t,x), u_2(t,x))\end{aligned}$$

are called the Hamiltonian functions associated with the game (2.1)–(2.3).

We want to outline here the classical procedure used in Friedman's book [7] to prove the existence of a Nash equilibrium point $\overline{u}_1,\ \overline{u}_2$.

1. Suppose that, for any fixed $p\in\mathbf{R}^N$, there exist $u_1^*,\ u_2^*$ such that

$$\begin{aligned}&u_1^*(t,x,p) \in \operatorname{argmax}_{\{u_1\in U_1\}} H_1(t,x,p,u_1(t,x),u_2^*(t,x)),\\ &u_2^*(t,x,p) \in \operatorname{argmax}_{\{u_2\in U_2\}} H_2(t,x,p,u_1^*(t,x),u_2(t,x))\\ &\text{are measurable in } (t,x)\in\Omega_T \text{ and continuous in } p.\end{aligned}\qquad (2.13)$$

2. Solve the parabolic system

$$\begin{aligned}(2.14)\qquad &\frac{\partial V_1(t,x)}{\partial t} - \sum_{h,k=1}^{N} a_{hk}(t,x)\frac{\partial^2 V_1(t,x)}{\partial x_h \partial x_k}\\ &= H_1(t,x,\nabla_x V_1, u_1^*(t,x,\nabla_x V_1), u_2^*(t,x,\nabla_x V_2)),\end{aligned}$$

$$\begin{aligned}&\frac{\partial V_2(t,x)}{\partial t} - \sum_{h,k=1}^{N} a_{hk}(t,x)\frac{\partial^2 V_2(t,x)}{\partial x_h \partial x_k}\\ &= H_2(t,x,\nabla_x V_2, u_1^*(t,x,\nabla_x V_1), u_2^*(t,x,\nabla_x V_2)),\\ &V_1 = g_1(t,x),\ V_2 = g_2(t,x) \quad \text{on } \partial_p\Omega_T.\end{aligned}$$

3. Prove that the pair of functions $(\overline{u}_1, \overline{u}_2)$ with values

$$\overline{u}_1(t,x) :\equiv u_1^*(t,x,\nabla_x V_1(t,x)),$$

$$\overline{u}_2(t,x) :\equiv u_2^*(t,x,\nabla_x V_2(t,x))$$

is a Nash equilibrium point (see Definition 2.1).

Therefore to obtain Nash equilibrium points for the associated stochastic differential game, we look for a "sufficiently regular" solution of system (2.14).

A similar procedure is used, in the elliptic case, by Bensoussan and J. Frehse [2], [3], [4] to study systems of Bellman equations.

We want to emphasize that the results of Friedman and Bensoussan and J. Frehse on the existence of classical solutions and of Nash equilibrium points are obtained under the assumption that there exist some feedback

$$u_1^* \in \operatorname{argmax}_{\{u_1 \in U_1\}} H_1(t,x,p,u_1,u_2^*), \qquad u_2^* \in \operatorname{argmax}_{\{u_2 \in U_2\}} H_2(t,x,p,u_1^*,u_2)$$

that are continuous in p (see, for example, assumption (D) [7, section 17, p. 497]). If we assume that the sets U_i, $i = 1, 2$, are compact, the assumption on the continuity of the feedback can be too restrictive.

Weaker assumptions on the regularity of the feedback can be found in [8] and [9].

In this paper we consider a model problem with U_1, U_2 compact sets in $\mathbf{R}$, affine dynamics of the game, and affine payoff.

Let us list the assumptions:

$$U_1 = U_2 = [0,1], \tag{2.15}$$

$$\begin{aligned} &f(x,u_1(t,x),u_2(t,x)) :\ \Omega \times U_1 \times U_2 \to \mathbf{R}^N, \\ &f(x,u_1(t,x),u_2(t,x)) = f_1(x)u_1(t,x) + f_2(x)u_2(t,x), \\ &f_i(x) :\ \Omega \to \mathbf{R}^N, f_i(x) \in C^1(\overline{\Omega}),\ i = 1,2, \end{aligned} \tag{2.16}$$

$$\begin{aligned} &l_i(x,u_1(t,x),u_2(t,x)) :\ \Omega \times U_1 \times U_2 \to \mathbf{R}, \\ &l_i(x,u_1(t,x),u_2(t,x)) = l_i(x)u_i(t,x), \quad i = 1,2, \\ &l_i(x) :\ \Omega \to \mathbf{R}^N,\ l_i(x) \in C^1(\overline{\Omega}), \quad i = 1,2, \end{aligned} \tag{2.17}$$

$$g_i(t,x) \in H^{1+\alpha}(\overline{\Omega}_T),\ \alpha \in (0,1), \quad i = 1,2, \tag{2.18}$$

$$a_{hk}(t,x) \in C^2(\overline{\Omega}_T),$$

$$\nu|\xi|^2 \le \sum_{h,k=1}^{N} a_{hk}(t,x)\xi_h\xi_k \le \mu|\xi|^2, \quad \nu,\mu > 0, \tag{2.19}$$

$$\text{for all } (t,x) \in \Omega_T \text{ and for all } \xi \in \mathbf{R}^N.$$

Taking into account the affine structure of f and l in (2.16)–(2.17), the functions H_1 and H_2 in (2.7) become

$$\begin{aligned} &H_1(x,p,u_1(t,x),u_2(t,x)) = \big(p \cdot f_1(x) + l_1(x)\big)u_1(t,x) + p \cdot f_2(x)u_2(t,x), \\ &H_2(x,p,u_1(t,x),u_2(t,x)) = \big(p \cdot f_2(x) + l_2(x)\big)u_2(t,x) + p \cdot f_1(x)u_1(t,x). \end{aligned} \tag{2.20}$$

From (2.15) and (2.20), for any fixed p, we have

$$\begin{aligned}
&\overline{u}_1(t,x) \in \operatorname{argmax}_{\{u_1\in U_1\}} H_1(x,p,u_1(t,x),\overline{u}_2(t,x))\\
&= \operatorname{argmax}_{\{u_1(t,x)\in[0,1]\}} \big(p\cdot f_1(x)+l_1(x)\big)u_1(t,x) + p\cdot f_2(x)\overline{u}_2(t,x)\\
&= \operatorname{Heav}\big(p\cdot f_1(x)+l_1(x)\big), \qquad (2.21)
\end{aligned}$$

where $\operatorname{Heav}(\eta)$ is the Heaviside graph defined as $\operatorname{Heav}(\eta)=1$ if $\eta>0$, $\operatorname{Heav}(\eta)=0$ if $\eta<0$, and $\operatorname{Heav}(0)=[0,1]$.

Analogously

$$\overline{u}_2(t,x) \in \operatorname{Heav}\big(p\cdot f_2(x)+l_2(x)\big). \qquad (2.22)$$

From (2.20), (2.21), (2.22), the Hamiltonian functions assume the form

$$\begin{aligned}
H_1(x,p,\overline{u}_1(t,x),\overline{u}_2(t,x)) &\equiv \max_{\{u_1\in U_1\}} H_1(x,p,u_1(t,x),\overline{u}_2(t,x))\\
&= \big(p\cdot f_1(x)+l_1(x)\big)_+ + p\cdot f_2(x)\overline{u}_2(t,x), \qquad (2.23)\\
H_2(x,p,\overline{u}_1,\overline{u}_2) &\equiv \max_{\{u_2\in U_2\}} H_2(x,p,\overline{u}_1(t,x),u_2(t,x))\\
&= \big(p\cdot f_2(x)+l_2(x)\big)_+ + p\cdot f_1(x)\overline{u}_1(t,x), \qquad (2.24)
\end{aligned}$$

where we denoted by $(h)_+$ the positive part of the function h.

Taking, for any fixed p,

$$u_1^*(t,x,p) \in \operatorname{Heav}\big(p\cdot f_1(x)+l_1(x)\big), \qquad (2.25)$$

$$u_2^*(t,x,p) \in \operatorname{Heav}\big(p\cdot f_2(x)+l_2(x)\big), \qquad (2.26)$$

we have that u_1^*, u_2^* do not satisfy (2.13) because they are not continuous in p. Hence, in this case, we cannot use the results of [7].

From (2.25), (2.26), the parabolic system (2.8), (2.9) becomes

$$\begin{aligned}
\frac{\partial V_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_1}{\partial x_h \partial x_k} \in{}& \Big(\nabla_x V_1\cdot f_1(x)+l_1(x)\Big)\operatorname{Heav}(\nabla_x V_1\cdot f_1(x)+l_1(x))\\
&+ \nabla_x V_1\cdot f_2(x)\operatorname{Heav}(\nabla_x V_2\cdot f_2(x)+l_2(x)) \text{ in } \Omega_T, \qquad (2.27)
\end{aligned}$$

$$\begin{aligned}
\frac{\partial V_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_2}{\partial x_h \partial x_k} \in{}& \Big(\nabla_x V_2\cdot f_2(x)+l_2(x)\Big)\operatorname{Heav}(\nabla_x V_2\cdot f_2(x)+l_2(x))\\
&+ \nabla_x V_2\cdot f_1(x)\operatorname{Heav}(\nabla_x V_1\cdot f_1(x)+l_1(x)) \text{ in } \Omega_T, \qquad (2.28)
\end{aligned}$$

$$V_1(t,x)=g_1(t,x),\ V_2(t,x)=g_2(t,x) \quad \text{on } \partial_p\Omega_T. \qquad (2.29)$$

This is a uniformly parabolic system strongly coupled by the Heaviside graph containing the first order derivatives of the unknown functions.

Equations (2.27) and (2.28) are to be interpreted in the following way:

$$\frac{\partial V_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_1}{\partial x_h \partial x_k} = \Big(\nabla_x V_1\cdot f_1+l_1\Big)h_1(t,x) + \nabla_x V_1\cdot f_2 h_2(t,x),$$

$$\frac{\partial V_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_2}{\partial x_h \partial x_k} = \Big(\nabla_x V_2\cdot f_2+l_2\Big)h_2(t,x) + \nabla_x V_2\cdot f_1 h_1(t,x),$$

$$h_1(t,x)\in\operatorname{Heav}(\nabla_x V_1\cdot f_1(x)+l_1(x)),\ h_2(t,x)\in\operatorname{Heav}(\nabla_x V_2\cdot f_2(x)+l_2(x)).$$

Following the previous scheme, first we investigate the existence of a solution V_1, V_2 of (2.27)–(2.29). Next, if we find sufficient regularity, it will be possible to prove the existence of a Nash equilibrium point.

In section 3 we provide an existence result for a solution V_1, V_2 in $H^{1+\alpha}(\overline{\Omega}_T) \cap W_q^{1,2}(\Omega_T)$ of the system (2.27)–(2.29), and in section 4 we prove the existence of a Nash equilibrium point.

3. Existence of a solution to the parabolic system. We give the following definition.

DEFINITION 3.1. (V_1, V_2) *is a* strong *solution of the system* (2.27)–(2.29) *if*

(a) $V_1(t,x),\ V_2(t,x) \in H^{1+\alpha}(\overline{\Omega}_T) \cap W_q^{1,2}(\Omega_T)$ *for some* $\alpha \in (0,1),\ q > N+2$*;*

(b) *equations* (2.27)–(2.28) *hold almost everywhere and* (2.29) *holds.*

THEOREM 3.2. *Under assumptions* (2.15)–(2.19)*, taking* $\mathrm{Heav}(\eta) = 1$ *if* $\eta > 0$*,* $\mathrm{Heav}(\eta) = 0$ *if* $\eta < 0$*, and* $\mathrm{Heav}(0) = [0,1]$*, there exists at least a strong solution* $(V_1,\ V_2)$ *of the parabolic system* (2.27)–(2.29)*.*

Proof. Let us consider the approximating problems obtained by replacing the Heaviside graph $\mathrm{Heav}(\eta)$ with smooth functions H_n:

$$
\begin{aligned}
&H_n(\eta) \in C^\infty(\mathbf{R}),\ H_n(\eta) \in L_\infty(\mathbf{R}),\\
&H_n(\eta) = 0 \text{ if } \eta \le 0, \quad H_n(\eta) = 1 \text{ if } \eta \ge \frac{1}{n},\\
&H_n' \ge 0,\\
&H_n(\eta) \to \mathrm{Heav}(\eta) \text{ in } L_p(K),\ p > 1,\ K \subset \mathbf{R} \text{ is any compact of } \mathbf{R},\\
&H_n(\eta) \to \mathrm{Heav}(\eta) \text{ in } C^0 \text{ outside a neighbourhood of } \eta = 0.
\end{aligned}
\tag{3.1}
$$

We denote by V_{1n}, V_{2n} the solution of the problem

$$
\begin{aligned}
&\frac{\partial V_{1n}}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 V_{1n}}{\partial x_h \partial x_k} = \Big(\nabla_x V_{1n} \cdot f_1 + l_1\Big) H_n(\nabla_x V_{1n} \cdot f_1 + l_1)\\
&+ \nabla_x V_{1n} \cdot f_2 H_n(\nabla_x V_{2n} \cdot f_2 + l_2) \text{ in } \Omega_T,
\end{aligned}
\tag{3.2}
$$

$$
\begin{aligned}
&\frac{\partial V_{2n}}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 V_{2n}}{\partial x_h \partial x_k} = \Big(\nabla_x V_{2n} \cdot f_2 + l_2\Big) H_n(\nabla_x V_{2n} \cdot f_2 + l_2)\\
&+ \nabla_x V_{2n} \cdot f_1 H_n(\nabla_x V_{1n} \cdot f_1 + l_1) \text{ in } \Omega_T,
\end{aligned}
\tag{3.3}
$$

$$
V_{1n} = g_1,\ V_{2n} = g_2 \ \text{ in } \partial_p \Omega_T. \tag{3.4}
$$

From [11, Theorem 7.1, p. 596] on quasi-linear parabolic systems with smooth coefficients, there exists an unique solution of problem (3.2)–(3.4), $V_{1n}(t,x)$, $V_{2n}(t,x) \in H^{2+\alpha}(\Omega_T)$.

At this point, regarding the terms $H_n(\nabla_x V_{1n} \cdot f_1 + l_1) + f_2 H_n(\nabla_x V_{2n} \cdot f_2 + l_2)$ and $H_n(\nabla_x V_{2n} \cdot f_2 + l_2) + f_1 H_n(\nabla_x V_{1n} \cdot f_1 + l_1)$ in (3.2)–(3.3) as bounded uniformly on n, from [11, Theorem 9.1, p. 341], we find an uniform estimate in $W_q^{1,2}$:

$$
\|V_{1n}\|_{q,\Omega_T}^{(2)} + \|V_{2n}\|_{q,\Omega_T}^{(2)} \le C(\|H_n\|_{q,\Omega_T}, \|g_1\|_{q,\partial_p\Omega_T}^{(2-1/q)}, \|g_2\|_{q,\partial_p\Omega_T}^{(2-1/q)}) \le C, \tag{3.5}
$$

where C is independent of n and $q > 1$.

By means of an embedding theorem (see, for example, [11, Chapter 2, Lemma 3.3]), taking $q > N+2$, we obtain

$$
|V_{1n}|_{\Omega_T}^{(1+\alpha)} + |V_{2n}|_{\Omega_T}^{(1+\alpha)} \le C, \qquad \alpha = 1 - \frac{N+2}{q}, \tag{3.6}
$$

where C is independent of n.

We can now extract two subsequences, which we denote again by V_{1n}, V_{2n} such that

$$\begin{aligned} &V_{in} \to V_i \text{ in } C^0(\Omega_T), \quad i=1,2, \\ &\frac{\partial V_{in}}{\partial x_h} \to \frac{\partial V_i}{\partial x_h} \text{ in } C^0(\Omega_T), \quad i=1,2,\ h=1,\dots N. \end{aligned} \tag{3.7}$$

From the weak precompactness of the unit ball of $W^{2,1}_q$, we have

$$\begin{aligned} &\frac{\partial V_{in}}{\partial t} \rightharpoonup \frac{\partial V_i}{\partial t} \text{ weakly in } L_2(\Omega_T), \quad i=1,2, \\ &\frac{\partial^2 V_{in}}{\partial x_h \partial x_k} \rightharpoonup \frac{\partial^2 V_i}{\partial x_h \partial x_k} \text{ weakly in } L_2(\Omega_T), \quad i=1,2,\ h,k=1,\dots N. \end{aligned} \tag{3.8}$$

From (3.7), (3.8)

$$V_1(t,x),\ V_2(t,x) \in H^{1+\alpha}(\Omega_T) \cap W^{1,2}_q(\Omega_T), \text{ with } \alpha = 1 - \frac{N+2}{q}. \tag{3.9}$$

Now we have to prove that V_1, V_2 solve (2.27)–(2.28) almost everywhere in Ω_T.

From assumptions (3.1) and (3.8), the two sequences $H_n(\nabla_x V_{1n} \cdot f_1 + l_1)$, $H_n(\nabla_x V_{2n} \cdot f_2 + l_2)$ are uniformly bounded in $L_2(\Omega_T)$, and hence we can extract two subsequences such that

$$\begin{aligned} &H_n(\nabla_x V_{1n} \cdot f_1 + l_1) \rightharpoonup h_1(t,x) \text{ weakly in } L_2(\Omega_T), \\ &H_n(\nabla_x V_{2n} \cdot f_2 + l_2) \rightharpoonup h_2(t,x) \text{ weakly in } L_2(\Omega_T). \end{aligned} \tag{3.10}$$

We now show that $h_i(t,x) \in \mathrm{Heav}(\nabla_x V_i \cdot f_i + l_i)$ almost everywhere $i=1,2$. To do this let us consider the following sets:

$$\mathcal{P}_i :\equiv \{(t,x) \in \Omega_T : \nabla_x V_i(t,x) \cdot f_i(x) + l_i(x) > 0\},$$

$$\mathcal{N}_i :\equiv \{(t,x) \in \Omega_T : \nabla_x V_i(t,x) \cdot f_i(x) + l_i(x) < 0\},$$

$$\mathcal{Z}_i :\equiv \{(t,x) \in \Omega_T : \nabla_x V_i(t,x) \cdot f_i(x) + l_i(x) = 0\},$$

$$i = 1,2.$$

From (3.7), we have that, for a sufficiently large n, $\nabla_x V_{in}(t,x) \cdot f_i(x) + l_i(x) > 0$ for all $(t,x) \in \mathcal{P}_i$. Hence, from (3.1), we obtain that

$$H_n(\nabla_x V_{in}(t,x) \cdot f_i(x) + l_i(x)) \to 1 = \mathrm{Heav}(\nabla_x V_i(t,x) \cdot f_i(x) + l_i(x))$$

for all $(t,x) \in \mathcal{P}_i$, $i=1,2$.

Analogously, in $\mathcal{N}_i$, for a sufficiently large n, $\nabla_x V_{in}(x,t) \cdot f_i(x) + l_i(x) < 0$, and hence

$$H_n(\nabla_x V_{in}(x,t) \cdot f_i(x) + l_i(x)) \equiv 0 = \mathrm{Heav}(\nabla_x V_i(x,t) \cdot f_i(x) + l_i(x))$$

for all $(t,x) \in \mathcal{N}_i$, $i=1,2$.

In $\mathcal{Z}_i$, from the assumptions on H_n (see (3.1)), we have that $0 \le h_i \le 1$ almost everywhere, and hence

$$h_1(t,x) \in \mathrm{Heav}(\nabla_x V_1(t,x)\cdot f_1(x) + l_1(x)) \text{ almost everywhere in } \Omega_T, \tag{3.11}$$

$$h_2(t,x) \in \mathrm{Heav}(\nabla_x V_2(t,x)\cdot f_2(x) + l_2(x)) \text{ almost everywhere in } \Omega_T. \tag{3.12}$$

At this point, from (3.7), (3.8), (3.10), (3.11), (3.12), we obtain that V_1, V_2 satisfy (2.27)–(2.28) almost everywhere in Ω_T and from the regularity of the functions V_1, V_2, we have that $V_1(t,x) = g_1(t,x)$, $V_2(t,x) = g_2(t,x)$ for all $(t,x) \in \partial_p\Omega_T$. □

REMARK 3.1. *If we choose $W(\eta) \in \mathrm{Heav}(\eta)$, we are not able to solve the problem*

$$\begin{aligned} \frac{\partial V_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_1}{\partial x_h \partial x_k} &= \big(\nabla_x V_1\cdot f_1 + l_1\big)W(\nabla_x V_1\cdot f_1 + l_1) \\ &\quad + \nabla_x V_1\cdot f_2\, W(\nabla_x V_2\cdot f_2 + l_2), \end{aligned} \tag{3.13}$$

$$\begin{aligned} \frac{\partial V_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 V_2}{\partial x_h \partial x_k} &= \big(\nabla_x V_2\cdot f_2 + l_2\big)W(\nabla_x V_2\cdot f_2 + l_2) \\ &\quad + \nabla_x V_2\cdot f_1\, W(\nabla_x V_1\cdot f_1 + l_1), \end{aligned} \tag{3.14}$$

because we cannot exclude that $\mathrm{meas}\{(t,x)\in\Omega_T : \nabla_x V_i\cdot f_i(x) + l_i(x) = 0\} > 0$, $i = 1,2$. *Hence we cannot prove that*

$$H_n(\nabla_x V_{in}\cdot f_i + l_i) \rightharpoonup W(\nabla_x V_i\cdot f_i + l_i), \quad i = 1,2,$$

but only that

$$H_n(\nabla_x V_{in}\cdot f_i + l_i) \rightharpoonup h_i \in \mathrm{Heav}(\nabla_x V_i\cdot f_i + l_i), \quad i = 1,2.$$

4. Existence of a Nash equilibrium point. We now prove the following.

THEOREM 4.1. *Suppose that the assumptions of Theorem* 3.2 *hold. Let* $(V_1,\ V_2)$ *be a strong solution of the parabolic system* (2.27)–(2.29); *then any admissible control* $(\overline{u}_1, \overline{u}_2)$ *such that*

$$\overline{u}_1(t,x) \in \mathrm{Heav}(\nabla_x V_1(t,x)\cdot f_1(x) + l_1(x)), \tag{4.1}$$

$$\overline{u}_2(t,x) \in \mathrm{Heav}(\nabla_x V_2(t,x)\cdot f_2(x) + l_2(x)) \tag{4.2}$$

is a Nash equilibrium point for the stochastic differential game (2.1)–(2.2) *with payoff* (2.3).

Proof. The existence of a strong solution $(V_1,\ V_2)$ of the parabolic system (2.27)–(2.29) is stated by Theorem 3.2.

To prove that $\overline{u}_i(t,x) \in \mathrm{Heav}(\nabla_x V_i(t,x)\cdot f_i(x) + l_i(x))$, $i = 1,2$, are the values of a Nash equilibrium point, as in Definition 2.1, we have to show that

$$\begin{aligned} &J_1(t,x,\overline{u}_1,\overline{u}_2) \ge J_1(t,x,u_1,\overline{u}_2), \\ &J_2(t,x,\overline{u}_1,\overline{u}_2) \ge J_2(t,x,\overline{u}_1,u_2) \end{aligned} \tag{4.3}$$

for all $(u_1,u_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ admissible controls.

Let us denote

$$\begin{aligned} &v_1(t,x) :\equiv J_1(t,x,\overline{u}_1,\overline{u}_2), \\ &v_2(t,x) :\equiv J_2(t,x,\overline{u}_1,\overline{u}_2). \end{aligned} \tag{4.4}$$

Using a generalization of Itô's formula applied to functions in $W_q^{1,2}$ (see, for example, [1, Theorem 4.1, p. 126]), we have that the couple (v_1, v_2) solves the following parabolic system (here and in the following we omit, for the sake of brevity, the dependence on the variables (t, x)):

$$\frac{\partial v_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 v_1}{\partial x_h \partial x_k} = H_1(x, t, \nabla_x v_1, \overline{u}_1, \overline{u}_2) \tag{4.5}$$
$$= (\nabla_x v_1 f_1 + l_1)\overline{u}_1 + \nabla_x v_1 f_2 \overline{u}_2 \ \text{ in } \ \Omega_T,$$

$$\frac{\partial v_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 v_2}{\partial x_h \partial x_k} = H_2(x, t, \nabla_x v_2, \overline{u}_1, \overline{u}_2) \tag{4.6}$$
$$= (\nabla_x v_2 \cdot f_2 + l_2)\overline{u}_2 + \nabla_x v_2 f_1 \overline{u}_1 \ \text{ in } \ \Omega_T,$$

$$v_1 = g_1(t, x), \ v_2 = g_2(t, x) \ \text{ on } \ \partial_p \Omega_T. \tag{4.7}$$

From (4.1), (4.2), we have

$$\frac{\partial v_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 v_1}{\partial x_h \partial x_k} \in (\nabla_x v_1 \cdot f_1 + l_1)\text{Heav}(\nabla_x V_1 \cdot f_1 + l_1)$$
$$+ \nabla_x v_1 \cdot f_2 \text{Heav}(\nabla_x V_2 \cdot f_2 + l_2) \ \text{ in } \ \Omega_T, \tag{4.8}$$
$$\frac{\partial v_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 v_2}{\partial x_h \partial x_k} \in (\nabla_x v_2 \cdot f_2 + l_2)\text{Heav}(\nabla_x V_2 \cdot f_2 + l_2)$$
$$+ \nabla_x v_2 \cdot f_1 \text{Heav}(\nabla_x V_1 \cdot f_1 + l_1) \ \text{ in } \ \Omega_T,$$

$$v_1 = g_1(t, x), \ v_2 = g_2(t, x) \ \text{ on } \ \partial_p \Omega_T. \tag{4.9}$$

Let us now fix $(u_1, u_2) \in \mathcal{U}_1 \times \mathcal{U}_2$ admissible controls and denote

$$w_1(t, x) :\equiv J_1(t, x, u_1, \overline{u}_2), \tag{4.10}$$
$$w_2(t, x) :\equiv J_2(t, x, \overline{u}_1, u_2).$$

The couple (w_1, w_2) solves the following parabolic system:

$$\frac{\partial w_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 w_1}{\partial x_h \partial x_k} = H_1(x, t, \nabla_x w_1, u_1, \overline{u}_2) \tag{4.11}$$
$$= (\nabla_x w_1 f_1 + l_1)u_1 + \nabla_x w_1 f_2 \overline{u}_2 \ \text{ in } \ \Omega_T,$$

$$\frac{\partial w_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk} \frac{\partial^2 w_2}{\partial x_h \partial x_k} = H_2(x, t, \nabla_x w_2, \overline{u}_1, u_2) \tag{4.12}$$
$$= (\nabla_x w_2 \cdot f_2 + l_2)u_2 + \nabla_x w_2 f_1 \overline{u}_1 \ \text{ in } \ \Omega_T,$$

$$w_1 = g_1(t, x), \ w_2 = g_2(t, x) \ \text{ on } \ \partial_p \Omega_T, \tag{4.13}$$
$$w_1, w_2 \in W_q^{1,2}(\Omega_T).$$

From the expressions (2.20) of H_1, H_2, taking into account (2.10), (2.11), we have that, for any p fixed,

$$(pf_1 + l_1)u_1(t, x) \le (pf_1 + l_1)\overline{u}_1(t, x), \tag{4.14}$$
$$(pf_2 + l_2)u_2(t, x) \le (pf_2 + l_2)\overline{u}_2(t, x).$$

Consider now the functions $z_1 :\equiv v_1 - w_1$, $z_2 :\equiv v_2 - w_2$. From systems (4.5)–(4.7) and (4.11)–(4.13) we have

$$\begin{aligned}
\frac{\partial z_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 z_1}{\partial x_h \partial x_k} &= (\nabla_x v_1 \cdot f_1 + l_1)\overline{u}_1 + \nabla_x v_1 \cdot f_2 \overline{u}_2 \\
&\quad - (\nabla_x w_1 \cdot f_1 + l_1)u_1 - \nabla_x w_1 \cdot f_2 \overline{u}_2 \quad \text{in } \Omega_T, \\
\frac{\partial z_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 z_2}{\partial x_h \partial x_k} &= (\nabla_x v_2 \cdot f_2 + l_2)\overline{u}_2 + \nabla_x v_2 \cdot f_1 \overline{u}_1 \\
&\quad - (\nabla_x w_2 \cdot f_2 + l_2)u_2 - \nabla_x w_2 \cdot f_1 \overline{u}_1 \quad \text{in } \Omega_T, \\
z_1 = z_2 &= 0 \quad \text{on } \partial_p \Omega_T.
\end{aligned} \tag{4.15}$$

Taking into account (4.14), we obtain

$$\begin{aligned}
\frac{\partial z_1}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 z_1}{\partial x_h \partial x_k} &\geq (\nabla_x v_1 \cdot f_1 + l_1)u_1 + \nabla_x v_1 \cdot f_2 \overline{u}_2 \\
&\quad - (\nabla_x w_1 \cdot f_1 + l_1)u_1 - \nabla_x w_1 \cdot f_2 \overline{u}_2 \\
&= \nabla_x z_1 \cdot \Big(f_1 u_1 + f_2 \overline{u}_2 \Big) \quad \text{in } \Omega_T,
\end{aligned} \tag{4.16}$$

$$\begin{aligned}
\frac{\partial z_2}{\partial t} - \sum_{h,k=1}^{N} a_{hk}\frac{\partial^2 z_2}{\partial x_h \partial x_k} &\geq (\nabla_x v_2 \cdot f_2 + l_2)u_2 + \nabla_x v_2 \cdot f_1 \overline{u}_1 \\
&\quad - (\nabla_x w_2 \cdot f_2 + l_2)u_2 - \nabla_x w_2 \cdot f_1 \overline{u}_1 \\
&= \nabla_x z_2 \cdot \Big(f_2 u_2 + f_1 \overline{u}_1 \Big) \quad \text{in } \Omega_T, \\
z_1 = z_2 &= 0 \quad \text{on } \partial_p \Omega_T.
\end{aligned} \tag{4.17}$$

Equations (4.16), (4.17) are no longer coupled and the terms $f_1 u_1 + f_2 \overline{u}_2$, $f_2 u_2 + f_1 \overline{u}_1$ are known and bounded. Hence we can apply an extension of the maximum principle to parabolic equations whose coefficients are in L^∞ (see, for example, [10, Chapter 7]), obtaining

$$z_1(t,x) \geq 0, \quad z_2(t,x) \geq 0 \quad \text{in } \Omega_T. \tag{4.18}$$

Taking into account (4.4) and (4.10), from (4.18) we obtain (4.3), i.e., the result. □

REMARK 4.1. *The results proved in section* 3 *and* 4 *hold true even if we take* $M > 2$ *players and if we take the functions* f *and* l *linear and dependent explicitly on* t*, i.e.,*

$$\begin{aligned}
f(t,x,u_1,u_2) &= f_1(t,x)u_1 + f_2(t,x)u_2 + f_3(t,x), \\
l_1(t,x,u_1,u_2) &= l_1(t,x)u_1 + h_1(t,x), \\
l_2(t,x,u_1,u_2) &= l_2(t,x)u_2 + h_2(t,x).
\end{aligned}$$

The only difference is the appearance in (2.27)–(2.28), *as source terms, of the functions* $f_3(t,x) + h_1(t,x)$ *and* $f_3(t,x) + h_2(t,x)$*, respectively.*

REMARK 4.2. *In* [12], *Olsder studied the Nash equilibria of the following nonzero-sum deterministic differential game with open-loop bang-bang controls:*

$$\dot{x} = (1-x)u_1 - xu_2,$$

with payoff

$$J_1 = \int_t^T (c_1 x - u_1)\, ds, \quad J_2 = \int_t^T (c_2(1-x) - u_2)\, ds,$$

and controls subject to

$$0 \le u_i(t) \le 1.$$

Because of the hard constraints, also in this case, the optimal controls contain Heaviside functions.

REMARK 4.3. *If we change the control sets taking* $U_1 = U_2 = [-1, 1]$, *as done in* [5] *in the deterministic case, the optimal feedback equilibria are*

$$\overline{u}_1 \in \operatorname{sign}\big(p \cdot f_1 + l_1\big),$$
$$\overline{u}_2 \in \operatorname{sign}\big(p \cdot f_2 + l_2\big),$$

where $\operatorname{sign}(\eta) = 1$ *if* $\eta > 0$, $\operatorname{sign}(\eta) = -1$ *if* $\eta < 0$, *and* $\operatorname{sign}(0) = [-1, 1]$.

The Hamiltonian functions take the form

$$H_1(x, p, \overline{u}_1, \overline{u}_2) = \big|p \cdot f_1(x) + l_1(x)\big| + p \cdot f_2(x)\overline{u}_2,$$
$$H_2(x, p, \overline{u}_1, \overline{u}_2) = \big|p \cdot f_2(x) + l_2(x)\big| + p \cdot f_1(x)\overline{u}_1,$$

and also in this case our method can be applied.

Acknowledgments. The author would like to thank Martino Bardi, who stated the problem, for his helpful comments and suggestions. The author thanks the referees for their useful remarks.

A SUFFICIENT CONDITION ON RIESZ BASIS WITH PARENTHESES OF NON–SELF-ADJOINT OPERATOR AND APPLICATION TO A SERIALLY CONNECTED STRING SYSTEM UNDER JOINT FEEDBACKS*

BAO-ZHU GUO† AND YU XIE‡

Abstract. This paper gives an abstract sufficient condition on Riesz basis with parentheses property for the generators of C_0-groups in Hilbert spaces whose eigenvalues are comprised of some finite unification of separable sets after taking the algebraic multiplicities into account. The condition is then applied to the closed-loop system of a serially connected string system under joint damping feedbacks to show that there is a family of generalized eigenfunctions that form a Riesz basis with parentheses in the state space. The spectrum-determined growth condition is concluded as a consequence.

1. Introduction.

The Riesz basis property of linear infinite-dimensional systems $\dot{x}(t) = Ax(t)$ in Hilbert spaces is usually studied in the context of stability. The property is also closely related to the moment method, a powerful method in the study of controllability of hyperbolic systems [1], [19], [25]. Being the basis of frequency analysis, Riesz basis generation is one of the fundamental properties for vibrating systems. The verification of Riesz basis generation usually solves another difficult problem, the so-called spectrum-determined growth condition. The Riesz basis property also offers insight into the solution under the expansion of nonharmonic Fourier series. A recent interesting result [10] says that when A generates a C_0-group and the one-dimensional control operator b is unbounded but admissible [23], then under conditions that the eigenvalues are simple and separable, system $\dot{x}(t) = Ax(t) + bu(t)$ is exactly controllable if and only if $\dot{x}(t) = Ax(t)$ is a Riesz spectral system [4].

Let us recall that a sequence $\{Y_i\}_{i=1}^{\infty}$ in H is called a basis if any element $Y \in H$ has a unique representation

$$Y = \sum_{i=1}^{\infty} \alpha_i Y_i \tag{1}$$

with respect to the norm of H. It is called a Riesz basis for H if

(a) $\overline{\text{span}}\{Y_i\} = H$ and

(b) there exist positive constants m and M such that for an arbitrary positive integer n and arbitrary scalars $\alpha_i, i = 1, 2, \ldots, n$, one has

$$m \sum_{i=1}^{n} \mid \alpha_i \mid^2 \leq \left\| \sum_{i=1}^{n} \alpha_i Y_i \right\|^2 \leq M \sum_{i=1}^{n} \mid \alpha_i \mid^2 .$$

Furthermore, a basis $\{Y_i\}_{i=1}^{\infty}$ up to normalization is called a *Riesz basis with parentheses* if (1) converges unconditionally in H only after putting some of its items in parentheses in a way that is independent of Y (see [20]). We refer the reader to [25] for more details on Riesz bases. The Riesz basis property was confirmed for Euler–Bernoulli equations in [8], [5] for one beam and in [6] for two connected beams by the methods of perturbation. General results by perturbation methods to general collocated systems can be found in [7]. The perturbation methods, however, are not applicable to string equations [18]. For the Riesz basis property of one string equations under boundary feedbacks, we refer to [21], [22] and the references therein. Two connected strings under joint feedbacks were discussed recently in [24], where a sufficient condition was developed with the help of the basis property of functions of exponentials in L^2 space under the basic condition that the eigenvalues are algebraically simple and separable.

In this article, we develop an abstract sufficient condition on the Riesz basis with parentheses property for generators of C_0-groups in Hilbert spaces. The distinct contributions of this paper are that (a) the functions of exponentials formulated by eigenvalues are not necessarily Riesz basis in $L^2(0, T)$ but are Riesz basis on their closed span in $L^2(0, T)$ for some $T > 0$; (b) the eigenvalues are allowed to be algebraically multiple; (c) the eigenvalues are comprised of some finite unification of separable sets after taking the algebraic multiplicities into account; (d) the result can be used to deal with the Riesz basis (with parentheses) property of N-connected string equations under joint linear feedback controls. The main tool used in this paper, which is different from Levin and Golovin's theorem [1] used in [24], is the notion of generalized divided difference (GDD) introduced very recently in [2] and [3].

The paper is organized as follows. In section 2, we give an abstract sufficient condition on the Riesz basis with parentheses property for generators of C_0-groups in Hilbert spaces. Section 3 is devoted to the application of a serially connected string equation under joint damping feedbacks. It is shown that the associated system operator generates a C_0-group, and its root subspace is complete in the state space. Moreover, there is a family of generalized eigenfunctions that forms a Riesz basis with parentheses in the state space. The spectrum-determined growth condition is concluded as a consequence.

2. A sufficient condition on the Riesz basis with parentheses. Assume that B is a discrete operator in a separable Hilbert space $\mathbf{H}$ (that is, there is a $\mu \in \sigma(B)$ such that $(\mu - B)^{-1}$ is compact in $\mathbf{H}$). Let us recall that a nonzero $Y \in \mathbf{H}$ is called a generalized eigenvector of B, corresponding to an eigenvalue μ, if there is a positive integer n such that $(\mu - B)^n Y = 0$. The number (denoted by $n_{a\mu}$) of all linearly independent generalized eigenvectors is called the algebraic multiplicity of μ. μ is said to be algebraically simple if $n_{a\mu} = 1$. It is well known in functional analysis that each eigenvalue of a discrete operator must have finite algebraic multiplicity. A nonzero $Y \in \mathbf{H}$ is called an eigenvector of B if $(\mu - B)Y = 0$. The number (denoted by $n_{g\mu}$) of all linearly independent eigenvectors is called the geometric multiplicity of μ. μ is said to be geometrically simple if $n_{g\mu} = 1$. Suppose that $\sigma(B) = \{\mu_n\}_{n\in\mathbb{Z}}$,

where (and henceforth) $\mathbb{Z}$ stands for some set of integers and each μ_n is of algebraic multiplicity m_n. Thus we have a set of complex exponentials associated with μ_n:

$$E_n(t) = \{e^{\mu_n t}, te^{\mu_n t}, \dots, t^{m_n-1}e^{\mu_n t}\}.$$

The Riesz basis property of $\{E_n(t)\}$ in $L^2(0,T)$ has been studied extensively by former Soviet mathematicians (Levin, Pavlov, Nikolskiĭ, and many others), and necessary and sufficient conditions are already available in the literature [1], [9], [25] for the case that the $\{\mu_n\}$ are separable (a set Ω of complex plane is called separable if $\inf_{a,b\in\Omega,a\neq b}|a-b|>0$). It was shown recently in [24] that the Riesz basis property of $\{E_n(t)\}$ in $L^2(0,T)$ is closely related to the Riesz basis generation of the root subspace of A, provided that each eigenvalue is algebraically simple ($m_n = 1$). Since it is difficult to check the algebraic multiplicity and the separability of the eigenvalues in applications, we have to generalize the results of [24] in order to deal with the cases where the eigenvalues are not simple and separable. For this purpose, we need the help of the concept of generalized divided difference (GDD) introduced in [2] and [3].

DEFINITION 2.1. *Let $\mu_k, k = 1,2,\dots,m$, be arbitrary complex numbers (not necessarily different). The GDD of order zero of the function $e^{\mu t}$ corresponding to the point μ_1 is defined as $[\mu_1](t) = e^{\mu_1 t}$. GDD of the order $n-1, n \le m$ of $e^{\mu t}$ corresponding to $\{\mu_k, k = 1,2,\dots,n\}$ is defined by*

$$[\mu_1,\mu_2,\dots,\mu_n](t) = \begin{cases} \dfrac{[\mu_1,\mu_2,\dots,\mu_{n-1}](t) - [\mu_2,\mu_3,\dots,\mu_n](t)}{\mu_1-\mu_n}, & \mu_1 \neq \mu_n, \\ \dfrac{\partial}{\partial\mu}[\mu,\mu_2,\dots,\mu_{n-1}](t)|_{\mu=\mu_1}, & \mu_1 = \mu_n. \end{cases}$$

The following formula is valid for any $\{\mu_k\}_{k=1}^n$:

$$[\mu_1,\mu_2,\dots,\mu_n](t) = \int_0^1 d\tau_1 \int_0^{\tau_1} d\tau_2 \dots \int_0^{\tau_{n-2}} d\tau_{n-1} t^{n-1} e^{t[\mu_1+\tau_1(\mu_2-\mu_1)+\dots+\tau_{n-1}(\mu_n-\mu_{n-1})]}. \tag{2}$$

And hence if $\mathrm{Re}\mu_n \le \mathrm{Re}\mu_{n-1} \le \cdots \le \mathrm{Re}\mu_1$, then

$$|[\mu_1,\mu_2,\dots,\mu_n](t)| \le t^{n-1}e^{\mathrm{Re}\mu_1 t} \qquad \forall\, t \ge 0. \tag{3}$$

Note that if $\mu_i = \mu, i = 1,2,\dots,n$, then

$$[\mu_1,\mu_2,\dots,\mu_i](t) = t^{i-1}e^{\mu t}, \qquad 1 \le i \le n.$$

Generally, if there are m number of different elements in $\{\mu_1,\mu_2,\dots,\mu_n\}$, $\{\mu_1,\mu_2,\dots,\mu_n\} = \{\nu_1,\nu_2,\dots,\nu_m\}$, each ν_k repeats n_k times, $\sum_{k=1}^m n_k = n$. Then by Lemma 3.1 of [3], the GDD $[\mu_1,\mu_2,\dots,\mu_n](t)$ is the linear combination of functions $t^{j-1}e^{\nu_k t}, 1 \le j \le n_k, 1 \le k \le m$, and the coefficients of the leading terms $t^{n_k-1}e^{\nu_k t}$ are not equal to zero. The latter implies conversely that for any $1 \le k \le n_m$, $t^{k-1}e^{\nu_m t}$ is also the linear combination of $[\mu_1](t), [\mu_1,\mu_2](t), \dots, [\mu_1,\mu_2,\dots,\mu_n](t)$. In particular, we have the following proposition.

PROPOSITION 2.2. *Let $\{\mu_1,\mu_2,\dots,\mu_n\} = \{\nu_1,\nu_2,\dots,\nu_m\}$, $\nu_i \neq \nu_j$, $i \neq j$, $1 \le i, j \le m$, and each ν_j repeat n_j times, $\sum_{j=1}^m n_j = n$. Then any $\phi(t) = \sum_{j=1}^m e^{\nu_j t}\sum_{i=1}^{n_j} a_{ij}t^{i-1}$ can be represented as*

$$\phi(t) = \sum_{i=1}^n G_i[\mu_1,\mu_2,\dots,\mu_i](t),$$

where $G_1 = \sum_{j=1}^m a_{1j}$.

Let $\Omega = \{\mu_k\}_{k\in\mathbb{Z}}$ be a sequence in $\mathbb{C}$. Suppose Ω is a union of N separable sets Ω_j (each μ_k is assigned according to its multiplicity): $\Omega = \bigcup_{j=1}^{N} \Omega_j$ and $\sup_k |\mathrm{Re}\mu_k| < \infty$. Suppose that $\{\mu_k\}$ have been ordered in such a way that $\{\mathrm{Im}\mu_k\}$ forms a nondecreasing sequence [2]. Define

$$D^+(\Omega) = \lim_{r\to\infty} \frac{n^+(r)}{r},$$

where

$$n^+(r) = \sup_{x\in\mathbb{R}} \#\{\mathrm{Im}(\Omega) \cap [x, x+r)\}.$$

Let $\delta = \min_j[\inf_{a,b\in\Omega_j, a\neq b} |a-b|]$. For any $x \in \mathbb{R}$, suppose that there are M balls with radius $\delta/3$, which covers the compact region $\Omega(x) = \{\mu || \mathrm{Re}\mu| \le \sup_k |\mathrm{Re}\mu_k|,\ \mathrm{Im}\mu \in [x, x+1]\}$ of $\mathbb{C}$. Note that M is independent of x by unit shift. Then there are at most NM number of μ_k inside $\Omega(x)$. Hence, for any $r > 0$, we have

$$n^+(r) = \sup_{x\in\mathbb{R}} \#\{\mathrm{Im}(\Omega)\cap[x,x+r)\} \le \sup_{x\in\mathbb{R}} \#\{\mathrm{Im}(\Omega)\cap[x,x+([r]+1))\} \le ([r]+1)NM,$$

where $[r]$ denotes the maximal integer not exceeding r. Therefore, $D^+(\Omega) \le NM$. In particular,

$$D^+(\Omega) < \infty. \tag{4}$$

For any $\mu \in \mathbb{C}$, denote by $D_\mu(r)$ a disk with center μ and radius r. Let $G^p(r)$, $p = 1, 2, \ldots$, be the connected components of the union $\cup_{\mu\in\Omega} D_\mu(r)$ and write $\Omega^p(r) = \{\mu_{j,p}\}$ for the subsequence of Ω in $G^p(r)$, $\Omega^p(r) = \Omega \cap G^p(r)$. Then Lemma 1 of [2] says that, for any $r < r_0 = \delta/(2N)$, the number of $\Omega^p(r)$ is less than or equal to N. Set

$$\Omega^p(r) = \{\mu_{j,p}\}, \qquad j = 1, 2, \ldots, M^p(r) \le N. \tag{5}$$

Denote by

$$\varepsilon^p(\Omega, r) = \{[\mu_{1,p}], [\mu_{1,p}, \mu_{2,p}], \ldots, [\mu_{1,p}, \mu_{2,p}, \ldots, \mu_{M^p,p}]\}$$

the family of GDD corresponding to $\Omega^p(r)$. Then the following result, which is Theorem 3 of [2], characterizes the basis property of $\varepsilon^p(\Omega, r)$ in L^2 space.

PROPOSITION 2.3. *Assume that $\Omega = \{\mu_k\}_{k\in\mathbb{Z}}$ is defined as above. Then for any $2\pi D^+(\Omega) < T < \infty$ the family $\varepsilon^p(\Omega, r)$ forms a Riesz basis in the closed subspace of $L^2(0, T)$ spanned by itself.*

With these preliminary results, we come to the proof of the abstract result which links the Riesz basis property of the corresponding family of GDD in L^2 space and that of the root subspace of associated operators in cases that the eigenvalues are comprised of some finite unification of separable sets after taking the algebraic multiplicities into account.

LEMMA 2.4. *Let $\mathbf{H}$ be a separable Hilbert space. Suppose $\{e_n(t)\}_{n\in\mathbb{Z}}$ forms a Riesz basis in the closed subspace spanned by itself in $L^2(0, T)$, $T > 0$. Then for any $\phi \in L^2(0, T; \mathbf{H})$, $\phi(t) = \sum_{n\in\mathbb{Z}} e_n(t)\phi_n$, there exist constants $C_1, C_2 > 0$ such that*

$$C_1 \sum_{n\in\mathbb{Z}} \|\phi_n\|^2_{\mathbf{H}} \le \|\phi\|^2_{L^2(0,T;\mathbf{H})} \le C_2 \sum_{n\in\mathbb{Z}} \|\phi_n\|^2_{\mathbf{H}}. \tag{6}$$

Proof. Take some orthonormal basis $\{\psi_n\}$ of $\mathbf{H}$, and for almost all $t \in [0,T]$ expand ϕ as

$$\phi(t) = \sum_{n\in\mathbb{Z}} \langle \phi(t), \psi_n\rangle_{\mathbf{H}} \psi_n, \qquad t \in [0,T] \text{ a.e.}$$

Then

$$\|\phi(t)\|^2_{\mathbf{H}} = \sum_{n\in\mathbb{Z}} |\ \langle \phi(t), \psi_n\rangle_{\mathbf{H}}\ |^2 \qquad \forall t \in [0,T] \text{ a.e.} \tag{7}$$

Since for any $m \in \mathbb{Z}$, $\langle \phi(t), \psi_m\rangle_{\mathbf{H}} \in \text{span}\{e_n(t)\}_{n\in\mathbb{Z}}$ and

$$\langle \phi(t), \psi_m\rangle_{\mathbf{H}} = \sum_{n\in\mathbb{Z}} \langle \phi_n, \psi_m\rangle_H e_n(t) \qquad \forall\ m \in \mathbb{Z} \text{ in } L^2(0,T). \tag{8}$$

By assumption,

$$C_1 \sum_{n\in\mathbb{Z}} |\ \langle \phi_n, \psi_m\rangle_{\mathbf{H}}\ |^2 \le \int_0^T |\ \langle \phi(t), \psi_m\rangle_{\mathbf{H}}\ |^2\, dt \le C_2 \sum_{n\in\mathbb{Z}} |\ \langle \phi_n, \psi_m\rangle_{\mathbf{H}}\ |^2 \tag{9}$$

for some constants $C_1, C_2 > 0$ that depend on $\{e_n(t)\}$. Hence it follows from (7) that

$$\begin{aligned} C_1 \sum_{m\in\mathbb{Z}} \sum_{n\in\mathbb{Z}} |\ \langle \phi_n, \psi_m\rangle_{\mathbf{H}}\ |^2 &\le \sum_{m\in\mathbb{Z}} \int_0^T |\ \langle \phi(t), \psi_m\rangle_{\mathbf{H}}\ |^2\, dt \\ &= \int_0^T \|\phi(t)\|^2_{\mathbf{H}} dt \le C_2 \sum_{m\in\mathbb{Z}} \sum_{n\in\mathbb{Z}} |\ \langle \phi_n, \psi_m\rangle_{\mathbf{H}}\ |^2 . \end{aligned} \tag{10}$$

Note that

$$\phi_n = \sum_{m\in\mathbb{Z}} \langle \phi_n, \psi_m\rangle_{\mathbf{H}} \psi_m, \qquad \|\phi_n\|^2 = \sum_{m\in\mathbb{Z}} |\langle \phi_n, \psi_m\rangle_{\mathbf{H}}|^2. \tag{11}$$

Then (6) follows from (10). □

Assume further that B generates a C_0-group on $\mathbf{H}$ and that its root subspace (the closed subspace spanned by all generalized eigenvectors of B) is complete in $\mathbf{H}$: $Sp(B) = \mathbf{H}$. Suppose

$$\sigma(B) = \bigcup_{p\in\mathbb{Z}} \Omega(p), \quad \Omega(p) = \{\nu_j^p\}_{j=1}^{N^p}, \quad \text{Re}\nu_1^p \ge \text{Re}\nu_2^p \ge \cdots \ge \text{Re}\nu_{N^p}^p, \quad \nu_i^n \ne \nu_j^m,$$

unless $m = n, i = j$. Assume that each ν_j^p has algebraic multiplicity m_j^p and that both the number N^p of $\Omega(p)$ and m_j^p have uniform upper bound; i.e., there exists an $N > 0$ such that $\sup_p[N^p \max_{1\le j\le N^p} m_j^p] \le N$. Set $\tilde{m}_0^p = 0$, $\tilde{m}_l^p = \sum_{q=1}^l m_q^p, l = 1, \ldots, N^p$. Arranging $\Omega(p)$ again according to multiplicity, we obtain a new set $\Lambda^p = \{\{\mu^p_{i+\tilde{m}^p_{j-1}}\}_{i=1}^{m_j^p}\}_{j=1}^{N^p}$,

$$\mu^p_{i+\tilde{m}^p_{j-1}} = \nu_j^p, \quad 1 \le i \le m_j^p, \quad 1 \le j \le N^p. \tag{12}$$

Hence we write (accounted by multiplicity) $\sigma(B) = \bigcup_{p\in\mathbb{Z}} \Lambda^p$. Make the family of GDD be as follows:

$$E_p(t) = \{[\mu_1^p](t), [\mu_1^p, \mu_2^p](t), \ldots, [\mu_1^p, \mu_2^p, \ldots, \mu^p_{\tilde{m}^p_{N^p}}](t)\}. \tag{13}$$

Now we are in a position to prove the main result of this section.

THEOREM 2.5. *If there exists a $T>0$ such that the family of GDD $\{E_p(t)\}_1^\infty$ defined by* (13) *forms a Riesz basis in the closed subspace spanned by itself in $L^2(0,T)$, then*

(a)

$$S_\infty(B) = \left\{ x \in \mathbf{H} | x = \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} x \right\} = \mathbf{H}, \tag{14}$$

where $\mathbb{P}_{\nu_j^p}$ denotes the eigen-projection of B corresponding to eigenvalue ν_j^p;

(b) *there are constants $M_1, M_2 > 0$ such that*

$$M_1 \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} x \right\|^2 \le \|x\|^2 \le M_2 \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} x \right\|^2 \qquad \forall\, x \in \mathbf{H}; \tag{15}$$

(c) *the spectrum-determined growth condition holds:*

$$\omega(B) = \inf\{\omega | \textit{there exists } M>1 \textit{ such that } \|e^{Bt}\| \le Me^{\omega t}\} = S(B) = \sup_{\nu\in\sigma_p(B)} \mathrm{Re}\nu.$$

Proof. We first prove (15). Since B generates a C_0-group, there are $M, \omega > 0$ such that

$$\|e^{Bt}\| \le Me^{\omega|t|} \qquad \forall\, t \in \mathbb{R}.$$

Take $x_0 \in S_\infty(B),\ x_0 = \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} x_0$. Then

$$e^{Bt}x_0 = \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} e^{\nu_j^p t} \sum_{i=1}^{m_j^p} \frac{(B-\nu_j^p)^{i-1}}{(i-1)!} t^{i-1} \mathbb{P}_{\nu_j^p} x_0 = \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} e^{\nu_j^p t} \sum_{i=1}^{m_j^p} a_{ij}^p t^{i-1}, \tag{16}$$

where we set $a_{ij}^p = \frac{(B-\nu_j^p)^{i-1}}{(i-1)!} \mathbb{P}_{\nu_j^p} x_0$. By Proposition 2.2, we can write

$$e^{Bt}x_0 = \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \sum_{i=1}^{m_j^p} G^p_{i+\tilde{m}^p_{j-1}}(x_0)[\mu_1^p, \mu_2^p, \ldots, \mu^p_{i+\tilde{m}^p_{j-1}}](t). \tag{17}$$

Further, by assumption and Lemma 2.4, there are constants $C_1, C_2 > 0$ such that

$$C_1 \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \sum_{i=1}^{m_j^p} \|G^p_{i+\tilde{m}^p_{j-1}}(x_0)\|^2 \le \int_0^T \|e^{Bt}x_0\|^2 dt \le C_2 \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \sum_{i=1}^{m_j^p} \|G^p_{i+\tilde{m}^p_{j-1}}(x_0)\|^2. \tag{18}$$

In particular,

$$C_1\sum_{p\in\mathbb{Z}}\|G_1^p(x_0)\|^2=C_1\sum_{p\in\mathbb{Z}}\left\|\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x_0\right\|^2\le\int_0^T\|e^{Bt}x_0\|^2dt\le\frac{M^2}{2\omega}(e^{2\omega T}-1)\|x_0\|^2. \tag{19}$$

Next, since $Sp(B)=\mathbf{H}, Sp(B)\subset\overline{S_\infty(B)}=\mathbf{H}$, we see that (19) holds for all $x_0\in\mathbf{H}$. Setting $M_1=C_1\frac{2\omega}{M^2}(e^{2\omega T}-1)^{-1}$, we obtain the first inequality of (15). Finally, from (18),

$$C_1\sum_{j=1}^{N^p}\sum_{i=1}^{m_j^p}\|G^p_{i+\tilde m^p_{j-1}}(x_0)\|^2\le\int_0^T\|e^{Bt}x_0\|^2dt\le\frac{M^2}{2\omega}(e^{2\omega T}-1)\|x_0\|^2\text{ as }x_0\in S_\infty(B).$$

In particular, by letting $x_0=\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x\in S_\infty(B), p\ge1, x\in H$, we obtain

$$\begin{aligned}C_1\sum_{j=1}^{N^p}\sum_{i=1}^{m_j^p}\|G^p_{i+\tilde m^p_{j-1}}(x)\|^2&=C_1\sum_{j=1}^{N^p}\sum_{i=1}^{m_j^p}\|G^p_{i+\tilde m^p_{j-1}}(x_0)\|^2\\&\le\int_0^T\|e^{Bt}x_0\|^2dt\le\frac{M^2}{2\omega}(e^{2\omega T}-1)\left\|\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x\right\|^2\qquad\forall\,x\in\mathbf{H}.\end{aligned} \tag{20}$$

Hence, from (18) and (20), we see that for any $x\in\mathbf{H}$

$$\begin{aligned}\|x\|^2&=\frac1T\int_0^T\|e^{-Bt}e^{Bt}x\|^2dt\le\frac{M^2e^{2\omega T}}{T}\int_0^T\|e^{Bt}x\|^2dt\\&\le\frac{M^2e^{2\omega T}}{T}\frac{M^2}{2\omega}(e^{2\omega T}-1)C_1^{-1}C_2\sum_{p\in\mathbb{Z}}\left\|\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x\right\|^2.\end{aligned} \tag{21}$$

Setting $M_2=C_2M^4e^{2\omega T}(2\omega TC_1)^{-1}(e^{2\omega T}-1)$ yields the second inequality of (15).

To show (14), we need to show that $S_\infty(B)$ is a closed subspace of $\mathbf{H}$. By virtue of Theorem 3.5 of [13], it suffices to show that there exists $M_0>0$ such that

$$\left\|\sum_{p=\tilde M}^{\tilde N}\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x\right\|^2\le M_0\|x\|^2\qquad\forall x\in\mathbf{H}\ \text{ and integers }\tilde M,\tilde N.$$

Let $x=\sum_{p=\tilde M}^{\tilde N}\sum_{j=1}^{N^p}P_{\nu_j^p}z, z\in\mathbf{H}$. Then $\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}x=\sum_{j=1}^{N^p}\mathbb{P}_{\nu_j^p}z$. From (15)

$$\frac{M_1}{M_2}\|x\|^2\le M_1\sum_{p=\tilde M}^{\tilde N}\left\|\sum_{j=1}^{N^p}P_{\nu_j^p}x\right\|^2=M_1\sum_{p=\tilde M}^{\tilde N}\left\|\sum_{j=1}^{N^p}P_{\nu_j^p}z\right\|^2\le\|z\|^2\qquad\forall\,z\in\mathbf{H},$$

and hence

$$\left\| \sum_{p=\tilde{M}}^{\tilde{N}} \sum_{j=1}^{N^p} P_{\nu_j^p} z \right\|^2 \le \frac{M_2}{M_1} \|z\|^2 \qquad \forall z \in \mathbf{H},\ \tilde{N} > 1.$$

Equation (14) is thus proved. Finally, since $\mathrm{Re}\mu_1^p \ge \mathrm{Re}\mu_2^p \ge \cdots \ge \mathrm{Re}\mu_{i+\tilde{m}_{j-1}^p}^p$, it follows from (3) that

$$|[\mu_1^p, \mu_2^p, \ldots, \mu_{i+\tilde{m}_{j-1}^p}^p](t)| \le t^N e^{S(B)t} \qquad \forall\, t \ge 1. \tag{22}$$

From (15), (16), (17), and (22), we get

$$\begin{aligned}
\|e^{Bt}x_0\|^2 &\le M_2 \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} e^{Bt} x_0 \right\|^2 = M_2 \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} e^{\nu_j^p t} \sum_{i=1}^{m_j^p} \frac{(B-\nu_j^p)^{i-1}}{(i-1)!} t^{i-1} \mathbb{P}_{\nu_j^p} x_0 \right\|^2 \\
&= M_2 \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} \sum_{i=1}^{m_j^p} G_{i+\tilde{m}_{j-1}^p}^p(x_0) [\mu_1^p, \mu_2^p, \ldots, \mu_{i+\tilde{m}_{j-1}^p}^p](t) \right\|^2 \\
&\le M_2 \sum_{p\in\mathbb{Z}} \sum_{j=1}^{N^p} \sum_{i=1}^{m_j^p} \|G_{i+\tilde{m}_{j-1}^p}^p(x_0)\|^2 N t^{2N} e^{2S(B)t} \qquad \forall\, x_0 \in \mathbf{H}.
\end{aligned}$$

This, together with (20) and (15), gives

$$\|e^{Bt}x_0\|^2 \le C t^{2N} e^{2S(B)t} \sum_{p\in\mathbb{Z}} \left\| \sum_{j=1}^{N^p} \mathbb{P}_{\nu_j^p} x_0 \right\|^2 \le C M_1^{-1} t^{2N} e^{2S(B)t} \|x_0\|^2,$$

where C is a constant. The proof is complete. □

3. Application to an N-connected string equation. In this section, we are concerned with the following system of $N+1$ serially connected strings under joint feedback controls:

$$\begin{cases}
y_{tt}(x,t) - c_i^2 y_{xx}(x,t) = 0, \quad i-1 < x < i, i = 1, 2, \ldots, N+1, \\
y(0,t) = y(N+1,t) = 0, \\
y(i^-,t) = y(i^+,t), \\
c_i^2 y_x(i^-,t) - c_{i+1}^2 y_x(i^+,t) = k_i y_t(i,t), \quad i = 1, \ldots, N, \\
y(x,0) = y_0(x), \quad y_t(x,0) = y_1(x),
\end{cases} \tag{23}$$

where $t > 0, k_i \in \mathbb{R}, c_i > 0, i = 1, 2, \ldots, N$.

Let the underlying state Hilbert space $\mathcal{H} = H_0^1(0, N+1) \times L^2(0, N+1)$. Define an inner product in $\mathcal{H}$ as

$$\langle (f_1,g_1),(f_2,g_2)\rangle_H = \sum_{i=1}^{N+1}\int_{i-1}^{i}[c_i^2 f_1'(x)\overline{f_2'(x)}+g_1(x)\overline{g_2(x)}]dx \qquad \forall\,(f_1,g_1),(f_2,g_2)\in\mathcal{H}. \tag{24}$$

Introduce operator $\mathcal{A}$ in $\mathcal{H}$:

$$\mathcal{A}(f,g)=(g(x),c_i^2 f''(x)),\quad i-1<x<i,\ i=1,2,\dots,N+1,\quad \forall\,(f,g)\in D(\mathcal{A}), \tag{25}$$

where

$$\begin{aligned} D(\mathcal{A})=\{(f,g)\in H\mid f,g\in H_0^1(0,N+1), f|_{[j-1,j]}\in H^2(j-1,j), 1\le j\le N+1,\\ c_i^2 f'(i^-)-c_{i+1}^2 f'(i^+)=k_i g(i), 1\le i\le N\} \end{aligned} \tag{26}$$

with $f|_{[a,b]}$ denoting the restriction of f on $[a,b]$. Set $Y(t)=(y(\cdot,t),y_t(\cdot,t)), Y_0=(y_0(\cdot),y_1(\cdot))$. Then system (23) can be written as an evolutionary equation in $\mathcal{H}$:

$$\begin{cases} \dfrac{dY(t)}{dt}=\mathcal{A}Y(t), \quad t>0,\\ Y(0)=Y_0. \end{cases} \tag{27}$$

Throughout the paper, we always make the following assumption on the string system (23):

$$|k_i|\neq c_i+c_{i+1},\quad i=1,2,\dots,N. \tag{28}$$

Note that this condition is very minor. It holds for almost all constants c_i, k_i.

THEOREM 3.1. *Under condition* (28)*, the operator* $\mathcal{A}$ *defined by* (25) *and* (26) *generates a* C_0*-group on* $\mathcal{H}$.

Proof. For any $(f_1,g_1),(f_2,g_2)\in\mathcal{H}$, define a new inner product of the following in $\mathcal{H}$:

$$\begin{aligned} \langle (f_1,g_1),(f_2,g_2)\rangle_* = \sum_{i=1}^{N+1}\int_{i-1}^{i}\Bigg[A_i(x)\cdot\frac{c_i f_1'(x)+g_1(x)}{2}\cdot\frac{c_i\overline{f_2'(x)}+\overline{g_2(x)}}{2}\\ +B_i(x)\cdot\frac{c_i f_1'(x)-g_1(x)}{2}\cdot\frac{c_i\overline{f_2'(x)}-\overline{g_2(x)}}{2}\Bigg]dx, \end{aligned} \tag{29}$$

where $A_i(x), B_i(x)$, defined on $[i-1,i], i=1,2,\dots,N+1$, are positive differentiable functions to be determined later. It is obvious that the norm induced by the new inner product is equivalent to that induced by (24). We claim that, under this new inner product, $\mathcal{A}$ is a densely defined m-dissipative operator and hence generates a C_0-group in $\mathcal{H}$ (see [17]). Indeed, for any $(f,g)\in D(\mathcal{A}), (f,g)\neq 0$,

$$\begin{aligned}
\operatorname{Re}\langle \mathcal{A}(f,g),(f,g)\rangle_* &= \sum_{i=1}^{N+1} \operatorname{Re}\int_{i-1}^{i} \left[A_i(x)\cdot \frac{c_i g'(x)+c_i^2 f''(x)}{2}\cdot \frac{c_i\overline{f'(x)}+\overline{g(x)}}{2} \right. \\
&\qquad \left. + B_i(x)\cdot \frac{c_i g'(x)-c_i^2 f''(x)}{2}\cdot \frac{c_i\overline{f'(x)}-\overline{g(x)}}{2} \right] dx \\
&= \sum_{i=1}^{N+1} \operatorname{Re}\int_{i-1}^{i} \left\{ c_i A_i(x)\cdot \left[\frac{c_i f'(x)+g(x)}{2}\right]'\cdot \left[\frac{c_i\overline{f'(x)}+\overline{g(x)}}{2}\right] \right. \\
&\qquad \left. - c_i B_i(x)\cdot \left[\frac{c_i f'(x)-g(x)}{2}\right]'\cdot \left[\frac{c_i\overline{f'(x)}-\overline{g(x)}}{2}\right] \right\} dx \\
&= \sum_{i=1}^{N+1} \left[\frac{c_i A_i(x)}{2}\left|\frac{c_i f'(x)+g(x)}{2}\right|^2\Bigg|_{i-1}^{i} - \frac{c_i}{2}\int_{i-1}^{i} A_i'(x)\left|\frac{c_i f'(x)+g(x)}{2}\right|^2 dx \right. \\
&\qquad \left. - \frac{c_i B_i(x)}{2}\left|\frac{c_i f'(x)-g(x)}{2}\right|^2\Bigg|_{i-1}^{i} + \frac{c_i}{2}\int_{i-1}^{i} B_i'(x)\left|\frac{c_i f'(x)-g(x)}{2}\right|^2 dx \right] \\
&= I_1 + I_2,
\end{aligned} \tag{30}$$

where

$$\begin{aligned}
I_2 &= \sum_{i=1}^{N+1} \frac{c_i}{2}\int_{i-1}^{i} \left[B_i'(x)\left|\frac{c_i f'(x)-g(x)}{2}\right|^2 - A_i'(x)\left|\frac{c_i f'(x)+g(x)}{2}\right|^2 \right] dx \\
&\le M\,\|(f,g)\|_*^2
\end{aligned} \tag{31}$$

with M being a positive constant, and

$$\begin{aligned}
I_1 &= -\frac{1}{2}\sum_{i=1}^{N+1} c_i \left[B_i(x)\left|\frac{c_i f'(x)-g(x)}{2}\right|^2\Bigg|_{i-1}^{i} - A_i(x)\left|\frac{c_i f'(x)+g(x)}{2}\right|^2\Bigg|_{i-1}^{i} \right] \\
&= -\frac{1}{2}\left\{ c_1\left[A_1(0)\left|\frac{c_1 f'(0)+g(0)}{2}\right|^2 - B_1(0)\left|\frac{c_1 f'(0)-g(0)}{2}\right|^2 \right] \right. \\
&\qquad + c_{N+1}\left[B_{N+1}(N+1)\left|\frac{c_{N+1} f'(N+1)-g(N+1)}{2}\right|^2 \right. \\
&\qquad\qquad \left. - A_{N+1}(N+1)\left|\frac{c_{N+1} f'(N+1)+g(N+1)}{2}\right|^2 \right] \\
&\qquad + \sum_{i=1}^{N}\left[c_i B_i(i)\left|\frac{c_i f'(i^-)-g(i^-)}{2}\right|^2 + c_{i+1}A_{i+1}(i)\left|\frac{c_{i+1} f'(i^+)+g(i^+)}{2}\right|^2 \right. \\
&\qquad \left. \left. - c_i A_i(i)\left|\frac{c_i f'(i^-)+g(i^-)}{2}\right|^2 - c_{i+1}B_{i+1}(i)\left|\frac{c_{i+1} f'(i^+)-g(i^+)}{2}\right|^2 \right] \right\} \\
&= -\frac{1}{2}[c_1 I_1' + c_{N+1} I_2' + I_3'].
\end{aligned} \tag{32}$$

From the first boundary condition of (23), we obtain

$$\begin{cases} \dfrac{c_1 f'(0) - g(0)}{2} = \dfrac{c_1 f'(0) + g(0)}{2}, \\ \dfrac{c_{N+1} f'(N+1) - g(N+1)}{2} = \dfrac{c_{N+1} f'(N+1) + g(N+1)}{2}. \end{cases} \tag{33}$$

Substituting (33) into (32) yields

$$\begin{aligned} I_1' &= A_1(0) \left| \frac{c_1 f'(0) + g(0)}{2} \right|^2 - B_1(0) \left| \frac{c_1 f'(0) - g(0)}{2} \right|^2 \\ &= [A_1(0) - B_1(0)] \left| \frac{c_1 f'(0) + g(0)}{2} \right|^2, \\ I_2' &= B_{N+1}(N+1) \left| \frac{c_{N+1} f'(N+1) - g(N+1)}{2} \right|^2 \\ &\quad - A_{N+1}(N+1) \left| \frac{c_{N+1} f'(N+1) + g(N+1)}{2} \right|^2 \\ &= [B_{N+1}(N+1) - A_{N+1}(N+1)] \left| \frac{c_{N+1} f'(N+1) - g(N+1)}{2} \right|^2. \end{aligned} \tag{34}$$

Now we choose $A_1(x), B_1(x), A_{N+1}(x), B_{N+1}(x)$ so that $A_1(0) \geq B_1(0), B_{N+1}(N+1) \geq A_{N+1}(N+1)$. This implies $I_1' \geq 0, I_2' \geq 0$. Similarly, from the third boundary condition of (23) we obtain

$$\begin{aligned} &\frac{c_i f'(i^-) - g(i^-)}{2} - \frac{c_i f'(i^-) + g(i^-)}{2} = \frac{c_{i+1} f'(i^+) - g(i^+)}{2} - \frac{c_{i+1} f'(i^+) + g(i^+)}{2}, \\ &c_i \left[\frac{c_i f'(i^-) - g(i^-)}{2} + \frac{c_i f'(i^-) + g(i^-)}{2} \right] - c_{i+1} \left[\frac{c_{i+1} f'(i^+) - g(i^+)}{2} + \frac{c_{i+1} f'(i^+) + g(i^+)}{2} \right] \\ &\quad = -k_i \left[\frac{c_i f'(i^-) - g(i^-)}{2} - \frac{c_i f'(i^-) + g(i^-)}{2} \right]; \end{aligned} \tag{35}$$

that is,

$$\begin{pmatrix} 1 & 1 \\ c_i + k_i & -c_{i+1} \end{pmatrix} \begin{pmatrix} \frac{c_i f'(i^-) - g(i^-)}{2} \\ \frac{c_{i+1} f'(i^+) + g(i^+)}{2} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ -c_i + k_i & c_{i+1} \end{pmatrix} \begin{pmatrix} \frac{c_i f'(i^-) + g(i^-)}{2} \\ \frac{c_{i+1} f'(i^+) - g(i^+)}{2} \end{pmatrix}. \tag{36}$$

Under condition (28),

$$\begin{aligned} \begin{pmatrix} \frac{c_i f'(i^-) + g(i^-)}{2} \\ \frac{c_{i+1} f'(i^+) - g(i^+)}{2} \end{pmatrix} &= \begin{pmatrix} 1 & 1 \\ -c_i + k_i & c_{i+1} \end{pmatrix}^{-1} \begin{pmatrix} 1 & 1 \\ c_i + k_i & -c_{i+1} \end{pmatrix} \begin{pmatrix} \frac{c_i f'(i^-) - g(i^-)}{2} \\ \frac{c_{i+1} f'(i^+) + g(i^+)}{2} \end{pmatrix} \\ &= \begin{pmatrix} \frac{c_{i+1} - c_i - k_i}{-k_i + c_i + c_{i+1}} & \frac{2c_{i+1}}{-k_i + c_i + c_{i+1}} \\ \frac{2c_i}{-k_i + c_i + c_{i+1}} & \frac{c_i - c_{i+1} - k_i}{-k_i + c_i + c_{i+1}} \end{pmatrix} \begin{pmatrix} \frac{c_i f'(i^-) - g(i^-)}{2} \\ \frac{c_{i+1} f'(i^+) + g(i^+)}{2} \end{pmatrix}. \end{aligned} \tag{37}$$

Thus,

$$\begin{aligned}
&\left|\frac{c_i f'(i^-)+g(i^-)}{2}\right|^2 \\
&\quad=\left|\frac{c_{i+1}-c_i-k_i}{-k_i+c_i+c_{i+1}}\cdot\frac{c_i f'(i^-)-g(i^-)}{2}+\frac{2c_{i+1}}{-k_i+c_i+c_{i+1}}\cdot\frac{c_{i+1}f'(i^+)+g(i^+)}{2}\right|^2 \\
&\quad\le 2\left[\left(\frac{c_{i+1}-c_i-k_i}{-k_i+c_i+c_{i+1}}\right)^2\left|\frac{c_i f'(i^-)-g(i^-)}{2}\right|^2\right. \\
&\qquad\left.+\left(\frac{2c_{i+1}}{-k_i+c_i+c_{i+1}}\right)^2\left|\frac{c_{i+1}f'(i^+)+g(i^+)}{2}\right|^2\right].
\end{aligned} \tag{38}$$

Similarly,

$$\begin{aligned}
\left|\frac{c_{i+1}f'(i^+)-g(i^+)}{2}\right|^2 &\le 2\left[\left(\frac{2c_i}{-k_i+c_i+c_{i+1}}\right)^2\left|\frac{c_i f'(i^-)-g(i^-)}{2}\right|^2\right. \\
&\quad\left.+\left(\frac{c_i-c_{i+1}-k_i}{-k_i+c_i+c_{i+1}}\right)^2\left|\frac{c_{i+1}f'(i^+)+g(i^+)}{2}\right|^2\right].
\end{aligned} \tag{39}$$

Next, substituting (38) into (32) produces

$$\begin{aligned}
I_3' &= \sum_{i=1}^{N}\left[c_iB_i(i)\left|\frac{c_i f'(i^-)-g(i^-)}{2}\right|^2+c_{i+1}A_{i+1}(i)\left|\frac{c_{i+1}f'(i^+)+g(i^+)}{2}\right|^2\right. \\
&\qquad\left.-c_{i+1}B_{i+1}(i)\left|\frac{c_{i+1}f'(i^+)-g(i^+)}{2}\right|^2-c_iA_i(i)\left|\frac{c_i f'(i^-)+g(i^-)}{2}\right|^2\right] \\
&\le \sum_{i=1}^{N}\left[c_iB_i(i)-2c_iA_i(i)\left(\frac{c_{i+1}-c_i-k_i}{-k_i+c_i+c_{i+1}}\right)^2\right. \\
&\qquad\left.-2c_{i+1}B_{i+1}(i)\left(\frac{2c_i}{-k_i+c_i+c_{i+1}}\right)^2\right]\left|\frac{c_i f'(i^-)-g(i^-)}{2}\right|^2 \\
&\quad+\left[c_{i+1}A_{i+1}(i)-2c_iA_i(i)\left(\frac{2c_{i+1}}{-k_i+c_i+c_{i+1}}\right)^2\right. \\
&\qquad\left.-2c_{i+1}B_{i+1}(i)\left(\frac{c_i-c_{i+1}-k_i}{-k_i+c_i+c_{i+1}}\right)^2\right]\left|\frac{c_{i+1}f'(i^+)+g(i^+)}{2}\right|^2.
\end{aligned} \tag{40}$$

Choosing $A_i(i), A_{i+1}(i), B_i(i), B_{i+1}(i), i=1,\dots,N$, properly so that $I_3'\ge 0$, we get

$$\operatorname{Re}\langle\mathcal{A}(f,g),(f,g)\rangle_* \le M\,\|(f,g)\|_*^2 \qquad \forall\,(f,g)\in D(\mathcal{A}). \tag{41}$$

That is, $\mathcal{A}-\lambda$ is dissipative for any $\lambda\ge M$. Referring to Lemma 3.3 below, we can take real $\lambda>M, \lambda\in\rho(\mathcal{A})$ so that $\mathcal{A}-\lambda$ satisfies all conditions of the Lumer–Phillips theorem (see, e.g., [17, p. 14]). Therefore, $\mathcal{A}-\lambda$ generates a C_0-semigroup on $\mathcal{H}$ and so does $\mathcal{A}$. Meanwhile, it is seen also that the above analysis is still valid after exchanging k_i with $-k_i$ under the condition (28).

We accomplish the proof by showing that $-\mathcal{A}$ also generates a C_0-semigroup on $\mathcal{H}$. To this end, consider the following equation:

$$\begin{cases} z_{tt}(x,t) - c_i^2 z_{xx}(x,t) = 0, \quad i-1 < x < i, i = 1, 2, \ldots, N+1, \\ z(0,t) = z(N+1,t) = 0, \\ z(i^-,t) = z(i^+,t), \\ c_i^2 z_x(i^-,t) - c_{i+1}^2 z_x(i^+,t) = -k_i z_t(i,t), \quad i = 1, \ldots, N, \\ z(x,0) = z_0(x), \quad z_t(x,0) = z_1(x). \end{cases} \tag{42}$$

System (42) can be written as an evolutionary equation in $\mathcal{H}$:

$$\begin{cases} \dfrac{dZ(t)}{dt} = \mathcal{B}Z(t), \quad t > 0, \\ Z(0) = Z_0 = (z_0, z_1), \end{cases} \tag{43}$$

where $Z(t) = (z(\cdot,t), z_t(\cdot,t))$ and $\mathcal{B}$ is given by

$$\begin{cases} \mathcal{B}(f,g) = (g(x), c_i^2 f''(x)), \quad i-1 < x < i, i = 1, 2, \ldots, N+1, \qquad \forall\, (f,g) \in D(\mathcal{A}), \\ D(\mathcal{B}) = \{(f,g) \in H | f, g \in H_0^1(0, N+1), f|_{[j-1,j]} \in H^2(j-1, j), 1 \le j \le N+1, \\ \qquad\qquad c_i^2 f'(i^-) - c_{i+1}^2 f'(i^+) = -k_i g(i), 1 \le i \le N\}. \end{cases} \tag{44}$$

Since the assumption (28) is also valid for system (42), it follows from the result justified that $\mathcal{B}$ generates a C_0-semigroup on $\mathcal{H}$. Hence for any $Z(0) \in D(\mathcal{B})$ there exists a unique classical solution $Z(t)$ to (43), since such a $Z(t)$ is well defined; that is to say, both $z(\cdot,t)$ and $z_t(\cdot,t)$ make sense for any $t \ge 0$. Let

$$W(t) = (w_1(\cdot,t), w_2(\cdot,t)) = (z(\cdot,t), -z_t(\cdot,t)).$$

Then it is seen that

$$\dot{W}(t) = -\mathcal{A}W(t),\ W(0) = (z_0, -z_1). \tag{45}$$

On the other hand, it is seen that $(z_0, z_1) \in D(\mathcal{B})$ if and only if $(z_0, -z_1) \in D(\mathcal{A}) = D(-\mathcal{A})$. We thus have proved that for any $W(0) \in D(-\mathcal{A})$ there exists a unique classical solution to (45). Since $\rho(-\mathcal{A}) \neq \emptyset$ from Lemma 3.3 below, it follows from Theorem 1.3 of [17, p. 102] that $-\mathcal{A}$ generates a C_0-semigroup on $\mathcal{H}$. Therefore, $\mathcal{A}$ generates a C_0-group on $\mathcal{H}$. □

Remark 3.2. It should be pointed out that the proof of Theorem 3.1 is similar to the approach used in [16]. However, since (23) and the equations studied in [16] are not always equivalent (see, e.g., [14]), we cannot transform (23) into the form of the latter. That is why we start directly from (23).

LEMMA 3.3. *Under condition* (28), $\mathcal{A}$ *is a discrete operator, and hence the spectrum* $\sigma(\mathcal{A})$ *of* $\mathcal{A}$ *consists of isolated eigenvalues only, and each eigenvalue is geometrically simple.*

Proof. Let $\lambda \in \mathbb{C}$. For any given $(f,g) \in \mathcal{H}$, find a pair $(u,v) \in D(\mathcal{A})$ so that

$$(\lambda - \mathcal{A})(u,v) = (f,g). \tag{46}$$

We then have that $v = \lambda u - f$ and u satisfies the following equation:

$$\begin{cases} \lambda^2 u - c_i^2 u'' = \lambda f + g \qquad \forall\, x \in (i-1,i),\ i = 1,2,\dots,N+1, \\ u(0) = u(N+1) = 0, \\ u(i^-) = u(i^+), \\ c_i^2 u'(i^-) - c_{i+1}^2 u'(i^+) = \lambda k_i u(i) - k_i f(i), \quad i = 1,\dots,N. \end{cases} \tag{47}$$

Solving (47) for $u(x)$ produces

$$u(x) = \begin{cases} a_1 \left(e^{\frac{\lambda}{c_1}x} - e^{-\frac{\lambda}{c_1}x} \right) - \displaystyle\int_0^x \frac{e^{\frac{\lambda}{c_1}(x-s)} - e^{-\frac{\lambda}{c_1}(x-s)}}{2\lambda c_1} (\lambda f + g)(s)ds, \quad x \in (0,1), \\ a_{i1} e^{-\frac{\lambda}{c_i}x} + a_{i2} e^{\frac{\lambda}{c_i}x} - \displaystyle\int_{i-1}^x \frac{e^{\frac{\lambda}{c_i}(x-s)} - e^{-\frac{\lambda}{c_i}(x-s)}}{2\lambda c_i} (\lambda f + g)(s)ds, \\ \qquad\qquad x \in (i-1,i),\ i = 2,\dots,N, \\ a_{N+1} \left[e^{\frac{\lambda}{c_{N+1}}(x-(N+1))} - e^{-\frac{\lambda}{c_{N+1}}(x-(N+1))} \right] \\ - \displaystyle\int_N^x \frac{e^{\frac{\lambda}{c_{N+1}}(x-s)} - e^{-\frac{\lambda}{c_{N+1}}(x-s)}}{2\lambda c_{N+1}} (\lambda f + g)(s)ds, \quad x \in (N,N+1), \end{cases} \tag{48}$$

where $a_1, a_{N+1}, a_{i1}, a_{i2}, i = 2,3,\dots,N$, are constants depending on λ. Substituting $u(x)$ into the boundary condition of (47), we see that $a_1, a_{N+1}, a_{i1}, a_{i2}, i = 2,3,\dots,N$, satisfy the following algebraic system of equations:

$$\begin{cases} a_1(e^{\frac{\lambda}{c_1}} - e^{-\frac{\lambda}{c_1}}) - a_{21}e^{-\frac{\lambda}{c_2}} - a_{22}e^{\frac{\lambda}{c_2}} = \dfrac{1}{\lambda}(f_{11} + g_{11}), \\ a_1 c_1 (e^{\frac{\lambda}{c_1}} + e^{-\frac{\lambda}{c_1}}) + a_{21}e^{-\frac{\lambda}{c_2}}(-k_1 + c_2) + a_{22}e^{\frac{\lambda}{c_2}}(-k_1 - c_2) = \dfrac{c_1}{\lambda}(f_{12} + g_{12}) - k_1 f(1), \\ a_{i1}e^{-\frac{i\lambda}{c_i}} + a_{i2}e^{\frac{i\lambda}{c_i}} - a_{i+1,1}e^{-\frac{i\lambda}{c_{i+1}}} - a_{i+1,2}e^{\frac{i\lambda}{c_{i+1}}} = \dfrac{1}{\lambda}(f_{i1} + g_{i1}), \\ -a_{i1}c_i e^{-\frac{i\lambda}{c_i}} + a_{i2}c_i e^{\frac{i\lambda}{c_i}} + a_{i+1,1}e^{-\frac{i\lambda}{c_{i+1}}}(-k_i + c_{i+1}) + a_{i+1,2}e^{\frac{i\lambda}{c_{i+1}}}(-k_i - c_{i+1}) \\ \qquad = \dfrac{c_i}{\lambda}(f_{i2} + g_{i2}) - k_i f(i), \quad i = 2,\dots,N-1, \\ a_{N1}e^{-\frac{N\lambda}{c_N}} + a_{N2}e^{\frac{N\lambda}{c_N}} - a_{N+1}(e^{-\frac{\lambda}{c_{N+1}}} - e^{\frac{\lambda}{c_{N+1}}}) = \dfrac{1}{\lambda}(f_{N1} + g_{N1}), \\ -a_{N1}c_N e^{-\frac{N\lambda}{c_N}} + a_{N2}c_N e^{\frac{N\lambda}{c_N}} + a_{N+1}[e^{-\frac{\lambda}{c_{N+1}}}(-k_N - c_{N+1}) - e^{\frac{\lambda}{c_{N+1}}}(-k_N + c_{N+1})] \\ \qquad = \dfrac{c_N}{\lambda}(f_{N2} + g_{N2}) - k_N f(N), \end{cases} \tag{49}$$

where

$$
\begin{cases}
f_{i1} = \displaystyle\int_{i-1}^{i} \frac{e^{\frac{\lambda}{c_i}(i-s)} - e^{-\frac{\lambda}{c_i}(i-s)}}{2c_i}\lambda f(s)ds \\
\quad = \displaystyle\int_{0}^{1} \frac{e^{\frac{\lambda}{c_i}(1-s)} - e^{-\frac{\lambda}{c_i}(1-s)}}{2c_i}\lambda f(i-1+s)ds, \\
f_{i2} = \displaystyle\int_{i-1}^{i} \frac{e^{\frac{\lambda}{c_i}(i-s)} + e^{-\frac{\lambda}{c_i}(i-s)}}{2c_i}\lambda f(s)ds, \\
g_{i1} = \displaystyle\int_{i-1}^{i} \frac{e^{\frac{\lambda}{c_i}(i-s)} - e^{-\frac{\lambda}{c_i}(i-s)}}{2c_i} g(s)ds, \\
g_{i2} = \displaystyle\int_{i-1}^{i} \frac{e^{\frac{\lambda}{c_i}(i-s)} + e^{-\frac{\lambda}{c_i}(i-s)}}{2c_i} g(s)ds \\
\quad = \displaystyle\int_{0}^{1} \frac{e^{\frac{\lambda}{c_i}(1-s)} + e^{-\frac{\lambda}{c_i}(1-s)}}{2c_i} g(i-1+s)ds, \\
\qquad\qquad\qquad\qquad i = 1, 2, \ldots, N.
\end{cases} \tag{50}
$$

Consider the determinant of the coefficients matrix $\Delta(\lambda) = [\Delta_1(\lambda), \Delta_2(\lambda)]$, where

$$
\begin{cases}
\Delta_1(\lambda) = \begin{pmatrix}
e^{\frac{\lambda}{c_1}} - e^{-\frac{\lambda}{c_1}} & -e^{-\frac{\lambda}{c_2}} & -e^{\frac{\lambda}{c_2}} \\
c_1(e^{\frac{\lambda}{c_1}} + e^{-\frac{\lambda}{c_1}}) & (-k_1 + c_2)e^{-\frac{\lambda}{c_2}} & (-k_1 - c_2)e^{\frac{\lambda}{c_2}} \\
0 & e^{-\frac{2\lambda}{c_2}} & e^{\frac{2\lambda}{c_2}} \\
0 & -c_2 e^{-\frac{2\lambda}{c_2}} & c_2 e^{\frac{2\lambda}{c_2}} \\
\vdots & \vdots & \vdots \\
0 & 0 & 0
\end{pmatrix}, \\
\Delta_2(\lambda) = \begin{pmatrix}
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
-e^{-\frac{2\lambda}{c_3}} & -e^{\frac{2\lambda}{c_3}} & \cdots & 0 \\
(-k_2 + c_3)e^{-\frac{2\lambda}{c_3}} & (-k_2 - c_3)e^{\frac{2\lambda}{c_3}} & \cdots & 0 \\
\vdots & \vdots & \vdots & 0 \\
0 & 0 & \cdots & \theta
\end{pmatrix},
\end{cases} \tag{51}
$$

with $\theta = -e^{-\frac{\lambda}{c_{N+1}}}(k_N + c_{N+1}) + e^{\frac{\lambda}{c_{N+1}}}(k_N - c_{N+1})$. Taking $e^{\frac{\lambda}{c_1}}$ out of the first column, $e^{-\frac{\lambda}{c_2}}$ from the second column, $e^{2\frac{\lambda}{c_2}}$ from the third column of $\Delta(\lambda)$, and so on, we obtain

$$
\begin{aligned}
& e^{-\lambda\sum_{i=1}^{N+1}\frac{1}{c_i}} \det(\Delta(\lambda)) \\
& \quad = \det \begin{pmatrix}
1 & -1 & 0 & 0 & \cdots & 0 & 0 \\
c_1 & -k_1 + c_2 & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & 1 & -1 & \cdots & 0 & 0 \\
0 & 0 & c_2 & -k_2 + c_3 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & 1 & 1 \\
0 & 0 & 0 & 0 & \cdots & c_N & k_N - c_{N+1}
\end{pmatrix} + o(1) \\
& \quad = -\prod_{j=1}^{N}(-k_j + c_j + c_{j+1}) + o(1) \qquad \text{as } \mathrm{Re}\lambda \longrightarrow +\infty.
\end{aligned} \tag{52}
$$

Hence, if condition (28) holds, $\det(\Delta(\lambda))$ is an entire function not identical to zero. Additionally, when $\det(\Delta(\lambda)) \neq 0$, the system of equations (49) admits a solution $a_1, a_{N+1}, a_{i1}, a_{i2}, i = 2, \ldots, N$,

$$
\begin{cases}
a_1 = \dfrac{1}{\det(\Delta(\lambda))}\left[\displaystyle\sum_{i=1}^{N} \Delta_{2i-1,1}(\lambda)\frac{f_{i1}+g_{i1}}{\lambda} - \Delta_{2i,1}(\lambda)\left[\frac{c_i(f_{i2}+g_{i2})}{\lambda} - k_i f(i)\right]\right], \\
a_{N+1} \\
\quad = \dfrac{1}{\det(\Delta(\lambda))}\left[\displaystyle\sum_{i=1}^{N} -\Delta_{2i-1,2N}(\lambda)\frac{f_{i1}+g_{i1}}{\lambda} + \Delta_{2i,2N}(\lambda)\left[\frac{c_i(f_{i2}+g_{i2})}{\lambda} - k_i f(i)\right]\right], \\
a_{l1} \\
\quad = \dfrac{1}{\det(\Delta(\lambda))}\left[\displaystyle\sum_{i=1}^{N} -\Delta_{2i-1,2(l-1)}(\lambda)\frac{f_{i1}+g_{i1}}{\lambda} + \Delta_{2i,2(l-1)}(\lambda)\left[\frac{c_i(f_{i2}+g_{i2})}{\lambda} - k_i f(i)\right]\right], \\
a_{l2} \\
\quad = \dfrac{1}{\det(\Delta(\lambda))}\left[\displaystyle\sum_{i=1}^{N} \Delta_{2i-1,2l-1}(\lambda)\frac{f_{i1}+g_{i1}}{\lambda} - \Delta_{2i,2l-1}(\lambda)\left[\frac{c_i(f_{i2}+g_{i2})}{\lambda} - k_i f(i)\right]\right], \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad l = 2, \ldots, N,
\end{cases}
\tag{53}
$$

where $\Delta_{ij}(\lambda), 1 \leq i, j \leq 2N$, is the algebraic cofactor of ith row and jth column of the matrix $\Delta(\lambda)$.

From the discussion above and the Sobolev embedding theorem, we see that under the condition (28), for any $\lambda \in \rho(\mathcal{A})$, $(\lambda - \mathcal{A})^{-1}$ is compact and $(u, v) = (\lambda - \mathcal{A})^{-1}$ (f, g) is given by (48) with the coefficients $a_1, a_{N+1}, a_{i1}, a_{i2}, i = 2, 3, \ldots, N$, in (53). Therefore, the spectrum $\sigma(\mathcal{A})$ of $\mathcal{A}$ consists of isolated eigenvalues only, and $\lambda \in \sigma(\mathcal{A})$ if and only if $\det(\Delta(\lambda)) = 0$.

Moreover, it is seen from (48) and (53) that for any $\lambda \in \rho(\mathcal{A})$, $(\lambda - \mathcal{A})^{-1}$ is of the form

$$
(\lambda - \mathcal{A})^{-1}(f, g) = \frac{G(\lambda, (f, g))}{\det(\Delta(\lambda))} \qquad \forall\ (f, g) \in \mathcal{H}, \tag{54}
$$

where $G(\lambda, (f, g))$ is an $\mathcal{H}$-valued entire function with order at most 1. The order of $\det(\Delta(\lambda))$ is just 1 (see [25]).

Finally, simple computations show that the rank of the matrix $\Delta(\lambda)$ is less than its order by one. Hence, each eigenvalue of $\mathcal{A}$ is geometrically simple. □

THEOREM 3.4. *Under condition* (28)*, the root subspace of $\mathcal{A}$ is complete in H: $Sp(\mathcal{A}) = \mathcal{H}$.*

Proof. From Theorem 3.1, $\mathcal{A}$ generates a C_0-group and so does $\mathcal{A}^*$. Hence $R(\lambda, \mathcal{A}^*)$ is uniformly bounded along the negative real axis as $\lambda \to -\infty$. Notice that $(\overline{\lambda} - \mathcal{A}^*)^{-1}(f, g) = G^*(\lambda, (f, g))/\overline{\det(\Delta(\lambda))}$ $\forall\ (f, g) \in \mathcal{H}$, and the eigenvalues of $\mathcal{A}$ are symmetric about the real axis. Taking $\rho_2 = \rho = 1, n = 2, \gamma_1 = \{\lambda | \arg \lambda = \pi\}$, we see that all conditions of Theorem 4 of [24] are satisfied. The result follows. □

Finally, we go to the main result of this section: the Riesz basis generation of the root subspace of operator $\mathcal{A}$. Before doing this, we introduce the concept of a sine-type function.

Recall that an entire function f is called exponential type (see, e.g., [25]) if there are constants $C, D > 0$ such that

$$|f(z)| \leq Ce^{D|z|}$$

for all complex numbers z. The function of exponential type f is called *sine-type* if the following two conditions are satisfied [1, Definition II.1.27]:

(a) The zeros of f lie in a strip $\{z \in \mathbb{C} || \text{Im} z| \leq h\}$ for some $h > 0$.

(b) There are $c_1, c_2 > 0$, $y_0 \in \mathbb{R}$ such that for all $x \in \mathbb{R}$, $c_1 \leq |f(x + iy_0)| \leq c_2$.

The class of sine-type functions was first introduced in [11] to deal with problems of interpolation by entire functions and in studying Riesz basis in L^2 space. The distribution of the zeros of a sine-type function is given by the next important proposition (Proposition II.1.28 in [1]; see also [12]).

PROPOSITION 3.5. *Let f be a sine-type function. Its set of zeros (a multiple zero is repeated in a number of times equal to its multiplicity) is a finite unification of separable sets. Consequently, the multiplicities of zeros of sine-type functions are uniformly upper bounded.*

Now let

$$F(z) = \det(\Delta(z)). \tag{55}$$

Then the zeros of F consist of eigenvalues of $\mathcal{A}$. (However, the multiplicity as zero of F may be different from algebraic multiplicity as eigenvalue of $\mathcal{A}$.) Since $\mathcal{A}$ generates a C_0-group, all zeros of F lie in a strip parallel to the imaginary axis. From (51) and (52), it is seen that $F(iz)$ is a function of exponential type, and $|F(iz)|$ has positive lower and upper bound along a straight line parallel to the real axis in the lower half complex plane. Therefore, $F(iz)$ is a sine-type function. It then follows from Proposition 3.5 that the zeros of $F(iz)$ can be decomposed into a finite union of separable sets (accounted according to their multiplicity as zeros of F). Furthermore, since each $\lambda_n \in \sigma(\mathcal{A})$ is geometrically simple, the algebraic multiplicity of λ_n is equal to the order of $R(\lambda, \mathcal{A})$ at λ_n (see [15]), which is less than or equal to the multiplicity of λ_n as the zero of F by the decomposition (54). Therefore, from Proposition 3.5, we know that for all $\lambda_n \in \sigma(\mathcal{A})$ the algebraic multiplicity m_n of each is uniformly upper bounded:

$$\sup_{\lambda_n \in \sigma(\mathcal{A})} m_n < \infty. \tag{56}$$

Thus the eigenvalues of $\mathcal{A}$ can be decomposed into a finite union of separable sets (accounted according to their algebraic multiplicity as eigenvalues of $\mathcal{A}$):

$$\text{eigenvalues of } \mathcal{A} = \Lambda = \bigcup_{n=1}^{N} \Lambda_n, \qquad \inf_{i \neq j, \lambda_i, \lambda_j \in \Lambda_n} |\lambda_i - \lambda_j| > 0 \quad \forall\, 1 \leq n \leq N. \tag{57}$$

Let $\delta = \min_{1 \leq n \leq N} \inf_{i \neq j, \lambda_i, \lambda_j \in \Lambda_n} |\lambda_i - \lambda_j| > 0$. Then for any $r < r_0 = \delta/(2N)$, by the discussion in section 2, there exist $\Lambda^p = \{\lambda_{j,p}\}_{j=1}^{M^p}, M^p \leq N, p \in \mathbb{Z}$, the pth connected component of intersection of Λ with $\bigcup_{n \in \mathbb{Z}} D_{\lambda_n}(r)$, where $D_{\lambda_n}(r)$ is the circle centered at λ_n with radius r such that

$$\sigma(A) = \bigcup_{p \in \mathbb{Z}} \Lambda^p. \tag{58}$$

We may assume without loss of generality that $\{\lambda_n\}$ are arranged so that $\mathrm{Im}\lambda_n$ are nondecreasing and $\mathrm{Re}\lambda_{1,p} \geq \mathrm{Re}\lambda_{2,p} \geq \cdots \geq \mathrm{Re}\lambda_{M^p,p}$. Form a family of GDD as follows:

$$E^p(\Lambda, r) = \{[\lambda_{1,p}](t), [\lambda_{1,p}, \lambda_{2,p}](t), \ldots, [\lambda_{1,p}, \lambda_{2,p}, \ldots, \lambda_{M^p,p}](t)\}, \quad p \in \mathbb{Z}.$$

It is seen from (4) that $D^+(\Lambda) < \infty$. From Proposition 2.3, for any $T > 2\pi D^+(\Lambda)$, the family of GDD $\{E^p(\Lambda, r)\}_{p\in\mathbb{Z}}$ forms a Riesz basis in the closed subspace spanned by itself in $L^2(0,T)$. Specifically, suppose that each $\Lambda^p = \{\lambda_j^p\}_1^{N^p}$ has N^p different elements and that each appears m_{pj} times, $\sum_{j=1}^{N^p} m_{pj} = M^p$. Since $M^p \leq N$, all conditions of Theorem 2.5 are satisfied. We thus have proved the following result on the Riesz basis generation of the root subspace of $\mathcal{A}$.

THEOREM 3.6. *Under condition* (28)*, the operator* $\mathcal{A}$ *defined by* (25) *and* (26) *has the following properties:*

(a) *There exists* $\epsilon > 0$ *such that* $\sigma(\mathcal{A}) = \bigcup_{p\in\mathbb{Z}}\{\lambda_i^p\}_{i=1}^{N^p}$ *(the multiplicity is not accounted), where* $\sup_p N^p < \infty$, $|\lambda_i^p - \lambda_j^q| \geq \epsilon\ \forall p, q \in \mathbb{Z},\ p \neq q, 1 \leq i \leq N^p$, $1 \leq j \leq N^q$.

(b) *The algebraic multiplicity* m_{pi} *of* $\lambda_i^p \in \sigma(A)$ *is uniformly upper bounded:*

$$\sup_{p\in\mathbb{Z}, 1\leq i\leq N^p} m_{pi} < \infty.$$

(c)

$$Y = \sum_{p\in\mathbb{Z}} \sum_{i=1}^{N^p} \mathbb{P}_{\lambda_i^p} Y \qquad \forall\, Y \in \mathcal{H}, \tag{59}$$

where $\mathbb{P}_{\lambda_i^p}$ *is the eigen-projection of* $\mathcal{A}$ *corresponding to* λ_i^p.

(d) *There are constants* $M_1, M_2 > 0$ *such that*

$$M_1 \sum_{p\in\mathbb{Z}} \left\| \sum_{i=1}^{N^p} \mathbb{P}_{\lambda_i^p} Y \right\|^2 \leq \|Y\|^2 \leq M_2 \sum_{p\in\mathbb{Z}} \left\| \sum_{i=1}^{N^p} \mathbb{P}_{\lambda_i^p} Y \right\|^2 \qquad \forall\, Y \in \mathcal{H}. \tag{60}$$

(e) *The spectrum-determined growth condition holds:*

$$\omega(\mathcal{A}) = S(\mathcal{A}).$$

Remark 3.7. Assertion (e) in Theorem 3.6 was proved in [14], [16] by completely different arguments, while in this article it becomes an immediate consequence of Riesz basis generation. It should be mentioned that if condition (28) is not satisfied, there may be cases like $\sigma(\mathcal{A}) = \emptyset$ when, e.g., $N = 1, c_1 = c_2 = 2, k_1 = 4$. In this case, we certainly could not talk about a Riesz basis. Finally, we point out that the method presented in this paper can be applied to system (23) with different boundary conditions as well.

The property expressed by (59) and (60) is nothing other than the *Riesz basis with parentheses* [20]. Further, if we know that the eigenvalues of $\mathcal{A}$ are separable, the Riesz basis with parentheses reduces the usual Riesz basis. Unfortunately, it is not clear whether or not separability holds.

FINITE TIME STABILITY AND ROBUST CONTROL SYNTHESIS OF UNCERTAIN SWITCHED SYSTEMS*

Y. ORLOV†

Abstract. Stability analysis is developed for uncertain nonlinear switched systems. While being asymptotically stable and homogeneous of degree $q < 0$, these systems are shown to approach the equilibrium point in finite time. Restricted to second order systems, this feature is additionally demonstrated to persist regardless of inhomogeneous perturbations. Based on this fundamental property, switched control algorithms are then developed to globally stabilize uncertain minimum phase systems of uniform m-vector relative degree $(2, \dots, 2)^T$. The controllers constructed do not rely on the generation of sliding motions while providing robustness features similar to those possessed by their sliding mode counterparts. The proposed synthesis procedure is illustrated via application to a friction servo-motor.

Key words. robust stability, nonautonomous switched system, homogeneity, finite time stabilization

1. Introduction.

Finite time stability of asymptotically stable homogeneous systems has been well recognized for only continuous vector fields [16]. Extending this result to switched systems presents a formidable problem and requires proceeding differently because a smooth homogeneous Lyapunov function, whose existence was proven in [27] for continuous asymptotically stable homogeneous vector fields, can no longer be brought into play.

In the present work the finite time stability property is established for homogeneous asymptotically stable switched systems of homogeneity degree $q < 0$. Exemplified with a second order system, the finite time stability is additionally demonstrated to remain in force regardless of inhomogeneous perturbations. This fundamental property forms a basis for subsequent robust synthesis of globally stabilizing controllers of uncertain nonlinear minimum phase systems of uniform m-vector relative degree $(2, \dots, 2)^T$ (see [9] for the relative degree concept).

The strategy of the discontinuous controllers constructed is to drive the system to the zero dynamics manifold in finite time and maintain it there in spite of the parameter uncertainties and external disturbances, both with a priori known norm bounds. Desired robustness properties are thus provided and asymptotic stability of the closed-loop system is guaranteed.

The sliding mode control technique has long been recognized as a powerful control method to counteract nonvanishing external disturbances and unmodelled dynamics [32, 33]. In contrast to this standard technique, the present synthesis does not rely on the generation of sliding modes, while exhibiting an infinite number of switches on a finite time interval. This phenomenon, called the Fuller phenomenon, is now fully understood from optimal control theory [13, 34] where it has been extensively exploited for higher (greater than 1) relative degree systems to attain optimal

performance. A controller which exhibits the Fuller phenomenon is referred to as a chattering controller [34] that has become standard in the literature.

Typically, optimal chattering controllers appear to minimize a degenerate quadratic criterion, viewed over an infinite horizon under instant control constraints and dependent upon the output of the system. Due to this, the input-output stability property is only guaranteed while admitting instability of the overall system. In order to ensure asymptotic stability of the closed-loop system, suboptimal (twisting, supertwisting, and others) chattering control algorithms, also referred to as second order sliding mode control algorithms, have subsequently been developed for SISO (Single Input-Single Output) systems (see the very recent survey [12] and references therein). While retaining useful robustness features against matching disturbances, these algorithms have greatly reduced undesired high-frequency oscillations of the closed-loop system compared to those caused by their standard sliding mode counterparts (see [3, 4] for further details).

Until recently, attempts to extend the aforementioned algorithms to MIMO (Multi Input-Multi Output) systems were hampered by the lack of suitable analysis tools for switched systems and, consequently, the lack of consistent control synthesis methodology. In the present work chattering control synthesis is constructively developed for uncertain nonlinear MIMO systems, regardless of whether the optimal performance is achieved. To facilitate the exposition, the model chosen for treatment is confined to that of uniform m-vector relative degree $(2, \dots, 2)^T$. A possible extension of chattering control synthesis to MIMO systems of higher relative degree does not seem trivial and is beyond the scope of the paper.

Attractive features of the chattering controllers proposed are illustrated by application to finite time stabilization of a servo-motor. It should be noted that allowing relatively strong Coulomb friction in this application precludes the use of continuous regulators. Indeed, the closed-loop system in that case would have a nontrivial set of equilibrium points and it would therefore be driven to a wrong endpoint. As opposed to continuous controllers, the chattering controllers are demonstrated to be capable of providing the desired system performance in spite of significant uncertainties in the system description as is typically the case in control of electromechanical systems with complex backlash/friction phenomena.

The paper is organized as follows. Basic definitions are given in section 2. Finite time stability of nonautonomous switched systems is proven in section 3. Perturbation analysis of second order homogeneous switched systems is developed in section 4. Chattering control synthesis and its interpretation in an electromechanical application are proposed in section 5. Finally, section 6 presents some conclusions.

2. Basic definitions. The model of a nonautonomous switched system in question is given by

$$\dot{x} = \varphi(x, t), \tag{2.1}$$

where $x = (x_1, \dots, x_n)^T$ is the state vector, $t \in \mathbf{R}$ is the time variable, and the function $\varphi = (\varphi_1, \dots, \varphi_n)^T$ is piece-wise continuous. Recall that the function $\varphi : \mathbf{R}^{n+1} \to \mathbf{R}^n$ is piece-wise continuous iff $\mathbf{R}^{n+1}$ is partitioned into a finite number of domains $G_j \subset \mathbf{R}^{n+1}$, $j = 1, \dots, N$, with disjoint interiors and boundaries ∂G_j of measure zero such that φ is continuous within each of these domains and for all $j = 1, \dots, N$ it has a finite limit $\varphi^j(x, t)$ as the argument $(x^*, t^*) \in G_j$ approaches a boundary point $(x, t) \in \partial G_j$.

Throughout, the precise meaning of the differential equation (2.1) with a piecewise continuous right-hand side is defined in the sense of Filippov [10].

DEFINITION 2.1. *Given the differential equation* (2.1) *let us introduce for each point* $(x,t) \in \mathbf{R}^n \times \mathbf{R}$ *the smallest convex closed set* $\Phi(x,t)$ *which contains all the limit points of* $\varphi(x^*,t)$ *as* $x^* \to x$, $t = const$, *and* $(x^*,t) \in \mathbf{R}^{n+1} \setminus (\cup_{j=1}^N \partial G_j)$. *An absolutely continuous function* $x(\cdot)$, *defined on an interval* I, *is said to be a solution of* (2.1) *if it satisfies the differential inclusion*

$$\dot{x} \in \Phi(x,t) \tag{2.2}$$

almost everywhere on I.

By Theorem 8 of [10, p. 85], system (2.1) has a solution for arbitrary initial conditions $x(t_0) = x^0 \in \mathbf{R}^n$. This solution is locally defined on some time interval $[t_0, t_1)$; however, generally speaking it is nonunique.

It is worth noticing that the above model (2.1) admits a sliding motion on the boundary set $\mathcal{N} = \bigcup_{j=1}^N \partial G_j$ with an infinite number of switches on a finite time interval. Thus, a larger class of switched systems is captured in comparison to that of [8, 22, 23] where infinitely fast switching is explicitly ruled out.

Along with the differential equation (2.1), we deal with its perturbed version

$$\dot{x} = \varphi(x,t) + \psi(x,t), \tag{2.3}$$

where ψ is a piece-wise continuous function whose components $\psi_i, \dots, \psi_n$ are locally uniformly bounded within a ball B_δ, centered at the origin with radius δ; i.e.,

$$|\psi_i(x,t)| \le M_i, \quad i = 1, \dots, n, \tag{2.4}$$

for almost all $(x,t) \in B_\delta \times \mathbf{R}$ and some constants $M_i \ge 0$, fixed a priori. The above equation is further viewed as a differential equation with rectangular uncertainties. A solution concept for such an uncertain differential equation is introduced as follows.

DEFINITION 2.2. *An absolutely continuous function* $x(\cdot)$, *defined on an interval* I, *is said to be a solution of the uncertain differential equation* (2.3) *with the rectangular uncertainty constraints* (2.4) *iff it is a solution of* (2.3) *on the interval* I *in the sense of Definition* 2.1 *for some piece-wise continuous function* ψ *subject to* (2.4).

As a matter of fact, the differential equation (2.1) with no uncertain term ψ is particularly represented in the form of (2.3), (2.4) with $M_i = 0$ for all $i = 1, \dots, n$.

It should be pointed out that an uncertain system (2.3) with uncertainty constraints (2.4) can be represented as a differential inclusion of the form

$$\dot{x} \in \Phi(x,t) + \Psi, \tag{2.5}$$

where $\Phi(x,t)$ is the same as it appears in Definition 2.1, Ψ is the Cartesian product of the intervals $\Psi_i = [-M_i, M_i]$, $i = 1, \dots, n$, and the set

$$\Phi(x,t) + \Psi = \{\phi + \psi : \phi \in \Phi(x,t),\ \psi \in \Psi\}.$$

If $\varphi(x,t) = \varphi(x)$ is time-independent, the uncertain system (2.3), (2.4) is governed by the autonomous differential inclusion (2.5), in spite of the presence of the uncertain time-varying term $\psi(x,t)$.

Stability of a switched system (2.1) with possibly nonuniquely defined trajectories and stability of an uncertain system (2.3), (2.4) to be uniform in the uncertainty are introduced by means of the corresponding differential inclusion. In turn, stability of

a differential inclusion (2.2) is defined as follows. Suppose $x = 0$ is an equilibrium point of the differential inclusion (2.2) and $x(\cdot, t_0, x^0)$ denotes a solution $x(\cdot)$ of (2.2) under the initial conditions $x(t_0) = x^0$.

DEFINITION 2.3. *The equilibrium point $x = 0$ of the differential inclusion* (2.2) *is stable* (*uniformly stable*) *iff for each $t_0 \in \mathbf{R}$, $\varepsilon > 0$, there is $\delta = \delta(\varepsilon, t_0) > 0$, dependent on ε and possibly dependent on t_0* (*respectively, independent of t_0*) *such that each solution $x(\cdot, t_0, x^0)$ of* (2.2) *with the initial data $x^0 \in B_\delta$ exists on the semi-infinite time interval $[t_0, \infty)$ and satisfies the inequality*

$$\|x(t, t_0, x^0)\| < \varepsilon \quad \textit{for all } t \in [t_0, \infty).$$

DEFINITION 2.4. *The equilibrium point $x = 0$ of the differential inclusion* (2.2) *is said to be* (*uniformly*) *asymptotically stable if it is* (*uniformly*) *stable and the convergence*

$$\lim_{t \to \infty} \|x(t, t_0, x^0)\| = 0 \tag{2.6}$$

holds for all solutions of (2.2) *initialized within some B_δ* (*uniformly in the initial data t_0 and x^0, and all the solutions $x(\cdot, t_0, x^0)$*). *If the above convergence remains in force for all solutions of* (2.2) *regardless of the choice of the initial data* (*and, respectively, for each $\delta > 0$ the convergence is uniform in t_0 and $x^0 \in B_\delta$, and all $x(\cdot, t_0, x^0)$*), *the equilibrium point is said to be globally* (*uniformly*) *asymptotically stable.*

DEFINITION 2.5. *The equilibrium point $x = 0$ of the differential inclusion* (2.2) *is said to be globally* (*uniformly*) *finite time stable if, in addition to the global* (*uniform*) *asymptotical stability, the limiting relation*

$$x(t, t_0, x^0) = 0 \tag{2.7}$$

holds for each solution $x(\cdot, t_0, x^0)$ and all $t \geq t_0 + T(t_0, x^0)$, where the settling time function

$$T(t_0, x^0) = \sup_{x(\cdot, t_0, x^0)} \inf\{T \geq 0 : x(t, t_0, x^0) = 0 \textit{ for all } t \geq t_0 + T\} \tag{2.8}$$

is such that

$$T(t_0, x^0) < \infty \quad \textit{for all } t_0 \in \mathbf{R} \textit{ and } x^0 \in \mathbf{R}^n$$

(*respectively,* $\mathcal{T}(B_\delta) = \sup_{t_0 \in \mathbf{R},\, x^0 \in B_\delta} T(t_0, x^0) < \infty$ *for each* $\delta > 0$).

In application to the uncertain system (2.3), (2.4) the above definitions are specified as follows. In order to emphasize that these definitions require such a system to be uniformly stable not only in the initial data but also in the uncertainty, the corresponding system will be referred to as equiuniformly stable. Suppose that $x = 0$ is an equilibrium point of the uncertain system (2.3), (2.4) (i.e., $x = 0$ is a solution of (2.3) for some function ψ_0, admissible in the sense of (2.4)) and let $x_\psi(\cdot, t_0, x^0)$ denote a solution $x(\cdot)$ of (2.2) for some admissible function ψ under the initial conditions $x(t_0) = x^0$.

DEFINITION 2.6. *The equilibrium point $x = 0$ of the uncertain system* (2.3), (2.4) *is equiuniformly stable iff for each $t_0 \in \mathbf{R}$, $\varepsilon > 0$, there is $\delta = \delta(\varepsilon) > 0$, dependent on ε and independent of t_0 and ψ, such that each solution $x_\psi(\cdot, t_0, x^0)$ of* (2.3), (2.4) *with the initial data $x^0 \in B_\delta$ exists on the semi-infinite time interval $[t_0, \infty)$ and satisfies the inequality*

$$\|x_\psi(t, t_0, x^0)\| < \varepsilon \quad \textit{for all } t \in [t_0, \infty).$$

DEFINITION 2.7. *The equilibrium point $x = 0$ of the uncertain system* (2.3), (2.4) *is said to be equiuniformly asymptotically stable if it is equiuniformly stable and the convergence*

$$\lim_{t\to\infty} \|x_\psi(t, t_0, x^0)\| = 0 \tag{2.9}$$

holds for all solutions of (2.3), (2.4) *initialized within some B_δ, uniformly in the initial data t_0 and x^0, and all the solutions $x_\psi(\cdot, t_0, x^0)$. If this convergence remains in force for each $\delta > 0$, the equilibrium point is said to be globally equiuniformly asymptotically stable.*

DEFINITION 2.8. *The equilibrium point $x = 0$ of the uncertain system* (2.3), (2.4) *is said to be globally equiuniformly finite time stable if, in addition to the global equiuniform asymptotical stability, the limiting relation*

$$x_\psi(t, t_0, x^0) = 0 \tag{2.10}$$

holds for each solution $x_\psi(\cdot, t_0, x^0)$ and all $t \geq t_0 + T(t_0, x^0)$, where the settling time function

$$T(t_0, x^0) = \sup_{x_\psi(\cdot, t_0, x^0)} \inf\{T \geq 0 : x_\psi(t, t_0, x^0) = 0 \quad \textit{for all } t \geq t_0 + T\} \tag{2.11}$$

is such that

$$\mathcal{T}(B_\delta) = \sup_{t_0\in\mathbf{R},\, x^0\in B_\delta} T(t_0, x^0) < \infty \quad \textit{for each } \delta > 0.$$

In the present paper, we focus our analysis on the global equiuniform finite time stability of switched systems. The concept of homogeneity, studied earlier in [15, 35] and [27] for continuously differentiable and, respectively, continuous vector fields, plays a central role in our analysis. This concept is now generalized for differential inclusions and, particularly, for nonautonomous switched systems.

DEFINITION 2.9. *The differential inclusion* (2.2) (*the differential equation* (2.1) *or the uncertain system* (2.3), (2.4)) *is called locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$, where $r_i > 0$, $i = 1, \dots, n$, if there exist a constant $c_0 > 0$, called a lower estimate of the homogeneity parameter, and a ball $B_\delta \subset \mathbf{R}^n$, called a homogeneity ball, such that any solution $x(\cdot)$ of* (2.2) (*respectively, that of* (2.1) *or* (2.3), (2.4)), *evolving within the ball B_δ, generates a parameterized set of solutions $x^c(\cdot)$ with components*

$$x_i^c(t) = c^{r_i} x_i(c^q t) \tag{2.12}$$

and parameter $c \geq c_0$.

DEFINITION 2.10. *A piece-wise continuous function $\varphi : \mathbf{R}^{n+1} \to \mathbf{R}^n$ is called locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$, where $r_i > 0$, $i = 1, \dots, n$, if there exist a constant $c_0 > 0$ and a ball $B_\delta \subset \mathbf{R}^n$ such that*

$$\varphi_i(c^{r_1} x_1, \dots, c^{r_n} x_n, c^{-q} t) = c^{q+r_i} \varphi_i(x_1, \dots, x_n, t) \tag{2.13}$$

for all $c \geq c_0$ and almost all $(x, t) \in B_\delta \times \mathbf{R}$.

The global homogeneity concept for the differential inclusion (2.2) and that for the piece-wise continuous function φ are formally introduced by setting $\delta = \infty$ in the above definitions.

It is worth noting that Definitions 2.9 and 2.10 are consistent in the sense that homogeneity of the function φ ensures homogeneity of the corresponding differential equation (2.1).

LEMMA 2.11. *Let a piece-wise continuous function φ be locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$. Then the corresponding differential equation* (2.1) *is locally homogeneous of the same degree $q \in \mathbf{R}$ with respect to the same dilation $(r_1, \dots, r_n)$.*

Proof. Let $x(\cdot)$ be a solution of (2.1), evolving within B_δ. Then it is straightforward to verify that due to (2.13), the function $x^c(\cdot)$ with components (2.12) is also a solution of (2.1) for all $c \geq c_0$. Thus, the differential equation (2.1), whose right-hand side is locally homogeneous in the sense of Definition 2.10, is also locally homogeneous in the sense of Definition 2.9. Lemma 2.11 is proved. □

To this end, we present conditions for the uncertain system (2.3), (2.4) to be locally homogeneous.

LEMMA 2.12. *Let the following conditions be satisfied:*

1. *a piece-wise continuous function φ is locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$;*
2. *components ψ_i, $i = 1, \dots, n$, of a piece-wise continuous function ψ are locally uniformly bounded by constants $M_i \geq 0$;*
3. *$M_i = 0$ whenever $q + r_i > 0$.*

Then the uncertain differential equation (2.3) *with the uncertainty constraints* (2.4) *is locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$.*

Proof. Let $x(\cdot) = (x_1(\cdot), \dots, x_n(\cdot))^T$ be a solution of (2.3) under some piece-wise continuous function ψ, satisfying (2.4), and let $x(\cdot)$ evolve within a ball B_δ where the homogeneity condition (2.13) holds almost everywhere for all $c \geq c_0$. Then it is straightforward to verify that for arbitrary $c \geq \max(1, c_0)$ the function $x^c(\cdot)$ with components $x_i^c(t) = c^{r_i} x_i(c^q t)$, $i = 1, \dots, n$, is a solution of (2.3) with the piece-wise continuous function $\psi = \psi^c$ whose components are as follows:

$$\psi_i^c(x, t) = c^{q+r_i} \psi_i(c^{-r_1} x_1, \dots, c^{-r_n} x_n, c^q t).$$

Since by condition 3 of the lemma one has $c^{q+r_i} \leq 1$ whenever $M_i > 0$, the function ψ^c is also admissible in the sense of (2.4).

Thus, any solution of the uncertain differential equation (2.3), evolving within a homogeneity ball B_δ, generates a parameterized set of solutions $x^c(t)$ with the parameter c large enough. Hence, (2.3), (2.4) is locally homogeneous of degree $q \in \mathbf{R}$ with respect to dilation $(r_1, \dots, r_n)$. Lemma 2.12 is proved. □

3. Finite time stability of homogeneous systems. Finite time stability of continuous autonomous systems has recently been studied in [7]. When continuous, a globally homogeneous time-invariant vector field $\varphi(x)$ of degree $q < 0$ with respect to dilation $(r_1, \dots, r_n)$ is known to be globally finite time stable whenever it is globally asymptotically stable. The proof of this fact, given in [16], is based on the result from [27] that an autonomous continuous homogeneous system, if asymptotically stable, possesses a homogeneous Lyapunov function. However, the existence of a homogeneous Lyapunov function is no longer guaranteed for systems governed by differential inclusions (even the converse of Lyapunov's second theorem has not been successfully extended to this case). Therefore, the global finite time stability of these systems is established by going through a different route, which is closely related to rescaling of the time and state variables.

Going through this route allows one to additionally obtain an upper estimate

$$T(t_0, x^0) \le \tau(x^0, E_R) + \frac{1}{1-2^q}(\delta R^{-1})^q s(\delta) \tag{3.1}$$

of the settling-time function (2.8) via the reaching-time functions

$$\tau(x^0, E_R) = \sup_{x(\cdot, t_0, x^0)} \inf\{T \ge 0 : x(t, t_0, x^0) \in E_R \text{ for all } t_0 \in \mathbf{R},\ t \ge t_0 + T\} \tag{3.2}$$

and

$$s(\delta) = \sup_{x^0 \in E_\delta} \tau(x^0, E_{\frac{1}{2}\delta}), \tag{3.3}$$

where E_R denotes an ellipsoid of the form

$$E_R = \left\{ x \in \mathbf{R}^n : \sqrt{\sum_{i=1}^{n} \left(\frac{x_i}{R^{r_i}}\right)^2} \le 1 \right\}, \tag{3.4}$$

E_R is located within a homogeneity ball, $\delta \ge c_0 R$, and $c_0 > 0$ is a lower estimate of the homogeneity parameter.

THEOREM 3.1. *Let the differential inclusion* (2.2) *be locally homogeneous of degree* $q < 0$ *with respect to dilation* $(r_1, \dots, r_n)$ *and let the equilibrium point* $x = 0$ *of* (2.2) *be globally uniformly asymptotically stable. Then the differential inclusion* (2.2) *is globally uniformly finite time stable, and an upper estimate of the settling-time function* (2.8) *is given by* (3.1).

Proof. Due to the global uniform asymptotic stability of (2.2), all the trajectories of the differential inclusion, initialized within a compact set, are uniformly steered toward an arbitrarily small ellipsoid (3.4). Then the condition

$$x(t) \in E_R \quad \text{for } t \ge t_0 + \tau(x^0, E_R) \tag{3.5}$$

holds for an arbitrary solution $x(\cdot)$ of (2.2) initialized with $x(t_0) = x^0$, where the ellipsoid E_R has been assumed to be small enough to be located within a homogeneity ball.

Furthermore, given an a priori fixed $\delta \ge c_0 R$, where $c_0 > 0$ is a lower estimate of the homogeneity parameter, there exists $s(\delta) > 0$ such that for each initial time moment $\tilde{t}_0$ and all the solutions $\tilde{x}(\cdot)$ with $\tilde{x}(\tilde{t}_0) \in E_\delta$ one has $\tilde{x}(t) \in E_{\frac{1}{2}\delta}$ for $t \ge \tilde{t}_0 + s(\delta)$. Since the function $x^c(\cdot)$, whose components (2.12) are specified with $c = \delta R^{-1} \ge c_0$, is a solution of (2.2) by homogeneity, and, in addition, $x^c(\tilde{t}_0) \in E_\delta$ at $\tilde{t}_0 = c^{-q}(t_0 + \tau(x^0, E_R))$, it follows that

$$x^c(t) \in E_{\frac{1}{2}\delta} \quad \text{for } t \ge c^{-q}(t_0 + \tau(x^0, E_R)) + s(\delta). \tag{3.6}$$

The latter relation, rewritten in terms of $x(t)$ by means of (2.12) subject to $c = \delta R^{-1}$, is represented as follows:

$$x(t) \in E_{\frac{1}{2}R} \quad \text{for } t \ge t_1 = t_0 + \tau(x^0, E_R) + (\delta R^{-1})^q s(\delta). \tag{3.7}$$

Now, by applying the same derivation to a solution of (2.2) with $x(t_1) \in E_{\frac{1}{2}R}$, one obtains

$$x(t) \in E_{\frac{1}{4}R} \quad \text{for } t \ge t_2 = t_1 + 2^q(\delta R^{-1})^q s(\delta). \tag{3.8}$$

In general, the following relations are derived:

$$x(t) \in E_{2^{-(i+1)}R} \quad \text{for } t \geq t_{i+1} = t_i + 2^{qi}(\delta R^{-1})^q s(\delta),\ i = 1, 2, \dots, \tag{3.9}$$

by iterating on i. Since $\lambda = 2^q < 1$ by virtue of $q < 0$, the convergence of the time instants t_k, $k = 1, 2, \dots$, to a finite limit takes place:

$$\begin{aligned} \lim_{k\to\infty} t_k &= t_0 + \tau(x^0, E_R) + \lim_{k\to\infty} \sum_{i=0}^{k-1} \lambda^i (\delta R^{-1})^q s(\delta) \\ &= t_0 + \tau(x^0, E_R) + \lim_{k\to\infty} \frac{1-\lambda^k}{1-\lambda} (\delta R^{-1})^q s(\delta) \\ &= t_0 + \tau(x^0, E_R) + \frac{1}{1-\lambda} (\delta R^{-1})^q s(\delta) < \infty. \end{aligned} \tag{3.10}$$

Hence, relations (3.9) result in

$$x(t) \in \bigcap_{i=1}^{\infty} E_{2^{-i}R} = \{0\} \quad \text{for } t \geq t_0 + \tau(x^0, E_R) + \frac{1}{1-2^q} (\delta R^{-1})^q s(\delta), \tag{3.11}$$

thereby establishing both the required finite time convergence property for the locally homogeneous differential inclusion (2.2) and the upper estimate (3.1) of the settling-time function (2.8). Theorem 3.1 is thus proved. □

Remark 1. For a globally homogeneous differential inclusion (2.2) one can choose $\delta_0 = c_0 R_0$ and R_0 sufficiently large to guarantee that $x(t, t_0, x^0) \in E_{R_0}$ for all $t \geq t_0$. Then $\tau(x^0, E_{R_0}) = 0$, and the upper estimate (3.1) of the settling-time function (2.8) is simplified to

$$T(t_0, x^0) \leq \frac{c_0^q}{1-2^q} s(\delta_0) \tag{3.12}$$

with $\delta_0 = \delta_0(x^0)$ dependent on x_0.

An important corollary of Theorem 3.1 is obtained if the differential inclusion (2.2) is generated by an uncertain differential equation (2.3) with piece-wise continuous functions φ and ψ, which are locally homogeneous and locally uniformly bounded, respectively.

THEOREM 3.2. *Let the following conditions be satisfied:*

1. *the right-hand side of an uncertain differential equation* (2.3) *consists of a locally homogeneous piece-wise continuous function φ of degree $q < 0$ with respect to dilation $(r_1, \dots, r_n)$ and a piece-wise continuous function ψ whose components ψ_i, $i = 1, \dots, n$, are locally uniformly bounded by constants $M_i \geq 0$ within a homogeneity ball;*
2. *$M_i = 0$ whenever $q + r_i > 0$;*
3. *the uncertain system* (2.3), (2.4) *is globally equiuniformly asymptotically stable around the origin.*

Then the uncertain system (2.3), (2.4) *is globally equiuniformly finite time stable and its settling-time function* (2.11) *is estimated as* (3.1).

Proof. By Lemma 2.12, conditions 1 and 2 of the theorem guarantee that the uncertain system (2.3), (2.4) is locally homogeneous of degree $q < 0$ with respect to dilation $(r_1, \dots, r_n)$. Thus, coupled to condition 3 of the theorem, these conditions ensure that Theorem 3.1 is applicable to the uncertain system (2.3), (2.4). By applying Theorem 3.1 to this system, the proof of Theorem 3.2 is completed. □

Apparently, Remark 1 remains valid for an uncertain system (2.3), (2.4), the right-hand side of which consists of a globally homogeneous piece-wise continuous function φ of degree $q < 0$ and a globally uniformly bounded piece-wise continuous function ψ.

4. Stability analysis of uncertain second order systems. The aim of this section is to illustrate, by means of a simple example, that the finite time stability of an autonomous switched system remains in force regardless of some nonlinear time-varying perturbations.

A second order switched system of the form

$$\dot{x} = y, \quad \dot{y} = -a \operatorname{sign} x - b \operatorname{sign} y \tag{4.1}$$

is presently under study. Due to the discontinuous functions $\operatorname{sign} x$ and $\operatorname{sign} y$ that appear in the right-hand side of (4.1), solutions of this system are defined in the Filippov sense. By Definition 2.1, these solutions do not depend on how the discontinuous functions are specified on the switching lines, which is why there is no need to specify the function sign at 0.

System (4.1) turns out to be globally uniformly finite time stable if the inequalities

$$a > b > 0 \tag{4.2}$$

hold for the parameters of the system.

THEOREM 4.1. *Let the parameters of the switched system* (4.1) *be such that condition* (4.2) *is satisfied. Then system* (4.1) *is globally uniformly finite time stable around the origin.*

Proof. First, let us note that no motion appears on the axes $x = 0$ and $y = 0$ except the origin $x = y = 0$, which proves to be the only equilibrium point of the switched system (4.1). Indeed, if $x(t) = 0$ on a trajectory of (4.1), then it follows from the first equation of (4.1) that $y(t) = 0$ along the trajectory. In turn, if $y(t) = 0$ on a trajectory of (4.1), then due to the parameter subordination (4.2), the second equation of (4.1) fails to hold for $x \neq 0$.

Next, let us prove that system (4.1) is globally uniformly asymptotically stable. For this purpose, let us introduce the function $V(x, y) = a|x| + \frac{1}{2}y^2$, which is Lipschitz continuous, radially unbounded, and positive definite. The time derivative $\dot{V}(x(t), y(t))$ of the composite function $V(x(t), y(t))$, computed along the trajectories of system (4.1), is as follows:

$$\dot{V}(x(t), y(t)) = -b|y(t)| \tag{4.3}$$

everywhere but on the vertical axis y where $x = 0$ and the function $V(x, y)$ is not differentiable. Since no sliding motion appears on the vertical axis except the origin $x = y = 0$, where $\dot{V}(x(t), y(t)) = 0$, relation (4.3) remains in force for almost all t.

As mentioned before, the trajectories of (4.1) cross the switching lines $x = 0$ and $y = 0$ everywhere except the origin $x = y = 0$ so that all the system trajectories are uniquely continuable on the right. Hence, the extended version [1, 28] of Krasovskii–LaSalle's invariance principle [17, 18, 19] is applicable to the switched system (4.1). Since the equilibrium point $x = y = 0$ is the only trajectory of (4.1) on the invariance manifold $y = 0$ where $\dot{V}(x(t), y(t)) = 0$, this system is globally uniformly asymptotically stable by the aforementioned extension of the invariance principle.

Moreover, it is straightforwardly verified that the right-hand side of system (4.1) is globally homogeneous of degree $q = -1$ with respect to dilation $(2, 1)$. By applying Theorem 3.1 it follows that the autonomous switched system (4.1) is globally uniformly finite time stable around the origin. Theorem 4.1 is proved. □

Remark 2. It is of interest to note that under the parameter subordination

$$b \geq a > 0, \tag{4.4}$$

opposite to (4.2), system (4.1) is not even asymptotically stable. Indeed, the velocity vectors in the case of (4.4) are normal to and directed toward each other while approaching the horizontal axis x from different sides. By Definition 2.1, it follows that the trajectories of (4.1) cannot leave this axis. Thus, the horizontal axis consists of equilibrium points of system (4.1), which is why (4.1) is not asymptotically stable.

Along with system (4.1), we shall also study its nonlinear time-varying perturbation of the form

$$\dot{x} = y, \quad \dot{y} = -a \operatorname{sign} x - b \operatorname{sign} y - hx - py + \omega(x, y, t), \tag{4.5}$$

where h and p are parameters of the linear gain, and $\omega(x, y, t)$ is a piece-wise continuous nonlinear perturbation, uniformly bounded

$$|\omega(x, y, t)| \leq M \tag{4.6}$$

for all continuity points (x, y, t) and some $M > 0$. If the bound M is small enough, namely,

$$0 < M < b < a - M, \tag{4.7}$$

and the linear gain is nonpositive, i.e.,

$$h \geq 0, \qquad p \geq 0, \tag{4.8}$$

the uncertain system (4.5), (4.6) proves to be globally equiuniformly asymptotically stable. The global equiuniform finite time stability of this system can then be demonstrated by invoking Theorem 3.2, which turns out to be applicable to the uncertain system (4.5), (4.6) because its nominal model (4.1) has a globally homogeneous right-hand side of degree $q = -1$ with respect to dilation $r = (2, 1)$, thus satisfying condition 2 of Theorem 3.2. Summarizing, the following result is in force.

THEOREM 4.2. *Let conditions* (4.7), (4.8) *be satisfied. Then the uncertain switched system* (4.5), (4.6) *is globally equiuniformly finite time stable around the origin.*

The qualitative behavior of system (4.5) is depicted in Figure 1. Due to the parameter subordination (4.7), the velocity vectors of (4.5) point toward the same region in the switching lines

$$\begin{aligned} S_1 &= \{(x, y) \in \mathbf{R}^2 : x > 0,\ y = 0\}, \\ S_2 &= \{(x, y) \in \mathbf{R}^2 : x = 0,\ y < 0\}, \\ S_3 &= \{(x, y) \in \mathbf{R}^2 : x < 0,\ y = 0\}, \\ S_4 &= \{(x, y) \in \mathbf{R}^2 : x = 0,\ y > 0\}, \end{aligned} \tag{4.9}$$

regardless of uncertainty (4.6) affecting the system. Hence, the uncertain system (4.5)–(4.8) and, particularly, its unperturbed version (4.1) rotate around the origin

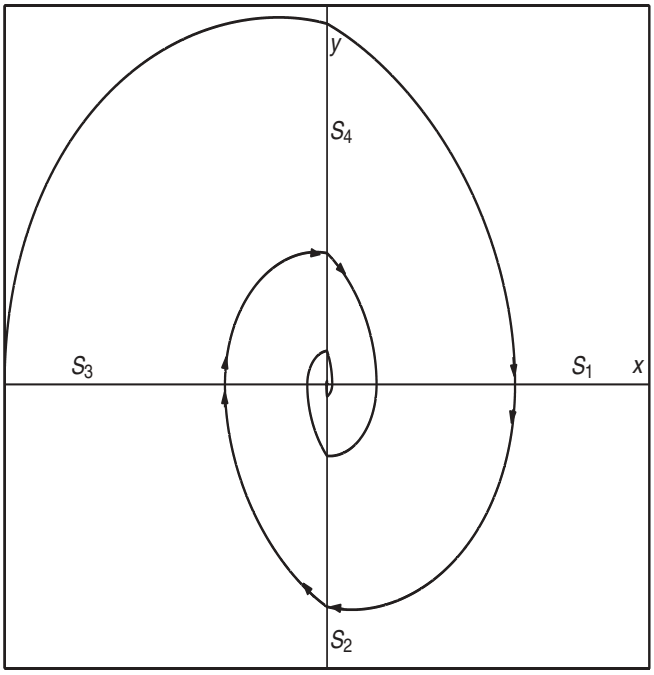

FIG. 1. *Phase portrait of the second order switched system* (4.5).

$x = y = 0$, while approaching the origin in a finite time. Thus, both the nominal system (4.1) and its uncertain counterpart (4.5)–(4.8) exhibit chattering modes with an infinite number of switches on a finite time interval. These systems do not generate sliding motions anywhere except the origin. If a trajectory starts there at any given finite time, there appears the so-called sliding mode of the second order (see [4, 11, 12, 20, 21] for advanced results on second order sliding modes).

4.1. Proof of Theorem 4.2. We break the proof into several simple steps.

1. *Equiuniform stability.* To demonstrate that the uncertain system (4.5)–(4.8) is equiuniformly stable we introduce the Lyapunov function

$$\tilde{V}(x,y) = a|x| + \frac{1}{2}(y^2 + hx^2). \tag{4.10}$$

Similar to (4.3), the time derivative of $\tilde{V}(x,y)$ along the trajectories $(x_\omega(\cdot), y_\omega(\cdot))$ of the uncertain system is negative semidefinite:

$$\begin{aligned} \dot{\tilde{V}}(x_\omega(t), y_\omega(t)) &= -b|y_\omega(t)| - py_\omega^2(t) + y_\omega(t)\omega(x_\omega(t), y_\omega(t), t) \\ &\le -(b - M)|y_\omega(t)| \end{aligned} \tag{4.11}$$

for almost all t. It follows that the uncertain system (4.5)–(4.8) is equiuniformly stable. Indeed, due to (4.11) the positive definite function (4.10) does not increase along the solutions of (4.5)–(4.8). Thus, initialized in an arbitrarily small vicinity

$$D_\epsilon = \{(x,y) \in \mathbf{R}^2 : \tilde{V}(x,y) \le \epsilon\} \tag{4.12}$$

of the origin, the uncertain system (4.5)–(4.8) cannot leave this vicinity, regardless of which admissible uncertainty ω affects the system.

2. *Semiglobal Lyapunov functions.* Our next goal is to construct a parameterized family of local Lyapunov functions $V_R(x,y)$, $R>0$, such that each $V_R(x,y)$ is well-posed on the corresponding compact set

$$D_R = \{(x,y) \in \mathbf{R}^2 : \tilde{V}(x,y) \le R\}. \tag{4.13}$$

In other words, $V_R(x,y)$ is to be positive definite on D_R whereas its time derivative, computed along the trajectories of the uncertain system (4.5)–(4.8) with initial conditions within D_R, is to be equiuniformly negative definite in the sense that

$$\dot{V}_R(x,y) \le -W_R(x,y) \tag{4.14}$$

for all $(x,y) \in D_R$ and some $W_R(x,y)$, positive definite on D_R.

Parameterized Lyapunov functions $V_R(x,y)$, $R>0$, with the properties above are constructed by combining the aforegiven Lyapunov function (4.10), whose time derivative along the system motion is only semidefinite, with the indefinite function $U(x,y)=xy$:

$$V_R(x,y) = \tilde{V}(x,y) + \kappa_R U(x,y) = a|x| + \frac{1}{2}(y^2+hx^2) + \kappa_R xy, \tag{4.15}$$

where the weight parameter $\kappa_R > 0$ is chosen small enough, namely,

$$\kappa_R < \min\left\{1, \frac{2a^2}{R}, \frac{a(b-M)}{a\sqrt{2R}+pR}\right\}. \tag{4.16}$$

Apparently, the function $V_R(x,y)$, thus constructed, is positive definite on compacta (4.13) because (4.13) implies that $|x| \le \frac{R}{a}$, $|y| \le \sqrt{2R}$, and therefore

$$\begin{aligned} a|x| + \frac{1}{2}(y^2+hx^2) + \kappa_R xy &\ge a|x| + \frac{1}{2}(y^2+hx^2) - \frac{1}{2}\kappa_R x^2 - \frac{1}{2}\kappa_R y^2 \\ &\ge \left(a - \frac{R}{2a}\kappa_R\right)|x| + \frac{1}{2}(1-\kappa_R)y^2 + \frac{1}{2}hx^2 > 0 \end{aligned} \tag{4.17}$$

for all $(x,y) \in D_R \setminus \{(0,0)\}$ and $\kappa_R > 0$, satisfying (4.16).

Moreover, the time derivative of (4.15), computed along the trajectories of the uncertain system (4.5)–(4.8) with the initial conditions within D_R, is equiuniformly negative definite. Indeed, differentiating the auxiliary function $U(x,y)=xy$ along the trajectories of the uncertain system (4.5)–(4.8) yields

$$\begin{aligned} \dot{U}(x_\omega(t), y_\omega(t)) &= y_\omega^2(t) - a|x_\omega(t)| - bx_\omega(t)\operatorname{sign} y_\omega(t) - hx_\omega^2(t) \\ &\quad - px_\omega(t)y_\omega(t) + x_\omega(t)\omega(x_\omega(t), y_\omega(t), t) \\ &\le y_\omega^2(t) - |x_\omega(t)|[a + b\operatorname{sign} x_\omega(t)\operatorname{sign} y_\omega(t) \\ &\qquad - \omega(x_\omega(t), y_\omega(t), t)\operatorname{sign} x_\omega(t)] - px_\omega(t)y_\omega(t) \\ &\le y_\omega^2(t) - (a-b-M)|x_\omega(t)| - px_\omega(t)y_\omega(t). \end{aligned} \tag{4.18}$$

Then, by employing (4.11) and (4.18) one has

$$\begin{aligned} \dot{V}_R(x_\omega(t), y_\omega(t)) &\le -(b-M)|y_\omega(t)| \\ &\quad + \kappa_R y_\omega^2(t) - \kappa_R(a-b-M)|x_\omega(t)| - \kappa_R p x_\omega(t)y_\omega(t). \end{aligned} \tag{4.19}$$

Since due to (4.11) all possible solutions of (4.5)–(4.8), initialized at $t_0 \in \mathbf{R}$ within the compact set (4.13), are a priori estimated by

$$\sup_{t\in[t_0,\infty)} \tilde{V}(x_\omega(t), y_\omega(t)) \le R, \tag{4.20}$$

it follows that

$$\begin{aligned}\dot{V}_R(x_\omega(t), y_\omega(t)) \le &-\left[b - M - \kappa_R\left(\sqrt{2R} + \frac{pR}{a}\right)\right]|y_\omega(t)| \\ &-\kappa_R(a - b - M)|x_\omega(t)| \le -c_R[|y_\omega(t)| + |x_\omega(t)|],\end{aligned} \tag{4.21}$$

where $c_R = \min\{b - M - \kappa_R(\sqrt{2R} + \frac{pR}{a}),\ \kappa_R(a - b - M)\} > 0$ by virtue of (4.16).

To this end, (4.21) results in

$$\dot{V}_R(x_\omega(t), y_\omega(t)) \le -K_R V_R(x_\omega(t), y_\omega(t)), \tag{4.22}$$

where

$$K_R = \frac{2ac_R}{\max\{2a^2 + hR,\ a\sqrt{2R} + 2\kappa_R R\}} > 0$$

and the upper estimate

$$V_R(x, y) \le \frac{2a^2 + hR}{2a}|x| + \frac{a\sqrt{2R} + 2\kappa_R R}{2a}|y|$$

of the Lyapunov function (4.15) on compacta (4.13) has been used. Thus, the desired equiuniform negative definiteness (4.14) is obtained with $W_R(x, y) = K_R V_R(x, y)$.

3. *Global equiuniform asymptotic stability.* Since the differential inequality (4.22) holds on the solutions of the uncertain system (4.5)–(4.8), initialized within the compact set (4.13), the function $V_R(x_\omega(t), y_\omega(t))$ exponentially decays

$$V_R(x_\omega(t), y_\omega(t)) \le V_R(x_\omega(t_0), y_\omega(t_0))e^{-K_R(t-t_0)} \tag{4.23}$$

on these solutions with the decay rate K_R, independent of the uncertainty ω. While being viewed on compacta (4.13), the functions $V_R(x, y)$ and $\tilde{V}(x, y)$ are equivalent in the sense that

$$L_R\tilde{V}(x, y) \le V_R(x, y) \le M_R\tilde{V}(x, y) \tag{4.24}$$

for all $(x, y) \in D_R$ and positive constants L_R, M_R, satisfying

$$L_R < \min\left\{\frac{2a^2 - R\kappa_R}{2a^2}, 1 - \kappa_R\right\}, \qquad M_R > \max\left\{\frac{2a^2 + R\kappa_R}{2a^2}, 1 + \kappa_R\right\}. \tag{4.25}$$

The above relations (4.23) and (4.24), coupled together, ensure that the function $\tilde{V}(x, y)$ exponentially decays

$$\begin{aligned}\tilde{V}(x_\omega(t), y_\omega(t)) &\le L_R^{-1}M_R\tilde{V}(x_\omega(t_0), y_\omega(t_0))e^{-K_R(t-t_0)} \\ &\le L_R^{-1}M_R R e^{-K_R(t-t_0)}\end{aligned} \tag{4.26}$$

on the solutions of (4.5)–(4.8), equiuniformly in the uncertainty ω and the initial data, located within an arbitrarily large set (4.13). Clearly, this proves that the uncertain system (4.5)–(4.8) is globally equiuniformly asymptotically stable.

4. *Global equiuniform finite time stability.* Due to (4.6) the piece-wise continuous uncertainty $\omega(x,y,t) - hx - py$ is locally uniformly bounded, whereas the right-hand side of the nominal model (4.1) is piece-wise continuous and globally homogeneous of degree $q = -1$ with respect to dilation $r = (2,1)$. Hence, the condition $q + r_2 \le 0$, required by Theorem 3.2, is satisfied, and Theorem 3.2 is applicable to the globally equiuniformly asymptotically stable uncertain system (4.5)–(4.8). By applying Theorem 3.2, the uncertain system (4.5)–(4.8) is thus globally equiuniformly finite time stable. The proof of Theorem 4.2 is completed.

5. Chattering control synthesis. The present section investigates the capability of a nonlinear system of the form

$$\begin{aligned} \dot z &= g(z,\xi,\dot\xi,t),\\ \ddot\xi &= f(z,\xi,\dot\xi,t) + u \end{aligned} \tag{5.1}$$

to be globally asymptotically stabilizable in spite of significant model uncertainties with a priori known norm bounds. Hereafter, $t \in \mathbf{R}$ is the time variable, $z \in \mathbf{R}^n$, $\xi, \dot\xi \in \mathbf{R}^m$ are the state components, $u \in \mathbf{R}^m$ is the input, $\xi \in \mathbf{R}^m$ is the output, and the nonlinear functions g and f have appropriate dimensions and involve the system uncertainties whose influence on the control process should be rejected.

The above system often arises in practice, e.g., to describe controlled electromechanical plants. It can be obtained via a nonlinear change of state coordinates and a feedback transformation from a general affine control system

$$\begin{aligned} &\dot x = a(x,t) + b(x,t)u, \quad x \in \mathbf{R}^{n+2m},\ u \in \mathbf{R}^m,\\ &y = h(x,t), \quad y \in \mathbf{R}^m, \end{aligned} \tag{5.2}$$

of uniform m-vector relative degree $(2,\dots,2)^T$ with the involutive distribution

$$B = \operatorname{span}\{b_1,\dots,b_m\},$$

the span of the columns of $b(x)$ (see [9] for details).

The following assumptions on system (5.1) are made throughout.

1. The functions $g(z,\xi,\dot\xi,t)$ and $f(z,\xi,\dot\xi,t)$ are piece-wise continuous in all the arguments, and, in addition, the function $g(z,\xi,\dot\xi,t)$ is continuous in $(\xi,\dot\xi)$ locally around $(\xi,\dot\xi) = 0$ for almost all z and t.

2. The function $g(z,\xi,\dot\xi,t)$ satisfies the linear growth condition

$$\|g(z,\xi,\dot\xi,t)\| \le k(\xi,\dot\xi,t)(1 + \|z\|) \tag{5.3}$$

in z everywhere in its domain (i.e., (5.3) can only be violated on the set where g undergoes discontinuities) with some continuous function $k(\xi,\dot\xi,t)$.

3. The system

$$\dot z = g(z,0,0,t) \tag{5.4}$$

has 0 as a globally uniformly asymptotically stable equilibrium.

Solutions of the state and zero dynamics differential equations (5.1) and (5.4), both with piece-wise continuous right-hand sides, are defined in the sense of Filippov according to Definition 2.1. Under assumption 1 on (5.1) the existence of a solution (possibly nonunique) of either equation with an arbitrary initial condition is

guaranteed by Theorem 8 of [10, p. 85]. Other assumptions are made for technical reasons. Assumption 2 is introduced to avoid the destabilizing effect of the peaking phenomenon (a detailed treatment of the peaking phenomenon in the continuous setting can be found in [29]). Assumption 3 means that (5.1) is a globally uniformly minimum phase system. The role of this notion is well known from the theory of smooth fields [9] and it is now under study for switched nonautonomous systems.

System (5.1) is operating under uncertainty conditions that imply imperfect knowledge of the nonlinearities f and g. The nonlinear gain g cannot destabilize the closed-loop system because of the minimum phase hypothesis, which is why no more information is required for this gain. The destabilizing term

$$f(z,\xi,\dot\xi,t) = f^{nom}(z,\xi,\dot\xi,t) + f^b(z,\xi,\dot\xi,t) \tag{5.5}$$

typically consists of a nominal part f^{nom} to be handled through nonlinear damping and an uncertain bounded gain f^b to be rejected. It is assumed that the nominal part f^{nom} is known a priori, whereas the components f^b_j, $j = 1,\dots,m$, of the bounded gain f^b are upper estimated:

$$|f^b_j(z,\xi,\dot\xi,t)| \le F_j < \infty \quad \text{for almost all } (z,\xi,\dot\xi,t) \in \mathbf{R}^{n+2m+1} \tag{5.6}$$

by constants F_j, also known a priori. Apart from this, both functions f^{nom} and f^b are assumed to be piece-wise continuous.

The following switched control law

$$u(z,\xi,\dot\xi,t) = -f^{nom}(z,\xi,\dot\xi,t) - \mu\dot\xi - \nu\xi - \beta\operatorname{sign}\xi - \gamma\operatorname{sign}\dot\xi, \tag{5.7}$$

with the parameter gains

$$\mu = \operatorname{diag}(\mu_j), \qquad \nu = \operatorname{diag}(\nu_j), \qquad \beta = \operatorname{diag}(\beta_j), \qquad \gamma = \operatorname{diag}(\gamma_j)$$

subject to

$$\mu_j \ge 0, \quad \nu_j \ge 0, \quad \beta_j - F_j > \gamma_j > F_j, \quad j = 1,\dots,m, \tag{5.8}$$

is proposed to stabilize the uncertain system (5.1), (5.5), (5.6) whose state $(z,\xi,\dot\xi)$ is available for measurements. Hereafter, the notation diag is used to denote a diagonal matrix of an appropriate dimension; $\operatorname{sign}\xi$ with a vector $\xi = (\xi_1,\dots,\xi_m)^T$ stands for the column vector $(\operatorname{sign}\xi_1,\dots,\operatorname{sign}\xi_m)^T$.

In what follows, the switched control law (5.7), (5.8) is proven to exhibit chattering modes, while driving the uncertain system (5.1) to the zero dynamics manifold $\xi = \dot\xi = 0$ in finite time. Desired stability properties are thus imposed on the closed-loop system.

THEOREM 5.1. *Let assumptions* 1–3 *be satisfied and let the uncertain system* (5.1), (5.5), (5.6) *be driven by the state feedback* (5.7) *such that condition* (5.8) *holds. Then the closed-loop system* (5.1), (5.5)–(5.8) *is globally equiuniformly asymptotically stable.*

Proof. The closed-loop system (5.1) driven by (5.7) is represented as follows:

$$\dot z = g(z,\xi,\zeta,t), \tag{5.9}$$

$$\dot\xi_j = \zeta_j, \qquad \dot\zeta_j = f^b_j(z,\xi,\zeta,t) - \nu_j\xi_j - \mu_j\zeta_j - \beta_j\operatorname{sign}\xi_j - \gamma_j\operatorname{sign}\zeta_j, \quad j = 1,\dots,m. \tag{5.10}$$

Due to assumption 1, Theorem 8 of [10, p. 85] is applicable to system (5.9), (5.10), and by applying this theorem, the system has a local solution for all initial data and uncertainties (5.6). Let us demonstrate that each solution of (5.9), (5.10) is globally continuable on the right.

Similarly to (4.11), the time derivative of the function $V_j(\xi_j, \zeta_j) = \beta_j|\xi_j| + \frac{1}{2}(\zeta_j^2 + \nu_j\xi_j^2)$, $j = 1, \dots, m$, computed along the trajectories of the corresponding subsystem (5.10), is negative semidefinite:

$$\dot{V}_j(\xi_j(t), \zeta_j(t)) \le -(\gamma_j - F_j)|\zeta_j(t)|. \tag{5.11}$$

As in the proof of Theorem 4.1, it follows that each solution of subsystem (5.10) subject to (5.6) is uniformly bounded in t.

In turn, for given continuous, uniformly bounded functions $\xi(t)$, $\zeta(t)$, all possible solutions of subsystem (5.9) remain bounded on any finite time interval due to the linear growth assumption (5.3) (assumption 2) on the right-hand side of (5.9). Indeed, an arbitrary solution $z(\cdot)$ of (5.9) is a priori estimated as

$$\|z(t)\| \le \|z(t_0)\| + \int_{t_0}^{t} k(\xi(t), \zeta(t), t)(1 + \|z(t)\|)dt, \tag{5.12}$$

and by applying Bellman–Gronwall's lemma to the integral inequality (5.12), $z(\cdot)$ is bounded on any finite time interval (t_0, t_1).

Thus, all possible solutions of the overall uncertain system (5.6), (5.9), (5.10) remain bounded on any finite time interval, and by property B of Theorem 9 of [10, p. 86], these solutions are globally continuable on the right.

Next let us observe that due to the uniform boundedness (5.6) of the uncertain terms $f_j^b(z, \xi, \zeta, t)$, $j = 1, \dots, m$, and by virtue of the parameter subordination (5.8), each subsystem (5.10) satisfies all the conditions of Theorem 4.2, and by applying this theorem, (5.10) is globally equiuniformly finite time stable. It follows that starting from a finite time moment, the overall uncertain system (5.6), (5.9), (5.10) evolves in the chattering mode on the zero dynamics manifold $\xi = \zeta = 0$, where its behavior is governed by the zero dynamics equation (5.4).

Now, to complete the proof, it remains to note that by assumption 3, the zero dynamics (5.4) is globally uniformly asymptotically stable. Coupled to the global equiuniform finite time stability of (5.10), this ensures that the closed-loop system (5.9), (5.10) is globally equiuniformly asymptotically stable, too. The proof of Theorem 5.1 is thus completed. □

5.1. Application to friction electromechanical systems. A simple physical interpretation of the chattering controller (5.7) is revealed by its application to the servo-motor governed by

$$j\ddot{\xi} = u - F(\dot{\xi}) + \omega(t), \quad \xi, u \in \mathbf{R}^1. \tag{5.13}$$

In the above equation, ξ denotes displacement, u is the control input, j is the inertia, ω is the external disturbance involving the transmitted torque (as a matter of fact, this function can be state-dependent; however, for simplicity it is viewed as an integrable function of time, computed along the system trajectories), and $F(\dot{\xi})$ is the friction force governed by the classical model

$$F(\dot{\xi}) = \alpha_v\dot{\xi} + \alpha_c \operatorname{sign}\dot{\xi} \tag{5.14}$$

with the viscous friction coefficient $\alpha_v > 0$ and the Coulomb friction level $\alpha_c > 0$. Solutions of the state equation (5.13) are defined in the sense of Filippov, and by virtue of Definition 2.1, there is no need to specify the above friction model on the discontinuity manifold $\dot{\xi} = 0$.

Since the phenomenon of friction is not yet completely understood and it is hard to model, the uncertain term $\omega(t)$ has been incorporated into the motor equation (5.13) to account for destabilizing model discrepancies such as the Stribeck effect and backlash, whose upper bounds are computed experimentally (see, e.g., [2]). Thus, an upper bound $F_0 > 0$ for the magnitude of the uncertain term is normally known a priori:

$$|\omega(t)| \le F_0 \quad \text{for all } t. \tag{5.15}$$

Motivated by application requirements, the control objective is to stabilize the servo-motor in finite time in spite of the uniformly bounded external disturbances whose influence on the control process should be rejected.

It is worth noting that continuous control algorithms do not admit even asymptotic stabilization of (5.13), (5.14) due to the presence of the discontinuous term $\alpha_c \operatorname{sign} \dot{\xi}$, corresponding to the Coulomb friction in (5.14). Indeed, the servo-motor (5.13), (5.14) enforced by an arbitrary continuous controller u has a nontrivial set of equilibrium points around the position $\xi = 0$ (see, e.g., [25]), thereby yielding an inappropriate solution to the stabilization problem. Thus, continuous controllers, particularly those especially developed in [6, 16] to stabilize frictionless oscillators in finite time, become unable to asymptotically stabilize the servo-motor (5.13), (5.14) with a nonzero Coulomb level α_c.

Hence, in order to attain asymptotic stability of the servo-motor (5.13), (5.14) with a nontrivial Coulomb friction level, discontinuous controllers have to be brought into play. Since standard sliding mode controllers are capable only of providing ultimate boundedness of the second order dynamic system in question [24], the chattering control algorithm (5.7), specified for the servo-motor (5.13), (5.14) by

$$u = -\mu\dot{\xi} - \nu\xi - \beta \operatorname{sign} \xi - \gamma \operatorname{sign} \dot{\xi}, \tag{5.16}$$

is chosen to stabilize the servo-motor in finite time. Due to the presence of the Coulomb friction, the subordination rule (5.8) for the parameters of the closed-loop system (5.13), (5.14), (5.16) is modified as follows:

$$\mu, \nu \ge 0, \qquad \beta - F_0 > \alpha_c + \gamma > F_0, \tag{5.17}$$

where μ, ν, β, γ are the parameter gains, α_c is the Coulomb level of the friction force (5.14), and F_0 is the upper bound (5.15) for the external disturbances.

In the particular case of $\mu = \nu = 0$ and $\beta > \gamma > 0$, the above controller (5.16) is nothing more than the so-called twisting controller from [20]. Adding a linear part with nonzero μ and ν into this twisting algorithm allows one to reduce the convergence time of the controller without enlarging the amplitude of switching used in the controller. Furthermore, in contrast to the twisting algorithm the pure switched position feedback

$$u = -\beta \operatorname{sign} \xi \tag{5.18}$$

is admitted by the proposed control law (5.16) when $\mu = \nu = \gamma = 0$. The switched position controller (5.18) still stabilizes the servo-motor (5.13), (5.14) in finite time

while rejecting the external disturbance (5.15) only when the upper bound F_0 is smaller than the Coulomb friction level α_c.

The performance of the chattering controller (5.16) and that of its position feedback version (5.18) were studied in [26] by simulation. In this study, a servo-motor was required to move from an initial static position to the origin $\xi = 0$, $\dot{\xi} = 0$, while the external disturbance was composed by the backlash model from [30] and the Stribeck friction force from Tustin's model [31].

As predicted by the theory, both closed-loop systems were driven to the origin in finite time in spite of the presence of backlash and Stribeck effect whereas better performance (settling time) was yielded by the state feedback controller. Thus, to decrease the settling time one should utilize a chattering state feedback controller (5.16) and increase the parameter gains of the controller. This may, however, excite unmodelled high-frequency dynamics of the system, thereby limiting the achievable performance.

6. Conclusions. Finite time stability of uncertain switched systems has been studied. These systems were shown to be globally equiuniformly finite time stable whenever they are globally equiuniformly asymptotically stable and homogeneous of degree $q < 0$. Restricted to second order systems, the finite time stability feature was additionally demonstrated to remain in force regardless of some inhomogeneous perturbations.

Based on these tools, discontinuous control algorithms have been developed to globally asymptotically stabilize uncertain minimum phase systems of uniform m-vector relative degree $(2, \dots, 2)^T$. The stabilizing strategy was to drive the system to the zero dynamics manifold in a finite time and maintain it there in spite of the parameter uncertainties and external disturbances. Desired robustness properties were thus provided and asymptotic stability of the closed-loop system was guaranteed.

The controllers constructed do not rely on the generation of sliding motions on the switching manifolds but on their intersections, thus exhibiting the so-called second order sliding modes [11] with an infinite number of switches on a finite time interval. In analogy to optimal control theory [34], such controllers have been referred to as chattering controllers regardless of whether the optimal performance is achieved.

Attractive features of chattering controllers have been illustrated by application to a servo-motor. The controllers were demonstrated to be capable of providing the desired system performance in spite of significant uncertainties in the system description, as is typically the case in control of electromechanical systems with complex hard-to-model nonlinear phenomena.

QUENCHED LARGE DEVIATIONS FOR ONE DIMENSIONAL NONLINEAR FILTERING*

ÉTIENNE PARDOUX† AND OFER ZEITOUNI‡

Abstract. Consider the standard, one dimensional, nonlinear filtering problem for diffusion processes observed in small additive white noise: $dX_t = b(X_t)dt + dB_t$, $dY_t^\varepsilon = \gamma(X_t)dt + \varepsilon dV_t$, where $B.,V.$ are standard independent Brownian motions. Denote by $q_1^\varepsilon(\cdot)$ the density of the law of Ξ_1 conditioned on $\sigma(Y_t^\varepsilon : 0 \le t \le 1)$. We provide "quenched" large deviation estimates for the random family of measures $q_1^\varepsilon(x)dx$: there exists a continuous, explicit mapping $\bar{\mathcal{J}} : \mathbb{R}^2 \to \mathbb{R}$ such that for almost all $B.,V.$, $\bar{\mathcal{J}}(\cdot, X_1)$ is a good rate function, and for any measurable $G \subset \mathbb{R}$,

$$-\inf_{x\in G^o} \bar{\mathcal{J}}(x, X_1) \le \liminf_{\varepsilon\to 0} \varepsilon \log \int_G q_1^\varepsilon(x)dx \le \limsup_{\varepsilon\to 0} \varepsilon \log \int_G q_1^\varepsilon(x)dx \le -\inf_{x\in \bar{G}} \bar{\mathcal{J}}(x, X_1).$$

1. Introduction and statement of results.

Consider the following one dimensional filtering problem, where the signal process $X.$ and the observation process $Y.^\varepsilon$, parametrized by a "small noise intensity" ε, are

$$\begin{aligned} dX_t &= b(X_t)dt + dB_t, \quad X_0 \sim p_0(\cdot), \\ dY_t^\varepsilon &= h(X_t)dt + \varepsilon dV_t. \end{aligned} \tag{1.1}$$

Here, $B.,V.$ are independent standard one dimensional Brownian motions, and the functions b, h, p_0 satisfy the following assumptions:[1]

(A-1) b, h, b', h' are Lipschitz functions,
(A-2) $h'(\cdot) \ge h_0 > 0$,
(A-3) $|\log p_0(x) - \log p_0(y)| \le c(1 + |x| + |y|)|x - y|$, $x, y \in \mathbb{R}$, and p_0 is uniformly bounded.

For technical reasons, we need to impose the following additional restriction:

(A-4) $h'b, h'h, h'', hb$ are Lipschitz functions and $\lim_{|x|\to\infty} h''(x) = 0$.

(A-4) implies that, outside large compacts, the observation function h is essentially linear. Let $\Omega_1 = \Omega_2 = C([0,1];\mathbb{R})$, $\Omega = \Omega_1 \times \Omega_2$, $\mathcal{F}_i$ be the Borel σ-algebra on Ω_i,

[1]Due to the one dimensional nature of our model, no generality is lost in assuming the diffusion coefficient of the signal process to be one. Indeed, if the signal process satisfies $d\Xi_t = \beta(\Xi_t)dt + \sigma(\Xi_t)dB_t$, with σ uniformly bounded away from zero, then the transformation $X_t = \bar{G}(\Xi_t)$, with $\bar{G}(x) = \int_0^x (1/\sigma)(u)du$, allows one to rewrite the problem in the form (1.1).

$i = 1, 2$, and $\mathcal{F}$ be the Borel σ-algebra on Ω; let P_1, P_2 denote the Wiener measure on Ω_1, Ω_2, and $P = P_1 \otimes P_2$. We define $B_t(\omega) = \omega_1(t)$, $V_t(\omega) = \omega_2(t)$, $0 \le t \le 1$. The pair (B, V) is then distributed according to P. The solution (X, Y^ε) of the SDE (1.1) is then an $\mathcal{F}$-measurable, $C([0,1]; \mathbb{R}^2)$-valued, random variable.

Let $\mu_t^\varepsilon(\cdot)$ denote the conditional law of X_t conditioned on $\mathcal{Y}_t^\varepsilon = \sigma\{Y_s^\varepsilon,\, 0 \le s \le t\}$, which we consider as an $\mathcal{F}$-measurable map from Ω to $M_1(\mathbb{R})$, the space of probability measures on $\mathbb{R}$. Note that μ_t^ε is in fact measurable with respect to the ε-dependent σ-algebra $\mathcal{Y}_t^\varepsilon \subset \mathcal{F}$.

It is known that μ_t^ε is absolutely continuous, with $\mu_t^\varepsilon(dx) = q_t^\varepsilon(x)dx$, and that as $\varepsilon \to 0$, the conditional law $\mu_1^\varepsilon(dx) = q_1^\varepsilon(x)dx$ of X_1, given $\mathcal{Y}_1^\varepsilon$, converges to the Dirac measure δ_{X_1}. (All these facts can be found, e.g., in [7].) In particular, X_1 is measurable with respect to the limiting σ-algebra $\mathcal{Y}_1^0$, since h is one-to-one. It is known from the results of Picard [7] that the conditional law μ_1^ε has a variance of order ε and can be well approximated by a Gaussian law, which is given by an extended Kalman filter.

Our goal in this paper is to establish a large deviations result in the following sense. Let G be a measurable subset of $\mathbb{R}$. By the above remarks, we know that on the event $\{X_1 \notin \overline{G}\}$, $\mu_1^\varepsilon(G) \to 0$, P-almost surely. It turns out that it goes to zero at exponential speed, i.e., roughly like $\exp[-c_1(G)/\varepsilon]$. What is the value of $c_1(G) = -\lim \varepsilon \log \mu_1^\varepsilon(G)$ (if this limit exists), the "rate function" that tells us at which speed the quantity $P(X_1 \in G \,|\, \mathcal{Y}_1^\varepsilon)$ goes to zero, whenever $X_1 \notin \overline{G}$? Clearly $c_1(G)$ must depend on X_1 (at least intuitively through its distance to $\overline{G}$), and we shall see that this is indeed the case. There is no surprise in the fact that $c_1(\cdot)$ is random, since it tells us at which exponential speed the random measures μ_1^ε converge to the random measure $\mu_1^0 = \delta_{X_1}$. Our results show that c_1 does not depend on anything else, in the sense that, conditionally on $\sigma(X_1)$, it is P-almost surely constant.

We call our result "quenched" (borrowing that terminology from the theory of random media), meaning that the randomness of the observation process is frozen. One could also discuss a "semiquenched" large deviations statement by computing the P_1-almost sure limit (if it exists) of

$$\varepsilon \log \int \int_G q_1^\varepsilon(x + X_1) dx dP_2,$$

while an "annealed" large deviations result would describe the asymptotic behavior of

$$\varepsilon \log E \int_G q_1^\varepsilon(x + X_1) dx.$$

Finally, one could also consider large deviations questions at the level of the conditional measure itself, for example questions concerning the rate of decay of probabilities of the form $P(q_1^\varepsilon(x)dx \in A)$, with A a measurable subset of the space of probability measures on $\mathbb{R}$. We hope to study all these elsewhere.

Let us now state our result. Define

$$\bar{\mathcal{J}}(x, X_1) = \int_{X_1}^x (h(y) - h(X_1)) dy.$$

Our main result is the following theorem. For standard definitions concerning the large deviation principle (LDP), see [3]. For a set $G \subset \mathbb{R}$, we denote by G^o its interior and by $\bar{G}$ its closure.

THEOREM 1.1. *Assume* (A-1)–(A-4). *Then the family of (random) probability measures $q_1^\varepsilon(x)dx$ satisfies a quenched LDP (on the space $\mathbb{R}$ equipped with the standard Euclidean norm) with continuous good rate function $\bar{\mathcal{J}}(\cdot, X_1)$. That is, for any measurable set $G \subset \mathbb{R}$,*

$$
\begin{aligned}
-\inf_{x\in G^o} \bar{\mathcal{J}}(x, X_1) &\le \liminf_{\varepsilon\to 0} \varepsilon \log \int_G q_1^\varepsilon(x)dx \le \limsup_{\varepsilon\to 0} \varepsilon \log \int_G q_1^\varepsilon(x)dx \\
&\le -\inf_{x\in \bar{G}} \bar{\mathcal{J}}(x, X_1), \quad P-a.s. \qquad (1.2)
\end{aligned}
$$

In fact, we have the estimate, valid for any fixed compact set $K_0 \subset \mathbb{R}$,

$$
\lim_{\varepsilon\to 0} \sup_{x\in K_0} |\varepsilon \log q_1^\varepsilon(x) + \bar{\mathcal{J}}(x, X_1)| = 0, \quad P-a.s. \qquad (1.3)
$$

(It will be obvious from the proof that the fixed time 1 can be replaced by any fixed time $t \in (0, \infty)$; that is, the statement of Theorem 1.1 remains true with q_t^ε and X_t replacing q_1^ε and X_1.)

Remarks.

1. In the particular case $h(x) = x$, Theorem 1.1 can be deduced from the results of [10].

2. The reader could wonder why the statement (1.2) is equivalent to the large deviations principle on $\mathbb{R}$ for P-almost ω, since in (1.2), the null set on which the statement does not hold true may depend on G. Note, however, that once the inequalities in (1.2) hold true for each interval $G = (a, b)$ on a set of full measure $\Omega_{a,b}$, we can set

$$
\Omega' = \cap_{a,b\in\mathbb{Q}} \Omega_{a,b}
$$

and conclude that $P(\Omega') = 1$ while (1.2) holds true for all $\omega \in \Omega'$ and all open intervals G with rational endpoints. Since the latter are a base for the topology on $\mathbb{R}$, one concludes (see, e.g., [3, Theorem 4.1.11]) that the full LDP holds for each $\omega \in \Omega'$.

We conclude this introduction with some comments about previous work and possible applications and extensions of our result. Our motivation for the study of the large deviations of the optimal filter is their utility in a variety of applications such as tracking (see [9]) or the study of the filter memory length (see [1]). In the one dimensional linear observation case studied in [10], precise pointwise estimates can be derived by comparison with the linear filtering problem, whose (Gaussian) solution is known explicitly. In contrast, here, the main tool used in the proof of Theorem 1.1 is the representation, due to Picard [7], of the density q_1^ε in terms of an auxiliary suboptimal filter, and the availability of good estimates on the performance of this suboptimal filter. These results are not available in the general multidimensional case. When they are, e.g., in the setup discussed in [8], we believe our analysis can be carried through. Hence, while our result is presently limited to one dimension, we expect that its multidimensional extension to the case where the dimensions of the state and observation coincide, and the observation function is one-to-one, could be deduced from the results of [8]. Extension to the case where the dimension of the observation is smaller than the dimension of the state (which is the most relevant case for applications) would require completely new additional ideas, since the result would be of a completely different nature (the limiting measure is no longer necessarily a Dirac measure, and even when it is, the convergence to the Dirac measure is at different speeds for different coordinates).

We finally note that Hijab [4] has derived a (path) quenched large deviations for the conditional density for systems in which both the signal and the observation noises are small. This is related, by a time change, to looking at short times (of order εT) of the filtering equations

$$dX_t^\varepsilon = \frac{1}{\varepsilon}\bar{b}(X_t^\varepsilon)dt + dB_t, \quad X_0^\varepsilon = x,$$
$$dY_t^\varepsilon = h(X_t^\varepsilon)dt + \varepsilon dV_t.$$

(Hijab's results are not stated in this way, but are equivalent to the description given here. Note that his setup is more general than ours in that it applies to the multi-dimensional setup and allows for general regular diffusion coefficients.) Hijab's results are not directly comparable with the LDP we derive here because of the different time interval on which they apply, and also because of the different type of conditioning. (His statement looks at the conditional density as a continuous functional of the observation trajectory, and considers the LDP when this trajectory is frozen. It is thus not directly applicable as a quenched statement.)

We refer the reader to [5] for a general introduction to stochastic calculus and stochastic differential equations, and to [6] for an exposition of nonlinear filtering theory.

Convention. Throughout the paper, when relevant, we make explicit on what parameters constants depend, even if the actual value of the constant may change from line to line. When nothing explicit is mentioned, i.e., a generic constant C is used, it is understood that it may depend on the trajectories $\{X_\cdot\}$, $\{V_\cdot\}$, but not on ε. For $\infty > t > 0$, we use the notation $||f||_t = \sup_{s\le t}|f(s)|$, with $||f|| := ||f||_{1/\varepsilon}$. Finally, we use θ^t to denote the shift operator, e.g., $\theta^t\tilde{m}(\cdot) = \tilde{m}(t+\cdot)$.

2. Picard's formulation and a path integral. The filtering problem we are going to analyze is (1.1), and the assumptions (A-1)–(A-4) will be assumed to hold throughout the paper. We also note that since nothing is changed (in terms of the filtering problem) by adding a constant to the observation function h, we may and will assume throughout the paper that $h(0) = 0$.

It is known from the results of Picard [7] that the conditional law $q_1^\varepsilon(x)dx$ has a small variance, and that there exist finite dimensional filters that provide good approximations of the unknown state. We shall now recall the formula derived by Picard [7] for $q_1^\varepsilon(x)$, which was used there to study approximate filters. It will be an essential tool for our large deviation results.

Define the approximate filter

$$dM_t^\varepsilon = b(M_t^\varepsilon)dt + \frac{1}{\varepsilon}(dY_t^\varepsilon - h(M_t^\varepsilon)dt),$$

with $M_0^\varepsilon = 0$, and let $\bar{m}_s = M_{1-s}^\varepsilon$ and $\tilde{m}_s = \bar{m}_{\varepsilon s}$, $s \in [0, 1/\varepsilon]$.

One of the main contributions of Picard in [7, Proposition 4.2] was to express the conditional density $q_1^\varepsilon(x)$ in terms of the law of an auxiliary process $\{\bar{X}_{1-t}^x, 0 \le t \le 1\}$, which fluctuates backward in time, starting at time 1 from the position x, around the trajectory of the approximate filter $M_\cdot^\varepsilon$. Performing a time change and a Girsanov transformation, Picard's result can be rewritten as follows.[2] Define the process

$$d\tilde{Z}_s^{\varepsilon,x} = \left[-h(\tilde{Z}_s^{\varepsilon,x}) + \tilde{m}_s h'(\tilde{Z}_s^{\varepsilon,x}) - \varepsilon b(\tilde{Z}_s^{\varepsilon,x})\right] ds + \sqrt{\varepsilon}d\tilde{W}_s, \quad \tilde{Z}_0^{\varepsilon,x} = x,$$

[2]For completeness, and since the computations involved are somewhat lengthy, we present the derivation in an appendix at the end of the paper.

with $\widetilde{W}$ a standard Brownian motion, independent of $B_\cdot, V_\cdot$. Throughout, we let $\mathbb{E}$ and $\mathbb{P}$ denote expectations and probabilities with respect to the law of the Brownian motion $\widetilde{W}_\cdot$. Then a version of the conditional density of X_1, given $\mathcal{Y}_1^\varepsilon$, is given by

$$q_1^\varepsilon(x) = \frac{\rho_1^\varepsilon(x)}{\int_{\mathbb{R}} \rho_1^\varepsilon(x)dx}, \tag{2.1}$$

where

$$\rho_1^\varepsilon(x) := e^{-F(x,\tilde{m}_0)/\varepsilon}\mathbb{E}\left[\exp\left(I_\varepsilon(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x},0) + \int_0^{1/\varepsilon} g_1(\tilde{Z}_s^{\varepsilon,x},\tilde{m}_s)ds + \frac{1}{\varepsilon}\int_0^{1/\varepsilon} g_2(\tilde{Z}_s^{\varepsilon,x},\tilde{m}_s)ds\right)\right], \tag{2.2}$$

and

$$\begin{aligned}
F(z,m) &= \int_0^z (h(y)-h(m))dy - mh(z) + h(m)z,\\
I_\varepsilon(z,m) &= \log p_0(z) + \frac{1}{\varepsilon}F(z,m),\\
g_1(z,m) &= -mh'(z)b(z) + \frac{mh''(z)}{2} + h(z)b(z) - \frac{h'(z)}{2} - \varepsilon b'(z) - h(z)b(m),\\
g_2(z,m) &= h(z)h(m) - \frac{h^2(m)}{2} - mh(z)h'(z) + \frac{m^2h'(z)^2}{2}.
\end{aligned}$$

Note that assumptions (A-1)–(A-4) ensure that, for each given m, $g_1(\cdot,m)$, $g_2(\cdot,m)$ are Lipschitz functions with Lipschitz constant uniformly bounded for m in compacts.

It is important to note that, above and throughout the paper, expressions of the form $\mathbb{E}(\cdot)$ may still be random, due to their possible dependence on $B_\cdot, V_\cdot$. Thus, any equality between such expressions is to be understood in an almost sure sense. We will not explicitly mention this in what follows.

Equipped with (2.2), one is tempted to apply standard tools of large deviations theory, viz. the large deviations principle for $\tilde{Z}_\cdot^{\varepsilon,x}$ and Varadhan's lemma, to the analysis of the exponential rate of decay of the $\mathbb{P}$ expectation in (2.2). This temptation is quenched when one realizes that, in fact, the rate of growth of ρ_1^ε is exponential in $1/\varepsilon^2$, and it is only after normalization that one can hope to obtain the relevant $1/\varepsilon$ asymptotics. This fact, unfortunately, makes the analysis slightly more subtle. In the next section, we present several lemmas, whose proof is deferred to section 4, and show how to deduce Theorem 1.1 from these lemmas. Before closing this section, however, we state the following easy a priori estimates. Recall that, according to our convention, $||X||_1 = \sup_{s\le 1}|X_s|$.

LEMMA 2.1. *$||X||_1 < \infty$, P-almost surely,*

$$|||\tilde{m}||| := \limsup_{\varepsilon\to 0}\sup_{t\in[0,1/\varepsilon]}|\tilde{m}_t| < \infty, \quad P-a.s.,$$

and for $T_\varepsilon = \log(1/\varepsilon)$, $|||\tilde{m}_X||| := \sup_{s\in[0,T_\varepsilon]}|\tilde{m}_s - X_1|$,

$$\limsup_{\varepsilon\to 0}|||\tilde{m}_X||| = 0, \quad P-a.s. \tag{2.3}$$

Further, there exists a constant $C_{V,X}$ depending only on $\{X_\cdot, V_\cdot\}$ such that

$$\sup_{s\in[0,T_\varepsilon]}|\tilde{m}_s - X_1| \le C_{V,X}/\sqrt{T_\varepsilon}, \quad P-a.s.$$

Proof of Lemma 2.1. The statement that $||X||_1 < \infty$ is part of the statement concerning existence of solutions to the SDE (1.1). Next, we prove that

$$\limsup_{\varepsilon\to 0} \sup_{t\le 1} |M_t^\varepsilon| < \infty. \tag{2.4}$$

Indeed, fix constants $C = C(||X||_1)$ and ε_0 such that $h(y) - h(x) + \sup_{\varepsilon\le\varepsilon_0} \varepsilon b(x) < 0$ for all $x \ge C$ and $|y| \le ||X||_1$ (this is always possible because b, h are Lipschitz and $h' > h_0$). Define the stopping times $\tau_0 = 0,\ \theta_0 = 0$ and

$$\tau_i = \inf\{t > \theta_{i-1} : M_t^\varepsilon = C\}, \qquad \theta_i = \inf\{t > \tau_i : M_t^\varepsilon = C + 1\}.$$

By definition, $M_t^\varepsilon \le C + 1$ for $t \in [\tau_i, \theta_i]$, while for $t \in [\theta_i, \tau_{i+1}]$ it holds that for all $\varepsilon < \varepsilon_0$,

$$M_t^\varepsilon = M_{\theta_i}^\varepsilon + \int_{\theta_i}^t \left[b(M_s^\varepsilon) + \frac{1}{\varepsilon}(h(X_s) - h(M_s^\varepsilon)) \right] ds + V_t - V_{\theta_i} \le C + 1 + 2||V||_1.$$

We conclude that $\sup_{t\le 1} M_t^\varepsilon \le C+1+2||V||_1 < \infty$ for all $\varepsilon < \varepsilon_0$. A similar argument shows that $\inf_{t\le 1} M_t^\varepsilon \ge -(C + 1 + 2\|V\|_1)$.

To see the stated convergence of $\tilde{m}_s$ to X_1, recall that X_t and V_t are almost surely Hölder(η) continuous for all $\eta < 1/2$. Fix $t_0 = 1 - 2\varepsilon T_\varepsilon$, $t_1 = 1 - \varepsilon T_\varepsilon$, $\delta_\varepsilon = 1/\sqrt{T_\varepsilon}$, and write $Y_t = M_t^\varepsilon - X_1$. With these notations,

$$Y_t = Y_{t_0} + \int_{t_0}^t \left[b(M_s^\varepsilon) + \frac{h(X_s) - h(X_1)}{\varepsilon} \right] ds + \frac{1}{\varepsilon} \int_{t_0}^t (h(X_1) - h(M_s^\varepsilon)) ds + (V_t - V_{t_0}).$$

By the first part of the lemma, it holds that $|Y_{t_0}| \le C$. We first show that for some $\tau \in (t_0, t_1)$ it holds that $|Y_\tau| \le \delta_\varepsilon$. Indeed, assume without loss of generality that $Y_{t_0} > \delta_\varepsilon$. Then, by the Hölder property of $X.$ and $V.$, it holds that

$$\sup_{t\in(t_0,t_1)} |V_t - V_{t_0}| \le C(\varepsilon T_\varepsilon)^\eta, \qquad \sup_{t\in(t_0,t_1)} |X_t - X_{t_0}| \le C(\varepsilon T_\varepsilon)^\eta.$$

Hence, if a τ as defined above does not exist, then necessarily, using the Lipschitz continuity of h,

$$-C \le C_1 \varepsilon T_\varepsilon \left(1 + \frac{(\varepsilon T_\varepsilon)^\eta}{\varepsilon} \right) - h_0 \delta_\varepsilon T_\varepsilon + C_1 (\varepsilon T_\varepsilon)^\eta,$$

which is clearly impossible unless $\varepsilon \ge \varepsilon_0$ for some $\varepsilon_0 > 0$. Now, for $\tau < t \le 1$ we claim that it is impossible that $Y_t > 2\delta_\varepsilon$. Indeed, let $\theta' = \inf\{\tau < t \le 1 : Y_t = 2\delta_\varepsilon\}$. Repeating the argument above, we now obtain that if such a θ' exists, it must hold that for some $\theta < 2\varepsilon T_\varepsilon$,

$$\delta_\varepsilon \le C_1 \theta + C_1 \frac{\theta^{\eta+1}}{\varepsilon} + C_1 \theta^\eta - \frac{h_0 \delta_\varepsilon \theta}{\varepsilon},$$

which again is impossible, unless $\varepsilon \ge \varepsilon_0'$, for some $\varepsilon_0' > 0$. The case of $Y_t < -2\delta_\varepsilon$ for some $t > t_0$ being handled similarly, the conclusion follows. □

3. Auxiliary lemmas and proof of Theorem 1.1. Let us set $J_\varepsilon(x) := \rho_1^\varepsilon(x) e^{F(x,\tilde{m}_0)/\varepsilon}$ and

$$\bar{L}_\varepsilon(x,t) = \exp\left(\int_0^t \left(g_1(\tilde{Z}_s^{\varepsilon,x}, \tilde{m}_s) + \frac{1}{\varepsilon} g_2(\tilde{Z}_s^{\varepsilon,x}, \tilde{m}_s)\right) ds\right) \tag{3.1}$$

and

$$L_\varepsilon(x,t) = \exp(I_\varepsilon(\tilde{Z}_t^{\varepsilon,x}, 0)) \bar{L}_\varepsilon(x,t). \tag{3.2}$$

Although both $\bar{L}_\varepsilon(x,t)$ and $L_\varepsilon(x,t)$ depend on the path $\tilde{m}.$, we omit this dependence when no confusion occurs, while $L_\varepsilon(x,t,m.)$ will denote the quantity $L_\varepsilon(x,t)$ with $\tilde{m}.$ replaced by $m.$, and similarly for $\bar{L}_\varepsilon$.

The following are the auxiliary lemmas alluded to above. The proof of the first, Lemma 3.1, is standard, combining large deviations estimates for solutions of SDEs (see, e.g., [2, Theorem 2.13, p. 91]) with Varadhan's lemma (see, e.g., [3, Theorem 4.3.1, p. 137]), and is omitted.

LEMMA 3.1 (finite horizon LDP). *Fix $T < \infty$ and a compact $K \subset\subset \mathbb{R}$. Define*

$$I_T(x,z) := \sup_{\phi \in H^1 : \phi_0 = x, \phi_T = z} \int_0^T g_2(\phi_s, X_1) ds - \frac{1}{2} \int_0^T \left[\dot{\phi}_s + h(\phi_s) - X_1 h'(\phi_s)\right]^2 ds.$$

Then, uniformly in $x, z \in K$, P-almost surely,

$$\limsup_{\delta \to 0} \limsup_{\varepsilon \to 0} \left| \varepsilon \log \mathbb{E}\left[\bar{L}_\varepsilon(x,T) \mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| < \delta\}}\right] - I_T(x,z)\right| = 0.$$

It is worth noting the following simpler representation of $I_T(x,z)$:

$$\begin{aligned} I_T(x,z) = \sup_{\phi \in H^1 : \phi_0 = x, \phi_T = z} \Bigg[& X_1(h(z) - h(x)) - h(X_1)(z - x) \\ & - \frac{1}{2} \int_0^T \left[\dot{\phi}_s - (h(X_1) - h(\phi_s))\right]^2 ds \Bigg]. \end{aligned} \tag{3.3}$$

From this representation, the following is immediate:

$$I_T(X_1, X_1) = 0, \tag{3.4}$$

and, with $V_T(x) := I_T(x, X_1)$, it holds that

$$V_T(x) \to_{T \to \infty} -X_1 h(x) + h(X_1) x. \tag{3.5}$$

This, and standard large deviations considerations, give the next result.

COROLLARY 3.2. *Fix a compact set $K \subset\subset \mathbb{R}$. Then uniformly in $x, z \in K$, P-almost surely,*

$$\begin{aligned} & \limsup_{T \to \infty} \limsup_{\delta \to 0} \limsup_{\varepsilon \to 0} \Bigg| \varepsilon \log \mathbb{E}\left[\bar{L}_\varepsilon(x,T) \mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| < \delta/2\}} \mathbf{1}_{\{|\tilde{Z}_{T/2}^{\varepsilon,x} - X_1| < \delta/2\}}\right] \\ & \qquad - h(X_1)x + h(x)X_1 - I_{T/2}(X_1, z) \Bigg| \\ & = \limsup_{T \to \infty} \limsup_{\delta \to 0} \limsup_{\varepsilon \to 0} \left| \varepsilon \log \mathbb{E}\left[\bar{L}_\varepsilon(x,T) \mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| < \delta/2\}} \mathbf{1}_{\{|\tilde{Z}_{T/2}^{\varepsilon,x} - X_1| < \delta/2\}}\right] - I_T(x,z)\right| \\ & = \limsup_{T \to \infty} \limsup_{\delta \to 0} \limsup_{\varepsilon \to 0} \left| \varepsilon \log \mathbb{E}\left[\bar{L}_\varepsilon(x,T) \mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| < \delta/2\}}\right] - I_T(x,z)\right| = 0. \end{aligned}$$

The key to the proof of Theorem 1.1 is a localization procedure that allows one to restrict attention to compact (in time and space) subsets. A first coarse step in that direction is provided by the next two lemmas.

LEMMA 3.3 (coarse localization 1). *For each $\eta > 0$ there exist constants $M_1 = M_1(|||\tilde{m}|||, \eta, |X_1|)$ and $\varepsilon_{00} = \varepsilon_{00}(|||\tilde{m}|||, \eta, |X_1|)$ such that, for all $\varepsilon < \varepsilon_{00}$,*

$$\int \rho_1^\varepsilon(x)\mathbf{1}_{\{|x|>M_1/\sqrt{\varepsilon}\}}dx \le e^{-\eta/\varepsilon}\inf_{|x|<1}\rho_1^\varepsilon(x) \le e^{-\eta/\varepsilon}\int \rho_1^\varepsilon(x)\mathbf{1}_{\{|x|\le M_1/\sqrt{\varepsilon}\}}dx, \quad P-a.s. \tag{3.6}$$

LEMMA 3.4 (coarse localization 2). *For each $\eta > 0$ and M_1, ε_{00} as in Lemma 3.3, there exist constants $M_i = M_i(|||\tilde{m}|||, \eta, |X_1|)$, $i = 2, 3$, with $M_3 \le M_2$ and $\varepsilon_0 = \varepsilon_0(|||\tilde{m}|||, \eta, |X_1|) < \varepsilon_{00}$, such that for all $\varepsilon < \varepsilon_0$, uniformly in $|x| \le M_1/\sqrt{\varepsilon}$,*

$$J_\varepsilon(x) \le 2\mathbb{E}\left[L_\varepsilon\left(x, \frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||\le M_3/\varepsilon\}}\right], \tag{3.7}$$

and uniformly in $|z| \le M_3/\varepsilon$, $T < 1/\varepsilon$,

$$\mathbb{E}\left[L_\varepsilon\left(z, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\right] \le 2\mathbb{E}\left[L_\varepsilon\left(z, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,z}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right]. \tag{3.8}$$

The following comparison lemma is also needed.

LEMMA 3.5. *There exists a function $g : \mathbb{R}_+ \mapsto \mathbb{R}_+$, depending on $|||\tilde{m}|||, |X_1|, \eta$ only, with $g(\delta) \to_{\delta\to 0} 0$, and an $\varepsilon_1 = \varepsilon_1(|||\tilde{m}|||, X_1, \eta) < \varepsilon_0$ such that for all $\varepsilon < \varepsilon_1$, $t \in [1/2\varepsilon, 1/\varepsilon]$, and $|x|, |y| \le M_3/\varepsilon$, $|x - y| < \delta$,*

$$\varepsilon \log\left(\frac{\mathbb{E}(L_\varepsilon(x, t, \theta^{1/\varepsilon-t}\tilde{m})\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_t\le M_2/\varepsilon\}})}{\mathbb{E}(L_\varepsilon(y, t, \theta^{1/\varepsilon-t}\tilde{m})\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,y}||_t\le M_2/\varepsilon\}})}\right) \le g(\delta), \tag{3.9}$$

and there exists a constant $C_1(|||\tilde{m}|||, X_1, \eta)$ such that, for all $\varepsilon < \varepsilon_1$,

$$\sup_{t\in[1/2\varepsilon,1/\varepsilon]} \varepsilon\left|\log\left(\frac{\mathbb{E}\left[L_\varepsilon(x, t, \theta^{1/\varepsilon-t}\tilde{m})\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_t\le M_2/\varepsilon\}}\right]}{\mathbb{E}\left[L_\varepsilon(X_1, t, \theta^{1/\varepsilon-t}\tilde{m})\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_t\le M_2/\varepsilon\}}\right]}\right)\right| \le C_1(1 + |x|). \tag{3.10}$$

The last step needed in order to carry out the localization procedure is the following.

LEMMA 3.6 (localization). *Fix a sequence T_ε as in Lemma 2.1. Then there exist constants $C_i = C_i(|||\tilde{m}|||, M_1, M_2, M_3, X_1) > 0$, $i \ge 2$, and $\varepsilon_2 = \varepsilon_2(|||\tilde{m}|||, M_1, M_2, M_3, X_1) < \varepsilon_1$ such that, for all $\varepsilon < \varepsilon_2$, $|x| \le M_1/\sqrt{\varepsilon}$, $|z| \le M_3/\varepsilon$, $\delta < 1$, and $1 \le T \le T_\varepsilon$,*

$$\begin{aligned}&\mathbb{E}\left[\bar{L}_\varepsilon(x, T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x}-z|<\delta\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T\le M_3/\varepsilon\}}\right]\\ &\quad\le \exp\left(\frac{C_2}{\varepsilon} - \frac{C_3(|z| - |x|)_+^2}{\varepsilon} + \frac{C_4(|x| + |z|)}{\varepsilon}\right),\end{aligned} \tag{3.11}$$

and, uniformly for $|z - X_1| < 1, |x - X_1| < 1$,

$$\mathbb{E}\left[\bar{L}_\varepsilon(x, T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x}-z|<\delta\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T\le M_3/\varepsilon\}}\right] \ge \exp\left(-\frac{C_2}{\varepsilon}\right). \tag{3.12}$$

We may now proceed to the proof of Theorem 1.1, as a consequence of the above lemmas. Fix an $\eta > 0$ as in Lemma 3.3, and for $\delta > 0$, $T > 0$ to be chosen below, with $T < T_\varepsilon$, T_ε as in Lemma 2.1, define

$$\begin{aligned}\tilde{J}_\varepsilon(x) &= \mathbb{E}\left(L_\varepsilon\left(x, \frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon, ||\tilde{Z}^{\varepsilon,x}|| \le M_2/\varepsilon\}}\right)\\ &= \sum_{i=-M_3/\varepsilon\delta}^{M_3/\varepsilon\delta} \mathbb{E}\left(L_\varepsilon\left(x, \frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}|| \le M_2/\varepsilon, ||\tilde{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon, |\tilde{Z}_T^{\varepsilon,x} - i\delta| \le \delta/2\}}\right)\\ &=: \sum_{i=-M_3/\varepsilon\delta}^{M_3/\varepsilon\delta} \tilde{J}_{\varepsilon,T}(x, i\delta). \qquad (3.13)\end{aligned}$$

Set $\mathcal{Z}_T^{\varepsilon,x} = \sigma(\tilde{Z}_t^{\varepsilon,x}, t \le T)$. Using the Markov property, and the fact that $M_3 < M_2$, one may write, for $|z| < M_3/\varepsilon$,

$$\begin{aligned}\tilde{J}_{\varepsilon,T}(x,z) = \mathbb{E}\Bigg[&\bar{L}_\varepsilon(x,T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| \le \delta/2\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon\}}\\ &\cdot \mathbb{E}\left(L_\varepsilon\left(\tilde{Z}_T^{\varepsilon,x}, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}|| \le M_2/\varepsilon\}} \mid \mathcal{Z}_T^{\varepsilon,x}\right)\Bigg]. \qquad (3.14)\end{aligned}$$

Applying (3.9) and the Markov property, it follows that on the event $\{|\tilde{Z}_T^{\varepsilon,x} - z| \le \delta/2\} \cap \{||\tilde{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon\}$, one has for $\varepsilon < \varepsilon_1$, and $|x| \le M_1/\sqrt{\varepsilon}$, $|z| \le M_3/\varepsilon$,

$$\begin{aligned}&\mathbb{E}\left(L_\varepsilon\left(\tilde{Z}_T^{\varepsilon,x}, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}|| \le M_2/\varepsilon\}} \mid \mathcal{Z}_T^{\varepsilon,x}\right)\\ &= \mathbb{E}\left(L_\varepsilon\left(\tilde{Z}_T^{\varepsilon,x}, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{\sup_{T \le t \le 1/\varepsilon} |\tilde{Z}_t^{\varepsilon,x}| \le M_2/\varepsilon\}} \mid \mathcal{Z}_T^{\varepsilon,x}\right)\\ &\le e^{g(\delta)/\varepsilon}\mathbb{E}\left(L_\varepsilon\left(z, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{\sup_{0 \le 1/\varepsilon - T} |\tilde{Z}_t^{\varepsilon,z}| \le M_2/\varepsilon\}}\right)\\ &= e^{g(\delta)/\varepsilon}\mathbb{E}\left(L_\varepsilon\left(z, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,z}||_{1/\varepsilon - T} \le M_2/\varepsilon\}}\right).\end{aligned}$$

Substituting in (3.14), one concludes that for all $\varepsilon < \varepsilon_1$ and $|x| \le M_1/\sqrt{\varepsilon}$, $|z| \le M_3/\varepsilon$,

$$\begin{aligned}\tilde{J}_{\varepsilon,T}(x,z)e^{-g(\delta)/\varepsilon} &\le \mathbb{E}\left[\bar{L}_\varepsilon(x,T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x} - z| \le \delta/2\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T \le M_3/\varepsilon\}}\right]\\ &\quad \cdot \mathbb{E}\left[L_\varepsilon\left(z, \frac{1}{\varepsilon} - T, \theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,z}||_{1/\varepsilon - T} \le M_2/\varepsilon\}}\right] \qquad (3.15)\\ &:= \hat{J}_{\varepsilon,T}(x,z) \le \tilde{J}_{\varepsilon,T}(x,z)e^{g(\delta)/\varepsilon}.\end{aligned}$$

Next, using (3.10) in the first inequality and Lemma 3.6 in the second, it follows that for all $\varepsilon < \varepsilon_2$; $T \in (1, T_\varepsilon)$, T_ε as in Lemma 2.1; and some constants C_i independent of T, ε,

$$\begin{aligned}\hat{J}_{\varepsilon,T}(x,z) &\le \mathbb{E}\left[\bar{L}_\varepsilon(x,T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x}-z|\le\delta/2\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T\le M_3/\varepsilon\}}\right]\\ &\quad\cdot\mathbb{E}\left[L_\varepsilon\left(X_1,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right]e^{C_1(|z|+1)/\varepsilon}\\ &\le \exp\left(\frac{C_2}{\varepsilon}-\frac{C_3(|z|-|x|)_+^2}{\varepsilon}+\frac{C_5(|x|+|z|)}{\varepsilon}\right)\\ &\quad\cdot\mathbb{E}\left[L_\varepsilon\left(X_1,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right].\end{aligned}\tag{3.16}$$

Similarly, for all $\varepsilon<\varepsilon_2$ and $|x-X_1|\le 1$, $|z-X_1|\le 1$,

$$\hat{J}_{\varepsilon,T}(x,z)\ge\exp\left(-\frac{C_2}{\varepsilon}\right)\mathbb{E}\left[L_\varepsilon\left(X_1,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right].\tag{3.17}$$

We next note that, due to the quadratic growth of $F(x,X_1)$ as $|x|\to\infty$, there exists a compact set $\mathcal{K}_1$, depending on $|||m|||, X_1, \eta, C_i$ only, such that

$$\begin{aligned}&\sup_{(x,z)\in(\mathcal{K}_1\times\mathcal{K}_1)^c}\frac{C_2}{\varepsilon}-\frac{C_3(|z|-|x|)_+^2}{\varepsilon}+\frac{C_5(|x|+|z|)}{\varepsilon}-\frac{F(x,X_1)}{\varepsilon}\\ &\qquad\le-\frac{F(X_1,X_1)}{\varepsilon}-\frac{C_2}{\varepsilon}.\end{aligned}\tag{3.18}$$

Thus, using (3.16) in the first inequality, (3.18) in the second, and (3.17) in the third,

$$\begin{aligned}&\sup_{\substack{|x|\le M_1/\sqrt{\varepsilon},|z|\le M_3/\varepsilon,\\(x,z)\in(\mathcal{K}_1\times\mathcal{K}_1)^c}}\hat{J}_{\varepsilon,T}(x,z)e^{-F(x,X_1)/\varepsilon}\\ &\le\mathbb{E}\left[L_\varepsilon\left(X_1,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right]\\ &\quad\cdot\sup_{\substack{|x|\le M_1/\sqrt{\varepsilon},|z|\le M_3/\varepsilon,\\(x,z)\in(\mathcal{K}_1\times\mathcal{K}_1)^c}}\exp\left(\frac{C_2}{\varepsilon}-\frac{C_3(|z|-|x|)_+^2}{\varepsilon}+\frac{C_5(|x|+|z|)}{\varepsilon}-\frac{F(x,X_1)}{\varepsilon}\right)\\ &\le\mathbb{E}\left[L_\varepsilon\left(X_1,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,X_1}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right]\exp\left(-\frac{C_2}{\varepsilon}-\frac{F(X_1,X_1)}{\varepsilon}\right)\\ &\le\hat{J}_{\varepsilon,T}(X_1,X_1)e^{-F(X_1,X_1)/\varepsilon}.\end{aligned}\tag{3.19}$$

It follows by substituting (3.19) into (3.15) that for all ε small enough and any $T\in(0,T_\varepsilon)$,

$$\sup_{|x|\le M_1/\sqrt{\varepsilon},|z|\le M_3/\varepsilon}\tilde{J}_{\varepsilon,T}(x,z)e^{-F(x,X_1)/\varepsilon}\le e^{2g(\delta)/\varepsilon}\sup_{x\in\mathcal{K}_1,z\in\mathcal{K}_1}\tilde{J}_{\varepsilon,T}(x,z)e^{-F(x,X_1)/\varepsilon}.\tag{3.20}$$

We may, by enlarging $\mathcal{K}_1$ if necessary, assume also that $[-1,1]\subset\mathcal{K}_1$. With η and $\mathcal{K}_1$ as above, next choose T large enough, δ small enough (with $g(\delta)<\eta/8$), and $\varepsilon_3(\delta,T,\eta,|||\tilde{m}|||,|||\tilde{m}_X|||,X_1)<\varepsilon_2$ such that, for all $\varepsilon<\varepsilon_3$, the following hold:

- The errors in the expression in Corollary 3.2 and in (3.5) are each bounded above by $\eta/8$, uniformly in $x,z\in\mathcal{K}_1$.
- $|F(x,\tilde{m}_0)-F(x,X_1)|\le\eta/8$, uniformly in $x\in\mathcal{K}_1$ (which is possible by Lemma 2.1 and the uniform continuity of $F(x,\cdot)$ for x in compacts).

- $\varepsilon \log 2 \le \eta/8$.
- $\varepsilon \log(2M_3/\varepsilon\delta) \le \eta/8$.

Hence, for $x \in \mathcal{K}_1$ and all $\varepsilon < \varepsilon_3$,

$$
\begin{aligned}
\varepsilon \log \rho_1^\varepsilon(x) &= -F(x,\tilde m_0) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\right) \quad \texttt{by (2.2)} \\
&\le -F(x,\tilde m_0) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,x}||\le M_3/\varepsilon\}}\right) + \varepsilon\log 2 \quad \texttt{by (3.7)} \\
&\le -F(x,X_1) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,x}||\le M_3/\varepsilon\}}\right) + \frac{\eta}{4} \quad \texttt{by } \varepsilon < \varepsilon_3 \\
&\le -F(x,X_1) + \varepsilon \log \tilde J_\varepsilon(x) + \frac{\eta}{4} \quad \texttt{by (3.13)} \\
&\le -F(x,X_1) + \varepsilon \log \sup_{z\in\mathcal{K}_1} \tilde J_{\varepsilon,T}(x,z) + \frac{\eta}{2} \quad \texttt{by (3.13) and (3.20)} \\
&\le -F(x,X_1) + \sup_{z\in\mathcal{K}_1}\Bigg[\varepsilon \log \mathbb{E}(\bar L_\varepsilon(x,T)\mathbf{1}_{\{|\tilde Z_T^{\varepsilon,x}-z|\le\delta/2\}}) \\
&\quad + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde m\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,z}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right)\Bigg] + \frac{5\eta}{8} \quad \texttt{by (3.15)} \\
&\le -F(x,X_1) + \sup_{z\in\mathcal{K}_1}\Bigg[h(X_1)x - h(x)X_1 + I_{T/2}(X_1,z) \\
&\qquad\qquad + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde m\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,z}||_{1/\varepsilon-T}\le M_2/\varepsilon\}}\right)\Bigg] \\
&\quad + \frac{7\eta}{8} \quad \texttt{by Corollary 3.2} \\
&\le h(X_1)x - h(x)X_1 - F(x,X_1) + \eta \\
&\quad + \sup_{z\in\mathcal{K}_1}\left[I_{T/2}(X_1,z) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde m\right)\right)\right] \\
&=: -\bar{\mathcal{J}}(x,X_1) + \eta + \mathcal{C}_\varepsilon, \qquad (3.21)
\end{aligned}
$$

where $\mathcal{C}_\varepsilon$ depends only on ε, and not on x, and is defined by the last equality. Similarly, for all $x \in \mathcal{K}_1$ and all $\varepsilon < \varepsilon_3$,

$$
\begin{aligned}
\varepsilon \log \rho_1^\varepsilon(x) &= -F(x,\tilde m_0) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\right) \quad \texttt{by (2.2)} \\
&\ge -F(x,\tilde m_0) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,x}||_T\le M_3/\varepsilon, ||\tilde Z^{\varepsilon,x}||\le M_2/\varepsilon\}}\right) \\
&\ge -F(x,X_1) + \varepsilon \log \mathbb{E}\left(L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{||\tilde Z^{\varepsilon,x}||_T\le M_3/\varepsilon, ||\tilde Z^{\varepsilon,x}||\le M_2/\varepsilon\}}\right) \\
&\quad - \frac{\eta}{4} \quad \texttt{by } \varepsilon < \varepsilon_3 \\
&= -F(x,X_1) + \varepsilon \log \tilde J_\varepsilon(x) - \frac{\eta}{4} \quad \texttt{by definition} \\
&\ge -F(x,X_1) + \varepsilon \log \sup_{z\in\mathcal{K}_1} \tilde J_{\varepsilon,T}(x,z) - \frac{\eta}{4} \quad \texttt{by definition}
\end{aligned}
$$

$$
\begin{aligned}
&\geq -F(x,X_1)+\sup_{z\in\mathcal{K}_1}\left[\varepsilon\log\mathbb{E}(\bar{L}_\varepsilon(x,T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x}-z|\leq\delta/2\}})\right.\\
&\quad\left.+\varepsilon\log\mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,z}||_{1/\varepsilon-T}\leq M_2/\varepsilon\}}\right)\right]-\frac{5\eta}{8}\quad\texttt{by (3.15)}\\
&\geq -F(x,X_1)+\sup_{z\in\mathcal{K}_1}\left[h(X_1)x-h(x)X_1+I_{T/2}(X_1,z)\right.\\
&\qquad\left.+\varepsilon\log\mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,z}||_{1/\varepsilon-T}\leq M_2/\varepsilon\}}\right)\right]\\
&\quad-\frac{7\eta}{8}\quad\texttt{by Corollary(3.2)}\\
&\geq h(X_1)x-h(x)X_1-F(x,X_1)-\eta\\
&\quad+\sup_{z\in\mathcal{K}_1}\left[I_{T/2}(X_1,z)+\varepsilon\log\mathbb{E}\left(L_\varepsilon\left(z,\frac{1}{\varepsilon}-T,\theta^T\tilde{m}\right)\right)\right]\\
&=-\bar{\mathcal{J}}(x,X_1)-\eta+\mathcal{C}_\varepsilon, \qquad (3.22)
\end{aligned}
$$

where $\mathcal{C}_\varepsilon$ is the same as in (3.21). Since $\bar{\mathcal{J}}(\cdot,X_1)$ is continuous and $\bar{\mathcal{J}}(X_1,X_1)=0$, it follows from (3.22) that

$$
\liminf_{\varepsilon\to0}\varepsilon\log\int_{\mathbb{R}}\rho_1^\varepsilon(x)dx-\mathcal{C}_\varepsilon\geq-2\eta. \qquad (3.23)
$$

On the other hand, for $\varepsilon<\varepsilon_3$,

$$
\begin{aligned}
\varepsilon\log\int_{\mathbb{R}}\rho_1^\varepsilon(x)dx&\leq\varepsilon\log(1+e^{-\eta/\varepsilon})+\varepsilon\log\int_{|x|\leq M_1/\sqrt{\varepsilon}}\rho_1^\varepsilon(x)dx\quad\texttt{by Lemma 3.3}\\
&\leq\varepsilon\log(1+e^{-\eta/\varepsilon})+\varepsilon\log2+\varepsilon\log\left(\frac{2M_3}{\varepsilon\delta}\right)\\
&\qquad+\sup_{|x|\leq M_1/\sqrt{\varepsilon},|z|\leq M_3/\varepsilon}\varepsilon\log\left(\tilde{J}_{\varepsilon,T}(x,z)e^{-F(x,X_1)/\varepsilon}\right)\\
&\qquad\qquad\texttt{by Lemma 3.4 and (3.13)}\\
&\leq\frac{5\eta}{8}+\sup_{x,z\in\mathcal{K}_1}\varepsilon\log\left(\tilde{J}_{\varepsilon,T}(x,z)e^{-F(x,X_1)/\varepsilon}\right)\quad\texttt{by (3.20)}\\
&\leq\frac{5\eta}{8}+\varepsilon\log\left(\sup_{x\in\mathcal{K}_1}\rho_1^\varepsilon(x)\right)\\
&\leq2\eta+\mathcal{C}_\varepsilon-\inf_x\bar{\mathcal{J}}(x,X_1)=2\eta+\mathcal{C}_\varepsilon \qquad (3.24)\\
&\qquad\qquad\texttt{by (3.21) and }\bar{\mathcal{J}}(x,X_1)\geq0.
\end{aligned}
$$

Consider now an open ball $B(x_0,r)\subset\mathbb{R}$. Then, using (3.24) in the first inequality and (3.22) in the last,

$$
\begin{aligned}
\liminf_{\varepsilon\to0}\varepsilon\log\int_{B(x_0,r)}q_1^\varepsilon(x)dx&=\liminf_{\varepsilon\to0}\left[\varepsilon\log\int_{B(x_0,r)}\rho_1^\varepsilon(x)dx-\varepsilon\log\int_{\mathbb{R}}\rho_1^\varepsilon(x)dx\right]\\
&\geq\liminf_{\varepsilon\to0}\left[\varepsilon\log\int_{B(x_0,r)}\rho_1^\varepsilon(x)dx-\mathcal{C}_\varepsilon-2\eta\right]\\
&\geq-\bar{\mathcal{J}}(x_0,X_1)-3\eta.
\end{aligned}
$$

Since η is arbitrary, one deduces that

$$\liminf_{\varepsilon\to 0} \varepsilon \log \int_{B(x_0,r)} q_1^\varepsilon(x)dx \geq -\bar{\mathcal{J}}(x_0, X_1). \tag{3.25}$$

To see the complementary upper bound for the ball $B(x_0, r)$, enlarge $\mathcal{K}_1$ if necessary so that $B(x_0, r) \subset \mathcal{K}_1$ (decreasing ε_3 above as a byproduct). Then, using (3.23) in the first inequality and (3.21) in the last,

$$\begin{aligned}
\limsup_{\varepsilon\to 0} \varepsilon \log \int_{B(x_0,r)} q_1^\varepsilon(x)dx &= \limsup_{\varepsilon\to 0} \left[\varepsilon \log \int_{B(x_0,r)} \rho_1^\varepsilon(x)dx - \varepsilon \log \int_{\mathbb{R}} \rho_1^\varepsilon(x)dx \right] \\
&\leq \limsup_{\varepsilon\to 0} \left[\varepsilon \log \int_{B(x_0,r)} \rho_1^\varepsilon(x)dx - \mathcal{C}_\varepsilon + 2\eta \right] \\
&\leq - \sup_{x\in B(x_0,r)} \bar{\mathcal{J}}(x, X_1) + 3\eta + \limsup_{\varepsilon\to 0} \varepsilon \log(2r).
\end{aligned}$$

Since η is arbitrary, the above, (3.25), and the continuity of $\bar{\mathcal{J}}(\cdot, X_1)$ imply that

$$\lim_{r\to 0} \limsup_{\varepsilon\to 0} \varepsilon \log \int_{B(x_0,r)} q_1^\varepsilon(x)dx = \lim_{r\to 0} \liminf_{\varepsilon\to 0} \varepsilon \log \int_{B(x_0,r)} q_1^\varepsilon(x)dx = \bar{\mathcal{J}}(x_0, X_1).$$

Next, [3, Theorem 4.1.11], the above, Remark 2 following Theorem 1.1, and the continuity of $\bar{\mathcal{J}}(\cdot, X_1)$ imply that the weak LDP holds for the sequence of (random) measures $\mu_1^\varepsilon(dx) = q_1^\varepsilon(x)dx$ on $\mathbb{R}$. To prove the full large deviations principle, it remains, by [3, Lemma 1.2.8], to prove the exponential tightness of the sequence μ_1^ε. That is, for each given L we must find a constant C_L such that

$$\limsup_{\varepsilon\to 0} \varepsilon \log \int_{[-L,L]^c} q_1^\varepsilon(x)ds < -L. \tag{3.26}$$

Since the proof of (3.26) uses some estimates from the proof of Lemma 3.3, to avoid repetitions we postpone it to the end of section 4.

Finally, we note that (1.3) is an immediate consequence of the estimates (3.21), (3.22), (3.24), and (3.23). □

4. Proofs of auxiliary lemmas. Throughout this section, C denotes a positive constant that depends on $|||\tilde{m}|||, |||\tilde{m}_X|||, C_{V,X}, X$ only, and whose value may change from line to line.

Proof of Lemma 3.3. The right-hand inequality is a trivial consequence of the left-hand one. To prove the latter, we first need an upper bound for the left-hand side of (3.6). A subsequent, easily derived lower bound on the middle term will conclude the proof. Define the function

$$H(x) = \int_0^x h(y)dy. \tag{4.1}$$

We note that

$$I_\varepsilon(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}, 0) - \frac{F(x, \tilde{m}_0)}{\varepsilon} = \frac{1}{\varepsilon} \left(H(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) - H(x) \right) + \log p_0(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) + \frac{\tilde{m}_0 h(x)}{\varepsilon}.$$

We first rewrite the $\tilde{Z}_t^{\varepsilon,x}$ equation as

$$\tilde{Z}_t^{\varepsilon,x} = x + \int_0^t [-h(\tilde{Z}_s^{\varepsilon,x}) + g(s, \tilde{Z}_s^{\varepsilon,x})]ds + \sqrt{\varepsilon}\tilde{W}_t,$$

and next deduce from Itô's formula that

$$\begin{aligned} &H(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) - H(x) \\ &\quad = \int_0^{1/\varepsilon} \left[-h^2(\tilde{Z}_s^{\varepsilon,x}) + (hg)(s, \tilde{Z}_s^{\varepsilon,x}) + \frac{\varepsilon}{2}h'(\tilde{Z}_s^{\varepsilon,x}) \right] ds + \sqrt{\varepsilon} \int_0^{1/\varepsilon} h(\tilde{Z}_s^{\varepsilon,x}) d\tilde{W}_s. \end{aligned}$$

It now follows from (2.2) and the (uniform in m in compacts) linear growth of $g_1(z,m)$ and $g_2(z,m)$ in z that for some C (depending on $|||\tilde{m}|||$ and X only) and all $\varepsilon \le 1$, $\delta > 0$,

$$\begin{aligned} &\rho_1^\varepsilon(x) \le \exp\left[\frac{C}{\varepsilon^2} + \frac{\tilde{m}_0 h(x)}{\varepsilon}\right] \left(\mathbb{E}\left[p_0(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}) \right]^{\frac{1+\delta}{\delta}} \right)^{\frac{\delta}{1+\delta}} \\ &\times \left(\mathbb{E} \exp\left[\frac{1+\delta}{\sqrt{\varepsilon}} \int_0^{1/\varepsilon} h(\tilde{Z}_s^{\varepsilon,x}) d\tilde{W}_s - \frac{1+\delta}{\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds + \frac{C}{\varepsilon} \int_0^{1/\varepsilon} |\tilde{Z}_s^{\varepsilon,x}| ds \right] \right)^{\frac{1}{1+\delta}}. \end{aligned}$$

Now, provided $\delta < 1$, we have $1 + \delta > \frac{(1+\delta)^2}{2}$, and thus there exists a $p > 1$ and a $p' > 0$ such that

$$1 + \delta = \frac{p(1+\delta)^2}{2} + p'.$$

Thus, with $q = p/(p-1)$,

$$\begin{aligned} &\left(\mathbb{E} \exp\left[\frac{1+\delta}{\sqrt{\varepsilon}} \int_0^{1/\varepsilon} h(\tilde{Z}_s^{\varepsilon,x}) d\tilde{W}_s - \frac{(1+\delta)^2 p}{2\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds \right.\right. \\ &\qquad \left.\left. - \frac{p'}{\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds + \frac{C}{\varepsilon} \int_0^{1/\varepsilon} |\tilde{Z}_s^{\varepsilon,x}| ds \right] \right)^{\frac{1}{1+\delta}} \\ &\le \left(\mathbb{E} \exp\left[\frac{p(1+\delta)}{\sqrt{\varepsilon}} \int_0^{1/\varepsilon} h(\tilde{Z}_s^{\varepsilon,x}) d\tilde{W}_s - \frac{(1+\delta)^2 p^2}{2\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds \right] \right)^{\frac{1}{p(1+\delta)}} \\ &\quad \times \left(\mathbb{E} \exp\left[-\frac{p'q}{2\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds + \frac{Cq}{\varepsilon} \int_0^{1/\varepsilon} |\tilde{Z}_s^{\varepsilon,x}| ds \right] \right)^{\frac{1}{q(1+\delta)}} \\ &= \left(\mathbb{E} \exp\left[-\frac{p'q}{2\varepsilon} \int_0^{1/\varepsilon} h^2(\tilde{Z}_s^{\varepsilon,x}) ds + \frac{Cq}{\varepsilon} \int_0^{1/\varepsilon} |\tilde{Z}_s^{\varepsilon,x}| ds \right] \right)^{\frac{1}{q(1+\delta)}}. \end{aligned}$$

Since $h(z)^2 \ge h_0^2 z^2$ (recall that $h(0) = 0$!), there exist $C(\delta) > 0$, $C_1(\delta)$ such that $p'qh(z)^2/2 - Cq|z| \ge C(\delta)z^2 - C_1(\delta)$, and hence, with $C_2(\delta) = C + C_1(\delta)\delta/p(1+\delta)$

(all constants here being positive and depending on $|||\tilde{m}|||, X$ only!),

$$\begin{aligned}\rho_1^\varepsilon(x) &\le \exp\left[\frac{C_2(\delta)}{\varepsilon^2}+\frac{\tilde{m}_0 h(x)}{\varepsilon}\right]\left(\mathbb{E}\left[p_0(\tilde{Z}^{\varepsilon,x}_{1/\varepsilon})\right]^{\frac{1+\delta}{\delta}}\right)^{\frac{\delta}{1+\delta}} \\ &\times\left(\mathbb{E}\exp\left[-\frac{C(\delta)}{\varepsilon}\int_0^{1/\varepsilon}|\tilde{Z}^{\varepsilon,x}_s|^2 ds\right]\right)^{\frac{\delta}{q(1+\delta)}} \\ &\le \exp\left[\frac{C_3(\delta)}{\varepsilon^2}\right]\left(\mathbb{E}\exp\left[-\frac{C(\delta)}{\varepsilon}\int_0^{1/\varepsilon}|\tilde{Z}^{\varepsilon,x}_s|^2 ds\right]\right)^{\frac{\delta}{q(1+\delta)}}.\end{aligned} \tag{4.2}$$

It thus remains to estimate the last factor in the above right-hand side. Define $\tau = \inf\{t>0 : |\tilde{Z}^{\varepsilon,x}_s| < x/2\}$ and fix $\eta>0$. We claim that for some $\eta>0$ small enough, it holds that for some $C_\eta>0$, x_0 and all $|x|\ge x_0$,

$$\mathbb{P}(\tau<\eta)\le \exp\left[-\frac{C_\eta x^2}{\varepsilon}\right]. \tag{4.3}$$

Assume (4.3), which will be proved below, and note that on the event $\{\tau\ge\eta\}$ we have that $\inf_{s\in(0,\eta]}|\tilde{Z}^{\varepsilon,x}_s| > x/2$. We deduce from (4.2)

$$\rho_1^\varepsilon(x)\le \exp\left[\frac{C_3(\delta)}{\varepsilon^2}\right]\times\left(\exp\left[-\frac{C_\eta x^2}{\varepsilon}\right]+\exp\left[-\frac{C(\delta)x^2\eta\delta}{4q(1+\delta)\varepsilon}\right]\right), \tag{4.4}$$

from which one easily concludes the bound

$$\rho_1^\varepsilon(x)\le \exp\left[\frac{C_4(\delta)}{\varepsilon^2}-\frac{Cx^2}{\varepsilon}\right] \tag{4.5}$$

for some constants $C_4(\delta)$ and C depending on $\delta, |||\tilde{m}|||, X$ only.

On the other hand, define the event

$$A_C=\left\{\sup_{t\in(0,1/\varepsilon)}\sqrt{\varepsilon}|\tilde{W}_t|\le C\right\}.$$

Then there exists a constant $C_3>0$ depending on C such that $\mathbb{P}(A_C)\ge C_3$. Note that on the event A_C, because $h'(\cdot)>0$ and h, b are Lipschitz, Gronwall's inequality implies that $\sup_{|x|\le 1, s\le 1/\varepsilon}|\tilde{Z}^{\varepsilon,x}_s|\le C'$ for some constant C' depending on $C, \tilde{m}, X$ only. Thus, on the event A_C,

$$\left|I_\varepsilon(\tilde{Z}^{\varepsilon,x}_{1/\varepsilon},0)+\int_0^{1/\varepsilon}g_1(\tilde{Z}^{\varepsilon,x}_s,\tilde{m}_s)ds+\frac{1}{\varepsilon}\int_0^{1/\varepsilon}g_2(\tilde{Z}^{\varepsilon,x}_s,\tilde{m}_s)ds\right|\le\frac{C_4}{\varepsilon^2},$$

where C_4 depends only on $\tilde{m}, X$ and the constants in Assumptions (A-1)–(A-4). Hence (cf. (2.2)), there exists a constant C_2 (again, depending on the same quantities only) such that, uniformly in $|x|<1$,

$$\rho_1^\varepsilon(x)\ge\exp\left[-\frac{C_2}{\varepsilon^2}\right]. \tag{4.6}$$

Equations (4.6) and (4.5) complete the proof of the lemma, once we prove (4.3).

Toward this end, assume without loss of generality that $x>0$, and set $\hat{h} = 2\sup_{y>0} h'(y)$. Using the Itô formula, one has

$$\begin{aligned}&\tilde{Z}_t^{\varepsilon,x} e^{\hat{h}t}\\ &= x + \int_0^t \left(\hat{h}\tilde{Z}_s^{\varepsilon,x} - h(\tilde{Z}_s^{\varepsilon,x}) + \tilde{m}_s h'(\tilde{Z}_s^{\varepsilon,x}) - \varepsilon b(\tilde{Z}_s^{\varepsilon,x})\right) e^{\hat{h}s} ds + \sqrt{\varepsilon}\int_0^t e^{\hat{h}s} d\tilde{W}_s.\end{aligned} \tag{4.7}$$

Hence, denoting $C_3 = |||\tilde{m}|||\sup_x h'(x)$, it follows that the event $\{\tau<\eta\}$ is contained in the event

$$\left\{\sup_{t\in(0,\eta)}\left|\sqrt{\varepsilon}\int_0^t e^{\hat{h}s} d\tilde{W}_s\right| \geq x - C_3\frac{e^{\hat{h}\eta}-1}{\hat{h}} - \frac{xe^{\hat{h}\eta}}{2}\right\} \subset \left\{\sup_{t\in(0,\eta)}\left|\sqrt{\varepsilon}\int_0^t e^{\hat{h}s} d\tilde{W}_s\right| \geq \frac{x}{4}\right\} =: B$$

if one chooses η small enough and x large enough. We have that

$$\mathbb{P}(B) \leq 4\exp\left(-\frac{Cx^2}{\varepsilon}\right)$$

for some constant C, which completes the proof of (4.3). □

Proof of Lemma 3.4. We prove only (3.7), the proof of (3.8) being similar. All we need to show is that for all $\varepsilon\leq\varepsilon_0$, $|x|\leq M_1/\sqrt{\varepsilon}$, and some M_2,

$$\mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right] \leq \mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|\leq M_2/\varepsilon\}}\right]. \tag{4.8}$$

We first bound the left-hand side of (4.8) for $\varepsilon\leq 1$. Recall the function H introduced in (4.1), and apply Itô's formula to develop $H(\tilde{Z}_t^{\varepsilon,x})$ between $t=0$ and $t=1/\varepsilon$, obtaining

$$\begin{aligned}\log L_\varepsilon\left(x,\frac{1}{\varepsilon}\right) - \frac{H(x)}{\varepsilon} &= -\frac{1}{2\varepsilon}\int_0^{1/\varepsilon}|h(\tilde{Z}_t^{\varepsilon,x}) - h(\tilde{m}_t)|^2 dt - \frac{1}{2\varepsilon}\int_0^{1/\varepsilon}|h(\tilde{Z}_t^{\varepsilon,x})|^2 dt\\ &\quad + \frac{1}{\sqrt{\varepsilon}}\int_0^{1/\varepsilon} h(\tilde{Z}_t^{\varepsilon,x}) d\tilde{W}_t + \int_0^{1/\varepsilon} g_{3,\varepsilon}(\tilde{Z}_t^{\varepsilon,x},\tilde{m}_t) dt + \log p_0(\tilde{Z}_{1/\varepsilon}^{\varepsilon,x}),\end{aligned}$$

where

$$g_{3,\varepsilon}(z,m) = g_1(z,m) - b(z)h(z) + \frac{1}{2}h'(z) + \frac{1}{2\varepsilon}m^2(h'(z))^2.$$

Note that $\log p_0(\cdot)$ is bounded above, and

$$|g_{3,\varepsilon}(z,\tilde{m}_t)| \leq C\left(\frac{1}{\varepsilon} + |z|\right).$$

Now since, for any $p>1$,

$$\mathbb{E}\left[\exp\left(-\frac{p^2}{2\varepsilon}\int_0^{1/\varepsilon}|h(\tilde{Z}_t^{\varepsilon,x})|^2 dt + \frac{p}{\sqrt{\varepsilon}}\int_0^{1/\varepsilon} h(\tilde{Z}_t^{\varepsilon,x}) d\tilde{W}_t\right)\right] = 1,$$

it follows from Hölder's inequality that for any $q > p > 1$ satisfying $1/p + 1/q = 1$,

$$
\begin{aligned}
& e^{-H(x)/\varepsilon}\ \mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right] \\
& \le \left(\mathbb{E}\left[\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\exp\left(C\int_0^{1/\varepsilon}\left(\frac{1}{\varepsilon}+|\tilde{Z}_t^{\varepsilon,x}|^2\right)dt\right)\right.\right. \\
& \left.\left.\times\exp\left(-\frac{q}{2\varepsilon}\int_0^{1/\varepsilon}|h(\tilde{Z}_t^{\varepsilon,x})-h(\tilde{m}_t)|^2dt+\frac{p}{2\varepsilon}\int_0^{1/\varepsilon}|h(\tilde{Z}_t^{\varepsilon,x})|^2dt\right)\right]\right)^{1/q},
\end{aligned}
\tag{4.9}
$$

where $C > 0$. However, note that, due to $h' \ge h_0$, there exists a constant C depending on $|||\tilde{m}|||$ such that

$$
\sup_{z\in\mathbb{R},|m|\le|||\tilde{m}|||}|z|^2-\frac{q}{2}|h(z)-h(m)|^2+\frac{p}{2}|h(z)|^2\le C.
$$

Substituting this into (4.9), one deduces that

$$
e^{-H(x)/\varepsilon}\mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right]\le\left(\mathbb{E}\left[\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\exp\left(\frac{C}{\varepsilon^2}\right)\right]\right)^{1/q}.
\tag{4.10}
$$

(Recall that the value of C may change from line to line!)

We prove below that, provided M_2 is large enough, there exists a $c > 0$ such that

$$
\mathbb{E}\left[\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right]\le\exp\left(-\frac{c}{\varepsilon^3}\right).
\tag{4.11}
$$

Combined with (4.10), this implies that, uniformly in $|x| \le M_1/\sqrt{\varepsilon}$,

$$
\mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right]\le\exp\left(-\frac{c}{\varepsilon^3}\right).
\tag{4.12}
$$

To see (4.11), let $H = \sup|h'|$, define $\theta_0 = 0$, and let

$$
\tau_i=\inf\left\{t>\theta_{i-1}:|\tilde{Z}_t^{\varepsilon,x}|>\frac{M_2}{2\varepsilon}\right\},\quad \theta_i=\inf\left\{t>\tau_i:|\tilde{Z}_t^{\varepsilon,x}|<\frac{M_2}{4\varepsilon}\right\}.
$$

Setting $f(z,m) = -h(z) + mh'(z) - \varepsilon b(z)$, we have that, for $|z| \in [M_2/4\varepsilon, M_2/\varepsilon]$, $t \le 1/\varepsilon$, and ε small enough, it holds that $h_0M_2/8\varepsilon \le |f(z,\tilde{m}_t)| \le 2HM_2/\varepsilon$ and $\mathrm{sign} f(z,\tilde{m}_t) = -\mathrm{sign}(z)$. Then, choosing $\eta = (16H)^{-1}$ for each i, it holds that

$$
\begin{aligned}
\mathbb{P}\left(\theta_i-\tau_i<\eta,\ \sup_{t\in[\tau_i,\theta_i]}|\tilde{Z}_t^{\varepsilon,x}|<\frac{M_2}{\varepsilon}\right)&\le\mathbb{P}\left(\sqrt{\varepsilon}\sup_{0\le t\le\eta}|W_t|\ge\frac{M_2}{4\varepsilon}-\frac{2H\eta M_2}{\varepsilon}\right)\\
&\le\mathbb{P}\left(\sqrt{\varepsilon}\sup_{0\le t\le\eta}|W_t|\ge\frac{M_2}{8\varepsilon}\right)\\
&\le\exp\left(-\frac{cM_2^2}{\varepsilon^3\eta}\right).
\end{aligned}
\tag{4.13}
$$

Similarly

$$
\begin{aligned}
\mathbb{P}\left(\theta_i-\tau_i\ge\eta,\ |\tilde{Z}_{\tau_i+\eta}^{\varepsilon,x}|\ge\frac{M_2}{2\varepsilon}\right)&\le\mathbb{P}\left(\sqrt{\varepsilon}W_\eta\ge\frac{h_0M_2\eta}{8\varepsilon}\right)\\
&\le\exp\left(-\frac{cM_2^2\eta}{\varepsilon^3}\right)
\end{aligned}
\tag{4.14}
$$

and

$$\mathbb{P}\left(\sup_{t\in[\tau_i,(\tau_i+\eta)\wedge\theta_i]}|\tilde{Z}_t^{\varepsilon,x}|>\frac{M_2}{\varepsilon}\right)\le\mathbb{P}\left(\sqrt{\varepsilon}\sup_{0\le t\le\eta}|W_t|\ge\frac{M_2}{2\varepsilon}\right)\le\exp\left(-\frac{cM_2^2}{\varepsilon^3\eta}\right). \tag{4.15}$$

Hence, using (4.13), (4.14), and (4.15),

$$\mathbb{E}\left[\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|>M_2/\varepsilon\}}\right]\le\frac{1}{\varepsilon\eta}\left(\exp\left(-\frac{cM_2^2}{\varepsilon^3\eta}\right)+\exp\left(-\frac{cM_2^2}{\varepsilon^3}\right)+\exp\left(-\frac{cM_2^2\eta}{\varepsilon^3\eta}\right)\right),$$

completing the proof of (4.11).

We now turn to the lower bound of the right-hand side of (4.8). Let, with $M_1'=M_1+1$,

$$\varepsilon_0=1\wedge\left(\frac{M_2}{M_1'}\right)^2.$$

For $\varepsilon\le\varepsilon_0$,

$$\left\{\|\tilde{Z}^{\varepsilon,x}\|\le\frac{M_1'}{\sqrt{\varepsilon}}\right\}\subset\left\{\|\tilde{Z}^{\varepsilon,x}\|\le\frac{M_2}{\varepsilon}\right\},$$

so that for some $c'>0$

$$\mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|\le M_2/\varepsilon\}}\right]\ge\mathbb{E}\left[L_\varepsilon\left(x,\frac{1}{\varepsilon}\right)\mathbf{1}_{\{\|\tilde{Z}^{\varepsilon,x}\|\le M_1'/\sqrt{\varepsilon}\}}\right]\ge\exp\left(-\frac{c'}{\varepsilon^{5/2}}\right)\mathbb{P}\left(\|\tilde{Z}^{\varepsilon,x}\|\le\frac{M_1'}{\sqrt{\varepsilon}}\right). \tag{4.16}$$

Finally (4.8) follows from (4.12), (4.16), and the estimate

$$\mathbb{P}\left(\|\tilde{Z}^{\varepsilon,x}\|\le\frac{M_1'}{\sqrt{\varepsilon}}\right)\ge\mathbb{P}\left(\sqrt{\varepsilon}\|\tilde{W}\|\le C\right)\ge c''>0. \qquad \square$$

Proof of Lemma 3.5. Note first that because of (A-4), there exists a constant $\kappa=\kappa(|||\tilde{m}|||)$ such that for all $z\notin[-\kappa,\kappa]$, all $\varepsilon<1/\kappa$, all $|m|\le|||\tilde{m}|||$, and all z',

$$\Delta(z,z',m)=-h(z)+h(z')+m[h'(z)-h'(z')]-\varepsilon[b(z)-b(z')]$$

satisfies $\operatorname{sign}(\Delta(z,z',m))=\operatorname{sign}(z'-z)$, while $|\Delta(z,z',m)|\ge h_0|z-z'|/2$.

Assume, without loss of generality, that $x<y$. Fix, for δ given, a smooth, even, nonnegative function $c(z)$ such that $c(|z|)$ is nonincreasing, $c(z)=\sqrt{\delta}$ for $|z|\le\kappa$, and $c(z)=0$ for $|z|>2\kappa$, with $||c'||\le10\sqrt{\delta}$. Define next the diffusions

$$\begin{aligned}d\xi_s^1&=[-h(\xi_s^1)+\tilde{m}_sh'(\xi_s^1)-\varepsilon b(\xi_s^1)+c(\xi_s^1)\mathbf{1}_{\{\tau>s\}}]ds+\sqrt{\varepsilon}dB_s,\quad\xi_0^1=x,\\ d\xi_s^2&=[-h(\xi_s^2)+\tilde{m}_sh'(\xi_s^2)-\varepsilon b(\xi_s^2)]dt+\sqrt{\varepsilon}dB_s,\quad\xi_0^2=y,\end{aligned}$$

where B is a Brownian motion independent of the process $\tilde{m}$, and $\tau=\min\{t:\xi_t^1=\xi_t^2\}\wedge1/\varepsilon$. Note that ξ^2 coincides in distribution with $\tilde{Z}^{\varepsilon,y}$, whereas the law of ξ^1

is absolutely continuous with respect to the law of $\tilde{Z}^{\varepsilon,x}$ with the Radon–Nikodym derivative given by

(4.17)
$$\Lambda = \exp\left(\frac{1}{\varepsilon}\int_0^\tau c(\xi_s^1)d\xi_s^1 - \frac{1}{2\varepsilon}\int_0^\tau c^2(\xi_s^1)ds - \frac{1}{\varepsilon}\int_0^\tau c(\xi_s^1)g(s,\xi_s^1)ds\right)$$
$$= \exp\left(\frac{1}{\varepsilon}[\bar{c}(\xi_\tau^1) - \bar{c}(\xi_0^1)] - \frac{1}{2\varepsilon}\int_0^\tau c^2(\xi_s^1)ds - \frac{1}{\varepsilon}\int_0^\tau c(\xi_s^1)g(s,\xi_s^1)ds - \frac{1}{2}\int_0^\tau c'(\xi_s^1)ds\right),$$

where $g(s,z) = -h(z) + \tilde{m}_s h'(z) - \varepsilon b(z)$ and $\bar{c}(z) = \int_0^z c(y)dy$.

Next, note that with $\zeta_s = \xi_s^1 - \xi_s^2$, and using that $x < y$, it holds that $\zeta_s \le 0$ for all s, while by definition, $|\zeta_0| \le \delta$. Hence, by the definition of $c(\cdot)$ and of κ, it holds that for all $\delta < \delta_1(\kappa, |||m|||)$,

$$\frac{d\zeta_s}{ds} \ge -\frac{h_0\zeta_s}{2} + \frac{c(\xi_s^1)\mathbf{1}_{s<\tau}}{2},$$

from which one concludes that $\zeta_s \ge -\delta e^{-hs/2}$. In particular, this implies that for all such δ,

$$\int_0^\tau c(\xi_s^1)\mathbf{1}_{\{\tau>s\}}ds = \int_0^\tau c(\xi_s^1)ds \le C\delta$$

for some constant $C = C(\kappa, |||\tilde{m}|||)$. Since $c(z) = 0$ for $|z| > 2\kappa$, and since $|g(s,z)|$ is bounded uniformly in $s \le 1/\varepsilon$ and $|z| \le 2\kappa$ (by a bound that depends only on $|||\tilde{m}|||$), the last inequality implies that

$$\left|\int_0^\tau c(\xi_s^1)g(s,\xi_s^1)ds\right| \le C\delta,$$

again for some constant C depending on $\kappa, |||\tilde{m}|||$ only. Finally, note that

$$\int_0^\tau c^2(\xi_s^1)ds \le \sqrt{\delta}\int_0^\tau c(\xi_s^1)ds \le C\delta^{3/2},$$

and that $|\bar{c}(z)| \le 2\kappa\sqrt{\delta}$. Substituting back into (4.17) and recalling that $\kappa = \kappa(|||\tilde{m}|||)$, one concludes the existence of a constant $C_2 = C_2(|||\tilde{m}|||)$ such that for all $\delta < \delta_1$,

$$e^{-C_2\sqrt{\delta}/\varepsilon} \le \Lambda \le e^{C_2\sqrt{\delta}/\varepsilon}. \tag{4.18}$$

Therefore, with $\mathbb{E}_B$ denoting expectation with respect to $B_\cdot$, and using the bound on Λ in the second inequality, and the Lipschitz property of g_1, g_2 together with the exponential decay of ζ_s in the third, and omitting the dependence on $\theta^{1/\varepsilon - t}\tilde{m}$

everywhere, it holds, for all $t > 1/2\varepsilon$, that

(4.19)
$$\begin{aligned}
&\mathbb{E}L_\varepsilon(x,t) \le 2\mathbb{E}L_\varepsilon(x,t)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||<M_2/\varepsilon\}}\\
&= 2\mathbb{E}_B\left(\mathbf{1}_{\{||\xi^1||<M_2/\varepsilon\}}\Lambda^{-1}\exp\left(I_\varepsilon(\xi_t^1,0)+\int_0^t\left(g_1(\xi_s^1,\tilde{m}_s)+\frac{1}{\varepsilon}g_2(\xi_s^1,\tilde{m}_s)\right)ds\right)\right)\\
&\le 2\mathbb{E}_B\Bigg(\mathbf{1}_{\{||\xi^2||<(M_2+1)/\varepsilon\}}\ \exp\Bigg(\frac{C_2\sqrt{\delta}}{\varepsilon}+I_\varepsilon(\xi_t^2+\zeta_t,0)\\
&\qquad\qquad +\int_0^t\left(g_1(\xi_s^2+\zeta_s,\tilde{m}_s)+\frac{1}{\varepsilon}g_2(\xi_s^2+\zeta_s,\tilde{m}_s)\right)ds\Bigg)\Bigg)\\
&\le 2\mathbb{E}_B\left(\exp\left(\frac{C_3\sqrt{\delta}}{\varepsilon}+I_\varepsilon(\xi_t^2,0)+\int_0^t\left(g_1(\xi_s^2,\tilde{m}_s)+\frac{1}{\varepsilon}g_2(\xi_s^2,\tilde{m}_s)\right)ds\right)\right)\\
&= 2\mathbb{E}\left(\exp\left(\frac{C_3\sqrt{\delta}}{\varepsilon}+I_\varepsilon(\tilde{Z}_t^{\varepsilon,y},0)+\int_0^t\left(g_1(\tilde{Z}_s^{\varepsilon,y},\tilde{m}_s)+\frac{1}{\varepsilon}g_2(\tilde{Z}_s^{\varepsilon,y},\tilde{m}_s)\right)ds\right)\right)\\
&= 2\exp\left(\frac{C_3\sqrt{\delta}}{\varepsilon}\right)\mathbb{E}L_\varepsilon(y,t)\\
&\le 4\exp\left(\frac{C_3\sqrt{\delta}}{\varepsilon}\right)\mathbb{E}\left(\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,y}||<M_2/\varepsilon\}}L_\varepsilon(y,t)\right),
\end{aligned}$$

yielding (3.9) for $x < y$ and $\delta < \delta_1$, with $g(\delta) = C_3\sqrt{\delta}$. Further, the same computation gives

$$4\mathbb{E}\left(L_\varepsilon(x,t)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||<M_2/\varepsilon\}}\right)\ge\exp\left(\frac{-C_3\sqrt{\delta}}{\varepsilon}\right)\mathbb{E}\left(L_\varepsilon(y,t)\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,y}||<M_2/\varepsilon\}}\right),$$

yielding, by exchanging the roles of x and y, (3.9) for $x > y$ and $\delta < \delta_1$ with the same $g(\delta)$. Finally, for $\delta > \delta_1$, iterate this procedure to obtain (3.9) with $g(\delta) = C_3\sqrt{\delta\wedge\delta_1}\lceil\delta/\delta_1\rceil$. Substituting $y = X_1$ into the latter version of (3.9) then gives (3.10). □

Proof of Lemma 3.6. Throughout the proof, we fix once and for all the sequence T_ε. All constants C_i used in the proof may depend on the choice of the sequence but not explicitly on ε.

We begin with the proof of (3.11). Using Girsanov's theorem, one finds that with $\bar{Z}_t^{\varepsilon,x} = x + \sqrt{\varepsilon}\tilde{W}_t$,

$$\begin{aligned}
&\mathbb{E}\left[\bar{L}_\varepsilon(x,T)\mathbf{1}_{\{|\tilde{Z}_T^{\varepsilon,x}-z|<\delta\}}\mathbf{1}_{\{||\tilde{Z}^{\varepsilon,x}||_T\le M_3/\varepsilon\}}\right]\\
&= \mathbb{E}\Bigg[\mathbf{1}_{\{|\bar{Z}_T^{\varepsilon,x}-z|<\delta\}}\mathbf{1}_{\{||\bar{Z}^{\varepsilon,x}||_T\le M_3/\varepsilon\}}\\
&\quad\cdot\exp\left(\frac{1}{\varepsilon}\int_0^T\left[-h(\bar{Z}_s^{\varepsilon,x})+\tilde{m}_s h'(\bar{Z}_s^{\varepsilon,x})-\varepsilon b(\bar{Z}_s^{\varepsilon,x})\right]d\bar{Z}_s^{\varepsilon,x}\right.\\
&\qquad\left.-\frac{1}{\varepsilon}\int_0^T\left(\frac{[h(\bar{Z}_s^{\varepsilon,x})-h(\tilde{m}_s)]^2}{2}+\frac{b^2(\bar{Z}_s^{\varepsilon,x})\varepsilon^2}{2}+\varepsilon b(\bar{Z}_s^{\varepsilon,x})h(\bar{Z}_s^{\varepsilon,x})\right.\right.\\
&\qquad\left.\left.-\varepsilon h'(\bar{Z}_s^{\varepsilon,x})b(\bar{Z}_s^{\varepsilon,x})\tilde{m}_s-\varepsilon g_1(\bar{Z}_s^{\varepsilon,x},\tilde{m}_s)\right)ds\right)\Bigg].
\end{aligned}\tag{4.20}$$

We consider the different terms in (4.20) separately. Note first that one may, exactly as in the course of the proof of Lemma 3.5, move from starting point x to starting point X_1 in the right-hand side of (4.20), with the effect of picking up a term bounded by $\exp(C|x|/\varepsilon)$ and widening the allowed region where $\bar{Z}_T^{\varepsilon,x}$ need to be; namely, for all $T_\varepsilon \geq T > 1$, the right-hand side of (4.20) is bounded by

$$\exp\left(\frac{C_1 + C_2|x|}{\varepsilon}\right) \mathbb{E}\Bigg[\mathbf{1}_{\{|\bar{Z}_T^{\varepsilon,X_1} - z| < \delta + |x| + |X_1|\}} \mathbf{1}_{\{||\bar{Z}^{\varepsilon,X_1}||_T \leq |x| + (M_3+1)/\varepsilon\}} \cdot \exp\left(\frac{1}{\varepsilon}\int_0^T \Big[-h(\bar{Z}_t^{\varepsilon,X_1}) + \tilde{m}_s h'(\bar{Z}_s^{\varepsilon,X_1}) - \varepsilon b(\bar{Z}_s^{\varepsilon,X_1})\Big] d\bar{Z}_s^{\varepsilon,X_1}\right)\Bigg]. \tag{4.21}$$

An integration by parts gives that

$$-\int_0^T h(\bar{Z}_t^{\varepsilon,X_1}) d\bar{Z}_t^{\varepsilon,X_1} = -\bar{\mathcal{J}}(\bar{Z}_T^{\varepsilon,X_1}, X_1) - h(X_1)(\bar{Z}_T^{\varepsilon,X_1} - X_1) + \frac{\varepsilon}{2}\int_0^T h'(\bar{Z}_t^{\varepsilon,X_1}) dt,$$

and hence, on the event $\{|\bar{Z}_T^{\varepsilon,X_1} - z| < \delta + |x| + |X_1|\}$, it holds that

$$-\int_0^T h(\bar{Z}_t^{\varepsilon,X_1}) d\bar{Z}_t^{\varepsilon,X_1} \leq -C(|z| - |x| - |X_1| - \delta)_+^2 + C. \tag{4.22}$$

Similarly, with $B(z) = \int_{X_1}^z b(x)dx$,

$$\int_0^T b(\bar{Z}_s^{\varepsilon,X_1}) d\bar{Z}_s^{\varepsilon,X_1} = B(\bar{Z}_T^{\varepsilon,X_1}) - \frac{\varepsilon}{2}\int_0^T b'(\bar{Z}_s^{\varepsilon,X_1}) ds \leq C(|z|^2 + |x|^2 + 1). \tag{4.23}$$

Finally, rewrite

$$\int_0^T \tilde{m}_s h'(\bar{Z}_s^{\varepsilon,X_1}) d\bar{Z}_s^{\varepsilon,X_1} = X_1 \int_0^T h'(\bar{Z}_s^{\varepsilon,X_1}) d\bar{Z}_s^{\varepsilon,X_1} + \int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,X_1}) d\bar{Z}_s^{\varepsilon,X_1}.$$

The first stochastic integral in the above expression is handled exactly as in (4.23), and substituting into (4.21) one concludes that the right-hand side of (4.20) is bounded by

$$\begin{aligned}
&\exp\left(\frac{C + C(|x| + |z|) - C(|z| - |x|)_+^2}{\varepsilon}\right) \mathbb{E}\left[\exp\left(\frac{1}{\varepsilon}\int_0^T (\tilde{m}_s - X_1) h'(\bar{Z}_s^{\varepsilon,X_1}) d\bar{Z}_s^{\varepsilon,X_1}\right)\right] \\
