is a compact set. To investigate the robustness with respect to noise with a family of nested patchy vector fields we generalize [1, Definition 2.3] to a family of nested patchy vector fields and we introduce the next definition.

DEFINITION 3.7. *Let $\chi : \mathbb{R}^n \to \mathbb{R}$ be a continuous map such that for all $x \neq 0$, $\chi(x) > 0$.*

- *We say that χ is an admissible radius for the measurement noise if for all x in $\mathbb{R}^n$ and for all α in $\mathcal{A}$ such that x in $\Omega_{\alpha,7}$, we have*

$$\chi(x) < \frac{1}{2} \min_{l\in\{1,\dots,6\}} d(\mathbb{R}^n \setminus \Omega_{\alpha,l+1}, \Omega_{\alpha,l}). \tag{27}$$

- *We say that χ is an admissible radius for the external disturbances if for all x in $\mathbb{R}^n$, we have $\chi(x) \leq r(C_x)$, where C_x is defined by* (26) *and the corresponding $r > 0$ is guaranteed by* 4 *in Definition* 3.1.

There exists an admissible radius for the measurement noises and for the external disturbances. (Note that with (17), the right-hand side of inequality (27) is strictly positive.)

In Definition 3.4, u does not depend on x. Therefore only the function k_d depend on the measurement noise. Thus the notions of the admissible radius for the measurement noise and for the external disturbances are completely independent.

We need to consider sufficiently fast π-solutions. To define *sufficiently fast* π-solutions, let us introduce the following definition.

DEFINITION 3.8. *Let $p : \mathbb{R}^n \to \mathbb{R}_{>0}$ be a function continuous on $\mathbb{R}^n \setminus \{0\}$. We say that the sampling schedule π of a π-solution (X, S_d) defined on $[t_0, T)$ is* subordinate to p *if for all $i \in \mathbb{N}$ and for all $t \in [\min(t_i, T), \min(t_{i+1}, T))$, we have*

$$t_{i+1} - t_i \leq p(X(t_i) + \xi(X(t_i), t_i)). \tag{28}$$

Now we study the properties of π-solutions.

4. Properties of π-solutions. In this section we study the properties of π-solutions of a system in closed loop with a hybrid patchy feedback. Let Ω be a nonempty open connected subset of $\mathbb{R}^n$ and let

$$(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$$

be a family of nested patchy vector fields such that (21) holds. Let (u, k_d) be the hybrid patchy feedback on Ω defined by (22)–(24). Let $\chi : \mathbb{R}^n \to \mathbb{R}$ be an admissible radius for the measurement noise and the external disturbances. Consider ξ and ζ satisfying our standing regularity assumptions and such that

$$\forall x \in \mathbb{R}^n, \quad \sup_{t\geq 0} |\xi(x,t)| \leq \chi(x), \quad \operatorname*{esssup}_{t\geq 0} |\zeta(x,t)| \leq \chi(x). \tag{29}$$

The perturbed system under consideration is

$$\begin{cases} \dot{x} = f(x, u(s_d)) + \zeta, \\ s_d = k_d(x + \xi, s_d^-). \end{cases} \tag{30}$$

Let $p : \mathbb{R}^n \to \mathbb{R}$ be a function continuous on $\mathbb{R}^n \setminus \{0\}$ and such that for all (ξ, ζ) with our regularity assumptions and (29), the following inequalities hold:[1]

A1. For all x in $\mathbb{R}^n$, $p(x) > 0$.

A2. For all x in $\mathbb{R}^n$,

$$p(x + \xi(x, 0)) < \frac{1}{4} \min_{l\in\{1,\dots,6\}} \min_{\alpha\in\mathcal{A},\ x+\xi(x,0)\in\Omega_{\alpha,7}} \frac{d(\mathbb{R}^n \setminus \Omega_{\alpha,l+1}, \Omega_{\alpha,l})}{\sup_{y\in\Omega_{\alpha,7},\ u\in K} |f(y,u)|}.$$

A3. For all x in $\mathbb{R}^n$, we have $p(x + \xi(x, 0)) < T(C_x)$, where T is defined by 4 in Definition 3.1 and C_x is defined by (26).

The existence of such a function p results from the fact that for all l in $\{1, \dots, 7\}$, $(\Omega_{\alpha,l})_{\alpha\in\mathcal{A}}$ is locally finite and results from (17).

DEFINITION 4.1. *A map $S_{d,\alpha} : [t_0, T) \to \{1, 2\}$ is said to have a* switch *at time t if $S_{d,\alpha}$ is not continuous at t.*

Given a sampling schedule π of $\mathbb{R}$ and a π-solution (X, S_d) of (30) and t in $[t_0, T)$, we denote the αth element of $S_d(t)$ by $S_{d,\alpha}(t)$. We start by locating the points where there exists α in $\mathcal{A}$ such that $S_{d,\alpha}$ may have a switch. Note that switches can occur only at sampling times, i.e., if there is a switch at time t, then there exists $i \in \mathbb{N}_{>0}$ such that $t = t_i$, $S_{d,\alpha}(t_i) \neq S_{d,\alpha}(t_{i-1})$.

[1] If $\sup |f(y, u)| = 0$, then assumption A2 forces no condition on p.

LEMMA 4.2. *Let (X, S_d) be a π-solution of* (30) *whose sampling schedule is subordinate to p and such that $S_{d,\alpha}$ has a switch at time $t_i \in (t_0, T)$.*

- *If the switch is such that $S_{d,\alpha}(t_{i-1}) = 1$ and $S_{d,\alpha}(t_i) = 2$, then, for all t in $[t_i, \min(t_{i+1}, T))$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha,7}) \setminus \Omega_{\alpha,5}$.*
- *If the switch is such that $S_{d,\alpha}(t_{i-1}) = 2$ and $S_{d,\alpha}(t_i) = 1$, then, for all t in $[t_i, \min(t_{i+1}, T))$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha,3}) \setminus \Omega_{\alpha,1}$.*

Proof. Let α in $\mathcal{A}$ and $i \in \mathbb{N}_{>0}$ such that $S_{d,\alpha}(t_{i-1}) = 1$ and $S_{d,\alpha}(t_i) = 2$. Then due to (6) and (23)–(24), $X(t_{i-1}) + \xi(X(t_{i-1}), t_{i-1})$ is in $\Omega_{\alpha,6}$. Thus with (27), assumption A2, and (29), it follows directly that, for all t in $[t_{i-1}, \min(t_{i+1}, T))$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha,7})$. Similarly we prove that, for all t in $[t_i, \min(t_{i+2}, T))$, $X(t) \notin \Omega_{\alpha,5}$. Thus we obtain that, for all t in $[t_i, t_{i+1})$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha,7}) \setminus \Omega_{\alpha,5}$.

The case $S_d(t_{i-1}) = 2$ and $S_d(t_i) = 1$ is established in the same way. ∎

Let us claim a result of existence.

LEMMA 4.3. *For all (x_0, s_0) in $\mathbb{R}^n \times \{1, 2\}^{\mathcal{A}}$ and for all sampling schedules π of $\mathbb{R}$, there exists a π-solution of* (30) *starting from (x_0, s_0).*

Proof. Let (x_0, s_0) be in $\mathbb{R}^n \times \{1, 2\}^{\mathcal{A}}$. Let $s_1 = k_d(x_0 + \xi(x_0, t_0), s_0)$ and α be in $\mathcal{A}$ such that $k_\alpha = u(s_1)$. From our regularity assumptions on f and ζ, the Carathéodory conditions are satisfied for the system

$$\dot{X} = f(X, k_\alpha) + \zeta, \qquad X(t_0) = x_0. \tag{31}$$

Let $t_0 \le T \le t_1$ and X defined on $[t_0, T)$ be a Carathéodory solution of (31). Let S_d be defined, for all t in $[t_0, T)$, by $S_d(t) = s_1$ for all t in $[t_0, T)$. Thus (X, S_d) is a π-solution of (30) starting from (x_0, s_0). ∎

We note that, as usual, maximal solutions of (30) must blow up if their domains of definition are bounded.

LEMMA 4.4. *Let $d_0 > 0$, ξ, and ζ satisfy our regularity assumptions and* (29). *Let $T > t_0$ and (X, S_d) be a d_0-maximal solution of* (30) *defined on $[t_0, T)$. Suppose that $T < +\infty$; then*

$$\limsup_{t \to T} \left(|X(t)| + \frac{1}{d(X(t), \partial\Omega)} \right) = +\infty.$$

Proof. Consider $d_0 > 0$, ξ, ζ satisfying our regularity assumptions and (29), $T > t_0$ and (X, S_d) a d_0-maximal solution defined on $[t_0, T)$. Suppose that the conclusion of Lemma 4.4 does not hold; i.e., there exists a compact subset C of Ω and times t_n in $[t_0, T)$ tending monotonically to T such that $(X(t_n), S_d(t_n))$ is in $C \times \{1, 2\}^{\mathcal{A}}$ for all n. We first establish the following.

Claim 4.5. For some n sufficiently large, for all $t \in [t_n, T)$, $X(t)$ is in the bounded open set $C + \mathrm{int}(B(0, 1))$.

Proof of Claim 4.5. If the conclusion of Claim 4.5 is not true, the continuity of X implies the existence of $s_n \in (t_n, T)$ such that

$$|X(t_n) - X(s_n)| = 1 \quad \text{and} \quad |X(t_n) - X(t)| < 1 \quad \forall t \in [t_n, s_n).$$

It follows that $X(t)$ is in the compact set $C + B(0, 1)$ for all t in $[t_n, s_n]$. Let

$$\rho = \max_{x \in C + B(0,1)} |\chi(x)|, \qquad \sigma = \sup_{\zeta \in B(0,\rho),\ x \in C + B(0,1),\ u \in K} |f(x, u) + \zeta|.$$

Then we have, for all t, s in $[t_n, s_n]$, $|X(t) - X(s)| \le \sigma |t - s|$. Therefore, for n sufficiently large,

$$1 = |X(t_n) - X(s_n)| \le \sigma |s_n - t_n| \le \sigma |T - t_n|.$$

This cannot hold for n large enough and proves Claim 4.5. ∎

Claim 4.5 implies that there exists σ in $\mathbb{R}_{\geq 0}$ such that, for all (s,t) in $[t_n, T)$, we have

$$|X(s) - X(t)| \leq \sigma |s - t|.$$

By invoking the Cauchy criterion, it follows that $X(t)$ has a limit x_0 when t tends to T. Note moreover that by Definition 2.1, there exists $i \in \mathbb{N}$ such that T is in $(t_i, t_{i+1}]$ and thus, for all α in $\mathcal{A}$, $\lim_{t \to T,\, t<T} S_{d,\alpha}(t)$ exists. We denote $s_0 = S_d^-(T)$. Due to Lemma 4.3, there exists a π-solution $(\widetilde{X}, \widetilde{S_d})$ starting from (x_0, s_0) and defined on $[t_0, \widetilde{T})$ with $\widetilde{T} > t_0$. Note that (X', S'_d) defined by

$$\begin{aligned} \forall t \in [t_0, T), \quad X'(t) = X(t), \quad S'_d(t) = S_d(t), \\ \forall t \in (T, T + \widetilde{T}), \quad X'(t) = \widetilde{X}(t - T), \quad S'_d(t) = \widetilde{S_d}(t - T), \end{aligned}$$

is a $\widetilde{\pi}$-solution of (30) defined on $[t_0, T + \widetilde{T})$ for the sampling schedule $\widetilde{\pi} = \pi \cup \{T\}$ whose restriction to $[t_0, T)$ is (X, S_d). Moreover $\widetilde{\pi}$ satisfies (11). So we have obtained a contradiction with the fact that (X, S_d) is a d_0-maximal solution. □

Now we can study the behavior of π-solutions between two switches. For all α in $\mathcal{A}$, let

$$\begin{aligned} \tau_\alpha = \sup \big\{ & T, X \text{ is a Carathéodory solution of } \dot{x} = f(x, k_\alpha) + B(0, \chi(x)) \\ & \text{with } X(t) \in \Omega_{\alpha,7}\ \forall t \in [0, T) \big\}. \end{aligned} \tag{32}$$

Note that there may exist α in $\mathcal{A}$ such that (s.t.) $\tau_\alpha = +\infty$. Let M be the subset of $\Omega \times \{1,2\}^{\mathcal{A}}$ defined by

$$M = \left\{ (x, s_d), \text{s.t.} \left\{ \begin{array}{c} \{\beta \in \mathcal{A},\ s_{d,\beta} = 1\} \text{ is empty or infinite} \\ \text{or} \\ x \in \Omega_{\alpha,5},\ \text{where } \alpha = \max\{\beta,\ s_{d,\beta} = 1\} \end{array} \right\} \right\}. \tag{33}$$

Note that we have the property

$$\forall x_0 \in \Omega, \quad \exists s_0 \in \{1,2\}^{\mathcal{A}}, \quad (x_0, s_0) \in M. \tag{34}$$

Example 4.6. *Let us particularize the set M for Artstein's circles. We have*

$$\begin{aligned} M = \Omega_{a,5} \times \{(1,2,2)\} \cup \Omega_{b,5} \times \{(s_d, 1, 2),\ s_d \in \{1,2\}\} \\ \cup\ \Omega_{c,5} \times \{(s_d, s'_d, 1),\ s_d, s'_d \in \{1,2\}\} \cup \Omega \times \{(2,2,2)\}. \end{aligned}$$

In the following we denote $\overline{m} = \{0, \ldots, m\}$ if $m \in \mathbb{N}$ and $\overline{m} = \mathbb{N}$ if $m = +\infty$.

Lemma 4.7. *Let $0 < T \leq \infty$ and (X, S_d) be a π-solution of (30) whose sampling schedule is subordinate to p, defined on $[0, T)$ and starting in M. Then, there exist $m \in \mathbb{N} \cup \{+\infty\}$, an increasing sequence of time instants $(T_j)_{j \in \overline{m}}$ in $[0, T)$, a sequence $(\alpha_j)_{j \in \overline{m}}$ in $\mathcal{A}$, and a sequence $(k_j)_{j \in \overline{m}}$ in K such that if we let $T_0 = 0$ and $T_{m+1} = T$ (if $m < +\infty$), we have for all $j \in \overline{m}$ the following:*

1. *For all t in (T_j, T_{j+1}), $u(S_d(t)) = k_{\alpha_j}$.*
2. *The map X is a Carathéodory solution of $\dot{x} = f(x, k_{\alpha_j}) + \zeta$ on (T_j, T_{j+1}).*
3. *For all t in $[T_0, T_1)$, $X(t)$ is in $\Omega_{\alpha_0,5}$.*
4. *For all t in $[T_j, T_{j+1})$, $X(t)$ is in $\operatorname{clos}(\Omega_{\alpha_j,3})$, if $j \geq 1$.*
5. *The sequence $(\alpha_j)_{j \in \overline{m}}$ is strictly increasing.*
6. *The inequality $T_{j+1} - T_j < \tau_{\alpha_j}$ holds.*

Proof. Note first that the switches may occur only at a sampling time. Thus we can define $m \in \mathbb{N} \cup \{+\infty\}$ and a sequence of sampling times $(T_j)_{j \in \overline{m}}$ in $[0, T)$ at which switches occur. Between two switches, S_d is constant and thus there exist a sequence α_j in $\mathcal{A}$ and a sequence of admissible controls such that the statements 1 and 2 hold. We denote again by $(T_j)_{j \in \overline{m}}$ the subsequence of $(T_j)_{j \in \overline{m}}$ such that we have, for all $j \in \overline{m}$,

$$\alpha_j \neq \alpha_{j+1}. \tag{35}$$

Let us prove statement 3 and $\alpha_0 < \alpha_1$.

Due to Definition 3.1, there exists a finite number of α in $\mathcal{A}$ such that $X(T_0)$ is in $\Omega_{\alpha,1}$; then due to (23), (27), and (29), there exists α in $\mathcal{A}$ such that $S_{d,\alpha}(T_0) = 1$, and thus by (22), we have $\alpha_0 = \max\{\alpha, S_{d,\alpha}(T_0) = 1\}$.

This implies with (33) that $X(T_0)$ is in $\Omega_{\alpha_0,5}$. Similarly, we can prove that, for all β in $\mathcal{A}$ such that $\alpha < \beta$, we have $X(T_0)$ is not in $\Omega_{\beta,1}$. Thus (29), the fact that χ is an admissible radius for the external noise, (28), and assumption A3 on the function p yield, for all t in $[T_0, T_1)$, $X(t)$ is in $\Omega_{\alpha_0,5}$. Therefore with Lemma 4.2, we deduce that S_{d,α_0} cannot switch at time T_1 and, for all t in $[T_1, T_2)$, $S_{d,\alpha_0}(t) = 1$.

Moreover, due to (22), for all t in (T_1, T_2), we have $S_{d,\alpha_1}(t) = 1$. So, due to (22) and (35), $\alpha_0 < \alpha_1$.

Let us prove the following Claim 4.8, which implies statements 4 and 5 of Lemma 4.7.

Claim 4.8. For all $j > 0$, $j \in \overline{m}$, and for all t in $[T_j, T_{j+1})$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha_j,3})$ and $\alpha_j < \alpha_{j+1}$.

Proof of Claim 4.8. Let us prove Claim 4.8 by induction.

The inequality $\alpha_0 < \alpha_1$ implies with (22) that $S_{d,\alpha_1}(T_0) = 2$. Thus with Lemma 4.2, (28), and assumption A3 we have, for all t in $[T_1, T_2)$, $X(t)$ is in $\mathrm{clos}(\Omega_{\alpha_1,3}) \backslash \Omega_{\alpha_1,1}$. Thus with Lemma 4.2, S_{d,α_1} cannot switch at time T_2 and we have, for all t in $[T_2, T_3)$, $S_{d,\alpha_1}(t) = 1$. Moreover due to (22), for all t in (T_2, T_3), we have $S_{d,\alpha_2}(t) = 1$. So, due to (22) and (35), $\alpha_1 < \alpha_2$.

One can inductively deduce statements 4 and 5 for $j \geq 2$ similarly. ∎

To complete the proof of Lemma 4.7, note that statement 6 is a consequence of (32) and statements 2, 3, and 4 ∎

Remark 4.9. Some observations are in order.

- Lemma 4.7 states that for all π-solutions starting in M, the sequence α is strictly increasing and there exists a bound on the time between two switches. This result is analogous to [1, Proposition 3.1]. However, for all π-solutions that do not start in M, the sequence can be nonincreasing. See Example 4.10. Thus we need to add an initial switch to make all solutions enter in M. This is the result stated in Lemma 4.11.
- M is forward invariant for the system (30) for all ξ and ζ satisfying our regularity assumptions and (29).

Example 4.10. *Figure* 4.1 *shows two different* π*-solutions of the hybrid patchy vector field of Artstein's circles by taking account of Lemmas* 4.2 *and* 4.7. *On the left, the* x*-component of* π*-solutions is depicted, and, on the right, we have the evolution of the controllers.*

- *The* π*-solution* (X, S_d)*, a solid line, starts in* M *(with* $x_0 \in \Omega_{a,5}$ *and* $s_0 = (1, 2, 2)$*) at* $T_0 = 0$ *and has one switch at time* T_1 *(with* $X(T_1) + \xi(X(T_1), T_1) \in \Omega_{c,2}$ *and* $S_d(T_1) = (1, 2, 1)$*). With the notations of Lemma* 4.7*, we have* $(\alpha_1, \alpha_2) = (a, c)$ *(see Figure* 3.2*), which is strictly increasing.*

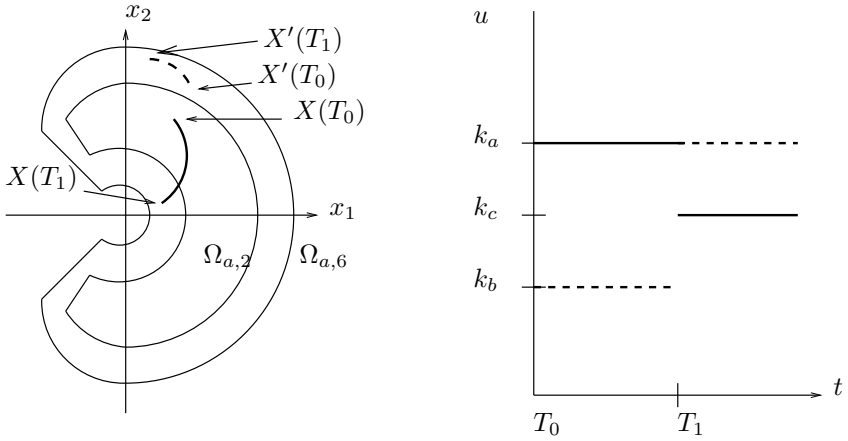

FIG. 4.1. *Two π-solutions with a hybrid patchy feedback. On the left is the x component and on the right is the evolution of the control.*

• *The other π-solution (X', S'_d), a dashed line, starts in the complement of M ($x_0 \in \Omega_{b,7} \setminus \Omega_{b,6}$ and $s_0 = (1,1,2)$) at $T_0 = 0$. There exists a measurement noise ξ satisfying* (29)*, vanishing for $t \neq T_0$, and such that $x_0 + \xi(x_0, T_0) \in \Omega_{b,6}$. Thus $S'_d(T_0) = (1,1,2)$. Therefore, with the notations of Lemma* 4.7*, we have $\alpha_1 = b$. There exists a time $T_1 > T_0$ such that $X'(T_1) \in \Omega_{b,7} \setminus \Omega_{b,6}$. Therefore $S'_d(T_1) = (1,2,2)$ and $\alpha_2 = a$. Thus $\alpha_1 > \alpha_2$ and the sequence is not strictly increasing.*

This example proves that the conclusions of Lemma 4.7 *do not hold for π-solutions which do not start in M (see statement* 5 *in Lemma* 4.7*).*

Due to property (34), we can add a switch to make all π-solutions enter in M. More precisely, let $(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$ be a family of nested patchy vector fields. Assume that we have (21). Then we can define a map $u : \{1,2\}^{\mathcal{A}} \to K$ by (22) and $\widetilde{k}_d : \mathbb{R}^n \times \{1,2\}^{\mathcal{A}} \to \{1,2\}^{\mathcal{A}}$ by

$$\begin{aligned} \widetilde{k}_d(x, s_d) \;&=\; k_d(x, s_d) \text{ if } \begin{cases} \{\beta \in \mathcal{A},\ s_{d,\beta} = 1\} \text{ is empty or infinite} \\ \text{or} \\ x \in \Omega_{\alpha,4},\ \text{where } \alpha = \max\{\beta, k_{d,\beta}(x, s_d) = 1\} \end{cases} \\ &\text{else} \\ &=\; s_0,\ \text{where } s_0 \text{ is such that } x \in \Omega_{\alpha,2},\ \text{and } \alpha = \max\{\beta, s_{0,\beta} = 1\}. \end{aligned} \tag{36}$$

Consider now the system

$$\begin{cases} \dot{x}(t) = f(x(t), u(s_d(t))) + \zeta(x,t), \\ s_d(t) = \widetilde{k}_d(x(t) + \xi(x,t), s_d^-(t)). \end{cases} \tag{37}$$

We rewrite Lemma 4.7 for all initial conditions.

LEMMA 4.11. *Let $0 < T \leq \infty$ and let (X, S_d) be a π-solution of* (37) *whose sampling schedule is subordinate to p, defined on $[0,T)$ and starting in $\mathbb{R}^n \times \{1,2\}^{\mathcal{A}}$. Then, there exist $m \in \mathbb{N} \cup \{+\infty\}$, an increasing sequence of time-instants $(T_j)_{j\in\overline{m}}$ in $[0,T)$, a sequence $(\alpha_j)_{j\in\overline{m}}$ in $\mathcal{A}$, and a sequence $(k_j)_{j\in\overline{m}}$ in K such that if we let $T_0 = 0$ and $T_{m+1} = T$ (if $m < +\infty$), we have, for all j in $\overline{m}$, the following:*

1. *For all* t *in* (T_j, T_{j+1}), $u(S_d(t)) = k_{\alpha_j}$.
2. *The map* X *is a Carathéodory solution of* $\dot{x} = f(x, k_{\alpha_j}) + \zeta$ *on* (T_j, T_{j+1}).
3. *For all* t *in* $[T_0, T_1)$, $X(t)$ *is in* $\Omega_{\alpha_0,4}$.
4. *For all* t *in* $[T_j, T_{j+1})$, $X(t)$ *is in* $\operatorname{clos}(\Omega_{\alpha_j,3})$ *if* $j \geq 1$.
5. *The sequence* $\alpha_1, \ldots, a_{m+1}$ *is strictly increasing.*
6. *The inequality* $T_{j+1} - T_j < \tau_{\alpha_j}$ *holds.*

Proof. The proof of statements 1 and 2 of Lemma 4.11 is analogous of the proof of statements 1 and 2 of Lemma 4.7.

Due to (36), $X(T_0) + \xi(X(T_0), T_0)$ is in $\Omega_{\alpha_0,4}$. Then due to (27) and (29), we have $X(T_0)$ is in $\Omega_{\alpha_0,5}$. Similarly, we can prove that, for all β in $\mathcal{A}$ such that $\alpha < \beta$, we have $X(T_0)$ is not in $\Omega_{\beta,1}$. Therefore with (29), the fact that χ is an admissible radius for the external noise, (28), and assumption A3 on the function p, we have statement 3.

This implies that $X(T_1)$ is in $\Omega_{\alpha_0,4}$ and therefore $(X(T_1), S_d(T_1))$ is in M and we deduce statements 4 to 6 of Lemma 4.11 from statements 4 to 6 of Lemma 4.7. ∎

Remark 4.12. Note that if there exists a switch (i.e., if $m > 0$ in Lemma 4.11), then, after the first switch, we have $\widetilde{k}_d(X(t) + \xi(X(t), t)) = k_d(X(t) + \xi(X(t), t))$. And thus after the first switch (if it exists), every π-solution of (37) is a π-solution of (30) and in particular we have the conclusion of Lemma 4.4.

5. Use of the asymptotic controllability. Now we use properties of a differential system in closed loop with a hybrid patchy feedback. The purpose of this section is to prove Theorem 2.7. Let us prove a generalization of [1, Proposition 4.1] which yields a feedback that is robust with respect to measurement noise.

PROPOSITION 5.1. *Let* (1) *be globally asymptotically controllable to the origin. Then for every* $0 < r < s$, *there exist* $T, R, \chi, d > 0$, *an open subset of* $\mathbb{R}^n$, $D^{r,s}$, *and a feedback control,* $u = u^{r,s} : \{1,2\}^{\mathbb{N}} \to K$, $k_d = k_d^{r,s} : \mathbb{R}^n \times \{1,2\}^{\mathbb{N}} \to \{1,2\}^{\mathbb{N}}$ *satisfying*

$$B(0,s) \setminus \operatorname{int}(B(0,r)) \subset D^{r,s} \subset B(0,R) \tag{38}$$

such that for any measurable maps $\zeta, \xi : [0, +\infty) \to \mathbb{R}^n$ *satisfying*

$$\sup_{t \geq 0} |\xi(t)| \leq \chi, \qquad \operatorname*{esssup}_{t \geq 0} |\zeta(t)| \leq \chi, \tag{39}$$

and for any initial state x_0 *in* $D^{r,s} \setminus \operatorname{int}(B(0,r))$, *and for any* s_0 *in* $\{1,2\}^{\mathbb{N}}$, *the perturbed system*

$$\begin{cases} \dot{x} = f(x, u(s_d)) + \zeta, \\ s_d = k_d(x + \xi, s_d^-) \end{cases} \tag{40}$$

admits a π*-solution* (X, S_d) *starting from* (x_0, s_0). *Moreover, for all* (x_0, s_0) *in* $\mathbb{R}^n \times \{1,2\}^{\mathbb{N}}$ *and for any d-maximal solution* (X, S_d) *starting from* (x_0, s_0) *and defined on* $[0, T)$, *there exists* $t_{X,S_d} \leq T$, *such that*

$$|X(t_{X,S_d})| < r. \tag{41}$$

Proof. We follow the proof of [1, Proposition 4.1] and we prove Proposition 5.1 in four steps.

Step 1. Fix $0 < r < s$. For each x_0 in $B(0,s)$, there exist a piecewise constant admissible control $u_0 = u_{x_0}$ and some constant $T_0 = T_{x_0}$ such that there exists a solution $X_0 = x(.; x_0, u_0)$ of $\dot{x} = f(x, u_0)$ for which the inequality

$$|X_0(T_0)| < \frac{r}{2} \tag{42}$$

holds. Moreover, by continuity, we can assume that we have

$$m_0 := \inf_{t\in[0,T_0]} |X_0(t)| > \frac{r}{4} \tag{43}$$

and, by possibly redefining u_0, we may assume that X_0 takes different values at any two different points t, t' in $[0, T_0]$. Let $\tau_{0,0} = 0 < \cdots < \tau_{0,N_0} = T_0$ be the points of discontinuity for u_0 on $[0, T_0]$ and $k_{0,j}$ in K be the corresponding values of u_0, i.e., we suppose that, for all j in $\{0, \ldots, N_0 - 1\}$ and for all t in $(\tau_{0,j}, \tau_{0,j+1})$, we have $u_0(t) = k_{0,j}$. Define

$$M_0 = M_{x_0} = \sup_{t\in[0,T_0]} |X_0(t)|. \tag{44}$$

There exist some strictly positive constants $c_0 = c_{x_0}$, $\overline{\rho}_0 = \overline{\rho}_{x_0}$ and $\overline{\chi}_0 = \overline{\chi}_{x_0}$ such that, for any fixed τ in $[0, T_0]$, any strictly positive radius $\rho \leq \overline{\rho}_0$ and $\chi \leq \overline{\chi}_0$, any initial point $\overline{x}$ in $B(X_0(\tau), \rho)$, and any Carathéodory solution $X_{\rho,\chi}(.)$ of

$$\dot{x} \in f(x, u_0(t)) + B(0, \chi) \tag{45}_\chi$$

starting from $\overline{x}$ at time $t = \tau$, we have

$$\sup_{[\tau, T_0+\rho]} |X_{\rho,\chi}(t) - X_0(t)| < c_0(\rho + \chi). \tag{46}$$

Let two strictly positive reals $\rho_0 \leq \overline{\rho}_0$ and $\chi_0 \leq \frac{\overline{\chi}_0}{2}$ be such that, letting

$$\rho_{x_0,1} = \rho_{0,1} = \rho_0, \tag{47}$$

and for all j in $\{2, \ldots, N_0 + 1\}$,

$$\rho_{x_0,j} = \rho_{0,j} = \Sigma_{k=0}^{j-2} 7^k c_0^{k+1} 2\chi_0 + 7^{j-1} c_0^{j-1} \rho_0,$$

we have

$$7\rho_{x_0,N_0+1} < \frac{r}{2} \tag{48}$$

and

$$\max_j \rho_{x_0,j} < \frac{1}{7} \min\left(m_0 - \frac{r}{8}, \overline{\rho}_0\right), \tag{49}$$

where m_0 is defined by (43). Thus it follows directly by induction that if for any fixed $j = 1, \ldots, N_0$ and for any $\overline{x}$ such that

$$\overline{x} \in B(X_0(\tau_{0,j}), 7\rho_{0,j}),$$

we consider any Carathéodory solution $X_{\rho_{0,j},2\chi_0}(.)$ of $(45)_{2\chi_0}$ starting from $\overline{x}$ at time $\tau_{0,j}$, then one has

$$\sup_{t\in[\tau_{0,j}, T_0+\rho_{0,j}]} |X_{\rho_{0,j},\chi_0}(t) - X_0(t)| < \rho_{0,j+1}. \tag{50}$$

Step 2. For j in $\{0, \ldots, N_0 - 1\}$ and for any $\overline{x}$ in $\mathbb{R}^n$, denote $\mathcal{A}_j(\overline{x}, t)$ the attainable set in time t for the Carathéodory solutions of $\dot{x} \in f(x, k_{0,j}) + B(0, 2\chi_0)$ starting from $\overline{x}$. Let us define for all l in $\{1, \ldots, 7\}$ and for all j in $\{1, \ldots, N_0 - 1\}$ the open sets

$$\Gamma_{x_0,j,l} = \bigcup_{\substack{\overline{x}\in \mathrm{int}(B(X_0(\tau_{0,j-1}), l\rho_{0,j})) \\ 0\leq t\leq \tau_{0,j}-\tau_{0,j-1}}} \mathcal{A}_j(\overline{x}, t)$$

and

$$\Gamma_{x_0,N_0,l} = \bigcup_{\substack{\overline{x}\in \mathrm{int}(B(X_0(\tau_{0,N_0-1}),l\rho_{0,j}))\\ 0\le t\le T_0+\rho-\tau_{0,N_0-1}}} \mathcal{A}_{N_0}(\overline{x},t).$$

Note that we have, for all j in $\{1,\dots,N_0\}$ and for all $l<l'$ in $\{1,\dots,7\}$,

$$\Gamma_{x_0,j,l} \subsetneq \mathrm{clos}(\Gamma_{x_0,j,l}) \subsetneq \Gamma_{x_0,j,l'}, \tag{51}$$

and, due to (44) and (50),

$$\Gamma_{x_0,j,l} \subset B(0,7\rho_{x_0,j+1}+M_{x_0}). \tag{52}$$

Moreover (43), (49), and (50) yield

$$B\left(0,\frac{r}{8}\right) \subset \mathbb{R}^n \setminus \Gamma_{x_0,j,l}. \tag{53}$$

Finally, for all N_0-tuple s with entries in $\{1,\dots,7\}$, let us define

$$\Delta_{x_0,s} = \bigcup_{j=1}^{N_0} \Gamma_{x_0,j,s(j)}, \qquad \Delta_{x_0} = \Delta_0 = \Delta_{x_0,\mathbf{1}_{x_0}},$$

where, for any point x_0 in $B(0,s)\setminus \mathrm{int}(B(0,r))$, we denote $\mathbf{1}_{x_0}$ (whose length depends on x_0) the following constant sequence:

$$\begin{array}{rcl} \mathbf{1}_{x_0} = \mathbf{1}_0 : \{1,\dots,N_0\} & \to & \{1,\dots,7\},\\ l & \mapsto & 1. \end{array}$$

Let $g_{0,j} = g_{x_0,j}$ be the vector field on $\mathbb{R}^n$ defined, for all j in $\{1,\dots,N_0-1\}$, by

$$g_{0,j}(x) = f(x,k_{0,j}). \tag{54}$$

Let $\mathcal{F}$ be the finite set $\mathcal{F}=\{1,\dots,7\}$. We can claim that

$$(\Delta_0, ((\Gamma_{0,j,l})_{l\in\mathcal{F}}, g_{0,j})_{j\in\{1,\dots,N_0\}})$$

is a family of nested patchy vector fields. Indeed note first that due to (51) we have (17); second, we have (18) because there exists $T>0$ such that all solutions of $(45)_{2\chi_0}$ starting in $\partial\Gamma_{x_0,j,l}\setminus\bigcup_{j'>j}\Gamma_{x_0,j',1}$ stay in $\mathrm{clos}(\Gamma_{x_0,j,l})$ for all t in $[0,T)$; third, the other properties to fulfill Definition 3.1 are obvious.

Let $p_0:\mathbb{R}^n\to\mathbb{R}$ satisfy assumptions A1 to A3 for this family of nested patchy vector fields and define

$$d_0 = \inf_{x\in\Delta_0} p_0(x).$$

Moreover, due to (54), we define a hybrid patchy feedback (u^0,k_d^0) as considered in Definition 3.4 and thus a feedback control $(u^0,\widetilde{k}_d^0)$ defined by (36). We take χ_0 smaller and suppose that

$$0<\chi_0<\frac{1}{2}\min_{j\in\{1,\dots,N_0\}}\min_{l\in\{1,\dots,6\}} d(\mathbb{R}^n\setminus\Gamma_{0,j,l+1},\Gamma_{0,j,l})$$

and note that χ_0 is an admissible radius for the external disturbances. Consider two measurable maps $\zeta, \xi : [0, +\infty) \to \mathbb{R}^n$ satisfying

$$\sup_{t\geq 0} |\xi(t)| \leq \chi_0, \qquad \operatorname*{esssup}_{t\geq 0} |\zeta(t)| \leq \chi_0,$$

and let (x_0, s_0) be an initial condition in $\Delta_0 \setminus B(0,r) \times \{1,2\}^{N_0}$. Due to Lemma 4.3, there exists (X, S_d) a d_0-maximal solution of (40) in closed loop with $(u^0, \widetilde{k}_d^0)$ starting from (x_0, s_0) and defined on $[0, T)$. Moreover, due to Lemma 4.11, there exist $H \in \mathbb{N} \cup \{+\infty\}$, a sequence of points $t_0 = 0 < \cdots < t_H \leq 2T_0$, and a sequence of indices $j_0, \ldots, j_H$ in $\{1, \ldots, N_0\}$, such that, for all h in $\{1, \ldots, H-1\}$,

$$\forall t \in [t_h, t_{h+1}), \quad X(t) \in \Gamma_{x_0, j_h, 7}, \tag{55}$$

$$t_{h+1} - t_h \leq \tau_{0, j_h}. \tag{56}$$

Note that due to Lemma 4.11, the sequence $j_1, \ldots, j_H$ described below is strictly increasing. Due to (52) and (55), (X, S_d) cannot blow up in $\Gamma_{x_0, j_h, 7}$ for all h in $\{0, \ldots, H-1\}$, and due to Lemma 4.4, (42), (48), (52), and (55), there exists $T^0_{X,S_d} \leq 2T_0$ such that we have the inequalities

$$\forall t \in [0, T^0_{X,S_d}), \quad |X(t)| \leq 7 \max_{j\in\{1,\ldots,N_0\}} \rho_{0,j+1} + M_0, \tag{57}$$

$$|X(T^0_{X,S_d})| < r. \tag{58}$$

Step 3. Since x_0 is in Δ_{x_0}, the family of open tubes $\{\Delta_{x_0},\ r \leq |x_0| \leq s\}$ forms an open covering of the compact set $B(0,s) \setminus \operatorname{int}(B(0,r))$. Let

$$\{\Delta_i,\ i \in \{1, \ldots, N(r,s)\}\}, \quad \Delta_i = \bigcup_{j=1}^{N_i} \Gamma_{i,j,1}, \quad \Gamma_{i,j,1} = \Gamma_{x_i, j, \mathbf{1}_{x_i}(j)},$$

be a finite subcover. Denote

$$k_{i,j} = k_{x_i, j}$$

and the vector field

$$g_{i,j}(x) = f(x, k_{i,j}) \tag{59}$$

defined on $\mathbb{R}^n$. The index set

$$\mathcal{A} = \{(i,j),\ i \in \{1, \ldots, N(r,s)\},\ j \in \{1, \ldots, N_i\}\}$$

can be totally ordered by letting

$$(i,j) < (h,k) \quad \text{if either } i < h \text{ or else } i = h,\ j < k. \tag{60}$$

Let

$$D^{r,s} = \bigcup_{i=1}^{N(r,s)} \Delta_i.$$

We can now define a family of nested patchy vector fields on $\Omega = D^{r,s}$. Let, for all $(\alpha, l) \in \mathcal{A} \times \mathcal{F}$, $\Omega_{\alpha,l}$ be the open set $\Gamma_{i,j,l}$, where $(i,j) = \alpha$. Note that due to (51), for

all $m > l$ in $\mathcal{F}$ and for all α in $\mathcal{A}$, (17) and (18) can be proved as in Step 2. Therefore we can claim that

$$(\Omega, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{A}})$$

is a family of nested patchy vector fields. Let $p^{r,s} : \mathbb{R}^n \to \mathbb{R}$ satisfy assumptions A1 to A3 for this family of nested patchy vector fields and

$$d^{r,s} = \inf_{x\in\Omega} p^{r,s}(x). \tag{61}$$

Moreover, due to (59), we can define a hybrid patchy feedback $(u^{r,s}, k_d^{r,s})$ and thus a feedback control $(u^{r,s}, \widetilde{k}_d^{r,s})$ as in (36). We let

$$\chi^{r,s} = \min_{1\le i\le N(r,s)} \chi_{x_i}, \tag{62}$$

which is an admissible radius for the external disturbances. We can choose $\chi^{r,s}$ smaller and suppose that

$$0 < \chi^{r,s} < \frac{1}{2} \min_{(i,j)\in\mathcal{A}} \min_{l\in\{1,\dots,6\}} d(\mathbb{R}^n \setminus \Gamma_{i,j,l+1}, \Gamma_{i,j,l}).$$

Then $\chi^{r,s}$ is an admissible radius for the measurement noise on $D^{r,s}$.

Step 4. For all x_0 in $B(0,s)\setminus B(0,r)$, let $T_{x_i} > 0$ be defined just at the beginning of Step 1, and let $\rho_{x_i} >$ be defined by $(45)_{\chi_0}$–(46). Moreover let $\chi^{r,s} > 0$ be defined by (62) and $d^{r,s}$ be defined by (61). Let

$$T = 2 \sum_{i=1}^{N(r,s)} T_{x_i},$$

and consider two measurable maps ξ and $\zeta : [0,+\infty) \to \mathbb{R}^n$ such that

$$\sup_{t\ge 0} |\xi(t)| \le \chi^{r,s}, \qquad \operatorname*{esssup}_{t\ge 0} |\zeta(t)| \le \chi^{r,s}.$$

Let (x_0, s_0) be an initial condition in $D^{r,s} \setminus B(0,r) \times \{1,2\}^{\mathcal{A}}$. Due to Lemma 4.3, there exists (X, S_d) a $d^{r,s}$-maximal solution of (40) in closed loop with $(u^{r,s}, \widetilde{k}_d^{r,s})$ starting from (x_0, s_0). Moreover, due to properties established in Step 3 and Lemma 4.11, there exist $H \in \mathbb{N}\cup\{+\infty\}$, a sequence of points $t_0 = 0 < \cdots < t_H \le T$, and a sequence of indices $\alpha_1, \dots, \alpha_H$ in $\mathcal{A}$, such that, for all h in $\{0, \dots, H-1\}$,

$$\forall t \in [t_h, t_{h+1}), \quad X(t) \in \Gamma_{\alpha_h,7}, \tag{63}$$

$$t_{h+1} - t_h < \tau_{\alpha_h}. \tag{64}$$

Note that due to Lemma 4.11, the sequence $\alpha_1, \dots, \alpha_H$ described above is strictly increasing. Due to (52) and (63), (X, S_d) cannot blow up in $\Gamma_{\alpha_h,7}$ for all h in $\{0, \dots, H-1\}$, and due to Lemma 4.4, (63), there exists $T_{X,S_d} \le T$ such that we have the inequalities

$$\forall t \in [0, T], \quad |X(t)| < R, \tag{65}$$

$$|X(T_{X,S_d})| < r, \tag{66}$$

where R is defined by

$$R = \sup_{1\leq i\leq N(r,s),1\leq j\leq N_i} \{7\rho_{x_i,j} + M_{x_i}\}. \tag{67}$$

This completes the proof of Proposition 5.1. □

PROPOSITION 5.2. *Let* (1) *be globally asymptotically controllable to the origin. Then for any fixed $\varepsilon > 0$, there exists $\sigma > 0$ such that for every $0 < r < s \leq \sigma$, there exist $T, R, \chi, d > 0$, an open subset of $\mathbb{R}^n$, $D^{r,s}$, and a feedback control, $u = u^{r,s} : 2^{\mathbb{N}} \to K$, $k_d = k_d^{r,s} : \mathbb{R}^n \times 2^{\mathbb{N}} \to 2^{\mathbb{N}}$ as in Proposition* 5.1 *with*

$$R < \varepsilon. \tag{68}$$

Proof. The proof is similar to the proof of [1, Proposition 4.2] and consists of properly choosing the piecewise constant admissible control u_{x_0} for each point x_0 in $B(0,s) \setminus \mathrm{int}(B(0,r))$.

To do this, fix $\varepsilon > 0$. Since (1) is globally asymptotically controllable, there exists $\sigma = \sigma(\varepsilon) > 0$ such that, for any fixed $0 < r < s \leq \sigma$, the conclusions of Proposition 5.1 hold together with

$$M_{x_0} < \frac{\varepsilon}{2},$$
$$\max_{j\in\{1,\dots,N_0+1\}} \rho_{x_0,j} < \frac{\varepsilon}{14}$$

for all x_0 satisfying $r < |x_0| < s$. With (65) and (67), this implies (68). □

We are now ready to prove Theorem 2.7.

Proof of Theorem 2.7.

Part 1: Definition of the feedback control. Let $(r_n)_{n\in\mathbb{Z}}$ and $(s_n)_{n\in\mathbb{Z}}$ be two decreasing sequences of strictly positive numbers such that

- for all n in $\mathbb{Z}$, we have $r_{n-1} < s_n$;
- s_n converges to zero as $n \to +\infty$;
- r_{-n} converges to infinity as $n \to +\infty$.

Let $T_n = T(r_n, s_n)$, $R_n = R(r_n, s_n)$, $\chi_n = \chi(r_n, s_n)$ be three sequences of strictly positive numbers and consider a sequence of hybrid patchy feedbacks

$$(D^{r_n,s_n}, u^{r_n,s_n}, k_d^{r_n,s_n}, ((\Gamma_{i,l}^n)_{l\in\{1,\dots,7\}}, k_i^n)_{i\in\{1,\dots,N_n\}})$$

such that

$$R_n < \frac{1}{n} \quad \forall n \in \mathbb{N}_{>0} \tag{69}$$

as in Proposition 5.2. The index set

$$\mathcal{B} = \{(n,i),\ n \in \mathbb{Z},\ i \in \{1,\dots,N_n\}\}$$

can be totally ordered with the same relation of order as (60), i.e., by letting

$$(n,i) < (m,j) \quad \text{if either } n < m \text{ or else } n = m,\ i < j.$$

Then we have the following family of nested patchy vector fields on $\mathbb{R}^n \setminus \{0\}$:

$$(\mathbb{R}^n \setminus \{0\}, ((\Gamma_{i,l}^m)_{l\in\mathcal{F}}, k_i^m),\ (m,i) \in \mathcal{B}).$$

We can define a hybrid patchy feedback (u, k_d) on $\mathbb{R}^n \setminus \{0\}$ as in Definition 3.4. Let $\chi : \mathbb{R}^n \setminus \{0\} \to \mathbb{R}_{>0}$ be a continuous map satisfying

$$\chi(x) \leq \min\left(\chi_n, \frac{|x|}{2}\right) \quad \text{if } x \in D^{r_n,s_n} \setminus \bigcup_{m>n} D^{r_m,s_m}. \tag{70}$$

We define $\chi(0) = 0$. The map χ is continuous at 0 and then χ is an admissible radius for the measurement noise and the external disturbances. Let $(u, \widetilde{k}_d)$ be the feedback control defined by (36) for the hybrid patchy feedback (u, k_d). Let us prove that $(u, \widetilde{k}_d)$ is a global robust stabilizing controller on $\mathbb{R}^n$, i.e., that the origin of system (37) is a robust globally asymptotically stable equilibrium as stated in Theorem 2.7.

Part 2: Theorem 2.7 for π-solutions. Let $p : \mathbb{R}^n \to \mathbb{R}$ be a function continuous on $\mathbb{R}^n \setminus \{0\}$ satisfying the properties A1, A2, and A3.

Existence of π-solutions. Consider ξ, ζ satisfying our regularity assumptions. Let (x_0, s_0) be in $\mathbb{R}^n \times \{1, 2\}^{\mathcal{B}}$. Let $s_1 = k_d(x_0 + \xi(x_0, 0), s_0)$ and α be in $\mathcal{B}$ such that $k_\alpha = u(s_1)$. From our regularity assumptions on f and ζ, the Carathéodory conditions are satisfied for system (31). Let $0 < T \leq t_1$ and $X : [0, T) \to \mathbb{R}^n$ be a Carathéodory solution of (31). Let S_d be defined by $S_d(t) = s_1$ for all t in $[0, T)$. The map (X, S_d) is a π-solution of (37) starting from (x_0, s_0).

Completeness and global stability for π-solutions. Let $\varepsilon > 0$. Let $n \in \mathbb{N}$ be such that $\varepsilon < R_{-n}$. Such an R_{-n} exists because we have $r_{-n} \leq R_{-n}$ and r_{-n} tends to infinity as $n \to +\infty$. Let $\chi_0 > 0$ be defined by

$$\chi_0 = \inf_{x \in B(0,R_{-n}) \setminus B(0,r_{-n})} \chi(x), \tag{71}$$

and let $d_0 > 0$ satisfy the inequalities

$$d_0 < \frac{d(\mathbb{R}^n \setminus B(0, s_{-n}), B(0, r_{-n}))}{\max_{x \in B(0,s_{-n}),\ u \in K} |f(x, u)|}, \tag{72}$$

and for all x in $B(0, R_{-n}) \setminus B(0, r_{-n})$, for all y in $B(0, \chi(x))$,

$$d_0 < p(x + y). \tag{73}$$

Note that due to (70), we have $d_0 > 0$ and $\chi_0 > 0$. Let ξ, ζ satisfy our regularity assumptions and (12). Let (X, S_d) be a d_0-maximal solution of (37) on $[0, T)$ starting from (x_0, s_0) with $|x_0| < s_{-n}$ and (11).

Note that due to (71)–(73), for all $i \in \mathbb{N}$ such that $X(t_i)$ is in $B(0, R_{-n}) \setminus B(0, r_{-n})$, we have (28) and, for all t such that $X(t)$ is in $B(0, R_{-n}) \setminus B(0, r_{-n})$, we have (29).

Therefore, due to Proposition 5.1 and to the definition of the feedback control, if there exists $i \in \mathbb{N}$ such that $X(t_i)$ is in $B(0, s_{-n}) \setminus B(0, r_{-n})$, then there exists $j > i$ such that $X(t_j)$ is in $B(0, r_{-n})$ and for all t in $[i, j]$, $X(t)$ is in $B(0, R_{-n})$. Moreover, due to (72), if there exists $i \in \mathbb{N}$ such that $X(t_i)$ is in $B(0, r_{-n})$, then, for all t in $[t_i, t_{i+1}]$, we have $X(t)$ is in $B(0, s_{-n})$.

Thus we have, for all t in $[0, T)$,

$$|X(t)| \leq R_{-n}. \tag{74}$$

Therefore the conclusion of Lemma 4.4 cannot hold ($\limsup_{t \to T} |X(t)| \neq +\infty$) and thus we have $T = +\infty$ and the maximality property.

Finally, note that $\delta(\varepsilon) = s_{-n}$ tends to $+\infty$ as ε tends to infinity because when ε tends to infinity, n tends to infinity, r_{-n} tends to infinity, and we have $r_{-n-1} < s_{-n}$. Thus we have the stability property.

Global attractivity for π-solutions. Let $\varepsilon > 0$ and $C > 0$. Let $n \in \mathbb{N}$ be such that $\frac{1}{n} < \varepsilon$ and such that $\delta < r_{-n}$. Let $d_0 > 0$ and $\chi_0 > 0$ be defined, respectively, by

$$d_0 = \inf_{x \in B(0,R_{-n}) \setminus B(0,r_n)} p(x), \tag{75}$$

$$\chi_0 = \inf_{x \in B(0,R_{-n}) \setminus B(0,r_n)} \chi(x). \tag{76}$$

Let ξ, ζ satisfying our regularity assumptions and (12). Let (X, S_d) be a π-solution defined on $[0, +\infty)$, starting from (x_0, s_0) whose sampling schedule satisfies $\overline{d}(\pi) < d_0$ and whose initial condition satisfies $|x_0| < C$. Due to Proposition 5.1, there exists $\widetilde{T}$ in $[0, T_{-n}+T_{-n+1}+\cdots+T_n]$ such that $|X(\widetilde{T})| < r_n$. Let $T' = \inf\{t \in [0, \widetilde{T}],\ |X(t)| < s_n\}$. Then due to the stability property and as $R_n < \frac{1}{n}$, we have

$$\forall t \geq \widetilde{T}, \quad |X(t)| \leq \frac{1}{n}.$$

Therefore we have (14) with $T = T_{-n} + \cdots + T_n$.

Part 3: Theorem 2.7 for the generalized solutions.

Existence and completeness for the generalized solutions. This results from the fact that every π-solution of (37) is a generalized solution of (37).

Global stability and global attractivity for the generalized solutions. Let $\varepsilon > 0$. Let $\chi_0 > 0$, $d_0 > 0$ and δ of $\mathcal{K}_\infty$, be such that we have the stability property (13) for all π-solutions of (37) whose sampling schedule satisfies (11) and for all ξ, ζ satisfying our regularity assumptions and (12).

Let X be a generalized solution of (37) starting from $x_0 \in B(0, \frac{\delta(\varepsilon)}{2})$ with ξ, ζ satisfying our regularity assumptions and

$$\sup_{x \in \mathbb{R}^n,\, t \geq 0} |\xi(x,t)| \leq \frac{\chi_0}{2}, \qquad \operatorname*{esssup}_{x \in \mathbb{R}^n,\, t \geq 0} |\zeta(x,t)| \leq \frac{\chi_0}{2} \tag{77}$$

and obtained as limit of π-solutions (X^n, S_d^n) whose sampling schedule satisfies (11). Let us prove (13).

For n sufficiently large, we have

$$\sup_J |e_n(t)| + \operatorname*{esssup}_J |d_n(t)| < \frac{\chi_0}{2} \tag{78}$$

for all J compact subinterval of $[0, T)$. Then for n sufficiently large, (X^n, S_d^n) is a π-solution of (37) whose sampling schedule satisfies (11) with a disturbance satisfying (12). Then we have (13) for this sequence of π-solutions. Therefore we have (13) for the generalized solution X.

The global attractivity property can be proved similarly.

Part 4: Theorem 2.7 for Euler solutions.

Existence and completeness for Euler solutions. Let x_0, s_0 in $\mathbb{R}^n \times \{1, 2\}^{\mathcal{B}}$ and π_n be a sequence of sampling schedules such that $\overline{d}(\pi_n) \to 0$ as n tends to infinity. Let (X^n, S_d^n) be a π_n-solution of (37), starting from (x_0, s_0) and defined on $[0, +\infty)$. Due to Part 2 of the proof of Theorem 2.7, this sequence exists for n sufficiently large and there exists R such that, for all t in $[0, +\infty)$ and for n sufficiently large, we have

$$|X_n(t)| < R.$$

Therefore with Ascoli's theorem, we can define X an Euler solution defined on $[0, +\infty)$ and starting from x_0.

Global stability and global attractivity for Euler solutions. Let $\varepsilon > 0$. Let $\chi_0 > 0$, $d_0 > 0$ and δ of $\mathcal{K}_\infty$ be such that we have the stability property (13) for all d_0-maximal solutions of (37) and for all ξ, ζ satisfying our regularity assumptions and (12).

Let X be an Euler solution of (37) starting from $x_0 \in B(0, \frac{\delta(\varepsilon)}{2})$ with ξ, ζ satisfying our regularity assumptions and (12) and obtained as limit of π-solutions (X^n, S_d^n) satisfying $\overline{d}(\pi_n) \to 0$ as n tends to infinity.

Let us prove (13).

For n sufficiently large, we have $\overline{d}(\pi_n) < d_0$. Then for n sufficiently large, (X^n, S_d^n) is a π-solution of (37) whose sampling schedule satisfies (11) with a disturbance satisfying (12). Then we have (13) for this sequence of π-solutions. Therefore we have (13) for the generalized solution X.

The global attractivity can be proved similarly.

This completes the proof of Theorem 2.7. □

THE VALUE OF ZERO-SUM STOPPING GAMES IN CONTINUOUS TIME*

RIDA LARAKI† AND EILON SOLAN‡

Abstract. We study two-player zero-sum stopping games in continuous time and infinite horizon. We prove that the value in randomized stopping times exists as soon as the payoff processes are right-continuous. In particular, as opposed to existing literature, we do *not* assume any conditions on the relations between the payoff processes.

Key words. Dynkin games, stopping games, optimal stopping, stochastic analysis, continuous time, stochastic duels

1. Introduction. In many competitive interactions the main strategic issue is timing. To model such situations, Dynkin (1969) introduced stopping games, as a variation of optimal stopping problems. In Dynkin's setup, two players observe the realization of a payoff process in discrete time. Once one of the players decides to stop, player 2 pays player 1 the amount indicated by the payoff process. However, at every given stage only one of the players is allowed to stop; the identity of that player is governed by another process. The strategic choice of each player is the choice of his stopping time. Dynkin (1969) proved that those games admit a value.

Dynkin's seminal paper was extended in various directions. Neveu (1975) allowed the players to stop *simultaneously* and provided a sufficient condition for the existence of the value. Several authors, including Bismut (1977), Alario-Nazaret, Lepeltier, and Marchal (1982), Lepeltier and Maingueneau (1984), and Stettner (1984) studied the problem in *continuous time*.

Yasuda (1985) studied stopping games in discrete time (with either finite horizon or discounted payoff), and allowed the players to choose *randomized* stopping times. Yasuda (1985) proved that the value exists under merely an integrability condition. Rosenberg, Solan, and Vieille (2001) studied the infinite horizon game in discrete time and proved an analogous result. Touzi and Vieille (2002) provided a sufficient condition that ensures the existence of the value in randomized stopping times in continuous time. As their proof utilizes a fixed point argument, it is not constructive.

In the present paper we prove that under merely integrability and continuity conditions, every stopping game in continuous time admits a value in randomized stopping times. In addition, we construct ε-optimal randomized stopping times which are as close as one wishes to (nonrandomized) stopping times; roughly speaking, there

is a stopping time μ such that for every δ sufficiently small there is an ε-optimal randomized stopping time that stops with probability 1 between times μ and $\mu + \delta$.

Several models that have been extensively studied in different disciplines and that fall into the category of stopping games are wars of attrition (see, e.g., Maynard-Smith (1974), Ghemawat and Nalebuff (1985), and Hendricks, Weiss, and Wilson (1988)), preemption games (see, e.g., Fudenberg and Tirole (1991, section 4.5.3)), duels, and pricing of options. We will illustrate the applicability of our results by discussing the last two models.

We first present the model of duels. In the simplest version, duels are two-player zero-sum games in which each of two gunners is endowed with a single bullet. The two gunners are located at some distance from each other and move closer to one another as time goes on. Since the accuracy of their shots improves as they get closer, it is not clear what the optimal moment is to shoot the opponent. If the accuracy is a stochastic process that depends on, e.g., wind velocity, the gunners face a stopping game.

Although for various classes of duels the existence of the value has been established, and optimal strategies have been computed (see, e.g., Blackwell (1949), Bellman and Girshick (1949), Shapley (1951), Karlin (1959), and the recent survey by Radzik and Raghavan (1994)), the general case is still open.

As we argue below, our results can be applied to any duel, regardless of the number of bullets each player initially has.

We now discuss the relevant literature in pricing of options. In most cases, a holder of an option has the right to exercise the option either on prespecified dates or whenever he chooses, so that the optimization problem reduces to an optimal stopping problem. Callable warrants (see, e.g., Merton (1973)) and convertible bonds (see, e.g., Brennan and Schwartz (1977)) allow for a certain action by the issuer as well. Recently Kifer (2000) introduced game contingent claims, which are general American options in which the issuer can terminate the contract early at some cost. Kifer showed that pricing these options boils down to determining the value of a certain stopping game, and he provided a general characterization for the value. Game contingent claims have been studied also by, e.g., Kallsen and Kühn (2004) and Kühn and Kyprianou (2003). Kyprianou (2004) used Kifer's characterization to explicitly calculate the value of game contingent claims in some cases. McConnell and Schwartz (1986) studied a specific example of callable option notes, which were actually issued in the 1980s.

In the formulation of game contingent claims in Kifer (2000), the right of the holder to exercise the option supersedes the right of the issuer to terminate the contract early, so that if those two events occur simultaneously, the holder gets to exercise the option. However, if the payment when those two events occur simultaneously is different from the payment if the holder were to exercise alone, or the issuer were to terminate the contract alone, Kifer's analysis would no longer be valid. Our result establishes the existence of the value in this case, and may be used, as was done by Kyprianou (2004), to find optimal strategies in given examples.

The paper is arranged as follows. The model and the main result appear in section 2, and the proof of the main result appears in section 3. Further topics, namely, introducing final payoffs and the right-continuity of the value process, are discussed in sections 3.4–3.5. We end by using the right-continuity of the value process to derive a more general existence result for noisy stochastic duels in section 3.6.

2. Model, literature, and main result. A *two-player zero-sum stopping game in continuous time* Γ is given by the following:

- A probability space $(\Omega, \mathcal{A}, P)$: $(\Omega, \mathcal{A})$ is a measurable space, and P is a σ-additive probability measure on $(\Omega, \mathcal{A})$.
- A filtration in continuous time $\mathcal{F} = (\mathcal{F}_t)_{t\geq 0}$ satisfying "the usual conditions." That is, $\mathcal{F}$ is right-continuous, and $\mathcal{F}_0$ contains all P-null sets: for every $B \in \mathcal{A}$ with $P(B) = 0$ and every $A \subset B$, one has $A \in \mathcal{F}_0$. All stopping times in what follows are of the filtration $\mathcal{F}$.
  Denote $\mathcal{F}_\infty := \vee_{t\geq 0}\mathcal{F}_t$. Assume without loss of generality that $\mathcal{F}_\infty = \mathcal{A}$. Hence $(\Omega, \mathcal{A}, P)$ is a complete probability space.
- Three uniformly bounded $\mathcal{F}$-adapted processes $(a_t, b_t, c_t)_{t\geq 0}$.[1]

DEFINITION 1. *A* randomized stopping time *is a progressively measurable function* $\phi : [0,1] \times \Omega \to [0, +\infty]$ *such that for every* $r \in [0,1]$, $\mu_r(\omega) := \phi(r, \omega)$ *is an optional stopping time.*

For strategically equivalent definitions of randomized stopping times, see Touzi and Vieille (2002). Throughout the paper, the symbols μ and ν stand for stopping times, while ϕ and ψ stand for randomized stopping times.

For every pair (μ, ν) of stopping times we denote

$$\gamma(\mu, \nu) = \mathbf{E}_P\left[a_\mu \mathbf{1}_{\{\mu<\nu\}} + b_\nu \mathbf{1}_{\{\mu>\nu\}} + c_\mu \mathbf{1}_{\{\mu=\nu<+\infty\}}\right].$$

The *expected payoff* that corresponds to a pair of randomized stopping times (ϕ, ψ) is

$$\begin{aligned}(1)\qquad \gamma(\phi, \psi) &= \int_{[0,1]^2} \gamma(\mu_r, \nu_s)\, dr\, ds \\ &= \mathbf{E}_{\lambda\otimes\lambda\otimes P}\left[a_{\mu_r} \mathbf{1}_{\{\mu_r<\nu_s\}} + b_{\nu_s} \mathbf{1}_{\{\mu_r>\nu_s\}} + c_{\mu_r} \mathbf{1}_{\{\mu_r=\nu_s<+\infty\}}\right].\end{aligned}$$

Though the payoff function given by (1) is bilinear, without strong assumptions on the data of the game, the payoff function is not continuous for the same topology which makes the space of randomized stopping times compact.

DEFINITION 2. *If* $\sup_\phi \inf_\psi \gamma(\phi, \psi) = \inf_\psi \sup_\phi \gamma(\phi, \psi)$, *then the common value is the* value in randomized stopping times *and is denoted by* V. *Every randomized stopping time* ϕ *such that* $\inf_\psi \gamma(\phi, \psi)$ *is within* ε *of* V *is* ε-optimal *for player* 1; ε*-optimal randomized stopping times for player* 2 *are defined analogously.*

Observe that for every ϕ one has $\inf_\psi \gamma(\phi, \psi) = \inf_\nu \gamma(\phi, \nu)$, where ν ranges over all stopping times. Indeed, for every ϕ and ψ one has, by Fubini's theorem,

$$\gamma(\phi, \psi) = \mathbf{E}_{\lambda\otimes\lambda\otimes P}[\gamma(\mu_r, \nu_s)] \geq \inf_s \mathbf{E}_{\lambda\otimes\lambda\otimes P}[\gamma(\mu_r, \nu_s)] \geq \inf_\nu \gamma(\phi, \nu) \geq \inf_{\psi'} \gamma(\phi, \psi').$$

This implies that $\sup_\phi \inf_\psi \gamma(\phi, \psi) = \sup_\phi \inf_\nu \gamma(\phi, \nu)$. Similarly, $\inf_\psi \sup_\phi \gamma(\phi, \psi) = \inf_\psi \sup_\mu \gamma(\mu, \psi)$, where μ ranges over all pure stopping times. Recall that one always has $\sup_\phi \inf_\psi \gamma(\phi, \psi) \leq \inf_\psi \sup_\phi \gamma(\phi, \psi)$.

Touzi and Vieille (2002) provided a restrictive condition that ensures the existence of the value. The main result we present is the following.

THEOREM 3. *If the processes* $(a_t)_{t\geq 0}$ *and* $(b_t)_{t\geq 0}$ *are right-continuous, and if* $(c_t)_{t\geq 0}$ *is progressively measurable, then the value in randomized stopping times exists.*

3. Proof of the main result and extensions. From now on we fix a stopping game Γ that satisfies the assumptions of Theorem 3.

[1] Our results hold for a larger class of payoff processes, namely, the class $\mathcal{D}$ that was defined by Dellacherie and Meyer (1975, section II-18). This class contains in particular integrable processes.

3.1. Preliminaries. The following lemma will be used in what follows.

LEMMA 4. *For every stopping time τ and every $\varepsilon > 0$ there is $\delta > 0$ such that $P(\{|a_t - a_\tau| < \varepsilon \ \ \forall t \in [\tau, \tau + \delta]\}) > 1 - \varepsilon$.*

A similar statement holds when one replaces the process $(a_t)_{t\geq 0}$ by the process $(b_t)_{t\geq 0}$.

Proof. For every $n \in \mathbf{N}$, set $A_n = \{\sup\{|a_t - a_\tau|, \tau \leq t \leq \tau + 1/n\} < \varepsilon\}$. Since $(a_t)_{t\geq 0}$ is right-continuous, $P(\cup_{n\in\mathbf{N}} A_n) = 1$, and the result follows. □

One then obtains the following result.

COROLLARY 5. *Let a stopping time τ and $\varepsilon > 0$ be given. There exists $\delta > 0$ sufficiently small such that for every $\mathcal{F}_\tau$-measurable set $A \subseteq \{\tau < +\infty\}$ and every stopping time μ that satisfies $\tau \leq \mu \leq \tau + \delta$,*

$$|\mathbf{E}_P[a_\mu \mathbf{1}_A] - \mathbf{E}_P[a_\tau \mathbf{1}_A]| \leq \varepsilon.$$

3.2. The case $a_t \leq b_t$ for every $t \geq 0$. In this section we prove the following result: when $a_t \leq b_t$ for every $t \geq 0$, the value in randomized stopping times exists and is independent of $(c_t)_{t\geq 0}$.

The idea is as follows. Assume player 1 decides to stop at time t_*. If $c_{t_*} \geq a_{t_*}$, and player 1 stops with probability 1 at time t_*, player 2 has no incentive to stop at t_* as well. However, if $c_{t_*} < a_{t_*}$, player 1 needs to mask the exact time in which he stops, so that player 2 cannot stop at the same time. Since payoffs are right-continuous, player 1 can stop randomly in a small interval after time t_*. This way he makes sure that player 2 does not know the exact moment he will stop, and since $a_t \leq b_t$ for every t, player 2 has no incentive to stop in this time interval. In both cases, whatever the process $(c_t)_{t\geq 0}$ is, if the game has not stopped before time t_* player 1 can guarantee a payoff close to a_{t_*}.

PROPOSITION 6. *If $a_t \leq b_t$ for every $t \geq 0$, then the value in randomized stopping times exists. Moreover, the value is independent of the process $(c_t)_{t\geq 0}$. If $a_t \leq c_t \leq b_t$ for every $t \geq 0$, then there are ε-optimal (nonrandomized) stopping times for both players that are independent of $(c_t)_{t\geq 0}$.*

Proof. Consider an auxiliary stopping game $\Gamma^* = (\Omega, \mathcal{A}, P; \mathcal{F}, (a_t^*, b_t^*, c_t^*)_{t\geq 0})$, where $a_t^* = a_t$ and $b_t^* = c_t^* = b_t$ for every $t \geq 0$.

Lepeltier and Maingueneau (1984) and Stettner (1984) proved that the game Γ^* admits a value, and that there are ε-optimal (nonrandomized) stopping times for both players. We denote the value of Γ^* by v^* and prove that it is the value in randomized stopping times of the original game. Since Γ^* does not depend on the process $(c_t)_{t\geq 0}$, the second assertion of the proposition follows.

Fix $\varepsilon > 0$. Let μ be an ε-optimal (nonrandomized) stopping time for player 1 in Γ^*. In particular, $\inf_\nu \gamma_{\Gamma^*}(\mu, \nu) \geq v^* - \varepsilon$.

We now construct a randomized stopping time ϕ that satisfies $\inf_\nu \gamma_\Gamma(\phi, \nu) \geq v^* - 3\varepsilon$. By Lemma 4 there is $\delta > 0$ such that $P(\{|a_t - a_\mu| < \varepsilon \ \ \forall t \in [\mu, \mu + \delta]\}) > 1 - \varepsilon$. Define a randomized stopping time ϕ by

$$\phi(r, \cdot) = \mu + r\delta \qquad \forall r \in [0, 1].$$

That is, ϕ stops at a random time in the interval $[\mu, \mu + \delta]$. We denote such a randomized stopping time by $\phi = \mu + r\delta$.

Let ν be any stopping time. Since μ is ε-optimal in Γ^*, by the definition of Γ^*, by Fubini's theorem, and since $\lambda \otimes P(\mu + r\delta = \nu) = 0$,

$$\begin{aligned} v^* - \varepsilon &\le \gamma_{\Gamma^*}(\mu, \nu) \\ &= \mathbf{E}_P[a_\mu \mathbf{1}_{\{\mu<\nu\}} + b_\nu \mathbf{1}_{\{\mu\ge\nu\}}] \\ &= \mathbf{E}_{\lambda\otimes P}[a_\mu \mathbf{1}_{\{\mu+r\delta<\nu\}} + a_\mu \mathbf{1}_{\{\mu<\nu<\mu+r\delta\}} + b_\nu \mathbf{1}_{\{\mu\ge\nu\}}]. \end{aligned} \tag{2}$$

Since $\lambda \otimes P(\mu + r\delta = \nu) = 0$ and $(c_t)_{t\ge 0}$ is progressively measurable,

$$\begin{aligned} \gamma_\Gamma(\phi, \nu) &= \mathbf{E}_{\lambda\otimes P}\left[a_{\mu+r\delta} \mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\nu \mathbf{1}_{\{\mu+r\delta>\nu\}} + c_\nu \mathbf{1}_{\{\mu+r\delta=\nu<+\infty\}}\right] \\ &= \mathbf{E}_{\lambda\otimes P}\left[a_{\mu+r\delta} \mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\nu \mathbf{1}_{\{\mu+r\delta>\nu\}}\right] \\ &= \mathbf{E}_{\lambda\otimes P}\left[a_{\mu+r\delta} \mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\nu \mathbf{1}_{\{\mu<\nu<\mu+r\delta\}} + b_\nu \mathbf{1}_{\{\mu\ge\nu\}}\right]. \end{aligned} \tag{3}$$

By Corollary 5, and since $a_t \le b_t$ for every $t \ge 0$,

$$\mathbf{E}_{\lambda\otimes P}[a_\mu \mathbf{1}_{\{\mu<\nu<\mu+r\delta\}}] \le \mathbf{E}_{\lambda\otimes P}[a_\nu \mathbf{1}_{\{\mu<\nu<\mu+r\delta\}}] + \varepsilon \le \mathbf{E}_{\lambda\otimes P}[b_\nu \mathbf{1}_{\{\mu<\nu<\mu+r\delta\}}] + \varepsilon. \tag{4}$$

Corollary 5 implies in addition that for every $r \in [0, 1]$

$$\mathbf{E}_{\lambda\otimes P}[a_\mu \mathbf{1}_{\{\mu+r\delta<\nu\}}] \le \mathbf{E}_{\lambda\otimes P}[a_{\mu+r\delta} \mathbf{1}_{\{\mu+r\delta<\nu\}}] + \varepsilon. \tag{5}$$

By (2)–(5),

$$v^* - \varepsilon \le \gamma_{\Gamma^*}(\mu, \nu) \le \gamma_\Gamma(\phi, \nu) + 2\varepsilon.$$

Since ν is arbitrary, $\inf_\nu \gamma_\Gamma(\phi, \nu) \ge v^* - 3\varepsilon$.

Consider a second auxiliary stopping game $\Gamma^{**} = (\Omega, \mathcal{A}, P; \mathcal{F}, (a_t^{**}, b_t^{**}, c_t^{**})_{t\ge 0})$, where $a_t^{**} = c_t^{**} = a_t$ and $b_t^{**} = b_t$ for every $t \ge 0$.

A symmetric argument to the one provided above proves that the game Γ^{**} has a value v^{**} and that player 2 has a randomized stopping time ψ that satisfies $\sup_\mu \gamma_\Gamma(\mu, \psi) \le v^{**} + 3\varepsilon$.

Since $c_t^{**} = a_t \le b_t = c_t^*$ for every $t \ge 0$, one has $v^{**} \le v^*$. Since $\sup_\mu \gamma_\Gamma(\mu, \psi) \ge \gamma_\Gamma(\phi, \psi) \ge \inf_\nu \gamma_\Gamma(\phi, \nu)$,

$$v^* \ge v^{**} \ge \sup_\mu \gamma_\Gamma(\mu, \psi) - 3\varepsilon \ge \inf_\nu \gamma_\Gamma(\phi, \nu) - 3\varepsilon \ge v^* - 6\varepsilon.$$

Since ε is arbitrary, $v^* = v^{**}$, so that v^* is the value in randomized stopping times of Γ, and ϕ and ψ are 3ε-optimal randomized stopping times for the two players. The first assertion of the proposition is established.

We now turn to the third assertion of the proposition. If $a_t \le c_t \le b_t$ for every $t \ge 0$, then $\gamma_{\Gamma^{**}}(\mu, \nu) \le \gamma_\Gamma(\mu, \nu) \le \gamma_{\Gamma^*}(\mu, \nu)$ for every pair of stopping times (μ, ν). Hence

$$\begin{aligned} v^{**} &= \sup_\mu \inf_\nu \gamma_{\Gamma^{**}}(\mu, \nu) \le \sup_\mu \inf_\nu \gamma_\Gamma(\mu, \nu) \\ &\le \inf_\nu \sup_\mu \gamma_\Gamma(\mu, \nu) \le \inf_\nu \sup_\mu \gamma_{\Gamma^*}(\mu, \nu) = v^* = v^{**}. \end{aligned}$$

Thus $\sup_\mu \inf_\nu \gamma_\Gamma(\mu, \nu) = \inf_\nu \sup_\mu \gamma_\Gamma(\mu, \nu)$: the value exists and there are ε-optimal stopping times for both players. Moreover, any ε-optimal stopping time for player 1 (resp., player 2) in Γ^* (resp., Γ^{**}) is also ε-optimal in Γ. In particular, if $a_t \le c_t \le b_t$ for every $t \ge 0$, both players have ε-optimal stopping times that are independent of $(c_t)_{t\ge 0}$. □

3.3. Proof of Theorem 3. Define a stopping time τ by

$$\tau = \inf\{t \geq 0, a_t \geq b_t\},$$

where the infimum of an empty set is $+\infty$. Since $(a_t - b_t)_{t\geq 0}$ is progressively measurable with respect to $(\mathcal{F}_t)_{t\geq 0}$, τ is a stopping time (see, e.g., Dellacherie and Meyer (1975, section IV-50)).

We show below that it is optimal for both players to stop at or around time τ (provided the game does not stop before time τ). Hence the problem reduces to the game between times 0 and τ. Since for $t \in [0, \tau[$, $a_t \leq b_t$, Proposition 6 can be applied.

The following notation will be useful in what follows. For a pair of stopping times (μ, ν) and a set $A \in \mathcal{A}$ we define

$$\gamma_\Gamma(\mu, \nu; A) = \mathbf{E}_P[\mathbf{1}_A(a_\mu \mathbf{1}_{\{\mu<\nu\}} + b_\mu \mathbf{1}_{\{\mu>\nu\}} + c_\mu \mathbf{1}_{\{\mu=\nu<+\infty\}})].$$

This is the expected payoff restricted to A. For a pair of randomized stopping times (ϕ, ψ) we define

$$\gamma_\Gamma(\phi, \psi; A) = \int_{[0,1]^2} \gamma_\Gamma(\mu_r, \nu_s; A) dr\ ds,$$

where μ_r and ν_s are the sections of ϕ and ψ, respectively.

Set

$$\begin{aligned} A_0 &= \{\tau = +\infty\}, \\ A_1 &= \{\tau < +\infty\} \cap \{c_\tau \geq a_\tau \geq b_\tau\}, \\ A_2 &= \{\tau < +\infty\} \cap \{a_\tau > c_\tau \geq b_\tau\}, \text{ and} \\ A_3 &= \{\tau < +\infty\} \cap \{a_\tau \geq b_\tau > c_\tau\}. \end{aligned}$$

Observe that (A_0, A_1, A_2, A_3) is an $\mathcal{F}_\tau$-measurable partition of Ω.

Define an $\mathcal{F}_\tau$-measurable function w by

$$w = a_\tau \mathbf{1}_{A_1} + c_\tau \mathbf{1}_{A_2} + b_\tau \mathbf{1}_{A_3}.$$

Define a stopping game $\Gamma^* = (\Omega, \mathcal{A}, P, (\mathcal{F}_t)_{t\geq 0}, (a_t^*, b_t^*, c_t^*)_{t\geq 0})$ by

$$a_t^* = \begin{cases} a_t & t < \tau \\ w & t \geq \tau \end{cases}, \qquad b_t^* = \begin{cases} b_t & t < \tau \\ w & t \geq \tau \end{cases}, \qquad c_t^* = \begin{cases} c_t & t < \tau \\ w & t \geq \tau \end{cases}.$$

That is, the payoff is set to w at and after time τ.

The game Γ^* satisfies the assumptions of Proposition 6 and hence, has a value V in randomized stopping times.

We now prove that V is the value of the game Γ as well. Fix $\varepsilon > 0$. We show only that player 1 has a randomized stopping time ϕ such that $\inf_\nu \gamma_\Gamma(\phi, \nu) \geq V - 7\varepsilon$. An analogous argument shows that player 2 has a randomized stopping time ψ such that $\sup_\mu \gamma_\Gamma(\mu, \psi) \leq V + 7\varepsilon$. Since ε is arbitrary, V is indeed the value in randomized stopping times of Γ.

Assume δ is sufficiently small so that the following conditions hold (by the proofs of Lemma 4 and Proposition 6 such δ exists):

(C1) There exists a stopping time μ such that the randomized stopping time $\phi^* = \mu + r\delta$ is ε-optimal for player 1 in Γ^*.

(C2) $P(\{\mu+\delta<\tau\}) \geq P(\{\mu<\tau\}) - \varepsilon/M$, where $M \in]0,+\infty[$ is a uniform bound of the payoff processes.

(C3) $P(\{|a_t - a_\tau| < \varepsilon, |b_t - b_\tau| < \varepsilon \quad \forall t \in [\tau, \tau+\delta]\}) > 1-\varepsilon$.

We now claim that we can assume without loss of generality that $\mu \leq \tau$. Indeed, assume that $P(\{\mu > \tau\}) > 0$. The set $\{\mu > \tau\}$ is $\mathcal{F}_\tau$-measurable. Define a stopping time $\mu' = \min\{\mu, \tau\}$. We will prove that the randomized stopping time $\phi' = \mu' + r\delta$ is also ε-optimal in Γ^*, which establishes the claim. Given a stopping time ν define a stopping time ν' by $\nu' = \min\{\nu, \tau\}$. By (C1),

$$\begin{aligned} V - \varepsilon &\leq \gamma_{\Gamma^*}(\mu + r\delta, \nu') \\ &= \gamma_{\Gamma^*}(\mu + r\delta, \nu'; \{\mu > \tau\}) + \gamma_{\Gamma^*}(\mu + r\delta, \nu'; \{\mu \leq \tau < \mu + \delta\}) \\ &\quad + \gamma_{\Gamma^*}(\mu + r\delta, \nu'; \{\mu + \delta \geq \tau\}). \end{aligned}$$

On the right-hand side the first term is equal to $\gamma_{\Gamma^*}(\mu' + r\delta, \nu; \{\mu > t\})$, by (C2) the second term is bounded by ε, and the third term is equal to $\gamma_{\Gamma^*}(\mu' + r\delta, \nu; \{\mu + \delta \geq \tau\})$. Therefore, by (C2),

$$\begin{aligned} V - \varepsilon &\leq \gamma_{\Gamma^*}(\mu' + r\delta, \nu; \{\mu > t\}) + \varepsilon + \gamma_{\Gamma^*}(\mu' + r\delta, \nu; \{\mu + \delta \geq \tau\}) \\ &\leq \gamma_{\Gamma^*}(\mu' + r\delta; \nu) + 2\varepsilon, \end{aligned}$$

as desired.

Define a randomized stopping time ϕ as follows:

$$\phi(r, \cdot) = \begin{cases} \mu + r\delta & \{\mu < \tau\} \cup A_0, \\ \tau & \{\mu = \tau\} \cap (A_1 \cup A_2), \\ \mu + r\delta & \{\mu = \tau\} \cap A_3. \end{cases}$$

The randomized stopping times ϕ and ϕ^* differ only over the set $\{\mu = \tau\} \cap (A_1 \cup A_2)$. Since over this set the payoff in Γ^* is w, provided the game terminates after time τ regardless of what the players play, and by (C2),

$$\inf_\nu \gamma_{\Gamma^*}(\phi, \nu) \geq V - 3\varepsilon. \tag{6}$$

Let ν be an arbitrary stopping time. Define a partition (B_0, B_1, B_2) of $[0,1] \times \Omega$ by

$$\begin{aligned} B_0 &= \{\mu + \delta < \tau\} \cup \{\nu < \tau\}, \\ B_1 &= \{\mu < \tau < \mu + \delta\} \cap \{\nu \geq \tau\}, \\ \text{and } B_2 &= \{\mu = \tau\} \cap \{\nu \geq \tau\}. \end{aligned}$$

Over B_0 the game terminates before time τ under (ϕ, ν). In particular,

$$\gamma_\Gamma(\phi, \nu; B_0) = \gamma_{\Gamma^*}(\phi, \nu; B_0). \tag{7}$$

By (C2), $P(B_1) < \varepsilon/M$, so that

$$\gamma_\Gamma(\phi, \nu; B_1) \geq \gamma_{\Gamma^*}(\phi, \nu; B_1) - 2\varepsilon. \tag{8}$$

Over $B_2 \cap A_0$ the game never terminates under (ϕ, ν), so that

$$\gamma_\Gamma(\phi, \nu; B_2 \cap A_0) = \gamma_{\Gamma^*}(\phi, \nu; B_2 \cap A_0) = 0. \tag{9}$$

Over $A_1 \cup A_2$, $\min\{a_\tau, c_\tau\} \geq w$, so that

$$\begin{aligned}\gamma_\Gamma(\phi,\nu; B_2 \cap (A_1 \cup A_2)) &= \mathbf{E}_{\lambda\otimes P}[\mathbf{1}_{B_2\cap(A_1\cup A_2)}(a_\tau \mathbf{1}_{\{\tau<\nu\}} + c_\tau \mathbf{1}_{\{\tau=\nu\}})] \\ &\geq \mathbf{E}_{\lambda\otimes P}[w\mathbf{1}_{\{\tau\leq\nu\}\cap B_2\cap(A_1\cup A_2)}] \\ &= \gamma_{\Gamma^*}(\phi,\nu; B_2 \cap (A_1 \cup A_2)).\end{aligned} \tag{10}$$

Finally, since $\lambda \otimes P(\{\mu + r\delta = \nu\}) = 0$, since $\{\mu = \tau\}$ on B_2, by Corollary 5, since $(c_t)_{t\geq 0}$ is progressively measurable, and since $a_\tau \geq b_\tau = w$ on A_3,

$$\begin{aligned}\gamma_\Gamma(\phi,\nu; B_2 \cap A_3) &= \mathbf{E}_{\lambda\otimes P}[\mathbf{1}_{B_2\cap A_3}(a_{\mu+r\delta}\mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\nu \mathbf{1}_{\{\mu+r\delta>\nu\}} + c_\nu \mathbf{1}_{\{\mu+r\delta=\nu\}})] \\ &= \mathbf{E}_{\lambda\otimes P}[\mathbf{1}_{B_2\cap A_3}(a_{\mu+r\delta}\mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\nu \mathbf{1}_{\{\mu+r\delta>\nu\}})] \\ &\geq \mathbf{E}_{\lambda\otimes P}[\mathbf{1}_{B_2\cap A_3}(a_\tau \mathbf{1}_{\{\mu+r\delta<\nu\}} + b_\tau \mathbf{1}_{\{\mu+r\delta>\nu\}})] - 2\varepsilon \\ &\geq \mathbf{E}_{\lambda\otimes P}[w\mathbf{1}_{B_2\cap A_3}] - 2\varepsilon \\ &= \gamma_{\Gamma^*}(\phi,\nu; B_2 \cap A_3) - 2\varepsilon.\end{aligned} \tag{11}$$

Summing (7)–(11) and using (6) gives us

$$V - 3\varepsilon \leq \gamma_{\Gamma^*}(\phi,\nu) \leq \gamma_\Gamma(\phi,\nu) + 4\varepsilon,$$

as desired.

3.4. On final payoff. Our convention is that the payoff is 0 if no player ever stops. In fact, one can add a final payoff as follows. Let χ be an $\mathcal{A}$-measurable and integrable function. The expected payoff that corresponds to a pair of pure strategies (μ,ν) is

$$\mathbf{E}_P[a_\mu \mathbf{1}_{\{\mu<\nu\}} + b_\nu \mathbf{1}_{\{\mu>\nu\}} + c_\mu \mathbf{1}_{\{\mu=\nu<+\infty\}} + \chi \mathbf{1}_{\{\mu=\nu=+\infty\}}].$$

The expected payoff can be written as

$$\begin{aligned}\mathbf{E}_P[\chi] + \mathbf{E}_P\Big[\Big(a_\mu - \mathbf{E}_P^{\mathcal{F}_\mu}[\chi]\Big)\mathbf{1}_{\{\mu<\nu\}} &+ \Big(b_\nu - \mathbf{E}_P^{\mathcal{F}_\nu}[\chi]\Big)\mathbf{1}_{\{\mu>\nu\}} \\ &+ \Big(c_\mu - \mathbf{E}_P^{\mathcal{F}_\mu}[\chi]\Big)\mathbf{1}_{\{\mu=\nu<+\infty\}}\Big],\end{aligned}$$

where $\mathbf{E}_P^{\mathcal{F}_\mu}[\chi]$ is the conditional expectation of χ given the σ-algebra $\mathcal{F}_\mu$.

Define a process $d_t := \mathbf{E}_P^{\mathcal{F}_t}[\chi]$. Since the filtration satisfies the "usual conditions," $(d_t)_{t\geq 0}$ is a right-continuous martingale (see, e.g., Dellacherie and Meyer (1980, section VI-4) or Lepeltier and Maingueneau (1984, Theorem 4)). Hence we are reduced to the study of the standard stopping game $\Gamma^* = (\Omega, \mathcal{A}, P, (\mathcal{F}_t)_{t\geq 0}, (a_t^*, b_t^*, c_t^*)_{t\geq 0})$ with $a_t^* = b_t - d_t$, $b_t^* = b_t - d_t$, and $c_t^* = c_t - d_t$.

3.5. Right-continuity of the payoff process. For every $s \geq 0$, let $\Gamma[s]$ be the stopping game that starts at time s. Formally, $\Gamma[s]$ is given by $(\Omega, \mathcal{A}, P, (\mathcal{F}'_t, a'_t, b'_t, c'_t)_{t\geq 0})$, where for every $t \geq 0$, $\mathcal{F}'_t = \mathcal{F}_{t+s}$, $a_t = a_{t+s}$, $b_t = b_{t+s}$, and $c_t = c_{t+s}$. Let v_s be the value of $\Gamma[s]$.

The next proposition states that if the payoff processes are right-continuous, the process $(v_t)_{t\geq 0}$ is right-continuous as well.

PROPOSITION 7. *If the processes $(a_t, b_t, c_t)_{t\geq 0}$ are right-continuous, then so is $(v_t)_{t\geq 0}$.*

Proof. For every $t \geq 0$, denote $\tau[t] = \inf\{t \geq s\colon a_s \geq b_s\}$ and define the sets $A_0[t], A_1[t], A_2[t]$, and $A_3[t]$ as in the proof of Theorem 3 with respect to $\tau[t]$. Set

$$w_t = a_{\tau[t]}\mathbf{1}_{A_1[t]} + c_{\tau[t]}\mathbf{A_2[t]} + b_{\tau[t]}\mathbf{1}_{A_3[t]}.$$

Now fix $t \geq 0$. On $\{a_t < b_t\}$, one has $w_t = w_s$ for every $s > t$ sufficiently close to t, so that by Lepeltier and Maingueneau (1984, Theorem 9), the value is right-continuous on this set.

On $\{a_t > c_t > b_t\}$, one has $v_s = c_s$ for every $s \geq t$ sufficiently close to t, and by the right-continuity of $(c_t)_{t\geq 0}$ the same conclusion holds.

On $\{a_t = c_t \geq b_t\}$, one has $\tau[t] = 0$ and $v_t = a_t = c_t$. Moreover, for every $\varepsilon > 0$ and every $s > t$ sufficiently small, one has (i) $a_s > a_t - \varepsilon = v_t - \varepsilon$ and $c_s > c_t - \varepsilon = v_t - \varepsilon$, so that $v_s > v_t - \varepsilon$, and (ii) $b_s < b_t + \varepsilon \leq v_t + \varepsilon$ and $c_s < c_t + \varepsilon = v_t + \varepsilon$, so that $v_s < v_t + \varepsilon$. In particular, $(v_t)_{t\geq 0}$ is right-continuous at t on this set.

A similar argument shows the right-continuity of $(v_t)_{t\geq 0}$ in all of the remaining cases. □

3.6. Noisy stochastic duels. As mentioned in the introduction, the right-continuity of the payoff process can be used to derive, by induction and proper definition of a final payoff, the existence of an equilibrium in a more general class of games, in which (i) each player has to act at most M times, and (ii) the payoff depends on the number of times each player acted, as well as on the exact times in which the players acted. That is, the game is given by a filtration $(\mathcal{F}_t)_{t\geq 0}$ and, for every $0 \leq n, m \leq M$, a right-continuous process $u_{m,n}(t_1, \dots, t_m, t'_1, \dots, t'_n)$ that is defined whenever $t_1 < t_2 < \cdots < t_m$ and $t'_1 < t'_2 < \cdots < t'_n$, and such that $u_{m,n}(t_1, \dots, t_m, t'_1, \dots, t'_n)$ is $\mathcal{F}_{\max\{t_m, t'_n\}}$-measurable. If player 1 acts at times $t_1 < \cdots < t_m$ and player 2 acts at times $t'_1 < \cdots < t'_n$, with $0 \leq m, n \leq M$, the payoff is $u_{m,n}(t_1, \dots, t_m, t'_1, \dots, t'_n)$. This implies, in particular, that every noisy stochastic duel in which each player is endowed with finitely many bullets, the payoff is 1 if player 1 hits player 2, the payoff is –1 if player 2 hits player 1, and the accuracy process is right-continuous, admits a value.

Details are standard and omitted.

EFFICIENT SOLUTION OF OPTIMAL CONTROL PROBLEMS USING HYBRID SYSTEMS*

MIREILLE BROUCKE†, MARIA DOMENICA DI BENEDETTO‡, STEFANO DI GENNARO§, AND ALBERTO SANGIOVANNI-VINCENTELLI¶

Abstract. We consider the synthesis of optimal controls for continuous feedback systems by recasting the problem to a hybrid optimal control problem: *synthesize optimal enabling conditions for switching between locations in which the control is constant.* An algorithmic solution is obtained by translating the hybrid automaton to a finite automaton using a bisimulation and formulating a dynamic programming problem with extra conditions to ensure non-Zenoness of trajectories. We show that the discrete value function converges to the viscosity solution of the Hamilton–Jacobi–Bellman equation as a discretization parameter tends to zero.

Key words. optimal control, hybrid systems, bisimulation

1. Introduction.

The goal of this paper is the development of a computationally appealing technique for synthesizing optimal controls for continuous feedback systems $\dot{x} = f(x, u)$ by recasting the problem as a hybrid optimal control problem. The hybrid problem is obtained by approximating the control set $U \subset \mathbb{R}^m$ by a finite set $\Sigma \subset U$ and defining vector fields for the locations of the hybrid system of the form $f(x, \sigma)$, $\sigma \in \Sigma$; that is, the control is constant in each location. The hybrid control problem is to synthesize enabling conditions such that a target set $\Omega_f \subset \Omega$ is reached while a hybrid cost function is minimized, for each initial condition in a specified set $\Omega \subset \mathbb{R}^n$.

Casting the problem as a hybrid control problem is not necessarily a simplification because, while algorithmic approaches for solving the controller synthesis problem for specific classes of hybrid systems have appeared [33, 52], no general, efficient algorithm is available. To be able to solve the (nonlinear) hybrid optimal control problem, we must exploit some additional property. We have a feasible and appealing approach if we can translate the problem to an equivalent discrete problem, which abstracts completely the continuous behavior. This translation is possible if we can construct a finite *bisimulation* defined on the hybrid state space, that is, an equivalence relation that induces a partition in each hybrid automaton location that is consistent with the continuous dynamics of that location. A finite bisimulation can be constructed using the geometric approach reported in [10], based on the following key assumption: $n-1$ *local (on* Ω*) first integrals can be expressed analytically for each vector field* $f(x, \sigma)$, $\sigma \in \Sigma$. This assumption is imposed in the transient phase of a feedback system's

response, when the vector field is nonvanishing and local first integrals always exist, although finding closed form expressions for them is not always easy or possible. Also, the assumption that the partition be a bisimulation is sufficient but not necessary for the overall approach.

If the assumption is met, then we can transform the hybrid system to a quotient system associated with the finite bisimulation, which is a finite automaton. The control problem posed on the finite automaton is to synthesize a discrete supervisor, providing a switching rule between automaton locations, that minimizes a discrete cost function approximating the original cost function, for each initial discrete state. We provide a dynamic programming solution to this problem, with extra constraints to ensure non-Zenoness of the closed-loop trajectories. By imposing non-Zeno conditions on the synthesis we obtain piecewise constant controls with a finite number of discontinuities in bounded time.

The discrete value function depends on the discretizations of U and of Ω using the bisimulation. We quantify these discretizations by parameters δ and δ_Q. The main theoretical contribution is to show that as $\delta, \delta_Q \to 0$, the discrete value function converges to the unique viscosity solution of the Hamilton–Jacobi–Bellman (HJB) equation.

There is a similarity between our approach to optimal control and *regular synthesis*, introduced in [8], in the sense that both restrict the class of controls to a set that has some desired property and both use a finite partition to define switching behavior. For linear systems, the results on regular synthesis are centered on the bang-bang principle [38], stating that a sufficient class of optimal controls is piecewise constant. If U is a convex polyhedron, then the number of discontinuities of the control is bounded. There is no hope that general bang-bang results are available due to Fuller's example [21, 29]. Nevertheless, in many applications the optimal control is a piecewise continuous function, and methods of regular synthesis of such controls are worth investigating. Our paper focuses on piecewise constant controls and provides a constructive approach to obtaining a cell decomposition, in the spirit of regular synthesis, by using a finite bisimulation, which further allows us to formulate the synthesis problem on its quotient system—a finite automaton.

The idea of using a time abstract model formed by partitioning the continuous state space has been pursued in a number of papers recently. Stiver, Antsaklis, and Lemmon [48] and Yang, Lemmon, and Antsaklis [53] used a partition of the state space to convert a hybrid model to a discrete event system (DES). This enabled them to apply controller synthesis for DESs to synthesize a supervisor. While our approach is related to this methodology, it differs in that we provide conditions for obtaining the partition. In [41] hybrid systems consisting of a linear time-invariant system and a discrete controller that has access to a quantized version of the linear system's output is considered. The quantization results in a rectangular partition of the state space. This approach suffers from spurious solutions that must be trimmed from the automaton behavior. Hybrid optimal control problems have been studied in papers by Witsenhausen [51], Branicky, Borkar, and Mitter [9], and Bensoussan and Menaldi [6]. The first two studies concentrated on problems of well-posedness, necessary conditions, and existence of optimal solutions but did not provide algorithmic solutions. Bensoussan and Menaldi considered a more general model than ours that included continuous dynamics with a measurable control input and a discrete part with impulsive control. Control switches can be autonomous or controlled and may have time delays. They characterized the viscosity solution of a dynamic programming problem

on their model. They constructed open-loop controls, whereas we obtain feedback controls, and they did not consider the numerical implementation.

There has recently been significant progress in developing numerical methods that incorporate geometric invariants of a dynamical or control system. In particular, in the area of geometric mechanics, numerical integrators have been developed that preserve the Hamiltonian, Lie group symmetries, and other integrals of motion [19, 27, 25, 28, 40]. See [36] for an overview of problems where geometric structure is exploited in numerical methods. Our work represents the first general methodology in which geometric invariants are explicitly considered in the numerical solution of optimal control problems. The geometric structure that is present in the optimal control problem is encoded in the bisimulation partition. In effect, the two-step procedure of a time discretization followed by the state discretization via finite element methods that together lead to a fixed point formulation of the approximate solution of a continuous time optimal control problem is circumvented. Instead an exact representation of the time evolution of the system is encoded in the finite element partition, enabling a simplified and more efficient formulation.

The paper is organized as follows. In section 2 we state the optimal control problem, while in section 3 the associated hybrid system is given. In section 4 we review how the bisimulation is constructed. Section 5 formulates the proposed solution using bisimulation and dynamic programming. In section 6 we prove the main theoretical result. In section 7 we present an algorithmic solution of the dynamic programming problem including a formal justification of the algorithm's optimality. In section 8 we give two simple examples. Section 9 summarizes our findings.

2. Optimal control problem. *Notation.* First, we introduce notation. $\mathbf{1}(\cdot)$ is the indicator function. $\mathrm{cl}(A)$ denotes the closure of set A. $\|\cdot\|$ denotes the Euclidean norm. Let $C^1(\mathbb{R}^n)$ and $\mathcal{X}(\mathbb{R}^n)$ denote the sets of continuously differentiable real-valued functions and smooth vector fields on $\mathbb{R}^n$, respectively. $\phi_t(x_0, \mu)$ denotes the trajectory of $\dot{x} = f(x, \mu)$ starting from x_0 and using control $\mu(\cdot)$.

Let U be a compact subset of $\mathbb{R}^m$; Ω an open, bounded, connected subset of $\mathbb{R}^n$; and Ω_f a compact subset of Ω. Define $\mathcal{U}_m$ to be the set of measurable functions mapping $\mathbb{R}^+$ to U. We define the minimum hitting time $T : \mathbb{R}^n \times \mathcal{U}_m \to \mathbb{R}^+$ by

$$T(x,\mu) := \begin{cases} \infty & \text{if } \{t \mid \phi_t(x,\mu) \in \Omega_f\} = \emptyset, \\ \min\{t \mid \phi_t(x,\mu) \in \Omega_f\} & \text{otherwise.} \end{cases} \tag{2.1}$$

A control $\mu \in \mathcal{U}_m$ specified on $[0, T]$ is *admissible* for $x \in \Omega$ if $\phi_t(x, \mu) \in \Omega$ for all $t \in [0, T]$. The set of admissible controls for x is denoted $\mathcal{U}_x$. Let

$$\mathcal{R} := \{x \in \Omega \mid \exists \mu \in \mathcal{U}_x.\ T(x,\mu) < \infty\}.$$

We consider the following stationary optimal control problem. Given $y \in \Omega$,

$$\text{minimize} \qquad J(y,\mu) = \int_0^{T(y,\mu)} L(x(t),\mu(t))dt + h(x(T(y,\mu))) \tag{2.2}$$

$$\text{subject to} \qquad \dot{x} = f(x,\mu), \qquad \text{a.e. } t \in [0, T(y,\mu)], \tag{2.3}$$

$$x(0) = y \tag{2.4}$$

among all admissible controls $\mu \in \mathcal{U}_y$. $J : \mathbb{R}^n \times \mathcal{U}_m \to \mathbb{R}$ is the *cost-to-go* function, $h : \mathbb{R}^n \to \mathbb{R}$ is the *terminal cost*, and $L : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is the *instantaneous cost*. At $T(y, \mu)$ the terminal cost $h(x(T(y, \mu)))$ is incurred and the dynamics are stopped. The control objective is to reach Ω_f from $y \in \Omega$ with minimum cost.

Assumption 2.1.

(1) $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ satisfies $\|f(x', u') - f(x, u)\| \le L_f\big[\|x' - x\| + \|u' - u\|\big]$ for some $L_f > 0$. Let M_f be the upper bound of $\|f(x, u)\|$ on $\Omega \times U$.

(2) $L : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ satisfies $|L(x', u') - L(x, u)| \le L_L\big[\|x' - x\| + \|u' - u\|\big]$ and $1 \le L(x, u) \le M_L$, $x \in \Omega$, $u \in U$, for some $L_L, M_L > 0$.

(3) $h : \mathbb{R}^n \to \mathbb{R}$ satisfies $|h(x') - h(x)| \le L_h\|x' - x\|$ for some $L_h > 0$, and $h(x) \ge 0$ for all $x \in \Omega$. Let M_h be the upper bound of $|h(x)|$ on Ω.

Remark 2.1. These assumptions ensure existence of solutions to (2.3) and uniqueness of the trajectories $\phi_t(x, \mu)$. Weaker assumptions are possible; see [4].

The *value function* or optimal cost-to-go function $V : \mathbb{R}^n \to \mathbb{R}$ is given by

$$V(y) = \inf_{\mu \in \mathcal{U}_y} J(y, \mu)$$

for $y \in \Omega \setminus \Omega_f$ and by $V(y) = h(y)$ for $y \in \Omega_f$. A control μ is called *ϵ-optimal* for x if $J(x, \mu) \le V(x) + \epsilon$.

It is well known [20] that V satisfies the HJB equation

$$-\inf_{u \in U}\Big\{L(x, u) + \frac{\partial V}{\partial x} f(x, u)\Big\} = 0 \tag{2.5}$$

at each point of $\mathcal{R}$ at which it is differentiable. The HJB equation is an infinitesimal version of the equivalent *dynamic programming principle* (DPP), which says that

$$V(x) = \inf_{\mu \in \mathcal{U}_x}\left\{\int_0^t L(\phi_s(x, \mu), \mu(s))ds + V(\phi_t(x, \mu))\right\}, \quad x \in \Omega \setminus \Omega_f,$$

$$V(x) = h(x), \qquad x \in \Omega_f.$$

The subject of assiduous effort has been that the HJB equation may not have a C^1 solution. This gap in the theory was closed by the introduction of the concept of viscosity solution [32, 14], which can be shown to provide the unique solution of (2.5) without any differentiability assumption. In particular, a bounded uniformly continuous function V is called a *viscosity solution* of HJB provided, for each $\psi \in C^1(\mathbb{R}^n)$, the following hold:

(i) if $V - \psi$ attains a local maximum at $x_0 \in \mathbb{R}^n$, then

$$-\inf_{u \in U}\Big\{L(x_0, u) + \frac{\partial \psi}{\partial x}(x_0) f(x_0, u)\Big\} \le 0;$$

(ii) if $V - \psi$ attains a local minimum at $x_1 \in \mathbb{R}^n$, then

$$-\inf_{u \in U}\Big\{L(x_1, u) + \frac{\partial \psi}{\partial x}(x_1) f(x_1, u)\Big\} \ge 0.$$

Assumption 2.2. For every $\epsilon > 0$ and $x \in \mathcal{R}$, there exists $N_\epsilon > 0$ and an admissible piecewise constant ϵ-optimal control μ having at most N_ϵ discontinuities and such that $\phi_t(x, \mu)$ is transverse to $\partial\Omega_f$.

The transversality assumption implies that the viscosity solution is continuous at the boundary of the target set, a result needed in proving uniform continuity of V

over a finite horizon. The assumption can be replaced by a small-time controllability condition. For a treatment of small-time controllability and compatibility of the terminal cost with respect to continuity of the value function, see [4]. The finite switching assumption holds under mild assumptions, such as Lipschitz continuity of the vector field and cost functions, and is based on approximating measurable functions by piecewise constant functions.

3. Hybrid system. The approach we propose for solving the continuous optimal control problem first requires a mapping to a hybrid system and, second, employs a bisimulation of the hybrid system to formulate a dynamic programming problem on the quotient system. In this section we define the hybrid system. First, we discretize U by defining a finite set $\Sigma_\delta \subset U$ which has a mesh size

$$\delta := \sup_{u \in U} \min_{\sigma \in \Sigma_\delta} \|u - \sigma\|.$$

We define the hybrid automaton $H := (\Sigma \times \mathbb{R}^n, \Sigma_\delta, D, E_h, G)$ with the following components.

State set. $\Sigma \times \mathbb{R}^n$ consists of the finite set $\Sigma = \Sigma_\delta \cup \{\sigma_f\}$ of control locations and n continuous variables $x \in \mathbb{R}^n$. σ_f is a terminal location when the optimal control problem is stopped and the target set is reached. The controller for σ_f may, for instance, be a linear feedback designed using the linearization of the system.

Events. Σ_δ is a finite set of control events.

Vector fields. $D : \Sigma \to \mathcal{X}(\mathbb{R}^n)$ is a function assigning an autonomous vector field to each location. We use the notation $D(\sigma) = f_\sigma$.

Control switches. $E_h \subset \Sigma \times \Sigma$ is a set of control switches. $e = (\sigma, \sigma')$ is a directed edge between a source location σ and a target location σ'. If $E_h(\sigma)$ denotes the set of edges that can be enabled at $\sigma \in \Sigma$, then $E_h(\sigma) := \{(\sigma, \sigma') \mid \sigma' \in \Sigma \setminus \sigma\}$ for $\sigma \in \Sigma_\delta$ and $E_h(\sigma_f) = \emptyset$. Thus, from a source location not equal to σ_f, there is an edge to every other location (but not itself), while location σ_f has no outgoing edges.

Enabling conditions. $G : E_h \to \{g_e\}_{e \in E_h}$ is a function assigning to each edge an enabling (or guard) condition $g \subset \mathbb{R}^n$. We use the notation $G(e) = g_e$. The optimal enabling conditions are unknown and must be synthesized.

3.1. Semantics. A state is a pair (σ, x), $\sigma \in \Sigma$ and $x \in \mathbb{R}^n$. In location $\sigma \in \Sigma_\delta$ the continuous state evolves according to the vector field $f(x, \sigma)$. In location σ_f, the vector field is $\dot{x} = f(x, \mu_f)$, where μ_f is the (not necessarily constant) control of the terminal location. Trajectories of H evolve in *steps* of two types. A *σ-step* is a binary relation $\xrightarrow{\sigma} \subset (\Sigma \times \mathbb{R}^n) \times (\Sigma \times \mathbb{R}^n)$, and we write $(\sigma, x) \xrightarrow{\sigma'} (\sigma', x')$ iff (1) $e = (\sigma, \sigma') \in E_h$, (2) $x \in g_e$, and (3) $x = x'$. A *t-step* is a binary relation $\xrightarrow{t} \subset (\Sigma \times \mathbb{R}^n) \times (\Sigma \times \mathbb{R}^n)$, and we write $(\sigma, x) \xrightarrow{t} (\sigma', x')$ iff (1) $\sigma = \sigma'$ and (2) for some $t \geq 0$, $x' = \phi_t(x, \sigma)$, where $\dot{\phi}_t(x) = f(\phi_t(x, \sigma), \sigma)$. Enabling conditions are *forced* in that an edge is taken instantaneously and as soon as it is enabled.

Example 3.1. Consider the time optimal control problem for the system

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= u. \end{aligned} \tag{3.1}$$

Suppose $\Omega = (-1, 1) \times (-1, 1)$ and $\Omega_f = \overline{B}_\epsilon(0)$, the closed epsilon ball centered at 0. The cost-to-go function is $J(x, \mu) = \int_0^{T(x,\mu)} dt$ and $U = \{u : |u| \leq 1\}$. We select

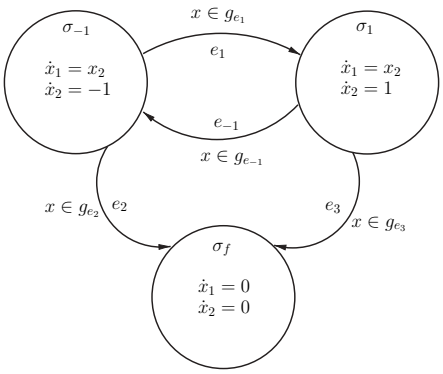

FIG. 3.1. *Hybrid automaton for time optimal control of a double integrator system.*

$\Sigma_\delta = \{-1, 1\}$, so that $\delta = 1$. The hybrid system is show in Figure 3.1. The state set is $\{\sigma_{-1} = -1, \sigma_1 = 1, \sigma_f\} \times \mathbb{R}^2$. $g_{e_{-1}}$ and g_{e_1} are unknown and must be synthesized, while $g_{e_2} = g_{e_3} = \Omega_f$.

4. Bisimulation. Let λ represent an arbitrary time interval. A *bisimulation* of H is an equivalence relation $\simeq \subset (\Sigma_\delta \times \mathbb{R}^n) \times (\Sigma_\delta \times \mathbb{R}^n)$ such that for all states $p_1, p_2 \in \Sigma_\delta \times \mathbb{R}^n$, if $p_1 \simeq p_2$ and $\beta \in \Sigma_\delta \cup \{\lambda\}$, then if $p_1 \xrightarrow{\beta} p_1'$, there exists p_2' such that $p_2 \xrightarrow{\beta} p_2'$ and $p_1' \simeq p_2'$. See Figure 4.1. Intuitively, a bisimulation is an equivalence relation defining a partition on the hybrid state space that preserves reachability over σ-steps and time steps. However, the definition leaves ambiguity about how the partition should be obtained. Alur and Dill [1] gave a construction for timed automata that was based on the first integrals of the continuous dynamics and on the syntax of the enabling and reset conditions. Their approach was first generalized in [10]. Time evolution of the original system is modeled as untimed transitions from equivalence class to equivalence class in the quotient system associated with the bisimulation. Transitions between locations of the hybrid automaton appear also as transitions in the quotient system. Thus if there is a finite number of equivalence classes of $\simeq$, then a finite transition system or finite automaton is obtained which gives a time abstract model of the original system, with reachability properties exactly preserved. For a more thorough discussion of results on bisimulations for hybrid systems, see [26, 2].

We declare the set of "interesting" equivalence classes of $\simeq$, which is assumed to be finite and is denoted Q, to be those that intersect $\Sigma_\delta \times \mathrm{cl}(\Omega)$. For each $q \in Q$ we define a distinguished point $(\sigma, \xi) \in q$, and we use the notation $q = [(\sigma, \xi)]$.

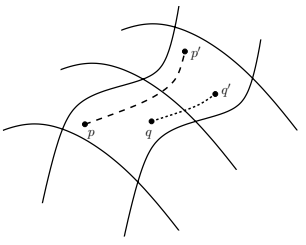

FIG. 4.1. *Illustration of the definition of bisimulation.*

We define a mesh size on Q by

$$\delta_Q = \max_{q \in Q} \sup_{(\sigma,x),(\sigma,y) \in q} \|x - y\|.$$

For each $q = [(\sigma, \xi)] \in Q$ we associate the duration τ_q, the maximum time to traverse q using constant control σ. That is,

$$\tau_q = \sup_{(\sigma,x),(\sigma,y) \in q} \{t \mid y = \phi_t(x, \sigma)\}.$$

This extra data associated with the bisimulation is required in our problem to obtain approximations of the cost functions L and h.

4.1. Geometric construction. We review our method for obtaining finite bisimulations [10] which relies on the following assumptions on the vector fields on Ω.

Assumption 4.1.

(1) For each $\sigma \in \Sigma_\delta$, there exist $n-1$ C^1 functions $\gamma_i^\sigma : \Omega \to \mathbb{R}$, $i = 1, \ldots, n-1$, whose time derivative along solutions of $\dot{x} = f(x, \sigma)$ in Ω is zero.

(2) There exists $m_f > 0$ such that $\|f(x, u)\| \geq m_f$ for all $x \in \mathrm{cl}(\Omega)$, $u \in U$.

Remark 4.1. There is an uncontested view promulgated by Poincaré that differential equations possessing a complete set of first integrals, i.e., completely integrable systems, are the exception rather than the norm. This has led to some confusion about when one can or cannot find first integrals for non-Hamiltonian systems. The primary source of confusion comes from the multiple meanings of the term *integrability*. It appears as a Liouville integrability (the version alluded to by Poincaré and further developed by Arnold [3]), local integrability, algebraic integrability, etc. A type of integrability suitable for non-Hamiltonian systems was proposed by Chavarriga et al. [13] with the terminology *weak integrability* (to contrast with *strong integrability* in the sense of Liouville). Weak integrability is meant to capture that many systems do not exhibit complex behavior such as chaos, even if they are not Hamiltonian.

Let $\dot{x} = f(x)$ be a differential equation with domain of definition $\mathcal{D} \subset \mathbb{R}^n$, and let $\mathcal{O}$ be a set of orbits of the system such that $\mathcal{D} \setminus \mathcal{O}$ is open. Following [13], we say a C^1 function $\gamma : \mathcal{D} \setminus \mathcal{O} \to \mathbb{R}$ is a *weak first integral* of the system $\dot{x} = f(x)$ if γ is constant on each solution of the system contained in $\mathcal{D} \setminus \mathcal{O}$ and γ is nonconstant on any open subset of $\mathcal{D} \setminus \mathcal{O}$. A system is said to be *weakly integrable* if it has $n-1$ functionally independent (on $\mathcal{D} \setminus \mathcal{O}$) weak first integrals.

The relaxation of the requirement that the first integral be a differentiable function on the entire domain of the differential equation means that, for instance, all linear systems are weakly integrable [11], whereas only the Hamiltonian linear systems (centers and saddles in the case of second order linear systems) are integrable in the strong sense. Assumption 4.1(1) is a weak integrability assumption.

There are many methods for finding first integrals, including Lie group symmetry analysis [7, 37], Lax pairs, Painleve analysis, and the Frobenius theorem, among others [16, 22, 46, 49]. A general reference and overview of the methods can be found in [24]. The best-known result for symbolic computation of first integrals is the Prelle–Singer procedure [39]. Reduce and Macsyma implementations of the Prelle–Singer procedure are described in [34, 46], while an implementation in higher dimensions is described in [35]. Algorithms for finding polynomial first integrals are described in [43, 44].

A bisimulation of $\Sigma_\delta \times \mathbb{R}^n$ is found by first constructing partitions for each location of H such that reachability properties are preserved over time steps. In section 5 we describe how to accomodate σ-steps in the quotient system. To obtain a partition

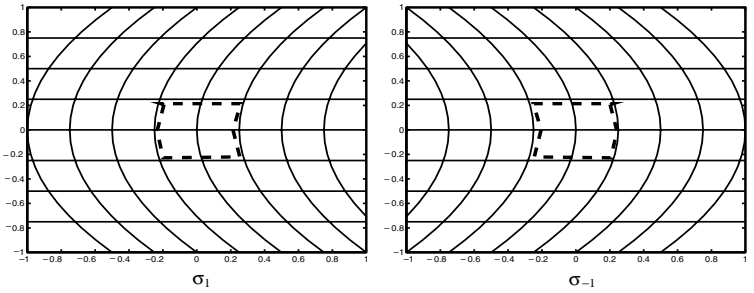

FIG. 4.2. *Partitions for states* σ_1 *and* σ_{-1} *of the hybrid automaton of Figure* 3.1.

consistent with the dynamics of location $\sigma \in \Sigma_\delta$ we use the level sets of the $n-1$ first integrals $\gamma_i^\sigma(x) = y_i^\sigma$, $i = 1, \ldots, n-1$, to bound the flow in $n-1$ independent directions, thus obtaining tubes of trajectories with a rectangular cross section. Next, the level sets of a submersion $\gamma_n^\sigma = y_n^\sigma$ that is transverse to the flow of $\dot{x} = f(x, \sigma)$ are used to divide the tube of trajectories into boxes, so that $(y_1^\sigma, \ldots, y_n^\sigma)$ form a set of Euclidean coordinates $\gamma^\sigma : \Omega \to [-1, 1]^n$ on Ω. That is, we assume that the level sets of γ_i^σ *foliate* the set Ω (see [30] for background on foliations) and, by appropriate scaling, their level values lie between -1 and 1 on Ω. We *discretize* the foliations associated with each γ_i^σ by selecting a finite number of level values. More precisely, fix $k \in Z^+$ and let $\Delta = \frac{1}{2^k}$. Define

$$C_k = \{0, \pm\Delta, \pm 2\Delta, \ldots, \pm 1\}. \tag{4.1}$$

Each $y_i^\sigma = c$ for $c \in C_k$, $i = 1, \ldots, n$, defines a hyperplane in $\mathbb{R}^n$ denoted $\tilde{W}_{i,c}^\sigma$ and a submanifold $W_{i,c}^\sigma = (\gamma^\sigma)^{-1}(\tilde{W}_{i,c}^\sigma)$. The collection of submanifolds for $\sigma \in \Sigma_\delta$ is

$$\mathcal{W}_k^\sigma = \{W_{i,c}^\sigma \mid c \in C_k, i \in \{1, \ldots, n\}\}. \tag{4.2}$$

$\Omega \backslash \mathcal{W}_k^\sigma$ is the union of $2^{n(k+1)}$ disjoint open sets $\mathcal{V}_k^\sigma = \{V_j^\sigma\}$. We define an equivalence relation $\simeq^e$ on $\mathbb{R}^n$ as follows. $y \simeq^e y'$ iff

(1) $y \notin [-1, 1]^n$ iff $y' \notin [-1, 1]^n$, and

(2) if $y, y' \in [-1, 1]^n$, then for each $i = 1, \ldots, n$, $y_i \in (c, c + \Delta)$ iff $y_i' \in (c, c + \Delta)$, and $y_i = c$ iff $y_i' = c$ for all $c \in C_k$.

We define the equivalence relation $\simeq$ on $\Sigma_\delta \times \mathbb{R}^n$ as follows. $(\sigma, x) \simeq (\sigma', x')$ iff (1) $\sigma = \sigma'$ and (2) $\gamma^\sigma(x) \simeq^e \gamma^\sigma(x')$.

Remark 4.2. A consequence of this construction is that if any trajectory of H passing through $q \in Q$ spends zero time in it, then $\tau_q = 0$.

Example 4.1. Continuing Example 3.1, a first integral for vector field $\dot{x}_1 = x_2$, $\dot{x}_2 = 1$ is $x_1 - \frac{1}{2}x_2^2 = c_1$, $c_1 \in \mathbb{R}$. For $\dot{x}_1 = x_2$, $\dot{x}_2 = -1$ a first integral is $x_1 + \frac{1}{2}x_2^2 = c_2$, $c_2 \in \mathbb{R}$. We select a transverse foliation for each vector field, given by $x_2 = c_3$. Partitions for locations σ_1 and σ_{-1} and $\Omega = (-1, 1) \times (-1, 1)$ are shown in Figure 4.2. The equivalence classes of $\simeq$ are pairs consisting of a control event in Σ_δ and of the interiors of regions, open line segments and curves forming the boundaries of two regions, and the points at the corners of regions. $\tau = 0$ for the segments transverse to the flow and the corner points. $\tau = \Delta$ for the interiors of regions and segments tangential to the flow, where $\Delta = .25$ in Figure 4.2.

5. Discrete problem. In this section we transform the hybrid optimal synthesis problem to a dynamic programming problem on a nondeterministic finite automaton.

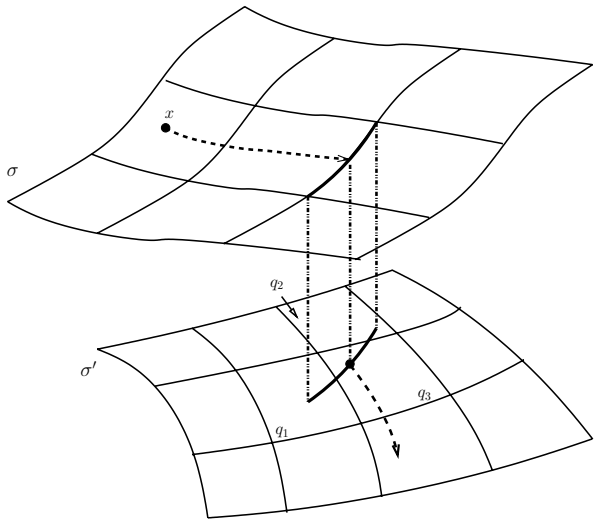

FIG. 5.1. *Partitions for states σ and σ' of a hybrid automaton, and the resulting nondeterminism in A.*

Consider the class of nondeterministic finite automata with cost structure represented by the tuple

$$A = (Q, \Sigma_\delta, E, \hat{L}, \hat{h}).$$

Q is the finite state set, as defined above, and Σ_δ is the set of control events as before. $E \subseteq Q \times Q$ is the transition relation encoding t-steps and σ-steps of H. $(q, q') \in E$, where $q = [(\sigma, \xi)]$ and $q' = [(\sigma', \xi')]$ if either (a) $\sigma = \sigma'$, there exists $x \in \Omega$ such that $(\sigma, x) \in q$, and there exists $\tau > 0$ such that for all $t \in [0, \tau]$, $(\sigma, \phi_t(x, \sigma)) \in q$ and $(\sigma, \phi_{\tau+\epsilon}(x, \sigma)) \in q'$ for arbitrarily small $\epsilon > 0$; (b) $\sigma = \sigma'$, there exists $x \in \Omega$ such that $(\sigma, x) \in q$, and there exists $\tau > 0$ such that for all $t \in [0, \tau)$, $(\sigma, \phi_t(x, \sigma)) \in q$ and $(\sigma, \phi_\tau(x, \sigma)) \in q'$; or (c) $\sigma \neq \sigma'$ and there exists $x \in \Omega$ such that $(\sigma, x) \in q$ and $(\sigma', x) \in q'$. Cases (a) and (b) say that from a point in q, q' is the first state (different from q) reached after following the flow of $f(x, \sigma)$ for some time. Case (c) says that an edge exists between q and q' if their projections to $\mathbb{R}^n$ have nonempty intersection.

Remark 5.1. The requirement that there be an edge from q to q' if their projections to $\mathbb{R}^n$ have nonempty intersection is illustrated in Figure 5.1. We have partitions for controls σ and σ', respectively. In the partition for σ, suppose a trajectory starting at x flows in time using control σ until state q of A is reached, at which time the control is set to σ'. The possible states of A that can be reached from q are q_1, q_2, q_3, and the one-dimensional equivalence classes between them. Hence, edges corresponding to these possible futures for the trajectory must be included in the definition of A. A consequence is that multiple trajectories of A can be defined starting from an initial state. One can think of this construction as overapproximating the identity map in terms of the equivalence classes of $\simeq$. This is the source of nondeterminacy of A.

Let $e = (q, q')$ with $q = [(\sigma, \xi)]$ and $q' = [(\sigma', \xi')]$. $\hat{L} : E \to \mathbb{R}$ is the *discrete instantaneous cost* given by

$$\hat{L}(e) := \begin{cases} \tau_q L(\xi, \sigma) & \text{if } \sigma = \sigma', \\ 0 & \text{if } \sigma \neq \sigma'. \end{cases} \tag{5.1}$$

$\hat{h} : Q \to \mathbb{R}$ is the *discrete terminal cost* given by

$$\hat{h}(q) := h(\xi).$$

The domain of $\hat{h}$ can be extended to Ω, with a slight abuse of notation, by

$$\hat{h}(x) := \hat{h}(q), \tag{5.2}$$

where $q = \arg\min_{q'}\{\|x - \xi'\| \mid q' = [(\sigma', \xi')]\}$. Finally, Q_f is the target set given by the overapproximation of Ω_f,

$$Q_f = \{q \in Q \mid \exists x \in \Omega_f \text{ s.t. } (\sigma, x) \in q\}. \tag{5.3}$$

5.1. Semantics. A transition or *step* of A from $q = [(\sigma, \xi)] \in Q$ to $q' = [(\sigma', \xi')] \in Q$ is denoted $q \overset{\sigma'}{\to} q'$. If $\sigma \neq \sigma'$, the transition is referred to as a *control switch*; otherwise, it is referred to as a *time step*. If $E(q)$ is the set of edges that can be enabled from $q \in Q$, then for $\sigma \in \Sigma_\delta$,

$$E_\sigma(q) = \{e \in E(q) \mid e = (q, q'), q = [(\sigma, \xi)], q' = [(\sigma', \xi')]\}.$$

If $|E_\sigma(q)| > 1$, then we say that $e \in E_\sigma(q)$ is *unobservable* in the sense that when control event σ is issued, it is unknown which edge among $E_\sigma(q)$ is taken. If $\sigma = \sigma'$, then $|E_\sigma(q)| = 1$, by the uniqueness of solutions of ODEs and by the definition of bisimulation.

A *control policy* $c : Q \to \Sigma_\delta$ is a map assigning a control event to each state; $c(q) = \sigma$ is the control event issued when the state is at q. A *trajectory* π of A over c is a sequence $\pi = q_0 \overset{\sigma_1}{\to} q_1 \overset{\sigma_2}{\to} q_2 \overset{\sigma_3}{\to} \cdots$, $q_i \in Q$. A trajectory is *non-Zeno* if between any two nonzero duration time steps there is a finite number of control switches. Note that this definition is slightly different from the traditional definition of non-Zeno trajectories of H [26], in which it is assumed that time steps always have a nonzero duration. Here zero-duration time steps can occur. Let $\Pi_c(q)$ be the set of trajectories starting at q and applying control policy c, and let $\tilde{\Pi}_c(q)$ be the set of trajectories starting at q, applying control policy c, and eventually reaching Q_f. If for every $q \in Q$, $\pi \in \Pi_c(q)$ is non-Zeno, then we say c is an *admissible control policy*. The set of all admissible control policies for A is denoted $\mathcal{C}$.

A control policy c is said to have a *loop* if A has a trajectory $q_0 \overset{c(q_0)}{\to} q_1 \overset{c(q_1)}{\to} \cdots \overset{c(q_{m-1})}{\to} q_m = q_0$, $q_i \in Q$. A control policy has a *Zeno loop* if it has a loop made up of control switches and/or zero duration time steps (i.e., $\tau_q = 0$) only.

LEMMA 5.1. *A control policy c is admissible iff it has no Zeno loops.*

Proof. First we show that a nondeterministic automaton with non-Zeno trajectories has a control policy without Zeno loops. Suppose not. Then a trajectory starting on a state belonging to the loop can take infinitely many steps around the loop before taking a nonzero duration time step. Such a trajectory must necessarily include a control switch (since a zero duration time step is always followed either by a nonzero duration time step or a control switch). Since this control switch occurs infinitely often in a finite time interval, the trajectory is Zeno, a contradiction.

Second, we show that a control policy without Zeno loops implies non-Zeno trajectories. Suppose not. Consider a Zeno trajectory that takes an infinite number of control switches in some finite time interval. Because there are a finite number of states in Q, by the Dirichlet principle [31], one of the states must be repeated in the sequence of states visited during the infinite number of control switches. Note that

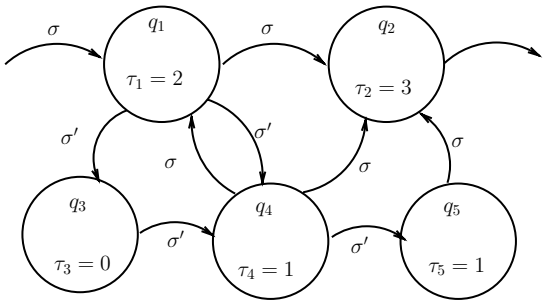

FIG. 5.2. *Fragment of automaton with a zero duration time step.*

this sequence can include zero duration time steps. This implies the existence of a loop in the control policy. Now we argue this loop is Zeno.

First, by Remark 4.2, if $\tau_q = 0$, then all trajectories spend zero time in q. Second, if $\tau_q > 0$, then there exists $\overline{\tau}_q > 0$ such that all trajectories spend at least $\overline{\tau}_q$ time in q. This follows from the boundedness of f and the bisimulation construction (trajectories cannot move between two level sets of γ_n^σ in arbitrarily small time). Since there is a finite number of states in Q, there exists $\overline{\tau} > 0$, the minimum time spent by any trajectory in a state $q \in Q$ with $\tau_q > 0$. The result is that Zeno trajectories only arise by an infinite number of control switches in a zero duration time interval. Hence, we have shown that the loop consists of control switches and/or zero duration time steps only, i.e., it is a Zeno loop. □

Example 5.1. Consider the automaton in Figure 5.2. Suppose that we define a control policy $c(q_1) = \sigma'$, $c(q_3) = \sigma'$, $c(q_4) = \sigma$, and $c(q_5) = \sigma$. Starting at q_1 two possible trajectories are $q_1 \xrightarrow{\sigma'} q_3 \xrightarrow{\sigma'} q_4 \xrightarrow{\sigma} q_2$, or $q_1 \xrightarrow{\sigma'} q_3 \xrightarrow{\sigma'} q_4 \xrightarrow{\sigma} q_1$. The first trajectory has a zero duration time step. The control is inadmissible since the second trajectory has a Zeno loop.

5.2. Dynamic programming. We formulate the dynamic programming problem on A. This involves defining a cost-to-go function and a value function that minimizes it over control policies suitable for nondeterministic automata.

Let $\pi = q_0 \xrightarrow{\sigma_1} q_1 \to \cdots \to q_{N-1} \xrightarrow{\sigma_N} q_N$, where $q_i = [(\sigma_i, \xi_i)]$ and π takes the sequence of edges $e_1 e_2 \dots e_N$. We define a *discrete cost-to-go* $\hat{J} : Q \times \mathcal{C} \to \mathbb{R}$ by

$$\hat{J}(q,c) = \begin{cases} \max\limits_{\pi \in \tilde{\Pi}_c(q)} \left\{ \sum\limits_{j=1}^{N_\pi} \hat{L}(e_j) + \hat{h}(q_{N_\pi}) \right\} & \text{if } \ \Pi_c(q) = \tilde{\Pi}_c(q), \\ \infty & \text{otherwise,} \end{cases}$$

where $N_\pi = \min\{j \geq 0 \mid q_j \in Q_f\}$. We take the maximum over $\tilde{\Pi}_c(q)$ because of the nondeterminacy of A: it is uncertain which among the (multiple) trajectories allowed by c will be taken so we must assume the worst-case situation. The *discrete value function* $\hat{V} : Q \to \mathbb{R}$ is

$$\hat{V}(q) = \min_{c \in \mathcal{C}} \hat{J}(q,c)$$

for $q \in Q \backslash Q_f$ and $\hat{V}(q) = \hat{h}(q)$ for $q \in Q_f$. We show in Proposition 5.2 that $\hat{V}$ satisfies a DPP that takes into account the nondeterminacy of A and ensures that optimal control policies are admissible. Let $\mathcal{A}_q$ be the set of control assignments $c(q) \in \Sigma_\delta$ at q such that c is admissible.

PROPOSITION 5.2. *$\hat{V}$ satisfies*

$$\hat{V}(q) = \min_{c(q)\in\mathcal{A}_q}\Big\{\max_{e=(q,q')\in E_{c(q)}(q)}\big\{\hat{L}(e)+\hat{V}(q')\big\}\Big\}, \quad q\in Q\setminus Q_f, \tag{5.4}$$

$$\hat{V}(q) = \hat{h}(q), \qquad q\in Q_f. \tag{5.5}$$

Proof. Fix $q\in Q$. By definition of $\hat{J}$,

$$\hat{J}(q,c) = \max_{e=(q,q')\in E_{c(q)}(q)}\{\hat{L}(e)+\hat{J}(q',c)\}. \tag{5.6}$$

By definition of $\hat{V}$,

$$\hat{J}(q,c) \geq \max_{e=(q,q')\in E_{c(q)}(q)}\{\hat{L}(e)+\hat{V}(q')\}.$$

Since $c(q)\in\mathcal{A}_q$ is arbitrary,

$$\hat{V}(q) \geq \min_{c(q)\in\mathcal{A}_q}\left\{\max_{e=(q,q')\in E_{c(q)}(q)}\{\hat{L}(e)+\hat{V}(q')\}\right\}.$$

To prove the reverse inequality suppose, by way of contradiction, there exists $\sigma'\in\Sigma_\delta$ such that

$$\hat{V}(q) > \max_{e=(q,q')\in E_{\sigma'}(q)}\{\hat{L}(e)+\hat{V}(q')\} := \hat{L}(e)+\hat{V}(\overline{q}). \tag{5.7}$$

Suppose an optimal admissible policy for $\overline{q}$ is $\overline{c}$. Define $c=\overline{c}$ on $Q\setminus\{q\}$ and $c(q)=\sigma'$. Then $\hat{J}(q,c)=\hat{L}(e)+\hat{V}(\overline{q})<\hat{V}(q)$. This gives rise to a contradiction if we can show c is admissible. Suppose not. Then there exists a loop of control switches and zero duration time steps containing q. Either the loop includes $\overline{q}$, implying $\hat{V}(\overline{q})=\hat{V}(q)$, which contradicts hypothesis (5.7), or the loop includes some other q' such that $(q,q')\in E_{\sigma'}(q)$, implying $\hat{V}(q')=\hat{V}(q)$. But $\hat{V}(\overline{q})\geq\hat{V}(q')$ since $\overline{q}$ gives the worst-case cost over edges with label σ'. This again contradicts hypothesis (5.7). ∎

5.3. Synthesis of g_e. The synthesis of enabling conditions or *hybrid controller synthesis* is typically a postprocessing step of a backward reachability analysis (see, for example, [52]). This situation prevails here as well: (5.4) and (5.5) describe a backward analysis to construct an optimal policy $c\in\mathcal{C}$. Once c is known, the enabling conditions of H are extracted as follows.

Consider each $e=(\sigma,\sigma')\in E$ of H with $\sigma\neq\sigma'$. There are two cases. If $\sigma'\neq\sigma_f$, then $g_e=\big\{x\mid(\sigma,x)\in q, q\in Q, c(q)=\sigma'\big\}$. That is, if the control policy designates switching from $q\in Q$ with label σ to $q'\in Q$ with label σ', then the corresponding enabling condition in H includes the projection to $\mathbb{R}^n$ of q. The second case when $\sigma'=\sigma_f$ is for edges going to the terminal location of H. Then $g_e=\big\{x\mid(\sigma,x)\in q, q\in Q_f\big\}$.

6. Main result. We will prove that $\hat{V}$ converges to V, the viscosity solution of the HJB equation, as $\delta_Q,\delta\to 0$. We make use of a filtration of control sets $\Sigma_k\equiv\Sigma_{\delta_k}$ corresponding to a sequence $\delta_k\to 0$ as $k\to\infty$ in such a manner that $\Sigma_k\subset\Sigma_{k+1}$. Considering (4.2), we define a filtration of families of submanifolds such that $\mathcal{W}_k^\sigma\subset\mathcal{W}_{k+1}^\sigma$ for each $\sigma\in\Sigma_k$.

The proof proceeds in three steps. In the first step we restrict the class of controls to piecewise constant functions whose constant intervals are a function of the state. In particular, the control is constant on equivalence classes of $\simeq$. As δ_k tends to zero this class of piecewise constant controls well approximates ϵ-optimal controls. The Arzela–Ascoli theorem is invoked to show that the limit of a sequence of approximations V_k of the value function using the aforementioned controls is a continuous function V_*. Using techniques of [4], V_* is shown to be the unique viscosity solution of HJB. In the second step we introduce the discrete approximations of L and h. The discrete approximation of h is a one-time error, while the error between L and $\hat{L}$ is shown to be $O(\delta_k^2)$ per interval τ. Since the number of intervals is $O(1/\delta_k)$, the error is $O(\delta_k)$. In the last step we introduce the discrete states Q. The error introduced at each control switch by the nondeterminacy of A is $O(\delta_k)$ and since there are a fixed number of control switches as $\delta_k \to 0$, this error can be made arbitrarily small.

Step 1*: Piecewise constant controls.* In the first step we define a class of piecewise constant functions that depend on the state and show that the value function which minimizes the cost-to-go over this class converges to the viscosity solution of HJB as $\delta_k \to 0$. The techniques of this step are based on those by Bardi and Capuzzo-Dolcetta [4] and are related to those in [12].

We consider the optimal control problem (2.2)–(2.4) when the set of admissible controls is $\mathcal{U}_k^1$, piecewise constant functions consisting of finite sequences of control events $\sigma \in \Sigma_k$, where each σ is applied for a time $\tau(\sigma, x)$ and the trajectory remains in Ω. Let $(\sigma, x) \in q$ for $q \in Q$ and define $\tau(\sigma, x)$ to be the minimum of the time it takes the trajectory starting at x and using control $\sigma \in \Sigma_k$ to reach (ta) $\partial\Omega_f$ or (tb) some x' such that $(\sigma, x') \notin q$. If a trajectory is at x_i at the start of the $(i+1)$th step, then the control σ_{i+1} is applied for time $\tau_{i+1} := \tau(\sigma_{i+1}, x_i)$ and $x_{i+1} = \phi_{\tau_{i+1}}(x_i, \sigma_{i+1})$. Thus U_k^1 is a class of piecewise constant controls whose constant intervals are based on the state partition induced by $\simeq$ (in contrast with a partition of the time interval): the control can only change values on the boundary of equivalence classes.

Let

$$\mathcal{R}_k^1 := \{x \in \Omega \mid \exists \mu \in \mathcal{U}_k^1 \cdot T(x, \mu) < \infty\}.$$

We define the cost-to-go function $J_k^1 : \Omega \times \mathcal{U}_k^1 \to \mathbb{R}$ as follows. For $x \in \Omega$ and $\mu = \sigma_1 \sigma_2 \ldots \in \mathcal{U}_k^1$, if $T(x, \mu) < \infty$, then

$$J_k^1(x, \mu) = \sum_{j=1}^{N} \int_0^{\tau(\sigma_j, x_{j-1})} L(\phi_s(x_{j-1}, \sigma_j), \sigma_j) ds + h(x_N),$$

where $N = \min\{j \geq 0 \mid x_j \in \Omega_f\}$. $J_k^1(x, \mu) = \infty$ otherwise. We define the value function $V_k^1 : \mathbb{R}^n \to \mathbb{R}$ as follows. For $x \in \Omega \setminus \Omega_f$,

$$V_k^1(x) = \inf_{\mu \in \mathcal{U}_k^1} J_k^1(x, \mu), \tag{6.1}$$

and for $x \in \Omega_f$, $V_k^1(x) = h(x)$. The following result is proved using standard arguments from dynamic programming [20].

PROPOSITION 6.1. *V_k^1 satisfies, for all $x \in \mathcal{R}_k^1$,*

$$V_k^1(x) = \min_{\sigma \in \Sigma_k} \left\{ \int_0^{\tau(\sigma, x)} L(\phi_s(x, \sigma), \sigma) ds + V_k^1(\phi_{\tau(\sigma, x)}(x, \sigma)) \right\}. \tag{6.2}$$

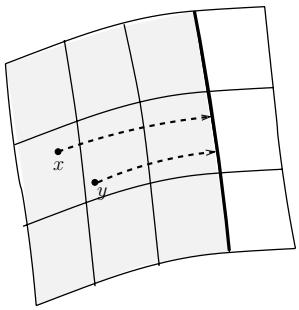

FIG. 6.1. *The shaded region is M^σ_{c-} while the bold curve on its boundary is M^σ_c.*

We would like to show that V^1_k is uniformly bounded and locally uniformly continuous. Considering uniform continuity of V^1_k, let C_k be as in (4.1) and γ^σ_n the submersion whose level sets are transverse to the flow of $\dot{x} = f(x, \sigma)$. Referring to Figure 6.1, for each $\sigma \in \Sigma_k$ and for each fixed $c \in C_k$ we define the regions in $\mathbb{R}^n$

$$M^\sigma_c := \{x \mid \gamma^\sigma_n(x) = c\},$$
$$M^\sigma_{c-} := \{x \mid \gamma^\sigma_n(x) \in (-1, c)\};$$

that is, M_{c-} is the strip of points belonging to a level set of γ^σ_n whose level value is between -1 and c.

Remark 6.1.

(a) If $x, y \in M^\sigma_{c-}$ for some $c \in C_k$ and $\tau(\sigma, x)$ and $\tau(\sigma, y)$ are defined using (tb), then $|\tau(\sigma, x) - \tau(\sigma, y)| \to 0$ and $\|\phi_{\tau(\sigma,x)}(x, \sigma) - \phi_{\tau(\sigma,y)}(y, \sigma)\| \to 0$ as $\|x - y\| \to 0$ in M^σ_{c-}, since M^σ_c is a smooth submanifold. See Figure 6.1. For the details, see [20, Theorem 6.1, pp. 91–94]. If instead $\tau(\sigma, x)$ and $\tau(\sigma, y)$ are defined using (ta) and σ is an ϵ-optimal control for x, then by Assumption 2.2 the same results hold.

(b) For each $x \in \cup_k \mathcal{R}^1_k$ and $\epsilon > 0$ there exists $m \in \mathbb{Z}^+$ and $\mu \in \mathcal{U}^1_m$ such that μ is an ϵ-optimal control for x w.r.t. V^1_k with at most N_ϵ discontinuities and such that $\phi_t(x, \mu)$ is transverse to $\partial\Omega_f$. This follows from Assumption 2.2, $V^1_k(x) \geq V(x)$, and the fact that we can well approximate an ϵ-optimal control for V by a control in $\mathcal{U}^1_m$ for large enough m.

The following lemma shows that V^1_k is locally uniformly continuous.

LEMMA 6.2. *For each $y \in \cup_k \mathcal{R}^1_k$ and $\epsilon > 0$, there exists $m_\epsilon \in \mathbb{Z}^+$ and $\eta_\epsilon > 0$ such that $|V^1_k(x) - V^1_k(y)| < 2\epsilon$ for all $|x - y| < \eta_\epsilon$ with $x \in \mathcal{R}^1_k$ and for all $k > m_\epsilon$.*

Proof. Fix $y \in \cup_k \mathcal{R}^1_k$. By Remark 6.1(b) there exists $m_1 > 0$ and $\mu \in \mathcal{U}^1_{m_1}$ such that μ is an ϵ-optimal control for y satisfying Assumption 2.2. Let $x \in \mathcal{R}^1_{m_1}$. Then $V^1_k(x) - V^1_k(y) \leq J^1_k(x, \mu_x) - J^1_k(y, \mu) + \epsilon$ for any $\mu_x \in \mathcal{U}^1_{m_1}$ and $k > m_1$. If we can show that for fixed y and μ there exists $\mu_x \in \mathcal{U}^1_{m_1}$ such that

$$J^1_k(x, \mu_x) - J^1_k(y, \mu) < \epsilon \tag{6.3}$$

for all $x \in \mathcal{R}^1_{m_1}$ sufficiently close to y, then $V^1_k(x) - V^1_k(y) \leq 2\epsilon$ for all $k \geq m_1$.

Conversely, by Remark 6.1(b) there exists $m_2 > 0$ and $\mu_x \in \mathcal{U}^1_{m_2}$ such that μ_x is an ϵ-optimal control for x satisfying Assumptions 2.2. Then $V^1_k(y) - V^1_k(x) \leq J^1_k(y, \mu) - J^1_k(x, \mu_x) + \epsilon$ for any $\mu \in \mathcal{U}^1_{m_2}$ and $k > m_2$. If we can show that for fixed y there exists $\mu \in \mathcal{U}^1_{m_2}$ such that

$$J^1_k(y, \mu) - J^1_k(x, \mu_x) < \epsilon \tag{6.4}$$

for all $x \in \mathcal{R}^1_{m_2}$ sufficiently close to y, then $V^1_k(x) - V^1_k(y) \geq -2\epsilon$ for all $k \geq m_2$. The result follows by letting $m_\epsilon = \min\{m_1, m_2\}$. Thus, we must show (6.3) and (6.4).

Consider first (6.3). Let $\mu = \sigma_1\sigma_2 \ldots \in \mathcal{U}^1_k$ be an ϵ-optimal control for y such that $y_N \in \partial\Omega_f$. By redefining indices, we can associate with μ the open-loop control $\tilde{\mu} = (\sigma_1, \tau_1)(\sigma_2, \tau_2)\ldots$, where τ_i is the time σ_i is applied. We claim there exists $\tilde{\mu}^x = (\sigma_1, \tau^x_1)(\sigma_2, \tau^x_2)\ldots$ such that as $x \to y$, (a) $x_j \to y_j$, (b) $\tau^x_j \to \tau_j$, and (c) $x_N \in \partial\Omega_f$. Let $T_k = \max_i \tau_i$. Then we have

$$\begin{aligned} J^1_k(x, \tilde{\mu}^x) - J^1_k(y, \tilde{\mu}) &\leq \sum_{j=1}^{N} \int_0^{\tau_j} |L(\phi_s(x_{j-1}, \sigma_j), \sigma_j) - L(\phi_s(y_{j-1}, \sigma_j), \sigma_j)| ds \\ &\quad + \sum_{j=1}^{N} \left| \int_{\tau_j}^{\tau^x_j} L(\phi_s(x_{j-1}, \sigma_j), \sigma_j) ds \right| + |h(y_N) - h(x_N)| \\ &\leq L_L T_k \exp(L_f T_k) \sum_{j=1}^{N} \|x_{j-1} - y_{j-1}\| \\ &\quad + M_L \sum_{j=1}^{N} |\tau^x_j - \tau_j| + L_h |x_N - y_N|. \end{aligned}$$

By the previous claim the right-hand side (r.h.s.) can be made less than ϵ. Thus, we need only show there exists $\tilde{\mu}^x = (\sigma_1, \tau^x_1)(\sigma_2, \tau^x_2)\ldots$, which satisfies the claim, and $\mu^x \in \mathcal{U}^1_k$ can be reconstructed from it, based on the discrete states in Q visited by $\phi_t(x, \tilde{\mu}^x)$.

We argue by induction. Suppose (a)–(c) hold at $j-1$. We show they hold at j. We need only consider the case when $y_{j-1} \in M^{\sigma_j}_{c-}$ and $y_j \in M^{\sigma_j}_c$ for some $c \in C_k$; that is, y_{j-1} lies upstream of y_j (trajectories flow in the increasing $\gamma^{\sigma_j}_n$ direction), while y_j lies on the boundary of an equivalence class where the control is allowed to switch values. For x_{j-1} sufficiently close to y_{j-1}, $x_{j-1} \in M^{\sigma_j}_{c-}$. By Remark 6.1(a) there exists τ^x_j such that $x_j = \phi_{\tau^x_j}(x_{j-1}, \sigma_j) \in M^{\sigma_j}_c$ and $\tau^x_j \to \tau_j$ and $x_j \to y_j$ as $x_{j-1} \to y_{j-1}$. The case $y_{j-1} \in M^{\sigma_j}_{c-}$ and $y_j \in \partial\Omega_f$ follows in the same way from Assumption 2.2. Proving (6.4) follows along the same lines as the proof for (6.3). ∎

To show boundedness of V^1_k, let $T(x) := \inf_{\mu \in \mathcal{U}^1_k} T(x, \mu)$. In light of Assumption 2.1(2), we have that for all $x \in \mathbb{R}^n$, $|V^1_k(x)| \leq T(x) \cdot M_L + M_h$. Consider the set $K_a := \{x \in \mathcal{R}^1_k \mid T(x) < a\}$. Then $|V^1_k(x)| \leq a \cdot M_L + M_h$ for all $x \in K_a$.

We have shown that on each $K_a \subseteq \mathbb{R}^n$, $\{V^1_k\}$ forms a family of equibounded, locally equicontinuous functions. It follows by the Arzela–Ascoli theorem [42] that along some subsequence k_n, $V^1_{k_n}$ converges to a continuous function V_*. The proof of the following result closely follows [4].

PROPOSITION 6.3. *V_* is the unique viscosity solution of HJB.*

Proof. We show that V_* solves HJB in the viscosity sense. Let $\psi \in C^1(\mathbb{R}^n)$ and suppose $x_0 \in \Omega$ is a strict local maximum for $V_* - \psi$. There exists a closed ball B centered at x_0 such that $(V_* - \psi)(x_0) > (V_* - \psi)(x)$ for all $x \in B$. Let $x_{0\delta_k}$ be a maximum point for $V^1_k - \psi$ over B. Since $V^1_k \to V_*$ locally uniformly it follows that $x_{0\delta_k} \to x_0$ as $\delta_k \to 0$. Then, for any $\sigma \in \Sigma_k$, the point $\phi_\tau(x_{0\delta_k}, \sigma)$ is in B (using boundedness of f), for sufficiently small δ_k and $0 \leq \tau \leq \tau(x_{0\delta_k}, \sigma)$, since $\tau(x_{0\delta_k}, \sigma) \to 0$ as $\delta_k \to 0$. Therefore,

$$V^1_k(x_{0\delta_k}) - \psi(x_{0\delta_k}) \geq V^1_k(\phi_\tau(x_{0\delta_k}, \sigma)) - \psi(\phi_\tau(x_{0\delta_k}, \sigma)).$$

Considering (6.2), we have

$$0 = -\min_{\sigma\in\Sigma_k}\left\{V_k^1(\phi_\tau(x_{0\delta_k},\sigma)) - V_k^1(x_{0\delta_k}) + \int_0^\tau L(\phi_s(x_{0\delta_k},\sigma),\sigma)ds\right\}$$
$$\geq -\min_{\sigma\in\Sigma_k}\left\{\psi(\phi_\tau(x_{0\delta_k},\sigma)) - \psi(x_{0\delta_k}) + \int_0^\tau L(\phi_s(x_{0\delta_k},\sigma),\sigma)ds\right\}.$$

Since $\psi \in C^1(\mathbb{R}^n)$, we have by the mean value theorem,

$$0 \geq -\min_{\sigma\in\Sigma_k}\left\{\frac{\partial\psi}{\partial x}(y)\cdot\int_0^\tau f(\phi_s(x_{0\delta_k},\sigma),\sigma)ds + \int_0^\tau L(\phi_s(x_{0\delta_k},\sigma),\sigma)ds\right\},$$

where $y = \alpha x_{0\delta_k} + (1-\alpha)\phi_\tau(x_{0\delta_k},\sigma)$ for some $\alpha \in (0,1)$. Dividing by $\tau > 0$ on each side and taking the limit as $\delta_k \to 0$, we have $V_k^1 \to V_*$, $x_{0\delta_k} \to x_0$, $\tau \to 0$, and $y \to x_{0\delta_k}$. By the fundamental theorem of calculus, the continuity of f and L, and the uniform continuity in u of the expression in brackets, we obtain

$$0 \geq -\inf_{u\in U}\left\{\frac{\partial\psi}{\partial x}(x_0)\cdot f(x_0,u) + L(x_0,u)\right\}.$$

This confirms part (i) of the viscosity solution definition. Part (ii) is proved in an analogous manner. □

Step 2: Approximate cost functions and overapproximation of Ω_f by Q_f. In this step we define a class of piecewise constant controls, denoted $\mathcal{U}_k^2$, nearly the same as $\mathcal{U}_k^1$, to accommodate that trajectories terminate at Q_f, not Ω_f, and we replace the cost functions L and h by approximations L^2 and $\hat{h}$, respectively. We define $\mathcal{U}_k^2 \subset \mathcal{U}_k^1$ to be the class of piecewise continuous controls whose constant time intervals $\tau(\sigma,x)$ are determined by the equivalence classes of $\simeq$ but not $\partial\Omega_f$. That is, case (ta) in the definition of $\tau(\sigma,x)$ in Step 1 is omitted. Next we define an approximate instantaneous cost $L^2 : \Omega\times\Sigma_k \to \mathbb{R}$ by

$$L^2(x,\sigma) := \hat{L}(e), \tag{6.5}$$

where $(\sigma,x) \in q$ and $e = (q,q')$ represents the time step. For $x \in \Omega$ and $\mu = \sigma_1\sigma_2\ldots \in \mathcal{U}_k^2$, if $T(x,\mu) < \infty$, the cost-to-go function $J_k^2 : \Omega\times\mathcal{U}_k^2 \to \mathbb{R}$ is

$$J_k^2(x,\mu) = \sum_{j=1}^N L^2(x_{j-1},\sigma_j) + \hat{h}(x_N),$$

where $N = \min\{j \geq 0 \mid x_j \in Q_f\}$. In other words, J_k^2 is a worst-case cost over a set of trajectories starting at x that visit the same sequence of equivalence classes of $\simeq$, and it is a worst-case cost w.r.t. J_k^1 because $\int_0^{\tau(\sigma,x)} L(\phi_s(x,\sigma),\sigma)ds \leq L^2(x,\sigma)$.

We define a value function $V_k^2 : \mathbb{R}^n \to \mathbb{R}$ as follows. For $x \in \Omega\setminus Q_f$,

$$V_k^2(x) = \inf_{\mu\in\mathcal{U}_k^1} J_k^2(x,\mu), \tag{6.6}$$

and for $x \in Q_f$, $V_k^2(x) = \hat{h}(x)$. For $x \in \Omega$ such that $V_k^2(x) < \infty$, V_k^2 satisfies the DPP

$$V_k^2(x) = \min_{\sigma\in\Sigma_k}\left\{L^2(x,\sigma) + V_k^2(\phi_{\tau(\sigma,x)}(x,\sigma))\right\}.$$

The proof is along the same lines as that of Proposition 5.2.

The following facts are useful for the subsequent result. The first lemma says that τ_q is order δ_k. The second lemma says that given two times τ and τ' that two trajectories spend, respectively, in the same equivalence class, $|\tau - \tau'|$ is order δ_k^2.

LEMMA 6.4. *If $\delta_k < \frac{m_f}{L_f}$, then for all $q \in Q$,*

$$\tau_q \leq \frac{\delta_k}{m_f - L_f \delta_k}. \tag{6.7}$$

Proof. Let $q \in Q$. Fix $x \in \Omega$ and $\sigma \in \Sigma_k$ such that $(\sigma, x) \in q$. We know $\|\phi_{\tau(\sigma,x)}(x,\sigma) - x\| \leq \delta_k$. We have

$$\begin{aligned}
\delta_k \geq \|\phi_{\tau(\sigma,x)} - x\| &= \left\| \int_0^{\tau(\sigma,x)} f(\phi_s(x,\sigma),\sigma) ds \right\| \\
&\geq \left\| \int_0^{\tau(\sigma,x)} f(x,\sigma) ds \right\| - \left\| \int_0^{\tau(\sigma,x)} [f(\phi_s(x,\sigma),\sigma) - f(x,\sigma)] ds \right\| \\
&\geq \tau(\sigma,x)\|f(x,\sigma)\| - \tau(\sigma,x) L_f \delta_k,
\end{aligned}$$

where in the last step we use the fact that $\|\phi_s(x,\sigma) - x\| \leq \delta_k$. Therefore,

$$\tau(\sigma,x) \leq \frac{\delta_k}{\|f(x,\sigma)\| - L_f \delta_k}.$$

Using Assumption 4.1(2) and taking the sup over all $\tau(\sigma,x)$ for q, the result follows. ∎

LEMMA 6.5. *Let $x, x' \in M_c^\sigma$ for some $c \in C_k$ and $\sigma \in \Sigma_k$ such that $\|x - x'\| \leq \delta_k$. Let τ, τ' be times such that $\phi_\tau(x,\sigma), \phi_{\tau'}(x',\sigma) \in M_{c+\Delta}^\sigma$. Then $|\tau - \tau'| \leq c_\gamma \tau \delta_k$ for some $c_\gamma > 0$.*

Proof. We have

$$\int_0^\tau \frac{d}{ds}(\gamma_n^\sigma(\phi_s(x,\sigma)))ds = \int_0^{\tau'} \frac{d}{ds}(\gamma_n^\sigma(\phi_s(x',\sigma)))ds.$$

Let $f = f(\phi_s(x,\sigma),\sigma)$, $f' = f(\phi_s(x',\sigma),\sigma)$, $d\gamma = \frac{d\gamma_n^\sigma(z)}{dz}|_{z=\phi_s(x,\sigma)}$, and $d\gamma' = \frac{d\gamma_n^\sigma(z)}{dz}|_{z=\phi_s(x',\sigma)}$. Then, rearranging terms,

$$\int_0^\tau (f' \cdot d\gamma')ds - \int_0^\tau (f \cdot d\gamma)ds = \int_{\tau'}^\tau (f' \cdot d\gamma')ds.$$

Let L_1 be the Lipschitz constant of $f \cdot d\gamma$ (using the fact that γ_n^σ is smooth). Then

$$\int_{\tau'}^\tau f' \cdot d\gamma' \leq L_1 \tau \|x - x'\| \leq L_1 \tau \delta_k.$$

Since γ_n^σ defines a transversal foliation to vector field $f(\cdot,\sigma)$, $f \cdot d\gamma > 0$. Let $c = \min_{s\in[\tau,\tau']}\{f' \cdot d\gamma'\} > 0$. Letting $c_\gamma = \frac{L_1}{c}$ we obtain the result. ∎

Remark 6.2. If $\mu \in \mathcal{U}_k^1$ is an ϵ-optimal control for x and the first time the trajectory $\phi_t(x,\mu)$ reaches Ω_f (Q_f) is T (T^2), then $T - T^2 \to 0$ and $|\phi_T(x,\mu) - \phi_{T^2}(x,\mu)| \to 0$ as $k \to \infty$. This follows from the fact that the distance between Ω_f and Q_f tends to zero as $k \to \infty$.

We denote by $\mu^2 \in \mathcal{U}_k^2$ the restriction of μ to $[0, T^2]$. Note that if the length of μ is $|\mu| = N$, then $|\mu_2| := N^2 \leq N$. Then we have the following result.

PROPOSITION 6.6. *Let $k_0 \in \mathbb{Z}^+$ be arbitrary, $x \in \mathcal{R}_{k_0}^1$, and $\mu \in \mathcal{U}_{k_0}^1$ be an ϵ-optimal control for x. Then $|J_k^1(x,\mu) - J_k^2(x,\mu^2)| \to 0$ as $k \to \infty$.*

Proof. Suppose $\mu = (\sigma_1, \tau_1)\dots(\sigma_N, \tau_N)$ and $\mu^2 = (\sigma_1, \tau_1)\dots(\sigma_{N^2}, \tau_{N^2})$, where $N^2 \leq N$. Thus, $N - N^2$ additional steps are required to reach $\partial\Omega_f$ after reaching Q_f. Then we have

$$\begin{aligned}\left|J_k^1(x,\mu) - J_k^2(x,\mu^2)\right| \leq \Bigg|&\sum_{j=1}^{N}\left[\int_0^{\tau(\sigma_j, x_{j-1})} L(\phi_s(x_{j-1},\sigma_j),\sigma_j)ds\right] + h(x_N) \\ &- \sum_{j=1}^{N^2}\left[\tau_{q_{j-1}} L(\xi_{j-1},\sigma_j)\right] - \hat{h}(x_{N^2})\Bigg|,\end{aligned}$$

where $(\sigma_j, x_{j-1}) \in q_{j-1}$ and $q_{j-1} = [(\sigma_j, \xi_{j-1})]$. There exists ξ_{N^2} such that $\hat{h}(x_{N^2}) = h(\xi_{N^2})$ and $\|x_{N^2} - \xi_{N^2}\| \leq \delta_k$. Also, using the mean value theorem, there exists $\tilde{t}_{j-1}$ with $\tilde{x}_{j-1} = \phi_{\tilde{t}_{j-1}}(x_{j-1}, \sigma_j)$ and $\|\tilde{x}_{j-1} - \xi_{j-1}\| \leq \delta_k$ such that

$$\begin{aligned}&\left|J_k^1(x,\mu) - J_k^2(x,\mu^2)\right| \\ &\quad\leq \sum_{j=1}^{N^2}\left|\tau(\sigma_j, x_{j-1})L(\tilde{x}_{j-1},\sigma_j) - \tau_{q_{j-1}}L(\xi_{j-1},\sigma_j)\right| \\ &\qquad + \left|\sum_{j=N^2+1}^{N}\left[\int_0^{\tau(\sigma_j,x_{j-1})} L(\phi_s(x_{j-1},\sigma_j),\sigma_j)ds\right]\right| + \left|h(x_N) - \hat{h}(x_{N^2})\right| \\ &\quad\leq \sum_{j=1}^{N^2}\tau_{q_{j-1}}L_L\delta_k + \sum_{j=1}^{N^2}[\tau_{q_{j-1}} - \tau(\sigma_j, x_{j-1})]L(\tilde{x}_{j-1},\sigma_j) \\ &\qquad + (T - T^2)M_L + L_h\|x_N - x_{N^2}\| + L_h\delta_k.\end{aligned}$$

The last three terms on the r.h.s. go to zero as $k \to \infty$ because of Remark 6.2 and since $\delta_k \to 0$. Using Lemma 6.4 the first summation decreases linearly as δ_k. Call the second summation on the r.h.s. B. Splitting B into sums over control switches and time steps, we have

$$\begin{aligned}B &\leq M_L\sum_{j=1}^{N^2}[\tau_{q_{j-1}} - \tau(\sigma_j, x_{j-1})]\mathbf{1}(\sigma_j = \sigma_{j-1}) \\ &\quad + M_L\sum_{j=1}^{N^2}[\tau_{q_{j-1}} - \tau(\sigma_j, x_{j-1})]\mathbf{1}(\sigma_j \neq \sigma_{j-1}) \\ &\leq M_L\sum_{j=1}^{N^2}c_{j-1}\tau_{q_{j-1}}\delta_k + M_L\sum_{j=1}^{N^2}\tau_{q_{j-1}}\mathbf{1}(\sigma_j \neq \sigma_{j-1})\end{aligned}$$

for some $c_{j-1} \in \mathbb{R}$. In the second line we used Lemma 6.5 and the fact that $\tau_{q_{j-1}} \geq \tau(\sigma_j, x_{j-1})$. Using Lemma 6.4 the first summation on the r.h.s. decreases linearly as δ_k. The second term on the r.h.s. goes to zero since, by Assumption 2.2, μ has a fixed number of control switches for all $k \geq k_0$. ∎

Step 3: Discrete states and nondeterminacy. In the last step we compare the value function $V_k^2(x)$ with the discrete value function $\hat{V}$ defined on A. The difference between the two is that trajectories defined over $\mathcal{U}_k^2$ do not include jumps, while trajectories whose time abstract versions are accepted by A can have jumps due to the nondeterminacy of A. Nevertheless, as $k \to \infty$ this discrepancy can be made negligible and we show that the difference between V_k^2 and $\hat{V}$ can be made arbitrarily small.

First we extend the domain of $\hat{V}(q)$, with an abuse of notation, by defining

$$\hat{V}_k(x) := \min_{\sigma \in \Sigma_k} \{\hat{V}(q) \mid (\sigma, x) \in q\}.$$

Also let $\hat{\mathcal{R}}_k = \{x \in \Omega \mid \hat{V}_k(x) < \infty\}$ and $\hat{\mathcal{R}} = \cup_k \hat{\mathcal{R}}_k$.

Remark 6.3.

(a) For each $x \in \cup_k \mathcal{R}_k^1$ and $\epsilon > 0$ there exists $m \in \mathbb{Z}^+$ and $\mu \in \mathcal{U}_m^2$ such that μ is an ϵ-optimal control for x w.r.t. V_k^2 with at most N_ϵ discontinuities. This follows from Remark 6.1(b) and the fact that trajectories in $\mathcal{U}_m^2$ are merely truncations of trajectories in $\mathcal{U}_m^1$.

(b) $\hat{\mathcal{R}} \subset \cup_k \mathcal{R}_k^1$, but the converse is not true, in general.

(c) If μ is an ϵ-optimal control for x w.r.t. V_k^2, then we can assume $\phi_t(x, \mu)$ does not self-intersect, for if it did we could find $\tilde{\mu}$, also ϵ-optimal, which eliminates loops in $\phi_t(x, \mu)$.

(d) $\|x - x'\| \to 0$ as $k \to \infty$ for all x, x', σ, $\sigma' \neq \sigma$ such that $([(\sigma, x)], [(\sigma', x')]) \in E$.

(e) For all $x \in \hat{R}$, $\hat{V}_k(x) \geq V_k^2(x)$. This follows because the argument of the max in the definition of $\hat{J}(q, c)$ is equal to $J_k^2(x, \mu)$, where c is a control policy as defined in section 5.1 with $c(q) = \sigma_1$, $(\sigma_1, x) \in q$, and $\mu = (\sigma_1, \tau_1) \ldots$ is the piecewise continuous control that corresponds to following policy c starting at x. Thus, $J_k^2(x, \mu)$ is the cost for a particular trajectory in $\tilde{\Pi}_c(q)$ which has no jumps at the control switches. Then we have $\hat{J}(q, c) \geq J_k^2(x, \mu)$, since $\hat{J}(q, c)$ maximizes over all trajectories in $\tilde{\Pi}_c(q)$.

PROPOSITION 6.7. *For all $x \in \hat{\mathcal{R}}$, $|\hat{V}_k(x) - V_k^2(x)| \to 0$ as $k \to \infty$.*

Proof. Fix $\epsilon > 0$ and $x \in \hat{\mathcal{R}}$. By Remark 6.3(a) there exists $m > 0$ and an ϵ-optimal control $\mu \in \mathcal{U}_m^2$ for x w.r.t. V_m^2. Denote $\mu = ((\sigma_1, \tau_1) \ldots (\sigma_N, \tau_N))$, where τ_i is the time σ_i is applied. Let c be any control policy on Q that is generated using δ_k and C_k, for $k \geq m$. Then, using Remark 6.3(e),

$$0 \leq \hat{V}_k(x) - V_k^2(x) \leq \hat{J}_k(q, c) - J_k^2(x, \mu) + \epsilon,$$

where $q = [(\sigma_1, x)]$. If we can show there exists $\overline{k} \geq m$ such that for $k > \overline{k}$, there exists a policy $\overline{c}$ such that

$$\hat{J}_k(q, \overline{c}) - J_k^2(x, \mu) < \epsilon,$$

then the result follows.

By Remark 6.3(d) and the transversality of $\phi_t(x, \mu)$ with the level sets of γ_n, we can find $\overline{k} \geq m$ such that for $k > \overline{k}$, there exists a family of (both continuous and discontinuous) trajectories Ψ_k starting at x with the following properties:

(1) $\phi_t(x, \mu) \in \Psi_k$.

(2) $\phi \in \Psi_k$ is defined over a control $\tilde{\mu} = ((\sigma_1, \tilde{\tau}_1), \ldots, (\sigma_N, \tilde{\tau}_N)) \in \mathcal{U}_k^2$ with the same sequence of control values as μ.

(3) $\phi \in \Psi_k$ switches controls on the same (transversal) submanifolds as $\phi_t(x, \mu)$ and reaches Q_f.

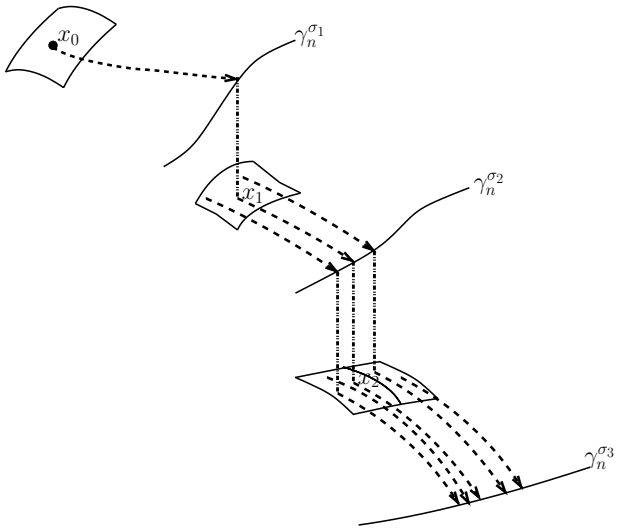

FIG. 6.2. *The family of trajectories* Ψ_k *in the proof of Proposition* 6.7.

(4) If $x_j^- = \phi_{\tau_j}(x_{j-1}, \sigma_j)$, then x_j, the initial condition of the next step, satisfies $([(\sigma_j, x_j^-)], (\sigma_{j+1}, x_j)]) \in E$. Thus, the trajectories of Ψ_k include jumps at the control switches modeling the nondeterminacy of A.

(5) If $\phi \in \Psi_k$ intersects $q \in Q$ in $\mathbb{R}^n$ at the jth step, then that is the only step where it intersects q. Also, all other $\phi' \in \Psi_k$ that intersect q do so at the jth step only. This requirement can be met for sufficiently large k by the fact that ϕ' has no self-intersections, by the fact that there are a finite number of steps, and by Remark 6.3(d). For if ϕ' has a self-intersection, then since ϕ' approaches $\phi_t(x, \mu)$ as $k \to \infty$, this would imply $\phi_t(x, \mu)$ has a self-intersection, contradicting Remark 6.3(c).

The family Ψ_k includes all trajectories starting at x, using the same sequence of control values as μ, and switching on the same equivalence class boundaries $\phi_t(x, \mu)$. Moreover, the initial condition at the start of each step can be any point in an equivalence class that has a nonempty intersection in $\mathbb{R}^n$ with the equivalence class reached at the end of the previous step. One visualizes a tube of trajectories that fans out with each successive control switch, as depicted in Figure 6.2. By choosing k sufficiently large and by transversality, all these trajectories reach Q_f.

Let $W_k(\phi) = \sum_{j=1}^{N} L^2(x_{j-1}, \sigma_j) + \hat{h}(x_N)$. Observe that for $\phi, \phi' \in \Psi_k$, $|W_k(\phi) - W_k(\phi')| \to 0$ as $k \to \infty$, using Lipschitz continuity of L and h and Remark 6.3(d). We can define a control policy $\overline{c}$ in which $q \in Q$ is assigned a time step if q is not visited by any trajectory in Ψ_k. If $q \in Q$ is visited by some $\phi \in \Psi_k$ in its jth step, then we assign $\overline{c}(q) = \sigma_j$. This gives a well-defined value for c because of Property 4. By construction, A accepts the time abstract trajectory starting at q corresponding to each trajectory of Ψ_k. $\overline{c}$ is admissible because otherwise some time abstract trajectory of A would have a Zeno loop. But a time abstract trajectory of A with a Zeno loop has a corresponding timed trajectory in Ψ_k that violates Property 4 of Ψ_k.

Now we observe that

$$\hat{J}(q, \overline{c}) = \max_{\phi \in \Psi_k} W_k(\phi) := W_k(\overline{\phi}).$$

Thus, $\hat{J}_k(q, \overline{c}) - J_k^2(x, \mu) \leq |W_k(\overline{\phi}) - W_k(\phi(x, \mu))| \to 0$ as $k \to \infty$. ∎

Combining Propositions 6.3, 6.6, and 6.7, we have the next theorem.

THEOREM 6.8. *For all* $x \in \hat{\mathcal{R}}$, $\hat{V}_k(x) \to V(x)$ *as* $k \to \infty$.

7. Implementation. So far we have developed a discrete method for solving an optimal control problem based on hybrid systems and bisimulation. Now we focus on the pragmatic question of how the discretized problem can be efficiently solved. In this section we propose a modification of the Dijkstra algorithm suitable for nondeterministic automata and prove that it is optimal and does not synthesize Zeno loops.

7.1. Motivation. Capuzzo Dolcetta and Evans [12] introduced a method for obtaining approximations of viscosity solutions based on time discretization of the HJB equation. The approximations of the value function correspond to a discrete time optimal control problem, for which an optimal control can be synthesized which is piecewise constant. Finite difference approximations were also introduced in [15] and [47]. In general, the time discretized approximation of the HJB equation is solved by finite element methods. Gonzales and Rofman [23] introduced a discrete approximation by triangulating the domain of the problem, while the admissible control set is approximated by a finite set. Gonzales and Rofman's approach is adapted in several papers, including [18]. The approach of [50] uses the special structure of an optimal control problem to obtain a single-pass algorithm to solve the discrete problem, thus bypassing the expensive iterations of a finite element method. See [45] for a recent adaptation of Tsitsiklis' approach. The essential property needed to find a single pass algorithm is to obtain a partition of the domain so that the cost-to-go value from any equivalence class of the partition is determined from knowledge of the cost-to-go from those equivalence classes with strictly smaller cost-to-go values. We obtain a partition of the domain provided by a bisimulation partition. *The combination of the structure of the bisimulation partition and the requirement of non-Zeno trajectories enables us to reproduce the essential property of* [50]*, so that we obtain a Dijkstra-like algorithmic solution.* Our approach has complexity $O(N \log N)$ if suitable data structures are used, where N is the number of locations of the finite automaton. The number N is, of course, exponential in n, the dimension of the continuous state space.

7.2. Nondeterministic Dijkstra algorithm. The dynamic programming solution (5.4)–(5.5) can be viewed as a shortest path problem on a nondeterministic finite graph subject to all optimal paths satisfying a non-Zeno condition. We propose an algorithm that is a modification of the Dijkstra algorithm for deterministic graphs [17]. First we define the notation. F_n is the set of states that have been assigned a control and are deemed finished at iteration n, while U_n are the unfinished states. At each n, $Q = U_n \cup F_n$. $\Sigma_n(q) \subseteq \Sigma_\delta$ is the set of control events at iteration n that take state q to finished states exclusively. $\tilde{U}_n$ is the set of states for which there exists a control event that can take them to finished states exclusively. $\tilde{V}_n(q)$ is a tentative cost-to-go value at iteration n. B_n is the set of best states among $\tilde{U}_n$.

The nondeterministic Dijkstra (NDD) algorithm first determines $\tilde{U}_n$ by checking if any q in U_n can take a step to states belonging exclusively to F_n. For states belonging to $\tilde{U}_n$, an estimate of the value function $\tilde{V}$ following the prescription of (5.4) is obtained: among the set of control events constituting a step into states in F_n, select the event with the lowest worst-case cost. Next, the algorithm determines B_n, the states with the lowest $\tilde{V}$ among $\tilde{U}_n$, and these are added to F_{n+1}. The iteration counter is incremented until it reaches $N = |Q|$. It is assumed in the following description that initially $\hat{V}(q) = \infty$ and $c(q) = \emptyset$ for all $q \in Q$.

PROCEDURE NDD.

$\mathsf{F}_1 = \mathsf{Q}_\mathsf{f}$; $\mathsf{U}_1 = \mathsf{Q} - \mathsf{Q}_\mathsf{f}$;
for each $\mathsf{q} \in \mathsf{Q}_\mathsf{f}$, $\hat{\mathsf{V}}(\mathsf{q}) = \hat{\mathsf{h}}(\mathsf{q})$;

for $\mathsf{n} = 1$ to N, do
  for each $\mathsf{q} \in \mathsf{U}_\mathsf{n}$,
    $\Sigma_\mathsf{n}(\mathsf{q}) = \{\sigma' \in \Sigma_\delta \mid \text{if } \mathsf{q} \xrightarrow{\sigma'} \mathsf{q}', \text{then } \mathsf{q}' \in \mathsf{F}_\mathsf{n}\}$;
  $\tilde{\mathsf{U}}_\mathsf{n} = \{\mathsf{q} \in \mathsf{U}_\mathsf{n} \mid \Sigma_\mathsf{n}(\mathsf{q}) \neq \emptyset\}$;
  for each $\mathsf{q} \in \tilde{\mathsf{U}}_\mathsf{n}$,
    $\tilde{\mathsf{V}}_\mathsf{n}(\mathsf{q}) = \min_{\sigma' \in \Sigma_\mathsf{n}(\mathsf{q})}\{\max_{\mathsf{e}=(\mathsf{q},\mathsf{q}') \in \mathsf{E}_{\sigma'}(\mathsf{q})}\{\hat{\mathsf{L}}(\mathsf{e}) + \hat{\mathsf{V}}(\mathsf{q}')\}\}$;
  $\mathsf{B}_\mathsf{n} = \operatorname{argmin}_{\mathsf{q} \in \tilde{\mathsf{U}}_\mathsf{n}}\{\tilde{\mathsf{V}}_\mathsf{n}(\mathsf{q})\}$;
  for each $\mathsf{q} \in \mathsf{B}_\mathsf{n}$,
    $\hat{\mathsf{V}}(\mathsf{q}) = \tilde{\mathsf{V}}_\mathsf{n}(\mathsf{q})$;
    $\mathsf{c}(\mathsf{q}) = \operatorname{argmin}_{\sigma' \in \Sigma_\mathsf{n}(\mathsf{q})}\{\max_{\mathsf{e}=(\mathsf{q},\mathsf{q}') \in \mathsf{E}_{\sigma'}(\mathsf{q})}\{\hat{\mathsf{L}}(\mathsf{e}) + \hat{\mathsf{V}}(\mathsf{q}')\}\}$;
  endfor
  $\mathsf{F}_{\mathsf{n}+1} = \mathsf{F}_\mathsf{n} \cup \mathsf{B}_\mathsf{n}$; $\mathsf{U}_{\mathsf{n}+1} = \mathsf{Q} - \mathsf{F}_{\mathsf{n}+1}$;
endfor

7.3. Justification. In this section we prove that the algorithm is *optimal*; that is, it synthesizes a control policy so that each $q \in Q$ reaches Q_f with the best worst-case cost. We observe a few properties of the algorithm. First, if all states of Q can reach Q_f in a nondeterministic sense, then $Q - Q_f = \cup_n B_n$. By nondeterministic sense we mean that for each $q \in Q$, there exists a control policy c such that $\Pi_c(q) = \tilde{\Pi}_c(q)$. Note that if this condition is not met, then it can happen that at some iteration of NDD, $\tilde{U}_n = \emptyset$ but $U_n \neq \emptyset$. Second, as in the deterministic case, the algorithm computes $\hat{V}$ in order of level sets of $\hat{V}$. In particular, $\hat{V}(B_n) \leq \hat{V}(B_{n+1})$. Finally, we need the following property.

LEMMA 7.1. *For all $q \in Q$ that can reach Q_f in a nondeterministic sense and for all $\sigma' \in \Sigma_\delta$,*

$$\hat{V}(q) \leq \max_{e=(q,q') \in E_{\sigma'}(q)} \{\hat{L}(e) + \hat{V}(q')\}.$$

Proof. Fix $q \in Q$ and $\sigma' \in \Sigma_\delta$. There are two cases.

Case 1.

$$\hat{V}(q) \leq \max_{e=(q,q') \in E_{\sigma'}(q)} \{\hat{V}(q')\}.$$

In this case the result is obvious.

Case 2.

$$\hat{V}(q) > \max_{e=(q,q') \in E_{\sigma'}(q)} \{\hat{V}(q')\}. \tag{7.1}$$

By assumption, q belongs to some B_n. Suppose without loss of generality that $q \in B_j$. Together with (7.1) this implies $q' \in F_j$ for all q' such that $q \xrightarrow{\sigma'} q'$. This, in turn, means that $\sigma' \in \Sigma_j(q)$ and according to the algorithm

$$\hat{V}(q) = \tilde{V}_j(q) \leq \max_{e=(q,q') \in E_{\sigma'}(q)} \{\hat{L}(e) + \hat{V}(q')\},$$

which proves the result. ∎

THEOREM 7.2. *Algorithm NDD is optimal and synthesizes a control policy with no Zeno loops.*

Proof. First we prove optimality. Let $V(q)$ be the optimal (best worst-case) cost-to-go for $q \in Q$ and $\overline{Q} = \{q \in Q \mid V(q) < \hat{V}(q)\}$. Let $l(\pi_q)$ be the number of edges taken by the shortest optimal (best worst-case) trajectory π_q from q. Define $\overline{q} = \arg\min_{q \in \overline{Q}} \{l(\pi_q)\}$. Suppose that the best worst-case trajectory starting at $\overline{q}$ is $\pi_{\overline{q}} = \overline{q} \xrightarrow{\sigma'} \overline{\overline{q}} \to \cdots$. We showed in the previous lemma that

$$\hat{V}(\overline{q}) \leq \max_{e=(\overline{q},q') \in E_{\sigma'}(\overline{q})} \{\hat{L}(e) + \hat{V}(q')\} = \hat{L}(e) + \hat{V}(\overline{\overline{q}}).$$

Since $\pi_{\overline{q}}$ is the best worst-case trajectory from $\overline{q}$ and by the optimality of $V(\overline{q})$,

$$V(\overline{q}) = \max_{e=(\overline{q},q') \in E_{\sigma'}(\overline{q})} \{\hat{L}(e) + V(q')\} = \hat{L}(e) + V(\overline{\overline{q}}).$$

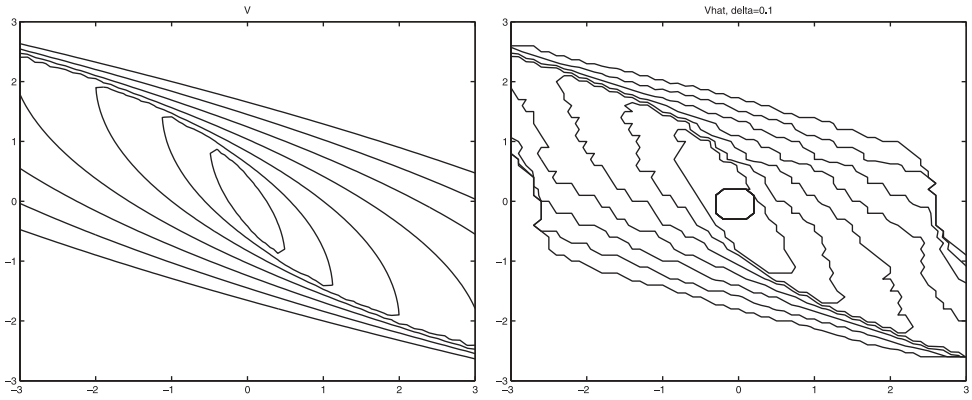
Since $\pi_{\overline{q}}$ is the shortest best worst-case trajectory, we know that $\overline{\overline{q}} \notin \overline{Q}$, so $V(\overline{\overline{q}}) = \hat{V}(\overline{\overline{q}})$. This implies $\hat{V}(\overline{q}) \leq \hat{L}(e) + V(\overline{\overline{q}}) = V(\overline{q})$, a contradiction.

To prove that the algorithm synthesizes a policy with no Zeno loops, we argue by induction. The claim is obviously true for F_1. Suppose that the states of F_n have been assigned controls forming no Zeno loops. Consider F_{n+1}. Each state of B_n takes either a time step or a control switch to F_n, so there cannot be a Zeno loop in B_n. The only possibility is for some $q \in B_n$ to close a Zeno loop with states in F_n. This implies there exists a control assignment that allows an edge from F_n to q to be taken, but this is not allowed by NDD. Thus, F_{n+1} has no Zeno loops. ∎

8. Examples. We consider two simple examples where the solution of the optimal control problem is known in order to illustrate the correctness of the method. The software that generates the optimal enabling conditions is broken into two programs, one that generates the automaton given the information about the bisimulation and one that runs the algorithm NDD. The first program takes as input the control values Σ_δ and the level values of γ_i^σ, $i = 1, \ldots, n$, $\sigma \in \Sigma_\delta$, defining the bisimulation. The functions γ_i^σ, $\hat{L}$, and $\hat{h}$ are compiled with the executable. A data structure that associates to each location of the finite automaton the lower and upper level values of each γ_i^σ allows time steps to be encoded symbolically, namely, by sorting nodes with equal upper and lower first integral level values in ascending order of γ_n^σ level values. The edges of the finite automaton that correspond to σ-steps are generated numerically by evaluating γ_i^σ for $i = 1, \ldots, n$ and each $\sigma \in \Sigma_\delta$ and thereby determining which equivalence classes overlap for each pair (l, l') of locations. In our implementation the grid of sample points is $\{x \in \Omega, \gamma_i \in C^k\}$ in order to correlate with the mesh size of the bisimulation partition. This numerical step can also be performed symbolically if the functions γ_i^σ are polynomials using a quantifier elimination algorithm [5]. However, the quantifier elimination step is expensive, and for approximate solutions it suffices to use a numerical approach.

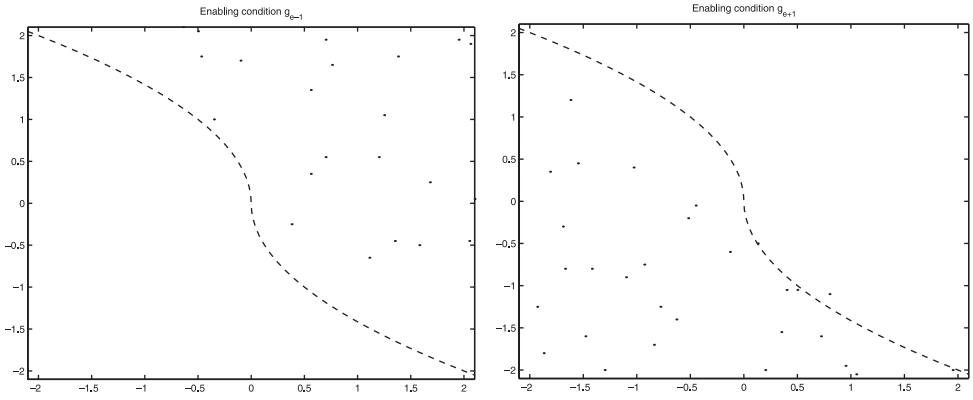
First we apply our method to Examples 3.1 and 4.1. The bang-bang solution obtained using Pontryagin's maximum principle is well known to involve a single switching curve. The continuous value function V is shown in Figure 8.1(a).

The results of algorithm NDD are shown in Figures 8.1(b) and 8.2. In Figure 8.2 the dashed line is the smooth switching curve for the continuous problem. The black dots identify equivalence classes where NDD assigns a control switch. Considering $g_{e_{-1}}$ we see that the boundary of the enabling condition in the upper left corner is a



(a) V (b) $\hat{V}$ for $\Delta = 0.1$.

FIG. 8.1. *Continuous and discrete value functions for double integrator.*



(a) g_{e-1} (b) g_{e1}

FIG. 8.2. *Enabling conditions.*

jagged approximation using equivalence classes of the smooth switching curve. Initial conditions in the upper left corner just inside the enabling condition must switch to a control of $u = -1$; otherwise the trajectory will increase in the x_2 direction and not reach the target. Initial conditions in the upper left corner just outside the enabling condition must allow time to pass until they reach the enabling condition, for if they switched to $u = -1$ they would be unable to reach the target. Hence the upper left boundary of the enabling condition is crisp. The lower right side of the enabling condition which has islands of time steps shows the effect of the nondeterminacy of automaton A. These additional time steps occur because it can be less expensive to take a time step than to incur the cost of the worst-case control switch. Indeed consider an initial condition in Figure 8.2(a) which lies in an equivalence class that takes a time step but should take a control switch according to the continuous optimal

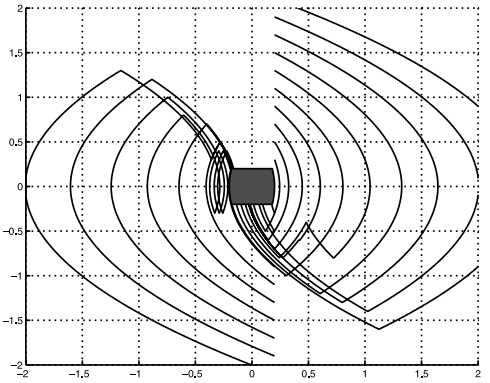


FIG. 8.3. *Trajectories of the closed-loop system.*

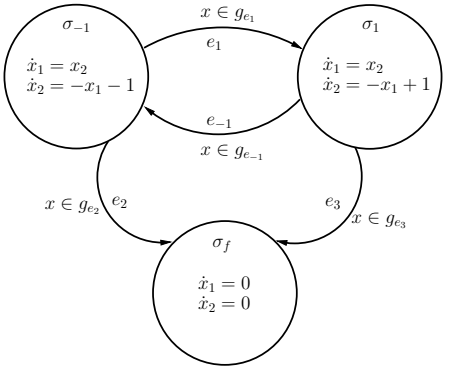

FIG. 8.4. *Hybrid automaton for example* 2.

control. Such a point will move up and to the left before it takes a control switch. By moving slightly closer to the target, the worst-case cost-to-go incurred in a control switch is reduced. Notice that all such initial conditions eventually take a control switch. This phenomenon of extra time steps is a function of the mesh size δ: as δ decreases there are fewer extra time steps. Finally we note that the two enabling conditions have an empty intersection, as expected to ensure non-Zeno trajectories.

Figure 8.3 shows trajectories of the closed-loop system using the controller synthesized by NDD. The central shaded region is an enlarged target set.

Next we consider the time optimal control problem for the system

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= -x_1 + u. \end{aligned} \tag{8.1}$$

Suppose $\Omega = (-1,1) \times (-1,1)$ and $\Omega_f = \overline{B}_\epsilon(0)$, the closed epsilon ball centered at 0. The cost-to-go function is $J(x,\mu) = \int_0^{T(x,\mu)} dt$ and $U = \{u : |u| \leq 1\}$. We select $\Sigma_\delta = \{-1, 1\}$ so that $\delta = 1$. The hybrid system is show in Figure 8.4. The state set is $\{\sigma_{-1} = -1, \sigma_1 = 1, \sigma_f\} \times \mathbb{R}^2$. $g_{e_{-1}}$ and g_{e_1} are unknown and must be synthesized, while $g_{e_2} = g_{e_3} = \Omega_f$. A first integral for (8.1) is $\sqrt{(x_1 - u)^2 + x_2^2} = c_1$, where $u = \pm 1$. The transverse foliation is chosen to be defined by the function $\arctan(\frac{x_2}{x_1 - u}) = c_2$. Partitions for locations σ_1 and σ_{-1} are shown in Figure 8.5. The results of algorithm NDD are shown in Figures 8.6(b) and 8.7. In Figure 8.7 the dashed line is the

FIG. 8.6. *Continuous and discrete value functions for example* 2.

switching curve for the continuous problem. As in the previous example the black dots identify equivalence classes where NDD assigns a control switch. Figure 8.8 shows trajectories of the closed-loop system using the controller synthesized by NDD. An enlarged target set is at the origin.

Remark 8.1. From these examples we observe that our method is best suited to problems when there are relatively few control switches, as each control switch incurs an error of order δ. Also the method is suited to problems where bang-bang controls are used. The method has advantages in situations where a fine time discretization of the vector field is needed for standard finite element methods. We do not require time discretization because of the particular choice of grid, which captures time evolution exactly. Finally, because the method requires computation of weak first integrals, only systems for which first integrals are computable in closed form are considered.

Table 8.1 shows the computation times for the two examples as a function of δ. The automaton size and the time in seconds to generate it appear in the second and

third columns. We report the time for file I/O, which otherwise would dominate the computation times. The time in seconds to run NDD and the size of the set F_n of finished states appear in the last two columns. Note that not all nodes are finished in the first example because the regions of $\mathbb{R}^2$ that are partitioned in the two locations do not overlap perfectly, resulting in the nonexistence of a trajectory that can reach the origin starting in a subset of the nonoverlapping areas.

9. Conclusion. In this paper we have developed a methodology for the synthesis of optimal controls based on hybrid systems and bisimulations. The idea is to translate the optimal control problem to a switching problem on a hybrid system whose locations describe the dynamics when the control is constant. When the vector fields for each location of the hybrid automaton have local first integrals which can be expressed analytically we are able to define a finite bisimulation using the approach of [10]. From the finite bisimulation we obtain a (time abstract) finite automaton on which a dynamic programming problem can be formulated that can be solved efficiently. We proposed an efficient single-pass algorithm to solve this dynamic programming problem and demonstrated its correctness on two simple examples.

BOUNDARY CONTROL OF THE LINEARIZED GINZBURG–LANDAU MODEL OF VORTEX SHEDDING*

OLE MORTEN AAMO†, ANDREY SMYSHLYAEV‡, AND MIROSLAV KRSTIĆ‡

Abstract. In this paper, we continue the development of state feedback boundary control laws based on the backstepping methodology, for the stabilization of unstable, parabolic partial differential equations. We consider the linearized Ginzburg–Landau equation, which models, for instance, vortex shedding in bluff body flows. Asymptotic stabilization is achieved by means of boundary control via state feedback in the form of an integral operator. The kernel of the operator is shown to be twice continuously differentiable, and a series approximation for its solution is given. Under certain conditions on the parameters of the Ginzburg–Landau equation, compatible with vortex shedding modelling on a semi-infinite domain, the kernel is shown to have compact support, resulting in partial state feedback. Simulations are provided in order to demonstrate the performance of the controller. In summary, the paper extends previous work in two ways: (1) it deals with two coupled partial differential equations, and (2) under certain circumstances handles equations defined on a semi-infinite domain.

Key words. partial differential equations, boundary control, stabilization, flow control

1. Introduction.

In this paper, we continue the development of state feedback boundary control laws based on the backstepping methodology [6], for the stabilization of unstable, parabolic partial differential equations [3, 2, 10, 14]. We consider the linearized Ginzburg–Landau equation given by

$$\frac{\partial A(\breve{x},t)}{\partial t} = a_1 \frac{\partial^2 A(\breve{x},t)}{\partial \breve{x}^2} + a_2(\breve{x}) \frac{\partial A(\breve{x},t)}{\partial \breve{x}} + a_3(\breve{x}) A(\breve{x},t) \tag{1}$$

for $\breve{x} \in (0, x_d)$, with boundary conditions

$$A(0,t) = u(t), \tag{2}$$

$$A(x_d,t) = 0, \tag{3}$$

and where $A : [0, x_d] \times \mathbb{R}_+ \to \mathbb{C}$, $a_2 \in C^2([0, x_d]; \mathbb{C})$, $a_3 \in C^1([0, x_d]; \mathbb{C})$, $a_1 \in \mathbb{C}$, $x_d > 0$, and $u : \mathbb{R}_+ \to \mathbb{C}$ is the control input. a_1 is assumed to have strictly positive real part. In order to achieve asymptotic stabilization of the equilibrium at $A \equiv 0$, backstepping is applied resulting in a boundary control law that essentially cuts the term $a_3(\breve{x}) A(\breve{x},t)$ from (1). The result extends the work of [10, 14] in two ways: (1) it deals with two coupled partial differential equations, and (2) under certain circumstances handles equations defined on a semi-infinite domain ($x_d \to \infty$). The theory is supplemented with a case study involving control of vortex shedding in bluff

body flows. Controllers for this problem have previously been designed for finite-dimensional approximations of (1) [7, 8, 1, 9]. In [12, 13], it was shown numerically that the Ginzburg–Landau model for Reynolds numbers close to R_c can be stabilized using proportional feedback from a single measurement downstream of the cylinder to local forcing at the location of the cylinder. In [5], an optimal solution to a boundary control problem formulated for a stationary Ginzburg–Landau model of superconductivity defined on a bounded domain was shown to exist, and the optimality system of equations was solved by employing the finite element method.

The paper is organized as follows. In section 2, equation (1) is rewritten in terms of real variables and coefficients, and the problem statement is given. The main result is stated in section 3. In section 4 partial differential equations governing the feedback kernel are derived, and in section 5 they are transformed to corresponding integral equations. We find a unique solution to the integral equations in section 6, and show that the solution also yields the unique feedback kernel. Stability properties of the chosen target system are established in section 7. In section 9, the results are applied to a model of vortex shedding behind a bluff body immersed in a moving fluid, and it is shown that stabilizing feedback kernels that have compact support can be found even when the domain is semi-infinite. Concluding remarks are offered in section 10.

2. Problem statement. We now rewrite (1) to obtain two coupled partial differential equations in real variables and coefficients by defining

$$\rho(x,t) = \Re(B(x,t)) = \frac{1}{2}\left(B(x,t) + \bar{B}(x,t)\right), \tag{4}$$

$$\iota(x,t) = \Im(B(x,t)) = \frac{1}{2i}\left(B(x,t) - \bar{B}(x,t)\right), \tag{5}$$

where

$$x = \frac{x_d - \breve{x}}{x_d} \text{ and } B(x,t) = A(\breve{x},t)\exp\left(\frac{1}{2a_1}\int_0^{\breve{x}} a_2(\tau)\,d\tau\right). \tag{6}$$

i denotes the imaginary unit, and $\bar{}$ denotes complex conjugation. Equation (1) becomes

$$\rho_t = a_R\rho_{xx} + b_R(x)\rho - a_I\iota_{xx} - b_I(x)\iota, \tag{7}$$

$$\iota_t = a_I\rho_{xx} + b_I(x)\rho + a_R\iota_{xx} + b_R(x)\iota \tag{8}$$

for $x \in (0,1)$, with boundary conditions

$$\rho(0,t) = 0,\ \iota(0,t) = 0, \tag{9}$$

$$\rho(1,t) = u_R(t),\ \iota(1,t) = u_I(t), \tag{10}$$

and where

$$a_R \triangleq \frac{1}{x_d^2}\Re(a_1),\ a_I \triangleq \frac{1}{x_d^2}\Im(a_1), \tag{11}$$

$$b_R(x) \triangleq \Re\left(a_3(\breve{x}) - \frac{1}{2}a_2'(\breve{x}) - \frac{1}{4a_1}a_2^2(\breve{x})\right), \tag{12}$$

$$b_I(x) \triangleq \Im\left(a_3(\breve{x}) - \frac{1}{2}a_2'(\breve{x}) - \frac{1}{4a_1}a_2^2(\breve{x})\right). \tag{13}$$

Notice that transformation (6) serves two purposes: it normalizes the domain, and removes the convective term in (1). The control input will be in the form

$$u_R(t) = \int_0^1 \left[k(1,y)\,\rho(y,t) + k_c(1,y)\,\iota(y,t)\right] dy, \tag{14}$$

$$u_I(t) = \int_0^1 \left[-k_c(1,y)\,\rho(y,t) + k(1,y)\,\iota(y,t)\right] dy. \tag{15}$$

It is the objective of this paper to find stabilizing feedback gain kernels k and k_c.

3. Main result. Our main result states well posedness and stability properties of system (7)–(10) in closed loop with (14)–(15). The proof of the theorem is given in section 8, following intermediate results.

THEOREM 1 (main result). *There exist feedback gain kernels, $k(1,\cdot), k_c(1,\cdot) \in C^2(0,1)$, such that for arbitrary initial data $\rho_0, \iota_0 \in L_\infty(0,1)$, system (7)–(10) in closed loop with (14)–(15) has a unique classical solution $\rho, \iota \in C^{2,1}((0,1)\times(0,\infty))$. The solution satisfies*

$$\|(\rho,\iota)\|_{H_1} \le M \|(\rho_0,\iota_0)\|_{H_1} e^{-ct}, \tag{16}$$

where $M > 0$ and c is a prescribable positive constant.

The basic idea of the control design is to show that the dynamics of the *original* system (7)–(10), with an appropriate choice for (14)–(15), is equivalent to the dynamics of a *target* system that has a specified structure, but whose zero-solution can be assigned desired stability properties by the choice of coefficients. This is achieved by finding an invertible coordinate transformation that transforms solutions of the original system into solutions of the target system, establishing equivalence of norms of solutions of the two systems. The transformation is found as the unique solution to a hyperbolic partial differential equation, as stated in the next section. The proof of existence and uniqueness of solutions to this equation offers a constructive procedure to compute the transformation.

4. Derivation of PDE for the kernels. We want to find a coordinate transformation

$$\tilde\rho(x,t) = \rho(x,t) - \int_0^x \left[k(x,y)\,\rho(y,t) + k_c(x,y)\,\iota(y,t)\right] dy, \tag{17}$$

$$\tilde\iota(x,t) = \iota(x,t) - \int_0^x \left[-k_c(x,y)\,\rho(y,t) + k(x,y)\,\iota(y,t)\right] dy, \tag{18}$$

transforming (7)–(10) into the exponentially stable system (under appropriate conditions on $f_R(x)$ and $f_I(x)$ that are stated in section 7)

$$\tilde\rho_t = a_R\tilde\rho_{xx} + f_R(x)\,\tilde\rho - a_I\tilde\iota_{xx} - f_I(x)\,\tilde\iota, \tag{19}$$

$$\tilde\iota_t = a_I\tilde\rho_{xx} + f_I(x)\,\tilde\rho + a_R\tilde\iota_{xx} + f_R(x)\,\tilde\iota \tag{20}$$

for $x \in (0,1)$, with boundary conditions

$$\tilde\rho(0,t) = 0,\ \tilde\iota(0,t) = 0,\ \tilde\rho(1,t) = 0,\ \tilde\iota(1,t) = 0, \tag{21}$$

and where $f_R, f_I \in C^1([0,1])$. The skew-symmetric form of (17)–(18) is postulated from the skew-symmetric form of (7)–(8). Notice that once the kernels, $k(x,y)$ and

$k_c(x,y)$, have been found, setting $x=1$ in (17)–(18) and using (21) yields the boundary control law (10) with (14)–(15).

LEMMA 2. *If the pair of kernels, $k(x,y)$ and $k_c(x,y)$, satisfy the partial differential equation*

$$k_{xx} = k_{yy} + \beta(x,y)k + \beta_c(x,y)k_c, \tag{22}$$

$$k_{c,xx} = k_{c,yy} - \beta_c(x,y)k + \beta(x,y)k_c \tag{23}$$

for $(x,y) \in \mathcal{T} = \{x,y : 0 < y < x < 1\}$, with boundary conditions

$$k(x,x) = -\frac{1}{2}\int_0^x \beta(\gamma,\gamma)d\gamma, \tag{24}$$

$$k_c(x,x) = \frac{1}{2}\int_0^x \beta_c(\gamma,\gamma)d\gamma, \tag{25}$$

$$k(x,0) = 0, \tag{26}$$

$$k_c(x,0) = 0, \tag{27}$$

where

$$\beta(x,y) = \left[a_R\left(b_R(y) - f_R(x)\right) + a_I\left(b_I(y) - f_I(x)\right)\right] / \left(a_R^2 + a_I^2\right), \tag{28}$$

$$\beta_c(x,y) = \left[a_R\left(b_I(y) - f_I(x)\right) - a_I\left(b_R(y) - f_R(x)\right)\right] / \left(a_R^2 + a_I^2\right), \tag{29}$$

and if (ρ,ι) satisfies (7)–(10) with (14)–(15), then $(\tilde{\rho},\tilde{\iota})$ satisfies (19)–(21).

Proof. Differentiating (17) with respect to time and inserting (7)–(8) we have

$$\begin{aligned}\tilde{\rho}_t(x,t) = {} & a_R\rho_{xx} + b_R(x)\rho - a_I\iota_{xx} - b_I(x)\iota \\ & - \int_0^x \Big[k(x,y)\left(a_R\rho_{xx} + b_R(y)\rho - a_I\iota_{xx} - b_I(y)\iota\right) \\ & \qquad - k_c(x,y)\left(a_I\rho_{xx} + b_I(y)\rho + a_R\iota_{xx} + b_R(y)\iota\right)\Big]dy.\end{aligned} \tag{30}$$

Integrating (30) by parts, and using (9), (26)–(27), and (17)–(18) yield

$$\begin{aligned}\tilde{\rho}_t(x,t) = {} & a_R\tilde{\rho}_{xx}(x,t) + a_R\frac{\partial^2}{\partial x^2}\int_0^x \left[k(x,y)\rho(y,t) + k_c(x,y)\iota(y,t)\right]dy \\ & + b_R(x)\tilde{\rho}(x,t) + b_R(x)\int_0^x \left[k(x,y)\rho(y,t) + k_c(x,y)\iota(y,t)\right]dy \\ & - a_I\tilde{\iota}_{xx}(x,t) - a_I\frac{\partial^2}{\partial x^2}\int_0^x \left[-k_c(x,y)\rho(y,t) + k(x,y)\iota(y,t)\right]dy \\ & - b_I(x)\tilde{\iota}(x,t) - b_I(x)\int_0^x \left[-k_c(x,y)\rho(y,t) + k(x,y)\iota(y,t)\right]dy \\ & - k(x,x)a_R\rho_x(x,t) + k(x,x)a_I\iota_x(x,t) - k_c(x,x)a_I\rho_x(x,t) - k_c(x,x)a_R\iota_x(x,t) \\ & + k_y(x,x)a_R\rho(x,t) - k_y(x,x)a_I\iota(x,t) + k_{c,y}(x,x)a_I\rho(x,t) + k_{c,y}(x,x)a_R\iota(x,t) \\ & - \int_0^x \left[k_{yy}(x,y)\left(a_R\rho(y,t) - a_I\iota(y,t)\right) + k(x,y)\left(b_R(y)\rho(y,t) - b_I(y)\iota(y,t)\right)\right. \\ & \left. + \; k_{c,yy}(x,y)\left(a_I\rho(y,t) + a_R\iota(y,t)\right) + k(x,y)\left(b_I(y)\rho(y,t) + b_R(y)\iota(y,t)\right)\right]dy.\end{aligned} \tag{31}$$

Applying the relation

$$\begin{aligned}\frac{\partial^2}{\partial x^2}\int_0^x \kappa(x,y)\upsilon(y,t)\,dy = {} & \int_0^x \kappa_{xx}(x,y)\upsilon(y,t)\,dy + \kappa_x(x,x)\upsilon(x,t) \\ & + \; \upsilon(x,t)\frac{d\kappa(x,x)}{dx} + \kappa(x,x)\upsilon_x(x,t)\end{aligned} \tag{32}$$

to appropriate terms in (31), and using (17)–(18) again, we get

$$\begin{aligned}(33)\quad \tilde{\rho}_t(x,t) &= a_R\tilde{\rho}_{xx}(x,t) - a_I\tilde{\iota}_{xx}(x,t) + b_R(x)\,\tilde{\rho}(x,t) - b_I(x)\,\tilde{\iota}(x,t)\\ &\quad + 2a_R\frac{dk(x,x)}{dx}\tilde{\rho}(x,t) + 2a_R\frac{dk_c(x,x)}{dx}\tilde{\iota}(x,t) + 2a_I\frac{dk_c(x,x)}{dx}\tilde{\rho}(x,t)\\ &\quad - 2a_I\frac{dk(x,x)}{dx}\tilde{\iota}(x,t) + \int_0^x R(x,y)\,\rho(y,t)\,dy + \int_0^x I(x,y)\,\iota(y,t)\,dy,\end{aligned}$$

where

$$\begin{aligned}(34)\quad R(x,y) &= a_R\left(k_{xx}(x,y) - k_{yy}(x,y)\right) + a_I\left(k_{c,xx}(x,y) - k_{c,yy}(x,y)\right)\\ &\quad + \left(2a_R\frac{dk(x,x)}{dx} + 2a_I\frac{dk_c(x,x)}{dx} + b_R(x) - b_R(y)\right)k(x,y)\\ &\quad + \left(-2a_R\frac{dk_c(x,x)}{dx} + 2a_I\frac{dk(x,x)}{dx} + b_I(x) - b_I(y)\right)k_c(x,y)\end{aligned}$$

and

$$\begin{aligned}(35)\quad I(x,y) &= -a_I\left(k_{xx}(x,y) - k_{yy}(x,y)\right) + a_R\left(k_{c,xx}(x,y) - k_{c,yy}(x,y)\right)\\ &\quad + \left(2a_R\frac{dk_c(x,x)}{dx} - 2a_I\frac{dk(x,x)}{dx} - b_I(x) + b_I(y)\right)k(x,y)\\ &\quad + \left(2a_R\frac{dk(x,x)}{dx} + 2a_I\frac{dk_c(x,x)}{dx} + b_R(x) - b_R(y)\right)k_c(x,y).\end{aligned}$$

Substituting (22)–(23) and (24)–(25) into (34)–(35) yields

$$\begin{aligned}(36)\quad &R(x,y)\\ &= \left(a_R\beta(x,y) - a_I\beta_c(x,y) - \left(a_R\beta(x,x) - a_I\beta_c(x,x)\right) + b_R(x) - b_R(y)\right)k(x,y)\\ &+ \left(a_R\beta_c(x,y) + a_I\beta(x,y) - \left(a_R\beta_c(x,x) + a_I\beta(x,x)\right) + b_I(x) - b_I(y)\right)k_c(x,y),\end{aligned}$$

and

$$\begin{aligned}(37)\quad &I(x,y)\\ &= \left(-\left(a_R\beta_c(x,y) + a_I\beta(x,y)\right) + a_R\beta_c(x,x) + a_I\beta(x,x) - b_I(x) + b_I(y)\right)k(x,y)\\ &+ \left(a_R\beta(x,y) - a_I\beta_c(x,y) - \left(a_R\beta(x,x) - a_I\beta_c(x,x)\right) + b_R(x) - b_R(y)\right)k_c(x,y).\end{aligned}$$

From (28)–(29), we see that

$$(38)\qquad a_R\beta(x,y) - a_I\beta_c(x,y) = b_R(y) - f_R(x)$$

and

$$(39)\qquad a_R\beta_c(x,y) + a_I\beta(x,y) = b_I(y) - f_I(x),$$

so it follows that

$$(40)\qquad R(x,y) = I(x,y) \equiv 0.$$

In view of (40), and using (24)–(25), (33) becomes

$$\begin{aligned}(41)\quad \tilde{\rho}_t(x,t) =& a_R\tilde{\rho}_{xx}(x,t) - a_I\tilde{\iota}_{xx}(x,t)\\ &+ \left(-\left(a_R\beta(x,x) - a_I\beta_c(x,x)\right) + b_R(x)\right)\tilde{\rho}(x,t)\\ &+ \left(a_R\beta_c(x,x) + a_I\beta(x,x) - b_I(x)\right)\tilde{\iota}(x,t).\end{aligned}$$

Equation (19) now follows by substituting (38)–(39) into (41). The boundary conditions (21) follow by setting $x = 0$ and $x = 1$ in (17)–(18), and using (9)–(10) and (14)–(15). Equation (20) follows similarly by starting from the time derivative of (18). □

5. Converting the PDE into an integral equation. In the following lemma, (22)–(27) is converted into an integral equation, that is suitable for analysis by a fixed point method to establish existence and uniqueness of solutions.

LEMMA 3. *Any pair of kernels, $k(x,y)$ and $k_c(x,y)$, satisfying* (22)–(27)*, also satisfy the integral equation*

$$\begin{aligned}(42)\quad G(\xi,\eta) =& -\frac{1}{4}\int_\eta^\xi b(\tau,0)\,d\tau\\ &+ \frac{1}{4}\int_\eta^\xi\int_0^\eta b(\tau,s)\,G(\tau,s)\,ds d\tau + \frac{1}{4}\int_\eta^\xi\int_0^\eta b_c(\tau,s)\,G_c(\tau,s)\,ds d\tau,\end{aligned}$$

$$\begin{aligned}(43)\quad G_c(\xi,\eta) =& \frac{1}{4}\int_\eta^\xi b_c(\tau,0)\,d\tau\\ &- \frac{1}{4}\int_\eta^\xi\int_0^\eta b_c(\tau,s)\,G(\tau,s)\,ds d\tau + \frac{1}{4}\int_\eta^\xi\int_0^\eta b(\tau,s)\,G_c(\tau,s)\,ds d\tau,\end{aligned}$$

where

$$(44)\qquad \xi = x + y,\ \eta = x - y,$$

$$(45)\qquad G(\xi,\eta) = k\left(\frac{\xi+\eta}{2},\frac{\xi-\eta}{2}\right),\ G_c(\xi,\eta) = k_c\left(\frac{\xi+\eta}{2},\frac{\xi-\eta}{2}\right),$$

$$(46)\qquad b(\xi,\eta) = \beta\left(\frac{\xi+\eta}{2},\frac{\xi-\eta}{2}\right),\ b_c(\xi,\eta) = \beta_c\left(\frac{\xi+\eta}{2},\frac{\xi-\eta}{2}\right).$$

Proof. Using the relations

$$(47)\qquad k_x(x,y) = G_\xi\frac{\partial\xi}{\partial x} + G_\eta\frac{\partial\eta}{\partial x} = G_\xi(\xi,\eta) + G_\eta(\xi,\eta),$$

$$(48)\qquad k_y(x,y) = G_\xi\frac{\partial\xi}{\partial y} + G_\eta\frac{\partial\eta}{\partial y} = G_\xi(\xi,\eta) - G_\eta(\xi,\eta),$$

$$\begin{aligned}k_{xx}(x,y) &= \frac{\partial}{\partial\xi}\left(G_\xi(\xi,\eta) + G_\eta(\xi,\eta)\right)\frac{\partial\xi}{\partial x} + \frac{\partial}{\partial\eta}\left(G_\xi(\xi,\eta) + G_\eta(\xi,\eta)\right)\frac{\partial\eta}{\partial x}\\ &= G_{\xi\xi}(\xi,\eta) + 2G_{\eta\xi}(\xi,\eta) + G_{\eta\eta}(\xi,\eta),\end{aligned}\qquad(49)$$

$$\begin{aligned}k_{yy}(x,y) &= \frac{\partial}{\partial\xi}\left(G_\xi(\xi,\eta) - G_\eta(\xi,\eta)\right)\frac{\partial\xi}{\partial y} + \frac{\partial}{\partial\eta}\left(G_\xi(\xi,\eta) - G_\eta(\xi,\eta)\right)\frac{\partial\eta}{\partial y}\\ &= G_{\xi\xi}(\xi,\eta) - 2G_{\eta\xi}(\xi,\eta) + G_{\eta\eta}(\xi,\eta),\end{aligned}\qquad(50)$$

(22)–(23) with boundary conditions (24)–(27) are transformed to

$$G_{\eta\xi}(\xi,\eta)=\frac{1}{4}\left[b(\xi,\eta)G(\xi,\eta)+b_c(\xi,\eta)G_c(\xi,\eta)\right], \tag{51}$$

$$G_{c,\eta\xi}(\xi,\eta)=\frac{1}{4}\left[-b_c(\xi,\eta)G(\xi,\eta)+b(\xi,\eta)G_c(\xi,\eta)\right], \tag{52}$$

$$G(\xi,0)=-\frac{1}{4}\int_0^{\xi}b(\tau,0)\,d\tau, \tag{53}$$

$$G_c(\xi,0)=\frac{1}{4}\int_0^{\xi}b_c(\tau,0)\,d\tau, \tag{54}$$

$$G(\xi,\xi)=0, \tag{55}$$

$$G_c(\xi,\xi)=0. \tag{56}$$

Integrating (51) and (52) with respect to η from 0 to η, we obtain

$$\begin{aligned}G_\xi(\xi,\eta)-G_\xi(\xi,0)=&\frac{1}{4}\int_0^{\eta}b(\xi,s)G(\xi,s)\,ds\\&+\frac{1}{4}\int_0^{\eta}b_c(\xi,s)G_c(\xi,s)\,ds,\end{aligned} \tag{57}$$

$$\begin{aligned}G_{c,\xi}(\xi,\eta)-G_{c,\xi}(\xi,0)=&-\frac{1}{4}\int_0^{\eta}b_c(\xi,s)G(\xi,s)\,ds\\&+\frac{1}{4}\int_0^{\eta}b(\xi,s)G_c(\xi,s)\,ds.\end{aligned} \tag{58}$$

Integrating (57) and (58) with respect to ξ from η to ξ, and using (53)–(56) we obtain (42)–(43). □

6. Analysis of the integral equation.

THEOREM 4. *Equation* (22)–(23) *with boundary conditions* (24)–(27) *has a unique* $C^2(\overline{T})$ *solution satisfying*

$$|k(x,y)|\le Me^{2Mx}, \tag{59}$$

$$|k_c(x,y)|\le Me^{2Mx}, \tag{60}$$

where M *depends only on* a_1, $a_2(\cdot)$, $a_3(\cdot)$, $f_R(\cdot)$, $f_I(\cdot)$, *and is given in* (65).

Proof. Set

$$G_0(\xi,\eta)=-\frac{1}{4}\int_\eta^{\xi}b(\tau,0)\,d\tau, \tag{61}$$

$$G_{n+1}(\xi,\eta)=\frac{1}{4}\int_\eta^{\xi}\int_0^{\eta}b(\tau,s)G_n(\tau,s)\,ds d\tau+\frac{1}{4}\int_\eta^{\xi}\int_0^{\eta}b_c(\tau,s)G_{c,n}(\tau,s)\,ds d\tau, \tag{62}$$

$$G_{c,0}(\xi,\eta)=\frac{1}{4}\int_\eta^{\xi}b_c(\tau,0)\,d\tau, \tag{63}$$

and

$$G_{c,n+1}=-\frac{1}{4}\int_\eta^{\xi}\int_0^{\eta}b_c(\tau,s)G_n(\tau,s)\,ds d\tau+\frac{1}{4}\int_\eta^{\xi}\int_0^{\eta}b(\tau,s)G_{c,n}(\tau,s)\,ds d\tau. \tag{64}$$

Denote

$$B = \sup_{(\xi,\eta)\in\mathcal{T}_1} |b(\xi,\eta)|,\ B_c = \sup_{(\xi,\eta)\in\mathcal{T}_1} |b_c(\xi,\eta)|,\ M = \max\{B, B_c\}, \tag{65}$$

where $\mathcal{T}_1 \triangleq \{\xi,\eta : 0 < \xi < 2, 0 < \eta < \min(\xi, 2-\xi)\}$. For $G_0(\xi,\eta)$ and $G_{c,0}(\xi,\eta)$ we have

$$|G_0(\xi,\eta)| \le \frac{1}{4}\int_\eta^\xi |b(\tau,0)|\,d\tau \le \frac{1}{4}B(\xi-\eta) \le \frac{B}{2}, \tag{66}$$

$$|G_{c,0}(\xi,\eta)| \le \frac{1}{4}\int_\eta^\xi |b_c(\tau,0)|\,d\tau \le \frac{1}{4}B_c(\xi-\eta) \le \frac{B_c}{2}, \tag{67}$$

where we have used the fact that $0 < \xi - \eta < 2$. Suppose that

$$|G_n(\xi,\eta)| \le MK^n\frac{(\xi+\eta)^n}{n!}, \tag{68}$$

$$|G_{c,n}(\xi,\eta)| \le MK^n\frac{(\xi+\eta)^n}{n!}, \tag{69}$$

where $K > 0$ is a constant that will be determined later. Clearly, (68)–(69) hold for $n = 0$. Noting that

$$\begin{aligned}
\int_\eta^\xi\int_0^\eta |G_n(\tau,s)|\,ds d\tau &\le \frac{MK^n}{n!}\int_\eta^\xi\int_0^\eta (\tau+s)^n\,ds d\tau \\
&= \frac{MK^n}{(n+1)!}\int_\eta^\xi \left[(\tau+\eta)^{n+1} - \tau^{n+1}\right]d\tau \\
&\le \frac{MK^n}{(n+1)!}\int_\eta^\xi (\tau+\eta)^{n+1}\,d\tau \\
&\le \frac{MK^n}{(n+1)!}\int_\eta^\xi (\xi+\eta)^{n+1}\,d\tau \\
&\le 2MK^n\frac{(\xi+\eta)^{n+1}}{(n+1)!}, \qquad (70)
\end{aligned}$$

we obtain from (62) that

$$|G_{n+1}(\xi,\eta)| \le \frac{1}{2}M(B+B_c)K^n\frac{(\xi+\eta)^{n+1}}{(n+1)!}, \tag{71}$$

and from (64) that $|G_{c,n+1}(\xi,\eta)|$ satisfies the same bound (71). Therefore, setting $K = M$, we obtain

$$|G_{n+1}(\xi,\eta)| \le MK^{n+1}\frac{(\xi+\eta)^{n+1}}{(n+1)!}, \tag{72}$$

$$|G_{c,n+1}(\xi,\eta)| \le MK^{n+1}\frac{(\xi+\eta)^{n+1}}{(n+1)!}. \tag{73}$$

Thus, (68) and (69) are proved by induction, and the series

$$G(\xi,\eta) = \sum_{n=0}^\infty G_n(\xi,\eta) \text{ and } G_c(\xi,\eta) = \sum_{n=0}^\infty G_{c,n}(\xi,\eta) \tag{74}$$

converge uniformly in $\overline{\mathcal{T}}_1$, and is a solution of (42)–(43). G and G_c are $C^2\left(\overline{\mathcal{T}}_1\right)$ since b and b_c are $C^1\left(\overline{\mathcal{T}}_1\right)$. The bounds (59)–(60) follow from (68)–(69), (74), and the fact that $K = M$. It can be shown by the method of successive approximations that if $(G_1, G_{c,1})$ and $(G_2, G_{c,2})$ are two different solutions of (42)–(43), the resulting homogeneous integral equation for $(G, G_c) = (G_1 - G_2, G_{c,1} - G_{c,2})$ has a unique solution $(G, G_c) = 0$, which proves that the solution (74) is unique. We can check that (74) satisfies (51)–(56) by direct substitution. Equations (51)–(56) have a unique solution by Lemma 3. □

Exponential stability of the target system (19)–(21) in the L_2 and H_1 norms is proved in the next section. In order to be able to imply stability of the closed loop system (7)–(10) from that result, we need to establish equivalence of norms of (ρ, ι) and $(\tilde{\rho}, \tilde{\iota})$ in L_2 and H_1. This is done by proving that transformation (17)–(18) is invertible. The inverse transformation has the form

$$\rho(x,t) = \tilde{\rho}(x,t) - \int_0^x \left[l(x,y)\,\tilde{\rho}(y,t) + l_c(x,y)\,\tilde{\iota}(y,t)\right] dy, \tag{75}$$

$$\iota(x,t) = \tilde{\iota}(x,t) - \int_0^x \left[-l_c(x,y)\,\tilde{\rho}(y,t) + l(x,y)\,\tilde{\iota}(y,t)\right] dy. \tag{76}$$

The following result holds for the kernels $l(x,y)$ and $l_c(x,y)$ of transformation (75)–(76).

THEOREM 5. *If the pair of kernels, $l(x,y)$ and $l_c(x,y)$, satisfy the partial differential equation*

$$l_{xx} = l_{yy} - \beta(y,x)l - \beta_c(y,x)l_c, \tag{77}$$

$$l_{c,xx} = l_{c,yy} + \beta_c(y,x)l - \beta(y,x)l_c, \tag{78}$$

with boundary conditions

$$l(x,x) = \frac{1}{2}\int_0^x \beta(\gamma,\gamma)d\gamma, \tag{79}$$

$$l_c(x,x) = -\frac{1}{2}\int_0^x \beta_c(\gamma,\gamma)d\gamma, \tag{80}$$

$$l(x,0) = 0, \tag{81}$$

$$l_c(x,0) = 0, \tag{82}$$

and if $(\tilde{\rho}, \tilde{\iota})$ satisfies (19)–(21), *then (ρ, ι) satisfies* (7)–(10) *with* (14)–(15). *System* (77)–(82) *has a unique $C^2\left(\overline{\mathcal{T}}\right)$ solution satisfying*

$$|l(x,y)| \le Me^{2Mx}, \tag{83}$$

$$|l_c(x,y)| \le Me^{2Mx}, \tag{84}$$

where M is given in (65).

Proof. The proof is similar to those of Lemmas 2 and 3, and Theorem 4. □

7. Stability analysis.

THEOREM 6. *Suppose $c > 0$, and select $f_R(x)$ and $f_I(x)$ such that*

$$\sup_{x\in[0,1]} \left(f_R(x) + \frac{1}{2}\left|f_I'(x)\right|\right) \le -\frac{1}{2}c. \tag{85}$$

Then the solution $(\tilde{\rho},\tilde{\iota})\equiv(0,0)$ *of system* (19)–(21) *is exponentially stable in the* $L_2(0,1)$ *and* $H_1(0,1)$ *norms.*

COROLLARY 7. *Suppose* $c>0$*, and set* $f_R(x)=-c$ *and* $f_I(x)\equiv 0$*. Then the solution* $(\tilde{\rho},\tilde{\iota})\equiv(0,0)$ *of system* (19)–(21) *is exponentially stable in the* $L_2(0,1)$ *and* $H_1(0,1)$ *norms.*

Proof. Consider the function

$$E(t)=\frac{1}{2}\int_0^1\left(\tilde{\rho}(x,t)^2+\tilde{\iota}(x,t)^2\right)dx. \tag{86}$$

Its time derivative along solutions of system (19)–(21) is

$$\begin{aligned}\dot{E}(t)&=\int_0^1\left[\tilde{\rho}\left(a_R\tilde{\rho}_{xx}+f_R(x)\tilde{\rho}-a_I\tilde{\iota}_{xx}-f_I(x)\tilde{\iota}\right)\right.\\&\qquad\left.+\tilde{\iota}\left(a_I\tilde{\rho}_{xx}+f_I(x)\tilde{\rho}+a_R\tilde{\iota}_{xx}+f_R(x)\tilde{\iota}\right)\right]dx\\&=\int_0^1\left(\tilde{\rho}\left(a_R\tilde{\rho}_{xx}+f_R(x)\tilde{\rho}-a_I\tilde{\iota}_{xx}\right)+\tilde{\iota}\left(a_I\tilde{\rho}_{xx}+a_R\tilde{\iota}_{xx}+f_R(x)\tilde{\iota}\right)\right)dx\\&=-\int_0^1 a_R\left(\tilde{\rho}_x^2+\tilde{\iota}_x^2\right)dx+\int_0^1 f_R(x)\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx+a_I\int_0^1\left(\tilde{\rho}_x\tilde{\iota}_x-\tilde{\iota}_x\tilde{\rho}_x\right)dx\\&\le\int_0^1 f_R(x)\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx.\end{aligned} \tag{87}$$

So, from (85), and the comparison principle, we have

$$E(t)\le E(0)e^{-ct}\text{ for }t\ge 0. \tag{88}$$

Set

$$V(t)=\frac{1}{2}\int\left(\tilde{\rho}_x^2(x,t)+\tilde{\iota}_x^2(x,t)\right)dx. \tag{89}$$

The time derivative of $V(t)$ along solutions of system (19)–(21) is

$$\begin{aligned}\dot{V}(t)&=\int_0^1\left(\tilde{\rho}_x\tilde{\rho}_{xt}+\tilde{\iota}_x\tilde{\iota}_{xt}\right)dx\\&=-\int_0^1\left(\tilde{\rho}_{xx}\tilde{\rho}_t+\tilde{\iota}_{xx}\tilde{\iota}_t\right)dx\\&=-\int_0^1\left[\tilde{\rho}_{xx}\left(a_R\tilde{\rho}_{xx}+f_R(x)\tilde{\rho}-a_I\tilde{\iota}_{xx}-f_I(x)\tilde{\iota}\right)\right.\\&\qquad\left.+\tilde{\iota}_{xx}\left(a_I\tilde{\rho}_{xx}+f_I(x)\tilde{\rho}+a_R\tilde{\iota}_{xx}+f_R(x)\tilde{\iota}\right)\right]dx\\&=-a_R\int_0^1\left(\tilde{\rho}_{xx}^2+\tilde{\iota}_{xx}^2\right)dx+\int_0^1 f_R(x)\left(\tilde{\rho}_x^2+\tilde{\iota}_x^2\right)dx\\&\quad+\int_0^1 f_I'(x)\left(\tilde{\iota}_x\tilde{\rho}-\tilde{\rho}_x\tilde{\iota}\right)dx-\frac{1}{2}\int_0^1 f_R''(x)\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx\\&\le\int_0^1 f_R(x)\left(\tilde{\rho}_x^2+\tilde{\iota}_x^2\right)dx+\int_0^1 f_I'(x)\left(\tilde{\iota}_x\tilde{\rho}-\tilde{\rho}_x\tilde{\iota}\right)dx-\frac{1}{2}\int_0^1 f_R''(x)\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx\\&\le\int_0^1\left(f_R(x)+\frac{1}{2}\left|f_I'(x)\right|\right)\left(\tilde{\rho}_x^2+\tilde{\iota}_x^2\right)dx+\frac{1}{2}\int_0^1\left(\left|f_I'(x)\right|-f_R''(x)\right)\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx\\&\le\int_0^1\left(f_R(x)+\frac{1}{2}\left|f_I'(x)\right|\right)\left(\tilde{\rho}_x^2+\tilde{\iota}_x^2\right)dx+\frac{1}{2}c_2\int_0^1\left(\tilde{\rho}^2+\tilde{\iota}^2\right)dx,\end{aligned}$$

$$\le-\frac{c}{2}V(t)+c_2E(0)e^{-ct}, \tag{90}$$

where we have used (85) and defined

$$c_2 \triangleq \max\left\{\sup_{x\in[0,1]}\left(\left|f_I'(x)\right| - f_R''(x)\right), 0\right\}. \tag{91}$$

From the comparison principle, we get

$$V(t) \le \left(V(0) + 2\frac{c_2}{c}E(0)\right)e^{-\frac{c}{2}t} - 2\frac{c_2}{c}E(0)\,e^{-ct}, \tag{92}$$

so we obtain

$$V(t) \le \left(V(0) + \frac{2c_2}{c}E(0)\right)e^{-\frac{c}{2}t} \text{ for } t \ge 0. \tag{93}$$

Since (Poincaré inequality)

$$E(t) \le \frac{1}{2}V(t), \tag{94}$$

we get

$$V(t) \le c_3 V(0)\,e^{-\frac{c}{2}t} \text{ for } t \ge 0, \tag{95}$$

with $c_3 = 1 + c_2/c$. □

8. Proof of Theorem 1. From Theorem 6, $(\tilde{\rho}, \tilde{\iota}) = 0$ is exponentially stable in the L_2 and H_1 norms. Since Theorems 4 and 5 establish equivalence of norms of (ρ, ι) and $(\tilde{\rho}, \tilde{\iota})$ in L_2 and H_1, the stability statements of Theorem 6 also hold for the solution $(\rho, \iota) \equiv (0, 0)$ of system (7)–(8). From standard results for uniformly parabolic[1] equations (see, for instance, [4]), it follows that system (19)–(20), with Dirichlet boundary conditions (21) and initial data $\tilde{\rho}_0, \tilde{\iota}_0 \in L_\infty(0,1)$, has a unique classical solution $\tilde{\rho}, \tilde{\iota} \in C^{2,1}((0,1)\times(0,\infty))$. The smoothness properties of k, k_c, l, and l_c stated in Theorems 4 and 5 then provide well posedness of system (7)–(10) in closed loop with (14)–(15).

9. Application to a model of vortex shedding. The objective of this section is to provide a numerical demonstration of our results applied to a fluid flow control problem. An interesting feature of the system we study in this example, is that it is defined on an infinite domain ($x_d \to \infty$), yet, we obtain feedback gain kernels which have compact support.

9.1. The model. In flows past submerged obstacles, the phenomenon of vortex shedding occurs provided the Reynolds number is sufficiently large. A popular prototype model flow for studying vortex shedding, is the flow past a two-dimensional circular cylinder, as sketched in Figure 1. The vortices, which are alternatively shed from the upper and lower sides of the cylinder, induce an undesirable periodic force that acts on the cylinder. The dynamics of the cylinder wake, often referred to as the von Kármán vortex street, is governed by the Navier–Stokes equation, however, in [13], a simplified model was suggested in terms of the Ginzburg–Landau equation

$$\frac{\partial A}{\partial t} = a_1\frac{\partial^2 A}{\partial \breve{x}^2} + a_2(\breve{x})\frac{\partial A}{\partial \breve{x}} + a_3(\breve{x})A + a_4|A|^2 A + \delta(\breve{x})u, \tag{96}$$

[1]System (19)–(20) is uniformly parabolic in $(0,1)$, with module of parabolicity a_R.

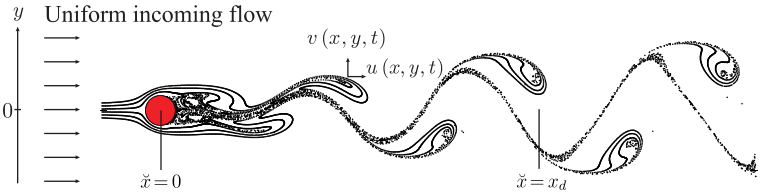

FIG. 1. *Vortex shedding from a cylinder visualized by passive tracer particles.*

where $\breve{x} \in \mathbb{R}$, $A : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{C}$, $a_1, a_4 \in \mathbb{C}$, and $a_2, a_3 : \mathbb{R} \to \mathbb{C}$. δ denotes the Dirac distribution and $u : \mathbb{R}_+ \to \mathbb{C}$ is the control input. Thus, actuation is in the form of local forcing at $\breve{x} = 0$, which is the location of the cylinder. The boundary conditions are $A(\pm\infty, t) = 0$, that is, homogeneous Dirichlet boundary conditions. $A(x, t)$ may represent any physical variable (velocities (u, v) or pressure p), or derivations thereof, along the centerline $y = 0$, see Figure 1. The choice will have an impact on the performance of the Ginzburg–Landau model, and associating A with the transverse fluctuating velocity $v(x, y = 0, t)$ seems to be a particularly good choice [11]. In order to implement the scheme in practice, transfer functions between $A(0)$ and the physical actuation, and the physical sensing and $A(x)$, would have to be determined, either experimentally or computationally. The physical actuation could for instance be micro/synthetic jet actuators distributed on the cylinder surface. Numerical values for the coefficients in (96) were determined from experiments in [13], and are reproduced in Appendix A.

We now simplify this problem to fit into the framework of the previous analysis. We linearize around the zero-solution, discard the upstream subsystem by replacing the local forcing at $\breve{x} = 0$ with boundary input at this location, and truncate the downstream subsystem at some $x_d > 0$. The resulting system is of the form (1)–(3), defined on the interval $[0, x_d]$. We justify the truncation of the system by noting that the upstream subsystem (the region to the left of the cylinder in Figure 1) is approximately uniform flow, whereas the downstream subsystem (the region to the right of the cylinder in Figure 1) can be approximated to any desired level of accuracy by selecting x_d sufficiently large. We are now in a position to apply our results, and we will do so for different choices of x_d.

In this numerical example, we set the Reynolds[2] number to $R = 50$, which corresponds to supercritical flow for which vortex shedding will occur in the uncontrolled case. For this choice of Reynolds number, the numerical coefficients of (7)–(8) derived from the coefficients given in Appendix A are $a_R = 0.156/x_d^2$, $a_I = 0$, and $b_R(x)$ and $b_I(x)$ are plotted in Figure 2 for $x_d = 2.5$, $x_d = 5$, and $x_d = 7.5$.

9.2. Feedback kernels. In terms of the feedback gain kernels, $k(1, x)$ and $k_c(1, x)$, the boundary feedback (2) is given by

$$u(t) = \int_0^{x_d} \frac{1}{x_d} \left(k\left(1, \frac{x_d - \breve{x}}{x_d}\right) - ik_c\left(1, \frac{x_d - \breve{x}}{x_d}\right)\right) \times \exp\left(\frac{1}{2a_1}\int_0^{\breve{x}} a_2(\tau)\, d\tau\right) A(\breve{x}, t)\, d\breve{x}. \tag{97}$$

[2]The Reynolds number for flow past a circular cylinder is usually defined as $R = \rho U_\infty D/\mu$, where U_∞ is the free stream velocity, D is the cylinder diameter, and ρ and μ are density and viscosity of the fluid, respectively. Vortex shedding occurs when $R > 47$.

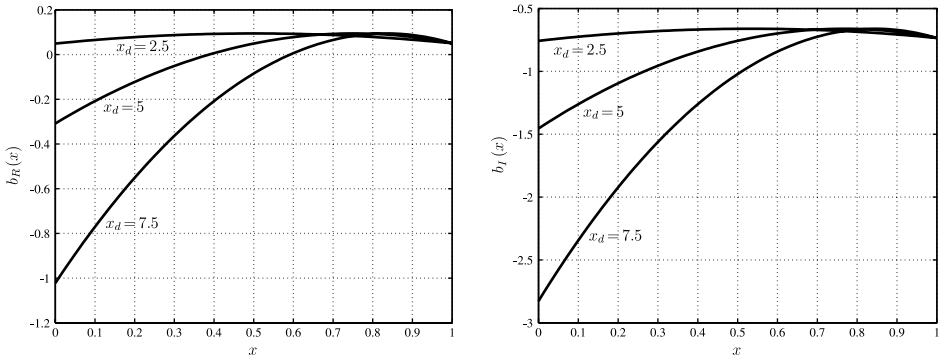

FIG. 2. $b_R(x)$ *and* $b_I(x)$ *for* $x_d = 2.5$, $x_d = 5$, *and* $x_d = 7.5$.

Thus, the feedback gain kernel for the original system (1)–(3) is complex-valued, and given by

$$k_u(\breve{x}) = \frac{1}{x_d}\left(k\left(1, \frac{x_d - \breve{x}}{x_d}\right) - ik_c\left(1, \frac{x_d - \breve{x}}{x_d}\right)\right)\exp\left(\frac{1}{2a_1}\int_0^{\breve{x}} a_2(\tau)\, d\tau\right). \tag{98}$$

Setting $f_R(x) = -0.2$ and $f_I(x) = 0$, exponential stability is assured by Corollary 7, and the stabilizing feedback gain kernel (98) can be calculated numerically using formulas (61)–(64), (74), (45)–(46), and (98). Figure 3 shows the feedback gain kernel (98) for $x_d = 2.5$, $x_d = 5$, and $x_d = 7.5$. It is clear that the feedback gain kernels grow rather rapidly with increasing x_d, which is an undesirable feature since we want to make x_d large in order to minimize the effect of truncating the downstream subsystem. The increase can be seen in connection with Figure 2, which shows that the absolute values of the differences $b_R(x) - f_R(x)$ and $b_I(x) - f_I(x)$ increase with increasing x_d. In other words, the control effort needed to change the dynamics of system (7)–(10) into that of (19)–(21) increases with the degree to which the two systems differ. Therefore, the functions $f_R(x)$ and $f_I(x)$ must be chosen more intelligently than the simple case of setting them constant. Theorem 6 allows some flexibility in choosing $f_R(x)$ and $f_I(x)$ within the constraints of (85). In order to postpone choosing x_d, we study f_R, f_I, b_R, and b_I as functions of $\breve{x}$ rather than x in the following. This is convenient since f_R, f_I, b_R, and b_I are invariant of x_d when treated as functions of $\breve{x}$. Recall that when x_d is chosen, the two domains are related by $x = (x_d - \breve{x})/x_d$. We propose to choose $f_R(\breve{x})$ and $f_I(\breve{x})$ as close to $b_R(\breve{x})$ and $b_I(\breve{x})$ as possible, without violating the conditions of Theorem 6, which we now write

$$\sup_{\breve{x}}\left(f_R(\breve{x}) + \frac{1}{2}\left|f_I'(\breve{x})\right|\right) \le -\frac{1}{2}c. \tag{99}$$

Towards that end, we first set them equal, that is $f_R(\breve{x}) = b_R(\breve{x})$ and $f_I(\breve{x}) = b_I(\breve{x})$, and plot (99) along with $-\frac{1}{2}c = -0.2$. The result is shown in Figure 4, for $\breve{x} \in [0, 20]$. The figure shows that the conditions for stability are already satisfied, without control, for $\breve{x} \in [x_s, 20]$ (in fact, the stability conditions are satisfied for $\breve{x} \in [x_s, \infty)$), which means that it suffices to alter $f_R(\breve{x})$ and $f_I(\breve{x})$ in $[0, x_s)$ in order to satisfy (99). Thus,

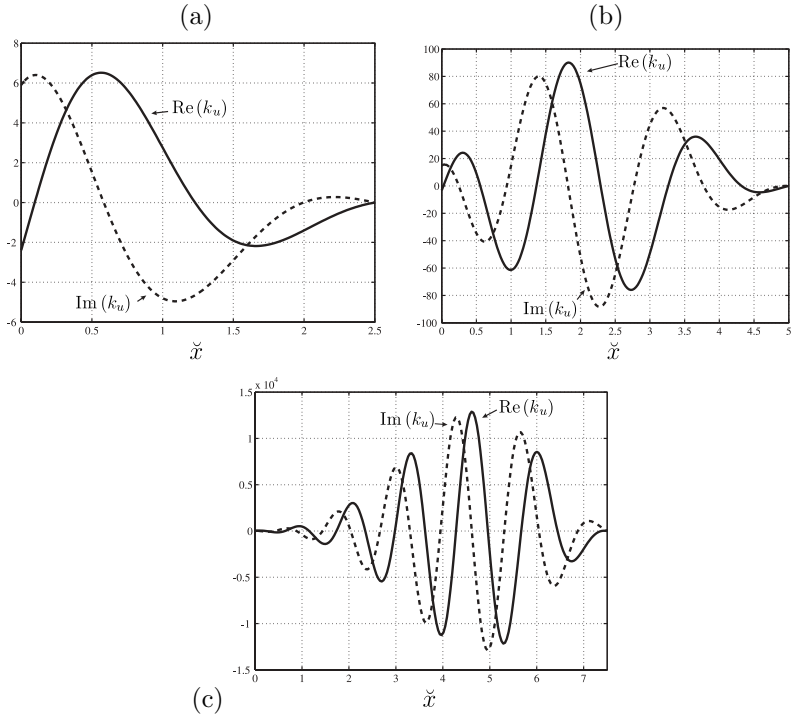

FIG. 3. *Feedback kernel* (98) *for* (a) $x_d = 2.5$, (b) $x_d = 5$, *and* (c) $x_d = 7,5$. $f_R(x) = -0.2$, *and* $f_I(x) = 0$.

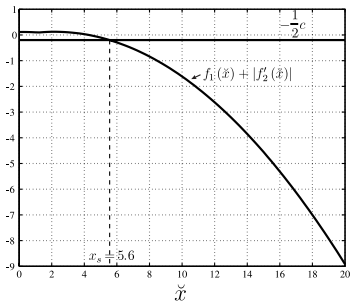

FIG. 4. *The stability criterion* (99), *when* $f_R(\breve{x}) = b_R(\breve{x})$ *and* $f_I(\breve{x}) = b_I(\breve{x})$, *is satisfied for* $\breve{x} \geq x_s$.

we set[3]

$$f_R(\breve{x}) = \begin{cases} -\frac{1}{2}c - \frac{1}{2}\left|b_I'(\breve{x})\right| & \text{for } 0 \leq x < x_s, \\ b_R(\breve{x}) & \text{for } \breve{x} \geq x_s, \end{cases} \tag{100}$$

$$f_I(\breve{x}) = b_I(\breve{x}) \text{ for all } \breve{x}. \tag{101}$$

With these choices of $f_R(\breve{x})$ and $f_I(\breve{x})$, we calculate numerically the stabilizing

[3]By the choice of x_s, $f_R(\breve{x})$ is continuous. In this example, we ignore the fact that our choice of $f_R(\breve{x})$ may not be C^1, although this can easily be achieved by smoothing $f_R(\breve{x})$ in a small neighborhood of x_s.

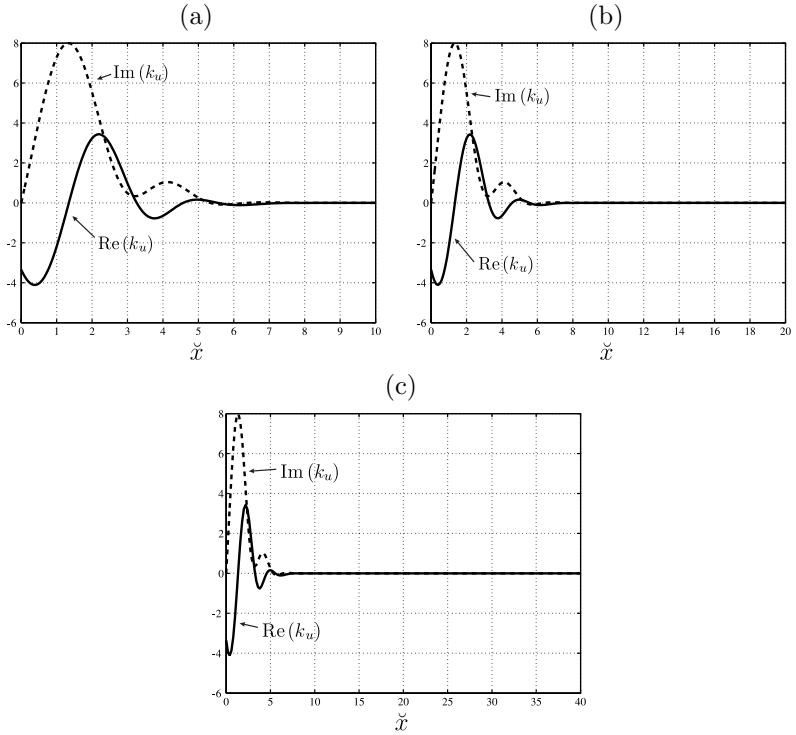

FIG. 5. *Feedback kernels* (98) *for* $f_R(\breve{x})$ *and* $f_I(\breve{x})$ *as defined in* (100)–(101)*, and for* $x_d = 10$ (a), 20 (b), *and* 40 (c).

feedback gain kernel (98) for $x_d = 10$, $x_d = 20$, and $x_d = 40$. Figure 5 shows the result. As expected, the feedback gain kernels look similar, and in particular, they appear to be zero for $\breve{x}$ larger than approximately 7.5. In fact, they are identical and have compact support, as stated formally in the next theorem.

THEOREM 8. *Given* $c > 0$*, suppose there exists* $x_s \in (0, \infty)$ *such that*

$$b_R(\breve{x}) + \frac{1}{2}\left|b_I'(\breve{x})\right| \leq -\frac{1}{2}c \quad \text{for } \breve{x} \geq x_s. \tag{102}$$

Then $f_R(\breve{x})$ *and* $f_I(\breve{x})$*, satisfying* (99)*, can be chosen such that* $f_R(\breve{x}) = b_R(\breve{x})$ *and* $f_I(\breve{x}) = b_I(\breve{x})$ *for* $\breve{x} \in [x_s, x_d]$*. The resulting stabilizing feedback gain kernel* (98) *has compact support contained in* $[0, 2x_s]$*. Moreover, all choices of* $x_d \geq 2x_s$ *will produce the same stabilizing feedback gain kernel* (98) *in* $[0, 2x_s]$*.*

Proof. The existence of $f_R(\breve{x})$ and $f_I(\breve{x})$ satisfying the criterion for stability (99) follows trivially from (102). To prove that the kernel has support contained in $[0, 2x_s]$, we show that it is identically zero outside this interval. We have that

$$b(\xi, 0) = \beta(x, x) = 0, \tag{103}$$

$$b_c(\xi, 0) = \beta_c(x, x) = 0 \tag{104}$$

for

$$\xi \in \left[0, 2\left(1 - \frac{x_s}{x_d}\right)\right). \tag{105}$$

It follows that

$$G_0(\xi,\eta)=0,\ G_{c,0}(\xi,\eta)=0 \text{ for } (\xi,\eta)\in\mathcal{T}_1,\ \xi\le 2\left(1-\frac{x_s}{x_d}\right). \tag{106}$$

Now, suppose that

$$G_n(\xi,\eta)=0,\ G_{c,n}(\xi,\eta)=0 \text{ for } (\xi,\eta)\in\mathcal{T}_1,\ \xi\le 2\left(1-\frac{x_s}{x_d}\right). \tag{107}$$

From (62) and (64), we get

$$G_{n+1}(\xi,\eta)=0\ G_{c,n+1}(\xi,\eta)=0,\ \text{for } (\xi,\eta)\in\mathcal{T}_1,\ \xi\le 2\left(1-\frac{x_s}{x_d}\right). \tag{108}$$

Thus, (107) is proved by induction, and

$$\left.\begin{array}{c} k(1,y)=G(1+y,1-y)=0 \\ k_c(1,y)=G_c(1+y,1-y)=0 \end{array}\right\} \text{ for } 0\le y\le 2\left(1-\frac{x_s}{x_d}\right)-1. \tag{109}$$

Therefore, $k_u(\breve{x})=0$ for

$$0\le\frac{x_d-\breve{x}}{x_d}\le 2\left(1-\frac{x_s}{x_d}\right)-1, \tag{110}$$

which yields

$$x_d\ge\breve{x}\ge 2x_s. \tag{111}$$

In order to prove the last part of the theorem, we need to show that for any $x_{d,1},x_{d,2}\in[2x_s,\infty)$,

$$\left.\begin{array}{c} \frac{1}{x_{d,1}}k_{x_{d,1}}\left(1,\frac{x_{d,1}-\breve{x}}{x_{d,1}}\right)=\frac{1}{x_{d,2}}k_{x_{d,2}}\left(1,\frac{x_{d,2}-\breve{x}}{x_{d,2}}\right) \\ \frac{1}{x_{d,1}}k_{c,x_{d,1}}\left(1,\frac{x_{d,1}-\breve{x}}{x_{d,1}}\right)=\frac{1}{x_{d,2}}k_{c,x_{d,2}}\left(1,\frac{x_{d,2}-\breve{x}}{x_{d,2}}\right) \end{array}\right\} \text{ for } \breve{x}\in[0,2x_s], \tag{112}$$

where the additional subscripts, $x_{d,1}$ and $x_{d,2}$, on variables identify the domain of the problem from which they stem. We have

$$k_{x_d}\left(1,\frac{x_d-\breve{x}}{x_d}\right)=G_{x_d}\left(2-\frac{1}{x_d}\breve{x},\frac{1}{x_d}\breve{x}\right). \tag{113}$$

From (103)–(105) it follows that

$$x_dG_{0,x_d}\left(2-\frac{1}{x_d}\breve{x},\frac{1}{x_d}\breve{x}\right)=-\frac{1}{4}\int_{\breve{x}}^{2x_s}b_{x_d}\left(2-\frac{1}{x_d}\tau,0\right)d\tau \tag{114}$$

for $x_d\ge 2x_s$. From the definition of b, we have that

$$x_{d,2}^2b_{x_{d,1}}\left(2-\frac{1}{x_{d,1}}\tau,0\right)=x_{d,1}^2b_{x_{d,2}}\left(2-\frac{1}{x_{d,2}}\tau,0\right) \tag{115}$$

for $\tau\in[0,2x_s]$. It follows from (114)–(115) that

$$x_{d,2}G_{0,x_{d,1}}\left(2-\frac{1}{x_{d,1}}\breve{x},\frac{1}{x_{d,1}}\breve{x}\right)=x_{d,1}G_{0,x_{d,2}}\left(2-\frac{1}{x_{d,2}}\breve{x},\frac{1}{x_{d,2}}\breve{x}\right). \tag{116}$$

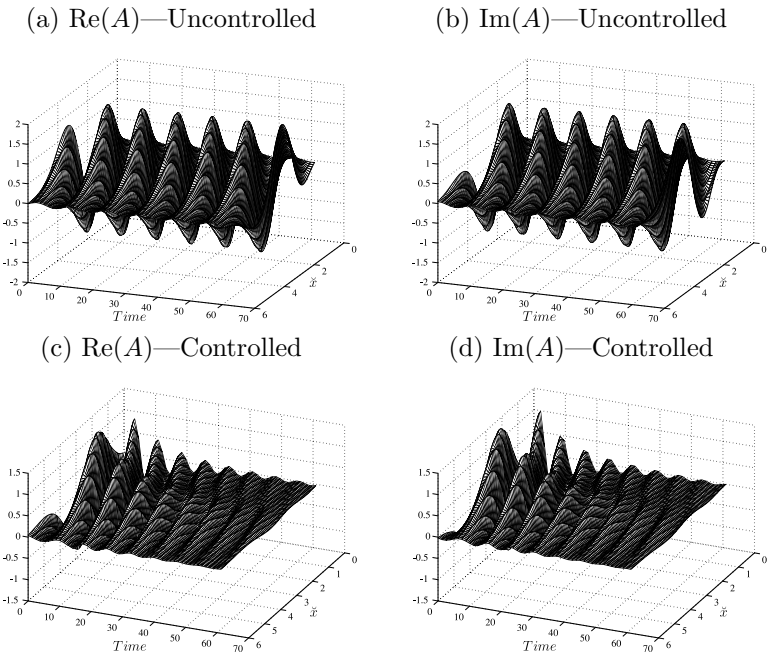

FIG. 6. *Comparison of the uncontrolled and controlled cases. For clarity, only a part of the computational domain is shown.*

Similar arguments for $G_{c,0}$, G_n, and $G_{c,n}$ yield

$$x_{d,2}G_{x_{d,1}}\left(2-\frac{1}{x_{d,1}}\breve{x},\frac{1}{x_{d,1}}\breve{x}\right)=x_{d,1}G_{x_{d,2}}\left(2-\frac{1}{x_{d,2}}\breve{x},\frac{1}{x_{d,2}}\breve{x}\right), \tag{117}$$

which in turn gives (112). □

The significance of Theorem 8 is that it guarantees stabilization of the system evolving on an infinite domain by solving the stabilization problem on a finite domain. The procedure for verifying the conditions of the theorem was demonstrated above, but for clarity we repeat it in the following remark.

Remark 9. The key to applying Theorem 8 is being able to find an x_s that satisfies (102). This is most easily done by inspecting a graph as the one shown in Figure 4. Once x_s is found, a possible choice of $f_R(\breve{x})$ and $f_I(\breve{x})$ is given in (100)–(101). Other choices are possible, and in particular, care should be taken to ensure necessary smoothness properties of $f_R(\breve{x})$. Also, note that the estimate for the support of (98) is not tight, as suggested by Figures 4 and 5, which indicate that $k_u(\breve{x})$ is supported on approximately $[0, 7.5]$ while $2x_s = 11.2$. Theorem 8 states that $[0, 7.5] \subseteq [0, 2x_s]$, which is true.

9.3. Numerical simulations. For completeness, we include numerical simulations of the controlled and uncontrolled systems. The simulations have been performed by discretizing (1) on the domain $\breve{x} \in [0, 15]$, using finite differences on a grid of 200 nodes. To make the simulation study more interesting, the nonlinear term in (96) is accounted for in the simulations. Figures 6(a) and 6(b) show the real and imaginary parts of $A(\breve{x}, t)$ for the uncontrolled case. The system is in a periodic state reminiscent of vortex shedding. Figures 6(c) and 6(d) show the real and imaginary parts of

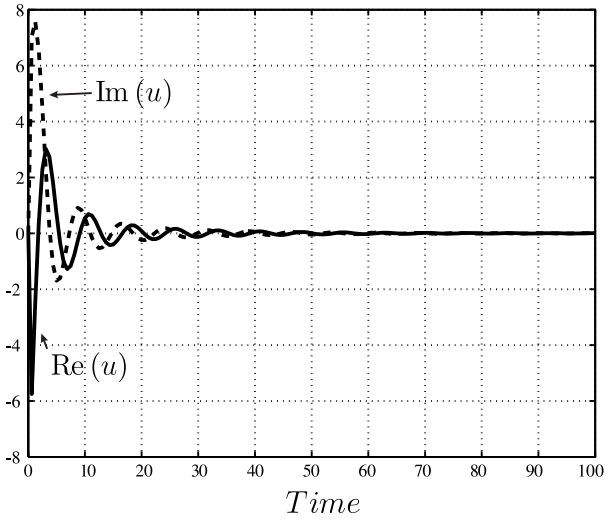

FIG. 7. *Control effort,* $u(t)$.

$A(\breve{x},t)$ for the controlled case. The figures show that $A(\breve{x},t)$ is effectively driven to zero by the control. Figure 7 shows the control effort.

10. Conclusions. This paper extends previous work in two ways: (1) it deals with two coupled partial differential equations, and (2) under certain circumstances handles equations defined on a semi-infinite domain. For the linearized Ginzburg–Landau equation, asymptotic stabilization is achieved by means of boundary control via state feedback in the form of an integral operator. The kernel of the operator is shown to be twice continuously differentiable, and a series approximation for its solution is given. Under certain conditions (given in (102)) on the parameters of the Ginzburg–Landau equation, compatible with vortex shedding modelling on a semi-infinite domain, the kernel is shown to have compact support, resulting in partial state feedback. Simulations are provided in order to demonstrate the performance of the controller.

Appendix A. Coefficients for the Ginzburg–Landau equation. The numerical coefficients below are taken from [13, Appendix A]

$$
\begin{aligned}
R_c &= 47,\\
x^t &= 1.183 - 0.031i,\\
\omega_0^t &= 0.690 + 0.080i + (-0.00159 + 0.00447i)(R - R_c),\\
k_0^t &= 1.452 - 0.844i + (0.00341 + 0.011i)(R - R_c),\\
\omega_{kk}^t &= -0.292i,\\
\omega_{xx}^t &= 0.108 - 0.057i,\\
k_x^t &= 0.164 - 0.006i,\\
\omega_0(\breve{x}) &= \omega_0^t + \frac{1}{2}\omega_{xx}^t\left(\breve{x} - x^t\right)^2,\\
k_0(\breve{x}) &= k_0^t + k_x^t\left(\breve{x} - x^t\right),
\end{aligned}
$$

$$
\begin{aligned}
a_1 &= \frac{1}{2} i \omega_{kk}^t, \\
a_2(\breve{x}) &= \omega_{kk}^t k_0(\breve{x}), \\
a_3(\breve{x}) &= -\left(\omega_0(\breve{x}) + \frac{1}{2}\omega_{kk}^t k_0^2(\breve{x})\right) i, \\
a_4 &= -0.0225 + 0.0671 i.
\end{aligned}
$$

Acknowledgment. We thank Professor Peter Monkewitz for helpful explanations on relationships between Navier–Stokes and Ginzburg–Landau models of vortex shedding and on implementability of GL-based controllers on NS simulations or experiments.

MULTIRATE PERIODIC SYSTEMS AND CONSTRAINED ANALYTIC FUNCTION INTERPOLATION PROBLEMS*

LI CHAI† AND LI QIU‡

Abstract. Multirate periodic systems and some related constrained analytic function interpolation problems are studied in this paper. After showing how to convert a general multirate periodic system to an equivalent linear time invariant (LTI) system with a structural constraint, we formulate some analytic function interpolation problems with such a constraint that can find various applications in the study of multirate and periodic systems. Both the solvability conditions and characterization of all solutions are presented to these constrained interpolation problems.

Key words. multirate systems, periodic systems, Nevanlinna–Pick interpolation

1. Introduction.

Periodic and multirate systems are finding more and more applications in control, signal processing, communication, econometrics, and numerical mathematics. There are several reasons for this.

• In signal processing, the use of periodic and multirate systems can often lead to the reduction of the required transmission rate, storage space, or computational complexity for a given task, depending on the application [24].

• In large-scale multivariable digital systems, often it is unrealistic, or sometimes impossible, to sample all physical signals uniformly at one single rate. In such situations, one is forced to use multirate sampling.

• Periodic and multirate systems can often achieve objectives that cannot be achieved by single rate systems. Examples include gain margin improvement and simultaneous stabilization [14].

The study of periodic systems can be traced back to [10]. Examples of more recent studies are [2, 15]. The study of multirate systems goes back to the late 1950s. A renewal of research on multirate systems has occurred since 1980 within the signal processing, communication, and control communities. The driving force for studying multirate systems in signal processing comes from the need for sampling rate conversion, subband coding, and their ability to generate wavelets. Multirate signal processing is now one of the most vibrant areas of research within the signal processing community; see the recent book [24] and references therein. In the communication community, blind identification and equalization call for the use of multirate sampling [23]. In the control community, two groups of research stand out: (i) using multirate control to achieve something that otherwise cannot be achieved by single rate control (see, for example, [14]) and (ii) optimal design of multirate controllers [7, 18].

A standard technique for treating periodic and multirate systems is called lifting in control theory [7, 14] and blocking in signal processing [15, 24]. First, we establish a setup of multirate periodic (MP) systems, which cover many familiar systems as special cases. Using the technique of lifting, an MP system can be converted to an equivalent linear time invariant (LTI) system satisfying a causality constraint that requires the feedthrough term to be block lower triangular. Motivated by this fact we propose and then study the problem of analytic function interpolation with an additional constraint that requires the value of the interpolating function at the origin to be block lower triangular [4, 5]. These constrained analytic function interpolation problems play the same role for multirate systems as their unconstrained counterparts do for single rate systems.

Analytic function interpolation problems have a very rich history in mathematics, and there has been a large volume of literature on this subject; see the recent books [1, 11, 13]. Many successful approaches have been proposed to solve the analytic function interpolation problems since the theory was first proposed at the beginning of the last century. In particular, Sarason [21] encompassed different classical interpolation problems in a representation theorem of operators commuting with special contractions, which was later developed to a general framework on commutant lifting theorem [11, 22]. On the other hand, using the realization method from the system theory, Ball, Gohberg, and Rodman [1] present another systematic way to deal with the interpolation of rational matrix functions. Recently, Foias et al. [12] combined the commutant lifting theorem from operator theory and state-space method from system theory to provide a unified approach for a more general setup of the problems, where they used the concept of operator-valued functions with operator arguments.

The increasing research interest on analytic function interpolation theory is also partly due to its wide applications in a variety of engineering problems such as those in control, circuit theory, and digital filter design [4, 8, 13]. The Nevanlinna–Pick (NP) interpolation theory was first brought into system theory by Youla and Saito, who gave a circuit theoretical proof of the Pick criterion [28]. In the early stage of the development of $\mathcal{H}_\infty$ control theory, the analytic function interpolation theory played a fundamental role [25]. A detailed review of this connection can be found in [13]. Recently, some new methods in high-resolution spectral estimation have been presented based on the NP interpolation with degree constraints [3]. The NP interpolation and Carathéodory–Fejér (CF) interpolation problems are also used extensively in robust model validation and identification [5, 6, 16].

In this paper, we propose a general model of multirate and periodic systems which covers single rate periodic systems and many other multirate systems in the literature as special cases. We also propose and solve some constrained analytic function interpolation problems that play the same role in multirate and periodic systems as the unconstrained counterparts do in single rate systems. That is, our results can be applied directly to multirate and periodic systems for $\mathcal{H}_\infty$ control, robust model validation and identification, etc. We present the necessary and sufficient solvability conditions and the parametrization of all solutions explicitly. The interpolation and distance problems involving analytic function with such structural constraints were first discussed in [13], but explicit solutions to the problem considered in this paper were not given there.

The notation used in this paper is standard. The real and complex numbers are denoted by $\mathbb{R}$ and $\mathbb{C}$, respectively. The open unit disc of the complex plane is denoted

by $\mathbb{D}$. Let

$$p = \begin{bmatrix} p_1 & \cdots & p_l \end{bmatrix} \text{ and } q = \begin{bmatrix} q_1 & \cdots & q_l \end{bmatrix} \tag{1.1}$$

be two vectors, where p_i and q_i, $i = 1, \ldots, l$, are nonnegative integers. Denote

$$|p| = \sum_{i=1}^{l} p_i \quad \text{and} \quad |q| = \sum_{i=1}^{l} q_i. \tag{1.2}$$

For $k = 0, \ldots, l$, define

$$\Pi_k(p) = \operatorname{diag}(0_{p_1}, \ldots, 0_{p_k}, I_{p_{k+1}}, \ldots, I_{p_l}), \tag{1.3}$$

$$\Pi_k(q) = \operatorname{diag}(0_{q_1}, \ldots, 0_{q_k}, I_{q_{k+1}}, \ldots, I_{q_l}), \tag{1.4}$$

where 0_n denote the $n \times n$ zero matrix and I_n the $n \times n$ unit matrix. Note that $\Pi_0(p) = I_{|p|}$, $\Pi_l(p) = 0_{|p|}$, $\Pi_0(q) = I_{|q|}$, and $\Pi_l(q) = 0_{|q|}$. The set of $|q| \times |p|$ matrices is denoted by $\mathbb{C}^{|q|\times|p|}$, and every such matrix is assumed to have an underlining partition so that its ijth block is q_i by p_j. Hence we have

$$\mathbb{C}^{|q|\times|p|} := \left\{ \begin{bmatrix} M_{11} & \cdots & M_{1l} \\ \vdots & \ddots & \vdots \\ M_{l1} & \cdots & M_{ll} \end{bmatrix} : M_{ij} \in \mathbb{C}^{q_i \times p_j} \right\}.$$

Note that the entry M_{ij} is "empty" if $q_i = 0$ or $p_j = 0$. The block lower triangular subset of $\mathbb{C}^{|q|\times|p|}$, denoted by $\mathcal{T}(q,p)$, consists of all matrices with $M_{ij} = 0, i < j$, and the strictly block lower triangular subset, $\mathcal{T}_s(q,p)$, consists of all matrices with $M_{ij} = 0, i \le j$. Let $\mathcal{H}_\infty^{|q|\times|p|}$ denote the Hardy class of all uniformly bounded analytic functions on $\mathbb{D}$ with values in $\mathbb{C}^{|q|\times|p|}$. For any $G(\lambda) \in \mathcal{H}_\infty^{|q|\times|p|}$, there exist $G_0, G_1, \ldots \in \mathbb{C}^{|q|\times|p|}$ such that $G(\lambda) = \sum_{m=0}^{\infty} \lambda^m G_m$ for $\lambda \in \mathbb{D}$.

2. Multirate periodic systems. To introduce the general setup of multirate periodic systems, we need the concept of signals with time-varying dimensions. A signal with time-varying dimensions is defined as

$$x = \{\ldots, x(-2), x(-1), |x(0), x(1), x(2), \ldots\},$$

where $x(k) \in \mathbb{R}^{p(k)}$ and $p(k)$ is a nonnegative integer for any k. Here the vertical line indicates the position of time zero. Note that when $p(k) = 0$, $x(k) \in \mathbb{R}^{p(k)}$ means that $x(k)$ is always equal to 0. If $p(k)$ is periodic with period l, i.e., $p(k+l) = p(k)$ for any k, we call x a signal with l-periodically time-varying dimensions. Define the l-step shift operator S^l as

$$\begin{aligned} &S^l\{\ldots, x(-1), |x(0), x(1), \ldots\} \\ &= \{\ldots, x(-l-1), |x(-l), x(-l+1), \ldots\}. \end{aligned} \tag{2.1}$$

Denote P_k as the truncation operator, i.e.,

$$P_k\{\ldots, x(k-1), x(k), x(k+1), \ldots\} = \{\ldots, x(k-1), x(k), 0, \ldots\}. \tag{2.2}$$

Consider the system G_{mp}, shown in Figure 2.1, where the input u with $u(k) \in \mathbb{R}^{p(k)}$ and output y with $y(k) \in \mathbb{R}^{q(k)}$ are signals with l-periodically time-varying dimensions; that is, $p(k)$ and $q(k)$ are periodic with period l. Assume that G_{mp} satisfy the following properties:

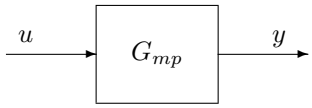

FIG. 2.1. *The multirate periodic system.*

(1) Linearity. The system G_{mp} is a linear operator.
(2) Periodicity. G_{mp} satisfies $G_{mp}S^l = S^l G_{mp}$, where S^l is given by (2.1).
(3) Causality. G_{mp} satisfies $P_k G_{mp}(I - P_k) = 0$, where P_k is given by (2.2).

In this paper, we focus on the systems that satisfy linear, periodic, and causal properties defined above. We call them multirate periodic (MP) systems. The general class of MP systems defined here covers many familiar classes of systems as special cases.

If $p(k) = p_1$ and $q(k) = q_1$ for all $k \in \mathbb{Z}$, then an MP system is a usual l-periodic system, for which there is a vast literature [2]. The multirate feature arises when $p(k)$ and $q(k)$ are truly time-varying. Let l be a multiple of m and n. If

$$u(k) \in \begin{cases} \mathbb{R}^{p_1} & \text{if } m|k \\ \{0\} & \text{otherwise} \end{cases} \quad \text{and} \quad y(k) \in \begin{cases} \mathbb{R}^{q_1} & \text{if } n|k \\ \{0\} & \text{otherwise} \end{cases},$$

then such an MP system is a dual rate system considered in [17]. Let l be a multiple of integers $m_i, i = 1, \ldots, s$, and $n_j, j = 1, \ldots, t$. If

$$u(k) = \begin{bmatrix} u_1(k) \\ \vdots \\ u_s(k) \end{bmatrix} \quad \text{and} \quad y(k) = \begin{bmatrix} y_1(k) \\ \vdots \\ y_t(k) \end{bmatrix},$$

where

$$u_i(k) \in \begin{cases} \mathbb{R}^{p_i} & \text{if } m_i|k \\ \{0\} & \text{otherwise} \end{cases} \quad \text{and} \quad y_j(k) \in \begin{cases} \mathbb{R}^{q_j} & \text{if } n_j|k \\ \{0\} & \text{otherwise} \end{cases},$$

then such an MP system becomes a general multirate system with uniform synchronized but different sampling in each input or output channel [7, 18, 20, 26]. The study of periodic and multirate systems in such a generality as indicated above, however, has never been done before.

Remark 1. One advantage of modelling a multirate system as a periodic system with periodically time-varying input-output spaces is that it better relates the present study to the rich theory on the usual periodic systems, as surveyed in [2]. Other advantages are its generality (it allows for nonuniform and asynchronous sampling) and its convenience (the treatments using this model take similar forms to those using other models, such as the one discussed in [7, 18]).

A standard method for the analysis of MP systems is to use lifting or blocking. For the MP system shown in Figure 2.1, define a lifting operator L_l on $\bigoplus_{k=-\infty}^{\infty} \mathbb{R}^{p(k)}$ by

$$L_l : \{\cdots | u(0), u(1), \cdots\} \mapsto \left\{ \cdots \middle| \begin{bmatrix} u(0) \\ u(1) \\ \vdots \\ u(l-1) \end{bmatrix}, \begin{bmatrix} u(l) \\ u(l+1) \\ \vdots \\ u(2l-1) \end{bmatrix}, \cdots \right\}.$$

L_l on $\bigoplus_{k=-\infty}^{\infty} \mathbb{R}^{q(k)}$ is defined similarly. Then the lifted system $G = L_l G_{mp} L_l^{-1}$ is an LTI system in the sense that $GS^1 = S^1 G$, where S^1 is the unit shift. Hence it has transfer function in the λ-transform ($\lambda = \frac{1}{z}$)

$$G(\lambda) = \begin{bmatrix} G_{11}(\lambda) & \cdots & G_{1l}(\lambda) \\ \vdots & \ddots & \vdots \\ G_{l1}(\lambda) & \cdots & G_{ll}(\lambda) \end{bmatrix}.$$

The LTI system G is not an arbitrary LTI system. Instead, its direct feedthrough term $G(0)$ is subject to a constraint that results from the causality of G_{mp} :

$$G_{ij}(0) = 0_{q(i)\times p(j)} \quad \text{for } 1 \le i < j \le l;$$

i.e., $G(0)$ is a block lower triangular matrix. Therefore the causality constraint can be represented by

$$G(0) \in \mathcal{T}(q, p),$$

where $p = [\ p(1) \quad \cdots \quad p(l)\ ]$ and $q = [\ q(1) \quad \cdots \quad q(l)\ ]$. Notice that the form of the causality here is simpler than that in [7, 18] due to the new form of the model.

3. Constrained analytic interpolation problems. In this section, we will present some constrained analytic function interpolation problems, which can be viewed as a multirate version of the standard interpolation problems. These constrained interpolation problems have various applications in MP systems as do their unconstrained counterparts in single rate systems. We first present a general case: a constrained tangential NP interpolation problem. Some more useful special cases are then formulated for convenience. In the following sections, we always assume that p, q, $|p|$, and $|q|$ are defined by (1.1)–(1.2).

Problem 1 (constrained tangential NP interpolation). Given $U \in \mathbb{C}^{|p|\times n}$, $Y \in \mathbb{C}^{|q|\times n}$, and $Z \in \mathbb{C}^{n\times n}$ with spectral radius $\rho(Z) < 1$, find (if possible) a function $G(\lambda) = \sum_{m=0}^{\infty} G_m \lambda^m \in \mathcal{H}_\infty^{|q|\times|p|}$ such that

(i) $\|G\|_\infty \le 1$,

(ii) $\sum_{m=0}^{\infty} G_m U Z^m = Y$,

(iii) $G(0) \in \mathcal{T}(q, p)$.

Roughly speaking, the integer n in the problem determines the number of interpolation conditions.

We can also formulate the following interpolation problems with block lower triangular constraints, which are special cases of Problem 1.

Problem 2 (constrained classical NP interpolation). Given a set of complex numbers $\lambda_\alpha \in \mathbb{D}$ along with matrices $U_\alpha \in \mathbb{C}^{|p|\times n}$ and $Y_\alpha \in \mathbb{C}^{|q|\times n}$ for $\alpha = 1, \ldots, s$, find (if possible) a function $G \in \mathcal{H}_\infty^{|q|\times|p|}$ such that

(i) $\|G\|_\infty \le 1$,

(ii) $G(\lambda_\alpha) U_\alpha = Y_\alpha$ for $\alpha = 1, \ldots, s$,

(iii) $G(0) \in \mathcal{T}(q, p)$.

Problem 3 (constrained CF interpolation). Given $U_\beta \in \mathbb{C}^{|p|\times n}$ and $Y_\beta \in \mathbb{C}^{|q|\times n}$, $\beta = 0, \ldots, r-1$, find (if possible) a function $G(\lambda) = \sum_{m=0}^{\infty} G_m \lambda^m \in \mathcal{H}_\infty^{|q|\times|p|}$ such that

(i) $\|G\|_\infty \le 1$,

(ii) $$\begin{bmatrix} Y_0 \\ Y_1 \\ \vdots \\ Y_{r-1} \end{bmatrix} = \begin{bmatrix} G_0 & 0 & \cdots & 0 \\ G_1 & G_0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ G_{r-1} & G_{r-2} & \cdots & G_0 \end{bmatrix} \begin{bmatrix} U_0 \\ U_1 \\ \vdots \\ U_{r-1} \end{bmatrix},$$

(iii) $G(0) \in \mathcal{T}(q,p)$.

Problem 4 (constrained simultaneous NP and CF interpolation). Given $U_{1,\beta} \in \mathbb{C}^{|p|\times n}$, $Y_{1,\beta} \in \mathbb{C}^{|q|\times n}$ for $j = 0,\dots,r-1$, and $U_\alpha \in \mathbb{C}^{|p|\times n}$, $Y_\alpha \in \mathbb{C}^{|q|\times n}$, and $\lambda_\alpha \in \mathbb{D}$ for $\alpha = 2,\dots,s$, find (if possible) a function $G(\lambda) = \sum_{m=0}^{\infty} G_m \lambda^m \in \mathcal{H}_\infty^{|q|\times|p|}$ such that

(i) $\|G\|_\infty \le 1$,

(ii) $$\begin{bmatrix} Y_{1,0} \\ Y_{1,1} \\ \vdots \\ Y_{1,r-1} \end{bmatrix} = \begin{bmatrix} G_0 & 0 & \cdots & 0 \\ G_1 & G_0 & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ G_{r-1} & G_{r-2} & \cdots & G_0 \end{bmatrix} \begin{bmatrix} U_{1,0} \\ U_{1,1} \\ \vdots \\ U_{1,r-1} \end{bmatrix},$$

(iii) $G(\lambda_\alpha)U_\alpha = Y_\alpha$ for $\alpha = 2,\dots,s$,

(iv) $G(0) \in \mathcal{T}(q,p)$.

Before giving the necessary and sufficient conditions of the above constrained analytic function interpolation problems, we need a result on matrix positive completion.

The matrix positive completion problem is as follows [9]: For a block matrix $B = [B_{ij}]_{i,j=1}^n$, given $B_{ij}, |j-i| \le m$, satisfying $B_{ij} = B_{ji}^*$, find the remaining matrices $B_{ij}, |j-i| > m$, such that the block matrix B is positive definite. The matrix positive completion problem was first proposed by Dym and Gohberg [9], who gave the following result.

LEMMA 3.1. *The matrix positive completion problem has a solution if and only if*

$$\begin{bmatrix} B_{ii} & \cdots & B_{i(i+m)} \\ \vdots & & \vdots \\ B_{(i+m)i} & \cdots & B_{(i+m)(i+m)} \end{bmatrix} \ge 0, \quad i = 1,\dots,n-m. \tag{3.1}$$

Reference [27] gave a detailed discussion of this problem and presented an explicit description of the set of all solutions via a linear fractional map whose coefficients are given in terms of the original data. However, Lemma 3.1 is sufficient for our purpose. We are now in a position to give the main result of this section.

THEOREM 3.2. *There exists a solution to Problem* 1 *if and only if*

$$Q - \tilde{Q} + Y^*\Pi_k(q)Y - U^*\Pi_k(p)U \ge 0 \tag{3.2}$$

for all $k = 1,\dots,l$, *where* Q *and* $\tilde{Q}$ *are, respectively, the unique solutions of Lyapunov equations*

$$Q = Z^*QZ + U^*U, \tag{3.3}$$

$$\tilde{Q} = Z^*\tilde{Q}Z + Y^*Y. \tag{3.4}$$

Here $\Pi_k(p)$ *and* $\Pi_k(q)$ *are defined in* (1.3)–(1.4).

Proof. The structural constraint on the interpolation function G can be viewed as an additional interpolation condition,

$$G(0)\,I = T,$$

for some $T \in \mathcal{T}(q,p)$. Set $\lambda_0 = 0$, $U_0 = I$, and $Y_0 = T$. By the solvability condition of the standard NP interpolation problem [12], the constrained interpolation problem has a solution if and only if there exists $T \in \mathcal{T}(q,p)$ such that

$$Q_a - \tilde{Q}_a \geq 0, \tag{3.5}$$

where Q_a and $\tilde{Q}_a$ satisfy

$$Q_a = \begin{bmatrix} \lambda_0 I & 0 \\ 0 & Z \end{bmatrix}^* Q_a \begin{bmatrix} \lambda_0 I & 0 \\ 0 & Z \end{bmatrix} + \begin{bmatrix} I \\ U^* \end{bmatrix} \begin{bmatrix} I & U \end{bmatrix}, \tag{3.6}$$

$$\tilde{Q}_a = \begin{bmatrix} \lambda_0 I & 0 \\ 0 & Z \end{bmatrix}^* \tilde{Q}_a \begin{bmatrix} \lambda_0 I & 0 \\ 0 & Z \end{bmatrix} + \begin{bmatrix} T^* \\ Y^* \end{bmatrix} \begin{bmatrix} T & Y \end{bmatrix}. \tag{3.7}$$

It is easy to see from (3.6)–(3.7) that

$$Q_a = \begin{bmatrix} I & U \\ U^* & Q \end{bmatrix} \text{ and } \tilde{Q}_a = \begin{bmatrix} T^*T & T^*Y \\ Y^*T & \tilde{Q} \end{bmatrix}.$$

Substituting Q_a and $\tilde{Q}_a$ into the inequality (3.5), we have

$$\begin{bmatrix} I - T^*T & U - T^*Y \\ U^* - Y^*T & Q - \tilde{Q} \end{bmatrix} \geq 0. \tag{3.8}$$

The left-hand side of (3.8) can be rewritten as

$$\begin{bmatrix} I & U \\ U^* & Q - \tilde{Q} + Y^*Y \end{bmatrix} - \begin{bmatrix} T^* \\ Y^* \end{bmatrix} \begin{bmatrix} T & Y \end{bmatrix}.$$

By the Schur complement, (3.8) is equivalent to

$$\begin{bmatrix} I & U & T^* \\ U^* & Q - \tilde{Q} + Y^*Y & Y^* \\ T & Y & I \end{bmatrix} \geq 0. \tag{3.9}$$

Therefore, the constrained NP interpolation problem has a solution if and only if (3.9) holds for a block lower triangular matrix T. This is a matrix positive completion problem. By Lemma 3.1, there is a block lower triangular T such that (3.9) holds if and only if

$$\begin{bmatrix} \Pi_k(p) & \Pi_k(p)U & 0 \\ U^*\Pi_k(p) & Q - \tilde{Q} + Y^*Y & Y^*[I_q - \Pi_k(q)] \\ 0 & [I_q - \Pi_k(q)]Y & I_q - \Pi_k(q) \end{bmatrix} \geq 0 \tag{3.10}$$

for $k = 0, \ldots, l$. Using the Schur complement twice, we can easily show that (3.10) is equivalent to

$$Q - \tilde{Q} + Y^*\Pi_k(q)Y - U^*\Pi_k(p)U \geq 0 \tag{3.11}$$

for $k = 0, \ldots, l$. We claim that inequality (3.11) when $k = l$ implies the case when $k = 0$. In fact, when $k = 0$, inequality (3.11) gives

$$Q - \tilde{Q} + Y^*Y - U^*U \geq 0. \tag{3.12}$$

Note that inequality (3.12) is equivalent to

$$Z^*(Q-\tilde{Q})Z \geq 0.$$

When $k=l$, inequality (3.11) gives

$$Q-\tilde{Q} \geq 0. \tag{3.13}$$

It is obvious that inequality (3.13) implies (3.12). □

Remark 2. If there is no constraint, then we have $l=1$. In this case, the condition in Theorem 3.2 becomes $Q-\tilde{Q} \geq 0$, which is a well-known result in the literature [1, 11, 12].

Remark 3. To verify the condition in Theorem 3.2, two Lyapunov equations, (3.3) and (3.4), can be combined into one:

$$Q-\tilde{Q} = Z^*(Q-\tilde{Q})Z + U^*U - Y^*Y.$$

However, Q and $\tilde{Q}$ will be used in the next section.

Q and $\tilde{Q}$ can be given directly from the original data in some special cases. We end this section by providing the explicit formula for these special cases.

COROLLARY 3.3. *There exists a solution to Problem* 2 *if and only if*

$$\left[\frac{U_\alpha^*U_\beta - Y_\alpha^*Y_\beta}{1-\lambda_\alpha^*\lambda_\beta} + Y_\alpha^*\Pi_k(q)Y_\beta - U_\alpha^*\Pi_k(p)U_\beta\right]_{\alpha,\beta=1}^{s} \geq 0 \tag{3.14}$$

for $k=1,\ldots,l$.

Proof. Note that Problem 2 can be viewed as a special case of Problem 1 with

$$\begin{aligned} Z &= \operatorname{diag}(\lambda_1 I_n, \ldots, \lambda_s I_n),\\ U &= [\ U_1 \quad \cdots \quad U_s\ ],\\ Y &= [\ Y_1 \quad \cdots \quad Y_s\ ]. \end{aligned}$$

Then it is easy to check that

$$Q = \left[\frac{U_\alpha^*U_\beta}{1-\bar{\lambda}_\alpha\lambda_\beta}\right]_{\alpha,\beta=1}^{s} \quad \text{and} \quad \tilde{Q} = \left[\frac{Y_\alpha^*Y_\beta}{1-\bar{\lambda}_\alpha\lambda_\beta}\right]_{\alpha,\beta=1}^{s}$$

are the solution of the Lyapunov equations (3.3) and (3.4), respectively. The result then follows from Theorem 3.2 directly. □

For $V = [\ V_0 \quad \cdots \quad V_{r-1}\ ]$, we use T_V to denote a corresponding lower Toeplitz matrix

$$T_V := \begin{bmatrix} V_0 & 0 & \cdots & 0\\ V_1 & V_0 & \ddots & \\ \vdots & \vdots & \ddots & 0\\ V_{r-1} & V_{r-2} & \cdots & V_0 \end{bmatrix}. \tag{3.15}$$

COROLLARY 3.4. *For the data of Problem* 3*, denote*

$$\begin{aligned} U &= [\ U_0 \quad \cdots \quad U_{r-1}\ ],\\ Y &= [\ Y_0 \quad \cdots \quad Y_{r-1}\ ]. \end{aligned}$$

Then there exists a solution to Problem 3 *if and only if*

$$T_U^* \begin{bmatrix} I_{p(r-1)} & 0 \\ 0 & I_p - \Pi_k(p) \end{bmatrix} T_U - T_Y^* \begin{bmatrix} I_{q(r-1)} & 0 \\ 0 & I_q - \Pi_k(q) \end{bmatrix} T_Y \geq 0 \tag{3.16}$$

for all $k = 1, \ldots, l$.

Proof. Note that Problem 3 can be viewed as a special case of Problem 1 with U, Y, and

$$Z = \begin{bmatrix} 0 & I_n & & 0 \\ & 0 & \ddots & \\ & & \ddots & I_n \\ & & & 0 \end{bmatrix}_{rn \times rn}.$$

Hence Q can be computed by

$$\begin{aligned} Q &= \sum_{m=0}^{\infty} Z^{*m} U^* U Z^m = \sum_{m=0}^{r-1} Z^{*m} U^* U Z^m \\ &= \begin{bmatrix} 0 \\ \vdots \\ 0 \\ U_0^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & U_0 \end{bmatrix} + \cdots + \begin{bmatrix} U_0^* \\ \vdots \\ U_{r-1}^* \end{bmatrix} \begin{bmatrix} U_0 & \cdots & U_{r-1} \end{bmatrix} \\ &= \begin{bmatrix} 0 & 0 & \cdots & U_0^* \\ \vdots & \vdots & \iddots & \vdots \\ 0 & U_0^* & \cdots & U_{r-2}^* \\ U_0^* & U_1^* & \cdots & U_{r-1}^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & U_0 \\ 0 & \cdots & U_0 & U_1 \\ \vdots & \iddots & \vdots & \vdots \\ U_0 & \cdots & U_{r-2} & U_{r-1} \end{bmatrix}. \end{aligned}$$

Similarly, we have

$$\tilde{Q} = \begin{bmatrix} 0 & 0 & \cdots & Y_0^* \\ \vdots & \vdots & \iddots & \vdots \\ 0 & Y_0^* & \cdots & Y_{r-2}^* \\ Y_0^* & Y_1^* & \cdots & Y_{r-1}^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & Y_0 \\ 0 & \cdots & Y_0 & Y_1 \\ \vdots & \iddots & \vdots & \vdots \\ Y_0 & \cdots & Y_{r-2} & Y_{r-1} \end{bmatrix}.$$

Condition (3.2) then becomes

$$Q - \tilde{Q} + Y^* \Pi_k(q) Y - U^* \Pi_k(p) U \geq 0. \tag{3.17}$$

By pre- and postmultiplying inequality (3.17) by

$$\begin{bmatrix} 0 & \cdots & I_n \\ \vdots & \iddots & \vdots \\ I_n & \cdots & 0 \end{bmatrix}_{rn \times rn},$$

we obtain another equivalent condition

$$T_U^* T_U - T_Y^* T_Y + \begin{bmatrix} Y_{r-1}^* \\ \vdots \\ Y_0^* \end{bmatrix} \Pi_k(q) \begin{bmatrix} Y_{r-1} & \cdots & Y_0 \end{bmatrix} - \begin{bmatrix} U_{r-1}^* \\ \vdots \\ U_0^* \end{bmatrix} \Pi_k(p) \begin{bmatrix} U_{r-1} & \cdots & U_0 \end{bmatrix} \geq 0.$$

This is exactly (3.16) after some simple algebraic manipulations. ∎

COROLLARY 3.5. *For the data of Problem* 4*, denote*

$$U_1 = \begin{bmatrix} U_{10} & \cdots & U_{1(r-1)} \end{bmatrix},$$
$$Y_1 = \begin{bmatrix} Y_{10} & \cdots & Y_{1(r-1)} \end{bmatrix}.$$

Then there exists a solution to Problem 4 *if and only if*

$$\begin{bmatrix} A_{11k} & A_{21k}^* \\ A_{21k} & A_{22k} \end{bmatrix} \geq 0 \tag{3.18}$$

for all $k = 1, \ldots, l$*, where*

$$A_{11k} = T_{U_1}^* \begin{bmatrix} I_{p(r-1)} & 0 \\ 0 & I_p - \Pi_k(p) \end{bmatrix} T_{U_1} - T_{Y_1}^* \begin{bmatrix} I_{q(r-1)} & 0 \\ 0 & I_q - \Pi_k(q) \end{bmatrix} T_{Y_1},$$

$$A_{21k} = \begin{bmatrix} \bar{\lambda}_2^{r-1} U_2^* & \cdots & \bar{\lambda}_2 U_2^* & U_2^* \\ \vdots & \cdots & \vdots & \vdots \\ \bar{\lambda}_s^{r-1} U_s^* & \cdots & \bar{\lambda}_s U_s^* & U_s^* \end{bmatrix} \begin{bmatrix} I_{p(r-1)} & 0 \\ 0 & I_p - \Pi_k(p) \end{bmatrix} T_{U_1} - \begin{bmatrix} \bar{\lambda}_2^{r-1} Y_2^* & \cdots & \bar{\lambda}_2 Y_2^* & Y_2^* \\ \vdots & \cdots & \vdots & \vdots \\ \bar{\lambda}_s^{r-1} Y_s^* & \cdots & \bar{\lambda}_s Y_s^* & Y_s^* \end{bmatrix} \begin{bmatrix} I_{q(r-1)} & 0 \\ 0 & I_q - \Pi_k(q) \end{bmatrix} T_{Y_1},$$

$$A_{22k} = \left[\frac{U_\alpha^* U_\beta - Y_\alpha^* Y_\beta}{1 - \bar{\lambda}_\alpha \lambda_\beta} - U_\alpha^* \Pi_k(p) U_\beta + Y_\alpha^* \Pi_k(q) Y_\beta \right]_{\alpha,\beta=2}^{s}.$$

Proof. Note that Problem 4 can be viewed as a special case of Problem 1 with U, Y, and Z, where

$$U = \begin{bmatrix} U_1 & U_2 & \cdots & U_s \end{bmatrix},$$
$$Y = \begin{bmatrix} Y_1 & Y_2 & \cdots & Y_s \end{bmatrix},$$
$$Z = \operatorname{diag}(Z_1, \lambda_2 I_n, \ldots, \lambda_s I_n),$$

$$Z_1 = \begin{bmatrix} 0 & I_n & & 0 \\ & 0 & \ddots & \\ & & \ddots & I_n \\ & & & 0 \end{bmatrix}_{rn \times rn}.$$

Some simple algebraic manipulations show that

$$Q = \begin{bmatrix} Q_{11} & Q_{21}^* \\ Q_{21} & Q_{22} \end{bmatrix} \quad \text{and} \quad \tilde{Q} = \begin{bmatrix} \tilde{Q}_{11} & \tilde{Q}_{21}^* \\ \tilde{Q}_{21} & \tilde{Q}_{22} \end{bmatrix}$$

satisfy the Lyapunov equations (3.3) and (3.4), respectively, where

$$Q_{11} = \begin{bmatrix} 0 & \cdots & 0 & U_{10}^* \\ 0 & \cdots & U_{10}^* & U_{11}^* \\ \vdots & \cdots & \vdots & \vdots \\ U_{10}^* & \cdots & U_{1(r-2)}^* & U_{1(r-1)}^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & U_{10} \\ 0 & \cdots & U_{10} & U_{11} \\ \vdots & \cdots & \vdots & \vdots \\ U_{10} & \cdots & U_{1(r-2)} & U_{1(r-1)} \end{bmatrix},$$

$$Q_{21} = \begin{bmatrix} \bar{\lambda}_2^{r-1} U_2^* & \cdots & \bar{\lambda}_2 U_2^* & U_2^* \\ \bar{\lambda}_3^{r-1} U_3^* & \cdots & \bar{\lambda}_3 U_3^* & U_3^* \\ \vdots & \cdots & \vdots & \vdots \\ \bar{\lambda}_s^{r-1} U_s^* & \cdots & \bar{\lambda}_s U_s^* & U_s^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & U_{10} \\ 0 & \cdots & U_{10} & U_{11} \\ \vdots & \cdots & \vdots & \vdots \\ U_{10} & \cdots & U_{1(r-2)} & U_{1(r-1)} \end{bmatrix},$$

$$Q_{22} = \left[\frac{U_\alpha^* U_\beta}{1 - \bar{\lambda}_\alpha \lambda_\beta} \right]_{\alpha,\beta=2}^{s},$$

$$\tilde{Q}_{11} = \begin{bmatrix} 0 & \cdots & 0 & Y_{10}^* \\ 0 & \cdots & Y_{10}^* & Y_{11}^* \\ \vdots & \cdots & \vdots & \vdots \\ Y_{10}^* & \cdots & Y_{1(r-2)}^* & Y_{1(r-1)}^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & Y_{10} \\ 0 & \cdots & Y_{10} & Y_{11} \\ \vdots & \cdots & \vdots & \vdots \\ Y_{10} & \cdots & Y_{1(r-2)} & Y_{1(r-1)} \end{bmatrix},$$

$$\tilde{Q}_{21} = \begin{bmatrix} \bar{\lambda}_2^{r-1} Y_2^* & \cdots & \bar{\lambda}_2 Y_2^* & Y_2^* \\ \bar{\lambda}_3^{r-1} Y_3^* & \cdots & \bar{\lambda}_3 Y_3^* & Y_3^* \\ \vdots & \cdots & \vdots & \vdots \\ \bar{\lambda}_s^{r-1} Y_s^* & \cdots & \bar{\lambda}_s Y_s^* & Y_s^* \end{bmatrix} \begin{bmatrix} 0 & \cdots & 0 & Y_{10} \\ 0 & \cdots & Y_{10} & Y_{11} \\ \vdots & \cdots & \vdots & \vdots \\ Y_{10} & \cdots & Y_{1(r-2)} & Y_{1(r-1)} \end{bmatrix},$$

$$\tilde{Q}_{22} = \left[\frac{Y_\alpha^* Y_\beta}{1 - \bar{\lambda}_\alpha \lambda_\beta} \right]_{\alpha,\beta=2}^{s}.$$

Condition (3.2) then becomes

$$Q - \tilde{Q} + Y^* \Pi_k(q) Y - U^* \Pi_k(p) U \geq 0. \tag{3.19}$$

By pre- and postmultiplying inequality (3.19) by

$$\begin{bmatrix} 0 & \cdots & I_n & \\ \vdots & \iddots & \vdots & 0 \\ I_n & \cdots & 0 & \\ & 0 & & I_{(s-1)n} \end{bmatrix},$$

we obtain condition (3.18) after some direct operator manipulations. □

Remark 4. Corollaries 3.3 and 3.4 can be directly used for robust model validation of multirate systems following the method for LTI systems studied in [6, 16].

4. Parametrization of all solutions. In this section, we characterize all solutions G to Problem 1 when the solvability condition is satisfied. We will consider only the generic case when $Q - \tilde{Q} > 0$. The unlikely case when $Q - \tilde{Q}$ is singular is technically more involved.

Since the characterization for the unconstrained case has been given in [12], our strategy in solving the constrained problem is then to choose, if possible, from this characterization all those solutions that satisfy the structural constraint. The same notation is used as in previous sections and more notation is needed. Given an operator Δ and two operator matrices

$$\Lambda = \begin{bmatrix} \Lambda_{11} & \Lambda_{12} \\ \Lambda_{21} & \Lambda_{22} \end{bmatrix} \quad \text{and} \quad \Gamma = \begin{bmatrix} \Gamma_{11} & \Gamma_{12} \\ \Gamma_{21} & \Gamma_{22} \end{bmatrix},$$

the linear fractional transformation associated with Λ and Δ is denoted by

$$\mathcal{F}(\Lambda, \Delta) = \Lambda_{11} + \Lambda_{12}\Delta(I - \Lambda_{22}\Delta)^{-1}\Lambda_{21},$$

and the star product of Λ and Γ is defined as

$$\Lambda \star \Gamma = \begin{bmatrix} \Lambda_{11} + \Lambda_{12}\Gamma_{11}(I - \Lambda_{22}\Gamma_{11})^{-1}\Lambda_{21} & \Lambda_{12}(I - \Gamma_{11}\Lambda_{22})^{-1}\Gamma_{12} \\ \Gamma_{21}(I - \Lambda_{22}\Gamma_{11})^{-1}\Lambda_{21} & \Gamma_{21}(I - \Lambda_{22}\Gamma_{11})^{-1}\Lambda_{22}\Gamma_{12} + \Gamma_{22} \end{bmatrix}.$$

Here we assume that the operator manipulations are all compatible. With these definitions, we have

$$\mathcal{F}(\Lambda, \mathcal{F}(\Gamma, \Delta)) = \mathcal{F}(\Lambda \star \Gamma, \Delta).$$

The following lemma from [19] will be used later.

LEMMA 4.1. *For $M \in \mathbb{C}^{|q|\times|p|}$, the following statements are equivalent:*

(1) *There exists $T \in \mathcal{T}(q,p)$ such that $\|M + T\| \le 1$.*

(2) *There exists*

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}$$

with $P_{11} \in \mathcal{T}(q,p)$, $P_{12} \in \mathcal{T}(q,q)$ invertible, $P_{21} \in \mathcal{T}(p,p)$ invertible, and $P_{22} \in \mathcal{T}_s(p,q)$ such that

$$\begin{bmatrix} M + P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}$$

is unitary.

A way to find P from M was given in [19]. Recall that an operator valued function Θ is said to be two-sided inner if Θ is an inner function and $\Theta(e^{jw})$ is almost everywhere unitary. For U, Y, and Z in Problem 1, assume that $Q - \tilde{Q} > 0$, where Q and $\tilde{Q}$ are defined by (3.3) and (3.4), respectively. By [12, Theorem III 7.2], there exist matrices $C \in \mathbb{C}^{n\times|p|}$ and $E \in \mathbb{C}^{|p|\times|p|}$ such that the state space model $\{Z, C, U, E\}$ is controllable and observable and the transfer function

$$\Theta(\lambda) := E + \lambda U(I - \lambda Z)^{-1}C \tag{4.1}$$

is two-sided inner in $\mathcal{H}^{|p|\times|p|}$. It follows from QR factorization that there is a special $\Theta(\lambda)$ such that $E^* \in \mathcal{T}(p,p)$ and (4.1) holds. By Cholesky factorization, there exist $N \in \mathcal{T}(q,q)$ and $S \in \mathcal{T}(p,p)$ such that

$$N^*N = [I + Y(Q - \tilde{Q})^{-1}Y^*]^{-1}, \tag{4.2}$$

$$S^*S = [I + C^*\tilde{Q}(Q - \tilde{Q})^{-1}QC]^{-1}. \tag{4.3}$$

Let $A_0 = (Q - Z^*\tilde{Q}Z)^{-1}Z^*(Q - \tilde{Q})$. It is shown in [12, Proposition V 1.7] that A_0 is stable. Define

$$\Phi(\lambda) = \begin{bmatrix} \Phi_{11}(\lambda) & \Phi_{12}(\lambda) \\ \Phi_{21}(\lambda) & \Phi_{22}(\lambda) \end{bmatrix},$$

where

$$\begin{aligned}
\Phi_{11}(\lambda) &= Y(I - \lambda A_0)^{-1}(Q - Z^*\tilde{Q}Z)^{-1}U^*, \\
\Phi_{12}(\lambda) &= N^{-1} - \lambda Y A_0(I - \lambda A_0)^{-1}(Q - \tilde{Q})^{-1}Y^*N^{-1}, \\
\Phi_{21}(\lambda) &= S\Theta^*(\lambda) - S^{-1}C^*Q(I - \lambda A_0)^{-1}(Q - \tilde{Q})^{-1}\tilde{Q}C\Theta^*(\lambda), \\
\Phi_{22}(\lambda) &= -\lambda S^{-1}C^*Q(I - \lambda A_0)^{-1}(Q - \tilde{Q})^{-1}Y^*N^{-1}.
\end{aligned}$$

The set of all $G(\lambda)$ solving the unconstrained interpolation problem is then given by

$$G(\lambda) = \mathcal{F}(\Phi(\lambda), V(\lambda)),$$

where $V(\lambda)$ is a contractive analytic function in $\mathcal{H}_\infty^{|q|\times|p|}$. Obviously, the set of all solutions to the constrained interpolation problem is

$$\{G(\lambda) = \mathcal{F}(\Phi(\lambda), V(\lambda)) : G(0) \in \mathcal{T}(q,p)\}. \tag{4.4}$$

It is easy to check that

$$\begin{aligned}
\Phi_{11}(0) &= Y(Q - Z^*\tilde{Q}Z)^{-1}U^*, \\
\Phi_{12}(0) &= N^{-1}, \\
\Phi_{21}(0) &= SE^* - S^{-1}C^*Q(Q - \tilde{Q})^{-1}\tilde{Q}CE^* \\
&= S[I - C^*Q(Q - \tilde{Q})^{-1}\tilde{Q}C]E^* \\
&= S^{-1}E^*, \\
\Phi_{22}(0) &= 0.
\end{aligned}$$

Now assume condition (3.2) in Theorem 3.2 is satisfied. Then there is a contractive analytic function $V(\lambda)$ in $\mathcal{H}_\infty^{|q|\times|p|}$ such that

$$G(0) = \Phi_{11}(0) + N^{-1}V(0)S^{-1}E^* \in \mathcal{T}(q,p).$$

That is,

$$\| - N\Phi_{11}(0)(S^{-1}E^*)^{-1} + N\hat{G}(0)(S^{-1}E^*)^{-1}\| \le 1.$$

By Lemma 4.1, there exists

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}$$

with $P_{11} \in \mathcal{T}(q,p)$, $P_{12} \in \mathcal{T}(q,q)$ invertible, $P_{21} \in \mathcal{T}(p,p)$ invertible, and $P_{22} \in \mathcal{T}_s(p,q)$ such that

$$B := \begin{bmatrix} -N\Phi_{11}(0)(S^{-1}E^*)^{-1} + P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}$$

is unitary. Define $\Psi = \Phi \star B$. It is easy to check that $\Psi_{11} \in \mathcal{T}(q,p)$, $\Psi_{12} \in \mathcal{T}(q,q)$, $\Psi_{21} \in \mathcal{T}(p,p)$, $\Psi_{22} \in \mathcal{T}_s(p,q)$, and both Ψ_{12} and Ψ_{21} are invertible. By setting a bijective map $R = \mathcal{F}(B,V)$, we have

$$G(\lambda) = \mathcal{F}(\Phi, V) = \mathcal{F}(\Phi, \mathcal{F}(B,R)) = \mathcal{F}(\Phi \star B, R) = \mathcal{F}(\Psi, R).$$

Note that $G(0) \in \mathcal{T}(q,p)$ if and only if $R(0) \in \mathcal{T}(q,p)$. Hence the set (4.4) can be rewritten as

$$\{G(\lambda) = \mathcal{F}(\Psi, R) : R \in \mathcal{H}_\infty^{|q|\times|p|} \text{ with } R(0) \in \mathcal{T}(q,p) \text{ and } \|R\| \le 1\}.$$

This gives us the main result of this section, the following theorem.

THEOREM 4.2. *For Problem* 1*, assume that* $Q - \tilde{Q} > 0$ *and the solvability condition* (3.2) *holds. Then the set of all interpolants* $G(\lambda)$ *is given by*

$$G(\lambda) = \mathcal{F}(\Psi(\lambda), R(\lambda)),$$

where R *is a contractive analytic function with* $R(0) \in \mathcal{T}(q,p)$.

5. Conclusion. In this paper, we study the MP systems and some related analytic function interpolation problems. We show that each MP system has an equivalent LTI system with a causality constraint which can be represented by a set of block lower triangular matrices. We then study some analytic function interpolation problems with such a constraint. The necessary and sufficient solvability conditions are given using the result of the positive matrix completion problem. Finally, all the solutions are presented in terms of linear fractional transformation.

OPTIMALITY OF STASIS AND SMALL SWITCHING CYCLES IN PLANAR SYSTEMS WITH TWO-VALUED CONTROLS*

STEWART D. JOHNSON†

Abstract. For planar ($x \in \mathbb{R}^2$) control systems $x' = f(x, \mu)$ with a two-valued control $\mu \in \{\mu_1, \mu_2\}$ we consider small cycles created by rapidly switching between the two control values. A two-cycle is a periodic cycle on which the periodic control changes value twice in one period. Stasis is a relaxed (i.e., probabilistic) control μ_{r} with a fixed point (called a stasis point) x_{r} where $0 = f(x_{\mathrm{r}}, \mu_{\mathrm{r}}) = \int f(x_{\mathrm{r}}, \mu)\, d\mu_{\mathrm{r}}$. Generically, stasis points can be approximated by two-cycles, and every two-cycle must contain a stasis point. Also generically, stasis points form curves (called stasis curves). The unit metric on these curves parameterize families of small two-cycles near the stasis curve. Under general conditions, we show that average performance is differentiable with respect to this parameterization, and thus necessary conditions for optimality of small two-cycles versus stasis can be explicitly calculated.

Key words. optimal control, optimal periodic control, relaxed control

AMS subject classifications. 37N35, 49N25, 49N20, 49K15, 49K30

1. Approximating optimal control.

The standard control problem involves optimizing (maximizing or minimizing) a performance function

$$Q = \int_0^T H(x, u, t)\, dt$$

over some set of *admissible controls* $u(t) \in \mathcal{U}$ subject to constraint by a differential equation

$$x' = F(x, u, t) \tag{1}$$

and possibly constrained by a variety of endpoint conditions on T, $x(0)$, and $x(T)$. Excellent introductions to control theory include [3, 10, 13].

Optimal periodic control [4, 6, 7] involves optimizing average performance

$$Q = \frac{1}{T} \int_0^T H(x, u, t)\, dt$$

over periodic trajectories of period T under a differential equation (1). This constrains $x(t) = x(t + T)$ and $u(t) = u(t + T)$ for all t, and in particular $x(0) = x(T)$.

The introduction of relaxed controls [2, 4, 6, 7, 12] raises several questions. First, when can a relaxed control be approximated by an admissible control? Certainly not all can be; an example appears later. Second, in the case where the relaxed control can be approximated, in what way does the performance depend on the approximation? What happens to performance as we take closer approximations to a relaxed control? We may expect continuity because performance is defined by an integral, but can

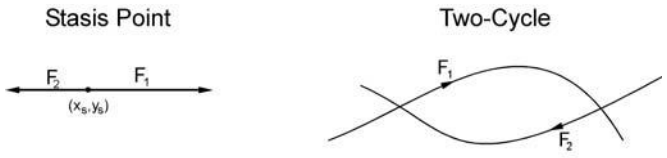

FIG. 1. *Stasis and two-cycles.*

we expect some form of smoothness near the "boundaries" of the set of admissible controls?

This paper contains an extensive analysis of these questions in a specific setting. We consider periodic optimization of $\mathbb{R}^2$ systems with control functions that switch between two fixed values. Such situations arise naturally in bang-bang controls [8, 9, 11].

We consider relaxed controls that produce fixed trajectories at antiparallel points called *stasis points* and consider periodic approximations that switch between values twice in one period, called *two-cycles* (see Figure 1). Under reasonable assumptions we show that stasis points are generically approximable by two-cycles, and that every two-cycle (or every n-cycle for that matter) must contain a stasis point. We show that stasis points generically form curves that parameterize the family of approximating two-cycles as two-parameter family. Performance is a differentiable function of this parameterization. In fact as the parameters converge to the relaxed control, performance has a finite one-sided derivative. This main result on differentiability is proven using a standardizing diffeomorphism and technical calculation.

The next section of this paper contains the basic constructs and topological results. Section 3 examines performance in this setting and ends with a statement of the main theorem. In section 4 we introduce a standardizing diffeomorphism and prove some basic analytic results in the standardized framework. Section 5 analyzes the family of two-cycles in the standard framework, and section 6 is a technical and very calculational proof of the main theorem. Finally, section 7 contains an application to a problem studied by Gilbert [5].

2. Stasis and switching two-cycles. Consider a controlled planar flow[1]

$$\begin{aligned} x' &= f(x, y, \mu), \\ y' &= g(x, y, \mu) \end{aligned} \tag{2}$$

with $(x, y) \in \mathcal{D} \subset \mathbb{R}^2$ and $\mu \in \mathbb{R}^n$. We restrict ourselves to two distinct values of the control parameter, μ_1, μ_2, and piecewise constant control functions $\mu(t)$ that switch between the two values. Taking $f_i(x, y) = f(x, y, \mu_i)$, $g_i(x, y) = g(x, y, \mu_i)$, this amounts to studying the pair of systems

$$\begin{aligned} x' &= f_1(x, y), & x' &= f_2(x, y), \\ y' &= g_1(x, y), & y' &= g_2(x, y). \end{aligned} \tag{3}$$

Trajectories in system (2) are composed of segments of trajectories from these two systems, as in Figure 2. Specifically, $x(t)$, $y(t)$, $\mu(t)$ is a trajectory for (2) iff $x(t)$, $y(t)$ is a trajectory for $x' = f_i(x, y)$, $y' = g_i(x, y)$ from (3) on the closure of any time interval where $\mu(t) = \mu_i$.

[1]This work is specific to planar geometry, and notation reflecting this bias is favored.

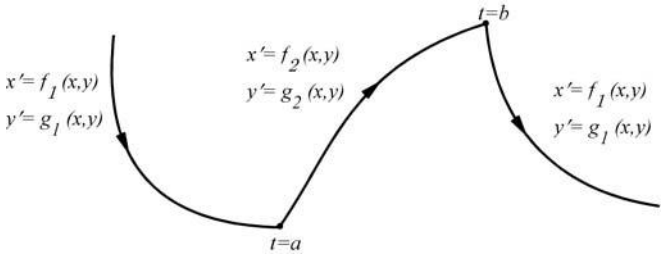

FIG. 2. *A switching trajectory.*

A *cycle* of length $T > 0$ is a nonstationary trajectory $x(t), y(t), \mu(t)$ defined for $[0, T]$ with $x(T) = x(0)$, $y(T) = y(0)$, and $\mu(t + T) = \mu(t)$. A cycle is *switching* if μ is discontinuous on $[0, T]$ and *nonswitching* if μ is constant. The cycle is a *two-cycle* if μ has exactly two discontinuities on $[0, T]$.

Without relaxed controls, a fixed trajectory can occur only at a fixed point in one of the two component systems. But if we allow relaxed controls, trajectories can be fixed at places where the two flows are antiparallel. Specifically, writing

$$\mathbf{F}_i = \begin{pmatrix} f_i \\ g_i \end{pmatrix},$$

a point $(x_s, y_s) \in \mathcal{D} \subset \mathbb{R}^2$ is a *stasis point* if (x_s, y_s) is not fixed in either system and, for some $\kappa > 0$,

$$\mathbf{F}_1(x_s, y_s) = -\kappa\, \mathbf{F}_2(x_s, y_s). \tag{4}$$

A trajectory can be fixed at a stasis point by a relaxed control

$$\mu = \begin{cases} 1 & \text{with probability } \frac{1}{\kappa+1}, \\ 2 & \text{with probability } \frac{\kappa}{\kappa+1}\ . \end{cases} \tag{5}$$

In the classic theory for smooth flows, a cycle in a simply connected domain must orbit a fixed point. Similarly, a switching cycle in a simply connected domain must orbit either a stasis or a fixed point.

LEMMA 1. *If $N \subset \mathcal{D}$ is a simply connected open set containing a switching cycle, then N contains a stasis point or a fixed point.*

Proof. Suppose N contains no stasis or fixed points. Let

$$\mathbf{U} = \frac{\mathbf{F}_1}{|\mathbf{F}_1|} + \frac{\mathbf{F}_2}{|\mathbf{F}_2|}\ .$$

This vector field is continuous and nonzero on simply connected N and is therefore parallel to $\mathbf{U} = \nabla H$ for some continuous surface $H : N \mapsto \mathbb{R}$. Let $x(t), y(t)$ be a trajectory under $\mathbf{F}_1$. Then

$$\begin{aligned} \begin{pmatrix} x' \\ y' \end{pmatrix} \cdot \mathbf{U} &\propto \mathbf{F}_1 \cdot \left(\frac{\mathbf{F}_1}{|\mathbf{F}_1|} + \frac{\mathbf{F}_2}{|\mathbf{F}_2|} \right) \\ &= |\mathbf{F}_1| + \frac{\mathbf{F}_1 \cdot \mathbf{F}_2}{|\mathbf{F}_2|} \\ &\geq 0 \end{aligned}$$

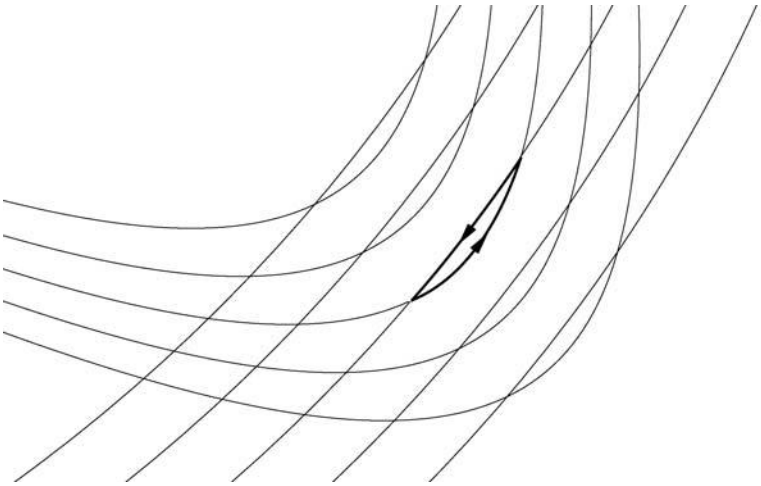

FIG. 3. *Small switching cycles.*

with equality only at a stasis point. This similarly holds for $\mathbf{F}_2$, and so values of $H(x(t), y(t))$ are strictly increasing on any switching trajectory, prohibiting a cycle. □

A switching cycle without stasis points (but with a fixed point) can be constructed from, for example, an inward spiral and a source.

The next lemma establishes generic existence of switching cycles near stasis points. The idea is that near a typical point, a smooth flow is approximated to the second order by a flow of constant curvature. The curvature of the two flows being different at a stasis point creates small cycles, as in Figure 3.

Difference in curvature near a stasis point is calculated as a change in flux of one vector field across trajectories of the other. That is, the flux of field $\mathbf{F}_1$ across $\mathbf{F}_2$ is simply the cross product:[2]

$$\mathbf{F}_1 \otimes \mathbf{F}_2 = \mathbf{F}_1 \cdot \mathbf{F}_2^{\perp} = -\mathbf{F}_1^{\perp} \cdot \mathbf{F}_2.$$

This value is zero at a stasis point. Small cycles exist when this value changes sign as a trajectory passes through a stasis point. We say a stasis point (x_s, y_s) is *regular* if

$$\frac{d}{dt}\, \mathbf{F}_1 \otimes \mathbf{F}_2\big|_{x_s, y_s} \neq 0,$$

where the derivative is taken along either flow. We have the following.

LEMMA 2. *Every neighborhood of a regular stasis point contains a switching cycle.*

The proof of this lemma follows by the construction of delta-cycles in section 5. Note that stasis points without switching cycles can be constructed with flows of equal curvature, as in Figure 4. Thus there are (nonregular) stasis points where there is no periodic approximation.

Stasis points are zero-level curves of the surface $\mathbf{F}_1 \otimes \mathbf{F}_2$, and regularity at a stasis point implies it is not a critical point of that surface. Hence we have the following lemma.

[2]Define the perpendicular operator as a clockwise right angle rotation $(x, y)^{\perp} = (y, -x)$.

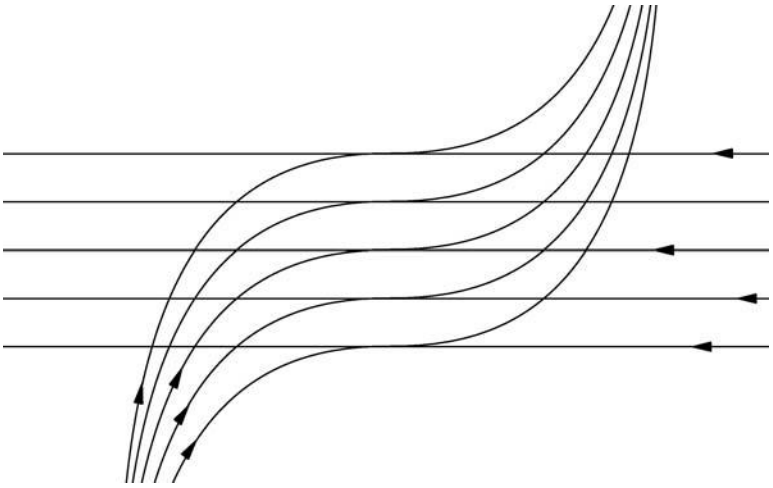

FIG. 4. *Stasis without cycles.*

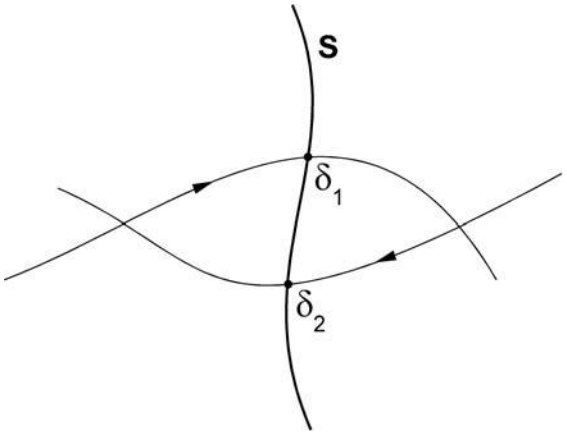

FIG. 5. *Two-cycle through* $\mathbf{S}(\delta_1)$ *and* $\mathbf{S}(\delta_2)$.

LEMMA 3. *For any regular stasis point, there exists a neighborhood in which the set of stasis points forms a smooth curve.*

Given a regular stasis point x_s, y_s, we can unit parameterize the stasis curve near (x_s, y_s) as $\mathbf{S}(\delta)$ with

$$\mathbf{S}(0) = (x_s, y_s). \tag{6}$$

Lemma 3 implies that $\mathbf{S}(\delta)$ is well defined in a neighborhood of $\delta = 0$. If ϵ is sufficiently small, pairs δ_1, δ_2 with $\epsilon > \delta_1 > \delta_2 > -\epsilon$ will uniquely determine a two-cycle that crosses the stasis line exactly twice, at δ_1 and δ_2, as in Figure 5.

We organize the subscripts so that for the two-cycle corresponding to $\delta_1 > \delta_2$, the trajectory segment under $\mathbf{F}_1$ will contain $\mathbf{S}(\delta_1)$ and the segment under $\mathbf{F}_2$ will contain $\mathbf{S}(\delta_2)$. This is accomplished by choosing the direction of parameterization so that

$$\mathbf{S}'(0)^{\perp} \cdot \nabla \left(\mathbf{F}_1 \otimes \mathbf{F}_2\right)\big|_{\mathbf{S}(0)} < 0. \tag{7}$$

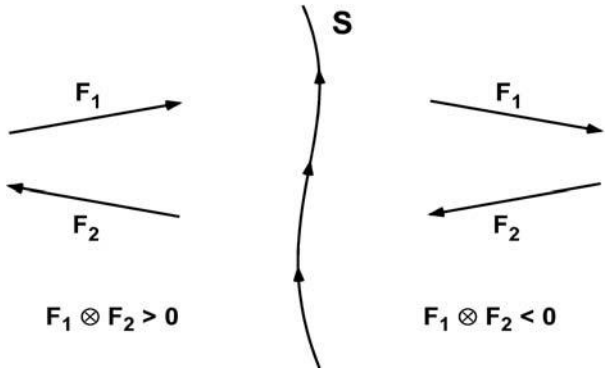

FIG. 6. *Direction of parameterization.*

That is, as we traverse $\mathbf{S}(\delta)$ in the positive direction, the value of $\mathbf{F}_1 \otimes \mathbf{F}_2$ is positive to the left and negative to the right, as in Figure 6.

By choosing the appropriate direction for time we are also free to assume, without loss of generality,

$$\mathbf{S}'(0)^{\perp} \cdot \mathbf{F}_1 > 0, \tag{8}$$

and this is consistent with Figures 5 and 6.

3. Performance of small cycles. The performance of small cycles is measured as the average performance over the cycle [4, 6, 7]. Thus if $x(t), y(t), \mu(t)$ is periodic of period T, and H is the payoff function, then performance is

$$Q = \frac{1}{T}\int_0^T H(x, y, \mu)dt.$$

With focus restricted to two values μ_1, μ_2 of the control parameter, we take $H_1(x, y) = H(x, y, \mu_1)$ and $H_2(x, y) = H(x, y, \mu_2)$. Thus if we have a two-cycle with one period defined by

$$u(t) = \begin{cases} \mu_1 & \text{for} \quad a \le t < b, \\ \mu_2 & \text{for} \quad b \le t < c, \end{cases}$$

we have the performance

$$Q = \frac{\int_a^b H_1(x, y)dt + \int_b^c H_2(x, y)dt}{c - a}. \tag{9}$$

For small ϵ, and $\epsilon > \delta_1 > \delta_2 > -\epsilon$, define $Q(\delta_1, \delta_2)$ as the performance of the two-cycle corresponding to δ_1, δ_2.

At a regular stasis point x_s, y_s we calculate the stasis performance from the relaxed control (5) and the relation (4):

$$\begin{aligned} Q^*(x_s, y_s) &= \frac{H_1(x_s, y_s) + \kappa\, H_2(x_s, y_s)}{\kappa + 1} \\ &= \frac{H_1(x_s, y_s)\,|\mathbf{F}_2(x_s, y_s)| + H_2(x_s, y_s)\,|\mathbf{F}_1(x_s, y_s)|}{|\mathbf{F}_1(x_s, y_s)| + |\mathbf{F}_2(x_s, y_s)|}. \end{aligned} \tag{10}$$

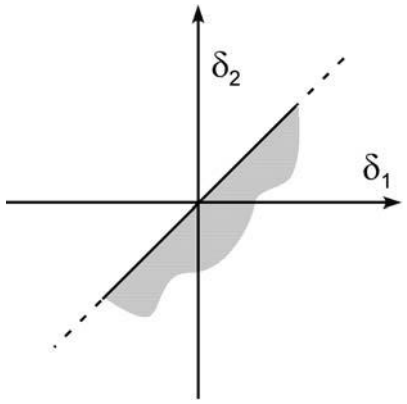

FIG. 7. *Half-closed neighborhood.*

Given a two-cycle, let D be the distance between the switching points $(x(a), y(a))$ and $(x(b), y(b))$, and rewrite (9) as

$$Q(\delta_1, \delta_2) = \frac{\int_a^b H_1(x,y)dt + \int_b^c H_2(x,y)dt}{c-a} = \frac{\frac{D}{c-b}\ \frac{1}{b-a}\ \int_a^b H_1(x,y)dt + \frac{D}{b-a}\ \frac{1}{c-b}\ \int_b^c H_2(x,y)dt}{\frac{D}{c-b} + \frac{D}{b-a}}.$$

Comparing this last expression to (10) and using the approximations

$$\begin{aligned} |\mathbf{F}_1(x_s, y_s)| &\approx \frac{D}{b-a}, \\ |\mathbf{F}_2(x_s, y_s)| &\approx \frac{D}{c-b}, \\ H_1(x_s, y_s) &\approx \frac{1}{b-a}\ \int_a^b H_1(x,y)dt, \\ H_2(x_s, y_s) &\approx \frac{1}{c-b}\ \int_b^c H_2(x,y)dt, \end{aligned}$$

it follows that

$$\lim_{\substack{\delta_1, \delta_2 \to \delta \\ -\epsilon < \delta_1 < \delta_2 < \epsilon}} Q(\delta_1, \delta_2) = Q^*(\mathbf{S}(\delta)).$$

Hence performance at stasis is approximated by performance on small two-cycles. Taking $Q(\delta, \delta) = Q^*(\mathbf{S}(\delta))$ defines $Q(\delta_1, \delta_2)$ as a continuous function for $\epsilon > \delta_1 \geq \delta_2 > -\epsilon$.

In general, there is some half-closed set in the δ_1, δ_2 plane containing $\delta_1 = \delta_2$ and contained in $\delta_1 \geq \delta_2$ near $(0, 0)$ (as in Figure 7) on which $Q(\delta_1, \delta_2)$ is defined and continuous. The following is the main theorem.

THEOREM 4. *If $\mathbf{S}(\delta)$ is a regular stasis curve in a neighborhood of $\delta = 0$, then $Q(\delta_1, \delta_2)$ is C^1 on the half-closed set $-\epsilon < \delta_1 \leq \delta_2 < \epsilon$ for some $\epsilon > 0$.*

Here we use the convention that a function is differentiable at a closed boundary if the one-sided derivatives exist and are continuous. The usefulness of this theorem

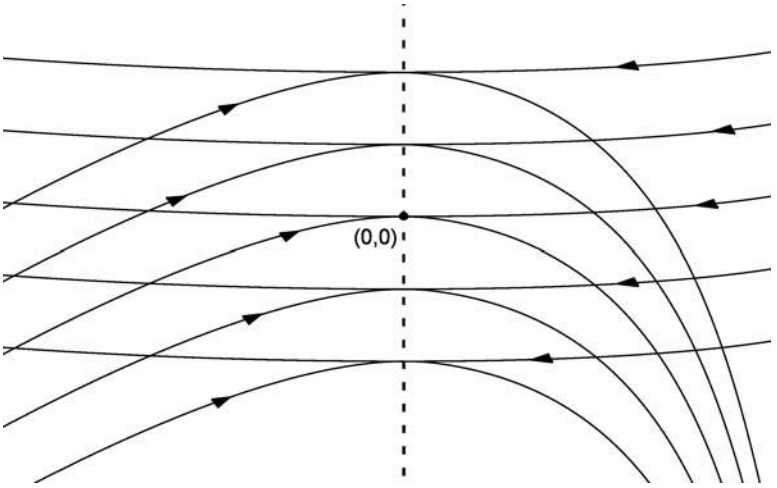

FIG. 8. *Rectification near stasis.*

lies in being able to calculate the partial derivatives and check for optimality. We demonstrate how to compute these partials in a direct computational proof of the theorem.

4. Rectification. We prove Theorem 4 by direct computation in a standardized reference frame. This section defines the standardizing diffeomorphism, of which several choices are possible. For example, we could rectify $\mathbf{F}_1$ by applying a diffeomorphism Φ that conjugates it to the constant flow $\widetilde{\mathbf{F}}_1 = \frac{d\Phi}{d(x,y)} \circ \mathbf{F}_1 \circ \Phi^{-1} = (1,0)$ (see [1]). After some experimentation, we find that applying a diffeomorphism that makes the two flows perpendicular to a vertical stasis line creates an efficient reference frame (see Figure 8). Specifically, on the neighborhood

$$R_\epsilon = \{-\epsilon < u < \epsilon,\ -\epsilon^2 < v < \epsilon^2\}, \tag{11}$$

our standard system is a pair of flows $\widetilde{\mathbf{F}}_i,\ i = 1, 2$, of the form

$$\begin{aligned} u' &= \kappa_i + \zeta_i u + \rho_i u^2 + \eta_i v + O(\epsilon^3), \\ v' &= \gamma_i u + \lambda_i u^2 + O(\epsilon^3) \\ &\text{with } \ \kappa_1\kappa_2 < 0 \ \text{ and } \ \kappa_1\gamma_2 - \kappa_2\gamma_1 \neq 0. \end{aligned} \tag{12}$$

Any C^3 system with a vertical stasis curve $u = 0$ and both flows horizontal through this curve must be of this form. By switching indices and/or the temporal direction we can, without loss of generality, assume

$$\kappa_1 > 0, \qquad \kappa_2 < 0, \qquad \kappa_1\gamma_2 - \kappa_2\gamma_1 < 0, \tag{13}$$

and this would be consistent with assumptions (7), (8) and Figures 5, 6.

LEMMA 5. *Any C^3 pair $\mathbf{F}_1, \mathbf{F}_2$ at a regular stasis point x_s, y_s with stasis curve $\mathbf{S}(\delta)$ can be rectified to the standard form* (12) *in a neighborhood R_ϵ for sufficiently small ϵ.*

Proof. In fact, this can be done in several ways. For example, since diffeomorphisms preserve stasis points, any nonsingular diffeomorphism

$$\Phi = \begin{pmatrix} u(x,y) \\ v(x,y) \end{pmatrix}$$

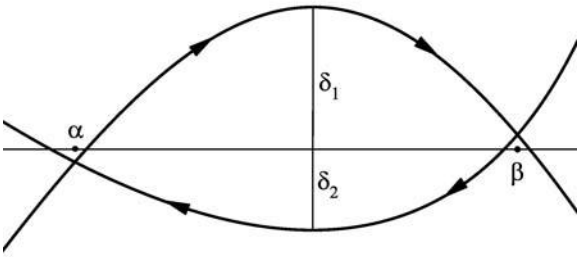

FIG. 9. *Delta-cycle.*

with $u = \mathbf{F}_1 \otimes \mathbf{F}_2$ will produce a conjugated system $\widetilde{\mathbf{F}}_1$, $\widetilde{\mathbf{F}}_2$ with $u = 0$ as the stasis line. Furthermore, taking v as any nontrivial solution to $v_x f_i + v_y g_i = 0$ for either $i = 1, 2$ will produce a conjugated system

$$\begin{pmatrix} \widetilde{f}_1 & \widetilde{f}_2 \\ \widetilde{g}_1 & \widetilde{g}_2 \end{pmatrix} = \begin{pmatrix} u_x & u_y \\ v_x & v_y \end{pmatrix} \begin{pmatrix} f_1 & f_2 \\ g_1 & g_2 \end{pmatrix}$$

that flows horizontally through $u = 0$. The flows are antiparallel on $u = 0$, and so $\widetilde{g}_i = v_x f_i + v_y g_i = 0$ for $u = 0$ for both $i = 1, 2$. We can even preserve the parameterization of the stasis curve by imposing the boundary values $v(\mathbf{S}(\delta)) = \delta$.

Since diffeomorphisms preserve regular stasis points, we have $\kappa_1 \kappa_2 < 0$ and

$$\frac{d}{dt}\, \widetilde{\mathbf{F}}_1 \otimes \widetilde{\mathbf{F}}_2 \,\big|_{0,0} = (\kappa_1 \gamma_2 - \kappa_2 \gamma_1)\ \frac{du}{dt}\bigg|_{u=0} = (\kappa_1 \gamma_2 - \kappa_2 \gamma_1)\, \kappa_i,$$

implying $\kappa_1 \gamma_2 - \kappa_2 \gamma_1 \neq 0$. □

It is thus sufficient to prove Theorem 4 for systems of form (12). The following lemma, which follows from direct computation, will be useful.

LEMMA 6. *For $\epsilon > 0$, $\kappa_i \neq 0$, the differential equation*

$$v'(u) = \frac{\gamma u + \lambda u^2 + O(\epsilon^3)}{\kappa + \zeta u + \rho u^2 + \eta v + O(\epsilon^3)}$$

with initial value $v(0) = \delta$ for $\delta^2 < \epsilon$ and $|u| < \epsilon$ has approximate solution

$$v(u) = \delta + \frac{\gamma}{2\kappa} u^2 + \left(\frac{\lambda\kappa - \gamma\zeta}{3\kappa^2} \right) u^3 + O(\epsilon^4).$$

5. Delta-cycles. For our standard system (12) in a neighborhood R_ϵ (defined (11)), and assuming $\kappa_1 \gamma_2 - \kappa_2 \gamma_1 < 0$, we construct the family of two-cycles in the form of *delta-cycles* as depicted in Figure 9. For δ_1,δ_2 values near zero, consider the trajectory $u_i(t), v_i(t)$ in system (12) starting at $(0, \delta_i)$. Applying Lemma 6 to the implicit functions $v_1(u)$ and $v_2(u)$ yields

$$\begin{aligned} v_1(u) - v_2(u) = (\delta_1 - \delta_2) &- \left(\frac{\kappa_1 \gamma_2 - \kappa_2 \gamma_1}{2\kappa_1 \kappa_2} \right) u^2 \\ &+ \left(\frac{\lambda_1 \kappa_1 - \gamma_1 \zeta_1}{3\kappa_1^2} - \frac{\lambda_2 \kappa_2 - \gamma_2 \zeta_2}{3\kappa_2^2} \right) u^3 + O(\epsilon^4). \end{aligned}$$

The assumptions $\kappa_1\gamma_2 - \kappa_2\gamma_1 < 0$ and $\kappa_1\kappa_2 < 0$ imply that for $\delta_1 > \delta_2$ sufficiently small, this expression will vanish at points $u = \alpha, \beta$ for $\alpha < 0 < \beta$, which can be explicitly approximated. For small values of A the cubic $A - Bx^2 + Cx^3 + O(A^2)$ has roots

$$x = \pm\sqrt{\frac{A}{B}} + \frac{AC}{2B^2} + O(A^{3/2}).$$

Hence,

$$\begin{aligned}\alpha = &-\sqrt{\frac{2\kappa_1\kappa_2}{\kappa_1\gamma_2 - \kappa_2\gamma_1}}\,(\delta_1 - \delta_2)^{1/2} \\ &-\frac{2}{3}\frac{\kappa_2^2\kappa_1\lambda_1 + \kappa_2^2\gamma_1\zeta_1 + \kappa_1^2\kappa_2 - \kappa_1^2\gamma_2\zeta_2}{(\kappa_1\gamma_2 - \kappa_2\gamma_1)}\,(\delta_1 - \delta_2) \\ &+ O(\epsilon^3),\end{aligned} \tag{14}$$

$$\begin{aligned}\beta = &\sqrt{\frac{2\kappa_1\kappa_2}{\kappa_1\gamma_2 - \kappa_2\gamma_1}}\,(\delta_1 - \delta_2)^{1/2} \\ &-\frac{2}{3}\frac{\kappa_2^2\kappa_1\lambda_1 + \kappa_2^2\gamma_1\zeta_1 + \kappa_1^2\kappa_2 - \kappa_1^2\gamma_2\zeta_2}{(\kappa_1\gamma_2 - \kappa_2\gamma_1)}\,(\delta_1 - \delta_2) \\ &+ O(\epsilon^3).\end{aligned} \tag{15}$$

This construction demonstrates the existence of two-cycles near a regular stasis point for sufficiently small $\delta_1 < \delta_2$, which proves Lemma 2.

6. Proof of Theorem 4. We are now prepared to prove Theorem 4 by direct calculation in the form of the following lemma.

LEMMA 7. *For systems ($i = 1, 2$)*

$$\begin{aligned}u' &= \kappa_i + \zeta_i u + \rho_i u^2 + \eta_i v + O(\epsilon^3), \\ v' &= \gamma_i u + \lambda_i u^2 + O(\epsilon^3)\end{aligned} \tag{16}$$

with $\kappa_1\kappa_2 < 0$, $\kappa_1\gamma_2 - \kappa_2\gamma_1 < 0$, and associated costs

$$H_i(u, v) = A_i + B_i u + C_i u^2 + D_i v + O(\epsilon^3),$$

for $\delta_1 \geq \delta_2$ sufficiently small we have

$$\begin{aligned}Q(\delta_1, \delta_2) = &\frac{\kappa_1 A_2 - \kappa_2 A_1}{\kappa_1 - \kappa_2} \\ &+ (A_1 - A_2)(\delta_1 - \delta_2)\frac{\left(\gamma_1\eta_1\kappa_2^2 - \gamma_2\eta_2\kappa_1^2 + 2\kappa_2^2\kappa_1\rho_1 - 2\kappa_1^2\kappa_2\rho_2\right)}{3(\kappa_1 - \kappa_2)^2(\kappa_1\gamma_2 - \kappa_2\gamma_1)} \\ &+ (A_1 - A_2)(\delta_1 - \delta_2)\frac{2\kappa_1\kappa_2(\zeta_2\kappa_1 - \zeta_1\kappa_2)(\lambda_2\kappa_1 - \lambda_1\kappa_2 + \gamma_2\zeta_1 - \gamma_1\zeta_2)}{3(\kappa_1 - \kappa_2)^2(\kappa_1\gamma_2 - \kappa_2\gamma_1)^2} \\ &+ (A_1 - A_2)(\delta_1\eta_1\kappa_2 - \delta_2\eta_2\kappa_1)\frac{1}{(\kappa_1 - \kappa_2)^2} \\ &+ (B_1\gamma_2 - B_2\gamma_1)(\delta_1 - \delta_2)\frac{\kappa_2\kappa_1(\zeta_1\kappa_2 - \zeta_2\kappa_1)}{(\kappa_1 - \kappa_2)(\kappa_1\gamma_2 - \kappa_2\gamma_1)^2}\end{aligned}$$

$$
\begin{aligned}
&+ \left(B_1\kappa_2 - B_2\kappa_1\right)\left(\delta_1 - \delta_2\right)\frac{\kappa_2\kappa_1\left(\kappa_1\lambda_2 - \kappa_2\lambda_1\right)}{\left(\kappa_1 - \kappa_2\right)\left(\kappa_1\gamma_2 - \kappa_2\gamma_1\right)^2}\\
&- \left(C_1\kappa_2 - C_2\kappa_1\right)\left(\delta_1 - \delta_2\right)\frac{\kappa_2\kappa_1}{3\left(\kappa_1 - \kappa_2\right)\left(\kappa_1\gamma_2 - \kappa_2\gamma_1\right)}\\
&- \left(D_1\gamma_1\kappa_2^2 - D_2\gamma_2\kappa_1^2\right)\left(\delta_1 - \delta_2\right)\frac{1}{3\left(\kappa_1 - \kappa_2\right)\left(\kappa_1\gamma_2 - \kappa_2\gamma_1\right)}\\
&- \left(D_1\delta_1\kappa_2 - D_2\delta_2\kappa_1\right)\frac{1}{\kappa_1 - \kappa_2}\\
&+ O\left(\left|\delta_1\right|^{3/2}, \left|\delta_2\right|^{3/2}\right).
\end{aligned}
$$

Proof. Given cost functions H_1 and H_2 and using the implicit functions $v_1(u)$ and $v_2(u)$, we have from (9)

$$
Q(\delta_1, \delta_2) = \frac{\int_\alpha^\beta \frac{H_1(u, v_1(u))}{f_1(u, v_1(u))}\, du + \int_\alpha^\beta \frac{H_2(u, v_2(u))}{f_2(u, v_2(u))}\, du}{\int_\alpha^\beta \frac{1}{f_1(u, v_1(u))}\, du + \int_\alpha^\beta \frac{1}{f_2(u, v_2(u))}\, du}. \tag{17}
$$

Using Lemma 6 we expand the integrands

$$
\begin{aligned}
\frac{H_i(u, v_i(u))}{f_i(u, v_i(u))} &= \frac{A_i + B_i u + C_i u^2 + D_i v_i(u)}{\kappa_i + \zeta_i u + \rho_i u^2 + \eta_i v_i(u)}\\
&= \frac{A_i}{\kappa_i} + \left(\frac{D_i\kappa_i - A_i\eta_i}{\kappa_i^2}\right)\delta_i + \left(\frac{B_i\kappa_i - \zeta_i A_i}{\kappa_i^2}\right)u\\
&\quad + \left(\frac{2C_i\kappa_i^2 + D_i\gamma_i\kappa_i - 2A_i\rho_i\kappa_i - A_i\eta_i\gamma_i - 2\zeta_i\kappa_i B_i + 2\zeta_i^2 A_i}{2\kappa_i^3}\right)u^2\\
&\quad + O(\epsilon^3).
\end{aligned} \tag{18}
$$

Hence the integrands in (17) are essentially quadratic. With α, β from (14), (15) we compute for general quadratics with coefficients a_i, b_i,

$$
\begin{aligned}
&\frac{\int_\alpha^\beta \left(a_1 + a_2 u + a_3 u^2 + O(\epsilon^3)\right)\, du}{\int_\alpha^\beta \left(b_1 + b_2 u + b_3 u^2 + O(\epsilon^3)\right)\, du}\\
&\quad = \frac{a_1}{b_1} + \frac{2\left(\kappa_2^2\kappa_1\lambda_1 - \zeta_1\gamma_1\kappa_2^2 - \kappa_1^2\kappa_2\lambda_2 + \kappa_1^2\gamma_2\zeta_2\right)}{3b_1^2\left(\gamma_2\kappa_1 - \gamma_1\kappa_2\right)^2}\left(a_2b_1 - a_1b_2\right)\left(\delta_1 - \delta_2\right)\\
&\qquad + \frac{2\kappa_2\kappa_1}{3b_1^2\left(\gamma_2\kappa_1 - \gamma_1\kappa_2\right)}\left(b_1a_3 - a_1b_3\right)\left(\delta_1 - \delta_2\right) + O(\epsilon^3).
\end{aligned}
$$

The theorem follows from substituting a_i, b_i using (18):

$$
\begin{aligned}
a_1 &= \frac{1}{\kappa_1^2}\left(A_1\kappa_1 + \delta_1 D_1\kappa_1 - \delta_1 A_1\eta_1\right)\\
&\quad - \frac{1}{\kappa_2^2}\left(A_2\kappa_2 + \delta_2 D_2\kappa_2 - \delta_2 A_2\eta_2\right),\\
a_2 &= \frac{1}{\kappa_1^2}\left(B_1\kappa_1 - A_1\zeta_1\right) - \tfrac{1}{\kappa_2^2}\left(B_2\kappa_2 - A_2\zeta_2\right),
\end{aligned}
$$

$$a_3 = \frac{1}{2\kappa_1^3}\left(A_1(2\zeta_1^2 - 2\rho_1\kappa_1 - \eta_1\gamma_1) - 2B_1\zeta_1\kappa_1 + 2C_1\kappa_1^2 + D_1\gamma_1\kappa_1\right)$$
$$- \frac{1}{2\kappa_2^3}\left(A_2(2\zeta_2^2 - 2\rho_2\kappa_2 - \eta_2\gamma_2) - 2B_2\zeta_2\kappa_2 + 2C_2\kappa_2^2 + D_2\gamma_2\kappa_2\right),$$
$$b_1 = \frac{1}{\kappa_1^2}(\kappa_1 - \delta_1\eta_1) - \frac{1}{\kappa_2^2}(\kappa_2 - \delta_2\eta_2),$$
$$b_2 = -\frac{\zeta_1}{\kappa_1^2} + \frac{\zeta_2}{\kappa_2^2},$$
$$b_3 = \frac{1}{2\kappa_1^3}(2\zeta_1^2 - 2\rho_1\kappa_1 - \eta_1\gamma_1) - \frac{1}{2\kappa_2^3}(2\zeta_2^2 - 2\rho_2\kappa_2 - \eta_2\gamma_2). \qquad \square$$

7. Example: Vehicle cruise. Suppose you can switch between the two following systems:

$$\text{COASTING:} \quad y' = -f(y).$$
$$\text{ENGAGED:} \quad y' = M - g(y) - f(y).$$

Here, we can think of y as velocity and $f(y)$ as friction. As would arise in bang-bang controls, we consider M the maximum thrust we can apply, and $g(y)$ the cost or discount from applying that thrust at speed y. We impose the restriction that y must stay close to a prescribed average velocity R. Define u as the difference between the actual and target velocities, $u = y - R$, and let v be position $v' = u$. With $F(u) = f(u + R)$ and $G(u) = g(u + R)$ we have the pair of systems

$$\begin{array}{ll} u' = -F(u), & u' = M - G(u) - F(u), \\ v' = u, & v' = u\,. \end{array}$$

This is in standard form (12), has $\lambda_i = \eta_i = 0$, $\gamma_i = 1$, and

$$\begin{aligned} \kappa_1 &= -F(0), \\ \zeta_1 &= -F'(0), \\ \rho_1 &= -\frac{1}{2}F''(0), \\ \kappa_2 &= M - F(0) - G(0), \\ \zeta_2 &= -F'(0) - G'(0), \\ \rho_2 &= -\frac{1}{2}F''(0) - \frac{1}{2}G''(0). \end{aligned}$$

Taking performance as minimizing the average thrust discount,

$$Q = \frac{1}{T}\int_0^T G(u(t))\,dt,$$

we take $A_1 = B_1 = C_1 = D_1 = A_2 = B_2 = 0$, $C_2 = G'(0)$, and $D_2 = \frac{1}{2}G''(0)$, yielding

$$Q(\delta_1, \delta_2) = -\frac{1}{3}(\delta_2 - \delta_1)\,(M - F(0) - G(0))\ \frac{d}{du}\left(G'(u)\left(\tfrac{F(u)}{M-G(u)}\right)^2\right)_{u=0}.$$

On the other hand, if performance is measured as average thrust, we define

$$I(t) = \begin{cases} 0 & \text{if COASTING,} \\ 1 & \text{if ENGAGED} \end{cases}$$

and take

$$Q = \frac{1}{T}\int_0^T M\ I(t)\ dt.$$

Taking $A_1 = B_1 = C_1 = D_1 = B_2 = C_2 = D_2 = 0$ and $A_2 = M$ we get

$$Q(\delta_1, \delta_2)$$
$$= \frac{(\delta_1 - \delta_2)F(0)(M - F(0) - G(0))}{3(M - G(0))^4}\left((M - G(0))\frac{d^2}{du^2}\big(F(u)(M - G(u))\big)_{u=0} + 2\left(G'(0)\right)^2 F(0)\right).$$

The coefficient $\frac{F(0)(M-F(0)-G(0))}{3(M-G(0))^4}$ and the expression $M - G(0)$ are always positive (if the vehicle can move at all), and so optimality is indicated by the second derivative of $F(u)(M - G(u))$. If

$$\frac{d^2}{du^2}\big(F(u)(M - G(u))\big)_{u=0} > -\frac{2\left(G'(0)\right)^2 F(0)}{M - G(0)},$$

then stasis is never optimal. In particular if G is constant, $\frac{d^2F}{du^2}(0) > 0$ implies that stasis is not optimal. This yields a general and quite powerful converse to Theorem 8 in [5].

ABSOLUTE STABILITY CRITERIA FOR A GENERALIZED LUR'E PROBLEM WITH DELAY IN THE FEEDBACK*

A. A. ZEVIN† AND M. A. PINSKY‡

Abstract. A nonautonomous linear system controlled by a nonlinear sector-restricted feedback with a time-varying delay is considered. Delay-independent sufficient conditions for absolute stability and instability (expressed in the transfer function of the linear part and the sector bounds) are established. For a system with an exponentially stable linear part, an upper bound for the Lyapunov exponent is found. It is shown that if the transfer function is sign-constant, asymptotic stability of the system with the margin-linear feedback guarantees absolute stability of the considered system; thus, such systems satisfy the known Aizerman conjecture. They include, in particular, a closed-loop system consisting of any number of time-varying first order links and feedback with arbitrary delay. Under some additional condition (which is certainly true for a time-invariant linear block), the obtained stability criterion is precise. The approach employed in the proofs is based on a direct analysis of the corresponding Volterra equation which contains only the transfer function of the linear block and, therefore, embraces a wide range of control systems. As an example, a second order system is considered; it is shown that here the obtained stability bound is reached for a linear feedback with a periodic delay function.

Key words. Lur'e problem, time-varying system, delay in feedback, absolute stability condition, Aizerman class

1. Introduction.

The classical Lur'e problem is to find conditions for absolute stability of a control system consisting of a linear block and a nonlinear feedback contained within a prescribed sector [1]. Over the last few decades there has appeared an extensive literature devoted to the problem and its generalization. Most of the known results are obtained by the frequency domain or Lyapunov function methods and relate to systems with a time-invariant or periodic linear block (e.g., [2, 3, 4, 5, 6, 7, 8, 9, 10]). The Lyapunov method enables us, in principle, to tackle arbitrary time-varying systems; however, finding the Lyapunov function for such systems is, generally, a difficult problem.

In [11] sufficient stability conditions for the Lur'e problem that are equally applied to time-invariant and time-varying systems were found. The results are based on a direct analysis of the corresponding integral Volterra equation regarding the input of the nonlinear block $\sigma(t)$. In the current paper we extend this approach to systems with delay in the feedback. Namely, we assume that the corresponding output is of the form $\varphi = \varphi(\sigma(t-\tau(t)), t)$ where the function $\tau(t)$ is piecewise continuous, nonnegative, and bounded for $t \in [0, \infty)$. The corresponding integral equation becomes

$$\sigma(t) = f(t) + \int_0^t w(t,s)\varphi(\sigma(s-\tau(s)), s)\,\mathrm{d}s, \tag{1.1}$$

where $w(t,s)$ is the transfer function of the linear block. Note that no other information on the linear block is employed, so the last may be described, in particular, by

partial differential or integral equations.

The piecewise continuous scalar valued function $f(t)$ describes oscillation of the corresponding linear system in the absence of the feedback caused by nonzero initial conditions and, perhaps, external perturbation disappearing at infinity. We assume that the linear block is asymptotically stable; thus

$$|f(t)| \to 0 \text{ as } t \to \infty. \tag{1.2}$$

The function $\varphi(\sigma, t)$ belongs to the class $\Phi(K_1, K_2)$, i.e., satisfies the inequality

$$K_1\sigma^2 \le \varphi(\sigma, t)\sigma \le K_2\sigma^2, \quad \sigma \in (-\infty, \infty). \tag{1.3}$$

We assume that with a given initial function $\sigma(t)$ for $t < 0$, the solution $\sigma(t)$ of (1.1) is continuable on $[0, \infty)$.

DEFINITION 1. *System* (1.1) *is called absolutely stable in the class* $\Phi(K_1, K_2)$ *if for any functions* $f(t)$, $\varphi(\sigma, t)$, *satisfying conditions* (1.2), (1.3), *and any piecewise continuous nonnegative bounded for* $t \in [0, \infty)$ *function* $\tau(t)$, *the corresponding solution* $\sigma(t)$ *of* (1.1) *satisfies the condition*

$$|\sigma(t)| \to 0 \text{ as } t \to \infty. \tag{1.4}$$

If condition (1.4) is not fulfilled for some $\varphi(\sigma, t)$, $\tau(t)$, and $f(t)$ from the indicated classes, the system is referred to as unstable.

Putting $\varphi_1(\sigma, t) = \varphi(\sigma, t) - K_1\sigma - K\sigma, K = 0.5(K_2 - K_1)$, and retaining the previous notation, we reduce (1.3) to the form

$$-K\sigma^2 \le \varphi(\sigma, t)\sigma \le K\sigma^2, \quad \sigma \in (-\infty, \infty). \tag{1.5}$$

Thus, we replace the class $\Phi(K_1, K_2)$ by $\Phi(-K, K)$; therewith we assume that the transfer function $w(t, s)$ in (1.1) is changed correspondingly.

In section 2 a value K_* is found such that for $K < K_*$, the system is absolutely stable independent on the delay function $\tau(t)$ (see Theorem 1). If the linear block is exponentially stable and the function $f(t)$ exponentially tends to zero, so does the solution $\sigma(t)$; Theorem 2 provides an upper bound for the corresponding Lyapunov exponent. For a class of linear blocks (including, in particular, the autonomous ones) the value K_0 is found such that the system is unstable in the class $\Phi(-K_0, K_0)$ for any $\tau(t)$ (see Theorem 3).

In section 3 systems with a nonnegative transfer function are considered. It is shown (see Theorem 4) that asymptotic stability for $\varphi(\sigma, t) = K\sigma$ guarantees absolute stability of the system in the class $\Phi(-K, K)$. Thus, such systems for arbitrary delay $\tau(t)$ in the feedback satisfy the Aizerman conjecture [12] (note that the known results of this kind [13, 14, 15] relate to time-invariant systems). Under some additional condition, a precise upper bound for the stability sector is found (see Theorem 5).

In section 4 applications of the obtained results to some systems are discussed. It is shown that a closed-loop system consisting of any number of first order time-varying links and arbitrary delay in the feedback satisfies the Aizerman conjecture in the class $\Phi(-K, K)$. For a second order time-invariant system, delay independent bounds K_* and K_0 are found in explicit forms; the bound K_* is precise because it is reached for some periodic delay $\tau(t)$.

2. Absolute stability and instability criteria. Suppose that the linear block is exponentially stable; then

$$|w(t,s)| \le C\exp[-\Delta(t-s)], \tag{2.1}$$

where the constants C and $\Delta > 0$ are independent of t and s.

Let us put

$$W(t) = \int_0^t w(t,s)|\mathrm{d}s,$$

$$W_+(t_k) = \sup W(t) \quad \text{for } t \ge t_k, \tag{2.2}$$

$$W_\infty = \overline{\lim_{t\to\infty}}\, W(t) = \lim_{t_k\to\infty} W_+(t_k).$$

Here W_∞ is the upper limit of $W(t)$ as $t \to \infty$; it coincides with the conventional limit when the last exists. This is certainly the case when the linear block is time-invariant. In fact, in such a system $w(t,s) = w(t-s)$, so, setting $t - s = z$, we obtain

$$W(t) = \int_0^t w(z)|\mathrm{d}z. \tag{2.3}$$

The function $W(t)$ in (2.3) increases monotonically and, therefore, tends to the limit.

The following theorem establishes a sufficient condition for absolute stability of system (1.1), (1.5).

THEOREM 1. *If*

$$K < K_* = 1/W_\infty, \tag{2.4}$$

the system is absolutely stable in the class $\Phi(-K,K)$.

Proof. Let $\sigma(t)$ be a solution of (1.1). First let us show that for any $t_1 \ge 0$, there exists $t_m \ge t_1$ such that $|\sigma(t_m)| \ge |\sigma(t)|$ for $t \in [t_1,\infty)$. In fact, otherwise there is a sequence $t_1, t_2, \ldots,\ t_k \to \infty$ as $k \to \infty$, such that $|\sigma(t)| \le |\sigma(t_k)|$ for $t \in [t_1, t_k]$. Then from (1.1) and (1.5) we have

(2.5)

$$|\sigma(t_k)| \le R(t_k,t_1) + K\int_{t_1}^{t_k} |w(t_k,s)\|\sigma(s-\tau(s))|\mathrm{d}s \le R(t_k,t_1) + KW(t_k)|\sigma(t_k)|,$$

where

$$R(t_k,t_1) = |f(t_k)| + K\int_0^{t_1} |w(t_k,s)\|\sigma(s-\tau(s))|\mathrm{d}s.$$

Observing that $W(t_k) \le W_+(t_k), W_+(t_k) \to W_\infty, R(t_k,t_1) \to 0$ as $t_k \to \infty$, and, by (2.4), $KW_\infty < 1$, we find that inequality (2.5) cannot hold for large k. The contradiction obtained shows that there exists a sequence $t_m, m = 1,2,\ldots$, such that $t_m \to \infty$ as $m \to \infty$ and $|\sigma(t_m)| \ge |\sigma(t)|$ for $t \in [t_m,\infty)$. Evidently, $|\sigma(t_m)| \ge |\sigma(t_{m+1})| \ge 0$; therefore there exists $\sigma_\infty = \lim|\sigma(t_m)|$ as $t_m \to \infty$. Let us prove that $\sigma_\infty = 0$.

By assumption, $\tau(t) \le h$ for some h. Assuming $t_m - t_i \ge h$, analogously (2.5), we find

(2.6)
$$|\sigma(t_m)| \le R(t_m, t_i) + K \int_{t_i}^{t_m} |w(t_m, s)||\sigma(s - \tau(s))|\mathrm{d}s \le R(t_m, t_i) + KW(t_m)|\sigma(t_i)|.$$

Since the sequence $|\sigma(t_m)|, m = 1, 2, \dots$, is convergent, then for any $\varepsilon > 0$, there exists i such that $|\sigma(t_i| - |\sigma(t_m| < \varepsilon$ for all $m > i$. Therefore, from (2.6) we find

$$|\sigma(t_m)|[1 - KW(t_m)] < R(t_m, t_i) + \varepsilon KW(t_m). \tag{2.7}$$

Since $R(t_m, t_i) < \varepsilon$ for large $t_m - t_i$, $\lim KW_+(t_m) = KW_\infty < 1$ as $t_k \to \infty$, and $W(t_m) \le W_+(t_m)$, then $KW(t_m) < 1$ for large m. Therefore, inequality (2.7) is true only if $|\sigma(t_m)| \to 0$ as $m \to \infty$, i.e., $|\sigma(t)| \to 0$ as $t \to \infty$. □

Suppose that along with (2.1),

$$|f(t)| \le C \exp(-\Delta_1 t) \tag{2.8}$$

for some $\Delta_1 > 0$. In particular, if $f(t)$ is a solution of the linear system in the absence of external perturbations, then $\Delta_1 = \Delta$.

DEFINITION 2. *System* (1.1) *is called absolutely exponentially stable in the class* $\Phi(K_1, K_2)$ *if for any functions* $\varphi(\sigma, t), f(t)$, *satisfying conditions* (1.3), (2.8) *and any piecewise continuous nonnegative bounded for* $t \in [0, \infty)$ *function* $\tau(t)$, *there exists a constant* $\beta > 0$ *such that for some* C, *the corresponding solution* $\sigma(t)$ *of* (1.1) *satisfies the inequality*

$$|\sigma(t)| \le C \exp(-\beta t).$$

The infimum of $\lambda = -\beta$ for which the value C exists is called the Lyapunov exponent of the function $\sigma(t)$ (see, for example, [16]).

The following theorem establishes an upper bound for the Lyapunov exponent of the solutions $\sigma(t)$ of system (1.1), (1.5).

Let β_* be the root of the equation

$$W_\infty(\beta, h) = 1/K, \tag{2.9}$$

where

$$W_\infty(\beta, h) = \overline{\lim_{t\to\infty}} W_+(\beta, h, t), \quad W_+(\beta, h, t) = \int_0^t \exp[\beta(t + h - s)]|w(t, s)|\mathrm{d}s.$$

THEOREM 2. *The Lyapunov exponent of the solution* $\sigma(t)$ *satisfies the inequality*

$$\lambda \le -\beta_*. \tag{2.10}$$

Proof. Setting in (1.1)

$$\sigma(t) = \exp(-\beta t) y(t), \tag{2.11}$$

where $\beta \in (0, \beta_* < \Delta_1)$, we obtain

$$y(t) = \exp(\beta t) f(t) + \exp(\beta t) \int_0^t w(t, s) \varphi[\exp(-\beta s) y(s - \tau(s)), s]\mathrm{d}s \tag{2.12}$$

whence analogously (2.5) we have

$$|y(t_k)| \le R(\beta, t_k, t_1) + KW(\beta, h, t_k)|y(t_k)|. \tag{2.13}$$

Clearly, $W_\infty(\beta, h)$ increases with β, so, in view of (2.9), $KW_\infty(\beta, h) < 1$ for $\beta < \beta_*$. Therefore, analogously to the proof of Theorem 1, we find that $y(t)$ is bounded on $(0, \infty)$, which, along with (2.11), proves the theorem. □

Let us now obtain a condition guaranteeing instability of the system. To this end, we put

$$W^0(t) = \int_0^t w(t, s)\, \mathrm{d}s. \tag{2.14}$$

Suppose there exists

$$W_0 = \lim_{t\to\infty} W^0(t) \ne 0. \tag{2.15}$$

THEOREM 3. *If*

$$K \ge K_0 = 1/|W_0|, \tag{2.16}$$

then system (1.1), (1.5) *is unstable.*

Proof. Let us put

$$f_0(t) = 1 - W^0(t)/W_0, \qquad \varphi_0(\sigma) = K_0\sigma \operatorname{sgn} W_0, \qquad \sigma(t) \equiv 1 \quad \text{for } t < 0. \tag{2.17}$$

In view of (2.15) and (2.17), $|f_0(t)| \to 0$ as $t \to \infty$; by (2.16), $\varphi_0(\sigma) \in \Phi(-K, K)$. By a direct substitution one can check that $\sigma(t) \equiv 1$ is the corresponding solution of (1.1). Since it does not satisfy condition (1.4), the system is unstable.

Let K_b be the value of the constant K such that the system is stable in the class $\Phi(-K, K)$ for $K < K_b$ and unstable for $K \ge K_b$. Then from Theorems 1 and 3 it follows that K_b satisfies the inequality

$$1/W_\infty \le K_b \le 1/|W_0|. \tag{2.18}$$

3. Systems with sign-constant transfer function. Suppose now that the transfer function $w(t, s)$ is sign-constant. Without loss of generality, we assume that

$$w(t, s) \ge 0 \quad \text{for} \quad t \ge s \ge 0 \tag{3.1}$$

because the case $w(t, s) \le 0$ is reduced to (3.1) by substitution: $w_1(t, s) = -w(t, s)$, $\varphi_1(\sigma, t) = -\varphi(\sigma, t)$.

THEOREM 4. *System* (1.1), (3.1) *is absolutely stable in the class* $\Phi(-K, K)$ *if it is stable for* $\varphi = K\sigma(t - \tau(t))$.

Proof. Let $\sigma_0(t)$ be the solution of the equation

$$\sigma_0(t) = f_0(t) + K\int_0^t w(t, s)\sigma_0(s - \tau(s))\, \mathrm{d}s, \tag{3.2}$$

where

$$\sigma_0(t) = |\sigma(t)| \text{ for } t < 0, \qquad f_0(t) = |f(t)| + \exp(-t) \text{ for } t \ge 0. \tag{3.3}$$

Clearly, $\sigma_0(t-\tau(s)) > |\sigma(t-\tau(s))| > 0$ for sufficiently small $t > 0$. Let us show that this inequality cannot break as t increases. In fact, let $\sigma_0(t_1-\tau(t_1)) = \sigma(t_1-\tau(t_1))$ for some t_1; then, subtracting (1.1) from (3.2), we find

(3.4)
$$0 = |f(t_1)| - f(t_1) + \exp(-t_1) + \int_0^{t_1} w(t_1,s)[K\sigma_0(s-\tau(s)) - \varphi(\sigma(s-\tau(s)),s)]\,\mathrm{d}s,$$

which is impossible, because the right-hand side of (3.4) is positive ($K\sigma_0 > \varphi(\sigma)$ for $\sigma_0 > |\sigma|$).

If $\sigma_0(t_1) = -\sigma(t_1)$, then, summing (3.2) and (1.1), we find

$$0 = |f(t_1)| + f(t_1) + \exp(-t_1) + \int_0^{t_1} w(t_1,s)[K\sigma_0(s-\tau(s)) + \varphi(\sigma(s-\tau(s)),s)]\,\mathrm{d}s,$$

where the right-hand side is also positive.

The obtained contradictions show that $\sigma_0(t) > |\sigma(t)|$ for $t > 0$ and, therefore, $\sigma(t) \to 0$ as $t \to \infty$.

Suppose, moreover, that limit (2.15) exists.

THEOREM 5. *For absolute stability of system* (1.1), (3.1), *it is necessary and sufficient that*

$$K < 1/W_\infty. \tag{3.5}$$

In fact, by (3.1), $W(t) = W^0(t), W_\infty = W_0$, so Theorem 5 follows directly from inequality (2.18).

4. Discussion. The obtained results embrace a wide range of control systems with, generally, time-varying linear block and arbitrary delay $\tau(t)$ in the feedback. In accordance with sufficient stability condition (2.4), such a system is absolutely stable in the class $\Phi(-W_\infty^{-1}+\varepsilon, W_\infty^{-1}-\varepsilon)$ where $\varepsilon > 0$ is an arbitrary small value. If the function $f(t)$ in (1.1) exponentially tends to zero, the stability is exponential; the corresponding Lyapunov exponent satisfies inequality (2.10) (see Theorem 2). If limit (2.15) exists, the system is certainly unstable in the wider class $\Phi(-W_0^{-1}, W_0^{-1})$ (see Theorem 3).

Note that these results can be extended to the case when the nonlinearity bounds are time-dependent, i.e.,

$$-K(t)\sigma^2 \le \varphi(\sigma,t)\sigma \le K(t)\sigma^2, \quad K(t) \ge 0. \tag{4.1}$$

In fact, as is clear from the proofs, it is only necessary to replace KW_∞ and KW_0 in the above conditions by

$$\overline{\lim_{t\to\infty}} \int_0^t |K(t)w(t,s)|\mathrm{d}s \quad \text{and} \quad \overline{\lim_{t\to\infty}} \int_0^t K(t)w(t,s)\,\mathrm{d}s, \tag{4.2}$$

respectively.

As is known, the Lur'e problem was first formulated for the system

$$\dot{x} = Ax + b\varphi(cx), \tag{4.3}$$

where $x \in R^n$, and b and c are column and row vectors, respectively. The problem is reduced to (1.1), where $\varphi = \varphi(\sigma)$, $\sigma = cx$, and $w(t,s) = w(t-s)$, because (4.3) is time-invariant.

In 1949 Aizerman conjectured [12] that system (4.3) is absolutely stable in the class $\varphi(\sigma) \in \Phi(K_1, K_2)$, provided that the linear system $\dot{x} = Ax + kbcx$ is stable for any $k \in [K_1, K_2]$. Subsequently, counterexamples showed that this conjecture is, in general, false (the history of the Aizerman conjecture can be found in Gil' [13]). So the problem is to find classes of systems satisfying the Aizerman conjecture. The first result in this direction was obtained by Gil' [13], who proved that if in system (4.3) the transfer function is nonnegative, then its absolute stability in the class $\Phi(0, K)$ is guaranteed by stability of the system $\dot{x} = Ax + Kbcx$. Recently he extended this result to distributed and delay time-invariant systems [14, 15].

In [11] time-variable systems with a nonnegative transfer function were considered via direct analysis of the corresponding Volterra equation. As a result, it was shown that stability of such a system for $\varphi(\sigma, t) = K\sigma$ guarantees absolute stability in the class $\Psi(-K, K)$. Theorem 4 of the present paper extends this result to systems with arbitrary delay $\tau(t)$ in the feedback. Namely, if the transfer function $w(t, s)$ is nonnegative, then for absolute stability of the system in the class $\Phi(-K, K)$, it is necessary and sufficient that it is asymptotically stable for $\varphi = K\sigma(t - \tau(t))$. If in (2.15) the limit W_0 exists (in particular, if the linear block is time-invariant), the precise bound for the stability sector equals $K = 1/W_\infty$ (Theorem 5) for any delay $\tau(t)$. Note that at first sight the invariance of the stability sector on $\tau(t)$ looks surprising; however, this is due to the fact that for $K = 1/W_\infty$ and $f(t)$, determined by (2.17), equation (1.1) admits the "unstable" solution $\sigma(t) \equiv 1$ for any $\tau(t)$.

When analyzing the Lur'e problem, the nonlinearity class $\Phi(K_1, K_2)$ is usually reduced to $\Phi(0, K)$ ($K = K_2 - K_1$) by substitution: $\varphi_1(\sigma, t) = \varphi(\sigma, t) - K_1\sigma$. It can be shown that on the transformation $\varphi_1(\sigma, t) = \varphi(\sigma, t) - c\sigma$, the corresponding transfer function $w(t, s, c)$ increases with c, provided that $w(t, s, c) > 0$ for $t \geq s \geq 0$. So, if for $c = K_1$ ($\Phi = \Phi(0, K)$) condition (3.1) is satisfied, then it certainly holds for $c = 0.5(K_1 + K_2) > K_1$ ($\Phi = \Phi(-K, K)$). The converse is not, in general, true; i.e., condition (3.1), which is valid in the class $\Phi(-K, K)$, may be lost on the transformation to the class $\Phi(0, K)$.

Clearly, on the transformation $\varphi_1(\sigma, t) = \varphi(\sigma, t) - c\sigma$, the lower bound of the stability sector, provided by Theorem 4, becomes $K(c) = -K + 2c$. Thus, the largest stability sector corresponds to the minimal value $c < 0$ for which the transfer function $w(t, s, c)$ is still nonnegative.

Let $[K_1^0, K_2^0]$ be the Hurwitz angle of linear system (1.1) with $\varphi(\sigma, t) = k\sigma$ (i.e., it is asymptotically stable for $K_1^0 < k < K_2^0$ and unstable or not asymptotically stable for $k = K_1^0$ and $k = K_2^0$). If the transfer function is nonnegative and the limit W_0 exists, then from Theorem 5 it follows that $K_2^0 = 1/W_\infty$. Since, by Theorem 4, stability for $\varphi(\sigma, t) = K\sigma$ provides stability in the class $\Phi(-K, K)$, then $K_1^0 \leq -K_2^0$. A more detailed analysis shows that $K_1^0 < -K_2^0$.

Let the linear block be a closed-loop system consisting of n (generally, time-varying) links. Suppose that the individual transfer functions $w_i(t, s), i = 1, \ldots, n$, are sign-constant. For a sign-constant input, the output of each link is sign-constant as well; therefore, so is the transfer function $w(t, s)$ of the entire linear block.

Suppose, in particular, that the links are of the first order; i.e., the linear block is described by the equations

$$\begin{aligned} &\dot{x}_1 + a_1(t)x_i = 0, \\ &\dot{x}_1 + a_i(t)x_i = k_i x_{i-1}, i = 2, \ldots, n. \end{aligned} \tag{4.4}$$

An extensive literature is devoted to an analysis of feasibility of the Aizerman

conjecture in closed-loop systems with the first order time-invariant links and time-invariant feedback $\varphi(\sigma)$. In particular, Bergen and Williams proved [17] that systems of the third order satisfy the Aizerman conjecture. Trukhan extended this result on systems with up to five stable links of the first order [18]. For an arbitrary number of links, the transfer function is positive, so stability in the class $\Phi(0, K)$ follows from the theorem of Gil' [13]. Let us show that the above findings enable us to essentially generalize these results in some respects.

Evidently, the individual transfer function of a link,

$$w_i(t,s) = \exp\left[-\int_s^t a_i(s)\mathrm{d}s\right],\ i = 1, \dots, n, \tag{4.5}$$

is positive; hence, the transfer function of time-varying system (4.4) is positive as well. So, from Theorem 4 it follows that system (4.4) with the feedback $\varphi(\sigma(t - \tau(t)), t)$ is absolutely stable in the class $\Phi(-K, K)$, provided that it is stable for $\varphi = K\sigma(t - \tau(t), t)$. If in (2.15) the limit W_0 exists, then for any prescribed delay $\tau(t)$, the obtained bound for the stability sector coincides with the upper bound of the Hurwitz angle, i.e., $K_* = 1/W_\infty = K_2^0$ (Theorem 5). However, as is mentioned above, the lower bound of the obtained stability sector, $-1/W_\infty$, is larger than K_1^0 (note that the results [17, 18] provide stability of the particular systems in the whole Hurwitz angle).

Consider now the second order system

$$\begin{gathered}\ddot{x}(t) + 2h\dot{x}(t) + (1 + h^2)x(t) + \varphi(x(t - \tau(t)), t) = 0,\\ -Kx^2 \le \varphi(x,t)x \le Kx^2, \quad \varphi(0,t) = 0.\end{gathered} \tag{4.6}$$

Here

$$w(t,s) = \exp[-h(t-s)]\sin(t-s), \qquad W^0(t) = 1/1 + h^2\exp(-ht)[h\sin t - \cos t];$$

thus $W_0 = 1/(1 + h^2)$. Integrating (2.2), we find (see [11]) $W_\infty = [1 + \exp(-\pi h)]/[1 + \exp(-\pi h)]$.

By Theorems 1, 2, and 3, for any $\tau(t)$, system (4.6) is absolutely exponentially stable if $K < K_* = 1/W_\infty = \coth(-\pi h/2)$ and unstable for $K \ge K_0 = 1 + h^2$.

The functions $K_*(h)$ and $K_0(h)$ are plotted in Figure 1; as shown, they approach each other as h increases. This, in particular, testifies that the impact of a delay $\tau(t)$ in the feedback on the system stability decreases with an increase of stability of the linear part.

Note that the obtained delay-independent stability condition is precise, because for $K_* = \coth(-\pi h/2)$, the function $\tau(t)$ can be found such that (4.6) is unstable. In fact, let us put

$$\varphi(x(t - \tau(t)), t) = K_* x(t - \tau(t)), \quad \tau(t) = t \text{ for } t \in [0, \pi), \quad \tau(t + \pi) = \tau(t). \tag{4.7}$$

Setting $x(0) = -1$, $\dot{x}(0) = 0$ and observing that $\varphi(x(t - \tau(t)), t) = K_*$ for $t \in [0, \pi)$, we find that the corresponding solution is

$$x(t) = \exp(-ht)\left(-\frac{K_*}{1 + h^2} - 1\right)(\cos t + h\sin t) + \frac{K_*}{1 + h^2}. \tag{4.8}$$

Setting in (4.8) $K_* = \coth(-\pi h/2)$, we obtain $x(\pi) = 1$, $\dot{x}(\pi) = 0$. Clearly, $\varphi(x(t - \tau(t)), t) = -K_*$ for $t \in [\pi, 2\pi)$, so analogously we find $x(2\pi) = -1$, $\dot{x}(2\pi) = 0$. Thus, the corresponding solution of (4.6) is 2π-periodic; therefore, in accordance with the above definition, the system is unstable.

A CORRECTED PROOF OF THE STOCHASTIC VERIFICATION THEOREM WITHIN THE FRAMEWORK OF VISCOSITY SOLUTIONS*

FAUSTO GOZZI†, ANDRZEJ ŚWIĘCH‡, AND XUN YU ZHOU§

Abstract. We present a full and corrected proof of the stochastic verification theorem that was first obtained by Zhou, Yong, and Li [SIAM J. Control Optim., 35 (1997), pp. 243–253].

Key words. stochastic optimal control, verification theorem, HJB equation, viscosity solution, superdifferential, Lebesgue point

1. Introduction. The dynamic programming approach is applied to optimal control problems, deterministic and stochastic alike, primarily via the so-called verification theorem. The verification theorem verifies whether a given admissible control is optimal and, more importantly, suggests a way of constructing optimal feedback controls. The classical version of the verification theorem (see, e.g., [4]), as with the dynamic programming at large, has the inherent deficiency of having to assume the smoothness of the value function, whereas it is by now well known that even the simplest optimal control problem may not possess a smooth value function. Therefore, it is imperative, to both the theoretical development and practical applications, that a nonsmooth version of the verification theorem be available. A verification theorem for deterministic optimal control within the framework of one of the nonsmooth analyses—namely, viscosity solutions—was put forward by Zhou in [9]. The stochastic version of the result in [9] was first correctly stated in [10], although with an incorrect proof. Specifically, in a key step in the proof of [10], a test function for the superdifferential was employed and Ito's formula was applied. However, the superdifferential is pointwisely associated with probability sample points, and thus the test function also implicitly depends on the sample points. In this case, Ito's formula would not apply. Another proof was presented in the book [8, Chapter 5, section 5.2]. It fixed the aforementioned problem of the original proof of [10] by incorporating the conditional probability, but unfortunately it still contained some, albeit technically subtle, gaps (see Remark 4.2 below for details). In this paper we give a corrected proof of the result in [10]. The proof presented here is based on arguments of the one in [8] and may at first appear to be very similar. However, it has a few delicate differences that take care of the points that were missing in the proof of [8]. Since the verification theorem is a result of fundamental importance, we think it is worthwhile to present

its full and detailed proof even though it may repeat some of the material available in the literature.

2. The stochastic optimal control problem. In this section we introduce a class of stochastic optimal control problems that we consider in the paper. We will use the following basic notation throughout the paper. A' will denote the transpose of a matrix A, and $\mathbb{R}^{n\times k}$ and $S^{n\times n}$ will denote, respectively, the set of all $n\times k$ matrices and the set of all $n\times n$ symmetric matrices. Given a probability space $(\Omega,\mathcal{F},P)$ with a filtration $\{\mathcal{F}_t : a\le t\le b\}$ $(-\infty<a<b<+\infty)$, a separable Banach space Z with norm $|\cdot|_Z$, and $1\le p<+\infty$, we define the set $L^p_{\mathcal{F}_t}(a,b;Z)=\{\phi(\cdot)=\{\phi(t,\omega) : a\le t\le b\}|\ \phi(\cdot)$ is an $\mathcal{F}_t$-adapted, Z-valued measurable process on $[a,b]$, and $\mathbb{E}\int_a^b|\phi(t,\omega)|_Z^p dt<+\infty\}$.

Let $T\in(0,+\infty)$ be a finite time horizon and let $(\Omega,\mathcal{F},\mathbb{P})$ be a complete probability space. For any initial data $s\in[0,T]$ and $y\in\mathbb{R}^n$, the state equation of the problem is

$$\text{(1)}\qquad \begin{cases} dx(t)=b(t,x(t),u(t))dt+\sigma(t,x(t),u(t))dW(t),\\ x(s)=y, \end{cases}$$

where W is an m-dimensional standard Brownian motion defined on $(\Omega,\mathcal{F},\mathbb{P})$, and $u(\cdot)$ (the control strategy) is a stochastic process with values in a control space U, adapted to the filtration (augmented by $\mathbb{P}$-null sets) generated by W. The functional to minimize is

$$J(s,y;u(\cdot))=\mathbb{E}\left[\int_s^T f(t,x(t),u(t))dt+h(x(T))\right],$$

where $u(\cdot)$ is a given control strategy and $x(\cdot)$ is the corresponding state trajectory solving (1). The infimum will be taken over a suitable set of admissible controls that will be defined below. Throughout the paper we will always assume that b,σ,f, and h satisfy the following hypothesis. (We use the symbol $|\cdot|$ to denote norms in various spaces.)

Hypothesis 2.1. The functions

$$\begin{aligned} &b:[0,T]\times\mathbb{R}^n\times U\to\mathbb{R}^n, && \sigma:[0,T]\times\mathbb{R}^n\times U\to\mathbb{R}^{n\times m},\\ &f:[0,T]\times\mathbb{R}^n\times U\to\mathbb{R}, && h:\mathbb{R}^n\to\mathbb{R} \end{aligned}$$

are uniformly continuous. Moreover, there exists a constant L such that for functions $\phi=b,\sigma,f,h$ we have

(i) $|\phi(t,x_1,u)-\phi(t,x_2,u)|\le L|x_1-x_2|$ $\forall t\in[0,T]$, $\forall x_1,x_2\in\mathbb{R}^n$, $\forall u\in U$;
(ii) $|\phi(t,0,u)|\le L$.

We will work, as in [8, Chapter 5, section 4], with the so-called weak formulation of control problems. For a given $s\in[0,T]$, we define the set of (weakly) admissible controls $U^w_{ad}[s,T]$ to be the collection of all 5-tuples $(\Omega,\mathcal{F},\mathbb{P},W,u(\cdot))$ satisfying the following conditions:

(i) $(\Omega,\mathcal{F},\mathbb{P})$ is a standard probability space.
(ii) $W=\{W(t) : s\le t\le T\}$ is an m-dimensional standard Brownian motion defined on $(\Omega,\mathcal{F},\mathbb{P})$ over $[s,T]$ (with $W(s)=0$ almost surely), and $\mathcal{F}^s_t$ is the augmented filtration generated by W. Moreover, $\mathcal{F}=\sigma(\cup_t\mathcal{F}^s_t)$ (see [6, p. 285] for details and the definition of augmented filtration).

(iii) $u : [s,T] \times \Omega \to U$ is a U-valued $\mathcal{F}_t^s$-adapted process where U is a given complete separable metric space.

We will write $(\Omega, \mathcal{F}, \mathbb{P}, W, u(\cdot)) \in U_{ad}^w[s,T]$, but occasionally we will write only $u(\cdot) \in U_{ad}^w[s,T]$ if no ambiguity arises.

We remark that in light of Hypothesis 2.1 for every $(s,y) \in [0,T] \times \mathbb{R}^n$ and $(\Omega, \mathcal{F}, \mathbb{P}, W, u(\cdot)) \in U_{ad}^w[s,T]$, there exists a unique solution $x(\cdot)$ of (1) (see, for instance, [8, Theorem 6.16]). It is called the state corresponding to the control strategy $u(\cdot) \in U_{ad}^w[s,T]$, and $(x(\cdot), u(\cdot))$ is called an admissible pair. The objective of the optimal control problem is to minimize the cost functional $J(s,y;u(\cdot))$ (for a given $(s,y) \in [0,T) \times \mathbb{R}^n$) over all $u(\cdot) \in U_{ad}^w[s,T]$. We denote the above problem by $C_{s,y}$ to emphasize the dependence on the initial time s and the initial state y. The value function for the problem is defined as

$$V(s,y) = \inf_{u(\cdot) \in U_{ad}^w[s,T]} J(s,y;u(\cdot)).$$

An admissible pair $(x^*(\cdot), u^*(\cdot))$ is called *optimal* for $C_{s,y}$ if $u^*(\cdot)$ achieves the minimum of $J(s,y;u(\cdot))$ over $U_{ad}^w[s,T]$.

In the dynamic programming approach to the problem, one proves that V is the unique classical solution of an associated Hamilton–Jacobi–Bellman (HJB) equation if $V \in C^{1,2}([0,T] \times \mathbb{R}^n)$. Defining the current value Hamiltonian H_{CV} as

$$H_{CV}(t,x,q,Q;u) = \frac{1}{2}\mathrm{tr}(\sigma(t,x,u)'Q\sigma(t,x,u)) + \langle q, b(t,x,u)\rangle + f(t,x,u)$$

and the infimum value Hamiltonian H_{MIN} as

$$H_{MIN}(t,x,q,Q) = \inf_{u \in U} H_{CV}(t,x,q,Q;u),$$

the HJB equation associated with the family of problems $\{C_{s,y}\}_{(s,y)\in[0,T]\times\mathbb{R}^n}$ is

$$(2) \quad \begin{cases} -v_t(t,x) - H_{MIN}\left(t,x,Dv(t,x),D^2v(t,x)\right) = 0, \ (t,x) \in (0,T) \times \mathbb{R}^n, \\ v(T,x) = h(x), \qquad x \in \mathbb{R}^n, \end{cases}$$

where Dv and D^2v denote, respectively, the gradient and Hessian of v with respect to x.

As a part of the dynamic programming approach, the so-called verification technique plays an important role in testing for the optimality of a given admissible pair and (more importantly) in constructing optimal feedback controls. The classical verification theorem is as follows (see Fleming and Rishel [4, Theorem VI.4.1] and Yong and Zhou [8, Theorem 5.1, p. 268]).

THEOREM 2.2. *Let $W \in C^{1,2}([0,T] \times \mathbb{R}^n)$ be a solution of the HJB equation* (2). *Then we have the following.*

(a) *$W(s,y) \le J(s,y;u(\cdot))$ for any $(s,y) \in [0,T] \times \mathbb{R}^n$ and any $u(\cdot) \in U_{ad}^w[s,T]$.*

(b) *Suppose a given admissible pair $(x^*(\cdot), u^*(\cdot))$ for the problem $C_{s,y}$ satisfies*

$$(3) \quad -W_t(t,x^*(t)) - H_{CV}\left(t,x^*(t),DW(t,x^*(t)),D^2W(t,x^*(t));u^*(t)\right) = 0$$

$\mathbb{P}$-a.s., a.e. $t \in [s,T]$. Then $(x^*(\cdot), u^*(\cdot))$ is an optimal pair for the problem $C_{s,y}$.

Remark 2.3. Equality (3) is equivalent to the more familiar

$$H_{CV}\left(t,x^*(t),DW(t,x^*(t)),D^2W(t,x^*(t));u^*(t)\right) = H_{MIN}\left(t,x^*(t),DW(t,x^*(t)),D^2W(t,x^*(t))\right).$$

However, as is generally well known, the value function is not smooth and the HJB equation may not have a smooth solution at all. The verification theorem, whose proof is presented in this paper, is a nonsmooth version of Theorem 2.2. We refer the reader to [10, 8] for more discussion on this verification theorem and its consequences.

3. Preliminaries: Stochastic processes, Lebesgue points, and viscosity solutions. In this subsection we present some preliminary results needed in the main proof.

3.1. Viscosity solutions and semidifferentials. To make the paper self-contained, we present the definition of viscosity solution we will be using. It is slightly different from the typical and most commonly used definition (see [1, 5, 8]).

First, by a parabolic neighborhood of a point (t_0, x_0), we mean the intersection of an open neighborhood of (t_0, x_0) with the set of all (t, x) such that $t \geq t_0$.

DEFINITION 3.1. *An uppersemicontinuous (respectively, lowersemicontinuous) function v on $(0,T] \times \mathbb{R}^n$ is called a viscosity subsolution (respectively, supersolution) of* (2) *if*

$$v(T,x) \leq (\geq) h(x) \qquad \text{for } x \in \mathbb{R}^n$$

and if

$$-\phi_t(t_0,x_0) - H_{MIN}(t_0,x_0,D\phi(t_0,x_0),D^2\phi(t_0,x_0)) \leq (\geq) 0 \tag{4}$$

whenever $v - \phi$ attains a local maximum (respectively, minimum) at (t_0, x_0) in a parabolic neighborhood of (t_0, x_0) for $\phi \in C^{1,2}((0,T) \times \mathbb{R}^n)$. A function v is called a viscosity solution of (2) *if it is both a viscosity subsolution and a viscosity supersolution of* (2).

The typical definition uses full (two-sided) neighborhoods instead of parabolic (one-sided) ones. However, it is well known that both definitions are equivalent. To see this, suppose that v is a viscosity subsolution in the two-sided sense and that $v - \phi$ has a one-sided local maximum at (t_0, x_0), which can obviously be assumed to be strict. Then it is easy to see that for small $\mu > 0$, the functions $v - \phi - \frac{\mu}{t - t_0}$ have two-sided local maxima at points (t_μ, x_μ) such that $(t_\mu, x_\mu) \to (t_0, x_0)$ as $\mu \to 0$. Therefore from the two-sided definition we get

$$-\phi_t(t_\mu,x_\mu) - H_{MIN}(t_\mu,x_\mu,D\phi(t_\mu,x_\mu),D^2\phi(t_\mu,x_\mu)) \leq -\frac{\mu}{(t-t_\mu)^2} \leq 0$$

and, letting $\mu \to 0$, we obtain (4).

Definition 3.1 is equivalent to the one in which test functions are replaced by parabolic semijets, i.e., second order parabolic sub- and superdifferentials (see [1]).

DEFINITION 3.2. *We say that $(p,q,Q) \in D^{1,2,+}_{t^+,x} v(t,x)$, the second order one-sided parabolic superdifferential of v at (t,x), if, for all $y \in \mathbb{R}^n, s \geq t$,*

$$v(s,y) \leq v(t,x) + p(s-t) + \langle q, y-x\rangle + \frac{1}{2}\langle Q(y-x), y-x\rangle + o(s-t+|y-x|^2).$$

The second order one-sided parabolic subdifferential of v at (t,x), $D^{1,2,-}_{t^+,x} v$ is defined by reversing the inequality, i.e., $D^{1,2,-}_{t^+,x} v(t,x) = -D^{1,2,+}_{t^+,x}(-v)(t,x)$.

The equivalence of Definition 3.1 and the definition in which derivatives of test functions are replaced by elements of super- and subdifferentials are established with the help of a well-known result that we present below and whose proof can be found, for instance, in [8, Chapter 4, Lemma 5.4].

LEMMA 3.3. *Let v be an uppersemicontinuous function on $(0,T)\times\mathbb{R}^n$ and let $(t_0,x_0)\in(0,T)\times\mathbb{R}^n$. Then $(p,q,Q)\in D^{1,2,+}_{t^+,x}v(t_0,x_0)$ if and only if there exists a function $\phi\in C^{1,2}((0,T)\times\mathbb{R}^n)$ such that $v-\phi$ attains a strict global maximum at (t_0,x_0) relative to the set of (t,x) such that $t\geq t_0$ and*

$$(\phi(t_0,x_0),\phi_t(t_0,x_0),D\phi(t_0,x_0),D^2\phi(t_0,x_0))=(v(t_0,x_0),p,q,Q). \tag{5}$$

Moreover, if v has polynomial growth, i.e., if

$$|v(t,x)|\leq C(1+|x|^k)\quad \text{for some } k\geq 1,\ (t,x)\in(0,T)\times\mathbb{R}^n, \tag{6}$$

then ϕ can be chosen so that $\phi,\phi_t,D\phi,D^2\phi$ satisfy (6) *(with possibly different constants C).*

3.2. Lebesgue points. Here we recall and present a few results on Lebesgue points for functions with values in abstract spaces.

DEFINITION 3.4. *Let Z be a Banach space and let $z:[a,b]\to Z$ be a measurable function that is Bochner integrable. We say that t is a right Lebesgue point of z if*

$$\lim_{h\to 0^+}\frac{1}{h}\int_t^{t+h}|z(r)-z(t)|_Z dr=0.$$

We then have the following result (see, for instance, [2, Theorem 9, p. 49]).

LEMMA 3.5. *Let $z:[a,b]\to Z$ be as in Definition* 3.4. *Then the set of right Lebesgue points of z is of full measure in $[a,b]$.*

The following simple lemma ensures that any process in $L^1_{\mathcal{F}_t}(a,b;\mathbb{R}^k)$ for some $k\geq 1$ can be regarded as the Bochner integrable function $z:[a,b]\to L^1(\Omega;\mathbb{R}^k)$.

LEMMA 3.6. *Any $z\in L^1_{\mathcal{F}_t}(a,b;\mathbb{R}^k)$ is Bochner integrable when regarded as a map from $[a,b]$ to $L^1(\Omega;\mathbb{R}^k)$.*

Proof. According to [3, p. 92], if $(\Omega,\mathcal{F},\mathbb{P})$ is a complete probability space, Z is a separable Hilbert space, and $\mathcal{F}$ is countably generated apart from null sets, then the space $L^1(\Omega;Z)$ is separable. Since the filtration generated by a Wiener process is always countably generated (see, for instance, [7, Exercise 4.21, Chapter 1]), the space $L^1(\Omega;\mathbb{R}^k)$ is separable. Since

$$\int_a^b|z(t,\cdot)|_{L^1(\Omega;\mathbb{R}^k)}dt<+\infty,$$

we only need to show that the function z is measurable as a map from $[a,b]$ to $L^1(\Omega;\mathbb{R}^k)$. By the separability of $L^1(\Omega;\mathbb{R}^k)$, the measurability is equivalent to the weak measurability, so it is enough to show that for every function $w\in L^\infty(\Omega;\mathbb{R}^k)$, the map

$$t\to\mathbb{E}(z(t,\omega)\cdot w(\omega))$$

is Lebesgue measurable. But this is obvious from Fubini's theorem, as

$$\mathbb{E}\int_a^b|z(t,\omega)\cdot w(\omega)|dt<+\infty. \qquad \square$$

The following technical result will be used in the proof of the verification theorem.

PROPOSITION 3.7. *Let the standing assumptions of section 2 be satisfied and let* $(s,y) \in [0,T]\times\mathbb{R}^n$. *Given any admissible pair* $(x(\cdot),u(\cdot))$ *for the control problem* $C_{s,y}$, *define the processes*

$$z_1(r) = b(r,x(r),u(r)), \quad z_2(r) = \sigma(r,x(r),u(r))\,\sigma(r,x(r),u(r))'.$$

Then

$$\lim_{h\to 0^+} \mathbb{E}\frac{1}{h}\int_t^{t+h} |z_i(r)-z_i(t)|dr \to 0 \quad as \;\; h\to 0^+, \;\; a.e.\; t\in[s,T], \;\; i=1,2. \tag{7}$$

Proof. It is clear by Hypothesis 2.1 that $z_1, z_2 \in L^1_{\mathcal{F}_t}(s,T;Z)$ with $Z=\mathbb{R}^n$ and $Z=\mathbb{R}^{n\times n}$, respectively. Hence, by Lemma 3.6 they are Bochner integrable when regarded as $L^1(\Omega;Z)$-valued maps. It then follows from Lemma 3.5 that the set of right Lebesgue points of z_1 and z_2, as maps from $[s,T]$ to $L^1(\Omega;Z)$, is of full measure in $[s,T]$, which gives the claim. □

4. Verification theorem. We are going to prove the following theorem.

THEOREM 4.1. *Let* $U\in C((0,T]\times\mathbb{R}^n)$ *be a viscosity subsolution of the HJB* (2) *satisfying* (6) *for some* $k\geq 1$ *and such that* $U(T,x)=h(x)$. *Then we have the following.*

(a) $U(s,y)\leq J(s,y;u(\cdot))$ *for any* $(s,y)\in(0,T]\times\mathbb{R}^n$ *and any* $u(\cdot)\in U^w_{ad}[s,T]$.

(b) *Fix any* $(s,y)\in(0,T)\times\mathbb{R}^n$. *Let* $(x^*(\cdot),u^*(\cdot))$ *be an admissible pair for the problem* $C_{s,y}$. *Suppose that there exists* $(p^*,q^*,Q^*)\in L^2_{\mathcal{F}_t}(s,T;\mathbb{R})\times L^2_{\mathcal{F}_t}(s,T;\mathbb{R}^n)\times L^2_{\mathcal{F}_t}(s,T;S^{m\times n})$ *(where the filtration* $\mathcal{F}_t$ *is* $(\mathcal{F}^s_t)_{t\in[s,T]}$*) such that, for a.e.* $t\in[s,T]$,

$$(p^*(t),q^*(t),Q^*(t))\in D^{1,2,+}_{t^+,x}W(t,x^*(t)),\ \mathbb{P}\text{-}a.s., \tag{8}$$

and

$$\mathbb{E}\int_s^T [p^*(t)+H_{CV}(t,x^*(t),q^*(t),Q^*(t);u^*(t))]\,dt\leq 0. \tag{9}$$

Then $(x^*(\cdot),u^*(\cdot))$ *is an optimal pair for the problem* $C_{s,y}$.

Proof. Part (a) is obvious since $U\leq V$ in view of the standard comparison results for bounded viscosity sub- and supersolutions (see, for instance, [5, Theorem 9.1, Chapter V]). We just have to notice that if U satisfies (6) and K is big enough, then the function

$$U_\delta(t,x) = U(t,x) - \delta e^{K(T-t)}|x|^{k+1}$$

is a viscosity subsolution of (2) for every $\delta>0$ that is bounded from above. Similarly, one can perturb V to a supersolution V_δ since V satisfies (6) with $k=1$ under Hypothesis 2.1 (see [8, p. 178, Proposition 3.1]). The comparison then follows from the comparison for U_δ and V_δ upon letting $\delta\to 0$.

It remains to prove part (b) of the theorem. To simplify the notation, we set

$$f^*(t)=f(t,x^*(t),u^*(t)), \qquad h^*(t)=h(x^*(t)),$$
$$b^*(t)=b(t,x^*(t),u^*(t)), \qquad \sigma^*(t)=\sigma(t,x^*(t),u^*(t)).$$

Fix $t_0\in[s,T]$ such that (8) holds at t_0, and (7) holds at t_0 for $z_1(\cdot)=b^*(\cdot)$ and $z_2(\cdot)=\sigma^*(\cdot)\,\sigma^*(\cdot)'$. The set of such points is of full measure in $[s,T]$ by Proposition 3.7.

We now fix $\omega_0 \in \Omega$ such that the regular conditional probability given $\mathcal{F}_{t_0}^s$, denoted by $\mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)(\omega_0)$, is well defined (see [6, pp. 84–85] for the definition and properties of conditional expectation and the regular conditional probability). We consider the probability space $\left(\Omega, \mathcal{F}, \mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)(\omega_0)\right)$. In this probability space the random variables

$$x^*(t_0),\ p^*(t_0),\ q^*(t_0),\ Q^*(t_0)$$

are almost surely constant (see [8, Proposition 2.13, Chapter 1]) and are equal to

$$x^*(t_0,\omega_0),\ p^*(t_0,\omega_0),\ q^*(t_0,\omega_0),\ Q^*(t_0,\omega_0),$$

respectively. Denote $x_0 = x^*(t_0,\omega_0)$. We remark that in this probability space the Brownian motion W is still a standard Brownian motion although now $W(t_0) = W(t_0,\omega_0)$ almost surely. The space is now equipped with a new filtration $(\mathcal{F}_r^{t_0})_{r\in[t_0,T]}$ and the control process $u^*(\cdot)$ is adapted to this new filtration (see [8, p. 179] for more on this). The main point is that for $\mathbb{P}$-a.s., ω_0 the process $x^*(\cdot)$ is a solution of (1) on (t_0,T) in the new probability space $\left(\Omega, \mathcal{F}, \mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)(\omega_0)\right)$ with the initial condition $x^*(t_0) = x^*(t_0,\omega_0)$.

We will write $\mathbb{E}_{\omega_0}$ to denote the expectation with respect to the measure $\mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)(\omega_0)$ and will write $L^p_{\mathcal{F}_t,\omega_0}(t_0,T;Z)$ and $L^p_{\omega_0}(\Omega;Z)$ when these spaces are defined with respect to this measure.

Using Lemma 3.3, we now take a test function $\phi \in C^{1,2}((0,T)\times\mathbb{R}^n)$ such that

$$\phi(t,x) > U(t,x) \quad \text{for every } (t,x)\in(0,T)\times\mathbb{R}^n,\ (t,x)\neq(t_0,x_0), \tag{10}$$

$$\begin{aligned}&\left(\phi(t_0,x_0),\phi_t(t_0,x_0),D\phi(t_0,x_0),D^2\phi(t_0,x_0)\right)\\ &= \left(U(t_0,x_0),p^*(t_0,\omega_0),q^*(t_0,\omega_0),Q^*(t_0,\omega_0)\right),\end{aligned} \tag{11}$$

and such that $\phi, \phi_t, D\phi, D^2\phi$ are polynomially bounded; i.e., they satisfy (6). It is important to bear in mind that ϕ is a fixed deterministic function when (t_0,ω_0) is fixed.

We are going to apply Ito's formula to ϕ on the probability space $\left(\Omega, \mathcal{F}, \mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)(\omega_0)\right)$. To do this, we observe that the processes

$$\phi_t(r,x^*(r)),\quad \langle D\phi(r,x^*(r)),b^*(r)\rangle,\quad \frac{1}{2}\mathrm{tr}\left[\sigma^*(r)'D^2\phi(r,x^*(r))\sigma^*(r)\right]$$

belong to $L^1_{\mathcal{F}_t,\omega_0}(t_0,T;\mathbb{R})$ due to Hypothesis 2.1 on b and σ, to the estimate

$$\mathbb{E}_{\omega_0}\sup_{t_0\le r\le T}|x^*(r)|^l \le K_T(1+|x_0|^l) \quad \text{for every } l\ge 1 \tag{12}$$

(see, for instance, [8, Theorem 6.16, Chapter 1]), and to the polynomial growth of $\phi, \phi_t, D\phi, D^2\phi$. Moreover, by the same argument, the process

$$\sigma^*(r)'\phi_x(r,x^*(r))$$

belongs to $L^2_{\mathcal{F}_t,\omega_0}(t_0,T;\mathbb{R}^n)$. Therefore (see, for instance, [8, Chapter 1, section 5.3]) we can apply Ito's formula to obtain that, for any $h>0$,

$$\begin{aligned}&\phi(t_0+h,x^*(t_0+h)) - \phi(t_0,x^*(t_0))\\ &= \int_{t_0}^{t_0+h}\left[\phi_t(r,x^*(r)) + \langle D\phi(r,x^*(r)),b^*(r)\rangle + \frac{1}{2}\mathrm{tr}\left(\sigma^*(r)'D^2\phi(r,x^*(r))\sigma^*(r)\right)\right]dr\\ &\quad + \int_{t_0}^{t_0+h}\langle D\phi(r,x^*(r)),\sigma^*(r)\,dW(r)\rangle.\end{aligned}$$

In particular, taking the expected value $\mathbb{E}_{\omega_0}$, dividing both sides by h, and using (10), it follows that

$$\begin{aligned}
&\mathbb{E}_{\omega_0}\frac{1}{h}\left[U\left(t_0+h,x^*\left(t_0+h\right)\right)-U\left(t_0,x^*\left(t_0\right)\right)\right]\\
&\leq \mathbb{E}_{\omega_0}\left[\frac{1}{h}\int_{t_0}^{t_0+h}\left[\phi_t\left(r,x^*\left(r\right)\right)+\left\langle D\phi\left(r,x^*\left(r\right)\right),b^*\left(r\right)\right\rangle\right.\right.\\
&\qquad\left.\left.+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(r\right)'D^2\phi\left(r,x^*\left(r\right)\right)\sigma^*\left(r\right)\right)\right]dr\right].
\end{aligned}\tag{13}$$

We want to pass to the limit as $h\to 0^+$ above. To this end, we treat each term of (13) separately.

(I) First of all, thanks to the continuity of x^* and to the continuity of ϕ_t, we get

$$\frac{1}{h}\int_{t_0}^{t_0+h}\phi_t\left(r,x^*\left(r\right)\right)dr\to\phi_t\left(t_0,x^*\left(t_0\right)\right),\qquad \mathbb{P}\left(\cdot|\mathcal{F}_{t_0}^s\right)\left(\omega_0\right)\text{- a.s.}$$

Now, using estimate (12) and the polynomial growth of ϕ_t, we can apply the dominated convergence theorem to obtain

$$\lim_{h\to 0^+}\mathbb{E}_{\omega_0}\left|\frac{1}{h}\int_{t_0}^{t_0+h}\phi_t\left(r,x^*\left(r\right)\right)dr-\phi_t\left(t_0,x^*\left(t_0\right)\right)\right|=0.$$

(II) With regard to the second term of (13), we have

$$\begin{aligned}
&\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left\langle D\phi\left(r,x^*\left(r\right)\right),b^*\left(r\right)\right\rangle dr-\left\langle D\phi\left(t_0,x^*\left(t_0\right)\right),b^*\left(t_0\right)\right\rangle\\
&=\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left\langle D\phi\left(r,x^*\left(r\right)\right)-D\phi\left(t_0,x^*\left(t_0\right)\right),b^*\left(r\right)\right\rangle dr\\
&\quad+\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left\langle D\phi\left(t_0,x^*\left(t_0\right)\right),b^*\left(r\right)-b^*\left(t_0\right)\right\rangle dr.
\end{aligned}\tag{14}$$

Now

$$\begin{aligned}
&\left|\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left\langle D\phi\left(r,x^*\left(r\right)\right)-D\phi\left(t_0,x^*\left(t_0\right)\right),b^*\left(r\right)\right\rangle dr\right|\\
&\leq\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left|D\phi\left(r,x^*\left(r\right)\right)-D\phi\left(t_0,x^*\left(t_0\right)\right)\right|\left|b^*\left(r\right)\right|dr\\
&\leq\mathbb{E}_{\omega_0}\left[\frac{1}{h}\int_{t_0}^{t_0+h}\left|D\phi\left(r,x^*\left(r\right)\right)-D\phi\left(t_0,x^*\left(t_0\right)\right)\right|^2dr\right]^{\frac{1}{2}}\left[\frac{1}{h}\int_{t_0}^{t_0+h}\left|b^*\left(r\right)\right|^2dr\right]^{\frac{1}{2}}\\
&\leq\left[\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left|D\phi\left(r,x^*\left(r\right)\right)-D\phi\left(t_0,x^*\left(t_0\right)\right)\right|^2dr\right]^{\frac{1}{2}}\left[\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left|b^*\left(r\right)\right|^2dr\right]^{\frac{1}{2}}.
\end{aligned}$$

Using Hypothesis 2.1 and estimate (12), we have

$$\begin{aligned}
\mathbb{E}_{\omega_0}\frac{1}{h}\int_{t_0}^{t_0+h}\left|b^*\left(r\right)\right|^2dr&\leq\frac{1}{h}\int_{t_0}^{t_0+h}2L^2\left(1+\mathbb{E}_{\omega_0}\left|x^*\left(r\right)\right|^2\right)dr\\
&\leq 2L^2\left(1+K_T\left(1+|x_0|^2\right)\right),
\end{aligned}\tag{15}$$

whereas arguing as in part (I) for ϕ_t, we get

$$\lim_{h\to 0^+} \mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} |D\phi(r, x^*(r)) - D\phi(t_0, x^*(t_0))|\, dr = 0. \tag{16}$$

From (15) and (16), it follows that the first term of (14) goes to zero as $h \to 0^+$. For the second term of (14), we observe that

$$\begin{aligned} &\left| \mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} \langle D\phi(t_0, x^*(t_0)), b^*(r) - b^*(t_0) \rangle\, dr \right| \\ &\quad \le |D\phi(t_0, x_0)|\, \mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr. \end{aligned}$$

However, by the choice of t_0,

$$\begin{aligned} 0 &= \lim_{h\to 0^+} \mathbb{E} \frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr \\ &= \lim_{h\to 0^+} \mathbb{E}\left[\mathbb{E}\left[\frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr \middle| \mathcal{F}_{t_0}^s \right] \right] \\ &= \lim_{h\to 0^+} \mathbb{E}\left[\mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr \right]. \end{aligned}$$

This implies that $\mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr$ converges to 0 in $L^1(\Omega; \mathbb{R}^1)$ as $h \to 0^+$. Hence, there is a subsequence $h_l \to 0^+$ so that, for $\mathbb{P}$-a.s. ω_0,

$$\mathbb{E}_{\omega_0} \frac{1}{h} \int_{t_0}^{t_0+h} |b^*(r) - b^*(t_0)|\, dr \to 0.$$

This proves that the second term of (14) goes to zero as $h_l \to 0^+$.

(III) The third term of (13) is treated using the same ideas. Since

$$\operatorname{tr}(ABC) = \operatorname{tr}(BCA) \quad \text{and} \quad \operatorname{tr}(AB) - \operatorname{tr}(AC) = \operatorname{tr} A(B - C),$$

we have

$$\begin{aligned} &\mathbb{E}_{\omega_0}\left[\frac{1}{h} \int_{t_0}^{t_0+h} \left[\frac{1}{2} \operatorname{tr}\left(\sigma^*(r)' D^2\phi(r, x^*(r)) \sigma^*(r) \right) \right.\right. \\ &\qquad \left.\left. - \frac{1}{2} \operatorname{tr}\left(\sigma^*(t_0)' D^2\phi(t_0, x^*(t_0)) \sigma^*(t_0) \right) \right] dr \right] \qquad (17) \\ &= \mathbb{E}_{\omega_0}\left[\frac{1}{h} \int_{t_0}^{t_0+h} \frac{1}{2} \operatorname{tr}\left(\left[D^2\phi(r, x^*(r)) - D^2\phi(t_0, x^*(t_0)) \right] \sigma^*(r) \sigma^*(r)' \right) dr \right] \\ &\quad + \mathbb{E}_{\omega_0}\left[\frac{1}{h} \int_{t_0}^{t_0+h} \frac{1}{2} \operatorname{tr}\left(D^2\phi(t_0, x^*(t_0)) \left[\sigma^*(r) \sigma^*(r)' - \sigma^*(t_0) \sigma^*(t_0)' \right] \right) dr \right]. \end{aligned}$$

Now, employing the same arguments that we used to show that the right-hand side of (14) goes to zero, we obtain that the right-hand side of (17) goes to 0 as some subsequence $h_{l'} \to 0^+$.

Summing up, we have proved that, for any sequence $h \to 0^+$, one can find a subsequence $h_{l''} \to 0^+$ so that

$$\begin{aligned}
&\lim_{h_{l''}\to 0^+} \mathbb{E}_{\omega_0}\left[\frac{1}{h_{l''}}\int_{t_0}^{t_0+h_{l''}}\left[\phi_t\left(r,x^*\left(r\right)\right)+\left\langle D\phi\left(r,x^*\left(r\right)\right),b^*\left(r\right)\right\rangle\right.\right.\\
&\qquad\qquad\left.\left.+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(r\right)'D^2\phi\left(r,x^*\left(r\right)\right)\sigma^*\left(r\right)\right)\right]dr\right]\\
&\quad=\phi_t\left(t_0,x_0\right)+\left\langle D\phi\left(t_0,x_0\right),b^*\left(t_0\right)\right\rangle+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(t_0\right)'D^2\phi\left(t_0,x_0\right)\sigma^*\left(t_0\right)\right).
\end{aligned}$$

Consequently, the above holds for any sequence $h \to 0^+$. Passing to the limsup in (13) and using (11), we get that

$$\begin{aligned}
&\limsup_{h\to 0^+}\mathbb{E}_{\omega_0}\frac{1}{h}\left[U\left(t_0+h,x^*\left(t_0+h\right)\right)-U\left(t_0,x^*\left(t_0\right)\right)\right]\\
&\quad\le\phi_t\left(t_0,x_0\right)+\left\langle D\phi\left(t_0,x_0\right),b^*\left(t_0\right)\right\rangle+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(t_0\right)'D^2\phi\left(t_0,x_0\right)\sigma^*\left(t_0\right)\right)\\
&\quad=p^*\left(t_0,\omega_0\right)+\left\langle q^*\left(t_0,\omega_0\right),b^*\left(t_0,\omega_0\right)\right\rangle+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(t_0,\omega_0\right)'Q^*\left(t_0,\omega_0\right)\sigma^*\left(t_0,\omega_0\right)\right). \qquad (18)
\end{aligned}$$

Now, using (18) and applying Fatou's lemma, we get

$$\begin{aligned}
&\limsup_{h\to 0^+}\mathbb{E}\left[\frac{1}{h}\left[U\left(t_0+h,x^*\left(t_0+h\right)\right)-U\left(t_0,x^*\left(t_0\right)\right)\right]\right]\\
&\quad=\limsup_{h\to 0^+}\mathbb{E}\left[\mathbb{E}_{\omega_0}\frac{1}{h}\left[U\left(t_0+h,x^*\left(t_0+h\right)\right)-U\left(t_0,x^*\left(t_0\right)\right)\right]\right]\\
&\quad\le\mathbb{E}\left[\limsup_{h\to 0^+}\left[\mathbb{E}_{\omega_0}\frac{1}{h}\left[U\left(t_0+h,x^*\left(t_0+h\right)\right)-U\left(t_0,x^*\left(t_0\right)\right)\right]\right]\right]\\
&\quad\le\mathbb{E}\left[p^*\left(t_0\right)+\left\langle q^*\left(t_0\right),b^*\left(t_0\right)\right\rangle+\frac{1}{2}\mathrm{tr}\left(\sigma^*\left(t_0\right)'Q^*\left(t_0\right)\sigma^*\left(t_0\right)\right)\right] \qquad (19)
\end{aligned}$$

for a.e. $t_0 \in [s,T]$. The rest of the proof goes exactly as in [8, p. 272]. We apply [8, Lemma 5.2, p. 270] to the function $g(t) = \mathbb{E}\,U(t,x^*(t))$ and use (19) and (9) to obtain

$$\mathbb{E}\,U(T,x^*(T)) - U(s,y) \le -\mathbb{E}\int_s^T f^*(t)dt,$$

which, since $U \le V$ and $U(T,x^*(T)) = V(T,x^*(T)) = h(x^*(T))$, yields

$$\mathbb{E}\left[\int_s^T f\left(t,x^*(t),u^*(t)\right)dt + h(x^*(T))\right] \le V(s,y),$$

which means that the control $u^*(\cdot)$ is optimal. □

Remark 4.2. Now we are in a position to discuss the (subtle) gap presented in the proof of the book [8]. On page 271 of [8], equation (5.12) was derived by considering a Lebesgue point t of the integrand in the displayed equation immediately before (5.12). However, the test function ϕ there depends, though implicitly, on the variable t. Hence, it is not clear whether such a t exists in the first place. In this paper, we have fixed this problem via the Lebesgue points of the problem data ($b^*(\cdot)$ and $\sigma^*(\cdot)\sigma^*(\cdot)'$) viewed as $L^1(\Omega;\mathbb{R}^n)$ or $L^1(\Omega;\mathbb{R}^{n\times n})$-valued functions, together with some delicate estimates.

Acknowledgments. Part of this research was carried out when the third author was visiting Scuola Normale Superiore, Italy. The hospitality of the host, Giuseppe Da Prato, is gratefully acknowledged. Moreover, the authors thank the editors and two reviewers for their helpful comments and suggestions on an earlier version of the paper.

DIFFERENTIAL GAMES WITH ERGODIC PAYOFF*

MRINAL K. GHOSH† AND K. S. MALLIKARJUNA RAO‡

Abstract. We address a zero-sum differential game with ergodic payoff. We study this problem via the viscosity solutions of an associated Hamilton–Jacobi–Isaacs equation. Under certain condition, we establish the existence of a value and prove certain representation formulae.

Key words. differential games, value, Hamilton–Jacobi–Isaacs equation, viscosity solution

1. Introduction.

In this article, we consider a general, nonlinear controlled dynamical system

$$\dot{x}(t) = b(x(t), u_1(t), u_2(t)) \tag{1.1}$$

with performance index $r(x(t), u_1(t), u_2(t))$, where u_1, u_2 are controls. Associated to this controlled dynamical system we can pose two kinds of problem—$\mathcal{H}_\infty$ control and the differential game. In $\mathcal{H}_\infty$ control, the performance index is referred to as the output response and u_2 as disturbance. A closed set $\mathcal{T}$ with respect to which the undisturbed system ($u_2 = 0$) is stable and a constant γ are given. The problem is to find a strategy $\alpha = \alpha[u_2]$ such that

$$\int_0^t |r(x(s), \alpha[u_2](s), u_2(s))|^2 \, ds \le \gamma^2 \int_0^t |u_2(s)|^2 \, ds \tag{1.2}$$

for all $t \ge 0$ and all disturbances u_2. If we can find such a strategy, we say that the problem is solvable with disturbance attenuation level γ.

The other problem is the differential game problem. In this case, we call the performance index the running payoff function. There are two controllers or decision makers called players. Player 1 wishes to minimize the running payoff function on finite or infinite time horizon over his control variables $u_1(t)$, whereas Player 2 wishes to maximize the same over his control variables $u_2(t)$. Since the interests of the two players are conflicting, the basic problem is to resolve this conflict by arriving at solution that serves the interests of both players. In other words, we look for a min-max/max-min solution to this problem. For infinite horizon problems, one usually considers two payoff criteria: the discounted payoff criterion and the ergodic or averaged payoff criterion. These two payoff criteria are, in some sense, complementary to each other. The immediate future is far more important than the distant future in the discounted payoff criterion. Quite contrary to this, the finite time behavior of

the system is irrelevant in the ergodic payoff criterion. It is the asymptotic behavior of the ergodic payoff that matters. Thus in the ergodic payoff criterion, one looks for some kind of stability or averaging mechanism taking place.

The differential game (in the sense of Elliott–Kalton) with discounted payoff criterion has been studied extensively in the literature; see [1] and the references therein. The basic idea is to show that the lower and upper value functions satisfy the dynamic programming principle (DPP) and thus they are viscosity solutions to corresponding Hamilton–Jacobi–Isaacs (HJI) equations. If the Isaacs minimax principle holds, then by a minimax theorem, one obtains that the differential game has value. This procedures does not seem to be applicable to the differential games with ergodic payoff. Thus in order to study the differential games with ergodic payoff, we need to approach the problem in a different way.

In the traditional approach to differential games, one first establishes the DPP, which in turn leads to the HJI equations. In this article, we follow a reverse approach which was used by Świech [18] to treat a stochastic differential game with a finite horizon payoff criterion (see also [17]). The main idea is to use the integration along the trajectories of the controlled dynamical system to study the HJI equations. Since the HJI equation in general does not admit classical solutions, we need to use the concept of viscosity solutions introduced by Crandall and Lions [4]. We show that if the HJI equation corresponding to ergodic payoff criterion has a viscosity solution, then the scalar quantity appearing in the HJI equation is the ergodic value for the differential game problem under certain stability assumption on the dynamics. Further, under a dissipativity assumption, we show that the HJI equation has a viscosity solution. The novelty of this approach is that it is quite simple and it can be used to prove the DPP.

There is a close connection between $\mathcal{H}_\infty$ control and differential games. A $\mathcal{H}_\infty$ control problem can be viewed as a differential game problem (see [3]). Using this observation, several authors have studied HJI equations and established DPP for the solutions; see [6], [9], [13], [15], [16], and the references therein. In [16] an $\mathcal{H}_\infty$ control problem is considered and studied using the viscosity solution techniques. Some representation formulas are proved for the viscosity solutions of the associated HJI equation. As a consequence, the author obtained the DPP for the viscosity solutions and established the value function to be the minimal viscosity solution under some nonnegativity assumptions and certain stability assumptions. In [9], [13], an analogous problem in the stochastic case is considered. Here the authors first obtained the DPP. The value function is again shown to be the minimal viscosity solution. The results in the deterministic case are obtained by letting the diffusion coefficient be zero. Further in [13], the uniqueness of the viscosity solution is established in a certain class of functions with some growth conditions. Thus the results in these articles are similar to ours. However, the assumptions considered there are different from the assumptions in this article. Note that in the mentioned articles, the ergodic value corresponding to the associated differential game turns out to be zero. Thus the results presented in this article can be seen as more general concerning differential games with ergodic payoff. We now describe our problem.

Let U_i, $i = 1, 2$, be given compact metric spaces. Let $\mathcal{A}_i$, $i = 1, 2$, denote the set of all measurable functions $u_i : [0, \infty) \to U_i$. The set $\mathcal{A}_i$ is called the set of all admissible controls for player i. Consider the d-dimensional controlled dynamical system $x(\cdot)$ described by

$$\left\{ \begin{array}{rcl} \dot{x}(t) & = & b(x(t), u_1(t), u_2(t)),\ t > 0, \\ x(0) & = & x, \end{array} \right. \tag{1.3}$$

where $b : \mathbf{R}^d \times U_1 \times U_2 \to \mathbf{R}^d$ and $u_i(\cdot) \in \mathcal{A}_i$. We assume that

(A1) b is continuous and there exists a constant $C_1 > 0$ such that for all $u_1 \in U_1$ and $u_2 \in U_2$

$$|b(x, u_1, u_2) - b(y, u_1, u_2)| \le C_1|x - y|.$$

Let $r : \mathbf{R}^d \times U_1 \times U_2 \to \mathbf{R}^d$ be the payoff function. We assume that

(A2) r is continuous and there exists a constant $C_2 > 0$ such that for all $u_1 \in U_1$ and $u_2 \in U_2$

$$|r(x, u_1, u_2) - r(y, u_1, u_2)| \le C_2|x - y|.$$

Let Γ denote the set of all maps $\alpha : \mathcal{A}_2 \to \mathcal{A}_1$ that are nonanticipative in the sense that for any $t > 0$ and $u_2, \tilde{u}_2 \in U_2$, $u_2(s) = \tilde{u}_2(s)$ for all $s \le t$ implies $\alpha[u_2](s) = \alpha[\tilde{u}_2](s)$ for all $s \le t$. Similarly, Δ is defined to be the set of all maps from $\mathcal{A}_1$ to $\mathcal{A}_2$ that are nonanticipative.

Let

$$\rho^+(x) := \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \limsup_{T\to\infty} \frac{1}{T} \int_0^T r(x(t), \beta[u_1](s), u_1(s))\, ds,$$

$$\rho^-(x) := \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \limsup_{T\to\infty} \frac{1}{T} \int_0^T r(x(t), u_2(s), \alpha[u_2](s))\, ds.$$

The functions $\rho^+(x), \rho^-(x)$ are called the upper and lower ergodic value functions associated with the differential game. If $\rho^+(x) = \rho^-(x) = \rho$, a constant for all x, we say that the differential game with ergodic payoff criterion has a value.

The rest of the paper is organized as follows. In section 2, we prove that if the associated HJI equation has a viscosity solution (ρ, w), then the upper and lower values coincide with ρ, and thus the differential game has value. We then prove some more representation formulas for the ergodic value. We also prove DPP for viscosity solution and a partial uniqueness result for viscosity solutions. In section 3, we show the existence of a viscosity solution to the HJI equation in two ways under a suitable assumption. Section 4 contains some concluding remarks.

2. Viscosity solutions and ergodic value. Consider the following HJI equations

$$\rho = \inf_{u_1\in U_1} \sup_{u_2\in U_2} \{b(x, u_1, u_2) \cdot Dw(x) + r(x, u_1, u_2)\},\ x \in \mathbf{R}^d \tag{2.1}$$

and

$$\rho = \sup_{u_2\in U_2} \inf_{u_1\in U_1} \{b(x, u_1, u_2) \cdot Dw(x) + r(x, u_1, u_2)\},\ x \in \mathbf{R}^d. \tag{2.2}$$

Definition 2.1. *A viscosity subsolution of* (2.1) *is a pair* (ρ, w)*, where* ρ *is a real number and* $w(\cdot)$ *is an upper semicontinuous function such that for* $x \in \mathbf{R}^d$ *and a smooth function* ϕ*, we have*

$$\rho \le \inf_{u_1\in U_1} \sup_{u_2\in U_2} \{b(x, u_1, u_2) \cdot D\phi(x) + r(x, u_1, u_2)\}$$

whenever $w-\phi$ has a local maximum at x. A pair (ρ, w) of a real number ρ and a lower semicontinuous function $w(\cdot)$ is said to be a viscosity supersolution of (2.1) *if for $x \in \mathbf{R}^d$ and a smooth function ϕ, we have*

$$\rho \geq \inf_{u_1 \in U_1} \sup_{u_2 \in U_2} \{b(x, u_1, u_2) \cdot D\phi(x) + r(x, u_1, u_2)\}$$

whenever $w-\phi$ has a local minimum at x. A viscosity solution of (2.1) *is a pair (ρ, w) that is both viscosity sub- and supersolution of* (2.1)*. Similarly, a viscosity solution of* (2.2) *is defined.*

We now proceed to prove the main result of this section, which provides estimates for ρ^+ in terms of viscosity sub- and supersolutions of (2.1) and, similarly, for ρ^-, in terms of viscosity sub- and supersolutions of (2.2). We prove this result under the following additional assumption:

(A3) For each $x \in \mathbf{R}^d$, there is a constant $M = M(x) > 0$ such that $|x(t)| < M$ for all $t \geq 0$, where $x(\cdot)$ is the solution of (1.3) under any pair of admissible controls $(u_1(\cdot), u_2(\cdot)) \in \mathcal{A}_1 \times \mathcal{A}_2$.

Remark 2.2. Since for any $t, s \geq 0$,

$$x(t) - x(s) = \int_s^t b(x(\tau), u_1(\tau), u_2(\tau))\, d\tau$$

and $|x(\tau)| \leq M$ by assumption (A3), we can find a constant $C > 0$ such that

$$|x(t) - x(s)| \leq C|t - s|.$$

Thus under assumptions (A1) and (A3), the solutions of (1.3) are globally Lipschitz continuous.

We now state and prove the main result of this section. Throughout the section, we assume (A1)–(A3).

THEOREM 2.3. (i) *Let (ρ, w) be a viscosity subsolution of* (2.1)*. Then*

$$\rho \leq \sup_{\beta \in \Delta} \inf_{u_1(\cdot) \in \mathcal{A}_1} \liminf_{T \to \infty} \frac{1}{T} \int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds. \tag{2.3}$$

(ii) *Let (ρ, w) be a viscosity supersolution of* (2.1)*. Then*

$$\rho \geq \sup_{\beta \in \Delta} \inf_{u_1(\cdot) \in \mathcal{A}_1} \limsup_{T \to \infty} \frac{1}{T} \int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds. \tag{2.4}$$

(iii) *Let (ρ, w) be a viscosity subsolution of* (2.2)*. Then*

$$\rho \leq \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \liminf_{T \to \infty} \frac{1}{T} \int_0^T r(x(s), \alpha[u_2](s), u_2(s))\, ds. \tag{2.5}$$

(iv) *Let (ρ, w) be a viscosity supersolution of* (2.2)*. Then*

$$\rho \geq \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \limsup_{T \to \infty} \frac{1}{T} \int_0^T r(x(s), \alpha[u_2](s), u_2(s))\, ds. \tag{2.6}$$

Proof. We prove (iii) and (iv); (i) and (ii) can be proved similarly.

Let (ρ, w) be a viscosity subsolution of (2.2). Assume that w is $C^{1,1}$ (i.e., w is differentiable with bounded and Lipschitz derivatives). Let K be the common

Lipschitz constant associated with w, Dw. Then (ρ, w) satisfies (2.2) in the classical sense. In particular, for any $\epsilon > 0$ and any $x \in \mathbf{R}^d$,

$$\rho - \epsilon < \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} (b(x, u_1, u_2) \cdot Dw(x) + r(x, u_1, u_2)). \tag{2.7}$$

Set

$$\Lambda(x, u_2) = \inf_{u_1 \in U_1} (b(x, u_1, u_2) \cdot Dw(x) + r(x, u_1, u_2)).$$

Then it is easy to note that Λ is uniformly continuous on $\mathbf{R}^d \times U_2$. Since U_2 is separable, we can find a sequence $\{u_2^i\}$ in U_2 and a family of balls $\{B_{r_i}(x_i)\}$ covering $\mathbf{R}^d$ such that

$$\rho - \epsilon < \Lambda(x, u_2^i) \text{ for all } x \in B_{r_i}(x_i) \text{ and } i.$$

Note that here the sequence $\{u_2^i\}$ can be chosen to be finite since U_2 is compact. In that case, the sequence of balls $\{B_{r_i}(x_i)\}$ should be replaced by a finite family of open sets.

Define, $\psi : \mathbf{R}^d \to U_2$ by

$$\psi(x) = u_2^k \text{ if } x \in B_{r_k}(x_k) \setminus \bigcup_{i=1}^{k-1} B_{r_i}(x_i).$$

Then ψ is a Borel map and $\rho - \epsilon < \Lambda(x, \psi(x)) \ \forall x \in \mathbf{R}^d$. We make the following claims.

Claim A. For $x \in \mathbf{R}^d$, $m > 0$, there exists $\beta^m \in \Delta$ such that

$$(\rho - \epsilon)N - C\frac{N}{m} - \int_0^N r(x(s), u_1(s), \beta^m[u_1](s))\, ds \le w(x(N)) - w(x)$$

for any positive integer N, where $x(\cdot)$ is the solution of (1.3) with the initial condition $x(0) = x$ under controls $(u_1(\cdot), \beta^m[u_1](\cdot))$ and C is a constant depending on K, C_1, C_2 but not on x, N, and m.

Claim B. For each $\alpha \in \Gamma$, we can find $\tilde{u}_1(\cdot) \in \mathcal{A}_1$ and $\tilde{u}_2(\cdot) \in \mathcal{A}_2$ such that

$$\beta^m[\tilde{u}_1](\cdot) = \tilde{u}_2(\cdot) \text{ and } \alpha[\tilde{u}_2](\cdot) = \tilde{u}_1(\cdot). \tag{2.8}$$

Assuming the claims to be true, we complete the proof of (2.5). Divide the inequality in Claim A by N, and let $N \to \infty$ to obtain

$$(\rho - \epsilon) \le C\frac{1}{m} + \liminf_{N \to \infty} \frac{1}{N} \int_0^N r(x(s), u_1(s), \beta^m[u_1](s))\, ds. \tag{2.9}$$

Using (2.8) in (2.9), we deduce

$$(\rho - \epsilon) \le C\frac{1}{m} + \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \liminf_{N \to \infty} \frac{1}{N} \int_0^N r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Letting $m \to \infty$, we obtain

$$(\rho - \epsilon) \le \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \liminf_{N \to \infty} \frac{1}{N} \int_0^N r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

We now need to replace the limit along the integers by the limit along any real sequence. For this, choose any sequence $T_n \to \infty$. Then

$$\frac{1}{T_n}\int_o^{T_n} r(x(s),\alpha[u_2](s),u_2(s))\,ds$$
$$= \frac{1}{T_n}\int_0^{[T_n]} r(x(s),\alpha[u_2](s),u_2(s))\,ds + \frac{1}{T_n}\int_{[T_n]}^{T_n} r(x(s),\alpha[u_2](s),u_2(s))\,ds.$$

Using (A3), we note that the second term on the right-hand side of the above equality vanishes as $n \to \infty$. Note also the fact that

$$\left|\frac{1}{T_n}\int_0^{[T_n]} r(x(s),\alpha[u_2](s),u_2(s))\,ds - \frac{1}{[T_n]}\int_0^{[T_n]} r(x(s),\alpha[u_2](s),u_2(s))\,ds\right| \to 0$$

as $n \to \infty$. Thus

$$\lim_{n\to\infty}\frac{1}{T_n}\int_o^{T_n} r(x(s),\alpha[u_2](s),u_2(s))\,ds = \lim_{n\to\infty}\frac{1}{[T_n]}\int_o^{[T_n]} r(x(s),\alpha[u_2](s),u_2(s))\,ds.$$

Since this is true for any sequence (T_n) tending to ∞, we obtain

$$(\rho-\epsilon) \le \inf_{\alpha\in\Gamma}\sup_{u_2(\cdot)\in\mathcal{A}_2}\liminf_{T\to\infty}\frac{1}{T}\int_0^T r(x(s),\alpha[u_2](s),u_2(s))\,ds.$$

This proves (2.5) under the assumption that w is $C^{1,1}$. We now turn to the general case. Let w_ϵ be the sup-convolution of w, i.e.,

$$w_\epsilon(y) = \sup_{|z|\le M+2}\left\{w(z) - \frac{|z-y|^2}{2\epsilon}\right\}.$$

Then w_ϵ converges to w uniformly as $\epsilon \to 0$ on $B_{M+1} := \bar{B}(0, M+1)$, and w_ϵ are Lipschitz continuous and satisfy a.e. on B_{M+1}

$$\rho \le \inf_{u_2\in U_2}\sup_{u_1\in U_1}\{b(y,u_1,u_2)\cdot Dw_\epsilon(y) + r(y,u_1,u_2)\} + \sigma_1(\epsilon)$$

for some modulus σ_1 (see [10], [11]). For each $\delta > 0$, let w_ϵ^δ be a smooth approximation of w_ϵ such that $w_\epsilon^\delta, Dw_\epsilon^\delta$ are smooth and they converge to w_ϵ, Dw_ϵ uniformly on compact sets, respectively, and they all have the same Lipschitz constant. Now, using these facts, we can find another modulus σ_2 such that

$$\rho \le \inf_{u_2\in U_2}\sup_{u_1\in U_1}\{b(y,u_1,u_2)\cdot Dw_\epsilon^\delta(y) + r(y,u_1,u_2)\} + \sigma_1(\epsilon) + \sigma_2(\delta) \tag{2.10}$$

on $B_{M+1/2}$. Note that σ_2 may depend on ϵ and x. Observe that while proving (2.5), we have used the smoothness of w only in B_M. Thus we can use the above arguments with w_ϵ^δ and (2.10) to conclude

$$\rho \le \inf_{\alpha\in\Gamma}\sup_{u_2(\cdot)\in\mathcal{A}_2}\liminf_{T\to\infty}\frac{1}{T}\int_o^T r(x(s),\alpha[u_2](s),u_2(s))\;ds + \sigma_1(\epsilon) + \sigma_2(\delta),$$

where $x(\cdot)$ is the solution of (1.3) with the initial condition $x(0) = x$ under the controls $(\alpha[u_2](\cdot), u_2(\cdot))$. Now letting δ and then ϵ to 0, we obtain (2.5). This completes the proof of part (iii). We now proceed to prove the claims.

Proof of Claim A. Let $t = \frac{1}{m}$. Define

$$u_2^m(s) = \psi(x) \text{ for } s \in [0, t).$$

We extend the definition of $(u_2^m(\cdot), x(\cdot))$ to $[0, (i+1)\,t)$ assuming that it has been defined on $[0, i\,t)$ as follows. Let $x(\cdot)$ be the solution (2.1) with initial value x and controls $(u_1(\cdot), u_2^m(\cdot))$ in the interval $[0, it)$. Set

$$u_2^m(s) = \psi(x((i\,t)^-)) \text{ for } s \in [i\,t, (i+1)\,t).$$

Note that $x((it)^-)$ exists since $X(\cdot)$ is Lipschitz continuous and bounded. This defines $u_2^m(\cdot)$ on $\mathbf{R}$.

Let $x(.)$ be the solution of (1.3) with initial value $x(0) = x$ and controls $(u_1(\cdot), u_2^m(\cdot)\,)$. Then,

$$\begin{aligned}
&w(x((i+1)t)) - w(x(it)) \\
&\quad = \int_{it}^{(i+1)t} Dw(x(s)) \cdot b(x(s), u_1(s), u_2^m(s))\, ds \\
&\quad = \int_{it}^{(i+1)t} (Dw(x(s)) - Dw(x(it))) \cdot b(x(s), u_1(s), u_2^m(s))\, ds \\
&\qquad + \int_{it}^{(i+1)t} Dw(x(it)) \cdot (b(x(s), u_1(s), u_2^m(s)) - b(x(it), u_1(s), u_2^m(s)))\, ds \\
&\qquad + \int_{it}^{(i+1)t} (Dw(x(it)) \cdot b(x(it), u_1(s), u_2^m(s)) + r(x(it), u_1(s), u_2^m(s)))\, ds \\
&\qquad + \int_{it}^{(i+1)t} (r(x(s), u_1(s), u_2^m(s)) - r(x(it), u_1(s), u_2^m(s)))\, ds \\
&\qquad - \int_{it}^{(i+1)t} r(x(s), u_1(s), u_2^m(s))\, ds.
\end{aligned}$$

Note that w, Dw, b are all Lipschitz along the trajectory $x(\cdot)$ and they are bounded by assumptions (A1) and (A3). Using these facts in the above together with the definition of ψ, we obtain,

$$\begin{aligned}
w(x((i+1)t)) - w(x(it)) &\geq -C \int_{it}^{(i+1)t} (s - i\,t)\, ds + (\rho - \epsilon) \int_{it}^{(i+1)t} ds \\
&\quad - \int_{it}^{(i+1)t} r(x(s), u_1(s), u_2^m(s))\, ds \\
&= -C\,t^2 + (\rho - \epsilon)t - \int_{it}^{(i+1)t} r(x(s), u_1(s), u_2^m(s))\, ds
\end{aligned}$$

for a constant $C > 0$ which will depend only on x and other Lipschitz constants. Now define a strategy $\beta^m \in \Delta$ by $\beta^m[u_1](\cdot) = u_2^m(\cdot)$ for $u_1(\cdot) \in \mathcal{A}_1$. Note that $\beta^m[u_1](\cdot)$ on

$[it,(i+1)t)$ depends only on $[0,it)$. Adding these inequalities for $i=0,\dots,Nm-1$, we get the inequality stated in Claim A.

Proof of Claim B. We define such controls inductively. Let $\tilde{u}_2(\cdot)=\psi(x)$ on $[0,t)$. Define $\tilde{u}_1|_{[0,t)}=\alpha[\tilde{u}_2]|_{[0,t)}$. Having known $\tilde{u}_1(\cdot)$ and $\tilde{u}_2(\cdot)$ on $[0,it)$, we define $\tilde{u}_2(\cdot)$ on $[it,(i+1)t)$ by $\tilde{u}_2(s)=\psi(x(it)^-)$, where $x(\cdot)$ satisfies

$$\dot{x}(s)=b(x(s),\tilde{u}_1(s),\tilde{u}_2(s)),\ s\in[0,it)$$

and $x(0)=x$. It is now easy to check (2.8). This completes the proof of Claim B.

We now prove part (iv). Let w be a viscosity supersolution of (2.2) and assume $w\in C^{1,1}$. The proof for general w follows from an argument as in that of (iii). One has for any $\epsilon>0$ and any $x\in\mathbf{R}^d$,

$$\sup_{u_2\in U_2}\inf_{u_1\in U_1}(b(x,u_1,u_2)\cdot Dw(x)+r(x,u_1,u_2))<\rho+\epsilon.$$

Set

$$\Lambda(x,u_1,u_2)=(b(x,u_1,u_2)\cdot Dw(x)+r(x,u_1,u_2)).$$

By the uniform continuity of Λ, we can find a countable family $B_{r_i}(x_i)\times B_{r_i}(u_2^i)$ covering $\mathbf{R}^d$ and a sequence $u_1^i\in U_1$ such that

$$\Lambda(x,u_1^i,u_2)<\rho+\epsilon\quad\forall\ (x,u_2)\in B_{r_i}(x_i)\times B_{r_i}(u_2^i).$$

Define a map $\psi:\mathbf{R}^d\times U_2\to U_1$ by

$$\psi(x,u_2)=u_1^k \text{ if } (x,u_2)\in B_{r_k}(x_k)\times B_{r_k}(u_2^k)\setminus\bigcup_{i=1}^{k-1}B_{r_i}(x_i)\times B_{r_i}(u_2^i).$$

Then ψ is Borel measurable and

$$\Lambda(x,\psi(x,u_2),u_2)<\rho+\epsilon\quad\forall(x,u_2).$$

Claim C. For each integer $m>0$, there exists $\alpha^m\in\Gamma$ such that

$$\int_0^N r(x(s),\alpha^m[u_2](s),u_2(s))\,ds+w(x(N))-w(x)\le(\rho+\epsilon)N+C\frac{N}{m}$$

for all positive integers N and $u_2(\cdot)\in\mathcal{A}_2$, where $x(\cdot)$ is the solution of (1.3) with the initial condition $x(0)=x$ under controls $(\alpha^m[u_2](\cdot),u_2(\cdot))$ and C is a constant independent of N and m.

Assuming that the claim is true, we see, on dividing by N and letting $N\to\infty$,

$$\limsup_{N\to\infty}\frac{1}{N}\int_0^N r(x(s),\alpha^m[u_2](s),u_2(s))\ ds\le(\rho+\epsilon)+\frac{C}{m},$$

which implies

$$\inf_{\alpha\in\Gamma}\sup_{u_2(\cdot)\in U_2}\limsup_{N\to\infty}\frac{1}{N}\int_0^N r(x(s),\alpha[u_2](s),u_2(s))\ ds\le\rho.$$

From this one can deduce (iv).

Proof of Claim C. Let $t = 1/m$. Define $\alpha^m[u_2](s)) = \psi(x, u_2(s))$ for $s \in [0, t)$. Assuming that we have defined $\alpha^m[u_2](\cdot), x(\cdot)$ on $[0, it)$, we extend its definition to $[0, (i+1)t)$ as follows. Let $x(\cdot)$ satisfy (1.3) in $(0, it)$ with the initial condition $x(0) = x$ under the controls $(\alpha^m[u_2](\cdot), u_2(\cdot))$. Then define $\alpha^m[u_2](s) = \psi(x((it)^-, u_2(s)))$ for $s \in [it, (i + 1)t)$. This defines $\alpha^m \in \Gamma$.

Now let $x(\cdot)$ denote the solution of (1.3) with the initial condition $x(0) = x$ under the controls $(\alpha^m[u_2](\cdot), u_2(\cdot))$. Then, for any i, as in Claim A, we can show that

$$w(x((i + 1)t)) - w(x(it)) \le C\, t^2 + (\rho + \epsilon)t - \int_{it}^{(i+1)t} r(x(s), \alpha^m[u_2](s), u_2(s))\, ds.$$

Summing over i from 0 to $Nm - 1$, we obtain Claim C. □

As an immediate consequence of the theorem, we obtain the following comparison principle.

COROLLARY 2.4. *Assume that* (ρ, w), $(\bar\rho, \bar w)$ *are viscosity sub- and supersolutions of* (2.1) *(or* (2.2)*). Then,* $\rho \le \bar\rho$.

Proof. We prove for the case of (2.1). The proof of (2.2) follows similarly. By parts (i) and (ii) of Theorem 2.3, we have

$$\rho \le \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \liminf_{T\to\infty} \frac{1}{T} \int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds$$

and

$$\bar\rho \ge \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \limsup_{T\to\infty} \frac{1}{T} \int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds.$$

Hence $\rho \le \bar\rho$. □

Remark 2.5. In this corollary, we have not assumed any growth on w and $\bar w$. If w and $\bar w$ are given to be bounded, then one can give a very simple proof of this comparison principle using comparison principle for stationary HJI equations (see [12]).

Note that under assumptions (A1)–(A3), if (2.1) has a viscosity solution (ρ, w), then $\rho = \rho^+$, and if (2.2) has a viscosity solution $(\bar\rho, w)$, then $\rho = \rho^-$, using Theorem 2.3. Thus if the Isaacs minimax condition holds, i.e., for any $x, p \in \mathbf{R}^d$, if we have

$$\inf_{u_2\in U_2} \sup_{u_1\in U_1} \{b(x, u_1, u_2) \cdot p + r(x, u_1, u_2)\} = \sup_{u_1\in U_1} \inf_{u_2\in U_2} \{b(x, u_1, u_2) \cdot p + r(x, u_1, u_2)\},$$

then, using Fan's minimax theorem [8] we can deduce the following result. We omit the details.

THEOREM 2.6. *Assume that the Isaacs minimax condition holds. Assume that* (ρ, w) *is a viscosity solution of* (2.1) *or equivalently of* (2.2)*. Then* $\rho = \rho^+(x) = \rho^-(x)$ *for all* $x \in \mathbf{R}^d$.

By interchanging the roles of taking limits as $T \to \infty$ and taking infimum and supremum over controls in the proof of the Theorem 2.3, we obtain the following result.

THEOREM 2.7. *Let* (ρ, w) *be a viscosity solution of* (2.1)*. Then*

$$\rho = \lim_{T\to\infty} \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \frac{1}{T} \int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds.$$

Similarly, if $(\bar{\rho}, \bar{w})$ *is a viscosity solution of* (2.2)*, then*

$$\bar{\rho} = \lim_{T\to\infty} \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \frac{1}{T} \int_0^T r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Remark 2.8. Let $w^+(T,x)$ and $w^-(T,x)$ denote the upper and lower value functions of the finite horizon problem with horizon T, dynamics (1.3), payoff function r, and zero terminal cost; i.e., they are defined as follows:

$$w^+(T,x) := \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \int_0^T r(s, x(s), u_1(s), \beta[u_1](s))\, ds$$

and

$$w^-(T,x) := \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \int_0^T r(s, x(s), \alpha[u_2](s), u_2(s))\, ds,$$

where $x(\cdot)$ is solution of (1.3) with the initial condition $x(0) = x$ under respective controls. Then the conclusion of the above theorem can be restated as

$$\rho = \lim_{T\to\infty} \frac{w^+(T,x)}{T} \text{ and } \bar{\rho} = \lim_{T\to\infty} \frac{w^-(T,x)}{T}.$$

This can be seen as the longtime behavior of viscosity solutions of HJI equations corresponding to differential games on finite horizon. We refer to [2], [14] for the study of longtime behavior of viscosity solutions of Hamilton–Jacobi equations.

We now give another representation formula for ρ in terms of the discounted value of the differential game. Let w_λ denote the upper value of the differential game on an infinite horizon with discount factor $\lambda > 0$, i.e.,

$$w_\lambda(x) = \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \int_0^\infty e^{-\lambda s} r(x(s), u_1(s), \beta[u_1](s))\, ds;$$

then

$$\rho = \lim_{\lambda\to 0} \lambda w_\lambda(x).$$

An analogous statement holds for the lower value function. This is the content of our next result. We closely follow the arguments in the proof of Theorem 2.3.

THEOREM 2.9. (i) *Let* (ρ, w) *be a viscosity solution of* (2.1)*. Then*

$$\rho = \lim_{\lambda\to 0} \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \lambda \int_0^\infty e^{-\lambda s} r(x(s), u_1(s), \beta[u_1](s))\, ds.$$

(ii) *Similarly, if* (ρ, w) *is a viscosity solution of* (2.2)*, then*

$$\rho = \lim_{\lambda\to 0} \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \lambda \int_0^\infty e^{-\lambda s} r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Proof. We prove only (ii); (i) can be proved in an analogous way. Again we prove this under the additional assumption that w is $C^{1,1}$. The proof of the general case can be done as before.

Fix x. Let $\beta^m \in \Delta$ be as in the proof of Theorem 2.3. Let $u_1(\cdot) \in \mathcal{A}_1$. Let $x(\cdot)$ denote the solution of (1.3) with the initial condition $x(0) = x$ under the controls $(u_1(\cdot), \beta^m[u_1](\cdot))$. Then for a.e. s,

$$\frac{d}{ds}e^{-\lambda s}w(x(s)) = e^{-\lambda s}b(x(s), u_1(s), \bar{u}_2) \cdot Dw(x(s)) - \lambda e^{-\lambda s}w(x(s)).$$

Now following the arguments in the proof of Claim A of Theorem 2.3, we obtain

$$\begin{aligned}
&e^{-\lambda(i+1)t}w(x((i+1)t)) - e^{-\lambda it}w(x(it)) \\
&\qquad = \int_{it}^{(i+1)t} e^{-\lambda s} Dw(x(s)) \cdot b(x(s), u_1(s), \beta^m[u_1](s))\, ds \\
&\qquad \geq -C \int_{it}^{(i+1)t} e^{-\lambda s}(s - i\,t)\, ds + (\rho - \epsilon) \int_{it}^{(i+1)t} e^{-\lambda s}\, ds \\
&\qquad\quad - \int_{it}^{(i+1)t} e^{-\lambda s} r(x(s), u_1(s), \beta^m[u_1](s))\, ds \\
&\qquad \geq -C\, t \frac{1}{\lambda}\left[e^{-\lambda it} - e^{-\lambda(i+1)t}\right] + (\rho - \epsilon)\frac{1}{\lambda}\left[e^{-\lambda it} - e^{-\lambda(i+1)t}\right] \\
&\qquad\quad - \int_{it}^{(i+1)t} e^{-\lambda s} r(x(s), u_1(s), \beta^m[u_1](s))\, ds.
\end{aligned}$$

Adding these inequalities for $i = 0, \ldots, Nm - 1$, and multiplying by λ, we get

$$\begin{aligned}
\lambda e^{-\lambda N} w(x(N)) - \lambda w(x) \geq C\frac{1}{m}[1 - e^{-\lambda N}] + (\rho - \epsilon)[1 - e^{-\lambda N}] \\
- \lambda \int_0^N e^{-\lambda s} r(x(s), u_1(s), \beta^m[u_1](s))\, ds.
\end{aligned}$$

Now letting $N \to \infty$, we obtain

$$\rho - \epsilon + \lambda w(x_0) \leq \lambda \int_0^\infty e^{-\lambda s} r(x(s), u_1(s), \beta^m[u_1](s))\, ds - C\frac{1}{m}.$$

Using (2.8), we get

$$\rho - \epsilon + \lambda w(x_0) \leq \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \lambda \int_0^\infty e^{-\lambda s} r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Now taking limit as $\lambda \to 0$ and then $\epsilon \to 0$, we get

$$\rho \leq \liminf_{\lambda \to 0} \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \lambda \int_0^\infty e^{-\lambda s} r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Similarly, we can obtain

$$\rho \geq \limsup_{\lambda \to 0} \inf_{\alpha \in \Gamma} \sup_{u_2(\cdot) \in \mathcal{A}_2} \lambda \int_0^\infty e^{-\lambda s} r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

This completes part (ii). □

Remark 2.10. If (ρ, w) is a viscosity subsolution of (2.2), then note that the following result holds:

$$\rho \le \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \liminf_{\lambda\to 0} \lambda \int_0^\infty e^{-\lambda s} r(x(s), \alpha[u_2](s), u_2(s))\, ds.$$

Similar statements hold for the other cases.

We now present a dynamic programming principle for the viscosity solutions of (2.1) and (2.2).

THEOREM 2.11. (i) *Let (ρ, w) be a viscosity solution of* (2.1). *Then for any $T > 0$,*

$$w(x) = \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \left[\int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds + w(x(T)) \right] - \rho T.$$

(ii) *Let (ρ, w) be a viscosity solution of* (2.2). *Then for any $T > 0$,*

$$w(x) = \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \left[\int_0^T r(x(s), \alpha[u_2](s), u_2(s))\, ds + w(x(T)) \right] - \rho T.$$

Proof. We prove (ii); (i) can be proved analogously. Let $T > 0$ and m a positive integer. Take $t = T/m$. As in Claim C, we obtain $\alpha^m(.)$, given ϵ, $u_2(.)$, such that

$$w(x(T)) - w(x) \le -\int_0^T r(x(s), u_1(s), u_2(s))\, ds + (\rho + \epsilon)T - C\frac{T^2}{m}.$$

Therefore

$$w(x) \ge \inf_{\alpha\in\Gamma} \sup_{u_2(\cdot)\in\mathcal{A}_2} \left(\int_0^T r(x(s), \alpha[u_2](s), u_2(s))\, ds + w(x(T)) \right) - \rho T.$$

We can prove the other inequality similarly. □

We now turn our attention to the uniqueness of w. Define a set Z as follows: $z \in Z$ if $z = \lim_{t_n\to\infty} x(t_n)$, where $t_n \to \infty$ and $x(\cdot)$ is a solution of (1.3) with an initial condition $x(0) = x_0$ for some $x_0 \in \mathbf{R}^d$ under some controls $(u_1(\cdot), u_2(\cdot)) \in \mathcal{A}_1 \times \mathcal{A}_2$. Then Z is nonempty under assumption (A3). We now show that if (ρ, w_1) and (ρ, w_2) are two viscosity solutions of (2.1) such that $w_1 \equiv w_2$ on Z, then $w_1 \equiv w_2$.

THEOREM 2.12. *Let (ρ, w_1) and (ρ, w_2) be two viscosity solutions of* (2.1) *such that $w_1 \equiv w_2$ on Z. Then $w_1 \equiv w_2$. An analogous result holds for* (2.2).

Proof. We prove this for the case when w_1, w_2 are $C^{1,1}$. The general case follows similarly as in the proof of Theorem 2.3. Let m be a positive integer. Let α^m be as in Claim C when we take $w = w_2$, and let β^m be as in Claim A when we take $w = w_1$. Taking α^m as α in (2.9), we obtain $\tilde{u}_1(\cdot) \in \mathcal{A}_1$ and $\tilde{u}_2(\cdot) \in \mathcal{A}_2$ such that

$$\beta^m[\tilde{u}_1](\cdot) = \tilde{u}_2(\cdot) \text{ and } \alpha^m[\tilde{u}_2](\cdot) = \tilde{u}_1(\cdot).$$

Using this, we obtain

$$w_1(x(N)) - w_1(x) \ge -\int_0^N r(x(s), \alpha^m[\tilde{u}_2](s), \tilde{u}_2(s))\, ds + (\rho - \epsilon)N - C\frac{N}{m}$$

and

$$w_2(x(N)) - w_2(x) \leq -\int_0^N r(x(s), \alpha^m[\tilde{u}_2](s), \tilde{u}_2(s))\ ds + (\rho - \epsilon)N + C\frac{N}{m}.$$

From these two inequalities, we obtain

$$w_1(x) - w_2(x) \leq w_1(x(N)) - w_2(x(N)) + 2C\frac{N}{m}. \tag{2.11}$$

Using the compactness and equi-Lipschitz continuity of trajectories, we get a trajectory $\bar{x}(\cdot)$ such that $x(\cdot) \to \bar{x}(\cdot)$ as $m \to \infty$. (Note that $x(\cdot)$ above depends on m.) Now from (2.11) we obtain by letting $m \to \infty$

$$w_1(x) - w_2(x) \leq w_1(\bar{x}(N)) - w_2(\bar{x}(N)).$$

Now letting $N \to \infty$, we see that

$$w_1(x) - w_2(x) \leq 0.$$

Similarly, we can prove

$$w_2(x) - w_1(x) \leq 0.$$

Thus $w_1 \equiv w_2$. □

Remark 2.13. The uniqueness result in [13] is established under certain growth conditions on the solutions. Here we have obtained similar results without any such condition. Our uniqueness result, however, is not complete. We have shown that if two solutions coincide on the set Z, then they are identical. In view of this, it would be interesting to investigate the structure of Z.

3. Existence results. In the previous section, we studied some representation formulas related to the viscosity solutions of (2.1) and (2.2). We now study the existence of viscosity solutions to (2.1) and (2.2). We refer to [9] for analogoues results. Here we present two simple proofs of the existence result.

To this end we make the following assumption.

(A4) There exists a constant $C_3 > 0$ such that for all $x, y \in \mathbf{R}^d$ and $(u_1, u_2) \in U_1 \times U_2$,

$$\langle b(x, u_1, u_2) - b(y, u_1, u_2),\ x - y\rangle \leq -C_3|x - y|^2.$$

Remark 3.1. (i) Let $(u_1(\cdot), u_2(\cdot)) \in \mathcal{A}_1 \times \mathcal{A}_2$. Let $x(\cdot)$ and $y(\cdot)$ denote the solutions of (1.3) with the initial conditions $x(0) = x$ and $y(0) = y$, respectively, under these controls. Then using (A4), we get

$$\frac{d}{dt}|x(t) - y(t)|^2 \leq -C_3|x(t) - y(t)|^2.$$

Now using Gronwall's inequality, we obtain

$$|x(t) - y(t)| \leq |x - y|e^{-C_4 t}$$

for a constant $C_4 > 0$.

(ii) Using Gronwall's inequality, it is easy to see that (A1) and (A4) together imply (A3).

We now give some examples where (A4) holds.

Example 3.2. (i) *Let U_1, U_2 be subsets of $\mathbf{R}^m$ and $\mathbf{R}^q$, respectively, for some m and q. Let b be given by*

$$b(x, u_1, u_2) = Bx + C_1u_1 + C_2u_2 + b_1(x, u_1, u_2),$$

where B is a $d\times d$ matrix, C_1 a $d\times m$ matrix, C_2 a $d\times q$ matrix, and $b_1 : \mathbf{R}^d\times U_1\times U_2 \to \mathbf{R}^d$. We assume the following:

$$\exists \alpha > 0 \text{ such that } \langle Bx, x\rangle \le -\alpha|x|^2$$

and

$$|b_1(x, u_1, u_2) - b(y, u_1, u_2)| \le \alpha_1|x - y| \text{ for some } \alpha_1 < \alpha.$$

Under these assumptions, it is easy to verify that (A4) *is satisfied.*

(ii) *Let U_1, U_2 be as above and let b be given by*

$$b(x, u_1, u_2) = A + B_1u_1 + B_2u_2 + \bar{b}(x),$$

where A is a $d\times d$ matrix, B_1 a $d\times m$ matrix, and B_2 a $d\times q$ matrix. Assume that there are matrices C_1, C_2 of orders $d\times m$ and $d\times q$, respectively, such that $A+B_1C_1+B_2C_2$ is stable. Further assume that $\bar{b}$ is bounded and Lipschitz continuous. Then (A4) *is satisfied.*

We now prove the existence via the vanishing limit in the discounted payoff criterion.

THEOREM 3.3. *Assume* (A1), (A2), *and* (A4). *Let w_λ be the unique viscosity solution in the class of linear growth functions of*

$$\lambda w_\lambda(x) = \inf_{u_1(\cdot)\in\mathcal{A}_1} \sup_{u_2(\cdot)\in\mathcal{A}_2} \left(b(x, u_1, u_2)\cdot Dw_\lambda(x) + r(x, u_1, u_2)\right). \tag{3.1}$$

Then $\lambda w_\lambda(x) \to \rho$, a constant as $\lambda \to 0$. Also for any $\bar{x} \in \mathbf{R}^d$, $w_\lambda(\cdot) - w_\lambda(\bar{x})$ converges uniformly on compact sets to a continuous function $w(\cdot)$. Thus (ρ, w) is a viscosity solution of (2.1) *for any $\bar{x} \in \mathbf{R}^d$. Moreover, $\rho = \rho^+(x)$ for all $x \in \mathbf{R}^d$. An analogous result holds for the existence of a viscosity solution to* (2.2).

Proof. Using standard results in differential games and viscosity solutions [1], we have

$$w_\lambda(x) = \sup_{\beta\in\Delta} \inf_{u_1(\cdot)\in\mathcal{A}_1} \int_0^\infty e^{-\lambda t} r(x(t), u_1(t), \beta[u_1](t))\, dt.$$

Let $u_1(\cdot) \in \mathcal{A}_1$ and $u_2(\cdot) \in \mathcal{A}_2$. Then using Remark 3.1(i), we see that

$$\left| \int_0^\infty e^{-\lambda s} r(x(s), u_1(s), u_2(s))\, ds - \int_0^\infty e^{-\lambda s} r(y(s), u_1(s), u_2(s))\, ds \right| \le \frac{1}{C_4 + \lambda}|x - y|,$$

where $x(\cdot), y(\cdot)$ are solutions of (1.3) with initial conditions $x(0) = x$ and $y(0) = y$, respectively, under the controls $(u_1(\cdot), u_2(\cdot))$. Using this fact, it is easy to note that w_λ is Lipschitz continuous where the Lipschitz constant is independent of λ. Therefore by Ascoli-Arzela's theorem for a fixed $\bar{x}$, $w_\lambda(x) - w_\lambda(\bar{x})$ converges locally uniformly to a continuous function $w(x)$ and $\lambda w_\lambda(x)$ converges to a constant ρ. By the stability of viscosity solutions, we note that (ρ, w) is a viscosity solution of (2.1). Now by Theorem 2.6, $\rho = \rho^+(x)$ for all $x \in \mathbf{R}^d$. ∎

We now turn our attention to the increasing horizon limit case. Let $T > 0$ and w_0 be any Lipschitz continuous function. Now consider the HJI equation in $(0,T) \times \mathbf{R}^d$,

$$\left\{ \begin{array}{rcl} w_t(t,x) & = & \inf\limits_{u_1 \in U_1} \sup\limits_{u_2 \in U_2} \{b(x,u_1,u_2) \cdot Dw(t,x) + r(x,u_1,u_2)\}, \\ w(0,x) & = & w_0(x). \end{array} \right. \tag{3.2}$$

Then we have the following theorem.

THEOREM 3.4. *Assume* (A1), (A2), *and* (A4). *Let* $w(t,x)$ *be the unique viscosity solution of* (3.2) *in the class of linear growth functions. Then* $\frac{w(T,x)}{T} \to \rho$, *a constant, and* $w(T,x) - \rho T$ *converges locally uniformly to a continuous function* $w_\infty(x)$ *such that* (ρ, w_∞) *is a viscosity solution of* (2.1). *Moreover,* $\rho = \rho^+(x)$ *for all* $x \in \mathbf{R}^d$. *An analogous results holds for* (2.2).

Proof. Using standard results in differential games and viscosity solutions [7], we have the following representation formula for $w(t,x)$:

$$w(T,x) = \sup_{\beta \in \Delta} \inf_{u_1(\cdot) \in \mathcal{A}_1} \left[\int_0^T r(x(s), u_1(s), \beta[u_1](s))\, ds + w_0(x(T)) \right].$$

As in above theorem, using Remark 3.1(i), we can show that

$$|w(T,x) - w(T,y)| \leq \frac{1 - e^{-C_{10}T}}{C_{10}} |x - y|.$$

Using Ascoli-Arzela's theorem, it is easy to see that $\frac{w(T,x)}{T} \to \rho$, a constant $w(T,x) - \rho T \to w_\infty(x)$ locally uniformly to a continuous function $w_\infty(x)$. We now need to show that (ρ, w_∞) is a viscosity solution of (2.1). Let

$$w^\epsilon(t,x) = w(t/\epsilon, x) \text{ for } t \in [0,1].$$

Then $w^\epsilon(t,x) - \rho \frac{t}{\epsilon} \to w_\infty(t,x)$ locally uniformly as $\epsilon \to 0$. Now it is easy to see that w^ϵ is viscosity solution of

$$\left\{ \begin{array}{rcl} \epsilon w_t^\epsilon(t,x) & = & \inf_{u_1 \in U_1} \sup_{u_2 \in U_2} \{b(x,u_1,u_2) \cdot Dw^\epsilon(t,x) + r(x,u_1,u_2)\}, \\ w(0,x) & = & w_0(x) \end{array} \right.$$

in $(0,1) \times \mathbf{R}^d$. Using the stability of viscosity solutions [5], we get that (ρ, w_∞) is a viscosity solution of (2.1). This completes the proof. □

4. Conclusions. In this paper, we have studied a zero sum differential game with ergodic payoff. We have identified the scalar appearing in the HJI equation as the ergodic value. Under a dissipativity-type condition, we have also established the existence of a viscosity solution to HJI equations. We have carried out two asymptotics, namely, we have shown that the ergodic value is the vanishing limit of the discounted value. At the same time, the ergodic value is also the time averaged limit of the finite horizon value. Finally we wish to mention that although we have identified the scalar appearing in the HJI equation as the ergodic value, we have not been able to establish the uniqueness (in some sense) of the solution of the HJI equation. We have obtained only a partial uniqueness result. Thus the uniqueness issue and the existence of viscosity solution to HJI equations under (A3) alone still remain problems that need further investigation.

Acknowledgments. The authors thank two anonymous referees for pointing out some errors and for drawing attention to related literature in an earlier version of this paper. They also thank M. Rajesh for pointing out an error in a preliminary draft of this paper.

NONCONVEX DUALITY IN OPTIMAL CONTROL*

F. H. CLARKE† AND C. NOUR†

Abstract. We derive a representation of the minimum cost of an optimal control problem in terms of the upper envelope of generalized semisolutions of the Hamilton–Jacobi equation.

Key words. optimal control, duality, Hamilton–Jacobi equations, viscosity solutions, proximal analysis, nonsmooth analysis

AMS subject classifications. 49J24, 49L25, 49J52

1. Introduction.

We consider in this article the following optimal control problem (P) in Mayer form: to minimize the cost functional

$$\ell(T, x(T))$$

over the (absolutely continuous) trajectories x on some interval $[0, T]$ of a differential inclusion

$$\dot{x}(t) \in F(x(t)) \text{ a.e.}$$

subject to the boundary conditions and state constraint

$$x(0) = x_0,\ x(T) \in C,\ x(t) \in A\ \forall\, t \in [0, T].$$

The horizon $T \geq 0$ is free in this problem. We assume that the set A is closed, that C is compact, and that the extended-valued function $\ell : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ is lower semicontinuous and satisfies the following growth condition:

$$\text{(GC)} \qquad \lim_{t \to +\infty} \inf_x \ell(t, x) = +\infty.$$

As for the multivalued function F, we assume that it takes nonempty compact convex values, has closed graph, and satisfies a linear growth condition: for some positive constants γ and c, and for all $x \in \mathbb{R}^n$,

$$v \in F(x) \Longrightarrow \|v\| \leq \gamma \|x\| + c.$$

Finally, we assume that (P) is nontrivial in the sense that there is at least one admissible trajectory for which the cost is finite.

We associate with F the following function h, the (lower) Hamiltonian:

$$h(x, p) := \min\{\langle p, v\rangle : v \in F(x)\}.$$

†Institut Girard Desargues, Université Lyon I, 21 avenue Claude Bernard, 69622 Villeurbanne Cedex, France (clarke@igd.univ-lyon1.fr, chadi@igd.univ-lyon1.fr). The first author is a member of IUF (Institut Universitaire de France), and the research of the second author was supported by LNCSR (Lebanese National Council of Scientific Research).

There is a well-known relationship between the value of the problem (P) on the one hand and certain solutions of a Hamilton–Jacobi inequality in terms of h on the other; let us recall it now. Let $\psi(t,x)$ be a smooth function satisfying

$$\psi_t(t,x) + h(x,\psi_x(t,x)) \geq 0 \ \ \forall (t,x), \ \ \psi(t,x) \leq \ell(t,x) \text{ if } x \in C.$$

Then it follows from the Hamiltonian inequality that for any trajectory $x(\cdot)$ of the differential inclusion, the function $t \mapsto \psi(t,x(t))$ is nondecreasing. Accordingly, for any $T \geq 0$ we have $\psi(T,x(T)) \geq \psi(0,x(0))$. If we now restrict the trajectories to those that are admissible for (P), we deduce

$$\ell(T,x(T)) \geq \psi(0,x_0).$$

There results a lower bound for the value of (P):

$$\inf(P) \geq \sup \psi(0,x_0),$$

where the supremum is taken over all functions ψ as described above.

The term *nonconvex duality* has been applied in optimal control to situations in which equality holds in this last relation. The basic idea is at the heart of Carathéodory's method in the calculus of variations, which is also known as that of *verification functions*. It is also related to the *generalized flows* of Young, as observed by Vinter [27], and Vinter and Lewis [29], [30], who have extended this duality to the setting of optimal control; see also [10], [12], [16], [21], [25], [26], [33], and [34].

In addition to the above equality, it is natural to ask under what conditions the supremum on the right is attained (see Remark 2.5). Since this fails in general for smooth functions ψ, this question led Clarke and others to introduce a generalized solution concept for nonsmooth solutions of the Hamilton–Jacobi equation [4], [11], [19], [22]; these have turned out to be what is now known as viscosity semisolutions. The method of verification functions extended in this way has been used to solve explicitly a number of problems in optimal control; see Clarke [5] for a thorough discussion of the method and for examples.

The issue of generalized solutions inevitably involves nonsmooth analysis, and here we employ the tools of proximal analysis [8]. Let us recall a basic definition in the subject. Let $f : \mathbb{R}^n \longrightarrow \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function with dom $f := \{x : f(x) < +\infty\} \neq \emptyset$. A vector $\xi \in \mathbb{R}^n$ is a proximal subgradient of f at $x \in \text{dom} f$ if and only if there exist positive numbers σ and ν such that

$$f(y) - f(x) + \sigma \|y - x\|^2 \geq \langle \xi, y - x \rangle \ \ \forall y \in B(x;\nu).^1$$

The set (which could be empty) of all proximal subgradients of $f(\cdot)$ at x is denoted by $\partial_P f(x)$ and is referred to as the proximal subdifferential. The proximal density theorem asserts that $\partial_P f(x) \neq \emptyset$ for all x in a dense subset of dom$f$. The limiting subdifferential of f at $x \in \text{dom} f$ is defined by

$$\partial_L f(x) := \{\lim \xi_i : \xi_i \in \partial_P f(x_i), x_i \longrightarrow x \text{ and } f(x_i) \longrightarrow f(x)\}.$$

We remark that one can use the proximal subdifferential to define generalized solutions of the Hamilton–Jacobi equation, and the resulting solutions coincide (in the

[1] $B(x;\nu) := \{y \in \mathbb{R}^n : \|y - x\| < \nu\}$ and its closure is denoted by $\bar{B}(x;\nu)$. The open unit ball is denoted by B, and its closure by $\bar{B}$.

present context) with the viscosity solutions of Crandall and Lions and the minimax solutions of Subbotin (see, for example, [7], [8], [9], [13], [15], [20], and [31]). Let the extended Hamiltonian $\bar{h}$ be the function given by

$$\bar{h}(x,\theta,\zeta) := \theta + h(x,\zeta).$$

We define Ψ to be the set of all locally Lipschitz functions ψ on $\mathbb{R}\times\mathbb{R}^n$ that satisfy the proximal Hamilton–Jacobi inequality

$$\bar{h}(x,\partial_L\psi(t,x)) \geq 0 \ \ \forall (t,x)\in\mathbb{R}\times A$$

as well as the boundary condition

$$\psi(t,x)\leq \ell(t,x) \ \ \forall (t,x)\in\mathbb{R}\times C.$$

The following is the main result.

THEOREM 1.1.

$$\min(P) = \sup_{\psi\in\Psi}\psi(0,x_0).$$

This result unifies, and extends in a number of ways, the ones in the literature, which treat for the most part the fixed-horizon case (see, for example, [2], [3], [8, Chapter 4], [17], [18], [23], [24], and [32]). We remark that the fixed-horizon case is obtained by taking $\ell(T,x)$ equal to $+\infty$ whenever T differs from the given horizon T_0; see section 3 for a discussion of this and other special cases. Our theorem, whose proof is self-contained modulo some basic facts from proximal analysis, is also new with respect to its very mild regularity hypotheses on F (which need not even be continuous), as well as the presence of a unilateral state constraint. The fact that locally Lipschitz functions figure in our duality also gives easy access to smooth duality of the type found by Vinter [27]. Furthermore, we extend his result by obtaining in the case of the minimal time problem a duality which features only smooth solutions of an *autonomous* Hamilton–Jacobi inequality. Section 3 is devoted to specializations such as these, while the next section gives the proof of the theorem.

2. Proof of Theorem 1.1. First we note that under our hypotheses on F, any trajectory can be extend indefinitely both forward and backward, so all trajectories can be considered as being defined on $]-\infty,+\infty[$. Using (GC) and since C is compact, we have that ℓ is bounded below over $[0,+\infty[\times C$. Then we can assume that ℓ is bounded below over $\mathbb{R}\times\mathbb{R}^n$ by a constant ω. By the compactness property of trajectories and by (GC), it is easy to prove that the problem (P) admits a solution. For all $k\in\mathbb{N}^*$, we consider the function ℓ_k defined by

$$\ell_k(t,x) := \inf_{(\tau,y)\in\mathbb{R}\times\mathbb{R}^n}\{\ell(\tau,y)+k\|(t-\tau,x-y)\|^2\}. \tag{2.1}$$

The sequence $(\ell_k)_k$ is the quadratic inf-convolution sequence of ℓ. The following lemma, whose standard proof we omit (see [8, Theorem 1.5.1]), gives some properties of ℓ_k.

LEMMA 2.1. *For all $k\in\mathbb{N}^*$, we have*

(i) *$\ell_k(\cdot)\leq\ell(\cdot)$ and the set of minimizing points (τ,y) in (2.1) is nonempty;*

(ii) *ℓ_k is locally Lipschitz, bounded below by ω and satisfies (GC);*

(iii) *For all* $(t,x) \in \mathbb{R} \times \mathbb{R}^n$,

$$\lim_{k \longrightarrow +\infty} \ell_k(t,x) = \ell(t,x).$$

We also consider a locally Lipschitz approximation for the multifunction F. By [8, Proposition 4.4.4] there exists a sequence of locally Lipschitz multifunctions $\{F_k\}$ also satisfying the hypotheses of F such that

- for each $k \in \mathbb{N}$, for every $x \in \mathbb{R}^n$,

$$F(x) \subseteq F_{k+1}(x) \subseteq F_k(x) \subseteq \overline{co}\, F(x + 3^{-k+1}B);$$

- $\bigcap_{k \geq 1} F_k(x) = F(x)\ \forall x \in \mathbb{R}^n$.

A well-known method of approximating the terminally constrained problem (P) by a problem free of such constraints involves the imposition of a penalty term. To use this technique, the inf-convolution technique and the preceding approximation we consider for all $k \geq 1$ the following optimal control problem:

(P_k): Minimize $\ell_k(T, x(T)) + k d_C(x(T)) + k \int_0^T d_A(x(t))\, dt$ over points $T \geq 0$ and absolutely continuous functions $x : [0, +\infty[\longrightarrow \mathbb{R}^n$ that satisfy

$$\dot{x}(t) \in F_k(x(t)) \quad \text{a.e. } t \in [0, +\infty[, \quad x(0) = x_0.$$

LEMMA 2.2. *There exists a sequence* λ_n *strictly increasing in* $\mathbb{N}^*$ *such that*

$$\lim_{n \longrightarrow +\infty} \min(P_{\lambda_n}) = \min(P).$$

Proof. We denote by $(\bar{T}, \bar{x}(\cdot))$ a solution of (P) and by $(T_k, \bar{y}_k(\cdot))$ a solution of (P_k), (the existence of the solutions is easy to check). For all $k \in \mathbb{N}^*$ we have

$$\min(P_k) = \ell_k(T_k, \bar{y}_k(T_k)) + k d_C(\bar{y}_k(T_k)) + k \int_0^{T_k} d_A(\bar{y}_k(t))\, dt$$

and

$$\min(P) = \ell(\bar{T}, \bar{x}(\bar{T})).$$

Since $F \subset F_k$, $(\bar{T}, \bar{x}(\cdot))$ is admissible for (P_k) we have

$$\begin{aligned} \min(P_k) &= \ell_k(T_k, \bar{y}_k(T_k)) + k d_C(\bar{y}_k(T_k)) + k \int_0^{T_k} d_A(\bar{y}_k(t))\, dt \\ &\leq \ell_k(\bar{T}, \bar{x}(\bar{T})) \\ &\leq \ell(\bar{T}, \bar{x}(\bar{T})) \\ &= \min(P), \end{aligned}$$

hence

$$\omega \leq \ell_k(T_k, \bar{y}_k(T_k)) \leq \ell(\bar{T}, \bar{x}(\bar{T})) \tag{2.2}$$

and

$$k d_C(\bar{y}_k(T_k)) + k \int_0^{T_k} d_A(\bar{y}_k(t))\, dt \leq \ell(\bar{T}, \bar{x}(\bar{T})) - \omega. \tag{2.3}$$

By Lemma 2.1 there exists $(s_k, z_k) \in \mathbb{R} \times \mathbb{R}^n$ such that

$$\ell_k(T_k, \bar{y}_k(T_k)) = \ell(s_k, z_k) + k\|(s_k - T_k, z_k - \bar{y}_k(T_k))\|^2, \tag{2.4}$$

and hence using (2.2) we get that

$$k\|(s_k - T_k, z_k - \bar{y}_k(T_k))\|^2 \leq \ell_k(T_k, \bar{y}_k(T_k)) - \omega \leq \ell(\bar{T}, \bar{x}(\bar{T})) - \omega. \tag{2.5}$$

We claim that $\lim_{k \longrightarrow +\infty} T_k \neq +\infty$. Indeed, by (2.5) we have that there exists a sequence a_n strictly increasing in $\mathbb{N}^*$ such that $\lim_{n \longrightarrow +\infty}(s_{a_n} - T_{a_n}) = 0$. Then if $\lim_{n \longrightarrow +\infty} T_{a_n} = +\infty$, we get that $\lim_{n \longrightarrow +\infty} s_{a_n} = +\infty$. Since ℓ satisfies (GC) we have

$$\lim_{n \longrightarrow +\infty} \ell(s_{a_n}, z_{a_n}) = +\infty,$$

and hence by (2.4)

$$\lim_{n \longrightarrow +\infty} \ell_{a_n}(T_{a_n}, \bar{y}_{a_n}(T_{a_n})) = +\infty,$$

but this contradicts (2.2). Then we can assume that there exists $b \geq 0$ such that $T_k \in [0, b]$.

Since $F_k(\cdot) \subseteq \overline{co}\, F(\cdot + 3^{-k+1}B)$ and using the compactness of trajectories (see [1] and [14]), there exists a trajectory $\bar{y}(\cdot)$ of F on $[0, +\infty[$ which satisfies $\bar{y}(0) = x_0$, and there is a subsequence $\bar{y}_{k_i}$ of $\bar{y}_k$ such that $\bar{y}_{k_i}$ converges uniformly to $\bar{y}(\cdot)$ on $[0, b]$. Moreover, since $T_k \in [0, b]$, there exists a subsequence of T_k, which converges to a point in $[0, b]$. These considerations with (2.2), (2.3), and (2.5) give that there exists a sequence λ_n strictly increasing in $\mathbb{N}^*$ such that

- the sequence T_{λ_n} converges to a $\bar{T}_0 \in [0, b]$,
- the sequence $\bar{y}_{\lambda_n}$ converges uniformly on $[0, b]$ to the trajectory $\bar{y}(\cdot)$,
- the sequence $\lambda_n\|(s_{\lambda_n} - T_{\lambda_n}, z_{\lambda_n} - \bar{y}_{\lambda_n}(T_{\lambda_n}))\|^2$ is convergent,
- the sequence $\lambda_n d_C(\bar{y}_{\lambda_n}(T_{\lambda_n})) + \lambda_n \int_0^{T_{\lambda_n}} d_A(y_{\lambda_n}(t))\, dt$ is convergent, and
- the sequence $\ell_{\lambda_n}(T_{\lambda_n}, \bar{y}_{\lambda_n}(T_{\lambda_n}))$ is convergent.

Since the sequence λ_n is strictly increasing in $\mathbb{N}^*$ we get

$$\lim_{n \longrightarrow +\infty} z_{\lambda_n} = \bar{y}(\bar{T}_0) \quad \text{and} \quad \lim_{n \longrightarrow +\infty} s_{\lambda_n} = \bar{T}_0.$$

Hence by the convergence of the sequence $\lambda_n d_C(\bar{y}_{\lambda_n}(T_{\lambda_n})) + \lambda_n \int_0^{T_{\lambda_n}} d_A(y_{\lambda_n}(t))\, dt$ and using Lebesgue's theorem we have

$$\bar{y}(\bar{T}_0) \in C \ \text{ and } \ \bar{y}(t) \in A \ \ \forall\, t \in [0, \bar{T}_0].$$

Then $(\bar{T}_0, \bar{y}(\cdot))$ is admissible for the problem (P). Hence

$$\begin{aligned}
\min(P) &= \ell(\bar{T}, \bar{x}(\bar{T})) \\
&\geq \lim_{n \longrightarrow +\infty} \min(P_{\lambda_n}) \\
&= \lim_{n \longrightarrow +\infty} [\ell_{\lambda_n}(T_{\lambda_n}, \bar{y}_{\lambda_n}(T_{\lambda_n})) + \lambda_n d_C(\bar{y}_{\lambda_n}(T_{\lambda_n})) + \lambda_n \int_0^{T_{\lambda_n}} d_A(\bar{y}_{\lambda_n}(t))\, dt] \\
&\geq \lim_{n \longrightarrow +\infty} \ell_{\lambda_n}(T_{\lambda_n}, \bar{y}_{\lambda_n}(T_{\lambda_n})) \\
&= \lim_{n \longrightarrow +\infty} [\ell(s_{\lambda_n}, z_{\lambda_n}) + \lambda_n\|(s_{\lambda_n} - T_{\lambda_n}, z_{\lambda_n} - \bar{y}_{\lambda_n}(T_{\lambda_n}))\|^2] \\
&\geq \liminf_{(s', z') \longrightarrow (\bar{T}_0, \bar{y}(\bar{T}_0))} \ell(s', z') \\
&\geq \ell(\bar{T}_0, \bar{y}(\bar{T}_0)) \\
&\geq \min(P).
\end{aligned}$$

Then

$$\min(P) = \lim_{n \longrightarrow +\infty} \min(P_{\lambda_n}) = \ell(\bar{T}_0, \bar{y}(\bar{T}_0)),$$

which completes the proof of the lemma. □

We continue the proof of Theorem 1.1 and we remark that problem (P_{λ_n}) is exactly the following problem:

Minimize $\hat{\ell}_{\lambda_n}(T, z(T))$ over points $T \geq 0$ and absolutely continuous functions $z : [0, +\infty[\longrightarrow \mathbb{R}^{n+1}$ that satisfy

$$\dot{z}(t) \in \hat{F}_{\lambda_n}(z(t)) \quad \text{a.e. } t \in [0, +\infty[, \quad z(0) = (0, x_0), \tag{2.6}$$

where $\hat{F}_{\lambda_n}$ is the augmented locally Lipschitz multifunction defined by $\hat{F}_{\lambda_n}(y, x) := \{\lambda_n d_A(x)\} \times F_{\lambda_n}(x)\ \forall (y, x) \in \mathbb{R} \times \mathbb{R}^n$ and $\hat{\ell}_{\lambda_n}$ is the locally Lipschitz and bounded below function defined by $\hat{\ell}_{\lambda_n}(t, y, x) = \ell_{\lambda_n}(t, x) + \lambda_n d_C(x) + |y|\ \forall (t, y, x) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$. Let $\hat{V}_{\lambda_n} : \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n \longrightarrow \mathbb{R}$ be the value function of the problem (P_{λ_n}); that is, for every $(\tau, \beta, \alpha) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$, $\hat{V}_{\lambda_n}(\tau, \beta, \alpha)$ is the minimum of the following problem:

Minimize $\hat{\ell}_{\lambda_n}(T, z(T))$ over points $T \geq \tau$ and absolutely continuous functions $z : [\tau, +\infty[\longrightarrow \mathbb{R}^{n+1}$ that satisfy

$$\dot{z}(t) \in \hat{F}_{\lambda_n}(z(t)) \quad \text{a.e. } t \in [\tau, +\infty[, \quad z(\tau) = (\beta, \alpha). \tag{2.7}$$

It is easy to verify that $\hat{V}_{\lambda_n}$ is locally Lipschitz and satisfies

$$\hat{V}_{\lambda_n}(\cdot) \leq \hat{\ell}_{\lambda_n}(\cdot) \tag{2.8}$$

and

$$\hat{V}_{\lambda_n}(\tau, \beta, \alpha) = \hat{V}_{\lambda_n}(\tau, 0, \alpha) + \beta \quad \forall (\tau, \beta, \alpha) \in \mathbb{R} \times [0, +\infty[\times \mathbb{R}^n. \tag{2.9}$$

Using the logic known as the *principle of optimality* and since the minimum which defines $\hat{V}_{\lambda_n}(\tau, \beta, \alpha)$ is attained for all $(\tau, \beta, \alpha) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$, we can easily prove that the system $(\hat{V}_{\lambda_n}, \hat{F}_{\lambda_n})$ is *strongly increasing* on $\mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$ (that is, the function $\hat{V}_{\lambda_n}(\cdot, z(\cdot))$ is increasing on $[a, b]$ whenever z is a trajectory of $\hat{F}_{\lambda_n}$ on some interval $[a, b]$). Then by [8, Proposition 4.6.5][2] we have

$$\theta + \lambda_n d_A(x)\xi + h_{\lambda_n}(x, \zeta) \geq 0^3 \tag{2.10}$$

$\forall (\theta, \xi, \zeta) \in \partial_P \hat{V}_{\lambda_n}(t, y, x)$, $\forall (t, y, x) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^n$.

If we consider $\psi_{\lambda_n} : \mathbb{R} \times \mathbb{R}^n \longrightarrow \mathbb{R}$ defined by $\psi_{\lambda_n}(t, x) = \hat{V}_{\lambda_n}(t, 0, x)\ \forall (t, x) \in \mathbb{R} \times \mathbb{R}^n$, then since $\hat{V}_{\lambda_n}$ is locally Lipschitz and by (2.8), (2.9), and (2.10) we have

1. ψ_{λ_n} is locally Lipschitz on $\mathbb{R} \times \mathbb{R}^n$,
2. $\psi_{\lambda_n}(0, x_0) = \hat{V}_{\lambda_n}(0, 0, x_0) = \min(P_{\lambda_n})$,
3. $\lambda_n d_A(x) + \bar{h}_{\lambda_n}(x, \partial_P \psi(t, x)) \geq 0\ \forall (t, x) \in \mathbb{R} \times \mathbb{R}^n$, and
4. $\psi_{\lambda_n}(t, x) \leq \ell_{\lambda_n}(t, x) \leq \ell(t, x)\ \forall (t, x) \in \mathbb{R} \times C$.

By point 3 and by a simple argument we have that ψ_{λ_n} satisfies the following limiting proximal Hamilton–Jacobi equation: $\bar{h}_{\lambda_n}(x, \partial_L \psi_{\lambda_n}(t, x)) \geq 0\ \forall (t, x) \in \mathbb{R} \times A$. Then since $\bar{h}_{\lambda_n}(\cdot) \leq \bar{h}(\cdot)$ we get $\psi_{\lambda_n} \in \Psi$. Therefore

$$\sup_{\psi \in \Psi} \psi(0, x_0) \geq \psi_{\lambda_n}(0, x_0) = \min(P_{\lambda_n});$$

[2] This proposition gives a proximal characterization for the strong increase property.

[3] h_{λ_n} is the lower Hamiltonian corresponding to F_{λ_n}.

then

$$\min(P) = \lim_{n \longrightarrow +\infty} \min(P_{\lambda_n}) \leq \sup_{\psi \in \Psi} \psi(0, x_0).$$

Now we show the reverse inequality.[4] Let $\psi \in \Psi$. We make the *temporary hypothesis* that F is locally Lipschitz. Then we have the following lemma.

LEMMA 2.3. *For all open and bounded subset $S \subset \mathbb{R}^{n+1}$, for all $\varepsilon > 0$, there exists a neighborhood U of A such that*

$$\bar{h}(x, \partial_P \psi(t, x)) \geq -\varepsilon \quad \forall (t, x) \in S \cap \{\mathbb{R} \times U\}.$$

Proof. We reason by the absurd. We assume that there exist an open and bounded subset $S \subset \mathbb{R}^{n+1}$ and a $\varepsilon > 0$ such that for all neighborhood U of A, there exist $(t, x) \in S \cap \{\mathbb{R} \times U\}$ and $(\theta, \zeta) \in \partial_P \psi(t, x)$ such that

$$\theta + h(x, \zeta) < -\varepsilon.$$

Then there exist two sequences $(t_n, x_n) \in S$ and (θ_n, ζ_n) such that

$$(t_n, x_n) \longrightarrow (t_0, x_0) \in \mathbb{R} \times A,$$

$$(\theta_n, \zeta_n) \in \partial_P \psi(t_n, x_n),$$

and

$$\theta_n + h(x_n, \zeta_n) < -\varepsilon. \tag{2.11}$$

Since ψ is locally Lipschitz and S is bounded, the sequence (θ_n, ζ_n) is bounded and then we can assume that it converges to a point (θ_0, ζ_0). By the definition of ∂_L we get that $(\theta_0, \zeta_0) \in \partial_L \psi(t_0, x_0)$. By (2.11) and since F is locally Lipschitz we find that

$$\theta_0 + h(x_0, \zeta_0) \leq -\varepsilon$$

and this gives a contradiction since $\psi \in \Psi$. □

Now let $(\bar{T}, \bar{x}(\cdot))$ be a solution of the problem (P); then by [8, Proposition 4.1.4] there exists $\rho > 0$ such that $\bar{x}(t) \in B(0; \rho)\ \forall\, t \in [0, \bar{T}]$. We apply the preceding lemma for $S =]-1, \bar{T}+1[\times B(0; \rho)$, and for $\varepsilon > 0$, we get that there exists a neighborhood U_ε of A such that

$$\bar{h}(x, \partial_P \psi(t, x)) \geq -\varepsilon \quad \forall (t, x) \in S \cap \{\mathbb{R} \times U_\varepsilon\}.$$

But $S \cap \{\mathbb{R} \times U_\varepsilon\} =]-1, \bar{T}+1[\times \{B(0; \rho) \cap U_\varepsilon\}$; then since $[0, \bar{T}] \subset]-1, \bar{T}+1[$, $\bar{x}(t) \in B(0; \rho) \cap U_\varepsilon\ \forall\, t \in [0, \bar{T}]$ and by [8, Proposition 4.6.5] we get that

$$\psi(0, x_0) \leq \varepsilon \bar{T} + \psi(\bar{T}, \bar{x}(\bar{T}))$$

but $\psi(\bar{T}, \bar{x}(\bar{T})) \leq \ell(\bar{T}, \bar{x}(\bar{T})) = \min(P)$; then

$$\psi(0, x_0) \leq \min(P) + \varepsilon \bar{T},$$

[4] We cannot directly deduce this inequality like in the smooth case since the multifunction F is not locally Lipschitz and the Hamilton–Jacobi inequality is satisfied only on a closed subset and then we cannot apply the monotonicity of trajectories [8, Proposition 4.6.5].

and hence by taking $\varepsilon \longrightarrow 0$ we get

$$\psi(0, x_0) \leq \min(P),$$

and therefore

$$\min(P) \geq \sup_{\psi \in \Psi} \psi(0, x_0).$$

To remove the need for the locally Lipschitz hypothesis on F we use the sequence F_k. First we have the following lemma.

LEMMA 2.4. *For all $n \in \mathbb{N}$ there exists $k_n \geq n$ such that*

$$\bar{h}_{k_n}(x, \partial_L \psi(t, x)) \geq \frac{-1}{n} \quad \forall (t, x) \in]-1, \bar{T}+1[\times\{A \cap \bar{B}(0; \rho)\}.$$

Proof. We reason again by the absurd. Assume that there exists $n_0 \in \mathbb{N}$ such that for all $k > n_0$ there exists $(t_k, x_k) \in]-1, \bar{T}+1[\times\{A \cap \bar{B}(0; \rho)\}$ and $(\theta_k, \zeta_k) \in \partial_L \psi(t_k, x_k)$ such that

$$\theta_k + h_k(x_k, \zeta_k) < -\frac{1}{n_0}. \tag{2.12}$$

Since the sequence (t_k, x_k) is bounded, we assume that it converges to a point $(t_0, x_0) \in \mathbb{R} \times A$. On the other hand, the sequence (θ_k, ζ_k) is also bounded since ψ is locally Lipschitz, and then we can assume that it converges to a point (θ_0, ζ_0). Using [8, Exercise 1.11.21] we have $(\theta_0, \zeta_0) \in \partial_L \psi(t_0, x_0)$. Now let $\varepsilon > 0$; then since F is upper semicontinuous we have that for k sufficiently large $F(x_k + 3^{-k+1}B) \subset F(x_0) + \varepsilon \bar{B}$. Hence $F_k(x_k) \subset F(x_0) + \varepsilon \bar{B}$. Using the definition of the lower Hamiltonian, we get that $h_k(x_k, \zeta_k) \geq h(x_0, \zeta_k) - \varepsilon \|\zeta_k\|$. Then by (2.12), we have

$$\theta_k + h(x_0, \zeta_k) - \varepsilon \|\zeta_k\| < -\frac{1}{n_0}.$$

But h is continuous in the second variable. Then if we take $k \longrightarrow +\infty$ in the preceding inequality we get

$$\theta_0 + h(x, \zeta_0) - \varepsilon \|\zeta_0\| \leq -\frac{1}{n_0}.$$

Since ε is arbitrary we find that

$$\theta_0 + h(x, \zeta_0) \leq -\frac{1}{n_0},$$

and this gives a contradiction with $\psi \in \Psi$. □

By the preceding lemma, there exists a subsequence F_{k_i} of F_k and a sequence $\varepsilon_i > 0$ such that $\varepsilon_i \longrightarrow 0$ and

$$\bar{h}_{k_i}(x, \partial_L \psi(t, x)) \geq -\varepsilon_i \quad \forall (t, x) \in]-1, \bar{T}+1[\times\{A \cap \bar{B}(0; \rho)\}.$$

We continue as in the Lipschitz case and we find the result. □

Remark 2.5. If we suppose in the definition of Ψ that the functions ψ are continuous and satisfy the proximal Hamilton–Jacobi equation (∂_P instead of ∂_L), then the first inequality

$$\min(P) \leq \sup_{\psi \in \Psi} \psi(0, x_0)$$

remains true, and the equality holds if we assume in addition that $A = \mathbb{R}^n$ and F is locally Lipschitz. Moreover, in this case if we eliminate the terminal constraint $x(T) \in C$, then the supremum in $\sup \psi(0, x_0)$ is attained since the value function of (P) becomes an element of Ψ. Finally, an earlier result of Clarke [6, Theorem 3.7.6] shows that even in the presence of terminal constraints, but still under the extra hypotheses, the supremum is attained if solutions are *normal*. It is an open question whether the attainment of the supremum can be asserted in the fully general context.

3. Consequences and extensions. In this section we give some applications of our main result. In the next subsection we give necessary and sufficient optimality conditions. In subsection 3.2, we treat several types of optimal control problems (fixed time problem and free time problem with finite and infinite horizon). Vinter's smooth duality is studied in subsection 3.3.

3.1. Characterization of optimality. Theorem 1.1 leads directly to the following optimality conditions.

COROLLARY 3.1. *Let $(\bar{T}, \bar{x}(\cdot))$ be an admissible trajectory for (P). Then $(\bar{T}, \bar{x}(\cdot))$ is a minimizer for (P) iff there exists a sequence of functions $\{\psi_i\}$ in Ψ such that*

$$\lim_{i \longrightarrow +\infty} \psi_i(0, x_0) = \ell(\bar{T}, \bar{x}(\bar{T})).$$

Proof. Let $(\bar{T}, \bar{x}(\cdot))$ be an admissible trajectory for (P) and assume that $(\bar{T}, \bar{x}(\cdot))$ is a minimizer for (P). Then by Theorem 1.1 we have

$$\ell(\bar{T}, \bar{x}(\bar{T})) = \sup_{\psi \in \Psi} \psi(0, x_0).$$

Hence the necessary condition follows by taking a maximizing sequence $\{\psi_i\}$ for the supremum $\sup_{\psi \in \Psi} \psi(0, x_0)$.

For the sufficient condition, let $(\bar{T}, \bar{x}(\cdot))$ be an admissible trajectory for (P) and suppose that there exists a sequence of functions $\{\psi_i\}$ in Ψ such that

$$\lim_{i \longrightarrow +\infty} \psi_i(0, x_0) = \ell(\bar{T}, \bar{x}(\bar{T})).$$

Since $\psi_i \in \Psi$ and by Theorem 1.1 we have

$$\lim_{i \longrightarrow +\infty} \psi_i(0, x_0) \leq \min(P).$$

But $(\bar{T}, \bar{x}(\cdot))$ is an admissible trajectory for (P); then

$$\min(P) \geq \lim_{i \longrightarrow +\infty} \psi_i(0, x_0) = \ell(\bar{T}, \bar{x}(\bar{T})) \geq \min(P),$$

and then

$$\ell(\bar{T}, \bar{x}(\bar{T})) = \min(P),$$

which completes the proof. □

3.2. Special cases.

1. *Fixed time problem.* If we take $\ell(t,x) = I_{\{T_0\}\times C}(t,x) + \ell_0(x)$, where $T_0 \geq 0$ is fixed, $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a lower semicontinuous function, and $I_{\{T_0\}\times C}$ denotes the indicator function of $\{T_0\} \times C$, then we can treat the fixed time case. In this case we obtain the same duality as in Theorem 1.1 but the boundary condition becomes

$$\psi(T_0, x) \leq \ell_0(x) \ \ \forall x \in C.$$

   If we assume that $A = \mathbb{R}^n$ and F is locally Lipschitz, then we can consider in the preceding duality continuous functions ψ and we can replace ∂_L by ∂_P, and this gives a slightly strengthened version of [8, Corollary 4.7.7].[5]
2. *Free time problem with finite horizon.* Problems in which T varies in a compact interval (as is the case in Vinter's work) can be treated by taking (for example) $\ell(t,x) = I_{[0,1]\times C}(t,x) + \ell_0(x)$, where $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a lower semicontinuous function. In this case the boundary condition is

$$\psi(t,x) \leq \ell_0(x) \ \ \forall (t,x) \in [0,1] \times C.$$

3. *Free time problem with infinite horizon.* We now consider the free time problem in its most familiar form, where T is completely unrestricted. We suppose that in (P) we have $\ell(t,x) = t + \ell_0(x)$ $\forall (t,x) \in \mathbb{R} \times \mathbb{R}^n$, where $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a lower semicontinuous function bounded below. In this case and by Theorem 1.1 we have that

$$\min(P) = \sup_{\psi \in \Psi} \psi(x_0),$$

   where Ψ is the set of all functions $\psi : \mathbb{R}^n \longrightarrow \mathbb{R}$ which satisfy
   - ψ is locally Lipschitz on $\mathbb{R}^n$,
   - $1 + h(x, \partial_L \psi(x)) \geq 0$ $\forall x \in A$, and
   - $\psi(x) \leq \ell_0(x)$ $\forall x \in C$.

   We remark that in this result, only autonomous functions ψ contribute to the upper envelope. This follows since in this case we can take in the proof of Theorem 1.1, $\ell_k := t + \ell_0^k$, where ℓ_0^k is the quadratic inf-convolution of ℓ_0, and then we get that the function $\hat{V}_{\lambda_n}(\cdot,\cdot,\cdot)$ satisfies

$$\hat{V}_{\lambda_n}(\tau,\beta,\alpha) = \tau + \hat{V}_{\lambda_n}(0,0,\alpha) + \beta \quad \forall (\tau,\beta,\alpha) \in \mathbb{R} \times [0,+\infty[\times\mathbb{R}^n.$$

3.3. Smooth duality. Another important application of our main result extends the smooth duality theory of Vinter [27], whose methods do not apply to the cases in which T is either fixed or totally unrestricted. For this, we need the following technical extension of Theorem 1.1.

COROLLARY 3.2. *There exists $\delta_{x_0} > 0$ such that*

$$\min(P) = \sup_{\varphi \in \Phi} \varphi(0, x_0),$$

where Φ is the set of all functions $\varphi : \mathbb{R} \times \mathbb{R}^n \longrightarrow \mathbb{R}$ which satisfy
- $\varphi \in C^1(\mathbb{R}^{n+1}, \mathbb{R})$,
- $\varphi_t(t,x) + \langle \varphi_x(t,x), v \rangle \geq 0$ $\forall (t,x) \in \mathbb{R} \times A$ $\forall v \in F(x)$, *and*

[5] In [8, Corollary 4.7.7] ℓ is continuous and the functions ψ are defined on $]-\infty, T_0] \times \mathbb{R}^n$.

• $\varphi(t,x) \le \ell(t,x)\ \forall (t,x) \in [0,\delta_{x_0}]\times C$.

Proof. We fix a constant δ_{x_0} such that for any trajectory $(\bar{T}, \bar{x}(\cdot))$ solving the problem (P) we have $\bar{T} \le \delta_{x_0}$ (the existence of δ_{x_0} follows from (GC)). Now let $\varphi \in \Phi$. Since φ is a C^1 function on $\mathbb{R}^{n+1}$, we have

$$\partial_L \varphi(t,x) = \{\varphi'(t,x)\}$$

for all $(t,x) \in \mathbb{R}\times\mathbb{R}^n$. Then we have $\varphi \in \Psi$.[6] By Theorem 1.1 we get

$$\min(P) = \sup_{\psi\in\Psi} \psi(0,x_0) \ge \sup_{\varphi\in\Phi} \varphi(0,x_0).$$

For the reverse inequality, let $\psi \in \Psi$. Using the fact that if ψ is differentiable at $(\tau,\alpha) \in \mathbb{R}\times\mathbb{R}^n$, then $\psi'(\tau,\alpha) \in \partial_L\psi(\tau,\alpha)$, we have that for all $(\tau,\alpha) \in \mathbb{R}\times A$ such that ψ is differentiable at (τ,α),

$$\psi_t(\tau,\alpha) + \langle \psi_x(\tau,\alpha), v\rangle \ge 0\ \forall v \in F(\alpha).$$

Since ψ is locally Lipschitz and by Rademacher's theorem, we have that ψ is differentiable a.e. $(\tau,\alpha) \in \mathbb{R}\times\mathbb{R}^n$. Now we make the *temporary hypothesis* that F is Lipschitz and $A = \mathbb{R}^n$. Then using a standard mollification technique (convolution with mollifier sequence) we have the following lemma.

LEMMA 3.3. *For all $\varepsilon > 0$ there exists $\varphi_\varepsilon \in \Phi$ such that*

$$\varphi_\varepsilon(0,x_0) \ge \psi(0,x_0) - \varepsilon.$$[7]

Clearly this lemma gives the desired inequality. To remove the need for the Lipschitz hypothesis on F and the assumption $A = \mathbb{R}^n$, it is sufficient to use the sequence F_k and the penalization term $k\int_0^T d_A(x(t))\,dt$ as in the proof of Theorem 1.1. □

It is clear that Corollary 3.2 leads to a version of the necessary and sufficient conditions of Corollary 3.1 in which only smooth semisolutions are used. Let us now examine more closely this type of smooth duality in the three special cases of subsection 3.2.

1. *Fixed time problem.* We take $\ell(t,x) = I_{\{T_0\}\times C}(t,x) + \ell_0(x)$, where $T_0 \ge 0$ is fixed and $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R}\cup\{+\infty\}$ is a lower semicontinuous function, then by Corollary 3.2 (we take $\delta_{x_0} = T_0$) we obtain a similar duality but as in the nonsmooth case the boundary condition becomes

$$\varphi(T_0,x) \le \ell_0(x)\ \ \forall x \in C.$$

2. *Free time problem with finite horizon.* We take $\ell(t,x) = I_{[0,1]\times C}(t,x) + \ell_0(x)$, where $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R}\cup\{+\infty\}$ is a lower semicontinuous function. By Corollary 3.2 (we take $\delta_{x_0} = 1$) we obtain

$$\min(P) = \sup_{\varphi\in\Phi} \varphi(0,x_0),$$

where Φ is the set of all functions $\varphi : \mathbb{R}\times\mathbb{R}^n \longrightarrow \mathbb{R}$ which satisfy

[6] We can replace in Theorem 1.1 the condition $\psi(t,x) \le \ell(t,x)\ \forall (t,x) \in \mathbb{R}\times C$ by $\psi(t,x) \le \ell(t,x)$ $\forall (t,x) \in [0,\delta_{x_0}]\times C$.

[7] As mentioned above, this lemma follows using a standard mollification technique. We also use the following remark: if $\varphi(t,x)$ is a smooth function which satisfies $\varphi_t(t,x) + \langle \varphi_x(t,x), v\rangle \ge \varepsilon$ $\forall (t,x) \in \mathbb{R}\times A$, $\forall v \in F(x)$, then the function $\varphi^\varepsilon(t,x) := \varphi(t,x) - t\varepsilon$ satisfies $\varphi^\varepsilon_t(t,x) + \langle \varphi^\varepsilon_x(t,x), v\rangle \ge 0$ $\forall (t,x) \in \mathbb{R}\times A$, $\forall v \in F(x)$.

- $\varphi \in C^1(\mathbb{R}^{n+1}, \mathbb{R})$,
- $\varphi_t(t,x) + \langle \varphi_x(t,x), v\rangle \geq 0 \ \forall (t,x) \in \mathbb{R}\times A$, $\forall v \in F(x)$, and
- $\varphi(t,x) \leq \ell_0(x) \ \forall (t,x) \in [0,1]\times C$.

This is essentially the case treated by Vinter in [27]. We remark that the nonautomous case (when F and ℓ_0 depend on t) can be obtained by the well-known device of state augmentation (see [8, Chapter 4]).

3. *Free time problem with infinite horizon.* We take $\ell(t,x) = t + \ell_0(x)\ \forall (t,x) \in \mathbb{R}\times\mathbb{R}^n$, where $\ell_0 : \mathbb{R}^n \longrightarrow \mathbb{R}\cup\{+\infty\}$ is a lower semicontinuous function bounded below. This is the most familiar case of the minimal time problem, and Vinter has remarked [28] that his generalized flows approach does not appear to yield a duality involving solutions of the autonomous Hamilton–Jacobi inequality (as one would hope). However, we obtain the following:[8]

$$\min(P) = \sup_{\varphi\in\Phi} \varphi(x_0),$$

where Φ is the set of all functions $\varphi : \mathbb{R}^n \longrightarrow \mathbb{R}$ which satisfy

- $\varphi \in C^1(\mathbb{R}^n, \mathbb{R})$,
- $1 + \langle \varphi'(x), v\rangle \geq 0 \ \forall x \in A$, $\forall v \in F(x)$, and
- $\varphi(x) \leq \ell_0(x) \ \forall x \in C$.

A well-known and more special case of the present framework involves the minimal time function associated to the target C and under the state constraint A:

$T_C^A(\alpha) := \inf T \geq 0$ over trajectories of $\dot{x}(t) \in F(x(t))$ which satisfy

$$x(0) = \alpha, \quad x(T) \in .C, \quad x(t) \in A \ \ \forall\, t \in [0,T].$$

We then obtain the following new characterization of T_C^A:

$$T_C^A(\alpha) = \sup_{\varphi\in\Phi} \varphi(\alpha),$$

where Φ is the set of all functions $\varphi : \mathbb{R}^n \longrightarrow \mathbb{R}$ which satisfy

- $\varphi \in C^1(\mathbb{R}^n, \mathbb{R})$,
- $1 + \langle \varphi'(x), v\rangle \geq 0 \ \forall x \in A$, $\forall v \in F(x)$, and
- $\varphi(x) \leq 0 \ \forall x \in C$.

FEEDBACK CLASSIFICATION OF MULTI-INPUT NONLINEAR CONTROL SYSTEMS*

ISSA AMADOU TALL†

Abstract. We study the feedback group action on multi-input nonlinear control systems with uncontrollable mode. We follow slightly an approach proposed in Kang and Krener [W. Kang and A. J. Krener, *SIAM J. Control. Optim.,* 30 (1992), pp. 1319–1337] which consists of analyzing the system and the feedback group step by step. We construct a normal form which generalizes, on one hand, the results obtained in the single-input case and, on the other hand, those recently obtained by the same author in the controllable case. We illustrate our results by studying the Caltech Multi-Vehicle Wireless Testbed (MVWT) and the prototype of Planar Vertical TakeOff and Landing aircraft (PVTOL). We also study the notion of *bifurcation of controllability* for systems with one nonzero uncontrollable mode. We first show that the equilibria for those systems is a p-dimensional submanifold (p equals number of inputs). Provided that one term in their normal form is nonzero, we show that these systems are linearly controllable, hence stabilizable, at any nearby equilibrium point of the origin.

Key words. feedback, multi-input, homogeneous, normal form, uncontrollable, control system

1. Introduction.

During the last twenty years the problem of transforming a nonlinear control system

$$\Pi \ : \ \dot{\zeta} = f(\zeta, u), \quad \zeta(\cdot) \in \mathbb{R}^n \quad u(\cdot) = (u_1(\cdot), \ldots, u_p(\cdot))^T \in \mathbb{R}^p$$

by a feedback transformation of the form

$$\Upsilon \ : \ \begin{array}{rcl} \bar{\zeta} & = & \varphi(\zeta), \\ u & = & \gamma(\zeta, \bar{u}) \end{array}$$

to a simpler form has been extensively studied by several authors. Necessary and sufficient geometric conditions for smooth linearizability, that is, smooth feedback equivalence to a linear system, have been obtained independently by Hunt and Su [16], Hunt, Su, and Meyer [17], and Jakubczyk and Respondek [21] among others. Those conditions turn out to be restrictive, except for the planar case, and a natural problem that arises is to find normal forms for nonlinearizable systems. Four basic methods have been proposed to study feedback equivalence problems. The first method is based on the theory of singularities of vector fields and distributions and their invariants, and using that method on a large variety of feedback classification problems have been solved; see, e.g., [4, 6, 10, 17, 18, 21, 22, 23, 31, 36, 39, 51]. The second approach, proposed by Gardner [10], uses Cartan's method of equivalence [5] and describes the geometry of feedback equivalence, [11, 12, 13, 35]. The third method, inspired by the Hamiltonian formalism for optimal control problems, has been developed by Bonnard [3, 4] and Jakubczyk [19, 20] and has led to a very nice

description of feedback invariants in terms of singular extremals. Most recently, Kang and Krener [29] adapted Poincaré's technique for linearization of dynamical systems (see, e.g., [1]) to control systems. Their idea consists of analyzing the system Π and the feedback transformation Υ step by step in order to produce a simpler equivalent system, also step by step. They first obtained quadratic normal forms under quadratic changes of coordinates and feedback for single-input control systems with controllable linearization. Later, Kang [24] generalizes this result to all degrees for the same class of control systems. He also obtained [25] quadratic normal forms for systems with uncontrollable linearization. The method introduced by Kang and Krener finds its importance in replacing the solving of partial differential equations by that of algebraic equations.

Since then many results have followed. Tall [41, 43] and Tall and Respondek [49] obtained canonical forms and dual canonical forms for single-input nonlinear control systems with controllable linearization, then normal forms for single-input nonlinear control systems with uncontrollable linearization [44] (see also Krener, Kang, and [32]), as well as the corresponding homogeneous invariants. Hence, the feedback classification of single-input nonlinear control systems is almost complete, and the aim of this paper is to deal with the multi-input nonlinear control systems. Preliminary results for two-input control systems, with controllable mode, have been recently obtained by Tall and Respondek [47] and completed by Tall [42] for multi-input systems with controllable mode. This paper gives a generalization of those results to multi-input systems with uncontrollable mode.

Motivations for studying normal forms for multi-input systems are underlined by the huge varieties of applications derived for single-input systems. Indeed, in the single-input case, the theory of normal forms has proved to be very useful in analyzing structural properties of nonlinear control systems. It has been used to study bifurcations and stabilizations of nonlinear systems [7, 14, 26, 27, 28], has led to a complete description of symmetries around equilibrium [37, 38, 48], and allowed the characterization of systems equivalent to feedforward forms [45, 46, 50]. The same approach has been introduced to study observability of control systems [33, 34, 2], the problem of output regulation, and the model matching problem.

The study of linearly uncontrollable systems is also motivated by the numerous engineering applications and the fact that the qualitative properties like controllability and stabilizability are generic, that is, invariant under a small variation of parameters at a point where the system is linearly controllable. Furthermore, it is known that local bifurcations at a point where the system is linearly controllable can be removed or delayed by pole placement. For those systems that are not linearly controllable, nonlinear phenoma like bifurcations are expected around the critical points.

In this paper we construct a normal form for multi-input nonlinear control systems with uncontrollable linearization which generalizes the results obtained in the single-input case [24, 41, 43, 44, 49] and the two-input case [47].

The organization of the paper is as follows. Section 2 deals with basic notations. In section 3, we construct a normal form for multi-input nonlinear control systems with uncontrollable linearization. We illustrate our results by two physical examples. We also discuss the notion of *bifurcation of controllability* for systems with one nonzero uncontrollable mode. We first show that the set of equilibria of these systems is a p-dimensional surface, and at any nearby equilibrium point of the origin, these systems became linearly controllable. Section 4 deals with the proofs of our results.

2. Notations and preliminaries. All objects, that is, functions, maps, vector fields, control systems, etc., are considered in a neighborhood of $0 \in \mathbb{R}^n$ and assumed to be C^∞-smooth. Consider the system

$$\Pi \ : \ \dot{\zeta} = f(\zeta, u), \quad \zeta(\cdot) \in \mathbb{R}^n, \ u(\cdot) = (u_1(\cdot), \dots, u_p(\cdot))^T \in \mathbb{R}^p.$$

We will assume throughout the paper that the point $(0,0) \in \mathbb{R}^n \times \mathbb{R}^p$ is an equilibrium point, that is, $f(0,0) = 0$, and let

$$\Pi^{[1]} \ : \ \dot{\zeta} = F\zeta + Gu = F\zeta + G_1 u_1 + \dots + G_p u_p$$

be its linear approximation around the equilibrium point $(0,0) \in \mathbb{R}^n \times \mathbb{R}^p$, where

$$F = \frac{\partial f}{\partial \zeta}(0,0), \qquad G_1 = \frac{\partial f}{\partial u_1}(0,0), \dots, G_p = \frac{\partial f}{\partial u_p}(0,0).$$

We assume that the linear approximation is uncontrollable which means that there exists a nonnegative integer $q \in \mathbb{N}^*$ such that

$$\operatorname{span}\left\{ F^i G_s : \ 0 \le i \le n-1, \ 1 \le s \le p \right\} = \mathbb{R}^{n-q}.$$

We will also assume that $G_1 \wedge \dots \wedge G_p \neq 0$, that is, the $n \times p$ matrix whose columns are $G_1, \dots, G_p$ to be of constant rank p.

Let $(r_1, \dots, r_p)$, $1 \le r_1 \le \dots \le r_p = r$, be the largest, in the lexicographic ordering, p-tuple of nonnegative integers, with $r_1 + \dots + r_p = n$, such that

$$\operatorname{span}\left\{ F^i G_s : \ 0 \le i \le r_s - 1, \ 1 \le s \le p \right\} = \mathbb{R}^{n-q}.$$

For the simplicity of the presentation we will suppose that $r_1 = \dots = r_p = r$, and we will show how the general case deduces.

By a smooth linear feedback transformation it is always possible to bring the pair (F, G) into the Brunovský–Jordan canonical pair $(\tilde{A}, \tilde{B})$, where

$$\tilde{A} = \operatorname{diag}(J, A_1, \dots, A_p), \ \tilde{B} = (0, B_1, \dots, B_p) = \operatorname{diag}(0, b_1, \dots, b_p)$$

with J the Jordan canonical form of dimension q, (A_s, b_s) the Brunovský single-input canonical form of dimension $r_s = r$ for any $1 \le s \le p$.

For simplicity we will set

$$A = \operatorname{diag}(A_1, \dots, A_p), \ B = (B_1, \dots, B_p) = \operatorname{diag}(b_1, \dots, b_p).$$

We will denote coordinates of $\mathbb{R}^q \times \mathbb{R}^{n-q}$ by $(z^T, x^T)^T$, where $z = (z_1, \dots, z_q)^T$ and $x = (x_1^T, \dots, x_p^T)^T$ with $x_s = (x_{s,1}, \dots, x_{s,r})^T$ for any $1 \le s \le p$. For the fixed value q, we will denote by $\mathcal{S}_q(\mathbb{R}, 0)$, the set of all functions, either smooth or formal, depending on the variables $z = (z_1, \dots, z_q)^T \in \mathbb{R}^q$.

Let $h = h(z, x, u)$ be a smooth $\mathbb{R}$-valued function defined in a neighborhood of the point $(0,0,0) \in \mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p$. By

$$h(z,x,u) = h^{[0]}(z,x,u) + h^{[1]}(z,x,u) + h^{[2]}(z,x,u) + \dots = \sum_{m=0}^{\infty} h^{[m]}(z,x,u)$$

we denote its Taylor series expansion at $(0,0,0) \in \mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p$ with respect to the variables x and u, where $h^{[m]}(z,x,u)$ stands for a homogeneous polynomial of degree m

of the variables x and u whose coefficients are functions of the variable $z \in \mathbb{R}^q$, that is, in $\mathcal{S}_q(\mathbb{R},0)$.

To fix the ideas, the functions $x_{1,1}^3$, $z^2x_{1,1}^3$, $\cos z\ x_{1,1}^3$, $(1-e^z)x_{1,1}x_{2,1}^2$, $\sin z\ x_{1,2}u_2^2$, and $z_1z_2u_1^2u_2 + x_{1,1}x_{2,1}u_1$ are all polynomials of degree 3.

Choose $d \in \mathbb{N} \cup \{\infty\}$ large enough and consider the Taylor series expansion of order d of the system Π

$$\Pi^{\leq d} : \begin{cases} \dot{z} = Jz + \sum\limits_{m=1}^{d} g^{[m-1]}(z,x,u) + O(z,x,u)^d, \\ \dot{x} = Ax + Bu + \sum\limits_{m=0}^{d} f^{[m]}(z,x,u) + O(z,x,u)^{d+1}, \end{cases} \tag{2.1}$$

where we already assumed that the linear part is in Brunovský–Jordan form, and the Taylor series expansion of order d of the transformation Υ,

$$\Upsilon^{\leq d} : \begin{cases} \bar{z} &= \psi(z,x) = z + \sum\limits_{m=1}^{d} \psi^{[m-1]}(z,x) + O(z,x)^d, \\ \bar{x} &= \phi(z,x) = x + \sum\limits_{m=0}^{d} \phi^{[m]}(z,x) + O(z,x)^{d+1}, \\ u &= \gamma(z,x,\bar{u}) = \bar{u} + \sum\limits_{m=0}^{d} \gamma^{[m]}(z,x,\bar{u}) + O(z,x,\bar{u})^{d+1}. \end{cases} \tag{2.2}$$

The variables z and $\bar{z}$ (resp., (x,u) and $(\bar{x},\bar{u})$) will be called the *uncontrollable variables* associated with the uncontrollable part (resp., *controllable variables* associated with the controllable part) of the system.

Above, and throughout the paper, we mean by $g^{[m-1]}(z,x,u)$ and $\psi^{[m-1]}(z,x)$ (resp., $f^{[m]}(z,x,u)$, $\phi^{[m]}(z,x)$ and $\gamma^{[m]}(z,x,\bar{u})$) that each of their components is a homogeneous polynomial of degree $m-1$ (resp., of degree m) of the *controllable variables*. Moreover, $O(\cdot)^k$ denotes terms of degree k and higher of the controllable variables.

Notice that although we bring the linear approximation (F,G) of the system into Brunovský–Jordan canonical form, that is, the uncontrollable part in Jordan form of dimension q, and the controllable part in Brunovský form of dimension $n-q$, we still have terms of degree 0 and degree 1. However, the first jets of these terms is zero at the origin.

3. Main results. In this section we will establish our main results. We will give, in subsection 3.1 below, the normal forms we obtain for general control systems. The results are given in the simplest case where the controllability indices are equal. We will show that the general case deduces by extended the system. In subsection 3.2, we will study two physical examples: The Caltech Multi-Vehicle Wireless Testbed (MVWT) and the prototype of a Planar Vertical TakeOff and Landing (PVTOL) aircraft. In subsection 3.3, we discuss the notion of *bifurcation of controllability* for systems with one nonzero uncontrollable mode. We first show that the set of equilibria of these systems is a p-dimensional surface, and at any nearby equilibrium point of the origin, these systems become linearly controllable.

3.1. Normal forms. Let $1 \leq s \leq p$. We denote

$$\bar{z} = (\bar{z}_1, \ldots, \bar{z}_q)^T, \qquad \bar{x}_s = (\bar{x}_{s,1}, \ldots, \bar{x}_{s,r})^T, \qquad \text{and} \qquad \bar{x}_{s,r+1} = \bar{u}_s$$

and we set $\hat{x}_{s,i} = (\bar{x}_{s,1}, \ldots, \bar{x}_{s,i})$ for any $1 \leq i \leq r+1$.

For any $1 \leq s \leq t \leq p$ and any $1 \leq i \leq r+1$, we also denote

$$\pi^s_{t,i}(\bar{x}) = (\hat{x}_{1,i}, \dots, \hat{x}_{s,i}, \hat{x}_{s+1,i-1}, \dots, \hat{x}_{t-1,i-1}, \hat{x}_{t,i}, \hat{x}_{t+1,i-1}, \dots, \hat{x}_{p,i-1})^T.$$

For $i = 1$ the expressions $\hat{x}_{t,i-1}$ will be taken to be empty. Few examples are given right after the theorem to make these notations comprehensible.

Our main result for general control systems, that is, for control systems with *uncontrollable linearization* is as follows.

THEOREM 3.1. *For any $d \in \mathbb{N} \cup \{\infty\}$, the system $\Pi^{\leq d}$, defined by* (2.1)*, with* uncontrollable linearization *is feedback equivalent, by a feedback transformation $\Upsilon^{\leq d}$ of the form* (2.2)*, to the following normal form:*

$$\Pi^{\leq d}_{NF} : \begin{cases} \dot{\bar{z}} = J\bar{z} + \bar{g}^{[0]}(\bar{z}) + \sum\limits_{m=2}^{d} \bar{g}^{[m-1]}(\bar{z}, \bar{x}, \bar{u}) + O(\bar{z}, \bar{x}, \bar{u})^d, \\ \dot{\bar{x}} = A\bar{x} + B\bar{u} + \sum\limits_{m=2}^{d} \bar{f}^{[m]}(\bar{z}, \bar{x}, \bar{u}) + O(\bar{z}, \bar{x}, \bar{u})^{d+1}, \end{cases}$$

where for any m,

$$\begin{aligned} \bar{g}^{[m-1]}(\bar{z}, \bar{x}, \bar{u}) &= \sum_{j=1}^{q} \bar{g}^{[m-1]}_j(\bar{z}, \bar{x}, \bar{u}) \tfrac{\partial}{\partial \bar{z}_j} \\ \bar{f}^{[m]}(\bar{z}, \bar{x}, \bar{u}) &= \sum_{k=1}^{p} \sum_{j=1}^{r-1} \bar{f}^{k[m]}_j(\bar{z}, \bar{x}, \bar{u}) \tfrac{\partial}{\partial \bar{x}_{k,j}}, \end{aligned} \tag{3.1}$$

with

$$\begin{aligned} \bar{g}^{[1]}_j(\bar{z}, \bar{x}, \bar{u}) &= \sum_{1 \leq s \leq p} \bar{x}_{s,1} R_{j,s}(\bar{z}) \\ \bar{g}^{[m-1]}_j(\bar{z}, \bar{x}, \bar{u}) &= \sum_{1 \leq s \leq t \leq p} \sum_{i=1}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i} P^{[m-3]}_{j,i,s,t}(\bar{z}, \pi^s_{t,i}(\bar{x})) \\ &+ \sum_{1 \leq s < t \leq p} \sum_{i=2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1} Q^{[m-3]}_{j,i,s,t}(\bar{z}, \pi^t_{t,i-1}(\bar{x})) \end{aligned} \tag{3.2}$$

for any $1 \leq j \leq q$ and

$$\begin{aligned} \bar{f}^{k[m]}_j(\bar{z}, \bar{x}, \bar{u}) &= \sum_{1 \leq s \leq t \leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i} P^{k[m-2]}_{j,i,s,t}(\bar{z}, \pi^s_{t,i}(\bar{x})) \\ &+ \sum_{1 \leq s < t \leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1} Q^{k[m-2]}_{j,i,s,t}(\bar{z}, \pi^t_{t,i-1}(\bar{x})) \end{aligned} \tag{3.3}$$

for any $1 \leq k \leq p$ and any $1 \leq j \leq r-1$.

Above, the functions $P^{[m-3]}_{j,i,s,t}$, $Q^{[m-3]}_{j,i,s,t}$, $P^{k[m-2]}_{j,i,s,t}$, and $Q^{k[m-2]}_{j,i,s,t}$ stand for homogeneous polynomials of the indicated controllable variables $\bar{x}$ and $\bar{u}$ whose coefficients depend on the uncontrollable variable $\bar{z}$.

To make the notations $\pi^s_{t,i}(\bar{x})$ somewhat understandable, suppose $p = 3$. Then we have

$$\pi^1_{2,2}(\bar{x}) = (\bar{x}_{1,1}, \bar{x}_{1,2}, \bar{x}_{2,1}, \bar{x}_{2,2}, \bar{x}_{3,1}) \text{ and } \pi^2_{2,2}(\bar{x}) = (\bar{x}_{1,1}, \bar{x}_{1,2}, \bar{x}_{2,1}, \bar{x}_{2,2}, \bar{x}_{3,1}).$$

We also have

$$\pi^1_{2,1}(\bar{x}) = (\bar{x}_{1,1}, \bar{x}_{2,1}), \quad \pi^2_{2,1}(\bar{x}) = (\bar{x}_{1,1}, \bar{x}_{2,1}), \quad \text{and} \quad \pi^1_{3,1}(\bar{x}) = (\bar{x}_{1,1}, \bar{x}_{3,1}).$$

Notice that the above normal form is a natural combination of the two extreme cases: that of dynamical systems and that of systems with controllable linearization.

Indeed, if $q = n$, that is, we deal with a dynamical system, then the coordinates $(\bar{x}_1^T, \dots, \bar{x}_p^T)^T$ are not present and the normal form $\Pi_{NF}^{\leq d}$ reduces to a dynamical system $\dot{\bar{z}} = J\bar{z} + \bar{g}^{[0]}(\bar{z})$ containing resonant terms only. This is, of course, Poincaré normal form of a vector field under a formal diffeomorphism. On the other hand, if $q = 0$, that is, if the linearization of the system is controllable, the coordinates $\bar{z} = (\bar{z}_1, \dots, \bar{z}_q)^T$ are not present and our normal form reduces to

$$\begin{aligned}\bar{f}_j^{k[m]}(\bar{x}, \bar{u}) = &\sum_{1\leq s\leq t\leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i} P_{j,i,s,t}^{k[m]}(\pi_{t,i}^s(\bar{x})) \\ &+ \sum_{1\leq s<t\leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1} Q_{j,i,s,t}^{k[m]}(\pi_{t,i-1}^t(\bar{x}))\end{aligned}$$

for any $1 \leq k \leq p$ and any $1 \leq j \leq r-1$, and $\bar{f}_j^{k[m]}(\bar{x}, \bar{u}) = 0$ otherwise. This latter case will be summarized in the following corollary. It gives the normal form for multi-input control systems with controllable linearization (see [42]).

COROLLARY 3.2. *The system* $\Pi^{\leq d}$, *defined by* (2.1), *with* controllable linearization, *is feedback equivalent by a polynomial feedback transformation* $\Upsilon^{\leq d}$ *of the form* (2.2), *to the following normal form:*

$$\Pi_{NF}^{\leq d} \ : \ \dot{\bar{x}} = A\bar{x} + B\bar{u} + \sum_{m=2}^{d} \bar{f}^{[m]}(\bar{x}, \bar{u}) + O(\bar{x}, \bar{u})^{d+1},$$

where

$$\bar{f}^{[m]}(\bar{x}, \bar{u}) = \sum_{k=1}^{p} \sum_{j=1}^{r-1} \bar{f}_j^{k[m]}(\bar{x}, \bar{u}) \frac{\partial}{\partial \bar{x}_{k,j}},$$

with

$$\begin{aligned}\bar{f}_j^{k[m]}(\bar{x}, \bar{u}) = &\sum_{1\leq s\leq t\leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i} P_{j,i,s,t}^{k[m-2]}(\pi_{t,i}^s(\bar{x})) \\ &+ \sum_{1\leq s<t\leq p} \sum_{i=j+2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1} Q_{j,i,s,t}^{k[m-2]}(\pi_{t,i-1}^t(\bar{x}))\end{aligned}$$

for any $1 \leq k \leq p$ *and any* $1 \leq j \leq r-1$.

Particular case $p = 2$ and $r = 3$. In this particular case the normal form will be given by

$$\Pi^{\leq d} \ : \ \begin{cases} \dot{\bar{x}}_{1,1} &= \bar{x}_{1,2} + \bar{f}_1^{1[2]}(\bar{x}, \bar{u}) + \cdots + \bar{f}_1^{1[d]}(\bar{x}, \bar{u}) + O(\bar{x}, \bar{u})^{d+1}, \\ \dot{\bar{x}}_{1,2} &= \bar{x}_{1,3} + \bar{f}_2^{1[2]}(\bar{x}, \bar{u}) + \cdots + \bar{f}_2^{1[d]}(\bar{x}, \bar{u}) + O(\bar{x}, \bar{u})^{d+1}, \\ \dot{\bar{x}}_{1,3} &= \bar{u}_1, \\ \dot{\bar{x}}_{2,1} &= \bar{x}_{2,2} + \bar{f}_1^{2[2]}(\bar{x}, \bar{u}) + \cdots + \bar{f}_1^{2[d]}(\bar{x}, \bar{u}) + O(\bar{x}, \bar{u})^{d+1}, \\ \dot{\bar{x}}_{2,2} &= \bar{x}_{2,3} + \bar{f}_2^{2[2]}(\bar{x}, \bar{u}) + \cdots + \bar{f}_2^{2[d]}(\bar{x}, \bar{u}) + O(\bar{x}, \bar{u})^{d+1}, \\ \dot{\bar{x}}_{2,3} &= \bar{u}_2, \end{cases}$$

where for any $2 \leq m \leq d$ and any $k = 1, 2$ we have

$$\begin{aligned}\bar{f}_1^{k[m]}(\bar{x},\bar{u}) &= \bar{x}_{1,3}^2 P_{1,3,1,1}^{k[m-2]}(\hat{x}_{1,3},\hat{x}_{2,2}) + \bar{x}_{2,3}^2 P_{1,3,2,2}^{k[m-2]}(\hat{x}_{1,2},\hat{x}_{2,3}) \\ &+ \bar{x}_{1,3}\bar{x}_{2,3} P_{1,3,1,2}^{k[m-2]}(\hat{x}_{1,3},\hat{x}_{2,3}) + \bar{x}_{1,3}\bar{x}_{2,2} Q_{1,3,1,2}^{k[m-2]}(\hat{x}_{1,2},\hat{x}_{2,2}) \\ &+ \bar{u}_1^2 P_{1,4,1,1}^{k[m-2]}(\hat{u}_1,\hat{x}_{2,3}) + \bar{u}_2^2 P_{1,4,2,2}^{k[m-2]}(\hat{x}_{1,3},\hat{u}_2) + \bar{u}_1\bar{u}_2 P_{1,4,1,2}^{k[m-2]}(\hat{u}_1,\hat{u}_2) \\ &+ \bar{u}_1\bar{x}_{2,3} Q_{1,4,1,2}^{k[m-2]}(\hat{x}_{1,3},\hat{x}_{2,3})\end{aligned}$$

and

$$\begin{aligned}\bar{f}_2^{k[m]}(\bar{x},\bar{u}) &= \bar{u}_1^2 P_{2,4,1,1}^{k[m-2]}(\hat{u}_1,\hat{x}_{2,3}) + \bar{u}_2^2 P_{2,4,2,2}^{k[m-2]}(\hat{x}_{1,3},\hat{u}_2) + \bar{u}_1\bar{u}_2 P_{2,4,1,2}^{k[m-2]}(\hat{u}_1,\hat{u}_2) \\ &+ \bar{u}_1\bar{x}_{2,3} Q_{2,4,1,2}^{k[m-2]}(\hat{x}_{1,3},\hat{x}_{2,3}).\end{aligned}$$

We recall that $\hat{x}_{1,i} = (\bar{x}_{1,1},\ldots,\bar{x}_{1,i})$ and $\hat{x}_{2,i} = (\bar{x}_{2,1},\ldots,\bar{x}_{2,i})$. Moreover,

$$\hat{u}_1 = (\bar{x}_{1,1},\bar{x}_{1,2},\bar{x}_{1,3},\bar{u}_1) \text{ and } \hat{u}_2 = (\bar{x}_{2,1}\bar{x}_{2,2},\bar{x}_{2,3},\bar{u}_2).$$

When the initial system is affine in the control, then in the normal form, the homogeneous polynomials $P_{j,4,1,1}^{k[m-2]}(\hat{u}_1,\hat{x}_{2,3})$, $P_{j,4,2,2}^{k[m-2]}(\hat{x}_{1,3},\hat{u}_2)$, and $P_{j,4,1,2}^{k[m-2]}(\hat{u}_1,\hat{u}_2)$ are all zero.

Generalization. Now let us assume that the controllability indices are not equal. Without loss of generality, we suppose that $1 \leq r_1 \leq \cdots \leq r_p = r$. We then define the sequence of indices $d_1 \geq \cdots \geq d_p = 0$ so that $r_1 + d_1 = \cdots = r_p + d_p = r$.

It thus suffices to extend each subsystem, say the kth subsystem of (2.1) given by

$$\Pi_k^{\leq d} : \begin{cases} \dot{x}_{k,1} &= x_{k,2} + \sum_{m=0}^{d} f_1^{k[m]}(z,x,u) + O(z,x,u)^{d+1}, \\ &\vdots \\ \dot{x}_{k,r-1} &= x_{k,r} + \sum_{m=0}^{d} f_{r_k-1}^{k[m]}(z,x,u) + O(z,x,u)^{d+1}, \\ \dot{x}_{k,r} &= u_k, \end{cases}$$

as follows. We define $\tilde{x}_k = (\tilde{x}_{k,1},\ldots,\tilde{x}_{k,r})$ so that

$$\tilde{x}_{k,d_k+1} = x_{k,1},\ldots,\tilde{x}_{k,r} = x_{k,r_k} \text{ and } \dot{\tilde{x}}_{k,1} = \tilde{x}_{k,2},\ldots,\dot{\tilde{x}}_{k,d_k} = x_{k,1}.$$

This means that the kth subsystem is extended as

$$\tilde{\Pi}_k^{\leq d} : \begin{cases} \dot{\tilde{x}}_{k,1} &= \tilde{x}_{k,2}, \\ &\vdots \\ \dot{\tilde{x}}_{k,d_k} &= \tilde{x}_{k,d_k+1}, \\ \dot{\tilde{x}}_{k,d_k+1} &= \tilde{x}_{k,d_k+2} + \sum_{m=0}^{d} \tilde{f}_{d_k+1}^{k[m]}(z,\tilde{x},u) + O(z,\tilde{x},u)^{d+1}, \\ &\vdots \\ \dot{\tilde{x}}_{k,r-1} &= \tilde{x}_{k,r} + \sum_{m=0}^{d} \tilde{f}_{r-1}^{k[m]}(z,\tilde{x},u) + O(z,\tilde{x},u)^{d+1}, \\ \dot{\tilde{x}}_{k,r} &= u_k, \end{cases}$$

where

$$\tilde{f}_{d_k+1}^{k[m]}(z,\tilde{x},u) = f_1^{k[m]}(z,x,u),\ldots,\tilde{f}_{r-1}^{k[m]}(z,\tilde{x},u) = f_{r_k-1}^{k[m]}(z,x,u).$$

In this case all extended subsystems will have the same controllability index r, and by Theorem 3.1 the extended system will be equivalent to the normal form $\Pi_{NF}^{\leq d}$ given by (3.2)–(3.3) with $\bar{g}_j^{[m-1]}(\bar{z},\bar{x},\bar{u})$ and $\bar{f}_j^{k[m]}(\bar{z},\bar{x},\bar{u})$ *depending exclusively on the variables* $\bar{z},\bar{u}$ and $\bar{x}_{s,d_s+1},\ldots,\bar{x}_{s,r}$ (not on the added variables $\bar{x}_{s,1},\ldots,\bar{x}_{s,d_s}$) for all $1 \leq s \leq p$. Moreover, the first d_k components $\bar{f}_1^{k[m]}(\bar{z},\bar{x},\bar{u}),\ldots,\bar{f}_{d_k}^{k[m]}(\bar{z},\bar{x},\bar{u})$ remain zero (see Example 1 for illustration).

3.2. Examples. In this subsection we will illustrate our results by considering two physical examples: The MVWT and the prototype of a PVTOL.

Example 1. Multi-Vehicle Wireless Testbed. We consider the MVWT, presented in [8, 9] and we study the normal form of one vehicle. The equations of motion of an MVWT vehicle (see [8, 9]) are given by

$$\begin{cases} m\ddot{x} &= -\eta\dot{x} + (F_s + F_p)\cos\theta, \\ m\ddot{y} &= -\eta\dot{y} + (F_s + F_p)\sin\theta, \\ J\ddot{\theta} &= -\psi\dot{\theta} + (F_s - F_p)l, \end{cases}$$

where (x,y) denotes the position of the center mass of the vehicle, θ the angle of the axis of the vehicle with the horizontal (x-axis), m the mass of the vehicle, J the rotational inertia, F_s and F_p denote the starboard and port fan forces, respectively, and l (r in [8, 9]) the common moment arm of the forces. The center mass of the vehicle and the center of geometry are assumed to coincide. The constants η and ψ stand, respectively, for the coefficients of viscous friction and rotational friction.

Let us introduce the variables

$$\begin{array}{lllllllllll} z_1 &=& y, & x_{1,1} &=& x, & x_{2,1} &=& \theta, & u_1 &=& F_s + F_p, \\ z_2 &=& \dot{z_1}, & x_{1,2} &=& \dot{x}_{1,1}, & x_{2,2} &=& \dot{x}_{2,1}, & u_2 &=& F_s - F_p. \end{array}$$

The equations of motion of an MVWT vehicle are rewritten as

$$\begin{cases} \dot{z}_1 &= z_2, \\ \dot{z}_2 &= -\eta z_2 + u_1 \sin x_{2,1}, \\ \dot{x}_{1,1} &= x_{1,2}, \\ \dot{x}_{1,2} &= -\eta x_{1,2} + u_1 \cos x_{2,1}, \\ \dot{x}_{2,1} &= x_{2,2}, \\ \dot{x}_{2,2} &= -\phi x_{2,2} + u_2 l. \end{cases} \tag{3.4}$$

We can notice that the system is affine and its distribution $\mathcal{G} = \operatorname{span}\{g_1, g_2\}$, where

$$g_1 = \begin{pmatrix} 0 \\ \sin x_{2,1} \\ 0 \\ \cos x_{2,1} \\ 0 \\ 0 \end{pmatrix} \qquad \text{and} \qquad g_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

is involutive and of constant rank 2. An equilibrium point for the system (3.4) is given by any constant position and orientation

$$(z_1^e, z_2^e, x_{1,1}^e, x_{1,2}^e, x_{2,1}^e, x_{2,2}^e)^T = (z_1, 0, x_{1,1}, 0, x_{2,1}, 0)^T.$$

The linearization of the system (3.4) around an equilibrium (we assume $x_{2,1} = 0$) is given by

$$\left\{\begin{array}{rcl} \dot{z}_1 &=& z_2, \\ \dot{z}_2 &=& -\eta z_2, \\ \dot{x}_{1,1} &=& x_{1,2}, \\ \dot{x}_{1,2} &=& -\eta x_{1,2} + u_1, \\ \dot{x}_{2,1} &=& x_{2,2}, \\ \dot{x}_{2,2} &=& -\phi x_{2,2} + u_2 l. \end{array}\right.$$

It is easy to see that this linear system is not controllable because

$$\operatorname{span}\left\{ F^i G_k,\ 0 \le i \le 5,\ 1 \le k \le 2 \right\} = \mathbb{R}^4,$$

where

$$F = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & -\eta & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & -\eta & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & -\phi \end{pmatrix}, \qquad G_1 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \qquad \text{and} \qquad G_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}.$$

It thus follows that $q = 2$, and the computation of the controllability matrix shows that $r_1 = r_2 = 2$.

The feedback transformation defined by

$$u_1 = \frac{1}{\cos x_{2,1}} \bar{u}_1 + \eta \frac{x_{1,2}}{\cos x_{2,1}} \qquad \text{and} \qquad \bar{u}_2 = \frac{u_2}{l} + \frac{\phi}{l} x_{2,2}$$

takes the system into the following form:

$$\left\{\begin{array}{rcl} \dot{z}_1 &=& z_2 \\ \dot{z}_2 &=& -\eta z_2 + \eta x_{1,2} \tan x_{2,1} + \bar{u}_1 \tan x_{2,1}, \\ \dot{x}_{1,1} &=& x_{1,2}, \\ \dot{x}_{1,2} &=& \bar{u}_1, \\ \dot{x}_{2,1} &=& x_{2,2}, \\ \dot{x}_{2,2} &=& \bar{u}_2. \end{array}\right.$$

The change of coordinates given by

$$\left\{\begin{array}{rcl} \bar{z}_1 &=& z_1, \\ \bar{z}_2 &=& z_2 - x_{1,2} \tan x_{2,1}, \\ \bar{x}_{1,1} &=& x_{1,1}, \\ \bar{x}_{1,2} &=& x_{1,2}, \\ \bar{x}_{2,1} &=& x_{2,1}, \\ \bar{x}_{2,2} &=& x_{2,2} \end{array}\right.$$

brings the system into the form

$$\left\{\begin{array}{rcl} \dot{\bar{z}}_1 &=& \bar{z}_2 + \bar{x}_{1,2} \tan \bar{x}_{2,1}, \\ \dot{\bar{z}}_2 &=& -\eta \bar{z}_2 - \bar{x}_{1,2} \bar{x}_{2,2} (1 + \tan^2 \bar{x}_{2,1}), \\ \dot{\bar{x}}_{1,1} &=& \bar{x}_{1,2}, \\ \dot{\bar{x}}_{1,2} &=& \bar{u}_1, \\ \dot{\bar{x}}_{2,1} &=& \bar{x}_{2,2}, \\ \dot{\bar{x}}_{2,2} &=& \bar{u}_2. \end{array}\right.$$

Since

$$\bar{x}_{1,2}\tan\bar{x}_{2,1}=\bar{x}_{1,2}\sum_{\nu=0}^{\infty}(-1)^{\nu}\frac{\bar{x}_{2,1}^{2\nu+1}}{(2\nu+1)!}=\bar{x}_{1,2}\bar{x}_{2,1}\sum_{\nu=0}^{\infty}(-1)^{\nu}\frac{\bar{x}_{2,1}^{2\nu}}{(2\nu+1)!},$$

$$\bar{x}_{1,2}\bar{x}_{2,2}(1+\tan^2\bar{x}_{2,1})=\bar{x}_{1,2}\bar{x}_{2,2}\left(1+\sum_{\nu=0}^{\infty}(-1)^{\nu}\frac{\bar{x}_{2,1}^{2\nu+1}}{(2\nu+1)!}\right),$$

we conclude that the system is in normal form (compare with Theorem 3.1), with

$$\bar{g}_1^{[m-1]}(\bar{x})=\begin{cases}\bar{x}_{1,2}\bar{x}_{2,1}Q_{1,2}^{[m-3]}(\bar{x})=\pm\bar{x}_{1,2}\bar{x}_{2,1}\frac{\bar{x}_{2,1}^{m-3}}{(m-2)!} & \text{if } m \text{ is even,}\\ 0 & \text{if } m \text{ is odd}\end{cases}$$

and

$$\bar{g}_2^{[m-1]}(\bar{x})=\begin{cases}-\bar{x}_{1,2}\bar{x}_{2,2} & \text{if } m=3,\\ \bar{x}_{1,2}\bar{x}_{2,2}P_{2,2}^{[m-3]}(\bar{x})=\pm\bar{x}_{1,2}\bar{x}_{2,2}\frac{\bar{x}_{2,1}^{m-3}}{(m-3)!} & \text{if } m\geq 4 \text{ is odd,}\\ 0 & \text{if } m \text{ is even.}\end{cases}$$

Example 2. Planar Vertical TakeOff and Landing. In this example we study a simple toy aircraft of prototype PVTOL presented in [15, 40]. The equations of motion of the PVTOL (see [15, 40]) are given by

$$\begin{cases}\ddot{x} &= -\sin\theta u_1+\epsilon^2\cos\theta u_2,\\ \ddot{y} &= \cos\theta u_1+\epsilon^2\sin\theta u_2-1,\\ \ddot{\theta} &= u_2,\end{cases}$$

where (x,y) denotes the position of the center mass of the aircraft, θ the angle of the aircraft relative to the x-axis, " -1" the gravitational acceleration, and $\epsilon\neq 0$ the (small) coefficient giving the coupling between the rolling moment and the lateral acceleration of the aircraft. The control inputs u_1 and u_2 are the thrust (directed out the bottom of the aircraft) and the rolling moment.

We introduce the variables

$$\begin{array}{ccccccccccc} x_{1,1} & = & y, & x_{2,1} & = & x, & x_{2,3} & = & \theta, & w_1 & = & u_1-1,\\ x_{1,2} & = & \dot{x}_{1,1}, & x_{2,2} & = & \dot{x}_{2,1}, & x_{2,4} & = & \dot{x}_{2,3}, & w_2 & = & u_2.\end{array}$$

The equations of motion of the PVTOL are rewritten as

$$\begin{cases}\dot{x}_{1,1} &= x_{1,2},\\ \dot{x}_{1,2} &= \cos x_{2,3}w_1+\epsilon^2\sin x_{2,3}w_2+\cos x_{2,3}-1,\\ \dot{x}_{2,1} &= x_{2,2},\\ \dot{x}_{2,2} &= -\sin x_{2,3}w_1+\epsilon^2\cos x_{2,3}w_2-\sin x_{2,3},\\ \dot{x}_{2,3} &= x_{2,4},\\ \dot{x}_{2,4} &= w_2.\end{cases} \tag{3.5}$$

The system is affine and its distribution $\mathcal{G}=\operatorname{span}\{g_1,g_2\}$, given by

$$g_1=\begin{pmatrix}0\\ \cos x_{2,3}\\ 0\\ -\sin x_{2,3}\\ 0\\ 0\end{pmatrix}\qquad\text{and}\qquad g_2=\begin{pmatrix}0\\ \epsilon^2\sin x_{2,3}\\ 0\\ \epsilon^2\cos x_{2,3}\\ 0\\ 1\end{pmatrix},$$

is involutive and of constant rank 2. The equilibria is defined by

$$(x^e_{1,1}, x^e_{1,2}, x^e_{2,1}, x^e_{2,2}, x^e_{2,3}, x^e_{2,4}, w^e_1, w^e_2)^T = (c, 0, 0, 0, 0, 0, 0, 0)^T,$$

where c is any constant. The linearization of the system (3.5) around the equilibria is given by

$$\begin{cases} \dot{x}_{1,1} &= x_{1,2}, \\ \dot{x}_{1,2} &= w_1, \\ \dot{x}_{2,1} &= x_{2,2}, \\ \dot{x}_{2,2} &= -x_{2,3} + \epsilon^2 w_2, \\ \dot{x}_{2,3} &= x_{2,4}, \\ \dot{x}_{2,4} &= w_2. \end{cases}$$

It is easy to see that the linear system is controllable with controllability indices $r_1 = 2$ and $r_2 = 4$. Indeed,

$$\text{span}\left\{ G_1, FG_1, G_2, FG_2, F^2G_2, F^3G_2 \right\} = \mathbb{R}^6,$$

where

$$F = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \qquad G_1 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \qquad \text{and} \qquad G_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ \epsilon^2 \\ 0 \\ 1 \end{pmatrix}.$$

Since $r_1 = 2 < r_2 = 4$ we have $d_1 = 2$ and $d_2 = 0$. Thus we extend the system as

$$\begin{cases} \dot{\tilde{x}}_{1,1} &= \tilde{x}_{1,2}, \\ \dot{\tilde{x}}_{1,2} &= \tilde{x}_{1,3}, \\ \dot{\tilde{x}}_{1,3} &= \tilde{x}_{1,4}, \\ \dot{\tilde{x}}_{1,4} &= \cos\tilde{x}_{2,3} w_1 + \epsilon^2 \sin\tilde{x}_{2,3} w_2 + \cos\tilde{x}_{2,3} - 1, \\ \dot{\tilde{x}}_{2,1} &= \tilde{x}_{2,2}, \\ \dot{\tilde{x}}_{2,2} &= -\sin\tilde{x}_{2,3} w_1 + \epsilon^2 \cos\tilde{x}_{2,3} w_2 - \sin\tilde{x}_{2,3}, \\ \dot{\tilde{x}}_{2,3} &= \tilde{x}_{2,4}, \\ \dot{\tilde{x}}_{2,4} &= w_2, \end{cases}$$

where

$$\tilde{x}_{1,3} = x_{1,1}, \quad \tilde{x}_{1,4} = x_{1,2}, \quad \tilde{x}_{2,1} = x_{2,1}, \quad \tilde{x}_{2,2} = x_{2,2}, \quad \tilde{x}_{2,3} = x_{2,3}, \quad \tilde{x}_{2,4} = x_{2,4}.$$

The feedback transformation defined by

$$w_1 = \frac{1}{\cos\tilde{x}_{2,1}} v_1 - \epsilon^2 \tan\tilde{x}_{2,1} v_2 + \frac{1}{\cos\tilde{x}_{2,1}} - 1 \qquad \text{and} \qquad w_2 = v_2$$

takes the system into the following form:

$$\begin{cases} \dot{\tilde{x}}_{1,1} &= \tilde{x}_{1,2}, \\ \dot{\tilde{x}}_{1,2} &= \tilde{x}_{1,3}, \\ \dot{\tilde{x}}_{1,3} &= \tilde{x}_{1,4}, \\ \dot{x}_{1,4} &= v_1, \\ \dot{\tilde{x}}_{2,1} &= \tilde{x}_{2,2}, \\ \dot{\tilde{x}}_{2,2} &= -\tan\tilde{x}_{2,3}v_1 + \frac{\epsilon^2}{\cos\tilde{x}_{2,3}}v_2 - \tan\tilde{x}_{2,3}, \\ \dot{\tilde{x}}_{2,3} &= \tilde{x}_{2,4}, \\ \dot{\tilde{x}}_{2,4} &= v_2. \end{cases}$$

The change of coordinates given by

$$\begin{cases} \bar{x}_{1,1} &= \tilde{x}_{1,1}, \\ \bar{x}_{1,2} &= \tilde{x}_{1,2}, \\ \bar{x}_{1,3} &= \tilde{x}_{1,3} - \epsilon^2 \int_0^{\tilde{x}_{2,3}} \frac{dt}{\cos t}, \\ \bar{x}_{1,4} &= \tilde{x}_{1,4} + \tilde{x}_{1,4}\tan\tilde{x}_{2,3} - \frac{\epsilon^2}{\cos\tilde{x}_{2,3}}\tilde{x}_{2,4}, \\ \bar{x}_{2,1} &= \tilde{x}_{2,1}, \\ \bar{x}_{2,2} &= \tilde{x}_{2,2}, \\ \bar{x}_{2,3} &= -\tan\tilde{x}_{2,3}, \\ \bar{x}_{2,4} &= -\tilde{x}_{2,4}(1+\tan^2\tilde{x}_{2,3}) = \dot{\tilde{x}}_{2,3} \end{cases}$$

followed by the feedback

$$\bar{u}_1 = v_1, \text{ and } \bar{u}_2 = \dot{\tilde{x}}_{2,4} = -v_2(1+\tan^2\tilde{x}_{2,3}) - 2\tilde{x}_{2,4}^2\tan\tilde{x}_{2,3}(1+\tan^2\tilde{x}_{2,3})$$

brings the system into

$$\begin{cases} \dot{\bar{x}}_{1,1} &= \bar{x}_{1,2}, \\ \dot{\bar{x}}_{1,2} &= \bar{x}_{1,3}, \\ \dot{\bar{x}}_{1,3} &= \bar{x}_{1,4}, \\ \dot{\bar{x}}_{1,4} &= \bar{u}_1, \\ \dot{\bar{x}}_{2,1} &= x_{2,2} + \bar{x}_{1,4}\bar{x}_{2,3}, \\ \dot{\bar{x}}_{2,2} &= \bar{x}_{2,3} - \bar{x}_{1,4}\bar{x}_{2,4} + \epsilon^2(1-\bar{x}_{2,3}^2)\bar{x}_{2,4}^2, \\ \dot{\bar{x}}_{2,3} &= \bar{x}_{2,4}, \\ \dot{\bar{x}}_{2,4} &= \bar{u}_2. \end{cases}$$

Comparing with Corollary 3.2 we get

$$\begin{aligned} \bar{f}_1^{2[2]}(\bar{x}) &= \bar{x}_{1,4}\bar{x}_{2,3}Q_{1,4,1,2}^{2[0]}(\bar{x}), \\ \bar{f}_2^{2[2]}(\bar{x}) &= \bar{x}_{1,4}\bar{x}_{2,4}P_{2,4,1,2}^{2[0]}(\bar{x}) + \bar{x}_{2,4}\bar{x}_{2,4}P_{2,4,2,2}^{2[0]}(\bar{x}), \\ \bar{f}_2^{2[4]}(\bar{x}) &= \bar{x}_{2,4}\bar{x}_{2,4}P_{2,4,2,2}^{2[2]}(\pi_{2,4}^2(\bar{x})), \end{aligned}$$

where

$$Q_{1,4,1,2}^{2[0]}(\bar{x}) \equiv 1, \quad P_{2,4,1,2}^{2[0]}(\bar{x}) \equiv -1, \quad P_{2,4,2,2}^{2[0]}(\bar{x}) = \epsilon^2, \quad P_{2,4,2,2}^{2[2]}(\bar{x}) = -\epsilon^2\bar{x}_{2,3}^2.$$

This means that the system (3.5) is equivalent to the normal form

$$\begin{cases} \dot{\bar{x}}_{1,3} &= \bar{x}_{1,4}, \\ \dot{\bar{x}}_{1,4} &= \bar{u}_1, \\ \dot{\bar{x}}_{2,1} &= x_{2,2} + \bar{x}_{1,4}\bar{x}_{2,3}, \\ \dot{\bar{x}}_{2,2} &= \bar{x}_{2,3} - \bar{x}_{1,4}\bar{x}_{2,4} + \epsilon^2(1-\bar{x}_{2,3}^2)\bar{x}_{2,4}^2, \\ \dot{\bar{x}}_{2,3} &= \bar{x}_{2,4}, \\ \dot{\bar{x}}_{2,4} &= \bar{u}_2. \end{cases}$$

Notice that the *added variables* $\bar{x}_{1,1}$ and $\bar{x}_{1,2}$ are not present in the normal form. We may also notice that in both *Examples* 1 and 2 the transformations taking the corresponding systems into their normal forms are smooth, actually they are analytic. Though little is known about the convergence of the formal transformations taking a system into its normal form, this gives hope.

3.3. Nearby controllability. In this subsection we generalize a result obtained earlier in collaboration with Kang et al. [30]. We proved that for systems with one nonzero uncontrollable mode the set of equilibria is a smooth curve passing by the origin. Moreover, provided that some term in the normal form is nonzero, the system becomes linearly controllable at these equilibria (except at the origin). This is called a *bifurcation of controllability* and the conclusion drawn from this study is that we can stabilize the system at any nearby point of the origin.

A parallel analysis could be made for multi-input systems with one nonzero uncontrollable mode. Indeed, consider the system $\Pi^{\leq d}$ defined by (2.1) and assume that $q = 1$, i.e., $J = \lambda$. The equilibria set of this system is

$$E = \left\{ (z, x) \in \mathbb{R} \times \mathbb{R}^{n-1} \text{ such that } \exists u \in \mathbb{R}^p : H(z, x, u) = 0 \right\},$$

where $H(z, x, u) = (g(z, x, u), f(z, x, u))$ with

$$\begin{aligned} g(z, x, u) &= \lambda z + \sum_{m=1}^{d} g^{[m-1]}(z, x, u) + O(z, x, u)^d, \\ f(z, x, u) &= Ax + Bu + \sum_{m=0}^{d} f^{[m]}(z, x, u) + O(z, x, u)^{d+1}. \end{aligned}$$

We will show that E is a surface parameterized by $x^1 = (x_{1,1}, x_{2,1}, \ldots, x_{p,1})^T$. If we denote by $\mathbf{x}_s = (x_{s,2}, \ldots, x_{s,r})^T$ for all $1 \leq s \leq p$ and $\mathbf{x} = (\mathbf{x}_1^T, \ldots, \mathbf{x}_p^T)$, then we have

$$\frac{\partial H(z, x, u)}{\partial (z, \mathbf{x}, u)}\Big|_{(z,x,u)=0} = \text{diag } (\lambda, \text{Id}_{\mathbb{R}^{n-1}}).$$

Since $\lambda \neq 0$, the matrix diag $(\lambda, \text{Id}_{\mathbb{R}^{n-1}})$ is invertible. The *implicit function theorem* implies that the equation

$$H(z, x, u) = H(z, x^1, \mathbf{x}, u) = 0$$

has a solution in a neighborhood of the origin parameterized by the variables x^1, that is, there exist functions

$$z = z^e(x^1), \quad \mathbf{x} = \mathbf{x}^e(x^1), \quad u = u^e(x^1)$$

so that for some open neighborhood $\mathcal{V}$ of the origin in $\mathbb{R}^p$, we have

$$H(z^e(x^1), x^1, \mathbf{x}^e(x^1), u^e(x^1)) = 0 \text{ for all } x^1 \in \mathcal{V} \subset \mathbb{R}^p.$$

We thus deduce that the equilibria set is a surface parameterized by the variables x^1.

Let us denote by E_0 the subset of E defined by

$$E_0 = \left\{ (z, x) \in E \text{ such that } x_{s,1} \neq 0 \text{ for all } 1 \leq s \leq p \right\}.$$

Consider the normal form of $\Pi^{\leq d}$ given by (3.1)–(3.3), where (since $q = 1$) we have

$$\begin{aligned}\bar{g}_1^{[m-1]}(\bar{z},\bar{x},\bar{u}) &= \sum_{1\leq s\leq t\leq p}\sum_{i=1}^{r+1}\bar{x}_{s,i}\bar{x}_{t,i}P_{1,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i}^{s}(\bar{x}))\\ &+ \sum_{1\leq s<t\leq p}\sum_{i=2}^{r+1}\bar{x}_{s,i}\bar{x}_{t,i-1}Q_{1,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i-1}^{t}(\bar{x}))\end{aligned}$$

for any $m \geq 3$.

An analogous result to that given in [30] could be formulated as follows.

THEOREM 3.3. *Consider the system $\Pi^{\leq d}$ defined by (2.1) for $d \in \mathbb{N}\cup\{\infty\}$ sufficiently large enough. If there are integers $3 \leq m \leq d$ and $1 \leq s \leq t \leq p$ so that*

$$P_{1,1,s,t}^{[m-3]}(\bar{z},\pi_{t,1}^{s}(\bar{x}))\Big|_{\bar{z}=0} = P_{1,1,s,t}^{[m-3]}(\bar{x}_{1,1},\ldots,\bar{x}_{s,1},\bar{x}_{t,1}) \neq 0,$$

then the system $\Pi^{\leq d}$ is linearly controllable at any point of E_0.

The proof of this result is straightforward and follows the same steps as in [30]. The domain where the system is linearly controllable could be, of course, larger than the subset E_0, but this will depend on the normal form.

Example 3. Consider the system

$$\left\{\begin{array}{rcl}\dot{z} &=& z + x_{1,1}x_{2,1},\\ \dot{x}_{1,1} &=& x_{1,2},\\ \dot{x}_{1,2} &=& x_{1,3},\\ \dot{x}_{1,3} &=& u_1,\\ \dot{x}_{2,1} &=& x_{2,2},\\ \dot{x}_{2,2} &=& u_2,\end{array}\right.$$

which is already in normal form. Its equilibria set is given by

$$E = \left\{\, (-x_{1,1}x_{2,1}, x_{1,1}, 0, 0, x_{2,1}, 0)^T \in \mathbb{R}^6 :\ (x_{1,1}, x_{2,1})^T \in \mathbb{R}^2 \,\right\}.$$

The system is not linearly controllable at the origin but it is at any other point of E. Indeed, put

$$f(z,x,u) = (z + x_{1,1}x_{2,1}, x_{1,2}, x_{1,3}, 0, x_{2,2}, 0)^T,$$

$$g_1(z,x,u) = (0,0,0,1,0,0)^T, \text{ and } g_2(z,x,u) = (0,0,0,0,0,1)^T.$$

(i) If $x_{1,1} \neq 0$, we have

$$\operatorname{span}\left\{\, g_1, ad_f g_1, ad_f^2 g_1, g_2, ad_f g_2, ad_f^2 g_2 \,\right\}(z,x) = \mathbb{R}^6$$

for all $(z,x) \neq (0,0)$ in E.

(ii) If $x_{2,1} \neq 0$, we have

$$\operatorname{span}\left\{\, g_1, ad_f g_1, ad_f^2 g_1, ad_f^3 g_1, g_2, ad_f g_2, \,\right\}(z,x) = \mathbb{R}^6$$

for all $(z,x) \neq (0,0)$ in E.

In this example the linear controllability occurs outside the subset E_0 for which we have $\bar{x}_{1,1} \neq 0$ and $\bar{x}_{2,1} \neq 0$.

However, if we replace $\dot{z} = z + x_{1,1}x_{2,1}$ by $\dot{z} = z + x_{1,1}^2 x_{2,1}^2$, then the linear controllability will occur only inside E_0.

4. Proofs of main results. The aim of this section is to prove Theorem 3.1. The proof of Corollary 3.2 is given in [42].

Consider the system $\Pi^{\leq d}$ defined by (2.1). Following [44] it is possible to show that the terms $f^{[0]}(z)$ and $f^{[1]}(z,x)$ can be removed. Thus, without loss of generality we will assume that the system $\Pi^{\leq d}$ is of the form

$$\Pi^{\leq d}: \begin{cases} \dot{z} = Jz + g^{[0]}(z) + \sum_{m=2}^{d} g^{[m-1]}(z,x,u) + O(z,x,u)^d, \\ \dot{x} = Ax + Bu + \sum_{m=2}^{d} f^{[m]}(z,x,u) + O(z,x,u)^{d+1}. \end{cases} \tag{4.1}$$

We like to study the action of the feedback transformation

$$\Upsilon^m: \begin{cases} \bar{z} &= z + \psi^{[m-1]}(z,x), \\ \bar{x} &= x + \phi^{[m]}(z,x), \\ u &= \bar{u} + \gamma^{[m]}(z,x,\bar{u}) \end{cases}$$

on the system $\Pi^{\leq d}$ up to some degree. First, remark that the inverse of this transformation is such that

$$\begin{cases} z &= \bar{z} - \psi^{[m-1]}(\bar{z},\bar{x}) + O(\bar{z},\bar{x})^m, \\ x &= \bar{x} - \phi^{[m]}(\bar{z},\bar{x}) + O(\bar{z},\bar{x})^{m+1}, \\ u &= \bar{u} + \gamma^{[m]}(\bar{z},\bar{x},\bar{u}) + O(\bar{z},\bar{x},\bar{u})^{m+1}. \end{cases}$$

Then the uncontrollable part is transformed as

$$\begin{aligned} \dot{\bar{z}} &= \dot{z} + \frac{\partial \psi^{[m-1]}}{\partial z}(z,x)\dot{z} + \frac{\partial \psi^{[m-1]}}{\partial x}(z,x)\dot{x} \\ &= Jz + g^{[0]}(z) + \cdots + g^{[m-1]}(z,x,u) + O(z,x,u)^m \\ &+ \frac{\partial \psi^{[m-1]}}{\partial z}(z,x)(Jz + g^{[0]}(z)) + \frac{\partial \psi^{[m-1]}}{\partial x}(z,x)(Ax + Bu) + O(z,x,u)^m \\ &= J\bar{z} + g^{[0]}(\bar{z}) + \cdots + g^{[m-1]}(\bar{z},\bar{x},\bar{u}) - \left(J + \frac{\partial g^{[0]}}{\partial z}(\bar{z})\right)\psi^{[m-1]}(\bar{z},\bar{x}) \\ &+ \frac{\partial \psi^{[m-1]}}{\partial z}(\bar{z},\bar{x})(J\bar{z} + g^{[0]}(\bar{z})) + \frac{\partial \psi^{[m-1]}}{\partial x}(\bar{z},\bar{x})(A\bar{x} + B\bar{u}) + O(\bar{z},\bar{x},\bar{u})^m. \end{aligned}$$

It clearly appears that the terms of degree $m-2$ or less of the uncontrollable part remain unmodified while the terms of degree $m-1$ or higher are modified.

Similarly, we can show that

$$\begin{aligned} \dot{\bar{x}} &= A\bar{x} + B\bar{u} + f^{[2]}(\bar{z},\bar{x},\bar{u}) + \cdots + f^{[m]}(\bar{z},\bar{x},\bar{u}) - A\phi^{[m]}(\bar{z},\bar{x}) - B\gamma^{[m]}(\bar{z},\bar{x},\bar{u}) \\ &+ \frac{\partial \phi^{[m]}}{\partial z}(\bar{z},\bar{x})(J\bar{z} + g^{[0]}(\bar{z})) + \frac{\partial \phi^{[m]}}{\partial x}(\bar{z},\bar{x})(A\bar{x} + B\bar{u}) + O(\bar{z},\bar{x},\bar{u})^{m+1}, \end{aligned}$$

which means that the terms of degree $m-1$ or less of the controllable part are preserved while the terms of degree m or higher are modified.

To study the action of the feedback transformation Υ^m on the terms of degree m (terms of degree $m-1$ of the uncontrollable part and of degree m for the controllable part) of the system $\Pi^{\leq d}$, it is enough to study their action on a *homogeneous system* of the form

$$\Pi^m: \begin{cases} \dot{z} = Jz + g^{[0]}(z) + g^{[m-1]}(z,x,u), \\ \dot{x} = Ax + Bu + f^{[m]}(z,x,u). \end{cases} \tag{4.2}$$

The proof of Theorem 3.1 will follow if we show that, by a feedback transformation Υ^m, we can take the system (4.2) into the normal form

$$\Pi^m_{NF}: \begin{cases} \dot{\bar{z}} = J\bar{z} + g^{[0]}(\bar{z}) + \bar{g}^{[m-1]}(\bar{z},\bar{x},\bar{u}), \\ \dot{\bar{x}} = A\bar{x} + B\bar{u} + \bar{f}^{[m]}(\bar{z},\bar{x},\bar{u}), \end{cases}$$

where the components of $\bar{g}^{[m-1]}(\bar{z},\bar{x},\bar{u})$ and $\bar{f}^{[m]}(\bar{z},\bar{x},\bar{u})$ are given by (3.1)–(3.3).

Indeed, if this is true we then consider the system $\Pi^{\leq d}$ of the form (4.1) and we first apply a quadratic feedback transformation Υ^2 to take it to the form

$$\Pi^{\leq d}: \begin{cases} \dot{\bar{z}} = J\bar{z} + g^{[0]}(\bar{z}) + \bar{g}^{[1]}(\bar{z},\bar{x},\bar{u}) + \sum\limits_{m=3}^{d} g^{[m-1]}(\bar{z},\bar{x},\bar{u}) + O(\bar{z},\bar{x},\bar{u})^d, \\ \dot{\bar{x}} = A\bar{x} + B\bar{u} + \bar{f}^{[2]}(\bar{z},\bar{x},\bar{u}) + \sum\limits_{m=3}^{d} f^{[m]}(\bar{z},\bar{x},\bar{u}) + O(\bar{z},\bar{x},\bar{u})^{d+1}, \end{cases}$$

where the vector fields $\bar{g}^{[1]}(\bar{z},\bar{x},\bar{u})$, and $\bar{f}^{[2]}(\bar{z},\bar{x},\bar{u})$ are in their normal forms, and the vector fields $g^{[m-1]}(\bar{z},\bar{x},\bar{u})$ and $f^{[m]}(\bar{z},\bar{x},\bar{u})$ stand for the new transformed vector fields. We thus apply a cubic transformation Υ^3 to take the system above into the form

$$\Pi^{\leq d}: \begin{cases} \dot{\bar{z}} = J\bar{z} + g^{[0]}(\bar{z}) + \bar{g}^{[1]}(\bar{z},\bar{x},\bar{u}) + \bar{g}^{[2]}(\bar{z},\bar{x},\bar{u}) + \sum\limits_{m=4}^{d} g^{[m-1]}(\bar{z},\bar{x},\bar{u}) + O(\bar{z},\bar{x},\bar{u})^d, \\ \dot{\bar{x}} = A\bar{x} + B\bar{u} + \bar{f}^{[2]}(\bar{z},\bar{x},\bar{u}) + \bar{f}^{[3]}(\bar{z},\bar{x},\bar{u}) + \sum\limits_{m=4}^{d} f^{[m]}(\bar{z},\bar{x},\bar{u}) + O(\bar{z},\bar{x},\bar{u})^{d+1}, \end{cases}$$

where $\bar{g}^{[1]}(\bar{z},\bar{x},\bar{u})$, $\bar{g}^{[2]}(\bar{z},\bar{x},\bar{u})$, $\bar{f}^{[2]}(\bar{z},\bar{x},\bar{u})$, and $\bar{f}^{[3]}(\bar{z},\bar{x},\bar{u})$ are in their normal forms. The vectors $g^{[m-1]}(\bar{z},\bar{x},\bar{u})$ and $f^{[m]}(\bar{z},\bar{x},\bar{u})$, for $m \geq 4$ are the new transformed vector fields. The process continues until the original system is in the desired normal form.

Proof of Theorem 3.1. As stated above, we need to prove that the homogeneous system $\Pi^{[m]}$ could be transformed into the normal form $\Pi^{[m]}_{NF}$ by a homogeneous transformation Υ^m. The proof will be divided into two parts. In the first part we will deal with the controllable mode and in the second part we will consider the uncontrollable mode.

(i) Consider the kth subsystem

$$\Pi^{k[m]}: \begin{cases} \dot{x}_{k,1} &= x_{k,2} + f_1^{k[m]}(z,x,u), \\ &\vdots \\ \dot{x}_{k,r-1} &= x_{k,r} + f_{r-1}^{k[m]}(z,x,u), \\ \dot{x}_{k,r} &= u_k. \end{cases}$$

Let us denote by $\mathfrak{P}^m(\mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p)$ the set of all homogeneous polynomials of degree m in the variables $(x,u) \in \mathbb{R}^{n-q} \times \mathbb{R}^p$ whose coefficients are functions of the variable $z \in \mathbb{R}^q$.

For a fixed j, $1 \leq j \leq r-1$ we define the set $\mathfrak{F}^m_j(\mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p)$ of all

homogeneous polynomials $h^{[m]}(z,x,v) \in \mathfrak{P}^m(\mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p)$ such that

$$h^{[m]}(z,x,v) = \sum_{1\le s\le t\le p} \sum_{i=j+2}^{r+1} x_{s,i}x_{t,i} P^{k[m-2]}_{j,i,s,t}(z, \pi^s_{t,i}(x)) + \sum_{1\le s<t\le p} \sum_{i=j+2}^{r+1} x_{s,i}x_{t,i-1} Q^{k[m-2]}_{j,i,s,t}(z, \pi^t_{t,i-1}(x)).$$

For simplicity we will just refer to $\mathfrak{P}^m(\mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p)$ and $\mathfrak{F}^m_j(\mathbb{R}^q \times \mathbb{R}^{n-q} \times \mathbb{R}^p)$ as $\mathfrak{P}^m$ and $\mathfrak{F}^m_j$, respectively. Denote by $\mathfrak{E}^m_j$ the subspace of $\mathfrak{P}^m$ so that

$$\mathfrak{P}^m = \mathfrak{F}^m_j \oplus \mathfrak{E}^m_j.$$

We want to prove that the subsystem $\Pi^{k[m]}$ could be transformed into the normal form

$$\Pi^{k[m]}_{NF} : \begin{cases} \dot{\bar{x}}_{k,1} &= \bar{x}_{k,2} + \bar{f}^{k[m]}_1(\bar{z},\bar{x},\bar{u}), \\ &\vdots \\ \dot{\bar{x}}_{k,r-1} &= \bar{x}_{k,r} + \bar{f}^{k[m]}_{r-1}(\bar{z},\bar{x},\bar{u}), \\ \dot{\bar{x}}_{k,r} &= \bar{u}_k, \end{cases}$$

where for any $1 \le j \le r-1$, the homogeneous polynomial $\bar{f}^{k[m]}_j(\bar{z},\bar{x},\bar{u})$ is of the form (3.3). Assume that the first $j-1$ components $f^{k[m]}_1(z,x,u), \dots, f^{k[m]}_{j-1}(z,x,u)$ of $\Pi^{k[m]}$ are already in their normal forms and let us focus exclusively on the jth component $f^{k[m]}_j(z,x,u)$.

Since $f^{k[m]}_j(z,x,u) \in \mathfrak{P}^m$, it decomposes uniquely as

$$f^{k[m]}_j(z,x,u) = \bar{f}^{k[m]}_j(z,x,u) + \tilde{f}^{k[m]}_j(z,x,u),$$

where $\bar{f}^{k[m]}_j(z,x,u) \in \mathfrak{F}^m_j$ and $\tilde{f}^{k[m]}_j(z,x,u) \in \mathfrak{E}^m_j$. We may remark that $\tilde{f}^{k[m]}_j(z,x,u)$ is necessarily affine in u; otherwise its projection on $\mathfrak{F}^m_j$ will not be zero.

We may also suppose that $\tilde{f}^{k[m]}_j(z,x,u)$ doesn't depend on u. Indeed, if

$$\tilde{f}^{k[m]}_j(z,x,u) = \sum_{t=1}^{p} u_t R^{k[m-1]}_{j,t}(z,x) + \hat{f}^{k[m]}_j(z,x)$$

it suffices to take the change of variable

$$\bar{x}_{k,j} = x_{k,j} - \sum_{1\le t\le p} \int_0^{x_{t,r}} R^{k[m-1]}_{j,t}(z,x)d\epsilon,$$

to get rid of those terms that depend on u. Of course, in order for the integral to make sense, the variable $x_{t,r}$ of the polynomial $R^{k[m-1]}_{j,t}(z,x)$ will be replaced by the parameter of integration ϵ.

Now, if we assume that $\tilde{f}^{k[m]}_j(z,x,u)$ doesn't depend on u, it suffices to take the change of coordinates

$$\bar{x}_{k,j+1} = x_{k,j+1} + \tilde{f}^{k[m]}_j(z,x)$$

to get the jth component $f_j^{k[m]}(z,x,u)$ into its normal form. As we now see, the procedure didn't modify the previous $j-1$ components because the change of coordinates involves only the variables $x_{k,j}$ and $x_{k,j+1}$, which didn't appear *linearly* in these components. For the same reason, it doesn't modify the other subsystems. This ends the proof of this part.

(ii) (a) The proof of this part will be done by induction. Consider the subsystem

$$\Pi^{[m-1]} \ : \ \dot{z} = Jz + g^{[0]}(z) + g^{[m-1]}(z,x,u) \tag{4.3}$$

with $m \geq 3$ and assume that for some $2 \leq l \leq r$, this system has been transformed so that

$$g^{[m-1]}(z,x,u) = \tilde{g}^{[m-1]}(z,x,u) + \hat{g}^{[m-1]}(z,x,u),$$

where for any $1 \leq j \leq q$ we have

$$\begin{aligned}\tilde{g}_j^{[m-1]}(z,x,u) = &\sum_{1\leq s\leq t\leq p} \sum_{i=l+1}^{r+1} x_{s,i}x_{t,i}P_{j,i,s,t}^{[m-3]}(z,\pi_{t,i}^s(x)) \\ &+ \sum_{1\leq s<t\leq p} \sum_{i=l+1}^{r+1} x_{s,i}x_{t,i-1}Q_{j,i,s,t}^{[m-3]}(z,\pi_{t,i-1}^t(x))\end{aligned}$$

and $\hat{g}^{[m-1]}(z,x,u)$ depends only on the variables z and $x_{s,1},\ldots,x_{s,l}$ for $1 \leq s \leq p$. We emphasize here that $\hat{g}^{[m-1]}(z,x,u)$ doesn't depend on any variable $x_{s,k}$ for $k \geq l+1$.

Each component of $\hat{g}^{[m-1]}(z,x,u)$ could be uniquely decomposed as follows:

$$\begin{aligned}\hat{g}_j^{[m-1]}(z,x,u) = &\sum_{1\leq s\leq t\leq p} x_{s,l}x_{t,l}P_{j,l,s,t}^{[m-3]}(z,\pi_{t,l}^s(x)) \\ &+ \sum_{1\leq s<t\leq p} x_{s,l}x_{t,l-1}Q_{j,l,s,t}^{[m-3]}(z,\pi_{t,l-1}^t(x)) \\ &+ \sum_{1\leq t\leq p} x_{t,l}R_{j,l,t}^{[m-2]}(z,x) + S_{j,l}^{[m-1]}(z,x),\end{aligned}$$

where the polynomials $R_{j,l,t}^{[m-2]}(z,x)$ and $S_{j,l}^{[m-1]}(z,x)$ depend only on the variables z and $x_{s,1},\ldots,x_{s,l-1}$ for $1 \leq s \leq p$.

It then suffices to apply the change of variables given, for any $1 \leq j \leq q$, by

$$\bar{z}_j = z_j - \sum_{1\leq t\leq p} \int_0^{x_{t,l-1}} R_{j,l,t}^{[m-2]}(z,x)d\epsilon,$$

to get rid of the terms $\sum 1 \leq t \leq p x_{t,l}R_{j,l,t}^{[m-2]}(z,x)$. For the need of the integral we replace the variable $x_{t,l-1}$ in $R_{j,l,t}^{[m-2]}(z,x)$ by the parameter of integration ϵ.

This means that we transform the subsystem (4.3) into the form

$$\Pi^{[m-1]} \ : \ \dot{\bar{z}} = J\bar{z} + g^{[0]}(\bar{z}) + g^{[m-1]}(\bar{z},\bar{x},\bar{u})$$

with

$$g^{[m-1]}(\bar{z},\bar{x},\bar{u}) = \tilde{g}^{[m-1]}(\bar{z},\bar{x},\bar{u}) + \hat{g}^{[m-1]}(\bar{z},\bar{x},\bar{u}),$$

where for any $1 \leq j \leq q$ we have

$$\tilde{g}_j^{[m-1]}(\bar{z},\bar{x},\bar{u}) = \sum_{1\leq s\leq t\leq p}\sum_{i=l}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i}P_{j,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i}^{s}(\bar{x})) + \sum_{1\leq s<t\leq p}\sum_{i=l}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1}Q_{j,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i-1}^{t}(\bar{x}))$$

and $\hat{g}^{[m-1]}(\bar{z},\bar{x},\bar{u})$ depends only on the variables $\bar{z}$ and $\bar{x}_{s,1},\ldots,\bar{x}_{s,l-1}$ for $1 \leq s \leq p$. This proves the induction argument. If we take $l = 2$, then $\hat{g}^{[m-1]}(\bar{z},\bar{x},\bar{u})$ will depend only on the variables $\bar{z}$ and $\bar{x}_{s,1}$ for $1 \leq s \leq p$, which means that

$$\hat{g}^{[m-1]}(\bar{z},\bar{x},\bar{u}) = \sum_{1\leq s\leq t\leq p} \bar{x}_{s,1}\bar{x}_{t,1}P_{j,1,s,t}^{[m-3]}(z,\pi_{t,1}^{s}(x)).$$

We thus deduce that

$$g_j^{[m-1]}(\bar{z},\bar{x},\bar{u}) = \sum_{1\leq s\leq t\leq p}\sum_{i=1}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i}P_{j,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i}^{s}(\bar{x})) + \sum_{1\leq s<t\leq p}\sum_{i=2}^{r+1} \bar{x}_{s,i}\bar{x}_{t,i-1}Q_{j,i,s,t}^{[m-3]}(\bar{z},\pi_{t,i-1}^{t}(\bar{x}))$$

and this achieves the proof of this part.

(ii)(b) When $m = 2$, the homogeneous vector field $g^{[m-1]}(z,x,u)$ is linear with respect to the variables x and u, that is,

$$g^{[m-1]}(z,x,u) = \sum_{1\leq t\leq p}\sum_{i=1}^{r+1} x_{t,i}P_{i,t}^{[0]}(z),$$

where $P_{i,t}^{[0]}(z) = \big(P_{1,i,t}^{[0]}(z),\ldots,P_{q,i,t}^{[0]}(z)\big)^T$ is a vector field that depends exclusively on the variable z.

The method is to apply first a change of coordinates of the form

$$\tilde{z} = z - \sum_{1\leq t\leq p} x_{t,r}P_{r+1,t}^{[0]}(z)$$

to annihilate the terms

$$\sum_{1\leq t\leq p} x_{t,r+1}P_{r+1,t}^{[0]}(z) = \sum_{1\leq t\leq p} u_t P_{r+1,t}^{[0]}(z).$$

Then, apply a change of coordinates of the form

$$\bar{z} = \tilde{z} - \sum_{1\leq t\leq p} x_{t,r-1}\tilde{P}_{r,t}^{[0]}(\tilde{z})$$

to annihilate the terms

$$\sum_{1\leq t\leq p} x_{t,r}\tilde{P}_{j,r,t}^{[0]}(\tilde{z}),$$

where $\tilde{P}^{[0]}_{j,r,t}(\tilde{z})$ denotes the new terms obtained after the first change of coordinates.

We keep applying this method until we get

$$g^{[1]}(z,x,u) = \sum_{1\le t\le p} x_{t,1} P^{[0]}_{1,t}(z).$$

This completes the proof of item (ii) and that of the theorem. ∎

AN OUTER APPROXIMATION METHOD FOR THE VARIATIONAL INEQUALITY PROBLEM*

R. S. BURACHIK†, J. O. LOPES†, AND B. F. SVAITER‡

Abstract. We study two outer approximation schemes, applied to the variational inequality problem in reflexive Banach spaces. First we propose a generic outer approximation scheme, and its convergence analysis unifies a wide class of outer approximation methods applied to the constrained optimization problem. As is standard in this setting, boundedness and optimality of weak limit points are proved to hold under two alternative conditions: (i) boundedness of the feasible set, or (ii) coerciveness of the operator. To develop a convergence analysis where (i) and (ii) do not hold, we consider a second scheme in which the approximated subproblems use a coercive approximation of the original operator. Under conditions alternative to both (i) and (ii), we obtain standard convergence results. Furthermore, when the space is uniformly convex, we establish full strong convergence of the second scheme to a solution.

Key words. maximal monotone operators, Banach spaces, outer approximation algorithm, semi-infinite programs

1. Introduction.

We investigate a broad class of outer approximation methods for solving the classical monotone variational inequality problem in a reflexive Banach space. First we recall this problem and then we describe those methods. Let B be a real reflexive Banach space with dual B^*. The notation $\langle v, x\rangle$ stands for the duality product $v(x)$ of $v \in B^*$ and $x \in B$. Given $T\colon B \rightrightarrows B^*$ a maximal monotone operator and $\Omega \subset B$ a nonempty closed and convex set, the *variational inequality problem* for T and Ω, $VIP(T, \Omega)$ is as follows. Find x^* such that

$$x^* \in \Omega,\ \exists\ u^* \in T(x^*):\ \ \langle u^*, x - x^*\rangle \geq 0\ \forall\ x \in \Omega. \tag{1.1}$$

The set Ω will be called the *feasible set* for problem (1.1). In the particular case in which T is the subdifferential of a proper, convex, and lower semicontinuous function $f\colon B \longrightarrow \mathbb{R} \cup \{+\infty\}$, problem (1.1) reduces to the *convex optimization problem*:

$$\min_{x\in\Omega} f(x). \tag{1.2}$$

Outer approximation methods solve problem (1.1) by generating and solving a sequence of problems with feasible sets Ω^k which contain the original feasible set Ω but have a simpler structure. These methods were introduced for solving optimization problems four decades ago in the form of cutting plane methods [10, 32].

Outer approximation schemes typically arise when the set Ω is of the form $\Omega = \cap_{y\in Y}\Omega_y$, where Y is infinite and $\Omega_y := \{x \in B \mid g(x,y) \leq 0\}$ with each $g(\cdot,y) : B \to \mathbb{R}$. Feasible sets of this kind appear in several areas of applications (see, e.g., [23, 22, 17, 13, 3, 19]). In this situation, a common choice is to replace the feasible set of the original problem by $\Omega^k := \cap_{y\in Y^k}\Omega_y = \{x \in B \mid g(x,y) \leq 0\, \forall\, y \in Y^k\}$, where $Y^k \subset Y$ is finite and conveniently chosen.

For this kind of Ω, outer approximation methods for problem (1.2) are classified according to the way in which the sets $\Omega^k \supset \Omega = \cap_{y\in Y}\Omega_y$ are defined. We mention here *cutoff* methods (e.g., those in [10, 28, 32, 45, 48] for $B = \mathbb{R}^n$), *filtered* cutoff methods (e.g., those in [2, 14, 16, 43, 44] for $B = \mathbb{R}^n$), and *disintegration schemes* [20], like the ones proposed in [12, 21, 36, 38, 39] for the minimization of quadratic functions in Hilbert spaces and extended in [33] to the minimization of a convex function in a Banach space. Recently, Combettes gave in [11] a unified convergence analysis which includes and extends all the above-mentioned outer approximation methods. A basic assumption for obtaining convergence of these methods is that either all sets Ω^k are contained in some bounded set or some coerciveness property of the objective function f. These *boundedness* assumptions are a standard requirement in the analysis of all the mentioned methods. (See the excellent surveys [40, 24] and references therein.) The goal for the present work is twofold. First, we develop a convergence analysis which can be applied to more general and flexible schemes for successive approximation of variational inequalities, under the standard boundedness assumptions. Our analysis covers as a particular case the outer approximation scheme studied in [11] for problem (1.2) (and hence all the above-mentioned algorithms). We prove that our generic scheme generates a bounded sequence and that all weak accumulation points are solutions of $VIP(T,\Omega)$. Second, we obtain the same convergence results in the absence of boundedness assumptions. For doing this, we consider subproblems (P_k), where the original operator is replaced by a suitable coercive regularization. Our work is built around the following generic outer approximation scheme for solving $VIP(T,\Omega)$.

ALGORITHM.

Initialization. Take $\Omega^1 \supseteq \Omega$,

Iterations. For $k = 1, 2, \ldots$, find $x^k \in \Omega^k$, a solution of the approximated problem (P_k), defined as

$$\exists\, u^k \in T(x^k) \quad \text{with} \tag{1.3}$$

$$\langle u^k, x - x^k\rangle \geq 0 \forall\, x \in \Omega^k. \tag{1.4}$$

In our first generic scheme we relax the inequality in (1.4). Namely, the iterate $x^k \in \Omega^k$ is taken such that

$$\exists\, u^k \in T(x^k) \;\text{ with } \langle u^k, x - x^k\rangle \geq -\varepsilon_k \;\forall\; x \in \Omega^k, \tag{1.5}$$

where $\varepsilon_k > 0$ and $\Omega^k \supset \Omega$ is convex and closed. In the second scheme, we relax (1.3). More precisely, the approximate solution $x^k \in \Omega^k$ is such that

$$\exists\, u^k \in T_{\lambda_k}(x^k) \;\text{ with } \langle u^k, x - x^k\rangle \geq 0 \;\forall\; x \in \Omega^k, \tag{1.6}$$

where $\lambda_k > 0$, $\Omega^k \supset \Omega$ is closed and convex and T_{λ_k} is a suitable coercive approximation of T. Schemes in which the approximated subproblems use a coercive regularization of T are a common approach for solving noncoercive variational inequalities. Two classical examples of these are *proximal-like* regularizations (see, e.g., [29, 30])

and Tikhonov regularizations [42, 18]. The latter kind of regularization has been extensively studied in the last two decades (see [34] and the references therein). Mosco [35] studied the convergence of what is now called the Mosco scheme, which combines the Tikhonov regularization with a perturbation of the feasible set. This approach is followed in [34], where, as in [35, section 5], the approximating feasible sets are assumed to converge in the sense of set-convergence to the original feasible set. In [34], the authors studied variational inequalities in Hilbert spaces and the operator T is assumed to be point-to-point.

Classical application of all these approximating schemes is in perturbation theory of variational boundary value problems for the operator T. (See, e.g., problems (p') and (p'_n) and Corollary 1 in [35, pp. 555–556].)

The paper is organized as follows. Section 2 contains some theoretical preliminaries which are necessary for our analysis. In section 3 we give a unified analysis for a broad family of outer approximation algorithms, in which the iterates solve problem (1.5). We prove existence of this sequence and establish optimality of all weak accumulation points under standard boundedness assumptions. In section 4 we relax the boundedness assumptions and consider a sequence $\{x^k\}$ as in (1.6). Under suitable assumptions, we prove that the iterates are bounded and all its accumulation points are optimal. Moreover, we establish strong convergence of the whole sequence to a solution when B is uniformly convex.

2. Theoretical preliminaries. From now on B is a real Banach space. Let $T\colon B \rightrightarrows B^*$ be an arbitrary point-to-set operator. We recall some basic definitions:

- domain of T, $D(T) := \{x \in B \,|\, T(x) \neq \emptyset\}$;
- graph of T, $G(T) := \{(x,u) \in B \times B^* \,|\, u \in T(x)\}$;
- range of T, $R(T) := \{u \in B^* \,|\, u \in T(x) \text{ for some } x \in B\}$;
- the operator T is *monotone* if for all $x, y \in B$, $u \in T(x)$, and $v \in T(y)$,

$$\langle u - v, x - y\rangle \geq 0;$$

  if this inequality holds strictly whenever $x, y \in B$, $u \in T(x)$, $v \in T(y)$, and $x \neq y$, then T is *strictly monotone*;
- the operator T is *maximal monotone* if it is monotone and for any monotone $\tilde{T}\colon B \rightrightarrows B^*$, $G(T) \subset G(\tilde{T}) \Rightarrow T = \tilde{T}$.

An example of maximal monotone operator is the *normality operator*. Let $\Omega \subset B$ be closed, convex, and nonempty.

- The normality operator of Ω is $N_\Omega\colon B \rightrightarrows B^*$,

$$N_\Omega(x) = \begin{cases} \{u \in B^* | \langle u, z - x\rangle \leq\ 0\ \forall z \in \Omega\} & \text{if } x \in \Omega, \\ \emptyset & \text{otherwise.} \end{cases}$$

Maximal monotonicity of N_Ω follows from Ω being closed, convex, and nonempty.

It is easy to verify that $VIP(T, \Omega)$, as defined in (1.1), is equivalent to the inclusion problem (or generalized equation): Find x^* such that

$$0 \in (T + N_\Omega)(x^*).$$

If $T + N_\Omega$ is onto, then this problem, and hence $VIP(T, \Omega)$, has a solution. In this paper, existence of solutions of variational inequality problems will be based on surjectivity of sums of maximal monotone operators. The following definitions will be needed.

DEFINITION 2.1 ((see [37])). *An operator $T: B \rightrightarrows B^*$ is*

1. coercive *if $D(T)$ is bounded or for any $x \in D(T)$,*

$$\lim_{\|z\| \to +\infty} \langle v, z - x\rangle / \|z\| = +\infty \text{ holds for each selection } v \in T(z);$$

2. regular *if for any $y \in D(T)$ and $u \in R(T)$*

$$\sup_{(z,v) \in G(T)} \langle v - u, y - z\rangle < \infty.$$

The next proposition will be used for establishing existence of solutions of the subproblems (P_k).

PROPOSITION 2.2 (see [8, Lemma 2.7]). *Suppose that B is reflexive. Let $T_1, T_2: B \rightrightarrows B^*$ be maximal monotone operators such that*

(a) *$T_1 + T_2$ is maximal monotone;*

(b) *T_1 is regular and onto. Then $T_1 + T_2$ is onto.*

To establish condition (a) of the above proposition we will use a classical theorem, due to Rockafellar [41]. Denote by $\text{int}(A)$ the topological interior of the set A.

PROPOSITION 2.3 (see [41, Theorem 1]). *Suppose that B is reflexive. Let $T_1, T_2: B \rightrightarrows B^*$ maximal monotone operators . If $D(T_1) \cap \text{int}(D(T_2)) \neq \emptyset$, then $T_1 + T_2$ is a maximal monotone operator.*

To check for condition (b) of Proposition 2.2, we will need two auxiliary results.

THEOREM 2.4 (see [4, p. 147]). *Suppose that B is reflexive. Let $T: B \rightrightarrows B^*$ be a maximal monotone operator. If T is coercive (in particular, if $D(T)$ is bounded), then T is surjective.*

The fact stated next relates the two concepts given in Definition 2.1.

THEOREM 2.5 (see [37, p. 122]). *Let $T: B \rightrightarrows B^*$ be a monotone operator. If T is coercive, then T is regular.*

The discussion of the maximality of monotone operators and their surjective properties requires the introduction of duality maps. Asplund [1] showed that when B is a reflexive Banach space, there exists an equivalent norm on B which is everywhere Gâteaux differentiable except at the origin and such that the corresponding dual norm on B^* is also everywhere Gâteaux differentiable except at the origin.

From now on, we assume that B is a *reflexive* real Banach space. For simplifying the notation, we also assume that the given norm on B already has these special properties. We use the same notation $\|\cdot\|$ for this norm on B and its associated norm on the dual B^*. Denote by J the Gâteaux gradient of the function $\varphi(x) := (1/2)\|x\|^2$. Thus, J is the *duality mapping*, which assigns to each $x \in B$ the unique $J(x) \in B^*$ such that

$$\langle x, J(x)\rangle = \|x\|^2 = \|J(x)\|^2. \tag{2.1}$$

PROPOSITION 2.6. *Let $J: B \to B^*$ be the duality mapping described above. The following assertions hold:*

(i) *$J(-x) = -J(x)$ and $J(\lambda x) = \lambda J(x)$ $\forall \lambda > 0$.*

(ii) *Let $w = J(x)$; then $\langle w, z - x\rangle \leq \frac{1}{2}(\|z\|^2 - \|x\|^2)$ $\forall z \in B$.*

(iii) *If $\widetilde{T}$ is maximal monotone, then $\forall \lambda > 0$, $\widetilde{T} + \lambda J$ is maximal monotone and onto, and $(\widetilde{T} + \lambda J)^{-1}$ is a single-valued and maximal monotone operator.*

Proof. Item (i) follows from (2.1), and (ii) uses the fact that $J(\cdot) = \partial(\frac{1}{2}\|\cdot\|^2)$. To prove (iii), note that Proposition 2.3 implies maximal monotonicity of $\widetilde{T} + \lambda J$. The

surjectivity of $\widetilde{T} + \lambda J$ and the assertion on $(\widetilde{T} + \lambda J)^{-1}$ follow from [41, Proposition 1]. □

Our convergence theorems require two conditions on the operator T, namely, para- and pseudomotonicity, which we discuss next. The notion of paramonotonicity was introduced in [7] and further studied in [9, 26]. It is defined as follows.

DEFINITION 2.7. *The operator T is* paramonotone *in Ω if it is monotone and $\langle v-u, y-z\rangle = 0$ with $y, z \in \Omega$, $v \in T(y), u \in T(z)$ implies that $u \in T(y), v \in T(z)$. The operator T is* paramonotone *if this property holds in the whole space.*

PROPOSITION 2.8 ((see [26, Proposition 4])). *Assume that T is paramonotone on Ω and $\overline{x}$ is a solution of $VIP(T, \Omega)$. Let $x^* \in \Omega$ be such that there exists an element $u^* \in T(x^*)$ with $\langle u^*, x^* - \overline{x}\rangle \leq 0$. Then x^* also solves $VIP(T, \Omega)$.* Paramonotonicity can be seen a condition which is weaker than strict monotonicity. The remark below contains some examples of operators which are paramonotone.

Remark 2.9. If T is the subdifferential of a convex function $f : B \to \mathbb{R} \cup \{\infty\}$, then T is paramonotone. When $B = \mathbb{R}^n$, a condition which guarantees paramonotonicity of $T : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is when T is differentiable and the symmetrization of its Jacobian matrix has the same rank as the Jacobian matrix itself. However, relevant operators fail to satisfy this condition. More precisely, the *saddle-point operator* $\mathbf{\Lambda}(x, y) := (\partial_x L(x, y), -\partial_y L(x, y))$, where L is the Lagrangian associated to a constrained convex optimization problem, is not paramonotone, except in trivial instances. For more details on paramonotone operators see [26].

Next we recall the definition of pseudomonotonicity, which was taken from [6] and should not be confused with other uses of the same word (see, e.g., [31]).

DEFINITION 2.10. *Let B be a reflexive Banach space and the operator T such that $D(T)$ is closed and convex. T is said to be* pseudomonotone *if it satisfies the following condition. If the sequence $\{(x^k, u^k)\} \subset G(T)$ satisfies that*

(a) *$\{x^k\}$ converges weakly to $x^* \in D(T)$,*

(b) *$\limsup_k \langle u^k, x^k - x^*\rangle \leq 0$,*

then for every $w \in D(T)$ there exists an element $u^* \in T(x^*)$ such that

$$\langle u^*, x^* - w\rangle \leq \liminf_k \langle u^k, x^k - w\rangle.$$

Remark 2.11. If T is the gradient of a Gâteaux differentiable convex function $\varphi : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$, then T is pseudomonotone. Indeed, using a fact proved in [37, p. 94], it holds that $\nabla\varphi$ is *hemicontinuous* (i.e., for every fixed $x, y \in \mathbb{R}^n$, the real-valued mapping $t \mapsto \langle \nabla\varphi((1-t)x + ty), x - y\rangle$ is continuous). On the other hand, point-to-point hemicontinuous operators defined on $\mathbb{R}^n$ are always pseudomonotone (see e.g., [37, p. 107]), which yields $T = \nabla\varphi$ pseudomonotone, as claimed. Combining the latter statement with Remark 2.9, we conclude that every T of this kind is both para- and pseudomonotone. An example of a nonstrictly monotone operator which is both para- and pseudomonotone is the subdifferential of the function $\varphi : \mathbb{R} \to \mathbb{R}$ defined by $\varphi(t) = |t|$ for all t.

DEFINITION 2.12 (see [5, p. 51]). *We say that B is* uniformly convex *if $\forall\ \varepsilon > 0\ \exists\ \delta > 0$ such that*

$$\forall\ x, y \in B, \|x\| \leq 1, \|y\| \leq 1 \text{ and } \|x - y\| > \varepsilon \ \Rightarrow\ \left\|\frac{x+y}{2}\right\| < 1 - \delta.$$

PROPOSITION 2.13 (see [5, Proposition III.30]). *Assume that B is uniformly convex and that $\{y^k\}$ is a sequence converging weakly to y^*. Suppose further that $\limsup \|y^k\| \leq \|y^*\|$; then $\{y^k\}$ converges strongly to y^*.*

3. A general outer approximation scheme for $VIP(T,\Omega)$. Let $\Omega \subset B$ be a nonempty closed and convex set and let $T\colon B \rightrightarrows B^*$ be a maximal monotone operator. In this section we present a unified convergence analysis of a general and flexible scheme for successive approximation of variational inequalities. Recall that $VIP(T,\Omega)$ is defined by

$$\begin{aligned} &\text{find } x^* \in \Omega \text{ such that there exists } u^* \in T(x^*) \text{ with} \\ &\langle u^*, x - x^* \rangle \geq 0 \ \forall\, x \in \Omega. \end{aligned} \tag{3.1}$$

To present a convergence analysis which can be applied to a wide family of outer approximation schemes, we fix a sequence $\{\Omega^k\}$ of convex closed subsets of B and a sequence $\{\varepsilon_k\} \subset \mathbb{R}_+ := \{t \in \mathbb{R} \,:\, t \geq 0\}$ verifying

(i) $\Omega \subset \Omega^k$ for all k,

(ii) $\lim_k \varepsilon_k = 0$.

These sequences define our approximating problems. Namely, given Ω^k and ε_k, define the *kth approximating problem* as

$$(P_k) \qquad \begin{cases} \text{find } x^k \in \Omega^k \text{ such that there exists } u^k \in T(x^k) \text{ with} \\ \langle u^k, x - x^k \rangle \geq -\varepsilon_k \ \ \forall\, x \in \Omega^k. \end{cases}$$

Definition 3.1. *Fix $\{\Omega^k\}$ and $\{\varepsilon_k\}$ as in* (i) *and* (ii).

(a) *A sequence $\{x^k\}$ will be called an* orbit *when x^k solves (P_k) for all k.*

(b) *An orbit $\{x^k\}$ will be called* asymptotically feasible *(AF, for short) when all weak accumulation points of $\{x^k\}$ belong to Ω.*

Example 1. A broad family of outer approximation methods for the convex constrained optimization problem (1.2) generates AF orbits. This is shown in [11], where the author provides a unified convergence analysis for a wide class of outer approximation schemes devised for problem (1.2). The feasible set considered in [11] is explicitly defined in the form

$$\Omega := \{x \in B \mid g(x,y) \leq 0 \ \forall\, y \in Y\}, \tag{3.2}$$

where Y is an arbitrary set of indexes and the constraint functions $g(\cdot,y)\colon B \longrightarrow \mathbb{R} \cup \{+\infty\}$ satisfy the basic assumptions:

(G_1) $\{x \in B \mid g(x,y) \leq 0\}$ is nonempty and convex for all $y \in Y$.

(G_2) For all $y \in Y$ and for very sequence $\{z^k\} \subset B$ such that

$$\begin{cases} w - \lim_k z^k = z \\ \limsup_k g(z^k, y) \leq 0, \end{cases} \quad \Longrightarrow \quad g(z,y) \leq 0,$$

where $w-\lim$ stands for weak limit in B. In [11] $T = \partial f$, where f is lower semicontinuous, convex, and verifies the following assumptions:

(F_1) For some closed convex set $E \supset \Omega$, there exists a point $u \in \mathrm{dom} f \cap \Omega$ such that the set $C := \{x \in E \mid f(x) \leq f(u)\}$ is bounded.

(F_2) f is *uniformly convex with modulus of convexity c* on C, i.e., [46, 47]

$$\text{for all } x,y \in C, \quad f\left(\frac{x+y}{2}\right) \leq \frac{f(x)+f(y)}{2} - c\left(\|x-y\|\right), \tag{3.3}$$

where $c : \mathbb{R}_+ \to \mathbb{R}_+$ is nondecreasing and $(\forall\, \tau \in \mathbb{R})$ $c(\tau) = 0 \Leftrightarrow \tau = 0$. The outer approximation scheme studied in [11, Algorithm 1.1] has for kth approximating problem the minimization of f in a set $\Omega^k \supset \Omega$. Hence this (P_k) verifies conditions

(i) and (ii), where $T = \partial f$ and $\varepsilon_k = 0$ for all k. As a conclusion, [11, Algorithm 1.1] also generates an orbit in the sense of Definition 3.1(a). Therefore, our approach contains the methods extended by [11, Algorithm 1.1]. The analysis presented in [11] establishes conditions under which [11, Algorithm 1.1] generates an AF orbit. However, assumptions (F_1) and (F_2) force every AF orbit to converge strongly to the unique solution of (1.2). See also [40, Theorem 4.1], where other methods (from the family of cutting plane methods [10] for the convex semi-infinite programming problem) are proved to generate AF orbits. When the objective and constraint functions are smooth, a family of schemes which generates AF orbits is found in [24, Theorem 7.2]. Throughout our work we consider the following assumptions:

(H_1) $D(T) \cap \operatorname{int}(\Omega) \neq \emptyset$ or $\operatorname{int}(D(T)) \cap \Omega \neq \emptyset$.

(H_2) T paramonotone and pseudomonotone with closed domain.

(H_3) The solution set S^* of $VIP(T, \Omega)$ is nonempty.

For the case in which the feasible set Ω is given as in (3.2), we will assume that the set Y and the function $g\colon B \times Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ satisfy the following assumptions:

(G_1) Y is a weakly compact set contained in a reflexive Banach space.

(G_2) $g(\cdot, y)$ is a proper, lower semicontinuous and convex function $\forall y \in Y$.

(G_3) g is weakly continuous on $B \times Y$.

A relevant question regarding AF orbits is which extra conditions guarantee optimality of all weak accumulation points. In our analysis, we use the assumption of para- and pseudomonotonicity (see Remarks 2.9 and 2.11).

LEMMA 3.2. *Let $\{x^k\}$ be an* AF *orbit for $VIP(T, \Omega)$. If (H_2) and (H_3) hold, then every weak accumulation point of $\{x^k\}$ is a solution of $VIP(T, \Omega)$.*

Proof. Assume that x^* is a weak accumulation point of $\{x^k\}$. Then, there exists a subsequence $\{x^{k_j}\}$ converging (weakly) to x^*. For each j, x^{k_j} solves (P_{k_j}), and therefore, there exists $u^{k_j} \in T(x^{k_j})$ such that

$$\langle u^{k_j}, x^{k_j} - x \rangle \leq \varepsilon_{k_j} \ \forall x \in \Omega^{k_j} \text{ and } \forall k_j.$$

Then by (i) we have

$$\langle u^{k_j}, x^{k_j} - x \rangle \leq \varepsilon_{k_j} \ \forall x \in \Omega \text{ and } \forall k_j. \tag{3.4}$$

Since $\{x^k\}$ is AF, $x^* \in \Omega$ and hence

$$\langle u^{k_j}, x^{k_j} - x^* \rangle \leq \varepsilon_{k_j} \quad \forall k_j.$$

Using also (ii) we have

$$\limsup_j \langle u^{k_j}, x^{k_j} - x^* \rangle \leq \limsup_j \varepsilon_{k_j} = 0. \tag{3.5}$$

Take $\overline{x} \in S^*$. By pseudomonotonicity of T, we conclude that there exists $u^* \in T(x^*)$ such that

$$\liminf_j \langle u^{k_j}, x^{k_j} - \overline{x} \rangle \geq \langle u^*, x^* - \overline{x} \rangle.$$

Since $\overline{x} \in \Omega$, (3.4) implies that

$$\liminf_j \langle u^{k_j}, x^{k_j} - \overline{x} \rangle \leq \liminf_j \varepsilon_{k_j} = 0.$$

Combining the last two inequalities we have that

$$\langle u^*, x^* - \overline{x} \rangle \leq 0.$$

Finally, by paramonotonicity of T and Proposition 2.8 we conclude that x^* is a solution of the $VIP(T,\Omega)$. ∎

We saw in Example 1 that many well-known outer approximation schemes for the convex constrained problem solve the subproblems (P_k) exactly, i.e., with $\varepsilon_k = 0$ for all k. Thus a relevant question is whether problem (P_k) admits an *exact* solution.

PROPOSITION 3.3. *Assume (H_1) holds and suppose that one of the following assumptions holds:*

(a) *There is a bounded set K such that $K \supset \Omega^k$ for all k.*

(b) *T is coercive.*

Then every (P_k) admits an exact solution.

Proof. Define the operator $T_k{=}T + N_{\Omega^k}$. For all k it holds that

(1) $D(T_k) = D(T) \cap D(N_{\Omega^k}) = D(T) \cap \Omega^k \neq \emptyset$ by (H_1) and (i).

(2) $T_k = T + N_{\Omega^k}$ is maximal monotone by (H_1) and Proposition 2.3. If (a) holds, then by (1) and (i), $D(T_k)$ is bounded; thus T_k is onto by Theorem 2.4. This implies that (P_k) admits an exact solution in this case. Now suppose that T is coercive. In this case, T is regular by Theorem 2.5. On the other hand, $R(T) = B^*$ by Theorem 2.4. Since (2) holds, it follows from Proposition 2.2 that T_k is onto. Thus (P_k) has a solution. ∎

Now we are in position to present our first convergence result. We point out that this result is an extension to $VIP(T,\Omega)$ of, e.g., [2, Theorem 2.1], [11, Proposition 3.1(i)], [24, Theorem 7.2], and [40, Theorem 4.1].

THEOREM 3.4. *Let the sequence $\{x^k\}$ be an* AF *orbit. Assume that (H_2) and (H_3) hold. If one of the conditions*

(a) *there exists $\overline{\Omega}$ a bounded set such that $\overline{\Omega} \supset \Omega^k$ for all k, or*

(b) *T is coercive*

holds, then $\{x^k\}$ is bounded and each accumulation point is a solution of $VIP(T,\Omega)$.

Proof. By Lemma 3.2, it is enough to establish boundedness of $\{x^k\}$. Assume (a) holds. By (i), we have that $\{x^k\} \subset \overline{\Omega}$, and hence the sequence is bounded. Assume now that (b) occurs, and suppose that $\{x^k\}$ is unbounded. By definition of (P_k), there exists $u^k \in Tx^k$ with

$$\lim_k \langle u^k, x^k - x\rangle / \|x^k\| \leq \lim_k \varepsilon_k / \|x^k\| = 0,$$

where we used unboundedness of $\{x^k\}$ and condition (ii). However, the above expression contradicts the coercivity of T. Hence $\{x^k\}$ is bounded. ∎

Example 2. Consider now problem $VIP(T,\Omega)$, where the feasible set Ω is given as in (3.2). We describe next an outer approximation scheme for this problem. Assume that the set Y and the function $g\colon B \times Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ satisfy assumptions (G_1) and (G_3).

Before stating the algorithm, we need some notation:

- Y^k is a finite subset of Y.
- $\Omega^k := \{x \in B |\ g(x,y) \leq 0\ \forall\ y \in Y^k\}$.
- Given x^k solution of (P_k), define the *kth auxiliary problem* as

$$(A^k)\ \begin{cases} \text{find } y^{k+1} \in Y \text{ such that} \\ y^{k+1} \in \arg\max_{y \in Y}\ g(x^k, y). \end{cases}$$

ALGORITHM 1.
Step 0. Initialize: *Set $k = 1$, and choose any $Y^1 \subset Y$ finite and nonempty.*
Iteration: *For $k = 1, 2, \ldots,$*
Step 1. *Given Ω^k, find x^k solution of (P_k).*
Step 2. *For x^k obtained in Step 1, solve A^k.*
Step 3. (Check for solution and update if necessary.)
If $g(x^k, y^{k+1}) \leq 0$ stop. Otherwise, set

$$Y^{k+1} := Y^k \cup \{y^{k+1}\}. \tag{3.6}$$

Step 4. *Set $k := k + 1$ and return to Step 1.*

If Algorithm 1 stops at step 3, then $x^k \in S^*$. Indeed, if the solution y^{k+1} of the *kth auxiliary problem* A^k obtained in Step 2 satisfies

$$g(x^k, y^{k+1}) \leq 0,$$

then it holds that $g(x^k, y) \leq 0$ for all $y \in Y$, i.e., $x^k \in \Omega$. Thus,

$$\langle u^k, x - x^k \rangle \geq 0 \ \forall \ x \in \Omega,$$

so that x^k is a solution of problem (1.1). This justifies the stopping rule of Step 3. In the particular case in which B is finite dimensional, $T = \partial f$, and $\varepsilon_k = 0$ for all k in problem (P_k), the scheme above is the simplest exchange method [24, section 7.1] for the numerical solution of semi-infinite optimization problems. The analysis for this particular case was developed in [2, Theorem 2.1], where the authors proved, under the hypothesis of boundedness of Ω^1, that the orbit generated by Algorithm 1 is AF and every accumulation point of the orbit is a solution. The proof of the asymptotic feasibility of the orbit is omitted here, since it can be transferred, in a straightforward way, to our more general setting. Optimality of the weak accumulation points also holds in our setting, under the conditions of Theorem 3.4.

Remark 3.5. Under the assumptions $(G_1) - (G_3)$, define $h(x) := \max_{y \in Y} g(x, y)$. Then h is convex and weakly continuous. Therefore, if the conditions of Theorem 3.4 are met, then for every $\beta > 0$ and every orbit $\{x^k\}$ generated by Algorithm 1 in Example 2 there exists k_0 such that $h(x^k) \leq \beta$ for all $k \geq k_0$. Indeed, suppose that there exists $\beta_0 > 0$ and a subsequence $\{x^{k_j}\} \subset \{x^k\}$ such that $h(x^{k_j}) \geq \beta_0$ for all j. By Theorem 3.4, the subsequence $\{x^{k_j}\}$ is bounded and AF. Without loss of generality, assume the whole subsequence $\{x^{k_j}\}$ converges weakly to some $\bar{x} \in \Omega$. Using also the assumption on β_0, we have that

$$\beta_0 \leq \lim_j h(x^{k_j}) = h(\bar{x}) \leq 0,$$

a contradiction. This fact will be useful later on, to define suitable approximated solutions for this particular instance of $VIP(T, \Omega)$ in the case in which boundedness assumptions do not hold.

4. Convergence without boundedness assumptions. In the convergence analysis of the previous section, existence and boundedness of the iterates are proved under the boundedness assumptions of Theorem 3.4. Our aim in this section is to define outer approximating schemes with the same convergence properties, but under alternative assumptions. To achieve this goal, we define subproblems using a Tikhonov regularization of T. As is standard in this kind of regularization, we will force the

parameters to go to zero, to establish convergence of the method. We will consider outer approximations Ω^k for an arbitrary closed and convex set Ω as well as for the case in which the set Ω is given as in Example 2:

$$\Omega := \{x \in B \mid g(x,y) \leq 0 \ \forall\ y \in Y\}. \tag{4.1}$$

Throughout this section, we will always assume that the set Y of indexes and the constraint functions $g(\cdot, y)\colon B \longrightarrow \mathbb{R} \cup \{+\infty\}$ verify the assumptions $(G_1) - -(G_3)$.

4.1. Approximated solutions of $VIP(T, \Omega)$. Fix $x^0 \in B$ and $\lambda > 0$. Define $T_\lambda(x) := T(x) + \lambda J(x - x^0)$, where J is the duality mapping given in (2.1). It is well known that T_λ is coercive. We use T_λ for defining approximated solutions of $VIP(T, \Omega)$.

DEFINITION 4.1. *Fix $\lambda > 0$, $\beta > 0$, and $x^0 \in B$; an element $\widetilde{x} =: \widetilde{x}(\lambda, \beta, x^0)$ (i.e., depending on λ, β, x^0) is said to be an* approximated solution of $VIP(T, \Omega)$ *when*

(1) $\exists\ \widetilde{\Omega} \supseteq \Omega$ *and* $\widetilde{x} \in \widetilde{\Omega}$ *solves* $VIP(T_\lambda, \widetilde{\Omega})$;

(2) $\widetilde{x} \in x^0 + (1+\beta)(\Omega - x^0)$.

In the particular case in which Ω is given as in (4.1)*, an element $\widetilde{x} =: \widetilde{x}(\lambda, \beta, x^0)$ is an* approximated solution of $VIP(T, \Omega)$ *if it verifies condition* (1) *and*

(2′) $h(\widetilde{x}) \leq \beta$,

where $h(x) = \max_{y \in Y} g(x, y)$.

The parameter λ used in Definition 4.1(1) has a *regularizing* role, since it defines subproblems with coercive operator T_λ. The role of the parameter $\beta > 0$ in Definition 4.1(2) or (2′) is to control the infeasibility of the iterates $\widetilde{x}$. When Ω is as in (4.1), we can connect conditions (2) and (2′). To do this we need the following simple lemma.

LEMMA 4.2. *Fix $x^0 \in B$ and let $\hat{h} : B \to \mathbb{R} \cup \{\infty\}$ be convex and continuous, and suppose that $\emptyset \neq \Omega_0 \subset \{x \in B \mid \hat{h}(x) \leq 0\}$. Then for all $\gamma > 0$ there exists $\beta = \beta(\gamma)$ such that $\inf_{z \in \Omega_0} \hat{h}\left(x^0 + (1+\beta)(z - x^0)\right) < \gamma$.*

Proof. The proof is a consequence of the continuity of $\hat{h}$. Suppose that for some $\gamma_0 > 0$ the conclusion of the lemma does not hold and fix $z^0 \in \Omega_0$. Then for all k we must have $\hat{h}(x^0 + (1 + \frac{1}{k})(z^0 - x^0)) \geq \gamma_0$. Call $\tilde{x}^k := x^0 + (1 + \frac{1}{k})(z^0 - x^0)$. Then $\gamma_0 \leq \lim_k \hat{h}(\tilde{x}^k) = \hat{h}(z^0) \leq 0$, a contradiction. ∎

Take $\Omega_0 := \Omega$ and $\hat{h}(\cdot) := \max_{y \in Y} g(\cdot, y)$ in the lemma above and choose an arbitrary $\gamma > 0$. By the lemma, there exists β small enough and $z \in \Omega$ such that $\tilde{x} := x^0 + (1+\beta)(z - x^0)$ verifies $h(\tilde{x}) < \gamma$, i.e., $\tilde{x}$ verifies condition (2′) for γ. In this sense, we can say that condition (2) is stronger than (2′). On the other hand, condition (2) may never be met, no matter how small the parameter β in condition (2′). Indeed, observe that condition (2) holds only for a vector $\tilde{x}$ when $[\tilde{x}, x^0] \cap \Omega \neq \emptyset$. It is easy to find examples in which h and Ω admit a sequence $\{\tilde{x}^k\}$ verifying $\lim_k h(\tilde{x}^k) = 0$ with $[\tilde{x}^k, x^0] \cap \Omega = \emptyset$ for all k.

Remark 4.3. Observe that when $\lambda = \beta = 0$, $\widetilde{x}$ as in Definition 4.1 solves $VIP(T, \Omega)$.

Remark 4.4. Algorithm 1 in Example 2 provides a set $\widetilde{\Omega}$ and a point $\widetilde{x}$ verifying (1) and (2′) of the definition above. More precisely, fix $\lambda > 0$ and consider an orbit $\{x^k\}$ of Algorithm 1, applied to solve problem $VIP(T_\lambda, \Omega)$. Assume also that all problems (P_k) in Algorithm 1 are *exact*, i.e., $\varepsilon_k = 0$ for all k. Since T_λ is coercive, the assumptions of Theorem 3.4(b) hold. Therefore, $\{x^k\}$ is well defined and bounded, and every weak accumulation point is a solution. Given arbitrary $\beta > 0$, and using Remark 3.5, we conclude that for some k_0, it holds that $h(x^{k_0}) \leq \beta$. So (2′) holds for $\widetilde{x} := x^{k_0}$. By definition, $\widetilde{x} = x^{k_0} \in \Omega^{k_0} = \{x \in B \mid g(x,y) \leq 0 \forall\ y \in Y^{k_0}\} \supset \Omega$ and solves

$VIP(T_\lambda, \Omega^{k_0})$, so $\widetilde{x} = x^{k_0}$ and $\widetilde{\Omega} = \Omega^{k_0}$ verify (1). Using the approximated solutions given by Definition 4.1, we consider the following outer approximation scheme.

ALGORITHM 2.

Step 0. Initialize: Take $x^0 \in B$ and $\{\lambda_k\}, \{\beta_k\} \subset \mathbb{R}_+$.

Iteration: For $k = 1, 2, \ldots,$

Step 1. Given λ_k, β_k, find $\widetilde{x}^k = \widetilde{x}(\lambda_k, \beta_k, x^0)$ an approximated solution of $VIP(T, \Omega)$ (in the sense of Definition 4.1).

Step 2. If $\widetilde{x}^k = x^0$ and $\widetilde{x}^k \in \Omega$, stop. Otherwise,

Step 3. Set $k := k + 1$ and return to Step 1.

Remark 4.5. Regarding the stopping criterion in Step 2, if $\widetilde{x}^k = x^0$ and $\widetilde{x}^k \in \Omega$, we have by condition (1) of Definition 4.1 that

$$0 \in T_{\lambda_k}(x^0) + N_{\widetilde{\Omega}^k}(x^0) = T(x^0) + \lambda_k J(x^0 - x^0) + N_{\widetilde{\Omega}^k}(x^0) = T(x^0) + N_{\widetilde{\Omega}^k}(x^0).$$

Then x^0 is a solution of $VIP(T, \widetilde{\Omega}^k)$. Since $x^0 \in \Omega$, it is also a solution of $VIP(T, \Omega)$. Iterates as in Definition 4.1(1) always exist.

PROPOSITION 4.6. *Assume* (H_1) *holds. Given* $\widetilde{\Omega} \supset \Omega$ *and* $\lambda > 0$*, there exists a unique solution* $\widetilde{x}$ *of* $VIP(T_\lambda, \widetilde{\Omega})$.

Proof. Uniqueness of the solution follows from the fact that T_λ is strictly monotone. The existence is a consequence of the surjectivity of $T_\lambda + N_{\widetilde{\Omega}}$. Indeed, since T_λ is coercive, by Theorems 2.4 and 2.5, it is regular and onto. To use Proposition 2.2, we only have to check that $T_\lambda + N_{\widetilde{\Omega}}$ is maximal monotone. But this fact follows readily from Proposition 2.4, (H_1) and the fact that $\widetilde{\Omega} \supset \Omega$. ∎

PROPOSITION 4.7. *Assume* (H_3) *holds. Let the sequence* $\{\widetilde{x}^k\}$ *be generated by Algorithm* 2 *with approximated solutions as in Definition* 4.1(1) *and* (2). *Take* $\lambda_k, \beta_k \to 0$ *with* $\sup_k \left[\frac{\beta_k}{\lambda_k} + \frac{\lambda_k}{\beta_k}\right] \le c_0$ *for some* $c_0 > 0$. *Then every orbit of Algorithm* 2 *is bounded and* AF.

Proof. By condition (2) in Definition 4.1, there exists $y^k \in \Omega$ such that

$$\widetilde{x}^k = x^0 + (1 + \beta_k)(y^k - x^0), \tag{4.2}$$

where $x^0 \in B$ is given in Step 0 of Algorithm 2. Therefore, boundedness of the orbit will be guaranteed if we show that $\{y^k\}$ is bounded. Using condition (1) in Definition 4.1, we have that $\widetilde{x}^k$ verifies

$$u^k + \eta^k + \lambda_k J(\widetilde{x}^k - x^0) = 0 \text{ with } u^k \in T(\widetilde{x}^k),\ \eta^k \in N_{\widetilde{\Omega}^k}(\widetilde{x}^k).$$

Since $\eta^k \in N_{\widetilde{\Omega}^k}(\widetilde{x}^k)$, we can write

$$\langle u^k, x - \widetilde{x}^k \rangle \ge \lambda_k \langle J(x^0 - \widetilde{x}^k), x - \widetilde{x}^k \rangle \ \forall\ x \in \widetilde{\Omega}^k, \tag{4.3}$$

where we also used Proposition 2.6(i). Take $\overline{x} \in S^*$; then there exists $\overline{v} \in T(\overline{x})$ such that

$$\langle \overline{v}, z - \overline{x} \rangle \ge 0\ \forall z \in \Omega. \tag{4.4}$$

Using monotonicity of T and (4.3) for $x = \overline{x}$, we have that

$$\langle \overline{v}, \overline{x} - \widetilde{x}^k \rangle \ge \lambda_k \langle J(x^0 - \widetilde{x}^k), \overline{x} - \widetilde{x}^k \rangle.$$

By Proposition 2.6(ii) with $z = x^0 - \overline{x}$ and $x = x^0 - \widetilde{x}^k$ we get

$$\langle J(x^0 - \widetilde{x}^k), \overline{x} - \widetilde{x}^k \rangle \ge \frac{1}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2).$$

The last two expressions yield

$$\langle \overline{v}, \overline{x} - \widetilde{x}^k \rangle \geq \frac{\lambda_k}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2). \tag{4.5}$$

Use (4.4) for $z = y^k$ to conclude that $\langle \overline{v}, y^k - \overline{x} \rangle \geq 0$. Adding and subtracting $\widetilde{x}^k$ in the right-hand side of this inner product, we obtain

$$\beta_k \langle \overline{v}, x^0 - y^k \rangle = \langle \overline{v}, y^k - \widetilde{x}^k \rangle \geq \langle \overline{v}, \overline{x} - \widetilde{x}^k \rangle,$$

where we also used (4.2). Combine the last expression with (4.5) to get

$$\begin{array}{rcl} \beta_k \langle \overline{v}, x^0 - y^k \rangle & \geq & \frac{\lambda_k}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2) \\ & = & \frac{\lambda_k}{2}\left((1+\beta_k)^2\|y^k - x^0\|^2 - \|x^0 - \overline{x}\|^2\right), \end{array}$$

where we used (4.2) in the equality. Rearranging the last expression, we get

$$\begin{array}{rcl} 0 & \geq & \langle \overline{v}, y^k - x^0 \rangle + \frac{(1+\beta_k)^2}{2}\left(\frac{\lambda_k}{\beta_k}\right)\|y^k - x^0\|^2 - \frac{1}{2}\left(\frac{\lambda_k}{\beta_k}\right)\|x^0 - \overline{x}\|^2 \\ & \geq & \langle \overline{v}, y^k - x^0 \rangle + \frac{1}{2\,c_0}\|y^k - x^0\|^2 - \frac{c_0}{2}\|x^0 - \overline{x}\|^2, \end{array} \tag{4.6}$$

where we used $\frac{(1+\beta_k)^2\lambda_k}{\beta_k} \geq 1/c_0$ and $\frac{\lambda_k}{\beta_k} \leq c_0$ in the second inequality. The right-hand side of the last inequality is a convex quadratic function on y^k; thus the sequence $\{y^k\}$ must be bounded. Equivalently, $\{\widetilde{x}^k\}$ is bounded. Now we proceed to prove that every weak accumulation point is feasible. Let $\{\widetilde{x}^{k_j}\} \subseteq \{\widetilde{x}^k\}$ be a subsequence weakly convergent to x^*. By definition of $\widetilde{x}^{k_j}$ we have that $\widetilde{x}^{k_j} - x^* = y^{k_j} - x^* + \beta_{k_j}(y^{k_j} - x^0)$. Since $\lim_j \beta_{k_j} = 0$ and $\{y^{k_j}\} \subset \Omega$ is bounded, we conclude that $w - \lim_j y^{k_j} = x^*$. Since Ω is closed and convex, it is weakly closed, and hence $x^* \in \Omega$. □

Recall that a Slater condition for Ω as in (4.1) requires the existence of a point x^0 such that $g(x^0, y) < 0$ for all $y \in Y$. However, by assumptions (G_1) and (G_3), we have that the Slater condition is equivalent to the existence of some $\alpha > 0$ such that

$$g(x^0, y) \leq -\alpha \ \forall\ y \in Y. \tag{4.7}$$

So, under our hypotheses there is no loss of generality by calling (4.7) a *Slater condition* for Ω. The next result is analogous to Proposition 4.7, for the case in which the set Ω is as in (4.1), and the approximate solutions are taken as in Definition 4.1(1) and (2′).

PROPOSITION 4.8. *Assume that* (H_3) *holds. Let* Ω *be as in* (4.1) *and such that a Slater condition holds for* Ω. *Take* $\lambda_k \to 0$ *and suppose that there exists* $c_0 > 0$ *with* $\sup_k \frac{\beta_k}{\lambda_k} \leq c_0 < \infty$. *Assume also that in Step* 0 *of Algorithm* 2 *we use the* x^0 *provided by* (4.7). *Then every orbit* $\{\widetilde{x}^k\}$ *of Algorithm* 2 *is bounded and* AF.

Proof. Let x^0 and $\alpha > 0$ be such that (4.7) holds, and fix $c > c_0$. Since $\lambda_k \to 0$, there exists $k_0 \in \mathbb{N}$ such that

$$0 < \frac{c\,\lambda_k}{\alpha} < 1 \text{ for all } k \geq k_0. \tag{4.8}$$

Using that $c > c_0$, we get

$$0 < \beta_k < c\lambda_k = \frac{c\alpha\lambda_k}{\alpha} < \frac{c\alpha\lambda_k}{\alpha - c\lambda_k} \tag{4.9}$$

for all $k \geq k_0$. Define now the auxiliary sequence $x^k := \widetilde{x}^k + \frac{c\lambda_k}{\alpha}(x^0 - \widetilde{x}^k)$. We claim that $x^k \in \Omega$ for all $k > k_0$. Indeed, by convexity of h and (4.8) we have that

$$h(x^k) \leq \frac{c\lambda_k}{\alpha} h(x^0) + \left(1 - \frac{c\lambda_k}{\alpha}\right) h(\widetilde{x}^k) \ \forall \ k > k_0.$$

Using (4.7) and the fact that $\widetilde{x}^k$ is an approximated solution, we get

$$h(x^k) \leq \frac{c\lambda_k}{\alpha}(-\alpha) + \left(1 - \frac{c\lambda_k}{\alpha}\right)(\beta_k);$$

now using (4.9) for all $k > k_0$ we get

$$h(x^k) \leq -c\lambda_k + \left(1 - \frac{c\lambda_k}{\alpha}\right)\left(\frac{c\alpha\lambda_k}{\alpha - c\lambda_k}\right) = -c\lambda_k + c\lambda_k = 0. \tag{4.10}$$

Therefore $\{x^k\} \subseteq \Omega$ for all $k > k_0$. Using the fact that $\widetilde{x}^k$ verifies condition (1) in Definition 4.1, and following the same steps as in the proof of Proposition 4.7 (see equations (4.3)–(4.5)), we arrive to the inequality

$$\langle \overline{v}, \overline{x} - \widetilde{x}^k \rangle \geq \frac{\lambda_k}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2), \tag{4.11}$$

where $\bar{x}$ is a solution of $VIP(T, \Omega)$ and $\bar{v} \in T(\bar{x})$. Using definition of $\bar{x}$ and the fact that $x^k \in \Omega$, we get $\langle \overline{v}, x^k - \overline{x} \rangle \geq 0$. Summing and subtracting $\widetilde{x}^k$ in the right-hand side of this inner product, we obtain

$$\langle \overline{v}, x^k - \widetilde{x}^k \rangle \geq \langle \overline{v}, \overline{x} - \widetilde{x}^k \rangle. \tag{4.12}$$

Using definition of $\{x^k\}$ and combining (4.12) and (4.11), we have

$$\frac{c\lambda_k}{\alpha}\langle \overline{v}, x^0 - \widetilde{x}^k \rangle \geq \frac{\lambda_k}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2). \tag{4.13}$$

Dividing by $\lambda_k > 0$, we conclude that

$$\frac{c}{\alpha}\langle \overline{v}, \widetilde{x}^k - x^0 \rangle + \frac{1}{2}(\|x^0 - \widetilde{x}^k\|^2 - \|x^0 - \overline{x}\|^2) \leq 0, \tag{4.14}$$

which, in the same way as in the last part of Proposition 4.7, yields boundedness of $\{\widetilde{x}^k\}$. Now let $\{\widetilde{x}^{k_j}\} \subseteq \{\widetilde{x}^k\}$ be a subsequence weakly convergent to x^*. Using Definition 4.1(2′) we have that $h(\widetilde{x}^{k_j}) \leq \beta_{k_j}$ for all j. Since h weakly continuous and $\beta_k \to 0$, we get that $h(x^*) \leq 0$. Thus $x^* \in \Omega$, and hence the orbit $\{\widetilde{x}^k\}$ is AF. □

We proved so far that under suitable assumptions on the data, Algorithm 2 generates an orbit which is bounded and AF. We present below conditions under which these two properties guarantee optimality of weak accumulation points.

THEOREM 4.9. *Let the sequence $\{\widetilde{x}^k\}$ be generated by Algorithm 2, where the iterates $\widetilde{x}^k$ verify condition (1) of Definition 4.1 with parameters $\{\lambda_k\}$ such that $\lim_k \lambda_k = 0$. Suppose that (H_2) and (H_3) hold. If $\{\widetilde{x}^k\}$ is bounded and AF, then one of the following holds:*

(i) *Algorithm 2 has finite termination, and the last iterate is a solution of $VIP(T, \Omega)$.*
(ii) *Algorithm 2 generates an infinite orbit, and every weak accumulation point of $\{\widetilde{x}^k\}$ is a solution of $VIP(T, \Omega)$.*

Proof. Case (i) has been taken care of in Remark 4.5. Thus it is enough to consider the case in which Algorithm 2 generates an infinite orbit. Since $\widetilde{x}^k$ verifies condition (1) of Definition 4.1, we have as in (4.3),

$$\langle u^k, x - \widetilde{x}^k\rangle \geq \lambda_k \langle J(x^0 - \widetilde{x}^k), x - \widetilde{x}^k\rangle \ \forall\ x \in \widetilde{\Omega}^k. \tag{4.15}$$

Take x^* a weak accumulation point of $\{\widetilde{x}^k\}$ and a subsequence $\{\widetilde{x}^{k_j}\} \subset \{\widetilde{x}^k\}$ weakly converging to x^*. Using the last expression, together with the fact that $\Omega \subseteq \widetilde{\Omega}$, we can write for every $x \in \Omega$,

$$\begin{array}{rcl} \langle u^k, \widetilde{x}^k - x\rangle & \leq & \lambda_k \langle J(x^0 - \widetilde{x}^k), \widetilde{x}^k - x\rangle \\ & \leq & \lambda_k \|J(x^0 - \widetilde{x}^k)\|\ \|\widetilde{x}^k - x\| \\ & = & \lambda_k \|x^0 - \widetilde{x}^k\|\ \|\widetilde{x}^k - x\|, \end{array} \tag{4.16}$$

where we used the Cauchy–Schwartz inequality and definition of J. Since $\lim_k \lambda_k = 0, x^* \in \Omega$, and $\{\widetilde{x}^k\}$ is bounded, from (4.16) for $k = k_j$ we get that

$$\limsup_j \langle u^{k_j}, \widetilde{x}^{k_j} - x^*\rangle \leq 0. \tag{4.17}$$

Using $\widetilde{x}^{k_j} \xrightarrow{w} x^*$, (4.17), and pseudomonotonicity of T for $\overline{x} \in S^*$ we conclude that there exists $u^* \in T(x^*)$ such that

$$\liminf_j \langle u^{k_j}, \widetilde{x}^{k_j} - \overline{x}\rangle \geq \langle u^*, x^* - \overline{x}\rangle. \tag{4.18}$$

On the other hand, using (4.16) for $\overline{x} \in S^*$ and $k = k_j$ we get

$$\liminf_j \langle u^{k_j}, \widetilde{x}^{k_j} - \overline{x}\rangle \leq 0. \tag{4.19}$$

Using also (4.18) we get

$$\langle u^*, x^* - \overline{x}\rangle \leq 0. \tag{4.20}$$

Finally, by paramonotonicity of T and the above inequality, we can use Proposition 2.8 to guarantee that x^* is a solution of the $VIP(T, \Omega)$, as we wanted to prove. ∎

Our next convergence result requires the approximated solutions $\widetilde{x}$ to stay close enough to the original set Ω. Fix $\theta > 0$ and $r > 1$. We say that $\widetilde{x}$ is a *metric*-approximated solution if it verifies Definition 4.1(1) and the condition $(2'')$:

$$d(\widetilde{x}, \Omega) := \inf_{z \in \Omega} \|\widetilde{x} - z\| \leq \theta \lambda^r,$$

where λ is the parameter used in Definition 4.1(1).

Remark 4.10. When Ω is as in (4.1), condition $(2'')$ can be guaranteed when the *Hoffman global error bound* [25] holds:

$$\exists\, \theta > 0\ \forall\, x \notin \Omega,\ d(x, \Omega) \leq \theta \max_{y \in Y} g(x, y) = \theta\ h(x). \tag{4.21}$$

An error bound of this kind has been proved to hold in a Banach space in [15]. Namely, assume that (G_1)–(G_3) hold. Suppose also that there exist $\delta, \gamma > 0$ such that

- (G_4) $\Omega(\delta) := \{x \in B \mid h(x) \leq -\delta\} \neq \emptyset$ and
- (G_5) $Haus(\Omega, \Omega(\delta)) < \gamma$ (where $Haus(\cdot, \cdot)$ stands for the Hausdorff distance between sets).

Then [15, Proposition 1] proves that

$$\forall\, x \notin \Omega,\ d(x,\Omega) \leq \delta^{-1}\gamma\, h(x). \tag{4.22}$$

Therefore, when assumptions (G_1)–(G_5) hold for Ω, condition $(2'')$ is a consequence of Definition 4.1$(2')$ with $\beta = \lambda^r$. For alternative conditions under which a global error bound of the kind (4.21) holds in a Banach space, see [27].

In the theorem below we prove boundedness of the orbit generated by Algorithm 2, as well as optimality of all weak limit points. In the case in which B is uniformly convex, we get full strong convergence and we characterize the limit of $\{\widetilde{x}^k\}$ as the closest point to x^0 in the solution set.

THEOREM 4.11. *Let the sequence $\{\widetilde{x}^k\}$ be generated by Algorithm 2, where the iterates satisfy conditions (1) of Definition 4.1 and $(2'')$ for $\lambda = \lambda_k$. Assume that $\lambda_k \to 0$ and that (H_2) and (H_3) hold. Then the sequence $\{\widetilde{x}^k\}$ is bounded and every weak limit point is a solution of $VIP(T,\Omega)$. Moreover, if B is uniformly convex, then the sequence $\{\widetilde{x}^k\}$ converges strongly and the limit point is the unique x^* characterized by*

$$\{x^*\} = \arg\min_{y\in S^*} \|x^0 - y\|^2.$$

Proof. We prove first that $\widetilde{x}^k$ is bounded. The approximated solution $\widetilde{x}^k$ is such that

$$u^k + \eta^k + \lambda_k J(\widetilde{x}^k - x^0) = 0 \text{ with } u^k \in T(\widetilde{x}^k),\ \eta^k \in N_{\widetilde{\Omega}^k}(\widetilde{x}^k). \tag{4.23}$$

Let $y \in S^*$; then there exists $v \in T(y)$ such that

$$\langle v, x - y\rangle \geq 0\ \forall x \in \Omega. \tag{4.24}$$

Thus by Proposition 2.6(ii),

$$\|x^0 - y\|^2 \geq \|x^0 - \widetilde{x}^k\|^2 + 2\langle J(x^0 - \widetilde{x}^k), \widetilde{x}^k - y\rangle. \tag{4.25}$$

Define $A := 2\langle J(x^0 - \widetilde{x}^k), \widetilde{x}^k - y\rangle$; (4.23) implies that

$$A = \frac{2}{\lambda_k}(\langle u^k, \widetilde{x}^k - y\rangle + \langle \eta^k, \widetilde{x}^k - y\rangle).$$

Using the definition of normality operator and monotonicity of T we obtain

$$A \geq \frac{2}{\lambda_k}\langle v, \widetilde{x}^k - y\rangle. \tag{4.26}$$

Combining (4.26) and (4.25) we get

$$\|x^0 - y\|^2 \geq \|x^0 - \widetilde{x}^k\|^2 + \frac{2}{\lambda_k}\langle v, \widetilde{x}^k - y\rangle. \tag{4.27}$$

We claim that for all $y\ \in S^*$

$$\|x^0 - y\|^2 \geq \|x^0 - \widetilde{x}^k\|^2 - 2\theta{\lambda_k}^{r-1}\|v\|\ \forall\ k. \tag{4.28}$$

Indeed, assume first that $\widetilde{x}^k \in \Omega$, and by (4.24) and (4.27) we have that $\|x^0 - y\|^2 \geq \|x^0 - \widetilde{x}^k\|^2$, and hence (4.28) holds. Assume now that $\widetilde{x}^k \notin \Omega$. Let p^k be the projection of the $\widetilde{x}^k$ in Ω; we obtain

$$\begin{array}{rcl} \frac{2}{\lambda_k}\langle v, \widetilde{x}^k - y\rangle & = & \frac{2}{\lambda_k}\left[\langle v, \widetilde{x}^k - p^k\rangle + \langle v, p^k - y\rangle\right] \\ & \geq & \frac{2}{\lambda_k}\langle v, \widetilde{x}^k - p^k\rangle \geq -\frac{2}{\lambda_k}\|v\|\|\widetilde{x}^k - p^k\| \\ & \geq & -2\theta\lambda_k^{r-1}\|v\|, \end{array} \tag{4.29}$$

where we used the Cauchy–Schwartz inequality, (4.24), and condition $(2'')$. Combining (4.27) with (4.29), we conclude (4.28). Thus our claim is true and hence $\{\widetilde{x}^k\}$ is bounded. Let $\{\widetilde{x}^{k_j}\} \subseteq \{\widetilde{x}^k\}$ be a subsequence weakly convergent to x^*. Since $\lambda_{k_j} \to 0$, condition $(2'')$ readily implies the existence of a sequence $\{y^{k_j}\} \subset \Omega$ such that $w - \lim_j y^{k_j} = x^*$. Using the fact that Ω is convex and (strongly) closed, it is also weakly closed, and hence $x^* \in \Omega$. Now, using the last part of the proof of Theorem 4.9 (see equations (4.16) to (4.20)), every limit point of $\{\widetilde{x}^k\}$ is a solution of $VIP(T, \Omega)$. We proceed now to prove the last assertion of the theorem. Assume that B is uniformly convex, and take again the subsequence $\{\widetilde{x}^{k_j}\}$ weakly converging to x^*. We know that $x^* \in S^*$. By (4.28) for $k = k_j$ and $y = x^*$ we get

$$\|x^0 - x^*\|^2 \geq \|x^0 - \widetilde{x}^{k_j}\|^2 - 2\theta{\lambda_{k_j}}^{r-1}\|v\|.$$

Taking limsup for $j \to \infty$ in the expression above and using that $\lambda_k \to 0$, we have that

$$\|x^0 - x^*\|^2 \geq \limsup_{j\to\infty} \|x^0 - \widetilde{x}^{k_j}\|^2. \tag{4.30}$$

Since $\{x^0 - \widetilde{x}^{k_j}\}$ weakly converges to $x^0 - x^*$ we apply Proposition 2.13 to conclude that $\{\widetilde{x}^{k_j}\}$ converges strongly to x^*. Now, taking limits for $j \to \infty$ in (4.28) for $k = k_j$ we get

$$\|x^0 - y\|^2 \geq \|x^0 - x^*\|^2 \ \forall\ y\ \in S^*.$$

Thus,

$$x^* \in \arg\min_{y\in S^*} \|x^0 - y\|^2.$$

This point is unique by strict convexity of $\|\cdot\|^2$. □

Acknowledgment. The authors are very thankful to the two referees, whose helpful and essential corrections greatly improved an earlier version of the manuscript.

ASYMPTOTIC STABILITY FOR INTERMITTENTLY CONTROLLED SECOND-ORDER EVOLUTION EQUATIONS*

A. HARAUX†, P. MARTINEZ‡, AND J. VANCOSTENOBLE‡

Abstract. Motivated by several works on ordinary differential equations, we are interested in the asymptotic stability of *intermittently controlled* partial differential equations. We give a condition of asymptotic stability for second-order evolution equations uniformly damped by an on/off feedback. This result extends to the case of partial differential equations a previous result of R. A. Smith concerning ordinary differential equations.

Key words. damped wave equation, second-order evolution equations, asymptotic behavior, on-off damping

1. Introduction. Motivated by several works on ordinary differential equations, we are interested in the asymptotic stability of *intermittently controlled* partial differential equations. This question has been widely studied in the case of ordinary differential equations (see, for example, [1, 9, 10, 25, 27, 28]). The typical problem is the oscillator damped by an *on/off* damping:

$$u'' + u + a(t)u' = 0, \quad t > 0, \tag{1.1}$$

where $a : \mathbb{R}_+ \to \mathbb{R}_+$ is continuous nonnegative. For each solution u of (1.1), we define its energy by

$$\forall t \geq 0, \quad E_u(t) = \frac{1}{2}u(t)^2 + \frac{1}{2}u'(t)^2.$$

The derivative of the energy is

$$E'(t) = u(t)u'(t) + u'(t)u''(t) = -a(t)u'(t)^2,$$

hence the energy is always nonincreasing, but remains constant on the time intervals for which $a = 0$, and the decay is "very small" if a is "very small." Denote $\ell := \lim_{t\to\infty} E(t)$. Many authors (see, in particular, [1, 9, 10, 25, 27, 28]) investigated the links between the distribution of sets where a is positive and the property $\ell = 0$.

Assume that there exists a sequence $(I_n)_{n\geq 0}$ of disjoint open intervals in $(0, +\infty)$, denoted by $I_n = (a_n, b_n)$, where $b_n \leq a_{n+1}$ for all $n \in \mathbb{N}$, and such that

$$\forall t \in I_n, \quad 0 < m_n \leq a(t) \leq M_n < \infty.$$

Roughly speaking, the energy is strictly decreasing on the time intervals I_n and just nonincreasing elsewhere. It is natural to wonder whether the decay on the time

†Laboratoire Jacques-Louis Lions, U.M.R C.N.R.S. 7598, Université Pierre et Marie Curie, Boite courrier 187, 75252 Paris Cedex 05, France (haraux@ann.jussieu.fr).
‡Laboratoire M.I.P., U.M.R. C.N.R.S. 5640, Université Paul Sabatier Toulouse III, 118 route de Narbonne, 31 062 Toulouse Cedex 4, France (martinez@mip.ups-tlse.fr, vancoste@mip.ups-tlse.fr).

intervals I_n is sufficient to drive the energy to zero. Obviously some condition on the length of the intervals I_n has to be imposed to ensure $\ell = 0$. Smith [27] proved the following *sufficient condition of asymptotic stability*:

THEOREM 1.1. [27]. *Assume that*

$$\sum_{n=0}^{\infty} m_n T_n \delta_n^2 = +\infty, \tag{1.2}$$

where m_n and M_n are the minimum and the maximum values of $a(t)$ in I_n, T_n is the length of I_n and $\delta_n = \min(T_n, (1+M_n)^{-1})$. Then (1.1) *is asymptotically stable; i.e., every solution u of* (1.1) *satisfies $E_u(t) \to 0$ as $t \to \infty$.*

For example, in the case of a damping such that $0 < m \le a(t) \le M$ for all $t \in I_n$ for all $n \in \mathbb{N}$, the condition (1.2) reduces to

$$\sum_{n=0}^{\infty} T_n^3 = +\infty. \tag{1.3}$$

It is noteworthy that (1.3) is also necessary in the following sense: given $\varepsilon > 0$ as small as we want, Pucci and Serrin [25] constructed an example for which the sequence $(T_n)_n$ satisfies

$$\sum_{n=0}^{\infty} T_n^{3-\varepsilon} = +\infty, \quad \text{while} \quad \sum_{n=0}^{\infty} T_n^3 < +\infty,$$

and suitable initial conditions such that the energy decays to some $\ell > 0$.

Note also that, under condition (1.2), *the distribution of the intervals I_n has no importance.* Only their size is important.

Condition (1.2) also requires that the damping coefficient a is not "too small" or "too large," in order to prevent "underdamping" or "overdamping." These phenomena are also a source of lack of strong stability (see [20, 22, 26], where the stability is studied for the wave equation, but always under the condition that the function a remains positive).

To our knowledge, stability properties for such "intermittently controlled" systems have not yet been studied in the case of *partial* differential equations.

In [21], we studied the effect of an on/off feedback on the wave equation. We considered the simplified case of a damping coefficient a that is $2T$-periodic and such that $a(t) = a_0 > 0$ on $(0, T)$ and $a(t) = 0$ on $(T, 2T)$. In particular, the condition (1.2) was always satisfied. And we studied the wave equation damped by a *boundary* on/off feedback or by a *locally distributed* on/off feedback. In both cases, we proved that the situation is *radically different* from the case of ordinary differential equations. Indeed, we proved that, except for a countable number of exceptional values of T, asymptotic stability occurs (and more precisely, exponential stability). But, for the exceptional values of T, asymptotic stability does not occur. This means that *the distribution of the intervals I_n is very important in the case of the locally damped wave equation.* This phenomenon is related to the optics rays propagation and the geometric condition of Bardos, Lebeau, and Rauch [2, 3]. See further comments in section 3.3.

In [21], the only case for which the situation was not different from the situation of the ordinary differential equations was the wave equation damped by an *uniformly distributed* on/off feedback. In that case, asymptotic stability occurs for any value of T. Thus the distribution of the intervals damping has no importance.

In the present work, we now study the wave equation *uniformly damped* by a *general on/off feedback* (in particular, not necessarily periodic). We prove that *"the uniformly damped wave equation behaves exactly like the oscillator"* in the sense that Theorem 1.1 is still true.

More generally, we prove this result in an abstract setting that includes both the oscillator and wavelike or platelike equations and that also includes *bounded or unbounded* and *linear and nonlinear* damping operators.

In particular, this gives for the result of Smith a new proof quite different from the original one, which was relying on monotonicity properties of the solutions of (1.1). Our method is based on a preliminary result which is interesting in itself: we provide an estimate of the energy decay on a *short* time interval (see Theorem 3.1). This estimate is true for both ordinary and partial differential equations.

The paper is organized as follows.

- In section 2, we introduce our abstract setting and we give the result of well-posedness (Theorem 2.1).
- In section 3, we provide an estimate of the energy decay on a *short* time interval (Theorem 3.1) and we deduce the asymptotic stability result (Theorem 3.2) extending the previous result of Smith. Then we make some further comments concerning the case of locally distributed dampings to explain the necessity of considering only uniformly distributed dampings.
- In section 4, we give some examples.
- In section 5, we present another application of the method to the case of a positive-negative damping (Theorem 5.1).

2. Abstract setting and well-posedness. Let H be a real Hilbert space endowed with the scalar product $(\cdot,\cdot)_H$ and the norm $|\cdot|_H$.

Assume that $A : D(A) \subset H \to H$ is a linear self-adjoint and coercive operator on H with dense domain. We define $V = D(A^{1/2})$ endowed with the scalar product $((\cdot,\cdot))_V$ and the norm $\|\cdot\|_V$ defined by

$$\forall v \in V, \quad \|v\|_V^2 = |A^{1/2}v|_H^2 = \langle \tilde{A}v, v\rangle_{V',V},$$

where $\tilde{A} \in \mathcal{L}(V, V')$ represents the extension of A.

Also let W be a Hilbert space endowed with the norm $\|\cdot\|_W$ and such that

$$V \hookrightarrow W \hookrightarrow H \equiv H' \hookrightarrow W' \hookrightarrow V'$$

with dense imbeddings. We also assume that A satisfies the following property:

$$\begin{aligned} &\exists \lambda_0,\, C_0 > 0, \ \text{ such that, } \forall \lambda \in [0, \lambda_0], \\ &\quad (I + \lambda A)^{-1} \in \mathcal{L}(W) \ \text{ and } \ \|(I + \lambda A)^{-1}\|_{\mathcal{L}(W)} \le C_0. \end{aligned} \tag{2.1}$$

Next we consider a *time-dependent* operator B such that

$$B \in L^\infty(J, \mathrm{Lip}\,(W, W')), \qquad B(t)0 = 0, \tag{2.2}$$

$$\forall t \in J,\ \forall w,\, z \in W, \quad \langle B(t)w - B(t)z, w - z\rangle_{W',W} \ \ge\ 0, \tag{2.3}$$

$$\forall t \in J,\ \forall w \in W, \quad \langle B(t)w, w\rangle_{W',W} \ \ge\ b^2(t)\|w\|_W^2, \tag{2.4}$$

$$\forall t \in J,\ \forall w,\ z \in W, \quad \|B(t)w - B(t)z\|_{W'} \ \leq\ Cb(t)^2\|w - z\|_W, \tag{2.5}$$

where $J = [0, T]$ with $T > 0$ and where $b(t) \geq 0$ with $b \in L^2(J)$. Note that $B(t)$ is *a priori unbounded and nonlinear*. (The choice $W = H$ corresponds to the particular case of a bounded operator.)

Now we consider the following second-order evolution equation

$$u'' + Au + B(t)u' = 0, \quad t > 0, \tag{2.6}$$

with the initial conditions

$$u(0) = u_0 \in V, \quad u'(0) = u_1 \in H \tag{2.7}$$

and we prove that this problem is well-posed.

THEOREM 2.1. *Under the previous assumptions, for any* $(u_0, u_1) \in V \times H$, *there exists a unique solution* $u \in L^2(0, T; V) \cap W^{1,2}(0, T; H) \cap W^{2,2}(0, T; V')$ *with* $bu' \in L^2(0, T; W)$ *and* $B(t)u' = b(t)h(t)$, $h(t) \in L^2(0, T; W')$ *of*

$$u'' + Au + B(t)u' = 0 \quad \text{in } L^2(0, T; V')$$

such that

$$u(0) = u_0 \in V, \quad u'(0) = u_1 \in H.$$

In addition $u \in C([0, T]; V) \cap C^1([0, T]; H)$ *and the energy of the solution* u *defined by*

$$\forall t \geq 0, \quad E_u(t) \ :=\ \frac{1}{2}\|u(t)\|_V^2 + \frac{1}{2}|u'(t)|_H^2,$$

is absolutely continuous on $[0, T]$ *with*

$$E_u'(t) = -\langle B(t)u'(t), u'(t)\rangle_{W',W} \quad \text{a.e on } \{t,\ b(t) > 0\},$$

and

$$E_u'(t) = 0 \quad \text{a.e on } \{t,\ b(t) = 0\}.$$

For the proof of Theorem 2.1, we first need the following lemma.

LEMMA 2.1. *Let* $b = b(t) \geq 0$ *and consider*

$$u \in L^2(0, T; V) \cap W^{1,2}(0, T; H) \cap W^{2,2}(0, T; V')$$

with

$$bu' \in L^2(0, T; W),$$

where $V \subset W \subset H$ *with continuous and dense imbeddings. Let*

$$f = bg, \ \text{with } g \in L^2(0, T; W'),$$

and assume

$$u'' + Au = f \quad \text{in } L^2(0, T; V').$$

Then, in fact, $u \in C([0,T];V) \cap C^1([0,T];H)$ *and the energy* $E_u(t)$ *is absolutely continuous on* $[0,T]$ *with*

$$E_u'(t) = \langle g(t), b(t)u'(t)\rangle_{W',W}.$$

Proof of Lemma 2.1. Let $J_\lambda = (I+\lambda A)^{-1} : H \to H$ for $\lambda > 0$. We have $J_\lambda \in \mathcal{L}(H)$, $J_{\lambda|V} \in \mathcal{L}(V)$, and $J_{\lambda|W} \in \mathcal{L}(W)$ for $\lambda \le \lambda_0$. And by (2.1), $\{J_\lambda\}_{0<\lambda\le\lambda_0}$ is uniformly equicontinuous on $W \to W$.

We claim that

$$\forall \varphi \in W, \quad J_\lambda \varphi \to \varphi \ \text{ in } W \quad \text{as } \lambda \to 0. \tag{2.8}$$

Indeed (2.8) is well-known if $\varphi \in V$, and since V is dense in W, the result follows by density.

Then we introduce

$$u_\lambda := J_\lambda u \ \text{ and } \ f_\lambda := J_\lambda(bg) = bJ_\lambda g.$$

We clearly have $u_\lambda \in L^2(0,T;D(A))$, $u_\lambda' \in L^2(0,T;D(A))$, and $u_\lambda'' \in L^2(0,T;V) \subset L^2(0,T;H)$.

Setting

$$E_\lambda(t) := \frac{1}{2}\|u_\lambda(t)\|_V^2 + \frac{1}{2}|u_\lambda'(t)|_H^2,$$

we have, a.e. on $(0,T)$,

$$E_\lambda' = ((u_\lambda, u_\lambda'))_V + (u_\lambda', u_\lambda'')_H = (Au_\lambda + u_\lambda'', u_\lambda')_H = b(J_\lambda g, u_\lambda')_H,$$

with $J_\lambda g \in L^2(0,T;V) \subset L^2(0,T;H)$.

Let α, β be two points of $[0,T]$ such that $\alpha < \beta$. Then we have

$$E_\lambda(\beta) - E_\lambda(\alpha) = \int_\alpha^\beta (bJ_\lambda g, u_\lambda')\,ds = \int_\alpha^\beta (J_\lambda g(s), b(s)u_\lambda'(s))\,ds. \tag{2.9}$$

On the other hand, we can prove

$$J_\lambda g \to g \ \text{ in } \ L^2(0,T;W') \ \text{ as } \lambda \to 0 \tag{2.10}$$

and

$$bu_\lambda' = J_\lambda b u' \to bu' \ \text{ in } \ L^2(0,T;W) \ \text{ as } \lambda \to 0. \tag{2.11}$$

Indeed, for the first property, we notice that $J_\lambda \in \mathcal{L}(W')$ for $0 < \lambda \le \lambda_0$ with a uniformly bounded norm (by duality, from (2.1)). Then $J_\lambda g(t) \to g(t)$ as $\lambda \to 0$, in W' a.e. on $(0,T)$, and

$$\|J_\lambda g(t) - g(t)\|_{W'} \le C\|g(t)\|_{W'}.$$

From Lebesgue's theorem, it follows that

$$\|J_\lambda g - g\|_{W'}^2 \to 0 \quad \text{in} \quad L^1(0,T) \ \text{ as } \lambda \to 0,$$

which gives (2.10).

Next, from (2.8), we also have $J_\lambda b(t)u' \to b(t)u'$ as $\lambda \to 0$ in W a.e. on $(0,T)$, and by (2.1), we have

$$\|J_\lambda b(t)u'(t) - b(t)u'(t)\|_W \le C\|b(t)u'(t)\|_W.$$

From Lebesgue's theorem, it follows that

$$\|J_\lambda bu' - bu'\|_W^2 \to 0 \quad \text{in} \quad L^1(0,T) \quad \text{as} \quad \lambda \to 0,$$

which gives (2.11).

Now assume for a moment that α and β are *both* such that

$$[u(\alpha), u'(\alpha)] \in V \times H \quad \text{and} \quad [u(\beta), u'(\beta)] \in V \times H.$$

Then as $\lambda \to 0$, we can pass to the limit in (2.9) to obtain

$$E_u(\beta) - E_u(\alpha) = \int_\alpha^\beta (g(s), b(s)u'(s))_{W',W}\, ds. \tag{2.12}$$

Now let α be *fixed* for a while and apply (2.12) with $\beta = \beta_n \to t \in [0,T]$ as $n \to +\infty$. We obtain that $E(\beta_n)$ is bounded and therefore (replacing if necessary $(\beta_n)_n$ by a subsequence) we have

$$(u(\beta_n), u'(\beta_n)) \rightharpoonup (\varphi, \psi) \quad \text{weakly in } V \times H \quad \text{as } n \to +\infty.$$

On the other hand, by the regularity assumptions on u, we have

$$(u(\beta_n), u'(\beta_n)) \to (u(t), u'(t)) \quad \text{strongly in } H \times V' \quad \text{as } n \to +\infty.$$

It follows that $(u(t), u'(t)) = (\varphi, \psi)$ and therefore $u(t) \in V$ and $u'(t) \in H$. Since this is valid for *any* t, (2.12) becomes true for any (α, β).

Now the vector $Y(t) = (u(t), u'(t))$ is weakly continuous on $[0,T]$ and its norm is continuous by (2.12). The remainder of the proof is obvious from (2.12). □

Proof of Theorem 2.1. (i) Uniqueness. Let u and $\tilde{u}$ be two solutions with the same initial data. We have

$$u'' + Au + B(t)u' = 0 \quad \text{and} \quad \tilde{u}'' + A\tilde{u} + B(t)\tilde{u}' = 0.$$

Then $z := \tilde{u} - u$ satisfies

$$z'' + Az = B(t)u' - B(t)\tilde{u}',$$

with

$$bz' \in L^2(0,T;W)$$

and

$$B(t)u' - B(t)\tilde{u}' = bg, \quad g \in L^2(0,T;W').$$

From Lemma 2.1, we deduce

$$E_z'(t) = \langle g(t), b(t)z'\rangle_{W',W} = \begin{cases} -\langle B(t)\tilde{u}' - B(t)u', \tilde{u}' - u'\rangle_{W',W} & \text{if } b(t) > 0, \\ 0 & \text{if } b(t) = 0. \end{cases}$$

Thus $E_z(t) = \frac{1}{2}[\|z\|_V^2 + \|z'\|_H^2]$ is nonincreasing by (2.3). Since $E_z(0) = 0$, we obtain $z \equiv 0$, i.e., $\tilde{u} \equiv u$. □

(ii) Existence. We introduce, for $\psi \in W$,

$$C(t)\psi := \begin{cases} \frac{1}{b(t)} B(t) \left(\frac{\psi}{b(t)} \right) & \text{if } b(t) > 0, \\ 0 & \text{if } b(t) = 0. \end{cases}$$

It is clear that $C(t) \in \mathrm{Lip}\,(W, W')$ for all $t \in J$ and $\|C(t)\psi_1 - C(t)\psi_2\|_{W'} \le C\|\psi_1 - \psi_2\|_W$ for all $t \in J$ and $\psi_1, \psi_2 \in W$.

Next, for (u^0, u^1) given in $V \times H$ and for $0 < \lambda \le \lambda_0$, we solve

$$\begin{cases} u_\lambda'' + Au_\lambda + J_\lambda B(t) J_\lambda u_\lambda' = 0, \quad t \in J, \\ u_\lambda(0) = u_0, \quad u_\lambda'(0) = u_1. \end{cases} \tag{2.13}$$

We have

$$u_\lambda \in \mathcal{C}^0([0,T]; V) \cap \mathcal{C}^1([0,T]; H) \cap \mathcal{C}^2([0,T]; V'),$$

and

$$\int_0^T \langle B J_\lambda u_\lambda', J_\lambda u_\lambda' \rangle_{W',W}\, ds + E_\lambda(T) = E_\lambda(0) = \frac{1}{2}[\|u_0\|_V^2 + \|u_1\|_H^2] = E(0), \tag{2.14}$$

which is fixed. Equation (2.13) can also be written as

$$u_\lambda'' + Au_\lambda + b(t) J_\lambda C(t)(b(t) J_\lambda u_\lambda') = 0. \tag{2.15}$$

From (2.14) we deduce that $bJ_\lambda u_\lambda'$ is bounded in $\mathcal{W} := L^2(J; W)$. Thus

$$B(t) J_\lambda u_\lambda' = b(t) C(t)(b(t) J_\lambda u_\lambda') = b h_\lambda,$$

where h_λ is bounded in $\mathcal{W}' := L^2(J; W')$.

Finally, u_λ is bounded in $L^\infty(J; V) \cap W^{1,\infty}(J; H)$ and we may assume that there exists a subsequence such that

$$u_{\lambda_n} \rightharpoonup u \quad \text{weakly in } L^2(J; V) \cap H^1(J; H) \quad \text{as } n \to +\infty,$$

and

$$bJ_{\lambda_n} u_{\lambda_n}' \rightharpoonup z \quad \text{weakly in } \mathcal{W} \quad \text{as } n \to +\infty.$$

Since $u_{\lambda_n}' \rightharpoonup u'$ weakly in $\mathcal{H} := L^2(J; H)$ as $n \to +\infty$, we have (taking the inner product with some test function $\varphi \in H^1(J; D(A))$, for instance)

$$bJ_{\lambda_n} u_{\lambda_n}' \rightharpoonup bu' \quad \text{weakly in } \mathcal{H} \quad \text{as } n \to +\infty.$$

Therefore, $bu' = z \in \mathcal{W}$ and

$$bJ_{\lambda_n} u_{\lambda_n}' \rightharpoonup bu' \quad \text{weakly in } \mathcal{W} \quad \text{as } n \to +\infty.$$

On the other hand, we have (taking if necessary a subsequence)

$$C(t)(bJ_{\lambda_n} u_{\lambda_n}') \rightharpoonup \psi \quad \text{weakly in } \mathcal{W}' \quad \text{as } n \to +\infty.$$

It is not difficult, using a suitable test function, to check that

$$J_{\lambda_n} C(t)(bJ_{\lambda_n} u'_{\lambda_n}) \rightharpoonup \psi \quad \text{weakly in } \mathcal{W}' \quad \text{as } n \to +\infty,$$

so that, passing to the limit in (2.15),

$$u'' + Au + b\psi = 0 \quad \text{in } L^2(J; V'). \tag{2.16}$$

To obtain $b\psi = B(t)u'$, it remains to show that

$$\psi = C(t)bu'. \tag{2.17}$$

We introduce $\mathcal{C} : \mathcal{W} \to \mathcal{W}'$ defined by

$$\forall \varphi \in \mathcal{W}, \quad (\mathcal{C}\varphi)(t) := C(t)\varphi(t) \quad \text{a.e. on } J.$$

We remark that

$$\begin{aligned}\langle \mathcal{C}(bJ_\lambda u'_\lambda), bJ_\lambda u'_\lambda \rangle_{\mathcal{W}',\mathcal{W}} &= \int_0^T \langle b\mathcal{C}(bJ_\lambda u'_\lambda), J_\lambda u'_\lambda \rangle_{W',W}\, dt \\ &= \int_0^T \langle B(t)J_\lambda u'_\lambda, J_\lambda u'_\lambda \rangle_{W',W}\, dt = E(0) - E_\lambda(T).\end{aligned}$$

Whereas, due to Lemma 2.1, we have

$$E(T) + \langle \Psi, bu' \rangle_{\mathcal{W}',\mathcal{W}} = E(0).$$

Since

$$E(T) \le \liminf_{n\to+\infty} E_{\lambda_n}(T),$$

we obtain

$$\begin{aligned}E(0) - \langle \Psi, bu' \rangle_{\mathcal{W}',\mathcal{W}} &\le \liminf_{n\to+\infty} E_{\lambda_n}(T) \\ &= \liminf_{n\to+\infty} \left(E(0) - \langle \mathcal{C}(bJ_{\lambda_n} u'_{\lambda_n}), bJ_{\lambda_n} u'_{\lambda_n} \rangle_{\mathcal{W}',\mathcal{W}}\right) \\ &= E(0) - \limsup_{n\to+\infty} \langle \mathcal{C}(bJ_{\lambda_n} u'_{\lambda_n}), bJ_{\lambda_n} u'_{\lambda_n} \rangle_{\mathcal{W}',\mathcal{W}}.\end{aligned}$$

Hence

$$\limsup_{n\to+\infty} \langle \mathcal{C}(bJ_{\lambda_n} u'_{\lambda_n}), bJ_{\lambda_n} u'_{\lambda_n} \rangle_{\mathcal{W}',\mathcal{W}} \le \langle \Psi, bu' \rangle_{\mathcal{W}',\mathcal{W}}.$$

Then we can apply the following lemma.

LEMMA 2.2. *Let $\mathcal{W}$ be a Hilbert space and let $\mathcal{C} : \mathcal{W} \to \mathcal{W}'$ be monotone and Lipschitz continuous. Assume that $(z_n)_n$ is a sequence of $\mathcal{W}$ such that $z_n \rightharpoonup z$ weakly in $\mathcal{W}$ and $\mathcal{C}z_n \rightharpoonup \Psi$ weakly in $\mathcal{W}'$ as $n \to +\infty$.*

If

$$\limsup_{n\to+\infty} \langle \mathcal{C}z_n, z_n \rangle_{\mathcal{W}',\mathcal{W}} \le \langle \Psi, z \rangle_{\mathcal{W}',\mathcal{W}},$$

then $\Psi = \mathcal{C}z$

For the proof of this lemma, let $K : \mathcal{W}' \to \mathcal{W}$ be the duality map. Then $C := K\mathcal{C} : \mathcal{W} \to \mathcal{W}$ satisfies the assumptions of Proposition 2 of [8, p. 41]. (See also Brezis [5].)

This provides (2.17) and the proof of Theorem 2.1 is finished. ∎

3. Asymptotic stability.

3.1. An energy decay estimate on a short time interval. Assume that (2.1)–(2.5) hold. In order to study the asymptotic behavior of the energy, we first prove the following result, interesting in itself, concerning the *estimate of energy decay on a short interval of time*.

THEOREM 3.1. *Let $T > 0$ be fixed and assume that there exist $M, m > 0$ such that*

$$\forall t \in (0,T), \quad \forall v \in W, \quad \langle B(t)v, v\rangle_{W',W} \geq m\|v\|_W^2, \tag{3.1}$$

and

$$\forall t \in (0,T), \quad \forall v \in W, \quad \|B(t)v\|_{W'}^2 \leq M\langle B(t)v, v\rangle_{W',W}. \tag{3.2}$$

Then there exists $c > 0$ (independent of T) such that, for all $(u_0, u_1) \in V \times H$, the solution u of (2.6)–(2.7) satisfies

$$E(T) \;\leq\; \frac{1}{1 + c\,\frac{m}{T^{-3}+T^{-1}+MmT^{-1}}}\,E(0). \tag{3.3}$$

Theorem 3.1 is interesting in itself because it provides an estimate of the decay of the energy that is valid for t *small*. In particular, $E(t) < E(0)$. It has to be noted that, in general, estimates of the decay of the energy are provided for t *large enough*, even in the case of uniformly distributed damping terms. Of course if the damping is locally distributed in the domain, it is impossible to expect that $E(t) < E(0)$ for $t > 0$ small. (See, for example, [11, 12, 15, 16, 17, 18, 19, 23, 24] for classical estimates of the energy decay when t is large enough.)

Proof of Theorem 3.1. Following [7], we set

$$\theta(t) = t^2(T-t)^2.$$

Note that

$$\forall t \in [0,T], \quad |\theta'(t)| = |2t(T-t)(T-2t)| \leq 2T\theta^{1/2}(t), \tag{3.4}$$

$$\max_{t\in[0,T]} \theta(t) = \frac{T^4}{16}, \tag{3.5}$$

and

$$\int_0^T \theta(t)\,dt = \frac{T^5}{30}. \tag{3.6}$$

We also introduce $K_W, K'_W > 0$ such that

$$\forall v \in W, \quad K'_W|v|_H \leq \|v\|_W \leq K_W\|v\|_V = K_W|A^{1/2}v|_H. \tag{3.7}$$

First note that the energy of u is nonincreasing and satisfies

$$E(0) - E(T) = \int_0^T \langle Bu', u'\rangle_{W',W} \geq 0. \tag{3.8}$$

Multiplying (2.6) by θu, we obtain

$$\begin{aligned}\int_0^T \theta|A^{1/2}u|_H^2 &= -\int_0^T \theta\langle u''+Bu',u\rangle_{V',V}\\ &= \int_0^T ((\theta u)',u'))_H - \int_0^T \theta\langle Bu',u\rangle_{W',W}\\ &= \int_0^T \theta'(u,u')_H + \int_0^T \theta|u'|_H^2 - \int_0^T \theta\langle Bu',u\rangle_{W',W}\\ &\le \varepsilon\int_0^T \theta'^2(t)|u|_H^2 + \frac{1}{4\varepsilon}\int_0^T |u'|_H^2 + \int_0^T \theta(t)|u'|_H^2\\ &\quad + \eta\int_0^T \theta\|u\|_W^2 + \frac{1}{4\eta}\int_0^T \theta\|Bu'\|_{W'}^2,\end{aligned}$$

for all $\varepsilon,\eta>0$. Using (3.7), (3.4), (3.5) and (3.2) we deduce

$$\begin{aligned}\int_0^T \theta|A^{1/2}u|_H^2 &\le 4\frac{K_W^2}{{K'_W}^2}T^2\varepsilon\int_0^T \theta|A^{1/2}u|_H^2 + \frac{1}{4\varepsilon}\int_0^T |u'|_H^2\\ &\quad + \frac{T^4}{16}\int_0^T |u'|_H^2 + K_W^2\eta\int_0^T \theta|A^{1/2}u|_H^2 + \frac{T^4}{16}\frac{M}{4\eta}\int_0^T \langle Bu',u'\rangle_{W',W}.\end{aligned}$$

We choose ε and η such that

$$4\frac{K_W^2}{{K'_W}^2}T^2\varepsilon = K_W^2\eta = 1/4,$$

hence

$$\frac{1}{4\varepsilon} = 4\frac{K_W^2}{{K'_W}^2}T^2; \quad \frac{1}{4\eta} = K_W^2.$$

Thus we obtain

$$\begin{aligned}\frac12\int_0^T \theta|A^{1/2}u|_H^2 &\le \frac{1}{4\varepsilon}\int_0^T |u'|_H^2 + \frac{T^4}{16}\int_0^T |u'|_H^2 + \frac{T^4}{16}\frac{M}{4\eta}\int_0^T \langle Bu',u'\rangle_{W',W}\\ &= \left(4\frac{K_W^2}{{K'_W}^2}T^2 + \frac{T^4}{16}\right)\int_0^T |u'|_H^2 + \frac{K_W^2T^4M}{16}\int_0^T \langle Bu',u'\rangle_{W',W}.\end{aligned}$$

Hence,

$$\int_0^T \theta|A^{1/2}u|_H^2 \le F(T)\int_0^T |u'|_H^2 + \frac{K_W^2MT^4}{8}\int_0^T \langle Bu',u'\rangle_{W',W},$$

where

$$F(T) := 8\frac{K_W^2}{{K'_W}^2}T^2 + \frac{T^4}{8}.$$

Using

$$\forall t\in[0,T], \quad 2E(t) = |A^{1/2}u(t)|_H^2 + |u'(t)|_H^2 \ge 2E(T),$$

we deduce

$$\int_0^T \theta(2E(T) - |u'|_H^2) \le F(T) \int_0^T |u'|_H^2 + \frac{K_W^2 M T^4}{8} \int_0^T \langle Bu', u' \rangle_{W',W}.$$

Hence, using (3.5) and (3.7),

$$\begin{aligned} E(T) \int_0^T \theta &\le \frac{1}{2} \left(F(T) + \frac{T^4}{16} \right) \int_0^T |u'|_H^2 + \frac{K_W^2 M T^4}{16} \int_0^T \langle Bu', u' \rangle_{W',W} \\ &\le \frac{1}{K_W'^2} \left(4 \frac{K_W^2}{{K_W'}^2} T^2 + \frac{3T^4}{32} \right) \int_0^T \|u'\|_W^2 + \frac{K_W^2 M T^4}{16} \int_0^T \langle Bu', u' \rangle_{W',W}. \end{aligned}$$

Thus, using (3.6), there exists a constant $c > 0$ (independent of T) such that

$$E(T) \le \frac{1}{c}(T^{-3} + T^{-1}) \int_0^T \|u'\|_W^2 + \frac{1}{c} M T^{-1} \int_0^T \langle Bu', u' \rangle_{W',W}.$$

Using (3.1) and (3.8), we find

$$\begin{aligned} E(T) &\le \frac{1}{cm}(T^{-3} + T^{-1}) \int_0^T \langle Bu', u' \rangle_{W',W} + \frac{1}{c} M T^{-1} \int_0^T \langle Bu', u' \rangle_{W',W} \\ &= \frac{1}{cm}(T^{-3} + T^{-1} + MmT^{-1})(E(0) - E(T)). \end{aligned}$$

Hence

$$E(T) \ \le \ \frac{1}{1 + c \frac{m}{T^{-3} + T^{-1} + MmT^{-1}}} \ E(0). \qquad \square$$

3.2. A condition for asymptotic stability. Assume that (2.1)–(2.5) hold for any $T > 0$. Then (2.6)–(2.7) is well-posed and it follows from Theorem 3.1 that the result of Smith [27] may be extended to the case of problem (2.6)–(2.7).

THEOREM 3.2. *Consider a sequence $(I_n)_{n \ge 0}$ of disjoint open intervals in $(0, +\infty)$, denoted by $I_n = (a_n, b_n)$, where $b_n \le a_{n+1}$ for all $n \in \mathbb{N}$, and assume that, for all $n \ge 0$, there exist $M_n, m_n > 0$ such that*

$$\forall t \in I_n, \quad \forall v \in W, \quad \langle B(t)v, v \rangle_{W',W} \ge m_n \|v\|_W^2, \tag{3.9}$$

and

$$\forall t \in I_n, \quad \forall v \in W, \quad \|B(t)v\|_{W'}^2 \le M_n \langle B(t)v, v \rangle_{W',W}. \tag{3.10}$$

Assume that the following condition holds:

$$\sum_{n=0}^{\infty} m_n T_n \min \left(T_n^2, \frac{1}{1 + m_n M_n} \right) = +\infty, \tag{3.11}$$

where T_n denotes the length of I_n. Then (2.6)–(2.7) is asymptotically stable; i.e., for all $(u_0, u_1) \in V \times H$, the solution u of (2.6)–(2.7) satisfies $E_u(t) \to 0$ as $t \to \infty$.

Remark 1. Moreover, the proof of Theorem 3.2 also provides an estimate of the decay of the energy: if there exists $C > 0$ such that

$$\forall n \in \mathbb{N}, \quad u_n := m_n T_n \min \left(T_n^2, \frac{1}{1 + m_n M_n} \right) \le C,$$

then there exists $\omega > 0$ such that

$$\forall n \in \mathbb{N}, \forall t \geq b_n, \quad E(t) \leq E(0) \exp\left(- \omega \sum_{p=0}^{n} u_p \right).$$

Remark 2. Note that condition (1.2) implies condition (3.11). Note also that, in the case of ordinary differential equations, Pucci and Serrin [25] improved the condition of [27] and proved asymptotic stability under the following condition:

$$\sum_{n=0}^{\infty} m_n T_n \min\left(T_n^2, \frac{1}{1 + \frac{m_n}{T_n} \int_{I_n} a} \right) = +\infty.$$

We do not know if this weaker condition is also sufficient in the case of the partial differential equations (2.6).

Proof of Theorem 3.2. For all $n \geq 0$, we denote $I_n = (a_n, b_n)$ and we apply Theorem 3.1 to the time interval I_n instead of $(0, T)$, which implies

$$E(b_n) \leq \frac{1}{1 + ck_n} E(a_n),$$

where, for all $n \geq 0$,

$$k_n := \frac{m_n}{T_n^{-3} + T_n^{-1} + M_n m_n T_n^{-1}} > 0.$$

Using that the energy is nonincreasing, we deduce, for all $n \geq 0$,

$$\begin{aligned} E(a_{n+1}) \leq E(b_n) &\leq \frac{1}{1 + ck_n} E(a_n) \\ &\leq \left(\prod_{p=0}^{n} \frac{1}{1 + ck_p} \right) E(a_0) \leq \left(\prod_{p=0}^{n} \frac{1}{1 + ck_p} \right) E(0). \end{aligned}$$

Since the energy is nonincreasing, in order to prove Theorem 3.2, it is sufficient to prove that $E(a_{n+1}) \to 0$ as $n \to \infty$. Thus it is sufficient to prove that

$$\prod_{p=0}^{+\infty} \frac{1}{1 + ck_p} = 0, \quad \text{or} \quad \sum_{p=0}^{+\infty} \ln\left(\frac{1}{1 + ck_p} \right) = -\infty.$$

If $k_p \not\to 0$ as $p \to \infty$, then the result follows, and if $k_p \to 0$ as $p \to \infty$, then it reduces to prove that $\sum_{p=0}^{+\infty} k_p = +\infty$. This condition is equivalent to (3.11) since

$$\begin{aligned} \frac{1}{2} m_n T_n \min\left(T_n^2, \frac{1}{1 + m_n M_n} \right) \leq k_n &= \frac{m_n T_n}{\frac{1}{T_n^2} + 1 + m_n M_n} \\ &\leq m_n T_n \min\left(T_n^2, \frac{1}{1 + m_n M_n} \right), \end{aligned}$$

which ends the proof of Theorem 3.2. Note also that condition (1.2) implies condition (3.11) since

$$m_n T_n \delta_n^2 \leq m_n T_n \min\left(T_n^2, \frac{1}{1 + m_n M_n} \right),$$

which proves Remark 2. It remains to prove Remark 1. Using $k_p \geq u_p/2$, we have

$$E(b_n) \leq \prod_{p=0}^{n} \frac{1}{1+cu_p/2}\, E(0) = \exp\left(-\sum_{p=0}^{n} \ln\left(1+cu_p/2\right)\right) E(0).$$

Since $\ln(1+cx/2) \geq \ln(1+cC/2)x/C$ for all $x \in (0,C)$, we obtain

$$E(b_n) \leq \exp\left(-\frac{\ln(1+cC/2)}{C} \sum_{p=0}^{n} u_p\right) E(0). \qquad \square$$

3.3. Further comments. The main restrictive assumption of our general setting is that the damping term $B(t)u'$ is assumed to be *uniformly* distributed in space. However, this restriction is crucial if we want to consider an *on/off* damping. Our result does not apply to an on/off damping that is only *locally* distributed in space, even if the geometric condition of Bardos, Lebeau, and Rauch [2, 3] is satisfied.

Let us explain why the case of a locally distributed on/off damping, for example, $B(t)u' = a(t,x)u'$, is out of reach, at least under such a general form. Indeed, even for a very simple example, the situation is complicated and the statement of the results depends on a lot of parameters.

Let us consider the one-dimensional wave equation in $(0,1)$:

$$\text{(3.12)} \qquad \begin{cases} u'' - u_{xx} = -b(t)c(x)u', & x \in (0,1),\ t>0, \\ u(t,0) = u(t,1) = 0, & t>0, \\ u(0,\cdot) = u_0 \in H_0^1(0,1),\ u'(0,\cdot) = u_1 \in L_0^2(0,1). \end{cases}$$

Here we consider $a(t,x) = b(t)c(x)$ and we can distinguish three cases.

1. *The locally distributed (non on/off) case.* Our result does not apply to this case. Actually, it was not the purpose of the present paper, since this case has been widely studied in the literature. Let us recall some well-known results.

First, we consider the time-independent case:

$$a(t,x) = c(x), \quad \text{i.e., } b(t) \equiv 1,$$

with

$$c(x) \geq c_0 > 0 \quad \text{for all } x \in \omega,$$

where ω is an open subset of $(0,1)$. If ω is nonempty, then asymptotic stability holds. More generally, this result is well known in higher dimension spaces, provided that ω satisfies the geometric condition of Bardos, Lebeau, and Rauch [2, 3]. On the other hand, this kind of result may be extended to the time-dependent case

$$a(t,x) = b(t)c(x),$$

provided that

$$0 < \sigma(t) \leq b(t) \leq 1/\sigma(t),$$

with the condition

$$\int_0^{+\infty} \sigma(\tau)\, d\tau = +\infty.$$

See, for example, [20, 22, 26]. Notice that this allows us to consider a time-dependent damping, but not an on/off damping, since the assumption $b(t) > 0$ is needed.

2. *The uniformly distributed on/off case.* In the present paper, we consider a damping that is uniformly distributed in space, but is allowed to be on/off in time. For example, we assume

$$a(t,x) = b(t)c(x) \geq c_0 b(t),$$

with $c_0 > 0$ and where $b(t) = 0$ on an infinite union of intervals. In this case, Theorem 3.2 gives a sharp condition of asymptotic stability. (See section 4 for several examples of application of Theorem 3.2.)

3. *The locally distributed on/off case.* Now let us turn to the more general case of a locally distributed on/off damping, and let us see why its study is out of reach, at least in a general setting.

We consider the following "simple" example:

$$c(x) = \chi_\omega(x), \quad \text{where } \omega = (1/2 - \lambda, 1/2 + \lambda),$$

with $0 < \lambda \leq 1/2$, and $b : \mathbb{R}_+ \to \mathbb{R}_+$ is T-periodic such that

$$b(t) = 1 \quad \text{on} \quad [0,T) \quad \text{and} \quad b(t) = 0 \quad \text{on} \quad [T,2T).$$

Notice that, for all $0 < \lambda \leq 1/2$, ω satisfies the geometric condition of Bardos, Lebeau, and Rauch [2, 3]. However, this is not sufficient to insure asymptotic stability in this case. Indeed the following result holds.

THEOREM 3.3. [21, Theorem 2.3, p. 340].

(i) *If*

$$\left(\frac{1}{T} \in 2\mathbb{N} \quad \textit{and} \quad 2\lambda < T\right),$$

then there exists initial condition $(u_0, u_1) \in H_0^1(0,1) \times L^2(0,1)$ *such that the energy of the solution of* (3.12) *remains constant with time:* $E(t) = E(0) > 0$ *for all* $t > 0$.

(ii) *If*

$$\left(\frac{1}{T} \in 2\mathbb{N} \quad \textit{and} \quad 2\lambda > T\right), \quad \textit{or} \quad \left(\frac{1}{T} \notin 2\mathbb{N}\right),$$

then the energy of the solutions of (3.12) *decays uniformly exponentially to* 0.

This result shows that the situation is much more complicated because both difficulties (coming from the fact the damping is *locally* distributed in space and is *on/off* in time) are considered. Notice that Theorem 3.3 is proved in [21] without using the notion of optic rays. However, the results can be explained with the following comments related to optic rays propagation.

First consider the case of a uniformly distributed damping, i.e., $\lambda = 1/2$. In this case, Theorem 3.3 insures that asymptotic stability holds for all $T > 0$. Notice that, in this case, it is clear that each optic ray crosses the damping space region during a period when the damping is effective.

Next consider the more interesting case of a locally distributed damping: $0 < \lambda < 1/2$. Now there are some values of T and some values of λ for which *some optic rays cross the space damping region only when the feedback is not active.* For example, take $T = 1/2$, $\lambda < T/2 = 1/4$, and consider the optic ray that leaves the

point $x = T/2 = 1/4$ and that goes to the left (toward the point $x = 0$) at time $t = 0$. This ray describes the segment $[1/4, 3/4]$ (that contains the damping region) during the time intervals $[T, 2T]$, $[3T, 4T], \dots$, thus during periods when $b(t) = 0$. The same situation occurs as soon as $1/T \in 2\mathbb{N}$ with $2\lambda < T$. In these cases, Theorem 3.3 provides negative results of stability, while it provides positive results in the other cases.

We see that all these results are coherent with the optic ray condition known for time-independent feedbacks [2, 3]. But now, the fact that the feedback depends on time has to be taken into account. And it seems to be crucial that *each optic ray crosses the damping space region during a period when the damping is effective.*

4. Some examples. We first consider the case of *ordinary differential equations* that has been widely studied (see, for example, [1, 9, 10, 25, 27, 28]).

Example 1 (the oscillator equation). Assume $a \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+)$ is a nonnegative function whose minimum and maximum values in I_n are denoted by α_n and A_n.

With $H = V = D(A) = \mathbb{R}$, $Au = u$, and $B(t) = a(t)Id$, Theorem 3.2 applies to the oscillator equation (1.1) (with $m_n := \alpha_n$ and $M_n := A_n$). Since (1.2) implies condition (3.11), this again gives Theorem 1.1 with a small improvement of the sufficient condition. (In particular, this gives a new proof of the result of Smith, very different from the original proof based on monotonicity properties.)

Taking $B(t) = a(t)f$, we may also consider the nonlinear oscillator

$$u'' + u + a(t)f(u') = 0, \qquad t > 0,$$

where we assume that $f \in \mathcal{C}^1(\mathbb{R})$ is such that $f(0) = 0$ and $0 < \beta \le f' \le B$. Hence B defined by $B(t)v := a(t)f(v)$ satisfies (3.9) and (3.10) with $m_n := \beta\alpha_n$ and $M_n := BA_n$.

Next we assume that Ω is a bounded open set of $\mathbb{R}^N$ with regular boundary and we turn to the case of *uniformly damped partial differential equations* with a *bounded* damping operator.

Example 2 (a wave equation). Let $a_1,\ a_2 \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+)$ be two nonnegative functions such that *either*

$$a_2(t) = 0 \quad \text{a.e. on } \mathbb{R}_+$$

or

$$\exists C > 0, \quad a_1(t) \le C a_2(t) \quad \text{for a.e. } t \in \mathbb{R}_+$$

and

$$\forall n \in \mathbb{N}, \quad \alpha_n \le a_1(t) + a_2(t) \le A_n \quad \text{for a.e. } t \in I_n.$$

Consider also $f \in \mathbb{C}^1(\mathbb{R})$ such that $f(0) = 0$ and $0 < \beta \le f' \le B$.

Then we study the following damped wave equation:

$$\text{(4.1)} \qquad \begin{cases} u'' - \Delta u + a_1(t)f(u') - a_2(t)\Delta u' = 0, & x \in \Omega, t > 0, \\ u = 0, & x \in \partial\Omega, t > 0, \\ u(t=0) \in H^1_0(\Omega), \quad u'(t=0) \in L^2(\Omega). \end{cases}$$

We choose $H = L^2(\Omega)$, $A = -\Delta$ (with Dirichlet boundary conditions), $D(A) = H^2 \cap H^1_0(\Omega)$, and $B(t)v := a_1(t)f(v) - a_2(t)\Delta v$. The choice of W depends on a_2: in the case $a_2 \equiv 0$, $W = H$; otherwise $W = V$.

Consider $J = (0, T)$ with $T > 0$ and let us verify that the assumptions of Theorem 2.1 are satisfied. First (2.1) and (2.2) clearly hold. Then we write, for $w, z \in W$,

$$\langle B(t)w - B(t)z, w - z\rangle_{W',W} = a_1(t)\int_\Omega (f(w) - f(z))(w - z)\,dx + a_2(t)\int_\Omega |\nabla(w - z)|^2\,dx \geq 0,$$

which gives (2.3). On the other hand, for $w \in W$, we have

$$\langle B(t)w, w\rangle_{W',W} = a_1(t)\int_\Omega f(w)w\,dx + a_2(t)\int_\Omega |\nabla w|^2\,dx \geq a_1(t)\beta\|w\|_H^2 + a_2(t)\|w\|_V^2.$$

If $a_2 \equiv 0$, then $W = H$ and we choose $b(t) = \sqrt{\beta a_1(t)}$. In the other case, $W = V$ and we choose $b(t) = \sqrt{a_2(t)}$. Thus (2.4) is also satisfied. Finally, we write, for $w, z \in W$,

$$\|B(t)w - B(t)z\|_{W'}^2 \leq 2a_1(t)^2\|f(w) - f(z)\|_{W'}^2 + 2a_2(t)^2\|\Delta w - \Delta z\|_{W'}^2 \leq 2a_1(t)^2B^2\|w - z\|_H^2 + 2a_2(t)^2\|\Delta w - \Delta z\|_{W'}^2.$$

In the case $a_2 \equiv 0$, we deduce

$$\|B(t)w - B(t)z\|_H^2 \leq 2a_1(t)^2B^2\|w - z\|_H^2 \leq 2\frac{B^2}{\beta^2}b(t)^4\|w - z\|_H^2.$$

In the case $a_2 \not\equiv 0$, we deduce

$$\|B(t)w - B(t)z\|_{H^{-1}(\Omega)}^2 \leq 2[B^2C^2a_2(t)^2\|w - z\|_{L^2(\Omega)}^2 + a_2(t)^2\|w - z\|_{H_0^1(\Omega)}^2] \leq Kb^4(t)\|w - z\|_{H_0^1(\Omega)}^2,$$

where $K > 0$ is a constant. Thus (2.5) proved in both cases. Hence Theorem 2.1 insures the well-posedness of (2.6)–(2.7).

For the study of asymptotic stability, we verify that (3.9) and (3.10) are satisfied.

First case: $a_2 \equiv 0$ ($W = H$). We write for all $n \geq 0$, $t \in I_n$, $v \in W$,

$$(B(t)v, v)_H = a_1(t)\int_\Omega f(v)v\,dx \geq \alpha_n\beta\|v\|_H^2,$$

and

$$\|B(t)v\|_H^2 = a_1(t)^2\int_\Omega f(v)^2\,dx \leq A_nBa_1(t)\int_\Omega f(v)v\,dx = A_nB(B(t)v, v)_H.$$

Thus (3.9) and (3.10) are satisfied for $m_n := \beta\alpha_n$ and $M_n := BA_n$.

Second case: $a_2 \not\equiv 0$ ($W = V = H_0^1(\Omega)$). We write for all $n \geq 0$, $t \in I_n$, $v \in W$,

$$\langle B(t)v, v\rangle_{V',V} \geq a_2(t)\|w\|_V^2 \geq \alpha_n\|w\|_V^2,$$

and

$$\begin{aligned}\|B(t)v\|^2_{H^{-1}(\Omega)} &= \|a_1(t)f(v) - a_2(t)\Delta v\|^2_{H^{-1}(\Omega)}\\ &\le 2a_1(t)^2\int_\Omega f(v)^2\,dx + 2a_2(t)^2\|\Delta v\|^2_{H^{-1}(\Omega)}\\ &\le 2Ca_2(t)a_1(t)B\int_\Omega f(v)v\,dx + 2a_2(t)^2\int_\Omega \nabla v^2\,dx\\ &\le 2(BC+1)a_2(t)\left(a_1(t)\int_\Omega f(v)v\,dx + a_2(t)\int_\Omega \nabla v^2\,dx\right)\\ &\le 2(BC+1)A_n\langle B(t)v, v\rangle_{H^{-1}(\Omega),H^1_0(\Omega)}.\end{aligned}$$

Thus (3.9) and (3.10) are satisfied for $m_n := \alpha_n$ and $M_n := 2(BC+1)A_n$.

Applying Theorem 3.2, we deduce that (3.11) is a sufficient condition of asymptotic stability for (2.6).

Note that we may also consider the more general case

$$B(t)v := a_1(t)f(v) + a_2(t)(-\Delta)^{1/2}g((-\Delta)^{1/2}v).$$

Note also that in the particular case of a linear bounded damping $B(t)v := a(t)v$, this completes the work done in [21], where we studied the case of a locally damped wave equation with a periodic on/off damping.

Example 3 (some plate equations). In the same spirit, taking $H = L^2(\Omega)$, $A = \Delta^2$, $V = H^2_0(\Omega) = \{v \in H^2(\Omega) \mid v = 0 \text{ and } \frac{\partial v}{\partial \nu} = 0 \text{ on } \partial\Omega\}$ and $D(A) = H^4 \cap H^2_0(\Omega)$, we may consider the following damped plate equation:

$$\text{(4.2)}\quad \begin{cases} u'' + \Delta^2 u + a_1(t)f(u') - a_2(t)\Delta u' + a_3(t)\Delta g(\Delta u') = 0, & x \in \Omega, t > 0,\\ u = 0, \quad \dfrac{\partial u}{\partial \nu} = 0, & x \in \partial\Omega, t > 0,\\ u(t=0) = u_0 \in H^2_0(\Omega), \quad u'(t=0) = u_1 \in L^2(\Omega). \end{cases}$$

Here the damping operator is defined by

$$B(t)v := a_1(t)f(v) - a_2(t)\Delta v + a_3(t)\Delta g(\Delta v),$$

and the choice of W depends on the assumptions on the functions a_i. There are 3 cases : $W = H$, $W = H^1_0(\Omega)$ and $W = V$. For the applications of Theorems 2.1 and 3.2, we leave the details to the reader.

5. Another result: The case of a positive-negative damping. In this part, we study the case of a "positive-negative" damping. We assume that H, $D(A)$, and V are defined as in section 2 and that A still satisfies assumption (2.1) with $W = H$. And we consider a time-dependent operator B such that $B \in L^\infty_{\text{loc}}(\mathbb{R}_+, \text{Lip}(H))$. (Note that we only consider the case of a bounded operator B, so we assume in this part that $W = H$.)

Now we assume that B is a "positive-negative" feedback: let $(t_n)_{n\in\mathbb{N}}$ be a strictly increasing sequence of $\mathbb{R}^+$ such that $t_n \to +\infty$ as $n \to +\infty$. For all $n \in \mathbb{N}$, we define $I_{2n} := (t_{2n}, t_{2n+1})$ and $I_{2n+1} := (t_{2n+1}, t_{2n+2})$, and we assume that B is positive on I_{2n} and negative on I_{2n+1}. *Hence the energy decays on the time intervals I_{2n} and increases on the time intervals I_{2n+1}.*

We also assume that, for all $n \in \mathbb{N}$, there exist three positive constants m_{2n}, M_{2n}, M_{2n+1} such that

$$\text{(5.1)}\qquad \forall t \in I_{2n}, \quad \forall v \in H, \quad (B(t)v, v)_H \ \ge\ m_{2n}\|v\|^2_H,$$

$$\forall t \in I_{2n}, \quad \forall v \in H, \quad \|B(t)v\|_H^2 \ \leq \ M_{2n}(B(t)v, v)_H, \tag{5.2}$$

$$\forall t \in I_{2n+1}, \quad \forall v \in H, \quad -M_{2n+1}\|v\|_H^2 \ \leq \ (B(t)v, v)_H \ \leq \ 0. \tag{5.3}$$

Note that the well-posedness of (2.6)–(2.7) is classical (using standard arguments on Lipschitz perturbations of contraction semigroups).

Then, from Theorem 3.2, we deduce the following sufficient condition of asymptotic stability.

THEOREM 5.1. *Assume* (2.1), (5.1), (5.2), (5.3). *Assume that the following condition holds:*

$$\begin{cases} \sum\limits_{p=0}^{+\infty} M_{2p+1}T_{2p+1} < \infty, \\ \sum\limits_{p=0}^{+\infty} m_{2p}T_{2p}\delta_{2p}^2 = +\infty, \end{cases}$$

where T_p *denotes the length of* I_p *and* $\delta_p = \min(T_p, (1 + M_p)^{-1})$. *Then equation* (2.6)–(2.7) *is asymptotically stable; i.e., for all* $(u_0, u_1) \in V \times H$, *the solution* u *of* (2.6)–(2.7) *satisfies* $E_u(t) \to 0$ *as* $t \to \infty$.

Remark. This gives a result of stability in the case of a globally distributed time-dependent feedback of indefinite sign. This completes [21], where we studied the wave equation damped by a time-dependent boundary feedback of indefinite sign. See also [4, 6] for results in the case of space-dependent feedback of indefinite sign.

Proof of Theorem 5.1. For all $n \in \mathbb{N}$, applying Theorem 3.1 on the time intervals I_{2n}, we obtain

$$E(t_{2n+1}) \leq \frac{1}{1 + c\frac{m_{2n}}{T_{2n}^{-3} + T_{2n}^{-1} + M_{2n}m_{2n}T_{2n}^{-1}}} E(t_{2n}).$$

On the other hand, on the time intervals I_{2n+1}, we can write

$$0 \leq E'(t) = -\langle B(t)u', u'\rangle_{W',W} \leq M_{2n+1}\|u'(t)\|_H^2 \leq 2M_{2n+1}E(t).$$

Thus

$$E(t_{2n+2}) \leq E(t_{2n+1})e^{2M_{2n+1}T_{2n+1}}.$$

Hence

$$E(t_{2n+2}) \leq \left(\prod_{p=0}^{n} e^{2M_{2p+1}T_{2p+1}} \frac{1}{1 + c\frac{m_{2p}}{T_{2p}^{-3} + T_{2p}^{-1} + M_{2p}m_{2p}T_{2p}^{-1}}} \right) E(0).$$

In particular, we deduce a condition of asymptotic stability:

$$\sum_{p=0}^{+\infty} \left(2M_{2p+1}T_{2p+1} - \ln\left(1 + c\frac{m_{2p}}{T_{2p}^{-3} + T_{2p}^{-1} + M_{2p}m_{2p}T_{2p}^{-1}} \right) \right) = -\infty.$$

For example, we may assume

$$\begin{cases} \sum\limits_{p=0}^{+\infty} M_{2p+1}T_{2p+1} < \infty, \\ \sum\limits_{p=0}^{+\infty} m_{2p}T_{2p}\delta_{2p}^2 = +\infty, \end{cases}$$

or we may assume

$$\begin{cases} \sum_{p=0}^{+\infty} m_{2p} T_{2p} \delta_{2p}^2 = +\infty, \\ M_{2p+1} T_{2p+1} = o(\ln(1 + m_{2p} T_{2p} \delta_{2p}^2)). \end{cases} \qquad \square$$

ALGORITHMS FOR COUNTABLE STATE MARKOV DECISION MODELS WITH AN ABSORBING SET*

K. HINDERER† AND K.-H. WALDMANN†

Abstract. We consider a countable state Markov decision process with bounded reward function and an absorbing set. At first we generalize known properties and derive new properties of the critical discount factor, which is roughly defined as the maximal discount factor under which for V, the maximal expected infinite-stage discounted reward, there is guaranteed existence, boundedness, and computability by the successive approximation method. The emphasis of the paper is on algorithms for computing V exactly (recursion in state space and policy iteration) or approximately (value iteration combined with an extrapolation and finite state approximation). Our extrapolation method is motivated by and based on the Perron–Frobenius theory for nonlinear operators. As a by-product we obtain an efficient algorithm for determining the distribution of the entrance time of a Markov chain into an absorbing set. Further results concern asymptotically ε-optimal policies and a new turnpike theorem. Some of the results need tightness of the transition law, which turns out to be equivalent to compactness of a nonlinear operator, which is crucial for our study.

Key words. Markov decision processes, transient Markov decision processes, extrapolation methods, Perron–Frobenius theory, expected total reward criterion, absorbing sets

1. Introduction.

We consider a Markov decision process (MDP) with countable state space S, countable action space A, finite subsets $D(s)$ of admissible actions in state $s \in S$, constraint set $D := \{(s,a) \mid s \in S,\ a \in D(s)\}$, stochastic transition law p from D into S, bounded reward function $r : D \to \mathbb{R}$, and (constant) discount factor $\beta > 0$. (In the literature the case $\beta > 1$ is often treated by replacing $\beta \cdot p$ by a nonnegative transition law; see, e.g., Veinott (1969), Zijm (1983).) For $(s,a) \in D$, $M \subset S$ we use $p(s,a,M) := \sum_{s' \in M} p(s,a,s')$. As usual, a deterministic Markov policy $\pi = (f_0, f_1, \dots)$ is a sequence $f_0, f_1, \dots \in F := \{f : S \to A \mid f(s) \in D(s) \text{ for all } s \in S\}$ of decision rules, each specifying action $a_n = f_n(s_n)$ to be taken in state s_n at time n. Thus F^∞ is the set of all deterministic Markov policies. Mainly one is interested in stationary policies $\pi = (f, f, \dots)$ for some $f \in F$, for which we also write f.

In economical applications MDPs with $\beta \le 1$ dominate. However, there are several *cases where $\beta > 1$ is appropriate:*

(a) Many MDPs with unbounded r and $\beta < 1$ can be reduced by means of a bounding function to an MDP' with bounded r' (see Remark 3.3(a)) and a discount factor β' which easily can be larger than one.

(b) There are applications where the nonnegative matrix $\beta \cdot p$ has the interpretation of an expectation, e.g., in the control of branching processes; cf. Sladky (1980), where five examples from the literature are reviewed, and McNamara (1991).

(c) Consider an MDP which subsumes a "time factor" and a "risk factor" under a discount factor $\beta(s,a)$ depending on the actual state and action and possibly larger than one for some (s,a). As shown in section 3 this case can be reduced to an MDP'

†Institut für Mathematische Stochastik and Institut für Wirtschaftstheorie und Operations Research, Universität Karlsruhe, D-76128 Karlsruhe, Germany (karl.hinderer@math.uni-karlsruhe.de, waldmann@wior.uni-karlsruhe.de).

with discount factor $\beta' := \max_{(s,a)} \beta(s,a) > 1$. For an economic interpretation, cf. Branger (2001).

(d) Consider an MDP with discount factor $\alpha \leq 1$ which is nonstationary only because rewards earned in later periods have a larger utility, expressed by a "utility factor" $\gamma > 1$ per period. Then the reward $r(s_n, a_n)$ in period n enters the balance as $(\alpha\gamma)^n \cdot r(s_n, a_n)$, which of course can be treated as a stationary MDP with discount factor $\beta := \alpha\gamma$, possibly larger than one.

An important role will play *absorbing sets* $J_0 \subset S$, $J_0 \neq S$, defined by the requirement that $p(s, a, S - J_0) = 0$, $r(s,a) = 0$ for $s \in J_0$, $a \in D(s)$. Note that the empty set is always absorbing, but mainly we are interested in $J_0 \neq \emptyset$. An MDP may have several nonempty absorbing sets and the union of all absorbing sets is the largest absorbing set (provided that $r \not\equiv 0$). Throughout the paper J_0 denotes an arbitrary absorbing set. $J := S - J_0$ is called the *essential state space.*

Denote by $V(s)$ $[v_n(s)]$ the maximal expected infinite-stage [n-stage] reward when the process starts in $s \in S$ (and when a bounded terminal reward function v_0 is used), provided V exists.

The following property of our MDP with an absorbing set J_0 is of major interest.

(Pβ) *There exists $V(s)$ for $s \in S$, V is bounded, and successive approximation holds*, i.e., V can be approximated uniformly by v_n, starting with any bounded v_0 with $v_0 = 0$ on J_0.

One of the earliest results for standard MDPs (i.e., when J_0 is empty) says that (Pβ) holds whenever $\beta < 1$, and simple examples show that (Pβ) may fail for certain (not necessarily for all) r if $\beta \geq 1$. However, it has also been known for a long time that (Pβ) holds for $\beta = 1$ provided J_0 is nonempty and reached by the process with probability one for each initial state s; cf. Proposition 2.6(c_7).

Given an absorbing set J_0, a useful notion for a systematic study of the validity of (Pβ) in case $\beta \geq 1$ is the so-called *critical discount factor* $\beta^* = \beta^*(J_0)$, which we define as the supremum of those $\beta \in (0, \infty)$, for which (Pβ) holds for each choice of r (bounded and $r(s,a) = 0$ for $s \in J_0$, $a \in D(s)$). Due to Proposition 2.2(iii) below, this definition is consistent with the use in Hinderer and Waldmann (2003) for finite S and A (pp. 2 and 3) and Borel S and A (p. 13). (Note that in the latter paper V and v_∞ are denoted by V_∞ and V, respectively.) Obviously, $\beta^* = 1$ if $J_0 = \emptyset$. Furthermore, the largest absorbing set J_0 has the largest β^* (see Proposition 2.2(i)).

For finite S and A the number $\beta^* \in [0, \infty]$ is studied in detail in Hinderer and Waldmann (2003). In particular, it turned out that $1/\beta^* = \lambda^*$, the spectral radius of the nonlinear operator H associated with the transition law (cf. section 2) and, using a result in Rieder (1976), that this holds even for Borel S and A.

Characterizations of β^* are contained in many further papers on MDPs with an absorbing set. For finite S and A they are extensively studied in the classical paper of Veinott (1969). Extensions to a countable state space, Borel state space, compact sets of admissible actions, and/or unbounded rewards can be found, e.g., in Hordijk (1974), Pliska (1978), and Hernández-Lerma and Lasserre (1999). We also refer to Whittle (1983), Bertsekas (2000/2001), and the references given there.

The *main contributions* in the present paper (sections 4 through 10) concern algorithms for computing V, exactly or approximately, in case of $\beta < \beta^*$. This task motivated our choice of a countable state and action space: most numerical methods work only for countable or even finite S and A (e.g., turnpike theorems). For this reason we also did not present possible extensions of our results in sections 2 and 3 for more general S and A.

Our main results and the organization of the paper are as follows. Section 2 contains properties of H and β^* needed later on. In particular, characterizations of β^* and equivalent conditions for $\beta < \beta^*$, $\beta^* = 1$, and $\beta^* > 1$ are given. Some are generalizations to countable S and A and some are new even in the finite case. In particular, the special case of transient MDPs is characterized. Some of these and later results require tightness of the transition law (condition (A0), which turns out to be equivalent to compactness of H; cf. Proposition 2.1). Sometimes (e.g., for the characterization of β^* in Proposition 2.2(vi) as the largest of the maximal eigenvalues of linear operators H_f) we use spectral properties of H resulting from Ogiwara (1995). A brief derivation of standard results (optimality equation, optimality of a stationary policy, value iteration) and of the contraction of the optimal reward operator U follow in section 3. Our algorithms begin (section 4) with a recursion in the state space for obtaining V on a subset $\tilde{I}_k$ of J. We give a necessary and sufficient condition for $\tilde{I}_k = J$ and introduce an MDP' with (smaller) essential state space $J - \tilde{I}_k$ to which the methods of sections 5 and 7 through 9 can be applied. Our extrapolation methods are introduced and studied in great detail in section 5. Such methods have a long tradition in solving the standard MDP with $\beta < 1$. For MDPs having a transition law with unequal row sums there are a few references (including Hübner (1980)) only. One reason may be that the unequal row sums make a natural extension of the classical MacQueen extrapolation inefficient. On the other hand, an extrapolation method due to Schellhaas (1974), which is scarcely noticed in the literature, is more able to deal with unequal row sums. It forms the basis of our approach. Our results include sufficient conditions for the existence, monotonicity, and convergence of lower and upper bounds for V and lower bounds for "good" decision rules f, using again Perron–Frobenius results from Ogiwara (1995) and Bohl (1974). Our lower bounds are similar to those obtained in Hübner (1980); our upper bounds are new, also for $\beta < 1$. For V_f, the expected infinite-stage reward when using the stationary policy f, we obtain simpler bounds and insight into the speed of convergence of the bounds, as observed in numerical work. As a by-product we obtain (Example 5.6) an efficient method for determining the distribution $P_{fs}(\tau > n)$, $n \in \mathbb{N}$, of the entrance time of a Markov chain into an absorbing set. The paper proceeds with some numerical results in section 6. A slight improvement of the policy iteration is given in section 7. A finite state approximation, suggested in a natural way by our tightness assumption (A0), is considered in section 8. In particular, bounds and convergence results are given. In section 9 we deal with asymptotically ε-optimal policies, which can be combined with our extrapolation method. The paper closes with a turnpike theorem, which improves earlier results.

Notation. We use $\mathbb{N}_0$ ($\mathbb{N}$) to denote the set of all nonnegative (positive) integers. For $v, v' \in \mathbb{R}^J$ we write $v \le v'$ (resp., $v < v'$) if $v(s) \le v'(s)$ (resp., $v(s) < v'(s)$) holds for all $s \in J$. We write $\sum_i A_i$ for the union of disjoint sets A_i, and $A - B$ to denote $\{a \in A \mid a \notin B\}$.

2. The critical discount factor. Let $\tau := \inf\{n \in \mathbb{N} \mid \zeta_n \in J_0\} \le \infty$ denote the entrance time into J_0, i.e., the first time the state process (ζ_n) is in the absorbing set J_0, when the process starts in some state in J. Given a policy $\pi \in F^\infty$ and an initial state $s \in J$, the distribution of τ can be obtained by evaluating $P_{\pi s}(\tau > n)$, $n \in \mathbb{N}_0$, recursively, where $P_{\pi s}$ denotes the distribution of (ζ_n) and $E_{\pi s}$ the associated expectation.

The expected infinite-stage discounted reward up to absorption starting in $s \in J$

and following $\pi \in F^\infty$ is defined by

$$V_\pi(s) := E_{\pi s} \sum_{n=0}^{\tau} \beta^n r(\zeta_n, f_n(\zeta_n)) = E_{\pi s} \sum_{n=0}^{\infty} \beta^n r(\zeta_n, f_n(\zeta_n)),$$

provided that the expectation exists. Then a policy π^* is called optimal if $V_{\pi^*}(s) = V(s) := \sup_{\pi \in F^\infty} V_\pi(s)$, $s \in S$. We also say that a decision rule f^* is optimal if the associated stationary policy is optimal.

Let $\mathfrak{V}_0$ denote the set of all bounded functions on S which vanish on J_0. Note that $V_\pi \in \mathfrak{V}_0$, $\pi \in F^\infty$, and thus $V \in \mathfrak{V}_0$.

We also consider the expected N-stage discounted reward up to absorption, defined by

$$v_{N,\pi}(s) := E_{\pi s} \left(\sum_{n=0}^{N-1} \beta^n r(\zeta_n, f_n(\zeta_n)) 1_{[\tau > n]} + \beta^N v_0(\zeta_N) 1_{[\tau > N]} \right), \quad s \in S,$$

for $\pi \in F^\infty$ and terminal reward $v_0 \in \mathfrak{V}_0$, and put $v_N := \sup_{\pi \in F^\infty} v_{N,\pi}$.

Let $\mathfrak{V}$ denote the Banach space of all bounded functions on J (w.r.t. the supremum norm $\|v\| := \sup_{s \in J} |v(s)|$), $\mathfrak{V}_+ := \{v \in \mathfrak{V} \mid v \geq 0\}$, and $\mathfrak{W} := \{v \in \mathfrak{V} \mid \inf v > 0\}$. If $v \in \mathfrak{V}$ and $w \in \mathfrak{W}$, then $v/w \in \mathfrak{V}$ and the norm $\|v\|_w := \|v/w\|$ induced by w is equivalent to the supremum norm, since $\|v\| \leq \|v\|_w \cdot \|w\| \leq \|v\| \cdot (\|w\| / \inf w)$.

Where no confusion is possible, we also denote $V|J$, the restriction of V to J, by V, and analogously for V_f, $v_{N,\pi}$, and v_N.

On $\mathfrak{V}$ define the operators H, H_f, $f \in F$, well known from the literature, by

$$Hv(s) := \sup_{f \in F} H_f v(s) := \sup_{f \in F} \sum_{s' \in J} p(s, f(s), s') v(s'), \quad s \in J.$$

The sup is attained since $D(s)$ is finite for all s. H and H_f map $\mathfrak{V}$ and $\mathfrak{V}_+$ into itself. The operator H has the desirable properties of being monotone (i.e., $Hv \leq Hv'$ for $v \leq v'$), positively homogenous (i.e., $H(\lambda v) = \lambda H v$ for $\lambda \geq 0$), and subadditive (i.e., $H(v + v') \leq Hv + Hv'$). Moreover, H_f, $f \in F$, are linear and continuous.

For an arbitrary operator T from $\mathfrak{V}$ into $\mathfrak{V}$ (with $Tv \in \mathfrak{V}_+$ for $v \in \mathfrak{V}_+$) we use the following definitions according to Ogiwara (1995, pp. 47–49): (i) The operator norm is $\|T\| := \sup\{\|Tv\| \mid v \geq 0,\ \|v\| \leq 1\}$; (ii) $\lambda \in \mathbb{R}_+$ is called an eigenvalue of T if $Tv = \lambda v$ for some $v \in \mathfrak{V}_+$, $v \not\equiv 0$; (iii) T is compact if T is continuous and if the image under T of each bounded subset of $\mathfrak{V}_+$ is relatively compact. The latter property holds if and only if each sequence $(v_n)_1^\infty \subset \mathfrak{V}_+$ with $\|v_n\| \leq 1$ for all n has a subsequence (v_{n_k}) such that Tv_{n_k} converges in norm to some $v \in \mathfrak{V}_+$. (i) and (iii) are equivalent to the usual definition for continuous linear operators, while (ii) is narrower than the usual definition.

Let $D|_M := \{(s,a) \in D \mid s \in M\}$, $M \subset S$. Some of our results are based on the following assumption.

(A0) The set $(p(s,a,.),\ (s,a) \in D|_J)$ of substochastic measures on J is (uniformly) tight, i.e., for each $\varepsilon > 0$ there exists a finite set $K \subset J$ such that $\sup_{(s,a) \in D|_J} \{p(s,a,J-K)\} \leq \varepsilon$.

If S is finite, then (A0) holds trivially. Thus our results extend those in Hinderer and Waldmann (2003). For the classical problem of selling an asset (cf., e.g., DeGroot (1970)), (A0) can easily be shown to hold. A cash management system (cf., e.g., Hinderer and Waldmann (2001)), where the cash balance $s + a$ after transferring

money at the beginning of a period (always) belongs to a finite set $\{m^-, \dots, m^+\}$ (with $m^\pm \in \mathbb{Z}$), is a simple example with $J_0 = \emptyset$, for which (A0) holds. Similar in structure is the following more technical example with $J = \mathbb{N}_0$, $J_0 = \{-1\}$, $A = \mathbb{Z}$, $s' = \max\{-1, s + a + x\}$, where $P(X = x) > 0$, $x \in \mathbb{Z}$. Let $D(s) = \{\underline{a} - s, \dots, \overline{a} - s\}$, $s \in J$ (with $\underline{a}, \overline{a} \in \mathbb{N}$). Then, for all $\varepsilon > 0$, there exists $x_\varepsilon \in \mathbb{N}$ such that $P(X > x_\varepsilon) \le \varepsilon$. Finally, selecting $K_\varepsilon := \{0, \dots, \overline{a} + x_\varepsilon\}$, it follows that $p(s, a, J - K_\varepsilon) = P(s + a + X > \overline{a} + x_\varepsilon) \le P(X > x_\varepsilon) \le \varepsilon$, $(s, a) \in D|_J$.

If $J_0 = \emptyset$ (hence $p(s, a, .)$ are probability measures), condition (A0) can be expressed via metrics on the space of probability measures on J; see Dudley (1989, Theorem 11.5.4).

Given (A0), the operators H and H_f, $f \in F$, are compact. Indeed, building on Lemma 11.2 in Hordijk (1974), we obtain the next result. Its proof shows, by the way, that Lemma 11.2 cited before also holds for substochastic matrices $(p(i, j))$, provided tightness is defined as in (A0).

PROPOSITION 2.1. *H is compact if and only if* (A0) *holds. Then also H_f, $f \in F$, is compact.*

Proof. First note that H is continuous on $\mathfrak{V}$ (hence on $\mathfrak{V}_+$) whether or not (A0) is true, since $\|Hv - Hw\| \le \|v - w\|$, $v, w \in \mathfrak{V}$. (a) Assume (A0). Select $(v_n) \subset \mathfrak{V}_+$ and $\|v_n\| \le 1$, $n \in \mathbb{N}$. It follows as in the proof of Lemma 11.2 in Hordijk (1974) that given $\varepsilon > 0$ there exist $v_{n_k} \subset \mathfrak{V}_+$, $v^* \in \mathfrak{V}_+$ and $N \in \mathbb{N}$ such that for all $f \in F$ there holds $\|H_f v_{n_k} - H_f v^*\| \le 3\varepsilon$ for $k \ge N$. In particular, H_f is compact. Moreover, it follows that $\|Hv_{n_k} - Hv^*\| \le \sup_{f \in F} \|H_f v_{n_k} - H_f v^*\| \le 3\varepsilon$ for $k \ge N$; hence also H is compact.

(b) Assume that H is compact. Select finite sets $K_n \subset K_{n+1}$, $n \in \mathbb{N}$, with $\cup_n K_n = J$ and put $v_n = 1_{J - K_n}$. Then $v_n \in \mathfrak{V}_+$ and $\|v_n\| \le 1$, $n \in \mathbb{N}$, and $Hv_n(s) = \max_{a \in D(s)} p(s, a, J - K_n)$, $s \in S$, decreases to zero since $D(s)$ is finite. The convergence is uniform since H is compact. Thus, if $\varepsilon > 0$, there exists $n \in \mathbb{N}$ such that $\sup_{(s,a) \in D|_J} \{p(s, a, J - K_n)\} \le \varepsilon$. □

Let $H^{n+1} v := H(H^n v)$, $v \in \mathfrak{V}$, $n \in \mathbb{N}_0$. Analogously for H_f, $f \in F$. Let $e_0 := 1$ and

$$e_n(s) := H^n 1(s) = \sup_{\pi \in F^\infty} P_{\pi s}(\tau > n) \ge P_{fs}(\tau > n) = H_f^n 1(s) =: e_{n,f}(s), \quad s \in J.$$

Obviously $\|e_n\| = \|H^n 1\|$ is an upper bound for the probability that the process has not yet entered the absorbing set J_0 at time n. The asymptotic behavior of $\|e_n\|$ plays a key role in determining the critical discount factor β^*.

To begin with, let $\lambda_f^* := \inf_{k \in \mathbb{N}} \|e_{k,f}\|^{1/k}$, $f \in F$, be the spectral radius of the continuous linear operator H_f. Applied to H, introduce $\lambda^* := \inf_{k \in \mathbb{N}} \|e_k\|^{1/k}$.

PROPOSITION 2.2. *There holds the following:*

(i) $0 \le \lambda^* = \lim_{n \to \infty} \|e_n\|^{1/n} \le \|e_1\| \le 1$.

(ii) $\lambda^* = \lim_{n \to \infty} (\|H^n v\|_w)^{1/n}$ *for all* $v, w \in \mathfrak{W}$.

(iii) *The critical discount factor β^* is equal to $1/\lambda^*$.*

(iv) $0 \le \lambda_f^* \le \lambda^*$ *for all* $f \in F$.

Under (A0) *we additionally have the following:*

(v) *Let $\lambda^* > 0$. Then λ^* is an eigenvalue of H. Moreover, it is the largest one.*

(vi) $\lambda^* = \sup_{f \in F} \lambda_f^*$, *and the supremum is attained.*

Proof. (i) Based on the inequalities $0 \le \|e_{n+m}\| \le \|e_n\| \|e_m\| \le 1$ for $n, m \in \mathbb{N}_0$, existence of $\lim_{n \to \infty} \|e_n\|^{1/n}$ and equality with $\inf_{k \in \mathbb{N}} \|e_k\|^{1/k}$ can be shown as in the case of a linear operator (cf., e.g., Kato (1980, p. 27)). Thus (i) holds.

(ii) Part (ii) is an immediate consequence of $\|e_n\| \le \|H^n v\|/\inf v \le \|H^n v\|_w \cdot (\|w\|/\inf v) \le \|e_n\| \cdot (\|v\|/\inf v)(\|w\|/\inf w)$, $n \in \mathbb{N}$, and (i).

(iii) Note that $1/\lambda^*$ is the radius of convergence of the power series $\sum_{n=0}^{\infty} \|e_n\| x^n$. Thus $c := \sum_{n=0}^{\infty} \beta^n \|e_n\| < \infty$ for $\beta < 1/\lambda^*$. Now we get, using $\|r\| \le M$ for some $M < \infty$,

$$E_{\pi s} \sum_{n=0}^{\infty} \beta^n |r(\zeta_n, f_n(\zeta_n))| \le Mc < \infty.$$

Thus V exists and $|V(s)| \le Mc$; hence $V \in \mathfrak{V}_0$. Moreover,

$$|V_\pi(s) - v_{N,\pi}(s)| \le \alpha_N := M \cdot \sum_{n=N}^{\infty} \beta^n \|e_n\| + \beta^N \|e_N\| \|v_0\|.$$

Hence $\|V - v_N\| \le \alpha_N \to 0$ as $N \to \infty$, which proves that $1/\lambda^* \le \beta^*$. The proof of $1/\lambda^* \ge \beta^*$ is a copy of the proof of Theorem 2.7(a) in Hinderer and Waldmann (2003) with $b = 1_J$.

(iv) Part (v) results from the compactness, positive homogeneity, and monotonicity of H and Proposition 3.1.5 in Ogiwara (1995), observing that $\mathfrak{V}_+$ is a closed convex cone with interior point $v \equiv 1$ and that $0 \le v \le w$ implies $\|v\| \le \|w\|$.

(v) Fix $f \in F$. Recall that $e_{n,f} \le e_n$, $n \in \mathbb{N}$. Together with (i) we then obtain $0 \le \lambda_f^* \le \lambda^*$. Hence $0 \le \sup_{f \in F} \lambda_f^* \le \lambda^*$.

Now, if $\lambda^* = 0$, then (vi) holds trivially. Otherwise, using (v), λ^* is an eigenvalue of H and thus of H_g for some $g \in F$. Together with Proposition 3.1.7(iii) in Ogiwara (1995) for $T := H_g$ we then obtain $\lambda^* \le \lambda_g^*$, which completes the proof of Proposition 2.2(vi). □

It follows from Proposition 2.2(iii) that $\beta^* = 1$ if the MDP has (besides J_0) another absorbing set disjoint from J_0.

PROPOSITION 2.3. *The following are equivalent:*

(a_1) $\beta < \beta^*$.
(a_2) $\beta^m \|e_m\| < 1$ *for some* $m \in \mathbb{N}$.
(a_3) $\beta^n \|e_n\| \to 0$ *as* $n \to \infty$.
(a_4) $\sum_{n=0}^{\infty} \beta^n \|e_n\| < \infty$.
(a_5) $\beta^n \|e_n\| \le c \cdot \delta^n$ *for all* $n \in \mathbb{N}$ *and some* $c \in \mathbb{R}_+$ *and* $\delta \in (0,1)$.
(a_6) $\lim_{n\to\infty} \beta^n \|H^n v\|_w = 0$ *for all* $v \in \mathfrak{V}$, $w \in \mathfrak{W}$.

If (A0) *holds, then* (a_1) *is equivalent to*

(a_7) $\beta \lambda_f^* < 1$ *for all* $f \in F$.

Proof. Let $\beta < \beta^* = 1/\lambda^*$. Then, using Proposition 2.2(i), $\beta \|e_n\|^{1/n} \le \delta < 1$ for $n \ge N$, say. Hence (a_1) $\Rightarrow$ (a_5) $\Rightarrow$ (a_4) $\Rightarrow$ (a_3) $\Rightarrow$ (a_2). (a_2) implies $\beta\lambda^* = \inf_{k\in\mathbb{N}} \beta \|e_k\|^{1/k} < 1$. Hence ($a_2$) $\Rightarrow$ (a_1). Since $0 \le \beta^n \|H^n v\|_w \le (\|v\|/\inf w)\beta^n \|e_n\|$, ($a_3$) $\Rightarrow$ (a_6). Choosing $v = w = 1$, (a_6) $\Rightarrow$ (a_3). Under (A0) (a_1) $\Leftrightarrow$ (a_7) results from Proposition 2.2(vi). □

For later use denote by MDP_f, $f \in F$, the special MDP with $D(s) = \{f(s)\}$, $s \in S$. Let $r_f(s) := r(s, f(s))$, $f \in F$, $s \in S$.

Remark 2.4. (a) As in Hinderer, Waldmann (2003), condition (a_7) is the link to many additional equivalent properties. For example, under (A0) property (a_4) is equivalent to each of the following properties:

(a_4') $\sum_{n=0}^{\infty} \beta^n \|e_{n,f}\| < \infty$ for all $f \in F$.
(a_4'') $\sum_{n=0}^{\infty} \beta^n e_{n,f}(s) < \infty$ for all $f \in F$, $s \in J$.

Indeed, applying Proposition 2.3 to MDP_f, we find $\sum_{n=0}^{\infty} \beta^n \|e_{n,f}\| < \infty$ is equivalent to $\beta\lambda_f^* < 1$. Hence $(a_4) \Leftrightarrow (a_4')$. Clearly $(a_4') \Rightarrow (a_4'')$. On the other hand, fix $f \in F$ and let $\sum_{n=0}^{\infty} \beta^n e_{n,f} < \infty$. Then $\beta^n e_{n,f}$ converges to zero pointwise. Let $\gamma := \max\{1, \beta\}$. Given (A0), for all $0 < \varepsilon < 1/\gamma$, there exists a finite set K such that $p(s, f(s), J - K) \le \varepsilon$, $s \in J$. Moreover, there exists $n \in \mathbb{N}$ such that $\beta^{n+j} e_{n+j,f} \le \varepsilon$, $j \in \mathbb{N}_0$, on K. It follows for all $s \in J$ that $\beta^{n+1} e_{n+1,f}(s) = \beta H_f(\beta^n e_{n,f})(s) \le \beta[(1-\varepsilon)\varepsilon + \varepsilon\gamma^n] \le \gamma\varepsilon[(1-\varepsilon)(1-\gamma\varepsilon)^{-1} + \gamma^n]$. Induction on j then gives $\beta^{n+j} e_{n+j,f} \le \gamma\varepsilon(1-\varepsilon)(1-\gamma\varepsilon)^{-1} + (\gamma\varepsilon)^j \gamma^n$, $j \in \mathbb{N}$. Hence $\beta^n \|e_{n,f}\| \to 0$, which is equivalent to $\sum_{n=0}^{\infty} \beta^n \|e_{n,f}\| < \infty$ by Proposition 2.3 (applied to MDP_f). Thus $(a_4'') \Rightarrow (a_4')$.

(b) Pliska (1978) treats a semicontinuous model and does not suppose (A0). He shows $\sup_{f \in F} \sum_{n=0}^{\infty} \beta^n \|e_{n,f}\| < \infty \Leftrightarrow \sup_{f \in F} \beta^m \|e_{m,f}\| < 1$ for some $m \in \mathbb{N} \Leftrightarrow \sup_{f \in F} \beta^n \|e_{n,f}\| \le \alpha\gamma^n$, $n \in \mathbb{N}$, for some positive numbers α and γ with $\gamma < 1$. Moreover, each of these properties is shown to imply $\sup_{f \in F} \beta\lambda_f^* < 1$.

(c) Veinott (1969), Hordijk (1974), and Pliska (1978) show for different state and action spaces that $\sup_{f \in F} \|\sum_{n=0}^{\infty} \beta^n H_f^n 1\| < \infty$ implies that $\sup_{\pi \in F^\infty} \|\sum_{n=0}^{\infty} \beta^n H_\pi^n 1\| < \infty$, where $H_\pi^0 v := v$, $H_\pi^n := H_{f_0}, \dots, H_{f_{n-1}}$, $n \in \mathbb{N}$, for $\pi = (f_0, f_1, \dots) \in F^\infty$, which for our model also follows from $(a_4'') \Leftrightarrow (a_4)$. Hernández–Lerma and Lasserre (1999) suppose $\sup_{\pi \in F^\infty} \|b^{-1} \sum_{n=0}^{\infty} H_\pi^n b\| < \infty$ in a transient model with unbounded reward function and weight function b as in Remark 3.3(a). Their assumption is equivalent to $\sup_{\pi \in F^\infty} \|\sum_{n=0}^{\infty} \hat{\gamma}^n \hat{H}_\pi^n 1\| < \infty$ in the reduced model (provided that $0 < \hat{\gamma} < \infty$). Further, given (A0), the last property is equivalent to (a_4) (in the reduced model with $\beta = \hat{\gamma}$).

(d) Proposition 2.2(iii) as well as the equivalence of (a_1)–(a_4) of Proposition 2.3 are obtained in Hinderer and Waldmann (2003), too, for a model with standard Borel state and action spaces.

Next we distinguish between $\beta^* = 1$ and $\beta^* > 1$.

PROPOSITION 2.5. *Assume* (A0). *Then the following are equivalent:*

(b_1) $\beta^* = 1$.

(b_2) *There exists* $s_0 \in J$ *such that* $e_n(s_0) = 1$ *for all* $n \in \mathbb{N}$.

(b_3) *There exist* $M \subset J$, $M \neq \emptyset$, *and* $f \in F$ *such that* $p(s, f(s), M) = 1$ *for all* $s \in M$.

(b_4) *There exist* $f \in F$ *and* $s_0 \in J$ *such that* $P_{fs_0}(\tau = \infty) = 1$.

Proof. (i) Let $\beta^* = 1$. Then $\|e_n\| = 1$, $n \in \mathbb{N}$, by Proposition 2.2(iii). Since λ^* is an eigenvalue of H (cf. Proposition 2.2(v)), there exists $e^* \ge 0$ with $\|e^*\| = 1$ and $He^* = e^*$. By Proposition 2.1 there exists a finite $K \subset J$ such that $p(s, a, J-K) \le 1/2$ for all $(s, a) \in D|_J$. $K \neq \emptyset$, since otherwise $e_1(s) = \max_{a \in D(s)} p(s, a, J) \le 1/2$ for $s \in J$, which contradicts $\|e_1\| = 1$. Assume $e^* \le \alpha$ on K for some $\alpha \in (0, 1)$. Then, for all $f \in F$, $s \in J$, we get $H_f e^*(s) \le \alpha p(s, f(s), K) + p(s, f(s), J - K) \le \alpha(1 - p(s, f(s), J-K)) + p(s, f(s), J-K) \le \alpha + (1-\alpha)/2$. Thus $e^*(s) = \sup_{f \in F} H_f e^*(s) \le \alpha + (1 - \alpha)/2$, which contradicts $\|e^*\| = 1$. Thus $e^*(s_0) = 1$ for some $s_0 \in K$ and, since $e^* \le e_n \le 1$ for $n \in \mathbb{N}$, $e_n(s_0) \ge e^*(s_0) = 1$, $n \in \mathbb{N}$. This verifies $(b_1) \Rightarrow (b_2)$.

(ii) Assume $(b2)$. Then $\|e_n\| = 1$, $n \in \mathbb{N}$. Hence we can use e^* from (i), which implies that $M := \{s \in J \mid e^*(s) = 1\}$ is nonempty. There exists $f \in F$ such that $1 = e^*(s) = He^*(s) = H_f e^*(s)$, $s \in M$. Fix $s \in M$ and assume $p(s, f(s), M) < 1$ in contrast to $(b3)$. By (A0) there exists a finite $K \subset J$ such that $p(s, f(s), M) + p(s, f(s), J - K) < 1$. Put $\alpha := \max\{e^*(s') \mid s' \in (J - M) \cap K\}$ if $(J - M) \cap K \neq \emptyset$

and $\alpha := 0$ else. Then

$$\begin{aligned} 1 = H_f e^*(s) &= p(s, f(s), M) + \sum_{s' \in J-M} p(s, f(s), s') e^*(s') \\ &\le p(s, f(s), M) + \alpha p(s, f(s), (J-M) \cap K) + p(s, f(s), (J-M) \cap (J-K)) \\ &\le 1 - (1-\alpha) p(s, f(s), (J-M) \cap K). \end{aligned}$$

This implies $p(s, f(s), (J-M) \cap K) = 0$, since $\alpha < 1$, and hence $1 \le p(s, f(s), M) + p(s, f(s), J-K) < 1$, which is a contradiction. Hence $(b_2) \Rightarrow (b_3)$.

(iii) Let $M \subset J$, $f \in F$ such that $p(s, f(s), M) = 1$, $s \in M$. Then $e_{1,f}(s) \ge p(s, f(s), M) = 1$, $s \in M$. Thus suppose $e_{n,f} = 1$ on M to hold for some $n \in \mathbb{N}$. Then $e_{n+1,f}(s) = \sum_{s' \in M} p(s, f(s), s') e_{n,f}(s') + \sum_{s' \in J-M} p(s, f(s), s') e_{n,f}(s') \ge p(s, f(s), M) = 1$ for all $s \in M$, which gives $e_{n,f} = 1$ on M (and thus $\|e_{n,f}\| = 1$) for all $n \in \mathbb{N}$. Hence $P_{fs}(\tau = \infty) = \lim_{n\to\infty} P_{fs}(\tau > n) = \lim_{n\to\infty} e_{n,f}(s) = 1$, $s \in M$. This proves $(b_3) \Rightarrow (b_4)$. Assume (b_4). From Proposition 2.2(i) applied to MDP_f, we then obtain $\lambda_f^* = 1$. Finally, using Proposition 2.2(iv) and $\lambda^* \le 1$ (by Proposition 2.2(i)), we have $\lambda^* = 1$. Hence $(b_4) \Rightarrow (b_1)$, which completes the proof. □

PROPOSITION 2.6. *The following are equivalent:*

(c_1) $\beta^* > 1$.

(c_2) *Each of the statements* (a_2)–(a_6) *of Proposition* 2.3 *with* $\beta = 1$.

Moreover, under (A0), (c_1) *is equivalent to each of the following conditions:*

(c_3) *There is a finite partition* $J_1, \dots, J_m$ *of* J *with nonempty sets*

$$J_k := \{s \in J \mid e_k(s) < 1 = e_{k-1}(s)\}, \quad 1 \le k \le m.$$

(Thus $e_m < 1$, *and* $m \le |J|$ *if* J *is finite.)*

(c_4) $E_{fs}(\beta^\tau) < \infty$ *for all* $f \in F$, $s \in J$, *and some* $\beta > 1$.

(c_5) $E_{fs}(\tau^k) < \infty$ *for all* $f \in F$, $s \in J$, $k \in \mathbb{N}$.

(c_6) $E_{fs}(\tau) < \infty$ *for all* $f \in F$, $s \in J$.

(c_7) $P_{fs}(\tau < \infty) = 1$ *for all* $f \in F$, $s \in J$.

(c_8) $\lambda_f^* < 1$ *for all* $f \in F$.

(c_9) *The MDP is transient, i.e.,* $\sum_{n=0}^\infty \sup_{s\in J} E_{\pi s} 1_J(\zeta_n) < \infty$ *for* $\pi \in F^\infty$.

Proof. (i) $(c_1) \Leftrightarrow (c_2)$ and, given (A0), $(c_1) \Leftrightarrow (c_8)$ are obvious from Proposition 2.3.

(ii) If $\beta^* > 1$, then $\|e_n\| < 1$ (hence $e_n < 1$) by Proposition 2.3(a_2) with $\beta = 1$ for some $n \in \mathbb{N}$. Put $M_\nu := \{s \in J \mid e_\nu(s) = 1\}$, $\nu \in \mathbb{N}_0$. Then $M_n = J - \sum_{k=1}^n J_k = \emptyset$ and since $M_{\nu+1} \subset M_\nu$, $\nu \in \mathbb{N}_0$, there exists a smallest $m \le n$ such that $M_n = \emptyset$. Then $J_1, \dots, J_m$ is a partition of J. Moreover, $J_k \ne \emptyset$ for $1 \le k \le m$. For a proof assume that $J_k = M_{k-1} - M_k = \emptyset$ for some $1 \le k \le m$. First $M_{k-1} \ne \emptyset$. Then an argument similar to part (ii) of Proposition 2.5 with M and e^* replaced by M_{k-1} and e_{k-1}, respectively, and exploiting $1 = H_f e_{k-1}(s)$, $s \in M_{k-1}$, for some $f \in F$ shows that $p(s, f(s), M_{k-1}) = 1$ for all $s \in M_{k-1}$. Then $\beta^* = 1$ by Proposition 2.5(b_3), which is a contradiction. Altogether we have $(c_1) \Rightarrow (c_3)$.

(iii) Assume (c_3). We prove that $\|e_{m+1}\| < 1$. (Then (c_1) holds by Proposition 2.3(a_2) with $\beta = 1$.) By (A0) there exists a finite $K \subset J$ such that $p(s, f(s), J - K) \le 1/2$ for $f \in F$, $s \in J$. Since $\alpha := \max_{s' \in K}\{e_m(s')\} < 1$ we get as in part (ii) of the proof of Proposition 2.5 $H_f e_m(s) \le \alpha p(s, f(s), K) + p(s, f(s), J-K) \le (\alpha+1)/2$. Thus $e_{m+1}(s) = \sup_{f\in F} H_f e_m(s) \le (\alpha+1)/2 < 1$ for $s \in J$.

(iv) Assume (c_1). Then there exists some $\beta \in (1, \beta^*)$. Using Proposition 2.3(a_4), we get (cp. (2.9) in Hinderer, Waldmann (2003))

$$\infty > \sum_{n=0}^{\infty} \beta^n \|e_n\| \geq \sum_{n=0}^{\infty} \beta^n e_{n,f}(s) = P_{fs}(\tau = \infty) + (\beta - 1)^{-1} \left[E_{fs}(\beta^\tau) - 1\right]$$

for $s \in J$, $f \in F$, which implies $E_{fs}(\beta^\tau) < \infty$. Hence $(c_1) \Rightarrow (c_4)$. Since $E_{fs}(\beta^\tau) \geq ((\ln \beta)^k / k!) E_{fs}(\tau^k)$ for $k \in \mathbb{N}$, we next obtain $(c_4) \Rightarrow (c_5) \Rightarrow (c_6) \Rightarrow (c_7)$.

(v) (c_7) implies $\lim_{n\to\infty} P_{fs}(\tau > n) = \lim_{n\to\infty} e_{n,f}(s) = 0$, $s \in J$, $f \in F$. H_f is compact by Proposition 2.1. Thus $(e_{n_k+1,f})_1^\infty = (H_f e_{n_k,f})_1^\infty$ converges in norm to 0 for some $(n_k) \subset \mathbb{N}$. Since $(\|e_{n,f}\|)$ is decreasing, we get $\lim_{n\to\infty} \|e_{n,f}\| = 0$. Applying Proposition 2.3(a_3) and (a_7) with $\beta = 1$ to MDP_f, it follows that $\lambda_f^* < 1$. Finally, from Proposition 2.3(a_7) and (a_1), $\beta^* > 1$. Hence $(c_7) \Rightarrow (c_1)$.

(vi) Condition (a_4) from Proposition 2.3 with $\beta = 1$ implies (c_9), since $E_{\pi s} 1_J(\zeta_n) \leq \|e_n\|$. Moreover, $(c_9) \Rightarrow (a_4') \Rightarrow (a_4)$ by Remark 2.4(a) with $\beta = 1$, since $\sup_{s\in J} E_{fs} 1_J(\zeta_n) = \|e_{n,f}\|$, which completes the proof. ∎

3. The optimality equation and related results. For all $s \in J$, $a \in D(s)$, $v \in \mathfrak{V}$ introduce

$$Lv(s,a) := r(s,a) + \beta \sum_{s' \in J} p(s,a,s') v(s'),$$
$$Uv(s) := \sup_{f \in F} U_f v(s) := \sup_{f \in F} Lv(s, f(s)).$$

The supremum is attained, since $D(s)$ is finite for all $s \in S$. Moreover, $U_f v = r_f + \beta H_f v$ and $U(v + w) \leq Uv + \beta H w$ for $v, w \in \mathfrak{V}$.

THEOREM 3.1. *Assume $\beta < \beta^*$. Then the following occur.*

(i) *Value iteration works; i.e., for all $v_0 \in \mathfrak{V}$ it holds that $v_n := U^n v_0$ converges in norm to V.*

(ii) *V is the unique bounded solution of the optimality equation*

$$V(s) = \max_{a \in D(s)} \left\{ r(s,a) + \beta \sum_{s' \in J} p(s,a,s') V(s') \right\}, \quad s \in J.$$

(iii) *f is optimal if and only if f is a maximizer of LV (i.e., $UV(s) = LV(s, f(s))$, $s \in J$); thus there exists an optimal stationary policy.*

Proof. (i) is obvious from Proposition 2.2(iii).

(ii) Let $\beta < \beta^*$. Then $\beta^m \|e_m\| < 1$ for some $m \geq 1$ by Proposition 2.3, hence U^m is contractive (w.r.t. the sup-norm) on the Banach space $\mathfrak{V}$. Moreover, the unique fixed point v^*, say, of U^m is also the unique fixed point of U. First, $Uv^* = U^{m+1} v^* = U^m (Uv^*)$ implies $Uv^* = v^*$. Second, $Uw^* = w^*$ results in $U^m w^* = w^*$ and thus $w^* = v^*$.

(iii) follows (i) as usual, using (ii) for MDP_f. ∎

If $\beta < \beta^*$, then there exists $m \in \mathbb{N}$ such that $\eta := 1 - \beta^m \|e_m\| > 0$ by Proposition 2.3(a_2). Then $w := \eta^{-1} \sum_{j=0}^{m-1} \beta^j e_j \geq 1/\eta$, hence $w \in \mathfrak{W}$, and we have $1 - 1/w(s) \leq M$, $s \in J$, for some $M \in (0,1)$. Now, $1 + \beta H w - w \leq e_0 + \eta^{-1}(\beta^m e_m - e_0) = \beta^m (e_m - \|e_m\|)/\eta \leq 0$ by subadditivity of H, which implies $\beta H w / w \leq 1 - 1/w \leq M$. Hence $\rho := \beta \|Hw\|_w < 1$. We then get the contraction property $\|Uv - Uv'\|_w \leq \beta \sup_{f\in F} \|H_f(v - v')/w\| \leq \beta \|Hw\|_w \|v - v'\|_b$ for $v, v' \in \mathfrak{V}$.

As a by-product, we get a short constructive proof for a result due to van Hee and Wessels (1978) in case of $\beta \le 1 < \beta^*$; see also Zijm (1978).

PROPOSITION 3.2. *Let $\beta < \beta^*$ and $\varepsilon > 0$ such that $\beta\lambda^* + \varepsilon < 1$. Then there exists some $\bar{w} \in \mathfrak{W}$ such that U is contractive with module $\beta\|H\bar{w}\|_{\bar{w}} \le \beta\lambda^* + \varepsilon$.*

Proof. Since $\gamma := \beta/(\beta\lambda^* + \varepsilon) < \beta^*$, we can replace β by γ in the construction of w above. Then we get $\gamma\|H\bar{w}\|_{\bar{w}} < 1$ and thus $\beta\|H\bar{w}\|_{\bar{w}} < \beta\lambda^* + \varepsilon$. □

Now introduce $\gamma^{\pm} := \pm\sup\{\pm r(s,a)/w(s) \mid (s,a) \in D\}$. Note that $\gamma^- \le 0 \le \gamma^+$. Then, based on w, $u^{\pm} := \gamma^{\pm}(1-\rho)^{-1}w$ fulfill $\pm Uu^{\pm} \le \pm u^{\pm}$ and thus initiate monotone sequences of iterates converging to V by Theorem 3.1(i). Hence they define rough bounds $u^- \le Uu^- \le V \le Uu^+ \le u^+$ for V on J and, additionally, may be used as an initial value v_0 for a monotone sequence of iterates.

If J is finite, using $\tilde{J}_0 := \emptyset$, $\tilde{J}_k := J_1 \cup \cdots \cup J_k$, $1 \le k \le m$, the partition $J_1, \ldots, J_m$ of J can be rewritten as

$$J_k = \{s \in J - \tilde{J}_{k-1} \mid p(s,a,J_0 + \tilde{J}_{k-1}) \ge \varepsilon_k \text{ for all } a \in D(s)\}$$

for suitable constants $\varepsilon_1, \ldots, \varepsilon_m \in (0,1)$. This fact can be used to construct a constant

$$\rho := 1 - \min_{1\le k\le m} \frac{\varepsilon_1 \ldots \varepsilon_m(1-\varepsilon_k)}{1-\varepsilon_1\ldots\varepsilon_k} \in (0,1) \tag{3.1}$$

and a function $w \in \mathbb{R}^J$, $w(s) := 1 - \prod_{j=1}^{k}\varepsilon_j$ for all $s \in J_k$, $1 \le k \le m$, for which it holds that $w > 0$ and $Hw \le \rho w$.

For a proof first note that w is constant on J_k and $0 < w(s) \le w(s') \le 1$ for $s \in J_k$, $s' \in J_{k'}$, $1 \le k \le k' \le m$. Hence, for $s \in J_k$, $1 \le k \le m$, we have

$$\begin{aligned}
Hw(s) &= \max_{a\in D(s)} \left\{ \sum_{\nu=1}^{k-1} (1-\varepsilon_1\ldots\varepsilon_\nu) p(s,a,J_\nu) + \sum_{\nu=k}^{m} (1-\varepsilon_1\ldots\varepsilon_\nu) p(s,a,J_\nu) \right\} \\
&\le \max_{a\in D(s)} \{(1-\varepsilon_1\ldots\varepsilon_{k-1}) p(s,a,J_0+\tilde{J}_{k-1}) \\
&\qquad + (1-\varepsilon_1\ldots\varepsilon_m)(1-p(s,a,J_0+\tilde{J}_{k-1}))\} \\
&\le (1-\varepsilon_1\ldots\varepsilon_{k-1})\varepsilon_k + (1-\varepsilon_1\ldots\varepsilon_m)(1-\varepsilon_k) \\
&= \frac{1-\varepsilon_1\ldots\varepsilon_k - \varepsilon_1\ldots\varepsilon_m(1-\varepsilon_k)}{1-\varepsilon_1\ldots\varepsilon_k} \cdot (1-\varepsilon_1\ldots\varepsilon_k) \\
&\le \max_{1\le k\le m} \frac{1-\varepsilon_1\ldots\varepsilon_k - \varepsilon_1\ldots\varepsilon_m(1-\varepsilon_k)}{1-\varepsilon_1\ldots\varepsilon_k} \cdot w(s) \\
&= \rho w(s).
\end{aligned}$$

Furthermore, since $\max_{1\le k\le m}\{1-\varepsilon_1\ldots\varepsilon_m(1-\varepsilon_k)(1-\varepsilon_1\ldots\varepsilon_k)^{-1}\} \ge 1-\varepsilon_1\ldots\varepsilon_m$, we additionally have $\rho \in (0,1)$. Thus, for finite J and $\beta = 1$ (or applied to $\beta H \le \beta\rho w$ provided that $\beta\rho < 1$) also these ρ and w can be used to construct $u^{\pm}$ as above.

A similar approach in Tseng (1990) for a transient model with $\beta = 1$ yields $w' > 0$ and $\rho' \in (0,1)$, say, with $Hw' \le \rho' w'$, where $\rho' := (1-\varepsilon^{2m-1})(1-\varepsilon^{2m})^{-1}$. Our contraction factor ρ, however, is smaller. Indeed, choosing $\varepsilon = \min\{\varepsilon_1, \ldots, \varepsilon_m\}$, then ρ reduces to $1 - \varepsilon^m(1-\varepsilon)(1-\varepsilon^m)^{-1}$, which is less than ρ'.

Remark 3.3. (a) Consider the more general model MDP, which has a bounding function $b : S \to \mathbb{R}_+$, $b \not\equiv 0$ (i.e., using $0/0{:=}0$, $\sup_{(s,a)\in D} |r(s,a)|/b(s) < \infty$, $\sup_{s\in S} |v_0(s)|/b(s) < \infty$, $\gamma := \sup_{(s,a)\in D} b^{-1}(s) \sum_{s'\in S} p(s,a,s')b(s') < \infty$) and a variable discount factor $\beta(s,a) \ge 0$ with $0 < \bar{\beta} := \sup_{(s,a)\in D} \beta(s,a) < \infty$.

This model can be reduced to an MDP' with constant discount factor β' and bounded r' and v'_0, provided that $\gamma > 0$, as follows: $S' := S + \{\hat{s}\}$, $A' := A$, $D'(s) := D(s)$, $s \in S$, $D'(\hat{s}) := A$, $p'(s,a,s') := \beta(s,a)p(s,a,s')b(s')/[\bar{\beta}\gamma b(s)]$, $(s,a) \in D$, $s' \in S$, $r'(s,a) := r(s,a)/b(s)$, $v'_0(s) := v_0(s)/b(s)$, $(s,a) \in D$, $\beta' := \bar{\beta}\gamma$. The missing values of p', r', and v'_0 are determined by the requirement that $\{\hat{s}\}$ is absorbing.

The asserted reduction holds since one easily verifies that for all $v : S \in \mathbb{R}$ with $\|v\|_b < \infty$ there holds $Lv(s,a)/b(s) = L'((v/b) \cdot 1_S)(s,a)$, $(s,a) \in D$. It follows that $v_n(s)/b(s) = v'_n(s)$, $s \in S$, $n \in \mathbb{N}$, and that $f' : S \to A$ is a maximizer of $L'v'_{n-1}$, if and only if $f'|S$ is a maximizer of Lv_{n-1}.

(b) The reduction in (a) is useful in cases where $\gamma > 1$, where the discount factor is a constant $\beta \in (1/\gamma, 1)$ (hence $\beta' = \beta\gamma > 1$), and where $\beta'^* \geq \gamma$, in the following way: While the standard result about MDPs with bounding functions yields, e.g., the existence of V^β only for $0 < \beta < 1/\gamma$, Proposition 2.2(i) and Theorem 3.1 show that $V'^{(\beta\gamma)}$, and hence also V^β exists for $0 < \beta < 1$.

A simple example is the classical asset selling problem (cf., e.g., DeGroot (1970)) with $\mathbb{N}_0$-valued offers having expectation $\mu > 0$, with state space $S := \mathbb{N}_0 + \{\tilde{s}\}$ for an absorbing state $\tilde{s}$, and with bounding function b, where $b(s) = 1 + s$ for $s \in \mathbb{N}_0$ and $b(\tilde{s}) = 1$. Then $\beta'^* = \gamma = 1 + \mu > 1$.

(c) A terminal reward $\tilde{r}_{J_0}(s)$, say, when entering an absorbing state $s \in J_0$, can be easily handled by considering the equivalent model with the one-stage rewards $r'(s,a) := r(s,a) + \beta \sum_{s' \in J_0} p(s,a,s')\tilde{r}_{J_0}(s')$, $(s,a) \in D|_J$, and $r'(s,a) := 0$ otherwise.

4. Recursion in the state space and the model MDP′. Observe that $\beta p(s,a,s) < 1$ for all $\beta < \beta^*$, $s \in J$, and $a \in D(s)$, which follows from Proposition 2.3(a_4) and $\sum_n (\beta p(s,a,s))^n \leq \sum_n \beta^n \|e_n\|$. Introduce

$$I_1 := \{s \in J \mid p(s,a,s) = p(s,a,J) \text{ for all } a \in D(s)\}$$

and, using $\tilde{I}_0 := \emptyset$, $\tilde{I}_{\nu-1} := \sum_{\ell=1}^{\nu-1} I_\ell$, for $\nu > 1$ define

$$I_\nu := \{s \in J - \tilde{I}_{\nu-1} \mid p(s,a,s) + p(s,a,\tilde{I}_{\nu-1}) = p(s,a,J) \text{ for all } a \in D(s)\}.$$

Obviously $I_\nu = \emptyset$ for some $\nu \in \mathbb{N}$ implies $I_j = \emptyset$ for $j \geq \nu$. Then, for all $k \in \mathbb{N}$, one easily sees that V can be obtained by recursion in the state space on the subsets $I_1, \ldots, I_k$ of J according to

$$V(s) = \max_{a \in D(s)} \left\{ \frac{1}{1 - \beta p(s,a,s)} \left[r(s,a) + \beta \sum_{s' \in \tilde{I}_{\nu-1}} p(s,a,s')V(s') \right] \right\}, \quad s \in I_\nu,\ 1 \leq \nu \leq k.$$

If $I_\nu = \emptyset$ for some $\nu \in \mathbb{N}$, then the recursion in the state space stops with the largest k such that $I_k \neq \emptyset$. *If $\tilde{I}_k = J$, then V can be completely determined by a finite recursion in the state space.* To give a necessary and sufficient condition for this case in Proposition 4.1 below, define an operator $\tilde{H}$ on J by $\tilde{H}v(s) := \max_{a \in D(s)} \sum_{s' \in J - \{s\}} p(s,a,s')v(s')$ for all $s \in J$, $v \in \mathfrak{V}$. Set $\tilde{e}_t := \tilde{H}^t 1$, $t \in \mathbb{N}_0$.

PROPOSITION 4.1. *If $\beta < \beta^*$, then recursion in the state space stops with $\tilde{I}_k = J$ if and only if $\tilde{e}_k \equiv 0$.*

Proof. (a) We prove by induction on $j \in \mathbb{N}$ that $I_j = [\tilde{e}_j = 0 < \tilde{e}_{j-1}] := \{s \in J \mid \tilde{e}_j(s) = 0 < \tilde{e}_{j-1}(s)\}$. First, $\tilde{e}_0 \equiv 1$; hence $s \in I_1 \Leftrightarrow \tilde{e}_1(s) = 0$. Let $I_\ell = [\tilde{e}_\ell = 0 < \tilde{e}_{\ell-1}]$ hold for some $j \geq 1$ and all $1 \leq \ell \leq j$. Then $\tilde{I}_j = [\tilde{e}_j = 0]$; hence,

$\tilde{e}_{j+1}(s) = \max_{a\in D(s)} \sum_{s'\in[\tilde{e}_j>0]-\{s\}} p(s,a,s')\tilde{e}_j(s')$, $s \in J$. Now $s \in I_{j+1} \Leftrightarrow (\tilde{e}_j(s) > 0) \wedge (p(s,a,[\tilde{e}_j > 0] - \{s\}) = 0$ for all $a \in D(s)) \Leftrightarrow (\tilde{e}_j(s) > 0) \wedge (\tilde{e}_{j+1}(s) = 0)$. Now the induction is complete.

(b) From (a) it follows that $\tilde{I}_k = J$ if and only if $\tilde{e}_k \equiv 0$, which is the assertion. □

If $J' := J - \tilde{I}_k \neq \emptyset$ and $I_\nu = \emptyset$ for $\nu \geq k+1$, then V coincides on J' with the value function V', say, of an MDP' with essential state space J' and absorbing set $J'_0 := J_0 + \tilde{I}_k$, where $r'(s,a) := r(s,a) + \beta \sum_{s'\in J-J'} p(s,a,s')V(s')$ for $(s,a) \in D|_{J'}$ (and $r' = 0$ on $D|_{J'_0}$). Note that $(\beta^*)' \geq \beta^*$ holds for the critical discount factor of the reduced model MDP'.

As far as we know, recursion in the state space occurs in the literature only for specific models; cf., e.g., Hinderer (1971). Related general results can be found in Bertsekas (2001, pp. 97 and 133).

5. An extrapolation method. In what follows we consider a sequence (v_n) of successive approximations $v_n = Uv_{n-1}$, $n \in \mathbb{N}$, starting with some $v_0 \in \mathfrak{V}$. It is convenient to rewrite v_n as $v_n = U_{f_n}v_{n-1}$ for some maximizer f_n of Lv_{n-1}. Furthermore, let $d_n := v_n - v_{n-1}$ denote the difference of two successive approximations. Of course, $d_n \in \mathfrak{V}$.

Value iteration is now combined with an extrapolation, giving upper and lower bounds for V of the form $v_n + c_n^{\pm} d_n$ at each step n of iteration.

Our extrapolation method is based on the assumption that $d_1 \geq 0$. Then $d_n \geq 0$ for all $n \geq 1$. If $r \geq 0$, then $d_1 \geq 0$ trivially holds using initial value $v_0 \equiv 0$. Otherwise, we have to construct $d_1 \geq 0$ in an initial step. More details will be given below.

For $n \geq 2$ let

$$\alpha_n^- := \inf_{s\in J} \{d_n(s)/d_{n-1}(s) \mid d_{n-1}(s) > 0\}$$

(with $\alpha_n^- := 0$, if $d_{n-1} \equiv 0$). Note that $0 \leq \alpha_n^- d_{n-1} \leq d_n \leq \beta H d_{n-1}$. Together with Lemma 3.1.7(iii) in Ogiwara (1995) (which holds without (A0)) we then get $\alpha_n^- \leq \beta\lambda^*$. Using monotonicity of H_{f_n} we further get $\beta H_{f_n} d_n \geq \beta H_{f_n}(\alpha_n^- d_{n-1}) = \alpha_n^-[U_{f_n}v_{n-1} - U_{f_n}v_{n-2}] \geq \alpha_n^-[v_n - Uv_{n-2}] = \alpha_n^- d_n$ and thus $d_{n+1} \geq \beta H_{f_n} d_n \geq \alpha_n^- d_n$, which implies $\alpha_n^- \leq \alpha_{n+1}^-$. Moreover, if $\alpha_n^- > 0$ and $d_n > 0$ for some $n \geq 2$, then $d_{n+j} \geq (\alpha_n^-)^j d_n > 0$ for all $j \in \mathbb{N}$, which leads to $\alpha_{n+j}^- = \inf_{s\in J}\{d_{n+j}/d_{n+j-1}\} > 0$, $j \in \mathbb{N}$.

Next, for $k \geq 1$ select $\delta_k \in \mathfrak{V}$ such that $\hat{d}_k := d_k + \delta_k \in \mathfrak{W}$. Let

$$\hat{\alpha}_{k,m}^+ := \sup_{s\in J}\{\beta^m H^m \hat{d}_k(s)/\hat{d}_k(s)\}, \quad m \in \mathbb{N}.$$

Obviously H^m is monotone and positively homogeneous. It follows from Proposition 2.2(i) that H^m has the spectral radius $(\lambda^*)^m$. Using $\beta^m H^m \hat{d}_k \leq \hat{\alpha}_{k,m}^+ \hat{d}_k$, we obtain $\hat{\alpha}_{k,m}^+ \geq (\beta\lambda^*)^m$ (without (A0)) by Lemma 3.1.7(ii) in Ogiwara (1995) for $T := H^m$. Furthermore, by applying Proposition 2.3(a_6) with $v = w = \hat{d}_k$, we get $\hat{\alpha}_{k,m}^+ \to 0$ as $m \to \infty$, if $\beta < \beta^*$. In particular, $\hat{\alpha}_{k,m}^+ < 1$ for large enough m. More details on the choice of δ_k will be given below.

For fixed $f \in F$ we call the operator H_f *primitive* if for each $v \in \mathfrak{V}_+$, $v \not\equiv 0$, $v \notin \mathfrak{W}$ there exists $m = m(v) \in \mathbb{N}$ such that $H_f^m v \in \mathfrak{W}$. For finite sets J this definition is consistent with the usual one (i.e., for some $k \in \mathbb{N}$ the matrix associated with H_f^k has positive entries only).

THEOREM 5.1. *Let $d_1 \geq 0$ and $\beta < \beta^*$. Then,*

(i) *For all $n > 1$ it holds that $\alpha_n^- \leq \beta\lambda^* < 1$ and*

$$V \geq V_{f_n} \geq w_n^- := v_n + \alpha_n^-(1-\alpha_n^-)^{-1}d_n \geq v_n.$$

(ii) *Let $\hat{d}_k \in \mathfrak{W}$ for some $k \in \mathbb{N}$, and $m \in \mathbb{N}$ such that $\hat{\alpha}_{k,m}^+ < 1$. Then for all $n \geq k$*

$$V - v_n \leq \sup_{s\in J}\left\{\frac{d_n(s)}{\hat{d}_k(s) - \beta^m H^m \hat{d}_k(s)}\right\} \cdot \sum_{j=1}^m \beta^j H^j \hat{d}_k \leq \frac{\|d_n/\hat{d}_k\|}{1-\hat{\alpha}_{k,m}^+} \cdot \sum_{j=1}^m \beta^j H^j \hat{d}_k.$$

In particular, if $d_{n-1} \in \mathfrak{W}$, $d_n = \beta H d_{n-1}$, and $\alpha_n^+ := \sup_{s\in J}\{d_n(s)/d_{n-1}(s)\} < 1$ hold for some $n \in \mathbb{N}$, then

$$V \leq w_n^+ := v_n + \alpha_n^+(1-\alpha_n^+)^{-1}d_n.$$

(iii) *The weights $c_n^- := \alpha_n^-/(1-\alpha_n^-)$ are increasing in n, $\lim_{n\to\infty} c_n^- \leq \beta\lambda^*/(1-\beta\lambda^*)$. Furthermore, the lower bounds w_n^- are increasing in n and converge in norm to V as $n \to \infty$.*

(iv) *Under the assumptions in* (ii) *we get $\hat{w}_{n+m,k,m}^+ \leq \hat{w}_{n,k,m}^+ := v_n + \|d_n/\hat{d}_k\|(1-\hat{\alpha}_{k,m}^+)^{-1} \cdot \sum_{j=1}^m \beta^j H^j \hat{d}_k$. Furthermore, both upper bounds in* (ii) *converge in norm to V as $n \to \infty$.*

(v) *Let J be finite. Assume that LV has the unique maximizer f and let H_f be primitive. Then the procedure either stops with $d_n \equiv 0$ (hence $V = v_n$) for some $n \in \mathbb{N}$ or the weights $c_n^+ := \alpha_n^+/(1-\alpha_n^+)$ are decreasing in $n \geq n_0$ and both $c_n^\pm$ converge to $\beta\lambda_f^*/(1-\beta\lambda_f^*)$. If λ_f^* is also an eigenvalue of H with positive eigenvector, then $\lambda_f^* = \lambda^*$.*

Proof. By assumption, $\beta < \beta^*$ and thus $\beta\lambda^* < 1$ by Proposition 2.2(iii). Furthermore, remember that $\alpha_n^- \leq \beta\lambda^*$ (hence $\alpha_n^- < 1$) and $d_{n+1} \geq \beta H_{f_n} d_n \geq \alpha_n^- d_n$. Together with $U_{f_n} v_{n-1} = v_n$,

$$U_{f_n} w_n^- - w_n^- = \beta H_{f_n} d_n + \alpha_n^-(1-\alpha_n^-)^{-1}\beta H_{f_n} d_n - \alpha_n^-(1-\alpha_n^-)^{-1}d_n \geq 0,$$

which implies $V_{f_n} \geq w_n^-$ (and thus (i)) by Theorem 3.1(i) for MDP_f and the monotonicity of U_{f_n}. Additionally exploiting $0 \leq \alpha_n^- \leq \alpha_{n+1}^-$, we get

$$w_{n+1}^- - w_n^- = d_{n+1} + \alpha_{n+1}^-(1-\alpha_{n+1}^-)^{-1}d_{n+1} - \alpha_n^-(1-\alpha_n^-)^{-1}d_n \geq 0,$$

which gives monotonicity of w_n^- in n. Since $V \geq w_n^- \geq v_n$, $n > 1$, convergence in norm of the lower bounds follows from Theorem 3.1(i). The properties of c_n^- immediately follow from those of α_n^-. Thus (iii) holds.

We continue with the first part of (ii). By construction and since $\hat{\alpha}_{k,m}^+ < 1$, $\eta := \hat{d}_k - \beta^m H^m \hat{d}_k \in \mathfrak{W}$. Set $c := \sup_{s\in J}\{d_n(s)/\eta(s)\}$. Then, for some $f \in F$,

$$\begin{aligned} U\left(v_{n-1} + c\sum_0^{m-1}\beta^j H^j \hat{d}_k\right) - \left(v_{n-1} + c\sum_0^{m-1}\beta^j H^j \hat{d}_k\right) \\ = U_f v_{n-1} + c\sum_0^{m-1}\beta^{j+1} H_f H^j \hat{d}_k - v_{n-1} - c\sum_0^{m-1}\beta^j H^j \hat{d}_k \\ \leq d_n - c(\hat{d}_k - \beta^m H^m \hat{d}_k) = d_n - \eta \cdot \|d_n/\eta\| \leq 0. \end{aligned}$$

Next $V \le U(v_{n-1} + c\sum_0^{m-1} \beta^j H^j \hat{d}_k) \le v_n + c\sum_1^m \beta^j H^j \hat{d}_k$, which follows from Theorem 3.1(i) and from $U(v+w) \le Uv + \beta Hw$ for $v, w \in \mathfrak{V}$. It gives the left-hand inequality. The right-hand inequality then follows from the definition of $\hat{\alpha}^+_{k,m}$. The second part of (ii) follows from the first part by choosing $k := n-1$, $m := 1$, and $\delta_{n-1} :\equiv 0$; hence $\hat{\alpha}^+_{n-1,1} = \alpha^+_n$.

From $d_{n+j} \le \beta^j H^j d_n \le \|d_n/\hat{d}_k\| \beta^j H^j \hat{d}_k$, $1 \le j \le m$, we obtain $\|d_{n+m}/\hat{d}_k\| \le \hat{\alpha}^+_{k,m} \|d_n/\hat{d}_k\|$ and then, using $v_{n+m} - v_n = \sum_{j=1}^m d_{n+j}$, that $\hat{w}^+_{n+m,k,m} - \hat{w}^+_{n,k,m} \le \|d_n/\hat{d}_k\| [1 + \hat{\alpha}^+_{k,m}(1-\hat{\alpha}^+_{k,m})^{-1} - (1-\hat{\alpha}^+_{k,m})^{-1}] \times \sum_{j=1}^m \beta^j H^j \hat{d}_k = 0$. From $d_n \le \beta H d_{n-1}$ we further obtain $\|d_n\| \le \|d_1\| \beta^{n-1} \|e_{n-1}\|$. Now Proposition 2.3($a_3$) completes (iv).

Theorem 5.1(v). Since f is the unique maximizer of LV, we obtain from Theorem 10.1 (below) that for some $n_0 \ge 1$ there holds $d_n = \beta^{n-n_0} H_f^{n-n_0} d_{n_0}$ for $n > n_0$. Put $k := n_0$. Assume $d_k \equiv 0$. Then $V = v_k$. Otherwise $d_k \not\equiv 0$. If $d_k \notin \mathfrak{W}$, primitivity of βH_f (applied to $v = d_k$) gives $d_{k+m} \in \mathfrak{W}$ for some $m \in \mathbb{N}$. Hence, if $d_k \not\equiv 0$, there is $l \ge k$ such that $d_l \in \mathfrak{W}$. Now we apply Satz III.2.7 in Bohl (1974) with the following choices (and observing that primitive linear operators are called "streng-monoton" there): $X := \mathfrak{V}$, $K := \mathfrak{V}_+$, $\bar{e} :\equiv 1$, $S = T := H_f$, $e_0 := d_l$. Then it follows that $\alpha^\pm_n$, $n > l$, are monotone in n and that $\lim_{n\to\infty} \alpha^\pm_n = \beta\lambda^*_f$. The properties of $c^\pm_n$ now easily follow from those of $\alpha^\pm_n$. If λ^*_f is an eigenvalue of H with positive eigenvector, then $\lambda^*_f = \lambda^*$ by Ogiwara (1995, Lemma 3.1.7(ii) and (iii)). □

The asymmetry in the bounds results from the sublinearity of H. The lower bounds are easy to calculate and need $d_1 \ge 0$ only. The upper bounds are based on $\hat{d}_k \in \mathfrak{W}$ and need some additional effort due to the computation of $\beta^j H^j \hat{d}_k$, $1 \le j \le m$, up to some $m \in \mathbb{N}$ such that $\hat{\alpha}^+_{k,m} < 1$. To reduce the computational effort, we may use these fixed objects for more than one step of iteration. In this case, we only have to adapt v_n and $\|d_n/(\hat{d}_k - \beta^m H^m \hat{d}_k)\|$ (resp., $\|d_n/\hat{d}_k\|$) by switching from n to $n+1$, which can be easily realized.

We may use $\delta_1 = e_0 - d_1$ in order to obtain $\hat{d}_1 = e_0 \in \mathfrak{W}$. Then, for $m \in \mathbb{N}$ such that $\beta^m \|e_m\| < 1$, it follows from Theorem 5.1(ii) for $n \ge 1$ that

$$V - v_n \le \sup_{s\in J} \left\{ \frac{d_n(s)}{1 - \beta^m e_m(s)} \right\} \cdot \sum_{j=1}^m \beta^j e_j \le \frac{\|d_n\|}{1 - \beta^m \|e_m\|} \cdot \sum_{j=1}^m \beta^j e_j.$$

Mainly, however, we are interested in applying (ii) with $\delta_k = 0$, provided that $d_k \in \mathfrak{W}$. Extensive numerical results show that the extrapolation method works very well and, in particular, is highly superior to an extrapolation method of the MacQueen type, which cannot balance out the unequal row sums in the defining matrices of H. Some numerical results are displayed in section 6. Finally, if $d_k \notin \mathfrak{W}$, we may use $\hat{d}_k = d_k + \varepsilon e_0$ for some $\varepsilon > 0$.

Due to $d_n \ge \alpha^-_n d_{n-1}$, Theorem 5.1(i) improves the lower bound in Schellhaas (1974, Satz 4.1), which may be written as $v_{n-1} + \alpha^-_n (1-\alpha^-_n)^{-1} d_{n-1}$ and which is derived under the additional assumptions that J is finite, $\beta < 1$, and $0 < d_n < d_{n-1}$. His upper bounds $w^+_n := v_{n-1} + \alpha^+_n (1-\alpha^+_n)^{-1} d_{n-1}$ are constructed in the same way and need the verification of $Uw^+_n \le w^+_n$.

Theorem 5.1 can be combined with the following proposition.

PROPOSITION 5.2. *Let $\beta < \beta^*$, $d_1 \ge 0$. If $Hd_n = 0$ on $M_n := \{s \in J \mid d_n(s) = 0\}$ for some $n \in \mathbb{N}$, then*

(i) *$p(s, a, J - M_n) = 0$ for $(s,a) \in D|_{M_n}$,*

(ii) *$V = v_k = v_n$ on M_n, $k \ge n$.*

Proof. (i) is a consequence of $d_n = 0$ on M_n, $d_n > 0$ on $J - M_n$, and

$$0 = Hd_n(s) = \max_{a \in D(s)} \left\{ \sum_{s' \in M_n} p(s,a,s')d_n(s') + \sum_{s' \in J - M_n} p(s,a,s')d_n(s') \right\}, \quad s \in M_n.$$

(ii) Observe that $0 \le d_{n+k} \le \beta^k H^k d_n$, $k \in \mathbb{N}$. Together with (i), $H^k d_n = 0$, $k \in \mathbb{N}$, on M_n. Hence $d_{n+k} = 0$ on M_n and thus $v_n = V$ on M_n by Proposition 2.2(iii). □

On the basis of Proposition 5.2, value iteration can be continued after the first n steps with $MDP^{(n)}$, say, with essential state space $J - M_n$ and one-stage rewards $r(s,a) + \beta \sum_{s' \in M_n} p(s,a,s')v_n(s')$, $(s,a) \in D|_{J-M_n}$.

Fix $n \in \mathbb{N}$ and assume $d_1 \ge 0$, $\beta < \beta^*$. Let $e_n = 0$ on some $\hat{M}_n \subset J$. Then, using $e_{n+1} \le e_n$ and $0 \le d_{n+k} \le \beta^{n+k} H^{n+k} d_1 \le \|d_1\| \beta^{n+k} e_{n+k}$, $k \in \mathbb{N}$, a simple argument leads to $v_n = V$ on $\hat{M}_n$. Furthermore, if $\hat{M}_n = J$, then $v_n \equiv V$, and value iteration stops after n steps of iteration. See also Proposition 4.1.

Hübner (1980) derives bounds for general S, A under an assumption "$d_n \in \mathcal{T}$," which includes "$d_n \ge 0$" and weakens "$d_n > 0$" similar to Proposition 5.2. He has found the lower bound for V given in Theorem 5.1(i) under the assumptions $V = \lim_{N \to \infty} v_N$, and $\alpha_n^- < 1$ (cf. Theorem 3 and Remark 7 there). The lower bound also follows from Example 3.2 in Waldmann (1985) (within a general framework for constructing extrapolation functions) if $V = \lim_{N \to \infty} v_N$. Additional assumptions are not needed there.

Let $d_{n-1} \in \mathfrak{W}$ and $\beta \|Hd_{n-1}/d_{n-1}\| < 1$. Then, by applying Theorem 5.1(ii) with $k = n-1$ and $m = 1$, we get the (right-hand) upper bound $v_n + \|d_n/d_{n-1}\|(1 - \beta\|Hd_{n-1}/d_{n-1}\|)^{-1}\beta Hd_{n-1}$ for V, which is superior to the upper bound given in Hübner (1980, Theorem 2 and Remark 7), due to $\beta Hd_{n-1} \le \beta \|Hd_{n-1}/d_{n-1}\| d_{n-1}$.

Example 5.3. Consider the standard Markov decision model with finite state space S and $J_0 = \emptyset$. Then $e_n \equiv e_{n,f} \equiv 1$, $n \in \mathbb{N}$, and $\beta^* = \lambda^* = \lambda_f^* = 1$ for all $f \in F$ by Proposition 2.2. Assume f to be the unique maximizer of LV and H_f to be primitive. Then, from Theorem 5.1(v), either both $c_n^{\pm}$ converge to $\beta/(1-\beta)$ as $n \to \infty$ or the value iteration stops with $V = v_n$ for some n.

Analogous bounds for v_N, which are based on v_n and d_n for $n \le N$, exist and belong to $\mathfrak{V}$ for all $\beta > 0$. The initial value v_0 (terminal reward) is now fixed and cannot be chosen such that $d_1 \ge 0$ holds.

THEOREM 5.4. *Let $N \in \mathbb{N}$, $1 < n < N$, and α_n^- and $\hat{\alpha}_{k,m}^+$ be as in Theorem* 5.1.

(i) *If $d_{n-1} \ge 0$, then*

$$v_n + \sum_{j=1}^{N-n} (\alpha_n^-)^j d_n \le v_{n+1} + \sum_{j=1}^{N-n-1} (\alpha_{n+1}^-)^j d_{n+1} \le v_N.$$

(ii) *Let $\hat{d}_k \in \mathfrak{W}$ for some $k \le n$. Then, for $\ell, m \in \mathbb{N}$ such that $N - n \le \ell m$,*

$$v_N \le v_n + \|d_n/\hat{d}_k\| \cdot \sum_{i=0}^{\ell-1} (\hat{\alpha}_{k,m}^+)^i \sum_{j=1}^{m} \beta^j H^j \hat{d}_k.$$

Proof. (i) uses $\alpha_n^- d_n \le d_{n+1}$, $\alpha_n^- \le \alpha_{n+1}^-$, and $v_N - v_n = \sum_{j=1}^{N-n} d_{n+j}$. For the proof of (ii) one uses $d_{n+j} \le \|d_n/\hat{d}_k\| \cdot \beta^j H^j \hat{d}_k$ for $j \ge 1$, derives $\beta^{mi} H^{mi} \hat{d}_k \le$

$(\hat\alpha^+_{k,m})^i \hat d_k$ by induction on $i \in \mathbb{N}$, and finally uses $v_N - v_n \le \sum_{j=1}^{lm} d_{n+j} \le \|d_n/\hat d_k\| \cdot \sum_{i=0}^{l-1}\sum_{\nu=1}^{m} \beta^\nu H^\nu(\beta^{mi} H^{mi} \hat d_k)$. □

Theorem 5.4(i) verifies the lower bounds presented in Theorem 3 of Hübner (1980), which have been derived there under the stronger assumption $d_{n-1} \in \mathcal{T}$. Applying Theorem 5.4(ii) with $\hat d_k = d_{n-1}$, $m = 1$, $\ell = N - n$, we get the upper bound $v_n + \|d_n/d_{n-1}\| \cdot \sum_{i=0}^{N-n-1} (\hat\alpha^+_{n-1,1})^i \beta H d_{n-1}$, which is smaller than the bound $v_n + \|d_n/d_{n-1}\| \cdot \sum_{i=1}^{N-n} (\hat\alpha^+_{n-1,1})^i d_{n-1}$ given in Theorem 2 there (due to $\beta H d_{n-1} \le \hat\alpha^+_{n-1,1} d_{n-1}$).

The need of an increasing sequence (v_n) of value iterates may be seen as a restriction of our method. We therefore give some hints for choosing a suitable initial value v_0 in order to destroy any doubts.

(a) Choose $v_0 \equiv 0$ in case of $r_f \ge 0$ for some $f \in F$. Then $v_0 \le U v_0$ trivially holds.

(b) Select some $f \in F$. Iterate up to some $m \in \mathbb{N}$ such that $\beta^m \|e_{m,f}\| < 1$. Then $v_0 := \inf_{s\in S}\{r_f(s)/(1 - \beta^m e_{m,f}(s))\} \sum_{j=0}^{m-1} \beta^j e_{j,f} \in \mathfrak{V}$ and we have $U_f v_0 \ge v_0$ and thus $U v_0 \ge v_0$. Moreover, for any $\varepsilon \in \mathfrak{W}$, replacing r_f by $r_f - \varepsilon$ in the definition of v_0, we additionally have $d_1 = U v_0 - v_0 \in \mathfrak{W}$. Finally, if $e_{1,f}$, $f \in F$, and d_1 belong to $\mathfrak{W}$ (or alternatively $\alpha_2^- > 0$, $d_1 \in \mathfrak{W}$), then $d_n \in \mathfrak{W}$, $n \in \mathbb{N}$.

(c) Select $f \in F$. Based on MDP_f we may choose w and ρ as in section 3. Then for $v_0 := u^-$ it holds that $U v_0 \ge v_0$.

(d) Since $V_f = U_f V_f \le U V_f$ for all $f \in F$, we may also compute V_f for some $f \in F$ and start with $v_0 = V_f$.

In Example 5.6 below we present an important case where it is useful to have bounds for V_f for a single $f \in F$. First note that Theorem 5.1 can be applied to MDP_f, replacing H by H_f, d_n by $d_{n,f}$, etc. Note that $e_{n,f} \le e_n$; hence $\beta_f^* \ge \beta^*$. Several results, e.g., in Theorem 5.1(ii), simplify since $d_{n+1,f} = \beta H_f d_{n,f}, n \in \mathbb{N}$, by linearity of H_f. In particular, we obtain the following:

(i) For $n \ge 2$ there holds $\alpha^-_{n,f} \le \beta\lambda_f^* < 1$, the weights $c^-_{n,f} := \alpha^-_{n,f}/(1-\alpha^-_{n,f}) d_{n,f}$ and the lower bounds $w^-_{n,f} := v_{n,f} + c^-_{n,f} d_{n,f} \le V_f$ increase, and $w^-_{n,f}$ converges in norm to V_f.

(ii) The upper bounds for V_f, obtainable from Theorem 5.1(ii), can be rewritten in a simpler way. In particular, $V_f - v_{n,f} \le \|d_{n,f}/(d_{n-m,f} - d_{n,f})\|(v_{n,f} - v_{n-m,f}) \le \hat\alpha^+_{n-m,m,f}(1-\hat\alpha^+_{n-m,m,f})^{-1}(v_{n,f} - v_{n-m,f})$ for $k = n-m$ and all $1 \le m < n$ such that $d_{n-m,f} \in \mathfrak{W}$ and $\hat\alpha^+_{n-m,m,f} := \|d_{n,f}/d_{n-m,f}\| < 1$. Actually the two bounds coincide since $\|v/(1-v)\| = \|v\|/(1-\|v\|)$ for $\|v\| < 1$.

Since finiteness of J is only needed in Theorem 5.1(v) to apply the turnpike Theorem 10.1 below, we additionally obtain the following proposition.

PROPOSITION 5.5. *Fix $f \in F$. Assume $\beta < \beta_f^*$ (hence $\beta\lambda_f^* < 1$), $d_{1,f} \ge 0$, that H_f is primitive, and that H_f^ν is compact for some $\nu \in \mathbb{N}$. (The latter holds under* (A0)*, in particular if J is finite.) Then either $d_{n_0,f} \equiv 0$ for some $n_0 \in \mathbb{N}$ (and then $V_f = v_{n_0,f}$) or $d_{n,f} \in \mathfrak{W}$ for $n \ge n_1$. In the latter case the following hold for $n > n_1$:*

(i) *The weights $c^+_{n,f} = \alpha^+_{n,f}/(1-\alpha^+_{n,f})$ decrease in n, and, as well as $c^-_{n,f}$, converge to $\beta\lambda_f^*/(1-\beta\lambda_f^*)$ as $n \to \infty$.*

(ii) *The bounds $w^+_{n,f} := v_{n,f} + c^+_{n,f} d_{n,f}$ decrease in n and converge in norm to V_f.*

Example 5.6. *Mean entrance time of a Markov chain into an absorbing set.* Applied to $r_f = 1_J$ and $\beta = 1$, the total expected reward $V_f(s)$ equals the expected entrance time $E_{fs}(\tau)$ into J_0 and we obtain $v_{n,f} = \sum_{j=0}^n e_{j,f}$ (with $v_{0,f} = e_{0,f}$). Hence, if $d_{n-1,f} = e_{n-1,f} \in \mathfrak{W}$ and $\|e_{n,f}/e_{n-1,f}\| < 1$ (hence $\beta_f^* > 1$ by Proposition

2.6), then by Theorem 5.1(i) and (ii)

$$\sum_{j=0}^{n} e_{j,f}(s) + \frac{\alpha_{n,f}^{-}}{1-\alpha_{n,f}^{-}}\, e_{n,f}(s) \le E_{fs}(\tau) \le \sum_{j=0}^{n} e_{j,f}(s) + \frac{\alpha_{n,f}^{+}}{1-\alpha_{n,f}^{+}}\, e_{n,f}(s), \quad s \in J,$$

where $\alpha_{n,f}^{\pm} = \pm \sup_{s\in J}\{\pm e_{n,f}(s)/e_{n-1,f}(s)\}$. Additionally, if H_f is primitive and H_f^{ν} is compact for some $\nu \in \mathbb{N}$, then, by Proposition 5.5(i), the weights $c_{n,f}^{\pm} = \alpha_{n,f}^{\pm}/(1-\alpha_{n,f}^{\pm})$ are monotone in n and converge to $\lambda_f^*/(1-\lambda_f^*)$ as $n \to \infty$ or value iteration stops with $e_{n,f} \equiv 0$ for some n.

Remember that $P_{fs}(\tau > n) = e_{n,f}(s)$, $s \in J$. Note that $e_{n+1,f} = H_f e_{n,f} \le \alpha_{n,f}^{+} e_{n,f}$. Hence $\alpha_{n+1,f}^{+} \le \alpha_{n,f}^{+}$ (additionally using $e_{n+1,f} \le e_{n,f}$ and putting $0/0 = 0$). Analogously, $\alpha_{n+1,f}^{-} \ge \alpha_{n,f}^{-}$. Thus we also obtain bounds

$$(\alpha_{n,f}^{-})^k e_{n,f} \le (\alpha_{n+1,f}^{-})^{k-1} e_{n+1,f} \le e_{n+k,f} \le (\alpha_{n+1,f}^{+})^{k-1} e_{n+1,f} \le (\alpha_{n,f}^{+})^k e_{n,f}, \quad k \in \mathbb{N},$$

for the (whole) distribution of τ at each step n of iteration.

Applied to the mean run length of a quality control scheme the procedure works very well (cf. Waldmann (1986a, 1986b) for details). Bearing in mind that λ_f^* is nearly one and that the second largest eigenvalue is small compared with λ_f^*, this is no longer surprising looking at the asymptotic properties (Proposition 5.5(i)) of our extrapolation method.

6. A numerical example. Our numerical results are based on an MDP (Problem I) with essential state space $J = \{1, 2, 3\}$, discount factor $\beta = 1$, transition law p, and one-stage reward r as in Table 6.1.

Remember that $\hat{\alpha}_{k,m}^{+} \ge (\beta\lambda^*)^m$. Thus $\beta^* > 1$ can be verified by the extrapolation itself. In particular, by applying Theorem 5.1(ii) with $k = n$, $\hat{d}_n = d_n$, and $m = 1$, at the first step n with $\hat{\alpha}_{n,1}^{+} < 1$ we know that $\beta^* > 1$ and thus Theorem 5.1 works. Since $r \ge 0$, we start with $v_0 \equiv 0$. The resulting bounds for V are displayed in Table 6.2. Missing upper bounds due to $\hat{\alpha}_{n,1}^{+} \ge 1$ are marked by "∞."

Changing the sign of $r(2,1)$ (Problem II), we can still apply Theorem 5.1 with $v_0 \equiv 0$ and get the same results as in Table 6.2, since $r_f \ge 0$ for $f \equiv 2$. For $f \equiv 1$,

however, we have to construct an initial value v_0. Based on MDP_f we then get (cf. section 3) a partition $J_1 = \{1, 3\}$, $J_2 = \{2\}$ of J with $\varepsilon_1 = 1/4$, for example, $\varepsilon_2 = 1/2$, $\rho = 13/14$, $w(1) = w(3) = 3/4$, $w(2) = 7/8$, and, finally, $v_0 = (-192, -224, -192)^T$. It is not surprising that the worse initial value v_0 leads to an increase in the number of iterations (due to a later stabilization of the upper bounds). Compared with an extrapolation of the MacQueen type, however, these bounds are strongly superior.

7. The policy iteration method. The policy iteration is a standard procedure in obtaining V and an optimal policy. The special case of primitive operators H_f, however, has not been studied explicitly to the best of our knowledge.

THEOREM 7.1 (A0). *Assume $\beta < \beta^*$. Let $f \in F$.*

(i) *If $UV_f = V_f$, then $V = V_f$.*

(ii) *Otherwise, there is some $g \in F$ such that $U_g V_f \geq V_f$, $U_g V_f \neq V_f$, and $V_g \geq V_f$, $V_g \neq V_f$. Additionally, if H_g is primitive, then $V_g \geq V_f + \varepsilon$ for some $\varepsilon > 0$.*

Proof. (i) and the first part of (ii) follow by standard arguments. For the second part of (ii) we first observe that $\beta^n H_g^n(v - v') = U_g^n v - U_g^n v'$ holds for all $v, v' \in \mathfrak{V}$, $n \in \mathbb{N}$. Since H_g is primitive, there is some $m \in \mathbb{N}$ such that $H_g^m(U_g V_f - V_f) \in \mathfrak{W}$. Hence $U_g(U_g^m V_f) - U_g^m V_f \in \mathfrak{W}$. Furthermore, using monotonicity of U_g, we obtain from Theorem 3.1(iii), applied to MDP_g, $U_g^n V_f \uparrow V_g$ as $n \to \infty$. Hence $V_g - V_f \geq U_g^{m+1} V_f - U_g^m V_f \in \mathfrak{W}$. □

At each step of iteration, V_f can be obtained by solving the infinite linear system of equations $V_f = U_f V_f$ by known methods or alternatively by Theorem 5.1 and Proposition 5.5.

8. Finite state approximations of the MDP. Finite state approximations have a long tradition in dynamic programming. See Sennott (1999) for recent work on this subject and the references given there.

Applied to the MDP, assumption (A0) suggests an approximation scheme in a natural way. Thus, depending on a finite set $K \subset J$ with $\rho(K) := \sup_{(s,a) \in D|_J} \{p(s, a, J - K)\}$ and $c \in \mathbb{R}$, introduce $MDP^{(K,c)}$, say, with finite essential state space $J^{(K)} := K \subset J$, extended absorbing set $J_0^{(K)} := J_0 + (J - K)$, transition law $p^{(K)}(s, a, s') = p(s, a, s')$, $(s, a) \in D|_K$, and reward function $r^{(K,c)} := r + \beta c \rho(K)$ on $D|_K$ ($r^{(K,c)} = 0$ otherwise).

Since $p^{(K)}$ is independent of c, then also $e_n^{(K)}$ (resp., $e_{n,f}^{(K)}$, $f \in F$), which is defined in analogy to e_n (resp., $e_{n,f}$), does not depend on c. One easily verifies that $e_n^{(K)} \leq e_n$, $n \in \mathbb{N}$, on K. Hence $\lambda^{*(K)} := \inf_{n \in \mathbb{N}} \|e_n^{(K)}\|^{1/n} \leq \inf_{n \in \mathbb{N}} \|e_n\|^{1/n} = \lambda^*$.

Now Proposition 2.2 implies $\beta^{*(K)} = 1/\lambda^{*(K)} \geq 1/\lambda^* = \beta^*$. Thus, for $\beta < \beta^*$, let $V^{(K,c)}$ (resp., $V_f^{(K,c)}$, $f \in F$) be defined in analogy to V (resp., V_f).

$MDP^{(K,c)}$ behaves as an absorbing MDP with finite state and action spaces, which has been studied in detail in Hinderer and Waldmann (2003). In this section we look at bounds for V based on $V^{(K,c)}$, are interested in ε-optimal policies for MDP resulting from extensions of optimal ones for $MDP^{(K,c)}$, and look at the convergence of a pure truncation method. For the last approach let $D^*(s)$, $s \in J$, be the set of all maximum points of $LV(s,\cdot)$. For the model $MDP^{(K,c)}$ define $D^{*(K,c)}(s)$ analogously.

LEMMA 8.1. *For $\beta < \beta^*$, $c \in \mathbb{R}$, and $\delta > 0$ we have on finite $K \subset J$*

(i) $V_f^{(K,c+\delta)} - V_f^{(K,c)} = \beta\delta\rho(K) \cdot \sum_{n=0}^{\infty} \beta^n e_{n,f}^{(K)}$ *for all $f \in F$,*

(ii) $0 \leq V^{(K,c+\delta)} - V^{(K,c)} \leq \beta\delta\rho(K) \cdot \sup_{f\in F} \sum_{n=0}^{\infty} \beta^n e_{n,f}^{(K)} \leq \beta\delta\rho(K) \cdot \sum_{n=0}^{\infty} \beta^n e_n^{(K)}$.

Proof. (i) results from $r^{(K,c+\delta)} = r^{(K,\delta)} + \beta\delta\rho(K)$ on $D|_K$ and the linearity of the expectation operator; (ii) is an immediate consequence of (i), since $V^{(K,c)} = \sup_{f\in F} V_f^{(K,c)}$ by Theorem 3.1(iii) and $e_{n,f}^{(K)} \leq e_n^{(K)}$. □

In the following theorem we make use of rough bounds $c^{\pm}$ of V on $J - K$, e.g., $c^{\pm} := \pm\max\{0, \sup_{s\in J}\{\pm\hat{u}^{\pm}(s)\}\}$ with $\hat{u}^{\pm} := u^{\pm}$ or $\hat{u}^{\pm} := Uu^{\pm}$ and $u^{\pm}$ as defined in section 3.

THEOREM 8.2. *Let K be a finite subset of J, $\beta < \beta^*$, and $c^- \leq 0 \leq c^+$ such that $c^- \leq V(s) \leq c^+$ for all $s \in J - K$. Then the following hold:*

(i) $V^{(K,c^-)} \leq V \leq V^{(K,c^+)}$ *on K.*

(ii) *Let $g \in F$ be optimal for $MDP^{(K,c^-)}$. Then, for all $f \in F$ such that $f = g$ on K and $c^- \leq V_f(s)$, $s \in J - K$, it holds that $V_f \geq V - \varepsilon$ on K, where $\varepsilon := \beta(c^+ - c^-)\rho(K) \cdot \sum_{n=0}^{\infty} \beta^n e_n^{(K)}$.*

(iii) *Assume* (A0). *Then there exist $K_n \subset K_{n+1}$, $n \in \mathbb{N}$, with $\cup_n K_n = J$ such that $\rho(K_n) \to 0$ as $n \to \infty$. Furthermore, for all $s \in J$, $\lim_{n\to\infty} V^{(K_n,0)}(s) = V(s)$, and the cluster points of all (a_n), where $a_n \in D^{*(K_n,0)}(s)$, belong to $D^*(s)$.*

Proof. (i) Since $p(s,a,J-K) \leq \rho(K)$, $(s,a) \in D$, and $c^+ \geq 0$ hold by assumption, we have, for $s \in K$,

$$V(s) = UV(s) \leq \max_{a\in D(s)} \left\{ r(s,a) + \beta \sum_{s'\in K} p(s,a,s')V(s') + \beta c^+\rho(K) \right\} =: U^{(K,c^+)}V(s).$$

Monotonicity of $U^{(K,c^+)}$ and Theorem 3.1(i) (applied to $MDP^{(K,c^+)}$) then give $V \leq V^{(K,c^+)}$ on K, since V is bounded on K and since $\beta^{*(K)} \geq \beta^*$, and analogously for the lower bound.

(ii) Let g be optimal for $MDP^{(K,c^-)}$ and $f = g$ on K. By a similar argument as in (i) we get $V_f = U_f V_f \geq U_f^{(K,c^-)} V_f = U_g^{(K,c^-)} V_f$. Using Theorem 3.1(iii) applied to $MDP^{(K,c^-)}$, it follows that $V_f \geq (U_g^{(K,c^-)})^n V_f \to V_g^{(K,c^-)}$. Thus $V_f \geq V_g^{(K,c^-)} = V^{(K,c^-)}$ on K. Together with (i) and Lemma 8.1(ii) it then follows that $V - V_f \leq V^{(K,c^+)} - V^{(K,c^-)} \leq \varepsilon$ on K.

(iii) The existence of the sets K_n is obvious. Put $V^{(n,c)} := V^{(K_n,c)}$. Fix $s \in J$. Then $s \in K_n$ for all $n \geq n_0$ and some $n_0 \in \mathbb{N}$. Recall that $c^- \leq 0 \leq c^+$. Then, using (i) and $V^{(n,c^-)} \leq V^{(n,0)} \leq V^{(n,c^+)}$, we have $|V(s) - V^{(n,0)}(s)| \leq V^{(n,c^+)}(s) - V^{(n,c^-)}(s)$, which converges to zero as $n \to \infty$ by $\rho(K_n) \to 0$ and Lemma 8.1(ii).

For $n \geq m$, using (i), $e_j^{(K_m)} \leq e_j$, and Lemma 8.1(ii), $V^{(n,0)} - V^{(m,0)} \leq |V - V^{(n,0)}| + |V - V^{(m,0)}| \leq 2\beta(c^+ - c^-)\rho(K_m) \sum_{j=0}^{\infty} \beta^j \|e_j\| =: \eta(m)$ on K_m and $V^{(n,0)} \leq$

$\|u^+\|$ on K_n (e.g., by verifying $U^{(K_n,0)}u^+ \le u^+$ on K_n) and thus on $K_n - K_m$. Fix $s \in J$. Let $N \in \mathbb{N}$ such that $s \in K_N$. Then, for $N \le m \le n$, $w_n \le w_m + \varepsilon_m$, where $w_n(a) := r(s,a) + \beta \sum_{s' \in K_n} p(s,a,s')V^{(n,0)}(s')$, $a \in D(s)$, and $\varepsilon_n := \beta\eta(n) + \beta\|u^+\|\rho(K_n)$. Since $\varepsilon_n \to 0$ as $n \to \infty$, Proposition 10.1 in Schäl (1975) completes the proof of (iii). □

9. Asymptotically ε-optimal policies. The infinite-stage model is often used as an approximation of a finite-stage model with a large horizon. We say that a decision rule $f \in F$ is asymptotically optimal if $\|v_N - v_{N,f}\| \to 0$ as $N \to \infty$. Furthermore, f is said to be ε-optimal for some $\varepsilon \in \mathfrak{V}_+$ if $V_f \ge V - \varepsilon$, and asymptotically ε-optimal if $\|v_N - v_{N,f} - \varepsilon\| \to 0$ as $N \to \infty$.

THEOREM 9.1. *Let $\beta < \beta^*$. Then the following hold:*

(i) *f is asymptotically optimal if and only if f is a maximizer of LV.*

(ii) *Let f be ε-optimal. Then f is also asymptotically ε-optimal. Furthermore, for $c^\pm \in \mathbb{R}$ such that $c^- \le v_0 - V \le c^+$ on J, and all $N \in \mathbb{N}$ it holds on J that*

$$0 \le v_N - v_{N,f} \le \max\{0, c^+\}\beta^N e_N - c^-\beta^N e_{N,f} + \varepsilon. \tag{9.1}$$

Proof. (i). Let f be asymptotically optimal. Then $\|V - U_f V\| \le \|V - U_f^N V\| \le \|V - v_N\| + \|v_N - v_{N,f}\| + \|U_f^N v_0 - V_f\| + \|V_f - U_f^N V\|$, which converges to zero as $N \to \infty$ by Theorem 3.1 and the definition of asymptotical optimality. On the other hand, if f is a maximizer of LV, it is optimal by Theorem 3.1; hence $\|v_N - v_{N,f}\| \le \|v_N - V\| + \|V_f - U_f^N v_0\|$, which also converges to zero as $N \to \infty$ by Theorem 3.1. Thus (i) holds. If f is ε-optimal, then $V \le V_f + \varepsilon = U_f^N V_f + \varepsilon \le U_f^N V + \varepsilon$ for $N \in \mathbb{N}$. Furthermore, for $N \in \mathbb{N}$, $U^N v_0 - U^N V \le \beta^N H^N(v_0 - V)$ and $U_f^N v_0 - U_f^N V = \beta^N H_f^N(v_0 - V)$. Applied to $v_N - v_{N,f} \le v_N - V - (v_{N,f} - U_f^N V) + \varepsilon$ we then get (9.1), which implies (ii), since $\beta^N e_{N,f} \le \beta^N e_N \le \beta^N \|e_N\| \to 0$ by Proposition 2.3(a_3). □

Combining the value iteration with an extrapolation as in Theorem 5.1, we get $w_n^- \le V_{f_n} \le V \le w_n^+$ for suitable $w_n^\pm \in \mathfrak{V}$ at step n of iteration. Then Theorem 9.1(ii) works with $c^\pm := \pm \sup_{j \in J}\{\pm[v_0(s) - w_n^\mp(s)]\}$, and $\varepsilon := w_n^+ - w_n^-$. The upper bound in (9.1) can be simplified to $[\max\{0, c^+\} - c^-]\beta^N e_N + \varepsilon$, since $c^- \le \inf_{s \in S}\{v_0(s) - V(s)\} \le 0$. Using the following Proposition 9.2, e_N can be bounded from above by $\|e_m\|^{\lfloor N/m \rfloor}$, and $\|e_m/e_{m-1}\|^{N-m} e_m$, respectively, for $N \ge m$.

PROPOSITION 9.2. *For $m, n \in \mathbb{N}$ it holds that*

(i) $\beta^n e_n \le \max_{0 \le t < m}\{\beta^t e_t\}(\beta^m \|e_m\|)^{\lfloor n/m \rfloor}$,

(ii) $e_n \le \|e_m/e_{m-1}\|^{n-m} e_m$, $m \le n$.

Proof. (i) Rewrite n as $km + \nu$ with $k := \lfloor n/m \rfloor$, $\nu := n - m\lfloor n/m \rfloor$. Then, since $e_{t+\nu} \le \|e_t\| \cdot e_\nu$ for $t \ge 0$, we get $\beta^n e_n \le \beta^\nu e_\nu \beta^{mk}\|e_{mk}\| \le \beta^\nu e_\nu (\beta^m \|e_m\|)^k \le \max_{0 \le t < m}\{\beta^t e_t\}(\beta^m \|e_m\|)^k$.

(ii) Note that $e_m \le e_{m-1}$. Let $c := \|e_m/e_{m-1}\|$. Then monotonicity of H implies $e_n = H^{n-m} e_m \le H^{n-m}(c \cdot e_{m-1}) = cH^{n-m-1} e_m \le \cdots \le c^{n-m} e_m$. □

10. A turnpike theorem. Next we are interested in a turnpike theorem on the basis of ε-optimal decision rules. For $\beta < \beta^*$, let F^* (resp., F_n^*) be the set of all maximizers of LV (resp., Lv_{n-1}). Then the number

$$N^* := \inf\{N \in \mathbb{N} \mid F_n^* \subset F^* \text{ at all stages } n \ge N\}$$

is called the turnpike horizon of F^*, provided N^* is finite. It is shown in the following Theorem 10.1 that a turnpike horizon N^* exists for an MDP with a finite state space S. The proof is constructive and leads to an upper bound for N^*. Then, applied

to $MDP^{(K,c)}$ with countable S, the extension of each maximizer $f_n^{(K,c)} \in F_n^{*(K,c)}$, $n \geq N^{*(K,c)}$, is an ε-optimal decision rule in MDP in the sense of Theorem 8.2(ii).

We exclude the trivial case $F^* = F$ since then $N^* = 1$, and suppose S to be finite. Let $\mathrm{sp}v := \max_{s\in S} v(s) - \min_{s\in S} v(s)$ denote the span of v extended to S with $v = 0$ on J_0. Furthermore, let $D^*(s) \subset D(s)$, $s \in J$, be the set of all maximum points of $LV(s,\cdot)$. Put $B := \{s \in J \mid D^*(s) \neq D(s)\}$. Since B is finite, there exists $\gamma \in (0,\infty)^B$

$$\gamma(s) := V(s) - \max_{a\in D(s)-D^*(s)} \{LV(s,a)\}, \quad s \in B.$$

To give a finite upper bound N, say, for N^*, we use

$$\delta(s) := 1 - \max_{a'\in D^*(s)} \min_{a\in D(s)-D^*(s)} \sum_{j\in S} \min\{p(s,a,j), p(s,a',j)\}, \quad s \in B,$$

and $\mu := \beta \cdot \max_{s\in B} \delta(s)/\gamma(s)$. Then, since $\lim_{k\to\infty} \mathrm{sp}(v_k - V) = 0$, we have

$$N := \inf\{n \in \mathbb{N} \mid \mathrm{sp}(v_{k-1} - V) \cdot \mu < 1 \text{ for all } k \geq n\} < \infty.$$

To simplify the computation of N, note that $\mathrm{sp}(U^t v_{k-1} - U^t V) \leq \beta^t \|e_t\| \mathrm{sp}(v_{k-1} - V)$ for all $t, k \in \mathbb{N}$. Thus, if $\beta < \beta^*$, we have some $m \in \mathbb{N}$ such that $\beta^m \|e_m\| < 1$, and it holds that

$$N = \inf\{n \in \mathbb{N} \mid \mathrm{sp}(v_{k-1} - V) \cdot \mu < 1 \text{ for all } n \leq k < n + m\}. \tag{10.1}$$

Put

$$\kappa := 1 - \min_{s'\in S} \max_{a'\in D^*(s')} \min_{(s,a)\in D} \sum_{j\in S} \min\{p(s,a,j), p(s',a',j)\}.$$

If $\beta\kappa < 1$, then, for $n \in \mathbb{N}$,

$$\bar{N}(n) := \inf\left\{k \geq n \mid \mathrm{sp}(v_{n-1} - V) \cdot (\beta\kappa)^{k-n}\mu < 1\right\} < \infty.$$

Alternatively we may use $n \in \mathbb{N}$ and $m \in \mathbb{N}$ such that $\beta\|e_m\|^{1/m} < 1$ in order to get

$$\hat{N}(m,n) := \inf\left\{k \geq n \mid \mathrm{sp}(v_{n-1} - V) \cdot \max_{0\leq t<m} \{\beta^t \|e_t\|\} (\beta^m \|e_m\|)^{\lfloor (k-n)/m \rfloor} \mu < 1\right\} < \infty.$$

THEOREM 10.1. *Assume S to be finite. Let $\beta < \beta^*$ and $F^* \neq F$. Then $N^* \leq N < \infty$. Furthermore,*

(i) *if $\beta\kappa < 1$, then $N = \inf\{t \in \mathbb{N} \mid \mathrm{sp}(v_{t-1} - V) \cdot \mu < 1\} \leq \bar{N}(n) < \infty$, $n \in \mathbb{N}$;*

(ii) *if $m \in \mathbb{N}$ such that $\beta\|e_m\|^{1/m} < 1$, then $N \leq \hat{N}(m,n) < \infty$ for $n \in \mathbb{N}$.*

Proof. (a) Extend $v \in \mathbb{R}^J$ to $v \in \mathbb{R}^S$ with $v = 0$ on J_0. Let $f, h \in F$. Fix $s, s' \in S$. For $j \in S$ set $x_j := p(s, f(s), j)$, $y_j := p(s', h(s'), j)$. Then, using $(x-y)^+ = x - x \wedge y$, $(x-y)^- = y - x \wedge y$ for $x, y \in \mathbb{R}$,

$$\begin{aligned} H_f v(s) - H_h v(s') &= \sum_{j\in S} (x_j - y_j)^+ v(j) - \sum_{j\in S} (x_j - y_j)^- v(j) \\ &\leq \sum_{j\in S} x_j \cdot \max v - \sum_{j\in S} y_j \cdot \min v - \sum_{j\in S} x_j \wedge y_j \cdot \mathrm{sp}v \\ &= \left[1 - \sum_{j\in S} p(s, f(s), j) \wedge p(s', h(s'), j)\right] \cdot \mathrm{sp}v. \end{aligned}$$

(b) Fix $k \geq N$. We have to show that $F_k^* \subset F^*$. Assume $F_k^* \not\subset F^*$. Then there exists a maximizer f_k of Lv_{k-1} with $f_k(s) \notin D^*(s)$ for some $s \in J$. By definition, $s \in B$. Now, by applying (a) with $s = s'$, $v = v_{k-1} - V$, $f = f_k$, and $h \in F^*$ such that $\delta(s) = 1 - \min_{a \in D(s) - D^*(s)} \sum_{j \in S} p(s,a,j) \wedge p(s,h(s),j)$, we get

$$\begin{aligned}
&U_h v_{k-1}(s) - U_{f_k} v_{k-1}(s) \\
&\quad = U_h v_{k-1}(s) - U_h V(s) + U_h V(s) - U_{f_k} V(s) - (U_{f_k} v_{k-1}(s) - U_{f_k} V(s)) \\
&\quad = V(s) - U_{f_k} V(s) - [\beta H_{f_k}(v_{k-1} - V)(s) - \beta H_h(v_{k-1} - V)(s)] \\
&\quad \geq \gamma(s) - \beta\delta(s) \cdot \operatorname{sp}(v_{k-1} - V) \\
&\quad \geq \gamma(s)[1 - \mu \cdot \operatorname{sp}(v_{k-1} - V)].
\end{aligned}$$

Hence $U_h v_{k-1}(s) - U_{f_k} v_{k-1}(s) > 0$, which is the desired contradiction that f_k is a maximizer of Lv_{k-1}.

(c) We prove $N \leq \bar{N}(n)$. Put $Q(s',a') := 1 - \min_{(s,a) \in D} \sum_{j \in S} p(s,a,j) \wedge p(s',a',j)$. Select $h(s') \in D^*(s')$ as the minimum point of $Q(s',\cdot)$, $s' \in S$. Applying (a) with $v = v_{k-1} - V$, and $f = f_k$, we have for suitable $s, s' \in S$

$$\begin{aligned}
\operatorname{sp}(v_k - V) &= (v_k - V)(s) - (v_k - V)(s') \\
&\leq \beta H_{f_k}(v_{k-1} - V)(s) - \beta H_h(v_{k-1} - V)(s') \\
&\leq \beta Q(s', h(s')) \cdot \operatorname{sp}(v_{k-1} - V) \\
&\leq \beta \max_{s' \in S} \min_{a' \in D^*(s')} Q(s', h(s')) \cdot \operatorname{sp}(v_{k-1} - V) \\
&= \beta\kappa \cdot \operatorname{sp}(v_{k-1} - V).
\end{aligned}$$

This verifies, since $\beta\kappa < 1$, formula (10.1) and that $N \leq \bar{N}(n) < \infty$.

(d) Exploiting $\operatorname{sp}(U^t v_{n-1} - U^t V) \leq \beta^t \|e_t\| \cdot \operatorname{sp}(v_{n-1} - V)$ and Proposition 9.2(i), the proof of (ii) is similar to (i). □

Theorem 10.1 improves (in case of $\beta < \beta^*$) Theorems 2.3, 2.4, and 3.1 in Hinderer and Hübner (1977) in three respects: a larger γ, smaller δ and κ, and a slightly improved upper bound for $\|e_{n-1}\|$, which results from Proposition 9.2(ii).

A NEW APPROACH TO DETECTABILITY OF DISCRETE-TIME INFINITE MARKOV JUMP LINEAR SYSTEMS*

EDUARDO F. COSTA†, JOÃO B. R. DO VAL‡, AND MARCELO D. FRAGOSO§

Abstract. This paper deals with detectability for the class of discrete-time Markov jump linear systems (MJLS) with the underlying Markov chain having countably infinite state space. The formulation here relates the convergence of the output with that of the state variables, and due to the rather general setting, a novel point of view toward detectability is required. Our approach introduces invariant subspaces for the autonomous system and exhibits the role that they play. This allows us to show that detectability can be written equivalently in term of two conditions: stability of the autonomous system in a certain invariant space and convergence of general state trajectories to this invariant space under convergence of input and output variables. This, in turn, provides the tools to show that detectability here generalizes uniform observability ideas as well as previous detectability notions for MJLS with finite state Markov chain, and allows us to solve the jump-linear-quadratic control problem. In addition, it is shown for the MJLS with finite Markov state that the second condition is redundant and that detectability retrieves previously well-known concepts in their respective scenarios. Illustrative examples are included.

Key words. detectability, stochastic systems, Markov jump systems, infinite Markov state space, optimal control

1. Introduction.

Structural concepts such as observability and detectability have a solid ground in system theory, as the imposing literature for linear and linear-Gaussian systems conveys (see, e.g., [15]). For instance, in control problems, detectability firmly associates the solution for the optimal problems with stability of the corresponding controlled system, whereas, for filtering, it makes the system observations meaningful for state estimates by connecting convergence of the output with convergence of the state. Although the theory involving these concepts is quite developed and a number of results are available in the context of linear deterministic systems, there is still a great deal of research activity in this area (see, e.g., [13, 17] and references therein).

Among the most important properties of detectability for the linear deterministic scenario, we mention that

(i) detectability can be expressed in terms of the parameters of the autonomous version of the system, e.g., by requiring that nonobserved modes of the autonomous system are stable.

(ii) Detectability generalizes observability.

Another important but less acknowledged property is that

(iii) detectability is a necessary and sufficient condition to guarantee convergence of the state from convergence of the output (under regular nonsingular linear state feedback controls).

Property (iii) ensures that the optimal control solution is stabilizing and makes output observations meaningful in filtering problems.

Due to its generic formulation, these properties constitute a paradigm for more general contexts. The challenge then is how to devise a detectability concept for a certain class of systems that allows one to employ the structure of the system to retrieve properties (i)–(iii).

In this spirit, the authors have recently developed a notion of detectability (called weak detectability) that generalizes previous detectability ideas for MJLS with finite Markov chain state, retrieves the properties (i)–(iii), and allows an associate observability matrix, in an extension to the well-known deterministic concepts, see [1] and [2]. In this process all but one[1] of the linear deterministic concepts are retrieved.

However, as far as the authors are aware, these ideas have no parallel in more complex scenarios such as the MJLS with countably infinite state space of the Markov chain. This is a rather general class of systems that includes the classes of finite MJLS and linear deterministic systems, as well as deterministic time varying systems. Previous works dealing with infinite MJLS are [7, 8, 9, 10].For this class of systems, up to this date there is no detectability concept that retrieves properties (i)–(iii) above. For instance, the stochastic notion in [7] can be expressed in terms of the autonomous system data, thus satisfying (i), but (ii) does not hold and only the sufficiency part of (iii) holds; in [4] we derive a detectability notion in the perspective of (iii) for which (ii) holds, but it does not satisfy (i).

These shortfalls come, in part, from the analytical complexity inherent to the infinite many Markov state contexts, and the loss of some friendlier structures of the simpler cases. In particular, the main difficulty arises from the fact demonstrated in this paper that converging input and output *do not* ensure convergence of state trajectory to the observed space; see Example 2 in connection. In the simpler case of finitely many Markov states, the above convergence relation holds, and apart from ensuring stability within the observed space, with detectability it guarantees convergence of the state trajectory to the origin. This is the mechanism that fails here, and in this regard we can conclude that any detectability concept with the perspective of (i) (stable nonobserved modes) by itself cannot provide the property in (iii) and thus, it cannot ensure that the optimal control is stabilizing.

In this paper, with the aim of studying detectability for MJLS with countably infinite state space of the Markov chain and to retrieve (i)–(iii), we introduce a novel point of view toward detectability by considering the paradigmatic property in (iii) as a general, direct, and intuitive notion of detectability, which relates the convergence of the input and output with that of the state variables. Then we introduce certain invariant subspaces for the autonomous system, which play a key role to relate detectability with stability and convergence of the state trajectory; this allows us to show that detectability here generalizes uniform observability ideas as well as previous detectability notions for MJLS with finite state Markov chain, and to solve the jump-linear-quadratic control problem. In order to show some nuances of the approach developed here, and to clarify the role of some tools, we also analyze the MJLS with finite state Markov chain and present illustrative examples.

[1]The observability idea that after a number of observations that equals the system dimension, the initial state value can be precisely retrieved. This is inherently a nonstochastic idea.

An outline of the content of this paper is as follows. In section 2 we provide the bare essential of notations, state the model, and discuss the general ideas of the paper. Section 3 provides some preliminaries. Necessary and sufficient conditions for detectability are treated in section 4, and some sufficient conditions are presented in section 5. The finite MJLS is analyzed in section 6, and the control problem is studied in section 7. Some illustrative examples are exhibited in section 8. Finally, section 9 presents some conclusions.

2. Problem formulation and general ideas. Let $\mathbb{R}^n$ represent the usual linear space of all n-dimensional vectors and $\mathcal{R}^{r,n}$ (respectively, $\mathcal{R}^n$) the normed linear space formed by all $r \times n$ real matrices (respectively, $n \times n$). For $V \in \mathcal{R}^{n,r}$, V' denotes the transpose of V. $\sigma^+(V)$ and $\sigma^-(V)$ stand, respectively, for the largest and smallest singular value of V and $\|V\| = \sigma^+(V)$. For $V, W \in \mathcal{R}^n$, $V > W$ ($V \geq W$) indicates that $V - W$ is positive definite (semidefinite).

Let $\mathcal{H}_\infty^{r,n}$ denote the linear space formed by sequences of matrices $H = \{H_i \in \mathcal{R}^{r,n}; i \in \mathcal{Z}\}$ such that $\sup_{i\in\mathcal{Z}} ||H_i|| < \infty$; also, $\mathcal{H}_\infty^n \equiv \mathcal{H}_\infty^{n,n}$ and $\|H\|_\infty = \sup_{i\in\mathcal{Z}} \|H_i\|$. For $H, V \in \mathcal{H}_\infty^n$, $H \geq V$ indicates that $H_i \geq V_i$ for each $i \in \mathcal{Z}$; similarly, for $H \in \mathcal{H}_\infty^{r,n}$ and $V \in \mathcal{H}_\infty^{n,s}$, the "product" HV indicates the element of $\mathcal{H}_\infty^{r,s}$ formed by the sequence $\{H_iV_i, i \in \mathcal{Z}\}$, and equivalent understanding should apply to any basic mathematical operation involving elements of $\mathcal{H}_\infty^{r,n}$. In what follows, capital letters denote elements of $\mathcal{H}_\infty^{r,n}$, and capital letters with an index denote elements of $\mathcal{R}^{r,n}$.

The system we deal with is the discrete-time MJLS with infinite countably Markov chain, defined in a fixed stochastic basis $(\Omega, \mathfrak{F}, (\mathfrak{F}_k), \mathcal{P})$ by

$$\Psi : \begin{cases} x(k+1) = A_{\theta(k)}x(k) + B_{\theta(k)}u(k), & k \geq 0, \\ y(k) = C_{\theta(k)}x(k) + D_{\theta(k)}u(k), & x(0) = x,\ \theta(0) = \theta, \end{cases} \tag{1}$$

where y is the output process and u is the input, an $(\mathfrak{F}_k)$-adapted process. The mode θ is the state of an underlying discrete-time Markov chain $\Theta = \{\theta(k); k \geq 0\}$ taking values in $\mathcal{Z} = \{1, 2, \dots\}$ and having a stationary transition probability matrix $\mathbb{P} = [p_{ij}]$, $i, j \in \mathcal{Z}$. The state of the system is the compound variable $(x(k), \theta(k))$. The matrices A_i belong to the sequence of matrices $A \in \mathcal{H}_\infty^n$, and similarly for $B \in \mathcal{H}_\infty^{n,r}$, $C \in \mathcal{H}_\infty^{q,n}$, and $D \in \mathcal{H}_\infty^{q,r}$. In addition, without loss of generality, we also assume that $C'D = 0$.

In this paper we deal with detectability for systems described by (1). The departure point is the following concept of detectability that follows from property (iii) of section 1. We emphasize that the specific notion of convergence is not relevant; the essence of the concept is the relation among convergence of state, input and output, and a particular sense of convergence is adopted later in connection with the choice of the cost functional.

DEFINITION 1 (detectability). *The system Ψ is detectable if the state converges provided that the output and the input converge.*

With the detectability concept above at hands, which trivially embraces property (iii) in the introduction, the issues pursued here are primarily summarized as follows:

(I) Relate the concept with the autonomous version of the system, aiming at mimicking item (i) mentioned in the introduction.

(II) Show that it retrieves property (ii) mentioned in the introduction.

(III) Investigate the extent to which the above concept is related to the weak detectability concept in [1] and [2] for MJLS, and the usual concept for deterministic linear systems.

We consider a cost functional that is an ℓ_2-measurement of the output (the expected accumulated energy in the output process path),

$$\mathcal{Y}_u(x,\theta) = E_{x,\theta}\left\{\sum_{k=0}^{\infty} |y(k)|^2\right\}, \tag{2}$$

defined for an admissible control u whenever $x(0) = x$ and $\theta(0) = \theta$. We also denote for the autonomous system obtained from Ψ with $u \equiv 0$,

$$\mathcal{Y}_0(x,\theta) = \mathcal{Y}_{u\equiv 0}(x,\theta). \tag{3}$$

In agreement with (2), we adopt the corresponding ℓ_2-convergence notion for each Ψ-processes, namely, we say that the output y converges whenever $\mathcal{Y}_u(\cdot,\cdot) < \infty$; similar notion holds for u and x.

Our approach starts from a novel point of view, which hinges on the following steps. We first locate an invariant linear subspace for the autonomous system, in the sense that the trajectories remain almost surely confined to it. Then we indicate the role that the invariant space plays in the convergence of an arbitrary state trajectory, showing that the existence of an invariant space for which the autonomous system is stable, together with the convergence to this set of an arbitrary trajectory, is equivalent to convergence to the origin of such a trajectory (see section 4 and Theorem 12).

Note that the announced result reduces to a tautology if the invariant space is taken to be the origin, and to make the above result suitable to deal with (I), we seek the largest of such an invariant space. It turns out to be the linear subspace $\mathcal{F} = \{(x,\theta) : \mathcal{Y}_0(x,\theta) < \infty\}$, and in Theorem 18 we state that detectability according to Definition 1 is equivalent to requiring that

(A1) the autonomous system is stable in $\mathcal{F}$,

(A2) the state x converges to $\mathcal{F}$ provided that both y and u converge.

Notice that condition (A1) accounts for the autonomous version of system Ψ only, and it is consistent with the notion of detectability for finite dimensional linear deterministic systems. Together with condition (A2) for system Ψ (not only the autonomous version), they build the essentials to complete the aforementioned mechanism yielding (iii). Due to (A2), a complete counterpart for property (i) is not viable in the present setup (see Example 3 in connection), and any attempt to enlarge $\mathcal{F}$ is worthless, as we show in Lemma 17.

Section 5 addresses (II), where we show that detectability according to Definition 1 generalizes uniform observability as in [1, 3, 5, 12], which, by its turn, generalizes previous observability concepts for MJLS, like those in [11]. We also show that an earlier ℓ_2-detectability concept in [7] is stricter than detectability. Moreover, we introduce a notion of uniform observability in the invariant space $\mathcal{F}$ that serves as a sufficient condition for (A2). See Proposition 28 for a summary.

Regarding (III), in section 6 we show that $\mathcal{F}^{\perp}$ is uniformly observable in the finite Markov chain case, which renders condition (A2) always true. Thus, we have that detectability is equivalent to (A1) in the finite case, allowing us to show that the weak detectability in [2] and the usual detectability concept in the deterministic linear case are necessary and sufficient conditions (in their particular contexts) for detectability according to Definition 1 (see Remark 3). The fact that (A2) holds true for the case in which the Markov chain is finite explains why no such condition appears in those simpler scenarios. By contrast, (A2) may fail in the infinite Markov chain case, as illustrated in Example 2.

Another important feature of the setting and results here is that, unlike previous ones, the focus is not constrained (i.e., is not *ad hoc*) to the optimal jump-linear-quadratic (JLQ) control and/or controls in linear feedback form, where detectability appears as a dual notion to stabilizability. It covers any $(\mathfrak{F}_k)$-adapted converging control that induces a finite cost $\mathcal{Y}_u$ for each initial state, assuring that it is stabilizing, and clearly encompassing the optimal solution (see Remark 1). In particular for the JLQ control, we show that the solution to the associated infinite coupled algebraic Riccati equation is unique (see section 7).

3. Preliminaries. In this section we introduce some basic machinaries, which will allow us to devise our approach toward detectability for (1). We consider the autonomous version of (1), which will be essential to relate detectability with stability and convergence of the state trajectory (see (A.1) and (A.2) in section 2). We define the various essential elements such as invariant space, some notions of convergence, some useful spaces, operators, and some preliminary results.

We consider the autonomous version of system (1):

$$\Psi_0 : \begin{cases} x_0(k+1) = A_{\theta(k)}x_0(k), & k \geq 0, \\ y_0(k) = C_{\theta(k)}x_0(k), & x_0(0) = x, \theta(0) = \theta. \end{cases}$$

Sometimes we refer to the autonomous system by the pair $(A, \mathbb{P})$ or by the triplet $(A, C, \mathbb{P})$. In addition, in what follows, for each $i \in \mathcal{Z}$, let $\mathcal{S}_i \subset \mathbb{R}^n$ stand for a vector subspace and let $\mathcal{S} = \{\mathcal{S}_i, i \in \mathcal{Z}\}$.

DEFINITION 2 (Ψ_0-invariant space). *Consider the autonomous system Ψ_0. We say that $\mathcal{S}$ is an invariant space if $x_0(k) \in \mathcal{S}_{\theta(k)}$ implies that $x_0(t) \in \mathcal{S}_{\theta(t)}$ almost surely (a.s.) for each $t \geq k$.*

DEFINITION 3 (projections onto $\mathcal{S}^{\perp}$). *For each $i \in \mathcal{Z}$, let $P_i \in \mathcal{R}^n$ denote the orthogonal projection onto $\mathcal{S}_i^{\perp}$. Clearly, $P = \{P_i, i \in \mathcal{Z}\} \in \mathcal{H}_\infty^n$.*

DEFINITION 4 (Ψ_0-convergence). *We say that $x(\cdot)$ converges (in the ℓ_2 sense) to the Ψ_0-invariant space $\mathcal{S}$ if*

$$\sum_{k=0}^{\infty} E_{x,\theta}\{|P_{\theta(k)}x(k)|^2\} < \infty.$$

We say that $x(\cdot)$ converges if it converges to the trivial Ψ_0-invariant space $\mathcal{S} = 0$.

DEFINITION 5 (ℓ_2-stability). *Consider the autonomous system Ψ_0. We say that $(A, \mathbb{P})$ is ℓ_2-stable in the invariant space $\mathcal{S}$ if $x_0(\cdot)$ converges for each initial condition $\theta \in \mathcal{Z}$ and $x \in \mathcal{S}_\theta$. We say that $(A, \mathbb{P})$ is ℓ_2-stable if it is ℓ_2-stable in $\mathcal{S}$ with $\mathcal{S}_i = \mathbb{R}^n$, $i \in \mathcal{Z}$*

Notice that $x(\cdot)$ converges if and only if $\sum_{k=0}^{\infty} E\{|x(k)|^2\} < \infty$, since $P = I$ whenever $\mathcal{S}$ is trivial. Also, ℓ_2-stability of $(A, \mathbb{P})$ is equivalent to convergence of $x_0(\cdot)$ for each initial condition $\theta \in \mathcal{Z}$ and $x \in \mathbb{R}^n$.

We will need the following property related with the concept of ℓ_2-stability in $\mathcal{S}$ and the projections P.

LEMMA 6. *Assume that $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$. Then, $(A - AP, \mathbb{P})$ is ℓ_2-stable.*

Proof. Consider the following version of system Ψ:

$$x_P(k+1) = (A_{\theta(k)} - A_{\theta(k)}P_{\theta(k)})x_P(k), \quad x_P(0) = x,\ \theta(0) = \theta. \tag{4}$$

Let us employ the trajectory of system Ψ_0, $x_0(k) = A_{\theta(k-1)} \cdots A_{\theta(0)}x_0$, with initial condition x_0 being the projection of x into $\mathcal{S}_\theta$, i.e., $x_0 = (I - P_\theta)x$. Since $\mathcal{S}$ is a invariant space, we have that $x_0(k) \in \mathcal{S}_{\theta(k)}$, $k \geq 0$.

We start by showing inductively that $x_P(\cdot)$ evolves as an open-loop trajectory according to $x_P(k) = x_0(k)$, for $k \geq 1$, for all $x \in \mathbb{R}^n$. For $k = 1$ we have that

$$x_P(1) = (A_\theta - A_\theta P_\theta)x = A_\theta(I - P_\theta)x = x_0(1).$$

From the induction assumption, we have that $x_P(k) = x_0(k)$ for $k \geq 1$, and recalling that $x_0(k) \in \mathcal{S}_{\theta(k)}$ we evaluate

$$x_P(k+1) = (A_{\theta(k)} - A_{\theta(k)}P_{\theta(k)})x_0(k) = A_{\theta(k)}x_0(k) = x_0(k+1)$$

and the induction is completed. Due to the facts that (i) $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$, (ii) $x_P(1) = x_0(1) \in \mathcal{S}_{\theta(1)}$ a.s., and (iii) $x_P(k)$, $k \geq 1$ evolves as a trajectory of the autonomous system for any $x_P(0) = x$, $\theta(0) = \theta$, we have from the definition of ℓ_2-stability in $\mathcal{S}$ that $x_P(\cdot)$ converges and, thus, $(A - AP, \mathbb{P})$ is ℓ_2-stable. □

In what follows, we introduce a certain space $\mathcal{H}_F^n$, an element $X(k)$ related with the second moment of the state, an operator $\mathcal{L}$ related with the evolution of $X(k)$, and some associated results which will be useful to present the results of the paper in a concise manner.

Let $\mathcal{H}_1^n$ denote the linear space formed by sequences of matrices $H = \{H_i = H_i' \geq 0; i \in \mathcal{Z}\}$ such that $\sum_{i\in\mathcal{Z}} tr\{H_i\} < \infty$. Let $\mathcal{H}_F^n \subset \mathcal{H}_1^n$ denote the closed cone formed by sequences of symmetric positive semidefinite matrices $H = \{H_i = H_i' \geq 0; i \in \mathcal{Z}\}$. For $H, V \in \mathcal{H}_F^n$ we define the inner product

$$\langle H, V\rangle = \sum_{i\in\mathcal{Z}} tr\{H_i'V_i\}$$

and the Frobenius norm

$$\|H\|_F = \langle H, I\rangle. \tag{5}$$

Recall from the definition of the Ψ_0-invariant subspace $\mathcal{S}$ that $\mathcal{S}_i = \{x : P_i x = 0\}$. In connection, we define the spaces $\bar{\mathcal{S}} = \{H \in \mathcal{H}_F^n : PHP' = 0\} \subset \mathcal{H}_F^n$ and $\bar{\mathcal{S}}^\perp = \{H \in \mathcal{H}_F^n : H - PHP' = 0\}$. PHP' is the orthogonal projection of H onto $\bar{\mathcal{S}}^\perp$; indeed, P inherits from P_i the property that $P^2 = P$, and it is easy to check that $\langle PHP', H - PHP'\rangle = \langle H, PHP' - P^2HP^{2\prime}\rangle = 0$.

Definition 7 (convergence in $\mathcal{H}_F^n$). *We refer to convergence of sequences in $\mathcal{H}_F^n$ in the ℓ_1 sense: we say that a sequence $H(\cdot) \in \mathcal{H}_F^n$ converges to the space $\bar{\mathcal{S}}$ whenever $\sum_{k=0}^\infty \|PH(k)P'\|_F < \infty$; we say that $H(\cdot)$ converges if it converges to the trivial space $\bar{\mathcal{S}} = 0$.*

We define $X(\cdot) \in \mathcal{H}_F^n$ and $U(\cdot) \in \mathcal{H}_F^r$ as

$$\begin{aligned} X_i(k) &= E\{x(k)x(k)'1_{\{\theta(k)=i\}}\} \\ U_i(k) &= E\{u(k)u(k)'1_{\{\theta(k)=i\}}\}\ \forall i \in \mathcal{Z}, k \geq 0, \end{aligned} \tag{6}$$

where $1_{\{\cdot\}}$ is the Dirac indicator function. We write $X_0(\cdot)$ when we refer to the autonomous system. We define $\mathcal{Y}_u^{t,T}$ similarly to the functional $\mathcal{Y}$ in (2) as follows:

$$\mathcal{Y}_u^{t,T}(x,\theta) = E_{x,\theta}\left\{\sum_{k=t}^{t+T-1} |y(k)|^2\right\} = \sum_{k=t}^{t+T-1} \Big(\langle X(k), C'C\rangle + \langle U(k), D'D\rangle\Big) \tag{7}$$

whenever $x(0) = x, \theta(0) = \theta$; for simplicity we write $\mathcal{Y}_u^{t=0,T}(x,\theta) = \mathcal{Y}_u^T(x,\theta)$ and also $\mathcal{Y}_{u\equiv 0}^T(x,\theta) = \mathcal{Y}_0^T(x,\theta)$.

Using the notation above we can write $E_{x,\theta}\{|x(k)|^2\} = \|X(k)\|_F$ and this provides a connection between convergence in the ℓ_1 sense of $X(\cdot) \in \mathcal{H}_F^n$ with the ℓ_2 convergence of $x(\cdot)$. A further connection is presented in the next lemma; the proof is presented in Appendix 9.

LEMMA 8. *$x(\cdot)$ converges to $\mathcal{S}$ if and only if $X(\cdot)$ converges to $\bar{\mathcal{S}}$.*

Now, let us define for $V \in \mathcal{H}_\infty^{n,r}$ the linear operator $\mathcal{L}_V : \mathcal{H}_F^r \to \mathcal{H}_F^n$

$$\mathcal{L}_{Vi}(H) = \sum_{j\in\mathcal{Z}} p_{ji} V_j H_j V_j'. \tag{8}$$

It is shown in [7] that the limit in (8) is well defined. We denote $\mathcal{L}^0(H) = H$, and for $k \geq 1$, we can define $\mathcal{L}^k(H)$ recursively by $\mathcal{L}^k(H) = \mathcal{L}(\mathcal{L}^{k-1}(H))$. Also, $r_\sigma(\mathcal{L})$ denotes the spectral radius of $\mathcal{L}$. Operator $\mathcal{L}$ is related to system Ψ as follows; the result is adapted from [7].

PROPOSITION 9. *The following assertions hold:*

(i) $X_0(k+1) = \mathcal{L}_A(X_0(k)),\ k \geq 0$;

(ii) $(A, \mathbb{P})$ *is ℓ_2-stable if and only if* $r_\sigma(\mathcal{L}_A) < 1$.

For the nonautonomous system Ψ, the evolution of X is still related to the operator $\mathcal{L}$, as follows. See Appendix 9 for the proof.

LEMMA 10. *Let $\alpha \neq 0$. Then,*

$$X(k+1) \leq (1+\alpha^2)\mathcal{L}_A(X(k)) + (1+1/\alpha^2)\mathcal{L}_B(U(k)),\ \ k \geq 0.$$

The following basic properties concerning the operator $\mathcal{L}$, which are easy to check by inspection, will be useful.

PROPOSITION 11. *The following properties hold, for $V, W \in \mathcal{H}_\infty^n$ and $H, Y \in \mathcal{H}_F^n$:*

(i) $\mathcal{L}_{VW}(H) = \mathcal{L}_V(WHW')$;

(ii) $\mathcal{L}_{V+W}(H) \geq (1-\alpha^2)\mathcal{L}_V(H) + (1-1/\alpha^2)\mathcal{L}_W(H)\ \forall \alpha \neq 0$;

(iii) $\mathcal{L}_{V+W}(H) \leq (1+\alpha^2)\mathcal{L}_V(H) + (1+1/\alpha^2)\mathcal{L}_W(H)\ \forall \alpha \neq 0$;

(iv) $\mathcal{L}_V(H) \geq \mathcal{L}_V(Y)$ *whenever* $H \geq Y$;

(v) $||\mathcal{L}_V(H)||_F \leq ||V||_\infty^2 ||H||_F$.

We finish the section with the following facts that we believe are worth mentioning. $\bar{\mathcal{S}}$ inherits from $\mathcal{S}$ the property that it is a Ψ_0-invariant subspace, that is, $PX_0(k)P' = 0$, $k \geq 0$, implies that $PX_0(t)P' = 0$, $t \geq k$. The notion of convergence in $\mathcal{H}_F^n$ is usual, in the sense that a sequence $H(\cdot) \in \mathcal{H}_F^n$ converges to the space $\bar{\mathcal{S}}$ if and only if $\sum_{k=0}^\infty \inf_{V\in\bar{\mathcal{S}}} \|H(k) - V\|_F < \infty$. Actually, the proof follows immediately from the fact that for each $H(k)$ there exists $V \in \bar{\mathcal{S}}$ for which $\|H(k) - V\|_F = \|PH(k)P'\|_F$ (indeed, $V = H(k) - PH(k)P'$).

4. A necessary and sufficient condition for detectability. We show in section 4.1 that a general state trajectory $x(\cdot)$ converges if and only if there exists an invariant space $\mathcal{S}$ for which: (i) $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$ and (ii) $x(\cdot)$ converges to $\mathcal{S}$. In section 4.2 we introduce the Ψ_0-invariant space $\mathcal{F}$ and we show the appropriateness of $\mathcal{F}$ to formulate the equivalence between detectability and conditions (A1) and (A2).

4.1. Conditions for state convergence. In this section we examine the state convergence of system Ψ and its interplay with the Ψ_0-invariant subspace $\mathcal{S}$. The first requirement is the existence of a Ψ_0-invariant space $\mathcal{S}$ in which $(A, \mathbb{P})$ is ℓ_2-stable, namely, the condition (A1) holds.

Notice that (A1) does not impose any condition on the system Ψ (or, even on Ψ_0) in the subspaces orthogonal to $\mathcal{S}$. From this perspective, one can infer that (A1) can be employed only to establish the convergence of Ψ_0-trajectories that remain a.s. in $\mathcal{S}$ or, at most, of Ψ_0-trajectories that converge to $\mathcal{S}$. Surprisingly, the combination of (A1) with convergence to $\mathcal{S}$ of Ψ-trajectories guarantee the convergence of any trajectory of Ψ with converging inputs, as the next theorem shows. Clearly, if $\mathcal{S}$ is trivial, Theorem 12 becomes a tautology.

THEOREM 12. *Consider system Ψ and assume that the input converges. The state $x(\cdot)$ converges if and only if there exists an invariant space $\mathcal{S}$ such that the following conditions hold:*

(i) *$(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$;*
(ii) *$x(\cdot)$ converges to $\mathcal{S}$.*

Proof. (Necessity.) Since $x(\cdot)$ converges to the origin, $\mathcal{S} = 0$ trivially satisfies (i) and (ii).

(Sufficiency.) We show that $x(\cdot)$ converges provided (i) and (ii) hold and $u(\cdot)$ converges. Recall from Lemma 6 that condition (i) provides that $(A - AP, \mathbb{P})$ is ℓ_2-stable for P the projection in $\mathcal{S}$ and from Proposition 9 (ii) we have that $r_\sigma(\mathcal{L}_{A-AP}) < 1$. Let $\alpha \neq 0$ be such that $(1+\alpha^2)^2 r_\sigma(\mathcal{L}_{A-AP}) < 1$. For ease of notation, we define the operators $\hat{\mathcal{L}}, \tilde{\mathcal{L}}, \bar{\mathcal{L}} : \mathcal{H}_F^n \to \mathcal{H}_F^n$ as

$$\begin{aligned} \hat{\mathcal{L}}(H) &= (1+\alpha^2)^2 \mathcal{L}_{A-AP}(H), \\ \tilde{\mathcal{L}}(H) &= (1+\alpha^2)(1+1/\alpha^2)\mathcal{L}_{AP}(H), \text{ and} \\ \bar{\mathcal{L}}(H) &= (1+1/\alpha^2)\mathcal{L}_B(H) \end{aligned}$$

for $H \in \mathcal{H}_F^n$. We also define the series $Z(\cdot)$ with $Z(k) \in \mathcal{H}_F^n$, $k \geq 0$, by

$$\begin{cases} Z(k+1) = \hat{\mathcal{L}}(Z(k)) + \tilde{\mathcal{L}}(X(k)) + \bar{\mathcal{L}}(U(k)), \ k \geq 0, \\ Z(0) = X(0). \end{cases}$$

Noticing that

$$Z(m) = \hat{\mathcal{L}}^m(X(0)) + \sum_{k=0}^{m-1} \hat{\mathcal{L}}^k\Big(\tilde{\mathcal{L}}(X(-k+m-1)) + \bar{\mathcal{L}}(U(-k+m-1))\Big),$$

we write

$$\begin{aligned} \sum_{m=0}^{\infty} \langle Z(m), I\rangle &= \sum_{m=0}^{\infty} \langle \hat{\mathcal{L}}^m(X(0)), I\rangle \\ &\quad + \sum_{m=0}^{\infty}\sum_{k=0}^{m-1} \Big\langle \hat{\mathcal{L}}^k\Big(\tilde{\mathcal{L}}(X(-k+m-1)) + \bar{\mathcal{L}}(U(-k+m-1))\Big), I\Big\rangle. \end{aligned} \tag{9}$$

For the second term in the right-hand side of (9) we evaluate

$$
\begin{aligned}
(10)\qquad &\sum_{m=0}^{\infty}\sum_{k=0}^{m-1}\left\langle \hat{\mathcal{L}}^k\Big(\tilde{\mathcal{L}}(X(m-k-1))+\bar{\mathcal{L}}(U(m-k-1))\Big), I\right\rangle\\
&=\sum_{k=0}^{\infty}\sum_{m=k+1}^{\infty}\langle \hat{\mathcal{L}}^k\Big(\tilde{\mathcal{L}}(X(m-k-1))+\bar{\mathcal{L}}(U(m-k-1))\Big), I\Big\rangle\\
&=\sum_{k=0}^{\infty}\left\langle \hat{\mathcal{L}}^k\left(\sum_{m=0}^{\infty}\tilde{\mathcal{L}}(X(m))+\bar{\mathcal{L}}(U(m))\right), I\right\rangle\\
&=\sum_{k=0}^{\infty}\langle \hat{\mathcal{L}}^k(\Upsilon), I\rangle,
\end{aligned}
$$

where we set

$$
\Upsilon=\sum_{m=0}^{\infty}\tilde{\mathcal{L}}(X(m))+\hat{\mathcal{L}}(U(m))=(1+\alpha^2)(1+1/\alpha^2)\sum_{m=0}^{\infty}\mathcal{L}_{AP}(X(m))
+(1+1/\alpha^2)\sum_{m=0}^{\infty}\mathcal{L}_B(U(m)).
$$

We need to show that Υ is well defined, i.e., that $\Upsilon\in\mathcal{H}_F^n$; the result is presented in the next lemma.

LEMMA 13. *$\|\sum_{k=0}^{\infty}\mathcal{L}_B(U(k))\|_F<\infty$ if $u(\cdot)$ converges.*
$\|\sum_{k=0}^{\infty}\mathcal{L}_{AP}(X(k))\|_F<\infty$ if condition (ii) *in Theorem* 12 *holds.*

Proof. From Proposition 11 (v), we obtain

$$
(11)\qquad \left\|\sum_{k=0}^{\infty}\mathcal{L}_B(U(k))\right\|_F\le\sum_{k=0}^{\infty}\|\mathcal{L}_B(U(k))\|_F\le\|B\|_{\infty}^2\sum_{k=0}^{\infty}\|U(k)\|_F<\infty.
$$

For the second assertion, we employ Proposition 11 (i), (v), to evaluate

$$
\begin{aligned}
(12)\qquad \left\|\sum_{k=0}^{\infty}\mathcal{L}_{AP}(X(k))\right\|_F&\le\sum_{k=0}^{\infty}\|\mathcal{L}_{AP}(X(k))\|_F=\sum_{k=0}^{\infty}\|\mathcal{L}_A(PX(k)P')\|_F\\
&\le||A||_{\infty}\sum_{k=0}^{\infty}\|PX(k)P'\|_F.
\end{aligned}
$$

Since from the assumption $x(\cdot)$ converges to $\mathcal{S}$, we have that $\sum_{k=0}^{\infty}\|PX(k)P'\|_F<\infty$ from Lemma 8 and the result follows. □

Proof of sufficiency of Theorem 12 continued. Lemma 13 provides, under the assumptions of the theorem, that Υ is well defined, and from (9) and (10) we obtain

$$
(13)\qquad \sum_{k=0}^{\infty}\|Z(k)\|_F=\sum_{k=0}^{\infty}\langle\hat{\mathcal{L}}^k(X(0)+\Upsilon), I\rangle,
$$

and recalling that $r_\sigma(\hat{\mathcal{L}})<1$, we have that

$$
(14)\qquad \sum_{k=0}^{\infty}\|Z(k)\|_F<\infty.
$$

Now we show by induction that

$$X(k) \leq Z(k) \; \forall k \geq 0. \tag{15}$$

For $k = 0$ we defined $Z(0) = X(0)$; assuming $X(k) \leq Z(k)$ one can check employing Lemma 10 and Proposition 11 (iii), (iv), that

$$\begin{aligned} X(k+1) &\leq (1+\alpha^2)\mathcal{L}_{A+AP-AP}(X(k)) + (1+1/\alpha^2)\mathcal{L}_B(U(k)) \\ &\leq (1+\alpha^2)^2\mathcal{L}_{A-AP}(X(k)) + (1+\alpha^2)(1+1/\alpha^2)\mathcal{L}_{AP}(X(k)) \\ &\qquad + (1+1/\alpha^2)\mathcal{L}_B(U(k)) \\ &= \hat{\mathcal{L}}(X(k)) + \tilde{\mathcal{L}}(X(k)) + \bar{\mathcal{L}}(U(k)) \\ &\leq \hat{\mathcal{L}}(Z(k)) + \tilde{\mathcal{L}}(X(k)) + \bar{\mathcal{L}}(U(k)) = Z(k+1) \end{aligned}$$

and the induction is complete. From (15) we obtain that for each $k \geq 0$, $Z(k) - X(k) \geq 0$ in such a manner that $Z(k) - X(k) \in \mathcal{H}_F^n$ and $\langle Z(k) - X(k), I \rangle \geq 0$. This leads to $\|Z(k)\|_F \geq \|X(k)\|_F$ and from (14) we obtain

$$\sum_{k=0}^{\infty} ||X(k)||_F \leq \sum_{k=0}^{\infty} ||Z(k)||_F < \infty,$$

and Lemma 8 with trivial $\mathcal{S} = 0$ provides that $x(\cdot)$ converges. □

4.2. The main result. The first result of this section follows in a straightforward manner from Theorem 12 and the definition of detectability. We omit the proof.

LEMMA 14. *System Ψ is detectable if and only if there exists an invariant space $\mathcal{S}$ such that the following conditions hold:*

(i) *$(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$;*

(ii) *$x(\cdot)$ converges to $\mathcal{S}$ provided that $y(\cdot)$ and $u(\cdot)$ converge.*

Notice that, for $\mathcal{S}$ trivial, Lemma 14 becomes a tautology; indeed, item (i) holds trivially and item (ii) reduces to the definition of detectability. The larger the invariant space $\mathcal{S}$ is, the more significant the result will be. Along this line, in this section we introduce the set $\mathcal{F} = \{\mathcal{F}_i, i \in \mathcal{Z}\}$ as

$$\mathcal{F}_i = \{x \in \mathbb{R}^n : \mathcal{Y}_0(x, i) < \infty\} \quad \forall i \in \mathcal{Z} \tag{16}$$

and we show that $\mathcal{F}$ is the largest of such Ψ_0-invariant space.

The first step is to show that $\mathcal{F}$ is indeed a Ψ_0-invariant space. We need the following preliminary result, adapted from [7].

PROPOSITION 15. *For each $t \geq 0$, there exists $H \in \mathcal{H}_F^n$ such that $\mathcal{Y}_0^t(x, i) = x' H_i x$.*

LEMMA 16. *$\mathcal{F}$ is a Ψ_0-invariant space.*

Proof. ($\mathcal{F}_i$ is a vector subspace.) For $x_1, x_2 \in \mathcal{F}_i$ and $\alpha, \beta \in \mathbb{R}$, from Proposition 15 it is simple to check that

$$\begin{aligned} \mathcal{Y}_0^T(\alpha x_1 + \beta x_2, i) &= (\alpha x_1 + \beta x_2)' H_i (\alpha x_1 + \beta x_2) \\ &\leq 2\alpha^2 x_1' H_i x_1 + 2\beta^2 x_2' H_i x_2 \\ &= 2\alpha^2 \mathcal{Y}_0^T(x_1, i) + 2\beta^2 \mathcal{Y}_0^T(x_1, i) \quad \forall T \geq 0. \end{aligned}$$

Taking limits, we obtain

$$\mathcal{Y}_0(\alpha x_1 + \beta x_2, i) \leq 2\alpha^2 \mathcal{Y}_0(x_2, i) + 2\beta^2 \mathcal{Y}_0(x_2, i) < \infty$$

in such a manner that $\alpha x_1 + \beta x_2 \in \mathcal{F}_i$.

($\mathcal{F}$ is invariant.) We set $x_0(k) \in \mathcal{F}_{\theta(k)}$ and assume without loss that $k = 0$. Let us deny the assertion and assume that $x_0(s) \notin \mathcal{F}_{\theta(s)}$ for some $s > 0$, with probability (w.p.) $\epsilon > 0$. In this situation, it is simple to check that

$$\forall \gamma > 0, \exists t_\gamma > 0 : \sum_{k=s}^{s+t_\gamma} \|y_0(k)\|^2 \geq \gamma \quad \text{w.p. } \epsilon. \tag{17}$$

Employing the Tchebychev inequality, we evaluate

$$E\left\{\sum_{k=s}^{s+t_\gamma} \|y_0(k)\|^2\right\} \geq \gamma P\left\{\sum_{k=s}^{s+t_\gamma} \|y_0(k)\|^2 > \gamma\right\} = \gamma\epsilon, \tag{18}$$

and we conclude that $\mathcal{Y}_0(x(0), \theta(0)) \geq \gamma\epsilon$ for all $\gamma > 0$, which is a contradiction in view of the fact that $x_0(0) \in \mathcal{F}_{\theta(0)}$. □

Next we show that $\mathcal{F}$ is the largest Ψ_0-invariant space that possibly meets the condition (i) in Lemma 14.

LEMMA 17. *If $\mathcal{S}$ is such that $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$, then $\mathcal{S} \subset \mathcal{F}$.*

Proof. Let us deny the assertion of the lemma and assume that there exists $i \in \mathcal{Z}$ for which $\mathcal{F}_i \subset \mathcal{S}_i$ strictly. We have that there exists $x \in \mathcal{S}_i$ with $x \notin \mathcal{F}_i$ and from the definition of $\mathcal{F}$ we conclude that $\mathcal{Y}_0(x, i) = \infty$, which provides that the associated output does not converge. Then, $(A, \mathbb{P})$ is not ℓ_2-stable in $\mathcal{S}$. □

Lemmas 14 and 17 allow us to derive the main result of the paper.

THEOREM 18. *System Ψ is detectable if and only if the following conditions hold:*

(A1) *$(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{F}$;*

(A2) *$x(\cdot)$ converges to $\mathcal{F}$ provided $y(\cdot)$ and $u(\cdot)$ converge.*

Proof. (Sufficiency.) (A1) and (A2) satisfy the conditions for detectability in Lemma 14.

(Necessity.) Since $(A, C, \mathbb{P})$ is detectable, from Lemma 14 we have that there exists $\mathcal{S}$ for which $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{S}$ and Lemma 17 provides that $\mathcal{S} \subset \mathcal{F}$. Lemma 14 also yields that $x(\cdot)$ converges to $\mathcal{S}$ provided $y(\cdot)$ and $u(\cdot)$ converges; this fact together with the fact that $\mathcal{S} \subset \mathcal{F}$ lead immediately to (A2).

Now, notice from the concept of detectability that, in particular for the autonomous system Ψ_0, $x_0(\cdot)$ converges whenever the corresponding output $y(\cdot)$ converges or, equivalently, whenever $x(0) \in \mathcal{F}_{\theta(0)}$. This means that $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{F}$ and (A1) holds. □

5. Sufficient conditions for (A1) and (A2). In this section we deal with other detectability and observability concepts that appear in the literature of MJLS and we present the role that they play as sufficient conditions (expressed entirely in terms of the autonomous version of the system) for (A1) and (A2), and therefore for the detectability concept here.

Initially, we introduce a concept of uniform observability related to the Ψ_0-invariant space $\mathcal{S}$. From (7), recall that we set $\mathcal{Y}_0^T(x, \theta) = E\{\sum_{k=0}^{T-1} |y_0(k)|^2\}$, where $y_0(\cdot)$ denotes the output trajectory of the autonomous system Ψ_0 with $x_0(0) = x$.

DEFINITION 19 (uniform observability w.r.t. $\mathcal{S}$). *Consider the autonomous system Ψ_0. We say that $(A, C, \mathbb{P})$ is uniformly observable with respect to (w.r.t.) $\mathcal{S}$ if*

there exists $T, \epsilon > 0$ *such that* $\mathcal{Y}_0^T(x,\theta) \geq \epsilon\|x\|^2$ *whenever* $x \in \mathcal{S}_\theta^\perp$. *We say that* $(A, C, \mathbb{P})$ *is uniformly observable if it is uniformly observable w.r.t.* 0.

A particular case of this concept with trivial $\mathcal{S}$ appears in [1, 3, 5, 12], and it generalizes previous observability concepts for MJLS, like the ones appearing in [11].

In Lemma 22 in what follows, we show that uniform observability is a sufficient condition for the state convergence to $\mathcal{S}$ and, in particular, for (A2) to hold when $\mathcal{S} \subset \mathcal{F}$. For the proof, we need the next two lemmas; their proofs are presented in Appendix 9. Recall that P_i denotes the orthogonal projection onto $\mathcal{S}_i^\perp$, $i \in \mathcal{Z}$.

LEMMA 20. *If* $(A, C, \mathbb{P})$ *is uniformly observable w.r.t.* $\mathcal{S}$, *then there exist* $T, \epsilon > 0$ *such that* $\mathcal{Y}_0^T(x,\theta) \geq \epsilon|P_\theta x|^2$ *for each* $x \in \mathbb{R}^n$ *and* $\theta \in \mathcal{Z}$.

LEMMA 21. *There exist* $\delta_1, \delta_2 > 0$ *for which*

$$\mathcal{Y}_u^{t,T}(x,\theta) \geq \delta_1 E\{\mathcal{Y}_0^T(x(t),\theta(t))\} - \delta_2 \sum_{k=t}^{T+t-1} E\{|u(k)|^2\} \; \forall x \in \mathbb{R}^n \text{ and } \theta \in \mathcal{Z}.$$

LEMMA 22. *If* $(A, C, \mathbb{P})$ *is uniformly observable w.r.t.* $\mathcal{S}$, *then* $x(\cdot)$ *converges to* $\mathcal{S}$ *provided that* $y(\cdot)$ *and* $u(\cdot)$ *converge. In addition, if* $\mathcal{S} \subset \mathcal{F}$, *then* (A2) *holds.*

Proof. Provided that $u(\cdot)$ and the output $y(\cdot)$ converge, i.e., $E[\sum_{k=0}^\infty \|u(k)\|^2] < \infty$ and $\mathcal{Y}_u(x,\theta) < \infty$, respectively, we show that $(A, C, \mathbb{P})$ uniformly observable w.r.t. $\mathcal{S}$ suffices for convergence of the state to $\mathcal{S}$, namely, $E[\sum_{k=0}^\infty \|P_{\theta(k)}x(k)\|^2] < \infty$. For each $t \geq 0$, we employ Lemmas 20 and 21 to evaluate

$$\begin{aligned}(19)\quad \mathcal{Y}_u(x,\theta) \geq \mathcal{Y}_u^{t,\infty}(x,\theta) &= \sum_{k=0}^\infty \mathcal{Y}_u^{t+kT,T}(x,\theta) \\ &\geq \sum_{k=0}^\infty \left(\delta_1 E\{\mathcal{Y}_0^T(x(t+kT),\theta(t+kT))\} - \delta_2 \sum_{\ell=t+kT}^{t+(k+1)T-1} E\{|u(k)|^2\} \right) \\ &\geq \delta_1 \epsilon \sum_{k=0}^\infty E\{|P_{\theta(t+kT)}x(t+kT)|^2\} - \delta_2 \sum_{k=0}^\infty E\{|u(k)|^2\}.\end{aligned}$$

Summing (19) for $t = 0, \ldots, T-1$, we obtain

$$T\mathcal{Y}_u(x,\theta) \geq \delta_1 \epsilon \sum_{m=0}^\infty E\{|P_{\theta(m)}x(m)|^2\} - T\delta_2 \sum_{k=0}^\infty E\{|u(k)|^2\},$$

which leads to

$$\sum_{m=0}^\infty E\{|P_{\theta(m)}x(m)|^2\} \leq \frac{T}{\delta_1\epsilon}\mathcal{Y}_u(x,\theta) + \frac{T\delta_2}{\delta_1\epsilon}\sum_{k=0}^\infty E\{|u(k)|^2\} < \infty$$

and the first assertion is proven.

Now, from Definition 19 we obtain that if $(A, C, \mathbb{P})$ is uniformly observable w.r.t. $\mathcal{S} \subset \mathcal{F}$, then it is uniformly observable w.r.t. $\mathcal{F}$. The result then follows immediately from the first assertion. ∎

Notice from Lemma 22 with trivial $\mathcal{S}$ that, if $(A, C, \mathbb{P})$ is uniformly observable, then $x(\cdot)$ converges to $\mathcal{S} = 0$, provided $y(\cdot)$ and $u(\cdot)$ converges, i.e., $(A, C, \mathbb{P})$ is detectable, which implies the following corollary.

COROLLARY 23. *If* $(A, C, \mathbb{P})$ *is uniformly observable, then* Ψ *is detectable.*

Next, we are concerned with an earlier ℓ_2-detectability sense; see [7] in a setting similar to the one of this paper, or [8] in the continuous time case, or [6] and [12] in the finite dimensional case.

DEFINITION 24 (ℓ_2-detectability). *Consider the autonomous system Ψ_0. We say that $(A, C, \mathbb{P})$ is ℓ_2-detectable if there exists $L \in \mathcal{H}_\infty^{q,n}$ for which $(A + LC, \mathbb{P})$ is ℓ_2-stable.*

LEMMA 25. *If $(A, C, \mathbb{P})$ is ℓ_2-detectable, then system Ψ is detectable.*

Proof. We assume that $(A, C, \mathbb{P})$ is ℓ_2-detectable and $y(\cdot)$ and $u(\cdot)$ converge, and we show that $x(\cdot)$ converges in a similar manner to the proof of sufficiency of Theorem 12. Here we only point out the differences. For $L \in \mathcal{H}_\infty^{q,n}$ as in the ℓ_2-detectability definition, $r_\sigma(\mathcal{L}_{A+LC}) < 1$, see Proposition 9 (ii) in connection. We chose $\alpha \neq 0$ in such a way that $(1+\alpha^2)^2 r_\sigma(\mathcal{L}_{A+LC}) < 1$ holds. The operators $\hat{\mathcal{L}}, \tilde{\mathcal{L}}, \bar{\mathcal{L}} : \mathcal{H}_F^n \to \mathcal{H}_F^n$ are defined as

$$\begin{aligned}
\hat{\mathcal{L}}(H) &= (1+\alpha^2)^2 \mathcal{L}_{A+LC}(H), \\
\tilde{\mathcal{L}}(H) &= (1+\alpha^2)(1+1/\alpha^2)\mathcal{L}_{LC}(H) \text{ and} \\
\bar{\mathcal{L}}(H) &= (1+1/\alpha^2)\mathcal{L}_B(H) \quad \text{for } H \in \mathcal{H}_F^n.
\end{aligned}$$

In parallel with Lemma 13, we also need to show that $\sum_{k=0}^\infty \mathcal{L}_{LC}(X(k)) < \infty$. In fact, since $y(\cdot)$ converges for the autonomous system $(A+LC, \mathbb{P})$, we get that $\mathcal{Y}_0(x, \theta) < \infty$ and from (7) we evaluate

$$\infty > \mathcal{Y}_0(x,\theta) \geq \sum_{k=0}^\infty \langle X(k), C'C \rangle = \sum_{k=0}^\infty \|C'X(k)C\|_F$$

and employ Proposition 11 (i), (v), to obtain

$$\begin{aligned}
(20) \qquad \left\| \sum_{k=0}^\infty \mathcal{L}_{LC}(X(k)) \right\|_F &\leq \sum_{k=0}^\infty \|\mathcal{L}_{LC}(X(k))\|_F = \sum_{k=0}^\infty \|\mathcal{L}_L(CX(k)C')\|_F \\
&\leq ||L||_\infty \sum_{k=0}^\infty \|CX(k)C'\|_F < \infty. \qquad \square
\end{aligned}$$

Remark 1. In [7] it is shown that ℓ_2-detectability (together with ℓ_2-stabilizability) ensures that the optimal linear state feedback control that arises in the JLQ problem is ℓ_2-stabilizing, considering an additional assumption on matrices D_i as in Lemma 35. Lemma 25 generalizes this result in the sense that $x(\cdot)$ converges provided that the output and input converge; here, neither optimality nor linear state feedback is required.

The next concept is named W_S-detectability, and it was introduced in [5] as an attempt to deal with detectability in the present context. It can be seen as a particularization of detectability with $u \equiv 0$.

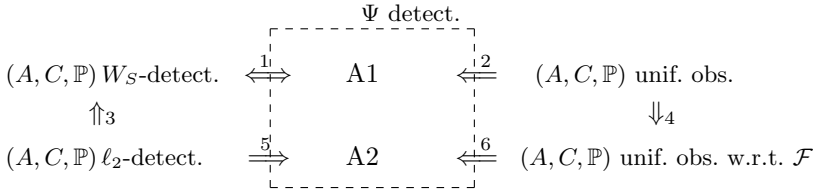
DEFINITION 26 (W_S-detectability). *Consider the autonomous system Ψ_0. We say that $(A, C, \mathbb{P})$ is W_S-detectable provided that $x_0(\cdot)$ converges whenever the output $y_0(\cdot)$ converges.*

It follows directly from the definitions that the concept is equivalent to ℓ_2-stability in $\mathcal{F}$.

PROPOSITION 27. *$(A, C, \mathbb{P})$ is W_S-detectable if and only if $(A, \mathbb{P})$ is ℓ_2-stable in $\mathcal{F}$ ((A1) holds).*

We finish with a summary of the main results of this section. For ease of reference, the relations are numbered. The relation (1) follows from Proposition 27, (2) follows from Corollary 23 and Theorem 18, (3) and (5) follows from Lemma 25, (4) follows immediately from definition, and (6) follows from Lemma 22.

PROPOSITION 28. *The following relations hold:*



Remark 2. In principle the detectability concept depends on the nonautonomous system (made explicit by assumption (A2)). However, for systems that are ℓ_2-detectable, uniformly observable, or uniformly observable w.r.t. $\mathcal{F}$, (A2) always holds true, as indicated in Proposition 28. In section 6 we show that this is also the situation for MJLS with finite Markov state.

6. Finite MJLS. Recall from the main result of the paper, Theorem 18, that the system is detectable if and only if (A1) and (A2) hold. In this section, we show that (A2) is made redundant when the Markov state space is finite, $\mathcal{Z} = \{1, \dots, N\}$. This leads to the main result of the section: (A1) is a necessary and sufficient condition for detectability, in parallel with detectability notions for linear deterministic systems and previous concepts for MJLS [2]. The result here also generalizes previous results in the literature, which require that the control is in the linear state feedback form.

We start showing that uniform observability w.r.t. $\mathcal{S}$ always holds with $\mathcal{S} = \mathcal{N}$, where the set $\mathcal{N} = \{\mathcal{N}_i, i \in \mathcal{Z}\}$ is defined as

$$\mathcal{N}_i = \{x \in \mathbb{R}^n : \mathcal{Y}_0(x, i) = 0\}, \quad i \in \mathcal{Z}. \tag{21}$$

Notice by inspection of (16) and (21) that $x \in \mathcal{F}_\rangle$ whenever $x \in \mathcal{N}_\rangle$, thus yielding that $\mathcal{N} \subset \mathcal{F}$. One can also check that $\mathcal{N}$ is an invariant space, in a similar manner to the proof of Lemma 16. We state this property formally.

PROPOSITION 29. *$\mathcal{N}$ is an invariant space, $\mathcal{N} \subset \mathcal{F}$.*

The preliminary results of Proposition 30 and Lemma 31 in what follows will be needed. First, let us generalize the definition of the cost functional $\mathcal{Y}_0$, as follows. Suppose that the initial conditions (x, θ) are random variables with x a second order random variable. In this situation, we set $X(0) \in \mathcal{H}_F^n$ such that $X_i(0) = E\{xx' 1_{\{\theta=i\}}\}$. Conversely, given any $X \in \mathcal{H}_F^n$, there exists a second order r.v. x and some distribution for θ in such a way that we can represent $X_i = E\{xx' 1_{\{\theta=i\}}\}$. These considerations allow us to generalize the definition of $\mathcal{Y}_0$ by writing, for each $X \in \mathcal{H}_F^n$,

$$\mathcal{Y}_0^T(X) = \sum_{k=0}^{T-1} \langle X_0(k), C'C \rangle \tag{22}$$

whenever $X(0) = X$. Notice that $\mathcal{Y}_0^T(x, \theta) = \mathcal{Y}_0^T(X)$ whenever X is defined as above with $X_\theta = xx'$ and $X_i = 0$, $i \neq \theta$.

The next preliminary result is adapted from [3, Prop. 1].

PROPOSITION 30. *Assume that $\mathcal{Z} = \{1, \dots, N\}$. If $\mathcal{Y}_0^{n^2 N}(X) = 0$, then $\mathcal{Y}_0^t(X) = 0$ for all $t \geq 0$.*

LEMMA 31. *Let P be the projection onto $\mathcal{N}^\perp$. The following assertions hold:*

(i) $\mathcal{Y}_0(X) = 0$ *if and only if* $P'XP = 0$*;*

(ii) $(A, C, \mathbb{P})$ *is uniformly observable w.r.t.* $\mathcal{N}$ *if there exists* $\epsilon > 0$ *for which* $\mathcal{Y}_0^T(X) \geq \epsilon \|X\|_F$ *whenever* $X - PXP' = 0$.

For the proof of Lemma 31, see Appendix 9.

LEMMA 32. *Assume that* $\mathcal{Z} = \{1, \ldots, N\}$. *Then,* $(A, C, \mathbb{P})$ *is uniformly observable w.r.t.* $\mathcal{N}$.

Proof. Let P be the projection onto $\mathcal{N}^\perp$ and recall that $\bar{\mathcal{N}} = \{H \in \mathcal{H}_F^n : PHP' = 0\}$ and $\bar{\mathcal{N}}^\perp = \{H \in \mathcal{H}_F^n : H - PHP' = 0\}$. Let us show that there exist $\epsilon > 0$ such that $\mathcal{Y}_0^T(X) \geq \epsilon \|X\|_F$ whenever $X \in \bar{\mathcal{N}}^\perp$. Let us deny this assertion and assume that there exists a sequence $X_m \in \mathcal{N}_C$, $m = 1, 2, \ldots$, for which

$$\mathcal{Y}_0^{n^2N}(X_m) \leq m^{-1}, \tag{23}$$

where

$$\mathcal{N}_C = \{X \in \bar{\mathcal{N}}^\perp : \|X\|_F = 1\} \subset \bar{\mathcal{N}}^\perp.$$

For the countably finite case, one can check that $\mathcal{N}_C$ is a compact set and this leads to the fact that there exists a subsequence X_{m_k} that converges to

$$\bar{X} \in \mathcal{N}_C \subset \bar{\mathcal{N}}^\perp. \tag{24}$$

Moreover, it is not difficult to check that $\mathcal{Y}_0^{n^2N}(\cdot)$ is continuous; this fact and (23) allow us to write that $\mathcal{Y}_0^{n^2N}(\bar{X}) = \lim_{k\to\infty} \mathcal{Y}_0^{n^2N}(X_{m_k}) \leq \lim_{k\to\infty} k^{-1} = 0$. Then, Proposition 30 yields that $\mathcal{Y}_0(\bar{X}) = 0$ and from Lemma 31 (i) we conclude that $\bar{X} \in \bar{\mathcal{N}}$, which is a contradiction, in view of (24). We have shown that there exist $\epsilon > 0$ such that $\mathcal{Y}_0^T(X) \geq \epsilon \|X\|_F$ whenever $X \in \bar{\mathcal{N}}^\perp$; Lemma 31 (ii) completes the proof. □

The result of Lemma 32 cannot be extended to the countably infinite case, as we show in the following counterexample. In connection, note that the set $\mathcal{N}_C$ in the proof of Lemma 32 is no longer compact.

Example 1. Let $n = 1$, $p_{i\,i+1} = 1$, $A_i = 1$, $C_i = r^i$, $|r| < 1$. It is simple to check that $\mathcal{Y}_0(x, i) = r^i(1 - r)|x|^2$, in such a manner that for each $\gamma > 0$ there exists i such that $\mathcal{Y}_0(x, i) < \gamma|x|^2$, which implies that $(A, C, \mathbb{P})$ is not uniformly observable w.r.t. $\mathcal{N}$.

The next result follows from Lemmas 22 and 32 and the fact that $\mathcal{N} \subset \mathcal{F}$ (see Proposition 29); the proof is omitted.

LEMMA 33. *Assume that* $\mathcal{Z} = \{1, \ldots, N\}$. *Then,* (A2) *holds.*

The next result is immediate from Lemma 33 and Theorem 18. We state the result in terms of the triplet $(A, C, \mathbb{P})$ to emphasize that the detectability concept depends only on the autonomous version Ψ_0 of the system.

THEOREM 34. *Assume that* $\mathcal{Z} = \{1, \ldots, N\}$. $(A, C, \mathbb{P})$ *is detectable if and only if* (A1) *holds.*

Remark 3. The relation between detectability and other detectability concepts for finite scenarios is discussed here. The weak detectability concept for MJLS with finite Markov state was introduced in [2]. It requires that $x(\cdot)$ converges provided $\mathcal{Y}_0(x, \theta) = 0$. In [5] it was shown that this concept is equivalent to W_S-detectability when reduced to the finite case. Assuming $\mathcal{Z} = \{1, \ldots, N\}$, Proposition 27, Theorem 34, and the aforementioned facts provide the following relations:

$$\text{weak detectability} \Leftrightarrow W_S\text{-detectability} \Leftrightarrow \text{A1} \Leftrightarrow \text{detectability}. \tag{25}$$

For (finite dimensional) linear deterministic systems, it was shown in [2] that the weak detectability concept retrieves the usual detectability concept. Then, from the relations in (25) we conclude that, for linear deterministic systems,

usual detectability concept $\Leftrightarrow$ *detectability.*

7. Detectability and the jump linear quadratic problem. In this section we are concerned with the JLQ problem, which consists of obtaining the control $u(\cdot)$ that minimizes the cost functional $\mathcal{Y}_u(x,\theta)$. We also consider the related infinite coupled algebraic Riccati equations (ICARE).

We assume here with no loss of generality that the control is in linear state feedback form, $u(k) = G_{\theta(k)}x(k)$, $G \in \mathcal{H}_\infty^{r,n}$. Indeed, it is a well-known fact that the optimal control is in this form; see, e.g., [7]. In connection, we denote $\mathcal{Y}_G(\cdot) = \mathcal{Y}_u(\cdot)$ to emphasize the dependence on G.

Also a standard assumption in the JLQ problem, that $\inf_{i\in\mathcal{Z}} \sigma^-(D_i'D_i) = \xi > 0$, is in force here. In this situation, the convergence of the input and the output are directly connected and the condition in (A2) (e.g., in Theorem 18) related to the input is not essential; the following lemma formalizes the result.

LEMMA 35. *If* $\inf_{i\in\mathcal{Z}} \sigma^-(D_i'D_i) = \xi > 0$ *and* $\mathcal{Y}_u(x,\theta) < \infty$, *then* $u(\cdot)$ *converges.*

Proof. Employing (7) and the assumptions in the lemma, we evaluate $\infty > \mathcal{Y}_u(x,\theta) \geq \sum_{k=0}^{\infty}\langle U(k), D'D\rangle \geq \xi \sum_{k=0}^{\infty} \|U(k)\|_F$. □

The next result establishes that a linear state feedback control is stabilizing whenever the associated cost is bounded.

LEMMA 36. *Assume that* $(A, C, \mathbb{P})$ *is detectable. If* $G \in \mathcal{H}_\infty^{r,n}$ *is such that* $\mathcal{Y}_G(x,\theta) < \infty$ $\forall x \in \mathbb{R}^n, \theta \in \mathcal{Z}$, *then* $(A + BG, \mathbb{P})$ *is* ℓ_2*-stable.*

Proof. Consider the system Ψ in closed loop form with $u(k) = G_{\theta(k)}x(k)$,

$$\begin{cases} x(k+1) = (A_{\theta(k)} + B_{\theta(k)}G_{\theta(k)})x(k), \quad k \geq 0, \\ y(k) = (C_{\theta(k)} + D_{\theta(k)}G_{\theta(k)})x(k). \end{cases} \tag{26}$$

For each initial condition $x \in \mathbb{R}^n$ and $\theta \in \mathcal{Z}$ we have from the lemma that $\mathcal{Y}_u(x,\theta) = \mathcal{Y}_G(x,\theta) < \infty$, which means that the associated output $y(\cdot)$ converges; moreover, Lemma 35 provides that $u(\cdot)$ converges. In this situation, detectability yields that $x(\cdot)$ converges, and we conclude that $(A + BG, \mathbb{P})$ is ℓ_2-stable. □

In what follows, we consider the following ICARE in the unknown $R \in \mathcal{H}_F^n$ that arises in the JLQ problem (see, e.g., [7]):

$$0 = \big(A_i + B_iG_i\big)' \sum_{j\in\mathcal{Z}} p_{ij}R_j\big(A_i + B_iG_i\big) + C_i'C_i + G_i'D_i'D_iG_i, \tag{27}$$

$$G_i = -\left(D_i'D_i + B_i' \sum_{j\in\mathcal{Z}} p_{ij}R_jB_i\right)^{-1} B_i' \sum_{j\in\mathcal{Z}} p_{ij}R_jA_i, \quad i \in \mathcal{Z}. \tag{28}$$

The following results are adapted from [7].

PROPOSITION 37. *Assume that* $R \in \mathcal{H}_F^n$ *satisfies the ICARE* (27)–(28). *The following assertions hold:*

(i) $\mathcal{Y}_G(x,\theta) \leq x'R_\theta x$;

(ii) *If* $(A+BG, \mathbb{P})$ *is* ℓ_2*-stable, then* $R \in \mathcal{H}_\infty^n$ *is the unique solution of the ICARE. Moreover, the solution of the JLQ problem is* $u(k) = G_{\theta(k)}x(k)$, *where* G *is given by* (28).

THEOREM 38. *Assume that* $(A, C, \mathbb{P})$ *is detectable according to Definition* 1. *Then, the ICARE has at most one solution. Moreover, if* $R \in \mathcal{H}_F^n$ *is the solution of the ICARE, then* $(A + BG, \mathbb{P})$ *is* ℓ_2*-stable with the optimal control* (28).

Proof. Let $R \in \mathcal{H}_F^n$ be a solution of the ICARE. From Proposition 37 (i) we have that $\mathcal{Y}_G(x, \theta) \leq x' R_\theta x$, for each x, θ, and Lemma 36 provides that $(A + BG, \mathbb{P})$ is ℓ_2-stable. Hence, Proposition 37 (ii) yields that R is the unique solution of the ICARE and the optimal control is given by (28). □

Remark 4. The results in this section generalize previous result in [7] from the fact that detectability here generalizes the ℓ_2-detectability notion employed there; see Lemma 25.

8. Examples. We start this section with an example showing that (A2) does not necessarily hold for MJLS with infinite countably Markov chain. Then Example 3 shows that the detectability notion according to Definition 1 depends on the collections of matrices B and D, and thus it cannot be related to the autonomous version Ψ_0 only.

We also show, via Example 4, that the detectability concept here generalizes the earlier ℓ_2-detectability and uniform observability concepts, in the sense that the converse relations of Proposition 28 involving those concepts does not hold.

Example 2. This example illustrates that (A2) does not necessarily hold true for MJLS with infinite countably Markov chain. Indeed, we present a system for which the state trajectory does not converge to $\mathcal{F}$ under converging input and output.

Assume that $p_{i\,i+1} = 1$, $i \in \mathcal{Z}$, in such a manner that $\theta(k) = k + i$ a.s. whenever $\theta(0) = i$. Let $n = 1$, $A_i = B_i = 1$, $D_i = 0$, $i \in \mathcal{Z}$. As regards to $C \in \mathcal{H}_F^1$, we set $C_1 = 0$ and $C_i = (i-1)^{-1/2}$, $i \geq 2$, in order to get that $C_{\theta(k)} = (k+i-1)^{-1/2}$, $k \geq 1$.

It is simple to check for the autonomous system that $\mathcal{Y}_0(x, \theta) = \sum_{k=0}^{\infty} x^2/(k + i - 1)$, which converges if and only if $x = 0$, thus leading to

$$\mathcal{F} = 0.$$

Now, for simplicity, we consider fixed initial conditions $x = 1$ and $\theta = 1$. Consider the control given by $u(0) = 0$ and $u(k) = (k+1)^{-1/2} - k^{-1/2}$, $k \geq 1$. We get that $x(k) = k^{-1/2}$, $k \geq 1$ is the corresponding trajectory. It is a simple matter to check that (see [16, Chap. 2.6])

$$E_{x,\theta}\left\{\sum_{k=0}^{\infty} |u(k)|^2\right\} = \sum_{k=1}^{\infty} \frac{(k^{1/2} - (k+1)^{1/2})^2}{k(k+1)} \leq \sum_{k=1}^{\infty} \frac{1}{k(k+1)} = 1, \tag{29}$$

and we have that the input converges. As regards to the output, we first evaluate

$$E\left\{\sum_{k=0}^{\infty} x(k)' C'_{\theta(k)} C_{\theta(k)} x(k) | x = \theta = 1\right\} = \sum_{k=1}^{\infty} \frac{1}{k^{4\times 1/2}} = \sum_{k=1}^{\infty} \frac{1}{k^2} \leq \sum_{k=0}^{\infty} \frac{1}{2^k} \leq 2,$$

where, in the last inequality, we employed the evaluation in [16, Chap. 3.1]). Together with (29), they provide that

$$\mathcal{Y}(1, 1) \leq 3,$$

which means that the output converges. However, we can also write that

$$E_{x,\theta}\left\{\sum_{k=0}^{\infty} |x(k)|^2\right\} = \sum_{k=0}^{\infty} \frac{1}{k} = \infty,$$

and the state does not converge to the trivial $\mathcal{F}$. Thus, (A2) does not hold and the system is not detectable. It is also interesting to mention that from Proposition 29 we have that $\mathcal{N} = 0$ and, thus, the example also illustrates that the state trajectory does not converge to the nonobserved space, despite the fact that both input and output converge.

Example 3. In the system of Example 2, let $B_i = 0$, $i \in \mathcal{Z}$. In this case, $\mathcal{Y}(x,i) = \mathcal{Y}_0(x,i) = \sum_{k=0}^{\infty} x^2/(k+i-1)$, and the output converges if and only if $x(0) = x = 0$. Then, the system is trivially detectable in the sense of Definition 1. On the other hand, recall that the system in Example 2 is not detectable. This makes clear the dependence of the detectability concept on $B \in \mathcal{H}^{n,r}$ and $D \in \mathcal{H}^{q,r}$ and not only on the parameters of the autonomous system, which shows that the class of systems studied here share with general nonlinear systems the characteristic that observability and detectability in general depends on features of the input class.

Example 4. Consider the following version of the JLQ problem of section 7:

$$\min_u \mathcal{Y}_u^{k_0}(x,\theta), \quad \text{where } \mathcal{Y}_u^{k_0}(x,\theta) = E\left\{\sum_{k=0}^{k_0} |y(k)|^2\right\}, \tag{30}$$

y is the output of system Ψ defined in (1) and k_0 is a $\mathfrak{F}_k$-stopping time defined as the time that the Markov chain $\Gamma = \{\gamma(k), k \geq 0\}$ taking values on the set $\{n, f\}$ first enters the state f, i.e., $k_0 = \inf\{k : \gamma(k) = f\}$. We assume that the transition probabilities are given by $q_{nn} \geq 0$, $0 \leq q_{nf} \leq \nu < 1$ and $q_{ff} = 1$ (f is a cemetery state).

A possible physical interpretation is that the cemetery state f represents a critical failure of the system, which forces the system to stop for maintenance at time k_0; n and f stand for *normal* and *failure,* respectively.

We start showing that the problem (30) can be cast as the JLQ problem for the MJLS defined as

$$\bar{\Psi}: \begin{cases} \bar{\theta} \text{ takes values on } \bar{\mathcal{Z}} = \{(f), (1,n), (2,n), \dots\}; \\ \bar{\mathbb{P}}: \ \bar{p}_{ff} = q_{ff} = 1, \ \bar{p}_{(i,n)(j,n)} = (1-q_{nf})p_{ij}, \ \bar{p}_{(i,n)f} = q_{nf}; \\ \text{system matrices: } \bar{A}_f = 0, \ \bar{A}_{(i,n)} = A_i, \ i \neq f, \text{ and similarly for } \bar{B}, \bar{C}, \bar{D}; \\ \text{initial conditions: } \begin{array}{l} x(0) = x; \\ \bar{\theta}(0) = f \text{ if } \gamma(0) = f; \ \bar{\theta}(0) = (\theta(0), n) \text{ otherwise.} \end{array} \end{cases} \tag{31}$$

LEMMA 39. *The problem* (30) *is equivalent to the JLQ problem for system* $\bar{\Psi}$.

Proof. Let us define the $\mathfrak{F}_k$-stopping time $t_0 = \inf\{k : \bar{\theta}(k) = f\}$. It is a simple matter to check that the random variables t_0 and k_0 have the same statistics and similarly for the variables of system Ψ and $\bar{\Psi}$ for $k \leq t_0$ (e.g., $y(k)$ and $\bar{y}(k)$ are statistically identical for $k \leq t_0$). Let $\bar{Y}_u(\cdot)$ represent the cost functional in (2) associated with system $\bar{\Psi}$. Then, we can write

$$\begin{aligned} \bar{Y}_u(x,\theta) &= \sum_{k=0}^{\infty} E\{|\bar{y}(k)|^2 1_{\{k \leq t_0\}}\} + \sum_{k=0}^{\infty} E\{|\bar{y}(k)|^2 1_{\{k > t_0\}}\} \\ &= \sum_{k=0}^{\infty} E\{|\bar{y}(k)|^2 1_{\{k \leq t_0\}}\} = \sum_{k=0}^{\infty} E\{|y(k)|^2 1_{\{k \leq k_0\}}\} = \mathcal{Y}_u^{k_0}(x,\theta). \end{aligned} \tag{32}$$

∎

The next lemma establishes that system $(\bar{A}, \bar{C}, \bar{\mathbb{P}})$ is a counterexample for the converse of Corollary 23; namely, it shows that the uniformly observable systems

form a strictly subset of the set of detectable systems. The proof is presented in Appendix 9.

LEMMA 40. *If* $(A, C, \mathbb{P})$ *is uniformly observable, then system* $\bar{\Psi}$ *is detectable.* $(\bar{A}, \bar{C}, \bar{\mathbb{P}})$ *is not uniformly observable.*

Example 5. Let us consider systems that present Markov chains with distinct communicating classes $\mathcal{Z}_j = \{i_{n_{j-1}}, \ldots, i_{n_j}\}$, $n_0 = 1$, $j = 1, \ldots, N$, for which $P\{\theta(k+1) \in \mathcal{Z}_j | \theta(k) \in \mathcal{Z}_i\} = 0$ for all $i \neq j$. Let us denote such a system by Ψ_c; we also denote $A^j = (A_i)$, $i \in \mathcal{Z}_j$ and similarly for C^j and $\mathbb{P}^j$. We refer to the system associated with a class $\mathcal{Z}_j$ as a subsystem $(A^j, C^j, \mathbb{P}^j)$.

The following result is adapted from [5].

PROPOSITION 41. *Consider system* Ψ_c. *Assumption* (A1) *holds for* $(A, C, \mathbb{P})$ *if and only if* (A1) *holds for each subsystem* $(A^j, C^j, \mathbb{P}^j)$, $j = 1, \ldots, N$.

Let us construct in this example a system Ψ_c composed of one uniformly observable subsystem plus one finite dimensional subsystem, composed by the two classes $\mathcal{Z}_1 = \{1, 2\}$ and $\mathcal{Z}_2 = \{3, 4, \ldots\}$, and probability matrix

$$\mathbb{P} = \begin{bmatrix} p_{11} & (1-p_{11}) & 0 & \ldots & \\ (1-p_{22}) & p_{22} & 0 & \ldots & \\ 0 & 0 & p_{33} & p_{34} & \ldots \\ \vdots & \vdots & p_{43} & p_{44} & \ldots \\ & & \vdots & \vdots & \end{bmatrix},$$

and data $A_1 = a_1$, $A_2 = a_2$, $C_1 = 1$, $C_2 = 0$, $p_{11} > 0$, and $p_{22}a_2^2 > 1$. We assume that $(A^2, C^2, \mathbb{P}^2)$ is uniformly observable.

It is shown in [1] that $(A^1, C^1, \mathbb{P}^1)$ is uniformly observable. Since uniform observability implies (A1) (see Proposition 28), we have that (A1) holds for both $(A^1, C^1, \mathbb{P}^1)$ and $(A^2, C^2, \mathbb{P}^2)$ and Proposition 41 yields that (A1) holds for the overall system Ψ_c.

Uniform observability also implies uniform observability w.r.t. $\mathcal{F}$ for each subsystem (see Proposition 28), and it is simple to check that the overall system is uniformly observable w.r.t. $\mathcal{F}$. In this situation, Proposition 28 yields that (A2) holds for the overall system.

Then, Theorem 18 implies that system Ψ_c is detectable. However, for this simple example, it was shown in [5] that the overall system is not ℓ_2-detectable. This implies that the converse of Lemma 25 does not hold, and we conclude that detectability here generalizes ℓ_2-detectability.

9. Conclusions. This paper deals with detectability for discrete-time Markov jump linear systems with countably infinite Markov state. Beginning with Definition 1, which expresses an idea that at same time is purposeful and captures the abstract notion of detectability, we show that it can be written down in terms of conditions (A1) and (A2). Condition (A1) alone refers to the autonomous systems and its behavior within the invariant space $\mathcal{F}$. It is reminiscent of detectability concepts related with finite dimensional linear systems. Condition (A2) refers to the complete system Ψ and its behavior within set $\mathcal{F}^\perp$. It comes as an essential condition, connected to the fact that the observed part of the autonomous system, represented by $\mathcal{F}^\perp$, may not be uniformly observable, contrary to the finite dimensional case. Example 2 shows that (A2) may fail in the infinite Markov state case. This clarifies that, unlike the finite dimensional contexts, the detectability notion yielding property (i) (stated in section 1) cannot be expressed in terms of the parameters of the autonomous version Ψ_0;

thus, (iii) cannot be completely reproduced. Exceptions are pointed out in Remark 2.

Regarding the issues (I)–(III), note that (I) is accomplished in the sense that we show that $\mathcal{F}$ is the largest Ψ_0 invariant space for which (A1) and (A2) together possibly hold. Along this line, a remarkable feature is that (A2) is weaker than the natural extension of the finite dimensional case, that the trajectories converge to the nonobservable space $\mathcal{N} \subset \mathcal{F}$. In addition, (II) and (III) are accomplished by showing that the notion of detectability generalizes previous notions of ℓ_2-detectability and uniform observability, as well as detectability notions for the finite Markov state case and the usual detectability concept for linear deterministic systems, in their respective scenarios. Moreover, these relations provide a generalization for earlier results concerning stability of trajectories with associated finite cost, in the sense that here we are not constrained to linear feedback form nor optimal control; see Remark 1). A particularization of the results for the JLQ optimal control problem, which was the initial motivation for this work, provides that the JLQ control is stabilizing and the solution to the associated ICARE is unique.

Finally, although the analysis here concludes a circle of ideas toward detectability of MJLS, which has began in [1, 3], we believe that the approach via invariant subspaces proposed here may be useful elsewhere, in contexts such as nonlinear systems or other infinite dimensional systems.

Appendix: Proof of Lemmas 8 and 10.

Proof of Lemma 8. It is simple to check that

$$\begin{aligned} E[|P_{\theta(k)}x(k)|^2] &= tr\{E[P_{\theta(k)}x(k)x(k)'P'_{\theta(k)}]\} \\ &= \sum_{i\in\mathcal{Z}} tr\{P_iE[x(k)x(k)'1_{\{\theta(k)=i\}}]P_i'\} \\ &= \sum_{i\in\mathcal{Z}} tr\{P_iX_i(k)P_i'\} = \|PX(k)P'\|_F, \end{aligned}$$

which provides that $\sum_{k=0}^{\infty} E[|P_{\theta(k)}x(k)|^2] < \infty$ if and only if $\sum_{k=0}^{\infty} \|PX(k)P'\|_F < \infty$. □

Proof of Lemma 10. For any scalar $\alpha \neq 0$, we have that

$$\begin{aligned} X_i(k+1) &= E\{[A_{\theta(k)}x(k) + B_{\theta(k)}u(k)][A_{\theta(k)}x(k) + B_{\theta(k)}u(k)]'1_{\{\theta(k+1)=i\}}\} \\ &\le E\{[(1+\alpha^2)(A_{\theta(k)}x(k)x(k)'A'_{\theta(k)}) \\ &\qquad + (1+1/\alpha^2)(B_{\theta(k)}u(k)u(k)'B'_{\theta(k)})]1_{\{\theta(k+1)=i\}}\} \\ &= \sum_{j\in\mathcal{Z}} E\{[(1+\alpha^2)(A_jx(k)x(k)'A'_j) \\ &\qquad + (1+1/\alpha^2)(B_ju(k)u(k)'B'_j)]1_{\{\theta(k+1)=i,\theta(k)=j\}}\} \\ &= (1+\alpha^2)\sum_{j\in\mathcal{Z}} p_{ji}E\{A_jx(k)x(k)'A'_j1_{\{\theta(k)=j\}}\} \\ &\qquad + (1+1/\alpha^2)\sum_{j\in\mathcal{Z}} p_{ji}E\{B_ju(k)u(k)'B'_j1_{\{\theta(k)=j\}}\} \\ &= (1+\alpha^2)\mathcal{L}_A(X(k)) + (1+1/\alpha^2)\mathcal{L}_B(U(k)), \quad k \ge 0. \end{aligned}$$

□

Appendix: Proofs of Lemmas 20 and 21.

Proof of Lemma 20. Since $P_i x$ is the projection of x onto $\mathcal{S}_i^{\perp}$, we have that $P_i x \in \mathcal{S}_i^{\perp}$ and from the hypothesis of the lemma we have that there exists $T, \epsilon > 0$ such that $\mathcal{Y}_0^T(P_i x, \theta) > \epsilon |P_i x|^2$. Employing this fact and Proposition 15 we evaluate, for $\alpha > 0$,

$$\begin{aligned}\mathcal{Y}_0^T(x,i) &= x'Hx = (x - P_i x + P_i x)'H(x - P_i x + P_i x)\\ &\geq (1-\alpha^2)(x - P_i x)'H(x - P_i x) + (1 - 1/\alpha^2)(P_i x)'H(P_i x)\\ &\geq (1 - 1/\alpha^2)(P_i x)'H(P_i x) = (1 - 1/\alpha^2)\mathcal{Y}_0^T(P_i x, i)\\ &> (1 - 1/\alpha^2)\epsilon |P_i x|^2. \qquad \square\end{aligned}$$

The next results are needed for the proof of Lemma 21.

LEMMA 42. *$E_{x,\theta}\{\mathcal{Y}_0^T(x(t), \theta(t))\} = \mathcal{Y}_0^T(X(t))$.*

Proof. Using (7) we can write that

$$\mathcal{Y}_0^{t,T}(x,\theta) = \sum_{k=t}^{t+T-1} \langle X(k), C'C\rangle = E_{x,\theta}\{\mathcal{Y}_0^T(x(t),\theta(t))\}.$$

However,

$$\sum_{k=t}^{t+T-1} \langle X(k), C'C\rangle = \sum_{\ell=0}^{T-1} \langle \tilde{X}(\ell), C'C\rangle = \mathcal{Y}_0^T(\tilde{X}(0)),$$

where $\tilde{X}_i(\ell) = X_i(t+\ell) = E_{x,\theta}\{x(t+\ell)x(t+\ell)' 1_{\{\theta(t+\ell)=i\}}\}$ for $\ell = 0, \ldots, T-1$, which shows the result. $\square$

LEMMA 43. *Let $V \in \mathcal{H}_\infty^n$. The following inequality holds:*

$$\langle \mathcal{L}_V(X(k)), C'C\rangle \geq (1-\alpha^2)\langle \mathcal{L}_V(\mathcal{L}_A(X(k-1))), C'C\rangle - \kappa \|U(k-1)\|_F \tag{33}$$

for some $0 < \alpha < 1$ and $\kappa > 0$.

Proof. From Lemma 10 we evaluate

$$\begin{aligned}\langle \mathcal{L}_V(X(k)), C'C\rangle \geq{}& (1-\alpha^2)\langle \mathcal{L}_V(\mathcal{L}_A(X(k-1))), C'C\rangle\\ &+ (1 - 1/\alpha^2)\langle \mathcal{L}_V(\mathcal{L}_B(U(k-1)), C'C\rangle\end{aligned} \tag{34}$$

and for the second term on the right-hand side of (34) we employ Proposition 11 (v) to obtain, for $0 < \alpha < 1$,

$$\begin{aligned}&(1 - 1/\alpha^2)\langle \mathcal{L}_V(\mathcal{L}_B(U(k-1))), C'C\rangle\\ &\qquad \geq (1 - 1/\alpha^2)\|C\|_\infty^2 \|V\|_\infty^2 \|B\|_\infty^2 \langle U(k-1), I\rangle\\ &\qquad = -\kappa\langle U(k-1), I\rangle,\end{aligned} \tag{35}$$

where $\kappa = -(1 - 1/\alpha^2)\|C\|_\infty^2 \|V\|_\infty^2 \|B\|_\infty^2 > 0$. The result follows immediately from (34) and (35). $\square$

Proof of Lemma 21. From (33) with $V = I$, we get that

$$\langle X(m), C'C\rangle \geq (1-\alpha^2)\langle \mathcal{L}_A(X(m-1)), C'C\rangle - \kappa \|U(m-1)\|_F. \tag{36}$$

For the first term on the right-hand side of (36), we employ (33) with $V = A$, and we repeat this step recursively for $m = k-1, \dots, t+1$, to obtain

$$\begin{aligned}\langle X(k), C'C\rangle &\geq (1-\alpha^2)^{k-t}\langle \mathcal{L}_A^{k-t}(X(t)), C'C\rangle \\ &\quad - \kappa \sum_{\ell=t}^{k-1} (1-\alpha^2)^{-\ell+k-1}\|U(\ell)\|_F.\end{aligned} \tag{37}$$

Noticing that $(1-\alpha^2)^{k-t} \geq (1-\alpha^2)^T$ for $k-t \leq T$ and $-(1-\alpha^2)^k \geq -1$ for all $k \geq 0$, we get that

$$\langle X(k), C'C\rangle \geq (1-\alpha^2)^T \langle \mathcal{L}_A^{k-t}(X(t)), C'C\rangle - \kappa \sum_{\ell=t}^{k-1} \|U(\ell)\|_F \tag{38}$$

for $t \leq k \leq T+t-1$. Then, from (7) and (38) we evaluate

$$\begin{aligned}\mathcal{Y}_u^{t,T}(x,\theta) &= \sum_{k=t}^{T+t-1} \langle X(k), C'C\rangle + \langle U(k), D'D\rangle \\ &\geq (1-\alpha^2)^T \sum_{k=t}^{T+t-1} \langle \mathcal{L}_A^{k-t}(X(t)), C'C\rangle - \kappa \sum_{k=t}^{T+t-1}\sum_{\ell=t}^{k-1} \|U(\ell)\|_F \\ &\geq (1-\alpha^2)^T \sum_{k=0}^{T-1} \langle \mathcal{L}_A^{k}(X(t)), C'C\rangle - \kappa T \sum_{k=t}^{T+t-1} \|U(k)\|_F\end{aligned}$$

or, equivalently,

$$\mathcal{Y}_u^{t,T}(x,\theta) \geq \delta_1 \mathcal{Y}_0^T(X(t)) - \delta_2 \sum_{k=t}^{T+t-1} \|U(k)\|,$$

where $\delta_1 = (1-\alpha^2)^T$ and $\delta_2 = \kappa T$. Lemma 42 completes the proof. □

Appendix: Proof of Lemma 31. For the proof of Lemma 31, we write X in the following form [14, Them. 7.5.2],

$$X_i = v_i^1 v_i^{1\prime} + \cdots + v_i^{r_i} v_i^{r_i\prime}, \tag{39}$$

where $v_i^m \in \mathbb{R}^n, m = 1, \dots, r$, and $r_i = \operatorname{rank}(X_i) \leq n$, and we write the trajectory $X(k)$ as a linear combination of trajectories $X^{i,m}(k)$ associated with initial condition v_i^m, as follows.

Let $x^{i,m}(0) = v_i^m \in \mathcal{N}(\mathcal{O}_i)$. Let $x^{i,m}(k) \in \mathbb{R}^n$, $m = 1, \dots, r_i$, be given by the difference equation $x^{i,m}(k+1) = A_{\theta(k)} x^{i,m}(k)$, $\theta(0) = i$. Let $X^{i,m}(k) \in \mathcal{H}_F^{n0}$ be the second moment matrix $X_j^{i,m}(k) = E\{x^{i,m}(k)x^{i,m}(k)' 1_{\{\theta(k)=j\}}\}$, $j \in \mathcal{Z}$. Notice that $X_i^{i,m}(0) = v_i^m v_i^{m\prime}$ and $X_j^{i,m}(0) = 0$ for $j \neq i$, and we can write $X_i = \sum_{j\in\mathcal{Z}} \sum_{m=1}^{r_j} X_i^{j,m}(0)$. Then, from the linearity of the operator $\mathcal{L}$ we have that, provided $X(0) = X$,

$$X_{0,i}(k) = \sum_{j\in\mathcal{Z}} \sum_{m=1}^{r_j} X_i^{j,m}(k)$$

which leads to

$$\begin{aligned}\mathcal{Y}_0(X) &= \sum_{k=0}^{\infty}\langle X_0(k), C'C\rangle = \sum_{k=0}^{\infty}\left\langle \sum_{j\in\mathcal{Z}}\sum_{m=1}^{r_j} X^{j,m}(k), C'C\right\rangle \\ &= \sum_{j\in\mathcal{Z}}\sum_{m=1}^{r_j}\sum_{k=0}^{\infty}\langle X^{j,m}(k), C'C\rangle = \sum_{j\in\mathcal{Z}}\sum_{m=1}^{r_j}\mathcal{Y}_0(v_j^m, j). \qquad \square\end{aligned} \tag{40}$$

Proof of Lemma 31. (i) Notice that (39) provides that

$$\begin{aligned}PXP' = 0 &\Leftrightarrow P_i v_i^m v_i^{m\prime} P_i' = 0 \quad \forall i, m \\ &\Leftrightarrow v_i^m \in \mathcal{N}_i \quad \forall i, m \Leftrightarrow \mathcal{Y}_0(v_i^m, i) = 0 \quad \forall i, m.\end{aligned} \tag{41}$$

From (40), $\mathcal{Y}_0(X) = 0$ is equivalent to $\mathcal{Y}_0(v_i^m, i) = 0$, for each i and m, and, from (41), this is equivalent to $PXP' = 0$.

(ii) We shall show that $\mathcal{Y}_0(x, i) \geq \epsilon|x|^2$ whenever $x \in \mathcal{N}_i^{\perp}$. Let $X \in \mathcal{H}_F^n$ be defined as $X_i = xx'$ and $X_j = 0$, $j \neq i$. Since $x \in \mathcal{N}_i^{\perp}$, we have that $P_i x = x$ and it is simple to check that $PXP' = X$ and $X \in \bar{\mathcal{N}}^{\perp}$. Then, from the assumption in the lemma, we obtain $\mathcal{Y}_0(X) \geq \epsilon\|X\|_F$ and it follows that $\mathcal{Y}_0(x, i) = \mathcal{Y}_0(X) \geq \epsilon\|X\|_F = \epsilon|x|^2$. $\square$

Appendix: Proof of Lemma 40.

Proof of Lemma 40. First we show that (A2) holds for $(\bar{A}, \bar{C}, \bar{\mathbb{P}})$. Notice that the requirements in Assumption (A2) hold trivially whenever $\bar{\theta}(0) = f$; indeed, $\bar{x}(k) = 0$, $k > 0$, a.s..

Now consider $\bar{\theta}(0) \neq f$. From the uniform observability of $(A, C, \mathbb{P})$ we have that there exists $T, \epsilon > 0$ for which $\sum_{k=0}^{T-1} E\{|y(k)|^2 | T < k_0\} > \epsilon|x_0|^2$. Then, we define the stopping time $t_0 = \inf\{k : \bar{\theta}(k) = f\}$ and similarly to (32) we evaluate

$$\begin{aligned}\mathcal{Y}_0^T(x, \theta) &\geq \sum_{k=0}^{T-1} E\{|\bar{y}(k)|^2 1_{\{t_0 \geq T\}}\} = \sum_{k=0}^{T-1} E\{|y(k)|^2 1_{\{k_0 \geq T\}}\} \\ &= P\{k_0 \geq T\}\sum_{k=0}^{T-1} E\big\{|y(k)|^2 \big| k_0 \geq T\big\} \geq P\{k_0 \geq T\}\epsilon|x|^2.\end{aligned}$$

Since $q_{\theta f} \leq \nu < 1$, we have that $P\{k_0 \geq T\} > 0$ whenever $\theta(0) = \theta \neq f$ ($\gamma(0) \neq f$). This allows us to write

$$\mathcal{Y}_0^T(x, \theta) \geq \epsilon_2|x|^2, \quad \theta \neq f, \tag{42}$$

where $\epsilon_2 = \epsilon P\big\{k_0 \geq T \big| \theta \neq f\big\} > 0$.

Now we show that (A1) holds for $(\bar{A}, \bar{C}, \bar{\mathbb{P}})$, that is, we show that $\mathcal{Y}_0(x, \theta) = \infty$ provided that $\sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2\} = \infty$. Note that we can assume that $\theta(0) \neq f$, otherwise we have that $\sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2\} = |x|^2 < \infty$. We evaluate, for any $\ell \geq 0$,

$$\begin{aligned}\mathcal{Y}_0(x, \theta) &\geq \sum_{k=\ell}^{\infty} E\{|\bar{y}(k)|^2\} = \sum_{m=0}^{\infty}\sum_{k=mT+\ell}^{(m+1)T+\ell-1} E\{|\bar{y}(k)|^2\} \\ &\geq \sum_{m=0}^{\infty}\sum_{k=mT+\ell}^{(m+1)T+\ell-1} E\{|\bar{y}(k)|^2 1_{\{t_0 > mT+\ell\}}\} \\ &= \sum_{m=0}^{\infty} P(t_0 > mT+\ell)\sum_{k=mT+\ell}^{(m+1)T+\ell-1} E\big\{|\bar{y}(k)|^2 \big| t_0 > mT+\ell\big\},\end{aligned}$$

and since $t_0 > mT+\ell$ implies in particular that $\theta(mT+\ell) \neq f$, we get from (42) that

$$\begin{aligned}\mathcal{Y}_0(x,\theta) &\geq \sum_{m=0}^{\infty} P(t_0 > mT+\ell)\epsilon_2 E\big\{|\bar{x}(mT+\ell)|^2 \big|\, t_0 > mT+\ell\big\} \\ &= \epsilon_2 \sum_{m=0}^{\infty} E\{|\bar{x}(mT+\ell)|^2 1_{\{t_0 > mT+\ell\}}\}.\end{aligned} \tag{43}$$

Summing up (43) for $\ell = 0,\ldots,T-1$, we obtain

$$T\mathcal{Y}_0(x,\theta) \geq \epsilon_2 \sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2 1_{\{t_0>k\}}\}. \tag{44}$$

Now, recalling that $\theta(0) \neq f$, we evaluate

$$\begin{aligned}E\{|\bar{x}(k)|^2 1_{\{t_0>k\}}\} &= P\{t_0 > k\} E\big\{|\bar{x}(k)|^2 \big|\, t_0 > k\big\} \\ &= (1-q_{nf})^k E\big\{|\bar{x}(k)|^2 \big|\, t_0 > k\big\} = (1-q_{nf})^k E\big\{|\bar{x}(k)|^2 \big|\, t_0 = k\big\} \\ &= \frac{(1-q_{nf})}{q_{nf}}(1-q_{nf})^{k-1} q_{nf} E\big\{|\bar{x}(k)|^2 \big|\, t_0 = k\big\} \\ &= \frac{(1-q_{nf})}{q_{nf}} P\{t_0 = k\} E\big\{|\bar{x}(k)|^2 \big|\, t_0 = k\big\} = \frac{(1-q_{nf})}{q_{nf}} E\big\{|\bar{x}(k)|^2 1_{\{t_0=k\}}\big\} \\ &= \epsilon_3 E\{|\bar{x}(k)|^2 1_{\{t_0=k\}}\},\end{aligned} \tag{45}$$

where $\epsilon_3 = (1-q_{nf})/q_{nf}$. Finally, (44), (45), and the fact that $\bar{x}(k) = 0$ a.s. for each $k > t_0$ lead to

$$\begin{aligned}T\mathcal{Y}_0(x,\theta) &\geq \epsilon_2 \sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2 1_{\{t_0>k\}}\} \\ &= \epsilon_2 \frac{\epsilon_3}{1+\epsilon_3} \frac{1+\epsilon_3}{\epsilon_3} \sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2 1_{\{t_0>k\}}\} \\ &= \epsilon_2 \frac{\epsilon_3}{1+\epsilon_3} \left(\sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2 1_{\{t_0>k\}}\} + \sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2 1_{\{t_0=k\}}\} \right) \\ &= \epsilon_2 \frac{\epsilon_3}{1+\epsilon_3} \sum_{k=0}^{\infty} E\{|\bar{x}(k)|^2\} = \infty.\end{aligned}$$

We have shown that (A1) and (A2) holds for $(\bar{A}, \bar{C}, \bar{\mathbb{P}})$; Theorem 18 provides the first assertion in the lemma. For the second assertion, note that $\mathcal{Y}_0(x,\theta) = 0$ whenever $\theta = f$. □

Acknowledgment. The authors would like to express their gratitude to the referees for their suggestions and helpful comments. We are particularly grateful to one of the referees for the comment that we have added to Example 3, besides many others.

SOME RESULTS ON TWO-PERSON ZERO-SUM LINEAR QUADRATIC DIFFERENTIAL GAMES*

PINGJIAN ZHANG†

Abstract. Considered in this paper are the two-person zero-sum linear quadratic differential games. It is shown that the value of the game exists if and only if both the upper and lower values exist. As a consequence, we prove that another necessary and sufficient condition for the existence of the values of the game is the existence of an open loop–open loop saddle point. An example is also given in which the lower value exists but the upper value does not exist.

Key words. differential games, value of games, saddle points, integral equations, optimal controls

AMS subject classifications. 90D05, 90D25, 45B05

DOI. 10.1137/S036301290342560X

1. Introduction.

Since the 1980s, much work has been contributed to linear quadratic differential games due to their essential role in modern robust control and H^∞-optimization design; see, e.g., [1], [3], [7]. In this paper, we consider the two-person, zero-sum linear quadratic differential games on a finite horizon. It is well known that the solvability of the corresponding Riccati differential equations is equivalent to the existence of the H^∞-optimal control [1]. In [2], the relationship between saddle points of the game and the solvability of various Riccati differential equations is studied. It is shown that

(a) if the Riccati differential equation admits a solution, then the game admits a closed loop–closed loop saddle point;
(b) if both the Riccati differential equation and the lower Riccati differential equation (for definitions, see [2]) admit a solution, then the game admits a closed loop–open loop saddle point;
(c) if both the Riccati differential equation and the upper Riccati differential equation (for definitions, see [2]) admit a solution, then the game admits an open loop–closed loop saddle point.

Note that nothing is said about the open loop–open loop saddle point. This paper is to address this issue. Obviously, the existence of open loop–open loop saddle points guarantees the existence of the value of the game; we shall show that this is also necessary. This follows easily from our main result, which states that a necessary and sufficient condition for the existence of the value of the game is that both the lower value and the upper value of the game exist. Examples show that, except for the open loop–open loop saddle point, existence of any other type of saddle point cannot guarantee the existence of the open loop value of the game.

Consider the following dynamic system:

$$\dot{x} = Ax + Bu + Gv \qquad \text{in} \quad [0, T], \tag{1.1}$$

$$x(0) = x_0 \tag{1.2}$$

with quadratic index

$$J(u,v)=\int_0^T (|u|^2-|v|^2+x'Qx)dt+x(T)'Wx(T), \tag{1.3}$$

where $T>0$ is a given final time, and where A,B,G,Q,W are matrices of suitable dimension such that Q and W are symmetric but not necessarily nonnegative. Moreover, without loss of generality, cross terms in (u,v,x) are not present in the quadratic form because they can be eliminated by appropriate transformations. Let

$$v^-(x_0)=\sup_{v\in L^2(0,T;\mathbb{R}^m)}\inf_{u\in L^2(0,T;\mathbb{R}^l)} J(u,v)$$

be the open loop lower value of the game and

$$v^+(x_0)=\inf_{u\in L^2(0,T;\mathbb{R}^l)}\sup_{v\in L^2(0,T;\mathbb{R}^m)} J(u,v)$$

be the open loop upper value of the game. If both $v^-(x_0)$ and $v^+(x_0)$ exist and $v^-(x_0)=v^+(x_0)$, then we say that the open loop value of the game exists and is $v(x_0)=v^-(x_0)=v^+(x_0)$. Hereafter, unless stated otherwise, the value, the lower value, and the upper value of the game mean the open loop value, the open loop lower value, and the open loop upper value of the game, respectively . Obviously, we always have

$$v^-(x_0)\le v^+(x_0).$$

Natural questions are, Do the lower value and the upper value exist? Are they equal to each other if both of them exist? How are they related to the existence of saddle points? In section 3, we discuss an example in which the lower value exists while the upper value does not. We then prove the main theorem of the paper in section 4, using results established on Fredholm integral equations in section 2. Some final remarks are given in section 5.

2. Solution set of Fredholm integral equations. It is convenient to introduce some technical notation that will be used throughout the paper. Let $M^+=BB', M^-=GG', M=M^+-M^-$ define the following linear operators:

$$\begin{aligned}
&L: L^2(0,T;\mathbb{R}^n)\to L^2(0,T;\mathbb{R}^n), && (Lx)(t)=\textstyle\int_0^t e^{A(t-s)}x(s)ds,\\
&\hat{L}: L^2(0,T;\mathbb{R}^n)\to \mathbb{R}^n, && (\hat{L}x)(t)=\textstyle\int_0^T e^{A(T-s)}x(s)ds,\\
&S:\mathbb{R}^n\to L^2(0,T;\mathbb{R}^n), && (Sy)(t)=e^{At}y,\\
&\hat{S}:\mathbb{R}^n\to\mathbb{R}^n, && \hat{S}y=e^{AT}y
\end{aligned}$$

with the adjoint operators given by

$$\begin{aligned}
&L^*: L^2(0,T;\mathbb{R}^n)\to L^2(0,T;\mathbb{R}^n), && (L^*x)(t)=\textstyle\int_t^T e^{A'(s-t)}x(s)ds,\\
&\hat{L}^*:\mathbb{R}^n\to L^2(0,T;\mathbb{R}^n), && (\hat{L}^*y)(t)=e^{A'(T-t)}y,\\
&]2pt]S^*: L^2(0,T;\mathbb{R}^n)\to\mathbb{R}^n, && S^*x=\textstyle\int_0^T e^{A't}x(t)dt,\\
&\hat{S}^*:\mathbb{R}^n\to\mathbb{R}^n, && \hat{S}^*y=e^{A'T}y.
\end{aligned}$$

Moreover, define operators

$$K=L^*QL+\hat{L}^*W\hat{L},\qquad \hat{K}=L^*QS+\hat{L}^*W\hat{S}.$$

Using these operators, the system (1.1)–(1.2) can be rewritten as

$$x = Sx_0 + LBu + LGv$$

with

$$x(T) = \hat{S}x_0 + \hat{L}Bu + \hat{L}Gv$$

and the index (1.3) can be written as a bilinear form in Hilbert space $L^2(0,T;\mathbb{R}^l) \times L^2(0,T;\mathbb{R}^m)$:

$$\begin{aligned} J(u,v) \quad &= ((I + B'KB)u, u) - ((I - G'KG)v, v) + 2(B'KGv, u) \\ &\quad + 2(B'(L^*QS + \hat{L}^*W\hat{S})x_0, u) + 2(G'(L^*QS + \hat{L}^*W\hat{S})x_0, v) \\ &\quad + \langle (S^*QS + \hat{S}^*W\hat{S})x_0, x_0\rangle, \end{aligned}$$

where $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ denote the inner product in L^2 and the Euclidean space, respectively. Therefore, the game problem is converted into the min-max problem of bilinear forms in Hilbert space.

Remark 1. Under coercivity assumptions on $I + B'KB$ and $I - G'KG$, the game problems admits a unique open loop–open loop saddle point which can be constructed explicitly. In this paper, no such coercivity conditions are imposed, and the usual Riccati equation approach cannot be applied.

Remark 2. The problem setting of this paper can be easily generated for the time-varying systems, where the transition matrix $\Phi(t,s)$ replaces $e^{A(t-s)}$ in the operators defined above.

We will first establish some preliminary results.

LEMMA 2.1. *Let $\mathcal{N}(A)$ denote the kernel of operator A, and let $C, D \in \mathcal{L}(X)$ be linear bounded operators on some Hilbert space X. Then $\mathcal{N}(I+CD) = C\mathcal{N}(I+DC)$.*

Proof. Let $(I+CD)x = 0$. Then $x = -CDx$ and $(I+DC)Dx = D(I+CD)x = 0$, that is, $Dx \in \mathcal{N}(I + DC)$, and hence $x = -CDx \in C\mathcal{N}(I + DC)$. Conversely, let $x = Cp$ for some $p \in \mathcal{N}(I+DC)$. Then $(I+CD)x = (I+CD)Cp = C(I+DC)p = 0$, and hence $x \in \mathcal{N}(I + CD)$. □

Consider the Fredholm integral equation with parameter v:

$$(I + KM^+)p = Gv + \hat{K}x_0. \tag{2.1}$$

Let $V(x_0) = \{v \in L^2(0,T;\mathbb{R}^m) : v$ be such that (2.1) has solution.$\}$. If $V(x_0)$ is not empty, then we can pick a $v \in V(x_0)$ and let $P(v,x_0)$ be the solution set of (2.1) corresponding to v. If we choose one $p \in P(v,x_0)$, then $P(v,x_0)$ can be expressed as

$$P(v,x_0) = p + N, \tag{2.2}$$

where $N = \mathcal{N}(I + KM^+)$. The following theorem characterizes the set $V(x_0)$.

THEOREM 2.2. *$V(x_0)$ is given by*

$$V(x_0) = \{v \in L^2(0,T;\mathbb{R}^m) : (v, G'q) + \langle x_0, q(0)\rangle = 0 \ \forall q \in N\}.$$

Proof. Let $q \in N$; then $q = -KM^+q$ and $q(0) = -\hat{K}^*M^+q$ by simple verification. Therefore, by virtue of Lemma 2.1 and the fact that operator K is compact; hence

$I + KM^+$ has closed range. Thus

$$\begin{aligned} & (v, G'q) + \langle x_0, q(0)\rangle = 0 \ \forall q \in N \\ \Leftrightarrow \quad & (v, G'KM^+q) + (\hat{K}x_0, M^+q) = 0 \ \forall q \in N \\ \Leftrightarrow \quad & (KGv + \hat{K}x_0, M^+q) = 0 \ \forall q \in N \\ \Leftrightarrow \quad & KGv + \hat{K}x_0 \perp \mathcal{N}(I + M^+K) \\ \Leftrightarrow \quad & KGv + \hat{K}x_0 \in \mathcal{R}(I + KM^+). \qquad \square \end{aligned}$$

COROLLARY 2.3. *The following statements hold:*

(1) $V(0) = (G'N)^\perp$.

(2) *If $V(x_0)$ is not empty. Then $V(x_0) = v + V(0)$ for arbitrary $v \in V(x_0)$.*

THEOREM 2.4. *Suppose $V(x_0)$ is not empty. Then for every $v \in V(x_0)$, $G'P(v, x_0) \cap V(x_0)$ contains exactly one element.*

Proof. Fix $v \in V(x_0)$. Then $G'P(v, x_0) = G'p + G'N$ for some $p \in N$. Let $\mathbf{P}_{G'N}$ and $\mathbf{P}_{(G'N)^\perp}$ be projections onto $G'N$ and $(G'N)^\perp$, respectively. Decompose $v = v_1 + v_2$ with $v_1 = \mathbf{P}_{G'N}v, v_2 = \mathbf{P}_{(G'N)^\perp}v$, and $G'p = q_1 + q_2$ with $q_1 = \mathbf{P}_{G'N}G'p, q_2 = \mathbf{P}_{(G'N)^\perp}G'p$. Then, since $q_2 \in (G'N)^\perp$, $v_1 + q_2 \in V(x_0)$ by Corollary 2.3. Moreover, since $q_2 = G'p - q_1 \in G'p + G'N$ and $v_1 \in G'N$, $v_1 + q_2 \in G'p + G'N = G'P(v, x_0)$. Thus, we have verified that

$$\mathbf{P}_{G'N}v + \mathbf{P}_{(G'N)^\perp}G'p = v_1 + q_2 \in G'P(v, x_0) \cap V(x_0).$$

To prove the uniqueness, let $u_1, u_2 \in G'P(v, x_0) \cap V(x_0)$. Then $u_1 - u_2 \in G'N$; on the other hand, $u_1 - u_2 \in V(0) = (G'N)^\perp$, and hence $u_1 = u_2$. $\square$

Now, denote the only element in $G'P(v, x_0) \cap V(x_0)$ by $G'p_*$; although p_* might not be unique in $P(v, x_0)$, $G'p_*$ is uniquely determined. Therefore, we are able to define the operator

$$D^{x_0} : V(x_0) \to V(x_0), \qquad D^{x_0}v = G'p_*.$$

In particular, we can define

$$D : V(0) \to V(0), \qquad Dv = G'p_*^0.$$

To characterize these operators, let $(I + KM^+)_{N^\perp}$ be the restriction of $I + KM^+$ on $N^\perp$. Then $(I + KM^+)_{N^\perp}$ is a bijection from $N^\perp$ to $\mathcal{R}(I + KM^+)$ and hence has a bounded inverse. Now choose

$$p_* = ((I + KM^+)_{N^\perp})^{-1}(KGv + \hat{K}x_0).$$

Then

$$D^{x_0}v = G'((I + KM^+)_{N^\perp})^{-1}(KGv + \hat{K}x_0) \tag{2.3}$$

and

$$Dv = G'((I + KM^+)_{N^\perp})^{-1}KGv. \tag{2.4}$$

THEOREM 2.5. *D is a compact, self-adjoint operator on $V(0)$.*

Proof. Since K is compact, so is D. To show that D is self-adjoint, let $v_i \in V(0), p_i \in P(v_i, 0), i = 1, 2$; then

$$\begin{aligned} & (Dv_2, v_1) - (Dv_1, v_2) \\ = \ & (G'p_2, v_1) - (G'p_1, v_2) \\ = \ & (Gv_1, p_2) - (Gv_2, p_1) \\ = \ & (Gv_1, KGv_2 - KM^+p_2) - (Gv_2, KGv_1 - KM^+p_1) \\ = \ & -(KGv_1, M^+p_2) + (KGv_2, M^+p_1) \\ = \ & -((I + KM^+)p_1, M^+p_2) + ((I + KM^+)p_2, M^+p_1) \\ = \ & 0. \end{aligned}$$

This completes the proof. □

3. A game in which value does not exist. Consider the following dynamics:

$$\dot{x} = x + u + v, \quad x(0) = 0,$$

with index

$$J(u, v) = \int_0^1 (u^2 - v^2 + 2x^2)dt.$$

We claim that the lower value of the game is 0, whereas the upper value does not exist. To prove $v^-(0) = 0$ is easy: for each control action v, $J(-v, v) = 0$, and thus $\inf J(u, v) \leq 0$, and hence $v^-(0) \leq 0$. On the other hand, $v^-(0) \geq \inf J(u, 0) = 0$. Now let's deal with the hard part; we need to show $v^+(0) = \infty$. Fix control action u. We write the index as

$$J(u, v) = -((I - 2L^*L)v, v) + 4(L^*Lu, v) + ((I + 2L^*L)u, u),$$

where L is the integral operator defined in section 2. Since the underlying Riccati differential equation blows up in interval [0, 1], by virtue of results in [4] and [6], $I - 2L^*L$ is not positive definite; i.e., there exists a nonzero $\bar{v}$ such that $((I-2L^*L)\bar{v}, \bar{v}) \leq 0$. In fact, strict inequality holds. To see this, take $\bar{v}(t) = 1$ on [0, 1]. We calculate $((I - 2L^*L)\bar{v}, \bar{v}) \approx 1 - 2 * 0.757762 < 0$, and thus $\sup\{J(u, v); v \in L^2(0, 1)\} = \infty$ for every u given, which shows that the upper value of the game does not exist.

Remark 3. It is easy to construct similar examples in which the upper value exist but the lower value does not exist and examples in which neither the lower value nor the upper value exists.

Remark 4. The example game admits an open loop–closed loop saddle point as well as a closed loop–closed loop saddle point because both the Riccati differential equation and the lower Riccati differential equation admit a solution on [0, 1] (see [2]).

4. Main results and proof. The main results in this paper are contained in the following.

THEOREM 4.1. *Consider the game problem* (1.1)–(1.3). *The following statements are equivalents:*

(1) *There exists an open loop–open loop saddle point* $(u^*, v^*) \in L^2(0, T; \mathbb{R}^m) \times L^2(0, T; \mathbb{R}^l)$ *such that*

$$J(u^*, v) \leq J(u^*, v^*) \leq J(u, v^*) \quad \forall u \in L^2(0, T; \mathbb{R}^m), v \in L^2(0, T; \mathbb{R}^l).$$

(2) *The value of the game exists.*

(3) *Both the lower value and the upper value exist.*

To prove the theorem, some lemmas are needed. Using the notation of section 2, we rewrite the index as

$$J(u,v) = ((I+E)u,u) + 2(f(v,x_0),u) + J(0,v),$$

where

$$E = B'L^*QLB + B'\hat{L}^*W\hat{L}B = B'KB$$

and

$$f(v,x_0) = B'KGv + B'\hat{K}x_0.$$

Obviously, the lower value exists if and only if both of the following conditions hold:

(A) There exists $v \in L^2(0,T;\mathbb{R}^m)$ such that

$$\hat{J}(v) = \inf_u J(u,v) > -\infty. \tag{4.1}$$

(B) Let $\hat{V}(x_0) = \{v \in L^2(0,T;\mathbb{R}^m) : v \text{ is such that (4.1) holds true}\}$. Then

$$\sup\{\hat{J}(v) : v \in \hat{V}(x_0)\} < \infty. \tag{4.2}$$

By standard extremal theory (see, e.g., [5]), (4.1) holds if and only if $I+E \geq 0$ and

$$f(v,x_0) \in \mathcal{N}(I+E)^{\perp} = \mathcal{R}(I+E). \tag{4.3}$$

Moreover, u is an optimizer if and only if

$$f(v,x_0) + (I+E)u = 0. \tag{4.4}$$

Our first observation is the following.

LEMMA 4.2. *Suppose the lower value exists. Then $\hat{V}(x_0)$ coincides with $V(x_0)$.*

Proof. Let $v \in \hat{V}(x_0)$. Then, by definition and (4.3),

$$(f(v,x_0),u) = (B'KGv + B'\hat{K}x_0, u) = 0 \forall u \in \mathcal{N}(I+E). \tag{4.5}$$

Notice that $B\mathcal{N}(I+E) = \mathcal{N}(I+M^+K)$ by Lemma 4.2, and that (4.5) is equivalent to

$$KGv + \hat{K}x_0 \in (\mathcal{N}(I+M^+K))^{\perp} = \mathcal{R}(I+KM^+); \tag{4.6}$$

hence $v \in V(x_0)$. Since the above procedure is invertible, the opposite inclusion also holds. □

LEMMA 4.3. *Suppose the lower value exists. Then for $v \in V(x_0)$,*

$$\hat{J}(v) = -(v,v) + (Gv,p) + \langle x_0, p(0)\rangle, \tag{4.7}$$

where $p \in P(v,x_0)$ and $\hat{J}(v)$ is independent of the choice of p.

Proof By (4.4), the optimizer u can be expressed as

$$u = -B'(KBu + KGv + \hat{K}x_0). \tag{4.8}$$

Let $p = KBu + KGv + \hat{K}x_0$. Then $u = -B'p$ and $p = KB(-B'p) + KGv + \hat{K}x_0$, and thus $p \in P(v, x_0)$. Conversely, let $p \in P(v, x_0)$, $u = -B'p$ must be the optimizer for $J(u, v)$. Therefore,

$$\begin{aligned}
\hat{J}(v) &= ((I+E)u, u) + 2(f(v, x_0), u) + J(0, v) \\
&= (f(v, x_0), u) + J(0, v) \\
&= (B'KGv + B'\hat{K}x_0, -B'p) + J(0, v) \\
&= -(Q(LGv + Sx_0), LM^+p) - \langle W(\hat{L}Gv + \hat{S}x_0), \hat{L}M^+p\rangle \\
&\quad -\|v\|^2 + (Q(LGv + Sx_0), LGv + Sx_0) + \langle W(\hat{L}Gv + \hat{S}x_0), \hat{L}Gv + \hat{S}x_0\rangle \\
&= -\|v\|^2 + (Gv, L^*Qx + \hat{L}^*Wx(T)) + \langle x(0), S^*Qx + \hat{S}^*Wx(T)\rangle \\
&= -\|v\|^2 + (Gv, p) + \langle x_0, p(0)\rangle
\end{aligned}$$

and $\hat{J}(v)$ does not depend on the choice of p. □

LEMMA 4.4. *Suppose the lower value exists. Then it equals* $\langle x_0, p(0)\rangle$, *and is independent of the choice of solution* p *to the following Fredholm equation:*

$$(I + KM)p = \hat{K}x_0. \tag{4.9}$$

Proof. We want to calculate $\sup\{\hat{J}(v); v \in V(x_0)\}$. Fix $\bar{v} \in V(x_0)$ and $\bar{p} \in P(\bar{v}, x_0)$; then $v \in V(x_0)$ can be written as $v = \bar{v} + v^0$ and $p \in P(v, x_0)$ can be written as $p = \bar{p} + p^0$ for some $v^0 \in V(0)$ and $p^0 \in P(v^0, 0)$. Similar to Theorem 2.5, it can be shown that

$$-(G\bar{v}, p^0) + (Gv^0, \bar{p}) = \langle x_0, p^0(0)\rangle.$$

Then

$$\begin{aligned}
\hat{J}(v) &= -\|\bar{v} + v^0\|^2 + (G(\bar{v} + v^0), \bar{p} + p^0) + \langle x_0, \bar{p}(0) + p^0(0)\rangle \\
&= -\|\bar{v}\|^2 + (G\bar{v}, \bar{p}) + \langle x_0, \bar{p}(0)\rangle - \|v^0\|^2 + (G\bar{v}p^0) \\
&\quad + \langle x_0, p^0(0)\rangle + (Gv^0, \bar{p}) + (Gv^0, p^0) - 2(\bar{v}mv^0) \\
&= \hat{J}(\bar{v}) - \|v^0\|^2 + (v^0, G'p^0) - 2(v^0, \bar{v} - G'\bar{p}).
\end{aligned}$$

Hence,

$$\sup_{v \in V(x_0)} \hat{J}(v) = \hat{J}(\bar{v}) + \sup_{v^0 \in V(0)} (-((I - D)v^0, v^0) - 2(v^0, \bar{v} - D^{x_0}\bar{v})). \tag{4.10}$$

Again, by standard extremal theory, $\sup_{v \in V(x_0)} \hat{J}(v)$ is finite if and only if

$$I - D \geq 0$$

and

$$\bar{v} - D^{x_0}\bar{v} \in \mathcal{N}(I - D)^\perp = \mathcal{R}(I - D).$$

Moreover, if $v^0 \in V(0)$ is such that

$$\bar{v} - D^{x_0}\bar{v} + (I - D)v^0 = 0,$$

then $v^* = \bar{v} + v^0$ is the optimizer for $\hat{J}(v)$. Recalling definitions (2.3)–(2.4), we have

$$v^* = D^{x_0}\bar{v} + Dv^0 = D^{x_0}(\bar{v} + v^0) = D^{x_0}v^*.$$

Now let $v = v^*$, and let p be any $p^* \in P(v^*, x_0)$ in (4.7). Then we have

$$\sup_{v \in V(x_0)} \hat{J}(v) = \hat{J}(v^*) = -\|v^*\|^2 + (v^*, G'p^*) + \langle x_0, p^*(0)\rangle = \langle x_0, p^*(0)\rangle,$$

which is independent of the choice of p^*.

Finally, we verify that p^* satisfies the Fredholm equation (4.9). In fact, since $p^* \in P(v^*, x_0)$, we have $(I + KM^+)p^* = KGv^* + \hat{K}x_0$; moreover, $v^* = D^{x_0}v^* = G'p^*$, and hence $(I + KM)p^* = \hat{K}x_0$. □

LEMMA 4.5. *Suppose the upper value exists. Then it equals* $\langle x_0, p(0)\rangle$ *and is independent of the choice of solution* p *to the Fredholm equation* (4.9).

Proof. Notice that

$$\inf_u \sup_v J(u, v) = -\sup_v \inf_u (-J(u, v)).$$

Hence, if the upper value exists, then, by Lemma 4.4,

$$\sup_v \inf_u (-J(u, v)) = \langle x_0, q(0)\rangle, \tag{4.11}$$

where q satisfies

$$(I + KM)q = -\hat{K}x_0$$

and (4.11) is independent of the choice of q, or equivalently, the upper value equals $\langle x_0, p(0)\rangle$ and is independent of the choice of solution p to the Fredholm equation (4.9). □

Proof of Theorem 4.1. 1) ⇒ 2) and 2) ⇒ are obvious. We need only prove 3) ⇒ 1).

By virtue of Lemma 4.4, if the lower value exists, then there exists $v^* = G'p^* \in V(x_0)$, where p^* satisfies (4.9). Let u^* be the optimizer of $J(u, v^*)$. Then $u^* = -B'p^*$ and

$$J(u^*, v^*) \le J(u, v^*).$$

Similarly, if the upper value exists, the same (u^*, v^*) verifies

$$-J(u^*, v^*) \le -J(u^*, v).$$

Thus, (u^*, v^*) constitutes the desired open loop–open loop saddle point. □

5. Concluding remarks. This paper studies the two-person, zero-sum linear quadratic differential games on a finite horizon. Some necessary and sufficient conditions for the existence of the value of the game are derived. Although we obtain the open loop–open loop saddle points whenever the value of the game exists, nothing is said about their synthesis as state feedback. In subsequent papers, we shall further investigate the relationship among open loop saddle points, closed loop saddle points, value of the game, and the Riccati differential equations. Another future research will discuss infinite horizontal differential game problems.

Acknowledgment. The author would like to thank the referees for their constructive suggestions which improved this work.

ON THE ATTAINABLE SET FOR TEMPLE CLASS SYSTEMS WITH BOUNDARY CONTROLS*

FABIO ANCONA† AND GIUSEPPE MARIA COCLITE‡

Abstract. Consider the initial-boundary value problem for a strictly hyperbolic, genuinely nonlinear, Temple class system of conservation laws

$$u_t + f(u)_x = 0, \qquad u(0,x) = \overline{u}(x), \qquad \begin{cases} u(t,a) = \widetilde{u}_a(t), \\ u(t,b) = \widetilde{u}_b(t), \end{cases} \tag{1}$$

on the domain $\Omega = \{(t,x) \in \mathbb{R}^2 : t \geq 0,\ a \leq x \leq b\}$. We study the mixed problem (1) from the point of view of control theory, taking the initial data $\overline{u}$ fixed and regarding the boundary data $\widetilde{u}_a$, $\widetilde{u}_b$ as control functions that vary in prescribed sets $\mathcal{U}_a$, $\mathcal{U}_b$, of $\mathbf{L}^\infty$ boundary controls. In particular, we consider the family of configurations

$$\mathcal{A}(T) \doteq \{u(T,\cdot);\ u \text{ is a sol. to (1)},\ \widetilde{u}_a \in \mathcal{U}_a,\ \widetilde{u}_b \in \mathcal{U}_b\}$$

that can be attained by the system at a given time $T > 0$, and we give a description of the attainable set $\mathcal{A}(T)$ in terms of suitable Oleinik-type conditions. We also establish closure and compactness of the set $\mathcal{A}(T)$ in the $\mathbf{L}^1$ topology.

1. Introduction.

Consider the initial-boundary value problem for a strictly hyperbolic, genuinely nonlinear, system of conservation laws in one space dimension

$$u_t + f(u)_x = 0, \tag{1.1}$$

$$u(0,x) = \overline{u}(x), \tag{1.2}$$

$$u(t,a) = \widetilde{u}_a(t), \tag{1.3}$$

$$u(t,b) = \widetilde{u}_b(t) \tag{1.4}$$

on the strip $\Omega = \{(t,x) \in \mathbb{R}^2;\ t \geq 0,\ x \in [a,b]\}$. Here, $u = u(t,x) \in \mathbb{R}^n$ is the vector of the conserved quantities, $\widetilde{u}_a, \widetilde{u}_b$ are measurable, bounded boundary data, and the flux function $f : U \mapsto \mathbb{R}^n$ is a smooth vector field defined on some open set $U \subseteq \mathbb{R}^n$ that belongs to a class of fields introduced by Temple [29, 28] for which rarefaction and Hugoniot curves coincide. We recall that, for problems of this type, classical solutions may develop discontinuities in finite time, regardless of the regularity of the initial and boundary data. Hence, it is natural to consider weak solutions in the sense of distributions. Moreover, since, in general, the Dirichlet conditions (1.3)–(1.4) cannot be fulfilled pointwise a.e. (see [7, 19]), different weaker formulations of the boundary condition have been considered in the literature (see [1, 20, 27] and references therein). Here, following Dubois and LeFloch [19], we will adopt a formulation of (1.3)–(1.4)

based on the definition of a time-dependent set of *admissible boundary data* that is related to the notion of the Riemann problem.

In the present paper, having in mind applications of Temple systems to problems of oil reservoir simulation, multicomponent chromatography, and traffic flow models, we study the effect of the boundary conditions (1.3)–(1.4) on the solution of (1.1)–(1.2) from the point of view of control theory. Namely, following the same approach adopted in [4, 5, 21] for scalar conservation laws, we fix an initial data $\overline{u} \in \mathbf{L}^\infty([a,b])$ and consider the family of configurations

$$\mathcal{A}(T;\mathcal{U}_a,\mathcal{U}_b) \doteq \{u(T,\cdot);\ u \text{ sol. to (1.1)–(1.4)},\ \widetilde{u}_a \in \mathcal{U}_a,\ \widetilde{u}_b \in \mathcal{U}_b\} \tag{1.5}$$

that can be attained at a given time $T > 0$ by solutions to (1.1)–(1.4), with boundary data $\widetilde{u}_a$, $\widetilde{u}_b$ that vary in prescribed sets $\mathcal{U}_a$, $\mathcal{U}_b \subset \mathbf{L}^\infty(\mathbb{R}^+)$ of *admissible boundary controls.* In the case of scalar, convex conservation laws, it was proved in [4], by using the theory of generalized characteristics [17], that the profiles $w(x)$ which can be attained at a fixed time $T > 0$ are only those for which the map $x \mapsto \frac{f'(w(x))}{x}$ is nonincreasing. Under the assumption that $f'(u) \geq 0$ for all u, and for solutions of the mixed problem (1.1)–(1.4) on the region Ω, this condition is equivalent to the Oleinik-type inequalities

$$D^+ w(x) \leq \frac{f'(w(x))}{(x-a)f''(w(x))} \quad \text{for a.e. } x \in [a,b] \tag{1.6}$$

($D^+ w$ denoting the upper Dini derivative of w). For general $n \times n$ systems, a complete characterization of the attainable set does not seem possible, due to the complexity of repeated wave-front interactions. However, in the particular case of Temple systems, wave interactions can change only the speed of wave-fronts without modifying their amplitudes, due to the special geometric features of such systems. Therefore, the only restriction to boundary controllability is the decay due to genuine nonlinearity. We then consider here a convex, compact set $\Gamma \subset U$ and provide a description of the attainable set

$$\mathcal{A}(T) \doteq \mathcal{A}(T;\mathcal{U}^\infty,\mathcal{U}^\infty), \qquad \mathcal{U}^\infty \doteq \mathbf{L}^\infty([0,T],\Gamma)$$

in terms of certain Oleinik-type conditions. We also establish the compactness of $\mathcal{A}(T)$ in the $\mathbf{L}^1$ topology, as was shown in [4] for the scalar case. These results are useful in applications to calculus of variations and optimal control problems where the cost functional depends on the profile of the solution to (1.1)–(1.4) at a fixed time T. An example is given by a model of two-component chromatography that describes a liquid flowing through a tube packed with solid particles that absorbs (with different rates of adsorption) two interacting chemical substances dissolved in the liquid. In case one is interested in producing the separation of the two substances, the controller acts by varying the concentration of the solutes entering the tube to maximize the concentration of each substance in the liquid phase on opposite sides of the tube.

The paper is organized as follows. Section 2 contains the basic definitions and the statement of the main results, together with a discussion of the two-component chromatography problem. We also provide in this section a review of the existence and well-posedness theory for the mixed problem (1.1)–(1.4), and a description of a front tracking algorithm that will be used throughout the paper. In section 3 we establish some preliminary estimates and a regularity result concerning the global structure of solutions to the mixed problem (1.1)–(1.4) generated by a front tracking algorithm. The proof of the main results is contained in section 4.

2. Preliminaries and statement of the main results.

2.1. Formulation of the problem. Let $f : U \mapsto \mathbb{R}^n$ be the flux function of the strictly hyperbolic system (1.1) defined on a neighborhood of the origin $U \subseteq \mathbb{R}^n$. Denote by $\lambda_1(u) < \cdots < \lambda_n(u)$ the eigenvalues of the Jacobian matrix $Df(u)$, and let $\{r_1(u), \ldots, r_n(u)\}$ be a basis of right eigenvectors of $Df(u)$. By possibly considering a sufficiently small restriction of the domain U, we may assume that the following *uniform* strict hyperbolicity condition holds.

(SH) For every $u, v \in U$, the characteristic speeds at these points satisfy

$$\lambda_i(u) < \lambda_j(v) \quad \forall 1 \le i < j \le n. \tag{2.1}$$

We also assume that there is a fixed set of characteristic lines entering the interior of the strip $[a, b] \times \mathbb{R}^+$ at the boundaries $x = a$, $x = b$, i.e., that for some index $p \in \{1, \ldots, n\}$, there holds

$$\lambda_p(u) < 0 < \lambda_{p+1}(u) \quad \forall u \in U, \tag{2.2}$$

and we let $\lambda^{\min}$, $\lambda^{\max}$ denote the minimum and maximum characteristic speed so that there holds

$$0 < \lambda^{\min} \le |\lambda_i(u)| \le \lambda^{\max} \quad \forall u \in U. \tag{2.3}$$

Moreover, we assume that each ith characteristic field r_i is *genuinely nonlinear* in the sense of Lax [22], and that system (1.1) is of Temple class according to the following definition.

DEFINITION 2.1. *A system of conservation laws is of Temple class if there exists a system of coordinates $w = (w_1, \ldots, w_n)$ consisting of Riemann invariants, and such that the level sets $\{u \in U;\ w_i(u) = \text{constant}\}$ are hyperplanes (see* [28]*).*

By possibly performing a translation of coordinates, it is not restrictive to assume that the Riemann invariants are chosen so that $\partial_i \lambda_i(w) > 0$, $i = 1, \ldots, n$, for all $w = w(u)$, $u \in U$. Throughout the paper, we will often write $w_i(t, x) \doteq w_i(u(t, x))$ to denote the ith Riemann coordinate of a solution $u = u(t, x)$ to (1.1). We recall that, for a Temple class system, Hugoniot curves and rarefaction curves coincide and are straight lines [29]. Moreover, as observed in [3], thanks to the existence of Riemann coordinates one can show that the assumption (SH) implies the invertibility of the map $f : U \mapsto f(U)$.

We next introduce a definition of weak solution to (1.1)–(1.4) which includes an entropy admissibility condition of Oleinik type on the decay of positive waves, to achieve uniqueness. The boundary conditions (1.3)–(1.4) are formulated in terms of the weak trace of the flux $f(u)$ at the the boundaries $x = a$, $x = b$ and are related to the notion of the Riemann problem in the same spirit of [19]. To this purpose, letting $u(t, x) = W(\xi = x/t; u_L, u_R)$, $u_L, u_R \in U$, denote the self-similar solution of the Riemann problem for (1.1) with initial data

$$u(0, x) = \begin{cases} u_L & \text{if } x < 0, \\ u_R & \text{if } x > 0 \end{cases}$$

for any given boundary state $\widetilde{u} \in U$, we define the set of *admissible states at the boundaries*

$$\begin{aligned} \mathcal{V}_a(\widetilde{u}) &\doteq \{W(0+; \widetilde{u}, u_R);\ u_R \in U\}, \\ \mathcal{V}_b(\widetilde{u}) &\doteq \{W(0-; u_L, \widetilde{u});\ u_L \in U\}. \end{aligned} \tag{2.4}$$

DEFINITION 2.2. *A function $u : [0,T] \times [a,b] \mapsto U$ is an entropy weak solution of the initial-boundary value problem (1.1)–(1.4) on $\Omega_T \doteq [0,T] \times [a,b]$ if it is continuous as a function from $]0,T]$ into $\mathbf{L}^1$, and the following properties hold:*

(i) *u is a distributional solution to the Cauchy problem (1.1)–(1.2) on Ω_T in the sense that, for every test function $\phi \in \mathcal{C}_c^1$ with compact support contained in the set $\{(t,x) \in \mathbb{R}^2;\ a < x < b,\ t < T\}$, there holds*

$$\int_0^T \int_a^b (u(t,x) \cdot \phi_t(t,x) + f(u(t,x)) \cdot \phi_x(t,x)) dx\, dt + \int_a^b \overline{u}(x) \cdot \phi(0,x) dx = 0;$$

(ii) *the flux $f(u)$ admits weak* traces at the boundaries $x = a$, $x = b$, i.e., there exist two measurable functions $\Psi_a, \Psi_b : [0,T] \mapsto \mathbb{R}^n$ such that*

$$f(u(\cdot,x)) \xrightarrow[x \to a^+]{*} \Psi_a, \qquad f(u(\cdot,x)) \xrightarrow[x \to b^-]{*} \Psi_b \quad \text{in } \mathbf{L}^\infty([0,T]), \tag{2.5}$$

and the boundary conditions (1.3)–(1.4) are satisfied in the following sense:

$$\Psi_a(t) \in f(\mathcal{V}_a(\widetilde{u}_a(t))), \qquad \Psi_b(t) \in f(\mathcal{V}_b(\widetilde{u}_b(t))) \quad \text{for a.e. } 0 \le t \le T; \tag{2.6}$$

(iii) *u satisfies the following entropy conditions on the decay of positive waves in time and space. There exists some constant $C > 0$, depending only on the system (1.1), so that*

(a) *for any $0 < t \le T$, and for a.e. $a < x < y < b$, there holds*

$$w_i(t,y) - w_i(t,x) \le C \cdot \left\{ \frac{y-x}{t} + \log\left(\frac{y-b}{x-b}\right) \right\} \quad \text{if } i \in \{1,\dots,p\}, \tag{2.7}$$

$$w_i(t,y) - w_i(t,x) \le C \cdot \left\{ \frac{y-x}{t} + \log\left(\frac{y-a}{x-a}\right) \right\} \quad \text{if } i \in \{p+1,\dots,n\}; \tag{2.8}$$

(b) *for a.e. $a < x < b$, and for a.e. $0 < \tau_1 < \tau_2 \le T$, there holds*

$$w_i(\tau_2,x) - w_i(\tau_1,x) \le C \cdot \left\{ \frac{\tau_2-\tau_1}{x-b} + \log\left(\frac{\tau_2}{\tau_1}\right) \right\} \quad \text{if } i \in \{1,\dots,p\}, \tag{2.9}$$

$$w_i(\tau_2,x) - w_i(\tau_1,x) \le C \cdot \left\{ \frac{\tau_2-\tau_1}{x-a} + \log\left(\frac{\tau_2}{\tau_1}\right) \right\} \quad \text{if } i \in \{p+1,\dots,n\}. \tag{2.10}$$

Remark 2.3. The set of admissible flux values at the boundaries $x = a$, $x = b$, can be expressed in Riemann coordinates as

$$\begin{aligned} f(\mathcal{V}_a(\widetilde{u})) &= \{f(u);\ w_i(u) = w_i(\widetilde{u}) \qquad \forall i = p+1,\dots,n\}, \\ f(\mathcal{V}_b(\widetilde{u})) &= \{f(u);\ w_i(u) = w_i(\widetilde{u}) \qquad \forall i = 1,\dots,p\}. \end{aligned} \tag{2.11}$$

Hence, by the invertibility of the map $f : U \mapsto f(U)$, the above boundary conditions (2.6) are equivalent to the set of equalities

$$\begin{aligned} &w_i(f^{-1}(\Psi_a(t))) = w_i(\widetilde{u}_a(t)) \quad \text{for a.e. } 0 \le t \le T,\ di = p+1,\dots,n, \\ &w_i(f^{-1}(\Psi_b(t))) = w_i(\widetilde{u}_b(t)) \quad \text{for a.e. } 0 \le t \le T,\ i = 1,\dots,p. \end{aligned} \tag{2.12}$$

This means that the boundary conditions (2.6) guarantee that, at almost every time $t \in [0,T]$, the solution to the Riemann problem for (1.1), having left and right initial

states $u^L = \widetilde{u}_a(t)$, $u^R = f^{-1}(\Psi_a(t))$, contains only waves with negative speeds, while the solution to the Riemann problem with initial states $u^L = f^{-1}(\Psi_b(t))$, $u^R = \widetilde{u}_b(t)$, contains only waves with positive speeds. Thus, in particular, such solutions do not contain any front entering the domain $[t, +\infty[\times]a, b[$.

In the present paper we regard the boundary data as admissible controls and, in connection with a fixed convex, compact set $\Gamma \subset U$ having the form

$$\Gamma = \{u \in U;\ w_i(u) \in [\alpha_i, \beta_i],\ i = 1, \dots, n\}, \tag{2.13}$$

we study the basic properties of the *attainable set* for (1.1)–(1.2), i.e., of the set

$$\mathcal{A}(T) \doteq \{u(T, \cdot);\ u \text{ is a sol. to (1.1)–(1.4)},\ \widetilde{u}_a, \widetilde{u}_b \in \mathbf{L}^\infty([0, T], \Gamma)\} \tag{2.14}$$

which consists of all profiles that can be attained at a fixed time $T > 0$ by entropy weak solutions of (1.1)–(1.4) (according to Definition 2.2) with a fixed initial data $\overline{u} \in \mathbf{L}^\infty([a, b], \Gamma)$ and boundary data $\widetilde{u}_a$, $\widetilde{u}_b$ that vary in

$$\mathcal{U}_T^\infty \doteq \mathbf{L}^\infty([0, T], \Gamma). \tag{2.15}$$

We will establish a characterization of (2.14) in terms of certain Oleinik type estimates on the decay of positive waves, and we will prove the compactness of (2.14) in the $\mathbf{L}^1$ topology.

2.2. Statements of the main results. For any $\rho > 0$, consider the set of maps

$$K^\rho \doteq \left\{ \varphi \in \mathbf{L}^\infty([a, b], \Gamma);\ \begin{array}{l} \dfrac{w_i(\varphi(y)) - w_i(\varphi(x))}{y - x} \le \dfrac{\rho}{x - a} \left\{ \begin{array}{l} \text{for a.e. } a < x < y < b, \\ \text{if } i \in \{p+1, \dots, n\} \end{array} \right. \\ \dfrac{w_i(\varphi(y)) - w_i(\varphi(x))}{y - x} \le \dfrac{\rho}{b - y} \left\{ \begin{array}{l} \text{for a.e. } a < x < y < b, \\ \text{if } i \in \{1, \dots, p\} \end{array} \right. \end{array} \right\}. \tag{2.16}$$

The inequalities in (2.16) reflect the fact that positive waves entering through the boundaries $x = a$, $x = b$ decay in time. Therefore, their density (expressed in terms of Riemann coordinates) is inversely proportional to their distance from their entrance point on the boundary.

THEOREM 2.4. *Let* (1.1) *be a system of Temple class with all characteristic fields genuinely nonlinear, and assume that the strict hyperbolicity condition* (SH) *is verified. Then, for every fixed* $\overline{\tau} > 0$, *there exists* $\rho = \rho(\overline{\tau}) > 0$ *such that*

$$\mathcal{A}(\tau) \subseteq K^\rho \quad \forall \tau \ge \overline{\tau}. \tag{2.17}$$

Moreover, taking $T \doteq \frac{4(b-a)}{\lambda^{\min}}$, *there exists* $\rho' < \rho(T)$ *such that*

$$K^{\rho'} \subseteq \mathcal{A}(\tau) \quad \forall \tau > T. \tag{2.18}$$

Remark 2.5. Observe that, given $\varphi \in K^\rho$, any map $x \mapsto w_i(\varphi(x))$, $i \in \{1, \dots, n\}$, is essentially bounded and has finite total increasing variation on subsets of $[a, b]$ bounded away from the end points a, b. Hence, any map $x \mapsto w_i(\varphi(x))$, $i \in \{1, \dots, n\}$, also has finite total variation on such sets and, in particular, it admits left and right limits in any point $x \in]a, b[$. Moreover, since an element φ of K^ρ is defined up to $\mathbf{L}^1$

equivalence, we may always assume that there is a right continuous representative of $w_i(\varphi)$, $i \in \{1, \dots, n\}$, that satisfies the inequalities appearing in the definition of K^ρ.

Remark 2.6. It can be easily seen that, no matter how small we choose ρ, it is not possible, in general, to reach at a time $T < \frac{2(b-a)}{\lambda^{\max}}$ any prescribed profile $\varphi \in K^\rho$ with an entropy weak solution u to (1.1)–(1.4) that starts with a fixed initial data $\overline{u}$. This is due to the fact that in this case the domains of determinacy of the line segments $t = 0$, $a \le x \le b$, and $t = T$, $a \le x \le b$ have a nonempty intersection and hence the determination of the possible solution u induced by $u(T, x) = \varphi(x)$, $x \in [a, b]$, and $u(0, x) = \overline{u}(x)$, $x \in [a, b]$ would be, in general, inconsistent. We expect that the same type of noncontrollability result holds for time larger than $\frac{2(b-a)}{\lambda^{\max}}$. This raises the question concerning the identification of a minimum time $T_m < \frac{4(b-a)}{\lambda^{\min}}$ for which the inclusion (2.18) of Theorem 2.4 is verified, although a definite answer to such a problem does not seem possible due to the complexity of the wave-front structure of a solution to the mixed problem (1.1)–(1.4).

THEOREM 2.7. *Under the same assumptions of Theorem* 2.4*, the set* $\mathcal{A}(T)$ *is a compact subset of* $\mathbf{L}^1([a, b], \Gamma)$ *for each* $T > 0$.

2.3. An application: Chromatography of two solutes. Chromatography is a process used by chemists and engineers to separate two (or more) chemical species in a fluid phase by selective adsorption on a solid medium. We consider here the case of a mixture of two interacting solutes S_1 and S_2 dissolved in a liquid with concentrations c_1 and c_2 which passes through the interstices of a solid bed of particles packed in a tube. The solid surface of the filtering bed absorbs different amounts of the two solutes, while it is possible for the particles of each substance to pass from the fluid to the solid phase, and vice versa. The different rates of adsorption of the two solutes causes the less strongly adsorbed solute, say S_2, to move ahead of the more strongly adsorbed one S_1, thus inducing a separation of the two chemical substances. If we make the assumption of local equilibrium in the tube between the liquid and solid phase for each substance, one can express the solid concentrations of the two substances n_1, n_2 as functions of both liquid concentrations. In the case of the Langmuir isotherm equilibrium, the solid concentrations take the form (see [24])

$$n_i \doteq \frac{N_i k_i c_i}{1 + k_1 c_1 + k_2 c_2}, \quad i = 1, 2, \tag{2.19}$$

where k_1, k_2 are constitutive constants depending on the temperature, while N_i denotes the limiting value of n_i (representing the maximum concentration of the solute that can be adsorbed by the solid medium). After performing a suitable transformation of the independent variables, one can express the mass conservation equations for the two species as (see [26])

$$\begin{aligned} [c_1]_x + \left[\frac{\gamma c_1}{1 + c_1 + c_2}\right]_t &= 0, \\ [c_2]_x + \left[\frac{c_2}{1 + c_1 + c_2}\right]_t &= 0 \end{aligned} \tag{2.20}$$

for some constant $\gamma \in]0, 1]$. Notice that the mathematical roles played by the space-like variable x and by the timelike variable t in (2.20) is the opposite of the typical roles played by such variables in most physical hyperbolic systems. Because of the particular nonlinearity relation (2.19) of the Langmuir isotherm, (2.20) enjoy the special geometric properties of Temple systems. Moreover, by direct computations,

one can verify that (2.20) satisfies all the other assumptions made in Theorems 2.4–2.7, namely the following hold (see [26]):

- system (2.20) is strictly hyperbolic if we assume that the state variables c_i take values in some fixed interval $[\overline{c}_i, \overline{d}_i]$ (which corresponds to requiring that the concentrations are nonnegative and do not approach infinity);
- both characteristic speeds of (2.20) are positive and genuinely nonlinear if $\gamma \in]0,1[$ (while, in the case $\gamma = 1$, the first characteristic speed is genuinely nonlinear and the second is linearly degenerate).

A general introduction to the mathematical modeling of chromatography and a detailed analysis of the equilibrium system in the special case of Langmuir isotherm is provided by Rhee, Aris, and Amundson in [25, 26].

We are concerned here with the problem of controlling the feed data c_1^f, c_2^f, i.e., the concentrations of the two solutes S_1, S_2 entering the tube in a time interval $[0,T]$, to maximize the separation of the two substances at time T. Namely, we are interested in maximizing the difference between the distributions of S_1 and S_2 on opposite sides of the tube at a fixed time T. Let $x = 0$ and $x = L$ denote the locations, respectively, of the inlet and outlet of the tube, and suppose that $\overline{c}_1$, $\overline{c}_2$ are the initial distributions in the liquid of S_1 and S_2 at time $t = 0$. Then, consider the functional

$$J(x, c^f) \doteq \int_0^x (c_1(T,\xi) - c_2(T,\xi))d\xi + \int_x^L (c_2(T,\xi) - c_1(T,\xi))d\xi, \tag{2.21}$$

where $(c_1, c_2)(t,x)$ denotes the solution to the mixed problem for (2.20) on the strip $[0,\infty[\times[0,L]$, with initial data $\overline{c} = (\overline{c}_1, \overline{c}_2)$ and boundary data $c^f = (c_1^f, c_2^f)$. Notice that, since both characteristic speeds are positive, the set $\mathcal{V}_L(\widetilde{c})$ of admissible states at the right boundary $x = L$ (defined as in (2.4)) turns out to be equal to the whole space $\mathbb{R}^2$ for every $\widetilde{c} \in \mathbb{R}^2$. Hence, the only significant boundary condition is assigned at the left boundary $x = 0$. Then, assuming that C_i denotes the maximum amount of concentration of the solute S_i that can be introduced in the tube in the time interval $[0,T]$, we are led to study the maximization problem

$$\max_{x\in[0,1], c^f \in \mathcal{U}_T^\infty} J(x, c^f), \tag{2.22}$$

where the set of admissible boundary controls is given by

$$\mathcal{U}_T^\infty \doteq \left\{ \widetilde{c} \in \mathbf{L}^\infty([0,T]) : \widetilde{c}_i(t) \in [\overline{c}_i, \overline{d}_i],\ \int_0^T \widetilde{c}_i(t) \le C_i \right\}. \tag{2.23}$$

With the same arguments we will use to establish Theorem 2.7 one can prove the compactness of the attainable set $\mathcal{A}(T)$ in the case of a system like (2.20) where the mathematical roles played by the x-t variables is reversed w.r.t. (1.1) and in connection with a set of admissible boundary controls that satisfy an additional integral constraint as in (2.23). Then, observing that the map

$$(x, c) \mapsto \int_0^x (c_1(\xi) - c_2(\xi))\, d\xi + \int_x^L (c_2(\xi) - c_1(\xi))\, d\xi \tag{2.24}$$

is continuous as a functional from $[0,L] \times \mathbf{L}^1([0,T])$ to $\mathbb{R}$, we deduce that the maximization problem (2.22) admits a solution.

2.4. Existence and uniqueness of solutions. We describe here a front tracking algorithm that generates approximate solutions to (1.1) on the strip $[a,b]\times\mathbb{R}^+$ continuously depending on the initial and boundary data, which represents a natural extension of [3, 12]. Fix an integer $\nu\geq 1$ and consider the discrete set of points in Γ whose coordinates are integer multiples of $2^{-\nu}$:

$$\Gamma^\nu \doteq \{u\in\Gamma;\ w_i(u)\in 2^{-\nu}\mathbb{Z},\ i=1,\dots,n\}. \tag{2.25}$$

Moreover, consider the domain

$$\mathcal{D}^\nu \doteq \{(u,u',u'');\ u\in\mathbf{L}^\infty([a,b],\Gamma^\nu),\ u',u''\in\mathbf{L}^\infty(\mathbb{R}^+,\Gamma^\nu),\ u,u',u'' \text{ piecew. const.}\}. \tag{2.26}$$

On $\mathcal{D}^\nu$ we now construct a flow map E^ν whose trajectories are front tracking approximate solutions of (1.1). To this end, we first describe how to solve a Riemann problem with left and right initial states $u^L,u^R\in\Gamma^\nu$. In Riemann coordinates, assume that

$$w(u^L)\doteq w^L=(w_1^L,\dots,w_n^L),\qquad w(u^R)\doteq w^R=(w_1^R,\dots,w_n^R).$$

Consider the intermediate states

$$z^0\doteq u^L,\dots,\qquad z^i\doteq u(w_1^R,\dots,w_i^R,w_{i+1}^L,\dots,w_n^L),\dots,\qquad z^n\doteq u^R. \tag{2.27}$$

The solution to the Riemann problem (u^L,u^R) is constructed by piecing together the solutions to the simple Riemann problems (z^{i-1},z^i), $i=1,\dots,n$. If $w_i^R<w_i^L$, the solution of the Riemann problems (z^{i-1},z^i) will contain a single i-shock, connecting the states z^{i-1}, z^i and traveling with the Rankine–Hugoniot speed $\lambda_i(z^{i-1},z^i)$. Here and in what follows, by $\lambda_i(u,u')$ we denote the ith eigenvalue of the averaged matrix

$$A(u,u')\doteq\int_0^1 Df(\theta u+(1-\theta)u')\,d\theta. \tag{2.28}$$

If $w_i^R>w_i^L$, the exact solution of the Riemann problem (z^{i-1},z^i) would contain a centered rarefaction wave. This is approximated by a rarefaction fan as follows. If $w_i^R=w_i^L+p_i2^{-\nu}$ we insert the states

$$z^{i,\ell}\doteq(w_1^R,\dots,w_i^L+\ell 2^{-\nu},w_{i+1}^L,\dots,w_n^L),\qquad \ell=0,\dots,p_i, \tag{2.29}$$

so that $z^{i,0}=z^{i-1}$, $z^{i,p_i}=z^i$. Our front tracking solution will then contain p_i fronts of the ith family, each connecting a couple of states $z^{i,\ell-1}$, $z^{i,\ell}$ and traveling with speed $\lambda_i(z^{i,\ell-1},z^{i,\ell})$.

For any given triple of (piecewise constant) initial and boundary data $(\overline{u},\widetilde{u}_a,\widetilde{u}_b)\in\mathcal{D}^\nu$, the approximate solution $u(t,\cdot)\doteq E_t^\nu(\overline{u},\widetilde{u}_a,\widetilde{u}_b)$ is now constructed as follows. At time $t=0$, for $a<x<b$ we solve the initial Riemann problems determined by the jumps in $\overline{u}$ according to the above procedure, while at $x=a$ we construct the solution to the Riemann problem with left and right initial states $u^L=\widetilde{u}_a(0+)$, $u^R=\overline{u}(a+)$ and take its restriction to the interior of the domain Ω. In the same way, at $x=b$ we take the restriction to the interior of Ω of the solution to the Riemann problem with initial states $u^L=\overline{u}(b-)$, $u^R=\widetilde{u}_b(0+)$. This yields a piecewise constant function with finitely many fronts, traveling with constant speeds. The solution is then prolonged up to the first time t_1 at which one of the following events takes place:

(a) two or more discontinuities interact in the interior of Ω;

(b) one or more discontinuities hit the boundary of Ω;

(c) the boundary data $\widetilde{u}_a$ has a jump;
(d) the boundary data $\widetilde{u}_b$ has a jump.

If case (a) occurs, we then solve the resulting Riemann problems applying again the above procedure, while in cases (b), (c), and (d) we construct the solution to the Riemann problem with left and right initial states $u^L = \widetilde{u}_a(t_1+)$, $u^R = u(t_1, a+)$, or $u^L = u(t_1, b-)$, $u^R = \widetilde{u}_b(t_1+)$ and take its restriction to the interior of the domain Ω. This determines the solution $u(t,\cdot)$ until the time $t_2 > t_1$ where one of the events (a), (b), or (c) again takes place, etc. Notice that at any time where case (b) occurs but (c) or (d) do not take place, no new wave is generated. Therefore, waves entering the domain Ω at the boundaries $x = a$, $x = b$ are produced only by the jumps of the boundary data $\widetilde{u}_a$, $\widetilde{u}_b$.

As in [3, 12], one checks that the approximate solution u constructed with this algorithm is well defined for all times $t \geq 0$. Indeed, the following properties hold.

- The total variation of $u(t,\cdot)$, measured w.r.t. the Riemann coordinates $w_1(t,\cdot), \dots, w_n(t,\cdot)$ is nonincreasing in time.
- The number of wave-fronts in $u(t,\cdot)$ is nonincreasing at each interaction. Hence, the total number of wave-fronts in $u(t,\cdot)$ remains finite.

It is then possible to define a flow map

$$\mathbf{p} \mapsto E^\nu_t \mathbf{p}, \quad \mathbf{p} \doteq (\overline{u}, \widetilde{u}_a, \widetilde{u}_b) \in \mathcal{D}^\nu, \quad t \geq 0, \tag{2.30}$$

of approximate solutions of (1.1). By construction, each trajectory $t \mapsto E^\nu_t \mathbf{p}$ is a weak solution of (1.1) (because all fronts of $u(t,\cdot) \doteq E^\nu_t \mathbf{p}$ satisfy the Rankine–Hugoniot conditions) but may contain discontinuities that do not satisfy the usual Lax stability conditions (due to the presence of rarefaction fronts). On the other hand, one can verify as in [3, Lemma 4.4] that, due to genuine nonlinearity, the amount of positive waves in $u(t,\cdot)$, measured w.r.t. the Riemann coordinates $w_1(t,\cdot), \dots, w_n(t,\cdot)$, decays in time and space. Hence, for a.e. $a < x < y < b$, one obtains the Oleinik-type estimates

$$\begin{aligned} w_i(t,y) - w_i(t,x) &\leq C \cdot \left\{ \frac{y-x}{t} + \log\left(\frac{y-b}{x-b}\right) \right\} + N_\nu 2^{-\nu} \quad \text{if } i \in \{1,\dots,p\}, \\ w_i(t,y) - w_i(t,x) &\leq C \cdot \left\{ \frac{y-x}{t} + \log\left(\frac{y-a}{x-a}\right) \right\} + N_\nu 2^{-\nu} \quad \text{if } i \in \{p+1,\dots,n\}, \end{aligned} \tag{2.31}$$

where N_ν denotes the maximum number of shocks of each family present in the initial data $\overline{u}$, and in the boundary data $\widetilde{u}_a$, $\widetilde{u}_b$. Similarly, one can check that along the x-sections, for a.e. $0 < \tau_1 < \tau_2$, there holds

$$\begin{aligned} w_i(\tau_2,x) - w_i(\tau_1,x) &\leq C \cdot \left\{ \frac{\tau_2-\tau_1}{x-b} + \log\left(\frac{\tau_2}{\tau_1}\right) \right\} + N_\nu 2^{-\nu} \quad \text{if } i \in \{1,\dots,p\}, \\ w_i(\tau_2,x) - w_i(\tau_1,x) &\leq C \cdot \left\{ \frac{\tau_2-\tau_1}{x-a} + \log\left(\frac{\tau_2}{\tau_1}\right) \right\} + N_\nu 2^{-\nu} \quad \text{if } i \in \{p+1,\dots,n\}. \end{aligned} \tag{2.32}$$

Remark 2.8. Observe that if $u(t,x)$ is a front tracking solution of the Cauchy problem for (1.1) (with initial data $\overline{u}(x) \doteq u(0,x)$) constructed by the algorithm in [12] on the upper half plane $\mathbb{R}^+ \times \mathbb{R}$, then the restriction of $u(t,\cdot)$ to the interval $[a,b]$ coincides with the front tracking solution $E^\nu_t(\overline{u}, \widetilde{u}_a, \widetilde{u}_b)$ of the mixed problem for (1.1), with boundary data $\widetilde{u}_a(t) \doteq u(t,a)$, $\widetilde{u}_b(t) \doteq u(t,b)$.

As $\nu \to \infty$, the domains $\mathcal{D}^\nu$ become dense in

$$\mathcal{D} \doteq \{(\overline{u}, \widetilde{u}_a \widetilde{u}_b);\ \overline{u} \in \mathbf{L}^\infty([a,b],\Gamma),\ \widetilde{u}_a, \widetilde{u}_b \in \mathbf{L}^\infty(\mathbb{R}^+,\Gamma)\}. \tag{2.33}$$

Thus, following the same technique adopted in [3], one can define a flow map E_t on $\mathcal{D}$ as a suitable limit of the flows E_t^ν in (2.30) that depends Lipschitz continuously on the initial and boundary data. Namely, the following holds.

THEOREM 2.9. *Let* (1.1) *be a system of Temple class with all characteristic fields genuinely nonlinear, and assume that the strict hyperbolicity condition* (SH) *holds. Then, there exists a continuous map*

$$(t, \overline{u}, \widetilde{u}_a, \widetilde{u}_b) \mapsto E_t(\overline{u}, \widetilde{u}_a, \widetilde{u}_b), \quad t \geq 0,\ (\overline{u}, \widetilde{u}_a, \widetilde{u}_b) \in \mathcal{D}, \tag{2.34}$$

and some constant $C > 0$ depending only on the system (1.1) *and on the domain Γ, so that, for every fixed $0 < \delta < (b-a)/2$ and for all $\mathbf{p}_1 \doteq (\overline{u}, \widetilde{u}_a, \widetilde{u}_b)$, $\mathbf{p}_2 \doteq (\overline{v}, \widetilde{v}_a, \widetilde{v}_b) \in \mathcal{D}$, letting $L_t \doteq L_t(\delta) = C(1 + \log(t/\delta))$, there holds*

$$\begin{aligned} &\|E_t\mathbf{p}_1 - E_t\mathbf{p}_2\|_{\mathbf{L}^1([a+\delta, b-\delta])} \\ &\quad \leq L_t \cdot \Big\{ \|\overline{u} - \overline{v}\|_{\mathbf{L}^1([a,b])} + \|\widetilde{u}_a - \widetilde{v}_a\|_{\mathbf{L}^1([0,t])} + \|\widetilde{u}_b - \widetilde{v}_b\|_{\mathbf{L}^1([0,t])} \Big\} \end{aligned} \tag{2.35}$$

for all $t \geq \delta$. Moreover, the map $(t,x) \mapsto E_t(\overline{u}, \widetilde{u}_a, \widetilde{u}_b)(x)$ yields an entropy weak solution (in the sense of Definition 2.2*) to the initial-boundary value problem* (1.1)–(1.4) *on Ω that admits strong $\mathbf{L}^1$ traces at the boundaries $x = a$ and $x = b$, i.e., there exist two measurable maps $\psi_a, \psi_b : \mathbb{R}^+ \mapsto U$ such that*

$$\begin{aligned} \lim_{x \to a^+} \int_0^\tau |E_t(\overline{u}, \widetilde{u}_a, \widetilde{u}_b)(x) - \psi_a(t)|\, dt = 0, \\ \lim_{x \to b^-} \int_0^\tau |E_t(\overline{u}, \widetilde{u}_a, \widetilde{u}_b)(x) - \psi_b(t)|\, dt = 0 \end{aligned} \tag{2.36}$$

$\forall \tau \geq 0$.

The proof of Theorem 2.9 can be obtained with arguments entirely similar to those used to establish [3, Theorem 2.1], where a continuous flow of solutions to (1.1) is constructed in the case of a mixed problem on the quarter of plane $\{(t,x) \in \mathbb{R}^2;\ t \geq 0,\ x \geq 0\}$, with a single boundary at $x = 0$.

Concerning uniqueness, with the same arguments in [3] one obtains the following result which is the extension of [3, Theorem 2.2] to the present case of a domain Ω with two boundaries at $x = a$ and at $x = b$.

THEOREM 2.10. *Let* (1.1) *be a system of Temple class satisfying the same assumptions as in Theorem* 2.9. *Let $u = u(t,x)$ be an entropy weak solution to the mixed problem* (1.1)–(1.4) *on the region $\Omega_T \doteq [0,T] \times [a,b]$ (in the sense of Definition* 2.2*). Assume that the following conditions hold.*

(i) *The map $(t,x) \to (u(t,\cdot), u(\cdot,x))$ takes values within the domain*

$$\mathcal{D}_T \doteq \{(\overline{u}, \widetilde{u}_a, \widetilde{u}_b);\ \overline{u} \in \mathbf{L}^\infty([a,b],\Gamma),\ \widetilde{u}_a, \widetilde{u}_b \in \mathbf{L}^\infty([0,T],\Gamma)\}. \tag{2.37}$$

(ii) *There holds*

$$\operatorname*{ess\,sup}_{t \to 0^+} \int_a^b |u(t,x) - \overline{u}(x)|\, dx = 0. \tag{2.38}$$

(iii) *There holds*

$$\operatorname*{ess\,sup}_{x\to a^+}\int_0^T |w_i(u(t,x))-w_i(\widetilde{u}_a(t))|\,dt=0 \quad \forall i=p+1,\dots,n, \tag{2.39}$$

$$\operatorname*{ess\,sup}_{x\to b^-}\int_0^T |w_i(u(t,x))-w_i(\widetilde{u}_b(t))|\,dt=0 \quad \forall i=1,\dots,p. \tag{2.40}$$

Then, u coincides with the corresponding trajectory of the flow map E_t provided by Theorem 2.9*, namely one has*

$$u(t,\cdot)=E_t(\overline{u},\widetilde{u}_a,\widetilde{u}_b)(\cdot) \quad \forall 0\le t\le T. \tag{2.41}$$

The next result shows that the conditions (2.38)–(2.40) are certainly satisfied by entropy weak solutions to the mixed problem (1.1)–(1.4) obtained as the limit of front tracking approximations.

THEOREM 2.11. *Let* (1.1) *be a system of Temple class satisfying the same assumptions as in Theorem* 2.9*. Consider a sequence $u^\nu(t,\cdot):[a,b]\mapsto\Gamma^\nu$ of wave-front tracking approximate solutions of the mixed problem for* (1.1) *(constructed with the above algorithm) that converges in $\mathbf{L}^1$, as $\nu\to\infty$, to some function $u(t,\cdot):[a,b]\mapsto\Gamma$, for every $t\in[0,T]$, and assume that the corresponding sequences of boundary data $\widetilde{u}_a^\nu$, $\widetilde{u}_b^\nu$ converge in $\mathbf{L}^1$ to $\widetilde{u}_a\doteq u(\cdot,a),\widetilde{u}_b\doteq u(\cdot,b)$. Then, there exist the right limit at $x=a$ and the left limit at $x=b$ of the map $x\to u(t,x)$ for every $t\in[0,T]$, and the right limit at $t=0$ of the map $t\to u(t,x)$ for every $x\in[a,b]$. Moreover, there is a countable set $\mathcal{N}\subset\mathbb{R}$ such that $u(t,a)=u(t,a+),u(t,b)=u(t,b-)$ for all $t\in[0,T]\setminus\mathcal{N}$, and $u(0,x)=u(0+,x)$ for all $x\in[a,b]\setminus\mathcal{N}$, and setting $\overline{u}\doteq u(0,\cdot)$, there holds* (2.41)*.*

Remark 2.12. It was shown in [3, Lemma 2.1] that an alternative way to prove the essential limits (2.39)–(2.40) is to employ the distributional entropy inequalities associated with the "boundary entropy pairs" for (1.1), introduced by Chen and Frid in [14, 15].

In order to prove Theorem 2.11, we will show in the next section that, for Temple systems, solutions of the mixed problem (1.1)–(1.4) with possibly unbounded variation enjoy the same regularity property (of being continuous outside a countable number of Lipschitz curves) possessed by solutions with small total variation of a general system, thus extending the regularity results obtained under the smallness assumption of the total variation by DiPerna [18] and Liu [23] (for solutions constructed by the Glimm scheme) and by Bressan and LeFloch [13] (for solutions generated by a front tracking algorithm).

PROPOSITION 2.13. *In the same setting as Theorem* 2.11*, consider a sequence $u^\nu(t,\cdot):[a,b]\mapsto\Gamma^\nu$ of wave-front tracking approximate solutions of the mixed problem for* (1.1) *(constructed with the above algorithm) that converges in $\mathbf{L}^1$, as $\nu\to\infty$, to some function $u(t,\cdot):[a,b]\mapsto\Gamma$, for every $t\in[0,T]$. Then, there exist a countable set of interaction points $\Theta\doteq\{(\tau_l,x_l);\ l\in\mathbb{N}\}\subset\Omega_T\doteq[0,T]\times[a,b]$, and a countable family of Lipschitz continuous shock curves $\Upsilon\doteq\{x=y_m(t);\ t\in]r_m,s_m[,\ m\in\mathbb{N}\}$, such that the following hold.*

(i) *For each $m\in\mathbb{N}$, and for any $\tau\in]r_m,s_m[$ with $(\tau,y_m(\tau))\notin\Theta$, there exist the derivative $\dot{y}_m(\tau)$ and the left and right limits*

$$\lim_{(s,y)\to(\tau,y_m(\tau)),\,y<y_m(\tau)} u(s,y)\doteq u^-, \qquad \lim_{(s,y)\to(\tau,y_m(\tau)),\,y>y_m(\tau)} u(s,y)\doteq u^+. \tag{2.42}$$

Moreover, these limits satisfy the Rankine–Hugoniot relations

$$\dot{y}_m(\tau)\cdot(u^+-u^-)=f(u^+)-f(u^-) \tag{2.43}$$

and for some $i\in\{1,\dots,n\}$ there hold the Lax entropy inequalities

$$\lambda_i(u^+)<\dot{y}_m(t)<\lambda_i(u^-). \tag{2.44}$$

(ii) *The map u is continuous outside the set $\Theta\cup\Upsilon$.*

3. Preliminary results. In this section we first provide some estimates on the distance between two rarefaction fronts of a front tracking solution (constructed by the algorithm described in section 2.4) similar to [12, Lemma 4], [8, Proposition 4.5]. We next show how to approximate the profile $u(t,\cdot)$ of a solution of the mixed problem (1.1)–(1.4), with a function taking values in the discrete set Γ^ν defined at (2.25), which enjoys the same type of estimates on the positive waves as $u(t,\cdot)$. We conclude the section establishing the regularity result stated in Proposition 2.13 on the global structure of solutions to the mixed problem for (1.1), which in turn yields Theorem 2.11.

LEMMA 3.1. *There exists some constant $C_1>0$ depending only on the system* (1.1) *such that the following holds. Consider a front tracking solution $u(t,x)$ with values in Γ^ν, constructed by the algorithm of section* 2.4 *on the region $[\tau,\tau']\times[a,b]$. Then, given any two adjacent rarefaction fronts of u located at $x(t)\le y(t)$, $t\in[\tau,\tau']$, and belonging to the same family, there holds*

$$|y(\tau')-x(\tau')|\le|y(\tau)-x(\tau)|+C_1(\tau'-\tau)2^{-\nu}. \tag{3.1}$$

Proof. Consider two adjacent rarefaction fronts of the kth family $x(t)\le y(t)$, $t\in[\tau,\tau']$, and let $\tau_1<\cdots<\tau_N$ be the interaction times of $x(t)$ in the interval $[\tau,\tau']$. Set $\tau_0\doteq\tau$, $\tau_{N+1}\doteq\tau'$, and fix $\alpha\in\{0,\dots,N\}$. Let $t\to z(t;s,x)$ be the characteristic curve of the kth family starting at (s,x), i.e., the solution to the ODE

$$\dot{z}=\lambda_k(u(t,z)),\qquad z(s;s,x)=x.$$

Notice that, although the above ODE has a discontinuous right-hand side (because of the discontinuities in the front tracking solution u), its solution $z(\cdot;s,x)$ is unique and depends Lipschitz continuously on the initial data x since it crosses only a finite number of jumps (see [10]). Choose $t_0<t_1<\tau_{\alpha+1}$ so that the characteristic curve $z(\cdot;t_0,x(t_0))$ does not cross any wave-front of the other families in the interval $[t_0,t_1]$, and then, by induction, define a sequence of times $\{t_i\}_{i\in\mathbb{Z}}\subset]\tau_\alpha,\tau_{\alpha+1}[$ so that

$$\begin{gathered}\tau_\alpha<t_{-i-1}<t_{-i}\le t_0\le t_i<t_{i+1}<\tau_{\alpha+1},\quad i\in\mathbb{N},\\ \lim_{i\to-\infty}t_i=\tau_\alpha,\qquad\lim_{i\to+\infty}t_i=\tau_{\alpha+1},\end{gathered} \tag{3.2}$$

with the properties that the characteristic curve of the kth family starting at $(t_i,x(t_i))$, does not cross any wave-front of the other families in the interval $[t_i,t_{i+1}]$, for each $i\in\mathbb{Z}$. Thus, setting

$$u_i^+\doteq u(t_i,x(t_i)+),\qquad u_i^-\doteq u(t_i,x(t_i)-)$$

and observing that, by construction, one has $|w(u_i^+)-w(u_i^-)|<2^{-\nu}$, we derive

$$\begin{aligned}|z(t_{i+1};t_i,x(t_i))-x(t_{i+1})|&\le(t_{i+1}-t_i)\cdot|\lambda_k(u_i^+)-\lambda_k(u_i^+,u_i^-)|\\&\le c\cdot(t_{i+1}-t_i)\cdot|w(u_i^+)-w(u_i^-)|\\&\le c\cdot(t_{i+1}-t_i)\cdot2^{-\nu}\end{aligned} \tag{3.3}$$

for some constant $c > 0$ depending only on the system. Relying on (3.3), and since $z(\tau'; t_{i+1}, x)$ depends Lipschitz continuously on the initial data x, we deduce that there exists some other constant $c' > 0$, depending only on the system and on the set Γ, so that there holds

$$\begin{aligned} |z(\tau'; t_i, x(t_i)) - z(\tau'; t_{i+1}, x(t_{i+1}))| &\leq c' \cdot |z(t_{i+1}; t_i, x(t_i)) - x(t_{i+1})| \\ &\leq c' \cdot c \cdot (t_{i+1} - t_i) \cdot 2^{-\nu} \end{aligned} \tag{3.4}$$

for any $i \in \mathbb{Z}$. Thus, by (3.2) and thanks to (3.4), we obtain

$$\begin{aligned} |z(\tau'; \tau_\alpha, x(\tau_\alpha)) - z(\tau'; \tau_{\alpha+1}, x(\tau_\alpha))| &\leq \sum_{i \in \mathbb{Z}} |z(\tau'; t_i, x(t_i)) - z(\tau'; t_{i+1}, x(t_{i+1}))| \\ &\leq c' \cdot c \cdot (\tau_{\alpha+1} - \tau_\alpha) \cdot 2^{-\nu}. \end{aligned} \tag{3.5}$$

Repeating this computation for every interval $]\tau_\alpha, \tau_{\alpha+1}[$, $\alpha \in \{0, \dots, N\}$, we get

$$\begin{aligned} |z(\tau'; \tau, x(\tau)) - x(\tau')| &\leq \sum_{\alpha=0}^{N} |z(\tau'; \tau_\alpha, x(\tau_\alpha)) - z(\tau'; \tau_{\alpha+1}, x(\tau_\alpha))| \\ &\leq c' \cdot c \cdot (\tau' - \tau) \cdot 2^{-\nu}. \end{aligned} \tag{3.6}$$

Clearly, one obtains the same type of estimate as (3.6) for the other rarefaction front $y(t)$, i.e., there holds

$$|z(\tau'; \tau, y(\tau)) - y(\tau')| \leq c' \cdot c \cdot (\tau' - \tau) \cdot 2^{-\nu}. \tag{3.7}$$

On the other hand, by (2.3), we have

$$|z(\tau'; \tau, x(\tau)) - z(\tau'; \tau, y(\tau))| \leq |x(\tau) - y(\tau)| + 2\lambda^{\max} \cdot (\tau' - \tau). \tag{3.8}$$

Thus, (3.6)–(3.8) together yield (3.1), concluding the proof. □

In the following, in connection with any (right continuous) piecewise constant map $\psi : [a, b] \mapsto 2^{-\nu}\mathbb{Z}$, we will let $\pi(\psi) = \{x_0 = a < x_1 < \cdots < x_{\overline{\ell}} = b\}$ denote the partition of $[a, b]$ induced by ψ, in the sense that $\psi(x)$ is constant on every interval $[x_\ell, x_{\ell+1}[$, $0 \leq \ell < \overline{\ell}$. Then, given $\rho > 0$, for any $\nu \geq 1$, consider the set of piecewise constant maps

$$K^\rho_\nu \doteq \left\{ \varphi : [a, b] \mapsto \Gamma^\nu; \quad \begin{aligned} &\frac{w_i(\varphi(x_k)) - w_i(\varphi(x_h))}{x_k - x_h} \leq \frac{5\rho}{x_h - a} \begin{cases} \text{for} & a < x_h < x_k < b, \\ & x_h, x_k \in \pi(w_i \circ \varphi), \\ \text{if } i \in \{p+1, \dots, n\} \end{cases} \\ &\frac{w_i(\varphi(x_k)) - w_i(\varphi(x_h))}{x_k - x_h} \leq \frac{5\rho}{b - x_k} \begin{cases} \text{for} & a < x_h < x_k < b, \\ & x_h, x_k \in \pi(w_i \circ \varphi), \\ \text{if } i \in \{1, \dots, p\} \end{cases} \end{aligned} \right\}. \tag{3.9}$$

The next lemma shows that we can approximate in $\mathbf{L}^1$ any map $\varphi \in K^\rho$ with a piecewise constant function $\varphi_\nu \in K^\rho_\nu$.

LEMMA 3.2. *For any given $\varphi \in K^\rho$, there exists a sequence of right continuous maps $\varphi_\nu \in K^\rho_\nu$, $\nu \geq 1$, such that*

(a) *for every $i \in \{1, \dots, n\}$, and for any $x_h \in \pi(w_i \circ \varphi_\nu)$, there holds*

$$w_i(\varphi_\nu(x_{h+1})) > w_i(\varphi_\nu(x_h)) \Longrightarrow w_i(\varphi(x_{h+1})) = w_i(\varphi(x_h)) + 2^{-\nu}; \tag{3.10}$$

(b) *there holds*

$$\varphi_\nu \to \varphi \qquad \text{in } \mathbf{L}^1([a,b]). \tag{3.11}$$

Proof. (1) First observe that, by Remark 2.5, any map $x \mapsto w_i(\varphi(x))$, $i \in \{1,\dots,n\}$, has finite total variation on $[a+\varepsilon, b-\varepsilon]$, $\varepsilon > 0$. Hence, we may assume that $w_i(\varphi(\cdot))$ admits left and right limits in any point $x \in]a,b[$ and that $w_i(\varphi(x)) = w_i(\varphi(x^+)) \doteq \lim_{\xi\to x^+} w_i(\varphi(\xi))$ for all $i \in \{1,\dots,n\}$. Let $\{y_{i,m};\ m \in \mathbb{N}\}$ be the countable set of discontinuities of $w_i(\varphi(\cdot))$, $i \in \{1,\dots,n\}$. Then, we can find a partition $\xi^1_{i,m} = y_{i,m} < \xi^2_{i,m} < \cdots < \xi^{\ell_{i,m}}_{i,m} = y_{i,m'}$ of each interval $[y_{i,m}, y_{i,m'}[$ where $x \mapsto w_i(\varphi(x))$ is continuous, so that

(i) for every $1 < \ell < \ell_{i,m}$ there holds

$$w_i(\varphi(\xi^\ell_{i,m})) \in 2^{-\nu}\mathbb{Z}; \tag{3.12}$$

(ii) for every $1 \le \ell < \ell_{i,m}$ one has

$$|w_i(\varphi(x)) - w_i(\varphi(\xi^\ell_{i,m}))| \le 2^{-\nu} \quad \forall x \in [\xi^\ell_{i,m}, \xi^{\ell+1}_{i,m}[. \tag{3.13}$$

Notice that the Oleinik-type conditions stated in the definition of K^ρ imply that, at any discontinuity point $y_{i,m}$ of $w_i(\varphi(\cdot))$, one has

$$\lim_{\xi\to y^-_{i,m}} w_i(\varphi(\xi)) > w_i(\varphi(y_{i,m})). \tag{3.14}$$

(2) Let $\varphi_\nu : [a,b] \mapsto \Gamma^\nu$ be the piecewise constant, right continuous map defined by setting, for every $i \in \{1,\dots,n\}$ and for any interval $[y_{i,m}, y_{i,m'}[$, where $w_i(\varphi(\cdot))$ is continuous,

$$w_i(\varphi_\nu(x)) \doteq \begin{cases} 2^{-\nu}\lfloor 2^\nu w_i(\varphi(\xi^1_{i,m}))\rfloor & \text{if } \begin{cases} x \in [\xi^1_{i,m}, \xi^2_{i,m}[, \text{ and} \\ w_i(\varphi_\nu(\xi^1_{i,m})) \\ \le 2^{-\nu}(\lfloor 2^\nu w_i(\varphi(\xi^1_{i,m}))\rfloor + 2^{-1}), \end{cases} \\ 2^{-\nu}(\lfloor 2^\nu w_i(\varphi(\xi^1_{i,m}))\rfloor + 1) & \text{if } \begin{cases} x \in [\xi^1_{i,m}, \xi^2_{i,m}[, \text{ and} \\ w_i(\varphi_\nu(\xi^1_{i,m})) \\ > 2^{-\nu}(\lfloor 2^\nu w_i(\varphi(\xi^1_{i,m}))\rfloor + 2^{-1}), \end{cases} \\ w_i(\varphi(\xi^\ell_{i,m})) & \text{if} \quad x \in [\xi^\ell_{i,m}, \xi^{\ell+1}_{i,m}[, \quad 1 < \ell < \ell_{i,m}, \end{cases} \tag{3.15}$$

where $\lfloor\cdot\rfloor$ denotes the integer part. Notice that, by construction and because of (3.12)–(3.14), the map $\varphi_\nu : [a,b] \mapsto \Gamma^\nu$ enjoys the following property:

$$\left.\begin{array}{l} w_i(\varphi_\nu(x_k)) > w_i(\varphi_\nu(x_h)) \\ x_h < x_k \in \pi(w_i \circ \varphi_\nu) \end{array}\right\} \Longrightarrow w_i(\varphi(x_k)) > w_i(\varphi(x_h)) + 2^{-(\nu+1)}. \tag{3.16}$$

Therefore, since $\varphi \in K^\rho$, relying on (3.13), (3.16), we deduce that for every $w_i(\varphi_\nu(\cdot))$, $i \in \{p+1,\dots,n\}$, and for any $x_h < x_k \in \pi(w_i \circ \varphi_\nu)$ such that $w_i(\varphi_\nu(x_k)) > w_i(\varphi_\nu(x_h))$, there holds

$$\begin{aligned} \frac{w_i(\varphi_\nu(x_k)) - w_i(\varphi_\nu(x_h))}{x_k - x_h} &\le \frac{w_i(\varphi(x_k)) - w_i(\varphi(x_h)) + 2^{-(\nu-1)}}{x_k - x_h} \\ &\le \frac{5(w_i(\varphi(x_k)) - w_i(\varphi(x_h)))}{x_k - x_h} \\ &\le \frac{5\rho}{x_h - a}. \end{aligned} \tag{3.17}$$

Clearly, with the same computations we can show that, for every $w_i(\varphi_\nu(\cdot))$, $i \in \{1,\dots,p\}$, and for any $x_h < x_k \in \pi(w_i \circ \varphi_\nu)$, there holds

$$\frac{w_i(\varphi_\nu(x_k)) - w_i(\varphi_\nu(x_h))}{x_k - x_h} \le \frac{5\rho}{b - x_k}. \tag{3.18}$$

The estimates (3.17)–(3.18), together, imply that $\varphi_\nu \in K^\rho_\nu$, while (3.13) yields (3.11). On the other hand, observe that, by construction and because of (3.14), the map φ_ν satisfies condition (3.10), which completes the proof of the lemma. □

We now provide a further estimate on the distance between two rarefaction fronts of a front tracking solution that, at a fixed time τ, attains a profile belonging to the set (3.9).

LEMMA 3.3. *Consider a front tracking solution $u(t,x)$ with values in Γ^ν, $\nu \ge 1$, constructed by the algorithm of section* 2.4 *on the region $[\tau,\tau'] \times [a,b]$. Assume that $u(\tau',\cdot)$ is right-continuous, verifies condition* (a) *of Lemma* 3.2*, and satisfies*

$$u(\tau',\cdot) \in K^{\rho'}_\nu, \qquad \rho' \doteq \frac{\lambda^{\min}}{6C_1}, \tag{3.19}$$

where $\lambda^{\min}$, C_1 are the minimum speed in (2.3) *and the constant of Lemma* 3.1*. Then, given any two adjacent rarefaction fronts of u located at $x(t) \le y(t)$, $t \in [\tau,\tau']$, and belonging to the same family, there holds*

$$x(\tau) < y(\tau). \tag{3.20}$$

Proof. To fix the ideas, assume that $x(t) \le y(t)$ are the locations of two adjacent rarefaction fronts of the $k \in \{p+1,\dots,n\}$th family and hence, by (2.2), have positive speeds. Observe that, by condition (a) of Lemma 3.2, one has

$$w_k(u(\tau', y(\tau'))) - w_k(u(\tau', x(\tau'))) = 2^{-\nu}. \tag{3.21}$$

Moreover, since u is a front tracking solution constructed by the algorithm of section 2.4 on the region $[\tau,\tau'] \times [a,b]$, we can apply Lemma 3.1. Thus, using (2.3), (3.1), and (3.21), and recalling the definition (3.9) of $K^{\rho'}_\nu$, we deduce

$$\begin{aligned} y(\tau') - x(\tau') &\le y(\tau) - x(\tau) + C_1(\tau' - \tau)2^{-\nu} \\ &\le y(\tau) - x(\tau) + C_1 \frac{x(\tau') - x(\tau)}{\lambda^{\min}} \cdot (w_k(\varphi_\nu(y(\tau'))) - w_k(\varphi_\nu(x(\tau')))) \\ &\le y(\tau) - x(\tau) + C_1 \frac{5\rho'}{\lambda^{\min}} \cdot (y(\tau') - x(\tau')) \end{aligned}$$

which, because of (3.19), implies

$$y(\tau) - x(\tau) \ge \left(1 - C_1 \frac{5\rho'}{\lambda^{\min}}\right) \cdot (y(\tau') - x(\tau')) > 0,$$

proving (3.20). □

We next derive a regularity property enjoyed by general solutions of Temple systems with boundary variation defined as a limit of front tracking approximations, which allows us to establish Proposition 2.13. This is an extension of the regularity results obtained in [18, 23, 13] for the solution with small total variation of general systems. The arguments of the proof are quite similar to the corresponding result

in [13], but we will repeat some of them for completeness, referring to [13] (see also [9, Theorem 10.4]) for further details.

LEMMA 3.4. *Let* (1.1) *be a system of Temple class satisfying the same assumptions as in Theorem* 2.9. *Consider a sequence* $u^\nu(t,\cdot) : [c,d] \mapsto \Gamma^\nu$, $t \in [r,s]$, *of front tracking approximate solutions of the mixed problem for* (1.1) *(constructed by the algorithm of section* 2.4*) that converges in* $\mathbf{L}^1$, *as* $\nu \to \infty$, *to some function* $u(t,\cdot) : [c,d] \mapsto \Gamma$, *for every* $t \in [r,s] \subset \mathbb{R}^+$. *Assume that*

$$Tot.Var.(u^\nu(t,\cdot)) \leq M, \quad Tot.Var.(u^\nu(\cdot,x)) \leq M \quad \forall t,x,\nu, \tag{3.22}$$

for some constant $M > 0$, *here and throughout the following,* $Tot.Var.(w)$ *denotes the total variation of the function* w. *Then, there exist a countable set of interaction points* $\Theta \doteq \{(\tau_l, x_l);\ l \in \mathbb{N}\} \subset D \doteq [r,s] \times [c,d]$, *and a countable family of Lipschitz continuous shock curves* $\Upsilon \doteq \{x = y_m(t);\ t \in]r_m, s_m[,\ m \in \mathbb{N}\}$, *such that the following hold.*

(i) *For each* $m \in \mathbb{N}$, *and for any* $\tau \in]r_m, s_m[$ *with* $(\tau, y_m(\tau)) \notin \Theta$, *there exist the left and right limits* (2.42) *of* u *at* $(\tau, y_m(\tau))$ *and the shock speed* $\dot{y}_m(\tau)$. *Moreover, these limits satisfy the Rankine–Hugoniot relations* (2.43) *and the Lax entropy inequality* (2.44), *for some* $i \in \{1,\dots,n\}$.

(ii) *The map* u *is continuous outside the set* $\Theta \cup \Upsilon$.

Proof. 1. To establish (i) we need to recall some technical tools introduced in [13] (see also [9, Theorem 10.4]). For every front tracking solution u^ν, we define the *interaction and cancellation measure* μ^{IC}_ν that is a positive, purely atomic measure on D, concentrated on the set of points P where two or more wave-fronts of u^ν interact. Namely, if the incoming fronts at P have size $\sigma_1,\dots,\sigma_\ell$ (w.r.t. the Riemann coordinates) and belong to the families $i_1,\dots,i_\ell$, respectively, we set

$$\mu^{IC}_\nu(P) \doteq \sum_{\alpha,\beta} |\sigma_\alpha \sigma_\beta| + \sum_i \left(\sum_{\{i_\alpha;\, i_\alpha = i\}} |\sigma_\alpha| - \left| \sum_{\{i_\alpha;\, i_\alpha = i\}} \sigma_\alpha \right| \right). \tag{3.23}$$

Since μ^{IC}_ν have a uniformly bounded total mass, by possibly taking a subsequence we can assume the weak convergence

$$\mu^{IC}_\nu \rightharpoonup \mu^{IC} \tag{3.24}$$

for some positive, purely atomic measure μ^{IC} on D. Call Θ the countable set of atoms of μ^{IC}, i.e., set

$$\Theta \doteq \left\{P \in D;\ \mu^{IC}(P) > 0\right\}.$$

For every approximate solution u^ν taking values in Γ^ν, $\nu \geq 1$, and for any fixed $\varepsilon \geq 2^{-\nu}$, by an *$\varepsilon$-shock front of the ith family* in u^ν we mean a polygonal line in D, with nodes $(\tau_0, x_0), \dots, (\tau_N, x_N)$, having the following properties.

(I) The nodes (τ_h, x_h) are interaction points or lie on the boundary of D, and the sequence of times is increasing $\tau_0 < \tau_1 < \cdots < \tau_N$.

(II) Along each segment joining (τ_{h-1}, x_{h-1}) with (τ_h, x_h), the function u^ν has an i-shock with strength $|\sigma_h| \geq \varepsilon$.

(III) For $h < N$, if two (or more) incoming i-shocks of strength $\geq \varepsilon$ interact at the node (τ_h, x_h), then the shock coming from (τ_{h-1}, x_{h-1}) has the larger speed, i.e., is the one coming from the left.

An ε-shock front, which is maximal with respect to the set theoretical inclusion, will be called a *maximal ε-shock front*. Observe that, because of (III), two maximal ε-shock fronts of the same family either are disjoint or coincide. Moreover, by (3.22), the number of maximal ε-shock fronts that start at the boundary of D is uniformly bounded by $3M/\varepsilon$. On the other hand, the special geometric features of Temple class systems guarantee that no new shock front can arise in the interior of D. Indeed, the coinciding shock and rarefaction assumption together with the existence of Riemann invariants prevents the creation of shocks of other families than those of the incoming fronts at any interaction point. Therefore, for fixed $\varepsilon > 0$, and $i \in \{1, \dots, n\}$, the number of maximal ε-shock fronts of the ith family remains uniformly bounded by $M_\varepsilon \doteq 3M/\varepsilon$ in all u^ν, $\nu \geq 1$. Denote such curves by

$$y^\varepsilon_{\nu,m} : [t^{\varepsilon,-}_{\nu,m}, t^{\varepsilon,+}_{\nu,m}] \mapsto \mathbb{R}, \qquad m = 1, \dots, M_\varepsilon.$$

By possibly extracting a further subsequence, we can assume the convergence

$$y^\varepsilon_{\nu,m}(\cdot) \longrightarrow y^\varepsilon_m(\cdot), \qquad t^{\varepsilon,\pm}_{\nu,m} \longrightarrow t^{\varepsilon,\pm}_m, \qquad m = 1, \dots, M_\varepsilon,$$

for some Lipschitz continuous paths $y^\varepsilon_m : [t^{\varepsilon,-}_m, t^{\varepsilon,+}_m] \mapsto \mathbb{R}$, $m = 1, \dots, M_\varepsilon$. Repeating this construction in connection with a sequence $\varepsilon_k \to 0$, and taking the union of all the paths thus obtained, we find, for each characteristic family $i \in \{1, \dots, n\}$, a countable family of Lipschitz continuous curves $y_m : [t^-_m, t^+_m] \mapsto \mathbb{R}$, $m \in \mathbb{N}$. Call Υ the union of all such curves.

2. Consider now a point $P = (\tau, y_m(\tau)) \notin \Theta$ along a curve $y_m \in \Upsilon$ of a family $i \in \{1, \dots, n\}$. Notice that, by construction and because of (3.24), no curve in Υ can cross y_m at P. Moreover, by (3.22), the function $u(\tau, \cdot)$ has bounded variation, and hence there exist the limits

$$\lim_{x \to y_m(\tau)-} u(\tau, x) \doteq u^-, \qquad \lim_{x \to y_m(\tau)+} u(\tau, x) \doteq u^+. \tag{3.25}$$

We claim also that the limits (2.42) exist and thus coincide with those in (3.25). To this end observe that, by construction, there exists a sequence of shocks curves $y_{\nu,m}$ of the ith family converging to y_m, along which each approximate solution u^ν has a jump of strength $\geq \varepsilon^*$, for some $\varepsilon^* > 0$. Then, relying on the assumption

$$\mu^{IC}(\{P\}) = 0 \tag{3.26}$$

and letting $B(P, r)$ denote the ball centered at P with radius r, one can establish the limits

$$\lim_{r \to 0+} \limsup_{\nu \to +\infty} \left(\sup_{(t,x) \in B(P,r) x < y_{\nu,m}(t)} |u^\nu(t, x) - u^-| \right) = 0, \tag{3.27}$$

$$\lim_{r \to 0+} \limsup_{\nu \to +\infty} \left(\sup_{(t,x) \in B(P,r) x > y_{\nu,m}(t)} |u^\nu(t, x) - u^-| \right) = 0, \tag{3.28}$$

which clearly yield (2.42). Indeed, if, for example, (3.27) do not hold, by possibly taking a subsequence we would find $\varepsilon > 0$ and points $P_\nu \doteq (t_\nu, \xi_\nu) \to P$ on the left of $y_{\nu,m}$ such that

$$|u^\nu(t_\nu, \xi_\nu) - u^-| \geq \varepsilon \quad \forall \nu.$$

On the other hand, by the first limit in (3.25), and since $u^\nu(\tau,x)\to u(\tau,x)$ for a.e. $x\in[\alpha,\beta]$, we could also find points $Q_\nu\doteq(\tau,\xi'_\nu)\to P$ on the left of $y_{\nu,m}$ such that

$$u^\nu(\tau,\xi'_\nu)\to u^-,\quad \frac{|\xi_\nu-\xi'_\nu|}{|t_\nu-\tau|}>\lambda^{\max}\quad\forall\nu,$$

where $\lambda^{\max}$ denotes the maximum speed at (2.3). But then, for each solution u^ν, the segment $\overline{P_\nu Q_\nu}$ would be crossed by an amount of waves of strength $\geq\varepsilon$. Hence, by strict hyperbolicity and genuine nonlinearity, this would generate a uniformly positive amount of interaction and cancellation within an arbitrary small neighborhood of P (see [9, Theorem 10.4, Step 5]) which by the definition (3.23) and because of (3.24) contradicts the assumption (3.26).

To complete the proof of (i), observe that, by construction, the states $u^-_{\nu,m}(\tau)$, $u^+_{\nu,m}(\tau)$ to the left and right of the jump in u^ν at $y_{\nu,m}(\tau)$ satisfy the Rankine–Hugoniot conditions. Thus, relying on (3.27)–(3.28) and on the convergence $y_{\nu,m}\to y_\nu$, one deduces (2.43). The proof of (ii) can be established with the same type of arguments (see [9, Theorem 10.4, Step 8]). □

As an immediate consequence of Lemma 3.4, we derive Proposition 2.13, stated in section 2.4.

Proof of Proposition 2.13. Consider a sequence $u^\nu(t,\cdot):[a,b]\mapsto\Gamma^\nu$ of front tracking approximate solutions of the mixed problem for (1.1) on the region $\Omega_T\doteq[0,T]\times[a,b]$ that converges in $\mathbf{L}^1$, as $\nu\to\infty$, to some function $u(t,\cdot):[a,b]\mapsto\Gamma$ for every $t\in[0,T]$. Observe that by Theorem 2.9 one can find another sequence $\{v^\nu\}_{\nu\geq1}$ of approximate solutions of (1.1) on the region Ω_T, whose initial and boundary data have a number of shocks $N_\nu\leq\nu$ for each characteristic family, and such that

$$\|u^\nu(t,\cdot)-v^\nu(t,\cdot)\|_{\mathbf{L}^1([a,b])}\leq1/\nu\quad\forall t\in[1/\nu,T].$$

Then, thanks to the Oleinik estimates (2.31)–(2.32) and because all v^ν take values in the compact set (2.13), there will be, for every fixed $\varepsilon>0$, some constant $M_\varepsilon>0$ such that

$$\begin{aligned}\text{Tot.Var.}\{v^\nu(t,\cdot);\ [a+\varepsilon,b-\varepsilon]\}&\leq M_\varepsilon\quad\forall t\in[\varepsilon,T],\\ \text{Tot.Var.}\{v^\nu(\cdot,x);\ [\varepsilon,T]\}&\leq M_\varepsilon\quad\forall x\in[a+\varepsilon,b-\varepsilon]\end{aligned}\tag{3.29}$$

$\forall\nu\in\mathbb{N}$. Thus, writing Ω_T as the countable union

$$\Omega_T=\cup_k D_k,\quad D_k\doteq[1/k,T]\times[a+(1/k),b-(1/k)],$$

and applying Lemma 3.4 to each sequence of maps $v^\nu_k\doteq v^\nu\restriction_{D_k},\nu\geq1$, defined as the restriction of v^ν to the domain D_k, we clearly reach the conclusion of Proposition 2.13. □

We are now in position to establish Theorem 2.11, relying on Proposition 2.13 and Theorem 2.10.

Proof of Theorem 2.11. Let $u^\nu(t,\cdot):[a,b]\mapsto\Gamma^\nu$ be a sequence of front tracking approximate solutions of the mixed problem for (1.1) on the region $\Omega_T\doteq[0,T]\times[a,b]$ that converges in $\mathbf{L}^1$, as $\nu\to\infty$, to some function $u(t,\cdot):[a,b]\mapsto\Gamma$ for every $t\in[0,T]$. Since, by construction, each u^ν is a weak solution of (1.1) and because $u^\nu(0,\cdot)\to u(0,\cdot)=\overline{u}$, the limit function u also is a weak solution of the Cauchy problem (1.1)–(1.2) on the region Ω_T. Moreover, applying Proposition 2.13, we deduce that u admits at $t=0$ and at $x=a$, $x=b$ the left and right limits stated in Theorem 2.11. On

the other hand, by the same arguments used in the proof of Proposition 2.13, we may assume that the initial and boundary data of each approximate solution u^ν have at most $N_\nu \leq \nu$ shocks for every characteristic family. Then, letting $\nu \to \infty$ in (2.31)–(2.32), by the lower semicontinuity of the total variation we find that u satisfies the entropy conditions (2.7)–(2.10) on the decay of positive waves. It follows that u is an entropy weak solution of the mixed problem (1.1)–(1.4) according to Definition 2.2. Hence, observing that by construction the map $(t,x) \to (u(t,\cdot), u(\cdot,x))$ takes values within the domain $\mathcal{D}_T$ defined in (2.37), and applying Theorem 2.10, we deduce that (2.41) is verified. □

4. Proof of Theorems 2.4–2.7.

Proof of Theorem 2.4. We shall first prove that, for every fixed $\overline{\tau} > 0$, there exists some constant $\rho = \rho(\overline{\tau}) > 0$ so that (2.17) holds. Given $\widetilde{u}_a \in \mathcal{U}_\tau^\infty$, $\widetilde{u}_b \in \mathcal{U}_\tau^\infty$, $\tau \geq \overline{\tau}$, let $u = u(t,x)$ be an entropy weak solution of (1.1)–(1.4) on the region $[0,\tau] \times [a,b]$ according to Definition 2.2. Then, the Oleinik-type estimates (2.8) on the decay of positive waves imply that, for $i \in \{p+1,\dots,n\}$, $\tau \geq \overline{\tau}$, and for a.e. $a < x < y < b$, there holds

$$\begin{aligned} \frac{w_i(\tau,y) - w_i(\tau,x)}{y-x} &\leq C \cdot \left\{ \frac{y-x}{\tau} + \log\left(\frac{y-a}{x-a}\right) \right\} \\ &\leq (b-a)C \cdot \left\{ \frac{1}{\overline{\tau}} + \frac{1}{x-a} \right\} \\ &\leq \frac{C(b-a)((b-a)+\overline{\tau})}{\overline{\tau}} \cdot \frac{1}{x-a}. \end{aligned} \tag{4.1}$$

Clearly, with the same computations, relying on the Oleinik-type estimates (2.7), we deduce that, for $i \in \{1,\dots,p\}$, $\tau \geq \overline{\tau}$, and for a.e. $a < x < y < b$, there holds

$$\frac{w_i(\tau,y) - w_i(\tau,x)}{y-x} \leq \frac{C(b-a)((b-a)+\overline{\tau})}{\overline{\tau}} \cdot \frac{1}{b-y}. \tag{4.2}$$

Hence, taking

$$\rho \geq \frac{C(b-a)((b-a)+\overline{\tau})}{\overline{\tau}} \tag{4.3}$$

from (4.1)–(4.2), we derive $u(\tau,\cdot) \in K^\rho$, which proves (2.17).

Concerning the second statement of the theorem, we will show that, letting $\lambda^{\min}$ and ρ' be the minimum speed in (2.3) and the constant (3.19) of Lemma 3.1 and taking

$$T \doteq \frac{4(b-a)}{\lambda^{\min}}, \tag{4.4}$$

the relation (2.18) is verified, i.e., given $\varphi \in K^{\rho'}$ and $\tau > T$, there exist $\widetilde{u}_a \in \mathcal{U}_\tau^\infty$, $\widetilde{u}_b \in \mathcal{U}_\tau^\infty$, and a solution $u(t,x)$ of (1.1)–(1.4) on $[0,\tau] \times [a,b]$ (according to Definition 2.2), such that $u(\tau,\cdot) \equiv \varphi$. Notice that, by Remark 2.5, we may assume that $w_i(\varphi(x))$ admits left and right limits in any point $x \in]a,b[$ and that $w_i(\varphi(x)) = w_i(\varphi(x^+)) \doteq \lim_{\xi \to x^+} w_i(\varphi(\xi))$ for all $i \in \{1,\dots,n\}$. The proof is divided into two steps.

Step 1. *Backward construction of front tracking approximations.* Letting $\rho' > 0$ be the constant in (3.19), consider a sequence $\{\varphi_\nu\}_{\nu \geq 1}$ of (right continuous) piecewise constant maps in $K_\nu^{\rho'}$, satisfying the conditions (a) and (b) of Lemma 3.2, and take

a piecewise constant approximation $\overline{u}^\nu : [a,b] \mapsto \Gamma^\nu$ of the initial data $\overline{u}$, so that $\overline{u}^\nu \to \overline{u}$ in $\mathbf{L}^1$. Given $\tau > T$ (T being the time defined in (4.4)), for each $\nu \geq 1$, we will construct here a front tracking solution $u^\nu(t,x)$ of (1.1) on the region $[0,\tau]\times[a,b]$, with initial data $u^\nu(0,\cdot) = \overline{u}^\nu$, so that

$$u^\nu(\tau,\cdot) = \varphi_\nu. \tag{4.5}$$

This goal is accomplished by proving the following two lemmas.

LEMMA 4.1. *Let $T, \rho' > 0$ be the constants in* (4.4) *and* (3.19). *Then, for every (right continuous) $\varphi_\nu \in K_\nu^{\rho'}$, $\nu \geq 1$, satisfying condition* (a) *of Lemma* 3.2 *and for any $\tau > T$, there exists a front tracking solution $u^\nu(t,x)$ of* (1.1) *on the region $[(3/4)T,\tau]\times[a,b]$, with boundary data $\widetilde{u}_a^\nu \doteq u^\nu(\cdot,a)$, $\widetilde{u}_b^\nu \doteq u^\nu(\cdot,b) \in \mathbf{L}^\infty([(3/4)T,\tau],\Gamma^\nu)$, so that*

$$u^\nu((3/4)T,x) \equiv \omega, \quad u^\nu(\tau,x) = \varphi_\nu(x) \quad \forall x \in [a,b] \tag{4.6}$$

for some constant state $\omega \in \Gamma^\nu$.

Proof. Given $\tau > T$ and $\varphi_\nu \in K_\nu^{\rho'}$, $\nu \geq 1$, satisfying condition (a) of Lemma 3.2, we will use the algorithm described in section 2.4 to construct backward in time a front tracking solution that takes value φ_ν at time τ. To this end, we first observe that according to the algorithm of section 2.4, we can always construct the backward solution of a Riemann problem with terminal data

$$u(t,x) = \begin{cases} u^L & \text{if } x < \xi, \\ u^R & \text{if } x > \xi \end{cases} \tag{4.7}$$

if the terminal states $u^L, u^R \in \Gamma^\nu$ have Riemann coordinates

$$w(u^L) \doteq w^L = (w_1^L, \ldots, w_n^L), \qquad w(u^R) \doteq w^R = (w_1^R, \ldots, w_n^R)$$

that satisfy

$$w_i^L < w_i^R \Longrightarrow w_i^R = w_i^L + 2^{-\nu} \quad \forall i. \tag{4.8}$$

Indeed, if we consider the intermediate states

$$z^i = \begin{cases} u^L & \text{if } i = 0, \\ u(w_1^L, \ldots, w_{n-i}^L, w_{n-i+1}^R, \ldots, w_n^R) & \text{if } 0 < i < n, \\ u^R & \text{if } i = n, \end{cases} \tag{4.9}$$

we realize that, because of (4.8), the solution of every Riemann problem with initial states (z^{i-1}, z^i) (defined as in section 2.4) contains only a single front. Thus, we can construct the solution to the Riemann problem with terminal data (4.7) in a backward neighborhood of (t,ξ) by piecing together the solutions to the simple Riemann problems (z^{i-1}, z^i), $i = 1, \ldots, n$.

A front tracking solution u^ν can now be constructed backward in time starting at $t = \tau$ and piecing together the backward solutions of the Riemann problems determined by the jumps in φ_ν. The resulting piecewise constant function $u^\nu(\tau-,\cdot)$ is then prolonged for $t < \tau$ tracing backward the incoming fronts at $t = \tau$, up to the first time $\tau_1 < \tau$ at which two or more discontinuities cross in the interior of Ω. Observe that, since u^ν is a front tracking solution constructed by the algorithm of section 2.4 on the region $[\tau_1,\tau]\times[a,b]$, we can apply Lemma 3.3. Hence, it follows that the left and

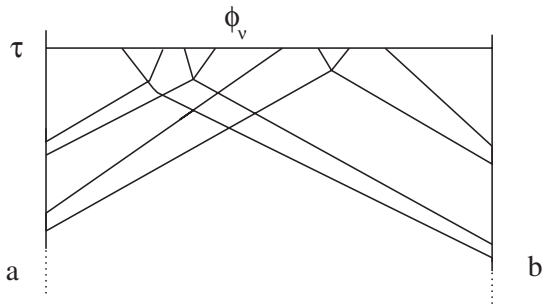

FIG. 1.

right states of the jumps occurring in $u^\nu(\tau_1,\cdot)$ satisfy condition (4.8), because (3.20) guarantees that two (or more) adjacent rarefaction fronts of the same family cannot cross at time τ_1. We then solve backward the resulting Riemann problems applying again the above procedure. This determines the solution $u^\nu(t,\cdot)$ until the time $\tau_2 < \tau_1$ at which another intersection between its fronts takes place in the interior of Ω, and so on (see Figure 1).

With this construction we define a front tracking solution $u^\nu(t,x)$ on the whole region $[(3/4)T,\tau]\times[a,b]$ that verifies the first equality in (4.6) and corresponds to the boundary data $\widetilde{u}^\nu_a \doteq u^\nu(\cdot,a)$, $\widetilde{u}^\nu_b \doteq u^\nu(\cdot,b) \in \mathbf{L}^\infty([(3/4)T,\tau],\Gamma^\nu)$. Clearly, the total number of wave-fronts in $u^\nu(t,\cdot)$ decreases, as $t \downarrow (3/4)T$, whenever a (backward) front crosses the boundary points $x=a$, $x=b$. Since (2.3) implies that the maximum time taken by fronts of u^ν to cross the interval $[a,b]$ is $(b-a)/\lambda^{\min}$, the definition (4.4) of T guarantees that all the (backward) fronts of u^ν will hit the boundaries $x=a$, $x=b$ within some time $\tau' \in](3/4)T,\tau[$, which shows also that the second equality in (4.6) is verified, thus completing the proof. □

LEMMA 4.2. *Let $T>0$ be the constant in* (4.4). *Then, for any piecewise constant function $\overline{u}^\nu \in \mathbf{L}^\infty([a,b],\Gamma^\nu)$ and for every state $\omega\in\Gamma^\nu$, there exists a front tracking solution $u^\nu(t,x)$ of* (1.1) *on the region $[0,(3/4)T]\times[a,b]$, corresponding to some boundary data $\widetilde{u}^\nu_a,\widetilde{u}^\nu_b \in \mathbf{L}^\infty([0,(3/4)T],\Gamma^\nu)$, so that*

$$u^\nu(0,x)=\overline{u}^\nu(x), \quad u^\nu((3/4)T,x)\equiv\omega \quad \forall x\in[a,b]. \tag{4.10}$$

Proof. The approximate solution u^ν is constructed as follows. By Remark 2.8, for $t\in[0,T/4]$, we can define $u^\nu(t,x)$ as the restriction to the region $[0,T/4]\times[a,b]$ of the front tracking solution to the Cauchy problem for (1.1), with initial data

$$\overline{u}(x)=\begin{cases}\overline{u}^\nu(a+) & \text{if } x<a,\\ \overline{u}^\nu(x) & \text{if } a\le x\le b,\\ \overline{u}^\nu(b-) & \text{if } x>b\end{cases}$$

(constructed as in [12] with the same type of algorithm described in section 2.4). Observe that, since u^ν contains only fronts originated at the points of the segment $\{(0,x);\ x\in[a,b]\}$, because of (2.3), (4.4), these wave-fronts cross the whole interval $[a,b]$ and exit from the boundaries $x=a$, $x=b$ before time $T/4$ (see Figure 2). Hence, there will be some state $\omega'\in\Gamma^\nu$ such that

$$u^\nu(T/4,x)\equiv\omega' \quad \forall x\in[a,b]. \tag{4.11}$$

Thus, introducing the intermediate state

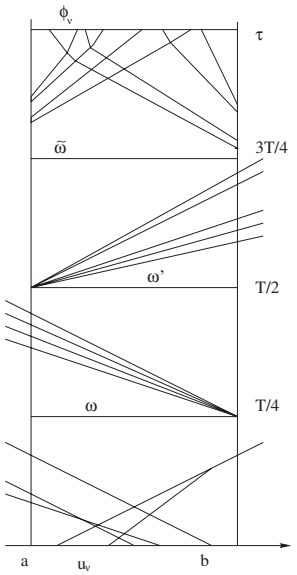

FIG. 2.

$$\widetilde{\omega} \doteq (\omega_1, \dots, \omega_p, \omega'_{p+1}, \dots, \omega'_n)$$

between ω' and ω, we will define $u^\nu(t,x)$, for $t \in [T/4, T/2]$, as the restriction to the region $[T/4, T/2] \times [a,b]$ of the approximate solution to the Riemann problem for (1.1), with initial data

$$u^\nu(T/4, x) = \begin{cases} u(\omega') & \text{if } x < b, \\ u(\widetilde{\omega}) & \text{if } x > b, \end{cases} \tag{4.12}$$

while, for $t \in [T/2, (3/4)T]$, we will let $u^\nu(t,x)$ be the restriction to the region $[T/2, (3/4)T] \times [a,b]$ of the approximate solution to the Riemann problem for (1.1), with initial data

$$u^\nu(T/2, x) = \begin{cases} u(\omega) & \text{if } x < a, \\ u(\widetilde{\omega}) & \text{if } x > a. \end{cases} \tag{4.13}$$

By the definition of $\widetilde{\omega}$, and because of (2.3), (4.4), on $[T/4, T/2]$ the solution of the Riemann problems with initial data (4.12) contains only wave-fronts originated at the point $(T/4, b)$ that cross the whole interval $[a,b]$ and exit from the boundary $x = a$ before time $T/2$. Similarly, still by (2.3), (4.4), for $t \in [T/2, (3/4)T]$ the solution of the Riemann problem with initial data (4.13) contains only wave-fronts originated at $(T/2, a)$ that cross the whole interval $[a,b]$ and exit from the boundary $x = b$ before time $(3/4)T$ (see Figure 2). Hence, $u^\nu(t,x)$ is a front tracking solution defined on the whole region $[0, (3/4)T] \times [a,b]$ that corresponds to the boundary data $\widetilde{u}^\nu_a \doteq u^\nu(\cdot, a)$, $\widetilde{u}^\nu_b \doteq u^\nu(\cdot, b) \in \mathbf{L}^\infty([0, (3/4)T], \Gamma^\nu)$, and verifies the conditions (4.10). □

Step 2. *Convergence of the approximate solutions.* By Step 1, for a given $\varphi \in K^{\rho'}$ (with ρ' as in (3.19)), we have found a sequence of initial data $\overline{u}^\nu$ and boundary data $\widetilde{u}^\nu_a, \widetilde{u}^\nu_b \in \mathcal{U}^\infty_\tau$, so that, letting $u^\nu(\tau, \cdot) \doteq E^\nu_\tau(\overline{u}^\nu, \widetilde{u}^\nu_a, \widetilde{u}^\nu_b)$ be the corresponding front tracking solution, there holds

$$\overline{u}^\nu \to \overline{u}, \qquad u^\nu(\tau, \cdot) \to \varphi \quad \text{in } \mathbf{L}^1([a,b]). \tag{4.14}$$

By the same arguments used in the proof of Proposition 2.13, we may assume that the initial and boundary data of each approximate solution u^ν have at most $N_\nu \leq \nu$ shocks for every characteristic family. Then, thanks to the Oleinik-type estimates (2.31) and because u^ν are uniformly bounded since they take values in the compact set (2.13), for every fixed $\varepsilon > 0$, there will be some constant $C_\varepsilon > 0$ such that

$$\begin{aligned} &\text{Tot.Var.}\{u^\nu(t,\cdot);\ [a+\varepsilon, b-\varepsilon]\} \leq C_\varepsilon \quad \forall t \in [\varepsilon, \tau], \\ &\int_{a+\varepsilon}^{b-\varepsilon} |u^\nu(t,x) - u^\nu(s,x)|\, dx \leq C_\varepsilon |t-s| \quad \forall t, s \in [\varepsilon, \tau] \end{aligned} \tag{4.15}$$

$\forall \nu \in \mathbb{N}$. Hence, applying Helly's theorem, we deduce that there exists a subsequence $\{u^{\nu_j}\}_{j\geq 0}$ that converges in $\mathbf{L}^1([a,b],\Gamma)$ to some function $u_\varepsilon(t,\cdot)$, for any $t \in [\varepsilon,\tau]$. Therefore, repeating the same construction in connection with a sequence $\varepsilon_k \to 0+$ and using a diagonal procedure, we obtain a subsequence $\{u^{\nu'}(t,\cdot)\}_{\nu'\geq 0}$ that converges in $\mathbf{L}^1([a,b],\Gamma)$ to some function $u(t,\cdot)$ for any $t \in [0,\tau]$. Then, by Theorem 2.11, there holds (2.41), with $\widetilde{u}_a \doteq u(\cdot,a), \widetilde{u}_b \doteq u(\cdot,b) \in \mathcal{U}_\tau^\infty$, while (4.14) implies $u(\tau,\cdot) = \varphi$, which shows $\varphi \in \mathcal{A}(\tau)$. This completes the proof of Theorem 2.4. □

We next establish the compactness of the attainable set (2.14) stated in Theorem 2.7. The proof is quite similar to that of [3, Theorem 2.3]. We repeat it for completeness.

Proof of Theorem 2.7. Fix $T > 0$, and consider a sequence $\{u^\nu\}_{\nu\geq 0}$ of entropy weak solutions to the mixed problem for (1.1) on $\Omega_T \doteq [0,T] \times [a,b]$ (according to Definition 2.2), with fixed initial data $\overline{u} \in \mathbf{L}^\infty([a,b],\Gamma)$. Since all u^ν are uniformly bounded and because of the Oleinik-type estimates (2.7)–(2.8), one can find, for every $\varepsilon > 0$, some constant $C_\varepsilon > 0$ so that (4.15) holds. Thus, with the same arguments used in Step 2 of the previous proof, we can construct a subsequence $\{u^{\nu'}\}_{\nu'\geq 0}$ so that, for any $t \in [0,T]$, $u^{\nu'}(t,\cdot)$ converges in $\mathbf{L}^1$ to some function $u(t,\cdot)$, which is continuous as a map from $]0,T]$ into $\mathbf{L}^1([a,b],\Gamma)$ and satisfies the entropy conditions (2.7)–(2.10) on the decay of positive waves. On the other hand, the weak traces $\Psi_a^{\nu'}, \Psi_b^{\nu'}$ of the fluxes $f(u^{\nu'})$ at the boundaries $x = a$, $x = b$ are uniformly bounded, and hence are weak* relatively compact in $\mathbf{L}^\infty([0,T])$. Thus, by possibly taking a further subsequence, we have

$$\Psi_a^{\nu'} \overset{*}{\rightharpoonup} \Psi_a, \qquad \Psi_b^{\nu'} \overset{*}{\rightharpoonup} \Psi_b \quad \text{in } \mathbf{L}^\infty([0,T]) \tag{4.16}$$

for some maps $\Psi_a, \Psi_b \in \mathbf{L}^\infty([0,T])$. Notice that, by the properties of the Riemann invariants, the set $f(\Gamma)$ is closed and convex, and hence also the weak limits Ψ_a, Ψ_b take values in $f(\Gamma)$. Moreover, since each u^ν is a distributional solution of (1.1)–(1.2) on Ω_T, the limit function u also is a distributional solution of the Cauchy problem (1.1)–(1.2) on the region Ω_T. Then, setting $\widetilde{u}_a \doteq f^{-1} \circ \Psi_a, \widetilde{u}_b \doteq f^{-1} \circ \Psi_b$, it follows that u is an entropy weak solution of the mixed problem (1.1)–(1.4) (with boundary data in $\mathcal{U}_T^\infty$) according to Definition 2.2, which shows that $u(T,\cdot) \in \mathcal{A}(T)$. This completes the proof of Theorem 2.7. □

5. Conclusion. The results presented in this paper represent a contribution to the development of a general theory on boundary controllability for systems of nonlinear hyperbolic equations within the context of entropy weak solutions. As is shown in [11] there is no hope of establishing exact controllability results for general systems of conservation laws due to the wave-front structure of the weak solutions, which may present shock waves that can never be canceled by interactions with rarefaction waves of the same characteristic family and that at the same time give rise to new shock

fronts by interacting with shock waves of the other characteristic families. Here we have analyzed the exact boundary controllability for the simplest class of nonlinear hyperbolic systems: the class of Temple systems with genuinely nonlinear characteristic fields, whose study is motivated by applications to multicomponent chromatography.

A natural direction in which to pursue this analysis is to consider Temple systems with linearly degenerate characteristic fields (or with a general "nonconvex" flux) which appear in several traffic flow models [6, 16] where one is usually interested in controlling the inflow of cars at the entry of a given road. Another relevant direction worthy of investigation is the controllability of systems of balance laws, i.e., of systems of conservation laws with the presence of source terms. Systems of balance laws belonging to Temple class arise, for example, in modeling chromatography reactors where chemical reactions take place allowing the different solutes (dissolved in the liquid) to transform into each other (see [25, 26]).

All of this type of analysis refers to the case of boundary control problems where total control on the boundary values is available. Of course one may consider more general controllability problems where the control acts only on some of the boundary conditions. For example, we may consider the system of isentropic gas dynamics describing a gas confined in a cylinder within two pistons. In this case it is reasonable to expect that, by controlling only the speed of one piston, it is possible to asymptotically stabilize the system at any constant state. To this purpose it is natural to study first the boundary controllability of the linearized system. A generic condition that guarantees the exact boundary controllability in finite time of a linear hyperbolic system with constant coefficients is obtained in [2].

Acknowledgment. The authors would like to thank Prof. Alberto Bressan for suggesting the problem.

OPTIMAL BOUNDARY CONTROL FOR THE EVOLUTIONARY NAVIER–STOKES SYSTEM: THE THREE-DIMENSIONAL CASE*

A. V. FURSIKOV†, M. D. GUNZBURGER‡, AND L. S. HOU§

Dedicated to the memory of Olga Aleksandrovna Ladyzhenskaya

Abstract. Optimal boundary control problems for the three-dimensional, evolutionary Navier–Stokes equations in the exterior of a bounded domain are studied. Control is effected through the Dirichlet boundary condition and is sought in a subset of the trace space of velocity fields with almost minimal possible regularity. The control objective is to minimize the drag functional. The existence of an optimal solution is proved. A strong form of an optimality system of equations is derived on the basis of regularity results established in this work for the adjoint Oseen equations with regular initial data which do not satisfy the compatibility conditions.

Key words. optimal control, Navier–Stokes equations, boundary value problem, drag reduction

1. Introduction.

This paper is devoted to the investigation of using boundary controls to minimize the drag about a three-dimensional body B moving at a constant velocity $\mathbf{v}_\infty$ in a fluid. The fluid flow is assumed to be governed by the time-dependent, viscous, incompressible Navier–Stokes system. The drag minimization problem is formulated as an optimal boundary control problem by introducing an appropriate drag functional and by choosing a suitable control space. The two-dimensional analogue of this problem was studied in [8], and this paper represents a continuation of that work in the three-dimensional case. Our aims are to prove the existence of an optimal solution and derive an optimality system of equations. In order to achieve these aims, we will need to define the correct mathematical formulation of the optimal control problem in question.

The type of optimal control problem we study has the following form:

$$\mathcal{J}(\mathbf{v}) \to \inf, \tag{1.1}$$

$$\mathrm{NS}(\mathbf{v}, p_1) = \mathbf{0}, \quad \mathbf{v}\big|_{t=0} = \mathbf{v}_0, \quad \mathbf{v}\big|_{|\mathbf{x}|\to\infty} = \mathbf{v}_\infty, \quad \mathbf{v}\big|_{(0,T)\times\partial B} = \mathbf{b}, \tag{1.2}$$

$$R(\mathbf{b}) \le M. \tag{1.3}$$

Here, $\mathbf{v}(t,\mathbf{x})$ and $p_1(t,\mathbf{x})$ for $t \in [0,T]$ and $\mathbf{x} \in \Omega \equiv \mathbb{R}^3 \setminus B$ are the vector-valued velocity field and scalar-valued pressure field, respectively, of the fluid flow surrounding the body B; we attach the coordinates to B, i.e., we treat B as fixed so that the fluid is in motion relative to B. Also, $\mathcal{J}(\mathbf{v})$ is the drag functional, $\mathrm{NS}(\mathbf{v}, p_1) = \mathbf{0}$ is

the Navier–Stokes system, $\mathbf{v}_0$ is the initial condition, and $\mathbf{b}$ is the Dirichlet boundary condition which acts as the control in our problem.

It is clear that the correct physical setting of the optimal drag reduction problem must contain the constraint (1.3), where $R(\mathbf{b})$ is a norm-like functional for functions defined on the boundary $\Sigma = (0,T)\times\partial\Omega \equiv (0,T)\times\partial B$. Indeed, if (1.3) is not imposed or the constant M in that condition is too large, then, instead of drag reduction, the boundary control $\mathbf{b}$ can actually push the body B in the direction opposite to $\mathbf{v}_\infty$ (see the relevant discussions in [8]).

Note that choosing the appropriate form for $R(\mathbf{b})$ is not a trivial task, since choosing R to be a simple functional such as the $\mathbf{L}^2(\Sigma)$-norm is unsuccessful even in two-dimensional case (see [8]); of course, in three dimensions, it is impossible as well. The correct choice of $R(\mathbf{b})$ is strictly connected to choosing a proper boundary control space. That is, they must be chosen in such a way that the validity of the use of the Lagrange multiplier principle is guaranteed (see [2, 6]). This amounts to the requirement that the state space $\mathbf{W}$ must be sufficiently regular so that the derivative operator $\mathrm{NS}'(\widetilde{\mathbf{v}}) : \mathbf{W} \to \mathbf{F}$ is an epimorphism for some suitably chosen function space $\mathbf{F}$. It turns out that this requirement can be met if the solution to the Navier–Stokes equations is unique within the space $\mathbf{W}$. It is well known (see [5]) that if we restrict ourselves to Hilbert space settings, then $\mathbf{W}$ should have the following form to ensure the uniqueness property:

$$\mathcal{V}^{(s)}(Q) \equiv \{\mathbf{v} \in L^2(0,T;\mathbf{H}^s(\Omega)) : \partial_t \mathbf{v} \in L^2(0,T;\mathbf{H}^{s-2}(\Omega)),\ \operatorname{div}\mathbf{v} = 0\} \tag{1.4}$$

for $s \geq 3/2$, where $Q \equiv (0,T)\times\Omega$ and the function spaces used will be precisely defined in subsection 2.4. In other words, if the smoothness of functions from $\mathbf{W}$ is less than $\mathcal{V}^{(3/2)}(Q)$, then it is not clear how to prove surjectivity of the operator $\mathrm{NS}'(\widetilde{\mathbf{v}}) : \mathbf{W} \to \mathbf{F}$ or the solvability of the corresponding Oseen equations with such nonsmooth coefficients. To find a suitable norm R, we could simply take the norm of space of restrictions to Σ of a function belonging to the space $\mathcal{V}^{(3/2)}(Q)$, whose trace space was already characterized in [9]. However, to simplify the definition of R, we choose the weakest norm R which avoids fractional derivatives and whose natural domain of definition is a subspace of the trace space of $\mathcal{V}^{(3/2)}(Q)$ (see [10]). Precisely, we choose

$$R(\mathbf{b}) \equiv \|\mathbf{b}\|^2_{\mathbf{H}^1(\Sigma)} = \int_\Sigma \left(|\partial_t \mathbf{b}|^2 + |\nabla_\tau \mathbf{b}|^2 + |\mathbf{b}|^2\right) ds\, dt, \tag{1.5}$$

where $\mathbf{H}^1(\Sigma)$ is the Sobolev space of vector-valued functions defined on Σ possessing square integrable first derivatives. (The definition of surface gradient ∇_τ will be given below; see (2.11).)

Since the norm (1.5) we choose for the boundary data $\mathbf{b}$ is stronger than the norm for the space generated by restricting the space (1.4) to the boundary, we should choose the solution space $\mathbf{W}$ for the Navier–Stokes equations to be the one that corresponds to the boundary norm (1.5) instead of choosing $\mathbf{W}$ to be simply (1.4). The problem of characterizing such a space $\mathbf{W}$ was solved in [10].

Note that our aim is to investigate the case for which there are no restrictions on the magnitude $|\mathbf{v}_\infty|$ of the velocity $\mathbf{v}_\infty$ of the body B. It is precisely the case of large $|\mathbf{v}_\infty|$ that is most interesting in applications. To fulfill such investigation under general assumptions is not possible because of the absence of theorems regarding the existence of smooth solutions for the three-dimensional evolutionary Navier–Stokes equations with arbitrary data; only when the corresponding norms of the data are sufficiently small has the existence of a smooth solution been proved.

To circumvent this difficulty we consider the following concrete and physically reasonable situation. Let a body B move in a steady-state regime with velocity $\mathbf{v}_\infty$. Then, at the instant t_0 (say $t_0 = 0$), we switch on the control $\mathbf{b}$ on ∂B and solve the optimal drag reduction problem over the time interval $(0, T)$, where $T > 0$ is a given arbitrary number. In contrast to the evolutionary case, the existence of a smooth solution $\mathbf{v}_0$ for the steady-state three-dimensional Navier–Stokes equations with the adhesion condition on ∂B and an arbitrary data $\mathbf{v}_\infty$ at infinity has been proved. So, we can take this steady-state solution $\mathbf{v}_0$ as the initial condition in (1.2); this in turn will allow us to investigate optimal control problem (1.1)–(1.3) on the basis of local existence theorems of smooth solutions for the three-dimensional evolutionary Navier–Stokes equations in a neighborhood of $\mathbf{v}_0$. In addition, we will fulfill the locality condition by choosing a sufficiently small parameter M in (1.3). Of course, in such an approach M depends on $|\mathbf{v}_\infty|$:

$$M(|\mathbf{v}_\infty|) \to 0 \qquad \text{as} \qquad |\mathbf{v}_\infty| \to \infty. \tag{1.6}$$

The plan described above will be realized mathematically in this paper. We point out one difficulty arising in this realization that is connected with the property $\mathbf{v}_0(x) - \mathbf{v}_\infty \notin \mathbf{L}^2(\Omega)$ for the steady-state solution. This property does not complicate very much our proof of the existence theorem for the control problem (1.1)–(1.3). However, the problem of constructing a weak solution for the optimality system becomes quite difficult. We will invoke a special form of the abstract Lagrange multiplier principle (see [6, Chap. 2, Thm. 1.6, Thm. 1.8]); to apply this result we are forced to introduce some special Orlicz spaces which are connected with the properties of a vector field $\mathbf{v}_0(x) \to \mathbf{v}_\infty$.

In section 2, we give a precise statement of the optimal control problems we consider. In section 3 and Appendix A, we establish regularity results for the Navier–Stokes system as well as for linearized Navier–Stokes systems and the adjoint linearized Navier–Stokes systems. Although several of these results are of interest in their own right, they are used in this paper as auxiliary results to help us prove the main results of this paper: the existence of optimal solutions and the derivation of weak and strong forms of an optimality system. Section 4 is devoted to the proof of the existence theorem for the control problems defined in section 2. In sections 5–7, we derive corresponding weak and strong forms of the optimality systems.

Finally, we emphasize that we consider this investigation to be a major, but not final, step towards a complete solution of the drag reduction problem. Even after this paper and [8, 9, 10], there remain a number of unresolved problems. For example, by virtue of (1.6) for sufficiently large $|\mathbf{v}_\infty|$, the size of the bound M in (1.3) may become too small to be of practical use in applications. The issue of how to increase M in this situation goes beyond the scope of this paper. Nevertheless, we consider the resolution of this issue quite realistic; indeed, as was shown in [7, 15], it is quite possible to solve nonlocal control problems in the space of smooth solutions for the three-dimensional evolutionary Navier–Stokes equations if the control function is supported on the whole boundary.

2. Formulation of the problem. In this section, we provide a precise statement of the optimal control problems treated in this paper.

2.1. The state system and the cost functional. As discussed in section 1, we consider the problem of using boundary controls to minimize the drag about a three-dimensional body B moving at a constant velocity $\mathbf{v}_\infty$ in a viscous fluid. In

coordinates attached to the body B, this problem transforms into the drag reduction problem for a fixed body B surrounded by a fluid flow having velocity $\mathbf{v}_\infty$ at infinity. Mathematically, the fluid flow is described as follows. Let $B \subset \mathbb{R}^3$ be a bounded domain and let $\Omega \equiv \mathbb{R}^3 \setminus B$. Suppose that the boundary $\partial\Omega$ of Ω is of class C^∞ and is a connected surface. (We impose the last assumption only because it is reasonable from the physical point of view; the generalization of our results to the case of unconnected $\partial\Omega$ is a simple matter.) In the flow domain Ω, we consider the Navier–Stokes system

$$\left\{\begin{array}{l} \partial_t \mathbf{v} - \Delta \mathbf{v} + (\mathbf{v}\cdot\nabla)\mathbf{v} + \nabla p_1 = \mathbf{0} \quad \text{in } Q, \\ \operatorname{div} \mathbf{v} = 0 \quad \text{in } Q, \\ \mathbf{v}|_{t=0} = \mathbf{v}_0 \quad \text{for } \mathbf{x} \in \Omega, \\ \mathbf{v}|_\Sigma = \mathbf{b} \quad \text{with} \quad \displaystyle\int_{\partial\Omega} \mathbf{b}\cdot\mathbf{n}\, ds = 0 \quad \text{for } t \in (0,T), \\ \mathbf{v} \to \mathbf{v}_\infty \quad \text{as } |\mathbf{x}| \to \infty, \end{array}\right. \tag{2.1}$$

where $Q = (0,T)\times\Omega$, $\Sigma = (0,T)\times\partial\Omega$, $\mathbf{v}(t,\mathbf{x}) = \big(v_1(t,\mathbf{x}), v_2(t,\mathbf{x}), v_3(t,\mathbf{x})\big)$ for $t \in [0,T]$, $\mathbf{x} \in \Omega$ is the velocity field, and $\nabla p_1(t,\mathbf{x})$ is a pressure gradient.

The vector field $\mathbf{b}$ is defined on Σ and is the control available to effect optimization. We wish to minimize the work due to drag through a proper choice of $\mathbf{b}$. The work due to drag, or the drag functional, is defined by the formula

$$\mathcal{W} = \int_0^T \int_{\partial\Omega} (\mathbf{v} - \mathbf{v}_\infty)\cdot \mathcal{T}\mathbf{n}\, ds\, dt,$$

where $\mathcal{T} = -p_1 I + 2\mathcal{D}$ is the stress tensor, $\mathcal{D} = \mathcal{D}(\mathbf{v}) = (\nabla\mathbf{v} + \nabla\mathbf{v}^T)/2$ is the rate of deformation tensor, and $\mathbf{n}$ is the unit, outward-pointing normal along the boundary $\partial\Omega$. We can derive, just as in the two-dimensional case (see [8]), the following equivalent expression for $\mathcal{W}$:

$$\begin{aligned} \mathcal{J}(\mathbf{v}) = \int_0^T \int_\Omega \mathcal{D}(\mathbf{v}) : \mathcal{D}(\mathbf{v})\, d\mathbf{x}\, dt + \frac{1}{2}\int_0^T \int_{\partial\Omega} |\mathbf{v} - \mathbf{v}_\infty|^2 \mathbf{v}\cdot\mathbf{n}\, ds\, dt \\ + \frac{1}{2}\int_\Omega |\mathbf{v}(T,\mathbf{x}) - \mathbf{v}_\infty|^2\, d\mathbf{x} - \frac{1}{2}\int_\Omega |\mathbf{v}_0 - \mathbf{v}_\infty|^2\, d\mathbf{x}. \end{aligned} \tag{2.2}$$

The functional (2.2) is precisely the functional to be minimized through a proper choice of the boundary control $\mathbf{b}$ on Σ.

2.2. The initial condition. The correct choice for the initial data $\mathbf{v}_0(\mathbf{x})$ is an important issue since it is related to the physical context in which we formulate the optimal control problem and affects the mathematical proof of existence of optimal solutions. As was mentioned in section 1, we suppose that $\mathbf{v}_0(\mathbf{x})$ is the solution of the steady-state Navier–Stokes problem:

$$\left\{\begin{array}{l} -\Delta\mathbf{v}_0 + (\mathbf{v}_0\cdot\nabla)\mathbf{v}_0 + \nabla p_0 = \mathbf{0} \quad \text{in } \Omega, \\ \operatorname{div}\mathbf{v}_0 = 0 \quad \text{in } \Omega, \\ \mathbf{v}_0\big|_{\partial\Omega} = \mathbf{0}, \\ \mathbf{v}_0 \to \mathbf{v}_\infty \quad \text{as } |\mathbf{x}| \to \infty. \end{array}\right. \tag{2.3}$$

The no-slip condition $\mathbf{v}_0\big|_{\partial\Omega} = \mathbf{0}$ is imposed purely for simplicity and is quite reasonable from a physical point of view. There is no difficulty in treating the case for which $\mathbf{v}_0$ satisfies an inhomogeneous boundary condition.

The following proposition asserts the existence of a solution of (2.3).

PROPOSITION 2.1. *There exists a solution* $(\mathbf{v}_0, p_0) \in [C^\infty(\overline{\Omega})]^4$ *to* (2.3) *satisfying*

$$\|\mathbf{v}_0 - \mathbf{v}_\infty\|_{\mathbf{L}^6(\Omega)} + \|\nabla \mathbf{v}_0\|_{\mathbf{L}^2(\Omega)} + \|\nabla \mathbf{v}_0\|_{\mathbf{C}^2(\overline{\Omega})} \le C|\mathbf{v}_\infty|. \tag{2.4}$$

A proof of this result can be found in, e.g., [11, 13]. Thus, throughout, we assume that the data $\mathbf{v}_0$ in the initial condition in (2.1) is a $\mathbf{C}^\infty(\overline{\Omega})$ solution of (2.3) satisfying (2.4).

2.3. Change of variables. We introduce the change of variables

$$\mathbf{w}(t,\mathbf{x}) = \mathbf{v}(t,\mathbf{x}) - \mathbf{v}_0(\mathbf{x}) \qquad \text{and} \qquad p(t,\mathbf{x}) = p_1(t,\mathbf{x}) - p_0(\mathbf{x}). \tag{2.5}$$

The unknown vector field $\mathbf{w}$ is more convenient to work with than $\mathbf{v}$ due to its zero initial condition and its vanishing values at infinity. After substitution of (2.5) into (2.2) we see that the last two integrals in (2.2) contain two terms $\mathbf{v}_0 - \mathbf{v}_\infty$ that do not belong to $\mathbf{L}^2(\Omega)$. But these terms annul each other. So the problem of minimizing the functional (2.2) subject to (2.1) and (1.3) is then recast as an optimization problem for $\mathbf{w}$ as follows: minimize the functional

$$\begin{aligned} \mathcal{J}(\mathbf{w}) = {} & \int_0^T \int_\Omega \mathcal{D}(\mathbf{w}+\mathbf{v}_0) : \mathcal{D}(\mathbf{w}+\mathbf{v}_0)\, d\mathbf{x}\, dt + \frac{1}{2}\int_0^T \int_{\partial\Omega} |\mathbf{w}-\mathbf{v}_\infty|^2 \mathbf{w}\cdot\mathbf{n}\, ds\, dt \\ & + \frac{1}{2}\int_\Omega (|\mathbf{w}(T,\mathbf{x})|^2 + 2[(\mathbf{w}(T,x)\cdot(\mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty)])\, d\mathbf{x} \end{aligned} \tag{2.6}$$

subject to the constraints

$$\partial_t \mathbf{w} - \Delta \mathbf{w} + [(\mathbf{w}+\mathbf{v}_0)\cdot\nabla]\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{v}_0 + \nabla p = \mathbf{0} \quad \text{in } Q, \tag{2.7}$$

$$\operatorname{div} \mathbf{w} = 0 \quad \text{in } Q, \tag{2.8}$$

$$\mathbf{w}|_{t=0} = \mathbf{0} \quad \text{in } \Omega, \tag{2.9}$$

$$\mathbf{w} \to \mathbf{0} \quad \text{as } |\mathbf{x}| \to \infty, \tag{2.10}$$

$$R(\mathbf{w}) = \int_\Sigma \left(|\partial_t \mathbf{w}|^2 + |\nabla_\tau \mathbf{w}|^2 + |\mathbf{w}|^2 \right) ds\, dt \le M. \tag{2.11}$$

Recall that the surface gradient $\nabla_\tau \mathbf{w}\big|_\Sigma = (\nabla \mathbf{w})\big|_\Sigma - (\partial_n \mathbf{w})\big|_\Sigma$, where $\nabla \mathbf{w}$ is the usual gradient of $\mathbf{w}$ in $\mathbb{R}^3$ and $(\partial_n \mathbf{w})$ is the derivative of $\mathbf{w}$ with respect to the outward-pointing unit normal $\mathbf{n}$ on $\partial\Omega$.

In addition, we suppose that $\mathbf{w}$ satisfies the compatibility condition

$$\big(\mathbf{w}(t,\mathbf{x})|_\Sigma\big)|_{t=0} = \mathbf{0} \quad \text{in } \partial\Omega. \tag{2.12}$$

We omitted, from the system (2.7)–(2.11), the boundary condition and eliminated the unknown Dirichlet boundary control $\mathbf{b}$ in (2.1); instead, the Dirichlet control is expressed by $\mathbf{w}|_\Sigma$.

By virtue of (2.5) and $\mathbf{v}_0|_{\partial\Omega} = 0$, the functional $R(\mathbf{w})$ and the parameter M in (2.11) coincide with R and M in (1.3) and (1.5).

Note that functional (2.6) is well defined on $\mathbf{w}$ satisfying (2.7)–(2.11): this is shown in subsection 3.2.

2.4. Function spaces. In this subsection, we define function spaces for the state variables and the Dirichlet controls. The structure of the space where we look for the solution of the optimal control problem is quite complicated because it should be the space where solutions of the Navier–Stokes equations are unique, and besides it has to contain all solutions of the boundary value problem for the Navier–Stokes equations with arbitrary Dirichlet boundary conditions from $\mathbf{H}^1(\Sigma)$ (i.e., with not so smooth conditions) but with the right side belonging to the Lebeque space. Besides, we recall definitions of well-known Sobolev spaces.

The Sobolev spaces $H^k(\Omega)$ with k a nonnegative integer are defined by

$$H^k(\Omega) = \big\{u \in L^2(\Omega) \ : \ \|u\|^2_{H^k(\Omega)} \equiv \sum_{|\alpha|\le k} \int_\Omega |D^\alpha u(\mathbf{x})|^2 \, d\mathbf{x} < \infty\big\},$$

where $\mathbf{x} \in \Omega \subset \mathbb{R}^3$, $\alpha = (\alpha_1, \alpha_2, \alpha_3)$ is a multi-index (α_j being a nonnegative integer), $|\alpha| = \alpha_1 + \alpha_2 + \alpha_3$, and $D^\alpha = \partial^{|\alpha|}/(\partial x_1^{\alpha_1} \partial x_2^{\alpha_2} \partial x_3^{\alpha_3})$. The Sobolev space $H^s(\Omega)$ for an arbitrary $s > 0$ is defined through the interpolation of the spaces $H^k(\Omega)$ for integer k; see [14]. By definition, $H_0^s(\Omega)$, $s > 0$, is the closure of $C_0^\infty(\Omega)$ in $H^s(\Omega)$. The space $H^{-s}(\Omega)$, $s > 0$, is defined as the dual space of $H_0^s(\Omega)$, i.e., $H^{-s}(\Omega) = (H_0^s(\Omega))'$, with the norm

$$\|f\|_{H^{-s}(\Omega)} = \sup_{\phi \in H_0^s(\Omega),\, \phi \ne 0} \frac{\langle f, \phi \rangle}{\|\phi\|_{H_0^s(\Omega)}},$$

where $\langle \cdot, \cdot \rangle$ denotes the duality between $H^{-s}(\Omega)$ and $H_0^s(\Omega)$ generated by the scalar product in $L^2(\Omega)$. Sobolev spaces on $\partial\Omega$ are denoted by $H^r(\partial\Omega)$ and are defined with the help of partition of unity techniques; for details, see, e.g., [14]. Vector-valued spaces (including vector-valued Sobolev spaces) are denoted by boldface letters, e.g., $\mathbf{H}^s(\Omega) = [H^s(\Omega)]^3$ for all $s \in \mathbb{R}$, $\mathbf{H}_0^s(\Omega) = [H_0^s(\Omega)]^3$, and $\mathbf{H}^r(\partial\Omega) = [H^r(\partial\Omega)]^3$. For $s \ge -1$, we define the divergence-free spaces

$$\mathbf{V}^s(\Omega) \equiv \big\{\mathbf{v} \in \mathbf{H}^s(\Omega) \ : \ \operatorname{div} \mathbf{v} = 0\big\}. \tag{2.13}$$

Also, we define

$$\mathbf{V}_0^0(\Omega) = \big\{\mathbf{v} \in \mathbf{L}^2(\Omega) \ : \ \operatorname{div} \mathbf{v} = 0, \ (\mathbf{v} \cdot \mathbf{n})|_{\partial\Omega} = 0\big\} \tag{2.14}$$

equipped with the $\mathbf{L}^2(\Omega)$ norm where both equalities are understood in the sense of distributions.

For $s \ge 0$, we introduce the spaces of functions depending on both spatial and temporal variables:

$$H^{1,s}(Q) = \big\{y(t, \mathbf{x}) \in L^2(0, T; H^{s+1}(\Omega)) \ : \ \partial_t y \in L^2(0, T; H^s(\Omega))\big\}$$

where $Q = (0, T) \times \Omega$ and

$$H^{1,s}(\Sigma) = \big\{y(t, \mathbf{x}) \in L^2(0, T; H^{s+1}(\partial\Omega)) \ : \ \partial_t y \in L^2(0, T; H^s(\partial\Omega))\big\},$$

where $\Sigma = (0, T) \times \partial\Omega$. Analogously, we introduce the following spaces of solenoidal vector fields defined on Q:

$$\mathbf{V}^{1,s}(Q) = L^2(0, T; \mathbf{V}^{s+1}(\Omega)) \cap H^1(0, T; \mathbf{V}^s(\Omega)). \tag{2.15}$$

Recall that Ω is the exterior of a bounded domain $B \subset \mathbb{R}^3$. Let $\rho > 0$ be a fixed number satisfying

$$\partial\Omega \subset \{\mathbf{x} \in \mathbb{R}^3 \ : \ |\mathbf{x}| < \rho\}. \tag{2.16}$$

For arbitrary $k \geq 0$, we set

$$\Omega_{\rho+k} = \Omega \cap \{\mathbf{x} \in \mathbb{R}^3 \ : \ |\mathbf{x}| < \rho + k\} \quad \text{and} \quad Q_{\rho+k} = (0,T) \times \Omega_{\rho+k}. \tag{2.17}$$

Let X_1 and X_2 be two Hilbert spaces. Then, the direct sum $X_1 + X_2 = \{x = x_1 + x_2 : x_1 \in X_1, x_2 \in X_2\}$ is also a Hilbert space with norm defined by

$$\|x\|^2_{X_1+X_2} = \inf_{x=x_1+x_2, x_1\in X_1, x_2 \in X_2} \Big(\|x_1\|^2_{X_1} + \|x_2\|^2_{X_2} \Big). \tag{2.18}$$

Evidently, (2.18) defines a Hilbert norm. We now define the space $\mathbf{V}^{1,1/2}_\rho(Q)$, which was introduced in [10]. Let $\rho > 0$ be fixed and satisfy (2.16). Then

$$\begin{aligned} \mathbf{V}^{1,1/2}_\rho(Q) = \big\{ \mathbf{v} \in \mathbf{V}^{1,1/2}(Q) \ : \ \operatorname{supp} \mathbf{v} \subset Q_{\rho+2}, \ \mathbf{v}\big|_{t=0} = \mathbf{0}, \\ \Delta\mathbf{v} \in \mathbf{L}^2(Q_{\rho+2}) + \mathbf{L}^2(0,T; \nabla H^{1/2}(\Omega_{\rho+2})) \big\} \end{aligned} \tag{2.19}$$

equipped with the norm

$$\|\mathbf{v}\|^2_{\mathbf{V}^{1,1/2}_\rho(Q)} = \|\mathbf{v}\|^2_{\mathbf{V}^{1,1/2}(Q)} + \|\Delta\mathbf{v}\|_{\mathbf{L}^2(Q_{\rho+2}) + \mathbf{L}^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))},$$

where the space $\nabla H^{1/2}(\Omega_{\rho+2}) = \{\nabla q(\mathbf{x}) : q \in H^{1/2}(\Omega_{\rho+2})\}$ is equipped with the norm

$$\|\nabla q\|_{\nabla H^{1/2}(\Omega_{\rho+2})} \equiv \|\nabla q\|_{(H^{1/2}_{00}(\Omega_{\rho+2}))'}.$$

We recall from [14] that $H^{1/2}_{00}(\Omega_{\rho+2})$ and $[H^{1/2}_{00}(\Omega_{\rho+2})]'$ are defined as follows. Let $r(\mathbf{x}) \in C^\infty(\overline{\Omega_{\rho+2}})$, $r(\mathbf{x}) > 0$ for $\mathbf{x} \in \Omega_{\rho+2}$, and $r(\mathbf{x}) = \operatorname{dist}(\mathbf{x}, \partial\Omega_{\rho+2})$ in a sufficiently small neighborhood of $\partial\Omega_{\rho+2}$. Then,

$$H^{1/2}_{00}(\Omega_{\rho+2}) = \big\{ u \ : \ u \in H^{1/2}(\Omega_{\rho+2}), \ r^{-1/2}u \in L^2(\Omega_{\rho+2}) \big\}$$

with the norm

$$\|u\|^2_{H^{1/2}_{00}(\Omega_{\rho+2})} = \|u\|^2_{H^{1/2}(\Omega_{\rho+2})} + \|r^{-1/2}u\|^2_{L^2(\Omega_{\rho+2})}.$$

By $(H^{1/2}_{00}(\Omega_{\rho+2}))'$ we denote the dual space of $H^{1/2}_{00}(\Omega_{\rho+2})$ with the norm

$$\|f\|_{(H^{1/2}_{00}(\Omega_{\rho+2}))'} = \inf_{\phi \in H^{1/2}_{00}(\Omega_{\rho+2}),\, \phi \neq 0} \frac{\langle f, \phi \rangle}{\|\phi\|_{H^{1/2}_{00}(\Omega_{\rho+2})}},$$

where $\langle \cdot, \cdot \rangle$ denotes the duality generated by the scalar product in $L^2(\Omega_{\rho+2})$.

Following the notation $\mathcal{V}^{(2)}(Q)$ introduced in [8], we define the spaces

$$\begin{aligned} \mathcal{V}^{(2)}_0(Q) = \big\{ \mathbf{v} \in L^2(0,T; \mathbf{V}^2(\Omega)) \ : \\ \partial_t \mathbf{v} \in L^2(0,T; \mathbf{V}^0(\Omega)), \ \mathbf{v}\big|_{t=0} = \mathbf{0}, \ \mathbf{v}\big|_\Sigma = \mathbf{0} \big\} \end{aligned} \tag{2.20}$$

The former is a subspace of the latter with the homogeneous boundary value. Analogous to (2.20), we introduce

$$\mathcal{V}_T^{(2)}(Q) = \big\{\mathbf{v} \in L^2(0,T;\mathbf{V}^2(\Omega)) \ : \ \partial_t \mathbf{v} \in L^2(0,T;\mathbf{V}^0(\Omega)), \mathbf{v}|_{t=T} = \mathbf{0}, \mathbf{v}|_\Sigma = \mathbf{0}\big\}. \tag{2.21}$$

Now, we can define the space in which the solution of the boundary value problem (2.7)–(2.10) is sought:

$$\mathbf{W} \equiv \mathbf{W}(Q) = \big\{\mathbf{v} \in \mathbf{V}_\rho^{1,1/2}(Q) + \mathcal{V}_0^{(2)}(Q) \ : \ \mathbf{v}\big|_\Sigma \in \mathbf{H}^1(\Sigma)\big\}. \tag{2.22}$$

The Sobolev space $\mathbf{H}^1(\Sigma)$ is defined with the help of partition of unity techniques; see [14]. The norm of the space $\mathbf{W}$ is defined by

$$\|\mathbf{v}\|_{\mathbf{W}}^2 = \|\mathbf{v}\|_{\mathbf{V}_\rho^{1,1/2}(Q)+\mathcal{V}_0^{(2)}(Q)}^2 + \|\mathbf{v}\|_{\mathbf{H}^1(\Sigma)}^2.$$

The boundary control will be sought in the following subspace of $\mathbf{H}^1(\Sigma)$ satisfying a compatibility condition at $t = 0$ (see (2.12)):

$$\widehat{\mathbf{H}}^1(\Sigma) = \Big\{\mathbf{v} \in \mathbf{H}^1(\Sigma) \ : \ \mathbf{v}|_{t=0} = \mathbf{0}, \ \int_{\partial\Omega} \mathbf{v}(t,\mathbf{x}) \cdot \mathbf{n}(\mathbf{x})\, ds = 0 \text{ a.e. } t \in [0,T]\Big\}. \tag{2.23}$$

We establish a compact embedding result that is used to prove, in Theorem 4.1, the existence of solutions of the optimization problems posed in section 2.5. Let ρ satisfying (2.16) be fixed, let $k > 0$ be arbitrary, and let $Q_{\rho+k}$ be defined as in (2.17). Let the function space $\mathbf{W}(Q_{\rho+k})$ be defined in exactly the same way as $\mathbf{W}(Q) \equiv \mathbf{W}$ (see (2.22)): we simply replace Q and Ω by $Q_{\rho+k}$ and $\Omega_{\rho+k}$, respectively.

LEMMA 2.2. *For each $k \in (0,\infty)$, the embedding $\mathbf{W}(Q_{\rho+k}) \hookrightarrow \mathbf{L}^2(Q_{\rho+k})$ is compact.*

Proof. From definitions (2.19), (2.20), and (2.22) for $\mathbf{W}(Q_{\rho+k})$ and definition (2.15) for $\mathbf{V}^{1,s}(Q_{\rho+k})$ (with Q replaced by $Q_{\rho+k}$ and Ω by $\Omega_{\rho+k}$ in all these relations), we easily conclude that the embedding $\mathbf{W}(Q_{\rho+k}) \hookrightarrow \mathbf{V}^{1,1/2}(Q_{\rho+k})$ is continuous. As is well known (see, e.g., [17, Chap. 4, sect. 3]), the embedding $\mathbf{V}^{1,1/2}(Q_{\rho+k}) \hookrightarrow \mathbf{L}^2(Q_{\rho+k})$ is compact. Combining these two results implies the desired assertion. ∎

2.5. Precise statement of the control problems. We now state precisely the optimal control problems to be studied.

PROBLEM I. *Let $\mathbf{v}_\infty \in \mathbb{R}^3$ and $M > 0$ be given, and suppose that $\mathbf{v}_0$ is constructed as in Proposition* 2.1. *Seek a $(\mathbf{w}, \nabla p) \in \mathbf{W} \times [L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2})) + \mathbf{L}^2(Q)]$ that minimizes the functional* (2.6) *subject to the constraints* (2.7)–(2.12).

As in [8], we may replace the constraint (2.11) by adding a corresponding penalty term in the functional and consider the following penalized variant of the above optimal control problem.

PROBLEM II. *Let $\mathbf{v}_\infty \in \mathbb{R}^3$ and $N > 0$ be given, and suppose that $\mathbf{v}_0$ is constructed as in Proposition* 2.1. *Seek a $(\mathbf{w}, \nabla p) \in \mathbf{W} \times [L^2(0,T;\nabla H^{1/2}(\Omega_{N+2})) + \mathbf{L}^2(Q)]$ that*

minimizes the functional

$$\begin{aligned}\mathcal{J}_N(\mathbf{w}) &= \int_0^T \int_\Omega \mathcal{D}(\mathbf{w}+\mathbf{v}_0) : \mathcal{D}(\mathbf{w}+\mathbf{v}_0)\, d\mathbf{x}\, dt \\ &+\frac{1}{2}\int_\Omega (|\mathbf{w}(T,\mathbf{x})|^2 + 2[(\mathbf{w}(T,x)\cdot(\mathbf{v}_0(\mathbf{x})-\mathbf{v}_\infty)])\, d\mathbf{x} \\ &+\frac{1}{2}\int_0^T \int_{\partial\Omega} |\mathbf{w}-\mathbf{v}_\infty|^2 \mathbf{w}\cdot\mathbf{n}\, ds\, dt + \frac{N}{2}\int_\Sigma \left(|\partial_t \mathbf{w}|^2 + |\nabla_\tau \mathbf{w}|^2 + |\mathbf{w}|^2\right) ds\, dt\end{aligned} \tag{2.24}$$

subject to the constraints (2.7)–(2.10) *and* (2.12).

DEFINITION 2.3. *An element* $\mathbf{w} \in W$ *is called admissible if it satisfies* (2.7)–(2.12) *in the case of Problem* I *and satisfies* (2.7)–(2.10) *and* (2.12) *in the case of Problem* II. *The set of admissible elements is denoted by* $\mathcal{U}_{\rm ad}$.

DEFINITION 2.4. *An element* $\widehat{\mathbf{w}} \in \mathcal{U}_{\rm ad}$ *is called a solution of Problem* I *if*

$$\mathcal{J}(\widehat{\mathbf{w}}) = \inf_{\mathbf{w}\in\mathcal{U}_{ad}} \mathcal{J}(\mathbf{w}),$$

where $\mathcal{J}$ *is defined by* (2.6). *An element* $\widehat{\mathbf{w}} \in \mathcal{U}_{\rm ad}$ *is called a solution of Problem* II *if*

$$\mathcal{J}_N(\widehat{\mathbf{w}}) = \inf_{\mathbf{w}\in\mathcal{U}_{\rm ad}} \mathcal{J}_N(\mathbf{w}),$$

where $\mathcal{J}_N$ *is defined by* (2.24).

3. Preliminary results. In this section, we collect results that will be needed for the analysis of the optimal control problems defined in section 2.5.

3.1. Boundary value problems with inhomogeneous boundary conditions. To prove the existence of solutions (see section 4) of the optimal control problems stated in section 2.5, we need results regarding the existence and uniqueness of a solution of the boundary value problem (2.7)–(2.10) with an inhomogeneous Dirichlet boundary condition on Σ satisfying the compatibility condition (2.12). We rewrite that boundary value problem in terms of $\mathbf{w}$ as follows:

$$\begin{cases} \partial_t \mathbf{w} - \Delta\mathbf{w} + [(\mathbf{w}+\mathbf{v}_0)\cdot\nabla]\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{v}_0 + \nabla p = \mathbf{0} & \text{in } Q, \\ \operatorname{div}\mathbf{w} = 0 & \text{in } Q, \\ \mathbf{w}|_{t=0} = \mathbf{0} & \text{in } \Omega, \\ \mathbf{w}|_\Sigma = \mathbf{b}, \\ \mathbf{w} \to \mathbf{0} & \text{as } |\mathbf{x}| \to \infty. \end{cases} \tag{3.1}$$

We assume that the Dirichlet boundary data $\mathbf{b} \in \widehat{\mathbf{H}}^1(\Sigma)$.

The solution $(\mathbf{w}, \nabla p)$ of (3.1) is sought in $\mathbf{W} \times [L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2})) + \mathbf{L}^2(Q)]$. This boundary value problem was analyzed in [10]. The key step was to prove the following result concerning the extension of the Dirichlet boundary condition $\mathbf{b}$ from Σ into Q.

PROPOSITION 3.1. *There exists a continuous extension operator*

$$\mathcal{E} : \widehat{\mathbf{H}}^1(\Sigma) \to \mathbf{V}_\rho^{1,1/2}(Q). \tag{3.2}$$

With the help of Proposition 3.1, the following result was also established in [10].

PROPOSITION 3.2. *Assume that* $\mathbf{b} \in \widehat{\mathbf{H}}^1(\Sigma)$ *and*

$$\|\mathbf{b}\|^2_{\mathbf{H}^1(\Sigma)} \le \epsilon, \tag{3.3}$$

where $\epsilon > 0$ *is sufficiently small. Assume further that* $\mathbf{v}_0 \in \mathbf{C}^\infty(\overline{\Omega})$ *and* $\mathbf{v}_0$ *satisfies* (2.4). *Then, there exists a unique solution* $(\mathbf{w}, \nabla p)$ *of problem* (3.1) *belonging to* $\mathbf{W} \times [L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2})) + \mathbf{L}^2(Q)]$ *and satisfying the estimate*

$$\|\mathbf{w}\|^2_{\mathbf{W}} + \|\nabla p\|^2_{L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))+\mathbf{L}^2(Q)} \le C(\epsilon), \tag{3.4}$$

where $C(\epsilon)$ *is a positive continuous function defined for all sufficiently small* ϵ.

3.2. The correctness of the functionals (2.6) and (2.24). Here we show that all integrals from (2.6) and (2.24) converge for each $\mathbf{w} \in \mathbf{W}$ satisfying (2.7)–(2.10). Indeed, the convergence of all terms except $\mathbf{w}(T,x) \cdot (\mathbf{v}_0(x) - \mathbf{v}_\infty)$ follow directly from the inclusion $\mathbf{w} \in \mathbf{W}$. Since by (2.4) we have $\mathbf{v}_0 - \mathbf{v}_\infty \in \mathbf{L}^6(\Omega)$, to prove the convergence of this aforementioned term we need to check that $\mathbf{w}(T,x) \in \mathbf{L}^{6/5}(\Omega)$.

LEMMA 3.3. *Let* $\mathbf{w} \in \mathbf{W}$ *satisfy* (2.7)–(2.10). *Then,* $\mathbf{w}(T,x) \in \mathbf{L}^{6/5}(\Omega)$.

Proof. Evidently, it is enough to prove the inclusion $\mathbf{w}(T,x) \in \mathbf{L}^{6/5}(\mathbb{R}^3 \setminus \Omega_{\rho+2})$ where ρ is the number from definitions (2.19) and (2.22). Using the techniques of [10] we extend a solution $\mathbf{w} \in \mathbf{W}$ of (2.7)–(2.10) from $[0,T]\times\mathbb{R}^3\setminus Q$ into a vector field $\widetilde{\mathbf{w}}$ on $[0,T]\times\mathbb{R}^3$ satisfying $\widetilde{\mathbf{w}} \in L^2(0,T;\mathbf{V}^2(\mathbb{R}^3)) \cap H^1(0,T;\mathbf{V}^0(\mathbb{R}^3))$ and $\widetilde{\mathbf{w}}|_{t=0} = 0$. We also extend the gradient ∇p in (2.7)–(2.10) from $[0,T]\times\mathbb{R}^3\setminus Q$ into $\nabla\widetilde{p} \in L^2((0,T)\times\mathbb{R}^3)$, and extend $\mathbf{v}_0(x)$ into a C^∞-vector field on $\mathbb{R}^3$. Substituting $(\widetilde{\mathbf{w}}, \nabla\widetilde{p})$ into the left-hand side of (2.7), we obtain

$$\partial_t\widetilde{\mathbf{w}} - \Delta\widetilde{\mathbf{w}} = -[(\widetilde{\mathbf{w}} + \mathbf{v}_0)\cdot\nabla]\widetilde{\mathbf{w}} - (\widetilde{\mathbf{w}}\cdot\nabla)\mathbf{v}_0 + \nabla\widetilde{p} + \mathbf{g}(t,\mathbf{x}) \quad \text{in } (0,T)\times\mathbb{R}^3, \tag{3.5}$$

$$\operatorname{div}\widetilde{\mathbf{w}} = 0 \quad \text{in } (0,T)\times\mathbb{R}^3, \qquad \widetilde{\mathbf{w}}|_{t=0} = \mathbf{0} \quad \text{in } \mathbb{R}^3, \tag{3.6}$$

where $\mathbf{g}(t,\mathbf{x}) \in L^2((0,T)\times\mathbb{R}^3)$ and $\operatorname{supp}\mathbf{g} \subset Q_{\rho+2}$. Evidently, $\mathbf{g} \in L^{6/5}((0,T)\times\mathbb{R}^3)$.

Recall that if $\Omega \subset \mathbb{R}^3$ is a domain and $Q = [0,T]\times\Omega$, then the Sobolev space $W^{1,2}_q(Q)$ with $1 \le q < \infty$ is defined as follows:

$$W^{1,2}_q(Q) = \Big\{ u(t,x) \in L^q(Q) \,:\, \|u\|^q_{W^{1,2}_q(Q)} \equiv \int_Q |u|^q + |\partial_t u|^q + |\nabla u|^q + \sum_{i,j=1}^{3} \left|\frac{\partial u}{\partial x_i \partial x_j}\right|^q dx < \infty \Big\}. \tag{3.7}$$

By virtue of Sobolev embedding theorem (see [3]), if $1 < p < q < \infty$ then the following embeddings are continuous:

$$W^{1,2}_p(Q) \subset L^q(Q) \quad \text{for } \frac{1}{p} - \frac{1}{q} \le \frac{2}{5} \tag{3.8}$$

and

$$\nabla W^{1,2}_p(Q) := \{\nabla f : f \in W^{1,2}_p(Q)\} \subset L^q(Q) \quad \text{for } \frac{1}{p} - \frac{1}{q} \le \frac{2}{5}. \tag{3.9}$$

Using Holder's inequality, (3.8), (3.9), and (2.4), we obtain

$$\|(\widetilde{\mathbf{w}}\cdot\nabla)\widetilde{\mathbf{w}}\|_{L^{6/5}(Q)}\le\|\widetilde{\mathbf{w}}\|_{\mathbf{L}^3(Q)}\|\nabla\widetilde{\mathbf{w}}\|_{\mathbf{L}^2(Q)}\le\|\widetilde{\mathbf{w}}\|^2_{\mathbf{W}_2^{1,2}(Q)},$$

$$\|(\widetilde{\mathbf{w}}\cdot\nabla)\mathbf{v}_0\|_{L^{6/5}(Q)}\le\|\widetilde{\mathbf{w}}\|_{\mathbf{L}^3(Q)}\|\nabla\mathbf{v}_0\|_{\mathbf{L}^2(Q)}\le c\|\widetilde{\mathbf{w}}\|_{\mathbf{W}_2^{1,2}(Q)},$$

and

$$\|(\mathbf{v}_0\cdot\nabla)\widetilde{\mathbf{w}}\|_{L^{3/2}(Q)}\le\|\mathbf{v}_0\|_{\mathbf{L}^6(Q)}\|\nabla\widetilde{\mathbf{w}}\|_{\mathbf{L}^2(Q)}\le C\|\widetilde{\mathbf{w}}\|_{\mathbf{W}_2^{1,2}(Q)}.$$

Thus, $(\widetilde{\mathbf{w}}\cdot\nabla)\widetilde{\mathbf{w}}+(\widetilde{\mathbf{w}}\cdot\nabla)\mathbf{v}_0\in\mathbf{L}^{6/5}(Q)$ and $(\mathbf{v}_0\cdot\nabla)\widetilde{\mathbf{w}}\in\mathbf{L}^{3/2}(Q)$ so that the right-hand side of (3.5) belongs to $\mathbf{L}^{3/2}([0,T]\times\mathbb{R}^3)$. By virtue of the well-known estimates for solutions of the Cauchy problem for the Stokes equations (see [13, Chap. 4, sect. 6]) we obtain from (3.5) and (3.6) that $\widetilde{\mathbf{w}}\in\mathbf{W}^{1,2}_{3/2}([0,T]\times\mathbb{R}^3)$. Using this inclusion we deduce

$$\|(\mathbf{v}_0\cdot\nabla)\widetilde{\mathbf{w}}\|_{L^{6/5}(Q)}\le\|\mathbf{v}_0\|_{\mathbf{L}^6(Q)}\|\nabla\widetilde{\mathbf{w}}\|_{\mathbf{L}^{3/2}(Q)}\le C\|\widetilde{\mathbf{w}}\|_{\mathbf{W}^{1,2}_{3/2}(Q)}.$$

Therefore, the right-hand side of (3.5) belongs to $\mathbf{L}^{6/5}(Q)$, which implies that $\widetilde{\mathbf{w}}\in\mathbf{W}^{1,2}_{6/5}(Q)$ so that $\widetilde{\mathbf{w}}(T,\cdot)\in\mathbf{L}^{6/5}(\mathbb{R}^3)$. □

3.3. Linearized boundary value problems. To derive and analyze (see section 5) weak formulations of the optimality systems for the control problems, we will need the following theorem concerning the solvability of the (homogeneous) boundary value problem for the Oseen equations

$$\begin{cases}\partial_t\mathbf{h}-\Delta\mathbf{h}+[(\widehat{\mathbf{w}}+\mathbf{v}_0)\cdot\nabla]\mathbf{h}+[\mathbf{h}\cdot\nabla](\widehat{\mathbf{w}}+\mathbf{v}_0)+\nabla q=\mathbf{g} & \text{in } Q,\\ \operatorname{div}\mathbf{h}=0 & \text{in } Q,\\ \mathbf{h}|_{t=0}=\mathbf{0} & \text{in } \Omega,\\ \mathbf{h}|_{\Sigma}=\mathbf{0},\\ \mathbf{h}\to\mathbf{0} & \text{as } |\mathbf{x}|\to\infty\end{cases}\tag{3.10}$$

that are the linearization of (3.1) about a given vector field $\widehat{\mathbf{w}}\in\mathbf{W}$.

PROPOSITION 3.4. *Assume that* $\mathbf{v}_0\in\mathbf{C}^\infty(\overline{\Omega})$ *satisfies* (2.4), $\widehat{\mathbf{w}}\in\mathbf{W}$, *and* $\mathbf{g}\in\mathbf{L}^2(Q)$. *Then, there exists a unique solution* $(\mathbf{h},\nabla q)\in\mathcal{V}_0^{(2)}(Q)\times\mathbf{L}^2(Q)$ *of the problem* (3.10). *Moreover,*

$$\|\mathbf{h}\|^2_{\mathcal{V}_0^{(2)}(Q)}+\|\nabla q\|^2_{\mathbf{L}^2(Q)}\le C\|\mathbf{g}\|^2_{\mathbf{L}^2(Q)}.\tag{3.11}$$

The proof is well known; see, e.g., [5, 10, 13, 16].

3.4. Adjoint boundary value problems. To derive strong forms (see sections 6 and 7) of the optimality systems, we will need results concerning the solvability and regularity of the adjoint boundary value problem for (3.10):

$$\begin{cases}\partial_t\mathbf{q}+\Delta\mathbf{q}+[(\widehat{\mathbf{w}}+\mathbf{v}_0)\cdot\nabla]\mathbf{q}-[\nabla(\widehat{\mathbf{w}}+\mathbf{v}_0)]^*\,\mathbf{q}+\nabla r=\mathbf{k} & \text{in } Q,\\ \operatorname{div}\mathbf{q}=0 & \text{in } Q,\\ \mathbf{q}|_{t=T}=\mathbf{q}_0(\mathbf{x}) & \text{in } \Omega,\\ \mathbf{q}|_{\Sigma}=\mathbf{0},\\ \mathbf{q}\to\mathbf{0} & \text{as } |\mathbf{x}|\to\infty,\end{cases}\tag{3.12}$$

where $[\nabla\widehat{\mathbf{w}}]^*\,\mathbf{q} = (\sum_{i=1}^3 \frac{\partial \widehat{w}_i}{\partial x_j} q_i,\ j = 1,2,3)$ for $\widehat{\mathbf{w}} = (\widehat{w}_1, \widehat{w}_2, \widehat{w}_3)$ and $\mathbf{q} = (q_1, q_2, q_3)$. The following assertion concerning the unique solvability of (3.12) in the case of $\mathbf{q}_0 = \mathbf{0}$ is completely analogous to Proposition 3.4; the proof is also identical to that of the proposition.

PROPOSITION 3.5. *Assume that* $\mathbf{v}_0 \in \mathbf{C}^\infty(\overline{\Omega})$ *satisfies* (2.4), $\widehat{\mathbf{w}} \in \mathbf{W}$, $\mathbf{k} \in \mathbf{L}^2(Q)$, *and* $\mathbf{q}_0 = \mathbf{0}$. *Then, there exists a unique solution* $(\mathbf{q}, \nabla r) \in \mathcal{V}_T^{(2)}(Q) \times \mathbf{L}^2(Q)$ *of the problem* (3.12) (*with* $\mathbf{q}_0 = \mathbf{0}$) *satisfying the estimate*

$$\|\mathbf{q}\|^2_{\mathcal{V}_T^{(2)}(Q)} + \|\nabla r\|^2_{\mathbf{L}^2(Q)} \le C\|\mathbf{k}\|^2_{\mathbf{L}^2(Q)}. \tag{3.13}$$

We will also need results concerning problem (3.12) with $\mathbf{k} = \mathbf{0}$ and $\mathbf{q}_0 \neq \mathbf{0}$. In this case, we reduce (3.12) to the following system through the change of variable $\tau = T - t$ and redenoting τ by t:

$$\begin{cases} \partial_t \mathbf{q} - \Delta\mathbf{q} - [(\widehat{\mathbf{w}} + \mathbf{v}_0)\cdot\nabla]\mathbf{q} + [\nabla(\widehat{\mathbf{w}} + \mathbf{v}_0)]^*\,\mathbf{q} - \nabla r = \mathbf{0} \quad \text{in } Q, \\ \operatorname{div}\mathbf{q} = 0 \quad \text{in } Q, \\ \mathbf{q}|_{t=0} = \mathbf{q}_0(\mathbf{x}) \qquad \text{in } \Omega, \\ \mathbf{q}|_\Sigma = \mathbf{0}, \\ \mathbf{q} \to \mathbf{0} \quad \text{as } |\mathbf{x}| \to \infty. \end{cases} \tag{3.14}$$

Using well-known energy methods (see [13, 16]), we can prove the following result.

LEMMA 3.6. *Assume that* $\mathbf{v}_0 \in \mathbf{C}^\infty(\overline{\Omega})$ *satisfies* (2.4), $\widehat{\mathbf{w}} \in \mathbf{W}$, *and* $\mathbf{q}_0 \in \mathbf{V}_0^0(\Omega)$. *Then there exists a solution* $(\mathbf{q}, \nabla r)$ *of the problem* (3.14) *satisfying the energy estimate*

$$\begin{aligned} &\|\mathbf{q}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\nabla\mathbf{q}\|^2_{\mathbf{L}^2(Q)} \\ &\qquad \le C\big(\|\widehat{\mathbf{w}}\|_{\mathbf{V}^{1,1/2(\Omega)}} + \|\nabla\mathbf{v}_0\|_{\mathbf{C}(\overline{\Omega})}\big)\|\mathbf{q}_0\|^2_{\mathbf{L}^2(\Omega)}, \end{aligned} \tag{3.15}$$

where $C(\gamma)$ *is a positive function increasing in* γ.

Improved estimates for $\mathbf{q}$ when $\mathbf{q}_0$ is smoother will also be needed in order to derive strong forms of the optimality systems; these estimates are obtained in Appendix A.3.

4. Existence of solutions for the optimal control problems.

4.1. The solvability of Problem I. We consider the solvability of Problem I formulated in section 2.5.

THEOREM 4.1. *Suppose that the constant* M *in* (2.11) *is sufficiently small. Then there exists a solution* $(\widehat{\mathbf{w}}, \nabla\widehat{p}) \in \mathbf{W} \times (\mathbf{L}^2(Q) + L^2(0,T;\nabla H^{1/2}(\Omega)))$ *for Problem* I.

Proof. Recall that a pair $(\mathbf{w}, p) \in \mathbf{W} \times \mathbf{L}^2(Q)$ is called admissible if it satisfies (2.7)–(2.12) and the functional (2.6) evaluated at $(\mathbf{w}, p)$ is finite. Evidently, the admissible set $\mathcal{U}_{\rm ad} \neq \emptyset$, as $(\mathbf{w}, p) = (\mathbf{0}, 0) \in \mathcal{U}_{\rm ad}$. Let $\{(\mathbf{w}_n, \nabla p_n)\} \in \mathcal{U}_{\rm ad}$ be a minimizing sequence for the functional $\mathcal{J}(\mathbf{w})$:

$$\lim_{n\to\infty} \mathcal{J}(\mathbf{w}_n) = J_{\min} \equiv \inf_{(\mathbf{w},\nabla p)\in\mathcal{U}_{\rm ad}} \mathcal{J}(\mathbf{w}).$$

By virtue of (2.11) we have $\|\mathbf{w}_n|_\Sigma\|^2_{\mathbf{H}^1(\Sigma)} \le M$. Let $\mathbf{b}_n \equiv \mathbf{w}_n|_\Sigma$; note that $\mathbf{b}_n \in \widehat{\mathbf{H}}^1(\Sigma)$. Consider the boundary value problem (3.1) with $\mathbf{b} = \mathbf{b}_n$. Let $\epsilon > 0$ be a sufficiently

small number determined by Proposition 3.2 and suppose $M < \epsilon$. Proposition 3.2 then implies that

$$\|\mathbf{w}_n\|_{\mathbf{W}}^2 + \|\nabla p_n\|_{L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))+\mathbf{L}^2(Q)} \le C(M), \tag{4.1}$$

where $C(M)$ is a positive constant depending on M. The estimate (4.1) allows us to choose a subsequence of $\{\mathbf{w}_n\}$ (denoted by the same) such that

$$\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}} \quad \text{weakly in } \mathbf{W}.$$

The definition of $\mathbf{W}$ (see (2.22)) then implies that

$$\mathbf{w}_n|_\Sigma = \mathbf{b}_n \rightharpoonup \widehat{\mathbf{b}} \equiv \widehat{\mathbf{w}}|_\Sigma \quad \text{weakly in } \widehat{\mathbf{H}}^1(\Sigma). \tag{4.2}$$

Since $\mathbf{b}_n$ satisfies (2.11) and the set $\{\mathbf{w} \in \widehat{\mathbf{H}}^1(\Sigma) : \mathbf{w} \text{ satisfies (2.11)}\}$ is convex and closed (hence sequentially weakly closed), we see that $\widehat{\mathbf{b}} \in \widehat{\mathbf{H}}^1(\Sigma)$ and $\mathbf{b}$ satisfies (2.11). $\widehat{\mathbf{w}}$ obviously satisfies (2.8)–(2.10). To prove that $\widehat{\mathbf{w}}$ satisfies (2.7) with some $\nabla\widehat{p} \in L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2})) + \mathbf{L}^2(Q)$, we proceed by noting that

$$\begin{aligned}&\int_Q (\partial_t \mathbf{w}_n - \Delta \mathbf{w}_n)\cdot\boldsymbol{\phi}\,d\mathbf{x}\,dt\\ &\qquad\to \int_Q (\partial_t \widehat{\mathbf{w}} - \Delta\widehat{\mathbf{w}})\cdot\boldsymbol{\phi}\,d\mathbf{x}\,dt \qquad \forall\,\boldsymbol{\phi} \in L^2(0,T;\mathbf{V}_0^1(\Omega)),\end{aligned} \tag{4.3}$$

where $\mathbf{V}_0^1(\Omega)$ is defined by (A.2). Using Lemma 2.2 with $k = 1,2,3,\dots$, we may choose subsequences $\{\mathbf{w}_{n,k}\}$ converging to $\widehat{\mathbf{w}}$ in $\mathbf{L}^2(Q_{\rho+k})$. Then, by choosing the diagonal subsequence $\{\mathbf{w}_j\}$, we infer that

$$\mathbf{w}_j \to \widehat{\mathbf{w}} \qquad \text{strongly in } \mathbf{L}^2(Q_{\rho+k}) \text{ for each } k = 1,2,3,\dots. \tag{4.4}$$

We now take the $\mathbf{L}^2(Q)$ inner product between an arbitrary $\boldsymbol{\phi} \in L^2(0,T;\mathbf{V}_0^1(\Omega))$ and (2.7) for $(\mathbf{w}_j, \nabla p_j)$. The term involving ∇p_j obviously vanishes. Integrating by parts and passing to the limit with the help of (4.3) and (4.4), we obtain the following equation for $\widehat{\mathbf{w}}$:

$$\begin{aligned}\int_Q \Big(\boldsymbol{\phi}\cdot\partial_t\widehat{\mathbf{w}} + (\nabla\widehat{\mathbf{w}}) : (\nabla\boldsymbol{\phi}) + (\widehat{\mathbf{w}}\cdot\nabla)\mathbf{v}_0\cdot\boldsymbol{\phi} - [(\widehat{\mathbf{w}}+\mathbf{v}_0)\cdot\nabla]\boldsymbol{\phi}\cdot\widehat{\mathbf{w}}\Big)\,d\mathbf{x}\,dt\\ = 0 \qquad \forall\,\boldsymbol{\phi} \in L^2(0,T;\mathbf{V}_0^1(\Omega)).\end{aligned} \tag{4.5}$$

Since $\widehat{\mathbf{w}} \in \mathbf{W}$, we see from definition (2.22) that

$$\widehat{\mathbf{w}} = \mathcal{E}\widehat{\mathbf{b}} + \mathbf{w}, \tag{4.6}$$

where $\mathcal{E}$ is the extension operator of Proposition 3.1, $\mathcal{E}\widehat{\mathbf{b}} \in \mathbf{V}_\rho^{1,1/2}(Q)$, and $\mathbf{w} \in \mathcal{V}_0^{(2)}(Q)$. Substitution of (4.6) into (4.5) yields

$$\begin{aligned}&\int_Q \Big(\partial_t\mathbf{w} - \Delta\mathbf{w} + (\mathbf{w}\cdot\nabla)(\mathbf{v}_0 + \mathcal{E}\widehat{\mathbf{b}})\\ &\qquad\qquad + [(\mathcal{E}\widehat{\mathbf{b}} + \mathbf{v}_0 + \mathbf{w})\cdot\nabla]\mathbf{w} - \mathbf{f}_1 + \nabla p_1\Big)\cdot\boldsymbol{\phi}\,d\mathbf{x}\,dt\\ &\quad= \int_Q \Big(\partial_t\mathbf{w} - \Delta\mathbf{w} + (\mathbf{w}\cdot\nabla)(\mathbf{v}_0 + \mathcal{E}\widehat{\mathbf{b}})\\ &\qquad\qquad + [(\mathcal{E}\widehat{\mathbf{b}} + \mathbf{v}_0 + \mathbf{w})\cdot\nabla]\mathbf{w} - \mathbf{f}_1\Big)\cdot\boldsymbol{\phi}\,d\mathbf{x}\,dt\\ &\quad= 0 \qquad \forall\,\boldsymbol{\phi} \in L^2(0,T;\mathbf{V}_0^1(\Omega)),\end{aligned} \tag{4.7}$$

where $-\mathbf{f}_1 = \partial_t \mathcal{E}\widehat{\mathbf{b}} + \mathbf{g} + (\mathcal{E}\widehat{\mathbf{b}} \cdot \nabla)\mathbf{v}_0 + [(\mathcal{E}\widehat{\mathbf{b}} + \mathbf{v}_0) \cdot \nabla]\mathcal{E}\widehat{\mathbf{b}}$ and $-\Delta\mathcal{E}\widehat{\mathbf{b}} = \mathbf{g} + \nabla p_1$ with $\mathbf{g} \in \mathbf{L}^2(Q)$ and $\nabla p_1 \in L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))$. The inclusions $\mathbf{w} \in \mathcal{V}_0^{(2)}(Q)$ and $\mathcal{E}\widehat{\mathbf{b}} \in \mathbf{V}_\rho^{1,1/2}(Q) \subset \mathbf{V}^{1,1/2}(Q)$ and Sobolev embedding theorems imply that $\mathbf{f}_1 \in \mathbf{L}^2(Q)$ and

$$\partial_t \mathbf{w} - \Delta\mathbf{w} + (\mathbf{w} \cdot \nabla)(\mathbf{v}_0 + \mathcal{E}\widehat{\mathbf{b}}) + [(\mathcal{E}\widehat{\mathbf{b}} + \mathbf{v}_0 + \mathbf{w}) \cdot \nabla]\mathbf{w} \in \mathbf{L}^2(Q).$$

Recalling the Weyl decomposition

$$\mathbf{L}^2(Q) = \mathbf{V}_0^0(\Omega) \oplus \nabla H^1(\Omega),$$

where $\mathbf{V}_0^0(\Omega)$ is defined by (2.14) and

$$\nabla H^1(\Omega) = \{\mathbf{v} \in \mathbf{L}^2(\Omega) \ : \ \mathbf{v} = \nabla p, \ p \in H^1_{\mathrm{loc}}(\Omega)\},$$

we obtain from (4.7) that there exists a $\nabla p \in L^2(0,T;\nabla H^1(\Omega))$ such that

$$\begin{aligned} \partial_t \mathbf{w} - \Delta\mathbf{w} + (\mathbf{w} \cdot \nabla)(\mathbf{v}_0 + \mathcal{E}\widehat{\mathbf{b}}) \\ +[(\mathcal{E}\widehat{\mathbf{b}} + \mathbf{v}_0 + \mathbf{w}) \cdot \nabla]\mathbf{w} + \nabla p - \mathbf{f}_1 = \mathbf{0} \quad \text{in } Q, \end{aligned} \tag{4.8}$$

where (4.8) is understood as an equality in $\mathbf{L}^2(Q)$. Substituting (4.6) into (4.8) yields the equality

$$\partial_t \widehat{\mathbf{w}} - \Delta\widehat{\mathbf{w}} + (\widehat{\mathbf{w}} \cdot \nabla)\mathbf{v}_0 + [(\widehat{\mathbf{w}} + \mathbf{v}_0) \cdot \nabla]\widehat{\mathbf{w}} + \nabla\widehat{p} = 0 \qquad \text{in } Q,$$

where $\nabla\widehat{p} = \nabla p_1 + \nabla p \in L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2})) + L^2(0,T;\nabla H^1_{\mathrm{loc}}(\Omega))$. Thus, we have proved that $(\widehat{\mathbf{w}}, \nabla\widehat{p})$ satisfies (2.7).

Since $\mathbf{w}_n \rightharpoonup \widehat{\mathbf{w}}$ in $\mathbf{W}$ and the functional

$$\begin{aligned} \mathcal{J}_1(\mathbf{w}) = \int_0^T \int_\Omega \mathcal{D}(\mathbf{w} + \mathbf{v}_0) : \mathcal{D}(\mathbf{w} + \mathbf{v}_0)\, d\mathbf{x}\, dt \\ + \frac{1}{2} \int_\Omega (|\mathbf{w}(T,\mathbf{x})|^2 + 2[(\mathbf{w}(T,x) \cdot (\mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty))])\, d\mathbf{x} \end{aligned}$$

is convex (and therefore it is lower semicontinuous with respect to weak convergence), we deduce that

$$\mathcal{J}_1(\widehat{\mathbf{w}}) \le \liminf_{n\to\infty} \mathcal{J}_1(\mathbf{w}_n). \tag{4.9}$$

The facts that Σ is compact and $\dim\Sigma = 3$ allow us to use embedding theorems to deduce that the embedding $\widehat{\mathbf{H}}^1(\Sigma) \hookrightarrow \mathbf{L}^3(\Sigma)$ is compact. Then (4.2) implies $\mathbf{w}|_\Sigma = \mathbf{b}_n \to \widehat{\mathbf{b}} = \widehat{\mathbf{w}}|_\Sigma$ strongly in $\mathbf{L}^3(\Sigma)$. Thus, by defining the functional

$$\mathcal{J}_2(\mathbf{w}) = \frac{1}{2} \int_0^T \int_{\partial\Omega} |\mathbf{w} - \mathbf{v}_\infty|^2 \mathbf{w} \cdot \mathbf{n}\, ds\, dt,$$

we have

$$\mathcal{J}_2(\widehat{\mathbf{w}}) \le \lim_{n\to\infty} \mathcal{J}_2(\mathbf{w}_n). \tag{4.10}$$

The relations (4.9) and (4.10) and the equality $\mathcal{J}(\mathbf{w}) = \mathcal{J}_1(\mathbf{w}) + \mathcal{J}_2(\mathbf{w})$ yield

$$\mathcal{J}(\widehat{\mathbf{w}}) \le \liminf_{n\to\infty} \mathcal{J}(\mathbf{w}_n) = J_{\inf}.$$

Therefore, the pair $(\widehat{\mathbf{w}}, \widehat{p})$ is a solution of Problem I. □

4.2. The solvability of Problem II. We next prove that there exists a solution to Problem II for sufficiently large N, where N is the parameter appearing in the definition of $\mathcal{J}_N(\mathbf{w})$; see (2.24).

THEOREM 4.2. *Suppose that the parameter N of the functional $\mathcal{J}_N(\mathbf{w})$ satisfies $N \geq N_0$ for a sufficiently large, fixed constant $N_0 > 0$. Then there exists a solution $(\widehat{\mathbf{w}}, \widehat{p}) \in \mathbf{W} \times [\mathbf{L}^2(Q) + L^2(0,T; \nabla H^{1/2}(\Omega_{\rho+2}))]$ for Problem* II.

Proof. Recall that a pair $(\mathbf{w}, \nabla p) \in \mathbf{W} \times \mathbf{L}^2(Q)$ is called admissible for Problem II if it satisfies (2.7)–(2.10) and (2.12). We denote by $\mathcal{U}_{\rm ad}^N$ the set of all admissible pairs for Problem II.

Let $\epsilon > 0$ be a sufficiently small number such that for any boundary data $\mathbf{b} \in \widehat{\mathbf{H}}^1(\Sigma)$ satisfying (3.3), the assertions of Proposition 3.2 are true. We fix the constant M in (2.11) as

$$M \in (0, \epsilon). \tag{4.11}$$

Let $(\widehat{\mathbf{w}}, \widehat{p})$ be a solution of Problem I (the existence of such a pair is guaranteed by Theorem 4.1). We define $N_0 > 0$ by the relation

$$\frac{2}{N_0}\mathcal{J}_{N_0}(\widehat{\mathbf{w}}) \equiv \frac{2}{N_0}\mathcal{J}(\widehat{\mathbf{w}}) + R(\widehat{\mathbf{w}}) = \epsilon, \tag{4.12}$$

where the functionals $\mathcal{J}_N$, $\mathcal{J}$, and R are defined by (2.24), (2.6), and (2.11), respectively. The number N_0 satisfying (4.12) is well defined thanks to (4.11) and the estimate $R(\widehat{\mathbf{w}}) \leq M$ for every solution $\widehat{\mathbf{w}}$ of Problem I. Thus, for each $N > N_0$ we have

$$\frac{2}{N}\mathcal{J}_N(\widehat{\mathbf{w}}) \leq \frac{2}{N_0}\mathcal{J}_{N_0}(\widehat{\mathbf{w}}) = \epsilon. \tag{4.13}$$

Set

$$\mathcal{U}_{\rm ad}^{N,\epsilon} = \Big\{(\mathbf{w}, \nabla p) \in \mathcal{U}_{\rm ad}^N \ : \ \frac{1}{N}\mathcal{J}_N(\widehat{\mathbf{w}}) \leq \epsilon\Big\}.$$

By virtue of (4.13), $\mathcal{U}_{\rm ad}^{N,\epsilon}$ is not empty. We now choose a minimizing sequence $\{(\mathbf{w}_n, \nabla p_n)\} \subset \mathcal{U}_{\rm ad}^{N,\epsilon}$ for Problem II:

$$\lim_{n\to\infty} \frac{2}{N}\mathcal{J}_N(\mathbf{w}_n) = J_{N,\inf} \equiv \inf_{(\mathbf{w},\nabla p)\in\mathcal{U}_{\rm ad}^{N,\epsilon}} \frac{2}{N}\mathcal{J}_N(\mathbf{w}).$$

Since $\mathbf{w}_n \in \mathcal{U}_{\rm ad}^{N,\epsilon}$, it follows from (4.13) and (2.6) that for every $N > N_0$,

$$R(\mathbf{w}_n|_\Sigma) \leq \epsilon. \tag{4.14}$$

Denoting $\mathbf{b}_n \equiv \mathbf{w}_n|_\Sigma$ and using (4.14) and (2.11) (the definition of functional R), we see that $\|\mathbf{b}_n\|_{\mathbf{H}^1(\Sigma)} < \epsilon$, i.e., the boundary condition $\mathbf{b}_n$ satisfies the assumptions of Proposition 3.1. Thus, $(\mathbf{w}_n, \nabla p_n)$, being the solution of (3.1) with $\mathbf{b}$ replaced by $\mathbf{b}_n$, satisfies the estimate (3.11) in which $\mathbf{w}$ and p are replaced by $\mathbf{w}_n$ and p_n, respectively. Then, by repeating the relevant segment of the proof of Theorem 4.1, we prove the existence of a solution $(\widehat{\widehat{\mathbf{w}}}, \widehat{\widehat{p}})$ for ProblemII. ∎

5. A weak formulation of an optimality system for Problem II and regularity of the adjoint velocity.

5.1. Abstract Lagrange multiplier principles. We consider an abstract minimization problem. Let X_1 and X_2 be two Banach spaces. Let $f : X_1 \to \mathbb{R}$ and $g : X_1 \to \mathbb{R}$ be functionals and $F : X_1 \to X_2$ be a mapping. We seek a $z \in X_1$ such that

$$f(z) = \inf_{u \in \mathcal{U}_{\rm ad}} f(u), \tag{5.1}$$

where

$$\mathcal{U}_{\rm ad} = \big\{u \in X_1 : F(u) = 0 \text{ and } g(u) \le 0\big\}.$$

The Lagrange functional for the minimization problem (5.1) is defined by

$$\mathcal{L}(z, \lambda_0, \lambda, q) = \lambda_0 f(z) + \langle F(z), q\rangle + \lambda g(z) \tag{5.2}$$

for all $z \in X_1$, $\lambda_0 \in \mathbb{R}$, $\lambda \in \mathbb{R}$, and $q \in X_2^*$, where X_2^* is the dual space of X_2 and $\langle\cdot,\cdot\rangle$ denotes the duality pairing between X_2 and X_2^*. We quote a standard abstract Lagrange principle in the following particular form (see [2]).

THEOREM 5.1. *Let z be a solution of* (5.1). *Assume that the mappings f, g, and F are continuously differentiable and that the image of the operator $F'(z) : X_1 \to X_2$ is closed. Then there exists a $q \in X_2^*$, $\lambda_0 \in \mathbb{R}$, and $\lambda \in \mathbb{R}$ such that the triplet $(q, \lambda_0, \lambda) \neq (0, 0, 0)$ (i.e., the quantities in the triplet do not all vanish simultaneously),*

$$\langle \mathcal{L}_z(z, \lambda_0, \lambda, q), h\rangle = 0 \qquad \forall\, h \in X_1, \tag{5.3}$$

$$\lambda_0 \ge 0, \quad \lambda \ge 0, \quad \textit{and} \quad \lambda g(z) = 0, \tag{5.4}$$

where $\mathcal{L}_z(\cdot,\cdot,\cdot,\cdot)$ denotes the Fréchet derivative of $\mathcal{L}$ with respect to the first argument. Furthermore, if $F'(z) : X_1 \to X_2$ is an epimorphism and the constraint $g(z) \le 0$ is absent in problem (5.1), *then $\lambda_0 \neq 0$ and λ_0 can be taken as* 1.

5.2. The weak formulation of an optimality system. In this subsection we apply Theorem 5.1 to derive a weak form of an optimality system of equations for Problem II by applying a trick employed in [6, Chap. 1, Thm. 1.8] that consists of using the space of variations which does not contain the solution of the considered extreme problem.

In order to apply Theorem 5.1, we first have to define the space $\mathbf{V}_{A^*}(Q)$ in which we search for the adjoint vector field for the optimality system. This space is determined in Appendix B; see (B.14).

THEOREM 5.2. *Assume that $(\widehat{\mathbf{w}}, \nabla\widehat{p}) \in \mathbf{W} \times [\mathbf{L}^2(Q) + L^2(0, T; \nabla H^{1/2}(\Omega_{\rho+2}))]$ is a solution for Problem* II. *Then there exists a $\widehat{\mathbf{q}} \in \mathbf{V}_{A^*}(Q)$ such that*

$$\begin{aligned}
&\int_Q \big\{\partial_t \mathbf{h} - \Delta\mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}})\cdot\nabla]\mathbf{h} + (\mathbf{h}\cdot\nabla)(\mathbf{v}_0 + \widehat{\mathbf{w}})\big\}\cdot\widehat{\mathbf{q}}\, d\mathbf{x}\, dt \\
&+2\int_Q \mathcal{D}(\widehat{\mathbf{w}} + \mathbf{v}_0) : \mathcal{D}(\mathbf{h})\, d\mathbf{x}\, dt + \int_\Omega (\widehat{\mathbf{w}}(T, \mathbf{x}) + \mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty)\cdot\mathbf{h}\, d\mathbf{x} \\
&+\int_\Sigma \Big(\mathbf{h}\cdot(\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}}\cdot\mathbf{n} + \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2\mathbf{h}\cdot\mathbf{n} \\
&\qquad + N[\partial_t\widehat{\mathbf{w}}\cdot\partial_t\mathbf{h} + \nabla_\tau\widehat{\mathbf{w}} : \nabla_\tau\mathbf{h} + \widehat{\mathbf{w}}\cdot\mathbf{h}]\Big)\, ds\, dt = 0 \qquad \forall\, \mathbf{h} \in \mathbf{V}_A^{1,2}(Q)
\end{aligned} \tag{5.5}$$

Proof. First we convert Problem II into an equivalent optimal control problem through the change of variables

$$\mathbf{w} = \widehat{\mathbf{w}} + \mathbf{z} \quad \text{and} \quad \nabla p = \nabla \widehat{p} + \nabla p_1. \tag{5.6}$$

The optimal control problem for $(\mathbf{z}, \nabla p_1)$ is

$$\mathcal{J}_N(\widehat{\mathbf{w}} + \mathbf{z}) \to \inf \tag{5.7}$$

subject to the constraints

$$\partial_t \mathbf{z} - \Delta \mathbf{z} + [(\mathbf{v}_0 + \widehat{\mathbf{w}} + \mathbf{z}) \cdot \nabla]\mathbf{z} + (\mathbf{z} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0) = -\nabla p_1, \qquad \operatorname{div} \mathbf{z} = 0, \qquad \text{in } Q, \tag{5.8}$$

$$\mathbf{z}|_{t=0} = \mathbf{0} \quad \text{and} \quad \mathbf{z} \to \mathbf{0} \text{ as } |\mathbf{x}| \to \infty. \tag{5.9}$$

We consider the problem (5.7)–(5.9) for $\mathbf{z}$ running through the space $\mathbf{V}^{1,2}_A(Q)$ defined in Appendix B; see (B.21). Evidently, for each $\mathbf{z} \in \mathcal{W}^{(2)}_0(Q)$ (this space is defined in (B.21)), the left-hand side of the first equation in (5.8) belongs to $\mathbf{L}^2(Q)$. Let

$$P : \mathbf{L}^2(Q) \to L^2(0, T; \mathbf{V}^0_0(\Omega))$$

be the projection operator. Then Weyl's decomposition allows us to transform (5.8) into

$$P\Big(\partial_t \mathbf{z} - \Delta \mathbf{z} + [(\mathbf{v}_0 + \widehat{\mathbf{w}} + \mathbf{z}) \cdot \nabla]\mathbf{z} + (\mathbf{z} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0)\Big) = 0 \quad \text{and} \quad \operatorname{div} \mathbf{z} = 0. \tag{5.10}$$

The embedding $\mathcal{W}^{(2)}_0(Q) \hookrightarrow \mathbf{W}$ and the assumption

$$(\widehat{\mathbf{w}}, \widehat{p}) \in \mathbf{W} \times [\mathbf{L}^2(Q) + L^2(0, T; \nabla H^{1/2}(\Omega_{\rho+2}))]$$

being a solution for Problem II imply that $\widehat{\mathbf{z}} \equiv \mathbf{0}$ is a solution of optimal control problem (5.7) and (5.9)–(5.10). We now apply Theorem 5.1 to this control problem. We set $X_1 = \mathbf{V}^{1,2}_A(Q)$ and $X_2 = \mathbf{V}_A(Q)$ (see (B.21) and (B.12)). We define the mappings $f : X_1 \to \mathbb{R}$ and $F : X_1 \to X_2$ as follows:

$$\begin{aligned} &f(\mathbf{z}) = \mathcal{J}_N(\mathbf{z} + \widehat{\mathbf{w}}), \\ &F(\mathbf{z}) = P\Big(\partial_t \mathbf{z} - \Delta \mathbf{z} + [(\mathbf{v}_0 + \widehat{\mathbf{w}} + \mathbf{z}) \cdot \nabla]\mathbf{z} + (\mathbf{z} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0)\Big). \end{aligned} \tag{5.11}$$

Note that the constraint (5.9) is built into the space X_1 and the inequality constraint $g \le 0$ is absent in Problem II. We have to show that f and F defined in (5.11) are continuously differentiable. Here, we will only prove the continuous differentiability of F since this is more difficult than the corresponding property of f. The proof that the operator defined by the left-hand side of (5.8) acts continuously from X_1 to $\mathbf{L}^2(Q)$ is evident. To prove its continuity from X_1 to $\mathbf{L}^{6/5}(Q)$ we have to repeat the proof of Lemma 3.3 for all terms except for $(\mathbf{v}_0 \cdot \nabla)\mathbf{z}$. Using Holder's inequality and interpolation bound, we have

$$\begin{aligned} \|(\mathbf{v}_0 \cdot \nabla)\mathbf{z}\|_{L^{6/5}(Q)} &\le \|\mathbf{v}_0\|_{\mathbf{L}^6(Q)} \|\nabla \mathbf{z}\|_{\mathbf{L}^{3/2}(Q)} \\ &\le \|\mathbf{v}_0\|_{\mathbf{L}^6(Q)} \|\nabla \mathbf{z}\|^{1/2}_{\mathbf{L}^{6/5}(Q)} \|\nabla \mathbf{z}\|^{1/2}_{\mathbf{L}^2(Q)} \le C \|\nabla \mathbf{z}\|_{\mathbf{V}^{1/2}_A(Q)}. \end{aligned}$$

Therefore, the continuity of $F(z)$ from (5.11) is reduced to the proof of the continuity of the projector $P : \mathbf{L}_A(Q) \to \mathbf{V}_A(Q)$ that is actually contained in the proof of decomposition (B.16). Hence we have proved the continuity of $P : \mathbf{L}_A \to \mathbf{V}_A$. Consequently, we have proved the continuity of $F : \mathbf{V}_A^{1,2}(Q) \to \mathbf{V}_A(Q)$.

The derivative of F at the solution $\mathbf{0}$ for the problem (5.7) and (5.9)–(5.10) is given by

$$F'(\mathbf{0})\mathbf{h} = P\Big(\partial_t \mathbf{h} - \Delta \mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{h} + (\mathbf{h} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0)\Big)$$

and the operator $F'(0) : X_1 \to X_2$ is continuous, which can be proved in a way analogous to the proof of the continuity of operator F. To show $F'(0)$ is surjective, it suffices to prove that for each $\mathbf{f} \in \mathbf{V}_A(Q)$ there exists a solution $\mathbf{h} \in \mathbf{V}_A^{1,2}(Q)$ for the problem

$$\partial_t \mathbf{h} - \Delta \mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{h} + (\mathbf{h} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0) + \nabla p = \mathbf{f} \tag{5.12}$$

$$\operatorname{div} \mathbf{h} = 0, \quad \mathbf{h}|_{t=0} = \mathbf{0}, \quad \mathbf{h}|_{\Sigma} = \mathbf{0}, \quad \text{and} \quad \mathbf{h} \to \mathbf{0} \text{ as } |\mathbf{x}| \to \infty \tag{5.13}$$

with some $\nabla p \in \mathbf{L}^2(Q) \cap \mathbf{L}^{6/5}(Q)$.

Since $\mathbf{V}_A(Q) \subset \mathbf{L}^2(Q)$, by virtue of Proposition 3.4 there exists a unique solution $\mathbf{h} \in \mathcal{W}_0^{(2)}(Q)$ of (5.12) and (5.13). Moving the last three terms in the left-hand side of (5.12) to the right-hand side and using arguments of the proof of Lemma 3.3, we see that this new right-hand side belongs to $\mathbf{L}^{6/5}(Q)$. Extending $\mathbf{h}$ in (5.12) from $(0,T) \times \Omega$ into $\widetilde{\mathbf{h}} \in \mathcal{W}_0^{(2)}((0,T) \times \mathbb{R}^3)$ and using estimates of solutions of the Cauchy problem for the Stokes equations, we obtain, as in the proof of Lemma 3.3, that $\mathbf{h} \in \mathcal{W}_0^{(2)}((0,T) \times \mathbb{R}^3) \cap \mathbf{W}_{6/5}^{1,2}$. Hence $\widetilde{\mathbf{h}} = \widetilde{\mathbf{h}}|_Q \in \mathbf{V}_A^{1,2}(Q)$.

Hence, we have verified all assumptions of Theorem 5.1 and that theorem implies that there exists a $\hat{\mathbf{q}} \in \mathbf{V}_{A^*}(Q)$ such that (5.3) holds with $\lambda_0 = 1$, λ absent, and

$$\begin{aligned} \mathcal{L}(\mathbf{z}, \lambda_0, \mathbf{q}) &= \mathcal{J}_N(\mathbf{z} + \widehat{\mathbf{w}}) \\ &+ \int_Q \Big(\partial_t \mathbf{z} - \Delta \mathbf{z} + [(\mathbf{v}_0 + \widehat{\mathbf{w}} + \mathbf{z}) \cdot \nabla]\mathbf{z} + (\mathbf{z} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0)\Big) \cdot \hat{\mathbf{q}}\, d\mathbf{x}\, dt. \end{aligned} \tag{5.14}$$

Equation (5.3) with $\mathcal{L}$ defined by (5.14) takes on the form of (5.5). ∎

We express $\widehat{\mathbf{q}}(t, \mathbf{x})$ in the form

$$\widehat{\mathbf{q}}(t, \mathbf{x}) = \mathbf{q}(t, \mathbf{x}) - (\mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty), \tag{5.15}$$

where $\mathbf{v}_0(\mathbf{x})$ is the steady state solution from Proposition 2.1 and $\mathbf{v}_\infty \in \mathbb{R}^3$ is the vector from (2.4). By virtue of definitions (B.3), (B.4), and (B.14), the inclusion $\mathbf{v}_0(x) - \mathbf{v}_\infty \in \mathbf{L}^6(Q) \cap \mathbf{C}^\infty(Q)$ implies $\mathbf{v}_0(x) - \mathbf{v}_\infty \in \mathbf{V}_{A^*}(Q)$. Since $\hat{\mathbf{q}} \in \mathbf{V}_{A^*}$, we have $\mathbf{q} \in \mathbf{V}_{A^*}$.

5.3. Regularity of the adjoint velocity in the optimality system. In this subsection we will derive some regularity estimates for the adjoint variable $\mathbf{q}$ defined by Theorem 5.2 and (5.15).

We substitute (5.15) in (5.5) and restrict, in (5.5), $\mathbf{h}$ to $\mathbf{V}_A^{1,2}(Q) \cap \mathcal{V}_0^{(2)}(Q)$ (see (2.20)). Then we obtain

$$\begin{aligned}
&\int_Q \Big[\partial_t \mathbf{h} - \Delta \mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{h} + (\mathbf{h} \cdot \nabla)(\mathbf{v}_0 + \widehat{\mathbf{w}})\Big] \cdot \Big[\mathbf{q} - (\mathbf{v}_0 - \mathbf{v}_\infty)\Big]\, d\mathbf{x}\, dt \\
&\quad + \int_Q 2\mathcal{D}(\mathbf{h}) : \mathcal{D}(\mathbf{v}_0 + \widehat{\mathbf{w}})\, d\mathbf{x}\, dt \\
&\quad + \int_\Omega \mathbf{h}(T,x) \cdot \big[\widehat{\mathbf{w}}(T,x) + (\mathbf{v}_0(x) - \mathbf{v}_\infty)\big]\, d\mathbf{x} = 0 \quad \forall\, \mathbf{h} \in \mathbf{V}_A^{1,2} \cap \mathcal{V}_0^{(2)}(Q).
\end{aligned} \tag{5.16}$$

The relation (5.16) implies that $\mathbf{q} \in L^2(0,T;\mathbf{V}_0^0(\Omega))$ is the generalized solution of the boundary value problem

$$P\Big(\partial_t \mathbf{q} + \Delta \mathbf{q} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{q} - [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^* \mathbf{q}\Big) = P\Phi, \tag{5.17}$$

$$\operatorname{div} \mathbf{q} = 0, \qquad \mathbf{q}\big|_\Sigma = \mathbf{0}, \qquad \mathbf{q} \to \mathbf{0} \text{ as } |\mathbf{x}| \to \infty \tag{5.18}$$

and

$$\mathbf{q}\big|_{t=T} = -P\widehat{\mathbf{w}}(T,\cdot). \tag{5.19}$$

Here

$$\Phi(t,x) = \Delta \mathbf{v}_0 + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{v}_0 - [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^*(\mathbf{v}_0 - \mathbf{v}_\infty) - \Delta(\mathbf{v}_0 + \widehat{\mathbf{w}}). \tag{5.20}$$

We emphasize that the "initial" condition for $\mathbf{q}$, i.e., the right-hand side of (5.19), does not contain $\mathbf{v}_0 - \mathbf{v}_\infty$ although this term is present in integral over Ω in (5.16). We have the following regularity result for $\mathbf{q}(T,\cdot)$.

LEMMA 5.3. *Let* $\widehat{\mathbf{w}} \in \mathbf{W}$ *be a solution of Problem* I *or* II. *Then* $P\widehat{\mathbf{w}}(T,\cdot) \in \mathbf{H}^{3/4}(\Omega) \cap \mathbf{V}_0^0(\Omega)$, *where* P *is the projection operator defined by* (A.16).

Proof. We consider the operator $P = P_0 : \mathbf{L}^2(\Omega) \to \mathbf{V}_0^0(\Omega)$, which was defined as the Weyl orthogonal projection operator. We recall that for $s \in [0,2]$, $P\mathbf{H}^s(\Omega) \subset \mathbf{H}^s(\Omega)$ and the operator $P : \mathbf{H}^s(\Omega) \to \mathbf{H}^s(\Omega)$ is bounded. Indeed, for each $\mathbf{u} \in \mathbf{L}^2(\Omega)$, $P\mathbf{u} = \mathbf{u} - \nabla p$, where $\nabla p \in G_0 \equiv \{\nabla\phi \in \mathbf{L}^2(\Omega) : \phi \in H^1_{\mathrm{loc}}(\Omega)\}$ is the solution of the variational problem

$$\int_\Omega \nabla p(\mathbf{x}) \cdot \nabla\phi(\mathbf{x})\, d\mathbf{x} = \int_\Omega \mathbf{u} \cdot \nabla\phi(\mathbf{x})\, d\mathbf{x} \quad \forall\, \nabla\phi \in G_0. \tag{5.21}$$

The existence and uniqueness of a solution for this problem is well known (see [13]). Let $\mathbf{u} \in \mathbf{H}^2(\Omega)$. Integration by parts in (5.21) yields that ∇p is the solution of the boundary value problem: $\nabla p \in \mathbf{L}^2(\Omega)$,

$$-\Delta p = \operatorname{div} \mathbf{u} \quad \text{in } \Omega \qquad \text{and} \qquad \frac{\partial p}{\partial n}\Big|_{\partial\Omega} = (\mathbf{u} \cdot \mathbf{n})\big|_{\partial\Omega}.$$

By elliptic regularity and the regularity for div-curl problems (see [16]), we obtain that $p \in H^2_{\mathrm{loc}}(\Omega)$ and

$$\|\nabla p\|_{\mathbf{H}^2(\Omega)} \le C\Big(\|\operatorname{div} \mathbf{u}\|_{H^1(\Omega)} + \|(\mathbf{u} \cdot \mathbf{n})\big|_{\partial\Omega}\|_{H^{3/2}(\partial\Omega)}\Big) \le C\|\mathbf{u}\|_{\mathbf{H}^2(\Omega)}.$$

Thus, we have that the operators $I - P : \mathbf{L}^2(\Omega) \to \mathbf{L}^2(\Omega)$ and $I - P : \mathbf{H}^2(\Omega) \to \mathbf{H}^2(\Omega)$ are bounded. By interpolation theorems, the operator $P : \mathbf{H}^s(\Omega) \to \mathbf{H}^s(\Omega)$ and $I - P : \mathbf{H}^s(\Omega) \to \mathbf{H}^s(\Omega)$ are bounded for each $s \in [0,2]$.

Since $\widehat{\mathbf{w}} \in \mathbf{W} \subset L^2(0,T;\mathbf{H}^{3/2}(\Omega))$, we deduce that

$$P\widehat{\mathbf{w}} \in L^2(0,T;\mathbf{H}^{3/2}(\Omega)). \tag{5.22}$$

Because $\widehat{\mathbf{w}}$ is a solution of Problem I or II, it satisfies (2.7)–(2.10). Integrating (2.7) over $t \in [0,\tau]$ and then applying the operator P, we obtain

$$P\widehat{\mathbf{w}}(\tau,\cdot) = \int_0^\tau \Big(P\Delta\widehat{\mathbf{w}}(t,\cdot) - P[(\widehat{\mathbf{w}}+\mathbf{v}_0)\cdot\nabla]\widehat{\mathbf{w}} - P(\widehat{\mathbf{w}}\cdot\nabla)\mathbf{v}_0 \Big)\, dt. \tag{5.23}$$

Since $\widehat{\mathbf{w}} \in \mathbf{W}$ and therefore $\Delta\widehat{\mathbf{w}} = g + \nabla p$ with $g \in \mathbf{L}^2(Q)$, $\nabla p \in L^2(0,T;\nabla H^{1/2}(\Omega))$, we easily see that

$$P\widehat{\mathbf{w}}(t,\cdot) \in L^2(0,T;\mathbf{V}_0^0(\Omega)) \text{ and } \widehat{\mathbf{w}} \in L^2(0,T;\mathbf{H}^{3/2}(\Omega)) \cap L^\infty(0,T;\mathbf{H}^1(\Omega)).$$

From the last inclusion, the inclusion $\mathbf{v}_0 \in \mathbf{C}^2(\overline{\Omega})$, and Sobolev embedding theorems, we conclude that the integrand from the right-hand side of (5.23) belongs to $L^2(0,T;\mathbf{V}_0^0(\Omega))$. Hence, by differentiating (5.23) with respect to τ we obtain

$$\partial_t P\widehat{\mathbf{w}}(t,\cdot) \in L^2(0,T;\mathbf{V}_0^0(\Omega)) \subset L^2(0,T;\mathbf{L}^2(\Omega)). \tag{5.24}$$

Then (5.22), (5.24), and the trace theorems of [14] imply that

$$P\widehat{\mathbf{w}}(t,\cdot) \in \mathbf{C}(0,T;\mathbf{H}^{3/4}(\Omega)). \qquad \square$$

The spaces $\mathbf{V}_\sigma^s$ used below are defined and studied in Appendix A.1.

THEOREM 5.4. *Assume that* $\mathbf{q} \in \mathbf{V}_{A^*}(Q)$ *satisfies* (5.16). *Then for each* $\delta > 0$, $\mathbf{q} \in L^2(0,T-\delta;\mathbf{V}_\sigma^2(\Omega)) \cap H^1(0,T-\delta;\mathbf{V}_\sigma^0(\Omega))$. *Furthermore, there exists a constant* $C > 0$ *such that for each* $\delta \in [0,T]$ *and each* $\epsilon \in (0,1/2)$, $\mathbf{q}$ *satisfies the estimate*

$$\begin{aligned} &\int_0^{T-\delta} \Big(\|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}_\sigma^2(\Omega)} + \|\partial_t\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}_\sigma^0(\Omega)} \Big)\, dt \\ &\le C\Big(\delta^{-\epsilon-1/2}\|P\widehat{\mathbf{w}}(T,\cdot)\|^2_{\mathbf{V}_\sigma^{-\epsilon+1/2}(\Omega)} + \|P\Phi\|^2_{L^2(0,T;\mathbf{V}_\sigma^0(\Omega))} \Big). \end{aligned} \tag{5.25}$$

In particular, $\mathbf{q}$ *satisfies* (5.17) *in* $L^2(0,T-\delta;\mathbf{V}_\sigma^0(\Omega))$ *and* (5.18) *for every* $\delta \in (0,T)$ *and satisfies* (5.19) *in the space* $\mathbf{V}_\sigma^{-\epsilon+1/2}(\Omega)$ *for every* $\epsilon \in (0,1/2)$.

Proof. Since $\widehat{\mathbf{w}} \in \mathbf{W}$ and $\mathbf{v}_0 \in C^\infty(\overline{\Omega})$ satisfies (2.4), the vector field Φ defined by (5.20) belongs to $L^2(0,T;\mathbf{V}_0^0(\Omega))$. Therefore problem (5.17)–(5.19) has a solution $\widetilde{\mathbf{q}} \in L^2(0,T;\mathbf{V}_\sigma^1(\Omega))$. This follows directly from Proposition 3.5 and Lemma 3.6. Moreover, since $\Phi \in \mathbf{L}^2(Q)$, Proposition 3.5 and Theorem A.8 imply that $\widetilde{\mathbf{q}} \in L^2(0,T-\delta;\mathbf{V}_\sigma^2(\Omega)) \cap H^1(0,T-\delta;\mathbf{V}_\sigma^0(\Omega))$ for all $\delta \in (0,T)$ and $\widetilde{\mathbf{q}}$ satisfies (5.25).

Multiplying (5.17) by $\mathbf{h} \in \mathcal{V}_0^{(2)}(Q)$, integrating over Q, and performing integration by parts, we see that $\widetilde{\mathbf{q}}$ is a generalized solution of (5.17)–(5.19), i.e., $\widetilde{\mathbf{q}}$ satisfies (5.16).

Now we prove the uniqueness of the generalized solution in the space $\mathbf{V}_{A^*}(Q)$ for (5.17)–(5.19) (recall that the space $\mathbf{V}_{A^*}(\Omega)$ contains $L^2(0,T;\mathbf{V}_0^0(\Omega))$.) Let $\mathbf{q}$ and $\widetilde{\mathbf{q}}$ both belong to $\mathbf{V}_{A^*}(Q)$ and satisfy (5.16). Denote $\mathbf{g} = \mathbf{q} - \widetilde{\mathbf{q}}$. Substituting (5.16) for $\widetilde{\mathbf{q}}$ from (5.16) for $\mathbf{q}$ we obtain

$$\int_Q \Big([\partial_t\mathbf{h} - \Delta\mathbf{h} + [(\mathbf{v}_0+\widehat{\mathbf{w}})\cdot\nabla]\mathbf{h} + (\mathbf{h}\cdot\nabla)(\widehat{\mathbf{w}}+\mathbf{v}_0) \Big) \cdot \mathbf{g}\, d\mathbf{x}\, dt = 0 \tag{5.26}$$

$$\forall\, \mathbf{h} \in \mathbf{V}_A^{1,2}(Q) \cap \mathcal{V}_0^{(2)}(Q).$$

Let us consider the boundary value problem

$$P\big(\partial_t \mathbf{h} - \Delta \mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{h} + (\mathbf{h} \cdot \nabla)(\widehat{\mathbf{w}} + \mathbf{v}_0\big) = \mathbf{g}_1, \tag{5.27}$$

$$\operatorname{div} \mathbf{h} = 0, \qquad \mathbf{h}\big|_{\Sigma} = \mathbf{0}, \qquad \mathbf{h} \to 0 \text{ as } |\mathbf{x}| \to \infty, \qquad \text{and} \qquad \mathbf{h}\big|_{t=0} = \mathbf{0}, \tag{5.28}$$

where $\mathbf{g}_1 \in \mathbf{V}_A(Q)$. The problem (5.27)–(5.28) is equivalent to the problem (5.12)–(5.13), whose solvability has been established in the proof of Theorem 5.2. Thus, for each $\mathbf{g}_1 \in \mathbf{V}_A(Q)$ there exists the unique solution $\mathbf{h} \in \mathbf{V}_A^{1,2}(Q)$ of (5.27)–(5.28). The spaces $\mathbf{V}_A(Q)$ and $\mathbf{V}_{A^*}(Q)$ are dual, and therefore by a well-known corollary of the Hanh–Banach theorem, for a given $\mathbf{g} \in \mathbf{V}_{A^*}$ there exists a $\mathbf{g}_1 \in \mathbf{V}_A(Q)$ (which we consider here as a functional on $\mathbf{V}_{A^*}(Q)$) such that $\|\mathbf{g}_1\|_{\mathbf{V}_A(Q)} = 1$ and

$$\int_Q \mathbf{g}_1 \cdot \mathbf{g}\, d\mathbf{x}\, dt = \|\mathbf{g}\|_{\mathbf{L}_{A^*}(Q)}. \tag{5.29}$$

If we substitute into (5.26) the solution $\mathbf{h}$ of (5.27)–(5.28), we obtain that the left-hand side of (5.26) is equal to (5.29). Hence, $\mathbf{g} \equiv \mathbf{0}$ and uniqueness is proved. Equality (5.19) is true in the space $\mathbf{V}_\sigma^{-\epsilon+1/2}(\Omega)$ by virtue of Lemmas 5.3, A.4, A.6, and A.7. To summarize, we have proved all the assertions of Theorem 5.4. □

6. The strong form of the optimality system for Problem II. Using the regularity results for the adjoint velocity field established in Theorem 5.4, we now proceed to derive (see Theorem 6.4 below) the optimality system of partial differential equations and boundary, initial, and terminal conditions for Problem II.

6.1. The adjoint pressure. We first establish the existence of an adjoint pressure variable.

LEMMA 6.1. *Let* $\mathbf{q} \in L^2(0.T; \mathbf{V}_0^0(\Omega))$ *be the adjoint variable defined in* (5.15) *by* $\widehat{\mathbf{q}}$ *found in Theorem* 5.2. *Then there exists a distribution* $\widetilde{r}(t, \mathbf{x})$ *on* Q *such that the pair* $(\mathbf{q}, \nabla\widetilde{r})$ *is a solution of the problem* (5.18) *and*

$$\partial_t \mathbf{q} + \Delta \mathbf{q} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{q} - [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^* \mathbf{q} + \nabla\widetilde{r} = \Phi, \tag{6.1}$$

where Φ *is defined in* (5.20). *Furthermore,* $\nabla\widetilde{r}$ *has the decomposition*

$$\nabla\widetilde{r} = \nabla r_1 + \nabla r_2 + \nabla r_3, \tag{6.2}$$

with ∇r_i, $i = 1, 2, 3$, *satisfying the estimates*

$$\int_0^{T-\delta} \|\nabla r_1(t, \cdot)\|^2_{\mathbf{L}^2(\Omega)}\, dt \le C\Big(\delta^{-\epsilon-1/2} \|P\widehat{\mathbf{w}}(T, \cdot)\|^2_{\mathbf{V}^{-\epsilon+1/2}(\Omega)} + \|P\Phi\|^2_{L^2(0,T;\mathbf{V}^0_\sigma(\Omega))}\Big), \tag{6.3}$$

$$\operatorname{supp}(\nabla r_2) \in Q_{\rho+2}, \qquad \|\nabla r_2\|_{L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))} \le C\|\widehat{\mathbf{w}}\|_{\mathbf{V}_\rho^{1,1/2}(Q)}, \tag{6.4}$$

and

$$\|\nabla r_3\|_{\mathbf{L}^2(Q)} \le C\|(\Phi + \Delta\widehat{\mathbf{w}}) - \mathbf{w}_2\|_{\mathbf{L}^2(Q)} \le C_1\Big(\|\widehat{\mathbf{w}}\|_{\mathbf{V}_\rho^{1,1/2}(Q)} + \|\Delta\mathbf{v}_0\|_{\mathbf{L}^2(Q)}\Big), \tag{6.5}$$

where C in (6.3) *depends on* $\|\mathbf{v}_0\|_{\mathbf{C}^2(\overline{\Omega})}+\|\widehat{\mathbf{w}}\|_{\mathbf{V}^{1,1/2}(Q)}$, C_1 *in* (6.5) *depends on* $\|\mathbf{v}_0\|_{\mathbf{C}^2(\Omega)}+\|\nabla\mathbf{v}_0\|_{\mathbf{L}^2(\Omega)}+|\mathbf{v}_\infty|$, *and* $\mathbf{w}$ *is defined below in* (6.7).

Proof. First, we claim that (5.17) can be rewritten as (6.1). Indeed, since $\partial_t\mathbf{q}+\Delta\mathbf{q}+[(\mathbf{v}_0+\widehat{\mathbf{w}})\cdot\nabla]\mathbf{q}-[\nabla(\mathbf{v}_0+\widehat{\mathbf{w}})]^*\mathbf{q}\in\mathbf{L}^2((0,T-\delta)\times\Omega)$ for each $\delta\in(0,T)$, we obtain from Weyl's decomposition that there exists a $\nabla r_1\in\mathbf{L}^2((0,T-\delta)\times\Omega)$ for each $\delta\in(0,T)$ such that

$$\partial_t\mathbf{q}+\Delta\mathbf{q}+[(\mathbf{v}_0+\widehat{\mathbf{w}})\cdot\nabla]\mathbf{q}-[\nabla(\mathbf{v}_0+\widehat{\mathbf{w}})]^*\mathbf{q}+\nabla r_1=P\Phi. \tag{6.6}$$

Expressing ∇r_1 through (6.6) and using (5.25) and Sobolev embedding theorems, we deduce estimate (6.3). On the other hand, it follows from the definition of $\mathbf{W}$ and $\mathbf{V}_\rho^{1,1/2}(Q)$ (see (2.22) and (2.19)) and the inclusion $\widehat{\mathbf{w}}\in\mathbf{W}$, that

$$\widehat{\mathbf{w}}=\mathbf{v}_1+\mathbf{v}_2\quad\text{where}\quad\Delta\mathbf{v}_2=\mathbf{w}_2+\nabla r_2 \tag{6.7}$$

and where $\mathbf{v}_1\in\mathcal{V}_0^{(2)}(Q),\mathbf{v}_2\in\mathbf{V}_\rho^{1,1/2}(Q),\mathbf{w}_2\in\mathbf{L}^2(Q_{\rho+2})$, and $\nabla r_2\in L^2(0,T;\nabla H^{1/2}(\Omega_{\rho+2}))$. Evidently, the estimate (6.4) holds. Moreover, $P(\Phi+\Delta\widehat{\mathbf{w}}-\mathbf{w}_2)=\Phi+\Delta\widehat{\mathbf{w}}-\mathbf{w}_2-\nabla r_3$ so that (6.1) and the estimate (6.5) hold. ∎

We next show that the traces of $\partial\widehat{\mathbf{w}}/\partial n$ and r_2 with respect to Σ are well defined.

LEMMA 6.2. *Let r_2 be defined in* (6.7). *The restrictions of r_2 and $\partial\widehat{\mathbf{w}}/\partial n$ on Σ are well defined and*

$$\frac{\partial\widehat{\mathbf{w}}}{\partial n}\Big|_\Sigma\in\mathbf{L}^2(\Sigma)\qquad\text{and}\qquad r_2|_\Sigma\in L^2(\Sigma). \tag{6.8}$$

Proof. To define r_2 from (6.7) uniquely, we assume that $\int_{\Omega_{\rho+2}}r_2(t,\mathbf{x})\,d\mathbf{x}=0$ a.e. $t\in[0,T]$. Since the inclusion $\mathbf{v}_1\in\mathcal{V}_0^{(2)}(Q)$ implies that $\frac{\partial\mathbf{v}_1}{\partial n}|_\Sigma\in L^2(\Sigma)$, the inclusion $\frac{\partial\widehat{\mathbf{w}}}{\partial n}\in L^2(\Sigma)$ follows from (6.7) and $\frac{\partial\mathbf{v}_2}{\partial n}|_\Sigma\in L^2(\Sigma)$.

Using Lemma 4.4 from [9], we introduce coordinates (y_1,y_2,y_3) in $\Omega(\varepsilon)$ (an ε-neighborhood of $\partial\Omega$), where $y_3(\mathbf{x})=\operatorname{dist}(\mathbf{x},\partial\Omega)$ for $\mathbf{x}\in\Omega(\varepsilon)$ and $(y_1,y_2)=(y_1^k(\mathbf{x}),y_2^k(\mathbf{x}))$ are local coordinates in $\mathcal{U}^k$ and $\cup_k\mathcal{U}^k$ is a finite covering of $\partial\Omega$. For each k, the coordinates $(y_1,y_2,y_3)=(y_1^k,y_2^k,y_3)$ are orthogonal, i.e.,

$$\nabla y_i(\mathbf{x})\cdot\nabla y_j(\mathbf{x})=\delta_{ij},\quad i,j=1,2,3.$$

This property implies that if $\mathbf{v}(\mathbf{y})$ is a rewriting of a vector field $\mathbf{w}(\mathbf{x})$ in terms of the coordinates (y_1,y_2,y_3) and $\operatorname{div}\mathbf{w}(\mathbf{x})=\sum_{i=1}^3\partial_{x_i}w_i=0$, then $\operatorname{div}\mathbf{v}(\mathbf{y})=\sum_{i=1}^3\partial_{y_i}v_i=0$; see [4].

Let $\widehat{\mathbf{v}}(t,\mathbf{y})$, $\mathbf{z}(t,\mathbf{y})$, and $\nabla_\mathbf{y}s(t,\mathbf{y})$ be rewritings in terms of the coordinates (y_1,y_2,y_3) of the corresponding vector fields $\mathbf{v}_2(t,\mathbf{x})$, $\mathbf{w}_2(t,\mathbf{x})$, and $\nabla_\mathbf{x}r_2(t,\mathbf{x})$. Then, the decomposition $\Delta\mathbf{v}_2=\mathbf{w}_2+\nabla r_2$ can be rewritten as follows:

$$\Delta_y\widehat{\mathbf{v}}=\mathbf{z}+\sum_{i=1}^3C_i(\mathbf{y})\frac{\partial\widehat{\mathbf{v}}}{\partial y_i}+\nabla_\mathbf{y}s, \tag{6.9}$$

where $C_i(\mathbf{y})$ are certain infinitely smooth vector fields. We denote $Q(\varepsilon)=(0,T)\times\Omega(\varepsilon)$. Taking into account the fact that $\widehat{\mathbf{v}}\in\mathbf{H}^{1,1/2}(Q(\varepsilon))$, which in turn implies

$$\partial\widehat{\mathbf{v}}/\partial y_3\in L^2(0,T;\mathbf{H}^{1/2}(\Omega(\varepsilon)))\cap H^1(0,T;\mathbf{H}^{-1/2}(\Omega(\varepsilon))),$$

we obtain that, for $j=1,2$,

$$\frac{\partial^2\widehat{\mathbf{v}}}{\partial y_3\partial y_j}\in L^2(0,T;\mathbf{L}^2(0,\varepsilon;\mathbf{H}^{-1/2}(\partial\Omega_{(\cdot)}))), \tag{6.10}$$

where $(0,\varepsilon)$ is the interval for the local variables y_3 and $\partial\Omega_{(z)} = \{\mathbf{x} \in \Omega(\varepsilon) : y_3(\mathbf{x}) = z\}$, $z \in (0,\varepsilon)$. Relation (6.10) means that $\partial^2_{y_3y_j}\widehat{\mathbf{v}}(\cdot,y_3) \in L^2(0,T;\mathbf{H}^{-1/2}(\partial\Omega_{(y_3)}))$ for almost all y_3 and the function $y_3 \mapsto \|\partial^2\widehat{\mathbf{v}}/\partial y_3\partial y_j(\cdot,y_3)\|_{L^2(0,T;\mathbf{H}^{-1/2}(\partial\Omega_{(y_3)}))} \in L^2(0,\varepsilon)$. Differentiating the equality $\operatorname{div}\widehat{\mathbf{v}} = 0$ with respect to y_3 and taking into account (6.10), we obtain

$$\frac{\partial^2\widehat{v}_3}{\partial y_3^2} = -\frac{\partial^2\widehat{v}_1}{\partial y_3\partial y_1} - \frac{\partial^2\widehat{v}_2}{\partial y_3\partial y_2} \in L^2(0,\varepsilon;L^2(0,T;\mathbf{H}^{-1/2}(\partial\Omega_{(\cdot)}))). \tag{6.11}$$

Since $\widehat{\mathbf{v}} \in \mathbf{H}^{1,1/2}(Q(\varepsilon)) \subset L^2(0,T;\mathbf{H}^{3/2}(\Omega(\varepsilon)))$, we obtain

$$\widehat{v}_j \in L^2(0,\varepsilon;L^2(0,T;H^{3/2}(\partial\Omega_{(\cdot)}))), \quad j = 1,2,3. \tag{6.12}$$

Define the diffeomorphism $\kappa : \Omega(\varepsilon) \to (0,\varepsilon)\times\partial\Omega$ which transforms each point $\mathbf{x} \in \partial\Omega(\varepsilon)$ possessing coordinates $(y_1^k(\mathbf{x}), y_2^k(\mathbf{x}), y_3(\mathbf{x}))$ into the pair $(y_3(\mathbf{x}),\mathbf{z})$, where $y_3 \in (0,\epsilon)$ and $\mathbf{z} \in \partial\Omega$ is a point possessing coordinates $(y_1(\mathbf{x}), y_2(\mathbf{x}))$. Evidently, under this diffeomorphysm the inclusions (6.11) and (6.12) transform into the inclusions

$$\frac{\partial^2\widehat{v}_3}{\partial y_3^2} \in L^2(0,\varepsilon;L^2(0,T;H^{-1/2}(\partial\Omega))), \quad \widehat{v}_3 \in L^2(0,\varepsilon;L^2(0,T;H^{3/2}(\partial\Omega))). \tag{6.13}$$

The inclusions in (6.13) and trace theorems (see [14]) yield that

$$\frac{\partial\widehat{v}_3}{\partial y_3} \in C(0,\varepsilon;L^2(0,T;L^2(\partial\Omega))) \qquad \text{and} \qquad \frac{\partial\widehat{v}_3}{\partial y_3}\Big|_\Sigma \in L^2(\Sigma). \tag{6.14}$$

Since $\widehat{v}_3 \in H^{1,1/2}(Q(\varepsilon))$ and $z \in \mathbf{L}^2(Q(\varepsilon))$, (6.9) implies that

$$\begin{aligned}\partial_{y_3}\big(\partial_{y_3}\widehat{v}_3 - s\big) &= -\big(\partial^2_{y_1y_1} + \partial^2_{y_2y_2}\big)\widehat{v}_3 - z_3 + \sum_{j=1}^3 C_j^3(\mathbf{y})\frac{\partial\widehat{v}^3}{\partial y_j}\\ &\in L^2(0,\varepsilon;L^2(0,T;H^{-1/2}(\partial\Omega))).\end{aligned} \tag{6.15}$$

Moreover, since $\partial_{y_3}\widehat{v}_3 \in L^2(0,T;H^{1/2}(\Omega(\varepsilon)))$ and $s \in L^2(0,T;H^{1/2}(\Omega(\varepsilon)))$, we have that

$$\partial_{y_3}\widehat{v}_3 - s \in L^2(0,\varepsilon;L^2(0,T;H^{1/2}(\partial\Omega_{(\cdot)}))). \tag{6.16}$$

Applying the diffeomorphysm κ and after using trace theorems, we obtain from (6.15) and (6.16) that

$$\partial_{y_3}\widehat{v}_3 - s \in C(0,\varepsilon;L^2(0,T;L^2(\partial\Omega_{(\cdot)}))) \quad \text{and} \quad (\partial_{y_3}\widehat{v}_3 - s)\big|_\Sigma \in L^2(\Sigma). \tag{6.17}$$

Then (6.14) and (6.17) imply that

$$s|_\Sigma \in L^2(\Sigma). \tag{6.18}$$

Finally, (6.9) implies, for $k = 1,2$,

$$\frac{\partial^2\widehat{v}_k}{\partial y_3^2} = -\left(\frac{\partial^2}{\partial y_1^2} + \frac{\partial^2}{\partial y_2^2}\right)\widehat{v}_k - z_3 + \sum_{j=1}^3 C_j^k\frac{\partial\widehat{v}}{\partial y_j} - \frac{\partial s}{\partial y_k} \in L^2(0,\varepsilon;L^2(0,T;H^{-1/2}(\partial\Omega_{(\cdot)}))).$$

This relation together with (6.12) implies, by virtue of trace theorems, that

$$\frac{\partial \widehat{v}_k}{\partial y_3} \in C(0,\varepsilon; L^2(0,T; L^2(\partial\Omega_{(\cdot)}))) \quad \text{and} \quad \frac{\partial \widehat{v}_k}{\partial y_3}\Big|_{\Sigma} \in L^2(\Sigma), \quad k=1,2. \tag{6.19}$$

The relations (6.7), (6.14), (6.18), and (6.19) imply (6.8). □

Note that (6.3), (6.4), and (6.5) imply that $\widetilde{r}(t,\mathbf{x})$ determined in (6.2) has a well-defined trace on Σ and

$$\widetilde{r}|_{\Sigma} \in L^2(\Sigma). \tag{6.20}$$

6.2. An additional condition on the boundary. We now derive an additional condition that holds on the boundary. This is done, roughly speaking, by integration by parts in (5.5).

Let $\widehat{p}$ be the pressure in (2.7), where $\mathbf{w} = \widehat{\mathbf{w}}$. Using (6.7) and Lemma 6.2 and repeating relevant arguments from (6.1) to (6.20), we can derive from (2.7) that $\nabla\widehat{p}$ has a well-defined trace on Σ and

$$\widehat{p}|_{\Sigma} \in L^2(\Sigma). \tag{6.21}$$

Note that through the change of variable

$$\nabla\widetilde{r} = -\nabla r - \nabla\widehat{p}, \tag{6.22}$$

where $\widehat{p}$ is the pressure in the first equation in (2.7), we may convert (6.1) into

$$\partial_t \mathbf{q} + \Delta\mathbf{q} + [(\mathbf{v}_0 + \widehat{\mathbf{w}})\cdot\nabla]\mathbf{q} - [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^*\mathbf{q} - \nabla r = \Phi + \nabla\widehat{p}. \tag{6.23}$$

By (6.20), (6.21), and (6.22), $r|_{\Sigma}$ is well defined and

$$r|_{\Sigma} \in L^2(\Sigma). \tag{6.24}$$

In order to define r and $\widehat{p}$ uniquely we assume that

$$\int_{\partial\Omega} \widehat{p}(t,\mathbf{x})\, ds = 0 \qquad \text{and} \qquad \int_{\partial\Omega} r(t,\mathbf{x})\, ds = 0 \qquad \text{a.e. } t \in [0,T]. \tag{6.25}$$

LEMMA 6.3. *Let* $\mathbf{q} \in L^2(0.T; \mathbf{V}_0^0(\Omega))$ *be the adjoint variable defined in* (5.15) *by* $\widehat{\mathbf{q}}$ *found in Theorem* 5.2. *Then*

$$\begin{aligned} &\int_{\Sigma} \mathbf{h}\cdot\Big(\mathcal{T}(\widehat{\mathbf{w}},\widehat{p})\mathbf{n} + \mathcal{T}(\mathbf{q},r)\mathbf{n} + 2\mathcal{D}(\mathbf{v}_0)\mathbf{n} + (\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}}\cdot\mathbf{n} \\ &+ \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2\mathbf{n} + N(-\partial_{tt}\widehat{\mathbf{w}} + \widehat{\mathbf{w}})\Big)\, ds\, dt \\ &+ N\int_{\Sigma} \nabla_\tau\widehat{\mathbf{w}} : \nabla_\tau\mathbf{h}\, ds\, dt = 0 \quad \forall\, \mathbf{h} \in \widetilde{\mathcal{V}}_0^{(2)}(Q) \quad \textit{with} \quad \mathbf{h}(T,\cdot) = 0, \end{aligned} \tag{6.26}$$

where

$$\mathcal{T}(\widehat{\mathbf{w}},\widehat{p}) = -\widehat{p}I + 2\mathcal{D}(\widehat{\mathbf{w}}) \qquad \textit{and} \qquad \mathcal{T}(\mathbf{q},r) = -rI + 2\mathcal{D}(\mathbf{q}). \tag{6.27}$$

Proof. We substitute (5.15) into (5.5) and manipulate the resulting expression with $\mathbf{q}$ as follows. We subdivide Q into two disjoint cylinders $Q_{T-\delta} = (0, T-\delta)\times\Omega$ and $Q_\delta = (T-\delta, T)\times\Omega$. Denote $\Sigma_{T-\delta} = (0,T-\delta)\times\partial\Omega$. We express the integral

over Q in (5.5) as the sum of integrals over $Q_{T-\delta}$ and Q_δ and perform integration by parts over $Q_{T-\delta}$. This leads us to

$$
\begin{aligned}
&\int_{Q_{T-\delta}} \Big(- \big[\partial_t \mathbf{q} + \Delta \mathbf{q} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{q} \\
&\qquad - [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^* \mathbf{q}\big] \cdot \mathbf{h} \Big)\, d\mathbf{x}\, dt + \int_{Q_{T-\delta}} \mathbf{h} \cdot \Phi \, dx\, dt \\
&\quad + \int_{Q_\delta} \Big(2\mathcal{D}(\widehat{\mathbf{w}} + \mathbf{v}_0) : \mathcal{D}(\mathbf{h}) + \big[\partial_t \mathbf{h} - \Delta \mathbf{h} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{h} \\
&\qquad + (\mathbf{h} \cdot \nabla)(\mathbf{v}_0 + \widehat{\mathbf{w}})\big] \cdot (\mathbf{q} - \mathbf{v}_0 + \mathbf{v}_\infty) \Big)\, d\mathbf{x}\, dt \\
&\quad + \int_{\Sigma_{T-\delta}} \Big(\mathbf{h} \cdot 2\mathcal{D}(\mathbf{v}_0 + \widehat{\mathbf{w}})\mathbf{n} + \mathbf{h} \cdot \partial_n \mathbf{q} \Big)\, ds\, dt \\
&\quad + \int_\Omega (\mathbf{q}(T - \delta, \mathbf{x}) - \mathbf{v}_0 + \mathbf{v}_\infty) \cdot \mathbf{h}(T - \delta, \mathbf{x})\, d\mathbf{x} \\
&\quad + \int_\Omega (\widehat{\mathbf{w}}(T, \mathbf{x}) + \mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty) \cdot \mathbf{h}(T, \mathbf{x})\, d\mathbf{x} \\
&\quad + \int_\Sigma \Big(\mathbf{h} \cdot (\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}} \cdot \mathbf{n} + \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2 \mathbf{h} \cdot \mathbf{n} \\
&\qquad + N[\partial_t \widehat{\mathbf{w}} \cdot \partial_t \mathbf{h} + \nabla_\tau \widehat{\mathbf{w}} : \nabla_\tau \mathbf{h} + \widehat{\mathbf{w}} \cdot \mathbf{h}] \Big)\, ds\, dt = 0 \quad \forall\, \mathbf{h} \in \mathbf{V}_A^{1,2}(Q).
\end{aligned} \tag{6.28}
$$

Note that (6.22) and (6.25) imply

$$
\int_{\partial\Omega} \widetilde{r}(t, \cdot)\, ds = 0 \quad \text{a.e. } t \in (0, T). \tag{6.29}
$$

Expressing $\nabla \widetilde{r}$ by (6.1), we see that the integrals over $Q_{T-\delta}$ in (6.28) are equal to

$$
\int_{Q_{T-\delta}} \mathbf{h} \cdot \nabla \widetilde{r}\, d\mathbf{x}\, dt = \int_{\Sigma_{T-\delta}} \mathbf{h} \cdot \widetilde{r}\, \mathbf{n}\, ds,
$$

where the integration by parts is valid because of (6.8). Thus, (6.28) and the relation $\mathbf{v}_0|_{\partial\Omega} = 0$ reduce to

$$
\begin{aligned}
&\int_{Q_\delta} \Big\{ 2\mathcal{D}(\mathbf{h}) : \mathcal{D}(\mathbf{v}_0 + \widehat{\mathbf{w}}) + [\partial_t \mathbf{h} - \Delta \mathbf{h} + ((\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla)\mathbf{h} \\
&\qquad + (\mathbf{h} \cdot \nabla)(\mathbf{v}_0 + \widehat{\mathbf{w}})] \cdot (\mathbf{q} - \mathbf{v}_0 + \mathbf{v}_\infty) \Big\}\, d\mathbf{x}\, dt \\
&\quad + \int_{\Sigma_{T-\delta}} \mathbf{h} \cdot 2\mathcal{D}(\widehat{\mathbf{w}})\mathbf{n}\, ds\, dt + \int_{\Sigma_{T-\delta}} \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n})\, ds\, dt \\
&\quad + \int_\Omega \Big(\mathbf{h}(T, \mathbf{x}) \cdot (\widehat{\mathbf{w}}(T, \mathbf{x}) + \mathbf{v}_0(\mathbf{x}) - \mathbf{v}_\infty) \\
&\qquad + \mathbf{h}(T - \delta, \mathbf{x}) \cdot (\mathbf{q}(T - \delta, \mathbf{x}) - \mathbf{v}_0 + \mathbf{v}_\infty) \Big)\, d\mathbf{x} \\
&\quad + \int_\Sigma \Big(\mathbf{h} \cdot (\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}} \cdot \mathbf{n} + \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2 \mathbf{h} \cdot \mathbf{n} \Big)\, ds\, dt \\
&\quad + \int_\Sigma \Big(N(\partial_t \mathbf{w} \cdot \partial_t \mathbf{h} - \nabla_\tau \mathbf{w} : \nabla_\tau \mathbf{h} + \widehat{\mathbf{w}} \cdot \mathbf{h}) \Big)\, ds\, dt = 0 \quad \forall\, \mathbf{h} \in \mathbf{V}_A^{1,2}(Q).
\end{aligned} \tag{6.30}
$$

Now we examine passage to the limit in (6.30) as $\delta \to 0$. The integral over Q_δ tends to zero as $\delta \to 0$ since $\mathbf{h} \in \mathbf{V}_A^{1,2}(Q)$, $(q - \mathbf{v}_0 + \mathbf{v}_\infty) \in L_{A^*}(Q)$, and $\text{meas}(Q_\delta) \to 0$. By virtue of Lemma 6.2,

$$\int_{\Sigma_{T-\delta}} \mathbf{h} \cdot 2\mathcal{D}(\widehat{\mathbf{w}})\mathbf{n}\, ds\, dt \to \int_{\Sigma_T} \mathbf{h} \cdot 2\mathcal{D}(\widehat{\mathbf{w}})\mathbf{n}\, ds\, dt \quad \text{as } \delta \to 0.$$

Since $\mathbf{q}$ is a solution of (3.12), by Proposition 3.5 and Lemma 3.6 it satisfies the energy estimate so that $\mathbf{q} \in C([0,T]; \mathbf{L}_w^2(\Omega))$, where $\mathbf{L}_w^2(\Omega)$ is $\mathbf{L}^2(\Omega)$ endowed with the weak topology. Thus, the integral over Ω in (6.30) tends to zero as $\delta \to 0$ thanks to Theorem 5.4 and the fact that $\mathbf{h} \in \mathbf{V}_A^{1,2}(Q) \subset C([0,T]; \mathbf{L}_A(\Omega))$. We also have

$$\int_{\Sigma_{T-\delta}} \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n})\, ds\, dt \to \int_{\Sigma_T} \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n})\, ds\, dt \quad \text{as } \delta \to 0. \tag{6.31}$$

Indeed, (6.30) is valid for all $\delta > 0$ and each term in equality (6.30), except for the term $\int_{\Sigma_{T-\delta}} \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n})\, ds\, dt$, has a limit as $\delta \to 0$. These facts imply that the integral $\int_{\Sigma_{T-\delta}} \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n})\, ds\, dt$ has a limit which, by the definition of improper integrals, equals the right-hand side of (6.31). Hence, passing to limit in (6.30) as $\delta \to 0$ yields

$$\begin{aligned} &\int_\Sigma \Big(\mathbf{h} \cdot 2\mathcal{D}(\widehat{\mathbf{w}} + \mathbf{v}_0)\mathbf{n} + \mathbf{h} \cdot (\partial_n \mathbf{q} + \widetilde{r}\mathbf{n}) + \mathbf{h} \cdot (\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}} \cdot \mathbf{n} \\ &\qquad + \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2 \mathbf{h} \cdot \mathbf{n} + N(\partial_t \widehat{\mathbf{w}} \cdot \partial_t \mathbf{h} + \nabla_\tau \widehat{\mathbf{w}} : \nabla_\tau \mathbf{h} + \widehat{\mathbf{w}} \cdot \mathbf{n}) \Big)\, ds\, dt = 0 \\ &\quad \forall\, \mathbf{h} \in \mathbf{V}_A^{1,2}(Q). \end{aligned} \tag{6.32}$$

We now show that

$$\int_{\partial\Omega} \partial_n \mathbf{q} \cdot \mathbf{h}\, ds = 2 \int_{\partial\Omega} \mathbf{h} \cdot \mathcal{D}(\mathbf{q})\mathbf{n}\, ds. \tag{6.33}$$

For almost every $t \in [0,T]$, we have Green's identity

$$\int_\Omega \nabla \mathbf{q} : \nabla \mathbf{h}\, d\mathbf{x} = \int_{\partial\Omega} \partial_n \mathbf{q} \cdot \mathbf{h}\, ds - \int_\Omega \mathbf{h} \cdot \Delta \mathbf{q}\, d\mathbf{x}. \tag{6.34}$$

Since $\mathbf{q}\big|_{\partial\Omega} = \mathbf{0}$ and $\operatorname{div} \mathbf{h} = 0$, we obtain

$$\int_\Omega \nabla \mathbf{q} : \nabla \mathbf{h}\, d\mathbf{x} = \int_\Omega [\nabla \mathbf{q} + (\nabla \mathbf{q})^T] : \nabla \mathbf{h}\, d\mathbf{x} = 2 \int_\Omega \nabla \mathbf{h} \cdot \mathcal{D}(\mathbf{q})\, d\mathbf{x}$$

so that by applying Green's identity to the last term we have

$$\int_\Omega \nabla \mathbf{q} : \nabla \mathbf{h}\, d\mathbf{x} = 2 \int_{\partial\Omega} \mathbf{h} \cdot \mathcal{D}(\mathbf{q})\mathbf{n}\, ds - \int_\Omega \mathbf{h} \cdot \Delta \mathbf{q}\, d\mathbf{x}. \tag{6.35}$$

Equalities (6.34) and (6.35) imply (6.33).

Taking into account (6.21) and (6.24) and using (6.22) and (6.33), we can rewrite (6.32) as (6.26). ∎

6.3. The optimality system. We are now in a position to derive an optimality system for Problem II in the form of a boundary value problem. The surface Laplacian $\Delta_\tau \mathbf{u}$ defined on $\partial\Omega$ (and on Σ) can be determined by

$$\int_{\partial\Omega} \nabla_\tau \mathbf{u} : \nabla_\tau \mathbf{v}\, ds = -\int_{\partial\Omega} \mathbf{v} \cdot \Delta_\tau \mathbf{u}\, ds, \tag{6.36}$$

where $\mathbf{u}$ and $\mathbf{v}$ are the restrictions of $\mathbf{w}_i \in \mathbf{V}^2(\Omega)$, $i = 1, 2$, onto $\partial\Omega$, i.e., $\mathbf{u} = \mathbf{w}_1\big|_{\partial\Omega}$ and $\mathbf{v} = \mathbf{w}_2\big|_{\partial\Omega}$.

THEOREM 6.4. *Assume* $(\widehat{\mathbf{w}}, \widehat{p}) \in \mathbf{W} \times \mathbf{L}^2(Q)$ *is a solution for Problem* II *and* $\mathbf{q} \in L^2(0, T; \mathbf{V}^1_\sigma(\Omega))$ *is the Lagrange multiplier defined in* (5.15) *by* $\widehat{\mathbf{q}}$ *introduced in Theorem* 5.2. *Then there exists an* r *defined in the form of* (6.22), *with* $\widetilde{r}$ *defined in Lemma* 6.1 *such that the quadruple* $(\widehat{\mathbf{w}}, \widehat{p}, \mathbf{q}, r)$ *satisfies the partial differential equations*

$$\partial_t \widehat{\mathbf{w}} - \Delta \widehat{\mathbf{w}} + [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\widehat{\mathbf{w}} + (\widehat{\mathbf{w}} \cdot \nabla)\mathbf{v}_0 + \nabla \widehat{p} = \mathbf{0} \qquad \text{in } Q, \tag{6.37}$$

$$\operatorname{div} \widehat{\mathbf{w}} = 0 \qquad \text{in } Q, \tag{6.38}$$

$$\begin{aligned} -\partial_t \mathbf{q} - \Delta \mathbf{q} - [(\mathbf{v}_0 + \widehat{\mathbf{w}}) \cdot \nabla]\mathbf{q} + [\nabla(\mathbf{v}_0 + \widehat{\mathbf{w}})]^T \mathbf{q} + \nabla r \\ = \Phi - \nabla \widehat{p} \qquad \text{in } Q, \end{aligned} \tag{6.39}$$

where Φ *is defined by* (5.20) *and*

$$\operatorname{div} \mathbf{q} = 0 \qquad \text{in } Q, \tag{6.40}$$

where $\widehat{p}$ *and* r *satisfy* (6.25). *Furthermore,* $(\widehat{\mathbf{w}}, \mathbf{q})$ *satisfy the initial and terminal conditions*

$$\widehat{\mathbf{w}}(0, \mathbf{x}) = \mathbf{0} \quad \text{in } \Omega \tag{6.41}$$

and

$$\mathbf{q}(T, \mathbf{x}) + \widehat{\mathbf{w}}_\sigma(T, \mathbf{x}) = 0 \quad \text{in } \Omega, \tag{6.42}$$

where, by definition, $\mathbf{v}_\sigma = P\mathbf{v}$ *is the* $\mathbf{V}^0_0(\Omega)$*-projection of* $\mathbf{v}$, *and the lateral boundary conditions*

$$\mathbf{q}\big|_\Sigma = \mathbf{0} \tag{6.43}$$

and

$$\begin{aligned} \big[N(-\partial_{tt}\widehat{\mathbf{w}} - \Delta_\tau \widehat{\mathbf{w}}) + \mathcal{A}(\widehat{\mathbf{w}}) + \mathcal{T}(\mathbf{q}, \tau)\mathbf{n} \\ + \mathcal{T}(\widehat{\mathbf{w}}, \widehat{p})\mathbf{n} + 2\mathcal{D}(\mathbf{v}_0)\mathbf{n}\big]\big|_\Sigma = -\boldsymbol{\eta}(t)\mathbf{n}\big|_\Sigma, \end{aligned} \tag{6.44}$$

where $\mathcal{T}(\widehat{\mathbf{w}}, \widehat{p})$ *and* $\mathcal{T}(\mathbf{q}, \tau)$ *are defined by* (6.27),

$$\mathcal{A}(\widehat{\mathbf{w}}) = N\widehat{\mathbf{w}} + \frac{1}{2}|\widehat{\mathbf{w}} - \mathbf{v}_\infty|^2 \mathbf{n} + (\widehat{\mathbf{w}} - \mathbf{v}_\infty)\widehat{\mathbf{w}} \cdot \mathbf{n}, \tag{6.45}$$

and

$$\boldsymbol{\eta}(t) = \frac{\displaystyle\int_{\partial\Omega} \left[N\Delta_\tau \widehat{\mathbf{w}} - \mathcal{A}(\widehat{\mathbf{w}})\right] \cdot \mathbf{n}\, ds}{\displaystyle\int_{\partial\Omega} ds}. \tag{6.46}$$

Furthermore, the following compatibility conditions hold:

$$\begin{aligned} &\left(\widehat{\mathbf{w}}\big|_\Sigma\right)\Big|_{t=0} = \mathbf{0}, \quad \partial_t\big(\widehat{\mathbf{w}}\big|_\Sigma\big)_\tau\Big|_{t=T} = \mathbf{0}, \\ &\left(\big|(\widehat{\mathbf{w}} - \mathbf{v}_\infty)_\pi\big|_\Sigma + 2N\partial_t\big(\widehat{\mathbf{w}}\big|_\Sigma\big) \cdot \mathbf{n}\right)\Big|_{t=T} = 0, \end{aligned} \tag{6.47}$$

where $(\widehat{\mathbf{w}}|_\Sigma)_\tau$ *is the tangential projection of* $\widehat{\mathbf{w}}|_\Sigma$ *onto* Σ *and* $\mathbf{w}_\pi$ *is the projection of* $\mathbf{w}$ *in the following Weyl decomposition of* $\mathbf{V}^0(\Omega)$*:*

$$\mathbf{w} = \mathbf{w}_\sigma + \nabla w_\pi, \tag{6.48}$$

where $\mathbf{w}_\sigma \in \mathbf{V}_0^0(\Omega)$ *and* $\nabla w_\pi \in \nabla H_\pi(\Omega) \equiv \{\nabla\tau \in \mathbf{L}^2(\Omega) : \tau \in H^1_{\mathrm{loc}}(\Omega), \Delta\tau = 0\}$. *The primitive* w_π *of* ∇w_π *is determined by the equality*

$$\int_{\partial\Omega} w_\pi\, ds = 0. \tag{6.49}$$

Proof. The equations in (6.25) are simply conditions for pinning down $\widehat{p}$ and r uniquely and can always be satisfied by redefining $\widehat{p}$ and r if necessary.

The relations (6.37)–(6.38) and (6.41) were built into the formulation of Problem II and are automatically satisfied. Equalities (6.39)–(6.40) and (6.43) were proved in Theorem 5.4.

The equalities (6.26) and (6.36) yield

$$\begin{aligned} \int_\Sigma \mathbf{h} \cdot \Big(&\mathcal{T}(\widehat{\mathbf{w}}, \widehat{p})\mathbf{n} + \mathcal{T}(\mathbf{q}, r)\mathbf{n} + 2\mathcal{D}(\mathbf{v}_0)\mathbf{n} + \mathcal{A}(\widehat{\mathbf{w}}) \\ &+ \left[N(-\partial_{tt}\widehat{\mathbf{w}} - \Delta_\tau\widehat{\mathbf{w}})\right]\Big)\, ds\, dt = 0 \end{aligned} \tag{6.50}$$

for all $\mathbf{h} \in \mathbf{V}_A^{1,2}(Q)$, $\mathbf{h}(T, \cdot) = 0$, where $\mathcal{T}(\mathbf{w}, \widehat{p})$, $\mathcal{T}(\mathbf{q}, r)$, and $\mathcal{A}(\widehat{\mathbf{w}})$ are defined in (6.27) and (6.45). In [8], it was proved that

$$\int_\Sigma \mathbf{n} \cdot \left(\mathcal{T}(\widehat{\mathbf{w}}, \widehat{p})\mathbf{n} + \mathcal{T}(\mathbf{q}, r)\mathbf{n} + 2\mathcal{D}(\mathbf{v}_0)\mathbf{n} - N\partial_{tt}\widehat{\mathbf{w}}\right) ds\, dt = 0. \tag{6.51}$$

Recall that, by assumption, $\partial\Omega$ is connected set. (In the case of unconnected sets, the proof would be the same, but in the formulas (6.44) and (6.46) we would have to change $\eta(t)$ to $\eta_j(t)$ and $\partial\Omega$, Σ to $\partial\Omega_j$, $\Sigma_j = (0, T) \times \partial\Omega_j$, where $\partial\Omega_j$ is a connected component of $\partial\Omega$.) As is well known (see [9]), a vector field $\mathbf{g}(x'), x' \in \partial\Omega$, is a restriction on $\partial\Omega$ of a solenoidal vector field defined on Ω if and only if $\int_{\partial\Omega} \mathbf{g}\cdot\mathbf{n}\, ds = 0$. Hence, (6.50) and (6.51) imply (6.44) with $\eta(t)$ defined by (6.46).

The relations (6.47) can be proved in the same way as in [8]. ∎

7. The optimality system for Problem I. We now derive the optimality system for Problem I.

THEOREM 7.1. *Assume* $(\widehat{\mathbf{w}},\widehat{p}) \in \mathbf{W}\times\mathbf{L}^2(Q)$ *is a solution of Problem* I. *Then there exists a triple* $(\mathbf{q},\nabla\tau,\lambda)\in L^2(0,T;\mathbf{V}^1_\sigma)(\Omega)\times\mathbf{L}^2(Q)\times\mathbb{R}_+$ *such that* $(\mathbf{q},\nabla\tau,\lambda)\neq(\mathbf{0},\mathbf{0},0)$ *and* $(\widehat{\mathbf{w}},\widehat{p},\mathbf{q},\tau,\lambda)$ *satisfies* (6.37)–(6.43), (6.25), *and the boundary conditions*

$$\lambda(-\partial_{tt}\widehat{\mathbf{w}}-\Delta_\tau\widehat{\mathbf{w}})+\widetilde{\mathcal{A}}(\widehat{\mathbf{w}})+\mathcal{T}(\mathbf{q},\tau)\mathbf{n}+\mathcal{T}(\widehat{\mathbf{w}},\widehat{p})\mathbf{n}+\mathcal{D}(\mathbf{v}_0)\mathbf{n}=-\widetilde{\boldsymbol{\eta}}(t)\mathbf{n}, \tag{7.1}$$

where $\mathcal{T}(\widehat{\mathbf{w}},\widehat{p})$ *and* $\mathcal{T}(\mathbf{q},\tau)$ *are defined by* (6.30),

$$\widetilde{\mathcal{A}}(\widehat{\mathbf{w}})=\lambda\widehat{\mathbf{w}}+\frac{1}{2}|\widehat{\mathbf{w}}-\mathbf{v}_\infty|^2\mathbf{n}+(\widehat{\mathbf{w}}-\mathbf{v}_\infty)\widehat{\mathbf{w}}\cdot\mathbf{n}, \tag{7.2}$$

and

$$\widetilde{\boldsymbol{\eta}}(t)=\frac{\displaystyle\int_{\partial\Omega}\Big(\lambda\Delta_\tau\widehat{\mathbf{w}}-\widetilde{\mathcal{A}}(\widehat{\mathbf{w}})\mathbf{n}\Big)\,ds}{\displaystyle\int_{\partial\Omega}ds}. \tag{7.3}$$

In addition, the following compatibility conditions hold:

$$\lambda\partial_t\big(\widehat{\mathbf{w}}\big|_\Sigma\big)_\tau\Big|_{t=T}=\mathbf{0}\quad\text{and}\quad\Big(\widehat{w}_\pi\big|_\Sigma+2\lambda\partial_t\big(\widehat{\mathbf{w}}\big|_\Sigma\big)\cdot\mathbf{n}\Big)\Big|_{t=T}=0, \tag{7.4}$$

where $\widehat{\mathbf{w}}_\tau$ *is the tangential projection of* $\widehat{\mathbf{w}}$ *onto* Σ *and* $\widehat{w}_\pi$ *is defined by* (6.48) *and* (6.49). *Moreover, the nonnegativity and complementary slackness conditions hold, i.e.,*

$$\lambda\ge 0 \tag{7.5}$$

and

$$\lambda\Big[\int_\Sigma\Big(|\partial_t\widehat{\mathbf{w}}|^2+|\nabla_\tau\widehat{\mathbf{w}}|^2+|\widehat{\mathbf{w}}|^2\Big)\,ds\,dt-M\Big]=0. \tag{7.6}$$

Proof. First, we derive a weak form of optimality system for Problem I in exactly the same manner as was done in the appropriate part of Theorem 6.9 in [8] for the two-dimensional case:

$$\begin{aligned}
&\lambda_0\int_Q\mathcal{D}(\widehat{\mathbf{w}}+\mathbf{v}_0):\mathcal{D}(\mathbf{h})\,d\mathbf{x}\,dt\\
&\quad+\int_Q\big\{\partial_t\mathbf{h}-\Delta\mathbf{h}+[(\mathbf{v}_0+\widehat{\mathbf{w}})\cdot\nabla]\mathbf{h}+(\mathbf{h}\cdot\nabla)(\mathbf{v}_0+\widehat{\mathbf{w}})\big\}\cdot\widehat{\mathbf{q}}\,d\mathbf{x}\,dt\\
&\quad+\int_\Omega(\widehat{\mathbf{w}}(T,\mathbf{x})+\mathbf{v}_0(\mathbf{x})-\mathbf{v}_\infty)\cdot\mathbf{h}\,d\mathbf{x}\\
&\quad+\int_\Sigma\Big(\mathbf{h}\cdot(\widehat{\mathbf{w}}-\mathbf{v}_\infty)\widehat{\mathbf{w}}\cdot\mathbf{n}+\frac{1}{2}|\widehat{\mathbf{w}}-\mathbf{v}_\infty|^2\mathbf{h}\cdot\mathbf{n}\\
&\qquad+\lambda[\partial_t\widehat{\mathbf{w}}\cdot\partial_t\mathbf{h}+\nabla_\tau\widehat{\mathbf{w}}:\nabla_\tau\mathbf{h}+\widehat{\mathbf{w}}\cdot\mathbf{h}]\Big)\,ds\,dt=0\quad\forall\,\mathbf{h}\in\mathbf{V}^{1,2}_A(Q).
\end{aligned} \tag{7.7}$$

The difference between this integral equality and (5.5) is that, in (7.7), the parameter N is renamed to λ and λ_0 multiplies the first term. Therefore, if we repeat all the

arguments that lead to the assertions of Theorem 6.4, we obtain the optimality system (6.37)–(6.49), where N is renamed as λ and all terms generated by the first term in (5.5) are multiplied by λ_0. Hence, to prove Theorem 7.1, we have to show that $\lambda_0 \neq 0$. We do this analogously to the proof of the appropriate part of Theorem 6.9 in [8]. As in that theorem, the assumption that $\lambda_0 = 0$ leads to the inequality $\lambda > 0$. As a result, the proof is reduced to establishing the following assertion:

$$\begin{aligned} &\text{there exists a } \mathbf{y} \in \gamma_\Sigma \mathbf{V}_A^{1,2}(Q) \text{ such that} \\ &\int_\Sigma \Big(\partial_t \widehat{\mathbf{w}} \cdot \partial_t \mathbf{y} + \nabla_\tau \widehat{\mathbf{w}} : \nabla_\tau \mathbf{y} + \widehat{\mathbf{w}} \cdot \mathbf{y} \Big)\, ds\, dt \neq 0. \end{aligned} \tag{7.8}$$

Here, $\gamma_\Sigma \mathbf{V}_A^{1,2}(Q)$ is the set of restrictions of vector fields belonging to the space $\mathbf{V}_A^{1,2}(Q)$ defined in (B.22).

We prove (7.8) by contradiction. By virtue of (2.11), the solution $\widehat{\mathbf{w}}$ of Problem I satisfies $\widehat{\mathbf{w}} \in \mathbf{H}^1(\Sigma)$ and $\int_{\partial\Omega} \widehat{\mathbf{w}} \cdot \mathbf{n}\, ds = 0$ for almost every $t \in (0,T)$. As is well known, there exists a sequence $\mathbf{y}_n(t,x) \in \mathbf{C}^\infty(Q)$, $\int_{\partial\Omega} \mathbf{y}_n \cdot \mathbf{n}\, ds = 0$ a.e. $t \in (0,T)$, such that $\|\widehat{\mathbf{w}} - \mathbf{y}_n\|_{\mathbf{H}^1(\Sigma)} \to 0$ as $n \to 0$. It is well known (and the proof can be easily reproduced, e.g., from [9]) that there exists $\mathbf{z}_n \in \mathbf{V}_A^{1,2}(Q)$ such that $\mathbf{z}_n\big|_\Sigma = \mathbf{y}_n$. Hence, (7.6) and (7.8) imply that

$$\begin{aligned} 0 &= \int_\Sigma \Big(\partial_t \widehat{\mathbf{w}} \cdot \partial_t \mathbf{y}_n + \nabla_\tau \widehat{\mathbf{w}} : \nabla_\tau \mathbf{y}_n + \widehat{\mathbf{w}} \cdot \mathbf{y}_n \Big)\, ds\, dt \\ &\to \int_\Sigma \Big(|\partial_t \widehat{\mathbf{w}}|^2 + |\nabla_\tau \widehat{\mathbf{w}}|^2 + |\widehat{\mathbf{w}}|^2 \Big)\, ds\, dt = M. \end{aligned}$$

This contradiction completes the proof. ∎

Appendix A. Regularity results for some auxiliary boundary value problems. We now derive some nonstandard regularity results for the Stokes problem involving the function space $\mathbf{V}_\sigma^s(\Omega)$. We will also derive similar regularity results for the adjoint boundary value problem in the form (3.14). First, we introduce an appropriate functions spaces.

A.1. Spectral function spaces. In this subsection, we will define the function space $\mathbf{V}_\sigma^s(\Omega)$ and study its properties. The tools we will need are direct integrals and intermediate spaces. These spaces will be used in the study of the regularity for the adjoint velocity in the optimality system.

Consider the operator

$$A = P(-\Delta + I) : \mathbf{V}_0^0(\Omega) \to \mathbf{V}_0^0(\Omega), \tag{A.1}$$

where $P : \mathbf{L}^2(\Omega) \to \mathbf{V}_0^0(\Omega)$ is the orthogonal projection operator onto $\mathbf{V}_0^0(\Omega)$. The domain $\mathcal{D}(A)$ of the operator A is defined by $\mathcal{D}(A) = \mathbf{V}^2(\Omega) \cap \mathbf{V}_0^1(\Omega)$, where

$$\mathbf{V}_0^1(\Omega) = \{\mathbf{v} \in \mathbf{V}^1(\Omega) \ : \ \mathbf{v}|_{\partial\Omega} = \mathbf{0}\}. \tag{A.2}$$

Applying standard arguments for proving the solvability of the steady-state Stokes equations (see [13]), we can conclude that the operator A is a positive, self-adjoint operator whose spectrum lies in $[1,\infty)$. We wish to use a spectral decomposition theorem for self-adjoint operators. To this end we first recall the concept of a direct integral of Hilbert spaces (see [12] and [14, Chap. 1, sect. 2.3])

$$\Upsilon = \int_1^\infty \oplus H(\lambda)\, d\mu(\lambda). \tag{A.3}$$

Here, $d\mu(\lambda)$ is a nonnegative Borel measure supported in $[1,\infty)$, $H(\lambda)$ is a family of Hilbert spaces with norm and inner product denoted by $\|\cdot\|_{H(\lambda)}$ and $(\cdot,\cdot)_{H(\lambda)}$, respectively, and $H(\lambda)$ is assumed μ-measurable. The μ-measurability of $H(\lambda)$ is defined as follows: there exists a family $\mathcal{M}$ of functions $f\colon [1,\infty)\ni\lambda\mapsto f(\lambda)\in H(\lambda)$ satisfying

1. for all $f\in\mathcal{M}$, the function $\lambda\mapsto\|f(\lambda)\|_{H(\lambda)}$ is μ-measurable;
2. if a function $g:[1,\infty)\ni\lambda\mapsto g(\lambda)\in H(\lambda)$ is such that $\lambda\mapsto\big(f(\lambda),g(\lambda)\big)_{H(\lambda)}$ is μ-measurable for each $f\in\mathcal{M}$, then $g\in\mathcal{M}$; and
3. there exists a sequence $\{f_i\}_{i=1}^{\infty}\subset\mathcal{M}$ such that for every $\lambda\in[1,\infty)$ the set $\{f_i(\lambda)\}_{i=1}^{\infty}$ is dense in $H(\lambda)$.

In other words, $\mathcal{M}$ is the set of μ-measurable functions taking values in $H(\lambda)$. The space (A.3) is the set of functions $f\in\mathcal{M}$ for which

$$\|f\|_{\Upsilon}^2=\int_1^{\infty}\|f(\lambda)\|_{H(\lambda)}^2\,d\mu(\lambda).$$

The scalar product in Υ is defined by the formula

$$(f,g)_{\Upsilon}=\int_1^{\infty}(f(\lambda),g(\lambda))_{H(\lambda)}^2 d\mu(\lambda).$$

In [12], it was proved that Υ is a Hilbert space.

By virtue of the spectral decomposition theorem (see [12]) for the operator (A.1), there exists a direct integral of Hilbert spaces (A.3) and a unitary operator $U:\mathbf{V}_0^0(\Omega)\to\Upsilon$ which maps $\mathcal{D}(A)$ into

$$\Upsilon_A=\{f\in\Upsilon:\lambda f\in\Upsilon\},\qquad \|f\|_{\Upsilon_A}^2=\int_1^{\infty}\lambda^2\|f(\lambda)\|_{H(\lambda)}^2 d\mu(\lambda)$$

and satisfies $U(A\mathbf{v})=\lambda(U\mathbf{v})$. For $s\in[0,2]$, we introduce the spaces

$$\mathbf{V}_\sigma^s(\Omega)=\Big\{\mathbf{v}\in\mathbf{V}_0^0(\Omega)\ :\ U\mathbf{v}=\int_1^{\infty}\oplus\widehat{\mathbf{v}}(\lambda)\,d\mu(\lambda),\ \int_1^{\infty}\lambda^s\|\widehat{\mathbf{v}}(\lambda)\|_{H(\lambda)}^2 d\mu(\lambda)<\infty\Big\}\tag{A.4}$$

with norms

$$\|\mathbf{v}\|_{\mathbf{V}_\sigma^s(\Omega)}^2=\int_1^{\infty}\lambda^s\|\widehat{\mathbf{v}}(\lambda)\|_{H(\lambda)}^2 d\mu(\lambda).\tag{A.5}$$

The definition of the spectral decomposition implies that $\mathbf{V}_\sigma^0(\Omega)=\mathbf{V}_0^0(\Omega)$, $\mathbf{V}_\sigma^2(\Omega)=\mathcal{D}(A)=\mathbf{V}^2(\Omega)\cap\mathbf{V}_0^1(\Omega)$, and, in the spaces $\mathbf{V}_\sigma^s(\Omega)$, the norms (A.5) with $s=0,2$ are equivalent to the norms of $\mathbf{L}^2(\Omega)$ and $\mathbf{H}^2(\Omega)$, respectively. Furthermore, the following equality holds:

$$\mathbf{V}_\sigma^1(\Omega)=\mathbf{V}_0^1(\Omega)\tag{A.6}$$

and, in this space, $\|\cdot\|_{\mathbf{V}_\sigma^1(\Omega)}$ is equivalent to the $\mathbf{H}^1(\Omega)$ norm. Indeed, for each $\mathbf{v}\in\mathcal{D}(A)=\mathbf{V}_\sigma^2(\Omega)$, we have

$$\begin{aligned}\|\mathbf{v}\|_{\mathbf{H}^1(\Omega)}^2&=-\int_\Omega\mathbf{v}\cdot\Delta\mathbf{v}\,d\mathbf{x}+\|\mathbf{v}\|_{\mathbf{L}^2(\Omega)}^2\\&=\int_1^{\infty}(\lambda+1)\|\widehat{\mathbf{v}}(\lambda)\|_{H(\lambda)}^2\,d\mu(\lambda)\le 2\|\mathbf{v}\|_{\mathbf{V}_\sigma^1(\Omega)}^2.\end{aligned}$$

Also, we obviously have $\|\mathbf{v}\|_{\mathbf{V}^1_\sigma(\Omega)} \le \|\mathbf{v}\|_{\mathbf{H}^1(\Omega)}$. Hence, the completions of $\mathbf{C}^\infty_0(\Omega) \cap \mathbf{V}^0_0(\Omega)$ under $\|\cdot\|_{\mathbf{H}^1(\Omega)}$ and $\|\cdot\|_{\mathbf{V}^1_\sigma(\Omega)}$ yield the same space, i.e., (A.6) holds.

Let X and Y be Hilbert spaces satisfying

(A.7) $\quad X \subset Y \quad$ and $\quad X$ is dense in Y and is continuously embedded into Y.

Assume that $\Lambda : Y \to Y$ is a positive, self-adjoint linear operator with domain $\mathcal{D}(\Lambda) = X$ and that $\|\cdot\|_X$ is equivalent to the norm $X \ni u \mapsto (\|u\|^2_Y + \|\Lambda u\|^2_Y)^{1/2}$. Recall that the intermediate space $[X, Y]_\theta$, $\theta \in [0, 1]$, is by definition the space $\mathcal{D}(\Lambda^{1-\theta})$ endowed with the norm

$$\|u\|^2_{[X,Y]_\theta} = \|u\|^2_Y + \|\Lambda^{1-\theta} u\|^2_Y \qquad \forall\, u \in [X, Y]_\theta\,;$$

see [14] for details.

LEMMA A.1. *Suppose that X is a closed subspace of $\mathbf{H}^k(\Omega)$ with k being a positive integer, Y is a closed subspace of $\mathbf{L}^2(\Omega)$, $\|\cdot\|_X$ is equivalent to $\|\cdot\|_{\mathbf{H}^k(\Omega)}$, $\|\cdot\|_Y$ is equivalent to $\|\cdot\|_{\mathbf{L}^2(\Omega)}$, and X and Y satisfy* (A.7). *Then, for each $\theta \in [0, 1]$, $[X, Y]_\theta$ is a closed subspace of $\mathbf{H}^{k(1-\theta)}(\Omega)$ and the norm of $[X, Y]_\theta$ is equivalent to the norm of $\mathbf{H}^{k(1-\theta)}(\Omega)$.*

Proof. Recall that, by definition, $\mathbf{H}^{k(1-\theta)}(\Omega) = [\mathbf{H}^k(\Omega), \mathbf{L}^2(\Omega)]_\theta$. Denoting by I the embedding operator we see that $I : X \to \mathbf{H}^k(\Omega)$ and $I : Y \to \mathbf{L}^2(\Omega)$ are continuous. Hence, by interpolation theorems of [14, Chap. 1, sect. 5], we deduce that $I : [X, Y]_\theta \to \mathbf{H}^{k(1-\theta)}(\Omega)$ is also embedding and

$$\|u\|_{\mathbf{H}^{k(1-\theta)}(\Omega)} \le C\|u\|_{[X,Y]_\theta} \qquad \forall\, u \in [X, Y]_\theta. \tag{A.8}$$

We consider now a bounded extension operator $L : \mathbf{L}^2(\Omega) \to \mathbf{L}^2(\mathbb{R}^3)$ (i.e., $Lu(\mathbf{x}) = u(\mathbf{x})$ for every $\mathbf{x} \in \Omega$) such that its restriction on $\mathbf{H}^k(\Omega)$ is the bounded extension operator $L : \mathbf{H}^k(\Omega) \to \mathbf{H}^k(\mathbb{R}^3)$ (such an extension can be easily constructed by the well-known Whitney formula). Clearly, LX is a closed subspace of $\mathbf{H}^k(\mathbb{R}^3)$ and we equip LX with the $\mathbf{H}^k(\mathbb{R}^3)$ norm. Analogously, LY is a closed subspace of $\mathbf{L}^2(\mathbb{R}^3)$ and we equip LY with the $\mathbf{L}^2(\mathbb{R}^3)$ norm. Denote by r the restriction operator which maps any function $f(\mathbf{x})$ defined in $\mathbb{R}^3$ into the same function f restricted to Ω. Evidently, operators $r : LX \to X$ and $r : LY \to Y$ are continuous so that interpolation theorems imply that $r : [LX, LY]_\theta \to [X, Y]_\theta$ is also continuous and

$$\|\mathbf{u}\|_{[X,Y]_\theta} = \|rL\mathbf{u}\|_{[X,Y]_\theta} \le C\|L\mathbf{u}\|_{[LX,LY]_\theta} \qquad \forall\, \mathbf{u} \in [X, Y]_\theta. \tag{A.9}$$

The Sobolev norms on LX and LY can be expressed in terms of Fourier transforms:

$$\|L\mathbf{u}\|^2_{\mathbf{H}^k(\mathbb{R}^3)} = \int_{\mathbb{R}^3} (1 + |\boldsymbol{\xi}|^2)^k |\widehat{L\mathbf{u}}(\boldsymbol{\xi})|^2 \, d\boldsymbol{\xi} \quad \forall\, \mathbf{u} \in LX$$

and

$$\|L\mathbf{u}\|^2_{\mathbf{H}^k(\mathbb{R}^3)} = \int_{\mathbb{R}^3} |\widehat{L\mathbf{u}}(\boldsymbol{\xi})|^2 \, d\boldsymbol{\xi} \quad \forall\, \mathbf{u} \in LY.$$

Thus,

$$\|L\mathbf{u}\|_{[LX,LY]_\theta} = \|L\mathbf{u}\|_{\mathbf{H}^{k(1-\theta)}(\mathbb{R}^3)} \le C\|\mathbf{u}\|_{\mathbf{H}^{k(1-\theta)}(\Omega)} \qquad \forall\, \mathbf{u} \in [X, Y]_\theta, \tag{A.10}$$

where in the last step we used interpolation theorems on the extension operators $L : \mathbf{H}^k(\Omega) \to \mathbf{H}^k(\mathbb{R}^3)$ and $L : \mathbf{L}^2(\Omega) \to \mathbf{L}^2(\mathbb{R}^3)$. Combining (A.8), (A.9), and (A.10), we prove Lemma A.1. ∎

The following lemma is a direct consequence of Lemma A.1 by taking $k = 2$, $X = \mathbf{V}^2_\sigma(\Omega) = \mathbf{V}^2(\Omega) \cap \mathbf{V}^1_0(\Omega)$, and $Y = \mathbf{V}^0_\sigma(\Omega) = \mathbf{V}^0_0(\Omega)$.

LEMMA A.2. *For each $s \in [0,2]$, the norms $\|\cdot\|_{\mathbf{V}^s_\sigma(\Omega)}$ and $\|\cdot\|_{\mathbf{H}^s(\Omega)}$ are equivalent on the space $\mathbf{V}^s_\sigma(\Omega)$.*

Let $G \subset \mathbb{R}^3$ be a bounded domain with a C^∞ boundary ∂G. We consider the problem

$$\mathbf{curl}\,\mathbf{w} = \mathbf{v} \quad \text{in } G \qquad \text{and} \qquad \mathbf{w}\cdot\mathbf{n}\big|_{\partial G} = 0. \tag{A.11}$$

LEMMA A.3. *Assume that $\mathbf{v} \in \mathbf{H}^s(G) \cap \mathbf{V}^0(G)$, $s \geq 0$, and $\mathbf{v}\cdot\mathbf{n}\big|_{\partial\Omega} = 0$. Then there exists a solution $\mathbf{w} \in \mathbf{H}^{s+1}(G)$ for the problem* (A.11) *satisfying the condition $\mathbf{w}\big|_\Gamma = \mathbf{0}$.*

The proof of this lemma is entirely analogous to that of [9, Lem. 4.3] and is omitted here.

LEMMA A.4. *For each $s \in (0, 1/2)$, $\mathbf{V}^s_\sigma(\Omega) = \mathbf{H}^s(\Omega) \cap \mathbf{V}^0_0(\Omega)$.*

Proof. By virtue of Lemma A.2 and the definition of intermediate spaces, we have

$$\mathbf{V}^s_\sigma(\Omega) = \text{closure of } \mathbf{V}^2(\Omega) \cap \mathbf{V}^1_0 \text{ in } \mathbf{H}^s(\Omega). \tag{A.12}$$

Since the topology of $\mathbf{H}^s(\Omega)$ is stronger than the $\mathbf{L}^2(\Omega)$ topology, the right-hand side of (A.12) is a subset of $\mathbf{V}^0_0(\Omega)$, so that $\mathbf{V}^s_\sigma(\Omega) \subset \mathbf{V}^0_0(\Omega) \cap \mathbf{H}^s(\Omega)$. Next we proceed to prove the reverse embedding. Let an arbitrary $\mathbf{v} \in \mathbf{H}^s(\Omega) \cap \mathbf{V}^0_0(\Omega)$ be given, and we choose a sequence $\{\mathbf{v}_n\} \subset \mathbf{V}^2(\Omega) \cap \mathbf{V}^1_0$ such that $\|\mathbf{v}_n - \mathbf{v}\|_{\mathbf{H}^s(\Omega)} \to 0$ as $n \to \infty$. Let $\rho > 0$ be a fixed, sufficiently large number satisfying (2.16). We set

$$\Omega_\rho \equiv \{\mathbf{x} \in \mathbb{R}^3 : |\mathbf{x}| < \rho\} \cap \Omega \qquad \text{and} \qquad \Omega^c_\rho \equiv \mathbb{R}^3 \setminus \Omega_\rho.$$

Firstly, we decompose v as follows:

$$\begin{aligned} v(x) = v_1(\mathbf{x}) + v_2(\mathbf{x}), \quad &\text{where} \quad \operatorname{supp} v_1 \subset \Omega_{\rho+3}, \\ &\operatorname{supp} v_2 \subset \Omega^c_{\rho+2}, \quad v_i \in \mathbf{V}^0_0 \cap \mathbf{H}^s(\Omega),\ i = 1,2. \end{aligned} \tag{A.13}$$

Consider $w(x) \in \mathbf{H}^{s+1}(\Omega_{\rho+3})$ satisfying (A.11) with $G = \Omega_{\rho+3}$. The existence of such a vector field is established, e.g., in [9, 16]. Let $\varphi_1(\mathbf{x}) \in C^\infty(\Omega)$, $\varphi_1(\mathbf{x}) = 1$, for $|\mathbf{x}| < \rho + 1$, $\varphi_1(x) = 0$ for $|\mathbf{x}| > \rho + 2$, and $\varphi_2(\mathbf{x}) = 1 - \varphi_1(\mathbf{x})$. Then the functions

$$\begin{aligned} &v_1(\mathbf{x}) = \mathbf{curl}\,(w(\mathbf{x})\varphi_1(\mathbf{x})), \\ &v_2(\mathbf{x}) = \mathbf{curl}\,(w(x)\varphi_2(\mathbf{x})) \ \text{ for } |\mathbf{x}| < \rho + 3, \qquad v_2(\mathbf{x}) = v(\mathbf{x}) \ \text{ for } |\mathbf{x}| > \rho + 2 \end{aligned}$$

satisfy conditions (A.13).

It is enough to find sequences

$$\{v_{in}\} \subset \mathbf{V}^2(\Omega) \cap \mathbf{V}^1_0(\Omega) \quad \text{such that} \quad \|v_{in} - v_i\|_{H^s(\Omega)} \to 0 \quad \text{as} \quad n \to \infty \tag{A.14}$$

for $i = 1, 2$.

In the case $i = 2$, we can take as v_{2n} the Friedrichs average

$$v_{2n}(\mathbf{x}) = n^3 \int_\Omega j(n(\mathbf{x} - \mathbf{y}))v_2(\mathbf{y})\,d\mathbf{y},$$

where $j(\mathbf{x}) \in C^\infty_0(\mathbb{R}^3)$, $j(\mathbf{x}) \geq 0$, $\operatorname{supp} j \subset \{|\mathbf{x}| \leq 1\}$, and $\int_\Omega j(\mathbf{x})\,d\mathbf{x} = 1$. Evidently, $v_{2n} \in \mathbf{V}^2 \cap \mathbf{V}^1_0(\Omega)$. Since the $v_{2n}(\mathbf{x})$ are well defined for $\mathbf{x} \in \mathbb{R}^3$, the relation (A.14) can be proved in this case with the help of the Fourier transforms.

To prove (A.14) for $i = 1$, we consider (A.11) with $G = \Omega_{\rho+3}$, and $v(\mathbf{x})$ changed to $v_1(\mathbf{x})$. By virtue of Lemma A.3, there exists a solution $w_1(\mathbf{x}) \in H^{s+1}(\Omega_{\rho+3})$ of this problem which satisfies $w_1(\mathbf{x})|_{\partial\Omega_{\rho+3}} = 0$. This equality and the condition $0 < s < 1/2$ yield that $w_1(\mathbf{x}) \in H_0^{s+1}(\Omega_{\rho+3})$. By the definition of the space $H_0^{s+1}(\Omega_{\rho+3})$, there exists a sequence $w_{1n}(x) \in C_0^\infty(\Omega_{\rho+3})$ such that $\|w_{1n} - w_1\|_{H^{1+s}(\Omega_{\rho+3})} \to 3$ as $n \to \infty$. This relation implies that sequence $v_{1n} = \mathbf{curl}\, w_{1n}$ satisfies the relation (A.14). ∎

For $s \in [0,1]$, we may define $\mathbf{V}_\sigma^{-s}(\Omega)$ as the closure of $\mathbf{V}_0^0(\Omega)$ with respect to the norm

$$\|\mathbf{v}\|_{\mathbf{V}_\sigma^{-s}(\Omega)} = \Big(\int_1^\infty \lambda^{-s}\|\widehat{\mathbf{v}}(\lambda)\|^2_{H(\lambda)}\, d\mu(\lambda)\Big)^{1/2} \quad \text{if} \quad U\mathbf{v} = \int_1^\infty \oplus\widehat{\mathbf{v}}(\lambda)\, d\mu(\lambda). \tag{A.15}$$

LEMMA A.5. *For $s \in (0, 1/2)$, $\mathbf{V}_\sigma^{-s}(\Omega) \subset \mathbf{H}^{-s}(\Omega)$. Furthermore, the norm $\|\cdot\|_{\mathbf{V}_\sigma^{-s}(\Omega)}$ is equivalent to $\|\cdot\|_{\mathbf{H}^{-s}(\Omega)}$ on $\mathbf{V}_\sigma^{-s}(\Omega)$.*

This lemma can be proved with the help of Lemmas A.2 and A.4 just as the corresponding assertions in [6, Chap. 3, Lem. 4.5] were proved. We omit the details here.

A.2. Regularity results for the Stokes problem. For $s \in [0,1]$, we may define the operator $P = P_s : \mathbf{H}^{-s}(\Omega) \to \mathbf{V}_\sigma^{-s}(\Omega)$ by the formula

$$\langle P\mathbf{u}, \mathbf{v}\rangle_{\mathbf{V}_0^0(\Omega)} = \langle \mathbf{u}, \mathbf{v}\rangle_{\mathbf{L}^2(\Omega)} \qquad \forall\, \mathbf{v} \in \mathbf{V}_\sigma^s(\Omega), \tag{A.16}$$

where $\langle\cdot,\cdot\rangle_{\mathbf{V}_0^0(\Omega)}$ and $\langle\cdot,\cdot\rangle_{\mathbf{L}^2(\Omega)}$ denote the duality generated by the scalar products on $\mathbf{V}_0^0(\Omega)$ and $\mathbf{L}^2(\Omega)$, respectively. Note that for $s = 0$, P coincides with the orthogonal projection operator from $\mathbf{L}^2(\Omega)$ to $\mathbf{V}_0^0(\Omega)$; see the statement immediately following (A.1).

We first consider the Stokes problem with a vanishing forcing term and an inhomogeneous initial value $\mathbf{q}_0$. Note that $P\nabla r = \mathbf{0}$ for $\nabla r \in \mathbf{H}^{-s}(\Omega)$ and $P\partial_t\mathbf{q} = \partial_t\mathbf{q}$ for $\partial_t\mathbf{q}$ in $L^2(0,T;\mathbf{V}_\sigma^{-s}(\Omega))$; thus, we may write the Stokes problem as

$$\partial_t\mathbf{q}(t,\mathbf{x}) + A\mathbf{q} = \mathbf{0} \quad \text{in } Q \qquad \text{and} \qquad \mathbf{q}|_{t=0} = \mathbf{q}_0 \quad \text{in } \Omega, \tag{A.17}$$

where $A = P(-\Delta + I)$. Since we look for $\mathbf{q}$ in the space $L^2(0,T;\mathbf{V}_\sigma^{-s+2}(\Omega))$ and $-s+2 \ge 1$, a solution $\mathbf{q}$ to (A.17) automatically satisfies

$$\operatorname{div}\mathbf{q} = 0 \qquad \text{and} \qquad \mathbf{q}|_\Sigma = \mathbf{0}. \tag{A.18}$$

As was mentioned in Lemma 3.6, the existence and uniqueness of a solution $\mathbf{q} \in L^2(0,T;\mathbf{V}_\sigma^1(\Omega)) \cap H^1(0,T;\mathbf{V}_\sigma^{-1}(\Omega))$ to (A.17) is well known. The following regularity result holds.

LEMMA A.6. *Assume that $\mathbf{q}_0 \in \mathbf{V}_\sigma^s(\Omega)$, $s \ge 0$. Then a solution $\mathbf{q}$ of the problem* (A.17) *satisfies the estimate*

$$\begin{aligned}\int_t^\infty \Big(\|\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}_\sigma^{\nu+s+1}(\Omega)} + \|\partial_t\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}_\sigma^{\nu+s-1}(\Omega)}\Big)\, d\tau \\ = \|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}_\sigma^{\nu+s}(\Omega)} \le e^{-\nu}\Big(\frac{\nu}{2}\Big)^\nu t^{-\nu}\|\mathbf{q}_0\|^2_{\mathbf{V}_\sigma^s(\Omega)}\end{aligned} \tag{A.19}$$

for every $\nu \ge 0$.

Proof. We apply to (A.17) the unitary operator U introduced in the definition of the spectral decomposition of A as direct integrals. Then (A.17) reduces to

$$\int_1^\infty \oplus\Big(\partial_t\widehat{\mathbf{q}}(t,\lambda) + \lambda\widehat{\mathbf{q}}(t,\lambda)\Big)\, d\mu(\lambda) = 0$$

and

$$\int_1^\infty \oplus\Big(\widehat{\mathbf{q}}(t,\lambda)|_{t=0} - \widehat{\mathbf{q}}_0(\lambda)\Big)\, d\mu(\lambda) = 0.$$

By the definition of direct integrals, the integrands belong to different Hilbert spaces $H(\lambda)$ for different λ. This allows us to deduce that for almost every λ (with respect to the μ-measure),

$$\partial_t \widehat{\mathbf{q}}(t,\lambda) + \lambda \widehat{\mathbf{q}}(t,\lambda) = \mathbf{0} \quad \text{in } Q \qquad \text{and} \qquad \widehat{\mathbf{q}}(t,\lambda)|_{t=0} = \widehat{\mathbf{q}}_0(\lambda) \quad \text{in } \Omega. \tag{A.20}$$

Equalities (A.20) are understood as equalities in the Hilbert spaces $H(\lambda)$. More precisely, the first equality is considered in $L^2(0,T;H(\lambda))$. Equalities (A.20) imply

$$\widehat{\mathbf{q}}(t,\lambda) = e^{-\lambda t}\widehat{\mathbf{q}}_0(\lambda). \tag{A.21}$$

Using definitions (A.5) and (A.15) of the norms for $\mathbf{V}^s_\sigma(\Omega)$, we obtain

$$\|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{\nu+s}_\sigma(\Omega)} = \int_1^\infty e^{-2\lambda t}\lambda^{\nu+s}\|\widehat{\mathbf{q}}_0(\lambda)\|^2_{H(\lambda)}\, d\mu(\lambda). \tag{A.22}$$

By solving a simple extremal problem we obtain that, for each $t > 0$,

$$\max_{\lambda\in[1,\infty)} (e^{-2\lambda t}\lambda^\nu) = e^{-\max\{2t,\nu\}}\big[\max\{1,\nu/(2t)\}\big]^\nu \le e^{-\nu}\Big(\frac{\nu}{2}\Big)^\nu t^{-\nu}. \tag{A.23}$$

From (A.22) and (A.23) we deduce that

$$\|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{\nu+s}_\sigma(\Omega)} \le e^{-\nu}\Big(\frac{\nu}{2}\Big)^\nu t^{-\nu}\|\mathbf{q}_0\|^2_{\mathbf{V}^s_\sigma(\Omega)}. \tag{A.24}$$

Integrating (A.22) in t and applying (A.22) to the result, we have

$$\begin{aligned}\int_t^\infty &\|\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^{\nu+s+1}_\sigma(\Omega)}\, d\tau \\ &= \frac{1}{2}\int_1^\infty e^{-2\lambda t}\lambda^{\nu+s}\|\widehat{\mathbf{q}}_0(\lambda)\|^2_{H(\lambda)}\, d\mu(\lambda) = \frac{1}{2}\|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{\nu+s}_\sigma(\Omega)}.\end{aligned} \tag{A.25}$$

Differentiating (A.21) with respect to t and repeating the arguments used in deriving (A.25), we are led to

$$\begin{aligned}\int_t^\infty &\|\partial_t\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^{\nu+s-1}_\sigma(\Omega)}\, d\tau \\ &= \int_t^\infty\int_1^\infty e^{-2\lambda\tau}\lambda^{\nu+s+1}\|\mathbf{q}_0\|^2_{\mathbf{V}^s_\sigma(\Omega)}\, d\mu(\lambda)\, d\tau = \frac{1}{2}\|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{\nu+s}_\sigma(\Omega)}.\end{aligned} \tag{A.26}$$

Then inequalities (A.24)–(A.26) imply (A.19). □

We next consider the Stokes problem with nonzero forcing and the zero initial value:

$$\partial_t\mathbf{q}(t,\mathbf{x}) + A\mathbf{q} = \mathbf{h}(t,\mathbf{x}) \quad \text{in } Q \qquad \text{and} \qquad \mathbf{q}|_{t=0} = \mathbf{0} \quad \text{in } \Omega. \tag{A.27}$$

LEMMA A.7. *Assume* $\mathbf{h} \in L^2(0,T;\mathbf{V}^{-s}_\sigma(\Omega))$, $s \in [0,1]$. *Then the solution* $\mathbf{q}$ *of the problem* (A.27) *satisfies the equality*

$$\int_0^T \Big(\|\partial_t\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{-s}_\sigma(\Omega)} + \|\mathbf{q}(t,\cdot)\|^2_{\mathbf{V}^{2-s}_\sigma(\Omega)}\Big)\, dt = \int_0^T \|\mathbf{h}(t,\cdot)\|^2_{\mathbf{V}^{-s}_\sigma(\Omega)}\, dt. \tag{A.28}$$

Proof. As in the proof of Lemma A.6, we reduce the problem (A.27) to an ordinary differential equation problem for the spectral decomposition $\widehat{\mathbf{q}}(t,\lambda)$ of $\mathbf{q}(t,\mathbf{x})$:

$$\partial_t \widehat{\mathbf{q}}(t,\lambda) + \lambda \widehat{\mathbf{q}}(t,\lambda) = \widehat{\mathbf{h}}(t,\lambda) \quad \text{in } Q \tag{A.29}$$

and

$$\widehat{\mathbf{q}}(t,\lambda)|_{t=0} = \mathbf{0} \tag{A.30}$$

for μ-almost-every $\lambda \in [1,\infty)$, where $\widehat{\mathbf{h}}$ is the spectral decomposition of $\mathbf{h}$. We extend $\widehat{\mathbf{h}}$ in t by zero outside the interval $[0,T]$ and extend $\widehat{\mathbf{q}}$ by zero for $t<0$ and by $e^{-\lambda t}\int_0^T e^{\lambda\tau}\mathbf{h}(\tau,\lambda)\,d\tau$ for $t>T$. This integral defines the solution of (A.29) for $t>T$ if $\mathbf{h}=0$ for $t>T$. We still denote the extended functions by $\widehat{\mathbf{q}}$ and $\widehat{\mathbf{h}}$, respectively. By virtue of (A.30), the extended functions satisfy (A.29)–(A.30) for $t\in\mathbb{R}$. Applying the Fourier transform in t, i.e.,

$$\widetilde{\mathbf{q}}(\tau,\lambda) = \int_{\mathbb{R}} e^{-i\tau t}\widehat{\mathbf{q}}(t,\lambda)\,dt \qquad \text{and} \qquad \widetilde{\mathbf{h}}(\tau,\lambda) = \int_{\mathbb{R}} e^{-i\tau t}\widehat{\mathbf{h}}(t,\lambda)\,dt,$$

to (A.29) we obtain

$$\widetilde{\mathbf{q}}(\tau,\lambda) = \frac{\widetilde{\mathbf{h}}(\tau,\lambda)}{i\tau+\lambda} \quad \text{and} \quad i\tau\widetilde{\mathbf{q}}(\tau,\lambda) = \frac{i\tau\widetilde{\mathbf{h}}(\tau,\lambda)}{i\tau+\lambda}.$$

Taking the $\|\cdot\|_{\mathbf{V}_\sigma^{-s}(\Omega)}$ norms yields

$$\begin{aligned} &\|\widetilde{\mathbf{q}}(\tau,\cdot)\|^2_{\mathbf{V}_\sigma^{2-s}(\Omega)} + \|i\tau\widetilde{\mathbf{q}}(\tau,\cdot)\|^2_{\mathbf{V}_\sigma^{-s}(\Omega)} \\ &\quad = \int_1^\infty \left(\frac{\lambda^{2-s}}{|i\tau+\lambda|^2} + \frac{\lambda^{-s}|i\tau|^2}{|i\tau+\lambda|^2}\right)\|\widetilde{\mathbf{h}}(\tau,\lambda)\|^2_{H(\lambda)}\,d\lambda \\ &\quad = \int_1^\infty \lambda^{-s}\|\widetilde{\mathbf{h}}(\tau,\lambda)\|^2_{H(\lambda)}\,d\lambda = \|\widetilde{\mathbf{h}}(\tau,\cdot)\|^2_{\mathbf{V}_\sigma^{s}(\Omega)}. \end{aligned} \tag{A.31}$$

Applying Parseval's equality to both ends of (A.31) we obtain (A.28). (Note that standard uniqueness arguments applied to (A.27) imply that we have obtained estimates precisely for the solution of (A.27).) ∎

A.3. Regularity estimate for the solution of the adjoint boundary value problem. We will apply the regularity results for the Stokes problem to derive regularity estimates for the solution $\mathbf{q}$ of the adjoint boundary value problem (3.14). (3.14) can be rewritten as

$$\partial_t\mathbf{q}(t,\mathbf{x}) + A\mathbf{q} = L\mathbf{q} \quad \text{in } Q \qquad \text{and} \qquad \mathbf{q}|_{t=0} = \mathbf{q}_0 \quad \text{in } \Omega, \tag{A.32}$$

where

$$L\mathbf{q} = P\big(\mathbf{q} + [(\mathbf{v}_0+\widehat{\mathbf{w}})\cdot\nabla]\mathbf{q} - (\nabla\widehat{\mathbf{w}})^*\mathbf{q}\big). \tag{A.33}$$

Indeed, we consider the first equation in (A.32) in the space $L^2(0,T;\mathbf{V}_\sigma^{-s}(\Omega))$, $s\in[0,1]$. Since the definition (A.16) implies that P is a projection and we look for $\partial_t\mathbf{q}$ in $L^2(0,T;\mathbf{V}_\sigma^{-s}(\Omega))$, we have that $P\partial_t\mathbf{q} = \partial_t\mathbf{q}$. The equality $A = P(-\Delta+I)$ follows from the definitions (A.1) and (A.16) of the operators A (on $\mathbf{V}_0^0(\Omega)$) and P and

the definition of the space $\mathbf{V}_\sigma^{-s}(\Omega)$ (see (A.15)). Relations (A.18) are built into the space $L^2(0,T;\mathbf{V}_\sigma^{-s+2}(\Omega))$, $-s+2\geq 1$. Note that the existence and uniqueness of the solution was established in Lemma 3.6. We have the following regularity results for the adjoint boundary value problem.

PROPOSITION A.8. *Assume that* $\mathbf{q}_0\in\mathbf{V}_\sigma^s(\Omega)$ *for an* $s\in[0,1/2)$. *Let* $\mathbf{q}$ *be the unique solution of the problem* (A.32)–(A.33) *satisfying the inequality* (3.15). *Then the following estimate holds:*

$$\int_t^\infty \left(\|\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^2_\sigma(\Omega)}+\|\partial_t\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^0_\sigma(\Omega)}\right)d\tau\leq C_0t^{s-1}\|\mathbf{q}_0\|^2_{\mathbf{V}^s_\sigma(\Omega)}, \tag{A.34}$$

where the constant C_0 *depends only on* $\|\widehat{\mathbf{w}}\|_{\mathbf{V}^{1,1/2}(Q)}$ *and* $\|\mathbf{v}_0\|_{\mathbf{C}^2(\overline{\Omega})}$.

Proof. By virtue of Theorem 2.1, we have that

$$\sup_{\mathbf{x}\in\overline{\Omega}}|\mathbf{v}_0(\mathbf{x})-\mathbf{w}_\infty|+\sum_{i=1}^3\sup_{\mathbf{x}\in\overline{\Omega}}|\partial_{x_i}\mathbf{v}_0(\mathbf{x})|+\sum_{i,j=1}^3\sup_{\mathbf{x}\in\overline{\Omega}}|\partial_{x_i}\partial_{x_j}\mathbf{v}_0(\mathbf{x})|\leq C|\mathbf{v}_\infty|.$$

As indicated in Theorems 4.1 and 4.2 and by (2.22), (2.19), and (2.15), the function $\widehat{\mathbf{w}}$ satisfies

$$\widehat{\mathbf{w}}\in\mathbf{V}^{1,1/2}(Q)\subset\mathbf{C}([0,T];\mathbf{H}^1(\Omega)). \tag{A.35}$$

Therefore, for $\mathbf{q}\in L^2(0,T;\mathbf{V}^1_\sigma(\Omega))$, we have $(\mathbf{v}_0\cdot\nabla)\mathbf{q}\in L^2(0,T;\mathbf{L}^2(\Omega))$, and we obtain by Sobolev embedding theorems and the Holder inequality that

$$\begin{aligned}\Big|\int_\Omega(\widehat{\mathbf{w}}\cdot\nabla)\mathbf{q}\cdot\boldsymbol{\phi}\,dx\Big|&\leq\|\widehat{\mathbf{w}}\|_{\mathbf{L}^6(\Omega)}\|\nabla\mathbf{q}\|_{\mathbf{L}^2(\Omega)}\|\boldsymbol{\phi}\|_{\mathbf{L}^3(\Omega)}\\&\leq C\|\widehat{\mathbf{w}}\|_{\mathbf{H}^1(\Omega)}\|\nabla\mathbf{q}\|_{\mathbf{L}^2(\Omega)}\|\boldsymbol{\phi}\|_{\mathbf{H}^{1/2}(\Omega)},\end{aligned}$$

which, upon using (A.35), yields

$$\|(\widehat{\mathbf{w}}\cdot\nabla)\mathbf{q}\|_{L^2(0,T;\mathbf{H}^{-1/2}(\Omega))}\leq C\|\mathbf{q}\|_{L^2(0,T;\mathbf{V}^1_\sigma(\Omega))}\|\widehat{\mathbf{w}}\|_{\mathbf{V}^{1,1/2}(Q)}. \tag{A.36}$$

Similarly, we obtain

$$\begin{aligned}\Big|\int_\Omega(\nabla\widehat{\mathbf{w}})^*\mathbf{q}\cdot\boldsymbol{\phi}\,dx\Big|&\leq\|\nabla\widehat{\mathbf{w}}\|_{\mathbf{L}^2(\Omega)}\|\mathbf{q}\|_{\mathbf{L}^6(\Omega)}\|\boldsymbol{\phi}\|_{\mathbf{L}^3(\Omega)}\\&\leq C\|\nabla\widehat{\mathbf{w}}\|_{\mathbf{L}^2(\Omega)}\|\mathbf{q}\|_{\mathbf{H}^1(\Omega)}\|\boldsymbol{\phi}\|_{\mathbf{H}^{1/2}(\Omega)}\end{aligned} \tag{A.37}$$

and

$$\|(\nabla\widehat{\mathbf{w}})^*\mathbf{q}\|_{L^2(0,T;\mathbf{H}^{-1/2}(\Omega))}\leq C\|\mathbf{q}\|_{L^2(0,T;\mathbf{V}^1_\sigma(\Omega))}\|\widehat{\mathbf{w}}\|_{\mathbf{V}^{1,1/2}(Q)}. \tag{A.38}$$

From (A.33), (A.36), and (A.38), we deduce that

$$\|L\mathbf{q}\|_{L^2(t,T;\mathbf{V}_\sigma^{-1/2}(\Omega))}\leq C\|\mathbf{q}\|_{L^2(t,T;\mathbf{V}^1_\sigma(\Omega))},\qquad t\in(0,T). \tag{A.39}$$

We decompose the solution $\mathbf{q}$ of (A.32) into

$$\mathbf{q}=\mathbf{q}_1+\mathbf{q}_2, \tag{A.40}$$

where $\mathbf{q}_1$ is the solution of (A.17) and $\mathbf{q}_2$ is the solution of (A.27) with $\mathbf{h}=L\mathbf{q}$. Then, by Lemma A.7, we have

$$\|\mathbf{q}_2\|^2_{L^2(0,T;\mathbf{V}^{3/2}_\sigma(\Omega))}+\|\partial_t\mathbf{q}_2\|^2_{L^2(0,T;\mathbf{V}_\sigma^{-1/2}(\Omega))}\leq C\|L\mathbf{q}\|^2_{L^2(0,T;\mathbf{V}_\sigma^{-1/2}(\Omega))}. \tag{A.41}$$

The relations (A.40)–(A.41) and Lemma A.6 with $s+\nu = 1/2$ and (A.39) imply that, for each $t \in (0,T)$,

$$\int_t^T \Big(\|\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^{3/2}_\sigma(\Omega)} + \|\partial_t \mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^{-1/2}_\sigma(\Omega)} \Big)\, d\tau \le C\Big(\|\mathbf{q}_1(t,\cdot)\|^2_{\mathbf{V}^{1/2}_\sigma(\Omega)} + \|\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^1_\sigma(\Omega))} \Big). \tag{A.42}$$

Repeating arguments similar to those used in the derivation of (A.36)–(A.39), we obtain

$$\|L\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^{-\varepsilon}_\sigma(\Omega))} \le C \|\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^{3/2}_\sigma(\Omega))}, \tag{A.43}$$

where $\varepsilon > 0$ is an arbitrary small number. Also, analogous to (A.42), we have that

$$\|\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^{2-\varepsilon}_\sigma(\Omega))} + \|\partial_t \mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^{-\varepsilon}_\sigma(\Omega))} \le C\Big(\|\mathbf{q}_1(t,\cdot)\|^2_{\mathbf{V}^1_\sigma(\Omega)} + \|L\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^{-\varepsilon}_\sigma(\Omega))} \Big). \tag{A.44}$$

We substitute (A.43) into (A.44) and use the obtained estimate as well as the arguments which led us to (A.43) and (A.44) to deduce that (A.43) and (A.44) hold with $\varepsilon = 0$. Combining the estimates (A.42)–(A.44) (with $\varepsilon > 0$ and with $\varepsilon = 0$), we are led to

$$\int_t^T \Big(\|\mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^2_\sigma(\Omega)} + \|\partial_t \mathbf{q}(\tau,\cdot)\|^2_{\mathbf{V}^0_\sigma(\Omega)} \Big)\, d\tau \le C\Big(\|\mathbf{q}_1(t,\cdot)\|^2_{\mathbf{V}^1_\sigma(\Omega)} + \|\mathbf{q}\|^2_{L^2(t,T;\mathbf{V}^1_\sigma(\Omega))} \Big). \tag{A.45}$$

Applying Lemma A.6 with $\nu = 1 - s$ and the estimate (3.15) to the right-hand side of (A.45), we arrive at (A.34). ∎

Appendix B. Orlicz spaces. In section 5.2, we needed to determine the space in which to search for the adjoint vector field for the optimality system. For this purpose, we first calculate the dual space for the function space $L^2(Q) \cap L^{6/5}(Q)$. We can consider $L^2(Q) \cap L^{6/5}(Q)$ as the Orlicz space with the N-function

$$A(t) = \max\,(t^2, t^{6/5}), \qquad t \ge 0.$$

(For the N-function as well as other notations and assertions connected with Orlicz spaces, see [1, Chap. 8].) In other words, the Orlicz space $L^2(Q) \cap L^{6/5}(Q)$ can be defined as follows:

$$\begin{aligned} L^2(Q) \cap L^{6/5}(Q) &= L_A(Q) \\ &\equiv \Big\{ f(t,\mathbf{x}),\ (t,\mathbf{x}) \in Q : \int_Q A(|f(t,\mathbf{x})|)\, d\mathbf{x}\, dt < \infty \Big\}. \end{aligned} \tag{B.1}$$

The norm in a general Orlicz space $L_A(Q)$ is defined as follows:

$$\|f\|_{L_A(Q)} = \inf \Big\{ k > 0 : \int_Q A\Big(\frac{|f(t,\mathbf{x})|}{k} \Big)\, d\mathbf{x}\, dt \le 1 \Big\}. \tag{B.2}$$

Define the Legendre transform

$$A^*(s) = \max_{t \ge 0} (st - A(t))$$

for $A(t) = \max(t^2, t^{6/5})$. Then $A^*(s)$ is an N-function and the Orlicz space

$$L_{A^*}(Q) = \left\{ f(t,\mathbf{x}),\ (t,\mathbf{x}) \in Q : \int_Q A^*(|f(t,\mathbf{x})|)\, d\mathbf{x}\, dt < \infty \right\} \tag{B.3}$$

is the function space dual to space (B.1) (see [1, Chap. 8]). Straightforward calculations show that

$$A^*(s) = \begin{cases} 5^5 s^6/6^6, & s \in [0, 6/5], \\ s - 1, & s \in [6/5, 2], \\ s^2/4, & s \geq 2. \end{cases} \tag{B.4}$$

The norm $\|\cdot\|_{L_{A^*}(Q)}$ of the space $L_{A^*}(Q)$ is defined similarly to (B.2) with the help of the N-function $A^*(t)$.

Let us consider now the spaces $\mathbf{L}_A(Q)$ and $\mathbf{L}_{A^*}(Q)$ of vector functions that are defined by (B.1) and (B.3), respectively, where f is the vector function $f = (f_1(t,x), f_2(t,x), f_3(t.x))$.

LEMMA B.1. *The spaces $\mathbf{L}_A(Q)$ and $\mathbf{L}_{A^*}(Q)$ are dual.*

Proof. We will prove that $(\mathbf{L}_A(Q))^* = \mathbf{L}_{A^*}(Q)$, where $(\mathbf{L}_A(Q))^*$ is the adjoint space of $\mathbf{L}_A(Q)$. Each $\mathbf{v} \in \mathbf{L}_{A^*}(Q)$ forms a linear bounded functional on $\mathbf{L}_A(Q)$ by the formula

$$l(u) = \int_Q \mathbf{v}(t,x) \cdot \mathbf{u}(t,\mathbf{x})\, d\mathbf{x}\, dt \qquad \forall \mathbf{u} \in \mathbf{L}_A(Q) \tag{B.5}$$

because of the generalized Holder inequality (see [1, Chap. 8]):

$$\int_Q \mathbf{v}(t,x) \cdot \mathbf{u}(t,\mathbf{x})\, d\mathbf{x}\, dt \leq 2\|\mathbf{v}\|_{\mathbf{L}_{A^*}(Q)} \|\mathbf{u}\|_{\mathbf{L}_A(Q)}. \tag{B.6}$$

Therefore $\mathbf{L}_{A^*}(Q) \subset (\mathbf{L}_A(Q))^*$. To prove the inverse inclusion we establish first that $\mathbf{L}_A(Q)$ is isomorphic to $L_A(Q) \times L_A(Q) \times L_A(Q)$. For this we have to prove the estimates

$$\|\mathbf{v}\|_{\mathbf{L}_A(Q)} \leq \sum_{j=1}^3 \|v_j\|_{L_A(Q)} \leq 3\|\mathbf{v}\|_{\mathbf{L}_A(Q)} \quad \forall\, \mathbf{v} = (v_1, v_2, v_3) \in \mathbf{L}_A(Q). \tag{B.7}$$

Suppose first that for each j, $v_j(t,\mathbf{x}) \neq 0$ on a set of positive Lebesque measure. Then, using the definition (B.2), the inequality $|\mathbf{v}(\mathbf{x})| \leq \sum_{j=1}^3 |v_j(\mathbf{x})|$, and the convexity of $A(\lambda)$, we obtain

$$\begin{aligned}
\|\mathbf{v}\|_{\mathbf{L}_A(Q)} &= \inf\left\{ k > 0 : \int_\Omega A\left(\frac{|\mathbf{v}(\mathbf{x})|}{k}\right) d\mathbf{x} \leq 1 \right\} \\
&\leq \inf\left\{ k > 0 : \int_\Omega A\left(\frac{\sum_{j=1}^3 |v_j(\mathbf{x})|}{k}\right) d\mathbf{x} \leq 1 \right\} \\
&= \inf\left\{ \sum_{i=1}^3 k_i : k_i > 0,\ i = 1,2,3, \int_\Omega A\left(\sum_{j=1}^3 \frac{k_j}{k_1 + k_2 + k_3} \frac{|v_j(\mathbf{x})|}{k_j} \right) d\mathbf{x} \leq 1 \right\} \\
&\leq \inf\left\{ \sum_{i=1}^3 k_i : k_i > 0,\ i = 1,2,3, \sum_{j=1}^3 \frac{k_j}{k_1 + k_2 + k_3} \int_\Omega A\left(\frac{|v_j(\mathbf{x})|}{k_j} \right) d\mathbf{x} \leq 1 \right\} \\
&\leq \inf\left\{ \sum_{i=1}^3 k_i : k_i > 0, \int_\Omega A\left(\frac{|v_j(\mathbf{x})|}{k_j} \right) d\mathbf{x} \leq 1\ i = 1,2,3 \right\} \\
&\leq \sum_{i=1}^3 \inf\left\{ k > 0 : \int_\Omega A\left(\frac{|v_i(\mathbf{x})|}{k} \right) d\mathbf{x} \leq 1 \right\} = \sum_{i=1}^3 \|v_i\|_{L_A(Q)}.
\end{aligned}$$

This inequality and the homogeniety property of norms imply the first estimate in (B.7)

Denote $\hat{v}(t,\mathbf{x}) = \max_{j=1,2,3} |v_j(t,\mathbf{x})|$. For each $(t,\mathbf{x})$ we have

$$\frac{1}{3}|\mathbf{v}(t,\mathbf{x})| \le \hat{v}(t,\mathbf{x}) \le |\mathbf{v}(t,\mathbf{x})|$$

so that $A(\hat{v}(t,\mathbf{x})/k) \le A(|\mathbf{v}(t,\mathbf{x})|/k)$ for all $k > 0$. Thus,

$$\begin{aligned}\sum_{j=1}^{3} \|v_j\|_{L_A(Q)} \le 3\|\hat{v}\|_{L_A(Q)} &= 3\inf\left\{k>0:\ \int_Q A(\frac{|\hat{v}(t,\mathbf{x})|}{k})\,d\mathbf{x}\,dt \le 1\right\} \\ &\le 3\inf\left\{k>0:\ \int_Q A\left(\frac{|\mathbf{v}(t,\mathbf{x})|}{k}\right)d\mathbf{x}\,dt \le 1\right\} = 3\|\mathbf{v}\|_{\mathbf{L}_A(Q)}.\end{aligned} \tag{B.8}$$

The bound (B.8) implies the second estimate in (B.7).

The estimate (B.7) in the case when $v_j(t,\mathbf{x}) = 0$ almost everywhere for one or two j can be considered similarly. The case $v_j(t,\mathbf{x}) = 0$ a.e. for $j = 1,2,3$ is trivial.

By the lemma on the form of a functional on direct product of spaces (see [2, sect. 2.1.2]), each functional $\Lambda \in (L_A(Q) \times L_A(Q) \times L_A(Q))^*$ has the form

$$\Lambda(\mathbf{u}) = l_1(u_1) + l_2(u_2) + l_3(u_3) \quad \forall\ \mathbf{u} = (u_1,u_2,u_3) \in [L_A(Q)]^3, \tag{B.9}$$

where $l_j \in (L_A(Q))^*$, $j = 1,2,3$. By [1, Chap. 8], there exist $v_j \in L_{A^*}(Q)$, $j = 1,2,3$, such that

$$l_j(u) = \int_Q v_j(t,\mathbf{x})u(t,\mathbf{x})\,d\mathbf{x}\,dt, \quad j = 1,2,3 \quad \forall\ u \in L_A(Q). \tag{B.10}$$

Relations (B.9), (B.10), and the isomorphism $\mathbf{L}_A(Q) \cong L_A(Q) \times L_A(Q) \times L_A(Q)$ proved by (B.7) yield the embedding $\mathbf{L}_{A^*}(Q) \supset (\mathbf{L}_A(Q))^*$.

The proof of the relation $(\mathbf{L}_{A^*}(Q))^* = \mathbf{L}_A(Q)$ is similar. □

We will need the following assertion.

LEMMA B.2. *Let Y be a closed subspace of a reflexive space X. Assume that the norms $\|\cdot\|_X$ and $\|\cdot\|_Y$ are equivalent. Then Y is a reflexive space.*

Proof. By virtue of the Eberlein–Shmulian theorem [18, Appendix], the reflexivity of Y is equivalent to the following property: each bounded sequence $y_n \in Y$ has a subsequence $\{y_{n_k}\}$ converging weakly to a $\widehat{y} \in Y$. Let a bounded sequence $y_n \in Y$ be given. Since the sequence $\{y_n\}$ is bounded in X and X is reflexive, there exists a subsequence $\{y_{n_k}\} \subset \{y_n\}$ that converges weakly in X to a $\widehat{y} \in X$. Note that Y being closed and convex, it is sequentially weakly closed. By the Hahn–Banach theorem, the weak convergence in X of $\{y_{n_k}\} \subset Y$ implies the weak convergence in Y. Hence, Y is a reflexive space. □

B.1. Orlicz spaces of solenoidal fields. Now we consider solenoidal vector fields. Using the space of vector fields

$$\mathcal{V}(Q) = \{\mathbf{v}(t,\mathbf{x}) \in \mathbf{C}_0^\infty(Q):\ \operatorname{div}\mathbf{v} = 0, \quad \operatorname{supp}\mathbf{v} \subset\subset Q\}$$

we introduce

$$L^2(0,T;\mathbf{V}_0^0(\Omega)) = \text{closure of } \mathcal{V}(Q) \text{ in } \mathbf{L}^2(Q). \tag{B.11}$$

It is well known that $\mathbf{V}_0^0(\Omega)$ in (B.11) is the space (2.14). Define also

$$\mathbf{V}_A(Q) = \text{closure of } \mathcal{V}(Q) \text{ in } \mathbf{L}_A(Q). \tag{B.12}$$

Evidently $\mathbf{V}_A(Q) = L^2(0,T;\mathbf{V}_0^0(\Omega)) \cap \mathbf{L}^{6/5}(Q)$. We set

$$\mathbf{V}_{A^*}(Q) = \text{closure of } \mathcal{V}(Q) \text{ in } \mathbf{L}_{A^*}(Q). \tag{B.13}$$

All elements of the spaces (B.11), (B.12), and (B.13) possess the properties $\operatorname{div} \mathbf{u} = 0$ and $(\mathbf{u}\cdot\mathbf{n})|_{\partial\Omega} = 0$ (these equalities are understood in the sense of distributions).

Denote

$$\mathbf{G}_A(Q) = \{\nabla p \in \mathbf{L}_A(Q) :\ p \in L^2(0,T;H^1_{\mathrm{loc}}(\Omega))\}, \tag{B.14}$$

LEMMA B.3. *The relations* $(\mathbf{V}_{A^*}(Q))^* = \mathbf{V}_A(Q)$ *and* $(\mathbf{V}_A(Q))^* = \mathbf{V}_{A^*}(Q)$ *hold.*

Proof. We begin from the first identity. Each $\mathbf{u} \in \mathbf{V}_A(Q)$ defines a functional on $\mathbf{V}_{A^*}(Q)$ by (B.5) and (B.6). Hence $\mathbf{V}_A(Q) \subset (\mathbf{V}_{A^*}(Q))^*$. To prove the reverse inclusion let a functional $l \in (\mathbf{V}_{A^*}(Q))^*$ be given, and we extend it by the Hahn–Banach theorem into an $\widehat{l} \in (\mathbf{L}_{A^*}(Q))^*$. By Lemma B.1, there exists a $\mathbf{u} \in \mathbf{L}_A(Q)$ such that $\widehat{l}(\mathbf{v}) = \int_Q \mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}\,dt$. Thus,

$$l(\mathbf{v}) = \int_Q \mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}\,dt \qquad \forall\, \mathbf{v} \in \mathbf{V}_{A^*}(Q). \tag{B.15}$$

Note that the following decomposition is true:

$$\mathbf{L}_A(Q) = \mathbf{V}_A(Q) + \mathbf{G}_A(Q). \tag{B.16}$$

Indeed, since $\mathbf{L}_A(Q) \subset \mathbf{L}^2(Q)$, by virtue of Weyl's decomposition for each $\mathbf{u} \in \mathbf{L}_A(Q)$, there exist $\nabla p \in \mathbf{G}(Q) = \{\nabla p \in \mathbf{L}^2(Q) :\ p \in L^2(0,T;H^1_{\mathrm{loc}}(\Omega))\}$ and $\mathbf{w} \in L^2(0,T;\mathbf{V}_0^0(\Omega))$ such that

$$\mathbf{u} = \mathbf{w} + \nabla p. \tag{B.17}$$

To prove Weyl's decomposition, one defines $\nabla p(t,\mathbf{x})$ to be the solution of the problem

$$\int_Q \nabla p(t,\mathbf{x})\cdot\nabla q(t,\mathbf{x})\,d\mathbf{x}\,dt = \int_Q \mathbf{u}(t,\mathbf{x})\cdot\nabla q(t,\mathbf{x})\,d\mathbf{x}\,dt \qquad \forall\, \nabla q. \tag{B.18}$$

If $\nabla q \in \mathbf{L}^2(Q)$, then (B.18) defines $\nabla p \in \mathbf{L}^2(Q)$. But since $\mathbf{u} \in \mathbf{V}_A(Q) = \mathbf{L}^2(Q) \cap \mathbf{L}^{6/5}(Q)$, the right-hand side of (B.18) is a bounded functional with respect to $\nabla q \in \mathbf{L}^6(Q)$, so that $\nabla p \in \mathbf{L}^{6/5}(Q)$. Hence $\nabla p \in \mathbf{V}_A(Q)$ and, by (B.17), $\mathbf{w} \in \mathbf{V}_A(Q)$, which proves (B.16). Note that the relation $\mathbf{V}_A(Q) \cap \mathbf{G}_A(Q) = 0$ follows from the orthogonality between $\mathbf{w}$ and ∇p in $\mathbf{L}^2(Q)$.

Now we substitute (B.17) into (B.15) and take into account that $\int_Q \nabla p\cdot\mathbf{v}\,d\mathbf{x}\,dt = 0$ for every $\nabla p \in \mathbf{G}_A(Q)$ and every $\mathbf{v} \in \mathbf{V}_{A^*}(Q)$. As a result we deduce

$$l(\mathbf{v}) = \int_Q \mathbf{w}\cdot\mathbf{v}\,d\mathbf{x}\,dt \qquad \forall\, \mathbf{v} \in \mathbf{V}_{A^*}(Q) \tag{B.19}$$

with $\mathbf{w} \in \mathbf{V}_A(Q)$. Hence, we have proved the equality $(\mathbf{V}_{A^*}(Q))^* = \mathbf{V}_A(Q)$. This equality yields $(\mathbf{V}_A(Q))^* = \mathbf{V}_{A^*}(Q)$, since by Lemma B.2, the spaces $\mathbf{V}_A(Q))$ and $\mathbf{V}_{A^*}(Q)$ are reflexive. ∎

We set

$$\mathcal{W}_0^{(2)}(Q) = \{\mathbf{v} \in L^2(0,T;\mathbf{V}^2(\Omega)) : \partial_t \mathbf{v} \in L^2(0,T;\mathbf{V}^0(\Omega)),\ \mathbf{v}\big|_{t=0} = \mathbf{0}\} \tag{B.20}$$

and

$$\mathbf{V}_A^{1,2}(Q) = \mathcal{W}_0^{(2)}(Q)) \cap \mathbf{W}_{6/5}^{1,2}(Q), \tag{B.21}$$

where $\mathbf{W}_{6/5}^{1,2}(Q)$ is Sobolev space defined by (3.7).

RAPID EXPONENTIAL FEEDBACK STABILIZATION WITH UNBOUNDED CONTROL OPERATORS*

JOSE MANUEL URQUIZA†

Abstract. We study the wellposedness and the main features of a class of feedback control systems. The involved control system is composed of the generator of a strongly continuous group for the free part and of an unbounded control operator, so that the results can be applied to boundary or point control problems for partial differential equations of hyperbolic or Petrowski type. The feedback operator is explicit and one can achieve an arbitrary large decay rate for the closed-loop system. These results are proved under a controllability assumption and the proofs rely on general results about the algebraic Riccati equation associated with the linear quadratic regulator problem.

Key words. strongly continuous group, unbounded control operator, stabilization, controllability, algebraic Riccati equation, wave equation

1. Introduction.

The purpose of this paper is to depict a class of full state stabilizing feedback operators for some infinite-dimensional linear systems with unbounded control operators and to prove the wellposedness of the resulting closed-loop feedback systems. The class of infinite-dimensional equations that is considered contains time-reversible partial differential equations such as first-order hyperbolic, wave, and plate-like equations. The assumptions on the control operator allow us to consider boundary or point control problems for these equations.

One of the main features of the class of feedback operators which is presented in this paper is that they are built in a straightforward and explicit way. Moreover, the exponential decay rate of the resulting closed-loop feedback system can be made as large as desired by freely tuning a parameter on which the feedback operator depends. The controllability of the system is the main assumption for the results to hold.

This class of feedback operators was already known for finite-dimensional systems. Moreover, it constitutes a limiting but unexplored class of feedback operators studied recently by Komornik [12] for boundary control problems of partial differential equations. In [12], a lower bound of the exponential decay rate can also be chosen arbitrarily. For the class of feedback operators presented here, we can give the optimal decay rate explicitly as a function of the tuning parameter and of the growth bound of the backward in time semigroup associated with the system.

In order to state the problem treated in this paper an introductory exposition is given next. It begins with, in addition to well-known results of the control theory of linear finite-dimensional systems, some other results that seem to be scarcely present in the literature. These results are given in Russell's book [24] to which we refer the reader for details. They deal with easy ways to stabilize linear constant finite-dimensional systems that are controllable.

Consider the linear constant finite-dimensional system

$$\begin{cases} \dot{y}(t) = Ay(t) + Bu(t), \\ y(0) = y_0, \qquad y_0 \in \mathbb{R}^n, \end{cases} \tag{1.1}$$

where $A \in \mathbb{R}^{n,n}$, $B \in \mathbb{R}^{n,p}$ for some $n, p \in \mathbb{N}^*$. The control system (A, B) is said to be controllable in time $T > 0$ if for every $y_0, y_T \in \mathbb{R}^n$, there is a control u such that the solution y of (1.1) satisfies $y(T) = y_T$. A necessary and sufficient condition is that the symmetric matrix

$$\Lambda_{0,T} \equiv \int_0^T e^{-tA} B B^* e^{-tA^*} dt$$

is positive definite for some $T > 0$ (and thus for every $T > 0$). $\Lambda_{0,T}$ is called a *controllability gramian* and it can be used to derive a control candidate. For instance, with

$$u(t) = -B^* e^{-tA^*} \Lambda_{0,T}^{-1} y_0, \quad 0 \le t \le T,$$

the solution of (1.1) satisfies $y(T) = 0$.

Gramians can thus be used for the controllability problem, but can also be used for the stabilization problem, that is, to find a matrix operator $F \in \mathbb{R}^{p,n}$ such that all solutions of

$$\dot{y}(t) = Ay(t) + BFy(t) = (A + BF)y(t), \quad t \ge 0, \tag{1.2}$$

decay asymptotically to the null state.

If $\Lambda_{0,T}$ is positive definite, the same conclusion holds for the *modified gramians* $\Lambda_{\omega,T}$ defined for every $0 < T < \infty$ and every $\omega \ge 0$ by

$$\Lambda_{\omega,T} \equiv \int_0^T e^{-2\omega t} e^{-tA} B B^* e^{-tA^*} dt$$

and also for the *extended controllability gramians* $\Lambda_{\omega,\infty}$when ω is sufficiently large:

$$\Lambda_{\omega,\infty} \equiv \int_0^\infty e^{-2\omega t} e^{-tA} B B^* e^{-tA^*} dt \ > \ 0.$$

It is well known that, at least for linear constant finite-dimensional systems, controllability implies stabilizability. A common feature of the gramians described above is their ability to be used to build explicit asymptotically stabilizing feedback operators. Indeed, let $0 \le \omega < \infty$ and $0 < T \le \infty$ be such that $\Lambda_{\omega,T}$ is well defined and regular, and set

$$F_{\omega,T} = -B^* \Lambda_{\omega,T}^{-1}.$$

Then $A + BF_{\omega,T}$ is a stable matrix (all its eigenvalues have negative real parts), so that the solutions of (1.2) with $F = F_{\omega,T}$ decay uniformly and exponentially to zero: there is $M, \lambda > 0$ such that

$$\left| e^{t(A+BF_{\omega,T})} y_0 \right| \le M e^{-\lambda t} |y_0|, \quad t \ge 0, \tag{1.3}$$

for every $y_0 \in \mathbb{R}^n$.

For $\omega = 0$ and $0 < T < \infty$ this result was presented by Kleinman [10] and Lukes [21] in a finite-dimensional setting. The case $\omega > 0$, $0 < T < \infty$ appeared in Slemrod [26] in a broader setting including infinite-dimensional systems with bounded control operators. The result for this latter case was extended by Komornik [12] to unbounded control operators, with applications to some boundary or point control problems for partial differential equations.

The interest to take $\omega > 0$ lies in the fact that these feedbacks lead to an exponential stability of the system with an exponential decay rate greater than ω. As ω may be taken freely, the control system can be uniformly stabilized with an exponential decay rate as large as desired. This property has been called *complete stabilizability* [26]. Of course, it is well known that for controllable linear constant finite-dimensional systems, poles can be placed at will, but it seems that such a result is difficult to generalize to infinite-dimensional systems. Nevertheless, the uniform estimate (1.3) with $\lambda = \omega$ also holds for some infinite-dimensional systems to which applications of these feedback operators (with $\omega > 0$ and $T < \infty$) were done, although, for both finite-dimensional systems and infinite-dimensonal systems, we cannot say more about the *growth bound* (see the definition in the next section) of the closed-loop system in general when T is finite.

Also, based on Komornik's result [12], some numerical simulations have been conducted (see Briffaut [4]) on the spatial semidiscretizations of boundary control problems for some canonical partial differential equations of dynamical elasticity which have the particularity of being conservative systems. It appeared that the decay rate for the approximated systems was in fact approximately twice better than the theorical bound ω. From these observations, and by first considering some simple small finite-dimensional systems for which we can easily make the calculus explicit, we were led to consider the feedback operators built with the extended gramians, that is, to take $T = \infty$ (and ω sufficiently large). As a particular case of the main result to be proved here, we obtain that for the class of skew-adjoint operators ($A^* = -A$) the decay rate is exactly 2ω.

The easy way of using $\Lambda_{\omega,\infty}$ to stabilize a controllable system is mentioned in Russell's book [24, pp. 117–118] as Bass's method. According to [24], R. W. Bass introduced it in some *"Lecture notes on control and optimization presented at NASA Langley Research Center in August* 1961."

Assuming we are still in the finite-dimensional context, let us give some details and characteristics about this class of feedback operators and the resulting feedback systems. From the expression of $\Lambda_{\omega,\infty}$, we easily deduce that it solves the Liapunov equation

$$\Lambda_{\omega,\infty}(A + \omega I)^* + (A + \omega I)\Lambda_{\omega,\infty} = BB^*. \tag{1.4}$$

From the stability of $-(A + \omega I)$ and the controllability assumption, the theory says that it is its unique symmetric solution.

Multiplying this equation by $\Lambda_{\omega,\infty}^{-1}$, we obtain the relation

$$BB^*\Lambda_{\omega,\infty}^{-1} = \Lambda_{\omega,\infty}A^*\Lambda_{\omega,\infty}^{-1} + A + 2\omega I \tag{1.5}$$

from which we deduce that

$$A + BF_{\omega,\infty} = \Lambda_{\omega,\infty}\left(-A^* - 2\omega I\right)\Lambda_{\omega,\infty}^{-1}.$$

We thus have a simple expression for the feedback system and its spectral elements in terms of the free system characteristics. In particular, if $A^* = -A$, then the spectrum

of A is purely imaginary and the feedback operator translates it to the axis of abscissa -2ω. In the general case, the spectral values of $A + BF_{\omega,\infty}$ are those of $-A^*$ after a translation of 2ω. Moreover, its spectral elements can be expressed in terms of those of $-A^*$ and of the matrix operator $\Lambda_{\omega,\infty}$.

If we now do the left multiplication of the relation (1.5) by $\Lambda^{-1}_{\omega,\infty}$, we obtain

$$A^*P + PA + 2\omega\Lambda^{-1}_{\omega,\infty} - PBB^*P = 0 \tag{1.6}$$

with $P = \Lambda^{-1}_{\omega,\infty}$. Equation (1.6) is nothing but the algebraic Riccati equation in P deduced from the linear quadratic regulator problem for the control system (A, B) associated with the cost functional

$$\int_0^\infty \left[2\omega \left(\Lambda^{-1}_{\omega,\infty} y(t), y(t)\right)_{\mathbb{R}^n} + \|u(t)\|^2_{\mathbb{R}^p}\right] dt.$$

The purpose of this paper is to extend the result to unbounded operators A and B as they appear in boundary control problems for partial differential equations. To this end we follow the indirect way of considering the optimal control problem over an infinite time interval that this feedback operator solves. By conveniently choosing the quadratic cost functional, and proving that we have the expected feedback operator, the theorical results on the linear quadratic regulator problem established by Flandoli, Lasiecka, and Triggiani [7] give the wellposedness of the resulting feedback system.

A more direct way would consist in defining the feedback operator and establishing its admissibility. But if A and (most of all) B are unbounded operators, it does not seem to be a trivial task (see, for instance, Weiss [31] for definitions of admissible control and feedback operators).

Moreover, if the control operator B is bounded, then the operator equations that correspond in the finite-dimensional case to the matrix equations (1.4)–(1.6) are posed in the domain of the unbounded operator A or of its adjoint. Whereas with a more general (unbounded) control operator, B has to be replaced in (1.6) by a nonunique extension in order to obtain a suitable algebraic Riccati equation posed in the domain of A. This was noticed by Staffans [28] and Weiss and Weiss [33] and illustrated by Weiss and Zwart [32] with a demonstrative example. In order to prove our results we use a result of [7] which links the solution of the algebraic Riccati equation to the solution of a dual Riccati equation with bounded control operator and that reduces to the Liapunov equation (1.4) posed in the domain of A^*.

The main results of this paper are stated in the next section. Then in section 3 we recall some results on the linear quadratic regulator problem and prove the main results: the wellposedness and the additional stability properties of the closed-loop feedback system.

2. Notations, assumptions, and main results. Let U and Y be two separable Hilbert spaces, the control space and the state space, with norms denoted by $\|\cdot\|_U$ and $\|\cdot\|_Y$, and with associated scalar products denoted by $(\cdot,\cdot)_U$ and $(\cdot,\cdot)_Y$, respectively. For two Banach spaces E and F, $\mathcal{L}(E, F)$ denotes the space of linear bounded operators from E to F, and $\mathcal{L}(E, E)$ is denoted by $\mathcal{L}(E)$. Moreover, we denote by $L^2(I; E)$ and $\mathcal{C}^k(I; E)$ the space of square Lebesgue integrable functions on an interval I of the real line and the space of k times continuously differentiable functions on I with values in the Banach space E, respectively.

Following Flandoli, Lasiecka, and Triggiani [7], we consider the following dynamics

on Y:

$$\begin{cases} y(t) = e^{tA}y_0 + (Lu)(t), & y_0 \in Y, \\ (Lu)(t) = \displaystyle\int_0^t e^{(t-\tau)A}Bu(\tau)\ d\tau \end{cases} \tag{2.1}$$

that formally corresponds to the initial value problem

$$\begin{cases} \dot{y}(t) = Ay(t) + Bu(t) & \text{on } [\mathcal{D}(A^*)]', \\ y(0) = y_0, & y_0 \in Y. \end{cases} \tag{2.2}$$

A is an unbounded linear operator on Y with dense domain $\mathcal{D}(A)$ that we endow with the usual graph norm. A^* denotes the Y-adjoint of A and $[\mathcal{D}(A^*)]'$ is the dual of $\mathcal{D}(A^*)$ with respect to the Y-topology.

We shall make the following assumptions on operators A and B.

(H1) *A is the infinitesimal generator of a strongly continuous group e^{tA}, $t \in \mathbb{R}$, on Y.*

(H2) *B is linear continuous $U \longrightarrow [\mathcal{D}(A^*)]'$.*

The group property in assumption (H1) always holds for the linear time reversible systems we have in mind: second-order linear equations of hyperbolic or Petrowski type, first-order linear hyperbolic systems.

B is said to be a bounded control operator if $B \in \mathcal{L}(U, Y)$ and an unbounded one otherwise. Assumption (H2) on the control operator B enables one to consider boundary and point control problems for the examples of systems mentioned above (see [7], Lasiecka and Triggiani [15], and Bensoussan et al. [2], [3] for precise examples).

Note that, by identifying $[\mathcal{D}(A^*)]''$ with $\mathcal{D}(A)$, we get

$$B^* \in \mathcal{L}\left(\mathcal{D}(A^*); U\right).$$

As Y is assumed to be a Hilbert space, A^* is the generator of a strongly continuous semigroup which is the dual of the semigroup generated by A. Because of assumption (H1), it is the generator of a strongly continuous group e^{tA^*}, $t \in \mathbb{R}$ on Y.

We shall furthermore assume the following.

(H3) *Regularity property. For every $0 < T < \infty$ there is $C_T > 0$ such that*

$$\int_0^T \left\| B^* e^{-tA^*} y \right\|_U^2 dt \le C_T \|y\|_Y^2, \quad y \in \mathcal{D}(A^*). \tag{2.3}$$

(H4) *Controllability property. There is $T > 0$ and $c_T > 0$ such that*

$$\int_0^T \left\| B^* e^{-tA^*} y \right\|_U^2 dt \ge c_T \|y\|_Y^2, \quad y \in \mathcal{D}(A^*). \tag{2.4}$$

Usually, assumptions (H3) and (H4) are stated with $-A^*$ replaced by A^*, but, when considering the time reversibility assumption (H1), these assumptions are equivalent to the more standard ones (see Lemma 7.0 in Flandoli, Lasiecka, and Triggiani [7]). Note that, by density and continuity, inequalities (2.3) and (2.4) hold for any y on Y too.

By assumption (H3), we can extend the operator $B^*e^{-tA^*}$ to a continuous one from Y to $L_2(0, T; U)$. When B stands for a boundary control operator for a partial differential equation this assumption is a sharp trace regularity result with respect to partial differential equations theories for it is not obtained directly by just applying

the usual trace results (see, for instance, Lasiecka, Lions, and Triggiani [14] or Lions [19] in the case of the wave equation with Dirichlet boundary control). Also, it is well known that under this assumption the following regularity property holds [7]:

$$L \text{ continuous from } L^2(0,T;U) \text{ to } \mathcal{C}(0,T;Y) \quad \forall T > 0.$$

Assumption (H4) is the observability property for the dual system. Under all foregoing assumptions, we know (see Dolecki and Russell [6]) that it is equivalent to the controllability of the pair (A, B) over the time interval $(0, T)$:

For every $y_0,\ y_1 \in Y$ *there is* $u \in L^2(0,T;U)$ *such that the solution* y *of* (2.1) *satisfies* $y(T) = y^1$.

Moreover, it may hold only for T sufficiently large (like in the case of hyperbolic equations because of the finite speed of propagation). We refer the reader to Lions [19] and Komornik [11] for examples of this sort.

Before stating the main results we recall some basic facts about the asymptotic behavior of semigroups of linear operators that the reader can find in Pazy [23] and van Neerven [22]. Let us introduce *the type* $g(A)$ of a strongly continuous semigroup e^{At}, $t \geq 0$, of bounded linear operators on a Hilbert space Y:

$$g(A) = \inf_{t>0} \frac{1}{t} \log \left\| e^{tA} \right\|_{\mathcal{L}(Y)}.$$

$g(A)$ is also called the *growth bound* of the generated semigroup.

If $g(A) < 0$, then A is the generator of an exponentially stable semigroup and is said to be an exponentially stable generator. Moreover, $-g(A)$ is said to be the *stability margin* of the semigroup. Let us recall that $g(A)$ is finite or equal to $-\infty$,

$$g(A) = \lim_{t \longrightarrow \infty} \frac{1}{t} \log \left\| e^{tA} \right\|_{\mathcal{L}(Y)},$$

and $g(A)$ is the infimum of those $\omega \in \mathbb{R}$ for which there is $M_\omega > 0$ such that

$$\left\| e^{tA} \right\|_{\mathcal{L}(Y)} \leq M_\omega e^{\omega t}, \qquad t \geq 0.$$

Moreover, for every $\lambda \in \mathbb{R}$, the operator $A + \lambda I$ of domain $\mathcal{D}(A)$ is the generator of the strongly continuous semigroup $e^{\lambda t} e^{tA}$, $t \geq 0$, and

$$g(A + \lambda I) = g(A) + \lambda.$$

Finally, as Y is assumed to be a Hilbert space, $\left\| e^{tA} \right\|_{\mathcal{L}(Y)} = \left\| e^{tA^*} \right\|_{\mathcal{L}(Y)}$, $t \geq 0$, thus we have

$$g(A^*) = g(A). \tag{2.5}$$

We now state our main result.

THEOREM 2.1. *Consider* A *and* B *under assumptions* (H1)–(H4). *Let* $\omega \in \mathbb{R}$ *such that*

$$\omega > \max(g(-A), 0). \tag{2.6}$$

Then we have the following.

(i) *Operator* Λ_ω. *The symmetric positive operator* Λ_ω *defined by*

$$(\Lambda_\omega x, z)_Y = \int_0^\infty \left(B^* e^{-t(A+\omega I)^*} x, B^* e^{-t(A+\omega I)^*} z \right)_U dt\ , \qquad x,\ z \in Y, \tag{2.7}$$

is coercive and an isomorphism on Y.

(ii) *Wellposedness. Let* $F_\omega = -B^*\Lambda_\omega^{-1}$. *The operator* $A + BF_\omega$ *with*

$$\mathcal{D}(A + BF_\omega) = \Lambda_\omega\,(\mathcal{D}(A^*))$$

is the infinitesimal generator of the strongly continuous semigroup

$$T_\omega(t) = e^{t(A+BF_\omega)}, \quad t \geq 0,$$

on Y *and is exponentially stable.*

(iii) *Exponential decay rate. Let* $S_\omega(t)$ *be the strongly continuous semigroup on* Y *generated by* $-A^* - 2\omega I$. *Then*

$$T_\omega(t) = \Lambda_\omega S_\omega(t)\Lambda_\omega^{-1}, \quad t \geq 0, \tag{2.8}$$

so that $T_\omega(t)$ *is an exponentially stable semigroup of the type*

$$g(A + BF_\omega) = g(-A) - 2\omega. \tag{2.9}$$

Remark 2.2. (1) Assumption $\omega > g(-A)$ from (2.6) allows us to define the linear operator Λ_ω by (2.7), and together with assumption $\omega > 0$ they ensure that we have an exponentially stable resulting closed-loop feedback system as shown by (2.9). Moreover, ω is an upper bound of the stability margin which can thus be made as large as desired by conveniently choosing ω.

(2) In the case of skew-adjoint operators ($A = -A^*$, $\mathcal{D}(A^*) = \mathcal{D}(A)$), as announced in the introduction, the achieved stability margin is exactly 2ω since we have $g(-A) = g(A) = 0$.

3. Proof of the main results. The following proposition gives an existence and uniqueness result for a Liapunov equation and also assertion (i) of Theorem 2.1. It is a direct consequence of a more general result for Liapunov equations demonstrated by Grabowski [8] (see also Hansen and G. Weiss [9]). We omit the proof.

PROPOSITION 3.1. *Under assumptions* (H1)–(H4) *and with*

$$\omega > \max(0, g(-A))$$

the operator Λ_ω *as given by* (2.7) *is a well-defined self-adjoint bounded linear operator on* Y *and is coercive. Moreover,* Λ_ω *is the unique solution in* $\{\Lambda \in \mathcal{L}(Y); \Lambda = \Lambda^*\}$ *of the following Liapunov equation:*

$$\begin{aligned}&\forall x, z \in \mathcal{D}(A^*),\\ &\qquad (\Lambda_w(A + \omega I)^* x, z)_Y + (\Lambda_\omega x, (A + \omega I)^* z)_Y = (B^* x, B^* z)_Y.\end{aligned}$$

In the remaining part of this section we often use some general results on the linear quadratic regulator problem as they are given in the relatively complete text [7] (see also [15] for an exposition of the results) in order to establish the wellposedness of the particular feedback system we are dealing with.

We consider the optimal control problem on the infinite horizon:

For any $y_0 \in Y$, *find* $u^\infty \in \mathcal{U} \equiv L_2(0, \infty; U)$ *such that the solution* y^∞ *of* (2.1) *with* $u = u^\infty$ *satisfies*

$$J(y_0, u^\infty) = \inf_{u \in \mathcal{U}} J(y_0, u), \tag{3.1}$$

where

$$J(y_0,u) \equiv \int_0^\infty \left[(Ry(t),y(t))_Y + \|u(t)\|_U^2\right] dt$$

and y is the solution of (2.1) *due to u.*

Here, R is assumed to satisfy

$$R \in \mathcal{L}(Y), \quad R = R^* \geq 0. \tag{3.2}$$

From the general results in [7, Theorem 2.2, Theorem 2.3] we can extract the following result.

LEMMA 3.2. *Under assumptions* (H1)–(H4) *and with R satisfying* (3.2)*, there is $P_\infty \in \mathcal{L}(Y)$, $P_\infty = P_\infty^* \geq 0$, such that $A_{P_\infty} = A - BB^*P_\infty$ is the infinitesimal generator of an exponentially stable strongly continuous semigroup*

$$T_\infty(t) = e^{tA_{P_\infty}} = e^{t(A-BB^*P_\infty)}, \quad t \geq 0,$$

and P_∞ is a solution of the algebraic Riccati equation

$$\begin{aligned} &\forall x,z \in \mathcal{D}(A_{P_\infty}),\\ &\quad (Px,Az)_Y + (PAx,z)_Y + (Rx,z)_Y = (B^*Px,B^*Pz)_Y\,. \end{aligned} \tag{3.3}$$

If moreover $R > 0$, then P_∞ is the unique solution within the class of all $P \in \mathcal{L}(Y)$ such that

$$P = P^* \geq 0, \quad A^*P \in \mathcal{L}\left(\mathcal{D}(A_{P_\infty});Y\right).$$

Remark 3.3. Some of the statements of Lemma 3.2 hold in fact under weaker assumptions, but this lemma is sufficient for our purpose and we refer the reader to [7] for stronger results. Let us just report that under the assumptions of Lemma 3.2, the optimal pair (y^∞,u^∞) of the optimization problem (3.1) is such that

$$y^\infty(t) = T_\infty(t)y_0 = e^{t(A-BB^*P_\infty)}y_0, \quad t \geq 0,$$

and we have

$$(P_\infty y_0,y_0)_Y = J(y_0,u_\infty) \equiv \int_0^\infty \left[(Ry_\infty(t),y_\infty(t))_Y + \|u_\infty(t)\|_U^2\right] dt.$$

Some comments are in order. In order to prove Theorem 2.1, the strategy consists in taking $R = 2\omega\Lambda_\omega^{-1}$ and then deducing from the Liapunov equation (Proposition 3.1) and from the Riccati equation (3.3) that $P_\infty = \Lambda_\omega^{-1}$.

Unfortunately, the algebraic Riccati equation (3.3) holds in $\mathcal{D}(A_{P_\infty})$. As $\mathcal{D}(A_{P_\infty})$ depends on the solution itself, (3.3) is not suitable in order to achieve our goal. If the algebraic Riccati equation (3.3) were also valid on $\mathcal{D}(A)$, as it would be if the control operator B were bounded (see, e.g., Curtain and Zwart [5]), we could prove Theorem 2.1 directly.

In fact, as the left-hand side of (3.3) is well defined on $\mathcal{D}(A)$, (3.3) induces an extension $[B^*P]_e$ (in the linear span of $\mathcal{D}(A_{P_\infty})$ and $\mathcal{D}(A^*)$) so that we have

$$\begin{aligned} &\forall x,z \in \mathcal{D}(A),\\ &\quad (Px,Az)_Y + (PAx,z)_Y + (Rx,z)_Y = \left([B^*P]_e\,x,[B^*P]_e\,z\right)_Y \end{aligned} \tag{3.4}$$

with $P = P_\infty$. This extension of B^*P on $\mathcal{D}(A)$ was implicitly done in [7] to derive the same Riccati equation on $\mathcal{D}(A_{P_\infty})$ and $\mathcal{D}(A)$. This was pointed out by Weiss and Zwart [32], who show that extensions $[B^*P]_e$ of B^*P such that (3.4) holds are generally not unique. Starting from a uniquely identified extension of B^* and using the spectral factorization approach to the linear quadratic optimal control problem with unbounded control operators developed by Staffans [27], [28] and Weiss and Weiss [33], they determine the optimal feedback operator and give an associated Riccati equation on $\mathcal{D}(A)$ that does not correspond to (3.3) exactly. The authors of [32] recall that an additional spectral factorization assumption leads to a suitable Riccati equation on $\mathcal{D}(A)$.

Later or at the same time, using a perturbation/regularization approach Triggiani [29] and Barbu, Lasiecka, and Triggiani [1] better identified a suitable extension of B^* on $P\mathcal{D}(A)$ so that a Riccati equation on $\mathcal{D}(A)$ of the type of (3.4) holds.

We stop these comments here and refer the reader to the relevant literature for details since none of the algebraic Riccati equations on $\mathcal{D}(A)$ provided by the two approaches cited above will be directly used in the following. Instead, we use further results of [7] relating the Riccati operator P_∞ of Lemma 3.2 to the solution to a *dual* algebraic Riccati equation.

Given a self-adjoint positive operator $R \in \mathcal{L}(Y)$, consider the dual dynamics to (2.1)

$$\begin{cases} \dot{z}(t) = -A^*z(t) + R^{1/2}v(t) & \text{on } [\mathcal{D}(A)]', \\ z(0) = z_0, & z_0 \in Y. \end{cases} \tag{3.5}$$

For every $v \in L^2(0,T;Y)$ the solution z of (3.5) belongs to $C(0,T;Y)$ and $B^*z \in L^2(0,T;U)$ [7]. As usual, the controllability of the pair $\left(-A^*, R^{1/2}\right)$ in some time T means that the linear map

$$v \in L^2(0,T;Y) \longrightarrow z(T) \in Y,$$

where z is the solution of (3.5) with $z_0 = 0$, is onto. Consider now the following optimal control problem for this dual dynamics.

For every $z_0 \in Y$, find $v^\infty \in \mathcal{V} \equiv L^2(0,\infty;Y)$ such that the solution z^∞ of (3.5) *with $v = v^\infty$ satisfies*

$$K(z_0, v^\infty) = \inf_{v \in \mathcal{V}} K(z_0, v),$$

where

$$K(z_0, v) \equiv \int_0^\infty \left[\|B^*z(t)\|_U^2 + \|v(t)\|_Y^2 \right] dt$$

and z is the solution of (3.5) *due to v.*

From the results of Flandoli, Lasiecka, and Triggiani [7, Theorems 2.4, 2.6, and 2.7] we obtain the following one as a particular case.

LEMMA 3.4. *Under the assumptions of Lemma* 3.2, *if $\left(-A^*, R^{1/2}\right)$ is controllable, then P_∞ is positive definite and is an isomorphism on Y. If we set $Q_\infty = P_\infty^{-1}$, then Q_∞ is the unique solution in the class $\{Q \in \mathcal{L}(Y);\ Q = Q^* > 0\}$ of the dual algebraic Riccati equation*

$$\begin{aligned} &\forall x, z \in \mathcal{D}(A^*), \\ &\qquad (Qx, A^*z)_Y + (QA^*x, z)_Y + (RQx, Qz)_Y = (B^*x, B^*z)_Y. \end{aligned} \tag{3.6}$$

Moreover, $-A^* - RQ_\infty$ is the infinitesimal generator of a strongly continuous semigroup

$$S_\infty(t) = e^{t(-A^* - RQ_\infty)}, \quad t \geq 0,$$

on Y and we have the following relation:

$$S_\infty(t) = P_\infty T_\infty(t) Q_\infty, \quad t \geq 0. \tag{3.7}$$

Remark 3.5. The operator $Q_\infty = P_\infty^{-1}$ synthesizes the optimal pair (z^∞, v^∞) [7]:

$$z^\infty(t) = S_\infty(t) z_0 = e^{t(-A^* - RQ_\infty)} z_0, \quad t \geq 0,$$
$$v^\infty(t) = -R^{1/2} Q_\infty z^\infty(t), \quad \text{a.e. } t \geq 0.$$

Remark 3.6. The cited results of [7] use a lemma (Lemma 6.2 in [7]) whose proof contains a misprint in page 354, line 3, and the following lines were accidentally omitted [18], leading to confusion. The missing step in the proof of Lemma 6.2 is the demonstration of the dense inclusion of $\mathcal{D} \equiv P_\infty \mathcal{D}(A_{P_\infty})$ into $\mathcal{D}(A^*)$ (with our proper notations). As explained by Lasiecka and Triggiani [18] an exactly similar argument to the use of Lemma 6.2 of [7] occurs in Lasiecka [13, Proposition 3.1 to Lemma 3.1, pp. 249–251] with all the lines in place and gives the perfect counterpart of Lemma 6.2 in [7]. More precisely, it occurs in the first part of Lemma 3.1 in $\mathcal{D}(A^*_{P_\infty})$, but the same scheme of proof and the same arguments lead to the desired result. Finally, according to [18] it seems that under the same assumptions the stronger result $\mathcal{D} = \mathcal{D}(A^*)$ holds. This is, for instance, stated in [1] without proof, and [18] refers to the third volume to be published as a sequel to [16], [17]. A complete proof is to appear in [30].

We can now end the proof of Theorem 2.1 with the use of Proposition 3.1 and Lemmas 3.2 and 3.4.

Proof of Theorem 2.1. The proof of part (i) is given in Proposition 3.1. Again by Proposition 3.1 Λ_ω is the unique solution of the Liapunov equation

$$\begin{aligned} &\forall x, z \in \mathcal{D}(A^*), \\ &\quad (\Lambda_w(A + \omega I)^* x, z)_Y + (\Lambda_\omega x, (A + \omega I)^* z)_Y = (B^* x, B^* z)_Y. \end{aligned} \tag{3.8}$$

Thus Λ_ω satisfies

$$\begin{aligned} &\forall x, z \in \mathcal{D}(A^*), \\ &\quad (\Lambda_\omega A^* x, z)_Y + (\Lambda_\omega x, A^* z)_Y + 2\omega \left(\Lambda_\omega^{-1} \Lambda_\omega x, \Lambda_\omega z\right)_Y = (B^* x, B^* z)_Y. \end{aligned} \tag{3.9}$$

Set $R = 2\omega \Lambda_\omega^{-1}$. Since $\omega > 0$, R is also a coercive self-adjoint bounded linear operator on Y. By Lemma 3.2 there exists a positive self-adjoint bounded linear operator P_∞ satisfying (3.3) (and it is its unique solution in the sense explained in Lemma 3.2), and $A - BB^* P_\infty$ is an exponentially stable generator of a semigroup on Y. Assume that $\left(-A^*, R^{1/2}\right)$ is controllable in some time T; then Lemma 3.4 gives that P_∞ is an isomorphism and $Q_\infty = P_\infty^{-1}$ is the unique solution of the algebraic Riccati equation

$$\begin{aligned} &\forall x, z \in \mathcal{D}(A^*), \\ &\quad (Qx, A^* z)_Y + (QA^* x, z)_Y + 2\omega \left(\Lambda_\omega^{-1} Qx, Qz\right)_Y = (B^* x, B^* z)_Y \end{aligned} \tag{3.10}$$

in the class $\{Q \in \mathcal{L}(Y);\ Q = Q^*\}$. As Q_∞ is the unique solution, from (3.9) and (3.10) we deduce that

$$Q_\infty = \Lambda_\omega, \quad P_\infty = \Lambda_\omega^{-1}.$$

The proof of part (ii) is thus almost complete if we prove that with $R = 2\omega\Lambda_\omega^{-1}$ the pair $(-A^*, R^{1/2})$ is controllable. From Louis and Wexler [20] we know that if A generates a group, then (A, I) is controllable. From the invertibility of $R^{1/2}$ we easily get the desired result.

By Lemma 3.4 we have

$$S_\infty(t) = e^{(-A-RQ_\infty)^* t} = e^{(-A^*-2\omega I)t}, \quad t \geq 0,$$

and relation (3.7) in Lemma 3.4 writes

$$e^{(-A^*-2\omega I)t} = \Lambda_\omega^{-1} e^{\left(A-BB^*\Lambda_\omega^{-1}\right)t}\Lambda_\omega \ , \quad t \geq 0, \tag{3.11}$$

which reduces to (2.8) in Theorem 2.1. Relation $\mathcal{D}(A + BF_\omega) = \Lambda_\omega\left(\mathcal{D}(A^*)\right)$ and equality

$$g(A + BF_\omega) = g(-A^*) - 2\omega$$

are consequences of (2.8) or (3.11) and of the definition of the growth bound of a semigroup (see Schumacher [25, Lemma 4.5]). This ends the proof of part (ii) and part (iii) in Theorem 2.1. □

Acknowledgments. The author is indebted to F. Bourquin for his encouragements, to the anonymous referees whose suggestions have led to a significant improvement of the paper, and, last but not least, to I. Lasiecka and R. Trigianni for their extremely useful comments and suggestions.

STOCHASTIC CONTROL FOR LINEAR SYSTEMS DRIVEN BY FRACTIONAL NOISES*

YAOZHONG HU† AND XUN YU ZHOU‡

Abstract. This paper is concerned with optimal control of stochastic linear systems involving fractional Brownian motion (FBM). First, as a prerequisite for studying the underlying control problems, some new results on stochastic integrals and stochastic differential equations associated with FBM are established. Then, three control models are formulated and studied. In the first two models, the state is scalar-valued and the control is taken as Markovian. Either the problems are completely solved based on a Riccati equation (for model 1, where the cost is a quadratic functional on state and control variables) or optimality is characterized (for model 2, where the cost is a power functional). The last control model under investigation is a general one, where the system involves the Stratonovich integral with respect to FBM, the state is multidimensional, and the admissible controls are not limited to being Markovian. A new Riccati-type equation, which is a backward stochastic differential equation involving both FBM and normal Brownian motion, is introduced. Optimal control and optimal value of the model are explicitly obtained based on the solution to this Riccati-type equation.

1. Introduction.

Stochastic processes with long memory have been studied in the literature. One important class of such processes is the fractional Brownian motion (FBM). In recent years there has been considerable research interest in stochastic calculus for FBM. A central issue is to define a proper stochastic integral with respect to the FBM. Attempts were made in Lin [25] and Dai and Heyde [6]; however, the stochastic integrals defined in [25], [6] do not satisfy the familiar zero-mean property as opposed to the normal Brownian motion counterpart. More recently, Duncan, Hu, and Pasik-Duncan [9] employed the Wick calculus to define a fractional stochastic integral whose mean is indeed zero. This property is very convenient for both theoretical development and practical applications. A substantial stochastic calculus was established for this new integral in [9].

It is natural and interesting to study the optimal control of systems driven by fractional noises, namely, systems described by stochastic differential equations (SDEs) involving FBM. Some such control problems as well as their applications in mathematical finance have been studied in [3], [15], [20], [22] within the framework of fractional calculus of [9].

On the other hand, a classically important class of stochastic control problems is the so-called linear-quadratic (LQ) control class, where the system is linear with respect to the state and control variables and the cost functional is quadratic in the two variables. Such a problem can often be solved explicitly by solving a relevant Riccati equation. While stochastic LQ control for systems driven by the (normal) Brownian motion (i.e., the systems are perturbed by the usual "white noise") is a classical problem on which a vast amount of research has been done, there has recently been renewed interest in the problem, in the form of the so-called "indefinite stochastic LQ control." See [1], [4], [5], [23], [28], [29], and the references therein.

This paper represents the first attempt, to our knowledge, of systematically solving some optimal control problems on linear systems driven by FBM, including LQ control with fractional noises. The controlled systems under consideration include

$$dx_t = (A_t x_t + B_t u_t)dt + (C_t x_t + D_t u_t)dW_t^H, \quad x_0 = x \text{ is given} \tag{1.1}$$

and

$$dx_t = (A_t x_t + B_t u_t)dt + (C_t x_t + D_t u_t) \circ dW_t^H, \quad x_0 = x \text{ is given}, \tag{1.2}$$

where A_t, B_t, C_t, and D_t are given (matrix-valued) stochastic processes, $\{W_t^H, t \geq 0\}$ is an FBM of Hurst parameter $H \in [1/2, 1)$, and dW_t^H and $\circ dW_t^H$ are the Itô and Stratonovich integrals, respectively, as defined in [9]. Our problem is to minimize a cost functional under constraint (1.1) or (1.2).

The above problem, in its greatest generality, seems to be too difficult to solve at the moment owing to the long-range-dependence property of the FBM. In this paper we propose and study three special models. The first model is for system (1.1), where the state x_t is one-dimensional, D_t is absent, and the cost functional is quadratic. Moreover, we consider optimal control among the class of linear Markovian controls, namely, those of the form

$$u_t = K_t x_t, \tag{1.3}$$

where K_t is a deterministic (matrix-valued) function of t. (Notice that linear Markovian control constitutes an important control class due to its mathematical simplicity and ease of implementation. Also, it is well known that the optimal stochastic LQ control with normal Brownian motion turns out to be a linear Markovian control.) In this case, the optimal control (or, equivalently, the optimal K_t) is found based on the solution to a Riccati equation. This Riccati equation can be solved by using the classical theory. Thus, for this special yet interesting control model we obtain a complete solution to the LQ problem with fractional noises.

The second model is more general than the first in that $D_t \not\equiv 0$ and the cost functional is of a power form. The presence of D_t is a crucially different and difficult feature even in the normal stochastic LQ control (see [29] for detailed discussions). For this second model we use calculus of variation to obtain an integral equation that the optimal K_t must satisfy. We then demonstrate how to solve this integral equation in several special cases.

The third control model is an LQ problem, where the system is governed by (1.2), the state variable is multidimensional, and the admissible controls are not limited to being Markovian. However, D_t is assumed to be identically zero. We introduce a Riccati-type equation, which is a backward SDE involving integrals with respect to both FBM and normal Brownian motion. Assuming the solvability of this equation,

along with some technical conditions, we derive an optimal control along with the optimal value based on the completion-of-square technique. As a by-product the optimal control is in linear Markovian form. We also illustrate how we obtain such a Riccati-type equation heuristically using the method of approximation.

It is worth mentioning that the study of stochastic control problems with fractional noises will inevitably involve stochastic calculus on FBM, the associated stochastic integrals, and differential equations. However, a rich, complete theory on such calculus is still lacking because the very definition of the fractional stochastic integral we are employing was introduced only very recently [9]. Therefore, in this paper we make some effort to derive results on fractional stochastic calculus that are necessary for studying the subsequent control models. Some of the results are new and interesting in their own right.

The remainder of the paper is organized as follows. Section 2 is devoted to fractional stochastic calculus useful in what follows. Three different control models are treated in sections 3, 4, and 5, respectively. Finally, section 6 concludes the paper with some remarks.

2. Fractional stochastic calculus. This section presents stochastic calculus on FBM that is necessary for the control problems under investigation. Most of the results are new and interesting in their own right from the point of view of fractional calculus.

2.1. FBM. In this subsection we outline some of the notation and results of FBM. The primary reference in this regard is [9]. Let $\Omega = C_0(0, T; \mathbb{R})$ be the Banach space of a real-valued continuous function on $[0, T]$ with the initial value zero and the super norm. There is a probability measure P on $(\Omega, \mathcal{F})$, where $\mathcal{F}$ is the Borel σ-algebra on Ω, such that on the probability space $(\Omega, \mathcal{F}, P)$ the process $\{W_t^H, 0 \le t \le T\}$ defined as

$$W_t^H(\omega) = \omega(t) \ \ \forall \omega \in \Omega$$

is a (one-dimensional) Gaussian process with mean

$$\mathbb{E}\ W_t^H = W_0^H = 0 \ \ \forall t \in [0, T]$$

and covariance

$$\mathbb{E}\ \left(W_t^H W_s^H\right) = \frac{1}{2}\left(t^{2H} + s^{2H} - |t-s|^{2H}\right) \ \ \forall t, s \in [0, T].$$

This canonical process $\{W_t^H, 0 \le t \le T\}$ is called a (standard) FBM of *Hurst parameter* H. In this paper $H \in [\frac{1}{2}, 1)$ is fixed. An FBM with $H = \frac{1}{2}$ reduces to the (normal) Brownian motion.

An FBM generates a filtration $\{\mathcal{F}_t,\ 0 \le t \le T\}$ with $\mathcal{F}_t = \sigma\{W_s^H, 0 \le s \le t\}$. Throughout this paper, only the canonical process and the associated filtered probability space $(\Omega, \mathcal{F}, P; \mathcal{F}_t)$, as described above, are used. Also notice that the FBM is assumed to be one-dimensional only for notational simplicity; there is no essential difficulty with a multidimensional FBM, where each component is a one-dimensional FBM with the *same* Hurst parameter H.

The following lemma is useful (see [7], [13], [26]).

LEMMA 2.1. *An FBM W_t^H with $H \in (\frac{1}{2}, 1)$ can be represented as*

$$W_t^H = \int_0^t Z(t, s) dW_s, \tag{2.1}$$

where $\{W_t\,, 0 \le t \le T\}$ *is a one-dimensional Brownian motion, and*

$$Z(t,s) := \left(H - \frac{1}{2}\right) c_H s^{(1/2)-H} \int_s^t r^{H-1/2}(r-s)^{H-(3/2)} dr,$$

with

$$c_H = \sqrt{\frac{H(2H-1)\Gamma\left(\frac{3}{2} - H\right)}{\Gamma\left(H - \frac{1}{2}\right)\Gamma(2-2H)}}$$

($\Gamma(\cdot)$ *is the gamma function*). *Moreover,* W_t *and* W_t^H *generate the same filtrations.*

Similar to the normal Brownian motion, the FBM is not differentiable a.s. (almost surely). As the "derivative" of a Brownian motion is usually referred to as white noise, that of an FBM is referred to as *fractional noise*.

For a fixed $H \in (\frac{1}{2}, 1)$, denote a function $\phi : [0,T] \times [0,T] \to \mathbb{R}_+$ by

$$\phi(s,t) := H(2H-1)|s-t|^{2H-2} \quad \forall s,t \in [0,T], \tag{2.2}$$

and let $L_\phi^2([0,T])$ be the Hilbert space of Borel measurable, scalar-valued functions f such that

$$|f|_\phi^2 := \int_0^T\!\!\int_0^T \phi(s,t) f_s f_t ds dt < \infty, \tag{2.3}$$

with the norm $|f|_\phi$; see [11], [12], [13] for a detailed discussion on this space. The inner product on $L_\phi^2([0,T])$ is denoted by $\langle \cdot, \cdot \rangle_\phi$. Define a mapping Φ on $L_\phi^2([0,T])$:

$$(\Phi g)_t := \int_0^T \phi(t,s) g_s ds \quad \forall g \in L_\phi^2([0,T]). \tag{2.4}$$

Then one can define the ϕ-derivative of a random variable $F \in L^p(\Omega, \mathcal{F}, P)$ $(p \ge 1)$ in the direction of Φg, where $g \in L_\phi^2([0,T])$, by

$$D_{\Phi g} F(\omega) := \lim_{\delta \to 0} \frac{1}{\delta} \left\{ F\left(\omega + \delta \int_0^{\cdot} (\Phi g)_t dt\right) - F(\omega) \right\} \tag{2.5}$$

if the limit exists in $L^p(\Omega, \mathcal{F}, P)$. Moreover, if there is a process $\{D_s^H F,\ 0 \le s \le T\}$ satisfying

$$D_{\Phi g} F = \int_0^T [D_s^H F] g_s ds \quad \text{a.s.} \quad \forall g \in L_\phi^2([0,T]), \tag{2.6}$$

then F is said to be ϕ-*differentiable* and $D_s^H F$ is called the *Malliavin derivative* of F. Refer to [9], [19] for more information about the Malliavin derivative.

Finally, we remark that if $H = 1/2$, then the function $\phi(\cdot,\cdot)$ should be replaced by the Delta function $\delta(\cdot,\cdot)$ satisfying

$$\int_0^T \int_0^T \delta(s,s') f(s,s') ds ds' = \int_0^T f(s,s) ds \quad \forall f(\cdot,\cdot) \in L^1([0,T] \times [0,T]).$$

2.2. Stratonovich integrals. Next, we discuss the Stratonovich stochastic integral, which will be dealt with later in this paper. First of all, let X_t be a semimartingale of the form

$$X_t = X_0 + \int_0^t f_s ds + \int_0^t g_s dW_s,$$

where $\{W_s, 0 \le s \le T\}$ is the Brownian motion given by Lemma 2.1 and X_0 is a deterministic constant. If $f, g \in L^2_{\mathcal{F}}(0,T)$, where $L^2_{\mathcal{F}}(0,T)$ denotes the set of scalar-valued, $\mathcal{F}_t$-adapted, square integrable processes on $[0,T]$, then it is a well-known result that (see, e.g., [21, Chapter III])

$$\int_0^t X_s \circ dW_s = \int_0^t X_s dW_s + \frac{1}{2}\int_0^t g_s ds \quad \forall t \in [0,T], \tag{2.7}$$

where $\int_0^t X_s \circ dW_s$ denotes the Stratonovich (symmetric) integral with respect to the Brownian motion W_s. As a result,

$$\mathbb{E}\left(\int_0^T X_s \circ dW_s\right) = \frac{1}{2}\mathbb{E}\int_0^T g_s ds. \tag{2.8}$$

However, if a process Y_t is given as

$$Y_t = Y_0 + \int_0^t f_s ds + \int_0^t g_s dW_s^H, \tag{2.9}$$

where the stochastic integral with respect to the FBM W_s^H is defined as in [9], then we have a quite different result.

THEOREM 2.1. *Let f_s and g_s satisfy the following conditions:*

$$\mathbb{E}\int_0^T |f_s|^2 ds < \infty, \quad \sup_{0\le s\le T}\mathbb{E}\,|g_s|^2 ds < \infty, \quad \text{and} \quad \mathbb{E}\int_0^T |D_s^H g_s|^2 ds < \infty, \tag{2.10}$$

and let Y_t be given by (2.9)*, where $H \in (\frac{1}{2}, 1)$. Then*

$$\int_0^t Y_s \circ dW_s = \int_0^t Y_s dW_s \quad \forall t \in [0,T]. \tag{2.11}$$

As a consequence, we have

$$\mathbb{E}\left[\int_0^t Y_s \circ dW_s\right] = 0. \tag{2.12}$$

Proof. Under condition (2.10) on f and g we see that Y_t is well defined (see [9]). Let $\pi : 0 = t_0 < t_1 < t_2 < \cdots < t_n = t$ be a partition of the interval $[0,t]$. By definition,

$$\begin{aligned}
\int_0^t Y_s \circ dW_s &= \lim_{|\pi|\to 0}\sum_{k=0}^{n-1}\frac{1}{2}\left(Y_{t_k} + Y_{t_{k+1}}\right)\left(W_{t_{k+1}} - W_{t_k}\right) \\
&= \lim_{|\pi|\to 0}\sum_{k=0}^{n-1} Y_{t_k}\left(W_{t_{k+1}} - W_{t_k}\right) + \lim_{|\pi|\to 0}\sum_{k=0}^{n-1}\frac{1}{2}\left(Y_{t_{k+1}} - Y_{t_k}\right)\left(W_{t_{k+1}} - W_{t_k}\right) \\
&:= \lim_{|\pi|\to 0} I_1 + \lim_{|\pi|\to 0} I_2,
\end{aligned}$$

where the limit is taken in the sense of "in probability" and $|\pi| := \max_{0\le k\le n-1}(t_{k+1}-t_k)$. It is easy to see by the definition of the Itô integral that the term I_1 converges to $\int_0^t Y_s dW_s$.

To consider the term I_2 we estimate $\mathbb{E}\,|Y_{t_{k+1}}-Y_{t_k}|^2$. From the definition of Y_t it follows that

$$\begin{aligned}\mathbb{E}\,\left|Y_{t_{k+1}}-Y_{t_k}\right|^2 &\le 2\mathbb{E}\,\left|\int_{t_k}^{t_{k+1}} f_s ds\right|^2 + 2\mathbb{E}\,\left|\int_{t_k}^{t_{k+1}} g_s dW_s^H\right|^2\\ &:= 2(I_3+I_4).\end{aligned}$$

It follows from (2.10) that

$$I_3 \le \mathbb{E}\int_{t_k}^{t_{k+1}} |f_s|^2 ds\cdot|t_{k+1}-t_k|. \tag{2.13}$$

Moreover, by virtue of the Itô isometry [9, Theorem 3.9], we have

$$\begin{aligned}I_4 &= \int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}} \phi(t,s)\mathbb{E}\,(g_s g_t)\,dsdt + \mathbb{E}\,\left[\int_{t_k}^{t_{k+1}} D_s^H g_s ds\right]^2\\ &:= I_5+I_6.\end{aligned}$$

The assumption of the theorem and the definition of ϕ yield

$$\begin{aligned}I_5 &\le C\int_{t_k}^{t_{k+1}}\int_{t_k}^{t_{k+1}} \phi(t,s)dsdt\\ &\le C|t_{k+1}-t_k|^{2H},\end{aligned}$$

where here (and elsewhere) C is a generic positive constant that may vary from place to place. On the other hand,

$$I_6 \le \mathbb{E}\int_{t_k}^{t_{k+1}} |D_s^H g_s|^2 ds\cdot|t_{k+1}-t_k|.$$

Combining the above computations, we conclude that there is a constant C such that

$$\mathbb{E}\,|Y_{t_{k+1}}-Y_{t_k}|^2 \le C|t_{k+1}-t_k|^{2H} + U_k|t_{k+1}-t_k|, \tag{2.14}$$

where

$$U_k := \mathbb{E}\int_{t_k}^{t_{k+1}} (|f_s|^2+|D_s^H g_s|^2)ds.$$

Therefore,

$$\begin{aligned}2\mathbb{E}\,I_2 &\le \sum_{k=0}^{n-1}\mathbb{E}\,\left|Y_{t_{k+1}}-Y_{t_k}\right|\left|W_{t_{k+1}}-W_{t_k}\right|\\ &\le \sum_{k=0}^{n-1}\left[\mathbb{E}\,\left|Y_{t_{k+1}}-Y_{t_k}\right|^2\right]^{1/2}\left[\mathbb{E}\,\left|W_{t_{k+1}}-W_{t_k}\right|^2\right]^{1/2}\\ &\le C\sum_{k=0}^{n-1}(t_{k+1}-t_k)^{1/2+H} + C\sum_{k=0}^{n-1}[U_k(t_{k+1}-t_k)]^{1/2}\left[\mathbb{E}\,\left|W_{t_{k+1}}-W_{t_k}\right|^2\right]^{1/2}\\ &:= I_7+I_8.\end{aligned}$$

It is easy to check that

$$I_7 \le C \max_{0\le k\le n-1}(t_{k+1}-t_k)^{H-1/2}\sum_{k=0}^{n-1}(t_{k+1}-t_k) \to 0$$

and

$$\begin{aligned} I_8 &\le C\sum_{k=0}^{n-1} U_k^{1/2}(t_{k+1}-t_k) \\ &\le C\left(\sum_{k=0}^{n-1} U_k\right)^{1/2}\left(\sum_{k=0}^{n-1}(t_{k+1}-t_k)^2\right)^{1/2} \\ &\le C\left[\mathbb{E}\int_0^T (|f_s|^2+|D_s^H g_s|^2)ds\right]^{1/2}|\pi|^{1/2} \to 0. \end{aligned}$$

This implies that I_2 converges to 0 in $L^1(\Omega,\mathcal{F},P)$ and, consequently, in probability. This completes the proof. □

Remark 2.1. Whereas Theorem 2.1 is useful in section 5, it is also interesting in its own right. In particular, we see that (2.11) is different from the case when the integrand is a semimartingale; see (2.7). On the other hand, one has a different formula than (2.11) if the integration there is replaced by one with respect to the FBM W_s^H (under different conditions on the integrand, however); for details see [9, Theorem 3.12].

Remark 2.2. Since the Stratonovich-type integral can be represented by using the Itô-type integral [9], (2.9) and (2.10) are still true if Y_t is represented as a Stratonovich integral

$$Y_t = Y_0 + \int_0^t f_s ds + \int_0^t g_s \circ dW_s^H$$

under some mild conditions on f and g. Details are left to the interested readers.

2.3. Multiple integrals. In this section we recall some results from [9] on multiple integrals. These results are needed in this paper and we refer to [9] for more detail.

A function $f:[0,T]^n \to \mathbb{R}$ is called symmetric on $[0,T]^n$ if

$$f(s_{i_1},\dots,s_{i_n}) = f(s_1,\dots,s_n),\quad (s_1,\dots,s_n)\in[0,T]^n$$

for any permutation $(i_1,i_2,\dots,i_n)$ of $(1,2,\dots,n)$. Denote

$$\begin{aligned} L_\phi^2([0,T]^n) := \{&f:[0,T]^n\to\mathbb{R} \text{ is measurable and symmetric in its arguments,} \\ &|f|_\phi^2 := \langle f,f\rangle_\phi < \infty\}, \end{aligned}$$

where

$$\begin{aligned} \langle f,g\rangle_\phi := \int_{[0,T]^{2n}} &\phi(u_1,v_1)\phi(u_2,v_2)\cdots\phi(u_n,v_n)f(u_1,u_2,\dots,u_n) \\ &\cdot g(v_1,v_2,\dots,v_n)du_1du_2\cdots du_n dv_1dv_2\cdots dv_n. \end{aligned}$$

If $f \in L^2_\phi([0,T]^n)$, then the multiple Itô integral

$$\begin{aligned} I_n(f) \equiv I_{n,T}(f) &= \int_{0\le t_1,\dots,t_n\le T} f(t_1,\dots,t_n) dW^H_{t_1}\cdots dW^H_{t_n} \\ &= n! \int_{0\le t_1<\cdots<t_n\le T} f(t_1,\dots,t_n) dW^H_{t_1}\cdots dW^H_{t_n} \end{aligned}$$

is well defined, and (see [9, Lemma 6.6][1])

$$\mathbb{E}\ (I_n(f)I_m(g)) = \begin{cases} n!\langle f,g\rangle_\phi & \text{if } n=m, \\ 0 & \text{if } n\ne m. \end{cases} \tag{2.15}$$

The following result concerns the Malliavin derivative of a multiple integral.

THEOREM 2.2. *We have*

$$D^H_s I_n(f_n) = nI_{n-1}\left(\int_0^t \phi(s,r) f_{n-1}(r)dr\right) \quad \forall f_n \in L^2_\phi([0,T]^n), \tag{2.16}$$

where for any $0\le r\le T$, $f_{n-1}(r)$ denotes a function of $n-1$ variables given by

$$f_{n-1}(r)(s_1,\dots,s_{n-1}) := f_n(s_1,\dots,s_{n-1},r).$$

Proof. For all $\delta\in\mathbb{R}$ and $h\in L^2_\phi([0,T])$, one has

$$\begin{aligned} &I_n(f_n)(W^H + \delta\int_0^\cdot h(s)ds) \\ &\quad = I_n(f_n)(W^H) + \delta\sum_{k=1}^n \int_{0<s_1,\dots,s_n<T} \\ &\qquad\qquad \cdot f_n(s_1,\dots,s_n) dW^H_{s_1}\cdots \widehat{dW^H_{s_k}}\cdots dW^H_{s_n} h(s_k)ds_k + o(\delta) \\ &\quad = I_n(f_n)(W^H) + \delta n\int_0^T I_{n-1}(f_{n-1}(r))h(r)dr + o(\delta), \end{aligned}$$

where $\widehat{dW^H_{s_k}}$ means that the $dW^H_{s_k}$ term is taken off the product. Thus

$$\begin{aligned} D_{\Phi g}F &= n\int_0^T I_{n-1}(f_{n-1}(r))\Phi g(r)dr \\ &= n\int_0^T I_{n-1}(f_{n-1}(r))\int_0^T \phi(s,r)g(s)dsdr. \end{aligned}$$

By the definition of D^H_s (see (2.6)) we have

$$\begin{aligned} D^H_s I_n(f_n) &= n\int_0^T \phi(s,r) I_{n-1}(f_{n-1}(r))dr \\ &= nI_{n-1}\left(\int_0^T \phi(s,r) f_{n-1}(r)dr\right). \end{aligned} \tag{2.17}$$

□

[1]There is a typo in [9, Lemma 6.6]: the factorial $n!$ is missing from the term $\langle f,g\rangle_\phi$ on the right-hand side of (6.5) there.

We also need to employ the multiple Stratonovich integrals. For this we first recall the definition of the k-trace Tr_ϕ^k. Let $f \in L^2_\phi([0,T]^n)$. For any positive integer $k \le n/2$, the k-trace of f is defined as a function of $n-2k$ variables:

$$\mathrm{Tr}_\phi^k f(t_1,\dots,t_{n-2k}) := \int_{[0,T]^{2k}} f(s_1,s_2,\dots,s_{2k-1},s_{2k},t_1,\dots,t_{n-2k}) \cdot\phi(s_1,s_2)\phi(s_3,s_4)\cdots\phi(s_{2k-1},s_{2k})ds_1\cdots ds_{2k}$$

if the right-hand side is integrable.

The multiple Stratonovich integral

$$S_n(f) \equiv S_{n,T}(f) = \int_{0\le t_1,\dots,t_n\le T} f(t_1,\dots,t_n)\circ dW_{t_1}^H\cdots\circ dW_{t_n}^H = n!\int_{0\le t_1<\cdots<t_n\le T} f(t_1,\dots,t_n)\circ dW_{t_1}^H\cdots\circ dW_{t_n}^H$$

is well defined, and one has the following Hu–Meyer formula (see [16], [17], [18], and [9, equation (6.10)]):

$$S_n(f) = \sum_{k\le[n/2]} \frac{n!}{2^k k!(n-2k)!} I_{n-2k}(\mathrm{Tr}_\phi^k f). \tag{2.18}$$

2.4. SDEs with FBM. As the dynamics of the control problems under consideration in this paper is described by SDEs with FBM, we need first to study linear fractional SDEs in this section.

We introduce the two linear equations

$$\begin{cases} dx_t = A_t x_t dt + C_t x_t dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic,} \end{cases} \tag{2.19}$$

and

$$\begin{cases} dx_t = A_t x_t dt + C_t x_t \circ dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic,} \end{cases} \tag{2.20}$$

where dW_t^H and $\circ dW_t^H$ denote, respectively, the Itô-type and Stratonovich-type differentials in the sense of [9].

THEOREM 2.3. *If A_t and C_t are measurable and essentially bounded deterministic functions in t, then* (2.19) *admits a unique solution. Moreover, the solution satisfies*

$$\sup_{0\le t\le T} \mathbb{E}\,|x_t|^p < \infty \quad \forall\, p \ge 1. \tag{2.21}$$

Furthermore, the solution $x.$ has a continuous modification.

Proof. The results in which $H = \frac{1}{2}$ are clearly true by virtue of the classical SDE theory for normal Brownian motion. So we assume $H > \frac{1}{2}$. Let $\Psi(t,s)$ denote the fundamental solution associated with the deterministic part of (2.19), namely, $\Psi(t,s)$ satisfies

$$\frac{d}{dt}\Psi(t,s) = A_t\Psi(t,s)\,, \quad 0 \le s < t\,; \quad \Psi(s,s) = I,$$

where I denotes the identity matrix. Since A_t is uniformly bounded in t, it is routine to prove, via Gronwall's inequality, that $\Psi(t,s)$ is uniformly bounded in (t,s). This in turn implies, via the above equation, that $\Psi(t,s)$ is Lipschitz in t with a Lipschitz constant independent of (t,s).

Equation (2.19) is thus equivalent to

$$x_t = \Psi(t,0)x_0 + \int_0^t \Psi(t,s)C_s x_s dW_s^H. \tag{2.22}$$

Replacing x_s in the integral by this equation we have

$$\begin{aligned} x_t = \Psi(t,0)x_0 &+ \int_0^t \Psi(t,s)C_s\Psi(s,0)x_0 dW_s^H \\ &+ \int_0^t \Psi(t,s_2)C_{s_2}\int_0^{s_2}\Psi(s_2,s_1)C_{s_1}x_{s_1}dW_{s_1}^H dW_{s_2}^H. \end{aligned}$$

Repeatedly applying this procedure, we obtain

$$\begin{aligned} x_t = \Psi(t,0)x_0 &+ \int_0^t \Psi(t,s)C_s\Psi(s,0)x_0 dW_s^H \\ &+ \sum_{n=2}^{\infty}\int_{0<s_1<\cdots<s_n<t}\Psi(t,s_n)C_{s_n}\Psi(s_n,s_{n-1})C_{s_{n-1}}\cdots \\ &\cdot\Psi(s_2,s_1)C_{s_1}\Psi(s_1,0)x_0 dW_{s_1}^H\cdots dW_{s_n}^H. \end{aligned} \tag{2.23}$$

Now we show that (2.23) is convergent in $L^2(\Omega,\mathcal{F},P)$ for any fixed t. Denote

$$f_{n,t}(s_1,\ldots,s_n) := \Psi(t,s_n)C_{s_n}\Psi(s_n,s_{n-1})C_{s_{n-1}}\cdots C_{s_2}\Psi(s_2,s_1)C_{s_1}\Psi(s_1,0)x_0, \tag{2.24}$$

where $0<s_1<\cdots<s_n<t$. We also use the notation $f_n^t \equiv f_n^t(\cdot,\ldots,\cdot)$ to denote the symmetric extension of $f_{n,t}$ to the domain $[0,t]^n$, namely,

$$f_n^t(s_1,\ldots,s_n) := \Psi(t,s_{i_n})C_{s_{i_n}}\Psi(s_{i_n},s_{i_{n-1}})C_{s_{i_{n-1}}}\cdots C_{s_{i_2}}\Psi(s_{i_2},s_{i_1})C_{s_{i_1}}\Psi(s_{i_1},0)x_0$$

if $s_{i_1}\le s_{i_2}\le\cdots\le s_{i_n}$, where $i_1,\ldots,i_n$ is a permutation of $1,2,\ldots,n$.

By virtue of the underlying assumption it is easy to see that there is a positive constant K_t, depending on t, such that

$$\sup_{0\le s_1,\ldots,s_n\le t}|f_n^t(s_1,\ldots,s_n)|\le K_t^n.$$

The right-hand side of (2.23) can be rewritten as

$$Z_t := \sum_{n=0}^{\infty}\frac{1}{n!}I_{n,t}(f_n^t),$$

where

$$I_{n,t}(f_n^t) := \int_{0<s_1,\ldots,s_n<t} f_n^t(s_1,\ldots,s_n)dW_{s_1}^H\cdots dW_{s_n}^H$$

is the multiple Itô integral defined in section 2.3. It follows from (2.15) that

$$\begin{aligned}\mathbb{E}\,|Z_t|^2 &= \sum_{n=0}^{\infty} \frac{1}{(n!)^2}\mathbb{E}\,\left[I_{n,t}(f_n^t)\right]^2 \\ &= \sum_{n=0}^{\infty} \frac{1}{n!}\langle f_n^t, f_n^t\rangle_\phi.\end{aligned}$$

By its definition (see section 2.3), we have

$$\begin{aligned}\langle f_n^t, f_n^t\rangle_\phi &= \int_{[0,t]^{2n}} \phi(s_1,t_1)\cdots\phi(s_n,t_n) f_n^t(s_1,\ldots,s_n) f_n^t(t_1,\ldots,t_n) ds_1\cdots ds_n dt_1\cdots dt_n \\ &\le K_t^{2n}\int_{[0,t]^{2n}} \phi(s_1,t_1)\cdots\phi(s_n,t_n) ds_1\cdots ds_n dt_1\cdots dt_n \\ &\le K_t^{2n},\end{aligned}$$

where K_t is a generic constant (depending on t) whose values may vary. This leads to

$$\mathbb{E}\,|Z_t|^2 \le \sum_{n=0}^{\infty}\frac{1}{n!}K_t^{2n} < \infty.$$

Hence, the right-hand side of (2.23) converges in $L^2(\Omega,\mathcal{F},P)$, and x_t is well defined.

Next we show that $\int_0^t C_s x_s dW_s^H$ is well defined for each $t\in[0,T]$, where $x.$ is defined by (2.23). Let us prove this for $t=T$, the other case being similar. From [9, p. 591] there are several conditions for defining $\int_0^T C_t x_t dW_t^H$. Let us check

$$\mathbb{E}\int_0^T |D_s^H(C_s x_s)|^2 ds < \infty.$$

Other conditions are routine and easier to check. Since C_t is a bounded deterministic function of t, it suffices to verify

$$\mathbb{E}\int_0^T |D_s^H x_s|^2 dt < \infty. \tag{2.25}$$

To this end, recall that f_n^t is the symmetric extension of $f_n(t;\cdot,\ldots,\cdot)$ defined by (2.20). With this notation we have

$$x_t = \sum_{n=0}^{\infty}\frac{1}{n!}I_{n,t}(f_n^t).$$

Its Malliavin derivative is given by, appealing to Theorem 2.2,

$$D_s^H x_t = \sum_{n=1}^{\infty}\frac{1}{(n-1)!}I_{n-1,t}\left(\int_0^t \phi(s,r) f_{n-1}^t(r)dr\right).$$

Therefore we have

$$\mathbb{E}\,|D_s^H x_t|^2 = \sum_{n=1}^{\infty}\frac{1}{(n-1)!}\left\langle \int_0^t \phi(s,r) f_{n-1}^t(r)dr\,,\int_0^t \phi(s,r) f_{n-1}^t(r)dr\right\rangle_\phi.$$

Since f_n^t is bounded on $[0,T]$, i.e.,

$$|f_n^t| \le K_T^n,$$

we have

$$\begin{aligned}
&\left|\left\langle \int_0^t \phi(s,r) f_{n-1}^t(r)dr\,, \int_0^t \phi(s,r) f_{n-1}^t(r)dr \right\rangle_\phi\right| \\
&\le \left| \int_0^t \int_0^t \int_{\substack{0<s_1,\dots,s_{n-1}<t \\ 0<t_1,\dots,t_{n-1}<t}} f_n^t(s_1,\dots,s_{n-1},r_1) f_n^t(t_1,\dots,t_{n-1},r_2) \right. \\
&\qquad \left. \cdot \phi(s_1,t_1)\cdots\phi(s_{n-1},t_{n-1}) ds_1 dt_1 \cdots ds_{n-1}dt_{n-1}dr_1 dr_2 \right| \\
&\le K_T^n,
\end{aligned}$$

where here and in what follows we use K_T to denote a generic constant, which depends only on T and may be different in different places. Consequently, we have

$$\sup_{0\le s,t\le T} \mathbb{E}\,|D_s^H x_t|^2 \le K_T. \tag{2.26}$$

This easily implies (2.25).

Next, to obtain estimate (2.21) we use a hypercontractivity inequality. Define the number operator $\Gamma(\alpha)$, where $\alpha \in \mathbb{R}$, as

$$\Gamma(\alpha)F := \sum_{n=0}^\infty \alpha^n I_{n,t}(g_n) \qquad \text{if} \quad F = \sum_{n=0}^\infty I_{n,t}(g_n),$$

where $g_n \in L_\phi^2([0,t]^n)$ with $\sum_{n=0}^\infty I_{n,t}(g_n)$ convergent in $L^2(\Omega,\mathcal{F},P)$. Nelson's hypercontractivity theorem (see [8], [14]) yields

$$\left(\mathbb{E}\,\left|\Gamma\left(\frac{1}{p-1}\right)F\right|^p\right)^{1/p} \le \left(\mathbb{E}\,|F|^2\right)^{1/2} \quad \forall p \ge 2.$$

Now for f_n^t defined earlier, we set

$$Z_{t,p} := \sum_{n=0}^\infty \frac{(p-1)^n}{n!} I_{n,t}(f_n^t).$$

By the same estimate for Z_t, we obtain

$$\mathbb{E}\,|Z_{t,p}|^2 < \infty.$$

However, noting that $\Gamma(\frac{1}{p-1})Z_{t,p} = Z_t$ and applying the hypercontractivity inequality to $F = Z_{t,p}$, we have

$$(\mathbb{E}\,|x_t|^p)^{1/p} \equiv (\mathbb{E}\,|Z_t|^p)^{1/p} \le \left(\mathbb{E}\,|Z_{t,p}|^2\right)^{1/2} < \infty \ \ \forall p \ge 2.$$

When $1 \le p < 2$, inequality (2.21) follows from the Cauchy–Schwarz inequality.

Finally, to see that $x_\cdot$ has a continuous version, we estimate $\mathbb{E}\,|x_t - x_s|^2$. We shall need the uniform Lipschitz condition of $\Psi(t,s)$ in t which was proved earlier. From expression (2.23) it follows that

$$x_t - x_s = \Psi(t,0)x_0 - \Psi(s,0)x_0 + \sum_{n=1}^{\infty} \frac{1}{n!}\left[I_{n,t}(f_n^t) - I_{n,s}(f_n^s)\right].$$

By the orthogonality of different chaos, we have

$$\begin{aligned}
\mathbb{E}\,|x_t - x_s|^2 &= \left[\Psi(t,0)x_0 - \Psi(s,0)x_0\right]^2 + \sum_{n=1}^{\infty} \frac{1}{(n!)^2}\mathbb{E}\,\left[I_{n,t}(f_n^t) - I_{n,s}(f_n^s)\right]^2 \\
&\le \left[\Psi(t,0)x_0 - \Psi(s,0)x_0\right]^2 + \sum_{n=1}^{\infty} \frac{1}{(n!)^2}\mathbb{E}\,\left[I_{n,s}(f_n^t) - I_{n,s}(f_n^s)\right]^2 \\
&+ \sum_{n=1}^{\infty} \frac{1}{(n!)^2}\mathbb{E}\,\left[I_{n,t}(f_n^t) - I_{n,s}(f_n^t)\right]^2 \\
&=: I_1 + \sum_{n=1}^{\infty} \frac{1}{(n!)^2} I_{2,n} + \sum_{n=1}^{\infty} \frac{1}{(n!)^2} I_{3,n},
\end{aligned}$$

where

$$\begin{aligned}
I_{2,n} &= \mathbb{E}\,\left[I_{n,s}(f_n^t) - I_{n,s}(f_n^s)\right]^2 \\
&= \mathbb{E}\,\left[I_{n,s}(f_n^t - f_n^s)\right]^2 \\
&= \langle f_n^t - f_n^s\,, f_n^t - f_n^s\rangle_\phi.
\end{aligned}$$

Now it is straightforward to see that

$$I_{2,n} \le n! K_T^n |t-s|^2.$$

Denote by $T_n(s,t)$ the region

$$\begin{aligned}
T_n(s,t) &:= \{0 < s_1 < \cdots < s_n < t\} \setminus \{0 < s_1 < \cdots < s_n < s\} \\
&= \cup_{k=0}^{n-1} \{0 < s_1 < \cdots < s_k < s, s_{k+1} < \cdots < s_n < t\} \\
&=: \cup_{k=0}^{n-1} T_{n,k}(s,t).
\end{aligned}$$

Then

$$\begin{aligned}
&\frac{1}{(n!)^2} I_{3,n} = \frac{1}{(n!)^2}\mathbb{E}\,\left[I_{n,t}(f_n^t) - I_{n,s}(f_n^t)\right]^2 \\
&= \mathbb{E}\,\left[\int_{T_n(s,t)} f_n(t,s_1,\ldots,s_n) dW_{s_1}^H \cdots dW_{s_n}^H\right]^2 \\
&= \int_{T_n(s,t)}\int_{T_n(s,t)} f_n(t,s_1,\ldots,s_n) f_n(t,t_1,\ldots,t_n)\phi(s_1,t_1)\cdots\phi(s_n,t_n) ds_1 dt_1 \cdots ds_n dt_n \\
&\le \sum_{k,j=0}^{n-1} \int_{T_{n,k}(s,t)}\int_{T_{n,j}(s,t)} f_n(t,s_1,\ldots,s_n) f_n(t,t_1,\ldots,t_n)\phi(s_1,t_1)\cdots\phi(s_n,t_n) ds_1 dt_1 \cdots ds_n dt_n \\
&\le \sum_{k,j=0}^{n-1} \sqrt{\int_{T_{n,k}(s,t)}\int_{T_{n,k}(s,t)} f_n(t,s_1,\ldots,s_n) f_n(t,t_1,\ldots,t_n)\phi(s_1,t_1)\cdots\phi(s_n,t_n) ds_1 dt_1 \cdots ds_n dt_n} \\
&\cdot \sqrt{\int_{T_{n,j}(s,t)}\int_{T_{n,j}(s,t)} f_n(t,s_1,\ldots,s_n) f_n(t,t_1,\ldots,t_n)\phi(s_1,t_1)\cdots\phi(s_n,t_n) ds_1 dt_1 \cdots ds_n dt_n}.
\end{aligned}$$

It is easy to check that for all $0 \le k \le n-1$, we have

$$\begin{aligned}
&\int_{T_{n,k}(s,t)} \int_{T_{n,k}(s,t)} f_n(t,s_1,\dots,s_n) f_n(t,t_1,\dots,t_n)\phi(s_1,t_1)\cdots\phi(s_n,t_n)ds_1dt_1\cdots ds_ndt_n \\
&\quad \le \int_{\substack{0<s_1<\cdots<s_k<T \\ 0<t_1<\cdots<t_k<T}} \int_{\substack{s<s_{k+1}<\cdots<s_n<t \\ s<t_{k+1}<\cdots<t_n<t}} f_n(t,s_1,\dots,s_n) f_n(t,t_1,\dots,t_n)\phi(s_1,t_1)\cdots \\
&\qquad \cdot\phi(s_n,t_n)ds_1dt_1\cdots ds_ndt_n \\
&\quad \le \frac{1}{k!(n-k)!} K_T^n |t-s|^{2H} \\
&\quad \le |t-s|^{2H} K_T^n/n!.
\end{aligned}$$

This concludes that

$$\frac{1}{(n!)^2} I_{3,n} \le \frac{1}{n!} K_T^n |t-s|^{2H}.$$

Observing that

$$I_1 \le K_T |t-s|^2,$$

we obtain

$$\mathbb{E}\ |x_t - x_s|^2 \le K_T |t-s|^{2H}.$$

Since $2H > 1$ we see that x_t has a continuous version by the Kolmogorov lemma. This completes the proof of the theorem. □

Remark 2.3. There has been some study on fractional SDEs (see, for example, [27], [24], and the references therein). However, we could not find any result on the type of equation (2.19) in the literature. When the equation is one-dimensional, explicit representation of the solution was obtained in [3], [19]; see also Theorem 2.5 below. Here we have used the Wiener chaos expansion approach to handle the multidimensional case. Note that the L^p estimate of solution (2.21) is also new.

THEOREM 2.4. *If A_t and C_t are measurable and essentially bounded deterministic functions in t, then* (2.20) *admits a unique solution.*

Proof. Similar to the argument proving Theorem 2.3, a solution candidate to (2.20) is

(2.27)

$$\begin{aligned}
Y_t := \sum_{n=0}^{\infty} \int_{0<s_1<\cdots<s_n<t} &\Psi(t,s_n)C_{s_n}\Psi(s_n,s_{n-1})C_{s_{n-1}}\cdots\Psi(s_2,s_1)C_{s_1}\Psi(s_1,0)x_0 \circ dW_{s_1}^H \\
&\cdots \circ dW_{s_n}^H.
\end{aligned}$$

Fix t. Since

$$\begin{aligned}
S_n := \int_{0<s_1<\cdots<s_n<t} &\Psi(t,s_n)C_{s_n}\Psi(s_n,s_{n-1})C_{s_{n-1}}\cdots\Psi(s_2,s_1)C_{s_1}\Psi(s_1,0)x_0 \circ dW_{s_1}^H \\
&\cdots \circ dW_{s_n}^H,
\end{aligned}$$

$n = 0, 1, 2, \dots$, are not orthogonal, we consider the convergence in $L_1(\Omega, \mathcal{F}, P)$. We have

$$\mathbb{E}\ |Y_t| \le \sum_{n=0}^{\infty} \mathbb{E}\ |S_n| \le \sum_{n=0}^{\infty} \left(\mathbb{E}\ |S_n|^2\right)^{1/2}.$$

Defining $f_{n,t}$ as in (2.24), we can write

$$S_n = \int_{0<s_1<\cdots<s_n<t} f_{n,t}(s_1,\dots,s_n) \circ dW_{s_1}^H \cdots \circ dW_{s_n}^H.$$

As before, let f_n^t be the symmetric extension of $f_{n,t}$ to $[0,t]^n$. Since A and C are bounded, we have $|f_{n,t}(s_1,\dots,s_n)| \le K_T^n$ for some constant K_T depending only on T.

With this notation we have

$$S_n = \frac{1}{n!} S_{n,t}(f_n^t),$$

where

$$S_{n,t}(f_n^t) := \int_{0<s_1,\dots,s_n<t} f_n^t(s_1,\dots,s_n) \circ dW_{s_1}^H \cdots \circ dW_{s_n}^H.$$

By the Hu–Meyer formula (see (2.18)) we have

$$S_{n,t}(f_n^t) = \sum_{k\le n/2} \frac{n!}{2^k k!(n-2k)!} I_{n-2k,t}\left(\mathrm{Tr}_\phi^k f_n^t\right).$$

Therefore

$$\mathbb{E}\,|S_{n,t}(f_n^t)|^2 = \sum_{k\le n/2} \frac{(n!)^2}{2^{2k}(k!)^2(n-2k)!} |\mathrm{Tr}_\phi^k f_n^t|_\phi^2. \tag{2.28}$$

But

$$\begin{aligned}
|\,\mathrm{Tr}_\phi^k f_n^t|_\phi^2 &= \int_{\substack{0<s_1,\dots,s_{2k}<t\\ 0<t_1,\dots,t_{2k}<t}} \int_{\substack{0<t_1,\dots,t_{n-2k}<t\\ 0<t_1',\dots,t_{n-2k}'<t}} f_n^t(s_1,s_2,\dots,s_{2k},t_1,\dots,t_{n-2k}) \\
&\qquad \cdot f_n^t(r_1,r_2,\dots,r_{2k},t_1',\dots,t_{n-2k}')\phi(s_1,s_2)\cdots\phi(s_{2k-1},s_{2k}) \\
&\qquad \cdot \phi(r_1,r_2)\cdots\phi(r_{2k-1},r_{2k})\phi(t_1,t_1')\cdots \\
&\qquad \cdot \phi(t_{n-2k},t_{n-2k}')ds_1dr_1\cdots ds_{2k}dr_{2k}dt_1dt_1'\cdots dt_{n-2k}dt_{n-2k}' \\
&\le K_T^n \int_{\substack{0<s_1,\dots,s_{2k}<t\\ 0<t_1,\dots,t_{2k}<t}} \int_{\substack{0<t_1,\dots,t_{n-2k}<t\\ 0<t_1',\dots,t_{n-2k}'<t}} \phi(s_1,s_2)\cdots\phi(s_{2k-1},s_{2k}) \\
&\qquad \cdot \phi(r_1,r_2)\cdots\phi(r_{2k-1},r_{2k})\phi(t_1,t_1')\cdots \\
&\qquad \cdot \phi(t_{n-2k},t_{n-2k}')ds_1dr_1\cdots ds_{2k}dr_{2k}dt_1dt_1'\cdots dt_{n-2k}dt_{n-2k}' \\
&\le K_T^n.
\end{aligned}$$

Therefore

$$\begin{aligned}
\mathbb{E}\,|S_n|^2 &\le \sum_{k\le n/2} \frac{K_T^n}{(k!)^2(n-2k)!} \\
&\le \frac{K_T^n}{n!}.
\end{aligned}$$

Thus Y_t is well defined. It is now routine to verify that Y_t is the solution to (2.20). □

Remark 2.4. Unlike with the case of Itô integral (see Theorem 2.3), it remains an open problem whether the solution in Theorem 2.4 has a continuous modification.

Remark 2.5. The nonhomogeneous versions of (2.19) and (2.20) are

$$\begin{cases} dx_t = (A_t x_t + f_t)dt + (C_t x_t + g_t)dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic} \end{cases} \tag{2.29}$$

and

$$\begin{cases} dx_t = (A_t x_t + f_t)dt + (C_t x_t + g_t) \circ dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic,} \end{cases} \tag{2.30}$$

respectively, where f_t and g_t are generally random processes. One may also use the Wiener chaos expansion technique to study the solvability of these equations, taking the "fundamental matrix" associated with the homogeneous versions (2.19) and (2.20) as the starting point. However, much more involved technicalities will have to be gone through. Details are left to the interested readers. Note that for studying the first and second control models in what follows (2.19) and (2.20) suffice since only the Markovian type of controls is considered.

The following theorem gives an explicit expression of the solution to (2.19) in the one-dimensional case. Note that the result was proved in [3] using the Wick product. Here we give a different yet simple proof.

THEOREM 2.5. *Let $n = 1$. If A_t and C_t are measurable and essentially bounded deterministic functions in t, then the solution of* (2.19) *can be represented as*

$$x_t = x_0 \exp\left[\int_0^t C_s dW_s^H + \int_0^t A_s ds - \frac{1}{2}\int_0^t \int_0^t \phi(s,s')C_s C_{s'} ds ds'\right]. \tag{2.31}$$

Proof. Define

$$\begin{aligned} y_t &:= \exp\left(\int_0^t C_s dW_s^H\right), \\ z_t &:= x_0 \exp\left\{\int_0^t A_s ds - \frac{1}{2}\int_0^t \int_0^t \phi(s,s')C_s C_{s'} ds ds'\right\} \\ &\equiv x_0 \exp\left\{\int_0^t A_s ds - \int_0^t \int_0^s \phi(s,s')C_s C_{s'} ds' ds\right\}, \\ \bar{x}_t &:= y_t z_t. \end{aligned}$$

It suffices to prove that $\bar{x}_t$ satisfies (2.19). To this end, noting that C_t is deterministic, we can apply a simplified Itô's formula ([9, Corollary 4.4][2]) to get

$$dy_t = C_t y_t dW_t^H + C_t y_t \int_0^t \phi(t,s)C_s ds\, dt. \tag{2.32}$$

[2]There is a typo in [9, Corollary 4.4]. The last expression on page 599 of [9] should be $\int_0^t \frac{\partial^2 f}{\partial x^2}(s,\eta_s)a_s \int_0^s \phi(s,v)a_v dv ds$.

Hence,

$$\begin{aligned} d\bar{x}_t = d(y_t z_t) &= y_t z_t \left[A_t dt - \int_0^t \phi(t,s') C_t C_{s'} ds' \, dt \right] \\ &\quad + y_t z_t \left[C_t dW_t^H + C_t \int_0^t \phi(t,s) C_s ds \, dt \right] \\ &= A_t \bar{x}_t dt + C_t \bar{x}_t dW_t^H. \end{aligned}$$

This completes the proof. □

The following two lemmas are useful in what follows. In particular, the first one represents the Malliavin derivative of the solution (2.31).

LEMMA 2.2. *Let x_t be the solution of* (2.19) *under the assumptions of Theorem* 2.5. *Then*

$$D_t^H x_t = x_t \int_0^t \phi(t,s) C_s ds \quad \forall t \in [0,T] \quad a.s. \tag{2.33}$$

Proof. Equation (2.19) is understood as

$$x_t = x_0 + \int_0^t A_s x_s ds + \int_0^t C_s x_s dW_s^H.$$

From the explicit expression (2.31) of the solution we could compute its Malliavin derivative. However, here we supply a simpler method. By [9, Theorem 4.2], we have

$$D_r^H x_t = \int_0^t A_s D_r^H x_s ds + \int_0^t C_s D_r^H x_s dW_s^H + \int_0^t \phi(r,s) C_s x_s ds \quad \forall r,t \in [0,T] \text{ a.s.}$$

Fix r. Denote $z_t := D_r^H x_t$. Then the above equation can be written as

$$dz_t = A_t z_t dt + C_t z_t dW_t^H + \phi(r,t) C_t x_t dt \tag{2.34}$$

with $z_0 = 0$. We want to solve this equation to find $D_r^H x_t$. Try the solution of the form $\tilde{z}_t := \rho_t x_t$, where ρ_t is deterministic and differentiable with $\rho_0 = 0$. Then

$$\begin{aligned} d\tilde{z}_t &= \dot{\rho}_t x_t dt + \rho_t A_t x_t dt + \rho_t C_t x_t dW_t^H \\ &= \dot{\rho}_t x_t dt + A_t \tilde{z}_t dt + C_t \tilde{z}_t dW_t^H. \end{aligned} \tag{2.35}$$

Comparing (2.35) with (2.34), we conclude that if $\dot{\rho}_t = \phi(r,t) C_t$, then z_t would be equal to $\rho_t x_t$ owing to the uniqueness of the solution to (2.34). This implies that

$$\rho_t = \int_0^t \phi(r,s) C_s ds.$$

The proof is completed. □

LEMMA 2.3. *Let x_t be the solution of* (2.19) *under the assumptions of Theorem* 2.5, *and let p_t and C_t be continuously differentiable deterministic functions in t. Then*

$$d(p_t x_t^2) = x_t^2 \left[\dot{p}_t dt + 2A_t p_t dt + 2p_t C_t \int_0^t \phi(t,s) C_s ds dt + 2C_t p_t dW_t^H \right]. \tag{2.36}$$

Proof. Again it suffices to consider the case when $H > \frac{1}{2}$. We apply Itô's formula [9, Theorem 4.5] to $p_t x_t^2$. To do this we need to check the following conditions:

(1) $\mathbb{E}\ \sup_{0\le s\le T}|A_t x_t|<\infty$;
(2) $\mathbb{E}\ \int_0^T |C_t x_t D_t^H x_t|^2 dt<\infty$;
(3) there is $\alpha>1-H$ such that $\mathbb{E}\ |C_t x_t - C_s x_s|^2 \le K|t-s|^{2\alpha}$, where $|t-s|\le\delta$ for some $\delta>0$ and $\lim_{|t-s|\to 0}\mathbb{E}\ |D_t^H(C_t x_t - C_s x_s)|^2=0$;
(4) the function $f(t,x):=p_t x^2$ has bounded derivatives.

Condition (4) can be replaced by the following (see [13]):

(4′) the function $f(t,x)$ has polynomial growth in x.

To prove (1), we use (2.31) to conclude that

$$\sup_{0\le t\le T}|A_t x_t| \le K_T \exp\left\{\sup_{0\le t\le T}\left|\int_0^t C_s dW_s^H\right|\right\}.$$

Condition (1) thus follows easily [10]. Next, combining (2.33) and (2.21) we derive condition (2).

To prove (3), since C_t is continuously differentiable, it suffices to show that

$$\mathbb{E}\ |x_t - x_s|^2 \le K|t-s|^{2\alpha}$$

and

$$\lim_{|t-s|\to 0}\mathbb{E}\ |D_t^H(x_t - x_s)|^2 = 0.$$

The first inequality (with $\alpha = H > 1-H$) was proved in the proof of Theorem 2.3, and the second equality is seen immediately by the fact that $D_r^H x_t = \int_0^t \phi(r,s)C_s ds$, which was proved in the proof of Lemma 2.2.

Finally, condition (4′) is obvious. Now applying [9, Theorem 4.5] we conclude that

$$\begin{aligned} d(p_t x_t^2) &= \dot p_t x_t^2 dt + 2p_t x_t dx_t + 2p_t C_t x_t D_t^H x_t dt \\ &= \dot p_t x_t^2 dt + 2A_t p_t x_t^2 dt + 2C_t p_t x_t^2 dW_t^H + 2p_t C_t x_t^2 \int_0^t \phi(t,s)C_s ds dt \\ &= x_t^2\left[\dot p_t dt + 2A_t p_t dt + 2p_t C_t \int_0^t \phi(t,s)C_s ds dt + 2C_t p_t dW_t^H\right], \end{aligned} \tag{2.37}$$

where the second equality is due to Lemma 2.2. This proves the lemma. □

3. Control model 1: Scalar state, quadratic cost, and Markovian control. We start with our first control model in this section. The controlled dynamics is given by the following Itô-type SDE, where the state is scalar-valued:

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)dt + (C_t x_t + D_t u_t)dW_t^H, \\ x_0 \in \mathbb{R} \qquad \text{given and deterministic,} \end{cases} \tag{3.1}$$

where A_t, $B_t := (B_t^1,\dots,B_t^m)$, C_t, and $D_t := (D_t^1,\dots,D_t^m)$, $0\le t\le T$, are given essentially bounded deterministic functions of t. A control $u_t = (u_t^1,\dots,u_t^m)^*$, $0\le t\le T$, where * denotes the matrix transpose, is taken to be of the Markovian linear feedback type, namely,

$$u_t = K_t x_t, \tag{3.2}$$

where $K_t := (K_t^1, \dots, K_t^m)^*$ is an essentially bounded deterministic function of t. Such a control is also referred to as an *admissible (Markovian linear feedback) control* in this section.

Under each admissible control $u_t = K_t x_t$, system (3.1) reduces to the following linear SDE:

$$\begin{cases} dx_t = (A_t + B_t K_t)x_t dt + (C_t + D_t K_t)x_t dW_t^H, \\ \\ x_0 \in \mathbb{R} \qquad \text{given and deterministic.} \end{cases} \tag{3.3}$$

Hence $K_\cdot$ itself, also termed the *feedback gain*, can be regarded as a control.

For every initial state x_0 and admissible control $u_t = K_t x_t$, there is an associated cost

$$J(x_0, u_\cdot) \equiv J(x_0, K_\cdot) := \mathbb{E}\left[\int_0^T (Q_t x_t^2 + u_t^* R_t u_t)dt + G x_T^2\right], \tag{3.4}$$

where $x_\cdot$ is the solution of (3.3) under the control $u_\cdot$ or, equivalently, $K_\cdot$ (note that the unique solvability of (3.3) under a given $K_\cdot$ is ensured by Theorem 2.3), Q_t and R_t are given essentially bounded deterministic functions in t, and G is a given deterministic scalar. Our optimal stochastic control problem is to minimize the cost functional (3.4), for each given x_0, over the set of all admissible Markovian linear feedback controls.

THEOREM 3.1. *Assume that for a.e.* $t \in [0,T]$, $D_t = 0$, $Q_t \geq 0$, *and* $R_t \succ \delta I$ *for some given* $\delta > 0$ *and* $G \geq 0$. *Then the Riccati equation*

$$\begin{cases} \dot{p}_t + 2p_t[A_t + C_t \int_0^t \phi(t,s)C_s ds] + Q_t - B_t R_t^{-1} B_t^* p_t^2 = 0, \\ \\ p_T = G \end{cases} \tag{3.5}$$

admits a unique solution $p_\cdot$ *over* $[0,T]$ *with* $p_t \geq 0$ *for all* $t \in [0,T]$. *Moreover, the optimal Markovian linear feedback control for problem* (3.3)–(3.4) *is given by*

$$\hat{u}_t = \hat{K}_t x_t \quad \textit{with} \quad \hat{K}_t = -R_t^{-1} B_t^* p_t. \tag{3.6}$$

Finally, the optimal value of (3.4) *is* $p_0 x_0^2$.

Proof. The unique solvability of the (classical) Riccati equation (3.5) was proved in, e.g., [29, Corollary 2.10 p. 297]. Next, for any admissible control $u_t = K_t x_t$, applying Lemma 2.3 to (3.3) with $D_t = 0$, we get

$$d(p_t x_t^2) = x_t^2 \left[\dot{p}_t + 2p_t(A_t + B_t K_t) + 2p_t C_t \int_0^t \phi(t,s)C_s ds\right] dt + 2x_t^2 C_t p_t dW_t^H.$$

Taking integration from 0 to T, we get

$$\begin{aligned} p_T x_T^2 = p_0 x_0^2 &+ \int_0^T x_t^2 \left[\dot{p}_t + 2p_t(A_t + B_t K_t) + 2p_t C_t \int_0^t \phi(t,s)C_s ds\right] \cdot dt \\ &+ 2\int_0^T x_t^2 C_t p_t dW_t^H. \end{aligned}$$

Denote $f_t := x_t^2 C_t p_t$. It follows from (2.21) that

$$\int_0^T \int_0^T \phi(s,t)\mathbb{E}\,|f_s f_t| ds dt < \infty.$$

On the other hand, $D_t^H x_t = x_t \int_0^t \phi(t,s) C_s ds$ by virtue of Lemma 2.2. So again by (2.21) we have

$$\sup_{0\le t\le T} \mathbb{E}\,|D_t^H x_t|^p < \infty \quad \forall\, p \ge 1.$$

This implies that f_t satisfies the condition of [9, Theorem 3.9] leading to $\mathbb{E}\int_0^T f_t dW_t^H = 0$. Hence

$$\mathbb{E}\,\left[p_T x_T^2\right] = p_0 x_0^2 + \mathbb{E}\,\int_0^T x_t^2 \Big[\dot{p}_t + 2p_t(A_t + B_t K_t) + 2p_t C_t \int_0^t \phi(t,s) C_s ds\Big] dt.$$

Since $p_T = G$, we obtain

$$\begin{aligned} J(x_0, K.) &= p_0 x_0^2 + \mathbb{E}\,\int_0^T x_t^2 \Bigg[\dot{p}_t + 2p_t(A_t + B_t K_t) + (Q_t + K_t^* R_t K_t) \\ &\qquad + 2p_t C_t \int_0^t \phi(t,s) C_s ds\Bigg] dt \\ &= p_0 x_0^2 + \mathbb{E}\,\int_0^T x_t^2 \Bigg[\dot{p}_t + 2p_t A_t + 2p_t C_t \int_0^t \phi(t,s) C_s ds + Q_t \\ &\qquad + (K_t + R_t^{-1} B_t^* p_t)^* R_t (K_t + R_t^{-1} B_t^* p_t) - B_t R_t^{-1} B_t^* p_t^2\Bigg] dt \qquad (3.7) \\ &= p_0 x_0^2 + \mathbb{E}\,\int_0^T (K_t + R_t^{-1} B_t^* p_t)^* R_t (K_t + R_t^{-1} B_t^* p_t) dt, \qquad (3.8) \end{aligned}$$

where the last equality was due to the Riccati equation (3.5). Equation (3.8) shows that the cost function achieves its minimum when $\hat{K}_t = -R_t^{-1} B_t^* p_t$, with the minimum value being $p_0 x_0^2$. This proves the theorem. □

Remark 3.1. It is interesting to note that the Riccati equation (3.5) corresponds to the following LQ control problem with (normal) Brownian motion:

$$\text{Minimize} \quad (3.4)$$

$$\text{subject to} \quad \begin{cases} dx_t = (A_t x_t + B_t u_t) dt + \tilde{C}_t x_t dW_t, \\ x_0 \in \mathbb{R} \qquad \text{given and deterministic,} \end{cases} \qquad (3.9)$$

where $\tilde{C}_t = \sqrt{2C_t \int_0^t \phi(t,s) C_s ds}$, assuming that $C_t \int_0^t \phi(t,s) C_s ds \ge 0$ for all $t \ge 0$; see [4]. This suggests that, in the current setting, the LQ control problem with FBM is equivalent (in the sense of sharing the same optimal feedback control and optimal value) to an LQ control problem with Brownian motion, where the diffusion coefficient of the state is properly modified.

4. Control model 2: Scalar state, power cost, and Markovian control. In this section we consider a more general model (than the one tackled in the previous section) where the dynamics is given by (3.1) but the cost functional is of the form

(4.1)

$$J(x_0, u.) \equiv J(x_0, u(\cdot)) = \mathbb{E}\,\left\{\int_0^T \left[Q_t x_t^\alpha + \sum_{i,j=1}^m R_{ij}(t) u_i(t)^{\beta_i} u_j(t)^{\beta_j}\right] dt + G x_T^\gamma\right\},$$

where α, β_i $(i = 1, 2, \dots, m)$, $\gamma \in \mathbb{R}$ are given, Q_t and $R_t \equiv R(t) = (R_{ij}(t))_{1\le i,j\le m}$ are given essentially bounded deterministic functions in t, and G is a given deterministic scalar. Moreover, we assume that $(R_{ij}(t))_{1\le i,j\le m}$ is positive definite for each $t \in [0, T]$. Here we interchangeably denote a control variable as

$$u_t \equiv u(t) = (u_t^1, \dots, u_t^m)^* \equiv (u_1(t), \dots, u_m(t))^*$$

for notational convenience. The problem is to find the *extreme* or *optimum* (i.e., minimum or maximum) of $J(x_0, u.)$, for each fixed $x_0 \in \mathbb{R}$, over the set of all admissible Markovian linear feedback controls of the form $u_t = K_t x_t$, subject to (3.1). With this type of control we can write $J(x_0, u.) = J(x_0, K.)$ as in the previous section. Note that whether the cost functional (4.1) assumes a minimum or maximum (or both) depends on the problem data, in particular, the ranges of α, β, and γ. The objective of this section is to derive *necessary conditions* for a solution to the extreme problem.

LEMMA 4.1. *For any admissible Markovian control $u_t = K_t x_t$, where $K_t \equiv K(t) = (K_1(t), \dots, K_m(t))^*$, the corresponding cost has the following representation:*

$$J(x_0, K.) = \int_0^T \left[Q_t \Theta_{\alpha,t} + \sum_{i,j=1}^m R_{ij}(t) K_i(t)^{\beta_i} K_j(t)^{\beta_j} \Theta_{\beta_i+\beta_j,t} \right] dt + G\Theta_{\gamma,T}, \tag{4.2}$$

where for any $\kappa \in \mathbb{R}$,

$$\begin{aligned} \Theta_{\kappa,t} &\equiv \Theta_{\kappa,t}(x_0, K.) \\ &:= x_0^\kappa \mathbb{E}\ \exp\left\{ \kappa \int_0^t (A_s + B_s K_s) ds \right. \\ &\qquad \left. + \frac{\kappa^2 - \kappa}{2} \int_0^t \int_0^t \phi(s, s')(C_s + D_s K_s)(C_{s'} + D_{s'} K_{s'}) ds ds' \right\}. \end{aligned} \tag{4.3}$$

Proof. Substituting the feedback control $u_t = K_t x_t$ into (3.1), we obtain

$$dx_t = (A_t + B_t K_t) x_t dt + (C_t + D_t K_t) x_t dW_t^H. \tag{4.4}$$

By Theorem 2.5, this equation can be solved explicitly as follows:

$$\begin{aligned} x_t = x_0 \exp\left\{ \int_0^t (C_s + D_s K_s) dW_s^H + \int_0^t (A_s + B_s K_s) ds \right. \\ \left. - \frac{1}{2} \int_0^t \int_0^t \phi(s, s')(C_s + D_s K_s)(C_{s'} + D_{s'} K_{s'}) ds ds' \right\}. \end{aligned} \tag{4.5}$$

Let $\kappa \in \mathbb{R}$. Since $\kappa \int_0^t (C_s + D_s K_s) dW_s^H$ is Gaussian, we have

$$\begin{aligned} &\mathbb{E}\ \exp\left\{ \kappa \int_0^t (C_s + D_s K_s) dW_s^H \right\} \\ &\quad = \exp\left\{ \frac{1}{2} \kappa^2 \mathbb{E} \left| \int_0^t (C_s + D_s K_s) dW_s^H \right|^2 \right\} \\ &\quad = \exp\left\{ \frac{1}{2} \kappa^2 \int_0^t \int_0^t \phi(s, s')(C_s + D_s K_s)(C_{s'} + D_{s'} K_{s'}) ds ds' \right\}, \end{aligned}$$

where the last equality is due to [9, Theorem 3.10]. It then follows from (4.5) that

$$\mathbb{E}\, x_t^\kappa = x_0^\kappa \mathbb{E}\, \exp\left\{\kappa \int_0^t (A_s + B_s K_s) ds \right. \tag{4.6}$$
$$\left. + \frac{\kappa^2 - \kappa}{2} \int_0^t \int_0^t \phi(s, s')(C_s + D_s K_s)(C_{s'} + D_{s'} K_{s'}) ds ds' \right\}$$
$$= \Theta_{\kappa,t}(x_0, K_\cdot) \equiv \Theta_{\kappa,t}.$$

The desired representation (4.2) thus follows immediately. □

THEOREM 4.1. *If $K_t \equiv K(t) = (K_1(t), \ldots, K_m(t))^*$ achieves an extreme for problems* (3.1) *and* (4.1)*, then it must satisfy*

$$\begin{aligned} &\alpha B_s \int_s^T Q_t \Theta_{\alpha,t} dt + (\alpha^2 - \alpha) \int_s^T \int_0^t Q_t \Theta_{\alpha,t} \phi(s', s) C_{s'} D_s ds' dt \\ &+ (\alpha^2 - \alpha) \int_s^T \int_0^t Q_t \Theta_{\alpha,t} \phi(s', s) D_{s'} K_{s'} D_s ds' dt + 2\tilde{R}(s) \\ &+ \sum_{i,j=1}^m \int_s^T R_{ij}(t) K_i(t)^{\beta_i} K_j(t)^{\beta_j} \Theta_{\beta_{ij},t} \left[\beta_{ij} B_s + (\beta_{ij}^2 - \beta_{ij}) \int_0^t \phi(s', s) C_{s'} D_s ds' \right. \\ &\qquad \left. + (\beta_{ij}^2 - \beta_{ij}) \int_0^t \phi(s', s) D_{s'} K_{s'} D_s ds' \right] dt \\ &+ \gamma G \Theta_{\gamma,T} B_s + (\gamma^2 - \gamma) G \Theta_{\gamma,T} \int_0^T \phi(s', s) C_{s'} D_s ds' \\ &+ (\gamma^2 - \gamma) G \Theta_{\gamma,T} \int_0^T \phi(s', s) D_{s'} K_{s'} D_s ds' = 0 \quad \text{a.e. } s \in [0, T], \end{aligned} \tag{4.7}$$

where

$$\beta_{ij} := \beta_i + \beta_j \tag{4.8}$$

and

$$\tilde{R}(t) := \left(\sum_{j=1}^m \beta_1 R_{1j}(t) K_1(t)^{\beta_1 - 1} K_j(t)^{\beta_j} \Theta_{\beta_{1j},t}, \right. \tag{4.9}$$
$$\left. \cdots, \sum_{j=1}^m \beta_m R_{mj}(t) K_m(t)^{\beta_m - 1} K_j(t)^{\beta_j} \Theta_{\beta_{mj},t} \right).$$

Proof. Since $K_\cdot$ attains the extreme value, it necessarily holds that

$$\left. \frac{d}{d\varepsilon} J(K_\cdot + \varepsilon \xi_\cdot) \right|_{\varepsilon = 0} = 0 \tag{4.10}$$

for all $\xi_\cdot \in C^\infty(0, T; \mathbb{R}^m)$, where $C^\infty(0, T; \mathbb{R}^m)$ denotes the set of all smooth ($\mathbb{R}^m$-valued) functions on $[0, T]$.

To compute derivative (4.10) we need to first compute $\frac{d}{d\varepsilon}\Theta_{\alpha,t}(x_0, K_\cdot + \varepsilon\xi_\cdot)|_{\varepsilon=0}$, which is given by

$$\begin{aligned}(4.11)\qquad &\frac{d}{d\varepsilon}\Theta_{\alpha,t}(x_0, K_\cdot + \varepsilon\xi_\cdot)\bigg|_{\varepsilon=0}\\ &\quad= \Theta_{\alpha,t}\bigg\{\alpha\int_0^t B_s\xi_s ds + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\\ &\qquad + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\bigg\}.\end{aligned}$$

Consequently,

$$\begin{aligned}\frac{d}{d\varepsilon}J(\hat{K}_\cdot + \varepsilon\xi_\cdot)\bigg|_{\varepsilon=0} &= \int_0^T Q_t\Theta_{\alpha,t}\bigg\{\alpha\int_0^t B_s\xi_s ds + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\\ &\quad + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\bigg\}dt\\ (4.12)\qquad &\quad + 2\sum_{i,j=1}^m\int_0^T \beta_i R_{ij}(t)K_i(t)^{\beta_i-1}K_j(t)^{\beta_j}\xi_i(t)\Theta_{\beta_{ij},t}dt\\ &\quad + \sum_{i,j=1}^m\int_0^T R_{ij}(t)K_i(t)^{\beta_i}K_j(t)^{\beta_j}\Theta_{\beta_{ij},t}\\ &\quad \cdot\bigg\{\beta_{ij}\int_0^t B_s\xi_s ds + (\beta_{ij}^2-\beta_{ij})\int_0^t\int_0^t \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\\ &\quad + (\beta_{ij}^2-\beta_{ij})\int_0^t\int_0^t \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\bigg\}dt\\ &\quad + H\Theta_{\gamma,T}\bigg\{\gamma\int_0^T B_s\xi_s ds + (\gamma^2-\gamma)\int_0^T\int_0^T \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\\ (4.13)\qquad &\quad + (\gamma^2-\gamma)\int_0^T\int_0^T \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\bigg\}\\ &= \int_0^T Q_t\Theta_{\alpha,t}\bigg\{\alpha\int_0^t B_s\xi_s ds + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\\ &\quad + (\alpha^2-\alpha)\int_0^t\int_0^t \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\bigg\}dt\\ (4.14)\qquad &\quad + 2\int_0^T \tilde{R}(t)\xi_t dt\\ &\quad + \sum_{i,j=1}^m\int_0^T R_{ij}(t)K_i(t)^{\beta_i}K_j(t)^{\beta_j}\Theta_{\beta_{ij},t}\\ &\quad \cdot\bigg\{\beta_{ij}\int_0^t B_s\xi_s ds + (\beta_{ij}^2-\beta_{ij})\int_0^t\int_0^t \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\end{aligned}$$

$$
\begin{aligned}
&+(\beta_{ij}^2-\beta_{ij})\int_0^t\int_0^t \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\Big\}dt\\
&+G\Theta_{\gamma,T}\Big\{\gamma\int_0^T B_s\xi_s ds+(\gamma^2-\gamma)\int_0^T\int_0^T \phi(s,s')C_sD_{s'}\xi_{s'}dsds'\\
&+(\gamma^2-\gamma)\int_0^T\int_0^T \phi(s,s')D_sK_sD_{s'}\xi_{s'}dsds'\Big\}. \qquad (4.15)
\end{aligned}
$$

Using the Fubini theorem

$$
\int_0^T\int_0^t\int_0^t g(t,s,s')dsds'dt=\int_0^T\int_s^T\int_0^t g(t,s',s)ds'dtds, \qquad (4.16)
$$

we obtain

$$
\begin{aligned}
&\frac{d}{d\varepsilon}J(K_\cdot+\varepsilon\xi_\cdot)\Big|_{\varepsilon=0}\\
&=\int_0^T\Big\{\alpha B_s\int_s^T Q_t\Theta_{\alpha,t}dt+(\alpha^2-\alpha)\int_s^T\int_0^t Q_t\Theta_{\alpha,t}\phi(s',s)C_{s'}D_sds'dt\\
&+(\alpha^2-\alpha)\int_s^T\int_0^t Q_t\Theta_{\alpha,t}\phi(s',s)D_{s'}K_{s'}D_sds'dt+2\tilde{R}(s)\\
&+\sum_{i,j=1}^m\int_s^T R_{ij}(t)K_i(t)^{\beta_i}K_j(t)^{\beta_j}\Theta_{\beta_i+\beta_j,t}\\
&\cdot\Big[\beta_{ij}B_s+(\beta_{ij}^2-\beta_{ij})\int_0^t\phi(s',s)C_{s'}D_sds'+(\beta_{ij}^2-\beta_{ij})\int_0^t\phi(s',s)D_{s'}K_{s'}D_sds'\Big]dt\\
&+\gamma G\Theta_{\gamma,T}B_s+(\gamma^2-\gamma)G\Theta_{\gamma,T}\int_0^T\phi(s',s)C_{s'}D_sds'\\
&+(\gamma^2-\gamma)G\Theta_{\gamma,T}\int_0^T\phi(s',s)D_{s'}K_{s'}D_sds'\Big\}\xi_s ds=0. \qquad (4.17)
\end{aligned}
$$

Since ξ_s is arbitrary, we obtain the desired equation, (4.7). □

The necessary condition (4.7), albeit complicated, is very general. Let us now discuss two special (yet interesting) cases, where this condition can be greatly simplified.

Case 1. Suppose there is no running cost, i.e., $Q_t\equiv 0$ and $R_t\equiv 0$. However, $G\neq 0$ and $\gamma\neq 0$ (otherwise the problem would become trivial). This kind of situation arises often in financial portfolio selection models, where only terminal wealth is of concern (see, e.g., [23, 29]). In this case condition (4.7) reduces to

$$
(\gamma-1)\int_0^T\phi(s',s)D_{s'}K_{s'}ds'\ D_s+(\gamma-1)\int_0^T\phi(s',s)C_{s'}ds'\ D_s+B_s=0\ \text{ a.e. } s\in[0,T]. \qquad (4.18)
$$

Equation (4.18) (with $K_\cdot$ being the unknown) is reduced to the *Carleman-type equation* in the following way. Rewrite (4.18) as

$$
\left[(\gamma-1)\int_0^T\phi(s',s)K_{s'}D_{s'}ds'+(\gamma-1)\int_0^T\phi(s',s)C_{s'}ds'\right]D_s=-B_s.
$$

Since the term inside the bracket is a real-valued function, a necessary condition that (4.18) has a solution is

$$\int_0^T \phi(s',s)K_{s'}D_{s'}ds' + \int_0^T \phi(s',s)C_{s'}ds' = \frac{\lambda_s}{1-\gamma}, \tag{4.19}$$

where λ_s is a real-valued function satisfying

$$\lambda_s D_s = B_s.$$

Equation (4.19) is equivalent to (noting that $\phi(s,t) \equiv \phi(t,s)$)

$$\int_0^T \phi(s,t)K_t D_t dt = \frac{\lambda_s}{1-\gamma} - \int_0^T \phi(t,s)C_t dt. \tag{4.20}$$

This equation, with $K.D.$ being the unknown, is of the following general Carleman type:

$$\int_0^T \phi(x,y)h(y)dy = g(x),$$

where g is a given function, h is the unknown function to be determined by this equation, and $\phi(x,y) = H(2H-1)|x-y|^{2H-2}$. The solution of this equation can be expressed explicitly as

$$h(x) = -a_H x^{1/2-H}\frac{d}{dx}\int_x^T \Big[w^{2H-1}(w-x)^{1/2-H}\frac{d}{dw}\int_0^w z^{1/2-H}(w-z)^{1/2-H}g(z)dz\Big]dw,$$

where

$$a_H := \frac{\Gamma(2-2H)}{2H\Gamma(\frac{1}{2}+H)\Gamma(\frac{3}{2}-H)^3};$$

see [11], [12], [13]. Applying this general formula to (4.20) we obtain $K.D.$. Note that, in general, $K.$ may not be unique if its dimension is strictly greater than 1.

A particular case for (4.18) is when $\gamma = 1$ *or* $D_s = 0$ a.e. $s \in [0,T]$. In this case, (4.18) implies it is necessary that $B_s = 0$ a.e. $s \in [0,T]$ (for there to be an extreme achieved by a Markovian control); hence system (3.1) becomes uncontrolled and the cost functional (4.1) is constant valued.

Case 2. Suppose $\alpha = \beta_{ij} = \gamma \neq 0$ for all i,j. Then (4.7) specializes to

(4.21)

$$\begin{aligned}
&\frac{2}{\alpha}\tilde{R}(s) + B_s\int_s^T \Theta_{\alpha,t}\left(Q_t + \sum_{i,j=1}^m R_{ij}(t)K_i(t)^{\beta_i}K_j(t)^{\beta_j}\right)dt \\
&\quad + (\alpha-1)D_s\int_s^T\int_0^t \Theta_{\alpha,t}\phi(s',s)(C_{s'}+D_{s'}K_{s'})\left(Q_t + \sum_{i,j=1}^m R_{ij}(t)K_i(t)^{\beta_i}K_j(t)^{\beta_j}\right)ds'dt \\
&\quad + G\Theta_{\alpha,T}\left[B_s + (\alpha-1)D_s\int_0^T \phi(s',s)(C_{s'}+D_{s'}K_{s'})ds'\right] = 0 \text{ a.e. } s \in [0,T].
\end{aligned}$$

If $\alpha = \gamma = 2$ and $\beta_i = \beta_j = 1$ for all i, j (i.e., the usual LQ case), then the above equation can be further simplified to

$$\begin{aligned} &K_s^* R_s \Theta_s + B_s \int_s^T \Theta_t (Q_t + K_t^* R_t K_t) dt \\ &\quad + D_s \int_s^T \int_0^t \Theta_t \phi(s', s)(C_{s'} + D_{s'} K_{s'})(Q_t + K_t^* R_t K_t) ds' dt \\ &\quad + G\Theta_T \left[B_s + D_s \int_0^T \phi(s', s)(C_{s'} + D_{s'} K_{s'}) ds' \right] = 0 \quad \text{a.e. } s \in [0, T], \end{aligned} \tag{4.22}$$

where $\Theta_t := \Theta_{2,t}$.

Therefore, in the LQ case, where the state is scalar and $D_t \neq 0$, one needs to solve the functional differential equation (4.22) in order to obtain an optimal Markovian feedback control. Recall that in section 3 we derived Riccati equation (3.5) for the LQ control when $D_t \equiv 0$. Let us now show that (3.5) can also be recovered from (4.22) under the assumptions of Theorem 3.1. To this end, first note that (4.22) reduces to the following when $D_t \equiv 0$:

$$K_s^* R_s \Theta_s + B_s \int_s^T \Theta_t (Q_t + K_t^* R_t K_t) dt + G B_s \Theta_T = 0 \quad \text{a.e. } s \in [0, T]. \tag{4.23}$$

Define

$$p_s := \Theta_s^{-1} \left[\int_s^T \Theta_t (Q_t + K_t^* R_t K_t) dt + G\Theta_T \right] \tag{4.24}$$

and

$$K_s := -R_s^{-1} B_s^* p_s. \tag{4.25}$$

It is clear that $K_\cdot$ defined above satisfies the necessary condition (4.23). Now we derive the equation that governs $p_\cdot$. Multiplying (4.24) by Θ_s and then taking derivative in s, we obtain

$$\dot{p}_s \Theta_s + p_s \dot{\Theta}_s + \Theta_s (Q_s + K_s^* R_s K_s) = 0. \tag{4.26}$$

However, (4.6) gives (noting $D_t \equiv 0$)

$$\dot{\Theta}_s = \Theta_s \left[2(A_s + B_s K_s) + 2(C_s + D_s K_s) \int_0^s \phi(s, s')(C_{s'} + D_{s'} K_{s'}) ds' \right]. \tag{4.27}$$

Plugging (4.27) into (4.26), noting (4.25), and going through some manipulation, we get that $p_\cdot$ satisfies Riccati equation (3.5) (that $p_T = G$ is evident from (4.24)).

It should be noted that the above derivation shows only that $K_\cdot$ defined by (4.25), where $p_\cdot$ is the solution to Riccati equation (3.5), satisfies the *necessary condition* of an optimum. Hence, it can by no means supersede Theorem 3.1.

Another interesting case for necessary condition (4.22) is when $H = \frac{1}{2}$ (i.e., the Brownian motion), whereas $D_t \neq 0$. In this case $\phi(s, t) = \delta(s, t)$, the Dirac delta function, and (4.22) becomes

$$\begin{aligned} &K_s^* R_s \Theta_s + [B_s + (C_s + K_s^* D_s^*) D_s] \int_s^T \Theta_t (Q_t + K_t^* R_t K_t) dt \\ &\quad + G\Theta_T [B_s + (C_s + K_s^* D_s^*) D_s] = 0. \end{aligned} \tag{4.28}$$

Let

$$p_s := \Theta_s^{-1}\left[\int_s^T \Theta_t(Q_t + K_t^* R_t K_t)dt + G\Theta_T\right] \tag{4.29}$$

and

$$R_s K_s = -\left[B_s^* + D_s^*(C_s + D_s K_s)\right] p_s, \tag{4.30}$$

or equivalently,

$$K_s = -(R_s + p_s D_s^* D_s)^{-1}[B_s^* + D_s^* C_s]p_s, \tag{4.31}$$

assuming that $R_s + p_s D_s^* D_s$ is invertible. On the other hand, in the present case, Θ_s satisfies

$$\dot{\Theta}_s = \Theta_s\left[2(A_s + B_s K_s) + (C_s + D_s K_s)^2\right]. \tag{4.32}$$

Going through the same argument as above, we can show that $p.$ follows:

(4.33)
$$\begin{cases} \dot{p}_s + (2A_s + C_s^2)p_s + Q_s - (B_s + C_s^* D_s)(R_s + p_s D_s^* D_s)^{-1}(B_s^* + D_s^* C_s)p_s^2 = 0, \\ p_T = G, \\ R_s + p_s D_s^* D_s \succ 0. \end{cases}$$

This is the standard (stochastic) Riccati equation (see [4]).

5. Control model 3: Vector state, quadratic cost, and general control with Stratonovich integral. In the two models previously studied, it is assumed that the state is scalar-valued and only Markovian-type feedback controls are considered. In this section, we investigate a general model, where the state is multidimensional and admissible controls are not necessarily Markovian. In addition, all the coefficients are allowed to be stochastic processes. The system is described by the linear dynamics

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)dt + C_t x_t \circ dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic,} \end{cases} \tag{5.1}$$

where $A_t, C_t, 0 \le t \le T$, are $n \times n$ matrix-valued $\mathcal{F}_t$-adapted stochastic processes, and $B_t, 0 \le t \le T$, is an $n \times m$ matrix-valued $\mathcal{F}_t$-adapted process. An *admissible control* u_t, $0 \le t \le T$, is an $\mathbb{R}^m$-valued $\mathcal{F}_t$-adapted process such that (5.1) has a unique solution. Notice that, unlike in the previous two models, the Stratonovich-type integral is involved in the dynamics.

Let Q_t and $R_t, 0 \le t \le T$, be given $n \times n$ and $m \times m$ matrix-valued $\mathcal{F}_t$-adapted stochastic processes, respectively, and let G be an $n \times n$ $\mathcal{F}_T$-measurable random matrix. Define the cost functional

$$J(x_0, u.) := \mathbb{E}\left[\int_0^T (x_t^* Q_t x_t + u_t^* R_t u_t)dt + x_T^* G x_T\right]. \tag{5.2}$$

The optimal stochastic control problem is to minimize the cost functional (5.2), subject to the dynamics (5.1), over the set of all admissible controls for each given x_0.

5.1. Optimal control. In this subsection we present the solution to the optimal control problem formulated above. Let W_t be the Brownian motion in the representation of the FBM W_t^H as given by Lemma 2.1. We introduce the following matrix-valued backward SDE (BSDE):

(5.3)
$$\begin{cases} dP_t + (A_t^* P_t + P_t A_t + Q_t - P_t B_t R_t^{-1} B_t^* P_t)dt + (C_t^* P_t + P_t C_t) \circ dW_t^H - \Lambda_t dW_t = 0, \\ P_T = G. \end{cases}$$

This is a Riccati-type equation. A *pair* of $n \times n$ matrix-valued $\mathcal{F}_t$-adapted processes, $(P_\cdot, \Lambda_\cdot)$, is called a solution of (5.3) if it satisfies

$$\begin{aligned} P_t = \quad & G + \int_t^T (A_t^* P_t + P_t A_t + Q_t - P_t B_t R_t^{-1} B_t^* P_t)dt \\ & + \int_t^T (C_t^* P_t + P_t C_t) \circ dW_t^H - \int_t^T \Lambda_t dW_t \ \text{ a.e. } t \in [0,T], \end{aligned}$$

with all the integrals above well defined. Notice that, unlike a standard BSDE (see [29]), (5.3) involves simultaneously both the Brownian motion and the FBM.

Now assume that Riccati equation (5.3) admits solution $(P_\cdot, \Lambda_\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n}) \times L^2_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n})$ with $\Lambda_\cdot$ being a semimartingale of the form

$$\Lambda_t = \Lambda_0 + \int_0^t \Theta_s ds + \int_0^t \Xi_s dW_s, \tag{5.4}$$

where Θ_s and Ξ_s are continuous $\mathcal{F}_t$-adapted processes. Then

$$d\langle \Lambda\,, W\rangle_t = \Xi_t dt,$$

where the bracket $\langle \Lambda\,, W\rangle$ denotes the quadratic variational process corresponding to Λ_t and W_t. Hence, we may rewrite the Riccati (5.3) as

$$\begin{cases} dP_t = -(A_t^* P_t + P_t A_t + Q_t - P_t B_t R_t^{-1} B_t^* P_t)dt, \\ \qquad\qquad -(C_t^* P_t + P_t C_t) \circ dW_t^H + \Lambda_t \circ dW_t - \frac{1}{2}\Xi_t dt, \\ P_T = G. \end{cases} \tag{5.5}$$

Let $u_\cdot$ be any given admissible control and $x_\cdot$ be the corresponding state process. Applying the Itô formula for the Stratonovich differential [9, Theorem 4.7], we have

$$\begin{aligned} d(x_t^* P_t x_t) = {} & (A_t x_t + B_t u_t)^* P_t x_t dt + x_t^* C_t^* P_t x_t \circ dW_t^H \\ & - x_t^* (A_t^* P_t + P_t A_t + Q_t - P_t B_t R_t^{-1} B_t^* P_t) x_t dt - \frac{1}{2} x_t^* \Xi_t x_t dt \\ & - x_t^* (C_t^* P_t + P_t C_t) x_t \circ dW_t^H + x_t^* \Lambda_t x_t \circ dW_t \\ & + x_t^* P_t (A_t x_t + B_t u_t) dt + x_t^* P_t C_t x_t \circ dW_t^H \\ = {} & \left[2u_t^* B_t^* P_t x_t - x_t^* (Q_t - P_t B_t R_t^{-1} B_t^* P_t) x_t \right] dt \\ & - \frac{1}{2} x_t^* \Xi_t x_t dt + x_t^* \Lambda_t x_t \circ dW_t. \end{aligned} \tag{5.6}$$

Integrating from 0 to T and taking expectation, we get

$$\begin{aligned}\mathbb{E}\ [x_T^* P_T x_T] = \quad & x_0^* P_0 x_0 + \mathbb{E}\int_0^T \left[2u_t^* B_t^* P_t x_t - x_t^*(Q_t - P_t B_t R_t^{-1} B_t^* P_t)x_t\right] dt \\ & -\frac{1}{2}\mathbb{E}\int_0^T x_t^* \Xi_t x_t dt + \mathbb{E}\left[\int_0^T x_t^* \Lambda_t x_t \circ dW_t\right].\end{aligned} \tag{5.7}$$

In view of the relation between the Itô integral and the Stratonovich integral [9, Theorem 3.12], we have

$$\begin{aligned}x_t &= x_0 + \int_0^t (A_s x_s + B_s u_s)ds + \int_0^t C_s x_s \circ dW_s^H \\ &= x_0 + \int_0^t [A_s x_s + B_s u_s + D_s^H(C_s x_s)]ds + \int_0^t C_s x_s dW_s^H.\end{aligned}$$

Writing it in component form, we have

$$x_t^i = x_0^i + \int_0^t g_s^i ds + \int_0^t h_s^i dW_s^H, \quad i = 1, 2, \ldots, n,$$

where g_s^i is the ith component of $A_s x_s + B_s u_s + D_s^H(C_s x_s)$ and h_s^i the ith component of $C_s x_s$. By the Itô formula [9, Theorem 4.6], we have

$$\begin{aligned}d(x_t^i x_t^j) &= x_t^i g_t^j dt + x_t^i h_t^j dW_t^H + x_t^j g_t^i dt + x_t^j h_t^i dW_t^H + h_t^j D_t^H x_t^i dt + h_t^i D_t^H x_t^j dt \\ &= g_t^{ij} dt + h_t^{ij} dW_t^H,\end{aligned}$$

where

$$g_t^{ij} := x_t^i g_t^j + x_t^j g_t^i + h_t^j D_t^H x_t^i + h_t^i D_t^H x_t^j$$

and

$$h_t^{ij} := x_t^i h_t^j + x_t^j h_t^i.$$

We also write $d\Lambda_t$ in component form:

$$d\Lambda_t^{ij} = \Theta_t^{ij} dt + \Xi_t^{ij} dW_t, \quad 1 \le i, j \le n.$$

Then taking into account that $dW_t^H dW = 0$ (which can be proved by the same estimate as that in the proof of Theorem 2.1), we have

$$d[\Lambda_t^{ij} x_t^i x_t^j] = \Lambda_t^{ij} g_t^{ij} dt + \Lambda_t^{ij} h_t^{ij} dW_t^H + x_t^i x_t^j \Theta_t^{ij} dt + x_t^i x_t^j \Xi_t^{ij} dW_t.$$

Taking the sum over i and j and then integrating, we obtain

$$x_t^* \Lambda_t x_t = x_0^* \Lambda_0 x_0 + \int_0^t M_s ds + \int_0^t N_s dW_s^H + \int_0^t x_s^* \Xi_s x_s dW_s,$$

where

$$M_s := \sum_{i,j=1}^n (\Lambda_s^{ij} g_s^{ij} + x_s^i x_s^j \Theta_s^{ij}), \quad N_s := \Lambda_s^{ij} h_s^{ij}.$$

We set

$$Y_t := x_0^* \Lambda_0 x_0 + \int_0^t M_s ds + \int_0^t N_s dW_s^H, \tag{5.8}$$

which is of the form (2.9). Assuming that the processes M_s and N_s satisfy conditions (2.10), it then follows from Theorem 2.1 that

$$\mathbb{E} \int_0^T Y_s \circ dW_s = 0.$$

On the other hand, the well-known relation between the Itô and Stratonovich integrals for Brownian motion yields (see [21])

$$\mathbb{E}\left[\int_0^T \left(\int_0^t x_s^* \Xi_s x_s dW_s\right) \circ dW_t\right] = \frac{1}{2}\mathbb{E} \int_0^T x_t^* \Xi_t x_t dt.$$

Therefore we obtain

$$\mathbb{E}\left[\int_0^T x_t^* \Lambda_t x_t \circ dW_t\right] = \frac{1}{2}\mathbb{E} \int_0^T x_t^* \Xi_t x_t dt.$$

It then follows from (5.7) that

$$\mathbb{E}\ [x_T^* P_T x_T] = \mathbb{E}\ \left[x_0^T P_0 x_0\right] + \mathbb{E} \int_0^T \left[2u_t^* B_t^* P_t x_t - x_t^* (Q_t - P_t B_t R_t^{-1} B_t^* P_t) x_t\right] dt.$$

Hence

$$\begin{aligned} J(x_0, u_\cdot) &= x_0^* P_0 x_0 + \mathbb{E} \int_0^T (2u_t^* B_t^* P_t x_t + u_t^* R u_t + x_t^* P_t B_t R_t^{-1} B_t^* P_t x_t) dt \\ &= x_0^* P_0 x_0 + \mathbb{E} \int_0^T \left(u_t + R_t^{-1} B_t^* P_t x_t\right)^* R_t \left(u_t + R_t^{-1} B_t^* P_t x_t\right) dt. \end{aligned}$$

Assuming that $R_t \succ 0$, the minimum of the above functional is achieved when $u_t = -R_t^{-1} B_t^* P_t x_t$ with the minimum value being $x_0^* P_0 x_0$, provided that the control $u_t = -R_t^{-1} B_t^* P_t x_t$ induces an admissible control.

Summarizing, we have obtained the following result.

THEOREM 5.1. *Assume that $R_t \succ 0$ a.e. $t \in [0,T]$ a.s. and that Riccati equation* (5.3) *admits a solution $(P_\cdot, \Lambda_\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n}) \times L^2_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n})$ with $\Lambda_\cdot$ being a semimartingale of the form* (5.4). *Moreover, assume that the process Y_t defined by* (5.8) *satisfies conditions* (2.10) *and that* (5.6) *holds. Then, the stochastic control problem* (5.1)–(5.2) *is solvable and the optimal control $\hat{u}_\cdot$ must be of Markovian feedback type, given explicitly by*

$$\hat{u}_t = -R_t^{-1} B_t^* P_t x_t, \tag{5.9}$$

provided that the control $\hat{u}_\cdot$ (5.9) *is admissible. Moreover, the minimum value is achieved as $J(x_0, \hat{u}_\cdot) = x_0^* P_0 x_0$.*

Remark 5.1. Even in the case when the system is driven by Brownian motion, to the best of our knowledge, equations involving the Stratonovich-type integral (5.1) have not been considered in the literature on stochastic LQ control.

Remark 5.2. In the Brownian motion case, the Riccati equation is a deterministic differential equation when all the coefficients A_t, B_t, and C_t are deterministic (see [4]). However, In the FBM case, Riccati equation (5.3) is still stochastic even when all the coefficients are deterministic.

5.2. Origin of the Riccati equation. In the previous subsection we established the optimal solution to the control problem (5.1)–(5.2) by making use of Riccati equation (5.3). The approach is a standard completion-of-square technique commonly employed for LQ control once the Riccati equation is in place. However, one may be curious as to how (5.3) was derived in the first place. In this subsection we present, in a rather formal way, how we get (5.3).

We first approximate the underlying FBM using an adapted convolution approach of Malliavin (see [2], [18]). Set $W_s^H = 0$ for $s \le 0$. Define

$$W_t^{H,\varepsilon} := \frac{1}{\varepsilon}\int_{t-\varepsilon}^{t} W_s^H ds. \tag{5.10}$$

The derivative of $W_t^{H,\varepsilon}$ is

$$\dot{W}_t^{H,\varepsilon} = \frac{1}{\varepsilon}\left(W_t^H - W_{t-\varepsilon}^H\right). \tag{5.11}$$

We approximate the stochastic differential system (5.1) by

$$\dot{x}_t^\varepsilon = A_t x_t^\varepsilon + B_t u_t + C_t x_t^\varepsilon \dot{W}_t^{H,\varepsilon} = (A_t + C_t \dot{W}_t^{H,\varepsilon}) x_t^\varepsilon + B_t u_t. \tag{5.12}$$

The above can be regarded as a controlled linear system with the normal Brownian motion (but the diffusion coefficient is zero) and *random* coefficient in drift. Consider an LQ control problem with dynamics (5.12) and cost functional (5.2). The corresponding Riccati equation, following [4], is

$$\begin{cases} dP_t^\varepsilon + \big[(A_t + C_t\dot{W}_t^{H,\varepsilon})^* P_t^\varepsilon + P_t^\varepsilon (A_t + C_t \dot{W}_t^{H,\varepsilon}) \\ \qquad\qquad + Q_t - P_t^\varepsilon B_t R_t^{-1} B_t^* P_t^\varepsilon\big] dt - \Lambda_t^\varepsilon dW_t = 0, \\ P_T^\varepsilon = G. \end{cases} \tag{5.13}$$

Arranging this equation properly, we get

$$\begin{cases} dP_t^\varepsilon + (A_t^* P_t^\varepsilon + P_t^\varepsilon A_t + Q_t - P_t^\varepsilon B_t R_t^{-1} B_t^* P_t^\varepsilon)dt - \Lambda_t^\varepsilon dW_t + C_t^* P_t^\varepsilon \dot{W}_t^{H,\varepsilon} dt \\ \qquad + P_t^\varepsilon C_t \dot{W}_t^{H,\varepsilon} dt = 0, \\ P_T^\varepsilon = G. \end{cases} \tag{5.14}$$

A (formal) limiting equation of (5.14) is exactly Riccati equation (5.3) introduced earlier. It should be noted that it is hard to prove the convergence of (5.14). Fortunately, once we have obtained the Riccati equation, albeit formally, we can then use the completion-of-square technique to solve the original control problem, as shown in the previous subsection.

It is also worth noting the difficulty in dealing with the controlled system

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)dt + (C_t x_t + D_t u_t) \circ dW_t^H, \\ x_0 \in \mathbb{R}^n \qquad \text{given and deterministic} \end{cases} \tag{5.15}$$

instead of (5.1). Going through the same approximation procedure as above, we get that (5.13) now becomes

$$\begin{aligned} dP^\varepsilon + \Big[(A_t + C_t\dot{W}_t^{H,\varepsilon})^* P_t^\varepsilon + P_t^\varepsilon (A_t + C_t \dot{W}_t^{H,\varepsilon}) + Q_t\Big] dt \\ - P_t^\varepsilon (B_t + D_t W_t^{H,\varepsilon}) R_t^{-1} (B_t + D_t W_t^{H,\varepsilon})^* P_t^\varepsilon dt - \Lambda_t^\varepsilon dW_t = 0. \end{aligned}$$

Rearranging, we have

$$\begin{aligned} dP_t^\varepsilon &+ \left[A_t^* P_t^\varepsilon + P_t^\varepsilon A_t + Q_t - P_t^\varepsilon (B_t + D_t W_t^{H,\varepsilon}) R_t^{-1} (B_t + D_t W_t^{H,\varepsilon})^* P_t^\varepsilon\right] dt \\ &-\Lambda_t^\varepsilon dW_t + C_t^* P_t^\varepsilon \dot{W}_t^{H,\varepsilon} dt + P_t^\varepsilon C_t \dot{W}_t^{H,\varepsilon} dt \\ &-P_t^\varepsilon D_t R_t B_t^* P_t^\varepsilon \dot{W}_t^{H,\varepsilon} - P_t^\varepsilon B_t R_t D_t^* P_t^\varepsilon \dot{W}_t^{H,\varepsilon} - P_t^\varepsilon D_t R_t^{-1} D_t P_t^\varepsilon (\dot{W}_t^{H,\varepsilon})^2 dt = 0. \end{aligned}$$

When $D_t \not\equiv 0$, the term $(\dot{W}_t^{H,\varepsilon})^2 dt$ presents, whose limit does not exist. This explains the difficulty of studying the case when $D_t \not\equiv 0$.

Let us conclude this section by remarking again that the discussion in this section, to some extent, is rather formal, in the sense that Theorem 5.1 depends upon the existence of a solution to Riccati equation (5.3) along with some required (very technical) conditions of the solution. Nevertheless, the highlight of this section is indeed the introduction of the new equation (5.3), which is a highly unconventional BSDE involving stochastic integrals with respect to both the normal and fractional Brownian motions. Research on this type of equation, we believe, will prove to be very interesting and challenging from both the BSDE and fractional analysis points of view.

6. Concluding remarks. In this paper we have attempted to systematically tackle an important class of stochastic control problems with linear dynamic systems involving FBM. Three specific control models have been studied. It should be noted that the results in this paper are far from complete. Indeed the paper is intended to be more inspirational—in the sense that it will inspire more research along the same line—than exhaustive and conclusive. Many interesting and challenging problems remain open. The foremost is the optimal control over the set of general controls—not necessarily that of the Markovian controls. The reason is that the FBM has long-range dependence; hence, it is natural to expect that the optimal control would not only depend on the present time, but on the past as well. In fact, we conjecture that the optimal control is generally linear but non-Markovian (in a special case, this fact has been proved in a recent paper [22]). In particular, it is interesting to seek the optimal control in the class of the controls

$$u_t = \int_0^t K(t,s) x_s ds.$$

We will study such problems in forthcoming papers.

Acknowledgments. We thank the two anonymous referees for their careful reading of an earlier version of the paper and for their constructive comments that led to an improved version. In particular, we are grateful to one of the referees for bringing the paper [22] to our attention.

STABILITY RADII OF POSITIVE LINEAR FUNCTIONAL DIFFERENTIAL EQUATIONS UNDER MULTI-PERTURBATIONS*

PHAM HUU ANH NGOC† AND NGUYEN KHOA SON‡

Abstract. We study stability radii of linear retarded systems described by general linear functional differential equations. A lower and an upper bound for the complex stability radius with respect to multi-perturbations are given. Furthermore, in some special cases concerning the structure matrices, the complex stability radius can precisely be computed via the associated transfer function. Then, the class of positive linear retarded systems is studied in detail. It is shown that for this class, complex, real and positive stability radius under multi-perturbations or multi-affine perturbations coincide and can be computed by simple formulae expressed in terms of the system matrices.

Key words. functional differential equation, retarded system, positive system, stability radius, multi-perturbation

1. Introduction.

Motivated by many application in control engineering, problems of robust stability of dynamical systems have attracted a lot of attention of researchers during the last 20 years. In the study of these problems, the notion of stability radius was proved to be a very effective tool. By definition, the stability radius of a given asymptotically stable system $\dot{x}(t) = Ax(t)$ is the *maximal* $\gamma > 0$ for which all the systems of the form

$$\dot{x}(t) = (A + D\Delta E)x(t), \qquad \|\Delta\| < \gamma$$

are asymptotically stable. Here, Δ is an unknown disturbance matrix, and D and E are given matrices defining the structure of the perturbations. Depending upon whether complex or real disturbances Δ are considered, this maximal γ is called a complex or real stability radius, respectively. The basic problem in the study of robustness of stability of the system is to characterize and compute these radii in terms of given matrices A, D, E. It is important to note that these two stability radii are in general distinct. The analysis and computation of the complex stability radius for systems under structured perturbations has been done first in [6] and extended later in many subsequent papers (see [7] for a survey up to 1990) while the computation of the real stability radius, being a much more difficult problem, has been solved only recently; see, e.g., [17].

The situation is much simpler for the class of positive systems. It has been shown in [19] that if A is a Metzler matrix (i.e., all off-diagonal entries of A are nonnegative) and D, E are nonnegative matrices, then the complex and the real stability radii coincide and can be computed directly by a simple formula. These results have been extended quite recently to infinite-dimensional positive systems in [3], [4], to positive

continuous time-delay systems in [21], [22], [23] and to discrete time-delay systems in [15], [10].

It is worth noticing that the notion of stability radius can be extended to various perturbation types [7]. Among perturbation types, two of the following perturbation types

$$A \to A + \sum_{i=1}^{N} D_i \Delta_i E_i \qquad \text{(multi-perturbation)}, \tag{1}$$

$$A \to A + \sum_{i=1}^{N} \delta_i A_i \qquad \text{(multi-affine perturbation)} \tag{2}$$

are most well known in control theory and include perturbation types studied in the literature. However, so far, the problem of finding computable formulas for stability radii of the linear systems $\dot{x}(t) = Ax(t),\ t \geq 0;\ x(k+1) = Ax(k),\ k \in \mathbb{N}$, under multi-perturbations still remains open; see, e.g., [8], [9]. In these papers, for multi-perturbations (1), only lower bounds for the real stability radius were obtained. In the literature, there are no results available on the computation of stability radii for this case.

The main purpose of this paper is to develop a framework for studying stability radii of general retarded systems described by linear functional differential equations of the form

$$\dot{x}(t) = A_0 x(t) + \int_{-h}^{0} d[\eta(\theta)] x(t+\theta)$$

under multi-perturbations (1), multi-affine perturbations (2), and to establish the previous results in this more general situation. Formulae will be derived for the stability radii of these general systems in terms of coefficient matrices appearing in the initial system equations.

The organization of the paper is as follows. In the next section, we summarize some notations and preliminary results which will be used in what follows. In section 3, a lower and an upper bound for the complex stability radius with respect to multi-perturbations are given. Furthermore, in some special cases concerning the structure matrices, the complex stability radius can precisely be computed via the associated transfer function. Then, for the class of positive functional differential equations it will be shown that the complex, real and positive stability radius under multi-perturbations coincide and a simple formula for their computation is established. In section 4, the class of multi-affine perturbations (which enables us to deal with diagonal disturbances) is considered and an explicit formula for computing the real stability radius of positive retarded systems is given. Two examples illustrate the obtained results.

2. Preliminaries. In this section we shall define some notations and recall some well known results which will be used in the subsequent sections. Let $\mathbb{K} = \mathbb{C}$ or $\mathbb{R}$, where $\mathbb{C}$ and $\mathbb{R}$ denote the sets of all complex and all real numbers, respectively. For an integer $l, q \geq 1, \mathbb{K}^l$ denotes the l-dimensional vector space over $\mathbb{K}$, $(\mathbb{K}^l)^*$ is its dual, and $\mathbb{K}^{l\times q}$ stands for the set of all $l \times q$-matrices with entries in $\mathbb{K}$. Inequalities between real matrices or vectors will be understood componentwise, i.e., for two real matrices $A = (a_{ij})$ and $B = (b_{ij})$ in $\mathbb{R}^{l\times q}$, we write $A \geq B$ if and only if $a_{ij} \geq b_{ij}$ for $i = 1, \ldots, l$, $j = 1, \ldots, q$. We denote by $\mathbb{R}_+^{l\times q}$ the set of all nonnegative matrices $A \geq 0$. Similar notations are adopted for vectors. For $x \in \mathbb{K}^n$ and $P \in \mathbb{K}^{l\times q}$

we define $|x| = (|x_i|)$ and $|P| = (|p_{ij}|)$. For any matrix $A \in \mathbb{K}^{n\times n}$ the *spectral radius* and *spectral abscissa* of A are denoted by $\rho(A) = \max\{|\lambda|; \lambda \in \sigma(A)\}$ and $\mu(A) = \max\{\mathrm{Re}\lambda; \lambda \in \sigma(A)\}$, where $\sigma(A) := \{s \in \mathbb{C}; \det(sI_n - A) = 0\}$ is the spectrum of A. $A \in \mathbb{R}^{n\times n}$ is called a *Metzler matrix* if all off-diagonal elements of A are nonnegative or, equivalently, $tI_n + A \geq 0$ for some $t \geq 0$. It is clear that any $A \in \mathbb{R}^{n\times n}_+$ is a Metzler matrix and, moreover, $\rho(A) = \mu(A)$.

A norm $\|\cdot\|$ on $\mathbb{K}^n$ is said to be *monotonic* if $\|x\| = \| \, |x| \, \|$ for all $x \in \mathbb{K}^n$. Every p-norm on $\mathbb{K}^n, 1 \leq p \leq \infty$, is monotonic. Throughout the paper, if not otherwise stated, the norm of a matrix $P \in \mathbb{K}^{l\times q}$ is understood as its operator norm associated with a given pair of monotonic vector norms on $\mathbb{K}^l$ and $\mathbb{K}^q$, that is, $\|P\| = \max\{\|Py\|; \ \|y\| = 1\}$. We note that the operator norm is in general not monotonic norm on $\mathbb{K}^{l\times q}$ even if $\mathbb{K}^l, \mathbb{K}^q$ are provided with monotonic norms. However, such monotonicity holds for nonnegative matrices. Moreover, we have (see, e.g., [19])

$$P \in \mathbb{K}^{l\times q}, \quad Q \in \mathbb{R}^{l\times q}_+, \quad |P| \leq Q \quad \Rightarrow \quad \|P\| \leq \| \, |P| \, \| \leq \|Q\|. \tag{3}$$

The matrix function $\eta(.) : \ [-h, 0] \to \mathbb{R}^{l\times q}$ is called a increasing matrix function if

$$\eta(\theta_2) \geq \eta(\theta_1) \quad \text{for} \quad -h \leq \theta_1 \leq \theta_2 \leq 0.$$

To make the presentation self-contained we now summarize in the following theorem some existing results on properties of Metzler matrices which will be used in what follows (see, e.g., [2], [19]).

THEOREM 2.1. *Suppose that $A \in \mathbb{R}^{n\times n}$ is a Metzler matrix. Then*

(i) (Perron–Frobenius) *$\mu(A)$ is an eigenvalue of A and there exists a nonnegative eigenvector $x \geq 0$, $x \neq 0$ such that $Ax = \mu(A)x$;*

(ii) *given $\alpha \in \mathbb{R}$, there exists a nonzero vector $x \geq 0$ such that $Ax \geq \alpha x$ if and only if $\mu(A) \geq \alpha$;*

(iii) *$(tI_n - A)^{-1}$ exists and is nonnegative if and only if $t > \mu(A)$;*

(iv) *given $B \in \mathbb{R}^{n\times n}_+$, $C \in \mathbb{C}^{n\times n}$, then*

$$|C| \leq B \quad \Longrightarrow \quad \mu(A + C) \leq \mu(A + B). \tag{4}$$

A matrix function $\eta(\cdot) : [\alpha, \beta] \to \mathbb{K}^{m\times n}$ is said to be of bounded variation if

$$\mathrm{Var}(\eta; \alpha, \beta) := \sup_{P[\alpha,\beta]} \sum_k \|\eta(\theta_k) - \eta(\theta_{k-1})\| < +\infty, \tag{5}$$

where the supremum is taken over the set of all finite partitions of the interval $[\alpha, \beta]$. The set $BV([\alpha, \beta], \mathbb{K}^{m\times n})$ of all matrix functions $\eta(\cdot)$ of bounded variation on $[\alpha, \beta]$ satisfying $\eta(\alpha) = 0$ is a Banach space endowed with the norm $\|\eta\| = \mathrm{Var}(\eta; \alpha, \beta)$. Since all matrix norms on $\mathbb{K}^{m\times n}$ are equivalent, it follows that the matrix function $\eta(\cdot) = (\eta_{ij}(\cdot)) \in \mathbb{K}^{m\times n}$ is of bounded variation if and only if each $\eta_{ij}(\cdot)$ is of bounded variation. Moreover, it is easy to show that if $\mathbb{K}^{m\times n}$ is provided with ∞-norm, then

$$\max_{1\leq i\leq m} \sum_{j=1}^{n} \mathrm{Var}(\eta_{ij}; \alpha, \beta) \leq \|\eta\| = \mathrm{Var}(\eta; \alpha, \beta) \leq \sum_{i=1}^{m} \sum_{j=1}^{n} \mathrm{Var}(\eta_{ij}; \alpha, \beta). \tag{6}$$

Given $\eta(\cdot) \in BV([\alpha,\beta],\mathbb{K}^{m\times n})$ then for any continuous functions $\gamma \in C([\alpha,\beta],\mathbb{K})$ and $\phi \in C([\alpha,\beta],\mathbb{K}^n)$, the integrals

$$\int_\alpha^\beta \gamma(\theta)d[\eta(\theta)] \quad \text{and} \quad \int_\alpha^\beta d[\eta(\theta)]\phi(\theta)$$

exist and are defined, respectively, as the limits of $S_1(P) := \sum_{k=1}^p \gamma(\zeta_k)(\eta(\theta_k) - \eta(\theta_{k-1}))$ and $S_2(P) := \sum_{k=1}^p (\eta(\theta_k) - \eta(\theta_{k-1}))\phi(\zeta_k)$ as $d(P) := \max_k |\theta_k - \theta_{k-1}| \to 0$, where $P = \{\theta_1 = \alpha \le \theta_2 \le \cdots \le \theta_p = \beta\}$ is any finite partition of the interval $[\alpha,\beta]$ and $\zeta_k \in [\theta_{k-1},\theta_k]$. It is immediate from the definition that

$$\begin{aligned} \left\| \int_\alpha^\beta \gamma(\theta)d[\eta(\theta)] \right\| &\le \max_{\theta\in[\alpha,\beta]} |\gamma(\theta)|\,\|\eta\|, \\ \left\| \int_\alpha^\beta d[\eta(\theta)]\phi(\theta) \right\| &\le \max_{\theta\in[\alpha,\beta]} \|\phi(\theta)\|\,\|\eta\|. \end{aligned} \tag{7}$$

Let $\mathbb{K}^n$ be endowed with a vector norm $\|\cdot\|$ and $C([-h,0],\mathbb{K}^n)$ be a Banach space of all continuous functions on $[-h,0]$ with values in $\mathbb{K}^n$ normed by the maximum norm $\|\phi\| = \max_{\theta\in[-h,0]} \|\phi(\theta)\|$. Let $L : C([-h,0],\mathbb{K}^n) \to \mathbb{K}^n$ be a linear bounded operator. Then, by the Riesz representation theorem, there exists unique matrix function $\eta = (\eta_{ij}(\cdot)) \in BV([-h,0],\mathbb{K}^{n\times n})$ which is *continuous from the left* (or briefly c.f.l.) on $(-h,0)$ such that

$$L\phi = \int_{-h}^0 d[\eta(\theta)]\phi(\theta) \qquad \forall \phi \in C([-h,0],\mathbb{K}^n). \tag{8}$$

For any vector norm on $\mathbb{K}^n$, we have by (7), $\|L\| \le \|\eta\|$. Moreover, if $\mathbb{K}^n$ is provided with the ∞-norm so that for all $x \in \mathbb{K}^n$ and $\theta \in [-h,0]$,

$$\|x\| = \max_{1\le i\le n} |x_i| \quad \text{and} \quad \|\eta(\theta)\| = \max_{1\le i\le n} \sum_{j=1}^n |\eta_{ij}(\theta)|,$$

then it can be shown immediately that $\|L\| = \|\eta\|$. In the subsequent sections the following subspace of $BV([-h,0],\mathbb{K}^{m\times n})$ will be used frequently :

$$NBV([-h,0],\mathbb{K}^{m\times n}) := \{\eta \in BV([-h,0],\mathbb{K}^{m\times n}); \eta(-h) = 0, \eta \text{ is c.f.l. on } [-h,0]\}. \tag{9}$$

It is clear that $NBV([-h,0],\mathbb{K}^{m\times n})$ is closed in $BV([-h,0],\mathbb{K}^{m\times n})$ and thus it is a Banach space with the norm $\|\delta\| = \mathrm{Var}(\delta;-h,0)$.

3. Stability radii of linear functional differential equations under multi-perturbations. Consider a linear retarded system described by the following general functional differential equation:

$$\begin{aligned} \dot{x}(t) &= A_0x(t) + Lx_t, \quad t \ge 0, \quad x(t) \in \mathbb{R}^n, \\ x(\theta) &= \phi_0(\theta), \qquad \theta \in [-h,0], \end{aligned} \tag{10}$$

where, for each $t \ge 0, x_t \in C([-h,0],\mathbb{R}^n)$ is defined by $x_t(\theta) = x(t+\theta), \theta \in [-h,0], A_0 \in \mathbb{R}^{n\times n}$ is a given matrix and $L : C([-h,0],\mathbb{R}^n) \to \mathbb{R}^n$ is a linear bounded operator defined by

$$L\phi = \int_{-h}^0 d[\eta(\theta)]\phi(\theta), \quad t \ge 0, \quad \phi \in C([-h,0],\mathbb{R}^n), \tag{11}$$

where $\eta(\cdot) \in NBV([-h,0],\mathbb{R}^{n\times n})$ is given (real $n\times n$-matrix function of bounded variation on $[-h,0]$) such that η vanishes at $-h$ and is c.f.l. on $[-h,0]$. We shall extend the definition of η to $\mathbb{R}$ by setting $\eta(\theta)=\eta(-h)=0$ for all $\theta\le -h, \eta(\theta)=\eta(0)$ for all $\theta\ge 0$.

It is well known that, for any given $\phi_0\in C:=C([-h,0],\mathbb{R}^n)$, the system (10)–(11) has a unique solution $x(\phi_0,\cdot)$ defined and continuous on $[-h,\infty)$ (see, e.g. [5]).

The system (10)–(11) is said to be exponentially asymptotically stable or, more simply, *Hurwitz stable*, if there are constants $c>0,\alpha>0$ such that for all $\phi\in C$, the solution $x(\phi,\cdot)$ of (10)–(11) satisfies

$$\|x(\phi,t)\|\le ce^{-\alpha t}\|\phi\|, \qquad t\ge 0.$$

Denote by $H(s)$ the characteristic quasi-polynomial of the system (10)–(11), that is,

$$H(s)=sI_n-A_0-\int_{-h}^{0}e^{s\theta}d[\eta(\theta)]. \tag{12}$$

Then the necessary and sufficient condition for the system (10)–(11) to be Hurwitz stable is

$$\sigma(A_0,\eta)\subset\mathbb{C}^-:=\{s\in\mathbb{C}:\operatorname{Re}\, s<0\}, \tag{13}$$

where $\sigma(A_0,\eta)$ denotes the set of all roots of the characteristic equation of the system (10)–(11):

$$\sigma(A_0,\eta):=\{s\in\mathbb{C}:\det H(s)=0\}. \tag{14}$$

By the property of $\sigma(A_0,\eta)$ it can be shown that (13) is equivalent to the condition

$$\mu(A_0,\eta):=\max\{\operatorname{Re} s: s\in\sigma(A_0,\eta)\}<0.$$

The number $\mu(A_0,\eta)$ is called the *spectral abscissa* of the retarded system (10)–(11).

Assume that the retarded system (10)–(11) is Hurwitz stable and subjected to multi-perturbations of the type

$$\begin{aligned} A_0\to A_{0\Delta}&=A_0+\sum_{j=1}^{N}D_{0j}\Delta_jE_{0j},\quad \Delta_j\in\mathbb{C}^{l_{0j}\times q_{0j}},\quad j\in\underline{N}:=\{1,2,\dots,N\},\\ \eta\to\eta_\delta&=\eta+\sum_{j=1}^{N}D_{1j}\delta_jE_{1j},\quad \delta_j\in NBV([-h,0],C^{l_{1j}\times q_{1j}}),\quad j\in\underline{N}, \end{aligned} \tag{15}$$

and thus the perturbed system is described by

$$\begin{aligned} \dot x(t)=&\left(A_0+\sum_{j=1}^{N}D_{0j}\Delta_jE_{0j}\right)x(t)+\int_{-h}^{0}d\left[\eta(\theta)+\sum_{j=1}^{N}D_{1j}\delta_j(\theta)E_{1j}\right]x(t+\theta),\quad t\ge 0,\\ &x(\theta)=\phi_0(\theta),\qquad \theta\in[-h,0]. \end{aligned} \tag{16}$$

Here $D_{ij}\in\mathbb{C}^{n\times l_{ij}}, E_{ij}\in\mathbb{C}^{q_{ij}\times n}, i\in I:=\{0,1\}, j\in\underline{N}$ are given matrices determining the *structure* of perturbations, Δ_j and $\delta_j(\cdot), j\in\underline{N}$ are unknown disturbances. We always assume that each disturbance matrix function $\delta_j(\cdot)$ is extended to the whole

$\mathbb{R}$ by $\delta_j(\theta) = \delta_j(-h) = 0$ for $\theta \le -h$, $\delta_j(\theta) = \delta_j(0)$ for $\theta > 0$. We shall measure the size of each perturbation $\tilde{\Delta} := [\Delta, \delta]$, where

$$\Delta := (\Delta_1, \dots, \Delta_N),$$
$$\delta := (\delta_1, \dots, \delta_N), \quad \Delta_j \in \mathbb{C}^{l_{0j} \times q_{0j}}, \quad \delta_j \in NBV([-h, 0], \mathbb{C}^{l_{1j} \times q_{1j}}), \quad j \in \underline{N},$$

by the norm

$$\|\tilde{\Delta}\| := \sum_{j=1}^{N} \|\Delta_j\| + \sum_{j=1}^{N} \|\delta_j\|, \quad \|\delta_j\| := \operatorname{Var}(\delta_j; -h, 0), \quad j \in \underline{N}. \tag{17}$$

Set

$$\mathcal{D}_{\mathbb{C}} := \{\tilde{\Delta} = [\Delta, \delta] : \Delta_j \in \mathbb{C}^{l_{0j} \times q_{0j}}, \quad \delta_j \in NBV([-h, 0], \mathbb{C}^{l_{1j} \times q_{1j}}), \quad j \in \underline{N}\},$$
$$\mathcal{D}_{\mathbb{R}} := \{\tilde{\Delta} = [\Delta, \delta] : \Delta_j \in \mathbb{R}^{l_{0j} \times q_{0j}}, \quad \delta_j \in NBV([-h, 0], \mathbb{R}^{l_{1j} \times q_{1j}}), \quad j \in \underline{N}\},$$
$$\mathcal{D}_{+} := \{\tilde{\Delta} = [\Delta, \delta] : \Delta_j \in \mathbb{R}_{+}^{l_{0j} \times q_{0j}}, \quad \delta_j \in NBV([-h, 0], \mathbb{R}^{l_{1j} \times q_{1j}}) \text{ is increasing}, \ j \in \underline{N}\}.$$

Then $\mathcal{D}_{\mathbb{C}}, \mathcal{D}_{\mathbb{R}}, \mathcal{D}_{+}$ are called, respectively, the *class of complex, real, nonnegative perturbations*. In what follows, we always define $\inf \emptyset = +\infty, 0^{-1} = +\infty$. To study robustness of stability of the retarded system (10)–(11) we introduce the following.

DEFINITION 3.1. *Let the retarded system* (10)–(11) *be Hurwitz stable. The complex, real and positive stability radius of the system with respect to perturbations of the form* (15)*, measured by the norm* (17)*, is defined, respectively, by*

$$r_{\mathbb{C}} = \inf\{\|\tilde{\Delta}\| \ : \ \tilde{\Delta} \in \mathcal{D}_{\mathbb{C}}, \ \sigma(A_{0\Delta}, \eta_\delta) \not\subset \mathbb{C}^-\}, \tag{18}$$

$$r_{\mathbb{R}} = \inf\{\|\tilde{\Delta}\| \ : \ \tilde{\Delta} \in \mathcal{D}_{\mathbb{R}}, \ \sigma(A_{0\Delta}, \eta_\delta) \not\subset \mathbb{C}^-\}, \tag{19}$$

and

$$r_{+} = \inf\{\|\tilde{\Delta}\| \ : \ \tilde{\Delta} \in \mathcal{D}_{+}, \ \sigma(A_{0\Delta}, \eta_\delta) \not\subset \mathbb{C}^-\}. \tag{20}$$

REMARK 3.2. (a) *It is important to note that we can consider the above problem with respect to the multi-perturbations of the form*

$$A_0 \to A_{0\Delta} = A_0 + \sum_{j=1}^{N_1} D_{0j} \Delta_j E_{0j}, \quad \Delta_j \in \mathbb{C}^{l_{0j} \times q_{0j}}, \quad j \in \underline{N}_1 := \{1, \dots, N_1\}, \tag{21}$$

$$\eta \to \eta_\delta = \eta + \sum_{j=1}^{N_2} D_{1j} \delta_j E_{1j}, \quad \delta_j \in NBV([-h, 0], \mathbb{C}^{l_{1j} \times q_{1j}}), \quad j \in \underline{N}_2 := \{1, \dots, N_2\}.$$

However, if, for instance, $N_1 > N_2$, then the parameter perturbations (21) *can be represented in the form* (15) *by setting D_{1j} or E_{1j} being equal to zero matrix for every $j \in \underline{N}_1, j > N_2$.*

(b) *In the particular case, if*

$$\eta(\theta) = \begin{cases} 0 & \text{if} \quad \theta = -h, \\ A_1 & \text{if} \quad \theta \in (-h, 0], \end{cases} \qquad \delta_j(\theta) = \begin{cases} 0 & \text{if} \quad \theta = -h, \\ \Delta_{1j} & \text{if} \quad \theta \in (-h, 0], \end{cases}$$

where A_1 is a given matrix and $\Delta_{1j} \in \mathbb{K}^{l_{1j}\times q_{1j}}, j \in \underline{N}, \mathbb{K} = \mathbb{R}, \mathbb{C}$ are unknown matrices then the problem of computing the stability radii of the system (10)–(11) *under multi-perturbations* (15) *returns the problem of computing the stability radii of delay-time system of the form*

$$\dot{x}(t) = A_0 x(t) + A_1 x(t-h), \qquad t \geq 0,$$

under multi-perturbations of the form

$$A_0 \to A_{0\Delta} = A_0 + \sum_{j=1}^{N} D_{0j}\Delta_{0j}E_{0j}, \quad \Delta_{0j} \in \mathbb{C}^{l_{0j}\times q_{0j}}, \quad j \in \underline{N},$$

$$A_1 \to A_{1\Delta} = A_1 + \sum_{j=1}^{N} D_{1j}\Delta_{1j}E_{1j}, \quad \Delta_{1j} \in \mathbb{C}^{l_{1j}\times q_{1j}}, \quad j \in \underline{N}, \tag{22}$$

and it has been just solved in [16].

We define the associated transfer functions $G_{(i,j;\ u,v)} : \mathbb{C}\backslash\sigma(A_0,\eta) \to \mathbb{C}^{q_{ij}\times l_{uv}}$ of the perturbed system (16) by setting

$$G_{(i,j;\ u,v)}(s) = E_{ij}H(s)^{-1}D_{uv}, \qquad i,u \in I; \quad j,v \in \underline{N}. \tag{23}$$

We need the following technical lemmas.

LEMMA 3.3 (see [23]). *Let the retarded system* (10)–(11) *be Hurwitz stable. Then, for $i,u \in I;\ j,v \in \underline{N}$, the function $s \to \|G_{(i,j;\ u,v)}(s)\|$ $(s \in \mathbb{C}, \mathrm{Re\ s} \geq 0)$ attains the supremum on $\imath\mathbb{R}$ and moreover,*

$$\max_{s\in\mathbb{C},\ \mathrm{Re}\, s\geq 0} \|G_{(i,j;\ u,v)}(s)\| = \max_{\omega\in\mathbb{R}} \|G_{(i,j;\ u,v)}(\imath\omega)\|. \tag{24}$$

LEMMA 3.4. *Let the retarded system* (10)–(11) *be Hurwitz stable. Then, for every $s_0 \in \mathbb{C}, \mathrm{Re}\ s_0 = 0$, $\max_{i\in I; j\in\underline{N}} \|G_{(i,j;\ i,j)}(s_0)\| \neq 0$, there exists a complex perturbation $\tilde{\Delta} := [\Delta, \delta]$, where $\Delta := (\Delta_1, \ldots, \Delta_N)$, $\delta := (\delta_1, \ldots, \delta_N)$, $\Delta_j \in \mathbb{C}^{l_{0j}\times q_{0j}}$, $\delta_j \in NBV([-h,0], \mathbb{C}^{l_{1j}\times q_{1j}})$, $j \in \underline{N}$ such that*

$$\|\tilde{\Delta}\| = \frac{1}{\max_{i\in I; j\in\underline{N}} \|G_{(i,j;\ i,j)}(s_0)\|} \quad \text{and} \quad \mu(A_{0\Delta}, \eta_\delta) \geq 0. \tag{25}$$

Moreover, if $G_{(i,j;\ i,j)}(0) \in {\mathbb{R}_+}^{q_{ij}\times l_{ij}}$ for every $i \in I, j \in \underline{N}$ then there exists a nonnegative perturbation $\tilde{\Delta} \in \mathcal{D}_+$ satisfying (25) *with $s_0 = 0$.*

Proof. Assume that $\max_{i\in I;\ j\in\underline{N}} \|G_{(i,j;\ i,j)}(s_0)\| = \|G_{(i_1,j_1;\ i_1,j_1)}(s_0)\|$ for some $i_1 \in I, j_1 \in \underline{N}$. From the definition of $\|G_{(i_1,j_1;\ i_1,j_1)}(s_0)\|$, there exists a vector $u_0 \in \mathbb{C}^{l_{i_1j_1}}, \|u_0\| = 1$ such that $\|G_{(i_1,j_1;\ i_1,j_1)}(s_0)u_0\| = \|G_{(i_1,j_1;\ i_1,j_1)}(s_0)\|$. Then, by the Hahn–Banach theorem, there exist $y^* \in (\mathbb{C}^{q_{i_1j_1}})^*, \|y^*\| = 1$ satisfying

$$y^*(G_{(i_1,j_1;\ i_1,j_1)}(s_0)u_0) = \|G_{(i_1,j_1;\ i_1,j_1)}(s_0)u_0\|.$$

Define $\Delta_{i_1j_1} := \|G_{(i_1,j_1;\ i_1,j_1)}(s_0)u_0\|^{-1}u_0y^* \quad \in \mathbb{C}^{l_{i_1j_1}\times q_{i_1j_1}}$. It is easy to see that $\|\Delta_{i_1j_1}\| = \|G_{(i_1,j_1;\ i_1,j_1)}(s_0)\|^{-1}$. We consider now the following step function:

$$\delta_{i_1j_1}(\theta) = \begin{cases} 0 & \text{if} \quad \theta = -h, \\ \Delta_{i_1j_1}e^{hs_0} & \text{if} \quad \theta \in (-h,0]. \end{cases}$$

It is clear that

$$\delta_{i_1j_1} \in NBV([-h,0],\mathbb{C}^{l_{i_1j_1}\times q_{i_1j_1}}), \qquad \|\delta_{i_1j_1}\| = \operatorname{Var}(\delta_{i_1j_1};-h,0) = \|\Delta_{i_1j_1}\|$$

and $\int_{-h}^{0} e^{s_0\theta} d[\delta_{i_1j_1}(\theta)] = \Delta_{i_1j_1}$. Setting $x := H(s_0)^{-1}D_{i_1j_1}u_0$, we have

$$\int_{-h}^{0} e^{s_0\theta} d[\delta_{i_1j_1}(\theta)]E_{i_1j_1}x = \Delta_{i_1j_1}E_{i_1j_1}x = u_0.$$

Therefore,

$$x = H(s_0)^{-1}D_{i_1j_1}\Delta_{i_1j_1}E_{i_1j_1}x = H(s_0)^{-1}D_{i_1j_1}\int_{-h}^{0} e^{s_0\theta} d[\delta_{i_1j_1}(\theta)]E_{i_1j_1}x \neq 0$$

and hence

$$H(s_0)x = D_{i_1j_1}\Delta_{i_1j_1}E_{i_1j_1}x = D_{i_1j_1}\int_{-h}^{0} e^{s_0\theta} d[\delta_{i_1j_1}(\theta)]E_{i_1j_1}x.$$

This implies

$$\begin{aligned}&\left(A_0 + \int_{-h}^{0} e^{s_0\theta} d[\eta(\theta)] + D_{i_1j_1}\Delta_{i_1j_1}E_{i_1j_1}\right)x\\ &\quad = \left(A_0 + \int_{-h}^{0} e^{s_0\theta} d[\eta + D_{i_1j_1}\delta_{i_1j_1}(\theta)E_{i_1j_1}]\right)x = s_0x.\end{aligned}$$

If $i_1 = 0$, then we define $\tilde{\Delta} := [\Delta,\delta] = ((\Delta_1,\dots,\Delta_N),(\delta_1,\dots,\delta_N))$, where $\Delta_j = \Delta_{i_1j_1}$ if $j = j_1$; otherwise $\Delta_j = 0, j \in \underline{N}$ and $\delta_j = 0$ for all $j \in \underline{N}$. Then the perturbation $\tilde{\Delta}$ satisfies (25). If $i_1 = 1$, then we define $\tilde{\Delta} := [\Delta,\delta] = ((\Delta_1,\dots,\Delta_N),(\delta_1,\dots,\delta_N))$, where $\Delta_j = 0$ for all $j \in \underline{N}$ and $\delta_j = \delta_{i_1j_1}$ if $j = j_1$ otherwise $\delta_j = 0, j \in \underline{N}$. Then we have $\tilde{\Delta}$ satisfying (25).

Moreover, if $G_{(i_1,j_1;\ i_1,j_1)}(s_0) \in \mathbb{R}_+^{q_{i_1j_1}\times l_{i_1j_1}}$ for $s_0 = 0$, then we have $\|G_{(i_1,j_1;\ i_1,j_1)}(0)\| = \max_{u\in\mathbb{R}_+^{l_{i_1j_1}},\|u\|=1}\|G_{(i_1,j_1;\ i_1,j_1)}(0)u\|$; see [11]. Thus we can choose $u_0 \in \mathbb{R}_+^{l_{i_1j_1}}$ such that $\|u_0\| = 1$ and $\|G_{(i_1,j_1;\ i_1,j_1)}(0)u_0\| = \|G_{(i_1,j_1;\ i_1,j_1)}(0)\|$. Since $G_{(i_1,j_1;\ i_1,j_1)}(0)u_0 \geq 0$ there exists by a theorem of Krein and Rutman [12] a positive linear form $y^* \in (\mathbb{C}^{q_{i_1j_1}})^*$ of dual norm $\|y^*\| = 1$ such that $y^*G_{(i_1,j_1;\ i_1,j_1)}(0)u_0 = \|G_{(i_1,j_1;\ i_1,j_1)}(0)u_0\|$. Hence the perturbation $\tilde{\Delta}$ constructed as above is nonnegative. The proof is complete. □

Using the above lemmas we obtain the following estimates for the complex radius.

THEOREM 3.5. *Let the retarded system* (10)–(11) *be Hurwitz stable and be subjected to multi-perturbations of the form* (15). *Then*

(26)
$$\frac{1}{\max_{i,u\in I;j,v\in\underline{N}}\{\max_{\omega\in\mathbb{R}}\|G_{(i,j;\,u,v)}(\imath\omega)\|\}} \leq r_{\mathbb{C}} \leq \frac{1}{\max_{i\in I;j\in\underline{N}}\{\max_{\omega\in\mathbb{R}}\|G_{(i,j;\,i,j)}(\imath\omega)\|\}}.$$

In particular, if $D_{ij} = D$ *for all* $i \in I; j \in \underline{N}$ *or* $E_{ij} = E$ *for all* $i \in I; j \in \underline{N}$, *then*

$$r_{\mathbb{C}} = \frac{1}{\max_{i\in I;j\in\underline{N}}\{\max_{\omega\in\mathbb{R}}\|G_{(i,j;\ i,j)}(\imath\omega)\|\}}. \tag{27}$$

Proof. Obviously, (27) is immediate from (26), if $D_{ij} = D$ for all $i \in I; j \in \underline{N}$ or $E_{ij} = E$ for all $i \in I; j \in \underline{N}$. Let $\tilde{\Delta} := [\Delta, \delta] = ((\Delta_1, \dots, \Delta_N), (\delta_1, \dots, \delta_N)), \Delta_j \in \mathbb{C}^{l_{0j} \times q_{0j}}$, $\delta_j \in NBV([-h, 0], \mathbb{C}^{l_{1j} \times q_{1j}})$, $j \in \underline{N}$ be destabilizing disturbances, so that $\sigma(A_{0\Delta}, \eta_\delta) \not\subset \mathbb{C}^-$. It follows that there exist a nonzero $x_0 \in \mathbb{C}^n$ and $s_0 \in \mathbb{C}, \operatorname{Re} s_0 \geq 0$ such that

$$\left(s_0 I_n - \left(A_0 + \sum_{j=1}^{N} D_{0j}\Delta_j E_{0j}\right) - \int_{-h}^{0} e^{s_0\theta} d\left[\eta(\theta) + \sum_{j=1}^{N} D_{1j}\delta_j(\theta)E_{1j}\right]\right)x_0 = 0.$$

This implies

$$H(s_0)x_0 = \left(\sum_{j=1}^{N} D_{0j}\Delta_j E_{0j} + \int_{-h}^{0} e^{s_0\theta} d\left[\sum_{j=1}^{N} D_{1j}\delta_j(\theta)E_{1j}\right]\right)x_0$$

or, equivalently,

$$x_0 = H(s_0)^{-1}\left(\sum_{j=1}^{N} D_{0j}\Delta_j E_{0j} + D_{1j}\int_{-h}^{0} e^{s_0\theta} d\left[\sum_{j=1}^{N} \delta_j(\theta)\right]E_{1j}\right)x_0.$$

Let $i_0 \in I, j_0 \in \underline{N}$ be indexes such that $\|E_{i_0 j_0} x_0\| = \max\{\|E_{ij}x_0\| : i \in I, j \in \underline{N}\}$ then from the last equality it follows that $E_{i_0 j_0} x_0 \neq 0$. Multiplying the last equation with $E_{i_0 j_0}$ from the left we can deduce

$$\sum_{j=1}^{N}\left(\|E_{i_0 j_0}H(s_0)^{-1}D_{0j}\|\|\Delta_j\| + \|E_{i_0 j_0}H(s_0)^{-1}D_{1j}\|\|\int_{-h}^{0} e^{s_0\theta} d[\delta_j(\theta)]\|\right) \geq 1. \tag{28}$$

Since, by (7), $\|\int_{-h}^{0} e^{s_0\theta} d[\delta_j(\theta)]\| \leq \|\delta_j\|, j \in \underline{N}$, (28) yields

$$\begin{aligned}&(\max_{i,u\in I;\ j,v\in\underline{N}} \|G_{(i,j;\ u,v)}(s_0)\|)\sum_{j=1}^{N}(\|\Delta_j\| + \|\delta_j\|)\\ &\quad = (\max_{i,u\in I;\ j,v\in\underline{N}} \|G_{(i,j;\ u,v)}(s_0)\|)\|\tilde{\Delta}\| \geq 1,\end{aligned}$$

and thus

$$\|\tilde{\Delta}\| \geq \frac{1}{\max_{i,u\in I;\, j,v\in\underline{N}} \|G_{(i,j;\,u,v)}(s_0)\|} \geq \frac{1}{\max_{i,u\in I;\, j,v\in\underline{N}}\{\max_{s\in\mathbb{C},\operatorname{Re} s\geq 0} \|G_{(i,j;\,u,v)}(s)\|\}}.$$

Therefore, by Lemma 3.3 and Definition 3.5, we have

$$r_{\mathbb{C}} \geq \frac{1}{\max_{i,u\in I;j,v\in\underline{N}}\{\max_{\omega\in\mathbb{R}} \|G_{(i,j;\ u,v)}(\imath\omega)\|\}}.$$

It remains to prove that

$$r_{\mathbb{C}} \leq \frac{1}{\max_{i,u\in I;j,v\in\underline{N}}\{\max_{\omega\in\mathbb{R}} \|G_{(i,j;\ u,v)}(\imath\omega)\|\}}.$$

However, this inequality follows from Lemma 3.4 and the definition of $r_{\mathbb{C}}$. This completes our proof. ∎

The above theorem includes, as a particular case, the results of Theorem 1 in [20] and of Theorem 3.3 in [23] where the formulae for complex stability radii of the linear retarded systems under single perturbations (i.e., $N = 1$) are established. The problem of computation of the real stability radius $r_{\mathbb{R}}$ is much more difficult and has been so far solved only for ordinary linear systems of the form $\dot{x}(t) = A_0x(t),\ t \geq 0$, where the system matrix A_0 is subjected to single perturbations; see, e.g., [17]. We note that, by definition, $r_{\mathbb{C}} \leq r_{\mathbb{R}}$, so $r_{\mathbb{C}}$ can be accepted as the lower bound for $r_{\mathbb{R}}$. Unfortunately, as shown in many previous papers (see, e.g., [7]) these two stability radii can be arbitrarily distinct. Therefore, it is an interesting problem to find classes of systems of practical interest for which these two stability radii coincide. Motivated by the results of [8], [9], [21], [22], [23], in this section we show that for the class of positive functional differential equations, the positive, real and complex stability radius under multi-perturbations coincide and can be computed by a simple formula.

Consider a linear system described by the functional differential equation of the form

$$\begin{aligned} \dot{x}(t) &= A_0x(t) + \int_{-h}^{0} d[\eta(\theta)]x(t+\theta) \quad t \geq 0, \quad x(t) \in \mathbb{R}^n, \\ x(\theta) &= \phi_0(\theta), \qquad \theta \in [-h, 0], \end{aligned} \tag{29}$$

where $\phi_0(\cdot) \in C([-h, 0], \mathbb{R}^n)$ is given and $\eta \in NBV([-h, 0], \mathbb{R}^{n\times n})$ being a given function of bounded variation such that $\eta(-h) = 0$ and η is c.f.l. on $[-h, 0]$. The solution of the system (29) will be denoted by $x(\phi_0, \cdot)$.

Definition 3.6. *System* (29) *is called positive if for every nonnegative initial function* $\phi_0 \in C([-h, 0], \mathbb{R}^n_+)$, *the corresponding solution* $x(\phi_0, \cdot)$ *satisfies* $x(\phi_0, t) \in \mathbb{R}^n_+$ *for every* $t \geq 0$.

The following theorem is a corollary of Proposition 3.5 in [14, p. 224].

Theorem 3.7 (see [23]). *The system* (29) *is positive if and only if* $A_0 \in \mathbb{R}^{n\times n}$ *is a Metzler matrix and* $\eta(.) \in NBV([-h, 0], \mathbb{R}^{n\times n})$ *is an increasing matrix function.*

From Theorem 3.7 it is easy to see that the linear retarded system of the form

$$\dot{x}(t) = A_0x(t) + A_1x(t-h), \qquad t \geq 0$$

is positive if and only if A_0 is a Metzler matrix and $A_1 \geq 0$.

In order to give characterization of the real stability radius of the positive systems, we need some technical lemmas. Define, for each $s \in \mathbb{C}$,

$$Q(s) = \int_{-h}^{0} e^{s\theta} d[\eta(\theta)].$$

Then, it follows from $\eta(.)$ to be an increasing matrix function that, for any $s \in \mathbb{C}$ and $x \in \mathbb{C}^n$,

$$|Q(s)x| = \left|\left(\int_{-h}^{0} e^{s\theta} d[\eta(\theta)]\right)x\right| \leq \left(\int_{-h}^{0} e^{\theta \operatorname{Re} s} d[\eta(\theta)]\right)|x| = Q(\operatorname{Re} s)|x|. \tag{30}$$

Lemma 3.8 (see [23]). *Assume* $A_0 \in \mathbb{R}^{n\times n}$ *a Metzler matrix and* $\eta(.) \in NBV([-h, 0], \mathbb{R}^{n\times n})$ *is an increasing matrix function. Let* $\mu_0 := \mu(A_0, \eta)$ *be the spectral abscissa of the delay system* (29) *and* $\mu_1 := \mu(A_0 + Q(\mu_0))$ *be the spectral abscissa of the matrix* $A_0 + Q(\mu_0)$. *Then we have*

$$\mu_0 = \mu_1.$$

LEMMA 3.9 (see [23]). *Let A_0 be a Metzler matrix and $\eta(\cdot) \in NBV([-1,0],\mathbb{R}^{n\times n})$ be an increasing matrix function. Then*

(i) *with the characteristic quasi-polynomial of the system* (29) *$H(s)$ defined by* (12)*, we have*

$$H(t_1)^{-1} \geq H(t_2)^{-1} \geq 0 \quad for \quad t_2 > t_1 > \mu(A_0,\eta); \tag{31}$$

(ii) *assume that the linear system* (29) *is Hurwitz stable and $D_{uv} \in \mathbb{R}_+^{n\times l_{uv}}, E_{ij} \in \mathbb{R}_+^{q_{ij}\times n}$ for some $i,u \in I; j,v \in \underline{N}$ and the transfer function $G_{(i,j;\ u,v)}(\cdot)$ is defined by* (23)*. Then*

$$\max_{\omega\in\mathbb{R}} \|G_{(i,j;\ u,v)}(\imath\omega)\| = \|G_{(i,j;\ u,v)}(0)\|. \tag{32}$$

We are now in position to prove the main result of this section.

THEOREM 3.10. *Let the linear retarded system* (29) *be positive and Hurwitz stable. Assume A_0,η are subjected to multi-perturbation of the form* (15)*, where $D_{ij} \in \mathbb{R}_+^{n\times l_{ij}}$, $E_{ij} \in \mathbb{R}_+^{q_{ij}\times n}$, $i \in I, j \in \underline{N}$. If $D_{ij} = D$ for all $i \in I, j \in \underline{N}$ or $E_{ij} = E$ for all $i \in I, j \in \underline{N}$, then we have*

$$r_{\mathbb{C}} = r_{\mathbb{R}} = r_+ = \frac{1}{\max_{i\in I, j\in\underline{N}} \|G_{(i,j;\ i,j)}(0)\|}.$$

Proof. From (27) and (32),

$$r_{\mathbb{C}} = \frac{1}{\max_{i\in I, j\in\underline{N}} \|G_{(i,j;\ i,j)}(0)\|}. \tag{33}$$

Since the system (29) is Hurwitz stable, positive, and $D_{ij} \in \mathbb{R}_+^{n\times l_{ij}}, E_{ij} \in \mathbb{R}_+^{q_{ij}\times n}, i \in I, j \in \underline{N}$, it follows from (31) that $G_{(i,j;\ i,j)}(0) \in \mathbb{R}_+^{q_{ij}\times l_{ij}}$ for all $i \in I, j \in \underline{N}$. By definition of r_+ and Lemma 3.4, we get

$$r_+ \leq \frac{1}{\max_{i\in I, j\in\underline{N}} \|G_{(i,j;\ i,j)}(0)\|}. \tag{34}$$

It follows from (33), (34), and the inequalities $r_{\mathbb{C}} \leq r_{\mathbb{R}} \leq r_+$ that

$$r_{\mathbb{C}} = r_{\mathbb{R}} = r_+ = \frac{1}{\max_{i\in I, j\in\underline{N}} \|G_{(i,j;\ i,j)}(0)\|}. \qquad \square$$

We illustrate the above result by two following simple examples.

Example 3.11. Consider a positive linear time-delay system described by the following scalar equation:

$$\dot{x}(t) = -x(t) + \int_{-1}^{0} e^{\theta} x(t+\theta) d\theta \quad t \geq 0, \quad x(t) \in \mathbb{R}. \tag{35}$$

It is easy to see that (35) can be represented of the form (29), with $\eta = e^{\theta} - e^{-1}$. Clearly, $\eta \in NBV([-1,0],\mathbb{R})$ and it is an increasing function on $[-1,0]$. Then, the characteristic quasi-polynomial of (35) is given by

$$H(s) = s + 1 - \int_{-1}^{0} e^{s\theta} d[\eta(\theta)] = s + 1 - \int_{-1}^{0} e^{(s+1)\theta} d\theta. \tag{36}$$

Therefore, $H(s) = 0$ if and only if $(s^2 + 2s)e^s + e^{-1} = 0$. By Theorem 13.9 in [1], it is easy to verify that all roots of this equation have negative real parts. Thus, the system (35) is Hurwitz stable. Assume the system (35) is perturbed as follows:

$$\dot{x}(t) = (-1 + \delta_0)x(t) + \int_{-1}^{0} (e^{\theta} + 2003\Delta_1(\theta) + 2002\Delta_2(\theta))x(t+\theta)d\theta, \tag{37}$$

where $\delta_0 \in \mathbb{R}$ is an unknown parameter scalar and $\Delta_1(\theta), \Delta_2(\theta)$ are unknown integrable functions on $[-1, 0]$. This perturbed system can be rewritten in the form

$$\dot{x}(t) = (-1 + \delta_0)x(t) + \int_{-1}^{0} d[\eta(\theta) + 2003\delta_1(\theta) + 2002\delta_2(\theta)]x(t+\theta), \tag{38}$$

where

$$\delta_1(\theta) = \int_{-1}^{\theta} \Delta_1(\tau)d\tau, \quad \delta_2(\theta) = \int_{-1}^{\theta} \Delta_2(\tau)d\tau, \quad \theta \in [-1, 0].$$

By Theorem 3.10, we conclude that the perturbed system (37) is Hurwitz stable for all $\delta_0 \in \mathbb{R},\ \Delta_1(\cdot),\ \Delta_2(\cdot) \in L_1([-1, 0], \mathbb{R})$ satisfying

$$|\delta_0| + V_{-1}^0(\delta_1) + V_{-1}^0(\delta_2) = |\delta_0| + \int_{-1}^{0} |\Delta_1(\theta)|d\theta + \int_{-1}^{0} |\Delta_2(\theta)|d\theta < r_{\mathbb{R}} = \frac{1}{2003e}.$$

On the other hand, if we take the perturbation $\delta_0 = 0,\ \Delta_1(\theta) = \frac{1-e^{\theta}}{2003},\ \Delta_2(\theta) = 0,\ \theta \in [-1, 0]$, then the perturbed system becomes

$$\dot{x}(t) = -x(t) + \int_{-1}^{0} x(t+\theta)d\theta, \quad t \geq 0, \quad x(t) \in \mathbb{R}$$

for which the characteristic quasi-polynomial is

$$H(s) = s + 1 - \int_{-1}^{0} e^{s\theta}d\theta.$$

Since, clearly, $H(0) = 0$ it follows that the perturbed system is not Hurwitz stable. Note that

$$|\delta_0| + V_{-1}^0(\delta_1) + V_{-1}^0(\delta_2) = \int_{-1}^{0} |\Delta_1(\theta)|d\theta = \frac{1}{2003e} = r_{\mathbb{R}}.$$

Example 3.12. Consider the positive linear delay system

$$\dot{x}(t) = A_0x(t) + A_1x(t-1), \qquad t \geq 0,$$

where

$$A_0 = \begin{bmatrix} -1 & 1 \\ 0 & -2 \end{bmatrix}, \qquad A_1 = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.$$

Then the characteristic equation of the system is

$$e^s(s^2 + 3s + 2) - 1 = 0.$$

By Theorem 3.9 in [1] this equation has only roots with negative real parts. Therefore, the above delay system is Hurwitz stable. Suppose the system matrices A_0, A_1 are subjected to parameter perturbations of the form

$$A_0 \to A_0 + D_{01}\Delta_{01}E_{01} + D_{02}\Delta_{02}E_{02},$$
$$A_1 \to A_1 + D_{11}\Delta_{11}E_{11} + D_{12}\Delta_{12}E_{12},$$

where

$$E_{01} = E_{02} = E_{11} = E_{12} = I_2,$$

$$D_{01} = \begin{bmatrix}1\\0\end{bmatrix}, \quad D_{02} = \begin{bmatrix}1 & 1\\0 & 1\end{bmatrix}, \quad D_{11} = \begin{bmatrix}0\\1\end{bmatrix}, \quad D_{12} = \begin{bmatrix}1 & 0\\1 & 1\end{bmatrix},$$

$\Delta_{01},\ \Delta_{11} \in \mathbb{K}^{1\times 2},\ \Delta_{02},\ \Delta_{12} \in \mathbb{K}^{2\times 2},\ \mathbb{K} = \mathbb{R}, \mathbb{C}.$

Then we get

$$G_{(0,1;\ 0,1)}(0) = (-A_0 - A_1)^{-1} D_{01} = \begin{bmatrix}2 & 1\\1 & 1\end{bmatrix}\begin{bmatrix}1\\0\end{bmatrix} = \begin{bmatrix}2\\1\end{bmatrix},$$

$$G_{(0,2;\ 0,2)}(0) = (-A_0 - A_1)^{-1} D_{02} = \begin{bmatrix}2 & 1\\1 & 1\end{bmatrix}\begin{bmatrix}1 & 1\\0 & 1\end{bmatrix} = \begin{bmatrix}2 & 3\\1 & 2\end{bmatrix},$$

$$G_{(1,1;\ 1,1)}(0) = (-A_0 - A_1)^{-1} D_{11} = \begin{bmatrix}2 & 1\\1 & 1\end{bmatrix}\begin{bmatrix}0\\1\end{bmatrix} = \begin{bmatrix}1\\1\end{bmatrix},$$

$$G_{(1,2;\ 1,2)}(0) = (-A_0 - A_1)^{-1} D_{12} = \begin{bmatrix}2 & 1\\1 & 1\end{bmatrix}\begin{bmatrix}1 & 0\\1 & 1\end{bmatrix} = \begin{bmatrix}3 & 1\\2 & 1\end{bmatrix}.$$

Therefore, if $\mathbb{R}^2$ is endowed with, respectively, with the 1-norm, 2-norm, ∞-norm, then by Theorem 3.10, the perturbed system

$$\dot{x}(t) = \left(A_0 + \sum_{j=1}^{2} D_{0j}\Delta_{0j}E_{0j}\right)x(t) + \left(A_1 + \sum_{j=1}^{2} D_{1j}\Delta_{1j}E_{1j}\right)x(t-1), \qquad t \geq 0,$$

remains Hurwitz stable for all $\Delta_{ij}, i \in \{0,1\}; j \in \{1,2\}$ satisfying

$$\sum_{i=0}^{1}\sum_{j=1}^{2} \|\Delta_{ij}\| < \frac{1}{5}, \quad \frac{1}{\sqrt{9+\sqrt{80}}}, \quad \frac{1}{5}, \text{ respectively.}$$

On the other hand, if, for instance, $\mathbb{R}^2$ is endowed with 1-norm then the destabilizing perturbation of minimal size $\sum_{i=0}^{1}\sum_{j=1}^{2} \|\Delta_{ij}\| = \frac{1}{5}$ is given by $\Delta := (\Delta_{01}, \Delta_{02}, \Delta_{11}, \Delta_{12})$, where $\Delta_{01} = (0,0), \Delta_{02} = \left[\begin{smallmatrix}0 & 0\\ \frac{1}{5} & \frac{1}{5}\end{smallmatrix}\right], \Delta_{11} = (0,0), \Delta_{12} = \left[\begin{smallmatrix}0 & 0\\ 0 & 0\end{smallmatrix}\right]$.

4. Stability radii of positive linear functional differential equations under multi-affine perturbations. In this section we study the robust stability of the positive system (29) where A_0, η are subjected to multi-affine perturbations of the following form:

$$\begin{aligned} A_0 &\to A_0 + \sum_{i=1}^{N_0} \alpha_i A_i, \\ \eta &\to \eta + \sum_{j=1}^{N_1} \beta_j \eta_j, \end{aligned} \tag{39}$$

where $A_i \in \mathbb{R}^{n\times n}, \eta_j \in NBV([-h,0],\mathbb{R}^{n\times n})$ are given and $\alpha_i, \beta_j \in \mathbb{C}$ are unknown scalar parameters. We note that the class of multi-affine perturbations of this type has been considered first in [8], [9], [18] for positive linear systems with no time delays and has just extended to positive time-delay systems in [22], [10]. In this section, we extend these results to general functional differential equations.

As in the previous section, we assume that A_0 is a Metzler matrix and $\eta \in NBV([-h,0],\mathbb{R}^{n\times n})$ is an increasing matrix function under which the linear retarded system (29) is positive. In view of positivity of the system under consideration, we assume that $A_i \in \mathbb{R}_+^{n\times n}, i \in \underline{N}_0 := \{1,2,\dots,N_0\}$, and $\eta_j \in NBV([-h,0],\mathbb{R}^{n\times n})$ are increasing, for all $j \in \underline{N}_1 := \{1,2,\dots,N_1\}$. We define the complex and the real stability radii of the linear retarded system (29) under affine parameter perturbations (39) by setting, for $\mathbb{K} = \mathbb{C}$ and, respectively, $\mathbb{K} = \mathbb{R}$,

$$r_{\mathbb{K}}^a = \inf\left\{ \max(\max_{i\in\underline{N}_0}|\alpha_i|;\ \max_{j\in\underline{N}_1}|\beta_j|) : \alpha_i,\beta_j \in \mathbb{K},\ \mu\Big(A_0 + \sum_{i=1}^{N_0}\alpha_i A_i, \eta + \sum_{j=1}^{N_1}\beta_j\eta_j\Big) \ge 0\right\}. \tag{40}$$

Similarly, the positive stability radius r_+^a is obtained by restricting, in the above definition, the disturbances $(\alpha,\beta) := ((\alpha_i)_{i\in\underline{N}_0}, (\beta_j)_{j\in\underline{N}_1})$ to be nonnegative.

It is clear that $r_{\mathbb{C}}^a \le r_{\mathbb{R}}^a \le r_+^a$. The following theorem gives us computable formulae of stability radii $r_{\mathbb{K}}^a, r_+^a, (\mathbb{K} = \mathbb{C}, \mathbb{R})$. For the simplicity of presentation, as in the previous section, let us define, for $s \in \mathbb{R}$ and $j \in \underline{N}_1$,

$$Q(s) = \int_{-h}^{0} e^{s\theta} d[\eta(\theta)]; \qquad Q_j(s) = \int_{-h}^{0} e^{s\theta} d[\eta_j(\theta)]. \tag{41}$$

By the above assumption, for all $s \ge 0, j \in \underline{N}_1$,

$$Q(0) \ge Q(s) \ge 0, \qquad Q_j(0) \ge Q_j(s) \ge 0. \tag{42}$$

THEOREM 4.1. *Suppose the positive linear retarded system* (29) *is Hurwitz stable and A_0, η are subjected to multi-affine perturbations of the form* (39)*. If the stability radii of the system are given by* (40)*, then*

$$r_{\mathbb{C}}^a = r_{\mathbb{R}}^a = r_+^a = \frac{1}{\mu[(-A_0 - Q(0))^{-1}(\sum_{i=1}^{N_0} A_i + \sum_{j=1}^{N_1} Q_j(0))]}. \tag{43}$$

Proof. Let $(\alpha,\beta) = ((\alpha_i)_{i\in\underline{N}_0}, (\beta_j)_{j\in\underline{N}_1})$ be an arbitrary nonnegative destabilizing perturbation, that is,

$$\mu_1 := \mu\Big(A_0 + \sum_{i=1}^{N_0}\alpha_i A_i, \eta + \sum_{j=1}^{N_1}\eta_j\Big) \ge 0.$$

Using Lemma 3.8 and Theorem 2.1(i) (Perron–Frobenius), we have

$$\Big(A_0+\sum_{i=1}^{N_0}\alpha_iA_i+\int_{-h}^{0}e^{\mu_1\theta}d\Big[\eta+\sum_{j=1}^{N_1}\beta_j\eta_j(\theta)\Big]\Big)y_0=\mu_1y_0$$

for some $y_0\in\mathbb{R}^n_+, y_0\neq 0$. Since the system (29) is Hurwitz stable, $\mu_0:=\mu(A_0,\eta)<0\leq\mu_1$. This yields to

$$H(\mu_1)^{-1}\Big(\sum_{i=1}^{N_0}\alpha_iA_i+\sum_{j=1}^{N_1}\beta_jQ_j(\mu_1)\Big)y_0=y_0, \tag{44}$$

where $H(s)=sI_n-A_0-Q(s)$ is the characteristic quasi-polynomial of the system (29). Let $\gamma=\max\{\max_{i\in\underline{N}_0}\alpha_i,\max_{j\in\underline{N}_1}\beta_j\}$. From $\mu_1\geq 0>\mu_0$, applying the Lemma 3.9(i), we have $H(0)^{-1}\geq H(\mu_1)^{-1}\geq 0$. Therefore, from (44)

$$\gamma\Big(H^{-1}(0)\Big(\sum_{i=1}^{N_0}A_i+\sum_{j=1}^{N_1}Q_j(0)\Big)\Big)y_0=\gamma By_0\geq y_0,$$

where $B:=H(0)^{-1}(\sum_{i=1}^{N_0}A_i+\sum_{j=1}^{N_1}Q_j(0))$. By Theorem 2.1(ii),

$$\mu(B)\geq\frac{1}{\gamma}>0.$$

Hence, $\gamma\geq\frac{1}{\mu(B)}$. Since this holds for arbitrary nonnegative perturbation (α,β), we conclude $r^a_+\geq\frac{1}{\mu(B)}$.

We shall prove that the converse inequality holds true. Since $B\geq 0$, by Theorem 2.1(i) (Perron–Frobenius), there exists a nonzero vector $y\in\mathbb{R}^n_+$ such that $By=\mu(B)y$. This implies

$$H(0)y=\Big(\sum_{i=1}^{N_0}\frac{1}{\mu(B)}A_i+\sum_{j=1}^{N_1}\frac{1}{\mu(B)}Q_j(0)\Big)y,$$

or, equivalently,

$$\Big(\Big(A_0+\sum_{i=1}^{N_0}\frac{1}{\mu(B)}A_i\Big)+\int_{-h}^{0}d\Big[\eta+\sum_{j=1}^{N_1}\frac{1}{\mu(B)}\eta_j(\theta)\Big]\Big)y=0.$$

It means that nonnegative perturbation (α^*,β^*) defined by $\alpha^*_i=1/\mu(B), i\in\underline{N}_0, \beta^*_j=1/\mu(B), j\in\underline{N}_1$ is destabilizing. By the definition of r^a_+, we have

$$r^a_+\leq\frac{1}{\mu(B)}.$$

Thus, we obtain

$$r^a_+=\frac{1}{\mu(B)}=\frac{1}{\mu[(-A_0-Q(0))^{-1}(\sum_{i=1}^{N_0}A_i+\sum_{j=1}^{N_1}Q_j(0))]}.$$

We are now ready to show that $r^a_{\mathbb{C}} = r^a_{\mathbb{R}} = r^a_+$. Suppose that $(\alpha, \beta) = ((\alpha_i)_{i\in\underline{N}_0}, (\beta_j)_{j\in\underline{N}_1})$ is an arbitrary complex destabilizing perturbation. Set

$$\mu_c := \mu\Big(A_0 + \sum_{i=1}^{N_0} \alpha_i A_i, \eta + \sum_{j=1}^{N_1} \beta_j \eta_j\Big) \geq 0,$$

$$\mu_+ := \mu\Big(A_0 + \sum_{i=1}^{N_0} |\alpha_i| A_i, \eta + \sum_{j=1}^{N_1} |\beta_j| \eta_j\Big). \tag{45}$$

By Lemma 3.8,

$$\mu_+ = \mu\Big(A_0 + \sum_{i=1}^{N_0} |\alpha_i| A_i + \int_{-h}^{0} e^{\mu_+ \theta} d\Big[\eta(\theta) + \sum_{j=1}^{N_1} |\beta_j| \eta_j(\theta)\Big]\Big). \tag{46}$$

On the other hand, from the definition of μ_c there exist a nonzero x and $\omega \in \mathbb{R}$ such that

$$\Big(A_0 + \sum_{i=1}^{N_0} \alpha_i A_i + \int_{-h}^{0} e^{(\mu_c + \imath\omega)\theta} d\Big[\eta(\theta) + \sum_{j=1}^{N_1} \beta_j \eta_j(\theta)\Big]\Big) x = (\mu_c + \imath\omega) x. \tag{47}$$

Since A_0 is a Metzler matrix, it follows that $t_0 I_n + A_0 \in \mathbb{R}^{n\times n}_+$, for some $t_0 \in \mathbb{R}$. From (47) we derive

$$\Big((t_0 I_n + A_0) + \sum_{i=1}^{N_0} \alpha_i A_i + \sum_{j=1}^{N_1} \beta_j \int_{-h}^{0} e^{(\mu_c + \imath\omega)\theta} d[\eta(\theta) + \eta_j(\theta)]\Big) x = ((t_0 + \mu_c) + \imath\omega) x.$$

It follows that

$$\begin{aligned}(t_0 + \mu_c)|x| &\leq |((t_0 + \mu_c) + \imath\omega)x| \\ &\leq \Big(|t_0 I_n + A_0| + \sum_{i=1}^{N_0} |\alpha_i| A_i + \sum_{j=1}^{N_1} |\beta_j| \int_{-h}^{0} |e^{(\mu_c + \imath\omega)\theta}| d[\eta(\theta) + \eta_j(\theta)]\Big)|x|\end{aligned}$$

and hence

$$\Big(A_0 + \sum_{i=1}^{N_0} |\alpha_i| A_i + \int_{-h}^{0} e^{\mu_c \theta} d\Big[\eta(\theta) + \sum_{j=1}^{N_1} |\beta_j| \eta_j(\theta)\Big]\Big)|x| \geq \mu_c |x|.$$

This yields, by virtue of Theorem 2.1(ii),

$$\mu\Big(A_0 + \sum_{i=1}^{N_0} |\alpha_i| A_i + \int_{-h}^{0} e^{\mu_c \theta} d\Big[\eta(\theta) + \sum_{j=1}^{N_1} |\beta_j| \eta_j(\theta)\Big]\Big) \geq \mu_c. \tag{48}$$

Combining (46) and (48), taking Theorem 2.1(iv) into account, we get $\mu_+ \geq \mu_c \geq 0$, which means that $(|\alpha|, |\beta|) := ((|\alpha_i|)_{i\in\underline{N}_0}, (|\beta_j|)_{j\in\underline{N}_1})$ is a nonnegative destabilizing perturbation. From the definition of $r^a_{\mathbb{C}}, r^a_+$, we conclude $r^a_{\mathbb{C}} \geq r^a_+$. In combining with the inequalities $r^a_{\mathbb{C}} \leq r^a_{\mathbb{R}} \leq r^a_+$, this implies $r^a_{\mathbb{C}} = r^a_{\mathbb{R}} = r^a_+$. In addition, from the

above arguments, we observe that $r^a_{\mathbb{C}} = r^a_{\mathbb{R}} = r^a_+ = \infty$ if and only if $\mu(B) = 0$. This completes our proof. □

Note that in the formula (43) μ can be replaced by ρ because for nonnegative matrices the spectral abscissa and the spectral radius coincide.

As an example, let, for $j \in \underline{N}_1$,

$$\eta(\theta) = \begin{cases} 0 & \text{if} \quad \theta = -h, \\ B_0 & \text{if} \quad \theta \in (-h, 0], \end{cases} \qquad \eta_j(\theta) = \begin{cases} 0 & \text{if} \quad \theta = -h, \\ B_j & \text{if} \quad \theta \in (-h, 0], \end{cases} \tag{49}$$

where $B_0, B_j \in \mathbb{R}^{n\times n}_+, j \in \underline{N}_1$. Then, by the above theorem, the real stability radius of the positive delay system $\dot{x}(t) = A_0x(t) + B_0x(t-h),\ t \geq 0$, under the affine parameter perturbations

$$\begin{aligned} A_0 &\to A_0 + \textstyle\sum_{i=1}^{N_0} \alpha_i A_i, \\ B_0 &\to B_0 + \textstyle\sum_{j=1}^{N_1} \beta_j B_j \end{aligned} \tag{50}$$

(with $A_i \geq 0, B_j \geq 0, i \in \underline{N}_0, j \in \underline{N}_1$) is given by

$$r^a_{\mathbb{C}} = r^a_{\mathbb{R}} = r^a_+ = \frac{1}{\rho[(-A_0 - B_0)^{-1}(\sum_{i=1}^{N_0} A_i + \sum_{j=1}^{N_1} B_j)]};$$

compare with [13], [22].
